PREFACE

The contributors of this handbook eagerly anticipate the next century of literacy education and research. In doing so, we have taken an optimistic look at how the concept of literacy is rapidly evolving by focusing on the myriad ways that learners gain knowledge and skills, rather than on the ways in which they do not. We realize that abandoning our irrational loyalty to a constrained perception of literacy is somewhat ironic: this myopic view has defined much of the research we have spent decades conducting. The innovations discussed in several of the handbook's chapters, for example, threaten the very notion of disseminating information by way of a typographic text such as this one. But we are too impressed by the instructional advances offered by embracing an expanded view of literacy to cling jealously to the past; we look hopefully to the future.

Around the world, learners in complex societies take in information visually, imitating practices of skills and attitudes they see demonstrated by others. These visual sources of information, from cave paintings forward, have supplemented oral communication. The art and forms of mediation for visual and verbal messages have developed in coordination with societal stratification and with institutions of support and education for particular segments of these arts. Technology, which has ranged from chunks of charcoal to the latest in electronic video and sound transmission, has mediated the visual and communicative arts and provided socialization into ways of using and appreciating these.

The move to an information economy has been serendipitous for the field of literacy education. The force of computers and other technologies in industry will continue, so that receiving an apprenticeship in a traditional field such as carpentry requires more than five years of education (while a college education usually takes only four). Automobile mechanics now must have multiple levels of certification in electronic engineering, and everyone from file clerks to professors must know how to manage electronic mail and combinations of video, audio, and print representations through their computers. If schools are to continue to see themselves as linked to the world of work and leisure in any way, their means of literacy education must reflect these worlds.

However, institutions of education have established hierarchies of acceptability for the visual and communicative

arts that often conflict with the rankings at work within economic and commercial sectors of the current information-based economy. The education systems of modern complex societies typically stress limited ranges of the visual and communicative arts as appropriate display forms, giving highest status to the printed word—notably to students' handwritten verbal representations of their knowledge. This designation of supreme status increasingly contrasts with the pragmatic roles that visual arts and oral language play in everyday bureaucratic interactions and workplaces of all types, including professional occupations. Commingled forms of representation mark every successful sales encounter, city commission presentation, and reporting of the news, whether on television or in newsprint. Similarly, combinations of pictures, words, graphs and charts, music, sound effects, smells, and animation characterize advertising, newspapers, the World Wide Web, MTV, and the evening news on local television channels. Everywhere outside of school, layering of information and multiple types of skills, as well as simultaneous transmission through different art forms, predominates.

From a very early age, children watch images shifting approximately every seven seconds on the television screen with the background "noise" of musical and verbal messages. Whether or not very young children understand all that is happening in rapid-fire media presentations matters far less than the fact that they come to expect these features of presentation to accompany information. Often before they can speak, children can dance, grimace, and make singing noises sufficient to allow adults to recognize these gestures as imitative of a particular advertisement or cartoon. As children grow older, they are increasingly able to comprehend the multiply layered visual and verbal information from television or computer screens while talking with a friend on the telephone or doing their homework.

Teachers dedicate considerable efforts to teaching young readers to scan primary and secondary written texts. Yet their instructional design often ignores the reality that in their spare time, these same students effortlessly "surf" television channels, often catching only a few seconds of "what's going on" before settling on a program they may watch for a few minutes. Even after selecting, young people often watch two or three programs simultaneously, flipping back and forth among

them. In viewing television, arcade games, or computer screens, youngsters manipulate controls so as to move rapidly from one type of program or activity to another, often while listening to music or carrying on conversations with friends. Despite the various sources of stimuli, in-depth viewing or engagement with computer technology follows personal interest and requires that the medium offer a continuing challenge. Computer games attract youth only so long as they are challenging; once youngsters have "cracked the system," or figured out how to win most of the time, they want to move on to another game. There is much to learn from this feature of the visual arts for teachers. Interests matter now more than ever for youth; and they offer the surest bridge between the simplex challenges and the success we envision for students—in and out of the classroom.

Throughout this volume such lessons, along with thoughtful pointers from the visual and communicative arts, appear often. The attempt here is to bring the visual arts into a central place in literacy and language education, along with the more established communicative arts of speaking and writing. Visual arts encompass everything from dramatic performances to comic books, television, and video arcade games; the communicative arts, such as reading, writing, and speaking, exist both independently and as integral elements of the visual arts. The role of the visual arts in the leisure activities of young people enables their extensive practice in essential skills, such as self-presentation, role-shifting, empathy-building, sense of plot development, and ability to focus on several things simultaneously. Yet these skills too rarely receive notice in classrooms.

In large part, ignorance of these skills for teachers and parents comes from an irrational loyalty to reading and writing—the expected communicative arts of school. The best reason many adults can give for not allowing more visual arts into the classroom is the fear that the time spent with such media forms will be taken away from the communicative arts. This view denies the layered forms that information takes on in the everyday world and reflects the usual adult views of the media as mutually exclusive. Yet in extra-classroom reality, visual arts motivate and serve as the overwhelmingly preferred companion to the communicative arts, so the mutually exclusive perception has no foundation in life outside the classroom. Moreover, all learners, young and old, constantly demonstrate our ability to attend to more than one thing at a time. (Consider, for example, the ways in which we can hold a telephone conversation in a phone booth while reading billboards and listening to two youngsters talking nearby.) Unless educators can move toward layering both information and forms of display, schools will grow increasingly further away from the learning skills and foundations of factual knowledge that adults in our society need. Acknowledging the responsibility to bring about such alterations in literacy education requires that we undertake numerous changes in attitudes and actions.

Picture books and artistically illustrated children's literature seem fine for very young children, but as we grow older and move through the educational system, we are expected to gain most from "grown-up books," whose every page is filled exclusively with words. In the United States, art books and published

collections of illustrations receive the dubious title of "coffee table books," reinforcing their marginal status and association with leisure as distinct from serious work. Mixtures of words and pictures, such as those characteristic of comic books, magazines, and newspapers seem to move the genre lower on the scale of educational acceptability. Teachers can help debunk the notions behind this bias by using informational nonfiction texts, maps, charts, board diagrams, and pictures in classrooms and by encouraging students to do the same in their projects. Numerous teachers, especially in elementary, English as a second language, and adult education already incorporate a broad range of visual and communicative arts into their teaching. The voices of many such teachers appear in this handbook. But much more work needs to be done to carry these trends through secondary schools and into colleges and universities.

Aside from persuasion by anecdotal observations and an array of articles addressing questions of the relative merit or harm of the media (especially television), scholars in psychology and other disciplines linked to education have paid little attention to issues such as cognitive processing across media and its appropriateness within different content areas. Only in the 1970s did the communicative arts transcend the locked focus on learning to read and begin to receive considerable attention from scholars, primarily sociolinguists and anthropologists. In the subsequent decades, volumes on literacy, language learning, early literacy, writing, bilingualism, and language education have come in increasing numbers each year not only from researchers but teachers and student writers as well. Much of that work is reviewed by contributors in this handbook. But the sum of their conclusions constitutes a mandate: this work must be supplemented with substantial study of the cognitive and affective dimensions of the visual arts and their links with linguistic processing.

With this volume, we hope to have started this effort. We want to break the trend of literacy educators' exclusive focus on learning as reading and writing, and urge intense consideration of all the ways that visual arts impact learners' preparation and practices of learning in formal classrooms. We hope to inspire more research on visual arts and the integration of visual representations of knowledge with verbal means. Such inquiries must evolve simply from reporting the pleasure that learners take in drawing or illustrating their narratives to analyzing how different kinds of visual arts promote the cognitive developments rarely fostered by exclusively verbal displays.

Certain teases already appear in the literature. For example, language teachers may be more inclined to consider using drama in their classrooms when they learn that at an early age, children from societies where verbal teasing is prevalent have more developed language repertoires than their counterparts in societies where such teasing is rare. The characteristic of teasing that allows this phenomenon is the encouragement of creative role-playing and thus taking on of other voices. Nonnative English speakers engaged in dramatic role-playing display competencies with English that could never emerge from pencil-and-paper testing or classroom dialogues. Similarly, students reluctant to engage in science or social studies come alive with hypertext discovering ample oral

collaborative opportunities to teach or tutor others about their knowledge. Video productions, photographic projects, and artistic creations of graphs, diagrams, and charts provide the chance for differential abilities of students to stand out, so that the hesitant writer receives praise as the superb illustrator.

This is not to suggest, however, that chances for displays of knowledge in multiple media should involve only those areas of students' personal preference or talent. Instead, the goal is to applaud the diverse talents that are hiding in our classrooms and thereby motivate learners to see themselves as learners and even experts in some areas while encouraging them to extend themselves in areas where they may have felt reluctant to go—such as writing or drawing.

Teachers already using visual and communicative arts in their literacy education need evidence from research to support their innovative creativity. They need to be able to comment in workshops with other teachers and in parent conferences on questions such as: What happens to retention and transfer of information and skills within active demonstration, as distinct from essay answers? Does active involvement with texts through drama or video production enable students to receive more information from such forms than when they simply view them? Can we achieve a more accurate rendering of a student's capabilities by tapping into multiple forms of demonstrating knowledge?

Only teachers and students themselves can best answer the question of the appropriateness of multiple forms of visual and communicative arts for all content or subject areas. They will ultimately discover, for example, whether or not musical demonstrations and practice will enable a deeper grasp of fractions. They will discover to what extent the learning of biochemistry or physics is enhanced by experience with computer simulations and laboratory manuals filled with illustrations. They will determine to what extent the preparation of graphs and charts to accompany an oral presentation on toxins in the air enhances the conceptual understanding of an English as a Second Language adult learner who wants to work in an environmental engineering firm. The context of classrooms and the insider perspectives of teachers and students must be sought out to provide answers to such questions. Otherwise, we will find ourselves at the end of another decade armed only with primarily programmatic statements, and scarcely any hard data to show the gains, losses, and trends that would come with serious consideration by literacy educators of both the visual and communicative arts.

The handbook editors and contributors have knowingly broached what they see as the likely direction of future literacy education. They do so with an admitted bias of hope. We would not be true to the purpose of this volume if we did not address these matters directly. Most educators conceive it as their exclusive task to teach reading and writing and to stress stable performance of such skills through response to school-given tasks and tests. They do much of their teaching through uniform sequences with extensive use of commercially prepared materials and curricular directives. These are obviously essential parts of providing a learning environment

that will enable learners to move through the formal educational system. But within literacy education, we feel there is special room for emphasizing the multiplicity and creative chaos of the visual and communicative arts adventure. We feel it essential to stress the uniqueness of each of the visual arts and their connections to many of the communicative arts. We urge serious consideration of this combination and the other classroom changes that follow from such consideration; among them, cross-age learning through production and reception of visual and verbal information and presentation, collaboration among students to prepare for presentation of learning activities for other students as well as for teachers and other authentic observers—even from outside the classroom.

We stand against the reducing of human learning to the representation of knowledge and skills primarily by written means. Teaching and learning are best when they represent the realm of freedom and creativity, as well as the stretching capacities of learners who know well how to adapt to being called upon to display knowledge under varying circumstances. The importance of granting somewhat equivalent rights of entry in classrooms to the visual *and* communicative arts appears particularly appropriate at the end of the twentieth century. Sociopolitical realities may well push harder than they have in the past on the vested interests of the standard approaches to literacy education that are typically represented in textbooks, standardized tests, teacher education, and curricular materials. We believe that combining presentation of materials and requests for displays of conceptual, discrete informational, and technical knowledge will enable all of us—students, teachers, teacher educators, and education researchers—to learn more.

We know of human beings that their changes in beliefs, attitudes, and theories come most easily after they have been entrained by certain actions; hence, ideology and belief often follow from rather than precede action. Teachers and students who already use and know the visual arts, whether through electronic technology or personal artistic talent represent the vanguard of a new paradigm. But they can take responsibility for bringing colleagues and students into action with the visual arts, so that changes in beliefs and motivations can follow from these actions. It is primarily by linking students, teachers, teacher educators, and researchers into communities of practice and inquiry that we can put to work a passion for what is possible and turn the next historical corner in a way that combines the best of the old and the new.

Finally, we would like to express our sincere thanks to every author and reviewer who participated in the development of this handbook. A special thanks is owed to the section editors without whose contributions this book would never have become a reality. We would also like to thank Dr. Linda Lungren, Michelle LeTourneau, Kelly Goss, Joan Irwin, Lloyd Chilton, Andrew Ambraziejus, Catherine Carter, and Ari Kast for their tremendous help with the production of this handbook.

James Flood is a Professor of Reading and Language Education at San Diego State University. Dr. Flood was a Fulbright scholar in Portugal and Past President of the National Reading Conference. A noted researcher, teacher, and author of books and articles on literacy issues and a member of the California Reading Hall of Fame, he is the cochair of the International Reading Association's Visual Literacy Committee.

Shirley Brice Heath is a Professor of English and Linguistics, with courtesy appointments in Anthropology and Education, at Stanford University. Recipient of awards from NCTE and the International Reading Association, Dr. Heath is consulting editor for major journals in human development, literacy studies, and cultural anthropology.

Diane Lapp is a Professor of Reading and Language Education at San Diego State University. A widely respected teacher, she is the recipient of the International Reading Association's Outstanding Teacher Educator Award and a member of the California Reading Hall of Fame. Dr. Lapp, a noted researcher and author of many literacy books and articles, is also the cochair of the International Reading Association's Visual Literacy Committee.

SECTION EDITORS

Donna E. Alvermann is Research Professor of Reading at the University of Georgia and Codirector of the National Reading Research Center (NRR), in collaboration with the University of Maryland. A widely published author, her research focuses on the role of classroom dialogue in content literacy instruction. She is particularly interested in alternative methodologies and their application for literacy research.

Victoria Chou is Professor of Reading, Writing, and Literacy and Acting Dean of the College of Education at the University of Illinois at Chicago. She studies variables that affect intercultural communication between teachers and students. She and Dr. Karen Sakash codirect Project 29, a DeWitt Wallace-Reader's Digest Pathways to Teaching Careers program that

supports cohorts of provisionally certified bilingual (Spanish-English) teachers in Chicago public schools.

Bernice E. Cullinan, Professor of Reading at New York University, is a Past President of the International Reading Association and a member of the IRA Hall of Fame. She is coauthor of *Literature and the Child, Fourth Edition*, with Lee Galda and *Language, Literacy and the Child, Second Edition*, with Galda and Dorothy Strickland. She serves on the Advisory Board of WGBH for the Arthur series.

Lee Galda, a Professor of Language Education at the University of Georgia, is coauthor of *Language, Literacy and the Child, Second Edition*, with Bernice Cullinan and Dorothy Strickland and coauthor of *Literature and the Child, Fourth Edition*, with Cullinan. She studies children's engagement with literature and the influences of home and school on literacy learning.

Paul Messaris is an Associate Professor at the Annenberg School for Communication, University of Pennsylvania, in Philadelphia, Pennsylvania. His book *Visual "Literacy": Image, Mind, and Reality* (Boulder, CO: Westview Press, 1994) received the Diamond Anniversary Book Award from the Speech Communication Association in 1996. His most recent text is *Visual Persuasion: The Role of Images in Advertising* (Thousand Oaks, CA: Sage Publications).

Nancy L. Roser is a Professor of Language and Literacy Studies and the Priscilla Flawn Regents Professor of Early Childhood Education at the University of Texas at Austin. She is also Project Director of the Texas Center for Reading and Language Arts and Codirector of the project producing Texas standards for the English Language Arts. A widely published author, she is also on the editorial board of several journals and a member of IRA's Visual Literacy Committee.

James R. Squire is a retired publisher and professor of English education. A lecturer at Harvard Graduate School of Education and Senior Research Associate at Boston University, he is the former Executive Secretary of NCTE. Past President of the NCRE, chair of the School Division of the Association of American Publishers, and Past President of the International

Reading Association Hall of Fame, he has received lifetime contribution awards from NCRE, NCTE, and AAP.

Dorothy S. Strickland is the State of New Jersey Professor of Reading at Rutgers University. A former classroom teacher, she is a Past President of the International Reading Association. She received IRA's Outstanding Teacher Educator of Reading Award, and she was elected to the IRA Reading Hall of Fame. Author of numerous publications, she was the 1994 recipient of the Rewey Belle Inglis Award for Outstanding Woman in the Teaching of English from NCTE.

AUTHORS

Hal Adams is president of the Neighborhood Writing Alliance and faculty member in the College of Education at the University of Illinois at Chicago. Hal conducts adult writing workshops in neighborhood branch libraries, public housing residences, and public schools (with parents) in Chicago. He publishes writing from the workshops in the *Journal of Ordinary Thought*.

Ann Alejandro is an experienced classroom teacher in the Rio Grande River Valley in South Texas. She has published articles in *Language Arts*, a journal of the National Council of Teachers of English. She attempts to expand the literacy of her students through experiences in art, which is the core of her language arts curriculum and writings.

JoBeth Allen is a Professor of Language Education at the University of Georgia. She has been involved with collaborative action research for the past 15 years and is the coauthor of three books reporting action research in whole language classrooms. She studies university / public school collaborations and the effect of such on the literacy development of students, teachers, and teacher educators.

Richard L. Allington is Professor of Education and Chair of the Department of Reading at the State University of New York at Albany. He has served as President of the National Reading Conference and as a member of the board of directors of the International Reading Association. His most recent book, *Schools That Work: All Children Read and Write* (Longmans), was coauthored with Pat Cunningham.

Claire L. Asam, a native Hawaiian educator, is the curriculum and assessment coordinator for the Kamehameha Elementary School in Honolulu, Hawaii. She is a doctoral student in educational administration at the University of Hawaii. Throughout her career she has focused on improving the educational success of Hawaiian students. Toward this end, she has been a research and demonstration teacher, language arts consultant, and program director.

Steven Z. Athanases is Research Associate in the School of Education at Stanford University where he directs a research project on classroom assessment in educational reform. A former high school speech and English teacher, he received NCTE's Promising Research Award in English

Education for his study of classroom discourse about literature and diversity.

Kathryn H. Au, Associate Professor in the College of Education at the University of Hawaii in Honolulu, is the coordinator of a teacher education program designed to increase the number of native Hawaiian teachers. She has been elected president of the NRC and a vice president of AERA. Her research interest is the school literacy development of students of diverse cultural and linguistic backgrounds. Her latest textbook is *Literacy Instruction in Multicultural Settings*.

Lawrence Baines is an Assistant Professor in the English Education program at Florida State University in Tallahassee, Florida. Baines also writes prose, screenplays, and music. He studies the interrelationships among film, video, and books and their roles in literacy learning and teaching.

Carolyn D. Baker is an Associate Professor in the Graduate School of Education at the University of Queensland, Brisbane, Australia. In her research she has applied ethnomethodological and conversation analytic approaches to the analysis of texts and talk, primarily in the field of education. She has published widely on early literacy materials and "talk around text" in classrooms.

Barbara Holland Baskin is a Professor at the State University of New York at Stonybrook and Director of Child and Family Studies. Her research and publication interests relate to educational computer games and programs as effective instructional tools that will enhance literacy development.

James F. Baumann is a Professor of Reading Education at the University of Georgia. During the 1994–95 academic year, while on leave from the university, he engaged in teacher research on communication and literacy while teaching second grade full-time at Fowler Drive Elementary School in Athens, Georgia. He is a member of the board of directors of the International Reading Association.

Debra L. Bayles is an Assistant Professor of Reading and Language Arts at San Diego State University. Her current research interests center on the exploration of alternative ways of knowing—especially as related to teacher preparation, writing development, and reading comprehension. She also writes musical and dramatic presentations and performs with various musical and artistic groups.

Vikram Bhagat is currently a senior at Stanford University where he is majoring in economics. In addition to his studies, he is extremely interested in the multiple formats, roles, and definitions of literacy and these relationships to the leisure activities of young people.

Eleanor Binstock is Assistant Professor of Education in the Interdisciplinary Studies Department of National-Louis University in Chicago, Illinois. She has produced and directed documentary films for the Chicago Council on Fine Arts, and developed and taught film workshops and video-based

curricula in the Alternative Schools Network in Chicago. Before that, she was an elementary school teacher in Montreal, Canada.

Betty Shockley Bisplinghoff is a classroom teacher in Athens, Georgia. She is a teacher researcher working on her doctorate in Language Education at the University of Georgia. She served as Director of the National Reading Research Center's School Research Consortium from 1993 to 1996 and is coauthor of two books reporting teacher research, *Engaging Children* and *Engaging Families*.

David Bloome is Professor of Education in the Department of Teaching and Learning at Peabody College of Vanderbilt University. He is the coeditor of *Linguistics and Education: An International Research Journal*, and author of numerous articles and books on social and cultural dimensions of language and literacy. His research has focused on classroom and community settings of literacy education.

Marc Brown, a noted author and illustrator, created the popular Arthur television series, which appears on WGBH, an educational television station in Boston. He is interested in supporting the literacy efforts of the classroom through television and other multimedia.

Bertram C. Bruce, a former senior researcher at Bolt, Berenak and Newman, is a Professor in the Department of Curriculum and Instruction at the University of Illinois. A well-known researcher and author, he studies issues related to many aspects of technology's role in education. He is a member of the International Reading Association's Visual Literacy Committee.

Beverly Bruneau is an Associate Professor in Teaching, Leadership, and Curriculum Studies at Kent State University. Her current research interests center on the development of constructivist preservice and continuing education programs, work with partnership primary schools, and the development of literacy teaching for kindergarten and primary children.

Wayne M. Butler serves as Acting Director of the University of Michigan's English Composition Board where he teaches writing on the Internet and works on university / public school on-line outreach projects. He has served on NCTE's Instructional Technology Committee, codeveloped the award-winning Daedalus Integrated Writing Environment, and is coauthor of *Writing the Information Superhighway* (Allyn and Bacon, 1997).

Robert Calfee is a Professor in the School of Education at Stanford University. A cognitive psychologist, his research interests include acquisition of early literacy and the influence of curricular and school context factors on the learning of young children. He is a member of the International Reading Association Hall of Fame.

John Carey is Managing Director of Greystone Communications, a telecommunications research and planning firm that he founded in 1980. He conducts research about new communi-

cations systems. Dr. Carey is also an Affiliated Research Fellow at Columbia University's Institute for Tele-Information and a consultant to the Freedom Forum Technology Studies Program.

Gen Ling Chang-Wells is a classroom teacher with the Toronto Board of Education. She is interested in the social constructivist model of learning and teaching and its relationship to helping children develop literacy strategies and an understanding of the meaning of historical time.

Joy Chu is a nationally recognized book designer and is frequently invited to serve as a judge in graphic arts shows. She is intricately involved in the many stages of book design. She is very interested in enhancing reading comprehension through the use of picture graphics.

Michelle Carey Clark is a third-grade teacher at Deerfield School in Short Hills, New Jersey. Through her integrated language arts instruction she helps students recognize the meaning of symbols and images as language cues, which, she believes, is a primary component of one's visual literacy experiences.

Marie M. Clay is Professor of Education Emeritus at the University of Auckland. She is a Past President of the International Reading Association and the author of numerous books and research studies on early childhood education and reading recovery. A widely respected scholar/educator, she is a member of the International Reading Association Hall of Fame.

Dwight Conquergood is Chair of Performance Studies at Northwestern University, and Faculty Associate at the Joint Center for Poverty Research, Northwestern University and University of Chicago. In addition to print publications, he has coproduced two award-winning documentaries based on his urban ethnographic research in Chicago: *Between Two Worlds: The Hmong Shaman in America* and *The Heart Broken in Half*.

Colette Daiute is Professor of Developmental Psychology at the City University of New York Graduate School. Dr. Daiute conducts research on the role of oral, written, and visual discourse in the development of knowledge and identity and its effect on literacy learning for all children.

Roger Desmond is Professor of Communication at the University of Hartford. A noted author, his most recent research has involved the creation and evaluation of print and video materials designed to teach young children about media and how they work. His most recent published research is an investigation of the role of media in the emotional states and moods of university undergraduates.

Anne Haas Dyson is a Professor at the Graduate School of Education, University of California, Berkeley. Her publications include *Multiple Worlds of Child Writers: Friends Learning to Write* (1989), *The Social Worlds of Children Learning to Write in an Urban Primary School* (1993), which won NCTE's 1994 David Russell Award for Distinguished Research, and *Writing Superheroes: Contemporary Childhood, Popular Culture, and Classroom Literacy* (1997).

Brian Edmiston is an Assistant Professor in the School of Teaching and Learning at Ohio State University. His research interests are in inquiry through drama, situated learning, dramatic play, learning to be ethical, and teacher research. Dr. Edmiston is the author, with Jeffrey Wilhelm, of *Imagining to Learn: Inquiry, Reading, Ethics, and Integration through Drama*.

Warwick Elley is Professor of Education at the University of Canterbury in New Zealand. A widely acclaimed researcher, scholar, and educator, he has conducted numerous studies on cross-national issues and their effect on the development and assessment of student literacy.

Patricia Enciso is an Assistant Professor in the School of Teaching and Learning at Ohio State University. She is currently a National Academy of Education Spencer Postdoctoral Fellow. Dr. Enciso has authored articles and chapters in *Language Arts, Reading and Writing Quarterly*, and *Reading Across Cultures: Teaching Literature in a Diverse Society* (edited by T. Rogers and A. Soter).

Roger Farr is a Chancellor's Professor at Indiana University. A Past President of the International Reading Association, he is currently the Director of the Center for Reading and Language Studies at Indiana University. Dr. Farr has written numerous standardized and performance assessments. His latest book, coauthored with Bruce Tone, is entitled *Portfolio and Performance Assessment: Helping Students Evaluate Their Progress as Readers and Writers*.

Linda Flower is Professor of Rhetoric and Director of the Center for University Outreach at Carnegie Mellon. From 1985 to 1995 she was Codirector of the National Center for the Study of Writing and Literacy at Berkeley and Carnegie Mellon. She is the author of *The Construction of Negotiated Meaning: A Social Cognitive Theory of Writing and of Problem-Solving Strategies for Writing in College and Community*.

Sarah Warshawer Freedman is a Professor of Education in the Graduate School of Education at University of California, Berkeley. She was the Director of the former National Center for the Study of Writing and Literacy. Her research interests include multicultural education and teacher research. Her most recent publication is "Exchanging Writing, Exchanging Cultures."

Vivian L. Gadsden is Associate Professor of Education and Director of the National Center on Fathers and Families at the University of Pennsylvania. Her work in visual and communicative literacy focuses on oral, reading, and written discourses across two and three generations within African-American, Latino, and white families. She also examines the implications of these discourses and interactions for children and adults learning in school, home, and community contexts.

Irene W. Gaskins is founder and director of the Benchmark School in Media, Pennsylvania. A widely recognized researcher and teacher, she studies issues related to reading and

writing acquisition and development. Her findings have become the foundation of many effective instructional strategies.

Phillip C. Gonzales is the Senior Project Director of GOALS 2000 Preservice Partnership Program in the Los Angeles County Office of Education and Professor in the Teacher Education Department at California State University, Dominguez Hills. His most recent publication, *ESL / Bilingual Framework for the States of Washington, Oregon, Idaho, Montana, Wyoming, South Dakota, and Colorado*, is published in each state by the Bilingual Education Division of the State Departments of Education.

Judith L. Green, Professor of Education in the Graduate School of Education at the University of California, Santa Barbara, teaches in language and literacy ethnographic research and classroom discourse. She is a founding member of the Santa Barbara Classroom Discourse Group, an ethnographic research community composed of teachers, students, and university-based researchers. Her research focuses on literacy and social construction of knowledge in classrooms.

Ian Greenberg, writer and art educator, directed the Aesthetic Education program at Webster University. She is author of *The Painter's Eye: Learning to Look at Contemporary American Art* and numerous other books. She believes that art is a primary means of enhancing literacy.

Michael Griffin is currently on the faculty of the School of Journalism and Mass Communication at the University of Minnesota. He has published numerous articles on media literacy and visual communication in the mass media; his forthcoming book is titled *Re-Visualizing Media: The Force of the Image in Mass Communication*. Griffin was recently honored with a prestigious Annenberg Scholars Program Fellowship for his work on the visual rhetoric of television news imagery.

Pamela L. Grossman is the Boeing Professor of Teacher Education at the University of Washington, Seattle. Her work has focused on the preparation of secondary English teachers and how student teachers use and modify conceptual and pedagogical tools in their classrooms. In addition, she is working on a new model of professional development that builds a community of learners among high school English and social studies teachers at a school site.

Mel Grubb is Consultant-in-Charge, Reading / Language Arts Unit, Division of Curriculum, Instruction, and Assessment in the Los Angeles County Office of Education. Dr. Grubb is responsible for the training of hundreds of Los Angeles English / language arts teachers to conduct staff development training. These teachers are actively responsible for much of the inservice conducted in the region's schools.

Sherry Guice, Director of Educational Outreach at the National Research Center on English Learning and Achievement, teaches graduate reading courses in the Reading Department at the State University of New York at Albany. She is interested in children's responses to literature and how teachers organize

situations where children learn to read and write. Her publications have appeared in *The Journal of Reading Behavior* and *The New Advocate*.

John T. Guthrie is a Professor of Human Development at the University of Maryland at College Park and Codirector of the National Reading Research Center. The former Director of Research for IRA, he is a Fellow in the American Psychological Association, American Psychological Society, and the National Council of Research in English. His many awards include the NRC Oscar Causey award for outstanding contributions to reading research and membership in the IRA Reading Hall of Fame.

Frederick L. Hamel is a doctoral student in curriculum and instruction at the University of Washington and a secondary English teacher at Bremerton High School. He received his M.A.T. in English education from the University of Chicago where he focused on methods for teaching writing. His current research interests include teacher learning and collegiality, student understanding of literature, and rhetorical theories of communication.

Violet J. Harris is an Associate Professor in the Department of Curriculum and Instruction at the University of Illinois at Urbana-Champaign. She is a University Scholar and recipient of awards and honors for her research on the historic development of literacy among African-Americans and multicultural children's literature.

John R. Hayes is Professor of Psychology and Director of the Center for Innovation in Learning at Carnegie Mellon University. He is a pioneer in studying writing as a problem-solving process and, with Linda Flower, created the first cognitive model of writers' composing processes. He has authored numerous books and articles, including a guide to research methods in writing, and studies of the evaluation of student writing.

Renee Hobbs, prominent authority on media literacy, is an Associate Professor of Communication at Babson College in Wellesley, Massachusetts, and Director of the Media Literacy Project at Clark University in Worcester, Massachusetts. Among other distinctions, she received the Golden Cable ACE Award (the cable industry's highest award) in 1995 for KNOW TV, a public-service media-literacy initiative.

Ana Huerta-Macias is currently an Assistant Professor and Coordinator of the TESOL Program in the Department of Curriculum and Instruction at New Mexico State University. Her research interests and publications are in the areas of bilingual education, sociolinguistics, family literacy, and teaching English to speakers of other languages. Most recently, she coedited *The Schooling of Latino Students: A Guide to Successful Practice, Volumes I and II*.

Glynda Hull is Associate Professor of Education and Director of the College Writing Programs at the University of California, Berkeley. Her recent research has focused on literacy and work,

and she has written as well about remediation, writing instruction, and technology. She is the author, with James Paul Gee and Colin Lankshear, of *The New Work Order* (Westview, 1996), and the editor of *Changing Work, Changing Workers* (SUNY, 1997).

C. Jane Hydrick, a 30-year classroom teacher, is Past President of the NCTE and a Director of the National Board for Professional Teaching Standards. She was named Tempe Woman of the Year in 1985, received the 1989 Excellence in Language Arts Teaching Award, and has written many journal articles as well as editing and authoring several books, her most recent of which is *Parent's Guide to Literacy in the 21st Century*.

Cynthia R. Hynd is Associate Professor of Developmental Studies at the University of Georgia and a principal investigator with the National Reading Research Center. Her eight years of public school teaching included service as a remedial reading specialist and special education teacher. Dr. Hynd's research focuses on the cognitive aspects of learning from text.

Roselmina Indrisano is Professor of Education and Chair of the Department of Educational Studies at Boston University. She is a Past President of the International Reading Association and Past President and member of its Reading Hall of Fame. A widely recognized scholar and educator, she studies many issues related to literacy development and enhancement of struggling readers and their families.

Eugene Jongsma is Director of Educational Assessment for Harcourt Brace School Publishers where he has developed a variety of assessment products, supervised the development of customized state assessments, and provided professional development in alternative assessments. Prior to joining Harcourt Brace, Dr. Jongsma served on the faculties of the University of New Orleans and Southern Methodist University.

Richard M. Kerper is Professor of Education at Millersville University of Pennsylvania where he specializes in children's literature and language arts. He studies the many ways children do and could use illustrations to enhance comprehension of informational books.

Barbara Kiefer is a Professor of Education at Teachers College, Columbia University, where she teaches children's, reading, and language arts. She is coauthor of *Children's Literature in the Elementary School, Sixth Edition*, with Charlotte Huck, Janet Hickman, and Susan Hepler.

Mara Krechevsky is an educational researcher at Project Zero at Harvard University. She has developed and tested innovative means of assessment and curriculum techniques that recognize multiple avenues for demonstrating intelligence. She has consulted with many schools across the country on the practical application of multiple intelligences theory.

Linda Labbo is an Assistant Professor of Education at the University of Georgia in the Department of Reading Education.

She has also served as a principal investigator with the National Reading Research Center and has published in scholarly journals such as *Journal of Literacy Research*, *Reading Research Quarterly*, and *Language Arts*. Her research interests focus on the role of technology in young children's emergent literacy development.

Carol D. Lee is an Associate Professor of Education and Social Policy at Northwestern University. Her research centers around ways of drawing on the cultural capital that African-American and other diverse students bring from their home and community experiences to promote academic literacy.

Twila C. Liggett is Executive Director of the renowned educational program Reading Rainbow. In addition, she is Project Administrator and Developer of the Nebraska Educational TV Project, University of Nebraska. She continually creates innovative ways to develop visual literacy.

Anthony (Tony) Lucki, Senior Vice President and Publisher, Harcourt Brace School Publishers, guides the development and design of media programs for teaching literacy across all curriculum areas. He is interested in the role of the text and multimedia in literacy development.

Ulla C. Malkus teaches Development and Psychology in the Psychology Department at Wheelock College in Boston, Massachusetts. Her expertise, which is in the area of the assessment of emergent literacy, has been developed while looking through the lenses of kindergarten teachers.

Ann Dacey McCann is an elementary school teacher for Howard County, Maryland, Public Schools. Prior to that she was a graduate research assistant for the National Reading Research Center. Her research interests include designing and evaluating learning contexts that foster literacy engagement through interdisciplinary teaching.

Michael C. McKenna is Professor of Reading Education at Georgia Southern University. His research into beginning readers' use of electronic (talking) books has included studies sponsored by the National Reading Research Center. He has written widely on various aspects of electronic literacy as well as issues related to the use of technology in literacy assessment.

Richard Peter Mesa ("Pete") is currently a Distinguished Visiting Professor at Mills College in Oakland, California. Prior to coming to Mills College, he taught at several other universities. In addition, in a career of 34 years, he has served at every level of the school system as an English teacher, high school principal, urban and suburban school superintendent, and as California's Chief Deputy Superintendent of Public Instruction.

Lesley Mandel Morrow is a professor at Rutgers University Graduate School of Education. She has published extensively in journals, book chapters, and her own books. She is a member of the board of directors of the International Reading Association, was the recipient of the Association's Outstanding

Teachers Educator of Reading Award, and Fordham University's Alumni Award for Outstanding Achievement.

Lorri Neilsen is Associate Professor of Literacy at Mount Saint Vincent University in Halifax, Nova Scotia. A former teacher of art, drama, and English, she now teaches courses in literacy, gender, and feminist inquiry. A writer of books and articles on literacy learning and teaching, she is also a poet and essayist.

Susan B. Neuman is an Associate Professor of Reading and Language Arts at Temple University. Her research focuses on the effects of television viewing and reading, as well as parent involvement and early literacy. She is the author of *Literacy in the Television Age: The Myth of the TV Effect* (Ablex, 1995, second edition), and numerous articles that explore the relationship among media.

Jim Nicholson is a writer with the Philadelphia Daily News and a former investigative reporter. His more than 30 years' experience in the news business has netted him numerous awards, including the Best Writing Award from the American Society of Newspaper Editors and the Knight-Ridder Editorial Excellence Award.

W. Nikola-Lisa is an Associate Professor of Education at National-Louis University where he teaches courses in literacy development. A well-known author and recipient of an Ezra Jack Keats Fellowship, he is author of *Bein' with You This Way*, *Night Is Coming*, and *Storm*.

Janet L. Olson is an Associate Professor of Visual Arts at Boston University's School for the Arts and Chair of the Department of Art Education. She has written extensively on the relationship between visual and verbal forms of expression as it relates to education. Her current research continues to explore the intriguing and natural partnership of drawing and writing.

Sharon O'Neal is Director of Language Arts for the Texas Education Agency. A former classroom teacher, she is very interested in language arts curriculum and assessment issues that affect the literacy development of first and second language English students. She has also been very involved in the development of professional literacy standards for Texas educators.

Georgette Comuntzis Page, a specialist in children's visual literacy, has conducted research on the relationship between children's cognitive development and their interpretations of various forms of visual media. She has worked at Children's Television Workshop as coordinator of formative research for Sesame Street and has been on the faculties of Westminster College in Salt Lake City and West Virginia University.

Christine C. Pappas is a Professor of the Reading, Writing, and Literacy and Curriculum Design Programs at the University of Illinois at Chicago. Her current research involves working collaboratively with teacher researchers who are transforming

literacy teaching-learning to develop culturally responsive pedagogy in urban schools.

Jeanne R. Paratore is an Associate Professor of Literacy, Language, and Cultural Studies at Boston University School of Education. A former classroom teacher who is very involved in field-based education, she is currently conducting research in three areas: family literacy, performance-based assessment, and peer discourse.

Katherine Paterson, an outstanding novelist, received the John Newbery Award in 1978 for *Bridge to Terabithia* and again in 1981 for *Jacob Have I Loved*. Her many books, which are loved by readers of all ages, are the basis of theatrical and media productions.

P. David Pearson is currently the John A. Hannah Distinguished Professor of Education at Michigan State University. He pursues research related to reading instruction and assessment. Past President of the National Reading Conference and the National Conference of Research in English, he was presented the NRC Oscar Causey Award for outstanding contributions to reading research and the IRA William S. Gray Citation of Merit for his contributions to theory, research, and practice.

Anthony D. Pellegrini is a Professor of Early Childhood Education at the University of Georgia. He studies children's early literacy and play. He has two recent books: *Observing Children in the Natural World: A Methodological Primer* (Erlbaum, 1996) and *The Development of School-Based Literacy: A Social Ecological Study* (in press with Lee Galda, Routledge).

Charles W. Peters, a secondary English language arts consultant for Oakland Intermediate School District in Waterford, Michigan, has authored many articles and book chapters and coedited two books. His most recent publication, "Language Arts and Curriculum Content: The Key to Aligning Instruction and Assessment in Literature-Based Approaches," will appear in *Literature-Based Instruction: Present Issues, Future Directions*, edited by Kathryn H. Au and Taffy E. Raphael.

Gary Pharness works in corporate settings around the issues of literacy and diversity. His expertise in communicative literacy is in bringing different stakeholders within a company together to build a culture of literacy that acknowledges all employees as having the capacity to think and to express their personal voice.

Gay Su Pinnell is Professor of Education at Ohio State University and has recently worked extensively in the area of Reading Recovery. A former classroom teacher and a well-established researcher and author, she is very interested in many factors that affect children's literacy acquisition and development. Her most recent text, *Guided Reading*, which was coauthored with Irene Fountas, is published by Heinemann.

Sheila A. Potter is an English Language Arts Specialist with the Michigan Department of Education and Codirector of the

Michigan English Language Arts Framework (MELAF) Project. She serves on the boards of directors for the Michigan Reading Association and the Michigan Council of Teachers of English. Among her many publications is a handbook on student literacy portfolios entitled "Portrait with Wings," which was distributed to all Michigan school districts.

Claire L. Ramsey is an Assistant Research Scientist at the University of California, San Diego, and a lecturer in the Teacher Education Program at University of California, San Diego. A hearing signer of ASL, she has worked as an interpreter, instructional assistant, and researcher in classrooms with deaf children and their deaf and hearing teachers at elementary, middle school, and college levels.

David Reinking is Professor of Education at the University of Georgia where he serves as head of the Department of Reading Education. He is also a principal investigator with the National Reading Research Center and is Editor of the *Journal of Literacy Research*, a journal published by the National Reading Conference. Professor Reinking's primary research interest is in the connection between technology and literacy.

Laurel Richardson is Visiting Professor in the Cultural Studies Program in the School of Educational Policy and Leadership and Professor of Sociology at Ohio State University. She has written social science as narrative poetry, lyric poetry, drama, and responsive readings. Her most recent book, *Fields of Play: Constructing an Academic Life*, is available through Rutgers University Press.

John Richmond is a British specialist on curriculum and instruction and is currently developing television programs for teachers and students. He is a member of the faculty of the University of Nottingham where he studies many areas of literacy development.

Roger R. Rogalin is the Senior Vice President and Publisher of Macmillan / McGraw-Hill's School Division where he supervises the design and development of print and nonprint media for school textbooks. A well-respected scholar, he is interested in the connections between media and text and their influences on literacy development. He is also the past president of the Association of American Publishers.

Tamara Hanneman Rubin, Editorial Director of *Scholastic Magazine*, oversees the creation and design of several Scholastic print and visual media products. She is interested in the role of display graphics, design, and color as sources that promote reading motivation.

Marilyn C. Scala is a special education teacher at Munsey Park Elementary School in Manhasset, New York. She is a participant in the Lincoln Center Institute, a partnership between Lincoln Center for the Performing Arts and school districts to provide aesthetic education programs for teachers and students. She has coauthored a book, *Three Voices: An Invitation to Poetry Across the Curriculum* (Stenhouse, 1995).

Virginia C. Schroder is the Elementary Curriculum and Staff Development Specialist for the Manhasset Public Schools, Manhasset, New York. She is coauthor of *Three Voices: An Invitation to Poetry Across the Curriculum* (Stenhouse, 1995) and writes regularly for *Creative Classroom*, the Children's Television Workshop magazine. Ms. Schroder is also a participant in the Lincoln Center for the Performing Arts Institute, a collaborative workshop for aesthetic education in the schools.

Dona Schwartz is an Associate Professor at the School of Journalism and Mass Communication at the University of Minnesota. Her research in visual communication involves interrelated areas of historical and institutional influences shaping visual media, its forms and contents, and audiences' interpretive processes. Her writing includes *Waucoma Twilight: Generations of the Farm* (Smithsonian Institution Press, 1992) and *Contesting the Super Bowl* (Routledge, 1997).

Robert E. Shafer is Professor of Education Emeritus at Arizona State University. A widely published researcher and author, he is a past chair of the International Consortium of English Associations and has studied language teaching in many English-speaking countries.

Joan M. Shiring coordinates the Secondary English Education program at the University of Texas at Austin. She currently teaches a variety of graduate and undergraduate courses, codirects the Austin Writing Project, and has contributed articles to the *English Journal*, *Language Arts*, *The Journal of Teacher Education*, and *English in Texas*.

Elaine R. Silliman is on the faculty of the University of South Florida. She studies the goal and purpose of communication in classroom functioning and school reform. Her research and writing reflects her belief that being literate transcends the oral and written media of communication.

Susanne L. Singleton is a freelance writer. She is a former English and social studies teacher and former Vice President of Macmillan / McGraw-Hill School Publishing. She is very interested in the relationships among and the teaching of the language arts, the visual arts, and literacy.

Steve Stahl is a Professor of Reading Education at the University of Georgia and a principal investigator at the National Reading Research Center. He was formerly at the Center for the Study of Reading at the University of Illinois. A former elementary school teacher, his research interests are centered around issues in reading instruction at the primary grades and the relationship between vocabulary knowledge and reading comprehension.

Carol Susann Stavropoulos is an Assistant Professor of Art at the University of Georgia. She has served as technical consultant and researcher for the Ohio Partnership for the Visual Arts, sponsored by the Getty Center for Education on the Arts. Dr. Stavropoulos is the chair of the Arts and Learning Special Interest Group of the American Educational Research Association.

Thomas G. Sticht, President of Applied Behavioral and Cognitive Sciences, Inc., and Project Coordinator for the San Diego Consortium for Workforce Education and Lifelong Learning, is a recipient of IRA's Albert J. Harris Award, a member of its Reading Hall of Fame, UNESCO's International Literacy Prize Jury, and the National Governor's Association's Advisory Group for National Education Goal 6 (adult literacy). He has also chaired the California State Legislature's Workforce Literacy Task Force.

Susan Strecker is a doctoral student in Language and Literacy Studies at the University of Texas at Austin and Early Childhood Education instructor at Texas Lutheran University. A former Texas Teacher of the Year, she is particularly interested in literacy acquisition and public policy.

Michael R. Strickland, who teaches at Jersey City State College, is a poet. His many books include *Families: Poems Celebrating the African American Experience* (with Dorothy Strickland), *Poems that Sing to You*, *African American Poets*, and *Another Haircut at Sleepy Sam's*.

Anne P. Sweet is a Senior Research Associate in the National Institute on Student Achievement, Curriculum and Assessment, Office of Educational Research and Improvement, U.S. Department of Education. She is the National Institute's team leader for humanities, language arts, and social sciences, and the U.S. Department's scientific and technical expert on research in reading and K-12 literacy. Her research interests include arts-based approaches to literacy learning.

Robert (Rob) J. Tierney is Professor of Language, Literacy and Culture at Ohio State University and Director of the School of Teaching and Learning. Former editor of the *Reading Research Quarterly*, Past President of the National Reading Conference, and past chair of National Council of Teachers of English Research Assembly, he has worked collaboratively with students, teachers, and groups such as Apple Computer's Classroom of Tomorrow, Children's Television Workshop, and others.

Josefina (Josie) Villamil Tinajero is Assistant Dean of the College of Education and Professor of Bilingual Education at the University of Texas at El Paso where she also directs the nationally acclaimed Mother-Daughter / Father-Son Programs. She is the president of TABE—the Texas Association for Bilingual Education. Her most recent publication is *The Power of Two Languages: Literacy and Biliteracy for Spanish Speaking Children* (Macmillan / McGraw-Hill).

Steven Tozer, Associate Professor in the College of Education at the University of Illinois at Chicago, studies the social foundations of education. His book, *School and Society*, devotes a chapter (with Arlette Willis) to analysis of literacy in ideological context.

Diane H. Tracey is an Assistant Professor of Reading at Kean College of New Jersey where she teaches graduate and undergraduate courses in reading and literacy education. Her

primary research interests include family literacy and the affective dimension of literacy learning.

JoAnne L. Vacca is a Professor of Curriculum and Instruction at Kent State University, Kent, Ohio. She was Chair of the Department of Teaching, Leadership and Curriculum Studies for ten years. A coauthor of *Content Area Reading* and *Reading and Learning to Read*, Dr. Vacca is Chair of the International Reading Association's Teacher Educator Award Committee.

Richard T. Vacca is a Professor of Teaching Leadership and Curriculum Studies at Kent State University, Kent, Ohio. A widely published author and a respected teacher, he is a recipient of the College Reading Association's 1989 A. B. Herr Award for Outstanding Contributions to Reading Education. Dr. Vacca served as the 42nd president of the International Reading Association in 1996–97.

Sheila W. Valencia is Associate Professor of Curriculum and Instruction at the University of Washington, Seattle. Her teaching and research focus on literacy instruction and assessment, with a special emphasis on classroom-based assessment. Dr. Valencia has served on the advisory boards of several national, state, and professional assessment projects including the National Academy of Education, National Task Force on Assessment, and the Joint Committee on Assessment of NCTE and IRA.

Richard L. Venezky is Unidel Professor of Educational Studies and Professor of Computer and Information Sciences and of Linguistics at the University of Delaware. He is also the National Research Director for the U.S. Secretary of Education's Initiative on Reading and Writing, President of the Reading Hall of Fame (1996–97), and director of computing for the Dictionary of Old English at the University of Toronto. His research interests include human information processing and literacy.

Kathy Waugh is Senior Editor at the Boston-based National Public Television station, WGBH. She directed the creation and development of the *Arthur* television series, which is broadcast nationally. She is interested in the role of television as a medium that will promote an expanded definition of what it means to be literate.

Lee Weinstein currently works in literacy and community development for organizations in the Downtown Eastside of Vancouver, designing literacy projects that reflect the lives of learners and their community. In addition to founding the Invergarry Learning Center in Surrey, B.C., he is the cofounder (with G. Pharness and others) of *Voices* magazine.

Gordon Wells is a Professor of Education in the Ontario Institute for Studies in Education in the University of Toronto. Dr. Wells' teaching is in the areas of language, literacy, and learning across the curriculum. His research is conducted collaboratively with teachers in the "Developing Inquiring Communities in Education Project," in which they are exploring the roles of spoken and written discourse in classroom activities.

Louise C. Wilkinson is Dean of the Graduate School of Education at Rutgers University. An elected Fellow of the American Psychological Association, she was appointed to National Review Panels for the U.S. Department of Education and the National Science Foundation. She has also served as a United States delegate to international education fora sponsored by the Organization for Economic Cooperation and Development, and the Organization for Asian Pacific Economic Cooperation.

Arlette Ingram Willis is an Assistant Professor with the Language and Literacy faculty in the Department of Curriculum and Instruction at the University of Illinois at Urbana-Champaign. Her current research and scholarly interests focus on preparing teachers to teach literacy in a diverse society, multicultural literature for grades 6–12, and historic barriers to literacy acquisition in the United States.

Michael Willmorth is a communication researcher at Boise State University in Idaho. He has conducted and published several studies on language and communication and has investigated the relationship between regional speech patterns and the mass media.

Karen K. Wixson is a Professor of Education and Associate Dean for Graduate Studies in the School of Education at the University of Michigan. She is currently studying the impact of the professional development component of the Michigan English Language Arts Framework (MELAF) project on teacher and district practices. She and others involved with this project recently published language arts articles discussing living and working with these standards.

Lauren L. Wohl is Director of Marketing and Publicist at Disney and Hyperion Books. She works with authors and film directors to coordinate books and films. She is very interested in unifying the multiple forms of communication in an attempt to strengthen children's literacy.

Jennifer Lynn Wolf has been a teacher of drama and English in secondary schools in California for the past ten years. Currently she teaches in the Cotati-Rhonert Park Unified School District in Sonoma County, California, where she attempts to expand student literacy through the use of multimedia.

Shelby A. Wolf is an Assistant Professor of Literacy Education at the University of Colorado at Boulder. Currently a National Academy of Education Spencer Postdoctoral Fellow, she is working on a study of preservice teachers' understandings of literacy. She is the coauthor of *The Braid of Literature: Children's Worlds of Reading* (Harvard University Press, 1992) and is working on a drama book with Dr. Heath entitled *A Different Stage: Multiple Selves in Community Youth Theatre*.

Karen D. Wood is a Professor of Reading Education at the University of North Carolina at Charlotte. A former middle school teacher and K–12 instructional coordinator, she is the author of numerous articles, chapters, and books relating current research and theory to classroom practice. Her current research interests involve strategies for improving students'

viewing abilities, meeting the needs of diverse learners in the classroom, and integrating flexible grouping across the curriculum.

Philip Yenawine is a partner in Development Through Art, an educationally based company. Formerly he served as director of art education at the Metropolitan Museum of Art. He is interested in the viewer's perception of art as a medium that expands one's literacy.

Jane Yolen, noted author, has won numerous awards: *Owl Moon* won the Caldecott Award in 1988; *The Emperor and the Kite* was a

Caldecott Honor Book; *The Devil's Arithmetic* won the Jewish Book Council Award, *Commander Toad in Space* won the Garden State Children's Book Award; *Piggins* won the Nebraska and New York State Children's Book Awards.

Josephine Peyton Young is a Graduate Research Assistant at the University of Georgia. She participates in the work of the National Reading Research Center. A former classroom teacher and musician, she examines images created in song as a means to motivate literacy learning for all children.

REVIEWERS

Arthur N. Applebee – Professor, State University of New York at Albany

Walter L. Buster – Teacher, Cotati-Rohnert Park Unified School District, California

Elizabeth Chiseri-Strater – Professor, University of North Carolina at Greensboro

Michelle Commeyras – Professor, The University of Georgia

Joan Curry – Professor, San Diego State University

Carol Dixon – Professor, University of California, Santa Barbara

Janet Emig – Emeritus Professor, Rutgers University

Nancy Farnan – Professor, San Diego State University

Sherri Furqueron – Director of Reading / Language Arts, Lightspan

James Paul Gee – Professor, Clark University

Celia Genishi – Professor, Teachers College, Columbia University

Kelly M. Goss – Teacher, San Diego Unified School District

Judith L. Green – Professor, University of California, Santa Barbara

Madeleine Grumet – Professor, City University of New York, Brooklyn College

John T. Guthrie – Professor, University of Maryland, College Park

Barbara Kapinus – Council of State School Officers, Maryland

Laurie Katz – Professor, Vanderbilt University

Judith Smith Koroscik – Professor, Ohio State University

Michelle M. LeTourneau – Teacher, San Diego Unified School District

Beverly Whitaker Long – Professor, University of North Carolina at Chapel Hill

Linda Lungren – Magnet Coordinator, San Diego Unified School District

Judith A. Meagher – Professor, University of Connecticut

Juel A. Moore – Principal, San Diego Unified School District

Elyse Pineau – Professor, Southern Illinois University, Carbondale

Georgiana Short – Professor, Ohio State University

Michael Smith – Professor, Rutgers University

John Stewig – Professor, University of Milwaukee

Lynne Thrope – Director, The Reading Room, El Cajon, California

Janice VanDyke – Instructor, San Diego State University

THEORETICAL BASES FOR
COMMUNICATIVE AND VISUAL
ARTS TEACHING

This page intentionally left blank

INTRODUCTION

Paul Messaris

ANNENBERG SCHOOL FOR COMMUNICATION
UNIVERSITY OF PENNSYLVANIA

In recent years the term “literacy” has undergone a notable transformation. In its original sense the term signified the ability to read and write—in other words, the cognitive skills associated with the use of written language. Nowadays, however, one frequently comes across references to “visual literacy,” “computer literacy,” “television literacy,” and the like. This extension of the literacy concept beyond the domain of verbal language is the result of a parallel change in conceptions of the proper scope of education. As the applications of image-based media in both homes and workplaces continue to expand, there is a growing realization that our educational system needs to do more in the way of preparing young people to deal effectively with nonverbal modes of communication—not at the expense of verbal language learning, but as a necessary complement to it. It is this broadening of educational focus that is reflected in the concept of multiple literacies.

The 10 chapters in this part of the handbook offer a theoretical basis for thinking about the integration of the multiple-literacies concept into the educational curriculum. In these chapters, as well as in the broader public discourse on these matters, the term literacy is used in two relatively distinct senses: on the one hand, it may be viewed positively, as an instrument for achieving intellectual growth. On the other hand, however, literacy is sometimes seen in a more negative light, as a means of defense against the potentially damaging influences of mass media. Although both of these aspects of literacy are important, the primary focus here is on the positive side of the phenomenon. In other words, literacy is treated mainly as a foundation for creative engagement with one’s social and physical environment.

In Chapter 1, “Literacy for the Information Age,” Renee Hobbs gives a more detailed account of the issues introduced above. Hobbs begins by pointing out that educators have traditionally taught *with* television and other media, as audio-visual aids, but not *about* these media. She then argues that the increasing importance of media messages in the lives of young people calls for a redefinition of the term “literacy,”

encompassing all forms of messages and including critical evaluation in addition to the skills of production and comprehension. Hobbs connects this expanded definition to five ideas which she considers essential components of any program in media literacy: all messages are the result of selection and choice among a variety of options; all messages are reflections of a particular view of social reality; the meanings of messages arise in the act of interpretation by individual receivers; the interpretation of messages is enhanced by an understanding of their economic, political, social, and aesthetic purposes; effective communication depends on an appreciation of the unique characteristics of each medium, format, and genre. According to Hobbs, this way of looking at literacy has significant implications for a wide variety of issues facing educators today, and she concludes by discussing several of these issues, including the relationship between schools and communities, multicultural education; ESL/bilingual education, the integration among various subject areas, and the development of new tools of assessment.

David Reinking, Linda Labbo and Michael McKenna reiterate the growing necessity for an expanded view of literacy. Their chapter “Navigating the Changing Landscape of Literacy: Current Theory and Research in Computer-Based Reading and Writing,” confronts the narrow perceptions which underlie a stagnant concept of literacy, focusing on the computer as a powerful impetus for growth. Their review of the computer’s profound influence on modern life serves as a compelling suggestion that literacy researchers begin to anticipate the inevitable rise of computer-based innovations, such as electronic text. They argue that the dominant role that electronic text will play in the near future requires that literacy researchers abandon their bias toward the printed text ... and that refusing to acknowledge it dooms them to obsolescence.

The paradigm shift that must precede optimal integration of computers into literacy programs necessitates the development of comprehensive pedagogical theories. The authors identify new research avenues, emphasizing the need for a broad base of theoretical perspectives. A critical element of

the requisite research on the sociocultural and instructional implications of electronic text is an inquiry into the qualities which are unique to electronic text. These distinguishing characteristics are: the interactivity and malleability of electronic texts, their organic inclusion of multimedia, or audiovisual effects, their flexible parameters of freedom and control, the richly varied textual structures they enable, and the new pragmatics and sociopolitical dimensions they contribute to the established literacy tradition.

In addition to the differences between electronic and printed texts, careful consideration of the generalizations that have emerged from classroom-based research will inform pedagogical theories about the computer's role in literacy development. Interestingly, these findings, which will inspire and guide future inquiry, are not always consistent with the assumptions on which much of the instructional use of computers is currently based.

The chapter closes with a discussion of the contemporary and past issues and trends in research on computer-based instruction. The authors note the promising shift from a constrained perspective on the computer's role within our established agenda to a fuller understanding of how it may substantially alter our notions of "reader," "writer," and "text."

The implications of an expanded definition of literacy are also addressed explicitly by Roger Desmond, in his chapter, "TV Viewing, Reading and Media Literacy." Desmond observes that the application of the literacy label to pictorial media has led to objections by writers who argue that video and print are not only logical opposites but also antagonistic to each other. Much of Desmond's chapter is devoted to a careful examination of one facet of this relationship, namely, the possibility that TV viewing has a negative impact on students' reading ability. In reviewing the research evidence on this topic, Desmond finds that there is indeed a recurring negative association between reading skills and viewing, but that the reasons for this association are not clear, since there is only mixed support for the most obvious explanation, that of simple displacement of one activity by the other. The likelihood that television is harmful to reading and school performance may be one reason for the fact that many media-literacy programs tend to emphasize the defensive side of the literacy concept. In noting this tendency, Desmond discusses the need to supplement it with an exploration of the ways in which media literacy can improve a viewer's capacity to use media as sources of information and insight. More specifically, he lists two components of this latter form of visual literacy: first, a viewer's ability to optimize the mental effort invested in the interpretation of any particular type of program; second, the ability to relate previous media experience and real-world knowledge to newly encountered content.

Susan Neuman also considers television's potential contribution to literacy development in her chapter, "Television as a Learning Environment: A Theory of Synergy." She demonstrates the qualitative differences among the various media, arguing that each of these distinct variations stimulates different cognitive processes. Accordingly, in order to develop the broadest range of processing skills, we must explore the ways

in which the media can complement each other. Her "Theory of Synergy" derives from and complements this notion. The theory suggests that the effects of combining media will exceed the sum of their individual merits; that is, coordinating media will amplify the cognitive benefits offered by each individually.

Neuman goes on to outline several variables which affect the phenomenon of media synergy: environmental influence, accord between learner interests and literacy-related media, and the skills necessary for effective media use. Having acknowledged the necessity of future exploration of these factors, she proceeds to discuss the implications of the theory with respect to television. She focuses on the roles of parents and educators in integrating this medium into literacy development programs. The examples cited here clearly illustrate the possibilities offered by the most readily accessible media options.

The theme of using television for purposeful instruction is also taken up by Michael Willmorth in his chapter, "Television and Language Learning." While Neuman and Desmond were concerned about students' skills in dealing with written language, Willmorth's focus is primarily on speech. As in the case of reading ability, there is some evidence suggesting a negative relationship between TV viewing and the development of spoken language. However, as Willmorth demonstrates, the interpretation of these findings is open to question, and the more commonly accepted view in this area of scholarship has tended to be that television experience makes little or no difference to a child's developing mastery of speech. This view is derived from the belief that the acquisition of spoken-language skills depends on the active give-and-take of interpersonal interaction, something that television cannot supply. Willmorth challenges this view in two ways: first, he points out that children's TV viewing often does entail interpersonal interaction, not with the set but with parents, siblings, or other covievers; second, he argues that, at least as far as vocabulary building is concerned, there are both theoretical and empirical reasons for assuming that active interaction may not be as crucial to language learning as previously supposed. With these considerations in mind, Willmorth goes on to discuss the application of television in the language classroom, with special emphasis on the use of TV materials that were not originally designed for instructional purposes. The discussion brings to a close this section's examination of the connection between media literacy and language.

In the next chapter attention shifts to visual matters. Under the rubric, "Visual Communication Skills and Media Literacy," Michael Griffin and Dona Schwartz develop a set of prescriptions for the types of visual knowledge that young people need in order to become competent participants in an increasingly visual culture. More than anything else, the authors argue that young people need to learn the distinction between pictures and reality. That is, they need to learn that photographic images are not simply direct records of the world around us. This learning entails an appreciation of the implications of framing and of other ways in which picture makers select what the viewer will see. It also entails the capacity to think about images in terms of their creators' intentions, as well as the conventions through which those

intentions are expressed. Educators concerned about such matters have often advocated training young people in media production as a method for encouraging their acquisition of these forms of knowledge. Both Schwartz and Griffin have conducted research on the consequences of this sort of visual training, and they report that it can indeed have the desired effect, although in its initial stages it often seems to result primarily in the unreflective copying of mass media conventions. With the aim of contextualizing the knowledge that comes from production experience, the authors suggest that students should also be taught the theory and social history of visual practices.

The visual aspects of media literacy are examined further in the next two chapters of Part I. Both chapters explore the broader cognitive ramifications of learning about visual media. In his discussion of "Visual Intelligence and Analogical Thinking," the author takes as his starting point the fact that visual imagery has historically played an important role in the advancement of science and technology. This fact suggests that there may be significant cognitive commonalities between scientific and artistic creativity. One kind of intellectual process that these two areas appear to share is analogical thinking: the ability to notice underlying similarities between objects or events that are superficially different from each other, and to use those similarities productively as vehicles for deeper understanding and more effective communication. After illustrating how this intellectual process works in scientific discovery and technical communication, the author gives a detailed description of the ways in which analogical connections operate in visual representations. These considerations lead to the conclusion that skill in dealing with visual media may productively be thought of as part of a more encompassing artistic/scientific intelligence.

A similar view of visual literacy motivates Georgette Page's chapter, "Visual Intelligence and Spatial Aptitudes." The latter term refers to a person's ability to form accurate mental models of two- and three-dimensional spatial relationships, and to envision how those relationships would appear from varying points of view. Fluency in this mode of thought is considered a crucial requirement of such occupations as architecture, whose domains of activity or reference are physical structures. Spatial aptitude may also be a prerequisite for some of the cognitive processes that a viewer must be able to perform in the course of interpreting the content of visual media. It is this possibility that Page is particularly concerned with in this chapter. Page has done a substantial amount of research on children's responses to visual media, and this chapter presents data from three of her studies. The aim of these studies was to investigate the relationship between children's spatial skills and their ability to comprehend the composition and the editing in various video clips. In all three studies, this relationship turned out to be positive: children who performed better on tests of spatial aptitude also had higher comprehension scores. Page compares these results with the findings of other researchers, and she concludes that

while her studies treated spatial aptitude as the causal variable, its relationship to spatial literacy may well be one of mutual reinforcement.

With the foregoing discussions of television and other visual media as a backdrop, the next chapter takes a look at the future. In the years ahead, literacy educators will face a rapidly changing media environment. The aim of John Carey's chapter, "Exploring Future Media," is to provide an overview of some of the challenges the environment will pose. After giving a detailed description of major technological developments that are expected to drive the evolution of new media forms, Carey offers a speculative account of potential implications of future media. Among other things, he predicts that new technologies may create greater opportunities for decentralized production and distribution of media materials; that a proliferation of available sources of media content may be accompanied by a narrower targeting of that content to specific audiences; that enhanced image quality and the integration of video and computers may lead to innovations in the "language" of visual media; and that novel forms of advertising may increasingly blur the distinction between commercial messages and program content. Adapting to such developments will be a demanding task, not only for students but also for their teachers.

The need for teachers to be open to new sources of knowledge, both inside and outside of the classroom, is a major concern of the chapter, "Balancing Act: Using Drama to Even the Exchange of Information in the Classroom." The author, Jennifer Lynn Massen, has extensive experience as a drama teacher, and she supports her argument with a wealth of examples drawn from this experience and from additional research. Using drama teaching as a paradigm for education in the communicative arts, Massen discusses a variety of ways in which drama in the classroom can be used to promote a reciprocal flow of information between students and teachers. To begin with, she points out that original productions can act as vehicles for introducing information from students' own lives and experiences into classes and youth groups. She argues further that the capacity to empathize with another person's point of view is central to good acting, and that drama is therefore a way of encouraging both teachers and students to acquire an understanding of multiple truths and perspectives. Another point Massen makes is that the inherently collaborative nature of theater promotes a healthy interdependence among participants—an outcome that is especially likely in contemporary youth drama groups, which typically eschew traditional distinctions between stars and supporting parts. Finally, Massen notes that the experience of producing drama gives the participants the satisfaction of genuine achievement. All these points could be adapted to the more general requirements of teaching about other communicative arts and media. Massen's discussion thus brings a reminder that a vital ingredient in the success of new literacy programs will be the interpersonal environment in which those programs are implemented.

LITERACY FOR THE INFORMATION AGE

Renee Hobbs

BABSON COLLEGE

For citizens living in the United States at the end of the 20th century, it hardly seems necessary to state the evidence which shows the dominance of film, television, and other mass media products on the lives of Americans (see Alton-Lee, Huthall, & Patrick, 1993; Howe, 1983; Kubey, & Csikszentmihalyi, 1990 for examples of recent evidence). There are few educators still in the practice of teaching who hold the same level of animosity toward television as the generation of teachers in the 1950s and 1960s, many of whom viewed television as their professional nemesis. Many teachers are increasingly using mass media "texts" to enrich their subject areas, comfortably moving between the textbook, the trade book, the newspaper, the film and the videotape in their efforts to bring rich ideas into the classroom.

As for the study of images and mass media in elementary and secondary schools, there has been increasing momentum among language arts and social studies teachers to include media analysis and production activities in the classroom. However, since the word "media" has become entrenched in the educational community as the province of librarians, and media technologies and messages conceived of as merely a delivery system to transfer messages, images have been relegated to the margins, taken for granted to serve as mere decoration. In a society where media use is the central leisure activity for most of its citizens and the dominant source of information about the world, the study of the mass media has been neglected in schools. Students have had little instructional support analyzing and thinking about media messages. Educators often mistakenly believe that they are engaged in expanding the concept of literacy when they use television to teach *with*, and few understand that media literacy consists of teaching *about* media as well.

So the problem is clear: our students are growing up in a world saturated with media messages, messages that fill the bulk of their leisure time and provide them with information about who to vote for and what consumer decisions

to make. Yet students receive little to no training in the skills of analyzing or evaluating these messages, many of which make use of language, moving images, music, sound effects, special visual effects and other techniques that powerfully affect our emotional responses.

Educators' exclusive focus on language is a legacy of the historical context of the past, when cultural survival depended upon the mastery of the printed word. While these skills are even more important today, language is only one of a number of symbol systems which humans use to express and share meaning. Changes in communication technologies over the past 100 years have created a cultural environment that has extended and reshaped the role of language and the written word. Language must be appreciated as it exists in relationship to other forms of symbolic expression — including images, sound, music and electronic forms of communication. Scholars and educators are coming to recognize that literacy is not simply a matter of acquiring decontextualized decoding, comprehension and production skills, but that the concept of literacy must be connected with the culture and the contexts in which reading and writing are used (Cook-Gumperz, 1986).

This chapter urges educators to consider this new definition of literacy, a definition adapted by the author based on the work of educators who identify themselves with the "media literacy" movement (Firestone, 1993):

Literacy is the ability to access, analyze, evaluate and communicate messages in a variety of forms.

Embedded in this definition are both a process for learning and an expansion of the concept of "text" to include messages of all sorts. This view of literacy posits the student as being actively engaged in the process of analyzing and creating messages, and as a result this definition reflects some basic principles of school reform, which generally include:

- inquiry based education
- student-centered learning

- problem solving in cooperative teams
- alternatives to standardized testing
- integrated curriculum

BASIC PROCESSES OF LITERACY: ACCESS, ANALYZE, EVALUATE AND COMMUNICATE

The four processes which constitute the new vision of literacy provide a powerful frame in which to consider how people develop skills in using language and other forms of symbolic expression. For example, the ability to *access* messages connects with those enabling skills that include decoding symbols and building broad vocabularies. It also involves those skills related to the locating, organizing and retrieving of information from a variety of sources. Additionally, access requires the ability to use the tools of technology, including video technology, computers and various on-line services. Access skills are often labeled as information literacy, or more recently, "driver training for the information superhighway."

The ability to *analyze* messages connects with those interpretive comprehension skills that include the ability to make use of categories, concepts or ideas; determine the genre of a work; make inferences about cause and effect; consider the specific strategies and techniques which are used to construct the work; and identify the author's purpose and point of view. At the secondary level, the ability to analyze messages may also include a recognition of the historical, political, economic or aesthetic contexts in which messages are created and consumed.

The ability to *evaluate* messages concerns those judgments about the relevance and value of the meaning of messages for the reader, including making use of prior knowledge to interpret a work; predicting a further outcome or a logical conclusion; identifying values in a message; and appreciating the aesthetic quality of a work. Although the skills of analysis and evaluation are frequently conflated by practitioners of media literacy, it is important to recognize that analysis skills depend upon the ability to grasp and make effective use of conceptual knowledge that is outside the student's own perspective, while evaluation skills make use of the student's existing world view, knowledge, attitudes and values.

The ability to *communicate* messages is at the heart of the traditional meaning of literacy, and the skills of writing and speaking have been highly valued by educators. In the last 20 years, writing has come to approach the primacy that reading has held in the language arts hierarchy. Communication skills are diverse and, to some extent, media-specific. General skills include: the ability to understand the audience with whom one is communicating; the effective use of symbols to convey meaning; the ability to organize a sequence of ideas, and the ability to capture and hold the attention and interest of the message receiver. Media-specific production skills for video include: learning to make effective choices in framing and point of view; learning to use visual and auditory symbolism; and learning how to manipulate time and space effectively through editing.

Expanding the Concept of "Text"

While the four concepts provide a new frame for thinking about the processes involved when people create and share messages, what makes the new vision of literacy so powerful is the application of these skills to *messages in a variety of forms*. At present, reading / language arts educators focus on literature as the core of the K-12 curriculum: the short story, poetry, drama and nonfiction are claimed to be ideal because they "motivate learning with appeal to universal feelings and needs ... classic literature speaks most eloquently to readers and writers" (California State Board of Education, 1986, p. 7).

But they also may seem disconnected and remote from the experiences of students, who have been "escorted across the globe even before they have permission to cross the street" (Meyrowitz, 1985, p. 238) by the television. Critics have claimed that, too often, a literature-based reading / language arts program "ignores the life experience, the history and the language practice of students" (Freire, & Macedo, 1987, p. 146), and that when literary materials are used primarily as vehicles for exercises in comprehension and vocabulary development, students may become alienated from the processes of reading and writing in a range of contexts.

In the past, educators have been comfortable to disenfranchise and overlook present-day cultural products, especially television, even though many works of literature which are now considered classic or traditional began their life as popular works designed for mass audiences (Beach, 1992). But just as scholars and critics have engaged in heated controversy over what texts are appropriate study objects to be included in the canon of essential literary works (Gless, & Herrnstein Smith, 1992), these debates are filtering into changes in the curriculum.

Many educators have discovered that the analysis of contemporary media can build skills that transfer to students' work with the written word. When educators permit and encourage the study of contemporary media products in classrooms, students develop skills that alter and reshape their relationship to media products. Nehamas (1992) explains that "[s]erious watching ... disarms many of the criticisms commonly raised about television." More important, analysis of media texts helps students gain interest in writing and speaking, and helps nurture students' natural curiosity and motivation. Consider a story presented by Lauren Axelrod (cited in White, 1993a), a high school teacher in Houston, Texas:

I used media literacy concepts to get my low-achievement students to tackle Conrad's *Heart of Darkness* and T.S. Eliot's *The Wasteland*. I started with an extensive analysis of the Francis Ford Coppola film, *Apocalypse Now*, and we discussed the film's narrative structure, mood, point of view, rhythm and character development. Then a team of students read Conrad while another team read Eliot. We then applied the same concepts to the short story and poem in group discussion and writing exercises. Finally, students created a videotape which compared and contrasted the three works with each other. I saw students turn on to literature in a way I never saw them engage with anything in the classroom.

Media education exists as an increasingly vital component of elementary education in Great Britain, Canada, Australia,

Spain and other nations. In Great Britain the mandate includes media education as a strand within the National Standards developed in English, which requires students to study the ways in which media products convey meanings in a range of media texts (Alvarado, & Boyd-Barrett, 1992; Bazalgette, 1992; Brown, 1991; Buckingham, 1991; Lusted, 1991; Masterman, 1985). While still controversial among those who favor a more traditional and narrow view of 'culture,' scholarly work in media pedagogy has grown widely, and consensus is growing about the set of concepts, skills and learning environments that best help strengthen students' ability to access, analyze, evaluate and communicate messages in many forms.

The New Vision: Key Analytic Concepts

Current approaches to reading / language arts often make use of a laundry list of concepts that inform the work of teachers and students in a classroom. Such lists are the result of adding new paradigms for learning upon older models. Layer by layer, the models now used in reading / language arts have become cumbersome and unwieldy (Hawthorne, 1992). Hawthorne writes, "The scope of English heightens the individuality of curricular patterns. ... Teachers are left to weave the various components into a coherent pattern for themselves and their students" (p. 116). But a simple and powerful new definition of literacy, as proposed in this report, makes it possible to identify the most important processes, concepts and skills for K-12 instruction and makes use of these with a wide variety of message forms, from folktales to commercials, from historical fiction to newspaper photography.

Media literacy incorporates the theoretical traditions of semiotics, literary criticism, communication theory, research on arts education and language development. Although the conceptual principles of the new vision of literacy have taken many forms for various curriculum writers in Great Britain, Canada, Australia and the United States, the following ideas are critical components of all programs.

All messages are constructions. Print messages are created by an author who selects the ideas and words to convey meanings. Images are created by a photographer who makes similar selections, and television programs are created by a group of people, led by a producer, who make choices about each image and word used from many possible options. The construction of messages requires careful thinking, creativity and organizational skills. Knowing how messages are constructed helps the reader to appreciate the artistry involved and to better interpret the meaning of a work.

Messages are representations of social reality. Messages have a relationship with the lived experiences of individuals in many cultures. Even when a message is imaginary, hypothetical or fantastic, it represents social reality, which is defined as the perceptions about the contemporary world that are shared among individuals. Messages also represent the social realities of times and places far removed, and help us make sense of the past, present and future. People need the ability

to judge the accuracy of particular messages that may or may not reflect social reality.

Individuals negotiate meaning by interacting with messages. The meaning of a message is found in the act of interpretation. Each reader or viewer uses prior knowledge and experience in the process of reading or critical viewing. A skillful reader or viewer examines many different stylistic features of the text and pays careful attention to the context in which the message occurs in the process of interpretation. Different individuals can find quality and beauty in various texts.

Messages have economic, political, social and aesthetic purposes. People create and share messages for many reasons, but in modern culture making money is one of the most important. Many messages produced in our culture have an economic purpose of some sort. When authors have political purposes, they use a message to gain power or authority over others. When their agenda is social, they use a message to present ideas about how people could or should behave, think or feel. When authors have an aesthetic motive, they use a message to experiment with different kinds of symbolic forms and ideas. Understanding how messages operate in terms of their economic, political, social and aesthetic purposes helps readers better understand the context of a work.

Each form of communication has unique characteristics. An author makes choices about which kinds of media are most appropriate to convey a particular message. Television news has characteristics that favor messages that are immediate and visual, while news photographs have characteristics that favor messages with an emotional component. When writing, an author must carefully choose the most effective genre in which to work, since an essay, a memo, a short story or a poem can all be effective forms, depending on the purpose, audience and content of the message. Being a good communicator means knowing which formats, genres and media to use in a wide variety of situations.

It is clear that the most dynamic concepts of current practice in reading / language arts instruction are wholly consistent with these key concepts. But when educators include the analysis and creation of film, photographs, newspapers, radio and television, new concepts are required to enable students to ask critical questions about these contemporary forms. Some of these concepts may be unfamiliar to reading / language arts teachers, particularly at the elementary level. For example, teachers in some communities have sometimes been reluctant to include the analysis of how messages have political or economic purposes. While it may be argued that analysis of the economics of literature is not of central value for young students, analysis of the economics of media messages is essential to help middle school and high school students understand the nature of communicative messages in contemporary culture. It would be irresponsible to include the study of film, television, newspapers or other mass media without providing students in grades 4 and up with a paradigm to help them understand the ways in which messages have value in the marketplace.

Media Literacy and Critical Thinking Skills

As glossily packaged and presented film, video and advertiser-supported materials enter the school classroom, teachers often consider video materials valuable because everyone in a classroom is presumed to be able to decode the messages on the screen. But the new vision of literacy presented in this chapter is not just aimed at cultivating the relatively simple process of decoding messages—it is the sophisticated analysis, evaluation and the active creation of messages that are the most significant, complex and vital skills needed for survival in an information age. These take a lifetime to master fully.

Even very young students can engage in conceptual analysis and evaluation of media messages, at a time when they are still beginning to master the decoding and comprehension skills required for print. According to Resnick (1987, p. 31):

The most important single message of modern research on the nature of thinking is that the kinds of activities traditionally associated with thinking are not limited to advanced levels of development. Instead these activities are an intimate part of even elementary levels of reading ... when learning is proceeding well.

When teachers make use of a full range of messages in developing children's literacy, higher-order cognitive skills can be integrated into the activities of very young children using media messages as study objects. This helps motivate students to master the basic accessing skills to crack the code of the printed word. These analytic concepts, already familiar to students in their work with media artifacts, can then be applied to print forms. Elementary teachers who have used this approach find that "much of the language used to view television critically is transferable to other media—noticing camera angles in photography, understanding differences between reality and fantasy. ... There are also many connections to teaching verbal and written skills" (Lacy, 1993, pp. 11, 12).

What happens, according to British educators, is that when students critically examine a wide range of texts in both print and visual media, they develop more complex expectations about everything they read and see. "Media education is often seen as a way of defending children from television. It ought to be seen as a way of giving them high expectations of television, of all media, and of themselves" (Bazalgette, 1992, p. 45). Such views represent the potential of expanded literacy in reshaping the character of our nation's near limitless appetite for mass media products and in doing so, helping citizens reconnect to the rich storehouse of literary treasures from many cultures, past and present. If media literacy skills help young people develop an appetite for reading, we would judge it a stunning success. If media literacy skills help young people develop an appetite for the stimulating, complex and provocative kinds of television programming increasingly more available as a result of cable television, then in time, we would expect media industries to begin increasing the quality of programming. Such goals have yet to be examined among researchers because, as yet, there are so few community or school-based laboratories where media literacy is being implemented at a system-wide level. (The author is aware of

only three districts in the United States which have attempted media literacy initiatives designed to reach all students in the school district: Billerica, Massachusetts; Cold Spring, Minnesota; and Dennis-Yarmouth, Massachusetts.)

THE CONSEQUENCES OF EXPANDING THE CONCEPT OF LITERACY

The new vision of literacy has consequences for some of the most important issues which face American educators today. As developed in the following pages, this chapter outlines how the new vision of literacy helps restore the important connection between the school and the culture, making education more relevant to the communities to which students belong. It also outlines how the new vision of literacy reflects the kind of authentic learning which occurs when reading and writing occur in contexts where "process, product and content are all interrelated" (Edelsky, Altwerger, & Flores, 1991, p. 9) and where language skills and language learning are conceived of as being inherently social processes, requiring direct engagement and experience tied to meaningful activity.

Building Relevance Between the Classroom and the Community

The claims by now are depressingly familiar: many students actively resist the process of learning in school, and while they can decode language, they cannot infer meaning; the school curriculum is fragmented and decontextualized, promoting indifference and intellectual dependency (Diaz, 1992; Hirsch, 1989). Fortunately, elementary educators have already begun to respond to these criticisms by making changes in their methods of instruction: moving away from a curriculum which emphasizes facts and isolated skills and toward an emphasis on collaborative, active learning which involves complex thought and interpretation.

Multicultural education is education that values human diversity and acknowledges that "alternative experiences and viewpoints are part of the growing process" (Grant, 1993). The new vision of literacy proposed in this report is fueled by this philosophy. It promotes cultural pluralism and social equality by making changes in the processes and content of school curriculum; in doing so, it is centered on "building meaningful relationships between curriculum and life" (Pang, 1992, p. 67).

Carlos Cortes argues that media literacy is essential to multicultural education, noting that media literacy strengthens students' knowledge about various media forms, helps develop analytic and creative skills in responding to media, and helps students become skilled in using print, images, sounds and other tools to express and share ideas. Cortes (1991, p. 153) writes, "Media can be used to stimulate students to consider multiple perspectives on current and historical multicultural dilemmas." Clearly, both multicultural education and the new vision of literacy proposed here share the goal of opening up the canon to expand the range of works which are studied in the classroom.

Not unexpectedly, much of the criticism that has developed about the inclusion of works by Hispanic Americans, Native Americans, African Americans and others can be directed at the new vision of literacy as well, which would include works from popular culture which some critics have labeled "trash." Educators who believe that "good literature" is a "salve one can apply to children from the wrong side of the tracks to heal them of their background" (Beach, 1992, p. 554) are likely to resist any effort which attempts to make the canon more responsive to the lives of students and their communities. But John Beach recognizes that the time is ripe to examine the variety of definitions of "good literature" and suggests that instead of viewing literature as a pyramid which places classic works at the top and works of popular culture at the bottom, it should be considered "like a tree with many branches; the 'best' can be found at the tip of each branch."

ESL / Bilingual Education. How might the new vision of literacy affect students who come to school speaking other languages besides English? According to bilingual / educators, the instructional methods which are most effective in ESL / bilingual education are identical with the active learner-centered model which the new vision of literacy promotes. Techniques which make use of drama, songs, objects and audiovisual materials to help convey meaning and content are highly effective.

In Portland, Maine, media artist Huey (also known as James Coleman) developed a media education program for ESL students speaking 27 languages, where students make film and video using animation and live-action techniques. Portland elementary teachers "have found that Huey's approach offers their students a creative way to improve their English, their public speaking and their communication skills in general. ... and it breaks down walls between schools and communities through cable TV and closed circuit screenings and student research within the community" (White, 1993b).

Writing for the College Board, Hirsch (1989, p. 60) notes:

Over and over again, teachers in ESL and bilingual classrooms have realized the power of authentic tasks to motivate communication and language learning. ... In searching for authentic tasks and materials, many ESL and proficiency teachers are looking beyond traditional textbooks to primary sources in the language they are teaching, including newspapers, television commercials, menus, hotel receipts, children's books, and journalism and fiction.

Parent Education. In some communities, parents are active and supportive players in the day-to-day life of the school. In too many communities, however, parents are disenfranchised partners in the educational process. In considering the relationship between the new vision of literacy and the home-school connection, it is necessary to identify the high level of ambivalence and concern that many citizens have with the ways film, television and other mass media have shaped public discourse. Many adults believe that television has damaged the process we use to elect public officials, that mass media organizations disrupt the private lives of individuals unnecessarily; that violence in film and television programming desensitizes people and alters their conceptions of the

social world; and that the values of sensationalism have reshaped culture and the arts (Bianculli, 1993).

The new vision of literacy proposed in this chapter is based on a fundamental truism about the purpose of democracy: in order for citizens to be engaged in self-governance, they must critically analyze and evaluate information and resources. This work is essential if citizens are to take meaningful action and make meaningful decisions on issues of concern to the community. But in a culture in which citizens see themselves as spectators and consumers, democracy is threatened. When citizens do not employ their skills of analysis and evaluation to information and entertainment products, apathy and cynicism reign.

The new vision of literacy could help encourage parents to more fully embrace their responsibilities to help their children interpret the meanings of the complex messages which bombard them everyday. Too often, parents feel intimidated by the activity of the classroom, by routines that are established by educators who may unintentionally disempower parents from embracing their own authority as interpreters of textual materials. While some parents may hesitate to voice their interpretations of a literary work, parents often feel quite comfortable discussing their interpretations of a film, a situation comedy, a dramatic series, a documentary or an op-ed article. The new vision of literacy creates opportunities for parents and their children to engage with the complex task of sorting out the meanings of the messages in the environment.

Making Classrooms Centers for Authentic Learning

Educators have been discussing how to make learning more authentic since the 19th century, when John Dewey first began outlining how children's own activity, their work, could be a vehicle for learning. When learning is authentic, the content of classroom discourse is meaningful and relevant to students; language skills are not taught in isolation; connections between subject areas are emphasized. According toSizer (1984), in authentic learning environments, students learn through direct experience with tasks they themselves value, with intellectual stimulation from teachers who ask thoughtful questions and provide supportive coaching.

The new vision of literacy helps nurture new relationships between teachers and students, helping rebind the current contrast that "exists between *paidia* (play) and *paideia* (education)" (Gallagher, 1992), based on the recognition that the aim of the reading / language arts teacher is to cultivate a learning environment where students bring their own naturally energetic exploration to the study of new ideas. Rather than considering language development as a series of isolated and fragmented skills, the new vision of literacy puts students at the center of the processes of accessing, analyzing, evaluating and communicating messages. Most important, the new vision of literacy is centered around empowerment, defined as the "process through which students learn to critically appropriate knowledge existing outside their immediate experience in order to broaden their understanding of themselves, the world and the possibilities for transforming the taken-for-granted assumptions about the way we live" McLaren, 1989, p. 186).

Integration with other subject areas. As is clearly evident, the new vision of literacy provides a simple, process-based model that makes connections between reading / language arts, the visual and performing arts, social studies and science. Shepard (1993, p. 35) explains how the new vision of literacy is an ideal tool for subject integration at the elementary level:

If media literacy is presented to [teachers] as just another add-on, there will be little hope for its adoption. If, however, media literacy is presented not just as something that meets students' needs, but something that will meet the teacher's need to integrate the disparate elements of a broad curriculum, then it stands a good chance of becoming an important part of the curriculum. In fact, media literacy functions so well as an integrator that it would be worth using even if it were not as intrinsically important as it is.

Since mass media artifacts are relevant to science, social studies, the visual and performing arts as well as reading / language arts, teachers can easily make connections that stretch across subject areas by teaching with media and teaching about media.

In some communities teachers across the core subject areas are being trained in how to integrate media literacy concepts into many curriculum areas. In Billerica, Massachusetts, teachers in language arts, social studies, health education, science and the visual and performing arts are discovering the synergy which results from team-developed initiatives. For example, in the spring of 1994, teachers collaborated on a district-wide program to help students critically analyze tobacco advertising as part of the health curriculum. Students examined the historical, political and economic dimensions of tobacco advertising; they reviewed, categorized and analyzed a huge volume of persuasive materials designed to make smoking look attractive; and they made their own public service messages, targeted at their own community, to persuade them against smoking. More than 2,000 students in grades K–12 participated in the project by designing slogans, writing newspaper editorials, designing billboards, bumper stickers, posters, radio ads and videotape public service announcements. Teachers persuaded the local billboard company to put up one student's billboard design on the major highway of the town, giving thousands of citizens the opportunity to read a child's message, and creating a powerful message for students. Such examples emphasize the ways in which media literacy activities bring a renewed sense of relevance between the worlds of the classroom and the world of contemporary culture.

Using new tools of assessment. When assessment is authentic, it has as its central purpose the goal of providing feedback to a child and his or her parents about the quality of the learning experience. When assessment is authentic, it mirrors the ways in which standards of quality are evaluated in the world outside of the classroom: through close examination of products and performances.

For more than a century, assessment in the United States has been shaped by the needs of scholars and academics to standardize and quantify learning experiences (Gould, 1981). This has led to an atomized, fragmented view of the learning process, one conducive to "data reduction." Now, educators are coming to recognize the need to reclaim the assessment

process, and as a result, diverse new forms of assessment are being used in schools.

The new vision of literacy provides simple and direct opportunities to observe, monitor and evaluate the processes of accessing, analyzing, evaluating and communicating messages in a range of informal and formal settings. Since the creation of messages is central to the new vision of literacy, portfolio-based models of assessment are consistent with the new vision. Indeed, the premise of the new vision is based on the idea that the processes of accessing, analyzing and evaluating messages all contribute to the creation and communication of messages, so that students can make direct connections between their reading and their writing, their viewing and analysis of images, and the process of creating messages using language, images, sounds, music, graphics and video.

The Toronto Board of Education's Benchmark Program has been using an assessment model designed to demystify educational goals and illuminate the nature of good performance (Larter, & Donnelly, 1993). By combining authentic performance activities with systematic observation and holistic evaluation, teachers can assess student skills in a way which most closely matches the broad general skills that are at the core of reading / language arts instruction. For example, in one benchmark of students' ability to comprehend nonprint information and their oral communication skills, grade 3 students in Toronto are asked to watch a videotape on owls and explain the major ideas in their own words. Students were found to generally lack strong skills in the comprehension of informative video, perhaps because their expectations about television shape their level of motivation and effort in decoding (Salomon, 1979). Such evidence reminds us of the lessons of the reading comprehension scholars—how important it is not to assume that our students understand what they see just because they see it.

The development of standards, tied to authentic performances, that allow educators to assess the quality of students' writing, speaking, listening and thinking skills is consistent with the new vision of literacy. The province of Ontario was the first in Canada to mandate that media literacy instruction be at least 30% of the reading / language arts program in grades 7–12. The performance of younger students from the Toronto Board of Education results suggests that students lack basic comprehension skills of information presented in video formats, pointing clearly to the necessity of direct instruction to help students in grades K–8 learn to comprehend, interpret and analyze a wide range of texts, including messages from television and the mass media.

Staff development issues. Teachers are just as ambivalent about media culture as the rest of the citizenry. As discussed earlier, teachers have a wide range of attitudes about the value and consequences of broadening the concept of literacy to include new materials, especially popular music, film, television and music videos. However, teachers who have attempted to incorporate these materials into their classroom realize that students have a tremendous amount of

knowledge and interest in these messages, and teachers and students can share together in the learning process.

It is not difficult for teachers to move from teaching exclusively with media to addressing media as study objects. Some teachers have described the process as similar to the process of "consciousness raising" about gender and race which many educators experienced in the 1970s. "It's like putting on a new pair of glasses—you see the same things [in media culture], but now I approach these messages differently," wrote one teacher in a program of teacher education at the Harvard Institute on Media Education, a staff development program in media literacy that was conducted by the author in 1993 and 1994 that attracted educators from across the nation.

But German educator Dichanz (1992) writes plainly about what it takes to make the new vision of literacy a reality in schools: "It is the staff that has to translate tasks ... into practical work, and it is that staff that has to be provided with the theoretical background for this new approach..." For U.S. educators, this means that the work of staff development is best accomplished, not by individual teachers acting independently, but through coordinated and sustained efforts, using resources and tools which help them gain access to new ideas and practice new strategies of managing classroom activity. Such work is well underway at the state, district and local levels. For example, the State of New Mexico has mandated

that all students complete a media literacy course before high school graduation, and begun a process of teacher training so that media literacy will be integrated into the curriculum at all grade levels. And in the community of Billerica, Massachusetts, after 3 years of study, 26 teachers have completed the first Master's Degree in Media Literacy, supported by Merrimack Education Center and Fitchburg State College, in order to implement a new vision of literacy in grades K-12 integrated within existing subject areas. Teachers graduating from this program are beginning to teach additional teachers in the New England area.

If media literacy is to emerge as a new vision of literacy for the information age, then a high degree of coordination will be required from among a range of shareholders: the scholarly community, educators in K-12 environments, parents, the publishing and media production industries, and the standardized testing industry. Given the decentralized nature of American schools, it is unlikely that such coordination will receive the support it needs, and more likely that media literacy initiatives will develop as a result of innovation and experimentation in the diverse "labs" of individual districts, schools and classrooms. For an institution which has historically clung to the concept of literacy as the central organizing force of education, we must respect the time it will take educators and scholars to promote the type of sustained and meaningful change that is needed for our schools.

TELEVISION AS A LEARNING ENVIRONMENT: A THEORY OF SYNERGY

Susan B. Neuman

TEMPLE UNIVERSITY

Television usurps so much of our children's time. Surely it must influence their reading growth and developing reading interests. Its lack of intellectual substance, its rapid pacing, its cluttered mixture of visual movement and sound—television's role in the precipitous decline in achievement scores and school standards seems so plausible, so blatant. Why, then, have not researchers found a stronger relationship between television and its deleterious effects on literacy?

Two schools of thought have emerged to answer this question. One claims that there simply are no effects. While viewing may relate to reading achievement, its impact may be just too minor to be considered (Cook, Curtin, Ettema, Miller, & Van Camp, 1986). On the other hand, the second view suggests that effects may be masked due to flawed research designs (Hornik, 1981). Weak, or unreliable measures of viewing behavior, lack of statistical controls, nonrepresentative samples all may have led to ambiguous results and limited progress in the field.

This chapter will maintain that neither school of thought adequately explains the nature of the relationship between television, reading and other media. Rather, it will be argued that a better explanation lies in a theory of synergy: namely, in contrast to one medium (like television) displacing another (like reading), children often engage in a spirited interplay between media (Neuman, 1995). As interests are established, children are likely to alternate between video-based and print-related experiences on the basis of their accessibility, and their capacity to make optimal use of the particular medium. These activities appear to be guided by children's rather consistent patterns of interest, instead of specific medium presentation.

A theory of synergy is based on two propositions: (a) that there are qualitative differences in the content of each medium's messages; and (b) that the skills acquired from media act conjointly in helping children construct meaning

and generate inferences in new contexts. This chapter will explore both propositions, then suggest implications for using television as a learning environment.

QUALITATIVE DIFFERENCES IN MEDIA

The premise that media convey information in qualitatively different forms is a legacy of Marshall McLuhan's elliptical phrase "the medium is the message" (McLuhan, 1964). Prior to McLuhan, there was an emphasis on a medium's content; following McLuhan, an emphasis on its form. In *The Gutenberg Galaxy* (1962) and *Understanding Media* (1964), McLuhan described every medium of communication as possessing a logic or grammar that constituted a set of devices for organizing experiences. Each medium employs specific symbols to tell a story and structures how individuals process and acquire information. A storybook, for example, uses print and illustrations to convey its message. Television uses both the integration of sound and visual images through movement to tell a story.

The distinctiveness of media derives from other critical aspects as well. Among these differences are the particular rules and conventions various media use in their treatment of material, the kinds of content they make available, their historical legacy, and the particular critical mass audience required by the economics of the industry to stay viable in the marketplace. All these factors suggest that while different media may convey similar material, each will do so in a qualitatively different form.

Media Comparison Studies. Intriguing insights by McLuhan led to a research tradition focusing on the distinctive cognitive consequences of media. Meringoff and her colleagues at

TABLE 2-1. Comparing Media

Study	Media compared	Results
Banker, & Meringoff (1982)	Film	Used various bases for substantiating inferences
	Silent film	Conveyed appropriate character affect
	Descriptive aural version of film	Made comments of how film was made
	Recorded story	Used more words in retellings Conveyed appropriate character affect Used more words in retelling Rarely used inferences other than those provided.
Beagles-Roos, & Gat (1983)	TV	Students scored higher in picture sorting. More uses of vague references in retellings Cited more details Justifications in references tied to story actions More expressive language Inferences drawn from verbal content and prior knowledge
	Radio	Produced most complete narratives
Char, & Meringoff (1982)	TV	Higher comprehension of vocabulary Higher vocabulary
	Storybook reading	
	Radio	Shown less comprehension of story Less comprehension of vocabulary Children's retention of action sequences greater
Hayes, Kelly, & Mandel (1986)	TV	Better comprehension More errors in summarizing
	Radio	Retention of dialogue not critical to story
Hoffner, Cantor, & Thorson (1988)	Audio only	Younger children had more difficulty understanding a narrative presented in an exclusively visual form than either audio only or audiovisual.
	Visual only	
	Audiovisual	
Meringoff (1980)	TV	Cited more character actions More physical gesturing Relied on visual content for inferences Recalled more figurative language Based inferences on textual content and outside story information.
	Storybook	
Neuman (1989)	TV	No significant differences in expressive language, retellings of story events and inferences
	Storybook	

Note. From Neuman, 1995.

Harvard's Project Zero (Meringoff et al., 1983) were among the first to investigate these distinctive features of learning from television and other media. One study (Meringoff, 1980), for example, analyzed children's apprehension of an African folktale presented in either an animated televised form or read aloud from a picture storybook. Verbal retellings indicated that children in the television group used character actions and visual cues to describe the story content, while the read-aloud group responded to aural cues or information not given in the story at all. These findings indicated that the specific details of content—the more subtle skills of drawing on one's prior knowledge—may vary according to the medium.

A large number of studies examining cross-media comparisons followed this initial research. Beagles-Roos and Gat (1983), for example, analyzed cross-media comparisons of television and radio on first and fourth graders' story comprehension. Children retold the story equivalently with radio and television presentations. However, there were striking differences across media *in the way* they told the story. The radio version induced children to go beyond explicit and implicit story content to substantiate their inferences, much like the storybook treatment in Meringoff's study. Students, viewing the televised presentation, once again based their inferences on story actions. In a more recent study, Greenfield and Beagles-Roos (1988) found greater imaginative responses to

TABLE 2-2. Differences in Processing Media

Differences relate to	Proposed by	Perceived relationship
AIME	Salmon (1984)	Some media require a different level of effort expenditure than others
Pacing	Singer (1980) Singer, & Singer (1983)	Invariant pacing leads to different level of processing than learner controlled media
Interactivity	Winn (1977) Bagley, & Hunter (1992)	One-way media trains children to learn by observing and imitating; interactive media is constructive

story information when listening to radio than in an animated film format. Other studies, listed in Table 2-1, describe well how different media may influence children's interpretations of stories.

Some researchers following in this tradition have gone so far as to argue that repeated exposure to a particular medium may actually "cultivate" specific cognitive skills (Gerbner, Gross, Morgan, & Signorielli, 1982; Salomon, 1979). In a series of studies measuring children's ability to internalize film-like codes, Salomon reported that students deficient in cue-attending were able to internalize the "zooming" of a camera lens into a stimulus field, increasing their cue-attending skills (Salomon, 1979). Similarly, he found that students could transfer metacognitive modes of representation learned through computer activities to new situations, suggesting that media codes could be internalized, schematized, and then applied to new circumstances (Salomon, 1986). These studies demonstrate an important insight relevant to educators of literacy: different media presentations (television, storybooks, radio, film) do elicit slightly different interpretations of a story which are based on the medium's attributes like sound, moving pictures, and print.

Differences in Processing. Symbol systems are but one aspect of the differences among media. Other attributes, such as the psychological energy needed to process information, the pacing of information, and level of interactivity can influence how and how much children learn from the media (Bagley, & Hunter, 1992; Salomon, 1984; Singer & Singer, 1983).

To focus specifically on processing differences, Salomon introduced the construct of *amount of invested mental effort* (AIME) (Salomon, 1984). According to this model, AIME reflects the level of processing or mental energy needed to be expended to comprehend a medium. Television, with its format and pictures, is regarded by most as an easy medium, requiring little effort to learn. As a result, he argues, children tend to view the medium rather mindlessly, missing valuable opportunities to learn from it. Print, on the other hand, is perceived as "tough," requiring more AIME, leading to greater in-depth processing. Reporting on the invested mental effort in reading a narrative story or a televised version, Salomon found that sixth graders invested more effort in reading, and made more correct inferences than when viewing the tele-

vised version. Further, children in both versions made more correct inferences the more effort they reported investing.

The concept of AIME, however, has been criticized for failing to reflect differences in effort expenditure that may be due to context and purpose: Television viewing in schools, for example, may reflect a very different AIME than viewing television at home before bedtime. Further, a recent study reported that children's mental-effort expenditure may also vary as a function of viewer age, type of program, and reading level (expert readers vs. novice, Bordeaux, & Lange, 1991). Still, Salomon's concept of AIME highlights a potentially important difference among media: children view certain media more efficaciously than others which may influence their ability to learn from them.

Another difference between media is their pacing. Some researchers (Singer, & Singer, 1983) have argued that the pacing of certain media like television or radio may influence how children process information. Singer (1980), for example, suggests that the invariant pacing of television makes it difficult to efficiently retrieve information from memory. The emphasis on visual images in television is thought to favor a holistic interpretation of events, rather than a careful and deeper analysis. Radio, too, requires the listener to react to its pacing. Reading, on the other hand, is slower-paced—by its very deliberation, it seems to provide an opportunity for greater integration of the material with patterns of memory, wishes, and intentions.

Closely related to the pacing of the medium is its level of interactivity (Bagley, & Hunter, 1992). As currently defined, television, radio, and film offer only a one-way mode of communication. Although in some cases audience members may interact with these media, it is only at a superficial level (home shopping networks; call-in shows). Reading and new technologies like CD-ROM, however, are thought to more actively involve the child in the construction of meaning. Reading challenges children to become participants in their own learning. Consequently, these variations among media, described in Table 2-2, suggest that children will engage and use different strategies in interpreting information from them.

A large number of critics, unfortunately, have described these differences in such a way as to suggest that one medium is "good" and another "bad." Such self-declared experts including salesmen (Mander, 1978), journalists (Winn, 1977), and even a hypnotist (Moody, 1980) have claimed that television "dulls the senses," "trains right brain synapses," and "controls," while reading "develops the powers of imagination and inner visualization." A counterthesis, described below, is that the skills and information children acquire from their many experiences with media provide them with knowledge and strategies which may ultimately contribute to their literacy learning.

THE COMPLEMENTARITY OF MEDIA

Suggesting there are distinctive features of media that may influence the way children interpret stories leads to a second premise: children enjoy and learn from many different media.

In the process of interacting with media, children use a wide range of physical, perceptual, and cognitive skills. As they engage in each activity, they acquire not only domain-specific information, but strategic knowledge regarding the medium's strengths and limitations. In some cases, for example, visually presented moving images may instill insight and understanding far better than verbal descriptions. Other times, learning may require a motoric response, like learning to drive or to fix a car. Consequently, learning requires knowledge transformations from many different types of experiences, media-related and others.

Observing children's everyday activity in their home environments clearly demonstrates the complementarity of media. To examine these issues, I observed children's uses of media in a year-long ethnography of three families (Neuman, 1995). In contrast to one medium displacing another, I found that media often served complementary needs. In these family contexts, there was not a one-way but a *reciprocal*, ongoing relationship between television viewing, video, records, radio, toys, and print. Children's interests often crossed media lines as they looked for opportunities to spend time with their favorite characters and stories. For example, a child's love of a particular character or set of characters like the Brady Bunch would find expression through many different media: records, books, video, television, toys, even lunch boxes and bedsheets. One of the mothers, for example, described her daughter's current interest this way:

Jennifer's just in love with Charlotte's Web right now. She tries to read a chapter when she wakes up in the morning. Then we got the video and I thought, "Oh dear"—here she was reading the book. But the video helped her get back into the book again, which surprised me. It brought her back to the book.

She just loves Templeton. The video makes it so funny. And she laughs about that. And then when she gets in the book, she laughs because she knows what's going to happen. Whereas, I could never get into Templeton—he was the terrible one. So I think the video has given her a new angle on Templeton.

In this case, Jennifer's interest in *Charlotte's Web* first began with her teacher reading the book at school. At other times, however, Jennifer became interested in reading as a result of watching television. For example, having seen *Rainbow Brite* on TV, she bought a little golden book that she learned to read independently. Later, with her mother's help, she used these resources to write and illustrate her own book. Such similar cross-media patterns occurred with *Winnie-the-Pooh*, *The Cat and the Hat*, as well as *The Carebears*, which Jennifer described in a message to her mother: "Carebear my fafrit movie the carebear storybook."

For another family, the Clarkes, television was occasionally used to directly encourage reading. Scanning the Disney Channel guide each week, the mother would videotape a number of classics, including *The Lion, the Witch and the Wardrobe*, and *The Lord of the Rings* that she wanted the children to eventually read. The videos were used as a way of helping children get into the story, which she later read during their evening storyhour.

Cross-media connections were also evident in the home of single parent Mary-Alice Conley, where television or video

often substituted for the children's storybook hour. Mary Alice rarely had time to read to the children. However, favorite books on video were a common feature in this household. I would often see the children watch stories like *The Velveteen Rabbit*, or *Green Eggs and Ham*, bought through the school book club. With no one to read the story to him, Alex repeatedly watched the video with intense interest, waiting for his favorite scene, "when all the toys get fired."

In this home, television was often used explicitly by Mary Alice as a catalyst for the children's literacy interactions. Linkages between Alex's interests in Sesame Street and print, for example, were seen in a calendar in his room, a primary vocabulary (and picture) learning game, an alphabet videotape, a Big Bird jigsaw puzzle, a subscription to the Sesame Street magazine and a Big Bird Cookbook. Similarly, Mary Alice joined another Book Club with many TV tie-ins for Stacey, who was just beginning to read on her own.

Television, film, and book characters all became embedded in children's pretend activities as well. For example, Jennifer incorporated the character of Heidi in a family play theme after watching on a few minutes of a Disney cartoon; Alex, who was 2½ years old, pretended to be "Big Bird" who was "always afraid," or "Snuffle-upagus" who always seemed to get into trouble. These characters were used in such common play themes as good versus evil, marriage and family, and fear of monsters. In fact, it was not uncommon for the children to invite particular friends over to play a mutually shared favorite of Rainbow Brite or Carebears. On some occasions, the older children invited their younger brother or sister to join in, but only if they were able to follow the story structure. When they did not, play was interrupted, as in the case when Jennifer yelled to her sister, "C'mon Leah, remember in Rainbowland you have to have a problem!" Such awareness of the implicit rules of the narrative was probably learned through multiple exposures to both video and print experiences.

The sheer variety of connections between television and print suggested that children's interests tended not to remain medium-specific. Seeking time beyond the immediate television or reading experience, children pursued their favorite stories and characters through multiple exposures with different media. In fact, the distinctions between media became increasingly blurred, as the children moved freely back and forth from visually oriented media (i.e., television, videotapes, movies) to print-oriented media (books, toy books, advertising circulars). Thus, contrary to displacing worthwhile activities, these observations indicated that television often served as a resource for children's emerging interests. Rather than conflict, there was a complementarity between children's media activities; children were the active agents in choosing leisure activities. Their media uses were guided by their interests and their practical assessment of attractive alternatives.

A THEORY OF SYNERGY

Synergy, however, goes beyond the assumption of complementarity. It assumes that the whole is greater than the

sum of its parts. Considering their distinctive characteristics, a theory of synergy suggests that each medium's physical features, its structure, its method of handling material, may add a new dimension to children's knowledge and the means they employ to attain new knowledge. Thus, rather than detract from literacy, some moderate amounts of television, video, and other media may expose children to an additional set of processing tools, which in combination with others, contributes to their ability to interpret events. Since children apparently engage in inferencing strategies while viewing (Neuman, 1992), it is possible that these cognitive abilities are refined through practice and enhanced through their application in another medium. For example, in examining third graders' recall and inferential abilities, I found that the students who were given multimedia exposures of a similar story recalled more story structural elements than those students receiving repeated exposures through one medium alone (Neuman, 1989).

Consequently, there may be a spiraling effect. A greater facility to process information may enhance children's capability to acquire new information. Such an analysis might account for the replicated finding that a modest amount of viewing appears to be positively related to young children's reading scores (Neuman, 1988; Williams, Haertel, Haertel, & Walberg, 1982). Children in the elementary years and below, who watch between 2 and 3 hours of television per day achieve higher reading proficiency scores than those watching less than 1 hour.

Although the concept of synergy requires further hypothesis testing, this area of research suggests several important implications in using media to foster learning (Neuman, 1995). First, whether or not, or to what extent, a medium like television may become a learning environment or remain "the vast wasteland," is subject to environmental influence. What children take away from the medium, how they use it, and how literate they become as viewers is shaped to a large extent by the way it is mediated by those in their environment. For example, though differing in pattern, each of the families that I observed in homes exercised controls over the amount and type of their children's television viewing. Television did not consume an inordinate amount of time in any of these families' daily lives, but was balanced with other interests and activities.

Second, the educative potential of a medium is mediated through linking children's interests directly with literacy-related materials. On numerous occasions, it was evident in home environments that cross-media connections were made intentionally to spark reading interests. In this respect, parents took seriously children's interests, which were shaped and transformed to reflect the educational priorities established by their families. Thus, in contexts where the mediational influences reinforce literacy practices, children's experiences with visual media may serve to support and enhance their emerging conceptions of print.

Third, there are skills involved in using media effectively. Cues provided by the medium itself, as in the case of television, which direct and guide viewers in their watching, can be informally taught through conversations by teachers, parents and children. For example, in several cases in the homes I

observed, children were made aware of some of the diverse technical elements of television and were encouraged to ask questions and to critically evaluate the explicit and implicit values in content. Acquiring this set of skills is an important process in orienting children to the language and grammar of television, and this process enables children to come to understand and anticipate story events.

While the virtue of books is widely accepted, few have acknowledged that television, radio, and other media can be used constructively for learning. Just as children are exposed to a diverse diet of genres and levels of reality and fantasy in reading, so too, can they learn about stories in a variety of media presentations. Such experiences may enrich children's understanding of stories and events, thus extending their engagement in literacy practices.

Implications of a Theory of Synergy for Television as a Learning Environment

In contrast to its critics, the bulk of the research evidence now suggests that television is intrinsically neither good nor "bad." Rather, it is a resource which like any other may be used or abused. Unfortunately, those who have condemned the TV set as a "mechanical" rival, prescribing to do away with it altogether, have failed to weigh its strengths and weaknesses. In doing so, they have ignored the possibilities of television as a means of extending children's interests and knowledge. These critics have also created an unnecessarily adverse distinction between what has traditionally been defined as "entertainment" and what is classified as "education"—a relationship that, in fact, may be more complementary than conflicting.

It is true that by design, television is not an instrument of teaching; yet the medium may have much to offer in educational value. For example, television is a remarkable disseminator of information. It has undoubtedly contributed to the public's knowledge and understanding of current social and political events. Similarly, television is a primary medium through which many children today are introduced to a wide variety of stories and genres. These opportunities could be used more fruitfully to help children see the important connections between their traditional school subjects and the different facets of our culture.

Too often many adults, particularly those in the educational community, have chosen to ignore television or even worse, have virulently attacked all uses of the medium. Articulating this perception in a public address, Jankowski (1986) reported:

It is a source of constant amazement to me that the television set, an inert, immobile appliance that does not eat, drink or smoke, buy or sell anything, can't vote, doesn't have a job, can't think, can't turn itself on or off, and is used only at our option, can be seen as the cause of so much of society's ills by so many people in education.

Unfortunately, the assumption that media draw children's attention away from learning, has fostered a rather narrowly defined view of how literacy develops and how learning is thought to occur. Reading graded materials, such as basal

readers, has often been considered the sine qua non in schools, sometimes at the cost of equally important hands-on experiences or activities involving other forms of symbolic representation. However, if children's ability to acquire literacy is said to be based on their prior knowledge, their conceptual understanding of language, and their uses of a variety of strategies, then there might be many paths to that goal, some of which may actually lie outside the printed page. For example, background knowledge derived from television, radio, and other sources, surely contributes to an individual's understanding and critical thinking when reading about similar events in newspapers and texts.

Indeed, children's interests in stories are often enhanced by their presentation in more than one medium. Cooper (1984), for example, found that after watching a televised version of a popular children's story, even the youngest children wanted to discuss its meaning, to explore the fiction further, to mull it over, and to go back to the book. We need to appreciate the special qualities inherent in each medium, to expose children to multiple genres and media presentations, and to build important connections between them.

Many children today are watching a great deal of televised fare that is inappropriate for their age and sophistication level. This concern raises two possible courses of action. If we take the position of technology determinist Neil Postman (1985) that "it is pointless to spend time or energy deploring television or even making proposals to improve it," then the only response is to lock the TV set up, or do whatever is necessary to keep it away from the innocent eyes of children. But if we believe that television can offer the potential to complement and enliven children's literacy experiences, it is imperative that greater efforts be made both to improve the quality of programming, and children's viewing habits. These efforts should involve all those concerned with children in our society. As Schramm, Lyle, and Parker (1961) found:

We have a resource in children and a resource in television. We are concerned that television should strengthen, not debilitate, the human resource. This end can be accomplished most easily not by unilateral activity on the part of the TV industry, or by parents or schools, but rather by mobilizing all the chief forces in society which bear on the television-child relationship. It must be a shared effort to meet a shared responsibility. (p. 188)

Television has the potential to extend learning and literacy well beyond the classroom walls. It requires, however, the guidance and supervision of parents, and the skills and vision of educators building linkages between home and school learning.

The Role of Parents. Since television viewing behaviors tend to be developed at an early age, parents have a critical role in shaping the medium as a learning environment. Parents' own television behaviors, for one, influence their children's viewing habits; simply put, those who view excessively can expect to have children who do likewise. In our reading clinic, for example, we found that one of our children was being kept up every night until 2:00 or 3:00 a.m. to watch television with his mother. The young boy arrived in school generally around 1:00 p.m. and very often fell asleep shortly after. We found that it was impossible to influence his viewing habits until we

attempted to modify his mother's. Even though young children and early teens may fail at the time to internalize their parents' behaviors, these models are likely to be manifested later in adulthood. Himmelweit and Swift's 20-year follow-up study, for example, suggests a remarkable similarity between the pattern of media preferences and behaviors that occurred among parents and their children as older adults (Himmelweit, & Swift, 1976).

Thus, if the television set is on continuously, and parents themselves watch indiscriminately, discouraging children from asking questions because they might interrupt the program or challenge its content, then their children will most likely view equally unselectively and unthoughtfully. Likewise, if parents selectively watch programs from a range of news-related and entertainment fare, discuss and encourage their children to explore new ideas without fear of reprisal, then their children are far more likely to view more of this type of content and use it more wisely as well.

Similarly, parents who themselves spend time reading, who read to their children and provide them with a wide variety of print-related materials are sending a powerful message about the functions and pleasures of reading. Like television viewing, these models might not immediately influence the time and effort children devote to reading in their free time. Rather, children tend to internalize these parental examples which serve an inestimable role in laying the foundation for later successful reading. When parents take a special interest in children's literature, share their own favorite childhood stories with their youngsters, help them relate their reading of newspapers, magazines and books to everyday events—all these activities develop and nurture reading as an integral part in children's lives.

Parents can also encourage greater connections with print media. Research suggests that although television often stimulates children's interests, these interests rarely lead to action because of the lack of accessibility to further activities or materials. Parents can help maintain these interests by linking television directly with other print-related activities. For example, there are many cross-media connections between children's favorite television characters, books, and films, with popular Reading Rainbow stories being among the favorite books selected by children. A great number of popular books are selected and written for screen adaptation; similarly, books based on television-related characters and events, known as TV tie-ins, tend to flood the juvenile marketplace. Available through supermarkets, bookstores, and book clubs in schools, these materials add a dimension to children's viewing experiences, not only by directly linking them to print, but by allowing them to experience their favorite characters and events in a different contextual setting. In addition, many libraries today offer a wide variety of videotaped renditions of popular books, including such favorites as *The Velveteen Rabbit*, *Charlotte's Web*, and *Curious George* adventures. Encouraging children to borrow these tapes is useful on a number of accounts: (1) it generates interest in visiting the library, (2) it allows parents to more carefully control the content of what children are viewing on television, and (3) it gives children the opportunity to view the content repeatedly until they have mastered the story. Just

like rereadings of favorite storybooks, children's comprehension of a televised story is enhanced by repeated presentations. Further, they often enjoy returning to the book after watching filmed versions of their favorite stories.

The Role of Educators. Today, teachers have many opportunities to use a wide variety of media materials in the classroom to enhance children's interests in stories. By experiencing similar stories across different media, children may become aware of the unique characteristics of each medium, as well as how the subtle distinctions within each contribute to differing adaptations and, occasionally, interpretations of characters and events in their favorite stories. Within the context of viewing, teachers may effectively highlight critical television viewing skills (Anderson, 1983) to encourage students to form purposes for viewing, to evaluate the plots of favorite stories, to judge the veracity of news stories or opinions, and apply the rules of logic and critical thinking to its content. Like other media, there are visual literacy skills, syntax and grammar skills to viewing television which may enhance students' learning from it.

In addition, other media, like newspapers and magazines tend to be an underutilized resource in linking children's interests in television and print. Magazines offer a diversity of content at children's reading levels in a brief, yet highly interesting format. Many of their favorite television characters, jokes from popular shows, and themes are featured in articles from such popular magazines as *Dynamite*, *Penny Power*, *3-2-1 Contact*, and *National Geographic World*, and newspapers. These media are also an excellent resource for

inclusion in classroom libraries, particularly for those students who are reluctant to read book-length materials.

PROMISING DIRECTIONS

Television is a unique mass medium, capable of transferring information and experiences, widely, quickly, and vividly with a realism and immediacy hardly matched by other mass media. We have not adequately explored its potential uses. In contrast, our focus to date has been on 'saving' children through either harnessing, eliminating, and discouraging television use. In only a few unique instances have we actually tapped the power of the medium to serve educational purposes. Surely our conceptions of its capacity to enhance children's learning and literacy have reflected the narrowness of our thinking rather than our broad vision.

Young children today possess a far more sophisticated knowledge of political and social events, richer vocabularies, and a greater familiarity of story genres, all of which have been influenced by the vast array of informational resources available to them. These sources of information need not compete with one another. Instead, they must join together to provide greater opportunities for learning and knowledge acquisition for an increasingly pluralistic society. Indeed, rather than banish new technologies, we must rejoice in the marvel of expanding knowledge bases, and explore ways of using this larger network of information to enrich children's lives and further their understanding of what it means to be truly literate.

TV VIEWING, READING AND MEDIA LITERACY

Roger Desmond

UNIVERSITY OF HARTFORD

Speaking of media literacy, network producer and documentary host Linda Ellerbee remarks, "It ought to be taught in elementary school—how to watch television. Teach them what a commercial is really selling them" (Bianculi, 1992, p. 158). Ellerbee articulates a perspective that elicits fierce opposition; skeptics argue that perceiving and understanding the audio and video collage of television is nothing like the cognitive activities involved in reading. Joshua Meyrowitz (1985) states flatly, "Understanding visual symbols has nothing to do with literacy". To underscore the ease of accessibility of television, he offers evidence from ratings demonstrating that adult programs are enjoyed by children and vice versa. It is important to note that Meyrowitz uses the term "visual literacy" somewhat interchangeably with media literacy, as do others (Messaris, 1994).

Those critics who argue that media literacy is not the same as literacy are correct in their rejection of the implied metaphorical correspondence; the elusive first time viewer, upon first confronting an action-adventure program has no linguistic symbols to decode, no letters to recognize, no grammatical rules to master in order to recognize that someone is chasing or being chased. One of the consequences of applying the literacy label is an automatic invocation of print as the logical opposite of video; the opposition emanates from a belief (to be examined in detail later) that video experiences displace reading. Regardless of the validity of the claim, there is accumulating evidence of interdependence among media in the construction of narratives by viewers and readers. Marsha Kinder (1990) makes a strong argument for interdependence in her study of intertextual relationships among books, television, video games and film in the construction of the *Teenage Mutant Ninja Turtle* narrative. Another author suggests that this intertextuality is facilitated by the growing tendency of cross-ownership of media: the comic, the movie and the toy

are all made and marketed by the same media agglomerate (Turow, 1992). We can acknowledge differences among media without rejecting the notion of media literacy. If the metaphor has substance, it will emerge in its explanatory power and the extent to which people recognize the problems which gave rise to the metaphor.

WHAT DOES IT MEAN TO BE MEDIA LITERATE?

There are two components of the definition implicit in the opinions cited earlier: teaching people to be critical consumers of entertainment and advertising fare, and teaching them to gain more insight and information from what they watch. In terms of the former position, a recently developed curriculum for high school students lists at least three general components of television literacy: (a) awareness of one's own relationship with the medium, including awareness of viewing habits and the categories of programming, (b) understanding the television industry and the conventions of television production, and (c) the critical-function, including awareness of the stereotypic distortion exhibited by many entertainment programs and the ways in which programming shapes our social customs and attitudes (Singer, & Singer, 1992). In a recent survey an evaluation of 26 critical viewing intervention and research programs for school children across the world, virtually every effort described embodies one or more of these three dimensions (Brown, 1991). Television is seen as a powerful force that needs counteracting with special training; to be a "critical" viewer is to be well trained in a kind of Deweyan skepticism.

Much less developed is the latter view of media literacy: improving the skills of viewers to extract more from the

He wishes to thank Kathleen Hall Jamieson and Elihu Katz for their support and encouragement of this project.

content than they typically do. While there has been some recent activity in this realm, the focus has been on viewers with some type of cognitive impairment, such as learning disabilities or emotional disturbance (Sprafkin, Gadow, & Kant, 1988; Sprafkin, Watkins, & Gadow, 1990). One study of the impact of viewing instructions on retarded adolescents and nonretarded fourth graders found that forewarning them that they would be tested after viewing produced no effects, but for both populations, instructions to watch "for fun" resulted in fewer propositions learned from the program than for all other conditions (Raynolds, 1991). While the majority of critical viewing programs has been conducted with children of preschool or elementary school ages, one educator provided "ideological decoding" training for adults and concluded that a program of how to "read between the lines" of television portrayals of politics, news events, and social issues was successful in elevating critical viewing skills in college students, but his evidence is entirely anecdotal (Brookfield, 1986). In a more formal investigation employing a lecture approach, seventh graders demonstrated more extensive learning of content from educational television programs than did controls (Von Kolnitz, 1986). The effect was particularly pronounced for students with high intellectual abilities (teacher designated).

Taken together, what these studies demonstrate is that it is *possible* to increase the amount and kind of information that people extract from the medium of television; whether these changes transfer to the everyday viewing context and whether they can overcome family patterns resistant to effortful viewing remain as unsolved problems for future research. In this context the work of Gavriel Salomon and the concept of AIME (amount of invested mental effort) is relevant; although there is convincing evidence that young viewers' and readers' investment of mental effort mediates what and how much they learn from television or print, there is need to clarify the role of mental effort for a definition of video literacy (Salomon, 1984). The conclusions of several studies suggest that television is often seen by viewers as inherently easier to decipher than print, which is why they invest less effort in viewing, but as one critic points out, observers globalize "television," ignoring the vast differences among formats and programs that they would acknowledge with respect to reading (Neuman, 1991). The literate viewer allocates AIME in the necessary amount for the appropriate category of program and learning goal, just as a reader allocates more AIME for a textbook than for a comic. Along with the critical function, then, we must include the concept of efficiency in a definition of media literacy; the literate viewer is one who can derive an adequate amount of information from each opportunity.

An additional dimension that has not been included in the goals of existing theory and research in the area is the set of skills involved in applying prior knowledge to the content of a television presentation, and the related skills of applying the fruits of media literacy to the world. In this regard there are several similarities among readers and viewers: both must be able to apply prior knowledge to a text or to a program to acquire new meanings, resolve ambiguities and account for missing information (Neuman, 1991). In the case of a young viewer, prior knowledge of a "cops n' robbers" script for

television programs will determine the amount of novel information that can be acquired (Collins, 1983). In terms of applying television or reading-derived information to social situations, a kind of "editor" must be part of the literacy equation or the cultivation of media-distorted information can occur (Signorielli, & Morgan, 1990). For the heavy viewer of many entertainment programs, the world is exaggerated in numerous ways; a literate viewer knows the difference between a satire like *The Simpsons* and a documentary about family life. In the majority of families and school reading programs, the distinction between fiction and reality is applied much more diligently to books than to television.

At this point, our definition of media literacy includes at least five dimensions: (1) awareness of one's own relationship with media, (2) knowledge of how media organizations shape their fare, and the conventions of production for each, (3) a critical-ideological awareness, (4) the role of effortfulness, and (5) relationships among prior knowledge, media comprehension and the "real" world. As Brown's (1991) survey illustrates, critical viewing research programs designed for children have concentrated much more on the first three than on the last two. In light of these dimensions, it is important to examine the rationale for efforts to increase media literacy. Primary among these has been the frequently voiced concern about the impact of television viewing on early readers. Media literacy programs, especially those that incorporate the first dimension of increasing awareness of media consumption patterns, have as one goal the reduction of television viewing and the increase of reading.

TELEVISION AND READING

Prior to the 1980s, the dominant conclusion of the majority of investigations of television's impact on reading was a simple, significant and straightforward negative association. More recent research has added complexity and some clarity to the elusive relationships among school achievement, reading comprehension, and extracurricular television viewing. One of the more frequently investigated hypotheses is displacement: Does TV viewing negatively affect the development of reading by taking the place of other activities? The question breaks down into two components: (a) Is there evidence that indicates that if children were not watching TV they would be reading or be engaged in other scholastically beneficial pursuits? and (b) Is there evidence that displacement results in the erosion of reading ability?

In terms of the first question, there is little evidence in support of a direct displacement effect, and some indirect evidence against it. Neuman (1988) examined the school performance data and self-reports of leisure time activities for over 2 million school children from 8 states, and found no impact of television on either school-related or leisure reading. She concludes that TV viewing is tied to a different set of gratifications than leisure reading, sports or time with friends. In a two-wave survey of high school students, Gaddy found weak displacement effects, and even weaker negative relationships between viewing and reading (Gaddy, 1986). In explaining his finding of small but consistently negative

associations he concludes that if television displaces as little as 15 minutes per day of homework, its negative impact on school achievement would be large, over time. He also found TV viewing to be the smallest predictor of academic achievement among all those that were measured.

With respect to whether displacement, when it does occur, results in decreased reading performance, Williams (1986) found, as have other investigators, that the introduction of television into the social system resulted in an initial displacement of traditional activities. During this early introductory period, there was evidence for decreased school achievement, with a relatively rapid recovery and an accommodation of the medium into other leisure activities. More recently, Mutz, Roberts, and van Vuuren (1993) found evidence for functional reorganization of time in an 8-year panel study of fifth graders following the introduction of television in South Africa. Initially, television displaced movie attendance and radio listening, with no subsequent return to previous levels of these activities over the long term. There was no evidence of displacement of academically important activities from both individual and aggregate analyses. In these few studies, there is mixed evidence of displacement, and when it has been observed, long term impact on reading ability is highly dependent upon subgroups and amount of viewing.

Direct Effects

Although she did not find a global displacement effect of television, Neuman (1988) did find a pronounced curvilinear relationship between time spent with television and several measures of reading comprehension and vocabulary. Elementary school children who watched TV between 2 and 4 hours per day exhibited no great differences in reading ability; those who watched 4 or more hours per day showed a steady decline in reading and vocabulary. The effect is not as dramatic for high school students, since they watch less television than their younger counterparts. The only published meta-analysis of the literature regarding TV viewing and reading (23 articles, 274 correlations) concludes that while the overall correlation of TV watching and achievement is negative but small, the effect of viewing is increasingly deleterious up to a level of 40 hours (Williams, Haertel, Haertel, & Walberg, 1982). A review of 30 years of research reveals a similar trend across a number of studies, and concludes that 3 hours per day of viewing may be the critical peak in the decline of reading ability (Reinking, & Wu, 1990). Apart from hours of viewing, the review posits home environment, types of programs watched, and several other variables as mediators in the observed relationships.

Another extensive literature review examines five research approaches that have been used in previous studies and concludes that those most vulnerable to "reading inhibition" are the heavy viewers, socially advantaged and more intelligent viewers (Beentjes, & van der Voort, 1992). They present evidence that suggests that children higher in s.e.s. are vulnerable to deleterious effects because they *would* spend time in intellectually stimulating activities if they were not watching television, whereas lower s.e.s. children would not. The

authors make a similar argument for IQ, citing two investigations that controlled for intelligence, and found a negative relationship between reading achievement and TV viewing only in more intelligent children. A panel study (one of the few in this area) found an initial high negative correlation between reading achievement and TV viewing which remained stable across 3 years, indicating no evidence for increasing levels of TV viewing as a causal factor in the reading-viewing equation (Ritchie, Price, & Roberts, 1987). The authors concede that although the relationships remained stable over time, and no increased displacement of reading by television was found, there is a clear possibility that the relationship between reading and television may be most critical prior to grade 3, when reading is described by Chall's (1983) second stage of reading. In terms of major conclusions from all of the research just reviewed, there are no individual investigations which support a "no effects" model regarding the impact of television viewing on reading achievement. The studies support models of either moderate or strong effects for children in specific categories, with heavy viewing as the most consistent mediator of the relationship between television viewing and reading achievement.

Toward Explanation of Relationships

If displacement alone is not the mechanism that explains the negative association between reading and TV watching, what other process might account for the recurring finding of negative correlations between reading and viewing television? One position which may help reveal a pattern throughout the research has been designated "concentration deprivation" (Beentjes, & van der Voort, 1991). They argue that television viewing, especially heavy viewing, may operate to decrease attention focusing, increase impulsiveness, and discourage task persistence in young viewers. In terms of attention, no research has directly investigated decreased attention span as a result of TV viewing, although educators often mention it as a probable outcome. If anything, research on attention to television suggests an alternating active-to-passive selective monitoring of the medium, with no evidence of a cognitive "drain" on other activities (Anderson, & Collins, 1988). Anderson and his colleagues have repeatedly found a cyclical attention sampling pattern when young children watch television, with more efficient sampling as children age (as children approach school age, for example, they pay more attention to regular television content than they do to commercials). In an investigation of attention to reading, Imai, Anderson, Wilkinson, and Yi (1992) find that first and third graders in reading lessons exhibit patterns of attention that bear some similarity to TV watching: they stop allocating attention when content becomes incomprehensible, just as children do when watching television. As Anderson (1992) summarized the lack of evidence for a negative impact of television on reading, "It is likely that attending to television does not constitute useful practice for developing the internal control necessary for sustaining active attention to difficult (and probably boring) academic content."

Impulsiveness and persistence have been studied in an experimental manipulation where 6-year-olds' viewing time

was reduced by half over a 6-week period. Greater impulsivity and more reading and coloring book activity were observed in those children who watched their usual amounts, while impulsivity was decreased in the television restricted group (Gadberry, 1980). When second graders watched *Sesame Street* for 8 days in school, they showed significantly less task perseverance for a school task than did controls (Salomon, 1984). Children's ability to wait quietly, a variable related to task accomplishment and persistence, has been found to be negatively associated with heavy viewing, particularly when viewing was not mediated by parents discussions (Desmond, Hirsch, & Nicol, 1988; Singer, Singer, Desmond, Hirsch, & Nicol, 1985).

As is apparent from even a cursory examination of this domain, what is lacking is an adequate theoretical framework to organize results and to stimulate further research. The term "concentration deprivation" is frustrating, in that it connotes a general mindlessness resulting from prolonged exposure to television, for which there is scant evidence. There is evidence that people allocate less mental effort to television than they do to reading, but there is also evidence that this can be modified by instruction (Kubey, & Czikszenmihalyi, 1990; Salomon, 1984). In terms of young children, one of the most disturbing aspects of the research to date is that few investigations have concentrated on children in the first and second grades, where reading begins. A critical period alluded to earlier may be the time when heavy viewing does the most damage to young readers. Only one study has examined the relationship in viewers of this age group, and concluded that kindergarteners and first graders who were heavy viewers of television were less capable initial readers 1 year later than were their lighter-viewing counterparts (Singer et al., 1988). In this study, as in most others where IQ was measured, there are correlations among viewing, IQ, and reading-related skills that are difficult to unpack in a manner that provides a causal explanation, but as was alluded to earlier, when IQ is controlled for, the negative association between viewing and reading remains. When IQ is a predictor, it is the more intelligent viewers who exhibit the strongest negative effects of viewing. What might occur during this formative time that renders the heavy viewer a less capable reader in later years? One component that may suffer is the child's ability to visualize characters and events in a written or spoken story in a manner that allows for memory, reflection, and internalization. In other words, the child begins to "frame" narratives in a television-like manner, where events are more important than motives or the inner states of characters in stories. An ongoing study of children's story comprehension suggests that 6-year-olds who saw audiovisually presented stories based more inferences about the story on characters' appearance and actions than did those who read stories (Brown, 1991). It is clear that the possibility of "narrative deprivation" needs further investigation. A large part of reading comprehension is the ability to reflect on the events and inner states of actors in a story, and as Singer has suggested, the pace of television does not allow much time for reflection (Singer, 1976). There is also evidence of a tendency for "scripted" television viewing to interfere with comprehension of viewing (Collins, 1983). Finally, in a 3-year panel study of children

aged 6–9, the heaviest viewers of television comprehended less of a program immediately after viewing than did lighter viewers, and this effect continued throughout the second year of the study (Singer et al., 1988). Taken together, these results suggest that heavy viewing during the hypothesized critical period may have negative implications for both television and reading story comprehension.

Until there is more research directed at the early reader-viewer, the bulk of evidence points to television viewing as one of several factors in the decline of reading comprehension in the past decade. As has been argued for viewing and aggression, it is also important to consider the aspects of these relationships that may be masked in the aggregation of results and debates over effect sizes; one disruptive child in a classroom may produce a chain reaction of tremendous import for the entire class (R. Kubey, personal communication, November 20, 1992). Similarly, one poor reader may demand inordinate amounts of time from a teacher at the expense of other students. Comstock and Paik's (1991) exhaustive analysis of the recurring negative correlation among viewing, reading and other concomitants of scholastic achievement concludes that, "There is no question that the amount of time spent viewing television by American children and teenagers is negatively associated with their academic performance" (p. 86). They, however, do not posit displacement as the only, or even the major contributor to the association: "The evidence supports a three-factor process in which large amounts of viewing not only (a) displace skill acquisition but also (b) interfere with further practice, or skill development and maintenance, and (c) lower the quality or value by decreased capacity of practice done in conjunction with television" (p. 136). In analyzing nine large-scale multivariate studies of the relationships among extracurricular factors and several indicators of academic achievement (including math and grades), they find that when the other predictors (s.e.s., ability, parents' education, special academic programs, etc.) are controlled for the negative association with television survives in six studies, and where it does not, the relationships are negative but not statistically significant. They argue for a "modest but important" causal relationship and an independent contribution to lowered achievement by television viewing. With respect to "practice in conjunction with television," Armstrong and Greenberg's (1990) finding of deficits in college students' performance of cognitive tasks done with a television on in the room is supportive of the relevance of the factor; the evidence points to a suppression of cognitive capacity, as opposed to distraction or heightened arousal. It is reasonable to assume that if adult cognitive task performance is hampered by an operating television set, children with developing cognitive capacity will be diminished more severely; homework done in front of a television will suffer. When relationships among homework, television viewing and parental influence were measured in a large national sample of high school students, homework had a direct impact upon achievement (positive) and television was negatively associated, though smaller in influence (Keith, Reimers, Fehrmann, Pottebaum, & Aubey, 1986). Results of causal modeling indicated that there was no evidence that homework displaced television viewing but that the obverse was true; as in other

studies cited earlier, the effects of television were most pronounced for high achievers. There was no evidence of parental involvement in encouraging homework or in decreasing television viewing; the authors point out that such involvement would have more impact with younger children.

In adult college students there is evidence that reading leads to increased vocabulary learning, while television exposure does not (West, & Stanovich, 1991). When intellectual ability (measured by S.A.T. scores) was controlled, casual reading by college students predicted vocabulary and cultural literacy, while television predicted only cultural literacy. Vocabulary, spelling ability, and verbal fluency have all been associated with print exposure, even when reading comprehension is controlled (Stanovich, & Cunningham, 1992). Why does experience in reading increase our linguistic knowledge base when experience with electronic media does not? An investigation of the linguistic complexity of media reveals that the majority of television programs employs a 4th-grade vocabulary; novel words are present in many categories of print (Hayes, & Ahrens, 1988). Neuman argues that the idea that leisure reading is better for children than leisure viewing may be a reflection of a "literacy bias" on the part of educators and caregivers (Neuman, 1991). The evidence suggests that reading leads to information gain that is relevant to scholastic achievement; television does not.

Based on the hypothesized critical period for television-related deficiencies, the research reviewed above suggests that those critical viewing programs designed to repair deficiencies in concentration, narrative comprehension, and other subskills associated with school performance will be most effective with children in grades K-2; programs specifically targeted at reducing displacement of reading for older children are likely to be ineffective; the magnitude of displacement effects is small, and existing programs have not demonstrated their effectiveness. In light of the consistency of the viewing-achievement relationship and the fact that sheer consistency in multivariate studies is only one indicator of viewing-to-achievement causality, the impact of leisure viewing on these processes remains as the rationale for critical viewing programs at the elementary school level.

Other Dimensions of the Concept

As the previous review suggests there is more to the concept of media literacy than critical viewing, and there is more to critical viewing than the improvement of reading. Although the primary rationale for American intervention programs has been television's potential impact on learning and achievement, there are other areas where the dual-edged sword of criticism and enhancement of learning have been applied. Aggression is one candidate for modification of television effects; the majority of critical viewing programs has attempted to heighten children's awareness of the unreality and inherent danger of televised aggression. One intervention that has been praised because of its focus on media-depicted aggression and its consequences for imitation is Huesmann's program, but even in light of his success, he warns about the intractability of aggressive media content (Huesmann, Eron, Klein, & Fischer, 1986). Other areas where arguments for

effective intervention have been advanced include gender and ethnic stereotyping, and advertising. Virtually all critical viewing programs in Brown's (1991) survey address gender and race issues but, again, from a critical or protectionist perspective. In the case of both gender and ethnicity, we can say that virtually every intervention program reviewed has demonstrated gains in awareness of television stereotypes and stereotypic and inaccurate portrayals. As is also the case with every program, we cannot say whether these gains persist beyond the few days, hours or weeks in their evaluation periods, or whether children transfer these lessons to everyday viewing. The same conclusion is true of advertising, but there have been many more programs with similar results: impressive but short-term gains.

Moving beyond the American model, Canada and Australia have implemented large-scale programs of media education that encompass all the goals of the American system but with the additional dimension that was earlier designated critical-ideological. In Australia these programs have been in place, and recent evaluation data suggest that they have merit in terms of attaining some long-term goals (McMahon, & Quin, 1992). Their successful implementation is one factor in the development of a media literacy movement in the United States, led primarily by educators with some support by television networks and cable operators and moderate support by PBS affiliates in the larger cities. The major difference between the path to implementation in the United States and other countries is that in the United States there is far less consensus among the scholarly community for a *need* for media literacy intervention, and paradoxically, there is a greater reliance on the academic community for approval of such programs. The result is that grant proposal approvals and endorsements for the activists from the research community have not been forthcoming. One important reason for this tension is that media educational activists have focused on the deficit model, promoting their programs as prophylactics for a host of diseases that have not been supported by existing media research. There is no doubt, however, that media literacy as an educational movement is "in the air." In 1992 alone there were five international conferences on the topic; two at the Annenberg School for Communication at the University of Pennsylvania, and one each at the Aspen Institute in Maryland, in Guelph, Canada and in Bitburg, Germany.

What is clear from the interactions of researchers and activists at these meetings is that the goals of the groups have been so different, and their educations have differed so much that necessary dialogue among them will be a long time coming. One issue that has the potential to unite them is the temporary abandonment of the deficit model, and a shift toward an acquisition model.

One problem inherent in such a shift is that the deficit model gets good press; media literacy activists are the first to admit that public fear of negative media effects is a politically correct entry into program acceptance by school administrators and parents (Davis, 1992). Ultimately, an acquisition model would provide a framework for questions regarding issues such as (a) transfer—how lessons from entertainment and in-school viewing are, are not or could be applied to other

domains of learning, (b) mental effort—how can viewers, listeners or users of CD-ROM, electronic games and so forth be stimulated to allocate more effort and attention to important content? and (c) can visual media production synthesize knowledge from other forms, for example, scriptwriting elicits research elicits reading skill and practice? These and other issues related to skill and information acquisition have the potential to unite the concerns of researchers, educators, and activists in ways that may prove fruitful for both producers and consumers of education.

What Research is Necessary?

The controversy surrounding the deficit model makes it a central priority for further research. The summary of work in the area cited earlier suggests that what we specifically do not need are more cross-sectional, correlational studies of relationships among leisure TV viewing, reading, and virtually every other indicator of scholastic achievement. Those data are in. What are necessary are some investigations that can assess the size of these relationships for significant population subgroups, and most important, nail down or at least disambiguate causality. A beginning step would be some longitudinal work. Earlier in this chapter a hypothesized critical period was invoked in an attempt to resolve some consistent lines of investigation into the relationships among media use and task persistence, practice in reading, math and other areas which may result in lowered abilities at later ages, where most of the current research is concentrated. If, as Anderson (1992) speculates, "It is possible that because young children find TV viewing easier than reading, that TV viewing displaces small but crucial amounts of leisure reading at the most critical ages" (p. 9), it is imperative that a time-series design with data points across the preschool years into grade 3 be employed. The work of Gadberry (1980) demonstrates the possibility that this work can be done, but her interrupted time-series analysis focused on only a few weeks of restricted viewing. Huesmann and Eron's (1986) investigation (over 20 years between measurements) of early viewing and aggression demonstrates the "payoff" of a longitudinal approach, but what is needed to resolve the causal role of early TV viewing is more frequent measurement of a difficult-to-measure population in the most formative years.

A second area of research concerns the entire notion of passivity; as Anderson (1992) points out, we lack a conceptual definition of this state, therefore pioneering efforts at conceptualization and operationalization are necessary. Passive viewing is one of the key elements of the deficit model in lay circles and popular writing; as such, it has been used to justify a need for media literacy. Even as a fuzzy concept, it is integrally linked with a number of important issues in cognition. It is possible that ultimately, a psychophysiological approach could yield a proxy, but early efforts have not paid off.

Among other gaps in our knowledge about television's relationship to education that were discussed earlier in the context of established knowledge is the issue of amount of viewing. It has seldom been adequately measured, but even with differential measures, it has traditionally been an inde-

pendent variable. As such, its use has yielded a number of qualifiers of negative effects based on heavy viewing; even skeptics such as Neuman (1991) allow that it is heavy viewers who suffer the greatest deficit. If one of the goals of media literacy is to reduce the deficit, it is imperative that research designs examine the impact of viewer training on the amount and kind of viewing. There is an implicit assumption in the media literacy movement that critical viewing can alter everyday patterns of viewing, but little evidence for or against the assumption exists. Previous work suggests that the context most amenable to viewing modification is the family (Bryant, 1990). The role of the family in mediating television comprehension and enjoyment has long been investigated in the traditions of effects research, phenomenological and cultural studies but is seldom discussed with respect to media literacy. Since the viewing done at home is the major concern of the deficit arguments, the role of the family context in reinforcing and originating media education is crucial. What are needed are methods of providing systems models of media education, and theoretically sound evaluations of those methods.

The research agenda for the acquisition model is far less certain. As noted earlier, the issue of transfer is salient for educators and researchers: transfer of insights and information *from* television to other domains of knowledge, transfer of world knowledge *to* television, and transfer of media education from schools *to* everyday viewing. An important initial effort might examine the benefits of television scriptwriting as an exercise and as a measure of learning. Are scripts generated by the media-educated richer, more complex, more informative, more "visually literate" than those written by untrained writers? With respect to education issues, would a term paper be written and researched with more quality and thoroughness if it were assigned as a documentary script? One of the important issues in transfer is the perspective taking that is required of a scriptwriter; how can this information be presented in a manner that elicits attention, yet instructs? It is also important to examine some of the cognitive subskills that may underlie educational achievement. One author has suggested spatial perception and visual-verbal associational ability as areas that may benefit from visual literacy (Messaris, 1994). Adoption of an acquisition model as a research agenda does not mean that theoretical work becomes evaluation research. Inquiry into the maximization of media education potential has implications for a broader spectrum of emotion and cognition than has been addressed by the deficit model. We may explore the connections among thought, form and content in a brand new arena.

What Media Education Might Become

The majority of forecasts regarding the future of media in the past few decades has fared miserably, primarily because it was made in the economic "blue sky" of the 1950s and 1960s when all things were possible (Jassem, & Desmond, 1986). In the harsher light of the current global economy, poorly designed and administered programs of media literacy will go the way of marching bands and instruction in the arts—"extras"

quickly and easily sliced from school budgets. Those that survive will require hard data on effectiveness from the research community, a difficult requirement in light of schisms between researchers and educator-advocates presented earlier. A great deal depends upon whether some good research is forthcoming; earlier suggestions represent a few possibilities, but theory building of the amount and kind witnessed in the search for connections between television and aggression or advertising and social behavior are necessary. In the past 20

years a number of models of the processes were developed, competition among them was partially resolved, new branches of the effects framework emerged, and just recently, recommendations have been heeded to some extent as evidenced by the Children's Television Act of 1990. If the same sort of concentrated labor is exhibited by investigators of media literacy, the necessary funds, coordination of efforts and concomitant publicity may enliven our research and enlighten our children.

TELEVISION AND LANGUAGE LEARNING

Michael Willmorth

BOISE STATE UNIVERSITY

Since the advent of audio(-visual) mass media—the phonograph, then radio, sound cinema, and finally television—hopes and fears have been expressed about their potential effects on the language used in the communities they serve. On the one hand, if good speech were used uniformly in the media, the pronunciation, vocabulary, and grammar used in everyday interpersonal interaction might be improved, should listeners take media speakers as behavioral models (Franklin, 1929, p. 315). On the other hand, if the speech heard in these media were not kept to sufficiently high standards, the language of the speech community might be degraded (Parsons, 1936, p. 27). Both positions generally assumed that, because the same linguistic messages would be heard by all media consumers regardless of regional and social differences in local speech varieties, there would, over time, be a leveling of these differences with each new generation of speakers.

This double-edged potential for influencing the language of a community is still believed to be one of the powers of television. Some teachers point to television as a source of models that speakers of nonstandard varieties might emulate to enhance career opportunities (Robbins, 1988). Others (and perhaps some of the same educators) have lamented that television provides numerous examples of “bad” language spoken by popular media figures, which are taken up by viewers and incorporated into subsequent face-to-face communication (Vann, 1991; “Mouths of babes,” 1992).

Predictions about these wide-ranging effects of television on language seem to inform common folk beliefs about language learning (Schieffelin, & Eisenberg, 1984, p. 390) in contemporary, technologically developed societies. A study of Chinese immigrant children to the United States by Ikeda (1992) found that, even though the children did not watch television with the goal of learning to speak and understand English, they believed they might gain some such knowledge in passing; their mothers, however, were sure that their

children’s TV viewing behavior would strongly affect their development of English language skills.

Anecdotal evidence, too, seems to support beliefs about the efficacy of television as an aid to language learning. In one case, an unusually bright boy—he graduated from college at the age of ten—claimed that he learned to speak by the time he was 10 months old, “in part by repeating what he heard on TV game shows. As for reading, the youngster, whose IQ was measured at 180-plus, said, ‘Some of my first words were from *TV Guide*’” (*TV Guide*, 1994, June 25). Another article profiled four immigrants to the United States who claimed to have learned about the English language and American culture in part while watching TV in the low-anxiety language-learning environment of their homes. At first they sought out easy-to-understand programs, which provided relatively simple verbal messages and significant amounts of redundant visual information to assist comprehension. As their skills with English improved, they sought out programs with more sophisticated language (Littwin, 1988).

In spite of these stories, however, most language researchers have credited television with very little, if any, influence on the language acquired and used by viewers. The apparent absence of the general leveling of linguistic variation in speech communities predicted in early speculation on the effects of mass media, already noted in 1938 by W. Cabell Greet (pp. 69, 70), is frequently offered as proof of TV’s impotence. Most researchers in language acquisition have historically focused on speech in interpersonal interaction rather than in the media. Among these investigators, a consensus appears to have formed that if television does anything more to influence language than speed the diffusion of a limited number of vocabulary items across dialect regions (Trudgill, 1983, p. 61), it is perhaps merely to provide fodder for conversation around water coolers and at cocktail parties. However, a growing number of studies focusing on language in the media and on language learning processes indicate that TV may have some pervasive and profound effects.

CRITIQUE OF TELEVISION'S ROLE IN LANGUAGE LEARNING

As research into language learning has been carried out primarily in the fields of linguistics and psychology, most findings have reflected their theoretical and methodological frames. Scientific responses to folk beliefs about the power of television in language learning have stressed the intra- and interpersonal processes that are of primary interest in these disciplines. Since the give-and-take nature of interpersonal interaction and the use of simplified codes by adults to speak to children, for example, are usually considered fundamental for the development of normal communicative competence, they have been used as criteria for dismissing the possibility that television can have a significant role to play (Rice, 1984, pp. 170, 171; Sachs, Bard, & Johnson, 1981). Also, since the relationships between mass media and interpersonal communication processes have not been widely explored in these research traditions, it is not surprising that most language acquisition experts have not found television to be particularly relevant.

The argument usually made to support this position contrasts the apparently passive nature of a child viewing television with the activity of the child in face-to-face interaction with an adult (Trudgill, 1983, p. 61). The time spent watching television is time not spent practicing conversational skills, therefore the language learner is linguistically deprived in relation to others who do engage in activities that promote or require speaking (Winn, 1985, p. 11). The viewer may even regress into an earlier, lower level of competence due to reliance on the visual elements in TV messages for comprehension (pp. 54, 55).

Other critics focus on the nature of the linguistic messages on television, suggesting that they are too complex, too rapidly deployed, or too removed from the here-and-now of the viewer's physical environment to engage or even be comprehensible to a language learner (Clark, & Clark, 1977, p. 330). A third reason offered for the inability of television to facilitate language acquisition is that mere exposure to language in use is insufficient; the language learner must actively use the code in order to internalize new words and grammatical rules (Hoff-Ginsberg, & Schatz, 1982, pp. 22, 23). Even if children do take linguistic material from TV and imitate it, they are probably dealing with it as meaningless sound constructions, not as words (Ervin-Tripp, 1971, pp. 198, 199).

These assessments seem to be confirmed in the equivocal or negative findings of some of the initial studies that attempted to test whether and how television might be related to language learning. Nelson (1973, pp. 63–65), for example, found a negative correlation between the amount of TV viewing and the progress of language development at the age of 18 months. Selnow and Bettinghaus (1982) found a similar result for preschool children:

1. Children who watched more television displayed less sophisticated language,
2. Children who displayed less sophisticated language tended to view more language-poor programs, and

3. Children who used more sophisticated language tended to view programs that modeled more sophisticated language (p. 477).

These studies seemed to indicate that, in general, more TV viewing is associated with less well-developed language skills. However, both studies have raised questions about this interpretation of the results. It may have been that the children either acquired the language level of the programs they watched or that they sought out programs according to their existing language levels.

Other research from the fields of mass communication and social and cognitive psychology has challenged three of the traditional assumptions about language acquisition: (a) the necessity of interpersonal interaction, (b) the incomprehensibility of linguistic messages on TV, and (c) the ineffectiveness of social learning. Work in these disciplines suggests other ways of conceptualizing the relationship of television to language learning.

LANGUAGE IN THE TELEVISION MESSAGE SYSTEM

Rice and Wartella (1981) criticize the notion that "television-viewing is not interactive, that the child is a captive audience who can only passively receive what is presented. Just as the model oversimplifies face-to-face interchanges, it also does not capture the subtleties inherent in television-viewing" (p. 370). Television messages are composed from three different codes: (1) iconic, (2) media-specific, and (3) generic. The iconic aspects include pictorial representations, which, if realistic, are fairly easily understood by any viewer regardless of language competence. Media-specific codes are those exclusive to the "grammar" of television messages, including fade-outs and cuts to indicate transitions of some sort; viewers become familiar with these conventions without much time or effort. Generic codes are used both within and outside of watching TV; one of the most important of these is language. A viewer must use knowledge of language in everyday interpersonal experience to understand linguistic messages on television (p. 370).

There are significant differences between engaging in interpersonal linguistic interaction and attending to the verbal messages of a television program (Olson, 1987). Hollenbeck and Slaby (1979) note that:

Infants learn to use contingent looking and vocalizing to elicit responses from adults. Yet, the high level of social control that infants typically attain with their caretakers stands in marked contrast to the complete lack of direct control that infants may achieve over the "social" stimulation produced by television. The same looking and vocalizing behaviors that serve infants so well while interacting with caretakers are responded to by television's characters, images, and sounds in a completely noncontingent way. (p. 45)

Nevertheless, young children can understand from TV pictures and sounds that a talking person is represented and may try to interpret such images with the same communicative strategies that they would employ in interpersonal

situations. One researcher reported the behavior of her 3-year-old son as he watched her appearance in a TV interview. The boy tried to engage her image by signaling both verbally and nonverbally, and when she did not respond, he believed that she was ignoring him and broke off his TV viewing session angrily and left the room (Greenfield, 1984, p. 53).

Selnow and Bettinghaus (1982) believe that there are some benefits in the differences between child-parent and child-TV language experiences:

Parents can interact with children and provide immediate feedback and reinforcement; television cannot. Parents can direct their messages to the interests of an individual child, whereas television, a mass medium, does not have this capacity. But television does offer messages pitched with a keen appeal to young viewers which engage them in the content. Furthermore, television can provide an assortment of language models and so display a greater variety of language styles than can be offered by parents. Beyond all this, television is always there, and is always available to a child at the touch of a button when parents may be preoccupied. (p. 471)

Thus, what the language learner loses in interaction is perhaps compensated to an extent by gaining access to varied and engaging material on demand.

INTERACTION IN TELEVISION VIEWING

The stereotypic image of the solitary TV-viewing child as a zombie mesmerized by the visual and sonic stimuli emanating from the set is in fact not confirmed by numerous studies of the lively activity that occurs among viewers. Far from suppressing interaction, it may stimulate it (Messaris, 1983, p. 293; Messaris, & Kerr, 1983). Young children are often praised by caregivers for mere mimicry of material from TV (Halpern, 1975, p. 66), but language learners also appropriate materials from TV to their own utterances in meaningful ways. Also, the use of the TV-viewing context as an occasion for verbal interaction may or may not be focused at any given moment on the TV message at hand.

Lemish (1987) carried out a study of 16 families with infants and toddlers to examine how TV viewing related to social interaction among the members of the household and to the acquisition of language skills by the young children. Toddlers walked up and touched the television set, talked back to *Sesame Street* characters, asked to have the set turned on, reiterated (outside of the viewing context) language they heard from television, and imitated TV action. Parents would call the attention of their children to objects on TV and would label or request a verbal label for objects familiar to the children. After the first birthday, the children practiced newly acquired words from TV with their parents as they watched (p. 42). The television-viewing activity was so closely linked with verbal interaction that it appeared to be integrated into the language-learning process for these children.

Lemish and Rice (1986) conducted a participant observation study of early TV experiences in the natural home environment. They found a strong relationship between TV viewing and language development in expanding vocabulary and practicing discourse. The way in which television is used

by mothers and their babies to explore and learn language is in many ways similar to the use of picture books in joint reading activities (Heath, & Branscomb, 1986).

Television provides occasions for verbal interaction among viewers of all ages. Some of the parent-child conversation involves interpretation and explanation of aspects of the TV message, including language itself (Winick, & Winick, 1979, p. 164). In a study focused on how children interact with others in the TV-viewing situation during commercials, Reid and Frazer (1980a) found that:

1. Commercials were used to draw others into conversations and activities related or unrelated to message content;
2. Attempts were made to gain information from parents or siblings in order to resolve ambiguities or complex message presentations; and
3. Commercials were used to avoid the demands and requests of others, especially those made by parents (p. 156).

At other times television may provide raw material for language play among children (James, & McCain, 1982, pp. 787, 788; Reid & Frazer, 1980b; Watson-Gegeo, & Boggs, 1977), an important activity in the development of linguistic skills. This practice of incorporating spoken material from TV into interpersonal interaction for playful or humorous purposes continues into adulthood. Alperstein (1990) describes how catch phrases from commercials are integrated and transformed into conversations among adults, where they may in turn be adopted indirectly by people who are not TV viewers. This practice may serve to facilitate social integration among people who do not know each other well but for whom TV images represent very familiar shared cultural knowledge.

COMPREHENSIBILITY OF TV SPEECH AS INPUT FOR LANGUAGE LEARNING

Certainly while much of the speech on television is incomprehensible for the beginning language learner, some programs are more incomprehensible than others, and many of them can be comprehended at different levels according to viewers' varying abilities. Huston and Wright (1983) note that the educational program *Sesame Street* contains a good deal of verbal humor and parody that children (the primary audience) would not be expected to understand. In fact, these elements apparently serve to make the program more appealing to older viewers, and so might promote joint viewing of the program by children and adults and reinforcement of the learning from TV through face-to-face interaction during viewing.

In spite of not getting the full range of meanings from the show, children may still understand enough of a television message to enjoy it and continue watching. Preverbal children may be fascinated by some programs and comprehend the activity represented in them going mainly by the visual elements on screen rather than by the verbal content (Huston, & Wright, p. 57). The visual elements of television may even serve to instill such linguistic knowledge as vocabulary by

providing more easily interpreted and redundant iconic information along with the verbal message (Rice, Huston, Truglio, & Wright, 1990, p. 427).

Even among children's programs there is a good deal of variation in the difficulty of the language used. Rice, Huston, and Wright (1982) described the linguistic features of five children's television programs and discovered that many of Clark and Clark's (1977) generalizations about television language were inaccurate:

The majority of comments in four of the programs were ones in which the speaker talked about things immediately accessible to view. Also, the stream of speech was not always rapid. In fact, the main characters of some programs had speaking styles consisting of a moderate, deliberate rate combined with a judicious use of pauses that distinctly marked linguistic units. Furthermore, there was considerable evidence of explicit attempts to adjust verbal messages to correspond to children's linguistic processing abilities, including various means of highlighting key linguistic messages. Another facilitative factor was the manner in which linguistic messages were combined with nonlinguistic production values. (Rice, 1984, p. 176)

Thus, some children's programs do not present overly complex verbal messages that are difficult to interpret; instead, they seem to be designed to match the linguistic capacities of their intended preschool audience.

Rice and Haight (1986) compared the nature of the speech used in two shows popular among very young viewers—*Sesame Street* and *Mr. Rogers' Neighborhood*—to the "motherese" of face-to-face communication. These programs seem to be addressing an audience of very young language learners, who, through their familiarity with these less complex utterances, may better comprehend the TV message. The speaking style in both these programs may share function as well as form with the similarly uncomplicated linguistic constructions adults may use with very young children in interpersonal interaction to facilitate language acquisition.

LANGUAGE ACQUISITION THROUGH OBSERVATIONAL LEARNING

While the primary focus in language acquisition research has traditionally been on interaction between language teachers and language learners, there have been a number of studies which provide evidence for the importance of observational learning. One argument is that because, on the average, children learn to comprehend over 14,000 words by the age of 6 (nine words per day), explicit tutoring for each word is not—indeed cannot be—required. It has been proposed that children utilize a "fast mapping" ability which allows them to "draw upon the linguistic and nonlinguistic context for a quick, initial, partial understanding of the word's meaning" as they overhear them used in the conversations of others (Rice, Buhr, & Nemeth, 1990, p. 33).

In general, personal participation in verbal activities is not required to gain an understanding of how particular verbal features are associated with aspects of the social situations in which language is used. It may be sufficient to be exposed to the ways in which language is used by certain sorts of

people in certain contexts to learn those associations (Schieffelin, & Ochs, 1986, p. 167). Rice (1984) points out that:

In the world that surrounds him, adults talk to other adults; children talk with other children, and there is a wide range of animate and inanimate actions, events, and interchanges that occur without regard to the presence of a youngster. The young language learner has ample opportunity to attend to, observe, and try to interpret the abundant and diverse real-world happenings that surround him. (pp. 171, 172)

In fact, Rice suggests that most of a child's language-learning opportunities are observational rather than participatory.

A study by Schiff (1979, cited in Rice, 1984, p. 173) found that, contrary to the results of similar research, hearing children raised by deaf parents and with relatively little exposure to hearing adults (and even less direct interaction with them) nevertheless learned oral language normally. As the children had been watching about 2 hours of TV each day, Rice (1984) believed it was "reasonable to suppose that the children's indirect, observational learning experiences (overhearing adult-to-adult conversations and observing patterns of verbal communication presented on TV) were also contributing significantly to their language learning" (p. 173).

Social learning theory provides an account of how it is that children acquire knowledge of the rules by which they can produce utterances that they have never heard or spoken before, one of the hallmarks of human language:

In this approach to the language learning process, the child induces, from observation of a model, a set of abstract rules governing the language produced by that model. Evidence of learning can be found in the application of these rules to the child's production of language from stimuli not duplicative of the modeling sequence. It is the generalization of these rule governed responses in novel circumstances which suggests that a learning process, and not mere mimicking, is in operation. (Selnow, & Bettinghaus, 1982, p. 470)

The theory does not discount the importance of direct tutoring in gaining knowledge of linguistic rules, where differential reinforcement of grammatical and ungrammatical utterances would occur (Bandura, & Harris, 1966, pp. 342, 343). As Wood (1981, p. 257) suggests, these two processes work together in language acquisition.

Early work in Albert Bandura's development of social learning theory tested the effectiveness of modeling for imparting the rules of verbal syntax to language learners. In a number of these studies, observational learning proved to be, at least in the short term, a very effective means for acquiring the rules for producing unfamiliar grammatical constructions (Bandura, & Harris, 1966; Carroll, Rosenthal, & Brysh, 1972; Odom, Liebert, & Hill, 1968; Rosenthal, & Carroll, 1972). Social learning can take place through watching modeled behavior on TV as well as in interpersonal interaction (Bandura, 1967). Without much in the way of incentives or need for practice, viewers may acquire a very wide range of behaviors, expectations, attitudes, and concepts without being particularly aware that they are in fact learning anything.

INCIDENTAL LANGUAGE LEARNING FROM TELEVISION

Rice (1984) believes that TV is "an important part of a child's everyday language-learning laboratory, along with all the other rich and varied communicative interactions he observes in the world around him" (p. 177). Given that children in the United States expose themselves so much to television programs, Selnow and Bettinghaus (1982) ask:

If the child speaks as his parents speak because he is frequently exposed to their language models, will it follow that greater exposure to television will lead to the development of language heavily influenced by television language models? (p. 471)

The few studies that have actually investigated language learning from television have focused mainly on the acquisition of vocabulary items.

In an experimental study on the ability of preschoolers to learn words from TV, Rice and Woodsmall (1988) found that learning of certain classes of words did indeed take place, and that fast mapping appeared to explain the accuracy with which the new vocabulary items were acquired. Five-year-olds were more accurate than 3-year-olds and gained relatively more words as well, suggesting that more advanced cognitive development or greater experience with observational learning also played a role. These findings were replicated by Rice et al. (1990), and Rice, Huston, et al. (1990) found that, from the ages of 3 to 5, naturalistic home viewing of *Sesame Street* led to the learning of new vocabulary items. Vocabulary improvement declined for older children in the study, which indicated the importance of age-appropriate verbal complexity in TV programs.

INCIDENTAL LANGUAGE SOCIALIZATION FROM TELEVISION

The socialization of an individual is usually considered as occurring through interpersonal interaction, but television also plays an important role in this process. It "bombards all classes, groups, and ages with the same perspectives at the same time" and is unique in "its ability to standardize, streamline, amplify, and share with virtually all members of society common cultural norms that had been local, parochial, and selective cultural patterns" (Gross, & Morgan, 1985, p. 222). In this regard, TV may be the most influential of all mass media because "unlike print media, television does not require literacy from its audience. Unlike the movies, television runs continuously. Unlike radio, television can show as well as tell" (p. 224). Dramatic entertainment on TV is educational in the way it presents lessons about the social world, and children are the most vulnerable class of viewers because they are less liable to clearly distinguish the fictive nature of television drama.

Corder-Bolz (1980) has described television as a secondary socializing agent. Like primary social agents, such as parents, teachers, and peers, TV provides information about social expectations; but unlike them, TV cannot act to enforce

compliance. However, in those domains in which television serves an individual as the sole or most credible source of information about social expectations, TV can become a powerful socializing agent (p. 116).

As a secondary socializing agent, television may supplement a viewer's sociolinguistic knowledge with stereotypes of how people outside the viewer's everyday local experience use language differently, and how to think about these differences.

Although they may never actually visit a courtroom, ranch, or spaceship, they may have TV-inspired ideas about the role of judges, ranch hands, and captains of spaceships, including the patterns of communication associated with each role. These examples could enhance children's awareness of such sociolinguistic variables as dialect differences, status indicators, styles of formal language, and conversational rules. (Rice, 1984, p. 177)

Hudson (1980) also names television as an important influence in language socialization in which "the child must become aware of a range of speech forms, although they may affect his own normal speech only peripherally, if at all" (pp. 16, 17). Thus television is implicated in the socialization of cultural knowledge, beliefs, and values about the world of language behavior.

The speech used in television dramatic entertainment is scripted, and therefore very likely to differ from the unrehearsed utterances produced by speakers in face-to-face interaction (cf. Ulrich, 1986). For example, a study of hesitation phenomena in three genres (documentary, family drama, and soap opera) by Johnson and Davis (1979) found that, contrary to expectations, unrealistic hesitations are characteristic of both scripted and unscripted TV dialogue. But the TV convention of naturalistic realism would lead one to expect that scripted or unscripted television dialogue not be so stylized, that viewers would not be able to understand such speech by applying the interpretive strategies for comprehending the speech they hear in interpersonal communication. Watching television may even contribute to the socialization of viewers toward the sorts of speech they do encounter in everyday interaction.

In the United States numerous distinct regional and social dialects of English are spoken, and television storytelling conveys messages about these varieties. Dillard (1985) observes that the mass media "have had a great deal of influence in determining what the American population in general has thought about dialects" (p. 205). Surveying one week of prime time entertainment programming, Willmorth (1988) found that northern U.S. dialects are overrepresented; such other regional dialects that do appear are leveled, often assigned to comedic characters or programs, and associated with relatively negative qualities in the characters that use them. Similarly, Rosenberg (1991) notes that regional dialects are hard to find on TV and are generally "rejected as unsuitable for national consumption" (p. F32).

One important social dialect of American English whose use in TV drama has received some attention is black English. To the extent it appears at all, it is generally homogenized and has served to stereotype characters into such categories as

"power assertive," "comedian," and "victim" (Fine, & Anderson, 1980; Holland, 1986). Asante (1980, pp. 186, 187) suggests that the lack of authentic ways of speaking for black characters on TV may produce identity confusion in black children. Dillard (1985) likewise believes that, "Representations of dialect and argot on television are so patently stereotyped, where they are not so reduced as to be completely washed out, that not even preteens can find much to identify with" (p. 204). Authentic black dialect is also restricted outside TV drama; while southern accents are permitted for white sportscasters, blacks are not permitted to use black dialect (Chad, 1989; Dillard, 1985, pp. 220, 221).

Television drama also presents viewers with images of how males and females speak differently and what consequences apply to characters who use these styles. Mulac, Bradac, and Mann (1985) found clear sex-role stereotyping of linguistic elements in both educational and entertainment programs for children. Young viewers apparently use their knowledge of these speech stereotypes to make attributions about the sexual orientations of characters (Edelsky, 1977). McCorkle's (1982) analysis of Saturday morning children's dramatic programs uncovered equivocal messages about the efficacy of appropriate verbal strategies—associated mainly with female characters—for resolving conflicts. Skewed representations of male and female speech are also found in programs for adults: although the same-sex relationships portrayed in soap operas are similar to those in everyday life, the preponderance of male-female relationships and the intimacy of those conversations seem unlike the daily patterns of social interaction (Fine, 1981).

Finally, television drama carries messages about the relationship between speaking style and social class. Goldsen (1975) found that, just as in everyday interaction, address forms in various genres of TV drama contain sociolinguistic cues about the relative statuses of characters. A study by Ellis and Armstrong (1989) on TV sitcom dialogue indicated that middle-class TV characters, particularly males, used more elaborated speech than lower-class characters and than female characters generally. Male lower-class characters, however, were the most stigmatized linguistically: they used the greatest number of nonstandard American English features (p. 157). Ellis and Armstrong suggest that these TV speech stereotypes "provide role models for viewers and implicit messages about how people of different sexes and social class communicate" (p. 167).

SUMMARY OF RESEARCH FINDINGS

Current research gives a more complex view of the relationship between TV and language learning than the oversimplified notions of, on the one hand, a powerful blanket effect, and, on the other, a complete lack of influence. The assumptions on which these assessments are based are faulty. First, not all aspects of productive language competence seem to be easily learned from television. Existing research confirms only the acquisition of vocabulary, which can be learned quickly and without tutoring through "fast mapping," as positively related to TV viewing. This does not mean, however, that

television may not also be found to promote the acquisition of other aspects of speaking that are perhaps more difficult to observe, such as grammar or accent, should sufficiently sensitive research methods be used.

Second, there is no single way of speaking that characterizes all TV programs. Different programs have different target audiences and the nature of the speech in those programs is designed accordingly (cf. Bell, 1984). Some programs are better suited to less experienced language users, while others contain more sophisticated linguistic messages for mature speakers. Within programs, too, different characters may use different speaking styles. It is precisely in this context that TV can imbue certain ways of speaking with relative values according to the types of characters who use them, and thus it may contribute to language socialization. Milroy and Milroy (1985), for example, believe that TV may play a large role in teaching comprehension of the leveled (standard) dialect and in promoting attitudes toward different ways of speaking and language varieties in the speech community (pp. 29–31). These attitudes may cause some speakers to seek to adopt more prestigious ways of speaking, as modeled on TV, for use in certain situations (cf. "Losing an accent," 1979; Walton, 1992).

Third, not all listeners will take TV to be a credible source of information on the use of speech styles in face-to-face interaction; for these viewers, television will, most likely, not serve as an effective socializing agent. One might hypothesize that heavier viewers and viewers with weak influences from the local primary socializing agents, including parents and peers, may be more influenced. But in the multistep flow of influence and information from the mass media to light viewers via face-to-face communication with heavier viewers, the reach of TV messages about language may extend beyond actual viewers (Kimball, & Joy, 1987).

Finally, it is necessary to acknowledge the interaction of interpersonal communication with TV viewing, not simply television viewing in and of itself, to understand the role that watching television has in language acquisition and socialization. It is in face-to-face interaction that much of the work is accomplished that instills communicative competence and where opportunities for practice with newly acquired language skills are provided. If TV influences language learning in a speech community, it is only in conjunction with the reinforcing function of interpersonal interaction in observational learning. This view finds some agreement with earlier assessments of ineffectiveness of TV in the absence of interpersonal interaction (Ervin-Tripp, 1971, p. 195; Snow et al., 1976, p. 2). Considering the research presented in this chapter, however, it appears that television does indeed function alongside face-to-face communication in speech communities to influence language learning.

TELEVISION AND LANGUAGE TEACHING

The responses of educators to the relationship of television with language learning can be grouped into at least three categories. Those who focus on the apparently negative consequences of TV viewing for language learners stress the

importance of reducing exposure to television (e.g., Winn, 1985). Others have taken TV viewing outside the classroom as a fact of modern life and have attempted to adapt traditional language-skills pedagogy accordingly. A third approach has involved bringing video into the language arts curriculum, both actual "off-the-air" programs and materials specially designed by educators to mimic many of the conventions of entertainment TV, but which function more efficiently as teaching aids.

Rather than complain about the possible deleterious effects of TV viewing on language skills, Becker (1973) adopted the approach that, "If you can't beat 'em, join 'em." Becker's monograph provides numerous examples of ways in which students' extracurricular exposure to television can be incorporated into language arts teaching strategies. Listening skills may be practiced by directing students to focus their attention on vocabulary and phrases, story comprehension, dialect and regional accent, figurative language, and accuracy of TV content. Speaking exercises might include oral class reports on viewed programs, using TV images as stimuli for verbalization, having students portray TV characters in role-play, and engaging students in vocabulary drills which use a game show format. Reading assignments may include books on TV personalities and behind-the-scenes descriptions of how TV programs are produced. Finally, teachers may have students write TV star biographies, compose letters to sponsors of TV shows or fan letters, write a different ending to a TV show viewed in class, and play critic by reviewing a TV show. Far from discouraging TV viewing, Becker even proposes that teachers assign programs to be watched as homework for subsequent in-class work.

Foreign language pedagogy has in recent years seen a great deal of attention paid to the use of "authentic" TV materials—those not originally designed as language teaching material. In many parts of the United States, foreign language TV stations and services provide news reports, commercials, and dramatic entertainment programming that can be used for in-class exercises (Berry-Bravo, 1991). News reports have timely and relevant content and a predictable format; they offer opportunities for practice with rapidly spoken numbers in sports and weather reports. News reports often repeat a limited number of vocabulary items and may help students acquire important general cultural knowledge about the places where the foreign language is spoken. Interviews on TV show body language and give examples of the filler words and transition phrases needed to maintain spontaneous dialogue; students can see and listen to a wide variety of interesting people, including Hispanic personalities speaking their native language. Television commercials contain intelligible native speech with idiomatic constructions and, like

news stories, can reflect cultural assumptions; as teaching materials they have the virtue of short duration and often humorous tone.

Berry-Bravo stresses that using authentic materials requires greater preparation time than canned instructional materials, such as leading discussions before and after viewing. Background information on geography, history, and politics may be required, as well as making transcripts and vocabulary glossaries, giving repeated viewings, and developing tests for comprehension of the viewed material. However, using authentic materials does increase student motivation, provides sustained exposure to a limited set of topics, and improves retention of vocabulary and awareness of cultural concepts.

Just as the format of *Sesame Street* was designed to take advantage of the attractiveness of TV commercials for young viewers to teach vocabulary (among other cognitive skills) (White, 1980, p. 210), a recent college-level Spanish language course, *Destinos*, is based on the very popular *telenovelas* (soap operas) of Latin American television. The creators of this telecourse believe that if "a language cannot be separated from culture, then television is a most appropriate medium for providing a dramatized, cultural context for language instruction" and that "television can take you to places in a way that even the most dedicated and excellent of instructors, with a plethora of visual props and aids, cannot" (VanPatten, Marks, & Teschner, 1992, p. 3). The series revolves around the travels of a private detective throughout the Spanish-speaking world in order to unravel a mystery, and along the way students are exposed to the numerous varieties of the language as well as cultural differences among the communities where they are spoken. Students are drawn in by the story, and are motivated to learn the language in order to follow it to its conclusion. Unlike "authentic" foreign language material, *Destinos* is constructed to assist gradual language learning, with later episodes containing more complex and more rapidly spoken Spanish.

There is no simple way to regard the relationship of television to language learning, and teachers of language skills have not achieved a consensus in thinking about television as enemy or friend. Attitudes range from considering television as having very negative effects, to having no appreciable effect, to having very positive effects on language learning. Considering what is known from current research into this issue, it seems most appropriate to recommend that language skills educators come to an understanding of how TV may play a role in their students' language learning processes and whether it can be applied positively in particular situations to achieve desired pedagogical goals.

VISUAL COMMUNICATION SKILLS AND MEDIA LITERACY

Michael Griffin and Dona Schwartz

UNIVERSITY OF MINNESOTA

After an actor was elected to the White House in 1980, there was a great deal written about Ronald Reagan as the first consummate TV president. Young people who had reached voting age during the 1970s voted for Reagan in surprisingly large numbers, and political commentators quickly pointed out that Reagan's strongest support was among 18–29 year-olds, the first generation to grow up completely in the television age. Journalists increasingly took for granted that television was the new kingmaker, especially after Reagan's landslide over Mondale in 1984, and the American voter became routinely characterized as a viewer of campaign images rather than an interpreter of campaign issues.

By the mid-1980s the notion that images are more potent than words, and that given a lack of congruence between visual and verbal information the visual will win out, had been repeated often enough to become accepted wisdom. The most frequently cited anecdote is a story by CBS correspondent Lesley Stahl concerning her coverage of the Reagan presidential campaign in 1984. As related in Martin Schramm's *The Great American Video Game* (1987, pp. 23–26, 33–36), Bill Moyers' PBS special *The Public Mind: Illusions of News* (1989), and Kiku Adatto's *Picture Perfect: The Art and Artifice of Public Image Making* (1993, pp. 58–60), Stahl did a piece for the CBS Evening News that she considered sharply critical of the television photo opportunities set up by the Reagan camp during the campaign. In the report she specifically pointed out the contradictions between photo opportunities staged by the White House (e.g., his ribbon-cutting at the opening of a new senior citizen center) and actual administration policies (e.g., pushing for cuts in aid for the disabled and elderly). To her surprise, however, she received a call from the White House praising the report for its wonderful visuals. "They don't listen to you if you are contradicting great pictures," a presidential aide told her.

In interviews and his own memoirs, Reagan media adviser Michael Deaver has confirmed that the White House "loved Stahl's story," and that in their view the nearly 5 minutes of visual imagery (time spent rebroadcasting photo opportunities coordinated by the Reagan staff) was fortuitous free publicity, a series of positive images of the President that easily overwhelmed the critical commentary contained in Stahl's voice over (Adatto, 1993, pp. 58–60; Deaver, 1987; Moyers, 1989).

The degree to which images inevitably overpower words remains an open question. In the case of the Lesley Stahl report, her words may not have effectively countered the images primarily because her commentary was not really very critical. A review of the videotape of the Stahl report suggests that her criticism was voiced diplomatically and counterbalanced by her open praise for Reagan's "brilliant" use of television. Recent research on television news imagery suggests that pictures are most often produced and edited to serve the news script, rather than the other way around, and though the relevance of news images to the verbal report may often be tenuous there is still insufficient evidence to indicate that television visuals communicate a separate and more powerful message than the spoken text (Griffin, 1992).

What does seem clear is that for some time now the public has encountered increasingly image-conscious mass media with increasingly sophisticated image-production technology. Expanding forms of television—from CNN satellite news coverage to MTV—epitomize this development. And each new genre of image-conscious media—the tabloid infotainment shows that purport to take viewers behind the scenes of each new scandal, the "reality-based" crime and rescue dramas that construct an eyewitness experience for those tuning in, the frenetic and overdesigned "zines" attempting to invent the "look" of urban-electronic America, or the ever more entertainment-oriented local news programs

striving to create “what viewers want to see”—provides innumerable examples of the artifice of image making and the disparity between pictures and reality.

Neil Postman (1985) argues eloquently that linguistic literacy does not provide adequate tools for the evaluation of this new “television-based epistemology.” Television shows us images rather than tells us about things, he says, and all “ways of knowing” in the modern world have come to be filtered through the “show business” paradigm of TV (pp. 78–80). Yet one does not even need to take the argument this far to recognize that television has become a predominant medium of communication in our society and that its audiovisual nature exhibits a syntax and structure quite different from books and newspapers. It is no longer tenable to think that verbal skills alone will equip today’s citizens for the audiovisual media environment they live in.

This chapter explores some of the factors involved in conceptualizing contemporary media literacy. What is required for basic media literacy at the end of the 20th century? To what extent does media literacy depend upon visual literacy and the teaching of visual communication skills? What is involved in training students to recognize and understand media forms, and in what contexts should these skills be taught?

UNDERSTANDING THE NATURE OF VISUAL REPRESENTATION

While young people today may be less inclined to read and thus less verbally literate than the previous generations, it has become a cliché that they are more visually facile and skilled. This increased “visual literacy” is attributed to children’s copious exposure to and experience with television, video games, and computers. But the nature of this presumed visual acumen has not been rigorously examined, and anecdotal accounts of teaching visual media production and analysis at the university level suggest that students often fail to manifest even rudimentary visual acuity, especially with regard to the properties of mass media images.

The most fundamental and persistent problem one encounters in teaching visual communication is the routine confusion of pictures and reality, the naive view that images produced by photographic media (i.e., most of the images we encounter) are simply direct mechanical records of the world around us. This confusion takes place on multiple levels: at the level of single, photographically “recorded” still images, at the level of selected and ordered sequences of “recorded” action, and at the level of conventional formats and structures for audiovisual storytelling and exposition.

The most basic misconception is that cameras replicate the processes of human vision, reproducing a sensory record that mimics the way we see. As Messaris (1994) convincingly argues, pictorial comprehension relies heavily on the presence in pictures of “the same kinds of informational cues that viewers employ in making sense of real-world vision” (p. 167). However, the common belief that the camera is simply an extension of the eye and that pictures allow us to “look in” on real-world figures, places, and events as “eyewitnesses” is an

enduring and influential myth. Of course, the myth is zealously promoted by a photographic industry eager to market the mechanical devices and supplies needed for “capturing reality” and by a television news industry invested in the conceit that they offer the viewer a “window on the world.” Educators hoping to develop more critical media viewing skills among their students fight an uphill battle against the preconceptions cultivated by the media themselves.

Seeing the Picture Frame

In introductory photography and visual communication courses an initial challenge for students is simply to recognize the existence and implications of the picture frame. The activity of “framing” as a conscious process of abstraction seems totally unfamiliar to the overwhelming majority of college students. Unlike our normal semicircular field of vision in which we rapidly change our point of focus across an otherwise low-resolution background, pictures frame an abstracted moment in time, a preselected field of view. Training photography students to see the entire frame (realizing that peripheral elements will appear in the picture as clearly as central ones) is a struggle, running counter as it does to normal visual scanning and selective focus. It takes conscious effort and substantial practice for students to finally eliminate the trees and lampposts growing out of subjects’ heads, and to notice and relate details from various areas of the frame, producing the kind of coherent, unified, and sharply demarcated image that we do not experience in natural vision.

Recognizing that the image frame encloses a purposeful abstraction from space and time does not make students immune to thinking about pictures as mechanical records, but it does give them the potential to recognize divergences between pictures and everyday visual experience. Awareness of the frame may be the most elementary building block in developing a consciousness of media selection and presentation, that is, media abstraction.

An understanding of pictures as abstractions paves the way for teaching about the psychological concepts of closure and gestalt, relating picture making to our desire to find resolution, coherence, and unity in the sensory surround (Arnheim, 1966, pp. 58–70; Gregory, 1970, pp. 11–31; Kohler, 1929; Zettl, 1990, pp. 114–119). The formally limited structure of pictures is very different from the fluid and ever-shifting processes of human vision, but the more condensed representation of pictures is a natural product of the human tendency toward simplification and resolution. Pictorial construction, then, seems to more closely parallel the mental processes of abstraction and categorization than the immediate sensory experiences of perception.

Interpreting Media Forms

The confusion of media and reality, that is, the failure to recognize the processes of mediation, involves more than the confusion of picture and subject. It is also encouraged by the naturalization of historically specific conventions of staging, camera movement, editing, image manipulation, narrative

construction, documentary exposition, and news reporting. Thus, sophisticated media viewing demands an awareness of media presentations as intentionally articulated. Since no form of visual media simply reproduces reality, yet nearly all forms represent selected facets of real things, the pertinent issue for viewers and producers alike is how images are being constructed and presented to convey a particular view. Discerning that view requires a sense of what producers are up to, the ability to recognize order, structure, and artifice—the application of what Worth and Gross (1974) call an “inferential interpretational strategy.”

In Worth and Gross’ heuristic, interpretational encounters with symbolic events are classified as “attributional” or “inferential.” Readers/viewers employ a strategy of attribution when they simply treat the symbolic representation of an event as evidence of the event’s existence, drawing from their own real-world experience to evaluate or respond to it. The concept of attribution is particularly applicable to photographic media, the iconicity of which encourages viewers to respond as if the representation were real, reacting empathetically toward actions on a movie screen or accepting the existence of a videotape as irrefutable evidence of a crime.

Readers/viewers employ a strategy of inference when they recognize that the symbolic event is created or structured by some controlling consciousness. In this case they assume that the event is selected and ordered with some intention in mind and attempt to discern the implications of the symbolic structure. The assumption of intention suggests an articulator who “means to imply” and an interpreter who “means to infer.” A movie viewer employing an inferential strategy would attend to cinematic techniques such as lighting, camera angle, and editing and infer their implications for character identification and narrative development.

In the Worth and Gross model, attribution and inference are not mutually exclusive, nor do they represent a rigid hierarchy in which viewers graduate from one to the other. But strategies of inference do depend upon an awareness and recognition of communicative structure. Those who can recognize the purposeful structuring of media representations have a much greater potential for moving between attribution and inference (or employing both in some proportion), while those who fail to do so must inevitably remain confined to attributional understandings and misunderstandings.

In terms of the attribution-inference model, teaching media literacy involves helping students attain a fuller range of interpretive skills. With regard to visual media, this entails moving beyond the naive acceptance of pictures as mere records of existence and building an understanding of how pictures are made and the nature of their complex relationship with reality. Media literacy, as it is defined here, involves knowledge of varying modes and styles of visual representation, not only an awareness of the selective abstraction inherent in picture making but a familiarity with the forms of symbolization that appear as proxies for reality. The predominant use of metonymy in film and television (the use of associated details or fragments to represent larger, unelaborated ideas, actions and events), together with the use of conventionalized editing formulas for constructing screen space and advancing narrative or expository progression,

produce recurrent syntactic patterns that make “literacy” a fitting analogy for these interpretive skills.

For example, characters in television dramas move from one scene to the next by means of routine elliptical editing. When “cops” in a police drama are called to the scene of a crime, they are often shown heading for the precinct door, or getting into a squad car, and then arriving in the next shot at some distant location. The details and duration of the trip are not represented. This metonymic compression of events, what Monaco calls “cinematic shorthand” in *How To Read a Film* (1981), involves predictable formulaic editing: actors walk away from the camera toward the door, the perspective cuts to a camera set-up outside on the street that pictures the actors emerging from the door and descending the steps to the sidewalk, the perspective cuts again to a camera set-up near the squad car and the camera pans with the actors as they get into the car, a cut to a more distant camera position gives us a brief shot of the car as it pulls away down the street, there is a cut to a shot of the squad car approaching the camera in a different setting, and finally, a closer shot of the officers jumping out of their car at the crime scene.

This quick series of six or seven shots normally lasts less than 10 seconds on the screen, yet will involve multiple takes from multiple camera set-ups to construct what appears to be a natural and seamless narrative event. Each apparently realistic scene in film and television is pieced together from a variety of shots and camera angles that compress, expand, shift, and alter perspective, time, and space. One of the ironies of film and television is the high degree of manipulation involved in constructing and maintaining the “natural” appearance of dramatic action. Perceptions of filmic realism seem to rely, in fact, on the consistency and familiarity of editing strategies.

Recognizing the presence or absence of these representational strategies, not to mention comprehending their function or impact, requires a conscious awareness of the symbolic system. When viewers watch characters from *Murphy Brown* engaged in comic banter around the coffee counter on their “news set,” do they respond to the scene as a realistic representation of a work environment and identify with the employee camaraderie and needling depicted? Or do they recognize the coffee counter as a stage prop, strategically placed to provide a location for the actors to gather and exchange their lines? Do they see the habitual appearance of the coffee counter in each episode simply as a reflection of the “reality” of coffee-break rituals in the workplace? Or do they recognize it as a dramatic arena in which performers’ relationships are displayed, entrances and exits are orchestrated, and a context for humorous one-liners is established?

These different interpretive strategies have significant implications for the way in which viewers respond to television content, as evidenced by the controversy surrounding Dan Quayle’s criticism of *Murphy Brown* when she became a single mother. In news reports and talk show discussions the issue was framed as a debate between the Vice President of the United States and *Murphy Brown*, as if *Murphy Brown* was a real mother rather than a fictional television character. This kind of confusion over the status of media representations has been recounted in numerous anecdotes, from reports of fans

at Star Trek conventions behaving as though Leonard Nimoy is really Mr. Spock, to accounts of the actor Robert Young receiving 5,000 requests for medical and emotional advice a week when he played the role of TV's Dr. Marcus Welby (Real, 1977, p. 121).

Many aspects of pictorial apprehension are a natural extension of unmediated visual perception (Messaris, 1994); therefore, it is not surprising to find cases in which viewers assume the existence of what they see in pictures. But what viewers of visual media most commonly see are metonymic "short-hands" for imagined realities that remain obscure or ambiguous. Much of the "live" coverage of the air war in the Persian Gulf consisted of reporter stand-ups in front of the blue cabanas of the Dhahran Hilton. Momentary streaks of light in the sky were touted as eye-witness evidence of Patriot missiles intercepting incoming Scuds (a belief which was later shown to be mistaken). Broadcast repeatedly, a brief excerpt of the Rodney King videotape became a synecdoche for police brutality everywhere, and a handful of images—flaming buildings, looters running in and out of storefronts, Reginald Denny being assaulted with a brick—were packaged together to present a simplistic symbol of the Los Angeles uprising.

Understanding the conventionalized nuances of a media system such as television requires a knowledge of how various genres of television programming are produced, the technical and structural choices available to producers, and the range of content selections and aesthetic decisions made by scriptwriters, photographers, set and graphics designers, and film and video editors. Since pictures tend to encourage attributional interpretation, critical viewing requires a heightened awareness of distinctions between fiction and nonfiction, reality and simulation. In order to engender critical viewing skills educators must develop and convey an appreciation of the multiple factors shaping the production and reception of media images of all kinds. The remainder of the chapter outlines factors to be considered in teaching about visual media, the role of aesthetics in media evaluations, and the place of media production in curricula designed to improve visual media literacy.

AESTHETICS AND VISUAL MEDIA

Aesthetic education is an important prerequisite for the recognition of visual media forms discussed above. The methods by which the subject matter of images is shaped and styled to meet the needs and practices of newspapers, magazines, film and television production, build upon a history of picture-making aesthetics that reaches back to ancient painting (Barnhurst, 1994). The relevance of aesthetics for this discussion does not revolve around philosophical notions of beauty as much as notions of appropriate and established forms and a recognition of differences in style. The pictorial style of most nature and calendar photography, picture postcards, tourism publicity, and Eastman Kodak brochures, for example, is directly descended from a tradition of photography that became established in photo societies of the 19th century (Griffin, 1995). In *Reading National Geographic* (1993), Catherine Lutz and Jane Collins provide a full historical exegesis

of the way in which this same pictorialist style has been employed on the pages of *National Geographic* to present a pleasant and photogenic vision of the "cultural other." A consciousness of continuities of style links such studies of modern media to the study of aesthetics and art history (Berger, 1972).

The capacity to discriminate stylistic difference and understand its implications is an essential component of visual media literacy. Awareness of the aesthetic possibilities in pictorial representation encourages a sensitivity to the modes and styles of representation in various media, including news and documentary, media in which the aesthetic dimension is often denied or ignored. In *Representing Reality* (1991), Bill Nichols analyzes the aesthetics of documentary film to classify the predominant styles of documentary representation, specifying the shifting relationships between the camera and its subjects, and the viewer and the world. By focusing his attention on aesthetics rather than content, Nichols explores the documentary as a system of address. Instead of explaining the content or meaning of a specific film presentation, he illuminates the "language" of documentary, offering the reader a taxonomy of analytic categories with which to evaluate the status of documentary claims.

For instance, Nichols identifies four "modes of documentary representation": expository, observational, interactive, and reflexive (1991, pp. 32–68). The expository film takes the form of a report or persuasive essay. It addresses the viewer directly, using titles or a narrator to describe or comment upon what is happening on-screen. The voice-over narration helps advance the argument made by the film. Educational films, the type that students seem to associate most often with "documentary," tend to be expository in style. Propaganda films also favor the expository mode of address.

The observational mode refers to films that eschew narration and editing in favor of simply following and "observing" subjects and events with the camera. In the history of American documentary film this style is routinely referred to as "direct cinema." Although virtually every film and video employs some editing, and it can be argued that the mere presence of the camera inevitably affects the people and actions around it, "the observational mode stresses the nonintervention of the filmmaker" (Nichols, 1991, p. 38). The absence of voice-over narration often heightens perceptions of objectivity because, as students frequently claim, there is no omniscient voice "telling me what to think." However, despite appearances to the contrary, all filmmakers embed a point of view in their films through the decisions they make in the production process.

The interactive mode describes films in which the filmmaker *does* intervene to address and interact with the film's subjects. Interviewing is commonly a central part of interactive documentary style, although various forms of verbal exchange or testimony, and even monologue can characterize the filmmaker's encounters with subjects. Nichols describes cases in which filmmakers interject themselves into the visual presentation implicitly as interviewers, explicitly as participants, and boldly as provocateurs. Images demonstrating the validity (or incredibility) of statements made on-camera are often integrated into the unfolding argument of the film.

While interactive documentaries give the impression of allowing interviewees to "speak for themselves," the kinds of interactions elicited and their sequencing offer yet another vehicle for the filmmaker's own voice.

The reflexive mode integrates some examination of the process of representation itself into the film's argument. This is a more complicated mode of address and it is the least commonly chosen. Reflexive films or videos examine *how* we depict and describe the world. Rather than revolving around relationships between filmmakers and subjects, they tend to be concerned with the link between filmmakers (or the film text) and viewers. Built upon skepticism about the ability of media to provide objective representations of real life, they attempt to encourage a heightened critical consciousness among their own viewers. These films raise epistemological questions about media images and at the same time they offer their own representations of the world.

Concepts such as Nichols' "modes of representation" provide tools for evaluating the status and validity of media presentations. Once students can discern variations in visual modes of address they can begin to consider the implications of differing styles. Making an assessment of "reality-based" TV shows such as *Cops*, *Top Cops*, or *Rescue 911*, for example, might involve identifying the mix of observational and interactional modes of representation that characterize these programs. A viewer who is aware of the significance of the visual form would be likely to notice the way that the subjective positioning of the camera within police and emergency vehicles identifies the viewer with the main "characters" of these programs and frequently places the viewer in a seemingly interactive relationship with the victims and criminals that the protagonists encounter. At the same time, however, a skilled viewer would see that segments of apparent interaction are embedded into an overarching observational strategy, with the camera pulling back to a more objective (or third person) perspective that lends an impression of distance and dispassionate reporting. By routinely mixing the two modes within the program structure the "reality-based shows" combine the drama and emotional attraction of fictional entertainment with the aura and legitimacy of documentary or news. A better understanding of how this is accomplished leaves the viewer less susceptible to easy manipulation.

Similarly, research on TV news has begun to move beyond content coding to analyses of the "visual grammar" of TV news and the implications of that grammar for the scope and nature of news reporting (Ericson, Baranek, & Chan, 1987; Griffin, 1992; Gruneau & Hackett, 1990; Hartley, 1992a, 1992b). One of the developments evident in all of this work is the abandonment of the presumption that journalistic images represent an attempt to convey objective reality. As Hartley (1992b) notes, journalism has become "the art of televisualization" (p. 140). Ericson et al. write, "Using their sources, journalists offer accounts of reality, their own version of events as they think they are most appropriately visualized. The object of their accounts is rarely presented for the viewer, listener, or reader to contemplate directly. This holds true even in television news, where pictures most often show the reporter and his sources giving a 'talking head' account. Rarely shown are the documents, behaviors, or other objects discussed. When they

are shown, it is usually to represent indexically or symbolically, rather than iconically" (p. 4).

In other words, rather than bringing us images of actual news events as they occur (something TV newscasts can rarely deliver) television news operations construct visual proxies and present symbols of information (shots of the White House to suggest presidential deliberations, images of youths on the street corner to symbolize crime, a graphic of a microscope to represent medical research). In fact, the main activity of TV news operations is the creation and interjection of these kinds of symbolic emblems to provide a continuous semblance of the "eyewitness coverage" that is not there. Thus, TV news must be seen not as a daily visual record of ongoing events, but as a set of "plausible stories" visualized by symbolic and fictional devices. As Hartley (1992b) has observed, "The ideology of eyewitness authenticity is much stronger than the actuality of newsgathering practices" (p. 144). Consequently, even in the case of news it is a consciousness of aesthetic constructions that opens the way to a valid appraisal of media performance.

PRODUCTION TRAINING AS A VEHICLE FOR AESTHETIC EDUCATION

One logical way of helping students explore the role and influence of aesthetic skills is to educate them in visual media production. Studies of children's art classes (Schwartz, 1979) and children's filmmaking (Griffin, 1985) suggest that kids at very young ages can learn to practice established conventions of image making. But the skills they acquire most readily are those that mimic popular media forms. With increased production experience, some children are able to expand their aesthetic awareness and media skills but this requires continued involvement with and practice of visual production.

Among a sample group of sixth graders enrolled in Philadelphia public school art classes (Schwartz, 1979), boys who had adopted comic book models as templates displayed remarkable self-confidence and derived significant pleasure from drawing. Acutely aware of their inadequacy, most of the other children avoided drawing altogether. Although comic books were not the teachers' preferred examples of artistry, they provided simple, schematic blueprints that offered success and immediate social reinforcement. During several months of classroom observation many students continued to reproduce the same comic book characters with little change. Those who demonstrated enthusiasm for drawing and received positive feedback from teachers and classmates displayed a wider variety of forms and types of pictures. The extra attention and practice yielded improved manual skills and aesthetic sophistication.

Similarly, a study of child filmmakers in the New York Young Filmmakers Program (Griffin, 1985) found that a large number integrated television content and formats in their own films. Films such as *The Bionic Woman* and the *Six Million Dollar Kid* were typical. Nearly all of the children between ages 7 and 14 continued to duplicate television content and TV editing formats through several successive film productions. But some of the 13- or 14-year-old children

who had been with the program long enough to complete four to six films, began to experiment with breaking the TV formulas and making more personal and aesthetically idiosyncratic films. As with the children's drawing, it seemed that initial experience led to the adoption of the most prevalently available models, but continuing experience and interest encouraged experimentation with a broader set of potential forms.

In university teaching as well, students often begin with the desire to learn only the most common industrial and technical formulas. Often, this desire is linked to the notion that reproducing industry norms is the surest path to successful employment. As their media experience grows, however, students often take an interest in pursuing a wider range of aesthetic possibilities. And it is most often these students who begin to exhibit a keener sense of differing media environments and practices, who, in effect, begin to develop the capacity to "code-switch" among them. This "code-switching" depends upon an understanding of the symbolic nature of visual images and their role in context-specific image systems.

Certainly, sophisticated interpretive abilities can be developed by students without extensive media production experience. At the same time, working professionals who produce visual media products on a daily basis may reveal little consciousness of the codes they employ, or the broader implications and possibilities of their work. Yet, hands-on experience with the production and manipulation of imagery seems to be a potentially effective means of cultivating a heightened awareness of style and an expanded range of aesthetic possibilities. As Gross (1974) suggests, such experience enhances "communicative competence."

THE HISTORY AND SOCIOLOGY OF VISUAL PRACTICES

The integration of hands-on training with theoretical and historical study of visual media further extends visual literacy skills. The processes of learning to control and manipulate framing, lighting, point of view, juxtaposition, and composition in the service of a specific goal can then be considered within the larger context of the history of art and media. Familiarity with the history of picture making inevitably leads to the recognition of a diversity of forms, contents, and expressive possibilities. It also reveals the relationship between particular aesthetic styles and genres and the institutional contexts from which they emerge.

Rosenblum (1978) makes the argument that aesthetic style must be viewed as a social process, studied as part of the larger social dynamic of which it is a part. To illustrate her point, Rosenblum describes the ways in which three stylistically distinct genres of photography—fine art, advertising, and photojournalism—are inextricably tied to the work routines, professional norms, and economic structures that shape these media production activities.

Helping students to understand that visual representations are both historically and socially situated deters them from deterministic assumptions that lead to complacent viewing. Students often claim that representations derive their

form and content from inherent qualities possessed by the medium or the genre itself: "News broadcasts appear the way they do because that's what a news broadcast *is*." Familiarity with the historical and social forces contributing to the evolution of contemporary American media allows viewers to regard media images as symbolic and communicative rather than as natural, commonsense occurrences. Seen within a comparative framework, the cultural specificity of American media becomes even more salient.

Understanding style as a product of distinct social worlds of media practice also provides a powerful corrective to the myth that pictures simply reproduce reality. Studies by Christopherson (1974), Tuchman (1978), Rosenblum (1978), Becker (1982), Schwartz (1986), Schwartz and Griffin (1987), and Griffin (1995) illuminate the nature of the social worlds of image production by examining such dynamics as: the ways in which industry imperatives constrain expressive potentialities, the identification of particular aesthetic styles with members of specific social groups, and the ways in which institutional reward structures shape the processes of representation. Finally, studying the historical and social contexts of image production produces an impression of the overarching symbolic environment within which media images of all kinds jostle and interact. Students not only need to be introduced to the distinct worlds of image production that characterize different media, different social groups, differing professional, industrial, and amateur spheres of activity, but also need to consider how all these modes of representation relate to mass produced forms of popular culture. Confronting both the diversity and the homogenization of symbolic output cannot help but challenge the passivity with which pictures are routinely encountered.

CONCLUSION

This chapter has argued that communication media in the late 20th century increasingly deliver information, advertising, and entertainment through complex arrangements of pictorial images and symbols, increasingly making issues of media literacy issues of visual communication. Thus, a sophisticated understanding of the nature of visual communication is essential to critical media consumption. Such heightened awareness involves moving beyond the naive treatment of pictures as simple records of reality to a recognition of the symbolic and metonymic quality of images within systems of conventionalized media representation. This, in turn, requires experience with the ways in which visual media presentations are created and packaged, experience gained through training in visual analysis and media production.

The education needed by a critical media viewer parallels that needed by a skillful media producer. Both require an appreciation of the aesthetic factors that structure media representations. Both require enough familiarity with picture making to avoid the pitfalls of naive attribution. Media viewers need sophisticated interpretive skills in order to assess the plausibility, validity, and value of visual images, the preeminent vehicles of the information age. Media producers need interpretive skills sophisticated enough to allow effective,

accurate message production that targets the intended audience.

Therefore, if media literacy is to become a goal of our educational system, teaching visual aesthetics and visual media production must become a routine part of elementary, secondary, and postsecondary curricula. Students must have regular opportunities to view and experiment with differing "modes of representation" (Nichols, 1991), and they must be encouraged to consider the implications of various production strategies for different "ways of seeing" (Berger, 1972). Historically, different styles of picturing the world have been linked to particular philosophical and socioeconomic systems. In the 20th century, industrial organizations for the mass production of images make this link more literal than ever. Only by critically examining the output of the commercial and noncommercial media around them, and by discovering through firsthand experience that alternative possibilities for pictorial production exist, can students become more aware of the production formulas of industrial media systems and the patterns of representation that result.

It is important that the interpretive skills of viewers not be limited to the most obvious levels of manifest content or the most conventional formulas of narrative exposition. The ability to consider new and unconventional media presentations, like the ability to read difficult material or solve unfamiliar

problems, is a skill that separates the educationally privileged from those who are less advantaged. As technology and society continue to change at an accelerating pace, the ability to grapple with ambiguity and unfamiliar form will become increasingly valuable, and viewers limited by static conceptions and inadequate skills will continue to fall farther behind.

Thus, the acquisition of visual literacy skills, often confused with the simple preference for images or the talent for video games that many kids exhibit, is a crucial issue for educators. Far from visually literate, children (and university students) demonstrably lack sophistication about aesthetic forms, pictorial artifice, and visual manipulation. The logical way to attack the problem is to renew the teaching of visual media analysis and production from the earliest grades. Art classes, once required of all students as a core part of the curriculum, have been cut back or eliminated in many schools, competing for a part of students' time with other "elective courses." Teachers must reassert the importance of art and its role in basic education alongside language, mathematics, social studies and reading. As we enter the 21st century and new media technologies blur distinctions between written and visual modes of address, visual literacy can no longer be taken for granted as a natural byproduct of television viewing and computer games.

VISUAL INTELLIGENCE AND ANALOGICAL THINKING

Paul Messaris

ANNENBERG SCHOOL FOR COMMUNICATION
UNIVERSITY OF PENNSYLVANIA

One of the most famous stories of scientific creativity concerns the chemist Friedrich von Kekule, who worked in the latter half of the 19th century. In 1865, Kekule was attempting to infer the internal structure of the benzene molecule. He knew that it was composed of six carbon atoms and six hydrogen atoms, but he was finding it very difficult to visualize how these atoms were arranged. His working assumption, that the atoms were lined up in rows, was incompatible with other known facts about carbon and hydrogen. One evening, after much puzzling over this problem, Kekule sat in a chair by his fireplace and dozed. Strings of atoms appeared before his eyes, and they began to twine and twist like snakes. And then, suddenly, one of the snakes reared back and seized on its own tail. At that instant, Kekule awoke with the solution to his problem immediately clear: as subsequent research confirmed, the structure of benzene is based on a string of six carbon atoms arranged in a circle (Findlay, 1965, p. 39).

This story has often been used as an illustration of the crucial role that visual images have played in the development of human knowledge. In Kekule's case, the images were purely internal, products of his "mind's eye." However, as a growing body of scholarship has demonstrated, the advance of science and technology has also been affected critically by the various visual media that people have used for recording the appearance of external reality. This point is the principal conclusion of William Ivins' (1953) influential history of woodcuts, engravings, and other early techniques for the exact reproduction of pictures. According to Ivins, the development of these techniques acted as a stimulus for several fields of knowledge, such as botany, whose progress had been impeded by the lack of means for the exact transmission of visual information. Similarly, in a recent detailed examination of the interplay between art and science in the Renaissance, Edgerton (1991) argues that both architecture and engineering were affected profoundly by the 15th-century invention of

linear perspective, which made it possible to create accurately scaled previsualizations of the appearance of three-dimensional structures. Indeed, as Edgerton had demonstrated in an earlier study, the first person to use linear perspective in a picture was most likely an architect, Filippo Brunelleschi (Edgerton, 1975).

Both Ivins and Edgerton, as well as other writers who have dealt with these matters, make a further point that is particularly relevant to the concerns of educators. They argue that, in addition to serving the purposes of specific scientific or technical tasks, visual media also contribute to the development of human intellect by enhancing their users' mental skills. This idea has become familiar to many educators through the well-known writings of Howard Gardner (1983, 1993), who has made the more general point that there are several distinct forms of intelligence, each of them related to particular modes of human communication. Gardner's discussion of visual media focuses on their connection to spatial intelligence, a set of mental skills having to do with the perception and comprehension of two- or three-dimensional shapes, objects, and relationships. Spatial intelligence is also the focus of Edgerton's and Ivins' writings. However, there is at least one other type of intellectual aptitude that has been associated with visual media, namely, analogical thinking (Hargittai, & Hargittai, 1994; Whittock, 1990). This aspect of visual intelligence will be the focus of the present chapter.

THE NATURE OF ANALOGICAL THINKING

Analogical thinking is the type of mental process illustrated by Kekule's vision of the snake biting its tail. In a detailed discussion of this story, Margaret Boden (1991, pp. 100, 101) pinpoints the essential features of that process: the ability to discern some structural similarity between two different

objects, events, or situations, and to get a better understanding of one of them on the basis of the characteristics of the other. In Kekule's case the image of the snake twisting itself into a circle gave him the idea that the line of carbon atoms in the benzene molecule could also twist itself into a closed loop. As Boden demonstrates, similar leaps of mind are central components of creative thinking not only in the sciences but also in the arts. The role of analogical reasoning in scientific discoveries has also been documented by John-Steiner (1985) and Mitchell (1993, p. 7), while Vosniadou and Ortony (1989, p. 1) have argued that analogy is "one of the most fundamental aspects of human cognition." A related belief in the significance of analogical thinking for educational attainment is reflected in the inclusion of analogy items in such standardized tests as the GRE (Bejar, Chaffin, & Embretson, 1991).

The important role that analogy can play in visual media is perhaps most evident in the case of informational displays. Boden (1991, p. 101) notes that maps, diagrams, scale models, and family trees are all instances of analogical representation. Detailed demonstrations aimed partly at visual educators of the informational uses of visual analogy have been provided by Edward Tufte (1983, 1990). For example, Tufte discusses a classic chart that he says "may well be the best statistical graphic ever drawn" (1983, p. 40). Created in 1861 by the French engineer Charles Joseph Minard, this chart displays the fate of Napoleon's army during its disastrous invasion of Russia in 1812–13. The line that plots the army's direction of travel across a map of Poland and Russia starts out thick and then gets progressively thinner as Napoleon's men begin to die off. When the line reverses direction and traces the path of Napoleon's retreat, it becomes linked to a scale indicating the plummeting temperatures that reduced the army's size even further. All of the correspondences between this chart and the reality that it represents—the thickness of the line and the size of the army, the line's path across the page and the army's direction of travel, the downward-pointing scale and the falling temperatures—are examples of analogical representation.

Although the analogical aspects of visual media may be particularly clear in the case of informational displays, analogy is also a significant feature of the more purely artistic uses of visual images. An illustration of visual analogy in an artistic context is provided by Rudolf Arnheim (1969, pp. 120–129) in a discussion of a class exercise requiring students to draw abstract pictures of a good marriage and a bad marriage. One of Arnheim's students drew two circular figures, the first one consisting of smoothly curving lines, the second of spikes. Another student drew a pair of interlocking yin-yang figures and contrasted that with a pair of figures separated by some distance. In other words, both students' drawings are based on implicit analogies between the properties of visual shapes—smoothness versus roughness; closeness versus distance—and the abstract characteristics of human activities or relationships. Arnheim suggests that such connections are at the heart of the process by which abstract visual designs are able to evoke meaning. Furthermore, it can be argued that similar connections account for a significant part of the meaning of representational art as well (e.g., see Arnheim, 1954,

pp. 425–443; Messaris, 1994, pp. 40–44; Zettl, 1990). The following pages contain a closer look at these aspects of visual analogy. The discussion begins with an examination of the composition of individual images and then goes on to consider the consequences of juxtaposing two or more images, either in movie sequences or in complex static displays.

VISUAL COMPOSITION

As indicated above, the analogical basis of visual composition has been explored by several writers. For pedagogical purposes, a particularly useful introduction to the topic is provided by Molly Bang (1991) in a book which is ostensibly aimed at young children but nevertheless contains a systematic theoretical treatment of its subject. Drawing on her professional background as a prominent illustrator of children's books, Bang frames her presentation as a step-by-step examination of the stylistic decisions involved in the creation of a single picture, *Little Red Riding Hood* stalked by the wolf in the forest. This discussion entails such simple questions as whether the wolf's features should be pointed or curved and whether its eyes should be red or mauve, but the discussion's culmination is a set of general principles accounting for the meanings of individual design elements (shapes, sizes, colors, etc.) and the relationships among them. The central premise underlying all these principles is that viewers respond to the abstract features of visual composition on the basis of unconsciously perceived analogies to elements of real-world experience. As Bang puts it:

This word *associate* is the key to the whole process of how picture structure affects our emotions. ... We associate pointed shapes with real pointed objects. We associate red with real blood and fire. Specific elements such as points or color or size seem to call up the emotions we felt when we experienced actual sharp points or colors or noticeably large or small things. (p. 102)

Similar assumptions about the meaning of visual composition can be found in the work of other practicing artists. Among painters in the Western fine-arts tradition, an especially noteworthy investigator of these matters was Georges Seurat, who eventually developed an explicit theory that parallels Bang's in its essential details (Homer, 1964; Lee, 1990). For instance, he believed that a wedge-like shape pointing toward the top of a canvas would evoke both dynamism—because of the association with the properties of knives or other sharp-edged objects—and buoyancy—because of the association with upward movement in general. Consequently, in his rendition of scenes in which these qualities were an appropriate part of the tone he was trying to convey, Seurat would incorporate upward-pointing wedge shapes in the composition even when that meant sacrificing some of the naturalistic appearance of the image. As Homer (pp. 220–234) has noted, this practice is evident in such paintings as "*Le Cirque*" (1891) and "*Le Chahut*" (1890), in which upward-pointing tapers are added to the facial features of a circus acrobat, in the former case, and a line of high-stepping dances, in the latter.

In recent years, the assumptions underlying practices of this sort have been tested experimentally by such researchers as Hartmut Espe, whose work deals with advertising and industrial design. In Espe's experiments, viewers are shown pictures of abstract two- or three-dimensional objects and asked to indicate what meanings these objects express. One of Espe's studies investigated viewers' responses to three kinds of shapes: angular (triangle, star), orthogonal (square, rectangle), and curved (circle, ellipse). Viewers were asked to rate these shapes on two dimensions of meaning: how powerful and how active they appeared. Espe's assumption about the angular shapes was very much the same as Bang's and Seurat's: by analogy to the properties of real-world angular objects (wedges, knives, etc.), he expected these shapes to be seen as both powerful and active. For reasons that should be equally apparent, he expected the orthogonal shapes to be rated powerful but inactive, and the curved shapes to be rated neither powerful nor active. All these expectations were confirmed by the experimental results, which can therefore be seen as providing empirical support for the theoretical approach represented by Bang, Seurat, and scholars like Arnheim. Espe has also found, however, that the role of analogy in visual interpretation can be affected critically by context. For example, when viewers are shown a circle in a context that makes it appear three-dimensional instead of flat, the ratings of activity and power go up, perhaps because it is now seen as analogous to a ball, with connotations of sports.

The kinds of visual analogies investigated by Espe and illustrated in the examples from Bang and Seurat are relatively simple in the sense that they involve actual physical similarities between elements of a visual design and objects in the real world. For educational purposes, examples such as these may be the most convenient means for introducing the concepts of analogical representation to students. It would be a mistake, however, to assume that the analogical meanings in real works of art can always, or even frequently, be accounted for in such direct terms. A crucial feature of analogical thinking in art is its capacity to evoke meaning on the basis of purely conceptual parallels between the formal properties of a picture and the structural characteristics of some aspect of real-world experience. This was the case in the examples cited earlier from Arnheim, whose students were able to give visual form to the emotional qualities of marital relationships. The connection between visual education and the enhancement of intelligence seems especially clear in such instances.

The use of visual analogy for the sorts of complex purposes illustrated by Arnheim has been examined cross-culturally in a series of related studies. This body of research began with an investigation by Fischer (1961), an anthropologist concerned with the art of traditional, preindustrial cultures. Fischer was interested in the possibility that there might be an analogical connection between the stylistic features of a society's visual arts and the broader cultural values of that society. More specifically, he assumed that the relationships among design elements in a society's artworks might mirror the society's prevailing patterns of social relationship. For example, equality in a society's interpersonal relationships might be reflected by symmetrical compositions in a society's art, while the

presence of rigid distinctions among the members of a society might be reflected in its art by distinct boundaries around the compositional elements. Fischer tested these assumptions with a sample of some 30 traditional cultures, such as the Ashanti, Balinese, and Navajo, from various parts of the world. The results of these tests strongly supported his theory. Furthermore, similar findings have since been reported by researchers working with other cultures (e.g., Dressler, & Robbins, 1975; Hatcher, 1988; Pocius, 1979). Taken together, these findings suggest that educating students about visual analogy in art may also give them a new window into other people's cultural values.

POINT OF VIEW IN VISUAL ART

The aspects of composition that have been examined up to this point have to do with the arrangement of design elements on the surface of the image. The time has now come to turn to a different type of compositional device in which analogical connections also play a major role. This device has to do with the point of view from which the image is presented to the viewer. In other words, what is at stake with this device is the viewer's placement relative to the people or places in a picture: close-up or more distant, eye-level or at an angle, and so on. The analogical basis of point of view has been analyzed in detail by Meyrowitz (1986), who argues that people respond to this device by analogy to the ways in which they respond to interpersonal distance and orientation in real-world social relationships. For example, since proximity in real life is related to intimacy and involvement, a close-up in an image should elicit relatively greater engagement from the viewer. Similarly, since bigger people are often stronger than smaller ones, a view from below may make the person in an image appear more powerful in the eyes of the spectator.

Point of view is an important compositional device in drawing, painting, and photography, as well as film and video camerawork. Indeed, in fictional movies the distance between the camera and the subject is one of the principal visual means for such effects as heightening the intensity of a scene as it moves towards its climax, maintaining the viewer's sympathy with the hero and emotional distance from secondary characters, or releasing the tension of the movie following the resolution of the action. Nevertheless, despite its importance in these and other situations, the potential uses of point of view often seem to be overlooked when nonprofessionals make pictures. Studies of amateur filmmakers and of young people learning to make movies find that both groups tend to record the action from a single, unvarying perspective (Chalfen, 1982; Griffin, 1985). It appears, therefore, that there is considerable scope for visual education in this area. Moreover, in view of the analogical connection between everyday social interactions and the uses of point of view in the visual media, it is conceivable that learning how to employ this compositional device effectively may have the additional consequence of strengthening students' real-world perspective-taking skills.

Yet another reason why visual educators might want to focus on point of view has to do with the political and

advertising applications of this device. There is considerable evidence that manipulations of point of view can be effective instruments of visual persuasion in commercial advertisements and in political imagery. At the same time, though, there is reason to believe that viewers tend to overlook these manipulations. Consequently, drawing students' attention to point of view could contribute to the development of informed, critical attitudes toward potential influences of the visual media. Some indication of the need for this form of visual education comes from an experiment by Mandell and Shaw (1973) concerning the use of low camera angles in political imagery. This convention has a long history, especially—though by no means exclusively—in totalitarian political regimes. In Mandell and Shaw's study, college students were asked to make judgments about a political figure appearing in a newscast. There were three versions of this person's image: one taken at eye-level, the others at angles of 12 degrees below and above his eyes. Each student saw only one of these three versions. As the authors had predicted, judgments of how powerful the person looked were significantly higher among the students who saw the low-angle version. However, most of the students did not seem conscious of the influence of angle of view. At the conclusion of the study, they were asked directly to comment about camera angles used in the newscast. Out of a total of 78 students who saw either the high- or the low-angle versions, only 13 showed some awareness of this convention in their responses (Mandell, & Shaw, 1973, p. 362). Since similar findings have been reported from a second study of college students' responses to point of view, it would appear that this device is a particularly suitable object for the attention of visual educators.

THE JUXTAPOSITION OF IMAGES

In addition to operating at the level of the individual image, analogical relationships can also be present in the meanings created by bringing two or more images together, either in static displays such as print ads and billboards or in movie sequences. A relatively simple form of analogy is often encountered in film and television editing, whenever the duration of the shots is varied in order to suggest a mood or an emotional tone. Common examples of this practice include the use of fast-paced editing to generate excitement and impart a sense of dynamism to the events in a movie, or slow editing as a means of making things seem more tranquil. These uses of editing rhythm have been tested systematically by Kraft (1986) and Penn (1971), in experiments involving multiple versions of film clips, edited at speeds ranging from relatively high to relatively low. Viewers were asked to rate the activity level of these film clips; as expected, those who saw the versions with faster editing tended to see the clips as more active, while slower versions appeared calmer and more passive. These findings seem readily predictable, and the analogical connections that account for them are probably too obvious to need much explanation. Presumably, viewers' reactions to the pace of the editing are reflections of the way in which people respond to speed and slowness in the events of everyday reality.

A revealing elaboration of this editing principle has been investigated by Welch, Huston-Stein, Wright, and Plehal (1979) in a well-known study of television commercials aimed at children. Aside from the rhythm or pace of editing, this study was also concerned with the nature of editing transitions. In particular, the authors made a distinction between straight cuts, which create an instantaneous transition from one shot to the next, and dissolves or fades, both of which entail a more gradual replacement of one shot by another. The study was based on the assumption that the editing styles of children's commercials would differ according to the gender of the children they were aimed at. An analysis of a sample of Saturday-morning TV ads found support for that view. Commercials aimed at boys were characterized by faster editing and greater use of straight cuts, while girls' commercials had a slower editing pace and were more likely to employ fades or dissolves. The authors interpret these stylistic characteristics as "subtle sex-role cues." In other words, the commercials' editing styles appear to be analogical representations of conventional conceptions of masculinity and femininity: on the one hand speed and abruptness, on the other a more measured and gentle way of being.

An obvious question raised by the Welch study is whether children are actually sensitive to these stylistic evocations of gender. This question was explored in an ingenious follow-up experiment by Huston, Greer, Wright, Welch, and Ross (1984), in which identical commercials were edited in two different ways, corresponding to the two stylistic tendencies observed in the previous study. Children were shown these commercials and asked to guess whether they were intended for girls or for boys. The results showed that the children did indeed seem to have an intuitive grasp of the meaning of these stylistic manipulations. To be sure, this finding does not necessarily mean that the children were able to employ analogical thinking, even implicitly, in making the connection between style and gender. It is possible that they simply recognized the meaning of the editing on the basis of their past experience as viewers of TV commercials. However, if their responses were based even partly on analogical thought processes, this finding is an impressive indicator of young children's capacity for analogical thinking at a relatively high level of abstraction.

VISUAL SIMILE AND METAPHOR

In the editing conventions discussed above, it is the timing of the images, rather than their actual content, that exhibits analogical characteristics. There is, however, a very different form of analogical editing in which the content itself is the key to the analogy. This form of editing has a long history and is often thought of as having originated in the films of Sergei Eisenstein and other directors working in the early years of Soviet cinema. A clear example occurs in a scene from Eisenstein's "Strike" (1925), in which striking workers are massacred by government troops: at the climax of the massacre, Eisenstein edits into the scene a number of shots of animals being butchered in a slaughterhouse. This cross-cutting between the two sets of images can be seen as the

equivalent of a simile. It explicitly juxtaposes two events and implies an analogical connection between them.

Analogical cross-cutting figures prominently in certain films of Eisenstein and his contemporaries in the then USSR. For several years, this device was also popular in Hollywood, where Charlie Chaplin's notorious comparison between factory workers and sheep ("Modern Times," 1936) was one of many direct imitations of Soviet-style editing. Eventually, though, these kinds of juxtapositions became a rarity in fictional movies. As film critic Andre Bazin (1967) argued, the interruption of a movie's story line by the insertion of an extraneous image may have been incompatible with Hollywood cinema's increasing tendency toward unobtrusive narration. Consequently, when such an interruption is encountered in more recent movies—as in Howard Hawks' juxtaposition of kissing lovers and colliding trains in "Man's Favorite Sport?" (1964)—it is almost invariably a deliberate parody.

At the same time when this earlier style of cross-cutting has declined, however, other varieties of visual simile have taken its place. A relatively subtle example of this development occurs in Kon Ichikawa's "The Makioka Sisters," a Japanese film made in 1983. Toward the end of this film there is a scene in which an unmarried woman, who has endured a series of disappointing attempts at third-party matchmaking, finally meets a man she finds attractive. As she faces him for the first time, Ichikawa's camera goes from a shot of her to a shot of wind-ruffled foliage—with red colors prominent—in the window behind her. To a certain extent, this transition is similar to Hawks' pairing of a kiss and a crash. Yet there is also an important difference between them. Hawks' colliding trains appear out of nowhere, in a location that has no spatial relationship to anything else in the movie. In Ichikawa's case, on the other hand, the camera never strays from the space or time of the story's unfolding action. In that sense, Ichikawa's analogy may be considered less obtrusive. It could be argued, therefore, that a viewer has to be somewhat more discerning to spot such an analogy, and that a filmmaker may need to be more resourceful in creating it (Clifton, 1983).

Even less obtrusive visual similes can occur when the two images that are being juxtaposed appear together in a single shot, or when an analogical juxtaposition also serves as a narrative transition. The former possibility is discussed at length by Whittock (1990, pp. 43ff.) in connection with a shot from John Ford's "The Searchers" (1956): the hero of the film (played by John Wayne), riding through a desert landscape, shares the frame with the towering form of an isolated, rugged butte. Citing an earlier analysis by John F. Scott, Whittock observes that, while the analogical connection between rider and background seems compelling once it has been pointed out, the lack of a cut or other deliberate device for highlighting the juxtaposition makes it very easy to miss. Even when there is a cut, though, a visual simile can still be unobtrusive if the cut also serves a narrative purpose, which may monopolize the viewer's attention. The classic example of this latter possibility occurs in Stanley Kubrick's "2001: A Space Odyssey" (1968): a protohuman primate who has just learned how to use a bone as an ax tosses it high into the air, where its spinning is replaced by the movement of a space station in

orbit above the Earth. This is a profound juxtaposition, comprising a wealth of analogical links, but the dramatic narrative leap with which these links coincide can deflect the viewer's attention away from nonnarrative levels of meaning.

Viewers' interpretations of a visual simile embedded in narrative editing have been investigated by Messaris (1981) in a study of college-students' responses to a 10-minute fiction film. In one of the scenes of this film, the protagonist, a fashionably dressed woman, walks into a clothing store; as she passes through the door, there is a cut to the interior of a church, and the same woman appears at the entrance. When the study was being planned, it had seemed to the author highly unlikely that any viewer would miss the analogical implications of the transition between store and church. It emerged, however, that only students with actual experience in filmmaking were particularly sensitive to that aspect of the transition's meaning. The study had been designed as a deliberate comparison among viewers with varying degrees of film-related experience. Students who had made films themselves exhibited a high level of awareness of the store/church analogy. As one of these students put it: "At that point I thought there was a ... over-obvious ... metaphor of fashionable store—church, you know, I thought kind of unsubtle" (pauses in original). And yet, despite this "over-obviousness," among the students without any filmmaking experience the most frequent interpretation of this sequence was purely narrative—that is, the store/church transition was interpreted only as a scene change from one location to another.

These results provide some indication of the potential value of film education for students' capacity to think analogically in contexts where they might not ordinarily be inclined to do so. However, the editing of fiction films is by no means the only source of examples of visual similes. While editing that is based only on analogy, without a narrative component, is now quite rare in mainstream fiction film and television, it appears to be gaining popularity in some forms of advertising and has become a staple of political ads and videos (see Morreale, 1991; Prince, 1990). Juxtaposition based on visual or conceptual analogy between two images is also very common in print advertising. For example, automotive advertisers have featured their products in association with lions (a Toyota ad emphasizing power and dominance over the competition), ice skaters (an Oldsmobile ad emphasizing smooth performance and elegant styling), jet airplanes (a Dodge ad emphasizing speed and power), eagles (a GM ad emphasizing speed and ease of travel), and tigers (the well-known Exxon series). Furthermore, there is another, related category of print advertising that also makes use of visual analogy but presents it in a distinctly different form. A case in point is a National Dairy board ad in which a glass of milk emerges out of a peeled banana. The object is to suggest nutritional equivalence, but this analogy is suggested through a merging or blending of the two foods, rather than a side-by-side pairing. As Kaplan (1990, 1992) has suggested, this kind of blending of the two terms of the analogy may appropriately be thought of as a visual metaphor.

How well do viewers cope with visual similes and metaphors? What role do visual experience and education play in

equipping a viewer for the analogical thinking required in such cases? These questions have been addressed by the present author in a study conducted with Karen Nielsen (see Messaris, 1994, pp. 111–112). This study explored viewers' responses to two instances of analogical editing used for advertising purposes: Ronald Reagan's 1984 reelection campaign film, in which images of Reagan's first-term inauguration are intercut with images of people from various walks of life going to work in the morning (a visual expression of the campaign theme, "Morning in America"); and a TV commercial for fruit preserves in which the picture of the product is juxtaposed with images of nature and life on the farm, presumably as a way of suggesting purity and wholesomeness. These ads were shown to viewers from a variety of backgrounds, including people professionally occupied in TV production.

The central question pursued in the study was whether viewers would see any analogical element in the editing structures of the ads—for example, a comparison between Ronald Reagan and his fellow citizens getting ready to do their respective jobs, or an implied similarity between the qualities of the preserves and those of pristine nature. The results of this study indicated that awareness of such analogical links was higher among TV professionals than among other viewers. For example, while 87% of the former referred to some kind of analogical connection in their interpretation of the Reagan campaign film, the corresponding figure for other college-educated viewers was 59%. In addition to illustrating yet another way in which visual expertise may lead to enhanced analogical thinking, these findings also suggest that teaching students about visual similes and metaphors could contribute to their skills as interpreters of visual advertising.

CONCLUSIONS

The main lessons that emerge from what has been said so far are two: first, that analogical linkages play a major role in a wide variety of visual conventions; second, that the capacity for analogical thought is an important component of intelli-

gence, in science as well as in art. More specifically, the presence of analogical relationships between image and meaning, or between one image and another, has been illustrated in connection with scientific or informational graphics; pictorial composition, the artistic and persuasive uses of point of view, editing rhythm, and visual similes or metaphors in advertising and in narrative cinema. It was noted that, aside from increasing students' fluency in analogical thinking, education about the uses of visual analogy might also improve perspective-taking skills (in the case of point-of-view conventions), as well as students' abilities to think critically about persuasive uses of visual media.

How might educators best respond to these opportunities? The various examples of visual analogy described in this chapter are partly intended as sources on which educators could draw in designing a visual curriculum. Students could be taught to recognize similar devices in artworks and in the mass media and to incorporate this recognition in their critical responses. Perhaps more important, such devices could also serve as models for students' own creative efforts in visual media. Not surprisingly, there is reason to believe that enhancement of visual intelligence is especially likely to occur when students have the opportunity to produce film or other media themselves (see Messaris, 1981; Tidhar, 1984), although there is some evidence that even the experience of viewing can serve as an effective cognitive stimulus in certain circumstances (see Salomon, 1979). Beyond encouraging their students to develop as visual thinkers, educators can also make important contributions to the ongoing task of assessment of aptitudes and achievements in this area. While sophisticated methods have already been developed for the measurement of some forms of visual skills—most notably, spatial intelligence (see Page's chapter in this volume)—there is much less precedent for the assessment of analogical thinking in visual matters. As Gardner (1993) has noted, there is a need for context-sensitive evaluation that measures visual skills as part of students' overall interactions with visual media, rather than through isolated tests. Educators who work directly with students in the classroom are particularly well-placed to respond to this need.

VISUAL INTELLIGENCE AND SPATIAL APTITUDES

Georgette Page

WEST VIRGINIA UNIVERSITY

Over time, developmentalists have taken many different perspectives in examining how children learn about their worlds. The theory of the great developmentalist Jean Piaget stresses the importance of interactions between children and their environment as they become more able to think logically and hypothetically (see Boden, 1979). Howard Gardner is another theorist who has looked at the interaction between child and environment; however, Gardner takes a broader stance and argues that, while Piaget thought he was including all intelligences in his theory, Piaget's theory only concerns the development of logical-mathematical knowledge (Gardner, 1993).

After examining a number of different populations such as prodigies, gifted, brain-injured, experts in different fields, and individuals from various cultures, Gardner (1983) became convinced that there are at least seven intelligences. Logical-mathematical intelligence is what the name indicates and is the ability to think logically, mathematically, and scientifically. Linguistic intelligence is shown in the works of novelists, poets, and others who use verbal language effectively. Spatial intelligence is the ability to form and transform mental images of three-dimensional reality and is evident in people such as sailors, painters, sculptors, engineers. Musical intelligence is obvious in master musicians such as Beethoven and Ellington. Bodily-kinesthetic intelligence is exemplified by dancers, athletes, and others who use all or part of their body in efficient ways. Finally, Gardner's theory suggests two forms of personal intelligence: interpersonal, involving skill in understanding other people, and intrapersonal, or the ability to know about oneself and use that knowledge to function competently in the world. This chapter concentrates on spatial intelligence and describes how children's abilities within that area of knowledge interact with visual literacy.

cise several other areas of cognition, depending upon what type of material is presented (e.g., understanding words, interpersonal relationships, or bodily movements). In interpreting a film or a television program, viewers need to make sense of visual conventions such as cuts, zooms, dollying, split screens, and mats. These features may particularly challenge young viewers since they are not always isomorphic with naturally occurring phenomena, yet viewers who are skilled within the spatial realm of intelligence are more likely to understand them. Also, the more skilled they are in understanding these elements of visual media, the more likely they are to be competent within the spatial realm of intelligence.

Children's responses to the formal features of television have been examined in several studies by developmentalists and others (e.g., Calvert, Huston, Watkins, & Wright, 1982; Singer, & Singer, 1981; Smith, Anderson, & Fischer, 1985; Wright, & Huston, 1983). In this body of research, age is the factor which has been used to explain viewers' varied understandings. Other studies by visual communication scholars have addressed more specifically the individual characteristics of young children as they interpret certain conventions. For example, Acker and Tiemens (1981) tested elementary school children's perceptions of the changes in size of a televised image (a candy bar). Children watched a videotape in which a split screen showed two people, one on the left side of the screen and the other on the right, each holding a candy bar. The image on the right was identical to the one on the left. As the children watched the videotape, they saw the size of the candy bar on each side of the screen change. On one side, the camera cut to a close-up of the candy; on the other side, the camera zoomed in to a close-up of the candy. When the children were asked which candy bar had more to eat, they pointed to the one in which the zoom was used. The authors based this finding on a characteristic of Piaget's preoperational stage of development in which children are unable to conserve—namely, recognize that an object depicted in another way is still the same object. Preoperational children have trouble keeping in mind the qualities that are

SPATIAL INTELLIGENCE

An important relationship exists between visual media and spatial intelligence even though visual media may also exer-

unchanging even though the object may appear to be different. In this video task, they had difficulty in conserving the fact that the candy bar was the same regardless of how it was portrayed on the two screens. When the camera cut to the close-up, they thought that it was not as big as the candy bar that "grew" as the camera zoomed in to the close-up (p. 341).

Although this study and others done by developmentalists and communication scholars illustrate that children interpret visual messages differently from adults, the researchers do not address spatial intelligence in any significant way to explain differences in comprehension. According to Gardner (1983), being competent within the spatial realm of intelligence involves several abilities, which concentrate on perceiving objects and their transformations in space. For instance, a person who has acquired spatial knowledge recognizes qualities of an object, perceives changes in that object, mentally rotates the object in space, and reproduces it by drawings, paintings, and other graphic depictions (p.173). A good example of spatial intelligence is illustrated by watching expert chess players.

Many of the abilities within the spatial realm pertain to perspectives or viewpoints and manipulation of objects in space. Visual media tap these skills when, for instance, producers depict characters simultaneously in two different spaces through matted images or split screens, cut from one shot to another within the same scene, or have cameras dolly around objects in a scene. Do young viewers use their spatial knowledge to help them make sense of these conventions? If so, how? This question has been explored in several studies by Comuntzis.

POINT OF VIEW: STUDY I

The researcher examined children's comprehension of different viewpoints on television to see how it related to spatial knowledge in the real world. A positive relationship was found between young children's scores on a perspective-taking task—namely, children determined different viewpoints of characters in a three-dimensional display—and their level of skill in interpreting successive changing points of view in a short videotaped scene.

Method

Ninety-three children, 3 to 6 years of age, watched a videotape in which viewpoints of two girls playing a game of checkers changed by long shots (LS), over-the-shoulder shots (OS), and close-ups (CU). The sequence of shots is used conventionally in dialogue scenes (Monaco, 1977). The producer takes an establishing shot (LS) of the entire place of action, then cuts to an OS, which shows the partial back of one character and the front of another, then cuts to a CU of the face of the actor whose back was seen in the OS, and finally ends with a cut to a CU of the other actor. Watching this sequence of shots, the children answered questions about the various points of view.

Children viewed the videotape individually, and the researcher stopped the tape at each different shot to ask the

child questions about the two characters' points of view. (Figure 7-1 illustrates these different shots). The actors in the televised scene were facing each other and saw different objects: a clock and picture were hung on the two walls behind them so that one could see the clock; the other, the picture. The questions posed to the children required "yes" or "no" answers; for instance, "Does Terry see the clock on the wall?" or "Does Annie see the picture on the wall?" "Does Terry see the side of Annie's face that you see?" Questions tapped the child's perspective-taking ability when viewing a televised dialogue scene. That is, the children revealed, by their answers, how skilled they were in understanding the points of view in each of the shots—LS, OS, and CU—in the scene.

Scoring

Answers to the questions enabled the experimenter to categorize children into levels of perspective-taking ability. Developmental literature on perspective taking in real-world situations provided the basis for establishing the criteria for the different levels of ability (e.g., Flavell, Flavell, Green, & Wilcox, 1981; Gzesh, & Surber, 1985; Schachter, & Gollin, 1979). Initially, perspective taking was examined by Piaget and Inhelder (1956) in their seminal "three mountain study." They found that preoperational children (around the ages of 2 to 7 years) were unable to understand that their view of a visual display was different from someone else situated in a different viewing position. Since then, others have studied perspective taking and shown that children as young as 3 and 4 years perform well (e.g., Borke, 1975; Cox, 1975; Light, & Nix, 1983; Pillow, & Flavell, 1986).

Within the literature, there are two basic levels of perspective-taking ability beyond having no perspective-taking ability (Level 0). Children who have no perspective-taking skill discern what they see and assume that everyone else, regardless of viewing position, sees the same thing. At Level I, the child knows that a person standing in one position does not see the same thing as one who is in another viewing position. At Level II, the child knows that the person may see the same object but not the same parts of the object as someone with a different view. The child progresses from knowing *what* to understanding *how* visual perspectives may be different.

In the study, two more levels were established to accommodate advanced skills of perspective taking which might be relevant to the interpretation of visual media. Level III is demonstrated by the viewer knowing the viewpoint of the actor whose back is to the audience in the OS. Level IV specifically pertains to the viewer's ability to understand the subjective viewpoint in a CU—namely, the CU of one actor is

the implied viewpoint of the other actor even though the actor is not visible.

Performances on the video task were compared to children's skill levels in a three-dimensional perspective-taking task. Figure 7-2 illustrates the "table task," in which dolls were situated around small blocks. On each side of the blocks were pictures (stickers) of familiar objects. The children were asked "yes" and "no" questions about what objects the dolls could see (e.g., "Does He-man see the heart?"). After they answered, they were placed at a level of ability. Score of children on performances in the table task was similar to that of the video task. The child who demonstrated knowledge of the visual perspectives at the first level understood what objects each character could see (e.g., He-man could see the elephant; Captain America could not see the flower). At the second level, children knew that each character saw the same object, but that they each saw different parts of the object. The highest level on the table task has been suggested in a study by Gzesh and Surber (1985) where children were asked to imagine, without actually seeing, a different perspective. At this highest level, the children accurately interpreted the *imagined* points of view of characters. For example, they correctly answered questions such as, "Pretend that Captain America is high up in the air over that block, and he's flying like Superman. Does he see the elephant's back?"

Results

Discriminant analyses were used in order to show how much the variables—table task performance, age, and sex—contributed to skill in comprehending the different changes in viewpoint on video. Age, followed by table task performance, contributed the most to performances on the video task. The average age for perspective takers (Levels I-IV) was 5 years 2

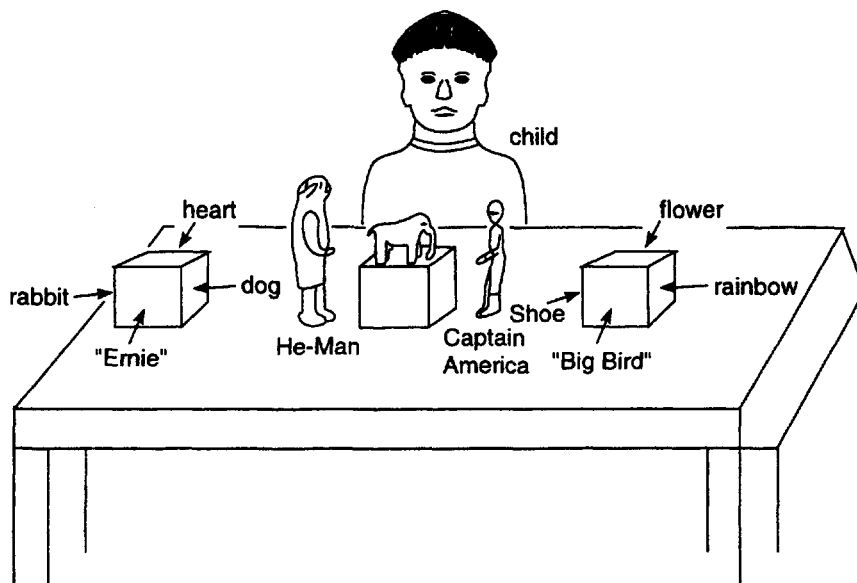

FIGURE 7-2 Three-dimensional display for table task

months; the average age of nonperspective takers (Level 0) was 4 years 3 months.

Experience with the medium of television did not influence the performances on the video task of this study. The children's parents were asked to record the number of hours their children watched TV in 1 week. Approximately one third of the sample responded to the task, and no relationship was found between these children's performances on the video task and the number of hours of television that they watched during a week.

The most important finding in the study supported the researcher's proposition that spatial intelligence is related to comprehension of the convention of changing viewpoints in television. Children who did well on the table perspective-taking task also performed at higher levels on the video task (i.e., Levels II–IV). These higher levels of ability in video perspective taking were demonstrated by children who could understand the more complicated shots in the televised scene. Thus, the argument may be made that in order for children to be skilled in following the changing viewpoints which occur in two-dimensional visual media such as film and television, they must first demonstrate competency as perspective takers in three-dimensional, actual situations. The data also suggest that spatial knowledge may be influenced by the viewer's understanding of changing perspectives on television.

POINT OF VIEW: STUDY 2

In a 1991 study on viewpoints by Comuntzis–Page, the LS and CU were examined in a segment of *Sesame Street* in which Bert and Ernie go to the movies. No OS shots were used in the segment, which makes the focus slightly different from the first study. The researcher questioned how young children interpreted the changes in points of view from shots of the muppets in the theater to shots of the film which the muppets are watching. For instance, could viewers understand that the muppets, not seen in the shots of the film, were indeed watching the screen? Did they understand that the muppets were watching a “movie”? How did the viewer interpret the CUs of the actors in the film?

Method

Thirty preschool-age children (mean age, 58.5 months) watched a videotaped segment of *Sesame Street* in which Bert and Ernie go to the cinema and join other muppets in the movie theater to watch a “Charlie Chaplin” film in which he has a romantic picnic with his female friend. The *Sesame Street* producer uses LSs and CUs to cut from shots of the muppets watching the movie to shots of the actors on the screen. The only connection with the audience in the theater during the shots of the movie screen occurs in Bert and Ernie's voice-over commentary. No over-the-shoulder shots, for instance, link the audience visually with the movie.

The experimenter paused the tape during various shots to assess whether children understood the different viewpoints

from theater to movie screen. Questions such as, “Do you see the back of Bert's head?” “Does Ernie see Bert's nose?” were asked in the LS of the muppets in the theater. In the CUs of the actors in the film, viewers answered questions such as, “Does the man see the woman?” “Does Ernie see the woman?”

Scoring

As in the first study, children were classified according to their ability to understand various viewpoints on the videotape. The levels of ability were slightly modified in this study since there were no OS depictions in the segment. The three levels of ability included: Level I—The viewer determined that an actor in the shot may or may not have the same viewpoint as the viewer. Level II—The viewer understood that the actor saw things which the viewer did not see. For instance, children at Level II knew that Bert could see the back of the muppet who sat in front of Bert in the theater even though those children were not able to see the muppet's back. Level III—The viewer understood the point of view of an actor not at all visible in the CU. Children's performances on the table task (used in the first study), their age, and sex were used as independent variables in this study.

Results

Several variables distinguished those children who were at Levels I–III on the video task from those who had no understanding of different perspectives (Level 0). Again, age was a significant factor, with the average age being 5 years 5 months for Levels I–III and 3 years 8 months for Level 0. The average age of the children at Level I in the video task in this study was the same as that found in the first study—4 years 9 months.

The table task in the study was also an important factor in video task performance. Children who performed at higher levels in the video task also had a clear understanding of differences in perspectives in the table task. For those who were classified within the three levels of perspective taking on the video task, the average performance level in the table task was 2.8, almost at the third level, whereas the average level for those children who did not understand the televised points of view (Level 0) was 0.44 in the table task. Moreover, the performances of children at the first and second levels on the video task were not as strongly related to their age. Rather, those children at Levels I and II, who were able to understand the different perspectives of the actors in the videotaped scene, also performed at high levels on the table task. Thus, a relationship once again was found between visual literacy, demonstrated in this study by skill in determining different points of view of characters in a videotaped scene, and spatial knowledge within the three-dimensional, real world.

The findings from both this study and the previous one agree with Gardner's theory of multiple intelligences to the extent that perspective taking in real-world situations is a spatial skill that is related to changing viewpoints depicted in two-dimensional visual media. A third study by the present author examined another skill within the spatial realm—block

building—to see if it, too, is relevant to young children's interpretations of visual media.

Developmental literature points to stages of block building, which advance, for the most part, by the experience a child (or adult) has with blocks and not so much by age. These stages are recognized by the qualities of constructions. Inexperienced block builders become more elaborate in their constructions as they progress through the stages. Seven stages have been described in elaborate detail by Johnson (1984); however, for the purposes of this study, three general levels were used: (1) blocks are put in simple patterns horizontally and/or stacked vertically; (2) blocks bridge and/or enclose spaces; and (3) blocks are placed in elaborate patterns, representations, and symbolizations (Isenberg, & Jalongo, 1984).

UNDERSTANDING THE SPACE OF MR. ROGERS' NEIGHBORHOOD

This study was the result of a comment heard in a PBS documentary by one of the producers of *Mr. Rogers' Neighborhood*. He said that little was known to them about how children make sense of the Neighborhood of Make-believe, a place where viewers are taken at some time during the program and where Mr. Rogers is the puppeteer for several puppets who interact with live actors. The researcher's purpose of the study was to look at how young children interpret the sequence of shots used to "transport" them from Mr. Rogers' living room to the Neighborhood of Make-believe and back to his living room. As in the previous two studies, a relationship was found between children's spatial intelligence, measured in this study by their block-building ability, and comprehension of the visuals depicted on television.

Method

Thirty-five 3- to 6-year-olds (average age, 59.6 months) participated in the study. Individually, they were interviewed by the researcher and her "Buddy," a teddy bear. The children were asked to play for a while and show "Buddy" what they could do with the blocks in the room. After 5 minutes of block play, the researcher showed a segment of Mr. Rogers' show in which the trolley, in medium shots, goes from his living room, through what is presumably a tunnel, into the Neighborhood of Make-believe and back through the tunnel at the end of the segment.

After seeing the tape, the children were asked to reconstruct for "Buddy," who was not watching the tape, the scene of the trolley going from one space to another (i.e., to and from Mr. Rogers' living room and the Neighborhood of Make-believe). The researcher handed the child props that represented objects and actors in the segment and asked the child to place them on a table in the same way they were seen in the television. Slides were taken of the children's constructions of blocks and props to record what they did and to determine if a relationship existed between the two tasks.

Scoring

Children scored according to how accurately they reconstructed the spatial layout of Mr. Rogers' two neighborhoods. If they showed that they were only guessing or had no idea as to what was shown on the segment, the children scored nothing. They were categorized at the first level (Level I) for representing the space with two or more mistakes. If they made only one error in the placement of props, they were placed at Level II and if they made no mistakes, they were at Level III. Children's stage of block building, age, and sex were compared with their scores on the video task.

Results

Results from *t* tests revealed that the most important variable that contributed to the accurate reconstruction of Mr. Rogers' set was block-building stage. Children who performed well in putting each prop in the correct place to represent the spatial layout of Mr. Rogers' living room and Neighborhood of Make-believe were also at advanced stages of block building. Particularly, children performing at Levels I and II in the reconstruction task also were at higher stages of block building.

Age also contributed to the subjects' skills in representing the placement of objects in the televised space. Children at Levels I–III on the reconstruction task were considerably older (average age, 61.6 months) than those who were unable to understand anything about the spatial layout of Mr. Rogers' show (average age, 44.5 months).

Discussion

The study of Mr. Rogers' Neighborhood was a preliminary attempt to investigate the factors that may influence children's comprehension of the spatial layout of a televised scene. The results show that a relationship exists between visual literacy and block building. Since block building is an important skill within the spatial realm, the findings from this study lend support to the notion once again that processing visual information that is depicted in visual media is closely related to children's spatial knowledge in the real world.

THE INFLUENCE OF VISUAL LITERACY ON SPATIAL INTELLIGENCE

Studies on perspective taking and reconstruction of space in relation to comprehension of some of the forms and conventions of television have attempted to explain the effects of spatial intelligence on visual literacy. The reverse may also be true: Spatial intelligence may be affected by a person being more or less visually literate. Paul Messaris (1994) suggests, "... enhanced literacy in visual media might entail a reciprocal enhancement of spatial intelligence" (p. 125). Studies by Gavriel Salomon have explored this possibility.

Salomon's work is concerned with how and why formal features of media affect mental processes as they do. He

carried out three experiments in which eighth graders were shown a painting by Brueghel. Sections of the painting were depicted by zooming in and out or by cutting, a method similar to that of the candy bar study by Acker and Tiemens (1981). The findings revealed that with the zoom, the children improved their recall of elements in the painting (Salomon, 1972). Salomon concluded that the children in these experiments used the conventions of media to help them understand more fully the visual information present in the painting. The study shows how a camera technique (zoom) can enhance a viewer's perception of a painting's elements. Thus, Salomon showed that, within the visual-spatial realm, experience with techniques used in one medium (film) may affect the comprehension of another medium (painting).

In another study, 76 ten- to eleven-year-olds viewed four different versions of an 8-minute televised film consisting of shots from various angles. Close-ups interchanged with long shots and zooms (Salomon, & Cohen, 1977). Children were more able to gather details when the zoom was used. The CU required them to glean information in bits and pieces and apply that information to the whole concept. On the other hand, the zoom enabled the children to see, without interruption, all the information as it related to the entire idea or object.

Salomon (1979) designed another investigation, reminiscent of the POV studies of Comuntzis, in which he hypothesized that the same improvements in spatial ability observed in his other studies could be repeated when he used the technique of changing viewpoints. His study, based on Piaget's "three mountain study," investigated what type of camera technique used for depicting different viewpoints would improve 7-year-olds' capacity to comprehend differences in perspectives.

Children in the study were assigned to one of four groups. The first condition was called "modeling" since it repeated the experience most viewers have in real-world situations—namely, they see the details of objects by walking around them and looking at them in one continuous motion. Modeling consisted of a film in which each of three familiar objects (a cup, a shoe, and an orange) was seen on a table in front of the viewer. A "smiley" face was placed behind each of the objects. A camera slowly moved around the table to where the face was and depicted "smiley's" viewpoint of each object.

A second condition was named "short-circuiting" because it jumped from one view of the object to another view. This condition was the same as the first except that instead of the camera's gradual movement, the 7-year-olds saw a slide of the initial position and a second slide of the final position of each rotation, which is similar to a cut used in film and television. The third condition was labeled "activation" since the viewers had to determine, without seeing, the various points of view. Activation consisted of slides of only the initial position; the viewers had to fill in the rest. The fourth condition had no treatment, only pretests and posttests which measured children's ability to change viewpoints in a three-dimensional display.

Results from this POV study by Salomon indicated that the activation and modeling groups did significantly better than

the short-circuiting group, which, in turn, did better than the control group. The researcher also concluded that the effects of the treatment condition were related to mental capabilities: the activation condition enhanced performances of the already skillful; the modeling condition aided performances of the initially less skilled; and the short-circuiting only slightly supported the abilities of the more advanced children. Salomon suggested that a proper way to use these conventions to cultivate skills is first by modeling and later by activation (1979, p. 154).

Visual literacy, as the studies by Salomon show, involves various cognitive skills of the viewer and can be used to improve children's spatial intelligence. This proposition is also supported in a study by Chava Tidhar (1984) on the effects of filmmaking on children's cognitive skills. The author's purpose was to investigate the effects of the filmmaking experience on real-world spatial skills.

Eighty-seven fifth graders who participated in the study were placed into four different groups that learned to use photography, photography plus scenario design, photography plus editing, or the inclusion of all three activities. A fifth group was a control group that engaged in recreational activities unrelated to film or television. Pre- and posttests revealed that the 55-hour course had a significant effect on improving the spatial aptitudes of the students.

Tidhar concluded that "mastery of these skills is important for the development of literate consumers to the visual media" (p. 963). The researcher also suggested that other areas of knowledge might be supported and improved by learning these cinematic skills. Referring to the previous work by Lavin and Silver (1979), she cited evidence suggesting that when children who suffered from language deficits participated in art activities, their readiness for studying language, mathematics, and abstract thinking improved. Thus, being visually literate has an impact on spatial as well as other intelligences.

CONCLUSION

This chapter has shown how spatial intelligence relates to young viewers' knowledge of visual media. Given the predominance of television in our society, children everywhere are exposed to its many different forms and conventions. Therefore, the question of whether the experience with visual media influences their understandings of various mediated codes is a complicated one. What emerges from the findings, nevertheless, is that children's interpretation of these visual forms depends in large part on their individual abilities within the spatial realm. Those who know and operate comfortably in this area are apt to comprehend televised conventions better than those who are not as competent within the spatial realm.

The impact that visual literacy has on spatial capabilities is evident as well. This proposition may seem contradictory, given the argument that spatial intelligence may help create visual literacy. However, the relationship is reciprocal and spiraling: First, children develop basic skills in spatial intelligence; then, they become more literate in their comprehen-

sion of visual media which, in turn, contributes to improving their spatial capacities. Educators and others whose work centers around children should note the evidence of the

investigations cited in this chapter and honor the important dance that takes place between spatial intelligence and visual literacy.

EXPLORING FUTURE MEDIA

John Carey

GREYSTONE COMMUNICATIONS

What will the communication landscape look like 10 or 20 years into the future? Will it resemble a Buck Rogers or Star Trek world with tele-transportation, hologram telephones and other science fiction gadgets or will it resemble everyday life today? It appears that there will be many changes in the media landscape, for example, large-screen, high resolution TV sets; personal computers with audio, video and high resolution graphics capabilities; new forms of mobile communications; and many new interactive technologies. Further, some of these changes may have important political and social implications. For example, high definition TV may boost the prospects for politicians with a different personality/beauty quotient than the current generation of politicians. However, the media landscape in the next 10 to 20 years is not likely to fulfill the dreams of today's science fiction writers.

How can we get a handle on future media and the implications they may have for those who teach about media? It is difficult if not impossible to accurately predict future media development and adoption. No attempt will be made to predict the future in this chapter. An alternative approach to understanding future media is to analyze technology developments and media usage patterns that are already at work and assess the implications if these trends continue in the marketplace. This approach assumes that the not-too-distant future is staring us in the face if we will just take time to examine it.

This chapter examines some current technological developments and reviews possible effects associated with them. The technological developments include higher resolution images for television sets and personal computer display monitors; increased bandwidth in telephone and cable television systems; new networks linking personal computers and portable communication terminals; multimedia or the addition of new media channels such as audio and video to technologies that previously did not have such capabilities; and interactive media. Some of the issues associated with these technological developments include: changes in the production and design of content for new media; new possibilities for expressive communication in channels with

greater bandwidth; adaptation of advertising to the new media environment; and changing characteristics of audience interactions with media.

TECHNOLOGICAL TRENDS

The telecommunications infrastructure in the United States is being upgraded at a very rapid pace (Kraushaar, 1994, pp. 1-5). This includes fiber-optic transmission, electronic digital switches, video servers and other components that increase the bandwidth or transmission capacity to schools, homes and businesses. Increased bandwidth linked with digital compression means that cable TV systems can have many more channels, telephone systems can carry video signals, and higher resolution images can be transmitted to TV sets, personal computer monitors and other display terminals. Higher resolution images include not only high-definition television (HDTV), which has been standardized, but also a broad spectrum of resolution enhancements that are possible in digital environments. In the future, a personal computer may display different types of visual information (e.g., text, graphics and video) with different degrees of resolution. Also, people may pay different prices for movies over fiber-optic cable based upon the resolution of the visual images, that is, movies delivered with higher resolution will require more bandwidth and therefore cost more.

At the same time, many new networks are coming into place. These include commercial on-line services and public networks such as the Internet. They also include private networks operated by state agencies and local area networks that link terminals in a school building or university campus. In addition, many of the new networks carry video via satellite or fiber-optic transmission for use in schools and businesses. The new networks link groups or communities of interest that are often geographically dispersed. Indeed, many of these communities were formed on the networks and would not have come into place without them.

With rapid technological change, it has also become more difficult to define media. The term multimedia has come into common usage to indicate a device that has some new capability. For example, a personal computer with a sound card or CD-ROM drive is often called a multimedia computer. The term multimedia implies that a device uses more than one medium to transmit or display information. In the past we gave such devices individualized names such as a television set. However, the evolution and upgrading of technology has been so rapid that there may be a reluctance to rename devices such as computers each year. The general trend captured by the term multimedia is nonetheless significant: commonplace technologies such as computers, telephones, radios and TVs are being upgraded to transmit or display additional media channels. For example, many radios and telephones can display text on small LED screens and many TVs can display a second channel superimposed as a window over the primary channel.

These technological developments are not taking place in the isolation of experimental laboratories. Many are moving quickly into homes, school and the work environment (Electronic Industries Association, 1994, pp. 5-35). The most important of the technologies entering these environments is undoubtedly the personal computer which can serve as a terminal for many present and future services. Indeed, the computer may become a household utility to provide a broad range of services much as a household stove is a utility for cooking many different types of meals.

Accompanying the diffusion of new technology, there has been a pattern of adopting multiple units of existing technologies. For example, the average U.S. home has two televisions, six radios and three telephones. Multiple units of a technology in homes support more individualized use of content. The old image of a family gathered around a television console in the living room has given way to family members spread throughout the house, each using personalized media. Similarly, in school environments, the number of personal computers per student has affected how they are used. With a very low computer-to-student ratio, the computer is largely a display device for teachers; with a moderate computer-to-student ratio, it becomes a time-shared work station; and with a high computer-to-student ratio, it becomes a personal tool of the student. The computer-to-student ratio increased steadily from the mid-1980s through the mid-1990s, thereby enhancing the computer's role as a personal tool of the student. However, poorer school districts still lag behind wealthier school districts in the number of computers available for instructional use, and many students still lack access to a personal computer (U.S. Department of Commerce, 1994, p. 169).

Interactive Media

Interactive media represent one of the most interesting technological developments. However, the term "interactive media" is used loosely and often inappropriately. It has become a popular term in advertisements for new technology and, like other catch phrases (e.g., "user friendly"), its relevance to a given technology can strain credibility. At the same time, it

may be premature to set down a rigid definition, since the characteristics of many technologies are evolving rapidly. For discussion purposes, it may be argued that interactive media include technologies that provide:

- person-to-person communication mediated by a telecommunications channel, for example, a telephone call, fax, or e-mail;
- group communications mediated by a telecommunication channel, for example, audio, video and computer conferences;
- person-to-machine interactions that simulate an interpersonal communication exchange, for example, a student using a personal computer software package that simulates a student-teacher dialogue or a bank customer using an automated teller machine (ATM) that simulates a transaction with a teller; and,
- person-to-machine interactions with multiple action-response sequences, for example, playing a video game.

In addition, a traditional one-way medium such as broadcast radio or television can make use of an adjunct technology to provide an interactive component to programming. Radio call-in programs and automated voting by television viewers who call a special 900 telephone number are two examples. In California, one company has employed a specially transmitted data signal to provide an interactive component for television programs. A subscriber to this service uses a special terminal to play along with game shows and predict the action on sports programming.

The excitement and interest in interactive media appear to stem from several sources. First, many of the advances in technology over the past decade (along with lower costs and widespread adoption of some technologies) have provided a base for the development of new interactive services. Second, there is a reasonably good track record and a very strong economic carrot for interactive services in business, including interactive videodisc-based training, on-line information services, videoconferencing, e-mail and faxes, among other services. Third, there is considerable activity in the development of new interactive services for education (e.g., interactive television via satellite and pc-based multimedia) and many needs (e.g., rural education services and higher education courses for working adults) that can be addressed through interactive media (Carey, 1991, p. 11). Finally, in spite of a shaky start in the 1980s for interactive consumer services such as videotex, the on-line industry has developed a reasonably large consumer market and the Internet has grown dramatically.

Beyond these incentives for new services to address specific needs and generate revenue, there appear to be some important social motivations and communication values underlying our fascination with interactive media. Some interactive media offer an opportunity for more individuals to create communications: many individuals creating content for many other individuals. This may appeal to a democratic value for broad participation in public discussion about social and political events. In addition, interactive media often require users to participate actively in the selection and processing of

information that is made available to them. Presumably, one cannot be a passive couch potato while using interactive media. Further, interactive media offer some opportunities to package and distribute information to highly specific groups of users. There are well-publicized examples of small software producers creating highly successful interactive services in basements or garages to the chagrin of large publishers and software producers. This may encourage us that the "little guy" can compete against large corporate entities in the interactive media arena (Thalhimer, 1994, p. 26).

Collectively, these values reflect a reaction against the forces that we associate with mass communication: large complex organizations creating public content that is distributed one-way to mass audiences. In this sense, the fascination with interactive media may represent a hope that they will enable us to break the control of one-way mass media on information and entertainment for the public.

IMPLICATIONS OF FUTURE MEDIA

The future media environment will affect many traditional media in terms of production, content and audience segmentation. For example, the reach of communication services will change. Among traditional mass media, some services have been targeting smaller audiences. In the next decade or two, other mass media services are likely to become more global, for example, some direct broadcast satellite services may be available in every country and some global newspapers may mix international, satellite-fed content with local content (all of which is printed locally). At the same time, some forms of interpersonal communication are expanding into wide-area group communication, for example, many e-mail systems have developed bulletin boards or conferences on topics. This information may be shared by a small group or hundreds of individuals spread across a wide region.

These trends suggest that over the next decade, the spectrum of information services is likely to be quite complex and the traditional communication taxonomies that the 20th century scholars have developed will have to be altered or replaced. A new classification system will have to include the reach of media (e.g., global, wide area, narrow area); access (e.g., public or private); characteristics of the audience (e.g., general or targeted); and direction of the information flow (e.g., one-way or interactive), among other characteristics and features.

Who Will Create Content?

Some of the most interesting questions about communication services in the future concern who will create them. Some academics and policy makers believe that the new technologies will help democratize media: they will break the traditional mass media model of information services in which a relatively small number of large institutions creates content for a mass audience. Presumably, desktop publishing and broadband switched networks will allow *many* groups to create information services for *many* distinct audiences. While this has occurred on the level of small-scale publishing,

it remains unclear whether traditional economic and marketplace forces will constrain such efforts on a larger scale. This is not to argue that small scale publishing of print or other materials will not have a powerful impact. It has been used to create and support revolutions; for example, Ayatollah Khomeini's use of audiocassettes to foment a revolution in Iran and Chinese students' use of fax to support their failed revolution in China. Further, desktop publishing has empowered many teachers to foment learning revolutions in the classroom.

In the future, more groups will be able to create and distribute information through private networks using new technologies and more groups will be able to create information for distribution on public networks such as the Internet. In the latter case, groups will create video press releases, packaged video segments for news programs, graphics and charts for newspapers, and so forth. This occurs now at a moderate level. In the future, it may flourish as technology empowers more groups to create such content. As a consequence, local producers of content such as teachers will have somewhat greater power relative to large publishers. At the same time, in other areas such as news production, the accuracy and reliability of diverse information sources may become a very contentious issue.

The broad public may also create content for news and other programming through their use of new technologies. A fiber-optic video network early in the next century may allow everyone watching a news program to respond instantly to questions posed by a reporter as well as vote at electronic town meetings. Prototype versions of such news programs and town meetings were tested in the 1970s, with mixed results (Becker, 1987, p. 120). Today, touchtone telephone can be used to obtain feedback from the public, but there is usually a delay of several hours or a day in receiving and tabulating the responses. In the future, instantaneous interactive formats will be available through fiber-optic technology. Even if the format is successful, it may prove to be a mixed blessing. The goal of soliciting broad public input to public affairs questions can be subsumed by media needs to entertain or political desires to manipulate public opinion.

At the other end of the scale, it is tempting to speculate about mergers among large media institutions and the convergence of mass media organizations with nonmedia organizations through their shared uses of communication technologies. What if news content were created not by traditional news organizations but rather by the Walt Disney Company, Bell Atlantic or a major international bank? This could occur in a few ways. First, major telecommunications organizations are developing large, multipurpose networks for consumers and, depending upon the regulatory climate, may produce news content for the networks. Such networks are likely to compete with traditional news organizations. Second, as major entertainment companies such as Walt Disney purchase broadcast networks and other companies with significant news operations, the traditional role of journalism may change. In an attempt to adapt to new technology environments such as DBS or fiber optics, the old guard of journalists in the news divisions might be swept aside and replaced by a new management team that would integrate

news operations with other divisions in the parent organization. A company like Walt Disney may not want their brand image associated with "bad news." Third, a major bank or stock broker might develop specialized, private information services for their clients which, over time, could evolve into a general news operation in order to enhance the appeal of the service: the bank would serve "all your financial and information needs."

Within education, there have also been some attempts to merge entertainment and education content under the control of media conglomerates, for example, Whittle Communications' Channel One. While the results of early efforts have been mixed from economic, pedagogical and policy perspectives, the carrot for schools of gaining free services and equipment as well as the profit incentive for businesses will undoubtedly lead to many additional efforts.

One way or the other, industry convergence and new information services are likely to lead to some form of challenge to independent journalism over the next few decades along with challenges to public, nonprofit control over education services.

Narrow Audience Content

It appears likely that many current trends in how people use media will not only continue but flourish over the next few decades. These include multiple units of technologies in households, a greater number of choices for information and entertainment, and more portable media. Accompanying these trends, content will become more personalized or targeted for specific audiences. This is often called narrowcasting or, in an advertising context, direct marketing. However, there are economic constraints on some forms of narrowcasting (Neuman, 1991, pp. 145–163). The high costs associated with producing and distributing television programs are likely to constrain the number of cable channels that can be supported in the marketplace. Similarly, rising postal rates may inhibit some forms of direct marketing.

In an electronic information environment, for example, an on-line service or the Internet, there are fewer constraints in targeting information at the level of an individual user. Moreover, developments in artificial intelligence will assist in processing specific content for specific individuals: systems will grow in their knowledge about individuals over time, by analyzing records of a consumer's usage patterns, and present desired content or advertising that is targeted for specific types of users. Indeed, the use of artificial intelligence to process information requests, develop profiles of users and present targeted information to consumers may become a significant component in the media environment over the next two decades.

The Effects of Technology on Information Formats and Style

The shape of content (format, style, length, etc.) is influenced by the characteristics of the technology employed to communicate it. Television news formats differ from newspaper

content, in part, because television can present powerful moving images but relatively few words while newspapers can present more words about a given story but limited visual images. What characteristics of communication technologies in the decades ahead are likely to shape future content? A technological infrastructure with fiber to the home and HDTV display screens will support highly detailed graphics and more data on the screen than is possible now. For this reason, the current trend of using more graphics and statistics in news, especially sports news, may flourish in the future technology environment. Fiber-optic technology will also support interactive services (e.g., live audience responses to questions posed in news programs) and on-demand services (e.g., ordering a specific movie to be delivered on a fiber-optic channel).

In addition, the use of personal computer memory to store text and video monitors to display text information has led to a number of important but subtle effects on information formats and style. For example, in an electronic text environment, the screen is a unit of content, just as a paragraph is a unit of content in a newspaper story. Similarly, the flow of information from one screen to another (e.g., tree and branching structure vs. hypercard stacks) affects the attention given to content items as well as the perceived relationship between different items. Indeed, an on-line text system is a distinct new medium and requires a different writing style as well as organization of content. Relatively few educators have begun to teach writing for screen-based text and relatively little research has addressed how students process information retrieved from data bases. For example, do students apply a critical perspective to information retrieved from data bases or do they accept it as true and accurate merely because it is stored in a computer?

One of the more dramatic features of HDTV has received relatively little attention—it displays skin tones and minor facial movements that are not readily captured on NTSC, even during a close-up shot. Minor changes in skin coloration can signal anger, excitement and other emotions. Minor facial movements convey a wide range of information and often provide clues concerning how a speaker feels about what he or she is saying. It remains unclear how program directors will use these screen characteristics or how viewers will interpret the new visual information.

Similarly, future large screens and wide screens with high resolution will offer an opportunity for our eyes to function as they do in face-to-face settings. That is, the screen will be able to display a large, high resolution panorama and each participant will be able to focus on large or small areas within the screen. Further, in a video windows environment, it may be possible to employ different resolutions for different visual elements on the screen; for example, the face of a speaker might be in one window with a very high resolution while the background screen might show other participants at a lower resolution.

The manipulation of time and space—through editing, slow motion, speeded up motion, etc.—can control how viewers perceive objects and actions. A viewer can see patterns that would not be perceived in everyday viewing of an object or action. Editing can also present multiple stories for

a viewer and move the viewer instantly into the past or the future. When rendered creatively, these features can communicate or evoke exhilaration, surprise and fascination. These characteristics of motion video have been available to designers for a long time through film and videotape. The new opportunity in the emerging multimedia environment will be to add user interaction as a design element. That is, a user can choose options about what to see and control the speed of the action. A user could also maneuver through content and edit together a story or gain a unique perspective about the stored content.

Enhancements to screen size and screen resolution as well as the possibility of utilizing multiple screens or multiple windows within a single screen will provide new tools for educators in designing audiovisual materials for the classroom. In distance learning, for example, teachers and students will be able to see details that were difficult to display in earlier media. Further, it will be possible to create a virtual classroom in which viewers' eyes move freely across a field of vision where previously the camera had to move as a surrogate for the eye.

Associated with these developments are many questions about the "language" of new visual media. For example, some of the new multimedia systems use icons and virtual space to represent categories of content and guide users to the programming. How do people interpret icons and determine how to move through virtual space? Further, how does the cognitive processing of new visual media relate to the ways people interpret and process traditional still pictures, film and television (Messaris, 1994, pp. 41–112)?

Content for Interactive Television

In the commercial world of interactive television developers, there has been much discussion about potential "killer applications"—services or content that will be very attractive to consumers and will drive interactive television into millions of homes. Movies-on-demand and interactive games are two candidate killer applications. However, it may be the case that there are no killer applications and that a critical mass of services will be required to attract large numbers of households. Historically, some media have benefited from so-called killer applications (e.g., pay movie channels helped cable grow during the great expansion period of the 1970s) while other media have required a critical mass of titles or applications (e.g., compact disc players and VCRs).

It is also useful to ask if anyone would be able to recognize a new and original killer application if one were to be created. As Marshall McLuhan noted a few decades ago, we tend to fill new media with content from earlier media (McLuhan, 1964, pp. 259–268). Thus, early radio was filled with vaudeville acts and early television was filled with radio shows that had been converted to a television format. Virtually every proposed service for interactive television is a modified version of content or a service that already exists: movies-on-demand is really a videocassette rental service directly to the home; most of the proposed interactive home shopping channels are variations on existing shopping channels or a video rendition

of catalogue shopping; and interactive games between households will allow two people to play a game together in different locations instead of in the same room. These are enhancements to existing services, and they may be very attractive. But they are not bold new applications for a new medium. If history repeats itself, genuinely new applications will not emerge for a few years and they will not be recognized as creative innovations for an even longer period of time.

Advertising

Advertising may play a crucial role in the development of interactive television. Interactive television commercials can provide many new features for advertisers and consumers alike. For example, consumers could choose which commercial they wish to watch or which version of a commercial to watch. Commercials can offer contests in which a viewer might learn instantly if she or he has won a prize. Also, consumers can instantly request additional information or actually make a purchase during a commercial. These features may make commercials more appealing to viewers and potentially reduce channel switching behavior during commercials.

It is intriguing to ask what radical new forms of advertising might emerge in an interactive television environment? British Airways has developed a novel interactive commercial for theatres in the UK. On screen, a couple is walking through a park in Paris. Suddenly, a woman in the theatre shouts, "That's my boyfriend. That's Nigel." The onscreen boyfriend turns to the camera and says, "Michelle, I can explain everything." The interaction then continues between the boyfriend on screen and the woman who was planted in the theatre. This novel and creative commercial requires considerable logistical support in a theatre environment. However, the concept lends itself quite well to an interactive television environment, that is, speaking to narrow audience segments (in the near term) and potentially to each individual viewer (in the long term). More important, the commercial provides an example of a radical departure from the norm.

Other trends in advertising involve mixing commercials and content on the same screen (e.g., the commercial appears in a window over programming) as a way to reduce channel surfing; superimposing commercial messages or symbols within content (e.g., digitally inserting a Coca Cola logo onto a basketball court at selected points during a game); and dispensing coupons during commercials via printers attached to TV sets. For students and media researchers alike these trends raise several questions. What impact will these techniques have upon the acceptance, believability and influence of commercials? Will the distinction between commercial messages and program content be further blurred for viewers? Are people more likely to be affected by a commercial if they participate in it?

The Consumer of Interactive Media

Do consumers want to interact with television? Interactive television appears to fly in the face of the so-called "couch potato" stereotype for television viewers. If television viewers

are so passive, what interest would they have in interacting with television programs? Of course, the stereotype of a passive, helpless viewer is a disputed concept (Neuman, 1991, pp. 80–85). Some researchers argue that TV viewers have always responded, directly or indirectly, to what they view. Further, there are many examples of viewers responding in large numbers to interactive telephone response polls in news programming and after major political speeches. In addition, the well-documented channel changing behavior of many viewers may be considered a simple form of interacting with television.

Nonetheless, the basic question of mass consumer appetite for interactive television remains unanswered. Further, what differences will we find among demographic groups? Will interactive television appeal more to males, as have on-line services and video games? Will usage skew toward younger audiences? A related question concerns the ability to maneuver through interactive systems. Will viewers who have experience with personal computers and automated teller machines find interactive television easier to use than those who do not have experience with other interactive technologies?

CONCLUSIONS

The adoption and use of future media technologies may provide us with an opportunity to study many important components of mediated communication. There is a large body of research that has examined mass media behavior and production conventions. However, an examination of consumer behavior and production conventions for interactive television and other new media is just beginning. A few of the issues that are likely to be addressed include: the growing sophistication of graphics in interactive systems and the reliance on them to convey meaning that was previously conveyed in text; the development of user behaviors in situations where there is/is not training or instructions on how to use a system; borrowing of conventions from older media in new multimedia systems; and, efficiency mechanisms (i.e., ways in which conventionalized messages can, over time, be communicated more quickly or simply).

For those who study the theoretical components of visual literacy, the new media will provide a rich laboratory for examining fundamental issues. For example, research scholars have devoted a great deal of energy to the exploration of visual communication processes that were at work in the early days of film and television. Through this research, they have tried to understand what components of visual literacy are based upon cognition and which components are learned (Messaris, 1994, pp. 14–21). With interactive visual media and other forms of multimedia, there will be an opportunity to study these issues in new contexts.

In the commercial marketplace, prospects for the future media environment are strong. There has been a growth in penetration of technologies (in homes, schools, and businesses) that will enable many to use interactive services, an improved telecommunications infrastructure to support the delivery of interactive services, and more experience in the design and marketing of interactive services. However, optimism must be tempered by the mixed track record of previous interactive technologies and uncertainty about current appetites for the new services that will be offered. In addition, some of the hopes and promises that are linked to the new media environment may not be realized. For example, the hope that new interactive media will lead to more information sources and greater diversity in content may fall short as traditional economic and institutional forces work upon the new multimedia environment.

From a teaching perspective, future media present many opportunities. There are both an opportunity and a strong need to train students about interactive media: what are the characteristics of these media; how does one write or design content for them; and, what social effects are associated with them; among other issues? In addition, the professional goals that teachers set for students and students set for themselves may change. While it is likely that many journalism and communication students will eventually create interactive multimedia services for great metropolitan newspapers or broadcast networks, it is just as likely that many students will create such services for telephone companies, computer software companies and noncommunication corporations such as banks or insurance companies.

BALANCING ACT: USING DRAMA TO EVEN THE EXCHANGE OF INFORMATION IN THE CLASSROOM

Jennifer Lynn Wolf

COTATI-RHONERT PARK UNIFIED SCHOOL DISTRICT, SONOMA COUNTY, CALIFORNIA

Do you think that to believe in the imaginative fiction of another person, and bring it to life, is a trifle? That is what we do to the work of the dramatist; we bring to life what is hidden under the words; we put our own thoughts into the author's lines, and we establish our own relationships to other characters in the play, and the conditions of their lives; we filter through ourselves all the materials that we receive from the author and the director; we work over them, supplementing them out of our own imagination. The material becomes part of us, spiritually, and even physically; our emotions are sincere, and as a final result we have truly productive activity. (Constantin Stanislavski, 1936, p. 52)

The exchange of knowledge in our classrooms too often flows in one direction only, dispersed unidirectionally from the teacher to the student. As a result, students may have little opportunity to "bring to life what is hidden under the words" or to filter themselves through the information given them. The result is too often work that is not "truly productive." Recent classroom research has suggested innovative and imaginative ways of rerouting the flow of information in the classroom by asking students to take on the responsibility for teaching one another, through cooperative learning (Kagan, 1990), peer editing (Reif, 1992), reciprocal learning (Campione, Rutherford, Gordon, Walker, & Brown, in press) and peer tutoring (Heath, & Mangiola, 1992). Teachers and their partners in education have also been exploring successful ways for students to gather information from primary sources outside of the classroom: elders who know history from a unique perspective; professionals who mentor students in school-arranged jobs; members of ethnic communities who add multi-cultural information to the curriculum; guest artists who can assist students in the creative process. These approaches relieve the teacher from the burden of

being the sole source of knowledge; instead, she becomes a kind of academic coach, designing and coordinating lessons within school curricula, facilitating new learning partnerships, providing supplementary information, observing, assisting, and evaluating student learners on an individual and as-needed basis.

In addition to dispensing knowledge to students and coaching students' gathering of knowledge, the teacher can also turn to students as a source of knowledge. In other words, the classroom can be structured so that information flows equally, or nearly equally, between the students and the teacher, so that the students and teacher share the responsibility of educating one another, each providing information that the other needs but does not have. As Stanislavski's words suggest, drama is an artistic process dependent upon such a reciprocal flow of information between its participants. Each brings knowledge and abilities that the others need in order to create a successful production. The playwright brings the language of the play's characters; the actors, the "sincere emotions" and imagination with which to bring the characters' words to life; and the director, the "materials" to fuse the relationships on stage into a polished performance.

Drama, then, with its plural emphases on reading, writing, speaking, and creating is a communicative art well-suited to increasing student literacy while at the same time improving the pedagogy that teaches it. This chapter argues that drama promotes the reciprocal exchange of information between students and teacher in four identifiable, and often overlapping, ways. Drama in the classroom: (1) brings missing information to the curriculum; (2) encourages understanding of multiple points of view and truths; (3) promotes creative

problem solving through healthy interdependence; and (4) offers the satisfaction of genuine achievement.

Each of these four reasons for teaching drama is explored from two perspectives, that of drama theory and that of contemporary drama practice in classrooms and youth groups. The classical drama theory describes a type of drama that is most often about producing scripted three-act plays containing a protagonist, antagonist, conflict, and climax, that is character-based, that has been influenced by Method Acting, and that assumes a formal relationship with the audience. This is the kind of drama most often produced on American stages and taught in universities and theater academies. The contemporary drama projects described in this chapter have been observed as part of the research project *Learning for Anything Everyday*, which is looking at successful neighborhood-based, inner-city youth groups (Heath, & McLaughlin, 1993; McLaughlin, Irby, & Langman, 1994), and in the course of the author's experiences while teaching drama in an inner-city high school. While each contemporary theater group and class observed is unique, their work hangs together on recognizably common elements: the young actors perform their own original work, they perform their work as an ensemble, and their work is often experience-based; their work is about communicating the messages of their own lives to community audiences, with whom they often also discuss their work directly after the performance is completed. Although the contemporary drama groups cited and described here clearly reveal a knowledge and use of the elements of classical drama theory, they also reveal a unique theater aesthetic. These drama groups have selected what they need from an existing theory and improvised on it to forge a new art form that better suits their needs. They provide us with excellent examples of learning through drama as well as fine examples of students who can regulate the flow of information around them, taking in teachers' ideas and providing in exchange new ideas of their own.

BRINGING MISSING INFORMATION INTO THE CURRICULUM

Drama, perhaps more than any other art form, is about bringing new voices to an audience, about publishing others' words in performance. It is about communication—among characters, within the community of plays and playwrights, from the artists to the audience. In coming to a performance, the audience is expected to carefully observe and seriously consider new voices and new ideas. Kathleen George (1994) advises beginning playwrights to start the process by communicating among themselves so that they will be better prepared to communicate with others. Her list of prewriting "key questions":

- What makes you angriest?
- What makes you happiest?
- What is your definition of a good life?
- What is your concept of a spiritual dilemma?
- What do you care about?
- What would you risk your life for?
- What makes you laugh? (p. xiii)

This list reinforces the notion of dramatic art as a responsibility to bring one's unique knowledge into the larger conversation.

When used as a lens through which to view plays of today's stage, George's questions focus attention on drama as an artistic tool for broadening conversations with audiences to include a wide range of new, controversial, and old ideas. Recent Pulitzer prize winning plays reveal as well as any drama's ability to serve nontraditional issues inside traditional ones to an audience. August Wilson's trilogy of generation plays—*Joe Turner*, *Ma Rainey's Black Bottom*, and *Fences*—is the beginning of "a cycle of plays designed to resurrect black voices from every decade of this century" (Moyers, 1989, p. 167). *The Kentucky Cycle* explores how the "settling" of European Americans in the Midwest was also the "unsettling" of the Native Americans. And Tony Kushner's *Angels in America* plays ask their audiences to simultaneously see people with AIDS as victims of a hard disease and as the best hope for defeating it.

Powerful plays like these also illustrate that drama communicates its new ideas through characters; characters who are like us in some ways, and also noticeably different from ourselves, thereby creating an interest in watching the play. Voices which speak compellingly to us from the stage may well be ones we would not listen to were we not sitting in seats facing a staged performance: *The Zoo Story's* insistent, homeless man in Central Park; *Night Mother's* reclusive, suicidal epileptic; *The Woman Warrior's* young Chinese American who relinquishes her ability to speak in the confusion of her dual-cultural existence. Playwright Kathleen Betsko speaks clearly in her own, unique voice about the responsibility she feels to bring to audiences the stories of the working-class coal mining women who would otherwise be isolated from the conversations of the theater:

I ended up as a playwright so that I can carry my old buddies around in three-D, have them talk to me on stage, pee my pants laughing with them as I used to. Many of them were as talented as me or more so. But they had too many problems, or Brown Lung, or a pack of kids at their knees, or unemployed husbands they couldn't leave to race off and get an education. But they gave me their vital language, their down-to-earth philosophies, and I hope I carry it all on. (Betsko, & Koenig, 1987, p. 56)

For August Wilson, characters demand that he represent them, that he give voice to their ideas that have so long been excluded from the conversation of the mainstream. His description of the play writing process acknowledges that acting as the bearer of missing information requires courage as you fuse your own self with the others who have been excluded:

I crawl up inside the material, and I get so immersed in it that as I'm inventing this world, I'm also becoming part of it. You discover that you're walking down this landscape of the self, and you have to be willing to confront whatever it is that you discover there. The idea is to emerge at the end of the landscape with something larger than what you had when you went in—something that is part of the illumination of the truth. (Moyers, 1989, p. 178)

That drama is about the responsibility to bring new and excluded voices to the stage offers hope to educators. Teachers who teach ethnically, linguistically, religiously, sexually,

and economically diverse classes know first hand that the stories, histories and dramas of their students' lives are all too often missing from the textbooks, reading lists, standardized tests, library catalogues and curricula which they are assigned to use. Even after a school or district realizes that a gap of missing information exists in the curriculum, there is most often substantial lag time between acknowledging the gap and providing the missing information in a useful, respectful way.

Teachers who know that they have already waited too long for the information that is missing from their curriculum, have a primary source of information available for immediate use inside their classrooms. Communicative arts teachers can use drama to invite students to bring the knowledge of their lives into the classroom in exchange for the knowledge that the teacher brings, and together they can create a more complete curriculum. In youth groups and classes in which the goal is to produce an original dramatic production, young performers become responsible for examining their own lives, opinions, and values in pursuit of an idea for a play, for creating characters and plots which bring their information to life in a compelling way, and for examining and rehearsing their ideas until they are worthy of formal presentation before others. In urban and inner-city areas across the United States, young people are learning that their unique knowledge is worthy of production.

In the last 3 years a group of Hmong teenagers in the Twin Cities of Minnesota have gathered together with a former teacher to produce ensemble plays about their experiences while immigrating to a new land and their memories of their first land (Hmong Theater Project, 1994; Hmong Youth Cultural Awareness Project, 1994). Each of the shows which they have written and performed has begun with the director asking the teen actors the question "What do you want to say?" Their most recent production is a dramatic collage of Hmong folktales which the students collected by interviewing community elders. Centered around the story of an orphan boy who is blessed with a dragon Princess for a wife until he takes her for granted, the play examines universal themes of trickery, greed, regret, and family love from a distinctly Hmong-American perspective. The actors are dressed in Hmong clothing and Birkenstock sandals, speak their lines in a combination of Hmong and English, play music on a makeshift orchestra of clay garden pots inspired by the gamelan orchestras of Southeast Asia, and perform to entertain an audience of both Hmong Americans and European Americans. After each performance, the Hmong players sit informally on the stage, inviting audience members to ask questions and adding to the information that they have just presented dramatically. They are careful to point out what they see as the most unique feature of their play—that they have scripted it. The students take pride in having not only collected their culture's stories, but also translated them to the permanence of the written word, an especially unusual act in a culture that for the majority of its existence has relied solely on oral language. As far as they know, their script is the only one of its kind, and the Hmong players clearly feel a responsibility as brokers of its cultural information.

A deaf teen actor and member of Central Touring Theater, an acting company which operates out of an urban high school in Minnesota, has taken on a similar responsibility of authoring a one-woman one-act play for her company's play writing festival. Typed in the same abbreviated language that the playwright uses to talk on her TTD phone system, her play *Sounds of Silence* (Hogue, 1994) begins with her protagonist taking pity on the audience for being deaf—deaf to her sign language. When she realizes that the audience cannot understand her signing of the lyrics to the Simon and Garfunkel song, she turns on a tape of the song to accompany her signing and asks the audience "Is that better?" This method of forcing an audience to take on a role other than their own (here the role of a deaf person) is a theatrically sophisticated means of bringing forth a message which the playwright feels has too long been kept from the general understanding: that the experience of being deaf is something from which hearing people could benefit. To illustrate her point, her opening monologue tells the story of the monarch butterflies which migrate over two thousand miles to the high mountain forests of Mexico. Once the butterflies arrive, the sound of their many wings beating back and forth in the trees where they land to recuperate is both the sound of silence and a sound which communicates.

Later in the play the protagonist takes on those who accuse her of being "not deaf enough" because she attends a hearing school, and those who ask her in ignorance how she can memorize her lines and drive a car, always coming back to the point that her deafness is only a handicap in the eyes of those who do not possess enough knowledge to see otherwise, those who have not known how to understand the silence of deaf communication.

Theater endeavors such as these offer fine examples of student artists offering new information to their audiences as well as exchanging information collaboratively with their adult directors. The Hmong players look to their director for the beginning question which provides the framework for considering the unique information they possess, as he then looks to them for their answers as the basis for the play.

ENCOURAGING UNDERSTANDING OF MULTIPLE TRUTHS AND POINTS OF VIEW

In the words of drama educator Dorothy Heathcote (1984, p. 79), "We begin this practice of playing [drama] at an early age because we realize that identifying with others is a human act of which we are capable." What Heathcote sees as instinctive human behavior—the desire to understand others by comparing and contrasting them to ourselves—Stanislavski pointed to as the basis of drama. He extended a curiosity about others into "a prime requirement for an actor," titled it "Characterization," and described it as "reincarnation" and "a real transformation—of body and soul" (Stanislavski, 1924, p. 33). A Russian acting teacher in the early 1900s, he observed and interviewed the greatest actors of his day, gathering methods that his students could use to convince audiences that they were someone other than themselves.

Actors today still subscribe to his method of acting for the guidance it offers in using the experiences and memories of one's life as an entry point into living the life of another on stage.

This is a fundamental challenge of acting—locating the place at which the actor and the character can meet and begin the process of creation. Regardless of the method of training the actor uses, the development of convincing real and imaginary others is a rigorous artistic challenge, one that draws on detailed observation, authentic research, and laborious repetition. The well-used textbook *Acting is Believing* (McGraw, 1980) establishes observation as the first step of characterization. One of its beginning exercises (p. 76) assigns students to “visit a busy railway station, hotel lobby or some other place where you will have opportunity to observe different people.” Observation of others provides the actor with the raw material with which to build a character who is more than just a series of actions: “Practice reproducing the observed details until you can do them accurately, until you feel you have captured some of the inner quality of the person.” The expectation is that observation and repetition will lead the actor to the construction of a complete other person—one the actor knows so well as to be able to predict his or her behaviors and decisions: “Prepare a short scene for which you supply circumstances leading to action that you believe would be true of the character you create.”

Northwestern University acting professor Bud Beyer begins his students on the journey of characterization by sending them to the zoo (Mekler, 1987). Here they are instructed, over a period of several visits, to choose an animal with which they feel a particular affiliation, and take notes on every detail they can possibly observe—“qualities of the spine, fluidity or rigidity, explosiveness of movement, the center of gravity, the breathing rhythms, the sensory alignment, the primary sense that the animal uses” (p. 318). Students are even encouraged to interview and observe the zoo keepers. When students finally present their animals in class, Beyer challenges them by interacting with them in unexpected ways that force them to improvise and raise the question—do they respond as the animal or themselves? In other words, how well do they understand the (animal) other they have been observing? A second other is created in the final stage of Beyer's exercise, when he asks his students “without much forewarning ... to begin to move out of the animal into a human form, carrying with them as many qualities of the animal as they can” (p. 318). This exercise demands a layering of points of view, finding an animal that has a bit of the actor in it, then creating an animal in which the actor is not visible, and then creating a third person who is something of the two previous characters and again something unique. The point of the exercise, says Beyer, “is to demonstrate the capacity of transformation that is possible by careful work” (p. 319).

Acting professor, playwright, and actor Anna Devere Smith (1993) warns that actors who do not work carefully enough at characterization fall into the trap of forcing the “character to walk in the actor's shoes.” For Devere Smith “the spirit of acting is the *travel* from the self to the other,” and she is interested in exploring with her students what prevents them from making this journey of characterization successfully. She

asks how inhibitions affect our ability to empathize.

If I have an inhibition about acting like a man, it may also point to an inhibition I have about seeing a man or hearing a man. To develop a voice one must develop an ear. To complete an action, one must develop a clear vision. (p. xxvii)

South American theater activist and teacher Augusto Boal (1992) urges his students to progress beyond “the starting point” of feeling the character's emotions to a more complete kind of empathy. “Exercises must be done,” he says, only with “the aim of ‘understanding’ the experience, not simply feeling it. [Actors] must know why a person is moved, what is the nature of this emotion, what its causes are—not limit [them] selves simply to the how” (p. 44).

Understanding, empathy and a clear vision are qualities that mark successful teachers and students as well as actors. Teachers who listen carefully and take the time to observe their students as individuals gather the information they need to design lessons and present information in ways that are appealing and logically connected to the students' lives. Students who understand what is important to the teacher and how she approaches information are better able to ask questions that get answers and present what they have learned in a way that can be appreciated. And in the classroom that contains a diversity of perspectives, the ability to accept multiple points of view is essential for both students and teachers if everyone is to be welcomed equally into the learning process.

At the same time, however, numerous scholars and critics have pointed out how understanding of multiple truths (Gardner, 1991; Rose, 1989; Witherall, & Noddings, 1991) is stifled by the structure of our classrooms. Curricula with strictly defined “scope and sequence” imply that knowledge is attained by traveling down a single path; standardized tests send a clear message that problems have one right answer; textbooks too often present single methods of explanation for complex situations; and our grading system reduces student achievements to a single, quantifiable mark. While our jobs, relationships, and daily lives present us with problems which require an understanding of multiple points of view to arrive at solutions, our classrooms do not.

Students in classrooms and youth groups where drama is used are not only offered an abundance of situations in which to practice understanding multiple points of view, but are also given the responsibility of presenting a variety of perspectives on stage. In a beginning drama class in Central High School in St. Paul, Minnesota, teacher Jan Mandell assigns students the task of developing and performing a short play that communicates to the audience some of their views on life. Through the process of improvisation and group discussion, the class discovers that they can not come to agreement on how they view the life that they are supposed to present on stage. Some students are frustrated with the violence, anger, and racism, which they see as increasing in their lives; others feel a responsibility to actively seek out the positive components of their lives and learn from them. What are the consequences, they wonder, of accepting and presenting a truth that is too negative? Too positive? How can they include both points of view?

Their discussions ultimately lead to a group-authored, one-act play entitled *Judgment Day* (Central Touring Theater, 1994) in which a group of omniscient beings comes to earth to decide whether humanity should be destroyed for its flaws or preserved for its good qualities. Their task is to collect instances of human behavior that support either argument and present them to a head "Watcher" who makes a final decision at the end of the play. This framework requires the students in the drama class to become Watchers themselves, collecting the events in their own lives which can be seen from two different perspectives. A fight in the hallway shows how violent and selfish adolescents can be, until the scene is extended to reveal conflict resolution through the use of a peer counselor. Healthy families are contrasted with unhealthy families; violence in a football game is contrasted with violence on the streets; the energy gang members spend destroying a neighborhood is juxtaposed against the energy a church puts into saving its community. All student actors are required to take on a number of roles within the play, to experience acting as human beings at their best and at their worst. In addition, the actors take on the role of Watcher, a characterization which results in judging their own behavior from a third perspective. Their decision at the end of the play? One that allows for multiple truths to coexist:

TOP WATCHER: I am very pleased with the savers and the destroyers of this case. I have come to a decision. I have decided to save and destroy America. We will come down, freeze dry America and turn it into a museum so that future generations can continue to learn from their mistakes.

The notion that drama is an art of multiple perspectives is also illustrated by a play submitted to the UC Berkeley New Plays Projects. Young playwright Joseph Brouillette not only wanted to bring to the stage information that has long been excluded from it, but was also determined to present the information from a variety of viewpoints. The result is his original one-act play, *20 Questions* (1994), which tells the story of coming out as a gay man interspliced and woven together with twenty monologues of gay men telling their own coming out stories. In his program notes the playwright is careful to explain that the play contains perspectives other than his own, that the monologues, instead of being of his own devising, come from interviews he conducted. Not all the men cast in the play are gay, and not all the gay men cast in the play are cast to deliver monologues which reflect their own experiences of coming out. Instead, each is required to find the elements within himself that allow him to relate to his character and use this as a basis for taking on the traits of another.

In San Francisco a small youth group of eight girls, directed by the author of this chapter, has taken on the task of creating a play which will show others what it is like to go to school in the inner city. The Director's Notes from their play program, describing how the play came about, reveal the girls' overriding concern for multiple truths:

In talking the girls came to three conclusions about their play-to-be:

1. They wanted to balance the good and the bad of going to school in the city, to be realistic while breaking down stereotypes;

2. They wanted to protect people's privacy—to tell the stories of going to school in the city, rather than the story of one person who goes to school in the city;

3. They wanted to tell their story by their own book—in their own words and in their own style, not by someone else's formula or expectations.

The result of their concerns is a one-act ensemble play examining six different aspects of school life from a multitude of viewpoints. In the first scene, each actor describes how she gets to school in the morning. The monologues illustrate as much about each girl as they do about methods of transportation:

A1: To get to school I catch the 44 at Hudson and Ingles. There's cockroaches on the bus. When they crawl outta them vents everyone yells, "Oooh! Step on em! Step on em!" but I just step outta the way cause I hate the way they crunch.

A2: I walk 8 blocks up to 18th Street to Castro and Market where I take the empty 37 at 7:30 AM. The fog makes it a clean and quiet time of day.

A3: I catch the 44 at 9th and Lawton at 7:45 or sometimes later. If there's ever a seat I might sit down and study for English. Otherwise I just stand up and hold on and try not to fall on anyone.

In the play's second scene, "Tardy," the girls take on the additional challenge of portraying the points of view of others they see and know at school. The girls explore the pervasive problem of students coming late to class at their school. They want to show that there are both legitimate reasons for coming to school late—"This girl got jumped on the 44—they cut off some of her hair with a switchblade. Then the cops came and made us all get off the bus;" "I'm sorry. I'm having an asthma attack;" "I had to take my little sister to school"—and reasons which do not deserve sympathy—"I just got here!;" "I had to go to the store ... Want one?" (offers a chip); "Didn't you see the fight on the second floor?" While short, each line underwent considerable debate between the actors and their director until it was agreed upon as accurate enough to be presented on stage. Looking at the first draft of the script, they immediately noticed an absence of references to drug use, something they saw as an unavoidable element of school life. At their school, "stoners" are known to cut class and walk the short distance to a canyon off school property to use and deal drugs, as well as hang out. The actors debated how, most realistically, to bring this information to their audience:

A1: A canyon excuse ... Let's see ... um ...

D: What would a stoner say, about being in the canyon?

A2: I was playing down at the rope swing.

A1: No, no. I was—

A3: (in slow, slurred speech) I got all the way down there and I got so stoned I couldn't find my way back!

A4: Oooh—somebody has to *be* a stoner?

A5: Yeah! (laughter)

A1: Let's see ... I don't know.

D: What would a stoner say, what would Jake (a student whom they all know to come to class high regularly) say if he came to class late?

A3: I couldn't find my way back.

A6: He'd be like "Dude—

- A2: He'd say "I was in the canyon smoking dope and I—
 A7: The "Dude!" He would definitely say "Dude."
 A1: Wait, wait. OK. "Dude I was in the canyon and I couldn't find my way out." (Lots of laughter and agreement—Yeah, Yeah!)
 A4: And you have to be completely stoned, like "Wha-at?"
 D: OK. She'll have to do the line like she's stoned?
 A1: Yeah, slow and stoned.

Though the actors are enjoying working at getting the line right and are laughing during this interaction, they are not celebrating drug use or condoning Jake's behavior. While they like Jake as a person and a classmate, they also know that he is failing his classes because of his drug problem. They want to represent him accurately on stage so that their audience can in turn consider the multiple truths of his situation: that he is both clever, and wasting his intellect on drugs; that he is presenting a blatantly unacceptable excuse for his tardiness, and in doing so is also asking for help with a serious problem. To present the story of their school, the actors realize the need to present the many others who make up the diverse student body. And to present these others, they have to observe and consider them carefully, to experiment with their language and motivations and actions until they can actually become them for a short time. And in becoming these characters they are accepting that there is more than one way to look at life, that each way brings with it its own set of consequences, and that nothing is simple or clear cut.

PROMOTING CREATIVE PROBLEM SOLVING THROUGH HEALTHY INTERDEPENDENCE

Theater is a truly collaborative art. Either artists working in different roles—playwright, actor, director, set designer, stage manager, etc.—pool their resources toward the collective effort of producing a play for an audience, or each member of the company agrees to work at each of the tasks required. Either way, drama is not a solo art. Even the rare one-person show requires a relationship between at least two parties—the actor and the audience. As a play does not come with a set of lock-step instructions, theater demands a flexible, complex form of cooperation of its participants—a simple doling out of tasks will not satisfy. Each individual member of a company is responsible for, not only bringing his or her expertise to the project, but also listening to the ideas of others and incorporating them into one's own to construct a creative whole greater than the sum of its parts.

Theater, then, is a discipline of both individual and collaborative responsibility. New York actress and acting teacher Uta Hagen warns actors in her text *Respect for Acting* (1973) to observe carefully delineated responsibilities.

No director can help you with your substitutions since he has not been a part of your life experience. He will help you with the character elements he is after, dictate the pace, the surroundings, the given circumstances, and define your relationship to the other characters in the play, but how you make these things real to yourself, how you make them exist is totally private work (p. 37).

Strasberg-trained acting teacher Sandy Meisner warns actors that they cannot embark upon the task of creating a role by themselves. "What you do," he tells his students, "doesn't depend on you, but what the other actor does to you. You can't do anything unless the other actor does something to make you do it" (cited in Mekler, 1987, p. 24). And so the drama artist is constantly negotiating between the responsibility of her individual talents and her responsibility to respond to fellow artists. Viola Spolin (1985) perceives this negotiation as a matter of "timing" in actors, a balance between several factors of "both self-awareness and the ability to attune to the scene, the other players and the audience" (p. 55).

In developing his increasingly well-known Theater of the Oppressed, theater teacher Augusto Boal (1985) expanded the traditional notion of theater ensemble to include the audience. He developed his new format amid the military coups and harsh dictatorships of Brazil of the mid 1960s. Designed for audiences of peasants and workers, his Forum Theater was designed to exceed the goal of entertaining an audience.

[Forum Theater] gave spectators themselves opportunity to discover their own solutions to their collective problems. Through storytelling techniques, Boal worked with groups to create a scene in which a protagonist is failing to achieve what s/he needs or desires. Audience members stop the dramatic action at any moment they feel the protagonist has an option s/he is not exercising. They then physically replace the protagonist in the scene and improvise their alternative action, thus rehearsing for social change. (Schutzman, & Cohen-Cruz, 1994, p. 2)

Boal's work draws a direct link between the traditional drama principles of ensemble work and creative problem solving. All those involved must allow for each other to the greatest extent possible: the playwrights by writing scripts that paradoxically encourage them to be changed; the actors on stage by acting convincingly enough so that those watching are drawn into participating, and the audience by watching carefully and critically enough so that they can suggest and act on alternatives not yet presented.

Since "drama consists of multiple attempts and multiple strategies to solve the problems confronting characters" (George, 1994, p. 10), it offers teachers and students a venue for creative problem solving through a healthy interdependence. When a group takes on the challenge of creating and performing its own dramatic piece, it is taking on a series of open ended artistic and management questions more complex than anything that a single individual would handle. Just as our school instruction has suffered from promoting the unrealistic notions of single points of view and exclusive truths, it does a disservice to students by suggesting that problems are best solved in a single, prescribed method. "There is a tendency in technologically oriented cultures," Elliot Eisner (1992) points out in his critique of education, "to conceive of rationality as a method of tightly linking means and ends" (p. 594). Youth and youth group leaders who work on drama know that means often lead to ends in unpredictable ways, and that the improvised qualities of interdependent collaboration can be an excellent method of creating solutions.

A feature common to contemporary youth drama groups performing original work is their insistence on the necessity of ensemble, eschewing traditional notions of star parts and minor roles, opting instead for making everyone equally responsible for the success of the show. Directors of contemporary youth drama spend significant amounts of their early rehearsal time engaged in exercises that build and strengthen their actors into an ensemble. A student in a high school advanced acting class describes how an exercise designed by their teacher to strengthen their ensemble brought with it unexpected benefits.

One time we had two people. One person writes the poem and the other person goes off and makes up a dance. And you put it together. That takes a lot of trust. To read a poem—and you don't know what the dance is about because you haven't seen it—and to come together and put it together. And we were so amazed about how everything just worked out . . . it's all about building trust.

Once rehearsal periods move from exercises to preparation of a production piece, actors are expected to hold on to the notion of ensemble even in the lure of the spotlight. When ensemble actors are not performing lines they are expected to collaborate and contribute to the strength of the dramatic message they are presenting, as this excerpt from one youth group director's end-of-rehearsal critique makes clear:

When someone's talking look at them! Don't talk to the person next to you. It doesn't mean that you're not on stage anymore. It means you are now a SUPPORTING character, instead of the lead right at that moment. So you watch what's going on. Throw your focus to the action of the play. When someone's talking look right at them and hear them! And REACT. And it's OK to react. As long as you are reacting TRUTHFULLY, that's fine. You know you're not into this play, you know, to make a joke? You're not here to show off for somebody who you want to impress? OK? Right? You're supporting what the play is saying.

In addition to the goal of working as an ensemble, the contemporary youth theater groups presented here share in common the goal of creating original material to perform. Each group observed has devised its own unique method of creating plays based on the talents of its ensemble members. One group begins by sitting around a tape recorder and discussing questions raised by their director, who then takes the tapes home, transcribes them, and brings them back the next day for use in devising a script centered around a theme that they identify as emerging from their conversation. Another group begins by brainstorming topics that interest them as problematic and then improvising scenes that move towards solutions. The director, in addition to structuring the initial improvisation exercises, works to join together what has been improvised into a sequential play, which the actors then rehearse to memorization. A third group chooses a theme important to them and then looks back into the immediate past of their lives and collects writings of all genres—school essays, journal entries, yearbook notes, newspaper articles, letters—related to their chosen theme. The director fashions the various writings into a draft of a script, which the group then rewrites through the rehearsal process. A fourth group, meeting daily, begins each morning by responding to writing prompts offered by the director, who then takes the

writings home and arranges them into a first draft of a script, taking care to switch lines between actors and writers, so that privacy is maintained and the challenge of characterization still exists. Each of these methods proves that an even exchange of information between the youths and adults is both possible and profitable. In these instances the young actors bring to the process their ideas, opinions, and questions to be used as themes for their plays. The adult directors bring their abilities to collect, edit, and oversee as a means of structuring the play. Both skills are necessary, and neither could complete a play without the other.

Perhaps not surprisingly, the brief play resulting from the fourth group, as its title *All-4-1* (FreeStreet Programs) suggests, brings the theme of working together to the stage. Their opening scene debates the definition and role of an ensemble on stage as well as in their lives in the tough inner city.

- ALL: All for one!
 A1: All for me—
 (group reacts)
 A2: No — all for me—
 A1: No — all for one — and that one is me —
 (group reacts)
 A3: Hey if you want me to be for you — you better be for me too—
 A4: If you want me to be for you — you better be for yourself
 A5: What do you mean for myself
 A6: How do you expect me to care about you if you don't care about yourself—
 A1: You better not be talking about me—
 A7: Why are you always trying to fight somebody—
 A1: Because I take care of myself I don't let anyone talk about me—
 A7: If you know the truth about yourself, you don't have to fight anyone on account of what they say.

THE SATISFACTION OF GENUINE ACHIEVEMENT

Uta Hagen's (1973) memories of how she came to love and respect the theater highlight the accomplishments available to those who pursue the art of drama: discipline, self-confidence, meaningful communication, the knowledge that you are contributing to the betterment of the community in which you live and work.

In my parents' home, creative instincts and expression were considered worthy and noble. Talent went along with a responsibility to it. I was taught that concentrated work was a thing of joy in itself. . . . They showed me that love of work is not dependent upon outward success. . . . that the theater should contribute to the spiritual life of a nation (Hagen, p. 7).

Putting up a dramatic production demands an honest revelation of the self, the repetition of rehearsal, the compromise of collaboration and the risk of taking on new challenges and then making them public before others for their critique. When playwrights, actors, technical designers, and directors set out to work on a play, they know that they will not see the results of their effort on stage for a delayed period of time.

Furthermore, the commitment they make to such a long-term project does not carry with it a guarantee of a successful outcome.

Art educator Judith Hanna (1992) argues for a closer connection between performance art (in her case, dance) and education in language that translates nicely into the achievements we want for our students in and beyond the classroom: "To create—and thus 'own'—a [production] is a badge of independence that shows publicly the result of motivation, hard work, perseverance, self-reliance, and responsibility" (p. 606). As Hanna's words of advocacy suggest, schools need to offer students ample opportunity for genuine achievement. Students need to take on challenges which last longer than a 50-minute class or even a 4-month semester; they need to be offered the opportunity not only to fail but to learn from their failures how to succeed. They also need to be offered the opportunity to present their achievements to a public larger than a single teacher—to experience community acceptance, and rejection of their efforts.

The Young Playwrights Festival in New York provides such an opportunity every year with its nationwide contest (Lamb, 1992). Writers younger than 18 are invited to submit original play scripts to the contest's panel of theater professionals for evaluation. Every play received is returned to the playwright with substantive typed comments and suggestions, written under the assumption that the young playwrights will continue to rewrite their pieces. The prize is an on-Broadway production of their play, complete with professional actors and directors. The student playwrights are flown to New York to participate in the rehearsal process as well as for opening night. One winner from the 1989 contest describes why embarking on the dramatic process is a risk, and why it is a risk worth taking:

Watching a play you've written be staged is similar to putting your new born baby on display in the window at Macy's and having to stand there and watching as people crowd around and begin to critique your child. In short it's nerve-racking, frightening, horrifying, exhilarating, and wonderful. Only when the curtain is finally closed can you breathe a sigh of relief. "I'm still alive, and I think I heard someone clapping." (Allard, 1991, p. 129)

It is easy to imagine that for the student accustomed to receiving praise in the form of a letter grade or brief written comments, standing on a stage and listening to people applaud could be a heady experience. Another defining feature of the young contemporary drama groups presented here is that after the traditional curtain call, the actors are expected to come back to the stage as themselves and answer questions from their audience about the work they have just performed.

Such postplay discussions serve a number of purposes: to remind the students that their responsibility to the play extends beyond accepting applause, to bring the audience to life for the actors, to allow yet further points of view into the dramatic discussion their play has begun, to allow the audience a chance to disagree with what they have seen or to find out more about it, and to give student actors ideas for new productions. In a postplay interview, a high school junior considered how speaking with the audience provides evidence of a genuine achievement:

I've felt people impacted by our work. I've had people come up to us and tell us that we made them think. And made them analyze and think about what they're doing in society and what society's doing to us. And that's a lot of proof in a lot of different ways.

A LOT OF PROOF IN A LOT OF DIFFERENT WAYS

It is in the spirit of the acceptor of what children bring to the situation—always the receiver, the curious one, the playwright, the creator of tensions and occasionally the director and actor—that I have to function. (Heathcote, 1980, p. 15)

It is no coincidence that educator Dorothy Heathcote turns to the words of drama to explain what she has learned about successful education—that it requires a teacher who is looking for ways to even the exchange of information in her classroom between her students and herself. For the teacher who is ready to evaluate her success in the classroom by asking the question "Am I learning as much from my students as they are learning from me?" drama offers a valuable tool. By bringing missing information to the curriculum, encouraging multiple points of view, promoting creative problem solving, and offering the satisfaction of genuine achievement, drama not only offers teachers techniques for evenly exchanging information with their students but also models what such a successful education can look like. It can look like young people writing, rehearsing, and reviewing the performance of their own lives; it can look like students and teachers using one another as valuable and necessary learning resources; it can look like Augusto Boal's fantasy of the best possible kind of magic education through drama:

I think this is how magicians should be: first they should do their magic to enchant us, then they should teach us their tricks. This is also how artists should be—we should be creators and also teach the public how to be creators, how to make art, so that we may all use that art together. (Boal, 1992, p. 29)

NAVIGATING THE CHANGING LANDSCAPE OF LITERACY: CURRENT THEORY AND RESEARCH IN COMPUTER-BASED READING AND WRITING

David Reinking and Linda Labbo

UNIVERSITY OF GEORGIA AND THE NATIONAL READING RESEARCH CENTER

Michael McKenna

GEORGIA SOUTHERN UNIVERSITY AND THE NATIONAL READING RESEARCH CENTER

A statistic from 1994 supports the assertion that the computer is the most important technological development of our time. In that year for the first time, the number of computers sold in the United States exceeded the number of televisions sold. The phenomenal rise in the sales of personal computer hardware and software from a modest start in the late 1970s is but one indication that the computer is central to how we define our world today as well as how we imagine our future. Given the proliferation of computer-based innovations across diverse everyday activities, it takes little imagination to see that advances in computer technology have become a catalyst for social and cultural change, much as television did almost a generation ago. But, the potential consequences of becoming digital, as one writer has put it (Negroponte, 1995), are likely to exceed exponentially the influence of television. Like television, computer technology promises to effect changes in popular culture; but unlike television, it is likely to effect profound changes in our intellectual lives as well (Lanham, 1993). Most important for the topic of this chapter, electronic forms of reading and writing will both contribute to and support those changes.

In fact, the brief history of the computer's influence on reading and writing is perhaps the best example of how broad and deep its influence has been on contemporary life. The technology of writing changed substantially with the introduction of word processing, which quickly became the most common application used by those who purchased personal microcomputers beginning in the late 1970s. Word process-

ing continues to evolve from its original use as a typographic tool for creating printed documents (see Bolter, 1991) to its increasing use as a digital tool for creating electronic multimedia documents. Another current example is the burgeoning use of the Internet for personal communication through e-mail and for disseminating information through on-line services and browser programs such as Mosaic and Netscape. The rise of the Internet is a major literacy event with indisputable, if not precisely discernible, societal and cultural implications in diverse areas such as education, advertising, mass communication, entertainment, and the political arena.

The pace at which the literate world is shifting from printed to digital forms of reading and writing has accelerated steadily since the introduction of the microcomputer. This trend can be seen at a number of levels. For more than a decade auto parts stores and bowling alleys have exchanged printed catalogs and score sheets for computer displays. More recently, we sign for deliveries using a stylus on an electronic tablet; hospital personnel use the same technology to record patients' medication and vital signs, which are transmitted electronically to a physician's office computer. More electronic encyclopedias are being sold today than their printed counterparts. Students at major universities such as Stanford, UCLA, and MIT, where many dorms have direct Internet connections, are using computers to register for courses, to research topics in libraries around the world, to submit their work to instructors, and to find out who in their dorm wants to chip in for a pizza. At the same time, the number of printed

books and journals purchased by research libraries has steadily declined since 1985, while the number of electronic journals has risen from around 100 in 1991 to more than 400 by late 1994 (Stix, 1994). National Public Radio reported recently that newspaper circulation worldwide has been declining between one and two percent each year since 1991. Increasingly scholars are bypassing conventional journal publication to share their research and ideas electronically as is evidenced by the inclusion of formats for electronic citations in the most recent edition of the APA style manual.

These developments suggest that we have moved beyond a threshold of debate about whether computers will have any long-lasting effect on conceptions of literacy, conceptions that there had been no need to examine when the dominance of print was unquestioned. Our position in this chapter is that we are riding a juggernaut of change that implies a fundamental examination of how we are to conceptualize literacy in a digital, posttypographic world (see Reinking, 1995). Technology can no longer be marginalized as only one among many focal points that capture the attention of educators and scholars interested in literacy. Instead, events dictate that technology move to the center of every research and educational agenda related to literacy. Not to do so, we would argue, will not only relegate much of the past and present literacy research base to obsolescence but will create a vacuum of careful thought based on systematic research. If that happens, literacy researchers will lose the opportunity to influence constructively the changes that seem to be inevitable and to assist educators and students adjust to those changes.

To prevent our efforts from becoming obsolete and to contribute useful understandings, it will be necessary first, for literacy educators and researchers, to acknowledge that important changes are occurring in the way that we read and write and likewise to contemplate the implications of these changes. We have found that doing so is not always easy because of the tendency to view electronic texts as only printed texts displayed on a computer screen. Much as the first automobiles were referred to as 'horseless carriages' a text on a computer screen is sometimes referred to (and made to resemble) a 'page' of text. The distinction between page and screen may seem inconsequential until one has fully considered the important practical and theoretical implications of displaying text electronically. Later in this chapter we elaborate on the critical differences between printed and electronic texts that we believe are useful in understanding the relevance of emerging forms of electronic texts, conceptualizing new ones, and generating questions for research.

Another reason why moving technology to the center of literacy research may be difficult is that doing so often negates the relevance or importance of previous research based on reading and writing printed materials. For example, of what practical significance is current research in teaching children strategies to comprehend printed texts if electronic texts change not only what strategies make sense but also the options for modeling and supporting those strategies? Also, how useful are theoretical constructs such as reader response and intertextuality when the distinction between readers and writers becomes less clear in electronic documents such as

hypertexts and when thousands of formerly disjoint texts can be displayed immediately and seamlessly on a single computer screen?

Literacy researchers, individually and collectively, may understandably be reluctant to embrace technology when it threatens their substantial investment in print-based research. Nonetheless, the changes that are occurring, almost daily, around us make it increasingly difficult to ignore the current and potential implications of electronic forms of reading and writing. But to navigate through a changing literacy landscape, many researchers will need a map that orients them not only to what is happening and its potential consequences but also to how their interests centered in conventional print might be transformed in a world of electronic reading and writing. That is our aim in this chapter.

We have divided this chapter into two main parts. The first part focuses on theoretical perspectives and research aimed at identifying the fundamental differences between printed and electronic texts. The second part identifies several generalizations and supporting research concerning the computer's role in the acquisition of literacy. We believe these latter generalizations may help researchers develop pedagogical theories for integrating computers into literacy instruction and to generate useful research questions aimed at studying the effects of electronic reading and writing in classrooms. However, we wish to emphasize that there is considerable overlap between the content of these two sections and they are separated only for the sake of an orderly presentation. That is, understanding the differences between printed and electronic texts has implications for pedagogy, and studying the use of computer technology in classrooms is enriched by understanding the uniqueness of electronic texts. Ironically, our limited ability to deal with this overlap is an artifact of the fact that we must conform to the linear and hierarchical structures expected by readers of a printed text. As we discuss subsequently, hypertext, an electronic text based on associational networks, would easily accommodate a more realistic representation of this overlap.

THEORETICAL PERSPECTIVES AND RELATED RESEARCH

Establishing well-defined theoretical perspectives is a mark of maturity in the study of any phenomenon or in efforts to demarcate a domain of research. Striving for such maturity, according to Thomas Kuhn's often-cited argument, is a defining characteristic of research when there is a major shift in scientific paradigms or world views. Given current trends, we do not think it is an overstatement to suggest that emerging forms of electronic reading and writing require a paradigmatic shift in traditional conceptions of literacy. If so, seeking useful theoretical perspectives can be a gateway to greater understanding of the changes that are occurring and consequently what research is most needed.

We wish to emphasize that citing Kuhn and mentioning theory in the context of scientific paradigms does not mean that we think theoretical speculation about electronic forms of reading and writing should be limited to positivistic

epistemologies, experimental designs, and quantitative methods. Indeed, a set of theoretical perspectives that is broad enough to encompass the pervasive effects of electronic reading and writing cannot be restricted to a single approach to research. For example, long before qualitative approaches had achieved widespread acceptance among educational researchers, Venezky (1983) proposed that computer-based instructional programs aimed at improving literacy could not be credibly evaluated exclusively through pre- and posttest designs with control groups. He argued that such approaches must be supplemented with data from questionnaires, interviews, and participant observations.

Likewise, we believe that useful theoretical perspectives must be broad enough to generate research questions across a wide range of literacy contexts and purposes. Researchers need to consider how digital texts affect literacy and learning in classrooms and schools as well as in the workplace. They also need to consider the sociocultural implications of electronic reading and writing for accomplishing work-related goals as well as for social and recreational purposes. The early and frequently atheoretical focus on using computers to dispense instruction for the purpose of accomplishing the goals of conventional print-based literacy (Reinking, & Bridwell-Bowles, 1991) must be replaced by a focus on determining the inherent characteristics of electronic reading and writing and how those differences might affect and effect classroom instruction and learning. In short, the most useful theoretical perspectives will help shape a new conception of literacy that accommodates electronic forms of reading and writing and will inform efforts to translate that new conception into a coherent agenda for research.

Differences Between Printed and Electronic Texts

Underlying an argument that new conceptions of literacy are needed is the assumption that electronic texts are substantially different from printed texts. Such differences, as we have noted at the outset of this chapter, may not be intuitively clear because of a natural inclination to conceptualize electronic texts in terms of the more familiar printed texts. Thus, it becomes especially important to identify, as precisely as possible, the new characteristics and capabilities of electronic texts that may be most basic to changing conceptions of literacy. We highlight those differences here although they have been more fully elaborated elsewhere (see Reinking, 1992, 1994, 1995; Reinking, & Chanlin, 1994). Also, we cite existing or potential research that illustrates the kinds of questions that an awareness of each difference might generate.

For the most part, this research is aimed at investigating the effects of electronic forms of reading and how the unique characteristics of electronic texts might be used purposefully to enhance comprehension and reading ability. By comparison, the empirical research related to electronic forms of writing remains relatively narrow, focusing predominantly on how word processing affects the writing of conventional printed texts (see the review by Reinking, & Bridwell-Bowles, 1991). Nonetheless, there has been increasing theoretical

speculation about how unique electronic forms of writing, specifically hypertexts, suggest new areas of empirical investigation (see Hawisher, & Selfe, 1991; Selfe, & Hilligoss, 1994).

Interactivity and Malleability. A major characteristic of electronic texts is that they are interactive because they are so malleable. As stated aptly by Kaplan (1991), "In the digitized world, texts are intrinsically fluid, malleable, protean. . . . And, it is no longer possible—even for the naive, atheoretical reader—to understand or even to approach them as fixed, stable, linear objects" (p. 19). The frequent description of reading as an interactive process, which preceded any serious attention to electronic texts by more than a decade, has had a metaphorical meaning when applied to printed texts because printed texts are inert, fixed, entities that challenge readers to make sense of them. Using the terms *interaction* or *transaction*, in the case of printed texts, is meant to emphasize that comprehension is the result of factors within texts and within readers and that readers must be cognitively active in relating textual information to their own knowledge. Electronic texts, however, can effect a literal interaction between readers, writers, and texts because texts presented digitally are by nature dynamic entities easily capable of being modified in response to the contingencies of a particular situation or the needs and wishes of individual readers or writers.

The term *interaction* when applied to electronic texts, therefore, can be much more like the give and take of a dialogue (Reinking, 1987). An electronic text, for example, can be programmed to monitor a particular reader's actions and evolving knowledge during reading, and it can adjust the textual presentation accordingly. An early study conducted by L'Allier (1980) illustrates how an awareness of this characteristic might generate research on new types of reading. In that study he adjusted expository texts using a complex algorithm that monitored individual student's reading rate, comprehension accuracy, and response times. In this adaptive reading condition, high school students who were identified as low achieving readers comprehended as much as their high achieving peers. Such an application suggests interesting pedagogical options for increasing learning from texts.

Since this early example, several other researchers have studied the effects of applications aimed at making reading more interactive (Blohm, 1982, 1987; MacGregor, 1988a, 1988b; Reinking, 1988; Reinking, & Rickman, 1990; Reinking, & Schreiner, 1985; Salomon, Globerson, & Guterman, 1989; Tobias, 1987, 1988). The conceptual basis for these applications has been the realization that computers make it possible to offer various forms of assistance to readers while they are reading. Cumulatively, the research on these applications suggests that providing such on-line assistance produces superior levels of understanding when compared to conventional printed texts (see Feldmann, & Fish, 1991 for an exception). For example, Reinking and Rickman (1990) had middle-grade students read several science texts presented either in a printed version accompanied by a conventional glossary or in an electronic version that provided on-line access to meanings of difficult words in the text. When reading the electronic version, students investigated the meanings of

more words, recognized the meanings of more difficult terms used in the passage, and demonstrated greater comprehension of the scientific principles discussed.

A study by Salomon et al. (1989) illustrates how existing theoretical perspectives related to printed texts can apply to a consideration of electronic texts' interactivity and malleability and how such a perspective might lead to theory-based instructional applications. In that study the researchers designed a computer application they described as a "reading partner" aimed at simulating the interactions between a reader and an "intellectual, pedagogical partner" (p. 621). Vygotsky's (1978) sociodevelopmental theory and his idea of learning within a zone of proximal development guided the development of the application and the experimental hypotheses. Results indicated improvements in 7th-grade students' reading and writing due to the expenditure of more mental effort and metacognitive activity in the computer-based reading condition when compared to conventional reading of printed texts.

Other perspectives that emphasize the interactivity of electronic texts have been drawn from literary theory. In fact, we believe that as researchers interested in literacy attend more to the differences between printed and electronic texts, they will be drawn increasingly toward literary theory as helpful in conceptualizing the nature and implications of these differences. Also, literary theorists and classicists have become interested in the literary and cultural implications of electronic reading and writing (e.g., Bolter, 1991; Edwards, 1991; Landow, 1992; Lanham, 1993; Moulthrop, & Kaplan, 1994). Landow, for example, uses Roland Barthes' theoretical distinction between a "readerly" and "writerly" texts which becomes an objective reality in electronic texts, where interactivity may be employed to blur the distinction between readers and writers. For example, in *Marble Springs* (Larson, 1993), an electronic fiction written as a hypertext, readers not only explore flexibly the lives of people who live in an imaginary frontier town, but they are invited to create new characters by adding prose and poetry to the original text and to create new links among the original textual nodes. As this example also illustrates, considering interactivity from the perspective of literary theory provides perspectives that have as much to do with writing as reading. However, there is irony in turning to literary theory to expand understanding of electronic reading and writing. As Bolter (1991) has pointed out, electronic texts make moot many of the debates among literary theorists. For example, arguing for a deconstructionist point of view hardly seems necessary when, as in the case of a hypertext, there is no single text to deconstruct and where readers are creating unique meanings by virtue of their idiosyncratic navigation through flexibly structured textual nodes.

Audiovisual Effects. Displaying texts electronically on a computer screen provides unprecedented opportunities to combine a wide range of audiovisual effects with written prose. Such effects include digital graphics, animations, movies, and speech. Thus, multimedia is a term (along with the newer term *hypermedia*) that can increasingly be applied to electronic reading and writing. Although it is possible to combine

printed materials with various other media such as film or tape recordings, the computer allows the capabilities of these and related media to be merged seamlessly with written prose and to be displayed, often simultaneously, by a single device. Also furthering the advantage of electronic texts in this regard is that a variety of audiovisual information is increasingly becoming available in digital forms (Negroponte, 1995). Once in digital form, such information can be easily and inexpensively incorporated into electronic texts. Also, the capability to create highly refined multimedia texts is becoming possible without highly specialized expertise, hardware, or software.

Thus, electronic texts have the potential to move written prose away from the center of textual meaning. When print is the only reasonable choice to disseminate texts widely, the alphabetic code is clearly one of the most efficient means of communicating information, especially abstract information. Although pictorial information such as illustrations, maps, and graphs, is often valued in printed texts, such information is typically viewed as ancillary to written prose. In electronic texts, on the other hand, it is conceivable that images and sound might play a much more central role in conveying meaning.

Several writers from various theoretical perspectives have highlighted the potential importance of electronic media in moving textual meaning away from the alphabetic code. Walter Ong's (1982) seminal work on the relation between orality and literacy is a frequently cited example in the current literature. Although he was writing at a time when microcomputers were a relatively new phenomenon, he predicted that the computer would play a role in furthering a "second orality" in which modern communication technology would restore some of the social and psychological orientations characteristic of primary oral cultures. More recently, writers such as Bolter (1991) have pointed out that electronic forms of reading and writing are reminiscent of primitive picture writing. Also, Lanham (1993) has pointed out that digital texts tend to draw a reader's attention to their visual characteristics as opposed to printed texts, which are typically designed to be transparent representations of meaning. In other words, we look more *at* the visual representation of electronic texts to derive meaning, not just *through* the visual representation of letters and words, as is the case in conventional printed texts. He has argued that this difference moves digital texts into a rhetorical position and away from the philosophical position occupied by conventional printed texts. Another example is Lemke (1994) who has pointed out the special relevance of semiotic theories in expanding conceptions of literacy to include multimedia documents.

Some existing theoretical perspectives that have been developed with conventional printed texts in mind remain relevant when applied to electronic texts. For example, Paivio's (1986) dual encoding hypothesis argues that textual information is more memorable when it is encoded both visually and linguistically. In fact, given the expanded possibilities of integrating visual (as well as auditory) material with written prose in electronic texts, it is likely that such a theory may be especially useful in guiding future research involving electronic reading and writing. Salomon's (1979; Salomon, Perkins, & Globerson, 1991) theoretical approach to defining

media, based on the interaction of technologies and symbol systems in effecting cognition and learning, is applicable to electronic texts. Using that theory, Reinking (1987) argued that printed and electronic texts can be defined as different media from a cognitive perspective. It might be argued from current trends that electronic texts are becoming different media in a sociocultural sense as well.

There is relatively little research examining the multimedia capabilities of electronic texts, and the existing research has several limitations (see Reinking, & Chanlin, 1994 for a comprehensive review of the literature and an extended discussion of these limitations). One limitation is that much of the research is atheoretical and aimed at investigating whether displaying essentially identical texts on paper or screen produces differences in reading performance. Such studies have produced little evidence that relatively superficial differences in the visual display produce any notable differences in reading performance, especially in areas such as comprehension and recall (Reinking, 1992). Another limitation, at least from the standpoint of literacy researchers, is that much of the available research focuses on comparing various types of graphical representations displayed on a computer screen without considering their relation to written prose. For example, there have been several studies comparing the effects of learning from static graphics in printed texts and animated graphical representations in a comparable electronic text (e.g., Rieber, 1990). These studies have found advantages for computer animations only under highly constrained conditions, and then only inconsistently. However, in these studies the relation of the animated graphics to the written text has not been carefully considered. A more useful approach can be found in a series of studies reported by Hegarty, Carpenter, and Just (1991) in which sophisticated eye movement equipment was used to monitor readers' attention to static and animated graphics showing the operation of a machine. They also systematically varied how the accompanying text related to each of the graphical representations. A finding that points to the potential value of this type of research is that participants in the experiment who had low mechanical ability benefited more when the accompanying text was coordinated with the animated graphical representation.

The audiovisual capabilities of electronic texts also suggest new possibilities for enhancing literacy instruction. For many years there has been ongoing research addressing such possibilities using synthesized or digitized speech (McConkie, 1983; Olson, Foltz, & Wise, 1986; Olson, & Wise, 1987; Reitsma, 1988; Roth, & Beck, 1987; Wise, 1992). For example, Reitsma used a computer to assist 6- and 7-year-old children with the pronunciation of unfamiliar words during independent reading. He found that this condition effectively increased reading rate and reduced reading errors when compared to oral reading guided by a teacher and reading while listening to a tape-recorded version of the experimental texts. In our own current work we are investigating the effects of providing early readers with phonic analogies under various conditions while they read computerized versions of children's books (McKenna, 1994). Much more research is needed to investigate how audiovisual effects might be used with written prose in electronic texts.

Expanded Boundaries of Freedom and Control. Conventional printed texts exist within relatively limited boundaries of freedom, in terms of a reader's options for obtaining access to a particular text upon demand, and of control, in terms of a writer's options for restricting a reader's access to textual information during independent reading. For example, in the first case, if one is reading a text that alludes briefly to a particular automobile engine about which one wishes more information, it may be tedious, at best, to obtain another text that provides the desired elaboration (e.g., a trip to the library). On the other hand, in the second case, many teachers have experienced the frustration of admonishing students to note a particular feature of a text (e.g., a table) at a particular point as they read an assignment knowing that many students will choose to ignore that admonition. Both of these limitations, in one case the lack of unencumbered access to text and in the other limited ability to exert control over what readers attend to during independent reading, can be removed by electronic texts. As illustrated by the burgeoning use of the Internet, electronic texts expand the boundaries of freedom to flexibly access many texts in many geographical locations upon demand. Perhaps less obvious, and often less welcome or appreciated by many (see Reinking, 1994), is the fact that electronic texts provide the opportunity to exercise unprecedented control over what a particular reader may attend to during independent reading. And, that control can be exercised contingently for different readers reading the 'same' text.

More freedom and more control in accessing texts when they are available electronically create a need for new theoretical perspectives that suggest ways in which such capabilities might affect literate activities. Some authors have attempted to do so, although most of the speculation and research available has focused on the ability to limit access to text. For example, Wilkinson (1983) pointed out that texts displayed on a computer screen were viewed as if through a window providing the capability to limit readers' access to various units of text. Daniel and Reinking (1987) pointed out that the capability to limit readers' access to texts during independent reading allowed writers to make decisions about the placement of text in three dimensions. In addition to arranging texts on the two-dimensional space of the printed page, writers of electronic texts have available a third dimension: time; that is, they can make decisions about when a reader can view a particular portion of a text. Interestingly, this capability has been used as a literary tool by serious writers of hypertextual fiction (see Coover, 1993), which is ironic in the sense that hypertexts have typically been cited as an example of how readers have more freedom when reading electronically. A review of Stuart Moulthrop's *Victory Garden* (Bolter, Joyce, Smith, & Bernstein, 1993) points out how Moulthrop occasionally uses "guard fields" as a literary device in this example of hypertextual fiction. Guard fields are a mechanism in hypertextual writing by which an author can ensure that specified textual nodes are unavailable to readers until other specified nodes have been selected.

One straightforward example of research using the capability of the computer to control readers' access to text is the

work of Tobias (1987, 1988). He investigated the effects of inserting questions in electronic texts that mandated review of relevant textual information when a reader answered a question incorrectly. That is, readers were not able to access subsequent portions of a text until they had reviewed an earlier portion of the text and corrected their response. Under such conditions he found that information related to the questions was better recalled in a posttest but that unrelated information was not recalled as well by readers who read the text and answered the questions without mandatory review, thus exacerbating a problem found in previous studies of inserted questions in printed texts. He hypothesized that readers who were required to review attended only to portions of the text containing information relevant to the question. Testing that hypothesis, Reinking, Pickle, and Tao (1996) found that readers did spend more time on paragraphs containing relevant information but the researchers also were able to use the capabilities of the computer to change that strategy by providing readers with a new question after mandatory review.

There has been relatively little theoretical speculation and research about the computer's capability to expand readers' freedom to access texts. Some literary theorists (e.g., Bolter, 1991; Landow, 1992; Lanham, 1993) have speculated broadly about the potential societal implications of this capability, but there has been no systematic theoretical speculation about how this capability might affect the reading of particular texts or the teaching of literacy in schools. Clearly, however, there are implications for accessing multiple texts in reading and writing and for helping students acquire strategies for locating and using information from diverse sources, which may require creative use of key word searches using Boolean principles of inclusion, exclusion, and overlap. Existing research derived from the concept of intertextuality, such as the work of Spivey and King (1989), is not clearly applicable to electronic reading and writing because that research is based on a conception of distinctly separate and disjoint texts that are written with the assumption that they will be read in relative isolation from other texts.

A recent study by Stahl, Hynd, Britton, McNish, and Bosquet (in press) illustrates the type of research that might be conducted to address the possibilities for teaching and learning created by the computer's capability to expand teachers' and students' freedom to access textual information. They used the computer to provide high school students with a wide array of historical documents and commentaries concerning the Gulf of Tonkin incident leading to the U.S. entry into the Vietnam War. They hypothesized that providing easy access to these source documents might lead students to approach this historical event more analytically like historians as opposed to focusing only on factual information. Although they found some evidence supporting this hypothesis, they concluded that students may need more exposure to this type of reading activity and perhaps instruction that helps them compare and contrast critically information from various sources.

The increased control that electronic texts allow has brought to the surface previously subtle ethical and philosophical issues related to the appropriateness of limiting readers' access to texts. Reinking (1994) has argued that such

control is exercised with printed texts but is often not obvious. For example, financial expediency frequently dictates that teachers only acquire what they consider to be a limited number of 'good' books for children to read in the classroom, thus limiting their choices by default. On the other hand, setting up what have been called "fire walls" to prevent children from accessing certain information on the Internet is an explicit act of control. Relevant to such considerations is the pragmatic perspective in literacy research provided by Cherryholmes (1993), who states that "It is often useful to accede power to texts because texts, in turn enhance the readers' power in other situations . . ." (p. 13). Such issues merit more discussion among researchers and educators who are attempting to understand more fully the implications of electronic reading and writing.

Alternative Textual Structures. A defining attribute of printed texts is that they have linear, hierarchical organizational structures. At the most basic level identifying some writing as a text has meant that it has a beginning, middle, and end. In addition to being linear, texts typically have implicit or explicit markers that indicate hierarchical relations among various elements or ideas contained in the text. In a narrative there are protagonists, major and minor characters, key events that advance the plot, and events of lesser importance that may be little more than interesting diversions. Most expository texts are radically hierarchical with many visual features such as headings to indicate explicitly the difference between super- and subordinate ideas and facts. Beginning writers and readers are explicitly taught to be aware of the linear, hierarchical characteristics of printed texts and to use that awareness as a guide to their own writing and reading. It is not required, of course, that conventional printed texts be written or read sequentially, or that readers or writers organize textual information hierarchically, but not to do so typically requires working against rather than in concert with the technology of print. An index or concordance is an example of how print-based texts acknowledge the legitimacy of nonlinear, nonhierarchical access to textual information, but such tools are post hoc constructions; no writer would consider starting the writing of a book by creating an index or concordance. Also, readers who begin an extended reading of a book with the index or concordance would soon find their task tedious and frustrating.

The technological capabilities and characteristics of electronic texts, on the other hand, do not demand linear and hierarchical structures; in fact, they invite more flexible organizational structures. It has been argued that a heterarchy is the most natural structure for electronic texts (Duchastel, 1986). An obvious example is that most informational computer programs are menu driven. Menu driven programs invite a reader to explore the information in idiosyncratic sequences, and the writers of such programs typically provide efficient tools for a reader to locate diverse information flexibly across the various menu options.

The best example of how electronic texts have the potential to reduce the dominance of linear, hierarchical structures in texts is a genre of electronic texts referred to as hypertext. Hypertext has existed as a relatively obscure concept since the early 1940s and as a term since the 1960s, but

textual node containing a segment of text, typically a single or several paragraphs in length. The lines indicate links created by the author allowing readers to move from one node to another. As can be noted by comparing the three examples, the associational networks can be simple, and thus more restrictive to a reader who has fewer options, or they can be more complex, and thus less restrictive to a reader who has many options for moving through the network. Smaller boxes within larger boxes indicate textual information subsumed by a superordinate text, thus demonstrating that hypertexts need not abandon hierarchical, and sometimes linear, structures entirely.

Several writers have presented theoretical perspectives that characterize the organizational structures of hypertexts and what effect they have on literacy. For example, Duchastel (1986) suggested that printed texts can be semantically structured or format structured. A linear, hierarchically structured text, such as a psychology textbook is semantically structured because any particular portion of the text is dependent to some degree on what comes before or after it. On the other hand, an airline schedule is format structured because it is designed to facilitate individualized searches for specific information. He argues that electronic texts, when compared to printed texts, enable a wider range of written materials (e.g., the psychology text) to be presented as format structured texts that are more individualized.

Bolter (1991), on the other hand, has focused on how structure can be viewed in terms of the dominant writing space, which he defines as the "physical and visual field defined by a particular technology of writing" (p. 11). Writing spaces produce what he calls the hard structures associated with the tangible materials of writing such as pages and the soft structures which emerge from them. Soft structures like hard structures may also be manifest visually, but they are more likely to become psychological elements used by readers and writers. In the case of print, a paragraph would be an example of a soft structure that has a visual representation on the printed page but that is also a psychological representation for organizing meaning. Bolter proceeds to discuss the possible hard and soft structures that may be associated with hypertext. For example, the computer screen is a hard structure that dictates to some degree the structure of electronic writing (as noted in the previous section where we discussed how it provides opportunities for controlling access to texts), and a link between hypertextual nodes might become a soft structure that could influence how writers and readers organize textual information.

Other writers such as Lanham (1993; see also Landow, 1992) tend to view structural differences between printed and electronic texts in literary terms. For example, he argues that the structure of electronic texts, particularly their ability to draw attention to their visual appearance, makes them a more rhetorical medium when compared to printed texts, which are inherently more philosophical and somber. Similarly, Bolter (1991) points out that the logic of philosophical arguments and the mental discipline necessary to present them are subverted by hypertexts because hypertexts provide a mechanism for presenting ideas in a format more consistent

with the divergent and often circuitous routes characteristic of uninhibited thinking.

Some researchers are beginning to study the effects of hypertext on reading and writing. For example, Spiro, Coulson, Feltovich, and Anderson (1988) have found evidence that medical students recall less factual information but are better able to apply the content of medical texts when it is presented in a hypertext instead of a conventional printed text (see also Mannes, & Kintsch, 1987). Leu and Hillinger (1994) and Horney (1994) have studied readers' strategies in using hypertextual information, especially when they have access to a variety of on-line assistance. Other researchers have focused on the navigational aids that may be needed to help readers orient themselves with complex mazes of hypertextual information (e.g., Beasley, & Lister, 1992; Gay, Trumbull, & Mazur, 1991). More research is needed to investigate the effects of hypertexts on writing, reading, and learning.

The New Pragmatics and the Sociopolitical Dimensions of Literacy. Becoming literate has always included learning about the pragmatics of reading and writing, which includes an awareness of the social and political aspects of literate activity. Included in this domain are awarenesses as diverse as knowing that a comic book and a Dickens novel carry entirely different cultural connotations, knowing when a handwritten letter may be more appropriate than a typed one, and understanding the capabilities, motives, and potential effects that influence a newspaper's decision to print some stories and reject others. This dimension of literacy, typically learned informally, is emphasized by Brandt (1990) when she states, "Learning to read and write is not learning how texts stick together but how people stick together through literate means" (p. 42).

It is becoming increasingly clear that electronic reading and writing are affecting the pragmatics of literacy. The most prominent example is the widespread use of e-mail for communicating with individuals and with various groups whose members share some common interests. The evolution of accepted forms, contents, and practices related to e-mail communication is not complete and these issues are eventually addressed by the members of virtually any e-mail discussion group. Such groups focus on questions such as: Who should be included or excluded from the group? What types of content are appropriate to post to the whole group? When is it acceptable to forward a message to someone without permission of the original sender? Are there guidelines for when it is better to reply to an individual rather than to the entire group? Should one be allowed to publicize a product or service in which one has some financial interest?

Beyond establishing practical conventions of appropriateness related to these questions (often referred to as *netiquette*), e-mail leads to other questions that are beginning to attract the attention of literacy researchers. For example, what are the characteristics of e-mail that promote what seems to be a greater degree of informality and openness in writing? Do writers who resist expressing themselves in printed forms do so more readily in e-mail? Does e-mail

encourage candidness, imperiousness, confrontational rudeness (often referred to as *flames*), and so forth. If so, why and what effects does participation in e-mail writing and reading produce on individual readers and writers? Fey (1994) has conducted research addressing the latter question using a feminist perspective to examine the interchanges among participants in an on-line college course. Is e-mail a catalyst for subverting established hierarchies of authority and decision making? Some studies suggest that it does in corporations (Kiesler, 1986) and in high schools (Neilsen, in press). How might e-mail be used to enhance the instruction of preservice teachers (e.g., Gallego, 1992; McIntyre, 1992; Myers, 1993)?

More studies are needed to address these and similar questions because the rise of e-mail and other forms of electronic texts is a major literacy event with far-reaching societal implications. For example, Rheingold (1993) has reflected extensively on his long-standing involvement with what he calls "virtual communities" on the Internet. He believes that electronic communities are analogous to the agora of ancient Greece "where citizens met to talk, gossip, argue, size each other up, [and] find the weak spots in political ideas by debating about them" (p. 14). And, as a free forum for expression he sees it as a powerful tool for extending democratic ideals. At the same time e-mail threatens some firmly entrenched notions about literacy. For example, the conversational informality of e-mail de-emphasizes the importance of accurate spelling and other mechanical aspects of writing. At another level, e-mail and other electronic forms of communication call into question the utility of current conceptions of copyright, plagiarism, and fair use. Also, it is beginning to undermine the utility of printed scholarly journals as the most efficient ways to disseminate and advance research (see Stix, 1994). Indeed, electronic texts advance postmodern views of literacy (Murphy, 1988) and have the potential to undermine the literary canon in the humanities (Bolter, 1991; Landow, 1992; Lanham, 1993). Issues of interest to the general public such as children's access to pornography on the Internet must also be addressed.

These developments and potential outcomes suggest that literacy research in a posttypographic world must gravitate even more toward a consideration of pragmatics particularly with regard to the social and political issues related to electronic reading and writing. Issues of policy must be carefully considered and researchers must seek to address questions that inform these discussions. In schools too we need to integrate a consideration of electronic literacy into the language arts curriculum (Reinking, 1994). Finally, in addressing issues related to pragmatics with regard to a changing literacy, we will benefit from taking an historical-analytic perspective (e.g., see Kaufer, & Carley, 1993), a perspective that has been less crucial when print was the only dominant form of reading and writing. By understanding more clearly the historical reasons that account for our conceptions of print-based literacy it will be easier to conceptualize and understand the transformations in literacy that we are currently experiencing.

GENERALIZATIONS CONCERNING LITERACY ACQUISITION AND CLASSROOM-BASED RESEARCH

During the 1980s most of the studies investigating instructional uses of computers for reading and writing were ad hoc comparisons of individual computer applications and conventional reading and writing activities. Focusing primarily on skill-based outcomes or specific products, these studies were not typically driven by any explicit psychological, social, or pedagogical theory (Reinking, & Bridwell-Bowles, 1991). However, more recent studies have followed the turn in literacy research toward conducting contextualized investigations of instruction taking into account the dynamic factors that shape teaching and learning in classrooms. Researchers interested in investigating the role of computer technology in shaping literacy in classrooms have begun to realize the inadequacy of limiting their investigations to conventional experimental designs (Baumann, Dillon, Shockley, Alvermann, & Reinking, 1996; Reinking, & Pickle, 1993). We believe that a few tentative generalizations can be made on the basis of this emerging research and that they can be useful in generating questions for research as well as in formulating a pedagogical theory for using computers in literacy instruction. In this section we present several representative generalizations along with examples of research that relate to them; however, we wish to emphasize that our list of generalizations is not exhaustive.

The effects of using computers for instruction are dependent upon a teacher's instructional philosophy and goals as much as upon the characteristics of the computer application or activity. Much of the interest in using computer technology in schools is based on the belief that it has the potential to expand instructional options and to transform positively the standard modes of teaching and learning in schools (Cuban, 1986; Newman, 1990; Papert, 1993; Sheingold, 1991). Yet, many writers have cautioned that there is nothing intrinsic to computer technology that will bring about educational reform (Cochran-Smith, Kahn, & Paris, 1990; Greenleaf, 1994; Mehan, 1989; Weir, 1989; Zorfass, & Remz, 1992). Indeed, a review of the literature examining the effects of using technology across the curriculum clearly indicates that simply introducing computer-based applications or activities into classrooms is not enough to achieve that potential (Means et al., 1993).

This conclusion holds when focusing exclusively on the language arts curriculum. The most extensively researched example is Bruce's long-term investigations of QUILL, a comprehensive application emphasizing process writing and reading for meaningful purposes in the middle grades (see Bruce, & Rubin, 1993 for an extensive summary). Across several years and many classrooms, Bruce and his colleagues concluded that teachers shaped the QUILL activities to fit their own views of reading and writing, sometimes subverting the specific intent of the program. They state that "rather than the new technology radically reshaping the learning environment, the computers themselves were shaped to fit the already established patterns" (Michaels, & Bruce, 1989,

p. 12) and that "... no innovation, no matter how well conceived, and ... how well intended or executed, can in and of [itself] be assured of achieving positive change in instruction" (p. 35). Yet, reflecting on their many years of experience Bruce and Rubin state that their "detailed, self-critical appraisal of the evidence [about QUILL] yields surprises and reveals a richness in what students and teachers do that belies both optimistic and pessimistic visions of technology in relation to educational change" (p. 1).

Bruce's conclusions are supported by several other studies examining diverse computer programs across the elementary grades. For example, Miller and Olson (1994) found that a 1st-grade teacher who was enthusiastic about integrating technology into her language arts curriculum advanced her own pedagogical goals for writing when implementing various story writing software into her classroom. Over time, the researchers documented how her use of the software enhanced her instruction but did not move her in new directions despite the possibilities offered by the software. Similarly, our own work (Labbo, Murray, & Phillips, 1995-96) documents how one primary grade teacher was guided by her literature-based philosophy of literacy instruction in creating computer-based writing centers. Likewise, Dickinson (1986) found that the classroom writing system a teacher had already established fashioned how students used word processing software.

On the other hand, there is evidence that under certain circumstances, usually over an extended period of time, appropriate software or computer-based activities can effect changes in the modes of teaching and learning in classrooms. For example, Cooper and Selfe (1990) report that computer conferencing in college courses gives students authority to resist an academic agenda that does not meet their needs or values. Landow (1992) also describes how replacing a conventional textbook in an undergraduate course on Victorian Literature with a hypertext that mingles texts created by faculty and graduate and undergraduate students radically reconfigures modes of teaching, learning, and assessment. Again, in our own work (Reinking, & Watkins, in press), we have found that over an entire school year introducing multimedia book reviews into middle-grade classrooms as an alternative to the conventional book report tended to disrupt conventional modes of instruction in ways that were often pleasant and appealing to teachers and students. We observed that for some teachers the various activities associated with this project led them to consider new instructional activities as extensions of the multimedia book reviews.

Integrating computers into reading and writing activities in the classroom can foster increases in collaboration and thus has potential to change the social organization of classrooms. A popular concern is that computers will create individuals who work in isolation and who prefer to interact with the computer rather than with people. There is no evidence to support this concern. Furthermore, we believe that the opposite conclusion is more accurate in classrooms. Computers, whether used to link people worldwide over the Internet or to engage students in classroom reading and writing activities, promote interaction and collaboration. In making this generalization we are drawing heavily on our own

research experiences in classrooms, but other studies too lend support to our position.

Several studies have highlighted the increases in social interaction that occur when word processing activities are introduced into classrooms. For example, Dickinson (1986) found that children who worked with a classroom writing buddy (often necessitated by virtue of the fact that few classrooms and labs have had enough computers for every student) discussed plans for their writing and reacted to each other's writing when they worked at the computer. Bruce, Michaels, and Watson-Gegeo (1985) found that computers encourage students to write in a variety of ways that include collaborations involving sharing notes, writing articles for the class newspaper, and reviewing books or plays. Heap's (1986) ethnographic study of 1st-grade students' writing provides evidence that the computer brought together peers of almost equal ability leading to interactions that allowed one or both to work within Vygotsky's (1978) zone of proximal development. Mehan (1989) noted that when 2nd- through 6th-grade students were allowed to work together on word processing, they were able to work out ideas collaboratively and were frequently made aware of points of view that differed from their own.

In our own work (Reinking, & Watkins, in press) we found that engaging students and teachers in learning Hypercard (a relatively simple but powerful authoring tool for creating computer presentations) and using it to create multimedia book reviews had noticeable effects on the social interaction and organization, at least during the times that students were engaged in that activity. For example, the ratio of student-to-teacher talk was greater during the activity, and teachers seemed to enjoy the fact that students often had more expertise than they did. Lower-ability students frequently took on a different persona when working on computer-based activities, frequently exhibiting more confidence and leadership when interacting with their high achieving peers. We also found that student-to-student interactions related to learning about the technology and meeting the challenges of programming their book reviews led to incidental sharing of information about enjoyable books. These findings are consistent with other studies that have found increases in social interaction when computers are integrated into various other areas of the curriculum (Friedman, 1990; McGee, 1987; Riel, 1989; Turner, & Depinto, 1992).

We believe that collaborative forms of reading and writing are likely to increase as electronic texts become more common in schools. As we have mentioned in a previous section, electronic texts blur the distinction between reader and writer by inviting readers to adapt and modify the texts of the original author, a possibility that could make writing and reading literally a socially constructed dialogue. Hypertexts in particular lend themselves to collaborative writing as Shirk (1991) has predicted; she states that "Writers will no longer create in solitary environments; they will become contributing members of hypertextual development teams" (p. 198). Classrooms may come to reflect what Landow (1992), in writing about the potential societal effects of electronic reading and writing, calls "a society of conversations in which no one conversation, no one discipline or

ideology, dominates or founds the others" (p. 70). More research is needed to investigate these possibilities in classrooms.

Computers can promote the integration of reading and writing activities for purposeful communication. Research has confirmed the intuitive belief that students write and read better when they are engaged in personally meaningful and purposeful tasks (Kirby, & Kirby, 1985). However, during the 1980s the use of computers in classrooms too often worked against this principle. Many writers (e.g., Smith, 1984) pointed out how commercial software dominated computer-based reading and writing activities in classrooms and how most of that software focused on teaching, drilling, practicing, and assessing isolated skills.

That criticism is less valid today for diverse reasons including the increased sophistication and availability of hardware and software as well as an increased technological astuteness among teachers and students. For example, more than 10 years ago a project using computers to link students in two schools, one in California and one in Alaska, was noteworthy; today such links are commonplace as is evidenced by a recent report that found that in 1994 more than 35% of the nation's schools had at least one Internet connection (Heavyside, Malitz, & Carpenter, 1995). Due to such developments more attention is being paid to how a variety of engaging computer-based activities can serve as a springboard to meaningful reading and writing across the curriculum. There are even preliminary indications that the dominance of the conventional textbook is being seriously threatened. For example, it has already been several years since the state of Texas qualified computer-based science programs as alternatives to textbooks on a state textbook adoption list.

There has been relatively little research focusing on how computers can promote integrated and meaningful reading and writing activities but a few examples can be cited. Labbo, Field, and Watkins (1995) reported preliminary findings from an ongoing study investigating the opportunities for literacy development that occur when the Internet is used to connect 3rd-grade students in two schools, one in the Southern United States and one in Taiwan. The children in both schools were motivated to interact frequently through e-mail which is more immediate, affordable, and accessible than letters or telephone calls. In their interchanges they raised questions about their counterparts' culture and they wrote descriptive reports in a hypertext format about family life, school life, cultural activities, and forms of government. The available technology allowed them to scan photographs of their families and to include transcripts and audio segments of interviews with their school principal and teacher. They also wrote journal entries about typical daily activities. Another example is a study by Turner and Depinto (1992) which found that students who composed hypermedia documents were motivated to think about how to present information that made sense to their peers. Such computer-based reading and writing has all the characteristics of meaningful, authentic reading and writing tasks that are currently being promoted among literacy educators, and they stand in stark contrast to both early uses of the computer in classrooms and to conventional academic tasks. More research is needed

to guide continued expansion of these types of activities in classrooms.

Computers can facilitate students' reading and writing by providing individualized assistance and by reducing the drudgery associated with some aspects of reading and writing. Salomon's (1979) theory of instructional media postulates that a critical attribute separating various instructional media is the degree to which a particular medium can supplant processes and skills necessary to acquire information from that medium or to perform a task with that medium. For example, motion pictures have an advantage over photographs because zoom and closeup shots can focus a viewer's attention to important details that might not be noticed by the viewer of a photograph. Using this theoretical position Reinking (1987) argued that printed and electronic texts should be considered different media because electronic texts provide many more opportunities for individual help and guidance during independent reading and writing. The examples of computer applications and research cited in earlier sections of this chapter devoted to the malleability of electronic texts and their capability to expand the boundaries of freedom and control in accessing textual information support this position. However, we provide additional examples here to highlight how these capabilities might figure in classroom instruction.

For example, in our own work (McKenna, 1994) we are investigating the effects of providing beginning readers with pronunciations of unfamiliar words sometimes accompanied by phonetically related words while reading popular children's books presented by a computer. We believe that electronic texts might provide options for innocuous and individualized phonics instruction without detracting from the enjoyment of children's literature. We believe that computer technology offers a variety of new instructional options for assisting students in learning fundamental but often mundane aspects of reading and writing and that such instruction can be accomplished in engaging ways that free teachers to concentrate on less transient aspects of literacy acquisition. We are also interested in related questions such as how far children might choose to read above their instructional level when they have access to supports that reduce the obstacles to successful reading. Our work extends several other rigorous, theory-based studies aimed at providing individualized assistance that reduces the difficulties facing some early readers. For example, Olson and his colleagues (Olson et al., 1986; Olson, & Wise, 1987) have experimented with various types of speech feedback; Reitsma (1988) has investigated how reading with computer-based speech feedback compares to teacher guided reading; and Roth and Beck (1987) have compared the effects of two theory-based computer word games with speech feedback on word recognition and comprehension.

Some of the research investigating the effects of word processing has focused on how it may assist young children overcome the limitations inherent in writing with conventional tools. For example Chang and Osguthorpe (1990) and Green (1984) have investigated how word processing supports emerging writers by providing visual, auditory, and motor help and by removing the often tedious aspects of early

writing such as forming letters with a pencil. Also, Phenix and Hannan (1984) suggest that word processors bolster young children's efforts to revise, reread, and rewrite narratives because they can focus more on the content of their message and less on penmanship and spelling. In a case study of a kindergarten student, Cochran-Smith et al. (1990) conclude that the effectiveness of word processing activities for children's writing development is dependent on the writing task, the child's literacy development, the instructional context, and features of the word processing software.

We believe more research is needed to explore such factors and how they relate to the computer's ability to individualize assistance and to reduce the need for less engaging aspects of reading and writing processes. Studies are needed to investigate how instructional activities derived from such awarenesses can be implemented in classrooms and what their effects are on teaching and learning. We need to determine what Salomon et al. (1991) have called effects *with* and *of* media. That is, what are the immediate consequences of reading or writing a particular text *with* a computer and what are the long-term effects *of* the computer on the way students approach reading and writing in general?

ISSUES AND TRENDS: PAST, PRESENT AND FUTURE

Researchers' interest in computer technology and literacy spans almost 30 years, beginning with Richard Atkinson's research on a computer-based initial reading program at Stanford University (Atkinson, & Hansen, 1966). However, except for a few large projects such as Atkinson's at Stanford, which were typically supported by large grants, most of the research involving computers has occurred since microcomputers were introduced in the late 1970s. During the intervening 15 years, the perspectives and questions motivating interest in computers and literacy have evolved as computer technology and knowledge of its use has become more sophisticated, as the availability and use of computers have increased in and out of schools, and as educators and researchers have come to understand more fully the computer's potential to alter traditional conceptions of schooling and literacy. There has been an increasing, although sometimes reluctant, acceptance of the idea that electronic forms of reading and writing are moving closer to the mainstream of literacy. The early conception of computers as instructional devices that provided novel opportunities for accomplishing the goals of the conventional language arts curriculum has gradually given way to a realization that computers may precipitate fundamental changes in how we read and write. This shift represents a maturing of the technology and our understanding and use of it. Also, given the almost daily expansion of opportunities for electronic reading and writing, there is no reason to think that this trend will abate. We expect to see even more dramatic changes over the next 15–30 years. In this concluding section we identify some specific current and emerging issues and trends that we believe to be noteworthy for literacy researchers.

The trend away from simple, atheoretical studies comparing the effects of literacy activities with and without a computer, which we noted in an earlier section of this chapter, can be cited here again. Early studies frequently lacked theoretical justification and methodological rigor, and they provided specious answers to wrong questions (e.g., see a critique of the extensive research on IBM's writing-to-read program by Krendl, & Williams, 1990). Such studies mirror the unproductive approach used to study a variety of earlier media such as instructional television, and leaving such research behind is a positive development indicating that an interest in computers and literacy is not as transient as has been the interest in other instructional media. Also, unlike early studies, recent research has focused more on conceptual factors that separate printed and electronic texts such as those we have highlighted in this chapter as opposed to visual factors, such as the optimal amount of text to display on a single screen. Relatively minor variations in the visual display of texts on computer screens have not produced robust effects on the most valued aspects of literacy such as reading comprehension (Reinking, 1992; Reinking, & Chanlin, 1994); thus, we see the decreasing interest in such factors as a positive development. We also see a shift from inter- to intramedia comparisons (a distinction first alluded to by Wright, 1987). Early studies focused on comparing electronic and printed texts usually with the tacit assumption that printed texts were the standard against which electronic texts must compare favorably to be of any value. Now we are seeing more studies content to investigate how differences in computer-based reading and writing activities might be improved without comparisons to ostensibly parallel print-based activities. Indeed, as printed and electronic texts continue to diverge, such comparisons make less sense intuitively and practically. For example, why should researchers compare writing with a word processor to writing with conventional materials when no one would seriously propose abandoning word processing? Likewise, most word processors now include means to incorporate video and sound into written documents, which take them beyond the realm of print.

Another notable trend is that research devoted to investigating the relation between computer technology and literacy has benefited from and contributed to the broader interest in contextualized research in classrooms. Researchers today are conducting investigations consistent with Weir's (1989) point of view when she states, "The kind of teaching and learning I am concerned with treats the computer as an adjunct to socially mediated learning, as part of a context, a constellation of children with children at the computer, of teachers with children with computers" (p. 61). Such a perspective is consistent with recent trends in educational research that emphasize what Salomon (1991) has called systemic, as opposed to analytic research. That is, researchers are looking more globally at the effects of introducing computer-based literacy activities into classrooms and schools. To do so they are using conventional qualitative approaches such as action research (e.g., Labbo et al. 1995–96). Notably, they are at the vanguard of efforts to develop new approaches to classroom research. For example, in our own work we have extended Newman's (1990) concept of a formative experiment as a means to

determine how computer-based activities can best accomplish specific literacy goals in classrooms (Baumann et al., 1996; Reinking, & Pickle, 1993; Reinking, & Watkins, in press). Also, Bruce and Rubin (1993) have introduced an approach to classroom research they call situated evaluation to study the effects of innovative reading and writing activities in classrooms.

Furthering the move toward classroom research is an increasing confidence that computer-based activities are not only likely to remain a part of classroom life but that they are moving steadily toward the mainstream of instruction. This point of view is reflected in calls for systematic instructional responses to the new skills and awarenesses that are necessary for readers and writers in a world where much reading and writing will take place electronically (Reinking, 1994). It is also reflected in the development of pedagogical theories centered in computer technology. For example, The Cognition and Technology Group at Vanderbilt University (1994) has developed a wide range of computer-based instructional activities centered in the concept of anchored instruction. In brief, anchored instruction postulates that students learn more when a variety of instructional activities, typically that include reading and writing, is related to a rich, shared experience presented as multimedia using a computer. More research is also investigating how young readers and writers experience emergent literacy when they have regular opportunities to engage in reading and writing activities involving computers. For example, in our own work (Labbo, 1994, 1995; Labbo, Reinking, & McKenna, 1995) we have examined kindergarten students' and teachers' extensive use of a word processing and drawing program as part of school and home activities. Our ethnographic data suggest that children take a variety of approaches in exploring software tools that allow them to express themselves symbolically. We found that children view the screen as a landscape to be explored, as canvas to be painted, as a page to be written upon, as a playground, and as a stage to narrate dynamic, spontaneous plays. Other mainstream researchers have also begun to conduct research into how computers figure into emergent literacy. For example, Sulzby (1994) has compared how literacy emerges in young children who have or have not had opportunities to use computers.

Another recent trend is the rise of perspectives on literacy that would have been unthinkable only a few years ago. More writers are not only questioning definitions of literacy based solely on print but are also beginning to identify explicitly the limitations of printed materials when compared to electronic forms of communication. The focus of this volume is a case in point. Another example is the topics of two plenary speeches presented at the 1994 meeting of the National Reading Conference (Flood, & Lapp, 1995; Reinking, 1995), a leading professional organization for literacy researchers. These talks focused, respectively, on the need to expand definitions of literacy to include visual literacy and on the need for literacy researchers to completely reorient their research agenda in light of the increasing prominence of electronic reading and writing. Also, members of The Cognition and Technology Group at Vanderbilt University (1994) have proposed the term 'representational literacy,' which is the ability to communicate ideas flexibly using multimedia. Other writers are seriously questioning whether our conventional bias for prose over other verbal and nonverbal modes of communication is justified (Bolter, 1991; Edwards, 1991; Landow, 1992; Lanham, 1989, 1993; Lemke, 1994; Tuman, 1992a, 1992b). Tuman (1992a) goes so far as to suggest that teachers of writing.

must confront the possibility that the sustained, detailed crafting of written language is too difficult a task, too removed from normal, informal, sporadic uses of language, to be the normative impulse driving the truly language arts curriculum... [because in doing so] we doom many students to be labeled as failures. (p. 124)

These broadened perspectives point to a heightened consciousness about aspects of literacy that have been either transparent or foreign when printed materials were the only reasonable standard for reading and writing. These perspectives also highlight the need to examine the changing landscape of literacy by opening up interdisciplinary dialogues among scholars in areas as diverse as sociology, history, communication, literary criticism, and education. We understand that to be a primary goal of this volume and hope that our perspective on current theory and research contributes to the dialogue.

**METHODS OF INQUIRY IN
COMMUNICATIVE AND
VISUAL ARTS TEACHING**

This page intentionally left blank

INTRODUCTION: EXPLORATIONS IN CROSSING BOUNDARIES

Donna E. Alvermann

UNIVERSITY OF GEORGIA

We shall not cease from exploration.
And the end of all our exploring
Will be to arrive where we started
And know the place for the first time.

—*T.S. Eliot*

The chapters in this part of the handbook are a diverse lot, bound together by their common focus on explorations into methodological inquiry in literacy. Because these chapters cross boundaries blurred by the ever expanding visions of literacy described in Part I of the handbook, they offer endless opportunities to explore new ways of representing data. They also offer openings into understanding familiar forms of inquiry—ethnographies, case studies, teacher research, university/school collaborations, alternative assessments—in new ways made possible by a heightened sensitivity to multiple literacies.

The authors of the chapters share at length how their explorations in crossing methodological boundaries have afforded them opportunities to push their own thinking about the role of the communicative and visual arts in literacy research. They do this in a number of ways. Some demonstrate how their broadened view of literacy—one that includes a variety of sign systems—has enabled them to capture the nuances of poetry, metaphors, computers, videos, performances, and works of art in developing finely tuned methods of inquiry. Others describe how exploring the intellectual sites of ethnographies and case studies has brought a new level of awareness to their own thinking about what constitutes literacy research. Still others address policy issues that affect how multiple literacies play themselves out in theory, research, and practice.

In the chapters that lead into this part on “Methods of Inquiry in Communicative and Visual Arts Teaching,” the authors disclose how they have chosen to represent findings from their interests in areas as diverse as sociology, educa-

tion, and the multimedia. For example, Laurel Richardson in her chapter, “Poetic Representation,” transforms an in-depth interview into a five-page narrative poem. In so doing she transgresses standard representational practices; as Richardson notes, prose may not be the most valid way to record people’s talk. Claiming that the form in which researchers write shapes the content of their findings, Richardson shows how issues of validity go unnoticed in writing up interviews in standard prose. She also demonstrates with nine lyric poems how a researcher can reduce the distance between “self” and “Other”—a feat that normative ethnographic writing cannot replicate.

A second chapter that deals with issues of representation is Lorri Neilsen’s “Remaking Sense, Reshaping Inquiry: Feminist Metaphors and a Literacy of the Possible.” Rejecting metaphors spawned by research that treats literacy as something to think about and do rather than live, Neilsen advocates exploring methods of inquiry that demystify research, make use of multiple sign systems, value multiple ways of knowing, and promote “response-ability” to sensory-rich literacy experiences. For her feminist sensibilities, no single metaphor will do to represent the living inquiry she espouses. Rather, what Neilsen is calling for are complexly situated metaphors that connect lives to words.

The chapter, “Learning with Multiple Symbol Systems: Possibilities, Realities, Paradigm Shifts and Developmental Considerations,” by Robert Tierney explores new methods of representing the dynamics of teaching and learning in non-verbocentric ways through multilayered text. Tierney develops the thesis that multimedia environments can serve as tools to transform how learners process and represent information. He does this by drawing on three examples from his own observations and research on how multiple symbol systems, when enlisted as vehicles for criss-crossing a variety of concepts, can support different ways of knowing and being known. In another chapter, “Transcription and Representa-

tion in Literacy Research," Carolyn Baker treats the process of transcribing talk and nonverbal activity as a method of inquiry. Claiming that this process is by no means neutral in terms of the decisions researchers make, Baker advances three themes about transcription practices as representations: they are forms of thinking and communicating that reflect cultural membership; they count as literacy practices in themselves; and they assign social and moral order to what is recorded. She also describes how description, layout, and formatting decisions leave traces of the theoretical and analytical work that went into producing them.

The next clustering of chapters includes three that were written to initiate and extend conversations about theoretical and practical applications of ethnographic and case study methodologies. The chapter "Ethnography and Ethnographers of and in Education: A Situated Perspective," by Judith Green and David Bloome, is an exploration of the influence of different intellectual sites on the relationship between theory and method. Green and Bloome trace some of the changes that have occurred in this relationship as members of various communities—social scientists, educational researchers, teachers, students, and ordinary citizens—engage in the practice of ethnography and ethnographic research. Their goal is to make visible a range of issues associated with the situatedness of this method of inquiry.

Steven Athanases extends the conversation begun by Green and Bloome. In his chapter, "Ethnography for the Study of Performance in the Classroom," Athanases explores why ethnography is well suited for studying performance. He identifies specific sites of learning (e.g., student planning time, rehearsals, performances, and reflections) that occurred in an ethnography he conducted of 10th-graders' performances of poetry. He also describes the different ways performance is used in K–12 classrooms and the potential of ethnography for studying such performance, including a brief overview of the key functions, features, and challenges of ethnographic methods.

In "Children Out of Bounds: The Power of Case Studies in Expanding Visions of Literacy Development," Anne Haas Dyson moves the conversation away from ethnography and into the realm of intense study of individual experience. She presents three cases written over a 15-year period to illustrate how her own changing frames for viewing those cases shaped their construction. Like the preceding authors in this cluster of chapters, Dyson deftly illustrates the methodological dynamics of her chosen line of inquiry. She also articulates how the dialogic process involved in constructing cases of young children's literacies can destabilize conceptual boundaries and cause one to cross over them.

Teacher research and collaborative inquiry between school- and university-based researchers constitute the next set of chapters in this part of the handbook. In the chapter, "Methodology in Teacher Research: Three Cases," James Baumann, JoBeth Allen, and Betty Shockley Bisplinghoff explore issues related to the tradition of teacher inquiry, including whether or not there is anything methodologically distinct about this form of research. Next they present three cases, each of which is representative of the diversity within the domain of teacher research and involves them as the inquir-

ers. The first two cases chronicle literacy acquisition in the primary grades, while the third explores the methodological diversity within the National Reading Research Center's teacher research community.

The theme of exploring methodological issues surrounding teacher inquiry is taken up with a different view in Christine Pappas' chapter, "Making 'Collaboration' Problematic in Collaborative School–University Research: Studying *with* Urban Teacher Researchers to Transform Literacy Curriculum Genres." Pappas argues that many of the uncertainties associated with school- and university-based collaborations are largely due to new conceptualizations about power/participant structures and the nature of knowledge, which, in turn, require changes in research methodologies. She asserts that because of these changes, collaboration itself must be made problematic.

In the last clustering of chapters in this part, Anne Sweet leads off with "A National Policy Perspective on Research Intersections Between Literacy and the Visual/Communicative Arts." She describes the national legislative arena and its role in creating a niche for the arts in an expanded view of literacy. She highlights the arts education research agenda, its interface with literacy education research, and the issues related to this interface. For example, Sweet addresses the problems encountered in designing interdisciplinary assessments in dance, music, theater, design, media, and visual arts. She closes with a look to the future and the prominence of problem-centered research with its emphasis on knowledge integration as opposed to the present focus on domain specific research.

Picking up on one of the issues addressed in Chapter 20, Carol Stavropoulos describes the steps taken to develop and test the quality of an instrument for assessing written statements about works of art. In this chapter, "Alternative Methodology for Diagnostic Assessment of Written and Verbal Responses to Works of Art," Stavropoulos uses Marc Chagall's *The Birthday* to explore the knowledge base and knowledge-seeking strategies an individual would need to respond to the Diagnostic Profile. Grounded in cognitive learning theory, the Diagnostic Profile assesses students' understandings of their own work as well as a range of art reproductions.

The implications of blurred boundaries and boundary crossings, which are integral to the whole notion of an expanded print literacy, are never more apparent than in Robert Calfee's chapter on "Assessing Development and Learning Over Time." As Calfee points out, one of the first challenges in developing a valid assessment of any kind is the ability to identify the construct that is to be assessed. Calfee tackles this challenge and other issues, such as measuring growth and validity, in his attempt to explore ways of linking conceptual analysis to the practical aspects of classroom assessment.

In summary, this part of the handbook, which describes methods of inquiry in communicative and visual arts teaching, contains numerous examples of border crossings—some more visible than others—but all within a view of the world that sees knowledge as connected, yet historically situated and partial. This world view is indispensable to understanding an expanded print literacy.

ETHNOGRAPHY FOR THE STUDY OF PERFORMANCE IN THE CLASSROOM

Steven Z. Athanases

STANFORD UNIVERSITY

Twenty-three fifth graders, stuck in a giant vat of imaginary taffy, move in slow motion, then following their teacher's coaching, freeze before moving again, now feeling their bodies grow light and bouncy on huge trampoline-like pillows. As the physical warm-ups end, the children listen as their teacher identifies the problem for today's improvisation workshop: How to dramatize challenges facing any one of the endangered species they have studied in science.

An 11th-grade U.S. History class quiets so that the first group can perform their original scripted dramatization of conflicts during the Civil Rights and Anti-War movements of the sixties, based on oral histories that the students audiotaped during fieldwork in the community. To introduce their scene, one group member performs a published poem thematically linked to these social movements.

In an undergraduate education course on literature for the high school, four students have selected key lines from Ibsen's *Ghosts* all spoken to Mrs. Alving, the protagonist, lines that speak society's narrow definitions of a woman's duty as wife and mother. The students encircle the class-as-Mrs. Alving, delivering the lines aggressively as if theirs are society's voices dictating duty, overlapping one another rapid-fire, then chanting the lines in a Greek chorus. Two students then move to the front of the room and assume the role of Mrs. Alving herself, one delivering some of her lines from the play, another speaking the inner thoughts Mrs. Alving may have felt the need to repress because of her socially inscribed roles.

These three classroom scenes are a small sample of the kinds of performance activities in which I have been engaged for over 20 years—as student, teacher, observer, and researcher. The scenes also suggest the range of ways in which performance activities occur in classrooms from kindergarten

through university, including imagination exercises and improvisations, original narratives and dramas constructed from oral history interviews, performances of poems and plays, and symbolic enactments of literary, historical, and sociological themes. Whether teachers use performance as an occasional instructional strategy or as the foundation of their curriculum, their use of performance typically invites students to assume roles of other real people and literary characters; to enact, embody, and usually voice people's stories, dilemmas, insights; to interpret and critique texts; or to dialogue or argue with others. Through the use of performance, a teacher vivifies how history tells stories of real people's struggles, how literature holds accounts of characters' lives, how a curriculum can live as students imagine themselves walking a mile in another's moccasins. In these ways, the teacher, in asking students to perform, moves well beyond a transmission model of teaching with passive learners, inviting students to imagine, act, embody, shape, and feel their way into a deep knowing of the course content.

While these experiences of classroom performance are relatively rare in U.S. schools, their use holds rich potential for student learning, particularly when coupled with a range of literacy activities that help students plan, rehearse, and reflect on their own and their peers' performances. Such activities, with the act of performance itself, may support, among other things, subject-matter learning, language growth, self-esteem building, and affective and cognitive gains. Little research, however, has documented what such performances and accompanying activities yield for student learning.

This chapter explores the use of ethnography as a research method well suited to the study of classrooms in which such acts of performance play a prominent role. I begin with a brief

survey of the ways in which performance is used primarily in K-12 classrooms and described in reports and textbooks. This survey includes arguments offered on behalf of performance as a learning strategy and, when results of studies of classroom performance are available, these are included. I then argue the need for research into classroom performance and describe ways in which ethnography is well suited to this task. For readers who are not experienced ethnographers, a brief overview of ethnography follows, highlighting its key functions, features, and challenges. Finally, the chapter identifies the ways in which ethnographic methods can document student learning through performance and related activities. These methods are illustrated by data from a recent study on the performance of poetry that I conducted with a class of 10th-grade students.

KINDS OF CLASSROOM PERFORMANCE

In a report on the state of performance studies, Strine, Long, and HopKins (1990) described ways in which the field, originally conceived as a means of studying literature, now embraces much more—other subject areas, other genres, other purposes. Their chronicle of historical change in production and scholarship in performance also provides a way of understanding changes in classroom uses of performance. I begin with a survey of performance of literature in classrooms—since historically this has been the most common focus of performance in schools—then briefly review some other recent forms of classroom performance.

Classroom Performance of Literature

Oral reading and creative drama have long held important places in some elementary school classrooms because these activities include, among other things, a sense of play, use of the imagination, narrative understanding, the body, the senses—elements and values often considered relevant to young children. At universities also, the study of oral interpretation of literature has long held a place in many departments of speech communication and communication studies. At the high school level, however, while some teachers have for many years used drama and other kinds of performance in their teaching, these instances in U.S. schools have been few overall, particularly in contrast to schools in the U.K. (Freedman, 1994; Squire & Applebee, 1968, 1969). Electives flourished in U.S. schools in the late 1960s and early 1970s in, for example, areas of theater and speech communication such as public speaking, oral communication, persuasion, acting, debate, drama and stagecraft, and oral interpretation. Universities graduated Speech Education majors to teach these courses and to direct related extracurricular activities.

By the early 1980s, however, high schools stripped electives from their programs, in many cases returning to only yearlong comprehensive English courses, in part because of general budget cuts in education, and because the graduation of the last post World War II baby boomers brought a sharp enrollment decline and difficulty in sustaining small elective

classes. Also, frequent press coverage of a decline in students' basic skills and of falling national test scores ushered in "accountability" in education and the perceived need to narrow English curricula to reading and writing, with speech and drama courses often perceived as unnecessary. Universities graduated fewer speech education majors since few school positions called for such preparation, and at some universities these degrees were eliminated altogether. In recent decades, if high schools offered students in-class speech and drama opportunities, it has been generally because English teachers have built them into their curricula, tying them closely to reading and writing instruction.

One result of the dearth of performance experience in middle schools and secondary schools is that, stripped of its origins in song, the poem and much other literature that students encounter have become merely printed text that students must read and study quietly and privately. This image of literature is far from that conceived by aesthetics and performance scholars such as William Craig Forrest who argued, "As with the musical score, the poem is a set of directions for performance" (1969a, p. 298). Seldom perceived in schools as a musical score or as material for dramatization or other forms of performance, literature has journeyed far from the stories of folklore and the oral narratives once widely spoken and sung to lute, lyre, and drum. In relatively rare cases, however, teachers use classroom performance for varied purposes, among these to engage students' thinking, emotions, voices, bodies, and communication skills in explorations into literature.

In a yearlong ethnography (Athanases, 1993), I studied two 10th-grade English classes in which the teachers diversified their literature curricula to include more works by authors of color, fostered response-centered instruction, and facilitated classroom discussions that featured student thinking. While discussions proved central to students' literary understanding and appreciation, they were subsets of rich oral language environments that included, among many forms of classroom communication, performances of literature. Table 11-1 shows the teachers' varied uses of performance events over

TABLE 11-1. Performance Events in Literature Study in Two 10th-Grade Classes During One School Year^a

1. Full-class oral reading of dramatic literature in the study of *Oedipus*, *Lysistrata*, *Antigone*, and *Othello*
2. Videotaped Renaissance newscasts using *Othello* as data source
3. Solo performance of soliloquies from *Othello*
4. Performances of scenes from original modern-day tragedies written in small groups—to parallel themes from tragedies written by the Greeks and by Shakespeare
5. Small group oral read-arounds of poetry
6. Solo performances of original poems thematically linked to poems in a unit on literature of discrimination
7. Scripted solo performances of thematically-linked poetry programs
8. Small group performances of scripted scenes adapted from *Black Boy*
9. Small group scripted dramatic scenes in project presentations on group novels, in which characters from various literary works meet

^a From Athanases (1993)

the course of the year. While the uses of performance of literature in classrooms vary, exemplified in Table 11-1, in K-12 classrooms they tend to fall within five categories.

Storytelling. Some teachers use storytelling as a way into literature and for an understanding of story and performance. In my own teaching of tenth graders, I preceded the study of Harper Lee's *To Kill a Mockingbird* with sessions of legend telling in a circle, lights off, curtains drawn (Athanases, 1984). After swapping local legends, we discussed what the legends shared, why we tell them, what keeps them alive—all as a set-up for the legend of Boo Radley which the students would encounter in Lee's novel. Fine (1990) described the swapping of folklore and performing "everyday" tales from students' own oral traditions as both a means of introducing students to performance and a way of understanding the nature of performance, its defining features, and its power.

Spontaneous Oral Readings. Teachers frequently invite students to read aloud from literary works in class and, in the case of dramatic works, occasionally invite students to read characters' parts so that the dialogue and conflicts of the drama can be heard. These are generally initial soundings, first encounters with literary works. Such readings can stimulate discussion and deepen student comprehension as the drama of the literature is heard. Thoughtful teachers know that students raised on media such as television, film, videos, and even CD-ROM need at least occasionally to have print voiced.

Dramatic Improvisations. Many published descriptive accounts of classroom performance concern the use of improvisational activities, particularly in the elementary grades but occasionally ranging up through even college-level courses. Authors of such works claim that improvisation can develop the child's understanding of the world (Heathcote, 1981), foster empathy (Wagner, 1990), clarify what students already know (Edmiston, Enciso, & King, 1987), enhance literary engagement and understanding (Rogers & O'Neill, 1993), and develop students' interpretive skills, including attention to textual details (Krondorfer & Bates, 1994). Many advocates of improvisation cite Dorothy Heathcote (whose teaching is described in Wagner, 1976), as an expert in leading classroom improvisation. Generally, advocates of this work value the process of learning to enact over performance as a theatrical product. In this vein, Stewig and Buege (1994) described ways to integrate "spontaneous drama" in whole language classrooms in the elementary grades, arguing that it is a language art that enables children to embody characters and situations, to explore nonverbal communication, and most important, to develop oral language proficiency.

Wagner (1990) identified two forms of improvisation. In *story drama*, students enact scenes related to literature under study. She described a set of activities she and a teacher conducted with seventh graders in the study of *Johnny Tremain* by Esther Forbes. Students participated in guided improvisations, followed by written reflections in diary entries that the fictive characters might have kept. In another activity, students clustered in written form traits and mental associations related to Johnny and Dove, the key characters in

conflict, enacted in pairs an imaginary scene of the two characters meeting, then wrote diary reflections after the conflict. In an extended illustration of *theme-oriented drama*, Wagner described how Dorothy Heathcote took her 6- to 8-year-old students through activities over a few days to help them understand differences between medical care of modern times and of the times of George Washington. Through coaching from their teacher and from other adult volunteers who played the roles of patients to the students' health care workers, students read and used the signs their teacher had prepared, prepared lists of health care problems and the supplies needed, wrote down directions for healing maladies, kept pencils behind their ears to maintain records of each patient's progress and detailed records for use by those on duty after the doctor or nurse would leave. Students engaged in historical imagining and empathy work, and practiced the use of more sophisticated language through their roles. In both forms of improvisation, teachers used purposeful designs to engage students in a range of literacy activities and acts of thinking. While the story drama form is more relevant to literature study, the wide range of literacy events built into both forms illustrates the learning potential of improvisation.

Similarly featuring this potential of story drama improvisation, Rogers and O'Neill (1993) identified four strategies that can help build bridges between literature and drama: the teacher assumes a role that asks the students to explore understanding; students conduct interviews in pairs from relevant imaginary perspectives; groups construct tableaux or still images of significant moments or abstract representations of textual elements; and a class conducts an inquiry, reflecting on literary events by putting a character on trial. In their work with one 9th-grade class, the authors found that writing-in-role following improvisations demonstrated literary engagement and understanding. With much older students in college level literature study, Krondorfer and Bates (1994) used improvisations in the form of "ritual enactment" in which a facilitator coached students through interviews, dialogues, and living sculptures that explored relationships among characters and events in the literary work and that brought to body and life students' responses to the literature, whether consciously or not.

Scripted Group Performance Based on Literary Works.

Group performance of nondramatic literature has long held a place in theatres and classrooms, generally defined as the scripting of full literary works, portions of works, or compiled scripts of several short or excerpted works (Coger & White, 1973; Kleinau & McHughes, 1980; Long, Hudson, & Jeffrey, 1977; Maclay, 1971). These performances, often called readers theatre, feature conflicts, tensions, characterization, thematic connections across collections of short works, and other literary elements. Chamber theatre (Breen, 1978), one form of readers theatre, features the staging of prose fiction, in which the performance preserves the narration by staging the narrator's relationship to the tale, as well as staging some form of the tale itself. A chamber theatre production of Ken Kesey's *One Flew Over the Cuckoo's Nest*, for example, would stage Chief Bromden's narration of the story, including his

dramatic visions of Nurse Ratched's monstrous treatment of patients in the psychiatric ward and his tale of the fog machine being turned on in the wards to blur the patients' thinking. In contrast, the motion picture of Kesey's novel gave viewers the action firsthand, rather than through the lens of Bromden's imagination.

For dramatic literature itself, Doyle (1993) advocated teaching students to ask critical questions of the literature and to enact scenes generated by those questions and issues, fostering a critical examination of culture. At the lower grade levels too, some teachers ask students to construct and perform short scripted dramatizations that feature key conflicts or themes from literary works, either as reconstructions of the works themselves or as original dramas borrowing themes and storylines from published works. In an account of group performances of literature in "classroom theatre," Wolf (1994) studied a class of 17 third- and fourth-grade predominantly special needs students, 11 of whom had been detained at some point in the primary grades and most of whom suffered from reading problems. In over ten sessions of classroom theatre led by a guest actor/director, students learned drama techniques, practiced warm-up exercises, and worked with basal reader selections and trade books on collaborative interpretation of text through script preparation, rehearsal, performance, and follow-up commentary. Wolf studied students' evolving notions of drama and their growth in dramatic interpretation.

First, students learned thoughtfully to consider multiple interpretations, drawing particularly on real-life experiences to sort through interpretive possibilities. They engaged in problem solving as they collaboratively constructed scripted scenes, negotiating plausible interpretations. In addition, the students engaged in a great deal of perspective taking, prompted by reflective writing tasks that asked "what-if" questions and by the director, teacher, and researcher who persistently asked such questions. Students gained a critical stance about their interpretive and performative choices, talking more and eventually initiating more criticism without the prodding of adults as they prepared final performance scripts. Wolf amply documented how "Undergirding an abbreviated line of spoken talk . . . is an analytic foundation of thought" (p. 35). Here group performance served aesthetic concerns but likewise triggered thinking and learning that could transfer to other situations and texts.

Solo Performance of Literature or of Excerpts From Literary Works. Some teachers have long emphasized the oral reading and memorization of dramatic monologues and soliloquies. Such acts of performance have provided students with opportunities to sound poetry and to speak the often heightened language of poets. In the case of texts with challenging language, such as Greek tragedies or Shakespeare's works, teachers often accompany oral work with written paraphrasing to foster students' comprehension of text. Seldom, however, do these events move beyond written paraphrasing and memorization of language to the performance interpretation of literature. This latter feature, however, has long been the focus of the field of oral interpretation, now more commonly referred to by speech communication scholars as performance studies.

Lee and Gura (1982) defined oral interpretation as "the art of communicating to an audience a work of literary art in its intellectual, emotional, and aesthetic entirety" (p. 3). It is the "aesthetic entirety" feature that particularly challenges the solo performer. Through the performance of an excerpt from a prose or dramatic work, the student is not merely an actor embodying a single role as part of a full play. Instead, the solo performer attempts to embody and convey a sense of the *full* scene or even full work of multiple characters, of action, of conflict. In the case of a collection of poems, the performer brings life to individual poems *and* may engage in literary teaching by selecting and sequencing poems to feature thematic and linguistic links—and then attempt to embody these features in performance.

Expanded Genres and Uses of Classroom Performance

Performance is used sometimes as an instructional strategy in varied subject areas in K–12 classes. In addition, the field of performance studies explores the nature of performance itself as it occurs in many genres in varied community settings and has embraced multiple genres and purposes for classroom performance, generally featuring college and university classes. For example, to link classroom learning with the world outside and to bring history alive, some teachers use the performance of oral history, in which students gather oral texts through fieldwork, then perform these histories as a means of understanding individuals, history, and culture (Stucky, 1995). Students conduct and tape a field interview, produce an interview transcript, construct a story from the transcript, and rehearse and perform that story. Fuoss and Hill (1992) described three kinds of assignments they use for teaching a university course in social movements: *unscripted* assignments that generally invite role-playing or improvisations, such as invented debates in which students argue from the perspectives of the social and historical figures they have studied; *scripted* assignments for which students perform extant texts (speeches, manifestos, poems, essays, letters); and *scripting* assignments, involving the original production of texts (e.g., an imaginary journal written by a social leader, an original narrative, or a manuscript constructed from several speeches, poems, or other texts). Students in a performance studies course at Northwestern University explored performance as dialogue between the lives of students at the university and survivors of the devastating 1972 Buffalo Creek flood in Appalachia (Olsen, 1992). Students staged an event to create a disruption real for audience members in the way that the flood disrupted the lives of Buffalo Creek residents; the director then interviewed audience members regarding their responses to the performance.

Park-Fuller and Pelias (1995) provided a catalogue of recent alternative performance genres in order to aid our understanding of this expanding field. In addition to *improvisation* in both writing and performing plays, the authors identified three other categories. *Storymaking* includes the construction of a script based on oral history interviews, and also includes the performance of personal narrative; conversational storytelling (a kind of staged swapping of tales); and fictive monologue, a scripted imaginary monologue of a fic-

tional character. The *replication of life performances* includes conversational replication, based on transcripts of conversations and interviews (such as Anna Deavere Smith's recent productions), and restored performances (notated scripts of prior live performances so that performers can reenact what others have done). Finally, *performance art* uses a postmodern sensibility in, among other things, breaking norms of unity and completeness, inviting audience members to collaborate in meaning making. These works use strategies such as juxtaposition, which places images and symbols above narrative; psychic display, through which performers reveal their often fragmented psyches and selves in unpredictable and often shocking ways; and intertextuality, which gives centrality in performance to the intersection of texts and genres.

STUDYING WHAT PERFORMANCE YIELDS

The teacher or researcher interested in investigating the learning that any one of these many forms of performance yields might ask any number of questions. The educational writers I have surveyed have tapped classroom experiences from their roles as teachers and researchers to make claims based on anecdotal evidence and, in some cases, on empirical study. Their many claims I have cataloged, when not supported by empirical work, could be tested through study. A whole range of questions could drive such work. How, for example, might performing Chief Seattle's speech on the destruction of the American land shape, alter, deepen a student's understanding of and appreciation for the environmental history of the United States or the Native American view of land? What impact does interviewing African-American veterans of the Vietnam War and performing their oral histories for peers have on students' understanding of that war, of the ways in which racism figured in the armed forces in the sixties? What kinds of cultural understanding and language opportunities does role-playing children in other societies enable young children to have? What do students learn about the language of poetry through speaking it, rehearsing it, singing it? In classrooms where performance plays a central role, what kinds of things occur in students' use of language, behavior, attitudes, and values? If classroom experiences with performance appear to have an impact on students, to what can we attribute this impact? What features of a performance-rich learning environment shape what kinds of student learning? In what ways? With which students? These are just a sampling of the many questions that thoughtful teachers and researchers might ask about the potential values of performance for students.

In addition to educational writers, scholars from fields as varied as literary criticism, performance studies, rhetoric, and aesthetics have argued, in varied ways, the merits of performance that can be tested through structured inquiry. Geiger (1973) argued that performance, more deeply than silent reading, aids the knowing and "realization" of experiences and thoughts suggested by a text. Berleant (1980) pushed it perhaps one step further: performance creates an experience that enables us to become one with the work.

Forrest (1969b) foregrounded the embodiment that performance fosters, citing how it creates the direct kinesthetic sensation of the speaking body (how the speech sounds and feels to the body), vital to language experience. Related to this, Conquergood (1991) has discussed the body as a site of knowing. Bacon (1972) attended to the felt level of literary experience. Performance, he argued, demonstrates not just what a poem says, but also how it feels: "in performance, with the matching of the body of the poem with the body of the reader, we have the poem incarnate" (p. 6). One poet supported this claim by testifying that at a performance of her own works, the performance "took me back to the pain of the poem's birthing."

In the often challenging arena of contemporary U.S. classrooms, performance can breathe life into the study of literature that students find so often unstimulating and even stifling (Cameron, 1981). Performance can provide the necessary component of active learning to the curriculum (Duke, 1974) and in this way fits neatly with Reader Response theory that features the readers' active meaning-making processes in transactions with literature (e.g., Bleich, 1978; Fish, 1980; Rosenblatt, 1978). Also, performance can help recover the orality of texts and a view of literature as a dynamic event, valuable for students who too often see texts merely as artifacts (Fine, 1990). Fine argued that curricula must counter the stifling effects of print:

Unless students understand that literature is a record of verbal performances, a translation of them into the print medium, and unless they learn how to restore the printed record to a live performance, then they will be cheated out of a full and rich experience with literature and the life it contains. (pp. 179, 180)

In addition, writers claim that performance fosters intimate encounters with heightened language, providing verbal models for students in language study. Others claim that learning to project to others meanings and feelings through performed language aids communicative competence. Finally, in the upper grades and college classrooms, making space for performance can rescue literature from the deadening effects of criticism, the overly analytical dismantling of texts that strips them of the life force that inspired their creation (Shattuck, 1980). These are but a sampling of the arguments that have been offered in support of performance.

The Need for Research into Classroom Uses of Performance

Despite a great deal of advocacy literature and testimonials regarding the values and practices of classroom performance, relatively little research has examined the process and the impact of such activity in classrooms. In the field of speech communication, for example, despite calls for measurement to discover more about the interpreter's response and the impact of performance on readers and performers (e.g., Klyn, 1965; Long, 1973; Strine et al., 1990), little research has tested the various theories and claims regarding the power of

performance in theaters and especially in classrooms. Herndon (1973) argued that the result suggested

an inexplicable mystical experience culminating in artistic expression. ... The uncertainty about what is referred to when interpreters use the phrase, 'the reader experiences the literature,' prevents one from asking pertinent questions and setting relevant problems for research. This phrase and other similar phrases suggest vague and mystical concepts, and they deserve the skeptical treatment they usually get from scholars in more factual fields.

In her review of research on the effects of drama on the language arts, Wagner (1988) too noted that research on classroom drama has been relatively sparse. Some studies, she noted, had found significant correlations or effects, such as work conducted by Pellegrini (1980), in which students' involvement in dramatic play enhanced story comprehension and understanding of syntactic structure; Pellegrini (1984), in which drama correlated with kindergartners' word-writing fluency; and Wagner (1986), where role-playing strengthened students' persuasive writing in grades 4 and 8. Wagner noted, however, that the mode of research up to this point had been almost exclusively studies comparing the differential effects of teaching strategies (such as role-playing and drama) on written products. Lacking in research literature on drama in education, however, was qualitative research providing richly detailed observations of drama in the classroom, "descriptions that capture the immediacy and power of the child's struggle to make meaning" (p. 52). What, in the process of drama, proves particularly powerful for children's learning? In what ways? With which children? What do features of drama and other forms of performance enable students to do?

The dearth of research into classroom performance of literature can be attributed, in part, to little evidence that performance of literature has been systematically integrated into K-12 classrooms. Second, views of performance as mere child's play, as a nonacademic, often messy curricular frill, have relegated performance to the curricular margins, seldom viewed as an instructional method with cognitive power. In addition, some view performance from purely an aesthetic view and believe that one cannot empirically examine artistic experience. This view reinforces the notion that performance is some mystical activity that cannot be taught or investigated.

Even if researchers are committed to documenting and examining performance, however, the daunting challenge of studying performance as it occurs in schools also helps explain the dearth of such research. For example, planning, rehearsal, and performance events can be so complex and interrelated that they elude easy investigation. Also, the logistics of tracking planning and rehearsal sessions can be staggering since they often occur in different groups simultaneously in single classrooms, in other school spaces teachers find for students' rehearsals, and in out-of-school settings. Finally, rehearsals and performances are fleeting and difficult to describe, let alone to evaluate.

Why Ethnography Is Well Suited for Studying Classroom Performance

Ethnography holds potential for investigations of classroom performance for various reasons. First, ethnography's reliance on long-term participation and observation as a primary method of data collection can enable the investigator to track the students' unfolding learning over time and during multiple phases of often rather long-term rehearsal periods or performance units. Ethnographic work can situate student performances in the context of the sweep of a school year, embedded in a full set of curricular activities. Teachers who use classroom activities dealing with performance frequently plan these for various times over the course of the school year. Ethnographic work can capture how things students learn in some domains get internalized and picked up in others.

Second, because it requires immersion into a culture, ethnography can enable a researcher to examine students' performance learning in multiple classroom and out-of-class contexts, and can prove particularly appropriate for investigating the development of a "performance culture" in classrooms where performance holds a central role in curriculum and instruction. The researcher can investigate cultural patterns related to learning: How do students learn in this environment to do what they learn to do? How does a class of students get socialized into the acts of performance? What kinds of student responses and learning occur during units in which performance holds a key place?

Third, ethnography requires attention to the contexts of the school, including homes from which learners come and the community locations to which students go when they leave the building. How does performance figure in these out-of-the-classroom settings where students spend time? This attention to context can help frame an understanding of cultural patterns that occur in classrooms.

Finally, as my survey of kinds of classroom performance has demonstrated, in addition to the act of performance itself, teachers often include many learning-rich activities surrounding performance. It might be recalled that in Wagner's study (1990), children produced written clusters of characters' traits and mental associations, enacted an imaginary conflict of two characters meeting, then wrote diary reflections on the conflict. Heathcote's students (Wagner, 1990) prepared lists of health care problems and wrote detailed records of patients' progress as they played the roles of health care workers. Students in Wolf's study (1994) practiced warm-up exercises, planned and wrote scripts, and engaged in reflective writing in response to "what-if" questions. When these literacy activities are foregrounded and the learning made concrete and visible, a window into the world of learning through performance is opened. Such an approach moves the focus from merely the culminating act of performance to encompass more broadly the cognitive, kinesthetic, aesthetic, and communicative processes that students exercise during performance study. All these processes invite examination. Here, again, ethnography is well suited to the task. Using multiple data collection tools, an

ethnography provides rich documentation of learning as it unfolds and varies over time, describing the varied processes and products of student learning.

PRINCIPLES FOR CONDUCTING ETHNOGRAPHY

Often, research considered “qualitative” in nature is referred to as ethnographic, even though it lacks the fundamental features of the disciplinary base of cultural anthropology. Principles for conducting anthropological research can guide ethnographic language studies in classrooms (e.g., Atkinson & Hammersley, 1993; Ellen, 1984; Goetz & LeCompte, 1984; Heath, 1982; Sanjek, 1990; Saville-Troike, 1982; Sperber, 1982). These principles are no doubt familiar to, and routinely shaping, the work of experienced ethnographers. For the less experienced in conducting ethnographic research, I provide an overview of the key purposes, features, and challenges of this method.

The central goal of ethnography is generally held to be the discovery of cultural patterns achieved through long-term fieldwork of participant observation. The researcher becomes immersed in the culture, using a relativistic view in which cultural norms are examined on their own terms, rather than through a deficit lens. The researcher situates the study of the culture firmly within contexts and intertwining social systems. In addition, extensive complementary scholarly study helps

frame emerging cultural patterns. A set of principles, shown in Table 11–2, can guide the work of the ethnographer studying classroom performance, language, and learning. These principles are detailed in various writings, including Talbert (1973) and Athanases and Heath (1995). In the latter work, Shirley Brice Heath and I provide an historical background to ethnography, then feature dilemmas the ethnographer faces, using an extended illustration of a yearlong study I conducted and the ways in which I attempted to solve methodological problems. While many of the principles identified in Table 11–2 may seem self-explanatory, some warrant elaboration.

Launching the Study

Because of the long-term nature of ethnography and the need to become intimately involved in the community studied, the researcher is wise to thoughtfully select sites in which productive study can occur over an extended period of time and to articulate criteria for the selection process so that readers can understand how to place a study within larger bodies of related work. What features of the sites will allow findings from this study to be compared with those of other research? Once sites have been selected and entry has been negotiated, researchers new to a setting need to pay particular care to building rapport with key informants, generally the teachers and students there. Researchers from universities are wise to pay special attention to this need, since they are members of an hierarchically structured educational system in which they generally hold higher status in positions removed from the daily demands and often harsh circumstances of teaching children. A nonjudgmental stance is essential. The ethnographer must try to view, describe, and frame a culture through new eyes. In addition, members of the culture who feel judged by an outsider may withhold valuable insights, leaving the study significantly less powerful in capturing insiders’ perspectives.

Ethnography can be an expensive enterprise because it requires large time commitments as the researcher becomes immersed in the culture. Beyond time, other costs can include the purchase of materials and purchase or rental of recording equipment during data collection, support services to handle data maintenance and organization, and research assistance to deal with extensive data analysis. Researchers planning ethnographic work are wise to seek release time from other duties in order to accommodate the extensive demands of fieldwork and to apply for grant support to defray costs. In addition, building ethnographic teams makes sense for sharing responsibilities of data collection and extensive analyses of qualitative data.

Data Collection

As the ethnographer becomes a frequent observer and perhaps participant in a culture, rigorously taking field notes, key informants from varied groups within the system can be consulted and interviewed for their perspectives on events. Various factors shape how cultural members perceive events,

TABLE 11–2. Principles in Conducting Classroom-Based Ethnographies of Literacy Learning^a

Focus	Principle
Launching the study	Select sites thoughtfully and clarify selection process Negotiate entry and build rapport carefully Seek support to deal with costs
Early stages	Decide locus for study Locate key informants Beware of the role of authority and power Build rapport and trust, then take notes
Data collection	Observe rigorously Capture teacher wisdom Interview multiple informants Account for the complexity of context Balance tight order with the evolving nature of the research process
Analysis	Engage in ongoing preliminary analysis Decide what to analyze fully Test multiple analytic frames
Writing	Clarify how assumptions drove procedures Decide how to report Insure credibility and rigor by considering issues of validity and reliability
Reciprocation	Make contributions to community members

^a Adapted from Talbert (1973) and from Athanases and Heath (1995)

including membership in groups defined by gender and ethnicity and level of power within the culture. To frame an understanding of a class or school activity, an ethnographer may wish to consult people from various levels of power within the school, as well as parents and informed community members. Triangulation of data from varied sources can aid validity of claims in the study. Within the class, then, the ethnographer may wish to seek, through student surveys and interviews, balanced perspectives on relevant issues from, for example, more vocal and less vocal students, more and less academically prepared students, key actors in focal events and those who are observers. Finally, the ethnographer may wish to tap the teacher's wisdom of practice (Shulman, 1987) through acts of reflection that reveal thinking (Schon, 1983). In brief discussions before and after class, in extended interviews, or in written or audiotaped logs, the teacher can provide insights into classroom events and student motivations, purposes for class behavior, and reasons behind spontaneous adaptations of lessons during class sessions.

To understand the conditions that have shaped what occurs in the setting, the ethnographer collects data on the multiple layers of context within which the setting is situated. This portion of the project can be daunting in its complexity. In a national study, McLaughlin and Talbert (1993) provided a helpful framework for examining the embedded contexts that matter for secondary school teaching. Data on how context shapes classroom culture can be collected and categorized at levels, beginning from the broadest: national context (reform initiatives, national schooling norms), professional contexts (associations, collaboratives, teacher education programs), higher education standards (university entrance requirements that drive secondary school curricula), parents/local community, school system, school organization, subject area/department, and the classroom (subject and students).

Maintaining a precise trail of data collection purposes and procedures can aid the reliability of an ethnography. Also, keeping data filed and labeled can prevent the sensation of being overwhelmed by the large and varied bodies of data often collected during ethnographic fieldwork, such as field notes, lesson handouts and copies of board notes, student work samples, audiotapes of conversations, and interview transcripts. In addition, ongoing analysis through early review and coding of such data can enable the researcher to use emerging cultural patterns and insights to shape further survey and interview questions and to begin to track evidence for early claims and evidence that counters those claims.

Analysis and Writing

Deciding which data to analyze in what ways proves one of the most challenging tasks for the ethnographer. Examining different slices of data in different ways will yield different portraits; the ethnographer may wish to explore various organizing systems and analytic schemes to determine what they will yield (Talbert, 1973). Holding in focus key research questions that have driven the study and that have emerged

from early analysis can guide the researcher in the selection of analyses to conduct fully.

Ethnographic writing can never be objective, never pure representation through good field notes and mere writing up of results (e.g., Clifford, 1986; Pratt, 1986). The ethnographer sees through a frame (Goffman, 1974) and is responsible for identifying that frame. How have theoretical assumptions, philosophical and political biases, and practical considerations shaped decisions in the study? A clear explication of these in report writing enables the reader to understand the study's construction. Balancing numbers with stories is another challenge that the ethnographer faces in report writing. Numbers can help structure a whole: how large a place did a kind of event occupy in a given lesson, week, unit of instruction, marking period, or school year? Such a framing can help the reader understand the typicality or anomaly of stories the ethnographer details and the degree to which the stories capture the logic of actual life in the culture (Geertz, 1973). How oral discourse is transcribed is a matter of both theory and practicality and this system should be clarified. Stretches of transcribed discourse, often lengthy in print, need to be carefully selected as illustrations of events and phenomena analyzed.

To establish credibility in the reporting of ethnography, the researcher may want to clarify data collection and analytic procedures that aid the validity and reliability of claims (cf. Goetz & LeCompte, 1984). For example, in the clarification of validity, the researcher may want to consider questions such as these (from Athanases & Heath, 1995): Do survey and interview questions feature issues relevant to concerns of teachers and students? Are they relevant to the theoretical framing of the study? Have data been sampled repeatedly to warrant claims of patterns? Have multiple data sources been sampled and triangulated to warrant claims? Have data and claims from varied groups been examined and triangulated to substantiate analysis?

The report might include ways for the reader to trust that the research record is sufficiently reliable that some replication of portions of the study could be conducted. In addition to clarification of how theoretical assumptions have shaped procedures, other aids to reliability are the following: a precise trail of research moves; some consistency in interview questions across informants; preservation of primary data (such as exact language of informants) in reporting; internal reliability checks in the form of participants' own comments on discourse; perspectives balanced by groups of informants; independent coding of interviews, artifacts, and discourse data; and reports of emerging patterns reviewed and critiqued by outsiders and insiders (e.g., teachers in the study) (Athanases & Heath, 1995).

Ethnographer Reciprocation

A long-standing principle guiding anthropological fieldwork is the obligation to demonstrate reciprocity to a community in which the researcher has benefited from the time and close study of community members. The ethnographer in a school setting can do this in many ways, determined by a match of

the needs of community members and the skills and resources of the researcher. Among these acts are providing resources for use in the site, assistance in lesson planning, reviews of student work, tutorial assistance, and clerical support in the form of filing, organizing, and constructing classroom exhibits.

ETHNOGRAPHIC TOOLS FOR THE STUDY OF CLASSROOM PERFORMANCE

A study that examines classroom performance in the context of a full literacy program might employ a range of data collection tools to capture student learning in the assortment of classroom activities that occur. For example, I recently conducted a study in a 10th-grade English class in which the teacher and I taught a unit on the performance of poetry and investigated how students came to understand the performance concepts taught and how students worked on interpreting poetry through performance. For one portion of the unit, each student worked with a single poem over an 8-day period. The setting was an urban public school serving primarily children of middle- to low-income families. The class was heterogeneously grouped and ethnically

diverse: more than one third of the students were African American, and the rest were Chinese American, Latino, Filipino, and European American. I refer to this study simply as the 10th-grade performance study.

Table 11-3 shows data collected during just the focal unit of the 10th-grade performance study. Other ethnographic data were collected during the school year, such as teacher interviews, observation field notes of class sessions, instructional artifacts, student work samples, and data on context.

The following discussion highlights some of the tools of Table 11-3 and explores ways in which the ethnographer might investigate student learning in the context of classroom performance. Some of these methods are most relevant to studies in which the researcher is also the classroom teacher or, as in the case of the 10th-grade performance study, works collaboratively with a teacher to design tools both to foster and to reveal student thinking and learning through the performance process. The data collection methods described address one very particular kind of classroom performance of literature (solo performance of individual poems). Principles and data collection tools are described, however, to provide ideas for ethnographers investigating many other forms of classroom performance.

Documenting Instruction and Its Impact

Due to its relative rarity in classrooms, performance of literature is often a new classroom practice for students. For this reason, documentation of instruction in performance can help frame an investigation into how students learn about performance and become socialized into classroom environments that foster certain kinds of performance. For the 10th-grade performance study, students' initial understandings of literature and performance were sampled before documentation of instruction on performance. Table 11-3 shows that data for investigating these initial understandings were collected using some conventional tools of ethnography: field notes, surveys, interviews, and taping. The student surveys were designed to capture students' varied perceptions of performance and its purposes, students' past experiences with performance, and their notions of literary interpretation (an area that may well be affected by students' involvement in the performance of literature). Student work samples and other data on student performance (including field notes and audiotapes of classroom interactions) provided profiles of students' practices in literary understanding before classroom initiation into the performance experience. The final item in this first category of data, however, shows an attempt to gather baseline data on students' responses to a single published poem that featured a dramatic situation described in challenging language.

Once instruction began, data for this portion of the 10th-grade performance study included field notes, supported by instructional artifacts and selected audiotapes or videotapes of teaching, which helped track the instruction students received. In addition, teacher and student postclass debriefings and longer interviews provided information on class participants' reflections on the instructional process and the content being taught. Similarly, in her study of elementary school

TABLE 11-3. Data from 10th-Grade Study of Solo Performance of Poetry

Focus	Data Collected
Students' initial understandings	Teacher reports: class community, student performance Observation field notes Audiotaped class sessions Survey: understandings, experiences with performance Written response to a single performed poem
Instruction on performance	Audiotaped whole-class instruction and discussions Observation field notes Instructional artifacts Interviews and debriefings with teachers, researcher Student interviews
Performance planning	Packets of written responses and planning notes
Rehearsals	Audiotaped small-group work sessions, discussions Student journal entries
Performances	Audiotaped performances in small groups Selected videotaped performances for full class Audiotaped assessment conferences: teacher and researcher Students' written reflections on their own and other students' performances
End of unit reflections	Student interviews Postwrite on same poem from beginning of unit Survey Class discussion

students' experiences of 10 weeks of classroom theatre, Wolf (1994) collected baseline data on students' notions of drama, then tracked the instruction conducted by a guest drama director and interviewed students regarding their notions of classroom drama and the sources of that understanding. She was able to learn from these data sources how students moved from a sense of drama as uncontrolled action with no limits and imitative of action films, to a deeper understanding of drama and what she called its rules, roles, and resources. Students reported certain features of instruction and classroom practice that shaped these new understandings.

Documenting Performance Planning and Learning

For group performances of various kinds, group planning sessions can be observed and taped to track how students construct scripts and performances and how they learn about literature, characters, and interpretation. Field notes and tapes of these planning sessions can be supported by copies of student planning notes. Particularly in the upper grades, when students plan solo performances of literature, copies of written work can enable student, teacher, and researcher to understand the student's evolving interpretations. The packet of written responses and planning notes identified in Table 11-3 as data on performance planning drew on activities Long and HopKins (1982) have described for cultivating the performer's resources and fostering application of performance understanding to multiple texts and performance experiences. In these activities, students engaged in a whole range of literacy events (reading, writing, imagining, researching, discussing, and speaking) as they planned for the rehearsal and performance process.

For example, in the activity Long and HopKins (1982) call "making plain sense," students do detective work with the literary text, noting and looking up unfamiliar references and challenging vocabulary so that they can make the language of the poem sufficiently comfortable for performance. One student in the 10th-grade performance study listed a set of 11 words and phrases that she needed to decode in her planning for a performance of Gwendolyn Brooks' "the mother" (1963), a poem in which the speaker reflects on the experience of apparently having more than one abortion. In these notes on just 2 of the 11 words from her planning packet, the student defines the difficult words and works through an understanding of how they apply to the drama of the poem:

pulp: A soft, moist mass of matter.

In the first stanza third line pulp means the baby is soft and moist. luscious: pleasant and sweet to taste.

In the first stanza ninth line luscious means that the lady feels like eating her child and she sighs to taste him because he is sweet and pleasant.

Later in the packet, this student identifies the action of the lines, naming verbs for what the poem's speaker *does* in each line (Long & HopKins, 1982). Along the left margin of a copy of Brooks' poem, the student has listed 14 verbs. For example, as the speaker describes in the second stanza of the poem how she hears the voices of "my dim killed children" and begins to talk to these lost ones, the student has written these verbs:

hears, regrets, begs, and blames. These are just a sampling of an array of activities students completed for their packets of planning notes.

Documenting Learning from Rehearsals

Early Stages. As Rosenblatt (1978) has demonstrated, a reader's perceptions of a literary work evolve over time and with new influences. In the case of students' performances of whole or excerpted literary works, one valuable source of data is students' evolving transactions with the literary work, starting with their earliest perceptions. Students can record their first or earliest silent encounters with or soundings of the work. These responses can be handled through written journal entries or through cassette tapes, becoming a record of the student's earliest responses as they unfold.

After the earliest readings and soundings, the student might write some responses in a performance journal. An example of what one student in the 10th-grade performance study wrote to try to work out the meaning of a challenging portion of his selected poem, Herbert Martin's "A Negro Soldier's Viet Nam Diary" (1973), follows:

I don't understand the meanings of these lines. At first the poem talked about how he discovered a mother and a child in a river. Then all of a sudden he throws in those lines. For ex. "Death hangs on the rice." What rice is he talking about? Also "The land bears no fruit" and "Grass is an amenity." I don't understand what that has to do with the rest of the poem. I guess he is saying that everything is a luxury. That we don't need these stuff except life.

Other prompts for these early performance encounters with a text might be those explored by Roloff (1973) in his meditation stage: What happened to me in this initial experience? What is this piece of literature all about?

Tracking the Rehearsals. With the rehearsal situated at the center of the learning experience, the performance journal can become a place for recording reflections in and out of class, during and after each rehearsal, from in-class small group "rough draft performance" sessions involving peer critiques and suggestions, to solo rehearsals in and out of class. Journal prompts can be general or focused, depending on student needs and on the focus of research. General prompts might build on Bleich's questions (1975) that trigger affective and associative responses: What do you *feel* when you rehearse this literary selection? What does the experience of performing the work remind you of?

Two oral interpretation textbooks provide more focused prompts. Gamble and Gamble (1977) suggest the following: (1) What types of feelings did the preceding passage evoke in you? (2) Can you point to specific phrases in the passage that you find particularly effective? (3) Why do you believe these phrases affect you as they do? Long and HopKins (1982) encourage students to talk back to the literary work, asking the author questions, an approach they model using one student's journal responses to a single poem. Journal entries such as these that explore new knowledge, new sense, new problems with a work prove particularly valuable for tracking evolving interpretations.

Documenting Performances

Table 11-3 shows that for the 10th-grade performance study, taped records of performances served as key data. The last piece of data on performances, however, features students' reflections. For example, before students performed for their peers, they wrote about their rehearsal process, responding to selected questions and suggestions such as: What problem or challenge did you find in performing this work? Why did this problem arise? How have you attempted to resolve it? Discuss something you came to realize, understand, or feel about the literary work through rehearsing it or an excerpt from it. Discuss something you especially want to convey in your performance. How have you attempted to do that in rehearsal? Discuss any risky performance choice you have made and why.

The student performing "A Negro Soldier's Viet Nam Diary" stated in his entry, "My character feels sick in the beginning. I want to show how he feels sorry and sick in the beginning, then gets angrier as the poem goes on." The following is an excerpt from another student's journal entry for this series of prompts. The student had rehearsed "Chase Henry" from Edgar Lee Masters' *Spoon River Anthology* (1982):

I especially wanted to convey the sense that Chase Henry was more than just "the town drunkard," that inside he was a thinking, feeling, perhaps even an intelligent drunkard. I did not want to simply play the stereotype of a town drunk.

Other sources of data for students' reflections on their performances are in-class discussions and workshops that invite students to explore as fully as possible how their interpretations of literary works compare with the interpretations that other readers bring to the same works (for example, when listeners ask questions of the performer and make concrete suggestions so that the performer may revise the performance). This process of "checking out" a reading in relation to that of others provides data for investigation and can yield various potential benefits for the student: self-enlightenment (Bleich, 1975), understanding of how one has or has not been alive to all the cues of a text (Rosenblatt, 1976, 1978), and practice in persuasion (Fish, 1980).

Documenting Reflections

Table 11-3 shows that for the final focus category of end of unit reflections, students were surveyed and interviewed and wrote on the same poem they had written about two months earlier. In cases where students have engaged in multiple performance experiences over the course of a semester or school year, students will have collected a great deal of data from their performance process, from perhaps taped protocols of responses and written or taped journal entries through various stages of the planning, rehearsal, and performance process. All of these data can serve as material for the student's investigation into his or her performance process, culminating in a short reflective journal entry or even a case

study analyzing a theme emerging from the data—something that pulls together the ongoing reflections from the many stages and experiences of the performance process.

CONCLUSION

For various reasons this chapter has identified, classroom performance of literature and performance in other subject areas in K-12 classrooms has not occupied central places in curricula in the United States. Many writers, however, have advocated the use of performance as a valuable tool for learning, particularly in literature study. When such performance does occur, it can assume many forms in literature study: storytelling, spontaneous oral readings, dramatic improvisations on literary texts, scripted and rehearsed solo and group performances of all or parts of literary works, and original dialogues, group projects, and video presentations using scripts built from or paralleling scenes in literature. In addition, classroom performance arises in other subject areas and in other genres, such as oral history, invented debates between historical figures, performances based on transcripts of conversations, and various kinds of performance art, to name just a few.

Despite the advocacy literature on performance, little research has provided thick descriptions of what occurs when students engage in performance processes. For the researcher interested in conducting investigations resulting in such descriptions, ethnography holds possibilities that this chapter has discussed. The ethnographer can investigate performance in the context of larger literacy curricula and can document the complexities of students' planning, rehearsals, performances, and reflections as essential sites for learning.

Conducting a rigorous ethnographic study, however, remains an extremely costly and demanding undertaking. The time commitment is great for developing an intimate knowledge of a community and culture, even when that community is one small class of students. Resources are generally needed to fund the time and materials for data collection and analysis. The large amount of data generally collected for an ethnography can overwhelm the researcher during both the collection and analysis of data. For the researcher committed to ethnography and able to secure the necessary resources, anthropological guidelines can help shape a careful study. This chapter has overviewed these guidelines and identified some of the key problem areas the ethnographer will need to address.

Finally, an ethnography of classroom performance can draw on a wide array of data collection tools to capture the learning students do in such work. This chapter has outlined a variety of such tools. In addition, brief illustrations have been provided from a recent study conducted in a 10th-grade English class, in order to make concrete the data collection tools described. Perhaps these research guidelines, data collection tools, and illustrations can help serve the cause of good research and can help advance the knowledge base on the power of classroom performance for student learning in literature, in other subject areas, and in classes that study performance itself.

TRANSCRIPTION AND REPRESENTATION IN LITERACY RESEARCH

Carolyn D. Baker

UNIVERSITY OF QUEENSLAND

MAKING AND USING TRANSCRIPTS IN LITERACY RESEARCH

The use of transcripts of talk and activity recorded in naturally occurring, routine classroom events and other settings such as homes and workplaces has become an important empirical and analytical resource in recent literacy research. This reflects the interests of many researchers in working from the data of everyday events as a basis for describing, explaining or theorizing how literacy activities are observably organized and accomplished by participants. Working with transcripts allows for claims and counterclaims about activities and practices to be referred to a permanent set of reanalyzable records. The analyses and theoretical claims that are produced on the basis of recordings and their associated transcripts are accountable to what other readers, viewers or listeners can see or hear for themselves in these records. Further, recordings and transcripts have the potential to generate multiple and possibly competing analyses and thus to make possible resistance to singular interpretations.

Transcripts from recordings are made in part because academic communications are organized primarily through print. For ethical reasons also, many research recordings cannot themselves be distributed. Representations of them need to be made. Talk and action have to be put on paper, or onto disk and screen, made into text. But the making of a transcript also has benefits interior to the study of recorded events. Transcription allows for more detailed and careful analysis than is possible with a witnessed but unrecorded scene. The making of a transcript “slows down” the talk and action for the analyst so that the detailed work of representing words and actions can be done. At any point in the transcription process the transcription-so-far “fixes” the talk and action onto paper. This allows for the notation, inspection and reinspection of what can be seen and heard to be occurring in

the audio- or videotape. Transcription (the process) is a method of inquiry, involving analysis from the beginning. The transcript (the product) reflects that inquiry. As a number of researchers have observed, transcription is more than a merely technical matter; the transcription process and its outcomes are by no means neutral.

In this chapter I will review published literature on the making of transcripts and their consequences in educational research. This literature is relatively consistent in pointing out the nonneutrality of transcription practices. I will connect and extend a number of these observations to advance the themes, (1) that the practices of transcription are forms of reasoning and writing that reflect cultural membership, (2) that practices of transcription are literacy practices in themselves: how do we put words and actions on paper? how do we write and draw our transcript characters? and (3) most important, that transcription practices assemble transcript characters in particular ways and assign social and moral order to the literacy scenes observed. Transcription is in all these senses a form of representation in social science (see as a comparison Lynch & Woolgar, 1990). In the second part of the chapter I review some specific issues in transcription to illustrate how aspects of description, layout and formatting amount to a form of educational ethnography that is consequential for how we represent and understand language and meaning, students and texts, teachers and authority.

TRANSCRIPTION AS THEORY AND PRACTICE

Beginning with the work of Ochs (1979) the process of transcription has been studied in terms of the choices transcribers need to make and the effects of these choices on the form and content of the transcript. These are discussed in terms of the problems of selective observation that occur

during transcription: "transcription is a selective process reflecting theoretical goals and definitions" (p. 44). As expressed in Green, Weade, and Graham (1988, pp. 17, 18):

The completed transcript reflects a set of theoretical assumptions about the nature of the work accomplished through face-to-face conversations, the roles and relationships of participants, and the nature of instructional conversation. ... transcription ... is a heuristic device and not a literal record.

Ochs also states (p. 44) that "the transcriptions are the researcher's data." This holds true in that the transcript, once produced, becomes the text from which the formal, written analysis is launched. The transcripts are certainly the reader's data, because what appears in the transcript is a selection and a reduction of what was potentially available to the transcriber to indicate on paper.

Ochs details a number of alternative representational devices in transcripts involving child language. In addition to discussing transcribers' theoretical interests, Ochs demonstrates how cultural assumptions enter into the making of transcripts. For example:

the perceived dominance of the adult may lead a transcriber or researcher to locate adult talk to the left of the child's talk on the transcript. This location, in turn, becomes a "natural" candidate for an interactional starting point." (1979, p. 51)

Transcription choices, then, may prereflectively evidence cultural assumptions, even aspects of social organization, in the way in which the transcript characters are visibly arranged in relation to each other, and other aspects of the interactional scene depicted. In this sense culture and implicit knowledge of social structure enter directly into the making of a transcript. They are captured in the texture of the transcript.

More recently Psathas and Anderson (1990), writing about the practices of transcription in conversation analysis, explain the work and the orientations to recorded interactions that are involved in following the Jeffersonian transcription system. In this approach "transcription, which of necessity entails repeated listenings to a tape, becomes an integral part of the analytic process" (p. 77). Regarding the issue of neutrality in transcription, Psathas and Anderson state (p. 75):

there is not, and cannot be, a 'neutral' transcription system. The presumably 'neutral' presentation of the details of produced speech/action would be the actual embodied and situated original spoken production.

In conversation analysis, the transcript is treated as an aid to interpretation of the recording, which remains the primary resource for analytic work. On the status of the transcript they comment (p. 77):

...the status of the transcript remains that of being 'merely' being a representation of the actual interaction—i.e., it is not the interaction and it is not the 'data'. ... The original recordings, which ... are not in and of themselves 'neutral' or 'objective' renderings of what actually occurred, and which we will henceforth nevertheless refer to as 'the data', remain unaltered. Any transcription made of these data can serve as a *version* of the data for particular analytic purposes.

For conversation analysis, according to Psathas and Anderson, repeated direct listening to the recording is the arbiter of the fidelity and adequacy of the transcription: reliability is essentially a practical matter (pp. 77, 97). Psathas and Anderson discuss various "seemingly 'innocent' decisions of format and presentation [that] can and do have substantial implications for the analysis" (p. 85). Some of these decisions and their consequences will be sketched later in this chapter.

Mishler (1991) begins his discussion of transcription with an analogy to photography, cautioning against naive realism and against supposing an "innocent relationship between photographer and scene" (pp. 258, 259): "the meaning of a representation is problematic and dependent on variations in craft and context." He discusses transcription as an interpretive practice of "entextualisation" that involves a number of procedural and methodological decisions. He draws attention not only to the crafting of the image but also its location amid other textual material. He says of photographs (p. 258):

What we assume to have been "really" there, and how the photographer selected and framed the event, and how the photograph is presented and located within the flow of other information, including other images ... along with the text that serves as its caption, all influence our understanding.

Applied to transcription in literacy research, this means that the presentation of transcript material (speech and action) in words, in particular formats or layouts, and/or in illustrations is read as part of a larger text. The photography analogy also supports Mishler's preference for a position in which objects and their representations are interconnected. This perspective places the interpretational and representational onus on the audio or video recording, on the transcribing, and on making the connection between image and reality (i.e., reading the image). The work of producing the transcript and its interpretation is seen to be cultural rather than merely technical.

Mishler is critical of Psathas and Anderson's privileging of the original recording as "the data"—as the reference against which the fidelity of the transcript can be determined (1991, p. 277). This privileging is done in conversation analysis along with the recognition that the recording is not ultimately the data (see quotation above). In practical terms transcribers have to work as if the recording represented the event or some significant aspects of it, even if that particular representation was just one of many other possibilities. At the same time it is instructive to consider the proposition put forward by Paoletti (1990) in a study of classroom interaction: it is not that the classroom produces the description, but that the description produces the classroom. Similarly, it is not that the speech or activity produces the transcription, but the transcription produces the character of the speech or activity for all practical purposes.

In addition to reviewing procedural and methodological decisions involved in making transcripts, Mishler comments on the effects of different transcription practices (1991, p. 270):

Transcriptions of speech, like other forms of representation in science, reflexively document and affirm theoretical positions about relations between language and meaning. Different

transcripts are constructions of different worlds, each designed to fit our particular theoretical assumptions and allows us to explore their implications. And ... they have a rhetorical function that locates them within a larger political and ideological context.

Mishler also notes (p. 277) that "the form of representation we use serves theoretical and rhetorical functions, and perhaps aesthetic ones as well." He presents different forms of transcription of the same recorded events to illustrate these points, drawing in part on the work of Michaels and Gee.

In a review of discourse analysis, Gee, Michaels and O'Connor (1992, p. 239ff.) include discussion of "transcription as an interpretive lens." Considerations of "how to display the talk or writing on a page" include representing the texture of the talk or writing through choices of format and speech delivery detail included or excluded. They illustrate that forms of transcription are consequential for what can be seen in the text/transcript by displaying two forms of a transcript of a "sharing time" story told by a student in a 2nd-grade classroom. The first version is organized by turns at talk; it includes questions interjected by the teacher during the delivery, and shows tone groupings, false starts, hesitations and the like. The second version organizes the student's story into lines and stanzas, adds headings, removes teacher turns, speech repairs and the like, and presents an "ideal" representation of the story. This second version allows one to see various aspects of structure and patterning in the story; it assigns a different order of competence to the student. This order of competence is brought out in the analysis of the second version of the transcript. Gee et al. (p. 240) point out that

In educational research, we are often dealing with students whose ways of speaking, writing, and reasoning diverge from those of the teacher (and researcher). In these cases, it is especially important to be mindful that the transcript will inevitably leave out some information or, by its display, make certain features more salient than others.

The speech and writing of students with different literacy practices from those of teachers may in some transcription formats appear confused or incompetent while in other formats designed to extract their previously invisible linguistic and cultural strengths appear to be competent practitioners of different literacies than those recognized in formal schooling. For transcribers, a consequence of these observations is that the selection of formats for transcription involves ethical as well as technical considerations.

A collection of papers on transcription (Edwards & Lampert, 1993) provides further comment on theoretical as well as technical and procedural aspects of transcription using different systems. Du Bois, Schuetze-Coburn, Cumming, and Paolino (1993) present a detailed account of how transcription is done using particular symbols to indicate discourse features. Similarly, Gumperz and Berenz (1993, p. 91ff.) explain the workings of transcription from "within a sociolinguistic and functional perspective." They begin with statements of their theoretical position and associated statement of intent of the transcription system (p. 91f.).

We assume ... that talk is basically interactive. ... What we seek to account for is the ongoing, cooperative process of conversing. ... Conversing in turn rests on speakers' and listeners' interpretation of verbal and nonverbal signs or contextualisation conventions. ...

Our transcription system attempts to set down on paper all those perceptual cues that past research and ongoing analyses show participants rely on in their online processing of conversational management signs. ... What is emphasized in our approach is the rhetorical impact these signs have in affecting the situated interpretations on which the conduct and outcome of the exchange depends. Transcription, when seen from this basically functional perspective, is an integral part of the analysis of inferential processes.

In this description of a transcription system it is clear that the system is designed to find and represent those discourse features that have been theorized as important to the organization of speaking and listening. Also, in presenting this theoretical perspective as a basis for describing the transcription system, the character of conversing, and thus the activities of conversationalists, have been represented already. This is evidence of the necessary reflection in any system of transcription of a theory of social action or a theory of social order.

These observations can be taken somewhat further. The work of transcription involves methods of organizing and formatting detail from the recording. It involves methods of making the heard or viewed event "orderly." In this sense transcription *assigns* a social, political, or moral order to the scene being transcribed. This point is crucially related to the place of transcription (and other forms of "representation") in ethnography. Woolgar's (1988) paper, "Reflexivity is the Ethnographer of the Text," discusses the relation between texts and the worlds they purportedly describe. He states (pp., 28, 29) that the conventions which structure the text

impose order upon a fluid (pre-textual) realm of actants and entities; they produce an ordered structure of categories, objects and subjects; they define distances and relationships between these entities; the moral order of rights and obligations—which of these entities can say and do what about whom.

Woolgar did not refer to educational research in making these points, or in calling the text itself "a species of social/cultural activity" that constructs its own subjects. But the parallel is clear. The philosophical problems encountered in imaging, framing, even captioning in an anthropological account are identical to those involved in educational research. "It is in and through textual representation that the character of the other is achieved"—in this case the character of the literacy scene, its members, their activities, their practices. According to Woolgar, "we need continually to interrogate and find strange the process of representation as we engage in it. This kind of reflexivity is the ethnographer of the text" (pp. 28, 29). This reflexivity is demonstrated in the analyses presented by Gee et al. (1992) in showing how the "character of the other"—in their case the competence of the student who speaks black English—is achieved textually (see also Ochs, 1979, pp. 70, 71 on showing the grammatical competence of the child).

Woolgar's reference to a "pre-textual" realm has a parallel in Dorothy Smith's (1990, p. 151ff.) discussion of "encoding

lived actualities." In her formulation of this process, texts (which may be taken to include transcripts) are accounts. Smith provides a statement concerning the misconstrued problem of capturing reality in a text:

In a sense, a lived actuality never happens, for it is always lived; what is, happens, or has happened arises only at the point where a recording is made, a story is told, a picture is taken. The ontological problem of correspondence between descriptive terms and objects or events is bypassed, as indeed it should be, in that "what actually happened/what is" arises only at that moment of reflection where experience is intended by an account or encoding aiming at an account. (p. 151)

What went into the production of the account (transcript), and its articulation to social relations, are often lost to readers of the text:

This is often a matter we don't attend to because in the social relation in which our own work is embedded we confront the text as our object. The text arises as an object in this relation of working. Its character as an object of that work becomes thematic in our consciousness. It does not appear before us in its active transactional being, as a moment in a sequence of practices concerted as a social relation. Our gaze, oriented toward the enterprise of inquiry, is not self-regarding. We do not in the orientation of our work recognize how at this moment, too, the text is taking on a distinctive character in the context of the social relations of our work and that this relation organises what we bring to bear upon the text as interpretive practices. (Smith, 1990, p. 154)

These discussions of the nonneutrality of transcription practices recognize that the analyst's practices of hearing and seeing, of interpreting and making sense of the scene, are always present in the text (transcript). The transcript is a product of the analyst's interpretive practices whether the notations used are innovated or whether they are conventionalized (as in the Jefferson transcription system: see Atkinson & Heritage 1984; Psathas & Anderson, 1990; or as in systems described in Edwards & Lampert, 1993). These practices are not individual: methods of hearing and seeing events are aspects of culture and are shared within language communities. Their sources are social as well as their effects in the representation, the transcript. It follows also that the process of transcription is itself a literacy practice. What transcribers do is to turn the spoken into the written in a way that is readable by other members of the research community. In attempting to preserve something of the aural and visual quality of the spoken or performed event, transcribers also attempt to transcribe so that a sequence of talk and interaction can be (imaginatively) heard as well as seen (Schenkein, 1978, p. xi; Mishler, 1991, p. 277).

TRANSCRIPTION AS TEXTUAL REPRESENTATION: AN ILLUSTRATION

Illustration of many of these points can be made with reference to a study in early literacy in which it was observed that beginning school reading books contain considerable amounts of speech written down in the form of text characters

talking to one another. This textual device could be designed to assist young students in the transition from oral to written language competence. In a study of the texts of beginning school reading books, Baker and Freebody (1989, pp. 75, 76) have shown some of the many ways in which "talk" can be reported on paper, each way itself characterizing the speakers in the "original" scene, the writer's relation to the heard talk, and the writer's implicit characterization of the interests of the reader of the text. The texts used here are fictional. There is no audio or video record of an "original" scene. This set of texts together serves a heuristic purpose for making points about how spoken language can be represented in writing, but they do not exhaust the possibilities.

Version One

Jill complained that her doll Bumpity had bumped into the toy-box. She inquired of Jack if he could assist her in opening it. After a little consideration and after examining the box, Jack declared that he was unable to open it, whereupon Jill suggested that her father would know how, since it has been his, and that they should take it downstairs to him.

Version Two

"Oh, dear!" said Jill
 "Bumpity bumped into the toy-box,
 and I cannot get it open.
 Jack, can you help me?"
 Jack looked at the toy-box.
 "I cannot open it," he said.
 "This is an old toy-box".
 "Let's take it down to father,"
 said Jill.
 "It is his old toy-box.
 He will know what to do with it".

Version Three

Jill	Oh, de:ar—Bumpity bumped into the toy-box and I can't get it open Jack—can you help me? (frustrated) (3.0)
Jack	I can't open it—this is an [old toy-box
Jill	[Let's take it down to father— it's his old toy-box—he'll know what to do with it.

In version one we have a highly "literate" characterization that on the one hand dispenses with an interest in actual words spoken while on the other hand uses various speech act verbs that characterize literate discourse (Olson & Astington, 1990). This particular usage makes the text characters, Jack and Jill, into literate, purposeful, logical, and methodical interactants. The text is written as if the narrator/reporter could know what is going on inside the heads and intentions of the speakers, as in much literary fiction. Note that as readers of the report we are heavily dependent on the narrator's characterization of who said what and how it was said. The use of indirect speech to characterize the gist of what went on, verbally, is akin to everyday descriptions of past events in which the actual words spoken are not accented through quotation marks.

In version two, the characters do their own speaking, and the narrator's metatextual voice is less visible/audible. The preferred verb of description is "said," which is less implicative of motive, purpose or effect than the verbs employed in version one. If Jill and Jack are still purposeful, logical and methodical interactants, this is accomplished here primarily through the grammatical and cooperative quality of their speeches, as conveyed in the reported talk. Version two should be recognizable as a segment from a basal reading series. It illustrates one way in which the written "representation" of oral events is presented in early reading materials (see also Baker & Freebody, 1986). Baker and Freebody surmised that this form of "representing" oral conversation is an implicit model for how children should talk in classrooms—in complete, correct sentences, one at a time. In comparison with version three, it is both idealized and undernotated, containing the straightforward reporting of what was said and done, in what order, and little else.

Several points can be made in relation to version three in light of transcription issues. In this version, the actual words and their sequential placement, an overlap, a prolonged vowel, and other devices indicate some of the auditory qualities of the speakers' interactions. The narrator disappears, replaced by a hypothetical transcriber. Note that in this version, the talk is represented in an ever-present tense, while in the previous two versions, the descriptions assign these events to history. This form of representation assists the convention used in most analyses of transcripts to comment on the talking and doing in the transcript in the present or present progressive tense (e.g., "Carol looks down at the book" or "teacher is pointing to the text"). In this way, analyses treat stretches of text as "as-they-happen" exemplars of what could occur again, rather than as historical records of unique events. This textual device helps construct the ordinariness, the routine character, and the replicability of events, and is part of the authentication process by which transcripts are assigned to an ever-present reality.

But in other respects, and inevitably, the auditory has been imbued with the character of writing. Ochs (1979, p. 61) raised the issue of whether people's speech should be represented phonetically or in terms of strictly standard orthography, resolving in favor of the modified orthography used in version three (see also Gumperz & Berenz, 1993, pp. 96, 97). A criticism of using modified orthography is that we can effectively construct our speakers as ungrammatical. Gumperz and Berenz (p. 97) warn about "diagnosis of participant categorization" through orthography choices, "especially in cases of stylistic mismatch among participants." Another issue arises in transcribing across accents: for example, American pronunciations are effectively captured in many conversation analysis transcripts. What is "said," what is "heard" and what is "written down" are not necessarily the same auditory phenomenon. Some auditory phenomena are difficult to represent: different kinds of laughter, for example (Jefferson, 1985; see also Du Bois et al., 1993, pp. 71, 72). Other points made by Heap (1982) are that people do not speak in upper- and lower-case letters. Similarly, they do not

speak "in" a right-hand column.

In version three above, the transcriber has described Jill as speaking in a frustrated voice but no parallel characterization of how Jack speaks is given. Hence the quality of Jill's speech is marked, while Jack's is left unmarked, as if he were speaking neutrally or normally. The marking of Jill's utterance in this way documents a course of reasoning and action that calls on the transcriber's knowledge of when and how a given utterance qualifies for marking against the backdrop of 'normal' or 'neutral' speech.

Aspects of the physical layout and the conventions of transcription systems—for example alignments of overlaps, putting question marks wherever there are rising intonations and not necessarily at the end of questions—are often initially counterintuitive practices for literate transcribers. A literate bias in transcription might produce representations of talk in ideal-literate form, as in version two, where we find *tidied-up* textbook versions of how people should speak. This literate bias might include transcribing grammatically, in phrases, sentences and clauses, with grammatically correct commas and full stops, even if the cadence of the speech can later be heard to violate these literate rules. Transcriptions of classroom talk often show student answers delivered with rising intonation at the end, indicated through question marks. Du Bois et al. (1993, pp. 55, 56) call this an "appeal" in which a speaker "seeks a validating response from a listener." These notations help construct textual portraits of students as seekers of validation from teachers: the analysis begins in the notation.

A transcript made with sequential organization (or some other characteristic) foregrounded, when studied closely, provides the transcriber and the subsequent reader with a particular way of hearing oral conversation, for example, in the Jefferson system as a finely tuned sequence of turns, rather than as parallel sets of statements or as a series of random sentences. In comparison, representations of talk-on-paper that separate different speakers' talk into different columns, for instance, structure a distance between speakers and/or their activities which can inform subsequent reading/hearing practices. Edwards (1993, p. 3), citing Ochs, comments that

arranging speaker turns one above the other gives the impression of symmetry and mutual interdependence between speakers, whereas arranging them in columns, one for each speaker, can give the impression of an asymmetry between them, with the left-most being the most dominant.

A comparison of these versions of a fictional interactional scene shows the kinds of reading practices that are called upon from very young readers in making sense of talk-on-paper: one of the earliest literacy practices encountered in school. The comparison of these versions also highlights some of the issues involved in transcription in terms of (1) the prereflective use of cultural knowledge in making practical decisions such as when speech warrants being marked as different from normal or neutral; (2) the use of formatting as a way of assigning qualities and relationships to text characters; and (3) the production of an interested,

constitutive representation of an interactional scene. Baker and Freebody (1986, 1989) argued that methods of representing talk in beginning school reading books were central to the constitution of childhood in early literacy materials.

ISSUES IN MAKING TRANSCRIPTS

Issues in transcription signaled by the preceding commentary include matters of description, matters of format and layout, and matters of depiction. Drawing on material from the literature reviewed and some additional illustrative cases, this section will address some of the practical matters involved in deciding how to characterize or represent people, their talk, their (inter)actions and the settings in which they interact.

Du Bois et al. (1993, pp. 45, 46) describe "broad" and "narrow" transcriptions:

... a fairly broad transcription... includes the most basic transcription information: the words and who they were spoken by, the division of the stream of speech into turns and intonation units, the truncation of intonation units and words, intonation contours, medium and long pauses, laughter, and uncertain hearings or indecipherable words. In a more detailed, "narrow" transcription, the transcriber would also include notation of, among other things, accent, tone, prosodic lengthening, and breathing or other vocal noises.

One practical consideration in making any transcript is how much notation to assign to the talk or action. This is normally decided in terms of what order of analysis is to be sustained with the transcript. Some aspects of formatting and speech delivery notation were introduced in the previous section. In the sections which follow, it is primarily other aspects of "broad" transcription that will be dealt with. The sources cited contain detail regarding the transcription of finer details of speech delivery.

The Indefinite Extendability of Description

The issue of the indefinite extendability of description is raised in a useful way by Schegloff (1988, p. 2), who makes the point that "'describing' is not only a feature, it is also a topic of social science inquiry." That is, how people do "describing" is a social activity that can be studied as a topic. This is because descriptions are the result of the reasoning practices that are used to decide how to describe something. This applies both to everyday, "vernacular" describing and also to description in social science. The problem is that because there is no limit to the ways in which any event, person, social (inter)action and so forth can be described, we need to decide some "selection principles" to guide how we describe what it is we study.

Ochs raised this problem by considering such matters as how much detail should go into a transcript, whether and how much the nonverbal should be notated, whether inflections should be included, and so on. Among the selection principles mentioned in her chapter are accuracy; economy (too much notation would make it difficult for a researcher to "sort out the forest from the trees") (1979, p. 50); prior knowledge of children, language and so forth, and the purposes of the research. Schegloff's (1988, pp. 21, 22) selection

principle is different. He claims that "[t]here is a line of response to the problem of multiple description which offers an alternative to the type of solution which finds the inexorable presence of value, presupposition or ideology."

... The crucial warrant that needs to be established for these descriptions is that they address aspects of the talk and other conduct which catch what is relevant for the participants.

The difference turns on whether we describe according to the displayed relevances of the participants in the scene or whether we describe according to the relevances of the researcher. Schegloff's ethnomethodological solution has not been applied consistently in literacy research. Descriptions are not always or necessarily connected to what the participants take themselves to be doing, or more precisely, how they characterize what they are doing in the course of doing it. Participants in everyday interaction do description and analysis no less than do researchers of those interactional scenes, thus providing researchers as well as each other with indications of the local relevancies in the setting (see also Baker, 1992).

Speaker Identification and Membership Categorization

The questions of how speakers in an interactional scene are identified, how they are characterized as speaking, and what they are characterized as doing, connect the issue of how the talk is heard by the transcriber/analyst with the issue of description, and through that how the procedures of transcription textually produce versions of social order.

Speier (1972) raised the problem of "speaker identification" as a general problem for conversational analysis. He wondered how transcribers/analysts could arrive at an appropriate characterization of the identities of the speakers in a conversational site. To what "membership categories" should they be assigned? The principled solution to the problem of who are these interactants speaking as, on any occasion, is found in identifying the self-characterizing work and scenic practices of the speakers themselves. Within an informal conversation, we can formulate our speaking as, say, educator, or parent, or woman, or friend. (This does not guarantee how we are heard as speaking, which is a problem *inter alia* of gender politics.) As Zimmerman (1992, p. 50) has described, "participants exhibit for one another (and for the analyst) their appreciation of who, situationally speaking, they are, and what, situationally speaking, they are up to." A further problem is that the identities adopted by speakers within a sequence of talk, or those attributed to them, can change.

Transcribers of classroom talk would normally take it that the interactional site 'naturally' contains the positions and identities of teachers and students, or in the case of early schooling, the relevant category-pair is often taken to be "teacher-children", which assigns a generational relevance to what is said and done. Having determined that classrooms contain the category-pair "teacher-student" as the essential frame for the analysis, this frame then informs the hearings that are made as well as the physical presentation of the transcript. This is a commonsense hearing of what kind of

setting this is, and whatever the identifiers, classroom talk is often immediately recognizable as just that kind of talk (Heritage, 1984, 280–290).

But it may not be warranted to treat the entire recording as a record of people speaking as teacher and students. An example from classroom talk will show the problem. This segment is drawn from a transcription of a 7th-grade lesson on sex roles in the middle ages and sex roles now, that was video recorded in a coeducational secondary school in New South Wales (see Baker & Davies, 1989). The relevant segment is a stretch of “teacher–student” talk about “poor women” in the middle ages:

- | | | |
|----|---|--|
| 60 | C | Cooked the meals for their husbands? |
| 61 | T | All right. What sort of stove did they have Charlie? |
| 62 | C | One () |
| 63 | T | Pardon? |
| 64 | C | Just an open fire () fire () hot. |
| 65 | T | (Don't Keith). What would that have meant; when they're cooking meals what would they need to have done before they could cook their meals. |
| 66 | C | Prepare it |
| 67 | T | Good—like doing what |
| 68 | C | Um |
| 69 | T | Pardon? |
| 70 | C | Um—starting the fire |
| 71 | T | Good. So. Getting all the wood—hmm. Martin? |
| 72 | M | They didn't have much meat so they had to get the water to boil the vegetables in. |
| 73 | T | Great, where did they get all the water from, John? |
| 74 | J | Um |
| 75 | T | Turn on the tap? |
| 76 | J | No, go down to the river or the moat or whatever. |
| 77 | T | or to the well. Yeah and draw the water. Good. ((writes on the board for five seconds)) Right. That'll do. Go across to the men. Oh, ho, what do <i>we</i> do in the old day, Penny? |
| 78 | P | The rich men would—um—rule? Or make sure the servants are doing their work. |
| 79 | T | Good. Right. We were the <i>rulers</i> —yes—give <i>orders</i> . We've changed since then haven't we? Do we give orders now? Stand up, Penny! No. Of course we don't. What else do rich men do, Diana? ((During the course of this delivery, the camera is on the face of a girl sitting in front of Penny. First there is a look of puzzlement, then a smile (of relief?))) |
| 80 | D | Go hunting? |

It seems that for most of this segment, the participants are speaking as teacher (of “history”) and students (of this same “history”). At line 77, what we noticed was a shift in self-assigned identity, in that at this point the teacher calls into relevance his identity *as a male*, and in doing so calls into relevance for what follows the gender identities of all the participants. It can be noticed that all those who have spoken on the topic up to this point have been boys. If the shift occurs from speaking as a teacher to speaking as a male on this occasion, similar shifts can occur in multiple ways. Gender can be used as topic and resource in talk. This shift by the teacher raises the problem whether it is plausible to describe all the preceding talk as gendered talk, even before any speaker has called one's gender into relevance. Is it appropriate to describe the whole preceding segment, (1) as talk “by

boys” (an analyst's category), (2) as talk by “some of the students” (another analyst's category), or (3) as talk “as boys”? To describe the participants as talking “as boys” is a stronger formulation that may not be warranted upon inspection of how the speakers themselves formulate who they are, doing what. To describe them talking “as boys” holds the student speakers “accountable by gender” for what they say. This problem is endemic to studies of gender in interaction where talk is gendered by the analyst (boy(s) said/did x, girl(s) said/did y) without reference to the membership categories being claimed by the speakers themselves.

To extend this problem into the visual accompaniments to this talk: the visual scene of the “joke” in line 79 assists in our hearing of and analysis of the latter part of this sequence. The teacher's “joke” was aimed at Penny, presumably to create a “funny” confusion of whether she was a target of “rich men giving orders” in the middle ages or a student target of a teacher in the here-and-now, or a female target of a male order-giver in the here-and-now. The analysis is made more complicated (and, alternatively, assisted) by the fact that the video recording does not show Penny's face during this speech by the teacher, but shows the face of another girl sitting in front of Penny. This girl's face looks blank for the first part of the speech, then puzzled / slightly frowning, then relaxes into a smile. It took a while for the “joke” to be understood *as a joke*: that Penny was not expected to obey the order to “stand up.” That we saw some doubt in the girl's face and that we then saw (what we think is) relief, is part of our work of characterizing this classroom lesson as presenting to students both a formal lesson message—that men and women should be equal—and an interactional subtext that simultaneously undermines that message. We also commented at various points on the teacher's use of his friendly, affectionate relationship with the students to effectively silence the girls. This is also a moral commentary. The analysis, then, was concerned with the politics of gender-talk in this particular lesson. In the course of analyzing lesson-knowledge and gender-talk, we produced an account of the politics and the moral ordering of this mixed-sex classroom, in which account the transcript was a central prop.

The question of who is speaking how to whom is related to the Quinean problem of opaque and transparent contexts of reference and attribution discussed by Coulter (1989, p. 47): an “opaque” description is one that is faithful to how the participant could have heard or seen some object or event while a “transparent” description can be provided by the analyst independent of how the participant could have seen it. We constructed the teacher as playing gender-games—addressing Penny “as a girl”—although there is no guarantee that he did. Moral implications of this problem of transparent and opaque descriptions have been identified by Jayussi (1984), showing how a reporter's categories of identification are part of the moral ordering involved in describing *any* social scene.

The Format and Layout of the Transcript

Ochs (1979) provides a detailed discussion of the textual effect of alternative transcript layouts. Transcript layout is

one aspect of the broader issue of mapping conversations (Green & Wallatt, 1981). Ochs mentions the literacy-related point that the material presented to the left is given primacy in the reading of a transcript and that choice about where to place nonverbal descriptions accentuates or demotes the importance of these. Hence the repetition of layouts such as:

- T Why did the farmer wear the boots, Jason?
Ja 'Cause 'cause he needed to walk through the mud to get to the barn? ((quietly, head down))

produces a reading and a characterization that is different from the repetition of layouts such as:

- T Why did the farmer wear the boots, Jason?
Ja ((quietly, head down)) 'Cause 'cause he needed to walk through the mud to get to the barn?

Similarly, if some speaker identifications are placed to the left of others or if multiple columns are used, some speakers are in effect given the initiative by coming first on the left of the page (cf. Ochs, 1979, p. 51).

- T Why did the farmer wear the boots, Jason?
Ja 'Cause, 'cause he needed...
T Good. He needed them.

Rather than repeat all of the pertinent points that Ochs makes about layout, only some points from her work will be extended here. One point is that transcribers give a speaker interactional priority through layout, influenced by cultural assumptions. This in turn influences possible readings of the transcript. In this way the transcript can easily reproduce a social organization of age relations in which adults are given priority. Second, Ochs' claim (1979, p. 49) that "the researcher may be quite subtly influenced by an adult's status as caretaker or competent speaker in *letting* this figure assume the predominant location on the page of description" (my emphasis), should not be taken to mean that no work is involved in the decision. That work is precisely an example of the use of a course of practical reasoning within a culture in which adults are 'naturally' seen to be in control. In fact, this idea, "let the adult go on the left" is a perfect analogy to formulations like "let ABC define the angle x " in a mathematical proof. The third point is that Ochs suggests that in transcription we can counter cultural biases with deliberate transcription choices, for example, by prioritizing the utterances of the student or child. That in itself would be another case of the use of a course of practical reasoning and action that, in this case, is sensitive to the social effects of writing the transcript one way or the other. That is, transcription is a form of social practice, a form of textual action and activity that reproduces, modifies or challenges relations among categories of people.

Another aspect of layout that is significant for how a transcript is read is the division of speech into analytic units. Du Bois et al. (1993) discuss intonation units and turns as fundamental divisions. In their system of transcription, each intonation unit is a "stretch of speech uttered under a single coherent intonation contour" and "each intonation unit appears on a separate line" (pp. 46, 47). Speaker identifications show turn beginnings, and within these turns at talk succes-

sive intonation units are presented on subsequent lines of text according to intonation contours. Similarly, Gumperz and Berenz (1993, p. 95, 96) attempt to capture the "rhythmic organization of the turn" through division of turns into "informational phrases." Green et al. (1988), and Bloome and Theodorou (1988) use "message units" of teacher talk to organize transcription from videotape, with nonverbal and other contextual information put in a right-hand column.

Psathas and Anderson (1990) also draw attention to transcription issues, including numbering and denoting turns and utterances, denoting silences and deciding on where to assign pauses. Among the points they make about details of silences (p. 89):

The 'location' of a silence has considerable significance in interaction. That is, a half-second pause occurring in the middle of someone's turn while, say, they are involved in a 'word-search' (a *within* turn silence) is a far different interactional matter from a half-second pause following the production of the first part of an adjacency pair, such as a 'question' or a 'request' (a *between* turn silence). While this is frequently a straightforward matter, occasions do arise where the 'ownership' of a spate of silence is in question, and can be central in the analysis.

A segment from a kindergarten literacy lesson illustrates this question of whose silence the pause is made out to be:

- 6 T Smarty pants, right. And *who* is Smarty Pants, do you think? Just by having a look at him on the front cover. Who do you think he is, Rachel?
7 R A clown
8 T A cu-lown right. Well turn over the front cover until we come to the *first page*. What can you see on that page what is he doing Linda?
(3.0)
9 T What is he doing? (2.0) Is he standing up like we stand up? His two feet? What's he doing, Sally Fraser?
10 S He's he's he's standing upside down.

This transcript was made from an audiotape. If the 3.0 second pause were attributed to Linda, this would make it her hesitation, calling into question her competence to answer. The audiotape cannot indicate the local circumstances of the silence, which could have included any number of matters concerning attention, gaze, or other situational factors. Transcribing the pause as a silence in the sequence of turns does not entirely vindicate Linda, given the placement of the pause and given readers' knowledge about classroom questioning routines. However, it is less implicative than transcribing it as Linda's pause (see also Edwards, 1993, p. 24; Gumperz & Berenz, 1993, pp. 93, 102, on the significance of assigning pauses). Atkinson and Drew (1979) show the significance in courtroom hearings of the assignment of pauses, hesitations or silences to speakers. The character or competence of the witness (e.g. Linda) can be at stake.

Depicting the Nonverbal

These observations on the production of transcripts also apply to making written/graphic records of nonverbal activity. With the increased use of videotapes even more selection decisions are encountered. As Bloom (1993, p.155) describes,

The amount of detail that is preserved on video tape is, quite literally, enormous, even though the information present in the original event is necessarily reduced. ... This detail can be overwhelming to the researcher in trying to decide what to include and what to leave out of the transcription. In the effort to preserve a description rather than an interpretation, we could easily be engulfed by the details.

Bloom's suggestion here is that transcribers of videotaped material see themselves not as describing the scene, but necessarily as interpreting. As indicated before, this resolves the issue from the start that any transcription is an interested representation of some of the possible features of the scene.

Ochs (1979) provides an extensive discussion of the representation of the relation between the verbal and nonverbal in transcripts. Descriptions of nonverbal features of literacy scenes involve additional and different kinds of attention, and these descriptions are also strongly informed by a researcher's analytic point or purpose.

Among the decisions Ochs reviews (1979, p. 52ff.) concerning the relation of verbal to nonverbal in the recorded video scene are whether the nonverbal should be placed to the left or right of or above the verbal material; whether the verbal and nonverbal should be separated into columns, thus creating two discrete streams of action; and whether the nonverbal should be bracketed, thus making the verbal the primary stream of action.

Ochs points out (1979, p. 56ff.) that since in the case of young children's talk, features of the immediate physical setting are important props in the organization of talk, these are fully part of the communicative scene and necessary to understanding the scene. In the following example (p. 56f.) the child had been indicating the relevancies in the scene:

This description [of talk, action and items in the child's reach] indicates the amount of nonverbal data that needs to be recorded to assess the nature of reference and other speech acts carried out by the child. For example, without indicating accompanying nonverbal behavior, we would not know if *steamroller* and *car* named the same referent, and we would not know the referents for the deictic terms *here's*, *here* and *that's*. The detailed recording of accompanying movements and eye gaze is, then, not superfluous to an analysis of communicative competence.

The problem of describing the nonverbal aspects of an interactional scene can be expressed as the problem of 'capturing' some theoretically, organizationally and locally pertinent details of the scene. The challenge is to produce a selective but theoretically useful *depiction* of the scene, which is partly analogous to the problem of captioning a photograph (cf. Woolgar, 1988) or headlining a newspaper report (McHoul, 1982, p. 118ff.). The problems of nonverbal depiction are ones in which the technical and theoretical problems of transcribing talk are potentially multiplied. At the same time the interplay of verbal and visual depiction can become reciprocal resources in making a theoretical point, or in finding new interests in the material.

Transcribing practices are also enabled and constrained by the kinds of recording that have been made. In classroom studies, for example, researchers using only a single video

camera will have to privilege some activities over others. Bloome and Theodorou (1988) used a videotape in which the camera stayed on a group of students; the teacher could be heard on the tape. In transcribing the videotape, the teacher's verbal communications were entered into a left-hand column. The right-hand column in which the students' actions and interactions were represented is far more elaborate, including stick figures depicting positions, postures and actions of the three girls. This is consistent with the intent of the study. The stick figures are powerful indicators of how little the girls were physically oriented to the teacher during the 5-minute segment recorded. In the transcript, the teacher appears as a disembodied voice off stage and to the left.

TRANSCRIPTION AS A COMMUNICATIVE AND VISUAL ART

In Davies and Munro's (1987) analysis of "order in apparent disorder: a classroom scene observed," the videotaped "scene observed" was/is apparently (on first or commonsense viewing) "disorderly." A student was initially viewed as intensely disruptive, quite out of control. Upon close analysis of moment to moment talk, action and interaction, and drawing on particular theoretical resources, the authors showed him to be acting rationally inside the moral organization of that classroom scene. This interpretive feat was accomplished with the aid of illustrations to accompany descriptions of verbal and nonverbal aspects of the scene.

The Picasso-like sketches made from tracing over video stills depict just those elements—no fewer and no more—of the postures and movements of the classroom participants that the analysis depends on. These sketches, following Livingston's (1987) discussion of proof-accounts in geometry, are potentially better than, and more elegant than, a photograph or a video still. They "capture," not the scene itself in some essential way, but what the researchers have attended to and found pertinent in the course of observing the relation of talk and action.

The transcript and the representation of the visual scene observed are interpreted with the surrounding text: the discussion. It is in the discussion that features of the transcript are highlighted and a particular story is told about the talk and action. Thus the transcript, as indicated by Mishler (1991) is part of a rhetoric and part of an aesthetic. "Cultural values and political ideologies provide additional interpretive vantage points to locate the social, cognitive or affective relevance of, for example, unfamiliar-looking persons or activities as exotic, sympathetic or dangerous" (p. 258).

In another classroom study using videotaped sequences, Paoletti (1990) examined the fine detail of the coordination of teacher's talk and action and students' talk and action. This study was framed by the idea that a classroom is produced through participants' descriptions and actions in the everyday course of their interactions, and that the classroom is produced differently by different participants. The study was written to resist singular interpretations of the classroom, and to use recorded data to open out different interpretations

which would lead to different possible subsequent courses of action. The published study included a number of transcribed classroom scenes with intervening discussion and analysis. Each of these transcriptions included verbal and accompanying nonverbal activity. These included "the year six girls" who were constructed as a group by the researcher on the basis of categorization done by the participants (teacher and students) themselves. The researcher presents the following scene in illustration of her witnessing this group's relationship with the teacher (pp. 130, 131):

- | | |
|---------|--|
| Teacher | Move one of those desks over there and have a group of five girls. ((desk is moved)) |
| Teacher | Jessica () paint |
| Jessica | ((Jessica whispers something to the teacher)) |
| Teacher | You just said you want to paint! (Go and sit there please.) ((annoyed expression)) ((Jessica sits down, head on hand; the teacher stands near Kate's desk and says, looking at Kate:)) |
| Teacher | Why is she upset? |
| Kate | I don't know. ((Kate answers the teacher looking at her and keeping eye contact with her.)) |
| Sarah | She just doesn't want to sit next to us. |
| Teacher | Yeah, why? |
| Sarah | ((I don't know,) you ask her. ((The teacher looks at them and then turns left and walks towards another group of desks.)) |

Paoletti (p. 131) states in relation to this scene: "The coldness, distance, awkwardness, and discomfort in this relationship became increasingly evident to me as observer, but was very subtly conveyed." This summary statement is similar to a caption to a photograph. The transcription attends considerably to eye contact as this had been identified *in situ* as an indicator of a problematic relationship between the teacher and these girls. Other groups of students were described in terms of their habits of distance or closeness in relation to the teacher.

In her account of the teacher's and students' collaborative work in constructing classroom order, Paoletti (1990, p. 132) offers the following demonstration from videotape:

- | | |
|---------|--|
| Teacher | ((To the class)) Right, by now everyone should be finished drawing and you should be up to the coloring and it doesn't have to be a marvellous decoration to hang on the wall, one colour is fine, and coloring very quickly is also fine, so you have to find out what to do next.
((At the word "drawing" all the children stop talking. After the teacher stops talking, for 10 seconds, the children keep silent, then a child starts to talk and others join in and, in about another 10 seconds, the level of noise is back at the situation before the teacher began to speak. The teacher keeps going around the desks.)) |
|---------|--|

This coordination of timing of teacher talk and student silence is shown to be repeated. The transcript is presented to show the precision with which the students hear and respond to the teacher's organizational talk and their level of cooperation with her. Once the phenomenon had been noticed in viewing and reviewing the videotape, a stopwatch was used to calculate the synchrony. The precision of the timing indicated in

the commentary represents the precision of the timing in the classroom. In this way the students as transcript characters are assigned a highly tuned attention to the teacher's organizational talk.

The transcription of videotaped scenes provides for the development of unique and creative responses to the challenges outlined in this chapter. In this sense transcription could be taken itself to be a species of "visual and communicative art."

THE TRANSCRIPT AS AN ACCOUNT OF THE PRACTICAL REASONING THAT PRODUCED IT

In his analyses of the proving of a Euclidean theorem, Livingston (1987) has traced the relation between the "lived work" of producing a proof, and the proof account (the text, the written proof that is given as a record of what was done). Each comprises half of the proof. The proof account (that which is written down in the course of proving) is a "guide to the practical action and practical reasoning that it is seen retrospectively to summarise and describe" (p. 100). Not all the reasoning and the choices and conventions that go into the work of proving appear in the proof account, although the proof account describes the kind of work that went into its own production. Livingston states that the proof "has its own texture of necessary and relevant—or identifying—detail" (p. 111). Like the proof account, a transcript is "a description of its own lived work" (p. 112). In reading a transcript we can recover how it was that this transcript could have been arrived at, and we can find the logic that went into its production. Paoletti's transcripts and commentaries provide well for this recovery.

This point about reading the "text" of a literacy event as an account is also informed by Smith's (1990, p. 153) interest in how texts are written and read:

In the process of writing, making corrections, in thinking again about how to address a topic, in thinking through a topic so that it can be first thought, then expressed, adequately, clearly, and well, a text is developed that depends upon and intends the interpretative schema that has entered normatively into its creation. In the production of the text the same circular process is at work as that which arises between text and reader. Hence the text can be said to intend interpretive procedures as those practices and methods of reading which will read it for the sense intended.

Transcripts, then, are accounts of the theoretical and analytical work that went into producing them. Making transcripts is part of the work of making sense of what is observed in recorded sounds and images. Making sense of events seen and heard involves characterizing them in some way, assigning some kind of order to them. The transcription process imposes structure and order on events in the "pre-textual" realm of everyday life. What structure, order, meaning, rationality or morality those events are made to have are products of the work of transcription. Transcription, in this sense, is a process of theorizing and demonstrating social order; the transcript is an account of that theory of social order.

METHODOLOGY IN TEACHER RESEARCH: THREE CASES

James F. Baumann, Betty Shockley Bisplinghoff, JoBeth Allen

UNIVERSITY OF GEORGIA

We found the prospect of becoming teacher researchers intriguing but also somewhat daunting. We imagined all research to be a tangle of experimental groups and control groups, double-tailed *t*-tests and analyses of variance. We doubted our competence and questioned our willingness to commit ourselves to the effort we knew such a project would require. We did, nevertheless, commit ourselves, because we felt it was important for teachers to take advantage of every opportunity to speak and be heard, to develop a voice, and to establish their credibility concerning educational issues....

[W]e came to believe that classroom research certainly could be done by teachers and that it was not necessarily a statistical analysis of a treatment applied to an experimental group. Our best insights came from observing and documenting our daily process. One team member commented:

You have a question, you're willing to document the process you go through [to answer it], and you're willing to share it in the end. That's what we need—people who will share their stories.... It's important that this kind of work comes from us, comes from teachers who are really teaching children and know. (Keffer et al., 1995, pp. 2, 4)

Keffer and her colleagues are teacher researchers in the School Research Consortium (SRC), a teacher-research community affiliated with the University of Georgia site of the National Reading Research Center (NRRC) (Baumann, Allen, & Shockley, 1994). Their reflection on the process of becoming teacher researchers is similar to that of other teacher researchers within the SRC (Allen, Shockley, & Baumann,

1995). Most initially doubted their ability to conduct research, feeling overwhelmed by the technical aspects of conventional research methods. However, with a commitment to classroom inquiry founded upon the desire to improve their own teaching and supported by committed colleagues struggling with the same issues, SRC members sought out, adapted, and sometimes created research methods for teacher inquiry (Baumann et al., 1995). A desire to understand the complexities of their classrooms, to improve their effectiveness as teachers, and to share their knowledge with others through stories provide SRC members the impetus to engage in research.

But what is teacher research, and what are the methods of teacher inquiry? Is there consensus about the characteristics of teacher research? Is teacher research an adapted or hybridized form of existing educational research paradigms, or is it a distinct research genre? Do teacher researchers simply borrow methods from established forms of disciplined inquiry, or is there something methodologically distinct about teacher research? Do teacher researchers tend to use similar methods, or does teacher research represent a wide array of methods and analyses? In this chapter, we address these and other questions relating to methodology in teacher research.

We do so by first surveying the tradition of teacher inquiry and the methods that have been recommended or employed, highlighting the historical and contemporary diversity of teacher-research methods and opinions about them. Next we

The research described in this chapter, as well as the writing of the chapter itself, was supported by the National Reading Research Center of the University of Georgia and the University of Maryland. The NRRC is supported under the Educational Research and Development Center's Program (PR/Award No. 117A20007) as administered by the Office of Educational Research and Improvement, U.S. Department of Education. The findings and opinions expressed here do not necessarily reflect the position or policies of the NRRC, the OERI, or the U.S. Department of Education.

We thank Dr. Dera Weaver, an English teacher at Athens Academy, and Dr. James McLaughlin, a professor of Elementary Education at the University of Georgia, for their thoughtful, detailed, and constructive comments on earlier versions of this chapter.

present three cases of teacher inquiry and associated methods. We describe cases that range from a solitary classroom inquiry to a teacher-research community. Case one, told by Jim Baumann, involves his experience as a solo teacher researcher in the year he left the university to teach second grade full time, during which he explored the journey he and his students took toward literacy. Case two, told by JoBeth Allen, is a methodological story of collaborative inquiry in which Betty Shockley Bisplinghoff, a 1st-grade teacher, Barbara Michalove, a 2nd-grade teacher, and JoBeth, a university researcher, worked together on a multiyear investigation of literacy acquisition by low-income, diverse elementary school children and their families. The third case, told by Betty Shockley Bisplinghoff as Coordinator of the SRC, explores the methodological diversity within the NRRC's teacher-research community. We conclude the chapter with our collective thoughts and reflections on methods for classroom-based inquiry.

We present these cases not as comprehensive of the range of teacher-research perspectives, nor even as being representative of those we describe (all our stories are unique in their own ways). Rather, the cases reflect the diversity within the domain of teacher research, a major theme of this chapter. By necessity, we focus on teachers rather than students because it is teachers who are in search of appropriate and useful methodology. However, we acknowledge that although professional growth and development are essential features of teacher inquiry, the ultimate purpose of the enterprise is to promote the educational, social, and emotional well-being of the students we teach in classrooms.

METHODOLOGY SURVEY

In this section, we provide a short historical review of teacher research, followed by a discussion of the fundamental principles that constitute teacher research. We then examine the diversity within teacher research perspectives and conclude with thoughts on the paradigmatic identity of teacher research.

A Brief History of a Long Tradition

Historical treatments of teacher research recount a long and robust past, with notable periods of interest and disinterest in the movement. McFarland and Stansell (1993) trace the roots of teacher research from 17th- and 18th-century theologians and philosophers, such as Comenius and Rousseau who advocated observation as a foundation for child development and learning, to 19th-century European educators such as Pestalozzi and Herbart who developed and used naturalistic methods of observation for studying teaching and learning. Olson (1990b) presents Francis Parker's and John Dewey's experimental schools in the United States and Lowry's (1908) involvement of teachers in research efforts as evidence of inquiry-based teaching at the close of the 19th century. Lytle and Cochran-Smith (1994) cite Dewey's (1904) promotion of teachers' reflection on their work as a critical milestone in the history of teacher research. With the advent of psychological

testing in the 1920s and 1930s, however, the prominence of teacher as inquirer diminished in relation to the rise of experimental investigations (Olson, 1990b), with interest not to resurface in earnest until after World War II.

All those who examine the history of teacher research (e.g., Lytle & Cochran-Smith, 1994; McFarland & Stansell, 1993; Olson, 1990b) point to the action research movement of the 1950s as evidence of the resurgence of classroom-based inquiry. Corey's *Action Research to Improve School Practices* (1953) was representative of a large body of work (e.g., Corey, 1954; Shumsky, 1958; Wann, 1952; see a review by Wallace, 1987) that promoted teachers' examination of their practice as a means to improve their teaching. Interest in action research diminished again in the late 1950s (see Olson, 1990b) due considerably to the criticism that research of this nature lacked scientific rigor (Corman, 1957; Hodgkinson, 1957). Nevertheless, some interest in action research continued through the 1960s and 1970s in the United States (e.g., Odell, 1976; Rainey, 1973) and to an even greater extent in Great Britain (e.g., Clark, 1972; Winter, 1982).

The significant British action research movement paralleled events in the United States, beginning in the late 1940s (Olson, 1990b) and blossoming in the late 1960s and early 1970s. It was led by Lawrence Stenhouse (1973, 1975, 1980; see Rudduck & Hopkins, 1985, for a collection of Stenhouse's writings), who formalized the action research movement with the creation of the Center for Applied Research in Education at the University of East Anglia. Through this center, Stenhouse promoted teacher research, often in collaboration with university faculty, as a means to engage in reflective action within classrooms and to promote teachers' status and professionalism. Stenhouse's colleague John Elliott (1991, 1993; Elliott & MacDonald, 1975) continued this work through the Cambridge Institute of Education, a teacher-research consortium whose members focused on locating and creating methods appropriate and useful for classroom research projects.

Since the early 1980s, there has been a virtual explosion of interest in, conducting and reporting of, and writing about teacher research. Current literature is filled with stories of teachers who turned to reflective, action-oriented teaching as a professional way of life (e.g., Bissex & Bullock, 1987; Cochran-Smith & Lytle, 1993; Goswami & Stillman, 1987). Over the last decade, teacher research has become an integral presence at professional conferences (e.g., numerous teacher-research presentations at the annual conventions of the International Reading Association and the National Council of Teachers of English) and within education periodicals (e.g., D'Alessandro et al., 1992; Dillon, 1988; Llorens, 1994; Teale, 1995; the initiation of *Teacher Research: A Journal of Classroom Inquiry* in 1993). Further, there has been a steady stream of published collections of teacher-research investigations (e.g., Allen, Cary, & Delgado, 1995; Daiker & Morenberg, 1990; Hansen, Newkirk, & Graves, 1985; Mohr & Maclean, 1987; Olson, 1990a; Patterson, Santa, Short, & Smith, 1993; Patterson, Stansell, & Lee, 1990; Pinnell & Matlin, 1989; Wells, 1994).

The prevalence of classroom inquiry as a methodological orientation for educational research by and with teachers has

not been reflected so widely in collections of research syntheses and perspectives. For example, as Cochran-Smith and Lytle (1990) note, the *Handbook of Research on Teaching* (Wittrock, 1986) fails to include reviews written by teachers and virtually ignores published teacher-researcher investigations (an exception being the methodology chapter by Erickson, who points to the power and promise of teacher researchers). Similarly, the first and second volumes of the *Handbook of Reading Research* (Pearson, 1984; Barr, Kamil, Mosenthal, & Pearson, 1991) have no chapters on, about, or by teacher researchers. The American Educational Research Association-sponsored *Complementary Methods for Research in Education* (Jaeger, 1988) fails to acknowledge teacher research as a method, and the National Conference on Research in English / National Council of Teachers of English-sponsored *Multidisciplinary Perspectives on Literacy Research* (Beach, Green, Kamil, & Shanahan, 1992) omits teacher research as a distinct perspective (although Moll, 1992, describes collaborative research with teachers in his chapter).

More recent volumes may indicate that teacher research has achieved some status within the established educational research community. For example, there is a chapter by Burton on teacher research within the International Reading Association / National Council of Teachers of English-sponsored *Handbook of Research on Teaching the English Language Arts* (Flood, Jensen, Lapp, & Squire, 1991); there is a "Teacher research in English" entry by Lytle and Cochran-Smith in the National Council of Teachers of English-sponsored *Encyclopedia of English Studies and Language Arts* (Purves, 1994); and, of course, there is the present chapter in this handbook.

In spite of the absence or delayed acceptance of teacher research within the realm of educational compendia, many individual writers have dealt with methodological issues. Buckingham's (1926) *Research for Teachers* may have been the first teacher-research "methods" text, and one of the few volumes available for many years, but a plethora of works is currently available (e.g., Brause & Mayher, 1991; Calhoun, 1994; Goswami & Stillman, 1987; Hopkins, 1993; Hubbard & Power, 1993; Kincheloe, 1991; Mohr & Maclean, 1987; Myers, 1985; Nixon, 1981; Oja & Smulyan, 1989; Sagor, 1992). But what are teacher-research methodologists reporting? What consensus or diversity is there under the broad umbrella of methods suggested and used in action and teacher research?

Principles and Consensus

In spite of considerable philosophical and methodological diversity within the teacher-research movement, there are several important common principles. One involves the perspective and process of classroom inquiry. Virtually all accounts refer to a teacher researcher's unique perspective, that is, a teacher's daily presence and intimate relationship with the research situation and participants. This insider, or emic, perspective (Cochran-Smith & Lytle, 1993, p. 43) enables a teacher to live the research experience in a

manner an outside (e.g., university) researcher cannot. Atwell (1993, p. ix) argues that the emic perspective brings power and insight to the research process: "My admittedly subjective role as provider for and teacher of these students, which I was careful to describe, did not negate my findings. My role as teacher made my findings possible, it made them specific and context rich, and it made them valuable to many of the teachers who read about them." Erickson (1986, p. 157), however, suggests that the emic nature of teacher research may simultaneously be a limitation: "In some ways the teacher's very closeness to practice, and the complexity of the classroom as a stimulus-rich environment, are liabilities for reflection."

A principle related to the insider perspective of teacher research is the interrelatedness of theory and practice and the critical reflection on them, that is, the notion of praxis (Cochran-Smith & Lytle, 1993; Kincheloe, 1991; Lather, 1986). Mayher and Brause (1991) see this process as theory building and fundamental to teacher research. They maintain that teaching practice stems from teachers' beliefs, or their theory of teaching. Therefore, a change in practice implies a change in personal theory. The process of theory/belief change involves "reflection-in-action of one's current practice; understanding and transforming research findings and theories so they can form the basis of practice; and sharing problems and reflections with colleagues both locally and nationally" (p. 23).

Another area of general consensus involves the fundamental elements of teacher research. Bissex (1987) states that a teacher researcher is an observer, a questioner, and a learner, all roles that result in a more complete teacher. Patterson and Shannon (1993) acknowledge differences among teacher researchers but describe similar fundamental qualities: "Diversity is a powerful characteristic of teacher research, but all researching teachers share a common process of reflecting on their practice, inquiring about it, and taking action" (p. 10). Burton (1991) also cites action and reflection as activities that teachers perform in classroom inquiry, but adds the element of reciprocity, that is, reflection leading to action and vice versa. Wells (1994, p. 26) takes these qualities and places them in an "action research cycle," which consists of four recursive components: observation, interpretation, planning for change, and action. Wells adds to these components the pervasive element that he calls the "practitioner's personal theory," which guides the research cycle. It is by making connections between practice and theory, Wells argues, that teachers create reflectiveness, the hallmark of teacher research.

Reflection and action alone, however, do not constitute teacher research. Although such qualities are necessary for teacher research and are likely to make one a better teacher, they are not sufficient for the process to occur. Teacher research must be a consciously initiated process that is implemented with a plan for data gathering and analysis. Patterson and Shannon (1993) state that "methods of inquiry need not be sophisticated, but they must be systematic" (p. 9). Cochran-Smith and Lytle (1990, p. 3) define teacher research as "systematic and intentional inquiry carried out by teachers." They elaborate as follows:

Systematic refers primarily to ways of gathering and recording information, documenting experiences inside and outside of classrooms, and making some kind of written record. *Systematic* also refers to ordered ways of collecting, rethinking, and analyzing classroom events for which there may be only partial or unwritten records. *Intentional* signals that teacher research is an activity that is planned rather than spontaneous. (Lytle & Cochran-Smith, 1994, p. 1154)

On the other hand, there is a fluid aspect to classroom inquiry. Hubbard and Power (1993) note that teacher-research methods might be “complicated and messy,” and “you cannot divide the process into neat linear steps” (p. xvii). Patterson and Shannon (1993) concur that teacher research is “organic, sometimes messy, unpredictable, and generative—just like the teachers’ lives in and out of school” (p. 9). In spite of this necessary flexibility and fluidity, teacher research is not amorphous. There is a structure to it as in other forms of disciplined inquiry (Shulman, 1988). The methodological structure of teacher research, as we will demonstrate in the following cases, involves organized documentation and data collection, systematic analyses, and thoughtful interpretations of results.

Epistemological Diversity

One characteristic in which teacher-research perspectives differ is in the manner in which knowledge is viewed and acquired. Cochran-Smith and Lytle (1993) offer a four-part structure of views of knowing through teacher research: “an approximation of university-based research; a more grassroots phenomenon that has its own internal standards of logic, consistency, and clarity; a reflective or reflexive process that is for the benefit of the individual; or a dialectical process of action and reflection aimed at social change” (p. 9). Drawing from this framework, we conceptualize the epistemological focus of teacher research as being established, pragmatic, or radical.

As Lytle and Cochran-Smith (1994) argue, some teacher researchers (e.g., Myers, 1985) take a fairly *established* approach, primarily viewing classroom inquiry as a means to replicate traditional, university-based methodology. This view of teacher research is much like the early iterations of action research, involving modification of extant educational research paradigms and tools to address hypothesis-testing types of teacher questions. Our conception of an established approach, however, goes beyond this quasi-positivistic view of teacher research to include teacher researchers who draw from existing research traditions, be they quantitative, qualitative, historical, philosophical, or others.

The *pragmatic* approach involves selecting or creating methodological tools and procedures appropriate for addressing teachers’ classroom-based research questions. Such tools are typically those employed in qualitative or interpretive research, but not always. Sagor’s (1992) five-step methodological process illustrates this pragmatic view: “The process of collaborative action research has five sequential steps: (1) problem formulation, (2) data collection, (3) data analysis, (4) reporting of results, [and] (5) action planning” (p. 10). Hubbard and Power (1993) represent the pragmatic perspec-

tive by offering various “research designs” (see chap. 3 and Appendix A) that teachers employed in their classroom studies. These designs typically involve question generation, selecting and collecting relevant data, data analysis, and reflection.

Teacher research, viewed from a *radical* epistemological orientation, is a means to free teachers from ideological constraints imposed by economic, social, and cultural conditions that impact education and teaching and learning in schools (e.g., Carr & Kemmis, 1986; Gitlin et al., 1992). For example, Berlin (1990, p. 14) likens teacher research to a militant exercise that involves a “long revolution.” Kincheloe (1991, p. 19) describes teacher research as “critically grounded action research” that presupposes, among other things, the rejection of positivistic perspectives and the underlying assumption that all in education is political in nature. Shannon (1990) urges teacher researchers to move away from action and naturalistic research toward critical research so that they can examine the politics of reading instruction and move toward the restructuring of the organization, goals, and procedures in literacy programs.

We place no relative value on these perspectives and readily admit that they are intellectual constructs to describe retrospectively the inquiry that teachers have done. Each perspective, with its differing assumptions about how to learn and know about classroom events, leads to different questions and thus different methods for addressing them. These multiple epistemologies support the emerging theme in this review that teacher research is defined and described by and through its diversity.

Paradigmatic Identity

We are left with the question of whether teacher research represents its own, unique methodological paradigm, or whether it is an evolutionary hybrid on the educational research family tree. Many teacher researchers and theorists (e.g., Bissex & Bullock, 1987; Mohr & Maclean, 1987) argue for its uniqueness, with Arwell (1993, p. viii) referring to a “new research paradigm.” We agree.

Cochran-Smith and Lytle (1993) assert that comparing teacher research with institutionalized (university) forms of research limits our understanding of classroom inquiry by teachers. Rather, they argue that “it is more useful to consider teacher research as its own genre, not entirely different from other types of systematic inquiry into teaching yet with some quite distinctive features” (p. 10). The variable features of teacher research, as Cochran-Smith and Lytle (figure on pp. 12, 13) describe, involve the ownership of teacher research, the nature and source of teachers’ research questions, the theoretical frames teachers bring to inquiry, and the generalizability and utility of what is learned. For example, with regard to research questions, Cochran-Smith and Lytle describe university-initiated research questions as “generally emerging from study of a discipline...and / or analysis of theoretical and empirical literatures,” as opposed to teacher-research questions “generally emerging from problems of practice” (p. 12). Our research on the evolution

of teachers' questions within the SRC (Baumann et al., 1994) supports the notion that the immediate, day-to-day realities of classroom life, not esoteric theoretical or empirical constructs, guide teachers in their inquiry.

As we attempt to demonstrate in the following cases, although distinctive from institutionalized education research, teacher research does not represent a routinized, prescriptive paradigm, nor do we believe it should. Rather, teacher research is an evolving philosophical orientation toward practical theory. Teacher-researchers wonder about the interrelated aspects of their work—who their children and care givers are, what their social and cultural experiences are, and what that means for teaching; they wonder what the curriculum shouts and whispers; they wonder what the political context of school and schooling says and hides. In short, they wonder how to do the work as best as they can.

Teacher research critics and skeptics may view this paradigm as lacking in structure and rules. That is not so as we have tried to demonstrate. Teacher research is not haphazard; it has definitive characteristics and principles of application. Indeed there is variety in how such principles are applied in the doing of teacher research, as each of us has experienced and as we shall demonstrate in the following cases. Therefore, we present these cases, not as comprehensive of the range of teacher-research perspectives, nor even as being representative of those we describe. The cases reflect the diversity within the domain of teacher research. Nevertheless, we believe that within this diversity emerge the essential qualities of the teacher-research genre: reflection and action through systematic, intentional inquiry about classroom life.

CASE ONE—INDIVIDUAL TEACHER RESEARCH: JIM'S EXPERIENCE

During the 1994–95 school year, I returned to teach elementary school full time after a 17-year hiatus, during which I had attended graduate school and worked as a university education professor. In the year back in the classroom, I conducted two teacher-research studies. The following narrative describes this experience and the methodological soul-searching involved in identifying and employing research perspectives appropriate for my teacher-researcher role. It is important that the reader realizes that, at the time of writing this (August 1995), I was only 2 months away from the classroom, and my studies were still underway (some data gathering continued and much analysis was before me). Therefore, my exploration of teacher-research methods continues, and this story does not yet have an ending.

Background

In 1994–95, I taught second grade at Fowler Drive Elementary School in Athens, Georgia. My position came about through a job exchange with Betty Shockley Bisplinghoff. Betty took leave from her teaching position at Fowler, where she had taught for 11 years, to come to the University of Georgia and pursue a doctoral degree in Language Education. At the

university, Betty taught my undergraduate Reading Education courses, while continuing to serve as Coordinator of the School Research Consortium.

I was assigned a 2nd-grade teaching position at Fowler. I prepared to teach by obtaining a Georgia teaching license, which required me to take a university course in exceptional children and pass a state-mandated teacher certification test; later I set up my classroom, designed my curriculum, and participated in new-teacher in-service. The first day of school was August 19, 1994, and from that point on, I taught all day, everyday for 180 school days, from 7:20 a.m. bus duty to after-school faculty meetings, Parent-Teacher Organization meetings, and evening homework and planning. I received no special privileges due to my university affiliation; rather, my duties and responsibilities were just like those of every other teacher at Fowler and in the district. My year in second grade was wonderful, exceeding my expectations with regard to the richness of my experience, what I learned, and what the children taught me (Baumann, 1995a, 1995b). An integral part of my teaching experience was to engage in yearlong, classroom-based inquiries through the NRRC's School Research Consortium.

In this case, I address methodological issues associated with classroom inquiry from the perspective of an individual teacher researcher. As noted in our introduction, each of these cases is unique and not intended to represent the experience of other individual or groups of teacher researchers. For example, my history as a university researcher, no doubt, influenced how I approached teacher research, and my research was supported by the NRRC. Further, I acknowledge that I was a novice teacher researcher when I began my year in second grade and, at this point, remained an apprentice at best. Nevertheless, I did teach full time while simultaneously studying teaching and learning in my classroom, and therefore was a teacher researcher in the fullest sense.

Methodological History

I have engaged in educational research for over 15 years. My doctoral program in the late 1970s involved learning how to conduct educational research within the quantitative, experimental tradition. I followed the experimental research path through much of my career, primarily conducting classroom-based intervention studies exploring the efficacy of various reading comprehension strategies and methods (e.g., Baumann, 1984, 1986; Baumann & Bergeron, 1993; Baumann, Seifert-Kessell, & Jones, 1992), although the manner in which I employed quantitative methods changed across these studies, primarily by increasing the external or ecological validity (Bronfenbrenner, 1976) through design modifications. I acknowledge the limits of quantitative, experimental research (see Baumann section in Baumann, Dillon, Shockley, Alvermann, & Reinking, 1996), but I continue to see value in research of this nature and may conduct additional experimental studies in the future.

In the past several years, however, I have expanded my repertoire of research methods in relation to questions that have not been readily answerable through the kind of experi-

mental / control group studies I conducted in the past. For example, during the 1993–94 school year, two 5th-grade teachers, Helene Hooten and Pat White, and I explored how to integrate planned, teacher-led instruction within a literature-based reading program framework (Baumann, Hooten, & White, 1996). Our purpose in this study was not to determine *whether* strategies could be infused within a literature-based framework; we felt confident that they could on the basis of extant research and our own experiences. Rather, we desired to find out *how* such a program of instruction could be designed, created, and modified to be as effective as possible. To answer this question, we selected an evolving research framework called *formative experiment* (Newman, 1990), which involves evaluating the factors that enhance or inhibit an instructional intervention's effectiveness and how the intervention might be adapted to achieve its educational goal (see Reinking section of Baumann et al., 1996).

This methodological structure worked well given our question. We spent a year teaching students reading strategies in conjunction with trade book reading while we gathered data on the successes and failures of our instruction and how we modified it on the basis of what we were learning. This methodological change from controlled experimental studies to the more "on-line" experimentation within the formative experiment framework paved the way for further growth as I sought methods compatible with my teacher-research questions.

Second-Grade Teacher-Research Studies

I conducted two studies during my year in second grade. One study was a self-examination of the impact that returning to teach had on me as a classroom teacher, a college instructor, and a researcher and writer (Baumann, 1995a). The second study, which built upon the collaborative 5th-grade study with Helene and Pat, examined how a teacher might integrate reading strategy instruction in word identification and comprehension into a literature-based framework across an entire school year (Baumann & Ivey, in press). Each study demanded its own methodology.

Impact of Returning to Teach. Clearly, given the introspective, personal nature of my return-to-teaching study, neither a conventional quantitative nor a formative experimental paradigm was appropriate. During the summer of 1993, while seeking an epistemological orientation for my self-study, JoBeth Allen introduced me to several important literatures that helped me make my initial methodological plans. One perspective came from the action research tradition (e.g., Corey, 1953; Wann, 1952, 1953), and, in particular, the *educative research* framework described and employed by Gitlin et al. (1992). According to Gitlin and colleagues, educative research "challenge[s] the creation of hierarchical differences within the educational community between teachers and academics" (p. 6). Educative research provides a mechanism for teachers' voices to be heard and respected and for them to take action on the basis of what they have learned. Further,

educative research recognizes the "importance of reciprocity and equity" and "brings individuals together in such a fashion that all participants have a say in setting the agenda or topic and all have the potential to benefit and learn from the experience" (p. 7). This perspective was appealing to me because I was going to be a teacher myself, and I anticipated having the voices of colleagues, parents, and the children themselves guide me in my inquiry.

The second perspective JoBeth introduced me to was *hermeneutic phenomenology*, the interpreted descriptions of lived experiences. Max van Manen's *Researching Lived Experience: Human Science for an Action Sensitive Pedagogy* (1990) seemed to be particularly relevant to my methodological needs. van Manen states that "hermeneutic phenomenological research edifies the personal insight (Rorty, 1979), contributing to one's thoughtfulness and one's ability to act toward others, children or adults, with tact or tactfulness" (p. 7). A phenomenological approach involves asking a "what is it like?" question. In my case the question was, "What is it like to return to teach elementary school after a 17-year hiatus?"

van Manen (1990) argues that the methodological structure for research from this perspective involves a "dynamic interplay" among the following activities, all of which seemed to characterize the study I conceived: "(1) turning to a phenomenon which seriously interests us and commits us to the world; (2) investigating experience as we live it rather than as we conceptualize it; (3) reflecting on the central themes that characterize the phenomenon; (4) describing the phenomenon through the art of writing and rewriting; (5) maintaining a strong and oriented pedagogical relation to the phenomenon; (6) balancing the research context by considering part and whole" (pp. 30, 31). The appeal of the hermeneutic phenomenological perspective was that it provided a framework for engaging in a self-study of my everyday lived experience (Dilthey, 1985) as a teacher. Critical elements of both educative and phenomenological research include personal histories, school histories, peer observation and commentary, and artifact collection and analysis—just the kinds of data that I anticipated collecting.

Teaching Reading Strategies Through Literature. In my second study, I wanted to examine carefully the process of implementing a reading strategy instructional program within a literature-based framework, but to do so from the teacher's perspective and developmentally across an entire school year. As this study was similar to the one Helene, Pat, and I had done in fifth grade the year before, which employed a formative experiment structure and which suited our needs quite well, I decided to use this paradigm again. Therefore, my plan was to document the ongoing effectiveness of incorporating word identification, vocabulary, comprehension, literary, and writing strategies into the literature we were experiencing in the classroom. I would accomplish this by collecting data as I progressed throughout the year, analyzing the efficacy of my developing instructional model, and modifying it as appropriate given ongoing results. Thus, as school began in August 1994, I felt well equipped methodologically to conduct the two studies I had planned.

Epistemological Evolution

Cathy Fleischer (1994) described her 14-year (and still ongoing) development as a teacher researcher as a “research odyssey” (p. 86), in which she simultaneously conducted classroom-based inquiry and read extensively about teacher research and literacy. This odyssey resulted in “connections and disconnections between my practice and my reading,” leading her “around bends, across barriers, toward a place and a stance teachers and researchers are surveying and may perhaps even occupy” (p. 7). Although my odyssey has been much less than 14 years (but is still ongoing), I too found, after teaching a class of 7- and 8-year-olds full days while trying to do research, that there are indeed bends and barriers in the road (Baumann, in press). Being the teacher while simultaneously trying to be a researcher is not the same as being an outside researcher working with one or more teachers (e.g., even though I taught classes of students regularly as part of the 5th-grade formative experiment, that experience was very different from being the classroom teacher who is there all day, everyday and is ultimately responsible for the children’s learning and well being).

In a conversation with JoBeth Allen (personal communication, August 10, 1995) about some of the salient characteristics of teacher research, she suggested a short list of three: (a) Teacher research must be doable, given everything else that is going on in a teacher’s life before, during, and after school. (b) Teacher research must be true to the intent behind it (reflective and action-oriented) and responsive to the students and their families. (c) Teacher research must be second to students; though not discrete from teaching and certainly capable of enhancing instruction, teacher research must never interfere with or detract from a teacher’s primary responsibility to help students learn and grow. In retrospect, my research perspective and methods have indeed evolved over my year in the classroom due to issues of doability, trueness and responsiveness, and the primacy of students. This fluidity, by necessity, was true for both the studies I conducted in my classroom.

Responsive and Unresponsive Methods. My back-to-teaching inquiry, as it evolved throughout the school year, became a more solitary study than I had anticipated. As a result, I found the collaborative educative research framework (Gitlin et al., 1992) not as responsive as I had expected. For example, a cornerstone of educative research is horizontal evaluation, which involves dialogue among those involved in the research: “Horizontal Evaluation is a process in which teachers collaboratively analyze the relationship between their teaching intentions and their practices” (p. 52). I had originally planned on achieving this collaboration by conferring regularly with my “trading-places” partner, Betty Shockley Bisplinghoff, as well as by having other elementary classroom teachers within the School Research Consortium observe my teaching and then discuss with me what they observed. Given the demands of teaching and the challenges I faced as a retro-novice (I viewed myself as a beginning teacher all over again), finding time to meet with Betty and having classroom visitors regularly was not a high priority. (And,

honestly, having guests in my classroom was not something I relished early in the year, as the blemishes exceeded the beauty in my teaching. In retrospect, this involved the issue of “studying up” versus “studying down” [see Allen, Buchanan, Edelsky, & Norton, 1992; Harding, 1987], as I realized that I would be the “subject” of someone else’s study [up] by having others in my classroom observing me. In short, I was threatened by the notion of visitors critiquing my teaching, which engendered strong emotions and taught me an important lesson about power relationships in research.) As a result, educative research as an epistemological framework essentially fell by the wayside during the school year; this implies no criticism of the method, only a mismatch between my goals and methods.

The hermeneutic phenomenology framework (van Manen, 1990) proved to be more resilient and responsive to my needs as a researcher. Although I continue to explore and learn about this perspective as I analyze data and write about my experience (I am no expert in “human science research”), the notion of a methodological approach that embraces the lived experience and is dependent upon anecdotal narrative felt right throughout the school year and still does. In fact, the notion of personal narrative as a primary method (e.g., Carter, 1993; Connelly & Clandinin, 1990; Krall, 1988) became more salient and integral to my research as the year progressed. My journal was narration, audio and video recordings of class events were stories in live action, and the interviews I conducted with children, parents, and others were first-person accounts.

Not all my data however, were “continuous narrative descriptions” (Erickson, 1986). Children’s writing, class artwork and other artifacts, numerous school documents, classroom photographs, and the like also were fodder for my analyses. I even found quantitative data—numbers, at least—feeding into my self-study. For example, the informal reading inventories that I conducted at the beginning, middle, and end of the school year provided estimates of students’ instructional reading levels, and these estimates proved to be instructive data for assessing children’s growth in reading ability across the school year (Baumann, 1995b). I also took a look, albeit a skeptical one, at the results from the March-administered standardized tests, in relation to more authentic measures of students’ growth and learning.

Formative Misfit. I also experienced methodological change in the reading strategies study, moving away from the formative experimental framework as the school year progressed. This occurred because the study, as conceived, was not doable and potentially jeopardized my teaching effectiveness. Formative experimentation requires that a researcher gather evaluative data in an ongoing manner to assess the impact of the instructional intervention, in this case my efforts to integrate strategies into literature-based instruction. I was able to do this the year before as a guest in Helene’s and Pat’s 5th-grade classrooms, but it did not work so well when I was the classroom teacher. Although I was preparing and teaching strategy lessons that conformed to the goals of the study, I was unable to gather the necessary ongoing, evaluative data (e.g., videotaping lessons, interviewing

children, having others observe my strategy lessons). As noted previously, this was because I was consumed with relearning how to teach youngsters: developing rapport with the children and their care givers; understanding their abilities, experiences, and environments; organizing my classroom and my days for effective instruction; preparing appropriate lessons; creating a management program that was comfortable and workable; and so forth. In short, for about the first half of the school year, I needed to devote my energy and time primarily to doing what it took to be the best teacher I could for my children and their families, and if that meant letting some planned data gathering slide, so be it.

All through this period and throughout the entire year, however, I did faithfully gather and create narrative data and continued daily to make lengthy journal entries in which I reflected on my work and its impact on me, my students, and their families. I also took numerous photographs, I continued to conduct informal reading inventories (IRI), and I saved almost everything: my detailed daily lesson plans, letters and notes to parents, originals or copies of just about everything the children produced in the way of written work and artwork, and so forth.

In early spring, I used NRRC project funds to employ Gay Ivey, then a doctoral student at the university, to assist in data collection for the strategies project. We reviewed the formative experimental frame and alternatives. In looking at the data gathered thus far, we decided that a qualitative, interpretive case study (Merriam, 1988) would be an appropriate means to address our research questions, which now were: What do children learn about reading and writing within a literature-based instructional environment? and How can reading and writing strategies be taught explicitly, efficiently, and with transfer? We chose a case study because it enabled us to engage in "an intensive, holistic description and analysis of a single entity, phenomenon, or social unit" (p. 16), in this instance second graders' literacy strategy development within a literature-based environment.

Given the modified research plan, Gay and I focused on data collection for the strategies study during the spring. She videotaped lessons I taught, and she kept a journal in which she documented the instruction, the students' reaction to it, and her evaluation of the instructional environment. I focused more on strategy instruction in my daily journal entries. Gay interacted with the children during strategy lessons (e.g., joining me during assisted reading times). She also conducted one-on-one, videotaped interviews with all the children, during which they read for her and demonstrated their strategy knowledge while she queried them about their reading habits, attitudes, skills, and knowledge of literature.

In sum, research methods evolved during the process of teaching in relation to doability, trueness and responsiveness, and my instructional responsibilities. Thus, the methods coming out of the teacher-research studies were not the same ones that I planned going into the experience. I believe that the flexibility I afforded myself as a teacher researcher to modify research methods resulted in studies that were more responsive to the questions I had posed. This flexibility and responsiveness is extending into data analyses.

Flexible Data Analyses

Even though I may not have been conscious of it at the time, I did engage in data analysis throughout the school year. This occurred as I reread my daily journal; examined prior lesson plans while making new ones; compared results of one IRI with results from prior administrations; reviewed photographs; examined children's writing folders and reading journals for progress; and looked back at report card narrative comments while writing new ones. Nevertheless, these ongoing data analyses, a phase that is just commencing, were not systematic. And given the methodologically evolutionary nature of these investigations, my analysis plans are likely to be modified further as analyses proceed.

Data Sources. Data that fed into both of my investigations include, but are not limited to, the following sources:

- My personal journal, which spanned the two and one-half year process of planning for, implementing, and reflecting on my teaching experience, including daily entries for the 180 school days in second grade.
- Daily lesson plans, which detailed all instructional activities and materials.
- Originals or copies of the children's work, including their writing folders, published class books, reading response journals, content subject projects, bulletin board displays, and artwork.
- Numerous still photographs of the children working in the classroom and playing on the playground, as well as photos of special events (e.g., a 2nd-grade operetta) and displays (e.g., bulletin boards, art displays).
- Letters and correspondence I wrote to parents and care givers and notes I received from them.
- Video recordings of classroom events, including our Reading Strategies period, DEAR (drop-everything-and-read) time, Reading / Writing Buddies time (each of my students read and wrote weekly with a 5th-grade student), daily Class Meeting, and the individual literacy interviews Gay Ivey conducted with each student.
- Gay Ivey's journal, which focused on children's growth in literacy strategies and literary knowledge.
- Various school and district documents (e.g., new teacher orientation packet, faculty meeting notes, after-school workshop materials, PTO materials).
- Informal Reading Inventories on all students, conducted three times (August, January, and May).
- Narrative statements I wrote about each child's academic and social progress.
- Post-school-year interviews with Betty Shockley Bisplinghoff, my "trading-places" partner; Patricia Brown and Kim Lord, the principal and assistant principal, respectively, at Fowler Drive; Sally Hudson-Ross, a colleague at the university who returned to teach high school on a similar job exchange the year prior to my experience; and Veda McClain, a graduate student at the university who had two children attending Fowler Drive.

- Audiotape transcripts or notes from post-school-year conversations I had with several of my students and their parents or care givers; these conversations occurred in the children's homes and involved the children's and parents' assessments of and feelings about their 2nd-grade experiences.

Return-to-Teaching Study Analysis. I am engaging in hermeneutic phenomenological reflection and writing (van Manen, 1990, chaps. 4, 5). This involves the process of thematic analysis, in which one uncovers the "structures of experience" within the "lifeworld" one is exploring. In my case, thematic analysis involves extracting and understanding the essence of what it means to return to the lifeworld of a classroom teacher. All data sources are feeding into thematic analysis, particularly the narrative elements (e.g., my journal, the interviews, home visit transcripts and accounts, Gay's journal). Visual and artistic sources (e.g., school photographs, children's work, video images) are also important data in phenomenological analysis.

Thematic analysis proceeds by isolating thematic statements within the data, interpreting emerging themes, and extracting essential themes. Hermeneutic phenomenological research is fueled by writing, which is not viewed as an end product but essential to the process of thematic analysis. As van Manen (1990, p. 124) states, "Writing is our method." Therefore, the texts I have created through my journal writing, anecdotal record keeping, interviews, and so forth constitute ongoing analysis, and they provide grist for subsequent writing, revising, and analysis.

As the first step in thematic analysis, I am organizing, preparing, and previewing all relevant data. For example, I am currently rereading my personal journal while simultaneously correcting errors in transcription. I have secured a qualitative text analysis computer program, which I may use for retrieval and analysis of journal textual information. I am also rereading and correcting transcription errors of the interviews with colleagues, as well as the records of the home visits (some of which were audio recorded and transcribed and others for which I took notes and wrote descriptions from them afterward). Gay Ivey has transcribed all videotapes. I will read them and view the tapes, looking for the essential themes in my teaching. I am reviewing all the photographs of the school year and inventorying them for content. These data, as well as the other sources noted above, are being entered into the thematic analysis process so that the essence of my lived experience in second grade can be identified and understood.

Strategies Study Analysis. For the qualitative, interpretive case study paradigm (Merriam, 1988), Gay and I identified categories and properties through the process of content analysis (Lincoln & Guba, 1985). Content analysis made sense because it would permit analysis following data collection at the end of the school year. We also decided on the comprehensive selection of participants (LeCompte, Preissle, & Tesh, 1993, p. 72) to ensure adequate representation of the classroom population, including in the population children who were in my class 7 or more months of the school year.

Prior to data analysis, Gay and I constructed two sets of files, which constituted the case study data base (Yin, 1984) or case record (Patton, 1980). The first set included separate files for each of the students, comprising relevant data sources for individual children, including response journals, writing folders, informal notes, artwork, informal reading inventories and other assessments, progress reports, word study notebooks, language experience stories, transcripts of individual interviews, and portions of Gay's journal in which specific children were mentioned. The second set of files included general data sources, such as Jim's daily plan book and personal journal, letters sent to parents, a still photo collection showing students and the classroom across the year, the research video library, and a collection of information on school- and district-wide policies and activities. Data analysis proceeded in four phases.

In Phase 1, we scheduled a series of conferences to study the data we had collected for each second grader. During each session, we individually examined a student's case folder and jointly viewed the videotape of Gay's interview with that student. We also examined relevant information from the general data files. Next, we discussed in-depth the different kinds of knowledge about reading and writing demonstrated by each student, as evidenced by various data sources. We audiotaped these meetings, and Gay converted the tapes to written form by reviewing the entire recording and writing in narrative form the significant points and descriptions about an individual students' literacy learning contained on the tape.

In Phase 2, we read each of these summaries, noting instances in which we had described students demonstrating both general and specific knowledge about reading and writing. We individually made lists of literacy learnings for each student, and then shared our lists with each other and discussed them. Jim then consolidated these individual lists into a comprehensive list of literacy learnings for each student.

Phase 3 of analysis involved looking across all the cases to find recurring patterns among the data. We individually created codes for the descriptors and examples of students' learning generated in Phase 2. Patterns of literacy learning were examined according to substance and frequency, and similar patterns were collapsed under common codes. We then compared the patterns we had generated independently and reached consensus on those we considered most pervasive. The patterns that emerged represented what students learned about reading and writing in second grade.

From these patterns, we induced and defined categories and properties. For example, one of our emerging patterns was students' enjoyment and knowledge of books and stories in a variety of literacy activities. We labeled this category "Engagement With Literacy." Within this category, we noticed that students demonstrated specific knowledge about books, authors, and illustrators. We also noticed that students had opinions about books and literature and expressed them freely in their reading and writing. Because these two observations were salient features of this category, they became defining properties of the category. We followed this same procedure to induce and define four other categories and their defining properties.

In order to ensure a match between these categories and properties and the data, we conducted a negative-case analysis, which constituted Phase 4. In this analysis, we revisited each student's case folder and other data sources, including videotapes and Jim's journal and daily plan book, to study the fit between each category and property and the data. When categories and properties did not adequately explain specific cases, we refined them to account for this mismatch. We proceeded through each case in this manner until we could account for all negative cases. The result was a group of categories and properties that were comprehensive in the sense that they identified specific conditions under which the findings occurred. As a final step in analysis, we conducted an audit check, inviting a person unfamiliar with our inquiry to revisit our analysis process to determine if the same categories and properties emerge (Baumann & Ivey, in press).

Methodological Musings

What has my experience taught me about teacher research and methods for it? I have learned that conducting classroom inquiry while being the teacher responsible for the class represents a research situation different from any other I have experienced (Baumann, in press). This uniqueness is attributed to a teacher researcher's emic position and total affinity with the research environment. While employing or borrowing from extant research traditions, particularly interpretive ones (Erickson, 1986), teacher research is more than an ethnographic approach to classroom research, and teacher research goes beyond participant observation. The teacher researcher is a doer-evaluator, the person who does the job while concurrently examining the work and its impact. This is akin to the reflective practitioner notion (Schon, 1983) but extends it to include the systematic collection, reflection, and analysis required for disciplined inquiry (Shulman, 1988). In short, the teacher researcher systematically studies her or his work with the objective of doing it better as a result. This is simultaneously a simple, powerful, and daunting goal.

The environmental affinity involved with teacher research accrues both benefits and costs. As a teacher researcher, there are many benefits: You are there all the time to see and experience the multiple dimensions of academic and social learning across an extended time period; you can act upon what you see and learn firsthand, evaluate the impact of your actions, and then initiate new actions; you have paradigmatic flexibility in selecting methods that match your research questions; your teacher-research efforts are professionally fulfilling, and your voice is credible when sharing what you learned.

On the cost side, teacher research is time-consuming, hard work that adds a layer to an already hectic professional work schedule (it did not become "organic" for me, as it has for others; see the following cases); you must guard against having the research interfere with or detract from your primary instructional responsibility; and you must be sensitive to elitism that might arise among individuals or groups of teacher researchers. In spite of its potential costs, I have no

doubt that my year would have failed to be as rich and significant as it was had I not systematically reflected on and acted upon my teaching. Although researching while teaching may not be for everyone (and maybe not an every-school-year event for those who do value it), I can attest that it does provide a teacher a powerful opportunity to learn, understand, and grow, both professionally and personally.

CASE TWO—COLLABORATIVE RESEARCH TEAM: BETTY, BARBARA AND JOBETH'S EXPERIENCE

In 1988, Betty Shockley Bisplinghoff was teaching first grade and Barbara Michalove (not an author on this chapter, Barbara Michalove is the third member of our research team) was teaching second grade at Fowler Drive Elementary, a school that was examining the effectiveness of its literacy instruction for students who struggled in school. The school invited JoBeth Allen, a local university teacher, into a long-term partnership to develop whole language instructional approaches and to study their influence on the children teachers worried about most, those who found learning to read and write difficult.

Several teachers were a part of the school's research group that first year, conducting case studies in their classrooms. However, Betty and Barbara collaborated closely with JoBeth, and a team was born which continues to the present. Our first study, a 4-year, multiple-case study culminated in *Engaging Children: Community and Chaos in the Lives of Young Literacy Learners* (Allen, Michalove, & Shockley, 1993); our second study was a 2-year study of home-school connections reported in *Engaging Families: Connecting Home and School Literacy Communities* (Shockley, Michalove, & Allen, 1995). We currently work together within the SRC.

Creating Responsive Methods

Over the course of these studies, we have created ways of gathering information and learning from it. Our research methods grew out of the realities of classroom life, which changed not only from year to year but from day to day. As each group of students was unique, opportunities for data collection were different. Since analysis was ongoing, we designed methods responsive to what we were (and were not) seeing and hearing.

Responsive data collection included (a) observational notes from both insider and outsider perspectives, focusing on individual learners; (b) observations of children and interviews with teachers and other adults outside the classroom setting; (c) ongoing records of student progress such as reading inventories, logs of one-to-one reading and writing conferences; (d) full-day observations of each classroom to record a fuller context than more focused reading and writing observations; and (e) interviews that JoBeth initially conducted outside of the classroom but that became more effective when Barbara conducted them within the instructional

context of the classroom. Responsive data analysis included weekly reviews of all data sources on a focal child, the writing and sharing of research narratives, and interpretive dialogue techniques.

We learned to research by engaging in the research process. We created, adapted, reflected on, and revised methods predominantly from qualitative research. Flexibility and invention are fundamental to many qualitative traditions according to LeCompte et al. (1993):

Sources and types of data are limited only by the creativity and energy of the researcher. ... Data, then, are any kind of information which researchers can identify and accumulate to facilitate answers to their queries. ... [A]s ethnographers negotiate initial relationships with participants ... they discover other possibilities for and limitations to acquiring data. (pp. 158, 159)

For *Engaging Children*, we began studying six children from Betty's and Barbara's classrooms, following their school experiences and literacy development for 3 years. Many of our methods grew out of our weekly data-analysis discussions. In the beginning, Barbara and Betty worried that to be considered "real researchers" they should be taking the kind of detailed observational notes JoBeth wrote. They even tried it—briefly. The result was intense frustration, sending them in search of methods that could be readily incorporated into their teaching lives. They came up with individual ways of detailing their decision making as teachers and documenting students' literacy development. This took time, however, and constant experimentation.

Betty harkened back to high school and college "research" experiences and found only the *Cliff Notes*, encyclopedia, and index card models. That first year she organized anecdotal notes by topics on index cards. Her next strategy, "read to learn," proved more fruitful. She read other teacher researchers like Nancie Atwell (1991) and Vivian Paley (1981, 1990) to learn how they integrated research with teaching. She began to identify links between thought and action, claiming her teaching journal as a legitimate and lasting record of experience. She used student conference logs and reading inventories as substantive accounts of individual and collective change over time. She cultivated the habit of dating work samples and anecdotal comments. She became the teacher with the notebook, recording direct quotes and descriptions as primary data sources.

The key came for Betty and Barbara when they made research a natural aspect of each day instead of one more thing to add on. Eventually, record keeping became an organic part of classroom routines (even though the records took many forms, from sticky notes to memos during telephone calls late at night). Both teachers developed forms of documentation that highlighted classroom experiences, a body of data that over time informed both daily practice and long-term research interests. JoBeth added the critical second pair of hands and eyes in each class; she focused on one child per visit, recorded conversations and other peer interactions, and documented the processes of text writing and reading. We were learning what each of us had to contribute to the collaboration and discussing on a weekly basis the kinds of information that were valuable.

From these discussions, we expanded our data collection from observational notes and teaching journals. We wanted more of the child's perspective, so we applied Almy and Genishi's (1979) guidelines:

- we asked children about themselves (in quarterly interviews);
- we observed children in various settings (individual, pairs, small groups, whole class);
- we studied children through others at school (we interviewed the media specialist, art, music, PE, and especially Chapter 1 and special education teachers) and in their lives outside of school (we interviewed the Boys Club director and made home visits); and
- we assessed development (daily writing, notes on classroom reading, and quarterly miscue and retelling analyses).

In addition, we set up weekly pen pal letters with JoBeth's undergraduate classes, through which we learned from the written dialogue as well as from the analyses of the preparatory teachers. JoBeth kept a research journal by tape-recording each day as she left the school. This provided a record of research decision points (Alvermann, 1988), that is, the development, modification, or abandonment of data collection or analysis strategies. Finally, in order to provide a richer context for readers, we stepped back from the living of classroom life and recorded and reflected on it in "a day in the life" of each classroom. These detailed, full-day transcripts of each classroom from JoBeth's observational vantage point, in combination with lesson plans and teaching journals, became Betty's and Barbara's teaching stories that laid the foundation for *Engaging Children*.

In our second study, we examined connections between home and school that Betty fostered with a set of "parallel practices" she had developed in first grade (home-school literacy journals; oral and written family stories; parent, child, teacher reflections). Barbara continued with the same children and families in second grade. By this time, Betty had come to view her classroom as "data world," a place where remarkable things happen everyday to gather, ponder, and interpret in relation to future teaching decisions. Consequently, she collected a great deal of information and asked parental permission to share what they were learning together with others, even though the first year was not designed as a research study. During the second year of the study, we were systematic in our data collection of the same sources of information and some additional ones. Table 13-1 shows the data collected and when we collected it.

Together we constructed and redesigned these methods, keeping them responsive to the children and to our ongoing analysis. For example, in the first study when a data analysis session focusing on the quarterly interviews JoBeth did with each child revealed that at least one child was "putting her on," Barbara suggested that she, as the teacher, should take over the interviewing, incorporating the questions into her daily reading and writing conferences. Barbara knew the children better and was able to embed questions in a logical

TABLE 13-1. Data Sources and Collection Time for *Engaging Families* Study

Information source	Collection
Tell Me About Your Child (letters from parents)	beginning of each year
Home Interest Inventory (by parents and children)	1st grade, beginning of year
Clay's Word Writing Assessment	1st, beg / mid / end
Standard Topic Writing	1st & 2nd, beg / mid / end
Informal Reading Inventory	1st & 2nd, beg / mid / end
Samples of Daily Writing	1st & 2nd, weekly
Houghton Mifflin Periodic Reading Survey	2nd, quarterly
Home-School Reading Journals (dialogue among families, children, and teacher)	1st & 2nd, all year
Family Stories (written by adult family members)	1st & 2nd, varied
Parent Reflections & Expectations Survey	1st & 2nd, end of year
Student Reflections & Expectations Survey	1st & 2nd, end of year
Anecdotal Notes	1st & 2nd, throughout
Parent Meetings (notes)	2nd, monthly

Note. In addition, Betty occasionally tape-recorded oral storytelling and videotaped a family storybook reading partly in her classroom. Barbara photographed classroom interactions and a family picnic at the park.

instructional framework and interpret responses in the full context of the classroom.

The study had built-in triangulation not only of data sources, as seen in Table 13-1, but also of perspectives. Betty and Barbara taught the children during different years, and JoBeth was an outsider. Frequently at data analysis sessions, especially in year two of both studies, Barbara discussed a child's current literacy and classroom life, Betty related that to the previous year, and JoBeth asked clarifying questions. At times these discussions led to the collection of new data or to the redesign of a current strategy. Thus, ongoing data analysis was critical to the design of responsive methods. It was also critical to building an interpretation of what we were living.

Interpretive Dialogue

Throughout our collaboration, we have discovered the power of talk to reflect on lived experience, to challenge interpretations, to generate assumptions, and to examine biases (e.g., JoBeth became worried that she was ignoring a child in the first study when she dreamed she had killed him). We created time to talk within a variety of structures, depending on the phase and focus of the project. These included a paid substitute teacher for weekly during-school data analysis sessions, weekly or biweekly work sessions at good restaurants, and week-long writing sessions at inspiring settings each summer (see the Appendix in Shockley et al., 1995).

In his chapter on qualitative methods in research on teaching in the 1986 handbook, Erickson wrote:

As Hymes notes (1982b), interpretive research methods are intrinsically democratic; one does not need special training to be able to understand the results of such research, nor does one need arcane skills in order to conduct it. Fieldwork research requires skills of observation, comparison, contrast, and reflection that all humans possess. In order to get through life we must all do interpretive fieldwork. What professional interpretive researchers do is to make use of ordinary skills of observation and reflection in espe-

cially systematic and deliberate ways. Classroom teachers can do this as well, by reflecting on their own practice. Their role is not that of the participant observer who comes from the outside world to visit, but that of an unusually observant participant who deliberates inside the scene of action. (1982, p. 157)

How did we deliberate on our observations? What forum allowed the comparison, contrast, and reflection necessary for interpretive research? We developed a process we call *interpretive dialogue*, carefully recorded analytic conversations about data that often served as oral drafts. Whether we were talking about one child and one week's data on that child at weekly Shockley Bisplinghoff / Allen or Michalove / Allen analysis meetings or a whole year's interactions with a family, we taped or hand-recorded our insights, both mundane and inspired. We also had frequent role dialogues concerning writing and authorship, discussing each writer's time, interest, strengths, weaknesses, and professional goals. We "listened" to and discussed other writing voices, novel research (e.g., *Praying for Sheetrock*, Green, 1991) as well as well-researched novels (e.g., *A Lesson Before Dying*, Gaines, 1993), and tried to honor our individual voices either by identifying section authors or writing in the lead author's voice.

As part of a larger school team in the first study, we wrote occasional research narratives, one- or two-page written interpretations of phenomena that interested, bothered, or puzzled us. This was a data-analysis strategy from the work of Jane Hansen, Donald Graves, Ruth Hubbard and colleagues (Hubbard & Stratton, 1985). Few people felt comfortable or had the time to write for each meeting (or even most of the meetings). However, we would come back to research narratives several years later and use them as a primary data analysis strategy in *Engaging Families*. We had a wide variety of information on each child / family / teacher relationship we were studying (see Table 13-1) which we analyzed individually (e.g., one week each of us would read all the data on Adrian); wrote a narrative interpretation of the issues, themes, and questions that resulted from the analysis; and

then met to read and compare our narratives on that focal child.

Although the key to data analysis for us has been interpretive dialogue, we did not discover how important it was until we tried another approach. JoBeth had been studying grounded theory (Glaser & Strauss, 1967) and suggested that we try the fine-grained coding of the constant comparative method. We spent several full days reading about the methodology, coding four sets of transcripts together, and generating an extensive code list. We agreed to code the other sets on our own and to come together weekly to compare our analyses. A short segment of the lengthy code sheet follows:

TQ	teacher question
/Y / N	yes / no (type TQ)
/auth	author focus
/lrn	learning focus
/lks	likes of reader
/gnr	genre focus (silly books)
/prc	process (is C reading book?)
/eval	evaluation (of reading process, development)

Using the emerging codes, we coded a fourth journal set together, adding and clarifying subcategories. Our retreat over, we agreed to meet once a week having each "coded" the same set of data (one family / child) independently.

A funny thing happened at the first weekly meeting: We decided that we did not like our analysis process. Betty, as principal investigator, crystallized the misgivings we were all feeling. She said, "I'm worried that we're missing the forest for the trees. We're breaking this rich interaction down into little codes that become almost meaningless." We discussed what is unique about teacher research. When JoBeth typed out the code sheet, the analysis became more mechanistic than insightful. We stopped talking about children and families and talked instead of matching, modifying, or adding codes. The agenda Betty had written for our meeting included the following quote from Nancie Atwell (1991):

I worry about attempts to package teacher research as another formula to be followed, shutting down the possibility of surprise through a slavish adherence to the conventions of experimental inquiry. ... It's [classroom research's] power lies in thinking side by side with others—our students among them—who care as much about writing, literature, and learning as we do. (p. xvi)

We decided that we were more interested in informing and affecting educational practice than in generating theories about it. We wanted to look closely at an experience that seemed meaningful to all participants and ask, What made this meaningful? What meanings did different people create from it? What difference for families, children, and teachers did the experience make?

Betty proposed a plan that we used the rest of the year:

1. Each researcher read through the original home-school journal to note illustrations, format, and so forth (we were missing a great deal by merely reading typed transcriptions). The visual display of data was more illuminating than the reduced transcripts.

2. Each researcher read the child's cumulative notebook Betty and Barbara had assembled, which included all data sources, making analytic memos as we read (journal transcripts had 3" right margins).
3. Each researcher wrote a 1–2 page narrative that included patterns of response and pivotal point of change, questions for further exploration, telling excerpts, and so forth.
4. At dinner meetings, we read the narratives aloud to each other, comparing insights, generating new questions, proposing issues and categories.
5. We made a three-column (one for each of us) chart of key insights, points of agreement and difference, and questions. We talked about the children, their families, and ourselves from our unique perspectives.
6. We continued to study the practices of other researchers.

We felt much truer to ourselves and to our data through our approach of written narratives and interpretive dialogue. The dread we had been feeling about line-by-line coding was replaced with an eagerness to read, write, ponder, discuss, and construct a meaningful interpretation. One reason we feel the process worked so well was that we had both the "insider's view" that teachers bring to school-based research, and an "outsider's view" (Erickson, 1986). Betty was the teacher who had generated the first year's data; she had a yearlong relationship with the children and families through which to interpret journals, reflections, and so forth. Barbara was the teacher who currently taught the children and interacted with the families; she was able to update the previous year's data with current information about how the child was developing, what pattern the 2nd-grade journal was taking, and so forth. JoBeth was the outsider, who did not know the children or their families; she asked questions that led us beyond the "taken for granted" and helped make the familiar strange for Betty and Barbara. Through interpretive dialogue in our weekly analysis sessions, and even more intensively during our summer writing sessions, we asked "From your perspective..." questions of each other, aware that it was not consensus we were after but multiple perspectives.

At several points in our data analysis, we stepped back from the individual children and families and generated broad, working assumptions about ourselves, the children, and their families. We asked ourselves, What are we learning? We generated assumptions, which we continuously modified by rereading the data. The following are a few examples:

Assumptions About Ourselves as Teachers

- When we learn from parents, we make more informed decisions on behalf of kids.
- When we listened to and read family stories and journal entries, we developed "funds of knowledge for teaching" (Moll, Amanti, Neff, & Gonzales, 1992).

Assumptions About Parents

- All these parents care about their kids just like we care about ours.
- The journal process supported and developed many

parents' sense of efficacy, both as parents and as teachers.

- Family members often provided very explicit literacy instruction. Many had a repertoire of literacy support strategies; they would nudge, back off, press, and encourage children to feel successful. Occasionally the interactions became stressful, but the journal often served as a way of changing to more enjoyable interactions.

Assumptions About Children

- Children grew in their ways of responding to literature, and they grew in their literary conversations, both oral and written.
- Children saw the adults closest to them—their parents and teachers—as readers and writers.

Just as in the first study (Allen et al., 1993) we had broadened the dialogue by interviewing many people inside and outside of the school, in the second study (Shockley et al., 1995) we invited families to participate in the dialogue that helped us learn why and in what unique ways they had interpreted the experiences. These “member checks” occurred in a variety of ways. We took notes at monthly parent meetings during which Betty and Barbara frequently asked parents for their perceptions. For example, at one meeting, we asked parents how they would describe the school, saying we felt giving the demographics was inadequate. At another, Betty read a draft of an article about our shared home-school experience and asked for feedback (Shockley, 1993). We occasionally called parents to clarify or interpret events. We included three Family Portraits in *Engaging Families* (Shockley et al., 1995); during the revision stage, we gave each family a draft of its portrait, the section we had written about them, and again asked for written or verbal feedback. We were delighted by the serious and helpful responses.

Finally, the interpretive dialogue was impetus for and integral to countless rounds of drafting, responding, and revising. There was a constant interplay between written and oral composition. Each summer we gathered all our data, notes from our weekly analyses (including research narratives), boxes of professional references related to our study, three computers, and literary fiction that provided models of effective writing. We retreated for a week to a lake, ocean, or mountainside sanctuary and wrote for two 3-hour blocks each day; in the evening we each read aloud what we had written that day, gave each other feedback, and made revision notes.

Research for us is a communicative art, an evolving lesson in constructing meaning. We talked to understand the children, each other, and ourselves. We wrote to talk and talked to write. We read to write, sharing and discussing the works of favorite fiction writers as well as professional educators. Through our collaboration, we grew professionally in ways that became fundamental to our definitions of ourselves as teachers. We wanted to share the power and joy of our experience with other teachers. Out of that desire we created a plan for a broad network of teacher researchers, the School Research Consortium. The next section details their methodological evolution and insights.

CASE THREE—TEACHER-RESEARCH COMMUNITY: THE SCHOOL RESEARCH CONSORTIUM EXPERIENCE

It is a research day. Teachers who work together as researchers within the School Research Consortium (SRC) knew time was what they needed, time away from their teaching duties and school sites periodically to review their research needs. This reserved time for research was divided into two parts: The first half of each research day was used by individuals and teams to talk and plan while the second half found us reunited as a whole community for additional discussions and updates. In the following dialogue, Buddy Wiltcher, Beth Tatum, Barbara Jarrard, Mindy Rhoades, and Patti McWhorter are meeting at Beth's house to discuss their research progress and plans.

- Patti:* It takes so long to write because we all feel like we need to tell our stories first.... That seems to be part of our research process when you live your research like that and like we're doing.
- Mindy:* Part of it is, it's your life.... You don't go and you don't just measure things.... It's not like chemistry.
- Barbara:* There's no right or wrong answer.
- Patti:* That may be part of the phenomena.
- Buddy:* The story's the background.
- Patti:* Right.... The story's the context.
- Mindy:* [Without it] It's like giving people a novel and saying, “Read Chapter 14!”

Stories of teacher research are contributing to a rich and varied legacy of lives and learnings within the context of classrooms. Such stories help build a tradition among and between teachers that can be resurrected and revised as others engage in similar adventures. Each story is a unique tale of successes, confusions, and disappointments. Though plotted in different ways, they remain true to an emerging genre defined by setting and character, that is, classrooms and students.

The SRC is a community of researchers who share their stories of research with one another and with a broader community of educators through oral and written retellings. The SRC is supported by the University of Georgia site of the NRRC. From its conception, the NRRC has viewed school-based research as central to its mission and has worked to support research agendas that teachers have identified as critical. The first SRC studies were initiated at the beginning of the 1993–94 school year. As a long-time teacher researcher in the local school district, I (Betty) have felt membership in this community beyond my role as SRC Coordinator. I write to give some order to the many stories embedded in the individual efforts to bring self-initiated research to practice.

The combined stories of the researchers within the SRC talk of a developing methodology that is both varied in adaptations and unified in purpose. By developing and documenting their particular pathways to understanding, teacher researchers capture a record of growth and change that too often has been lost to the profession.

TABLE 13-2. SRC Project Titles and Descriptions

Title	Description
Middle School Student's Favorite Books and Factors Affecting What They Choose to Read	As media specialists, Shu-Hsien Chen and Barbara Davis wanted to know more about students' book choices. They worried about the students they saw leaving the media center empty-handed and complaining, "I can't find a good book," so they designed a study that would be sensitive to the voices of the students and the teachers in their middle school. Using interviews and surveys, they identified favorite reading materials and the factors that affected the choice of those materials.
Literacy Education for a Democratic Society (LEADS)	JoBeth Allen and Barbara Michalove, along with a group of teachers from a variety of school systems in the Atlanta/Athens area, were interested in exploring issues of activism within the teaching profession. Currently the group is spending time discussing readings related to education for democracy in preparation for implementing and studying Literacy for a Democratic Society in its various classroom manifestations during the coming school year.
Bridging Picture Books and Chapter Books: The Reading Challenge Project for Third-grade Students	Nancy Baumann, Christine Fuentes, and Jane Holman shared a concern about the difficult transition many children seemed to have from reading picture books to reading chapter books. Their study aimed to find ways to better support students in making this literate leap.
Computer Journals	This was Tina Allen's first attempt at combining research with teaching. She was eager to build research into her Chapter 1 program as she worked to facilitate the writing development of two of her students through dialogic computer journals. But she found research to be an on-again, off-again process of adjustments.
Teachers as Writers: Focusing on the Classroom	Ann Keffer, Debby Wood, Shelley Carr, Leah Mattison, Barbara Lanier, and Randi Stanulis worked together for two years to understand how thinking of themselves as writers and actually experiencing the process within a community of teachers who write might help them better understand the issues their students faced as writers. They associated their first year of work together as a "magical" experience but then in a second year went through a period of serious concern about the demands of their combined roles as teachers and researchers.
Active Learning, Interactive Classrooms, and Literacy Instruction	Patti McWhorter, Barbara Jarrard, Mindi Rhoades, and Buddy Wiltcher have been working together for two years to coordinate and document the changes that take place for teachers and their students when their high school classrooms become more student-centered. In their view, "It is on this sharing of control, the subsequent shifting of roles and responsibilities, and the resulting effect on literacy instruction that our study is focused."
A Parallel Journey: The Role of Memoir and Personal Narrative in the Construction of Literate Relationships	Karen Hankins began her first year of study with a project designed to help her better support the three students in her kindergarten class who had been identified as being fetal-alcohol syndrome or crack babies. In her self-study, an extension of the first year's work with the students, she recorded and examined through memoir writing her life episodes that either enhanced or discouraged the potential for interactions and connections with these three children and their families. She also claimed that "by combining case study and memoir, I will be generating a method for reflective qualitative analysis."
Exploring How Elementary and Middle School Partnerships Encourage Students' Engagement in Literate Activities	Georgiana Sumner and Johni Mathis are sisters with a shared concern for finding ways to motivate students to read. Georgiana taught second grade and Johni taught eighth. They have worked together as researchers within the SRC for two years. Their second year experience gave rise to troubling concerns regarding the value of doing research that does not turn out to be an exciting proclamation of success with all students all the time.

Our stories have beginnings but not endings. We are still much immersed in our processes of becoming teachers who research. For purposes of this condensed version of our storytellings, only 8 of the 17 projects initiated by the 40 SRC

members will be highlighted. These story segments are taken from written reflections by the teacher researchers who were present at our last group meeting of the 1994-95 school year. Each teacher was asked to outline specific methodologies

used in her / his project and to briefly isolate and elaborate their data analysis procedures. The title, authors, and a highlight of their research stories are included in Table 13–2 to provide a sort of book-jacket look at the many concerns SRC researchers consider worthy of their time and study.

Learning by Doing

Much is new and unresolved for us as a community of teachers who also research our beliefs and practices. Sylvia Ashton-Warner (1963) in her book *Teacher* announced, “I know all this because I’ve done it” (p. 34). This kind of claiming to know by doing is the emerging hallmark of the SRC. As teachers, we often feel privileged by special insights that are possible because of our unique positioning within classrooms with students on a daily basis. As members of the SRC, we accept and celebrate this unique perspective. Instead of being educated ahead of time in a particular research tradition, we choose to start from our own beginning places, to develop methods that work for us. We are learning to adjust and adapt, and invent our research practices as we work to achieve better understandings. We are in the process of doing it for ourselves. Whatever has gone before will certainly serve us well in this endeavor, but nothing influences us more strongly than our own unique responses to researching as teachers.

Reducing our sense of professional isolation through our work together in the SRC has been a first step toward the construction of a professional identity that is grounded in our own developing research traditions. It helps us move beyond a profession of technicians who are judged by how well we are able to repeat the performances of others to what Seymour Papert (1993) termed an “epistemological pluralism” (p. 6). This view encourages a variety of responses and accepts the influences of multiple contexts and personalities. Papert further encourages this perspective with, “The problem for society is to give teachers the same pluralist support that the best of them give their students. Individuals at different places need support to move from where they are. . . . The practical consequence is that change cannot come about except pluralistically” (p. 75). The SRC acknowledges multiple perspectives through its support for varied and evolving methods and welcomes the particularity of response inherent in each teaching / researching situation.

In the following sections we outline aspects of evolving context-specific research methods—methods teachers are learning by doing. Teachers are beginning to trust themselves to be sensitive and systematic in developing their own research designs. As we share what we are learning about methods that work for us, we become what Nancie Atwell (1991) described as “adult[s] who learned in public” (p. 8). We risk this published reflection not only to offer ideas to other teacher researchers but also to enhance our learning-by-doing cycle of action and reflection. In Papert’s (1993) words, “In education, the highest mark of success is not having imitators but inspiring others to do something else” (p. 78). Teacher researchers need to know that there is room for their independent creations within what should be a constantly evolving research perspective.

Balancing Reactions

Achieving the Balance Between Teaching and Research. Bartoli (1995) in *Unequal Opportunity: Learning to Read in the U.S.A.* wrote, “I think the uses to which we put our research are every bit as important as the purity of the methodology—possibly more so” (p. xvi). This concept works well for what we have come to view as a central feature of our researching processes: the fit between teacher needs and student needs in the research process. The alignment of research to particular teacher and student needs is a key to unlocking passions for the process and principles for research design. Each new school year and each new group of students bring with them a revised set of challenges and opportunities. Being sensitive and responsible to this concept is unique to the research of teachers. Vivian Paley (1990), a long-time teacher researcher, adds credence to this kind of wisdom. She, too, has come to know by doing and recalls, “Such is the way life in the classroom reinterprets the research. Whatever else I may choose to watch and record, my subjects draw me into deeper concerns and more vivid visions of their world” (p. 19).

We are teachers and researchers on a day-to-day basis. Keeping our balance between these two dimensions of our professionalism is a new challenge. Many SRC members have experienced a kind of seesaw effect when the daily demands of teaching outweighed the more long-term commitment to studying it. This weight shifting has been most evident in the SRC when teachers change grade levels or when system responsibilities such as national testing or standards evaluations are imposed on an already full workload.

The Teachers as Writers group really felt the impact of these kinds of changes on their attitudes toward research during the 1994–95 school year. After a highly motivating and successful first year as teachers researching their own involvement with writing, they proceeded to what seemed a logical next step—documenting ways in which their personal insights and experiences with writing might prove helpful for supporting their students as writers. What originally seemed so simple and straightforward turned into a year overburdened by the presence of research. Members of the group reported feeling “guilty” all year because they kept putting off focusing on their research issues due to more pressing systemic demands. Debby said, “Our community changed, people changing grade levels. I hadn’t had a homeroom in five years; that’s real different for me.” Shelly agreed and added, “Ann was our glue. She was the only one who didn’t have change.” It was also the year their school had to do their 5-year standards accreditation review which required many more work hours.

This rising or sinking feeling can also be related to the group dynamics present with each new class of students. Listening closely to students may be one of the most important ways of gathering information for teacher researchers, but it is also one that keeps the teacher researcher off balance, unable to lay out a careful methodology in advance. Barbara Jarrard learned, “I really have to listen carefully to different groups of students.” Ann Keffer arrived at a similar understanding: “As important as it is to ask ourselves what

questions we most want to answer through our research, it is just as important to ask ourselves what questions a particular group of children are peculiarly suited to help us answer. . . . This year I've been stunned by how much my students can tell me if I just *listen*." Barbara Jarrard has also learned to capitalize on this knowledge source. She wrote, "I ask my students to help cover the parts of data collection I know I am not very good at by building in reflective pieces in their projects." Many SRC researchers are coming to agree with Nancie Atwell (1991): "When teachers conduct research in [their] classrooms, [they] learn that kids' knowledge counts—and the kids do too" (p.13). We seem to listen to our students more intentionally when we are involved as researchers. Communication between and among students and teachers can be facilitated when research finds a home in our schools.

Tina Allen identified student interviews as her most helpful data source. This talking-to-understand process was used successfully by most of the SRC researchers. Finding ways to accent connections with students through research can lead to heightened respect and awareness for both students and teachers. Linda Rief (1992), another teacher researcher explained:

I have to be a learner in and out of my classroom so I won't lose sight of what it's like for my students—so I will continue to hear their voices. I don't ever want to set myself up in the front of that classroom again sitting on a stool with all the answers. Like Byrd Baylor in her book *The Other Way to Listen* (Baylor & Parnall, 1978), I want always to remember, "If you think you're better than a horned toad you'll never hear its voice—even if you sit there in the sun forever." (p. 17)

Creating Methods That Help Keep the Balance. When our community first banded together, there were many discussions at SRC meetings about "What are data?" It was not an easy process deciding what to count as data sources and how to go about managing them. Teaching journals are probably the most often suggested form of documentation offered to teacher researchers. Several of the teachers in the SRC reported initial attempts to remain true to such a procedure only to feel troubled by it over time. Many tried to blend its use into practice but reported frustration with their attempts, as Barbara Jarrard's experience demonstrates:

I started out trying to keep notes in a writing journal but after a fairly good start at keeping up with it, it was always somewhere else when I wanted to jot something down, so I started writing on scraps of paper which sometimes got to the journal and sometimes didn't. As I realized this wasn't working very well for me, I began to jot notes at the end of my lesson plan in my plan book which gave me very limited space. Although this wasn't a perfect solution, it did teach me that writing a little was better than nothing and in many ways better than a lot. I can almost always find time for a little when sometimes I would not start to write a lot of information. At first I really felt everything I wrote down had to be perfect and complete and this compulsion was causing me to spend time I didn't have on what should have been just notes.

Karen Hankins too had her story of learning to cope with the many options and issues related to data collection

in school settings. She had journals and writing folders for each child but worried that her records could easily become incomplete when one of the journals was lost and when one of her students hid pieces of her writing. Her school copy-machine budget did not allow her to make ongoing copies of these materials either. She did develop a helpful habit of using yellow sticky notes as cues for future evaluation, placing them directly on collected data sources. She had a tape recorder running in her classroom on some days so she could listen to it at night. She found her own voice to be overly intrusive and described the experience as "so painful I just didn't do it as often as I should have." She also interviewed her students and their parents. In an honest reflection of "This is really how it is!", Karen remembered:

I jotted notes on everything from napkins at lunch to wrapping paper. I keep a journal but it is never with me when I need it! I don't carry it with me but sit and write when I am alone. I really wish I had the things I had written on. The best was a piece of laminating film that had dropped to the floor as we were trimming the edges of the laminated stage decorations while we watched the music teacher put the kids through a play practice. As I trimmed those edges, I was observing Nat.... It may give a person who keeps neat field notes a migraine thinking about it. But that piece of recycled school minutiae was a story in itself. It needed no date ... dress rehearsal day. It needed no context to give me a clue of where and what I was doing when I made the observation ... cutting the edges off stage decorations. It held in its lightweight transparency the weight of a teacher's cloudy thinking on those last days of school when she's trying to do three things at once....

Patti McWhorter's comments also illustrate this evolving process of data collection:

I discovered early in this process of becoming a teacher researcher that I could quickly go overboard in data collection. Saving all student work was impractical. . . . Copying was out; the budget was not large enough—nor was there enough time for me to do this. Audio and video taping was a good idea, but again, I had to decide what to tape. I think it all came down to predicting what would support, address, answer our research questions. Even then, things could take place spontaneously in class when I least expected it. At those points, I had to make myself jot notes in my journal or somewhere, so I could remember and describe those important moments.

My plan book, in the second year of my classroom research, became a research log. I adapted my daily planning sheet to accommodate daily observations and notes. Since my plan book became a research journal, it worked for me. The plan book was always there—open—ready for me to jot notes. It was efficient. I liked it. Since I have always been a teacher who does a lot of notes about "next time I teach this" in my plan book and folders, this method fit more naturally into my routine while teaching than a separate journal. I use a separate journal for more intense reflection—less quick jotting—when I really need to process something about my teaching or my professional life.

Debby Wood's honesty with respect to the trials of data collection is another indication of just how disconcerting dealing with data collection can seem:

We had such a hard time finding methods that we thought were practical and feasible. To this day, I have not been able to master the use of a teaching journal. The idea of being videotaped gives me hives. I don't know if it was because we were so exhausted from the first year or what ... but none of the traditional methods of collecting data were inviting to me ... I don't think I spent a lot of time reflecting on what type of data would best serve the project ... I thought of what strategies I could fit into my existing classroom structure and what wouldn't drive me insane.

Data collection methods were closely related to the issues of balancing research and teaching. As noted in the two previous cases, teachers had to create methods that were doable, that helped them integrate research and teaching, and that were responsive to students. Most of us would agree with Karen: "The data I collected was more what than why, more process than product, more pain than procedure."

Shu-Hsien Chen and Barbara Davis also told of having to modify their original research plan to better accommodate the demands of school life and how this worked to their advantage. Originally, Barbara was going to interview teachers and students during the school day. According to Shu-Hsien and Barbara:

The problem with interviewing the students during the school day was that the teacher's free time did not correlate with the students' free, less-restrictive time. As for the teacher interviews, the schedule during the course of the school day fell through. Consequently, it became necessary to do all interviews at the end of the day, after the children had been dismissed. Time restraints also necessitated that group interviews, rather than individual ones, be done. We were, however, surprised and happy with the results of these interviews and feel that the students and teachers spoke much more freely in group situations than they might have done in one-on-one interviews.

Finding that balance between plans and realities helped Shu-Hsien and Barbara insure not only a sense of success with the process but also a research surprise that will prove helpful to others in the SRC. Group interviews outside the demands and pressures of a school day created a fit between research needs and student needs, and it provided better data. Becoming sensitive to shifts and changes in situations and feeling free to adjust research designs accordingly can be a teacher researcher's friend or foe, depending on the level of frustration she or he is experiencing at the time.

There was one method that everybody seemed to designate as essential—the importance of talk. Patti went so far as to declare, "At the university there's time to talk. That time is a source of power. Until we acknowledge that, they keep and have the power and we have none." This reaction to the isolation many teachers feel as they work behind their classroom doors everyday expresses the need for more frequent and open participation opportunities for teachers. Rarely do they feel that their voices are being recognized in public discourses on teaching and learning. Debby Wood said matter-of-factly, "Conversation was our data." This power of talk was not only a method used for establishing relationships with data but also contributed greatly when interpreting data. We include a discussion of this most simple but essential methodological feature in the following description of data analysis.

Balancing the Effort. According to the Teachers as Writers group, "Talk *is* data" as well as data analysis. "We had our personal writing, but it was the talk about the writing that was important to us and led us to the insights we gained." In fact, talk was so important that Georgiana recommended that next year the SRC provides "two day release time ... one day to talk it all out. Day two ready to sit down to writing."

Joint interpretation of data seems critical to SRC researchers. This aspect of the process helps reduce feelings of professional isolation and develops broader understandings among researchers within the SRC community. Christine Fuentes found "that discussions among ourselves were the best motivators and clarifiers for the project and modifications that needed to be made." Shelley Carr wrote essentially the same thing: "Discussing methods with my partners and other researchers was the best help. ... All of our analysis happened during group meetings. ... Many of our findings seemed to just appear from our conversations." Debby Wood elaborated on the process, explaining: "We would read the transcripts individually and would highlight parts that struck us as important. Then, as a group, we would share and discuss these themes."

Talk with a trusted outsider was also an element of the process for several teacher researchers. Georgiana and Johni valued the participation of university researcher Michelle Commeyras. As a "distant observer," Michelle offered someone "to talk with" that was "supportive" and "nonjudgmental" who could add "a different perspective [that was] not bogged down with classroom details." Ann Keffer recognized much the same effect when she wrote, "Our own group meetings always re-energized us, but talks with Betty [Coordinator of the SRC] helped the most. I found it exciting and helpful when NRRC folks started sending me articles that might bear on our research."

Several members of the community noted a variation of the talking-to-learn feature, the importance of preparing public presentations. Speaking to others created self-imposed deadlines and, as Ann mentioned, helped in "organizing our thoughts." Patti extended this line of thinking:

I have slowly come to realize that preparing for conference presentations or workshops has pushed us to analyze what we know.... Somehow the live audience was the pressure we needed to get out of the "starting box" in data analysis. For me, this goes back to my need to talk out what I know, what I am learning in my research.

There is a necessary interaction of oral and written talk that can be used effectively by teacher researchers. Based on her years of experience as a teacher researcher, Barbara Michalove advocated "bringing written reflections" to group meetings because "they made me analyze and reflect throughout the year." She thinks that sharing these written reflections with a "committed group of teachers" helps maintain the connections between ongoing research and instructional decision making. Patti also discussed the significance of such interactions:

The most helpful data analysis I have done is that which takes place when our small department research team meets on release days. Time to talk and write together is crucial, and we have developed

an established routine. We work separately on our writing for the first few hours of the morning, then come together at lunch time to share what we have completed, moving on to the larger SRC meeting later in the day.

And finally, Debby provided the following summary of her data analysis insights:

I think it was important that we participated in this process [data analysis] throughout the year as opposed to waiting until summer. There would have been entirely too much data to analyze. The day-long retreats were by far the most beneficial type of support the SRC gave to me. The retreats enabled us to meet away from school and to focus on what we wanted to accomplish. There were no interruptions (from students, parents, or principals) and we thrived in this setting. We love the job we do with children ... but every once in a while it was such fun to have an "adult" day.

Learning From a Distance

As we stepped back from our deep commitment and involvement with our research community in order to compose this section, we created an opportunity to see anew, to relive experiences of the past 2 years. This distance allows us to find some peace in what often feels like almost too dynamic a process. Many outside of the education community believe that all teachers have to do is teach. They do not recognize or understand that their days are crowded with complex professional responsibilities that too often rest on the verge of toppling the apple cart. Adding research to the balance may not be for all teachers all the time, but, as we have learned in the SRC, once teachers bite from the research apple, many find that their sense of professionalism demands that they continue to pursue this opportunity. As Seymour Papert (1993) wrote, "Knowing that one can exercise choice in shaping and reshaping one's intellectual identity may be the most empowering idea one can ever achieve" (p. 125).

I believe that teacher researchers in the SRC may agree with Papert, but they recognize that this kind of professional fulfillment comes with a price. Adapting plan books as research records, learning to count on students as knowers, coming to value talk and writing as methods for knowing, and giving ourselves time to look back and review from a distance are helping us find our balance as teachers who also research. I believe Vivian Gussin Paley (1990) would concur as she once wrote, "Until I had my own questions to ask, my own set of events to watch, and my own ways of combining all of these with teaching, I did not learn very much at all" (p. 16). And as Ann points out so well,

Part of the story, too, is of our growing understanding of our roles as teacher researchers. After two years, we know that classroom research is not something one gets through with. Instead, it is a different approach to teaching in which theory informs practice and *practice informs theory* continually and immediately right in the classroom. If classroom research is to be an organic part of teaching, then it needs to be allowed to shape itself to the natural rhythms of a school year. The intensity with which we pursue our research needs to be allowed to ebb and flow to accommodate other demands on us and our students.

Barbara Jarrard discovered that "the material (data) I had collected the year before began to make more sense at a distance." Georgiana and Johni also found that relooking at data during the summer gave them information that was not apparent during the school year, noting that "your perceptions may not be what the facts are." Time to look back and not just forward is a difficult balance to achieve for teachers who always feel the encroaching demands of tomorrow before today is even finished. The new understandings that can emerge for teachers who research and who acquire the habits of data analysis as ongoing aspects of practice will know they have enriched their professional lives. When they share their stories with others, they give this understanding a life of its own that can travel through time from teacher to teacher, as Debby Wood was coming to recognize when she wrote,

[The first year of our study] was not child-focused so it didn't directly impact my instruction. But I was definitely affected personally and professionally. The interaction with my peers and the involvement with the SRC invigorated me and caused me to become excited about my profession and the possibility that I could possibly make a contribution to the profession as a whole. I'm sure this only made me better in my own classroom. We talk so much about self-esteem for our kids. Self-esteem isn't finite. I am still developing as a person and as a teacher. Becoming a teacher researcher helped me value myself as a teacher in a new and important way.

In *Seeing for Ourselves*, Glenda L. Bissex (1987) went so far as to say, "If teacher research had been on the horizon ten years ago, I might still be in a classroom myself rather than having been driven to choose between knowing and doing" (p. 5). Teacher researchers in the SRC are knowing and growing by doing.

CONCLUSION

What do our three teacher research cases say about methods for classroom-based inquiry? As in any collection of cases, they simultaneously represent uniqueness and commonality. A case is unique in that it is an "instance" or "example" of an event or situation (*Webster's*, 1980, p. 170). Our cases are unique because the experiences we have had are particular, and the voices we use to convey them are personal. Therefore, Jim makes no claim that his account of an individual teacher researcher is the same as others who have engaged in solitary classroom inquiry. JoBeth does not maintain that her description of their teacher / university researcher collaboration replicates the work of other such teams. Betty does not suggest that her unfinished story of the SRC duplicates the experience of other teacher-research communities. We have argued that teacher research is defined partly by its diversity, and we are confident that our cases support this assertion.

However, a case is "a set of circumstances or conditions" that contains "evidence supporting a conclusion or judgment" (*Webster's*, 1980, p. 170). Therefore, in spite of the diversity among our cases (and our acknowledgment that there are infinite other cases of teacher research, told and untold), our stories beg for a look across them to discover their commonalities. Thus, we structure our conclusion by

looking at differences and similarities in teacher research methodology.

Uniqueness

Teacher-research efforts differ not only in researcher configuration, as our cases demonstrate (e.g., single researcher, collaborative inquiry, community of researchers), but also in the purpose behind a study. Purposes become manifest in research questions, which we have found to vary in source and substance (Baumann et al., 1994). Teachers engage in research to explore various questions that range from micro- to macrolevel in foci; for example, how to help one child develop comprehension-monitoring ability to how to improve school- or system-wide comprehension strategies instruction. Whatever the question, however, pedagogy remains central; that is, how to do the work of teaching better.

Teacher research differs in epistemological orientation. Jim's single-classroom inquiry and the teacher / university researcher collaboration JoBeth described fit best within our "pragmatic" epistemological category (i.e., selecting or creating appropriate methodological tools). However, we have seen within the SRC "established" studies (i.e., replicating university-based methodology), particularly within the first year of the community, as some teachers worked from their prior understandings of what counted as research. We also have "radical" SRC studies (i.e., having educational policy or political change as a research goal), for example, the Allen / Michalove examination of literacy in a democratic society (see Table 13-2). Teachers do research from various philosophical and political perspectives, and we believe that these multiple ways of viewing the world add to the richness of the genre.

Teacher-research studies differ dramatically in the types of data collected and used. Personal narrative has proved to be a powerful data source in many SRC studies. Observations and interviews were essential data sources in the Michalove / Allen / Shockley Bisplinghoff research, as well as in several SRC studies. Like many teacher-researchers, Jim is finding his extensive daily journal as a rich, primary record of his experience; in contrast, several SRC researchers found alternatives to teaching journals more effective for documenting classroom events and reflecting on them. Betty's "data world" view of classrooms leads each teacher-researcher to collect and examine a unique assemblage of sources of information.

Also, data analysis procedures vary from study to study. As Betty has documented, SRC researchers have used verbal interpretations among and between research team members as viable and powerful mechanisms for examining and understanding data from their studies. In contrast, Jim has borrowed from extant methodological traditions to ground his analyses, although he has had to adjust methods according to their doability, responsiveness, and impact on his instructional responsibilities. Teacher researchers also create analysis methods, as evidenced by the interpretive dialogue procedure JoBeth described in their collaborative inquiry.

Thus, as our cases demonstrate, no two teacher-research studies are alike in form or function. However, each is driven by several basic tenets common to this developing form.

Commonality

As noted in our review, most descriptions of teacher research include the processes of action and reflection. As teacher researchers ourselves, we concurrently did the work of teaching while standing back and examining it. The seemingly paradoxical task of simultaneous doing and reflecting underscores the tension and exhilaration inherent in teacher research.

The emic view teachers have with respect to research is a distinguishing mark of classroom inquiry. Insider status provides a unique vantage point for a researching teacher's reflective actions, and distinguishing what constitutes teaching and what constitutes researching becomes difficult and unimportant. As the teacher researchers cited in Betty's SRC story so eloquently stated, theory and practice become blended, if not blurred, in teacher research. Practical theories and theoretical practices are inescapable outcomes of teachers studying their work.

Methodological evolution is an inevitable characteristic of teacher research. Jim's choice of methods, as sensible as they seemed prior to day 1 in second grade, was only temporary. As soon as he got into the classroom and began to wrestle with the realities of researching while teaching, he found that methods needed to be adapted or scrapped. Teacher researchers are thoughtful in the methods they choose, but they cannot adhere to them slavishly. Methods are no more than tools of the trade that may and must be modified to achieve the goals underlying the inquiry.

A corollary to the preceding is the necessity of pragmatism in methodology. Methods must work in an efficient and effective manner for teacher researchers. JoBeth's, Betty's, and Barbara's frustrating venture into constant comparison and grounded theory led them back to their interpretive dialogue method. Why? Because it brought them back to the real purpose of their inquiry. It kept the experience whole rather than fragmented; as a result, they again enjoyed, rather than dreaded, data analysis sessions. The SRC researchers failed to find research journals as easy to keep and useful as reported by other teacher researchers in the published studies they were reading. Instead, they found ingenious ways to make daily records of their research experiences, be they addenda to daily plans, a hybrid plan book / research journal, or literally notes on transparency scraps. If it worked methodologically, its use persisted; if it did not, it atrophied or was thrown away.

As Betty documents, SRC researchers found the opportunity to have professional conversations a powerful methodological tool in teacher research. Having the time to discuss what was going on in classrooms and in students' lives released them from the isolation and anonymity of teaching-as-usual. The professionalism, esprit de corps, and simple self-esteem engendered by focused conversations with colleagues deepened their interest in, commitment to, and need

for teacher inquiry. JoBeth described talk among team members and with the children and their parents as integral to their collaborative research. Even Jim, who studied himself and his classroom mostly in isolation throughout the school year, found post-school-year recorded conversations with colleagues, administrators, parents, and children extraordinarily illuminating.

We close by responding to the framing questions we posed at the beginning of this chapter. Teacher research is an evolving philosophical orientation toward practical theory; it is not simply an adapted or a hybridized conglomerate of existing educational research methods. It is true that teacher researchers adopt or adapt methodological tools from extant research traditions for data collection and analysis; this is in

keeping with the pragmatic nature of much teacher research. As we have shown, however, teacher researchers also invent or create their own methods. But methods do not equate to methodology, and it is not the source of the methodological tools themselves that distinguishes teacher research. Instead, it is the unique and common characteristics we have discussed that define teacher research as its own genre. Therefore, we maintain that teacher research is a distinct, communicative art, a self-perpetuating lesson on constructing meaning. The diversity within this changing, reflective, action-oriented research pedagogy makes it vibrant and fulfilling for those who engage in it and, we believe, enlightening and thought provoking for those who read, use, learn, and benefit from it.

ASSESSING DEVELOPMENT AND LEARNING OVER TIME

Robert Calfee

STANFORD UNIVERSITY

Not too many decades ago, *literacy* meant mastery of basic reading skills. *Evaluation* relied on reading speed and accuracy, behavioral objectives, and standardized test scores. *Measurement* was directly linked to “countable” indices. *Growth* meant changes in scale scores and grade-level equivalents. *Validity* was indexed by predictive and concurrent correlations. Quantitative methods ruled the roost.

Things have changed. Qualitative methods are ascendant. Definitions of *literacy* are much different. Print literacy is still important, and the “great debate” continues to rage (Chall, 1967, 1983, 1992). But the concept of literacy for tomorrow’s graduates reflects computer technologies and the information highway, and a shift from a factory society to a communication world. Today, educators have good reasons for incorporating communicative and visual arts into the literacy domain. The key word for *evaluation* is now assessment, the label for an emerging paradigm that is the antithesis of testing, a paradigm in which teachers employ portfolios and performances to judge complex performances by qualitative methods. *Measurement* now entails subjective ratings of student productions; “scoring” and “rubrics” are hot topics. *Growth* remains a puzzle. A purported advantage of the new assessments is that student progress is more obvious, but it is difficult to pin down the exact meaning of this claim. Finally, no other assessment topic has provoked as much discussion as the meaning of *validity* in the new paradigm. The dialogue arises partly because of the paradigm shift but also because of continued rethinking of the basic concept. Scholars have proposed radical changes in the definition of validity and its operationalization. Some suggest that validity inheres not in a particular instrument or method, but in interpretations and consequences. For test publishers and users accustomed to straightforward “validity coefficients,” the proposal is both revolutionary and disconcerting.

These four elements are the foundation for this chapter. The framework partly reflects my background and the charge by the Part editor, but also consideration of the topics covered by other writers on *Methods of inquiry*, who describe qualitative methods for understanding literacy in a variety of contexts and genres, but do not touch on the last three topics in my framework. My brief introductory discussion of literacy sets the stage, but I will rely on other Parts, especially Part I, for a more complete account.

Given the changes sketched above, all springing up within the past decade or two, covering the title would be a challenge under the best of circumstances. Advocates of quantitative and qualitative methods still live in largely different worlds, despite efforts at bridge building. Two of the topics—measurement and growth—have been largely disregarded in recent years, although the issues go back a long way (Calfee, 1993). The primary goal of this chapter is to present a conceptual framework linking these four elements. The second aim is to link this conceptual analysis to the practical aspects of classroom assessment, where the primary clients are teachers, students, parents, local administrators, while exploring how information from classrooms can serve external audiences.

As background for this chapter, I have relied on other handbooks (Barr, Kamil, Mosenthal, & Pearson, 1991; Belanoff, & Dickson, 1991; Berliner, & Calfee, in press; Bloom, Hastings, & Madaus, 1971; Bloom, Madaus, & Hastings, 1981; Flood, Jensen, Lapp, & Squire, 1991; Jackson, 1992; Linn, 1989; Pearson, 1984; Wittrock, 1986), selected journals (*Educational Measurement: Issues and Practice*; *Applied Measurement in Education*; *Review of Research in Education*; *Educational Assessment*), and several seminal volumes and articles (Baker, O’Neil, & Linn, 1993; Calfee, & Perfumo, 1996; Harlen, 1994; Kane, & Mitchell, in press; Linn, 1994; Moss, 1992, 1994a; OTA, 1992; Wiggins, 1993). I did not conduct an ERIC search, and have undoubtedly overlooked

some nuggets. I have not extracted all the “goodies” from the aforementioned sources; in particular, I have neglected the OTA and Harlen citations, which I might have referenced continuously to do full credit. Nor have I attempted to portray the domain of visual and communicative arts for literacy educators, other than to suggest the importance of such a portrayal for purposes of construct definition, and to offer a few thoughts about how I might attempt such a task. The coverage is more contemporary than historical; although we can learn many lessons from history, I had to choose among competing priorities.

The prevailing theme throughout the chapter is the notion that adequate assessment of complex learning and achievement requires informed professional judgment. I will return repeatedly to the classroom as a touchstone for playing out this theme. Now let me look in turn at each of the four basic elements: (a) building an explicit definition of communicative and visual literacy as a foundation for professional evaluation, (b) assessment as the assigning of value to performance, (c) measuring growth, and (d) establishing validity.

Literacy Constructs and Curriculum: Foundation for Professional Assessment

Assessment requires a purpose, an audience, a method, a report, but above all an object or event—a “something” (Herman, Aschbacher, & Winters, 1992). For literacy, that “something” is a construct encompassing a set of concepts and practices that describe skills and knowledge about language and print, as well as the course of study for supporting the development of these skills and knowledge. Literacy does not occur naturally but is the result of tutelage, most often through schooling. Not every reader will agree with this statement, but the evidence appears overwhelming (Honig, 1996; Pressley, & Rankin, 1994).

The Construct of Critical Literacy. A “construct” implies something that is constructed, and several edifices have arisen under the literacy banner. Basic print literacy, for instance, covers the skills of decoding, spelling, literal comprehension, and the rudiments of writing. The minimum competency tests mandated in the 1970s aimed to ensure that every high school graduate could demonstrate competence in these skills. Scarcely was the ink dry on these policies than the nation began to realize the limited value of these mandates.

The alternative to basic print literacy is less easily defined. Some authorities emphasize exposure to content (print literacy plus cultural literacy; Hirsch, 1987). Others emphasize higher-level thinking, which seems clearly preferable to lower-level thinking (Resnick, 1987). Within print literacy, reading and writing might seem complementary, but in fact the two domains are separated by a broad chasm conceptually, organizationally, and practically (Clifford-Jonich, 1987).

For present purposes I will employ the construct of *critical literacy* (Brown, 1991; Calfee, 1994; Calfee, & Patrick, 1995) as a starting point, recognizing the need to extend the idea to include the other domains emphasized in this handbook. Ten years ago, with communicative and visual literacy barely on the horizon, it made sense to me to define critical

literacy as “the capacity to use language in all forms—listening, speaking, reading, and writing—to think, to solve problems, and to communicate.” The inclusion of communication was innocuous; it ruffled no feathers, but neither did it arouse much attention. But today’s world includes the power of technology to expand exponentially our definition of communication, and to extend print to include other representational modes. *USA Today* illustrates the potency of combining print and picture; the personal computer offers opportunities to create visualizations of incredible power and complexity; classrooms sprout with “webs,” “story graphs,” and other graphic organizers (Nowak, & Gowin, 1984). I therefore propose a variation on the original definition—“the capacity to use language *and other media for representing ideas* to think, to solve problems, and to communicate”—recognizing the slimness of this proposal. Olson (1995) offers a similar recommendation—“Perhaps it is time that we further relax our definition of writing to include . . . any graphic form used to convey information” (p. 292). He also presents the idea that becoming print literate entails more than “getting meaning;” it also entails “an understanding of how a text works” (p. 294).

Extending this reasoning to the visual and communicative domains, let me suggest that fully literate individuals appreciate how visual and communicative technologies operate; they can dissect a graphic and analyze a discussion. Witte and his colleagues (Witte, & Flach, 1994; Witte, Flach, Greenwood, & Wilson, 1995) emphasize the communicative aspects of all symbol systems. “. . . Engaging in symbolization processes such as reading and writing appears to force one to reflect, sometimes consciously and sometimes not, on both what and how one knows as he or she judges the potential meaning signaled by a given text, whether one being read or one being written, against his or her internal representation of the world. [These critical thinking] functions . . . point to a third function embedded in communicative acts, namely, problem solving [which] itself is a meaning-constructive process that entails problem representation, reflecting on what one knows, and using strategies to orchestrate” (pp. 222, 223). Mislevy, Yamamoto, and Anacker (1991) make a similar point: “Learners become more competent not simply by learning more facts and skills, but by reconfiguring their knowledge, by ‘chunking’ information to reduce memory loads, and by developing strategies and models that help them discern when and how facts and skills are important” (p. 10). Moreover, fully literate persons are capable of self-assessment. They are able to monitor their performance, to check how they are doing, to use self-reflection for corrective feedback. Sizer (1995) expresses this idea with characteristic force: “Good schools not only frequently tell their students how they are doing, but get the students into the habit of asking the question for themselves. The expectation of illuminating feedback—indeed, aggressively searching it out—is one of the universal characteristics of an educated person” (p. vi).

Curriculum Constructs. It is tempting to pursue these issues further, but other chapters in this handbook must serve this purpose. I turn now to another matter: defining the curriculum of critical literacy. Once the characteristics of a fully literate person are specified, the next question is how to build

a road that helps a young child move from “here to there.” This task is complicated by the fact that today’s children spring from dramatically different backgrounds, and aspire toward dramatically different outcomes than those of previous eras. Commonalities exist. Sixth graders do not aim to go on welfare; they want to finish college and make a good living. On the other hand, not everyone aspires to become an algebraist, although top-lane mathematics is the entry point to the college track. Not everyone is enchanted by *Moby Dick*, although book reports can be the key to advanced placement.

One strategy for curriculum construction is to build a linear path, a scope-and-sequence chart, in which detailed objectives are taught at specific time points. A stage-based literacy curriculum (Chall, 1983, 1992) exemplifies this approach. The strategy works well for education as selection; much like sorting apples, a student’s place in the social hierarchy depends on the slot through which he or she falls. In this model, achievement uses the average as a standard; students who do not fulfill the norm for their cohort are “below average,” no matter how well or poorly they may do in absolute terms.

A second strategy views the learning as a natural matter. The “readiness” perspective falls within this category; when a child is ready to read, that is the time for instruction. The Whole Language philosophy reflects this assumption (Goodman, 1986). The curriculum emerges as individual students are immersed in literary works. A modicum of guidance by the teacher, and literacy will ensue.

A third strategy assumes that, to ensure that every student achieves his or her full potential, what is needed is an explicit but adaptable course of study—a developmental curriculum (Barr, 1984; Juel, 1991). The early years are critical, especially for those children from backgrounds that do not prepare them for the school regimen. The integrated primary model illustrates the possibilities of a flexible curriculum during the primary grades (Mason, 1984; McGee, & Richgels, 1990; Sulzby, & Teale, 1991). During the late elementary and middle school years, students must learn to apply the literacy skills that are the focus of this handbook. While we have models for the primary grades, the middle years pose a challenge to curriculum design, which call for a move from developmental growth toward subject matter competence. After leaving middle school, the high school student cannot expect to encounter an adaptable curriculum, however desirable that might be. High schools expect students to have mastered the fundamentals; teachers emphasize content over development.

Returning to the elementary and middle grades, what are the underlying principles of a developmental curriculum? The *Handbook of Research on Curriculum* (Jackson, 1992) offers interesting insights and analyses into this question but is mostly philosophical. The only reference to development is a brief commentary on possible implications of Piaget’s theory of stages for curriculum design. Gehrke, Knapp, and Sirotnik (1992), “In search of the school curriculum,” comment that dozens of images exist, none especially compelling: “Only a limited amount of research has focused on the state of the curriculum ... [In language arts] oral language is the step-child” (p. 69).

A comprehensive description of a developmental curriculum for print literacy is found in Moffett and Wagner (1992; also see Calfee, & Patrick, 1995; Paris, Wasik, & Turner, 1991), who lay out a course of study shaped around the changing capabilities of students from kindergarten through high school. This curriculum, which integrates reading, writing, and oral language, presents an ordered sequence of learning goals, but without the “linearity” of scope-and-sequence charts. The curriculum, built on a language experience philosophy (Allen, & Allen, 1982), relies on teachers as professionals who can adapt developmental concepts to different contexts. The surface events in a Moffett-Wagner curriculum may vary widely from one situation to another, but the underlying curriculum constructs will remain constant to the knowledgeable observer. It is not the constancy of the scope-and-sequence chart, nor the idiosyncrasy of the whole-language philosophy, but a design unlike either of these strategies.

How might a developmental curriculum incorporate the concepts of communicative and visual-graphic competence? At the outset, the construct of critical literacy sketched earlier is inherently communicative; one of the primary purposes of literacy learning is to provide individuals with tools that enhance interactions with one another. The integration of visual and graphic elements with other forms of print literacy is the challenge. Two recent innovations seem particularly noteworthy: (a) the use of graphic organizers as instructional strategies, and (b) the power of the personal computer for displaying rich and dynamic visual-graphic-print information, and as a tool for students (and teachers) to create their own visual-graphic-print products. Research has paid little attention to these elements until recently (Bromley, 1991; Heimlich, & Pittelman, 1986; Jonassen, 1985; Wright, Lickorish, Hull, & Ummelen, 1995), and the assumption seems to be that students can “naturally” learn how to process visual information. The expressive potential of this technology expands daily, and competence in multimedia comprehending and composing will certainly be highly valued in the years to come. The educational system is still largely in the dark ages when it comes to the resources, technological and human, needed to build a curriculum in this domain, but we need to think about the possibilities.

In the remaining sections of this chapter, the task of defining the construct and the curriculum will reemerge as fundamentally important. Evaluation is stymied when the thing to be appraised is ill-defined and evaluation becomes idiosyncratic. Psychological measurement turns out to be relatively straightforward for simple constructs, more difficult with complex constructs, and impossible when the construct is indeterminate. A substantial literature exists on models of learning and development, but these can be brought into play only if we know what is being learned and how it is being learned. Finally, whatever one’s views of validity, construct definition is central to the validation process.

This section thus ends with a challenge rather than a conclusion. Extending the construct of print literacy to include communicative and graphic features moves the concept into the future. But if schools are to realize the potential of this advance and if assessment policy is to support the effort, then

a significant task is the defining of a construct that lays out the curriculum from the early years of school onward describing what students need to learn and how teachers need to guide this learning within this domain.

In the remainder of the chapter I will rely for purposes of illustration on a definition for the domain of print literacy based on four strands (Calfée, & Drum, 1986): concept development, narrative comprehension and composition, expository comprehension and composition, and decoding-spelling. Each of these strands is separable, in the sense that different concepts and terminology apply, and that different curriculum paths are required. Any “real” literacy task may call on some or all of these domains; when I drive from Palo Alto to San Francisco, I operate my automobile as a “whole;” if it breaks down along the way, it helps to be able to trace the problem to one of a handful of independent systems. What I have not attempted to think through is the handful of additional components needed for a broader view of literacy that encompasses print, but also incorporates graphics and other communicative media.

Neither does this chapter attend to the instructional support needed to promote a curriculum. Surveys suggest that instruction in the elementary and middle grades still follows an assembly-line transmission model. Teacher talk dominates, and students are individually reinforced as they respond with correct answers. Visions of the classroom as a social-cognitive environment appear here and there: “Classroom instruction should provide an environment in which students are able to externalize their thoughts. . . [so that] the writer is able to step away from personal, abbreviated inner speech to external social speech” (Everson, 1991, p. 10). This allusion to Vygotskian learning offers an intriguing perspective but is far removed from present realities. Curriculum, instruction, assessment—coherence in the C-I-A troika—is probably critical for genuine educational reform.

The previous discussion has laid the foundation for considering different strategies for evaluation of visual and communicative literacy. Evaluation of student achievement has been a centerpiece of educational research for more than a century. Prior to the 1940s, studies of grading were commonplace. Beginning in the 1950s, research on standardized tests dominated the literature. The psychometric tradition discussed in the next section is well established, and I will assume that readers are familiar with this tradition, including both norm-referenced and criterion-referenced methods for assessing student achievement and program effectiveness (Linn, 1994).

Testing Psychometrics and Assessment. The foundation for the psychometric tradition is the notion of a trait “score,” defined operationally by a test. The trait may encompass a broad domain like vocabulary or comprehension, or focus on a more closely specified objective like “long-short vowels.” In either event, the starting point is the total score, the number of correct answers to 12 questions selected to sample the domain. The aim of psychometric analysis is to establish the reliability and validity of the total score. Reliability means that the set of questions—items or minitasks—contribute consistently to the total score. Validity means that the total score

correlates with other indices designed to tap the same domain.

Building on this foundation, psychometrists have moved the field to a high level of technical sophistication. In its simplest form, reliability is determined by the correlation of each item to the score. If a particular item rank-orders students differently than the total score, then the item undermines reliability. For practical purposes, psychometric reliability is the average correlation between individual items and the total scores. If every test item ranks students in the same order, then the total test score is reliable. To the degree that different items give different ranks, the test is unreliable.

Generalizability, a major extension of reliability (Cronbach, Gleser, Nanda, & Rajaratnam, 1972; Cronbach, Linn, Brennan, & Haertel, 1995; Shavelson, & Webb, 1991), advances the original ideas and methods in fundamentally important ways. Not only items, but all factors influencing the total score, can be included within a single coherent generalizability design. For example, suppose that some items on a vocabulary test require knowledge of Anglo-Saxon words while others are from Romance origins, and that some testees are English-only, while others come from a Spanish-language background. The test might appear unreliable because of differences in the rank-ordering of students and items from these two dimensions. Generalizability allows the psychometrician to identify different facets in the data structure, and to explore the reliability of total scores as well as profiles. For instance, the total scores might have limited reliability on first glance, but generalizability analysis might reveal that English-only students perform consistently better on Anglo-Saxon items while Spanish-background students do relatively better on Romance words. The potential of generalizability methods for establishing the reliability and validity of innovative assessments has yet to be fully realized; I will explore this matter more fully in the final section on validity.

Traditional testing has provoked critiques for more than a half-century (Gould, 1981; Haney, & Madaus, 1989; Hill, 1994). In the 1980s, scholars and practitioners began to propose a new strategy, *assessment*, as a complement if not a complete replacement for testing and psychometrics (for reviews, see Gipps, 1994; Glaser, 1981; Mitchell, 1992; Wiggins, 1993). Most discussions fall on the endpoints of the continuum in Table 14–1. Supporters of testing-psychometrics point to the trustworthiness and efficiency of traditional methods, and the perils of unproven methods (Hambleton, & Murphy, 1992; Mehrens, 1992). Advocates of innovative assessments typically meld their proposals into a total package that includes a social-cognitive curriculum, student-centered instruction, and professionalization of teaching (Mitchell, 1992; Wiggins, 1993). Researchers see assessment as an extension of qualitative methods and postmodernist philosophies, a counterpoint to quantitative methods and positivist philosophies. Practitioners view assessment as a way to empower the classroom teacher, while testing is a “time-clock” relic of the factory model of education.

While one can find early precursors of the current debate [e.g., Tyler (1934, 1989) in the 1930s; Bloom et al., 1981], a paradigm shift also seems brewing. Critical questions center

TABLE 14-1. Contrasts Between Externally Mandated Standardized Testing and Self-initiated Professional Assessment.

	Testing	Assessment
Purpose	External accountability	Classroom instructional decisions
Audiences	Policy makers Administrators General public	Teachers Students Parents
Methods	On-demand Multiple-choice Standardized conditions Objective scoring Psychometrics	Continuous performance Observation / "kid-watching" Less-than-fully-standardized Subjective rating Interpretive / hermeneutic
Dependability	Reliability based on interitem consistency Validity based on predictive correlations	Interrater and intertask consistency Trustworthiness based on moderation
Interpretation	Statistical indices Mastery of objectives Rank ordering of students Attainment of standards	Narrative descriptions Developmental progress Individual achievement Attainment of goals
Reporting	Statistical summaries and graphics Focus on total scores Demographic breakdowns Administrative unit breakdowns Official summary	Qualitative summaries and "stories" Emphasis on profiles Individual accounts School "report cards" Parent-student conference

around assessment concepts and methods, but equally important are (a) the match of assessment with curriculum outcomes, and (b) the role of the teacher as a professional assessor. Testing is seen as a match to a linear-behavioral curriculum, while assessment is better suited to dynamic-cognitive learning (Shepard, 1995). Testing places the teacher in the role of civil servant while assessment calls forth professional judgments. The choice of descriptive labels captures essential features of the debate.

Testing is typically connected with the multiple-choice format and behavioral objectives while assessment is linked to performance. Baker et al. (1993) provide one of the clearest conceptualizations of this idea, happily without beating any dead horses. Performance-based assessment uses open-ended tasks (directed toward production more than recognition), lays out complex tasks, offers students choice about the content and context for demonstrating competence, and situates the assessment in a setting where multiple skills are required, adequate time is allowed, and resources are available. The student can refer to books, notes, the library, other students—even the teacher! Baker et al. discuss the implications of this assessment strategy for various purposes and applications, and offer a balanced perspective on the advantages for improving the character and quality of instruction, which they weigh against a variety of risks.

A particularly significant issue is the feasibility of classroom-based assessment for large-scale accountability. Given the continuing pressure for public information about the public schools, the issue is not whether students will be "tested" (and programs evaluated), but how and by whom?

One strategy relies on externally mandated tests, the other on internally determined assessments. Many observers see the two as incompatible strategies (e.g., Cole, 1988; Gipps, 1994; Harp, 1991; Mehrens, 1992; Tierney, Carter, & Desai, 1991; Wixon, Valencia, & Lipson, 1994). Cost-efficient standardized testing is essential to ensure dependability and to avoid corruption. Assessment is a "teacher thing," and standardizing it destroys the idiosyncrasies that make it valuable in the local contexts.

One can find variations on these themes. Proponents of measurement-driven instruction (Popham, 1993) value tests as a policy lever for prescribing classroom practice. Others suggest that assessment systems may be valuable for their influence on classroom practice even when they are not trustworthy by psychometric standards (Gipps, 1994; Wiggins, 1993), but the data are not always supportive of this position (Martin-Kneip, Thornburg, & Cookson, 1994). The U.S. perspective on these issues, of course, reflects our history. While I cannot pursue the matter here, let me suggest that an examination of these issues in other settings might enlighten the current debate; the recent tensions in Great Britain between internally and externally mandated assessments of student achievement casts a different light on the meaning of accountability and the professional roles and responsibilities of teachers (Daugherty, 1995; Gipps, 1994; Harlen, 1994).

Following on this point, a central question in this chapter centers around the classroom teacher's role in the assessment of student progress through a complex developmental curriculum for purposes of internal (local) and external (public)

accountability. A key question centers on the potential for professional judgments of student achievement to attain the same status as the objective psychometric methods that have evolved during the past half century. As suggested in the previous section, professional judgments must be grounded in a clearly explicated curriculum construct. But in addition, other building blocks include extensions of psychometric concepts, developments in qualitative methodology, practical experience with professional discourse or “moderation” as a way of calibrating teacher judgments, and studies of the influence of organizational factors on the professionalization of teachers (Linn, & Baker, 1996; McLaughlin, & Shepard, in press).

Professional Judgments of Complex Performances. Can teachers, given appropriate conditions, produce from a rich and situated body of classroom evidence the formative and summative judgments that document students’ progress and accomplishments—judgments that are trustworthy and that carry added value beyond what can be learned from less expensive and more efficient alternatives? Human beings are certainly capable of performing such tasks. Reviewers of journal manuscripts (and handbook chapters) provide editors with written assessments that are complex, that are highly valued, and that are significant in high-stakes decisions—even though reviewers often disagree with one another. Physicians’ medical notes may seem cryptic to the uninitiated, but they provide the basis within the professional community for diagnosis and treatment. Travel guides and wine reviews rely on words to convey images and communicate appraisals. *Consumer Reports* offer pages of richly descriptive information about products and services. Professors grade undergraduates and certify doctoral candidates.

In these instances and others, the value and trustworthiness of the information builds on a dialogic process, where multiple sources of information receive careful reading and intense exchanges among the parties. Can we rely on subjective judgments? The answer is that we do, with great regularity. The key is the creation of communities within which focused discussions are the standard. Multiple reviews and second opinions are routine; when uncertain, the policy is to ask for further clarification. Above all, the user of the information must be able to “think about it;” passive acceptance of a judgment is a poor practice, even when the judge is held in high esteem. Esteem is an important element in the process; whether or not the reputation is justified, used-car salespeople are seldom viewed as trustworthy sources of information about automobiles.

Subjective judgments are valued when the judge is viewed as a professional, when the client lacks knowledge about the domain, when the judgment carries the weight of a community of experts, and when there is an aura of competence and confidence. These conditions are not commonplace for elementary and middle-grade teachers. They are isolated, they lack a professional language, and they do not feel that they are trusted (Fraatz, 1987). These descriptors apply to U.S. teachers; the situation may be different in other cultures.

Judgments and Ratings. Descriptions can be and often are the basis for numerical judgments. Journal reviewers fill out

rating scales, physicians estimate the success of a treatment, travel guides and wine books grant “stars,” Olympic judges of diving and skating hold up number cards, and *Consumers Union* offers a plethora of ratings. The numbers allow analyses not possible from the descriptions. In the Olympics, some events are inherently numerical; the person with the shortest time in the 100-meter dash or the longest throw in the javelin toss wins even if the commentator finds the style less than elegant. Other events—diving, gymnastics, ice skating—are assessed by qualitative appraisals of performance, assessments that lead to quantitative ratings. Consistency is a matter of immediate public record. When the judges raise their cards, the audience sees immediately the extent of agreement, and can appraise the meaning of disagreement (“It looks like Country X favors its athletes and dings those from Country Y”). The point is that human beings can perform complex assessment tasks with sufficient consistency and credibility to serve for significant decisions. Their numerical judgments are treated as “real numbers;” they are used to rank order candidates (and judges), they are averaged, they are used to calculate consistency, and so on.

The conditions for trustworthy assessments based on teacher judgments, whether qualitative or quantitative, are fairly well established, the most convincing examples springing from the British experiences (e.g., Black, 1994; Daugherty, 1995; Harlen, 1994; Mitchell, 1992), but also from American experiences with large-scale assessments of complex performances (e.g., Gearhart, Herman, Novak, Wolf, & Abdi, 1994; Koretz, Stecher, Klein, & McCaffrey, 1994). Teacher organizations in the United States, in collaboration with the National Council on Measurement in Education, have prepared standards for teacher assessment of students (AFT, NCME, NEA, 1990), but these are largely exhortations to handle problems that challenge current thought and practice in the area (e.g., “Teachers should be skilled in using assessment results when making decisions about individual students, planning teaching, developing curriculum, and school improvement” p. 32).

The starting point for trustworthy judgments is a well-defined construct: for a diving judge, the schema for an ideal diving performance; for an elementary teacher of children’s literature, the schema for a student’s analysis of the narrative genre (e.g., Wolf, & Gearhart, 1994). The construct is explicit for performers and judges, and for the audience as well. Next comes the creation of a task environment for performance. The situation often combines standardized and nonstandardized elements, the required and the free-form. But all participants know what counts and what does not, what can be done and what cannot.

Finally, the judges operate as individuals within a community. They are expected to justify their ratings, and may be dismissed (or disregarded) if they cannot sustain standards of consistency and explanation. The key is an ongoing dialogue among members of the entire community, but especially among the judges, to clarify and explicate the construct and the process. Again, the British experience with *moderation* demonstrates the practicality of this idea within the context of the teaching profession (Harlen, 1994; also LeMahieu, Gitomer, & Eresh, 1995; Mitchell, 1992, p. 161ff.). Unfortunately, it appears that these conditions are seldom achieved in

the lives of American teachers, for whom assessment is too often one more task piled on top of an impossible collection of mandates and responsibilities, a task for which they receive little professional preparation (for troubling examples, see Cizek, Rachor, & Fitzgerald, in press; Gearhart, 1994; Koretz et al., 1994; Moss et al., 1992; Stiggins, & Conklin, 1992; Valencia, Hiebert, & Afflerbach, 1994, especially the review by Wolf, 1994).

The Assessment of Literacy. Wines, cars, diving performance—these examples from the previous section pose a variety of challenges to judgment, but nothing compared to the assessment of literacy as defined in this section. The task can be trivialized—keep a record of pronunciation mistakes during oral reading, measure reading speed, count the number of details recalled from a passage. A behavioral curriculum, much like a 100-meter dash, may proceed by counting, “How many objectives has the student completed this month?” Gauging a student’s growth in the use of language to think and communicate, however, requires an analysis by the teacher that is inherently descriptive, qualitative, and narrative in character. A social-cognitive curriculum looks at both outcome and process, at individual work and team activities, at surface performance and deeper reasoning, at activities completed and at tasks attempted. None of these is inherently countable; at least what counts is generally not what can be counted. Student movement through a developmental curriculum is generally more narrative than linear: flashbacks, digressions, asides. The teacher is in a position to tell the story, to explore motivation, to recount the episodes, to identify critical events. These are idealizations, to be sure, and a barrier to reform of classroom assessment is the mind-set established by years of experience with a linear behavioral literacy curriculum. Tittle (1994) describes the importance for the teacher of establishing an epistemology that links *substance* (curriculum, teaching and learning, development and change), *assessment methodology* (task format, conditions, collection and analysis of evidence), and *interpretation* (critical evaluation, reporting methods). These facets open the way for developing a “psychology of the assessor,” but the job remains to be done.

A missing element in most literacy assessments is the link between student performance and curriculum benchmarks. Ideally, the teacher traces not a random or indeterminate “story,” but rather the student’s movement along the strands of the literacy curriculum. Qualitative assessments allow the teacher to adapt instruction for the class as a whole and for individual students, not through “individualization” but by shaping the environment for the entire “learning community.” The story, when well told, provides feedback to students and to parents, not as a “Johnny is doing well, but has a problem here,” but as a travelogue—“Johnny started here in September, here is where he is in March and how he got there, and here is where he needs to be in June and how we plan the rest of the trip” (e.g., Klimenkoff, & LaPick, 1996). It means reflecting on progress and successes, but also on challenges and failures. Mitchell (1992) observes that “[students saw] the portfolio as an opportunity to display success, [but] were

reluctant to understand it as a record of development..., which necessarily includes failure, a truth difficult for students to accept.” Other observers have noted teachers’ “success orientation,” the inclination to celebrate victories and ignore defeats (Cizek et al., in press). Complete stories can be told only against the framework of a clearly explicated developmental curriculum path, one where goals and standards are clearly explicated. As Gipps (1994) notes, “teachers cannot assess well a subject matter that they do not understand..., [They] need to understand the constructs they are assessing” (pp. 160, 161, also p. 138ff.).

Two contrasts serve as important themes for these stories: *profiles* versus *scores*, and *progress* versus *accomplishment*. As noted earlier, testing typically generates total scores, indicators of overall performance that summarize presumably complex performances. Even when test subscores are available, these are typically highly correlated, making it pointless to report subscore information (Davis, 1968; Thorndike, 1973). The implication seems to be that literacy is a unitary or “whole” construct.

An alternative interpretation starts with the notion of “unclean tests,” where situational demands unrelated to the construct influence overall performance. The “real test bias” (Hill, 1994; Mehrens, 1992), according to this interpretation, may reflect the impact on the student of a high-pressure, time-bound, decontextualized, and depersonalized situation lacking purpose, guidance, and audience. As Wiggins (1993) puts it, “Answer *my* question, *my* way. You have one try..., you cannot rethink your answer..., you get no feedback” (p. 130). Under these conditions, which challenge some students more than others, subtests are correlated because of common (and irrelevant) demands that have nothing to do with what is being assessed.

Haertel and Wiley (in press) address the same issue when they discuss the *intents* versus the *ancillaries* of a test design; a clean test (Calfée, & Drum, 1979; Calfée, & Venezky, 1969) is one in which the ancillary demands are minimized. The classroom teacher is uniquely positioned for this strategy—given that he or she has a clear idea of the strands that comprise the literacy curriculum. Numerous studies suggest that teachers in the elementary grades judge student’s reading by oral reading fluency (Allington, 1989), and that writing depends on mechanical features like spelling and grammatical conventions (Freedman, 1982). Oral language facility—listening comprehension and “story-telling” ability—tends to be disregarded, leading again to a one-dimensional characterization of student achievement.

If students’ strengths and weaknesses are to stand out in an assessment, the first requirement is that a few distinctive performance strands must be identified; the second requirement is that ancillary requirements be minimized. The reason for emphasizing profiles as a complement to or replacement for an overall indicator is that instructional decision making, as well as feedback to students and parents, is better guided by specific patterns. A few assessment systems incorporate this strategy (e.g., Barrs, Ellis, Hester, & Thomas, 1988; Barr, & Hallam, *California Learning Record*; Barrs, Ellis, Hester, & Thomas, *The Primary Language Record*; Darling-Hammond, & Godwin, 1993), but most classroom-based systems tend to

merge performance into a holistic summary (Goodman, Goodman, & Hood, 1989; Harp, 1991).

Informative profiles are more likely to emerge from classroom assessment because the teacher can adapt the conditions of assessment to eliminate irrelevant barriers, but patterns are likely to appear only when the teacher has a clear conception of the distinctive features of each strand, and if the number of distinctive strands is relatively small—4 to 8 elements. The multitude of objectives typical of behavioral programs quickly exceeds the teacher's grasp. Research and practice on profiles in the literacy field is modest at best. The volume by Cronbach and Gleser (1965) is the classic work, but has seen little extension into practice. A few studies have shown that trustworthy profiles do exist for writing (cf. Freedman, 1983 and Roid, 1994, for example). In print literacy, teachers know about the third grader with rich oral language but impoverished decoding and spelling skills. In graphic literacy, I recall vividly a demonstration lesson—an analysis of *Puss in boots*—during which a 4th-grade boy at a front desk just to my left showed little interest in the story. He participated not at all, but proceeded to sketch all of the major characters as the class discussion proceeded. My informal assessment led me to conclude that he understood the story, and had the talent to express his understanding, but not in the ways that are commonly accepted in the classroom.

The second distinction contrasts accomplishment and progress. In textbook approaches to literacy, these two come down to the same thing. Tests certify that a student has “mastered” behavioral objectives by passing 80% of the items on a prescribed test; the student may then move ahead to the next section of the textbook. This strategy rests on two assumptions. One is that learning is well represented by the progression of objectives. The other is that expertise is appropriately assessed by the tests and the 80% standard. Both of these assumptions are inadequate when literacy is defined by capability in using language to think and to communicate. The progression is not a matter of detailed objectives, nor is mastery akin to collecting scout badges.

Wiggins (1993, Chap. 2) distinguishes between growth—movement over time—and accomplishment, which he describes as “progress toward a goal.” Cizek (in press) offers a similar contrast between learning and achievement. Mislevy (1995) lays out a cogent argument about the distinctions between *trait / behavioral* and *cognitive / developmental* assessment; his language is demanding, but the analysis of the issues is penetrating. Johnny's story, stated earlier, illustrates the idea. Gauged against a developmental curriculum, the teacher's assessment may show that a fourth grader's expository compositions have moved from a level expected in 2nd-grade to a 3rd-grade level. The student has achieved a year's growth. On the other hand, the student has yet to accomplish the level expected of a fourth grader, and so has work ahead. Another facet of both growth and accomplishment is the quality of the performance; a composition may exhibit features of 3rd-grade work, but be rather shoddy. Greene (1991) describes the “process of making value judgments in accord with norms or principles or conceptions of the good made visible” (p. 13). The progression is not always linear. The student masters a strategy that applies to one set of tasks, and

then moves to a different level of challenge. “Learning is not always a matter of doing better” (Masters, & Mislevy, 1993); “Learners become more competent not simply by acquiring more facts and skills, but by reconfiguring their knowledge, by ‘chunking’ information to reduce memory loads, and by developing strategies and models that help them discern when and how facts are important” (Mislevy et al., 1991, p. 10).

Wiggins (1993, p. 171ff.) describes how the relative weighting of growth and accomplishment changes over the grades. In the early years of schooling, growth is more important, but as the student approaches certain critical mileposts (e.g., graduation from elementary and middle school, and perhaps the transition from third to fourth grade), then the level and quality of accomplishment become critical considerations. The teacher is in a position to establish the conditions of assessment: to set the same demanding tasks for all students, but offer more scaffolding for some students, to gauge the level of accomplishment relative to the difficulty of the task, to document the opportunity for students to learn and to perform.

At some point *standards* of achievement enter the discussion (Myers, 1994). While the politics of educational standards are relative newcomers, the pragmatics have been around for a long time. The most basic standard ranks candidates relative to one another on more or less explicit criteria. In the Olympics, only one person can receive a gold medal. In college admissions, only a fixed number of applicants can be admitted to top-ranked universities. The standard is relative to the cohort. Recent discussions—ranging from the 1970's minimum competency tests to the 1990's national standards—attempt to establish absolute standards. The assignment of grades, largely ignored in current discussions, offers an historical perspective on many of these issues. In surveys of grading practices (Brookhart, 1994), for instance, teachers express the tensions they confront in combining their impressions of developmental progress, attainment of expected level of performance, quality of the final product, effort and potential. The teacher's role vacillates between support and criticism; “Where teacher assessment is used for summative purposes then the relation between teacher and pupil can become strained, the teacher being seen as judge rather than facilitator” (Mitchell, 1992, p. 127).

Assessment strategies sensitive to these tensions clearly require informed professional judgment. The relevant evidence is difficult to standardize, the artifacts are complex, information is based not only on products but on observations over time about the process, and on discourse about the process. The teacher's role in this setting resembles that of an applied researcher (Cizek, in press; Hiebert, & Calfee, 1992; Sheingold, Heller, & Paulunknis, 1995), calling for conceptualization of the assessment question, the design of an assessment procedure, collection and analysis of data, interpretation and reporting, and a decision about how to proceed next. The assessment task must balance the collective and the individual; the teacher's observations of the class as a whole is often the soundest basis for major decisions, with attention to individuals for fine-tuning. A “testing” strategy typically focuses on individuals and downplays observations.

In practice, teachers often collect time-consuming test data that are uninformative and unused. For the entering kindergarten, as an example, knowledge of the alphabet is a trustworthy indicator of overall experience with print. The child who can name six letters in the middle of the alphabet is likely to come from a different background than the student who cannot name the letters. The teacher can administer lengthy batteries of other tests, but the additional information is likely to be negligible; far better to spend time investigating children's interests, styles, behavioral characteristics, and social preferences. Assessment that is algorithmic and routine is seldom informative; assessment that is incidental and unguided by clear purposes and questions is equally useless.

Human beings are clearly capable of complex judgments. Such judgments, whether qualitative or quantitative, require ongoing interaction within a professional community. They are most likely to be informative when guided by a clearly articulated purpose, audience, method, and plans for collection, analysis, interpretation, and reporting. For local purposes, qualitative-narrative accounts of student achievement are adequate. But other purposes call for numerical judgments. As Mitchell (1992) notes: "Judging is a teacher's professional responsibility. Whether this essay is a 3 or a 4, whether this answer has enough in it to make it acceptable or not, are questions demanding judgment informed by expertise, understanding of the reasons for the assessment, and knowledge of the use that will be made of the results. Numbers constitute the external sign that a judgment has been made according to a value system.... Purists will object that those who use educational evaluation should learn to read narrative assessments, but that does not work, for both practical and psychological reasons" (p. 137). It is to numbers that I turn next.

The Measurement of Achievement

Measurement is not a comfortable topic for elementary teachers, nor for those in high school English and Language arts. They are uneasy with mathematics in general, and they generally dislike the task of ranking and grading students. "Imagine using the word 'assess'... to describe children's growth and needs! If I interpret the definition correctly, it means deciding the value of things numerically... I shudder at these terms..." this from Suzanne Glazer (1994) as president of the International Reading Association. The reaction is understandable, although distressing. Mathematics instruction, despite recent developments, is ineffective for many students, including those who become teachers.

Why Measure Achievement? Advocates of qualitative assessment pose this question quite earnestly, and it deserves a serious response. One answer is that clients of the public schools deserve feedback, both relative ("How are we doing compared with others?") and absolute ("How are we doing compared with a preestablished standard of performance?"). At the local level, parents often want to know how their students are doing in general (understandable) and in comparison with other students (less understandable). On occasion, students also wonder about how they are coming along.

The typical response to these needs is to issue grades, with all of the tensions that this entails (Brookhart, 1994).

Measured achievement also serves for accountability. We live in a world where schools receive high-stakes grades (real estate agencies use the information for clients), where districts and even states are judged by the numbers, where the entire public school system is portrayed as succeeding or failing its responsibilities based on shifts of a few points on scales understood by a handful of exotic experts. One answer to "Why measure," therefore, is the pressure from various audiences for information about how well the schools are educating our children. If good indicators are not available, then bad ones will fill the gap. The information has to be simple, and simple is not easy. Some educators recommend that we rely on anecdotes (e.g., Gipps, 1994, p. 15ff.; Moss et al., 1992; Wixon et al., 1994), and argue against aggregate data. Unfortunately, stories can easily misrepresent typicality. So can statistics, to be sure, but our techniques for identifying lies in statistics are more advanced than those for challenging tall tales.

A second reason for measuring achievement is that the information has the potential to clearly document the growth and accomplishment of students both individually and collectively. Teachers frequently report that portfolio assessment helps them "see" student growth (Calfee, & Perfumo, 1996), and yet they are hard put to articulate what they mean by these statements. Growing children mark their heights monthly on the door frame; we can see that they are growing, but the marks change perceptions into indicators that open the way for greater precision and clearer communication. The argument is not that perceptions are better than ratings, nor that measures of growth are better than narratives of achievement. As noted earlier, the two are different in character and serve different purposes.

How Does Measurement Work? Measurement is assignment of numbers to objects or events according to a rule or operation—this adage from philosophy of science springs from the physical and natural sciences. A growing youngster compares the most recent mark and "counts" another inch of growth during the past 3 months; he is now only two inches shorter than his big sister. A variety of sophisticated mathematical operations spring forth within this simple context, operations that we take for granted outside of math classes.

Educational and psychological measurements pose more of a challenge than gauging height. *Educational measurement*, typically identified with psychometrics, has focused by and large on total test scores, where measurement begins by counting the number of correct answers on a norm- or criterion-referenced multiple-choice test (Linn, 1994). Complications arise in deciding what to measure and what it means, questions for the final section of this chapter. But testing is objective; computers can count the scores with little or no human intervention. *Psychological measurement*, in contrast, addresses the inherently subjective activity that takes place when human beings assign numbers to objects or events (Aftanas, 1988, 1994; Luce, & Krumhansl, 1988; Narens, & Luce, 1986). The earlier examples from Olympic

events illustrate the concept, but it is far more widespread than may be appreciated. Poker players estimate the odds. Drivers guess whether to pass another car on a two-lane road. These are relatively simple situations, to be sure, and other judgments are more complex (Anderson, 1991; Tversky, & Fox, 1995; Tversky, & Kahneman, 1982). For instance, college admissions officers routinely combine complex portrayals to rank order applicants, and prospective students do the same in deciding which college to attend.

Although much is known about how human beings measure and are measured, these two fields are separated by a deep chasm, which seems not to have narrowed in recent years (Cronbach, 1975; Shepard, 1992). I assume that most readers are already familiar with the psychometric tradition, and so this section will focus on psychological measurement, which may prove critical for understanding the assessment of student growth and achievement. Current discussions of teacher ratings have been dominated by psychometrics, and the psychology of the task has not yet been explored (Tittle, 1994; also Messick, 1984).

This section is organized around four issues: (a) categories of psychological measurement, (b) psychological strategies for measurement, (c) context effects in measurement, and (d) applications of psychological measurement to assessments of student performance. Stevens (1951) is the classical reference for the first topic. He studied the esoteric field of psychophysics, research by 19th-century German and American psychologists on sensory and perceptual systems. Why does one light seem twice as bright as another? Why is one smell twice as intense as another? Stevens described four *measurement categories*. Numbers can be assigned *nominally*, like those on the backs of football players, on Social Security cards, or on student records. *Ordinal* measurement is typified by street addresses or "next in line" slips; the distance between objects and events is not reflected in the numbers, nor is your "wait time." In *interval* measurement, like temperature readings or the distances between houses in a tract, equal distances are reflected in equal numeric intervals. Stevens' fourth category was *ratio* measurement, where "0" actually means zero; we depend on this scale when we measure fence boards or children's heights—no fair standing on a stool. Beyond Stevens is the *relative* scale, typically associated with the dreaded logarithm. If a cat gains a pound, the owner says "She's getting fat!"; if a horse gains a pound, the owner disregards it—increments are judged relative to the magnitude of the object (Calfee, 1975). Each of these five scales has specifiable properties and attributes. For instance, it does not make sense to average the numbers on the backs of football players. Nor do bricklayers, watchmakers, and astronomers use the same measurement systems in dealing with distance and weight.

Stevens' major achievement was to show that human beings could operate with remarkable fidelity in all of these categories, given appropriate preparation. He showed that psychological measurement depended on the conditions of assessment. Presented a set of objects to arrange on a scale from large to small, a person's judgments depended on the scale and the collection. Was the scale open or closed; was the question "large-small" or "larger-smaller?" Were the

endpoints of the scale clearly defined? Were the objects all clustered within a narrow range or spread more broadly? Was the distribution bell-shaped or skewed in one direction or another? Were the objects familiar or unusual?

Other researchers have investigated *strategies for judgments* of more complex objects and ratings. In these situations, subjective assessments of multidimensional objects or events are transformed into quantitative ratings. Odors vary in intensity, but also in pleasantness or disagreeability. Compositions vary in technical quality, but also in creativity or mundaneness. Research on psychological measurement has provided insight into these issues. For instance, Anderson's (1991) studies of impression formation illuminate the teacher's task in judging student achievements, especially the rendering of a summative judgment. Anderson's basic proposition is that human beings, confronted by a complex judgment, identify a small number of relevant dimensions, make independent judgments on each of these, and then "average" the judgments. The theory seems overly simple, but hundreds of studies offer support for the basic model (in education, cf. Freedman, 1993; Rotzel, 1974, for examples in writing and social studies).

The failures of the model are especially informative; they are generally situations when one particular feature of a situation is so compelling that it outweighs all others—a contextual effect. Most studies in this area have investigated intuitive assessments in laboratory settings and do not answer the question of how a trained judge might perform given clearly defined features and priorities. As in the instance of the psychometrist's total score, complications arise when the informant is being asked to give an overall impression based on competing subimpressions. Should the overall impression be an average of the components, a choice of the "best or worse," or a compensation (facet A is pretty bad, but B and C make up for it). A student portfolio contains five pieces, all of which are rough-drafts with poor spelling and grammar, miserable handwriting, one of which is simply too bad to believe, three of moderate quality as compositions, and then a personal narrative that is deep and compelling. How is the teacher to render an overall impression of this collection? Perhaps the best answer is that this is the wrong poor question, especially when the judgment is to be applied to a work (the student) in progress.

People's judgments are affected by *context*. Every measuring instrument is influenced by context, but the effects are often negligible. A yardstick, especially if it is made of aluminum, changes length with variations in temperature. Measurements of length in the Sahara and the Antarctic will differ slightly. People are also sensitive to particularities: the bombings of Dresden, Sarajevo, and the Oklahoma Federal building are more than memories of total tonnage and lives lost, more than the sum of the dreadful parts. Judgments depend on the situation (Parducci, 1995): some sailing days are better than others, and some tax returns are worse than others; billionaires have "bad hair days," and homeless children have moments of joy. These examples apply to teacher judgments of student achievement. Consider the assignment of grades, especially "grading on the curve." Assessment advocates tend to eschew grading. As a practical matter, teachers are often

required to give grades, in which case, whatever the evidence and the constraints (e.g., grading on the curve), the judgments will reflect the context. Teachers accustomed to higher levels of performance will center their judgment scale at a higher point than teachers whose students typically perform at lower levels. Teachers whose experience encompasses a broad spectrum of student achievements will establish a different range than those with more limited experience. Memory records experience, and assessment depends on experience. The benefit of professional moderation is that it transcends the individual.

How do these ideas apply to the *measurement* of student achievement? To the best of my knowledge, no effort has been made to link the psychology of measurement to the pragmatics of teacher judgments of student achievement. Instead, technical discussions of teacher ratings have been dominated by the psychometrics of interrater and intertask consistency, topics for the final section of the chapter. When teachers assign a number to a student performance, what are the characteristics of the measurement scale? It is presumably more than a nominal assignment. Is the difference between a “3” and a “4” the same as that between a “4” and a “5”? Does a rating of “4” mean that the performance is twice as good as a “2” rating?

Such questions focus attention on the system of rubrics and benchmarks that are typically employed in teacher judgments of student achievements. Despite the label of “authentic measurement” (Hambleton, & Murphy, 1992), most rating systems are crude efforts at measurement. They typically include four to six categories, each with a “rubric” description, and sometimes one or more benchmark examples (Calfee, & Masuda, in press). In practice, raters tend to avoid the highest and lowest categories, and so the ratings often cover only two to four categories. The resulting numbers convey little more than a general impression, so that the earlier questions about measurement quality seldom apply.

A further complication arises with holistic ratings. Student performances are usually multidimensional, and so a summary measurement requires combining information about several facets of the work sample. Consumers’ Union (CU) faces a similar challenge in rating products. Automobiles are complicated, and “measuring” overall quality is not a simple task. The CU proceeds by identifying a number of dimensions (appearance, handling, gas mileage, reliability), some of which can be assessed objectively, others requiring subjective judgments. The dimensions are clearly laid out, as are the weightings. Each dimension is independently measured, and then overall (holistic) measurements are generated by combining the various facets. The entire process is laid out explicitly for the audience, who can then make their own judgments about the final ratings.

To be sure, gauging student achievement is more complex than ranking automobiles. In addition to the “work product,” the teacher, especially in the early grades, must juggle quality, effort, and growth. Assessing an on-demand snapshot of student performance is difficult enough. For the classroom teacher, there is the additional task of placing the current achievement within a social temporal framework. Taylor (1994) describes the perils of approaching this task from a

“bean-counter” perspective, and addresses measurement as a psychometric rather than psychological issue. Delandshere and Petrosky (1994) inquire about the “measurement of complex performances,” and argue against “assigning a number to a complex performance.” They are undoubtedly correct when they advise against “translating complex interpretive statements into single ratings to provide data for statistical manipulation and evidence of reliability and validity.” This advice, while sound, overlooks the measurement processes and possibilities—and the practical fact that student achievements (and school accomplishments) will be measured for accountability purposes. This task will either be done well or poorly; research on psychological measurement offers ways to dramatically improve current practice.

Assessing Progress and Accomplishment

Earlier, Chapter 1 distinguished between the assessment of progress (a motion picture) and accomplishment (a snapshot). Assessing progress is the greater challenge. *Development*—growth, learning, and progress—is a complex word with shades of meaning, “To expand or realize the possibilities of; to bring gradually to a fuller, greater, or better state” (American Heritage). Assessing growth in literacy as conceptualized in this volume requires informed judgment, and hence must be grounded in qualitative description. But inherent in the concept of development is the notion of measurement: “fuller, greater, or better.” For many of today’s educational audiences, descriptions of growth do not suffice. Narratives may be a starting point for assessment, and may serve needs of local audiences—students and parents—but demands for summative aggregation come quickly to the fore when we move beyond these groups to the policy arena. Given that a teacher or other evaluator has created a narrative of student progress, how can the story be translated by “assigning numbers to objects and events?”

How to Measure Growth? The answer to this question is a critical “missing link” in current discussions of assessment methods. Tests address this issue—inadequately, in my judgment—by normative and statistical methods. Students read better, on average, as they move through the grades; operationally, they can answer more demanding questions about more complex passages. Average scores of students at the beginning and the end of third grade become the norm for those levels of schooling, and expected growth during third grade is estimated by statistical extrapolation from these averages and associated variabilities. If a student scores at the average test levels during both at the beginning and the end of third grade, then he or she has made a year’s progress. If the student is at average at the beginning but above average at the end, this represents more than a year’s growth, and so on.

Stories of student achievement yield neither numbers nor averages, and so a different strategy is needed for measuring growth. The construct of a developmental curriculum offers a strategy grounded not in norms (what happens to be) but in standards (what should be). In telling the story, the teacher’s task is to describe the student’s progress along the route. By

analogy, driving from New York to Chicago offers the traveler several choices, each with a different array of events. A northern route goes through Buffalo and Detroit, Niagara Falls and Motor City. A southern alternative crosses the Appalachians, Pittsburgh and Gary, Indiana. One can still ask "How far have we gone today?" and "How far do we have to go?" Road maps serve for measurement. In applying the metaphor to assessment of student achievement, the foundation is a clearly drawn road map—a developmental curriculum with standards and benchmarks. One strategy is represented by textbooks and scope-and-sequence charts, listing objectives to be mastered at specific grades. Much like an assembly line, the schedule specifies when each curriculum segment is to be attached.

In an alternative strategy, grade-in-school plays a role, but with significant differences. First, the criterion for grade-level mileposts rests not on statistical averages but on professional judgment, not on "what is" but "what should be." Second, standards of accomplishment are established for the *end* of the course of study "What should the fifth grader be able to do," and then these serve as goals for earlier years of schooling. A student's performance is judged not by performance relative to others in the grade cohort, but to his or her level of achievement on the curriculum map.

Developmental indicators can serve a variety of purposes. The individual student's achievement can be compared with classmates' achievements. Growth can be gauged by progress on the developmental map throughout the school year. As students approach critical mileposts in their school careers, it becomes increasingly important to attend to the distance between current achievement levels and the milepost levels. Nor does the final milepost in a series mark the end of the trail. For the traveler, attaining one goal can become a jumping-off spot for future achievements. Chicago is the gateway to the Rockies, the Sierra Nevada, and San Francisco. Reaching the final milepost does not mean completion of the journey but attainment of a standard, and an opportunity for further progress.

Providing a developmental road map places a different light on the concept of achievement standards. Some literacy programs, for instance, encourage students to compete in the number of books they read during a school year. Quantity does not ensure quality, however, and reading many books does not lead automatically to understanding and appreciation. Likewise, acceleration does not ensure depth of learning or mastery of skills.

Today's efforts to set literacy standards confuse several issues rather badly. Development, growth, progress toward accomplishment, and quality of performance are seldom separated. Rubric and benchmark systems are an amalgam of scales of excellence with a thin overlay of developmental progress (Calfee, & Masuda, in press). The primary criterion is "How good is the performance," followed by the secondary question "What is the developmental level of achievement?" This confounding leaves the assessment audience unclear about how to interpret the data. Should students be encouraged to give greater care to their present work, or should they move quickly to the next level? These tensions are heightened because the easiest targets for literacy assessment are often

surface features: for print literacy, the recounting of the literal features of a text, and for writing the conventions of vocabulary, spelling, punctuation, grammar, and handwriting. As long as purpose, audience, organization, and other deep-structure features of literacy are poorly operationalized, standards will reflect acquisition of basic skills, regardless of the rhetoric. When the dimensions of visual and communicative literacy are added to the mix, the challenge for assessment design becomes even greater, because the curriculum strands remain to be established in theory and in practice. The early sections of the handbook offer some clarity in this regard, but much work remains ahead to build a foundation for assessment.

Models of Growth. Another facet to the task of assessing development centers around the processes of learning and growth. In testing, a straight-line model of learning is either assumed (e.g., by calculating grade-level equivalents) or constructed (e.g., NAEP's standard scores). Percentile scores use a different approach; "growth" is defined as constant relative standing. The student who maintains the same rank over time is presumably learning at the same rate as his or her peers. A student who scores at the 50th percentile both at the beginning and ending third grade has made a year's progress relative to classmates. The student who starts at the 25th percentile in third grade and is still there at the end of the year has made no progress toward reaching the expected or 50th percentile.

How do individual students actually progress over time? Neither the psychometric models sketched above nor proposals by qualitative theorists have addressed this question. What should be measured? One answer appears in simple performance indicators like reading speed, number of books read, and length of a composition. Such indicators are scant images of the construct of literacy proposed in this volume.

Assuming that we can define a set of trustworthy indicators, there remains the task of assessing growth. The field of learning theory has been dormant in recent decades, but an important lesson from the 1950s and 1960s is that average trends can be misleading (Bower, & Hilgard, 1981, Chap. 12; also Rogosa, 1983). Figure 14-1 illustrates this point by contrasting patterns of individual learning with the average. The left-hand panel of Figure 14-1 compares individual and average trends for *linear* straight-line learning patterns over a three-point span. Average learning is identical in both the upper and lower plots. In the upper plot, however, rates of development are the same for every student, and the variability among individuals is slight. In the lower plot, students are similar at the beginning of the process, but variations in learning rates lead to large differences as time progresses. This "fanning," which appears in numerous achievement studies (e.g., Coleman, 1966; Stanovich, 1986), has been labeled the Matthew effect—the rich become richer and the poor become poorer.

The right-hand panel in Figure 14-1 shows how qualitatively distinctive learning models can generate similar average learning patterns. In the upper plot, Student A accelerates early in learning and then slows down, while Student C is slow at the start and then speeds up. Only Student B progresses in

FIGURE 14-1 Examples of different learning patterns for individual students.

the steady fashion suggested by the average. The lower panel portrays a variation on the same theme. Student A “gets it” during Time 1, Student C is lost until Time 3, while Student B proceeds in two equal increments. Steady or incremental learning is typical of instructional programs that rely on practice to promote growth, while insightful “all-or-none” learning results from instruction that emphasizes strategic learning. At the level of individual students, “stage” models like those proposed by Piaget and his colleagues predict jumps in performance, while behavioral models based on reinforcement concepts are more compatible with continuous growth. Another issue, almost as long lost as learning, is transfer (Foertsch, 1995). If education is to move beyond the transmission model, then whatever is taught is valuable not for whether it is learned, but for whether it provides the student with strategies for handling new situations.

As an aside, I should note the paucity of data for exploring the acquisition of reading and writing over extended periods of time. Tierney (1991) reviews the handful of studies available, noting that most of these are case studies in the primary grades, with relatively little information about the instructional context.

Profiles of Performance. While investigations of standardized achievement generally yield single-factor descriptions of reading (e.g., Davis, 1968), qualitative assessments offer promise for distinguishing a student’s relative strengths and weaknesses in various curriculum strands (Calfee, 1988; Calfee, & Masuda, in press). The earlier section on assessment introduced the concept of developmental *profiles* of student achievement. This idea is especially critical for understanding learning. The student who is enamored with baseball may excel in comprehending and composing expository passages, even though he or she is less capable at handling more literary works. Third graders with rich oral language may struggle with decoding and spelling. At any given grade level, a student’s achievement level and progress toward milestone goals can be represented by a profile rather than a single score. Likewise, one can imagine that different learning mod-

els and patterns of individual differences apply to different curriculum strands. As typically taught, for example, decoding and spelling skills are likely to progress incrementally, while awareness of plot and character may occur through insightful leaps. But any discussion of profile assessment must be related to what is being taught, how it is being taught, and the goals of instruction.

Relatively little work is available on the psychometrics of achievement profiles (however, cf. Cronbach, & Gleser, 1965), perhaps because of the insensitivity of standardized tests to the “intents” of achievement. For instance, something seems awry when standardized reading and mathematics are as highly correlated as subtests within reading and mathematics. A potential advantage of a qualitative approach to assessment—narrative descriptions correlated with developmental curriculum strands—is that the intuitions frequently voiced by classroom teachers can be transformed into indicators that inform both practice and accountability. California reading test scores appeared to decline in the 1990s, leading immediately to the call for a shift from a literature-based approach in reading instruction back to an emphasis on phonics (Honig, 1996). In fact, the California scores were holistic judgments, and could be explained equally well by low skill levels, poorly designed reading instruction, changes in student demographics, or large class sizes. The availability of longitudinal and qualitative profiles might have shifted the debate from politics toward an analysis of student profiles. If California had reviewed the assessment data to distinguish between the quality of students’ comprehension and composition *and* the level of basic skills in reading and writing, the State would have been in a stronger position to establish policy initiatives focused on an analysis of statewide strengths and weaknesses. Incidentally, profile analysis applies with equal force to individual students and to aggregate summaries.

But the individual student is the most important locus for action. Assessing development entails the measurement of growth. At one level, telling the story of a student’s progress is a starting point, and may serve immediate needs. On the other hand, if a teacher is to make a persuasive argument about a

student's growth, at least three criteria must be met. First, the "story of growth" must be translated into an explicit metric. This task is difficult under the best of circumstances, and teachers are generally neither prepared nor inclined to take on this job. The construct of a developmental curriculum offers a method for this translation with a substantial educational rationale, one that meshes well with the teacher's professional responsibilities and inclinations.

A second task centers around the concept of individual learning models. Substantial work, conceptual and practical, remains in this area. The scope-and-sequence charts of past decades are a poor match with a developmental approach toward social-cognitive learning: checklists of mastered objectives are no more adequate for this activity than appraising a painter's progress on an artwork by the amount of canvas covered with paint.

Finally, the tracking of profiles needs to be aimed toward curriculum-in-practice and overall accountability. The strengths and areas for improvement in one situation may be quite different from other situations. These judgments need to be contextualized by considerations of progress and accomplishment, of attainments and quality of performance.

Validating Teacher Assessments

The classical psychometric criteria for gauging the quality of an assessment are *reliability* and *validity*, the degree to which an assessment is consistent and means what it purports to mean. If one friend highly recommends movie X while a second pans it, then you should question the assessment process. If both friends agree that the movie is great but you find that you are horrified by the violence, you realize that you should have rephrased your question.

Note that the preceding summary of these two constructs did not use numbers, neither for the assessment nor for the appraisal of reliability and validity. Conventional psychometrics (e.g., Linn, 1989; Linn, 1994) typically begins with measurement: how reliable and valid are the *scores* for Text X? Reliability is measurable in this tradition; the correlation between the scores for two forms of the test, one index of reliability, yields a number that quantifies consistency and provides an index of the stability of individual scores. The most commonly employed indices of validity, *concurrent* and *predictive*, also employ correlations of the test score with other scores to measure validity.

These traditional methods are the foundations for the science (and pragmatics) of the assessment of human aptitudes and achievements. The *Standards for Educational and Psychological Measurement* (AERA, APA, & NEA, 1985), currently under revision, will undoubtedly take a somewhat different stance toward these concepts. It is unlikely, however, that the foundations will change substantially (e.g., Linn, 1994). These concepts and associated methods have their limitations, and have been the target of criticism in recent decades, but they remain fundamentally sound. Moreover, they have undergone substantial advances in recent decades. Messick (1995) captures the essence of these changes when he writes that "the term *score* is used generically in its broad-

est sense to mean any coding or summarization of observed consistencies or performance regularities on a test, questionnaire, observation procedure, or other assessment devices such as work samples, portfolios, and realistic problem simulations. [It] subsumes qualitative as well as quantitative summaries. ... Validity assumes both a scientific and a political role that can by no means be fulfilled by a simple correlation coefficient..." (pp. 741, 742). Critics of contemporary psychometrics seldom note that current testing practice takes limited advantage of recent advances. Psychometric principles apply equally to testing and assessment (Herman et al., 1992), and some of the more interesting explorations of the fundamentals have appeared in explorations of the potential of performance-based assessment for large-scale accountability (Baker et al., 1993; Freedman, 1993; Linn, & Baker, 1996; Shepard, 1989). The bottom line is that methods exist for reliable assessment, a fact that advocates of alternative methods must face.

Reliability and Generalizability. Reliability began with the idea of gauging consistency by the correlation between alternate forms of a test, or split-half scores of the same test. A specialization of this idea—each item on a multi-item test should correlate with the subtotal of other items—is now the basis for the various coefficients used in commercial tests. When a test publisher reports a high reliability coefficient, it means that all of the items rank students in the same order. Consistency is undercut by interactions between persons and items; if different items lead to different orderings of persons, then the total score is not trustworthy. Reliability, item correlations and person-item interactions are all indices of total score consistency; if reliability is high then item correlations are large and interactions small, and vice versa.

The stability of the total score depends directly on reliability (Cronbach et al., 1995). The *standard error of measurement* is an index of stability based on reliability. If the reliability coefficient is high for a test, then the standard error will be small; this means that if the same test or a different form of the test is readministered at a later time, then the person will receive the same score within a small margin of error. Low reliabilities mean high standard errors and wide variability over different administrations. Large standard errors are especially problematic for high-stakes decisions. The student placed in a remedial program or the school chosen for statewide honor may only reflect the luck of the draw when scores are unstable. In the field of standardized multiple-choice tests, publishers have learned how to construct tests with high reliability and stability. Administrators are understandably attracted by this feature of standardized tests—they seldom have to deal with surprises. The decision to retain a student or award a school based on standardized results is likely to hold up under reassessment. To be sure, the "meaning" of the assessment may be questioned, but that is seldom a critical matter for busy administrators.

Generalizability theory (Cronbach et al., 1972; Shavelson, & Webb, 1991; also Linn, 1989), actually a method rather than a theory, offers a sophisticated extension of the basic principles of item consistency for incorporating any number of

facets in a test design. Imagine an open-ended test with multiple tasks, multiple administrations over time, multiple contexts, and multiple judges. The assessment goal is to determine students' overall competence in constructing exhibitions to certify their language arts accomplishments for high school graduation. A generalizability design might include variations in genre (a personal narrative, an expository essay, and a dramatic presentation), completed at different times during the senior year, spanning a variety of tasks (written papers, oral declamations, dramatic performances), sometimes individually and sometimes as part of a team, each activity assessed by a team of three teachers against a variety of rubrics. The genius of the generalizability method is that it gauges the trustworthiness of the student's overall performance relative to each facet (and combination of facets) in the assessment design.

Suppose the aim is to assess students' language arts achievement. A generalizability design based on the earlier example might include data from 200 seniors, each of whom writes a personal narrative, composes an essay on "Advice to the junior class," and delivers a dramatic monologue of their choosing, each composition to be judged by three teachers on the dimensions of substance, style, and technical adequacy. Generalizability analysis provides indicators similar to the familiar reliability coefficient for each facet of the design. Based on research to be described below, it is likely that (a) teachers will agree on students' relative standing for each performance, but that (b) students will line up differently for the narrative, essay, and monologue. Under these conditions, it makes no sense to average the three ratings; a mid-range average could mean that a student does middling well on all three tasks, or excels in some but not others. Averaging the ratings obscures information about student strengths and weaknesses, and about areas for program improvement.

This example shows again the centrality of construct definition for assessing student achievements. A "simple" theory views literacy as a unitary entity; just as children can line up from short to tall, students can be also arranged in order from least to most literate. But suppose we ask students to line up from small to big; now at least two constructs are at work—height and weight. We can expect disagreements in the ordering depending on whether a judge gives more weight to one or the other dimension. Likewise, consider an assessment system in which third graders are asked to make a book, and the teacher assesses several facets of performance during the process: students' interest in the project, creativity in approaching the task, technical skill in revising the final product, and use of artistic elements in the work. My classroom visits suggest that students respond differently to these facets; initial interest can make a big difference, but creativity may not follow interest, and the best spellers and grammarians are not necessarily the most talented artists.

Applications of generalizability have yielded important findings in the area of performance-based assessment. For example, we know that, given adequate preparation and clear-cut criteria, teachers can render consistent judgments of complex student performances; task variation, however, leads to inconsistent ratings (Dunbar, Koretz, & Hoover,

1991; Nystrand, Cohen, & Dowling, 1993; Saner, McCaffrey, Stecher, Klein, & Bell, 1994). Different writing prompts yield different rankings of students, as do many other assignment variations. Although this result has been in the literature for a long time (Linn, 1994, remarks that "Ralph Tyler was onto the 'task' issue in 1934"), educators have yet to develop a "theory of tasks." The usual response is to view this facet as a nuisance, and to ask how many tasks must be administered in order to achieve a stable estimate of overall performance; the answer is typically four to eight tasks, an imposing demand given the time and costs of the typical performance-based exercise (Linn, & Burton, 1994).

A different strategy searches for systematic facets that might influence student performance. As suggested above, a "simple" construct may be more complex than is typically assumed. "Writing," for instance, may actually comprise separable dimensions, not all of which are equally important over tasks. At one level, it is fairly clear that students vary in their ability to handle the mechanics and the organizational requirements in composing papers. Asking judges to provide holistic scores across these dimensions is probably one source of interjudge variability. But I have a different idea in mind. Looking back at the earlier example, it seems quite possible that different talents and interests are called forth in creating a personal narrative, an expository essay, and a dramatic monologue. Moreover, different students may have experienced quite different instructional opportunities for handling these different forms. This line of reasoning need not lead to "situated anarchy," the belief that every writing experience is unique, but it does suggest that the literacy curriculum should identify a small number of distinctive strands, that instruction should cover these domains, and that assessment tasks should connect with specific subconstructs (Calfee, & Drum, 1979). This idea connects to the earlier discussion of profiles, but from a different vantage point.

The Varieties of Validity. Given some level of reliability, what about validity? Does the indicator assess what it purports to assess? Reliability and validity are typically viewed as quite distinctive, but certain statistical features of validity can be handled, in part at least, by generalizability methods. *Predictive validity* focuses on the question, to what degree does indicator A predict indicator B, where both indicators are supposed to tap the same construct? *Concurrent validity* asks, to what degree do several indicators, all presumably measuring the same construct and assessed at the same time, rank students in the same order. Time (predictive validity) and tasks and judges (concurrent validity), from the generalizability perspective, are simply design facets. If student scores are stable over one or more of these facets, then the assessment satisfies the requirements of statistical validity.

Construct validity, as noted at the beginning of the chapter, is the centerpiece of contemporary validity theory. Generalizability methods can also serve in evaluating construct validation. The formulation of a construct requires substantive thinking more than a methodological algorithm. But once a construct has reached some degree of clarity, then a generalizability design offers a way to appraise

the definition. The design presumably includes facets (e.g., topics, tasks, times, contexts, judges, rubrics) that operationalize the construct. To the degree that generalizability analysis reveals substantial inconsistencies associated with one or more facets of an assessment system, the overall score is of questionable trustworthiness. One conclusion from such findings is to distrust the assessment system (e.g., Koretz et al., 1994). Another approach is to search for consistent sources of the inconsistencies.

A central tenet of construct validity is the importance of bringing multiple sources of evidence to bear (Cronbach, & Meehl, 1955); an assessment must yield consistent evidence from different methods to ensure validity of the construct. When multiple sources are included in an assessment system—for example, the tasks in the narrative-essay-drama illustration—inconsistency may arise because different constructs are being tapped by different tasks. When generalizability analysis shows that performance varies across tasks, rather than fret about unreliability, educators might better reflect on the possibility that the tasks are linked to different talents. Portrayal of literacy as a holistic and naturalistic competence flies in the face of the rhetorical tradition, which suggests instead that different genres call forth different talents and interests. As the domain of literacy expands to include other dimensions—communicative and visual facets—we can expect to see the emergence of other constructs. The student who is facile with computer graphics as a mode of expression may not excel in the creation of printed texts, and it makes little sense to “average” performance over these domains. When teachers assess performance on different constructs without distinguishing among them, disagreement is predictable. Several studies of classroom grading have revealed just such idiosyncrasies in dimensions and criteria (Gearhart, 1994; Gearhart, Herman, Baker, & Whittaker, 1992; Moss et al., 1992; Valencia et al., 1994). Turning from emphasis on “total score” toward evaluation of performance profiles may significantly enlighten our conceptions of literacy and enhance the pragmatics of assessment.

While current views of validity agree on the centrality of *construct* validity, alternative proposals have emerged in recent years. Three of these developments are particularly relevant for present purposes: validity as *interpretative*, as *consequential*, and as *hermeneutic* (Shepard, 1993). All three take as a starting point the importance of establishing construct validity. All three complement technical methods of construct validation (e.g., generalizability) with qualitative strategies for “moderating” judgments. All three attempt to embrace a broad array of assessment policies, including standardized tests along with alternative methods. Finally, all three emphasize the policy aspects of assessment.

Given these commonalities, the three perspectives cast different lenses on the nature of validity, and on appropriate techniques for validation. Messick (1989) and Cronbach (1988) have offered lucid discussions of *validity as interpretation*. At its core, the theme is that an assessment—quantitative or qualitative—is not valid until the case is successfully argued. Student A scores at the 64th percentile in reading comprehension on the Iowa Test of Basic Skills; School B falls within the “comparison band” on the Maryland writing assess-

ment; California is next to last on the list of states for the National Assessment of Educational Progress. The validity of these *statements* depends on the meaning attributed to each, and to the strength of counterarguments against plausible alternative interpretations. Consider this set of possible meanings, each of which casts the information in a new light: Student A is in trouble, because she was at the 87th percentile last year; School B, which serves a poor neighborhood in Baltimore, is doing fine, because the comparison band predicts that students should be among the poorest writers in Maryland; California is actually in pretty good shape, given that its class size is highest in the nation.

An assessment, from the interpretive perspective, offers evidence as the starting point for a debate. The trustworthiness of the evidence must be substantiated as part of the argument, but the connection between the evidence and the interpretive claim must also be established. For instance, the teacher of Student A argues that the current score is invalid because a family tragedy occurred just before the test. The argument aims not at the technical features of the assessment instrument and process, but at the particularities of the situation. The Baltimore school board may see the school assessment as valid—even encouraging—but parents may not be satisfied with this conclusion. And California State Department of Education apologists may receive letters about the inconclusive research on the relation of class size to achievement, and asked by the legislature to come up with other explanations.

The point in these examples is that validation entails more than calculating a numerical index of consistency or correlation. Taken to the extreme, to be sure, the interpretive perspective can lead to a *reductio ad absurdum*; no assessment can ever be validated in the sense that it can withstand all counterarguments. A more sensible position proceeds in stages, much like a trial. The first challenge is the establishment of construct validity, demonstrating empirically that an assessment system captures a definable entity. The second challenge is to defend particular interpretations against competing explanations. This second task is more rhetorical than technical in character.

The debate hinges on the clarity of the construct, and it is against this backdrop that technical issues reenter the picture. Messick (1995) emphasizes two major threats to construct validity: *under-representation* and *irrelevant variance*. An assessment may be undercut because it focuses on narrow features of the construct domain; compositions are judged on surface features like spelling and punctuation, leading to the counterargument that the scores say little about more substantial features of writing competence. A comprehension test requires first graders to decode difficult and unfamiliar words; decoding is an ancillary demand that leads to variance irrelevant to the students’ ability to comprehend. Probably the greatest source of irrelevant variance for interpreting measures of student achievement centers around the issue of what they have been taught. The *Standards* (AERA, APA, & NEA, 1985) require that “When a test is used to make decisions about student promotion or graduation, there should be evidence that the test covers only the specific or generalized knowledge, skills and abilities that students have had an

opportunity to learn" (p. 53). Interpretation of student achievement is clouded whenever the instructional record is not part of the evidence.

Messick (1989) has also been the flag bearer for the concept of *consequential validity*. Here the argument goes beyond "What does the assessment mean?" to "What should we do—and what will happen if we do it?" The issues are particularistic, and raise matters of equity and opportunity. Of the hundreds of thousands of literacy assessments conducted yearly, most are inconsequential. Printouts of standardized test scores are forwarded to practitioners who file them in a closet; portfolios are assembled and then discarded at the year-end. Local newspapers report yearly test scores for local schools; few surprises for real estate agents, who clip the articles to show clients.

But consequences sometimes entail high-stakes decisions. A student is retained in grade; a school or district is taken over by a higher authority; an election for State Superintendent of Schools centers on trends in student achievement. Consequential validity builds on the foundations, but then poses cost-benefit questions for decision makers. Given that an indicator system possesses construct validity, and given that the interpretive argument is sound, then what courses of action are available, and what are the merits of each? Some observers (e.g., Haertel, & Wiley, in press) are concerned that defining validity to encompass a broad spectrum renders the concept virtually impossible to operationalize, and recommend a return to the essentials of construct validity and on psychometric methods for validating specific instruments or collections of instruments. These concerns have merit, and it may make sense, especially for complex constructs, to separate the issues of instrument validity, interpretive validity, and consequential validity. On the other hand, it seems important to keep consequences in view as the technical process moves along.

The *hermeneutic definition of validity* springs from the work of Moss (1994b, 1995) in the area of qualitative assessment. The term comes from the Greek, meaning "the art of interpretation," but carries connotations that go beyond the interpretive dimension discussed earlier to encompass the notion of a community of interpretation. "A hermeneutic approach to assessment involves holistic, integrative interpretations of collected performances that seek to understand the whole in light of its parts, that privilege readers who are most knowledgeable about the context in which the assessment occurs, and that ground those interpretations... in a rational debate among the community of interpreters" (1994b, p. 7).

At a practical level, Moss' work brings to mind the British tradition of *moderation* (Daugherty, 1995; Gipps, 1994, p. 75ff., 140ff.; Harlen, 1994). British teachers, especially those in the elementary grades, rely on practitioner judgments to gauge student progress. Several other countries employ similar techniques, but often to calibrate teacher judgments with external criteria. In moderation, the teaching community is responsible for defining criteria and standards through an ongoing process of discussion and debate. The aim in moderation is not to ensure that teacher judgments of complex performances toe the line with an external indicator, but

rather to engage teachers in an ongoing dialogue about the dimensions and characteristics of development and achievement.

A major barrier to hermeneutic validation in the American context is the autonomy and isolation of the individual classroom teacher. The "decoupled" character of U.S. schools has been well documented both in general and in the specific area of assessment and grading practices (Rosenholz, 1989). A second barrier is that U.S. teachers are less secure in their professional knowledge of subject matter and curriculum strategies. Several studies have documented the difficulty teachers experience in reaching agreement about portfolio assessment in local settings (e.g., Moss et al., 1992; Shepard, 1995; also Koretz et al., 1994).

Validity: Quo Vadis? An underlying theme in these discussions is the proper role of numbers and measurement for establishing the reliability and validity of teacher assessments of complex achievements. From one perspective, because we know how to define and quantify reliability, then it easily assumes priority. The counterargument holds that validity is more central than reliability, and that numerical indices of reliability are replaceable by qualitative judgments of dependability and trustworthiness (Gipps, 1994; Moss, 1994b; Wiggins, 1993). From this perspective, numbers—measurement, ratings, grades, coefficients, and so on—are not required for assessment, and may actually be inimicable with assessment policy and practice. The reply is that if student progress is to be assessed by teachers, and if these assessments are to become part of public discussions of school accountability, then numbers will almost certainly have to be part of the process. I agree with Wiggins that "schools would be instantly more accountable if we worried less about... tests and more about making the teacher's daily work public and giving the student performer a more powerful voice" (p. 264). Accomplishing this goal will probably require a balance between quantitative and qualitative indicators, between numbers and anecdotes. Teachers may be uneasy with mathematics, but they can learn to make consistent judgments even in today's complex contexts. Olympic judges do not have advanced degrees in probability theory. What is needed for the professional assessment of literacy achievement is greater clarity about the construct, more explicit rubrics and benchmarks, and improvements in the assessment process.

An important insight from this debate is the realization that validation requires more than numbers. Argumentation is essential (Cronbach, 1988; Kane, 1992), as is a research-oriented mind-set (Cizek, in press; Hiebert, & Calfee, 1992). Both competencies may actually pose greater challenges in the professional preparation of teachers than skill in handling numbers. Interestingly, most discussions of number-free validation seem inevitably to return to quantification, especially when the mandate is external and the stakes are high.

Reliability is another matter. As noted above, one opinion holds that reliability is irrelevant; if an assessment is valid, that matters most. While this proposition has been attractively framed, the counterargument seems overwhelming. If an

assessment is not trustworthy, if a judgment—no matter how arrived at or how complex in nature—reflects a particular set of circumstances, tasks, and assessors, then it cannot serve as a foundation for making a decision; Moss (1994a) argues that “reliability..., consistency, quantitatively defined, among measures that are intended as *interchangeable*..., is necessary to support inferences from particular samples of work evaluated by particular readers to the broader capabilities the assessments are intended to tap” (p. 111). It is easy to attack the claim that “validity depends on reliability.” Both concepts have been defined at times by operations too lean and limited. Recent developments suggest that the fundamental principles still have merit, but require a different rendering: an assessment must be trustworthy as a basis for sound interpretation. But trustworthiness can be operationalized—quantitatively—in a variety of ways. Cronbach et al. (1995) argue that, especially in domains where the stakes are high and public accountability is involved, we should make the best possible use of existing techniques to quantify trustworthiness through generalizability methods. Decisions at the classroom and school levels may not be typically considered high stakes, but are nonetheless highly consequential for individual students and teachers. A challenge for the future is the translation of contemporary insights about reliability and validity into a form that is accessible to practitioners and their clients—teachers and students, but also principals and parents—for application in the classroom and at the school level.

Connecting the Pieces

Rousseau (1762 / 1979) made it sound easy; the class-size in *Emile* was one, student and teacher were both motivated, and the critical issues (as reflected in the book’s index) were not assessment and accountability, but amour propre, anger, arts, and atheism. As narrative, this description of education can be compelling, but today’s teachers and students live in a different time and play on a different stage. Today’s conundrum is how to capture the essential richness of Rousseau in classrooms where teachers confront thirty-plus students with other matters on their MTV minds, while policy wonks and evaluators stand on the sidelines tapping out op-ed pieces on their laptop computers about the sad state of schools. A handbook is a serious document, but one can imagine the reaction of a classroom teacher to the previous material—“Give me a break!” In this section I will attempt to draw the pieces of this complex puzzle into a focused conclusion, one that connects research with practice.

The Main Argument. The purpose of this chapter is to address a practical need and offer a conceptual framework for action. The key words are *development*, *literacy*, *qualitative*, and *assessment*. We are emerging from an era when development meant mastery of objectives, when literacy was defined as a basic skill, when “qualitative” was neither defined nor valued, and when assessment was operationalized as testing. The underlying theme in earlier times was a factory model of schooling where teachers performed as civil servants, carrying out the orders of superiors, following the

instructions in teacher manuals. In tomorrow’s world, the headline is the move from an industrial society to an information age. The challenge is—on the fly—to transform schools into institutions where development is a key word, literacy is a high-level competence, qualitative portrayals are valued, and professional assessments are the foundation for accountability.

The starting point is a vision of what students should be able to “do” at the end of the course of study, and an image of the paths by which they may attain this achievement. This vision, the focus of other chapters in this handbook, constitutes the *construct* upon which the rest of the argument hinges.

The second element in the argument is the essentiality of informed professional judgment about literacy. When literacy is defined as mastery of basic skills, then assessment can be mechanized. The construct of critical literacy cannot be so easily gauged. Nonetheless, if schooling is to support the development of genuinely literate students, then professional preparation must ensure the internalization of the basic construct, along with methods of applied research that serve as the foundation for assessment in place of routine administration of standardized tests (Darling-Hammond, & Godwin, 1993; for specific recommendations about how teachers might conceptualize assessment, see Winograd, 1994). Part of the job in the United States is to construct a foundation for professional judgment in a policy context that asks for reform and improvement at the same time that demands on schools are increasing and resources are decreasing. Assessment practices and policies are important policy levers, and very public events for public schools. The result is that efforts at innovative assessment (e.g., in California, Kentucky, and Vermont) quickly attract attention. Special interest groups attack assessments for their own purposes, and technical panels challenge the adequacy of admittedly untested innovations. The resulting whiplash has understandable consequences; innovative programs are scuttled, and practitioners retreat to traditional ways.

The next two parts of the argument are tougher to expound. First is the tension between quantitative and qualitative assessment, which is palpable in contemporary discussions. If teachers are to gauge student achievement in ways that engage the public—students, parents, administrators, and the community—then measurement comes to the fore. A “gauge” is a “standard or scale of measurement, an instrument for measuring or testing.” Teachers face severe tensions when asked to gauge progress, level of accomplishment, and quality of performance (Gipps, 1994, p. 127). As noted earlier, they operate from a “success orientation;” their primary role is to support student learning, and they are uncomfortable with mixed messages—“You’re doing better, but not good enough.” They do not like to give low grades. If forced to do so, they will, but they are seldom required to justify their judgments.

Then there is the question of what it means to assess. Large-scale testing programs, in contrast to grades, must meet technical standards of reliability and validity. Until recently, these requirements were defined by psychometricians; practically speaking, test publishers produced standardized tests

that met administrative requirements even if teachers found the instruments somewhat mysterious and often irrelevant. Now teachers are invited or mandated to assess student achievements in complex domains for high-stakes decisions, and are challenged as individuals to meet psychometric criteria of reliability and validity. One response to this development is to ensure that teachers know more about these criteria (Stiggins, 1994). Another response is to reject the criteria. Neither response seems on target.

This chapter suggests that the key issues are *what* to assess and *how* to assess it. The touchstone for *what* is a coherent explication of a developmental literacy curriculum—what should students learn to become fully literate? The touchstone for *how* centers around the teacher's role as an applied researcher—not a transmitter of the canon, but a student of students.

Ancillary Issues. Several background matters remain unsettled at both conceptual and practical levels. First, techniques for the assessment of profiles and growth patterns of individual students are critical if teacher-based assessment is to go beyond narrative portrayal to a form adequate for public accountability. Unfortunately, the psychometrics of profile and growth models remain in a primitive state. Norm-referenced indices are routinely used to measure growth by standardized tests, but both grade-level and standardized scores have been subjected to serious criticism—this for the simple domain of standardized tests. Profile assessment remains largely an unexplored territory.

Another set of questions centers around the validity of less-than-fully-standardized student performances (Calfee, & Kapinus, in preparation). Consider the student writing portfolios now serving for assessment in many places. What should go into the portfolio? How much support should student receive in preparing and selecting entries for a portfolio? Should students be allowed to collaborate with one another in preparing entries? Should parents be allowed to help their children with portfolios? Should word processors and other technologies be allowed, and if so to what effect? (Powers, 1994). For assessors, how should they deal with portfolios that vary widely in the contents and the evidence of support? The tension is clear-cut. The argument can be made that decontextualized performance is invalid because it does not reflect a student's potential achievement. The complementary question is posed with equal clarity: "Whose work is it?" When students cooperate in completing an assignment, a student's achievement reflects not only his or her present capacity, but also the contribution of the group (Webb, 1993, 1995). Gearhart and Herman (1995), and Webb (1995) have laid out with extraordinary clarity the range of issues falling into this category. Data from portfolios and performance-based tasks are complex packages. How should the assessor weight the various contributions? Throw out the lowest score? Average everything? Make a holistic judgment? We are in the early stages of working out rationales and frameworks.

Finally comes the issue of equity (Garcia, & Pearson, 1994; Howe, 1994; Nettles, & Nettles, 1995). Students from homes that support the work of the school tend to do better on

virtually any kind of assessment than children from less supportive backgrounds. Some assessment advocates suggest that students from at-risk backgrounds will have a better chance to reveal their potential through authentic performances, but the scant evidence on this point points in the opposite direction (Badger, 1995; Darling-Hammond, 1994). Schools and teachers differ in the quantity and quality of instruction, in the opportunity to learn and the opportunity to perform. Assessments, unlike tests, can document opportunity to learn, but educators have discussed this potential only in passing, the practical implementation of the idea remains to be worked out, and legislative bodies have explicitly rejected the policy. As noted earlier, opportunity to learn is a standard for assessment, and at least one study suggests that it matters (LeMahieu et al., 1995). Opportunity to perform is another matter. Opponents rightly criticize the unfairness of decontextualized conditions typical in most testing. These criticisms do not guarantee that authentic assessment is any fairer.

One of the original virtues attributed to standardized tests was a degree of objectivity that eliminated teacher bias. This virtue remains the object of considerable debate, to be sure, but largely missing from the discussion of alternative strategies for assessing student achievements is the possibility that subjective judgments will be biased. I have not located any article that addresses bias in teacher-based assessment.

A Bottom Line. Bridging the gap between classroom-level assessment and externally-mandated testing remains a fundamental tension in American schools. The annual PDK-Gallup polls (Elam, Rose, & Gallup, 1993) have shown for decades that parents trust their local schools (and presumably local teachers), but that this trust declines precipitously when citizens judge schools outside of their neighborhoods. The external accountability movement that emerged with *A Nation at Risk* now takes shape as a national testing program, an idea could scarcely have been envisaged at mid-century. The fact is that, since the emergence of standardized tests and basal textbooks after World War II, we have had a national curriculum. The future of National Standards program is unpredictable at present, but if it becomes a reality, classroom teachers are likely to see it as another mandate rather than a professional opportunity. If so, the program is likely to undercut the aspirations described in this chapter. Bryk and Hermanson (1993) distinguish between assessment indicators that monitor and that enlighten: "The ultimate test of an indicator system is not whether we are better informed but whether we act more prudently" (p. 476).

But there is reason for some optimism. This handbook envisions a literacy that moves beyond print to encompass the emerging opportunities of new technologies that enhance communication across a broad range of media. The representation of speech by print amplified the potential of human minds both individually and collectively. A quarter-century ago, *Small Talk* emerged at the Xerox Research Park as the prototype for today's Macintosh and Windows environments. *Small Talk* was supported by some of the most powerful computing resources available at the time.

Today, you can purchase a personal computer orders of magnitude more powerful for the price of a 1970 Volkswagen bug. The information highway has redefined communication. The fundamental question seems clear: what literacy curriculum should we provide our children to

ensure that they move into the next century prepared to deal with these opportunities, and the barriers to achieving this goal? Assessment of student progress and accomplishments in this curriculum must be grounded in the answer to this question.

CHILDREN OUT OF BOUNDS: THE POWER OF CASE STUDIES IN EXPANDING VISIONS OF LITERACY DEVELOPMENT

Anne Haas Dyson

UNIVERSITY OF CALIFORNIA, BERKELEY

"You're not supposed to leave the underworld," screams Liliana (alias Venus) at Sammy (alias Pluto). The third graders are playing Greek gods. They have named the boundaries of the relevant worlds, and Sammy is clearly out of bounds. He is supposed to be on the sand by the climbing structure, not on the grass by the fence.

"But I'm good now," he pleads, trying to redefine himself. He is tired of the lonely and hot underworld and longing for the more sociable and tree-shaded space guarded by the firm Liliana.

Out on the playground, children claim and define spaces, be their game Greek gods or kickball, cops-'n-robbers or hopscotch. And, of course, who's "in" and who's "out" is often a matter of contention. In many ways, this same task of establishing and maintaining boundaries faces adults who construct case studies, that is, studies of "bounded systems" in all their dynamic complexity (Stake, 1988, p. 256). The case might be a particular community, group, or, of particular interest in this chapter, individual. Whatever the unit, however, the "case" has a way of going out of bounds, forcing the observer to reconsider the designated spaces.

Consider, for example, another scene involving 8-year-old Sammy, a "case" in an ongoing qualitative study; the "bounded system", the particular human experience being studied, is that of learning to write.

Sammy is sitting with bowed head and, I expect, bowed heart as well. He had looked forward all morning to Author's Theater, when his classmates would act out his story. But all had not gone

well, especially with Michael. Sammy had written the death of a superhero—an untenable text, according to Michael. Unable to ignore Sammy's misery, I tell him that just because Michael didn't like his story doesn't mean Michael doesn't like him. But Sammy is not buying this—and neither is his peer Makeda sitting beside him.

Makeda: But a story is kinda like *your* life. It's like it's kinda like it's what you're doing and they're doing. ... [to Sammy] Just say, "Oh yeah, I'm gonna get you. I'm not gonna be your friend no more. If you don't like my story, I don't like your story either." But *ignore* them when they're talking to you. That's what I do. Like Lettrice say, "I don't like your story." I say, "I don't like your story either. And I'm not your friend any more. And I'm going to ignore you next time." So she never did mess with me. (pause) She saw my big brother, she never did mess with me. She tried to get her whole gang on me, so I got my big brother. So that's what happened.

And Sammy and Makeda go to lunch.

I had begun by observing one child's writing but, soon, was enmeshed in a complex social drama featuring many children and the wider classroom and societal contexts in which their acts, and their writing, gained meaning. Moreover, I was attending to symbols other than the written marks on the page; as Sammy's story was enacted, discussed, argued about, and literally cried over, its personal and public meaning was mediated through many symbolic forms—spoken words as well as written ones, dramatic movement and expressive

gestures, and, potentially, illustrative drawings and decorative book designs.

Understanding Sammy's evolving history as a "writer" has demanded, therefore, that the conceptual boundaries—or definitions—of writing and of development be drawn in ways that accommodate his complex experience. And that experience forces me as an observer to attend to children other than Sammy, to symbols other than written ones. In this chapter, I explore the way in which the intense study of individual experience can destabilize, not physical playground boundaries, but *conceptual* ones and thereby allow new perspectives. Constructing or writing a case is a dialogic process, one that involves defining and redefining one's understandings. Moreover, this process may be enacted on a broader level when completed cases enter the public dialogue of professional gatherings and published accounts.

In the following sections, I first elaborate on the process of constructing a case and, second, the particular process of constructing cases of children learning written language. I highlight the use of interpretive methodology to construct cases (Geertz, 1973; Erickson, 1986); this methodology probes how specific people, in specific social circumstances, interpret or make sense of their everyday interactions. I then offer the case of three cases written successively over a 15-year period; collectively, these cases illustrate the methodological dynamics of case studies, the ways in which they may force an observer both to articulate conceptual boundaries and to go beyond them, to go out of bounds, as it were. Finally, in the concluding section, I consider the potential of case studies for crossing another kind of boundary, one that separates the diverse professionals concerned with children's lives (Florio-Ruane, 1991; Genishi, 1992)—and I also consider the limits imposed on that potential when such studies become prescriptive or normative guides.

In recent years, startling statistics have proclaimed the challenges facing our schools, especially schools like Sammy's, schools serving poor children in urban and rural settings. In its annual yearbooks, *The Children's Defense Fund* (e.g., 1994) presents the shameful statistics: the number of children living in poverty, labeled as "unready" for school, as "academically behind," and, eventually, as "dropouts." Of what importance, then, are the experiences of one child? Of what worth the hours, months, and, indeed, years that may be spent constructing a small number of cases? These, ultimately, are the questions addressed herein.

CONSTRUCTING A CASE: THE WORK OF DEFINITIONS AND DETAILS

Insight into the nature and the value of case construction comes, interestingly, from a biologist, Barbara McClintock. She was, wrote Stephen Gould (1987), committed to "following the peculiarities of individuals, not the mass properties of millions," (p. 167) and to tracing their complex interactions with each other and their environment—a commitment all the more intriguing because McClintock followed stalks of corn. In her own words, spoken to her biographer Evelyn Keller, one must understand

how it [each plant] grows, understand its parts, understand when something is going wrong with it. [An organism] isn't just a piece of plastic, it's something that is constantly being affected by the environment, constantly showing attributes or disabilities in its growth... No two plants are exactly alike. ... I start with the seedling and I don't want to leave it. I don't feel I really know the story if I don't watch the plant all the way along. So I know every plant in the field. I know them intimately and I find it a great pleasure to know them. (cited in Gould, 1987, pp. 167, 168)

McClintock was interested in the ways information is passed on through genes, not through language, and in biological actions and reactions—processes microscopically removed from the interpretive processes of most people's everyday lives. Still, her words and her concerns are relevant here, for they speak of the importance of theoretical definitions and empirical details.

Negotiating Theoretical Boundaries

McClintock followed the narrative thread of an individual, intent on understanding a phenomenon—the workings of biological inheritance and development. Her story disputed the notion of a simplistic, one-way flow of information, from genome, to RNA, to DNA; and it revealed a fluid and mobile process, one filled with "hierarchical systems of regulation and control" and surprising reversals, including information entering the genome from the outside environment (as it does in AIDS) (Gould, 1987, p. 159). A single organism reverberates in an environment and, in the process, reveals the complexity within and without and highlights potentially critical points of contact (of, to stretch a word, negotiation) with that environment.

McClintock, then, speaks about respect for bounded complexity, about attention to its unfolding story, and, thus, about cases. The singular defining feature of any case is, in fact, its boundedness (Geertz, 1973; Stake, 1988). Some unit of integrity (a person, a group, a community) is both outlined and contained by a researcher, who is studying, not the case itself, but a case of *something*, some phenomenon (e.g., not maize, but biological inheritance). Thus, the researcher is constantly making decisions about what is, or is not, within the constructed bounds, what is, or is not, relevant to such a case.

Inherent in this process of bounding is one critical challenge—and strength—of case study analysis: the need, in the midst of the flow of unbounded experience, to make decisions about basic definitions of what exactly is being bound. Writing of anthropological cases of communities, Clifford Geertz grapples with the same strength and challenge:

The locus of study is not the object of study. ... You can study different things in different places, and some things ... you can best study in confined localities. ... It is with the kind of material produced by ... almost obsessively fine-comb field study ... that the mega-concepts with which contemporary social science is afflicted—legitimacy, modernization, integration, conflict ... meaning—can be given the sort of sensible actuality that makes it possible to think not only realistically and concretely *about* them, but, what is more important, creatively and imaginatively *with* them. (1973, p. 23)

In interpretive research, one aims to understand some aspect of human experience and, given its complexity and, indeed, its abstractness, one needs to situate that experience within people's actions and reactions to the materiality, the local specificity, of their everyday worlds.

Working definitions in any one study *are* influenced by previous studies, where concepts were defined and elaborated. But the focus of the moment (i.e., the learning child in the viewing frame) exerts an influence as well. For the definitions arrived at must seem sensible (given the child's actions and reactions), just as McClintock's definitions had to allow for the actions and reactions of the maize. Thus, case studies have the potential to contribute new understandings of the concepts under study. In this chapter, the experience to be understood, to be conceived and reconceived, is that of learning to write.

Detailing Lived Experience

Implicit in the textual construction of a human actor is a second strength and challenge, one that highlights intentional *mind*, not genetic matter—the need to enter into, and try to understand, another's consciousness, another's world. And those "others" may be persons whose agency, whose actions and reactions, are often lost in a collective word that distances and dismisses (like "the masses" of the so-called Third World [Sahni, 1994] and "the at-risk" of the affluent one) or, in contrast, in a singular word that homogenizes and diminishes (like "the child" [Thorne, 1987]).

This strength, however, contains within it a potential weakness, the possibility of looking, not to understand, but to confirm what is "known," research reduced to illustrative anecdote of truths already held. Researchers, after all, are not ventriloquists (Geertz, 1988). They do not speak for others. They are writers who construct others' lives. Researchers' own life experiences and social positioning—their age, gender, ethnicity, indeed, their very status as outsider, "both enable and inhibit particular kinds of insight" (Rosaldo, 1989, p. 19).

But, as writers, they *can* work to make another's life world more perceptible, more accessible, by respecting the details of that world, the recurring themes and rhythms of the other's life scenes. Such respect entails time and presence—and painstaking reliving, as scrawled field notes are typed out, voice-packed audiotapes transcribed, and crumpled child papers are smoothed over again and again. And it also entails depicting the other's actions in descriptive words, rather than glossing them with abstractions like "competent," or not, "cooperative," or not, "motivated," or not; observers attend to the contextual specifics—the who's, what's, where's, and when's—of others' actions, attempting to grasp *their* value judgments, their interpretations (Bogdan, & Biklen, 1992).

Observers do, of course, have their own feelings about and reactions to the observed. Indeed, for both observing researchers (Ottenberg, 1990) and teachers (Almy, & Genishi, 1979; Florio-Ruane, 1989), those reactions and feelings are a potentially rich source of hypotheses about the other. It is this need to acknowledge but interrogate—literally bracket in one's notes—such responses that accounts, at least in part, for

the self-knowledge that may accompany attempts to understand others. For example, one might ask, who do I (and other participants in the scene) assume is competent or not? on the basis of what kinds of actions in what settings, using language to accomplish what purposes in what ways? What does this concept, *competence*, mean here?

Through such a dialogic process of considering and reconsidering the taken-for-granted, researchers seek a "textual connection," as Geertz (1988, p. 144) writes, a "common ground between the Written At and the Written About." That is, they use the limits of their own life experiences to understand another's. Thus, like its aesthetic cousin the literary text, the interpretive case has the potential to reveal "dimensions of . . . experience that are ordinarily invisible," to "hear aspects of it ordinarily lost in silence" (Greene, 1988, p. 19). This potential for seeing new dimensions of experience connects this second challenge with the first, the potential to go beyond old assumptions and conceptual boundaries, through, in McClintock's words, "the pleasure of know[ing] another."

STUDYING YOUNG WRITERS: THE BASICS OF LITERACY AND GROWTH

In studying literacy development, researchers face very basic definitional questions. Most important, perhaps, is: What is "it" that develops? What is reading, writing, or literacy? Where does one look for "it"? What boundaries should be drawn around "it"?

In the opening anecdote about Sammy, for example, is his writing in the *graphics* (e.g., Clay, 1975), in the exact words he formed on the page? Or is it in the *orthographics* (e.g., Read, 1971), in the linking of graphic signifier with signified in systematic ways? Or, maybe it is in Sammy's *process* (e.g., Graves, 1975), his planning of a message and his monitoring and revising of its objectified form. Yet another possibility: writing could be his *discourse* or *genre form* (e.g., Newkirk, 1987), his story—or, maybe, it's a *functional tool* at work in a particular *cultural event* (e.g., Heath, 1983), one involving the specifics of who, to whom, with what message and form, in what place and time, and, of course, for what reason. Or maybe writing is in the ideology of the society as a whole, its *societal discourse* (e.g., Gilbert, 1994); Sammy and Michael have different expectations about what can and cannot be written in the context of a superhero story—and Makeda has clear notions about what can or cannot be said about another's story (or at least about the stories of authors with big brothers).

In other words, should an observer attend primarily to the writing on the paper? the behavioral evidence of individual mind at work? the enactment of writing as social happening and cultural activity? or, perhaps, the textual constituents of ideological beliefs about what can or cannot be said by whom? Moreover, these questions can be asked from different perspectives. Sammy, Sammy's friends and family, his teacher, and his adult friend (the researcher) may all have different ways of defining what it means to write.

And as if these issues were not challenging enough, there are basic issues to be addressed about “development” as well. Again, what and where is it? Moreover, what sort of developmental pathway should one prepare to follow? Is growth a linear unfolding? a zigzagging phenomenon? a moving away from social supports? a gradual integration into social life?

Perhaps, to construct a case of Sammy’s development, one should focus on outer signs of his internal concepts of “writing,” looking for evidence of his mental grappling with unexpected information and unintended consequences (e.g., Ferreiro, 1978). Or, maybe one builds a case around collaborative encounters between Sammy and his teacher or more skilled peers, examining ways in which relative experts provide guidance (e.g., Snow, 1983). Or perhaps one should not assume singular teachers but make space for multiple co-participants in his writing activities and for changes in his way of participating with those others (e.g., Dyson, 1993a).

Over the last 25 years, researchers have conceptualized differently the mechanisms or processes of development, the desirable end goals, and the nature of expected pathways. Thus they have looked in different places for writing, both on and off the page. Reviews of expanding definitions of literacy (e.g., Nystrand, Greene, & Wiemelt, 1993) and of development (e.g., Bruner, & Haste, 1987) can be found elsewhere. The point herein is that it is these sorts of definitions that undergird researchers’ ways of drawing boundaries around, and paying attention to, children; such definitions influence what is foregrounded and what is left in the background, what is carefully detailed and what is glossed over. Conversely, it is the details—the descriptions of children’s “dailiness” (Polakow, 1992)—that in turn may challenge the viewing frame itself.

In writing cases, researchers must deal with the dangling threads—the child actions and reactions that cannot be understood, that suggest the need to refocus, to clarify and, sometimes, to redefine. Indeed, one theoretical perspective portrays the act of writing itself as a struggle with given words (like “literacy” and “development”). Writing is dialogic, argues Bakhtin (1981, 1986); it not only mediates interactions between writers and their audiences, but also mediates between writers’ minds and the collective mind of the discourse community that has given them their words. Thus, in constructing cases, writers negotiate with available words, stretching them, rethinking them, aiming to make them “fit” their data. Then, through publications like this handbook, they participate in the process of figuring out what can legitimately be said about “writing” and “development” within the circle of people concerned about children and literacy.

UNRAVELING CASES

To illustrate the methodological dynamics of case study construction, I present abbreviated forms of three cases: those of Rachel, Jake, and Tina. The cases were all constructed from transcripts, collected products, and observational notes and, within each, child use of imaginative narrative discourse is highlighted. The children themselves were from similar socio-cultural backgrounds (i.e., urban children whose heritage was

predominantly African-American, and whose socioeconomic circumstance was primarily working class); they were all given to imaginative storytelling, all had complex relationships with peers—and all were singularly complex people.

The children are of different ages: Rachel was just 5, Jake was 6, and Tina (a classmate of Sammy’s) was 7. The point of this analysis, however, is not to trace developmental patterns from child to child; rather, it is to examine the definitions, the viewing frame, that shaped each construction—and how that frame was complicated by the case itself. I chose these three from a larger set of 30, because they engendered clear and distinctive conceptual shifts. Tina, the most recent case, is presented most fully, but her case is set within the context of the preceding two.

For each case, I provide situational context, an edited sample of the case, details of analysis tools, and, finally, the conceptual understandings *and* puzzles yielded by the completed study. Collectively, the cases illustrate the boundary negotiation—and the theoretical re-envisioning—possible through sustained attention to the unfolding stories of children’s lives.

Rachel: Writing as Symbol System

The research focus on the first of these cases, that of Rachel, was very close, the viewing boundaries very tightly set. A pictorial metaphor for the case study of Rachel might be this picture by Rachel herself: the single child in the viewing frame (see Figure 15–1).

Rachel may well be halfway through college now, but I met her in the kindergarten. She was one of five focal children in a study of young children’s writing (Dyson, 1981, 1983). There was no child writing in her classroom, which had been designated my site by the school district. Therefore, I set up a classroom writing center and invited the children simply to come and write, however and whatever they wanted.

The center was not organized by any particular classroom social structure (other than as an optional individual choice during “free” activity time); there were no classroom expectations guiding what was produced, nor any social forums through which ways of talking about writing might become

FIGURE 15–1 Framing Rachel

routinized. As individual choice, a dominant purpose for most children at the center was to explore the medium itself. The children would arrange and rearrange known letters and letter-like forms on their papers, asking me if they would quite done "it" yet (i.e., written anything that could be read); and they also spent quite a bit of time writing known (or guessed at) names of important people in their lives. Most important, the children talked a great deal, to themselves, to me, and to each other. As a researcher, I was drawn to this talk and, thus, the specific question guiding the project became, What role does children's *oral* language play in their early *written* efforts?

Of all the regular child visitors to the center, Rachel stood out for her people-oriented personality; she was a mover and a shaker in the kindergarten scene. Relative to her peers, she was much more likely to use the writing center for the production of dramatic adventures. Now I would think of her as a performer in search of an audience (and I was convenient). Then I approached her primarily as a child writer; I asked what, how, and why she wrote and what role her talking—and Rachel was a talker—had in her efforts.

The Drama—and the Dramas of—Rachel. The following event is representative of how Rachel wrote a story and, also, of how I narrated the case of Rachel:

Rachel is composing an elaborate story about 2 feuding sisters, one in a series of stories about sisters who are always together but always at odds (just as Rachel describes her own relationship with her 7-year-old sister Julie). Rachel's dominant composing media are pictures and dramatic dialogue and gesture. As her picture takes shape, she acts out a scene in which one sister has just locked the other out of the house.

Rachel: "Sister, open up the door. [Rachel knocks twice on the table.] You dummy. Sister, you better come and open this door or else I'm gonna' throw this pumpkin shell on your head—"

Quite suddenly, Rachel has a plan:

That's what it's gonna be saying!

Rachel now writes the "teeny tiny" print-like markings, all in a line, in the uppermost left-hand side of her paper (see Figure 15-2). The writing, though small, stands for the loud orders and threats of the sister on the outs:

FIGURE 15-2 Rachel's feuding sisters

It says, "Open the door, Sister. Open, open, open, else I'm gonna' throw this pumpkin shell right on your head."

Later, Rachel explains to me (her so-called observer but, in this event, her audience) that she wrote little "'cuz I wanted you to try to guess."

Rachel did not always use such unconventional writing. Sometimes, her intention involved the more limited writing of names (e.g., a "note" or "letter," containing a picture and the addressee's name, or a list for "mommy so she'll know all of the my friends' names that was over here"). In those cases, her letters were legible and her words quite readable. For elaborate stories, though, pictures, dramatic talk, and "teeny tiny" writing were the favored media.

Defining the Viewing Frame: Analytic Tools. From much observing and taping of events like the story of the feuding sisters, file boxes began to fill with observational notes, transcripts, and child products. Using such diverse materials to construct a case requires a vocabulary or coding system, a way of describing the dimensions of the "bounded system" (e.g., the child's experience of writing); in this project, it required a means for describing how the children went about writing and the role of talk in that writing.

The nature of such a vocabulary is dependent upon those basic questions earlier discussed, including, What is writing? Where, in the mass of data, is it located? In the academic dialogue of the late 1970s, researchers emphasized the graphic and orthographic features of early writing (e.g., Bissex, 1980; Clay, 1975; Read, 1975) and the decision-making processes involved in crafting information on paper (e.g., Graves, 1975).

These definitions suggest that a researcher should focus on a child's ways of shaping (i.e., of planning, encoding, and monitoring) inner meanings in written forms and, also, the nature of the resulting forms. Thus, I constructed Rachel's case—and that of four other children—by describing her actions as she crafted meanings on paper. To do so, I developed an analytic vocabulary or category system that included four "components" of a child's writing process: *formulating a message, encoding the message, mechanically formulating letters or letter-like forms on paper, and decoding [or rereading] the message*. Accompanying each component was a list of "properties" or qualities that captured child variation in ways of enacting these components.

For example, in Rachel's feuding sisters story, the formulated message was *specific* (i.e., Rachel did not simply say "This is gonna say something about my sister.") and *coherent* (i.e., related to the other graphic marks, including the drawing, on the page). Her encoding was not *systematic* (e.g., Rachel was not using any evident orthographic system); and her forms were not *conventional*, although they were *linearly* arranged. In rereading, Rachel did not *segment her written message* (i.e., match portions of her oral message to her written one). On the other hand, in writing her lists, Rachel's specific message was systematically encoded (based on visual recall, however, rather than any sound / symbol matching), and her forms conventional.

In addition to writing process components, the category system included descriptors for the *functions* of children's

talk. For example, in Rachel's feuding sister story, talk served primarily to *represent* or narrate the story, although it also served to *evaluate* (i.e., to express Rachel's attitude toward the world, particularly the obnoxious behavior of sisters) and to *interact* (e.g., to ask me to attend to her story). It served minimally to help her *encode* (e.g., to help transfer oral symbols to written ones through "sounding out") or to *seek information* (e.g., to seek spellings).

Uneasy Answers: Rachel Pushes the Boundaries. Analyses of all children's visits to the center, and fine-grained analyses of the focal children's writing and talking, led to tentative conclusions. Talk, it seemed, was initially something young children do *about* writing (i.e., "This is my mama's name"), rather than something young children encode *in* their writing. Over time, children's speech becomes both writing's raw material and its guiding tool—young children use speech to monitor and encode their ideas. Thus, their writing becomes more able to stand on its own, independent of any accompanying talk.

This suggested developmental pattern fit with the then dominant definition of development (i.e., development is an orderly transformation of child behavior, reflecting underlying changes in conceptual systems [Piaget, & Inhelder, 1969]). Moreover, it was also compatible with the dominant view of writing development. That development was a moving apart, a child learning to articulate and manipulate meaning without support from the immediate material and social context (Olson, 1977). The sense of such a portrayal was dependent upon the viewing frame, upon those tight boundaries drawn around individual children and their writing processes.

But such narrow tight boundaries could not quite contain the lively Rachel. As composer, Rachel did much more than write—she also drew and dramatized. The roots of her eventual accomplishments as a storywriter could not be in that line of teeny tiny writing alone. Moreover, her composing processes, like that of all children, were highly variable but related to her end goal. Her action on the page could not be understood separately from her intention in the world.

Finally, those narrowly drawn boundaries were also at odds with the project's methodology. Such boundaries implied a telescopic perspective on children, an attempt to make sense of their behavior from the faraway viewpoint of the adult world. But *interpretive* methodology aims to situate child behavior within the meaningful webs of present aims and social connections. The next case, that of Jake, continued to fray the edges of the existent conceptual boundaries.

Jake: Writing as Mediational Tool

The project involving Jake aimed to examine one of the dangling threads from the study described above—the drawing, storytelling, and dramatic gestures that seemed to serve as the developmental roots of conventional writing, at least as much as if not more so than lines of child mock writing (Dyson, 1989). The project initially focused on eight focal children's use of multiple media in their composing and how their use of these media changed over time. But the situ-

ational context of this project was quite different from that of Rachel's, and its local particulars helped shape the unfolding project in general—and the unfolding story of Jake in particular.

Jake's school was a small magnet school of 80 children, kindergartners through third graders. All the children had the same language arts teacher (Margaret), and they all participated in a daily journal time. As part of that journal time, the children shared their written texts, and Margaret led the children in appreciatory talk about individuals' accomplishments as artists and composers. Thus, individual children's ways of writing were shaped by—and were shaping—the literacy life of the school as a whole; my own role as instigator and interactional partner during writing time was minimal. For example, the children did not ask me, "What did I write?", to quote Clay (1975); very quickly, most of the youngest children began to emulate the storywriting of the oldest ones.

During the first year of this 2-year project, Jake was a first grader—a talkative, outgoing one. Despite his own sense of being "slow" in learning to read and write, he was highly engaged during journal time. Like Rachel, he composed dramatic stories, primarily by drawing and talking. His stories, though, were not about relationships but about fast-paced adventures, often involving speedy vehicles, and clashes between the good guys and bad guys. Moreover, the stories were not used to gain the attention of an adult interested in children's writing; they were used to gain the attention of his peers, especially his "straight man," so to speak, the calm, quiet, and artistic Manuel.

The Drama—and the Dramas—of Jake. The following event illustrates Jake's propensity toward wild adventures, his playfulness, and, most especially, his delight in teasing his friend Manuel. The event centers on the drawing in Figure 15-3.

Jake has just drawn the ground and the sky and—
Jake: Now I'm gonna make a mechanical man.

Manuel, sensible and calm, seeks some clarification:

Manuel: A mechanical man? You mean a robot man?

Jake: Yeah, I'm gonna make a robot man. You got it, Manuel.

FIGURE 15-3 Jake's robot man and flying earthling

Jake begins to elaborate in his talk and in his picture:

Jake: Here's a bomb head. It's gonna explode. It hasn't even exploded yet. When it does—

Manuel's a bit concerned:

Manuel: I hope it explodes in the next century.

Jake: Here comes the bomb explosion! There is the fire, a little smoke. (makes quick back-and-forth motions with his marker) ... [omitted data] It's gonna explode in the next few days.

Manuel: I hope it happens on the weekend and then I won't be around.

Jake: Not for long this school will be around.

...

(adds another figure) I'm gonna make a flying earthling!

Jake's dynamic narratives were woven with talk and drawing; but his writing was neither dynamic nor narrative. Jake struggled with encoding, and, for support, he "copied off" his pictures, capturing only its static, flat surface. For his robot man story, he wrote:

Once upon a time there were two men. One was flying up in to the clouds. The other man was staying on the ground. The and...

Over the 2 years of the project, Jake's social nature and flair for the dramatic did not change—but his composing changed. As a second grader, Jake's drawings often were sequenced to reveal key moments in his story; further, his playful interactions with peers could now occur *during* writing. To give a flavor of these changes, I provide another sample of Jake in action one year after the "robot man" event.

As is his custom, Jake is sitting beside Manuel. While Manuel works on the story of a snowman who comes to life, Jake has other plans:

Jake: (to Manuel) I'm deadly. I'm deadly. I'm gonna put your name in this story and you are gonna be deadly too. I'm gonna make sure you get blown to pieces. (laughs)

Manuel: Blown to pieces. (softly and a bit awed)

Jake: Yes sir. You won't be able to see your mommy ever again.

Jake writes, *Once there was a boy that is named Manuel*. Manuel playfully retaliates:

Manuel: In my story, you're going to meet a magician who's going to turn *you* into a snowman.

Jake: Well, actually, guess wha—

Manuel: And melt you flat.

Jake seems to back down:

Jake: Actually, um, I I'm, I—we're gonna, I'm writing about um us flying the fastest jet in the world.

:

None of us—both of us are—isn't gonna get blown to pieces because it's the fastest jet—it can outrun any bullet.

Manuel: Oh wow! I like that.

Jake: And it's as bullet-proof as it can get.

But later:

Jake: Watch out Manuel! (writes *blow up*)

Manuel: Just at the very end when they're just so happy, it's

almost—they're just so happy and they read the entire story and they loved it, I get blown up.

Jake: Yeah.

Manuel: And they cry and cry and cry and cry—it's so dramatic.

Later, Jake reads his story to Manuel:

Once there was a boy that is named Manuel. Manuel is going to fly the fastest jet and I am going to fly the jet too. But Manuel's headquarters is going to blow up But I am OK. But I don't know about Manuel but I am going to find Manuel. But when I find him I like him. But I think I see him. He is in the jet. Manuel are you OK? yes I am OK. you are being attacked. I will shoot the bad guys out of the universe. OK yet shoot them now. The end.

In this event, as in others in the second grade, Jake played with Manuel, not only around his writing, but through the writing itself.

Defining the Viewing Frame: Analytic Tools. The case record of Jake was filled with the taped voices, written records, and collected products of the many children whose school lives were interwoven with his own. To make sense of Jake's data set—and that of 7 of his peers—I took from the literacy dialogue of the mid-1980s a definition of writing as a mediational tool used to participate in social events (Basso, 1974; Heath, 1983): Writing is not only a means of representing an individual's meaning; it also serves to mediate relationships between writers and others. Written forms do social work in the world. This definition of writing—this conceptual boundary—would frame both child writer and coparticipants in the observed event. Moreover, it would situate any particular event in a larger cultural world within which that event had some function and had gained some meaning.

Accompanying new views of literacy were new perspectives on development as well, most notably those inspired by the sociocultural theory of Vygotsky (1962, 1978). These perspectives also would draw a larger boundary around individual children, for those children would be seen as "grow[ing] *into* the intellectual life of those around them" (Vygotsky, 1978, p. 77; emphasis added). Vygotskian theory highlighted how children learned through interaction with others, and it emphasized language as the key learning tool; it was language that provided the cultural and cognitive link between child and adult mind and allowed the child to learn the ways of thinking—and the ways of reading and writing—of their society.

In Jake's case, however, the boundaries that "fit" the data were not those of child apprentices to adult-governed worlds (e.g., Heath, 1983; Ninio, & Bruner, 1978). The data were gathered through close observation of children, not through close observation of adult / child encounters. Those children had attended mainly to each other; adults had faded in and out of the viewing frame. Thus, in dialogue with both theory and data, I drew my analytic boundaries around children engaged with other children—children brought together and guided by adults in official worlds but children who organized their own life spaces in response to those worlds (Cook-Gumperz, 1981; Corsaro, 1985). Within such boundaries, it seemed possible to gain insight into the sociocultural

dynamics of learning to write, that is, of developing control over a mediational tool in the social world of school children.

The research question, then, became, how did writing come to be a useful tool within the social lives and the symbolic repertoire of Jake and his peers? In Jake's case in particular, composing served to mediate his relationship with Manuel, a regular coparticipant in his events. For both boys, writing had meaning in a larger school world in which child stories were tools for both immediate engagement and later appreciation ("Just at the very end ... they read the entire story ... I get blown up"). The picture in Figure 15-4, by Jake himself, is a kind of pictorial metaphor for Jake's case. It depicts the linked fates of Jake and Manuel: Manuel, who wanted to be an artist, is drawing a picture of Jake, who wanted to be a pilot.

To answer the project question, I developed coding categories to describe how children used talk, pictures, and written texts to create and to enter into their own and others' composed worlds. One set of categories referred to the functions of the children's language, for example to *represent* aspects of real and imaginary situations, to *interact* with others, and to *evaluate* or express their feelings and attitudes. Another set examined the *meaning elements* represented in children's interwoven talk, drawing, and writing, including, for example, objects, actors, actions, placement in space and time (past, present, future) and sensorimotor qualities (direction, force, speed, volume). It was this vocabulary that revealed, for example, that, as a first grader, Jake's narrative talk during drawing moved through time, but his written language was stuck within the static space / time dimensions of his completed picture frame.

Jake Pushes Boundaries. As the 2 years of the study passed, Jake and his peers both clarified and complicated the guiding definitions of writing and development. Like Rachel, Jake was a child who used stories to express his feelings about—his evaluations of—the world. But this use was not seen simply as an attribute of Jake or as a reflection of his experienced world, nor was his composing seen as a direct reflection of placement along a linear evolution of writing behavior. Rather, Jake's

ways of composing, like those of his peers, were seen as shaped at the intersection of his symbolic resources and social intentions, which were themselves influenced by the social structure and interactional possibilities of his classroom, and, more broadly, the culture of his school.

Initially, Jake and his peers used the familiar tools of drawing and talk to participate in journal time. But, gradually, functional shifts occurred: writing itself began to assume more of the social and intellectual work of composing. Thus, a 2nd-grade Jake interacted with—teased—his good friend Manuel through writing as well as through talk. He manipulated the words on the page in order to manipulate Manuel. Moreover, he used evaluative techniques (Labov, & Waletzky, 1967), like suspending narrative action at critical points (e.g., "I am OK but I don't know about Manuel"), to express his feelings about his world (especially his consistent theme of friends threatened but saved, by him of course).

But Jake's talk did not become less important; for Jake and his peers, as for academics, texts became the center of—embedded in—social interactions and intellectual debates. In fact, it was this embedding that fueled and guided his writing. *Jake was not moving away from the social world*; he was learning new ways of engaging with it.

As the preceding analysis of Jake's writing and development suggests, my interpretive methodology and my guiding definitions of writing—as mediational tool in sociocultural events—were more compatible than they had been in the cases of Rachel and her peers. Still, these new boundaries around Jake and his classmates began to fray even as they took form. One reason simply was time. It is different to spend 2 years with a child, rather than a few months, as with Rachel. Jake was not just a child writer; he was a complex character—a peer among children, a sometimes struggling student, and, he hoped, a "tough" and "slick" kid. His choices of topic, characters, and plot events, his way of interacting with others about his texts—all said something about Jake's relationship to his social world and, perhaps, to the ideological one also (e.g., to being a boy, a vulnerable child in what he regarded as the tough and "crazy part" of the city).

Yet, the specifics of content choices and, more broadly, of sociocultural identity did not figure in any prominent way in Jake's case. But this changed in Tina's school.

Tina: Writing as Social and Ideological Dialogue

In Geertz's (1973, p. 23) words, one can "study different things in different places"—and Tina's school was a place in which issues of identity became strikingly visible. Her urban K-3 school served primarily two neighborhoods, one an African-American, low-income and working-class community, where Tina lived, and the other, an integrated but primarily European-American working- and middle-class community. At the preceding school, Jake's close friends had included children from diverse ethnic backgrounds, most of whom lived in his integrated working-class neighborhood. Tina's close friends were also from her neighborhood, but it was not integrated. Tina, like most of her peers, interacted with those from across the economic divide primarily in official school activities.

FIGURE 15-4 Framing Jake and Manuel

Thus, studying child literacy in the context of child social relationships brought into the viewing frame the interrelated issues of race, class, gender, and culture. Indeed, in my first study at this site, I examined how young child composers made use of diverse cultural resources—the discourse traditions of their home community, those of the popular media, and those stressed in school (Dyson, 1993a).

The second project at the site (Dyson, 1995) began with an informal visit to Tina's second grade classroom during writing time, when I noticed the pervasiveness of superheroes, figures like teenage ninjas (both the human and the "mutant turtle" variety) and X-men (a team of mutant humans, both women and men, with great powers). These superheroes were especially visible during an optional practice named "Author's Theater" by the children's teacher, Kristin; in this practice, the children chose classmates to act out their written stories.

Given that popular media stories appeal to children's ideologically informed desires as members of particular gender and age groups and, less directly, of particular ethnicities and socioeconomic circumstances (Kline, 1993), I wondered how such stories figured into the social and literacy life of Kristin's children (e.g., who wrote such stories, to be enacted by whom, with what sort of changes over time in textual content and structure). Although superhero stories were written primarily by boys, some girls did evidence interest—all working class girls, among them, Tina.

A tiny child with large glasses, Tina was a complex character, one who voiced a strong sense of identity as an African American, as a caring person who "love[d] the world," and as a "tough" kid. "She thinks just because I'm small," that "I can't beat her up," said Tina one day in the midst of a verbal (or rather chillingly silent) fight with her good friend Makeda, "But I'll show her." The complexity of Tina—and her intense reaction to being excluded from anybody's story world—is evident in the summarized drama below.

The Drama—and Dramas—of Tina. For weeks, the boys in Tina's 2nd-grade class had been writing stories for Author's Theater about ninjas, ninja turtles, and X-men—and, for weeks, Tina had been begging for a part to play, with no luck at all. The only boy who regularly included girls in superhero dramas was Sammy, and he, like other boys, picked only Melissa or Sarah, two slender, middle-class, and outgoing white girls—just as were the ninja's "foxy babes" in the popular media stories.

In actuality, neither Melissa nor Sarah campaigned for these roles; indeed, they were not allowed to watch such movies and cartoons. In this classroom, evidenced knowledge of popular media superheroes was related to both gender and class. That is, working class girls, like Tina, generally could carry on informed discussions about these characters, even though they did not write about them. Yet, despite their knowledge and, in some cases, their active campaigning for roles, they were regularly excluded.

Tina had had it. Usually, when she wrote in her journal (entitled "The Peace Book"), she wrote brief texts expressing her love of family and friends. But on this day, Tina enticed her best friend Holly to write a superhero story with her. "And

no boys," she said firmly, "'cause the boys doesn't let us play."

Sitting side by side, Tina and Holly began playfully to plan an X-men story. (X-men stories were particularly appealing, since the X-men superhero team includes "strong" and "tough" girls, including girls of color.) When the children began, Tina planned to be the X-men character Rogue. But she quickly became "the toughest guy in the world. . . . We're all Blobs!" (Blobs are huge, fleshy mutant humans, virtually indestructible and very bad guys.) "'Cause if somebody threw a metal ball at me, the energy go right through me and I would never know. And we're sisters robbing the world. . . . And we'll never get sick. And we'll never die."

The sisters evolved, Tina becoming Uncle Blob, Holly niece Blob. As the girls became more and more animated, they moved to the classroom rug, deep in play. In the drama, Uncle Blob Tina captured the female X-men character Rogue, cutting off her long hair. Uncle Blob drank that hair, absorbing its fiery power, giving just a small bit to his begging niece Holly Blob. "The only thing you can do," he tells the girl, "is just shoot out fire at them [the X-men] and then just call me." (There are shades here of the ninja stories and of the girls who call for help.)

Class composing time ended before the children had put pencil to paper. The next day Tina was absent, and so each girl eventually authored her own X-men story. However, given the intensity of peer pressure, each girl also found it impossible to write the planned drama. For example, on the day Tina attempted to write her X-men story, both girls and boys begged for powerful good-guy roles—and expressed great unhappiness with the unapologetic bad guys Tina had in mind. This pressure resulted in a story without the Blob family but, also, a story without the usual good guys-defeat-the-bad-guys encounter. Following is an edited excerpt from Tina's story:

Once there were 4 X-men [Storm, Rogue, Jean Gray, and Archangel].
And the X-men fought others.
One X-men died.
And the rest of them were
sad. They cried.

This was an unusual superhero story for her class: there was a predominance of women, enacted primarily by girls of color; there was also a death among the good guys; and, most strikingly, a good cry by the superheroes. During the peer enactment of her story, Tina reinforced the disruption of the usual gendered order:

Tina: (reading) "One of the X-men *died*. . . . And the rest were very sad. They cried." Everybody [all of the child actors] cry now, even the *boys*.

As a third grader, Tina temporarily abandoned her interest in X-men stories—"too boyish," she explained; indeed, she even wrote a superhero story featuring a female victim ("Batman will save us girls," she wrote, "Hurry Batman hurry."). Yet, she consistently campaigned for roles in boys' superhero stories, roles in which sometimes "the girls win."

Moreover, in February of her 3rd-grade year, she began once again writing (and once again involving classmates

in) stories that displayed diverse gender relations, among them lovers or spouses, perpetrators / rescuers / victims, disciplinarian / disciplined, nurturer / nurtured, and teammates, with males and females in varied role combinations. As in the second grade, Tina's stories were linked to ongoing class issues and particular interpersonal engagements.

For example, in the last month of school, Tina wrote a superhero story that included diverse female / male roles. Moreover, it included both superhero themes from the popular media and information from a class unit on the superheroes of ancient Greece. In that unit, Tina chose Venus, goddess of beauty, as her project topic, as did her friend Makeda. Sitting side by side, Tina and Makeda initially drew Venus as fair-haired and white. Lena, also at their table, drew her goddess Black, but commented that she was sure it was "wrong," because "people from Greece are not Black."

"Yes, they can be," countered Tina. When Makeda reiterated that her Venus was white, Tina commented, "Well, maybe she's white to you, but not to me." And Tina (and later Makeda) drew a Black goddess as well. Moreover, Tina wrote the piece excerpted below, in which Venus, whose middle name is Tina, saves the world for both boys and girls:

Once there was a boy and girl in the park and two men was walking by the park and the men saw the two kids. So the two men started to run after them. And the kids ran. One man chased the girl the other ran after the boy. The boy name was Aloyse [a classmate] and the [girl] name was Asia [her sister]. So when Venus Tina heard about this she was mad. So she came down . . . and picked the kids up on her magical flying horse named Makeda. It was a girl horse and she took the two kids . . . in the sky. There was a big park on a cloud. There was a lot of kids play[ing] on flying horses. It was kids from [Tina's] school. . . . Then she took them home. They said what about those two mean men. Venus Tina made them nice. And on earth was fun again. She made parks safe for us kids of the world. By Tina. Love Tina.

Defining the Viewing Frame: Analytic Tools. In Tina's case study, the child in the viewing frame was interacting with others in the local situation but, at the same time, that local interaction was substantiating—and, in some ways, challenging—interactions that took place beyond the classroom walls. Understanding such complexity required a perspective on literacy that made explicit provision for the ideological dimension of language use.

Thus, I appropriated the language of Bakhtin's dialogism (1981, 1986; Volosinov, 1973), a theoretical perspective gaining increased visibility in the literacy dialogue of the 1990s. From a Bakhtinian vantage point, the conceptual boundary around Tina would include her interactional partners in the immediate social scene, just as it had in Jake's case. But the voices within that context would have ideological echoes. That is, from a dialogic perspective, writers not only use words in particular situations to interact with others; they also adopt or resist the expected words, the words available to them in those situations as women or men, as people of varied ages and heritages, of different roles, statuses and dispositions.

Moreover, this vantage point also suggested new visions of development. In these visions, children were not unproblematically "growing into the intellectual life of those around

them" (Vygotsky, 1978, p. 77). Rather, they were also growing into, or in some way against, the existent social order through which that life was enacted. Social identification and social conflict—not only internal psycholinguistic conflicts and interactional guidance—influence the direction of learning (Dyson, 1995; Goodnow, 1990). Thus, my research question became, what is the nature of the interplay between the changing interactional and ideological dynamics of individual children's classroom lives and the changing nature of their writing processes and products?

A pictorial metaphor for Tina's case in particular, might be the product in Figure 15–5, which Tina drew during her 3rd-grade lapse in social activism. Tina juxtaposed symbolic material: the words *no no X-men* ("too boyish," she had said) and, underneath, large, colorful depictions of Aladdin and Princess Jasmine, the romantic pair from a popular fantasy movie. Tina's product was clearly rooted in the social world of her classroom *and* in the ideological world as well.

To construct Tina's case, I used ethnographic analysis of all class members' official and unofficial discussions of gender, race, and power (i.e., strength) *and* case study analysis of the content and structure of the writing and talking of the focal children, including Tina.

Just as in the cases of Rachel and Jake, many children in Tina's room initially made minimal use of actual print. Indeed, their written texts functioned primarily as *props* for (or, more accurately, as "tickets" to) the theater: their texts were largely invisible; they stood up and pretended to read texts that were not actually written. And, as in Jake's case, over time children's texts became more central to their social life in this classroom. In this project, however, I aimed to detail the children's social goals and the precise ways in which texts mediate those goals.

Thus, I constructed a category system to describe the children's social goals (e.g., affiliating with others, resisting

FIGURE 15–5 Framing Tina's social and ideological world

them, or, more equitably, negotiating with them) and, also, the way in which the written texts served those goals. For example, their texts could serve as *representations of valued characters and actions*, as *reinforcers of their authority as authors*, their right to say how the world is, and as *dialogic mediators* between themselves and others, as ways of anticipating and responding to others' reactions to their stories.

Tina Pushes Boundaries. The data analysis for this project is ongoing as of this writing. Still, the initial construction of Tina's case has further clarified and complicated perspectives on writing and its development and, moreover, on the potential use of case study methodology itself. To construct the case of Rachel, a child's writing was set against the backdrop of a developmental scheme of child literacy. To construct the case of Jake, a child's writing was first situated within the interactional dynamics of his daily school life. To construct the case of Tina, a case informed by Bakhtinian theory, that writing was also set within the *ideological* dynamics of her classroom community; and those dynamics sometimes foregrounded gender, race, or class.

The goal of the ongoing project is not to compare individual cases that represent particular categories (e.g., to compare a representative boy to a representative girl, or a representative black child to a representative white child). Rather, the goal is to examine how individuals (like Tina) participate in the classroom context as a whole and the interplay between the interactional and ideological dynamics of that classroom life and the particulars of their ways of writing. Gender, race, and class are included in the analysis when they are foregrounded in those dynamics, that is, when they are underscored in the social conversation being furthered through writing. (Such a perspective on gender, race, and class is consistent with poststructuralist theory, which emphasizes the fluid nature of sociocultural identity; see, for example, Williams, 1991.)

In Tina's case, her ways of writing were interrelated with the micropolitics of the classroom. Thus, social conflicts—not only social interactions—helped make salient for her new kinds of writing choices, newly imagined ways of depicting human relationships. What I as an adult might label an ideological critique did not originate from teacher-led critical discussions, but from child-initiated and teacher-supported objections to perceptions of unfair play. That is, Tina did not initiate criticisms of textual representations in and of themselves (e.g., she did not object to women being “sexual objects” in media stories); she reacted to exclusion. For example, she raised the issue of race when she felt excluded from being a “goddess,” of gender when excluded from being a “good guy.”

In both the first and the second grade, Tina's ways of developing her texts (e.g., the characters she included, the elaborations of basic descriptions and actions she added) were linked, in part, to ongoing class discussions about issues of gender, which were interrelated in complex ways with those of race, and, in the third grade, sexual orientation. In Bakhtin's sense, Tina had something important to “say” in the ongoing class conversation. For example, in her Venus story, Tina notes that both the boy and the girl were

subject to the same fate (i.e., being chased by the mean men), and she explicitly marks the flying horse as a girl horse, as Makeda.

Further, Tina was not only developing her own text. She was a key player in the classroom collective; she “talked back” (hooks, 1990), raising issues that reverberated in the class and caused others to rethink—not in grand moments of collective classroom revolution, but in small moments of shifting positions. For instance, urged on by the resistance of her tough friend Tina (and encouraged by her approving teacher Kristin), Makeda imagined a Black Venus, despite the classroom books filled exclusively with fair-haired and light-skinned goddesses.

Just as Tina stretched the meaning of “Venus” in the local culture of her classroom to include her, so too the construction of her case has involved stretching definitions of literacy and of development to include the complexity of her experiences. Thus, like Rachel and Jake, Tina's case is providing material to think with, particularly, material to consider the interrelated ideological and interpersonal dynamics of learning to write. To use Geertz's words, Tina's case does not move from “already proven theorems to newly proven ones,” but rather “plung[es]” more deeply into the same thing, that is, into the experience of learning to write (1973, p. 25).

SHIFTING CONTEXTS: THE ROLE OF CASES IN PROFESSIONAL DIALOGUE

What, then, is the role of case studies in the repertoire of scholarly ways of studying literacy? What professional contribution can be made through close observation of small numbers of children, given the thousands of children in our schools?

To answer that question, one might turn it on itself and ask, what *can* be done with thousands of children *but* count them? In mass, children—and the challenges they present—are faceless, nameless, and overwhelming. But these massive numbers of children are not isolated individuals; they are social participants included, or so we hope, in particular classrooms and schools, in particular institutions and communities.

Through interpretive case studies, researchers offer educators in these places no specific laws of causation, no precise predictions of the outcomes of one teaching strategy or another. But they do offer, through the richness of singular experiences, opportunities to consider the complexities of teaching and learning by embedding them within the details of everyday life in school. It is precisely those details that account for the tremendous potential of case studies to *both* further and stifle professional dialogue.

Providing a Basis for Dialogue

In its careful grounding of important abstractions in mundane particulars, case study research offers diverse professionals a means for identifying and talking about the dimensions and dynamics of living and learning in classrooms (and other

settings as well). As Hymes (1972, p. xiv) noted in his discussion of educational ethnography, careful studies of particular classrooms and communities make available

helpful perspectives and insights but for them to be effective in a classroom, they must be articulated in terms of the features of that classroom and its community context. The participants in the situation must themselves in effect be ethnographers of their own situation. [For them, research] can suggest new things to notice, reflect upon, and do... [But] in the last analysis, it is the understanding and insight of those in the concrete situation that will determine the outcome.

The illustrative cases in this chapter all focused on the dimensions and dynamics of learning to write. In each case, children's engagement with literacy—and the observer's visions of child literacy—were shaped by the social situations in which they found themselves. Those situations were interpreted differently by children from different sociocultural backgrounds and, indeed, by children with different personal dispositions, interests, and styles. Thus, the cases yielded, not prescriptions for practice, but material for reflection about particular aspects of the situated nature of learning to write.

For example, the cases illustrated ways in which the symbolic resources available to children matter. Educators in diverse settings might ask: is it possible for children to, and do particular children choose to, accompany their writing with drawing or drama, with collaborative talk? What challenges do such media present (e.g., the challenge of transforming dramatic sound effects to black and white squiggles, static pictures to dynamic narratives)?

Further, the cases illustrated ways in which official and unofficial social dynamics matter to classroom learning. Children's social goals influence their ways of writing, as do their social partners, including those they write with and those they write for. Moreover, the sorts of public forums available for public sharing and community building are worthy of consideration. Educators might consider, what sort of public participation is possible? with what sort of assumed purpose and expected response? If purpose or response is altered, do and how do patterns of participation change?

Finally, classroom texts (both child- and adult-authored) generate their own set of possibilities and constraints. Educators might consider if, and how, the literate culture (i.e., the dominant topics, themes, genres) figures into the ideological and interpersonal dynamic of the class. Are there points of tension? of children written out (or written in) by others in ways that are uncomfortable for them? How is—could—such discomfort be evidenced?

Just as important as such potential points of reflection anticipated by a researcher are those that are unanticipated. Teachers and other professionals in diverse roles bring their own concerns and vantage points to the details of specific cases (Florio-Ruane, 1991). As Genishi (1992) notes, teachers in particular, are interventionists who construct "theories of practice" (p. 198) that will help them take action to support the individuals in their classrooms. Their particular perspectives may cause them to foreground different research details or data, to identify different dynamics. For example, Florio-Ruane discusses how teachers responded to data gathered in

their own classrooms by raising unanticipated issues about "contextual constraints that arise from outside the classroom" (p. 252), issues involving parents, administrators, textbook publishers, and politicians, among others.

Differing vantage points on the particularities of classroom life could be remarkably productive for all concerned. Indeed, they might contribute to the envisioned democratic participation in educational knowledge-creation discussed by Hymes (1972). As he notes, outside researchers can offer new perspectives, connecting local circumstances to overarching issues and to nonlocal but relevant experiences. But insiders by virtue of being insiders have access to the possibilities and problems of particular situations, access denied those whose participation is structured, at least in part, by theoretical and methodological demands. Yet, the very details that may contribute to dialogic encounters may also contribute to the rigidity of conceptual and professional boundaries.

Constructing Rigid Boundaries

When case study research yields texts of "classroom implications," details of behavior may be separated from the social and cultural circumstance that made those details locally sensible, and they may be separated as well from the conceptual issues that make those details nonlocally useful as material for reflection. Thus made anemic, case studies may give rise to illegal prescriptions, to suspect normative guides. Indeed, the very nature of researchers' written reports may infuse them with the artificial prescriptive authority of the distanced expert (Florio-Ruane, 1991).

For example, the "emergent literacy" behaviors of selected young children in particular settings have been represented as set "stages," as behaviors to be expected from other children in other contexts, children with different resources and end goals, children who may follow different developmental paths (for critiques, see Dyson, 1993b; Sahni, 1994). Interpretive methodology *is* used to ask basic developmental questions about changes over time in children's ways of participating in the everyday activities of family, peer, and community life (e.g., Corsaro, & Miller, 1992; Heath, 1983; Schieffelin, 1990). But exactly what sorts of child responses are universal, at what level of specificity, are questions, not taken-for-granted assumptions (Gaskins, Miller, & Corsaro, 1992).

Such caution is necessary, because people learn to read and write at different ages, with different guiding intentions and available materials, with the support of varied coparticipants, cultural resources, and symbolic tools (Farr, 1994; Sahni, 1994). First-grader Jake, for example, differed markedly from other portraits of beginning writers: he did not view writing as play (cf. Graves, 1983); he did not make extensive use of "invented" spellings (cf. Bissex, 1980); nor did he have any particular interest in writing personal narratives (cf. Sowers, 1985). The purpose of interpretive case studies is not to contribute to rigid developmental portraits. Rather, it is to gain insight into the complexity of literacy learning; any proposed universals must come from comparisons of cases carefully situated within diverse social circumstances.

This potential weakness—this use of detail, not to think with, but to prescribe from—also can occur in reference to teacher, rather than child, behavior. The specific procedures of specific teachers in specific school settings may become suggested “methods,” instructional scripts, which are then transferred to other settings and other participants with different human and material resources, and different curricular possibilities (e.g., Bartolome, 1994; Reyes, 1992). Case studies may thus become ideological tools that help transform human variety into human deficiency.

Such a use of case study details—with its accompanying dismissal of situational complexity and theoretical depth—is antithetical to the very nature of case studies. Indeed, it is precisely because such a use *is* inappropriate that case study methodology has the potential to further true professional dialogue. To return to Hymes’ (1972) insights, case studies may yield new ways of paying attention to, and potentially intervening in, the dimensions and dynamics of child learning in classrooms; but the transformation of new perspectives into specific interventions depends on the professional judgment of professional educators in particular circumstances.

Talking across Boundaries

In the introduction of this paper, Makeda said that a story was “kinda like *your* life,” and, in a very fundamental sense, she was right. Stories, including those we tell about other people, are also about ourselves, written from our particular vantage points. In interaction, each speaker or writer infuses given

words like literacy and development with new accents, new dimensions, because each is positioned differently in the social and ideological ground. Crossing conceptual boundaries is thus linked with crossing human ones: when we, with our diverse experiences and our common concerns, converse, we push each other out of bounds, we help each other attend to the world a bit differently.

Such ongoing conversations about children, teaching, and schooling are critical. Even in one school district teachers work in an amazing array of classroom situations, greeting children who bring to school diverse language and cultural resources, varied histories and relationships with literacy and, moreover, with educational and societal institutions. Rigid curricula and rigid teaching based on narrow visions of children’s lives will not help teachers in their work. Moreover, not only is there present diversity, chronologically, the contextual ground of education is always shifting; our ways of thinking and talking about children and education are grounded in particular historical, intellectual, and cultural conditions (Cherryholmes, 1988).

Promoting conversation will require changes in institutional organization and epistemological visions beyond the focus of this chapter. But surely, one possible means for bringing adults out of their own distinctive professional boundaries and into common conversation is a mutual interest in, appreciation of, and pleasure in knowing the young. When studied indepth, individual children emerge from the shadows, as Sammy did from the underworld, potentially enriching the ongoing conversation about literacy, development, and schooling.

ETHNOGRAPHY AND ETHNOGRAPHERS OF AND IN EDUCATION: A SITUATED PERSPECTIVE

Judith Green

UNIVERSITY OF CALIFORNIA, SANTA BARBARA

David Bloome

VANDERBILT UNIVERSITY

In this chapter, we explore sites of ethnography, not physical sites of people studied but intellectual sites that frame how ethnography is being undertaken in particular ways. The approach we have taken complements recent discussions of ethnography and ethnographic research in the social sciences and education emphasizing the scope of topics, research designs, methods, and theoretical traditions as well as differences from other qualitative and quantitative approaches to research (e.g., Duranti, & Goodwin, 1992; Egan-Robertson, & Willett, in press; Guthrie, & Hall, 1984; Hammersley, 1990; Spindler, & Spindler, 1987; Zaharlick, & Green, 1991). Yet, at the same time, our approach intends to provide another way of looking at ethnography and ethnographic research. As Brian Street's (1993b) review of Martyn Hammersley's (1992) book, *What's Wrong With Ethnography?* makes clear, ethnographic research has evolved and changed over the past 3 decades. Not only has the use of ethnography and ethnographic research become more sophisticated and researchers more aware of the complexities and issues involved, there have been important changes in what counts as ethnography and ethnographic research, who conducts such research, where and how the research agenda being pursued, and how such research contributes to evolving knowledge bases in education and the social sciences. These changes have led to enhanced understandings about how such research can be used to contribute to changes in various social institutions.

As a process of inquiry, ethnography has become a resource for a broad range of people including social scientists, teachers, students, and everyday members of society. Our discussion of ethnography as a process of inquiry differs from discussions of ethnography as primarily an act of writing (e.g., Clifford, & Marcus, 1986; van Maanen, 1988). We acknowledge that ethnography often involves writing about the culture of others (or as is more recently the case writing about the culture of one's own cultural group or subgroup) and that the writing process may influence the nature and meaning of inquiry. It is important to examine how writing is implicated in the meaning of ethnography (Atkinson, 1990). However, by emphasizing the inquiry process as the point of departure for discussing ethnography, rather than the writing as the point of departure, we emphasize ethnography as a way (or more accurately, as a set of ways) of exploring, knowing, and acting in and on the world neither subsumed by writing nor owned exclusively by academics. Through our analysis and discussion of various intellectual sites of ethnography, we make visible how the site shapes what counts as ethnography and how an ethnographic perspective and related practices inform the study of the social and cultural practices within and across social groups. As part of this discussion, we present the argument that ethnographic research, guided by social and cultural theories, provides a basis for the creation of a discipline within the field of education. This discipline has a set of methods, theories, questions, goals

and practices that define what counts as ethnography-in-Education and as knowledge needed to engage in this form of ethnography.

To construct this argument and to examine relationships between site and the practice of ethnography, we approached the task of defining what counts as ethnography in a manner that parallels the ways in which ethnographers, grounded in cultural anthropology, enter a social group to examine the practices that members need to know, understand, produce and predict to participate in socially and culturally appropriate ways (cf. Goodenough, 1981; Heath, 1982). In describing our approach to this task, we are providing the reader with information about our own framework of the study of everyday practices. This information is needed to understand what we have included in our discussion and how our theoretical and methodological perspectives shaped the presentation about ethnography. We began by applying an ethnographic perspective and asking ethnographic questions derived, in this case, from cultural anthropology as a way of making visible what those who engage in ethnography mean by this term:

Where and by whom is ethnography being undertaken?

What questions about ethnography are being asked?

Who is doing the asking, when, for what reasons, and under what conditions?

What significance(s) do the questions have?

To present the issues identified, we integrate the voices of the ethnographers and others with our own to illustrate a range of issues about ethnography across sites raised over the past 3 decades. We selected the last 3 decades as a focus since this period parallels the beginnings of formal areas of study using ethnography in education. The Council on Anthropology and Education was formed in 1968 and the National Institute of Education established a panel to frame ethnographic studies of teaching as a linguistic process in 1974. This panel's report led a federal grant program that funded more than 2 million dollars in grants on this topic in 1978 (see Green, 1983a, for a synthesis of this group of studies). In making visible the issues raised across sites, we show that the arguments are not unique to one site. Rather, they are general ones that cross sites. This approach provides a basis for constructing a grounded view of ethnography as the practice of researchers within particular fields and disciplines. Our goal in taking this approach is to help readers construct an understanding of the range of issues involved in taking up ethnography as a theoretically driven, situated approach, not to synthesize ethnographic research or to reproduce discussions of field methods that already exists. For readers interested in additional discussions about ethnography across disciplines, we recommend the following as illustrative of discussions in, anthropology: Agar (1980), Ellen (1984), Geertz (1973, 1983), Gumperz and Hymes (1972), Pelto and Pelto (1978); in sociology: Denzin (1989), Denzin and Lincoln, (1994a), Hammersley and Atkinson (1983), van Maanen (1988); and education: Erickson (1986), Gumperz (1986), Graddol, Maybin and Stierer (1994), Heath (1982), Hymes (1982), Spindler (1982), Wolcott (1975, 1982, 1987), Zaharlick and Green (1991). For a historical analysis of ethnography, see Ellen (1984), Clifford (1988), Gilmore

and Smith, (1982), Harrington (1982), and Vidich and Lyman (1994).

The discussion of what counts as ethnography is presented in three sections. In the first section, we examine ethnography within social science. Through this discussion, we identify issues and directions in ethnography as practiced by social scientists across the disciplines of anthropology and sociology. We begin the second section by making a heuristic distinction between ethnography-of-education (e.g., anthropologists or sociologists studying education) and ethnography-in-education (e.g., educational researchers, teacher educators, teachers, and students employing ethnographic research to study education). In this section, we focus on ethnography-in-education to show how ethnography has become both a research approach for and a resource used by university-based researchers, teachers and students in pre-schools, elementary, secondary and higher education to collaborate in the study of everyday life in and out of schools. As part of this section, we illustrate how students and teachers have taken up the role of social scientists and adopted ethnographic perspectives and practices in order to explore their own communities. In the third section, we describe how ordinary people take up ethnography and ethnographic writing by describing the Mass Observation Project in the UK. Through the Mass Observation Project, ordinary people have become ethnographers of everyday life in Britain and their written contributions provide both a 'people's ethnography' and an archive that is being used by university-based researchers and others. In discussing the Mass Observation Project, we raise issues about the writing and reading of ethnography and ethnographic research that are applicable across sites of ethnographic research.

SOCIAL SCIENCE AS SITES OF ETHNOGRAPHY

In a recently published dialogue between American ethnographer Louis Smith (1990) and British ethnographer Martyn Hammersley, Smith asks whether, "Ethnography is ethnography?" (p. 1). He answers his own question by arguing that:

Ethnography as a social science is fractured along national lines (e.g., USA, UK, and the Commonwealth), disciplines (e.g., education, sociology and anthropology), substantive interests (e.g., classroom analysis, innovation and evaluation), smaller interpersonal University groups (e.g., Stanford, Manchester, East Anglia, etc.), paradigmatic perspectives (e.g., neo-positivists, interpretivists and critical theorists) and commitment to action and reform (action researchers versus more academic interpreters and analysts). (pp. 1, 2)

For Smith, what counts as ethnography varies with different sites and actors: national sites, university groups, conceptual and theoretical perspectives (i.e., philosophical positions, and purposes for doing ethnography). See Atkinson, Delamont, and Hammersley (1988) for a discussion of the differences between British and U.S. ethnographic research; see Corenstein (1992) for a description of ethnographic research in education in Mexico. Viewed in this way, there is no

single place to go to define what counts as ethnography, only local sites inhabited by particular groups. Smith sees the differences as problematic, as fracturing the field, but he also argues that if we understand these differences, we can construct a productive dialogue among perspectives.

If we take Smith's challenge seriously, then the first task facing those of us who want to participate in such dialogues, engage in ethnographic research or use ethnographic research is to construct understandings of issues that shape what counts as ethnography in and across sites. However, as we illustrate in this section, defining what counts as ethnography is a complex and, at times, problematic task given the scope of issues, perspectives, and practices that come under the rubric of "ethnography" or "ethnographic."

Ethnography as Logics-in-Use

Ellen (1984) captured the variation suggested by Brian Street (1993a) and Louis Smith (1990) more than a decade ago in his book, *Ethnographic Research*, suggesting that concern over what counts as ethnography is not a new topic of discussion. In researching the history of ethnography for this textbook, he examined the ways in which the term ethnography was used across the academic fields of anthropology and sociology in the United States and the UK. His historical analysis showed that the term ethnography has been used to refer to a wide variety of phenomena and that there is a lack of common definition:

Consider, for example, the word "ethnography". This word is used regularly to refer to empirical accounts of the culture and social organization of particular human populations (as in "an ethnographic monograph", "an ethnography"). The implication is that of a completed record, a product. But then the sense alters somewhat if we speak of "ethnography" as opposed to "theory", or of "an ethnographic account" (meaning living people) as opposed to an historical or archaeological account. Different again from all of these is the use of the term to indicate a set of research procedures, usually indicating intensive qualitative study of small groups through "participant-observation". ... Finally, "ethnography" may refer to an academic subject, a discipline in the wider sense involving the comparative study of ethnic groups. ... Thus, ethnography is something you may do, study, use, read, or write. The various uses reflect ways in which different scholars have appropriated the term, often for perfectly sound conceptual reasons. We would not wish to suggest that the word be employed in one sense only, even if it were possible to effectively dictate that this should be so. However, it is important to know that the differences, often subtle, exist. (pp. 7, 8)

As indicated in this quotation, the definition of ethnography as a process, a product, an area of study, or a way of constructing knowledge of the world depends on the context of use. Rather than seek a single point of view, which Ellen suggests may not be possible or desirable, we should seek understandings of the differences, often subtle, among the different uses within and across sites.

At the same time that Ellen reported this state of affairs, we found a similar pattern in discussion of criteria for an adequate ethnography (Green, & Bloome, 1983). In reviewing criteria for ethnography framed within anthropology to in-

form its use within Education, we found little agreement about criteria for assessing what counts as ethnography. Analysis of criteria for ethnography and research claiming an ethnographic perspective led us to draw a distinction among three approaches to ethnography in traditional social sciences as well as in Education: doing ethnography, adopting an ethnographic perspective, and using ethnographic tools. We argued, then, and continue to argue here, that *doing ethnography* involves the framing, conceptualizing, conducting, interpreting, writing, and reporting associated with a broad, in-depth, and long-term study of a social or cultural group, meeting the criteria for doing ethnography as framed within a discipline or field. (For example in anthropology, see discussions of criteria by Sanday, 1976; Spindler, 1982; Wolcott, 1975. For a complementary argument and a set of criteria for qualitative research in general see Denzin, & Lincoln, 1994b; Howe, & Eisenhart, 1990.)

By adopting an *ethnographic perspective*, we mean that it is possible to take a more focused approach (i.e., do less than a comprehensive ethnography) to study particular aspects of everyday life and cultural practices of a social group. Central to an ethnographic perspective is the use of theories of culture and inquiry practices derived from anthropology or sociology to guide the research. The final distinction, *using ethnographic tools*, refers to the use of methods and techniques usually associated with fieldwork. These methods may or may not be guided by cultural theories or questions about the social life of group members.

Having established the historical and complex nature of exploring what counts as ethnography, we now consider factors that contribute to the differences within and across disciplines and academic fields to help readers examine what difference the differences make. For heuristic purposes, we distinguish between a field and a discipline within a field. We use field to refer to an academic area of study that serves to bound a body of knowledge, sets of questions and practices of members. We view sociology, anthropology and education as fields. When we refer to the area as a field we use a capital letter. A discipline is a subarea within a field that has a particular point of view or approach to the study of issues and phenomena of concern within the field. For example, cultural anthropology is a discipline within a field. A cognitive approach within cultural anthropology is a subdiscipline within a broader area of study. This heuristic approach examines how differences in naming elements of an academic tradition provide a basis for examining variation within a field as well as variation across fields. While social scientists agree that historically ethnography has its roots within anthropology, they also acknowledge that it has since become an approach used by anthropologists, sociologists, educational researchers, and others, to study particular questions and issues of interest to their respective disciplines and academic fields. Viewed in this way, ethnographers are members of different disciplinary traditions within particular academic fields who are trained in particular theories and methods of their traditions to ask and explore particular questions for particular purposes (Ellen, 1984; Heath, 1982; Vidich, & Lyman, 1994; Zaharlick, & Green, 1991). Three

examples, two from Anthropology and one from Sociology, make visible some of the issues involved in this way of viewing ethnography as situated practice.

In a special issue of the *Anthropology & Education Quarterly* on teaching fieldwork to educational researchers, George Spindler and Louise Spindler (1983) described the situated nature of ethnography as intellectual sites located in disciplinary traditions within an academic field:

...we teach our students to do anthroethnography, meaning that the major concepts, models, techniques and purposes of "our" ethnography issue from the discipline and theory of cultural anthropology. (p. 191)

The term anthroethnography locates the work of the Spindlers in the field of anthropology (for a similar discussion see Hymes, 1982). The choice of cultural anthropology further locates their work in a discipline within anthropology. This difference shapes the meaning of the concepts used, the models selected, the purposes of the research and the techniques used. Thus, the decision to frame their approach in Cultural Anthropology has consequences for each step of the inquiry and interpretation processes.

Arthur Vidich and Sanford Lyman (1994) make a similar distinction from a sociological perspective. In their chapter, "Qualitative Methods: Their History in Sociology and Anthropology," they define a set of issues and perspectives related to understanding ethnography as situated in a disciplinary site, an academic field. They situate ethnography in sociology and describe how a sociological "attitude" grounds what counts as ethnography:

Qualitative ethnographic social research, then, entails an attitude of detachment toward society that permits the sociologist to observe the conduct of self and others, to understand the mechanisms of social processes, and to comprehend and explain why both actors and processes are as they are. The existence of this sociological attitude is presupposed in any meaningful discussion of methods appropriate to ethnographic investigations. (p. 23)

Writing a decade apart, both sets of authors acknowledge the way in which disciplinary knowledge frames the "doing" of ethnography. For Vidich and Lyman (1994), the difference is in the development of a situated "attitude" framed by sociology. While they overview the historical roots of ethnography in anthropology, in the introduction to their chapter they also frame the current state of ethnography from a sociological perspective without providing a similar view of an anthropological attitude.

To help frame an anthropological attitude and to show the variation within an academic field, we represent an argument by Charles Harrington (1982). He argues that within anthropology, there is no common definition of ethnography. Rather, anthropology is, itself, a field with branches or disciplines including psychological, social, cultural, linguistic, visual anthropology among others. Within each site, branch or discipline, ethnographers engage in "ethnography" differently and the methodological practices used are themselves shaped by these differences. Through a discussion of participant observation, he shows that what counts as doing ethnography

as well as ethnographic methods, are situationally defined:

Cultural, social, psychological, and other branches of anthropology ... all share a dedication to the efficacy of a variety of techniques subsumed under the label "participant observation." By participant observation we mean not one technique, but rather a mélange of strategies aimed at producing an accurate model of the behaviors of particular people (including the related problems of how people justify their behaviors to themselves and how they describe them to others). ... Participant observation is usually carried out in explicit or implicit combination with other strategies designed to elicit different sorts of data. Various subgroups of anthropology have developed their own ancillary methods in response to the specific problems that each has chosen to solve. For example, psychological anthropology has emphasized the importance of the systematic observation and recording of data, the collection of life and family histories, the use of adaptations of psychologist's assessment techniques, and so on. (pp. 327, 328).

The anthropological attitude indicated in this description contrasts with the sociological one framed by Vidich and Lyman (1994). As Harrington (1982) states, anthropologists' goals are "aimed at producing an accurate model of the behaviors of particular people (including the related problems of how people justify their behaviors to themselves and how they describe them to others)." An anthropologist, therefore, seeks insider (emic) knowledge about how members understand, view and interpret the patterns of everyday life. This approach requires the anthropologist to seek understandings of what it means to be a member of the particular group, and to use the models they construct to participate in the events and practices of everyday life (Sanday, 1976), reducing the distance between those within the group and the anthropologist. Thus, the difference in relationship between the anthropologist and sociologist and the groups they study is a distinguishing feature across academic fields.

The distinctions within and across sites (fields and disciplines within a field) framed above reflect differences in theory-method relationships and, point of view and inquiry practices. These distinctions point to ways that such differences influence all aspects of the ethnographic approach including the questions asked and the ways methods and techniques are used. A more extensive discussion of theory-method-question relationships can be found in Zaharlick and Green (1991). They show the difference between ethnographers interested in ethnography of communication and those who adopt a cultural ecology point of view. Ellen (1984) provides a distinction between theory, method and technique that is useful in understanding the relationships among different dimensions of an ethnography:

Without claiming to provide the "correct" definitions, and while both recognizing that any definitions are (up to a point) arbitrary and that content of each category profoundly affects the others, we propose the following: (a) "theory": a supposition or body of suppositions designed to explain phenomena or data. (b) "methodology": the systematic study of the principles guiding anthropological investigation and the ways in which theory finds its application; an articulated, theoretically informed approach to the production of data, e.g., "Marxist methodology",

"ethnomethodology". (c) "method": a general mode of yielding data, e.g., interviewing. (d) "technique": a specific means of making particular methods effective, e.g., questionnaires, shorthand, kinship notations. "Methods" and "techniques" together constitute research procedures.

Thus, to understand what counts as ethnography in social science, readers must examine not only how ethnography is being undertaken but also the theories, purposes and questions of the disciplinary *and* academic field for the ethnography. Ethnography, thus, can be viewed as a logic-in-use (Pelto, & Pelto, 1978) within and across sites, and not as a unitary perspective with a single set of criteria for use.

The need to understand ethnography as a "logic-in-use" is not new. Almost two decades ago Ray Birdwhistell (1977) described the need for such an understanding in a response he gave to his students when they questioned about whether Margaret Mead and Gregory Bateson had a methodology:

I tried to make clear what was involved in the use of the phrase "a methodology" when talking about ethnography. I tried to clarify the idea that methodology, at least as taught and practiced by the ethnographers I have known best, is not merely a technique for eliciting information related to closed and immutable questions. Nor is it a bundle of techniques; some kind of handydandy tool kit prepacked for field use. ... I have come to the conclusion that the past twenty-five years have seen a separation of theory from methods of research procedure. This tendency becomes manifest in the choice and analysis of import of problem, in the location of observational site, in the preliminary isolation of data, in the development of relevant, consistent and explicit techniques of observation, in the recording and storage of data, in the orientation of rules of evidence, and, finally, in the methods of data and evidence assessment and presentation that permit and assist in ordering reexamination, and research. (p. 104, 105)

As Birdwhistell argues, knowledge of the theory-method relationships is central to understanding as well as engaging in all aspects of ethnography. Each decision contributes to the coherence of the logic-in-use. Without such understandings, researchers may separate theory and method in favor of focusing on one or the other dimension. He writes:

The interdependence of theory and methodology can be hidden by exclusive focus upon either philosophy or technique. Once separated, only the most sophisticated can reconstitute them into investigatory practice. ... There seems to have been a growing tendency, particularly among those disciplines concerned with what is termed "direct observation," for a number of investigators to reject the use of theory except as a device for the *interpretation* of data. (p. 104)

Shirley Heath (1982) illustrates the consequences of focusing on method or technique without considering theory-method relationships. In discussing the essentials of ethnography, she characterizes the early state of ethnography in education as involving some problematic elements. As part of this argument, she also draws distinctions between ethnography and other qualitative approaches.

Recently, researchers in the field of education have been particularly prone to use the terms *ethnography* or *ethnographic* to describe studies using participant observation, naturalistic inquiry, and open-ended research designs. ... Thus ethnography in education has become a set of techniques in search of a discipline

within the social sciences. A variety of researchers, many nonanthropologists, either "do ethnography" or critique ethnographic methods without reflecting the historical, methodological, and theoretical links of ethnography to cultural anthropology. Numerous methods and approaches, described as qualitative, naturalistic, ecological, and holistic, are identified as *ethnographic*, characteristics of or having the form of ethnography. Though it is not necessary to claim that only anthropologists can do ethnographic research, it is important to recognize that many of the methods, rationales for open-ended research techniques, and theoretical guides to interpretation of data gathered by these means derive in large part from anthropology. (p. 33)

Her argument does not claim ethnography for a particular group. She argues, however, that to avoid misappellation or misattribution, it is necessary to understand the historical roots of ethnography, to do more than adhere to the form of ethnography or use field methods, and to distinguish between "full-scale" ethnography and other forms of "ethnographic" studies. For her, this knowledge is essential if researchers are to claim that they are doing ethnography, not merely adopting ethnographic techniques. In this way, she draws a set of distinctions similar to those we described at the beginning of the section.

Her concern reflects the early stages of the relationship between ethnography and education that characterize the period from the the mid-1970s to the early 1980s. For an earlier argument on misappellation in education, see Ray Rist (1980). In this period of educational research, qualitative research and ethnographic research were emerging as a viable approach in Education. This period contrasts with the current state-of-affairs in which a significant body of research across different qualitative traditions and disciplinary perspectives has been accepted and published as evidenced by recent handbooks (Denzin, & Lincoln, 1994a; LeCompte, Milroy, & Preissle, 1994) and discussions of qualitative research (e.g., Guba, 1990; Jacob, 1987). As we will illustrate in the next section, the current ethnographic studies in education build on historical roots, while adapting ethnography to the questions, purposes, and theories of Education as an academic field of study.

The issues identified in this section show ethnography to be a theoretically driven approach that is situated within a particular site, a discipline within a field. These sites, and their related questions, purposes, and theories shape the practice of ethnography. Viewed in this way, ethnography is a situated approach to the study of everyday life, and ethnographic practices reflect the inquirer's disciplinary grounding and his or her logic-in-use. Thus, theory, purpose, and practice within the academic site help distinguish different views on ethnography, implicate particular relationships between researcher and member of the social group being studied, and distinguish it from other forms of qualitative research.

ETHNOGRAPHY AND ETHNOGRAPHIC STUDIES OF AND IN EDUCATION

In this section, we examine what counts as ethnography in relationship to Education, and how this relationship reflects

the academic field of the researcher—Anthropology, Sociology and Education. As part of this discussion, we will illustrate how ethnographic studies have contributed to the development of an academic field of Education that has its own theories, purposes, questions, practices, and literature.

Heuristically, there are two ways of distinguishing among ethnographic studies focusing on education as a site for inquiry: (1) ethnography and ethnographic studies *of* education; and (2) ethnography and ethnographic studies *in* education. The first, prototypically involves anthropologists and sociologists using education as a place of study to which they bring theoretical frames, tools of inquiry, and a history from their field and discipline within the field to construct an understanding of what counts as education to a local group. From this perspective, educational sites, such as schools, are primarily physical sites that become locations for the pursuit of social science research through ethnography and ethnographic research. Theories, questions and goals of this research are framed by the home disciplines and academic fields of the researcher, and not necessarily by educator's needs, issues or concerns (Gilmore, & Glatthorn, 1982; Green, & Wallat, 1981; Heath, & Peters, 1984; Spindler, 1982).

The second set, studies *in* education, can be heuristically defined as studies grounded in knowledge derived from the field of Education and the historical background of ethnography in anthropology and sociology. These studies, however, are guided by educational questions, purposes, needs, and concerns, which, as argued previously, shape the specific character of *ethnography in education*. From this perspective, education is both a physical site and an intellectual one with its own knowledge base, questions, and purposes. Ethnography *in education* is conducted by those inside this academic field, for example, teachers, students, teacher educators, administrators, using ethnographic perspectives and ethnographic tools for Education's purposes.

While this distinction is useful heuristically in framing the difference, in actual practice, the boundaries are often blurred (Geertz, 1983). Social scientists *of education* often collaborate with researchers and practitioners in education and employ the many kinds of knowledge generated within the disciplines *of education*; and those *in education* often employ frames, modes of inquiry and findings from the disciplines within the fields of anthropology and sociology. Thus, rarely is any ethnography or ethnographic study only *of education* or only *in education*. Nonetheless, the distinction is useful in examining the intellectual sites within which ethnography and ethnographic studies on education have been located.

This section begins with a brief discussion of ethnography of education to set the frame for the general discussion of this relationship and to provide a basis for readers to distinguish between this view and the ways that ethnography is currently in use in education. The discussion of ethnography in education provides a general argument about this conceptualization and then moves to specific examples of ethnographic research across multiple sites within education and the purposes each serves. The first part of this argument describes studies and directions that have been undertaken

by university-based researchers to illustrate how this perspective has contributed to a knowledge base for the field of Education. This discussion is followed by two newer areas of use that are currently contributing to this knowledge base: Teachers as ethnographers and students as ethnographers.

Ethnography of Education

The need for theory–method considerations in ethnography and ethnographic research of education is clear in the arguments presented by Heath (1982). To help shape the importance of this issue, we discuss briefly the educational ethnographer's task as framed within cultural anthropology. While specific areas of focus may differ within and across disciplines and theories guiding collection, analysis and interpretation may vary from one discipline to another, the general theory–method task remaining constant. What follows, then, is a sketch of the task; it is not a description of how to accomplish this task since that requires knowledge of questions, theories, and purpose of the research.

The ethnographer of education's task is to describe the culture of the social group being studied and to identify specific cultural patterns and structural regularities within the process of continuity and change that are ongoing dimensions of everyday life (Heath, 1982). One of the definitions of culture used frequently in ethnographic studies of education is one posed by Ward Goodenough (1981) for cognitive anthropology. Briefly, within this tradition, culture is defined as the norms that are constructed for ways of perceiving, believing, evaluating, and acting within a social group.

Another way of viewing the ethnographer's task is to see it as one of constructing a cultural grammar or abstract theory that describes the rules or norms that individuals within a society, community, or group have to know, produce, predict, interpret, and evaluate in a given setting or a social group in order to participate in socially and culturally appropriate ways (Heath, 1982; Zaharlick, & Green, 1991). To develop a theoretically driven working model of life within a social group, the ethnographer selects particular theoretical frameworks to guide analysis of the patterns and practices of members and how these bits of everyday life frame a particular view of the social organization. Through this lens, the ethnographer identifies key events or incidents (e.g., recurrent events and events that have sustaining influence); describes these events or incidents in functional and relational terms; explores links to other incidents, events, phenomena, or theoretical constructs; places the events in relation to other events or wider social contexts; and then constructs a description so that others may see what members of a social group need to know, produce, understand, interpret, and produce to participate in appropriate ways.

Viewed in this way, the task of the ethnographer of education is to understand what counts as education to members of the group and to describe how this cultural practice is constructed within and across the events and patterns of activity that constitute everyday life. To accomplish this, ethnographers must set aside their own definitions of actors, places, time(s), actions, events, and other aspects of everyday life (cf. Spradley, 1980), and identify and describe the emic (insider)

terms for these dimensions of everyday life. In other words, the ethnographer seeks understanding of the ways in which members of the group name, organize, and interact both in local events and across events over time. In this way, the ethnographer can identify what counts as education, who has access to education, who the actors are that are involved in education within and across events, what relationships exist between and among actors and events, and what factors support and constrain participation among other issues. Through analysis, the ethnographer also identifies the norms and expectations, roles and relationships, and rights and obligations of membership in a society, a community, a group or a classroom. In this way, the ethnographer makes extraordinary the ordinary, and makes visible the invisible patterns of ordinary life within a group.

This brief description of the ethnographer's task indicates the complexity of the task facing an ethnographer of *education* located in the social sciences and suggests further reasons for understanding the theoretical framework guiding individual ethnographies as well as studies stemming from particular sites. Spindler (1982) provides an example of why such knowledge is necessary and illustrates how he frames differences among perspectives. In discussing the "ethnography of schooling," he illustrates one way of defining disciplinary sites and institutional sites. As discussed earlier, Spindler's approach is grounded in anthroethnography, specifically a psychological anthropology focus. In defining an institutional site, Spindler makes a distinction between the "ethnography of schooling" and "educational ethnography."

The terms "ethnography of schooling" and "educational ethnography" mean nearly the same thing but are not exactly synonymous. At least in my usage, "educational ethnography" refers to the study of any or all educational processes whether related to a "school" or not. "Ethnography of schooling" is therefore a little narrower in that it refers to educational and enculturative processes that are related to schools and intentional schooling, though this concept leaves room for studies of playgrounds, play groups, peer groups, patterns of violence in schools and other aspects of school related life. (p. 2)

Thus, Spindler defines and frames different foci and inquiry related to ethnography and education. At the same time, he also indicates that some sites, questions, and foci are not part of or available to those within each perspective. In framing this distinction, he is creating a parallel argument to Harrington's (1982) presented previously, about the variation within an academic site. In drawing this distinction, he illustrates how intellectual sites influence the definition of the institutional site itself (e.g., education, schooling). The ethnography of education, then, can be viewed as consisting of a series of disciplinary sites and institutional sites that frame and are framed by theory-method relationships and research practices, for example, cognitive anthropology, psychological anthropology, and cultural ecology. As argued previously, these variations shape questions and reflect different logics-in-use (Pelto, & Pelto, 1978).

These differences are only problematic if we assume that we can ignore them and try to aggregate unproblematically data across studies, as if they all belonged to a single perspec-

tive. However, if we understand that the differences reflect the situated nature of ethnography and ethnographic research, then we can understand how such research varies according to questions, goals, techniques, practices and purposes of members of a social group (the ethnographers) located in a particular site (disciplinary, institutional, and physical). In constructing such understandings, we can productively engage in dialogues across perspectives and seek approaches to bringing together studies from different perspectives in ways that honor the differences, yet provide insights into the nature of educational practices of a group or institutional site. Green, (1983a) used this argument in constructing a synthesis of the 10 NIE research studies funded under the title "Teaching as a Linguistic Process in a Cultural Setting."

Viewed in this way, ethnography of education, like other forms of ethnography discussed previously, can be understood as the work of people living in a particular time and place, undertaking the study of social and cultural practices of everyday life from particular points of view for particular purposes. From this perspective, then, no single definition of ethnography of education exists, only situated definitions. What is common, however, across these different perspectives is the goal of generating knowledge about the social and cultural practices related to phenomena that researchers have named as "educative." Just what will count as the practice of educating, what slice of society will be examined (e.g., ethnic communities, classrooms and schools as communities, speech communities, etc.), and what tools the ethnographer will use depend on the theoretical framework and intellectual position selected.

Ethnography in Education: Framing Education as a Site of Ethnography

In the previous section, we discussed how social science researchers using ethnography and ethnographic research have viewed education as a physical and institutional site for applying disciplinary perspectives and research agenda. Traditionally, education has not been considered a field in the same ways that Anthropology and Sociology have been considered. Some have argued that it is not a field in the sense of having disciplinary frames, knowledge, and modes of inquiry; rather, it is a place to which researchers bring other theories and methods.

Given the scope and depth of the research that has been undertaken over the past three decades, we argue that Education is a field in the sense of having its own (a) history of inquiry, and (b) knowledge base that needs to be accounted for in conducting inquiry and interpreting and reporting of data. To illustrate the basis for this claim, we provide a brief history of research within one area of Education, research on teaching. In 1963, Donald Medley and Harold Mitzel (1963), in the first *Handbook of Research on Teaching* (Gage, 1963), argued that there was little direct observational research in classrooms. In 1973, Travers published the second *Handbook of Research on Teaching*, in which Barak Rosenshine and Norma Furst (1973) found that researchers had created more than 125 systems for observing but these had little or no

reliability or validity data. Building on a conceptual argument by Nathan Gage, they called for and framed a research tradition that is known as process-product research. At the same point of time, Michael Dunkin and Bruce Biddle (1974) published a review of systematic observational studies on teaching. They found that most studies were framed by personal, philosophical, experience- or commitment-based beliefs about teaching. There were few empirical or theoretically based studies. In addition, they concluded that there had been little research on teaching (and by implication, little research in education in general). They further argued that the primary focus of educational research at that time focused on issues of learning. In making this claim, they separated the two processes for heuristic purposes. They concluded their synthesis with a call for examining the language of the classroom in order to explore further research on teaching, a call that echoed an earlier one by Smith and Ennis (1961).

Ethnographic research was not represented in either of the first two handbooks or in the synthesis by Dunkin and Biddle (1974), since what little ethnographic research existed at that time was conducted in anthropology and sociology. That research did not examine classrooms as cultural sites but focused on education in other cultures or education at the societal level. Additionally, this work was not readily available since the key journal for this work, *The Anthropology & Education Quarterly*, had not published its first volume until 1975.

In the two decades since that period, there has been a substantial growth of research studies and systematic theory building from a broad range of perspectives including ethnography in and of education. This growth and the shift in recognition of ethnographic research is visible in the third *Handbook of Research on Teaching* (Wittrock, 1986). When this volume was published, three chapters foregrounded ethnographic research and ethnography as a method for educational research (Cazden, 1986; Erickson, 1986; Evertson, & Green, 1986). This handbook, therefore, reflected a shift in frameworks, in research practice, and in the knowledge base. The decade following the 1986 *Handbook of Research on Teaching* is characterized by a plethora of new handbooks across different areas or disciplines within education including Curriculum, Early Childhood Education, English Language Arts, Teacher Education, and Reading among others and an increase in the number of journals publishing research on teaching, including ethnographic studies of life in classrooms. These handbooks and journals reflect the growth of educational research and the development of a knowledge base for the field of Education to which ethnographic studies have made a major contribution.

In just over three decades, then, Education has developed a comprehensive knowledge base that includes work grounded in a variety of disciplines. This body of work includes studies of education and educational processes and practices from other fields, as well as studies in education that often draw on knowledge from these other disciplines and fields. These different traditions and foci within education can be conceived of as branches in the sense that Anthropology and Sociology have branches. In other words, they are intellectual sites for research in education, each focusing on

particular theories, processes, practices, questions and research agenda.

Ethnographic research in and of education has contributed to the growing knowledge base of Education in different ways. Given the scope of work from this tradition, it may be thought of as an area of study and not just a method of research. However, as we have described in this section, these two ways of generating knowledge about education are not the same. Metaphorically, while these two sites of ethnography may be overlapping locations, they are not the same locations. Each is guided by different theories, goals, values, and purposes that shape the use of a common set of tools. In the next section, we will illustrate the range of work and the variation in what counts as ethnography and ethnographic research in education.

ETHNOGRAPHY-IN-USE AMONG TEACHERS AND RESEARCHERS LOCATED IN CLASSROOMS

One way to describe the variation in the intellectual sites associated with ethnography and ethnographic research in education is to examine the knowledge bases employed in the studies, who counts as an ethnographer, and the research agenda each addresses. Our discussion below is not intended to be comprehensive, but to illustrate one way in which variation of ethnography and ethnographic studies in education might be described. Given space limitations we only discuss two areas, and even within these two areas we discuss a few topics, issues, and questions. The two areas were selected to highlight research directions and issues of interest to those concerned with the communicative arts and to illustrate how ethnographic research is contributing to the construction of the knowledge base of Education. The areas selected include: studies that have focused on classroom language (including multiple languages in classrooms), and studies of learning and knowledge in education. These categories are presented for heuristic purposes and reflect the primary focus of the different studies or focus on different places of education. These areas, therefore, provide a means of examining a limited, yet focused, view of research on *ethnography in education*.

Ethnographic Studies of Classroom Language, Social Organization and Linguistic Diversity in Classrooms

One of the primary areas of ethnographic research in education has been research that focuses on language or communication in classrooms. This area of ethnographic studies is interdisciplinary in that the studies in this area draw on frameworks from ethnography of communication, interactional sociolinguistics, social semiotics, functional linguistics, and studies of language learning in classroom. The earliest collection of published ethnographic work in this area is entitled, *Functions of Language in the Classroom*, edited by Courtney Cazden, Vera John and Del Hymes (1972). These studies were the stimulus for other ethnographic research

and contributed to the convening of a panel of international scholars in 1974 by the National Institute of Education (NIE) that conceptually framed a program of research on "Teaching as a linguistic process in a cultural setting." This panel consisted of researchers from linguistics, anthropology, education, and child development. These interdisciplinary scholars framed a research call that led to the funding of 10 research studies in 1978 from a range of theoretical frameworks but with a common goal—to understand how language use shaped access to schooling, how students learned language in school, and how the language use influenced the teacher's assessment of academic competence. The findings of this work were synthesized by Judith Green and colleagues (see Green, 1983a, 1983b; Green, & Smith, 1983).

During the same period, a number of edited collections and volumes reporting studies within this growing area were also published (e.g., Bloome, 1985; Cook-Gumperz, 1986; Gilmore, & Glatthorn, 1982; Green, & Wallat, 1981; Mehan, 1979; Wilkinson, 1982). As indicated previously, in 1986, this area of research was also represented in three chapters in the third *Handbook of Research on Teaching* (Wittrock, 1986): Cazden's chapter, "Classroom Discourse," Erickson's chapter, "Qualitative Methods on Research on Teaching," and Evertson and Green's chapter, "Observation as Theory and Method." Additionally, in 1988, Cazden published a book, *Classroom Discourse*, a term that captures a subset of the work in this area. This book brought together ethnographic and other research on classroom language concerned with questions of access, cultural variation, effective instruction, and learning. These books, therefore, represent ethnographic research on classroom language conducted in the United States and primarily, but not exclusively, in monolingual classrooms.

These publications along with other studies on classroom language, in the United States, the UK and elsewhere, can be viewed as constituting the beginning of a recognized knowledge base on classroom language in the United States on which subsequent studies of classroom language in education have been built. Note that none claimed to be a comprehensive review. Green's mandate was to synthesize and summarize the NIE funded studies, Wilkinson's book by its very nature was not intended to be comprehensive, and Cazden made clear that she is not attempting a comprehensive view but rather her own view. The point is not that they were comprehensive (either alone or collectively) but rather that their presence marked the emergence of a recognized knowledge base in education in the United States on classroom language. One further indication of the establishment of a knowledge base in education on classroom language is the establishment of research and theoretically oriented journals devoted to the topic: for example, *Linguistics and Education* edited and published in the United States and *Language and Education* edited in the UK and Australia and published in the UK.

Analysis of the focus of studies within this area of concentration shows that, regardless of the particular topic, the research examining classroom language has a common set of concerns—the social and cultural dynamics of the classroom. To show the range of issues addressed and different purposes for research from this perspective, we highlight a series of

studies. These studies make visible areas of common concern, the interdisciplinary nature of research in this area, issues of variation, and contributions of this work to the knowledge base in education.

A series of studies have examined how the structure of language use defines classroom culture, pointing out who gets to use what language (or languages), when, for what purposes, and with what social, cultural, and educational consequences (e.g., Au, 1980; Michaels, 1981; Philips, 1983). Of major concern has been the lack of access to appropriate and effective instruction and the misevaluation of student performance and competence. Thus, one of the sites in which ethnographic studies of classroom language have located themselves has been in the dialectic between access to academic language and achievement and students' home and community language and culture. While some researchers have constructed this dialectic to be one of congruence or incongruence (e.g., Au, 1980; Michaels, 1981), others have viewed the dialectic as defining dimensions of teacher-student talk (e.g., Floriani, 1993; Foster, 1995; Gilmore, 1987; Gutierrez, 1993; Kantor, Green, Bradley, & Lin, 1992; Lin, 1993; Mehan, 1979; Santa Barbara Classroom Discourse Group, 1992). Another set of studies has examined how language use shapes situated definitions of what counts as content area knowledge including literacy (e.g., Bloome, & Egan-Robertson, 1993; Cochran-Smith, 1984; Kantor, Miller, & Fernie, 1992; Myers, 1992), science (e.g., Bleicher, 1995; Lemke, 1990), mathematics (e.g., Brilliant-Mills, 1993; Campbell, 1986), and mathematics-science relationships in classrooms (Weade, 1992). (See also Emihovich, 1989.)

Social organization issues have also framed ethnographic studies of language in the classroom. Two examples illustrate how ethnographic research from differing perspectives has provided new understandings about the relationship between social organization and language. These studies show how ethnographic research often provides new ways of understanding old issues within education (e.g., grouping). They also illustrate further the interdisciplinary nature of ethnographic research.

Hilda Borko and Margaret Eisenhart's (1989) study of the language of different reading groups within the same classroom found that students learned how to talk and use written language appropriate to their reading group. When students did not use spoken or written language indicative of their reading group, it raised questions for the teacher about their reading group placement. Moving from one reading group to a higher group was not just a matter of reading achievement per se but required display of the spoken and written language appropriate to the higher reading group. However, once a student learned the spoken and written language of a particular reading group, it was difficult to display the language of a different reading group that might indicate a higher group placement. Additionally, if the student was placed in a higher reading group, but displayed the language from the lower reading group—which is what the student might expect to display,—this display would raise questions about whether the higher placement had been justified. Similarly, a series of ethnographic studies by James Collins (1987) shows that grouping placements had less to do with academic

competence than with students' social and linguistic behavior and what the teacher "took up." This research on classroom discourse and the social organization of the classroom, including grouping and other patterns of organizing students, makes visible ways in which classroom patterns and practices create differentiated language and learning environments, even within the same classroom and with the same teacher.

The research agendas of Borko and Eisenhart, and Collins concern issues of equity and evaluation. At the same time, their studies provide theoretical constructs in education about education. Further, the juxtaposition of these studies illustrates how two ethnographic studies can provide data on a common issue and how the findings of one can extend or contribute to those of another. For collections of ethnographic studies concerned with issues of equity that do not focus on language use in classrooms see, for example, Trueba, Guthrie, & Au, 1982; Arvizu, & Saravia-Shore (1990). Geertz (1983) provides an argument about theorizing in ethnography that provides an understanding of how such juxtapositions contribute to the development of a field. This argument, while not specifically focusing on ethnography in education, has implications for future construction of knowledge from such local studies in education:

The major theoretical contributions not only lie in specific studies—that is true in almost any field—but they are very difficult to abstract from such studies and integrate into anything one might call "culture theory" as such. Theoretical formulations hover so low over the interpretations they govern that they don't make much sense or hold much interest apart from them. That is so, not because they are not general (if they are not general, they are not theoretical), but because, stated independently of their applications, they seem either commonplace or vacant. One can, and this in fact is how the field progresses conceptually, take a line of theoretical attack developed in connection with one exercise in ethnographic interpretation and employ it in another, pushing it forward to greater precision and broader relevance, but one cannot write a "General Theory of Cultural Interpretation." Or, rather, one can but there appears to be little profit in it, because the essential task of theory building here is not to codify abstract regularities but to make thick description possible, not to generalize across cases but to generalize within them. (pp. 25, 26)

These studies show that the construction of knowledge about learning in groups in classrooms is not merely a process of aggregation. Additionally, with regard to intellectual sites, the ethnographic studies by Borko and Eisenhart, and Collins illustrate the interdisciplinary character of such research. These studies are located in the knowledge base that has been developed in education about classroom language and in the knowledge base developed about the social organization of classrooms and schools, and in knowledge from anthropology and sociolinguistics. It is the comingling of these multiple knowledge bases that creates an intellectual context for theory-method connections and for the interpretation of data.

Another area that ethnographic studies of classroom language have addressed is multiple languages in classrooms. Studies in education have examined how shifts of language are employed in teacher-student interaction (e.g., Ernst, 1994; Guthrie, 1985; Guthrie, & Guthrie, 1987; Heras, 1993;

Orellana, 1995; Tuyay, Jennings, & Dixon, 1995), student-student interactions (Duran, & Szymanski, 1995; Floriani, 1993; Gumperz, & Field, 1995) and in establishing or erasing borders between the classroom community and the home and neighborhood community (e.g., Willett, & Bloome, 1992). In these studies, and in ethnographic studies of classroom language in general, issues of language are not separated from social and cultural issues. For example, in Larry Guthrie and Grace Pung Guthrie's (1987) study of two bilingual classrooms, they found that the teachers' orchestration of the language used was both influenced by and created social dynamics in the classroom; and these social dynamics either facilitated or hindered the students' engagement in academic learning (see also Gutierrez, 1995).

This study also illustrates the ways in which knowledge from particular studies informs the construction of knowledge within a field. To construct their conceptual framework they (Guthrie, & Guthrie, 1987) grounded their study in a variety of fields: "anthropology, education, linguistics, psychology, and sociology" (p. 206). Citing Susan Ervin-Tripp and Claudia Mitchell-Kernan (1977), they note five themes that situate their theory-method relationships and that are found in other studies in education of classroom language:

1. First, the data source for studies of conversation or children's language should be natural language in context. (p. 207)
2. ...the study of discourse includes elements beyond the sentence level ... it has become apparent that multiple constraints beyond the sentence level operate on the production of speech. (p. 208)
3. [T]he social and situational context affect[s] linguistic rules and output. ... In the mutual construction of their discourse, actors make selections about what they want to say next (semantic options), about how to say it (social options), and about the form it will take (linguistic options). At the basis of all these choices, and impinging upon them, is a series of factors which can act as constraints. At the most general level, these include social and cultural facts such as social status and cultural norms. At the most narrow level are facts within the interaction itself, such as particular prosodic or phonological variations. (p. 209)
4. The fourth theme is that linguistic rules are variable. ... For example, ... phonological rules vary according to the situation. It should not, however, be assumed that there is any regular one-to-one correspondence between particular constraints and rules and particular discourse features. Constraints may operate singly or in combination and across the various discourse and linguistic levels. Factors of social status, for example, can just as well influence code choice as phonological variation; a contextualization cue as subtle as rise in intonation can result in a change of code, definition of the situation, or phonological choice. (p. 209)
5. [C]onversational utterances can serve multiple functions in context. (p. 210)

But their study was also grounded in experience with and concern for teaching and teacher education. They write,

Prospective and practicing teachers should be provided with examples of the various functions that L1 may serve in [bilingual education] instruction. Mere use of L1 is not the issue; it is *how* the bilingual teacher uses the students' language that is important. (p. 227)

The implications of their above research are not specific classroom applications but theoretical constructs in education, at the level noted earlier by Geertz (1973).

Also of prominent concern in the study of multiple languages in the classroom has been questions of how choice of language—by the school, teacher, and students—structures social relationships between the student and the school, and provides or denies access to academic knowledge and achievement. For example, Henry Trueba (1989) has shown how immigrant students to the United States, who are non-native speakers of English, are not only at risk of experiencing cultural trauma but also at risk of being constructed as learning disabled or otherwise incompetent. Part of what Trueba shows is that success and failure in school and classrooms are socially constructed (see also Bloome, 1989; Gumperz, 1986). Trueba's research agenda (see also Trueba, Jacobs, & Kirton, 1990), which is part of the intellectual site in which his study is located, is twofold: (1) to describe the experiences of some nonnative English speaking immigrant students in U.S. schools with a concern for social justice; and (2) to raise theoretical issues about how success and failure are constructed.

Similarly, a practice-based study by Nan Elsasser and Patricia Irvine (1985) shows how students' language can be taken from them, constructing them as incompetent. The students, enrolled in a writing program at the College of the Virgin Islands, were expected to write in English and to revile writing in their native Creole.

Experience has shown us that the writing problems of West Indian students are not due to "interference" in the structural linguistic sense of the term; rather, we find their reluctance to write directly attributable to the denigration of their native language and to their conviction that they do not, in fact, possess a true language but speak a bastardized version of English. It is difficult if not impossible to write without a language, and it is emotionally draining to attempt to develop voice and fluency in an educational system which has historically denigrated one's own language. (p. 406)

Their study was located in the effort to transform that course in the writing program; specifically, to "integrate the study of Creole and English" (p. 406). That is, no dichotomy was created between the study of social and educational life and social action. Indeed, it is through social action in the classroom that social, cultural, and linguistic phenomena become clear. Their research agenda is mutually concerned with social and cultural change and with effectiveness (in this case, the effectiveness of writing instruction).

Part of what Elsasser and Irvine (1985) show, as do studies by many other teacher researchers, some of which will be highlighted in the next section, is that one site of ethnographic studies in education is local knowledge and experience of curricular and instructional practice and its transformation. Further, they illustrate that who is an ethnographer in education is not confined to university-based "outsiders" studying the other, but includes teachers (and as described later, students) as well as other "insiders." While part of the knowledge base defining theory-method relationships in such studies involved classroom language, and local knowledge and experience, it also involves knowledge of the

efforts of educators to transform the language and languages of the classroom.

Ethnographic Studies of Learning and Knowledge in Education

Unlike psychological studies of learning and knowledge that begin with a priori definitions of knowledge and learning, the key question that ethnographers in education ask is: what counts as knowledge and learning in classrooms to teachers and students? That is, both knowledge and learning are treated as folk terms used by members of the community, in this case the classroom community, to designate particular social and cultural phenomena and relationships among these phenomena. From this perspective, knowledge and learning do not exist separate from the cultural and social constructions of members of the classroom.

In the general field of education, during the 1970s, a beginning knowledge base on classroom learning was developed by educational researchers who sought to identify in a systematic manner those factors that lead to greater academic achievement as well as ways in which children think. One area of this research is known as process-product studies, which correlated classroom factors with outcome measures. This approach led to the development of concepts, such as 'time-on-task' and 'academic engaged time', as major correlates of "learning" (e.g., Denham, & Lieberman, 1980). Another set of studies that examined what so-called effective teachers did in their classrooms led to the identification of a set of teacher behaviors associated with effective instruction (see Brophy, & Good, 1986; Rosenshine, & Stevens, 1984). Both sets of studies located classroom learning in academic lessons. Unasked were the kinds of questions that ethnographers in education might ask: for example, what counts as learning in and across "lessons" and time in this classroom; who has access to this learning; how do students perceive, understand, and participate in learning?

Ethnographic studies have begun to provide new insights into the ways in which learning is socially constructed in classrooms. For example, in a series of ethnographic studies of middle school classrooms, David Bloome (e.g., Bloome, & Argumedo, 1983; Bloome, Puro, & Theodorou, 1989) described how teachers and students coconstructed lessons and how they equated accomplishment of the lessons with academic learning. That is, 'doing lessons' was equated by members of the classroom with academic learning. Bloome described this phenomenon as cultural and social, and labeled it procedural display.

[Procedural display is] (a) the display by teacher and students, to each other, of a set of academic and interactional procedures that themselves count as the accomplishment of a lesson, and (b) the enactment of a lesson is not necessarily related to the acquisition of intended academic or nonacademic content or skills but is related to the set of cultural meanings and values held by the local education community for classroom education. (Bloome et al., p. 272)

Although the metaphor is not perfect, procedural display can be compared to a group of actors who know how to perform

their parts in a play, know their lines and how and when to say them, but who may have little or no understanding of the substantive meaning or significance of the play.

The construct, procedural display, challenged previous work that focused on observable behavior at the surface level. This construct shows that it is no longer possible to correlate surface level features of classroom life (e.g., academic engaged time) with outcome measures as a definition of learning. Learning in classrooms is a problematic construct because, among other reasons, teachers and students, in situ, hold definitions of what counts as learning and what does not count as learning and may orient their behavior to those definitions. These definitions are artifacts of both the broader classroom culture and the particular cultural dynamics of any specific classroom. (see also Fernie, Davies, Kantor, & McMurray, 1994; Myers, 1992; Prentiss, 1995; Rex, 1994; Santa Barbara Classroom Discourse Group, 1992).

Bloomer's ethnographic studies of procedural display are located in knowledge bases associated with classroom language studies, educational studies of learning, achievement, and effectiveness, discussions by ethnographers in education about definitions of learning in classrooms (e.g., Erickson, 1982; Green, Kantor, & Rogers, 1991; Spindler, & Spindler, 1987), as well as the ethnography of communication. This multidisciplinary perspective not only frames theory-method relationships but provides a means for problematizing basic concepts in education such as learning, achievement, lesson, accomplishment, teaching, and so forth (see also Weinstein, 1991). Furthermore, the problematizing of such basic concepts in education provides an intellectual site for ethnographic studies in education.

In a series of studies, Luis Moll and his colleagues have raised questions about the location of knowledge in classrooms (e.g., Gonzales et. al., 1993; Moll, & R. Diaz, 1987; Moll, & S. Diaz, 1987; Moll, & Greenberg, 1990). Typically, knowledge in classrooms is viewed as located in the teacher or textbook with each individual student viewed as a potential receptacle for that knowledge. Moll and his colleagues have suggested that knowledge be viewed as a series of funds, distributed among people within a social group (such as a household or community). Access to knowledge needs to be viewed within the context of the social network and social dynamics that connect the funds of knowledge within the social group. As the design of their research projects makes clear, such a conception of knowledge is not only applicable to students but also to teachers, in that it extends the boundaries of classroom learning beyond the classroom walls.

Our research project, still in progress, consists of three main, interrelated activities conducted simultaneously as part of a research / teaching system: (1) an ethnographic analysis of the transmission of knowledge and skills among households in a Hispanic community of Tucson; (2) creation of an after-school laboratory where researchers and teachers use community information to experiment with literacy instruction; and (3) classroom observations in which we examine existing methods of instruction and explore how to change instruction by applying what is learned in the after-school site. ... We build on the idea that every household is, in a very real sense, an educational setting in which the major

function is to transmit knowledge that enhances the survival of its dependents. The content and manner of this transmission, the households' zones of proximal development if you will, are the central features of the ethnographic study. In order to examine the instructional potential of these household activities, we have created an after-school "lab" within which researchers, teachers, and students meet to experiment with the teaching of literacy. We think of the lab setting, following Vygotsky, as a "mediating" structure that facilitates strategic connection, multiple paths, between classrooms and households. The goal of the lab is to support new teaching practices that make ample use of both the school's and community's resources. (p. 320)

As part of the ethnographic endeavor, Moll and his colleagues have collaborated with teachers and helped them conduct ethnographic studies of the households and communities of their students, gaining knowledge that can be used in their teaching. They have also collaborated with teachers in bringing parents into the classroom to share funds of knowledge from their households and communities. Like other ethnographers in education, the theoretical constructs about knowledge developed by Moll and his colleagues hover close to educational settings, both the classroom and other settings; and, like others, involve change, both as a consequence of the research and as part of the research.

The ethnographic studies highlighted in this section show the ways in which ethnographic studies in education have created the beginnings of a knowledge base on learning and knowledge. This knowledge base, in contrast to previous approaches, is framed more by questions and dialectics than by accumulated bits of abstracted knowledge. Such studies ask questions about what counts as knowledge and learning, where is it located, who gets to define it, how, and for what purposes. This research shows that such definitions are part of the situated tensions that teachers, students, parents, researchers, and others must address, especially as related to equity and effectiveness agendas.

SUMMARY OF ETHNOGRAPHY-IN-USE AMONG TEACHERS AND RESEARCHERS LOCATED IN CLASSROOMS

The research agenda of ethnographic studies in education can be viewed as framing a series of dialectics related to equity and effectiveness in education. Within the area of equity, the studies frame questions about access and cultural and social change in and through educational institutions: Does a focus on access obfuscate the need for cultural and social change in educational institutions? Does a focus on cultural and social change ignore the current needs of people from non-dominant communities to survive and succeed in the dominant culture? How, when, and where can questions of access and social and cultural change be brought together? Within the area of effectiveness, the studies frame questions about teacher practice, evaluation, decision making, and academic achievement: Who gets to define academic achievement? when? where? and how? How do such definitions themselves situationally define knowledge, learning, teaching, decision making? These questions are not static, but

change and evolve. From the perspective of the novice ethnographer in education, the task is to locate one's study within appropriate knowledge bases (both within education and from disciplinary and multidisciplinary perspectives) and research agendas in education, with associated theory-method relationships, as well as to locate one's study in an ongoing, evolving set of dialectics.

Ethnography-in-Use Among Students Located in Classrooms

In a small number of elementary, middle school, and secondary classrooms, students have taken up ethnography and ethnographic inquiry. Although conceptions of ethnography and ethnographic research are imported from the social sciences, how student ethnography and ethnographic inquiry gets defined depends on which students and teachers are using it, and how they frame the academic agenda of the classroom. In other words, student ethnography and ethnographic inquiry is situated in the particular social and cultural dynamics of a particular classroom, in its academic curriculum, and in the disciplinary and multidisciplinary perspectives associated with ethnographic research in the social sciences that the teacher elects to use as a frame. Theory-method relationships in student ethnographic inquiry, therefore, are framed by efforts to transform the classroom and the relationship of students to academic and community knowledge.

In this section, we discuss a small number of published descriptions of students as ethnographers to illustrate how the ethnographic inquiry gets defined by three academic agenda, which often overlap. The three academic agenda are: (1) the exploration of students' own communities, (2) the promotion of the learning of academic, disciplinary, based knowledge, and (3) social and political change in students' communities. In addition, each of the three academic agenda provides a different response to the questions: Who is an ethnographer? where and when was the ethnography undertaken? for what purpose? in what ways? with what outcome? These questions parallel those asked of any social group by an ethnographer and make visible ways in which ethnography has become a resource for everyday practice and academic study in educational settings.

Students' Ethnographic Study of Their Own Communities

One agenda of students' ethnographic study of their own communities has been to make their community's heritage, knowledge, and way of life, visible and respected. A similar agenda has been pursued by educators who have involved students in collecting and publishing oral histories and folk knowledge from their own communities (e.g., Montero-Sieburth, in press; Wiggington, 1986). Also similar educational efforts have involved students as sociolinguists of their own communities (e.g., Cheshire, & Edwards, in press; Thomas, & Maybin, in press; Wolfram, in press). One such project is reported in complementary chapters by Carmen Mercado

(in press), and Marceline Torres (in press), a university professor and middle school teacher, respectively, who collaborated on a students-as-ethnographers project. Mercado writes:

I did not set out to improve the reading scores of the sixth graders in Torres' class, even though that is what occurred. When I asked to be adopted by the class of my former graduate student, my purpose was to demonstrate to students and others that "under-achieving" students are capable of "college work." ... What began by posing a simple, but unexpected, question: "What do you want to learn about?" led to introducing students, first by me and then by Torres, to the ways of thinking and using language of ethnographic researchers. ... Ethnographic research contrasts sharply to the type of library research typically emphasized in schools. That "knowledge is all round us," and that it is "in people," is significant for students who do not see their world, their experiences, their forms of expression, in the texts they are required to read.

For Mercado and Torres, student ethnography and ethnographic inquiry was located in the dismantling of deficit models of urban students and in redefining knowledge and relocating it "in people." As Mercado explains, such relocations of knowledge involve shifts in social relationships.

Because constructing knowledge in this manner involves a relentless search to understand that which compels, through the eyes of different people, students engage in observations of and conversations with others whom *they* regard as authorities. Engaging in the practices of ethnographic researchers enables students to relate to their peers, their families, and members of their immediate community, as sources of academic knowledge.

Torres describes two types of events that defined social relationships for the students-as-ethnographers: "letters home" and "celebrations."

After deciding on a research topic and question, I had the students write letters to their parents, telling them about the research topic and why they were interested in it. ... They provoked conversations and letters back from parents as well as parent involvement. The "celebrations" were monthly meetings I arranged that were attended by students and parents. At the celebrations, students presented their research or gave a progress report ... letters home and the celebrations help redefine the possibilities of middle school classrooms.

These social relationships and social identities are part of the intellectual site of the ethnographic inquiry; that is, part of the theory-method connection. Unlike traditionally conceived ethnographic research in the social sciences, in which there is a distinction between the researcher and the researched, in the context of students studying their own communities, similar to what Jones (1988) has called native anthropology, students with the help of their teachers, are adapting ethnographic perspectives and techniques to study the community from within the community, as an insider.

Torres and Mercado engaged the students in a great deal of writing—what they call scribing, planning, reflecting, and sharing, and as such closely aligned ethnographic inquiry with writing. Thus, theory-method relationships were framed by the educational agenda of the students-as-ethnographers project: recreating definitions and locations of knowledge,

how to write and who is a writer, and educationally supportive social relationships. But the educational agenda and the research agenda come together and overlap with a political agenda. Mercado writes,

Especially those of us who come from marginalized communities, *we need to tell our own stories, we need to inform others of our cultural and linguistic heritages, and we need to preserve these treasures* (original emphases)

It is within these multiple agenda, then, that Torres and Mercado have situated and defined ethnography and ethnographic inquiry.

Students as Ethnographers and Disciplinary-Based Knowledge

A second way that students have taken up ethnography and ethnographic inquiry has been to engage students in ethnography as a resource for the acquisition of academic, disciplinary-based knowledge. In a collaborative ethnographic study (Yeager, Floriani, & Green, in press), Beth Yeager, a 5th- and 6th-grade teacher argues that disciplinary-based knowledge is not just knowledge of history or science. Rather, as she framed for students and parents, disciplinary knowledge is knowledge of how members of a discipline construct knowledge. Thus, Yeager told her students that they were to become mathematicians, social scientists, artists, writers among other positions to learn how to construct knowledge consistent with that used by members of each discipline.

Viewed from the perspective of “knowledge how,” Yeager et al. (in press) argue that a discipline can be viewed as a community, a social and cultural group, with its own ways of acting, believing, thinking, feeling, valuing, and using language (cf. Goodenough’s, 1981, definition of culture). Thus, as a social and cultural group, a disciplinary community can be studied in the same manner that other social and cultural groups can be studied, employing ethnography and ethnographic inquiry. Additionally, within education, such knowledge can be used as a focus for the curriculum rather than, or in addition to, the bits and pieces of information constructed through such disciplinary actions. In this way, Yeager et al. (in press) argue, knowledge can be viewed as an outcome of the actions of members of a discipline or group.

I have become concerned with helping my students acquire discipline-based knowledge. I want my students to understand how discipline knowledge is the product of actions of people and how they “take up” the actions associated with particular disciplines. I want them to be able to “envision” themselves as anthropologists, writers, scientists, and mathematicians.

To put my goals into practice, I create opportunities to explore how people in each discipline go about their work . . . What the ethnographic study has contributed to this process is a language to describe what it is I do and how we, the students and I, construct a common language for looking at learning and for exploring how others engage in similar processes in all aspects of everyday life.

For Yeager and her students, ethnography and ethnographic perspectives became resources for such an inquiry. Yeager is a member of the Santa Barbara Classroom Discourse Group, which is a group of university researchers and teacher re-

searchers involved in the collaborative study of classroom life. Collaborative ethnographic research has been ongoing in her classroom since 1991. She has involved both 5th and 6th grade students in ethnographic research. The study reported here was begun in the 1991 school year, but draws on research across all years.

As in the case of Mercado and Torres, the original purpose of the ethnographic research was not to use ethnography with students. For Floriani and Green, the goal was to document how the teacher constructed a community of learning with students. However, as is the case in ethnography, the researchers become responsive to the members’ goals and needs. Thus, the traditional role of ethnographer became reshaped by Beth Yeager:

I set the conditions for Ana and Judith’s entry to afford students an opportunity to become co-researchers in the ethnography and to establish a particular relationship between Ana and Judith as researchers and those of us in the classroom—“I would like you to be members of the community and to participate in and contribute to the life of this group.” . . .

Additionally, I asked Ana and Judith to share their fieldnotes and purposes for doing ethnography with the students. I used this sharing to help shape and define what anthropologists do and to set the stage for students to take up the roles and language of anthropologists as we began the study of history as a social science.

Thus, ethnography and ethnographic perspectives were used not only by the university researchers and teacher researchers but also by students-as-researchers as a frame—or, in Yeager’s words, a language—for exploring disciplinary knowledge and classroom life (including how they, as students, learn).

In this section, we are focusing primarily on the students’ take up of ethnographic perspectives for the study of disciplinary knowledge and of their classroom. Unlike the students in the previous section, the students in Beth Yeager’s class did not take up ethnography to explore their home communities or cultural heritage. In other words, their use of ethnography was situated in a different agenda and thus defined differently. Ethnography, for them, was a way of studying everyday life in their classroom as well as accessing disciplinary knowledge, not only in social science but in all areas of the curriculum.

Although Yeager provided the students with demonstrations and models of how members of academic disciplines construct knowledge (e.g., through videotapes of scientists in different fields doing their work; through examining the research processes of Ana and Judith), the primary means for engaging students in the ethnographic study of academic disciplines was to ask them to engage simultaneously in the role of a member in the discipline while reflecting on their thinking and what they were doing. This dialectical process was used throughout the year across discipline areas. Highlighted throughout the cycles of activity (units) through which the year was organized were seven principles or themes about inquiry (Yeager et al., in press):

1. Questions are formulated and reformulated throughout the inquiry process;
2. Data are constructed not found;

3. Observation is a selective process guided by personal as well as formal frames of reference;
4. Observation and data construction require a descriptive language;
5. Interpretation is based on evidence and point of view, not merely personal opinion;
6. Within a group, multiple interpretations of a text (visual, oral, aural, written) are possible and probable; and
7. Multiple ways of presenting information exist.

Regardless of the cycle of activity, whether mathematics, history, literature, natural sciences, academic writing, and so forth, the seven principles guided student inquiry and over time became a framework for students to understand themselves (as individuals and as a social group) as well as disciplinary communities. The seven principles also became a way for students to challenge each other's construction of knowledge within a particular unit of study, which broadened the definition of disciplinary inquiry to include the interaction that members of an academic community have with each other, through presentation, discussion, and writing. Students were expected to provide evidence for their claims about both content area learning and themselves as learners. (Brilliant-Mills, 1993; Floriani, 1993; Heras, 1993; Tuyay, Floriani, Yeager, Dixon, & Green, 1995).

The taking up of ethnographic inquiry by students in Yeager's class was a means of redefining academic knowledge in the classroom, and of making the processes of disciplinary-based academic communities open and accessible to students. This educational agenda became the context for defining what counted as ethnographic inquiry. That is, although building upon ethnographic perspectives and practices from outside the classroom, Yeager and her students redefined ethnographic inquiry in terms of their educational agenda. It became both a set of principles and a set of related activities that were recycled across various units of study representing multiple disciplinary communities.

Students as Ethnographers and Social and Political Change

In a sense, each of the studies of student-as-ethnographers involves social and political change. Torres and Mercado used students-as-ethnographers to counter deficit models of urban students, to validate community and family members as sources of knowledge, and to make visible the students' cultural and linguistic heritage. Yeager used students-as-ethnographers to open up academic disciplines and make them accessible as well as to make their own learning processes and practices available to them. In this section, we will discuss a students-as-ethnographers study which had an explicit agenda of social and political change to illustrate how such an agenda defines ethnography and ethnographic inquiry.

With the support of a cooperating teacher and the school administration, Ann Egan-Robertson (a university researcher) created a writing club in an urban school. Egan-Robertson describes her purpose as follows:

I had the opportunity to work with a small, multiracial group of

young women in a students-as-ethnographers project during the winter and spring of 1993. This project was a community writing club that I formed out of their eighthgrade English language arts class. Like other educators who work with teenagers, I am committed to finding ways of empowering students as active participants in our democracy and as readers, writers, and life-long learners. I am especially concerned about those students, all too numerous, who act as though their living does not matter. (Egan-Robertson, *in press*).

Egan-Robertson began the writing club by describing previous students-as-ethnographers projects in the Bronx (Mercado, *in press*; Torres, *in press*); Detroit (Curry, & Bloome, *in press*; Schaafsma, *in press*); the Piedmont Carolinas (Heath, & Branscombe, 1986); Saginaw (Robinson, & Stock, 1990); and Santa Barbara (Yeager et al., *in press*).

As I told them about each of these projects, I gave a couple of examples of questions and topics that the other student ethnographers had pursued and related those questions and topics to potential avenues for them. For example, tying to the Saginaw project [Robinson, & Stock, 1990], I said "You might want to ask, 'What's it like growing up as a female teenager in Riverside? What's it like growing up as an African-American young woman in Riverside? As a Latina? Or as a white young woman?'" This particular wording I used made an intertextual link between the extant students-as-ethnographers projects and their own project that proved to be very important. Another important framing I made in this initial meeting was the particularity of my offered questions. Rather than leaving the topic at "What's it like being a young woman growing up in Riverside?", I brought to that gender category the added categories of race and ethnicity.

Thus, although not determining the questions and topics that would guide the students' ethnographic inquiry, Egan-Robertson grounded their studies in previous student-as-ethnographers projects, both as intellectual sites (e.g., what questions and frames had been employed) and as a set of activities (e.g., use of ethnographic techniques, interviewing people in the community, etc.). About the questions that guided the students' ethnographic inquiry, Egan-Robertson writes:

From the start, students raised and discussed such serious questions as: "Why do men rape women?" and "Why do kids call me a 'wannabe' when I say I'm Puerto Rican?" Students began field notebooks at their first meeting, recording questions and writing on topics. While they generated many questions, each student eventually settled on one to pursue:

DeLayne: How can you avoid becoming an alcoholic if your parents are alcoholic?

Denise: Is racism a problem in Riverside?

Felicita: How do you deal with teenage pregnancy?

Sandra: Does music affect the way we think and feel about people?

Shanae: What's it like being or having two nationalities?

Marielis: What can help teenagers stay off the streets?

The questions and issues raised by the students are political ones, that derive from their own experiences as teenagers in their city. The questions are also related to the construct of personhood.

Personhood refers to how a culture or subculture, such as a school, defines "person" and what attributes it associates with

"person" (Besnier, 1993; Kondo, 1990). Personhood includes the ways that people construct identities in relation to one another. Personhood is not given or predetermined but is established through everyday interactions, which in turn, are influenced by historical and institutionalized contexts and narratives (Dubois, 1969; Galwatney, 1981; Street, 1993a; West, 1993). More simply put, to ask about personhood is to ask, "What does it mean to be a person in a particular cultural group, at a particular time, in a particular event?" (Egan-Robertson, in press)

The construct of personhood is an explicitly political question in the context of racism both in the students' city, in the United States in general, and in many other places in the world. Thus, Egan-Robertson viewed the students-as-ethnographers project as a way for the students to reconstruct personhood for themselves.

Egan-Robertson provided an opportunity for the students to examine how members of their own communities constructed and communicated knowledge about people's lives. Among other activities, she had the students interview two community activists, one an actress and director, the other a poet and playwright. The interviews with these activists connected the students with community-based ways of identifying, gaining, and representing knowledge. They learned about the importance of stories told at kitchen tables, the narratives that ordinary people told, and community theater. They began to view family and community members as oral historians and theorists.

In a sense, what Egan-Robertson did parallels Yeager's invitation to students to be ethnographers of academic disciplines, learning how members of a discipline construct and represent knowledge. But instead of focusing on academic communities and academic scholars, Egan-Robertson connected the students with their own communities and with community activists.

At the end of the project the students wrote up what they had learned, using a variety of formats that they had learned through their inquiry.

The way students wrote up their ethnographic reports was profoundly influenced by the literacy practices they encountered through their inquiry: seeing the Health Peer Educators' play, and hearing about Ashton's and Cruz's work in the political theater. The students also had the opportunity to work with Ashton as they wrote up their research. All of these activities led the students to write monologues, skits, and poetry. The students' writing reflects recent changes in ethnography, moving toward interdisciplinary perspectives and paying more attention to writing style (e.g., Holloway, 1991). Their writing is based on what they learned about themselves and their various communities as they did the ethnography. As they wrote, they used the community practices they accessed during their inquiry (Egan-Robertson, in press).

Thus, there was not a single, fixed definition of ethnographic research. Rather, it was defined by the educational agenda, both academic (e.g., improve student writing) and affective (e.g., improve student self-esteem), and by political agendas (e.g., counter racism, reconstruct personhood, contribute to the community). Further, as the students learned more about community-based practices for constructing and representing knowledge, those practices influenced the ongoing ethnographic inquiry;—how and where the students defined, gathered, interpreted, and represented data.

SUMMARY OF ETHNOGRAPHY IN EDUCATION: TOWARD THE CONSTRUCTION OF A DISCIPLINARY FOCUS WITHIN EDUCATION

In previous section on ethnography in education, we illustrated how ethnography and ethnographic perspectives have become a language of education, a productive resource for students for academic study, a way of taking action while learning content, and a way of bridging the proverbial gap between theory, research, and practice that has characterized much education research. In each example, students became ethnographers for particular purposes and engaged in ethnography in particular ways. In each, however, they shared a common concern for the study of culture and everyday life as constructed by members of a group. In this way, they were consistent with the purposes and goals of ethnography as framed within the social sciences, but were using ethnography for educational purposes. These studies, and those in the previous sections on ethnography in education, show how ethnography in education has contributed to a knowledge base for education.

These studies also show how ethnography frames a language of educational practice and everyday life. The scope of work presented suggests that ethnographic research, with its theories of culture and its concern for how members construct patterns of everyday life, is becoming an area of concentration within education and not merely a method for qualitative research. However, as illustrated across the examples in this section on ethnography in education, variation exists in this area just as in disciplines in anthropology or sociology. These variations, however, do not fracture the discipline; rather, they provide a rich source of information across levels of study, foci and purpose. This information provides a rich view of how local knowledge is constructed in particular schools, classrooms or groups, and how this knowledge is consequential for students as they build their repertoires for learning across intellectual and physical sites of schooling.

ORDINARY PEOPLE, ETHNOGRAPHY, AND ETHNOGRAPHIC WRITING

In this last section we discuss ordinary people as ethnographers. This section is based on and borrows from Bloome, Sheridan, & Street (1993). We focus on one example, the Mass-Observation Project. We begin with a brief description of the Mass Observation Project and then discuss issues involved in writing for the Archive and in reading materials in the Archive. Throughout we list questions about ethnography and ethnographic writing that are raised by the Mass-Observation Project. As with previous sections, our purpose is to illustrate how ethnography and ethnographic inquiry are located in particular intellectual sites. In this case, the intellectual site is located in the relationship of the ordinary people who write for the Mass-Observation Project and the scholars and others who read what is written.

The Mass-Observation Project and Archive

Mass-Observation (MO) started in 1937 as a 'people's anthropology' of life in Britain. Ordinary people were asked to write about their daily lives and events in their community. Other methods were also used to collect information about the lives of ordinary people: surveys, observations, interviews. The first phase of MO occurred in 1937 until 1950 with a good deal of attention devoted to the recording of civilian life during the World War II. The papers from that research were brought to The University of Sussex and the Mass-Observation Archive opened in 1975.

The second phase began in 1981. David Pocock and Dorothy Sheridan recruited people from all parts of the UK to write about their lives, either in the form of a diary or more often in the form of detailed replies to questions on specific themes. Since 1981 an enormous bank of written information about life in the UK has been accumulating, including over 400,000 pages of typed and handwritten material representing the combined contributions of over 2,500 volunteer writers.

Since its beginning, the basic process has remained the same. The Archive asks volunteers throughout the UK to write about specific events and issues. The people—known as Mass-Observation correspondents—send their writings to the Mass-Observation Archive Project at The University of Sussex Library which stores them. The MO correspondents have no official training as anthropologists, sociologists, and so forth, although a few may have taken higher education courses in those or related fields. University researchers, undergraduate and graduate students, and others, come to the Archive, and read what has been written. For a fuller account of how the project was launched and how it relates to the work of earlier MO, see Sheridan (1993).

Reading Mass-Observation Writing

There are many ways of reading the materials in the Mass-Observation Archive, we describe four here. Each way of reading involves assumptions about the nature of ethnographic writing and the nature of knowledge.

Reading Mass-Observation Writing as Knowledge Transmission. One way of reading is to assume that the writer is sending information he or she has gathered about the world to the Archive. Ordinary people are transmitting knowledge about their daily lives and communities to scholars, students and others. The MO correspondents can make available to people using the Archive knowledge about daily life in the UK that is otherwise unavailable, or at least, very difficult to get. Further, they make available knowledge from one period of time that may be useful to people decades later. One implication of reading the Archive materials as knowledge transmission is that the MO correspondents are defined as reporters or as field workers, gathering information and passing it on.

There is variation in the styles of writing used by the MO correspondents: some respond with exposition, others with

narrative, some write as if writing a letter to a friend, and occasionally, a few may write a poem as part of their response to a directive. One way to view the variety of ways of responding is that they are transmitting different types of knowledge and different contexts of knowledge (e.g., personal context, community context, historical context).

There are limitations to reading the Archive materials as "knowledge transmission." First, everyone has his or her biases and perspectives. What gets reported often reflects that. Many MO correspondents are aware that they have biases and they will often note in their writing that they are only describing things from their own perspective. The MO correspondents often make special efforts to gather information from other people so that what they report is not limited to their own point of view.

A second limitation in reading MO writing as knowledge transmission is that sometimes MO correspondents have other purposes than just knowledge transmission. They may be commenting on an event or giving a political opinion. Some MO correspondents enjoy the intellectual stimulation and writing practice involved in responding to a directive, and so they are not just reporting. Writers may also be constructing personalities / identities as writers that are different from how they represent themselves in other contexts. For instance, they may present themselves as "researchers," as "social commentators," as "ordinary people" (see below), all of which affect the "knowledge" they are "transmitting."

A series of questions can be posed about reading the Archive materials as "knowledge transmission":

- What is being reported?
- Who is doing the reporting?
- What kind of report is it?
- What is the nature of the knowledge that is in the report?
- What kinds of knowledge are being transmitted?
- What contexts of knowledge are being implied?
- What kind of reader is being imagined?
- In what way is the knowledge from different reports cumulative?
- What limitations are there about the knowledge being transmitted?

Reading Mass Observation Writing as Knowledge Construction. Readers are affected by what they already know about the topic and by the experiences they have had. Thus, reading is not just a matter of getting knowledge from the written text but is a process of knowledge construction. Similarly, when people write, both what they write and how they write are influenced by their knowledge and experiences in general, by their knowledge and experience as writers and readers, and by their purposes for writing and reading.

One important implication derived from viewing reading as knowledge construction is that the responses of the MO correspondents might be considered reports of their perceptions, memories, and interpretations of events rather than just unmediated descriptions of events. From the viewpoint of reading as knowledge construction, the MO Project is like a

survey or a large-scale experimental task. The directive is like a survey questionnaire or an experimental prompt, and what the MO correspondents write is like an answer to a survey question or a response to an experimental condition, respectively.

To the extent that researchers, students, or others using the Archive are interested in people other than the MO correspondents,—that is, they are using the MO Project as a representative sample,—the following questions should be asked:

- How well do the MO correspondents represent the broader population?
- What segments of the population do they represent?
- To what degree and how can inferences be made from their responses to the perceptions, views, and interpretations of others?

There is at least one more important implication of reading the MO Archive as knowledge construction. Researchers and others using the Archive are themselves readers. Their background knowledge, experiences, and purposes affect their understanding and interpretations of what they read and write no less than what occurs for the MO correspondents. The disciplinary background researchers and students bring to their reading also affects their understanding and interpretation. Given reading as knowledge construction, researchers' reports—like the writings of the MO correspondents—are also constructions of knowledge and not just factual reports.

Reading Mass Observation Writing as Social and Cultural Practices. Through their writing, the MO correspondents are establishing various social relationships with both the Archive and with the scholars and others reading the Archive materials. By how and what they write, the MO correspondents are promoting a particular social identity for themselves. This social identity may be working class, writer, ordinary person, artist, teacher, parent, son / daughter, elder, observer, responder, or more subtle and complex social identities that are difficult to describe within a few words. The social identities they present are part of the message and information communicated to the reader.

The writer's establishment of a social identity has implications for the reader's social identity and may promote a particular kind of reading. For example, the MO correspondent who presents an identity as an observer, promotes a reading of reports from field workers. The MO correspondent who writes as a son about his family, promotes perhaps a voyeuristic reading. The MO correspondent, who presents herself as an 'ordinary' person, may be inviting the reader to be a coconspirator in writing a history of 'ordinary' people. As the writers establish and maintain a social relationship with the MO Archive and Project they involve themselves in a set of social and cultural activities they might not otherwise be involved in (e.g., the cultural practice of making history by recording it). Writers may also be trying to influence opinion of future generations or they may be promoting an explicit or implicit political agenda.

It is not just the writing of the MO correspondents that needs to be viewed as social and cultural practice, but also the writing and reading of scholars using the MO Archive. One implication for scholars is to be aware of the assumptions and limitations of various social and cultural practices with regard to knowledge, description, interpretation, and narrative. Part of this awareness involves questioning the match, complementary nature, mismatch, or incompatibility of the writing and reading practices of researchers with those of the MO correspondents they are reading.

Reading Mass Observation Writing as Contested Social Practice. It was suggested in the previous section, that mismatches and incompatibility may occur between the writing and reading practices of MO correspondents and the scholars and others who come to the Archive to read the materials there. One set of conflicts may occur over how the MO correspondent and the researcher are defining each other (as discussed earlier). Conflicts may also occur in assumptions about the nature of knowledge. For example, a directive may be organized to elicit expository responses (following a "scientific" model of knowledge) while MO correspondents may choose to write narratives instead, redefine the question, or ignore the directive completely and write about something *they* believe that people using the Archive should know about and be interested in.

There may also be a conflict in how researchers using the Archive present their findings. Some researchers may package their findings from the Archive as scientific reports and coherent histories although the MO Project and Archive collection itself is not a single coherent history.

Incorporating issues from the previous sections and recognizing that writing and reading practices associated with the MO Project and Archive may involve contested social practices, there are questions about reading MO writing that should be asked:

- How are MO correspondents defined?—as recorders, as subjects, as readers, as mediators, as interpreters, as authors, as actors.
- How is the relationship of the MO correspondents to others defined?—as representative of a group, as a representative from a group, as marginal, as atypical.
- How is the writing of MO correspondents defined?—as report, as correspondence, as field notes, as diary, as data, as letters.
- How is the directive defined?—as prompt, as task, as experimental condition.
- How are the researchers defined?—as interpreters, writers, field workers, surveyors, readers, as well as by disciplinary identities (as anthropologist, as historian, as sociologist, etc.).
- How is knowledge defined?—as events, as a collection of facts, as perceptions, views, and interpretations, as social practices, as background and experience, as representative of ideas.
- How is knowledge produced?—extracted, discovered, transmitted, created, constructed, collected, organized.
- How is knowledge presented?—as description, as person-

hood, as hierarchies of concepts, as social practice, as narrative, as carnival.

Do particular uses of the Archive usurp the role of the MO correspondents as researchers themselves, and as researchers, their 'right' to provide interpretation of events?

Conflicts among MO correspondents and those who use the Archive will not be resolved by merely acknowledging all sides as valuable and ignoring what the conflicts reveal about the various enterprises that come under the rubric of ethnographic writing and reading. Rather than viewing conflicts as problems requiring resolution, the conflicts can be viewed as points of inquiry revealing even more insight about ethnographic writing and reading.

Conclusions of Ordinary People as Ethnographers

The questions that we have raised about reading MO writing apply broadly to the writing and reading of ethnography and ethnographic inquiry (there are, of course, other similar questions that need to be asked but were omitted for lack of space). These questions constitute an intellectual site, not only for the writing and reading of ethnography and ethnographic inquiry, but also for how ethnographic writing is employed to build knowledge and how such knowledge is integrated with other sources of knowledge. In brief, the theory-method domain of ethnography and ethnographic inquiry includes the writing and reading involved, as well as how relationships with other sources of knowledge are built.

FINAL COMMENTS

It is no longer possible to view ethnography and ethnographic research as monolithic. In our discussion of ethnography and ethnographic research as situated inquiry, we identified a series of intellectual sites which has contextualized how ethnography and ethnographic research has been taken up by social scientists, educational researchers, teachers, students, and ordinary people. The sites we have identified are not intended to be comprehensive; rather, they are illustrative of how various intellectual sites influence the relationship between theory and method.

We have treated ethnography and ethnographic research as a set of social and cultural practices employed by members of various 'communities': disciplinary-based communities, educational research communities, and classroom communities. As such, ethnographic practices—like any set of social and cultural practices—are ways that people in a site act and react to each other in pursuit of an agenda; including research agenda, educational agenda, and social, cultural and institutional change agenda. Like any set of social and cultural practices, although based on past practices that provide people with 'folk' models of what the practices 'look like,' how they are to be enacted, and what meaning and significance they have, no set of practices, including ethnographic practices, are fully predetermined. As such, ethnography and ethnographic research continues to evolve and change as a consequence of the new sites (intellectual, topical, institutional, educational, physical, geographical, social, and cultural sites) in which it is situated, and as a consequence of the people who take it up and the agenda they pursue.

REMAKING SENSE, RESHAPING INQUIRY: FEMINIST METAPHORS AND A LITERACY OF THE POSSIBLE

Lorri Neilsen

MOUNT SAINT VINCENT UNIVERSITY

The invisible woman in the asylum corridor sees others quite clearly, including the doctor who patiently tells her she isn't invisible.... The invisible woman has great compassion. So, after a while, she pulls on her body like a rumpled glove, and switches on her voice to comfort the elated doctor with words (Morgan, 1970).

Unable to see her, I speak in a kind of blindness, not knowing what dance is being made of me, what puns of the thumb, tough similes of the fingers, how I translate into bone (Atwood, 1995).

Our responsibility as literacy educators, we claim, is to bring literacy to life. We are midwives, we think, who watch reading and writing of the word become the Freirean reading and writing the world, who see inquiry into literacy as a process of changing the abstract noun into the transformative verb. Becoming literate is a form of intellectual inquiry, in teaching and in life. So we stand behind or beside, offer skills, arrange perspectives, invite dialogue, nudge, nurture, critique. And wait.

Over the years, as a feminist teaching literacy and the inquiry process, I have come to realize that only when we come to an understanding of the cultures of the home, the school, and the academy as sites of struggle and hope, encoded and inscribed with politically-charged values, expectations, and assumptions, do we begin to see inquiry and research in literacy as partial, limited, shifting, and actively constructed. We also see literacy as not merely an intellectual activity, but as a way we are in the world (Neilsen, 1989). Teachers who come to this understanding begin to see their own literacy as they see and know themselves: instrument, aspiration, connection, limitation. They begin to see themselves as integral, and hence responsible, to these cultures into which they inquire.

This process requires more than changing a noun to a verb. It is more than the cognitive transformations we often hope for, and it is much deeper. For the literacy we have been fostering in schools and in inquiry these many years has been a literacy devoid of our response-ability: of our ability, as passionate and breathing creatures, to respond to our world. To live in it, here: now, with all the ecological implications and baggage of a past and future together. Literacy, more than the head, is also of the heart, and of the body. Of many bodies, breathing together. To be attuned to the world in ways that make us clear-eyed conspirators in life we must pull literacy off the page and out of the individual intellect into our sense-making, body-resonant and earthly-connected selves. It is this aim that shapes the work I do as a literacy researcher and teacher educator.

Claiming feminist as a descriptor for my work and my life (and I cannot separate these) poses challenges not only as an academic but as a researcher. I know I want, like Marge Piercy, to see the earth split open, to see notions of science / inquiry and literacy turned in our collective hands, held against the heat of the sun until their essences have evaporated, their core images bleached, their edges blurred and rendered invisible. Our modernist notions have reified science and literacy, so that definitions meant in their day to clarify have, instead, closed off possibilities. But an exploration of a postmodern stance, a stance which makes essences and foundations problematic, does not mean that nothing exists, that no positions are taken. It only means that we must be comfortable marking a path on shifting ground, easy with the notion of seeing meaning between the cracks, locating signifiers in spaces that were not there yesterday and may not be there tomorrow.

It is this project of creating a path by walking which I describe here. Revisioning research into literacy required me to revise the work that I do with teachers. My teaching in feminist inquiry and literacy research have changed dramatically over the last 10 years as my senses of what counts as research and what counts as literacy continue to change. At this writing, I believe feminist inquiry to be a stance to the world which knows interpretation to be an ecological process, a project of integrating and furthering sustainable growth. We are connected, and we are response-able. And bringing history into our present, we are always just beginning.

IMPOSSIBLE METAPHORS

Traditional notions of literacy and literacy research have been guided by impossible metaphors which constrain our notion of literacy. Like carefully-dressed, clipboard-carrying assistants trailing theory down its many well-defined hallways only to discover darkness, dead ends, or a painted movie set, these metaphors have succeeded in shaping methods of inquiry. But they have not achieved what we hoped they would achieve: robust and generative understandings of what literacy is and does and can be; ways of supporting and sustaining growth in literacy for children of all cultures, between and within our national and global communities; educational reform, including schooling practices which invite students and teachers into, rather than alienate them from, themselves, their communities, and a sense of all that is possible.

Even our pluralizing the concept of literacy—computer, media, visual, among others—has not mitigated the stifling effects of how we think about those literacies; how we tend to define, and hence confine; to describe, only to prescribe; and to teach, which, too quickly, turns to test. The results are more than disastrous. They are dehumanizing.

The guiding metaphors which have taken us away from ourselves, turning us away from the possible, are multiple. Three I have found to be pervasive—the industrial model, the medical model, and the training model—have roots in educational research, but the growth still creeps among the public and policymakers, covering more ground than we have any hope of reclaiming. Each of these models is informed by a verbocentric ideology; each separates reading and writing from other ways of knowing. Each is more limiting than enabling.

The industrial, or mechanistic model (A. Neilsen, 1989) characterizes literacy in terms of parts and components within a well-functioning machine. Learning literacy involves learning perfectible subskills; teaching literacy involves sequencing the instruction of these skills in such a manner as to result in a well-functioning machine. In society, this industrial metaphor plays itself out in functional notions of literacy as a competence which is definable and measurable. It is also autonomous, largely pan-contextual, and inert.

The medical metaphor characterizes our literacy in terms of wellness or pathology. Terms such as deficiency, diagnosis, and treatment mark this approach to teaching and learning how to read and write. This view of literacy is similar to the

industrial metaphor in that diseased parts and aberrant behavior can, with the correct treatment, be replaced or eradicated. “Healthy” literate behavior is normal, standardized behavior: school reading and writing become the primary indicators of literacy and the sites for evaluation and assessment. Compliance becomes a marker for health. Like the industrial, functional view, the medical metaphor has definable boundaries for literate and nonliterate, and abnormal and normal.

The most popular metaphor for literacy education is the training center, a place where children, like caged animals, learn to press the right buttons to receive their reward. The rewards range from stickers to smiley faces to gold stars to scholarships. Those who do not perform as required receive frowns, F’s, the threat of being held back, or continual reminders of their status in the academic basement. The legacy of behaviorism lingers: during his first year of school my youngest son’s teacher devised a sticker system to encourage his sitting still to do his worksheets. My refusal to allow this both shocked and puzzled her: she sincerely believed that he would work for stickers. In the same way, our classroom practices assume a stimulus/response path into literacy which have the effect of disembodiment of text, textual practices, and knowing itself. And like the medical and industrial models which are its companions, the training model assumes cause and effect, and a dangerous linearity, instrumental utility, and predictability.

Each of these metaphors externalizes the learning and teaching of literacy, perpetuating the myth that literacy is something we think about and do, rather than something we live (Lytle, 1991; L. Neilsen, 1989). Each of these metaphors spawns research activity that serves to encode further the power of the metaphor in practice. How many years, for example, will we continue to isolate strategies for reading comprehension, teach them to an isolated sample in an anywhere-but-here classroom, and turn the results into textbook activities and teacher materials for widespread application? How much longer will we entertain the naive notion, whether it is wrapped in the garb of skill kits, whole language or process writing pedagogy, that there is *One Right Way*?

But, more germane to this discussion is that these metaphors for literacy learning and research are verbocentric and patriarchal: they reinforce the text’s power to create us in its image, an image whose values include preservation of the hierarchy, of competition, and of accountability, and whose means of naming the world have limited imaginings of text and textuality. Outside the discursive and textual practices we call literacy and literacy research there remain silent presences awaiting ears to hear, hands to touch. By looking to the spaces, the presences between, and their many shifting forms, we can seek revisionist and feminist metaphors of the possible. Like Shakespeare’s sister, these presences may have been there all along, if we would only imagine them.

Countless feminist researchers and educators have written about the tendency for institutions to appropriate text into their discursive practices in ways that alienate, silence, and violate the majority of the world’s population striving for a literacy of the possible (Rockhill, 1987; Smith, 1990). As Magda Gere Lewis tells it:

if we are not men, if we are not economically advantaged, if we survive by the labour of our hands, if we are not heterosexual, and if we do not embody and display the valued assets of the privilege of Euro-American culture, schools are not the sites of possibility which the rhetoric of educational discourse wishes to portray (1993, p. 193)

As a researcher and teacher educator, I must work on my own practice. I must seek an integrity between my pedagogy and my inquiry so that these practices continually find each other out. The questions, then, are not about course syllabi but about daily work in the relations among people and ideas. What do I do in my own classroom to perpetuate silence and disembodied knowing about literacy? And, by promoting principles of feminist inquiry that have evolved in my practices as a researcher, how do I avoid creating another regime which silences and alienates teachers from themselves and their inquiry? How do I engage in my own inquiry to nudge myself toward a more response-able way of living?

LIVING INQUIRY

The nights are cooler now that summer is passing; they seem darker, full of unplayed drama. An early morning walk reveals the goldenrods, now as tall as my child, and the velvet white stalks of pearly everlasting along the path. The air is heavy, even sweet, and the woods are so silent that, when I step on the spongy moss, I cannot hear my steps. It is only the tensing, and then breaking, of filament against my skin, a spider web spun across trees in the night, which reminds me that I am both myself and Other here. Here? Where is here? In these woods, in this part of the country, this season of my life, of my mind, of my body; this world of worlds.

Now what kind of blissed out academic prose is this, you may wonder? Bear with me. August is a rich month for me and it demands my experience of it by mediation of all my senses and means of understanding: somatic and kinaesthetic, visual, verbal. And so I walk, smell, swim, watch the stars, draw, write poetry, eat the summer harvest from the garden, sleep near an open window. I come to embody August.

Similarly, I come to embody inquiry and writing. Words have shaped, guided, informed, constrained, and told my life across many texts and many years. I sometimes see my writing in that cinematic trick-cum-cliche of the 1940s, the black and white pages of a calendar flipping, scrolling into another time and place, another dimension. Trinh T. Minh-Ha, describing Helene Cixous' writing as a process of inscribing, notes that the forms of Cixous' texts "cancel themselves out as they appear, (and) challenge the work's status as object (temporal, finite). Infinitely dividing and multiplying, they are engaged in a movement of otherness which never comes back to the same (1991, p. 141).

My love affair with words, like any love affair, is fraught with tension and passion. To begin writing, I do a dance I have since found is common: I read, I tidy the house, I ponder, flirt with an approach and then, with a shrug, abandon it, pore over books and papers and leave them open on the floor, the desk, the bed. I embrace the rhythm of certain ideas (right now I am waltzing with both Franck's notion of the reflex arc

and Haraway's revisionist take on objectivity). I will move across many floors of understanding, shadow dancing with many theories, until the gestures, the nuances of these ideas become part of me, part of how my mind moves into words and the life they carry. (Here, I am also tempted to play with an eating metaphor, describe how I chew on certain ideas, letting their juices drain down the back of my throat into some river of theoretical waters. The comparisons are many).

I will create a working environment, for a week or a month, that looks to others as though the room has been tossed by the mafia. My mind will buzz with words, with continuities and discontinuities, and I will argue with myself until I reach clarity, insouciance, arrogance, humility, or boredom; any of these states will be fine. It is the processing, the induction, after all; the reaching for a state "in medias res," hearing the hum in the center of silence. To write, I must wade into a textual ocean and disappear in order to appear. I come to embody words.

This state, I assure you, has nothing to do with finding the Muse, or being a prose prima donna. I believe insight (or perception, or creativity, whatever one wants to call the state) has more to do with how attuned we are to the world around us, how passionately we want to apprentice ourselves to its offerings, to cultivate awareness, than with divine intervention or cosmic chicanery.

Similarly, when I draw, an avocation of my youth which tapped me forcibly on the shoulder when I began teaching courses in feminist inquiry, I must become so saturated with my seeing that my fusion with the so-called object transcends conventional physical borders. Franck (1993) calls this a state of seeing / drawing, meditative activity that requires not that I "look at" (for that is what separates us from objects, creating other), but see: fully perceiving, the body, the eye, the hand becoming acutely sensitive antennae. Words fail here: I can only describe the state as a high thin wire of concentration, immensely relaxing, a state, paradoxical as this sounds, so "inside" the activity and myself that I am open to the universe.

And that is where writing and inquiry begin, I believe. At a place, or is it space? as individuals where we are so attuned to the process that we are connected to the world. This space is where literacy lives and breathes, where struggles and connection shift and strain. It is not an easy place to be in, but it is alive.

Name a human experience that calls on us as fully human and multidimensional and we all can list examples of that state of being. Settling into the fourth mile in a long run, kneading bread in the quiet of the morning, sitting in the audience in the last act of *Les Miz*, breast-feeding a child, weeding a garden, holding the hand of a dying friend in the dank and acrid smell of a hospital room, playing a video game, tinkering at the piano late on a winter's night. Each of these experiences opens up our perceptual pores, awakens in us a dimension, a responsiveness to the world in all its pain and beauty which may have lain dormant for some time. Typically, though, we let the stirring giant go back to sleep again, promising ourselves to allow life in more often.

What I want for myself and hope for children is to be fully alive, to be a sensuous, sensual, somatically-aware being, one

who feels and knows anguish and joy, sees the particulars of the world as well as its wholeness, celebrates and challenges what we mean by human in a diverse world.

Berman (1989) agrees. He is not, I think, hyperbolic in his assertion that when we lose awareness of our bodies, our sense of ourselves as a tiny cell in a larger living planet, we look for isms, and "from there it is a short step to seeing other isms as life-threatening, and to seeing the Other as an enemy" (p. 343). The despair of mothers of sons across enemy lines is silent testimony to our failure as a species to cherish life more than the contest of ideologies. The alarming rate of extinction of species on this planet reminds us, on that rare occasion when we stop to think about it, how we have made an Other of the organism which feeds us. Creating an Other allows us to avoid response, and hence, response-ability. Our romance with Cartesian simplicities has been a costly one, and we must draw it to a close. (But we must be careful, too, not to recast our talk of our humanity in neo-romantic terms: we fool ourselves if we think that a spine-tingling chorus of "We are the World" can make us feel sufficiently at one with the universe to drown out cries of terror or fill the tomb-like silence of famine).

WHEN WE DEAD AWAKEN

My aim, as a researcher and an educator, is to hone my own response-ability, and to foster that ability in others. In part, this response-ability must start with a "coming to our senses" that affirms our humanity:

There is, here, a stretching out to a Gaia-politik, the conviction that the flesh of my body is also the flesh of the earth, the flesh of experience. To know your own flesh, to know both the pain and joy it contains, is to come to know something much larger... (Berman, 1989, p. 344).

Once that awareness is reawakened, once we begin to hear, see, know, feel, and touch again, our alienation from others—from colleagues, from ideas, from the many Others we create to simplify our thinking and to dull our feeling—seems to diminish. We come back to ourselves, back to who we are and where we live. As researchers, we are better equipped to communicate our experience when we see the inquiry process as a relationship, not only among people or participants, but with our unarticulated selves and the earth which bears us.

One of the great disjunctures of education is the fact that, as adults, we are alienated from the thinking and feeling of our body selves (John-Steiner, 1985); but children, the putative beneficiaries of the school structures and curricula we create on their behalf, are not: they passionately and with joy use all their senses and abilities to create knowledge and to embrace the world (Gardner, 1982; John-Steiner, 1985).

Greene (1988) claims that the passivity and disinterest prevalent in classrooms, particularly in the areas of reading and writing, is a result of our failure to educate for freedom in schools. To do this, we must focus on "the range of human intelligences, the multiple languages and symbol systems available for ordering experience and making sense of the

lived world" (p. 125). Literacy educators are only now recognizing the powerful effect on learning and development of what Suhor has called transmediation (Suhor, 1984), moving across sign systems in a way that Siegel (1994) claims "offers learners rich potentials for gaining new insights and perspectives on the texts and concepts being explored—understandings that might remain untapped if language were the sole sign system used" (p. 3).

But how can we focus on the range of human possibility in children, when we fail to nurture those same possibilities, the uses of myriad symbol systems and ways of knowing, in ourselves? Where do we demonstrate or nurture our transmediative potential as adults? We can desecrate education's neglect of the arts and know that it is a long-standing neglect, borne of a utilitarian, functional, and materialist approach to education. We know that our attempts to weave the arts into curricula are an uphill struggle. We know that there remains a hierarchy of symbol systems and intelligences which define schooling and literacy: verbal and mathematical literacy continue to claim most of the nation's attention and the taxpayer's dollar. We watch, too, as the association of early literacy learning with nurturing and motherhood (Grumet, 1988; L. Neilsen, 1993b) becomes a double-edged sword: the body and the role of the mother in early education is at once idealized and trivialized. The embodied knowing associated with early learning, fully human sense-making, is tolerated until later school years, when induction into the Word of the father becomes necessary. Reading and writing become objects of study and control, separate from the learner, and employed to meet the ends of various contests of merit and manipulability, including assessment.

Nevertheless, in spite of these overwhelming obstacles, we have not adequately addressed our own complicity: what are we, as educators, doing to awaken in ourselves the responsiveness necessary to hone, promote, and celebrate our own multiple ways of knowing the world, of making sense? What are we doing to resist institutional practices which stifle our growth as professionals?

The metaphors we have used for literacy shape the educators as well as the learners. If we seek other metaphors, we may find that our perspective on literacy and learning changes, and so do we. In seminars on qualitative and feminist inquiry, I have attempted to promote new perspectives on our many human literacies in the hope that educators will take these perspectives into their lives and their classrooms and, as a result, teach with more confidence, autonomy, humility, and joy. Some may prefer to call these approaches methods of inquiry; perhaps they are simply (and complexly) the ways in which we are in many ways human. And perhaps, as researchers and educators, we can argue for their cultivation not as curricula, but as habits of mind (L. Neilsen, 1993).

CREATING A PATH BY WALKING

It will be hot in the city today but, here, on the rocks of Peggy's Cove, the early morning air is cold. The sun will burn off the fog by ten, but for now, we have sweaters and jackets as we walk among the whale-sized rocks whose lines dip toward the

Atlantic. Teachers all, we are careful to wear our sensible shoes; the notice posted near the lighthouse reminds all visitors that the sea here is merciless, that waves can, and do, reach up over the rocks and pull us in. I choose to walk among the rocks and around the cove itself, stopping to admire the brightly-colored homes of the residents. What must these people think when visitors arrive, as we have, at 7:00 a.m.? What must it be like having your community be the most well-known tourist attraction on the East coast of Canada?

Agnes is on the wharf, talking to the fishermen who are loading their lobster traps. John is behind the lighthouse, at the edge of the water, using a tape recorder to capture the sound of the waves crashing against the boulders. Linda is perched next to a pool, a microcosm of aqualife nestled in the boulders, observing the movements of insects and suckers. Patricia is sketching, using an HB pencil to show the play of shadow and line in the rocks as the sun begins to break through the fog. At the peak of the largest boulder, I can see Allison, prone on the grey expanse, a notebook in her hand. Near the shore, Carole aims her camera at a gull poised like a weathervane against the sky.

We are here before the busloads of tourists, and for a reason. The stunning beauty of Peggy's Cove is guaranteed to pull us out of words and texts and ideas into the physical power of the so-called natural world. It is guaranteed to bring us to our senses, and it does. This day-long event for graduate students, one which I often include when I am teaching a summer course, serves to remind us, as teachers, how bound we are to rooms and desks and constructions of words in various formats and guises. Invariably, we renew our long-forgotten commitment to worlds beyond the page when we are free to roam, to explore using all our senses, to record and reflect. And when we return to text, it is with revised, sense-charged notions. Typically, a day such as this produces poetry, which always surprises the writer: she or he will return to class the next day, poem in hand, full of wonder and renewed inspiration. I felt alive again on those rocks, and I wrote this: Is this real research, she will ask?

And it is here, then, that we can begin. What is research? Who does it? What counts as knowing, and whose knowing is valued? From the outset, I make my agenda explicit. As a researcher and as a teacher educator, my aims include the following:

- (1) To demystify and to reclaim research and the inquiry process.
- (2) To encourage the use of multiple sign systems, particularly as they reawaken body understanding and aesthetic sensibilities, in order to open up the inquiry process, and in so doing, to revitalize professional commitment.
- (3) To promote an understanding of our multiple selves in relation to the cultures of the home, the school, and the academy and in so doing, promote our response-ability in those cultures.
- (4) To encourage resistance of practices in the educational and institutional hierarchy which de-value situated inquiry and multiple ways of knowing; and to be open to understand how I am co-opted by those practices, and how I perpetuate them.

To Demystify and to Reclaim Research and the Inquiry Process

As people mature, they cease to believe in sides or Headmasters or highly ornamental pots. At any rate ... it is notoriously difficult to fix labels of merit in such a way that they do not come off (Woolf, 1929, p. 101)

Coming to the point of being able to articulate these aims for teaching and research has been a long and difficult process. Woven in the story of who I am and what I do as a researcher are, of course, the stories that form my history as a student, a teacher, a graduate student, and an academic (L. Neilsen, 1993). My struggle, which was much less painful than most, has served to remind me of my responsibility to other students, particularly women, who have felt outside themselves, silenced, and trivialized in education as a whole, and in the research process in particular. After all, research has created "a place where none of us lives and works—an 'objective' place wherein we are contrasted, compared, designed, and interpreted" (Chandler, 1992, p. 130). The study of research perspectives is often characterized by curricula which present research as "hygienic" (Stanley and Wise, 1993, p. 114) and "out there." This disjuncture between our intellectual work and our lives is crazy-making, creating invisible women (and men) walking the corridors of academe in search of something familiar to their lived worlds. Desperate for connection, we relent, and like Morgan's invisible woman, don a body and voice not our own, but which render us, for the time being, visible and heard.

The language of theory creates a valuing of propositional knowledge (Eisner, 1988), which generalizes more than it particularizes, and whose coin is the testable assertion. But, as Eisner states, our reliance on propositional knowledge diverts our attention from what he calls direct experience because we "know more than we can tell" linguistically (p. 16). Propositional knowledge is not only often contradictory to experience, particularly the experience of women and underrepresented groups in education, but its lifeless disembodied nature can, in fact, distort experience, and close possibility: "Our awareness is always limited by the tools we use. When those tools do not invite further sensory exploration, our consciousness is diminished" (p. 16). In effect, Stanley and Wise claim (1993), "there is a power relationship between theory and experience, and one consequence is that women are not only alienated from theory but also experience itself" (p. 162). We cannot see ourselves in the research reports and theoretical treatises that shape the research enterprise, and in trying to see ourselves in those terms, we blunt and diminish our exploration. Coming to research, we are required to wear the body of knowledge like a glove, and speak words only to make others happy.

We learn posturing so well that we risk mistaking it for the "real thing." Teachers who are also students of educational inquiry, are doubly obligated to be in drag; not only must they wear the dress of academic theory and jargon, but in their own work in classrooms, they have been expected for years to be "professionals": to silence or mask their preferences, their cultural biases, their ethnicity and their politics to uphold a discourse of neutrality and objectivity. They must play their

role so well that they are capable of inspiring shock in the student who sees them in blue jeans at the market, buying oranges and wine with their partner.

The task of demystifying and reclaiming research and the inquiry process begs the question, "What counts as research?" Discussions around the seminar table with teachers invariably reveal how deeply encoded conventional notions of research have become. Men and women alike, even those who have conducted their own classroom research, continue to believe that "real" research searches for an objective truth, is synonymous with "science," is conducted in institutions elsewhere by funded academics, and has little practical relevance to their home or their working lives. Research is logical, value-free, tidy, and replicable. Academic practices, which so often go unchallenged or deconstructed (and which I realize I perpetuate even in this article), reify text as the sole purveyor of research knowledge, elevate "scientists" and "science," and perpetuate verbocentric practices in inquiry at all levels. The practices of quoting research to settle issues of "proof" and of lifting arguments with a highly developed set of bibliographic muscles prevent everyone around the table—faculty and student alike—from recognizing the validity and authenticity of their own experience and from learning to open that experience to scrutiny.

As the seminar facilitator, my task becomes showing the many ways we can take apart existing research "products," to look behind them to see how they are constructed within political and personal exigencies and constraints, and to recognize their fleeting and mutable nature. Teachers who want to explore, for example, classroom talk, and who see that other researchers have published studies in that area, must be first convinced that classroom talk is not closed as a topic, "been done," or "covered already." They must then work to understand that their perspective on the subject will be unique. (Much of the work I do, I realize, is enmeshed in the problems created by our lack of professional esteem, how we are schooled to defer). I remind people that everybody comes from somewhere, including a researcher. Using my own studies works well: I can explain how the historical influences and relations of ruling within the field of literacy research and within my particular institution shape the way in which I do inquiry and write about it. The text they read, then, is connected to a face, a voice, and a history, none of which are "objective" or unflawed. The words I wrote, the published text, can then be seen as partial, provisional, exploratory, tentative.

What works best to dismantle notions of "research" and "researcher," however, has been to invite teachers to engage in their own inquiry; in particular, inquiry that arises from their own experience, not as individuals, but as situated, relational beings. This "kitchen table" inquiry, as I call it, aims to "create a space in the academy to make our inquiring selves the center of our own inquiry: the daily micropolitical acts, the many issues, circumstances, and challenges of the ordinary which reveal the politics of our behavior in our conflicting identities and relations" (L. Neilsen, 1993, pp 6–7). Such inquiry both reveals experience and makes it problematic, and because it is dialectical, it serves necessarily to change the circumstances in which we live and work by forcing new

syntheses, different identity relations. Like tai chi, the movements are not static; the body moves fluidly from one position to another, poised momentarily, each movement leading to the next in order to maintain balance. At each position, our perspective changes. To do inquiry, as we do tai chi, we learn to recognize that we have been making those movements all along, albeit with less purposefulness and discipline. Stylized moving with awareness, in tune with the world, makes inquiry come alive.

To Encourage the use of Multiple Sign Systems, Particularly as They Reawaken Body Understanding and Aesthetic Sensibilities, in Order to Open up the Inquiry Process, and in so Doing, to Revitalize Professional Commitment.

The governing of our kind of society is done in concepts and symbols. (Smith, 1987, p. 87)

The work of C.S. Peirce provides a basis for an understanding of sense-making, or meaning-making as a semiotic activity. A sign, he claims, is "something that stands to somebody for something in some respect or capacity." We make sense through a process of semiosis, in which our responding to a sign creates a "thirdness," our meaning or apprehension of / for the sign. What we have ignored in literacy education research, with only a few notable exceptions (Harste, 1989; Siegel, 1994), is the potential for semiotics in extending our understanding of reading and writing and the transmediative power of alternative sign systems in learning. Even those attempts to see literacy as a semiotic activity have tended to focus more on alternative modes of cognition, rather than full-bodied perspectives on learning. Not only has our classroom practice in supporting literacy learning been affected; so too has our inquiry. What counts as research and inquiry continues to be what can be documented and written in conventional text.

In Siegel's (1994) discussion of transmediation, the process of boundary crossing / mixing among sign systems in order to explore one way of knowing in terms of another, she draws on children's work in schools. But the potential for such transmediation holds for the research process in academic institutions as well:

"Transmediation thus stands as a critique of the status quo in schools, where the emphasis on rote learning and the display of ready-made knowledge has dulled the minds and senses of a generation of students and led them to believe that there is no ambiguity in learning, no risks to be taken, no new knowledge to be made". (p. 4)

So too are teachers dulled in their means of recognizing and creating the conditions for meaningful inquiry. Research is often presented as a product, a current truth, a template for teaching. Why watch this reading group, they may wonder, when the list of readings from my graduate course tells me that children will do X, Y, and Z, anyway? Why not simply read what others have studied rather than watch, hear, draw, record, smell, or interact in the busyness of classroom life in front of me? Here again, the dominant metaphors for literacy

learning, mediated through the printed word, shape teachers' practice. A simple shift in metaphorical thinking, from "if it's broke, fix it" to "if it's alive, feed it," might make all the difference, not only in the way she or he teaches, but in the means they use to begin their own inquiry.

The courses I have taught in inquiry (whether a general course in qualitative inquiry, or more specifically, feminist inquiry), have invited teachers to go beyond conventional texts and ways of knowing to exploring—or renewing—their multiple ways of making sense of the world. The courses require them to engage in learning using many sign systems (from music to the visual arts to performance art, among others), to communicate their learning using those systems, and to consider their classroom teaching in light of these multiple sense-making literacies. What are they doing about stretching themselves as fully sense-making humans, and what kind of environment are they creating for their students to do the same?

With the permission (or perhaps, requirement) to explore sign systems other than conventional written text, teachers exchange insights using video, pencil and charcoal drawings, watercolor and oil paintings, dramatic performances, scripted plays, musical compositions, photographic essays, computer graphics, children's books, fabric arts, dance, and comic routines. Typically, they relish the freedom that such expression affords, but they are also somewhat reticent to declare their enthusiasm to their colleagues. As exciting and renewing as these media are, they are nevertheless held in the same regard among professionals as they are in the school system: making a video for a university course, for example, is not considered as "rigorous" as reading three books and writing a term paper. Teachers begin to see that, regardless of the work in discourse these many years, only one definition of "text" prevails.

Like emerging limbs of a sapling, our many ways of knowing the world can be cut off early in our lives. School becomes a site for learning compliance, and robust and fecund creativity—the sort we see in artists and highly productive people—is seldom nurtured. The stories often told about highly creative people, such as those studied by Ghiselin (1952) or John-Steiner (1985), indicate that they often endure or ignore schooling to keep their creativity alive. But, unfortunately, so do we all. As adults, we squirrel away our instinctive needs to work in differing sign systems by slotting them into home or extracurricular activities such as organized art and music lessons; we trivialize these needs as *childish* or as *play* (and hence disruptive of our work ethic); or we meet the needs in socially approved and sanctioned ways, allowing glimpses of the possible only through the doodlings on the cover of a notebook, the dramatic hallway impersonations of a teacher or colleague, or the performative art of lying our way out of trouble or obligation.

But mature trees can often, given the proper conditions, support diverse growth, and I have found consistently in my inquiry courses that teachers who conduct their own inquiry into making meaning in diverse ways will renew their professional enthusiasm. Bridging various sign systems, playing with their intereducative potential, reminds teacher researchers that they are "whole" beings, aesthetically and somatically "real" and alive. Their confidence in having risked and

thrived, the inter-relationship of the learning that ensues, and the liberation from the word as the only signifier, all combine to shift ground, to propel them forward to a fertile awareness of themselves and their own students.

Piaget's student, Howard Gruber describes the "whole thinking" person as working with a number of interacting subsystems. Gardner's description of Gruber's perspective touches closely on the notion of transmediation, albeit in terms sounding more structural than semiotic: "A creative individual typically spawns a network of enterprises—a complex of searches that engages his [sic] curiosity over long periods of time. These activities usually sustain one another and give rise to an incredibly active creative life" (Gardner, 1982, p. 354.). Not surprisingly, the creative individual, Gardner claims, also experiences a "strong, almost primordial tie to the subjects of his [sic] curiosity ... a special intimacy with the natural world" (p. 355), a pleasurable tie with the work he compares to sexual involvement with a loved one. It may well be that opening our senses opens awareness, and such awakenings kindle or rekindle desire in all its forms.

Sign systems, however well we explore them, and however well we integrate or encourage transmediation among them, are not neutral, nor sapped of ideology. They are politically charged, encoded in our social practices in ways that can build empires and assign value. At a pragmatic level, disciplines and activities in schools are marked, encoded with political, economic and social importance or irrelevance. When teachers realize their response-ability in these cultures for assigning and assuming value to certain sign systems, it can open understanding about the everyday, and create opportunities to challenge the given, the values which form an unproblematic backdrop to everything they do. Suddenly, they will see schools in a different light, their work both as belonging to a culture of its own creation and responsible for its critique and renewal. They begin to question the verbi-centric bias in the public education system which marks survivors and champions as those who learn to negotiate and perpetuate the relations of ruling (Smith, 1987).

To Promote an Understanding of Our Multiple Selves in Relation to the Cultures of the Home, the School, and the Academy and in so Doing, Promote Our Response-Ability in Those Cultures

So, I think ... "our" problem, is how to have simultaneously an account of radical historical contingency for all knowledge claims and knowing subjects, a critical practice for which recognizing our own "semiotic technologies" for making meanings, and a non-nonsense commitment to faithful accounts of a "real" world, one that can be partially shared and that is friendly to earthwide projects of finite freedom, adequate material abundance, modest meaning in suffering, and limited happiness. (Haraway, 1991, p. 187)

While we engage in ongoing debates about the nature and existence of truth, looking askance at those claims that "no truth" exists as being equally problematic and equally modernist (if that matters), we still have to live and work, teach children, feed the dog, and pay for groceries. Some of us, like Stanley and Wise (1993), answer the phone to hear threats

and abusive comments about lesbians and gays; others hide from a man who hits when he drinks; and still others watch as the administrative position available in the school, and toward which they have directed all energies, goes to a youthful member of the "old boys' club."

This is not mere information; these are experiences that matter, that bring us to our senses. These are the "stones in our shoe" (L. Neilsen, 1994). We are eldest in a large family from rural Canada, or we are the child of an alcoholic, a new citizen of the country, or the sister of a man who has just died of AIDS. Each of us comes from somewhere, but that "somewhere" casts a different shadow in each of our encounters with others. The recognition that each of us is a constellation of differing positions according to the culture or context in which we find ourselves—and that these "multiple selves" negotiate and monitor ever-changing positions in a complex web of relations in the world—need not be an awareness which strikes fear of chaos. It can, instead, be a liberating recognition that the "self" is provisional, growing, elusive, but nevertheless, for the time being, here. Such awareness also brings with it the obvious: that the self is as the self does. We are what we do.

This kaleidoscope of shifting selves that we carry into the world each changing day, creates a similarly complex set of relations for the teacher encountering a roomful of children, each of whom brings equally complex kaleidoscopes and webs of relations. The study of teachers' lives, whether described from narrative, postmodern, or critical perspectives, is beginning to inform our understanding about actual people doing messy work in classrooms. Researchers who make it a point to "come clean," about their own experiences will, as Stanley and Wise (1993) put it, "present analytic accounts of how and why we think we know what we do about research situations and the people in them" (p. 166). We drop masks: by divulging who we are and where we come from, we are less likely to dismiss others' understandings as deficient, wrong, or lost in false consciousness.

When I work with teachers in inquiry seminars, they work with the situations or issues in their own home, work, or community which trouble, chafe, or intrigue them in some way. Research closer to home is less likely to be turned into an object, an Other, and the participants in the inquiry are more likely to have a face and a voice. These are situations from which the researcher cannot stand outside, but in which she participates, and often, through the process, inspires or affects change. Thus, this "kitchen table" inquiry has a particularly striking effect on peoples' assumptions about researcher stance. Questions about research ethics rise to the forefront.

In a recent discussion, an art teacher described her colleague's recent practice of using a repetitive, cut and paste task with paper in her first grade classroom. Although the teacher had observed the class only one day, she judged her colleague as having "taught art badly," of having stifled the children's creativity. But, someone in the seminar group asked, could there be other explanations? What are the assumptions here about inquiry and about teaching art? Another offered an alternative perspective on the activity: was this teacher, perhaps, aiming to provide young children with

an opportunity to practice motor skills and task completion, and not seeing this activity as related at all to art? How do we frame what we do? How do we frame what we see? Ought we to judge? How does the observed see herself and her intentions? How does the researcher see the teacher? Whose perspective is closer to "true"? Are our observations different when we see ourselves as colleagues, not researchers? What is a research stance? Who benefits from it? Who decides?

It becomes more difficult, as we engage in inquiry closer to the communities in which we live, to put on the body of a researcher like the rumpled glove, and to speak words outside of ourselves. It becomes more difficult, as we sit in a circle around the kitchen table, the seminar table, or the staff room table, to point a finger at others in the circle who do not meet our standards, or see from our perspective. For this reason, I believe it is important that our inquiry be situated in places we know, and in which we participate. It is only then that we face our response-ability, are less cavalier with our notions of what counts as ethical, and what constitute integrity and community. Flying into data plantations, in the colonialist version of "objective" research, has always allowed for the kind of symbolic violence that, around home or the kitchen table, would be resisted, might be considered intrusive, assumptive, arrogant, and exploitative.

To Encourage Resistance of Practices in the Educational and Institutional Hierarchy Which Devalue Situated Inquiry and Multiple Ways of Knowing; and to be Open to Understand How I am Co-opted by Those Practices, and How I Perpetuate Them.

... (academic scholarship) is in the mind, in logic, in a form of discourse which totally erases the body, the emotional, the symbolic, the multiplicities and confusions—and in all ways orders the chaos of our lived experiences so that we no longer feel their power, their immobilizing conflicts, as we live them. (Rockhill, 1987, 7)

My doctoral studies were filled with what might be called transmediative experiences. I particularly recall one "writing seminar" held by Donald Murray in which we engaged in another creative process, such as playing the piano or drawing, and wrote about how the processes informed one another. In other seminars writing as an art form was valued, encouraged, and expected; discursive, highly bibliographic academic writing played a part, but not the major part, in my studies. The education department in which I now teach has long held a reputation for holistic teaching practices, albeit varying interpretations of those, and for response-able, flexible, constructivist pedagogy. Students in our graduate program typically must spend the first part of their studies unlearning the institutional expectations and assumptions about university teaching and academic work they brought with them. It takes several months of waiting before I or my colleagues hear the incoming question "Is this what you want?" shift to "Let's talk about what I / we need to do, and how I / we can make that happen."

Still, as fortunate as I have been as a graduate student studying inquiry and a faculty member both teaching and

engaging in it, tensions remain. The symbolic order of educational research marks doctoral institutions such as the one I attended, as being from a "soft" research perspective, not "rigorous" or a place where "real" research is funded or pursued. The narrative and reflexive research practices associated with institutions such as these are often labeled unscientific, merely anecdotal. Regardless of the educational site, from an elementary to a university classroom, ways of pursuing our knowing have become gender coded, inscribing a public/private separation, where stories and the "personal" are considered of the private sphere, usually associated with women, and which run counter to the goals of the school which intends to prepare people, especially males, for induction into public life (Nicholson, 1994, p. 79).

Outside the places where I am able to live and work I realize, as Helene Cixous so accurately names it, I must salute and show my identity papers, or in Virginia Woolf's terms, to identify my Headmaster. While students in our program speak in passionate tones of the dramatic changes in their perspectives—indeed in their lives and their relationships with colleagues, family, and friends—as a result of studies in which they can explore alternative notions of literacy and inquiry, the universities which maintain the status quo, the patriarchal symbolic order, are nevertheless considered to be legitimate universities, the "scholarly" institutions. They are places where, the student query "what do you want?" is answered by the prevailing master narrative or the accompanying bibliography.

In the meantime, I continue to celebrate and support, theoretically and empirically, work which, by redefining literacy and inquiry, seems to be want to redefine scholarship as we know it. In a time of decaying institutions and irrelevant structures it is necessary that we engage in inquiry which calls on an understanding of our whole signifying beings and in so doing rewrites our institutional practices. We are at a critical point; we must realign signifiers in new fusions of possibilities. How many years and how many millions of dollars will we continue to spend on dead and dangerous metaphors, grasping for new ways to revive them? How many years do we expect a love of literacy to survive with the heart cut out of it, when we allow it to walk among us, disembodied, a head on a stick?

The inquiry I explore and which I propose here is not, nor should it be, the only form of inquiry offered or explored in feminist courses, or in any research program, for that matter. After all, theory as regime creates its own problems of oppression. What should these efforts be called? Feminist standpoint inquiry? situated, reflexive research? feminist ethnomethodology? interpretive inquiry? response-able research? perhaps this work is a step toward the joining of partial views and voices into a collective subject position. Or perhaps the work is more interesting for the new spaces it creates, the positions it disrupts.

And so the circle turns, and this time the view is different. I consider it a step toward achieving Haraway's "earthwide projects" and Berman's "gaia politik" to resist institutional practices which continue to define, and hence constrain research that grows out of a particular context by attempting to

name it, and to compare it to others' in different classrooms, and other inquiry collectives. Whose ends does it serve for us to agree on a definition of qualitative, or feminist, or science—to put fences around our isms and marshal our forces—if children and adults continue to wander the earth deadened to its promise and its pain? Virginia Woolf reminds me that we cease believing in sides as we mature, and the labels we use will come off anyway. Experience tells me, also, that even when I refuse a label, others will affix it on the work to quiet their own uncertainty. I cannot help that; but I can help myself and others teach and learn in more responsive ways.

Over the last 5 years my work with teachers has changed. Various, I have encouraged a focus on observation, reflection, reflexivity, and resistance, sometimes, or usually, all at once. The ways of inquiring and "telling" have included most aesthetic and technological media available. The "sites" for inquiry have ranged from a girls' soccer season to an immigrants' social club to the local newspaper, an individual's experience of racism in school, the experience of motherhood, to the conversational dynamic of our graduate seminar. In all cases, the researcher—with her perspectives, dilemmas, insights, and activity—is the sphere from which the inquiry begins, the axis on which the related and relational worlds spin.

Throughout these explorations, I have encouraged the body awareness and attunement that brings alive teacher researchers too long buried under dry and bloodless words. I have argued for the validity of inquiry that arises out of uncertainty, and indeed, invites more troubling of experience. And I have worked to support as many strategies for seeing, hearing, documenting, and codifying—a triangulation of methods, if you will, especially of methods that invite many forms of representing how we know.

A classroom, however, is still a classroom, and my own practices with people are open to question and to critique. For some, I realize, the kind of situated inquiry I promote creates its own form of tyranny, opening issues a person would rather not address. My pedagogy can be a breath of fresh air for some, a terrifying open space with no guide posts for others. I must learn to adapt practices that recognize such differences. I must also recognize my own complicity in maintaining the symbolic order that excludes underrepresented and silenced groups, and places students at the bottom of a hierarchy (L. Neilsen, 1993). Grades and other such markers are still there, in spite of our work to take evaluation out of institutional practice. We can support growth through critique and conversation, create all the communities of inquiry we wish, but the grade sheets continue to appear on our desks.

It is instructive to continue to ask the impossible: how can educational institutions, and the practices of pedagogy themselves (however "empowering") avoid becoming sites of oppression, silencing in their own way? We cannot aspire to other, more ideal classrooms, for I do not believe they exist. Classrooms are still situated within academic institutions which promote competition, and which, through policies and discourse, find ways of excluding many combinations of identities, and the lived realities they hold, all in the name of standards and rigor.

FEMINIST METAPHORS

Robin Morgan's *Invisible Woman* "sees others quite clearly, including the doctor who patiently tells her she isn't invisible." She "pulls on her body" and "switches on her voice" and, in so doing, calls attention to herself. Better to suffer this, she thinks, than for the young doctor to learn that "he himself is insane. Only the strong can know that" (p. 326).

Historically, voice—and its companion notions of ventriloquism, silence, and mutedness—has been a productive metaphor for women's experience of teaching and learning in the world (Belenky, Clinchy, Goldberger, & Tarule, 1986; Fine, 1992; Gere Lewis, 1993). But, is voice the foundational sound of our "true" selves, or do we produce many tones in many ways over many years? And from where do voices emanate? Equally compelling and useful has been the metaphor of the body, the corporeal being, whether we articulate it in terms of invisibility, embodied knowing / disembodied knowing, skin as a cover, role-playing or masks (Belenky et al., 1986; Grumet, 1988; Minh-Ha, 1991). Too often, however, we use the metaphor of body as an entity distinct from the mind. Cartesian perspectives on our work in the world have helped to form a basis for the metaphors for literacy which we now find wanting. What might happen if, we opened the gates separating mind, body, the world?

Shakespeare's sister, the 16th century fictional young woman born with a gift of poetry, is the ghost in our collective consciousness, reminding us all of the blunted possibilities of women's imaginings. Virginia Woolf, describing how the downward spiral to the young woman's death might have occurred, imagines her facing the impossible: "all the conditions of her life, all her own instincts, were hostile" to the development of her talent. Between her and the incandescence of mind needed to write poetry, were attitudes, social practices, and assumptions which were insurmountable, even in her own mind. "Her mind must have been strained by the need of opposing this, of disproving that" (p. 53), writes Woolf. In fact, Shakespeare's sister, shut in by the gates created in her world, would never have sought the horizon of her talents at all; from where she stood, it was impossible to even be aware of a horizon, let alone seek its possibilities.

Little has changed where issues of knowledge and inquiry for women and underrepresented groups are concerned. I continue to hear challenges about the "validity" or "reliability" of my argument for a living inquiry: how then can we compare, prove, sort, categorize, or place value such inquiry in the academy? A kitchen table metaphor for inquiry has a decidedly homespun, anti-intellectual flavor, challenging received notions of formal academic propriety. And yet I will continue to invite my colleagues to the conversation there. Such a conversation causes us all to examine again the split between the public and the private spheres: one, the political and social external world, and the other, the realm of privacy and subjectivity.

This, then, has been education. As Nicholson (1994) writes: "As one moves from the elementary to graduate and particularly professional schools, one finds an institution less

and less "homelike" and increasingly dominated by characteristics associated with the public world and masculinity" (p. 80). A living inquiry, as comfortable in the kitchen as the seminar room, attempts to bring research home (L. Neilsen, 1994), to be named and recognized in the same way that we continue to lobby for recognition of unpaid labor, for the value of story beside statistic. It is work of the heart, the hands, our sense-making bodies.

The issues are ones on which the world can tilt: learning about the world as through the body is inseparable from the mind; creating the discursive world from the axis of experiences of the silenced, the unnamed, and the disregarded; exposing and composing our lives as researchers by including and examining who we are and what we do in the name of inquiry. Such issues are issues of legitimacy, if we choose to use a morally-laden term, or perhaps, issues of value. What and who and how do we value, what means and why, when we set out on the inquiry path?

But like the histories of midwifery or herbal medicine—from necessary practice to a position outside the realm of "acceptable medical practice" to a growing, if qualified return to "legitimacy"—the history of inquiry, at least its history within the last 20 years, has been a battle of "regimes of truth" (Gore, 1993). But who is right is not nearly as interesting or productive as questions such as "Who benefits?" "What is the legacy of our work?" "Who and what are we not hearing, seeing, knowing?" Women who assisted at the birth of children are neither right or wrong; they are variously witches, shamans, friends, lovers, pariahs, health care providers, and licensed midwives. The work is necessary, and will be done. The times assign place, and the politics ascribe value.

In fact, it is not my intention to force the adoption of my research and teaching practices on anyone, only to invite teachers to embrace them, take them in, like Shakespeare's sister, for a time, to reawaken aspects of themselves and their professional lives, to live the inquiry, and to be confident in its own particular truth. These practices of feminist inquiry, while they are satisfying and challenging, are part of the diversity and richness that marks the inquiry process as a whole, part of a mix of perspectives and methods we need to spark learning and force change. Such diversity, to the extent that the practices are not oppressive or irresponsible, is to be embraced in the same way our multimodal literacies ought to be embraced. My argument is that feminist inquiry of the sort I practice and support, ought not, like the talents of Shakespeare's sister, be blunted by the thick resistance of the status quo. Nor ought it to be skewered on a standard to which it does not aspire: to be the whole answer. Such feminist praxis ought to claim a space in the house we are constructing, not perceived as a faint shadow in an asylum hallway. After all, as Haraway notes, "we could use some enforceable, reliable accounts of things not reducible to power moves and agonistic, high status games of rhetoric" (1991, p. 188).

Metaphors become our lenses, our seat on the ferris wheel, our foot on the rocky bottom of the ocean. They shape how we respond, and even who we are. Our metaphors for teaching and learning literacy with and for ourselves and our students have diminished our possibilities, closed us from

the constellations of codes and living responses that life opens up to us. Thirsty children are given recipes for water; soul-diminished teachers are given keys to the textbook storeroom. Both ought to be out looking for the horizon unravelling it, creating surprise.

No single metaphor can be selected here to speak for a feminist method of inquiry. But I am aware that metaphors that make sense—shape sense—for me in my teaching and inquiry practices are metaphors that call on the “body resonant.” Living inquiry means that a relational being, living in overlapping worlds, touches and responds to those around her as she pursues the work she deems important. As she moves within / out of these worlds, she and they are changed. More than speaking a single voice, her presence re / sounds, re / verberates; her senses take in all that surrounds her, and she in turn, gives back. Her many-toned voice is part of her presence; sometimes a song, sometimes a cry, or a whisper. Her body lives in the world—mind, emotion, and sentience as a breathing whole—like a cell lives within a larger being, exchanging life-giving synapses of the heart, the mind, and all that she is. Our body resonant is less like a corporeal entity, and more like a permeable membrane balancing forces of air and water, fire and earth. Literacies of the body resonant are living literacies. They are the joy and pain of engaging ourselves in the many ways that our sensory systems offer, knowing all the while that we are not aiming to reach an ideal holism, but rather to be awakened to the knowledge that links meanings with bodies, here and elsewhere. I am urging abandonment of metaphors for literacy that do not fit our world,

that cut off our circulation, parch our possibilities and clutter our lives with miseducative and unsustainable activity. We need complex, situated metaphors, opening a “view from a body, always a complex, contradictory, structuring and structured body, versus the view from above, from nowhere, from simplicity” (Haraway, 1991, p. 195).

No god’s (or goddess’) eye view is enough, and we have had too many in the inquiry business in education who aspire to that seat. Meanwhile, as academic arguments rage in the etherworld, the discursive system where “system / atic” inquiry is enforced, a Kurdish child new to Canada enters a school in Nova Scotia speaking no English. She feels the cold in the outside air and in the classroom climate. She aches with knowledge she cannot tell, and she sits near the window, her pencil poised on a paper with words to copy. Disembodied words, that do not touch any experience she knows. Elsewhere, the mother of two children enters a literacy program after 30 years of illiteracy and confesses that she no longer feels like a nobody. Literacy will make her somebody, she believes.

No body. Some / body. Dis / embodied. Our metaphors for literacy have created a world of schooled people outside their bodies, outside themselves, unable to connect their life to their words. New ways of imagining our literacies and our possibilities might help us all read, write, sing, touch, hear, and in richer ways resonate with the lives and the struggles of travelers we have missed on the paths. We are passionate, resonant bodies seeking connection and survival; it is a compassionate literacy to which we must aspire.

MAKING 'COLLABORATION' PROBLEMATIC IN COLLABORATIVE SCHOOL-UNIVERSITY RESEARCH: STUDYING WITH URBAN TEACHER RESEARCHERS TO TRANSFORM LITERACY CURRICULUM GENRES

Christine C. Pappas

UNIVERSITY OF ILLINOIS AT CHICAGO

Those who have been involved in school-university collaborations have frequently remarked that "collaboration is not always an easy process" (Oja & Smulyan, 1989, p. x), or have characterized it as a very "messy," "uncertain," and time-consuming enterprise (e.g., Bickel & Hattrup, 1995; Miller, 1990; Oakes, Hare, & Sirotnik, 1986; Prawat, 1991; Sirotnik, 1988). However, despite these difficulties, for several decades now many have taken on the challenge to create communities that educate both those of the university and the schools by expanding relationships and social networks with each other (Lieberman, 1986, 1992; Nespor & Barylske, 1991; Sirotnik & Goodlad, 1988; Tikunoff, Ward, & Griffin, 1979).

I will argue that this messiness in these collaborations is largely due to new conceptualizations about power/participant structures and the nature of knowledge, which, in turn, have required changes in educational research methodologies. The major aim of this chapter is to insist that because of these changes about power/knowledge, *collaboration* itself in collaborative arrangements has to be made constantly

problematic—that is, it has to be an ongoing, integral facet of methodological concern.

This chapter has been organized into three major sections. The first section sketches the changing power/knowledge perspectives that underlie collaborative school-university research projects. It starts by offering a framework for 'voice' from the work of Bakhtin (1981, 1986) to clarify whose voices have been privileged and whose voices have been silenced in traditional educational research. Then, because I believe that school-university collaborations are part of the larger challenge to traditional educational research, four areas of critique are briefly covered. At the end of this first section, characteristics of *collaborative action research*—which is the term frequently used to refer to many current school-university partnerships—are outlined to show how this research has been influenced by these four types of criticisms.

The second section describes a particular collaborative research action project in which I am involved that centers on

The research reported in this chapter has been supported by grants from Spencer Foundation and the Center for Urban Educational Research and Development, University of Illinois at Chicago. The views expressed are solely the responsibility of the author.

I wish to acknowledge the helpful advice and feedback I received on an earlier draft of this work from Vicki Chou, Micky Donahue, Fran Falk-Ross, Annette Henry, Celia Oyler, Bill Schubert, Tim Shanahan, and Steve Tozer. Of course, I am responsible for any leftover errors. I am also indebted to my other university research collaborators on our project—Diane Escobar, Shannon Hart, Jane Liao, Linda Montes, Caitlyn Nichols, Dian Ruben, Hank Tabak, and Liliana Barro Zecker.

urban elementary teacher researchers' attempts to change their literacy curriculum so that it realizes the aims of what Willinsky (1990) has called the "New Literacy." More specifically, these efforts consist of teachers redefining literacy by studying their roles and instructional interactions to make reading and writing more connected and meaningful to the real lives of their students. After covering the theoretical background of the project, various methodological techniques that we have employed—mostly in collecting data—are described so as to illustrate more generally the range of approaches being used in many collaborative projects. Then, there is a special focus on how videotaping has been used as a methodological instrument in our study to examine together the classroom interactions in our collaborative action research.

The third section identifies important ongoing issues and challenges for school–university collaborations. Since one cannot write a "methods" chapter without addressing the traditional research conventions of validity and reliability, changes in these two concepts are discussed first, and then two issues of representation are considered.

SECTION 1: CHANGING PERSPECTIVES REGARDING POWER AND KNOWLEDGE: THE DEVELOPMENT OF COLLABORATIVE ACTION RESEARCH

Changing Voices in Educational Research

Changes in power and knowledge exemplified in school–university collaborations are frequently expressed as finding, gaining, hearing, or creating *voices* (e.g., Gitlin & Russell, 1994; Miller, 1990; Richardson, 1994a; Schratz, 1993). Bakhtin's (1986) conception of 'voice' provides a useful initial frame to examine the kinds of relationships that are developed in these collaborative arrangements.

'Voice' is Bakhtin's notion for the "speaking personality, the speaking consciousness" (Holquist & Emerson, 1981, p. 434). Indeed, for Bakhtin, utterance (his term for text or the *real unit* of speech communication [oral or written]) exists only by being produced by a voice. Voice, here, is a point of view that always enacts particular social values by addressing—or being in dialogue with—other voices (Cazden, 1992; Wertsch, 1991). And, because language is fundamentally dialogic in that we use and create language by speaking with others, any new instance of use is entwined with other previous uses and voices. There is, then, *conflict* in this process—in Bakhtin's (1981) words, "[Language] is populated—overpopulated—with the intentions of others. Expropriating it, forcing it to submit to one's own intentions and accents, is a difficult and complicated process" (p. 294).

In such a view, because our language is already used and reflects previous *and* present speakers, the finding of our voice also involves hearing the echoes of others (Burbules, 1993). This may explain why the challenge of *altering* the traditional relation regarding power/knowledge between educators in universities and schools has been so distinctive

and also so difficult in collaborative ventures. These enterprises represent new ways to conduct educational research that are marked by attempts to develop a climate of open participation by partners so that the dialogue between them is one of discovery and exploratory, but frequently marked with uncertainty. Thus, there is a commitment to "see things through," and, despite the conflict the effort entails, a struggle to ensure that *all* voices are heard and valued.

Challenges to Traditional Educational Research

Most of traditional educational research—with its dichotomized stance on 'theory and practice'—has emphasized the view that researchers from the university produce the theoretical background for all and any educational innovation (Altrichter, Posch, & Somekh, 1993; Burbules, 1993; Carr & Kemmis, 1986; Cochran-Smith & Lytle, 1990, 1993; Gitlin & Russell, 1994; Lytle & Cochran-Smith, 1992). In such a hierarchical process, changes occur according to what has been termed a *technical rational view*, which has three major assumptions: that there are general solutions to practical problems; that such solutions can be developed outside of particular, practical classroom situations (that is, in university or other research or administrative centers); and that these solutions can then be translated into the teachers' actions in the classroom through training, publications, or administrative directives (Altrichter et al., 1993; Schon, 1983, 1987, 1991; Wells, 1994b). Clearly, in this "outside-in" assumption that sees knowledge for teaching being generated at the university and then used in schools (Cochran-Smith & Lytle, 1993), the *voices of teachers*—their speaking personalities or consciousnesses, their points of view, in Bakhtin's sense—have been missing. According to Gitlin (Gitlin, 1990; Gitlin et al., 1992), traditional educational research rarely involves a level of question-posing from teachers. As a result, this research silences teachers-as-subjects and "strengthens the assumptions that practitioners do not produce knowledge, that their personal knowledge is not useful" (Gitlin, 1990, p. 444). Little opportunities are available for teachers-as-subjects to play any role in the research process (Agar, 1980).

In the past couple of decades or so, different questions have been posed in educational research (Apple, 1993; Gitlin, et al., 1992; Ladwig, 1991; Noffke & Stevenson, 1995; Richardson, 1994a, 1994b): Who owns knowledge in education? Who benefits from research? To answer these questions, criticism of traditional educational research has been great, and embodied in this challenge are many influences that have contributed to the development and nature of school–university collaborations. I very briefly cover four of these influences: (1) the movement from quantitative to more qualitative studies and methodology; (2) critique from humanistic psychology and feminist theories on research; (3) the strong movement of teacher research; and (4) the increased emphasis of socioconstructivist or sociocultural views of learning.

Emphasis on Qualitative Research. Consideration about who owns knowledge in education and benefits from research has led to the view that alternative approaches in

educational inquiries have to emphasize the importance of meaning *in context* (Mishler, 1979). According to Schratz (1993), many researchers have been disturbed that educational research, based on positivist models and quantitative measures, has led to too much 'noise reduction.' In his words:

[V]ariables, experimentation and operationalization usually [transfer] the original 'voices' of its research subjects into statistical data, mathematical relations or other abstract parameters. Therefore, very little is left of the social context in which educational practices occur. What is left over represents the 'noise' in the transmission of data and is reduced to its minimal disturbance in the research process. Thus the original voices from the field become the disembodied voices in the discourse of quantitative research presented through reports, articles and books. (p. 1)

The applicability of quantitative, experimental methodologies to educational settings has been questioned because too often they restrict the researcher's attention to short-lived events, isolated variables, and a very narrow range of meanings. Such a research product, therefore, provides an extremely simplified picture of a complicated classroom reality (Oja & Smulyan, 1989). Moreover, because it necessitates that conditions of the experiment be kept constant, which conflicts with a teacher's needs to modify and improve the so-called 'treatment' throughout the research process, the usefulness of the research for teachers to inform their future practice is also limited (McCutcheon, 1981) or even antieducational (Torbert, 1981). In short, traditional educational research uses instruments of doubtful ecological validity (Walker, 1993).

Thus, new qualitative approaches in educational research—ranging from ethnographic studies, naturalistic inquiry, or case studies to more recent enterprises such as action research, biographical analyses, and profile studies—have been developed to study the context of classrooms and schools, which are the settings that constitute teachers' realities. Using techniques to minimize interference or disturbance, researchers attempt to study and understand the actual lived experiences of education. Even within these qualitative paradigms, reconceptualizations have emerged because the theory and methods in these fields—from which educational researchers have typically drawn on—have been reconsidered. For example, in anthropology, the traditional picture of the ethnographer as an objective, authoritative, politically neutral observer who is above and outside of the phenomenon being studied has been replaced with one where the ethnographer is seen as always being historically and culturally situated (Bruner, 1993). This means that because subjectivity is an integral component of all aspects of the research process, it has to be identified and acknowledged throughout (Peshkin, 1988; Reason, 1994b; van Maanen, 1995).

Ideas from Humanistic Psychology and Feminist Theories. The purpose of newer qualitative approaches is to change the nature of educational knowledge by admitting the emotive and frequently the more vexing qualities of individuals into the research process. This focus on *persons* has its roots in humanistic psychology (Reason, 1994a). For example, Heron and others (Heron, 1981a, 1981b, 1992; Rea-

son, 1988; Reason & Heron, 1986) have argued that traditional research methods in the social sciences are just not adequate, appropriate, or relevant for the study of persons, who are self-determining. That is, because such an approach excludes human subjects from the various facets of the inquiry process, including the knowledge of its outcomes, it cannot make any valid claim as a science of persons. For example, Heron (1981a) has argued:

[P]ersons, as autonomous beings, have a moral right to participate in decisions that claim to generate knowledge about them. Such a right ... protects them ... from being managed and manipulated. ... [T]he moral principle of respect for all persons is most fully honored when power is shared not only in the application ... but also in the generation of knowledge. (p. 155)

Thus, such a view argues that since participants in educational research are authors of their own intentions, choices, and actions, methods must be used to respect such agency in the generation of knowledge.

A similar stance is offered by feminist theories, many of which take seriously Foucault's (1980) notion of power-knowledge and how discourse is organized by sets of understandings that legitimate particular social attitudes and practices (Fairclough, 1992; Gore, 1993). As Luke and Gore (1992) argue, "A poststructuralist feminist epistemology accepts that knowledge is always provisional, open-ended and relational" (p. 7). This is because knowing is always a contextual matter—it is located in a historical and cultural context, and for that reason, there can be no finite or unitary truths. Moreover, there is an acknowledgement that this social inquiry is value laden (Lather, 1992; Neilsen, 1989).

Cameron, Frazer, Harvey, Rampton, and Richardson (1992) offer three major characteristics—which are similar to those of Heron's above—of what they term as 'empowering research.' The first argues that persons should not be treated as objects. That is, empowering research is research *with* subjects by seeking their active cooperation; it is always attempting to make research methods be more open, interactive, and dialogic. The second point argues that subjects have their own agenda, and therefore research should try to address them. Finally, the third argues that in the research process there should be efforts to give feedback to, and share knowledge with, subjects.

Teacher Research. Although the concept of teachers reflecting on their practices to construct their own theories of teaching and learning can be found as early as Dewey (1904) and Lewin (1948), the more current notion of teacher as researcher is most frequently traced to the idea of "action research" characterized in the work of Stenhouse (1985) and others (Elliot, 1985, 1991; Nixon, 1981).

Cochran-Smith and Lytle (1990, 1993) define teacher research as systematic, intentional inquiry by teachers. It is *systematic* in that there are ordered ways of gathering and documenting information or experiences in a written form, as well as ordered ways of recollecting, rethinking, and analyzing classroom events (for which there may be only partial or even unwritten records). Although insights can always be gained through more spontaneous teaching-learning activities,

teacher research is an *intentional*, planned endeavor. Finally, it is *inquiry* because it emanates from, or generates questions about, classroom events, and involves reflection by teachers to make sense of their experiences. There is a “Researching” (Berthoff, 1987)—looking and looking again at what happens in the classroom; it is taking on a learning stance toward classroom or school life.

Cochran-Smith and Lytle (1993) claim that knowledge for teaching promoted by teacher research is “inside/outside” and is intended “to call attention to teachers as knowers and to the complex and distinctly nonlinear relationships of knowledge and teaching as they are embedded in the contexts and the relations of power that structure the daily work of teachers and learners in both the school and the university” (p. xi). Thus, teacher research promotes a new, distinctive way of knowing of teaching, one that privileges teachers as those who have the authority to know—“to construct Knowledge (with a capital K) about teaching, learning, and schooling” (p. 43). Here, then, there is no need to “translate” findings in the traditional educational research sense, for teacher research is steeped in praxis (Lather, 1986a); it is critical reflection *on* practice (Noffke & Stevenson, 1995).

Some argue that there are alternative paradigms available for the teacher researcher (McCutcheon & Jung, 1990), and that there is a typology of forms possible in teacher research (Cochran-Smith & Lytle, 1993). Nevertheless, advocates of teacher research argue that not only does teacher research provide useful knowledge for teachers themselves or their own schools, it also generates knowledge for the larger educational community by contributing greatly to the general knowledge base for teaching (Cochran-Smith & Lytle, 1993; Duckworth, 1987; Hollingsworth & Sockett, 1994; Watt & Watt, 1993; Wells, 1994b).

Socioconstructivist and Sociocultural Views of Learning. Through their own research, teachers often inquire with their students, thereby enabling these students to be also empowered as knowers. Indeed, the notion of learners as active meaning makers, and learning as a fundamentally social and constructive activity, are concepts that have challenged traditional curriculum, teaching, and learning, as well as traditional educational research.

These ideas argue against the traditional curriculum, a model that Freire (1972) has criticized as the “banking concept of education,” where knowledge is seen as deposits into the heads of learners who are thought of as empty vessels. The kind of teaching–learning relationship being promoted here, then, is not one of transmission and reception, but instead is realized through collaborative interaction. As such, it also questions an individualistic conception of learning by emphasizing that learning activities take place not *within* individuals but in transactions *between* them (Wells & Chang-Wells, 1992). Thus, it reflects a sociocultural theory based on Vygotsky’s (1962, 1978) view of learning that has been extended by others (Gutierrez, 1994; Moll, 1990; Newman, Griffin, & Cole, 1989; Wells, 1994a; Wertsch, 1985, 1989, 1991). From such a perspective, the teaching–learning relationship represents the coconstruction of meaning and knowledge in which the teacher shares his or her expertise to

guide and assist learners to construct their own. As Kreisberg (1992) has articulated it, there is an emphasis here of power relationships as being *power with*, not *power over*.

School–University Collaborations as Collaborative Action Research

Challenges to traditional educational research have originated from many fronts. The four I have briefly sketched have contested and interrupted common views of power/knowledge and theory/practice, and these changes have provided a foundation on which many school–university research collaborations have been, and can be, built. Emphasis on keeping true to the personal, original voices in educational contexts has led to more qualitative approaches. Such interpretive orientations aim to be “empirical without being positivist; to be rigorous and systematic in investigating the slippery phenomenon of everyday [classroom and school] interaction and its connections, through the medium of subjective meaning, with the wider social world” (Erickson, 1986, p. 120). Humanistic psychological views and feminist theories have argued that participants in such endeavors need be more involved and considered throughout the whole process of research. Socioconstructivist/sociocultural views offer new conceptualizations about how teachers and students might work together so that knowledge can be seen as their joint construction of meaning (Miller, 1992; Oyler, 1993; Wells, 1994a; Wells & Chang-Wells, 1992). This classroom collaboration between teachers and students represents a constant struggle after our long-lasting transmission-oriented tradition in schooling. And, although the teacher–student collaboration in the classroom has not always been very explicit in the writings of collaborative studies, there is a *parallel* effort being enacted between participants in most school–university partnerships (Oyler & Pappas, 1992, also in preparation). To understand how teachers make sense of teaching and learning—to acknowledge and value their ways of knowing—fundamentally changes the discourse about theory and practice. Indeed, as van Manen (1990) argues, “We need to invent a concept of pedagogical reflection and action that effectively blurs and blocks the idea of the theory–practice relation” (p. 154). Such an enterprise rests on new assumptions about power/knowledge relations between school- and university-based researchers, and attempts to develop methodologies to empower these voices in research projects.

Currently many of these more recent partnerships are considered—either by name and/or by nature—to be collaborative action research. A general aim of collaborative action research (CAR) is the modification and elaboration of theories of teaching and learning. This research can take different forms, depending on the purpose of particular projects and the ways in which teachers or other school personnel are involved. However, according to Oja and Smulyan (1989), there are four major characteristics that CAR projects have in common. (Only a brief description is possible here—see Adelman, 1993; Kyle & Hovda, 1978; Oja and Smulyan, 1989, for more detailed and historical discussions.)

First, of course, CAR is *collaborative in nature*. That is, it permits mutual understanding among the participants through democratic decision making for some common action. There is an emphasis for both teachers and university researchers to work together to set common goals, plan the research, analyze data, and report results.

Responsibilities and roles are determined together, which may shift during the course of a project, but teacher- and university-researchers contribute their own knowledge and insights to the process. There is an assumption that participants communicate frequently and openly to prevent any possible conflicting perceptions stemming from their different social networks, values, expectations, and so forth, and to encourage and support teachers' ongoing practice and responsibilities.

Second, and obviously, CAR projects *focus on practice*. Most of the time CAR addresses the immediate problems defined by participating teachers. Sometimes, university researchers may have a particular issue or topic of interest for consideration and invite teachers to participate with them in investigating it. Or, teachers or a school may identify the problem and ask for university researchers' collaboration to help examining and studying it. Nevertheless, within each framework, there is a teacher-as-researcher emphasis of some kind.

Third, CAR enhances teachers' *professional development* by supporting or providing the impetus to improve and change their classroom practice. Through CAR they construct new knowledge to deal with their immediate difficulties, expand their professional knowledge, and acquire research skills for future teacher inquiry.

The last characteristic of successful CAR stresses the need for a *project structure* that enables the above three elements to occur. This structure requires: regular and open communication among participants; democratic project leadership; recurring cycles of planning, acting, observing, and reflecting; and positive relationships with the school or schools in which the project is conducted.

In the next section more specific methodologies are addressed by describing a particular collaborative action research project that focuses on changes in literacy teaching and learning in urban schools.

SECTION 2: AN EXAMPLE: STRUGGLES TO TRANSFORM LITERACY CURRICULUM GENRES TO PROMOTE NEW LITERACY GOALS

Theoretical Background of the Project

Our school-university research project involves collaboration with a small group of elementary teachers in two Chicago schools (8 in one school; 6 in the other) who have been attempting to develop literacy practices that are more "holistic" and student-centered. Thus, their approaches have involved moving away from transmission-oriented curriculum by adopting more socioconstructivist and sociocultural views of teaching/learning, as noted in Section 1. A major focus of

these teachers' struggles to be agents of change in their classrooms has centered around their questions of when and how to share authority and power with their students, most of whom are poor and who come from various ethnolinguistic backgrounds. That is, as these teacher researchers have begun to utilize a more collaborative style of teaching, they have grappled with new ways to fashion instructional interactions so they can share their expertise, but at the same time foster and facilitate children's active construction of their own knowledge and expertise (Kreisberg, 1992; Martin, 1993; Wells & Chang-Wells, 1992). Thus, as indicated in the introduction of the chapter, their inquiries involve efforts to implement "New Literacy" curriculum (Willinsky, 1990)—to make reading and writing more personally meaningful and powerful by connecting these processes to the real lives of students. In Willinsky's words:

The New Literacy speaks directly to teachers reasserting control over the work that goes on in the class, even as it attempts to hand a greater part of the locus of meaning over to the student. It represents a taking hold of the curriculum by the teacher at a fundamental level by challenging the meaning of literacy in the classroom as well as the nature of a teacher's work with the students. (p. 18)

In our project the study of these changes has centered around the analysis of classroom discourse. Classroom discourse is the medium by which most teaching takes place and in which students demonstrate to teachers much of what they have learned (Barnes & Todd, 1995; Cazden, 1986, 1988; Christie, 1987, 1989; Edwards & Westgate, 1994). As Lemke (1985a) has stated it, "Classroom education, to a very large degree, *is* talk: it is the social use of language to enact regular activity structures and to share systems of meaning among teachers and students" (p. 1).

Thus, this is a social-semiotic perspective (Halliday, 1978, 1993; Halliday & Hasan, 1985; Lemke, 1990; Young, 1992) that focuses on how these various educational routines are structured and shift during a school day. That is, these shifts in activities or routines are encoded in behavioral patterns, as well as through changing, corresponding linguistic patterns to express these different classroom meanings (Bloome & Bailey, 1992; Erickson & Shultz, 1977; Green, Kantor, & Rogers, 1991; Santa Barbara Classroom 1992). Using a term suggested by Christie (1987, 1989, 1993), I have called these demarcated event/participant structures or routines "curriculum genres" (Pappas, 1990, 1991, in press). That is, particular curriculum genres are particular activity structures, that is, each curriculum genre represents a socially recognizable sequence of actions that realizes particular meanings or purposes for teachers and students in the overall classroom curriculum. Thus, a curriculum genre, as an "action genre," is analogous to Bakhtin's (1986) idea of "speech genre."

Classroom discourse studies have indicated that most of the typical classroom talk in curriculum genres has properties that make it quite different from talk in most other settings. First, this talk is dominated by teacher questions, typically a certain kind of questions termed "pseudo" questions—ones for which the teacher already *knows* the answers (Dillon, 1994; Edwards & Mercer, 1987; Ramirez, 1988; Shuy, 1988;

Young, 1992). Second, these questions are frequently embedded in a characteristic initiate-respond-evaluate (IRE) talk structure that is controlled by the teacher (Cazden, 1988; Edwards & Mercer, 1987; Lemke, 1990; Sinclair & Coulthard, 1975; Young, 1992). In this IRE pattern, the teacher *initiates* a sequence or interaction by calling a child to respond, then the nominated child *responds* to the initiation or question posed by the teacher, and finally the teacher *evaluates* what the child has said before calling on the next child, and on and on. This IRE structure is the essence of traditional transmission-oriented education.

Children have unique personal characteristics, and in urban schools they come from a variety of cultural and linguistic backgrounds, which means that they also bring their own complex "ways with words" to classroom interactions (Heath, 1982, 1983; Lindfors, 1987; Michaels, 1981; Philips, 1972, 1983). The traditional IRE talk structure, with its strict teacher-dominated, turn-taking format, has been shown to affect minority students' learning adversely because it does not provide many opportunities for negotiation or consideration of these children's styles of interaction (Au & Jordan, 1981; Delpit, 1988, 1992; Foster, 1992; Heath, 1983; McCollum, 1991; Michaels, 1981; Philips, 1972, 1983; Reyes, 1991, 1992).

What is central in the present project, then, is how these urban teachers are trying *alternatives* to these IRE patterns to realize New Literacy ideas. By giving their students more control of their own literacy learning, they are attempting to transform literacy curriculum genres so that both teacher and student "voices" are privileged in collaborative transactions. Thus, struggles to develop curriculum genres that accommodate for diversity in this complex way are at the root of these teacher researchers' change.

Methodologies for Collaboration

Methodologies in our school-university collaboration have evolved over our almost 6-year partnership. My relationship with the teachers at the two schools began in 1989, the year when I began teaching at the University of Illinois at Chicago. This was also the year when Chicago Reform was initiated where school personnel at each Chicago public school worked together with its Local School Council to develop a Fifth-Year Plan. Teachers in the two schools sought me out for collaboration as they began to implement their respective plans, which called for their reexamining their language and literacy curriculum to make it more "holistic."

Throughout the years a small group of teachers from each school and I would meet regularly to discuss their inquiries about their struggles to enact collaborative styles of teaching literacy. As I had time, I would also observe in their classrooms, audiotape interactions in various curriculum genres, and write up fieldnotes that I would share with the teachers to promote ongoing investigation and discussion. Finally, external research support enabled us to extend this collaborative action research in a more systematic way. By using videotaping and other ethnographic techniques, we have been attempting to document the *process* by which urban elemen-

tary teachers develop culturally and linguistically responsive literacy pedagogy. However, I will concentrate mostly on what has been employed during the past school year (1994-95), which has been mostly a "data collection" year, to be followed by a year of our transforming, and writing up these data together. The purpose here is not to set forth some kind of methodological "ideal," but instead to be illustrative of some of the typical techniques that are being used in collaborative ventures. Moreover, my aim is not to be exhaustive in citing, or referring to, other projects, so those that are mentioned reflect the ones that have most informed our work.

Journals. In our study, teachers determine and choose the area—the curriculum genre—in which they do their literacy inquiries. In the fall I gave them a form that asked them what they would be studying during the year—the major questions they would be attempting to address in their inquiries, when they would be "doing" the inquiries, and in what initial ways we could help or support their inquiries. I also encouraged them to use their own private research journal, which is quite a common tool for reflection and documentation in collaborative work with teacher researchers (Clandinin & Connelly, 1991; Connelly & Clandinin, 1988; Miller, 1990; Stevenson, Noffke, Flores, & Granger, 1995). Because only some of the teachers had previously kept a journal, I shared with them the chapter of Altrichter et al. (1993) on "The Research Diary," which provides a rationale and useful suggestions for using one.

Many collaborative projects also use dialogue journals (Clandinin, 1993; Miller, 1990; Robinson, 1994; Stevenson et al., 1995), sometimes in addition to the private journals kept by teachers, where university- and teacher-researchers correspond back and forth to (and among) each other. This is particularly frequent when there is also a professor-student relationship present in the collaboration (e.g., see Gitlin's [Gitlin et al., 1992] Educative Research project that is part of a Cooperative Masters of Education Program, and Wells' [1994b] graduate courses on "Action Research in Language and Learning").

In our project teachers sometimes spontaneously refer to entries they have noted down in their journals during our weekly school meetings, and at our individual end-of-the-year interviews with them, they more purposefully consulted them (as well as their fieldnotes—see below) to talk to us about what stood out for them during the past year regarding their inquiries. Next year, as we begin to write up the past year's research, I expect that teachers will rely on these journals more in their further analysis, interpretation, and reflection of our collaborative research. Thus, journals—either private or dialogue—represent an important resource in collaborative research, as well as valuing of teachers' knowledge and voice in the process of research.

Fieldnotes. Another feature of many collaborative projects involves observations in particular teachers' classrooms by others—other teachers or outside university personnel—that are recorded through fieldnotes (Clandinin & Connelly, 1991; Connelly & Clandinin, 1988; Hollingsworth, 1994). In our project, three 2-member teams of university research-

ers—one at each of the two schools and one who worked in the four bilingual classrooms at both schools—completed the fieldnotes, which usually complemented videotaping records. Because I was in *all* of the 14 teachers' classrooms regularly to observe their inquiries (and several of the teachers had two inquiries), and could not manage in any practical way regularly to write up in-depth fieldnotes, I developed shortened versions of fieldnotes that I called "Summary/Queries." Instead of providing rich description and comments of what I saw or heard, which is what the other university researchers did, I provided a brief summary with perhaps a pertinent example or two of interaction and then posed questions or provided other comments for the teachers to consider relative to their inquiries. As I observed, I might have also thought of an article or book that could be helpful in a particular teacher's thinking about the problem or issue he or she is presently tackling, and I might have added a note that I would soon be bringing in that resource for his or her consideration. The teachers have reported that both of these versions of fieldnotes have been extremely invaluable in their inquiries.

Of course, writing fieldnotes has been a mainstay of ethnographic and qualitative research, but what is different in collaborative studies is that these fieldnotes are shared with teachers in an ongoing way. That is, unlike noncollaborative ethnographies where the researcher "keeps" the fieldnotes and rarely ever discloses them with the "subject(s)" of research, the purpose of observation here is to give feedback and support on what the teachers are attempting to accomplish in their inquiries.

In our case, then, one of our major university-researcher roles in our collaborative project was to observe (and videotape—see the next subsection) classroom activities and interactions in the various curriculum genres that constituted the teachers' inquiries. Therefore it was important that the teachers received our (my and other university researchers') fieldnotes of these observations as quickly as possible.

The university personnel were prepared for this task by reading and examining various perspectives on fieldnotes in qualitative research (Bogdan & Biklen, 1982; Delamont, 1992; Patton, 1990). We worked on devising a general framework that we could all follow but that still allowed for openness for our different styles. That is, we recognized that there is no such thing as "pure" description since "doing" fieldnotes is "the very act of constructing *data* out of *experience*" (Wolcott, 1994, p. 13).

Although I had anticipated that the past year of the project would mostly consist of "gathering data," the documentation of classroom life and talk could not be seen as *merely* description because some aspects of ongoing analysis and interpretation by all of us—university- and teacher-researchers—would be required to understand and support the course of the teachers' investigations. Thus, we also relied on Wolcott's (1994) recent suggestions on description, analysis, and interpretation of qualitative data to keep our use of fieldnotes (and other kinds of data) in a larger perspective during the past year.

This practice of sharing of fieldnotes (and other data gathered by different techniques) in an ongoing fashion is

distinctive in collaborative projects. It is also similar to methods employed in school profile studies in England (Rudduck, 1993) where outside researchers do fieldwork and rapid reporting on a topic or "area of significance" (Walker, 1980) that is identified ahead of time by a particular school. This approach also shifts the notion of the outside researcher as the prime interpreter of the data to the school audience—who was also the sponsor and subject of the research. Sometimes some version of this approach (but usually done by outside researchers *with* school personnel) is used as the initial phase in a longer project to identify the topic(s) to be studied in the latter phases by the collaborative school-university team (e.g., Oja & Smulyan, 1989).

Regular Meetings. We had weekly meetings of the university- and teacher-researchers at each school (as well as several meetings with all of the teachers), which were also videotaped. At these meetings, edited classroom videotapes of one or sometimes two teachers were examined—see below for a more detailed account of these meetings.

Having regular meetings between university- and teacher-researchers where all talk about and examine issues relevant to the project is a very common feature in collaborative studies, and for some, transcriptions of these conversations consist of one of the major sources of data (e.g., Hollingsworth, 1994; Miller, 1990). Rereading of these transcripts enables the collaborative group to identify themes and consider new interpretations.

Individual Interviews/Conversations. We had many incidental and informal conversations throughout the year, some of which were audiotaped, some of which were captured as "additions" to fieldnotes if they had been recently related to something that had happened in the classroom regarding a particular teacher's inquiry. We (the respective university research team and myself) also had individual end-of-the-year interviews with the teachers about what stood out for them—both ups and downs—regarding their inquiries. They prepared in advance for these conversations by going through their journals and fieldnotes.

The use of individual interviews or conversations that serve as data resources is frequent in collaborative projects. Members of the collaboration team may interview other teachers or school personnel, parents, or students on a particular topic or issue (Bickel & Hatrup, 1995; Connelly & Clandinin, 1988; Oja & Smulyan, 1989; Rudduck, 1993; Watt & Watt, 1993), and then analyze and interpret these together. In our case, the interviews provided a means to get the teachers' perspectives on what they believed were the critical points of their inquiries.

Summary. I have tried to describe some of the methodological tools that we have employed in our project to illustrate the typical approaches of collecting data in various collaborative projects. These are not the only ones we used in our project (for example, teachers also had their own audiotape recorders and taped certain classroom interactions when we were not present), nor do I suggest by the above list that these are the only ones available in collaborative action research projects (for example, see Walker 1993 in the use of photo-

graphs). However, it is important to note that most collaborations use several techniques in the research process to provide triangulation, and that these methods are sensitive to *being* collaborative.

In some projects—like ours—university researchers have major responsibilities collecting data in teachers' classrooms; in others, university personnel—especially if they also have roles as professors in courses, or if they are leaders of professional development school projects—serve mostly as facilitators of teachers' action research, where teachers collect most of the data in their own classrooms. The arrangements in collaborative ventures are quite varied.

Using Videotape as an Instrument in Collaborative Action Research

As already noted, videotaping was a major tool of data collection in teachers' classrooms and documentation of our collaborative work. Two-member teams, who worked with the same teachers the whole year, did the classroom videotaping. One person in the team operated the camera, and the other took the fieldnotes. The duration of these videotaping sessions varied according to the length of the curriculum genres in which teachers had their inquiries—as short as 20 minutes or as long as over an hour long. If we had shown the entire classroom videotape recording, we would have had no time for examination or discussion at our weekly meetings. Thus, an edited version (usually 10–15 minutes long) of one or two teachers' classroom footage was shared at these meetings. Since we did not want university researchers to make all of the decisions on what should and should not be included in an edited videotape, we developed a form that asked for teachers' input. After each videotaping session in a teachers' classroom, they noted on this form the "good" parts and "vulnerable" parts that they thought would be important to include in the editing. Using that as a guide, and the fieldnotes that were taken to complement the videotaping (which, as I have already noted, were given to the teacher within a day or so after our visit), we selected several portions that we believed captured the focus of the teacher's inquiry to date. The teacher then shared the video in an "author's chair" fashion a week or so later. Also, we found it useful to provide a brief note, on which we listed short descriptors of the edited segments, for everyone at the meeting so that we could all better follow what would be shown.

Below we focus on Dorothy's sharing of her inquiry of her Teacher-Led Reading-Aloud Curriculum Genre. Excerpts are provided both of her edited tape of the classroom discourse for a particular day, and the meeting discourse between her, other teachers in the group at her school, and university researchers (the research team who had been working with her in collecting the data, and myself).

Several teachers at this school and the other had been doing inquiries in the Teacher-Led Reading-Aloud Curriculum Genre, but each teacher had a different focus and specific questions that he or she was investigating. In her previous teaching experience, Dorothy had always felt more comfortable in dominating the discussions about books. However,

the past year she had wanted to understand her 3rd-grade, mostly Mexican-American students' responses to the multicultural literature she had collected during the summer to share for the year. Thus, she had an important reason to examine and change the typical ways she conducted the reading-aloud routine so as to encourage more student initiation and response to these books.

In a recent article, Mehan (1993) tells why he has used videotape as an instrument in educational research. He states, "[C]ognitive skills don't reside in the heads of people, including children in schools, they reside in social situations which are composed of people..." (p. 94). This is a 'situated cognition' perspective (Lave, 1988; Rogoff & Wertsch, 1984) that emphasizes that student performance varies as a function of the situation in which they find themselves. Thus, videotape enables the researcher, Mehan argues, to listen and look at this social life in classrooms more closely than is otherwise possible.

What I want to stress, here, is how listening to discourse afforded by videotape permits *teacher researchers*, like Dorothy, to "see" critical dimensions of their inquiries. It helps them—in collaboration with others—interrupt and examine carefully the everyday routines of teaching–learning they have chosen to investigate.

Throughout the year, Dorothy had drastically changed her style of interaction by providing "spaces" for student initiation. Here, we will be focusing on the classroom discussion that was initiated by a student question as she read *Darkness and the Butterfly* by Grifalconi (1987), and then our subsequent examination of that episode in our weekly meeting conversation that occurred a few weeks later when Dorothy shared the edited version that included that classroom footage. Thus, two types of discourse are provided here: first, discourse from the meeting is provided, then classroom discourse from the videotape, followed by more on our discussion in our meeting.

In our meeting that day we had already seen other segments of the videotape. Now we were noting on our editing sheet that the next part had to do with a boy's interruption of Dorothy's reading by asking, "Is that a poem?" I had been in the classroom that day, too, and I was recalling—before we had as yet viewed this particular videotape segment—my impression of it. (Present at the meeting that day were teacher researchers Dorothy, Hawa, Sonia, and Sue, and university researchers Chris, Diane, and Shannon.) Table 1 presents the explanation of transcription conventions.

Chris: This was really great in lots of ways. Again there's the notion of intertextuality cause they were talking about things they did on poetry. But it doesn't get to—-you didn't ask the kid "well why did you think..."

Dorothy: I see, I did ask [pointing to the video screen]—-somebody said it was a story though, so I moved it which kind of didn't make sense, but...

Chris: Which is okay, too. We should listen to it.
{Weekly Meeting, March 29, 1995}

Initially I brought up the idea of intertextuality as it occurred in the classroom discourse as I remembered it. "Intertextuality," as we have been using it in our project,

TABLE 18-1. Conventions of Transcription

Unit:	Usually corresponds to an independent clause with all dependent clauses related to it (complex clause or T-unit). Sometimes includes another independent clause, if there is no drop of tone and was added without any pausing. Units here are punctuated as sentences.
Turn:	Includes all of a speaker's utterances/units.
Key for Speakers:	First name is listed for university- or teacher-researcher. C, C1, C2, etc., are noted for individual children (with "m" or "f" to refer to the gender of a child): C is used if a child's voice cannot be identified; Cs represents many children speaking simultaneously.
--	False starts or abandoned language replaced by new language structures.
..	Small/short pause within unit.
... ..	Longer pause within unit.
...	Breaking off of a speaker's turn due to the next speaker's turn.
< >	Uncertain words
(***)	One word that is inaudible or impossible to transcribe.
(*** ***)	Longer stretches of language that are inaudible and impossible to transcribe.
<u>Underscore:</u>	Emphasis.
# #	Overlapping language spoken by two or more speakers at a time.
CAPS	Actual reading of a book.
{ }	Teacher's miscue or modification of a text read.
[]	Identifies what is being referred to or gestured and other nonverbal contextual information.
....	Part of a transcript has been omitted.

follows Bloome's (Bloome & Bailey, 1992; Bloome & Egan-Robertson, 1993) and Lemke's (1985b) ideas on the topic. When teachers leave "spaces" for student initiation, children frequently make intertextual links in the classroom discourse; that is, they connect other books, songs, movies, prior curricular information they have studied, personal stories from their home and community, and so forth, with the topic being discussed. According to Bloome, for these student offerings to be considered as instances of intertextuality, they must be proposed, recognized, acknowledged, and have social significance for the participants. Thus, intertextual links that begin from student initiation are characteristic of collaborative talk, which is something that Dorothy and the other teachers in the project are attempting to promote.

As you will see in the following excerpt, when the student asked about whether the book was a poem, the students, who had some earlier curricular experience regarding poems, had brought in their own ideas about the characteristics of them, mostly to argue that the present book was not a poem, but a story.

[Dorothy is reading about the part of the book where Osa, who is a girl who afraid of the dark, is talking to the Wise Woman, who is trying to help Osa overcome her fear. A boy in the back of the room raises his hand. Dorothy acknowledges him and he asks a question.]

Dorothy: ... "BUT LOOK AT THAT LITTLE BUTTERFLY, OSA; SHE MUST THINK SHE IS THE SMALLEST OF THE SMALL. DARKNESS PURSUES HER TOO--YET *SHE* FLIES ON!" SLEEPILY, OSA THOUGHT ABOUT THAT. "MAYBE SHE HAS A SECRET?" {AND} THEN SHE SHOOK HER HEAD. "BUT I HAVE NO WINGS TO FLY." OSA HEARD THE WISE {WOMAN CALL FORTH}: "YOU WILL FIND YOUR OWN WAY. YOU WILL SEE." OSA NODDED, AND BEFORE SHE KNEW IT, SHE FELL INTO A DEEP SLEEP. ...

Cm1: That's a poem?

Dorothy: Pardon me?

Cm1: That's a poem. Or is that a poem or is it a story?

Dorothy: Is this a poem or is it a story? What do you think?

Cm1: # A story. #

Cs: # Story. #

Dorothy: Why do you think it's a--excuse me, why do you think it's a story? Who else thinks it's a story?

Cs: [About 9 kids raise their hands.]

Dorothy: Cm2, why do you think it's a story?

Cm2: It doesn't have things(?) that rhyme.

Dorothy: It doesn't have very many rhyming words.

Cm2: It doesn't have stanzas.

Dorothy: It doesn't--it's not written in stanzas, good.

Cm3: It doesn't have four lines...

Dorothy: Okay, do some stanzas have four lines? Do all stanzas have four lines in a poem?

Cs: No.

Dorothy: No, do all stanzas have rhyming words?

Cs: No.

Dorothy: Is it too long?

Some Cs: # Yes. #

Some Cs: # No. #

Dorothy: Well, we haven't read very long poems, I agree. But poems can be very, very long. They can be longer than a story. (***) Do you think this story could be made into a poem?

Cs: Yes.

Dorothy: Probably so, probably so.

{Edited videotape shared March 29, 1995 from classroom videotape, March 1, 1995}

Actually, although the author/illustrator of the book, Grifalconi has written this book as a story, she has also included poem-like qualities in it, both in its format and in its lyrical phrasing. So, Cm1's question was probably a very reasonable one. And, the idea that there were not any stanzas in the book is not really accurate because the text was written in a stanza-like fashion—with each line beginning with a capital letter, for example. However, this was probably not very noticeable to the students since usually there was only one "stanza" per page and they would not have been able to see the punctuation from their seats.

Dorothy has subsequently looked at this book and the student's question about it quite differently since we have examined it in our meeting, but here in the upcoming excerpt of the meeting discussion her attention is on other facets of the interaction.

Diane: I thought that was a really good wrap up question, "Can this be made into a poem?" And all the kids answered, "Yeah, sure."

Dorothy: Well they did--they did kind of do a little bit of that when we kind of went in and out of poetry. I couldn't

get them to come up with a poem. We had a theme to send to the dental week or something and they just...

Chris: [facing Dorothy] See, it's just that the kind of conversation would have been quite different if you had said, "Tell me why did you—what makes you say that, what makes you think that this might be a poem?"

Dorothy: Mmm, I'm getting too direct here [pointing to the video screen]. The question is becoming looking for an answer instead of just a comment and let them go in what direction they—And I can hear that now, where I could never hear that, I mean, I wouldn't—I thought that was good! [As Dorothy talks, she waves her hand in front of her face as if to wave off her own lack of hearing herself before now.]

Chris: Yeah, yeah.

Dorothy: I mean I'm beginning to see that because you cut them off you're looking for yes or no, or the whole class responds...

Chris: Usually, yeah, usually there is a whole—yeah, there's a real clue when the whole class is going "yeaaaah" or "noooo" [lowers her voice and makes it long, like a mechanical answer, and the whole group laughs]. You know that "whoops, I'm definitely asking a pseudo question here!" But you know there's some points where that might be appropriate because you're trying to make connections to other kinds of instruction, you know.

Hawa: Or sometimes you get them when they say "yeah" and you ask them "why?" and they say, "uh, well, uh..."

Sonia: That's because they expect this, they expect...

Chris: Well, you know people call this procedural display and mock participation. In other words, kids know the routine but sometimes there's no—and lots of teachers accept that they've understood and it's really just surface procedures so people call it procedural display and mock participation. It's that IRE where the teacher does this, the kids say that, and teacher evaluates. It's the kind of thing that you guys are trying to challenge.

Sonia: It's hard...

Dorothy: It's hard, but it's neat though [pointing to the video screen]. It's hard too because—I think this is the first time that I've seen value in looking at my video. I can relate to things now and actually I heard that and it sounded awful. I mean just the kids says, "yesss" and before perhaps I would have thought, "Gee, isn't that good, they're all responding [sort of with an exaggerated smile as if to show how silly that was].

Shannon: And they all got the right answer.

Dorothy: And not even the right and wrong answer but just that they were...

Chris: Engaged.

Dorothy: [pointing to Chris] Yes, engaged. And somebody wasn't. Which isn't as good as...

Chris: Yeah, a kid could be looking over there [Chris turns in her seat to look away from the group] and said "yeah."

Dorothy: Right.

Chris: Well, maybe you can hear it because you have gone beyond in your inquiry in some way.

...[The discussion then changed topic to see and consider the last segment of the video.]

{Weekly Meeting, March 29, 1995}

There are two important, interrelated points I want to emphasize about this discussion. The first is that Dorothy had come to a critical understanding about her interactions with students in her inquiry. That is, she decided that what had been "comforting" to her or evidence of engagement in the responses of "yes" or "no" from students in certain classroom interactions is now problematic and indicative of mostly mock participation and procedural display (which I put a label to, drawing again from some ideas in Bloome's [1994] work) instead of more substantive meanings being developed. Thus, besides teachers making the effort to provide opportunities for students' initiations around books in classroom discourse, their learning best how to contingently respond to students' initiations to sustain and extend them is an issue in developing collaborative talk.

The second point is Dorothy's belief that there was great value in viewing the videotape of her classroom interactions because it enabled her to "hear" what she had not been able to hear before. Thus, she might have missed an important opportunity to respond to her student's question on this particular day in a way that might have contributed to her understanding of her students' understanding of this book, which was at the core of her inquiry. However, with the help of the videotape, she was given a chance to become more explicitly aware of what she has to do in the future to accomplish that goal in her inquiry.

Now, it might seem to readers of this chapter that I was extremely fortunate to have Dorothy's overt testimony on the value of videotaping as an important tool in her teacher inquiry, but many of the teachers have commented on its utility. In fact, it was teachers who had suggested its use in the first place, since they are unable to observe each other in their classrooms.

Moreover, although we had not expressly asked for it, several of the teachers discussed the advantages of the use of videotape in their inquiries in our individual end-of-the-year interviews. For example, in the beginning of her conversation with us, Hawa, who teaches second grade at the same school as Dorothy, listed what she saw as the "pluses" in her inquiry for the year, which also focused on the Teacher-Led Reading-Aloud Curriculum Genre. She stated that it had helped her better prepare for teaching—that is, she is now more aware how important it is to choose good literature and for what purpose. Moreover, it helped her think of sharing power with kids, since before then she had just wanted kids to listen to a book and afterwards to answer yes or no to the questions she had for them. Then she more specifically addressed how the videotape particularly contributed: "Another one was seeing yourself after you had—did a read-aloud ... seeing yourself on tape, saying 'ooh I did that,' or 'didn't do that,' or 'that was good,' or 'I liked that.' That's one of the positive things I liked about it, too."

Sarah, a colleague at the same school who taught a 2nd-grade bilingual class, also remarked on positive benefits of videotape. She felt that the sharing of videotapes promoted collaboration. She thought that it got the teachers in the group talking to each other at the meetings, of course, but also that it spilled over in that it fostered conversations about what they were doing among their group when they saw

each other in the halls, at lunch, or other times in school. Videotape, she also said, gave her "... 'a third eye' ... it gave me not only a resource but also an outlet ... to what was going on and what carried on. ... It makes everything self-conscious. ..."

In attempting to establish trustworthiness, qualitative researchers have frequently relied on videotape. For example, Lincoln and Guba (1985) comment on how videotape recordings (and cinematography) can provide the means to "capture and hold" episodes in the classroom that can later be examined and compared with other data, thereby furnishing referential adequacy for interpretations in studies. Certainly, videotape will serve this function for all of us in the research process in our collaborative project. But importantly, as I have tried to emphasize here, its utility from the teacher researchers' perspective is that videotape also directly informs their inquiries by enabling them to relive "being there," making it possible for them—actually, all of us who are attempting to document the changes—to interrupt, carefully examine, and transform their everyday routines in the classroom.

SECTION 3: ONGOING ISSUES AND CHALLENGES FOR COLLABORATIVE ACTION RESEARCH

There are many ongoing issues and challenges in present and future collaborative action research. However, here, I have concentrated on three, interrelated ones that have been especially relevant in our project, and are also likely to be pertinent in other collaborative school-university arrangements.

Issues of Validity and Reliability

Because collaborative action research involves an expanding notion of legitimate knowledge, teachers who have historically been silenced, now have opportunities to develop their voice. And, in telling their educational stories, they have the *right* to debate and challenge the authority of others—university researchers certainly, as well as business people and parents, and district and state policy makers. Thus, when the central purpose of the educational research process is to empower voice, concepts of validity and reliability have to be reconceptualized. For example, as Gitlin et al. (1992) argue, old views of validity have to be altered.

The validity or 'truthfulness' of the data can be understood no longer as something extracted by [a university researcher] armed with a set of research procedures, but rather as a mutual process pursued by [university- and teacher-researchers] ... that recognizes the value of practical knowledge, theoretical inquiry, and systematic examinations. The [university] researchers' knowledge is not assumed to be more legitimate than the [teacher researchers'], nor is their role one of helping the needy other. Rather, the researcher and [teacher researcher] attempt to come to a mutual understanding based on their own strongly articulated positions. (p. 27)

Thus, validity cannot be ignored, as Lather (1994) has recently argued, because "[it] is a 'limit question' of research,

one that repeatedly resurfaces, one that can neither be avoided nor resolved, a fertile obsession given its intractability..." (p. 37), but it has to be viewed differently from established renditions of it. In collaborative inquiry, all those involved are both *coresearchers*—everyone is involved in the thinking and decisions that generate ideas, manage the project, and come to conclusions about the whole research experience—and *cosubjects*—everyone participates in the inquiry enterprise that has been researched (Reason, 1994a). In such a reciprocity, validity has more to do with validating and developing insights among university- and teacher-researchers; it involves a dialogue on how to interpret data by considering alternative perspectives (Altrichter, 1993), or as Lather (1986b) suggests, it is 'catalytic validity,' which is the capacity of the research process to foster participants' knowing of their reality and urge them towards self-determined action. Thus, accomplishing a new rigor to promote a "validity of knowledge in process" (Reason & Rowan, 1981) is an ongoing challenge in collaborative action research.

Reliability has been seen in a new light as well. Naturally occurring situations, such as those found in classrooms, are very changeable. Moreover, the aim of collaborative action research is to disrupt the status quo by developing and putting into practice certain action strategies in the hope to change and improve it. Consequently, the traditional idea of reliability as a kind of "repeating the research," that is, the ability of different independent researchers being able to come up with the same conclusions by using the same procedures, is clearly problematic in collaborative research (Altrichter et al., 1993; Gitlin et al., 1992). When voice is the goal of research, it is not expected (indeed, nor even desirable) that team members of university- and teacher-researchers would initially come up with the same conclusions. Procedures have to be evolved in particular projects. As Gitlin, et al. (1992) argue: "Reliability ... cannot be based on duplicating procedures, but rather must center on attempts to satisfy the underlying principle of voice and its relation to a particular type of school change" (p. 28). Thus, because particular procedures cannot be applied unchanged from context to context, each collaborative project has its own challenge in developing its specific "reliability of voice."

Issues of the Representation of Teacher Researchers

It has been a practice to use pseudonyms for the names of participants (and their schools, communities, etc.) in educational research, and strong arguments have been lodged for the need to protect their identity (e.g., see Delamont, 1984, 1992). However, many teacher researchers, seeking recognition for their contributions in the collaborative work they do with university researchers, no longer want anonymity (although there are still others, who, due to the various circumstances teachers find themselves, do not wish to be so visible). In 1990, Shulman offered a useful discussion on the difficulties and ethical dilemmas that occur around this issue, especially on the vulnerability of teachers who forego anonymity and end up receiving disapproval and recrimination from their colleagues and administrators. Much more has to be

examined on this topic, but here I want to focus on tensions that arise around the issue of representation in writing up the work of collaborative school-university projects. Concerns are certainly present when the teachers are anonymous, but I will concentrate mostly when they are not.

Since 1990, it has become even more common to identify teachers in collaborative work, although it is done several ways. The cases where teacher researchers are authors of their own chapters within a book in which university researchers in the same project also have their own chapters and/or coedit the volumes are more straightforward. However, in other authoring situations, issues regarding the representation of teachers who wish to be identified are more difficult to sort out.

Any time a university researcher, who has a commitment to study and understand the perspective of an interacting individual, authors a text describing that individual, the sticky area of representation is evoked (Lincoln & Denzin, 1994). As Nespor and Barylske (1991) argue, representation is "not just a matter of epistemology or method, but a matter of power" (p. 806). When we (university researchers) represent others, there is always the potential to reduce them; that is, the relations of power in this discourse favor the representers (the university researchers) over the represented (the teachers we write about).

For example, many collaborative studies use narrative approaches in which interviews are gathered over time. Usually, the university researchers suggest an overall frame for the discussions, frequently identifying various topics, but for the most part teachers have considerable control over what they talk about and how they talk (see Cortazzi '1993' for a good review and critique of this approach and various schemes of narrative analysis). Once the interviews are transcribed, teachers are usually given these transcriptions for their review, elaboration, and clarification. Is this enough of a safeguard for the collaborating teachers when university researchers then write an article selecting quotes from these transcriptions—even when these quotes are long enough to give readers a good sense of these teachers' voices—to make theoretical points? (See Rudduck, 1993, for a discussion on issues regarding direct quotation.)

Or, how about me as the author of this chapter, writing about our project? I have checked with Dorothy and the other teachers about how I have written about them, but is this enough? (Dorothy O'Malley and the other teachers, Sarah Cohen, Hawa Jones, and Sonia Torres Pasewark, whose discourse is included in the excerpts have reviewed and have given me an okay on what I have written herein.) And, what about cases where university- and teacher-researchers are coauthors of a text, and presumably where the teachers have had ample opportunities to write segments of the text and to review other parts written by the university researchers? In these texts, there are genuine occasions to refer to the larger collaborative enterprise as a "we" experience. But, because such texts frequently focus on the teachers' experiences in their schools and classrooms, these teachers are usually written up in the third person. Is this just a more subtle way for the university researcher to inflate his or her control in the power relation with the teacher?

Thus, as Lincoln and Denzin (1994) state, "Writing the present is always dangerous, a biased project conditioned by distorted readings of the past and utopian hopes for the future" (p. 575). It is likely that there will be many instances where university- and teacher-researchers in collaborative action research will have constructed a common social network, and will have come to some consensus in the interpretations of the data of their projects—even if they have agreed to disagree or have included different perspectives. Nevertheless, it is also clear that much more work will be required on the problem of power and method in the production of academic discourse (Ladwig & Gore, 1994). *New* genres of discourse will need to be developed so that all participants' voices are realized in a democratic way, and undoubtedly this will be no easy task if we are reminded how hard it has been to include genres stemming from qualitative paradigms into educational research books and journals.

The Issue of Claiming Expertise Without an Authoritarian Voice and Its Implications in the Representation of University Researchers

There is another issue that is closely related to the issue of representation of teacher researchers. In many ways, it is the other side of the same coin for it considers university researchers' struggles to shed their authoritarian voices in collaborative arrangements, but at the same time their resistance to express the details of their part of the dialogue that they have with teacher researchers.

In the efforts to develop and leave "spaces" for the voices of teachers who have been historically silenced, there has been a tendency on the part of university researchers to draw back so as not to impose these outsiders' views too much. Yet, a "true" collaboration has to have both university- and teacher-researchers claiming their respective expertise in the research process (Oyler & Pappas, 1992, also in preparation). This is because in such a partnership there is an assumption that neither is more needy of the other, or that neither contributes knowledge to the collaborative process that is more legitimate (Gitlin et al., 1992; Treleaven, 1994). Too frequently, teachers sharing authority with their students have been conceived of as merely teachers moving away from the "hard place" of authoritarianism to the other side of the dichotomy, namely the "soft place" of abdicated authority (Oyler, 1996; Oyler & Becker, in press). Such a view does not regard this sharing of authority as the coconstruction of knowledge by *both* teachers and students. Thus, so as not to make the same mistake, university participants have to overcome their reluctance not to share their ideas or interpretations in collaborative inquiry.

That does not mean that in so doing, there would not be times when university researchers might go beyond their "claiming expertise" in their interactions with teacher researchers. For example, in the weekly meeting discourse provided in the previous section there were places where I shared my expertise, first by my asking her to reexamine her responses to the boy's question, since I thought it was so relevant to her inquiry, and then later when I brought up the

terms "mock participation" and "procedural display" to put a name on the phenomenon that Dorothy and the other teachers were recognizing *and* questioning in their practice. However, as I have reflected on my responses in this discourse with Dorothy, I felt that I might have cut her off a couple of times, and although I believe that my role is to ask questions for the teacher researchers to consider, I have also wondered if I might have been too pushy—that is, gone over some collaborative boundary, so to speak. What I am leading up to is that I am now publicly vulnerable in this exchange in terms of collaboration. However, as I have read and reviewed the many writings on collaborative action research, I have noticed that it is rare to find quotes of the discourse used by university researchers in this work. Thus, besides making problematic of the representation of teacher researchers, we have to think long and hard about why university researchers have been unable to represent themselves—warts and all—in academic discourse. Consequently, this is another ongoing challenge in developing new genres to report on collaborative action research.

Summary and Making 'Collaboration' Problematic to "Keep Voices Alive and Well"

Throughout this chapter I have stressed the importance and difficulty of making 'collaboration' ever present in the methodologies in collaborative action research. Because of the dominant perspectives in educational research, only by being vigilant in the entire collaborative research process will there

be any chance to "keep authentic voices alive and well" (Schatz, 1993). To return to the Bakhtinian framework offered in the first section of the chapter, as attempts are made to include the point of view and "speaking consciousness" of both university- and teacher-researchers in the dialogue of collaboration, there will be an ongoing conflict in this process because of this history.

Thus, methods of collaborative inquiry for social change cannot be conceived of in "mechanistic," superficial terms (Schensul & Schensul, 1992). Indeed, as Walker (1993) argues,

[Q]uestions about objectivity and subjectivity, representativeness, reliability, validity ... are often described as though they were simply technical problems, capable of reasonable resolution, but in practice they appear as moral dilemmas, concerned with selection, framing, judgment, risk and making one interpretation rather than another. (p. 90)

Moreover, as it challenges the traditional hierarchical differences between university researchers and teacher researchers within the educational community, collaborative action research represents a new activism to become practically critical as to promote democratic schooling (Gitlin, A., 1994; Noffke & Stevenson, 1995). That is, there is also a struggle to incorporate here a "political view of validity" (Gitlin, et al., 1992). Thus, as in jazz, new improvisations will need to be woven into the methods of this research (Oldfather & West, 1994) to achieve these good intentions of inclusion and emancipation.

POETIC REPRESENTATION

Laurel Richardson

OHIO STATE UNIVERSITY

How we write has consequences for ourselves, our disciplines and those publics we serve. *How* we are expected to write affects *what* we can write about. The *form* in which we write shapes its *content*. Prose is the form in which social scientists are expected to report their findings. Yet, virtually absent is any analysis or critique of this literary form as the sole legitimate carrier of knowledge.

For nearly a decade I have been exploring alternative forms of staging sociological texts (cf. Richardson 1990, 1992a, 1992b, 1993, 1995, 1996, forthcoming; Richardson & Lockridge 1991). My purposes have been several: to examine how knowledge claims are constituted in social scientific writing; to write more interesting sociology; and to reach diverse audiences. In this paper, after briefly discussing some postmodernist writing issues, I discuss one alternative way of staging findings, "poetic representation." I consider two kinds of poetic representation, the longer narrative poem and lyric poetry. My intent is not to argue that poetic representation is the only or even best way to represent all social scientific knowledge; but I do claim that poetic representation is a method for seeing the conventions and discursive practices we take for granted, and, that for some kinds of social scientific knowledge, poetic representation may be preferable to prose representation.

My theoretical positioning is that of a feminist-postmodernist-interpretivist. The core of that position is the *doubt* that any discourse has a privileged place, any method or theory a universal and general claim to authoritative knowledge. Truth claims are suspected of masking and serving particular interests in local, cultural and political struggles. Wherever truth is claimed so is power: the claim to truth is a claim to power. Once the veil of privileged truth is lifted, the opportunities for rethinking how we think and who can think and what we can think are legion; also comes the possibility of alternative criteria for evaluating social scientific production. Moral implications, practical applications, aesthetic pleasure, performativity, credibility, become other possible criteria for choosing one discourse over another. Social

scientists can, with philosophical impunity, interrupt their own discursive spaces, reflect on their modes of production, their power interests, and explore writing/performing/teaching/sharing their knowledge *both* as a "science" *and* as a public or aesthetic or practical or morally charged discourse.

Language is a constitutive force, creating a particular view of reality. This is as true of writing as it is of speaking, and as true of science as it is of poetry. Producing "things" always involves value—what to produce, what to name the products, and what the relationship between the producers and the products will be. Writing "things" is no exception. Writing always involves what Roland Barthes calls "the ownership of the means of enunciation." (Shapiro, 1985-86, p. 195). A disclosure of writing practices is thus always a disclosure of forms of power (Derrida, 1982). No textual staging is ever innocent (including this one).

Social scientific writing, like all other forms of writing, is a sociohistorical construction that depends upon literary devices (e.g., narrative, metaphor, imagery, invocations to authority, and appeals to audiences) not just for adornment, but for *cognitive* meaning. The truth value of social scientific writing depends upon a deep epistemic code regarding how knowledge *in general* is figured. Imminent in the prefiguring are metaphors so entrenched and familiar that they do their partisan work in the guise of neutrality, passing as literal (Derrida, 1982). For example, the grammatical split between subject and object goes wholly unnoticed as a metaphor for the separation of "real" subjects and objects, for "objectivity," and a static world, fixed in time and space. The temporal and human practices that reified the objects are rendered invisible, irrelevant. The technical mechanisms of explanation are quarantined from the human processes of interpretation. The actual linguistic practices in which the researcher/writer is engaged are hidden; but they are not eradicated.

A deep and totally unnoticed trope used by social scientists is reporting their findings in *prose*. In this chapter, I have myself used the prose-trope and will use it for the next several

pages. Its conventions allow me to stage my arguments in a way that are familiar to the reader, which is my goal in this chapter. The reader is not distracted by a different genre, and I am aided in my argument by the invisible power inherent in the adoption of conventional writing (essayic prose). Those conventions are particularly helpful in making abstract arguments, which I am rhetorically interested in doing before I demonstrate violations of those conventions.

In conventional social scientific writing, not only are the arguments written in prose, but the findings are, too. I however, wish to challenge, this ossification—prose reified as the only way to write “findings.” In what follows, I discuss two kinds of research findings staged as poetic representations: first, the writing-up of an in-depth interview as a narrative poem; and, second, the transformation of ethnographic materials into lyric poetry.

FROM IN-DEPTH INTERVIEW TO NARRATIVE POEM

In the routine work of the sociological interviewer, the interview is tape-recorded, transcribed as prose, and then cut, pasted, edited, trimmed, smoothed, and snipped, just as if it were a literary text, which it is, albeit usually without explicit acknowledgment or recognition of such by its sociological constructor. Normatively, underlying this process is the belief that the purpose of the text is to convey information, as though information consists of facts or themes or notions which exist independently of the context in which they were told, as if the story we have recorded, transcribed, edited and rewritten as snippets is the true one: a “science” story. Using standard writing conventions, including the use of prose, conceals the handprint of the sociologist who produced the written text.

Ironically, prose might not be the most “accurate” (i.e. “valid” and “scientific”) way to “report” speech. According to the oral historian, Dennis Tedlock (1983), when people talk, whether as conversants, storytellers, informants, or interviewees, their speech is closer to poetry than it is to sociological prose (p. 109). Nobody talks in “prose.” Everybody—so-called literate and nonliterate, adult and child, male and female—speaks using a poetical device, the pause. Indeed, in American speech, estimates are that about half of the time we are speaking, we are not; we are pausing (p. 198). And some 25% of pauses cannot be explained by physiological needs for breath or grammatical demands for closure, such as at the ends of sentences or clauses (p. 198). Unlike prose, poetry acknowledges pauses through the conventions of line breaks, spaces between lines and between stanzas and sections; a poem, therefore, more closely mimics actual speech by building its text upon both sounds and silence.

Most important, poetry and its related genres are both written and oral traditions. They can be read or performed. Drama (e.g., Ellis & Bochner, 1991; McCall & Becker, 1990; Richardson & Lockridge, 1991; Richardson, 1993, 1996), “ethnographic fiction” (e.g., Ellis, 1995; Krieger, 1983; Stewart, 1989), responsive reading (e.g., Richardson, 1992a), and poetry bring social theoretic understandings “live” to

different audiences: poetry bars, theaters, policy-making settings, literary conventions, street scenes, and mass media.

I have used poetic representation to “report” the “findings” of an interview I had with “Louisa May.” One evening, as part of a larger project on “unwed mothers,” I completed an in-depth interview with Louisa May. I transcribed the tape into 36 pages of prose, and then shaped the transcript into a 5-page poem. In so doing, I drew upon both scientific and literary criteria. In fashioning her poem, I used only her words, tone, and diction, but relied upon poetic devices such as repetition, off-rhyme, meter, and pauses to convey her narrative. The speech style is Louisa May’s, the words are hers, but the poetic representation is my own construction.

The way in which I have constructed the poem inscribes the interactional nature of the interview, the “talk” is one which has been produced in a particular kind of speech context—the sociological interview. I am the implied listener throughout the poem; when Louisa May speaks to me about the interview process itself, her words are italicized. The poem “shows” the sociological “buttress” to the “conversation,” reminding the reader that this is a rendering of a particular kind of speech performance. Louisa May’s story arises in the context of an interview; the context is written into the poem. Since an interview is a jointly constructed text arising from the intersection of two subjectivities in a particular social context (see especially Mischler, 1986), framing the “findings” as though they are independent of the method in which they were produced is falsifying, although a standard claims-making procedure.

Since “Louisa May’s Story of Her Life,” has been constructed as a poem, listeners / readers are not deluded into thinking that they are reading the one and only true story about her; rather, the facticity of its constructedness is ever present. As the poetic form plays with connotative structures and literary devices to convey meaning, poetic representations of “findings” have a greater likelihood of engaging readers in reflexive analyses of their own interpretive labors of the researcher’s interpretive labors of the speaker’s interpretive labors. The construction of “text” is thus positioned as joint, prismatic, open, and partial.

I have presented “Louisa May” to diverse audiences. The responses have been uniformly strong, sometimes heated. The “genre-breaking” writing displayed unexamined but foundational assumptions regarding the nature of “theory,” “data,” “findings,” “authority,” and “authorship.” Poets theorize about the social construction of “normality,” genre boundaries, and authorship. Women’s studies audiences theorize the poem as a method of revealing “findings” as masculinist—with poetry “feminizing” the product and its production. General audiences have used “Louisa May” as a springboard for discussing societal issues. Oral historians have seen poetic representation as a method of capturing an “essence,” that is lacking in their own conventions. Social workers and policy makers claim the poem has altered their stereotypical thinking. Some social scientists, and even some with constructionist and postmodernist leanings, though, have challenged the “validity” of the poem, demanding to see the transcript, although not to hear the tape, see a videotape, or talk directly to Louisa May—all possible grounds for

establishing validity that do not privilege a written document. I have been variously accused of exploiting Louisa May, of fabricating her, and of being her. I doubt if these accusations would have been made by poets or sociologists or feminists had I written conventionally.

For sociological readers, in addition, the poem may seem to lack certain sociological data. But this poem is based on Louisa May's sense of what is relevant, not the sociologist's; it is her narrative. For example, Louisa May does not talk about her education or occupation. Uneasiness that readers might have over their apparent lack of knowledge about Louisa May, I submit, reflects on the readers' unexamined assumptions. If they wonder, for example, how Louisa May supports herself and her daughter, are they tapping into their stereotypes about *unwed* mothers? Would they wonder about "support" if Louisa May were married or were Louis M.? If they feel they cannot understand her unless they know about her educational level, are they telling us about the place of education in their own lives? More generally, have the categories of sociology been so reified that even interpretivists feel they have to refract a person's life through a sociologically prescribed lens?

Here is "Louisa May's story," a poetic representation, a transcript masquerading as a poem / a poem masquerading as a transcript.

LOUISA MAY'S STORY

The most important thing
to say is that
I grew up in the South.
Being Southern shapes
aspirations shapes
what you think you are
and what you think you're going to be.

*(When I hear myself, my Ladybird
kind of accent on tape, I think, OH Lord,
You're from Tennessee.)*

No one ever suggested to me
that anything
might happen *with* my life.
I grew up poor in a rented house
in a very normal sort of way
on a very normal sort of street
with some very nice middle class friends

(Some still to this day)

and so I thought I'd have a lot of children.

I lived outside.

Unhappy home. Stable family, till it fell apart.
The first divorce in Milfrount County.

So, that's how that was worked out.

ii

Well, one thing that happens
growing up in the South

is that you leave. I
always knew I would

I would leave.
*(I don't know what to say...
I don't know what's germane.)*

My high school sweetheart and I married,
went north to college.
I got pregnant and miscarried,
and I lost the child.

*(As I see it now it was a marriage
situation which got increasingly horrendous
where I was under the most stress
and strain without any sense
of how to extricate myself.)*

It was purely chance
that I got a job here,
and Robert didn't.
I was mildly happy.

After 14 years of marriage,

That was the break.
We divorced.
A normal sort of life.

iii

So, the Doctor said, "You're pregnant."
I was 41. John and I
had had a happy kind of relationship,
not a serious one.
But beside himself with fear and anger,
awful, rageful, vengeful, horrid,
Jody May's father said,
"Get an Abortion."

I told him,
"I would never marry you.
I would never marry you.
I would never.

"I am going to have this child.
I am going to.
I am. I am.

"Just Go Away!"

But he wouldn't. He painted the nursery.
He slept on the floor. He went to therapy.
We went to LaMaze.

*(We ceased having a sexual relationship directly
after I had gotten pregnant and that has never
again entered the situation.)*

He lives 100 miles away now.
He visits every weekend.
He sleeps on the floor.
We all vacation together.
We go camping.

I am not interested in a split-family,
her father taking her on Sundays.
I'm not interested in doing so.

So, little Jody May always has had a situation which is
normal.

Mother—bless her—the word “married” never crossed
her lips.

*(I do resent mother's stroke. Other mothers
have their mother.)*

So, it never occurs to me really that we are unusual in
any way.

No, our life really is very normal. I own my house.
I live on a perfectly ordinary middle-class street.

So, that's the way that was worked out.

iv

She has his name. If she wasn't going to have a father,
I thought she should have a father, so to speak.

We both adore her.

John says Jody May saved his life.

OH, I do fear that something will change—

v

(Is this helpful?)

This is the happiest time in my life.

I am an entirely different person.

With no husband in the home there is less tension.
And I'm not talking about abnormal families here.
Just normal circumstances. Everyone comes
home tired.

I left the South a long time ago.
I had no idea how I would do it.

So, that's the way that worked out.

(I've talked so much my throat hurts.)

FROM ETHNOGRAPHIC MATERIALS TO LYRIC POETRY

I presented “Louisa May” to an ethnography conference,
along with a drama based on responses to the poem at
a sociology conference. Considerable discussion followed;
some conferees feared for ethnography's future. But a
conference organizer and coeditor of *The Journal of
Contemporary Ethnography (JCE)*, stood up in the front
row of the overfull auditorium and said with cheeky good
humor: We are the ethnographers. We decide what consti-
tutes ethnography. She then invited me to send poems, with
or without an introduction, to *JCE*. I sent the following, “Nine
Poems: Marriage and the Family,” without justification or
explication.

MARRIAGE AND THE FAMILY

Legacy

To comfort the mother
of the third born daughter
her father names her
after his own mother.

The third born becomes a mother.

She learns her namesake died
of pleurisy or suicide.
Her father doesn't remember.
Says it doesn't matter

Marriage

I used
to think it was
cute to have a lit-
tle shadow go in and out
with me.

The Good Doctor Said

Your son has inoperable
brain tumors. At puberty
he'll get progressively
weaker on his left side
until he takes to bed
catches cold and dies.

Treat him as normal.

Lullaby

Time
goes
slowly
thinking
about
dying
giving
me
more
time
to
think
about
dying

When he was a baby,
I wondered if he
would die in his sleep,
In my sleep.

Bill said it didn't matter.
Death, he said, is best
after a good night's sleep.

Taking Him to the Vet

He's shameless, Doctor.
Walks around with no clothes.
Growls at pussies,
sniffs.
Pees in public with others
of his sex and species,
impervious to breed.

I do believe he would bite
the hand that feeds him.

At night
He pants and moans and salivates.
He's shameless.

Will his Blue Cross cover?
How soon can you fix him?

Custody

See how the orange is segmented:
naturally. How apples resist
paring. How ocean water fills
a glass. My glass. Full tide
hovering at the rim. My hand
holding the ocean still,
still the undertow. See my hand
through the glass.

Being Single Is

drying a wishbone
by the kitchen window
'til the bone is chipped

to bits by trinkets
placed beside it,
or it rots, because

there is no one
to take one end
you the other

pulling, wishing
each against each
until the bone

breaks.

Surrounded By Men

Short ones, lover and friend,
beer drinking on the back porch,
comparing the lengths of their
manuscripts, their tenures.
Wisps of Tennyson and Chaucer.

Tall ones, sons, territorizing
the front yard. Shooting rockets,
burning fingers, spilling rock salt.

Commanding the living room, Father,
dead already eight years, today,
swollen with waiting-

Even The Knives Sleep

If I were a fork, I would know my place,
to the left of the plate, tines beckoning
a hand to cradle me,
me holding meat for the knife.
The blade slips between my tines
scraping edges.
There is no pain, and after

I am bathed in water
and returned to the space
I share with others of my kind.
We nestle together, edges cradling edges.
I am safe in the drawer.
Even the knives sleep.

Some reviewers wanted to know: How are these poems ethnography? Although initially I resisted writing about the poems, I decided that to do so afforded me an opportunity to think more about how knowledge-claims are constituted and supported. I am particularly interested in how my own branch of knowledge—that based on ethnographic qualitative research—is constituted as authoritative. I focus here primarily on issues of narrative and validity.

Poststructuralism proposes that systems of knowledge are narratively constructed. Traditionally, ethnographies, oral histories, social histories, biographies, and other qualitatively based research are constructed with fairly straightforward, obvious, and visible plot lines. The author intends that the reader "gets *the* story." "The story" is understood as taking place within or reflecting a particular social order or culture. Writing in-depth interviews as a long narrative poem, then, although transgressing representational practices, coheres with the narrative traditions of qualitative research. These transgressive writings reinscribe the possibility of "the plot line," the story, even as they challenge the *format* through which the story is told.

In "Nine Poems," however, the narrative is only implied. Nine Poems are short, *lyric poems*, each a "mini-narrative," an episode, representing an emotionally and morally charged experience. The order of the poems implies a plot, but the "spaces" between the poems invite greater readerly responses and interpretive work than would a long narrative poem. The nine poems could also be reordered, implying yet different plots. Subsuming "Nine Poems" under the rubric, "Marriage and the Family," moreover, implies a *metanarrative*, the sociocultural construction of those two concepts "marriage" and "family," and a seeming relationship between them, "marriage *and* the family." The implied narrative would change, if "Nine Poems" were subtitled, "Gender" or "Maturing," or "Socialization" or "Treason" or "Paper Airplanes."

If a goal of social science is to retell "lived experience," to make another world accessible to the reader, then, I submit that the lyric poem, and particularly a sequence of lyric poems with an implied narrative, may come closer to achieving that goal than other forms of ethnographic writing.

Lyric poetry may come closer to presenting "lived experience" for literary, sociological, and cultural reasons. "Poems exist in the realm of making (*mimesis*) rather than of knowing or doing; they are representations of human experience ... not speech uttered by, or speech acts performed by individuals who happen to be poets" (Borroff, 1993, p. 1032). That is, lyric poems are consciously constructed through literary devices such as sound patterns, rhythms, imagery, and page layout to evoke emotion. Like the lived experiences they represent, poems are emotionally and morally charged. Lyric poems concretize emotions, feelings, and moods—the most private kind of feelings—in order

to recreate an experience in another person. A lyric poem "shows" another person how it is to feel something. Even if the mind resists, the body responds to poetry. It is *felt*. To paraphrase Robert Frost, poetry is the shortest emotional path between two people.

Sociologically, each lyric poem represents a "candid photo" or an "episode" or an epiphany. People organize their sense of Self around and through such epiphanous moments (Denzin, 1989). Everyday life experiences are not organized around the long biographical account, the epic poem, the life history. Rather, people tell stories about events in their lives; the meaning of the event changes through the invocation of different implied narratives. Further, not all events are stuffed into the same narrative. A life may have a "plot line," but not everything lived—nor everything of import to the person—fits neatly into "a" plot. We are not characters. Our lives are not morals. They are not even ethnographic narratives.

Cultures provide prefabricated narratives for hooking up the events of our lives. As cultural studies and discourse analyses demonstrate, those narratives are multiple, contradictory, changing, and differentially available. As agents in our own construction, we choose among available "cultural stories," apply them to our experiences, sometimes get stuck in a particularly strong "meta-narrative," often operate with contradictory implied narratives, and sometimes seek stories which transgress the culturally condoned ones. Any or all of these processes through which the self is constructed and reconstructed may be going on simultaneously. Lyric representation mimics the complexity and openness of this human process—"shifting subjectivities"—by which we come to know, and not know, ourselves, and know ourselves, again, differently.

In addition to these narrative issues, "Nine Poems" raises another question: validity. In the long narrative poem, "Louisa May's Story" the reader is told that all the words, rhythms, and sound patterns come from an in-depth interview with Louisa May. Although I crafted the poem, my voice is distinguished from Louisa May's. That is, although the format is transgressive, in the production and sharing of "Louisa May" I adhered to a scientific protocol.

In "Nine Poems," however, the reader is not told the source of the poems. No "subversive repetition" of science practices is proffered. The poet and the poems are conflated. Are the poems from the life of a particular person, and if so, is that person one and the same as the poet? Or, did the poet compile the poems from interviews with different people or from a variety of texts?

But, does it matter—ethnographically—whose life is represented, or whether the poems represent a particular life? These questions are not asked in standard ethnographic codifications, where an "ideal-typic" portrait may be presented or a series of quotes from different interviews are collated under a theme, sometimes (I am told) quotes from the researcher, herself, secreted in amongst the others. If you care about whether the "I" of the poems is the "I" writing this essay, I ask you to ask yourself, "Why?" Do you have validity questions? Reliability questions? Truth questions? Emotional identification / disidentification con-

cerns? "Nine Poems" brings these ethnographic issues—always present, usually suppressed—into critical awareness.

If we suppose that the poems are a representation of a particular life, they simply fit within the tradition of making an individual (e.g., the jackroller, the children of Sanchez, Don Juan, etc.) the center of ethnographic writing. But if the poems are thought of as a representation of my own life, then the writing belongs to the newly developing sociology of subjectivity (Ellis & Flaherty, 1992; Ellis, 1995; Richardson, 1995). In literary writing and ethnographies of the self, the boundary line is personal; the boundary is between the foreign territory of one person's psyche and that of another. The Other that is the foreign territory, the "terra exotic," is the *inner experience*, the inner life of the writer. Writing about the Self as both subject and object distances the Self from the usual codifications of ethnography, even while the writing points out how the Self depends upon social and cultural discourses to "know" itself, to position itself. Lyric poems have the capability of reducing the "distance" between the "I" and the "Other" and between the "writing-I" and "experiencing-I" of the writer, and thus move us to rethink the boundaries between ourselves and our "work," help us feel how ethnography might be situated within the "Self" (Krieger, 1991).

I would submit that "good" ethnography, like "good" literary works, invites the reader to *experience* a culture or an event. If one wants to *feel* what the plague was like, one can read DeFoe's *Journal of the Plague Year*, which purports to be factual but is in fact a work of imagination. If one wants to *feel* what it was like to survive the Buffalo Creek disaster, one can read Kai Erikson's *Everything in Its Path*, which is categorized as ethnography, and reads like good fiction. If one wants to *feel* what it is like to experience emotional depression, one can read William Styron's *Darkness Visible*, which is a personal account by a novelist that exposes institutionalized medical ignorance, as might a good ethnography. In all of these instances—and many others—the reader is not simply "told," s/he *feels* the experience. In this deepest sense, ethnographic writing, then, is allied to the rhetorical and emotional center of literary writing.

How does the lyric poem fit in, then? The lyric poem's task is to represent actual experiences—episodes, epiphanies, misfortunes, pleasures—to capture those experiences in such a way that others can experience and *feel* them. Lyric poems, therefore, have the possibility of doing for ethnographic understanding what normative ethnographic writing cannot.

The question—"How is lyric poetry ethnography?"—must be, I submit, inverted. The question should rather be, "When is lyric poetry *not* ethnographic?" As an opening move to answer that question, I would suggest that had Keats' "Ode to a Nightingale" first appeared in a journal of ornithology, this fact would have forever influenced how the ode was read and understood by the literary critic. Knowledge is always contextual, legitimated by gatekeepers, and always exists inside a "meta-narrative." For now, "Nine Poems" appearing in *JCE* and in this book as ethnographic representation "is" ethnographic writing.

CONCLUSION

How we write has consequences for what we can know. Poetic representation is one possible way of knowing. By examining

the foundations of our claims to authoritative knowing and by exploring alternative representations, we may all be more knowledgeable.

ALTERNATIVE METHODOLOGY FOR DIAGNOSTIC ASSESSMENT OF WRITTEN AND VERBAL RESPONSES TO WORKS OF ART

Carol Susann Stavropoulos

UNIVERSITY OF GEORGIA

Instruments currently available to assess written statements about works of art do not adequately account for cognitive conceptions of learning. That is, they do not discriminate between the learner's knowledge-base and knowledge-seeking strategies, higher-order and lower-order understandings, and misunderstandings. The development of an assessment instrument, referred to as a Diagnostic Profile of art understandings, begins to lessen this gap in art education research on student assessment (Stavropoulos, 1992).

A study by Koroscik, Short, Stavropoulos, and Fortin (1992) found that components of a student's knowledge-base and knowledge-seeking strategies can be reflected in written statements about works of art. The purpose of this chapter is to focus on the interaction between the knowledge-base and knowledge-seeking strategies employed in the process of transfer. Building upon this theoretical framework and related research, the chapter will present categories for an alternative assessment instrument referred to as a Diagnostic Profile of art understandings.

The steps taken to develop and test the quality of this alternative assessment instrument will be summarized as follows: (a) the theoretical foundation directing the inquiry, (b) methodologies used in the development of assessment categories, (c) description of the Diagnostic Profile, (d) validity and reliability studies conducted to establish instrument quality, (e) the educational importance of future applications of an alternative methodology for assessing understandings of art, and (f) implications for the field of art education.

An oil painting entitled, *The Birthday*, painted between 1915 and 1923 by artist Marc Chagall was the primary focus of the research of Koroscik et al. (1992). Numerous criteria directed the selection of *The Birthday* in that study, for

example, it is highly representative of the artist's style, there is a sizable body of literature available on the work, it represents a moderate level of abstraction, and it has a theme to which many can relate (p. 156). *The Birthday* (see Plate 20-1) will be used throughout this chapter as a convenient way of providing illustrations of knowledge-base and knowledge-seeking strategies.

THE LEARNER'S KNOWLEDGE-BASE

The sum total of what an individual already knows is referred to as *prior knowledge* in the learning literature (Alexander, Schallert, & Hare, 1991). The importance of prior knowledge has been examined in such fields as computer programming (Linn, 1985), mathematics (Schoenfeld, 1985), medicine (Lesgold, et al., 1988), art education (Koroscik, 1982), and reading comprehension (Alvermann, Smith, & Readence, 1985; Wilson, & Anderson, 1986).

Prior knowledge has at least two facets: knowledge-base and knowledge-seeking strategies. In accounting for learning outcomes through transfer, Koroscik has proposed a theoretical framework highlighting the learner's knowledge-base and choice of knowledge-seeking strategies. Both facets must be engaged to some degree in order for transfer to occur (Koroscik, 1992-93, p. 7).

Koroscik (1992-93) defines the *knowledge-base* as "all the accumulated knowledge, skill, and experience a student currently possesses, including what the learner already knows about the material being studied" (p. 7). Emphasizing the learner's active role in this construction of knowledge, Koroscik's model of art learning differentiates knowledge-base from strategies that students use to acquire new

PLATE 20-I Marc Chagall. *The Birthday*, 1915–1923, oil on cardboard, 31 3/4 × 39 1/4 in/80.5 × 99.5 cm. The Museum of Modern Art, New York; acquired through the Lille P. Bliss Bequest.

knowledge and make use of existing knowledge. The learner can access relevant prior knowledge or irrelevant prior knowledge from the knowledge-base. Additionally, the strategies students employ in accessing knowledge in their possession range in effectiveness. Based on the interplay between knowledge-base and knowledge-seeking strategies, at least four conceivable learning outcomes can be isolated. These outcomes exist along a continuum (1992–93, 1993):

1. The learner does not possess adequate prior knowledge nor are effective knowledge-seeking strategies employed.
2. The learner possesses relevant prior knowledge but employs ineffective knowledge-seeking strategies.
3. The learner uses effective knowledge-seeking strategies but does not possess adequate prior knowledge.
4. The learner possesses relevant prior knowledge and uses effective knowledge-seeking strategies.

The interaction between the knowledge-base and knowledge-seeking strategies explains why learning outcomes can differ, and provides a foundation for developing a more comprehensive approach for assessing student understandings of artworks. An evaluative account and / or characterization of the outcomes that occur along these learning continua can distinguish less successful learners from more successful ones (Koroscik, 1982, 1990a, 1990b).

The Function of Prior Knowledge

Vosniadou and Brewer (1987) state, “the acquisition of new

knowledge from experience makes little sense without assuming some prior knowledge within which the new experience is interpreted; otherwise the new experience will be unintelligible” (pp. 51, 52). Therefore, for meaningful learning to occur, information to be learned must be connected to prior knowledge (Prawat, 1989; Vosniadou, & Brewer, 1987). Often students have difficulty in accessing, or fail to transfer their existing knowledge to new information (Alvermann, et al., 1985; Bransford, Sherwood, Vye, & Rieser, 1986). The extent to which learners can activate and transfer prior knowledge influences the degree to which new information and ideas are comprehended (Bransford, & Johnson, 1972; Dooling, & Lachman, 1971).

Encounters with visual art are interpreted through a student’s existing knowledge of art. For example, students would need to know something about Marc Chagall before they could understand Chagall’s influences on the French poet Paul Eluard (Crespelle, 1970), the Russian printmaker El Lissitzky (Alexander, 1978; Bolliger, 1957; Compton, 1985; Jager, 1970), and / or the Canadian choreographer Ginette Laurin (Pontbriand, 1990).

Formal and Informal Knowledge

Confrontations with a work of art such as Chagall’s painting *The Birthday*, have the potential to trigger a wide spectrum of prior knowledge within the learner’s / student’s / art viewer’s knowledge-base. The degree to which general or art-specific prior knowledge is activated determines

understanding (Koroscik, 1982).

A student can accumulate general knowledge that is related to art from everyday experience, that is, *informal knowledge* (Prawat, 1989). It is possible to rely on informal knowledge to identify the subject matter in *The Birthday*. For example, a student might cite the table in a home where enjoyable meals are served each day.

Prior knowledge specific to art might encompass viewing and art-making experiences that can be gained as a result of formal education. Knowledge gained in this manner can be referred to as *instructed* or *formal knowledge* (Prawat, 1989). For instance, the art teacher could instruct students that the interior space of *The Birthday* includes a bed. While students possess informal descriptive knowledge regarding beds, a bed cannot easily be identified in *The Birthday*. In the painting, the bed is actually cut off at the right-hand side of the composition, slightly tilted in perspective, and covered with scarves and what may be a pillow. As such, identification of the bed is difficult. Without instructed knowledge of the subject matter, the student might miss noting details that suggest that the interior space is actually Chagall's living quarters.

Informal and instructed knowledge can coexist in the student's knowledge-base. For example, a student might draw upon informal knowledge of birthday cake after the teacher has provided instructed knowledge of the birthday cake.

A question explored in this chapter is "What aspects of the knowledge-base should be the focus of an assessment instrument?" In terms of evaluation, this is an important question because there are direct relationships between the content taught in the classroom, learning outcomes or understandings that result, and existing assessment tools (Hamblen, 1988). If an assessment instrument is to measure outcomes that are reflective of student understandings, its dimensions should be representative of content that can bring about those understandings. However, there remains still much debate over the content of art education curricula, and what learning outcomes are considered desirable.

Dimensions of Art Understanding

While terminology may vary somewhat in analyzing works of art, art educators often use language that can be characterized as follows:

- *formal*—elements or principles of design, media, technique
- *descriptive*—objects, subject matter
- *interpretive*—meaning, emotion, feeling, expression
- *historical*—names, dates, information regarding the artist, and the artist's background

Recent college textbooks for the teaching of methods to prospective art teachers align curricular objectives in responding to works of art along formal, descriptive, interpretive, and historical dimensions of art understanding (Herberholz, & Hanson, 1990; Herberholz, & Herberholz, 1990; Hurwitz, & Day, 1991; Linderman, 1990; Wachowiak, & Clements, 1993). Art education textbook series, teacher guides, and curricula at the primary, elementary, and high

school levels incorporate formal, descriptive, interpretive, and historical dimensions of art understanding in suggested classroom lessons and topics of study (Briere, 1988; Brommer, 1982; Chapman, 1987, 1992; Fichner-Rathus, 1986; Hobbs, & Salome, 1991; Hubbard, 1987; Hubbard, & Rouse, 1981; Mittler, 1994; Mittler, & Ragans, 1992a, 1992b; Ragans, 1995). Even the National Teacher Examination (NTE) speciality area in art education and NTE core battery tests on general knowledge contain standardized assessment of formal, descriptive, interpretive, and historical dimensions of the prospective teacher's knowledge-base (DeMauro, 1989; NTE, 1987).

Current theories in art education incorporate perspectives based on formal, descriptive, interpretive, and historical foundations (Clark, Day, & Greer, 1987; Efland, 1990; Hurwitz, & Day, 1991; Smith, 1989). Cognitive theorists and researchers in the field of art education use similar distinctions to describe responses to works of art (Efland, 1990; Koroscik, 1990a, 1990b; Koroscik, Osmond, & DeSouza, 1988; Koroscik, et al., 1992; Parsons, 1987), as do art criticism specialists (Barrett, 1990, 1994a; Carney, 1994; Feldman, 1994). The underlying assumption is that each dimension of art facilitates art understanding in particular but overlapping ways. Therefore, an assessment instrument for art education might reflect the degree to which formal, descriptive, interpretive, and historical concepts and strategies incorporating their use are contained within the student's knowledge-base.

KNOWLEDGE-SEEKING STRATEGIES

Strategy refers to a spectrum of methods that assist knowledge acquisition and utilization (Prawat, 1989, p. 2). According to Alexander, et al. (1991) "the learner builds a meaningful framework from existing knowledge that will facilitate the interchange between what is already known and what is to be understood" (p. 331). Koroscik (1992-93) defines *knowledge-seeking strategies* employed in art learning situations as "the cognitive steps a student takes to construct new understandings, to seek new knowledge, and to apply previously acquired knowledge, skill, and experience (p. 7)." Efland (1990) contends that assessment of art understandings should focus on strategies used to organize knowledge. Therefore, an instrument that assesses art understandings should represent the student's employment of knowledge-seeking strategies.

As students construct new understandings, it is important that knowledge-seeking strategies are adopted to make efficient use of the knowledge-base. However, relevant knowledge that could prove useful in learning situations often remains inactive (Bransford, et al., 1986; Schoenfeld, 1985). Failure to access relevant knowledge might be due to gaps in the learner's knowledge of certain routines, processes, and strategies. According to Koroscik et al. (1992), "if a student chooses a search strategy that is inappropriate, there is little chance relevant knowledge will be transferred even if the student possesses it. And if effective search strategies are employed but the student's knowledge-base is lacking, understanding will be impaired or misguided" (p. 164).

Efland (1990) states, "the naive learner may have knowledge but not know how to apply it to new situations" (p. 52). More experienced art viewers "need to acquire procedures for using what they already know in order to identify what they don't know, thus organizing the search for new information" (Koroscik, 1988, p. 11).

Therefore, the concerns identified by Koroscik (1988) and Efland (1990) indicate a need for assessment tools including an inventory of learning strategies and outcomes. A model of learning and assessment should also differentiate between the types of prior knowledge that are brought to bear on understanding a work of art. This approach is superior to classical models that tend only to focus on the student's knowledge-base (Efland, 1990).

TRANSFER

Transfer is the result of employing knowledge-seeking strategies to make connections between the characteristics of the artworks and the student's accumulated knowledge or knowledge-base (Koroscik, 1992-93, 1993; Koroscik, et al., 1992). The connections a student may make might be referred to as "building bridges" (Nickerson, 1985). The "bridges" students build when viewing works of art can determine whether they arrive at lower-order understandings, higher-order understandings, and / or misunderstandings. According to Parsons (1990), a student may make connections

between the various aspects of the work itself (internal connections), and of any of those with the artist, with the history and culture within which the work was created, and / or the present art world and social setting in which it is viewed, including the emotional and intellectual state of the viewer. (p. 42)

Both instructed knowledge of formal, descriptive, interpretive, and / or historical dimensions of art and / or informal knowledge can be involved in transfer. Just as prior knowledge (both formal and informal) are unique to individuals, so too are the connections one brings to a work of art.

According to Prawat (1989), "the breadth and depth of a concept's connectedness—that is, how many other ideas it is connected to—is a good measure not only of its meaningfulness but also of its potential contribution to the coherence of a cognitive structure" (p. 8). Therefore, the organization of connections between the learner's knowledge-base and the characteristics of the work of art can range from simple to more complex in structure.

Efland (1990) suggests that deeper understandings are evidenced when concepts are integrated, (e.g., concepts acquired in the studio surface in critical and / or historical discussions about works of art). The literature on the phenomenon of transfer supports the view that deeper understandings happen when previously synthesized material from one learning situation aids in the successful understanding of another.

Low-Road Transfer and Lower-Order Understandings

Perkins and Salomon (1987) characterize the most common form of transfer as *low-road transfer*. The process of low-road

transfer can involve lower-order knowledge-seeking strategies such as application of familiar vocabulary, recall of facts, correct description of instances, and / or memorization. These knowledge-seeking strategies tend to occur as the automatic consequence of varied practice and are familiar operations performed intuitively and automatically (Perkins, & Salomon, 1987; Salomon, & Perkins, 1989).

For example, *The Birthday* depicts an interior space. This deduction might be based on the identification of furnishings such as a table, floor, and walls. Since the idea of these items within an interior space is not new, the need to think deeply about this aspect of the work is lessened. Understanding the concept of interior space represented in *The Birthday*, through low-road transfer, requires almost automatic recall-oriented associations rather than reflective thinking.

High-Road Transfer and Higher-Order Understanding

High-road transfer is defined by Perkins and Salomon (1987) as "deliberate mindful efforts to represent principles at a high level of generality, so that they subsume a wide range of cases" (p. 288). High-road transfer is a controlled and nonautomated process which demands greater mental effort (Perkins, & Salomon, 1987; Salomon, 1983; Salomon, & Perkins, 1989). According to Salomon and Perkins, when mindful processes are evoked, an obvious response might be withheld in favor of a closer examination of the underlying meaning. Looking closer at the problem facilitates alternative strategies, choices, and connections, which lead to the construction of new structures of understanding. Perkins and Salomon claim that high-road transfer is brought about by an ability to abstract and apply principles under appropriate conditions (pp. 290, 291).

For example, the relationship of levitation to the notion of love is cited frequently in the historical literature on *The Birthday*. The sensation brought about by love does not literally cause lovers to defy the laws of gravity and hover above the ground. It is an abstraction to reference the principle of gravity from the context of science and apply it to the context of *The Birthday*. For high-road transfer to occur, a richer set of connections must be made as in the following example:

The lighthearted, weightless sensation of love is symbolized by the two floating figures.

As illustrated, the process of high-road transfer involves the construction of meaning through a meshing of concepts. Meshing of concepts requires more than simply identifying that the couple in *The Birthday* are kissing. Constructing meaning in high-road transfer is a higher-order skill which promises deeper understandings and greater retention (Efland, 1990; O'Neal, 1992; Perkins, & Salomon, 1987; Salomon, & Perkins, 1989).

Understandings may therefore be said to vary in degrees of cognitive complexity (Efland, 1990; Nickerson, 1985; Parsons, 1987, 1990). According to Nickerson, "the richer the conceptual context in which one can imbed a new fact, the more one can be said to understand the fact" (pp. 235, 236).

Misunderstandings

Misunderstandings about works of art can impede meaningful learning (Efland, 1990; Efland, Koroscik, & Parsons, 1991; Koroscik 1990b; Parsons, 1990). According to Feltovich, Spiro, and Coulson (1988), some misunderstandings are more entrenched than others. An assessment instrument should be able to distinguish the misunderstandings a student brings to potential learning situations in art. To assess misunderstandings, a knowledge of the kinds of mistakes students make and their causes is required (Perkins, & Simmons, 1988).

One reason students do not fully understand works of art is because prior knowledge and/or the employment of a particular knowledge-seeking strategy prevents learning. When one learning encounter impairs another, negative transfer has occurred (Perkins, & Salomon, 1987, p. 287). Some misunderstandings are equivalent to negative transfer. For example, prior knowledge in reference to Marc and Bella Chagall's married life could inhibit an understanding of *The Birthday*. In this instance, a student might mistake the flowers Bella holds in her hand for a bridal bouquet. Based on this finding, the student might interpret the painting as a commemoration of Marc and Bella's wedding day. Actually, Bella brought the flowers to decorate Marc's apartment for his birthday celebration before the couple was married.

Other reasons students do not fully understand works of art is because they do not have an adequate knowledge-base and/or their knowledge-seeking strategies are limited. In these cases, terms like misunderstandings can be misleading because there is the implication that an error has been made "when the only error might be a limited frame of reference beyond which the student has no experience" (Confrey, 1987, p. 97). Supporting this stance, Parsons (1990) states "a child's present conceptions represent not a false, but a partial and incomplete understanding" (p. 41). Many young children would understand the birthday celebration depicted in *The Birthday*. However, a young child would not be expected to understand the metaphysical connotations attached to the imagery of Marc Chagall. While a young child may relate to the imagery, he/she may actually have an incomplete understanding of Chagall's paintings.

Multiple Interpretations

People generate many different interpretations of a work of art. If we are to assess a person's understanding of a work of an artist, we must first determine, at least to some extent, what understandings are desirable. According to Parsons (1990), desirable understandings are more easily identified in math and science because "a mis-conception contrasts naturally with a correct conception. It is much clearer in math and science which are the correct conceptions" (p. 40). Calling for a middle ground, experts agree that multiple interpretations of works of art are certainly possible, however, some interpretations are more convincing than others (Barrett, 1994b; Koroscik, 1992-93; Parsons, 1990, 1992). The field of medicine can lend a clue to this dilemma.

In medicine, assessment of a patient's symptoms and treatment plans are sequential diagnostic processes. Once a

patient's symptoms have been assessed, the doctor arrives at a diagnosis, and the treatment plan is elected (Miller, & Keane, 1972). For instance, multiple treatment plans exist for sufferers of migraine headache. The treatment of choice may have as much to do with the particular doctor, his or her training, experience, and philosophies, as it does with the patient. For instance, after ruling out the presence of a brain tumor or other such brain disorders, one general practitioner might prescribe narcotic pain medication to ease a migraine, while another might prescribe a high dose of aspirin. A university physician, because of campus drug problems, might be cautious about prescribing narcotic drugs for headaches. As an alternative, exercise and over-the-counter medications such as Tylenol®, may be recommended. One neurologist might suggest biofeedback while another may suggest a change in diet. A doctor of holistic medicine might suggest a stress management program, while still another might prescribe allergy tests or an optometry examination.

Hypothetically all of these treatment plans would seem to be legitimate and logical courses of action, even though they differ drastically. In the same vein, interpretations of art may vary, but still be legitimate and logical. For example, one critic may view a photograph by Mapplethorpe through the lens of technique and conclude that Mapplethorpe possesses notable skill in the mastery of photography. Another critic may view the same work through a descriptive lens and determine that the artist uses subject matter that some would consider offensive. Viewing the work of Mapplethorpe through an interpretative perspective, one might infer that he is communicating problems of society.

Parsons (1990) states a key question in this debate: "by whose standards are some interpretations to be judged less acceptable?" (p. 40). The answer to Parsons' question is suggested through the previous medical example. Like doctors, students come to art learning situations equipped with differing backgrounds, experiences, and understandings. Therefore, students may understand works of art differently. To gauge the nature and extensiveness of students' prior knowledge, learning outcomes in relation to art must be looked at with some flexibility.

LEARNING OUTCOMES

Efland (1990) points out that classical approaches to assessment in art education tend to focus on recall of vocabulary, definitions, and/or facts. Knowing to recall, define, and use specific vocabulary are examples of knowledge-seeking strategies that can result in lower-order learning outcomes. Recalled information, including definitions, often appears in a student's recitation of historical information and/or facts about an artwork. Lower-order outcomes can also be aligned with the learner's knowledge of formal qualities, subject matter (description), and expressive (interpretive) content of an artwork.

When students explore works of art for deeper understanding they engage a different set of knowledge-seeking strategies. For instance, when students apply search strategies involving analysis, comparisons, questions, judgments,

interpretations, explanations, extensions and / or challenges of the ideas of authorities, higher-order learning outcomes can occur (Stavropoulos, 1992–93a, 1992–93b). Higher-order outcomes can also be associated with formal, descriptive, interpretive, and historical dimensions of the learner's knowledge-base.

The range of lower-order and higher-order outcomes within the formal, descriptive, interpretive, and historical dimensions of the learner's knowledge-base will be illustrated in the sections that follow.

Formal Dimension of the Learner's Knowledge-Base

Formal qualities of artworks can be identified and discussed in reference to all periods and movements in the history of art. Barrett (1990) describes *form* as an artwork's structure, arrangement, and organization of the composition, construction, and elements and principles of design (p. 24). Barrett's description of medium, the material from which the art object is made (p. 26), is also related to the formal dimension.

Susan Compton, an art historian specializing in 20th-century Russian art, writes extensively on Russian artist, Marc Chagall. In a text documenting the work and life of Marc Chagall, Compton (1985) provides an account of information within the formal dimension for each of the artworks he produced. In reference to *The Birthday*, the medium employed by Chagall, oil paint on cardboard, is identified by Compton. It is important for any art historian to identify media for the reader. However, if a student simply names the medium as oil painting or identifies *The Birthday* as a painting, based on recall of a teacher's lecture, such an outcome could be considered evidence of shallow knowledge-seeking strategies and low-road transfer. There are numerous other formal qualities a student could also note in *The Birthday*, as follows:

- compressed space
- strong diagonals
- multiple points of view
- defiance of normal proportion
- asymmetrical balance
- saturated hues

Knowledge that *The Birthday* is a painting is obvious, and it is based on the practice of looking at other paintings. When knowledge is the consequence of varied practice, (e.g., a great deal of experience looking at paintings), low-road transfer has occurred (Salomon, & Perkins, 1989).

Comparing *The Birthday* to a preparatory sketch, Compton (1985) provides further discussion of formal qualities:

Whereas the drawing establishes the magical relationship of the hovering figures and indicates the detailed elements of the still-life on the table, the role of the table itself has become less important in the oil. For instead of being based purely on a triangle, the final composition depends on the balancing of the diagonals on the left by additions on the right, where the bed and shawl above it have been added. Likewise, the area above the table has been enlivened by a window. (p. 191)

Pointing to compositional devices employed by Chagall, Compton analyzes qualities within the formal dimension. This analysis of the underlying structure of *The Birthday* is mastered by looking closely at balanced diagonals defined by different images in the work. A student might arrive at a higher-order understanding of *The Birthday* by looking closely at its formal qualities. For example, a student might respond as follows:

Red / orange draws attention to the floor area, while the color black is important in shading and defining images in the work.

In this example, the student has employed knowledge-seeking strategies to access relevant prior knowledge of the effects and functions of color. The student has then applied this knowledge to *The Birthday*. The student is able to describe the impact of color in *The Birthday* and its tendency to draw the viewer's attention. The student has also determined that the use of black functions in modeling images in the work. This is high-road transfer because the student expended "greater mental effort" in performing an analysis of the formal qualities in *The Birthday* based on the effects and function of color. This analysis was facilitated by a "closer examination" of the underlying effects of the elements of design (Perkins, & Salomon, 1987; Salomon, 1983; Salomon, & Perkins, 1989).

A close examination of the work does not guarantee a high-road transfer, however, as evidenced in the misunderstanding revealed in this student's statement about *The Birthday*:

The colors Chagall selected to paint *The Birthday* represent the primary color scheme.

While there may be subtle traces of shades, tints or tones of primary colors, the overall color scheme of *The Birthday* is not based on this triadic group of colors. No particular color scheme can be discerned in *The Birthday*, only a brilliant vermilion dominates within a polychromatic family of colors. In this example, meaningful learning is impeded because the student has inaccurate knowledge of what constitutes a primary color scheme.

To assess levels of art understanding, instruments need to focus on the formal dimension of the learner's knowledge-base. The learner's formal knowledge-base might be verified in statements regarding the elements of art, organizational principles of design, surface characteristics, compositional devices, abstract, real and nonobjective qualities, technique, and materials.

Descriptive Dimension of the Learner's Knowledge-Base

In Compton's (1985) formal analysis of the composition of *The Birthday*, she also identifies figures, a still-life, table, bed, shawl, and window within the interior space. According to Barrett (1990), "descriptive statements are verifiable by observation and an appeal to factual evidence" (p. 12). Barrett explains that critics can obtain descriptive evidence by looking directly at what is seen in the work, that is, *internal description*. Barrett goes on to explain that "describing is a

logical place to start when viewing an exhibition or a particular photograph because it is a means of gathering basic information upon which understanding is built" (pp. 12, 13). Compton's use of description is generally confined to the subject matter. However, Barrett states, "descriptive statements about subject matter identify and typify persons, objects, places, or events in a photograph. When describing subject matter, critics name what they see and also characterize it" (p. 17). The following is another historian's descriptive characterization:

Chagall rented a room from a policeman, and that is what we see, faithfully reproduced: Bella's scarves hung up on the wall, the flitch church through the window (it also figured in *Over Vitebsk*), the *fortochka*, a small opening in the top of the window that is a typical feature of Russian houses, even the birthday cake on the table. (Makarius, 1988, p. 74)

A student may also describe subject matter of *The Birthday* as follows:

This is a picture of a man and a woman in a room kissing.

In this description, the student identifies the subject matter in the painting, including a man, woman, and the room. The student also mentions the action of kissing. Describing familiar images and actions requires a shallow, recall-oriented knowledge-seeking strategy. This is an example of low-road transfer because the knowledge-seeking strategy employed by the student does not lead to the construction of new structures of understanding.

In the statement that follows, the student has also identified the subject matter and the act of kissing:

There is a woman kissing a man who is suspended above her. She is also hovering above the ground. Perhaps it was the kiss that caused the couple to float.

Yet in this statement the student has searched for additional descriptive information. The search has prompted the student to provide a reason why the figures are shown floating. This statement is an example of high-road transfer because the student has made a controlled mental effort to explain the floating figures. The resulting higher-order understanding is supported by the scholarly literature on *The Birthday* which describes the painting in much the same way (Compton, 1985; Kamensky, 1989; Makarius, 1988; Sweeney, 1946; West, 1990).

Sometimes students make statements that are clearly contradictory to scholarly interpretations such as:

It appears the woman is kissing a ghost since he is floating in the air.

The student uses descriptive language in identifying the male figure in *The Birthday* as a ghost. Actually, Marc Chagall is portrayed as a man, not a ghost. The student's statement reveals a misunderstanding based on the subject matter. In this case, informal knowledge that ghosts float has impaired potential learning. Perkins and Salomon (1987) might say this as an instance of negative transfer. The student employed knowledge-seeking strategies that caused irrelevant information to be applied from his or her knowledge-base.

Interpretive Dimension of the Learner's Knowledge-Base

According to Barrett (1990), "interpretation occurs whenever attention and discussion move beyond offering information to matters of meaning" (p. 34). There is fairly consistent agreement across the art history literature as to meanings of *The Birthday*. Note the interpretive similarities in the following statements spanning 39 years:

In 1915 he [Chagall] had painted the first of what was to become a long series of paintings of lovers, each celebrating an anniversary of his marriage with Bella, her birthday, or his or their daughter, Ida's. (Sweeney, 1946, pp. 36, 37)

Love as romantic transcendence is most popularly expressed in the work of Marc Chagall (born 1887), as in *The Birthday*, which is so much in the spirit of our notions of perpetual courtship: the exchange of gifts on anniversaries; the perpetuation of courtesies and gallantries practiced before marriage. The charm and popularity of Chagall are in good measure traceable to our belief that the substance of love consists of just such rituals as the one celebrated in *The Birthday*. (Feldman, 1967, p. 24)

... this celebration by the lovers is equally fantastic, for their joy has levitated them from the ground. (Compton, 1985, p. 15)

The Birthday celebrates Chagall's reunion with Bella, whom he married in Vitebsk on 25 July 1915. It is the first of the famous motif of lovers floating in the air—to which Chagall would return again and again. This highly improbable stance adopted by the figures illustrates, both literally and metaphorically, the transports of love, but the interior is teeming with realistic detail. (Makarius, 1988, p. 74)

Each statement suggests *The Birthday* is about the ritual of a birthday. Each statement interprets the subjects as lovers. Since the theme of couples is easy for young people to relate to, it would not be unusual for a student to arrive at an accurate interpretation of *The Birthday* as follows:

The couple shown kissing in the picture are truly head over heels in love ... floating on air.

The student has closely examined the physical positioning of the figures in *The Birthday*. This knowledge-seeking strategy has facilitated access to relevant prior knowledge. First, the man and the woman are kissing and the student knows to classify them as a couple. Second, the student determines that the couple must be in love because they are represented as floating in air. Finally, the student associates the couple's incredible stance as reflecting two people that are "head over heels in love." High-road transfer is reflected in this statement because the student has constructed several new structures of understanding about the painting.

Sometimes ideas are not interrelated and result in lower-order understanding of *The Birthday* as follows:

The painting transmits a joyous, happy mood.

In this case, the student uses obvious adjectives to refer to the work of art. While the painting does transmit a joyous and happy mood, the student has not given any reasons to support that interpretation. This statement is an example of low-road transfer because a quick summation about mood is usually arrived at "intuitively and automatically" (Perkins, & Salomon, 1987).

When a student attempts to interpret meanings of *The Birthday*, it is possible to form a misunderstanding of the work as follows:

The work has a violent theme, a young couple in troubled times do not know how to release their aggression, so they take it out on each other.

The student has employed appropriate and useful knowledge-seeking strategies; however, the interpretation of a “violent theme” is diametrically opposed to the prevalent interpretation of the painting. The student has misinterpreted the painting by drawing upon incongruent information from his or her knowledge-base. Perkins and Salomon (1987) might also call this a negative transfer.

Historical Dimension of the Learner's Knowledge-Base

Historical knowledge might include factual information such as the name of the artist; personal data, such as age, sex, race; title and / or date of the work; historical period / movement; and information regarding where the artist lived and worked. Many sources on Chagall verify factual information of that nature (Arnason, 1976; Compton, 1985; de la Croix, & Tansey, 1980). It is necessary for historians to provide dates, titles, and information about artists, and these facts can also be useful in the classroom. However, when a student merely recites historical facts about a work of art, a lower-order understanding is the result. In responding to *The Birthday*, a student may recall factual information as follows:

The painting is called *The Birthday*. It was painted by the artist Marc Chagall in 1915–1923.

The student has given the title of the work of art, the artist name, and the date the work was created. Yet the student has not used this factual information to learn anything new—even though the title gives a strong clue as to the meanings of the work. Ineffective knowledge-seeking strategies used to access memorized information from the knowledge-base prevent the construction of new structures of understanding in this example.

However, facts in the learner's knowledge-base can be useful in the construction of new understandings, as shown in the following example:

The woman in *The Birthday* looks a lot like the woman depicted in a portrait called *Bella with a White Collar*, also by Marc Chagall. Chagall used the same woman as a model for other paintings. Bella is probably his wife.

In this example, the student has employed knowledge-seeking strategies to access relevant factual knowledge about another work by Chagall. Art historians explain that Chagall is well known for the series of paintings depicting his love for his wife, Bella. The student has expended “greater mental effort” to recall another one of these works by name. This is an example of high-road transfer because the “closer examination” resulted in construction of new structures of understanding. The comparison of the two works stimulated the student to correctly hypothesize an underlying theme present in many of Chagall's artworks.

Using knowledge-seeking strategies to access information regarding other works of art does not guarantee a higher-order understanding of *The Birthday* as shown in the following example:

Salvador Dali, the surrealist, has done many paintings that show human figures and other objects suspended in space: *The Madonna of Port Lligat*, *The Disintegration of the Persistence of Memory*, and *The Sacrament of the Last Supper*, to name a few. Since figures are suspended above the ground in *The Birthday*, this work by Chagall must be an example of Surrealism.

While mental energy is expended in making an interesting association between Dali and Chagall, the conclusion reached in this example is a reflection of misunderstanding. This misunderstanding might be due to a limited frame of reference (Confrey, 1987, p. 97). The Surrealists' concern with the “omnipotence of the unconscious mind” (Preble, & Preble, 1985, p. 378) was not considered in the statement. While aspects of Chagall's work are irrational, the unconscious is not a characteristic associated with *The Birthday*. Thus, the original misunderstanding has been compounded because of the attempt to compartmentalize the work of Chagall into one particular movement or style (Feltovich, et al., 1988; Perkins, & Simmons, 1988). When students learn about the history of art, they commonly associate artists with a particular period, movement, or style. There is not always consistent agreement in the art history literature on the stylistic categorization of Chagall's paintings. For example, in specifying stylistic influences on Chagall's work, Arnason (1976) discusses Chagall as follows:

From his background he acquired a wonderful repertoire of Russian-Jewish folk tales and a deep and sentimental attachment to the Jewish religion and traditions. There was also inbred in him a fairytale sense of fantasy. Out of these elements emerged his personal and poetic painting. . . . In Paris, Chagall entered the orbit of Apollinaire and the leaders of the new Cubism, as well as that of Modigliani, Soutine, and Jules Pascin. Chagall's Russian paintings had largely been intimate genre scenes, often brightened by elements of Russian or Jewish folklore. Bakst's school caused him to make bold efforts using fauve colors and constricted space. His intoxication with Paris opened a floodgate of experiments in fauve color and cubist space, and above all of subjects filled with lyric fantasy. Within two years of his arrival, Chagall was producing mature and weirdly poetic paintings. (p. 282)

The literature offers several viewpoints as to the historical period in which Chagall's work best fits. According to de la Croix and Tansey (1980), Chagall “accepted many aspects of the most sophisticated theories and practices of the times—Expressionism, Cubism, Fauvist color” (p. 832).

Assessing Learning Outcomes

Verbal responses to works of art can provide evidence of learning outcomes within the formal, descriptive, interpretive, and historical dimensions of the learner's knowledge-base. These learning outcomes reflect a variety of knowledge-seeking strategies that can account for degrees of lower-order and higher-order understandings. Therefore, the development of alternative methods for assessing student

understanding might focus on profiling the range of these learning outcomes.

AN ALTERNATIVE ASSESSMENT METHODOLOGY

The quality of assessment instruments used in education is critical because teachers, researchers, and evaluators come to conclusions and base important decisions on the results produced by such instruments (Fraenkel, & Wallen, 1990, p. 126). Current conceptions of learning discussed in this chapter form a theoretical framework upon which an assessment instrument for art education can be grounded. The theoretical framework of learning suggests that categories within an alternative assessment instrument might: (a) represent students' knowledge-base and knowledge-seeking strategies, and the process of transfer; (b) encompass terminology reflective of the field of art education; (c) be responsive to the educator with a background in the arts; and (d) be diagnostic in discriminating among lower-order and higher-order understandings, and misunderstandings.

Development of Categories

The research by Koroscik et al. (1992) motivated the development of an alternative assessment methodology that profiles lower-order and higher-order understandings, and misunderstandings of artworks. Results of study indicate that student understanding can be facilitated by presenting artworks within comparative contexts. Understanding is further facilitated when verbal cues are provided. Through an analysis of qualitative data, the research team found evidence to support the independent functioning of a student's knowledge-base and knowledge-seeking strategies. These findings indicate that a diagnostic assessment of art learning must encompass both facets of learning.

Further analysis of written statements from the Koroscik et al. (1992) study (also known as the Chagall Study) reveals a continuum of learning outcomes. These learning outcomes occur within the formal, descriptive, interpretive, and historical dimensions of art understanding. By adopting Guba's (1978) naturalistic inquiry methodology (also in Patton, 1990), written statements can be reduced and organized into diagnostic categories within the formal, descriptive, interpretive, and historical dimensions of art understanding.

According to Guba (1978), developing category systems first requires overcoming the problems of convergence and divergence. The first problem, *convergence*, arises "because the naturalistic inquirer must derive a set of units or categories within which he will classify and interpret observed outputs" (p. 50). Initially, when sorting data into categories, the researcher might ask: "do the same kinds of observations or comments recur at different times, from different informants or documents, in somewhat different contexts?" (p. 53).

In developing the diagnostic categories, convergence is addressed by seeking out these "recurring regularities." The rules of internal homogeneity and external heterogeneity are applied as recurring regularities were identified. *Internal*

homogeneity refers to the extent to which the data hold together in a meaningful way (Guba, 1978, p. 53). *External homogeneity* refers to the extent to which the categories differ from one another, that is, the difference should be "bold and clear" (p. 53).

The problem of *divergence*, as identified by Guba (1978), involves "the 'fleshing out' of categories with whatever additional information is required for completeness and thoroughness" (p. 49). A three-step process assisted the development of categories: extension, bridging, and surfacing. First, *extension* was employed by building on items of information already known. In the case of the Chagall Study (Koroscik, et al., 1992), student responses had already been identified as formal, descriptive, or interpretive in nature. These dimensions served as bases for more detailed categories. According to Guba, the evaluator "uses these items as bases for other questions or as guides in his examination of documents. Amoeba-like, he inches his way from the known to the unknown" (p. 70).

The second step in devising categories involved *bridging*, that is, making connections among different items. According to Guba (1978):

the inquirer begins with several known, but apparently disconnected, items of information. The term "disconnected" simply means that their relationships are not understood. That there are relationships is a premise of high probability because the items have been placed into the same category. The evaluator now uses these two points of reference for further inquiry in an effort to identify the connections and understand them. (p. 59)

Categories derived from the Koroscik et al. (1992) qualitative data, and sample statements representing each category facilitate the bridging process. First, the relationship of categories within the formal, descriptive, interpretive, and historical dimensions is studied for its connectedness. Also, the relationship of written statements representing individual categories is studied for its connectedness. Once the connections are identified, the third step of surfacing is carried out. According to Guba (1978) *surfacing* involves proposing and verifying new categories or information that should fit into the evaluation system (p. 59). The procedure of surfacing validates the appropriateness of examining supplemental data for "information that ought to be found in the field and then verifying its existence" (p. 59). A broad range of data is gathered from student populations representing a range of ages and abilities. These diverse and varied data sources aid in the expansion, refinement, and applicability of the diagnostic categories.

Koroscik's (1992-93) art learning model also qualifies as a surfacing directive. Grounded in cognitive learning theory, Koroscik's model represents facets that can be assessed in art education, including knowledge-base and knowledge-seeking strategies. Learning outcomes reflective of this model are easily identified in the Koroscik et al. (1992) data, and they mesh with categories previously established through extension and bridging. Therefore, the overall structural format for the Diagnostic Profile of art understandings is tied directly to Koroscik's art learning model.

Through extension, bridging, and surfacing, each learning outcome conveyed by students within the formal, descriptive, interpretive, and historical dimensions has been translated into a diagnostic category. Further, diagnostic categories within the formal, descriptive, interpretive, and historical dimensions have been characterized as lower-order and higher-order understandings, and misunderstandings (Stavropoulos, 1992, 1992–93a).

THE DIAGNOSTIC PROFILE

Grounded in current conceptions of learning, an alternative assessment methodology, referred to as the *Diagnostic Profile*, was developed from the categories. The Diagnostic Profile encompasses terminology reflective of the field of art education, and is responsive to the educator with a background in the arts. Categories within the Diagnostic Profile represent the application of the student's knowledge-base and knowledge-seeking strategies through the process of transfer. Further, this assessment instrument is diagnostic in its ability to discriminate between lower-order and higher-order understandings, and misunderstandings.

The Diagnostic Profile assesses student understandings from written and/or transcribed verbal statements about works of art. Written statements can be stimulated by a range of art reproductions, slides of artworks, actual works of art in museums or galleries, and the students' own artwork.

The Four Dimensions of the Diagnostic Profile

The Diagnostic Profile comprises four dimensions: formal, descriptive, interpretive, and historical. Each dimension contains a series of categories describing student learning outcomes (see Appendix A). All the dimensions within the Diagnostic Profile can be used for a complete analysis. However, a teacher may wish to employ selected dimensions in the analysis of written statements.

Formal dimension. Categories within the formal dimension represent a range of learning outcomes related to the formal qualities of artworks: elements of design (e.g., line, shape, color, texture); organizational principles of design (e.g., repetition, variation, transition, balance, unity); technical processes or media (e.g., impasto, printmaking, drawing, ink); and art styles (e.g., abstract, nonobjective, realistic).

Descriptive dimension. Descriptive dimension categories include learning outcomes related to the subject matter of artworks: objects or figures (e.g., images, symbols); artforms (e.g., landscape, still-life); and activities or actions.

Interpretive dimension. The categories within the interpretive dimension provide a broad spectrum of learning outcomes related to: expressive qualities of artworks; personal meaning and interpretations; and interpretive perspectives.

Historical dimension. The learning outcomes within the historical dimension categories focus on: personal data about the artist (e.g., name, race, birthplace); historical data about the work (e.g., title, date); classifications (e.g., Impressionism, Surrealism); stories, inspirations, mythology regarding the artwork; purpose, function, use of the artwork; and significance.

Identifying Scoring Units

Single words, clauses, sentences, phrases, and / or paragraphs can be used as units of analysis within students' written statements about works of art. As individual scoring units are identified, they are characterized as lower-order understandings, higher-order understandings, and / or misunderstandings.

A scoring unit can be a word, or a group of words in a clause or phrase, that may or may not comprise a whole sentence. A scoring unit can have one or more of the following in various combinations: subject noun, object noun, verb, adjective. Each of the following phrases equal a single scoring units:

- *a dog and a cat* (subject noun + subject noun)
- *a dog was running* (subject noun + verb)
- *the dog was running after a cat* (subject noun + verb + object noun)
- *the black dog was running after a white cat* (adjective + subject noun + verb + adjective + object noun)

Sometimes there are multiple scoring units in one sentence. Usually, these compound sentences are separated by coordinating conjunctions (e.g., then, and, but, or, however) or by punctuation (e.g., a dash, comma). Examples of compound sentences equal to two scoring units are shown below:

- *a dog is running after a cat while the pet owner watches* (subject noun + verb + object noun) [conjunction] (subject noun + verb)
- *a dog and a cat are in the background, and a hamster is in the foreground* (subject noun + subject noun + object noun) [conjunction] (subject noun + object noun)
- *a dog and a cat are playing with a ball while the children watch* (subject noun + subject noun + verb + object noun) [conjunction] (subject noun + verb)

Scoring units: Lower-order understandings. Each single word, clause, or sentence can be used as a unit of analysis for lower-order outcomes. For instance, a student can arrive at a lower-order understanding of *The Birthday* by simply identifying and / or describing an image as follows:

- man in the air

This statement is the equivalent of one scoring unit. The student recognizes a "man," and his placement, as "in the air." Simply recognizing an image, and it's location in the picture plane constitutes a lower-order understanding.

Scoring units: Higher-order understandings. Clauses, phrases, sentences, and / or paragraphs can be used as units of analysis for higher-order outcomes. Often, parts of higher-order units have been previously scored according to their lower-order content. For this reason, scoring for higher-order understanding is essentially a second screening or double-coding of a statement. For example, in the following statement, the student performs a higher-order formal analysis of *The Birthday* based on the elements of design:

- red / orange draws attention, black is important as a shading / defining color

In this example, the student has employed knowledge-seeking strategies to access relevant prior knowledge of the effects and functions of color. It is important to note that this analysis cannot be performed without the lower-order outcome of identification of color. Therefore, lower-order outcomes are analyzed separately from higher-order-outcomes.

Scoring units: Misunderstandings. Sometimes students misunderstand a work of art. Instances of misunderstandings are reflected in responses that contain incorrect information and / or conclusions. Students can arrive at misunderstandings with or without providing a supportive explanation for their response. For example, in the following statement the student has misunderstood *The Birthday*:

- the people are unhappy

The people in *The Birthday* are happily in love; therefore, this statement is contrary to the scholarly interpretations of the work. To arrive at this misunderstanding, the student renders the lower-order description of "people," and then applies lower-order interpretive language to characterize the people as "unhappy." If the student can provide reasons, explanation, and / or arguments to support the "unhappy people" point of view, such strategies applied in misunderstanding *The Birthday* would be considered higher-order.

Color Codings

Units within the written statement are first distinguished according to formal, descriptive, interpretive, or historical dimensions. It is also helpful to note the misunderstandings in this initial screening. This step is expedited by consistently color coding each unit with a transparent marker as:

- formal dimension—yellow
- descriptive dimension—orange
- interpretive dimension—pink
- historical dimension—green
- misunderstanding—double code with dimension color and blue

The process of color coding student responses is accomplished by studying one scoring unit at a time. For instance, the scoring unit, "there is contrast between black and white,"

is coded with a yellow marker because the student is referring to formal qualities. The scoring unit, "a dog is running," is coded with the orange marker because the student is describing subject manner. The scoring unit, "this gives me a happy feeling," is coded with a pink marker because the student is using interpretive language. The scoring unit, "Marc Chagall," is coded with a green marker because the student is giving historical information in reference to the artist's name.

The same color coding system is used to screen higher-order outcomes. When scoring lengthy statements, drawing a circle, or using a bracket to indicate the location of the higher-order outcome is clearer.

If a student incorrectly states that the artist is "Vincent Van Gogh," the statement would be double-coded green for the historical information and blue for the misunderstanding. If a student states, "the people in *The Birthday* are unhappy," the word "people" is coded orange, "unhappy" is coded pink, and "*The Birthday*" is coded green. In addition, since the student misunderstood the interpretive dimension of the work, the statement would also be double-coded with blue.

Assigning Category Codes with the Diagnostic Profile

After each unit has been color coded, the rater analyzes one dimension of the written statement at a time. The units of one particular color are analyzed according to the categories within the dimensions of the Diagnostic Profile.

The rater writes the category code next to each unit in the written statement. Lower-order outcomes can be revealed by the use of a single word, sentence, or phrase. Higher-order outcomes can be revealed by a phrase, sentence, and / or paragraph. The supportive responses (see Appendix B) are useful as standard examples that meet the criteria of particular categories.

Within each dimension (e.g., formal, descriptive, interpretive, historical) categories are coded with a letter. The letters stand for the particular dimension in the Diagnostic Profile:

- "F" = Formal Dimension
- "D" = Descriptive Dimension
- "I" = Interpretive Dimension
- "H" = Historical Dimension

Besides the letter code indicating the particular dimension in the Diagnostic Profile, a numerical code also appears next to each category. Categories that have numerical codes 0" through "4" are representative of lower-order outcomes. Categories with numerical codes "5" and higher are considered higher-order outcomes. Categories identified with negative numbers "–1" through "–3" delineate misunderstandings.

Both the letter and the corresponding number are combined to represent each of 60 categories within the Diagnostic Profile. For example, the category code "F2" illustrates a lower-order outcome in the formal dimension; the category code "D5" is considered a higher-order outcome within the descriptive dimension; and the category code "I10" is repre-

sentative of a higher-order outcome within the interpretive dimension.

Tally of Scores

A matrix can be constructed to tally the outcomes, as shown in Figure 20-1 below:

	F	D	I	H
Lower-order				
Higher-order				
Misunderstanding				
Total				

FIGURE 20-1 Diagnostic profile assessment tally sheet.

To record outcomes of a single student or an entire class, list each outcome on the appropriate line (lower-order understanding, higher-order understanding, or misunderstanding). As outcomes are recorded they should be placed under the appropriate dimension column.

Diagnosis: A Sample Scored Statement

The sample scored statement shown in Figure 20-2 has been stimulated by a series of related artworks. A key artwork, *The Birthday*, is placed within a context of other works of art inspired by the artist Marc Chagall, as follows:

- *Chagall*, a dance choreography by Ginette Laurin, 1988
- *To Marc Chagall*, a poem by Paul Eluard, 1911-1915
- *And Came the Dog and Ate the Cat*, a lithograph by El Lissitzky, 1919

In the scholarly literature on *The Birthday*, experts agree that certain characteristics are significant. These characteristics can be organized according to the dimensions of the Diagnostic Profile, as follows:

- Formal = juxtaposition, abnormal anatomical proportion
- Descriptive = floating, suspended figures
- Interpretive = lovers, relationship, romance
- Historical = Fauvist, Surrealist, Expressionist influence

Such a literature review on the key artwork, *The Birthday*, provides a baseline to judge students' statements about the artwork. If a student arrives at one or more of these understandings of *The Birthday*, they would receive a score that represents an agreement with the literature review in each dimension (category codes "F8," "D6," "I9" and / or "H9") as constructed in Figure 20-2:

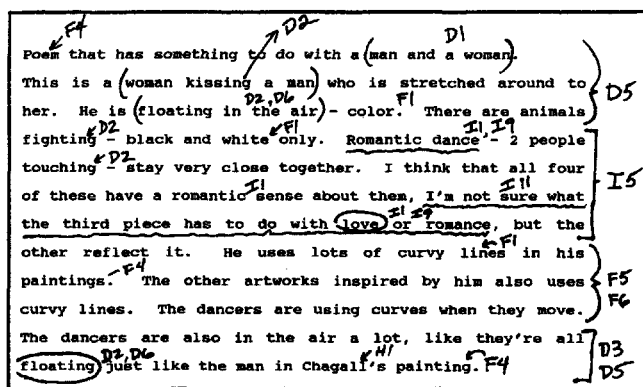

FIGURE 20-2 Sample scored statement.

Each of 27 items scored in the previous statement have been tallied as shown in Figure 20-3:

	F	D	I	H	Total
Lower-order	1,1,1,4,4,4	1,2,2,2,2,2,3	1,1,1	1	17
Higher-order	5,6	5,5,6,6	5,9,9,11		10
Misunderstanding					
Total	8	11	7	1	27

FIGURE 20-3 Tally of diagnostic profile scores.

Graphic Displays of Data

With simple computations based on the 27 items scored with the Diagnostic Profile (shown in Figure 20-3 above), the teacher can reach both qualitative and quantitative assessments of the student's knowledge-base and employment of knowledge-seeking strategies, discussed in the following sections.

Column graph. By constructing a simple column graph, the number of outcomes scored in the various dimensions can be quantified. Frequency of these responses with the formal, descriptive, interpretive, and historical dimensions of the Diagnostic Profile are organized into a column graph (Figure 20-4). The column graph can display visual evidence

FIGURE 20-4 Knowledge-seeking assessment column graph: Frequency of responses within the formal, descriptive, interpretive, and historical dimensions of the diagnostic profile.

of the student's concentration of search strategies in one dimension over another.

Pie chart. The pie chart shown in Figure 20–5 is similar in purpose to the column graph above. Like the column graph, the pie chart provides visual evidence of the student's concentration of search strategies in one dimension over another. However, the actual percentage of responses within the various dimensions of the Diagnostic Profile has been added to the pie chart. In the graphic depiction, the learner's knowledge-seeking strategies within the formal descriptive, interpretive, and historical dimensions of understanding are displayed.

Analysis of the pie chart provides specific quantitative information about the learner's response. Figure 20–5 illustrates that 29.63% of the student's knowledge-seeking strategies occur in the formal dimension, 40.74% are located within the descriptive dimension, 25.93% are found in the interpretive dimension, and only 3.70% are concentrated in the historical dimension.

Histogram. The extent of formal, descriptive, interpretive, and historical understanding can also be plotted from the tally sheet of diagnostic scores. A frequency distribution of individual scores can be depicted graphically to illustrate the degree of cognitive complexity reflected in the written statement. Based on the frequency of response (vertical axis), and the scores received in individual diagnostic categories within each dimension (horizontal axis), a histogram can be constructed, as shown in Figure 20–6.

The histogram in Figure 20–6 provides a more detailed visual account of the learning outcomes in the various dimensions. A diagnostic account of these learning outcomes can be extracted directly from the language used in the categories of the Diagnostic Profile. In the case of the sample statement, the student has concentrated knowledge-seeking strategies in the descriptive dimension, explaining the activities and actions taking place in the artworks. However, the histogram reveals that the student has also employed knowledge-seeking strategies involving the construction of a question pertaining to the meaning of the artworks (category

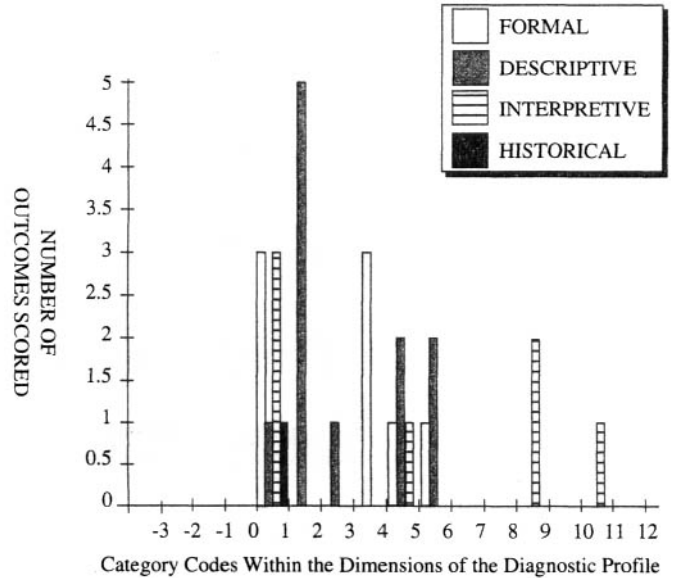

FIGURE 20–6 Degree of cognitive complexity histogram: Extent of formal, descriptive, interpretive, and historical understandings.

code "I11"). As a result of this knowledge-seeking strategy, the student has arrived at an interpretive understanding of the artworks reflective of the scholarly literature on the works of art (category code "I9").

Bar graph. Based on the tally of scores (Figure 20–3), the presence of lower-order and higher-order understandings also can be displayed in a bar graph. As shown in Figure 20–7, the bar graph makes diagnostic discriminations between learning outcomes reflective of lower-order and higher-order understandings. In addition, these learning outcomes have been isolated within each dimension of the student's knowledge-base (i.e., formal, descriptive, interpretive, and historical).

FIGURE 20–5 Knowledge-seeking assessment pie chart: Percentage of responses within the formal, descriptive, interpretive, and historical dimensions of the diagnostic profile.

FIGURE 20-7 Diagnostic assessment bar graph: Lower-order and higher-order understandings within the formal, descriptive, interpretive, and historical dimensions of the diagnostic profile.

ESTABLISHING THE QUALITY OF THE DIAGNOSTIC PROFILE

The quality of the Diagnostic Profile assessment was ascertained through traditional test and measurement procedures. These procedures are of two basic types: studies of validity, and studies of reliability. Generally, validity refers to the extent to which the instrument provides an accurate picture of the phenomena examined; and reliability refers to the extent to which the measurement procedure yields the same answer and whenever it is used (Kirk, & Miller, 1990). Validity and reliability studies enhance the likelihood that appropriate inferences will be drawn from data the instrument provide (American Psychological Association, 1985; Fraenkel, & Wallen, 1990; Krathwohl, 1988; Leedy, 1989; Messick, 1989). Overall, these validity and reliability procedures apply equally well to qualitative and quantitative data (Kirk, & Miller, 1990, p. 19). However, in selected instances the procedures have been redefined "to fit the realities of qualitative research, and the complexities of social phenomena" (Strauss, & Corbin, 1990, p. 249, 250).

Validity of the Diagnostic Profile has been estimated by two content validity studies, two criterion-related studies, and a construct validity study. Reliability of the Diagnostic Profile has been estimated by inter-rater and intra-rater reliability studies. Results of these studies are summarized in the following sections.

Content Validity

Two experts served as independent judges for content validity studies. One of the independent judges is an art educator who specializes in evaluation in art education. The expertise of the

second independent judge is in the application of non-Western art history to art education. Each of these two independent judges assessed the content of the Diagnostic Profile. A summary of the results of the analyses performed by the independent judges follows.

Importance and appropriateness of content. Judgments were rendered on the importance and appropriateness of categories in assessing art understandings. With a few minor exceptions, the diagnostic categories were considered important and appropriate.

Practicality. The complexity of the analysis performed by the Diagnostic Profile justifies its length, according to an independent judge. In addition, this judge responded positively to the procedural and administrative aspects of the Diagnostic Profile. She found the training procedures to be reasonable, and the methods of coding and reporting data were judged to be clear and concise.

Applicability to artforms. The independent judge with the art history specialization was asked to rate the diagnostic categories in terms of their applicability to a variety of artforms. Since the categories were originally derived from Western art, the results provided by the independent judge are encouraging. She verified that 98% of the categories could apply to Western art and fine art, and that 90% be used for non-Western art. In addition, the Diagnostic Profile is highly rated for its applicability to popular arts, folk art, crafts, antiques and heirlooms, and cultural artifacts.

Applicability to data. Both judges indicate that a diagnostic assessment can be applied to a variety of data. These might include written statements about a single work of art or multiple works of art, written statements that have been verbally cued, and oral statements that have been transcribed.

Diagnostic capabilities. The independent judges agree that the Diagnostic Profile could be used to determine formal, descriptive, interpretive, and historical understandings of art. The experts also indicate that the Diagnostic Profile could be used to assess understandings of students in kindergarten through grade 12. Furthermore, the Diagnostic Profile can be used to assess the understandings of undergraduate and graduate students.

Future implications. The Diagnostic Profile is judged to be clear "conceptually and in its application." An independent judge states the instrument and the theoretical model are "well-conceived." There is also support for using the Diagnostic Profile in art education research, program assessment, teacher assessment, student assessment, student self-assessment, and curriculum development. In conclusion, one independent judge states, "I find the implications for teacher training and on-going self evaluation (by the teacher) to be extremely intriguing."

Criterion-Related Validity

Two criterion-related studies were conducted with a 3rd/4th-grade art class and an 8th-grade art class (Stavropoulos,

1992–93b). The focus of these studies was on the relationship between an external criterion and the Diagnostic Profile findings. The principal investigator observed 3rd / 4th-grade and 8th-grade students and the instruction they received over a period of several weeks. A summary of these observations serves as an external criterion.

Data in the form of written statements were gathered from students at the end of the observational periods. The written statements were then scored with the Diagnostic Profile. The degree of criterion-related evidence of validity was reflected in how well the external criterion predicted student performance as assessed with the Diagnostic Profile.

3rd / 4th-grade class. Student writing samples were expected to be heavily influenced by the art teacher's instruction. During the 6-week observational and instructional period, students participated in the following activities:

- *lecture format*—students viewed slides in a dark room as the teacher read a script
- *questioning*—students were asked to recite historical facts about an artist and his artwork
- *reinforced vocabulary terms*—students repeatedly identified various art terms

Results of this study demonstrate an extremely strong relationship between the external criterion and the assessment of the 3rd / 4th-grade students' written statements. This criterion-related evidence of validity offers verification regarding the Diagnostic Profile's ability to discriminate lower-order understandings (see Stavropoulos, 1992–93b).

8th-grade class. Observations of the 8th-grade class revealed that students received instruction that encouraged higher-order thinking skills such as:

- *research*—students searched through classroom resources to learn about works of art
- *"put it in writing"*—students found the words to express their ideas in a cohesive written format
- *constructing arguments*—students were required to defend their stance with reasons
- *criticism*—students described, analyzed, interpreted, and judged works of art
- *aesthetic inquiry*—students considered social and cultural issues in the selection of artworks for a museum

The teacher's implementation of these instructional strategies encouraged students to become active participants in their own learning. As predicted, higher-order thinking skills were exhibited by the vast majority of students in the 8th-grade class.

Results of this study demonstrate a strong relationship between the external criterion and the assessment of the 8th-grade students' written statements with the Diagnostic Profile. This criterion-related evidence of validity provides convincing evidence of the Diagnostic Profile's effectiveness in discriminating higher-order understandings (see Stavropoulos, 1992–1993b).

Construct Validity Study

The objective of the construct validity study was to determine whether constructs in the Diagnostic Profile could be supported with a comprehensive data base. Results indicate that all categories within the Diagnostic Profile could be supported by responses from the data base (see Appendix B). A strong relationship was found between the data and the constructs in the Diagnostic Profile. Consequently, the Diagnostic Profile discriminated lower-order understandings from higher-order understandings, and identified misunderstandings.

According to Fraenkel and Wallen (1990) construct validity involves a variety of procedures that include evidence of content validity and criterion-related validity (p. 133). Therefore, construct validity of the Diagnostic Profile was further amplified by the favorable results of the content validity and the criterion-related validity studies previously discussed.

Rater Reliability

Reliability tests of the Diagnostic Profile focus on inter-rater and intra-rater consistency.

Participants. The principal investigator, an expert at using the Diagnostic Profile, served as the criterion rater. Since written statements about works of art are generated in art classrooms, it made sense for art teachers to serve as raters. Since the teachers in the study were to provide information to assist in the refinement of the Diagnostic Profile, they were selected on the basis of their commitment to assessment in art education. Both teachers had embarked on graduate work, and they were compensated \$300 for participating in the rater-reliability studies. Therefore, the teachers had a stake in the results.

Data base. The Diagnostic Profile can be used to assess written or transcribed verbal statements about works of art. Since people respond in many different ways to works of art, a comprehensive data base of written and transcribed verbal statements was gathered for the studies. The data base reflects variance in several areas: size of class, age, sex, ethnicity, grade level, economic standard, cultural background, and academic abilities.

Inter-Rater Consistency

The focus of the inter-rater reliability study was on how consistently three different raters assign scores to written statements using the Diagnostic Profile. The teachers learned how to use the Diagnostic Profile during several practice sessions.

Findings. Calculation of average reliability between pairs of raters was based on 109 checks. In the three comparisons, average reliabilities verified a "very strong association" in the assignment of scores as follows:

- 0.97—teacher A and teacher B
- 0.96—teacher A and the criterion rater

- 0.98—teacher B and the criterion rater

Several factors should be considered when interpreting the strong association between the raters' scores: (a) the teachers had an unusually high commitment level, (b) the teachers were financially compensated, and (c) the teachers received intensive practice sessions. Under normal circumstances, reliability would be expected to be somewhat lower. However, this study presents convincing evidence that with a reasonable amount of training art teachers can be taught to reliably score written responses with the Diagnostic Profile.

Intra-Rater Consistency

The intra-rater consistency study involved the comparison of scores assigned to identical written statements at different points in time. Four weeks elapsed between the two scoring periods, and no practice sessions were held for the intra-rater study.

Findings. The average reliability between time one and time two (i.e., four weeks later) was based on 42 checks. A "very strong association" was indicated between the scores as follows:

- 0.86—teacher A
- 0.88—teacher B
- 0.98—criterion rater (e.g., principal investigator)

Although there was a noted decline in the abilities of the teachers to apply the Diagnostic Profile, the retention rate held strong even after a 4-week interval.

The data suggest that the intervening time (4-weeks), does not adversely affect an art teacher's ability to reliably score written responses to art using the Diagnostic Profile. As the inter-rater and intra-rater studies involved the same participants and some of the same data, the limitations discussed in the inter-rater study apply to the findings of this study.

EDUCATIONAL IMPORTANCE OF FUTURE APPLICATIONS OF THE DIAGNOSTIC PROFILE

The Diagnostic Profile has the potential to assess understandings of students in kindergarten through grade 12. In addition, the Diagnostic Profile is also judged to be useful in assessing the understandings of college undergraduates and graduate students (Stavropoulos, 1992). Through both small and large scale research studies, assessment provided with the use of the Diagnostic Profile can demonstrate the effectiveness of teaching and learning. Therefore, the importance of the research contained in this chapter lies in future applications of the Diagnostic Profile assessment methodology.

Research on Art Education Programs

The Diagnostic Profile provides a means of assessing alternative art education programs, such as discipline-based art

education (DBAE). In a recent report submitted to the Getty Center for Education in the Arts, the Diagnostic Profile was reviewed:

The project team is very excited about the analytic scoring system [Diagnostic Profile] because it allows the team to assess constructs such as problem solving, higher-order thinking, and other sophisticated constructs that cannot be assessed using holistic scoring. It provides a mechanism to probe the viability of the theoretical framework....The potential of this system to document the impact of DBAE based instruction far exceeds anything that is currently available (Getty Center for Education in the Arts, 1991, pp. 21–22)

DBAE programs have been assessed with the Diagnostic Profile. For example, one quasi-experimental study focuses on the effects of a DBAE program on elementary students' written statements about artworks (French, 1992; Stavropoulos, 1994). Three intact 4th-grade classrooms received either a writing intensive approach to DBAE, a nonwriting approach to DBAE, or a traditional studio-based approach to art education throughout the school year. Long-term effects of these art curricula on 4th-grade students' ability to engage in higher-order thinking skills was determined by a qualitative analysis of pretest and posttest data with the Diagnostic Profile. According to the Diagnostic Profile analysis, both the nonwriting DBAE approach and the DBAE writing intensive approach had a notable impact on student ability to write about the art stimuli. However, the writing intensive approach to DBAE influenced students' ability to effectively discuss and understand a work of art most significantly. Further, the Diagnostic Profile was found to be extremely applicable and instrumental in making such discriminations.

Curriculum

Potential learning outcomes are reflected in categories of the Diagnostic Profile. These learning outcomes correspond to a novice-to-expert continuum and provide a hierarchical framework of art learning. The Diagnostic Profile can therefore serve as a curriculum scheme from which to design and guide instruction.

Research on Teachers

The Diagnostic Profile might also be used in research on teachers. For example, an independent judge suggests exploring teachers' attitudes toward using the Diagnostic Profile by asking:

How does the ability to generate supportive evidence of student learning outcomes with the Diagnostic Profile heighten teacher confidence and morale, sense of accomplishment, and self-esteem? Will using the Diagnostic Profile prompt ownership of the instrument?

Another study might be conducted to examine differences in how teachers interpret curricula. This research direction builds upon the two criterion-related validity studies performed on the Diagnostic Profile. Both the 3rd / 4th-grade teacher and the 8th-grade art teachers teach concepts of discipline-based art education; however, the art teachers

sharply contrast in how they operationalize discipline-based art education (Stavropoulos, 1992, 1992-93b). While it is clear that the two art teachers are dissimilar in their background qualifications and in the educational levels they teach, fluctuation in meeting discipline-based curricular objectives may be attributed to other variables. The Diagnostic Profile might be useful in isolating these variables.

Self-Assessment

The Diagnostic Profile might also be used to assess student understandings of artworks. It seems most appropriate to develop a form of the instrument for students to use in self-assessments. This feedback might help students grasp more fully aspects of their own educational progress.

Large-Scale Studies

The Diagnostic Profile enables random sampling from large populations. Results provided by large-scale studies can assist in designing more effective curricula, demonstrate to parents that art programs make a difference, and assist in advocacy efforts by providing comparative data. Such efforts might help secure funding for future research in art education and assist policy makers in arriving at more equitable decisions about the allocation of educational resources.

IMPLICATIONS FOR ART EDUCATION

The Diagnostic Profile contributes to the advancement of the field of art education by providing a means to assess student understandings of visual art. Standardized tests are not useful for assessing understanding because they are recall-oriented. They do not provide students with the opportunity to

use their prior knowledge to demonstrate organizational skills, give explanations and reasons for choices, and present arguments.

The instrument discussed in this chapter is diagnostic in its ability to discriminate among lower-order and higher-order understandings, and misunderstandings reflected in written statements. Learning outcomes in relation to the student's knowledge-base and choice of knowledge-seeking strategies can also be verified in written statements. When students write about works of art, their thinking processes can unfold, and their understandings are revealed (Efland, et al., 1991). Therefore, writing activities allow students to apply their prior knowledge to organizing information and to explaining answers or solutions related to works of art.

The Diagnostic Profile encompasses terminology reflective of the field of art education. Therefore, the Diagnostic Profile is responsive to educators who have backgrounds in the visual arts. Studies reported in this chapter indicate that the Diagnostic Profile is consistent and effective in: assessing formal, descriptive, interpretive, and historical understandings of artworks; and providing a reliable and valid assessment of student understandings of artworks. The Diagnostic Profile is unique in that it reflects current conceptions of art learning, and provides an analysis of student's thinking and understanding of visual art. The Diagnostic Profile goes beyond description based upon memorization and recall by: (a) delineating the student's construction of knowledge from a writing sample, (b) characterizing the interplay between students' knowledge-base and choice of knowledge-seeking strategies, (c) assessing a range of understandings and misunderstandings, and (d) diagnosing attributes and constraints in learning. With the capability to assess student understandings and misunderstandings of art, the Diagnostic Profile offers opportunities to reconfigure instructional materials to improve teaching and learning of the visual arts.

APPENDIX A : DIAGNOSTIC PROFILE OF ART UNDERSTANDINGS

FORMAL DIMENSION

Elements of Design and Principles of Organization,
Media and Technique

Lower-Order Understandings

- F0** Immature judgment, nebulous or unclear formal statement.
- F1** General recognition / identification / definition of elements, principles, marks, graphic details, grounds and / or perspective.
- F2** Identifies abstract, real, or nonobjective qualities.
- F3** Points out style or personal method used by the artist or ethnic group.
- F4** Correctly classifies work in terms of technique processes, media and / or materials used .

Higher-Order Understandings

- F5** Student actively searches work for formal understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).
- F6** Analyzes work in terms of the elements of design (e.g., line, shape, color, texture).
- F7** Analyzes work in terms of the principles of design (e.g., repetition, variation, action / movement, balance, unity, dominance, contrast).
- F8** Formal agreement with literature review.
- F9** Supported judgment and / or aesthetic reasoning (formal).
- F10** Formal questioning.
- F11** Extends and / or challenges technicians' appraisal regarding the technical process / medium utilized to make the work, through convincing argument which includes supportive examples or evidence. Extends and / or challenges historians' or critics' analysis of the work in reference to the elements and principles of design, through convincing argument which includes supportive examples or evidence.

Misunderstandings

- F1** Incorrect formal appraisal (Supported)
- F2** Incorrect formal appraisal (Unsupported)
- F3** Illogical formal findings

DESCRIPTIVE DIMENSION

Objects, Images and Scenes

Lower-Order Understandings

- D0** Immature judgment, nebulous or unclear descriptive statement.

- D1** Identifies lists, and demonstrates a general recognition of images, scenes, and / or symbols .
- D2** Student lists and / or explains activities (verb / and at least one noun).
- D3** Identification of artforms (e.g., landscape, portraiture, caricature, still-life, street scene) .
- D4** Examines and describes surface details of images.

Higher-Order Understandings

- D5** Student actively searches work for descriptive understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).
- D6** Descriptive agreement with literature review.
- D7** Supported judgment and / or aesthetic reasoning (descriptive).
- D8** Descriptive questioning.
- D9** Extends and / or challenges historians' and / or critics' description of the work through convincing argument which includes supportive examples or evidence.

Misunderstandings

- D1** Incorrect descriptive appraisal (Supported)
- D2** Incorrect descriptive appraisal (Unsupported)
- D3** Illogical descriptive findings v

INTERPRETIVE DIMENSION

Meaning, Emotion, Feelings, and Expression

Lower-Order Understandings

- I0** Immature judgement, nebulous or unclear interpretive statement.
- I1** General interpretive language.
- I2** Uncustomary / unexpected impression (viz., personal).
- I3** Relates work to "popular culturer (e.g., names pop culture).
- I4** Correctly relates work to a culture or religious belief system.

Higher-Order Understandings

- I5** Student actively searches work for interpretive understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).
- I6** Personal interpretation based on description of images, scene, and / or symbols.
- I7** Personal interpretation based on analysis of elements of design (e.g., line, shape, color, texture).
- I8** Personal interpretation based on analysis of principles of design (e.g., repetition, variation, dominance, balance, transition, unity, contrast, movement, action).
- I9** Interpretation agreement with literature review (e.g., cites conventional, feminist, psychoanalytic, Marxist interpretive perspectives).

- I10** Supported judgment and / or aesthetic reasoning (interpretive).
- I11** Interpretive questioning.
- I12** Extends and / or challenges historians' and / or critics' interpretation of the work through convincing argument which includes supportive examples or evidence.

Misunderstandings

- I1** Incorrect interpretive appraisal (Supported)
- I2** Incorrect interpretive appraisal (Unsupported)
- I3** Illogical interpretive findings

HISTORICAL DIMENSION

Historical Background Classifications and Shared Understandings

Lower-Order Understandings

- H0** Immature judgment, nebulous or unclear historical statement.
- H1** Artist's name(s), or ethnic group.
- H2** Personal data or background about artist (e.g., age, sex, race, culture, where artist was born, lived, worked and / or "stories" about artist's life) or ethnic group.
- H3** Title or date of work(s), the place or person(s) the work might depict.
- H4** Identifies, sorts, or classifies work(s) according to culture, period, movement, societies and associations; and / or form(s).

Higher-Order Understandings

- H5** Student actively searches work for historical understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).
- H6** Discusses the artist's inspiration or mythology about the origin of the form in a supportive explanation of the work.
- H7** Provides a supportive explanation of the work in reference to its purpose, function, or use.
- H8** Makes comparison(s) of other works by same artist or ethnic group(s) or different artist(s) and / or ethnic group(s).
- H9** Historical agreement with literature review (e.g., cites cultural significance of work in reference to artist, context, movement, ethnic group and / or society).
- H10** Supported judgment and / or aesthetic reasoning (historical).
- H11** Historical questioning.
- H12** Extends and / or challenges historians' and / or critics' appraisal, analysis, and / or theories applied to the work of art or artist through convincing argument which includes supportive examples and evidence.

Misunderstandings

- H1** Incorrect historical appraisal (Supported)
- H2** Incorrect historical appraisal (Unsupported)
- H3** Illogical historical findings

APPENDIX B : SUPPORTIVE RESPONSES FOR DIAGNOSTIC CATEGORIES

Sample student responses are given to support each category within the Diagnostic Profile. Following each sample is a code number that corresponds to the artwork, group of artworks, or artist that stimulated the response as shown below:

- (0) The artist, Marc Chagall.
- (1) *The Birthday*, a painting by Marc Chagall, 1915–1923.
- (2) *Chagall*, a dance choreography by Ginette Laurin, 1988.
To Marc Chagall, a poem by Paul Eluard, 1911–1915.
And Came the Dog and Ate the Cat, a lithograph by El Lissitzky, 1919.
The Birthday, a painting by Marc Chagall, 1915–1923.
- (3) *The Holy Coachman*, a painting by Marc Chagall, 1911–1912.
I and the Village, a painting by Marc Chagall, 1911–1912.
The Fiddler, a painting by Marc Chagall, 1912–1913.
The Birthday, a painting by Marc Chagall, 1915–1923.
- (4) *Jawlensky and Werefkin in a Meadow*, a painting by Gabriele Munter, 1908–1909.
Untitled #2, a painting by Richard Lindner, 1962.
The Dance of Life, a painting by Edvard Munch, 1899–1900.
The Birthday, a painting by Marc Chagall, 1915–1923.
- (5) *Los Mismos*, aquatint print from the Disasters of War series, by Francisco Goya, 1919.
- (6) The artist, Vincent Van Gogh.

Expert statements about works of art were also part of the sample selection. These statements were appropriated from two sources. Some expert statements came directly from books on art history and art techniques. Other statements were solicited from persons with advanced knowledge in visual art, art education, or art history. These statements are coded with the word “expert.”

SUPPORTIVE RESPONSES: FORMAL DIMENSION

Lower-Order Understandings

- F0 Immature judgment, nebulous or unclear formal statement.**
I like it because it has orangish-red in it (1).
the work is very good and detailed (5).
- F1 General recognition / identification / definition of elements, principles, marks, graphic details, grounds and / or perspective.**
red, blue, green (3).
perspective used (2).
- F2 Identifies abstract, real, or nonobjective qualities.**
a little abstract especially in distorting the features of the body (3).

none are realistic, again abstract (3).
but they are not realistic portrayals, the last one looks almost real with very little abstraction if any at all (3).

- F3 Points out style or personal method used by the artist or ethnic group.**
Van Gogh has an unusual brush stroke—very wild with energy (6).
- F4 Correctly classifies work in terms of technique processes, media and / or materials used.**
the way the paint is applied it seems to have been thinned and soaked into the canvas (3).
a ‘collage’ type picture, meaning that several pictures are painted on top of each other (3).
they used a shading technique (5).
one color will fade into the next (3).

Higher-Order Understandings

- F5 Student actively searches work for formal understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).**
he uses lots of curved lines in his paintings. The other painting inspired by him also uses curved lines. The dancers are using curves, when they move (2).
abstract work—a man and a woman . . . the pieces all fit to make up the images, yet they are all different shapes and colors (4).
- F6 Analyzes work in terms of the elements of design (e.g., line, shape, color, texture) .**
red / orange draws attention, black is important as a shading / defining color (3).
some [colors] are soft and timid while others harsh and bright (3).
the shapes of the faces are very similar (3).
- F7 Analyzes work in terms of the principles of design (e.g., repetition, variation, action / movement, balance, unity, dominance, contrast).**
dominant figures that the eye is attracted to (3).
detail around the sides draws the eye outward (3).
each has a main focal point (3).
black and white suggest opposition and contrast (2).
- F8 Formal agreement with literature review.**
Goya used an aquatint method of printing (expert).
- F9 Supported judgment and / or aesthetic reasoning (formal).**
doesn't give my eye a focal point, it isn't pleasant to look at (3).
cluttered . . . too many contrasting views (3).
the color white is used effectively as a receding color (3).
- F10 Formal questioning.**
We have studied many painting by Chagall in class. Has

Chagall ever worked in any other media, such as wood, clay, or printmaking? (0).

- F11 Extends and / or challenges technicians' appraisal regarding the technical process / medium utilized to make the work, through convincing argument which includes supportive examples or evidence. Extends and / or challenges a historian's or critic's analysis of the work in reference to the elements and principles of design, through convincing argument which includes supportive examples or evidence.**

Tamarind Book of Lithography states the stone should be lavigated before resensitization with acetic acid, in preparation for the second printing. However, when lavigating the stone there is the risk of scratching its surface, making additional lavigating necessary. With too much lavigating there is a good chance the ghost image would be lost on the stone, making further detailing of the image and future registration impossible. I have found the use of bleach cleanser to be a suitable alternative to the lavigation method. The mild abrasive in the cleanser removes the old ink, and the bleach eliminates the oil deposits. Resensitization with acetic acid is not affected (expert).

Misunderstandings

- F1 Incorrect formal appraisal (Supported) .**
 Marc Chagall does not proportion feet & hands correctly—they are stretched out (2).
 you can tell it's a black and white etching because of the deep lines and dark color (2).
- F2 Incorrect formal appraisal (Unsupported).**
 its done in ball-point pen (5).
 each painting uses the same color scheme of primary colors (3).
- F3 Illogical formal findings.**
 painting looks almost one-dimensional (4).

SUPPORTIVE RESPONSES: DESCRIPTIVE DIMENSION

Lower-Order Understandings

- D0 Immature judgment, nebulous or unclear descriptive statement.**
 I like it because of the people (1).
- D1 Identifies, lists, and demonstrates a general recognition of images, scenes, and / or symbols (nouns).**
 man and woman (4).
 body, face, village, church, cabins (3).
 image of an animal, a cow, and two people (3).
- D2 Student lists and / or explains activities (verbs).**
 2 people starting to kiss (3).
 man in air—backwards (2).
 men fighting with each other (5).
 this is an image of a person that appears to be flowing or flying near a church (3).

- D3 Identification of artforms (e.g., landscape, portraiture, caricature, still-life, street scene)**
 land types (5).
 portrait of a couple (1).
- D4 Examines and describes surface details of images.**
 the faces look like skeletons (5).
 goat face and a human face (3).
 scarves on the wall have a detailed paisley pattern (1).

Higher-Order Understandings

- D5 Student actively searches work for descriptive understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).**
 humans in inhuman states, and nonhumans in human states (3).
 there is a woman kissing a man who is stretched around her, he is floating in the air . . . there are animals fighting . . . 2 people touching very close together . . . the dancers are also in the air a lot, like they're all floating just like the man in Chagall's painting (2).
- D6 Descriptive agreement with literature review.**
 man playing the fiddle - standing on top of the world (3).
 portrayed in a floating, distorted manner (3).
 killing, rape (5).
- D7 Supported judgment and / or aesthetic reasoning (descriptive).**
 I don't like this piece because of the man's body and how its disfigured (4).
 I don't like this painting because the man's neck in the picture makes me feel strange and uncomfortable (4).
- D8 Descriptive questioning.**
 why are the walls of the apartment pictured in *The Birthday* decorated with colorful scarves? Was there a special reason for the scarves to be hung in this way? (1).
 a robot's knee is showing—why? (4).
 why is the lady so big? (4).
- D9 Extends and / or challenges historians' and / or critics' description of the work through convincing argument which includes supportive examples or evidence.**
 because the "bed image" is cut off at the right of the composition, slightly tilted in perspective, and covered with scarves, it could be very well be a pillow rather than a bed (1).

Misunderstandings

- D1 Incorrect descriptive appraisal (Supported).**
 it appears the woman is kissing a ghost since he is floating in the air (4).
 the look on the man and woman's face appears to be angry and they look as though they are arguing (1).

- D2 Incorrect descriptive appraisal (Unsupported).**
black and white monsters (2).
- D3 Illogical descriptive findings.**
there are martians invading a planet (1).

SUPPORTIVE RESPONSES: INTERPRETIVE DIMENSION

Lower-Order Understandings

- I0 Immature judgment, nebulous or unclear interpretive statement.**
I like it because it makes me happy (1).
- I1 General interpretive language.**
this work is very violent (5).
vulgar, disgusting (5).
- I2 Uncustomary / unexpected impression (viz., personal).**
murder, hate, killing—things I like (5).
- I3 Relates work to popular culture (e.g., names pop culture).**
Fiddler on the Roof (3).
Bart Simpson (5).
- I4 Correctly relates work to a culture or religious belief system.**
Reference to Christianity in all of them—the symbol of the cross (3).
A couple of them have a Christian theme (3).

Higher-Order Understandings

- I5 Student actively searches work for interpretive understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).**
they all involve two people or two major subjects; deal with love; romance in a bazaar way; eerie kind of love; not ordinary (4).
- I6 Personal interpretation based on description of images, scene, and / or symbols.**
man bending over woman—To me this signifies that a man bends over backward to make a woman happy (4).
a couple sitting on a hillside and they seem content with each other (4).
- I7 Personal interpretation based on analysis of elements of design (e.g., line, shape, color, texture).**
almost wicked because of the dark colors (3).
it looks like a happy wedding reception, but the bride is in red and the guests are in white (4).
- I8 Personal interpretation based on analysis of principles of design (e.g., repetition, variation, dominance, balance, transition, unity, contrast, movement, action).**
a light and joyous feeling caused by the delicate motion of the dancers—graceful movement (2).
create a sense of anxiety because there appears to be haphazard movement within each scene (2).

- I9 Interpretation agreement with literature review.**
someone being head over heels in love ... floating on air (3).
dreamy—reminds me of a dream. I think of floating—I like it—different (4).
it is about the horrors of war (5).
- I10 Supported judgment and / or aesthetic reasoning (interpretive).**
My favorite piece is the last one because its simple and peaceful (4).
Looks romantic—I like it—it reminds me of happy moments (4).
- I11 Interpretive questioning.**
were any other contemporaries of Chagall working with the theme of love during this time? (0).
did the euphoria of their love cause them to have an outer body experience? (1).
- I12 Extends and / or challenges historians' and / or critics' interpretation of the work through convincing argument which includes supportive examples or evidence.**
the title of the painting suggests the work should be interpreted as the celebration of a birthday. However, the two lovers pictured may have just been married. The woman holds the traditional bridal bouquet, they are so in love they have defied gravity (1).

Misunderstandings

- I1 Incorrect interpretive appraisal (Supported).**
all of these figures have very blank frozen looks on their faces ... I see it as being sick of the everyday monotony of life or as being bored with each other (4).
all of the people seem sad, with their heads hung, or facial expressions (4).
- I2 Incorrect interpretive appraisal (Unsupported).**
these artworks are about a man and woman interacting, generally sexually (4).
I'd say it looks like jealousy (4).
- I3 Illogical interpretive findings**
to me seems satanist. Like there is a heaven and hell (2).
all of them have a violent theme, a young couple in troubled times does not know how to release their aggressions, so they take it out on each other (2).

SUPPORTIVE RESPONSES: HISTORICAL DIMENSION

Lower-Order Understandings

- H0 Immature judgment, nebulous or unclear historical statement.**
I like it because it is Surrealistic (1).
- H1 Artist's name(s), or ethnic group.**
the work is painted by Marc Chagall (1).
- H2 Personal data or background about artist (e.g., age, sex, race, culture, where artist was born, lived,**

worked and / or “stories” about artist’s life) or ethnic group (e.g., culture, county, sex of artist).

he was born in Russia (0).

he had a studio in Paris (0).

H3 Title or date of work(s), the place or person(s) the work might depict.

the work is entitled *The Birthday* and was painted in 1915 (1).

outside the window is a view of Vitebsk (1).

H4 Identifies, sorts, or classifies work(s) according to culture, period, movement, societies and associations; and / or form(s).

Like the Impressionists, Van Gogh painted the light with his favorite color yellow (expert).

Chagall accepted the sophisticated theories and practices of the times: Expressionism, Cubism, and Fauvist color (expert).

Higher-Order Understandings

H5 Student actively searches work for historical understanding (e.g., compound sentences, complex thought structures, connection-making, comparisons, speculation, hypotheses, and / or conclusions).

this painting [*The Birthday*] incorporates the pure saturated color of the Fauvist, and the floating figures are reminiscent of Surrealism. In examining the tilted perspective of the table, and the multiple points of view, Cubist qualities become apparent (expert).

H6 Discusses the artist’s inspiration or mythology about the origin of the form in a supportive explanation of the work.

Chagall’s imagery is representative of his early life in a Russian village (0).

the Bwami society is compared to a tree with far reaching roots (expert).

H7 Provides a supportive explanation of the work in reference to its purpose, function, or use.

warriors’ tunics were occasionally worn by kings (expert).

H8 Makes comparison(s) of other works by same artist or ethnic group(s) or different artist(s) and / or ethnic group(s).

a comparison of Chagall’s interpretation of war with Picasso’s in the *Guernica* illuminates the broad scale of expressive emotion upon which art can play (expert).

H9 Historical agreement with literature review (e.g., cites cultural significance of work in reference to artist, context, movement, ethnic group and / or

society).

Chagall portrays the trials and persecutions of the Jewish people (0).

H10 Supported judgment and / or aesthetic reasoning (historical).

this is a successful work of art because it can touch people of different ages. Children can relate to the child-like quality of the execution—exact representation is not important, figures float about the picture plane. The work can remind the adult of happy childhood dreams and memories (1).

H10 Historical questioning.

the work of Chagall seems to have elements of several different styles and movements (Expressionism, Fauvist color, Fantasy, Surrealism, etc.). In what period of art history is Chagall’s work most associated? (0).

H12 Extends and / or challenges historians’ and/or critics’ appraisal, analysis and / or theories of the work with supportive examples, explanation, and / or evidence.

West (1990) reminds us that “indeed all such stories by Bella and Chagall himself must be read with the knowledge that they were writing retrospectively, and could thus construct their interpretations to suit themselves” (p. 80). I question West’s (1990) remarks, that in essence tend to reduce the credibility of the remembrances of Bella Chagall. It may be possible that Bella Chagall’s 1939 dedication to Marc Chagall, *First Encounter* (Chagall, 1973), provides the context for a deeper understanding of the painting *Above the Town*? This 1917 painting depicts Bella and Marc floating in the sky over Vitebsk. It is interesting to note that the view from the window of *The Birthday* has also been identified as Vitebsk. And further, Bella has on the same dress as she wears in *The Birthday*; Marc wears a similar green shirt and black pants. Could *Above the Town*, painted two years later than *The Birthday*, record the imaginary flight over Vitebsk that summer evening? (expert).

Misunderstandings

–H1 Incorrect historical appraisal (Supported).

the stories reflected in the works are from the past, maybe in the 19th century (3).

–H2 Incorrect historical appraisal (Unsupported).

its abstract expressionism (3).

–H3 Illogical historical findings.

the painting looks like it was done back in the era of Napoleon (2).

A NATIONAL POLICY PERSPECTIVE ON RESEARCH INTERSECTIONS BETWEEN LITERACY AND THE VISUAL / COMMUNICATIVE ARTS¹

Anne P. Sweet

OERI, U.S. DEPARTMENT OF EDUCATION

The focus of this chapter is on national education research programs in literacy and the visual/communicative arts from a federal policy perspective. A discussion on general trends and issues that are on the horizon within the national education sphere is undertaken. An examination of the Office of Educational Research and Improvement's (OERI) Research and Development Centers Program is presented within the context of a restructured OERI—the result of new legislation reauthorizing the existence of OERI as a federal research agency. Justification for an expanded view of the definition of literacy is offered. The intersections between literacy, the visual, and communicative arts are explored and the likelihood of carving out a niche for cross-cutting research in these areas is evaluated. Finally, directions are suggested for future K–12 literacy research that may be supported by OERI.

THE NATIONAL LEGISLATIVE ARENA: LAYING THE GROUND WORK FOR A NEW VISION OF SYSTEMIC EDUCATION REFORM

The last decade of this century is proving, legislatively, to be a unique time during the history of American education. Congress has set into motion a series of bold education reform initiatives that will substantially affect literacy, the communicative, and visual arts. These initiatives include the Goals 2000: Educate America Act, the School-to-Work Opportunities Act, expansion of the Head Start program, and

the restructuring of the Elementary and Secondary Education Act.

The Goals 2000: Educate America Act establishes a framework to identify world-class academic and occupational standards. Among other actions, this legislation:

- Codifies into law six National Education Goals established in 1990 by the President and the nation's Governors at the National Education Summit held in Charlottesville, Virginia. These goals deal with school readiness, school completion, student academic achievement, leadership in mathematics and science, adult literacy and safe and drug-free schools. Two added goals relate to parental participation and professional development of teachers. Goal 6 captures the literacy landscape: "Every adult American will be literate and possess the skills necessary to compete in a global economy...";
- Supports the development and adoption of challenging national performance standards (currently viewed as model content standards) that define what all students should know and be able to do in core subject areas including language and the arts, and supports local reform efforts to make these standards operational in every school and classroom throughout the nation;
- Strengthens and improves teacher training, textbooks, instructional materials, technologies and overall school services so that students will have the tools to achieve higher standards;

¹ The opinions expressed in this chapter are those of the author. No official endorsement by the U.S. Department of Education is intended nor should be implied.

- Encourages the development of innovative student performance assessments to gauge students' progress;
- Establishes a National Skills Standards Board to promote the development of occupational skill standards that will define what workers will need to know and to ensure that American workers are better trained and internationally competitive;
- Increases flexibility for states, school districts and schools by waiving rules and regulations that might impede local reform and improvement; and,
- Establishes a National Education Standards and Improvement Council (NESIC) to certify voluntary national state content, student performance, and opportunity-to-learn standards, and assessment systems.

Although the new National Partnership for Educational Excellence encourages a bottom-up approach, the federal government has played a key role in setting high standards. Title II of the Goals 2000 Act, created NESIC, in part, to work with a host of organizations to determine criteria for certifying that the national content standards that are or have been developed by national organizations of subject-matter experts in each subject area, including English and the arts, are (1) internationally competitive; (2) reflective of the best knowledge about teaching and learning; and (3) developed through a broad-based, open adoption process. However, there was little support for NESIC as reflected in amendments introduced to Congress to eliminate its formation. The thinking behind these amendments stemmed from a pervasive view that national standards should be put forth as models that are available for state and local school districts to use as exemplars in establishing their own sets of standards. Opportunity-to-learn standards faced similar opposition. Most recently, the 1996 federal budget bill that was signed into law on April 26, 1996, includes amendments that eliminate the authorization of NESIC and eliminates opportunity-to-learn standards from Goals 2000 and the Elementary and Secondary Education Act.

OERI's Mission and the Research and Development Centers Program

Public Law 103-227 went into effect on March 31, 1994, having been signed into law by President Clinton. The Goals 2000: Educate America Act and the Educational Research, Development, Dissemination, and Improvement Act of 1994 (Title IX) are included under this new law. Title IX authorizes a new OERI, giving it a broad mandate to conduct an array of research development, dissemination, and improvement activities to bolster education for all students. Under the new authorization, OERI has been granted legislative provisions to reinvent itself. Central to OERI's new mission is its charge to provide national leadership in expanding fundamental knowledge and understanding of education; promoting excellence and equity in education and the achievement of the National Educational Goals by spurring reform in the school systems of the United States; promoting the use and application of research and development to improve practice in the classroom; and, monitoring the state of education. A key

facet of Public Law 103-227 is that the OERI mission be accomplished in collaboration with researchers, teachers, school administrators, parents, students, employers, and policy makers.

Inherent is the federal government's responsibility to provide leadership in the conduct and support of scientific inquiry into the educational process. This includes the call for basic and applied research as pathways to improved practice. In so doing, OERI is propelled by the need for a stable, coherent, and long-term agenda in which the commitment to build knowledge, the identification of promising approaches, and the provision of technical assistance to those responsible for educating our nation's youth are included.

Among the set of principles that OERI must adhere to in order to realize its mission is one that speaks of preserving and enhancing the infrastructure of educational research and development. This means that OERI must continue to support work that is vital to the sustenance of education-related inquiry and ensure that the researcher talent pool flourishes. This principle comes with the recognition that all members of the education community must be supported in their professional development, including the efforts of researcher practitioners who are seeking to create the future in terms of their own vision. In so doing, OERI should confirm the belief that theory is grounded in practice. Moreover, it should actively support the notion that researchers and practitioners may assume alternating roles—that is, researchers and practitioners are teacher and learner, leader and follower. Collaborations among teacher-researcher colleagues should increase the likelihood that the fruits of OERI-sponsored research will be readily assimilated into everyday practice in classrooms. Finally, OERI should sustain its commitment to nurturing a program of research that is multidimensional and interdisciplinary.

The OERI is assuming a different structure as prescribed by the authorization legislation. New policies are to be guided by a research priorities plan developed by the agency's Assistant Secretary, in collaboration with a National Educational Research and Policy Priorities Board. OERI assumes an administrative structure that includes: National Research Institutes, a National Education Dissemination System, the National Center for Education Statistics, the National Library of Education, and the establishment of any other units deemed appropriate by the agency head (Assistant Secretary). The OERI research and development activities fall under the National Research Institutes, of which there are five: (1) The National Institute on Student Achievement, Curriculum, and Assessment; (2) The National Institute on the Education of At-Risk Students; (3) The National Institute on Early Childhood Development and Education; (4) The National Institute on Educational Governance, Finance, Policy-Making and Management; and (5) The National Institute on Postsecondary Education, Libraries, and Lifelong Learning. Each Institute will coordinate research and development centers, field-initiated research programs, special studies, and form lineages with the Office of Reform Assistance and Dissemination, which is a part of the National Education Dissemination System.

Within this structure, each of the National Research Institutes will carry out a research and development (R&D) pro-

gram for improving federal, state, Indian tribal, and local education policies and practices that is tailored to suit each Institute's particular mission. Within each Institute, a variety of strategies will be available to meet the research, development, and dissemination objectives although these strategies are likely to be confined by budgetary constraints. Each R&D program may conduct a portion of its activities internally but will achieve its objectives largely through awarding grants (including cooperative agreements) and contracts; providing technical assistance; conducting research syntheses; awarding graduate fellowships to individuals from groups traditionally underrepresented in the field of education; and selecting fellows to work within the agency. In addition, each Institute will coordinate its efforts with fellow Institutes, the regional laboratories, and other education agencies.

National programs for supporting research and achieving the Institutes' missions include Field Initiated Studies (FIS) and the National Research and Development Centers Program. Field initiated research is defined by the legislation as research in which topics and methods of study are generated by investigators, including teachers and other practitioners. The FIS competitions will reflect the missions of the Institutes.

By and large, however, the national R&D Centers will be the principal vehicles through which the Institutes' missions will be fulfilled. The legislation stipulates that no less than one third of the funds made available to the each Institute will be allocated to R&D Centers. In the language of the legislation, it is acknowledged that Centers are best designed to provide for and maintain a stable foundation of long-term research and development on core issues and concerns. The law calls for applicants for Center grant awards to demonstrate that they have assembled a group of high quality researchers sufficient to achieve the Center's mission, that the proposed organizational structure will facilitate achievement of the mission; and that the Center Director and support staff will devote a majority of their time to the Center's work. With the new authorization comes an Education Department thrust toward funding fewer R&D Centers at significantly higher dollar amounts—the law declares that no Centers may be competed for less than \$1.5 million annually.

Until recently, OERI supported 20 national research Centers that engaged in long-term programmatic research. Three of these Centers, in particular, were devoted predominantly to the study of K–12 literacy issues—the National Reading Research Center, the National Research Center on Literature Teaching and Learning, and the National Center for the Study of Writing and Literacy. Sweet and Anderson (1993) provided an informative discussion on the process that unfolded in setting a federal agenda for research on reading and holding a national R&D Centers Program competition in this area. The process resulted in the awarding of a National Reading Research Center to the University of Georgia and the University of Maryland, College Park collaboration, a 5-year grant that commenced in March 1992. The majority of these Center awards, excluding the National Reading Research Center, expired in late 1995. The lines of predominantly kindergarten through grade 12 literacy research that have been supported by the Office of Research in OERI are seated within the

National Institute on Student Achievement, Curriculum, and Assessment.

In the most recent Educational Research and Development Centers Program competition, the Secretary of Education gave absolute preference to those R&D Center applications that met the following general priority: Each national research and development center must

- (a) Conduct a coherent, sustained program of research and development to address problems and issues of national significance in its individual priority area, using a well-conceptualized and theoretically sound framework;
- (b) Contribute to the development and advancement of theory in the area of its individual priority (i.e., a priority specific to the mission of a particular R&D Center);
- (c) Conduct scientifically rigorous studies capable of generating findings that contribute substantially to understanding in the field;
- (d) Conduct work of sufficient size, scope, and duration to produce definitive guidance for improvement efforts and future research;
- (e) Address issues of both equity and excellence in education for all students in its individual priority area; and
- (f) Document, report, and disseminate information about its research findings and other accomplishments in ways that will facilitate effective use of that information in professional development for teachers, families, and community members, as appropriate.

There are seven absolute priorities, each of which points toward the problems that an R&D Center should address under a particular priority. These are:

1. Enhancing young children's development and learning;
2. Improving student learning and achievement;
3. Improving student assessment and educational accountability;
4. Meeting the educational needs of a diverse student population;
5. Increasing the effectiveness of state and local education reform efforts;
6. Improving postsecondary education; and
7. Improving adult learning and literacy.

Although K–12 literacy-related research may have been proposed under the majority of those absolute priorities enumerated above, absolute priority (2): Improving student learning and achievement, is the absolute priority under which most K–12 literacy research is apparent. Under this absolute priority, a national research and development center must

- (a) Conduct research and development on improving student achievement, which must comprise research and development on improving learning, teaching, and assessment within a content area; and
- (b) Include in its work, research or development related to the following topics:
 - (1) How students acquire knowledge and skills;
 - (2) Curriculum and effective instruction, including the use of technology, which reflects current un-

- derstanding of cognitive development, the social context of learning, and student motivation;
- (3) Effective professional development for teachers and other school professionals; and
 - (4) Assessment for improving teaching and learning, including the technical quality of such assessments.

The language in the general priority and priority (2) is excerpted from the *Federal Register Notice of Final Priority* which was published on September 14, 1995. It is in this notice of final priorities that the baseline for a 1996 competition for the Educational Research and Development Centers Program is made explicit. As a matter of course, OERI, through a series of meetings, regional hearings, and *Federal Register Notices*, solicited advice from parents, teachers, administrators, policy makers, business people, researchers, and others to identify the most needed research and development activities. After reviewing this advice, the Secretary published a notice in the *Federal Register* on April 10, 1995, inviting written public comments on proposed priorities for seven national research and development centers that would carry out sustained research and development to address nationally significant problems and issues in education. After reviewing these written public comments, OERI's National Educational Research Policy and Priorities Board made recommended changes to the Assistant Secretary. The Department incorporated these recommendations into the notice of final priorities. On September 14, 1995, the Secretary also published a notice in the *Federal Register* inviting applications under this competition.

The 1996 Educational Research and Development Centers Program competition was completed early in the year. It resulted in the awarding of seven national research and development Center grants. Although none of these 5-year grants is devoted exclusively to K-12 literacy research, the National Research Center on Student Learning and Achievement in English, awarded to the University at Albany, State University of New York, in collaboration with the University of Wisconsin at Madison, has a mission that is devoted to improving the teaching and learning of English, including students' skills with oral and written language and literature. This Center's scope also includes other academic subjects (e.g., math, science) where, increasingly, English skills are needed. There is the possibility that OERI will commence an R&D Center competition for research in reading after the current Reading Center grant award expires in early 1997. If substantial strides in students' achievement are to be realized, then research in reading must remain as a national priority. At the time of this writing, the fate of an OERI sponsored R&D Center for research in reading-literacy remains unsealed.

LAYING THE GROUNDWORK FOR A NATIONAL AGENDA ON LITERACY RELATED RESEARCH

A decade ago, schooling in the United States was literally turned upside down as national attention became critically focused on the quality of education that children were receiving and on the ability of educators to provide students with

the tools that they needed to compete successfully in American society and in a global economy. The release of the landmark report, *A Nation at Risk*, marked the beginning of a series of national studies and reports that deluged the national scene with analyses, criticisms, and recommendations for American education. These publications set into motion an education reform movement that has since maintained momentum. In *Integrated Language Arts: Controversy to Consensus* (Morrow, Smith, & Wilkinson, 1994), Louise Cherry Wilkinson described the need for a general and national educational forum in which the problems of education can be examined in light of research from a range of relevant disciplines. In so doing, she made a timely observation about research and the national debate on educational reform:

Too often, analyses of very complex issues and problems occur within a single discipline. Aspects of a problem that are unfamiliar to members of the discipline are ignored, and the resulting analysis is limited in scope and thus unsatisfactory. Furthermore, when educational issues are investigated by members of one discipline only, there is seldom an attempt to examine related issues from other fields or to apply methods developed in their fields that might prove illuminating. The national debate on educational reform has suffered from this myopia, as problems and issues are identified and analyses and solutions often are proposed within confines of a single disciplinary boundary. In the past, national discussions have been ill informed or uninformed by current research partly because there are far too few mechanisms for interdisciplinary analyses of significant issues. (p. xvii)

It is in the spirit of this observation that the following discussion proceeds strategically to make explicit the intersections that occur naturally across those disciplinary boundaries related to literacy. In this vein it becomes apparent that expanding traditional conceptions about literacy and the boundaries between learning disciplines is not only justifiable, but critical if we are to transform much more fully into a nation of learned, literate Americans. In the following section(s), what we know via research about the connections across the English language arts, the communicative arts, and the visual arts is discussed.

English Language Arts: Research Intersections

Through the years researchers have tended to study isolated pieces of the learning puzzle within restricted domains (e.g., beginning reading). It is not until very recently that researchers have begun to focus on learning as a process within the dynamics of various contents and contexts. New directions in research represent a shift in the way that researchers and practitioners have come to view learning, particularly language learning. Formerly, it was widely held that listening, speaking, reading, writing, and response to literature were discrete operations, learned largely through behavioral mechanisms, in hierarchical progression. As new theories of learning replaced this notion, a paradigm shift occurred in the view of language learning. The concern with form and structure gave way to the study of language function. In turn, this shift signaled a new generation of research investigation focusing on larger units of language in the context in which language is used and developed (Shuy, 1984).

There is a concrete connection between language and thought. Attention to this connection has its roots in philosophy (Schlesinger, 1971) and has been firmly established through research from many disciplines—ranging from research in hemisphericity (e.g., Gazzaniga, 1985), to research in cognitive science that is linguistically-based (e.g., Graesser, Millis, & Long, 1986). The primacy of language in cognition has been established by a large body of research which demonstrates that language is a form of thought; it is a mediator of thought, and it is a tool for enhancing thought (Marzano, 1991).

Clearly, there are common threads that weave a tapestry across the language arts. These threads are woven together through language and thought. The complex interplay between language and thought and the acquisition of reading, writing, listening, speaking, and content knowledge forms the basis for integration among the language arts. The discussion below will highlight these cross-cutting relationships based on what is known from research. The reader should note, however, that research knowledge about any one set of these relationships is not mutually exclusive. That is, the research findings often times cut across several dimensions (e.g., writing, literature, social interactions). The intricate nature of these relationships does not allow the research findings to fit neatly into discrete categories. In addition, linkages across literacy (including all the language arts) and the visual / communicative arts will be explored in the following discussion. In so doing, connections among these modes of discourse will be made explicit.

Reading, Writing, and Thinking Connections

Recent research supports the premise of modern theorists (Squire, 1984; Tierney & Pearson, 1983; Wittrock, 1984; and others) that reading and writing can be viewed in terms of the same general cognitive process—that is, gathering ideas, questioning, and hypothesizing. Reading and writing appear to differ, however, in the extent to which students call upon these cognitive strategies. These similarities and differences have been illustrated in studies by Langer (1986), Ryan (1985), and others. It is here that the cross path between the reading and writing processes adds power to student learning. McGinley and Tierney (1989) suggested that these similarities and differences may account for the advantages afforded when reading and writing work together. These advantages become apparent through the findings of recent studies.

A strand of experimental studies has focused on sharing from reading to writing. Bereiter and Scardamalia (1984) found that writing in conjunction with reading proved to be a powerful vehicle for learning, even more powerful than direct instruction. Conversely, some researchers have studied the influence of writing on reading. For instance, Clark's (1988) research showed that, not only did first graders write better when they were permitted to spell in free form, their reading achievement and word recognition ability improved as a result of the activity. These studies, among others, have shown that writing led to improved reading achievement, reading led

to better writing performance, and combined instruction led to improvement in both reading and writing (Tierney & Shanahan, 1991). A clear understanding of the shared knowledge development that might accrue from comprehensive, integrated reading and writing instruction is not apparent, hence there is a need for more experimental studies of reading and writing relations. Although studies have shown that instruction can have joint benefits for reading and writing achievement, they generally lack the detailed descriptions necessary to allow such findings to be applied broadly to instructional practice.

Another fruitful avenue of research is looking at how reading and writing can be used in combination to influence learning and thinking. The findings from several studies suggest that combined reading and writing fosters a more inquisitive attitude to learning, and that it facilitates the expansion and refinement of knowledge. The integrating effects that writing has upon long-term learning, especially of key issues related to a topic, have been affirmed in studies by Copeland (1987), Hayes (1987), and others. The effects that writing has upon thinking, however, may be even more important. One research finding that has been consistent thus far is that writing prompts readers to engage in the thoughtful exploration of issues, whether it be in the context of studying science, social studies, or literature. The effects that writing about literature have upon thinking and learning are explored in the works of Marshall (1987) and Salvatori (1985). Salvatori, for example, demonstrated that writing prompted readers to be less passive and more reflective, evaluative, and enthusiastic.

Similar findings have been forthcoming in studying the effects of writing upon reading in science and social studies (Newell, 1984; Penrose, 1988). Writing's association with greater student engagement with a content topic—for example, examining evidence, or marshaling ideas and reconstructing them—is indicated by findings from both of these studies. In a study by Tierney, Soter, O'Flahavan, and McGinley (1989), the question of whether thoughtful engagement would be attributed to writing alone, reading alone, or the effects of reading and writing together, was addressed. In their findings, it was suggested that if cognitive engagement in a task is reflected in more comments about thinking, more evaluative thinking, or a greater willingness to revise one's position, then reading and writing in combination is more likely to induce learners to be more engaged (Tierney & Shanahan, 1991).

Taken together, based on the research findings discussed above, it can be inferred that writing in conjunction with reading prompts learners to be more thoughtfully engaged in learning. Langer and Applebee (1986; 1987) extended this work by conducting a 3-year study that investigated the effects of different kinds of writing assignments upon thinking in high school science and social studies. They found that writing activities contributed to better learning, especially of less familiar material, than when reading was done alone; they also found that different kinds of writing tasks prompt different kinds of cognitive engagement. McGinley and Tierney (1988) extended this work and found that reading and writing served complementary as well as unique ways of thinking about topics.

Despite the substantial body of evidence accumulating to support a holistic view of language use as the way to promote academic achievement in any discipline, language for learning activities remain unavailable to most students (Healy & Barr, 1991). In Applebee's (1980) yearlong study of writing across the curriculum in secondary school, he found that pupils had few opportunities for doing expressive writing to aid their learning in content area classrooms. The findings of this study were confirmed by later studies (Applebee, Langer, & Mullis 1987). In sum, consistent support for viewing writing as a powerful tool for the enhancement of thinking and learning is provided by these research studies. Hence, writing is not only a medium of thought, but also a vehicle for developing it (Nickerson, 1984). Moreover, writing and reading together engage learners in a variety of reasoning operations—more so than when writing or reading are apart or when students are given a variety of other tasks to do along with their reading. Support for McGinley and Tierney's (1988) argument that "literacy should be understood as the ability to enlist a repertoire of discourse forms to explore and extend thinking and learning" (p. 13) is also provided by the work discussed above.

According to results from the 1992 NAEP reading assessment (Mullis, Campbell, & Farstrup, 1993) and the 1992 NAEP writing assessment (Applebee, Langer, Mullis, Latham, & Gentile, 1994), recent reforms in reading and writing instruction are taking root, although most teachers rely on eclectic approaches that draw from varied instructional traditions. Teachers of 4th-grade students who participated in NAEP's reading assessment reported that almost all (98%) were receiving at least moderate emphasis in integrated reading and writing instruction, while this approach was central for teachers of 54% of students. Interestingly, teachers of 8th-grade students who participated in NAEP's 1992 writing assessment also reported that integration of reading and writing was being given heavy emphasis for 54% of students in grade 8. These findings are consistent with research wherein the effectiveness of integrating reading and writing instruction has been demonstrated (Harste, Short, & Burke, 1988).

Finally, it must be recognized that research of this sort is in its infancy. Research in reading and writing remains largely unintegrated. Many more studies need to be conducted, especially those that consider the possibility that students can be taught to use reading and writing together in a strategic way, based on learners' goals and the thinking operations that these goals trigger.

Reading, Literature, and Discussion Connections

Readers both transform and are transformed by literary works. This phenomenon has become apparent through research findings on response to literature. This means that the reading experience is influenced by the stances that readers take toward texts (Britton, 1984; Rosenblatt, 1985; and others) as well as the cognitive and psychological processes they bring to the reading process (Applebee, 1978; Holland, 1985; and others). Although interpretations may differ from reader

to reader, common meanings within communities of readers come forth where readers share common backgrounds, psychological predispositions, and interpretive strategies (Beach & Brown, 1987; and others).

The relationship between level of reading proficiency, frequency of reading, and knowledge about literature is supported by substantial evidence. In an analysis of National Assessment of Educational Progress (NAEP) data, Ravitch and Finn (1987) reported that 11th-grade students averaged 48% incorrect responses in answering questions about authors, texts, and literary periods. Successful performance on the test, however, was directly related to the degree of leisure reading as well as the amount of instruction and homework students received. Based on this finding, it seems plausible that students acquire more knowledge about literature from additional reading. In addition, results of NAEP's 1990 reading assessment were presented in the report, *Reading In and Out of School* (Foertsch, 1992), where students who reported reading novels, poems, or stories on a daily basis for school assignments had higher average reading proficiency than students who reported doing so less frequently.

Moreover, there is evidence that discussions about what is read are related to reading proficiency. Studies of group discussion in literature indicate that high school students perceived little opportunity to express or reflect on private responses in larger group discussions (Gross, 1984). Discussion in classrooms is rare according to recent reviews of research (see Dillon, 1984). It has been observed that older students have fewer opportunities to engage in oral language experiences, such as small group discussions, theater and drama, and public speaking events in the classroom where, too often, teacher talk overwhelms student talk (Cazden, 1988; Wagner, 1991). As students advance through the grades, opportunities for them to use oral language in the classroom appear to decrease. Research shows that patterns of discourse that favor teacher talk in lieu of student talk severely restrict students' learning potential via their own spoken language. Not a great deal has happened to alter a phenomenon so common that, in her study of secondary English classrooms, Alvermann (1986) described discussion as the "forgotten language art." This is unfortunate because, as studies by Graup (1985) and others have found, students in discussion groups evidenced better comprehension than did individuals who did not participate in discussion groups (Beach & Hynds, 1991). These findings are supported by data presented in *Reading In and Out of School* (Foertsch, 1992)—1990 NAEP reading assessment results indicated that students who said that their teachers never asked them to talk about what they had read, to explain their understanding of what they had read, or discuss their interpretations, had a lower average reading proficiency than those students who reported engaging in these activities. This finding is similar for students who engage in discussion outside of school—according to the *Reading Report Card for the Nation and the States* (1993), 1992 NAEP reading assessment results indicated that students who reported at least weekly discussion about their reading with friends or family had higher average reading proficiency than students who reported little or no such discussion.

Many research studies (e.g., Berrill, 1988; Martin, 1983) have shown that students, given opportunities to talk and listen, can and do converse in productive ways to learn in all areas of the curriculum. In the case of literature, for example, encouraging students' personal responses improve their ability to construct meaning (Eeds & Wells, 1989; Galda, 1983). Over time, students develop more and more complex responses to literature that help them become better at constructing meaning. Questions, rethinking, and refined understandings result when students discuss their understandings of themes or concepts that appear in text (Langer, 1991; 1992). Moreover, Almasi and Gambrell (1994) found that students in peer-led discussions were able to recognize and resolve sociocognitive conflicts better than students in teacher-led discussions. Overall, their findings indicated that peer-led discussions produced richer and more complex interactions than did teacher-led discussions.

Thus, students' discussion in classrooms is important to their learning. Through research, Paley (1981) has shown that discourse among all ages serves as a catalyst for the development of logical reasoning skills in which students hear different points of view and collaborate to solve problems. The assumption that student-to-student verbal interactions about content improve learning and increase the level of thinking (Marzano, 1991) is supported through much of the research on small group interactions within the cooperative learning literature. Nystrand and Gamoran (1991) conducted a large scale study on instructional discourse, student engagement, and literature achievement. Using data on literature instruction from 58 8th-grade English classes, they found significant relationships with achievement: (a) students' disengagement adversely affected achievement; (b) procedural engagement (focus on classroom rules and regulations) had an attenuated relationship to achievement; and (c) substantive engagement (sustained commitment to the content and issues of academic study) had a strong, positive effect on achievement. All features of substantive engagement in this study involved reciprocal interaction and negotiation between students and teachers. Thus, the great importance of connecting literature and other texts with a variety of experiences and the prior knowledge of the reader has begun to become apparent. The notion that simply acquiring information—for example, facts and dates—amounts to significant learning, has been put to rest by the research findings cited above and related studies. More research is needed, particularly research that examines how certain instructional techniques—for example, discussions, journal writing, and formal papers—foster students' interpretations of literature and elaborations of response.

Speaking, Listening, and Learning Connections

Speaking and listening (oral language) are interrelated processes that occur within the context of social interaction. Oral language development is inextricably related to the development of literacy and learning in the content areas. The effective use of oral language is a powerful tool for communicating and learning. Current language research confirms the importance of oral communication in children's social and cognitive

development and provides the impetus to integrate speaking and listening activities. Moreover, it points to the importance of taking into account the interactive nature of communication and the context variables which may influence this process. The research of King (1984) and others confirms the human potential to construct meaning through language and to use language to learn. The research of Cazden, John, and Hymes (1972) brings attention to the functions of language and to communicative competence within the social context of the classroom. The social nature of learning implies that, because each context is different, participants must always evaluate what to say, consider options, and make choices. One choice is when and how to initiate an interaction with someone. Learning rests on taking these risks (Cook-Gumperz, 1986; Hansen & Graves, 1991). The importance of social interaction in the advancement of learning, as postulated by Vygotsky (1978) in what he referred to as a child's *zone of proximal development*, is now supported by a growing corpus of research literature. For example, Wilkinson's (1984) research points to the value of small group, peer-peer interaction for promoting academic and social learning. Children who rely on each other for help learn more than those who work alone (Cazden, 1988).

Theorists of situated cognition posit that there is no cognitive core that is independent of context and intention (Brown, Collins, & Duguid, 1989; Greeno, 1988; Resnick, 1990). The study of shared reasoning within the structure of discussions in school settings is proving to be a particularly promising area of research (Resnick, Salmon, Zeitz, Wathen, & Holowchak, 1993; and others). Social interaction provides a social support system, particularly for the acquisition of procedural knowledge (Brown & Palinscar, 1989; Pontecorvo, 1993). Devescovi and Baumgartner (1993), having analyzed joint book-reading with pairs of young children, concluded that peer interaction provided the context within which children transferred skills acquired through interacting with adults; moreover, this acquired knowledge was further developed and new knowledge was formed. Pontecorvo and Girardet (1993) found that students' engagement in small group discussions about content created extremely rich situations in terms of the production of high-level reasoning even in young children, similar to *cognitive apprenticeship* (Collins, Brown, & Newman, 1989) wherein reasoning is both a situated and a distributed action occurring in a social context of negotiation with others and with the task. This generation of work reflects a new perspective on learning and instruction in educational settings in which language is not only essential to the social construction of knowledge, but is an essential means of cultural transmission. Within this perspective, cognitive functioning is part of a larger social functioning that is situated in a cultural environment. Thus, cognition and learning, regarded as sociocognitive development, become elements of a deep socialization process in which they cannot be separated (Light & Butterworth, 1992; Perret-Clermont, 1993).

Children's stories, both oral and written, have been the subject of important research on the development of children's ability to construct coherent text (e.g., King & McKenzie, 1988). Many recent studies have shown that chil-

dren learn the structure as well as the linguistic features of narrative discourse, as they hear stories told and read (e.g., Cox & Sulzby, 1984). Children often display their knowledge by *talking like a book* when they pretend to read their favorite stories (e.g., Pappas & Brown, 1987). These studies suggest that reading aloud to children facilitates the development of narrative competence, particularly literate narrative. Moreover, the research suggests that communicative competence in the classroom cannot be broken down into fragments out of context, without destroying the essence of the process (Pinnell & Jaggar, 1991; Wilkinson & Spinelli, 1982).

Morrow (1988), in studying young children's literacy development, found that participation in one-to-one read-aloud events increased the quality and complexity of the children's responses. Also, repeated experiences with stories fostered a wider variety of responses and more complex, interpretive comments than did single readings of stories. Readers construct meaning as they interact with peers and adults in discussing stories (Jett-Simpson, 1989). This research, along with related studies (e.g., Teale & Sulzby, 1987; and others) has demonstrated that storybook reading involves far more than reading aloud the words of an author. The discussion among readers and listeners that occurs in response to the shared text is integral to the story-time experience. Eeds and Wells (1989) presented evidence that children support one another in their efforts to understand and reflect on stories. Dyson's (1983) research led her to conclude that children's interactions contribute substantially to intellectual development in general and literacy growth in particular, given tasks worth talking about and permission to talk. Moreover, Dyson (1987) and other researchers surmised that children engage in their most intellectually demanding work when they share ideas and opinions about stories, and share experiences related to stories read or told to them.

Broadly, research supports the integration of speaking and listening and the development of language curricula that provide students with opportunities to use language for a wide variety of purposes, in different situations, and with different audiences. For young children, Paley (1990) concluded that stories should be written down for retelling and dramatization. Related research (Goodall, 1988; Prater, 1987; and many others) has shown that wordless picture books can encourage a variety of stories based on the same illustrations (Bromley, 1992). Recent research has indicated that it is important to provide children with positive experiences involving stories and other literature on a daily basis (Morrow, O'Connor, & Smith, 1990). Opportunities for such experiences have included reading and retelling stories, discussing stories critically, role-playing, responding to stories both orally and in writing or through expressive art (e.g., drawing), and sharing books with peers. Pinnell and Jaggar (1991) pointed to studies of classroom processes (e.g., Delamont, 1983) to show that oral language functions in subtle, yet immensely important ways to give students access to learning.

Literacy, Communicative and Visual Arts Connections

Elkind (1988) observed that, in the study of literacy, it is important to look back to the images and feelings that pre-

cede the words and to explore the relationships between the way children see the world and the way it is interpreted in print. Although there is growing sentiment among educators for the integration of literacy and the visual/communicative arts, a comprehensive search of the literature produced very few empirical studies conducted on this topic during the past decade. The majority of studies that were conducted involved the use of drama in literacy learning. There is evidence that informal drama enhances children's oral language fluency, critical thinking, literacy learning, self-confidence, and feeling (Booth, 1987; Paley, 1981; Stewig, 1983; Wagner, 1988, 1991). As Christie (1990) observed, a growing body of research indicates that when children are given opportunities to engage in dramatization in *literate* play settings supplied with reading and writing material, they incorporate literacy into their play episodes readily. Research in play has pointed to young children's ability to shift into alternative roles and take on the perspective of others (Rubin, Fein, & Vandenberg, 1983; Wolf & Heath, 1992) in coming to understand the bounded and negotiated nature of theatrical interpretation (Wolf, 1994). In studying how children moved from a perception of drama as uninhibited expression to one that is bounded and negotiated as influenced by careful text interpretation, Wolf concluded that more opportunities need to be provided for children to "enter into an extended relationship with written text where they can discuss, dispute, challenge, and confirm each others' suggestions for text interpretation" (p. 42, 43). Tierney (1992) surmised that activities involving dramatic presentations will become more prevalent as the use of multimedia in classrooms increases.

Research conducted on classroom drama and the reading-writing process has shown that there is a significant, positive relationship among them. Students' participation in dramatic activities following reading improved their comprehension of text (Gray, 1987). Wagner (1986) found that role-playing helped writers identify the viewpoint of their intended audience when they were composing persuasive letters and develop their arguments accordingly. The results of Kardash and Wright's (1987) meta-analysis of 16 studies involving the use of drama with students in kindergarten through grade 7 indicated that drama had a moderately positive effect on their achievement in reading and on their oral language and written communication.

Researchers have found that children's narrative competence is dependent on encounters with many stories (Galda, 1984; Pellegrini & Galda, 1982; and others) in activities such as listening to someone tell a story, participating in storybook readings with adults, engaging in sociodramatic play, and taking part in dramatic reenactments of storybooks. Silvern, Taylor, Williamson, Surbeck & Kelly (1986) studied dramatic story reenactments (DSRs) with early elementary students and found that participants in DSRs, with or without adult guidance, recalled stories that they had reenacted better than children who participated in story discussion only. Martinez (1993) studied the use of DSRs in conjunction with early literacy development, as fostered by various forms of play. Having explored the question of why kindergarten children in a particular classroom were so intent on dramatizing stories from literature, she concluded that the literature-rich environ-

ment encouraged children to initiate these dramatizations, which in turn, likely nurtured the development of children's sense of story.

Studies (Dyson, 1982; Gundlach, 1982; and others) conducted on young writers have shown that children rely on varied media, especially drawing, as they learn about the critical features (structures and strategies) of each. Also, children's understanding of the drawing symbol system likely serves as a transition to the writing symbol system (Dyson, 1982; Ferreiro & Teberosky, 1982). Moreover, young children's texts are commonly composed of varied media, including drawing, writing, and talking. Dyson (1986) described how young children use drawing and talking as transitions to writing and concluded that "to understand the beginnings of literacy, researchers cannot be interested only in text... we have to look for its beginnings in all the kinds of making that children do. In this way, we will begin to understand, appreciate, and allow time for the often messy, noisy, and colorful process of becoming literate" (p. 408,409). Other researchers (Sulzby & Teale, 1991; Teale & Sulzby, 1987) who have studied emergent literacy have corroborated this observation.

In addition to the studies cited above, a review of the literature also yielded numerous, mostly descriptive accounts reported in magazines for teachers which largely described a range of promising practices. An initial account (Catchings, 1984) reported that integrating art lessons with reading activities raised children's reading test scores. A host of accounts described the use of drama and related strategies that helped children digest expository text (Putnam, 1991), decide how to make their writings better (Knipping, 1993), and described ways in which drama could be a frequent component of a teacher's lesson plans (Flynn & Carr, 1994). Other descriptions focused on visual and verbal/writing systems that mutually reinforced each other in an integrated approach to teaching art (Ernst, 1994); that led to students' in-depth written and oral responses to pictures (Stewig, 1986); that honored students' use of color, texture and dimension to communicate significant details in their writing (Hubbard, 1990); and, that led students to consider multiple interpretations with stories (Whitin, 1994).

Even fewer than the number of research studies and reports of promising practices relating to literacy and the arts are the actual number of integrated literacy/arts programs that have been implemented in the United States. As Sautter (1994) noted, compared to research in other areas of education, research into the effect of arts education on reading (and other subjects) is rather sparse and more research is clearly needed. Nonetheless, he argued that from the standpoint of education reform, there is not enough time to wait for more research to be done before creating more arts-integrated schools. One such program is the SPECTRA+ Program, which is a 4-year arts education model that was initiated in 1992. The empirical evaluation report (Luftig, in press) described the program's effects on 615 students at grades 2, 4, and 5 in two school districts. The 1993-94 data indicated that SPECTRA+ students benefited significantly in terms of their academic achievement and affective well-being. An-

other program of note is titled *Different Ways of Knowing* (DWO-K). The DWO-K, sponsored by the Galef Institute of Los Angeles, was designed to offer a thematic, interdisciplinary elementary social studies/literature curriculum that specifically encourages diverse forms of expression in the academic curriculum, including the visual and performing arts. In the third of a series of annual reports describing this national longitudinal study (Catterall, in press), significant effects of the program on student learning outcomes and on student achievement motivation and engagement were described, including indices of increased achievement in language arts, social studies content, and mathematics.

Yet another promising program is now in the planning stages by the College Board and Getty Center for Education in the Arts. This 4-year project is being designed to show how the arts can unify and strengthen the high school curriculum. The program will examine how different approaches to teaching that include the arts as a core element enhance student achievement. By late fall 1995, up to seven schools will be selected for the study. The high schools will develop and test model curricula integrating the teaching of the arts with more traditional core subjects such as history, literature, and science. A crucial element of the project will be the involvement of school districts, state agencies, and local universities in exploring the implications of unified high school curricula in such areas as student assessment, teacher preparation, and college admission. A nationwide survey conducted by the College Board in conjunction with this project revealed that there are very few well-established interdisciplinary programs of study including the arts in our nation's schools today.

In sum, research on the development of literacy through the arts is in its infancy. Programs such as those referenced above are creating a foundation of sound research upon which integrated curricula including literacy and the arts can be built. There is much to be learned about the efficacy of this approach to learning channeled through an expanded view of literacy.

We know that the construction of meaning involves multiple levels and forms of communication. Literacy is a complex system of interrelated processes and the development of literacy draws upon social and emotional experiences as well as cognitive ability. As such, the arts may provide one way for students to gain new insights into what they read and write. Hoyt (1992), a program specialist for Chapter 1 services, provided the following advice:

As we strive to help children make connections between their world and the world of print, we need to keep in mind that it isn't enough to have a reader's time and attention. We need to help learners activate their senses, their imaginations, their emotions and all their life experiences while interacting with text. With the support of multiple communication systems, even learners with special needs can bring life into the words on the page. (p. 584)

This ardent recommendation, coupled with the absence of a direct, broad-based core of research in this arena, points to the need for an expanded research agenda.

AN EXPANDED VIEW OF LITERACY LEARNING: A NICHE FOR THE VISUAL AND COMMUNICATIVE ARTS

The ways in which we conceive of learning and alternative ways of knowing are expanding our notions about what it means to be literate in today's society. A heightened awareness of multiple paths to learning and knowledge construction has begun to emerge. Reading and writing are at the core of traditional notions of literacy. It is generally accepted that reading is comprehending, that is, the construction of meaning. Readers construct meaning by interacting with text (Pearson, 1986) on the basis of their existing or prior knowledge about the world (Rumelhart, 1985). Writing is commonly viewed as a process through which writers make meaning and communicate it through composing (Flower & Hayes, 1984; Langer, 1986).

There are many pathways to learning and knowledge acquisition. When viewed as a cohesive whole, these pathways expand the boundaries of literacy in the traditional sense. The visual and communicative arts combine richly to provide abundant avenues that lead to what Eisner (1994) terms, multiple forms of literacy. Multiple forms of literacy constitute pathways that hold the potential to enable students not only to construct meaning but to diversify and thereby deepen the meaning they construct. Hence, education is viewed as a process that involves fostering students' ability to construct, diversify, and deepen meaning. In order to do so it is necessary for students to become skilled in the construction of such meanings within a variety of the forms that are available, including words, pictures, drama, music, mathematics, dance, and the like.

Related to this notion is Gardner's (1983) theory of multiple intelligences, which encompasses seven distinct intelligences: linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, interpersonal, and intrapersonal. According to this theory, different cultures value different intelligences. For example, spacial intelligence is valued in Eskimo cultures because physical survival depends upon discerning subtle differences in snow and ice surfaces. Linguistic and logical-mathematical intelligences have been traditionally valued in American culture. Eisner (1994) pointed out that limiting forms of representation to number and word has a handicapping effect on children whose aptitudes are in other areas. Moreover, students whose aptitudes are congruent with these predominantly valued forms of intelligence receive unfair status advantages in gaining access to systems throughout society at large, whether it be entry into highly esteemed colleges and universities or highly specialized jobs and professional careers. The broadening of our definition of intelligence, when combined with an expanded view of literacy that encompasses the visual and communicative arts, has the potential to make schooling relevant to the lives of all children across the diverse spectrum of backgrounds and subcultures. The education provided by our schools under this model includes a plethora of opportunities for children to develop their capacities and deepen their constructions of meaning through a variety of forms and experiences.

Eisner (1994) presented a cogent argument concerning matters of meaning and the different kinds of meaning that different forms of representation make possible. In *Cognition and Curriculum Reconsidered*, he addressed himself to the ways in which different kinds of meaning can be secured and the conditions within curriculum and teaching that foster what might be regarded as multiple forms of literacy:

What does it mean to secure poetic meaning, and what does poetic meaning help one understand? What kinds of meaning are accessible through the visual world? And how does one learn to read those meanings, not only within what we call works of art but within the environment at large? The curriculum that is made available to students in school is, in an essential sense, a means through which students can learn to encode and decode the meanings made possible through different forms of representation. Through this process, different kinds of intelligences are cultivated or, more broadly, cognition itself is expanded. (p. 23)

In effect, broadening the definition of literacy to include multiple forms of representation holds the potential to expand ways of knowing and the extent to which new knowledge is internalized by the learner.

The concept of multiple forms of representation is bolstered by the dual coding theory (Paivio, 1986), which posits that information that is encoded mentally in two ways is better comprehended and recalled than information encoded in only one way. This theory holds that cognition consists of two separate but interconnected systems. One is a verbal system that specializes in processing language, and the other is a nonverbal system (e.g., as images) for processing world knowledge of objects and events. Research (Mayer & Anderson, 1991; Sadoski, Goetz, & Fritz, 1993; Sadoski, Paivio, & Goetz, 1991) has shown support for this theory's assertion that when information is encoded both ways, it is elaborated, thus providing increased comprehension and strengthened memory trace. According to the dual coding theory, concrete language has a natural advantage over abstract language because it easily evokes integrated mental images. For example, the phrase *blue horizon* readily conjures up a mental image whereas the phrase *critical juncture* is more tentative. By and large, verbal and nonverbal codes are considered to be cumulative in effect. Moreover, dual coded information (concrete language) is likely to be recalled twice as fast as single coded information (abstract language). Broadly conceived, the dual coding theory provides a further basis for expanding the boundaries of traditional literacy to include the visual and communicative arts, replete with multiple codes and images that deepen students' comprehension.

Instructional Implications

There are a variety of ways to symbolize thoughts, experiences, and perceptions. Cecil and Lauritzen (1994) have added their voice to the growing notion that the arts can enhance literacy and tap linguistic, musical, logical-mathematical, spatial, body-kinesthetic, interpersonal and intrapersonal intelligence and that through these modes students can demonstrate their understanding of ideas. Moreover, they and others (e.g., Gallas, 1994) contend that if

children experience an expression through the arts and relate that expression to literacy (e.g., read a story and depict a main theme visually), both symbol systems are improved. Research findings in recent explorations of emergent literacy (e.g., Morrow, 1993; Teale, 1986; Teale & Sulzby, 1987) have bolstered primary teachers' knowledge that it is sound educational practice to allow children to draw a picture and then dictate a story to accompany it, or write it themselves using invented spellings. It is through this synergy across communication systems that children generate new meanings and expand existing ones as they labor to express themselves through a variety of forms or media. Lessons learned from research on emergent literacy have demonstrated the potential of this blend and flow across multiple ways of knowing to bolster literacy development. Emergent literacy research may be viewed as providing an impetus toward an expanded view of literacy that is still in its infancy.

Central to this expanded view of literacy is the recognition that different meanings are embedded within different forms (Eisner, 1994). These meanings can be distinguished from one another through distinctive features which allow individuals to both construct and experience particular kinds of meanings. The meanings related to each form are unique. One form or pathway cannot substitute for another, and each complements another. For example, the unique qualities of a text can combine with the unique qualities of an image to yield meaning that is expanded beyond that which could be created from either one solely. Research has demonstrated that concepts can be made clearer through the visual image. For example, in addition to reading conventional text, important lessons in ecology and the environment can be underscored and brought to life by showing children photographs of the erosion of the architectural monuments in Italy and Greece (Godfrey, 1992). With regard to visualization activities in a program that integrates literacy and the arts, it has been shown that encouraging children to actively visualize words and concepts may not only help them to enjoy reading more, but it can also improve their understanding of what they read (Long, Winograd, & Bridge, 1989; and others).

We have only to look back to the personal journals of Einstein, Darwin, and McClintock to further substantiate and exemplify the different meanings that emanate from different forms and that constitute alternate pathways to knowing. These eminent scientists described experiencing a mental process in which intuition, imagination, metaphor, and visualization combined to form creative thinking that enabled them to gain new and important insights (Fox-Keller, 1983; Rothenberg, 1979). Einstein related that "words or the language, as they are written or spoken, do not seem to play any role in my mechanism of thought... the... elements are, in my case, of visual and some of muscular type" (Hadamard, 1949, p. 142). Often lost in descriptions of individuals who exhibited a genius of one sort or the other is the widely agreed upon judgment among researchers that preparation is one of the most important conditions of creativity. Based on studies in this arena, it appears that a long period of time is essential for creative productivity even, for example, the most talented of our composers, painters, and poets (Hayes, 1990). It may be safe to conclude that schooling should not only provide our

children with the essential foundations of learning, but with abundant opportunities to use a broadened realm of expressive modes to study about and communicate their understanding of the world. This includes encouraging children to think divergently rather than convergently and pushing the boundaries of their thinking and communication through primacy of expression.

In a discussion on expanding the definition of narrative to include broader realms of communication and expression, Gallas (1994) presented a conceptual framework which suggests that for children in schools, deep transformative learning takes place when language is defined expansively. In *The Languages of Learning: How Children Talk, Write, Dance, Draw, and Sing Their Understanding of the World*, Gallas, a teacher researcher, wrote:

Children's narratives are not naturally confined to the spoken or written word. From early childhood on they tell stories in dramatic play, in their drawings and paintings, in movement and spontaneous song. As they move further into the adult world of signifying, spoken language does begin to take precedence, but in essence children do not *naturally* limit the forms that their expressions take. Because adult communication relies so heavily on spoken and written language, however, schools necessarily reflect that orientation and channel children's narratives into a very narrow realm of expressions, in effect limiting rather than broadening the child's expressive capabilities. (p. xv)

It is commonly the case that society at large relegates the adaptive use of song, movement, painting, sculpting, drama, and poetry to a small segment of our population. It does not necessarily follow that those areas of expression are available to only a few people who comprise an elite subculture of our society. Rather, it is more likely that these individuals have made a conscious choice to express meaning via these alternate pathways. Alternate forms of expression and meaning can be made available to all children in our schools. Gallas continued:

When children are continuously offered opportunities to express their stories about the world through many avenues, they show that the power and range of their intellectual and creative pursuits are unbounded; they create new kinds of learning communities that offer membership to every child; they teach us that the process of education transcends methodology and curriculum and is situated in the realm of possibility. They change our conceptions of who teaches whom in the classroom. Once we begin to understand the many paths that narrative can take through the modalities of talk, song, art, and movement into the written word, the practice of teaching and the process of learning are mutually transformed. (p. xvii)

Thus the arts hold the potential for offering students a way of pushing the boundaries of their learning. Dramas, poems, paintings, and the like provide forms of expression through which children can tell their stories and teachers can piece together a more complete picture of who their students are, what they understand, and what they can do. The essence of the message is that there are different ways of knowing and understanding the world, and there is a variety of forms that expression can take.

Drama, for example, is a highly effective mode of self-expression through which children can develop their commu-

nication abilities while fostering their creative imaginations. Cecil and Lauritzen (1994) maintained that children who are learning English as a second language (ESL) can more clearly begin to grasp concepts and have access to a variety of ideas through this unique and compelling art form. In a creative climate, literacy and the arts can blend and flow with synergy, and the uniqueness of each individual can emerge. Moreover, for ESL students or others with special needs (e.g., language delays), songs with their rhyme, rhythm, and repetition are particularly potent paths to language competence and literacy (Jalongo & Bromley, 1984).

Rudolf Arnheim (1969) argued in *Visual Literacy* that our visual perception of the world undergirds our cognitive processes, and that visual literacy and the enlightened eye are substantial life-long contributions to both intelligence and an aesthetic enjoyment of the universe. If this is indeed the case, photography, as a distinct art form, holds the potential to engage children in meaningful interactions with their world and facilitate the growth of visual-spatial intelligence and literacy. Gardner's (1990) ARTS PROPEL project uses photography as a means of offering many opportunities for students to engage in a host of authentic literacy experiences and intrinsically motivated learning. The photographic project is filled with occasions for dialogues, the use of a student-maintained portfolio of photographs, and a written journal. These components encourage literacy and effectively facilitate habits of working, self-initiated assessment, and self-sustained learning (Zessoules & Gardner, 1991). Moreover, Schwartz (1988) asserted that through photographic projects children become involved in their own self-motivated education and learn to read, to write, and to communicate with others, as well as to learn the art and techniques of photography.

This multiliterate approach to learning not only allows children to express themselves freely but also allows teachers to assess what students know in a variety of ways. A prime example of this assessment strategy is implanted within the Concept-Oriented Reading Instruction (CORI) model under development at the National Reading Research Center (NRRC), which is funded through a cooperative agreement with the U.S. Department of Education. The CORI model, designed to foster students' amount and breadth of reading, intrinsic motivations for reading, and strategies of search and comprehension, contains a framework which has five phases of reading instruction in a content domain: observing and personalizing, searching and retrieving, comprehending and integrating, communicating with others, and interacting with peers to construct meaning (Guthrie, McGough, & Bennett, 1994). Measures of learning include an assessment that traces students' performance as they use their knowledge and strategies to learn a new concept in a content domain like science. Within this performance assessment instructional unit, the broadest possible range of reading competencies is covered, including integrating illustrations with text—that is, students' expressing what they learn through drawing. Preliminary examination of individual student cases, gleaned from the federal monitor's (Sweet's) examination of case data collected in an ongoing study at the NRRC, showed that some students reveal content knowledge in their drawings that is not communicated in their writings about the same topic.

Instructional Implications for Content Disciplines

In the expanded view of literacy discussed in this chapter, I have focused on the visual and communicative arts within the social contexts of learning. This expanded view of literacy bears direct implications for instruction in subject disciplines that include science, mathematics, geography, and history, particularly since many schools are moving toward merging these disciplines with literacy learning. It seems desirable to provide students with instruction that promotes the interrelatedness of learning in lieu of parceling knowledge into conceptually discrete bundles. This means providing integrated experiences across curriculum areas and disciplines instead of segregating knowing into separate isolated packages. Research has begun to accrue most predominantly in literacy learning and science as a discipline. For example, Alvermann and Hinchman (1991) concluded that instruction can be designed to help students learn science content at the same time that they are learning science and reading process skills. Glynn (1994) found a model for teaching science concepts with analogy to be effective in connecting these concepts to new knowledge that students acquire from reading textbooks. Guthrie et al. (1994), in the concept-oriented reading instruction model described earlier in the chapter, found that helping students search for, comprehend, and integrate relevant scientific information enhances learning. Hynd, McNish, Qian, Keith, & Lay, (1994), in investigating the role of text and other factors in learning counterintuitive physics concepts, found a perceived lack of textbooks' effectiveness at inducing conceptual change. Finally, Morrow, Cunningham, and Murray-Olsen (1994), in examining current strategies for literacy development in early childhood science texts, found that textbook publishers used limited strategies to teach science that included integrated language arts elements. More research on the connections between literacy and science learning is indicated. Additionally, research is needed on literacy learning and learning in the adjunct disciplines of history, geography, and mathematics. For instance, as yet we know little about children's misconceptions of history and how these may be fostered inadvertently in some forms of text such as historical fiction.

The intersections between literacy learning and learning in content disciplines give rise to a host of important questions and considerations for research and practice, a full discussion of which is beyond the scope of this chapter. One such consideration that bears mentioning, however, is learning that occurs in out-of-school settings such as in the home and community (e.g., museums). We know that isolating the teaching of content is not productive. As Greeno (1989) observed, if the transfer of learning is to occur for students, then they need to see the connection between what they learn in school to what they experience outside of school. The school knowledge they acquire and the relationships they learn need to be situated in tasks that are somewhat parallel to life beyond the classroom. Content learning that is seated solely in the discrete structure of a discipline may have the effect of limiting students' ability to transfer and apply this knowledge in nonschool settings. Csikszentmihlyi and Hermanson (in press), in a discussion of museums and moti-

vation to learn, pointed out that learning transcends knowledge acquisition to involve an open process of interaction with the environment. Although cognitive processes are commonly regarded as more important than affective processes for learning, Schiefele (1991) and others have concluded that affective processes are at least as important for evoking broader conceptual understanding.

In conjunction with this supposition, another consideration that bears mentioning is the relationship between school learning and motivation. Motivational constructs have been found to predict school achievement (Wigfield & Eccles, 1992; and others). They have also been found to predict the use and self-regulation of cognitive strategies for learning from text (Nolen, 1988; Pintrich & DeGroot, 1990) and gaining conceptual knowledge (Deci, Hodges, Pierson, & Tomassone, 1992; and others). Although student self-reports have been used most frequently in motivation-related research, teacher perceptions also appear to be important. Researchers have reported that teacher perceptions of student engagement were found to have reciprocal effects with students' self-report of perceived control and academic performance (Skinner, Wellborn, & Connell, 1990) and reciprocal effects with teachers' own behavior as well as with students' self-reports of engagement (Skinner & Belmont, 1993). Moreover, Sweet and Guthrie (1994), in an exploratory study to investigate teachers' perceptions of students' motivation to read in school-based settings, found that students perceived by teachers to be highly motivated to read also had high report card grades in all school subjects and vice versa. Although we do not have fully developed theories of motivation that are specific to literacy acquisition, researchers have made substantial strides in examining more fully motivations as they relate specifically to literacy events. Gambrell and Morrow (in press) report on several other of these new studies. Thus, affective as well as cognitive and social aspects of learning are important factors that must be considered in planning for instruction within the broader context of literacy learning, discipline-based learning, and knowledge construction.

In sum, the various symbolic forms used in our society to create and convey meaning—literary text, mathematics, science, art, music, dance, poetry, and the like—possess their own parameters of possibility for the construction and recovery of meaning. Moreover, individuals actively maneuver within their environment through those forms offered by the culture at large via the languages, concepts, theories, and technologies that permit them to develop higher levels of cognitive functioning in different fields of competence and knowledge. In the school context, available forms of discourse are explicit and are organized as sets of concepts and procedures. Languages, sciences, arts, technologies, and cultural artifacts (e.g., books and instructional materials) are the means through which students' thinking and learning are expanded and modified (Pontecorvo, 1993). Given this knowledge, a host of issues and resultant questions that may comprise a research agenda for teaching and learning a broader range of literacy skills comes into play. For example: What kinds of meaning are available through the various symbolic forms? When symbolic forms are combined, how is

students' learning affected? How do students learn to *read* or construct meaning from various symbolic forms, and how can teachers best teach them to do so? Finally, how might students work with different symbolic forms and how might teachers evaluate what students learn? Research that brings us closer to providing answers to these and related questions is necessary under an expanded view of literacy. Answers to these types of questions are of crucial importance to the formation of curriculum policy. In turn, curriculum policy that is informed by a global view of literacy has the potential to deepen our children's thinking and learning substantially and thereby enable American students to become more competitive, internationally.

NATIONAL CONTENT STANDARDS FOR ARTS EDUCATION: HOW THEY RELATE TO LITERACY LEARNING

The U. S. Department of Education, other federal agencies, and foundations have made grants to major professional and scholarly organizations to develop voluntary national standards in different subjects that are designed to be internationally competitive. These standards are meant to serve as national benchmarks that states may use as guidance in developing their own standards. Standards being developed are of two kinds—content and performance. On the one hand, content standards are meant to define what all students should know and be able to do, to live and work in the 21st century. They describe the knowledge, skill, and understanding that students should have in order to attain high levels of competency in challenging subject matter. On the other hand, performance standards are meant to identify the levels of achievement in the subject matter that are set forth in the content standards. They state how well students demonstrate their competency in a subject.

A great deal of activity has already taken place in the movement to develop model content standards. The National Council of Teachers of Mathematics has prepared mathematics standards, and two key professional associations in literacy, the International Reading Association and the National Council for Teachers of English, coalesced to develop English Language Arts standards. The U.S. Department of Education has funded the creation of model content standards in areas including English, the arts, civics and government, foreign languages, geography, history, and science.

The national standards for arts education were completed in March 1994. The national standards for arts education are comprehensive in scope. Essentially, the standards delineate what students should know and be able to do by the time they graduate from high school: communicate at a basic level in the four arts disciplines—the visual arts, theatre, music, and dance; communicate proficiently in at least one art form; develop and present basic analyses of works of art; possess an informed acquaintance with exemplary works of art from a variety of cultures and historical periods; and, relate various types of arts knowledge and skills within and across the arts disciplines.

In the arts standards document, it was acknowledged that the arts are important to life and learning. In particular, it was recognized that there are a host of connections between and among the visual arts and literacy/communicative arts. Certain affirmations best captured these connections:

- The arts are a way of knowing. Students grow in their ability to apprehend their world when they learn the arts. As they create dances, music, theatrical productions, and visual artworks, they learn how to express themselves and how to communicate with others;
- The arts are indispensable to freedom of inquiry and expression;
- The modes of thinking and methods of the arts disciplines can be used to illuminate situations in other disciplines that require creative solutions; and
- The arts provide forms of nonverbal communication that can strengthen the presentation of ideas and emotions (*National Standards for Arts Education*, pp. 8, 9).

Although this discussion is limited to the visual arts section of the standards document, similar affirmations were stated for other arts areas in their respective sections.

A basic premise of these standards was that students in all grades will be actively involved in comprehensive, sequential programs that include creating, performing, and producing on the one hand, and study, analysis, and reflection on the other. Essentially, these standards provided a framework for helping students learn the characteristics of the visual arts by using a wide range of subject matter, symbols, meaningful images, and visual expressions, to reflect their ideas, feelings, and emotions; and to evaluate the merits of their efforts. The standards addressed these objectives in ways that promote acquisition of and fluency in new ways of thinking, working, communicating, reasoning, and investigating. They emphasized student acquisition of the most important and enduring ideas, concepts, issues, dilemmas, and knowledge offered by the visual arts. These included developing new techniques, approaches, and habits for applying knowledge and skills within the visual arts and to the world beyond.

It is evident that the national standards for arts education clearly relate to literacy and literacy instruction. Arts instruction and literacy instruction hinge upon expression as a primary mode of communication. The same tenet holds for art instruction as for literacy instruction—expression is a process of conveying ideas, feelings, and meanings through the selective use of the communicative possibilities of the visual arts, reading, writing, and oral language. To meet the standards, students must learn vocabularies and concepts associated with various types of work in the visual arts. Moreover, students must demonstrate their developing artistic competence through their literacy abilities and communicative art skills: “As they develop increasing fluency in visual, oral, and written communication, they must exhibit their greater artistic competence through all of these avenues.” (*National Standards for Arts Education*, p. 49)

In the arts standards document, it was asserted that the problem-solving activities inherent in art making help students develop cognitive, affective, and psychomotor skills.

Moreover, it was maintained that students get to select and transform ideas, discriminate, synthesize and appraise, and apply these skills to their expanding knowledge of the visual arts and to their own creative work. Children come to understand that making and responding to works of visual art are inextricably interwoven and that perception, analysis, and critical judgement are inherent to both. According to the standards document, arts education cultivates the whole child, gradually building many kinds of literacy while developing intuition, reasoning, imagination, and dexterity into unique forms of expression and communication.

ARTS EDUCATION RESEARCH AGENDA FOR THE FUTURE: HIGHLIGHTS AND INTERFACE WITH LITERACY RELATED ISSUES

In response to the continuing need and recognition of the importance of research on arts education, the Office of Educational Research and Improvement (OERI) and the National Endowment for the Arts (NEA) formed an alliance to facilitate the development of a research agenda in this domain. The result was a publication titled *Arts Education Research Agenda for the Future* (1994), which contains a national agenda for arts education research developed primarily through collaboration among and with arts educational professional organizations. The purpose of this document was to stimulate discussion among researchers and the broader community about the best directions for future research in the arts disciplines. A major goal was to engender research, in part, that sheds light on the fundamental question: Does arts education enhance the development of cognitive capacities, motivation to learn, self-esteem, appreciation of multiple cultures, performance and creative capacities, and appreciation of the arts? This question was posed with an eye toward improving our understanding of important aspects of arts education, as well as our understanding of other subject areas. It is anticipated that the arts research agenda will serve as a springboard for fostering similar efforts within other agencies, foundations, associations, and organizations concerned about the future of arts education as well as continued dialogue about research among representatives of the various arts disciplines.

This research agenda was by no means exhaustive. It contained sets of research questions organized into three areas: (1) curriculum and instruction; (2) assessment and evaluation; and (3) teacher education and preparation. There were several research questions posed under curriculum and instruction that addressed integrated curricula in the arts and across other subject areas. The three questions posed in this section of the agenda were: (a) What characteristics of artistic practice and arts education contribute to the development and implementation of cohesive and integrated curricula in the arts and across other disciplines? (b) How can the allocation and scheduling of instructional time and space contribute to more cohesive curricula within the arts and across all subject areas? and (c) How does an integrated curriculum that cuts across subject areas affect the individual arts disciplines? Although these types of research questions represented a

starting point, clearly they were quite general in nature, did not seat the arts within any particular subject matter, and did not seek to explore the intricacies of the relationships between the teaching and learning processes that unfold within the arts and other school subject domains. The agenda can and should likely be expanded to provide focus to research on the intersections between the arts and related subjects such as literacy and the communicative arts.

NATIONAL ARTS EDUCATION SURVEY: HOW IT CAN STIMULATE CROSS-CUTTING RESEARCH INQUIRY

The National Endowment for the Arts (NEA), through OERI, is supporting the development, administration, and analysis of a survey on the status of arts education in American schools in 1994. Public school principals were surveyed recently in order to document the current status of arts education as well as the growth or decline of the arts in schools over a 5-year period. The survey is meant to serve as a tool to inform policy developments and program planning for the NEA, OERI, and the Department of Education at large, as well as other public and private agencies by providing national-level data to provide answers to such questions as who is currently teaching the arts in grades K–12, what types of courses and instruction are students receiving, and to what extent are community arts resources being utilized in education programs? An earlier nationwide survey on the status of arts education was conducted by the National Arts Education Center at the University of Illinois (Leonard, 1991). Since that time, there has been no follow-up information available to identify changes in schools' approaches to arts education. Data from the new survey will not only render a more current picture of the status of arts education, but will allow for comparative analyses with a previous data source. It is anticipated that the *Arts Education Research Agenda for the Future*, coupled with the results of a *National Arts Education Survey*, will lead to the identification of numerous avenues for research inquiry.

Overriding issues to be addressed at the national level include answers to the following questions: Will federal dollars be forthcoming to support new avenues of research that are identified through these and related endeavors? If so, when and how much? Will research dollars be funneled through OERI? If so, how will monies be channeled to the research community—through R&D Center or other grant programs? And, which research issues are apt to receive priority attention?

NATIONAL ASSESSMENT OF EDUCATIONAL PROGRESS IN READING, WRITING, AND THE ARTS

The National Assessment of Educational Progress (NAEP) is a survey of the educational achievement of our nation's students in which changes in achievement are traced over time.

NAEP, the nation's primary indicator of what school children know and can do, emerged in 1969 as an educational indicator designed to provide useful information to educators and policy makers. The NAEP, a Congressionally mandated activity conducted through the U.S. Department of Education's National Center for Educational Statistics, was specifically designed to:

- Collect data from nationally representative samples of fourth, eighth and twelfth graders, reporting trends over time;
- Assess student achievement in reading and mathematics every 2 years, science and writing every 4 years, and history/geography at least once every 6 years;
- Detail performance by a cross section of students in each subject assessed, highlighting home and school factors related to achievement; and
- Report teachers' descriptions of their backgrounds, teaching experience, and instructional approaches.

A key characteristic of NAEP has been its objective to change and keep pace with current interests in education. The NAEP continually attempts to reflect changes in curriculum and educational objectives and respond to changes in assessment technology, such as adopting innovations in performance testing, including oral reading, and portfolios of reading and writing samples.

The NAEP's 1992 reading assessment was based on a newly developed framework that emerged though the consensus process. This framework portrays reading as a dynamic, interactive, and constructive process that is purposeful and meaning-oriented and that involves a complex interaction between the reader, the text, and the context. In this view of reading, the definition of literacy has been expanded beyond text comprehension and has advanced toward an interdisciplinary perspective. The 1992 NAEP reading assessment includes a consideration of reading for literacy experience, reading to be informed, and reading to perform a task. Constructing, extending, and examining meaning are critical aspects of the framework. The NAEP assessment asks students to build, extend, and examine text meaning from four critical stances: initial understanding, developing an interpretation, personal reflection and response, and demonstrating a critical stance. These stances provided a frame for generating questions and considering student performance at all grade levels.

Guided by the tenets of the reading framework, the NAEP reading assessment now includes longer passages of text that are more representative of the types of materials students typically encounter, including a range of literary, informational, and document materials. The questions that accompany the passages ask students to interpret, reflect on, and evaluate what they have read. At least half of the student response time at grade 4 and approximately three-quarters at grades 8 and 12 are devoted to questions requiring students to construct their responses, including at least one question per passage of text that calls for an extended response equaling a paragraph or more. There are some instances where students are required to integrate information from two

passages in order to answer certain questions. The reader is referred to *Reading Assessment Redesigned* (Langer et al., 1995) for a more in-depth discussion of these points.

At grade 4, paper-and-pencil assessment questions have been supplemented with the *Integrated Reading Performance Record*, a special study which consists of interviews with individual students about their independent and school-based reading experiences, and analyses of their oral reading behavior. Interview results are linked to students' performance on the written assessment. At grades 8 and 12, a portion of students are given a compendium of short stories, titled *The NAEP Reader*, from which to select and read one story, and then to answer open-ended questions about what they have read. These stories are drawn from a wide variety of sources, including short story collections, literature anthologies, and literary magazines.

For the area of writing, a new assessment was developed to assess fourth, eighth, and twelfth graders. This assessment includes 25- and 50-minute prompts and also provides space for students to plan and revise their writing. The *Nation's Writing Portfolio* includes three samples of 4th- and 8th-grade students' best writing, along with a teacher questionnaire and letters from students explaining their selections. Teachers assist students in selecting their best writing for the portfolio. The questionnaire that teachers respond to focuses on student assignments and instruction provided to students. Clearly, when one contrasts the most recent NAEP assessments with those used in prior years, it is evident that substantial progress has been made in redesigning the NAEP to more closely reflect current knowledge about students' learning and how best to gauge that learning.

What about arts education assessment? In the 1970s, NAEP conducted visual arts and music assessments. Since that time, however, this practice ceased. Most recently, the National Assessment Governing Board (NAGB), with funding from the National Endowment for the Arts, and in collaboration with the Getty Center for Education in the Arts, commissioned the development of a consensus framework for a planned national assessment of student performance in the arts in 1997, although field testing is ensuing in 1995 and 1996. As of this writing, limited funding will restrict the 1997 arts assessment to grade 8. The challenges encountered when building consensus for the reading framework and designing NAEP assessments in reading and writing were formidable. The challenges presented by engaging in an analogous process for the arts are equally imposing and strikingly unique. The task of designing an arts assessment is confounded by the fact that, at present, the arts are often a marginal experience for students at the elementary and middle school levels, while they are an elective subject(s) in secondary school. Moreover, arts education in many schools has been scaled down considerably, seldom including dance and theatre. The 1997 NAEP Arts Education Assessment is being designed in such a way as to acquire information that "will indicate where arts education needs to be strengthened and extended so that future citizens may fully realize their human heritage." (NAGB, 1994, p. 10)

The model of arts learning that will underlie the NAEP Arts Education Assessment has emerged through the NAEP

Framework consensus process and been influenced by the National Content Standards for Arts Education. This model projects a vision of arts education that integrates the aesthetic, social, cultural, and historical contexts of the arts with the knowledge and skills necessary to participate in the arts. NAEP is attempting to portray arts education as closely as possible to a vision of the arts as basic, unified, and pervasive. Given this objective, skills will not be considered as separable, and the achievement of students will be reported as a whole according to the various artistic processes. The assessment will consist largely of multiple related exercises organized around an arts activity—for example, theatre or dance. Portfolios will be explored extensively in a special study.

A topic for debate has been how to capture the interdisciplinary nature of much artistic work—the writing, design, and illustration of books; musical theatre; architecture. The NAEP Assessment includes all four strands—dance, music, theatre, and the visual arts—in the assessment, although the strands are separate. Design and media arts will be included within these strands as integral components. There are plans to conduct a special study to examine the interdisciplinary nature of the arts and explore the technical challenges associated with attempting to assess interdisciplinary action in this realm.

One of the biggest challenges faced in designing the NAEP arts assessment is how to gauge students' prior knowledge and experience with the arts. For example, without musical training, most students would not be able to perform successfully in items that require them to read music. Therefore, in order to obtain a valid assessment of students' performance in questions of this kind, their prior experience and training with the four different art forms should be determined. Another challenge is the difficulty inherent in reliably producing individual scores derived from a group assessment activity. An activity, such as a drama reenactment, is multidimensional whereas an individual item or set of items is constructed to measure a unidimensional quality. For this reason, it may become necessary for group assessment activities to be reported separately from students' performance in individual items. Also, group assessment activities are very costly to conduct, particularly when one considers that scorers must be employed to set up the activities as prompts for student action and interaction, provide the materials needed for each activity (e.g., musical instruments, art supplies), shoot videos of students engaging in each activity, and rate students' performance. Technical issues aside, NAEP assessment in the arts will take its place alongside of other arts assessments that have been or are being developed. However, NAEP can accomplish certain goals that no other assessment can when it comes to understanding what K-12 students know and can do because it is a large-scale, national assessment. Much can also be learned from other assessments, such as The Advanced Placement Studio Art Portfolio, an exemplary visual arts assessment from the College Board, and the portfolio assessments being developed by ARTS PROPEL in Pittsburgh and by the Florida Institute for Art Education in Florida.

CONCLUSIONS AND DIRECTIONS FOR FUTURE RESEARCH

The OERI, under its reauthorization, will function through an institute structure, as described earlier in this chapter. An important association through which the Institutes will achieve their missions is the Research and Development Centers Program. The OERI's national institutes, and the R&D Centers that are supported through these institutes will be driven by problem-centered research, which is a departure from years past wherein discipline-centered research shaped the nature of the research questions that were pursued. Problem-centered research is a practice-oriented approach to producing new knowledge. Research of this genre beckons the convergence of multiple disciplines and thereby accommodates an evolving, expanded view of literacy. Research of this kind invites knowledge integration activities. It is imperative that OERI supports domain knowledge integration activities in order to inform the ongoing national debate on educational reform. Domain knowledge integration may be viewed both as an end and as a means to an end. The objective of integrating knowledge across domain boundaries must be made explicit at the front end of the research enterprise. In so doing, research perspectives on a singular problem or issue multiply many fold and a wider lens is created to accommodate interdisciplinary inspections of the same problem or issue. Therefore, systematic views from different but complementary angles are sought here. Knowledge integration activities should facilitate analyses of complex issues and problems that transcend a single discipline. This approach holds promise for serving as a profitable vehicle through which interdisciplinary analyses of significant issues can occur.

In addition, it must be considered that this type of activity holds the potential to change substantially the nature of the research questions posed for exploration as well as the choice of methods used to explore these questions. Moreover, this approach can capitalize on research methods developed across a variety of disciplines that might add clarity to defining problems as well as seeking solutions. It is highly probable that questions of the variety posed on the same topic will lend themselves to a variety of research methodologies, thereby ensuring the collection of both quantitative and qualitative data, in tandem, that ultimately interface to tell a *bigger* story. Thus, genuine knowledge integration becomes a generative process which results in the creation of new knowledge that is inherently interdisciplinary. Designing research activities and creating funding mechanisms that enable this type of research inquiry to flourish would represent a sharp turn away from the all-too-prevalent myopic vision that advances simplistic solutions to a complex web of problems.

With specific regard to literacy, complex interactions between language and thought and the acquisition of reading, writing, listening, speaking, and literature/content knowledge have been shown to exist, although this line of research inquiry is still in its infancy. These cross-cutting relationships came to light as a result of recent changes in research focus on literacy, which include the development of interest in the early years of language acquisition and the emergence of

studies on multiple aspects of the language arts and their relation to one another. It was not until very recently that researchers began to focus on the cross-dynamics among the English language arts, taking into account the content and context of learning. Many more studies must be conducted in order to clarify our understandings about the nature of these intersections and their implications for instructional practice. In addition, it is the case that systematic research inquiry on the interactions between literacy, the communicative, and visual arts is scant. This arena is a fertile ground where future research focus is warranted. The dynamics between the English language arts and the visual arts need to be examined with an eye toward the development of prototypical models for instruction.

Moreover, careful research that examines integrative instructional trends that are evident in classrooms across the country needs to be undertaken. As Dorothy Strickland pointed out in *Integrated Language Arts: Controversy to Consensus* (Morrow et al., 1994),

...Drawing upon the best research from the past and merging it with more contemporary research findings, today's educators are making significant changes in the way literacy is taught. Terms such as literature-based curriculum, language across the curriculum, whole language, emergent literacy, and integrated language arts are used to describe the particular thrust of those changes. Regardless of the heading under which they appear, however, these curricular changes are very similar in that they emphasize process rather than product and view language as a complex whole rather than as a series of fragmented parts. (p. xix)

The curricular changes that Strickland had characterized share the common feature of intersecting the language arts and to a certain extent, the communicative/visual arts. They share an additional trait in that all of them lack substantial research investigation. That is, although these curricular changes (e.g., whole language, literature-based reading programs, and integrated language arts instruction) can trace their roots back to Dewey (1943), Smith (1971) and others, proponents rely on the vast bodies of research on how students learn, how students learn to read and write, and what constitutes effective instructional strategies in literacy. The paradigms themselves, as recently transformed into practice, are just becoming the subject of vigorous research inquiry. Proponents of these movements refer to the substantial bodies of research on learning, language, reading, writing, literature, instructional strategies, and social interactions to inform the knowledge base from which they operate. Doing so, however, can only be considered a starting point. It is clear that research utilizing a variety of methodologies is needed on all of these language oriented, process-type paradigms in order to explore and determine the instructional efficacy of each.

Significant changes in the methodologies used to study the language arts in particular have begun to emerge. Recently, a variety of perspectives from which to study the English language arts has become popular, including views based on anthropology, psychology, and ethnography. Future directions for research, in order to be fruitful, must expand efforts to study the integrative effects and interactions among and across the English language arts and the visual arts as well as

other forms of knowing. There is a pressing need to broaden the study of teaching, learning, and skill development in context over extended periods of time. This type of inquiry requires the conduct of longitudinal studies. Moreover, there is a need to inform these lines of inquiry by conducting research that is based on different kinds of research paradigms including qualitative, quantitative, experimental, and ethnographic methodologies. National research programs such as those supported by OERI and other federal agencies are challenged to take these considerations into account and to provide supportive leadership that would broaden as well as integrate the study of literacy and literacy development.

At the policy level, what can we hope to gain from an R&D Center(s) that focuses on teaching and learning and that incorporates issues pertaining to literacy? We can anticipate that the educational research which will be conducted over the 5-year grant award period will make some contributions to policy and practice that will influence immediate and specific applications in the field. This expectation may not always materialize to the extent that many policy makers, practitioners, and others may wish. Although an R&D Center holds the promise of generating research find-

ings over a 5-year grant period that can be useful in the relative near-term, many factors impinge upon this supposition, including the maturity of research lines of inquiry, research-problem orientation, and level of Center funding—to name but a few. More profitably, in order to increase the frequency and effectiveness of useful findings, we may look toward the Center's constructing, challenging, or changing the way policy makers and practitioners think about problems. Taken a step further, as Shavelson (1988) observed, we can look toward bringing science to bear on the mind frames of practitioners and policy makers in order to better understand how educational research might shape the policy debate or reconceptualize the nature of problems confronting practitioners. In so doing, we may become better able to formulate research questions, design studies, and translate our findings in ways that influence not only specific literacy practices but the construction of knowledge on the part of policy makers and practitioners. This end result is likely to alter the very nature of the research enterprise and positively impact the ways in which education research generally and literacy research specifically is viewed from both within and outside of the education arena.

LEARNING WITH MULTIPLE SYMBOL SYSTEMS: POSSIBILITIES, REALITIES, PARADIGM SHIFTS AND DEVELOPMENTAL CONSIDERATIONS

Robert J. Tierney

OHIO STATE UNIVERSITY

...Paintings continue to help Kunwinjku to understand the fundamental connection between individuals, and the social and ancestral order. Kunwinjku experience the worth of the knowledge revealed in paintings because it helps to structure so many aspects of their experience of the world in a way that makes such experience intelligible ... the experience of understanding the artistic system takes the revelations of the truth of knowledge relating to the Ancestral Beings. Paintings help to create the meaningful texture of their religious understanding.

—Taylor, 1987, pp. 336–338

...I'm a discourse surfer.... Of all of the things I have done, discourse surfing makes me the happiest. And, not incidentally, for me in deep ways it is the most powerful tool of all the tools I've learned to use....

Discourse surfers can surf any discourse if they are good enough. I'm not that good: I have a favorite spot, at which I'm most content, but there are plenty of great coves and public places where great things happen.

—Stone, (1995), p. 165

...the electronic future was not there in an envelope that we could either open or ignore, we have made it inevitable through countless acts of acquiescence.

—Bickert, (1994), p. 220

In contrast to Bickert, my thesis is that, under certain conditions, multimedia environments (involving the use of more than one medium, and regardless of whether it be the

electronic environment or involving everyday media such as paper, string, glue, tape) can serve as the basis for the social construction of self and others, making multiple probes about issues or concepts and problem solving, and empowering students in a host of ways. The presence of multiple symbol systems allows for constructing oneself and for achieving different “takes” on an issue or problem with one “take” supporting (complementing, extending, or challenging) another—that is, different ways of knowing and being known.

While I have not focused on theory so much as described practices, the descriptions lend themselves to sociosemiotic (e.g., Taylor, 1987), marxist (e.g., Habermas, 1983) and cognitive (e.g., Bruner, 1990) perspectives on learning. When such perspectives are applied, media can be seen as embedded within cultural practices and serving to signal and shape values as well as transform, challenge and shape self and others—both socially and culturally.¹

There are several key words that help capture the view that I am espousing. They are: learner-centered, multisymbolic, perspectival, communal, generative, developmental, systemic, representational, indeterminate, ongoing, and empowering. *Learner-centered* is intended to highlight the preeminent position of the student. I envision that our goal is not to have the media or an activity displace the student, but have the students achieve ownership of the media whereby they can use the media in various ways including developing representations of their own meaning making. *Multisymbolic* (as contrasted with unisymbolic or a reliance upon a limited range of media) is intended to highlight the

¹ Gee (1990) has described Discourse as “...a socially accepted association among ways of using language, of thinking, believing, valuing and acting that can be used to identify oneself as a member of a socially meaningful group or “social network” or to signal (that one is playing) a socially meaningful “role” (p. 143).

pursuit of media in various combinations. Media used together or in concert serve as ways of crisscrossing explorations en route to achieving multiple perspectives or being *perspectival*. Sometimes these perspectives are achieved by individuals working in collaboration with oneself; at other times they are achieved in collaborations with others. *Communal* is meant to suggest the various senses of community that media afford including the multiple roles in the context of ongoing conversations / collaborations with oneself and others. I have chosen the word *generative* as a way of pursuing a view of multimedia which involves new and open-ended uses rather than canned and receptive uses of knowledge. The word *developmental* reflects a concern with how media use shifts over time. As educators we need to develop an environment whereby we are sensitive to the students' emerging uses of media, developing expertise, growing understandings with media and expanding possibilities for media. *Systemic* reflects concerns with how media are woven into the social fabrics of the individual and group's experiences and relationships within different institutions such as schools.² *Representational* is used to suggest that these media afford new ways to represent ideas especially in combination with other ideas.³ *Indeterminate and ongoing* refer to the constant shifts that are incurred with meanings associated with such representation such that meaning should never be viewed as fixed.⁴ Finally, *empowering* is meant to suggest that the study of multimedia also has to do with empow-

ering individuals within different institutions. In other words, as individuals do or do not gain access and expertise, they may gain or lose access to certain opportunities which may carry with them an increase or decrease in power or the opportunity to participate in certain decision making.⁵

To illustrate the integration of media in teaching and learning and the conditions necessary for media to act as a meaning making tool, let me begin by offering three examples. The first describes my son's recent involvement with boogie boarding. The second is taken from one of the many projects pursued at one of the preschools within the Reggio Emilia project in Italy. The third is derived from my involvement with the Apple Classroom of Tomorrow; specifically, from my observations of students at West High School in Columbus, Ohio (Tierney, Kieffer, Stowell, & Desai, 1992).

Boogie Boarding

My son (Shaun), when he was nine years old, became rather engaged with boogie boarding on a recent extended trip to Australia. While his introduction to the sport had begun on

FIGURE 22-1 Shaun and his cousins outfit themselves.

² Green, Weede and Graham (1988) discuss schooling as "learning to student" rather than learning as may otherwise be defined. Street (1984) discusses the differences that may exist between literacy practices as defined within the institution of schools versus other cultural settings. The former tending to treat text as autonomous and the acquiring of psychological competence of a series of skills versus acquiring literacy practices.

³ The Cognition and Technology Group at Vanderbilt University have used the term representational literacy to refer to the flexible use of multimedia for communications and learning.

⁴ Bloome (1993) provides a detailed discussion of the indeterminate nature of meaning in reading and writing that can be extended to other forms of representation and argues for the "refractive" versus "reflective" nature of ongoing meaning making.

⁵ Critical theorists, sociolinguists, and various systemic linguists have underlined the extent to which various forms of literacy can serve to exclude or empower individuals or groups. (see Fairclough, 1992; Lemke, 1990; Luke, 1988; Wignell, Martin and Eggins, 1982). There have been a number of discussions to the extent to which technology may exclude certain groups from being afforded access. For example, with the advent of e-mail certain groups have the potential to shift all communications to e-mail thus excluding those who do not have or choose not to use this technology.

FIGURE 22-2 The group make their way through the waves in hopes of being optimally placed to catch certain waves .

the East Coast of the United States, his sustained and in-depth engagement occurred in Australia where his cousins loaned him a boogie board and engaged him in conversations about boogie boarding, including cutting, doing spinners and going for the better waves. With a little encouragement and without much of the paraphernalia (flippers, wet suits, gloves, helmet etc.), my son set out on his first trip to the beach with his cousins—a kind of an initiation for which my son needed little prodding. At the beach he watched other boogie boarders and, alongside his cousins, made his way through the breakers close to the shore where he caught (*OOPS*, almost caught) his first wave. In the ocean, he watched his cousins who were quite good and full of expert advice and whom he hoped would watch his successes. Once on shore again, the conversations represented a mixture of expletives about the great waves that were caught, some of the stunning wipeouts and analyses of how to better “read” the waves. Away from the shore, the conversations as well as the discussion of the

equipment continued—the advantages of wet suits, flippers, the kind of boogie board needed to maximize possibilities. Then there were the videos of surfing, magazines and posters being reviewed and analyzed. Then the return trips to the beach to try boogie boarding again and again—each time under somewhat different wave conditions. Before too long, boogie board posters surrounded bedroom walls and my son was negotiating with us how to apply his savings toward the purchase of his own “manta” board, flippers, and so forth. He began reading the newspaper for information about tides and weather forecasts as well as anything that might pertain to surfing conditions. Conversations addressed the sand bars, the uniqueness of each wave, each wave set, the dangers of rips, kinds of conditions, as well as issues of balance, weight distribution and the relationship of body position to direction and speed. And, sharks, stingers and seaweed were discussed.

It was not until I wrote this piece on boogie boarding that I truly realized what boogie boarding entailed. Consider, if you will, what my son learned: First, he learned a very sophisticated skill in becoming “a boogie board rider.” Such expertise, while seemingly frivolous, should not be slighted; it entails a knowledge of the ocean, especially waves, currents, tides, the dangers of rips, different kinds of breaks, and sealife. It also entails an understanding of flotation, momentum, water temperature, body temperature, sunlight—especially ultraviolet light, the effects of salt water, pollution, and the characteristics of various materials (rubber, foam, salt water, fiberglass) and their effects on one another.

Consider also the media that were used. My son enlisted conversations, photos, magazines, videos, first hand experience, observations, self and peer analysis and advice across a range of situations. At the same time he sent letters and e-mail messages back to the United States to friends about surfing and used his expertise to have conversations with grandparents, uncles, and his little brother. The media were rarely separate and discrete from these interactions; indeed, the media were embedded within and a part of the social situations. The media were a vehicle for learning (prompting questions, arousing interests, affording comparisons and connections, analysis, evaluation and goal setting). And, to be a boogie board rider entailed walking, talking, watching, and analyzing boogie boarding.

There is a great deal more that could be said. But suffice it to say, my son’s learning experience represents a kind of real world learning experience that involves various media in a complex and dynamic fashion that is inseparable from the learning experience itself. The media were used in combination with one another as boogie boarding was explored, problems were solved, new perspectives achieved, expertise developed and knowledge advanced.

Learning experiences such as this parallel some of the descriptions of learning in classrooms that afford similar possibilities with media. The projects that are pursued in conjunction with the Reggio Emilia preschools represent such situations. The Long Jump project is one such project.⁶

⁶ Unfortunately, a detailed description of the Reggio Emilia’s educational approach is beyond the scope of this paper since it would require an extensive discussion of a range of features: the involvement with parents and the community, the integrative nature of projects, the practical

FIGURE 22-4 Shaun cuts then turns trying to maximize his ride prior to deciding to exit the wave.

nature of these projects, the discussions among teachers regarding the development of projects, the use of children's ideas and multiple representation. I will focus on the use of media as a symbol system to represent, explore and engage with new ideas, and so forth.

Reggio Emilia "The Long Jump Project"

The Long Jump Project involved the development of an athletic event by four children who volunteered to plan and design it with occasional input from the whole class and the community. While some activities emerged, others were planned or facilitated by the teachers. The teachers identified the long jump events as an activity in which the students could become engaged and in so doing would learn about measurement, jumping, events, tools, and a host of other things. The project began with conversations surrounding the possibility of the class holding a long jump event. Those children who volunteered to organize the event began their extended exploration and preparation by studying how experts (i.e. Olympic athletes) do the long jump. They did so by discussing videos of athletes jumping and then pursuing the long jump themselves. There was a kind of spontaneous sharing of knowledge of jumping in conversations that related to what they were seeing and what they themselves could do or might do. Their conversations included a mix of observations, some firsthand experiences experimenting with the long jump and illustrations generated by the children. They needed not only to understand the long jump, but to be aware of how to actually organize an event which involved classmates being long jumpers and comparing the distances that they jumped. Discussions, observations and planning involved developing suggestions / plans for the physical space needed to run an event requiring a pit, a place to run to the pit, a spot to launch the jump and an area for spectators and judges. To these ends, an array of media was used, including drawing plans of the field, using replicas of people as a way of simulating jumping, enlisting strings and other media to assess distances jumped, and so forth. These experiences led to questions and further analyses and other problems to be solved (e.g., how to compare the length of the jumps with strings) and all of these rolled over to an expanding understanding which then informed plans. Sometimes in conversations peers advised one another, compared their observations, discussed replays of the simulations with replicas, examined one another's drawings and made decisions regarding what media tool would best serve certain purposes. Sometimes the discussions led to disagreements. For example, a lengthy discussion surrounding issues such as measuring distances never reached resolution (i.e. the comparative worth of strings and rulers). Also, the children became engaged in lengthy discussions of rules and etiquette as the students practiced the context of long jumping and used replicas or figures of jumpers jumping to simulate the event. Forman (1993) provides a chronological listing of activities involved in the project:

- Looking at and acting out photographs of Olympic long jumpers
- Verbal outpouring of initial knowledge of long jump making an initial sketch of track, jumpers and how to score
- Drawing the track layout
- Experimenting with running speed x jumping distance
- Laying out the track in the courtyard with white chalk
- Debating about handicap for girls using small replica objects
- Designing six posters for rules to the long jump
 - Place to start
 - Three false starts allowed

- Speed and place of run-up
- The touch of the foot
- Measurement of the footprint
- Presenting the rules to the whole class
- Designing training, clothes, diet
- Making posters calling for registration of each participant
- Making posters for designating ability flights
- Making posters for calendar of competition by ability flights
- Writing a letter of invitation to all children of the school
- Designing posters of citywide advertising
- Writing the rules for prizes
- Writing the closing speech for the competition
- Making a poster of rules for measuring three jumps per person
- Learning to measure distance—six phases
 - Using string to record the distance jumped
 - Trying to use the tape measure
 - Correcting the tape measure
 - Transcribing tape measure symbols to paper
 - Comparing the tape measure to carpenter's rule.
 - Reinventing convention place value notation
- Preparing insignia for each jumper to wear at meet
- Writing rules for the referee and assistants
- Implementing the plans: the day and the final competition
 - The run and the long jump measuring each jump with string
 - Posting the strings on the wall
 - Using the tape to measure the longest strings
 - Awarding the trophies
 - The kisses from the misses and misters (Forman, 1993, pp. 173–174)

During their experimentation and exploration, teachers supported the students and prompted comparisons, speculations, evaluations and further planning by them. Oftentimes the teachers encouraged the children to use props or illustrations to externalize their thoughts or to show them to others, and discussed ways in which they might share what they were doing with less informed others. To these ends, various symbol systems were used including different symbols for the same object (e.g., P for person or the use of small figurines) as they explored the long jump through diagrams and photographs and used a tape measure and carpenter's rule to explore ways to measure distance. Sometimes the discussion focused on the worth of different symbolizations and created what Forman described as "the type of constructive conflict we deem to be the power of this multisymbolic approach to education" (p. 187). As Forman stated, the essence of the project involved the following:

As these children sought to gain a more coherent understanding of time, distance, and rules of equity, they externalized their nascent theories as icons, gestures, speech, text, pictograms, diagrams and notations. These symbols were embedded in the coherence of a real-world event which in turn helped convert a random list of symbols into a symbol system. This holism assures that the symbol system will ultimately converge to deepen knowledge rather than increase facts. (p. 188)

In a host of ways the Reggio Emilia approach resembles the kind of learning with media engaged by my son as he developed expertise in boogie boarding. Just as my son enlisted a range of overlapping media, these preschoolers enlisted a variety of media throughout the project—even for the same activity. The extended projects involved a host of planned and

unplanned learning about sports, materials, the world around us, working with others, problem solving and the use of media. Also, the use of media and the projects themselves were socially constituted—that is, it is impossible to separate long jumping or boogie boarding from the other social negotiations and events that were occurring/developing. Just as these explorations are inseparable from the social fabric of the learning situation, the media serve as vehicles for learning and become part of what is being learned. In other words, the conversations, observations, and use of other tools have a symbiotic relationship with the events themselves.

Apple Classroom of Tomorrowsm.

The third situation involving media is drawn from one of the many projects that were observed in conjunction with a 6-year study of computer appropriation in a learning environment (an Apple Classroom of Tomorrowsm site) that provides students as much access to computers as students in regular classrooms have to books, pen and paper. The Apple Classroom of Tomorrowsm represents an attempt to provide students with state-of-the-art technology in a constructive learning environment wherein they enlist media to explore topics, solve problems and pursue their own projects. Students are able to interact with a community of learners in various subject areas within a context that allows them to explore and learn with a range of multimedia software, data bases, and word processing software. For example, in their science or history class, they might pull together projects using PageMaker, HyperCard and SuperCard, using a mix of scanned images, video, and multi-level stacks of ideas. They also have access to computers at home where they can pursue classwork or projects that they might decide to initiate themselves. Some may say that the site is too rare to be generalizable; I would disagree and argue that, as Clark and Salomon (1986) state, such a level of investment may be necessary to study the impact of computer media upon learning and to develop the culture of the classroom technology to the point at which computer use is universally appropriated. The site involved similar careful planning as that carried out by the teachers at the Reggio Emilia school. Projects and units were selected, planned and implemented with student problem solving and issues in mind. Throughout the projects the ACOT teachers considered ways to facilitate student engagement with issues, concepts and problems as they used media as adjuncts to their learning and simultaneously studied the value of the media for so doing. The students themselves provided one another help in various forms including expertise, if needed, as well as ongoing critical feedback.

The projects with which the students were engaged represented a wide range of problems, topics and issues. Students might be given the tasks such as developing and launching their own rockets; developing video portfolios about themselves; constructing a scaled-down version of the city of Columbus; helping develop leaflets for community agencies using desktop publishing and pursuing projects tied to different topics and themes. Often projects involved an extended exploration of a topic. Take, if you will, their exploration of

one such topic—the China project. This project was one of many projects in which students were encouraged to explore topics using a range of media as vehicles for such explorations and to culminate their explorations in the presentation of an exhibit or demonstrations for others (classmates, teachers, students in other classes, and interested public). The China project coincided with a rare exhibition of Chinese artifacts dating back to the earliest emperors in China. The students were encouraged to explore various facets of life in China during early imperial dynasties and, to these ends, were given access to the exhibit and other resources including experts of that period, video and laser disks. The students grouped themselves in terms of their interests and in the context of conversations with the collaborators, began gathering resources in the form of books, pamphlets, photographs, videos or other forms of resources. With the computer-based technologies and other media, each project became a composite of media involving the development and capturing of conversations, observations, scanned images, video clips, or experiencing firsthand food of the times, different ways of dressing, sporting activities, and so forth. The explorations of their specific topic involved a mix of conversations that were tied to readings, viewing films, examining actual artifacts at the exhibit, these aforementioned firsthand experiences and interviews with experts. Each student's explorations took a variety of different turns as they explored their topic with these media.

The media served as vehicles for developing understandings as well as a kind of portfolio from which they could either keep track of their explorations and palate from which they could pursue their own expressions or customized presentations. The students could be seen discussing what they wanted to do as they directed one another's attention to material that they had located in books and other reference material stacked on the floor, portions of video that they had discovered as well as scanned images and text that they had generated. As the stacks of material were examined the explorations of the topic and their projects moved forward. Sometimes the discussions centered upon the scope of the topic (what was relevant, what was irrelevant, how ideas were related); at other times the discussion focused on how the different media could complement one another or which medium was more effective. As they explored different topics they generated video screens which combined text, images and sound and these screens connected with one another sequentially and hierarchically. With the electronic media that they were using, they could insert graphics buttons, which, if clicked upon, accessed other layers of information (perhaps a map depicting the Great Wall, additional information on related events, a graphic display of the sequence of events, a video clip, etc.). The technology appeared to increase the likelihood of being able to pursue multiple lines of thought, as well as entertain different perspectives. Ideas were no longer treated as unidimensional and sequential; the technology allowed students to embed ideas within other ideas, as well as other forms of multilayering and interconnecting between ideas. The students spent a great deal of time considering how ideas were laid out—that is, how the issues that they were exploring might be explored across an array of still pictures,

video segments, text segments and sound clips. It was apparent that the students in the high access classroom had begun exploring images, sound tracks, and text interconnected in very complex ways (i.e., multifaceted, multilayered ways) using a smorgasbord of image, sound, and print. The presentations themselves included the computer-based presentation of a mix of multilayered visual information together with text on various facets of a topic. Supplementing the technology-based presentations were food tasting, posters, verbal presentations and demonstrations of sports.

The multisymbolic or multimedia texts that they created were, as the students stated, "more inviting, dynamic and open than regular text." Students realized the possibility of developing texts that were more pictorial and concrete at the same time as they allowed for making connections between concepts that were more complex, multilayered and immediately accessible. In conjunction with being able to explore the integrated use of various graphics (animation, video segments, scanned images or various ways to graphically depict data), they began to utilize various media as a way of achieving different perspectives on issues they were exploring in physics, history, and other subjects. Just as an author might look for the right word or twist in their text, these students were exploring ways to integrate images with written text to achieve different takes and twists. They found themselves free to develop texts that were nonlinear and multilayered.

If outsiders come to these learning situations with traditional views of media and learning, they may not realize what is occurring. Some might view these learning situations as different forms of project learning; others might see them as ways to make learning more concrete. However, educators attuned to the role of the media in transforming ways of knowing are likely to recognize that these situations represent environments where students are exploring their world with media that afford the enlistment of multiple symbol systems. Moreover, they are apt to see some confirmation of Olson's (1974) contention that the symbol systems create new possibilities for ways of knowing, including deepening and shifting understanding as well as transacting with others. These situations represent learning conditions that reflect an orientation to learners, learning and the role of media which is less traditional—especially in terms of the nature of knowledge, the pursuit of knowledge and the role multiple media assumes.

MAKING THE SHIFT

Obviously, media or various symbol systems can serve several masters. Indeed, some media may be enlisted solely as ways to enhance textbook-like approaches to teaching and learning. For example, images and sound may be embedded with an approach to teaching and learning which is rote and survey-like. Alternatively, media can be enlisted as vehicles for crisscrossing the exploration of topics and cases (or instantiations), affording different *takes* on a topic and facilitating the development of understandings that are transfer-

able to other situations. Accordingly, media may be used as a meaning-making tool that affords not only access to ideas but also ways to achieve *different* constructions and different takes on one's own multimedia compositions or those of others. The uses of these resources are not seen as ends unto themselves or as affording a comprehensive or definitive understanding but as a vehicle for achieving perspectives and making meanings.

Drawing upon work and studies of early literacy development (Harste, Woodward, & Burke, 1984), Seigel (1984) suggests that children have the potential to use symbol systems in concert with one another. By so doing, these symbol systems afford alternative perspectives that inform one another and invite reflection and invention. In other words, she argues that meaning and signification, not language, should be at the center of teaching and argues for a higher status for media. She and others emphasize, however, that to achieve these ends, displacement of the preeminent role granted print or the reverence for print's authority over other media is required (e.g., Bolter, 1991; Lanham, 1993; Lemke, 1994). 'Logophobia,' a term coined by Jacques Derrida, aptly captures the preoccupation with written language to the exclusion of other symbol systems.

In many classrooms as students move through the grades there may exist a tendency to stress the written text over and apart from other media. The stress is placed upon learning of the written language rather than learning with language. Many have argued that there exists a kind of verbocentricity that separates written language from other ways of knowing and that gives written language a status not only apart from but superior to other sign systems or media. Their argument is that the preeminence of language reflects the tendency for the language of schooling to be the object of learning rather than a resource for exploration. As an object, language constrains learning by emphasizing convention as being more important than invention and revering recitation, memorization and preset outcomes.

Moving toward the use of other symbol systems is not straightforward and appreciating what might be entailed in the shift is to see that it demands more than simply ridding ourselves of logophobia. The enlistment of a range of symbol systems does not ensure a shift away from how knowledge is viewed in schools and especially the orientation to the transmission and display of knowledge rather than to exploration and debate, problem solving or ongoing dialogue. Resnick (1989), Seely-Brown, Collins, and Duguid (1989) and Spiro, Coulson, Feltovich, and Anderson (1988) suggest that schools often treat knowledge and the learning of knowledge in a fashion that is inconsistent with how we understand that knowledge is actually acquired and structured. For instance, schools may approach knowledge as more generalizable and absolute than it actually is. Accordingly, rote learning and recall of factual information from lecture or textbook rendering are stressed, giving preeminence to the scope rather than the depth of knowledge. In the "real world", knowledge and the pursuit of knowledge appear to be quite different. Explorations of topics or engagement with problems are usually firsthand rather than summarized by others. In turn, a premium is placed upon one's ability to apply

knowledge of situations rather than to recall facts. Experiences with case-like leanings from a variety (but not exhaustive set) is viewed as developing expertise.

Similarly, schools may mirror an approach to learning that is antithetical to our current views of scholarly inquiry. While some schools have tended to approach inquiry positivistically and reductionistically, science has shifted to relativism or constructivism and sociolinguistics. For example, schools may approach knowledge as absolute, rather than relative. Some schools may emphasize preset objectives and measurable outcomes rather than emerging orientations and open-endedness. Of direct relevance to media, schools may highlight knowledge as generalizable and decontextualized rather than context-specific and derivative of the methods employed for different takes or perspectives. Media can serve such ends and perpetuate decontextualized learning or media can serve to contextualize learning including the heightening of context and virtual as well as firsthand encounters.

These days, the frameworks informing views of learning include ethnographies of communication, social semiotics, linguistic anthropology, sociolinguistics and sociohistories. Accordingly, while schools may view literacy as a set or series of fixed skills, researchers have shifted to the appreciation of the nature of literacy as indeterminate and ongoing. While schools have tended to treat education as dealing with cognitive outcomes which are apolitical, researchers have become increasingly concerned with the social dynamics and the political nature of what and how we teach.

Whether the media are software or involve "hands on" activities, educators need to consider the extent to which the software or activity lends itself to meaning making by the students, alternative ways of knowing including ways that are less obsessed with the written or spoken word as the sole vehicle and the power of the media to democratize, engage, empower and enhance the voices of students. Software that allows the possibility of using multimedia in generative, open-ended, flexible and empowering ways is to be preferred to software or activities that are prepackaged, preset, canned and constraining. Sometimes media detract from sustained engagement with ideas and perpetuate secondary almost summary-like renditions and engagements with ideas. Sometimes they do not. If these assumptions are accepted, then our goal would seem to be to engage students with the media whereby they can extend, alter (refract vs. reflect), create, speculate and use rather than recant or cut and paste the ideas of others. This entails preference being given for media that students will find inviting and useful for explorations of topics, problem solving and developing their own constructions or virtual words. It also entails affording students access to media that will afford them clout, opportunities and access to possibilities. Of course, media may result in the opposite—for example, if students are constrained and given access to media in a very limited fashion (preset and controlled by others) or are given such restricted access to media resources that they remain dependent upon others or are unable to realize the possibilities with the media.

Often when schools consider a shift toward multimedia they focus on the supplies and materials they need or what

they can afford in terms of technology. These are important considerations, but they should not be seen as more important than a consideration of how students and teachers view the role of the software or media's contribution. Sometimes the possibilities with software are limited by the orientation of the teacher or the predisposition of the students and how the media are integrated. For example, an emphasis upon the quality of a finished product may discourage students from taking risks and pursuing their own explorations of ideas and contribute to students' superficial use of the media and, in turn, limited exploration of topics. Sometimes the possibilities with media are constrained simply by resources and tend to perpetuate inequities that may preexist in school funding. Sometimes the possibilities are constrained by the nature of schooling, especially the extent to which schooling maintains control over the media, student learning with media and possible uses.

How we appropriate technology can have a profound effect on its eventual integration into our lives. Let me offer an autobiographical account to illustrate this point. The 1950s in Australia were a period of very rapid change in terms of technology. Two major shifts occurred relative to everyday media—families began to install phones in their homes (or I should say the post office did) and television was introduced to Australia. The shifts in views and uses of these media represented shifts in how individuals viewed technology as well as shifts in the technologies themselves. For example, initially the technologies appeared to have been used somewhat ceremoniously rather than spontaneously or incidentally. Expectations shifted from an initial reverence for the equipment to expectations that equipment should meet the users' needs (whether it be remote control, ear phones or speakers, etc., a wide array of choices in the physical and electronic features as well as programming capabilities). There was also a shift in the accessibility and control as the technology was improved to create more flexibility such as interfaces with other technologies including answering machines, faxes, VCRs, computers, and so forth. Eventually the technology itself became more integrated with our everyday lives. Let me illustrate:

I was 9 years old when the telephone was finally connected in my house. When the telephone was introduced, it was placed upon a special telephone table in the hallway along with its own little seat. Calls were a formality in lots of ways. They were often scheduled rather than enlisted incidentally. It was not initially a vehicle for lengthy conversations or spontaneous extended chats, but usually something that was an event of some proportion. Sometimes letters were written to apprise someone that you would call. Likewise phones were not used to deal so much with folks in your neighborhood, but places to which you could not walk or to which you might not carry a note. Oftentimes I would be asked to "run a message" from home to a neighbor's house. Also, for many years the telephone was not a substitute for the telegram. Indeed, I had a part-time job on weekends delivering telegrams on my bicycle. A person would not call to check on when you were leaving or coming. With the introduction of the telephone came telephone numbers not unlike addresses. To look at the telephone use nowadays we see a technology that is everyday, incidental, accessible and that affords new ways of exploring ideas and relationships. Telephones

are no longer viewed as a luxury but a necessity and the uses of the telephone are still expanding. Its use is woven into the fabric of everyday life for a range of purposes; communication, accessing information of certain kinds instantly, a means of negotiation, ways to achieve immediate feedback and to leave and send messages. For those of us who are e-mail users it integrates our written mail to a telephone via a computer such that we can exchange notes back and forth without the constraints of distance and time interfering with the ongoing communication and exchange of information that we need.⁷ The telephone now serves as a bulletin board for us or others as well as means of having food or other goods delivered to our door.

Television came to Australia with the Melbourne Olympic games in 1956. Prior to that time and for several years thereafter, radio was the primary vehicle for entertainment and broadcast news. Several of my friends had TV sets prior to my own family. Geoff Brown's family had one of the first sets and I still recall arriving at Geoff's house on a Friday night to watch my first TV show. I still have a vivid recollection of the living room darkened as if we were at a movie theater and our group glued to the set as we watched an old Edward G. Robinson movie. Watching TV became a regular Tuesday night event as my friends and I met at the Foxes' house to watch the Mickey Mouse club prior to going to Boy Scouts. A year or so later we bought our set. I already knew lots about televisions from being at my friends' houses. While turning the TV set off and changing channels was something that was similar to the radio and something that we all could do (but carefully), other fine tunings etc. were under the control of my father or older brother. Nowadays televisions afford us access to a wide range of viewing experiences that we might otherwise not have had. These range from seeing sports and other ways of life or world events as they unfold. Nowadays, my 5-year old controls a remote (sometimes channel surfing), manipulates the video player and witnesses people, places events as if he were there. The TV is also used for videogames, to make and play back video. Nowadays video screens have become commonplace as well as interactive but as yet only beginning to be enlisted to make and edit videos. With the advent of user friendly video production capabilities, it has also the potential to be a palate from which they can create their own video and text images as they engage simultaneously with others engaged from afar in also doing so. ...

While my autobiographical account or similar accounts may bring to the fore the shifts that occur with the integration of technology in one's lifetime over time, it should be noted that developmental studies of the appropriation of multiple symbol systems, especially tied to technological possibilities, are sorely lacking. We have studies that describe the extent to which technology is being used, but no studies (of which I am aware) that address these issues across time. There is also a dearth of longitudinal studies describing the engagement of individuals or societies with media. While we have detailed descriptions of the nature of students' development tied to

written language, similar studies of students' development of other symbol systems, such as video, separately or in combination with other media do not exist. While we have several different views of the integration of technology in the curriculum, we have few sustained studies.⁸

In my own work, I have tended to adopt the close-up lens within an institution constrained by curriculum, resources and teachers' changing views. With this close-up lens, what I have found in media use in classrooms is that individuals approach the introduction of media differently. In my observations of students in the ACOT classroom, I encountered a wide range of individual differences including varied dispositions with respect to appropriation and use of media. Interestingly, Seigel also suggests, but does not account for, the existence of individual differences with which students engage in the use of symbol systems. We live in a world that introduces us to new media possibilities and many of us approach these situations differently. Let me offer a final aside as an illustration of this point:

My two sons are rather shy and reserved when you place them in new situations. Recently they temporarily relocated in Australia where they encountered a whole range of new people and situations. Like many children, they are initially hesitant and perhaps withdrawn. However, once they learn the ropes or warm up to new people they become very interactive and explorative. Fortunately, they have cousins who have helped them with the transition. It is as if their confidence grows with the verbal and nonverbal conversations that are pursued. They begin to make the most of the situation in ways that you can never fully predict. Sometimes they embark upon experiences with others that open whole new worlds of possibilities to them, including long-standing relationships. Sometimes, they want out. As a parent I spend a great deal of my time being concerned about their engagement in these foreign situations and anxious that they will take advantage of the opportunity. I try to help them participate or simply become less wary. At the same time, I need to be very cautious that my goals for my children do not override a consideration for them, who they are etc.. Fortunately, my children will not shy away from letting me know what they are ready for and interested in pursuing and what they are not.

I would think that most of you are aware of situations similar to what I have described. But what has this got to do with the issues being addressed in this handbook? I would hypothesize that an introduction to and subsequent participation with media is not unlike my description of my sons in a new country. As mentioned earlier, often when schools consider a shift toward multimedia, they focus on the supplies and materials they need or what they can afford in terms of technology. These are important considerations, but they should not be seen as more important than a consideration of how the media might be integrated to meet individual

⁷ Various discussions and some research have focused on the nature and effects of e-mail. Reinking (1994) discusses e-mail and selected research on the effects of this medium on communication (e.g., Neilson, in press). A recent article by Mann (1995) describes e-mail use with comparisons to the use of pneumatic tubes in the late 1800s in Europe and discussed Verdi's rather prolific use of this medium rivaling some e-mail users of today.

⁸ As such studies are considered, one should recognize the differences that may exist across institutions. Schools, for example, may operate with media as they have done with other literacy in ways that limit access and restrict possibilities. Bloome (1994) suggests that curriculum and administrative constraints may predispose a view and use of media which delimits the possible integration of multimedia either by groups or individuals within these institutions.

needs. In planning for any kind of integration, we need to adopt a developmental orientation relative to media's fit in the classroom with regard for the students individually and collectively. If we are to enhance learning with multimedia we need a fuller understanding of issues of development lest we fail to appreciate and therefore dismiss the developments that are occurring and the factors that contribute to such developments.

Learning to do research on multimedia: some lessons

For a period of 6 years I was engaged in a series of studies directed at many of these same issues as I pursued my work in a site (the Apple Classrooms of Tomorrow[™] [ACOT[™]]) that afforded students access to state-of-the-art technologies with dynamic multimedia capabilities (see previous discussion). These studies included:

- attempts to define in broad and specific terms the nature of individual student learning that occurs as students appropriate the use of computers—in particular, longitudinal studies of students' computer acquisition appropriation over extended periods of time;
- attempts to define the specific impact of certain facets of video and HyperCard applications;
- attempts to define the specific assessment practices that are or might be enlisted by teachers, students or others—in particular, studies focusing upon the use of portfolios and the nature of teacher and student ongoing decision-making.

If you recall, the Apple Classroom of Tomorrow[™] (ACOT[™]) site afforded students as much access to computers as students in regular classrooms have to books, pen and paper. Students were able to interact with a community of learners in various subject areas within a context that allows them to explore and learn with a range of multimedia software, data bases, and word processing software. For example, in their science class or history class, they might pull together projects using Page Maker, HyperCard and SuperCard, using a mix of scanned images, video, and multilevel stacks of ideas. They also had access to computers at home where they can pursue classwork or projects that they might decide to initiate themselves.

In discussing computer acquisition, it is important to distinguish site from setting. I would define the site as a location, whereas setting is much more relative. Site does not serve the same function as setting for inhabitants. As I studied the engagement of different ACOT students, it was apparent that they have had different experiences, especially over time. There may be one site, but within that site there are multiple settings. The variations that occurred across individuals might be viewed as a kind of aptitude treatment interaction. However, I would suggest that the type of variation that I encountered was more complex than a simple two-factor interaction. There seemed to be a myriad of factors interacting with one another within the site. Moreover, as new applications emerged over time, new possibilities were grafted onto others. It is as if to study the impact of technology is to study change on top of change (see Reinking, & Bridwell-Bowles, 1991). Some specific technologies (e.g., HyperCard) had a major impact on students' uses of technology. But in ACOT the students had a certain history that predisposed them to consider the possibilities with certain technologies in terms of how they linked with other technologies, classwork and so on. In other words, in ACOT technology did not exist in isolation but inter-

acted with other technologies, as well as an array of variables, for example, the nature of the units of study; the nature of the student's goals, collaborations, view of expectations, expertise and approach; the nature and style of teacher and technological support; and so on. In other words, to study the impact of technology, involved the following: (1) recognizing that to study technology is akin to studying a moving target; (2) appreciating how technology is woven into the fabric of classroom; and (3) affording different perspectives on learning within the site—including takes across individuals, units of study and time.

In my own work, the lesson that I found hardest to learn was tied to my own verbocentric orientations and the past lens with which I wanted to study technology. As Olson suggested the function of media is not so much to convey old knowledge in new forms but rather to cultivate new ways of exploring and representing these ideas. The ramifications of this notion for studying computer appropriation seem immense. Put simply, I needed to see students appropriating technology on its own terms. It was not until by looking and listening closely to what the students were saying and doing that I began to realize that the lens that I had adopted was restricting our view of what was occurring. Indeed, I had unwittingly adopted the view of technology as merely an adjunct to learning—an adjunct that made learning more effective. Most past examinations have been restricted to the use of traditional indices that may not reflect the true nature of computer literacy (Baker, Herman, & Gearhart, 1988; Ross, Morrison, & Smith, 1989). As Baker, Gearhart, and Herman (1990) suggested, traditional indices do not appear to address the types of skills students acquire in high computer access classrooms. Or, as Ross et. al., commented, learning to use computers may expand the ability to use particular skills with the computer but not other abilities apart from them.

There was a need to characterize data in nonverbocentric fashion—that is, ideas that may not be unidimensional and sequential; ideas within other ideas, as well as multilayering and the complex ways in which ideas may be interconnected. There was a need to capture what was entailed as students began spending a great deal of time considering how ideas layout—that is, how the issues that they were exploring might be represented dynamically and complexly across an array of still pictures, video segments, text segments and sound clips interconnected in very complex ways (i.e., multifaceted, multilayered ways). With the introduction of desktop publishing, scanning capabilities and hypermedia, some major shifts occurred in how students represented ideas and approached the integration of ideas from various sources. Students realized the possibility of developing texts that, to use their words, were "dynamic rather than static," their approach to ideas became less logophobic or verbocentric, less linear and unidimensional. In conjunction with being able to explore the integrated use of various graphics (animation, video segments, scanned images or various ways to graphically depict data), they began to utilize various media as a way of achieving different perspectives on issues that they were exploring in physics, history and other subjects. Just as an author might look for the right word or twist in their text, these students were exploring ideas in new ways that very few past examinations had attempted to detail.

In addition, the types of involvements with technology also involved issues of power and relationships. These relationships involved teacher with student, student with student, student with other high schools students, students with the outside world, students with parents, and so forth. With the introduction of these multimedia came new possibilities for individuals and groups—an opportunity to achieve new relationships with oneself, new levels of decision making and different aspirations.

Attempts to portray computer appropriation and use such portrayals require a form of dynamic and interactive evaluation in which the students and teachers collaborate in the form of dynamic and reciprocal data analysis, collection and interpretation. In an attempt to involve myself in this dialectic, I extended our interaction with students and teachers beyond standard classroom observation followed by a set of predefined debriefing questions. I attempted to engage in a conversation with both students and teachers as the students progressed through these learning situations. The teachers shared with us their goals, plans and expectations for the projects, as we observed the students involved in lectures, class activities, and interactions with their peers outside of class. Through these observations and conversations we attempted to draw sketches of the students in the process of learning and thinking. These sketches attempted to visually represent the connections that the students were making in their thinking, their developing understandings, as well as their reactions to the interactive learning process. The students were asked to comment upon the sketches in terms of the adequacy of the representations. Had we indeed captured the nature of their thinking? What had been left out? Were the connections that we were making about their learning correct? Had we identified all aspects of the social setting as it impacted the development of their thinking? The sketches were also shared with teachers as our emerging understandings were compared with their perceptions of the learners. What emerged from these sketches and the conversations that occurred around them was a richer understanding of the students and the dynamic nature of their learning. As we talked with the teachers and students it quickly became apparent that students make numerous connections as they attempt to understand complex ideas, all of which are not apparent in any single observation, nor are they accessible from any one measure of student performance. As noted earlier, to accurately portray or to effectively assess learning, we need to develop collaborative and interactive methods for data collection, analysis and interpretation. I would suggest that if we are to capture the dynamic nature of learning which occurs in multiple settings we must find ways to capture the multiple voices, and in so doing renegotiate assessment in the classroom.

Summary and Remarks

Kozma (1991) has stated:

...that capabilities of a particular medium, in conjunction with methods that take advantage of these capabilities, interact with and influence the ways learners represent and process information and may result in more and different learning (p. 179).

Through the ages peoples have appropriated symbol systems as metaphorical vehicles with generative syntax and these symbol systems have afforded new possibilities for engagement with self, others and this world. Our various means of representation serve to open us to new possibilities, including achieving new insights and ways of transacting with others, ourselves, and ideas and problems. Recent descriptions of preschools in Italy and the United States describe similar phenomena when very young children are given the opportunity to use different media or symbol systems to explore their world or problem-solve. Their cutting and pasting, drawings, talk, play, and use of other media are used to achieve different perspectives on their world, to solve problems, make plans, and communicate with others. With advances in technology, the same is apparent with electronic media. Projects are apt to involve a mix of transactions including talk, faxes, word processing, scanning; video as different media are accessed separately and together for purposes of composing communications, pursuing problem solving, and as a means of exploring ideas, perspective taking and deepening or acquiring new understandings. I would suggest that the projects occurring in conjunction with the Apple Classroom of Tomorrow, the Reggio Emilia schools and my son's boogie boarding, share many things—especially the power of the symbol systems to engage students in deep and complex explorations of issues as well as constructive discussion and debate. At the same time these sites may be more an exception than a rule. Historically, classrooms have tended to access a limited range of media and the orientation to these media has been limited. Despite the recent developments with electronic media and the simultaneous access to video, graphics, other images, sound and text, the question remains: will multimedia be meaningfully integrated into the classroom? Will we simply acquiesce or will we recognize and embrace the potential to use multimedia as a tool to transform our lives?

Finally, I close with the following sketch that tries to capture some facets that I have addressed: the emphasis upon people rather than media, different individuals or the same person assuming multiple roles and achieving multiple perspectives, people engaged in a range of media reflecting varying technologies, people also engaged in conversation and reflection and an environment that is integral to the explorations occurring.

RESEARCH ON LANGUAGE
LEARNERS IN FAMILIES,
COMMUNITIES, AND
CLASSROOMS

This page intentionally left blank

INTRODUCTION

Victoria Chou

UNIVERSITY OF ILLINOIS AT CHICAGO

The nine chapters in part III use divergent research methods to portray language learners in dramatically different settings. Using innovative assessment approaches, discourse analysis, videotape and photography, and qualitative and ethnographic methods, these researchers focus on language learners shaped differently by race and ethnicity, gender, class and income, place, and age and generation. The authors remind us of learners older than those traditionally studied in K-12 settings. They study learners from the same family or the same community, variously defined, and learners who meet as strangers to one another. They portray language learners in, but mostly out of, formal school settings—from classrooms to homes to streets and other public spaces. They examine learners individually and learners in communication with one another. They reveal a variety of learners' literacies in terms of print, talk, and sign. The authors, themselves representative of a wide spectrum of literacy educators, come to know language learners in very different ways, and, together, they enlarge our view of who language learners are.

In the opening chapter, "Telling Their Stories, Singing Their Songs," Mara Krechevsky and Ulla C. Malkus focus on understandings of the preschool learner that stretch us beyond the linguistic and logico-mathematical. They describe how Project Spectrum, a research initiative based at Harvard Project Zero and Tufts University, deploys innovative assessments that provide opportunities for young children to express their strengths in different content areas. These alternative assessments are mapped onto the seven different intelligences identified by Howard Gardner in his well-known theory of multiple intelligences. Because the assessments enable teachers to recognize and appreciate multiple dimensions of what learners know, teachers are better able to structure classrooms and teach to accommodate individual abilities. Krechevsky and Malkus show readers how original assessments in the areas of language, visual arts, movement, and music can provide great depth and insight to profiles of individual preschoolers' abilities.

Claire Ramsey in "Deaf Children as Literacy Learners: Tom, Robbie, and Paul," draws attention to younger learners who are bilingual and bicultural. She writes of primary-grade deaf learners who use American Sign Language (ASL) as their preferred and primary mode of communication. She argues persuasively for a view of deaf education pedagogy that originates in a cultural view of deaf people. Such a view suggests that deaf children are members of an ethnolinguistic group using ASL, a genuine language maintained by a community of deaf signing people. Children growing up in a deaf community in an English speaking context are, effectively, bilingual or potentially bilingual. Ramsey studied how three deaf 2nd-grade boys proficient in face-to-face ASL approached literacy in settings where both signing and print coexist. In their mainstreamed classroom, where the boys were viewed as disabled, proficiency in ASL did not (could not) foster interaction with hearing classmates who did not know how to sign. In contrast, in their deaf classroom, where ASL communication was accepted as a matter of course, early literacy efforts were supported by ASL. Ramsey's observations lead her to conclude that literacy development is as systematic and rule-governed, as inclined toward sense-making, for ASL-signing children as it is for English-speaking children.

In "Youth Genre in the Classroom: Can Children's and Teachers' Cultures Meet?" Colette Daiute shifts to middle childhood and early adolescent learners. She explains aspects of *youth genre*, featuring discourse rooted in and influenced by youth peer culture. She finds that learners adopt youth genre to relate to one another, seeking to make sense of their world, without having to adopt the dominant adult school language—teachers' talk—completely. Across several transcripts of conversations of older children, Daiute shows us how youth genre is repeatedly characterized by features of reciprocity, experimentation, sense making, playfulness, and affectively charged language. We observe children solving a variety of challenging academic problems in intense give-and-take interactions, in contrast to adults' more characteristic internalized working out of problems. Daiute speculates that

youth genre works to scaffold learners' understanding of difficult problems, where less familiar adult or school genre may inhibit learners' understanding. She makes a series of specific recommendations to teachers for inviting children to use youth genre as a tool for learning in intellectually challenging and collaborative contexts.

The next three chapters portray adolescent and young adult learners. In "Bridging Home and School Literacies: Models for Culturally Responsive Teaching, A Case for African-American English," Carol D. Lee recalls the earlier theme of bilingualism, in this case, studying adolescent learners whose home literacies vary from their school literacies. In particular, she reviews discourse and rhetorical forms identified as part of the African-American verbal tradition. Then, drawing from the literature on effective teaching and learning, she shows how adolescents who are proficient in the nuances of this tradition can learn to extend their knowledge to other verbal traditions and acquire important literary concepts and strategies. In an intervention study, she illustrates that the metaphoric reasoning and ironic reasoning demanded by African-American adolescents' signifying dialogue can productively be tapped to interpret the predominantly white, male, and western literature in the school curriculum. Lee makes a convincing case for using this kind of cultural modeling as a scaffolding vehicle for all students to illuminate the "rites of passage" required in secondary English classrooms. She argues that capitalizing on home languages that differ from Edited American English advances literacy development and supports a model of culturally responsive pedagogy.

In contrast to Lee, in "Student Conversations: Provocative Echoes," Eleanor Binstock examines the nature of youth genre across cultures. Videotaping conversations over a year's time, Binstock engaged a group of Latino students attending an alternative high school on Chicago's south side in correspondence with a group of African-American students attending an alternative high school on the city's west side. The strategy enables us to learn what students who would not normally encounter one another reveal in dialogue together. The peer video conversations provided students with opportunities to name their experiences, to disclose life texts to one another, and to create new meanings within and between groups. The extended video conversations additionally allowed misunderstandings to be resolved and meanings clarified. Binstock's analyses of conversational excerpts reveal the sophisticated ways in which students employ rhetorical echoes to influence and shape mutual interaction: to underscore a point or a theme, to challenge and react, to ease border crossings among strangers. Educators, in turn, are afforded privileged opportunities to experience the diverse perspectives of cultural others.

In "Street Literacy," Dwight Conquergood takes readers further yet outside the adolescent mainstream and explores the outlawed literacy of street youth, encoded in graffiti writing. He reveals the oppositional, yet intricately coded language of signs in the context of the public subjection of street youth to search warrants, strip searches, and fingerprinting. He heightens our awareness of the tensions elicited by this form of visual communication: its hypervisibility and

its secrecy. When he decodes graffiti writing's alphabetic, iconographic, and corporeal dimensions in a photographic journey, he also comments on the playful, creative character of the writing. Conquergood captures the familiarizing, communal aspects of street literacy that draw its members into tightly knit groups. He shares three levels of performance featured in gang graffiti writing: collaborative writing constituting a well-orchestrated ensemble performance (e.g., of "making a wall"), using body surfaces to mirror and extend graffiti on buildings, and reading "play."

Adults in intergenerational familial relationships are the learners in Vivian Gadsden's chapter. In "Intergenerational Discourses: Life Texts of African-American Mothers and Daughters," Gadsden examines the convergences of issues of gender, race, and culture within the intergenerational oral and written discourses (life texts) of African-American women. In reviewing current understandings and unresolved issues in the field of intergenerational literacy learning, she addresses the researcher's role in disclosing—and therefore making vulnerable—what is typically not disclosed to outsiders. She frames her subsequent discussion by presenting both current and historical contexts for African-American women's literacy. Gadsden then examines the oral and written life texts of two and three generations of African-American mothers and daughters, predominantly from rural South Carolina. The discourses, in effect, create possible meeting places for women and girls to learn from one another, to come to respect persistence in the face of travails, and to share aspirations and concerns about achieving life goals, including the goal of literacy. The author closes the chapter by considering implications of these convergences for practice and research.

The last two chapters in the section predominantly address the literacy experiences of adult learners. In "Community Literacy: From Home to Work and Back," Gary Pharness and Lee Weinstein call upon their own histories as learners to help them understand the adult learners with whom they work. They argue that, additionally, an appreciation of adult learners' many contexts—family, community, and workplace—is essential in promoting their literacy, and doing so with integrity. They claim that these contexts can be understood through learners' own narratives, which can be the literature in a curriculum that connects isolated learners of diverse ethnicities and breaks down barriers. These narratives inform educators about what is and is not important to the adult learner and where educators might intervene, principles that have been realized at Invergarry Learning Centre in Surrey, B.C., Canada and in the journal *Voices*. Pharness and Weinstein raise thought-provoking questions about the relationships between concern for individual workers' literacy and stories, workers' performance in the workplace, and the collective building of community. They end the chapter by describing two community-building literacy projects in which they are presently involved: one, an intergenerational literacy project called Rainmaker; the other, a literacy project with a First Nations' aboriginal community.

Finally, Hal Adams' chapter, "A Grass Roots Think Tank: Linking Writing and Community-Building," amplifies the experience of linking literacy to community action. He docu-

ments how African-American parents in a west side Chicago elementary school so deepened their understandings of their own and others' experiences through processes of writing and discussion that they became motivated to take action to improve the quality of life in their community. Adams describes how the idea of a writing group founded on the notion that "every person is a philosopher" gave rise over time to parents' increased confidence in the worthwhileness of their experiences. Parents who initially joined the group to find out how to help their children with schoolwork returned to make sense of their experiences and to affirm each other's role in their common struggles against the stresses of poverty. Adams chronicles how the parents published their work in *The Journal of Ordinary Thought*, gave readings to audiences that included their children's classes, encouraged the founding of a neighborhood men's writing group and, eventually, initiated the Austin grass roots think tank that took concrete action to remedy community problems identified in the writing of community citizens.

Across the chapters in this section, all the authors conceive of language learners as distinctively influenced by their particular social and cultural contexts. Some learners' environments are nurturing, supportive, or at least relatively benign; others dwell in exceptionally hostile and oppressive, even menacing, surroundings. Across the chapters, we receive privileged glimpses of learners' lives, revealing the undeniably powerful influences of family and community, gender and race and ethnicity, age, and language(s).

The authors do not speak as a group, but a recurrent theme in their work is how the multiple influences imprinted in the learners can be called forth to serve as positive resources. The authors review a variety of ways to assess what learners know. In particular, the value of intensely personal oral and written narratives dominates the chapters. These narratives or life texts, as some authors have termed them, create extraordinary potential for self-knowledge and existential understandings; for community building and for educating others; and for community action, when used in learning environments where trust and respect prevail. The authors show how literacy learning as a social, contextualized process, can become entwined with the inscription of learners' lives in personal narratives. Collectively, these pieces yield important insights into how learners' social and cultural histories can contribute to our understanding of how, why, and when individuals learn and use literacy.

Finally, it comes as no surprise that we repeatedly come across the terms *sense making*, *risk taking*, and *playfulness* in this section. Over and over, the authors document language learners' affectively charged, intentional pursuit of meaning in the world around them. Interestingly, a number of authors profile learners bridging two languages by using the more familiar, more known language to make sense of the less familiar language. These specific efforts among bilingual and bidialectal learners are yet another instance of learners' proactive efforts to negotiate meaning-meaning across boundaries of culture and difference.

TELLING THEIR STORIES, SINGING THEIR SONGS

Mara Krechevsky

HARVARD UNIVERSITY

Ulla C. Malkus

WHEELLOCK COLLEGE

Walk into a typical preschool classroom and what are you likely to find? A variety of learning centers and materials, such as an art table, a nature area, a dramatic play area, blocks, puzzles, a math area, a reading corner, and a writing table, among others. Despite the diversity suggested by this array, much of the assessment of children's cognitive development has focused on two symbolic domains: language and mathematics. This conception of development is based on traditional notions of intelligence that take a unitary view of the human mind (Sattler, 1988). This model has had enormous impact not just on the way children are viewed in school but on Western thinking about intelligence in general. Children who do not exhibit competence in language and logic are often identified as at-risk for school failure. Some of these children may eventually fall through the cracks of the educational system if their strengths in other areas go unrecognized.

The aim of this chapter is to examine an approach to assessment that encourages teachers to look at young children's cognitive development in a more pluralistic way. Project Spectrum, a research initiative based at Harvard Project Zero and Tufts University, was developed as a way to uncover the many dimensions of the preschool learner's mind. Spectrum is an attempt to give children the opportunity to speak, sing, dance, draw—to express themselves in activities that are meaningful to them. We chose to focus on early childhood because of the relative plasticity of the young mind and the diversity of the preschool environment. We also saw assessment as a useful point of leverage for effecting educational change. The Spectrum assessments give teachers a framework for observing children and shaping their teaching and classrooms accordingly.

The Spectrum assessment framework is based on Howard Gardner's theory of multiple intelligences (Gardner, 1983)

and David Feldman's theory of nonuniversal development (1980, 1994; see also Ceci, 1990; Fodor, 1983; Keil, 1986). Instead of limiting our assessments to linguistic and logical-mathematical competencies, as many standardized tests do, the Spectrum approach addresses a broader range of abilities, including musical, spatial, bodily-kinesthetic, and social skills. In this chapter, we discuss the principles behind our assessment approach that enabled us to identify the full spectrum of abilities exhibited by preschool children. After a brief theoretical overview, we summarize the Spectrum approach to assessment and describe its underlying principles, providing examples from the domains of language, art, music, and creative movement.

BRIEF THEORETICAL OVERVIEW

The unitary view of intelligence was first proposed by Charles Spearman (1904, 1927). Spearman used statistical analyses of individuals' performances on a battery of tests to assert that a single general capacity underlies all intellectual activities. This point of view was furthered by Alfred Binet's (Binet & Simon, 1916) development of a measure that would predict which children would benefit from remedial help in school (Fancher, 1985). Although Binet did not suggest that his measures identified a single entity that could be considered a "general intelligence," his mental tests yielded a single numerical score. This "mental age" and later the "intelligence quotient" (IQ) were often regarded as a measure of general intelligence.

In contrast to the factor-analytic procedures used by researchers like Spearman to identify intellectual capacity, Gardner surveyed a wide range of evidence to support a more

The research reported in this chapter has been supported by generous grants from the William T. Grant Foundation, the Rockefeller Brothers Fund, and the Spencer Foundation. We are grateful to Howard Gardner, Thomas Hatch, Mindy Kornhaber, and Julie Viens for many helpful comments on earlier drafts.

pluralistic view of intelligence. For example, he looked at the development of abilities in a variety of domains of knowledge. He also examined the neurobiological literature to determine whether there was evidence for the separation of different mental functions in the brain. Other sources of evidence included literature on the existence of special populations like prodigies, idiot-savants, and autistic individuals; cross-cultural data; and a plausible evolutionary history. Based on this review, Gardner identified at least seven different intelligences: linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, interpersonal, and intrapersonal. Almost all human beings possess all of these intelligences; however, we differ in the relative strengths and weaknesses of individual cognitive profiles. Also, one never finds an intelligence in isolation; all meaningful tasks, roles, and products involve a combination of intelligences.

The research of David Feldman focused on the development of ability within particular domains of knowledge. According to Feldman, development within domains—areas of knowledge and practice ranging from language and music to map-making and chess—can traverse a continuum from universal to unique. For example, language is considered a universal arena of development, with virtually all individuals developing relatively high levels of performance, while the contributions of a writer like Toni Morrison would be considered unique. Other types of nonuniversal development include cultural (e.g., oral storytelling in nonliterate societies), discipline-based (e.g., poetry), and idiosyncratic (e.g., free verse). Project Spectrum's assessments are intended to address the nonuniversal end of Feldman's continuum of development. This chapter describes a set of measures designed to identify abilities that many teachers may currently overlook or consider "fringe" domains of cognitive growth.

The Spectrum Approach to Assessment

The Spectrum classroom encompasses learning activities in seven different content areas. Using multiple intelligences theory as a starting point, we conducted observations in preschool classrooms and consulted with teachers to determine which areas we would address. Through this process, we hoped to create developmentally appropriate assessments that were both grounded in theory and reflected the preschool environment. We also met with subject matter experts and reviewed the literature in different domains to ensure that the assessments tapped key abilities in each area. The list of 15 assessment activities is given below.

AREAS OF COGNITIVE ABILITY EXAMINED IN PROJECT SPECTRUM

Movement

Creative Movement Curriculum

Assesses children's abilities in five areas of dance and creative movement: sensitivity to rhythm, expressiveness, body control, generation of movement ideas, and responsiveness to music.

Obstacle Course

Assesses skills found in a variety of athletic activities such as coordination, timing, balance, and power.

Language

Storyboard Activity

Assesses a range of language skills including use of temporal markers, complexity of vocabulary and sentence structure, use of dialogue and narrative voice, and thematic coherence.

Reporter Activities

Assess children's abilities to describe experiences or events with regard to such criteria as level of detail, accuracy of content, relationships among events, and sentence structure.

Mathematics

Dinosaur Game

Assesses children's understanding of number concepts, counting skills, abilities to adhere to rules, and use of strategy.

Bus Game

Assesses children's abilities to create a useful notation system, perform mental calculations, and organize number information for one or more variables.

Science

Assembly Activity

Assesses children's mechanical abilities. Successful completion of the activity depends on fine motor, visual-spatial, observational, and problem-solving abilities.

Treasure Hunt Game

Assesses children's abilities to make logical inferences. Children are asked to organize information to discover the rule governing the placement of various treasures.

Sink and Float Activity

Assesses children's abilities to generate hypotheses based on their observations and to conduct simple experiments.

Discovery Area

Assesses children's observational skills and appreciation and understanding of natural phenomena through yearlong natural science activities.

Social

Classroom Model

Assesses children's abilities to observe and analyze social events and experiences in their classroom.

Peer Interaction Checklist

Assesses the behaviors in which children engage when interacting with peers. Different patterns of behavior yield distinctive social roles such as facilitator and leader.

Visual Arts

Art Portfolios

Contents of children's art portfolios are reviewed twice a year and assessed on criteria that include use of lines and shapes, color, space, detail, and representation. Children also complete four structured activities to supplement their portfolios.

Music

Singing Activity

Assesses children's abilities to maintain accurate pitch and rhythm while singing as well as their abilities to recall a song's musical properties.

Music Perception Activity

Assesses children's abilities to discriminate pitch. Activity consists of song recognition, error recognition, and pitch discrimination.

The assessments include both structured (e.g., music perception) and unstructured (e.g., creative movement) measures. Record keeping takes the form of scoresheets, observational checklists, and anecdotal descriptions. Although many of the assessments yield quantitative as well as qualitative results, the numerical data were used primarily for research purposes. At the end of the year, the information collected on children is described in a "Spectrum Profile," a narrative summary of children's areas of strength, either relative to their peers or to themselves. In addition to the profiles, parents receive a Parent Activities Manual with suggestions for out-of-school activities, grouped according to content area. As many schools and homes may not be equipped to address the full range of intelligences, a list of community resources is also included to provide additional services and programs.

Spectrum's approach to assessment is founded on four educational principles: emphasizing children's strengths, integrating curriculum and assessment, embedding the assessments in real-world activities and using materials that are authentic to the domains being assessed (see also, Krechevsky, 1991). Many of these principles are becoming accepted practice in the field (see, e.g., Bredekamp & Rosegrant, 1993; Meisels, Dorfman, & Steele in press). In the rest of this chapter, we describe how these four principles have been applied in the areas of language, art, music, and creative movement. Where relevant, we also place the Spectrum assessments in the context of past and current research on child development.

The preliminary results reported here are drawn from three preschool classrooms at the Eliot-Pearson Children's School at Tufts University in Medford, MA. These data were collected from 1985–88 on a sample of primarily European American, middle-income children, with an average class size of 20 children. Clearly, the way in which different abilities are expressed varies across cultural contexts, and many of the Spectrum assessments and scoring rubrics may need to be modified for other settings. (For a more complete description

of the Spectrum assessment program and the preliminary results reported in this chapter, see *Project Spectrum: Preschool Assessment Handbook* (Krechevsky, 1994).

Emphasizing Children's Strengths: A Look at Language

Perhaps the most important feature of the Spectrum assessment approach is its emphasis on identifying children's strengths. Rather than focusing on areas of weakness and trying to remediate them, the Spectrum measures explicitly target areas of strength. For instance, Spectrum's assessments in language provide a fine-grained analysis of children's skills in that domain, focusing on exceptional linguistic abilities. Teachers can then use this information to build on those competencies, perhaps using them to shore up areas where children are not as strong.

Many current researchers in the area of language development recommend that measures of young children's development focus on emergent literacy skills (e.g., Hiebert & Calfee, 1992; Snow, Tabors, Nicholson, & Kurland, in press; Sulzby, 1985; Teale, 1988). Sulzby (1985), for example, has devised a classification scheme for young children's emergent reading of storybooks. This scheme addresses children's shift from attending primarily to pictures to focusing more on print, and their shift from "reading" that relies on the conventions of oral language to "reading" that reflects the conventions of written language.

The above measures focus on the developmental sequences of emergent literacy through which virtually all children pass. In contrast, the Spectrum measures target nonuniversal development (toward the unique end of Feldman's continuum of development). The Spectrum language assessments examine both invented and descriptive narrative. The Storyboard Activity, Spectrum's invented narrative measure, is designed to tap such components of linguistic ability as thematic coherence, nature of narrative structure, and sentence structure. Children are asked to generate their own tales using a three-dimensional storyboard, including evocative props, creatures, people, and an ambiguous-looking landscape. Table 23–1 lists the component skills targeted by the Storyboard Activity.

After identifying children's primary language functions (e.g., use of descriptive, investigative, conversational, or storytelling language), teachers can assess their performance on each subskill. The scoring rubrics allow teachers to identify and document a range of linguistic competencies. For example, the category of expressiveness refers to sound effects used in support of a child's story. Level 1 is defined as "child uses little or no emphasis in her story; story is presented in a monotone voice;" Level 2 refers to children who use occasional sound effects (character voices, emphasis, singing); and Level 3 describes children who consistently use sound effects, lively character voices, and vivid narration.

While some children demonstrate unusual imaginative language skills, others may reveal strong descriptive narrative competence. Spectrum's Reporter Activities elicit children's abilities to report content accurately, to report detail selectively, and to identify sequential or causal relations. The assessment consists of a "Movie Report" and "Weekend

TABLE 23-1. Skills Targeted by the Storyboard Activity

Observer _____

Please comment as much as possible on the following:

- physical manipulation of props – for example, child seems overwhelmed by props or seems more interested in setting up scene than in telling story
- transformation of materials/activity – for example, child uses clay arch as rainbow or uses extra props box as a ship
- skills from different domains – for example, child sings her story or counts the objects on the storyboard

Be specific and detailed in your account of these and any other visual cues so that the scorer has a more complete sense of the physical dynamics of the child's storytelling.

News." In the Movie Report children watch a short movie or video and then recount what happened. The Weekend News Activity offers children regular opportunities to describe their weekend experiences. In addition to some of the language skills addressed in the Storyboard Activity, the Reporter Activities yield information pertaining to accuracy of content, expansion of main events, and relationships between events.

In the Storyboard Activity, most children in a Spectrum class of 3- and 4-year-olds were able to use both dialogue and narration. Several children also created a storyline that combined characters, props, and action in a common narrative problem. In the Reporter Activities, individual differences emerged in children's abilities to use language relevant to the experiences that they were describing (e.g., using phrases like "I goed there" as opposed to "My father brought me to the museum with knights with different kinds of helmets".) (We recognize the experientially dependent nature of the measures reported here and the need for further field-testing.) One boy's strength showed up in the imaginative detail of his movie report. He reported with great zeal that he saw a dog chase a cat, a kitty cat climb a tree, a bald eagle, a runaway bull, an ostrich, a dog that barked, and pigs that were killed for bacon. None of these features were in the film. While the detail in his report was rich and abundant, it was low on accuracy.

Not only do the measures just described provide a framework for assessing children's language abilities, the activities also enrich a teacher's curriculum by eliciting children's invented and descriptive narrative. Teachers can use their knowledge of children's competences to provide additional experiences in their areas of strength as well as to help them in areas in which they are struggling. For instance, if children exhibit a strength in language but not in creative movement, teachers can suggest that they act out a story or create movements to represent evocative words or expressions. The Spectrum approach offers one possible means for nurturing children's self-esteem as a direct result of meaningful work.

Integrating Curriculum and Assessment: The Case of the Visual Arts

A second educational principle that underlies the development of the Spectrum measures is blurring the line that traditionally divides curriculum and assessment (see also, Teale, 1988; Teale, Hiebert, & Chittenden, 1987). The Spectrum materials are designed to resemble other classroom activities and, ideally, are conducted by the teacher over time in the children's classroom. The Spectrum visual arts assessment is a particularly good illustration of this principle in that it builds on the teacher's regular art curriculum, supplementing it with four targeted exercises.

While many preschool environments are rich with artistic experiences, most teachers devote little attention to assessment in this area. Even when teachers do assess artistic ability, their assessments focus primarily on such exercises as collecting self-portraits in portfolios (see also Harris, 1963). Traditional spatial measures include asking children to copy

block designs and geometric patterns (Wechsler, 1967). The assessment guidelines developed by the National Association for the Education of Young Children suggest that artwork be collected to document "children's progress in the division and use of space, awareness of shapes, fine-motor control and eye-hand coordination, and sensitivity to materials" (Cherry, 1990, p. 60). While these categories address some of the same elements covered by the Spectrum assessments, they overlook such capabilities as expressiveness, imagination, and generativeness.

The Spectrum art assessment is embedded in a curriculum with a variety of activities entailing both two-dimensional (paint, markers, crayons, chalk) and three-dimensional (clay, wood-working, sculpture, collage) work. Much of this work is collected in portfolios and assessed at the end of each semester. Four targeted exercises give teachers the opportunity to compare children's work when presented with the same task and materials. The scoring categories used to monitor children's work in the portfolios include use of lines and shapes, color, composition, use of detail, expressiveness, and representation. Four additional categories—consistency, imagination, variety, and sense of completeness—help teachers record their overall impressions of children's work.

The four targeted exercises ensure that children complete a range of art projects they might not otherwise attempt. To establish a baseline for children's representational abilities, two of the Spectrum drawing activities entail drawing a farm animal and a picture of the child with his or her family. To make them meaningful to children, drawings are incorporated into group and individual books. The third drawing exercise is designed to tap children's abilities to use their imagination. For this activity, children are read a story about a strange creature visiting the planet and then asked to depict the creature. The fourth exercise is an open-ended, three-dimensional project incorporating such materials as clay, plasticine, wood scraps, popsicle sticks, and paste.

Most of the scoring categories used by Spectrum address whether children's abilities are characteristic or distinctive for their age group. For example, with regard to composition, preschool children often depict objects and figures in a scattered fashion around the page. Objects may be related to one another, but not to the page as a whole. Objects are also typically depicted in space as children understand them in relation to themselves. However, children with a strength in composition are most likely to portray objects in relation both to one another and the page. Some may use a baseline with a sky in their representational work. Their drawings may also demonstrate a sense of perspective, including such features as occlusion (partial view), three-dimensionality, and profile.

Most preschool children in the Spectrum classrooms produced art characteristic for their age. They often drew stick figures and "tadpole" people and used the materials in exploratory ways. As in language, some children exhibited distinctive ability in certain categories only. For example, one girl whose work was mainly exploratory demonstrated an unusual use of color. In each of her drawings and paintings she drew the color spectrum, varying it slightly with each piece. She also frequently experimented with color-mixing in her paintings. Another boy concentrated on representational

drawings with markers. He demonstrated an unusual command of detail, perspective, and composition. Some of his drawings showed figures in profile or partially obstructed objects. His use of lines also conveyed a sense of motion.

The Spectrum art portfolio integrates assessment with curriculum by situating the measures in the context of regular classroom activities. Again, as we saw with the language assessments, one contribution of Spectrum's visual arts assessment is that it gives teachers a frame of reference and a vocabulary for documenting their impressions of children's work. Teachers can come to understand the learner more completely. Instead of just saying, "I like your painting," or "This drawing is really good," teachers can differentiate and describe children's products according to a range of artistic features.

Contextualizing Assessment: The Movement Curriculum

Much of the way we think about and analyze children's development in early childhood programs is influenced by the division of human development into four domains: cognitive, physical, social, and emotional (e.g., Bredekamp & Rosegrant, 1993). Early childhood researchers and educators often refer to this four-part scheme both implicitly and explicitly in studying and tracking children's progress in different areas. For example, progress reports for young children focus primarily on the cognitive sphere of development, often addressing early symbol acquisition. If domains other than language and math are addressed at all, they are often lumped together in such phrases as "expresses ideas and emotions through drama, music, dance, and art," or they reflect mainly basic skills, for example, "can grip a pencil, uses glue to make collage, participates in finger plays."

The Spectrum approach, on the other hand, considers problem solving in areas like movement, visual arts, and music to reflect cognitive abilities analogous to those identified in language and math. We drew upon the concept of adult "end-states"—or significant roles in our society—to define the types of abilities we wanted to elicit. For instance, we looked at such vocations as storyteller, reporter, singer, naturalist, and mechanic in developing our assessment activities. By embedding the Spectrum assessments in meaningful, role-related activities, we were hoping to look beyond skills useful in the school context to include the range of abilities called upon in real-world situations.

Reflecting the abilities of athletes and dancers, Spectrum's assessments in the movement domain address both athletic and creative movement. Although movement is an important part of many early childhood programs, experiences in this area often revolve around such gross motor activities as running, jumping, balancing, and climbing. As children get older, a greater emphasis is placed on fine-motor development through activities like using scissors, holding markers, and playing with small manipulatives. As suggested earlier, assessments in this area typically focus on broad stages of development, with little opportunity for child input or choice (see, e.g., Folio & Fewell, 1974; Haines, Ames, & Gillespie, 1980; McCarthy, 1972). While the movement theorist Laban (1960), among others, has created a notational and interpretive

scheme for tracking children's growth in creative movement, teachers often find such procedures too complex for classroom use.

Since many preschool programs already include an athletic or outdoor activity time, we focus here on the more expressive dimensions of physical development. The Spectrum creative movement assessment is embedded in an ongoing classroom curriculum. Activities elicit five key abilities in creative movement and dance: sensitivity to rhythm, expressiveness, body control, ability to generate movement ideas, and responsiveness to music (see below for scoring criteria).

CREATIVE MOVEMENT SCORING CRITERIA

Sensitivity to Rhythm

Ability to synchronize movements to stable and changing rhythms (generated by an instrument or recorded music) or to set one's own rhythm.

Child attempts to move with the rhythm as opposed to being unaware of or disregarding rhythmic changes. Child can set a rhythm of her own through movement and regulate it for desired effects. Take note whether she uses one part of the body, for example, swinging her arm, or whether she moves her whole body in synchrony.

Expressiveness

Ability to evoke moods or images through movement. Stimulus can be verbal image, prop, or music.

Child is comfortable using gestures and body postures to express herself. She responds vividly to different verbal images and/or moods and tonal qualities of different instruments, for example, drum and bell. She also varies her response to music selections, interpreting the quality of music in her movements, for example, light and fluid movements for lyrical music versus strong and staccato movements for a march.

Body Control

Ability to place body, and to isolate and use body parts effectively, to achieve desired effects, for example, to freeze, balance, melt, and the like.

Child can play, sequence, and execute movements efficiently. Her movements do not seem random or disjointed. She accurately executes movement ideas proposed by adults or other children. Look for whether child can freeze her body when asked. Also notice *body awareness* (ability to identify and use different body parts like hips and shoulders, and to understand their functions) and *movement memory* (ability to replicate her own movements and those of others).

Generation of Movement Ideas

Ability to invent novel movement ideas or to offer extensions of ideas, for example, suggesting that classmates make their raised arms float like clouds in the sky. Execution of movement is not necessary to excel in this category.

Child responds immediately to ideas and images with original interpretation.

Responsiveness to music

Ability to respond in different ways to different kinds of music (combines sensitivity to rhythm and expressiveness).

Notice whether child responds primarily to rhythm or to mood of music, or to both. Also notice *use of space*, that is, ability to explore available space comfortably using different levels (high, middle, low) and to move easily and fluidly around the room. Look for whether child anticipates others in shared space or experiments with body in space, for example, turning and spinning.

For instance, in addition to asking children to execute specific movement sequences like balancing and skipping, we give children the opportunity to invent their own ideas for movement—important skills for choreographers. As a foundation for movement expressiveness, children explore different levels of space, for example, walking in “high” and “low” space. Later in the year, teachers can determine children’s understanding of the use of space by providing them with a variety of images (melting snowpeople, popcorn popping) and observing their responses. Rhythmic sensitivity is another important skill for dancers. To develop children’s rhythmic sensitivities, teachers present them with objects with a regular beat like clocks and metronomes. Children also dance to different tempos of music. Teachers document their observations by completing an observational checklist immediately following each movement session.

As stated earlier, one of the distinguishing features among children’s responses to the Spectrum movement activities is their ability to generate their own movement ideas, rather than watching and imitating what other children do. While many children simply repeat the teacher’s ideas, some expand upon or generate their own novel movements, for example, suggesting that children pretend to be “clocks.” One girl revealed unusual movements that reflected both the tempo and mood of the accompanying music. At the conclusion of one piece, she deliberately tried to end her dance in a pose that matched the quality of the music. Some children exhibited good body control and were confident and agile in their movements but were hesitant to experiment with more expressive types of movement. The strengths of these children might have been elicited more fully through athletic challenges rather than the creative movement sessions.

The Spectrum creative movement curriculum contextualizes assessment by enabling teachers to look at children’s abilities as they participate in activities authentic to the domain of dance. By designing our assessments with end-states like “dancer” in mind, we hope to ensure that the abilities being tapped are worthy of recognition and support.

Creating “Intelligence-Fair” Assessments: The Music Domain

Finally, the Spectrum assessments are based as much as possible on measures that are what we call “intelligence-fair.” Instead of looking at abilities through the windows of language and logic, like many standardized tests, the Spec-

trum measures use materials that reflect the characteristics of the domain being examined. For instance, the athletic movement component involves children completing an obstacle course while the mechanical science assessment entails presenting children with simple machines to take apart and reassemble. In music, in particular, the Spectrum approach departs from traditional paper-and-pencil measures. Instead of focusing on verbal or written responses, the music assessments rely on children singing songs and playing simple instruments.

Assessment of young children’s musical competencies has traditionally centered on the ability to distinguish differences in rhythm and pitch (Deutsch, 1983; Dowling & Harwood, 1986; Miller Walker, 1992). Many of the assessments of young children’s musical abilities rely on paper-and-pencil measures that were originally designed for older children (Miller Walker, 1992). For example, some of these assessments involve asking children to draw circles around pictures representing “same” and “different” sounds. One music educator argues that there are no appropriate standardized tests for preschool children (Flowers, 1993). Although some researchers in early childhood assessment are beginning to recognize the need to include music, among other art forms, as an important area of child development, these assessments mainly address children’s levels of engagement and participation, rather than differentiate the quality of musical competence (Meisels, 1993; Schweinhart & McNair, 1991).

The Spectrum music assessments tap children’s abilities in production and perception. The production measure, the Singing Activity, looks at the ability of children to sing new and familiar songs. Core components include grouping of notes, clarity of rhythm, contour of phrases, and singing in tune. For example, contour refers to the up-and-down motion of the melody. Children receive credit for adhering to the general direction of a phrase, even if individual notes are not accurate. Clarity refers to children’s ability to project an accurate sense of rhythm. Credit is given if they sing notes on the appropriate beats; if children are vague about the rhythm or invent their own rhythm during the song, they receive no credit.

On the birthday song exercise, part of the production measure, most of the children in the Spectrum classroom sang all the lyrics accurately and exhibited a strong sense of rhythm. A smaller group showed awareness of pitch distinctions, but few were able to maintain the correct key throughout the song. Several children who exhibited outstanding musical ability were also taught a more challenging tune. Although their singing did not reflect the mood or feeling of the melody, they were able to reproduce difficult pitches and intervals and to recreate the song’s beginning octave jump.

Complementing the production measure, a Music Perception Activity taps children’s abilities to perceive differences in musical qualities like pitch and rhythm. We designed the assessment to be “intelligence-fair” by using a performance-based mode of response for eliciting children’s perception abilities. Children are asked to play Montessori bells, which all look alike but yield different tones. Thus, the bells eliminate the visual cues of instruments like xylo-

phones and keyboards. The perception activity consists of five parts: song recognition, error recognition (identifying incorrect versions of well-known tunes), two pitch-matching exercises, and free play.

Most of the children participating in the Spectrum assessment were able to match pitches when asked to identify two bells that sounded the "same" from a series of three-bell sets. Two children who demonstrated unusual sensitivity to the manner in which the bells were played also commented on the different tones created by the wooden and plastic mallets. In the error recognition exercise, one boy articulated subtle distinctions among incorrect versions of the tune, characterizing the differences as "a little the same," "a lot different," and "a very lot different." During free play, some children were reluctant to touch the bells or played entire songs using only one bell, while others explored different arrangements and experimented with volume and rhythm on a number of bells.

As with any assessment, teachers should never rely on just one type of measure for determining perception and production abilities. The Spectrum activities are a vehicle for identifying children's strengths or testing emerging hypotheses about where children's strengths may lie. An important, supplementary source of information—which can also be considered "intelligence-fair"—is observing children's other musical activities in and outside of the classroom. Such observations are essential for additional documentation of children's growth in the domain.

CONCLUDING NOTE

Clearly, much of the work reported here is still in a preliminary stage. For example, the Spectrum activities need to be field-tested with larger and more diverse samples of children. Further, it would be a mistake to interpret this chapter as recommending that all children need to be assessed on all Spectrum measures. Given the daily challenges faced by teachers of young children in terms of class size, limited staff support, lack of time, and scarce resources, we believe it is most important to focus on those children who are not being adequately served by the traditional curriculum.

In this chapter, we have tried to suggest an alternative way of conceptualizing children's abilities in the communicative and visual arts. Rather than restricting our notion of cognitive activity to language and math, we consider problem solving in the visual arts, movement, and music to represent "intelligences" as well. The Spectrum framework offers a tool for differentiating and documenting aspects of children's development, which too often go unnoticed. If we begin to recognize and support children's strengths in a wider range of areas, we are likely to increase the chances for all children to experience success in domains valued in school. Ultimately, the promise of this approach will be realized when children's distinctive cognitive profiles can be discerned and nurtured in their educational, home, and community contexts.

DEAF CHILDREN AS LITERACY LEARNERS:

TOM, ROBBIE, AND PAUL

Claire L. Ramsey

UNIVERSITY OF CALIFORNIA, SAN DIEGO

INTRODUCTION

In this chapter I describe three young literacy learners in a public elementary school program for hearing impaired children. As in most deaf education settings, literacy in English is the dominant instructional goal. In contrast to most deaf education settings, however, in this classroom, discourse was structured by American Sign Language (ASL). Indeed, ASL was the primary medium of instruction for all school subjects, including English, as well as for social life among the deaf children and their teachers. In this setting, the presence of one deaf adult who is a native signer of ASL generated a context where deaf children could both engage in learning and express themselves as learners through their incipient ASL/English bilingualism. Although they found the learning tasks focused on reading and writing English to be difficult, the children's interest in language, writing, and other people, coupled with their ability to express their ideas through ASL, provides many insights into the nature of the literacy learning task for deaf children.

BACKGROUND

Currently most deaf children are enrolled in regular public elementary schools (Schildroth, 1988) in education programs where their time is distributed among special classes for deaf students and classes and activities where they are "mainstreamed" or integrated with hearing children. Signing interpreters are often provided in integrated settings. In special classes, a pedagogy called "total communication" (TC) is followed. Total communication teachers are generally hearing speakers of English who use spoken English accompanied by signs as the medium of instruction. Deaf adult staff mem-

bers are rarely found in elementary TC settings (Woodward, Allen, & Schildroth, 1988). The twin objectives of public school hearing impaired programs are to allow for instruction with normally hearing agemates as much as possible and to facilitate the acquisition of English among the deaf children. Despite the existence of such programs, and the highly intensive and technical methods for educating deaf children which have been developed over the years, deaf students in the United States generally fail to achieve competence in English and assimilation with hearing people that their education is expected to provide (Allen, 1986; Commission on Education of the Deaf, 1988; Quigley & Paul, 1984). As their school careers proceed, deaf students fall more and more behind their hearing agemates.

Although a great deal is known about the disappointing outcomes of schooling for many deaf students (e.g., Allen, 1986), many questions remain about the everyday enactment of deaf education. Trends in communication and instruction come and go in a virtually data-free vacuum. In addition, mainstreaming, although widespread, is also poorly understood, especially its potential effects on deaf students' learning (Commission, 1988; Ramsey, 1994). These gaps in knowledge have generated provocative theoretical and practical questions about deaf children's early school lives, especially their learning of basic literacy (Commission, 1988; Erting, 1981; Johnson, & Erting, 1989; Johnson, Liddell, & Erting, 1989; National Institute on Deafness and Other Communication Disorders, 1989; Padden & Ramsey, 1993; Quigley & Paul, 1984; Ramsey, Sterne, & Padden, 1994).

How do deaf children tackle basic literacy skills? What do they do with language in contexts where print and signing coexist? To shed light on this question, I spent a school year with three deaf second graders, Tom, Robbie, Paul, and their teachers, and classmates. I observed and participated in instructional and noninstructional school activities, using two

video cameras to videotape instruction, booksharing, writing, reading, classes with hearing children, and visits from local deaf community members. I made 68 visits and recorded 250 hours of videotape. I studied the school context from "top to bottom," in order to isolate the school's many influences on the deaf children's opportunities to participate in learning. At the institutional level, I noted practices that reflected national legislative goals for educating children with disabilities and traced ways in which the school's organizational response to these ideals negatively affected the deaf children, especially in integrated settings (Ramsey, 1994). In contrast, the special self-contained classroom for deaf children was organized by the teachers of the deaf, according to their educational goals for the children. Notably, deaf community norms, especially norms for use of signed communication, also shaped life in the special classroom (Ramsey, *in press*). In the local context of the deaf students' activities during literacy instruction, I noted the powerful influence of the social life of the classroom, where both ASL and English were used and valued. This paper focuses on Tom, Robbie, and Paul as learners, and on their notions about language and literacy, revealed in their activities and in their comments on reading, writing, signing, and talking.

The Boys, Their Teachers, and Their School

Tom, Paul, and Robbie were the only deaf children in second grade during the study year, although they were part of a larger special class that included deaf third graders who signed, and a group of hard-of-hearing second and third graders who spoke English and did not sign. The three boys (who all turned 9 during the study) were good friends who used signing as their primary and preferred mode of communication.

Tom has a profound, bilateral sensorineural hearing loss caused by meningitis, contracted when he was 12 months old. (The names of the school and all participants have been changed to protect their privacy). The only child of hearing, English-speaking parents, Tom entered the preschool hearing impaired program at Aspen School when he was 3 years old. His mother signed and his father signed "some." Both parents expected that Tom would be an ASL-signing deaf community member when he grew up.

Paul has a profound sensorineural hearing loss in his left ear, with no response to testing in his right ear. His deafness was also caused by meningitis when he was around 12 months old. Paul entered the Aspen School hearing impaired program when he was 5 years old, having had no previous schooling. He was an only child who lived in an extended family household with his parents, and his mother's sister and her sons, whom he referred to as his "brothers." His parents spoke English, although only his father was a native speaker. Paul's father, a beginning signer, was the only member of the household who signed.

Robbie has a profound sensorineural hearing loss in his left ear and a severe sensorineural hearing loss in his right ear. Robbie was born deaf, of unknown causes. Robbie and his parents participated in a university-based "parent-infant program" when he was a baby. When he was three, he joined the

Aspen School preschool program. (He and Tom entered the same year.) He was the middle child in a hearing English-speaking family, with an elder brother and a baby brother. According to the teachers, his mother signed and his father was a beginning signer.

Aspen Elementary School, the site of the study, is a public elementary school in an unincorporated urban area in the western United States. About 350 students attend the school. Nearly half of them qualify for the free or reduced price lunch program. Deaf and hard-of-hearing students comprise about 10% of the school population.

Robbie, Paul, and Tom spent half days in a self-contained special classroom for the deaf and half days in integrated settings, primarily a regular 2nd-grade classroom. As spoken English was the medium of instruction and the hearing teachers and students did not sign, an interpreter accompanied deaf children during mainstreaming periods. The boys joined the hearing children's class for math, social studies, art, science, and "specialist" classes (PE, music and library).

Three adults worked with the boys and their deaf and hard-of-hearing classmates. Ms. Roberts and Ms. Adams are teachers of the deaf and both are hearing, native speakers of English, who each learned ASL as an adult, after leaving graduate school. Mrs. Hart is the instructional assistant in the classroom. In contrast to Ms. Roberts and Ms. Adams, Mrs. Hart is a deaf native signer of ASL, and has deaf parents, children, and grandchildren. She began acquiring English speaking ability during her early school years. She had good second language competence in written English, but little confidence in her writing ability. Although she could detect speech and use spoken English intelligibly, she would not speak on the telephone. She identified herself as a culturally deaf person.

Bilingualism in Deaf Education

Since the early 19th century, American deaf education pedagogy has cycled through several major ideological changes. (See Lou, 1988, for a detailed review of this history.) Early 19th century deaf education was conducted through signing. By the late 19th century "oral" methods (where students learned to "lipread" and to speak) were dominant. Oralism, in turn, was displaced by total communication in the 1960s. Total communication returned signing to the classroom, although not the sign language of deaf people, ASL, nor their communication practices. Rather, several groups of educators fashioned systems of signing that they hoped would provide not only media for communication and instruction but models of English that would be clearly visible to deaf students. These systems are often referred to as "manually coded English" or by trademark names such as "SEE." In practice, total communication methods depend upon the medium of speech combined with one of these systems of signs, a method of communication that is not comfortable for most deaf adults. Neither oral methods nor the TC pedagogy have significantly altered the depressed schooling outcomes of deaf students. (See, Ramsey, 1989 and Supalla, 1986 for discussions of the formal linguistic and sociolinguistic weak-

nesses of the manually-coded English systems, and of communication practices in TC classes.)

As educational methods in classrooms for deaf children fluctuated, communities of deaf adults remained linguistically stable, using, maintaining, and elaborating their language as any speech community would over time. They transmitted ASL to their children (hearing and deaf) via precisely the same interactional paths that all communities use to pass on linguistic heritage to younger generations. Deaf people who did not grow up in deaf communities (e.g., those from hearing families) gained access to the deaf community and to ASL at various points in their lives (at school from deaf adults in nonclassroom settings, or from native-born deaf peers), and entered the world of deaf signers of ASL. Although ASL is signed language embedded in an English speaking context, it is unrelated to English, maintained by a cohesive speech community of deaf signing people and their deaf and hearing children.

In recent years deaf Americans, especially those who are teachers of the deaf, have spearheaded a reevaluation (at both the grass roots and professional levels) of the education that is offered to deaf children. The recurring problem, long noted by both deaf people and by teachers, is the difficulty of communication (and hence of teaching and learning) in classrooms for deaf students organized according to oral or TC pedagogies. As deaf adults began participating in and directing the discourse about the education of deaf children, images of deaf students began to change. Descriptions of deaf children as disabled persons needing auditory and speech rehabilitation began to fade. In their place, descriptions of deaf people as an ethnolinguistic group arose, where the young need "bilingual education" using ASL as the medium of instruction, not "special education" using invented or artificial languages or mechanistic methods. This cultural view of deaf people, existing alongside recent realizations of the multicultural nature of contemporary American life, has given rise to a new deaf education pedagogy, termed bilingual-bicultural (or bi-bi) education.

The analogy between the bilingual educational needs of deaf children and those of hearing ethnic minority children is not perfect. Critically, approximately 90% of deaf children are born into families of hearing people who have never met a deaf person and have little access to the deaf community, to its language and its practices. Unlike most Hispanic children, for example, most deaf children do not go home from school to deaf communities or to homes where all family members sign. Nonetheless, the powerful arguments in favor of using a natural human language, with an established "speech" community of signers and a historically-transmitted set of communication practices, have convinced some teachers and parents that ASL should be the medium of instruction for deaf children. Although only a few schools for deaf students have formally adopted a bi-bi stance toward education, many teachers and parents of deaf students see deaf children's educational needs from a nonmedical perspective, and make efforts to arrange for their children to have access to deaf native signers, and ASL and ASL-based communication practices at school.

Aspen School is such a case. While it is not formally a "bi-bi" school, ASL and deaf community ways with language are present in the classroom for deaf children. During her 12-year tenure in elementary deaf education classrooms, Ms. Roberts had begun taking ASL courses at night, believing that she could communicate and teach more successfully if she could use the language of deaf adults. In addition, when a position for an instructional assistant opened in her classroom, she encouraged the hiring of a deaf native signer, and Mrs. Hart joined the staff. Ms. Adams had recently received an M.A. in deaf education, after which she undertook a 2-year course in sign language interpreting to build her ASL skills. All three women believed that ASL was the best teaching tool they could bring to their classroom to help their deaf students learn and develop. With very little outside guidance, they attempted to make their classroom a culturally and linguistically friendly place for the deaf students.

Two Classrooms

Each school day Robbie, Tom, and Paul moved between the "deaf classroom" and the "mainstreaming classroom." In these two settings, they found a range of opportunities for using language face-to-face. It is important to understand the stark contrast between the deaf classroom, where teachers viewed the deaf children as bilingual (or potentially so), and mainstreaming settings, where teachers viewed the deaf children as disabled and in need of access to hearing children as language models.

Instruction in the mainstreaming classroom was teacher-centered, with an interpreter signing the teacher's speech for the deaf children. Since the teacher held the floor much of the time, most face-to-face communication in this room was among children, either "underground" and unofficial, or during recess or transitions between activities. I closely examined interactions among deaf and hearing children in this classroom to see how they managed to make contact with each other and to look for any hints that the deaf students were being assimilated into the mainstream hearing classroom culture. This is a positive outcome that administrators, policy makers, and parents have come to expect from integrated classrooms, although it is not clear how assimilation takes place when hearing children do not sign, and deaf children cannot speak.

Ideals about fostering opportunities for deaf children to mix with hearing children were not easily converted into practice. In fact, they were often incompatible with deaf children's specific educational needs. Since there was very little provision for teaching the hearing children to sign, and hearing and deaf peers could not communicate easily with each other, contexts of mainstreaming created constraints for the deaf children's communication. Although a sign language interpreter was always available to mediate their interactions, she did not have a niche in the hearing children's social life at school, and they avoided using her to communicate with the deaf children unless a dispute needed to be resolved.

For their part, the deaf children saved their interactional energy for communicating with other signing deaf children. They engaged with hearing children rarely, and only for

instrumental purposes, for example, to manage classroom business. Interaction initiated by hearing children with deaf children consisted of evaluations, directives, and unintelligible signing. This limited range of caretaker-like functions contributed to the status of "exotic mascots" that was often assigned to the deaf children in mainstream settings, where they were observed, commanded, praised or chided, but rarely included as peers in the group life of their hearing classmates.

In contrast, life in the deaf classroom was organized to promote a great deal of interaction and communication. This was facilitated by the teacher-student ratio, with three teaching adults working with only five or six students. Instruction took place through small group conversations, and children and adults were engaged with each other much of the time. Social life in the self-contained classroom was intelligible and engaging, structured as it was by ASL. Neither the three boys nor the adults used manually coded English for face-to-face communication. All participants, including the two hearing teachers of the deaf, signed ASL with varying degrees of skill. This was confirmed by a panel of native signer judges, none of whom knew the children or their teachers.

Yet, even in this intelligible classroom setting, patterned choices of interactional partners were based upon signing ability and gender. Tom, Robbie, and Paul preferred to interact with signers and with other boys. They did not favor their hard-of-hearing classmates in the deaf classroom who did not sign. Mrs. Hart was the preferred adult conversant. At the ages of eight and nine, the three boys were developing knowledge about the complicated linguistic world that all deaf people inhabit, where signing people and speaking people coexist. As the school year unfolded, I interviewed the boys about their lives at school. Each offered his observations about people at school and about communication, and made claims about his own writing, reading, and language. Additionally, the boys expressed some unconventional beliefs about hearing children's language and literacy.

Who Is Deaf?

All three focal boys asserted that they were deaf. Both Robbie and Paul assured me that they would be deaf when they grew up. Tom told me that Jesus would make him a hearing person, although when asked exactly how this would happen, he explained that the Jesus account was "just pretend." It is possible, however, that the second graders' definitions of "deaf" would undergo some change as they grew older. The deaf third grade students in the classroom expressed less certainty about their future status. One third grader told me that he would be both deaf and hearing when he grew up.

Robbie, Paul, and Tom made clear their knowledge that deaf people signed and hearing people did not. Hearing people could be diagnosed by their practice of talking to communicate. People who appeared to be able to both speak and sign had no clear status. Accordingly, the adults in the deaf classroom presented a problem. When confronted with the facts that we could all talk as well as sign, the children proposed various solutions. Paul declined to explain how Mrs. Hart could both talk and sign. He stated that she could

talk and that she was deaf, then summed up with a shrug, "I don't know." He was certain, however, that Ms. Roberts was deaf, and claimed that he did not know about Ms. Adams. Robbie resolved the problem by claiming that we were all both deaf and hearing. Tom claimed that I was hearing, that Mrs. Hart was "a little bit deaf" and that Ms. Roberts was a deaf person who could, for an unexplainable reason, talk. (Recall that Mrs. Hart was deaf, and Ms. Adams, Ms. Roberts, and I were all hearing signers.)

Tom also identified as "hearing" the hard-of-hearing children in his classroom who used hearing aids but did not sign. He laid out his reasoning on this topic by describing his hard-of-hearing classmate Drew's flaws as a signer, explaining, "She can't use her fingers right. It's awful." Tom reported that his parents were hearing people who could sign a little bit, then emphatically changed his mind, "NO, my mom and dad are hard-of-hearing." (See Padden & Humphries, 1988, for a discussion of the phenomenon of deaf children's definitions of "deaf" in the fuller context of American deaf culture.)

The boys' friendships and choices of interactional partners during instruction, and during lunchtime and recess (which were integrated activities) as well as their explicit expressions of friendship, complemented their claims about who fit into which category. The deaf children preferred to interact, eat, and play with other deaf children and stated this preference when asked. Paul explained to me that his friends were Robbie, Tom, and the deaf boys in the 3rd-grade group, and then very sweetly announced his affiliation with Tom, "Tom is my deaf."

Dealing with Hearing Children

The hearing 2nd-grade children in the mainstreaming classroom presented a less confusing diagnostic problem. According to Robbie, Paul, and Tom, these children were all hearing, and hearing children differed from deaf children in their communication abilities. For example, Robbie claimed that he himself never used his voice or tried to speak, and stated, "I sign, I'm deaf." In contrast, he maintained that hearing people (both his neighbors at home and his hearing classmates) simply did not sign, "They are hearing. Hearing people don't sign." Tom explained that the people in the mainstreaming classroom talked, and "I can't understand talking." Paul conceded that the children in the mainstreaming classroom were "different," and that they could do "a little bit of signing." In contrast, he reminded me that in the deaf classroom, "people know how to sign."

Although the boys willingly constructed categories for the various people in their worlds and acted on their preferences to play with children they could sign with, they obviously had interactions with hearing people. Robbie revealed that there were activities where hearing and deaf people could adjust to each other. (This is notable since, of the three boys, Robbie was the most uncooperative with any nonsigning substitute teachers who were temporarily assigned to the classroom.) For example, he claimed that math was hard, but it did not require "talking," so math lessons could take place among the hearing children. In his out-of-school life, he reported that playing Nintendo with nonsigning hearing neighbor children

was “easy, easy, easy” because it only involved “hitting the buttons” and “being careful.” For his part, Tom maintained the less charitable stance that people who could only sign a little bit were “stupid.”

It is clear that these deaf children lived in the so-called “hearing world.” Over the course of their young lives, they had observed hearing people and deaf people, as well as the activities that took place in their lives. Not surprisingly, they had formed preferences and certain (reasonable) beliefs about their own communication, especially about whom they could successfully communicate with and which activities might allow specific kinds of nonsigning interaction. The point here is that, in the context of their current school life, the focal boys were not only unconfused about their identities as deaf boys, they had begun to form a set of related beliefs about what “deaf” and “hearing” meant.

Relating Communication and Literacy: “Hearing Children Can’t Sign and Can’t Read”

The boys each outlined definitions of “reading and writing” suggesting that they expected that a connection between language used face-to-face and written language could be discovered or created. Their claims about deafness and the reading and writing abilities of hearing children with no access to signing and finger spelling indicated the symbolic order they were attempting to place on their social school world. In their world, both print and hearing people played prominent roles, and both needed to be accounted for.

For children conventionally regarded as suffering a “communication disorder,” the deaf boys had made surprisingly careful observations of communication practices in their social world at school. Specifically, they related their notions about categories of people, ways of communicating, and reading and writing in unconventional, but reasonable ways.

Robbie conceded that reading was hard, yet he claimed that hearing children would find reading even harder than deaf children, since hearing children could not fingerspell. He claimed that signing and fingerspelling helped with reading, while talking did not. Further, he claimed that “deaf people can write fast, and hearing people can’t. Hearing people can’t sign and deaf people write fast.” Despite Robbie’s child-like logic, he was approaching language use face-to-face and in print as metalinguistic objects about which speculations and statements could be made. Although he had not discovered the exact nature of the relation, he clearly assumed that one existed, and that it could be stated at a metalevel.

Tom was also casting around for an account of relations among symbol systems, social identities, and general language abilities. Initially he reported that the hearing children were “stupid.” He told me that they did not even have reading or spelling lessons, a sensible comment since he was never present in the mainstreaming classroom for these lessons and hence had never observed the hearing children engaging in spelling and learning-to-read rituals. (He actually regarded the perceived absence of reading books in the mainstreaming classroom as a positive feature. At one point during the school year, he reported that he preferred the mainstreaming class-

room for exactly that reason, since he disliked reading.) Despite this, he reported that learning to read was easy if you were smart (as he was), and that “girls” (specifically, his mom) loved to read. He preferred skateboarding over any school-like activity, such as reading.

Tom claimed that writing was hard and that the adults in the deaf classroom had various reasons for making their students write. He claimed that Mrs. Hart made him write because she was a mean and strict person, but that the other teachers made him write “because I make mistakes, and it’s hard.” Tom explained that the hearing children knew how to write and that it was easy for them. He concluded, however, that writing was not important.

Paul, who was a relatively new signer and was the last of the three boys to put reading and writing to use, had strong opinions about his own literacy skills. Simply put, he was thrilled that he could read and write, and took our interview as an opportunity to demonstrate his abilities by reading a familiar text, *The Little Red Hen*, to me. He told me that reading was both easy and important, “because it’s my favorite” and claimed that anyone could write. In Paul’s view, writing was important “because you need to write to work.” He was less clear about the hearing children’s literacy skills and practices, having no opinion on hearing children’s reading and guessing that writing was “the same” for deaf and for hearing children.

From their comments during interviews and conversations over the course of the study year, it was clear that the deaf children were alert to some of the ways that social life interacted with symbolic life. For example, they recognized that there were categories of people who conducted their social lives via distinct symbolic means—hearing people talk and deaf people sign. At the same time, in their own writing activities, it appeared that they were trying to forge for themselves relations among the symbolic means that were available to them in their school social world, especially during activities that centered on literacy.

Doing Writing

As I got to know the boys, I asked them many times in many different ways what they did when they wrote. Not surprisingly, I was unsuccessful in getting Robbie, Tom, and Paul to put their mental processes into explicit language. They had not yet developed the ability to reflect on or communicate about their own intellectual activities. Yet, even though they could not report their own mental processes, the boys’ communication with others and their signing to themselves during writing can be analyzed as externalized traces of the internal relations they were forging between their own face-to-face language and print.

Although each boy engaged in the same school activity, “writing,” each had his own way of approaching the task, and each depended on the social setting of the deaf classroom, as well as his ability to use ASL, as resources when confronting the task of writing.

Writing time took place daily in the deaf classroom, generally right before or directly after lunch. This event always took place at the “horseshoe table,” a U-shaped table located at the

side of the classroom. The children sat around the outside of the U, and one adult sat inside the U, all on low, child-sized chairs. If other adults were there, they sat with the children on the outside of the U.

There were no specific lessons about "English" or writing planned for these periods. The goal, according to Ms. Roberts, was to provide a time when the deaf students could practice getting their ideas out of their heads and onto paper via whatever means they wished to use. One adult was always available to help the children (often all three of them were present), the children were free to converse with each other, and a variety of resources was available (e.g., word lists, calendars, maps, books, and scratch paper). Instruction about English, and about such matters as the format of arranging written text on the page occurred in context, in response to the children's questions or problems with the immediate task. (During "language lessons," another daily instructional event, a more explicit version of English instruction was provided.) Within this social and symbolic setting, the focal boys took somewhat different paths to accomplishing the task of "writing."

"To write you have to be smart ... and ask.": The case of Robbie. Robbie's expressed attitude toward writing was that individuals and social settings both contributed to the accomplishment of writing. He clearly felt that his own contribution was being "smart." The contribution of the social setting was to answer or to provide resources when he asked questions and to provide partners and raw material for conversation. Like the other two boys, he assumed that support would be available whenever he needed it. He did not regard communication with peers and adults in the deaf classroom as troublesome or difficult, but as a routine feature of life. Unlike many deaf school children, he did not struggle to communicate with anyone in his classroom.

Robbie regarded himself as an expert on spelling and writing. He often offered unsolicited corrections to his friends' texts, reminding Paul, for example, that writing "two sister" was wrong—if there were two, then Paul had to add an "s" to sister to make it right. Even in cases where writing was not the task, Robbie stood his ground on his current suppositions about representing English. The three focal boys argued at length one day about creating a sign name for "Little Red Riding Hood." Although Tom and Paul proposed calling her RED, using a traditional ASL lexical item, Robbie argued long and hard that the sign should reflect features of the print letter R. His suggestion was to include an R handshape borrowed from fingerspelling to adequately represent her name, as a manually coded English system would. Although the boys' interactional world was structured by signing and ASL, and not by English, their access to English provided an avenue for making English, and representations of English words in spelling and writing, a topic of conversation.

Although Robbie himself volunteered information and instruction about writing to his peers (such that his bossiness was sometimes resented), when he required assistance himself he never asked peers for help, but always turned to an adult. He often used his voice (although it was generally unintelligible) in his attempts to solicit information about

English. Robbie's selective use of his voice is intriguing, especially since he identified himself as a deaf person who signed. In fact, as noted, he had denied speaking, told me that he never used his voice, and pouted and moped when the speech teacher came to pull him out for speech lessons. His use of his voice when he solicited help from signing people during literacy activities suggested that he had included spoken pronunciation of words as one feature of literacy tasks that he could exploit under very specific circumstances. That is, this strategy was useful only when his interlocutor could both talk and sign and was otherwise known to him as a helpful, supportive adult. At this stage of his life, he refused to exploit this sound resource when the interlocutor did not sign.

When Robbie sat down to write, he focused on his text. In addition to asking adults for assistance with vocabulary, he also turned inward, signing and fingerspelling to himself. He worked on ideas and planned texts with self-directed signing, which was sometimes translated from ASL to written English. He often monitored his sentences by reading and signing the text to himself after he had written it. During writing, he interacted with peers for various alternative purposes, to make personal comments about drawings or to gossip in ASL with Paul about Tom's dreamy, inattentive behavior.

"Mrs. Hart makes me write because she's mean, and I make mistakes.": The case of Tom. In second grade, Tom disliked school and viewed writing as well as reading as difficult potentially error-ridden tasks that included an element of punishment. Where Robbie and Paul treated print as a puzzle to be solved, Tom regarded it as dangerous territory.

Yet Tom's dislike of school tasks did not mean that he inhabited a symbolic wasteland. Although he was known to the other children and adults in the deaf classroom as both a good storyteller (a positive characterization) and a daydreamer (a negative characterization), he regarded himself as a creative person who "adores making things up." The truth is, however, that Tom often disengaged from ongoing school life to daydream and fantasize about Michael Jackson's dance moves, or about one of his other heroes from movies or television. He made varying accounts of his tendency to avoid schoolwork, including the outlandish explanation to Mrs. Hart (which he only attempted to use once) that he could not watch her signing or read that day because his eyes were slanted, since his grandfather on his mother's side was Japanese American.

Despite his resistance to engaging in the school activity of writing, his writing time activities suggested that he was actively involved in the enterprise of using symbols. At the very least, his idiosyncratic version of writing activities (which sometimes resulted in no writing) promoted the task of finding equivalents between signs and print words. It also gave him access to a unique social world which was structured by his preferred language, ASL, where the content and topic of conversation was writing, English, signing and the relations among them. Tom spent a great deal of writing time making elaborate drawings, from which he signed exciting stories. When encouraged to write his stories, he relied on the adults or the other children to help him with words or with spelling. Like Robbie, he signed to himself to plan and monitor texts,

although for Tom the process of putting his signed plans into print was very difficult.

"I love to write because it's my favorite.": The case of Paul. Of the three boys, Paul most recently acquired language and used print. He turned nine early in the study year and had only begun to learn to sign 3 years before. The teachers reported that during first grade he did not communicate fluently or often. According to Ms. Roberts, "something clicked" during second grade, and she was very pleased with his growing willingness to communicate and his interest in language.

Paul himself seemed to be aware of his growth. He was wildly proud when he memorized a spelling list, for example, and often tried to engage adults in spelling games. He began a conversation one day by announcing an inventory of signs, the English glosses for which he could spell by himself, and he sometimes stood at the chalkboard and produced long written inventories of words he knew. However, his hold on English was tenuous and he often lost confidence in his knowledge about words. Almost by reflex, one day he asked Lawrence (a hard-of-hearing classmate who was a beginning signer) to help him spell "school." Despite his pride in his growing sign and English print vocabularies, Paul was accustomed to not knowing how to spell all the words he wanted to write. However, he remembered part way through Lawrence's help that he could spell and write "school" by himself, so he blocked out Lawrence's fingerspelling by covering his own face with a book.

Paul maneuvered through the social life of writing time with functional ease, although he was not a skilled signer yet, and he could not always express himself in signing. He spent time carefully drawing pictures in his journal, and often sat quietly, thinking about his stories. His writing often began as an inventory of single words or very short sentences, like "Snow fun. Sled with brother." He asked for assistance with words from both peers and adults. However, he resisted teachers' attempts to model composing processes (e.g., What did the boy do next? What is in that box? How did the girl feel when she saw the Christmas tree?).

Paul's most serious social obstacle during writing time was getting the attention of potential interlocutors. He often tried to initiate conversations, got no response, then sat quietly and waited for someone to respond to him, as other people signed. (Ramsey et al., 1994 note a similar circumstance involving a "new signer" in an ASL-structured deaf education setting.) Whatever he lacked in communicative competence, Paul, like the other boys, operated as if he assumed that the social world of writing time was ultimately supportive and intelligible. He trusted that there were people who assumed that his signing, gesturing, and movement were meaningful and that they would attend to the meaning he was trying to express.

When he was writing, Paul worked with great concentration and disliked being bothered or interrupted. He had learned to use sternly explicit language with his peers during literacy activities. For example, when Tom interrupted his school work and was seeking a playmate or someone to tell stories or giggle with, Paul routinely looked him in the eye and

signed, "Stop it. I'm going to ignore you." When Tom was acting especially irritating, Paul and Robbie openly gossiped about him and shared their disapproval of his dreamy, silly ways.

Language and Literacy in ASL-Signing Deaf Children.

The interaction between face-to-face language and written language during Tom's, Robbie's, and Paul's literacy activities suggested that intelligible access to other people in the classroom setting fostered their engagement with the people around them, with themselves, and with the symbolic tasks of writing. First, the boys' certainty about who was deaf and who was hearing interacted with their observations about the ways different kinds of people communicated and extended to speculations about the ease with which different kinds of people could approach literacy. The boys appeared to expect that a relationship between ASL used face-to-face and English print could be either discovered or imposed upon their symbolic life during writing. The three boys approached writing in different ways, but all used ASL consistently, representationally, and heuristically with others to discuss topics, recount narratives, and to seek and offer help. They used ASL directly, signing to themselves to plan and monitor their own writing.

Despite their avoidance of English-based systems of signing, the data suggest that the boys knew something about English and about demonstrating school competence. When the adults asked them to "sign that in a sentence," the boys sometimes used English-like signs as embellishments to their performance although these performance sentences were almost never committed to print.

Relations Between Face-to-Face Language and Written Language

Among these three deaf children, face-to-face language and written language interacted in complex, theoretically intriguing ways. Robbie, Tom, and Paul are active social beings who observed and were able to comment on the "real" world around them at school. In addition, they engaged in strategic activities during writing in an effort to discover and create relations between their social lives, their internal mental lives, and their writing. I believe that both their capacities for expressing themselves and their strategies for writing were made possible by their ability to use ASL as their primary language and by their developing ASL/English bilingualism. Although they might appear to outsiders as "special education" students with a communication disability, they were unconfused about their own identities as deaf children who signed, and they were alert to and interested in the people around them. What is of most interest here is their forceful attempts to understand the relations between a person's way of communicating and his or her ways of learning and using print, and their own struggles to discover or impose this kind of relation between ASL and English. Their activities suggest that the social resources of the classroom, built around ASL, contributed to their early literacy.

Dyson (1991) outlines a view of writing development among hearing, speaking children that can also shed light on the deaf children's strategies for literacy learning and on the supportive role of ASL in these processes. In Dyson's view, written language is a symbol system with its own integrity, which children explore as their symbolic development unfolds. Written language itself is one of several culturally provided symbolic options. Children's explorations of this system are systematic and principled and follow predictable patterns whether they are English speaking children exploring written English or ASL-signing children exploring the written variety of another language such as English. Following Dyson's conception of early literacy development, I found that Robbie, Tom, and Paul:

- searched for equivalents between ASL and print English through translation processes;
- experimented with the forms of signs and of words in attempts to create relations between them as when the boys discussed whether or not Little Red Riding Hood's sign must include an "R";
- depended upon their stronger system, ASL, to help them in their attempts to solve the puzzles of English, as when they held metalevel discussions in ASL about English spelling and grammar;
- took conscious and reflective control of their own processes of thinking and writing, as when they planned and monitored their uses of English through ASL;
- actively participated in a social and cultural world that

included English, print, sound, and hearing people from their vantage points as signers of ASL.

This study was informed by a theoretical frame that combined an emphasis on the role of social and cultural life in learning with a focus on children as users of symbols who forge relations among the symbol systems to which they have access. This is not a framework designed to account for the problems of deaf children's development. Rather, it is a set of statements about human development, especially about the unfolding of our heritage as symbol users during childhood. Particularly since deaf children are expected to become as "normal" as possible, accounts of development under normal circumstances serve as excellent guides to understanding their development. I argue that deaf children's deepest needs, as well as their developmental accomplishments, are not critically different from those of any young children.

In their early school lives, deaf children need access to symbol systems and to other people, especially to natural human language and members of the speech community that use it. They need intelligible social settings, where they can not only understand and be understood by adults and peers but also comprehend the structure of activities and fully participate in them. Finally, deaf children need paths for engaging with the complex social settings where they are expected to learn. The findings of this study suggest that classroom settings structured by deaf ways and by ASL can provide these features and, in the process, promote acquisition of English and the development of literacy.

GLOSSARY

American Sign Language (ASL)

A signed language used among deaf people in North America, unrelated to English.

Bilateral hearing loss

Hearing loss in both ears.

Deaf (profound, severe)

Audiological condition of having impaired hearing. Profound losses are those measured at 91 dB or more. Severe losses are those measured between 71 and 90 dB.

Face-to-face language

Term used where “talk” or “oral language” might be used in descriptions of discourse among hearing people. These terms have specific connotations in the context of deafness and are avoided in this report.

Fingerspelling

Strings of handshapes that function as signed letter names for the alphabet.

Hearing

People who are not deaf. To the children in the study, “people who cannot sign.”

Hearing impaired

The preferred term in educational contexts to refer to the condition of deafness.

Mainstreaming

The practice of integrating able-bodied and disabled students in classrooms and other school settings.

Sensorineural

Hearing loss originating in the inner ear or auditory nerve. Contrasts with conductive hearing loss, caused by problems in the transfer of sound energy through the outer or middle ear.

YOUTH GENRE IN THE CLASSROOM: CAN CHILDREN'S AND TEACHERS' CULTURES MEET?

Colette Daiute

CITY UNIVERSITY OF NEW YORK, GRADUATE SCHOOL

Teaching can be characterized as the art of communicating across cultures. In every classroom, there exists a need for communication across the cultures of childhood and adulthood as well as across ethnic cultures. Nevertheless, children's discourse tends to be ignored or seen as something to be corrected. This chapter discusses *youth genre*—a form of discourse characteristic of children—and explains how it is a tool for learning.

Culture typically refers to ethnic and national groups, but childhood is also a culture. Children share symbols, practices, and values. They create rituals. They interpret the world around them in some similar ways. And they share a common language—a language that is different in several important ways from that of adults in their community (Daiute, 1993a). Childhood culture is embedded within traditional, ethnic cultures as it builds on the local adult world and sometimes forms in reaction to that world (Fiske, 1989; Willis, 1990). Childhood culture is dynamic, changing as children mature, and changing more quickly than traditional cultures. Childhood culture, like traditional cultures, is created in context and collaboration as children engage in activities that challenge them and that have meaning in their lives. The essence of childhood culture occurs in language, activities, and objects that children create to impose meaning on the world around them. Thus, sayings, games, clothing styles, musical tastes, and other shared obsessions are evidence of children's cultures. Overshadowed by traditionally noted ethnic and gender cultures, youth culture has not been recognized as an important force in children's lives, especially in their lives in school.

To some extent, children's culture is created by adults who cast their young in a role—like apprentices preparing for the real thing. Adults also construct institutions based on their notions of what appeals to children, as they have in television and advertising aimed at young audiences. Children are influ-

enced by these products; yet they also construct their own culture as they interpret and reconstruct the legacies offered by adults. Although many of us live with and teach children, few adults listen intently enough to children to become privy to the meanings and symbols of childhood culture. Teachers and parents who are sensitive to children's culture recognize the signs and symbols, perhaps noting "what third graders are like" or "interaction patterns typical of middle schoolers." Nevertheless, neither educators nor researchers have devoted much attention to understanding youth culture as a positive resource for children's cognitive development and learning.

Unfortunately, when youth culture is recognized it tends to be characterized in negative terms. Habits of dress, interest in electronic media, slang, and behaviors of youth culture are typically seen as undesirable. Demonstrations of youth culture are often seen as antithetical to learning. Some children fall collectively into antisocial behavior, but many participate in language and behavior that establish solidarity with a peer group. Children bring to the world unique perspectives with which they create meaning out of the world around them. Within some of the forms that are not so desirable to adults, children are making sense of the crises and stresses they observe. Language, dress, behavior, music, and visual creations by children not only set them apart as a group but also embody their interpretations of the adult world, not always reflecting an ideal world. Peer group identity has taken hold, moreover, in younger children, so children's culture begins to exert itself from 8 or 9 years.

A feature of childhood culture is its discourse—the language and underlying orientations that shape children's language. Discourse is one aspect of childhood culture that relates to literacy and learning in profound ways. Certain characteristics make up what I have called *youth genre*, after Bakhtin's notion of regularized speech genres (Bakhtin, 1986; Daiute, 1993a). Youth genre is a speech genre, influenced

by children's status as children. Children spontaneously construct their speech genres based on their own developmentally evolving perspectives, using patterns of thought that influence their theory building about other phenomena. Like the mature speech genres discussed by Bakhtin, youth genre reflects the structures and meaning-making practices of one culture that children participate in and that becomes increasingly important in middle childhood and adolescence—the culture of their peers. Since orientations and understandings as well as specific linguistic sequences constitute youth genre, it occurs across national culture and gender groups, even though children incorporate aspects of the dominant discourse in their talk.

The following conversation between two 4th-grade boys in a Midwestern city classroom is characteristically childlike. The boys were writing a report about the rain forest, which they had been studying in science and social studies.

- Richard: We saw what?
 Nicholas: We heard bees, insects.
 Richard: Yeah.
 Nicholas: The tree was humongous.
 Richard: The.
 Nicholas: Trees were.
 Richard: Did I spell humongous right?
 Nicholas: No.
 Richard: Oops. ...
 Nicholas: Let's just put giant.
 Later:
 Nicholas: No. Let's say, it was the biggest rain forest in the world, the Amazon.
 Richard: No, no it was biggest rain forest we saw in our life.
 Nicholas: Let's say it was the Amazon rain forest, the biggest one in the world.
 Richard: Okay, world. That ain't how to spell world.
 Nicholas: Unclear comment
 Richard: That's word. That ain't world.

This conversation includes several characteristics of youth genre. Richard and Nicholas worked interdependently; they experimented; their affect seems to be entwined with their thinking, and they worked in the details rather than through plans.

The boys built their conversation and thinking in a reciprocal way. They assumed a mutual orientation to the task at hand—writing a story situated in the rain forest. They asked each other questions, listened to, and built upon answers to those questions. Richard and Nicholas engaged in joint problem solving, identifying problems like which word to use and proposing solutions like using *giant* because they could spell that. Although they did not always agree on the solution to all the issues they raised, they maintained a mutual stance as evidenced by “let's” and by clarifying their own positions “Did I spell *humongous* right?”

Another aspect of youth genre that Richard and Nicholas' conversation illustrates is the experimental and creative quality of children's intellectual discourse. They tested ideas when they said “It was the biggest rain forest in the world,” “... in the Amazon,” “... that we saw in our life.” Through this progression of alternatives, they explored understandings about the rain forest and how to talk about it. This type of experimental

tion is rarely audible in adult problem solving, which tends to occur via planning (Flower & Hayes, 1981). Similarly, exaggeration is a characteristic of youth genre, serving as a tool for hypothesis testing. The boys' suggestions of *humongous* and *biggest rain forest in the world* reflect a typical way that children make descriptions, especially around subjects with which they are not familiar (Daiute, 1990, 1993b). Finally, Richard and Nicholas' conversation shows how children use affectively charged language, disagreeing in a forthright way, “That ain't world.”

A conversation by two 3rd-grade girls in an Eastern city writing a report about their class trip to the Gardener Museum reflects these aspects of youth genre in somewhat different ways.

- Lisa: Okay, does this sound good ? “When we went to the th-third floor, we wanted to know if we could go up to the fourth floor.”
 Kay: They said we couldn't because that's where Elisabel, Isabella, was ... like, that's where Isabella lived.
 Lisa: Okay, that's great. And then we would say, then we could say, “We couldn't cuz that's where.”
 Kay: Isabella lay-lived.
 Lisa: Lived.
 Kay: That's her bedroom.
 Lisa & Kay: And that's where she lay, she lays.
 Kay: She did ?
 Lisa: No.
 Kay: They buried her there ?
 Lisa: I think so.
 Kay: No, I think—
 Lisa: NO, they didn't!!!!
 Kay: No I think, I think—
 Lisa: they didn't bury her, cuz who would want her to be in a museum
 Kay: a museum, cuz then her body would like ...
 Lisa: rot?
 Kay: yeh... okay.
 Lisa: So, yeh.
 Kay: I know, she would turn to aaa (cough)
 Lisa: (unclear) ... so they said.
 Kay: she would sorta like form into the way she would like be, turned into ashes or something.
 Lisa: (anxious giggle)
 Kay: I know... Did you know that when we went there, when I was on the third floor, it gave me the creeps, cuz of those stairways, and it was dark sometimes and then light?

Lisa and Kay's conversation was animated. Lisa seems to have been pulled into an inquiry about Mrs. Gardner based on her affective reaction to Kay's proposal that the patron of the museum had been buried on the fourth floor of the museum, where the children were not permitted to go when they visited the museum. Lisa's comment “NO, she didn't!!!!” was marked by intensity and argumentative stance. Kay obviously understood this stance as directed toward the inquiry rather than toward her, so the intellectual discussion proceeded with Kay building on Lisa's discovery that a human body could not be buried in a museum because it “would rot.” Thus, Lisa and Kay's affective reactions to material served as catalysts to their cognitive work. Strong affective reactions like, “NO, they

didn't !!!!” seem to have organized the girls’ understanding because such remarks involved the children in exploring some aspect of the subject matter, as they took a stand on a particularly salient aspect of it. Many children draw on affective resources, especially when working with peers who do not constantly encourage them to be more “logical,” as adults do (Daiute, 1993a; Daiute, Campbell, Griffin, Reddy, & Tivnan, 1993). In this way, children’s affective orientations to an intellectual task organize intellectual interactions, such as when they become intrigued with figuring out some aspect of a task. This emotional stance on the task involves intensity, excitement, and other types of affective engagement.

A third excerpt by two 3rd-grade boys indicates a predominantly playful orientation to task, with the reciprocity, experimentation, and sense making done in the context of child-like verbal and social play.

- Russ: Put Mr. Columbus.
 Andy: Mr. Columbus.
 Russ: Columlumbus.
 Andy: Colum, Columbumps (laughter).
 Russ: Lumberjack (laughter).
 Andy: Colombos, Columbus, Columbus.
 Russ: Colummmmmbabababababbbb. Ohhew. B U S. I think that's how you spell it.
 Andy: Col-um-bus. Ya, you're right.
 Russ: Christopher Columbus. Collumm.
 Andy: Ya, where Columbus, Columbus. The Spaniard Christopher Columbus discovered America. Now do you know how to spell the last three letters of Christopher Columbus? Oh, I already asked you. Forget it.
 Russ: Actually he rediscovered American.
 Andy: No. U.S.
 Russ: And he even made friends with some Indians.
 Andy: Discovered!
 Russ: Ya, Discovered Japan (laughs) !
 Andy: Well, no. Discotti, discovered it. No, we're fine Rediscovered then.
 Russ: Okay, rediscovered America. No! It should be New England.
 Andy: Ya, 'cause he did.
 Russ: No, that was in revolutionary times.
 Andy: Rediscovered.
 Russ: I wonder if it should be New Spain or New England ?
 Andy: Forget it, I mean. Rediscovered America!
 Russ: No, rediscovered the West Indies, thinking it was Japan.
 Andy: Ya! Ya! Nice. All right. We got a smart person here, like moi! (giggle) No, rediscovered R E whoah! R E S C, S C O. Oh, I've got to find the V. I forgot where the V is.

As in this writing session excerpt of Andy and Russ’ report about an important event in the European Renaissance, a common characteristic across children’s talk is its playfulness (Daiute, 1990). Children who work with peers on challenging academic activities play with ideas and concepts as Andy and Russ did around places and characters’ perceptions and Lisa and Kay did around physical concepts (what would happen to a dead body in the museum?). Some children role-play, put themselves into stories, and tease each other, expressing feelings about their relationship to each other and to the task,

as did Andy when he expressed his satisfaction with Russ’ sentence and his own fact recall, *a smart person like moi*.

In summary, these excerpts reveal several orientations that characterize youth genres: reciprocity, experimentation, playfulness, affect, and sense making. Children tend to talk as one, interrupting each other, finishing each other’s sentences and, even when disagreeing, orienting to their tasks mutually. They play with ideas, sounds, and each other, and draw on their affective resources in ways that might seem illogical. Children’s works seem to evolve as an interplay of mind in context, while adults’ works seem to evolve more fully in their minds where the contexts have been internalized. The close scrutiny we have devoted to such interactions in previous research indicates these youth genre features serve as strategies children use in their intense pursuit to make sense of the world around them. These attempts are sometimes hidden from adults because the process of children’s sense making tends to be different from our own process of understanding. Underlying what might appear to be impolite, chaotic discourse is a probing experimentation, in which children select and explore problems that extend beyond their comfortable understanding. Our research has shown that such intense interaction tends to form a coherent discourse that is richer and more productive than conversations some of the same children have with their teacher (Daiute, Campbell, et al., 1993).

In spite of the common orientations underlying youth genre, there is also diversity in how individual children combine youth genre features. For example, the excerpt from one of Lisa and Kay’s collaborations was responsive, exploratory, affective, and meaning-based but not as playful as that of Andy and Russ. All the children progressed in their thinking by posing alternatives, but Lisa and Kay tended to explore an alternative in depth while the Richard–Nicholas and Andy–Russ pairs went for breadth.

The six children whose conversations are presented above come from four different ethnic/racial groups, including African-American, European American, Asian American, and Latino. Since the youth genre features I have outlined are orientations rather than specific sequences, these apply to different dialects and, I believe, different languages. The experimentation that Andy and Russ do through verbal play, Lisa and Kay do through a more affectively charged series of responses. Youth genre may, in fact, function as a unifying language for children—a language that they can use to relate as a group without adopting a mainstream, adult, school language completely.

Youth culture and discourse are not, however, monolithic. Longer excerpts illustrate how children weave their youth genre with their ethnic and gender genres. Like adults, children are influenced by all the cultures in which they participate, so youth culture is not isolated from these other influences. Youth culture and youth genres overlap the ethnic, gender, and other cultures with which they are entwined. What educators typically ask children to do when they enter school is to function almost exclusively in the culture of the school—which in many cases matches none of the multiple cultures children live in outside of school, neither their ethnic nor youth culture. This issue is, of course, especially acute for

children from minority groups. The children in our studies were attending desegregated schools, which means that they were working in a mainstream cultural model (Nelson-LeGall, 1994). Children in such situations may engage in a different discourse than they do in their neighborhoods, and a common peer culture discourse may be preferable to or more familiar than a mainstream adult discourse.

Children sometimes adopt specific youth genre features from the discourse of an ethnic group, as with "Yo!" which occurs in some African-American argot via popular media. Although children may adopt features of mainstream discourse into their youth genre (white middle-class boys calling each other by their last names as in sporting events), popular culture theory would predict this to occur less frequently than adoption from a minority culture, because youth culture is formed in part to distinguish itself from mainstream culture (Willis, 1990).

Television, popular music, and other electronic media serve a unifying function for youth culture. Certain symbols, discourse features, themes, and styles that appear in the visual, aural, and print media appeal to many children, so these media serve as a kind of meeting place. A cycle of influences has been established in the media by the fact that marketing research of children's preferences guides program development, and children are, in turn, influenced by the specific creations they experience in the media. Musical styles, modes of dress and discourse contribute to unify children across races, classes, genders, and continents. Children's interpretations and actions in relation to such media may differ across traditional cultures, but as a group that has some developmental as well as social perspectives in common, children in the middle years appear to make many similar interpretations in media worlds.

These descriptions of youth genre have evolved from research on children's conversations rather than being imposed from *a priori* categories; yet these qualities are also consistent in several ways with recent cognitive-developmental descriptions of thought by 8- to 11-year-olds (Daiute, 1993a). Youth genre features are consistent with thinking that has an "in-the-moment" quality (Case, 1991). Perception tends to dominate reflection at first, which is illustrated by Andy and Russ' play originating with letter sounds and progressing to aspects of meaning related to the topic. When mutually orienting themselves to the collaborative writing task, children also share their ideas and the labors of writing, including generating content, noting spelling mistakes, and typing. The mutually oriented, playful alternative-posing strategy reflects children's skill at using support to handle multiple variables of a complex task. Although the developmental stage theory proposed by Jean Piaget (1926) has been shown to require more sensitivity to cross-cultural factors and flexibility, general characteristics of thought seem to apply. For example, at younger ages children tend to focus on single aspects of a problem, gradually becoming facile at coordinating multiple variables in a complex problem. Similarly, at younger ages children tend to focus on salient features like visual images or sounds only later to begin explicitly manipulating abstract principles. These youth genres are also defined by how they differ from adults' approaches as identified in

research. The concept of youth genre, however, incorporates a sociocultural understanding of child development—an understanding that children are socialized to the values and practices of people around them.

Involvement in youth culture and the use of youth genre changes over time for children. Throughout childhood, the peer group becomes an increasingly salient reference point, with a general interest in others in the primary years, to a same-sex group focus in third and fourth grades, and increasingly differentiated social identities in adolescence (Erikson, 1956). Similarly, as children progress through these intricate peer orientations, their focus on their own ethnicity ebbs and flows as the multiple frames of reference have an impact on identity (Daiute & Shaw, 1993; Deaux, 1993; Heath & McLaughlin, 1993).

HOW DOES YOUTH GENRE SUPPORT CHILDREN'S LEARNING?

Educators need to pay attention to youth genre because it serves children as a tool for thinking and learning. In several studies, my colleagues and I have found that the more children tended to use youth genre around academic tasks, the more they made advances in challenging academic writing projects. For example, children who balanced their conceptual and linguistic play with more metacognitive talk, like labeling, explicit planning, and evaluation, tended to gain higher scores on their reports than did children who took a predominantly metacognitive approach (Daiute, 1990). In another study we found that children who engaged with partners in ways that were reciprocal, affectively charged, playful, and experimental tended to improve more on their academic writing than children who took fewer of these orientations (Daiute & Dalton, 1993; Daiute, Campbell, et al., 1993). These findings are consistent with the fact that metacognitive training tends to help only older children approaching adolescence (Bereiter & Scardamalia, 1987; Daiute, 1990; Palincsar & Brown, 1984). I interpret these findings to mean that as a familiar strategy, youth genre helps children focus on and master unfamiliar material. If each utterance serves the dual functions of imparting information and reflecting on information (Lotman, 1990), then a child's using his/her familiar language may better serve both functions than using a foreign language—like adult discourse. When children use developmentally inappropriate or unfamiliar discourse, such as discourse imitated from adults, while working with new material, the demands may be so great or so confusing that engaging in both a reporting function and an interpretive function may be impossible. Moreover, the very nature of youth genre, with its experimental, meaning-making and affective resources, is quite adapted to reflection and discovery, which may be most helpful when children encounter new material. More metacognitive orientations like analysis and planning are apt for refinement in later phases of acquaintance with a subject matter.

In addition to the form of youth genres, the content of children's conversations with peers appears to be around

issues that interest and challenge them. For example, in spite of the teacher's insistence that spelling was not important, third graders tended to focus on spelling as well as rhetorical features and critical content when they worked with their peers (Reddy & Daiute, 1993). Similarly, children explored a range of issues indicating that they were making sense of the values and meanings in relation to subject matter (Daiute & Shaw, 1993; Daiute, Campbell, et al., 1993). In analyses of conversations in one group of third graders, we found that they talked about issues of life and death, intergroup relationships, the best way to begin news stories, and many other important topics that were not explicitly part of the curriculum but that came into play in writing critically about the experiences they had in their classrooms (Daiute & Griffin, 1993).

Teachers have to work hard to keep youth genre out of the classroom—requiring quiet classrooms, separating children from their friends, using their own logic as a standard, and inculcating metacognitive strategies. Since youth genre somehow operates in spite of such organizations, some teachers create classroom communities that include children's voices and make youth genre not only a strategy for learning but also an object of study in comparison to school discourse.

In classrooms where children have the opportunity to engage in extended dialogue with peers as well as teachers, children rely on youth genre, like the dialects of their family backgrounds, to make sense of the material and skills they are trying to master. Teachers who are sensitive to children's need to draw on youth genre have ways of inviting it into the classroom to serve children as they work with challenging material, including the mastery of school-based adult genre.

Inviting Youth Genres into the Classroom

Teachers can structure the classroom so that children's discourse is a resource for intellectual development rather than a problem. Teachers need not use youth genre themselves, nor mention it explicitly, but by creating certain types of meaningful, challenging, collaborative contexts, they can invite children to use youth genre in the classroom. In this section, I suggest several ways of inviting children to use youth genre as a tool for learning.

Restructure the classroom so that children can use youth genre around important content. Adults often conflate the forms and contents of children's talk. It is very easy to assume that children are not talking about anything important when their talk is silly, imprecise, or emotional. On the contrary, children often rely on their spontaneous childlike language when they are engaged in profound inquiry. Just as Andy and Russ explored the important historical issue of what counts as a discovery in the midst of play with language and interpersonal relations, children have explored scientific, literary, and mathematical concepts in playful, affective, socially oriented language. For this reason, teachers should construct some challenging academic activities for children to do in dyads or small groups. Several consistent features of the tasks in our

research over 12 years seem to be optimum for engaging inquiry within youth genre.

The following task conforms to several principles that engage children's intellectual inquiry.

You have been asked to write a science textbook for next year's fourth grade. This text will be in story form to help children gain deeper knowledge of the way in which our planet depends on the rain forests. As part of creating this textbook, write some of the following stories:

Imagine you and your friend have been transported to the rain forest. You are walking along and you see a group of people burning down trees. Tell a story about what happens and why it is important.

This task was developed with several classroom teachers around material that children were having difficulty in mastering—understandings about the local and global interdependencies among flora, fauna, and people in the Amazonian rain forest (Daiute, Hartup, Sholl, & Zajak, 1993). Thus, at the center of the task was a difficult problem. Moreover, the children had the opportunity to work with several aspects of the subject matter in a series of similarly structured tasks. For example, while one story starter centered around competing needs of people who wanted to use the rain forest for local development and those who needed it for a more distant global balance, other tasks involved aspects of the rain forest habitat, including dangerous animals, the prevalence and paucity of certain types of food, and the outsiders' difficulty in finding their way in the rain forest. Before doing this writing, the children had a range of types of exposure to information and issues about the rain forest, including teacher-led discussions, readings, talks with environmental groups, educational videos, picture books, and so forth, so the children had information to draw upon. This information may, however, have been inert, and the collaborative narrative task engaged them in incorporating that tacit knowledge into their active meaning making.

Unfortunately, when teachers design collaborative learning activities, they often do so around "manageable" tasks that tend not to be intellectually challenging. Several common peer-mediated activities include applying editing checklists to peers' papers, brainstorming lists of topics, and practicing spelling. In contrast, our research suggests that teachers should invite children to put their heads together around the challenging new material of the day, as in this project, to write narrative texts about the rain forest for the next year's class. We found in our research, moreover, that working with concepts just after they had been introduced by the teacher proved to be a successful application of peer interaction (Daiute, Campbell, et al., 1993). Although it may seem counter intuitive to involve children in working together on material that they do not yet know much about, children tend to use the peer collaboration context to bring up related background knowledge, to identify relevant problems, and to develop their own inquiry goals in relation to the material. Similarly, many teachers engage large groups of children in making "maps" of words and concepts that children already know in relation to a new unit of study. Working on a concrete task with a peer creates an extended

and critical context in which to develop this knowledge in depth.

Collaborative projects should also play an explicit role in the classroom or school culture, so embedding tasks as part of a school newspaper, textbook, or extended letter provide a meaningful social context. Purposeful projects provide contexts, explicit goals, and audiences that invite children to frame their knowledge and work in ways that enhance the development of knowledge.

In our studies, children were required to create a written product as the focal point of their collaboration and problem solving. This written product not only provided an anchor for the children's talking and thinking, but it was also the type of intellectual object that children are required to use for subsequent learning in school. Thus, written language became an object of focus and inquiry as well as a tool for learning. As a matter of fact, we have found that even when children work with their best friends, they focus intensely on the text form and content and thus on written language and subject matter (Daiute, Hartup et al., 1993).

While collaboration is important for involving children in intellectual conversations with peers as well as teachers, it is important to balance collaborative tasks with similar individual tasks. Working individually on a similar piece about the rain forest allows children to transfer into their own personal repertoire some of the knowledge and strategies they explored when they were stretched in peer interaction.

Since youth genre tends to involve extended, sometimes tangential exploration, it is essential that children have ample time in each session for these collaborative projects. The richness of youth genre is in the posing of alternatives, focusing on some intriguing topic within an apparent tangent, and the gradual development of issues that children fix on affectively as they react to something in the task or to a partner's comments. Rather than being a waste of time, such forays into meaning that occur in youth genre around challenging topics are unique to peer interaction. Some of the same children who raised and explored probing questions with peers were intellectually cautious and taciturn when working with the teacher. Of course, teachers should work so that children feel safe with them, but their role is most profitably one of being the informant about the school culture and creator of engaging classroom contexts rather than trying to talk children's language. Children need to have the teacher's structure, support, and follow-up to peer talk. In other words, teachers can allow children to integrate their explicit teaching—content and skills—in the context of what the children know and how they know it.

Finally, youth genre is sometimes enriched by the use of multiple media. Just as oral language provides a rich, culturally salient context for written academic tasks, visual media can engage children with ideas and knowledge from various points of view. In research where children had access to images and sounds as they wrote their reports, we found that low-achieving students were able to think and write with much more skill than when they did not have access to visual media (Daiute, 1992; Daiute & Shaw, 1993).

Involve children in some explicit work on multiple cultures and discourses. For many of the same reasons why children need to use youth genres, they need to use their native languages and dialects to support classroom learning. Teacher can involve children in language research. Children can observe, videotape, and take notes on other children playing in the playground, on teachers talking to one another, and on their parents' behavior. (Heath & Mangiola, 1991). Children can also increase their awareness about language, culture, and power relations by writing plays and creating imaginary cultures. Invite children to create rituals and names for classroom contents and strategies.

Teachers can also do research on the themes and practices of the classroom, as do anthropologists. Teacher research is a good way to explore any questions about teaching and learning in the classroom, and it can be targeted at understanding how children's ways of talking reveal underlying orientations to school, subject matters, and knowledge. Such teacher research can reveal the topics and issues that children find intriguing and challenging. You can engage in research focusing on how children use language, paying attention to the imprecise phrasing, silly episodes, or tangents. If you pay attention to how they ask questions, describe, and explain, you can gain insights into the ways of thinking behind child-like language. A teacher-led research project on the youth genres in the classroom can be an entry point for understanding students' perspectives (Cochran-Smith & Lytle, 1992).

Children can act as experts, offering teachers information about their language and thinking, prompted by the teachers, questions about what they are thinking when they are engaged in challenging problems.

Teachers can help the children understand school-based knowledge or practice as a culture. Cultural mores underlie every aspect of the curriculum including topics, tasks, and assessments. Although education is in large part enculturation, the subject matter and methods are typically presented as objective and universally valued. Teachers can recognize and encourage youth culture at the same time as they make clear that they also represent diverse cultures.

Cultural differences in discourse become more marked in adults; thus in some cultures adults tend to give messages via stories that carry internal messages rather than spout explicit rules, but an interesting topic of study would be to explore differences between adults' and children's discourse within a culture.

Recognize the youth genres in your classroom. An important basis for teachers' work is understanding youth genre in the classroom and on the playground. Teachers can make an effort to understand how children interpret the world, in particular, the world in school. They can recognize the orientations (attitudes, outlooks) that underlie youth genre by noticing the symbols and orientations children have toward tasks, relationships, and physical phenomena. If teachers listen to the topics of children's spontaneous conversations during relatively unstructured time—walking to and from your room, during art, around journal writing, on the playground, they can learn more about children's concerns, needs, and spontaneous strategies. The curriculum goals may

not change, but ways of allowing children to participate in those goals may be quite different when children can draw on their strengths.

In the first section of this chapter, I explained the characteristic orientations of youth genre. When trying to recognize youth genre, you can learn about the specific brand of youth genre in your classroom by paying attention to the following outward signs. The topics that interest children hold keys to their culture. Nine- and ten-year old boys' interest in physical play and girls' interest in relationships are central themes. Topics that fascinate children can be related to subject matter to provide a base for new knowledge.

One problem for some teachers is that topics that fascinate children may seem taboo. Children are drawn to issues of life and death, identity, and injustice. For example, Lisa and Kay, like many other children, explored the issue of where Mrs. Gardner's body went after she died, and many children in that group were concerned over why they were not permitted to visit the fourth floor of the museum, which these and other children explored as an issue of justice as well as intrigue. Similarly, Andy and Russ became involved in exploring the issue of how Native Americans are slighted when people say that Christopher Columbus discovered America. In another dyad of third graders, a black girl and a white girl explored issues of identity by playing with the idea that they were sisters in a story where they had similar interests and personalities. Children tend to explore such issues through the details of specific events rather than to state explicitly that they are interested in "justice," "life and death," or "identity," so we need to be astute listeners to the underlying themes of children's talk. When such topics emerge as recurrent themes underlying children's conversations, it is the optimal time to explore such issues in relation to subject matter in your curriculum.

Another factor worthy of attention when basing new material on children's interests is that there may be gender differences in youth genre preferences. For example, while most children are fascinated by the issues mentioned above, girls and boys tend to differ in their focus on the ways in which they explore these issues, with girls tending to focus on issues of life/death, justice, and identity in relationships, and boys around events (Gilligan, 1982). It is important to be aware, however, that such gender distinctions do not apply in all contexts or for all children. Children's values reflect those of their parents, but there are kid values too. For example, friendship is in many cases more important to children than individual achievement.

When children depict violent scenes, they may be revealing stresses and trying to gain some control over phenomena that are difficult to understand (Bettelheim, 1975). The issues and values reflected in children's conversations reflect their family mores, too, so the themes are complex. To respect children's family values and to avoid reading complex themes too simplistically, some teachers may stay away from big issues in the classroom. One problem with such avoidance is that the issues form the basis of children's concerns and questions. Linking these concerns to academic knowledge can help children understand the value in what they are presented in school and can help with the develop-

ment of knowledge, which builds on prior knowledge and questions.

One way of finding out about current concerns and symbols is to ask children each year to create a book about their culture—what is important in their lives. When we did such a project, we were struck with the nature of symbols that children expressed and explored—the sophistication and diversity of their interpretations (Daiute & Shaw, 1993). For example, all the children selected an image of a Hershey bar, which one child had digitized into the computer in this multimedia project (Daiute, 1992). While this image seemed commercial and trivial compared to the possible images children could have gathered considering that they had photographic equipment, film, free processing, and access to lots of print and physical materials, the ways in which children wrote about this image were wide-ranging and profound. For example, one child used the image of a Hershey bar wrapper as a springboard to offer a sketch of her family relationships, all centered around their interest in candy, but going well beyond sweets. Another child who was an immigrant, discussed the image as an example of American culture, offering several ways in which the wrapper represented a culture where he evidently still felt very much like an outsider.

Children's interaction styles are important marks of youth genre, and as discussed above, important tools for learning. Their banter, laborious explanations, exaggeration, and teasing are all part of the problem-solving process.

Recognizing youth genre may be easier when contrasting it with adult genre—in particular school-based discourse. What teachers can do is to make explicit the orientations that underlie their own school discourse and relate these to the specific forms of their speech.

Many parents and teachers have had the experience of feeling like they were speaking a different language when speaking to children from 8 years up to early adolescence. Children seem to veer from the point, but we have to remember that our point may not be theirs. Children seem to be imprecise, but an important difference is that children explain with examples, details, sensations, while we tend to label our messages more explicitly, especially as they regard children. Interestingly, as most parents know, explicitness alone does not ensure that adults can communicate with children.

Teacher talk was noted as a form of discourse by Heath (1978), and others have noted major patterns of teachers' classroom talk including the Initiation-Response-Evaluation pattern noted by Mehan (1979). Guitierrez (1993) has described three patterns of teacher interaction in process writing classrooms. Cognitive science researchers examining interaction patterns across reading, writing, and math contexts noticed a variety of metacognitive strategies including planning and revising (Collins, Brown, & Newman, 1989; Flower & Hayes, 1981; Palincsar & Brown, 1984) with goal statements and explicit reflection as prominent features of experts' talk. Of course, not all adults are experts, nor all children novices (Daiute & Dalton, 1993), but teachers typically function as experts in classrooms. Interestingly, some children can assume certain features of teacher talk during their interactions, but these are usually minimal compared to

their use of youth genre. Thus, as shown in research on adults, teacher talk is not a monolithic genre, but there are some consistencies across previous descriptions of literate adults' approaches to reading and writing tasks, and these contrast to youth genre talk.

To explore adult/child differences as they are played out in the classroom, my colleagues and I did a study comparing children's peer interactions around literacy to teacher-student collaborations and found contrasts for each of the major youth genre characteristics. These contrasts are not absolute, and they vary across different adults. Teacher and youth genres contrast in several ways. The teacher's comments tended to maintain individual control, in contrast to the children's reciprocal orientation to each other and to their tasks. The teacher consistently referred more to her student partners than to herself, but organized those references in specific ways, such as when asking children "Do you want to type now?" or "Do you remember when (something specific happened)?" While the children tended to approach their literacy tasks playfully, experimenting and approximating, the teacher's movement through steps of a task and her reflections about it suggested recursive phases of planning and other strategic approaches. While the children eventually found effective writing strategies and demonstrated increasing control over written language through their effortful, probing, and playful work with ideas and text sequences, the teacher's talk suggested that she came to the task with definite ideas about how to make a good text—the elements that were required and the desired effects of different strategies. Another contrast is that the teacher's talk was more explicitly cognitive, including labeling, verbs of cognition, strategies, and content. Finally, the teacher used her talk to structure ideas and the composing process, while children seemed to use their talk and their interactions with peers to figure out what they were thinking. This sense-making quality of the children's peer talk sometimes became theory building, as when 8-year-old Brant explored his belief that news stories do not have to be true and, in fact, they were more interesting if not true.

In spite of the striking nature of these contrasts, I must reiterate that the teacher's interactions, like the speech genres they characterize, are not absolute. For example, the teacher was sometimes playful, yet her entry into youth genres tended to occur only with certain children.

Recognize subjectivity in the classroom. Just as no one curriculum is the right curriculum, there is no one way to orient one's self to the classroom. As we recognize how affect figures into learning and development, we can begin to recognize the diverse orientations that children have toward subject matter, situations, and people in school. A child's affective orientation toward school is influenced by experiences, cultural values, emotional factors, and emerging interpretations of the environment. It is crucial to understand this kind of subjective stance on school because it can block or facilitate learning. It is the rare child (or even adult) who can separate his or her subjective formulations from cognitive aspects of school tasks. Multicultural understandings have paved the way for diversity in the classroom, but not enough has been said

about the affective stances that organize interactions in school.

In education we have tended to think about affective issues in rather limited ways. The tradition of positive reinforcement is entrenched. While positive responses to children cannot be criticized, the role of positive reinforcement is problematic. There is such an emphasis on positive response that negative responses tend to be offered implicitly as in the statement—*Do you really want to be doing that now?* When discussions of affect in the classroom do occur they tend to focus on positive reinforcement and self-esteem. In the many attempts to build a positive basis for children's work, the tasks children are asked to do are often simplified and segmented to ensure their success. But, limiting tasks to make them manageable does not necessarily engage children affectively in ways that support development of discourse and thinking. Children need meaningful contexts of challenging activities that can draw on important affective aspects of their lives, such as interpersonal orientations, personal experiences, interpretations and evaluations of the world around them. Since such affective states are to some extent culturally determined, having extended projects rather than worksheets allows children a fuller range of responses, even though these present challenges and a full range of affects.

In our comparison of teacher-child and child-peer interactions, a striking difference between children's and teacher's talk was that children used a range of explicit negative as well as positive evaluations while the teachers' explicit evaluations were only positive. Children tended to take each other's evaluations at face value, sometimes asking the partner to say more about what he or she meant by a negative evaluation, sometimes disagreeing with the negative evaluation, and less often simply reposting with an unrelated negative evaluation. What is more important is that children used a range of affectively charged interactions that were not characteristic of the teacher's talk. For example, children alternately expressed joy, conflict, surprise, anxiety and other emotions. This range of affect occurred mostly in the peer interactions, perhaps appropriately kept in check when the children worked with the teacher who guided a logical approach to the task (Daiute, Campbell, et al., 1993). Thus, the nature of children's peer interactions suggests that children can profitably draw on affect for intellectual work.

One of the great challenges for classroom teachers is that children's needs and understandings do not exist in compartments, that is, cognitive, social, or emotional. Classroom teachers are trained to deal with the cognitive child—a child who does not exist. Children whose social and emotional needs are met elsewhere may be able to work in a compartmentalized fashion, but even those children are not best served by an exclusively cognitive reference point. The classroom teacher works on the cognitive child, and some permit social interaction in the classroom. A prevalent idea is that the counselor and family work on the affective child, peers work on the social child, especially on the playground and other nonschool settings. But children's needs are not so easily separated. The many different professionals who work with children can collaborate to serve their needs; thus, home-school, counselor-teacher collaborations would be helpful.

We need to organize classroom experience in a more integrated way.

It appears that many classroom teachers are aware of children's affective orientations in the classroom, often referring to children's "personalities." An exciting current area for research and practice is to increase awareness of the nature and importance of affective strategies in the classroom, to recognize how integral affect is to learning, and to learn how to support affective strategies while guiding children in developmentally appropriate ways toward metacognitive approaches. This, in turn, may diminish the separatist and limited view that affect comes before and after learning rather than as fuel for learning in an ongoing way.

Children's social interactions in the classroom reveal how they integrate, social, cultural, and affective resources to organize cognitive work. Adults are crucial to establishing the types of environments where children can turn these needs into intellectual functions rather than purely to survival or pleasure. Teachers need to think about how they respond to children working in youth genre and how they support child-hood discourse when it seems to flounder or go awry.

When structuring the classroom and interacting with children, teachers should try not to abstract away from what appear to be children's affective stances. Sarah Freedman has observed a major distinction between the organization of education in Great Britain as structured around child development and in the United States around curriculum (Freedman, 1994). In research comparing classrooms in Britain and the United States, Freedman found that British teachers tended to negotiate a curriculum with each child based partly on values in the school culture but determined mostly by the child's interests, needs, and modes of operating at the time. Based partly on being able to work with children over several years, these British teachers directly addressed each child's affective orientation—what the child was interested in at the time, how the child wanted to work, what "mood" the child was in, what exigencies were occurring that might have an impact on the particular writing assignment in question. In contrast, the teachers in the United States organized their classrooms and their work with children around the curriculum, so children's specific cultural, cognitive, and affective factors had little or no impact on what was expected of them. In the United States an assignment was rigid while in England it was by definition tailored to the child. One aspect of this comparison by Freedman that is particularly relevant to the discussion in this chapter is that the brand of child-centered approach in England was not only focused on the child's skills and needs as assessed by the teacher but by the ongoing influence of the child herself. When children's interpretations and intentions are incorporated in this way, the categories in the classroom go beyond culture and cognition.

Try to interpret the child's world from his or her perspective.

A 3rd-grade boy was having difficulty in writing. While most of his classmates produced page after page of stories and journals, he had difficulty with the fiction genre. We know from previous research that children tend to have a penchant for certain genres, therefore this child may have been one for whom nonfiction was basic. During a collaborative writing

activity, this boy, who worked jocularly with his friend, proposed a sentence that his partner found particularly funny. The partner laughed and laughed, falling off his chair, true to his dramatic orientation, saying "write another one, write another one." The formerly blocked writer, who was quite facile at punning, added several more sentences, complicating the predicament of the main character. When the teacher saw the resulting piece she was disappointed because the text appeared in comic book-like bubbles, but she refrained from instructing the child to use more extended prose form until after speaking with him. The teacher asked the child to talk about the story. She asked about Morris falling off his chair, and the child beamed because his friend had found his idea so funny. The teacher then realized that this child had found his genre—at least a genre that could form the basis of some fluency in writing and finding a voice. Realizing the meaning of this story—talk bubbles and all—for this boy, the teacher asked him to read it aloud so that the entire class could appreciate it. This teacher recognized many aspects of youth genre, including the need for genuine peer support and affect, especially this particular child who thrived on peer support. The teacher disliked comic books and wanted to privilege the prose genre, which she believed children needed for success in school, but in this case she subsumed her values to the value of this experience for the child. As the child became comfortable writing in the comic book genre, the teacher began to make connections with prose, providing translations herself and eventually creating activities that would involve the child's shuttling between familiar and unfamiliar modes of expression.

Emphasize function and sense as well as form and structure. Recognizing children's culture implies new roles for teachers and parents. They need to create contexts where the child's culture can flourish around academic as well as social issues. Supporting this youth culture also requires that the teacher take a stand in relation to it. While some teachers want to become part of youth culture, others stand respectfully back from it. Projects like writing a handbook for children in a lower grade or building a clubhouse engage children in meaningful, purposeful problem solving. The requirements of time for children to develop ideas in such contexts with peers suggest the need to move beyond the notion of the skills in sequence curriculum, which may allow teachers mere minutes to "cover" a topic. The structure provided by such projects to produce culturally meaningful artifacts differs markedly from lessons, tests, and worksheets that reify pieces of curriculum. Such isolated activities may be useful for rote learning but do not require the kind of intellectual engagement that leads children to seek out their peers for collaborative problem solving.

Invite conflict. One striking difference between teachers' and children's conversations and their contributions in conversations was that the teacher exerted all her control in positive terms. Very little conflict or disagreement was stated explicitly. Children across sociocultural groups in these studies tended to express disagreements and conflicts openly,

apparently as part of the problem-solving process. Girls and boys tended to do so differently, and African-American children tended to do so to a greater extent than European American children, but all children tended to do so more than the teacher. Although argument and counterargument are so important in intellectual work, children are engaged in such discourse only as they move toward high school. When children do engage in argumentative discourse, it is typically in an abstract form of exploring points of view on topics in essays or taking stands in debates. These activities would also be valuable for younger children.

The process of conflict could also be encouraged in classroom discourse. One way to allow children to explore ideas through disagreeing is to let them work with peers. We have found that children tend to disagree around issues that they want to understand but realize they do not. We have also noticed that children have a range of ways to resolve disagreements, many of which expand intellectual inquiry. Other researchers have also found that disagreeing is an essential aspect of cognitive development (Bearison, Magzamen, & Filardo, 1986), but productive disagreements do not overwhelm discussion. Children could be encouraged to discuss the topics about which they disagree, which would allow the teacher to monitor the process, and, more important, such discussions would reveal the topics that children find interesting and challenging.

Issues Around Inviting Youth Genre Into the Classroom

Some valid concerns can be raised about integrating youth genres into the classroom.

The need to learn school discourse. Some educators believe that the implicit job of American education is to engage children in mainstream school language, behaviors, and points of view. Debate about this goal is currently in progress around the meanings and methods of multicultural education, and an issue related to this phenomenon of youth genre is one that has been raised on behalf of minority children (Delpit, 1986). While some educators and theorists argue for challenging goals of social reproduction, others argue that, at least until the goals change, teachers should offer explicit instruction in all forms and subject matters required for a successful career in school.

One aspect of the argument for explicit instruction has been to raise questions about the value of "child-centered" practices common throughout the 1970s and 1980s, including open education and process of writing. According to one version of the argument for explicit instruction, these and other methods are successful only for children who are already privvy to mainstream practices (Delpit, 1986). Child-centered practices have also been criticized for having the goal of fluency and creativity, which minority children already possess, when what they need is to learn the rules of school. There has been little discussion in the context of this critique of how to evolve a form of explicit instruction that takes into account developmental factors. Various forms of explicit instruction have failed the same children that it is supposed to

help, and much of the discussion proposes the modeling of adult, metacognitive language and behaviors on children who are really too young to benefit from the methods described. The concept of scaffolding within the sociocultural approach takes the child into consideration by positing the gradual transfer of responsibility from the adult who has created a learning scaffold to the child, but the processes for such a transfer are extended over so much time that we need deeper understandings about how the scaffold and the emerging form underneath it relate to each other. Dyson (1993) has proposed the permeable curriculum, where the teachers' and children's worlds can meet. I am proposing that youth culture and youth genre be seen as strategies and objects of study so that children can use them in school to make sense of the multiple demands upon them.

This paper has discussed youth genre as a tool for children rather than the endpoint of education. Inviting youth genre into the classroom does not mean that children are left to flounder or to figure out on their own what they are supposed to do and to know. Rather, children use youth genre as a familiar tool so that they can work with new material.

The argument has also been made that learning a new domain is learning a new language, therefore, emphasis has been made on learning "science talk," for example (Lemke, 1990). While language is the socially mediated focus on knowledge, it is not the same as having the knowledge. Children, like great scientists, may use unscientific language (and thought) to explore and achieve scientific understanding. Moreover, they may use their most spontaneous everyday language to mediate difficult scientific understanding; thus, youth genre is an appropriate tool.

As all teachers know, children do not develop merely through exposure and repetition. One reason why learning takes time is that children need to consider and to reconstruct knowledge in their own terms. Youth genre provides a framework for thinking in a way that allows children to have mastery over unfamiliar material as they draw on the social and subjective skills at sense making they use in spontaneous learning. Allowing youth genre in the classroom can mean making the most out of the time spent on explicit instruction. The planned invitation of youth genre is akin to providing books, paper, and activities. The class can be prepared so that children use their spontaneous, meaning-oriented discourse after the teacher has imparted new material.

Youth genre as a haven. Another issue around merging youth genre into the classroom is that children may need to keep their culture separate to feel safe—safe to use their own language, to take intellectual risks, and to work from their own values. In fact, some scholars believe that youth culture is an ongoing deliberate reaction to adult culture as part of identity formation, especially in adolescents (Willis, 1990). Thus, attempts to pull youth culture into the mainstream may threaten it. A teacher's blurring the distinctions between adult and youth culture may be threatening to some children, but at the same time not providing contexts where children can draw on their meaning-making strategies, may leave these children out of the classroom circle. The multiple cultures in the classroom can all have a voice toward common ends.

Some Necessary Changes Beyond the Classroom

In many places, teachers have the power to create classroom cultures. Nevertheless, the culture beyond the classroom also plays a role in determining the extent to which children are allowed access to their familiar discourses as tools for learning in school. That most people participate in multiple discourse communities should be acknowledged beyond the classroom as well. If children are going to understand and participate in multiple discourses, school activities should include more collaboration between teachers and

children, administrators, teacher and children, and parents and schools. Such collaborations, like meaningful collaborations among children, challenge existing boundaries in education. Activities that enable people with different formal roles in education to work together toward shared goals can be contexts for authentic communication. If these activities are important, then people can use their authentic discourses to common ends and common developments. Thus, acknowledging and working with youth genre—like the other genres at play in school—is a significant step toward multicultural understanding.

BRIDGING HOME AND SCHOOL LITERACIES: MODELS FOR CULTURALLY RESPONSIVE TEACHING, A CASE FOR AFRICAN-AMERICAN ENGLISH

Carol D. Lee

NORTHWESTERN UNIVERSITY

Zora Neale Hurston's Janie Starks of *Their Eyes Were Watching God* philosophically proclaims,

Ah know all dem sitters-and-talkers gointuh worry they guts into fiddle strings till dey find out whut we been talkin' 'bout. Dat's all right, Phoeby, tell 'em. Dey gointuh make 'miration 'cause mah love didn't work lak they love, if dey ever had any. Then you must tell 'em dat love ain't somethin' lak uh grindstone dat's de same thing everywhere and do de same thing tuh everfytthing it touch. Love is lake de sea. It's uh movin' thing, but still and all, it takes its shape from de shore it meets, and its different with every shore (1990, p. 182).

The narrator's voice opens Toni Morrison's *The Bluest Eye* with

Here is the house. It is green and white. It has a red door. It is very pretty. Here is the family. Mother, Father, Dick, and Jane live in the green-and-white house. They are very happy. See Jane. She has a red dress. She wants to play. . .

Here is the house it is green and white it has a red door it is very pretty here is the family father dick and jane live in the green-and-white house they are very happy see jane she has a red dress she wants to play . . .

Here is the house it is green and white it has a red door it is very pretty here is the family mother father dick and jane live in the green and white house they are very happy see jane she has a red dress she wants to play who will play with jane . . .

Quiet as it's kept, there were no marigolds in the fall of 1941. We thought, at the time, that it was because Pecola was having her father's baby that the marigolds did not grow. A little examina-

tion and much less melancholy would have proved to us that our seeds were not the only ones that did not sprout; nobody's did. Not even the gardens fronting the lake showed marigolds that year. But so deeply concerned were we with the health and safe delivery of Pecola's baby we could think of nothing but our own magic; if we planted the seeds, and said the right words over them, they would blossom, and everything would be all right. . . (1970, pp. 1-3)

These two slices lifted from two classic African-American novels share several provocative characteristics. Each speaks in the voices of African-American English, the first in the vernacular and the second in a standard variety. The blackness swirling beneath the standard syntax represents a deep structural level of African-American culture. Morrison (1984) acclaims that African-American fiction often embodies attributes that reflect a black cultural tradition:

There are things that I try to incorporate into my fiction that are directly and deliberately related to what I regard as the major characteristics of Black art, wherever it is. One of which is the ability to be both print and oral literature. . . It should try deliberately to make you stand up and make you feel something profoundly in the same way that a Black preacher requires his congregation to speak, to join him in the sermon, to behave in a certain way, to stand up and to weep and to cry and to accede or to change and to modify—to expand on the sermon that is being delivered. (p. 341)

The attributes Morrison identifies include "an affective and participatory relationship between the artist . . . and the

audience," the influence of superstition and magic as ways of knowing, and the presence of ancestors as characters, narrators, elders, a pervasive and timeless presence who act as a kind of chorus. In the first three paragraphs of the opening of *The Bluest Eye*, Morrison "signifies" on or critiques a set of cultural assumptions that lie beneath the 1950s Dick and Jane basal readers. Signifying is a form of discourse within the African-American English speech community. It involves critique and often sarcastic or ironic commentary couched in language that is highly figurative and makes use of creative plays on the sounds and rhythms of words. Her opening "Quiet as it's Kept," with its vernacular expression, invites an intimate listener. Her invocation of magic, saying "the right words over them" recalls the role of superstition and magic in the folk beliefs of traditional southern African-American culture.

The vernacular and the standard syntax both exemplify and extend the talk of ordinary black folk on street corners, in barber shops, churches and at home. Hurston and Morrison's use of language that is both public and singular is reflected in Toni Morrison's (1984) commentary about African-American autobiography:

The autobiographical form is classic in Black-American or Afro-American literature because it provided an instance in which a writer could be representative, could say, 'My single solitary and individual life is like the lives of the tribe; it differs in these specific ways, but it is a balanced life because it is both solitary and representative.' (p. 339)

While the vernacular variety of African-American English is devalued in formal schooling, its structure and spirit are celebrated in diverse ways by some of the most startling authors in the canon of African-American fiction, poetry and drama. What is the dark pathway that leads these writers—Richard Wright, Ralph Ellison, Toni Morrison, Alice Walker, Zora Neale Hurston, Ishmael Reed, Sterling Brown, Gwendolyn Brooks, Sonia Sanchez, Amiri Baraka, Haki Madhubuti—to explore the magical underworld of this speech community through literary tropes and forms?

What engenders their love of language and literature, so that they are personally steeped in the great dances with language and divine like insights into the human experience reflected in the literatures of writers from around the world and across human history? I believe it may be their conscious immersion in the nuances of the African-American verbal tradition that leads them to push that tradition to its ever changing limits, while at the same time learning to appreciate the variations on language play that are evident in the traditions of meaning making in literature of all parts of the world. What role can schools play in drawing students to the edge of this language whirlpool and inspiring them to taste the waters? I will argue in this chapter that a model of cultural responsive pedagogy (Ladson-Billings, 1990, 1991) does offer one possible answer.

Another attribute these two selections of fiction by Hurston and Morrison share is that they are difficult for novices to penetrate, yet offer multiple nuances of meaning to the initiated. Their semantic and structural difficulties are worth the effort they require. In terms of their accessibility to

the uninitiated, they share bonds with W.B. Yeats, John Donne, Fyodor Dostoevsky, James Joyce, and others elected to the school canon of white western European and white, often male, U.S. writers who dominate the literature anthologies and reading lists of U.S. high schools (Applebee, 1993). It is possible that if we can illuminate the rites of passage required of our novice initiates in schools serving poor African-American, Native American, Latino and Latina, Hmong, Innuity, and Native Hawaiian students, among others, we can build bridges for all our students to become highly literate lovers of books. Building such bridges from the communities of ethnically and linguistically diverse students to the libraries in our schools is the subject of this chapter. The lens through which I view this construction is that of speakers of African-American English.

PROBLEMS IN THE FIELD

Current research findings document that reading comprehension can be explicitly taught (Pearson & Dole, 1987). There is also a body of research that suggests that while reading comprehension can be taught, teachers and basal reading programs often take students through activities requiring very literal levels of comprehension without teaching students how to construct inferences and read between the lines (Durkin, 1978–79). Much reading research has focused on processes involved in comprehending expository texts at the elementary school level or the college level. Within the research literature on teaching students how to read literature at the secondary school level, very little attention has been paid to teaching ethnically diverse literatures or teaching ethnically diverse students who are underachieving. In reviewing submissions to *Research in the Teaching of English*, Sandra Stotsky (1992) notes, "we have received too few ethnographic studies of effective literacy teaching of children at risk and low-achieving children. We need detailed descriptions of the contexts and conditions for successful classroom instruction, descriptions that provide some evidence of these children's growth as readers and writers" (p. 247).

The research which I describe in this chapter works on the assumption that reading literature is a strategy-directed activity (not strategy governed) requiring complex problem solving. According to Dole Duffy, Roehler, and Pearson (1991), "Strategies are thought of as conscious, instantiated, and flexible plans readers apply and adapt to a variety of texts and tasks. . . . Skills, by contrast, are viewed as highly routinized, almost automatic behaviors" (p. 242). Problem solving in an effort to construct interpretations of rich literature is complex because efforts do not necessarily lead to single right and wrong answers, while at the same time, solutions are constrained by authorial intent as conveyed in the language and rhetorical structure of the text in question. The knowledge required to play this game of interpretation includes knowledge of literary genres, literary techniques, other writings by the author, and knowledge of the social world reflected historically and culturally in the work in question.

The research I cite also assumes certain tenets about learning and teaching.

These tenets include the following:

- (1) Reading is an active process of constructing meaning, which implies that readers must
 - (a) know what to pay attention to in the text,
 - (b) monitor their ongoing understanding as they read,
 - (c) be flexible enough to test their understandings by evidence in both the text and the social world as they know it,
 - (d) be willing to hold conclusions in abeyance while waiting for confirmation,
 - (e) alter those understandings when the evidence warrants revision,
 - (f) transform their understandings into some form that is different from the literal text—perhaps through writing, drawing or dramatizing, and
 - (g) find ways to apply their understandings to contexts outside the text that are meaningful to them. (Anderson & Pearson, 1984; Dole et al., 1991; Garner, 1987; Spiro, 1980)
- (2) Learning new concepts is most efficient when students are able to draw upon knowledge of concepts, procedures and strategies that they know well in order to construct for themselves a mental representation of the new concept, procedure or strategy. This process is one of construction because students figure out how the new and old knowledge are linked, how they are the same, how they differ, sometimes resulting in qualitative or quantitative changes in the original understandings (Spiro, 1980).
- (3) Developing what Gardner (1991) calls genuine understanding or disciplinary expertise requires many opportunities to practice new procedures and strategies or to apply new concepts in problems that increase over time in complexity and to apply this evolving knowledge in multiple contexts that are socially meaningful.
- (4) While learning to apply this evolving knowledge, the student must receive strategic support or coaching while in the act of practice (Collins, Brown, & Holum, 1991).
- (5) Finally, the student must have opportunities to apply this new knowledge independently in settings and contexts that differ in small but meaningful ways from the contexts and settings in which the knowledge was learned, as evidence of some level of independent mastery.

While these tenets of learning, teaching and reading literature are not unique to any special ethnic or language community, their application, I believe, demands attention to the language, the social norms, and the cultural histories of the students one is teaching. Admittedly, this challenge becomes more difficult and complex when the student population is heterogeneous in terms of language, ethnicity and/or class.

However, while the data on achievement in integrated school settings are hopeful (Orfield & Ashkinaze, 1991), there still remains a significant difference in levels of achievement as measured by standardized test score data between white, middle-class students and students from poor, ethnically and linguistically diverse communities (Mullis, et al., 1991). While there are certainly reasons to question the validity of total reliance on standardized achievement measures of reading (Wolf, Bixby, Glenn, & Gardner, 1991), there are insufficient data on other more authentic forms of assessment to gauge achievement nationally and across large-scale school systems. In addition, demographic data indicate that by the middle of the 21st century, the majority population of the United States will be of people of color, and significant numbers of large, urban school districts contain many schools whose majority student population is "minority" and homogeneous (i.e., Chicago, Atlanta, New York, Detroit, Milwaukee). Thus, the need to address ethnic and language diversity is demanded both by current theories of learning, theories of reading comprehension, and by current and projected demographics.

In the sections that follow, I will describe research in which competencies in a devalued language variety, specifically African-American English, were used to teach important literacy concepts and strategies. I will also describe research that has uncovered the impact of such competencies on the acquisition of literacy both in and out of school. I conclude by arguing that the lessons learned from these research efforts looking at the relationship between competencies in African-American English and the acquisition of literacy offer important insights about supporting the literacy development of other students whose home language differs from the Edited American English (see Smitherman, 1994) that serves as the primary medium of instruction and the idealized standard of traditional U.S. schooling.

RESEARCH IN LANGUAGE AND LITERACY

African-American English

Black English or African-American English is one variety of English spoken by most African Americans. Research in linguistics from the 1970s used the label Black English Vernacular or BEV. Recently, African-American linguists have begun to use the label African-American-English and African-American English Vernacular. In this essay, I will alternate in using both labels, sometimes for historical accuracy and at other times for stylistic diversity. Labov (1972) reported that 80% of the black population in the United States spoke Black English at the time of his research. Lucas (1987) estimates that 60 to 70% of African-Americans speak Black English. These high percentages are reinforced considering that there are both standard and vernacular varieties of Black English and by the fact that code switching is an accepted linguistic phenomenon within many speech communities. According to Orlando Taylor (1992) there are both standard and vernacular varieties of African-American English. While most research has focused on the vernacular, insufficient

attention has been paid to its standard variations. Both standard and vernacular varieties have been described in terms of phonology, intonation, modes of discourse, and lexicon (Dillard, 1972; Mitchell, 1969; Smitherman, 1977). Smitherman documents the following categories of black discourse forms: call and response, signification, tonal semantics, and narrative sequencing. Other research analyzes the historical roots of African-American English and argues that there are Africanisms evident in the phonology, syntax and lexicon of African-American English (Mufwene, 1993; Smitherman, 1977; Turner, 1949; Vass, 1979). Smitherman (1977) has called African-American English as "Africanized English" (p. 103).

As with other vernacular varieties of English, Black English Vernacular has been stigmatized in the larger society and specifically in schools. Since BEV was viewed as having low status and speakers of BEV were seen as being "culturally deprived," curricula aimed at fixing this "cultural deprivation" were organized explicitly during the 1960s and 1970s, and attention to language use as a prelude to effective reading was a central premise of these curricula (Bereiter, 1965; Bereiter & Engleman, 1966). Under the assumption that African-American English interfered with the development of early reading abilities, basal readers in the primary grades were developed using African-American English Vernacular as the medium of communication and spelling reflected the so-called "dialect." In addition, highly prescriptive reading and language arts curricula such as the popular DISTAR program specifically had as one its goals the eradication of speech patterns of BEV. Research in the effectiveness of the "dialect" readers showed mixed results, with no clear advantage of using such readers to improve the early reading abilities of low-income African-American students. In fact, there is evidence that these "dialect" readers may have interfered with students' abilities to read (see Hall & Guthrie, 1980 for a full review).

By contrast, Labov (1972) shattered the myth that African-American English Vernacular was inferior and incapable of expressing complex thinking. On the basis of extensive ethnographic research in several urban centers, Labov demonstrated what he called "the logic of nonstandard Black English." Labov's work was followed by a number of studies that documented the rich and artistic qualities of BEV along with historical studies of its evolution (Abrahams, 1970; Kochman, 1972; Smitherman, 1977).

African-American English, Signifying and the Teaching of Literary Interpretation

Signifying is a form of discourse practiced widely among speakers of African-American English across generations. "Your house is so poor, they tore it down to put up a slum" (p. 111) and "Your house is so small, I walked through the front door and tripped over the back fence" (p. 113) are typical examples of signifying (Percelay, Ivey & Dweck, 1994). Signifying has been defined both in terms of its functions within a speech act (Abrahams, 1970; Kochman, 1972) as well as a rhetorical stance, an attitude toward language and a

means of cultural self-definition (Cooke, 1984; Gates, 1984, 1988; Mitchell-Kernan, 1981; Smitherman, 1977). Signifying can be used for the following functions within a speech act:

- (1) challenge and maintain a friendly, but intense verbal duel,
- (2) persuade—to direct through indirection . . . ,
- (3) criticize or insult either through carp or innuendo,
- (4) praise. . . ,
- (5) reverse a relationship,
- (6) to show off. . . (Lee, 1993).

As an attitude toward language, signifying involves speaking with innuendo and double meanings, playing rhetorically upon the meaning and sounds of words, and being quick and witty in one's response. Mitchell-Kernan (1981) describes signifying as a "way of encoding messages or meanings which involves, in most cases, an element of indirection" (p. 311). Smitherman (1977) summarizes the formal properties of signifying in the following way:

indirection, circumlocution; metaphorical-imagistic (but images rooted in the everyday, real world); humorous, ironic; rhythmic fluency and sound; teachy but not preachy; directed at persons or persons usually present in the situational context (siggers do not talk behind yo back); punning, play on words; introduction of the semantically or logically unexpected. (p. 121)

Popular categories of signifying include playing the dozens (i.e., talking about yo' mama), and cappin' or sounding (outperforming in a verbal duel of friendly insults), as in the following examples:

Dozens—Yo mamma so skinny, she do the hula hoop in a Apple-jack!

Cappin' or sounding—Someone says, "I went to your house and wanted to sit down. A roach jumped up and said 'Sorry, this seat is taken.' "You respond, "I went in yo house and stepped on a match and yo mama said, 'Who turned off the heat?'" (See Mitchell-Kernan, 1981; Percelay, et al., 1994; Smitherman, 1977; Taylor, 1982 for additional examples.)

It should be noted that the descriptive lexicon for categories of signifying and the term *signifying* itself change from one generation to another. Youngsters today do not use the terms signifying, dozens or sounding. However, the rhetorical characteristics and communicative functions of signifying and its various categories have remained consistent across many generations. When I first began this line of research, my teenage children became active researchers, bringing in current examples of signifying on television, the radio, and in rap music, while my mother and her friends shared examples and reminisced about their experiences signifying across their life-span.

Signifying is not limited to insult, but may also be both *metaphoric and informative* as in the following example, taken from Mitchell-Kernan (1981):

(Grace has four kids. She had sworn she was not going to have any more babies. When she discovered she was pregnant again, she wouldn't tell anybody. Grace's sister came over and they had the following conversation.)

Rochelle: Girl, you sure do need to join the Metrecal for lunch bunch.

Grace: (noncommittally) Yea, I guess I am putting on a little weight.

Rochelle: Now look here girl, we both standing here soaking wet and you still trying to tell me it ain't raining (p. 323)

In addition, signifying can serve *ironic functions* as in this next example, also taken from Mitchell-Kernan (1981). Mitchell-Kernan was conducting doctoral research on language patterns in the black community, including signifying. A young man in the park approaches her and she explains her interest in signifying. In the midst of their conversation, the young man flirts with the researcher through rapping and at the same time engages in a verbal duel through signifying. Rapping in this instance is not to be confused with the current genre of rap music, but rather is in this example a category of signifying talk in which young men, in particular, flirt and demonstrate braggadocio by playing with the sounds and innuendo of words. In the midst of their signifying dialogue, the young man responds:

Baby, you a real scholar. I can tell you want to learn. Now if you'll just cooperate a li'l bit, I'll show you what a good teacher I am. But first we got to get into my area of expertise. (p. 323)

A full analysis of the ironic nature of the full dialogues from Mitchell-Kernan (1981) quoted above are described in Lee (1994c).

African-American adolescents, in particular, regularly produce and interpret such figurative and ironic talk. I have argued that to process such figurative and ironic talk demands both metaphoric reasoning and ironic reasoning (Lee, 1993, 1994c). To reason or infer metaphorically involves establishing an unstated relationship between the topic and the vehicle of the metaphor, and then building levels of parallel associations that extend to the topic of the metaphor (Booth, 1974; Winner, 1988). Ironic reasoning differs from metaphoric reasoning in that the reader or listener must reject the surface meaning of the passage and then construct levels of meaning that are in contrast or even contradiction to the literal interpretation of the oral or written text. If underachieving African-American adolescents are able to carry out metaphoric and ironic reasoning in the contexts of signifying dialogues in their homes and communities, then they should be able to apply those reasoning strategies to texts of literature in the school curriculum where full interpretation demands a similar use of strategies.

Cultural Scaffolding: Bridging Home and School Knowledge

A classic problem in learning is where someone has schemata or organized bodies of knowledge of content, strategies or procedures that are applicable to a problem she is trying to solve, but cannot seem to make the connection between her existing knowledge base and the new problem (Rumelhart, 1980; Spiro, 1980). When a person is trying to solve a novel problem—whether one of literary interpretation or mathematical problem solving—she may not make the connection between her prior knowledge and the problem posed. This lack of connecting may be because the prior knowledge is

tacit, having evolved in everyday learning and socialization. Since that knowledge is known tacitly and not consciously, the realms in which the knowledge is applicable are often limited to the contexts in which it evolved. Such is the case with African-American adolescents' use of signifying. They can participate in signifying dialogue with little conscious reflection and can interpret signifying turns of talk with little conscious reflection. However, when asked what they did to arrive at the interpretations they construct, my research suggests that they are usually at a loss for words (Lee, 1993).

Where there is an overlap between what Moll and Greenberg (1990) refer to as "funds of knowledge in community contexts and funds of knowledge required to solve school based problems in an academic discipline," a potential model for what I call cultural scaffolding (Lee, 1993, 1995) exists. Cultural modeling as a scaffolding device is what I have attempted to illustrate in the research on signifying and literary interpretation that I describe in this chapter.

Signifying serves as an effective source for modeling powerful strategies for interpreting fiction because it overlaps both community-based and school-based funds of knowledge in ways that are complex. In texts of African-American fiction which are referred to by some as "speakerly" texts or "talking books" (Gates, 1988; Hurston, 1935; Reed, 1974), characters speak in language that reflects the many voices of the African-American speech community. Alice Walker (1988) comments about the source for the character Celie in *The Color Purple*:

Celie speaks in the voice and uses the language of my step-grandmother, Rachel, an old black woman I loved. Did she not exist; or in my memories of her, must I give her the proper English of, say, Nancy Reagan?

And I say, yes, she did exist, and I can prove it to you, using the only thing that she, a poor woman, left me to remember her by—the sound of her voice.

Her unique pattern of speech. Celie is created out of language. In *The Color Purple*, you see Celie because you 'see' her voice. To suppress her voice is to complete the murder of her. And this, to my mind, is an attack upon the ancestors, which is, in fact, war against ourselves.

For Celie's speech pattern and Celie's words reveal not only an intelligence that transforms illiterate speech into something that is, at times, very beautiful, as well as effective in conveying her sense of her world, but also what has been done to her by a racist and sexist system, and her intelligent blossoming as a human being despite her oppression demonstrate why her oppressors persist even today in trying to keep her down.... (pp. 63–64)

In such "speakerly" texts, authors use tropes, images, proverbial statements, allusions, discourse patterns, and narrative structures that are deeply entrenched in the language and lived experience of many in the African-American community. Through such rhetorical techniques, these authors couch multiple layers of nuanced meanings that wait to be unearthed by active readers. In some "speakerly" texts, such as *Their Eyes Were Watching God* (Hurston, 1990), *The Color Purple* (Walker, 1982), "My Man Bovanne," (Bambara, 1972), and *Mumbo Jumbo* (Reed, 1972), signifying, in particular, acts as both a rhetorical tool and a theme. Detailed analyses of the uses of signifying as both rhetorical tool and theme are

available in Lee (1993), Gates (1988), and Smitherman (1977). Jones (1991) provides a comprehensive analysis of the role of African-American oral patterns in African-American fiction.

To interpret complex literature requires knowledge of literary techniques, the structure of genres and the implications of those structures for interpretations of the work, and knowledge of what may be the archetypal themes explored in other works by an author. Efforts to construct interpretations of complex problems posed in fiction also require the reader to have knowledge of social norms, the social world in which the fiction is cast. Knowledge about contemporary and historical life in the African-American community is another form of prior knowledge which African-American adolescents potentially bring to the reading of African-American literary texts. However, it is crucial to point out that these links of linguistic and social knowledge are only potential levers for these students as readers. When either source of prior knowledge is either tacit or incomplete, appropriate activation of such prior knowledge during reading needs explicit support before, during, and after the act of reading. At the same time, the problem of interpretation is fundamentally of a different order when a novice reader brings neither the linguistic knowledge nor the social knowledge to a literary work in question. The conditions under which cultural scaffolding can occur, then, are not simple, yet the right mix can provide powerful learning experiences for students who traditionally underachieve.

I will describe below an instructional intervention based on the cultural scaffolding I have described (Lee, 1991, 1993, 1994b, 1995). The intervention took place in two urban high schools in a large midwest school district. The participants were high school seniors. Among the four classes participating in the quasi-experimental treatment, only 8.25% scored above the 50th percentile in reading comprehension on the standardized achievement test used by the district. At the time of the study, the graduate rates in the two schools were 39.8% and 50.9% respectively.
