# Advances in Civil and Industrial Engineering IV

Selected, peer reviewed papers from the
the 4th International Conference on
Civil Engineering, Architecture and Building Materials
(CEABM 2014),
May 24-25, 2014, Haikou, China

*Edited by*

**Guangfan Li, Chaohe Chen,**
**Bifeng Jiang and Qizhong Shen**

# Preface

The International Conference on Civil Engineering, Architecture and Building Materials provides a forum for accessing to the most up-to-date and authoritative knowledge from both industrial and academic worlds, sharing best practice in this exciting field of Civil Engineering, Architecture and Building Materials. The first CEABM was successfully taken place in Haikou, China, June 18-20, 2011, the second CEABM was in held in Yantai, China, from May 25 to 27, 2012 and the third in Jinan, from May 24 to 26, 2013. After the very successful previous issues, the 4th CEABM was successfully held in Haikou, China, from May 24 to 25, 2014.

All papers included in this collection had undergone the careful peer-review by the experts of international and domestic of China before it is selected for publications. This book covers the subject areas of Geotechnical Engineering, Geological Engineering, Tunnel, Subway and Underground Facilities, Seismic Engineering, Hydraulic Engineering, Water Resources and Hydrology, Coastal Engineering, Construction Technology, Water Supply and Drainage Engineering, Heating, Gas Supply, Ventilation, Air Conditioning Works and Daylighting Design, Oil, Gas and Mineral Exploration, Disaster Prevention and Mitigation, Cartography and Geographic Information System, Surveying Engineering, Applied and Computational Mechanics, CAD/CAE/Computer Technology, etc. We hope that this collection of papers will contribute in stimulating debate among scholars, researchers and academicians and we aspire that you find them interesting and thought-provoking.

We would like to thank the authors for their valuable contribution and we are grateful to our general chairs, session chairs and the reviewers for having read and commented on the papers. Our most sincere thanks go to all keynote speakers who shared with us their expertise and knowledge. We are grateful to all the sponsors for their technical and financial support. We would also like to express our gratitude to all the members of the Organizing Committee for the efforts they have made before and during the conference.

We look forward to meeting you all in the next CEABM conference.

*The Organizing Committee of CEABM 2014*

The 4th International Conference on

Civil Engineering, Architecture and Building Materials

(CEABM 2014)

### Organized by:

College of Civil Engineering and Architecture, Hainan University

Hainan Society of Theoretical and Applied Mechanics

# Conference Organization

### Chairman

Prof. Hongnan Li, Dalian University of Technology, China

### Co-Chairman

Prof. Chaohe Chen, South China University of Technology, China

### International Scientific Committee

Prof. J. H. Bungey, University of Liverpool, Liverpool, UK

Prof. K. J. Bathe, Massachusetts Institute of Technology, USA

Prof. Lawrence C. Bank, University of Wisconsin-Madison, USA

Prof. Longsheng Bao, Shenyang Jianzhu University, China

Prof. Tai Bao, Guizhou University, China

Prof. Wenbo Bao, Shenyang University of Technology, China

Prof. Chaohe Chen, Hainan University, China

Prof. Jian-Fei Chen, the University of Edinburgh, UK

Prof. Changyu Cui, Harbin Institute of Technology, China

Prof. Zhiheng Deng, Guangxi University, China

Prof. Shengguo Ding, Guizhou University, China

Prof. Yongfeng Du, Lanzhou University of Technology, China

Prof. Xiuli Du, Beijing University of Technology, China

Prof. Ping Feng, Tianjing University, China

Prof. Luciano Feo, University of Salerno, Italy

Prof. Yaojun Ge, Tongji University, China

Prof. Han-Bin Ge, Meiju University, Japan

Prof.Zong Woo Geem, iGlobal University, USA

Prof. I. E. Harik, University of Kentucky, USA

Prof. David Hui, University of New Orleans, USA

Prof. Yong Huang, Guizhou University, China

Prof. Zhihong Huang, Guizhou University, China

Prof. Tan Kiang Hwee, National University of Singapore

Prof. Tim Ibell, University of Bath, UK

Prof. Weiliang Jin, Zhejiang University, China

Dr.Tianjian Ji, The University of Manchester, UK

Prof. A. Kaveh, Iran University of Science & Technology, Iran

Prof. Kang Seok Lee, Chonnam National University, South Korea

Prof. Marcus M.K. Lee, the University of Southampton, UK

Prof. Zhuguo Li, Yamaguchi University, Japan

Prof. Hongnan Li, Dalian University of Technology, China

Prof. Zhengliang Li, Chongqing University, China

Prof. Zhengnong Li, Hunan University, China

Prof. Qiusheng Li, Hong Kong City University, Hong Kong

Prof. Aiqun Li, Southeast University, China

Prof. Hui Li, Harbin Institute of Technology, China

Prof. Shirong Li, Yangzhou University, China

Prof. Guangfan Li, Hainan University, China

Prof. Feng Liu, Guangdong University of Technology

Prof. Lijuan Li, Guangdong University of Technology

Prof. Tianqing Ling, Chongqing Jiaotong University, China

Prof. Ayman Mosallam, Univ of California Irvine, USA

Prof. Aftab Mufti, University of Manitoba, Canada

Prof. Antoine E. Naaman, University of Michigan, USA

Prof. Jianguo Nie,Tsing Hua University, China

Academician Prof. Wei Sun, Southeast University, China

Prof. Hamid Ronagh, The University of Queensland, Australia

Prof. R. Sri Ravindra rajah, University of Technology, Australia

Prof. Yaozong Shi, Highway Survey and Design Institute of Hainan Province

Prof. Ramiro Sofronie, University of Bucharest, Romania

Dr. Scott T. SMITH, Hong Kong University, Hong Kong

Prof. M. N. Soutsos, University of Liverpool, Liverpool, UK

Prof. Mark G Stewart, The University of Newcastle, Australia

Prof. J-G. Teng, Hong Kong Polytechnic University, Hong Kong

Prof. B. H. V. Topping, Heriot-Watt University, Edinburgh, UK

Prof. Tamon UEDA, Hokkaido University, Japan

Prof. Jinfeng Wang, Huaqiao University, China

Prof. Zhi-Shen Wu, Ibaraki University, Japan

Prof. Bo Wu, South China University of Technology, China

Prof. Hong Wang, Guizhou University, China

Prof. Yan Xiao, Hunan University, China

Prof. Shilang Xu, Zhejiang University, China

Senior Engineer. Jianxin Xu, China Communications Water Transportation Planning and Design Institute Co.,Ltd

Prof. Shanhua Xu,Xi'An Univ. of Architecture and Tech., China

Prof. Tao Xie, Guizhou University, China

Prof. Zhixin Yan, Lanzhou University, China

Prof. Jiru Zhang, Wuhan University of Technology, China

Prof. Chuangbin Zhou, Wuhan University, China

Prof. Lau Hieng Ho, Curtin University of Technology, Malaysia

Prof.Junan Shen, Georgia Southern University, USA

Prof. Mohammad Arif Kamal, Integral University, India

## Conference Secretary

Prof. Guangfan Li, Hainan University, China

# Table of Contents

**Preface and Conference Organiztaion**

## Chapter 1: Geotechnical Engineering

**3D Finite Element Analysis on Behaviour of Piled Raft Foundations**
A. Vu, D. Pham, T. Nguyen and Y. He 3

**A Modified Method to Fit Probability Distributions of Geotechnical Parameters Using Stochastic Weighted Entropy Principle**
S.J. Zhang, Z.J. Xu, L. Zhong and Z.R. Xiao 9

**A Research on Elastoplastic Theory Based on Full State Function**
Z.H. Wei, M.S. Wang and D.L. Zhang 17

**Affect of Large Deep Foundation Pit Dewatering on the Neighboring Buildings**
K.W. Ding, F. Zhao and X.Z. Zhang 24

**Analysis of Monitoring Results of a Deep Foundation Pit with Pile-Anchor Retaining Structure**
X.H. Yang, F.W. Wu, T. Chen and X. Liu 28

**Analysis on Strengthening of Plant to Slope Soil under Orthogonal States**
J.B. Gu 34

**Centrifuge Model Study of High Strength Piles Composite Foundation Settlement & Instability under Embankment in Different Kind Soils by Different Pile Spacing**
Q.J. Wang, S.J. Zhang, C. Guo and Z.R. Lu 38

**Comparative Experimental Research of Soil Freezing with Pressure and Non-Pressure**
S.Y. Zhang 48

**Discussion on Treatment Technology of Reinforcement Pile in Karst Area**
C.B. Zheng and J. Xu 52

**Effect of Variable Permeability Coefficient on Consolidation of Ultra-Soft Ground under Vacuum Preloading**
B.B. Xu, A.H. Liang and M.Y. Li 56

**Experimental Application of Fractal Theory into Selection of Subgrade Filling Materials**
X.G. Wang 61

**Experimental Study of Static Disintegration on Unsaturated Soil**
N.Q. Wang, Q.T. Wang, Q. Xue and X.L. Liu 68

**Experimental Study on Bubble Curtain Technology Applied in Underwater Blasting Damping**
H.Y. Hu, Y.C. Zhang, Z.M. Huang and C.X. Peng 73

**Experimental Study on the Position of Balanced Point of Large-Tonnage Pile with Self-Balanced Load Method in the Northwest Region**
Y. Xin, F. Yue, P. Li and G.S. Wang 78

**Finite Element Simulation and Stability Analysis of Composite Soil Nailing**
J. Zhao and L.L. Wang 83

**Fuzzy Mathematical Method of Slope Reliability Analysis in Surface Mine under Seepage Conditions**
K. Yang, H.X. Li and H. Han 89

**Influence of Density on Mechanical Properties for Coarse-Grained Soil Based on Percolation Theory**
Y.D. Huang, L.K. Yao and J. Wang 93

**Justification for Determination of the Depth of an Active Zone Based on the II Group of Limiting States**
N.L. Maksotovna and B.A. Nikolaevich 98

**Mechanics Analysis of Semi-Rigid Subgrade Pavement Structure**
L.Y. Su 105

**Model Test Study of Squeezed Branch Pile under Horizontal Vibration Load**
B. Lv and X.J. Gao 109

**Model Tests of Foundation Bearing Capacity of Sandy Soil and Pile Foundation Bearing Capacity**
S.J. Lu, H.D. Chen, W. Chen, T. Xiang and X.F. Hong 113

**Numerical Simulation of Load Transfer Mechanism of T-Shaped Soil-Cement Deep Mixing Column**
P.S. Xi, X.T. Zhang and B. Liu 118

**One-Dimensional Consolidation Modelling for Unlayered Soil**
I. Hanafi, F. Dimane, F. Mata Cabrera and J. Tejero Manzanares 123

**Practical and Experimental Study of Grouting Anchor in Slope Reinforcement Engineering**
G.R. Lu, L.W. Zhang and H.B. Wang 129

**Reliability Analysis on the Foundation Bearing Capacity in Ningbo Rail Transit Engineering**
J.F. Zhu, G.B. Liu and J.N. Ye 135

**Research on the Anchorage Technology of Steep Slope in Sanitary Landfill**
P. Li, H. Wang and Y. Xin 143

**Study on Graphic Method for the Stability of High Loess Slopes Based on MATLAB**
J.C. Hu, J.Y. Gao and Y.X. Chen 148

**Analysis about Stability of a Slope**
Y.J. Yin, G.H. Xu and Y.M. Qian 152

**Analysis of Micro-Seismic Monitoring Vibration on the Adjacent Buried Pipeline Affected by Impacting of Punching Pile Construction**
Y.H. She 156

**Consolidation of Unsaturated Soils due to Dissipation of Pore-Air Pressure**
H.F. Xu, W.J. Wang and Z.X. Zha 160

**Determine the Shear Strength of Aeolian Sand and Bearing Capacity**
Y.Z. Yin and Y.L. Wang 165

**Dynamic Response of Two-Dimensional Fluid-Saturated Porous Beam**
F.X. Zhou and Q. Ma 169

**Process Simulation and Formation Mechanism of Shear Band in Soil**
S.W. Hou, J.H. Qu, Y.F. Zhang and X.L. Du 175

**Research of the Shear Strength Test of the Soil on the Surface of Lop Nor Gobi**
L. Yin, S. Qiu, W.J. Li, H. Hu and Z.K. Chen 180

**Study of Soil Structural Parameters Based on the Gunary Model**
X.F. Huang, Y. Kong, B.S. Yang and P.F. Zhen 185

**Study on Static Strength of Aeolian Sand before and after Cyclic Loading**
D.P. Liu, X.H. Yang, J. Wang and Z.J. Mao 191

**Study on the Development of Plastic Zone Based on Strain Expressed Mohr- Coulomb Yield Condition**
C. Yang and T.G. Feng 195

**Testing Study on the Effects of Water Content on Permeability for Coal**
C.H. Zhang and X.P. Xu 201

**The Application of Cubic Spline Interpolation Function in Determining Rock Rheological Long-Term Strength**
M.L. Zhao and Q.Y. Zhang 205

**The Application of Vacuum Preloading Method in Soft Soil Foundation Underwater**
Y.Q. Feng and L. Zhang 209

**The Microstructure Formation Process Research in Loading Condition of Dredger Fill**
J. Wang and P.L. Cai 213

**The Research on Mean Spacing of Rock Fracture**
L. Jiang and Y.S. Zhang 219

**The Research Review of Underground Continuous Wall on Deformation Characteristic**
S.M. Zhang, T.K. Yuan, Y.K. Zhou, D.H. Li and K.H. Zhuo 224

**The Rheological Properties and Yield Stress Model of High-Density Slurry Added with Coarse Sands**
X.X. Zhang and D.P. Qiao 231

**3-D Numerical Study of Mechanical Behaviors of Pile-Anchor System**
R.C. Liu, B.S. Xu, B. Li and Y.J. Jiang 238

**A General Criterion for Complex Rocks and Soils and its Application**
H.N. Ruan, M.L. Luo, D. Wang and J.W. Ju 243

**A Method to Determine GSI Value by Using P-Velocity and its Application in Engineering**
Y. Zhao, L.Q. Wang, P. Zhou, Y. Han and G.R. Chen 250

**Analysis of Engineering Characteristics of Cement Soil with Low Mix Additions**
A.M. Liu 256

**Energy Characteristics of Brittle Rock in Failure Process**
A.J. Tang, C.G. Shi, Y. Wang and J.H. Wang 260

**Estimation Study on Shear Wave Velocity of Seabed Using GRNN**
S.J. Di, Z.G. Shan and X.Y. Xu 264

**P-Wave Attenuation Mechanism of Calcareous Sand under Explosion**
X.Y. Xu, S.J. Di, W.Q. Cheng, W. Li and W.B. Du 268

**Response of Non-Homogeneous Saturated Soils and Free-Field to Incident Plane SH Wave**
F.X. Zhou and R.X. Song 273

**Study of Key Parameters in the Process of Aeolian Sand Compactibility**
Y.Z. Yin and Y.L. Wang 278

**Construction Techniques and Mechanism of Pre-Anchoring Fissured Stope Hangingwall by Fully-Grouted Cable Bolts**
F.L. Zhan and P. Ye 283

**Numerical Analysis of the Bearing Behavior of Single Pile under Horizontal Load**
D.F. Ma, G.J. Guo, X. Yang and Z.D. Zhou 287

**Simplified Bishop Method Homogeneous Soil Slope Stability Analysis Based on the C# Language**
H.B. Wei, Q. Zhang and J.H. Zhao 291

**Study on Engineering Behavior of Non-Embedded Pile-Board Structure Crossing Over-Shallow-Embedded Metro**
C.B. Zhou, Q. Su, H. Bai, Y. He and W.H. Zhao 296

**The Analysis on Bearing Characteristic of Residue Pile Composite Foundation Formed by DDC**
Z.R. Liu, Q.J. Sun and Z.F. Yan 302

**The Explanation of Yield Surface Rotation of Sands by Principle of Thermodynamics with Internal Variables**
J.Y. Chen and Y. Hai 308

**The Studies of Rock Damage Softening Statistical Constitutive Model under True Triaxial Stress State**
H.M. Zhang, X.M. Xie and G.S. Yang 312

**A New Algorithm for Computing Threshold Value Used to Image Segmentation**
G.Y. Chen, D.Q. Liang, Y. Zhang and H.Y. Xie 316

**Comparison Analysis of Buildings Settlement, Calculated in Accordance with Rheological Properties of Soils (Based on the Geotechnical Conditions of St. Petersburg)**
A. Ekaterina 320

**Stability Analysis of Jinghua Gypsum Mine Golf in Jingmen City**
C.X. Chen, K.Z. Xia, Y.B. Dong, X.M. Liu and P.L. Huang 324

**Study on Deformation Property of Coarse Particles (Sulfate) Saline Soil with Field Test**
P. Yang, Y.F. Liu, H.Z. Mi and Y.P. Zhu 329

**Study on the Value Range of Horizontal Ground Stress in Initial Geostress Field Based on the Generalized Hoek - Brown Criterion**
Z. Ou, C.X. Chen, H. Fu and Y.C. Zhou 334

**Analysis of Long-Term Deformation of Reinforced Retaining Wall Using Optical Fiber Sensor Geotextile**
L. Lu, Z.J. Wang, H. Feng and K. Arai 338

**Analysis of Platform on Piles Application on Deformation Control of Underground Pipe in Reclamation Areas**
D.N. Zhou, Q. Shang and B. Xiao 344

**Research on Water Temperature Change of Hot Dry Rock Fracture Storage Layer in Shenyang**
J.B. Zhao, H.D. Song, D. Li and Z. Zhang 349

**Studies about Creep Characteristic of Silty Clay on Triaxial Drained Creep Test**
Y.F. Wang, Z.G. Zhou and Z.Y. Cai 355

**Test Study on Effects of Temperature, Sand Mix Ratios and Dry Density on Soil Water Characteristic Curves of Bentonite-Sand Mixtures**
X.W. Fang, C.N. Shen, C.H. Li and L. Wang 359

**The Prediction of Northern Slope Deformation and Failure Caused by the Transformation of Open-Pit to Underground Mining in the Yanqianshan Iron Mine**
A.L. Shao and H.L. Feng 364

**The Study on the Engineering Properties of Squeezed Branch Piles under Combined Load**
W.F. Han, B.B. Feng, J. Zhou and C.Y. Lu 371

**Triaxial Test Study on Marine Sediments Sample with Simulated Combustible Ice**
X.L. Wang, G.F. Li and J. Du 376

**Weak Form Quadrature Element Analysis of Diaphragm Walls**
Y. Li and H.Z. Zhong 380

**A Chemo-Elasto-Plastic Coupling Model for Sandstone Considering pH Effect**
X.H. Li, W. Wang, Z.Y. Tian and W.Y. Xu 386

**A Critical-Line-Based Predictive Model for Landslides**
G.T.C. Kung and Y.G. Tang 391

**Analysis and Process Control of the Deformation for Deep Excavation in Soft Clay**
H. Liu, W.B. Li and H.T. Liu 395

**Analysis of the Interaction of Foundation Pit Supporting Structure and Soil**
Y.Q. Feng and C.X. Liu 401

**Calculation for Earth Pressure of Cavity Expansion Considering Displacement**
W.M. Zhang and X. Huang 405

**Experimental Study on Shear Strength of Different Types of Soil**
H.M. Chen, F.H. Guo and X.Q. Zhou 409

**Failure Mechanism of Strip Footing on Geotextile-Reinforced Soil**
Z.J. Wang, L. Lu and B. Zheng 415

**Horizontal Displacement of GFRP Bars and PC Strand Combination of Technology Supporting Piles**
X.H. Li, Y.Y. Gao, C.X. Yue and C.Q. Hu 420

**Numerical Analysis of Stabilization of Slopes Overlying Bedrock Using Piles and Effect of Socketed Length of Pile on Stability**
M. Bakri, Y.Y. Xia and H.B. Wang 424

**Numerical Simulation Analysis of Bearing Characteristics on Super-Large Diameter Rock Socketed Pile**
C.Z. Gong, C.L. He and M.X. Zhu 432

**Prediction of Displacement Time Series Based on Support Vector Machines-Markov Chain**
F. Xu, W.X. Xu and K. Wang 436

**Project Design of Dewatering for Deep Foundation Pit in Dalian**
B.L. Guo and H.B. Liu 440

**Reinforcement and Characteristic Analysis of Bolt Technology Applied in Bedding Rock Slope**
E.H. Wang, Z.D. Wang, L.M. Jiang, L. Hao and A. Ran 445

**Analysis on Influencing Factors of Cement Stabilized Macadam Base of Compressive Strength in Shenyang Area**
Y. Xu, C.Z. Bai, Y.F. Zhang, X. Liu and D. Li 450

**Experimental Study on Dynamic Characteristics of Tailings**
J.B. Zhao, Y.C. Ji, X. Liu and D. Li 455

**Experimental Study on Engineering Characteristics of Basalt Residual Soil on High Slope**
K. Cui and Y. Yang 460

**Influences of Cross Section Parameters on Bending Resistance of TSC Pile**
X.Q. Wang, S.M. Zhang, J. Liao and Y.S. Huang 464

**Roadbed Treatment Research in Expansive Soil Area**
Z. Feng, C.J. Li and X.L. Gao 469

**Simplified Method for Estimating the Inner Support and Internal Force through Stand Column Uplift of Foundation Pit in Soft Soil**
Y. Liu, J.Y. Liu and T. Liu 474

**Slope Early Warning System Design and Preliminary Practice**
F. Xu, W.X. Xu and K. Wang 481

**Slope Stability Evaluation Based on PSO-PP**
K. Wang and F. Xu 486

**Stability Analysis of Tower Foundation for Transmission Line**
Z. Chen 490

**Study on Sheltering Effect of Underground Building to Horizontal Displacement of Retaining Wall of Foundation Pit**
Y. Liu, J.Y. Liu and S.B. Cai 494

**Study on the Stress and Strain of EPS Silt Light-Weight Soil by Laboratory Test**
Y. Feng and Y.B. Pei 499

**The Analys of Stability of Composite Soil Nail**
Y. Zeng 503

**The Application of Origin Software in the Data Processing of Rock Creep Experiment**
C.Y. Gao, J.G. Niu and Q.C. Gao 509

**The Experimental Study of the Influence of the Matric Suction on the Unsaturated Soil Strength**
C.R. Liu 514

**The Settlement Analysis of the Cement Fly-Ash Gravel Pile Composite Foundation of Baotou**
J. Li, Y. Xu and J. Yin 518

**Three-Dimensional Numerical Analyses of Pile Response due to Braceded Excavation-Induced Lateral Soil Movement**
L. Li, X.X. Hu, G.H. Dong and J. Liu 524

**3D Finite Element Numerical Analysis for Stability Calculation of High Steep Rock Slope**
X.F. Xie, Y.L. Liu, J.Y. Han and L. Xing 532

**A Certain Foundation Pit Support Design and Construction in Baotou**
X.K. Bao and M.H. Que 539

**A Study on Micro Pile Reinforcement Technology for the Accumulative Landslide of Expansive Soil**
H. He, Y. Xu, Z.Z. Huang and Z. Li 544

**Analyses of Anti-Seepage Measure for Expansive Soil Subgrade in Hefei**
Y. Wei, W.Z. Xing and Y. Shao 552

**Analysis on Deformation and Support Technology of Deep Soft Rock Roadway**
Y.S. Liu, W. Liu and X.Y. Dong 556

**Analytical Solution for Contaminant Extraction Using Well Injection Depth Extraction Technology Considering the Effect of Smear Zone**
H.Y. Wang, X.W. Tang and P.L. Gan 560

**Application of Fuzzy Set Theory to Evaluate the Stability of Slopes**
T. Mohamed and A. Kasa 566

**Application Research on Distributed Optical Fiber Monitoring Technology in Static Load Test of Large Diameter and Post-Grouting Filling Pile**
J.X. Chen, T.H. Zhou and Y.C. Guo 572

**Coaction Analysis on Pile-Net-Cushion-Soil**
R.F. Wang and K.Y. Wang 579

**Cone Penetration Test Study of Ultra Soft Soil after Vacuum Preloading**
J.Q. Yu, H.W. Li and W.S. Wang 585

**Defects Discrimination and Error Analysis of Wharf Bored Piles Detected by Low Strain Reflection Wave Method**
T. Li, Q.C. Qiu and J. Wang 589

**Double-Row Composite Anchor Bolt Design and Construction Monitoring Analysis of Green Building**
H.X. Li, Y.W. Wang and G.K. Fang 596

**Experiment Research of Rock Anchor Foundation on Sandstone Ground in Transmission Line**
Y. Zhang and W.F. Zheng 601

**Experimental Studies on Acoustic Emission of Different Damaged Concrete**
H.G. Ji, X.R. Li and C.L. Song 606

**Experimental Study on Post-Peak Failure Behavior of Rock Masses with Persistent Joint**
L. Wang, J. Yu and X. Hua 610

**Explanation of Phenomenological Characteristics in Seepage Force Concept System**
Y. Shen and W.H. Du 614

**Finite Element Analysis of Rock Bolt Foundation in Metallurgical Industrial Plant**
M.X. Tan and H.B. Liu 619

**Laboratory Studies on Acoustic Emission Characteristics to Coal Dynamic Response under Variable Accelerative Load**
X.H. Liu, C.X. Liu, S. Zhuang, L. Wang and S.S. Lin 623

**Mechanical Model of Pile-Soil Work Together**
S.J. Zhang 628

**Mechanics Analysis of Flexible Base Pavement Structure**
L.Y. Su 632

**Monitoring Analysis and Safety Evaluation of Deep Foundation Pit under Complex Conditions**
X.T. Zhang, Q.Y. Zhang, C. Wang and Y.F. Wang 636

**Analysis of Coral Reef Rock Mass Integrity Based on RMDI Method**
J.C. Wang, C.Y. Wang and Z.Q. Han 641

**Application of Curve Model Fitting Methods to Settlement Prediction**
M. Wu and J.L. Niu 651

**Effect of Overload on Bearing Capacity of FRP Reinforced Ground**
C.X. Bai, X.Y. Shao and Q.P. Wang 655

**Influence of Density on the Hydraulic and Mechanical Properties of Sands**
O. de Freitas Neto, O. Santos Jr and R. Severo 659

**Numerical Simulation of Failure Process on Soil Slope with Different Support Measures**
Y.W. Zhang, L.X. Tang, D.C. Bai and P. Zhou 665

**Prediction of Composite Foundation Settlement Based on Multi-Variable Gray Model**
Y. Wang and G. Yang 669

**Preparation of a New Type of Joint Filler and Study on Adhesion Performance**
X.W. Li and C. Sha 674

**Probability Statistical Model and Network Simulation Technology of Random Fractured Rock Mass**
C.X. Han, D.H. Zhou, W.Y. Liao, X. Chen, L.Q. Li and K.C. Yao 679

**Pullout Test Research on Interfacial Interaction of Reinforced Band and Gravelly Soil**
Y.L. Wang, Z.L. Cheng, W. Zhang, Y.Z. Zuo, Z.L. Yu and Y. Wang 684

**Research of Soundless Crack with Different Number of Drillholes**
L.X. Tang, D. Zhang, Z.T. An and J.Y. Zhang 689

**Research on Negative Skin Friction on Pile by a Simple Model Experiment**
T. Huang, J.H. Zheng and W.M. Gong 693

**Research on Stability of Foundation Pit Construction**
H.S. Dai and T. Yang 697

**Research on the Effect of One Debris Flow along Bailong River**
Y.Q. He, Y. Wu and S.L. Li 701

**Research on the Retention Capacity of Ruins Soil under Drying Condition**
P. Liu, H.Y. Zhang, Y. Chen, X.X. Shao and X.Y. Fu 705

**Stability Analysis on Anti-Slide Pile to Reinforce Slope Based on ABAQUS**
X.J. Gu, T.Q. Zhou and S.L. Lu 711

**Study on Optimization of Design Parameters for Composite Foundation with Cement-Fly Ash-Gravel Piles**
P.F. Luo, J.X. Tong, X.H. Sun, X.H. Yang, J. Zhang and M.L. Yan 715

**Study on the Design Method of Different Thickness-Diameter Ratios for Composite Foundation with Rigid Long and Short Piles**
J.X. Tong, X.H. Sun, P.F. Luo, N. Jia, X.H. Yang and M.L. Yan 723

**Study on the Effects of the Rainwater Seepage on Slope Stability**
J.S. Xun, X.T. Xu and R.Q. Bai 729

**Study on the Lateral Displacement of Super-Long Pile under a Asymmetrical Surcharge Load in Soft Clay**
Q. Li and X.L. Lu 733

**Temperature Field Numerical Analysis of Different Freeze Pipe Spacing of Vertical Frozen Soil Wall Reinforcement at Shield Shaft**
J. Hu, B.S. Jiang, H. Zeng, Y.N. Chen and Y.Y. Zhu 738

**The Applied Research of Underwater Vacuum Preloading Method in Soft Soil Foundation**
Y.Q. Feng and L. Zhang 742

**The Bearing Characteristics and its Influencing Factors of Reinforced Soil Foundation**
Y. Jiang, X.M. Wang, W.B. Sun and Y. Dong 746

**The Instability Mechanism of Soil-like Slope under the Action of Acid Corrosion in Open-Pit Copper Mine**
H.Y. Ju, G.Q. Gao, S.L. Liu, C.T. Luo and J.H. Li 750

**The Optimum Design of Slope Angle Based on Critical Sliding Field**
S.G. Sun, Y.N. Yi, Q.H. Cui and L. Jin 755

**Theoretical Analysis on Underwater Vibrating Compaction Technology of Scattering-Filling Rubble Stone Layer**
J.B. Fu, S.W. Yan and Z.J. Chen 760

**Three-Dimensional DEM Numerical Simulation of Rock Failure Progress with Different Microscopic Heterogeneities**
H. Chen, R. Fang, Y.J. Li and F.C. Zhang 767

**Analysis of Structural Soil's Shear Strength under Arbitrary Degree of Consolidation**
Y. Liu, C. Sun and S. Li 774

**Stability Monitoring Analysis on Side Slope Engineering Management of Longmenhao Primary School**
L.M. Wu, Z.J. Wang and S.Y. Liu 778

**The Stability of 3D-Geomat in Different Slope Gradient**
G.Y. Wang, J.P. Zhang and Y.S. Sun 782

**Monitoring and Analysis on the Supporting Structure for Deep Foundation Pit**
H.X. Sun, K. Zhang and S.L. Chen 787

**Numerical Analysis of Floatation Response of Buried Pipeline in Liquefied Soil**
S.N. Deng, W.T. Peng and J.Q. Lin 791

**Research on the Construction Monitoring for Enclosure Structure of Working well**
Y. Liao, J.H. Zhan and C. Li 797

**Experimental Study on Bearing Mechanism of Jacked Pipe Pile in Sand**
J.T. Wang 801

**On Stability and Deformation of Slurry-Trench Affected by Formation Equipment**
M.Y. Shi and F.G. Song 805

**Two-Dimensional Problem of Moisture Elasticity of Inhomogeneous Spherical Array with Cavity**
V.I. Andreev and A.S. Avershyev 812

## Chapter 1: Geotechnical Engineering

**Development of the Monitoring Guidance System for Slope Engineering**
D.H. Kong, Y.K. Ruan, Z.G. Zhang, W.F. Mao and M. Li 819

**The Application of BP Artificial Neural Network in Geotechnical Engineering**
N. Zhao 823

**Numerical Simulation of Slope Excavation in Highway Renovation and Expansion Project**
G.C. Luo, Z.M. He, X. Luo and Q.G. Hu 827

**On Fire Severity of Flammable Gas**
W.Z. Wu 831

**Study on Cover Backfilling of Open Pit to Underground Basing on Natural Classification**
C. Chen, D.Q. Gan, C.Q. Yu, A.D. Song, S. Wang, H.J. Lu and W.H. Zhang 835

## Chapter 2: Geological Engineering

**A New Geometrical Model of Fluid Flow in Rock Fractures for Valid Application of the Cubic Law**
H.G. Zhu, Y.D. Jiang, C. Yi and H.P. Xie 841

**Control Function of Corrosion of Calcareous Sandstone over Rock Mass Quality in One Hydroelectric Station on the Jinsha River**
S.Q. Lu and P. Zhu 847

**Dynamic Mechanism Research on the Tectonic Activation of Anninghe Rift**
J.Q. Liu and Y.S. Li 851

**Searching for the Shortest Seepage Path of 3D Network in Fractured Rock Masses**
B. Pan and Y.S. Zhang 857

**Development Features and Fractal Research of Fault Structure of No.5 Coal Seam in Chenghe-Second Coal Mine**
X.C. Xue and J. Wang 862

**The Application of Reservoir Geo-Modeling Technology in Section07, Ticleni Oilfield**
L.Y. Pang 866

**The Classification and Quality Evaluation of Rock-Mass Based on Limited Geological Information**
X.G. Wu, Z.Q. Yang, Q. Gao and D.H. Ba 870

**The Genesis Mechanism Analysis of Qinglong Landslide in the Central Region of Yunnan Province Water Source Diversion Reservoir Area of the Jinsha River**
T.J. Song, J.P. Chen, X.J. Li and J.Y. Yan 875

**Experimental Investigation on the Physical and Mechanical Features of Clay Shale in Bayingobi Basin of Inner Mongolia**
H.A. Liang, Q.R. Lu, S.J. Chen and H.Y. Hu 879

**Growth and Mechanics of Brittle Fault Systems in Rock Mass: An Example of Baihetan Hydropower Dam Area**
W.Q. Cheng, S.J. Di, X.Y. Xu and G. Song 883

**Sleeve Valve Pipe and Steel Pipe Micropile Fractured Tensile Reinforcement in Combination with the Application of a Mined-Out Area**
S.L. Tang, L. Yang, L.H. Sun and X.W. Li 887

**Evolution Characteristics of Permeability and Porosity of Mudding Weak Permeability Media with Nonlinear Flow**
Y.E. Deng, J. Yu and X. Peng 893

**Stability Analysis of Gypsum Mine Goaf Surface Based on Discrete Element Method**
X.M. Liu, C.X. Chen, K.Z. Xia and P.L. Huang 897

**Automated Analyzer, LOI and other Methods for Determination of Soil Organic Carbon**
Y.Y. Zhang and W.H. Zhang 903

**Determination of Volumetric Joint Count Based on 3D Fracture Network and its Application in Engineering**
J.L. Wu and J. He 907

**Relations between Paleoclimatological Conditions and Mineralogical Characteristics of Clays in Miocene Sediments at Linxia Basin, China**
N. Yu, H.L. Hong, Z.H. Li, K.X. Zhang and R.B. Li 912

**Research about Control Factors and Early Warning System of Early Warning System in Song Fangtun Oilfield**
N. Lv, Y.M. Wang and H.Y. Liu 919

**Stability Analysis of Puzi Landslide in Chongqing**
K. He and C.L. Chen 923

**The Landslides Developed with the Evolution of the River Terraces in the Loess Plateau, China**
X.L. Xing, X.K. Hou, T.L. Li and P. Li 927

**Application of Self-Drilling Anchor on Coal Gangue Slope Treatment**
T.L. Chen, J. Zhou, A.M. Wang and H. Li 935

**Researches on Slope Treatment Technologies under Complicated Geological Conditions in High Temperature and Rainy Regions**
R.X. Shan and H.P. Li 940

**Research on Two-Dimensional Landslide Model Control System Based on Support Vector Machine Modeling**
Z.T. Liu and Z.H. Feng 947

**Uncertainty Analysis and Monitoring of Earth Dam**
L.Q. Yang, R. Gao and Y. Wang 954

**Study on Rock Strength Characteristic by Point Load Test**
R.H. Wang, Y.Z. Jiang, J.L. Guo and T.C. Tang 958

**Research on the Mechanical and Thermophysical Properties of Frozen Soil in Cretaceous Formation**
H.D. Dai, M.L. Yin, T.Y. He, K. Liu, T. Li and T.Q. Zheng 962

**Coordinate Transformation and the Volume Covering Fractal Algorithm of Rock Surface Morphology**
K. Man, Y. Zhao and H.F. Li 966

**Study on Control Technology of Slope in Mountainous Areas of Southwest China under Complex Geological Conditions**
W. Yang and H.P. Li 971

**Anisotropic Bounding Surface Model in ABAQUS Software**
Y.Z. Qin and Q. Chen 977

## Chapter 3: Tunnel, Subway and Underground Facilities

**Construction Methods for Long-Span and Bifurcation Tunnel Structure**
C.L. Xin and B. Gao 983

**Effect of Time-Varying on Shield Tunnel Lining Structure**
F.J. Liu and J.F. Chen 987

**Analytical Hierarchy Process Based Post-Earthquake Health Diagnosis Method for Tunnel in South of China**
H. Huang, W. Zhang, L.F. Yang and Z. Chen 991

**Numerical Analysis of Construction Method in Shallow-Buried Large-Section Loess Tunnel**
Z.J. Sun 997

**Numerical Simulation of Effect of Foundation Pit Excavation on Underlain Shield Tunnel**
G. Wei, L.W. Hu and K.L. Chen 1001

**On Karst Water Inrush (Gushing) Geological Environment in Pingyang Tunnel**
Q.Q. Zhu, Q.Q. Miao and S.P. Jiang 1008

**Preliminary Ideas of the Metro Station Constructed by Shield Tunneling Method Combined with Prefabricated Method**
H.F. Su, W.N. Liu and F.C. Liu 1013

**Pre-Stressed Reinforcement and Security Analysis of Tunnel Lining with Dislocation and Cracks**
J.W. Zhang 1019

**Research on Layout of Measurement Points in Tunnel Lighting Experiment**
Q. Yang, B. Liang, G.B. Pan, S.Y. He, W. Chen, X.Y. Dang and Z.W. Wu 1024

**Study of Life Safety on the Fire Accidents in the Subway Station**
H. Xie, Y.Y. Xu, X. Zhang and J. Chen 1029

**Study on Emergency Evacuation in the Subway Fire Accidents**
H. Xie, Y.Y. Xu, X. Zhang and J. Chen 1033

**Study on Fire Smoke Movement of Urban Traffic Link Tunnel**
X.L. Yao and Z.G. Zhang 1037

**Research on the Regional Stress Field of Underground Powerhouse at the Right Bank of Baihetan Hydropower Station**
Q. Zhao, X.L. Leng and X. He 1042

**Study on the Blasting Excavation Method of Urban Shallow Tunnel**
Z.Q. Li and Z. Li 1051

**The Monitoring and Numerical Simulation Analysis on the Construction of a Shallow Underpass**
L.S. Liu and J. Zhao 1056

**Metro Station Deformation Caused by Deep Foundation Pit Construction**
C.L. Xin and B. Gao 1061

**New Developments and Applications in Rail Transit Construction Technology**
R.J. Li, R.L. Shan, Q.L. Liao and F.M. Wu 1065

**Numbering Analysis of Ground Settlement by Shield Method Based on the Model of Corrected 'Equivalent Circle Zone'**
Z.L. Zhou and S.G. Chen 1072

**Numerical Analysis on Interaction Induced by Crosswise Tunneling**
P.L. Gan, X.W. Tang, W.M. Shen and H.Y. Wang 1076

**Research on Key Technology of Shield Machine Main Drive Sealing**
R.J. Li, R.L. Shan, Y.X. Gui, J.Z. Yang and J. Liu 1081

**Review of Testing and Analysis on Metro-Induced Vibration**
J.W. Li 1088

**Stability Analysis of Wall Structure which its Depth is over Thousand m**
Y.H. Wang, X.C. Fu and X.H. Jing 1092

**Design of High Speed Railway Tunnel and its Construction Method in Abrupt Slope with Loose Rockmass**
X.J. Zhou, B. Jiang, R. Yang and C. Ning 1096

**Numerical Simulation for Construction Process Large-Span Flat Tunnel under the Condition of Shallow Buried**
J.J. Li, L. Tuo and G.J. Zhang 1100

**Study on FEM Numerical Simulation and Strain Monitoring of Tunnel Secondary Lining**
Y.N. Li, M. Liu, S. Wu, H. Liu, J.K. Su, Z.L. Zhang and C. Li 1105

**Study on Simulation Analysis of Excavation Deep Foundation Pit in Qingnian Road Station of Tianjin Subway Line 2**
Y. Bai, P.B. Cui, J.B. Wu and L. Wu 1112

**The Application of Getting $R_c$ Value from Point Load Test and Rebound Test by Tunnel Surrounding Rock Classification System**
R.X. Wang and Z.C. Yuan 1116

**The Dynamic Response of Shallow Buried Structure under the Action of Explosion Load**
Q. Zhang, H.B. Wei and J.H. Zhao 1122

**Discussion on Highway Tunnel Monthitoring Measurement Control Standards**
L.J. Tan, H.Q. Zhou and K.S. Chen 1127

**Research on early Concrete Crack Control of Shijiazhuang Subway Construction in Winter**
X.M. Yu, L.J. Cao and D.Y. Geng 1134

**Response of the Spiral Conveyor Spewing in Water-Rich Sand**
Y.R. Song, J. He, G.F. Chen, M. Hong and P.B. Li 1138

**Study on Deformation Prediction of the Tunnel Surrounding Rocks Based on Non-Equal Time-Interval Grey Model**
P.F. Geng, C.M. Yang, W.D. Guo and P. Wang 1143

**Mechanical Calculation for Collapse Mechanism of Surrounding Rock on Shallow Tunnel**
Y. Peng, J.S. Yang, Y.H. Shen and J.H. Liu 1148

**The Research on Environment Vibration due to Subway with Rail Pads of Frequency-Dependent Stiffness**
F. Yang, K. Wei and Y.C. Song 1153

**Tunnel Collapse Treatment Technique Research in Xinjiang Tianshan High-Altitude, Low-Temperature Mountain**
C.S. Zhu and X.H. Yang 1161

**Tunnel Lining Microstructure and Mechanical Properties of Evolutionary Analysis**
Y.D. Ma and S. Liang 1168

**BIM Technology Used in Underground Subway Station Planning Simulation**
H.K. Pu and Q.C. Wei 1174

**Comfortable Quality Analysis of Subway Station Vibration Induced by Multiple Trains**
B.Q. Zhang 1178

**Optimization of Tunnel Support Type through Fault Zone**
K. Li and H. Guo 1184

**Force Analysis of the Middle Wall in Multi-Arch Tunnel under Central Hole + CRD Method**
J. Li and Z.L. Wang 1188

**Force State of Country Rock and Supporting Structure in Multi-Arch Tunnel under Central Hole + CRD Method**
J. Li, Z.L. Wang and J.F. Zhong 1192

**Key Construction Technology of Shield Machine Passing through the Airport Apron in Shallow Soft Soil**
R.J. Li, R.L. Shan, R.S. Li, J.Y. Lv and Y.W. Song 1197

**Optimization of Construction Method for Shijiazhuang Xinbai Subway Station**
C.Y. Gao, J.G. Niu and D.Y. Geng 1203

**Study on Classification and Regulation for Defects on Railway Tunnel**
J.W. Zhang, S. Wang and H.X. Huang 1207

**The Dynamic Response of Zhengyangmen Gate Tower Induced by Beijing Metro Line 2**
Q. Song, J.Q. Guo, W.H. Chen and P. Guo 1212

**Study on Investigation and Analysis of Existing Railway Tunnel Diseases**
D.P. Zhao, X.R. Tan and L.L. Jia 1218

**Development States and Existing Problems Research of Nondestructive Testing of Bolt**
X.K. Bao, H.H. Liu and L.J. Liang 1223

**Identification of Surrounding Rock Parameters Based on MSVR**
X.L. Li, J.J. Zhang, F.M. Wang and B. Zhang 1227

**Kinematics Analysis of Working Edge Point for Gauge Disc Cutter in Cutterhead of Tunneling Machine**
Q.X. Wu, G.F. Tian, L. Chen and H.W. Ma 1232

**Mechanism Analysis and Prevention Method for Tunnel Fire**
J. Wu, F.M. Shen and P. Jiang 1238

**Metro Construction Safety Risk Assessment Based on the Fuzzy AHP and the Comprehensive Evaluation Method**
X. Zheng and F.H. Ma 1243

**Monitoring and Analysis for the Deformation of SMW Retaining Structures in Subway Station**
J.T. Xia, S.F. Zhang, H.R. Shen, Z.J. Liu and S.Q. Huang 1249

**Approach on Pollution Gases Diffusion Path of Small Spacing Tunnel Entrance Based on CFD**
Y.Y. Xing 1254

**Influence of Foundation Pit Excavation on Existing Shield Tunnel and its Protection Range**
X. Wen and C.R. Pang 1258

**LS-SVM-Markov Model for Tunnel Deformation Prediction**
G.T. Cai and S.J. Hu 1264

**Optimization of Stope Structural Parameters in Phosphorite Mine and its Stability Analysis**
X.X. Li and K.G. Li 1268

**Research of the Key Control Parameters Standard for Shield Tunnel Under-Crossing High Speed Railway**
Z. Liu and P. He 1273

**Research on Defects of Tunnel Portals during the Operation**
K.Z. Zhu and J.H. Luo 1279

**Study on Risk Trend Assessment of Metro Tunnel Crossing Underground Pipeline Based on Partial Connection Number**
H.T. Xie, B. Li and Y.S. Zhao 1283

**Water Inrush Risk Evaluation into the Tanjiaba Tunnel**
Y.B. Sun and M.Y. Feng 1288

**Numerical Analysis of Two Structural Schemes of the HK-Zhuhai-Macau Immersed Tunnel**
Y.J. Dai, M.J. Zhou, Y.F. Kong, X.D. Liu and Z.G. Zhang 1293

**The Deformation Characteristics Analysis of Metro Tunnel in Complicated Geological Conditions**
D.H. Qiu, S.C. Li, Y.G. Xue and F.D. Xie 1297

**Auger Bored Piles Application Works in the Subway**
Y. Wu 1301

**Impact of Urban Rail Transit on Residential Property Values in Hangzhou**
L.F. Ruan and J.P. Yin 1306

**Dynamic Accumulation Damage Characteristics of Initial Cracks for the Lining of High-Speed Railway's Tunnel**
X.Q. Wang and B. Cai 1311

**A Numerical Investigation on Time-Dependent Failure of Tunnels Based on the Long-Term Strength Characteristics of Rocks**
L.C. Li and M. Xing 1315

**Measurement and Research on Broken Zone of Surrounding Rock in Cha Zhen Tunnel**
R. Wang, Y. Liang and W. Qin 1321

**Numerical Simulation Study on Three-Step Method Construction for Neighborhood Tunnel**
L.L. Cai, X.Y. Yang and N. Guo 1327

**Study on Pressure Observation of Fully Mechanized Caving Faces in Coal Seams with Rock Burst Danger in Xiagou Coal Mine**
Z.C. Tian, Y.J. Liu, W.C. Wang and Y.H. Ren 1331

**Research on Geostatic Stress and Optimization of Bolt Support for Tilted Strata Roadway**
R.L. Shan, L. Tian, W.F. Zhao, J.Y. Lv, Y.H. Xiao, L.F. Wei and X.Y. Hao 1335

**Construction Monitoring Technology Analysis for Railway Tunnel**
J.F. Hou, J. Chen and R.L. Wang 1342

**Application of Grouting Reinforcement Technology in Pingshan Shaft Station**
L. Tian, J.Y. Xi, J. Liu, X.D. Liu, F. Shang and X. Dong 1347

**Research Status and Development Trends of Roadway Surrounding Rock Stability Classification**
R.L. Shan, X.S. Kong, J. Liu, J.F. Li, Y. Bai and Y.W. Song 1352

**Analysis on Changes of Mechanical Properties of Lining of Tunnels in Huangtu Regions Taking Account of Loess Cavity by Using ADINA**
H.P. Zhou, E.Y. Wang, Y.X. Hu, Z.Q. Liu and J.B. Cui 1358

**Research of Fractured Surrounding Rock Physical and Mechanical Characteristics in Shuguang Mine No.2 Mining Area**
H.J. Xue, J.L. Xue, M.L. Yin, J. Kong and Z.M. Gao 1364

**Finite Element Analysis on Causes of Crack in Large Underground Garage**
B. Shu and J.H. Peng 1369

**The Application of Fracture Mechanics in Highway Tunnel Lining Cracking**
S.Z. Chen 1377

**Studies on Damage Distinguishing of Underground Tunnel Structure Based on BP Neural Network**
X. Zuo, G.X. Chen and W.Q. Li 1382

**Non-Linear Free Vibration of Submerged Floating Tunnel Tether**
Z.B. Su and S.N. Sun 1388

**Numerical Simulation Method Utilization in Water Gushing Yield Forecasting of Paoziling Tunnel in Hunan Province, China**
Y.N. Yang, Q. Zhang and M. Xu 1392

**Reliable Design and Study on Highway Tunnel Lining Structure**
Z.L. Niu, Y.B. Qi, J.S. Huang, C. Wang and J.L. Li 1398

**The Example Analysis of the Transfer Stations of Subway**
L.J. Yu, Y.L. Li and K.M. Chen 1402

**Subway Station Group Decision and Evaluation of Fire Emergency**
L.J. Cao, X.M. Yu and D.Y. Geng 1408

**Based on Effect Coefficient Method of Metro Tunnel Collapse Risk Evaluation Model and its Application**
P.L. Cai, J. Wang and S.W. Tian 1412

## Chapter 4: Seismic Engineering

**Application of FEM Strength Reduction Dynamic Analysis in the Seismic Design of Reinforced Earth-Retaining Wall with Geo-Grid**
X.S. Tang, Y.R. Zheng and L. Jie 1419

**Damage Mechanism of Yiliang Earthquake on September 7, 2012**
Z. Lin, M. Tian, D.B. Chen and C.F. Li 1426

**Deformation and Energy-Based Seismic Damage Evaluation of Steel Reinforced Concrete and Reinforced Concrete Piers**
J.J. Lin, A.R. Liu, Q.C. Yu and J.D. Deng 1430

**Experimental Study on Dynamic Mechanical Properties of Galvanized Iron Wire under Seismic Strain Rate**
H. Zhang, J.H. Zhang, D.B. Wang and X. Li 1435

**Peak Story Drift of a Building Structure Subjected to Earthquakes**
J.H. Lin 1439

**Research Advances in Seismic Behaviors of Shear Wall with Opening**
L.Y. Gong, J.W. Chen and Y.P. Su 1443

**Response Modification Factor for Y-Eccentric-Braced Steel Frame Structures Designed Based on Chinese Code**
W.X. Yang, Q. Gu, P.Z. Cao and R.J. Shi 1449

**Seismic Performance of the Reinforced Concrete Frame Structures with Infilled Walls of Different Configuration**
M.S. Guan, H.B. Du, W. Chen and Y.H. Wu 1458

**Shaking Table Test Analysis of Bottom-Business Multi-Story Masonry Structure in Small and Middle Towns in the Southward**
Y.D. Liang, X. Guo, H.W. Yi, Y.Z. Li and J.Z. Jiang 1463

**Shaking Table Test of Reinforced Concrete Frame-Wall Model**
H. Zhang, B. Li, X. Li and D.B. Wang 1467

**Analysis on Self-Centering Capacity of Prefabricated Frame Joints**
Y. Zou, H. Lin and W.Q. Ma 1471

**The Effect of Damping on Seismic Performance of Steel Frame**
X.W. Wang and C.J. Hu 1477

**The Influence Analysis of Mechanical Behavior between Pile and Soil on End Bearing Pile Foundation's Dynamic Characteristic**
W. Hu, Y.H. Zhang and Y. Zhang 1481

**The Present Situation of Rural Housing and the Seismic Performance Analysis**
H. Li 1486

**Geotechnical Seismic Isolation System - Further Experimental Study**
W. Xiong, M.R. Yan and Y.Z. Li 1490

**Seismic Response Analysis of Deep Water Bridges with Pile Group Foundations**
D.X. Zhao, J.J. Wang and J.S. Su 1494

**Analysis of Strong Ground Motion Characterization in the 2013 Lushan Earthquake**
T. Yu, M. Lu and X.J. Li 1499

**Development and Prospect of China's Bridge Seismic Bearing**
L. Zhang, C.H. Zhao, L. Li and B.B. Fan 1506

**Feasibility Analysis of Applying Biomechanical Properties of Human Body to Seismic Design of Building Structure**
S.S. Wu, G.C. Kang, S. Wang and J.Y. Lian 1511

**A Method for Checking Eccentricity of Solid Concrete Piers with Low Longitudinal Reinforcement Ratio under a Minor Earthquake**
X.C. Chen, Z.W. Liu, Y.L. Zhang and L. Pei 1515

**Application of the Jerk Feedback on the Shaking Table**
F.F. Li, J.B. Ji, X.J. Li and N. Li 1521

**Data Processing and Preliminary Analysis of Strong Motion Records from the Ms7.0 Lushan, China Earthquake**
H.Y. Yu, B.F. Zhou, W.X. Jiang, C. Yang, Q.C. Xie, P.Y. Tan, S.M. Xu and X.F. Zhao 1528

**Permanent Displacement Identification Analysis in 2011 Mw9.0 Tohoku Earthquake, Japan**
B.F. Zhou, T.S. Song, R.Z. Wen and L.L. Xie 1533

**Research on Shaking Table Control Parameter Tuning Technology Based on System Identification**
J.B. Ji, L.J. Sun, P.Y. Zhan, J.K. Wang and L.L. Song 1538

**Research Summary of Vibration Reducing Performance for Infilled Wall**
M.S. Sun, S.Y. Qu, F.B. Meng and C.L. Li 1545

**Analysis on Seismic Performance of Beam and Plate Converter Floor**
G.T. Zhao and X.T. Kou 1551

**Ultimate State of Bridges with Rocking Isolation under Extreme Earthquakes**
T.Y. Lee, M.Y. Huang and K.J. Chung 1555

**Verification of LSSRLI-1 Applicability on Soft Sites Using Exact Solution**
R.S. Li and X.M. Yuan 1559

**Controls on Material and Mesh for Structural Nonlinear Time-History Analysis**
X.M. Chen, J. Duan, H. Qi and Y.G. Li 1564

**Influence of Saturation Degree on Deamplification of $P_1$ Wave through Multilayered Porous Media**
M.Y. Mehiaoui Hadjebar, M. Hadid and M. Berrah 1570

**Precise Integration Method of Pseudo-Dynamic Testing of Structures**
H.B. Wang and R. Liu 1574

**Reliability Analysis in Performance-Based Earthquake Engineering**
A. El Ghoulbzouri, Z. El Alami and S. El Hannoudi 1581

**An Energy Dissipation Device Based on Shape Memory Alloys for Frame Structures**
Y. Chen, N.L. Zhu and S. Gao 1591

**Analysis of the Influence of Mortise-Tenon Joint Damage on Seismic Performance of Ancient Timber Structure**
X.L. Wang and L. Jin 1595

**Demand Diagrams Based on Inelastic Spectra: A Proposal for the Implementation of the Capacity Spectrum Method in the Romanian Seismic Design Code**
I.G. Craifaleanu 1600

**Research of Soil Layers Amplification Effect Based on Strong Seismic Records and Calculations**
L. Wang and Y. Su 1604

**Research on Performance-Based Seismic Levels of Nonstructural Components**
H.H. Zhu and G. Zhao 1609

**Research on Seismic Damage of Buildings in the Beichuan Earthquake**
F. Wang and C. Ning 1613

**Seismic Analysis of 5-Span High-Speed Railway Continuous Girder Bridge**
J.H. Guo and M.Q. Lu 1618

**Seismic Performance Analysis of Steel Frame with Wedge Devices Based on the Energy Dissipation**
J.S. Lei, W.X. Luo, J.L. Jiang and W. Zhang 1624

**Seismic Performance Analysis on Single-Storey Masonry House with Sliding Damping Technology**
K. Yuan, Y.M. Li and B. Kang 1629

**Seismic Reduction and Control Analysis of Hybrid Structure with Viscous Dampers under Strong Earthquake**
S. Qiu, S.C. Deng and Z.Q. Zhu 1633

## Chapter 4: Seismic Engineering

**Simplified Dispersion Curves of Earthquake Love Wave for Rotational Seismic Motion Estimation**
Y.W. Liu and H.N. Li 1639

**Study on Seismic Behavior of Self-Centering Precast Frame**
H. Lin, T.Q. Li and Q. Wang 1645

**Study on Seismic Detection Applied in Mine Advance and Side**
Y.B. Hu, Y. Wang, Y.Q. Wu and Z.X. Liu 1649

**Study on the Anti-Seismic Performance of New Swing Structure System Based on PUSHOVER**
D. Liu 1653

**Study on the Seismic Safety of the Qinghai Traditional Dwellings**
M.J. Zhang, L.X. Liu and Y.N. Shi 1658

**A Suggestion on Uncertainty Correction of Ground Motion Attenuation in Probabilistic Seismic Hazard Assessment**
C.F. Wang, X.X. Tao, A. Z, K. Zhao and W. Jiang 1662

**Average Damage Ratio and Earthquake Damage Matrix of Non-Engineered Building in Seismogenic Provincial Regions in China**
J.H. Xing, M. Lu, Y.M. Zhao and Y. Yu 1667

**Collapse-Resistance Measure for the Bottom Frame Structure under Earthquake**
D.Z. Wang, J.W. Dai and R.C. Shan 1676

**Dynamic Analysis of Artificial Boundaries in Gravity Dam-Foundation Rock Interaction System**
W. Qiao and G.M. Liu 1680

**Dynamic Analyses of a Self-Anchored Suspension Bridge under Seismic Excitations**
C. Wang and Y.X. Wang 1687

**Inertial Coefficient Adopted in Pile-Pier Structure under Deep Water**
G.S. Sun, C. Liu, J. Xie and F.J. Ma 1692

**Numerical Analysis of Seismic Behavior of a Concealed Bracing Connection for Precast Concrete Shear Walls**
Q. Jin, W.N. Guo, W.J. Zhao, B. Zhang and D.P. Zhang 1696

**Seismic Performance of Base-Isolation Building Subjected to Near-Fault Ground Motion with Velocity Pulse**
Q.M. He, Y.Q. Li, Y.M. Zhao and Y. Yang 1700

**Seismic Response Analysis of Free Long-Span Submarine Flexible Pipelines under Earthquakes**
Y.L. Deng, Y. Bian and F. Lei 1704

**SRC Frame-RC Core Wall Hybrid Structures Collapse-Resistant Design**
Y.Y. Wu, Z.K. Cui, Q.Q. Gong and L. Zeng 1708

**Study on Seismic Performance of Irregular RC Frame with Specially Shaped Columns**
J. Tang and L. Wu 1712

**Study on Seismic Response Characteristics of Step-Terrace Frame Structure on the Slope**
L.P. Liu, J.J. Liu, A.L. Li and M.Z. Tan 1718

**Study on Simplification Conditions of Curved Regular Bridges under Seismic Effect**
T.Y. Song, Y. Shen and G.P. Li 1723

**Study on the Characters of Seismic Response Spectra Based on China Financial Information Mansion**
M. Li, Y.Q. Wang, W. Tao, B. Wang, Q.X. Yu, L.L. Wu and R.L. Shan 1729

**Time-Frequency Analysis of Non-Stationary Ground Motions via Multivariate Empirical Mode Decomposition**
Y.W. Su, G.Q. Huang and L.L. Peng 1734

**Study of Intake Tower under an Earthquake Using the Power Spectral Method Based on ANSYS**
X. Hua, C.Q. Yu, W.H. Zhu, K. Zhao and C.L. Huang 1742

**Studies on Seismic Measures to Improve Masonry Infilled Wall**
Y.J. Zhang, X.S. Duan, X.Y. Wang, C.L. Zhou and Y. Sun 1746

**A Suggestion to the Vertical Earthquake Action Stipulated in Seismic Design Specification**
H.M. Liu, X.X. Tao and J.Y. Wang 1750

**Seismic Response Analysis for Assembled Precast Concrete Residence**
Z.B. Meng, Y. Cao, G.D. Qiao and Y.S. Zhao 1755

**Study of Ultimate Displacement of Timber Structures in Chinese Ancient Buildings**
M.G. Xu and Z.W. Ding 1759

**Expected Annual Earthquake Loss Analysis Based on CMR of Structures**
L.N. Xian and X.Y. Ou 1763

**Earthquake Mitigation Effect Analysis of Hysteretie DamPers in Steel Frame**
C. Xu, Y.F. Niu and Y.X. Zhao 1767

**Analysis of Earthquake Damages and Seismic Reinforcement of Bridges**
B.B. Fan, C.H. Zhao, L. Zhang and L. Li 1771

**Research on Shaking Table Test of Base and Story Isolation Structures**
G.C. Zheng and H.L. Xu 1776

**Vulnerability Analysis of Existing Buildings under Seismos**
X.H. Meng and G.Z. Yang 1782

**Finite Element Analysis of Seismic Responses of a Large-Cantilever Stadium Structure**
Z.Y. Sun, Q. Jin, L.G. Jia, Q. Wang, Y. Ma and C. Xu 1786

## Chapter 5: Hydraulic Engineering, Water Resources and Hydrology

**A Two-Dimensional Numerical Model for Shallow Water Flows over Variable Topographies**
B. Lv and S.X. Li 1793

**An Inversion Method of the Material Parameters for Gravity Dams**
D.D. Zhang, X. Feng and J. Zhou 1799

**An New Approximate Formula for Contracted Depth in Quadratic Parabola Shaped Channels**
F.L. Li 1803

**Analysis of the Influence of Bottomland Change on Waterway Conditions in Liyushang in Middle Reaches of the Yangtze River**
Y.D. Zhu and J. He 1807

**Analysis on Hydrodynamic Load that Induces High Dam Body Vibration**
C.T. Wang, H.X. Ding and H. Lv 1812

**Analysis on Seepage Effects of Plastic Concrete Cut-Off Wall in Construction and Operation Period of Hydropower Station Tail Channel**
G.X. Yan and W. Wu 1816

**Application of MIKESHE Model in Water Environmental Management for Guishui River Basin**
Z. Zheng, J. Zhang, H.L. Gong and J.W. Huang 1823

**Design of a Pressurized Trapezoidal Shaped Conduit Using the Rough Model Method (Part 2)**
B. Achour and A. Bedjaoui 1828

**Evaluation of the Effects of Channel Regulation Engineering Works in Typical Braided Reach**
J.Q. Han and L.Q. Li 1842

**Experimental Study on Engineering Properties of Cemented Sand and Gravel**
H. Fu, J.G. Feng, H.Q. Han and H. Ling 1846

**Finite Element Analysis of Stress Deformation of Earth-Rock Dam on Narrow Valley**
F.Y. Chu 1852

**Philosophical Reflections on Chinese Water Resource Management**
Y.F. Liu, B.Q. Ruan and C.C. Xie 1856

**Research and Discussion of Impervious Wall Construction Based on Continuous Vertical Slotting Technology**
L.X. Zhang, Y. Li, Z. Zhang, J.T. Niu and H.Y. Yu 1860

**Research of Eco-Compensation among Basin Cascade Hydropower Station Development and Management**
X.M. Zhou and M. Zhao 1864

**Research on Channel Regulation Parameters of Daijiazhou Reach in Middle Yangtze River**
W.L. Liu 1870

**Research on the Feasibility of Water Diversion Project**
L.H. Zhang, G.H. Wang and X.H. Hao 1874

**Simulation Method of Particle Size Scale for Fine Sand Model**
W.L. Liu, X.F. Liu and P.J. Yue 1878

**Study on Navigation Technology of Waterway at Hub Downstream and Bridge Area Overlapping**
X. Liu 1883

**Study on Sandy Pebble Reach Riverbed Erosion and Deposition Basic Law after the Three Gorges Reservoir**
X.F. Liu, M.L. Zhang and Z.W. Ye 1888

**Study on the Horizontal Velocity Distribution in Natural Rivers**
H. Ge, L.L. Zhu and X.B. Zhang 1893

**Study on the Uplift Force of Plunge Pool Slab**
C.T. Wang, B.H. Xie and W.H. Zeng 1897

**The Direct Solution on Normal Depth of an Egg-Shaped Section Tunnel**
H. Wen 1901

**The Study of Available Water Resources in Northern Shaanxi**
X.J. Wu 1906

**Mechanical Characteristics Analysis on Flexible Mattress in Downstream Sinking Based on Lumped Mass Method**
Z.H. Sun and M.L. Cheng 1910

**Research on Navigable Ship Model Test in Curved Waterway**
C.H. Wang and X.B. Cheng 1918

**Data Assimilation of River Networks Using Extended Kalman Filter**
Y.F. Chen and J.L. Qian 1923

**Numerical Analysis of the Influences of Water Level on Seepage Stability of Tailing Dam**
F.D. He, X.F. Cao, X. Yang and Z.D. Zhou 1928

**Experimental Study on the Air-Cooling of Concrete Aggregate**
M. Zeng, C.H. Guo, Z.M. Kang, W. Guan, F. Lu, G. Wang and D.W. Tang 1932

**Sensitivity Analysis of Concrete Face Rock-Fill Dam Parametric Based on the Intelligent Algorithm**
Q. Yan, Z.H. Gao and Z.C. Song 1940

**Study on the Present Situation and Development of Groundwater Monitoring Technology**
Q.H. Guan, F.L. Li, X.Q. Chen, Y.F. Zhang and C.J. Tian 1946

**Impact of the Cascaded Reservoirs and the Tributaries Confluence on the Eco-Hydrology of the Reserve in the Upper Reaches of Yangtze River**
L. Zhao, Q.D. Peng, Q.C. Chen, C. Li and Z.J. Yin 1953

**Shape Optimization for Arch Dam with Sequential Quadratic Programming Method**
Y. Duan, W. Yuan and H.B. Liu 1961

**Unsteady Flow Impact on Downstream Waterways and Control Measures Research of Pingban Hub in Nanpanjiangjiang River of Guizhou**
X. Liu 1966

**3D Dynamic Numerical Simulation of Water Flow in Stilling Basin with Flaring Gate Pier**
C. Qiu and C.L. Liu 1971

**Finite Element Analysis of Seismic Response of Exposed Steel Penstock in Hydropower Station**
Y. Liu, C.Z. Shi and H.G. Wu 1975

**Joint Regulation and Storage of Surface Water and Groundwater in Rushan River Basin**
M.H. Niu, Z.H. Xu and X. Wang 1981

**Comprehensive Evaluation for Utilization Efficiency of Rain-Flood Resources in Rushan River**
S.F. Zhou, Z.H. Xu, S.S. Yang, K. Kong and Y. Xiu 1985

**Study on Tidal Current and Sediment for Dredging Project in Yamen Channel**
J. He, L.P. Shi and Y.J. Sun 1989

**Analysis of Monitoring and Settlement Prediction of Wenzhou Shoal Seawall**
H.Y. Wei, G.Q. Liang and C.J. Zhang 1993

**Comparative Study on Design of Exposed Penstock Laid on Ground Using Chinese and American Specifications**
L. Hu, H.G. Wu, C.Z. Shi and Y.H. Xie 2000

**Current Situation and Development of SHPF Project in China**
C.M. Guan 2007

**Geo-Stress Direction Evaluation Method Based on Numerical Simulation**
S.C. Xu and C.Y. Jin 2011

**Influence of the Bridge on the Flood Controlling in the River**
X.Z. Zhang, X.P. Dou, Z.X. Jiao and Y.Y. Song 2015

**Monthly Rainfall Analysis in West Part of Chongqing**
L. Qin, J.Y. Jin, Q. Zhang and D.K. Wang 2019

**Optimization Study on Drainage System for Canal of Middle Route Project of SNWT in Expansive Soil Area with High Groundwater Level**
H.d. Cui, J.F. zhang, G.S. zhu, D.X. Wu, W. Zhang and J.L. Wang 2023

**Precipitation Characteristics and Trend in the Hsiao-Ching River Basin of Jinan City during the Past 50 Years**
L. Lin, J. Liu, J.W. Huang, X.Q. Chen, Q.H. Guan and Y. Tang 2029

**Research on Structure Design of U Type Canal of Seepage-Proofing**
J.L. Sun, B. Zhang and S.J. Zhang 2033

**Simulation Study on Deposition Downstream Floodgates in Estuarine**
X.Z. Zhang, Y.Y. Song and S.M. Chen 2037

**Study on Time Effect of Rock Fill Dam Seepage Line**
X.Y. Tao, D. Xiang, W. Sun and Y. Li 2041

**Temperature Rebound Influenced by Environment Temperature Analysis of the Irrigated Area of a High Arch Concrete Dam under Constrcution**
X.H. Chen, Y.Y. Huang, B.L. Xu, D.D. Liu and X.B. Wei 2045

**The Numerical Simulation of the Flow Field in the Micro-Pressure Inner Loop Reactor**
J.C. Liu, Z.G. Yin and W. Ji 2050

**Vibration Analysis and Human Comfort Evaluation of Underground Hydropower House**
D. Fu and H.G. Wu 2055

**Working Performance of Anti-Arch Segments on the Left Bank Slope of Xiangjiaba Gravity Dam**
Q.J. Zhou, P. Gao, Z.G. Gong and H.F. Li 2063

**Main Engineering Geological Problems and Evaluation on the Reservoir Engineering of Yellow River Water Diversion and Irrigation Area**
Z.Q. Huang, T.L. Chen and A.M. Wang 2071

**Research on the Calculation Method of Earth Pressure on the Back Side of Large Cylinders**
J.L. He 2074

**Utilizing GIS in the Development of Water Quality River Modeling for Penchala River, Malaysia**
F. Othman, A.E. Mohamed Elamin, S.A. Hezza Azahar and S.A. Muhammad 2078

**Data Mining Model in Regional Target Decomposition of Water Resources Utilization Efficiency**
H.W. Chen, J.W. Huang, B. Li, S.D. Fu and X. Zhang 2082

**The RCC Arch Dam Analysis during Overload**
Y. Xia, Y.Y. Yu, X.L. Zhao and Z.Q. Zhang 2088

**Study on Damage of Concrete Dam Subjected to Combined Action of Earthquake and Slide Surge**
J. Li, Q. Xu, J.Y. Chen and G.S. Lu 2092

**Research on the Dam Foundation Stability and Reinforcement Measures of the 12th Sluice Section of Xiangjiaba Hydropower Station**
X.J. Wang and X.X. Zhao 2096

**Experimental Investigation on the Segregation of Landslide Dam Materials**
M. Zhang, F. Wang, G.J. Mouse, W.T. Luo, H.W. Zhang and Y.R. Liu 2103

**Relaxation Analysis of the Arch Dam Foundation Rock Masses of Jinping I Hydropower Project**
B. Xiao, D.N. Zhou and Z.H. Min 2108

## Chapter 6: Coastal Engineering

**Research on the Influence of Diking in Shallow Sea of Tangdao Bay on Marine Environment**
Y.H. Xu, X.H. Hao and X.M. Dong 2115

**System Analysis of Construction Quality Control Measures of Coastal Levee**
X.Q. Wang, H. Li and S.Y. Han 2120

**Experimental Study on Mooring Manner and Safety Operation for 450,000DWT Supertanker**
B. Jiang, X.J. Huang, Y.X. Lv and X.B. Zhang 2124

**Experimental Study on the Offshore Positioning and Installing of Large Caisson**
X.J. Huang, W.Z. Zhang, B. Jiang and Y.X. Lv 2129

**Two-Dimensional Finite Element Analysis of Laboratory Seawall Model**
J. Zhang, J.F. Zhai, X.M. Wang and J. Chen 2134

**Accuracy Comparison for the Ocean Tide Models in Estuarine Tidal Prediction, the Pearl River Estuary**
L. Zhu, X.L. Yin and L. Jiang 2141

**Numerical Model on Hydrodynamic Impact from HZM Bridge**
J. He, Y.J. Sun and X.S. Zhao 2146

**The Research of Flow Resistance Property in the Tugging and Mooring of Tube Segment**
Z.Z. Qiu and M. Dong 2150

**Tieshan Port Development Plan: Evaluation of the Long Wave Induced Resonance Using a Numerical Mild-Slope Model**
H.J. Zhao, J. Yang and G.P. Chen 2154

**Wave Kinematics and Pressure Field of Third-Order Theory for Bichromatic Bi-Directional Waves in Water of Finite Depth**
H. Huang and G.L. Li 2166

**A Kind of Floating Breakwater Sheltering Deep Water Aquaculture**
X.F. Cheng 2170

**Analysis of Gravity Foundation for Offshore Structure under Cyclic Loads**
R. Gao, L.Q. Yang and Y. Wang 2177

**Application Status and Development Trend Research of Ecological Revetment in Jiangsu Inland Waterway**
J. Zhang, J.F. Zhai, X.M. Wang and J. Chen 2181

**Computation and Analysis of Buttressed Quay's Floor**
Q.C. Ning, X. Yang, Y. Shi and L. Li 2185

**Research of Sediment Transport Trend and Erosion-Deposition Characteristic of Yangma Island Sea Area**
Y. Wang, W. Ye and M.C. Li 2189

**Study on the Evolution of Artificial Beach in Xiamen**
G.L. Wang 2194

**Three Dimensional Physical Model Study on Penang Fishing Port Project**
C.H. Zhang and B.L. Geng 2198

**Study on the Panel of the High-Pile Wharf Near Estuary Based on the Finite Element Method**
X. Yang, Q.C. Ning, Y. Shi and G.X. Xia 2202

**Appropriate Jackup Selection in Disturbed Wellsite by Pile Inserting and Pulling in Offshore Oilfield**
Y.N. An, Q.F. Song and J. Li 2206

## Chapter 7: Construction Technology

**Complementary Use of Inductive Test and Bending Test for the Characterization of SFRC**
L. Liao, S. Cavalaro, A. de la Fuente and A. Aguado 2213

**Research on New Type Quantitative Nondestructive Pre-Stress FRP Sheet Tension Fixture**
G.S. Zhu, L.S. Bao and C. Guo 2220

**Analysis on Impact of the Node Connection Pattern for Fastener-Style Steel Pipe Formwork Support**
L. Liu, B. Wang, J.C. Wang and Y.N. Liu 2224

**Analysis on Lateral Deformation of High-Formwork in Different Column's Spacing of Bridging**
L. Liu, B. Wang, Y.N. Liu and J.C. Wang 2228

**Influence of Bridging Arrangement Location on the Mechanical Characteristics of the High-Formwork Support System**
L. Liu, Y.N. Liu, B. Wang and J.C. Wang 2232

**Research on Influence of Concrete Pouring Sequence on Stability of High-Formwork Support System**
L. Liu, J.C. Wang, B. Wang and Y.N. Liu 2235

**The Integration of New Technology Research on Composite Inorganic Fiber Acoustic Insulation Spray in Engineering Construction**
J.Y. Shao and D. Wang 2239

**The Technology Innovation of Green Soft Ground Handling Based on Squeezing and Consolidation Composited**
J.Y. Shao and X. Zhang 2244

**Causes and Solutions for the Common Problems in Rotary Drilling Cast-in-Place Pile Construction**
Z.Y. Zhou and C.Y. Zhang 2249

**Determining the Degree of Mobility of Building Systems**
P.P. Oleinik, L.S. Grigoryeva and V.I. Brodsky 2253

**Engineering Application of Precast Assembly Integral Shear Wall Structure on Housing Industrialization**
Y. Wang, Y.N. Zhang, F. Yang and X.X. Xia 2257

**Features and Construction of Prefabricated Buildings**
Y.H. Zhao 2262

**Connecting Passage Construction for the Foundation Pit under Existing Optical Fiber Cable**
H.Q. Cao, N. Lou and W.J. Cui 2266

**Experimental Study of Effects of Operation Parameters on Efficiency of Vibratory Pile Driving**
H.P. Zheng, L. Chen, W. Wang, L.Q. Peng and J.Y. Zhang 2272

**The Study about Anti-Seismic Structures Stirrup Construction Blanking Length Theory Calculation**
H.L. Li, X.X. Cui and Y.H. Zhao 2277

**Components and Guidance for Constructional Rearrangement of Buildings and Structures within Reorganization Cycles**
A. Volkov, V. Chulkov, R. Kazaryan, M. Fachratov, O. Kyzina and R. Gazaryan 2281

**Mold-Unloading-Lifting and Lifting-Transportation's Construction Checking of Composite Wallboard in Industrial Production**
C.Y. Xu, L. Yan, C.L. Xu and S.K. Jiang 2285

**Discussions on Foundation Pit Construction Scheme of Large Building in Mountain Area**
M.J. Lin 2289

**Outstripping Engineering Preparation of Construction Sites**
P.P. Oleinik, L.S. Grigoryeva and V.I. Brodsky 2294

**Research on the Problems and Countermeasures for Steam Curing of Assembled Composite Wallboard**
C.Y. Xu, L. Yan, C. Li and Z.W. Cao 2299

**Temperature Cracks of Concrete Engineering Analysis and Treatment Measures**
G. Zhang 2303

**The Double-Layer Nonstationary Heat Conduction Measures to Prevent the Formation Ice-Dams on the Roof**
M. Petrichenko, D.V. Nemova, D.S. Tarasova and A.A. Staritcyna 2308

**Construction Technology of High-Rise Building Structure**
P. Cheng, X.F. Chen and L. Wu 2316

**Research on the Characteristics and Status of Recycled Concrete Filled Steel Tube**
B. Wang, X. Liu and X. Yu 2320

**The Countermeasures on Temperature and Shrinkage Crack of Mass Concrete**
X.C. Zheng, P.F. Li and S.Z. Sun 2324

**Reinforcement Method Choice of Deep Soft Soil Foundation**
C.M. Zhang, L.J. Liang and C. Huang 2328

**Bending Resistance of a Slender Plate Girder with Longitudinal Stiffener**
S.I. Gutiu and C. Moga 2332

**Processing Status and Utilization of Construction Waste in China and the West**
F.J. Liu and F.F. Suo 2336

## Chapter 8: Water Supply and Drainage Engineering

**Effects of Different Irrigation Amount on Yield and Quality of Greenhouse Tomatoes**
Z. Chen and M.A.M. Abdalhi 2343

**Emergency Supply of Drinking Water**
M. Teichmann, F. Kuda and Z. Proske 2346

**Integrated Fuzzy Evaluation of Raw Water Eutrophication Based on GIS**
J.P. Liu, J.W. Shao, F.L. Dong and X.Y. Ma 2350

**Research of Hydrodynamics of Biofilter with Surface Feed**
E.S. Gogina, O.V. Yantsen and O.A. Ruzhitskaya 2354

**Research on UV/$TiO_2$ Photocatalytic Oxidation of Organic Matter in Drinking Water and its Influencing Factors**
J.H. Zhao 2358

**The Development of Prestressed Concrete Cylinder Pipe in China**
H.Y. Zhang, H. Peng and X. Chen 2363

**The Single-Sludge Denitri-Nitrification System in Reconstruction of Wastewater Treatment Plants in the Russian Federation**
E. Gogina and I. Gulshin 2367

**Study on the Treatment of Compound Micro-Polluted Groundwater by Contact Oxidation Process under Different Filtration Rates**
Y.H. Zhao, J. Cheng, X. Yan and D. Wang 2370

**Ultra-High-Rise-Building Water Supply and Drainage System Design**
Y.N. Si, M. Zhou, Y.H. Liu and L. Deng 2374

**Treatment of Raw Water in Yangtze Chenhang Reservoir by Diatomaceous Earth Precoat Filtration**
W.Q. Zhou, D. Zhang, H. Ye, Z. Wang, Z. Yang and C.L. Zhang 2380

**Choosing an Optimal Trenchless Renovation Method for Pressure and Non-Pressure Pipes**
V. Orlov and I. Averkeev 2384

**Design and Development of the Urban Water Supply Pipe Network Information System Based on GIS**
X.H. Wang, Y.J. Liu, Z. Wang and W. Zhang 2389

**Model Precision Assessment of Water Distribution System Based on Uncertainty Analysis**
S.H. Shu, X.M. Zheng and J.L. Ruan 2394

**The Selection of Priority Pipe Sections for Sewer Network Renovation**
V. Orlov and A. Andrianov 2398

**Hydraulics of Looping**
J. Zolotova 2403

**The Water Usage Method and Spatial Structure Type of Spring Village in Northern China**
Y.W. Kong 2408

## Chapter 9: Heating, Gas Supply, Ventilation, Air Conditioning Works and Daylighting Design

**Simulation and Analysis of Thermal Performance of Internal Recycle Double Skin Facades**
C. Hui, Y.Q. Wang, B. Wang, W. Tao and S.L. Zheng 2415

**Analysis and Evaluation for the Economic Performance of Ground Source Heat Pump System with Waste Heat Recover**
Z.C. Zhao, W.X. Feng, H.J. Mi and Y. Xue 2421

**Experimental Investigations on Effect of Particles Removal in Cleanroom with Non-Unidirectional Airflow**
Y. Wang 2428

**Calculation and Analysis of Gravity Head Coefficient in Hot Water Heating System**
W.W. Xie and Y.Z. Fu 2432

## Chapter 9: Heating, Gas Supply, Ventilation, Air Conditioning Works and Daylighting Design

**Study on the Current Situation of Economic Analysis of Ice Storage Air-Conditioning System**
Y.N. Li, S.F. Wang, T.Z. Lv and S.F. Lang 2441

**A CFD Simulation of Indoor Natural Ventilation of a Residential District in Zhuzhou**
Z.Y. Wang, S.F. Yang, C.R. Liu, T.Y. Zhang and N. Cui 2447

**Analysis of Influence Factors on the Internal-Melt Ice-on-Tube while Melting**
Y. Liu 2452

**Effect of the Circulation Flow Velocity in Ground Heat Exchangers on System Operation**
Z.S. Qi, Q. Gao, Y. Liu, Z.H. Gao and L. Bai 2457

**Energy Saving Design of a Training Center in Dongguan**
X.J. Lai, Z.H. Du and Z.Q. Zhang 2461

**Calculation of the Maximum Length of the Directly Buried Cooling Pipes Applied in the District Cooling System (DCS)**
C.Y. Tan, H.H. Hu, M.M. Wang, Z.Z. Pan and H.Q. Wang 2466

**Discussion on Ventilation Requirement for Meeting Indoor Air Quality**
M.J. Lin, Q.Q. Liu and Z.M. Peng 2471

**Simulation Study on Characteristics of Ultra-Low Temperature Heat Pump Air Conditioning System for Pure Electric Vehicles**
H.J. Li, G.H. Zhou, A.G. Li, X.G. Li, J. Chen and T. Chen 2475

**The Effectiveness of Implementing Automated Ventilation System in Premises Intended for Public Using**
S. Shilkina and A. Trusov 2480

**"Breathing House" – New Air System for Healthy Residential Buildings**
T.X. Dong and Z.Y. Yan 2484

**Research on the Construction Technology of Radial Underground Heat Exchanger and its Heat Exchange Performance**
R.H. Wang, Q.H. Wang and Y. Feng 2488

## Chapter 10: Oil, Gas and Mineral Exploration

**Optimization of Acid Fracturing Design in Yubei Fractured Reservoir**
L.Y. Song, X.R. He and J.C. Zhang 2495

**Optimization of Black Oil Model-CO2 Flooding in Low Permeability Reservoir**
L.Y. Song, J.C. Wei, X.M. Xu and T. Gao 2502

**Experimental Study of Self-Suction Spraying with Pressure Gas and Water**
Z.F. Ma, G.R. Lin, Z. Zhang and H.L. Xie 2508

**Study on Surface Deformation Law of Western Chengchao Iron Induced by Underground Mining**
Y.C. Zhou, C.X. Chen, X.M. Liu and K.Z. Xia 2513

**Adsorption Research of Polymer on Oil Sands in Qidongyi Block of Xinjiang Conglomerate Reservoir**
X.B. Nie, Y. Guo, Q.X. Lou, W.D. Liu, L.H. Sun and J.Y. Li 2518

**Analysis on Permeability of High Permeability Layer-Penetration Oil Influencing Factors**
Y. Fang 2524

**Industry Clusters Innovation Action Model Based on the CAS Theory – Shanxi Magnesium Industry**
F.Z. Luo and S.L. Liu 2528

**Research on Construction Technology of the High Permeability Type Layer-Penetration Oil Production**
G. Hu 2533

**Research on High Permeability Layer-Penetration Oil Production**
Q. Guan 2539

**The Influences and the Mechanism of Action of Grinding Aid Agent during Micro Fine Particle of Lean Hematite Ore of Grinding Operation**
B. Liang, J.R. Zhang, M.M. Han and L.B. Zhao 2545

**Rapid Excavation Technical Research of Blasting Mining Face in Liangzhuang Mine**
Z.B. Yan, X. Xu, T.T. Li, S. Wu and S.Y. Ma 2550

**Numerical Simulation Study on Setting Stopping Line of Working Face in Shuguang Mine**
H.J. Xue, J. Chen, B. Liu, J. Kong and Z.J. Hao 2554

**The Research of Gas Drainage Technology in Daning Coal Mine**
Z.M. Zhao and G. Wang 2558

## Chapter 11: Disaster Prevention and Mitigation

**Analysis on Wind-Induced Vibration of Tall Buildings in Hilly Terrain**
Y. Sun, N. Deng and Z.L. Li 2567

**Energy Absorption Numerical Analysis of Mine Impingement Thin-Walled Components with Different Configurations**
Z. Tang, Y.S. Pan and X.J. Zhu 2572

**Freezing Damage Analysis of Jintaizi Fishing Floor Engineering in Fuyu**
L.J. Dou, W. Wang and M.Y. Xu 2579

**Mechanical Properties and Calculation Method for Monolayer Cable Net Glass Curtain Wall under Fire Conditions**
L.F. Gong, Y. Bai and S.Q. Li 2583

**Pregnant Mechanism and Mechanical Model of Rock Landslides in Chair-Shaped Cataclinal Bank Slopes**
X.C. Ma, X.C. Chen and Y.J. Feng 2589

**Research on Method for the Weight Definition of Evaluation Indicator in Dump Landslides Based on Rough Set**
T.T. Luan, Z.H. Xie and S.S. Liang 2600

**Study on Ignition Time of Radiation Cargo in Irradiation Room under Stuck Radioactive Sources**
X.L. Yao 2607

**The Coupling Interaction in the Rankine Method for Concrete Filled Steel Tube Columns under High Temperatures**
Y. Yao and X.X. Hu 2612

**The Design of Unascertained Fire Risk Evaluation System for High-Rise Civil Building Based on VB**
L.N. Zhang, J. An and Q. Zhang 2616

**A Study of Storm Surge Risk Index System**
Q. Liu and Z.Z. Yuan 2622

**Review of Different Methodologies and Risk Assessment Models Instorm Surge Disaster Management**
Q. Liu and S. Yang 2628

**A Forecast and Risk Assessment Model for Storm Surge Impacts**
L. Zhang, Q. Liu and S. Yang 2635

**Survey of Fire Load in Building Furniture Store**
J.P. Wang 2642

**The Research on Structure Fire Resistance Test of Fire Retardant Rigid Polyurethane**
J.P. Wang 2646

**Tornado Hazard Loss of Nuclear Power Plant Building during Design Service Period**
T. Song and L.Y. Lu 2649

**Comparative Analysis of Wind Load for Transmission Tower between Chinese and American Codes**
Z. Xu, Y.J. Zeng, D.J. Cao, X.J. Lang and L. Tian 2654

**Landslide Susceptibility Zonation Based on the Analytic Hierarchy Process and Information Method**
D.D. Qiu, R.Q. Niu and Y.N. Zhao 2658

**Modelling of the Human Behavior in Evacuation**
L. Wei, C.Y. Zhao and W.F. Yuan 2663

**Numerical Simulation on Ghosting Fire in the Confined Underground Space**
P.H. Zhang, X.W. Lu and X.M. Zhang 2667

**Research on Concrete Columns Seismic Performance of Super Early-Strength Composite Fibers after High Temperature**
C.Z. Sun, R.X. Wu and H.N. Zhao 2671

**The Analysis of Hysteretic Behavior of Concrete Filled Double Skin Steel Tubular after Exposure to Fire**
X. Liu, J.T. Bao and B. Wang 2675

**The Construction of Emergency Logistics System Framework and Information Platform System**
W.K. Chen and C. Hua 2679

**Vulnerability Assessment of Truss Structure Based on Strain Energy and Damage Scenarios**
Y. Xu, X.C. Yu and W.B. Li 2686

**Deformation Monitoring and Prediction of a Reservoir Landslide in Sichuan Province, China**
B. Han, S.S. Hou, B. Zhu, L.C. Wang, A. Li and H.J. Ye 2694

**Mechanical Performance Calculation of Single-Layer Cable Mesh Point-Supported Glass Curtain Wall under Fire Conditions**
L.F. Gong, Y. Bai and S.Q. Li 2702

**Design and Realization of 3S Technology-Based Geological Disaster Database System in Liaoning Province**
H. Ding, L.S. Sun, J.L. Wang and X. Wang 2708

**Monitoring of Flooding Water under Coal Mine Based on Improved Fuzzy Clustering**
M.Y. Nie, M.R. Zhou and X.Q. Fu 2713

**Review on Study of Fire Behavior of Bridges in China**
Y.J. Liu, Y. Yao, X.X. Li and X.D. Chen 2717

**Risk Assessment of Debris Flow Based on Multi-Objective Fuzzy Pattern Recognition Method in Mountain Highway Construction**
Y. Wang 2722

**Case Study of Fire Risk Management of Tourist Hotels**
R.J. Shiu, S.T. Cheng and I.T. Liu 2727

**Multivariate Geometric Factors Contributing to Crashes and Injuries in Mountainous Freeways: A Case Study from Jiangxi, China**
M. Li, Y.G. Wang and X. He 2731

**The Analysis of Safety Investment Behavior of the Long-Term Incentive Mechanism in Construction Enterprise**
Y.B. Shui, Q. Li and H. Li 2735

**Research on Functional Adaptation of Sport Venues as a Disaster Prevention Refuge**
L.D. Huang and T.Y. Zhang 2740

## Chapter 12: Cartography and Geographic Information System

**A Research on Digital City Three-Dimensional Visualization System Based on Skyline**
H.B. Dai, X.J. Yue and J.Y. Xu 2745

**A Study on Informatization Construction of Sharing "One Map" between Land and Planning Departments**
G. Yang and T.T. Zhou 2749

**The Visualization of Health Monitoring System for Bridge Using CORS and GIS**
Q.L. Kong, Y.H. Li, L.T. Han and J.Y. Guo 2756

**Research on the 3-D Scene Quick Build Method of Virtual City and Implementation Method of Basic GIS Function**
C. Yang, H. Li, P. Gao and R.C. Zhang 2760

**Application of Three-Dimensional Visualization Technology in Real Estate Management**
J. Cui, J.J. Ma, D.L. Ma and N.N. Yang 2765

**Calculation of Land Consolidation Potential Based on GIS**
Y.H. Liu and W.Q. Chen 2769

**Information Management of Maritime Work Based on GIS**
J.P. Liu, F.L. Dong and J.W. Shao 2774

**Design and Fabrication of Dynamic Thematic Maps Based on Flash**
Y.X. Xu and J.W. Yang 2778

**Development of Topographic Maps Symbols Library**
C.M. Sun and Y.X. Xu 2782

## Chapter 13: Surveying Engineering

**Application of Total Station in the Measurement of Transmission Line**
F.R. Gui 2789

**Chinese Geodetic Coordinate System 2000 and its Comparison with WGS84**
H.P. Li, S.F. Bian and Z.M. Li 2793

**Discussion on the Measurements in Cantilever Construction with Guyed Hanging Basket**

**Keywords:**Piled raft, Settlement, Plaxis 3D Foundation

**Abstract.**This paper highlights settlement behaviour of piled raft foundation by 3D finite element analysis through Plaxis 3D Foundation program. The effects of pile number, pile length, pile layout and pile spacing on the behaviour of piled raft foundation were studied.The numerical results show that:Piled raft foundation has much more efficency to reduce settlement than that of traditional raft foundation. The value of vertical defomation decreases as the result of the increase of pile number, pile length, pile spacing and vice versa. Pile layout has significant effect on both value and location of maximum settlement of piled raft foundation.

## Introduction

In the recent years, piled raft foundation (PRF) has been more and more popularly applied to increase load capacity and reduce settlement in a very economic way comparing with traditional foundation concepts. Many researchs on piled raft foundation engineering have been published, such asBaziar et al. [1], Poulos et al. [2], Poulos[7], Randolph[8], Poulos and Davis [9]. Analysis methods related to PRFwere presented in[3-6].

This study concentrates on the effect of engineering factors related to pile in raft foundation such as number of pile, pile length, pile layout and pile spacing on the behaviour of the piled raft foundation; analysis is carried out by 3D finite element method via Plaxis 3D Foundation software.

## Finite Element Modelling

Among different numerical modeling approaches, finite element technique is popular in recent years in the field of foundation engineering. To date, a variety of finite element computer programs have been developed with a number of useful facilities and to suit different requirements. The analysis method in this study refers to three dimensional finite element methods (FEM)[10] via Plaxis 3D Foundation software. In the analysis, raft and piles are in elastic state. The nonlinear behavior of soil has been modeled with elastic idealplastic constitutive model with a Mohr Coulomb yield criterion.

The finite element mesh can be generated automatically after the full geometry model has been defined and all the components have their initial properties. The elements used for meshing of subsoil are 15-node wedge elements.

## Numerical examples and parametric studies

A 8x8x1m piled raft with massive circular piles which have diameter of 0.4m and length of 10m is used as numerical example for parametric studies. Foundation is subjected to a 100KN/m$^2$ uniformly distributed load. The displacement due to effect of selfweight was ignored.The model was extended in both horizontal directions to a width of 16m to advoid any influence of the outer boundary. Number of pileswas varied to investigate the effect on the settlement of foundation with different layout such as: raft foundation without piles, raft foundation with various pile layouts from one to nine piles.This raft was also used to consider the influence of the pile length and the pile layout.Horizonal dimensions of the raft were changed according to the change of pile spacing

butthe dimension between the border pile row and the raft edge of 2D (D is pile's diameter) was kept remain.

The surveyed ground includes 2 layers with the thickness of layers are 5m and 18m respectively. Soil properties and material model are shown in the

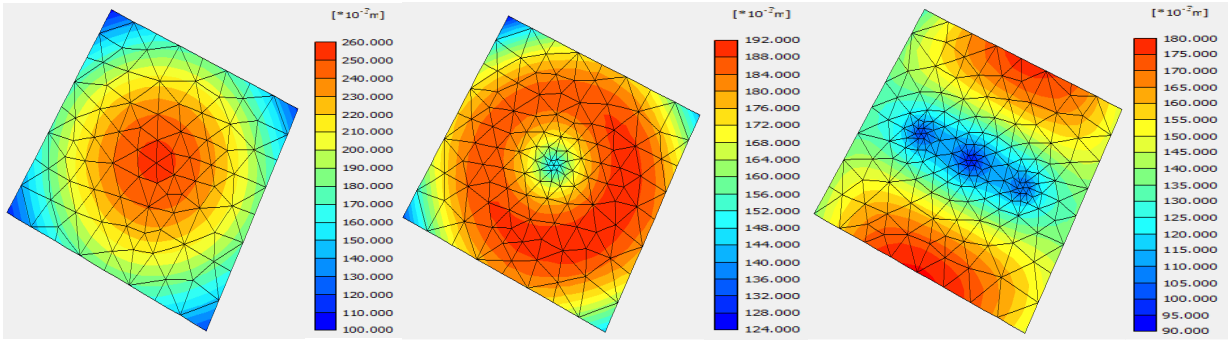
Table 1. Pile and raft are concrete with the behaviour of linear elastic and Young modulus of $2.9*10^7 kN/m^2$.

Table 1. Soil properties

| Properties | Layer 1 | Layer 2 |
|---|---|---|
| Depth (m) | 0-5 | 5-23 |
| Unit weight ($kN/m^3$) | 16 | 17 |
| Material model | Mohr Coulomb | Mohr Coulomb |
| Cohesivec ($kN/m^2$) | 10 | 5 |
| Internal friction angle (degree) | 15 | 25 |
| Deformation modulus ($kN/m^2$) | 4500 | $2*10^4$ |
| Poisson's ratio | 0.3 | 0.2 |

### *3.1. Effect of number of piles*

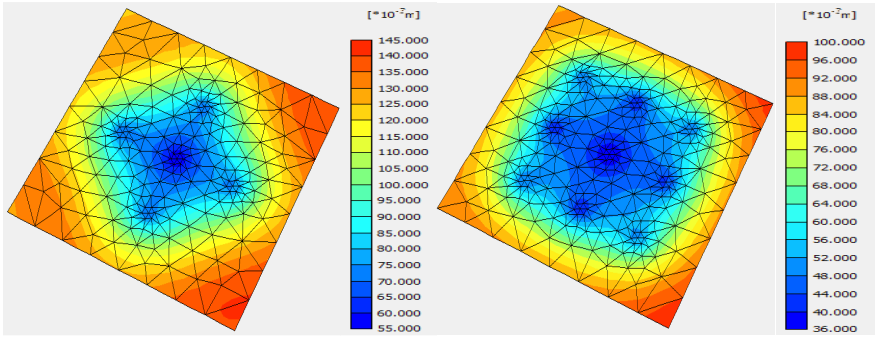
Apiled raft foundation 8x8x1m, which has variablenumber of piles was loaded with a uniformly distributed force of $100kN/m^2$. The results of settlement of the foundation in cases of raft only, raft with single pile, raft with 3 piles, raft with 5 piles and raft with 9 piles were illustrated in Fig. 1(a-e) respectively.



a) Raft without piles $U_{max}= 252.55*10^{-3}m$

b) Raft with 1 pile $U_{max}= 190.78*10^{-3}m$

c) Raft with3 pile $U_{max}= 176,41*10^{-3}m$



d) Raft with 5 piles $U_{max}= 140.44*10^{-3}m$

e) Raft with 9 piles $U_{max}= 98.15*10^{-3}m$

Fig. 1Settlement of the raft with different number of piles

Fig. 2 and Fig. 3show the load-settlement curves at center of the raft and at midle point of the raft edge.

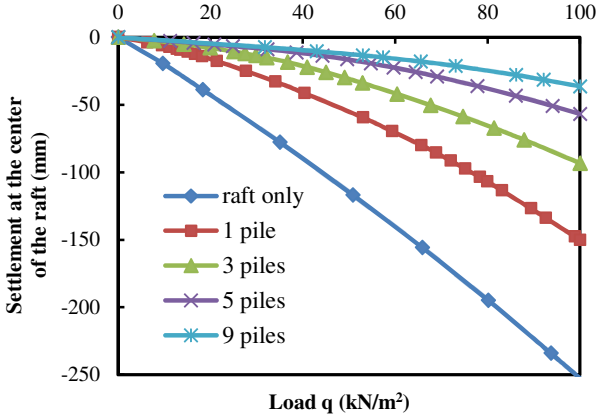


Fig. 2 Load-settlement curve at the centre of the raft

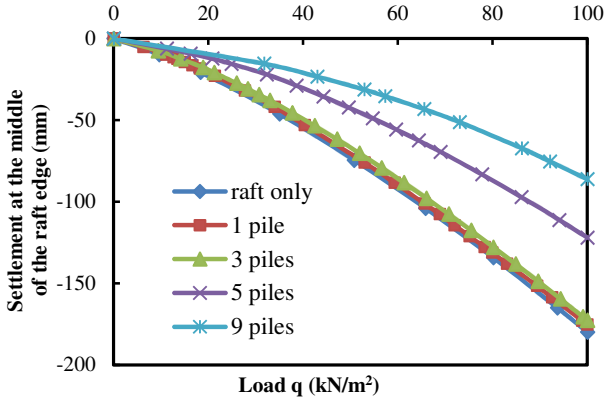

Fig. 3 Load-settlement curve at the middle of the raft edge

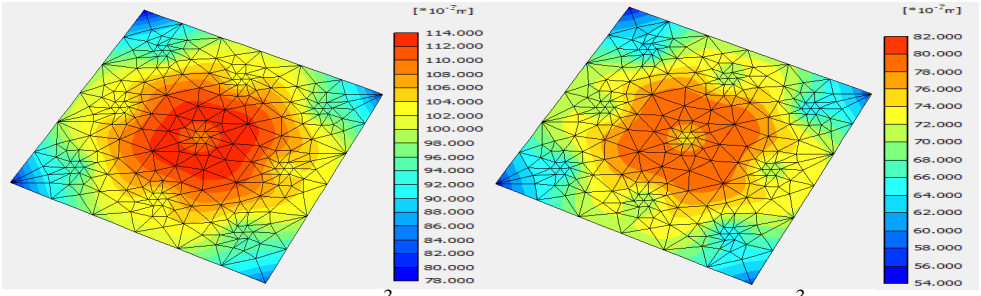
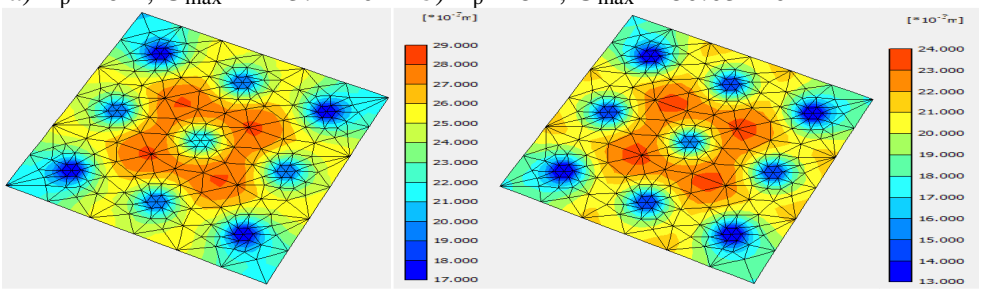
The numerical results show that: piled raft foundation is more efficient than traditional raft foundation in reducing settlement. The increase of pile number results in the decrease of global and diffirential settlement and vice versa.

### *3.2. Effect of pile length*

A piled raft foundation 6x6x1m, which was reinforced by 9 piles with diameter of 0.4m,was loaded with a uniformly distributed force of 100kN/m$^2$. The pile spacing was S=5D=2m. The distance from border pile row to the raft edge was 2.5D=1m. The Fig. 4(a-d) show the results of the foundation settlement in cases thatthe length of piles were 6m, 8m, 10m and 12m respectively.



a) $L_p$ = 6m, $U_{max}$ = 113.2*10$^{-3}$mb) $L_p$ = 8m, $U_{max}$ = 80.03*10$^{-3}$m



c) $L_p$ = 10m, $U_{max}$ = 28.26*10$^{-3}$md) $L_p$ = 12m, $U_{max}$ = 23.38*10$^{-3}$m

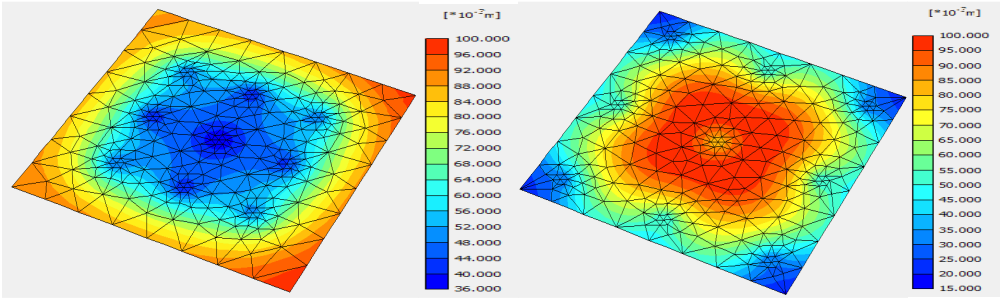
Fig. 4Settlement of the raft with different piles length, number of piles are 9

Numerical results show that the vertical displacement declined due to the growth of pile length. However, the efficency in the settlement decrease is not the same in cases of different pile length increases. The maximum settlement was reduced by 33.17*10$^{-3}$m from 113.2*10$^{-3}$m to 80.03*10$^{-3}$m, approximate 29.3% when the pile length varied from 6m to 8m. The maximum settlement was reduced significantly by 51.77*10$^{-3}$m from 80.03*10$^{-3}$m to 28.26*10$^{-3}$m, approximate 64.7% when the pile length varied from 8m to 10m. Meanwhile, the maximum settlement unnoticealely

decreased only by 4.88*10$^{-3}$m from 28.26*10$^{-3}$m to 23.38*10$^{-3}$m, approximate 17.3% when the pile length increase from 10m to 12m.

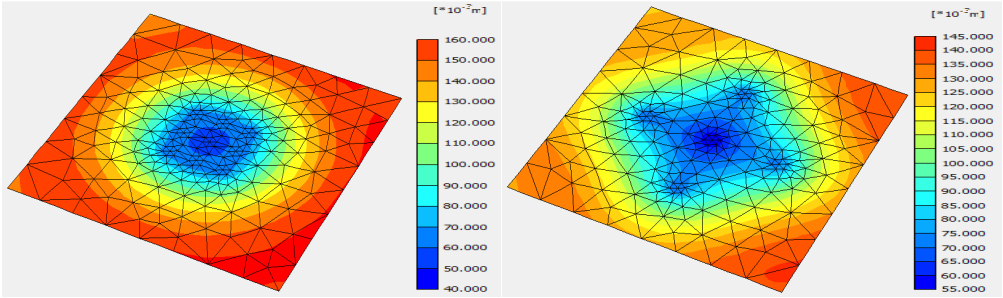
### *3.3. Effect of pile layout*

Both the location and the value of the maximum settlement was highly infuenced by the pile layout.Fig. 5(a-c)express the different results on the settlement when the raft was embeded with the same 9 piles but different layout.Fig. 5a and b (pile spacing was 5D and 8D respectively) illustrate the similar value around 98*10$^{-3}$mbut different location of maximum settlement to each other. Meanwhile, the maximum settlement in Fig. 5c (pile spacing S=2D and piles concentrated to the center of the raft) was 154.30*10$^{-3}$m which was much bigger than those in the previous cases. TheFig. 5d shows the settlement of the raft which was embeded with 5 piles. As can be seen that this value was smaller than the value in Fig. 5c although there were more piles in Fig. 5c (9 piles) comparing toFig. 5d (only 5 piles).



a) Raft with 9 piles, S=5D, $D_b$=2mb) Raft with 9 piles, S=8D, $D_b$=0.8m

$U_{max}$ = 98.15*10$^{-3}$m $U_{max}$ = 98.83*10$^{-3}$m.



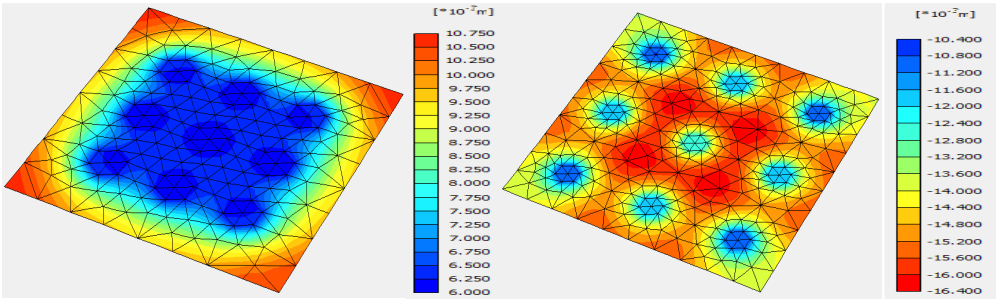
c) Raft with 9 piles, S=2D, $D_b$=3.2md) Raft with 5 piles, S=5D, $D_b$=2m

$U_{max}$ = 154.30*10$^{-3}$m $U_{max}$ = 140.34*10$^{-3}$m.

Fig. 5 Effect of pile'slayout on the maximum settlement of the foundation

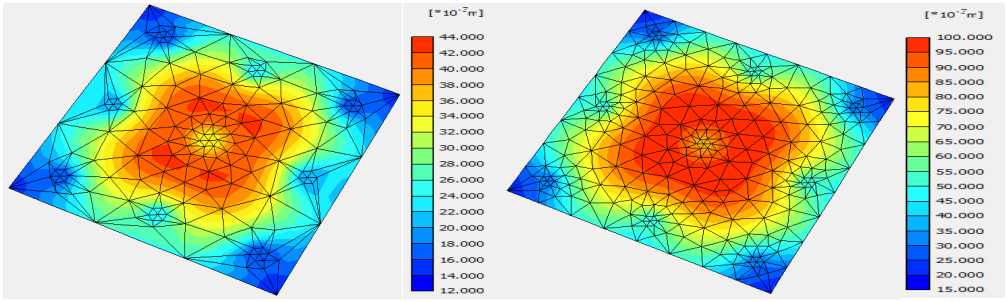
### *3.4. Effect of pile spacing*

Effect of pile spacing was studied by using 9-pile-rafts, which had varied pile spacing as 2D, 4D, 6D and 8D and unchanged dimention from border pile row to the raft edge of 2D.The results shown in Fig. 6illustrate that the settlement will increase due to the growth of pile spacing and vice versa. However the effect of increase of pile spacing on the settlement was not unchanged. The maximum vertical displacement grew up only by 5.64*10$^{-3}$m (about 53%) when the spacing increased from 2D to 4D. Meanwhile, when the spacing increased from 4D to 6D and from 6D to 8D, the maximum settlements experienced the growths from 16.26*10$^{-3}$m to 42.37*10$^{-3}$m (increase about 160%) and from 42.37*10$^{-3}$m to 98.83*10$^{-3}$m (increase about 133%).



a) Pile spacing S=2D
$U_{max} = 10.62*10^{-3}$m

b) Pile spacing S=4D
$U_{max} = 16.26*10^{-3}$m



c) Pile spacing S=6D
$U_{max} = 42.37*10^{-3}$m

d) Pile spacing S=8D
$U_{max} = 98.83*10^{-3}$m

Fig. 6 Effect pile spacing on the settlement of the foundation

## Conclusion

The numerical results reveal the following conclusions:

(1) The settlement behaviour of piled raft foundation was depended on several factors such as number of piles, pile length, pile layout and pile spacing.

(2) The increase of pile number will lead to the decrease of both global and differential settlement.

(3) The settlement of the foundation will be reduced due to the growth of pile length and vice versa.

(4) The layout of piles have significant effect on not only the value but also the location of maximum settlement.

(5) The settlement behaviour of pile raft foundation is also affected by pile spacing, an increase of pile spacing will lead to an increase of settlement and vice versa.

**Key words:** geotechnical parameter; entropy principle; small samples; stochastic weighted; probability distribution

**Abstract.** Due to various uncertainties, most of geotechnical parameters are small samples, which causes much trouble when the probability distribution of geotechnical parameter is fitted using traditional distributions. This paper uses stochastic weighted method to improve the small samples of Geotechnical parameters into big samples, thus solving the problems caused by the small samples. Meanwhile, the probability density function of geotechnical parameter is derived based on maximum entropy principle, the advantage of presented method is verified through Kolmogorov-Smirnov Test. Case study shows that the proposed method not only overcomes the dependence of conventional fitting methods on classical probability distributions, but also the fitting more close to the fact because the data come from the big sample improved by geotechnical parameters, which has important engineering significance.

## Introduction

It is well accepted that uncertainties in geotechnical engineering design are unavoidable and numerous practical advantages are realizable if uncertainties and associated risks can be quantified[1]. The values of soil properties used in geotechnical engineering and geomechanics involve a significant level of uncertainty arising from several sources such as: inherent stochastic heterogeneity (also referred to as spatial variability), measurement errors, statistical errors (due to small sample sizes), and uncertainty in transforming the index soil properties obtained from soil tests into desired geomechanical properties[2].

The reliance on the observational method is an implicit recognition of this critical aspect. There is a growing awareness that explicit recognition and treatment of uncertainties can serve to supplement traditional risk reduction methods such as the observational method. Deng presented a distribution-free algorithm by combing maximum entropy with sample moments for estimating probability curves directly from experimental or field sample data of rock stochastic variables. Zheng[3] study Each stochastic variable influencing on the reliability of the vertical bearing capacity for pile in the dimensionless limit state equation, and use the maximum entropy principle to transform iterative calculation of reliability index into a maximum entropy density function calculation.

Based on the principle of information spread, Gong[4] proposed normal information spread estimation method(NISEM) to generate probability density functions ogeotechnical parameters with small samples. Zhou[5] employed the polynomial approximation based on stochastic weighted method to generate probability density functions of geotechnical parameters with small samples, and used stochastic weighted method to resample from the present samples so as to get the origin moment of the total. Zhang[6], Kwak[7], Li[8] and Dithinde[9] used normal distribution and log-normal distribution to fit the bias factor of axial capacity for piles aiming to analysis reliability influenced by various uncertainties.

Currently, Maximum entropy(Maxent) principle has been increasingly used to calculate the probability distribution. Jaynes[9] presented the maximum entropy(Maxent) principle as a rational approach for choosing the most unbiased probability distribution, amongst all possible distributions. When only moment constraints are considered, Phillips[10] introduced the use of the maximum entropy(Maxent) method for modeling species geographic distributions with presence-only data. Hyon[11] employed the maximum entropy principle for finite extensible nonlinear elasticity(FENE) model to obtain the solution which maximizes the entropy of FENE model in stationary situations. Zhao[12] proposed the fuzziness of the damage process to be given full consideration when to analyze the reliability of vertical capacity of pile under the condition of the model subjected to vertical load of pile using the principle of maximum entropy(MaxEnt). Banavar[13] presented an application of the principle of maximum entropy(MaxEnt) to understanding species diversity in ecology and introduce a new statistical ensemble corresponding to the distribution of a variable population of individuals into a set of species not defined a priori. The deficiency of above studies is dependent on classical probability distributions.

This paper uses the stochastic weighted method to improve the small samples of geotechnical parameters into big samples. Meanwhile, the probability density function of geotechnical parameter is derived based on maximum entropy principle. Finally, the validity of presented method is illustrated through case study.

## Stochastic weighted method

Stochastic weighted method proposed by Zheng[14] overcome the deficiencies of Bootstrap method used to deal with confidence interval and estimating error. Currently, stochastic weighted method has been employed to solve the problems caused by small sample of engineering.

Assuming the geotechnical parameters $X=(x_1,x_2,\cdots,x_n)$ as independent and identical distribution, the mean and variance of independent and identical distribution are $\bar{x}$ and $S_X^2$. The mean and variance of total sample for geotechnical parameters are $\mu$ and $\sigma^2$. Therefore, there is a deviation between fact value and statistic characteristics of geotechnical according to statistic principle, which is

$$R_n^{(1)}=\bar{x}-\mu_x, R_n^{(2)}=\frac{n}{n-1}S_x^2-\sigma_x^2 \tag{1}$$

Based on stochastic weighted method, establishing the weighted statistic of deviation $R_n^{(1)}$ and $R_n^{(2)}$ as

$$\left.\begin{aligned} D_n^{(1)} &= \sum_{i=1}^{n} V_i x_i - \bar{x} \\ D_n^{(2)} &= \frac{n}{n-1}\sum_{i=1}^{n} V_i (x_i - \bar{x})^2 - \frac{n}{n-1} S_x^2 \end{aligned}\right\} \tag{2}$$

where $(v_1, v_2, \cdots, v_n)$ is Dirichlt variables obeying $\mathrm{D}(1,1,\cdots,1)$.

According to Eq.(1) and Eq.(2), the following equation can be obtained

$$E[D_n^{(1)}] = E[R_n^{(1)}], \quad E[D_n^{(2)}] = E[R_n^{(2)}] \tag{3}$$

Based on Eq.(3), the statistic characteristics of $\mathrm{D}_n^{(1)}$ and $\mathrm{D}_n^{(2)}$ can approximately replace statistic characteristics of $R_n^{(1)}$ and $R_n^{(2)}$, respectively. Consequently, according to Eq.(1), Eq.(4) can be written as

$$\mu_x = \bar{x} - R_n^{(1)}, \quad \sigma^2 = \frac{n}{n-1} S_x^2 - R_n^{(2)} \tag{4}$$

Substitution of Eq.(2) into Eq.(4) and subsequent equation leads to the following solution:

$$\left.\begin{aligned} \hat{\mu}_x &= 2\bar{x} - \sum_{i=1}^{n} V_i x_i \\ \hat{\sigma}_x^2 &= 2\frac{n}{n-1} S_x^2 - \sum_{i=1}^{n} V_i (x_i - \bar{x})^2 \end{aligned}\right\} \tag{5}$$

where $\hat{\mu}_x$ and $\hat{\sigma}_x$ are the estimated values of the mean $\mu$ and the variance $\sigma^2$.

**Maximum entropy principle and computational process**

How to ensure which result occurs is the main characteristic of a stochastic test, it is an important problem because the uncertainties caused by a stochastic test can be quantitatively analyzed if the results are available. Zheng[3] defined a measure of uncertainty, referred to as entropy, similar to that used in thermodynamics and statistical mechanics to solve above problem. For a continuous stochastic variance *x*, the entropy can be expressed as

$$H[f(x)] = -\int_R f(x) \ln f(x) dx \tag{6}$$

where $f(x)$ is the probability density function of $x$; $R$ is the domain of $x$; $H[f(x)]$ is the information entropy of $x$.

Based on probability statistics theory, the main probabilistic characteristics of stochastic variables can be described using first four moments. Accordingly, the probability density function should satisfy the following conditions

$$\left.\begin{aligned} & f(x) \geq 0 \\ & \int_R x^i f(x) dx = \mu_i \quad i = 0,1,2,3,4 \end{aligned}\right\} \tag{7}$$

Information entropy is a parameter to measure system information, and the less degree of system uncertainty is, the less entropy is, but system can offer more information; In contrast, larger entropy can be obtained when the degree of system uncertainty becomes larger, and then less information from system is available. Therefore, if the entropy of a distribution subjected to a set of constraints reaches the maximum value, then the information of this distribution is most objective, and the model of this distribution can be formulized as[3]

$$\text{Max.} \quad H = -\int_R f(x)\ln f(x)dx \tag{8}$$

Eq.(8) is a optimization model containing constraint conditions, which can be solved using variation method. Dividing the domain $R$ into $2n$ equal segments described in Fig.(1), and the step length is $h$, hence $x_i = ih$. Therefore, Eq.(7) and Eq.(8) can be transform as

$$\int_{-n}^{n} a_i f(ih)dx = \mu_i \quad i = 0,1,2,3,4 \tag{9}$$

$$H = -\sum_{i=-n}^{n} hf(ih)\ln f(ih) \tag{10}$$

where

$$\begin{cases} a_0 = h;\ a_1 = ih^2;\ a_2 = (i^2 + 0.083)h^3; \\ a_3 = (i^3 + 0.25i)h^4; a_3 = (i^4 + 0.125i^2 + 0.0125)h^5 \end{cases} \tag{11}$$

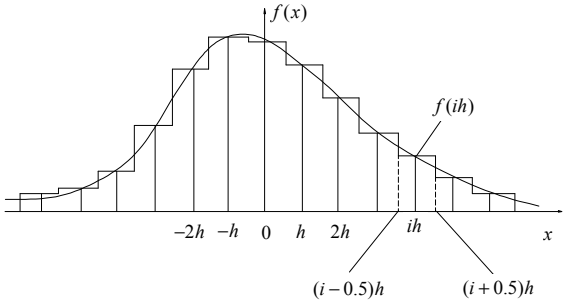

**Fig 1. The diagrammatic sketch of the defining field of stochastic variable** $x$

Based on lagrange multiplier $\lambda_0, \lambda_1, \lambda_2, \lambda_3, \lambda_4$, Establishing Lagrangian function as

$$L = \sum_{i=-n}^{n} [f(ih)(-\ln f(ih) + \sum_{j=0}^{4} a_j \lambda_j) \tag{12}$$

According to Fermat's theorem and $\frac{\partial L}{\partial f(ih)} = 0$, Eq.(13) can be obtained

$$f(ih) = \exp(-1 + \sum_{j=1}^{5} a_j \lambda_j) \tag{13}$$

$f(ih)$ is a function including five variables according to Eq.(11) and Eq.(13). Substitution of Eq.(13) into Eq.(9) and subsequent equation leads to a nonlinear equations including five variables $\boldsymbol{\lambda} = \lambda_0, \lambda_1, \lambda_2, \lambda_3, \lambda_4$ as

$$F(\boldsymbol{\lambda}) = 0 \tag{14}$$

Newton iteration method is a good method to solve the nonlinear equations, which is employed the nonlinear equation as Eq.(14), and the computation is come true using MANLAB programming language.

**Computation step of stochastic weighted entropy**

In engineering practice, geotechnical parameter samples are mostly small samples due to various uncertainties arising from the variability exhibited by properties of geotechnical materials from one location to the other, even within nominally homogeneous profiles. The geotechnical parameters $x_0, x_1, \cdots, x_n$ is from total distribution. Based stochastic weighed entropy, the probability density function of geotechnical parameters can be obtained using following steps.

Firstly, the data from engineering are arranged as the observed sample $X = (x_0, x_1, \cdots, x_n)$, thus the observed sample is a small sample.

Secondly, the small sample $X = (x_0, x_1, \cdots, x_n)$ of geotechnical parameters is improved into big samples, thus solving the problems caused by the small samples $\widehat{X_i} = \sum_{i=1}^{N} v_i x_i$. To improve the computational accuracy, weighted times should be as many as possible.

Thirdly, The subsample of geotechnical parameter is given through *N*-times simulations using Monte Carlo simulation method.

Fourthly, the first four moments of probability density function for geotechnical parameters is computed using subsample.

Fifthly, the entropy density function of geotechnical parameters is calculated using maximum entropy principle.

**Case study**

Dithinde[9] presents four load test databases from South Africa for driven piles in noncohesive soils (29 tests), bored piles in noncohesive soils (33 tests), driven piles in cohesive soils (59 tests), and bored piles in cohesive soils (53 tests). Xu[15] used a method for data processing and optimization in geotechnical engineering to optimize above data, and good data are obtained in table 1 and table 2. In table 1 and table 2, $\lambda_R$ is the ratio of measured value and calculated value of capacity for piles.

Based on classical probability distributions, the statistical parameters and types of distributions optimal probability distribution are shown in table 3.

**Tab.1 Good data of $\lambda_R$ for driven piles**

| Case number | $\lambda_R$ | Case number | $\lambda_R$ |
|---|---|---|---|
| 1 | 0.93 | 6 | 0.96 |
| 2 | 0.95 | 7 | 1.21 |
| 3 | 0.85 | 8 | 1.10 |
| 4 | 1.13 | 9 | 1.00 |
| 5 | 1.33 | 10 | 1.05 |

**Tab.2 Good data of $\lambda_R$ for bored piles**

| Case number | $\lambda_R$ | Case number | $\lambda_R$ |
|---|---|---|---|
| 1 | 1.04 | 11 | 1.03 |
| 2 | 1.22 | 12 | 0.80 |
| 3 | 1.11 | 13 | 1.02 |
| 4 | 0.97 | 14 | 0.79 |
| 5 | 1.13 | 15 | 0.97 |
| 6 | 1.15 | 16 | 1.27 |
| 7 | 0.93 | 17 | 0.99 |
| 8 | 1.02 | 18 | 0.78 |
| 9 | 0.83 | 19 | 0.86 |
| 10 | 0.97 | 20 | 0.90 |

**Table 3 Statistical parameters and probabilistic distributions of parameters**

| Types of piles | Statistical parameters | Types of distribution |
|---|---|---|
| driven piles | $\mu = 1.275, \sigma = 0.198$ | Normal distribution |
| bored piles | $\alpha = 1.81, \beta = 2.15$ | $\beta$ distribution |

Testing sample is weighted by 100-times using the proposed method, then employing maximum entropy principle to fit the probability distribution of weighted sample, the entropy density function $f(x)$ of $\lambda_R$ can be obtained. Fig.2 and Fig.3 shown the comparisons of distribution curves of experimental data for driven piles and bored piles.

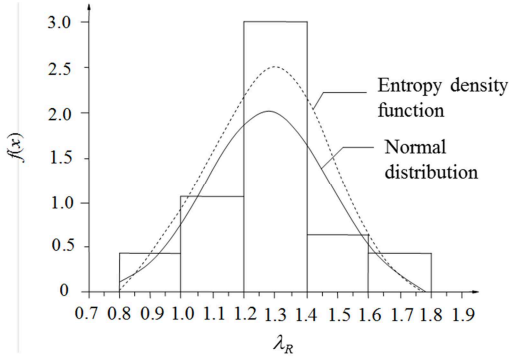

**Fig.2 Comparison of distribution curves of experimental data (driven piles)**

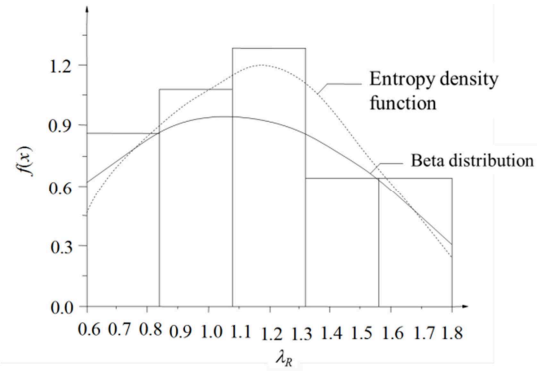

**Fig.3 Comparison of distribution curves of experimental data (bored piles)**

From Fig.(2) and Fig.(3), the proposed method has an advantage that its fitting is more accuracy than classical probability distribution.

In order to further test the valid of the proposed method, K-S(Kolmogorov-Smirnov) testing method is used to compare with the two methods. Assuming the empirical distribution and total distribution are $F_n(x)$ and $F(x)$, respectively. The maximum difference between $F_n(x)$ and $F(x)$ is $D_n$ which can be written as

$$D_n = \max |F_n(x_i) - F(x_i)| \quad i = 1, 2, \cdots, n \tag{15}$$

Assuming the testing level and critical value are $\alpha = 0.05$ and $D_{n,\alpha}$, respectively. According to K-S(Kolmogorov-Smirnov) testing method, the probability distribution of geotechnical parameters accept the distribution of $F(x)$ if the statistic value $D_n$ is not less than critical value $D_{n,\alpha}$.

On the condition that the testing level is $\alpha = 0.05$, the probability distribution of geotechnical parameters may accept several types of probability distributions. Accordingly, to improve the fitting accuracy, a goodness-of-fit test is employed, and the fitting degree is [16]

$$\varphi = 1 - \frac{D_n}{D_{n,\alpha}} \tag{16}$$

Based on Eq.(16) and K-S(Kolmogorov-Smirnov) testing method, the testing results are shown in table 4. From table 4, the fitting accuracy of proposed method is better than traditional method.

**Table. 4 Results of Kolmogorov-Smirnov testing**

| Types of piles | Significance level $\alpha$ | Critical value $D_{n,\alpha}$ | Traditional method $D_n$ | Proposed method $D_n$ |
|---|---|---|---|---|
| driven piles | 0.05 | 0.25907 | 0.07992 | 0.06965 |
| bored piles | 0.05 | 0.28724 | 0.14131 | 0.06098 |

## Conclusion

Due to soil parameter uncertainty arises from the variability exhibited by properties of geotechnical materials from one location to the other, even within nominally homogeneous profiles, geotechnical parameters samples are mostly small samples. This paper put forward a modified method to fit probability distribution of geotechnical parameters according to stochastic weighted entropy, and the following results can be obtained:

(1) This paper uses the stochastic weighted method to improve the small samples of geotechnical parameters into big samples, thus solving the problems caused by the small samples;

(2) Based on maximum entropy principle and stochastic weighted method, the entropy density function of geotechnical parameters is calculated, which not only assures the convergence, but also successfully eliminates the dependence on classical probabilistic distribution. The calculation results are closer to the fact since the data directly comes from samples;

(3) Whether From the comparisons of histogram and curve fitting, or from the results of K-S(Kolmogorov-Smirnov) testing method, the fitting accuracy of proposed method is better than traditional method.

**Keywords:** complex materials; structural materials; full state function; strength theory; constitutive relation.

**Abstract.** The analysis of structural materials, especially the theoretical research, is always a challenge. Starting from the structural characteristics of the material, the theory of full state function about the strength - stiffness - strain that reflects the properties of structural material is established on the basis of the structural state of the material. The full state function is an important method to solve this problem. In order to further analyze the characteristics of the full state function, the full state function, strength theory of the material and the constitutive relation found are first studied. It is found that the full state function can more comprehensively reflect the properties of the structural material. The full state function accommodates the strength theory in the classical elastic-plastic theory. The full constitutive relation of the materials can be derived from the full state function. That is to say, the full state function can unify the strength theory and constitutive relation in the classical theory and can be used for the analysis of the structural materials. The full state function is more than a mere form, because it has explicit physical and mechanical meanings.

## Introduction

In order to describe and solve the structural problems of the materials on the macroscopic scale, literature [1-5] put forward the full state function to describe the properties of the structural materials. The elastic properties of the materials mainly refer to the properties and characteristics of the materials when the morphology of the material remains unchanged. However, the plastic properties of material in the macroscopic sense are the manifestation of the properties of material in the process from one structural state to another. Under a specific structural state, the stress intensity, stiffness and geometric pattern of the material constitute the basic features of the material. In the macroscopic sense, the statistically continuous variations of the material described by the critical strength, stiffness and geometry in all structural states constitute the full state function that reflects the material properties. In the classical elastic-plastic theory, the methods describing the plastic properties are mainly divided into strength theory and constitutive relation. But the classical elastic-plastic theory is only suitable for simple materials without structurality. For materials with strong structurality, the full state function theory works better. This article mainly discusses the mutual influence between the full state function, strength criterion and constitutive relation of the material.

## Conditions for deriving the full state function and its meaning

The full state function theory is based on the basic assumption that the material has structure, which is the cornerstone of this theory. This is essentially different from the classical elastic-plastic theory and falls into the category of mechanical theory for complex materials.

The basic assumptions for the existence of full state function:

(1) Any material has structurality that exists on different scales of the material. The structurality of the material varies with the scale.

(2) The structurality of the material can be described by the model of granular material.

(3) The structural state of the material can be described by the connections between granules and the resulting geometry and constitutive relation in the model of granular material.

(4) Any structural state of the material can be homogenized over a certain area (statistical domain) to obtain the changing values of structural strength, stiffness and geometric pattern under this particular state.

(5) The shift from one structural state to another of the material complies with certain rules [4-5].

The structure of the material will change when influenced by environmental factors, that is, it will shift from one structural state into another. In the granular material model, the structural state is closely related to the granule morphology, granule size distribution, spatial scale and density of granules in space. Of all possible structural state, one structural state cannot shift into another state unless under appropriate conditions. Some structural states can be mutually transformed, but others cannot. The structural states that can be reached are called the attainable structural state. All the attainable structural states form the network of attainable structural states. The values of critical strength, stiffness and geometric variation of structure in all structural states can be fitted into hypersurface equation in the σ-D-ε phase space according to the network of attainable structural states.

$$\Phi\ (\sigma_{ij}^{s}, D_{ijkl}^{e}, \varepsilon_{ij}^{s}) = 0 \tag{1}$$

$\sigma_{ij}^{s}, D_{ijkl}^{e}, \varepsilon_{ij}^{s}$ are corresponding to the critical strength, structural stiffness and the strains of geometric variation between adjacent structures under a specific structural state. This function describes the relation between the critical strength, stiffness and geometric strain under different structural states of the material macroscopically. Thus, it is called the full state function of materials.

For the classical elastic-plastic material which is isotropically continuous, $D^e$ is a constant. Thus equation (1) can be written in the following form:

$$\Phi\ (\sigma_{ij}^{s}, \varepsilon_{ij}^{s}) = 0$$

This, in fact, is the strength criterion of the homogeneous materials, or known as yield function.

**Elastoplastic Theory Based on Full State Function**

According to the definition, full state function reflects the basic performance of materials under a unification framework, so the performance characteristics of materials described by the classical elastoplastic theory can be fully reflected by full state function. Starting with the theory of full state function in this article, the loading condition, flow rule, strength theory and constitutive relation in the classical elastoplastic theory are discussed in the following contents.

**Increments and energy equations in the form of full state function of materials**

According to the form of full state function, its full state potential function is the surface equation in phase space that is determined by modulus of elasticity, critical structural strength and strain tensor.

$$\Phi\ (D_{ijkl}^{e}, \sigma_{ij}^{s}, \varepsilon_{ij}^{p}) = 0$$

It is a hypersurface in phase space σ-D-ε. Its tangent plane equation is solved:

$$\frac{\partial \Phi}{\partial D_{ijkl}^{e}}(D_{ijkl}^{e} - D_{ijkl}^{e0}) + \frac{\partial \Phi}{\partial \sigma_{ij}^{s}}(\sigma_{ij}^{s} - \sigma_{ij}^{s0}) + \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}}(\varepsilon_{ij}^{p} - \varepsilon_{ij}^{p0}) = 0 \tag{3}$$

Where $D_{ijkl}^{e0}$, $\sigma_{ij}^{s0}$ and $\varepsilon_{ij}^{p0}$ are coordinate values on the surface of the selected point.

Suppose $dD_{ijkl}^{e} = D_{ijkl}^{e} - D_{ijkl}^{e0}$, $d\sigma_{ij}^{s} = \sigma_{ij}^{s} - \sigma_{ij}^{s0}$, $d\varepsilon_{ij}^{p} = \varepsilon_{ij}^{p} - \varepsilon_{ij}^{p0}$ that, an equation in the incremental form can be obtained:

$$\frac{\partial \Phi}{\partial D_{ijkl}^{e}} dD_{ijkl}^{e} + \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} d\sigma_{ij}^{s} + \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} d\varepsilon_{ij}^{p} = 0 \tag{4}$$

where *i, j* and *k* are summation subscripts. Where the material structure is considered, the incremental form is used to represent a full constitutive relation of the material.

This full constitutive relation contains the constitutive relation of simple and homogeneous materials in the classical theory in form.

For elastic-perfectly plastic materials, it can be considered that

When $D_{ijkl}^{e} = \text{constant}$, $dD_{ijkl}^{e} = 0$, so equation (4) is converted into

$$\frac{\partial \Phi}{\partial \sigma_{ij}^s} d\sigma_{ij}^s + \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} d\varepsilon_{ij}^p = 0 \tag{5}$$

Given that the total strain of the material is, $d\varepsilon_{ij} = d\varepsilon_{ij}^e + d\varepsilon_{ij}^p = \frac{d\sigma_{kl}^s}{D_{ijkl}^e} + d\varepsilon_{ij}^p$ ,It is substituted into the above equation to obtain $d\varepsilon_{ij}^p = d\varepsilon_{ij} - \frac{d\sigma_{kl}^s}{D_{ijkl}^e}$,

$$\frac{\partial \Phi}{\partial \sigma_{ij}^s} d\sigma_{ij}^s + \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} (d\varepsilon_{ij} - \frac{d\sigma_{kl}^s}{D_{ijkl}^e}) = 0 \tag{6}$$

After sorting,

$$(\frac{\partial \Phi}{\partial \sigma_{ij}^s} D_{ijkl}^e - \frac{\partial \Phi}{\partial \varepsilon_{ij}^p}) d\sigma_{ij}^s = -\frac{\partial \Phi}{\partial \varepsilon_{ij}^p} D_{ijkl}^e d\varepsilon_{kl} \tag{7}$$

In addition, under the incremental form, the increasing amount of energy can be shown by the following equation:

$$\Pi = \sigma_{ij}^s d\varepsilon_{ij}^s + \frac{1}{2} d\varepsilon_{ij}^s d\sigma_{ij}^s \tag{8}$$

Considering plastic deformation, i.e. the structural change of material, must be located on a surface of full state function, so the surface is equivalent to a constraint condition of energy variation. In other words, when stress and strain increments are variables, the range of variation must be constrained by the surface (equation 5). Thus, according to Lagrangian method, there is

$$\Pi = \sigma_{ij}^s d\varepsilon_{ij}^s + \frac{1}{2} d\varepsilon_{ij}^s d\sigma_{ij}^s + \lambda (\frac{\partial \Phi}{\partial \sigma_{ij}^s} d\sigma_{ij}^s + \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} d\varepsilon_{ij}^p) \tag{9}$$

Where $\boldsymbol{\lambda}$ is the constraint constant. This is the energy variation equation when stress and strain increments are variables.

Based on the principle of minimum energy, the stationary point of energy variation can be solved. The following equation is obtained:

$$\frac{\partial \Pi}{\partial (d\varepsilon_{ij}^s)} = \sigma_{ij}^s + \frac{1}{2} d\sigma_{ij}^s + \lambda \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} = 0 \tag{10}$$

$$\frac{\partial \Pi}{\partial (d\sigma_{ij}^s)} = \frac{1}{2} d\varepsilon_{ij}^s + \lambda \frac{\partial \Phi}{\partial \sigma_{ij}^s} = 0 \tag{11}$$

If simultaneous equation is established with equation (5), the expressions of the stress and strain increments of the stationary point can be solved.

**Loading condition under full state function of materials**

When the stress increment is an independent variable, according to the definition of full state function of materials, all components of stress increment will change on the surface of the full state function. This condition can be solved according to equation (10):

$$\lambda = -\frac{\sigma_{ij}^s + \frac{1}{2} d\sigma_{ij}^s}{\frac{\partial \Phi}{\partial \varepsilon_{ij}^s}} = -\frac{\sigma_{kl}^s + \frac{1}{2} d\sigma_{kl}^s}{\frac{\partial \Phi}{\partial \varepsilon_{kl}^s}} \tag{12}$$

This is the loading condition under full state function. From equation (12) it can be seen that the variation of stress increment should meet a certain condition. This condition is related not only to the stress increment, but also to the strength of structural status and derivative of component in the strain direction of the full state function. Moreover, this condition has the stronger constraint than the loading condition in the classical elastoplastic theory. That is because once any component of stress increment is determined, other components are also determined.

**Flow rule under full state function of materials**

Equation (11) is converted into

$$d\varepsilon_{ij}^{s} = -2\lambda \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \tag{13}$$

If $k = -2\lambda$ , there is $d\varepsilon_{ij}^{s} = k \frac{\partial \Phi}{\partial \sigma_{ij}^{s}}$. This is similar to the flow rule in the classical elastoplastic theory.

Thus, it can be seen that the flow rule is the relationship between strain increment and full state function obtained based on the energy principle, in the concept of full state function, and under the condition that components of the stress increment are variables. Besides, the equation of the stationary point of surface constraint of the full state function is also considered.

**Constitutive relation under full state function of the materials**

According to equation (10),

$$\frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} = -\frac{\sigma_{ij}^{s} + \frac{1}{2} d\sigma_{ij}^{s}}{\lambda} \tag{14}$$

It is substituted into equation (3) to obtain

$$\frac{\partial \Phi}{\partial \sigma_{ij}^{s}} d\sigma_{ij}^{s} - \frac{1}{\lambda}(\sigma_{ij}^{s} + \frac{1}{2} d\sigma_{ij}^{s}) d\varepsilon_{ij}^{s} = 0 \tag{15}$$

Let $H = (\sigma_{ij}^{s} + \frac{1}{2} d\sigma_{ij}^{s})\, d\varepsilon_{ij}^{s}$ , this is the expression of energy increment. That is

$$\frac{\partial \Phi}{\partial \sigma_{ij}^{s}} d\sigma_{ij}^{s} - \frac{1}{\lambda} H = 0 \tag{16}$$

Moreover, equations (10) and (11) are converted into

$$\begin{cases} \sigma_{ij}^{s} + \frac{1}{2} d\sigma_{ij}^{s} = -\lambda \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} \\ d\varepsilon_{ij}^{s} = -2\lambda \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \end{cases} \tag{17}$$

These equations are multiplied with each other and summation is performed to obtain

$$(\sigma_{ij}^{s} + \frac{1}{2} d\sigma_{ij}^{s}) d\varepsilon_{ij}^{s} = 2\lambda^{2} \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} \tag{18}$$

Thus, $H = 2\lambda^{2} \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}}$ , which is substituted into equation (16) to obtain

$$\frac{\partial \Phi}{\partial \sigma_{ij}^{s}} d\sigma_{ij}^{s} - 2\lambda \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} = 0 \tag{19}$$

According to the rule of work hardening in the classical elastoplastic theory, [6] is obtained.

$$A = (-1) \frac{\partial F}{\partial H_{a}} \frac{\partial H_{a}}{\partial \varepsilon_{ij}^{s}} \frac{\partial g}{\partial \sigma_{ij}^{s}} \tag{20}$$

Where $A$ is the parameter of work hardening, and $\boldsymbol{F}$, $\boldsymbol{H_a}$ and $\boldsymbol{g}$ are the plastic potential function, the strain hardening function and the yield function, respectively.

If it is considered that the full state function consists of plastic potential function and yield function, there is

$$A = (-1) \frac{\partial \Phi}{\partial \sigma_{ij}^{s}} \frac{\partial \Phi}{\partial \varepsilon_{ij}^{s}} \tag{21}$$

Thus,

$$\frac{\partial \Phi}{\partial \sigma_{ij}^s} d\sigma_{ij}^s + 2\lambda A = 0 \tag{22}$$

If equation (13) and $d\varepsilon_{ij}^p = d\varepsilon_{ij} - \frac{d\sigma_{kl}^s}{D_{ijkl}^e}$ are considered,

$$d\sigma_{ij}^s = (D_{ijkl}^e - \frac{\frac{\partial \Phi}{\partial \sigma_{ij}^s} D_{ijpq}^e D_{qpkl}^e \frac{\partial \Phi}{\partial \sigma_{kl}^s}}{A + \frac{\partial \Phi}{\partial \sigma_{mn}^s} D_{mnuv}^e \frac{\partial \Phi}{\partial \sigma_{uv}^s}}) d\varepsilon_{ij} \tag{23}$$

In this way, the expression of constitutive relation of a material is obtained. It is similar to that in the classical elastoplastic theory. However, the function reflecting the material performance in this article is the full state function of the materials.

**Stress-strain path with the minimum energy under full state function of materials**

According to the principle of the minimum energy, equations (10) and (11) can be obtained, and simultaneous equations are established with (5):

$$\sigma_{ij}^s + \frac{1}{2} d\sigma_{ij}^s + \lambda \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} = 0, \quad \frac{1}{2} d\varepsilon_{ij}^s + \lambda \frac{\partial \Phi}{\partial \sigma_{ij}^s} = 0, \quad \frac{\partial \Phi}{\partial \sigma_{ij}^s} d\sigma_{ij}^s + \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} d\varepsilon_{ij}^p = 0 \tag{24}$$

By solving,

$$\lambda = -\frac{1}{2} \frac{\frac{\partial \Phi}{\partial \sigma_{ij}^s} \sigma_{ij}^s}{\frac{\partial \Phi}{\partial \sigma_{ij}^s} \frac{\partial \Phi}{\partial \varepsilon_{ij}^s}}, \quad d\sigma_{ij}^s = \frac{\frac{\partial \Phi}{\partial \sigma_{kl}^s} \sigma_{kl}^s}{\frac{\partial \Phi}{\partial \sigma_{mn}^s} \frac{\partial \Phi}{\partial \varepsilon_{mn}^s}} \frac{\partial \Phi}{\partial \varepsilon_{ij}^s} - 2\sigma_{ij}^s, \quad d\varepsilon_{ij}^s = \frac{\frac{\partial \Phi}{\partial \sigma_{kl}^s} \sigma_{kl}^s}{\frac{\partial \Phi}{\partial \sigma_{mn}^s} \frac{\partial \Phi}{\partial \varepsilon_{mn}^s}} \frac{\partial \Phi}{\partial \sigma_{ij}^s} \tag{25}$$

This is the change path of stress-strain in the incremental form under the condition of minimum energy. Starting with the initial point of stress state, which may be under the minimum energy state, the stress-strain changes along the surface of full state function of the material, i.e. the path of changes, form the minimum energy path. The meaning of the minimum energy path is that the material structural change, which is the plastic change macroscopically, has the condition of deformation optimization, and this provides a new solution for some problems (such as plastic working and material creep).

## Discussions on Full State Function and Relevant Issues

The presentation of full state function of materials is to suggest a concrete idea and analytical method for solving the problems of structural materials. Through the above discussion, with full state function as the constraint condition, the principle of minimum energy is adopted to derive nearly all theoretical points and conclusions involved in the classical elastoplastic theory. These mainly include loading condition, flow rule, strength theory and constitutive relation. According to the principle of minimum energy, when the strain increment is a variable, the loading criterion can be obtained based on the equation of stationary point, when the stress increment is a variable, the flow rule will be obtained based on the equation of stationary point; when strain and stress increments are both variables, the constitutive relation is obtained. Therefore, the theoretical method of full state function cannot only help build a new theoretical system for solving the problems of structural materials, but also completely covers the main theoretical points and conclusions in the classical elastoplastic theory.

Loading condition, flow rule, strength theory and constitutive relation in the classical elastoplastic theory are all based on a series of assumptions. The reason is that these assumptions generally consider the homogeneous materials, but neglect the material structures. In other words, the important natures of structural materials are simplified, which make the features of the materials to lose their important inner connections. As a result, the connections between these features have to be rebuilt by relying on certain assumptions. The theory of full state function of materials takes structural materials as the research basis and restores the nature of material plasticity into variation of material structures, which fundamentally reflects the material performance. In this way, the theories of loading condition, flow rule, strength theory and constitutive relation are unified with their methods.

For stress-strain paths of materials, the theory of full state function of materials can provide good explanation and analysis. The surface of full state function of the materials is affected not only by stress state, but also by strain and structural stiffness of the material. Therefore, the stress state does not comprehensively reflect the actual state of the materials, and different stress paths or stress-strain paths are reflected on different points on the surface of full state function. In addition, the stress-strain path with the minimum energy reflects an important feature of materials, i.e. stress and deformation of the materials will occur along this path or around the path to the greatest degree. This provides important guidance for the optimization of material processing and analysis of creep property.

## Conclusion

According to the previous discussion, it can be found that the full state function, strength criterion and constitutive relation of the materials are the function reflecting the properties of the material with structurality. The full state function unifies the strength criterion and constitutive relation in then sense of both form and concept. According to the relationship between they, the following conclusions can be explicitly obtained:

(1) The full state function based on the variation of the structural state of the material is the envelope surface of the strength surface under all structural states.

(2) From the equation of a tangent plane in full state function, the full constitutive relation of the material in the increment form can be derived.

(3) According to the principle of minimum energy, full state function of the materials can be used to derive the main theoretical conclusions in the classical elastoplastic theory, including loading condition, flow rule, strength theory and constitutive relation.

(4) Form the above three conclusions, it can be deduced that the full state function of the materials is the ideal approach to fully describe the performance of the structural materials. Theoretically, it is a method that can unify strength theory, flow rule and constitutive relation, and has beauty in coordination and consistency.

(5) The full state function accommodates the strength theory and constitutive relation with clear physical and mechanical meanings. It represents a complete system.

The derivation of the specific form of the full state function for the material needs to combine with the structure model of the material. At present, this article only preliminarily explores the characteristics, meaning and usage of the full state function of the materials. Many other related problems remain to be studied.

**Keywords**:foundation pitdewatering;environmental impact appraisal model ;FLAC$^{3D}$; surface subsidence;

**Abstract:**Take the *ground-water lowering of foundation pit project* in DA Dongmen subway station in Hefei as an example, introduce a kind of environmental impact appraisal model,using softwareFLAC$^{3D}$ to imitate the key index--surface subsidence, offers relevant safe bases to construct security monitoring department.

## Introduction

With the constant development of the urban construction in china, more and more cities start the construction of the subway. Subway Foundation Pit always construct in dense buildings,so we must calculate and control the surface subsidence owing to pit dewatering for the purpose of reduce the influence of groundwater decline before pit construct on neighboring buildings. Especially to the large deep pit with complex hydrogelogical conditions , whose dewatering is a large area project , which influence more, forming precipitation funnel curve to produce additional deformation on structure around and do great damage to surrounding environment.

## 2.Engineering Situation

### 2.1Subject of the station

The station is the transfer of subway line one and line two, total construction area is 34837m$^2$. Station one is four floor three-span undergorund box-type frame structure,station standard is 145.44m long,23.5m wide and 31.7m deep; station two is three floor three-span undergorund box-type frame structure,station standard is 220.5m long,23.5m wide and 24.4m deep; The abnormal joints of the two station is threefloor many-span box-type structure. The most kind of soil thickness of the station is about 4m,the minimum is 1m and the maximum is 5.3m. The enclosure structure adopts the diaphragm wall, cross plate joint,which is 1.2m thickness in station one and 2.0m thickness in station two. All usingcover and excavation top-down method to construct.

### 2.2 Hydrology geological condition in this field

The subway station includes two layers of groundwater---perched water and confined water.Perched water: buried 1.35 ~ 5.50m deep; 10.17m ~ 13.98m elevation. Aquifer include powder quality clay and miscellaneous fill lay.Confined water: buried 1.2 ~ 4.9m deep; 10.77m ~ 14.77m elevation. Aquifer include Powder soil fine sand lay.( Permeability coefficient are 5.8*10$^{-4}$cm/s and 2.3*10$^{-3}$cm/s).

Geological parameter of the station as the following table shows:

**Table.1 Geological parameter**

| Soil layer | Thickness (m) | Density (kg/m3) | Shear modulus (Mpa) | Volume modulus (Mpa) | Permeability coefficient m2/Pa.sec | Poisson ratio |
|---|---|---|---|---|---|---|
| Powder soil | 2 | 1.7 | 4.32 | 7.45 | $2.7*10^{-13}$ | 0.4 |
| Flour sand | 10 | 1.87 | 9.92 | 17.1 | 1.3*10-$^{12}$ | 0.35 |
| Powder quality clay | 14 | 1.77 | 10.83 | 18.6 | $1.0*10^{-15}$ | 0.35 |
| Sandstone | 4 | 1.9 | 11.36 | 19.6 | $1.3*10^{-15}$ | 0.32 |
| Rock | 10 | 2.1 | 20.6 | 35.6 | $2.8*10^{-19}$ | 0.3 |

## 3. Appraise system in environmental impact of precipitation

The dewatering of the large deep pit causes the surface subsidence around, leading to the fact the building around and underground pipeline slope, crack. So, it is a very important job to carry on the analysis of environmental impact as to the precipitation project of the area where the geological condition of hydrology is complicated. There have foundation of counting based gray theory, BP nerve networkmethod, GIS environmental impact method,etc. At present we introduce a environmental evaluation method.

This kind of method is based on a simple, scientific appraisal method of fuzzy mathematics, it considers the inherent environment (Hydrology geological condition of the project) and two pieces of influence of response of the surrounding environment,constructs 8 kinds of evaluation indexes,dispel dimensional difference, carry on standardized treatment, correspond to four think result (excellent, good, medium, and poor) . The evaluation indexes include precipitation patterns,compressibility,hydrological effects ,the water volume of foundation pit lateral wall, boundary load distribution,subsequent life of buildings,foundation form of buildings and the uneven settlement .The Correspondingweight matrix is[0.2376 0.0594 0.0179 0.0950 0.0505 0.1239 0.0659 0.3498]

## 4. The settlement imitate calculating

### 4.1Set up models and net subdivision

For simplified calculation, a longitudinal section which fetches the foundation pit imitates and analyzes, the length of foundationpit is 6m, width 24m, excavate deep 32m, adopts the underground continuous wall as enclosing and protecting structure and concurrently stagnant water curtain when excavated of foundation pit, it is here from the foundation pit to dredge the dry well and fix up. The final size of the model is confirmed as 6m * 180m * 60m cuboid as shown in Fig. 1.

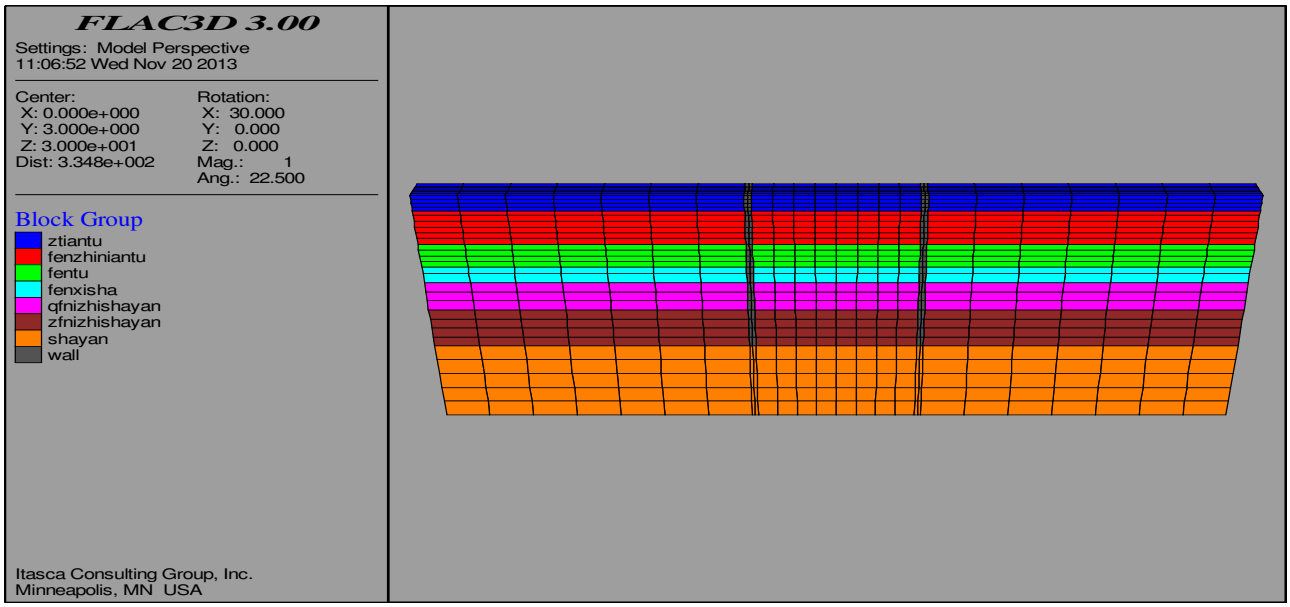

**Fig .1 Calculate models**

### 4.2 Establish the border and initial condition

Set up the horizontal direction to restrain on both sides of the model, exercise restraint in moving horizontally; Above surface freedom border, bottom set up competence and verticality restrain, restrain competence from, move vertically, the bottom of the model is the waterproof border, it is the border of influent to lower the well.

### 4.3 Model calculating andResult of calculation of simulation

We can realize precipitation by establishment of the hole water pressure strength. Divided into two steps specifically: First of all, change hole water pressure model behind the strength, carry on fluid flow calculation of the steady state; Then close the influent mode subsequently, only carry on quiet strength analysis.Then choose the earth's surface, and several point of 60m order as the characteristic of studying from foundation pit 0 - 20 - 40 edge, click these and join to transform into the straight line of the characteristic, characteristic deformation situation of straight line that choose at observing the earth's surface come, describe different water level ground verticality displacement situation lower dark, curve out of shape of straight line of characteristic (subside groove) Paint it in Fig2.

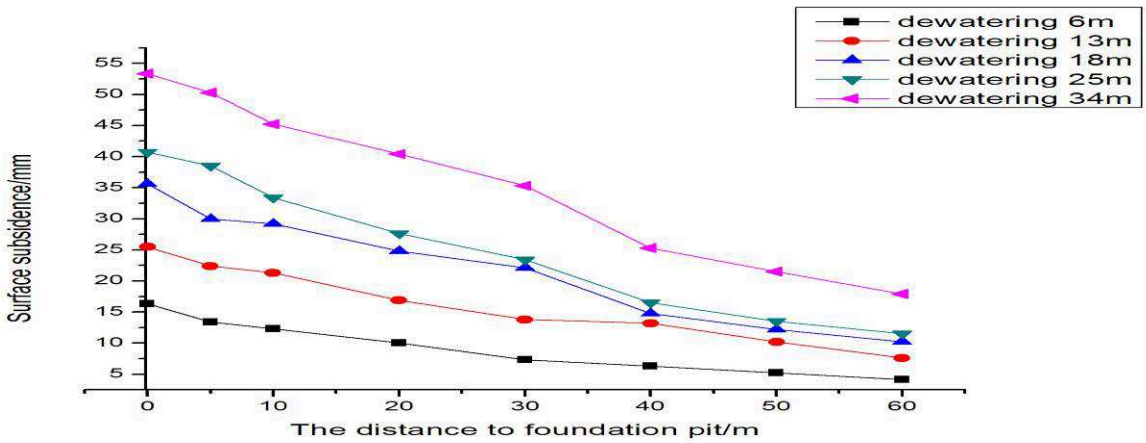

**Fig .2The curve of finite element**

## Conclusion

From the appraisal system of the environmental impact of precipitation,we can know in order to reduce the influence on the environment of precipitation of large area in the large deep foundation pit, we must control the ground and subside and the building does not subside evenly in the coverage of precipitation radius in a situation that geological condition of hydrology and precipitation are designed and has been already made. Take DA Dongmen subway station in Hefei as an example,we must set up the monitoring point in sphere of influence buildings, such as four corners in the building corner, the connects place with new of old building, expansion joint and both sides deep foundation that bury different. Each building assign subside measuring point and tilt measurement points. The address select of cracks observed situation monitoring points combined buildings are arranged on the side of a building near the wall surrounding the crack spacing of 20 ~ 30m uniform layout level observation wells. Site monitoring using the method offollow-up observations timed observation combining. Monitoring frequency can be adjusted according to changes in the size of the monitoring data, monitoring data when there are mutations, monitoring frequency encryption to 2 to 3 times / d.

Through the observation of the water level observation wells in precipitation process,we must ensure that the groundwater level changes between successive walls and buildings within the specified range, kept lowering the water table depth within 1m. By monitoring the building ,we found there is no cracks in the building , meetting regulatory requirements of the maximum settlement building and the maximum tilt , to protect the safety of the building.

**Keywords:** deep foundation pit; structure monitoring; settlement

**Abstract.** According to characteristics and surrounding environments of a deep foundation pit with pile-anchor retaining structure, a monitoring program was developed. The monitoring focused on horizontal displacements of retaining piles, subsidence of soil surrounding foundation pit and settlements of buildings near foundation pit. The results show that the maximum displacements are in middle position of sides and at corners of foundation pit. The horizontal displacements and settlements of pits are efficiently rejected by anchors. The displacements of buildings near foundation pit are affected by many factors, such as the excavation speed and anchor. The displacement exists characteristics of time and spatial effects. The monitoring results provide a reliable basis for the safety construction and rational organization of construction.

## Introduction

With the rapid developments of city, the spaces are limited more and more. If construction project is in a limited space, had to development to underground. To build a large-scale underground building first needs to carry on excavations and supports of deep foundation pit. In construction process, pressure states of soil inside and outside foundation pit have being changed from static earth pressure to passive or active earth pressure, which lead deformations of soil[1]. In order to ensure safety and quality of foundation pit, it need to timely evaluate the effectiveness of support structure. It is important that real-time monitoring has been built for support structures, surrounding soils and adjacent buildings. Monitoring data can be referred to as "thermometer" for buildings[2]. By analyzing the monitoring data have become one of the main methods to study deep foundation pit[3].

Pile anchor retaining structure consists of pile and prestressed anchor, which widely applied in deep excavation projects. In construction of pile anchor structure, the first work is to do retaining piles and stratified to move soil, and then do prestressed anchors hierarchically from top to bottom in retaining piles. Because retaining piles and prestressed anchors into working states are different and supporting structures to withstand pressures of soil are increasing, the stresses states of retaining piles and anchors have been changed. In this paper, based on the monitoring data, it will be analyzed horizontal displacements at top of supporting piles, ground surface settlements and changes of building displacements near pit to study deformation rules of pile anchor retaining structure and influence rules for surrounding environment.

## Engineering situations

The project is a public service building with 16 floors and a large underground parking which site was hillside with high to southwest and low to northeast. The excavation depth of pit for underground parking is changed with site topography, depth ranges are from 8m to 13m and the maximum depth is in southwest corner. Foundation plane sizes are about 85m in length and 30.9m in width. A 3m high stone masonry bulkhead built by adjacent department is about 4m far from west side of pit, there are two buildings with single storey near southwest corner and a six storey building far from 11m on south side and a road with width of 5m adjacent to east side. The city main road locates in north side which is far away from pit that can not consider the influences of foundation pit. According to

environmental conditions, pile anchor retaining structures are set in west, south and east side. 1 to 4 prestressed anchors are set up respectively in dado piles with the different height of soil retaining. The total length of pile anchor retaining wall is about 145m.

**Engineering geological conditions**

According to geological survey report, the site stratums from top to bottom were plain fill layer, silty clay layer and gravel with clay layer. The natural foundation bearing capacities of each soil layer and representative values of main properties in physical and mechanical are shown in table 1.

Table 1 Physico-mechanical parameters

| Geotechnical layer | State | Characteristic value of foundation bearing capacity [$f_{ak}$/kPa] | Modulus of elasticity [$E_s$/MPa] | Internal friction Angle [$\Phi$/°] | Cohesion [$C$/kPa] |
|---|---|---|---|---|---|
| Plain fill | Losse-slightly dense | 80 | 4.3 | 6.5 | 10.0 |
| Silty clay | Hard plastic | 220 | 7.0 | 17.0 | 22.0 |
| Silty clay | Hard plastic | 230 | 7.1 | 17.0 | 22.5 |
| Silty clay | Waxiness-soft plastic | 120 | 4.8 | 10.0 | 16.0 |
| Gravel with clay | Moderate density | 420 | 20.0 | 30.0 | / |
| Limestone | Slightly weathered | 5000 | | | |

The hydrogeological conditions of site are in moderate. Perched water from domestic water and atmospheric precipitation is filled with in plain fill layer and excreted to low-lying place. The moisture content in silty clay layer is poor which is relatively impermeable layer. The layer of gravel with clay is aquifer and strong permeable layer in which has rich phreatic water. A small amount of bedrock fissure water contains in limestone fissures. The depth of static water level at each hole is between 2.00m to 7.20m.

Plain fill, silty clay and gravel with clay soil represented as special soil. The distribution of plain fill layer is uneven and bearing capacities are low, this layer is not foundation bearing stratum. During foundation pit excavation, slope gradient should be increased in plain fill layer. Silty clay represented as state of hard plastic and soft plastic, buried depth is deeper and partial thickness is larger which brings adverse effects to pile foundations. It should be considered carefully influences in easy deformations if select pile foundation. Layer of gravel sand with clayey soil contain rich water and is a strong permeable layer, pile foundation construction in this layer is difficult. The geological distributions in influence depth of dado pile are shown in Fig.1.

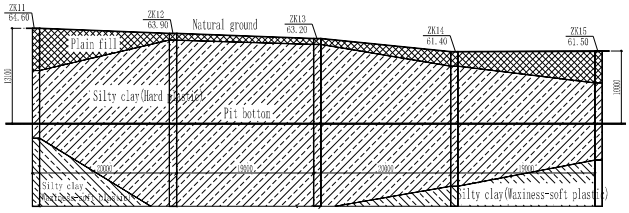

Fig. 1 Geological distribution of retaining pile excavation depth range

**Monitoring schemes of foundation pit**

The stabilities of retaining structure is not only related to safety of projects, but also to protect buildings, roads and pipeline facilities near foundation pit. Therefore, it must be taken the information

management methods to control constructions and effective monitoring for foundation pits. The arrangements of monitoring points for retaining structure should be able to reflect the actual states and change trends and meet the requirements of monitoring. Safety level of this foundation pit is in second stage determined by national standrads[4]. With the requirements[5], monitoring points are arranged at the key feature points of internal forces and deformation in supporting structure. The layout of monitoring points is shown in Fig.2.

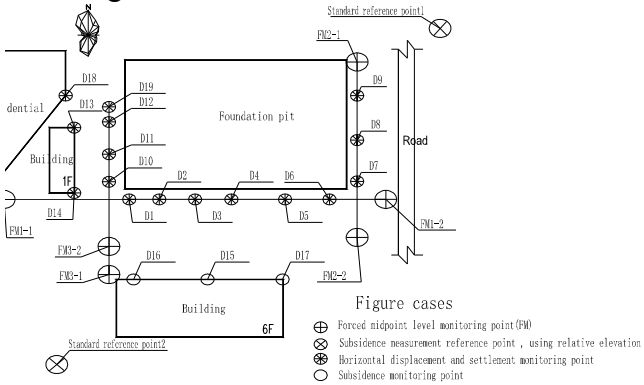

Fig. 2 Schematic drawing of monitoring points arrangement

## Monitoring method

The monitoring instruments and measurement methods are chosen by current national codes[5]. Differential settlements are measured by DSZ2 water levels and DS1 level micrometers and by using micrometer method. Horizontal displacements are observed by DJ2 level optical theodolites and by using collimation line method and small angle measurement method.

The monitoring datum points buried for horizontal displacements are met up with current national codes[6]. The observation piers for forced to center are set up and using precision optical devices for centering detections, the error of centering measure is less than 0.5mm.

## Analysis of monitoring results

There are two purposes for monitoring deep foundation pit which are foundation pit monitoring and environmental monitoring. Foundation pit monitoring includes monitoring for retaining pile wall, supports, anchors, stresses and deformations of soil as well as underground water level changes. Environmental monitoring includes monitoring for displacements and deformations of stratum surrounding deep foundation pit, underground pipelines, buildings and roads nearby deep foundation pit. With actual characteristics of this project, the monitoring works are for horizontal displacements and settlements of pile anchor retaining structure and buildings near foundation pit.

## The horizontal displacements at top of retaining wall piles

The monitoring results at piles top on south side of deep foundation pit are shown in Fig.3.

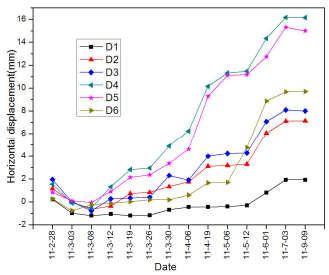

Fig.3 Curves of horizontal displacement with times at pile top on south side

It can be seen from Fig.3 that horizontal displacements with excavation are presented as a step by step process which are increased at first, then partial reduced and tended to stable. Horizontal displacements tend to increased with excavation, the growths were become slowly after last row of anchors completed, and then finally tended to stable. Horizontal displacements in middle place of side were decreased after building basement floors have been done. The reasons for this phenomenon are that there are earth pressures on retaining piles which lead retaining pile slip to foundation pit and bending deformations. With increase of depth, earth pressures increase which caused horizontal displacements to increase continuously. When excavation to a certain depth, the first row of prestressed anchor on retaining piles has been constructed, the bending deformations of retaining piles are in control soon and this made retaining piles produce large anti-pressure to soil. When excavation to another depth, horizontal displacements will increase again. With second rows of prestressed anchor completed, the bending deformations of retaining piles are under control and make back pressure to soil. After basement floor completion, horizontal displacements appear rebound phenomenon because the actions of prestressed made by anchors and earth pressures decreased with retaining soil thickness changed by basement floor. The basement floor stiffness is larger and has obviously embedded effects to retaining piles. Prestressed anchors can effectively restrain horizontal displacements of retaining pile and improve whole supporting structure stiffness. Further studies showed that horizontal displacements can be reduced by the second rows of prestressed anchor.

The maximum horizontal displacement is in middle of south side and value is 16.16mm which illustrated this supporting structure are meet with requirements of national standards and the structure has been in safe state. The monitoring results are consistent with research conclusions that the larger deformations are in middle of sides and corners of foundation pit.

## The settlements of pile

The settlement results of pile on south, west and east side of foundation pit are given in Fig.4 to Fig.6.

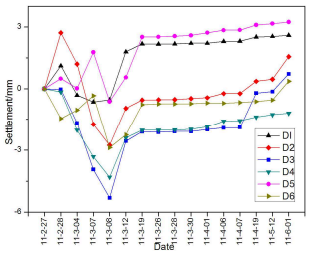

Fig.4 Settlements on south side

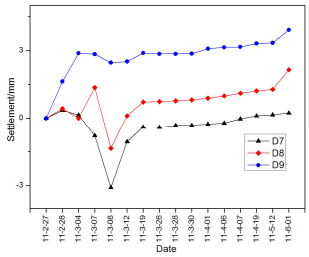

Fig.5 Settlements on west side

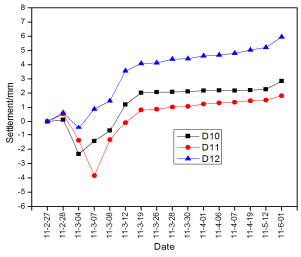

Fig.6 Settlements on east side

It is shown from Fig.4 to Fig.6 that the settlements of pile at beginning of excavation were increased. After the first row of anchor completed, the growths of settlements were become slowly and even trend to rebound. With excavation depth increase, settlements of piles began to increase again, then rebounded slightly after the second rows of anchor completed and trended to stable. The reasons for this are due to inhibitions of prestressed anchor on retaining pile settlements. The maximum settlement points are located in corners and in middle place of long sides. In process of construction, the monitoring in these areas should be strengthened. If an exception occurs, must alarm immediately to prevent accidents.

## Spatial and Time effects

With engineering practices, it can be found that distances from pit edges, arrangements of supporting structure, time effects and applied effective prestress of anchors have obvious influences on settlements of building near foundation pit. According to monitoring data, the settlement curves of buildings near south and west side of pit are shown in Fig.7 and Fig.8.

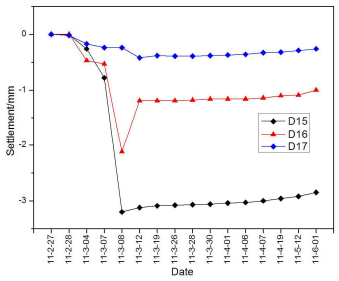

Fig.7 Settlements of building on south side

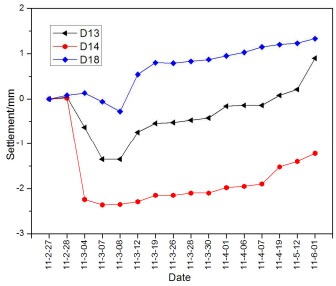

Fig.8 Settlements of building on west side

The maximum settlements are in southwest corner and central of south side, the values are 2.36mm and 3.20mm. Theoretical analysis show that deformations are most sensitive at corners and center of sides. Ground settlement near these places is also larger. After excavation, states of soil surrounding pit are changed to free and make soil slip slowly to free surfaces which causes soil shear failure and leads soil near pit sides to become soft and compressibility, then leads nearby buildings to produce new settlements. The influences for building settlements are greatly by distances far from pit. The changes of settlement have obvious spatial effects.

Building settlements near pit are changed slowly in initial period and the amount of settlements is small. After a row of prestressed anchors completed, building settlements are changed obviously, then tends to stable. Settlements have obvious hysteresis characteristics with depth of pit, thus settlements of buildings have been manifested after a depth completed for periods of time. The main reasons are that slip creep and shear failure occurred to soil near foundation pit has a lag phase which caused process of settlements has significant time effects.

## Conclusion

Settlements and horizontal displacements of supporting structure and ground surfaces, vertical displacements of buildings nearby foundation pit are all within bounds of current national standards, supporting structures are in safety and stability. The environment monitoring results are particular and true. With analysis, the conclusions can be obtained as following:

1) Displacements and settlements of pile anchor retaining structure were influenced greatly by prestressed anchor. It can effectively reduced horizontal displacements and settlements of supporting structure. By observing horizontal displacements and settlements, it can effectively monitor the states of supporting structures and find abnormal phenomena in time.

2) During excavation, the maximum deformations appeared in middle part of sides and at corners of foundation pit.

3) There are many factors influenced settlements of buildings, such as distances from pit boundaries, arrangements of supporting piles, time effects and so on. The greatest impact is distances between buildings from pit boundaries. Process of settlements of buildings nearby pit has significant spatial and time effects.

# Analysis on Strengthening of Plant to slope soil under orthogonal states

Junbin Gu

Architecture and Civil Engineering School, Inner Mongolia University of Science and technology, Baotou, 014010, China

gu613@163.com

**Keyword:** the orthogonal states, plant, soil, strengthening

**Abstract.** In the traditional slope engineering, the slope processing mainly emphasizes the strength effect, and ignore the damage to the environment. Along with people are to landscape and strengthening of environmental protection consciousness, the slope protection method of tradition can not satisfy the requirement of people.Use Interaction of plant roots and rock-soil body to reinforcement and anchorage on the slope surface protection and reinforcement, which can meet the design requirement for stability of slope surface and restore the damaged natural ecological environment. This paper set up the relations between the tensile strength of plant root and the root diameter, establish the theoretical calculation model of the interaction between plant roots and soil, and study the strengthening of plant roots to soil.

## Introduction

In recent years, the slope plant protection research has been carried out both at home and abroad and has a lot of literature.But the research of plant protection mainly explore the construction technology and protective effect of slope plants for further study the slope plant protection. And in order to prevent blindness in design and construction must intensive study the mechanism action of the slope plant protection.Through the data access and analysis, the plant roots have the anchoring effect of deep roots and the reinforcement effect of shallow root, and both can reinforce the slope from the mechanics aspects. The deep vertical root through the potential shear surface to resist the shallow landslide; the small diameter and high dense fibrous improve soil shear strength [1]. So this paper mainly study the strengthening of plant root to soil in the plant slope protection.

## The mechanical effect and mechanical model of plant protection

**The mechanical effect of plant protection.** The vertical root of plants through the shallow slope to loose the weather belt, and anchorage on the depth and stability rock layer to have the effect of prestressed anchor: The plant lateral roots form the reticular structure in the surface soil, lash the soil around and make into soil form the reinforcement whole, so form the three-dimensional structure of solid protective with vertical root have net and pile effect in soil structure, increased the tensile strength and shear strength in the soil, so as to improve the safety factor of slope as shown in Fig.1. Root reinforcement effect of slope soil related to the root distribution form,the root content in the soil and the root strength[2], the herbs as the example for research in this paper.

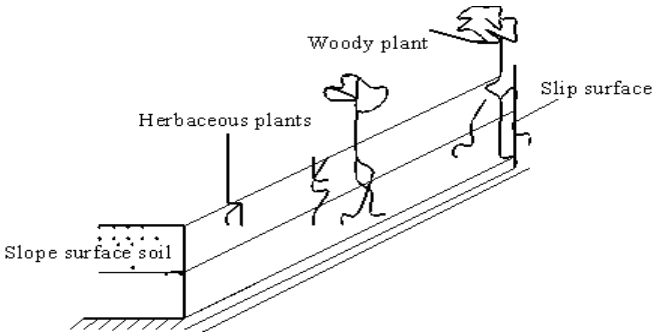

Fig.1 The map of plant roots and slope effect

**The mechanics model of interaction between Plant roots and soil.**The herbs roots distribution characteristics shown that root distribution density gradually decreases and thin down from the surface in soil, the slope soil can be regarded as soil and root composite material in the scope of the root intertwining,and the herb roots as the fiber function so according to the reinforced soil principle analyze on the stress state of the upper slope, the roots distribution in the soil as the the reinforced fiber distribution and the three-dimensional reinforcement. Below to establish the mechanics model of interaction between Plant roots and soil[3] as shown in Fig.2, which shown the extension direction of the root and soil shear zone orthogonal conditions[4].

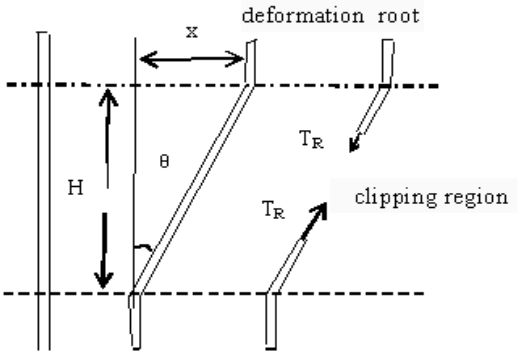

Fig.2 The mechanism analysis diagram of balance model for single root force under orthogonal status

Orthogonal:

$$\tau_R = \frac{T}{a}\sin\theta + \frac{T}{a}\cos\theta\tan\varphi \tag{1}$$

In the formulas, $\tau_R$ for due to the effect of root reinforcement to increase the shear strength of soil; T for the single tensile resistance; $a$ for the soil area of single function; $\theta$ for shear angle; $\varphi$ for the internal friction angle of soil.

## Research strengthening of plant roots to soil

**The relationship between tensile strength and root diameter of the plant root.**In the experiment, selected the bermudagrass, White clover and amorpha fruticosa as test object, select several root form each plant roots type and make its diameter distribution change is larger and continuous. The root tensile strength may refer to applied for the calculation method of steel reinforced concrete structures:

$$P = 4F / \pi D^2 \tag{2}$$

In the formulas,P for the root tensile strength; F for the root tensile resistance (the root is pulled when the weight of the sandbags); D for the section diameter when root tensile (assume the root end face is round).Test results of statistics as shown in Tab.1and the relation curve of the root tensile strength and the root diameter as shown in Fig.3, Fig.4, Fig.5.

Tab.1 The relationship statistics data between the root tensile strength and the root diameter

| | | the root diameter for D(mm)and the root tensile strength for P(MPa) | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Bermud | The root section diameter | 0.240 | 0.283 | 0.383 | 0.480 | 0.700 | 0.720 | 0.780 |
| agrass | The root tensile strength | 58.83 | 65.05 | 65.06 | 48.58 | 26.50 | 24.82 | 23.34 |
| White | The root section diameter | 0.887 | 0.927 | 0.986 | 1.265 | 1.724 | 2.020 | 2.053 |
| clover | The root tensile strength | 9.74 | 11.54 | 11.75 | 11.50 | 9.10 | 8.88 | 8.56 |
| amorpha | The root section diameter | 0.67 | 1.28 | 1.70 | 1.78 | 1.81 | 1.85 | 2.20 |
| fruticosa | The root tensile strength | 10.32 | 10.54 | 10.25 | 10.16 | 10.10 | 10.02 | 9.86 |

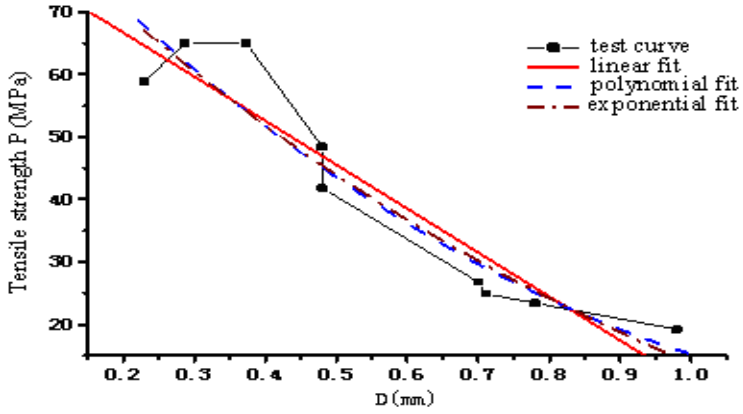

Fig.3 The relationship between the root tensile strength and the root diameter for Bermuda grass

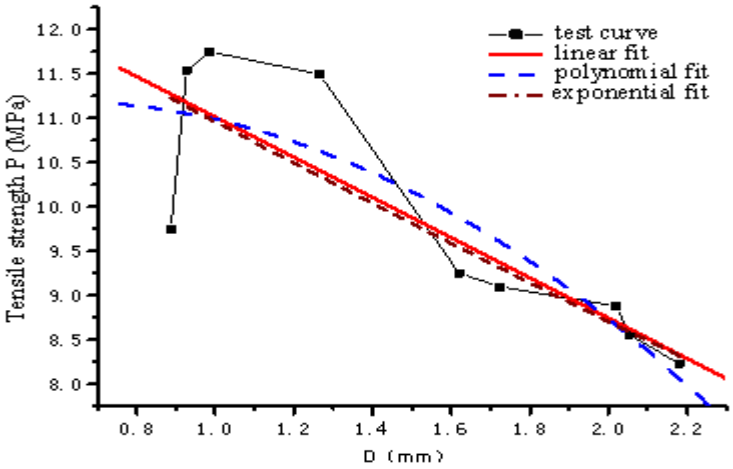

Fig.4 The relationship between the root tensile strength and the root diameter for White clover

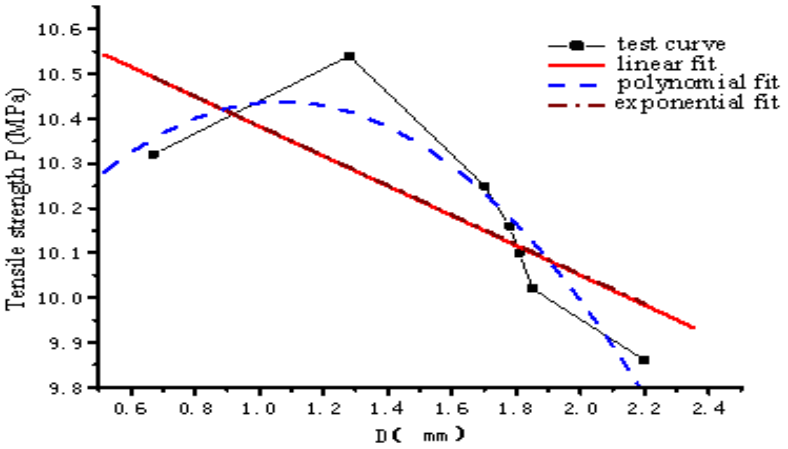

Fig.5 The relationship between the root tensile strength and the root diameter for Amorpha fruticosa

The fitting effect found that polynomial fitting is better for Bermuda grass and Amorpha fruticosa, and exponential fit is better for White clover.Analyzed on the relationship between the root deformation angle and the soil shear strength under orthogonal state for three roots meet above conditions, and the relationship between the root tensile strength and the root of the roots diameter (d = 0.1 ~ 0.3 mm) are as follows:

Bermuda grass : $y = 44.4314x^2 - 123.4059x + 93.1668$

White clover: $T(N) = -21.3117 + 34.6929e^{-0.0724d}$ (3)

Amorpha fruticosa: $T(N) = -0.5137d^2 + 1.0992d + 9.8501$

**Research results**.Using the formula (1) and (3) calculate the reinforcement effect of three plants to soil ,and the results are shown in Tab.2. Further analyze the change law of the soil shear strength with the deformation Angle change by MATLAB is shown in Fig.6.

Tab.2 The strengthening effect of different plants to soil

| Plant Type | Bermuda grass | White clover | Amorpha fruticosa |
|---|---|---|---|
| $\tau_R$ (KPa) | 1424.36 | 250.275 | 193.519 |

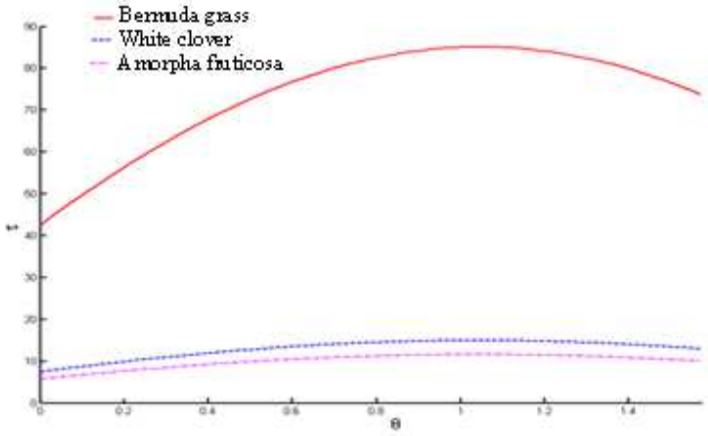

Fig.6 The relationship between the soil shear strength and the root deformation angle under orthogonal state

Angle increased in a certain Angle, when the deformation Angle reaches to1 radian, the soil shear strength reach to the maximum, and the soil shear strength has the decrease tendency along with the deformation Angle continues to increase. This phenomenon is due to the reinforcement effect of root to soil by the synthesis function of two component of the root tensile strength. When the deformation Angle increases, the root tensile strength in the horizontal component increases and the vertical component decreases. Due to the root reinforcement effect is the synthesis of the two parts, Fig.6 is obtained when the extent of the increase is greater than the extent of decrease.

## Conclusion

Plant roots have a strengthening effect on slope soil, on the other hand, the plant also cannot leave the soil environment,which need to achieve the desired mineral nutrients and moisture from the soil. so the effect of plants and slope soil is mutual, plant roots affect the stability of the slope geotechnical by mechanics effect .The slope plants have similar function as anchor or pile, but should not simply analogy of the mechanical strengthening effect of the slope plants and the effect of anchor or pile, should put the favorable and unfavorable factors taken together to study the strengthening effect of plant roots to soil slope.

**Keywords:** Centrifuge Model; Composite Foundation; High Strength Piles; Embankment; Instability.

**Abstract:** A series of centrifuge model tests has been conduced to examine the behavior of high strength piles composite foundation stability under railway embankment in silt or clay or sand different kind of soils. The high strength composite foundation has a symmetrical plan layout consisting of 3×4, 4×6, and 5×8 piles with a center-to-center spacing of 6 or 4 or 3 times pile width. The piles are under the same height of railway embankment, with the same length, and on the same lying soil layer. The high strength composite foundation stability test results are expressed in terms of soils kinds-pile displacement response of the composite foundation, embankment load experienced by soil between piles and piles in the composite foundation, and bending moment profile along individual pile. It is established that the high strength composite foundation stability efficiency reduces significantly with decreasing of the strength of soil between piles in composite foundation. The tests reveal the shadowing effect phenomenon in which the marginal piles experienced larger laterally and bending moment than that of the central piles. The shadowing effect is most significant for the lead row piles and considerably less significant for subsequent rows of middle piles. The approach adopted by many researchers of taking the average performance of piles in the same row is found to be inappropriate for the middle rows, of piles for composite foundation as the outer piles in the row carrying significantly more laterally load and experience considerably higher bending moment than those of the inner piles.

## Introduction

The performance of high strength composite foundations subject to embankment load is of considerable importance in Chinese super railway practice, for mostly Chinese super railway embankment foundations are reinforced by high strength piles during the past ten years (for example, Beijing-Shanghai High Speed Railway et al. 2011). In the field, piles are often arranged in gropes, and the behavior of piles of composite foundation may differ substantially from that of a single pile. The composite modulus (JGJ 79-2002 Technical Code for Ground Treatment of Buildings of China) is commonly employed to evaluate the stability of high strength composite foundation. Several full-scale field tests on composite subject to embankment loads have been reported. These include studies on composite foundation (for example, Cui 2009). Some degree of understanding on the performance of high strength composite foundation has been gained from these field studies.

Laboratory studies such as centrifuge model tests could provide further insight on the behavior of composite foundations. At present, much of the centrifuge model studies on composite foundation were carried out (for example, Wang et al. 2010; BUI et al. 2009). Relatively few centrifuge model studies were conducted to investigate the stability of composite foundation and majority of these studies concentrated on the study of settlement (for example, Wang et al. 2010). A series of centrifuge

model tests was, therefore, initiated to examine the behavior of high strength composite foundation in silt or clay or sand to research the soil between piles character effect on the composite foundation stability. In addition, the test observations are compared with those obtained from field studies.

## Experimental Setup

All the tests were conducted at 50 g on the Southwest Jiaotong University (SJU) of China, which has a radius of 3 m and comprises a balanced arm with dual swing platforms. The centrifuge has a capacity of 100 g tones and a maximum acceleration of 200 g. Details of the SJU Centrifuge are given in BUI et al. (2009). Fig.1 shows a sketch of the model setup. The rectangular stainless steel model container has an internal diameter of 600×600×800mm.

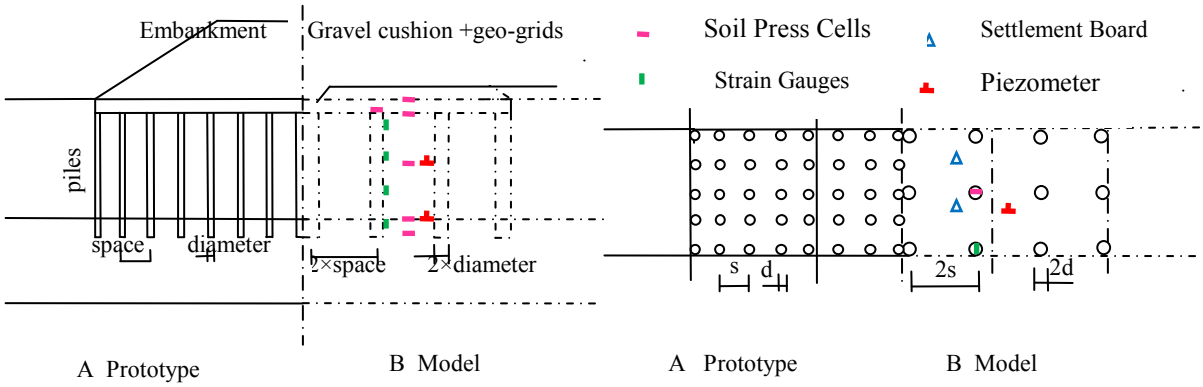

Fig.1. Centrifuge model setup

Tab.1 Physical and mechanical parameters of model

| | Parameter | Com Mod | Ten Str | Ela Mod | Un-Com Str | Max Dry Den | Max Dia |
|---|---|---|---|---|---|---|---|
| Materials type | | $E_{1-2}$ | $\sigma_t$ | E | $\sigma_c$ | $\rho_{dry}$ | D |
| | | (MPa) | (kN/m) | (MPa) | (MPa) | (kN/m$^3$) | (mm) |
| Soils | Silt | 2.28 | | | | | |
| | Clay | 4.30 | | | | | |
| | Sand | 6.25 | | | | | |
| Geo-grille | Gauge | | 1.60 | | | | |
| Pile | Concrete | | | 1417 | 8.4 | | |
| Emb | Granite | | | | | 19 | |
| Cushion | Sand | | | | | | 1.5 |

The model pile is 20 cm long with the lower 2 cm pile length to be inserted into the sand lying layer. At 50 g, the simulated prototype embedment pile length is 10 m. The geo-grille is made of gauge, that tensile strength is 1.6 kN/m (80 kN/m prototype scales). The gravel cushion is made of 10 mm (0.5m prototype scale) thick sand, which maximum diameter is 0.4 mm (2 cm prototype scales). It is very difficult to layered setup embankment, so the whole embankment is made of 120 mm (6 m prototype scale) thick weathered granite once. Train and rail load is replaced by 65mm×14mm (3.25m×53.8kPa prototype scale) steel plate.

The model pile is made of the real material as cement gravel (gravel size 1:50 scale reduction) instrumented with 14 coordinate points to enable bending moment measurements along the pile profiles, 4 strain gauges (from pile top 1, 7, 13, 19 cm) to enable pile stain along the piles. At each

level, two active strain gauges were glued onto the opposite faces of the model pile and connected to two dummy gauges on a strain meter mounted on board the centrifuge to form a Wheatstone full bridge circuit. The instrumented pile surface was glued by a thin layer of sand to enhance the interaction with the soils having a final pile width of 2cm.

Three soil press cells (from pile top 0,9,18 cm) were installed in the soils between piles to enable soil press along the pile depth, two soil press cells in cushion and lying soil layer, and one soil press cells on the pile top, respectively. Two settlement boards were instrumented on the surface of cushion at the center and toe of embankment, respectively. Two pore water pressure gauges (from pile top 9, 18 cm) were instrumented.

The material parameter of the model embankment fill, piles, and soils between piles equals to the prototype, for select the real material in the model. Tab.1 shows the details of the materials parameter of the test. For the soil lying layer, a 30-mm-thick sand layer was first placed at the bottom of the model container before placement of soils between piles.

The soils between piles were prepared in the following manner. First, the soil was then placed in the model container to a height of about 200 mm and then consolidated under its self-weight in the centrifuge at 50 g to allow the express pore water pressure in the soil to dissipate through the soil surface and the openings located close to the bottom of the container via the bottom sand layer. Ground settlements and pore water pressures in the soil were measured to monitor the progress of soil consolidation.

## Test Procedure and Configurations

After completion of consolidation for soils between piles, the centrifuge was stopped to facilitate pile and embankment installation. The test pile was precast, for facilitating strain gauges; the other piles were cast-in-place. The pile installation had to be done at 1 g, as it was very difficult to control the pile penetration depth in soil under high-g condition. Fig.2 shows test loading progress. As the embankment was whole precast, that changed the acceleration of the test by trisection to simulate the embankment filling progress. After that, if the model didn't destructed, put on the steel plate, and went on accelerating for 3.5 h to simulate the foundation consolidation 1 year under train and rail load.

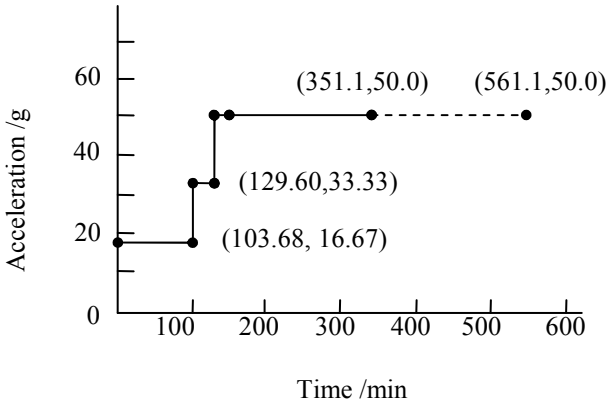

Fig.2. Test loading progress

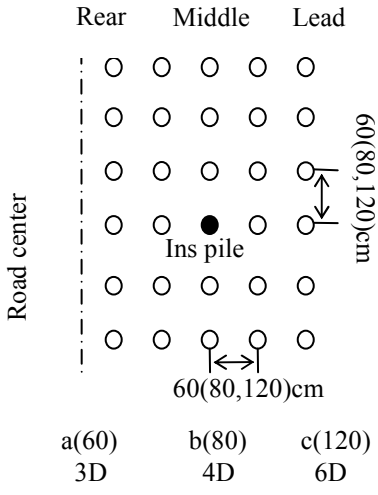

Fig.3. Plan view of pile configuration

Composite foundation of up to 40 piles was investigated in the present study. Figs.3 provide a plan view of the composite foundation configuration for tests involving piles with center-to-center pile spacing 3(4, 6) D (D=pile width). In all cases, tests were carried out in all silt, clay, and sand. The definition of lead row piles (piles in the row furthest away from the center of the embankment), middle row piles (middle second and third rows in the case of 5×8 pile group) and rear row piles as well as center piles for individual pile row is also given in Fig.3. Owing to limited number of recoding

channels in the strain meters, only one pile can be instrumented in one test. The location of the instrumented pile for each test is also shown in Fig.3.

## Load-settlement Responses of Composite Foundation

From this point onwards, all the test results are presented in prototype scale unless otherwise stated. The strain-length of piles in silt, clay, and sand are represented by the curve in Figs. 4 (a-c), respectively. As expected, the piles strains are not fixed values but variables along the pile length, which are corresponding to the following theoretical calculations. In the calculations, the piles stresses are a group of curves, from stress-strain compatible theory, the piles strains are also a group of curves. There are the maximums of the piles stresses in the piles up middle, and minimums in the pile two tops. These deformation and stress phenomena are coinciding with the composite foundation settlement theory reported by Guo. (2012). on it, there is an equal settlement surface in the composite foundation, where the settlements of soils and piles are equal. The axial forces of the piles are a group of exponential curves, and the maximums on the upper third of the piles.

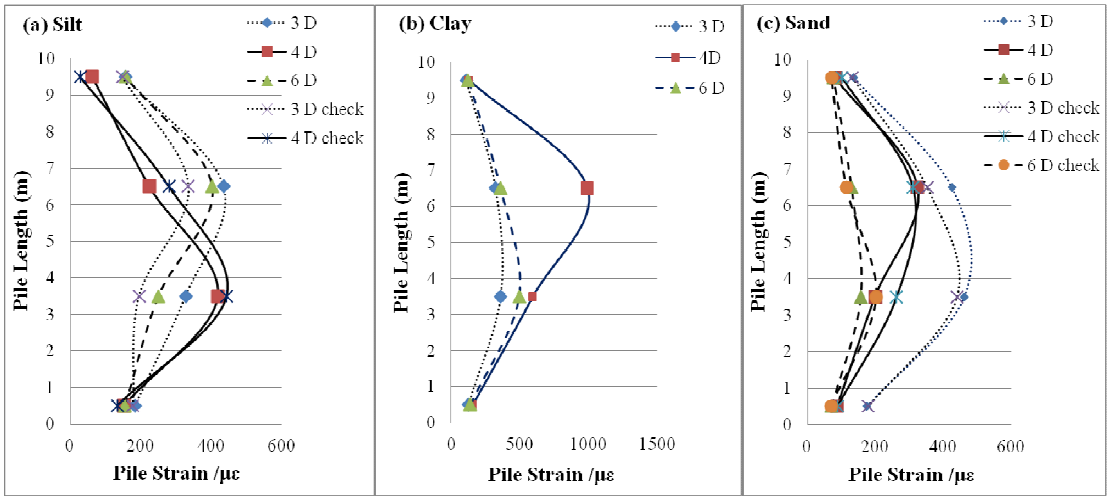

Fig.4. Pile length-strain of different soils

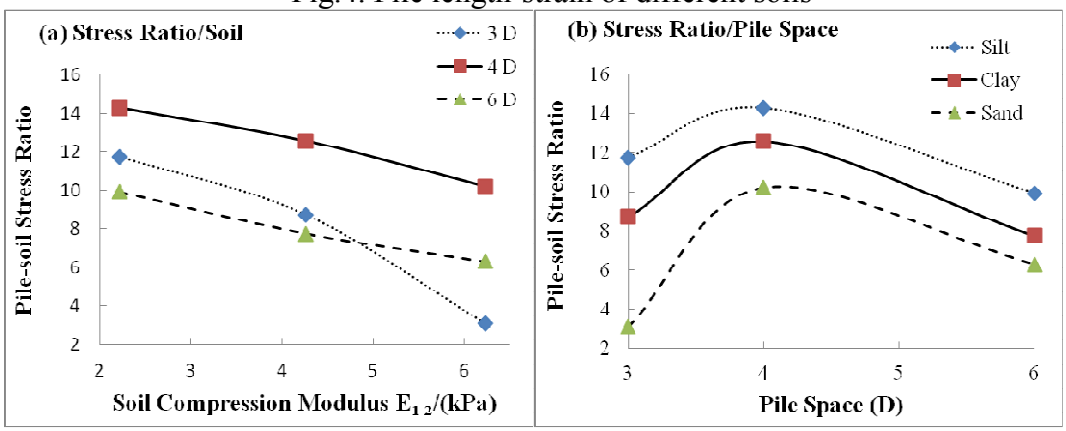

Fig.5. Pile-soil stress ratio at top

In silt, the pile strains along the length are complicated. There is not a clear rule to reflect the piles strains along the length with different piles spaces. It is similar that the 3D and 4D are larger than 6D in the middle of piles. It because that the geo-grids on the top of 6D piles were impaled, which leaded the 6D piles couldn't be fully used as the 3D and 4D piles to bear the embankment load.

In clay, the 4D are larger than 3D and 6D obviously, which illustrated the 4D piles is fully used. It because that the geo-grids on the top of 6D piles were impaled, which leaded the 6D piles couldn't be fully used as the 3D and 4D piles to bear the embankment load. The single pile in 3D piles group bead fewer loads than 4D, for the 3D's replacement ratio larger than 4D's. We can conclude the 4D piles space is optimal space in clay.

In sand, the 3D are larger than 4D, and 4D larger than 6D recursive, which illustrated the single pile in 3D piles group bead fewer loads than 4D, and 4D fewer than 6D, for the 3D's replacement ratio larger than 4D's, and 4D's larger than 6D's.

The pile-soil stress ratios at top changing with different kind soils and pile spaces are represented by the curve in Figs. 5 (a-b), respectively. As expected, the pile-soil stress ratio decreases with the soil compression modulus E1-2 increasing, but the 4D's ratio is always larger than the others, by different soils' modulus. The pile-soil stress ratio first increases then decreases with the soil pile spaces increasing, and at the 4D has the maximum; that ratio in silt is larger than clay, and in clay larger than sand, by different pile spaces.

As the sand is stiffer than clay, and clay is stiffer than silt, the load-displacement response of a pile in sand is stiffer than that of clay, and in clay is stiffer than that of silt. However in silt of 6D space, the geo-grids may be impaled by piles, which may lead to the stress between piles and soils renew distribution. By the Figs. 4 to 5, we can conclude that the 4D pile space is the most economic and reasonable to control the composite foundation settlement, in different kind soils.

**Load-instable Responses of Composite Foundation**

The load-instable responses of composite foundation in silt, clay, and sand with 3D, 4D, and 6D spaces are researched in these tests. The failure models of high strength composite foundation are affected by multi-factors, as embankment stiffness, piles and soils strength, and pile spaces etc. By preliminary analysis, the failure models can be itemized as pile impale geo-grids and cushions, slope shear failure, and piles flexural failure are represented by the pictures in Figs. 6 to 8, and failure types schematic diagram Fig.9, respectively. These failure types are similar to that that reported on piles in clay by A.T.C.Goh. (1997).

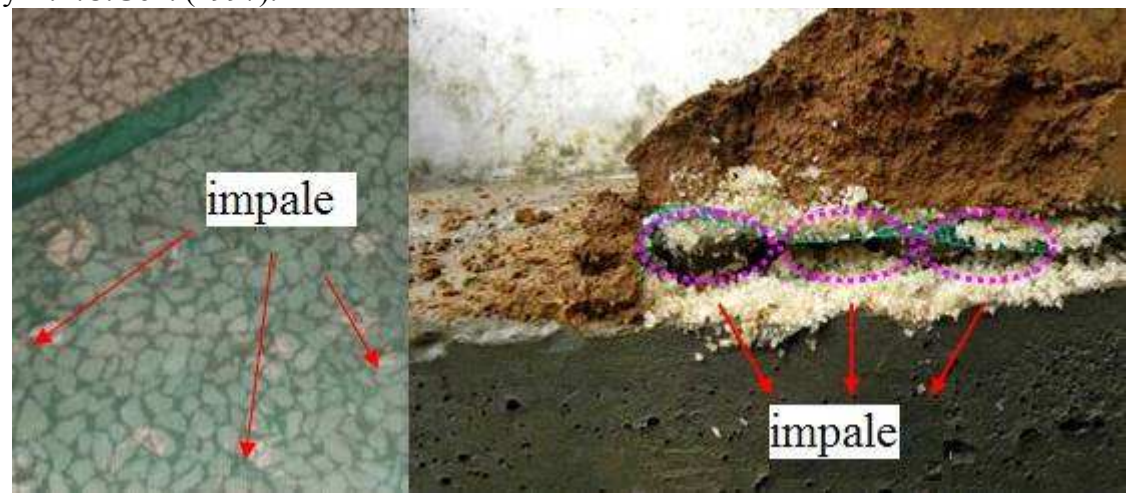

Fig.6. Piles impale geo-grids and embankment

Piles impaled geo-grids and cushions in all cases. There are many holes in the geo-grids impaled by piles, obviously cracks on the pile top embankment slope. Because the piles strength is much larger than soils, that make differential stress between piles and soils, and lead to the stress concentration in the pile top gravel cushion and geo-grids. There are radial cracks in embankment toe on piles top, which even leads to the embankment hang in the air. If the impaling too large, the piles and soils cooperative work will be destroyed, and then the composite foundation will be make part failure. It is unavoidable of pile impaling in the geo-grids and cushion, which is the precondition of the soils between piles playing a role in composite foundation (for example, Guo et al. 2010). That can be reduced by put reinforced concrete caps on the piles top (for example, BUI et al. 2009), in practice engineering.

Slope shear failures took place in clay and silt of 6D spacing in these series tests. Soils masses of lateral toe of slope are out-shifting significantly, there are a series cracks near the slope toe, obviously impaling on the most lateral piles top geo-grids and cushion. The most outsides row piles near the

slope toe outward inclined significantly, some of them even break, the next decreased, and the center hardly inclined. Shear failure plane cut off the outsides piles and breakthrough the slope toe. This observation on piles and embankments slope shear failures is similar to that reported on piles in clay by Zheng. (2012).

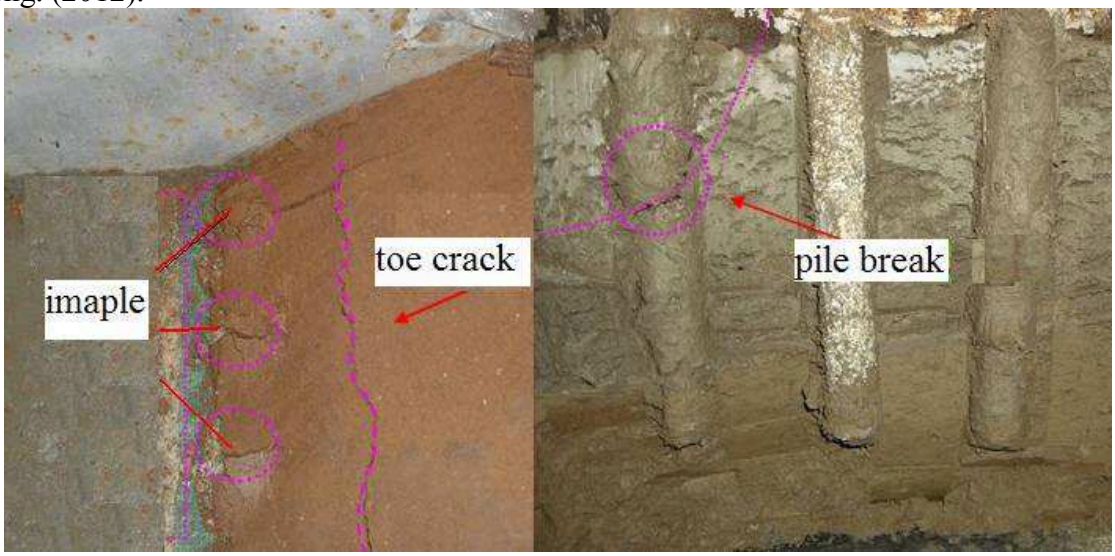

Fig.7. Slope shear failure

Because of the shape of embankment slope and mechanical characters of railroad, there are larger shear stresses in the embankment, especially at the slope toe. The shear stresses are mostly supported by the outside piles and soils, however the insides piles and soils little, for the symmetry of embankment structure and the barrier effect of piles group. From the deformation of different parts of composite foundation, the lateral displacement is decreasing from slope toe to center, the inside piles are just major vertical settlement. From the stress distribution of the foundation, in the center piles and soils lateral deformations are confined by the interactions of piles. However, the outside piles and soils lack lateral constrained and bearing the larger shear stresses, which make them easy fracture. When the outside piles and soils cannot support the shear stress, the foundation will take place shear failure. The theory on composite foundation failures are demonstrated by Guo. (2012).

Piles flexural failure took place in silt of 6D spacing in these series tests. The most outsides piles have significantly incline and flexural deformation; the piles top are excluded the slope toe; there are a lot of radio cracks on the piles top slope toes. From the composite foundation outside to inside, the piles inclination decreased, the most inside piles just have only micro scale inclination. The most outside row piles and the next break at middle section or on the soil interface. There are obviously out-up-shifts of the soils between the outside and next row piles, at the same time, the embankment having a larger settlement. This observation on piles and flexural failures is similar to that reported on piles in clay by Zheng. (2012). However, the model piles are replaced by aluminium alloy pipe, which could not reflect the true failure character of piles, especially the brittle fracture of the concrete type material piles.

Fig.8. Piles flexural failure

The main reasons of piles flexural failure are the larger piles spacing and lower strength of soils between piles. From outside to inside of the composite foundation, the main load directions supported by piles are changing from incline to vertical. There are settlement and lateral sway of the soils between piles under the embankment load. If the pile spacing is too large (6D in these tests), the strength of soils too low (silt in these tests), and the embankment too high, the lateral sway of inside soils will make the pile subject to bending load, which lead to piles flexural failure. As the outside row piles failure, the next row piles will continue failure, that make the lateral support of piles further weakened. At the same time, the soils between piles will support increased load, if the soils strength is too low, the composite foundation will be overall instable. While soil strength difference between the upper and lower soil interface (silt and sand interface in these tests) is too large, the piles is more like cantilever beam, that make the piles flexural failure at interface.

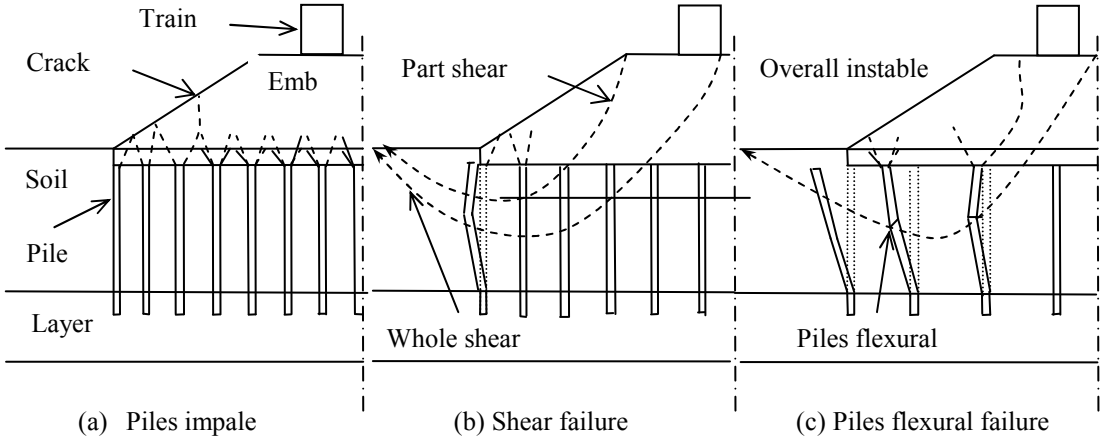

Fig.9. Composite foundation failure types

Considering the variation in soil properties in various piles spacing studies, the experimental failure types observed in the present study are reasonably consistent with those obtained from the early studies.

## Conclusions

Centrifuge model tests have been performed to investigate the behavior of high strength piles composite foundation in silt, clay, and sand under railway embankment and train load. The tests involved the high strength piles number ranging from 12 to 40, with center-to-center pile spacing of 3, 4, or 6D. The following conclusions can be obtained from the present study:

1. The embankment load of per pile supported is complicated in different kinds of soils with various piles spacing in the composite foundation. If the soils strength between piles is too low (silt in these tests) the load of per pile supported have not obvious regular with the pile spacing changing. The writer think that, as the soils strength is too low and the piles too high, the piles and soils cannot coordinate work together. It means that cannot make up the true composite foundation, for the soils between piles cannot give piles enough lateral constraint. That makes the piles like alterable system in structure engineering; there are no constraints on piles. It is no use to increase the piles number in composite foundation to decrease the pile spacing, consequently decrease per pile supported load. That has been proved by engineering practice in Xia-Shen railway of china, where the piles spacing is 3D, the soils between piles is silt. However, the embankment also took place overall instability when filling to 6m. It can conclude that the high strength piles composite foundation is not suitable using in soft soils as silt and mud areas.

2. With the soils strength increasing (clay in these tests), the soils and piles can constitute a coordinate work group as composite foundation, where the soils and piles can transfer load interaction effectively. There is an optimal piles spacing (4D in these tests), at this piles spacing, the piles strains

have a maximum at the up third of piles, the piles-soils stress ratio also has a maximum. By the optimal piles spacing, the piles and soils strengths can get a full used to realize the safety and economic of composite foundation. It can give a good reference to designer to determine the piles spacing in composite foundation, which has been used in Shi-Ji passenger special line of china. In sand, as its strength is high, the piles-soils stress ratio is less than in clay at the same pile spacing, which means the piles cannot be full used as in clay. It is diseconomy to constitute high strength piles composite foundation in sand.

3. In line with the findings of Guo et al. (2012) and Dong et al. (2010), the equal settlement surface of composite foundation is observed in the up third of piles, where the soils and piles have an equal settlement. The piles stress along length is an exponential function curves, and at the equal settlement surface, it has the maximum. On the up conclusions, Guo et al. (2012) deduced a series group stress-strain coordinate function of soils and piles in composite foundation under embankment load. By which, the strain and stress of the piles, soils between piles and cushion are separated calculated, it is good supplement to composite modulus calculating method of composite foundation settlement (JGJ 79-2002 Technical Code for Ground Treatment of Buildings of China).

4. the composite foundations failure types under a higher embankment load in 3,4,6D piles spacing, including piles impale geo-grids in every test, part shear failure in clay (4D) and whole shear failure in silt (6D), overall instable of piles flexural failures in silt (6D) are observed, respectively. The piles up stick gravel cushion, and under stick layers soils are necessary to constitute the composite foundation, in Guo et al. (2010). However, the pile impale geo-grids is need avoid, which can be resolved by giving a reinforced concrete cap on the pile top in engineering practices. The shear failures are a more general phenomena than others failure types, especially in homogeneous ground. However, in composite foundation the high strength piles can lead to more complicated failures types. The shadowing effect is most significant for the lead row piles and less significant on subsequent rows of trailing piles. Hence, if uniform pile type and size have been adopted for a composite foundation, appropriate checks should be conducted to evaluate whether the lateral load carrying and bending moment capacity of the lead row piles, in particular the outer lead piles, would be exceeded. In many previous research studies, the average performance of piles in the same row rather than the performance of individual piles is employed in the analysis. This simplification is found to be acceptable for the lead and rear row piles where the behavior of the outer and center piles do not differ much (Zheng et al. (2010)). However, for the middle pile rows (middle row in the case of the 4D, middle second and third rows in the case of the 3D), the present study reveals that the center piles often carries much less load and bending moment than those of the outer piles in the same row. Thus, appropriate caution should be taken when designing piles in the middle rows of a large composite foundation in view of the large difference in the load and bending moment between the outer and center piles.

**Acknowledgments**

The present study is part of the research collaboration between the Southwest Jiaotong University of China and The Third Railway Survey and Design Institute Group Corporation of China. The writers would like to express their gratitude to the technical staff of the Geotechnical Centrifuge Laboratory at Southwest Jiaotong University of China for their assistance and contributions in conducting the centrifuge model tests. The professor of Qian-Su in reviewing some of the testing schedule is gratefully appreciated. The authors sincerely thank the National Natural Science Foundation of China for the financial support provided to this research project (Grant No. 51308255).

# Comparative Experimental Research of Soil Freezing with Pressure and Non-pressure

Zhang shiyin

School of Civil Engineering and Architecture, Anhui University of Science and Technology, Huainan Anhui 232001

**Keywords:** Freeze under pressure; Freeze without pressure; Contrast test

**Abstract:** Use two kinds of soil, processes the uniaxial compressive strength test under the condition of pressure and zero pressure freeze, concludes different test results. That is the uniaxial compressive strength of frozen soil under pressure is higher than that without pressure, and laboratory test data as the basis for the design of the temporary support is relatively safe.

## Introduction

Freezing method uses the technique of artificial refrigeration, ices the water in the formation. So the natural soil turns into frozen soil. It can increases strength and stability of soil, and can isolate the connection of groundwater and underground engineering, in order to excavation and ling construct the underground engineering in the protection of frozen wall. The essence is using artificial refrigeration changes soil properties temporarily to consolidate layer. At present, freezing construction method applied in coal mine construction, currently frozen construction method is widely used in engineering, it is not only used in mine construction, foundation, but used in urban underground railway, river tunnels and other projects. But when the natural soil turn into frozen soil, its strength has relationship with its composition, moisture content, density, liquid limit, pressure and salinity. Now, in the design of frozen soil wall, strength index of frozen soil is usually settled in the laboratory, but the soil in the depths is under pressure in all directions, when the soil is taken into lab, crustal stress has been released, that is to say the strength index is measured after the crustal stress has been released. So whether the measured the frozen strength under stress and it at no stress is equal is a deep research of us.

## The contents and methods of test

Strict implementation of《Standard for Soil Test Method》GB/T 50123-1999 standard and《Physical and Mechanical Properties Experiment of Artificial Frozen Soil》MT/T 593-2011. Test content includes homemade container that the volume won't expansion when freeze, conventional physical property test of soil, Including moisture content, density, liquid limit and plastic limit, unconfined compressive strength test of soil, uniaxial compressive freezing strength test of soil samples without restrictions around, uniaxial compressive freezing strength test of soil samples in the condition of restrictions around.

## Soil sample and instrument

Soil sample is from a mine shaft of Huaibei, depth of 130 to 140 meters, taking into account the soil deep in the ground pressure and soil samples frozen frost force basically the same, tests using different clay and sand, test instrument is the self-developed WDT-100KN electro hydraulic soil pressure testing machine. (See Fig 1)

The test uses remolded soil, in order to compare the sample uniform, contrast, all of the soil sample after drying and pulverizing together with an amount of water, making certain the soil moisture content. Then wet 48 hours and sufficiently stirred to a uniform moisture content of the soil samples. The soil properties shown in table1.

Fig1 Testing machine

Table1 Soil properties

| Level number | Name of soil sample | Depth | Moisture content W% | Wet density ρ g/cm3 | Dry density ρ d g/cm3 | Liquid limit $W_l$% | Plastic limit Wp% | Plastic limit index Ip | Liquid limit Index Il |
|---|---|---|---|---|---|---|---|---|---|
| 1 | clay | 132.9 | 20.92 | 2.05 | 1.70 | 43 | 23 | 20 | -0.104 |
| 2 | Fine sand | 140.6 | 17.83 | 2.09 | 1.77 | | | | |

## Test results and analysis

### Test results

The test results shown in table2.

Table2 Test results

| Level number | Name of soil sample | The experimental condition | Test temperature (℃) | Test force (kN) | Stress (kN) | Axial deformation (mm) | Axial strain (%) |
|---|---|---|---|---|---|---|---|
| 1 | clay | No pressure, room temperature | 15 | 1.19 | 0.61 | 19.65 | 19.56 |
| 1 | clay | No pressure, room temperature | 15 | 1.29 | 0.66 | 18.20 | 19.00 |
| 2 | Fine sand | No pressure, room temperature | 15 | 1.46 | 0.74 | 16.31 | 19.14 |
| 2 | Fine sand | No pressure, room temperature | 15 | 1.58 | 0.80 | 16.71 | 19.64 |
| 1 | clay | No pressure, frozen soil | -5 | 4.61 | 2.39 | 14.36 | 19.20 |
| 2 | Fine sand | No pressure, frozen soil | -5 | 4.55 | 2.38 | 13.41 | 16.77 |
| 1 | clay | Pressure, frozen soil | -5 | 4.95 | 2.52 | 13.16 | 16.45 |
| 2 | Fine sand | Pressure, frozen soil | -5 | 5.11 | 2.62 | 13.35 | 16.69 |
| 1 | clay | No pressure, frozen soil | -10 | 7.53 | 3.88 | 11.35 | 13.57 |
| 2 | Fine sand | No pressure, frozen soil | -10 | 7.95 | 4.15 | 10.63 | 13.48 |
| 1 | clay | Pressure, frozen soil | -10 | 8.77 | 4.41 | 10.35 | 12.87 |
| 2 | Fine sand | Pressure, frozen soil | -10 | 8.87 | 4.62 | 10.43 | 12.68 |
| 1 | clay | No pressure, frozen soil | -15 | 10.94 | 5.55 | 9.65 | 12.07 |
| 2 | Fine sand | No pressure, frozen soil | -15 | 11.44 | 5.81 | 9.81 | 12.27 |
| 1 | clay | Pressure, frozen soil | -15 | 11.82 | 6.12 | 5.95 | 5.97 |
| 2 | Fine sand | Pressure, frozen soil | -15 | 11.89 | 6.09 | 7.79 | 9.74 |

**The uniaxial compressive strength of frozen soil is larger than the one of normal soil**
According to the test results, the uniaxial compressive strength of frozen is larger than that of no-frozen, and generally 2-4 times, what's more, the lower the temperature, the greater its compressive strength, but to a certain low temperature, with the decrease of temperature, the compressive strength increase is not obvious. For some formation, lower freezing temperature is good for enhance the strength of soil, but to a certain temperature, increase its strength by reducing the temperature is limited.

**The compressive strength of frozen soil under pressure is higher than that without pressure**
As we all know, deep soil layer is affected by the overlying strata pressure, it has some stress, tests have proved that, the compressive strength of frozen soil under stress is larger than that after release the stress, this has a certain relationship with the condition of freezing.

## Analysis

According to analysis of test results, there are several points that the axial compressive strength of samples under pressure is larger than without pressure.
1, The specimens have frost heave, from the freezing test have found that samples is limited in the lateral, but after the soil specimen whose ends have no restrictions(under no pressure) freeze, two ends of the sample have bulging phenomenon, it is obviously that the sample has frost heave in the freezing. So it is indicating that when the specimen is freezing, the volume increases, the density becomes small.
2, Usually, sample freezing in sealed container will produce frost heave, but there are constrains on sample from container in all directions, specimen size can not be increases, but with the same quality, the density will larger than it in no constraint.
3, For the sample is restrained by the fix container device, and the specimen produces frost heave force in freezing, but the frozen sample volume is still the same with before freezing, samples must digest the volume that was produced when freezing, so the sample particle must be rearranged, it will into an more reasonable and close state, therefore, the density under pressure frozen is larger than that without pressure frozen, this is the reason why the uniaxial compressive strength under pressure is larger than it without pressure.

## The conclusion

According to the above analysis, the compressive strength of frozen soil under pressure is larger than it without pressure, the frozen test data that usually completed in the laboratory, its strength is lower than it in the original deep frozen soil, so using laboratory test data as the basis of engineering design for the temporary support is relatively safe.

**Keywords:** Limestone cave;Reinforcement;Pressure grouting;High pressure grouting; Supplementary pile

**Abstract.** With the example of pile foundation engineering in the limestone karst fissure reinforcement, discusses the principle of reinforcement of pile foundation in karst area, introduces some construction technology of pile foundation reinforcement, the reinforcement design principles and the reinforcement scheme is briefly discussed, and combined with the engineering practice and put forward a set of safety, economy and reasonable treatment plan, to reinforcement technology promote the karst pile foundation bottom cave, fracture.

## Introduction

With the rapid development of Chinese economy, more and more high-rise building project, the bearing capacity of foundation design requirement is more and more big, need to design of bored pile foundation in karst area, and is often accompanied by cave, resulting in pile foundation bearing capacity decreased significantly, and the adverse effects of great uncertainty, impact structure safety engineering; these problems according to the own experience analysis.

## Introduction to engineering

### 1.1 Engineering survey

A university library, the library is something 150m, north-south width of 157m, 7 layers, high41.7m, frame structure, the foundation for bored pile foundation pile, single column, pile diameter is 600mm, φ800mm, φ1000mm and φ1200mm, a total of 362 trees. The pile foundation construction ends with drilled core testing, test results showed the presence of karst cave, fissure part of pile end below 5 meters, the cave filling of clay in different degree, rock crushing, does not meet the specification requirements; safety, economy and reasonable based on the principle, must exist at the ends of piles or fissure cave on the shallow part of the reinforcement, ensure the safety of the building.

### 1.2 Engineering geological conditions

According to the "report" the geotechnical engineering investigation, site soil layer from top to bottom are as follows:

The miscellaneous fill: the average thickness of 1.46m; ②The average thickness 2.77 m; ③Clay: the silty clay: the average thickness of 1.02 m; ④The average thickness of sand: 3.52 m; ⑤The average thickness of clay: 3.12 m; ⑥The whole weathered diorite Bin Yan: exposing the maximum thickness of 31.20m (nonexposed); ⑦The strong weathered diorite Bin Yan: exposing the layer 1.80 ~ 12.30m; ⑧The weathered diorite Bin Yan: to expose the thickness of 1.2 ~ 6.10m, ⑨Limestone weathering: the main form in karst caves fracture, exposing the maximum thickness is 18.90m.

## Reinforcement scheme design

### 2.1 Design principles

According to the characteristic of bearing capacity of single pile foundation of different values, respectively, for each problem pile according to current calculation of the bearing capacity of pile bearing capacity, compared with the lack of data [1], consider using pressure grouting, grouting pressure, grouting and grouting strengthening side, adding the bored pile, processing method based on fourth, lack of size selection of bearing capacity of the different processing methods, selection of reinforcement method is mainly based on the following principles:

(1) When the bearing capacity of single pile pressure grouting is greater than the bearing capacity of single pile and pile end value, no cave development, the core drilling hole sealing treatment using pressure grouting method (I).

(2) When the pile end existent cave, pile bearing stratum of rock fragmentation, pile bearing stratum argillaceous limestone or porphyrite, pile end rock cracks developed, if after grouting reinforcement of bearing capacity of single pile is larger than the single pile stress value, through core drilling hole using high pressure grouting the reinforcement treatment on the method (II).

(3) When after grouting reinforcement of bearing capacity of single pile bearing capacity of single pile is less than the value, if the difference between the two is smaller, the pile end of karst strata on the top of thick, strengthened by grouting and the side grouting reinforcement (III).

(4) When after grouting reinforcement of bearing capacity of single pile bearing capacity of single pile is less than the value, if the pile end of karst strata on the top of the thinner or single pile bearing capacity than the bearing capacity of single pile is small is big, the addition of bored pile reinforcement (IV).

### 2.2 Reinforcement schemes

According to the design drawings [2] all kinds of pile bearing capacity of single pile, survey report and core drilling test results on the problems of the pile one one was used to analyze the bearing capacity calculation, the final classified on the need to deal with the pile; do not meet the design requirements of a total of 197 tall pile, classified processing in accordance with the above four kinds of processing methods, so this part of the bearing capacity of pile foundation can meet the design requirements, which uses two times of high pressure grouting bolt (in bored pile construction of pile side is φ220) was used to reinforce the 10 trees, using pressure grouting plugging of drilling core hole 66 trees, high-pressure grouting (only φ48 steel tube as the high pressure grouting pipe), the 89 trees strengthen the pile pressure grouting, supplement 10, and 22the diameter of 600mm or 800mm. Pressure grouting, grouting by drilling core drilling test of the implementation of the original.

## Reinforcement construction scheme

### 3.1 Pressure grouting construction

3.1.1 Pressure grouting construction method

Pressure grouting construction method is as follows: decentralization of grouting pipe, hole cleaning, grouting, repeated grouting, the next cycle of operation.

(1) To the grouting pipe: according to the design drawings in the pile hole grouting plastic tube (or pipe down). The grouting pipe length should be greater than the grouting depth 30cm ~ 50cm for grouting and ground pipe connected.

(2) The hole cleaning: after running the grouting pipe, the grouting pipe connection to the mud pump through grouting hose ground detection hole, wash with water, back out until the hole in the water not containing impurities.

(3) Slip casting : the special mixing barrel grouting and grouting pump, injection pump working pressure should meet the requirements of construction (less than 0.5MPa). According to the design, preparation of slurry, slurry mixing evenly, with the mix with the use of grouting slurry pump to be reinforced with Kong Zhong, grouting with the grouting pipe up, but ensure the nozzle always buried in the slurry below 1 ~ 1.5 meters.

(4) Repeated grouting: by perfusion of the water cement ratio, along with the solidification cement grout, grouting holes will have certain decline in [3], in order to ensure grouting and the existing pile surface as high, at the first end 45min grouting to a grouting, grouting, grouting pipe end to enter into the liquid level of not less than 50cm, grouting slurry returning to the pile surface. Liquid filling slurry to repeatedly until after the final set of pile top elevation consistent before the slurry coagulation.

3.1.2 Quality assurance measures

(1) Water cement ratio is 0.6 ~ 0.7, to ensure that the use of cement and water to be weighing.

(2)The water to be neutral water does not contain impurities.

(3) The grouting pipe to ensure smooth and at any time to check the dimensions on the grouting pipe.

(4) Grouting pressure is 0.2 ~ 0.5Mpa.

**3.2 High pressure grouting and high-pressure grouting strengthening**

3.2.1 The process

The process is as follows: embedded grouting pipe and an exhaust pipe→ sealing hole→hole cleaning→ water pressure→high pressure grouting→the next cycle of two high-pressure grouting→ plugging grouting pipe→ the next cycle.

(1) Embedded grouting pipe and the exhaust pipe: according to the design drawings in the pile hole to pre process of high pressure grouting good pipe, and the sealing position with steel welded tripod 6.5, the exhaust pipe is tied to the high pressure grouting pipe, the exhaust pipe mouth over the tripod position 5 ~ 10cm high; pressure grouting pipe length should be greater than the grouting depth 30cm ~ grouting hose to the ground and connected with the 50cm tube

(2) Sealing: dry cement mortar rigid according to the sealing length of hole sealing, dry harden cement mortar shall be compacted layer by layer.

(3) The hole cleaning: sealing 24 ~ 48 hours after injection to be empty, strengthened by high pressure grouting hole, until the exhaust hole in the water does not contain impurities square hole cleaning.

(4) Water pressure: empty after water pressure with wedge, exhaust hole is blocked, carry out the high water pressure, the pile bottom sediment and soft soil is split, the pressure is not less than 0.2MPa.

(5) High pressure grouting: high pressure grouting pressure after the water, open the exhaust pipe, high pressure grouting, when the slurry from the exhaust pipe to return does not contain impurities, the exhaust pipe is welded, then the high pressure grouting in high pressure grouting pipe. Grouting slurry to a special stirring barrel and grouting pump, injection pump working pressure should meet the requirements of construction (less than 5MPa). According to the design, preparation of slurry, slurry mixing evenly, with the mix with the mud pump to be reinforced hole grouting, grouting pressure not less than the design pressure, and loading time of not less than 5min.

(6) Plugging grouting pipe: high pressure grouting sealing grouting pipe after the high pressure grouting pipe welded to prevent slurry returning to surface.

3.2.2 Quality assurance measures

(1) Water cement ratio is 0.6 ~ 0.7, the cement and water to weighing.

(2) The water to be neutral water does not contain impurities.

(3) Grouting pipe to ensure the smooth and have good weldability.

(4) High pressure grouting pressure is 2 ~ 3Mpa, grouting pressure with shockproof pressure meter, loading time must use the meter

(5)The high pressure grouting pipe machining welded to ensure weld height, the electrodes shall comply with the relevant standards of the state.

**Comparison of the test, test and economic effect**

Do not meet the requirements of the specification of the pile after treatment, entrust the local detection unit for the treatment of pile load test, the core drilling test and dynamic test and other

methods of detection, the pile can meet the design requirements, to achieve the desired results, treatment scheme of the project than the conventional filling pile or pile again drilling, a comprehensive analysis on the basis of pile bottom karst fissure size and distance from the bottom of pile is different, different processing methods for the project to save millions of dollars, but also saves time, achieved very good results.

## Conclusion

Treatment technology of grouting pile foundation construction in karst area is currently the most effective method of treatment, reliable reinforcement, it is a settlement of single pile construction in the reconstruction of the investigation report and the actual construction geology is inconsistent, and provides a new idea of pile end rock integrity can not meet the specification requirements of processing. Individually for each does not meet the requirements of the standard calculation of pile separately, comparing several schemes, different requirements by different processing plan.

**Keywords:** Ultra-soft ground; Vacuum preloading; Finite element; Variable permeability coefficient

**Abstract.** In this paper, a soil-water coupled finite element analysis incorporated the macro-element method is carried out to investigate the effect of variable permeability coefficient on the consolidation of the ultra-soft ground using vacuum preloading. Sys cam-clay model is employed as the constitutive model of the ultra-soft soils. When the drain space becomes from 60cm to 40cm, there is significant acceleration in the numerical settlement of the ground using the constant permeability coefficient, which is quite different from the observational results. When the variable permeability coefficient where a liner relationship between the void $e$ and the logarithmic value of permeability coefficient $\ln k$ is adopted is employed, there is a good accordance between the numerical and observational settlements. According to the distribution of variation in the void, the largest variation in the void occurs at the top several layers and therefore the predominant settlement can be attributed to the volumetric compression of the top several layers.

## Research Background

Land reclamation has been the main treatment to relieve the land shortage in Binhai New Area of Tianjin. The reclaimed ground consists of ultra-soft dredged soils from Bohai sea, which is of very high water content, low bearing capacity and small permeability. The vacuum preloading has been extensively used in the land reclamation in the coastal region. Large-scale field tests about the vacuum preloading of the ultra-soft ground have been carried out by Liang et al. [1] and they found that when the space of the plastic vertical drain varies from 60cm to 40cm, the degree of vacuum pressure increases correspondingly but there is no obvious acceleration in the settlement, which may attribute to the decreasing void during the vacuum preloading. In order to explain the above phenomena, many scholars have investigated the influence of the variable permeability caused by the decreasing void on the vacuum preloading theoretically and numerically [2,3,4]. However, there is no systematical finite element analysis about the influence of variable permeability coefficient on the consolidation of the ultra-soft ground. In this paper, a soil-water coupled finite element analysis incorporated the macro-element method is carried out to demonstrate the effect of the variable permeability coefficient on the vacuum preloading.

## Introduction of the Macro-element Method

One of the difficulties in the numerical calculation of the vacuum preloading is the mesh partition. It is well known that there is much difference between the size of the ground and the size of the plastic vertical drain. If specific meshes are assigned to the vertical drain, the mesh will become too fine to

finish the calculation in a rational period. In addition, when a three-dimensional vacuum preloading problem is simplified as a two-dimensional plane strain problem the numerical drain space ratio and discharge capacity should be adjusted artificially according to the practical ones [5,6]. Based on the soil-water continuity equation proposed by Akai and Tamura [7], Seikiguchi et al. [8] introduced the concept of the macro-element method for two-dimensional consolidation problems. As shown in Fig. 1, the plastic vertical drain is simplified as the pore water pressure $u_D$ inside the element, which is not necessary to designate specific meshes for the vertical drains. Through changing $u_D$, the pore water can flow into/out of the element and the volume of element is variable as if there were plastic vertical drains.

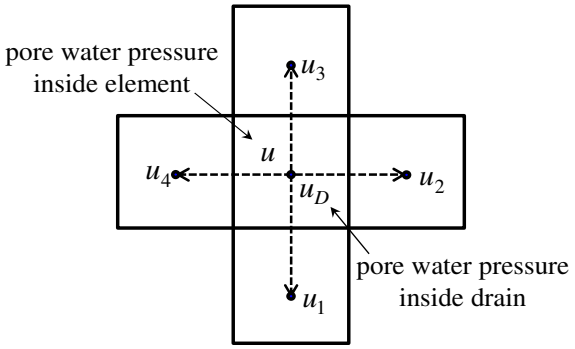

Fig. 1. Sketch of pore water flow among element, vertical drain and adjacent elements

## Calculation Conditions

**Mesh Partition.** The reclaimed ground is with the width of 96m, length of 150m and depth of 4m with ultra-soft dredged soils. The plastic vertical drain is placed with the width of 14m and the depth of 3.5m, where the improved area is marked as the macro-element area in Fig. 2. Based on the practical field tests, the equivalent well space $d_e$, the well diameter $d_w$ and the discharge capacity $k_w$ are 0.6 or 0.4m, 6.75cm and 4.0cm/s respectively, that is the drain spacing ratio $n = d_e / d_w$ is around 9 or 6. The hydraulic boundary is also shown in Fig. 2, where the vacuum pressure -80kPa is applied at the top of the plastic vertical drain. The undrained boundary is applied at the bottom of the drain to represent the sealing of the drain at the bottom. At the right side of the macro-element area, the undrained condition is applied from the top surface until 1.5m underground to act as the clay sealing wall. In the left side of the ground, the undrained condition is used considering the symmetry

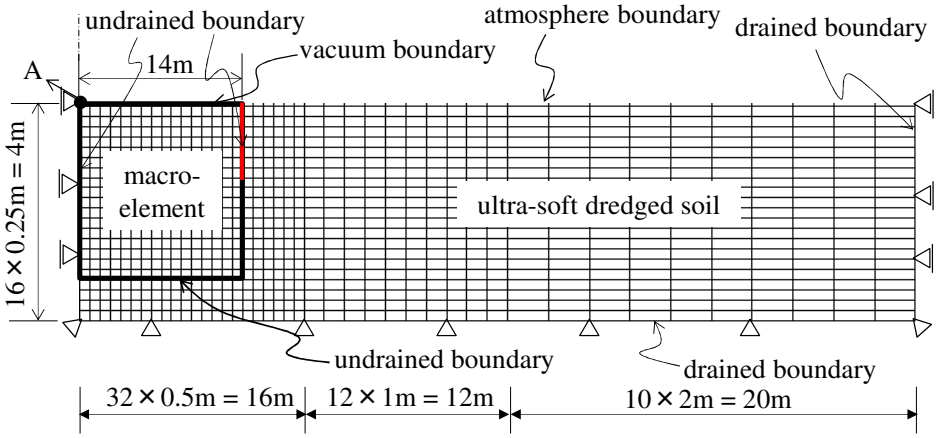

Fig. 2. Mesh partition and boundary conditions

**Soil Parameters.** The sys cam-clay model [9], which is able to describe the different extent of disturbance of soils by introducing the concept of structure, overconsolidation and anisotropy, is employed as the constitutive model of the ultra-soft soils. Through the curve fitting of the experimental and numerical results of the one-dimensional compression test as shown in Fig. 3, the

soil parameters can be determined in Table 1. In Fig. 3, there is a sudden decrease in the specific volume around 10kPa. Through assigning appropriate degree of structure and overconsolidation, such decrease can be reproduced accordingly.

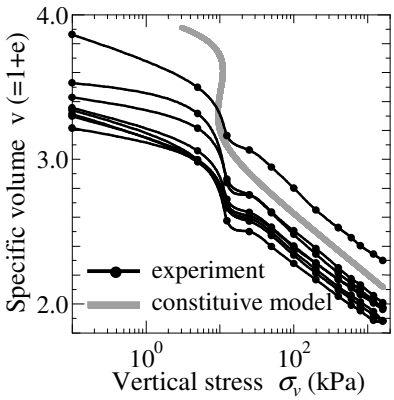

Fig. 3. Curve fitting of experimental and numerical results for one-dimensional compression test

Table 1 Soil parameters and initial values of ultra-soft soil

| *Elasto-plastic parameters* | | *Initial values* | |
|---|---|---|---|
| compression index $\tilde{\lambda}$ | 0.29 | specific volume $v_0$ | 4.0 |
| swelling index $\tilde{\kappa}$ | 0.015 | stress ratio $\eta_0$ | 0.75 |

## Calculation Results

**Settlement.** The observational and numerical settlements at node *A* in Fig. 2 when the drain spacing ratio is 9 are shown in Fig. 4. As can be seen, there is a good accordance between two settlements, which proves that the soil parameters employed in Table 1 is reliable. The slight differences may attribute to the instable vacuum pressure at the initial stage.

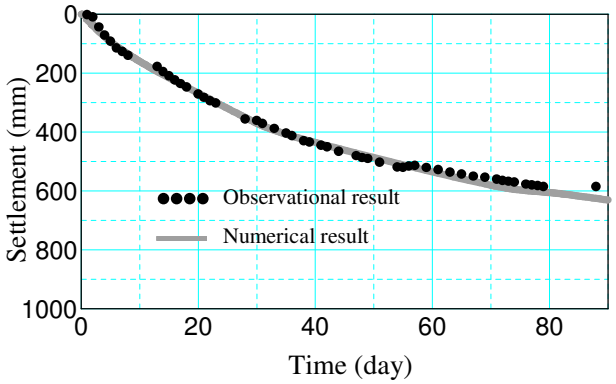

Fig. 4. Observational and numerical settlements at node *A* ($n$=9)

As explained by Xu et al. [10], one of the merits of the macro-element method is that it is unnecessary to re-divide the mesh when different drain spacing ratios are employed. Therefore, using the same mesh partition the numerical settlement can be presented in Fig. 5. Initially, the numerical result corresponds to the observational one very well until around 20d after the application of the vacuum pressure. However, the difference becomes more and more remarkable as the time of the vacuum preloading elapses when the constant permeability coefficient $k$ is adopted, which can attribute to the decreasing permeability caused by the decreasing void as the progress of the vacuum preloading.

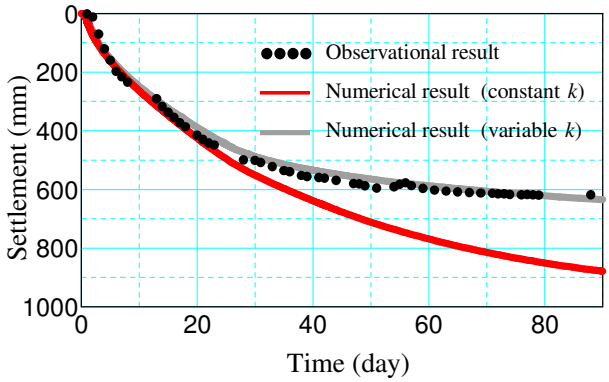

Fig. 5. Observational and numerical settlements at node $A$ ($n$=6)

In order to investigate the effect of the variable permeability coefficient $k$ on the vacuum preloading, a linear relationship between the void of the ultra-soft soil and the permeability coefficient is used as shown in Eq. (1). Here, $e_0$ is the initial void and $k_0$ is the initial permeability coefficient. $c_k$ can be determined by the try-and-error method. Limited to the space of this paper, the determination of $c_k$ is neglected and we directly assign 0.8 to it. Fig. 5 also presents the settlement of node $A$ when the variable permeability coefficient is employed, in which Eq. (1) is used. As can be seen, there is a very good correspondence between the observational and numerical settlements. Compared with the case where the constant $k$ is used, the permeability coefficient gradually decreases as the void becomes smaller in the variable-$k$ case. Moreover, the smaller the drain space is, the larger the variation of the permeability is. Therefore, it is very necessary to consider the variation of permeability coefficient for the consolidation of the ultra-soft ground, especially when there is a considerable change in the void of the ground.

$$e - e_0 = c_k \left( \ln k - \ln k_0 \right). \tag{1}$$

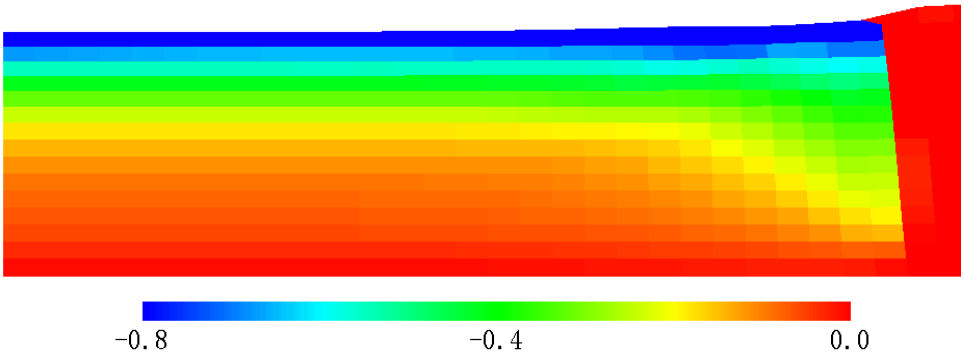

Fig. 6. Distribution of variation in the void in the ground of the improved area when 70d vacuum consolidation ($n$=6)

**Distribution of Variation of the Void.** The distribution of variation in the void of the improved ground after the vacuum pressure has been applied for 70d is shown in Fig. 6. In the color legend, the red end (0.0) represents that there is no void change and the blue end (-0.8) means that there is void decreasing, namely volumetric compression. As can be seen, the decrease of the void becomes smaller and smaller from top to bottom. Therefore, the decrease of the permeability coefficient also becomes smaller and smaller downward. In addition, the predominant volumetric compression concentrates at the top several layers. It can be known that the volumetric compression in the top several layers contributes to the main settlement at the ground surface, even though the length of the plastic vertical drain is very large. At the boundary of the improved area and unimproved area, due to the undrained condition of the clay sealing wall, there is no variation of void in the unimproved area.

## Conclusions

In this paper, a soil-water coupled finite element analysis incorporated the macro-element method is carried out to investigate the effect of variable permeability coefficient on the consolidation of the ultra-soft dredge ground during the vacuum preloading. The conclusions are as follows:

(1) In the vacuum preloading of the ultra-soft ground, it is necessary to consider the decrease of the permeability coefficient when the void becomes smaller accompanying the volumetric compression.

(2) As the drain space changes from 60cm to 40cm, there is no obvious acceleration in the settlement of the surface due to the significant decrease of the permeability. The smaller the drain space is, the larger the variations of the void and the permeability coefficient are.

(3) The variation of the void gradually decreases from top to bottom, namely the variation of permeability coefficient deceases downward and the settlement of at the ground surface can be mainly attributed to the volumetric compression of the top several layers.

# Experimental application of fractal theory into selection of subgrade filling materials

Xigang Wang[1, a]

[1]College of resources and civil engineering , Liaoning institute of science and technology,176 xianghuai Road, shiqiaoziDistrict, Benxi city, Liaoning province, China 117004

[a]fx_wxg@163.com

**Keywords:**fractional dimension; dopant amount; settlement and deformation; prediction model

**Abstract.**To investigate the settlement deformation of subgrades, we used fractal theory and soil section technology to study the original foundation soil, and soils filled with 4%, 8%, 12%, 16%, 20% and 24% of A material. The results show that under consolidation pressure of 500 KPa and after one dry-wet circulation, the fractal dimension was 1.7 in the original soil, 1.78 in the soil filled with 4% A material, and 1.93 in the soil filled with 24% A material. Along with the increased dopant amount of A material, the fractal dimension of soil mass gradually increased, but after the dopant amount reached 24%, the increasing rate was very slow. With the increased addition of A material, the compression deformation gradually weakened, but after the dopant amount reached 24%, the changing rate was very small. We derived a prediction model between the dopant amount at a certain particle size and the fractional dimension. This model can be used to predict the dopant amount at a certain size. The reasonableness of this model when using single size was validated via engineering practice.

## Introduction

Because of the formation history and stress history, rock-soil porous materials will lead to heterogeneity in rock-soil engineering materials. Unsaturated rock-soil mass is largely affected by porosity and suction. The key in studying the macromechanic properties of rock-soil materials is how to accurately describe their microstructral composition. It is hard to study the internal microstructure of soil mass via traditional geometrical methods.

Based on fractal geometry theory and related experimental data, we analyzed the pore microstructure of rock-soil porous media and found the obvious fractal properties of rock-soil materials. Studying the macromechanic properties of rock-soil materials via analysis of internal microstructure will help to better serve engineering practice [1,2].

The subgrades of high-speed rails require strict settlement control, thus raising demand for the properties of filling materials to be used in subgrades. Generally, the quality of the original foundation soil does not meet engineering demands, and in most cases, we have to dope additional materials to improve the soil mass. However, a low addition will not yield the expected effect, while a high addition is not economic. In this paper, thus, based on engineering practice, we use fractal theory to analyze the soil mass materials, to determine fractal dimensions, and determine the dopant amount of materials on basis of relationship between fractional dimension and soil-mass compressed deformation. We expect to provide better services for engineering.

## Experimental analysis

Images were recorded by electron microscopy and processed on Image-Pro Plus (IPP). The original foundation soil, and the soils filled with 4%, 8%, 12%, 16%, 20% and 24% of A material were marked as groups 1 to 7.

### 1.1 Sample collection

Three types of soil were collected with a thin-walled steel cylinder (height 30 cm, radius 12 cm). Each type of soil was set with 4 samples, which underwent 0, 1, 3, and 5 dry-wet circulations respectively. The samples were consolidated under 500 KPa.

### 1.2 Preparation of soil sections

The soils were compressed under the consolidation pressure to a height < 30 cm. Considering the boundary effect, we cut off the uppermost 4 cm soil from each sample. Then a soil section was collected at each 3 cm. Seven sections were cut from each sample.

## Soil-mass fractional dimension

### 2.1 Fractal dimension of original area distributing of particles

The rock soil mass is composed of a pore structure and a particle structure. Via soil sections and IPP [3,4,5,6], we obtained pore distribution rules, pore number and size, relationship between pore area and size. Based on these data, the fractal dimension of particle original area distribution was used via box counting method as follows:

$$A(\geq R) = A_T\left[1\text{-}(\frac{R}{R_{max}})^{2\text{-}D_0}\right] \quad (1)$$

where R——reference particle size

$R_{max}$——maximum particle size

$A(\geq R)$——total area of particles≥R

$A_T$——total area of the reference range

$D_0$——fractal dimension of pore original area distribution

Logarithm of two sides of Eq. (1) yields:

$$\ln[1 - A(\geq R)/A_T] = (2 - D)\ln(R/R_{max}) \quad (2)$$

With $\ln[1 - A(\geq R)/A_T]$ as Y-axis and $\ln(R/R_{max})$ X-axis, the experimental data were fitted to obtain a linear slope k. The fractal dimension of original area of foundation soil was calculated as follows:

$$D_0 = 2\text{-}k \quad (3)$$

### 2.2 Distributing fractal dimension of tested soils

Based on soil section technology and image processing technology, with particle sizes 4, 3.5, 2, 3, 2.5, 2.5, 1, 0.5 cm as dividing sizes, the experimental data were used to analyze the relationships between fractal dimension of original area of foundation soil and particle size (Fig. 1).

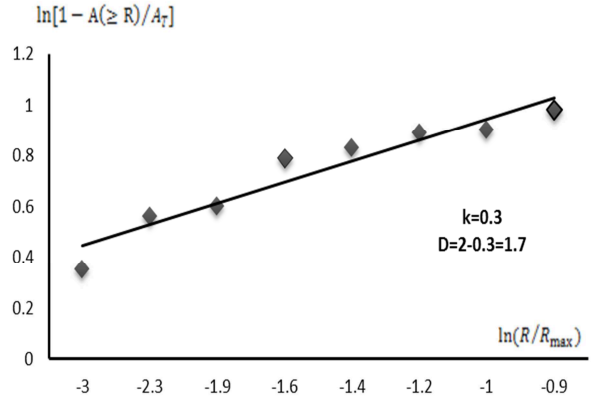

Fig.1 Fractal dimension of original area of foundation soil

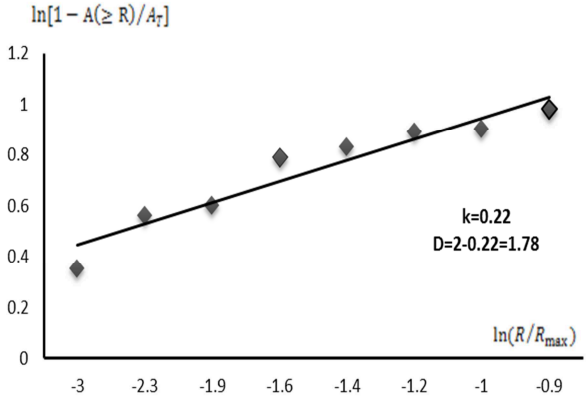
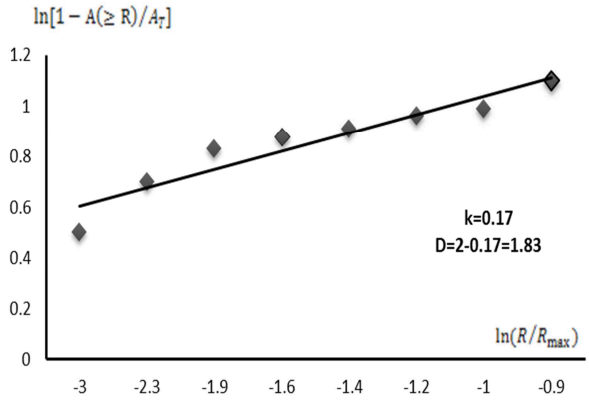
Figure 1 shows that the logarithms of particle size and particle area are in linear relationship, with slope of 0.3. Based on Eq. (3), the fractal dimension of original particle is 1.7.

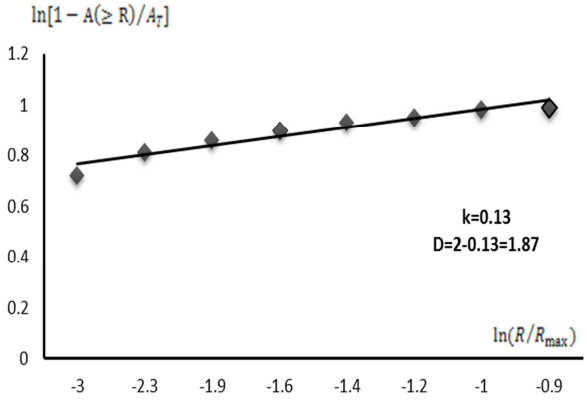
Similarly, the soil masses of groups 2 -7 were analyzed, and the relationships between the fractal dimension of original area and particle size are showed in Fig. 2.



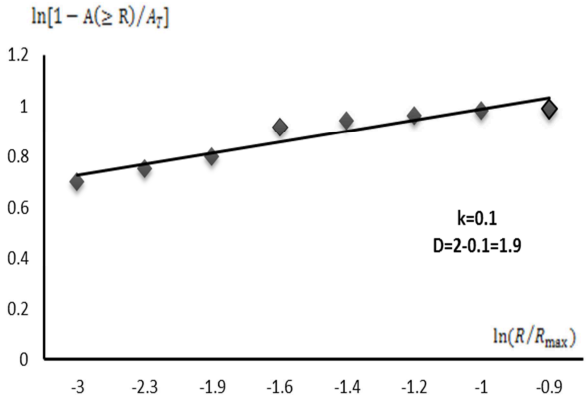
a:dopant amount of material A = 4%



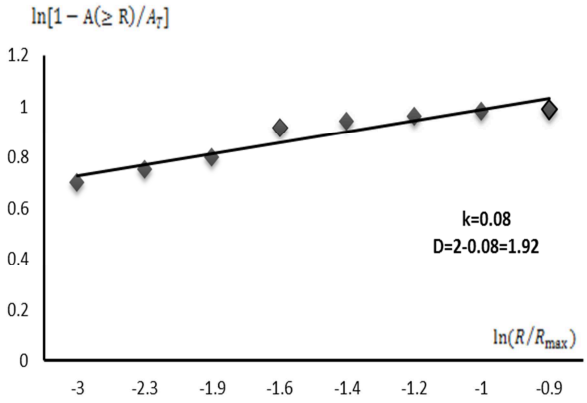
b:dopant amount of material A = 8%



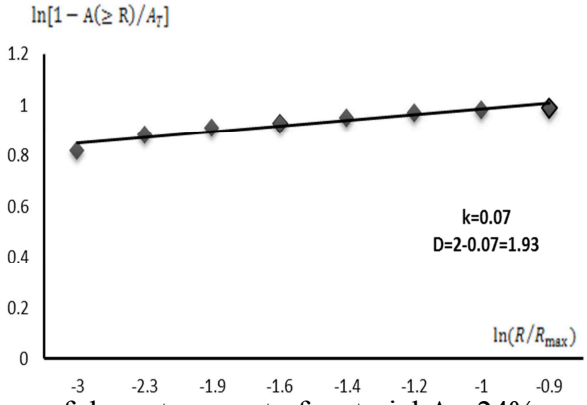
c: dopant amount of material A =12%



d:dopant amount of material A =16%



e:dopant amount of material A = 20%



f:dopant amount of material A =24%

Fig. 2 Relationship between fractal dimension and dopant amount of A material

Figure 2 shows that the fractal dimensions of groups 2 to 7 are 1.78, 1.83, 1.87, 1.9, 1.92, and 1.93, respectively.

The relationship between dopant amount of A material and fractal dimension is showed in Fig. 3.

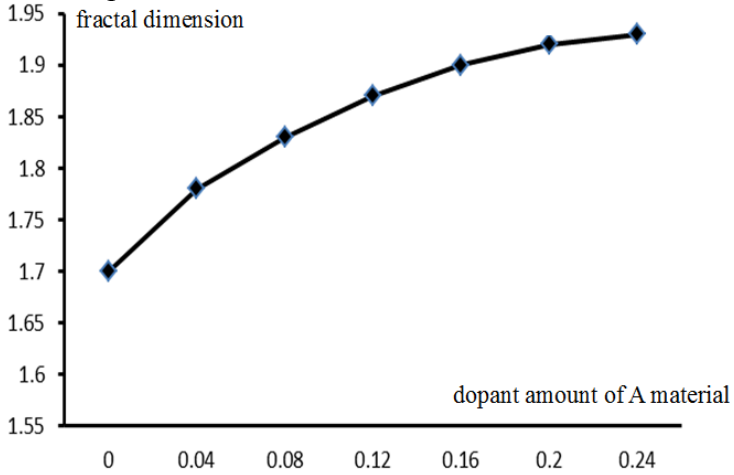


Fig.3 Relationship between fractal dimension and dopant amount of A material

Clearly, along with the increased dopant amount of A material, the fractal dimension of soil-mass original area distribution gradually increases; at dopant amount of 20% or 24%, the increasing rate of fractal dimension slows down, indicating that A material effectively fills the pores of large particles.

Each soil sample was cut into 7 sections which were not of the same the depth. Experiments show that the soil-mass fractal dimensions from each section are inconsistent, and the relationships between fractal dimension and depth are showed in Fig. 4.

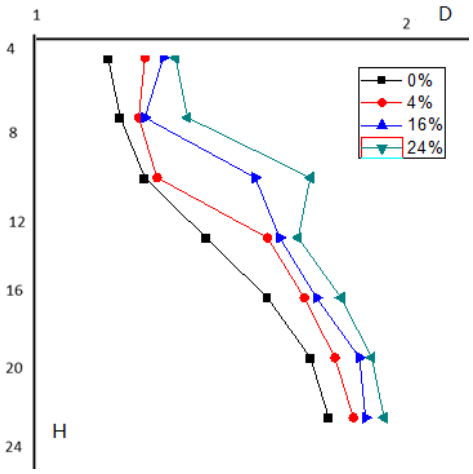

Fig. 4 Relationship between fractal dimension after 1 dry-wet circulation and depth

Clearly, for the same soil sample, under the consolidation pressure, the soil-mass fractal dimension gradually increased along with the increased depth; at the same depth, the fractal dimension also rose along with the increased dopant amount of A material.

### 2.3 Deformation and distributing fractal dimension

By measuring the deformation of each type of soil, we built the relationships between fractal dimension and deformation (Fig. 6).

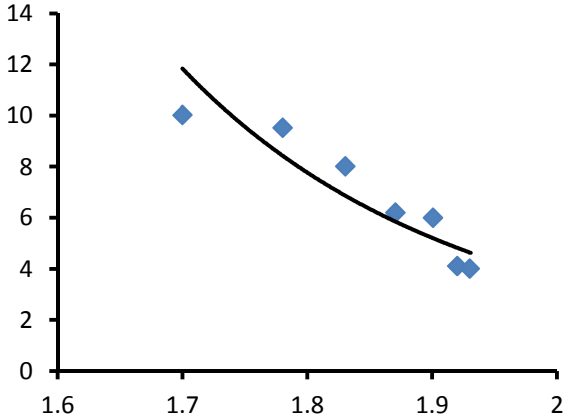

Fig. 5 Relationship between fractal dimension and deformation

Clearly, the deformation was maximized in the original foundation soil; along with the increased dopant amount of A material, soil-mass deformation was enhanced; when the dopant amount was 20%, the soil mass deformation changed very slightly; the deformations were not very different between dopant amounts of 24% and 20%. These results indicate that the dopant amount of 24% A material could well inhibit the soil mass deformation. In this project, addition of 24% A material into the original foundation soil can improve the deformation resistance of soil mass.

### Relationship between fractal dimension and dopant amount

We suppose the volume of original foundation soil is V, the addition of the modifying soil is a*V; when the addition of the modifying soil is equal to the volume of particles with size > R in the original soil, then most pores in the original soil will be filled in, resulting in small consolidation deformation in the mixed foundation soil.

The modified soil was further divided to obtain the relationship between particle size and pore volume. Then we can know the volume of pores between particle sizes R1→R2 (R1<R2). This interval of pores will be filled in with a modifying material with single particle size of R1. In this way, in each interval, we can obtain the particle size of the doped modifying material. Based on the pore

volume, we can determine the dopant amount. A more detailed division will result in less sedimentation in the original foundation soil.

Based on fractal theory and by studying Menger sponges, we obtain the pore volume of particle size ≥ R1 in the modified soil is:

$$V(R_1) = V * （R_1/R_{max}）^{3-D} \quad (4)$$

The pore volume of particle size ≥ R2 in the modified soil is

$$V(R_2) = V * （R_2/R_{max}）^{3-D} \quad (5)$$

where $V(R_1)$ and $V(R_2)$ are the pore volumes of particle size ≥ R1 and ≥ R2 respectively;$R_{max}$ is the maximum particle size. Then the pore volume in the interval R1→R2 (the added volume of the modifying material) is:

$$V(R_1 \to R_2) = V(R_1) - V(R_2) = V * (\frac{R_1 - R_2}{R_{max}})^{3-D} \quad (6)$$

Then the ratio of the modifying material to the modified soil is:

$$a = V(R_1 \to R_2)/V = (\frac{R_1 - R_2}{R_{max}})^{3-D} \quad (7)$$

Then we will study one and two modifying materials.

When the project only utilizes modifying material A with a single particle size, then the dopant amount of A material is:

$$a_1 = \frac{\int_R^{R_{max}} V*(\frac{R-R_{max}}{R_{max}})^{3-D} dR}{V} = \frac{-（R-R_{max}）^{4-D}}{{R_{max}}^{3-D}} \quad (8)$$

If the particle size of material B is R1, the particle size of material C is R2, then the dopant amounts of B and C are:

$$b_1 = \frac{\int_{R_1}^{R_2} V*(\frac{R_1-R_2}{R_{max}})^{3-D} dR}{V} = \frac{-（R_1-R_2）^{4-D}}{{R_{max}}^{3-D}} \quad (9)$$

$$c_1 = \frac{\int_{R_2}^{R_{max}} V*(\frac{R_2-R_{max}}{R_{max}})^{3-D} dR}{V} = \frac{-（R_2-R_{max}）^{4-D}}{{R_{max}}^{3-D}} \quad (10)$$

Then the equation will be validated using the material A with single particle size. Based on the relations between fractal dimension and deformation (Fig. 5), we obtain a suitable fractal dimension, which is in 2D plane, but the fractal dimensions obtained from Eqs. (7-10) are in 3D space. Thus, the fractal dimension in 2D is transformed to the fractal dimension in 3D as follows:

$$D = D_0 + 1 \quad (11)$$

In Fig. 5, D0=1.93, D=2.93, the particle size of material A is 0.16 cm, and the maximum particle size of original foundation soil is 0.4 cm. With Eq. (8), we know when the dopant amount of material A is 23%, the result was close to the dopant amount of 24% in the experiment, thus validating the reasonableness of the equation.

## Conclusions

(1) Along with the increased amount of material A, the fractal dimension of filling material distribution gradually increases, and the fractal dimension of soil mass gradually increases. At dopant amount of 24%, the changing rate of fractal dimension slows down. Along with the increased amount of material A, the compressed deformation was weakened, and after 24%, the deformation was reduced.

(2) Based on fractal theory, we built a prediction model between the dopant amount of modifying material and the distributing fractal dimension. The applicability of this model was validated via engineering practice.

**Keywords:** Unsaturated Loess; Disintegrating test; Moisture content; Degree of compaction

**Abstract.** In order to explore the disintegration characteristics of compacted loess, through the unsaturated soil disintegration instrument by independently developed,conduct the soaking disintegration experimental study on remolded soil unsaturated samples,obtained a series of experimental results:①The curves can be divided into the slow disintegration, rapid disintegration and stabilization of disintegration in three stages，the degree of compaction and water rate impact on rapidly disintegrating stage;②When the degree of compaction is certain,the disintegration rate decreased with the water contented increasing,the decreased amplitude is increasing with the moisture content increased to18%,the disintegration characteristics disappeared with the moisture content increased to 22%;③When the initial moisture content is certain, the disintegration rate decreased with the degree of compaction increasing, The time significantly prolonged when the disintegration completed. the decreased amplitude is increasing with the degree of compaction increased to 95%,the disintegration characteristics basically disappeared. Based on the relationship of degree of compaction and the moisture content to void ratio, the thesis establishes the model between the disintegration rate and the effective porosity ratio,the formula can be used to calculate the disintegration rate of compacted loess.The specific conclusions are:①When the critical moisture content increased to 22%,the disintegration characteristics disappeared;②When the critical degree of compaction increased to95%， the disintegration characteristics also disappeared.

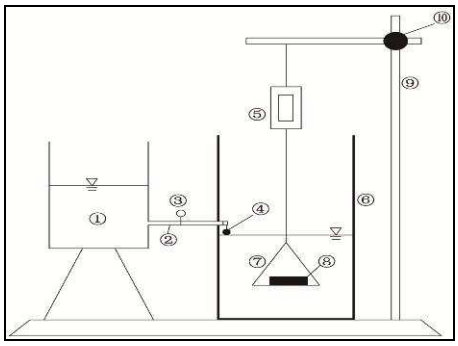
## Introduction

Because of the special properties of water-sensitive of Loess,The slope(manmade slope ) destruction caused by the disintegration (wet)plagued the construction in Loess areas.Studies have shown that:the disintegration not only beneficial to the slope remodeled,which can emptied slope with the intensified corroding, also can changed the slope shape and slope[1].For this reason,exploring the process and the mode of action of disintegration on unsaturated soil has practical value.A lot of research has been carried out about disintegration on unsaturated soil, [2~3]Carried out soaking disintegration experiments on compacted loess,analyzed the disintegration law influenced by the degree of compaction and moisture content,establishment the correlation between the rate of disintegration and the void ratio,illustrates the nature impact on disintegration by the degree of compaction and moisture content;[4]Analyzed the relationship between the disintegration amount with different depths and the roots;[5]Carried the disintegration experiment with the samples of different initial matric suction by self-made instrument;[6]Conducted disintegration test and triaxial permeability under different initial states on compacted loess；

[7]partitioned the Chinese loess region based on the differences of disintegration characteristic;[8~9]analyzed the disintegration mechanism in the embankment slope in situ test.Due to the hysteresis of its research methods and means,so far there is no general applicability of the disintegration experimental apparatus on unsaturated soil. In this paper,we try to developed the experimental apparatus,to explore the disintegration mechanism on unsaturated soil .

## Experimental Equipment and Scheme

**Experimental Equipment.** Based on the knowledge of soil-water action process, the thesis designed disintegration tester for unsaturated soil as (Fig.1) shows.The experimental instruments constitute of disintegrating device, water control device and the iron sets.The advantages show as follows: ① The water control device can automatically recharge the disintegrating device by the F1 type float valve,the Water supply device can achieve high automation and accurate level;②the test instrument has the advantages of simple structure,reasonable design and manufacture easily,and the error is small, the results are accurate.



Remarks:①water control device②glass catheter③The switch④the F1 type float valve⑤E-Rally⑥Plexiglas cylinder (diameter 15cm)⑦Barbed plate (size 10cm × 10cm, mesh0.5cm × 0.5cm )⑧Soil samples⑨the iron sets⑩The lifting switch

Fig.1 The disintegration device for unsaturated soil

**Experimental Scheme**. Sample preparation: Take an undisturbed Lishi loess as studying object, prepare 20 cylindrical samples groups which volume is 200cm$^3$,the degree of compaction are 85%, 90%, 95%, 100%; 10%, water content are12%,14%, 16%, 18%, 22%.

In order to eliminate the dimension of the test, represented by the cumulative disintegration disintegration of modulus, calculated by the following equation:

$$B_t = \frac{M_0 - M_t}{M_0} \tag{1}$$

Formula: Bt cumulative disintegration modulus (dimensionless), M0 is Rally initial reading, Mt tension meter readings at time t;

Disintegration rate calculated by the following equation:

$$V = \frac{B_b - B_a}{T_a - T_b} \tag{2}$$

Formula: V is the rate of disintegration (min-1), Bb, Ba, respectively corresponding to the point b and a cumulative disintegration modulus, Tb, Ta b, respectively, and a point corresponding to the point of disintegration time (min) .

The test process:① determination of soil natural moisture content, liquid limit, plastic limit and other basic physical parameters;②determination of unsaturated soil under different degree of compaction conditions, disintegrating relationship between the amount of time;③determination of unsaturated soil under different moisture conditions, disintegrating relationship between the amount of time. During the experiment, the water temperature controlled at 20 ~ 22 °, the disintegration of

the dissolution of the body characteristics observed specimen to specimen disintegration is complete, collation and analysis of data.

**Analysis of Experimental Results**

**The effect of initial moisture content to the disintegration.**Figure 2 is the disintegration curve between the modulus (Bt) and time(T) under different moisture conditions when the degree of compaction is 95%.Analyzed of experimental data shows that:(1)the disintegration curve can be divided into three sections: the samples did not change significantly in the stages 0 ~ 5min , only a small sample of soil particle caving out the surface,this stage reflects the process of the water enters the sample porosity when the specimen immersion in water,5 ~ 20min is the rapidly disintegration stage,with the gradual increase of the moisture content in the sample, the soil particles disintegrant off from outside to inside like the flocculent or Chunky.However,the disintegration rate is stable,the disintegrating basically completed used 20min,the disintegrant modulus at around 0.8;However, the sample still ongoing disintegrant at steady rate with the water content was 22%.（2）When the degree of compaction at a certain level,the total sample disintegration rate decreases with increasing water content.（3）When the initial moisture content of the sample is not the same,the completion time is also showing slight difference,the completion time take 11min, 14min, 16min, 18min, 20min under the initial moisture content are 10%, 12%, 14%, 18%, 16%.This shows that,the initial water content is not only reduced the water absorption capacity of specimen, also has a certain effect to Slow down the disintegration rate.Figure 3 is the disintegration curve between the modulus (Bt) and time(T) under different moisture conditions when the degree of compaction is 85%.Which has the same disintegration law to Figure2, the total sample disintegration rate decreases with increasing water content.We can get the law from Figure2 and Figure3 that the decreased amplitude is increasing with the moisture content increased to18%,the disintegration characteristics disappeared with the moisture content increased to 22%.The disintegration rate calculated by formula (2) as the results in table1.The relationship between disintegrating rate and moisture content as shown in Figure6.

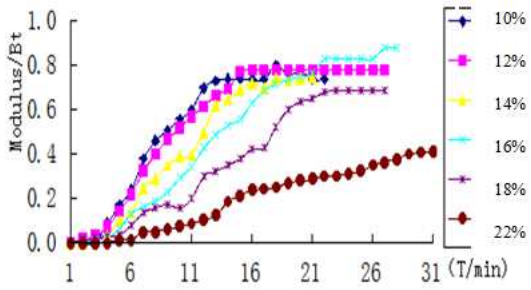


Fig.2 The disintegration curve on different moisture content of the degree of compaction is 95%

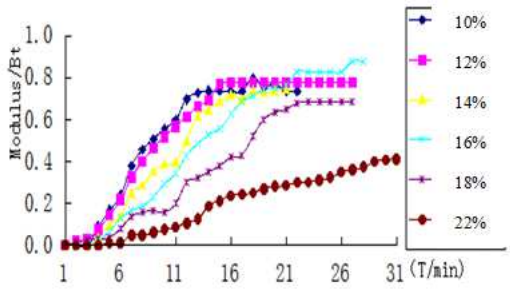

Fig.3 The disintegration curve on different moisture content of the degree of compaction is 85%

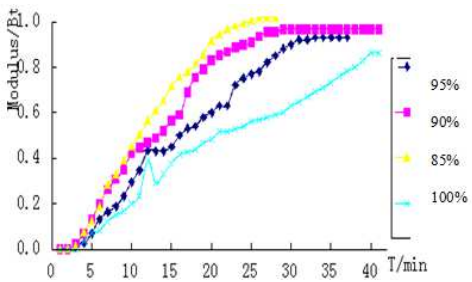

Fig.4The disintegration curve on different degree of compaction of the initial moisture content is 12%

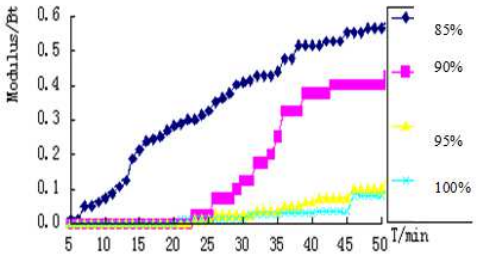

Fig.5The disintegration curve on different degree of compaction of the initial moisture content is 20%

**The effect of the degree of compaction to the disintegration.**When the unsaturated soil compacted,the structure changed, the soil porosity and water absorption capacity decreased,the disintegration rate also slowed down significantly.Figure4 and Figure5 are the disintegration curve between the modulus (Bt) and time(T) under different degree of compaction when the initial moisture conditions are 12% and 20%.Analyzed of experimental data shows that:The disintegration curve are similar with Figure2 and Figure3,also with obvious stages;the total sample disintegration rate decreases with increasing degree of compaction.the disintegration characteristics disappeared with the degree of compaction increased to 95%.Figure 5 indicates that the regularity of the disintegration characteristics performance significantly influenced by the degree of compaction.

**prediction of disintegration rate based on the effective porosity ratio**

the effective porosity ratio refers to ratio of the volume of air in soil to the volume of soil particles.It has the correlation between moisture content and degree of compaction as follows:

$$e_i = \rho_s\left(\frac{100}{K\rho_{\max}} - \frac{\omega}{100}\right) - 1 \qquad (3)$$

Formula:$e_i$ is effective porosity ratio; $\rho_s$ as particle density (g/cm$^3$); ω is the moisture content (%); $\rho_{max}$ is the maximum dry density of soil (g/cm$^3$); K is the degree of compaction (%). In this experiment: $\rho_s$ is 2.7g/cm$^3$, $\rho_{max}$ is 1.97g/cm$^3$.

After the regression analysis,get the relationship between the rate of disintegration and effective porosity ratio,as table 2 and Figure 7.The regression results as follows:

$$V_i = 0.0134 + 4.3019e_i - 13.98e_i^2 \qquad (4)$$

The correlation coefficient is $R^2$=0.856,achieved a high correlation level.

Table1 The relationship between the rate of disintegration and the initial moisture content

| | K=85% | K=90% | K=95% | K=100% |

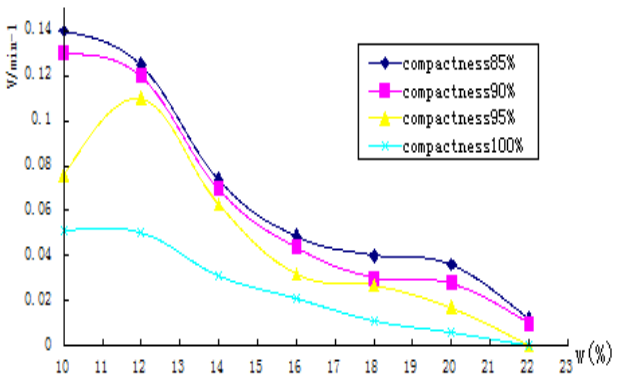

Fig.6 The relationship between the rate of disintegration and the initial moisture content

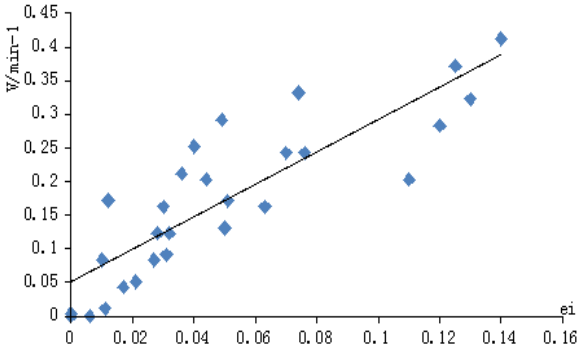

Fig.7 The relationship between the rate of disintegration and the the effective porosity ratio

## Conclusion

(1)The disintegration of unsaturated soils developed instrument can achieve the disintegration experiment of unsaturated soil in hydrostatic water.The water control device can realized automatic replenishment, and the precision could meet the test requirements.

(2) The degree of compaction and moisture content are the main factors affecting disintegration of unsaturated soil.The disintegration rate presents decrease trend with the increasing of The initial moisture content and the degree of compaction.

(3) Based on the relationship of degree of compaction and the moisture content to void ratio, the thesis establishes the model between the disintegration rate and the effective porosity ratio,the formula can be used to calculate the disintegration rate of compacted loess.

**Keywords:** bubble curtain, shield, underwater blasting, wave absorbing, damping

**Abstract:** With the further development of urban construction, engineering blasting has had a wide range of applications. However, its application environment has become more and more complex relatively. Underwater blasting, one of the applications of engineering blasting, has been increasingly used in construction of subsea tunnel and immersed tube in recent years though it has a complex influence on surroundings in operation. For the study of shock wave absorption technology of underwater blasting, this paper analyses the effectiveness of bubble curtain shielding technology used in the underwater explosion by field experiment. The test result shows that intensity of underwater shock wave approximately reduced by 80% after passing through the bubble curtain, which indicates that the bubble curtain can effectively reduce the shock wave pressure in water; vibration caused by shock wave in water approximately reduced by 20% after passing through the bubble curtain, which reflects propagation law of shock wave has changed due to the effect of the curtain.

## Introduction

With the development of urban large-scale underground construction, the range of applications of blasting has become wider and wider, transferred from sparsely populated wilderness to densely populated city, extended from land to water. Blasting greatly accelerates construction speed and saves construction cost, which has a remarkable technical and economic effect. However, because of the increased complexity of blasting situation, people are increasingly concerned about its harm to the surrounding environment. Blasting seismic effects have varying degrees of influence or damage on the buildings and facilities in surrounding area. In this regard, to reduce or eliminate the effects of blasting on the surrounding environment through blasting vibration reduction technology is very urgent and important in engineering practice.

There are both similarity and difference between underwater blasting and land blasting. The former not only generates seismic wave, but also produce water shock wave. The hazard of water shock wave cannot be ignored, which has characteristics of big impulse and slow damping and threatens security of aquatic life, water construction, ships and underwater operation personnel. To the land bursting, because of its current extensive applications, there are many more mature shock absorption technologies now, such as millisecond blasting shock absorption technology, pre-split blasting shock

absorption technology, isolation holes (slots) damping technology, etc. Because of the different construction environment between the underwater blasting and the land blasting, the shock absorption technology of underwater blasting still needs more research and development and to be tested by applying it to engineering practice.

This paper analyses the effectiveness of bubble curtain shielding technology used in the underwater explosion by field experiment, so as to provide more experience for its applying to the engineering practices.

## Bubble Curtain Shielding Technology

The concept of the bubble curtain was first proposed by engineer Adolph in Canadian Industrial Co. Ltd. and applied to underwater blasting in construction of Canada Ortario hydropower station [1,2]. Subsequently, the bubble curtain technology had been widely used and studied in countries due to the significant effect on attenuation of underwater shock wave and seismic effect in underwater blasting. Our predecessors had explained the bubble curtain attenuation law from the viewpoint of acoustic and thermodynamic or from the point of view of energy, and made a theoretically reasonable exposition by introducing Bp value which is parameter to describe the reduction degree of underwater shock wave [3]. The bubble curtain can well weaken underwater shock wave pressure so that constructions around the blasting area can be protected effectively [4].

Bubble curtain shielding technology means: One or more bubble curtains are laid between explosive and object of protection. When underwater shock wave reaches the bubble curtain, diffuse reflection is generated on surface of rising bubbles. Meanwhile, underwater shock wave compresses the bubbles, which makes most energy of the shock wave expended during the bubble compression process, so that the pressure caused by underwater shock wave is greatly reduced and thus the object is protected.

## Bubble Curtain Decompression Experiment

To test shock wave absorption effect of bubble curtain, an experiment was designed, and its plane layout is shown in Figure 1，field test results is shown in Figure 2 and Figure 3.

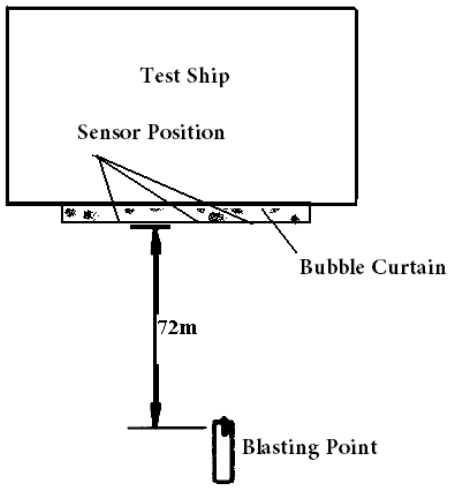

Fig. 1 Bubble Curtain Installation Diagram

Fig.2 Field Test photo (Sensor placement site)

Fig. 3 Field Test photo (Bubble curtain generator site)

Monitoring equipment selected in the experiment is a high-resolution seismograph of Strata View TM type developed by EG & G which is an American company and it has a total of 24channels, referred to as R-24. This instrument has high-performance with the characteristics of automatic gain and accurate 18-bit analog conversion. Measured dynamic range is up to 113db; tuning distortion is less than 0.01%; sensitivity is 57.6mv/cm after enlargement process.

Curtain parameters are shown in Table 1, and blasting parameters in test are shown in Table 2.

Tab. 1 Bubble Curtain Parameters

| Air Jet Pipe | | | | Air Jet Hole | | | | Air Demand | Pressure |
|---|---|---|---|---|---|---|---|---|---|
| Diameter (mm) | Length (m) | Space (m) | Row | Hole Space (mm) | Hole Number | Aperture (mm) | Reflex Angle (degree) | ($m^3$/min) | (MPa) |
| 80 | 24 | 0.5 | 2 | 20 | 236 | 3 | 90 | 25.5 | 1.03 |

Tab. 2 Blasting Parameters

| Test Number | Total Quantity (kg) | Largest Quantities of Once Blasting (kg) | Hole Number | Aperture (mm) | Hole Space (m) | Hole Depth (m) | Row Space (m) | Distance (explosive source to measuring point) (m) |
|---|---|---|---|---|---|---|---|---|
| 1 | 210 | 25 | 74 | 105 | 2.2 | 1.93 | 1.6 | 72 |
| 2 | 267.5 | 35 | 72 | 105 | 2.2 | 1.90 | 1.6 | 72 |
| 3 | 252.5 | 30 | 60 | 105 | 2.2 | 2.17 | 1.6 | 72 |
| 4 | 155 | 17.5 | 46 | 105 | 2.2 | 1.92 | 1.6 | 72 |

## Experiment Results

Field test results are shown in Table 3. It can be seen from the table, the underwater shock wave pressure behind the bubble curtain is far less than that in front of the curtain and the strength of the shock wave is reduced by 80%, which indicates that the bubble curtain can effectively reduce the underwater shock wave pressure. Unlike the changes of pressure, underwater shock wave vibration is not reduced significantly, by about 20%, which reflects the propagation law of the "new" shock wave changes after it passes through the bubble curtain.

Tab. 3 Site Monitoring Results

| Test Number | Total Quantity (kg) | Largest Quantities of Once Blasting (kg) | Distance (explosive source to measuring point) (m) | Underwater Shock Wave Pressure(MPa) | | Underwater Shock Wave Vibration Velocity (cm/s) | |
|---|---|---|---|---|---|---|---|
| | | | | in front of the Curtain | behind the Curtain | in front of the Curtain | behind the Curtain |
| 1 | 210 | 25 | 72 | 0.0277 | 0.0046 | 1.06 | 0.75 |
| 2 | 267.5 | 35 | 72 | 0.0340 | 0.0075 | 1.21 | 0.96 |
| 3 | 252.5 | 30 | 72 | 0.0317 | 0.0053 | 1.15 | 0.89 |
| 4 | 155 | 17.5 | 72 | 0.0236 | 0.0051 | 0.97 | 0.78 |

## Conclusion

Field test of bubble curtain shows that the bubble curtain shielding technology has significant influence on reducing shock wave pressure generated by underwater blasting. However, its effect on vibration reduction is not very obvious relatively. In this regard, consider a way that combines the bubble curtain technology with the damping technology in land blasting and apply it to the underwater blasting, which can achieve the great effect on pressure and vibration reduction at the same time, but this requires a further study.

**Keywords:** Loess region, Large-tonnage pile, Self-balanced load test, Balanced point position

**Abstract.** The self-balanced test technology has been widely applied in the eastern soft soil region for many years due to its economy and convenience. However, few engineering practices could be found in the northwest loess region. In this paper, self-balanced load tests were conducted in the large-tonnage piles of a bridge project in Gansu Province. The methods determining the position of pile balanced point were studied. The positions of balanced points of test piles were also simulated using Finite Element Method (FEM). The test results show that the self-balanced method has good applicability for loess in the northwest region. The pile side friction is fully exerted and the test data could be reasonable and reliable. Besides, the shortages of traditional empirical method could be made up for if FEM is adopted, which makes the accuracy of the balanced point position improve effectively and provide a reference for field trials.

## Introduction

In recent years, with the increase of engineering construction, the tonnage and diameter of pile has been larger and larger and higher bearing capacity is designed. Traditional static load test is costly and time-consuming, as well as the test results could not meet the design requirements frequently especially for large-tonnage piles [1,2]. The self-balanced test technology could solve these problems well, so it has been widely applied in the eastern region [3]. However, few engineering practices could be found in the loess of the northwest region. Effective local experience is scant especially for piles with large tonnage and high bearing capacity.

In this paper, a bridge project in Gansu Province was taken as an example to study the method of determining the position of balanced point of pile. The self-balanced load tests were conducted in the large-tonnage piles and the balanced point positions of test piles were simulated by FEM, which could provide practical experience for further application in the northwest region.

## Project Profile

The bridge project was located in the intersecting site of the two main roads near the Yellow River. The bridge spanned 240m and was between stations 0+240 and 0+480. Continuous box girders with variable cross-section were used on the main bridge and small precast box girders were adopted for 1~30m in the west and 2~30m in the east on the approach bridge. The pile foundation was taken. The technical indexes of the soil were shown in Table 1.

Three piles were selected to be tested respectively. All the test piles were designed as friction piles with the pile diameter of 1.5m and the standard value of concrete compressive strength of 30MPa. The designed ultimate bearing capacity of a single pile ranged from 3400kN to 10000kN. The whole test was conducted according to the specifications to verify whether the bearing capacity of pile meet the design requirements.

Table 1 Technical indexes of the soil

| Number | Stratum | Thickness (m) | Allowable values of foundation bearing capacity (kPa) |
|---|---|---|---|
| 1 | miscellaneous fill | 0.7～2.4 | 110 |
| 2 | silt | 3.2～7.0 | 130 |
| 3 | round gravel | 0.3～1.5 | 400 |
| 4 | egg stone | 5.4～6.6 | 500 |
| 5 | sandstone of strong weathering | 3.0～3.5 | 300 |
| 6 | sandstone of middle weathering | 25～27 | 400 |

**Estimated Results of Load Cell Position**

The upper and lower sections of pile would reach the ultimate bearing capacity at the same time and be in a state of equilibrium if the load cell is located in the actual position of pile balanced point. Combined with the geotechnical parameters of the test pile area, the position of load cell could be estimated by:

$$Q_{au}^{R}+G_{u}=Q_{ad}^{R}+Q_{d} \tag{1}$$

$$Q_{au}^{R}=UL_{a}\tau_{-}^{R} \tag{2}$$

$$G_{u}=\frac{\pi D^{2}}{4}L_{a}\gamma \tag{3}$$

$$Q_{ad}^{R}=U(L-L_{a})\tau_{+}^{R} \tag{4}$$

$$Q_{d}=\frac{\pi D^{2}}{4}q_{pk} \tag{5}$$

Where $L$, $L_a$ and $D$ were the parameters representing the whole pile length, the length of the upper pile and the diameter of pile respectively. $Q_{au}^{R}$ and $Q_{ad}^{R}$ were the parameters which showed the side frictions of the upper and the lower pile. $G_u$ and $Q_d$ were equal to the dead weight of the upper pile and the bearing capacity of pile tip. $\gamma$ was a parameter that represented the density of pile. $\tau_{-}^{R}$, $\tau_{+}^{R}$ and $q_{pk}$ were the parameters showing the standard values of both side friction of the two sections and resistance of pile tip. According to the technical indexes of the soil, the load cell positions of test piles could be estimated and listed in Table 2.

**Simulation of Balanced Point Position**

**Numerical Models.** The traditional empirical method could not reflect the influence of pile-soil interaction on large-tonnage piles and large errors could be found in the test results [4]. Therefore, the finite element software MIDAS was used to simulate the load cell position. The position estimated by the traditional formulas was adopted. According to the results of the soil tests and design documents, the technical indexes of the simulated models were listed in Table 3.

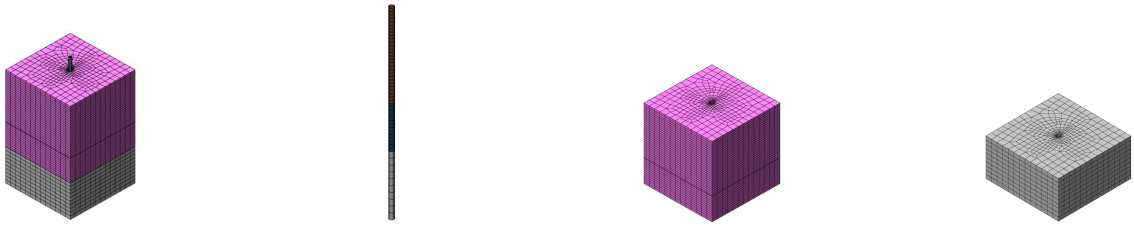
Table 2 Technical indexes of test piles

| Test pile number | 1# | 2# | 3# |
|---|---|---|---|
| Effective length(m) | 42.0 | 30.0 | 30.0 |
| Load cell position (over the pile tip) | 13.5m | 10.0m | 10.0m |
| Designed ultimate bearing capacity (kN) | 10000 | 7200 | 5000 |
| Two-way loading maximum (kN) | 6000 | 4320 | 3000 |

Table 3 Technical indexes of the simulated models

| Item | Elastic modulus (GPa) | Poisson ratio | Cohesion (kPa) | Friction angle (°) |
|---|---|---|---|---|
| Loess | 0.025 | 0.38 | 25 | 30 |
| Breccia | 0.04 | 0.2 | 50 | 40 |
| Silt | 0.017 | 0.4 | 23 | 26 |
| Reinforced concrete pile | 23 | 0.2 | —— | —— |

The pile 1# was chosen to be simulated in this paper. The load cell position was estimated 13.5m over the pile tip, which divided the pile into the upper and the lower sections. The thickness of the load cell was not considered in comparison with pile length. Linear elastic model was for pile and D-P model was for soil in the process of simulation. Both the pile and the soil were set as the solid elements. The finite element models were shown in Fig. 1.

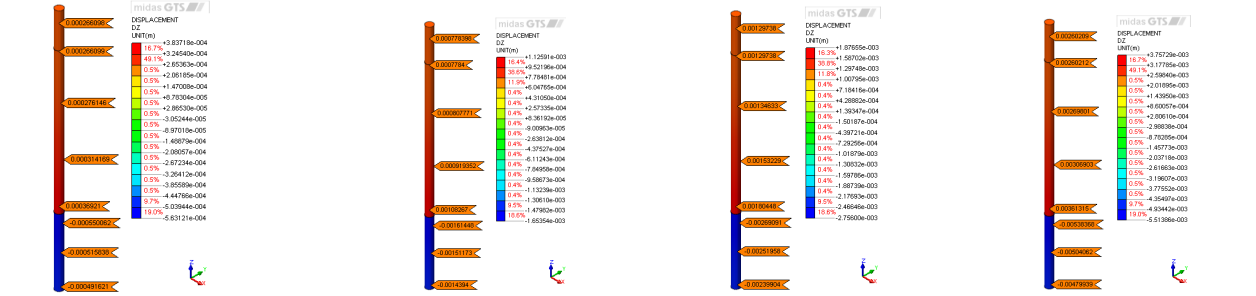


(a) (b) (c) (d)

(a)Model for the whole pile-soil element (b) Model for the pile
(c)Model for the loess (d) Model for the silt

Fig. 1 The finite element models

**Results of Numerical Simulation.** The load was added to the model of 600kN each grade of 10 grades. Part of the simulated displacement figures of the upper and the lower piles were listed in Fig.2. The corresponding displacements were listed in Table 4.



(a)Loading 600kN (b)Loading 1800kN (c)Loading 3000kN (d)Loading 6000kN

Fig. 2 Simulated displacements of the upper and the lower piles

Table 4 Simulated displacement values of pile 1#

| Item | Load (kN) | Displacements of upper pile (mm) | Displacements of lower pile (mm) |
|---|---|---|---|
| 1 | 600 | 0.36 | -0.56 |
| 2 | 1200 | 0.75 | -1.1 |
| 3 | 1800 | 1.13 | -1.65 |
| 4 | 2400 | 1.51 | -2.2 |
| 5 | 3000 | 1.89 | -2.76 |
| 6 | 3600 | 2.26 | -3.31 |
| 7 | 4200 | 2.64 | -3.86 |
| 8 | 4800 | 3.02 | -4.41 |
| 9 | 5400 | 3.4 | -4.96 |
| 10 | 6000 | 3.78 | -5.51 |

As shown in Table 4, the displacement values of the lower pile were larger than that of the upper pile in the same grade when the load cell was 13.5m over the pile tip. The lower pile would reach the ultimate bearing capacity and be destroyed first, which indicated that the position of balanced point

estimated by the traditional empirical method was not fully accurate and was lower than the actual balanced position of pile [5,6].

**Self-balanced Test**

Considering the results of numerical simulation, the patented load cell with 70cm in height and 15cm in range was put 16m over the pile tip in the self-balanced test. The displacements were measured by the displacement sensor of the accuracy of 0.01mm.The slow load method was adopted in accordance with the specifications. The test results of pile 1# were shown in Table 5.

Table 5 Test results of pile 1#

| Number | Load (kN) | Accumulative upward displacements (mm) | Accumulative downward displacements (mm) |
|---|---|---|---|
| 0 | 0 | 0 | 0 |
| 1 | 600 | 0.06 | 0.29 |
| 2 | 1200 | 0.17 | 0.66 |
| 3 | 1800 | 0.29 | 1.14 |
| 4 | 2400 | 0.48 | 1.75 |
| 5 | 3000 | 0.7 | 2.29 |
| 6 | 3600 | 1.01 | 2.76 |
| 7 | 4200 | 1.39 | 3.26 |
| 8 | 4800 | 1.91 | 3.79 |
| 9 | 5400 | 2.51 | 4.31 |
| 10 | 6000 | 3.27 | 5.12 |

The pile-soil correction factor $\gamma$ of the upper pile was 1.0. The ultimate bearing capacity of pile 1# could be determined by formula (6).

$$Q_u=\gamma(Q_{us}-W)+Q_{ud}=(6000-\pi\times0.752\times28.5\times25)\times1.0+6000=10742\text{kN} \quad (6)$$

**Results Comparison**

From Table 4 and Table 5, the simulated values and measured values of longitudinal displacement for pile 1# at each grade could be compared and analyzed in Table 6. The corresponding load-settlement curves were shown in Fig. 3. A conclusion could be found that measured values of downward and upward displacement approximated the simulated values at the same load. Meanwhile, measured pile bearing capacity could meet the design requirements when the load cell was put over the pile tip for 16m. It indicated that this position approached the actual balanced point position and the self-balanced test results were reasonable and reliable.

Table 6 Contrastive results of simulated and measured displacements

| Load (kN) | Displacements of upper pile (mm) | | Displacements of lower pile (mm) | |
|---|---|---|---|---|
| | Simulated values | Measured values | Simulated values | Measured values |
| 600 | 0.36 | 0.06 | -0.56 | -0.29 |
| 1200 | 0.75 | 0.17 | -1.10 | -0.66 |
| 1800 | 1.13 | 0.29 | -1.65 | -1.14 |
| 2400 | 1.51 | 0.48 | -2.20 | -1.75 |
| 3000 | 1.89 | 0.70 | -2.76 | -2.29 |
| 3600 | 2.26 | 1.01 | -3.31 | -2.76 |
| 4200 | 2.64 | 1.39 | -3.86 | -3.26 |

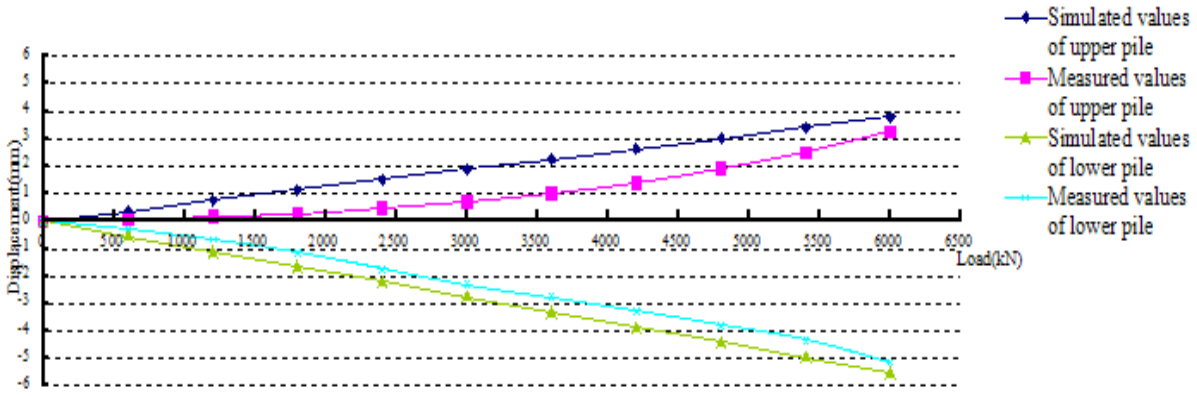

Fig. 3 Load-settlement curves of the simulated and measured values

## Conclusions

Based on the results obtained from the self-balanced tests and numerical simulation of large-tonnage piles, the following conclusions could be drawn:

(1) According to the traditional empirical formulas from (1) to (5), the load cell position of pile 1#could be estimated to be 13.5m over the pile tip.

(2) Numerical simulation of pile 1# was done, which indicated that the displacement values of the lower pile were larger than that of the upper pile at the same grade when the load cell was 13.5m over the pile tip. The lower pile would reach the ultimate bearing capacity and be destroyed first, showing that the position of balanced point estimated by the traditional empirical method was lower than the actual balanced position of pile.

(3) The self-balanced test was conducted after the load cell position of pile 1# was adjusted to be 16m over the pile tip. The test results approximated the simulated results, showing that this position was closer to the actual balanced point position of pile and the self-balanced test results were reasonable and reliable.

**Keywords:** composite soil nailing; finite element analysis; deformation; incidence-angle of soil-nails; safety factor.

**Abstract.** Under the condition of plane strain, a 2D elastoplastic FEM is used to analyze the behavior of composite soil nailing bracing of deep excavation, then finite element method of stability analysis is applied to evaluate the stability of the soil-nail wall. The authors analyzed the difference between composite soil nailing and normal soil nailing. Through analyzing the effect of bracing parameters on the deformation behavior and stability of the excavation, some useful conclusions are obtained to provide certain references for the design and construction of composite soil nailing.

## Introduction

Composite soil nailing technique is a geotechnical comprehensive bracing technology composite with other soil-reinforcement technologies in the soil nailing structure. It maintains the advantages of traditional soil nailing, brings about small deformation and has extensive application. Composite soil nailing is a joint application of active bracing and passive bracing and a combination of flexible bracing and rigid bracing. Its mechanism can be summarized as load sharing, impermeability and sealing, passing loads, partial stabilization and advanced reinforcement. There are three basic forms of common composite soil nailing, such as soil-nail with cement - soil piles (waterproof curtain), soil-nail with advanced micro-piles and soil-nail with pre-stressed anchor (rope).

Many Chinese scholars did some researches on the new form of composite soil nailing. Yang Linde et al [1] conducted elastoplastic analysis on the composite soil nailing of Cement - soil Piles by means of FEM based on mucky-excavation engineering practice of Shanghai and explored its law of deformation and mechanism. Song Erxiang et al [2] focused on the soil deformation and the selection of mechanical parameters under the excavation condition for composite soil nailing FEM. Song conducted more thorough researches on the composite soil nailing in the joint form of cement-mixing piles and soil-nails. It is believed that there are significant differences on the mechanism of the composite soil nailing and the normal soil nailing. Xu Changjie et al [3] discussed the effect of different bracing methods and bracing parameters on the deformation in the way of plane elastic-plastic FEM on the basis of engineering practice. Yang Qian et al [4] studied the action principle of composite soil nailing through model testing. Li Xiangfan et al [5] observed on the scene that the composite soil nailing deformation could be divided into three stages according to location, size and priorities of cracks and analyzed the production mechanism of cracks in each stage. Although many researchers yielded fruitful results, engineering practice is still ahead of the theoretical study in the current status.

Taking composite soil nailing bracing combined of the soil-nails and the soil-cement mixing piles for example, the partial excavation and bracing process of composite soil-nail wall with the cement mixing piles is simulated through elastic-plastic finite element analysis of the composite soil nailing plane with Z_Soil (a geotechnical engineering FEM software).Its action principle is also analyzed and compared with pure soil nailing excavation. Then the excavation stability is been evaluated by finite element stability analysis, which provide certain references for the design and construction.

## Finite Element Simulation of Composite Soil Nailing

**Constitutive Model of Soil**. Drucker-Prager model and Mohr-Coulomb model are two common elastoplastic constitutive model in geotechnical engineering. They both consider the influence of hydrostatic pressure on the yield strength. However, D-P model has many advantages over M-C. model. D-P model has smooth yield surface and it's easy to determine parameters and calculate etc. Therefore, the D - P model is adopted in the elastic-plastic model calculation during the excavation in this paper. Its yield function is expressed as:

$$F = \alpha I_1 + \sqrt{J_2} = k \,. \tag{1}$$

Equation (1) is a general expression of geotechnical materials. $I_1$ is the first invariant tensor, $J_2$ is the second invariant of stress deviator, $\alpha$ and $k$ are the strength parameters of geotechnical materials. Different yield criterion can be achieved in the FEM by changing the expression of $\alpha$ and $k$. When equation (1) is compared with the Mohr-Coulomb formula on the condition of plane strain, non-associated flow rule ( $\varphi = 0$ ) is adopted to obtain the following formula

$$\alpha = \frac{\sin\phi}{3}, k = c\cos\phi \,. \tag{2}$$

The criterion precisely matches M-C criterion and it still belongs to the generalized Mises criterion.

**Build Computation Model**. The bracing system is simplified as a two-dimensional plane-strain problem. Quadrilateral parametric element is used to discrete soil. Soil-nails are simplified as a elastic rod unit only in tension. Drucker-Prager ideal-elastoplastic model is applied to the soil and mixing piles. According to engineering experience and measured results, force on the sprayed concret surface in composite soil nailing is small, so the effect of surface-layer is omitted in calculation. The concept of interface units is introduced to simulate the interaction between soil and soil-nails and an elastoplastic model is used to describe the characteristic of the interface.

When the interface unit is elastic, shear stress:

$$|\tau| < \sigma_n \tan\phi_i + c_i \,. \tag{3}$$

When the interface unit is plastic, shear stress:

$$|\tau| = \sigma_n \tan\phi_i + c_i \,. \tag{4}$$

In the formulas, $\phi_i$ and $c_i$ are the friction angle and cohesion of interface unit, $\sigma_n$ is the normal stress on the interface unit, $\tau$ is the shear stress. Parameters of Soil contact-surface is discounted from soil-strength parameters. Cohesion and friction angle of contact-surface is 70% of the soil cohesion and friction angle.

## Finite Element Analysis of the Excavation Stability

The traditional method of excavation stability analysis uses limit equilibrium method [6,7] .These analysis methods usually assume the sliding-surface shape to be fold line, single arc, double arc and logarithmic spiral line etc. without considering the stress-strain relationship of soil when seeking safety factor. Neither the joint action nor the deformation coordination of the soil and retaining structures (soil-nails and cement mixing piles) is considered.

As a powerful numerical method, FEM considers the stress-strain relationship of soil. It can not only calculate the internal force of nail and simulate excavation process etc., but also consider the

non-uniformity and the anisotropic character of the soil. In this paper, FEM is applied to evaluate the stability of excavation slope. As to the plane strain, shear strength of soil obeys Mohr-Coulomb strength criterion. So the soil shear strength of any point on the potential sliding surface is [8]

$$\tau_f = \sigma_n \tan\phi + c \,. \tag{5}$$

In the formula, $\sigma_n$ is normal stress, $\phi$ and $c$ are internal friction-angle and cohesion of the soil. Stability safety-coefficient along the sliding surface is defined as

$$F_s = \frac{\int_l (\sigma_n \tan\phi + c) dl}{\int_l \tau dl} \,. \tag{6}$$

FEM is adopted to analyze composite soil nailing to get the stress distribution of excavation- soil. Then pattern searching method of the generalized mathematical programming is adopted to analyze potential sliding surface. The stability safety-coefficient is regarded as the objective function and the minimum value of the objective function among the assumed sliding surface is searched out as the most dangerous sliding surface.

## Analysis of an Engineering Example

**Project Overview.** As shown in Fig.1, half of the calculation model is analyzed according to the Symmetry of the excavation structure. The overall height of the model is 18m, width is 30m. The depth of the excavation is 8m, which is divided into 6 steps, 1.5m for the former five steps and 0.5m for the last step. Five rows of soil-nails are established, whose level interval is 1.0m, vertical distance is 1.5m,length is 8m.Drilling diameter of soil-nails is 0.1m. Diameter of cement-soil mixing piles is 1.0m, length is 12m. The excavation is vertical. Calculation parameters are listed in table 1.

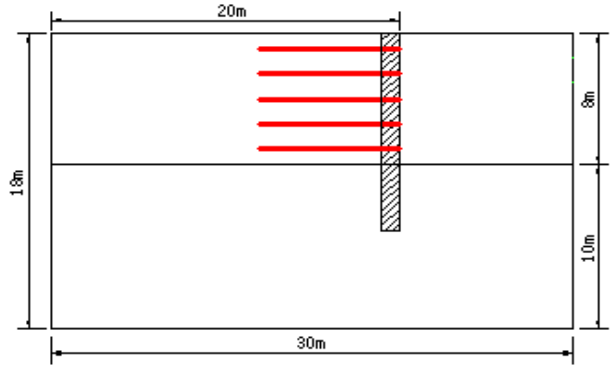

**Fig. 1** Finite element model

**Table 1** Calculation parameters of Composite soil nailing

| | $\gamma$ kN·m$^{-3}$] | $c$ kPa | $\varphi$ ° | $k$ | $n$ | $E$ Gpa | $\upsilon$ | $f_y$ Mpa |
|---|---|---|---|---|---|---|---|---|
| Soil | 20 | 10 | 30 | 200 | 0.5 | | 0.3 | |
| Soil-nail | 25 | | | | | 30 | 0.2 | 310 |
| Mixing Pile | 20 | 120 | 30 | | | 0.1 | 0.25 | |

**Note:** soil-nails use the equivalent elastic modulus. The elastic modulus of the soil is determined by the equation $E = kp_a\left(\frac{\sigma_{3\max}}{p_a}\right)^n$ .

**Computational Results. (1) Horizontal displacement of excavation sidewall.** Figure 2 shows the comparison of the horizontal displacement of the excavation sidewall between pure soil nailing and composite soil nailing. Compared with the pure soil nailing, the excavation-sidewall deformation of composite soil nailing is in bulging shape. The maximum horizontal displacement location is not on the top of the excavation, but in the middle to the lower part; Due to mixing piles, the horizontal displacement is greatly reduced. Mixing piles belong to the pre-reinforcement, the composite soil nailing deformation depends on the joint influence of the mixing pile stiffness and strengthened soil stiffness. Since the mixing pile stiffness is larger, its effect on the deformation is dominant. As a result, composite soil nailing deformation is greatly reduced.

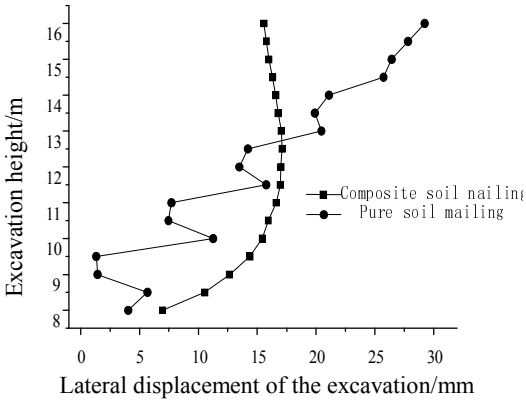

**Fig. 2**Horizontaldisplacement of excavation sidewall

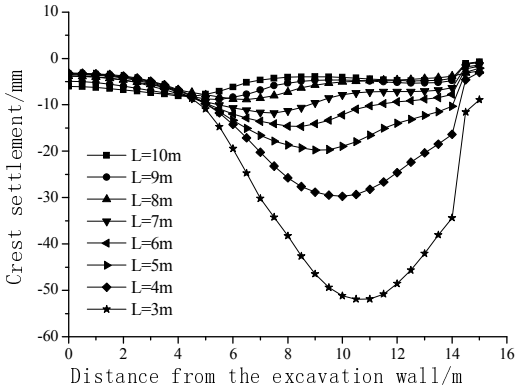

**Fig. 3**Influence of soil-nail length on the subsidence of excavation ground

**(2) Settlement of the excavation surface.** The largest settlement of composite soil nailing is located near 0.9H after mixing piles, which is different from that of pure soil nailing. The maximum settlement location of the pure soil nailing excavation-surface is near the top of the slope. Because of mixing piles, the composite soil nailing surface settlement is greatly reduced than that of pure soil nailing. It is suggested that mixing piles play an important role in restricting on the surface settlement.

**(3) Stability of the excavation.** Safety factor of pure soil nailing excavation is 1.37 in the FEM. While the one of composite soil nailing excavation is1.71. So cement mixing piles greatly improve the stability of the excavation.

**Analysis of Composite Soil Nailing Influence Factors. (1) Influence of soil-nail length.** Considering the influence of soil-nail length, soil nails were horizontally arranged. And the length varied from 3m to 10m. Figures3and4 show the influence of soil-nail length on the excavation deformation. Figure 5 shows the influence of soil-nail length on the excavation stability. As can be seen, with the increase of soil-nail length, firstly not only the ground settlement and lateral deformation of the excavation are greatly reduced but also the stability of the excavation is improved; secondly, the maximum settlement location of the excavation surface moves away from the excavation wall and the maximum lateral displacement location of the excavation moves down; Thirdly, surface-settlement and horizontal displacement of the excavation walls of soil-nail cement-mixing pile composite bracing decrease and the reducing speed also decreases slowly; Moreover, safety factor of the excavation increases, but the reducing speed decreases slowly. In conclusion, it is effective on controlling displacement and improving the stability to increase the soil-nail length. But it seems not very economical to increase the soil-nail length in engineering when it is a little longer.

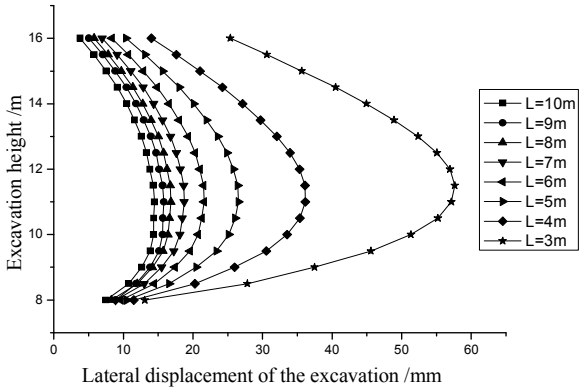

**Fig. 4** Influence of soil-nail length on the excavation lateral displacement

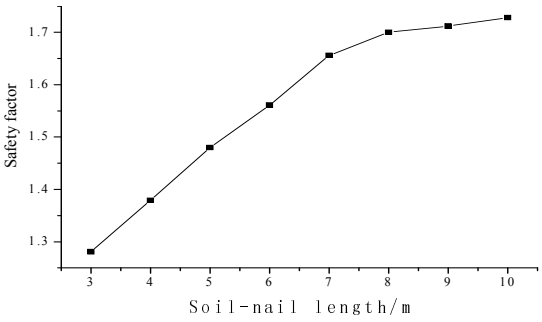

**Fig. 5**Influence of soil-nail length on the excavation stability

**(2) Influence of soil-nail inclination on stability.** Many scholars analyzed the best angle of setting soil-nails. However, most of them took the limit equilibrium method and only conducted research on pure soil nailing. In this paper, FEM was adopted to analyze the stability of the excavation and study the variation by setting the soil-nails into different angles. The results show that when soil-nails are long enough (L>H), the safety factor decreases as soil-nail inclination increases and the optimal incidence-angle of the soil-nails is horizontal. When soil-nails are a little shorter (L<H), the safety factor firstly increases and then decreases as soil-nail inclination increases. The optimal incidence-angle of the soil-nail tilts downward about 10 °.

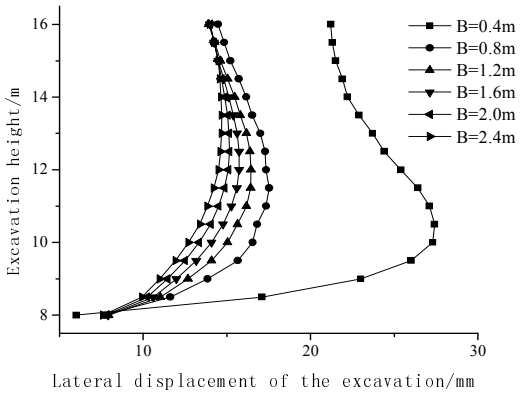

**Fig. 6** Excavation lateral displacement of different mixing-pile thicknesses

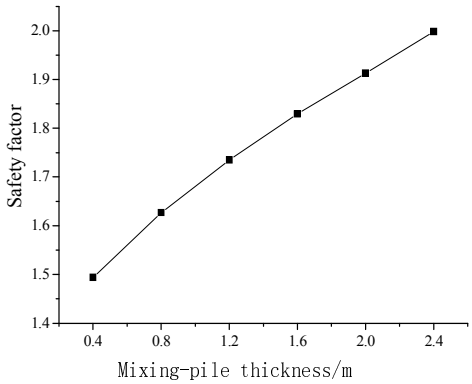

**Fig. 7** The excavation safety-factor of different mixing-pile thicknesses

**(3) Influence of mixing pile thickness.** The thicknesses of the cement mixing piles (B) were set into 0.4m, 0.8m, 1.2 m, 1.6m, 2.0m and 2.4m. As shown in figure 6, the horizontal displacement form of the excavation wall remains the same under different mixing pile thicknesses. The maximum displacement occurs in the lower part of the excavation. The maximum lateral displacement location moves up as the mixing pile thickness increases. When the mixing pile thickness reaches a certain value, the decrease of displacement is smaller as the mixing pile thickness increases. Obviously it is not economical in the project. As can be seen in the figure7, within a reasonable range of mixing pile thicknesses, safety factor almost increases linearly as the mixing-pile thickness increases. If the mixing pile thickness continues to increase, it will result in waste in the project.

## Conclusions

Through the finite element analysis for simulation and stability of composite soil nailing structure and the comparison with the normal-pure soil nailing, there is obvious difference between the two mechanisms. Deformation of composite soil nailing is greatly reduced and the maximum horizontal displacement location is in the middle to the lower part which improves the stability of the excavation bracing system.

Through the analysis of different bracing parameters and the research of excavation deformation and stability, we can get the following conclusions, which provide certain references for the design and construction.

(1) The increase of soil-nail length reduces the deformation of the excavation. However, it seems not very economical to increase the length of the soil-nail in engineering when it reaches a certain length.

(2) When the soil-nail is long enough, the safety factor decreases as soil-nail inclination increases. The optimal incidence-angle of the soil-nail is horizontal. When the soil-nail is a little shorter, the safety factor first increases and then decreases as soil-nail inclination increases. The optimal incidence-angle of the soil-nail tilts downward, about 10 °.

(3) As the mixing pile thickness increases, safety factor of the excavation almost increases linearly. But when the mixing pile thickness increases to a certain extent, it is not obvious to control the deformation of the excavation.

**Keywords:** Surface mine; Reliability analysis; Fuzziness;Fuzzy point evaluation

**Abstract.** With the development of the economy, the increasing height of slopes in surface mine will seriously threaten the security in Coal Mine Area. Therefore, how to accurately evaluate slope stability has become one important problem. Based on reliability theory and fuzzy theory, a new reliability analysis method-fuzzy point evaluation method is presented in this paper. It is more practical and efficient for slope reliability assessment because traditional evaluation method doesn't consider the fuzziness of parameters. As a typical example, we applied the technique to a surface mine case under seepage conditions, and made comparison with the traditional reliability analysis approach. The results indicate that the conclusions from both methods are essentially consistent. However, because considers the fuzziness of parameters, fuzzy point evaluation method has more actual instructive significance comparing with the traditional mothod.

## Introduction

China is a large country of coal consumption. Large-scale coal mining will produce a large number slopes in surface mine. With the development of the economy, the increasing height of slopes will seriously threaten security in Coal Mine Area Therefore, how to accurately evaluate the stability of slopes in open-pit mine has become one important problem which has to be solved as soon as possible.

The variability of physical and mechanical parameters exists objectively. When the variability is considered, reliability method is more consistente with the actual project situation. However, traditional reliability analysis only take into account the randomness of parameters but ignore the fuzziness. For the uncertain parameters influenceing the stability of slopes, their fuzziness is impersonally existent and it comes from people's awareness. Therefore, There are some limitations by classical random reliability analysis. in this case, using a fuzzy number to reflect the uncertainty is warranted. In this paper, a fuzzy point estimate method are put forward for the reliability analysis of coal gangue hills based on reliability theory and fuzzy theory. This mehtod fuzzily processes every uncertain parameter and each of the fuzzy variables is to be discretized into appropriate $\alpha$-cut. Through taking finite $\alpha$ values on the interval [0,1], reliability index and failure probability are obtained. Therefore, this method is more practical and efficient and also consistent with people's experience.[1,2]

## Fuzzy point evaluation method

**Trapezoid Membership Function.** The membership function of a trapezoid fuzzy number is as shown in fig 1.

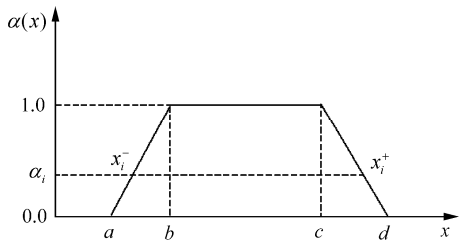

Fig.1 Trapezoidal fuzzy number

a，b，c and d can be calculated according to formulae (1) :

$$\left.\begin{aligned} a &= E(x_i) - m_1\sigma(x_i) \\ b &= E(x_i) - m_2\sigma(x_i) \\ c &= E(x_i) + m_2\sigma(x_i) \\ d &= E(x_i) + m_1\sigma(x_i) \end{aligned}\right\} \tag{1}$$

Where: $m_1$， $m_2$ can take values on the interval [0.5,3]. So, the membership function could be written:

$$\alpha(x) = \begin{cases} \dfrac{x-a}{b-a} & (a < x \le b) \\ 1 & (b < x \le c) \\ \dfrac{d-x}{d-c} & (c < x \le d) \end{cases} \tag{2}$$

**Fuzzy Point Evaluation Method.** In classical reliability theory, structure state was decided by function $z = g(x_1, x_2, \cdots, x_n)$. When take a $\alpha$-level, the rth origin moments of the function can be denoted as below[3~5]:

$$z_{\alpha_i}^r = p_+ g^r(x_{\alpha_i}^+) + p_- g^r(x_{\alpha_i}^-) \tag{3}$$

Where: $i = 1, 2, \cdots, N$； $r = 1, 2$； $p_+$ and $p_-$ are obtained by the following formula:

$$p_\pm = 1 \pm \sum_{i=1}^{M-1} \left( \sum_{j=i+1}^{M} \frac{\rho_{ij}}{\sqrt{\prod_{i=1}^{M}\left[1 + \left(\frac{\beta(1)_i}{2}\right)^2\right]}} \right) \tag{4}$$

Where: $\rho_{ij}$ is correlation coefficient between $x_i$. $\beta(1)_i$ is skewness coefficient of $x_i$. When don't consider the correlation between mechanical parameters, there are $p_+ = p_- = 1$.

The rth origin moments of the function can be calculated according to:

$$E[z^r] = \frac{\sum_{i=1}^{N} \alpha_i z_{\alpha_i}^r}{N} \tag{5}$$

So, the reliability index can be calculated:

$$\beta = \frac{E(z)}{E(z)} \tag{6}$$

## Engineering project

In order to study the feasibility of the reliability analysis method mentioned above, we carried out validation through an engineering project as below. As shown in figure 2, the mining was conducted in the area on three levels of 320m, 300m and 280m of the north-east of Xue-feng sandstone open pit.[6]. The statistical results of cohesion and friction coefficient as shown in table 1.

Table 1 Statistical results of mechanical parameters

| statistic characters | | means | standard deviations | coefficients of variation |
|---|---|---|---|---|
| Ⅰ interlayer | Frictioncoefficient | 0.725 | 0.092 | 0.127 |
| | cohesion（Mpa） | 0.055 | 0.002 | 0.042 |
| Ⅱ interlayer | friction coefficient | 0.692 | 0.092 | 0.133 |
| | cohesion（Mpa） | 0.057 | 0.003 | 0.053 |
| Ⅲ interlayer | friction coefficient | 0.714 | 0.085 | 0.119 |
| | cohesion（Mpa） | 0.058 | 0.002 | 0.041 |
| Rock density (g/cm3) | | 2.70 | 0.299 | 0.111 |

In this paper, steady seepage conditions were considered. The adopted water levels are 60m on the upper reaches acnd 40m in the downstream. The calculated equipotential lines are shown in fig 3.

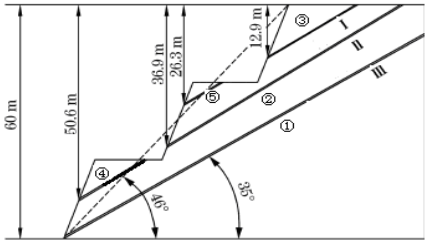

Fig.2 Section of a slope with several slide surfaces

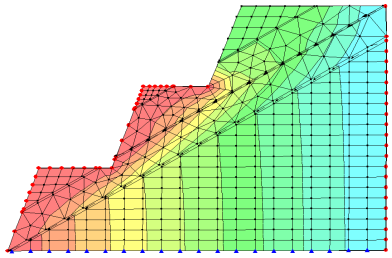

Fig.3 Equipotential lines of steady seepage

$g(x) = FS - 1$ was adopted in calculating reliability index of five sliding surfaces. Where: $FS$ is safety factor and it is obtained by Janbu method in this paper.

First, the reliability index $\beta$ under seepage conditions was calculated by traditional method which doesn't consider the fuzziness of parameters . The results are listed in table 2.

Table 2 Reliability index calculated by traditional method for different sliding surface

| Number of sliding surface | ① | ② | ③ | ④ | ⑤ |
|---|---|---|---|---|---|
| Reliability index $\beta$ | 2.41 | 3.02 | 3.64 | 4.27 | 4.67 |

Then, we adopt fuzzy point evaluation method to calculate $\beta$ for different sliding surface on eight $\alpha$-cuts. When $m_1$=1, $m_2$=0.5, the 1st and 2nd order moment of $FS$ are shown in table 3.

Table3 The 1st and 2nd order moment of function for different α –levels for every slip surface

| Slip surface | ① | | ② | | ③ | | ④ | | ⑤ | |
|---|---|---|---|---|---|---|---|---|---|---|
| $\alpha$ | FS+ | FS- | FS+ | FS- | FS+ | FS- | FS+ | FS- | FS+ | FS- |
| 0.1 | 1.762 | 1.410 | 1.986 | 1.584 | 2.415 | 1.820 | 2.786 | 2.011 | 3.024 | 2.432 |
| 0.2 | 1.758 | 1.419 | 1.975 | 1.592 | 2.407 | 1.828 | 2.780 | 2.018 | 3.018 | 2.439 |
| 0.3 | 1.749 | 1.427 | 1.967 | 1.607 | 2.398 | 1.840 | 2.771 | 2.031 | 3.011 | 2.447 |
| 0.4 | 1.740 | 1.436 | 1.952 | 1.614 | 2.391 | 1.851 | 2.764 | 2.047 | 3.004 | 2.459 |
| 0.5 | 1.732 | 1.448 | 1.944 | 1.628 | 2.383 | 1.859 | 2.759 | 2.054 | 2.994 | 2.470 |
| 0.6 | 1.726 | 1.450 | 1.929 | 1.635 | 2.371 | 1.866 | 2.750 | 2.063 | 2.989 | 2.582 |
| 0.7 | 1.721 | 1.467 | 1.920 | 1.650 | 2.364 | 1.874 | 2.742 | 2.075 | 2.981 | 2.596 |
| 0.8 | 1.628 | 1.479 | 1.912 | 1.662 | 2.354 | 1.901 | 2.735 | 2.082 | 2.976 | 2.701 |

According to formula(6), the reliability index can be calculated and the rusults are shown in table 8.

Table 8 Reliability index calculated by fuzzy point evaluation method for different sliding surface

| Number of sliding surface | ① | ② | ③ | ④ | ⑤ |
|---|---|---|---|---|---|
| Reliability index $\beta$ | 2.53 | 3.26 | 3.92 | 4.57 | 5.02 |

Compare the results of the two methods, reliability indexes are shown in figure 4.

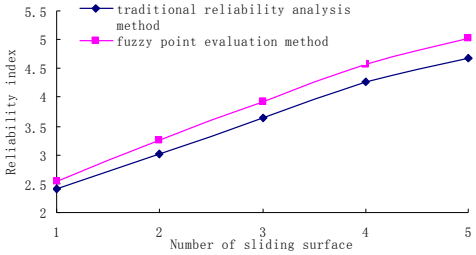

Fig 4. Comparison of reliability indexes by two methods

From the above figure, we can see that the reliability indexes of slide surfaces calculated by fuzzy point evaluation method are essentially consistent with the results by traditional method, which shows this method is feasible. Furthermore, because considers the fuzziness of parameters, fuzzy point evaluation method has more actual instructive significance comparing with the traditional method.

## Conclusions

In this paper, a fuzzy point estimate method for slopes in surface mine under seepage conditions is presented based on reliability theory and fuzzy theory. Because considers the fuzziness of parameters, it is a more practical and efficient stability assessment method comparing with the traditional reliability analysis method. However, further study should be done in the following aspects:

In this paper, the parameters are assumed independent. So, considering the influence of correlation is the next thing to do.

The selection of membership function lacks of enough practice. It should be perfected by engineering experience.

**Keywords:** percolation; coarse-grained soil; renormalization group; density

**Abstract.** Coarse-grained soil is the main material of embankment dams, it is one of the major study objectives of soil mechanics. This paper introduces a method that utilizes percolation theory to explore the influence of soil density on mechanical property from the micro perspective. First it proposes the concept of stress network among particles; then it introduces the method of applying renormalization group theory for deducing; finally it derives the conclusion that in a uniform coarse-grained soil, the porosity and the mechanical property present a relationship of linear.

## Introduction

Soil is generally composed by solid particles, liquid phase and gas phase, while the liquid and gas phases can also be called as pore phase so as to form non-uniform aggregation with random structure. Hence, the properties of the three components as well as their proportion and interaction determine the physical and mechanical property of the soil. Currently, the study on soil mechanical property is mainly under the assumption condition of continuity, utilizes the overall medium as calculation model for the actual granule, and the model nature is represented by the constant determined by the experiments. Theories considering the actual soil particle composition structure, and studying the granular medium model of single particle and overall performance still need further development. This paper introduces a method that utilizes percolation theory to explore the influence of soil density on mechanical property from the micro perspective.

## Definition of stress network among particles

The first task is to make the soil structure abstract as the model required in percolation theory[1]. The natural structure of coarse-grained soil is featured with the point-to-point single-grained structure among particles. If the dry interspace is considered only, which means the interspace pressure is atmospheric pressure, the force in the granular system will be spread by contact points under load effect. The stress transmitted through contact system is called intergranular stress. As for the particles than can be simplified into balls, it is believed that the stress transmission path between the two contacted particles is a straight-line segment connecting the two sphere centers, and this line segment obviously passes the contact points. Such line segment is defined as “key” in the stress network among particles, and the corresponding segment endpoints or the particle center is defined as “base” (or grid point), and the integration of all bases and keys forms the so-called stress network among particles. Therefore, when the soil particle structure determines, the stress network among particles is also uniquely determined. It is also thought that the granular interaction obeys the probability principle, which is reflected that key or base is connected through a certain probability rate of $p$. However, the size of $p$ depends on the physical property and contact status of the particle itself such as the influence of irregular particle surfaces on the contact degree, but has nothing to do with the particle structure. It can be regarded that the mechanical phenomenon represented by stress network among particles is to make the soil structure abstract as 3D structure. When $p=1$, the constructional elements in the same structure is with the largest mechanical strength. On the other hand, when $p<1$, for network with different structures, there will be a critical connection probability $p_c$ for each. When

$p<p_c$, the network structure is broken into limited-sized fragments like the rickety components that can not bear strength. When $p \geq p_c$ , it can be expanded into limitless connected network, and $p_c$ is called percolation threshold value. However, $p \geq p_c$ is regarded as the necessary condition for soil to become the stress body; meanwhile, the mechanical strength will be higher when the value of $\Delta p = p - p_c$ is larger. In this sense, $p_c$ also becomes an indicator for reflecting the soil mechanical property. Its feature is that $p_c$ has nothing to do with the physical property of particles but it is only determined by the topological structure of stress network among particles. As for the soil with the same physical property but different granule structure, $p$ is a fixed value, while the changes of $\Delta p$ depends on the changes of $p_c$. Based on this, quantitative analysis for the influence of soil structure on mechanical property can be conducted and the concept of stress network among particles makes percolation model theory become possible.

**Deducting percolation threshold value with renormalization group theory**

Taking the theoretically densely-ranged balls of the same particle diameter as the example, this paper introduces the method of applying renormalization group theory[2] for deducing $p_c$. As shown in figure1a, when investigating under the 2D situation, the stress network among the densely-ranged balls is the two-dimensional lattice of triangles.

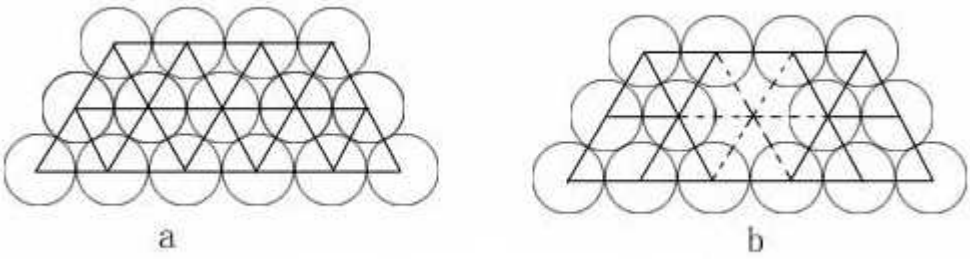

**Fig. 1. Diagram of stress network among particles**

If some place lacks one particle, which means there is a hole, the stress network will show the state of solid lines in Figure 1.b. However, it can still be regarded that the stress network is still a complete triangle lattice, but the corresponding base and key at the hole (as shown by the dotted lines in Figure 1.b) are always at non-conducting state. The purpose of such processing is to apply the renormalization group theory in the positional space to deduct percolation threshold value when hole occurs. Take the base percolation model as the example, and the operation process of renormalization group theory is as follows:

1. As a kadanoff's transformation[3], the lattice constant will be expanded into three times so as to transform the original lattice into new triangle lattice. Here it is unnecessary to worry about the problem of prominent "surface effect" caused by the small value of cell, for what matters is the interrelation of hole probability $h$ and $p_c$ not the absolute value of $p_c$.

2. Formulate the conducting direction of cells. It is believed stress can be transmitted in any direction; hence the conducting cells will be in conducting state as long as there are two lattice points in the cells. For instance, the Figure 2.a is a cell in the conducting state. If the lattice point at the right bottom corner becomes a hole in such cell, this cell is still in a conducting state as in Figure 2.b. However, if the lattice point at left bottom corner also becomes a hole, this cell is no longer conducting as in Figure 2.c. According to this, the conducting state of cells can be determined by the conducting state of lattice points and the distribution state of holes.

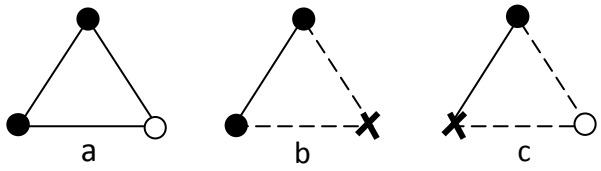

**Fig. 2. Configuration example for lattice points and holes**

●--- Lattice points in conducting state

○--- Lattice points in non-conducting state

×---Holes

3. Calculate the conducting probability of cells. According to the above provisions, 10 kinds of conducting configurations from 64 kinds of configurations can be found so as to draw out $p'$, the conducting probability of cell.

$$p' = p^3[(1-h)^3 + 3h(1-h)^2] + 3p^2(1-p)[(1-h)^3 + h(1-h)^2] \quad (1)$$

In this formula, $p'$refers to the conducting probability of cells， $p$ refers to the conducting probability of lattice points, while $h$ means hole ratio.

4. Determine the fixed points under renormalization group transformation. $p'$ is the function of $p$ and $h$, that is, $p' = R_b(p,h)$. From the definition of fixed points in renormalization group, it can be obtained that

$$R_b(p^*,h) = p^*(1-h) \quad (2)$$

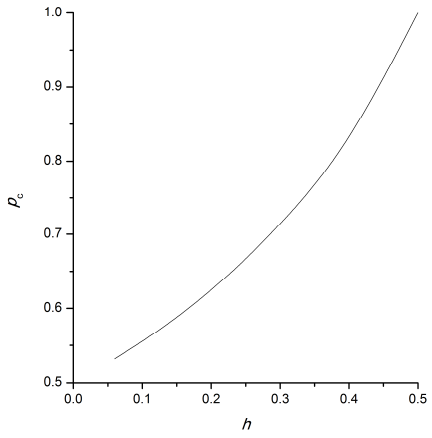
When various numbers of $h$（$0 \le h \le 0.5$）are substituted into Formula(2), the corresponding points can be obtained. If $h$=0.06, the equation will be

$$p^* = 1.0528p^{*3} + 2.82p^{*2}(1-p^*) \quad (3)$$

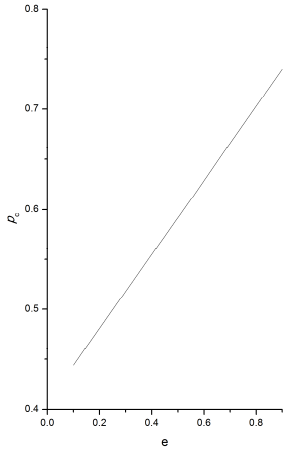
For $p^* > 1$ is of no meaning, in the range of $0 \le p^* \le 1$, it can be obtained

$$p_1^* = 0; p_2^* = 0.531915$$

As the critical points can be corresponded only in unstable fixed points, it can be obtained that $p_c = p_2^* = 0.531915$, which is the percolation threshold value of stress network among soil particles when $h$=0.06. In this way, the relation curve of $p_c$ and $h$ is shown in Figure 3.a.



**a**



**b**

**Fig. 3. The relationship of $p_c$ and h, $p_c$ and $e$**

## Summary

If the proportion of particle volume to the total soil volume is $V_0$ when there is no hole, the void ratio will be $e=\frac{1-V_0}{V_0}$. When the soil hole ratio is $h$, it can be obtained that

$$e=\frac{(1-V_0)+V_0h}{V_0(1-h)} \tag{4}$$

In this way, the derivation method of composite function can be applied to solve the derivative of $p_c$ to $e$. Moreover, the densely-ranged balls of the same particle diameter $V_0$ =0.74 is substituted to solve

$$\frac{dp_c}{de}=\frac{dp_c}{dh}\cdot\frac{dh}{de}=\frac{4p_c^2h-4^2p_c+3p_c}{4p_ch^2+8p_ch-4p_c+3h+3}\cdot\frac{1}{V_0(1+e)}=0.37 \tag{5}$$

That $\frac{dp_c}{de}$ is equal to a constant proves the linear relationship between $p_c$ and $e$. In this way, after using e for coordinate conversion of $h$, the relation curve of $p_c$ and $h$ shown in Figure 3.a will become a straight line as in Figure 3.b. Such linear relationship is determined by the renormalization group Formula (2), while the renormalization group formula depends on the topological structure of stress network among particles and kadanoff's transformation method. As the topological structure of stress network of unchanged holes is adopted and the processing method of reflecting its influences only in transformation law is applied, strictly educing the functional relation between $p_c$ and $e$ in mathematics becomes possible, which further realizes the goal of quantitative analysis for the influences of soil density on mechanical property from micro perspective. According to the indoor experimental results, when the sandy soil is of different void ratio, its corresponding mechanical property index is as shown in Table 1[4]. From Table 1, it can be found that the relation between $e$ and $\varphi$ in silt is completely non-linear; the relation between $e$ and $E_0$ in fine sand is non-linear; while the relationship between $\varphi$ or $E_0$ and $e$ for either coarse sand or medium sand is definitely linear.

**Table 1. The average mechanical property index of sandy soil**

| Type | Void ratio e | Internal friction degree φ (degree) | Modulus of deformation E0 (MPa) |
|---|---|---|---|
| Coarse sand | 0.4~0.5 | 42 | 46 |
| | 0.5~0.6 | 40 | 40 |
| | 0.6~0.7 | 38 | 33 |
| Medium sand | 0.4~0.5 | 40 | 46 |
| | 0.5~0.6 | 38 | 40 |
| | 0.6~0.7 | 35 | 33 |
| Fine sand | 0.4~0.5 | 38 | 37 |

| | | | |
|---|---|---|---|
| | 0.5~0.6 | 36 | 28 |
| | 0.6~0.7 | 32 | 24 |
| | 0.5~0.6 | 36 | 14 |
| Silt | 0.6~0.7 | 34 | 12 |
| | 0.7~0.8 | 28 | 10 |

There are many other factors affecting the soil mechanical property. As for cohesiveless soil, the influence of density on mechanical property is large. The bigger the density is; the more soil contact points are, the stronger the connection is, the weaker the soil compression is, and the larger the internal friction angle is. That is, the higher the soil strength is. This is a well-known rule. On the other hand, for the sandy soil with bigger particle diameter, it is general with the property of uniform-sized particles and obvious single grain structure, which is similar to the established model with the balls of the same diameter as the background. Therefore, the conclusion that the influence of void ratio on mechanical property is linear can be applicable to it, and can be reflected from the indoor experimental data. This conclusion also has guiding significance for analyzing the influence of homogeneous gravel soil density on mechanical property.

**Key words:** depth of the active zone, thickness, geomechanics, soil mechanics, calculation of (soil) settlement.

**Abstract.** The problems of the amendments in the updated edition of SNIP 2.02.01-83 * "Foundations of buildings and structures" SP 22.13330.2011 "Foundations of buildings and structures" are discussed in the article". Theoretically, the depth of the core is not justified anywhere and the restrictions are made only on the basis of experimental data. The importance of the amendments should be displayed theoretically.

In according to the newly adopted regulatory framework the results of the foundation settlement calculations for the limited states of the second (II) group by the layer-stack summation method with the justification of the amendments in the updated edition of SNIP 2.02.01-83 * "Foundations of buildings and structures" SP 22.13330.2011 "Foundations of buildings and structures" are shown in this article.

In the second part of the article the optimum width selection calculation results of projected foundation and identification of the economic benefits of decisions made are shown.

## Introduction

The main and obligatory calculation is designing based on the II group of limiting states [2-5]. For a foundation [8] this is mainly a definition of its settlement. Definition of the foundation settlement [9] is an integral part of designing since bases and foundations are the most important bearing elements of buildings and constructions [13-17]. Reliability of a construction [12], by which we understand the ability of a construction to carry out demanded functions within the calculated period of exploitation, as a whole depends on the correct calculation of the designed foundation and the base beneath the foundation.

The cost of a foundation [20, 21] if a building or a construction is erected is estimated as 12% of the entire cost, if we talk about working hours they reach up to 15% and more of the whole number of working hours, and as to the duration of works to construct a foundation it takes up to 20% of the construction period. If there are immersed parts of buildings or hard soil conditions the above mentioned figures may significantly increase [6]. Therefore improvements in designing and technological solutions in the area of foundation construction lead to saving of budget and working resources as well as to shortening of construction period [6].

Updated edition of SNIP 2.02.01-83 * "Foundations of buildings and constructions" SP 22.13330.2011 was released on 28.12.2010 in which there were changes related to conditions of the definition of the depth of the active zone as well as to foundation settlement [1, 10].

Analysis of the amendments to the regulatory document revealed the absence of the theoretical justification of the decrease of the depth of the active zone, limitations for the depth of the active zone were accepted on the basis of experimental data or test data also a question related to methodology or to the absence of methodology of calculation of foundation settlement based on SP 22.13330.2011 "Foundations of buildings and constructions" emerged [7].

**Design conditions**

It was possible to theoretically justify [23] the amendments made with the help of calculation of settlement by the means of layer by layer summation of mat footing of the following parameters: width b=1,2 m., depth of base of the foot of foundation allocated above the natural relief d=1,8 m., average pressure beneath the foot of foundation P=285 kPa. The base is arranged in the following layers:

1. Fine sand of the specific weight $\gamma_1$=18,7 kN/m$^3$ , deformation module $E_1$=14,4 MPa;
2. Sand of average size of the specific weight $\gamma_2$=19,2 kN/m$^3$, deformation module $E_2$=18,6 MPa;
3. Sand of average size of the specific weight $\gamma_2$=19,8 kN/m$^3$, deformation module $E_2$=18,8 MPa

Received results are displayed in the Table 1.

**Results and discussion**

Settlement of such foundation [18,19] calculated in accordance with SNIP 2.02.01-83 * "Foundations of buildings and constructions" where the depth of the active zone should meet the condition,

$$\max\sigma \leq 0{,}2\gamma H \quad (1)$$

and according to SP 22.13330.2011 "Foundations of buildings and constructions" with the condition,

$$\max\sigma \leq 0{,}5\gamma H \quad (2)$$

does not exceed the permissible therefore the depth of the active zone with the changes made is mathematically justified [7].

Results of the comparison of the active regulatory documents (a SP 22.13330.2011 Updated version of 2.02.01-83 * "Foundations of buildings and constructions" at the moment functions only like a recommendation designer has a right to use the definition of the depth of the active zone in accordance with the both documents) demonstrate that there is no significant loss of the reliability of foundations (picture 1). Moreover the limitation of the depth of the active zone according to SNIP 2.02.05-.85* “Bases of hydro technical constructions” is $\max\sigma \leq 0{,}2\gamma H$ [11].

The investigations [22] of calculation under which settlement does not exceed the acceptable with a huge bias, sets a new goal. Namely working hours needed to construct a foundation should be optimized. It is possible by the means of a calculation of the settlement of foundation based on the method layer by layer summation decreasing the width of foundation.

Results of the calculation of foundation settlement for a foundation with the following parameters width b=1 m. are given in the Table 2, and width b=0.8 m are given in the Table 3.

|---|---|---|---|---|
| | | concrete | broken stone | sand |
| 1,2 | 100 | 100 | 100 | 100 |
| 1 | 92,74 | 83,33 | 90,91 | 90,91 |
| 0,8 | 85,58 | 66,67 | 81,82 | 81,82 |

According to the calculations settlement of foundation despite the decrease in width stays within acceptable limits therefore working hours may be optimized and reduced by 7,26 – 14,42 % as well as materials used by 34,69 – 69,69 %.

## Summary

1. Foundation settlement calculated according to new regulations in all studied cases stays within acceptable limits which allows to decrease working hours and amount of materials used.
2. Production approach for the choice of optimal width of designed foundation may be used as a recommendation and may function as a starting point for a research of shallow foundations of other types and sizes.

# Mechanics Analysis of semi-rigid subgrade pavement structure

Liya Su

Architecture and Civil Engineering School, Inner Mongolia University of Science and technology, Baotou, 014010, China

suliya1@.imust.cn

**Keyword:** Asphalt Pavement, Semi-rigid foundation, modulus of elasticity, reasonable thickness

**Abstract.** The semi-rigid base asphalt pavement structure was choose often used to the highway in our country, but the semi-rigid base asphalt pavement early damage almost has become a common phenomenon.In this paper, the rule and trend of mechanics response about pavement structure (the vertical displacement and tensile stress) were analyzed under the semi-rigid base choose different elasticity modulus and thickness by ANSYS for muti-layer foundation of semi-rigid base pavement design to provide reference.

## Introduction

The semi-rigid base asphalt pavement is the main road structure form in China[1], the many advantages of the semi-rigid base material for thinning, and reduced the construction cost to provide the reliable guarantee for asphalt layer, but with the increase of traffic volume and vehicle load, the semi-rigid base itself defects and overloading problems caused the early damage,which reduce the service life and service quality of Pavement in a large extent. Among the reason is complex, pavement structure is the key factor. Therefore, it is necessary to analyze mechanical state of pavement structure select different structure parameters combination under the load ,so as more clear understand stress distribution of the semi-rigid base asphalt pavement under different structure combination state and determine the reasonable structure and horizon of pavement structure, which makes the good performance of pavement structure has meet the traffic demand.

## Establish the finite element model of semi-rigid pavement

The pavement structure is actually a three-dimensional engineering structures, it can support any form load,so describing the road system performance of the best model is 3D model.The three-dimensional finite element model is realized in three-dimensional space within the scope of discure pavement structure and consider any distribution load form.The size of the model will not be taken to infinity in Finite element analysis, the model size will get as larger as possible, but the size is too large will greatly increase the computational effort. So we should rationally determine the size of the calculation model and don't increase too much computation work guarantee the calculation accuracy[2].

In ANSYS analysis,Different element meshing have a great influence on computed result,and the precision of calculation results improve with the rapid growth of grid from the basic theory of finite element.But the grid too small to need improve the performance of the computer, and element increase will increase the rounding error of computation. So this paper the element meshing adopt mapped mesh method, In the load was divided secretly, and element division gradually increased away from the traffic load, soil base divided relatively sparse as shown in Fig.1.

In the calculation process, the the boundary conditions of model are as follows: a certain depth of soil base bottom is fixed and the constraint around.The two face parallel to the z axis no displacement along x direction, before and after plane perpendicular to the z axis no the displacement along y direction, each structural layer of pavement adopt completely continuous contact and Bond together by glue of Booleans to simulate the completely continuous calculation. The maximum deflection,the peak value of maximum stress and its location of pavement structure were analyzed when conditions.

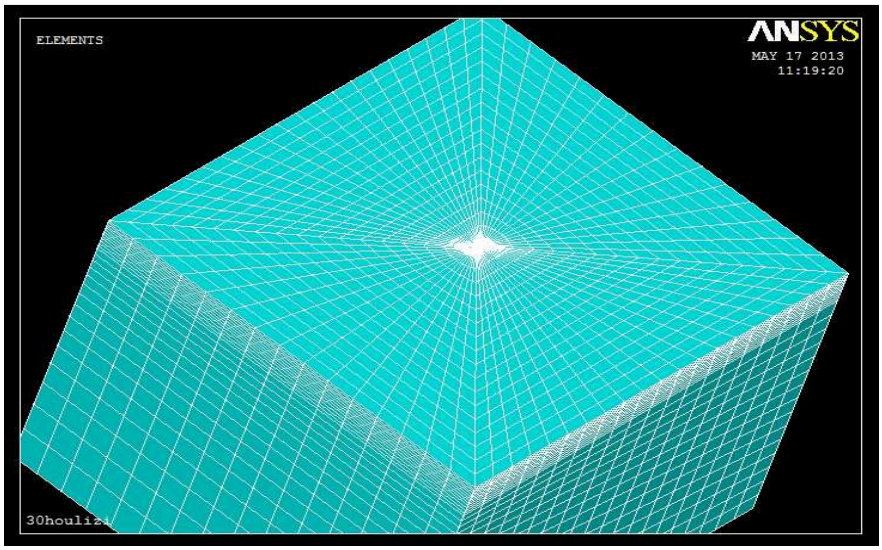

Fig.1 Grid Meshing by ANSYS

Pavement as a kind of multilayer elastic system, each structure layer on its stress state will be different degrees impact under the load. For pavement model under wheel load , the displacement and stress values were calculated to comparison. A single axle beer load two-wheel group 100kN as standard axle load by BZZ-100 said in the calculations,a single wheel surface equivalent diameter from 21.3cm and the center distance of two rounds for1.5 times the equivalent diameter [3].

Maximum stress of each layer reduced with the center distance of two rounds increased , so the center of two rounds was selected as the calculation basis by changing the elastic modulus or thickness of semi-rigid base to analyze its reasonable value range.

**Mechanics effect of elastic modulus on pavement structure**

Analyzed on the deflection value and stress to get the reasonable value range of elastic modulus about semi-rigid base under the condition of the semi-rigid base thickness unchanged and change the elastic modulus as shown in Tab.1.

Tab.1 The structural parameters I of semi-rigid base asphalt pavement

| | elastic modulus(MPa) | thickness (cm) |
|---|---|---|
| asphalt concrete pavement | 1400 | 20 |
| semi-rigid base | undetermined | 30 |
| semi-rigid bottom base | 600 | 20 |
| soil matrix | 60 | 600 |

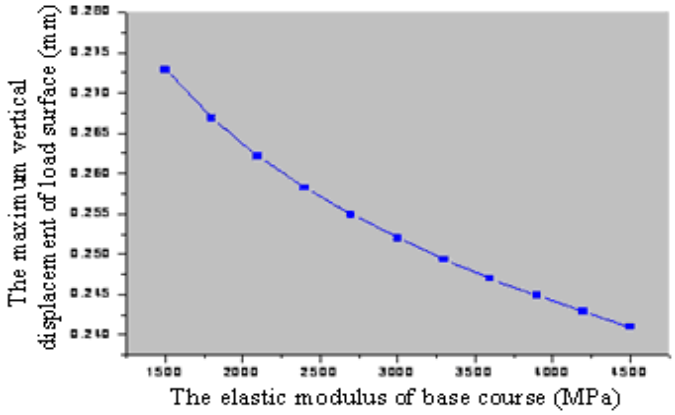

Fig.2 The relation of base elastic modulus and maximum load surface vertical displacement

Road surface deflection value and the elastic modulus of semi-rigid base meet linear relationship. With the elastic modulus of semi-rigid base materials increased, road deflection value decreases as shown in Fig.2. when elastic modulus of base layer reaches a certain value, the road deflection may not decrease.

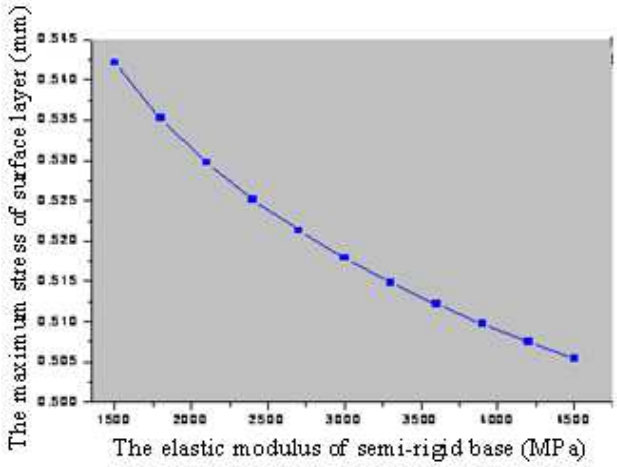

Fig.3 The relation of base elastic modulus and maximum surface layer stress

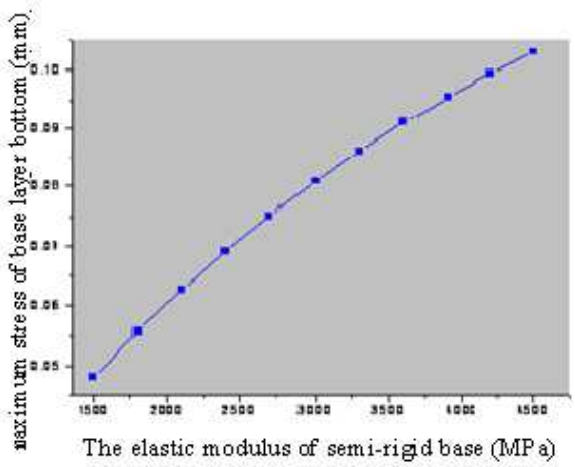

Fig.4 The relation of base elastic modulus and maximum base layer bottom stress

Fig.3 and Fig4 shown that the relationship between elastic modulus of base layer and the various structural layers of the tension and compression stress, for the surface layer, the influence of elastic modulus on resilient deflection reduced with the increase of material elastic modulus, and the curve slope gradually reduce, the sensitivity get smaller and smaller.Tensile stress of base layer bottom increased with the elastic modulus of base layer increased, but when the elastic modulus of base layer reach 4500MPa, the tensile stress of base layer bottom still in the range of allowable stress. Accordingly, elastic modulus of base layer have a reasonable value range.

**Mechanical effect of the basic thickness on pavement structure**

keeping the constant elastic modulus of the semi-rigid base and changing the thickness of the semi-rigid base, through analyzed on the deflection value and stress value to conclude that the reasonable value range of thickness about semi-rigid base and the relationship with the condition of pavement structure,as shown in Tab.2.

Tab.2 The structural parameters II of semi-rigid base asphalt pavement

| | elastic modulus(MPa) | thickness (cm) |
|---|---|---|
| asphalt concrete pavement | 1400 | 20 |
| semi-rigid base | 1500 | undetermined |
| semi-rigid bottom base | 600 | 20 |
| soil matrix | 60 | 600 |

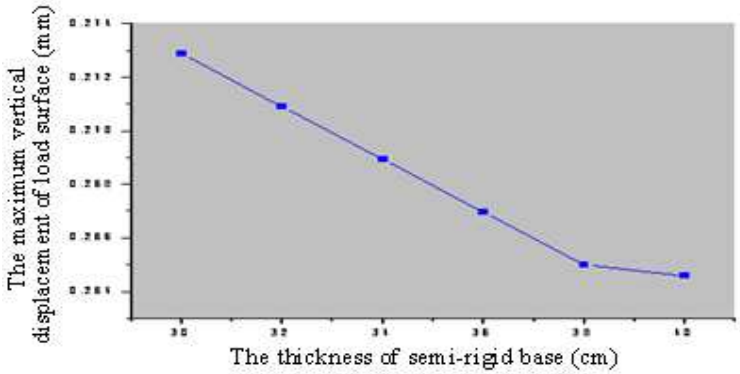

Fig.5 The relation of base thickness and maximum load surface vertical displacement

Fig.5 shown that the influence of the thickness of semi-rigid base on deflection and the influence of elastic modulus is the same.

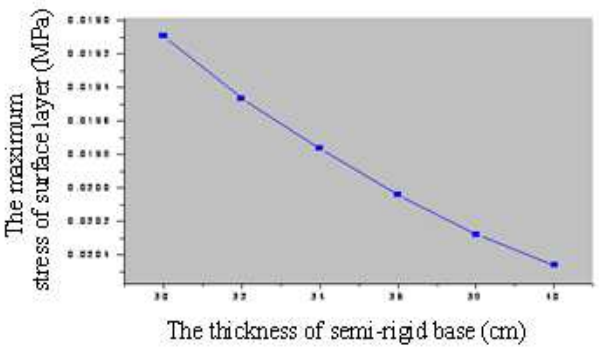

Fig.6 The relation of base thickness and maximum surface layer stress

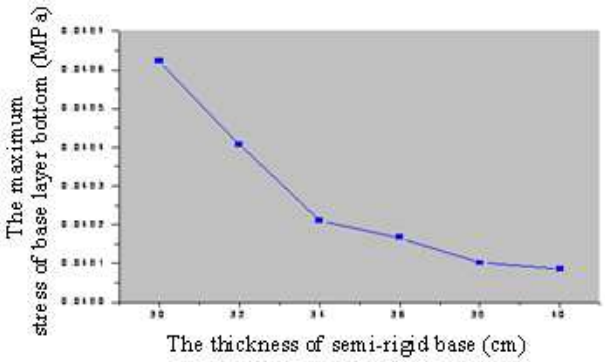

Fig.7 The relation of base thickness and maximum base layer bottom stress

Fig.6 and Fig.7 shown that the changing rule of the normal stress of each layer or base bottom with the thickness of semi-rigid base is similar as with the elastic modulus change. Both of the influence law of tensile stress about various structural layers in the bottom is the same.

## Conclusion

Mechanics analysis of the semi rigid base asphalt pavement structural by the ANSYS. When select different elastic modulus and thickness of semi-rigid material, analysis and checking calculation of the mechanical response of various design parameters on pavement under the traffic load (stress and displacement component).Through calculation and analysis get the following conclusions:

Elastic modulus of semi-rigid base materials between1500MPa and 3000MPa, and thickness control under 35cm is more reasonable. Many units construction in this area in the process, thickness generally is 32cm, thickness of the semi-rigid base about Prominent sections could reach 40cm in the overload and heavy load problem.

Sensitivity index of general mechanical on the semi rigid base change decreased with the elastic modulus and thickness of semi-rigid base increase. With elastic modulus and thickness of the semi-rigid base increased, the change value of each index is more and more small, so the blind increased elastic modulus and thickness of semi-rigid base no practical significance.

At present, many units are studying a new pavement structure form [4], such as in the laying thickness is less than 30cm of flexible base asphalt and aggregate on semi-rigid base, or directly adopt asphalt stabilized macadam base and grading macadam road base combination for whole flexible asphalt pavement structure. Research results shown that the new type pavement structure has better mechanical properties and the thinner thickness, the overall performance,anti-rutting ability and the resist fatigue cracking ability are superior to the traditional semi-rigid base structure. This new structure will be the future trend and direction of the road structure design.

# Model Test Study of Squeezed Branch Pile under Horizontal Vibration Load

Bing LV[1, a] ,Xiaojuan GAO[1, b]

[1] School of Civil Engineering, Henan University of Science and Technology, China, Luoyang, 471023

[a]lvbing1987.happy@163.com, [b]gaoxjly@163.com

**Keywords**: squeezed branch pile, horizontal vibration, model test, pile-soil dynamic interaction

**Abstract.**Based on the self-design model experimental system of dynamic soil-pile dynamic interaction, strong horizontal dynamic load was exerted to two models of squeezed branch pile, and the bearing plate location of the two squeezed branch piles is different. The model experiment adopt digital frequency converter to control the loading frequency, and use spring of different stiffness coefficient to achieve different load level. In order to analyze the action of bending moment and the status of lateral earth pressure changes, different sizes of excitation frequency and excitation load were setted during the test.

## Introduction

As the squeezed branch pile is widely used in civil engineering structures, relevant technical regulations are designed, especially construction machinery equipment and technology are becoming ripe gradually. The superior economic and technical performance of squeezed branch pile are gradually recognized. Due to its special section properties, the plates or branches of pile increase the inertia moment of pile body and the ability of resistancing loads, so its bearing capacity is greatly improved [1]. There are many engineering examples and theoretical analysis about squeezed branch pile under horizontal static load and vertical static load, while related research of the squeezed branch pile under horizontal dynamic load is rare and there is no theoretical analysis. But in practical engineering, pile foundation is often under the horizontal vibration load, such as: wave load, continuous running vehicle load, mechanical vibration load and earthquake load, wind load, etc. Under the effect of strong horizontal vibration force, the pile foundation is a complex system of pile-soil dynamic interaction. As time went on, stiffness of pile and the energy of the system lost due to damping [2]. Roger and Harry found the most significant factor of pile foundation dynamic is the yield displacement of soil and soil spring [3]. Novak has carried on the large size model pile dynamic test research, and the experimental results showed that dynamic response have some typical nonlinear characteristics. Under the circular vibration loads, a separation gradually created between pile and soil, which lead to a decline of stiffness and damping of the pile [4]. In general, experimental study on horizontal dynamic load of pile foundation is relatively few, and the level of dynamic load test of squeezed branch pile is more rarely.

## Summary of the test

**Study of model test facility.** To study the bearing capacity of squeezed branch pile under lateral vibration load, the model test of squeezed branch pile was conducted in cohesive soil. The soil taken from the construction site was divided three layers and put into box and tamped. After the soil was tamped, the physical and mechanical properties were measured again to made the tamped soil be same as the natural soil .The soil box used for model test is 1.2m length, 0.8m width and 1.0m height. One side of the box are made in glass, another threes sides are made in steel. The model pile made with steel of 0.8mm depth, the pile is 900mm length, 800mm length of pile was embedded in soil and 100mm length was exposed in air to convenience to application load (Fig.1). The diameter of the pile is 60mm, and eight strain gauges were attached symmetrically to each pile to measure the strain of measurement points during loading. Strain gauges were coated with structural plastic to prevent

moisture. Three pressure cells were buried in front of the pile 30mm in different depths along the pile for measure the earth pressure. The experiment facility is shown in Fig.2.

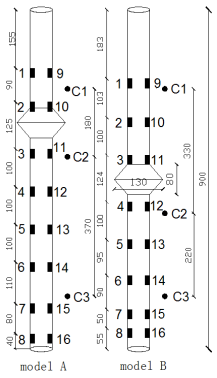

Fig.1 Sketch of model piles, strain gauges and pressure cells(unit: mm)

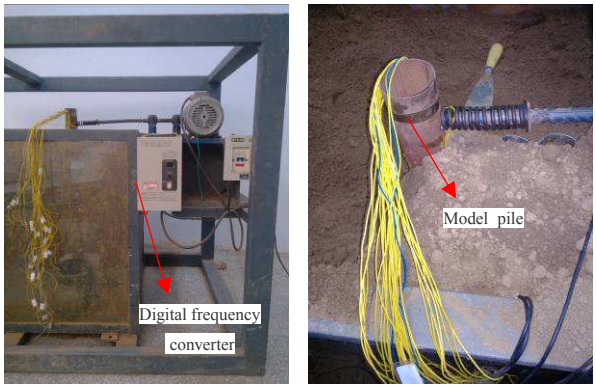

Fig.2 Sketch of test set

**Load control.** To achieve circular horizontal vibration loads, a motor was used to drive the eccentric wheel to rotate, and the eccentric wheel was contacted with a dowel bar. A spring is sheathed on the dowel bar and in contact with the pile. When the motor is started to work, the rotating speed of motor is excitation frequency of the load. Eccentricity of the eccentric wheel is 5mm. Loading position at a distance of pile top is 60mm. The magnitude of the load depends on the spring's stiffness coefficient and expansion. Expansion of spring is determined by the position and the size of eccentric wheel. Four springs with different stiffness coefficients are applied to the test. The determination of four loads' amplitude are respectively 45.1N, 78.4N, 141.1N, 220.5N. In order to measure the effect of vibration frequency, set the vibration frequency in the range of 1~30 Hz. Due to the pile-soil system is nonlinear, the size of dynamic loads and the loading process all have influence on its dynamic characteristics, so set the excitation load and excitation frequency from small to large during the test

## Results analysis

**Effects of excitation frequency.** The load bearing behaviors of the squeezed branch pile under horizontal dynamic load are shown in Fig.3 and Fig.4. As shown in Fig.3, with the increase of excitation frequency, the dynamic bending moment decreases in the upper part and the lower portion is gradually increased. On the whole, the maximum bending moment is occurs in about 1/3 the depth

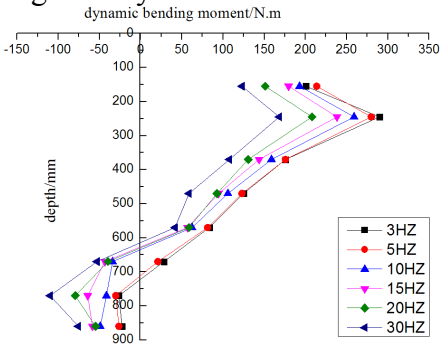

Fig.3 Relationship of dynamic bending moment and excitation frequency of model A(220.5N)

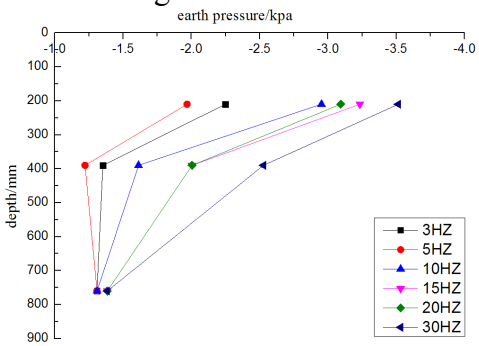

Fig.4 Relationship of earth pressure and excitation frequency of model A (45.08N)

of the pile top. The inflection points appeared in 724mm, 710mm, 634mm, 630mm, 632mm, 610mm depth, respectively, which have a upward trend. In practical engineering, this means the anti-lateral displacement ability of super-structures is improved. Fig.4 shows that under certain load, with the increase of excitation frequency, lateral earth pressure showed an increasing trend on the whole, and the main influence depth is in a 2/3 length from the top of the pile. Select the load level is 78.4N and measuring point is 2 of model A, and the time-strain curve of measuring point under the action of

different frequency is plotted in Figure 5. It can be seen strain in the excitation frequency of 3 Hz and 7 Hz mainly concentrated in 10μ~50μ;when the excitation frequency is 20 Hz, strain mainly concentrated in 10μ~40μ;when the excitation frequency is 30 Hz, strain mainly concentrated in 15μ~30μ. Other measuring points have the similar statistical variation. This shows that with increase excitation frequency, stress conditions of pile is changed, meanwhile the deformation of the cross-section is reduced. As can be seen from Fig 3 to Fig 5, with the increase of the excitation frequency, bearing capacity of pile-soil system is increased. This indicates that increase the excitation frequency has a better influence on the dynamic bearing capacity of squeezed branch pile. It has increased the level of dynamic bearing capacity.

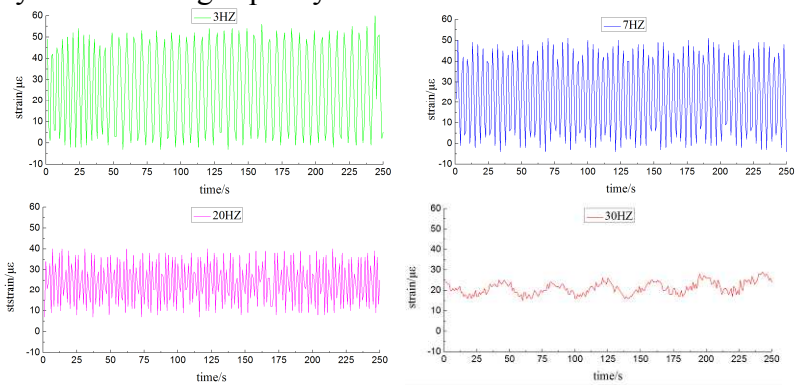

Fig.5 Time-strain curve of measuring points under the action of different frequency

**Effects of excitation load.** Set the excitation frequency of 3 Hz, and the load bearing behaviors of the squeezed and branch pile under different horizontal dynamic loads is shown in Fig.6.It can be seen from Figure 6, increase dynamic excitation load level has a significant impact to the bearing capacity of the pile. With increase the excitation load, dynamic response of squeezed branch pile gradually decreased with depth. Set the excitation frequency of 15 Hz, and the behaviors of lateral earth pressure is shown in Fig.7. It can be seen that the increase of excitation load will cause a significant increase in lateral earth pressure.

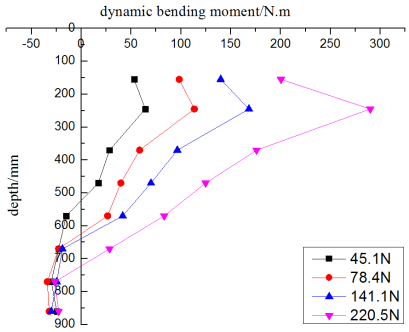

Fig.6 Relationship of dynamic bending moment and horizontal dynamic load of model A (3Hz)

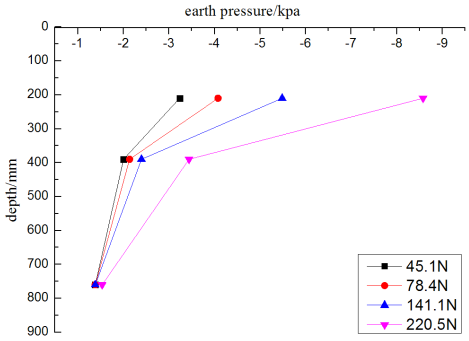

Fig.7 Relationship of earth pressure and horizontal dynamic load of model A (15Hz)

With the increase of depth, the variation amplitude decreased gradually. Figure 6 and Figure 7 shows that, with the increase of excitation load, bending moment and soil pressure showed a phenomenon of nonlinear increase. One reason is that the material of pile and soil is nonlinear, and the other reason is because the soil is elastic-plastic material. Soil resistance not only depends on the excitation load size and the deformation velocity of pile, but also depends on residual deformations of the soil. The gap between pile and soil has not been filled with new soil and creates separation, then generate a dynamic amplification phenomenon. Obviously, this situation is not conducive to the absorption of vibration energy.

**The influence of bearing plate's position.** It is worth mentioning that bearing plate's position changed the stress of squeezed branch pile obviously. Compare Figures 6 and 8, set the excitation frequency of 3 Hz. when the excitation load is 141.1N , the maximum dynamic bending moment of

model A is 70.2N.m, which occurred in the measuring point 2 ; the maximum dynamic bending moment of model B is 176.1N.m, which occurred in the measuring point 2 .When the excitation load is 220.5N, the maximum dynamic bending moment of model A is 290.2N.m, which occurred in the measuring point 2 ;the maximum dynamic bending moment of model B is 297.7N.m, which occurred in the measuring point 3.

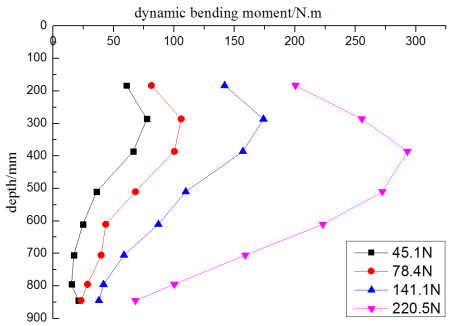

Fig.8 Relationship of dynamic bendingmomentand horizontal dynamic load of model B (3Hz)

The maximum bending moment of two piles both occurred in about 1/3 the depth of pile top, but under the same excitation frequency and excitation load, envelope of bending moment size of model A is significantly smaller than model B. That is to say the setting of bearing plate changed the deformation and stress state of squeezed branch pile, and the ability of pile body balance bending moment is improved. Setting bearing plate in the upper position of the pile body is beneficial to the improvement of the horizontal dynamicbearing capacity. In Fig.6, the rotation centers are respectively appeared in 526mm,627mm, 645mm, 726mm depth, which have a downward trend, while the rotation center of model B is close to the bottom of pile. Obviously, the model A's ability of constraint upper building to resist horizontal dynamic load is weaker than model A

## Conclusions

This paper designed the device of squeezed branch pile under horizontal vibration load. Two different bearing plate position of squeezed branch pile model tests were carried out. The main conclusions are shown as follows:

1. The test results revealed that with the increase of vibration frequency, the dynamic response of squeezed branch pile has a tendency to decrease on the whole. With the increase of excitation load, dynamic bending moment and lateral earth pressure gradually increased. The dynamic response of squeezed branch pile decreases with depth, and the influence is mainly distributed in 2/3 of the depth from the top of the pile.
2. The setting of bearing plate changed the deformation and stress state of squeezed branch pile. The ability of pile body balance bending moment is improved, which is a structure optimization design of pile foundation. Setting bearing plate in the upper position of the pile body is beneficial to the improvement of the horizontal dynamic bearing capacity.
3. Circular vibrating load will make the soil residual deformation gradually increased, and the soil's capacity to absorb vibration energy descend. The effects of the dynamic magnification phenomenon caused by excitation load will reduce the bearing capacity level of squeezed branch pile.

**Keywords:** Foundation Settlement, Bearing Capacity, Pile Foundation, Sandy Soil, Model Test

**Abstract.** Using self-made model device, researchers studied the characteristics of foundation settlement of sandy soil and pile foundation load-bearing in sandy soil. Through weight loading, researchers analyzed the phenomenon of foundation settlement. Then, researchers embedded friction piles in sand, so as to analyzed pile foundation bearing capacity. The methods and results of the research can provide guidance for teaching of Soil mechanics and foundation engineering.

## Introduction

The settlement in foundation engineering has always been one of the main topics of soil mechanics. Because of the growing scarcity of land resources，high buildings are rising and a large number of high buildings and municipal engineering have to be built over soft foundation due to urban development. Under this background, the problems in the foundation engineering must be focused on. There are a lot of methods for foundation treatment. During the construction, we commonly used foundation or pile foundation to bear load. So, it is a priority of foundation engineering to correctly recognize the load-bearing characteristics of foundation and pile foundation.

In the past, most of the research for the two bearing problems adopted theoretical analysis, while less involved model tests. Therefore, in view of the characteristics of foundation settlement of sandy soil and pile foundation load-bearing in sandy soil, researchers designed two model tests to study the settlement and bearing capacity of foundation engineering. The result can provide some theoretical guidance for foundation treatment in practical engineering.

## Test Methodology

In this experiment, dry sand was chosen to simulate the foundation soil. Before the test, it is necessary to determine some relevant physical indicators of sandy soil. First of all, 300 grams of sand soil was taken to determine particle proportion, water content and grain size distribution respectively. These experimental results show that the soil particle proportion is 6.8%,and the water content of soil is $2.66g/cm^3$.In addition，the grain size analysis test results are showed in table1 and figure1.

Table 1 Soil sieving results

| Sieve pore diameter d / mm | Quality of soil on sieve m / g | The proportion of soil on sieve ω / % | The proportion of soil which smaller than Sieve pore diameter Σ ω / % |
|---|---|---|---|
| 1 | 13.329 | 4.46 | 95.54 |
| 0.5 | 45.697 | 15.30 | 80.24 |
| 0.25 | 157.213 | 52.62 | 27.62 |
| 0.125 | 79.335 | 26.56 | 1.06 |
| 0.075 | 2.471 | 0.83 | 0.23 |
| <0.075 | 0.696 | 0.23 | |

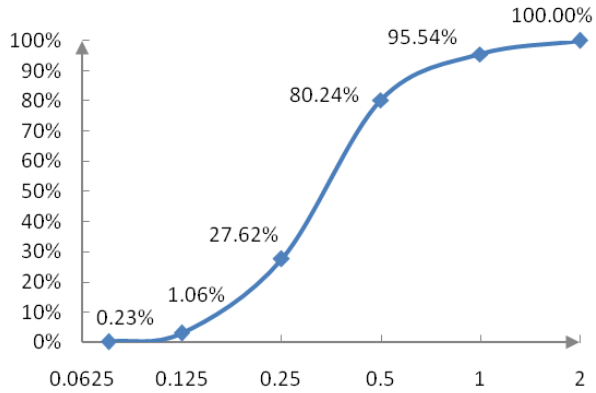

Fig. 1 Particle grading curve

From figure 1，it is possible to work out some physical indicators of soil. The results are as follows.

Non-uniformity coefficient: $C_u = \frac{d_{60}}{d_{10}} = 1.542$

Curvature coefficient: $C_c = \frac{d_{30}^2}{d_{60} \times d_{10}} = 1.104$

Fineness modulus: $M_x = \frac{(A_{0.15} + A_{0.3} + A_{0.6} + A_{1.18} + A_{2.36}) - 5A_{4.75}}{100 - A_{4.75}} = 1.64$

According to the result of fineness modulus, the sandy soil must be classified as fine sand. Also, on the basis of non-uniformity coefficient, the soil sample is uniform. So, the soil has poor compactness, which be recognized as badly graded soil.

**The Model Test of Foundation Bearing Capacity.** The figure 2 shows the device schematic drawing.

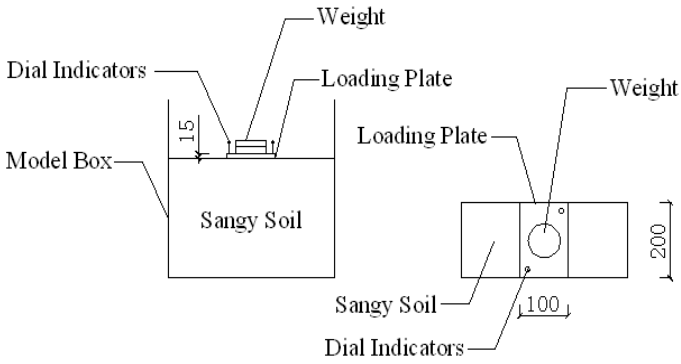

Fig. 2 Device schematic drawing

In this test, the sandy soil which had been determined particle proportion, water content and grain size distribution was used to simulate the foundation soil. And a steel plate which was 20cm long, 10cm wide and 1.5cm thick was used to simulate the foundation. Also, it was able to simulate the phenomenon of foundation settlement through loading on steel plate.

Two dial indicators installed diagonally on the bearing plate were used for the test. Before the test, initial reading should be record. In data processing, average reading of dial indicators was taken as the actual settlement under load. The method of loading step by step was used for this test. To be specific, the weight of 10.2 kg per level should be load on, so as to generate same load size to facilitate comparison of the test results. After each loading, the researchers recorded readings 3 minute intervals until the difference of the latter and the former is less than 0.01 mm. Notice that the weight must be handled with care each time to avoid disturbing steel plate. Also, it is vital to make sure that weights remain upright to prevent the non-uniform stress.

Stop loading the moment that following situation appears:
(1) The soil around bearing plate presents lateral extrusion obviously.
(2) The foundation settlement increases sharply.
(3) Due to leaning of bearing plate, weight cannot be load on.

**The Model Test of Pile Foundation Bearing Capacity.** This test, only a few different from the former, mainly researched the character of load-bearing of friction pile group foundation. In this test, researchers used a steel plate which was 20cm long, 20cm wide and 1.5cm thick to simulate the foundation.and embedded four aluminum half-round tubes of which radius was 1.5cm and length was 20cm to simulate friction piles. The device schematic drawing is as figure 3 shows. The four tubes were pre-buried in soil under the corners of the steel plate to guarantee consistency for the position of each one relative to the center of pile cap which aimed to eliminate the influence of pile group effect caused by pile cap stiffness.

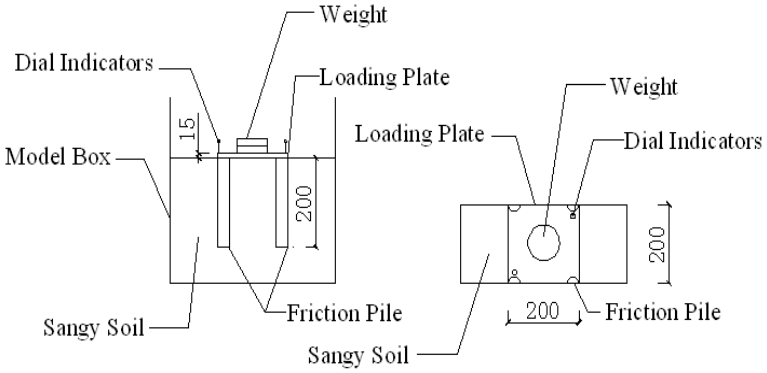

Fig. 3 Device schematic drawing

In the process of embedment, each tube must be straight and at the same height, while flat surface of aluminum half-round tubes were ensured to be pressed hardly to glass wall of model box. When placing bearing plate, researchers made it direct connected with tip of pile to guarantee effective simulation of pile bearing. The steps of loading weight and the termination conditions were same as the model test of foundation bearing capacity of sandy soil.

## Results and Analysis

**The Model Test of Foundation Bearing Capacity.** The figure 4 and 5 respectively show the **foundation settlement of the second and the ninth weight grades.**

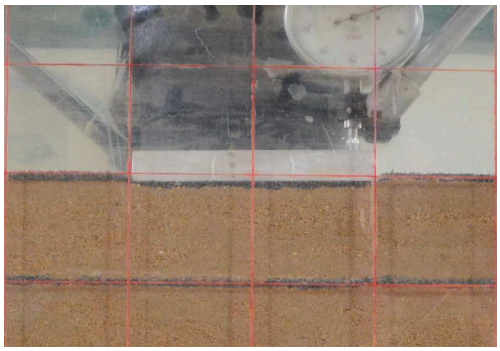

Fig. 4 Foundation settlement of the second weight grades

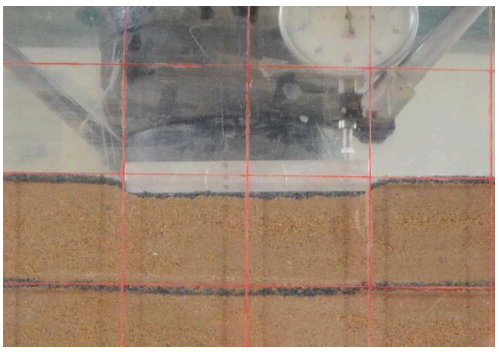

Fig. 5 Foundation settlement of the ninth weight grades

According to the results of model test of sandy soil foundation bearing capacity，researchers plotted a p-s curve as figure 6 shows.

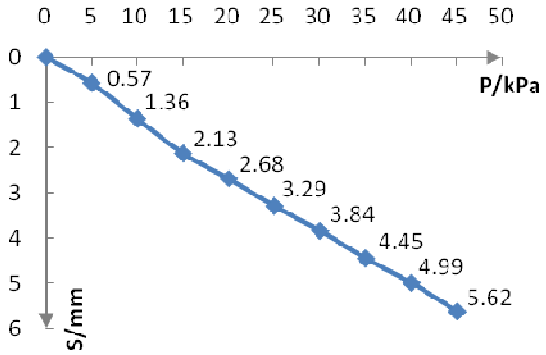

Fig. 6 P-s curve

Researchers calculated absolute value of the slope of straight lines connecting adjacent two points. The results are as follows: 0.114, 0.158, 0.154, 0.110, 0.122, 0.110, 0.122, 0.108 and 0.126. From the slope change, it can be analyzed that, except a few points, most of them can be connected as a straight line. It shows that the soil were in compaction stage, a linear change phase, in the process of loading. In this stage, the soil kept elastic equilibrium, and shear stress of any point in the soil was less than the shear strength of soil. As weight loading step by step, elastic deformation was undergoing in the foundation soil, while foundation settlement was increasing gradually. However, the load caused by upper structure had not reached critical edge pressure of foundation soil and it had not appeared plastic deformation in the foundation.

When reached the tenth weight grades, bearing plate tilted and weight cannot be load on any more, so the test was terminated. In order to guarantee the accuracy of test data, researchers taken the first nine sets of results of the dial indicator reading for analysis.

The cause of bearing plate tilting was the eccentricity pressure. In the process of loading, researchers could not strictly guarantee weight vertical loading which led to uneven settlement of foundation. When differential settlement of both sides accumulated to a certain extent, the upper structure collapsed marking the termination of the test before reaching critical edge pressure.

**The Model Test of Pile Foundation Bearing Capacity.** Figure 7 shows pile foundation settlement of ultimate bearing capacity. According to the results, researchers plotted a p-s curve as figure 8 shows.

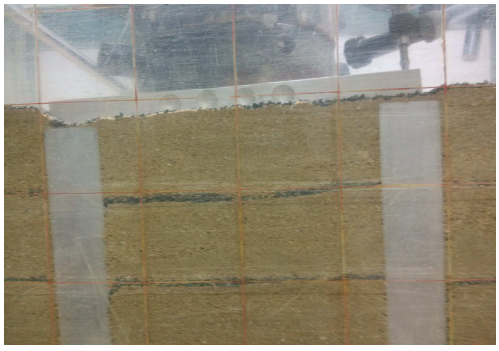

Fig. 7 Ultimate bearing capacity

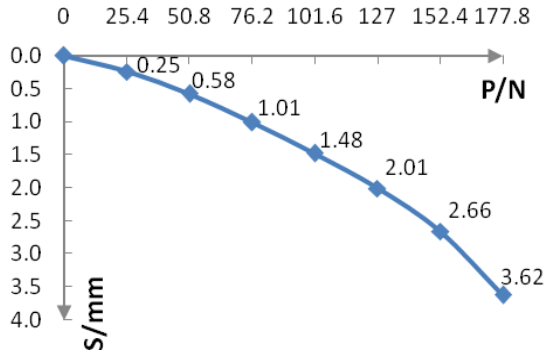

Fig. 8 P-s curve

When reached the eighth weight grades (each pile was under the load of 203.2 N theoretically), pile foundation settlement was increasing so sharply that led to weight collapsed, then, the test terminated. The moment of collapsing, bearing plate tilted greatly. Therefore, the pile foundation settlement under the eighth weight grades could not be read accurately by dial indicators. In order to guarantee the precision of the test results, researchers took the first seven sets of data to plot a p - s curve.

The pile foundation bearing capacity of the test depends on three aspects:

(1) The strength of pile body material
(2) The bearing capacity of foundation soil
(3) The influence of the pile group effect

In the test, aluminum half-round tubes were chosen to simulate friction piles due to high strength. Thus, in this test, the material strength of pile body was not the main influence on pile foundation bearing capacity. This conclusion can be proved from the result that the pile had not been destroyed. At the same time, on the premise of pile body material strength was enough high, and the pile group effect under vertical load was not the main role in pile foundation bearing capacity. Therefore, in this test, the bearing capacity of foundation soil had most impact on pile foundation bearing capacity. In other words, the process of loading step by step was also the process of foundation destruction.

From figure 8, with the method of slope analysis similar to the model test of foundation bearing capacity, it is possible to plot a p-s curve formed by the first five results, which is nearly a straight line. It suggests that before the sixth time loading, the soil should be in compaction stage keeping elastic equilibrium. After the sixth time loading (each pile loaded 152.4 N), the p -s curve slope increased obviously, and after that it is still increasing. It indicates that foundation soil were into shear stage. Thus, the time for foundation reaching plastic load was between the fifth time loading and the sixth time loading. In the shear stage, the p - s curve no longer keep linear, and it developed plastic deformation area in foundation soil. As the load increasing, the plastic deformation area is expanding, and the elastic deformation area is narrowing down with it, until a continuous slip plane is formed in the soil when the external load comes to the ultimate load of foundation. (Researchers did not draw the point of ultimate load in figure 7)

## Conclusion

This paper reflects the process of sandy soil foundation settlement and pile foundation settlement through two model test. Also, it reasonably explains the mechanism of two kinds of settlement and summarizes its characteristics through the analysis of test results. However, the test equipment this paper introduced has certain limitation to simulate the whole process of sandy soil foundation settlement.

**Keywords:** T-shaped soil-cement deep mixing column; Load transfer; Numerical simulation; Design parameter.

**Abstract:** T-shaped soil-cement deep mixing column load transfer mechanism is different from the general section column. Basing on the fast Lagrangian finite difference method, we study the load transfer mechanism of T-shaped soil-cement deep mixing column at different load levels, expanding head height and the ratio of upper and lower pile diameter. By the numerical simulation we obtained that the axial force plummeted value of expanding head flange increases with the load and the ratio of upper and lower pile diameter increasing, it will decreases when the height of expanding head increasing.This paper can provide a reference for the design of T-shaped soil-cement deep mixing column.

## Introduction

T-shaped soil-cement deep mixing column is a kind of new technology which combain bidirectional soil-cement deep mixing column with the section-varied soil-cement deep mixed column. It was designed after analysis the shortcomings of the existing soil-cement deep mixing column and the load transfer mechanism of soil-cement deep mixing column foundation and the soil arching effect[1-3]. In process of generate column, the power system driven two groups mixing blades that install drill pipe and the blades forward and reverse rotationon mixing soil-cement, by the mixing blades automatic retractable, it will make the upper section of the pile expanding and form a shape similar nails soil-cement deep mixing pile [1,4], shown in Figure 1.

## Material parameters and calculation models

As a new kind of soft soil foundation treatment method, if we want to accurately grasp the design and construction methods, we need to study its axial force transfer mechanism. In this paper, basing on the field and laboratory tests obtain the parameters of pile and soil, using the fast Lagrangian finite difference method calculate load transfer mechanism, analysis the parameters at difference load level, expanding head height and the ratio of upper and lower pile diameter impact on the load transfer mechanism.

The model uses the finite difference numerical simulation software FLAC3D, while the calculation range meet certain conditions, then the model constraint type of lower and side boundary has little effect on the results[1], considering the meshing influence computing speed, set the model bottom boundary two times the pile length from the surface and horizontal boundary has a distance of 20m to the center of the pile, fixed the model lower boundary, the side boundary only constraint corresponding horizontal displacement. Due to FLAC3D internal no thickness of contact element, this can solve the existing problem of shear between the pile and soil. Contact surface calculation parameters take normal stiffness was 0.53MPa, shear stiffness was 0.26Mpa, cohesion was 30kPa, friction was 15 degree.The pile calculation parameters shown in Table 1, calculate soil parameters shown in Table 2.

Mohr-Coulomb model is most widely used soil constitutive model in geotechnical engineering, general soil test can determine the soil parameters, not need do Senior experiments, so select this

model to calculate and checking this model can better control accuracy 5% .Build calculation model shown in Figure 2.

## Research column load transfer mechanism

To study the influence of load level, expanding head height, ratio of upper and lower pile diameter to T-shaped soil-cement deep mixing column load transfer mechanism and characteristic parameters(the variable cross-section of the axial force plummeted value), table 3 for the numerical simulation (column length were taken 16.5m, rigid pile load).

Table3 List of numerical simulation conditions

| parameter | conditions one | conditions two | conditions three |
|---|---|---|---|
| load | change | ultimate bearing capacity | |
| expanding head height | 4m | change | 4m |
| upper and lower pile diameter ratio | 2 | 2 | change |
| lower pile diameter | 500mm | 500mm | 500mm |

## Comparison of numerical simulation and measured data.

To verify the numerical simulation results whether accurately reflect the T-shaped soil-cement deep mixing column load transfer mechanism, test highway T-shaped soil-cement deep mixing column section A, K30+100~140 in Shanghai, Jiangsu and set stress gage on column (column length was 16.5m, upper and lower pile diameter was 1000mm and 500mm, expanding head height was 4m), At the end of pile construction set stress gage within two hours. Ensure the stress gage location accurate include level and depth direction in the process. Upper four stress gage range is 1MPa, the lower two range is 0.6MPa, stress gage depth in Figure 3.

Figure4 was numerical simulation and measured data contrast, the curve was the relationship on axial force and depth under 250kN and 550kN in top of the pile. From Figure 4, the axial force have a big chance in depth 4m and this place was expanding head height, we can conclusion that expanding head height have an influence on axial force transfer. It was obvious that in depth range of stress gage

the numerical simulation results was very consistent with field data, so the numerical simulation results can reflect the true work condition of T-shaped soil-cement deep mixing column.

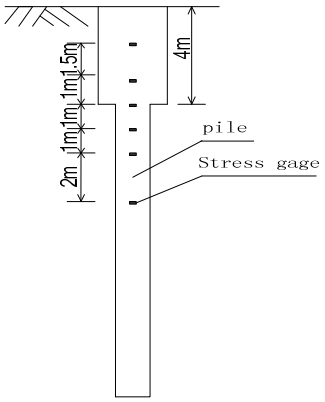

Fig. 3 Stress gage depth

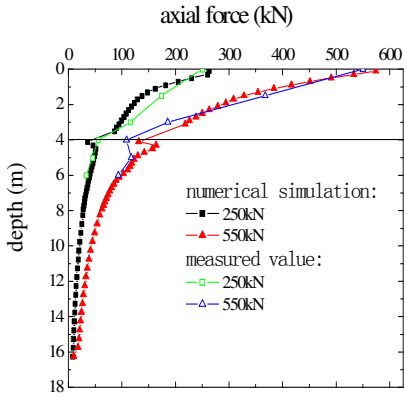

Fig. 4 Comparison numerical simulation and measured data

**Load grade impact on load transfer mechanism.**

Working condition one: load transfer mechanism numerical simulation under different load level results in Figure 5, Figure 6

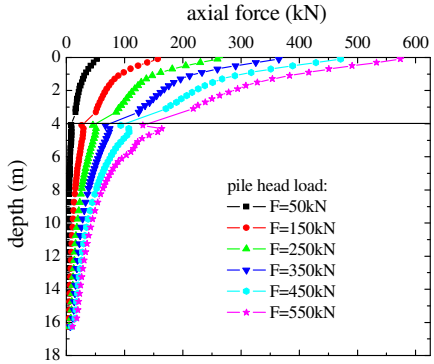

Fig. 5 Axial force change at different load levels

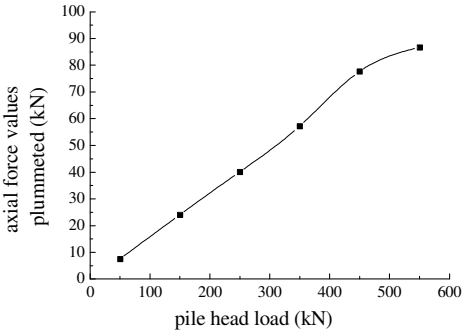

Fig. 6 Variable cross-section of the axial force plummeted values and the load curve

Figure 5, Figure6 show: axial force gradually decay with depth increasing, axial force range in expanding depth decay faster than the lower axial force, variable cross-section axial force appears plummeted phenomenon, plummeted value( the minus on upper and lower axial force in variable cross-section)increases linearly with the pile head load growth, but when the pile head load close to the ultimate load, plummeted value rate of increase was significantly smaller. This is mainly due to the expanding head flange of pile action and the pile load transfer to the soil under flange, so that axial force appears plummeted.

T-shaped soil-cement deep mixing column bearing capacity offered by the soil around the pile, the pile tip resistance and soil supporting force under expanding head flange composed, collaborative work, when pile bearing capacity close to the limit load, the soil bearing capacity under expanding head flange close to the limit[8], a small load increments, may have a relatively large soil subsidence, therefore can provide support force for the pile is relatively small increments. Due to the expansion head flange effect, part of the pile axial force is transmitted to the soil around the pile, produce a negative relative displacement between pile and soil in the lower part of the expanding head flange 30cm, pile-soil contact surface appearance of negative skin friction[9,10], leading to the maximum axial force lower expanding head occurs in 0.1 ~ 0.3m.

**Expanding head height impact load transfer mechanism.**

Working condition two: when expanding head height was 1m, 2m, 3m, 4m, 5m, 6m 16.5m, the ultimate bearing capacity have the simulation results shown in Figure 7, Figure 8.

Figure 7, Figure8 show: in ultimate load, axial force gradually decay with increasing depth and expanding head height greater the axial force increases, but the axial force attenuation trend consistent; the axial force range of expanding head depth decay faster than the lower decay rate; in variable cross-section the axial force appears plummeted phenomenon and plummeted value decreases with expanding head height increases, plummeted value come to stable when the expanding head height increased to 3m later. It is worth noticing that different expanding head height of deep mixing column, the lower section of the pile maximum axial force basically the same under ultimate load.

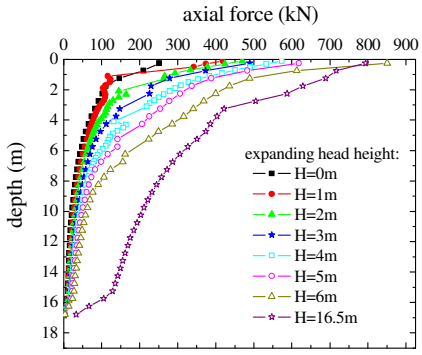

Fig. 7 Axial force curve in different expanding head height under ultimate load

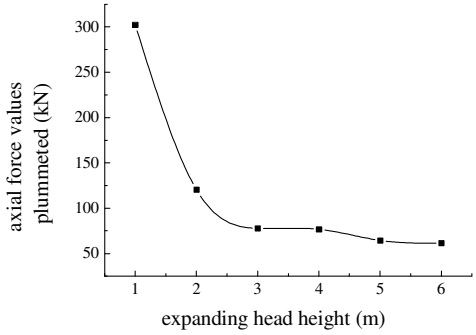

Fig. 8 Variable cross-section of the axial force values plummeted and expanding head height curve

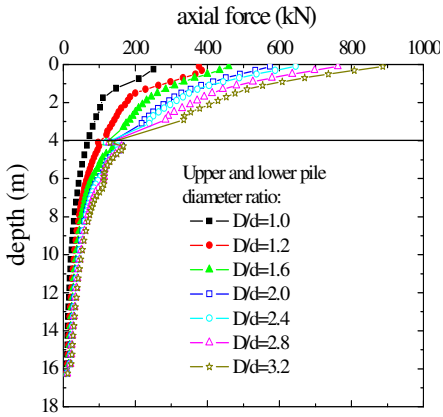
Diameter 1000mm conventional bidirectional soil-cement deep mixing column (H=16.5m), the axial force was significantly higher than other shaped deep mixing column under ultimate load; while diameter 500mm conventional bidirectional soil-cement deep mixing column (H=0m), in the range of expanding head depth axial force was significantly lower than other shaped deep mixing column under ultimate load, but the depth below 1m and expanding head height 1m they axial force curve are basically the same; the ultimate bearing capacity of expanding head height 6m deep mixing column slightly lower than the diameter 1000mm conventional bidirectional soil-cement deep mixing column.

**The ratio of upper and lower pile diameter impact load transfer mechanism.**

Working condition three: the ratio of upper and lower diameter is 1.2, 1.6, 2.0, 2.4, 2.8 and 3.2, the numerical simulation results under ultimate bearing capacity shown in Figure 9, Figure 10.



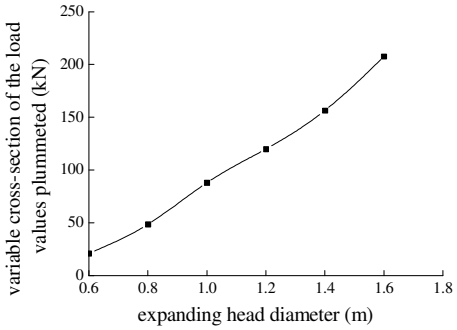


Figure 9, Figure10 show: under ultimate load, the axial force gradually decay with increasing depth; in variable cross-section axial force appears plummeted phenomenon, plummeted value increase with

the ratio of upper and lower pile diameter geater and the relationship obedience quadratic relationships. This mainly due to axial load consistent in ultimate load, but the flange area and expanding diameter into a quadratic relationship. In addition, for different expanding head diameters deep mixing column, the maximum axial force is very close below variable cross-section. In the role of ultimate load for expanding head height 4m deep mixing column, the ratio of upper and lower pile diameter should be controlled within 2.0.

## Conclusions

Through the numerical simulation on load transfer mechanism of T-shaped soil-cement deep mixing column, finally we obtain the following conclusions:

(a) The axial force increases with the load levels increasing.
(b) The axial force decay velocity of expanding head is much faster than the lower part.
(c) Axial force plummeted value under expanding head flange increases with the load and the ratio of upper and lower diameter increasing, but it will decreases when the expanding head height increasing. The changes amplitude relative decreases when expanding head height is greater than 3m.
(d) Within 30cm below the expanding head flange occurs negative friction zones; The influence sphere has connection to load and the ratio of upper and lower pile diameter, it will increase when the ratio of upper and lower pile diameter increasing.

**Keywords:** consolidation, modeling, one dimension, unlayerd soil.

**Abstract.** In this work, one-dimensional problem has a well-known linear solution and, thus, provides a simple verification of the consolidation capability using numerical solution. The coupling is approximated by the effective stress principle, which treats the saturated soil as a continuum, assuming that the total stress at each point is the sum of an effective stress carried by the soil skeleton and a pore pressure in the fluid permeating the soil. This fluid pore pressure can change with, and the gradient of the pressure through the soil that is not balanced by the weight of fluid between the points in question will cause the fluid to flow: the flow velocity is proportional to the pressure gradient in the fluid according to Darcy's law. A typical case is a consolidation problem. Here the addition of a load to a body of soil causes pore pressure to raise initially; then, as the soil skeleton takes up the extra stress, the pore pressures decay as the soil consolidates. The Terzaghi problem is the simplest example of such a process. For illustration purposes, the problem is treated with and without finite-strain effects. The numerical solution agrees reasonably well with the analytical solution, with some loss of accuracy at later times.

## Introduction

The one-dimensional consolidation theory by Terzaghi & Fröhlich constitutes the basis of Soil Mechanics [1]. Evaluation of expected settlements depends on the determination of consolidation parameters, which could be evaluated by laboratory tests, field tests, and empirical correlations. Consolidation parameters interpreted from laboratory tests could be subject to inaccuracies resulting from factors such as sample disturbance, sample size, and strain rate. For field tests, existing correlations are typically used to interpret consolidation parameters.

A numerical solution of one-dimensional consolidation of layered soils with such defined boundaries is derived by using the method of Laplace transform and its numerical inverse. The solution is explicitly expressed and conveniently coded into a computer program for ease and efficiency of practical use. Analytical solutions of one-dimensional consolidation of single-layered soil are also derived by using the method of analytical inverse Laplace transform and the method of separation of variables as well. By comparing these two analytical solutions and comparing with an available analytical solution for two-layered soil with pervious boundaries, the proposed numerical solution for layered soils is validated. Good agreement is obtained, and the accuracy of the numerical solution is verified. Moreover, the dissipation of excess pore water pressure and the increase of degree of consolidation with time for a four-layered soil are investigated to assess the effects of the adopted drainage boundary conditions on consolidation [2]. Other authors presented an analytical solution to the problem of 1-D consolidation of single-layered soil, wherein $k_v$ is constant and Es varies with depth, with this problem considered as a special case of the problem of consolidation of non-homogeneous soil above. The semi-analytical solution for the consolidation problem of

single-layered or multi-layered soil with $k_v$ and $m_v$ varying with depth, but this solution may only be applicable to NC clay. Based on this solution, the consolidation behavior can be discussed [3].

some studies were conducted on the 1-D nonlinear consolidation problem, in which the coefficient of permeability $k_v$ and that of volume compressibility $m_v$ both directly relate to $c_v$ and vary with the effective stress and void ratio [4]. For single-layered foundation, this paper takes into consideration single-drainage situation and time-dependent loading.

**One dimensional modelling**

The problem is shown in a body of soil 2.54 m high is confined by impermeable, smooth, rigid walls on all but the top surface. On that surface perfect drainage is possible, and a load is applied suddenly. Gravity is neglected. Because of the boundary conditions, the problem is one-dimensional, the only gradient being in the vertical direction.

The soil is assumed to be linear elastic, with a Young's modulus of 689.5 GPa and Poisson's ratio of 0.3. The specific weight of the pore fluid is assumed to be 276.8 $10^3$ N/m$^3$. The permeability is assumed to vary linearly with the void ratio, with a value of 8.47 $10^{-8}$ m/sec at a void ratio of 1.5 and a value of 8.47 $10^{-9}$ m/sec at a void ratio of 1.0. The void ratio is assumed to be 1.5 initially throughout the sample. Abaqus uses effective permeability, which is permeability divided by the specific weight of the pore fluid. Therefore, the fluid in this problem is assigned the value 276.8 $10^3$ N/m$^3$ for the specific weight and the permeability is scaled accordingly.

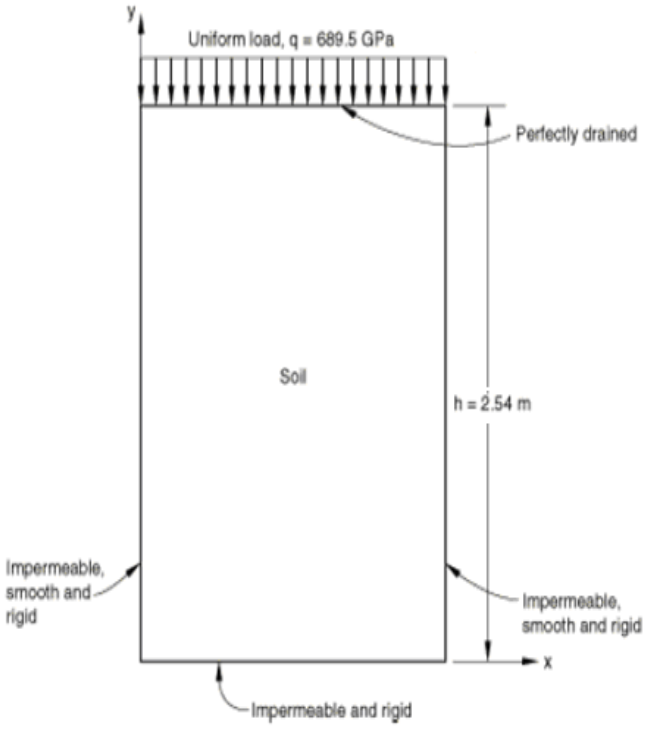

Figure 1. Consolidation problem geometry

The boundary conditions are as follows: On the bottom and two vertical sides, the normal component of displacement is fixed, and no flow of pore fluid through the walls is permitted. This latter is the natural boundary condition in the fluid mass conservation equation, so no explicit specifications need to be made. On the top surface a uniform downward load is applied suddenly. The magnitude of this load is taken to be 689.5 GPa. This large load will cause considerable deformation, thus illustrating the difference between the small- and large-strain solutions. This surface allows perfect drainage so that the excess pore pressure is always zero on this surface.

The problem is run in two steps. The first step is a single increment of a soil consolidation analysis with an arbitrary time step, with no drainage allowed across the top surface. This establishes the initial

solution: uniform pore pressure equal to the load throughout the body, with no stress carried by the soil skeleton. The actual consolidation is then done with a second soils consolidation step, using automatic time stepping.

An important issue in such consolidation problems is the choice of initial time step. As the governing equations are parabolic, the initial solution (immediately after the sudden change in load) is a local, "skin effect," solution. In this one-dimensional case the form of the initial solution is sketched in figure 2 for illustration purposes. With a finite element mesh of reasonable size for modelling the solution at a later time (when the changes in pore pressure have diffused into the bulk of the body soil), this initial solution will be modelled poorly. With smaller initial time steps the difficulty becomes more pronounced, as sketched in figure 2.

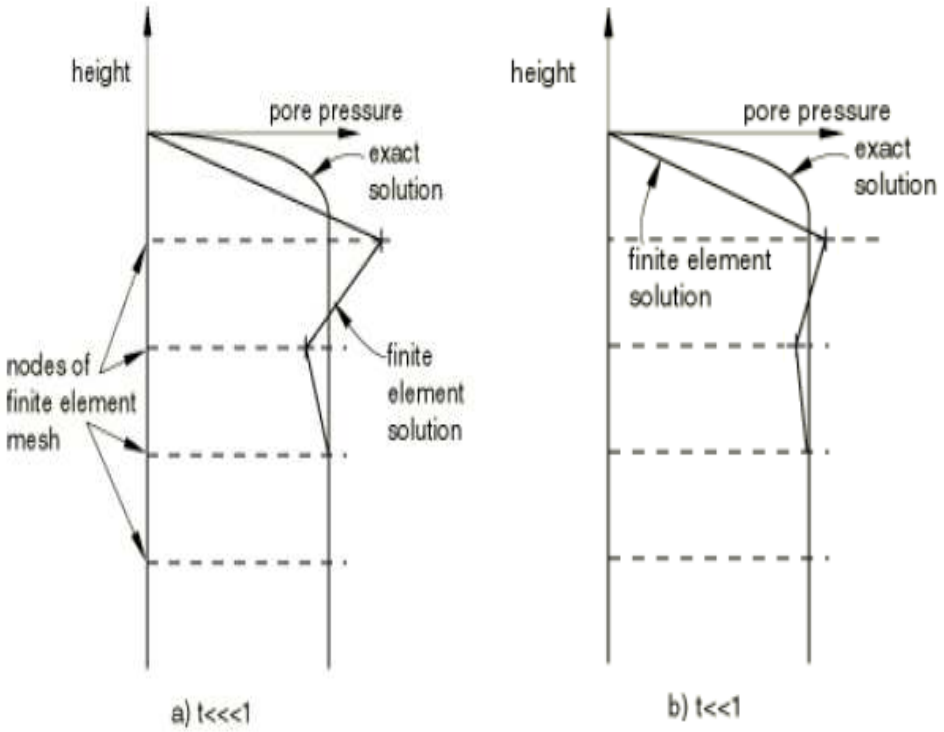

Figure 2. Solutions at t <<1

As in any transient problem, the spatial element size and the time step are related to the extent that time steps smaller than a certain size give no useful information. This coupling of the spatial and temporal approximations is always most obvious at the start of diffusion problems, immediately after prescribed changes in the boundary values. For this particular case the issue has been discussed in detail by Vermeer and Verruijt [5], who suggest the simple criterion:

$$\Delta t \geq \frac{\gamma_w}{6Ek}(\Delta h)^2 \tag{1}$$

where $\Delta h$ is a characteristic element size near the disturbance (that is, near the draining surface in our case), E is the elastic modulus of the soil skeleton, k is the soil permeability, and $\gamma_w$ is the specific weight of the permeating fluid. For our model we choose $\Delta h = 254$ mm (10 in); and we have $E = 689.5$ GPa, $k = 8.47\ 10^{-8}$ m/s, $\gamma_w = 2.768\ 10^5$ N/m3, which gives $\Delta t \geq 0.05$ s. Based on this calculation, an initial time step of .06 sec is used. This gives an initial solution with no "overshoot" at all, as expected. In this case we wish to continue the analysis to steady-state conditions. This is defined by asking Abaqus to stop when all pore pressure change rates fall below 11.5 KN/m$^2$/s.

**Results and conclusion**

In the small-strain analysis the steady-state condition (rate of change of pore pressure with time below the prescribed value) is reached after 20 increments, the last time increment taken being 491 seconds — about 8000 times the initial time increment. This very large change in time increment size is typical of such diffusion systems and points out the value of using automatic time stepping with an unconditionally stable integration operator for such problems.

The results of the small-strain analysis are summarized in figures 3-4. Figure 3 shows pore pressure profiles (pore pressure as a function of elevation) at various times in the solution.

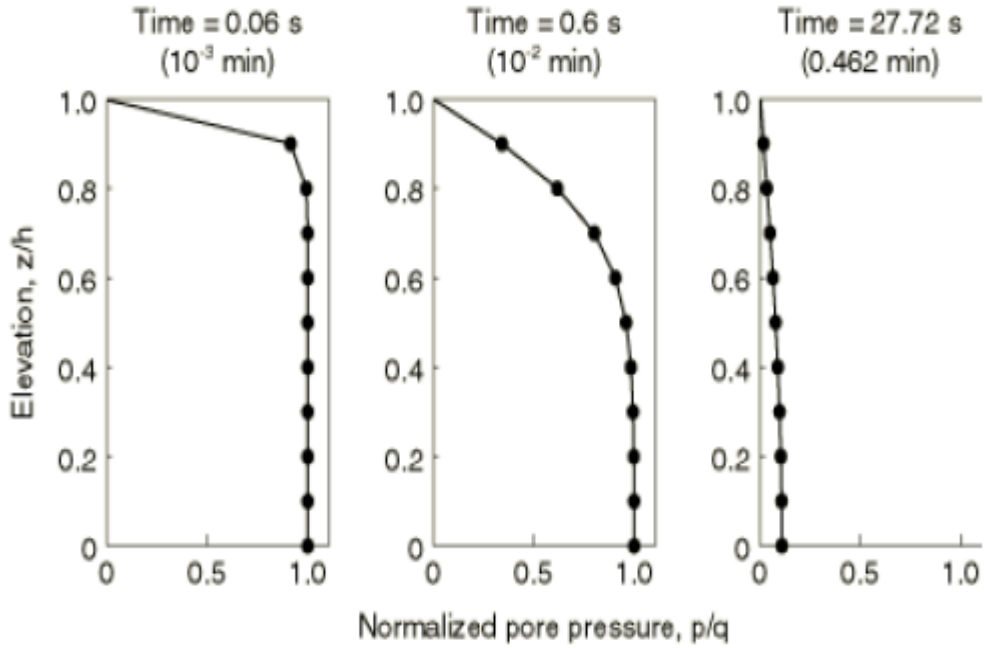

Figure 3. Pore pressure at various times

As we would expect, the solution begins by rapid drainage at the top of the sample and loss of pore pressure in that region. This effect propagates down the sample until the entire sample is steadily losing pore pressure throughout its length. At steady state the solution has zero pore pressure everywhere, with the load being carried as a uniform effective vertical stress. Figure 4 shows this transfer of load from the fluid to the skeleton at the 1.905 m elevation as a function of time.

Figure 5 compares these numerical results with the solution quoted in Terzaghi and Peck [1]. Here the downward displacement of the top surface of the soil, as a fraction of its steady-state value (the degree of consolidation), is plotted as a function of normalized time, defined as:

$$time\ factor = \frac{kE}{H^2 \gamma_w} t \tag{2}$$

Where k is the permeability of the soil, E is the Young's modulus of the soil, $\gamma_w$ is the specific weight of the pore fluid, H is the height of the soil sample, and t is time.

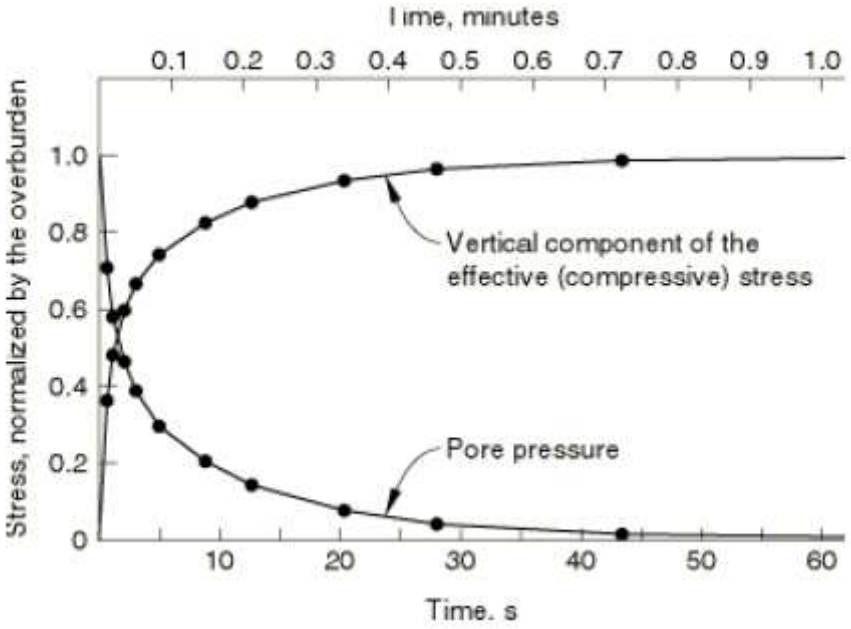

Figure 4. Pore pressure and effective stress

Figure 5 shows that the numerical solution agrees reasonably well with the analytical solution, with some loss of accuracy at later times. This latter effect is attributable to the coarse time stepping tolerance chosen. Higher accuracy could be obtained with a tighter tolerance on the allowable pore pressure stress change parameter. However, the solution is clearly adequate for design use.

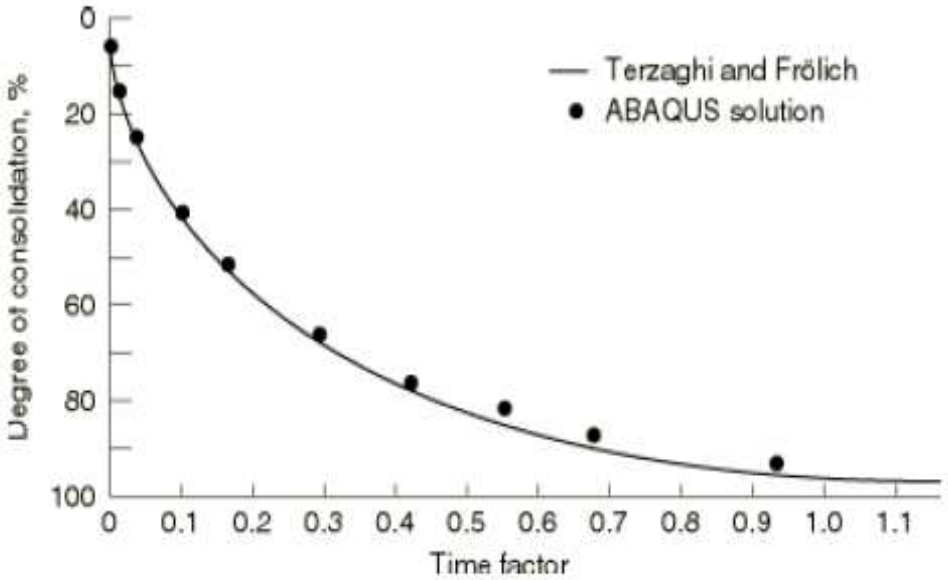

Figure 5. Degree of consolidation Vs time factor

In the finite-strain analysis of soils, changes in the void ratio can lead to large changes in permeability, therefore affecting the transient response in a consolidation analysis. Typical soils show a strong dependence of permeability on the void ratio (as soil compacts, it becomes increasingly harder for fluid to pass through it), with the consequence that “plugging” may result. This means that a soil that was relatively permeable in its original state becomes less permeable as it consolidates.

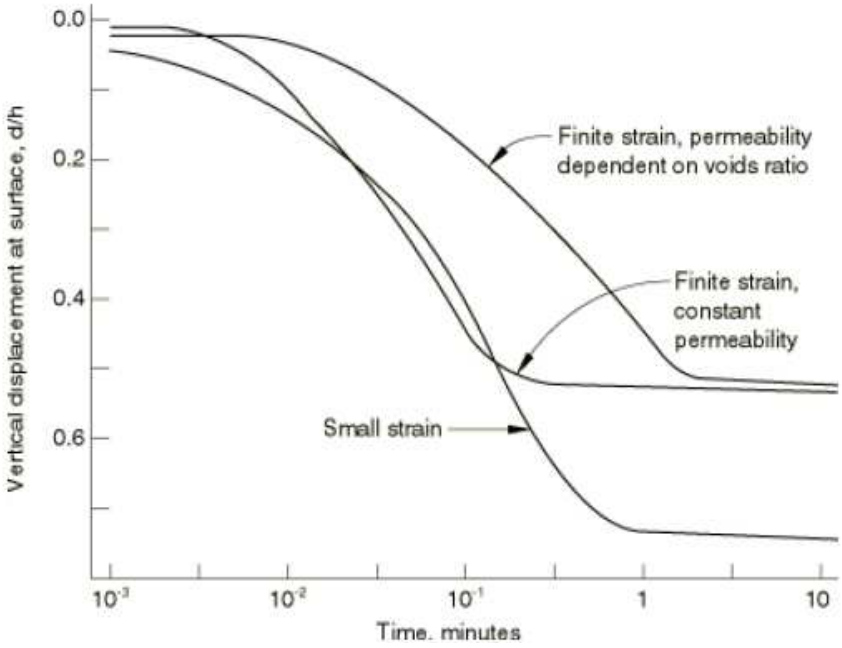

Figure 6. Comparisons of finite- and small-strain solutions to the Terzaghi consolidation problems

In this work the permeability of the soil is assumed to decrease by an order of magnitude as the void ratio decreases from its initial value of 1.5 to a value of 1.0. Such logarithmic dependence of permeability on the void ratio is not uncommon in fully saturated clays. Two finite-strain analyses are run, one with permeability treated as a constant and a second with this variation in permeability. The results are shown in figure 6, together with the results of the small-strain analysis under similar load. The "plugging" effect of void ratio dependence of permeability is clearly seen in this figure. Since the permeability decreases with the consolidation of the soil, the time required for all excess pore pressure to dissipate increases. The final value of displacement under the applied load is not a function of permeability and is correctly predicted by both large-strain analyses. It is interesting to observe that, if the permeability is not dependent on the void ratio, the finite-strain results show more rapid initial consolidation than the corresponding small-strain analysis.

**Keywords:** Grouting anchor; Slope strengthening; Experimental study; Effective anchorage length

**Abstract.** Anchoring technique has been widely used in slope engineering because of its reinforcing function to rock and soil mass. Yet the full understanding of the anchoring mechanism still lags behind the engineering practice. This paper introduces the design process and construction technology of the grouting anchor in slope reinforcement engineering. Based on bolt grouting test, it is found that the effective anchorage length of the grouting anchor depends on the size of the anchor solid and relative physical and mechanical properties of surrounding rock and soil. Research shows that the distribution of shear stress is uneven along the anchoring length. It mainly amasses within the front 1/3 part of the anchoring and increases with the development of outside load. The conclusion is helpful to describe the anchoring mechanism and instructive for engineering practice.

## Introduction

Engineering practice shows that the rock anchorage technique can fully call their own strength in rock and soil mass and has the fewer disturbances to the rock mass itself; in addition, it is an efficient economy reinforcement technique. So rock anchorage technique attracts the favor of the engineers and has been widely used in geotechnical engineering[1-3]. Although certain progress of rock anchorage technique has been made in experimental study and in application, the full understanding of the anchoring mechanism obviously lags behind the engineering practice. The anchorage parameters mostly depend on practical experience and engineering analogy method, which cannot fully reflect the anchoring performance of slope rock mass mechanical behavior. Design method, mechanical effect and reinforcement mechanism of rock anchorage technique need to be further studied. In this paper, the experimental study of rock anchorage technique was performed based on an engineering practice of highway slope reinforcement and the findings were helpful for reveal the anchoring mechanism and engineering practice.

## Application of grouting anchor in slope reinforcement of Dongguan to Shenzhen expressway

**Project profile.** This project is located in K15 section of Dongguan to Shenzhen expressway. And the pile number is K15 + 720 to K15 + 904, and the vertical height of slope is 53.94 m.

Due to the poor cohesive force of upper debris slope, the well-developed fractures of lower strongly weathered argillaceous siltstone, and the enough region rainwater, the whole slope can't be natural stability. Considering the physical and mechanical properties of rock mass slope and other influencing factors on slope stability, spray anchor reinforcement measures were adopted in this project.

**Outline of grouting anchor design.** The design process of the anchor rod was shown in figure 1.

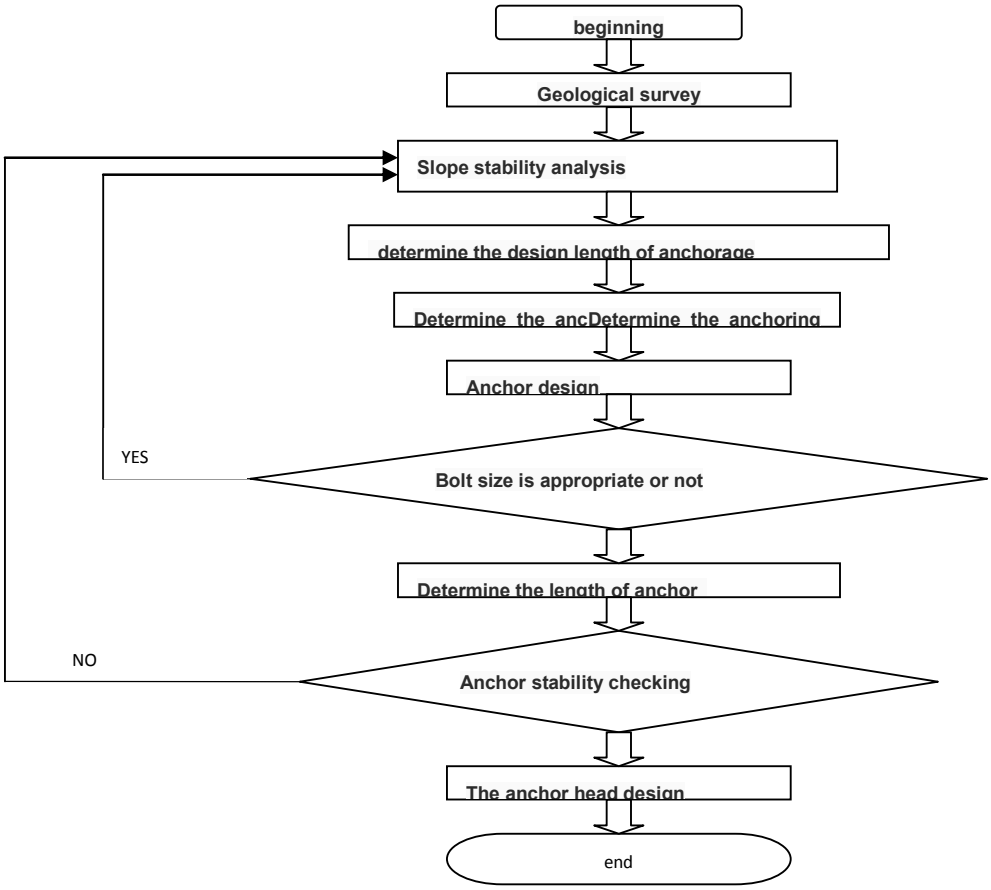

Fig.1 Design process of bolt

The slope stability analysis and the calculation method of anchoring force are as follows: Circular arc failure mode was chosen considering that the slope was mainly composed of diluvial gravel soil and broken rock mass. Based on Swedish article point's method, the slope safety factor calculation formula was obtained as

$$Fs = \frac{\text{Anti-sliding moment}}{\text{Slipping torque}} = \frac{CL + tg\phi \sum (W_{\mathrm{i}} \cos \alpha_{\mathrm{i}} - U_{\mathrm{i}})}{\sum W_{\mathrm{i}} \sin \alpha_{\mathrm{i}}} \tag{1}$$

where $C$ is cohesive force of rock and soil mass, $L$ is the length of the sliding surface, $\varphi$ is the frictional angle of rock and soil mass $W_i$ is the $i$th market its own weight, $\alpha_i$ is the $i$th strips sliding surface inclination and $U_i$ is the $i$th strips surface water pressure.

When the anchoring force $T$ was applied to the slope, the formation of safety coefficient can be described as

$$F_s = \frac{CL + \left[\sum (W_i \cos\alpha - U_i) + T\cos\theta\right] tg\varphi}{\sum W_i \sin\alpha_i - T\sin\theta} \tag{2}$$

in which, θ is the vertical angle between the anchor axis and the sliding surface.

And Equitation (3) can be easily gotten with Equitations (1) and (2)

$$T = \frac{[F_S] \cdot \sum W_i \sin\alpha_i - tg\varphi \sum (W_i \cos\alpha_i - U_i) - CL}{[F_S]\sin\theta + \cos\theta\, tg\varphi} \tag{3}$$

in which, [ $F_s$ ] is the allowable slope safety factor.

Specially, in the grouting bolt[4], the anchoring force can be described as

$$T = \pi L d q_s \tag{4}$$

where $L$ the length of the anchoring body, $d$ is the diameter of anchor solid and $q_s$ is the bond strength between anchor solid surface and the surrounding rock mass.

According to the calculating results, design length of anchor was 10 meters to 14 meters, the lip angle between anchor and horizontal plane was 15 degree, and the spacing of anchors was 2 meters to 4 meters. Rebar with diameter of 25 mm was chosen as the material type of anchor, poured with cement paste around the total length of the anchor.

## Construction technology.

### Anchor hole forming

A diameter of 110mm was set as the aperture of anchor hole, and QZ100K portable pneumatic DTH drilling rig was used for the anchor hole forming. During the forming process of anchor hole, residue was timely cleaned and a bracket with lip angle of 15 degree was used to control the forming angle of drilling rig.

### Manufacture and installation of anchor

Anchors were made with rebar of 25mm in diameter, and before that rust cleaning was performed on rebar materials. Position brackets were installed every two meters to ensure the center position of anchor with enough thickness of the protective layer. Precise process control during installation process of anchors was carried out to prevent anchor hole collapse.

### Cement slurry preparation and its grouting process

Cement slurry was made of No. 425 Portland cement with a water cement ratio of 0.45 to 0.5, the mixing time was set as no less than 3 minutes. And when the anchor grouting pipe was extended to about 10 cm to 15 cm distance from the bottom of anchor hole, the cement slurry then was started pouring into the anchor hole. During the pouring course of cement slurry, the anchor grouting pipe was gradually pulled out but should guarantee that the nozzle was always buried in the slurry till cement slurry overflowing from orifice. Then sealing belt was filled in the orifice under a pressure of 0.2 MPa to 0.5MPa.

## Field experiment

To study the anchorage mechanism of anchor and evaluate the rationality of the design, anchor test in the construction site was carried out.

**Overview.** The field test of anchor includes two parts, drawing test and strain monitoring test. For the former one, the purpose is to estimate the average surface friction stress $q_s$ between anchors and the anchor hole wall as well as the impact of anchorage length on anchors. For the latter one, the purpose was to investigate the distribution of axial stress and cohesive stress, which was implemented by setting strain sensor on the surface of anchor body.

Two sets of drawing tests were performed, one was located in the soil and the other was located in the rock mass. In each group, three anchor bolts with different anchorage length, which was 3.5 m, 5.5 m and 11.5 m, respectively, were tested independently. Fig. 3 shows the results of the drawing test.

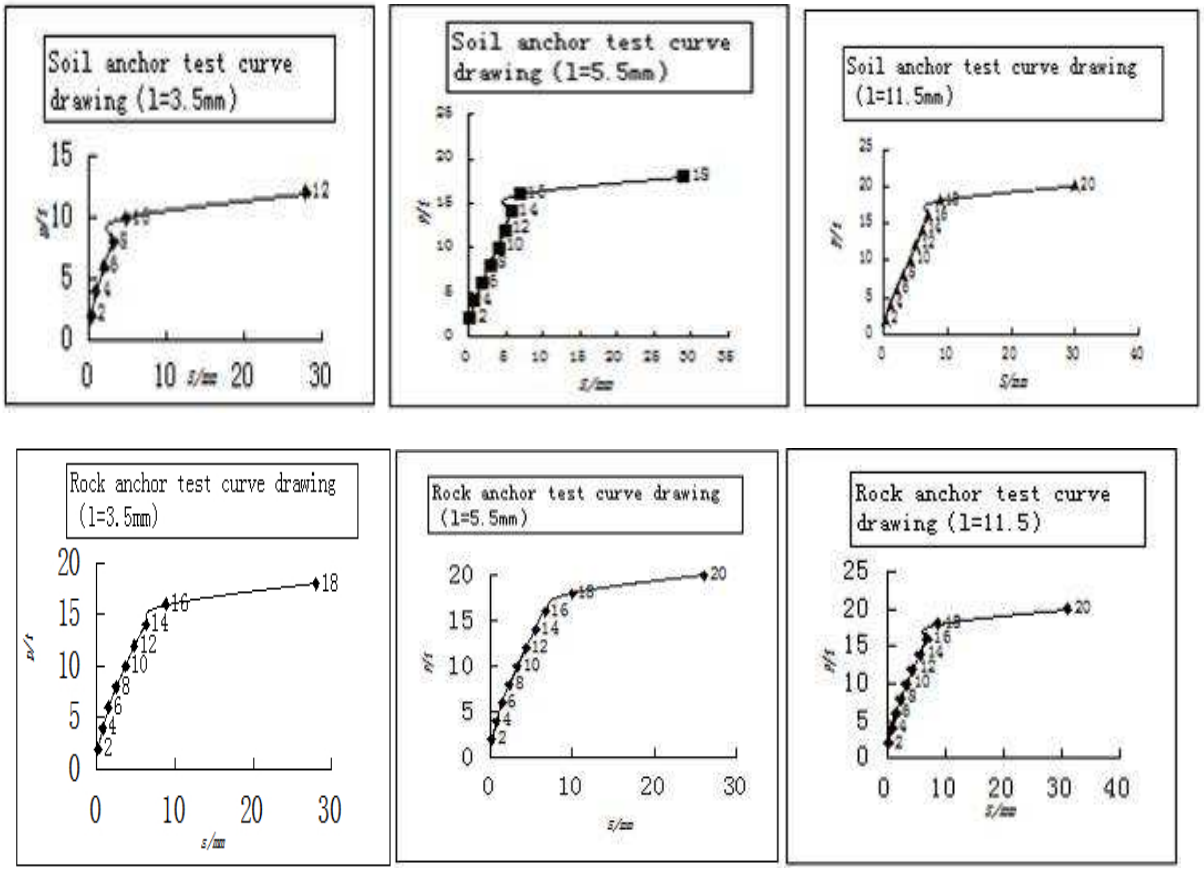

Fig.2 Drawing test results

For the strain monitoring test, two anchor bolts, with a bolt length of 14 m, there into, non anchorage length of 1.5 m and anchorage length of 12.5 m, were pasted with strain sensors. One anchor was located in the soil and the other was in rock mass.

As paste technology of strain sensors is one of the most important factors that influencing the test results, the below process was carried out in this research: the gauge location of the anchor bolt was polished well and carefully cleaned with acetone, then strain sensors were pasted. Yet only the anchor bolt located in soil and its sensors was well preserved in this research, and the cable of sensors placed on anchor in rock mass was destructed because of the curiosity of field workers. Table 1 shows the measured data of strain during drawing test.

Table 1 Measured strain on anchor bolt during drawing test

| Length along anchor bolt/m | Strain data under different drawing load (kN) /microstrain | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | 40 | 60 | 80 | 100 | 120 | 140 | 160 | 180 | 200 |
| 1 | 412 | 628 | 834 | 1038 | 1293 | 1458 | 1673 | 1986 | 2288 |
| 2 | 118 | 295 | 442 | 683 | 898 | 1201 | 1412 | 1785 | 2011 |
| 4 | 8 | 16 | 20 | 138 | 326 | 528 | 735 | 892 | 1025 |
| 6 | 0 | 5 | 1 | 0 | 38 | 66 | 152 | 223 | 358 |
| 8 | 4 | 4 | 5 | 3 | 16 | 25 | 38 | 71 | 112 |
| 12 | 2 | 4 | 3 | 0 | 5 | 10 | 12 | 33 | 48 |

**Analysis of experimental results.**

**Analysis of drawing test results**

Observing the loading curves in Fig. 2, it can be seen that the anchorage force increase with the anchoring length, but there is a effective anchorage length, over that the further augment of

anchoring length cannot significantly increase the anchorage force of anchor bolt. Fig. 3 gives the comparison of anchorage force and anchoring length located in the soil and in the rock mass, and it can be concluded that the value of effective length relates to the characteristics of hole wall. It's about 6.0m in the soil and about 4.0m in the rock mass.

The average surface friction resistance $q_s$ can be calculated using equation (4) and the relationship curve between $q_s$ and anchoring length can be obtained, shown in Fig. 4. It can be concluded that the average surface friction resistance decreases with the increase of the anchorage length.

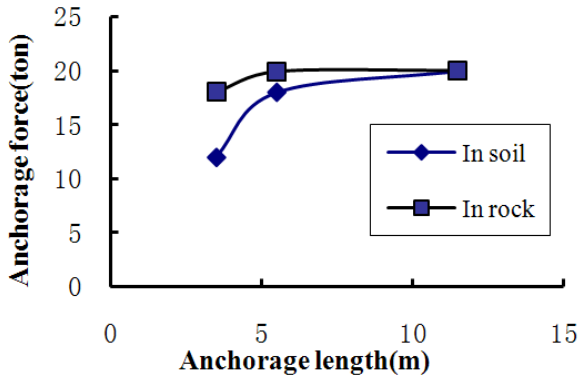

Fig.3 Relation curve between anchorage force and length

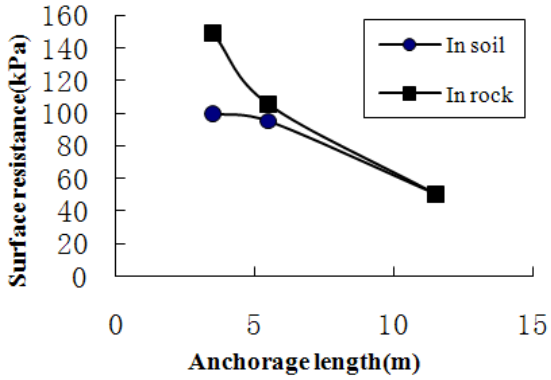

Fig.4 Relationship between average surface friction resistance and anchoring length

**Axial force and shear stress distribution along anchorage section**

According to the measured data in Table 1, anchor axial force $P$ is calculated by

$$P = K_0 EA\varepsilon \tag{5}$$

where $K_0$ is coefficient related to sensitivity of sensor resistors and cable length, $E$ is the elastic modulus of anchor bolt, which was $2\times10^5$ MPa, $A$ is the cross-sectional area of anchor bolt and $\varepsilon$ is the strain.

The calculation results of axial force $P$ is shown in Fig. 5. It can be seen that the axial force mainly concentrated in the front of anchor bolt while subjected to external load, and in the root of anchoring segment there was almost no axial force emerged. With the increase of external load, the distribution range of axial force gradually developed, that is to say, the spread of the axial force exhibits be progressive.

Shear stress between the anchor and cement paste (that is the cohesive force on the anchor bolt) can be calculated by the difference of axial stress in different cross sections of anchor bolt, and Fig. 6 shows the distribution of shear stress.

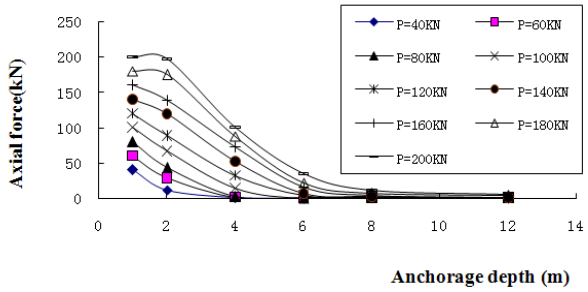

Fig. 5 Axial force curve of every measured point on bolt

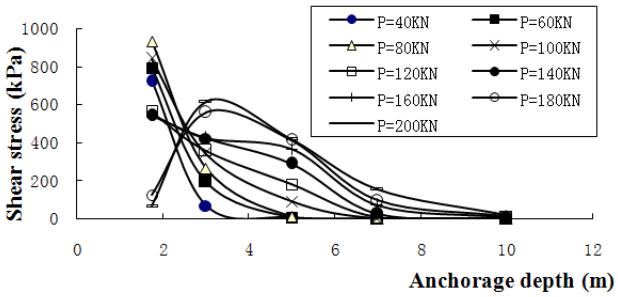

Fig.6 Distribution of shear stress between bolt and grouting

It is known from Fig. 6 that shear stress between slurry and anchor was unevenly distributed along the depth of grouting anchor, and mainly concentrated in the first third segment. Yet the peak value of shear stress moves to the bottom with the increase of the external load. But drawing test, which was traditionally adopted as the standard of grouting effect and capacity of anchor solid, can only examine the front part of grouting body. For grouting anchor bolt, drawing test can't well access the solidity of cement past and it's not comprehensive taking drawing test as the exclusive criteria, especially for grouting anchor with long length in rock mass.

## Conclusions

Based on the above test and analysis results, following conclusion can be concluded:

(1) There is an effective anchoring length in anchor grouting, which depends on the physical and mechanical properties of anchor solid and surrounding media.

(2) Shear stress in anchor solid unevenly distributes along the length of anchoring section, and mainly concentrated in the former 1/3 segment of anchor bolt. With the increase of external load, peak value of shear stress moves to the bottom of grouting anchor.

(3) It's not comprehensive taking drawing test as the exclusive criteria for grouting anchor with long length.

**Keywords:** foundation bearing capacity; reliability; checking point; natural density; vane strength

**Abstract:**According to the first-stage geologic investigation reports of the line 1 and line 2 in Ningbo rail transit, the natural density ($\rho$) and the vane strength ($C_u$) probability distribution of the typical layers in Ningbo area were studied in this paper. Besides, the reliabilities of the typical layers foundation bearing capacity in Ningbo area were evaluated by the checking point method. It is found that (1) the natural densities of the typical layers in Ningbo area show good normal distribution as their corresponding variation coefficients ($\delta$) are small. Unfortunately, the vane strengths of the typical soils in Ningbo area show poor normal distribution as their corresponding variation coefficients ($\delta$) are large. (2) The soil parameters variation has significant influence on the reliability index $\beta$. Moreover, $\beta$ is more sensitive to the variation of $\rho$ than to the variation of $C_u$. (3) As the safety coefficient methods can not consider the influence of the soil parameters variation on the foundation stability, it is suggested that the foundation stability in Ningbo area should be evaluated by the reliability analysis method.

## Introduction

Soil is a natural and historical product. As the different physical and chemical reactions and different historical conditions and different transportations and migrations, soil has significant variation. Therefore, the soil at different points has different physical and mechanical properties even if they look like uniform ostensibly[1]. The constant variation of soil varies with the mineral composition and buried depth and stress history and water content and density during the formation of soil and it does not decrease with the increase of the tests and the improvement of test technology. Therefore, how to consider the uncertainty of soil has become one of the important problems for most engineers.

Foundation bearing capacity is an important research subject in soil mechanics. Unfortunately, the randomness of geological conditions and the discreteness of the sampling sites in investigation always are not considered in dealing with the problem of the foundation bearing capacity. Then, the safety factor method in which all the soil parameters are considered to be constant is used in practical engineering. However, it is not coincided with the fact and results in a large number of engineering accidents[2].

Reliability analysis methods can consider the uncertainties of soil and should be widely used in the geotechnical design theoretically. However, the probability distribution of soil parameters cannot be determined accurately due to the limited investigation data. Then, the application of reliability theory into geotechnical engineering is restricted[3-6].

In this study, the physical parameter including the natural density ($\rho$) and the vane strength ($C_u$) probability distributions of the typical soils were studied in Ningbo area based on the first-stage geologic investigation reports of the line 1 and line 2 in Ningbo rail transit. Then, the reliability of the foundation bearing capacity in Ningbo rail transit engineering was analyzed by the checking point method. The reliability analysis method can be widely used in the geotechnical design in Ningbo rail transit engineering.

**Physical parameters probability distribution of typical layers in Ningbo area**

The Ningbo city is on the east of the Ningbo-Shaoxing plain of Zhejiang in China, and some typical layers such as mucky clay, slush, clay-silt sand, clay, sandy silt, silt and so on had been spontaneously developed during the long and complex geologic evolution. As there is little work on the statistic analysis of the physical parameters in Ningbo area, the application of the reliability theory into the geological design had been seriously limited.

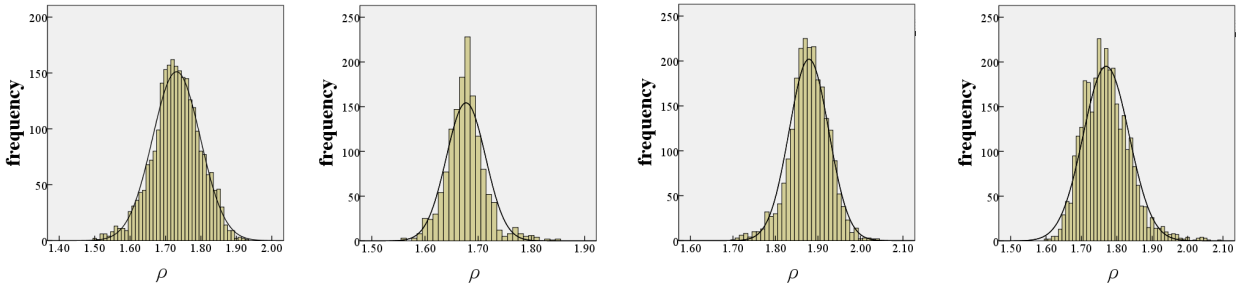
The line 1 in Ningbo rail transit is the main trunk in the east-west direction of the Ningbo rail transit network planning. Meanwhile, the line 1 with a total of 45.99 km long runs through the Haishu Old City, Sanjiankou, Jiangdo New City. Moreover, it is surrounded by the central region of Beilun to its east, Gaoqiao town to its west. The line 2 with a total of 50 km long in Ningbo rail transit is the main trunk in the southwest-northeast direction of the Ningbo rail transit network planning, and it begins at Gulin in Yingzhou and ends in Beilun. According to the first-stage geologic investigation reports of the line 1 and line 2 in Ningbo rail transit with a total of 4 bid sections and 2343 effective borehole and 58984 effective data, The statistic analysis on the physical parameter of every layer such as the natural density ($\rho$) and the vane strength ($C_u$) in Ningbo area were studied. Due to space limitation, only 4 typical layers shown in Table 1 are selected to study the bearing capacity reliability of foundation soil in Ningbo area.

**Table1 Category and depth of typical layers in Ningbo area**

| Soil Numbers | Soil categories | Average depth $h$(m) | Average buried depth $H$(m) |
|---|---|---|---|
| ①$_{3\text{-}0}$ | mucky clay | 2.0 | -2.0 |
| ②$_{2\text{-}1}$ | slush | 2.5 | -4.5 |
| ③$_{2\text{-}0}$ | silty clay | 9.5 | -14.0 |
| ④$_{2\text{-}0}$ | clay | 8.0 | -22.0 |

**1.1 Distribution of natural density**

The frequency histogram of the natural density associated with every typical layers are shown in Fig 1. Moreover, the statistical indexes of the natural density associated with every typical layers including the average value ($\mu$) and standard deviation ($\sigma$) and the variation coefficient ($\delta$) are shown in Table 2.



**(a) Layer ①$_{3\text{-}0}$ (b) Layer ②$_{2\text{-}1}$ (c) Layer ③$_{2\text{-}0}$ (d) Layer ④$_{2\text{-}0}$**

**Fig.1 Natural density histograms of typical layers**

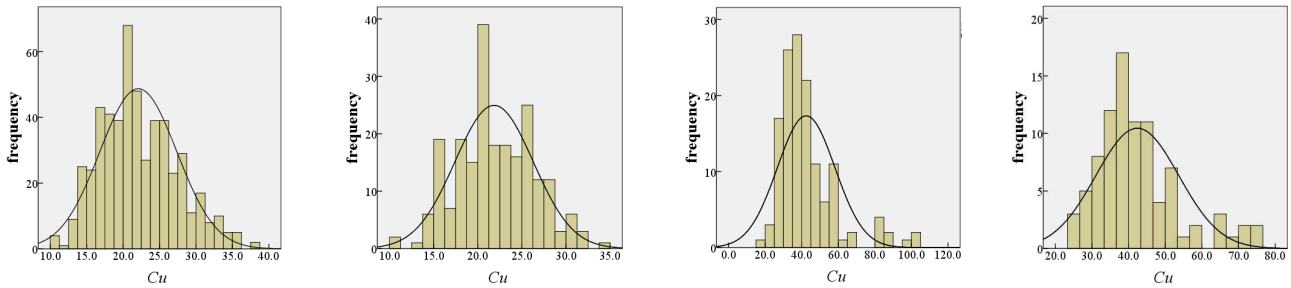
**Table2 Natural density probability statistical table of typical layers**

| Layers | $N$ | $\mu$ (g/cm$^3$) | $\sigma$ (g/cm$^3$) | $\delta$ |
|---|---|---|---|---|
| ①$_{3\text{-}0}$ | 2557 | 1.731 | 0.068 | 0.039 |
| ②$_{2\text{-}1}$ | 2078 | 1.675 | 0.039 | 0.023 |
| ③$_{2\text{-}0}$ | 2361 | 1.879 | 0.047 | 0.025 |
| ④$_{2\text{-}0}$ | 3119 | 1.770 | 0.062 | 0.035 |

From Fig.1 and Table 2, it can be seen that: the variation degrees of the natural density ($\rho$) are low, where the maximum variation coefficient is 0.039 and minimum variation coefficient is only 0.023. Furthermore, the natural density probabilities of all typical layers in Ningbo area show good normal distribution.

### 1.2 Distribution of vane strength parameters

The Vane test has proven to be a simple but effective method in measuring the shear strength of soft soil since they have a flow on smooth surfaces and are common in devices used in different types of rheometers (parallel disc rheometers or coaxial cylinders). Therefore, the vane strength ($C_u$) of four typical layers in Ningbo area is tested and the frequency histogram of the vane strength associated with every typical layers are shown in Fig 2. Moreover, the statistical indexes of the vane strength associated with every typical layers including the average value ($\mu$) and standard deviation ($\sigma$) and the variation coefficient ($\delta$) are shown in Table 3.



**(a) Layer ①$_{3\text{-}0}$** **(b) Layer ②$_{2\text{-}1}$** **(c) Layer ③$_{2\text{-}0}$** **(d) Layer ④$_{2\text{-}0}$**

**Fig.2 Vane strength $C_u$ histograms of typical layers**

**Table3 Vane strength probability statistical table of typical layers**

| Layers | $N$ | $\mu$ (g/cm$^3$) | $\sigma$ (g/cm$^3$) | $\delta$ |
|---|---|---|---|---|
| ①$_{3\text{-}0}$ | 517 | 22.086 | 5.290 | 0.240 |
| ②$_{2\text{-}1}$ | 222 | 21.847 | 4.436 | 0.203 |
| ③$_{2\text{-}0}$ | 137 | 42.392 | 15.765 | 0.372 |
| ④$_{2\text{-}0}$ | 89 | 42.366 | 11.326 | 0.267 |

From Fig.2 and Table 3, it can be seen that: the variation degrees of the natural density ($\rho$) are low, where the maximum variation coefficient is 0.372 and minimum variation coefficient is only 0.203. Furthermore, the natural density probabilities of all typical layers in Ningbo area show normal distribution.

### Checking point method

In the standardized normal space, the reliability index is defined as the minimum distance between the origin of coordinates and the limit state curve by Hasofer and Lind (1974). Then, the vertical line is drawn through the origin of coordinates to the limit state curve and the intersection is called checking point.

In the checking point method, all the random variables are considered to be in normal distribution. Its procedure is as follows:

(1) Supposed that the random variables including $X_1$, $X_2$,…, $X_n$ are in normal distribution. Then, the performance function of the structure is $Z$=g($X_1$, $X_2$,…, $X_n$). Given that the checking point $\boldsymbol{X}^*$ is $(x_1^*, x_2^*, \cdots, x_n^*)$ and by taking the first-order terms of a Taylor series expansion the performance function is derived as:

$$Z \approx g(x_1^*, x_2^*, \cdots, x_n^*) + \sum_{i=1}^{n} \frac{\partial g(x^*)}{\partial X_i}\left(X_i - x_i^*\right) \tag{1}$$

The associated average value ($\mu$) and standard deviation ($\sigma$) are

$$\mu_Z = E(Z) = g(x_1^*, x_2^*, \cdots, x_n^*) + \sum_{i=1}^{n} \frac{\partial g(x^*)}{\partial X_i}\left(E(X_i) - x_i^*\right) = g(x_1^*, x_2^*, \cdots, x_n^*) + \sum_{i=1}^{n} \frac{\partial g(x^*)}{\partial X_i}\left(\mu_{X_i} - x_i^*\right) \tag{2}$$

$$\sigma_Z^2 = E(Z - E(Z))^2 = \sum_{i=1}^{n}\sum_{j=1}^{n} \frac{\partial g(x^*)}{\partial X_i}\frac{\partial g(x^*)}{\partial X_j} E[(X_i - \mu_{X_i})(X_j - \mu_{X_j})] = \sum_{i=1}^{n}\left[\frac{\partial g(x^*)}{\partial X_i}\sigma_{X_i}\right]^2 \tag{3}$$

The associated reliability index is

$$\beta = \frac{\mu_Z}{\sigma_Z} = \frac{g(x_1^*, x_2^*, \cdots, x_n^*) + \sum_{i=1}^{n} \frac{\partial g(x^*)}{\partial X_i}\left(\mu_{X_i} - x_i^*\right)}{\sqrt{\sum_{i=1}^{n}\left[\frac{\partial g(x^*)}{\partial X_i}\sigma_{X_i}\right]^2}} \tag{4}$$

As the checking point $\boldsymbol{X}^* = (x_1^*, x_2^*, \cdots, x_n^*)$ is unkown, the reliability index cannot be computed by equations.

Moreover, the relationship between the checking point and the reliability index can be[2]:

$$x_i^* = \mu_{X_i} + \beta\sigma_{X_i}\cos\theta_{X_i} \tag{5}$$

In the standardized normal space, the sensitivity coefficient $\alpha_{Xi}$ can be :

$$\alpha_{X_i} = \cos\theta_{X_i} = \frac{-\frac{\partial g(x^*)}{\partial X_i}\sigma_{X_i}}{\left(\sum_{i=1}^{n}\left[\frac{\partial g(x^*)}{\partial X_i}\sigma_{X_i}\right]^2\right)^{1/2}} \tag{6}$$

where, $\alpha_{Xi}$ is the sensitivity coefficient which denotes the relative influence of the $i^{th}$ random variation on the standard deviation.

The failure probability can be:

$$P_f = 1 - \Phi(\beta) \tag{7}$$

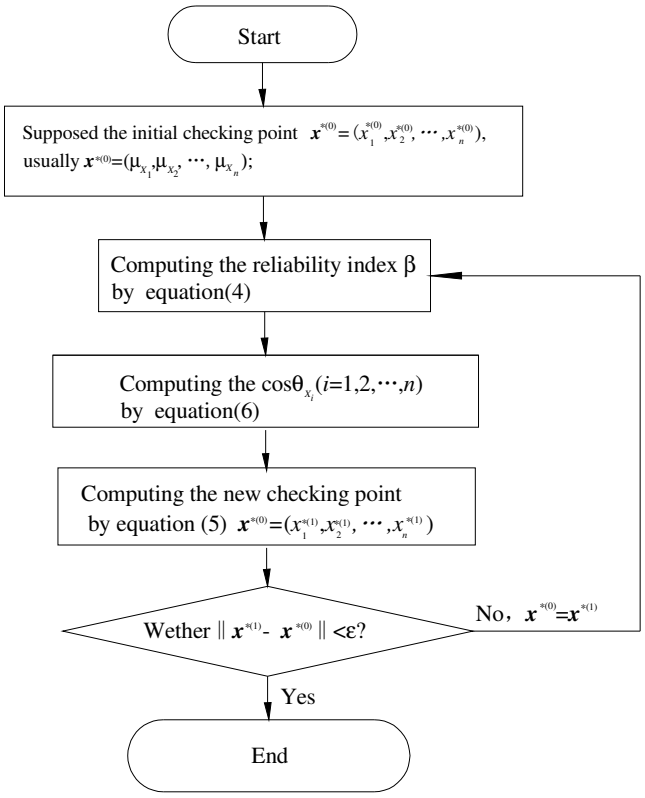


**Fig.3 Flow chart of the checking pint method**

where, $\Phi(\beta)$ denotes the cumulative probability function on normal distribution.

Based on the above formulae, the reliability index can be performed and the incremental procedure can be implemented as shown in Fig. 3. Furthermore, the correspondent failure probability can be computed by the equation (7).

## Reliability analysis on the foundation bearing capacity in Ningbo rail transit engineering

### 3.1 Stability analysis on the soil foundation

The vane shear test can be used to predict the foundation bearing capacity of soft clay such as mucky clay and slush and collapsible loess and so on. The empirical formula is:

$$f_a = 2C_u + \gamma H \tag{8}$$

where

$C_u$ is the modified vane shear strength of soil (kPa);

$\gamma$ is the unit weight of foundation soil (kN/m$^3$);

$H$ is the foundation buried depth (m).

The correspondent safety factor $F_s$ is:

$$F_s = \frac{2C_{um} + \gamma_m H}{p_m} = \frac{2C_{um} + \rho_m g H}{p_m} \tag{9}$$

where

$p_m$ is the mean value of the foundation pressure (kPa);

$C_{um}$ is the mean value of the shear strength of foundation soil (kPa);

$\gamma_m$ is the mean value of unit weight of foundation soil (kN/m$^3$);

$\rho_m$ is the mean value of natural density of foundation soil (g/cm$^3$);

$g$ is the acceleration of gravity (m/s$^2$)。

### 3.2 Limit state equation

The correspondent limit state equation is :

$$p - 2C_u - \gamma H = p - 2C_u - \rho g H \tag{10}$$

where

$p$ is the foundation pressure (kPa);

$\rho$ is the natural density of the foundation soil (g/cm$^3$).

### 3.3 Determination of the random variation

Based on the above engineering condition, the foundation buried depth $H$ and the acceleration of gravity $g$ can be considered as constant in the practical reliability design. However, the variation of other parameters such as the shear strength $C_u$ and the natural density of foundation soil and the foundation pressure are large and they should be considered as random variation.

### 3.4 Computation of the reliability index

The mean value of the foundation pressure $p_m$ is 200 kPa and its correspondent variation coefficient $\delta_p$ is 0.25. Moreover, in each layer the vane shear strength $C_u$ and the natural density $\rho$ are independent on each other and both of them are in good normal distribution. The statistic results are shown in Table 4.

**Table4 Calculation parameters of each typical layer**

| Layers | $H$(m) | $C_u$ | | $\rho$ | |
|---|---|---|---|---|---|
| | | $\mu$ (kPa) | $\delta$ | $\mu$ (g/cm$^3$) | $\delta$ |
| ①$_{3-0}$ | 2.0 | 22.086 | 0.240 | 1.731 | 0.039 |
| ②$_{2-1}$ | 4.5 | 21.847 | 0.203 | 1.675 | 0.023 |
| ③$_{2-0}$ | 14.0 | 42.392 | 0.372 | 1.879 | 0.025 |
| ④$_{2-0}$ | 22.0 | 42.366 | 0.267 | 1.770 | 0.035 |

As shown in Table 5, the reliability index $\beta$ and the failure probability $P_f$ of each layer can be computed by equations (4)-(7).

**Table5 Foundation bearing capacity calculated results of each typical layer**

| Layers | $F_s$ | $\beta$ | $P_f$(%) |
|---|---|---|---|
| ①$_{3-0}$ | 0.390 | -2.33 | 99.01 |
| ②$_{2-1}$ | 0.588 | -1.50 | 93.32 |
| ③$_{2-0}$ | 1.289 | 2.54 | 0.55 |
| ④$_{2-0}$ | 2.332 | 4.72 | 0.00 |

From Table5, it can be shown that:

(1) As the safety factors are less than 1 and the failure probabilities are more than 93%, both the layer ①$_{3-0}$ and ②$_{2-1}$ cannot be used as the foundation bearing layer.

(2) The safety factor and the failure probability of layer ③$_{2-0}$ are 1.289 and 0.55%, respectively. Moreover, the safety factor of layer ④$_{2-0}$ is 2.332 and its correspondent failure probability is 0.

Although it is theoretically valid to take the layer ④$_{2-0}$ as the foundation bearing layer, the construction cost is greatly raised as the buried depth of layer ④$_{2-0}$ is large than layer ③$_{2-0}$. Therefore, it is more reliable to choose the layer ③$_{2-0}$ as the foundation bearing layer.

### 3.5 Sensibility analysis on the variation

Supposed that the The mean value of the foundation pressure $p_m$ is 200 kPa and its correspondent variation coefficient $\delta_p$ is 0.25. The layer ③$_{2\text{-}0}$ and layer ④$_{2\text{-}0}$ are taken as the foundation bearing layer, respectively. Their correspondent mean values of the vane shear strength and the natural density are kept invariant and their variation coefficients change from 0.1 to 0.7. Then, the correspondent reliability indexes are shown in Fig.4 and Fig.5.

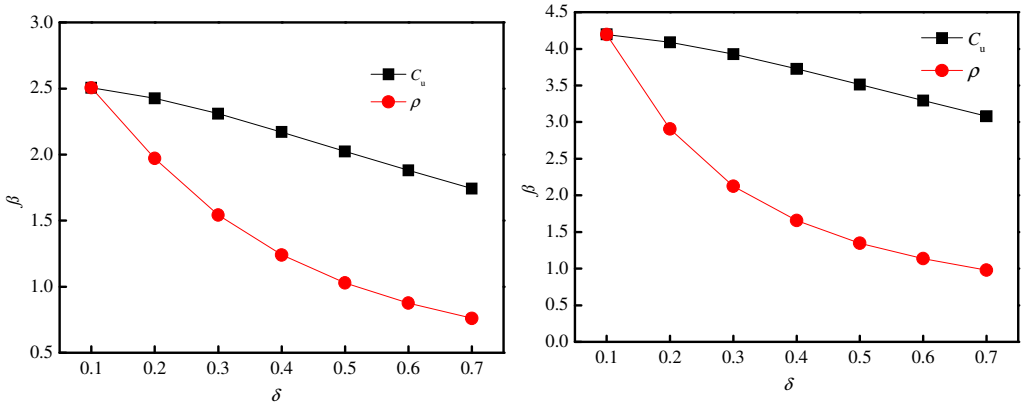

**Fig.4 Relationship between the variation coefficient and reliability in layer ③$_{2\text{-}0}$ and ④$_{2\text{-}0}$**

From Fig.4 and Fig.5, it can be seen that:

(1) The variation of soil parameter has a significant influence on the reliability index. Furthermore, the reliability index is more sensitive to the natural density than to the vane shear strength.

(2) As the mean value of the vane shear strength and the natural density and the foundation pressure are instant, the safety factor of layer ③$_{2\text{-}0}$ and layer ④$_{2\text{-}0}$ computed by equation (9) are 2.07 and 2.332, respectively. Furthermore, the stability of each layer is safe.

(3) However, the reliability index has a significant change due to the different variation coefficients. With the increase of variation coefficient, the reliability index of layer ③$_{2\text{-}0}$ decreases from 2.51 to 0.76 and the correspondent failure probability increase from 0.60% to 22.36%. Moreover, the reliability index of layer ④$_{2\text{-}0}$ decreases from 4.20 to 0.98 and the correspondent failure probability increase from 0 to 16.35%.

(4) From analysis it above can be seen that, safety factor method cannot consider the influence of the variation coefficient and may provide the wrong conclusion. However, the reliability analysis method can reflect the influence of the variation coefficient on the failure probability of foundation soil. Therefore, it is suggested that the safety of the foundation soil should be assessed by the reliability analysis method in practical engineering.

## Conclusions

(1) The natural density of every typical layer in Ningbo area has little variation and shows good normal distribution. In addition, the variation degree of the vane shear strength of every typical layer in Ningbo area is high and shows normal distribution.

(2) The variation of soil parameter has a significant influence on the reliability index and the reliability index is more sensitive to the natural density than to the vane shear strength.

(3) Safety factor method cannot consider the influence of the variation coefficient and may provide the wrong conclusion. It is suggested that the safety of the foundation soil should be assessed by the reliability analysis method in practical engineering.

**Keywords:** Sanitary landfill, HDPE membrane, Anchoring trench, Limit equilibrium theory

**Abstract.** The process of urbanization has brought prosperity of economy and improvement of people's living standard, but larger and larger life garbage in the city could be found due to excessive concentration of population. Sanitary landfill method has been widely applied in many cities for convenience and economy. Anti-seepage treatment and anchorage technology are two key issues to reduce the pollution of leachate on surrounding environment and underground water sources with construction of modern sanitary landfill area. In this paper, the anchorage technology of high-density polyethylene (HDPE) membrane was researched on the steep slope in the valley-type sanitary landfill. The test and theory of anchorage were also studied in the northwest region. The results show that anchorage force reaches the maximum when the anchoring platform is horizontal. It keeps the geomembrane more stable if the slope angle is within 45° when the slope height is over 6m.

## Introduction

Many landfill sites in the northwest region locate in the steep valley, with the slope more than 45° and the slope height more than 8m, which makes it difficult to lay and anchor the HDPE membrane[1]. Therefore, how to prevent seepage in northwest is a difficult problem in sanitary landfill design and construction. The fixation of HDPE geomembrane on the side slope of landfill site depends on anchorage facilities at the foot of each slope. Anchoring trench is adopted in the rock and soil foundation, while the anchor bolt, nail, or a special HDPE geomembrane embedded lock bar in the concrete, masonry and reliably batholith. At present, anchoring trench is the main form, the direction of the anchoring platform is horizontal and the form of cross section of the anchoring trench is rectangle. However, the earthwork excavation volume with this method is large and the cost is high. In order to reduce the cost, a proposed anchoring trench form along the direction of the slope is adopted, but the anchoring force by this method is lesser and geomembrane may take off the anchor. In order to guarantee the integrity and avoid the damage of the geomembrane, it should prevent geomembrane from excessive tensile stress [2,3]. Generally, tensile strength of the geomembrane is calculated by limit equilibrium method of slope stability analysis and researched through experiment combined with limit equilibrium theory [4].

## Limit Equilibrium Analysis Method of Geomembrane Anchorage

**Analysis of the Vertical Pressure of Dump Body.** The structure diagram of dump body in landfill was shown in Fig. 1.The dump body was assumed to be uniform distribution, whose initial unit weight before compaction was $\gamma_0$ and unit weight after compaction was $\gamma_1$. $\theta$ standed for the slope angle of the sanitary landfill area and h was for the height of the slope. The angle of repose of dump body on the anchoring platform was $\beta$ as well as the foot of the slope was set to be the coordinate origin for 0.

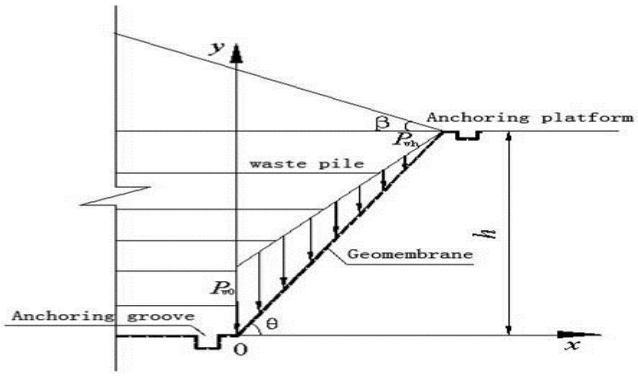

Fig. 1 Structure diagram of dump body

On the top of the anchoring platform, namely the position of y=h, the vertical earth pressure $P_{vh}$ of overlying soil adding to the geomembrane was zero. While for y=0, the vertical earth pressure $P_{vh}$ of the foot of the slope could be calculated by formula (1-1):

$$P_{v0} = \gamma_1 h(1+\cot\theta\cdot\tan\beta) \tag{1-1}$$

Then the vertical earth pressure $P_{vy}$ of overlying soil at $y=y_0$ could be given by:

$$P_{vy} = \gamma_1\left[h+(h-y_0)\cot\theta\tan\beta\right] \tag{1-2}$$

The vertical pressure that geomembrane received was non-uniform distribution and the maximum would occur at the foot of the slope, which was shown in Fig. 1. The total vertical pressure of HDPE for unit width was calculated by formula (1-3):

$$P_{v,total} = \frac{1}{2}\gamma_1 h^2(1+\cot\theta\tan\beta) \tag{1-3}$$

The additional stress at the foot of the slope was caused by the compaction of garbage layer and given by:

$$P_r = (\gamma_1-\gamma_0)\cdot h\cdot(1+\cot\theta\tan\beta) \tag{1-4}$$

The total average additional tension along the slope surface that geomembrane received was calculated by:

$$P_T = \frac{1}{2}(\gamma_1-\gamma_0)h^2(\sin\theta+\cos\theta\tan\beta) \tag{1-5}$$

**Calculation of the Residual Downward Tension of Geomembrane.** Here was a assumption that the geotextile was fully contacted with the geomembrane without relative sliding. The friction $P_\tau$ of both the upper and the lower surfaces of geomembrane was obtained as follows:

$$P_\tau = P_{\tau au} - P_{\tau ad} = (C_{au}-C_{ad})\cdot\frac{h}{\sin\theta}+\frac{1}{2}\gamma_1 h^2(1+\cot\theta\tan\beta)\cos\theta(\tan\delta_u-\tan\delta_d) \tag{1-6}$$

Where $C_{au}$ was a parameter showing the cohesion of geomembrane and the upper geotextile while $C_{ad}$ represented the cohesion of geomembrane and the lower compacted soil respectively. $\delta_u$ and $\delta_d$ were the corresponding friction angels.

The unbalanced tension and anchorage force were needed to make the geomembrane stable if $P_T > P_\tau$. When the landfill body tension $P_T=P_\tau$, The geomembrane could be in limit equilibrium state and remain the tensile stability if $P_T = P_\tau$ .The geomembrane would not slide along the slope and anchorage treatment was not required if $P_T < P_\tau$.

The average residual downward tension of geomembrane along the slope was calculated by:

$$P_r = P_T - P_\tau = \frac{1}{2}h^2\cdot(1+\cot\theta\tan\beta)\left[(\gamma_1-\gamma_0)\sin\theta-\gamma_1\cos\theta(\tan\delta_u-\tan\delta_d)\right]-\frac{(C_{au}-C_{ad})\cdot h}{\sin\theta} \tag{1-7}$$

**Calculation of Geomembrane Tension and Anchorage Force.** The geomembrane tension and the anchorage force of anchoring platform must be used to balance the residual downward tension of geomembrane. Based on this theory, the following assumptions could be made:

(1) There was no relative sliding between the geomembrane and the geotextile.

(2) The geomembrane tension that was close to the anchoring platform was regarded as non-uniform distribution.

(3) The stress-strain relations of geomembrane conformed to the characteristics of elastic material when the tensile rate was less than the yielding tensile rate of geomembrane.

According to the above assumptions, the tension of geomembrane could be given by:

$$P_t = E\Delta l \tag{1-8}$$

Where $E$ was a parameter that represented the elastic modulus of geomembrane and $\Delta l$ was the parameter showing the elongation of geomembrane along with the slope surface.

According to the design and stability requirements of sanitary landfill area, the tensile strength of HDPE should be less than or equal to the tensile yield strength of geomembrane, namely $[P_t] \le T_f$ .The direction of anchoring platform was horizontal and rectangular cross section was adopted for anchoring trench as shown in Fig. 2.

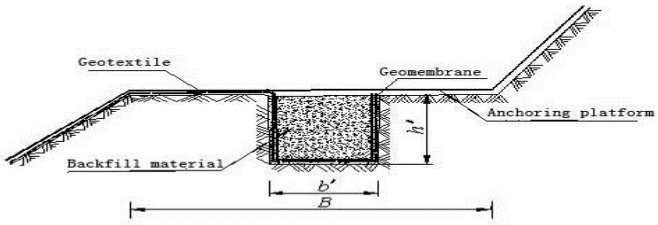

Fig. 2 Sectional view of anchoring trench on anchoring platform

According to the principle of unbalanced friction, the anchorage force Pa provided by the anchoring trench was obtained by:

$$P_a = 2\left[\left(C'_{\mathrm{au}} - C'_{\mathrm{ad}}\right)\cdot h' + \frac{1}{2}\gamma_2 h'^2 k_0\left(\tan\delta'_{\mathrm{u}} - \tan\delta'_{\mathrm{d}}\right)\right] + \left[\left(C'_{\mathrm{au}} - C'_{\mathrm{ad}}\right)\cdot b' + \frac{1}{2}\gamma_2 h'^2(\tan\delta'_{\mathrm{u}} - \tan\delta'_{\mathrm{d}})\right]$$
$$+\left[\left(C'_{\mathrm{au}} - C'_{\mathrm{ad}}\right)\cdot b' + \frac{1}{2}\gamma_2 h'^2(\tan\delta'_{\mathrm{u}} - \tan\delta'_{\mathrm{d}})\right] \tag{1-9a}$$

Where $C'_{\mathrm{au}}$ was a parameter showing the cohesion of geomembrane and the upper geotextile while $C'_{\mathrm{ad}}$ represented the cohesion of geomembrane and the lower compacted soil respectively. $k_0$ was a coefficient representing the static pressure of lateral and equaled to 0.5. $\gamma_2$ was on behalf of the unit weight of packing in the anchoring trench. $\delta'_{\mathrm{u}}$ and $\delta'_{\mathrm{d}}$ were the corresponding friction angels. The formula (1-9a) could be simplified as follows:

$$P_a = (C'_{\mathrm{au}} - C'_{\mathrm{ad}})(2h' + b') + \gamma_2 h'^2(\tan\delta'_{\mathrm{u}} - \tan\delta'_{\mathrm{d}}) \tag{1-9b}$$

The rectangular anchoring trench was adopted for the steep slope in order to decrease excavated volume and construction cost, which was shown in Fig. 3. If the friction and cohesion between the materials and geomembrane were ignored at the top of anchoring trench, the anchorage force of anchoring trench could be given by:

$$P_a = (C'_{\mathrm{au}} - C'_{\mathrm{ad}})(h' + b') + \frac{3}{4}\gamma_2 b'^2(\tan\delta'_{\mathrm{u}} - \tan\delta'_{\mathrm{d}}) \tag{1-9c}$$

(1) The geomembrane would slide or fracture along the slope surface if $P_r > P_t + P_a$ .The above phenomenon could be distinguished by the following three conditions:

- The phenomenon of anchor falling would happen in geomembrane if $[P_t] > P_a$ .
- The phenomenon of anchor falling or fracture would happen with the same probability in geomembrane if $[P_t] = P_a$ .
- The phenomenon of fracture would happen in geomembrane if $[P_t] < P_a$ .

(2)The geomembrane stayed in the limit equilibrium state if $P_r = P_t + P_a$ .

(3)The geomembrane was in stable state if $P_r < P_t + P_a$ , which was expressed in two ways:

- The slope geomembrane could remain stability relying on the anchoring platform only without tensile deformation if $P_r \le P_a$ , which indicated $P_t = 0$ .

Tensile deformation could be found in the geomembrane if $P_r > P_a$ , namely $P_t > P_r - P_a$ .

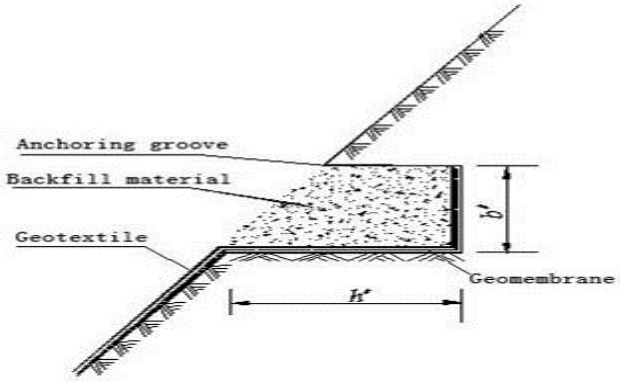

Fig. 3 Sectional view of anchoring trench along the slope surface

## Engineering Examples

**Parameter Selection.** The calculated parameters of anchorage force of geomembrane on the steep slope were showed in Table 1. If the influences of the construction process on the compactness of dump body and the slope geomembrane were ignored, the initial weight $\gamma_0$ and final unit weight $\gamma_1$of dump body were set 11kN/m$^3$ and 15kN/m$^3$.The three kinds of anchoring trenchs with the rectangular cross-section of 0.5m, 0.8m, 1.0m in depth and 0.5m, 0.8m, 1.2m in width were adopted respectively. The unit weight $\gamma_2$ of cohesive soil after compaction was 19kN/m$^3$. In this study, the anchoring technology of HDPE for steep slope was researched ,which indicated the angel of slope was ranging from 40 ° to 60 ° and the height of slope was 6 m, 8 m, 10 m and 12 m respectively. Considering the whole stability of dump body with the increase of height, the value of tan$\beta$ was equal to 0.33 according to the engineering experience.

Table 1 Calculated parameters of anchorage force of geomembrane on the steep slope

| Item | Example 1 | Example 2 | Example 3 (Test) |
|---|---|---|---|
| $C_{au}$(kPa) | 2 | 1 | 0.27 |
| $C_{ad}$(kPa) | 0.5 | 0.5 | 0.15 |
| $\delta_u$(°) | 15 | 10 | 17 |
| $\delta_d$(°) | 5 | 3 | 5 |
| $C'_{au}$(kPa) | 3 | 2 | 0.27 |
| $C'_{ad}$(kPa) | 1 | 0.4 | 0.15 |
| $\delta'_u$ (°) | 20 | 15 | 17 |
| $\delta'_d$(°) | 5 | 5 | 5 |

**The Anchoring Force Calculation.** The cross section with $b' \times h'$ of 0.5×0.5m, 0.8×0.8m and 1.2×1.0m referred to as section 1, section 2 and section 3 respectively, the anchoring force of the level and the vertical anchoring trench were represented by $P_1$ and $P_2$ respectively. Anchoring force in different examples was shown in Table 2.

Table 2 The anchoring force

| Section Type | Section Size ($b' \times h'$) (m) | Example 1 (kN·m$^{-1}$) | | Example 2 (kN·m$^{-1}$) | | Example 3 (kN·m$^{-1}$) | |
|---|---|---|---|---|---|---|---|
| | | $Pa_1$ | $Pa_2$ | $Pa_1$ | $Pa_2$ | $Pa_1$ | $Pa_2$ |
| section 1 | 0.5×0.5 | 4.3 | 3.0 | 3.3 | 2.2 | 1.2 | 0.9 |
| section 2 | 0.8×0.8 | 8.2 | 5.7 | 6.0 | 4.2 | 2.9 | 2.2 |
| section 3 | 1.2×1.0 | 11.7 | 10.1 | 8.6 | 7.2 | 6.4 | 3.4 |

**Geomembrane Residual Tension Under P*r* in Calculation.** According to the formula (1-9), residual tension Pr was calculated with different geomembrane anchoring height and different slope angle, the results were shown in Table 3.

Table 3 Residual tension $P_R$ (Unit: kN·m$^{-1}$)

| Height(m) | Angle(°) | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | 40º | | | 45º | | | 50º | | |
| Example | 1 | 2 | 3 | 1 | 2 | 3 | 1 | 2 | 3 |
| 6 | -1.4 | 24.2 | 0.5 | 9.3 | 32.1 | 11.3 | 18.8 | 39.1 | 21.2 |
| 8 | 3.5 | 45.1 | 1.3 | 22 | 58.9 | 20.5 | 38.6 | 71.3 | 38 |
| 10 | 11.4 | 72.3 | 2.5 | 40 | 93.8 | 32.7 | 65.3 | 114 | 60 |
| 12 | 22 | 106 | 4.1 | 62.7 | 136.7 | 47.5 | 98.8 | 163.6 | 86.7 |

| Height (m) | Angle(°) | | | | | |
|---|---|---|---|---|---|---|
| | 55º | | | 60º | | |
| Example | 1 | 2 | 3 | 1 | 2 | 3 |
| 6 | 27.4 | 45.4 | 30.2 | 35 | 50.9 | 38.4 |
| 8 | 53.4 | 82.4 | 54 | 66.7 | 92.1 | 68.6 |
| 10 | 88.2 | 130.1 | 84.9 | 108.7 | 145.3 | 107.6 |
| 12 | 131.4 | 188.8 | 122.6 | 160.6 | 210.5 | 155.3 |

## Geomembrane Tensile Slope Stability Analysis

In this study, geomembrane was assumed to meet the stress-strain relationship of elastic material before reaching the tensile strength. Taking geomembrane allowing tension as the maximum tension, then the maximum tensile force $P_{max}$ of geomembrane on the slope of reservoir could be expressed by formula (2-1). In order to prevent a larger tensile deformation of geomembrane which could cause damage to the landfill anti-seepage engineering, the allowing tension of 30kN/m is adopted in this study (i.e., the tensile strength of HDPE membrane was 20MPa).

$$P_{t\max} = [P_t] + P_a \tag{2-1}$$

## Conclusions

(1) In the three kinds of working conditions, the anchoring force increased with the increasing section size of anchoring trench.

(2) In the same condition, anchorage force reached the maximum when the direction of the anchoring platform was horizontal.

(3) The friction angle had larger influence on the anchoring force than the cohesive force.

(4) Residual tension increased with the increase of the slope angle or the slope height. In the three kinds of working conditions, example 2 had the largest residual tension. When the slope height was over 6m, it should keep the slope angle within 45° to make the geomembrane stable.

**Keywords:** Water contents, Stability analysis, Graphic method, MATLAB,GUI.

**Abstract.** High loess slopes are easily unstable because of the water sensitivity of loess, therefore, the study on stability of high loess slopes is a very important task for water and soil conservation on loess plateau. Forcus on the inefficiency of current graphic method, after considering main influencing factors of stability of high loess slopes, such as lithology, topography, groundwater conditions, slope water content and seismic intensity, etc., on the basis of graphic method, an automatic table lookup program was developed, moreover, the interfaces of graphic method were compiled based on MATLAB platform, which could automatically generate plenty of obvious characteristics of slope data for further modeling.

## Introduction

Because loess has water sensitivity, high loess slopes tends to lose stability when they encounter water. Therefore, it is quite necessary to study stability of high loess slopes to reduce losses caused by landslide hazard. Generally, methods for stability analysis of loess slopes can be divided into qualitative analysis method, quantitative analysis method, uncertainty analysis method and intelligent analysis method [1]. In detail, because analysis charts about stability of slopes are easy to use and their results are visual, they are advocated by people being engaged in slope design and monitoring. In 1937, Taylor [2] put forward a stability chart for the first time. Later, Bishop and Morgenstern (1960) [3,4], Morgenstern(1963)[5] and Spencer(1967) [6] et al. designed various kinds of nomograph. In 1998, Jing Li and Xinhua Zhou et al.[7] improved Bishop method, considered main factors that affected high loess slopes simultaneously and designed an analysis chart related to stability of loess slopes. The chart solution is simple and direct, while its chart lookup efficiency is low. Thus, we need to improve the analysis chart about stability and develop an automatic chart lookup program to generate a number of slope data with obvious features. This seems to be quite necessary and is of practical significance. This thesis takes high slopes at tablelands on the left bank of Weihe River water transfer channel of Baiji Valley as an example and develops an automatic table lookup program on the basis of graphical method. Based on MATLAB platform, it generates a number of slope data with obvious features automatically, which provides data support for follow-up modeling.

## Research thought

The research thought is shown as follows. First of all, according to the feature that loess has water sensitivity, this thesis mainly considers the factor water content and obtains the relationship between cohesive force and internal friction angle as well as that between cohesive force and water content (i.e., $w \sim c$ and $w \sim \phi$) by experimental data fitting. Besides, it achieves the relationship between weight and water content according to empirical formula. Then, it takes high slopes at tablelands on the left bank of Weihe River water transfer channel of Baiji Valley as an example to determine data range of each impact factor (IF) and generate calculating parameters about slopes by random

assortment. Finally, it improves the graphical method, develops an automatic table lookup program according to calculating parameters about slopes, obtains safety factors via table lookup and gets safe states in accordance with specifications. In doing so, it obtains slope data for use of BP neural network modeling.

**Data acquisition**

**3.1 Impacts of water content on physical and mechanical parameters.**Impacts of water content on cohesive force are very obvious. According to researches implemented by Li Wang, Jinqian Dang[8] and Sen'an Zhang[9] et al., quantitative relational expression about cohesive force $c$ and water content $w$ is obtained.

$$\lg\left(\frac{c}{100}\right) = A - Bw \tag{1}$$

Where $c$ stands for cohesive force of soil body (kPa);

$w$ represents water content of soil body (%);

$A, B$ are parameters, whose values vary with changes in regions. According to average values of measured data about the three places including Qianyang, Binxian County and Baoji, their average is A=0.709 and B=0.044 [8], respectively.

Jinqian Dang et al. [10] carried out profound researches on water content and intensity parameters of Malan loess in Guanzhong area, Shaanxi Province. In accordance with experimental data fitting, they obtained the relational expression about the internal friction angle $\phi$ and the water content $w$, as shown in the following:

$$\phi = 24.3 - 0.1096w \tag{2}$$

The research shows that wet unit weight grows with increase in water content under the condition that dry unit weight is constant [8]. Average dry unit weight of loess is 15kN/m3 [11]. According to empirical formula, the relational expression about weight of soil body $\gamma$ and water content $w$ is shown as follows:

$$\gamma = 15(1 + w) \tag{3}$$

Where $\gamma$ and $w$ represent weight (kN/m$^3$) and water content (unit: 1) of loess.

**3.2 Value range of Ifs.** Analyses and selection of soil indicators are keys to analyses related to stability of high loess slopes. Researches indicate that stability of high loess slopes are mainly affected by seven factors including weight of soil body, cohesive force, internal friction angle, slope ratio, slope height, pore pressure and seismic intensity [12]. This thesis takes high slopes at tablelands on the left bank of Weihe River water transfer channel of Baiji Valley as an example and determines reasonable value range of each IF.

**3.2.1 Water content of high slopes' soil body.** In accordance with results of actual measurement on water content of high slopes' geological sections at Bapji Valley, water content of parts whose distance to the surface of slopes is 20-30m is 20%-26% generally. Rainfall and changes in surface water have significant impacts on water content of soil body. Specifically, if there is heavy rainfall a wet year appears, water content of soil body will be improved, the state that water content is saturate or partially saturate will appear and high slopes may be damaged. The value range of water content, which this thesis selects, is [15%, 28%], including the whole range of variation from unsaturation to saturation of soil body.

**3.2.2 Intensity index.** Thus, based on Formula (1) and Formula (3), we can confirm that range of cohesive force is [30 kPa,110 kPa] and weight is [17.28 kN/m3,19.20 kN/m3]. In addition, a relatively large range is set for internal friction angle, i.e., [22°, 30], in order that most values of internal friction angle about loess can be contained.

**3.2.3 Slope height.** The research finds that height of the high slope with the most serious destroy is 40- 73m [13]. Therefore, value range of high slopes, which is set in this thesis, is [30 m, 105 m].

**3.2.4 Slope ratio.** In consideration of abrupt slopes and steep slopes, gradient in this thesis is 15° $\varphi_f$ ≤m≤70°. Then, slope ratio is 0.4≤m≤3.7, where the slope ratio m=1/tan($\varphi_f$).

**3.2.5 Pore water pressure coefficient.** The research points out that underground water depth at edge of tablelands is between 30m and 60m [8]. It is assumed that underground water depth is 45m and pore water pressure in soil body is calculated according to hydrostatic pressure ($\gamma_u = -1$) and three situations about pore water pressure coefficient, i.e., $\gamma_u = 0$, $\gamma_u = 0.25$ and $\gamma_u = 0.5$. In this way, range of pore water pressure coefficient is confirmed to be {-1,0,0.25,0.5}.

**3.2.6 Seismic intensity.** This thesis confirms that value of seismic intensity is {0,7,8,9}, which equals earthquake magnitudes 0, 5.5, 6.0 and 6.5.

**3.2.7 Generate samples.** According to value range of each IF, $c$, $\phi$, m and slope height H are generated randomly. Meanwhile, $\gamma_u$, seismic intensity q and weight $\gamma$ are combined randomly. As a result, calculating parameters of slopes are obtained, and safety factors of slopes are got by table lookup.

**3.2.8 Conformation of safe state.** By consulting original Technical Summary about Weihe River Water Transfer Project of Baoji Valley, slopes are considered to be destroyed and stable when Fs<1.1 and Fs>1.1, respectively [14]. According to this, s safe state of slopes is confirmed (when they are stable, s=1; when they are destroyed; s=0). Accordingly, data about high loess slopes when changes in water content are considered are generated. Besides, it considers that generated data have consistency and satisfy requirements of follow-up BP neural network modeling.

## Analytical system by the graphical method

In accordance with the literature [8], the graphical method is remolded and the analytical system by the graphical method is developed. Fig. 1 shows the interface that appears after entering the system from menus in the main interface.

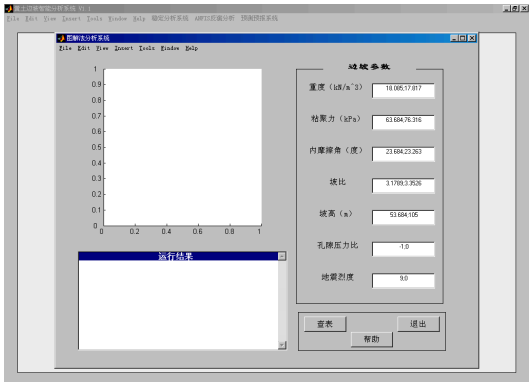

Fig. 1 Design about interface of the analytical system

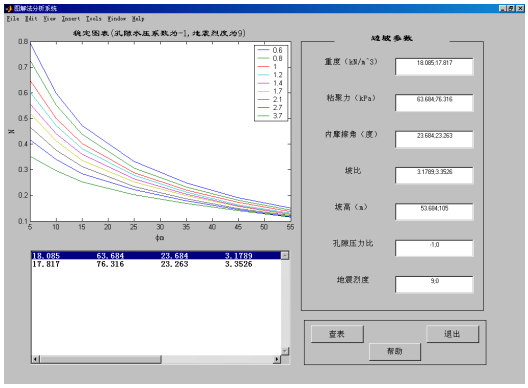

Fig. 2 Functional design of the analytical system

**4.1 Calculate safety factors by table lookup.** In the column of slope parameters, semicolons are used for partition. After each group of parameters has been input, values of each group of safe factors can be obtained by chart lookup function. Besides, each group of slope parameters and safety factors are shown in listbox at left bottom of the interface.

**4.2 Display functions of searched charts.** If we click any group of data in the listbox, the searched chart will appear in the plotting area. Besides, chart title will show corresponding values of the two parameters pore pressure ratio and seismic intensity. Additionally, abscissa $\phi_m = arctg(c/\gamma Htg\phi)$ and ordinate $N = \tan\phi / F$, as shown in Fig. 2, where the legend refers to slope ratio.

## Conclusion

This thesis takes high slopes at tablelands on the left bank of Weihe River water transfer channel of Baiji Valley as an example, regards water content as a main factor, extends functions of the graphical method based on MATLAB, improves the graphical method, develops an automatic table lookup program and generates data about high loess slope under the situation that changes in water content is considered. Such data have consistency and satisfy data requirements of BP neural network modeling.

# Analysis about Stability of a Slope

Yajun Yin[1,a], Guanghan Xu[1,b], Yongmei Qian[1,c]

[1]Jilin Jianzhu University, Changchun, China

[a]1638715111@qq.com, [b]513917884@qq.com, [c]654675316@qq.com

**Keywords:** Slope; Stability; Analysis

**Abstract.** Based on the engineering geological conditions of an artificial slope is analyzed using a combination of numerical simulation, the slope ratio method and other methods, the slope stability was evaluated, It has a certain reference to artificial slope stability evaluation that similar to a combination of soil and rock.

## Introduction

The rear side of the new factory building form an L-shaped artificial slope after excavation, maximum slope height of nearly 22m, the length of nearly 300m, As the impact of the recent rain, the local section appears landslide phenomenon.

Original topography of slope area belongs to the hilly and alluvial plain border zone, currently, the plant has undergone significant changes in topography situation affected by pre-construction.

The study focused on the eastern side of the north-south direction of slope, slope length of about 145m, high maximum slope about 22m.To facilitate the study of the problem, according to the slope morphology of the slope, slope height, slope and material composition ,lithology characteristics, etc, the current slope is divided into three sections. Ⅰ area locates by the eastern side of north zone of slope along the SN trending, Ⅱ area for its southerly zone; southern slope of the EW trending is divided Ⅲ area.

District Ⅰ mainly soil slope, slope shape irregular, slope height and slope changes greater, lush vegetation on the slope; Ⅱ area covers with a thin layer of Quaternary on the slope, the highly weathered granite is exposed, the moderately weathered granite appears at the slope toe. Slope shape more complete, high slope greater maximum 22m, slope about 51 °;Ⅲ district slope is the recent formed by the artificial slope cutting, the highly weathered granite is exposed in the slope, smaller slope height, max 8.5m, an average slope is 38 °.

According to the classification principles of building slope engineering technical specification, Ⅰ area, Ⅱ district slope is secondary slope;Ⅲ district slope is three-level slope.

## the Stability Study of Slope

**Formation Lithology.** The main substance of slope is: (1) containing gravel silty clay, Quaternary eluvial, slope wash, plastic - hard plastic state; (2) strongly weathered granite; (3) moderately weathered granite.

**the Mode Research of Slope Instability.** Complexity, diversity, and environmental differences in the occurrence of rock structure, determine its modes are varied. The rock slope instability modes are summarized by the former as flat, circular, wedge, dumping, outburst and other forms. Therefore, study the stability of a slope, you first need to determine likely instability modes under certain geological conditions, on this basis, then for the unstable modes have been identified

through analysis of mathematical mechanics and test methods to determine the security situation of slope.

1. Ⅱ zone structure characteristics of slope rock mass

a. The rock mass weathering characteristics

Weathered rock is mainly affected by topography, lithology, structure, groundwater and other factors,Grading of the weathering degree of rock mass in the slope can be simply divided into strongly ~ moderately weathered, weathering forms are mainly dominated by area. As the top of the slope at the excavation of relatively shallow, thick Quaternary cover, under which is strongly weathered granite, rocks are weathered becoming gravel block whose color is dark brown,the trock mineral composition is difficult to distinguish, softer rock.

Excavation at the slope toe is the deepest, and appears massive rock, mineral composition is difficult to distinguish, relatively hard rock is characterized by medium weathered state, but the number of exposed scale is not big.

b. Structural characteristics of rock mass

Within the range of rock slope there is a series of internal discontinuities, the structural surface rock, mainly for construction joint surface and weathered surface fissures. Geological survey of surveying and mapping and the revelation through exploratory trench at slope toe, reflect the region densely jointed rock slope, poor integrity of the rock mass.

Strongly weathered granite is showed as crushing, structural surface is given priority to with weathering fracture, soft rock, rock is scattered structure, which belongs to the structure of the overall fragmentation.

Moderately weathered granite is hard rock, surface structure based mainly on construction joints, there are larger differences in the joints intensity, in the fractured parts of the joints, the rock is broken, showing cracked mosaic structure. Local joint fissure that was not developed assumes fractured block structure. Comprehensive evaluation, it generally belongs to cracked mosaic structure.

2. Ⅱdistrict jointed rock mass slope fracture development features

Site slope outcrop in poor condition, so dig the trench where the toe of the slope and the slope are, through artificial way to expose, and conduct a statistical work of joints.From the statistical results of joint fissures of slope rock mass, cracks in the direction of the N-W gives priority to, a few for east-west, inclination concentrated between 50°~ 70, is steeply dipping fractures.

3. Ⅱdistrict slope hydrogeological conditions

Nearby slope range groundwater is main types of bedrock fissure water (shallow weathered fissure water), aquifer for weathered granite, average water depth is 3.60m-8.50m, the water level elevation generally is 99.22m-111.79m. Groundwater recharge mainly depends on rainfall, drainage through underground runoff. There is relationship between groundwater flow and topography, flow direction from the terrain height to low-lying. Trench excavation of the site accumulated a certain amount of water, can consider to seep from the slope groundwater as part of the sources, which can be inferred from the bedrock groundwater water level line.

4. Ⅱarea slope instability mode

A large number of studies show that, similar to District II slope characteristics, the main consideration should be given to the slope in rock slope as the basic characteristics of the unstable mode.

As mentioned earlier, area II slope surface covered with residual thin sediment layer, the slope angle is 51 °, no deformation. But the slope toe outcropped granite, under the condition of slope toe was excavated two groups, affected by the failure phenomenon, the wedge sliding. affected by the

surface structure of the two groups, there has been sliding wedge failure phenomena. From the analysis of development characteristics of slope rock mass joint fissure, most joints fissure in NW-NNW direction, tendency of SW, it is the main control structure of causing planar sliding surface,meanwhile, this group fissure combines with joint fissure of another group nearly EW can cause sliding wedge.

**Stability Analysis of Slope.** 1. Slope stability analysis based on strength subtraction. Slope stability has been a hot research topic in the field of geotechnical engineering, people usually adopt safety coefficient method to evaluate the stability of the state. Its principle is simple, clear physical meaning, is still the most important indicators and concepts for the slope stability analysis. Strictly speaking, the safety factor is an evaluation index based on limit equilibrium analysis methods, numerical simulation is parallel with the limit equilibrium analysis methods, focusing on rock mass stress - strain that the analysis of failure mechanism. In the early days of slope stability analysis, which does not exist intersection points between the two. Strength reduction method based on numerical simulation technology changes this situation.

In the strength reduction method, safety factor of slope stability is defined as: While the slope just reaches the critical failure state, the degree reduce on rock soil shear strength, that safety factor is defined as ratio of the actual shear strength of rock soil and the shear strength after reduction when happens critical failure.Points of strength reduction method is using type 1, type 2 to adjust the strength indicators $c$ and $\phi$ of rock and soil ( in the type, $c_F$ is cohesive force after the reduction, $\phi_F$ is friction angle after the reduction, $F_{trial}$ is reduction factor), then make numerical analysis for the slope stability, continuously increase the reduction factor, calculate repeatedly, until it reaches the critical damage, the reduction factor is the factor of safety. The calculation formula is as follows:

$$c_F = c / F_{trial} \tag{1}$$

$$\phi_F = \tan^{-1}((\tan\phi) / F_{trial}) \tag{2}$$

In this slope, strongly weathered granite is considered as structure characteristics of cataclastic rock mass, moderately weathered granite is considered as the structure character of inlaid cataclastic rock mass. Integrating structural characteristics of rock mass, referring to successful cases at home and abroad other slope engineering, mechanics parameters of the slope granite are recommended as shown in table 1.

Table 1 Mechanical properties of granite indicators recommended values

| Project | The recommended value of strongly weathered granite | The recommended value of weathered granite |
|---|---|---|
| Natural density (KN/m3) | 23.3 | 25.5 |
| Shear wave velocity (m/s) | 587 | 1230 |
| The internal friction angle (degrees) | 32 | 40 |
| Cohesion (kPa) | 30 | 45 |
| Poisson's ratio | 0.36 | 0.25 |
| The softening coefficient | 0.56 | 0.87 |

This paper adopts the fast Lagrange difference algorithm, uses Mohr Kulun constitutive model, puts convergence in numerical calculation as a criterion of instability, to make calculation of fast Lagrange finite difference. The data as shown in table 2.

Table 2 Numerical calculation parameters of slope

| Strata \ Parameters | Density ρ(kg/m3) | Cohesion c（kPa） | The angle of internal friction Φ（°） |
|---|---|---|---|
| Residual gravel containing silty clay | 1960 | 22.3 | 14.5 |
| Strong weathered granite | 2300 | 30 | 32 |
| Moderately weathered granite | 2500 | 45 | 40 |

According to the calculation knows that the safety factor of slope is 2.25, the overall security is assured, however, in view of the analysis of eluvial soil at top of slope shows that there is a trend that soil displacement occurs. Calculations indicate that the plastic deformation occurs only in a shallow portion of soil distribution.

2. The slope ratio method. According to "technical code for building slope engineering" (GB 50330-2002)Chapter 12, when engineering conditions permit, should give priority to the slope ratio method for stability analysis.

The site survey results shows that, Ⅱ area upon slope is covered by a thin layer of clay, the rock in the slope is moderate weathering granite, the slope rock mass can be divided into class ii, put the slope covered with soil as loading into account, rock slope is height of about20m, according to Table 12.2.2, which allows the value of the slope ratio (aspect ratio) is 1:0.35 to 1:0.5, which allows a maximum slope angle should be 60 °, the actual average slope slope angle is 51, within the allowable range of the slope ratio. Even taking into account the unfavorable loading factors on the slope, the slope stability is also no problem.

## Conclusions

For the slope be given priority to with the soil and cataclastic rock slope, the rain wash out is not only the various influence on slope stability, but is very active. It turns out that most of the damage and the sliding of slope are concerned with the role of water. Waterproof slope is very important, the use of spray anchor bracing approach to security closure slope to prevent water entering, excluding the impact of water, is a good way to maintain slope stability.

The project involves the slope according to the morphological characteristics, lithology, rock mass structural features, such as rock engineering geological conditions and the distribution of positions, is divided into three different sections, respectively, according to the specific circumstances of different sections of the slope, using the corresponding appropriate analytical methods, its stability was evaluated.

# Analysis of Micro-seismic Monitoring Vibration on the Adjacent Buried Pipeline Affected by Impacting of Punching Pile Construction

Yanhua She

College of Urban Construction, Yangtze University, Jingzhou 434023 China

syh916@126.com

**Keywords:** punching pile construction; buried pipeline; micro-seismic monitoring; vibration control

**Abstract.** Impact loads caused by punching pile construction of highway bridges are bound to disturb stratum surrounding the buried pipeline adjacent to, which would adversely affect the normal use and safe operation of buried pipelines. Through developing field micro-seismic trial, the characteristics of vibration attenuation and sphere of influence were analyzed, in order to assess its impact on buried pipeline nearby. It drew conclusions that the amplitude of vibration energy had been enlarged with the presence of the pipeline; It should conduct the surface peak velocity above the pipeline as the main control index in routine vibration monitoring of pile foundation construction adjacent to buried pipeline; by positioning analysis of impacting vibration source, the rupture area of rock and soil around the pipeline caused by the vibration was determined, and security measures for pipeline protection was proposed. It provides a new method of control technology for pile foundation construction.

## Introduction

Pile foundation construction of highway bridge adjacent to pipeline once caused the leakage of natural gas pipeline, it would bring about serious social damage. Therefore, the influence of vibration caused by impact drilling construction of bridge pile foundation on buried pipeline must be carried on the safety monitoring and control effectively. The vibration produced by construction impact loads is extremely complex on the role and influence of pipe soil coupling. Both theoretical analysis and numerical calculation are considerable limitations. To explore other research methods, especially the field measurement method has been the goal of many researchers pursuing. This paper attempts to use HZ-MS48 microseismic signal data acquisition system to carry on the test, recording the transmitted signal of vibration wave propagation in rock and soil medium and analyzing attenuation characteristics and influence scope of vibration waves, in order to assess its impact on the adjacent buried pipeline. The research also is further exploration for the study on microseismic monitoring technology application in geotechnical engineering about pile construction vibration.

## Microseismic Monitoring Study

The researchers has been made a lot of achievements on the application of microseismic technique to different extent such as the oil and gas[1], mining[2-3], underground engineering [4], civil engineering[5] and so on. But many problems in theory research and application remain to be resolved.

To understand the effect of construction vibration on buried pipeline clearly, microseismic monitoring test was carried on the field. The test site located in Juma River No.8 bridge of Zhang jiakou to Shi jiazhuang expressway from Laiyuan to Laishui. Shaanxi-Beijing natural gas pipeline crossed the bridge between the fourth and fifth hole, with the nearest distance of 6.3m from pipe. Bridge pile foundation mainly adopted the impact drilling to construct.

**The Testing Arrangement.** The distance between the pipeline and impact pile hole center was 8.12m. Pipe buried 1m depth. Three measuring points were arranged along the pipe axis (x axis) and four measuring points were arranged along the pipe radial direction (y axis), where except 3# and 5# measuring points arranged on the pipeline, others assigned on the ground. The layout of three

component geophones were shown in Fig.1. Measuring point coordinates were shown in Tab.1. Microseismic monitoring on test was shown in Fig.2.

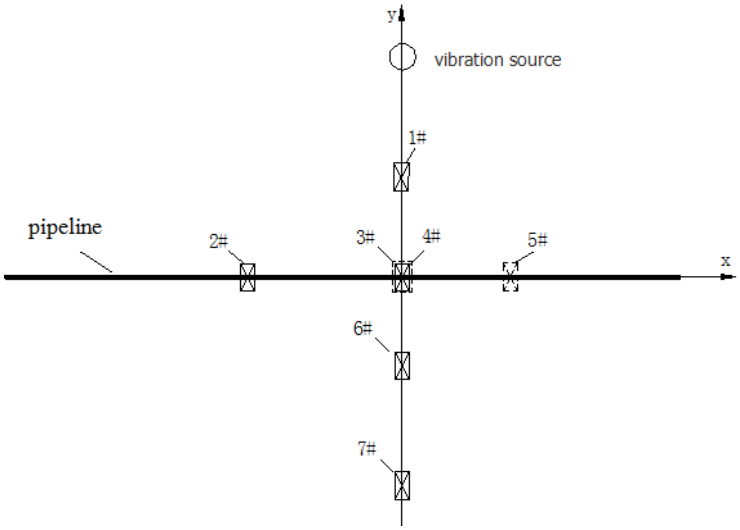

Fig.1 Layout of three component geophone

Tab.1 Coordinate of testing points

| measuring points | | 1# | 2# | 3# | 4# | 5# | 6# | 7# |
|---|---|---|---|---|---|---|---|---|
| coordinate (m) | x(East) | 0.00 | -4.18 | 0.00 | 0.00 | 2.09 | 0.00 | 0.00 |
| | y(North) | 2.00 | 0.00 | 0.00 | 0.00 | 0.00 | -2.00 | -6.05 |
| | z(Elevation) | 0.00 | 0.00 | 0.90 | 0.00 | 0.90 | 0.00 | 0.00 |
| remarks | | Test points 1,4,6,7 were used to analyze the vibration attenuation with distance; Test points 3,4 used to analyze the vibration velocity relationship between pipeline and ground; Test points 1,2,3,5 were used to analyze the impact vibration energy and vibration properties. | | | | | | |

(a) monitoring device (b) geophone embedding (c) data acquisition

Fig.2 Real-time monitoring by micro-seismic system

**Signal Acquisition.** The parameters of punching hammer were: weight m=5t ,bottom radius R=0.9m, punching depth from 0m to h=10m. When punching depth was 1.3m, the vibration source basically was at the same level of the pipeline, with vibration source coordinates (0,8.12,1.30). Microseismic events were collected at s=0.5m~2.5m for the stroke. By the field test and measurement, the typical microseismic events of points 1, 3, 4, 6 were shown in Fig.3 and Fig.4(n-horizontal radial, e-Horizontal tangential, v-vertical direction).

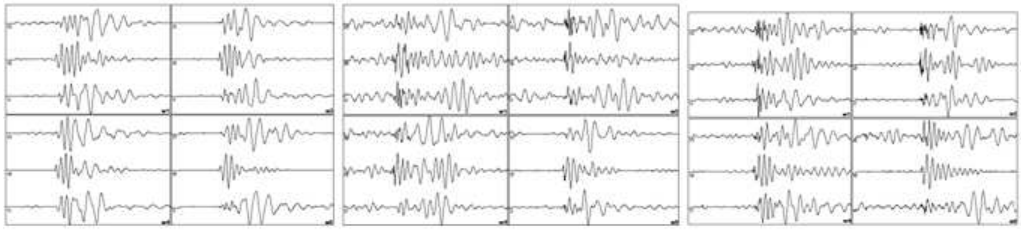

Fig.3 Three component velocity waveforms of microseismic events of different stroke

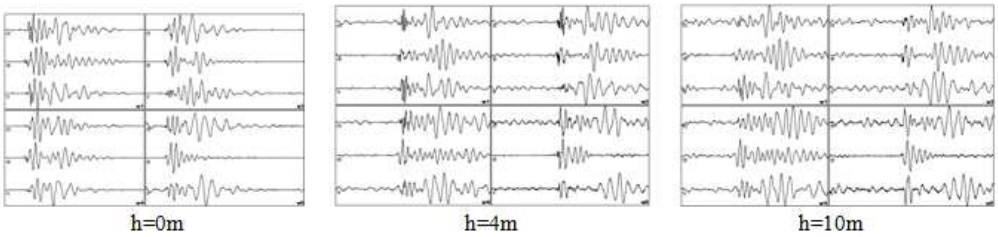

Fig.4 Typical velocity waveforms of microseismic events on different vibration source

## The Test Data Processing and Analysis

**Analysis of The Vibration Characteristics and Effect on Buried Pipeline.** The power spectral characteristics of typical microseismic signal were shown in Fig.5. From the figure, the energy of vibration wave focused on low frequency range of 10~50Hz. It had high signal-to-noise ratio and the vibration energy in other frequency bands was very small.

As shown in Fig.6, vibration velocity of testing points before and after buried pipeline decreased first and then increased, that was vibration energy had been enlarged because of the pipeline.

Considering the different impact source location, vibration velocity in three direction of measuring points was shown in Tab.2.

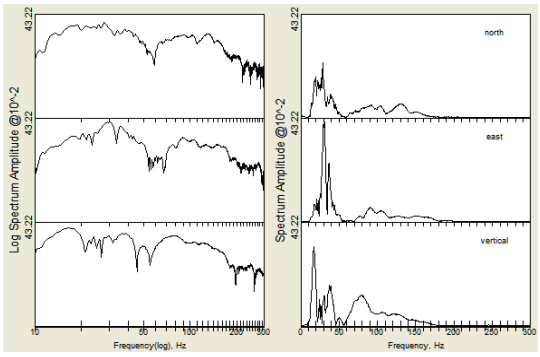

Fig.5 Spectrum analysis of typical microseismic signal

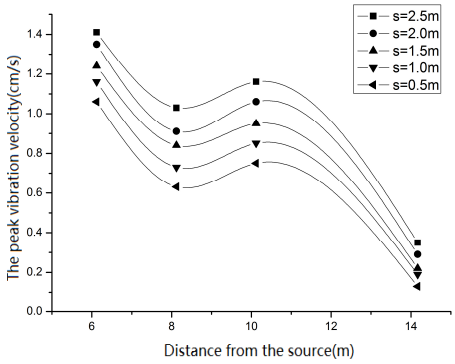

Fig.6 Curves of vibration velocity attenuation along horizontal distance

Tab.2 The peak vibration velocity of testing points on diffent vibrating source

| source position (m) | velocity of measuring point (cm/s) | | | | | |
|---|---|---|---|---|---|---|
| | 3#(on the pipe) | | | 4#( ground above the pipe) | | |
| | n | e | v | n | e | v |
| H=0.0 | 1.28 | 0.56 | 1.43 | 1.33 | 0.62 | 1.52 |
| H=1.3 | 1.56 | 0.73 | 1.41 | 1.24 | 0.58 | 1.48 |
| H=4.0 | 1.30 | 0.42 | 1.11 | 1.06 | 0.39 | 1.21 |
| H=8.0 | 0.92 | 0.25 | 0.74 | 0.63 | 0.18 | 0.85 |
| H=10.0 | 0.77 | 0.16 | 0.48 | 0.42 | 0.10 | 0.65 |

As shown in Tab.2, vertical vibration velocity on ground above the pipe was primary monitoring target, in the conventional vibration monitoring of pile foundation construction adjacent to buried pipeline. When the peak vibration velocity on ground being controlled, it can guarantee vibration velocity of the pipeline in the safe range. It also concluded that when the pile hole was close to buried pipeline, adopting manual excavation pile hole to the depth below the pipeline level can be adopted , in order to effectively reduce the pipeline vibration velocity and ensure the safe operation of the pipeline.

**Determine the Impact Rupture Zone.** Selecting microseismic events at 1, 2, 3, 5 measuring points, source localization analysis was be carried on. P wave arrival time picking of one microseismic event was as shown in Fig.7. The positioning results were as shown in Fig.8, with vibration position(0,8,1.5),which was in comparison with the actual.

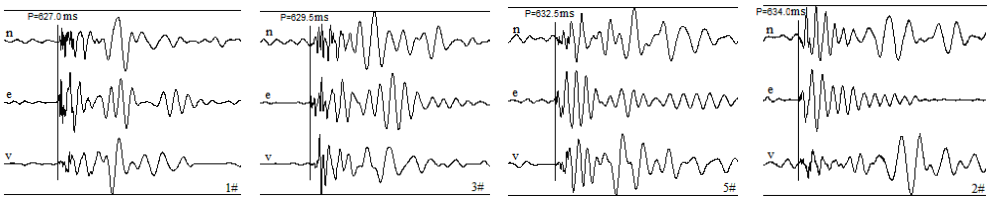

Fig.7 Picking out arriving time of P-wave

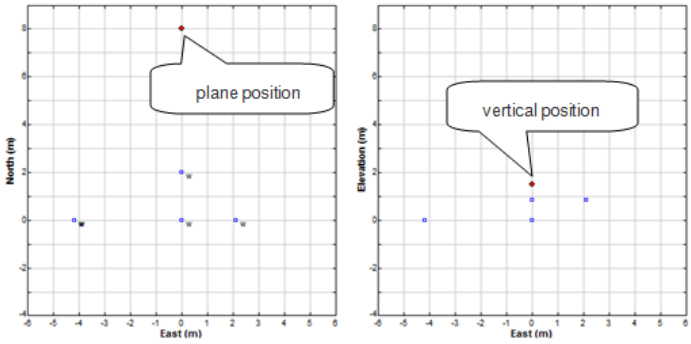

Fig.8 Location result of microseismic events

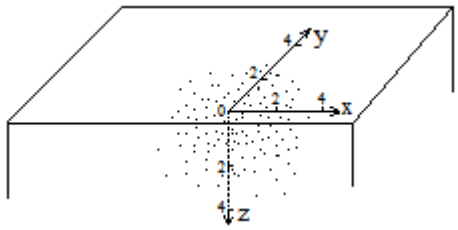

Fig.9 Failure region caused by vibration(unit：m)

Location analysis for all microseismic events can obtain the rupture area of rock and soil caused by vibration, approximately three times of hammer radius, as shown in Fig.9. Therefore, if the pipeline was located out of three times hammer radius (3R), it can guarantee the vibration caused by impacting construction producing no damage for rock soil around the pipe, so as to avoid the threat of pipeline safety.

## Conclusions

Vibration velocity of testing points before and after buried pipeline decreased first and then increased, that was vibration energy had been enlarged because of the pipeline. Vertical vibration velocity on ground above the pipe was primary monitoring target. When the peak vibration velocity on ground being controlled, it can guarantee vibration velocity of the pipeline in the safe range. Failure region of rock and soil caused by vibration was about 3 times of the hammer radius. Therefore, if the pipeline was located outside 3 times of the hammer radius, rock soil around pipe can be guaranteed no damage .It put forward a new method for researching the vibration caused by bridge pile foundation construction.

# Consolidation of Unsaturated Soils Due to Dissipation of Pore-air Pressure

XU Hao-feng[a], WANG Wen-jun[b], ZHA Zhi-xiang[c]

Ningbo Institute of Technology, Zhejiang University, Ningbo 315100, China

[a]xuhaofeng@nit.zju.edu.cn, [b]wwjcumt@nit.zju.edu.cn, [c]zhazx71@126.com

**Keywords:** unsaturated soils; consolidation; pore-air.

**Abstract.** One-dimensional consolidation equation of unsaturated soils was derived in order to solve this special case of consolidation. The presented equation, not similar to Terzaghi's equation, is a type of absolute nonlinear partial differential equation, and it was solved by finite difference method. An example was analyzed and the case of incompressible fluid consolidation was compared. Finally the experimental results from laboratory tests reported in the literature, was fitted by the presented equation, and the agreement was good. The results show that (1) the process of pore-air pressure dissipation is similar to that of pore-water pressure of saturated soils; (2) the compressibility of pore fluid is not an advantageous factor to quicken the consolidation; (3) the presented equation is effective to analyze the process of consolidation of unsaturated soils which consolidate mainly due to the dissipation of pore-air pressure.

## Introduction

According to existence style of air phase (or water phase), there are three types of unsaturated soils[1]. The first type of unsaturated soils is soils of which the degree of saturation is very high ($S_r$>85%) and the pore water contains air bubbles. The second type of unsaturated soils is soils where both air phase and water phase are continuous. The third one is soils that the air phase is continuous while the water phase is discontinuous and the degree of saturation is very low ($S_r$<40%). Because of the complexity of air phase, the consolidation of unsaturated soils is more difficult than saturated soils.

Studies on consolidation of unsaturated soils are often on the first and the second types[2-10]. And there are few researches about the third type of unsaturated soils. Only in Fredlund's monograph[11], the one dimensional consolidation equation of dry soils has been mentioned. It is necessary to research the consolidation of the third type of unsaturated soils. If the consolation rule of the third one could be understood, it would advantage the research on consolidation of the second type of unsaturated soils. It has been discovered that the consolidation process of the second type of unsaturated soils could be divided to two parts: the pressure of pore air has been dissipated firstly, and secondly it is followed by the dissipation of pore water pressure [12].

The consolidation caused by pore air would be different to the dissipation of pore water pressure of equation of saturated soils- Terzaghi's equation.

In this paper, the one dimensional consolidation equation of unsaturated soils due to dissipation of pore-air pressure is derived. Subsequently it is solved by finite difference method. And the characteristic of consolidation has been discussed. In addition, the experimental results from laboratory tests reported in the literature [13], is fitted by the presented equation.

## Organization of the Text One-dimensional consolidation equation due to dissipation of pore air pressure

Hypotheses are following: (1) only air can flow through the pore and the infiltration of pore water can be neglected; (2) pore air is perfect gas, and it is isothermal process; (3) both pore water and pore air would not transform to each other; (4) the deformation is small and the soil skeleton is linear elastic; (5) both soil grain and pore water are uncompressible; (6) soil is homogeneous, and the coefficient of

compressibility and the coefficient of infiltration of pore air are constant. Then the equations can be provided as following.

**Continuity equation of pore air.** According to the conservation of mass, the continuity equation of pore air can be expressed as

$$\frac{\partial(\rho_a n_a)}{\partial t} = \nabla \cdot (\rho_a v_a) + q \tag{1}$$

Where, $\rho_a$ is density of pore air (kg/m$^3$); $n_a$ is pore air porosity of soil $n_a=V_a/V$, ($V_a$, V are volume of pore air and soil respectively); $v_a$ is flow velocity of pore air (average velocity relative to the whole section)( m/s); q is the unit injection into the collection or the unit outflow from the source (kg/(m$^3$•s), if there is no collection or source, then q=0.

**Expression of pore air's density.** According to ideal gas equation, we can get

$$\rho_a = \frac{u_a \omega}{RT} \tag{2}$$

Where, $u_a$ is absolute pressure of gas (kPa); R is gas factor (J/(mol•K)); ω is molecular weight of gas (g/mol); T is absolute temperature (K).

**Equation of motion of pore air (Darcy's law).** Supposing gas seepage accords with Darcy's law, we can get

$$v_a = \frac{k}{\mu} grad(u_a) \tag{3}$$

Where, k is valid permeability of pore air in soil (m$^2$); μ is coefficient of viscous of gas (Pa•s).

**Formula of effective stress of pore air.** The formula of effective stress about pore air can be expressed as

$$\sigma = \sigma' + u'_a \tag{4}$$

Where, σ is the total stress on soils (kPa); σ′ is effective stress; u′$_a$ is excess pore air pressure.

**Relationship of stress and strain.** Supposing the volume of pore water is constant during the process of consolidation, we can get

$$\frac{\partial n_a}{\partial t} = \frac{\partial n}{\partial t} = -m_v \frac{\partial \sigma'}{\partial t} \tag{5}$$

Where, $m_v$ is the coefficient of volume compressibility of soil (kPa$^{-1}$); n is porosity of soil.

**One-dimensional equation of consolidation due to dissipation of pore air pressure.** Substituting these above expressions into the equation of continuity and supposing the total stress σ is constant, we can get

$$(n_a + m_v u_a)\frac{\partial u_a}{\partial t} = \frac{k}{\mu}[(\frac{\partial u_a}{\partial z})^2 + u_a \frac{\partial^2 u_a}{\partial z^2}] \tag{6}$$

The above expression is just the one-dimensional consolidation equation of unsaturated soils due to dissipation of pore air pressure.

## Solution for consolidation equation

**Analytic model of consolidation.** The thickness of soil stratum loaded by p is 2H, two sides are air permeable. The boundary condition is: if z=0 or z=2H, then $u_a=p_{atm}$ (t>0); if t=0, then $u_{a0}=p_{atm}+p_0$

(where is initial increment of pore air pressure). Because of the compressibility of pore air, $p_0$ is not equal to the load p. Supposing the instantaneous deformation is $\Delta h_{is}$ and the final deformation is $\Delta h$, $p_0$ can be defined as

$$p_0 = (1 - \frac{\Delta h_{is}}{\Delta h}) p \tag{7}$$

**Solution by finite difference method.** The style of consolidation equation is elegant, but it is not easy to be solved. In order to solve this whole nonlinear partial differential equation, the finite difference method is adopted in the paper. Supposing the space step length is $\Delta z$, the time step length is $\Delta t$, the number of time node is i (i=0,1,2,…), the number of space node is j (j=0,1,2,…,n), the equation can be transferred as

$$u_{ai+1,j} = \frac{k\Delta t}{\mu(n_a + m_v u_{ai,j})(\Delta z)^2}[(u_{ai,j+1} - u_{ai,j})^2 + u_{ai,j}(u_{ai,j+1} - 2u_{ai,j} + u_{ai,j-1})] + u_{ai,j} \tag{8}$$

Where, $\Delta z=2H/n$. And by analysis the increment of time $\Delta t$ can be gotten as

$$\Delta t = \frac{\mu(n_a + m_v u_{a0})(\Delta z)^2}{\chi k u_{a0}} \tag{9}$$

Where, coefficient $\chi$ is used to adjust the time step length in order to control the speed of convergent. The smaller the coefficient $\chi$ is, the fast the convergent is. However if the convergent is too fast, the analysis would not be stable. So the appropriate value of coefficient $\chi$ should be selected according to the fact.

The condition of certain solution can be transferred and expressed as: initial condition is $u_{a0,j}= p_{atm}+p_0$ (j=0,1,2,…,n); boundary condition is $u_{ai,0}= u_{ai,n}=p_{atm}$ (i=0,1,2,…), where $p_{atm}$ is atmosphere pressure (kPa).

## Example and discussion

**Example analysis.** Supposing the parameters for analysis in the soil stratum as following: $\mu=1.3\times10^{-8}$ kPa•s, $k=1.6\times10^{-12}m^2$, $n_a=0.5$, $m_v=2.0\times10^{-4}kPa^{-1}$, $p_{atm}=100kPa$, $u_{a0}=400kPa$, 2H=20m, $\Delta z=1m$, $\chi=2.8$, we can get $\Delta t=4.21s$. So the distribution of pore air pressure along depth with time can be analyzed, as shown in Fig.1.

It is obvious that the process of consolidation due to dissipation of pore air pressure can be simulated successfully by finite differential method.

**Comparison with consolidation of incompressible fluid.** If the pore fluid is incompressible, then the equation of consolidation can be derived as Eq.10.

$$\frac{\partial u_a}{\partial t} = \frac{k}{\mu m_a}\frac{\partial^2 u_a}{\partial z^2} \tag{10}$$

If the boundary condition and the initial condition are same, we can get the analytic solution of Eq.10 as Eq.11.

$$u_a(z,t) = p_0 \sum_{m=1}^{\infty} \frac{2}{M} \sin\frac{Mz}{H} e^{-M^2 T_v} + p_{atm} \tag{11}$$

Where,

$$M=(2m-1)\pi/2,\ T_v=\frac{kt}{\mu m_a H^2} \tag{12}$$

Then the process of consolidation due to compressible fluid can be compared with incompressible fluid. The results have been shown in Fig.2.

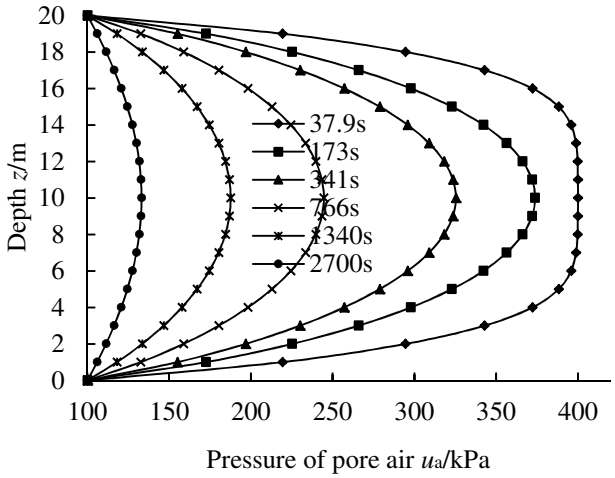

Fig. 1 Distribution of pore-air pressure along depth in different time

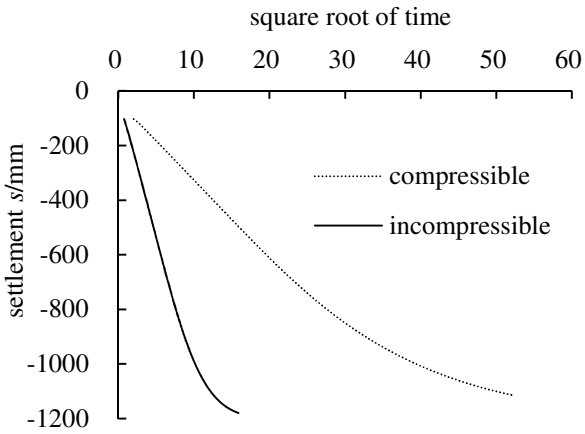

Fig. 2 Comparison of compressible and incompressible fluid's consolidation- Settlement versus time

From Fig.2, it can be concluded that the compressibility is not an advantageous factor to quicken the consolidation. As we all know, the instantaneous deformation would occur because of the compressibility of pore fluid. But the residual settlement would be finished slowly.

## Comparison with experimentation

There are trial datum of confined compression test in Shao et.al [13]'s research on remolding unsaturated loess. The parameters' values of soil are: $d_s$=2.7, $w_l$=30.6%, $w_p$=18.7%, w=14%, $\rho_d$=1.60g/cm$^3$, $S_r$=55%. Analyzing the typical deformation curve in that paper, the process of consolidation can be divided into two stages as shown in Fig.3. This viewpoint is also indicated by Ausilio, et.al.[12]

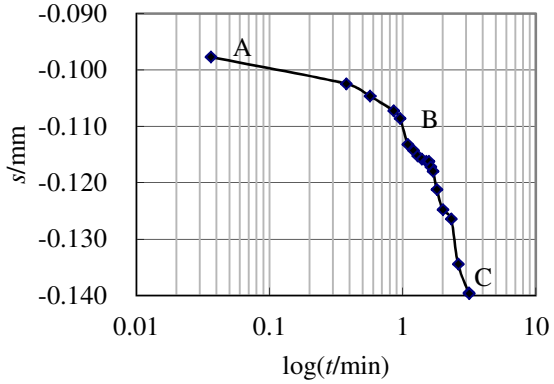

Fig. 3 The s-logt's curve in consolidation process of unsaturated soil

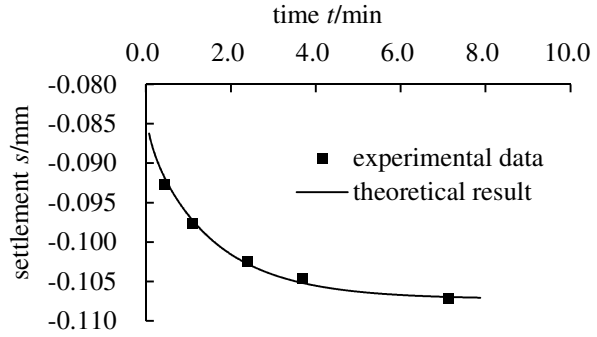

Fig.4 Comparison between experimental results and the numerical results of consolidation analysis by this study

The stage of AB in Fig.3 can be regarded as the stage of consolidation due to dissipation of pore air pressure. And according to the equation provided in the paper, comparison between the result of analysis and trial datum can be drawn as shown in Fig.4. The values of parameters for analysis are following: $\mu=1.3\times10^{-8}$kPa•s, $k=6.67\times10^{-18}$m$^2$, $n_a$=0.18, $m_v=3.5\times10^{-5}$kPa$^{-1}$, the initial settlement $s_0$=0.082mm, $\Delta z$=1mm, $\chi$=2.8, $\Delta t$=0.72s and the initial pore air pressure $u_{a1}$=182.6kPa, the pore air pressure in the end of stage AB $u_{a2}$=146.5kPa. And the height of soil is 2cm.

It can be seen from Fig.4 that the simulation is very perfect. And it indicates that the equation of consolidation for dissipation of pore air pressure can be used to analyze the first stage of consolidation of unsaturated soils.

## Conclusions

The consolidation of unsaturated soils can be divided into two stages. The equation which can describe the first stage of consolidation has been derived and founded in this paper. The conclusions are following:

(1) The equation is very different to Terzaghi' equation. It is a whole nonlinear partial differential equation.

(2) The characteristic of dissipation of pore air pressure in consolidation of unsaturated soils is similar to that of pore water pressure in saturated soils.

(3) The compressibility of pore fluid would slow down the consolidation.

The equation founded in the paper has been validated by the experimental results. And it is able to simulate the consolidation due to dissipation of pore air pressure.

# Determine the Shear Strength of Aeolian Sand and Bearing Capacity

Yingzi Yin [1, a] , Yalei Wang [1,b]

[1]Architecture and civil engineering school , Inner Mongolia University Of Science & Technology, Baoyou 014010, China

[a]yinyingzi2005@126.com

[b]414287459@qq.com

**Key Words** : shear strength; cohesion; internal friction angle; bearing capacity

**Abstract**: In this article, through aeolian sand sample study in Inner Mongolia Baotou area, to determine the aeolian sand maximum dry density and optimum moisture content. On this basis, the aeolian sand cohesion and internal friction angle were measured by the quick direct shear test when aeolian sand was at the optimum moisture content and near the most largest compactness. And the bearing capacity of retaining wall model which regarded aeolian sand as fillers was determined. Then bearing capacity change of aeolian sand wrapped before and after was compared. Experimental results showed that: when the aeolian sand was in the wet and compacted state, its cohesion was 3.31 kPa and internal friction angle was 36.8°. The aeolian sand bearing capacity was 153.8kPa by the plate loading test. The aeolian sand wrapped with a geotextile bearing capacity was 194.1kPa. Through the aeolian sand research of Baotou area, it provides a useful reference for the construction of highway and railway and application of wrap-reinforced retaining wall which is a new retaining structure in the region, and the aeolian sand is treated as a special filling material in these structures.

## Introduction

In the vast desert areas in China, especially in the western arid regions, the natural environment is very harsh and the economy is backward. But there are abundant natural gas, oil, coal and other resources. In order to speed up the economic development of these areas，the research for construction of roads and railways in desert regions is an urgent demand. These areas lack of building materials, only aeolian sand can be provided. The bearing capacity of aeolian sand is small, and it is not easy to compact. In this paper, the shear strength and bearing capacity of aeolian sand in Baotou area were studied through experiment. The results show that the aeolian sand package can effectively improve the bearing capacity. This provides a reference for the railway and highway construction in desert areas and the application of wrap-reinforced retaining wall in this area.

## Shear strength of aeolian sand

2.1 *Experimental Procedure*

(1) Compacted the aeolian sand with standard heavy compaction test method, and we could obtain that the maximum dry density and optimum water content were respectively 1.576g/cm$^3$ and 17%.

(2) Added a certain amount of water into the Aeolian sand to adjust to the optimum water content and compact the sand. Taked the aeolian sand Sample with foil sample, the volume of foil sample was 60.351cm$^3$, the height was 2cm, A=30.16 cm$^2$, C=1.549kPa/0.01mm, and quick direct shear test was made.

(3) The experimental results are shown in table 1 below.

**Table 1 Test results of experimental**

| Vertical pressure (kPa) | 50 | 100 | 200 | 300 | 400 |
|---|---|---|---|---|---|
| Shears trength | 37.176 | 66.607 | 168.841 | 243.193 | 286.565 |

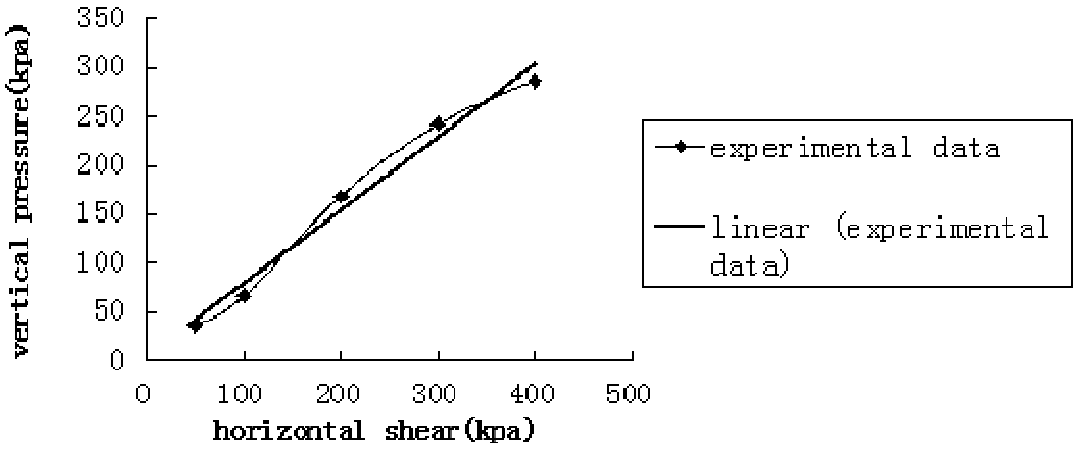

**Figure 1 The shear strength and vertical pressure relation curve of aeolian sand under wet condition**

2.2 *Analysis of experimental results*

It can be concluded from the test results that in the wet state, the cohesion c=3.31kPa, Internal friction angle is36.8° . In general, aeolian sand in natural condition has a very low moisture content, the cohesions is almost 0. The aeolian sand in optimum moisture content and compaction condition shows a false cohesive force phenomenon because of water.

## Bearing capacity of aeolian sand

3.1 *Model of package reinforced retaining wall*

As shown in Figure 2, the model is 150cm in height, 180cm in width, 200cm in length. According to the data of previous test about lay-down thickness on wet aeolian sand, Each layer of lay-down thickness is 40cm. Put the next layer after compaction, and each layer of eolian sand is usually set.

**Figure 2 Model of package reinforced retaining wall**

3.2 Measure the bearing capacity of the aeolian sand with plate load test

3.2.1 Experimental Procedure

(1) Spread the geotextile(5m in length, 1.8m in width) on the test ground, then mixed a certain amount of aeolian sand in accordance with the optimum water content(about 17%). Then put the sand on the geotextile. The range was 2m long, 1.8m wide. The lay-down thickness was 40cm.

(2) Compacted the aeolian sand uniformly with small ramming machine, made sure the compacting factor was greater than 0.96, then pack with the geotextile.
(3) According to the above method, and then put two layer and compact.
(4) Fixed a 500mm*500mm*20mm steel plate on the bottom of test case, and placed it in the middle of the aeolian sand, and fixed the four corners of the top surface of the wooden case with four pins. Recorded the height with level before loading.
(5) Each level was loaded in accordance with 25kPa. Observed a sedimentation of bearing plate with level. Took the load when l/b=0.01, namely, sedimentation was 5mm. The results were shown in Table 2. From the experimental data in the Table 3-1, it can be obtained that the bearing capacity of aeolian sand after packaging was 194.1kPa.

**Table 2 Aeolian sand packaged by geotextile at optimum moisture content and compaction degree was 0.96**

| load(kPa) | 25 | 50 | 75 | 100 | 125 | 150 | 175 | 200 | 225 |
|---|---|---|---|---|---|---|---|---|---|
| sedimentation (mm) | 0.07 | 0.17 | 0.29 | 0.47 | 0.97 | 2.22 | 3.87 | 5.35 | 6.7 |

The bearing capacity of aeolian sand before packaging could be measured by the above similar experimental procedure. The results were shown in Table 3. Took the load when l/b=0.01, namely, sedimentation was 5mm, and from the experimental data in the Table, it could be obtained that the bearing capacity of aeolian sand before packaging was 153.8kPa.

**Table 3 Aeolian sand with optimum moisture content and compaction degree was 0.96**

| Load(kPa) | 25 | 50 | 75 | 100 | 125 | 150 | 175 | 200 | 225 |
|---|---|---|---|---|---|---|---|---|---|
| Sedimentation (mm) | 0.25 | 0.5 | 0.55 | 1.38 | 3.7 | 4.58 | 5.80 | 6.73 | 7.7 |

3.3 *Comparison of aeolian sand's bearing capacity before and after packaging*
From the Table 3, it can be obtained that the bearing capacity of compact aeolian sand before packaging is 153.8kPa. From the Table2, it can be obtained that the bearing capacity of compact aeolian sand after packaging with geotextile is 194.1kPa. Obviously, the bearing capacity of aeolian sand after packaging is effectively improved. From the experimental data we can learn that the bearing capacity of aeolian sand after packaging increases by 26.2%. As the aeolian sand is packaged with geotextile, the aeolian sand is provided a lateral restraint force with the geotextile. Thus it obviously improves the bearing capacity of aeolian sand.

## Conclusion

This paper studies the aeolian sand by experiment in west area, Inner Mongolia. The results show that：
(1) It can be concluded from the test results that in the wet state the cohesion c=3.31kPa, and internal friction angle is $36.8^{\circ}$ for aeolian sand. The aeolian sand at optimum moisture content and compaction condition shows a false cohesive force phenomenon because of water.
(2)Measured the bearing capacity of the aeolian sand before and after packaging with plate load test. The result shows the bearing capacity of aeolian sand before packaging is 153.8kPa, the bearing capacity of aeolian sand after packaging is 194.1kPa. Obviously the bearing capacity of aeolian sand after packaging is effectively improved. The bearing capacity of aeolian sand after packaging increases by 26.2% compared with before.

**Keywords:** Theory of saturated porous media, Two-dimensional beam, Dynamic response, Dynamic characteristics

**Abstract.** The dynamic response of the two dimensional fluid-saturated porous beam has been studied based on the linear elastic theory and the Biot's model for saturated porous media, in which the compressibility of solid particles and fluid and the viscosity of pore fluid are taken into account. By adopting Fourier series expansion and solving ordinary differential equations, the calculation formula for dynamic response of a two dimensional simply-supported fluid-saturated porous beam is established. The dynamic response characteristics of the forced vibration under uniformly distributed harmonic load are analyzed as a numerical example. Moreover, the solid displacement and pore fluid pressure of the two-dimensional fluid-saturated porous beam would be affected by the surface in filtration conditions, pore fluid permeability coefficient and loading frequency parameters etc.

## Introduction

Since Biot (1956) put forward the basic equations describing the dynamic characteristics of saturated porous media, many scholars have studied the problem of saturated porous medium dynamic from different aspects, including analytical studies of dynamic response of saturated porous media problems [1,2], numerical solution analysis [3,4] and wave propagation characteristics of saturated porous media analysis [5,6] and so on. The current research on the saturated porous media wave problems mainly focus on the geometric characteristics of geotechnical materials infinite half space domain or a layer of finite thickness, and on the research of all kinds of fluid saturated porous material fluid solid coupling dynamic static response is far behind the development of single-phase continuum elastic mechanics.

In terms of fluid saturated porous medium beam and rod structure, Li [7] application of Biot wave model has studied the vibration and quasi-static response of saturated porous elastic beam and rod in the case of liquid along the axial diffusion, pointed out that the phenomenon of Mandel-Cryer also exists in the porous elastic deformation response of beams and rods, and on this basis has studied the dynamic buckling of the porous elastic beam. Based on the three-dimensional equations of incompressible saturated porous media theory, Yang Xiao established the mathematical model of micro- incompressible saturated porous beam and rod linear deformation, using Laplace transform studied the quasi-static and dynamic bending at both ends of the permeable cantilever, and analytical studies the linear dynamic response of simply supported saturated porous elastic, for the analysis of the saturated porous elastic beam nonlinear bending problem. In addition, the saturated porous elastic beam non-linear bending problems were analyzed.

All above, simplified theoretical modeling analysis was adopted in the current research on fluid-saturated porous material of structure. However, studies showed that the mechanical quantity could not be polynomial along the thickness of coordinate variables. Given various simplified theories, only the partial fundamental equations could meet the required conditions and this error would increase with the increase of girder thick. Based on the Biot theory of porous media, the dynamic response governing equation of two dimensional fluid-saturated porous beam was established in this paper. The transient vibration response of simply supported fluid saturated porous beam was researched. Moreover, the influence on the solid displacement and pore fluid pressure of

the two-dimensional fluid-saturated porous beam was studied as different surface infiltration conditions, pore fluid permeability coefficients and loading frequency values.

## The Governing Equation of Fluid-saturated Porous Beam and Transient Response

**Basic Equation.** Based on the Biot theory of porous media, the basic equation of homogeneous saturated porous media was

$$\sigma_{ij} = \lambda\varepsilon_{kk}\delta_{ij} + 2\mu\varepsilon_{ij} - \alpha p\delta_{ij} b = 1/K_f \tag{1}$$

$$p = M\zeta - \alpha \mathrm{M}\varepsilon_{kk}\zeta = -w_{i,i} \tag{2}$$

$$\varepsilon_{ij} = \frac{1}{2}(u_{i,j} + u_{j,i}) \tag{3}$$

$$\sigma_{ij,j} = \rho\ddot{u}_i + \rho_f\ddot{w}_i \rho = (1-n)\rho_s + n\rho_f \tag{4}$$

$$-p_{,i} = \rho_f\ddot{u}_i + m\ddot{w}_i + b\dot{w}_i \tag{5}$$

The governing equation could be obtained from (1) to (5):

$$\mu\nabla^2 \mathrm{u} + (\lambda + \mu + \alpha^2 M)\mathrm{grad}e - \alpha M\mathrm{grad}\zeta = \rho\ddot{\mathrm{u}} + \rho_f\ddot{\mathrm{w}} \tag{6}$$

$$\mathrm{grad}(\alpha Me - M\zeta) = (\rho_f\ddot{\mathrm{u}} + m\ddot{\mathrm{w}}) + b\dot{\mathrm{w}} \tag{7}$$

In the above equations, $u$ and $w$ were the displacement vectors of the solid skeleton and pore fluid. $\zeta = -w_{i,i}$; $\varepsilon_{ij}$ was the strain vectors of the solid skeleton. $m = \rho_f / n$ ,where $n$ was the porosity of soil. $\rho_f$ was pore fluid pressure. $\mu$ and $\lambda$ were Lame constants of solid skeleton; $\rho$ was total density of the saturated soil and could be derived by $\rho = (1-n)\rho_s + n\rho_f$ ,where $\rho_s$ and $\rho_f$ were density of solid grains and pore fluid respectively. $b = 1/k_f$ , $k_f$ was the dynamic permeability. $\alpha$ and $M$ were the Biot parameters of the two-phase material compressibility. Moreover, $\alpha = 1 - K/K_s$ , $1/M = (\alpha - n)/K_s + n/K_f$ . $K$ , $K_s$ $K_f$ were the Bulk modulus of the solid skeleton, solid particles and pore fluid.

**Dynamic Models of Two Dimensional Simply Supported Beam.** The beam length and depth were denoted by *L* and *h* as shown in Fig. 1.

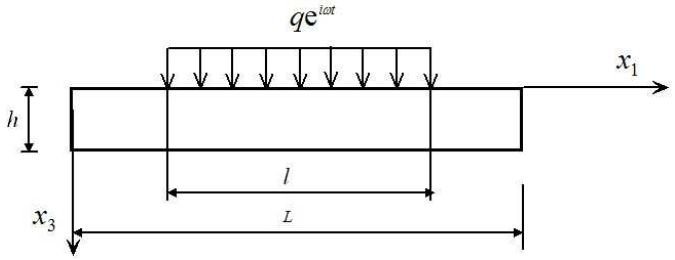

Fig. 1 Simply-supported two dimensional fluid-saturated porous beam

Eages of the beam were assumed to be simply supported as shown in formula (8)

$$\sigma_{11} = 0\ ,\quad u_3 = 0\ ,\quad w_3 = 0 \quad \text{at } x_1 = 0, L \tag{8}$$

This set of edge conditions was identically satisfied by setting

$$u_1 = \sum_{m=0}^{\infty} U_1(x_3)\cos\frac{m\pi x_1}{l}\mathrm{e}^{iwt}\ ,\quad w_1 = \sum_{m=0}^{\infty} W_1(x_3)\cos\frac{m\pi x_1}{l}\mathrm{e}^{iwt} \tag{9a}$$

$$u_3 = \sum_{m=0}^{\infty} U_3(x_3)\sin\frac{m\pi x_1}{l}\mathrm{e}^{iwt}\ ,\quad w_3 = \sum_{m=0}^{\infty} W_3(x_3)\sin\frac{m\pi x_1}{l}\mathrm{e}^{iwt} \tag{9b}$$

Substitute Eq.(9) into Eq.(6) and Eq.(7) and the matrix equation could be obtained:

$$\begin{bmatrix} \rho w^2-\mu\xi_1^2-(\lambda+\mu+\alpha^2M)\xi_1^2+\mu F^2 & \rho_f w^2-\alpha M\xi_1^2 & (\lambda+\mu+\alpha^2M)\xi_1 F & \alpha M\xi_1 F \\ \rho_f w^2-\alpha M\xi_1^2 & mw^2-ibw-M\xi_1^2 & \alpha M\xi_1 F & M\xi_1 F \\ -(\lambda+\mu+\alpha^2M)\xi_1 F & -\alpha M\xi_1 F & \rho w^2-\mu\xi_1^2+(\lambda+\mu+\alpha^2M)F^2+\mu F^2 & \rho_f w^2+\alpha MF^2 \\ -\alpha M\xi_1 F & -M\xi_1 F & \rho_f w^2+\alpha MF^2 & mw^2-ibw+MF^2 \end{bmatrix} \begin{bmatrix} P_1 \\ P_2 \\ P_3 \\ P_4 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \tag{10}$$

Where $F = \mathrm{d}/\mathrm{d}x_3$ . The non-trivial solution of equation (10) yielded (11)

$$\begin{bmatrix} U_1 \\ W_1 \\ U_3 \\ W_3 \end{bmatrix} = \begin{bmatrix} h_i & h_1 & h_3h_4 & -h_3h_4 & h_5 & -h_5 \\ 1 & 1 & h_3 & -h_3 & h_6 & -h_6 \\ h_1h_2 & -h_1h_2 & h_4 & h_4 & h_7 & h_7 \\ h_2 & -h_2 & 1 & 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} A\mathrm{e}^{r_1x_3} \\ K\mathrm{e}^{-r_1x_3} \\ B\mathrm{e}^{r_3x_3} \\ R\mathrm{e}^{-r_3x_3} \\ C\mathrm{e}^{r_5x_3} \\ S\mathrm{e}^{-r_5x_3} \end{bmatrix} \tag{11}$$

Where $A, K, B, R, C, S$ were six arbitrary constants. Using stress-displacement relationships the following expressions for stresses were obtained:

$$\begin{bmatrix} \sigma_{11} \\ \sigma_{33} \\ \sigma_{13} \\ p \end{bmatrix} = \begin{bmatrix} \sigma_{11}' \sin\xi_1 x_1 e^{iwt} \\ \sigma_{33}' \sin\xi_1 x_1 e^{iwt} \\ \sigma_{13}' \cos\xi_1 x_1 e^{iwt} \\ p' \sin\xi_1 x_1 e^{iwt} \end{bmatrix} \tag{12}$$

Where

$$\begin{bmatrix} \sigma_{11}' \\ \sigma_{33}' \\ \sigma_{13}' \\ p' \end{bmatrix} = \begin{bmatrix} g_1 & g_1 & g_2 & -g_2 & g_3 & -g_3 \\ g_4 & g_4 & g_5 & -g_5 & g_6 & -g_6 \\ g_7 & -g_7 & g_8 & g_8 & g_9 & g_9 \\ g_{10} & g_{10} & g_{11} & -g_{11} & g_{12} & -g_{12} \end{bmatrix} \begin{bmatrix} A\mathrm{e}^{r_1x_3} \\ K\mathrm{e}^{-r_1x_3} \\ B\mathrm{e}^{r_3x_3} \\ R\mathrm{e}^{-r_3x_3} \\ C\mathrm{e}^{r_5x_3} \\ S\mathrm{e}^{-r_5x_3} \end{bmatrix} \tag{13}$$

Take the local load by Fourier series expansion into the following form:

$$q_n = \begin{cases} \dfrac{l}{L}q & n=0 \\ \dfrac{2q}{n\pi}\sin(\dfrac{n\pi l}{L}) & n>0 \end{cases} \tag{14}$$

Therefore, according to the boundary conditions of upper and lower beam surfaces, Eq.(11) and Eq. (13) could determine the undetermined constants *A, K, B, R, C* and *S*, combined (9) and (11) - (14) could get dynamic response of displacement and stress under local load.

**Numerical Examples and Analysis**

In order to analyze the fluid saturated porous two-dimensional beam under dynamic load response, the physical and mechanical parameters of saturated porous materials were selected including $n$=0.19 $E = 1.44\times10^7\,\mathrm{pa}$ , $\nu = 0.2\,pu_3 f = 50Hz$ , $\rho_s = 2.458\mathrm{kg/m}^3$ , $\rho_f = 1.000\mathrm{kg/m}^3$ , $K_s = 3.6\times10^7\,\mathrm{pa}$ , $K_f = 3.3\times10^6\,\mathrm{pa}$ and $k_f = 1.9\times10^{-7}\,\mathrm{m}^4/\mathrm{kNs}$ .When dynamic load amplitude $q = 1000\mathrm{pa}$ , the changing curves of the beam middle pore fluid pressure $p$ and vertical displacement $u_3$ along the

beam height were analyzed at different load frequencies, permeability coefficients and harmonic load frequency of 5Hz，50Hz，100Hz，150Hz respectively. As can be seen from Fig. 2 and Fig.3, whether the upper and lower surfaces were permeable freely or completely not, the cross-section of the pore fluid pressure in the magnitude and vertical displacement would increase with load frequency rising, but the flooding conditions of the upper and lower surfaces had little effect on the vertical displacement of the solid skeleton in this paper.

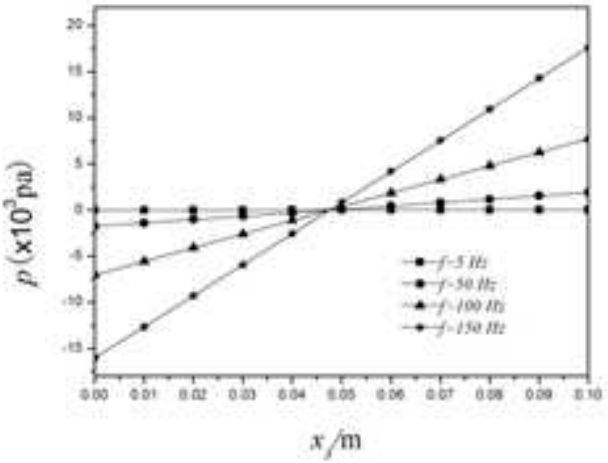

Fig. 2 The fluid pressure along the beam thickness varying with $f$ under free permeable condition

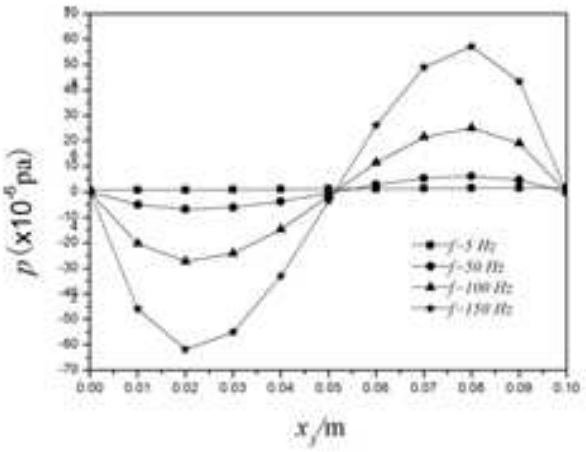

Fig. 3 The fluid pressure along the beam thickness varying with $f$ under impermeable condition

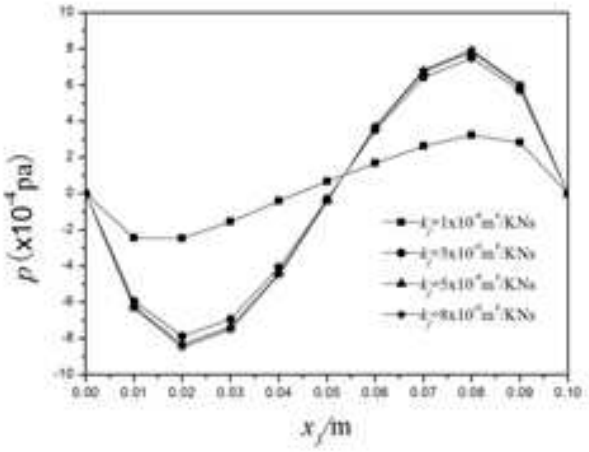

Fig. 4 The fluid pressure along the beam thickness varying with $k_f$ under free permeable condition

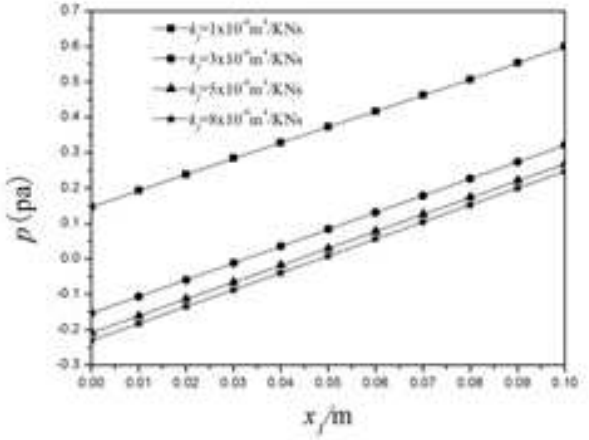

Fig. 5 The fluid pressure along the beam thickness varying with $k_f$ under free impermeable condition

In order to analyze the influence of dynamic response that permeability coefficient to fluid-saturated porous beam, Fig. 4 and Fig. 5 were plotted in the upper and lower surface of freedom permeable or completely impermeable the cross-section of the pore fluid pressure $p$ and vertical displacement $u_3$ along the curve beam height when load frequency was f=50Hz. As can be seen from the diagrams, the influence of fluid permeability coefficient and the permeable conditions of upper and lower surfaces on the fluid pressure was large, but little effect could be found on the vertical displacement of the solid skeleton.

## Conclusions

Based on the results obtained from the numerical example, the following conclusions could be drawn:

(1) In the role of local harmonic load, the cross-section of the pore fluid pressure in the magnitude and vertical displacement increases with load frequency increasing, but the flooding conditions of the upper and lower surfaces has little effect on the vertical displacement of the solid skeleton.

(2) Large influence of fluid permeability coefficient and the permeable conditions of the upper and lower surfaces could be found on the fluid pressure, but little on the vertical displacement of the solid skeleton. Moreover, the changes of both permeability coefficient and load frequency has little effect on the total stress components of the beam cross-section.

**Keywords:** shear band; strain energy; deformation process; formation mechanism

**Abstract.** Shape multiformity and formation mechanism of shear band in normal consolidated soil were analyzed based on Modified Cam-Clay model under plane strain condition. The results proved that shear band forms because of impact action caused by strain energy releasing. End restraint and initial defect can induce and control the formation process and shape of shear band. The interaction of different boundary and initial defect settings was analyzed in order to obtain the mechanism and deformation process of shear band.

## Introduction

Progressive development of shear band is a hot spot and a difficult point on geotechnical research. The formation mechanism of shear band is the research base on both soil body stability and progressive failure. The remarkable understanding to process of shear band would have great helpful to the civil engineering design and construction.

Numerical simulation can be used as methods of finite difference, finite element, discrete element method and so on. Zienkiewicz [1] first proposed the adptive mesh technique to refresh the finite mesh in order to satisfy the failure question. Belytschko et al [2] raised extended finite element thought and meshless method. Wang et al [3] used discrete element to research particle breakage under high pressure and plane strain conditions. Powrie et al [4] researched end friction of triaxial test by using particle flow method. Castelli et al [5] simulated the propagation law of shear band in defect material using boundary element method. Lu [6] came forward principal stress conditions of shear band process and failure under plane strain conditions.

Formation mechanism and development process of shear band under plane strain condition using modify cam model was analyzed in this paper. The results show that strain energy is the formation mechanism of shear band. The development process of shear band has the relationship with interaction of boundary and initial defect, local strains of different parts also have progressive order.

## Formation Mechanism of Shear Band

The soil parameters used in constitutive model was the same as parameters of Sam [7], in which $\alpha$=50kPa, $\beta$=1.0, M=1, $\lambda$=0.174, $\kappa$=0.026, $e_0$=0.889, $\mu$=0.28, k=25mm/s. Pore pressure element CPE8RP was used. Sample size was 50mm$\times$100mm, and was divided into 20$\times$40=800 elements. The simulation process was two steps, the cell pressure 100kPa was put in first step, strain controlled loading under unconstrained condition was put in second step. Top and bottom of sample were displacement boundary conditions, left and right boundaries were stress conditions. Fig.1 is the vertical log strain results of one defect element which location at top left corner of sample. The initial yield strength of defect element was 15kPa, while other elements were 50kPa [8].

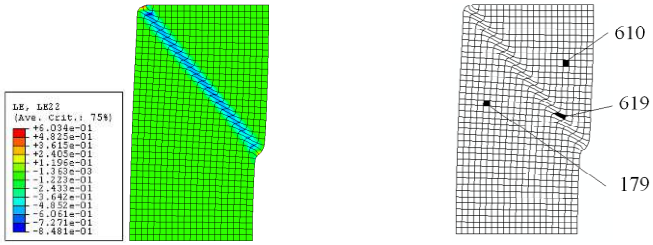

**Fig.1 Log strain result and location of representative elements**

The formation mechanism of shear band is analyzed using strain paths and deformation characters of elements in shear band and non shear band area. As fig.1 shows that the elements named 179, 610, 619 were selected to do comparative analysis. The effective stress paths of the three elements are showed in fig.2. The three stress paths are same before peak stress value, while the shear stresses are all decreasing after peak shear stress value. The average stress laws are different. The element 610 is above the shear band, the average effective stress is decreasing lightly after peak value. While the element 619 is in the shear band, the average effective stress is decreasing greatly after peak value. And the element 179 is below the shear band, the average effective stress is increasing after peak value. The analysis results of effective stress path show that the element porosity in shear band area is increasing, the bearing capacity decreased rapidly, the weak element that can endure deformation is formed. A series of continuous weak elements are formed in sample after peak shear stress, which offered conditions for formation of macro shear band.

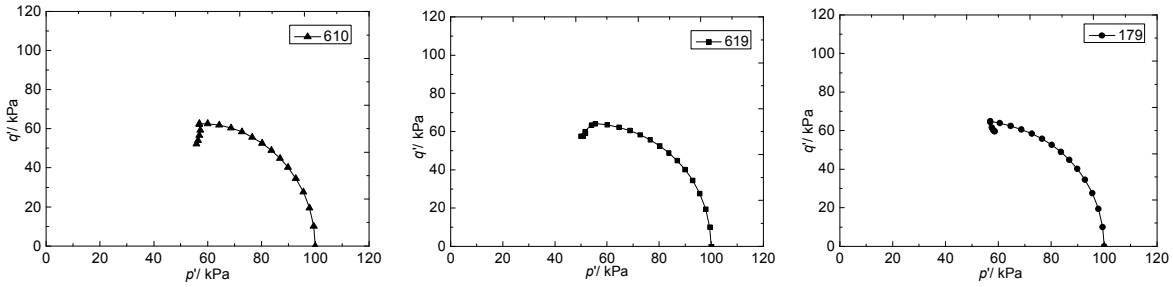

**Fig.2 Effective stress path of the representative elements**

The vertical stress-strain curves of the three representative elements are contrasted in fig.3. Element 610 and 619 are in the same vertical line. Element 179 and 619 are in the same horizontal line. Element 610 and 179 in non shear band area are in a state of unloading, while deformation of element 619 in shear band is increasing rapidly.

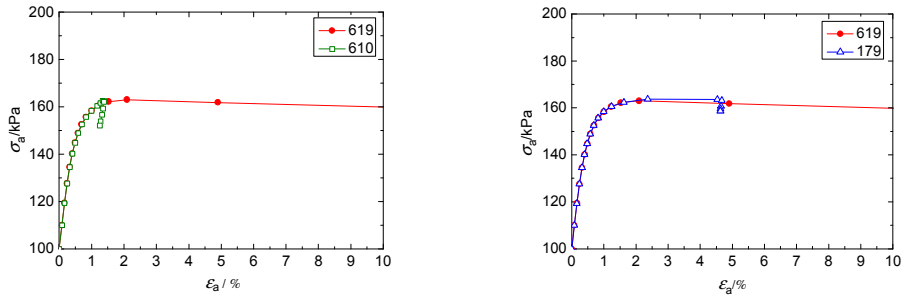

**Fig.3 Vertical stress and strain relationship of the representative elements**

The reason can be explained with strain energy mechanism. The internal strain energy of element is increasing to the maximum value during loading until the peak stress. Element 619 can not bear the strain energy because of porosity increasing and stiffness decreasing after peak stress. The released energy of 610 is put on 619 rapidly, which cause the deformation of 619 increasing rapidly. Then the macro shear band is formed. The element 610 is in a state of unloading because of energy releasing.

Table 1 shows strain change of the two representative elements in non shear band area. The relative response is the ratio between difference of peak strain and final strain and peak strain value.

The non shear band area has response phenomenon which means the area in a unloading state during the shear band development process. For this kind of single shear band as the element 179 and 610 results shows, the upper shear zone is given priority to vertical response, lower shear zone is given priority to level response. Just like the fault in geology, predominantly vertical response of the upper plate and predominantly level response of the lower plate interacts together, then releasing strain energy, the shear band of sample is formed followed the maximum shear stress surface.

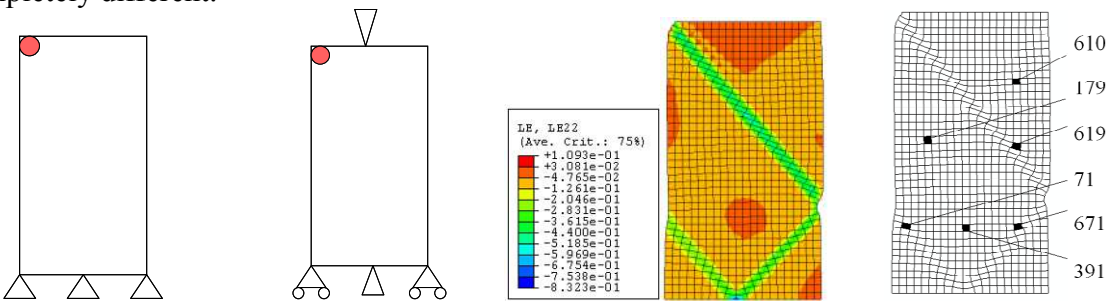
**Table 1 Element strain in non shear band area**

| Element number | Strain type | Peak value time | Peak value strain | Final strain | Relative response |
|---|---|---|---|---|---|
| 179 | $\varepsilon_a$ | 500 | -0.04637 | -0.04558 | 1.7% |
| | $\varepsilon_r$ | 500 | 0.04674 | 0.04632 | 0.9% |
| 610 | $\varepsilon_a$ | 460 | -0.01591 | -0.01475 | 7.3% |
| | $\varepsilon_r$ | 460 | 0.01387 | 0.01248 | 10.0% |

In conclusion, the fundamental cause of formation of shear band is the releasing of elastic strain energy. Based on the MCC model, shear process is controlled by strain. The physical process of shear band formation is presented as follows. Defect element induces the inhomogeneous deformation, the element on some shear surface first reaches the shear strength and is unable to bear the loading, while elements in other area that do not reach the shear strength still can resist. To break this balance by keep loading, the results are strain response of element which does not reach the strength. The releasing elastic strain energy make the weak element which reaches the strength happen deformation. The response impact action is the reason that loading decreasing and deformation increasing at the same time, then continuous and macro shear band is formed.

## Formation Process of Shear Band

The formation process of shear band is complicate and effected by boundary conditions. For the same initial defect and different boundary displacement condition, the formation processes of shear band are completely different.

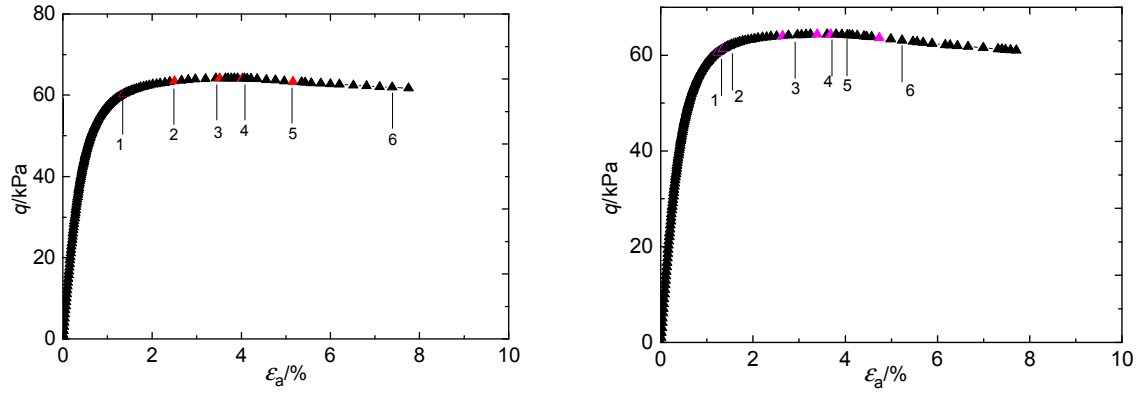


**(a) Boundary condition 1 (b) Boundary condition 2 (c) Strain nephogram (d) Responsible element location**

**Fig.4 Boundary conditions and results**

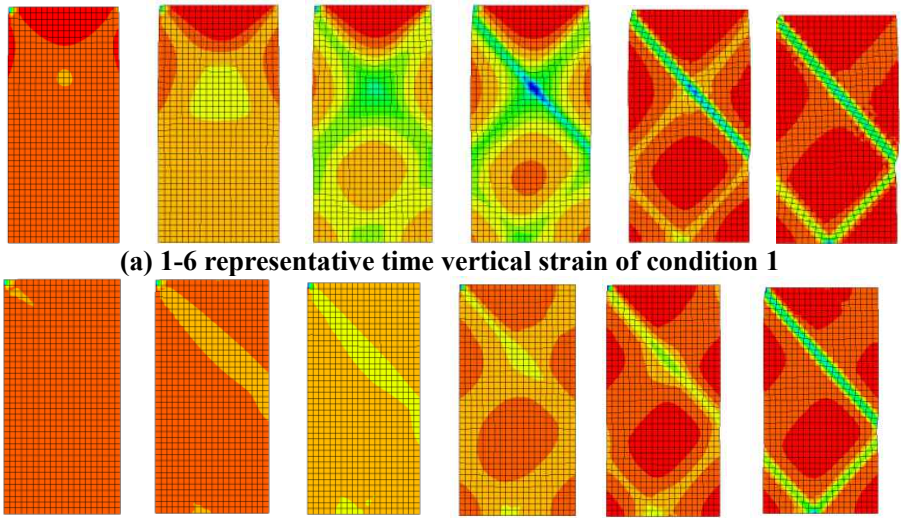
Take the conditions in fig.4 (a) (b) as an example, the formation process of shear band is researched. They have the same final type of shear band as fig.4 (c) shows. The location of representative elements is showed in fig.4 (d).

Fig.5 is the stress relationship under interaction of boundary condition 1 and 2. Six representative time points for each condition are selected to explain the deformation process of shear band, the corresponding vertical strain nephograms are presented in fig. 6. Shear stresses are both have softening phenomenon for the two conditions. For the condition 1, the interaction of fully end friction and initial defect is clearly effect the strain localization as the strain nephograms of point 1 and 2 shows. The strain localization area is cross, but initial defect win the competition in the end. For the condition 2, top displacement boundary is not strong enough to compete with initial defect, so the shear band is single section mainly controlled by defect. After the stress peak value, the types of shear band are same as strain nephogram of point 5 and 6 shows.



(a) Boundary condition 1 (b) Boundary condition 2

**Fig.5 Stress relationship under interaction of boundary condition 1 and 2**

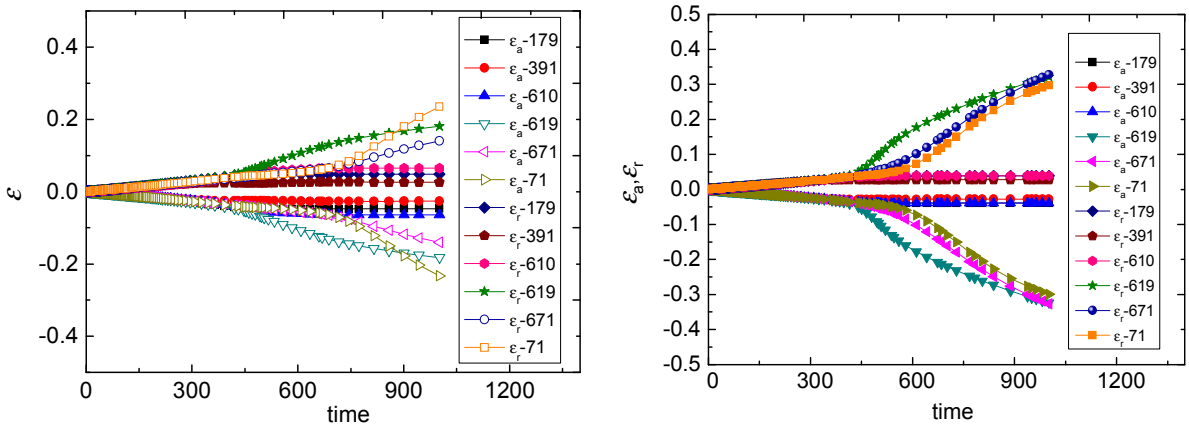


(a) 1-6 representative time vertical strain of condition 1

(b) 1-6 representative time vertical strain of condition 2

**Fig.6 Formation progress under interaction of boundary condition 1 and 2**

Representative elements 179,391,610,619,671,716 in fig. 4 (d) are used to analyze the process of shear band. The elements 619,671,71 are in the three section shear band respectively. Fig.7 is the strain curve with time of the representative elements. It can be seen that strains of 619, 671 and 71 are increasing at different time which means that the different section of shear band has order to develop. The conclusion is match with the strain results and also shows the formation process of shear band.



(a) Boundary condition 1 (b) Boundary condition 2

**Fig.7 Strain and stress of the representative elements**

## Conclusions

Formation mechanism and development process of shear band under plane strain condition were researched using numerical simulation method.

The fundamental cause of formation mechanism of shear band is the releasing of elastic strain energy. The response impact action is the reason that loading decreasing and deformation increasing at the same time, then continuous and macro shear band is formed.

The formation process of shear band is complicate and effect by boundary conditions. For the same initial defect and different boundary displacement condition, the formation process of shear band are completely different and effect by competition and interaction of boundary and initial defect, local strains of different parts also have different progressive orders.

**Keywords:** Lop Nor, gravelly gobi, surface soil, shear strength, in-situ shear test

**Abstract.** By applying the self-made field in-situ direct shear equipment, it makes a series of in-situ direct shear test researches on the soil （＜10cm）on the surface of the gravelly gobi in Lop Nor, Xinjiang, achieving its shear strength parameter. The conclusion that this paper gets not only provides the key parameters needed for the design of the gobi surface soil collection machine and the relevant assessment experiments, but also offers the reference for evaluating the similar soil shear strength of the gobi engineering construction.

## Introduction

According to the regional development plan, it intends to apply the milling collection machine to collect a certain thick surface soil from the region of Lop Nor gobi. In this field, the design and calculation of the milling collection machine are of great importance. Firstly, it must know the material indexes of the research object such as the shear strength parameter of the surface soil to be collected.

Based on the current literature[1] released, there is few research about the characteristics of Lop Nor gobi. Also, the cognition on the characteristic of the physical parameter of the soil is limited. Most of soil parameters are not well determined. Even, some parameters are unknown. The soil in the region of Lop Nor gobi is generally the gravelly soil with quite poor viscosity. So, it is very hard to obtain the undisturbed sample of the soil for the laboratory test according to the demand. The test result also has quite great limitation. The regular height of the strain-controlled direct shear apparatus is only 20mm, which cannot be taken for the test on the gravelly soil sample[2]. Thus, considering the current situation of the shortage of the research on the characteristics of the surface gravelly soil in the gobi region, this paper, on the basis of Mohr-Coulomb principle, measures the shear strength parameters of the surface soil with a certain thickness with the self-made field in-situ direct shear apparatus, to provide the reference for the design of the milling collection machine and calculation.

## Introduction of Components of Gobi Soil in the Research Area

Due to the long synthetic effects of the wind transport, freeze-thaw cycle, hydration-dehydration cycle and the crystallization & dissolution of the salt, the surface gobi soil in the research zone is mostly covered by the gravel, which is called gravel screen. Its particle is quite even. The material source is the broken objects of the mountain through the weathering. The substance components are basically same. With regard to the lithology, most are quartzite, granite and sandstone. According to the atomic absorption spectrometry analysis, its chemical components are listed in the table 1.

Table 1 Main chemical components of the gobi soil in Lop Nor region

| SiO2 | Al2O3 | Fe2O3 | CaO | MgO |
|---|---|---|---|---|
| 59.59% | 10.64% | 2.48% | 13.71% | 1.76% |

Through the analysis on the screen experiment of the particles sampled from the soil, the particle grading of the soil is measured and tested. From it, it can be seen that the surface soil is generally composed of lots of gravels and sands. The grading is not good (Cu=20~25). Also, it contains a small quantity of argillaceous interstitial matrix, of which the content of the gravel（＞2.0mm）is about 30%~50% and the content of the sand with the coarse sand (1~0.25mm) is about 47%~68%. The content of the silt and the argillaceous matrix is less than 5% of the overall contents, evenly spreading between the sand and gravel. The gobi particle grading of the research zone is shown in fig.1.

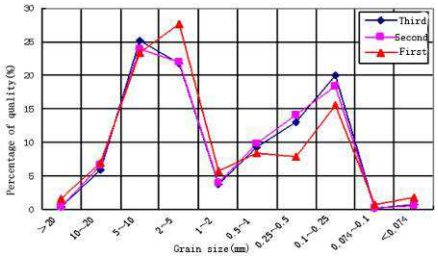

Fig.1 Particle grading curve of the gobi sol in Lop Nor region

## Content and Method of the Test

### Design of Field In-situ Direct Shear Apparatus[3]

The in-situ shear test is a kind of test method to measure the gobi gravel soil shear strength (cohesion C and internal friction angle Φ) value. This method takes into account the influence of the structural plane of the sand. The test result is quite consistent with the actual situation.

The in-situ direct shear test belongs to the on-site quick shear test. Because the regular field direct shear apparatus cannot meet the demand of the test on the shear strength characteristics of the gobi gravelly surface soil, the author makes a set of field in-situ direct apparatus by himself to conduct a series of tests on the gobi surface soil in the Lop Nor region, as shown in Fig.2.

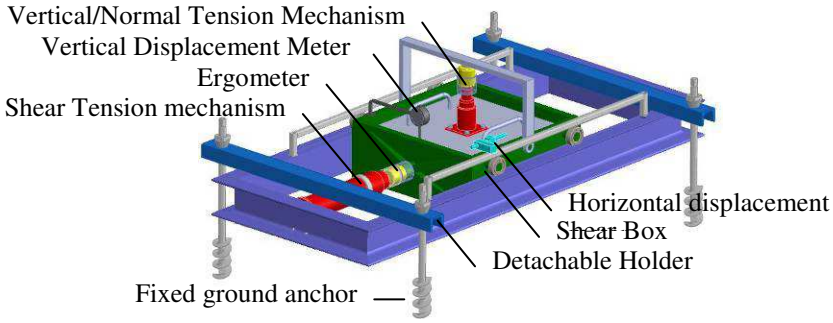

Fig.2 Field In-situ Direct Shear Apparatus Design Model

The field in-situ direct shear apparatus is designed based on the principle of the stain-controlled direct shear apparatus. This apparatus has the structure in split mounting type, chiefly consisting of the detachable outside frame, shear transmission mechanism, vertical tension mechanism and shear box as well as measurement system. Through adding a certain vertical load and horizontal shear force on the gobi sand soil, the shear plane of the sample determined is broken and then the shear stress of the sample is recorded. The sand sample is obtained in the way of pressing the shear box into the soil. According to the regulation of GB/T 50123-1999 Soil Test Method Standard, to measure the strength index of the coarse-grained soil, the specification of the shear box can be generally computed in accordance with the formula (1).

$$\frac{D}{d_{\max}} \geq 8 \sim 12, \quad \frac{H}{d_{\max}} \geq 4 \sim 8 \tag{1}$$

In the formula, d max refers to the largest size of the sand particle(mm); D is the diameter of the sample(mm) and H is the sample height(mm).

According to the sampling analysis of gobi gravelly soil in the Lop Nor region, the largest particle size of the soil collected should be Φ2.5cm. Through the calculation, the size range of the shear box is

D≥20～30cm and H≥10～20cm. The design of the shear box is square. The square shear box has the high stiffness and highly accurate measurement with the convenient installation of the measurement instruments while it stands the shear stress. Hence, while the round shear box is equivalent to the square one, the size of its section ranges from L≥17.7～26.6cm.

The performance indexes of the field in-situ direct shear apparatus design are that the clearance area of the shear box is 1000cm$^2$(preparation) and the vertical pressure is 30kN as well as the horizontal thrust is 40kN. It all takes the jack for loading. Four~six helical vane fixed steel chisels fix the outside frame. Compared with the regular direct shear apparatus, it is more suitable for measuring the shear strength of the coarse particle material such as the sand and gravelly soil.

**Test Method**

Based on the principle that the test point must be representative and easy to guarantee, it selects three sample zones to carry out the test of the gobi surface soil shear strength parameter measurement. The depths of three soils tested are respectively 2cm, 5cm and 10cm. For each depth, 4 samples are prepared. It is actually an unconsolidated and undrained quick shear test.

Fig.3 Field In-situ Direct Shear Test Site

After the test zone is selected on site, the contour with the area of 1000m2 is marked on the earth’s surface. Meanwhile, the rock and earth mass outside the line is dug to the deep layer needed for the test and then the shear box covers on the prepared sample. The fine sand is used to fill the gap between the shear box and the soil sheared. Next, the equipments (fig.3) including the force transferring rectangular tube columns, jack, ergometer, compression frame and the fixed steel chisel are installed in proper order. When the test holder is installed, it applies the flat-pushing way to implement the shear test. The normal stress gradually increases by using 30kN jack according to the preset values of 25kPa, 50kPa, 100kPa and 200kPa. In the pressure increase course, the normal stress doesn’t change. Besides, the action point of the normal stress and the shear stress goes through the center of the sample. The horizontal shear stress is added by using 40kN jack from 8th to 10th grade. The shear stress loading rate takes the time as the control factor. The rate should be controlled within 3mm/min. Each 1min, it is read. And then, it carries out shearing till the sample is broken or cut. While the shear deformation reaches the sample length of 0.05~0.10 or while the shear displacement greatly changes during a period and the shear and normal stress tend to be unstable, it is judged that the sample shear is broken. After the accomplishment of the shear test, the largest shear stress and the corresponding normal stress(the normal stress value may grow in the implementation of the shear engineering) values are recorded, to describe the geology of the sample. Besides, the up and down difference of the shear plane is measured. The actual shear area is checked. The relationship curve between the shear stress and normal stress is drawn. The simple linear regression equation is achieved. Finally, according to the graphical method, the eigenvalue of the gobi surface soil shear strength is acquired.

**Analysis of the Test Results[4]**

**The Deformation Characteristics of Gobi Surface Soil**

As a whole, the characteristic curve of the relationship between the gobi surface soil shear stress and the horizontal displacement(please see fig.4) is inclined to the downward concave. The expression of the soil sheared is reflected by the existing peak strength. In terms of the relationship between the

stress and strain, it is usually reflected through the obvious resultant stress-strain curve. While we observe the broken plane after the soil shearing, the bottom slip surface of the broken plane of the sample appears downward cambered shape. It is due to the up and down change while it is in the place with quite large particles. In other words, the situation that the broken plane bypasses the stones for the upward bend occurs while other broken planes are quite flat. It is because the broken plane can directly go through the place with quite small particles by cutting stones. It is a significant feature of the gravelly surface soil used to tell from other materials.

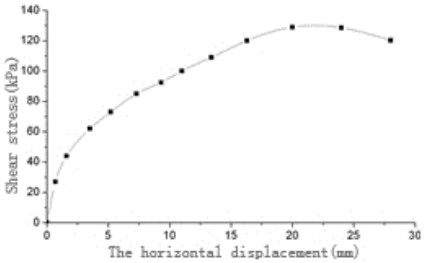

Fig.4 Shear stress-displacement characteristic curve

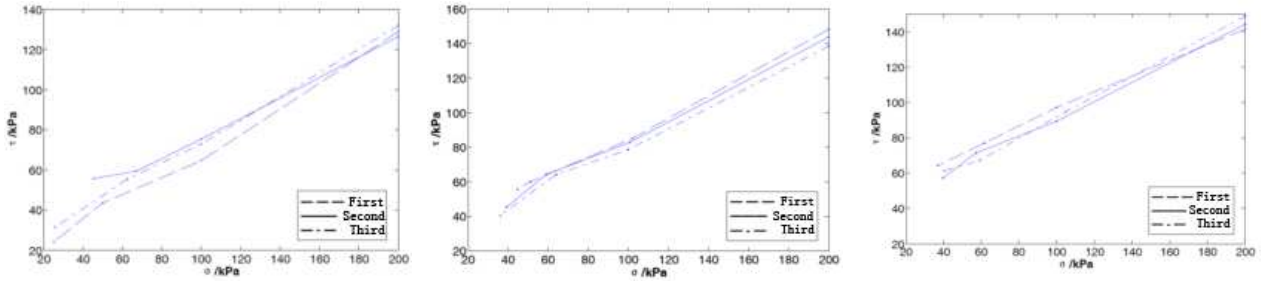
**Calculation of the Shear Strength Parameters of the Gobi Surface Soil**

According to the soil shear strength formula proposed by the Mohr-Coulomb principle[3], it can be known that there is the linear relationship between the shear strength r and the normal stress σ for cutting the broken plane. As long as the cohesion c and internal friction angle ϕ, the shear strength of the gobi surface soil can be solved.

In accordance with the test plan, it makes three groups of tests aiming to the layer of different depths. After the test result is organized, the curves of the relationship between the normal load of different-layer failure planes and the shear strength are drawn, as presented in fig.5.



1) 2cm 2) 5cm 3) 10cm

Fig.5 The curve of the relationship between the normal load of different layer and the shear strength

Through the curve of the relationship between the normal loading of the failure plane and the shear strength, the simple linear regression equation is obtained. The shear strength parameters of the gobi surface soil in the test place are solved, as table 2 shows.

Table 2 Result of Lop Nor gobi soil in-situ shear test

| Depth | 2cm | 5cm | 10cm |
|---|---|---|---|
| Internal Friction Angle ϕ (°) | 20.4～25.3 | 25.2～25.7 | 20.7～24.2 |
| CohensionC (kPa) | 15.3～23.5 | 27.2～33.1 | 41.5～51.6 |

Through analyzing the rule of the shear strength, the following conclusion can be gotten.

From Fig.5, we can see that there is nearly the linear relationship between the shear strength τ and the normal stress of the sheared failure plane σ. We get that the relevant coefficient[5] of the simple linear regression equation is 0.98. It proves that the Mohr-Coulomb principle is applicable for the gobi surface soil. Also, it indicates that the way of using the self-made field in-situ direct shear apparatus to measure the gobi surface soil shear strength parameter is feasible.

The cohesion of the gobi surface soil significantly changes with the change of the depth. c=15.3kPa ～ 51.6kPa. The soil structure refers to the shape, size, arrangement and mutual relationship of the soil particles or soil aggregation. The soil structure can be classified into three

basic types that are the single grain structure, honeycomb structure and flocculent structure[6]. According to the formation of the gobi soil, it can be classified as the single grain soil. However, the gobi soil has the great cohesion. It is not the pure single grain soil. Its cohesion has been beyond the range of the single grain soil. It is because a small quantity of clays in the gobi soil form a colloidal shape between the gravel and heap sand to make them be a whole under the long-time pressure of its self-weight. Meanwhile, the sizes of the gobi soil particles are different. They occlude and embed each other, greatly enhance the cohesion of the gobi soil. What's more. The deeper the soil is, the larger the cohesion will be. It is a soil that is never mentioned in the regular classification. Therefore, for some aspects in the engineering work, it only takes the relevant regulations in the standard for reference.

The change of the internal friction angle of the gobi surface soil is relatively small. $\varphi$=20.4°～25.7°. It is obviously affected by the water content of the soil and the density. The water content of the surface soil is basically same as the size of the void content. They are respectively 0.9% and 35%.

From the curve relationship between the shear stress and the vertical stress shown in Fig.5, Fig.6 and Fig.7, the shear strength of the sand increases with the growth of the vertical pressure. The shear deformation regularity of three-layer depth is quite good, with the low dispersion. It indicates that the data achieved under such experimental conditions is reliable.

## Conclusions

Through proving that Mohr-Coulomb standard is applicable for the gobi surface soil with the test, it verifies that the method of using the self-made field in-situ direct shear apparatus to measure the shear strength parameter of the gobi surface soil is feasible. Compared with the common direct shear apparatus, it is practical and time-saving, with the simple structure.

- The cohesion of the gobi surface soil strengthens with the increase of the depth. c=15.3kPa～51.6kPa. The change of the internal friction angle is relatively small. $\varphi$=20.4°～25.7°.
- The shear strength of the gobi surface soil increases with the rise of the vertical pressure. The shear deformation regularity of the soil of different depths is quite good, with the low dispersion. Thus it can be seen that the data obtained under such experimental conditions is reliable.
- The gobi surface soil can be interpreted by the resultant stress-strain relationship curve. Yet, it has the features significantly different from other materials. That is, the failure plane can either cut the small neighboring stone or bypass the big stone depending on the difference of the shear strength.
- The field in-situ test makes up some defects of the laboratory soil test. The indexes gotten are the real and natural reflection of the soil. So, it is more scientific and reasonable to use it for the engineering design.

**Keywords:** confined compression; compacted loess; the stress-strain relationship; structural parameter; the Gunary Model; the two-parameter liner reciprocal function

**Abstract.** Structural study of the soil is an important research content of soil mechanics. Based on the previous research results of soil structure, this paper puts forward the Gunary Model as a completely new form to describe the stress-strain relationship of soil, to discuss the method to determine soil strain considering structural parameter under the new model, to give the relevant function of the stress controlling structural parameter with stress. The results show that the Gunary Model is applicable to characterize the stress-strain relationship of soil, the parameter $c$ controls the fitting accuracy and decides the curve shape; by using the stress-strain expression of the Gunary Model, this paper finds the calculated value of stress controlling structural parameter and stress meets the two-parameter linear reciprocal function form.

## Introduction

SHEN Z J refers structural study of the soil as "the core of soil mechanics of the 21st century" [1]. XIE D Y summarizes the study results, and believes that the research method of micro-structure morphology, solid mechanics and soil mechanics are three basic ways of research on structural study of the soil, and he proposes a method to determine the soil strain considering structural parameter [2]. LUO Y S believes that the method to determine the soil strain considering parameter has many flaws under complex stress state, through the research of loess under dynamic, static stress state, proposes the method to determine the soil stress considering structural parameter [3].CHEN X analyzes two typical methods about how to determine the soil structural parameter, and puts forward an expression with an unified form and simple style [4].The value of soil structural parameter is determined by test data of undisturbed, remolded and saturated undisturbed soil samples. At present, there is more and more research on the soil structural parameter, there has been confined compression consolidation test, conventional triaxial compression test, and unsaturated soil triaxial compression test. The research involves in soil damage, complex stress and other fields, research results are increasingly rich.

The method to determine the soil strain considering structural parameter is the first canonical method that being proposed. The purpose of this study is to use a new description of the soil stress-strain relationship, combining with the relevant experimental results, to discuss the method about how to determine soil strain considering structural parameter under the new model, to give the relevant function of the stress controlling structural parameter with stress, and to validate the rationality of the new model.

## The proposal and application of a new model

**Propose a new model.** Under the confined compression state, $\sigma$ represents the vertical compression stress, $\varepsilon$ represents the vertical compression strain, then the soil stress-strain curve is shown in Fig.1.

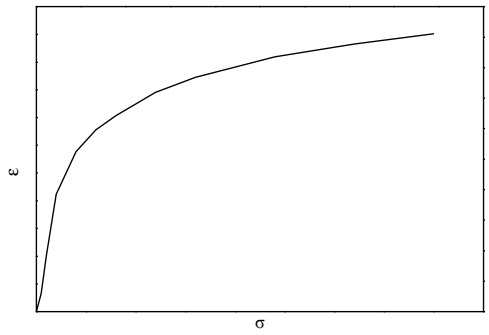

Fig.1 The curve of soil stress-strain relationship under confined compression

Fig.1 shows the soil stress-strain relationship under confined compression. As can be seen from Fig.1, the soil stress-strain curve under confined compression can be simply considered as a monotonically increasing convex function, with the increase of stress, the strain is increasing more and more slowly. In 1963, Konder proposed the Hyperbolic Model to characterize the dynamic skeleton curve of soil stress and strain [5], so, the soil stress-strain relationship can be expressed as formula (1).

$$\varepsilon = \frac{\sigma}{a + b\sigma} \tag{1}$$

Where $\varepsilon$ = the vertical compression strain of soil; $\sigma$ = the vertical compression stress of soil; $a$, $b$ =the test parameters.

It is clear that the Hyperbolic Model curve form and the soil stress-strain relationship curve form are very close with each other, so the Hyperbolic Model is widely recognized and used.

With the development of the urban road traffic, housing and other livelihood infrastructures in the northwest loess area, studies of compacted loess are increasing, and its main research content is the study of deformation characteristics. A lot of experiments prove that the soil secant modulus-stress linear relationship can not reflect the actual situation of loess in a higher compactness because in this case the soil secant modulus-stress relationship is appearing as a non-linear form. Base on the study of highway, airport construction and other projects in loess region, CHEN K Y and HU C M believe that the stress-strain relationship of compacted loess conform the power function form [6, 7]. The author finds by experimental studies that the power function has a higher fitting precision in high compactness conditions, but with the decrease of compactness the fitting accuracy and stability are decreasing too, at the same time, the soil secant modulus-stress relationship appears as a linear form, therefore, the form of power function cannot be applied. Thus, to construct a new model which has an extensive applicability, fitting accuracy and high stability is very important. The author extents the Hyperbolic Model, and introduces a new parameter to get the new model which is named as the Gunary Model, the specific form as shown in formula (2).

$$\varepsilon = f(\sigma) = \frac{\sigma}{a + b\sigma + c\sqrt{\sigma}} \tag{2}$$

Where $\varepsilon$ = the vertical compression strain of soil; $\sigma$ = the vertical compression stress of soil; $a$, $b$, $c$ =the test parameters.

As can be seen from formula (1) and formula (2), when the value of parameter $c$ is small, the Gunary Model approaches to the Hyperbolic Model, when the value of parameter $c$ is zero, the Hyperbolic Model can be considered as a special case of the Gunary Model. In order to visualize fitting curve shape of the Gunary Model, the numerical curves are shown in Fig.2.

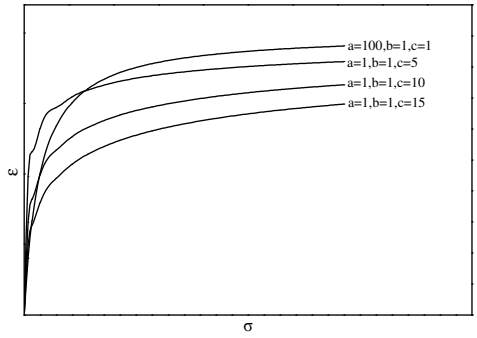

Fig.2 Fitting curves using the Gunary Model

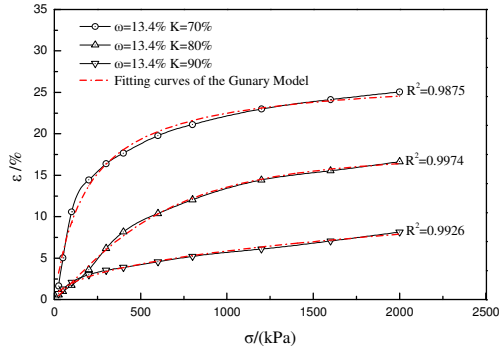
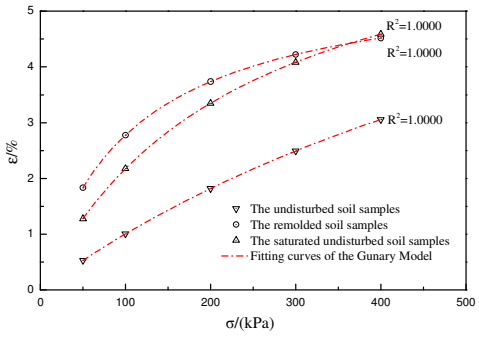
Fig.2 shows the fitting curves using the Gunary Model. As can be seen from Fig.2, the Gunary Model fitting curve form meets the stress-strain relationship curve form under confined compression. Under the same stress if the formula has equal $a$ and $b$ value, the smaller $c$ value the lager strain value, similar to the lower compactness of compacted loess. Under the same lower stress if the formula has equal $b$ and $c$ value, the larger $a$ value the smaller strain value, when the stress exceeds a certain value, the stress-strain curve tends to approach gentle by requiring a higher stress.

**The application of a new model.** This article will list Yan' an compacted $Q_2$ loess research achievements and quote partial reference [4] original date, the Gunary Model will be extended to the general soil stress-strain relationship description, and the details as shown in Fig.3.



(a) Compacted $Q_2$ loess in Yan' an region



(b) Loess in Yang' ling region

Fig. 3 The curves of stress-strain relationship of different kinds of loess

Where $K$ = compactness; $\omega$ = moisture content; $R^2$ = the correlation coefficient.

Fig. 3 shows the curves of the stress-strain relationship of different kinds of loess. It can be seen from Fig.3 that the Gunary Model can describe different types of loess and various forms of stress - strain curves, the fitting curves meet the development of actual form, meanwhile, it has a higher accuracy. Fig.3-(b) shows the correlation coefficient of the undisturbed, the remolded, the undisturbed saturated soil samples are all 1.0, indicating that Gunary model is suitable to describe the general soil stress-strain relationship, structural parameters study below will use the Gunary Model soil stress-strain relationship.

## Formula derivation and test methods

**Structural parameters.** By using unconfined compression test to make compression curves about the undisturbed soil samples, the remodeled soil samples, the undisturbed saturated soil samples of the same kind of soil, that is, three-line method. By using three-line method the author discusses the method to calculate strain considering structural parameter, it can also be called the stress controlling method, and the specific form as shown in formula (3).

$$m_\sigma = \frac{m_1}{m_2} = \frac{\varepsilon_s / \varepsilon_o}{\varepsilon_o / \varepsilon_r} = \frac{\varepsilon_s \varepsilon_r}{\varepsilon_s^{\,2}} \tag{3}$$

Where $m_\sigma$ = stress controlling structural parameter; $m_1$ =variability; $m_2$ = stability; $\varepsilon_o$, $\varepsilon_r$, $\varepsilon_s$ = strain of undisturbed, remolded, undisturbed saturated samples.

$E_{\sigma i} = \sigma / \varepsilon$ is defined as the stress controlling secant modulus under the confined compression, by introducing the secant modulus method, formula (3) is converted to formula (4).

$$m_\sigma = \frac{\varepsilon_s \varepsilon_r}{\varepsilon_s^{\,2}} = \frac{(\sigma_s / E_{\sigma s})(\sigma_r / E_{\sigma r})}{\sigma_o / E_{\sigma o}} = \frac{E_{\sigma o}^{\,2}}{E_{\sigma s} E_{\sigma r}} \tag{4}$$

Where $\varepsilon_o$, $\varepsilon_r$, $\varepsilon_s$ =strain of undisturbed, remolded, undisturbed saturated samples; $\sigma_o$, $\sigma_r$, $\sigma_s$ = stress of undisturbed, remolded, undisturbed saturated samples; $E_{\sigma o}$, $E_{\sigma r}$, $E_{\sigma s}$ = secant modulus of undisturbed, remolded, undisturbed saturated samples.

As mentioned above, the soil stress-strain relationship under confined compression meets the Gunary Model, here, the author controls the same value $\sigma$ as the stress of undisturbed, remolded, undisturbed saturated samples, so the strain considering structural $m_\sigma$ can be got by

$$E_{\sigma i} = h(\sigma) = a + b\sigma + c\sqrt{\sigma} \tag{5}$$

$$m_\sigma = \frac{E_{\sigma o}^{\,2}}{E_{\sigma s} E_{\sigma r}} = \frac{h(\sigma_o)^2}{h(\sigma_s) h(\sigma_r)} \tag{6}$$

Where $E_{\sigma i}$ = stress controlling secant modulus under confined compression; $a$, $b$, $c$ = the test parameters.

**Test methods.** Test soil samples are taken from Yang' ling, Shan' xi province, confined compression consolidation stress test will be controlled at 50kPa, 100kPa, 200kPa, 300kPa, 400kPa, including the same moisture content, dry density natural undisturbed soil samples, remodeled soil samples and natural saturated undisturbed samples[4].

## Results and analysis

**Structural parameter based on the Gunary Model.** Results of soil stress-strain relationship based on the Gunary Model are shown in Table 1 and Fig.3-(d).

Table 1 The stress-strain relationship fitting parameters based the Gunary Model

| Samples | $a$ | $b$ | $c$ | $R^2$ |
|---|---|---|---|---|
| The undisturbed samples | 89.1058 | 0.1043 | -2.3484E-13 | 1.0000 |
| The remolded samples | 18.4887 | 0.1752 | 4.8771E-14 | 1.0000 |
| The saturated samples | 32.2181 | 0.1375 | -1.08867E-14 | 1.0000 |

Note: The original test data from the reference [4]; E(n) means 10 ^ (-n)

Where $R^2$ = the correlation coefficient; $a$, $b$, $c$ = the test parameters.

As can be seen from Table 1 and Fig.3-(d) that the Gunary Model can characterize soil stress - strain relationship, the correlation coefficients are all 1.0, the fitting precision is of high value, $c$ value, although it is a very small number, but here, it cannot be ignored because that $c$ value plays a controlling role for fitting accuracy, if the value is taken as 0, the fitting expression turns into a form

of the Hyperbolic model equation, although the correlation coefficient is approximately 1.0, but the three-parameter fitting accuracy is better than two-parameter fitting. Meanwhile, the study of the deformation properties of compacted loess in Yan' an find the $c$ value determines the shape of the secant modulus-stress curve, the smaller the $c$ value, the closer the curve tends to linear relationship.

Using formula (2) - (6) to calculate the stress controlling structural parameters, and finishing the test results are shown in Table 2, Fig.4.

Table 2 The measured and calculated values of stress controlling structural parameters

| $\sigma$/kPa | $m$ | $m_\sigma$ | $\delta$/% |
|---|---|---|---|
| 50 | 6.77 | 8.352 | 23.36 |
| 100 | 6.49 | 5.985 | -7.77 |
| 200 | 3.66 | 3.783 | 3.36 |
| 300 | 2.80 | 2.777 | -0.82 |
| 400 | 2.21 | 2.216 | 0.26 |

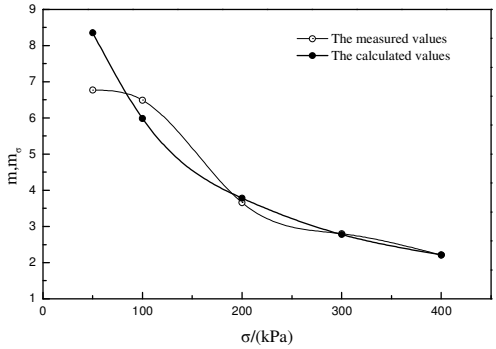


Fig.4 The curve of the measured and calculated values of stress controlling structural parameters

Where $\sigma$=stress; $m$=the measured stress controlling structural parameter; $m_\sigma$ = the calculated stress controlling structural parameter; $\delta$ = relative tolerance.

Fig.4 shows the curve of the measured and calculated values of stress controlling structural parameters. As can be seen from Table 2 and Fig.4 the measured and calculated stress controlling structural parameter values relative tolerance is lager at lower stress, when the stress is 50kPa, the relative tolerance is the biggest one. With the increase of stress, the relative tolerance gradually decreases and tends to 0. The measured results and the calculated results have a higher agreement, and explain the applicability of the Gunary Model. The measured and calculated stress controlling structural parameter value all decrease with the increase of stress, the measured values present in a form of anti-S-curve diminishing, the calculated values present in the form of a concave curve diminishing with a gradually decreasing rate.

With the increase of stress, the calculated parameter is decreasing regularly, the author finds that the calculated stress controlling structural parameters can be described by the two-parameter liner reciprocal function, and the specific form as shown in formula(7).

$$m_\sigma = \frac{a}{1+b\sigma} \tag{7}$$

Where $a$, $b$ = the test parameters.

Using formula (7) represents the relationship between the calculated stress controlling structural parameter and stress, and finishing the test data as shown in Fig.5.

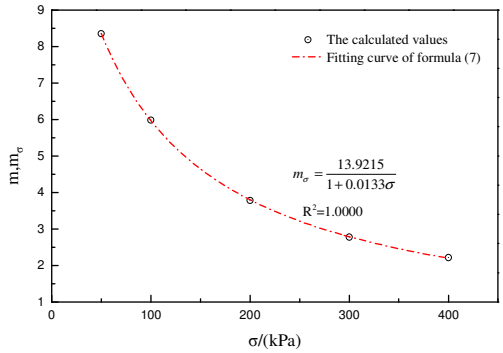

Fig.5 The fitting curve of the relationship between the calculated stress controlling structural parameter and stress

Fig.5 shows the fitting curve of the relationship between the calculated stress controlling structural parameter and stress. As can be seen from Fig.5, the fitting correlation coefficient is 1.0, the fitting accuracy is very high, and nearly perfectly correlate, indicating that the relationship between the calculated stress controlling structural parameter and stress can be described by the two-parameter liner reciprocal function.

## Summary

The Gunary Model from is applicable to characterize the soil stress-strain relationship, the parameter $c$ controls the fitting accuracy and decides the curve shape. By using the stress-strain expression of the Gunary Model, this paper finds the calculated stress controlling structural parameter and stress meets the two-parameter linear reciprocal function form.

**Keywords:** Aeolian sand; static strength; confining pressure; cyclic loading; consolidation ratio; initial static deviator stress

**Abstract.** Aeolian sand is one commonly used subgrade filling in Xinjiang Oasis-desert region, engineering practices also proved its applicability as subgrade filling. In order to find the law of Aeolian sand subgrade static strength after cyclic loading, the paper studied the static strength of Aeolian sand before and after cyclic loading through the dynamic and static triaxial tests. It is concluded that the greater cyclic loading is, the more Aeolian sand static strength peak decreases. When cyclic loading is small, the bigger confining pressure and consolidation ratio are, the static strength peak increases more after cyclic loading. The bigger initial static deviator stress is, the more Aeolian sand static strength peak reduces. The frequency of cyclic loading has little effect on static strength. In order to keep the stability of low embankment, we should restrict overload , ensure subgrade and foundation consolidation adequately, use gravel or geosynthetic materials to package edge of roadbed, so as to increase confining pressure. The research results can provide reference for the design and construction of Aeolian sand low subgrade in Xinjiang Oasis-desert region.

## Introduction

Highway will appear large settlement under long time traffic cyclic loading, this will lead to a lot of diseases of pavement, especially for the low embankment expressway. To this kind of expressway, dynamic stress which is transmitted to subgrade and foundation from vehicle is larger. Strength and stiffness of subgrade and foundation will reduce, the same situation to bearing capacity of foundation. These will lead to more larger settlement and early damage of pavement structure. The research of low embankment expressway is carried out in Xinjiang Oasis-desert region now. The static strength of Aeolian sand before and after cyclic loading is one of the important works to the highway whose subgrade is filled with Aeolian. We can take effective measures to prevent the road early damage after we know the strength change of Aeolian. For the strength change of geotechnical materials after the cyclic loading, many scholars have carried on the related research work. Saturated soft clay shear strength changes after cyclic loading was studied by Wang[1]. The degradation of undrained shear strength of undisturbed and remolded marine clay after cyclic loading was studied by Wang[2]. The degradation of static shear strength of undisturbed silt soft clay in the Yangtze estuary after complex cyclic loading was studied by Luan[3]. As to the degradation static strength of Aeolian sand before and after cyclic loading, there is almost no research focusing on it. The paper studied it through dynamic and static triaxial tests and got some laws which can be reference to the Aeolian embankment road design and construction in Xinjiang Oasis-desert.

## Laboratory test

The Aeolian sand used in the tests comes from Xinjiang Oasis-desert region. The parameters of the Aeolian sand is shown in table 1.

Table 1 Parameters of Aeolian sand

| sample | Dry density/g/cm$^3$ | optimum water content/% | the quality percentage of different size | | | | Cu | Cc |
|---|---|---|---|---|---|---|---|---|
| | | | 0.3-0.6 | 0.15-0.3 | 0.15-0.074 | <0.074 | | |
| Aeolian sand | 1.811 | 12 | 15.4 | 70.9 | 10.8 | 2.9 | 1.7 | 0.75 |

The test equipment is the hollow cylinder torsional shear apparatus(HCA) that was produced by GDS company. HCA is mainly composed of confining pressure controller, back pressure controller, inner pressure controller, pressure chamber, the axial load drive, measurement equipment, data acquisition instrument, computer etc. , the equipment can be used to the static and dynamic real triaxial shear test. HCA can applicate radial and ring load, the maximum load frequency is 2hz and the maximum axial load is 10kn. Loading waveform can be generated by the servo system, which can be sine wave, triangle wave, square wave, half sine wave and user-defined waveforms. In this paper, dynamic loading waveform is half sine wave. The stress and the strain control method can be used in static triaxial test, The paper used the strain control method.

The experiment is divided into two parts, the first part is direct to carry on the static load test. The second is carrying on a certain cycles of dynamic load tests and then carrying on the static load test[4-5]. Specific testing schemes are shown in table 2.

Table 2 Triaxial test schemes

| sample number | Confining pressure | Cyclic dynamic stress | Consolidation ratio | Load frequency | initial static deviator stress | Loading way |
|---|---|---|---|---|---|---|
| S1 | 20 | | 1 | | 0 | Carrying on static load under strain control |
| S2 | 30 | | 1 | | 0 | |
| S3 | 40 | | 1 | | 0 | |
| S4 | 20 | 20 | 1 | 1 | 0 | Carrying on static load after 5000 times cyclic loading |
| S5 | 20 | 30 | 1 | 1 | 0 | |
| S6 | 20 | 40 | 1 | 1 | 0 | |
| S7 | 20 | 20 | 1.5 | 1 | 0 | |
| S8 | 20 | 20 | 2 | 1 | 0 | |
| S9 | 20 | 20 | 1 | 1.2 | 0 | |
| S10 | 20 | 20 | 1 | 1.5 | 0 | |
| S11 | 20 | 20 | 1 | 1 | 10 | |
| S12 | 20 | 20 | 1 | 1 | 20 | |
| S13 | 30 | 20 | 1 | 1 | 0 | |
| S14 | 40 | 20 | 1 | 1 | 0 | |

Test procedure can be divided into three steps. The first step is making samples based on the maximum dry density that was gotten from the Aeolian sand compaction test, then the sample is placed on the base of the pressure chamber, in the process of placing to prevent disturbance of the sample. The second step is injecting water to pressure chamber and the sample is saturated. Then samples consolidate under different confining pressure and consolidation completion standard is back pressure volume remaining constant. The third step is applying on static load and different cyclic dynamic loading on sample. For dynamic loading samples, static load is applied on after 5000 times cyclic dynamic loading.

## Test results

Samples S1, S2 and S3 respectively consolidated under effective confining pressure 20Kpa, 30Kpa, 40Kpa, then were applied on static load directly. Static strength and strain relationships are shown in fig.1, we can see from fig.1 that static strength of S1, S2 and S3 is increasing when strain is increasing in the early stage of the load. When the strain is 2% or so, the three samples static strength reach the peak. The peak respectively are 147Kpa, 169Kpa and 186Kpa. After reaching peak, the sample structure damaged. When strain further increasing, the static strength slowly began to decrease.

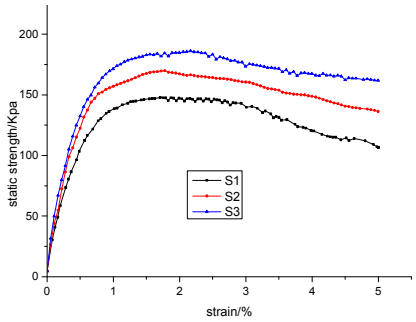

Fig.1 Relationships of static strength and strain under different size static loading

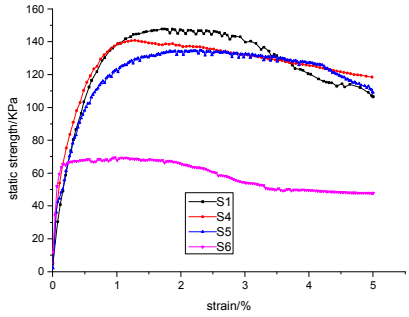

Fig.2 Relationships of static strength and strain under different size cyclic loading

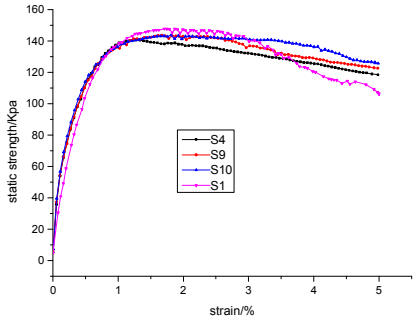

Fig.3 Relationships of static strength and strain under different cyclic loading frequency

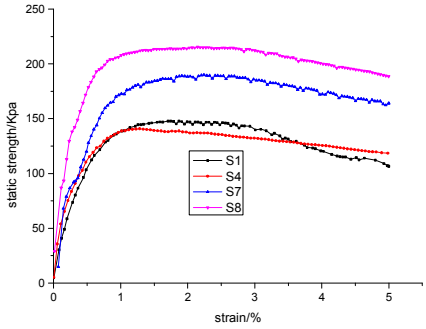

Fig.4 Relationships of static strength and strain under different consolidation ratio

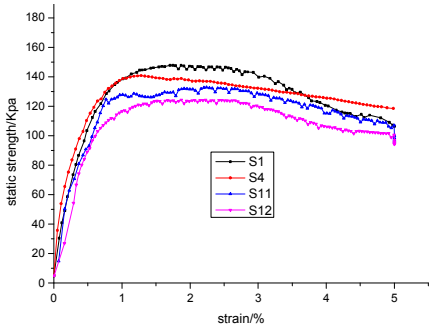

Fig.5 Relationships of static strength and strain under different initial static deviator stress

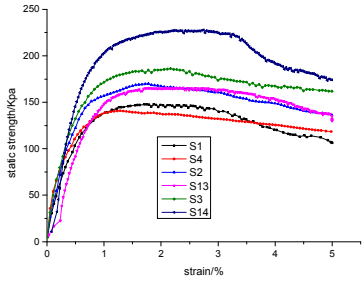

Fig.6 Relationships of static strength s and strain under different confining pressure before and after cyclic loading

Sample S4, S5 and S6 consolidated under 20kpa effective confining pressure ,then were applied on 20kpa, 30kpa and 40kpa cyclic loading for 5000 times, after that the samples were applied on static load. The results are shown in fig.2, meanwhile we compared the result with the result of S1. From fig.2, we can see that the static strength peak of S4 has little change comparing with S1, this shows that 5000 times cyclic loading of 20kpa has little influence on static strength. when cyclic loading is 30kpa, the static strength peak decreases from 147kpa to 134kpa, This shows that 5000 times cyclic loading of 30kpa has certain influence on static strength. when cyclic loading is 40kpa, the static strength peak is 70kpa, this is consistent with that S6 has a larger cumulative plastic deformation after 5000 times cyclic loading, and at the same time the sample structure is damaged. Because the dynamic stress passed from overload vehicles to Aeolian sand subgrade is bigger and it is easy to cause subgrade destruction, in order to prolong the service life of road, we should restrict overload, especially serious overload in practice.

The relationships between static strength of S1, S4, S9 and S10 and strain are shown in fig. 3. From fig. 3, we can see that when cycle loading is 20kpa and cycle loading frequency are respectively 1hz, 1.2hz and 1.5hz, the static strength after 5000 times cycle loading has little change with S1 that has no cycle loading. The static strength peak of S1, S4, S9 and S10 is about 140kpa, so it shows that cycle loading frequency has little effect on static strength as long as the size of the dynamic load is in a low level.

The relationships between static strength of S1, S4, S7 and S8 and the strain are shown in fig.4. From fig. 4, we can see that the greater consolidation ratio, the greater the static strength. When consolidation ratio is 1,1.5 and 2, the static strength peak are respectively 140kpa, 180kpa and 215kpa after 5000 times 20kpa cyclic loading. This shows that the greater consolidation ratio is, the more compact the Aeolian sand structure is, the greater the static strength peak is regardless of having cyclic loading or no. So for Aeolian sand subgrade, foundation and roadbed having fully consolidation and keeping enough compaction has vital significance to ensure the roadbed strength.

The relationships between static strength of S1, S4, S7 and S8 and the strain are shown in fig. 5. It shows in fig. 5 that the larger the initial static deviator stress is, the smaller the static strength peak is after cyclic loading. When static deviator stress are 0kpa, 10kpa and 20kpa, the static strength peak are 140kpa,132kpa and 123kpa respectively. It shows that the degradation of static strength is larger after cyclic loading when the initial static deviator stress is larger.

The relationships between static strength of S1, S2, S3,S4,S13 and S14 and the strain are shown in fig. 6. We can see from fig. 6 that the greater confining pressure is, the bigger static strength peak is when other conditions are equal. When confining pressure is 20kpa, static strength peak of S4 is slightly less than that of S1 .When confining pressure is 30kpa, static strength peak of S13 is basically equal to that of S2 .When confining pressure is 40kpa, static strength peak of S14 is greater than that of S3. It shows that Aeolian sand became more compact when confining pressure is 40kpa after 5000 times cyclic loading, so static strength peak becomes bigger.

In practice, gravel or geosynthetics is used to package edge of Aeolian sand subgrade, this increases Aeolian sand subgrade confining pressure, so Aeolian sand strength after cyclic loading will increase and the stability of subgrade is ensured.

## Conclusions

Static strength peak decreases with the increase of cyclic loading at a certain confining pressure. Aeolian sand sample structure has been damaged after 5000 times cyclic loading When cyclic loading is 40kpa and static strength peak is only 70kpa decreasing by about 50% comparing with sample applied on static load directly. So in practice, we should restrict overload to ensure subgrade stability. Cycle loading frequency has little effect on static strength as long as the size of the dynamic load is in a low level. The greater consolidation ratio is, the more compact the Aeolian sand structure is, the greater the static strength peak is regardless of having cyclic loading or no. So for Aeolian sand subgrade, foundation and roadbed having fully consolidation and keeping enough compaction have the vital significance to ensure the roadbed strength. The degradation of static strength is larger after cyclic loading when the initial static deviator stress is larger. The greater confining pressure is, the bigger static strength peak is.

**Keywords:**slope stability; Mohr- Coulomb yield condition;plastic zone; strength reduction FEM

**Abstract:** At present, there is a lot of research for slope stability, the inherent reason of slope instability is geotechnical material will get plastic deformation under load. In this paper, Mohr-Coulomb yield condition is transformed strain expressed to stress expressed.Based on this, analysis the effects that geotechnical material parameters internal friction angle φ,cohesion c and Poisson's ratiovto Mohr- Coulomb yield condition and the development of soil plastic zone.In addition, using the strength reduction FEM simulating the change of plastic zone distribution caused by change of the geotechnical materials parameters .The results show that the internal friction angle φ, cohesion c are reducted, the plastic zone expand;Increasing the Poisson's ratio ν, narrowing the slope's plastic zone;Plastic zone's different distribution is caused by different material parameters affect the yield surface.

## Introduction

In the analysis of slope stability, finite element method can overcome the disadvantage that soil hypothesis as a rigid by limit equilibrium method, considering the nonlinear constitutive relation and can be applied to any complex boundary conditions[1]. Strength reduction FEM was first proposed by Zienkiewicz[2] in 1975 is becoming a new trend. Ugai (1989) [3], Matsui and San (1992) [4], Dawson and Roth (1999) [5] all have done further research, The results show that strength reduction FEM and limit equilibrium can be made almost close to the safety factor and the critical slip surface.

The soil produces plastic deformation is the intrinsic reasons of slope's failure. So it is necessary to start from the classical elastic-plastic theory, analysis of rock and soil mechanical parameters for the development of plastic zones. In this paper ,writer deduced strain expressed Mohr- Coulomb yield condition to analysis of the effect of parameters on the yield condition .The results are verified with the strength reduction FEM.

## The strain expressed Mohr- Coulomb yield condition

**Deduction.** When the objects within a point to produce plastic deformation, strain components need to meet the conditions is called the strain expressed yield condition. The material is assumed isotropic,yield function's strain space in six-dimensional can be discussed in the three-dimensional[6]. The strain yield function can be expressed as:

$$\left.\begin{aligned} f(\varepsilon 1, \varepsilon 2, \varepsilon 3)=0 \\ f(I_1', J_2', J_3')=0 \\ f(I_1', J_2', \theta\varepsilon')=0 \end{aligned}\right\} \quad (1)$$

By the generalized Hooke's law: $\sigma_{ij}=\frac{E}{1+\nu}(\varepsilon_{ij}+\frac{\nu}{1-2\nu}\varepsilon_{ij}\delta_{ij})$ （2）

The stress tensor and the deviatoric stress tensor invariants for（3）:

The strain tensor and the deviatoric strain tensor invariants for（4）:

$$\left.\begin{aligned} I_1&=\sigma_1+\sigma_2+\sigma_3\\ I_2&=-(\sigma_1\sigma_2+\sigma_2\sigma_3+\sigma_3\sigma_1)\\ I_3&=\sigma_1\sigma_2\sigma_3\\ J_1&=0\\ J_2&=\frac{1}{2}s_{ij}s_{ij}\\ J_3&=S_1S_2S_3 \end{aligned}\right\} \quad (3) \qquad \left.\begin{aligned} I_1'&=\varepsilon_1+\varepsilon_2+\varepsilon_3\\ I_2'&=-(\varepsilon_1\varepsilon_2+\varepsilon_2\varepsilon_3+\varepsilon_3\varepsilon_1)\\ I_3'&=\varepsilon_1\varepsilon_2\varepsilon_3\\ J_1'&=0\\ J_2'&=\frac{1}{2}e_{ij}e_{ij}\\ J_3'&=e_1e_2e_3 \end{aligned}\right\} \quad (4)$$

According to the formula (3), (4) and (2), the invariants' transformation formulas between stress space and strain space is (5):

$$\left.\begin{aligned} I_1&=\frac{E}{1-2\nu}I_1'=3K\,I_1'\\ J_2&=(\frac{E}{1+\nu})^2J_2'=4G^2J_2'\\ J_3&=(\frac{E}{1+\nu})^3J_3'=8G^3J_3'\\ I_3&=(\frac{E}{1+\nu})^3J_3'-\frac{1}{3}\frac{E}{1-2\nu}(\frac{E}{1-2\nu})I_1'J_2'+\frac{1}{27}(\frac{E}{1+\nu})^3(I_2')^3 \end{aligned}\right\} \quad (5)$$

and $\theta_\sigma=\theta_\varepsilon$ ； $\mu_\sigma=\mu\varepsilon$ （6）

The stress expressed Mohr- Coulomb yield condition:

$$F=\frac{1}{3}I_1\sin\varphi+(\cos\theta_\sigma-\frac{1}{\sqrt{3}}\sin\theta_\sigma\sin\varphi)\sqrt{J_2}-c\cos\varphi=0 \quad (7)$$

The conversion formula (5) into (7) can get the strain expressed Mohr- Coulomb yield condition:

$$f=2\sin\varphi\frac{1+\nu}{1-2\nu}\varepsilon_m+2(\cos\theta_\varepsilon-\frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)\sqrt{J_2'}-\frac{1+\nu}{E}c\cos\varphi=0 \quad (8)$$

convert the formula (8) into the general form of generalized Mises yield condition:

$$\alpha' I_1'+\sqrt{J_2'}-k'=0 \quad (9)$$

which $\alpha'=\frac{1}{3}\sin\varphi\frac{1+\nu}{1-2\nu}/(\cos\theta_\varepsilon-\frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)$ $k'=\frac{1+\nu}{E}c\cos\varphi/[2(\cos\theta_\varepsilon-\frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)]$

**Analysis of generalized Mises yield condition (α', k').**In stress space, When the yield condition should be invariant of stress tensor function, can be written as follows:$F=F_1(I_1)+F_2(J_2,\theta_\sigma)$.Similarly, can also use the strain tensor invariant to describe: $f=f_1(I_1')+f_2(J_2',\theta_\varepsilon)$

Which $f_1(I_1')$ only affect hexagonal size in π plane; $f_2(J_2',\theta_\varepsilon)$ determin the shape of the yield locus in π plane.

The yield surface of Mohr- Coulomb yield condition is a cone surface of an irregular hexagon section,because the geotechnical materials in the compressed states and extended state have different strain Rhodes angle θε.

We assume that the shape of the yield surface has been determined, the impact functions on the yield surface are mainly a 'and k', the derivative of material parameters as follows:

The partial derivative of the Poisson's ratio ν：

$\partial \alpha'/\partial \nu = \sin\varphi/[(1-2\nu)^2.(\cos\theta_\varepsilon - \frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)]$

$\partial k'/\partial \nu = c\cos\varphi/[2E.(\cos\theta_\varepsilon - \frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)]$

the range of strain Rhodes angle: $-\frac{\pi}{6} \le \theta\varepsilon \le \frac{\pi}{6}$, then $\cos\theta\varepsilon - \frac{1}{\sqrt{3}}\sin\theta\varepsilon\sin\varphi > 0$,so $\partial \alpha'/\partial \nu \ge 0$，$\partial k'/\partial \nu \ge 0$.To Mohr- Coulomb yield surface ,when the Poisson's ratio ν is greater，pyramid surface of hexagonal cross-section will expand in the longitudinal and transverse in the strain space.Strain space is divided into two parts，f（εij）<0，as elastic state；f（εij）=0，the material in yield surface has begun to yield. With yield surface expand, the degree of difficulty of geotechnical materials reach yield condition increases,then the plastic zone's development will decrease.

Similarly ,the partial derivative of the rock soil cohesion c ：

$\partial k'/\partial c = (1+\nu)\cos\varphi/2E(\cos\theta_\varepsilon - \frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi) > 0$

The cohesion c is larger, the larger k' constant.Pyramid surface of hexagonal cross-section is longitudinal extending in the strain space,the yield surface expand,then the plastic zone's development will decrease.

The partial derivative of internal friction angle φ ：

$\partial\alpha'/\partial\varphi = (1+\nu)\cos\theta_\varepsilon\cos\varphi/[3(1-2\nu)(\cos\theta_\varepsilon - \frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)^2] > 0$

The internal friction angle increases, the yield surface will be expanded.The plastic zone's development will decrease.

$\partial k'/\partial\varphi = (1+\nu)\cos\theta\varepsilon(\frac{1}{\sqrt{3}}\tan\theta_\varepsilon\sin\varphi)/2E(\cos\theta_\varepsilon - \frac{1}{\sqrt{3}}\sin\theta_\varepsilon\sin\varphi)^2$, when $\frac{1}{\sqrt{3}}\tan\theta_\varepsilon\sin\varphi > 0$, $\varphi < 19.47°$, the φ is larger, the larger k constant,pyramid surface of hexagonal cross-section is longitudinal extending in the strain space,the yield surface expand.Then the plastic zone's development will decrease. Contrarily ,when$\varphi > 19.47°$,the plastic zone's development will increase.

**The basic idea.** Based on strain expressed Mohr- Coulomb yield condition, this paper has theoretically analyzed the effect the Poisson's ratio ν, internal friction angle φ, cohesion c to yield surfaces and plastic zone's development[7].Combine a classic example of slope stability analysis ,using the strength reduction FEM to validate the analysis[8,9].

## Example and numerical simulation

**Parameters of the model .** A homogeneous slope is shown in figure 1, height of slope H=10.0m,soil bulk density γ=20kN/m3,cohesion c=12.38kPa, elastic modulus E=100Mpa,take a different value of internal friction angle $\varphi$ as 10°,15°,20°,25°,30°. Reduct the shear strength parameters c and φ[10].

$$\tau_r = \frac{\tau_f}{F_r} = \frac{\sigma\tan\varphi + c}{F_r} = \sigma\frac{\tan\varphi}{F_r} + \frac{c}{F_r},\ \varphi_r = \arctan(\frac{\tan\varphi}{F_r}),\ c_r = \frac{c}{F_r} \quad (10)$$

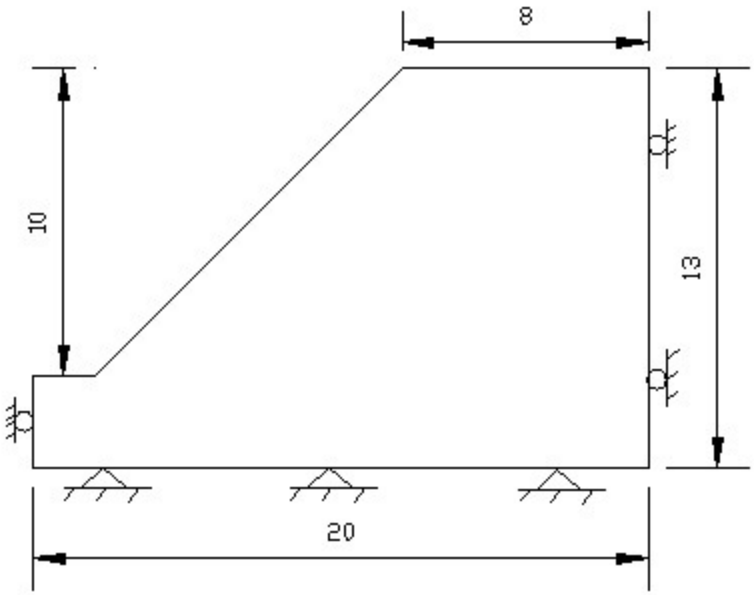

Fig.1 Computational geometry model

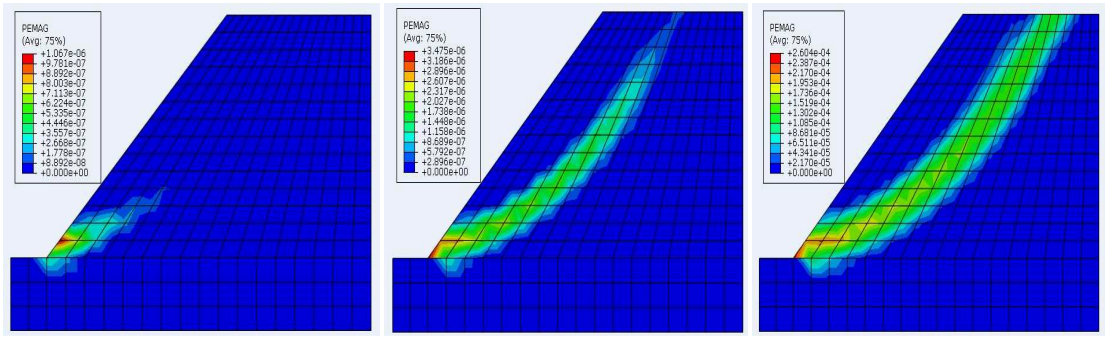
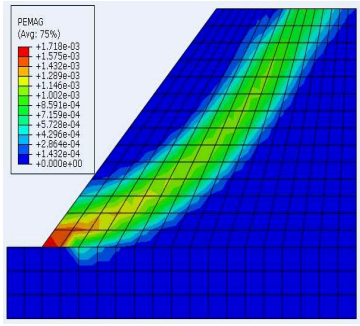
**Effect of friction angle and cohesion changes on the plastic zone development**. Strength reduction principle is gradually reducting the soil shear strength c and $\varphi$ according to formula (10) in a certain ratio.With increasing the reduction factor Fr， the plastic zone development increased significantly.When the friction angle is 20 °， The plastic zone of slope distribution shown in Figure 2.when $\varphi$ gets other values, development of plastic zones are in the same law.



$F_r$=0.94 $F_r$=0.98 $F_r$=1.00

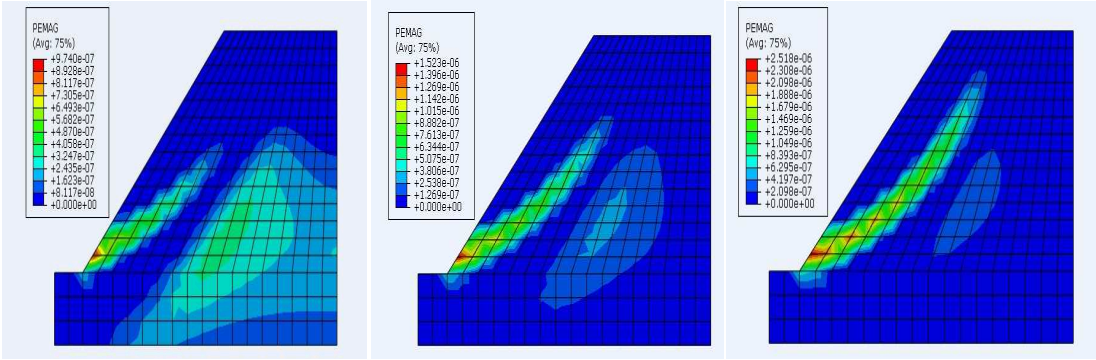


$F_r$=1.05

Fig.2 The plastic zone distribution

**Effect of Poisson's ratio ν on the plastic zone development.** The plastic zone distribution with Poisson's ratio ν variation in internal friction angle 25 °,shown in figure 3.From the plastic zone distribution， the influence of Poisson's ratio ν for the development of the plastic zone is very

obvious，With the increase of Poisson's ratio ν, plastic zone decreases. when φ gets other values, development of plastic zones are in the same law.



v=0.25 v=0.29 v=0.33

Fig.3The plastic zone distribution of different v values when φ=25°

## Conclusion

In this paper, using the classical elastic-plastic mechanics theory, convert stress expressed Mohr- Coulomb yield condition to strain expressed Mohr- Coulomb yield condition, then get the effects that the parameters of geotechnical materials Poisson's ratio ν, cohesion c and internal friction angleφ to Mohr- Coulomb yield surface. With increasing the reduction factor Fr (so the cohesion c and internal friction angle φ decrese),the plastic zone development increased significantly. With the increase of Poisson's ratio ν, plastic zone decreases. Results of numerical simulation are consistent with the theoretic analysis. Therefore, the plastic zone distribution of slope is internal caused of geotechnical material parameters' effect on the yield surface . For the slope with different characters of soil , the distribution of plastic zone development must be different.This research has guiding significance for practical engineering applications

**Keywords:** water content, coal, permeability, slippage effects

**Abstract.** To obtain the effects of water content on the permeability of coal, briquette specimen were obtained from Wulong Mine, Liaoning Province. The permeability of the air drying, bounding water and saturating specimens were tested with self-made equipment respectively, and the effects of water content on permeability for coal were studied. The results showed that: (1)The permeability of specimens decreases with confining pressure increasing, and the air drying and bounding water specimens take on obvious slippage effect. However the saturated specimens never take on slippage effects. It is because the channels of saturated coal sample are occupied by water. When the gas goes through specimens, gas never is absorbed. Collision between gas and the channel wall decreases, and the slippage effect disappears. (2) With water content increasing, the permeability of specimens decreases. (3)The permeability of specimens increases when pore pressure increases.

## Introduction

Scientific prediction of gas flow and aggregation in coal seams is the key issue to prevent the disaster of methane [1-3]. Permeability of coal, affected by stress, temperature and many other factors, is a pivotal parameter to predict gas flow in coal seams.

C.H. Zhang[4] carried out experiments of gas flow on coal and the effects of pore pressure on coal permeability and slippage was analyzed. Y.J. Yu[5] studied the effects of temperature and failure on permeability. Z.P. Meng[6] explored coal's permeability under whole stress-strain curves. J. Xu[7] researched permeability of coal containing gas under varying temperatures and stress. Coal samples containing gas were tested by Z.H. Zhu[8], and the permeability was studied by varied stress path. The effects of coal matrix shrinkage on permeability were studied by S.J. Peng[9]. The effects of temperature and the average effective stress on coal permeability was analyzed by Z. Wang[10]. The effects of ultrasonic functions for coal with low permeability on desorption was tested by X.C Xiao [11].

Coal always suffers from groundwater. It is of great significance to study the effects of groundwater on permeability of coal for prediction of the gas flow and accumulating laws. However, the present researches rarely are reported.

In this paper, the briquette specimens were obtained from Fuxin Mine in Liaoning Province. The self-made tri-axial experiment setup of coupled deformation and gas flow was employed to test the permeability of the drying, bounding water and saturating samples under varying confining pressure and pore pressure. The effects of water content on permeability for coal were studied, and the results are provided to help the prediction of gas flow.

## Experiment

**Preparation** The raw coal was obtained from Fuxin Mine in Liaoning Province. Due to the heterogeneity of raw coal, the briquette specimens were used in the experiment. The raw coal was powdered less than the size of 0.15 mm. The coal powder was mixed with proper water. Then the coal powder with water was put in the forming mould, and 25 ton pressure was kept 20 min by testing machine. As a result 6 standard samples with the size of Φ 50 mm x 100 mm were made. The porosity of the samples was about 14%. The samples were kept 48 hours in a drying baker at the temperature of 100. After that 2 drying samples, 2 samples with bounding water and 2 saturating samples were

made respectively. The average water content for every group was 0.01%, 3.6% and 9.9%, respectively.

**Experimental Equipment and Experimental Procedures** In this paper the self-made tri-axial stress-seepage equipment was used. The equipments includes true triaxial permeameter, test hydraulic pump, digital pressure gauge, regulating pressure valves, six-port valve, pipes, nitrogen and energy storage tank, et al. And it can be seen in Figure 1.

The basic steps can be followed as: First, the prepared standard coal sample was put into the tri-axial stress gripper, and was sealed with heating shrinkable tube. Second, confining pressure was constantly applied, and then pore pressure was applied (nitrogen). When that was stable he gas flow was measured and the permeability was calculated according to the following formula:

$$k = \frac{2p_0 Q\mu L}{A(P_1^2 - P_2^2)} \quad . \tag{1}$$

Where, $k$ is permeability, $\mu m^2$; $P_0$ is standard atmospheric pressure，MPa; $P_1$ is gripper inlet pore pressure，MPa; $P_2$ is gripper outlet pore pressure ;$L$ is the length of the coal samples, in mm; $Q$ is standard atmospheric pressure(20°) air flow, in ml/min; $\mu$ is the gas dynamic viscosity coefficient, in Pa·S; $A$ is section area of coal samples，$mm^2$.

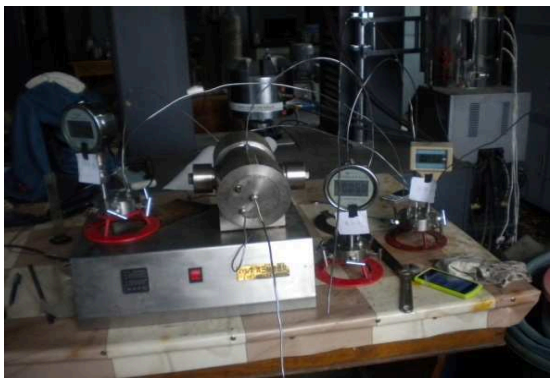

**Fig.1** Permeability test equipment
(Real Photo of Permeability Apparatus：Gas permeability equipment )

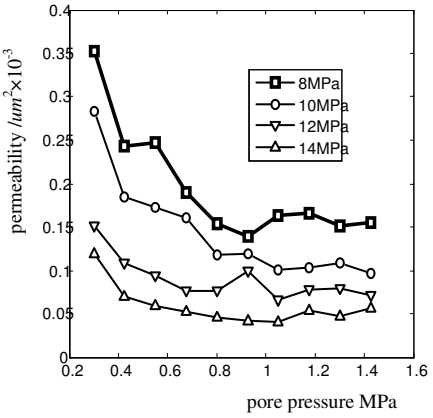

**Fig.2** Permeability of dried coal

**Experimental Results and Analysis** The average permeability of the three different groups under varying confining pressure and pore pressure is obtained through the experiment. The results are shown from Fig.2 to Fig.4.

Fig.2 is the permeability of the dry coal sample under varying confining pressure and pore pressure. It can be seen from Fig.2 with the confining pressure increasing the permeability decreases. While with pore pressure increasing, the permeability initially decreases then increases slowly. That approximately takes on a "V" curve, and it is so called *slippage effects* (or *Klinbenberg effects*). In Fig.3 the permeability of bounding water specimen is seen under varying confining pressure and pore pressure. It can be seen from Fig.3 that the relationship between pore pressure and permeability is similar with that of drying coal samples. Namely that also takes on slippage effects.

Comparing Fig.2 with Fig.3, it can be seen that the permeability of bounding water specimen is significantly lower than that of drying specimen. It is mainly because that the existence of bounding water occupies partial space of pores or fracture in specimen, and the flow channel becomes narrow. The slippage effects can be described by Klinbenberg equation as:

$$k = k_0(1 + \frac{b}{p}) \quad . \tag{2}$$

Where, $k_0$, $b$ are fitting coefficient, determined by fitting the experimental data, $p$ is pore pressure.

Eq.2 is employed to fit the experimental data in Fig.2and Fig.3, and the fitting results are listed in Table 1.It can be seen from Table.1 that the relationship between pore pressure and permeability for drying and bounding water specimens can be well fitted by.Eq.2.

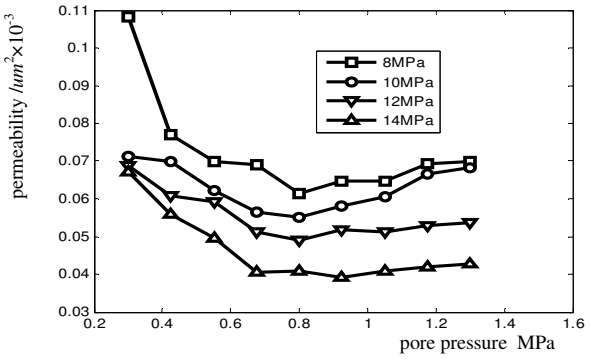

**Fig.3** Permeability of bounding water specimen

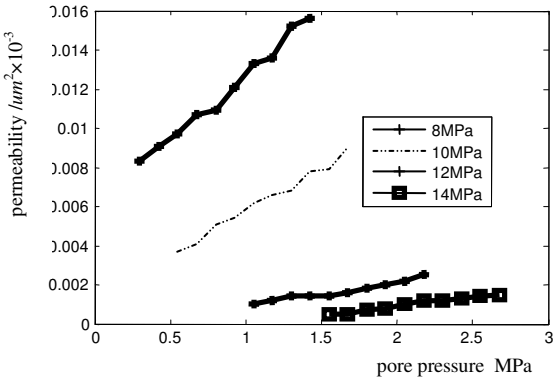

**Fig.4** Permeability of saturating coal sample 1

The relationship between pore pressure and permeability of saturated specimens under varying confining pressure can be seen in Fig.4. It can be seen from Fig.4 that the permeability gradually increases when port pressure increases, and the slippage effects disappear. The main reason is the channel in saturated specimens is occupied by water, when the gas goes through, the gas can't be adsorbed by the channel wall. As a result, the slippage effects disappear. The permeability of saturated water specimens increases when pore pressure increases.

**Table.1** Fitting results for drying, bounding water and saturating specimens

| groups | confining pressure/MPa | $k_0$ | $k_1$ | $b$ | correlation coefficient |
|---|---|---|---|---|---|
| drying | 8 | 0.085 | / | 0.897 | 0.957 |
| | 10 | 0.046 | / | 1.496 | 0.980 |
| | 12 | 0.050 | / | 0.548 | 0.906 |
| | 14 | 0.023 | / | 1.040 | 0.891 |
| bounding water | 8 | 0.050 | / | 0.290 | 0.874 |
| | 10 | 0.058 | / | 0.062 | 0. 849 |
| | 12 | 0.045 | / | 0.152 | 0.910 |
| | 14 | 0.030 | / | 0.354 | 0.951 |
| saturating | 8 | / | 0.637 | 0.561 | 0.994 |
| | 10 | / | 0.612 | 0.518 | 0.988 |
| | 12 | / | 1.341 | 0.653 | 0.986 |
| | 14 | / | 0.974 | 0.576 | 0.975 |

It also can be seen from Fig.4 that the permeability of saturated specimens decreases significantly. That is mainly because that free water occupies partial space of pores and fractures and the gas flow is blocked. With confining pressure increasing, the permeability of saturated specimens decreases. When pore pressure increases the permeability increases as well. Obviously the permeability of saturated specimens is decided by confining pressure. It is because under the effective confining pressure the coal has a tendency of being pressed, which makes pores space smaller, and the permeability decreases. The relationship between effective confining pressure and permeability can be written by:

$$k = k_1 \exp(-a\sigma') . \quad (3)$$

*Where,* $k_1$, $a$ are fitting coefficient, respectively, $\sigma'$ is effective confining pressure.

Eq.3 is employed to fit the experimental data in Fig.4, and the fitting results are listed in Table 1.

It can be seen from Table.1 that the relationship between permeability and effective confining pressure can be well fitted by Eq.3. In other words, the permeability of saturated specimens takes on negative exponent form with effective confining pressure.

## Conclusions

In this paper effects of water content and confining pressure on the permeability are studied by tri-axial seepage experiments, and our main conclusions include:

(1)The permeability of specimens decreases with confining pressure increasing, and air drying and bounding water specimens take on obvious slippage effect. However the saturated specimens never take on slippage effect. It is because the channels of saturated coal sample are occupied by water. When the gas goes through specimens, gas never is absorbed. Collision between gas and the channel wall decreases, and the slippage effect disappears.

(2) With water content increasing, the permeability of specimens decreases.

(3)The permeability of specimens increases when pore pressure increases.

(4) The permeability of saturated specimens takes on negative exponent form with effective confining pressure.

# The application of cubic spline interpolation function in determining rock rheological long-term strength

Moli Zhao[a] , Qiangyong Zhang[b]

Geotechnical and Structural Engineering Research Center，Shandong University，Jinan，Shandong 250061，China

[a]hello-zml@163.com, [b]qiangyongz@sdu.edu.cn

**Keywords:** Rock rheological mechanics; Rheological long-term strength; Isochronous curve method; Cubic spline interpolation; Maximum deviation point

**Abstract.** The rheological long-term strength is determined according to the triaxial rheological test data of diabase at the dam area of Dagangshan Hydropower Station. Firstly, based on the stress-strain isochronous curve method and connected the test points with cubic spline interpolation function, the maximum deviation point in the long-term interval is determined as the turning point and established the long-term strength by nonlinear least square method. The results show that this method is consistent with the other methods. Finally, the advantage and disadvantage of this method is analyzed. This method can overcome the randomness of artificial selecting the turning points. Therefore, maximum deviation point method is relatively a reasonable and effective method to determine the rheological long-term strength of rock.

## Introduction

Long-term strength as a time effect parameter is one of the important parameters in the long term stability analyses. When the stability of geotechnical engineering is calculated, the long-term strength will always be considered as an important index[1,2]. In geotechnical engineering with long term loading, the actual stress must less than the long-term strength in order to limit the rock creep. The long-term strength of rock is the maximum stress of rock with long time loading and no destruction.

Generally, the long-term strength is calculated by the triaxial rheological tests[3]. Direct method and indirect method are two mainly methods to determine the value of long-term strength[4]. Chen[5] proposed the third yield value theory, which is a popular method to determine the value of long-term strength using stress-strain isochronous curves. Li[6] obtained the long-term value used three method they are isochronous stress strain cluster method, the relationship between steady state creep rate and stress, crash time with damage stress in fractures and creep loading pressure.

However, it is artificial that use the method of isochronous stress strain cluster to obtain the long-term strength through selecting the turning points. The artificially selecting the turning point are daunted in some papers[7,8]. Then, in this paper, the cubic spline interpolation function and calculating the maximum deviation points method are used to obtain the turning points. This method can overcome the randomness of artificial selecting the turning points.

## Fundamental principles

In order to obtain the long-term strength of diabase with triaxial loading, Dagangshan hydropower bedrock diabase triaxial rheology test data are used. The cylinder diabase specimens have diameter of 50mm and high 100mm. The creep tests were carried out by using rock servo-controlled triaxial rheology equipment RLW-1000KN with 20±1°C room temperature. For diabase specimens, the triaxial creep tests were performed under the condition of confining pressures of 10MPa and 20Mpa. During the creep tests, pre-determined multi-step loading stress levels were applied in steps. Fig.1-2 show the two kinds of tests axial creep curves with specific confining pressure. Fig.3-4 are the isochronous spline cluster of diabase under multi-stage axial loading at confining pressure 10MPa and20MPa.

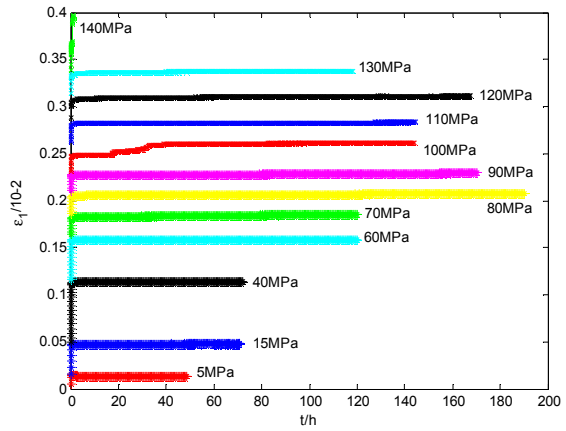

Fig.1 Axial creep curves of jointed diabase under multi-stage axial loading at confining pressure of 10MPa

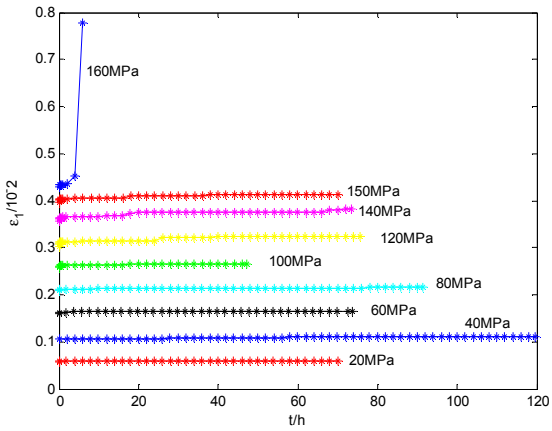

Fig.2 Axial creep curves of diabase under multi-stage axial loading at confining pressure of 20MPa

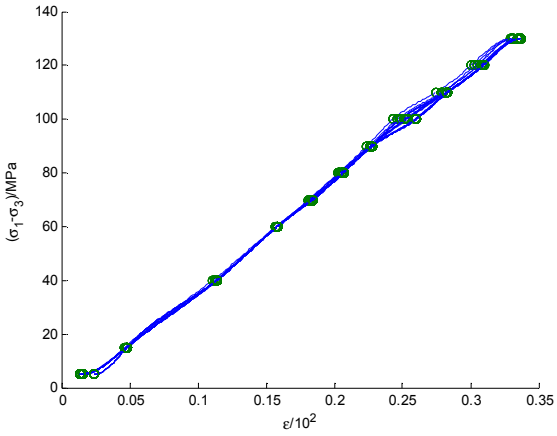

Fig.3 Isochronous spline cluster of jointed diabase under multi-stage axial loading at confining pressure of 10MPa

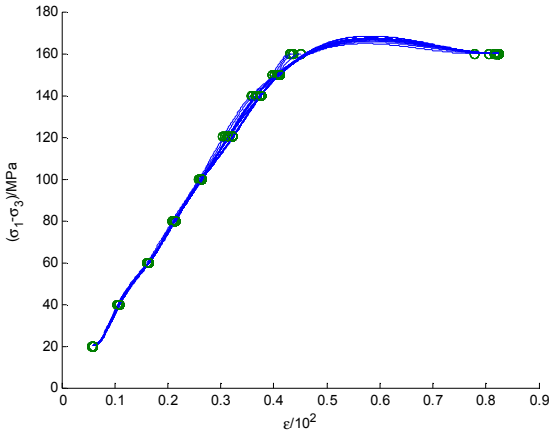

Fig.4 Isochronous spline cluster of diabase under multi-stage axial loading at confining pressure of 20MPa

**The range of Long-term strength**

From Fig.3 with the differential stress increasing at confining pressure of 10MPa, it is obtained that the increase rate of strain with differential stress more than 90MPa is bigger than the differential stress in 0-80MPa. Hence, under the confining pressure of 10MPa the value of long-term strength added the confining pressure must be in the range [100, 110] MPa. At the confining pressure of 20MPa the value of long-term strength added the confining pressure must be in the range [120,140] MPa. Because the creep property of the rock are strongly linked with the stress value, the stable creep or acceleration creep will be appear when the axial loading increased to a limited value of stress. The range of long-term strength using this method is coincidence with the method unstable creep criterion. So, the range will be used to get the third yield point.

**Calculating the Long-term strength value**

Using the data of the tests at the confining pressure of 10MPa and 20MPa, the cubic polynomials are obtained using the cubic spline interpolation method. Then, the maximum deviation point in the range of long-term strength will be found as the turning point. Supposing the function of the cubic polynomial is $y=f(x)$ and $a$, $b$ are the x-axis coordinate of the internal endpoint. So the maximum deviation point is the point on the curve of the cubic polynomial in the range, which has the maximum distance from the points on the line to the line AB. Fig.5 shows the geometric relationship of the maximum deviation point. The x-axial coordinate of the maximum point can be obtained using

$$f'(c)=\frac{f(b)-f(a)}{b-a}. \tag{1}$$

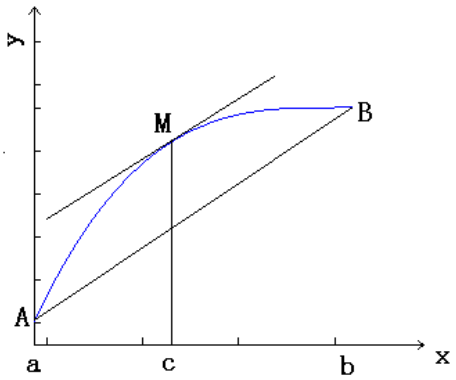

Fig.5 Maximum deviation point M

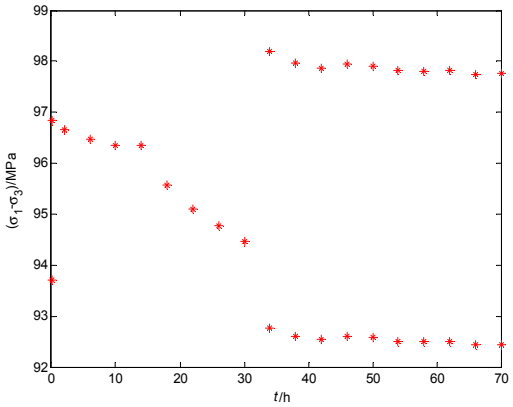

Fig.6 Maximum deviation points of diabase under multi-stage axial loading with confining pressure of 10MPa in ($\sigma_1$-$\sigma_3$)-t figure

From the results of calculation, not all ranges have only one maximum deviation point. Some ranges have two maximum deviation points. Because the function is cubic polynomial, in the case of $x\in[a, b]$ with $f''(x)=0$ , the range will has two deviation points as in Fig.6. If the range has two deviation, we will choose the lower stress value as the established maximum deviation point. The exponential equation (2) is used to determine the long-term strength value

$$\sigma = A + B\exp(-at) \tag{2}$$

Where A, B are the undetermined coefficient. So, the stress $\sigma$ reaches $\sigma_\infty$ with the time $t$ tending to positive infinity. Then the equation (2) can be expressed as

$$\sigma = \sigma_\infty + (\sigma_0 - \sigma_\infty)\exp(-at) \tag{3}$$

Where $\sigma$ is the differential stress of the maximum and minimum principle stress. Fitting the maximum deviation points with nonlinear least square method, the undetermined coefficient and $\sigma_\infty$ can be found. The value of $\sigma_\infty$ is the long-term strength of the rock with respect to the corresponding confining pressure. At confining pressure 10MPa, the long-term strength $\sigma_\infty$ is 103.5088MPa, the creep fracture strength $\sigma_f$ is 150MPa and $\sigma_\infty/\sigma_f$ =0.69. At confining pressure 20MPa, the long-term strength $\sigma_\infty$ is 124.94MPa, the creep fracture strength $\sigma_f$ is 180MPa and $\sigma_\infty/\sigma_f$=0.693.

## Comparison analyses with different method

Table 1 gives the data comparison of various methods to determine the long-term strength. It is demonstrated the long-term strength obtained with unstable creep criterion is lower than the value with other methods. The reason of this phenomenon is the value of the long-term strength with unstable creep criterion equaling to the stress of the first point in the range. While the value of the long-term strength with the isochronous stress strain method and the maximum deviation point method in this paper equaling to the stress of the turning point in the range. Considering the limitation of the test, it is impossible to divide the stress stage very closely. Therefore, the unstable creep criterion is more conservative and the value is more lower than other methods. We also find that the value of long-term strength with deviation point method is approximately with the value used by isochronous stress strain method. Deviation point method making use of the cubic spline interpolation function to fit the test data which can keep the smooth and continuity of the whole system. This method can overcome the randomness of artificial selecting the turning points. Even though, sometimes we will get two deviation points in the range. In order to the safety of engineering, it is reasonable to choose the lower value as the deviation point. So the deviation point method is a reliable method to acquire the value of long-term strength.

Table 1 Comparison of various methods to determine the long-term strength

| Methods | | Confining pressure/MPa | |
|---|---|---|---|
| | | 20MPa | 10MPa |
| Isochronous stress strain method | $\sigma_\infty$/MPa | 124.4 | 104.2 |
| | $\sigma_\infty/\sigma_f$ | 0.691 | 0.695 |
| Unstable creep method | $\sigma_\infty$/MPa | 120 | 70 |
| | $\sigma_\infty/\sigma_f$ | 0.667 | 0.467 |
| Volume method | $\sigma_\infty$/MPa | 124 | 50 |
| | $\sigma_\infty/\sigma_f$ | 0.689 | 0.333 |
| Maximum deviation point method | $\sigma_\infty$/MPa | 124.9 | 103.5 |
| | $\sigma_\infty/\sigma_f$ | 0.693 | 0.69 |

## Conclusions

A method for determining the long-stem strength value is presented in order to overcome the randomness of artificial selecting the turning points. This maximum deviation point method can be obtained the long-term strength value using the triaxial creep test data at different confining pressure. This method is easily programming and standardizing. From the results of calculation, the value of long-term strength with deviation point method is approximately with the data obtained by isochronous stress strain method. The long-term strength value with unstable creep criterion is lower than the value with other methods. From the results we can see the deviation point method is a reliable method to determine the value of long-term strength.

**Keywords:** Soft foundation, Shear strength, Vacuum preloading, Construction technology

**Abstract.** On the basis of engineering project in coastland, this article analyzes the construction technology and reinforcement mechanism of vacuum preloading reinforces soft soil foundation. By indoor soil test of Reinforcement of soil before and after processing, comparing the change of the physical and shear strength index, verify vacuum preloading method underwater is effective means in handing soft ground and provide some experience for regional development and promotion of underwater application of vacuum preloading technology.

## Introduction

With the development of high heavy buildings in coastal cities, Traditional foundation treatment methods cannot satisfy the requirement of engineering practice, Some composite foundation treatment methods and new foundation treatment technology have been applied in engineering practice. Composite foundation treatment method is not permutation and combination of simple foundation treatment method. It needs reasonable combination to achieving the goal of 1+1>2. The soft soil foundation vacuum preloading underwater is one of composite foundation treatment technology. It could quicken the progress of soil consolidation and strength, reducing project duration, saving material and cost of investment. In order to develop and disseminate vacuum preloading underwater technology, this article combining an engineering example in the coastal area, analyze the application problems of vacuum preloading underwater technology handing soft ground to provide some experience for construction technology and design of vacuum preloading underwater in the coastal areas.

## Project Overview

One construction sites being high-rise and super-tall residential groups, locate one provinces and cities area, belonging to coast accumulation landforms. Proposed projects main building is 12~33 layers, above the ground height being 48~100m, setting 2 layers basement. This project ±0.00 height is 4.9m, the basement floor bottom elevation being -5.6m, cushion layer thickness being 0.2m, the upper structure with frame-shear wall or frame shear wall structure. The primordial terrain belong coast accumulation landforms and now formed by man-made. The land form is flat and the site leveling elevation is 5.9m. The field southwest, southeast and northeast still exist surface water for a long time, surface water depth being about 1.00m. In view of silt soft soil layer which appeared saturated flow state is thick of 0.00m~20.10m has widespread distribution in this area and the overlying filling being owe consolidation soil, for reducing the adverse effects of consolidation settlement which occurred in the soft soil layer in the stage of the project being completed. So this silt soft soil layer site will use vacuum preloading underwater method to reinforce foundation.

From top to bottom soil name and lithology abased on drilling results are shown in table 1.

**Table 1. The name, Thickness and Status of Soil Layer**

| Number | Code | Soil Name | Thickness (m) | Geotechnical Condition |
|---|---|---|---|---|
| ① | $Q_1^{ml}$ | Artificial Filled Soil | 0.50~8.60 | Loose State |
| ② | $Q_2^{ml}$ | Artificial Reclaimed Soil | 0.50~14.00 | Saturation and Loose State |
| ③ | $Q_2^{mc}$ | Sludge | 1.40~18.80 | Saturation and Flowing Plastic |
| ④ | $Q^{el}$-1 | Clay | 0.70~4.80 | Saturation and Plasticity |
| ⑤ | $Q^{el}$-2 | Gravelly Sand | 0.80~5.95 | Saturation and Slightly Less Dense |
| ⑥ | $Q^{el}$-3 | Gravelly Cohesive Soil | 1.00~5.70 | Saturation and Hard Plasticity |
| ⑦ | $\gamma_4$ | Completely Weathered Granite | 0.70~12.70 | Earthy |
| ⑧ | $\gamma_3$ | Intensely Weathered Granite | 0.15~15.50 | Soil Clip Pieces |
| ⑨ | $\gamma_2$ | Moderately Weathered Granite | 0.50~5.60 | Core Into Earthy |

## The Construction Process

Place the sand blanket after site clearing , make the curtain of construction clay and drive plastic drainage plate (Type B plastic drainage plate of the SPB100 series, section size 4’100mm),layout vacuum lines (PVC outer membrane type filter tubes, pipe diameter>50mm), inbuilt vacuum probe, inbuilt monitoring devices, excavation pressure membrane channel, pave earthwork cloth, vacuum membrane, fill the cofferdam and impoundment while evacuating (pour the water being pumped into the cofferdam, forming constant water load), after prepressing the load 90 days, go on evacuating if the degree of consolidation can not meet the requirements, otherwise, unloading, completion and acceptance can be performed.

## Reinforcement Mechanism of Vacuum Preloading Underwater

Reinforcement mechanism of vacuum preloading have three point. The first point is that the load coming into thin film above is equal to the load coming into inside and outside differential pressure; The second point is that the underground water level lower, additional stress increasing, couple with additional pressure of foundation soil increasing. The third point is that closed bubbles discharge, the permeability of soil increasing. Under positive pressure, saturated soil has a small number of closed bubbles which have plugged gap to reduce the permeability of soil, speeding up the consolidation process. In this project, vacuum conditions need to extract a large number of groundwater, together with auxiliary seal measures of membrane, like membrane ditch stored water together, enclosed sheet pile wall stored and so on. Membrane water storage can play a role of sealing membrane to ensure the membrane under vacuum degree; it also could have the effect of preloading load. The actual load is equal to the membrane under vacuum preloading load and the sum of membrane water pressure load. In vacuum load and membrane water pressure load, pore water was ruled out slowly and the volume decrease slowly, foundation consolidation deformation, and the same time, with the super hydrostatic pressure disappearing gradually, effective stress increase gradually, the strength of the foundation soil increasing gradually. Like this using water as extraction by the preloading load, could avoid using large material stack, reducing the construction cost greatly, getting on economic and practical effect.

**Analysis of Indoor Soil Test Results Before and After Processing**

The project had indoor geotechnical experiment for mud soil before processing and made an evaluation of the physical and mechanical properties of soil. According to the national standard «Standard for soil test method» (GB/T50123-1999), this test takes with 21 pieces of undisturbed soil sample. Test results are shown in Table 2.

**Table 2. Mud Soil Before Processing Physical and Mechanical Properties Statistical Table**

| Items | Min | Max | Average Value | Standard Deviation | Coefficien of Variation | Correction Factors | Standard Values |
|---|---|---|---|---|---|---|---|
| Water Content $w$ (%) | 52.40 | 71.30 | 60.90 | 6.140 | 0.10 | 1.039 | 63.200 |
| Density $\rho$ (g/cm$^3$) | 1.550 | 1.670 | 1.620 | 0.034 | 0.021 | 1.008 | 1.63 |
| Proportion $G$s | 2.660 | 2.690 | 2.670 | 0.009 | 0.003 | 0.999 | 2.670 |
| Void Ratio $e$ | 1.406 | 1.938 | 1.660 | 0.150 | 0.090 | 1.035 | 1.718 |
| Liquid Limit $w_L$ (%) | 42.70 | 54.00 | 47.50 | 3.960 | 0.083 | 1.030 | 48.90 |
| Plastic Limit $w_P$ (%) | 25.10 | 31.30 | 27.60 | 2.098 | 0.076 | 0.973 | 26.90 |
| Plasticity Index $I_P$ | 17.60 | 24.20 | 19.90 | 1.979 | 0.100 | 1.038 | 20.60 |
| Liquidity Index $I_L$ | 1.530 | 1.790 | 1.670 | 0.080 | 0.048 | 1.018 | 1.700 |
| Coefficient of Compressibility $a_{1\text{-}2}$ ( $MP_a^{-1}$ ) | 1.060 | 1.950 | 1.320 | 0.306 | 0.232 | 1.099 | 1.450 |
| Compression Modulus $E_{1\text{-}2}$ ($MP_a$ ) | 1.500 | 2.500 | 2.100 | 0.318 | 0.154 | 0.934 | 1.900 |
| Internal Friction Angle $\varphi$ ($^0$) | 2.000 | 4.200 | 3.100 | | | | |
| Cohesive Force $c$ ($kP_a$ ) | 2.000 | 5.000 | 3.500 | | | | |

In this field, mud soil adopt vacuum joint impoundment preloading to reinforce, According to the national standard «Standard for soil test method» (GB/T50123-1999), this test takes with 21 pieces of undisturbed soil sample. Test results are shown in table 3.

From table 2 and table 3 above it can be seen that the natural water content of processed mud soil detected in the field has decreased 3.8% in the measuring depth, void ratio decreased 2.56% liquidity index decreased 3.6%, coefficient of compressibility decreased 10.34%, modulus of compression increased 5.2%, cohesion increased 47.7%, illustrating that this field's mucky soil layer which take the method of vacuum combined with water storage stack preloading to reinforce do has certain effects.

**Table 3. Mud Soil After Processing Physical and Mechanical Properties Statistical Table**

| Items | Min | Max | Average Value | Standard Deviation | Coefficien of Variation | Correction Factors | Standard Values |
|---|---|---|---|---|---|---|---|
| Water Content $w$ (%) | 50.60 | 68.30 | 59.00 | 5.125 | 0.087 | 1.032 | 60.80 |
| Density $\rho$ (g/cm$^3$) | 1.580 | 1.700 | 1.630 | 0.034 | 0.021 | 1.002 | 1.65 |
| Proportion $G$s | 2.660 | 2.730 | 2.680 | 0.016 | 0.006 | 0.998 | 2.680 |
| Void Ratio $e$ | 1.421 | 1.874 | 1.619 | 0.141 | 0.087 | 1.032 | 1.670 |
| Liquid Limit $w_L$ (%) | 44.10 | 52.40 | 47.30 | 2.160 | 0.046 | 1.016 | 48.00 |
| Plastic Limit $w_P$ (%) | 25.90 | 30.70 | 28.00 | 1.481 | 0.053 | 0.982 | 27.50 |
| Plasticity Index $I_P$ | 18.20 | 22.00 | 19.70 | 0.972 | 0.049 | 1.018 | 20.00 |
| Liquidity Index $I_L$ | 1.400 | 1.800 | 1.600 | 0.134 | 0.084 | 1.031 | 1.640 |
| Coefficient of Compressibility $a_{1\text{-}2}$ ( MP$_a^{-1}$ ) | 0.940 | 1.470 | 1.190 | 0.179 | 0.150 | 1.088 | 1.300 |
| Compression Modulus $E_{1\text{-}2}$ (MP$_a$ ) | 1.800 | 2.600 | 2.200 | 0.281 | 0.130 | 0.924 | 2.000 |
| Internal Friction Angle $\varphi$ ($^0$) | 2.000 | 2.600 | 2.400 | 0.154 | 0.065 | 0.964 | 2.300 |
| Cohesive Force $c$ (kP$_a$ ) | 2.000 | 9.000 | 5.100 | 1.868 | 0.367 | 0.797 | 4.000 |

## Conclusions

- Vacuum preloading underwater has a certain reinforcement effect for mud soil in coastal region.
- Vacuum preloading underwater can improve the physical and mechanical properties index of mud soil.
- Vacuum preloading underwater can improve the shear strength of mud soil.

# The Microstructure Formation Process Research in Loading Condition of Dredger Fill

Jia WANG , Penglin CAI

College of Construction Engineering Jilin university, Changchun 130062,China

**Keyword:** reclaimed soil; microstructure; Consolidation settlement

**Abstract.** This paper takes some sections of Tianjin coast for example, explore the microstructure morphology and index-load combination in the condition of different settling time with load combination about reclaimed soil on the basis of sampling and testing of original state reclaimed soil. Including apparent form, size, directionality gap , formation of the skeleton and bulk density changes of the flocculation body aggregate. It found the characteristics and regularities of microstructure of reclaimed soil in the initial settlement. The research claims the structure of reclaimed soil is enhanced and the change of soil microstructure has positive significance to the engineering geological properties. in the process of consolidation

## The introduction

In coastal areas, it is relatively prominent problem about shortage of land resources in the process of urbanization. The geographical expansion of cities is strictly limited by the land use of construction land, Reclaimed soil[1] is using dredge and mud to pump mud and port formed by hydraulic fill by sedimentary soil at the bottom of the rivers. It has the high water content, high compressibility, high clay content, organic matter, flow, etc. This article mainly research self-organizing microstructure of reclaimed soil[2]

## Test method and instruments

Test instrument has adopted by the vacuum freeze-drying (dexa), scanning electron microscopy fracture method is used to carry on the processing in the microstructure of soil samples in the sample preparation, soil sample is cutted into appropriate size of the soil sample in the beginning. Then sublimating freeze-dried in freeze-dried instrument, after the sample is freeze-dried thoroughly, breaking out the fracture surface at one end of the article in the soil sample as the microstructure of soil test ,last, getting the microstructure image information after coating the ESM scanning electron microscopy (esm) analysis.

## 3 Results and discussion

3.1. The flocculation body and aggregate

This paper studies aggregate collection in the apparent morphology, flocculation body size of aggregate, flocculation body aggregate stereospecificity, flocculation body internal mineral aggregate stereospecificity, reunion body porosity and degree of osteoporosis on the free settling 0 days, five days, ten days, 20 days of reclaimed slurry flocculation body in the process of self-organization and observes its change with time and load regulation.

By the above-mentioned, as the free settling time increased, reclaimed slurry aggregate is smaller from 0 to 10 days in compaction process beginning to form mineral composition with smaller clay

mineral aggregate from high moisture content and solid mineral composition of low flocculation body[3] .Since 10 ~ 40 days, these small molding clay mineral aggregate is forming larger aggregates the new self organization core under the action of self organization in reclaimed mud system.

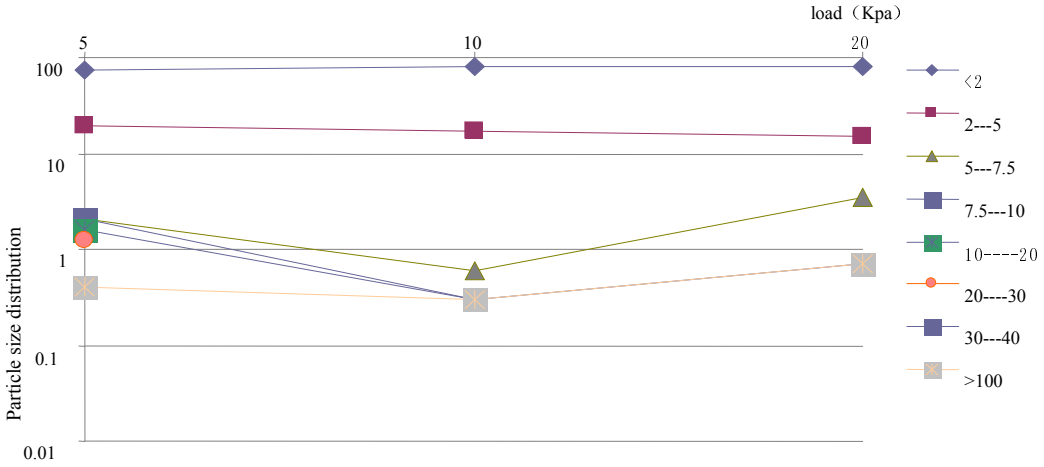

Fig.1 Particle size composition （10d）

3.2 The change of particle diameter

Particle size composition has also changed in the whole process of subsidence. <2 μ m particle concentration is stable and 2～5 μ m particles showed a trend of decrease in the initial settlement, And 7.5 to 10 microns particles, > 100 microns particles increased obviously, it is Show that 2 ~ 7.5 microns particles are widely involved in 7.5 ~ 10 microns particle, > 100 microns particle group formation. the effect of the < 2 microns particle was not significant as shown in figureTo the middle and later periods of the settlement , < 2 microns particles is reducing in a certain degree , The 2 ~ 5 microns particles increased, it shows that < 2 microns particles are widely involved in the formation of 2 ~ 7.5 microns particles. The general trend is: Growth over time, Smaller particles gradually is consumed in the process of large particles formed, But the vast majority of < 2 microns mineral particles is independent individual form in the aggregate ,as show in fig.1.

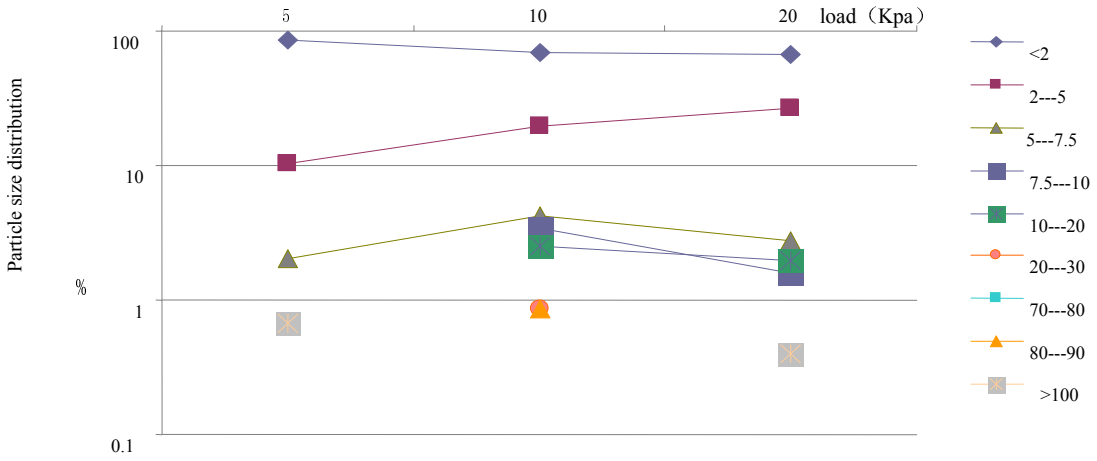

Fig.2 Particle size composition （40d）

3.3 Mineral grain orientation in the aggregate

The directionality of internal mineral of clay mineral aggregate is divided into two stages in the condition of different settling time and load.

The first stage is the initial settlement. Internal mineral aggregate of directional property mainly depends on its initial core directional property of minerals. Some layer or flaky mineral around the core minerals in a smaller angle, However, filamentous with layered clay minerals contact in the form of the point – surface for the most part of The columnar filamentous clay mineral. porosity is larger and aggregate density is low. As show in the fig(3 ,4).

The second stage is the combination of self-organization between aggregate[4]. Especially under the load, The arrangement of collection is in order 。And internal mineral aggregate tend towards the direction of perpendicular to the load, parallel to the horizontal direction. Aggregate in the process may be the whole rotation in the process.

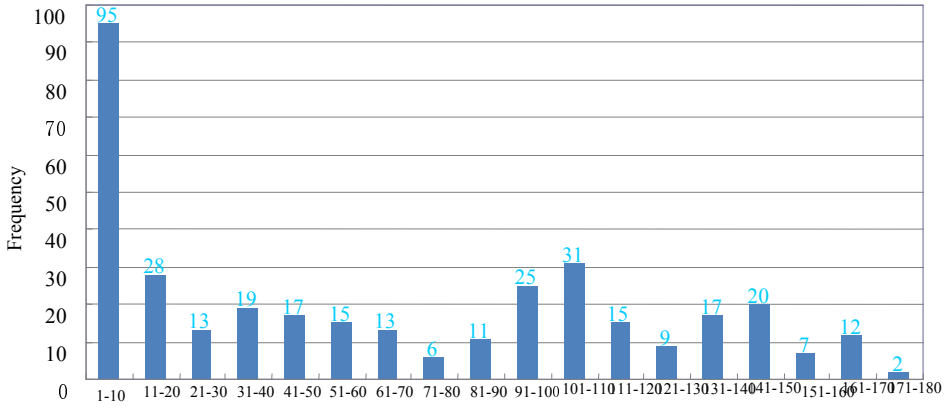

Fig.3 Distribution of long axis and the X axis Angle distribution internal mineral aggregate (10 days 10kPa-4000times)

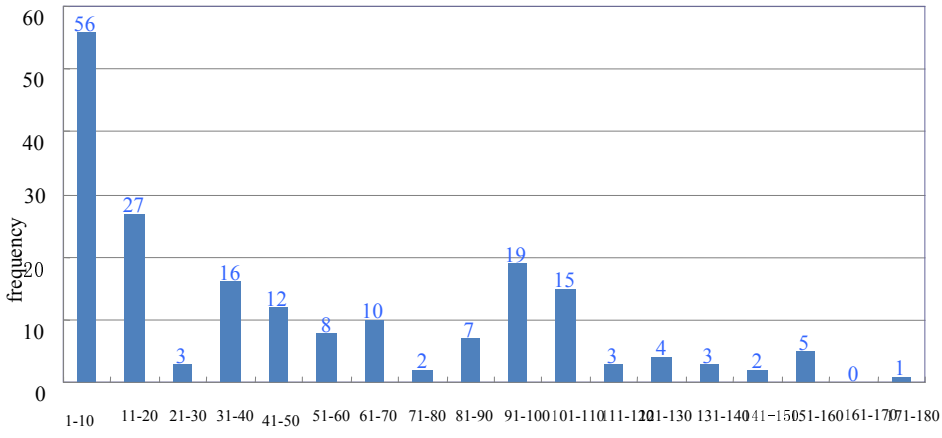

Fig.4 Distribution of long axis and the X axis Angle distribution internal mineral aggregate (10 days 20kPa-4000times)

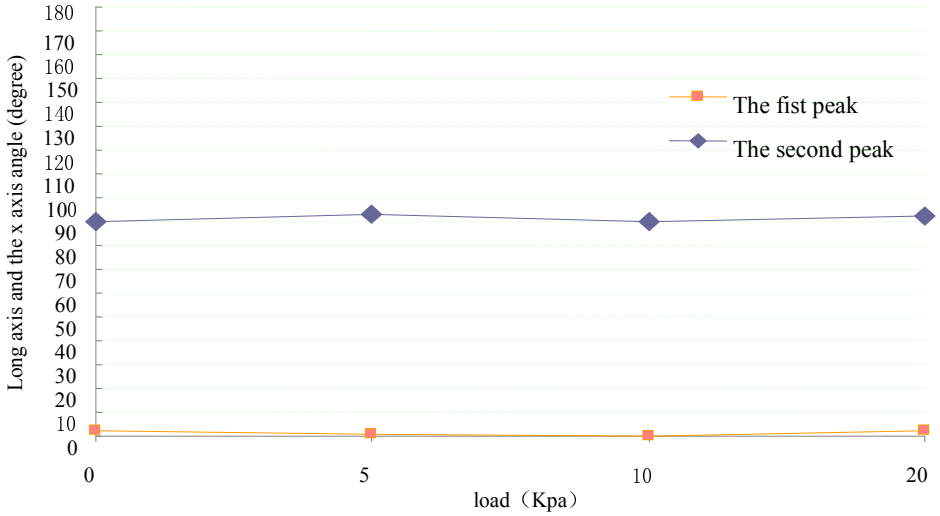

Fig.5 Distribution of long axis and the X axis Angle distribution internal mineral aggregate (40 days 0kPa-4000times)

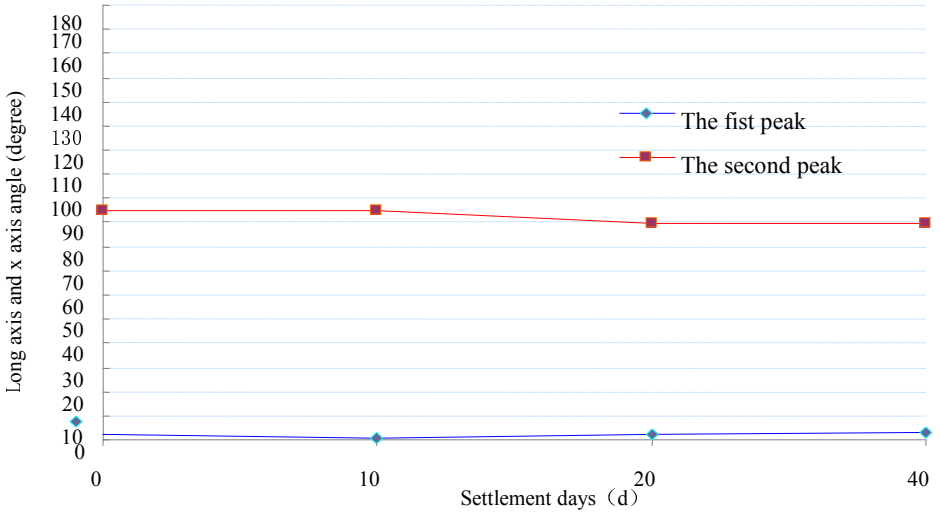

Fig.6 Distribution of long axis and the X axis Angle distribution internal mineral aggregate (40 days 0kPa-4000times)

3.4 Aggregate surface morphology

The aggregate surface morphology has experienced from complex to simple.

The aggregate surface is irregular and there are seemingly villous flake and filamentous clay minerals attached on the surface of the flocculation body aggregate disorderly in the beginning. Flake clay mineral attached to the surface of the flocculation body aggregate irregularly in the condition of no load in ten days of settlement. After loading, The surface morphology is changed .For example mineral particles disappear, clay minerals present layer accumulation, flaky mineral almost parallel to surface, the surface is relatively dense. From 20 days to 40 days, self organization restructuring of aggregate has been completed ,the surface of the aggregate is formed by a collection of complex curved surface, The two clay mineral is closely adsorbed on the surface collection. The direction of mineral plane approach aggregation .The surface of aggregate is smooth and dense. There will be no loose mineral On the surface and cascading mineral edge is visible. It shows that aggregate has a great influence on the surface morphology of form in drainage consolidation of compaction .Surface morphology of the aggregate can also be seen as a factor in reclaimed soil density index[5]. as show in the fig.5

3.5 Gap and bulk density changes of the flocculation body and aggregate

The aggregate pore become close in the body in the process of self-organization of the flocculation body and aggregate，As shown in fig.6.，Suspension of flocculating substance turns into solid flocculation body[6] and Loose flocculating body forms and encrypts fast in the initial flocculation body formation from 0 to 10 days. Flocculation body shapes preliminary through the formation of self-organization of original clay mineral flocculating substance. Micrograph shows that loose mineral stack and small clay mineral particles adsorbed on the surface of the flocculation body astatic. But not dense, irregular surface morphology, villous, sheet, flocculation body has a bigger hole, higher osteoporosis. Self- organization of flocculation structures again under the synergy from 10 to 20 days.

During this period small flocculation body gradually become adsorbed or united by bulky flocculation or aggregation then become honeycomb or grid frame structure and appear larger pores. Composite flocculation body or collection experience drainage consolidation process which the pore water gradually eliminate and the pore become smaller again under the load from 20 to 40 days . As shown in fig.7 its bulk density also increases dramatically in the whole settlement and loading process.

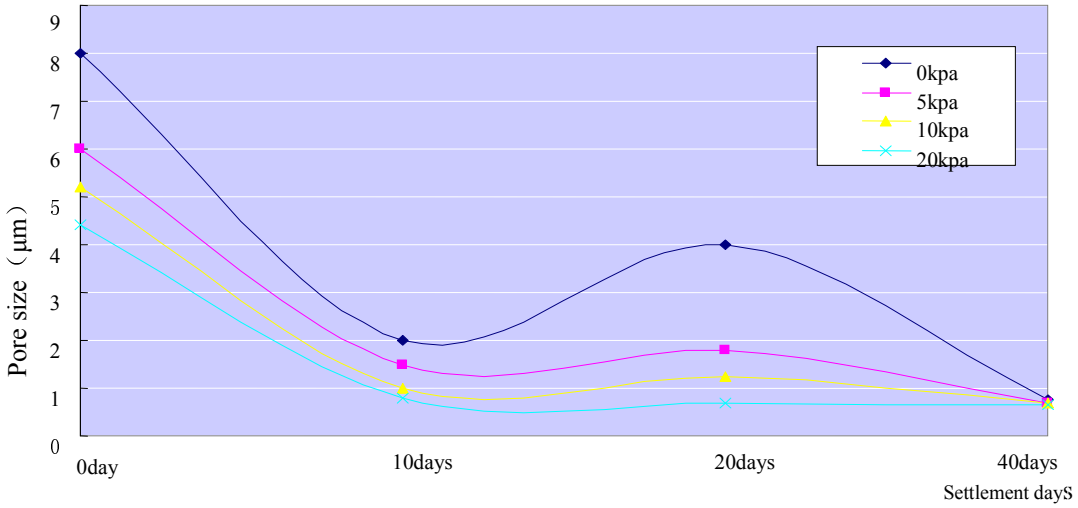

Fig.7. The change of Bulk density and void ratio in the process of initial settlement about filling slurry

3.6 The formation of the skeleton

Test shows that mineral grains and aggregate reclaimed soil skeleton basic form, as well as different forms of changes have taken place in the connection form under the condition of different load or different settlement time. The basic form of skeleton is loose mesh sheet cellular structure and the main connection form is edge surface and mineral grains of linear flake the flocculation body aggregate. The basic form of skeleton is from loose mesh flake honeycomb to the density of honeycomb irregular crumb and crumb honeycomb assembly as the settling time increase. The strength of the reclaimed soil continuously strengthen because skeleton experienced from a single mineral to aggregate skeleton, the structure strength of monomer fossil skeleton is low but structure strength of the aggregate skeleton is higher in the whole[7].

## Conclusions

1. Reclaimed aggregate generated in mud from big to small of the formation of compact process to form small clay mineral aggregate as the free settling time increased. The directional property of internal mineral of aggregate occur two stages of differentiation in the condition of different settlement time and load combination. The first stage is directional property of internal mineral aggregate mainly depends on its initial core directional property of minerals. The second stage is the tendency of internal mineral of the organization is perpendicular to the load.

2. The pores become compacted in aggregate. The pore surface form of reclaimed soil is related to settling time and soil skeleton connection form has changed. for example, skeleton structure is from a single mineral transform into aggregates. The trend of particle size composition is the smaller particles gradually is consumed in the process of large particles formed but the vast majority of < 2 microns mineral particles in the aggregate keep the independent individual form of minerals with growth time in the whole process of settling

**Keywords:** Rock Fracture; Mean Spacing; Linear Density; Linear Density Correction

**Abstract.** The mean spacing of rock fracture is a very important parameter base to evaluate rock mass，a number of rock studies base on it. Object of this paper is Beishan preselected area in Gansu Province, China. A uthor use GPS-RTK to measure the fracture's endpoints and inflection, then process the resulting coordinate, building a three-dimensional model of rock fracture by using three-dimensional software and meshing the three-dimensional model, Through the analysis of fractures in each grid to calculate the linear density of rock fracture, after the orientation and inclination correction on linear density, it can be converted to an mean spacing of rock fractures. The mean spacing of rock fracture can be directly used for rock mass classification in GSI rock systems, and has a great significance in rock engineering studies.

## Introduction

In the study of stability in geotechnical engineering, the study of engineering rock mechanics parameters is one of the key issues[1]， the rock mass engineering support, stability evaluation and numerical simulation all need a selection of mechanical parameters on rock mass strength, and the choice of parameters plays a vital role which result the accuracy of the calculated[2]. Situ testing of rock mechanics parameters has a long cycle, high cost and testing difficulty, Moreover the test results are often presented certain discrete[3]. In the current surrounding rock grading system, only GSI surrounding rock grading system is directly related to rock parameters (such as the Hoek-brown strength criterion and Mohr-Coulumb strength criteria parameters and rock modulus). Through the quantitative surrounding rock grading system, it can reduce the reliance on engineering experience and very convenient[4]. In the process of calculation GSI, the selection of the mean spacing of rock fracture is particularly important, it is difficult to measure directly, so in this paper study the rock fracture's mean spacing through the the endpoints and the inflection point coordinates of rock fracture and other basic information.

## Mean Spacing

The mean distance between Structural plane can be estimated by studying its linear density, Its reciprocal is the mean spacing. Order to area C's third group of field(Area C' fracture is characterized by occurrence can be divided into three groups) in Bei Shan as the research object, first simple treatment the endpoints and inflection point coordinates of fracture which measured by GPS, then establish fracture geometry by using three-dimensional modeling software, finally derived each fissure lines' information.

First read the endpoint and inflection point coordinates of fracture which measured by GPS, as shown in figure 1. Then read the fissure line information which obtained by three-dimensional modeling software, on this basis, according to the point and line information to create fracture line, as shown in figure 2.

According to the read point and create line fitted to free-form surfaces, can reflect the surface fluctuation of the actual area to a certain extent, as shown in figure 3. Subsequently, from the x, y, z three directions will be cut off from the surface every 5m, forming the 5 m intervals grids, as shown in figure 4.

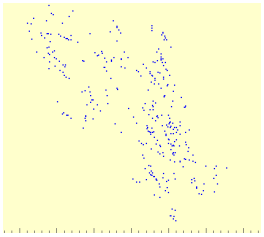

Fig.1 The endpoint and inflection point of fracture's figure

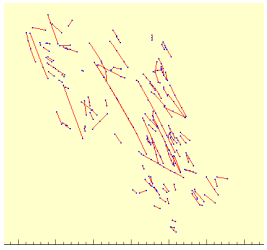

Fig.2 Points and lines created by fractures

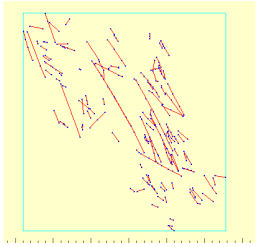

Fig.3 Point and line created by fracture fitted to free-form surfaces

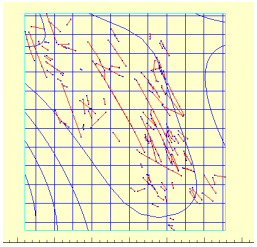

Fig.4 Fracture fitting surface mesh

Figure 3 is the top view of mesh surface of fractures in area C third group, and it can be understood as the grid projected on the horizontal plane. In Figure, Y direction refers to the North, X direction refers to the East. The statistical linear density in both directions that is north-south direction and east-west direction, denoted $n_{SN}$ and $n_{EW}$. The value approach to a grid that is 5m as a unit, optional 5m, 10m, 15m ..... to calculate the length L, count the number of fractures m in the calculation of the length L. The ratio of the number of fissures m to the calculation of the length L is linear density. To reduce the linear density error, number of fractures m in each length L must be greater than or equal 3, selected five groups of maximum linear density in each direction for conservative considering, denoted $n_{SNi}$ and $n_{EWi}$. Then average linear density in each direction, we can obtained the linear density of fractures $n_{SN}$ and $n_{EW}$ in both directions. The judgment is beginning with minimum length that L is 5m, and then expand the length if the data is not enough.

$$n_{SNi} = \frac{m_{SNi}}{L_{SNi}}, \quad n_{EWi} = \frac{m_{EWi}}{L_{EWi}} \tag{1}$$

$$n_{SN} = \frac{\sum_{1}^{5} n_{SNi}}{5}, n_{EW} = \frac{\sum_{1}^{5} n_{EWi}}{5} \tag{2}$$

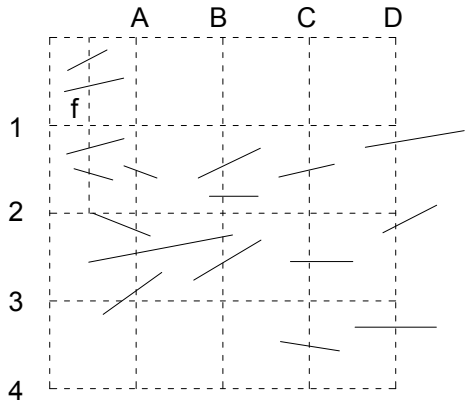

Fig.5 Example of extracting the value of linear density

Considering the diversity of the selected object , here is a small example that counting linear density $n_{SN}$ of north-south direction in order to facilitate understanding and easy to get linear density of fractures (Figure 5). First, consider the case that only a single grid and gauge length is 5m,

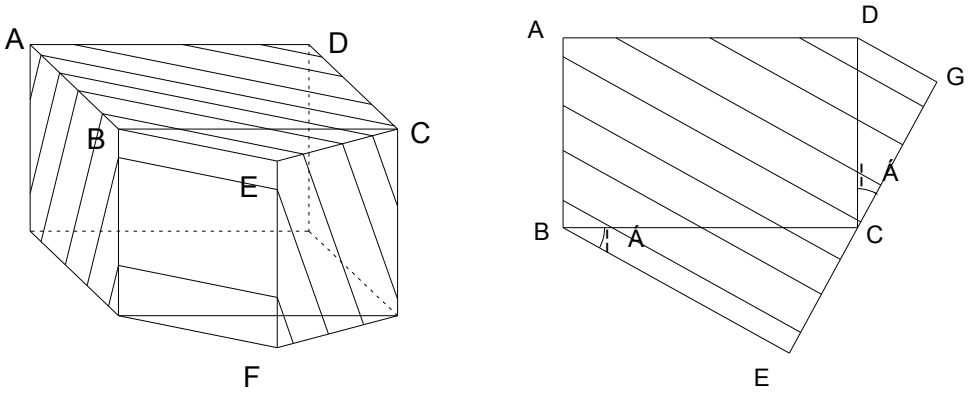
only A2 ~ A3 segment has three fissures in Fig, record 1 data; Object that is extended to two grids and gauge length is extended to 10m, B1~B3 segment has four fissures, which also consider the case that fractures does not on the grid line, for example, there are four fissures on the line f, record two copies of the data; Then object that is extended to three grids and gauge length is extended to 15m, C1~C4 and D1~D4 segment both has three fissures, record two copies of the data. Linear density is 0.6,0.4,0.4,0.2,0.2 respectively obtained from five data, and average linear density $n_{SN}$ is 0.36.

Table 1 is data of linear density for the third group of area C, including five linear density statistics of north-south and east-west direction. The intensity of this group can be found better, fissures are more than three in a grid, and the resulting of each linear density rather average.

Table 1 Value of linear density (Unit: bar / m)

| set | North-south direction | | | | East-west direction | | | |
|---|---|---|---|---|---|---|---|---|
| | Number of fissures $m_{SN}$ | Gauge length $L_{SN}$ | Linear density $n_{SNi}$ | Average linear density $n_{SN}$ | Number of fissure $m_{EW}$ | Gauge length $L_{EW}$ | Linear density $n_{EWi}$ | Average linear density $n_{EW}$ |
| 1 | 4 | 5 | 0.8 | | 5 | 5 | 1.0 | |
| 2 | 4 | 5 | 0.8 | | 5 | 5 | 1.0 | |
| 3 | 4 | 5 | 0.8 | 0.76 | 6 | 5 | 1.2 | 1.0 |
| 4 | 3 | 5 | 0.6 | | 4 | 5 | 0.8 | |
| 5 | 4 | 5 | 0.8 | | 5 | 5 | 1.0 | |

**Tendency correction of linear density**



a）Perspective view b）Top view

Fig.6 Tendency correction of linear density

According to the above method to find a linear density inaccurate. In Figure 1.6, ABCD surface is horizontal, BA refers to the North, BC refers to the east, the value of linear density in east-west direction is equal to the number of fractures on BC segment divided by the length of BC segment, the value of linear density in north-south direction is equal to the number of fractures on CD segment divided by the length of CD segment. But in the top view, fissures is not perpendicular to BC or CD segment, when considering only factors of the horizontal plane, the actual value of linear density in east-west direction should be equal to the number of fractures on BC segment divided by the length of CE segment, empathy the actual value of linear density in north-south direction should be equal to the number of fractures on CD segment divided by the length of CG segment. So it needs to be tendency correction for the linear density, as follows:

When the tendency that $\alpha = 0$: no tendency correction, $n_{EW}$ is the linear density .

When the tendency that $0 < \alpha < 90$：

$$n_{SN}' = \frac{n_{SN}}{\sin\alpha}, n_{EW}' = \frac{n_{EW}}{\cos\alpha} \tag{3}$$

When the tendency that $\alpha = 90$： no tendency correction, $n_{SN}$ is the linear density.

When the tendency that $90 < \alpha < 180$：

$$n_{SN}' = \frac{n_{SN}}{\sin\alpha}, n_{EW}' = -\frac{n_{EW}}{\cos\alpha} \tag{4}$$

When the tendency that $\alpha = 180$： no tendency correction, $n_{EW}$ is the linear density .

When the tendency that $180 < \alpha < 270$：

$$n_{SN}' = -\frac{n_{SN}}{\sin\alpha}, n_{EW}' = -\frac{n_{EW}}{\cos\alpha} \tag{5}$$

When the tendency that $\alpha = 270$： no tendency correction, $n_{SN}$ is the linear density .

When the tendency that $270 < \alpha < 360$：

$$n_{SN}' = -\frac{n_{SN}}{\sin\alpha}, n_{EW}' = \frac{n_{EW}}{\cos\alpha} \tag{6}$$

When the tendency that $\alpha = 360$： no tendency correction, $n_{EW}$ is the linear density .

The consolidated available:

$$n_{SN}' = \begin{cases} \dfrac{n_{SN}}{|\sin\alpha|}, & \text{if } \alpha \neq 0、90、180、270 \text{ or } 360 \\ n_{SN}, & \text{if } \alpha = 90 \text{ or } 270 \\ \text{Not exist}, & \text{if } \alpha = 0 \text{ or } 180 \text{ or } 360 \end{cases} \tag{7}$$

$$n_{EW}' = \begin{cases} \dfrac{n_{EW}}{|\cos\alpha|}, & \text{if } \alpha \neq 0、90、180、270 \text{ or } 360 \\ \text{Not exist}, & \text{if } \alpha = 90 \text{ or } 270 \\ n_{EW}, & \text{if } \alpha = 0 \text{ or } 180 \text{ or } 360 \end{cases} \tag{8}$$

**Inclination correction of linear density**

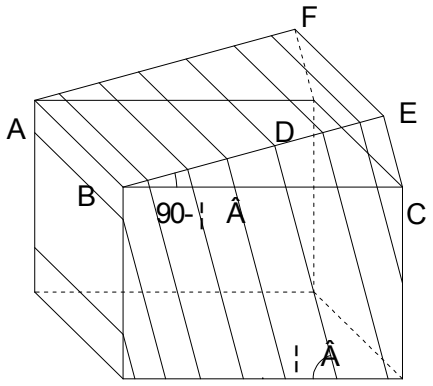


Fig.7 Inclination correction of linear density

Linear density represents linear density that in the horizontal after tendency correction, is not the linear density that in the vertical plane. In Figure 7,the value of linear density is equal to the number of fractures on BC segment divided by the length of BE segment after tendency correction, Therefore, there is a need for further inclination correction of linear density, as follows:

$$n_{SN}''=\frac{n_{SN}'}{\sin\beta},\quad n_{EW}''=\frac{n_{EW}'}{\sin\beta} \tag{9}$$

Where $\beta$ is the Inclination of the fracture, $n_{SN}'$ and $n_{EW}'$, respectively, are line density for the north-south and east-west direction after tendency correction.

**The corrected average distance**

Model and mesh three sets of data of area C respectively, then statistics linear density of north-south and east-west direction, after tendency and inclination correction of the linear density can get the average density of three groups of fractures respectively, and finally get the average fracture spacing of the three groups, as shown in Table 2.

Table 2 The mean spacing of rock fractures case

| set | Propensity (deg) | Dip (deg) | $n_{SN}$ (/m) | $n_{EW}$ (/m) | $n_{SN}'$ (/m) | $n_{EW}'$ (/m) | $n_{SN}''$ (/m) | $n_{EW}''$ (/m) | Mean spacing(m) |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 99.23 | 22.25 | 0.54 | 0.80 | 0.55 | 4.99 | 1.44 | 13.17 | 0.14 |
| 2 | 302.34 | 86.39 | 1.44 | 1.56 | 1.70 | 2.92 | 1.71 | 2.92 | 0.43 |
| 3 | 47.00 | 83.86 | 0.76 | 1.00 | 1.04 | 1.47 | 1.05 | 1.47 | 0.79 |

**Conclusion**

Three-dimensional model of the joints created based on three-dimensional software effectively utilizes the existing GPS-RTK coordinates of rock fractures, there is no need to repeat the measurement data, and mean spacing of rock fractures can be calculated according to the three-dimensional model. Work does not need to operate in the field, this approach allows more convenient for field measurements. However, data processing and modeling process is somewhat complicated, it will take some time to complete, therefore hope that future research can raise more convenient method to calculate the mean spacing of rock fissures.

**Keywords:** Underground Continuous Wall, Deformation Characteristic, Calculation Method

**Abstract.** Underground continuous wall has received more and more attention in the construction field as the important part in the foundation engineering. Pointing at the deformation characteristic of continuous wall, the factors which influent the deformation of continuous including the intrinsic mechanical characteristic and time effect in the construction area. The main calculation methods and various of calculation models are concluded as well as the construction technology, which concludes the research production in the continuous wall field and pointing the direction for the following research.

## Introduction

The underground continuous wall technology was first applied in impermeable wall in Santa Malia Dam in Italy. The appearance of numerous construction machines applied in continuous wall in Japan in the 1960s offer a condition which promotes this technology progress in the global scope. The first case applying the continuous wall technology in high-rise buildings in China is a bank building in Taiwan in 1971.Since then, the continuous wall technology has drawn great attention and obtained a widespread application in the deep foundation construction.

At the same time, the calculation methods and construction technology is updating rapidly which adding the fresh blood to the underground continuous wall construction. For example, Jun Sun`[1] put forward the predict method of continuous wall based on immune RBF neural network in 2003, and the efficient construction method named "Three Walls in One Wall" proposed by Fen Yuan[2]. All these late-model technology together promote the development of underground continuous wall technology.

## Deformation factors

There are two main aspects that influence the deformation of underground continuous wall,one is a series of internal factors like the depth ratio and reinforcement ratio of the underground continuous wall, the other is the construction conditions and time effect. For the internal factors,the depth ratio and reinforcement are regarded as elements forming the fuzzy relationship matrix to conclude the fuzzy principle of the deformation which is almost the same comparing the result in traditional calculation method[3]. The result of the above method indicate that when the depth ratio is constant, the value of deformation is decrease with the increase of the reinforcement ratio,but it is nor a linear relationship. At the same time,the principle concluding from the practical projects is the same with the result calculating through the above theory method[4].

Compared with the internal factors, the influence of construction condition to the underground continuous wall is more unpredictable and diversification. For example,the main reason of the tremendously increasing of the pit deformation is the not timely supporting and dewatering. While the loading around the pit is also an important reason to explain the deformation of the pit.Mingtao Lu[5] emphasize the influence of the surcharge behind the underground continuous wall and proposes a series of guiding suggestions of the continuous wall construction combining the monitoring data of a deep pit in Wuhan. At the same time, Zhongjun Wang[6] also put forward similar views and undertake the research in the area of how the confined water and loading affect the stability of continuous wall through finite element analysis.

In addition, Wei Fan[7] raise the opinion that contact surface of soil also have a certain effect on the deformation of underground continuous wall. The result that put the contact surface of soil into consideration is more consistent than the result not, which is lower in the pit deformation and ground subsidence outside the pit.

The principle of the underground continuous wall deformation is confirmed in the No.1 subway construction projects in Hangzhou last year.Lishen Hu[8] combine the monitoring data in deep pit of Train Station and the finite element analysis,bring the view that the supporting and dewatering problem are the main reasons for the continuous wall deformation.Cong Lei[9] also draws a similar conclusion through the design and monitoring data of continuous wall in the construction process in Pengbu Station.

## Calculation method

The main part of the underground continuous wall design is to calculate and design the exterior-protected construction. Hence, choosing a appropriate approach is the key to design the continuous. These methods can roughly divided into three groups: the conventional design method(the static equilibrium method),the elastic resistance method,the finite element method.

**Confirm the value of m** The value of m(proportional coefficient of horizontal resistance coefficient) is a discrete quantity in the design of underground continuous wall. There are two approaches to confirm this value in standard:horizontal loading test of single pile method and empirical formula calculation method. However, both of them exist defects and have a large deviation to the actual value.

Qiang Wang[10] proposes the method that back calculate the value of m through the real deformation of underground continuous wall. First of all, analyze the elastic foundation beam to establish the calculation function to get the value of m,and then optimize the result to confirm the value of m to forecast the next stage of the deformation. This method takes full advantage of the actual working conditions,which makes the result relatively accurate. At the same time, Xiliang Gao[11] holds the opinion that the deviation of the value of m have a large effect on the calculation of continuous deformation,and verify the accuracy of the method that use displacement to back calculate m.

**Incremental iteration method** Incremental iteration method is been applied widely in the practical projects process as a design method which takes the relationship of underground continuous wall construction into consideration.Shijin Feng[12] puts forward apply the incremental iteration method considering the influence of wall displacement to analyze the situation of undergrounder continuous wall's displacement. The influence that incremental displacement affect the incremental loading is linear.

$$\Delta p_{i+1}^{n} = \Delta p_{i}^{n} \pm \Delta \delta_{i}^{n} k_{s}^{n} \quad (1)$$

In the function, i means computation times in the incremental iteration method,i=1,2,3$\cdots$. $\Delta \delta_{i}^{n}$ means the displacement in the i time. $k_{s}^{n}$ means the rigidity of soil spring in the No.n construction condition. $\Delta p_{i}^{n}$ means the increasing load in the i time.

The overall stiffness matrix $[K_{n}^{p}]$ is used to calculate the final incremental displacement and loading as this stage of displacement and loading adding up to the last stage to get the total displacement and internal force.

**Fuzzy reliability analysis** Yongjin Tang[13] expand the the fuzzy relation matrix adding the thickness of the continuous wall, the depth of the pit,the depth ratio and the reinforcement ratio based on the previous matrix to forecast the horizonal displacement of continuous wall. Comparing the theory result with the displacement data of practical projects, the success rate (means the error is less than 2‰)reach 75% which can definitely illustrate that this method is reasonable and pertinence in the forecast of the deformation of the underground continuous wall.

It seems that the notion of fuzzy reality has been introduced into the analysis of construction reality,but there are also some problems to be solved,among which the standard of function choice is the most difficult to choose. Because the function is the precondition of the analysis,which has a direct effect on the calculation result. Different function has different result.Jie Sun[14] chooses three typical function: the falling trapezoid distribution,second-degree parabola distribution and the ridge shaped distribution to infer the influence of different function choice. The general principles are concluded by analyzing and comparing：second-degree parabola distribution is the most successful function in these three ones which is consistent with theoretical results;the falling trapezoid distribution gets a conservative results compared with the ridge shaped distribution.

**Conclude the principle of deformation in statistical method** Hu Feng[15] collects a great deal of practical project data on underground continuous wall, concludes the principle of continuous wall deformation. In this research, Hu Feng collects 58 monitoring data in Shanghai arear and apply the statistical theory to analyze the relationship among the displacement of maintenance system, soil properties and the system stiffness. Some laws can been concluded,displacement of the continuous wall appears over the excavation face and the relationship between the the thickness of soil and the deformation of continuous is close.

At the same time, Zhonghua Xu[16] also collect the monitoring data in Shanghai arear to confirm the above research,which promotes the development of the statistical theory in the civil engineering research.

## Model establishment

**Soil coupled creep model** According to the accumulation of practical experience, Haizhu Guo[17] finds that model combined time hardening exponential function law and failure criterion of Druker-Prager can reflect the time effect in the pit construction. The data from the model is coincide with that from the real construction process utilizing the data in the triaxial rheology experiment as the model's parameters.

If the Soil coupled creep model is extended and applied in the 3D simulation of deep pit supporting system, which will better reflect the effect of time and space. Compared with the elastic model and elastoplastic model, this model is more consistent with the actual projects.

Zhao baoyun[18] combined the creep model with $FLAC^{3D}$ software to explore the application in the design of slope stability whose working mechanism is similar withe continuous wall.

**Mohr Coulomb elastoplastic model** Dongxu Shang[19] applies the simulation software,simulating an underground continuous wall project of a building to analyze the deformation of the pit and the soil subsidence around the pit. In the process of the model construction, the soil model is Mohr Coulomb model,the steel support model is beam unit model,and the continuous wall model is shell unit model. According to the data from the simulation soft, the result shows a obvious tendency toward the monitoring data.

**Mechanical model of tubular pile (closed wall)** Based on the principle of elastic mechanics, Hua Wen[20] puts forward mechanical model of tubular pile (closed wall),which use semi-inverse method and principle of superposition to get side friction on both side of the pile. In this way, the analytical solution of axial strain on the surface of the pile and the unit side friction.

This method points at the rectangular closed continuous wall which can not calculate in the traditional method for the foundation subsidence and inner friction existence. The application of analytical solution is introduced by the model test of the rectangular closed continuous wall which offer the theory evidence for the data analysis of the rectangular closed continuous wall.

**Parabolic cylinder model** Based on the underground continuous wall in the station pit in Lingbo, Shilong Ding[21] apply the parabolic cylinder model in the analysis of cell wall stability in the situation of overloading. The purpose of this research is to explore how the model parameters affect the sensitivity and safety factor of cell wall stability. The result is verified by the monitoring data of the position, depth an verticality of cell wall which offer the theoretical and practical basis for the similar projects in Lingbo arear.

## The deformation law of continuous wall in the vertical force

**The research of closed continuous wall** The rectangular closed continuous wall is new type of bridge foundation, which is connected by rigid joint to form the closed rectangular frame.Hua Wen [22]applies the simulating method to explore how the distance of closed wall affect the group effect in the vertical load. Two model wall in different section size are used in the test,where the length of the model wall in group A is shorter than that in group B while the thickness and heigh is the same. According to the figure analysis after the test, several conclusion can be got,the character of closed wall is to form a group of walls rather than a single wall, the work principle of which is also totally different from the single wall. Enlarging the distance between the walls can promote the effect of internal resistance force and the soil stress. In the situation of keeping the thickness and heigh are uncharge, enlarging the wall in a certain value can improve the group effect and carrying capacity effectively to gain better economic benefit.

At the same time, Bo Zhang[23] and Zhang Song [24]simulate analyze the closed continuous wall in the FLAC-3D to explore the influence of the angle of internal friction on the closed wall in the vertical force,concluding that the most of the load is born by the side friction of the continuous wall foundation. The principle of the bearing mechanism is similar with the end bearing friction pile foundation, the vertical bearing capacity increase significantly with the increase of soil modulus.

**Continuous wall is born the vertical force in the soft soil** To improve the continuous pressed capacity in the soft soil is a unsolved problem.Yin Jiao[25] put forward to apply wall grouting to improve the compressive strength of underground continuous wall, which has been proved by the simulation method in the construction scene. According the analysis data, several conclusion can been shown, firstly, wall grouting can significantly improve the limit vertical compressive capacity and vertical stiffness,specially the resistance force in the end of the continuous wall. After the wall grouting, the main settlement of the continuous wall is result from the elastic deformation of wall subsoil.

Yu Weijian[26] used numerical analysis model and calculation to find out the stability situation of the surrounding rock in the vertical which is helpful to the research of continuous wall. Combined with safety monitoring, Liang Gui-lan[27] also discuss the stability Analysis of surrounding rock, getting the likely research result with Yu Weijian

## New technology of construction

**"Three Walls in One Wall"** Combining the reforming project in Shanghai the Bund, Fen Yuan proposes the new conception of "Three Walls in One Wall",which utilizes the continuous wall and inner wall as the flood control wall, developing the function of enclosure wall,load bearing wall and flood control wall for continuous wall.

There are two key technologies in this project,one is rotary drilling to clean the riprap layer near the river,which minimizes the adverse effects on the flood control wall foundation. The other is cell wall reinforcement to connect the continuous curtain cutting off the connection with the water. The depth of the curtain reach the impermeable layer,which enhance the stability of the cell wall.

**Construction method of barrette** Barrette is a single rectangular continuous wall to bear the load from the upper part of the structure. The surface area and flexural rigidity is bigger than the circular pile which can fully utilize the side resistance force and improve the bearing capacity. In the last several years, this pile have been widely applied in the high-rise buildings, elevated road and other foundational constructions[28].

Guohui Lei[29] make 3D discrete of the pile body along the depth and cross section in 3D analysis, applying the Mindlin function and the static equilibrium law to construct the displacement function of pile and the soil around the pile, which infer the equation describing the relationship between the load on the barrette and the displacement of pile.

## Construction materials and components

**GFRP bar** Glass Fiber Reinforced polymer(called GFRP foe short)is a new type of fibrous composite.GFRP replaces traditional bar in shield driving part for which is lighter than others. The GFRP bar is usually used in the continuous wall because it will not influent the mechanical performance of the continuous wall and can directly drill the continuous wall when the shield In and out of the tunnel[30].

**The I-shaped steel joints** Aiming to solve the difficulties in the locking pipe and joint box connecting in underground continuous wall, Jian Shen[31] combines the project in the Shanghai World Expo to introduce the I-shape steel joints application in the continuous wall. This type of joint can be a permanent part of the continuous wall which solve the pipe laying problem in the continuous

wall construction. According to three dimensional finite element analysis, the joint proved to be safe and reliable.

**Combine continuous wall and steel support** Based on the metro station pit project in Shengzheng, Qinxi Zhang[32] explore the supporting system combining the continuous wall and steel support in the soft simulation and field measurement. The result show that the restriction of the steel supporting is a vain effect in controlling the pit deformation. Hence, minimizing the stress loss and supporting the frame in time should be promised during the progress of the pit digging.

At the same time, Meng Qingshan[33] also utilize the steel pile to enhance the strength of retaining wall whose mechanical principle is likely with the continuous wall. This construction method has been widely used in the practical projects.

## Summary

The development of continuous wall at the present stage, the latest construction technology and conception have been introduced in this article. For making the design of the continuous wall trend to be more reasonable and normative, the next study can be turned to the below arear.

The time and space effect is unpredictable when it influent the continuous wall deformation. In the deformation prediction progress, more factors should be taken into consideration to make it more comprehensive and reasonable. At the same time, the management in the construction field should trend to standardization, avoiding the bias loading phenomenon.

The vertical load is not frequent like the lateral load ,but the vertical also has a certain effect on the continuous wall. For this reason, the deformation forecast of continuous in the vertical force should also be taken into consideration to make the forecast more reasonable.

The design of underground continuous wall combining with new materials and various of functional joints have been arisen in the construction technology. This technologies not only enhance the stability of the continuous wall, but also realize various of continuous wall for different functions, which improve construction efficiency.

# The rheological properties and yield stress model of high-density slurry added with coarse sands

ZHANG Xiu-xiang[1, a], QIAO Deng-pan[1, b]

[1.] Faculty of land and resources engineering, Kunming University of Science and Technology , Kunming 650093, China

[a:]15887221514@163.com，[b:]1215550723@qq.com

**Key words：** Coarse sands; Rheological properties; High-density slurry; Yield stress model;

**Abstract：** In order to determine the concentration range of high-density slurry with coarse sands for suiting pipeline transportation in Jinchuan mine, at the same time find a suitable model to predict yield stress. In this paper, based on the coarse sand of Jinchuan mine as material to prepare high-density slurry, studied on the rheological properties. Through two-factor variance analysis, qualitative and ration analysis of the effect was conducted on the cement content and mass concentration to rheological parameters. The results show that the rheological model of the coarse sand is similar to that of Bingham plastic fluid, the mass concentration has a significant effect on viscosity and yield stress, and the viscosity is significantly affected by the cement content. The mass concentration of 82%-84% is suitable gravity transportation in pipeline. Meanwhile the relation model is established between yield stress and water-cement ratio, aggregate volume concentration, the model has high precision. These provide technical basis for designing filling system and ensuring the stability of slurry transportation, and a new idea for the research of rheological properties.

## Introduction

For filling mining method, whether the slurry can realize steady transmission in tube is the key, the liquidity must content with the requirements of pipeline. On the premise of confirming stowing gradient, it is the prerequisite that ensure smoothly transport the slurry to the mined empty area in the form of gravity or pumping [1, 2]. Solving some technical problems which including preparation craft of slurry, the resistance calculation, pipeline design, and parameter optimization of pipeline transportation has a direct relationship with rheological properties and influencing factors of slurry.

In this paper, on the basis of the experiment carried out rheology test for high-density slurry of coarse sand, provided qualitative and quantitative analysis to the influence of cement content on the rheological parameters, revealed its influences and identified optimal concentration for pipeline. Yield stress model was put forward.

## 1 Test

### 1.1 Experimental material

(1)The coarse sands come from Jinchuan mine. The density of coarse sand is 2409 $Kg \cdot m^{-3}$, packing density is 0.595 by experimental determination.

(2) The result of grading is in Tab 1 through experimental determination.

**Tab 1** Grading of coarse sands

| Sieve mesh/（mm) | Cumulative distribution of screen underflow/（%） |
|---|---|
| 16 | 97 |
| 10 | 83 |
| 5 | 61 |
| 0.3 | 25 |
| 0.08 | 3 |

This engineering practice has showed that if the value of fine aggregate is too low, it will cause clogging in pipeline.

Tab 1 show that the particle which less than 0.3 mm is 25%, accords with the regulations of < construction code of pumped concrete> in AIJ, as well as china's regulations specify that the sand content of passing 0.315 mm mesh is no less than 15%[3]. So it is suitable for pipeline transportation.

1.2 Testing instrument

The test used Brookfield（DV-Ⅱ+Pro) , chose the HA (# 2) rotor, the computer program was set as 50 speed point that the rotor speed increase from 20 RPM to 200 RPM, each speed point wait 5s,1s gather a numeric, five data of each speed point take the average.

1.3 The design and method of experiment

The slurry for rheological test need to the conditions of high concentration and high flow， it still disagree about that the definition of high concentration and high flow [4,5]， Through a lot of experiments, this paper thinks the standard of high concentrations and high flow is that the slurry keep no separation and non-hierarchical after standing five minute and has the characteristics of slow slump-loss and non-bleeding, furthermore, slump is greater than or equal to 220mm, divergence is greater than 450mm, collapsed slump is less than 1s. Configuring slurry which concentration is from76% to 85% for observing in the lab, results show that 76%-79% have serious segregation, 80% is mild segregation, when comes to 81% has been basically no segregation. Slump, divergence and collapsed slump have reached the above requirement. So this test configures19 groups slurry which added quantity concrete separately are310 $kg \cdot m^{-3}$,280 $kg \cdot m^{-3}$,250 $kg \cdot m^{-3}$ and 220 $kg \cdot m^{-3}$ , mass concentration is from81% to 85%, (as when added quantity concrete of the slurry is 220 $kg \cdot m^{-3}$ , mass concentration is 81% ,the slurry had mild segregation, so didn't do rheological) , put the slurry into 1000 ml beaker with stirring for rheological test. The experimental scheme is shown in Table 2.

**Tab 2** The pilot scheme of rheology

| Slurry with coarse sands | Added quantity concrete/($kg \cdot m^{-3}$) | mass concentration/（%） |
|---|---|---|
| Rheological experiments | 310, 280, 250, 220 | 81%, 82%, 83%, 84%, 85% |

## 2. Experimental results and analysis

Drafted curves according to the shear stress and shear rate which get from different added quantity concrete and mass concentration:

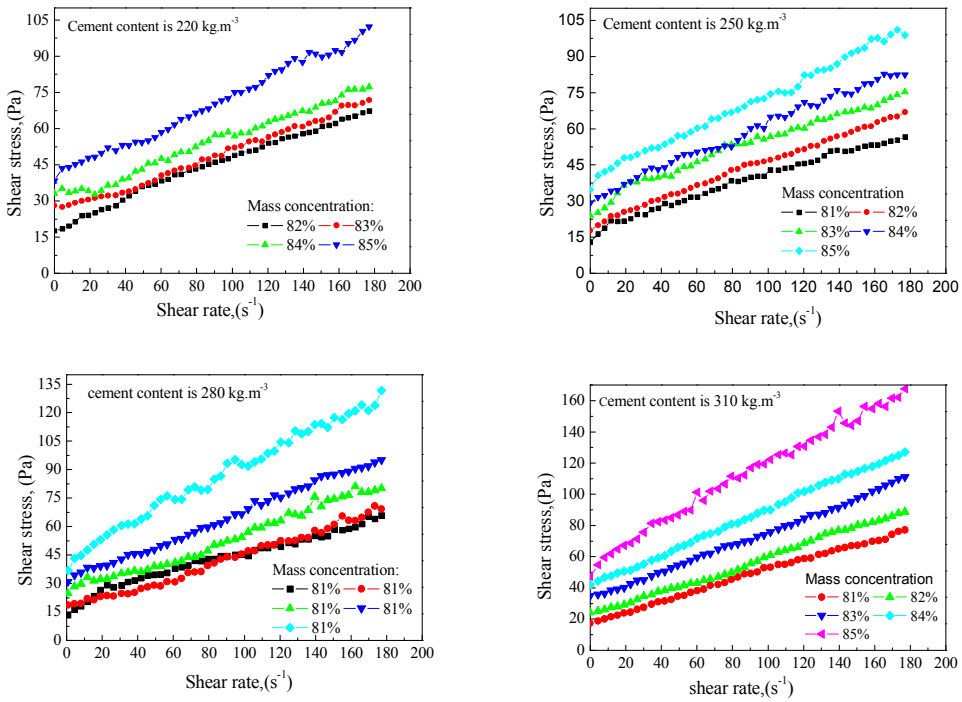

**Fig 1** Relation curve between shear rate and shear stress when cement content is separately 310 kg·m$^{-3}$, 280 kg·m$^{-3}$, 250 kg·m$^{-3}$, 220 kg·m$^{-3}$

Fig. 1 show that the rheological curve is a straight line of not through the origin. Straight line has an intercept on shear stress axis, the rheological process shows the characteristics of viscoplastic body , slope of the line is the plastic viscosity, the rheological index is one, belongs to Bingham plastic model(see Eq.(1))：

$$\tau = \tau_0 + \eta\gamma \qquad (1)$$

Where τ is the shear force (Pa), $\tau_0$ is the yield stress (Pa), η denotes the consistency coefficient (Pa·s), γ represents the shear rate(s$^{-1}$).

Used regression analysis software applying Bingham plastic model to fit the curves for obtaining the value of yield stress and viscosity, the results put in Tab3.

**Tab 3** Rheological parameters of regression analysis about the experiment of coarse sand

| Cement content (kg·m$^{-3}$) | Mass concentration (%) | Water-cement ratio | Volume concentration of aggregate | Yield stress （Pa) | Viscosity （Pa·s) | Correlation index |
|---|---|---|---|---|---|---|
| 310 | 81 | 1.262 | 0.5087 | 13.01 | 0.334 | 0.997 |
| | 82 | 1.211 | 0.5245 | 17.14 | 0.380 | 0.996 |
| | 83 | 1.159 | 0.5408 | 22.97 | 0.430 | 0.998 |
| | 84 | 1.105 | 0.5574 | 31.69 | 0.488 | 0.999 |
| | 85 | 1.050 | 0.5746 | 46.16 | 0.633 | 0.991 |

| | 83 | 1.281 | 0.5510 | 24.18 | 0.324 | 0.983 |
| | 84 | 1.221 | 0.5676 | 31.53 | 0.366 | 0.996 |
| | 85 | 1.161 | 0.5847 | 44.01 | 0.484 | 0.989 |

| | | | | | | |
|---|---|---|---|---|---|---|
| 250 | 81 | 1.560 | 0.5292 | 19.11 | 0.227 | 0.988 |
| | 82 | 1.497 | 0.5450 | 20.25 | 0.264 | 0.997 |
| | 83 | 1.433 | 0.5612 | 25.47 | 0.283 | 0.989 |
| | 84 | 1.366 | 0.5779 | 31.37 | 0.305 | 0.995 |
| | 85 | 1.298 | 0.5949 | 39.06 | 0.350 | 0.995 |
| 220 | 82 | 1.699 | 0.5553 | 20.03 | 0.258 | 0.993 |
| | 83 | 1.625 | 0.5714 | 24.81 | 0.263 | 0.994 |
| | 84 | 1.550 | 0.5881 | 30.34 | 0.267 | 0.988 |
| | 85 | 1.472 | 0.6051 | 39.69 | 0.346 | 0.992 |

## 3 Analysis the influencing factor of rheological parameters

### 3.1 The impact analysis for viscosity

Used analysis of variance to judge whether every factor has a significant influence on viscosity, the results are shown in Tab.4：

**Tab. 4** Two-factor variance analysis of viscosity

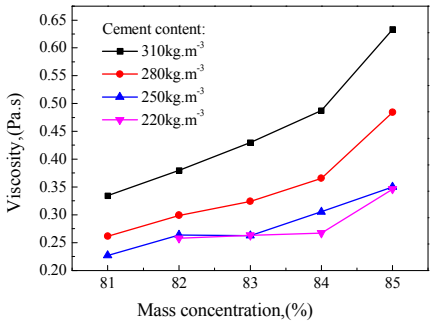
| Soruce of variation | SS | Df | MS | F Value | P-value |
|---|---|---|---|---|---|
| FactorA | 0.1002 | 3 | 0.0334 | 27.2643 | 7.54E-05 |
| FactorB | 0.0555 | 3 | 0.0185 | 15.1097 | 0.0007 |
| Error | 0.0110 | 9 | 0.0012 | | |
| Sum | 0.1667 | 15 | | | |

Note：Factor A represents cement content, factor B represents mass concentration

Significance test:：

Tab.4 shows that FA=27.2643>$F_{0.99}(3,9)$=6.99，FB=15.1097> $F_{0.99}(3,9)$=6.99, so factor A and factor B are highly significant. But cement content has more influence on viscosity.

According to the result of two-factor variance analysis, drew curves about factors which are highly significant and yield stress, as shown in Figure 2, 3.



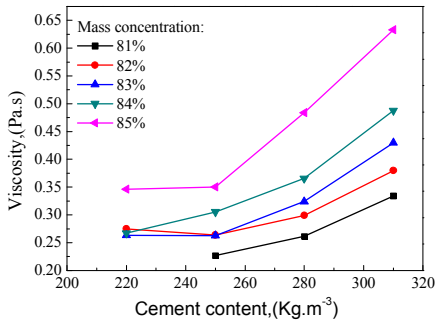


**Fig 2** Effect of mass concentration on viscosity **Fig 3** Effect of cement content on viscosity

Fig2 shows that under certain cement content, viscosity presents a growing trend with increasing concentration. The increase of concentration means the decrease of water-cement ratio, free water of slurry becomes less, unit of skeleton structure becomes more, the internal friction of slurry grows, and the final viscosity becomes larger. The viscosity increases relatively moderate from 81% to 84%, but increases greatly from 84% to 85%. When choose the concentration for pipeline should be less than 84%.

Fig3 shows under a certain mass concentration, the more the cement content increases, the bigger the viscosity is, the increase in the amount of cement makes W/C become smaller, makes the

slurry thickening, and the volume of coarse sand, friction becomes bigger, ultimately viscosity becomes larger. The viscosity changes little from 220 kg·m$^{-3}$ to 250 kg·m$^{-3}$, then rises quickly between 250 kg·m$^{-3}$ and 310 kg·m$^{-3}$.

### 3.2 The impact analysis for yield stress

In order to examine the influence of cement content and mass concentration on the yield stress, the double factors variance analysis is presented in Tab 5.

**Tab 5** Two-factor variance analysis of yield stress

| Soruce of variation | SS | Df | MS | F-Value | P-value |
|---|---|---|---|---|---|
| FactorA | 1.1635 | 3 | 0.3878 | 0.0425 | 0.9873 |
| FactorB | 1089.2872 | 3 | 363.0958 | 40.2566 | 1.53E-05 |
| Error | 81.1758 | 9 | 9.0195 | | |
| Sum | 1195.2681 | 15 | | | |

Significance test:

Tab.5 shows that FA = 0.0425<$F_{0.99}$(3,9)=6.99, FB=40.2566>$F_{0.99}$(3,9)=6.99, factor B are highly significant, that is, mass concentration has more influence on viscosity.

In order to clearly observe the influence of concentration on yield stress plotted curves as follow Fig4:

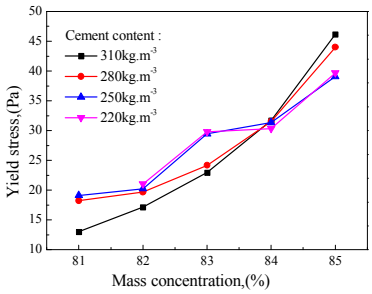

**Fig.4** Effect of mass concentration on yield value of stress

Four curves from Fig.4 show under the same cement content, with the increase of concentration, yield stress shows a clear upward trend. when the concentration is less than 84%, the more the amount of cement added, the smaller the yield stress is, can be explained that the increase of cement means the decrease of coarse sand and the contact points between particles, the opportunity to form a skeleton structure becomes small, the resistance of the slurry becomes small; When the slurry concentration reaches 85%, yield stress becomes larger obviously. So the concentration should be less than or equal to 84% for pipeline.

### 3.3 The model of yield stress

It is apparent from the description, the value of yield stress has close relationship with water, cement and aggregate, so the three factors should be considered. In order to explore the quantitative relationship between them, put the values of three factors inTab3. The relation curves between yield stress and aggregate volume concentration ($C_V$) as well as water-cement ratio (W/C) see Fig 5, 6; get the regression equations using curves in Fig5, 6 are shown in Tab 6.

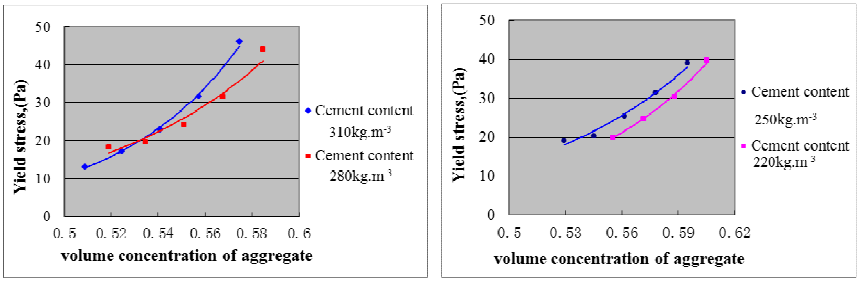

**Fig. 5** The relation curves between aggregate volume concentration and yield stress

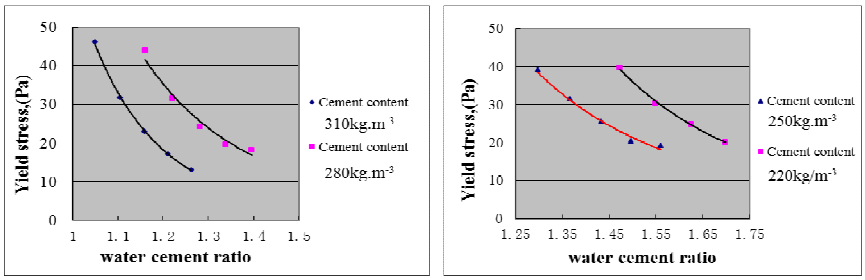

**Fig .6** The relation curves between water-cement ratio and yield stress

**Tab. 6** The equation of the relation between yield stress and $C_V$ as well as W/C

| Cement content ($kg \cdot m^{-3}$) | The relation equation between $C_V$ and yield stress | $R^2$ | The relation equation between W/C and yield stress | $R^2$ |
|---|---|---|---|---|
| 310 | $Y=0.0008e^{19.127x}$ | 0.998 | $Y=63.52x^{-6.813}$ | 0.970 |
| 280 | $Y=0.0143e^{13.617x}$ | 0.964 | $Y=85.97x^{-4.883}$ | 0.999 |
| 250 | $Y=0.0433e^{11.398x}$ | 0.977 | $Y=111.20x^{-4.072}$ | 0.982 |
| 220 | $Y=0.0106e^{13.573x}$ | 0.997 | $Y=245.11x^{-4.729}$ | 0.998 |

Tab.6 shows that the volume concentration of aggregate has exponent relation on yield stress, there lies in an negative exponential function between W/C and yield stress. Put forward the yield stress model：

$$\tau_0 = \alpha * \exp(C_V) * \left(\frac{W}{C}\right)^b \quad (2)$$

Where $\tau_0$ is the yield stress (Pa), W/C denotes water cement ratio, α and b are constant, $C_V$ represents aggregate volume concentration.

Moreover，W/C, volume concentration and packing density in expression are dimensionless quantity; the dimension of yield stress is only related to α, so set the dimension of α as Pa.

According to the data in Tab 3, used Eq. 2 to regression, the value are shown in Tab 7：

**Tab. 7** The regression model at each dosage of cement

| Cement content ($kg \cdot m^{-3}$) | Regression model | Correlation $R^2$ | F value | Significance |
|---|---|---|---|---|
| 310 | $\tau_0 = 35.596 * \exp(C_V) * \left(\frac{W}{C}\right)^{-6.606}$ | 0.9992 | 14591.101 | highly significant |
| 280 ` | $\tau_0 = 50.109 * \exp(C_V) * \left(\frac{W}{C}\right)^{-4.964}$ | 0.9734 | 712.012 | highly significant |
| 250 | $\tau_0 = 69.726 * \exp(C_V) * \left(\frac{W}{C}\right)^{-4.401}$ | 0.9741 | 2206.195 | highly significant |
| 220 | $\tau_0 = 99.638 * \exp(C_V) * \left(\frac{W}{C}\right)^{-4.013}$ | 0.9906 | 5253.134 | highly significant |

Tab.7 shows that as the cement content decreasing, coefficient α and b take on an increasing tendency, accords with the physical laws. The correlations are greater than 0.97, shows the accuracy and reliability of the model. The coefficient α still needs further research.

## Conclusion

1. Under a certain mass concentration the more the cement content increases, the bigger the viscosity is. When the slurry concentration reaches 85%, yield value of stress becomes larger obviously，under a certain cement content, viscosity with increasing concentration presents a growing trend, increases greatly from 84% to85%. From 81% to 84% is suitable for pipeline, considering the dehydration of underground, suggest that the range of concentrations is 82%-84%.

2. A large number of rheological experiments show that under the same cement content, with the water-cement ratio reducing, the yield stress is significantly increased; W/C is a negative exponential function with yield stress. With the increase of aggregates and concentration，yield stress becomes larger. The volume concentration of aggregate has exponent relation on yield stress. After synthetically consider the influence of water, cement and the property of aggregate on yield stress, the prediction model of yield stress is proposed, this equation has some advantages such as simple formula, definite physical meaning and high accuracy etc.

Equation is as follows:

$$\tau_0 = \alpha * \exp(C_v) * \left(\frac{W}{C}\right)^b$$

This equation can reduce a large number of complex experiments in mine for obtaining yield stress, and has a significance to be promoted.

**Keywords:** pile-anchor system; sensitivity analysis; numerical simulation; FLAC$^{3D}$

**Abstract:** Mechanical behaviors of pile-soil effect and anchor-soil effect are significantly important in supporting engineering activities of foundation pit. In this paper, finite difference method (FDM) was utilized to perform the numerical simulation of pile-anchor system, composed of supporting piles and pre-stressed anchor cables. Numerical simulations were on the basis of the foundation pit of Jinan's West Railway Station, and 3D simulation analysis of foundation pit has been prepared during the whole processes of excavation, supporting and construction. The paper also analyzed the changes of bending moments of piles and axial forces of cables, and discussed mechanical behaviors of pile-anchor system, through comparisons with field monitoring. The results show that the parameters concluding vertical gridding's number, cohesion of pile and soil, and pile stiffness have robust influences on supporting elements' behaviors. Mechanical behaviors of supporting pile and axial forces of anchor cable changed dramatically, indicating that the potential failure form was converted from toppling failure to sliding failure.

## Introduction

Pile-anchor supporting system is consisted of supporting pile and anchor cable. The system can robustly control the displacement of soil, by utilizing the passive stress mechanism of pile and active stress mechanism of anchor cable, and finally maintain the safety of the foundation pit. This system can strictly dominate the displacement of foundation pit, having the merits of strong supporting effects, low-cost and easy-construction [1].

Shen and Bang [2] studied the influents of supporting parameters during the process of excavation, using the finite element method (FEM). Jiang and Lin [3] exhibited an expression to calculate the maximum displacement of pile-anchor supporting system, based on the abundant monitoring data. Their expresses theoretically depicted the relations of maximum displacement and various engineering aspects. However, the thorough understanding of mechanical behaviors of pile-anchor supporting system is still a difficult task, due to the complexities and uncertain of geo-technical conditions.

In this paper, finite difference method (FDM) was utilized to perform the numerical simulation of pile-anchor system, composed of supporting piles and pre-stressed anchor cables. Numerical simulations were on the basis of the foundation pit of Jinan's West Railway Station, and 3D simulation analysis of foundation pit has been performed during the whole processes of excavation, supporting and construction.

## Project overview

The foundation pit of station square located in Jinan city of Shandong province, China, with a length of 470m and a width of 346m. The depth of the foundation pit is approximately 15m, and the underground water level is in the range of -14m ~ -19m. The foundation is mainly composed of clay soil, as well as a portion of land pebble.

According to the engineering geology, hydrogeology, the surrounding environment and the correlated technical specifications, the foundation pit of station square is designed with pile-anchor supporting system. The depth of the foundation pit is 14m. The pile-anchor supporting system is composed by a row of pile and four rows of pre-stressed anchor cables, as shown in Fig. 1.

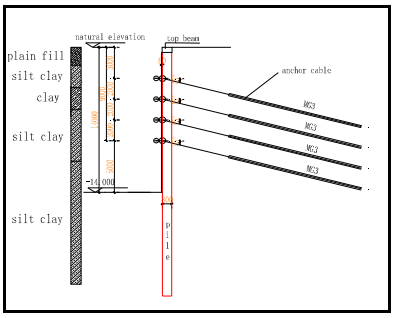

Fig.1 Supporting scheme

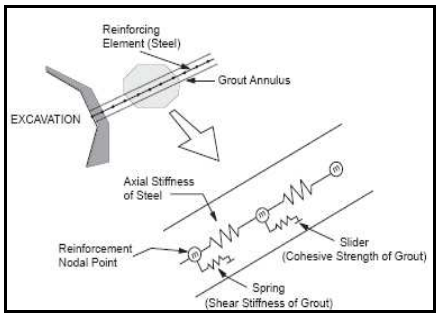

Fig.2 Mechanical representation of fully bonded reinforcement

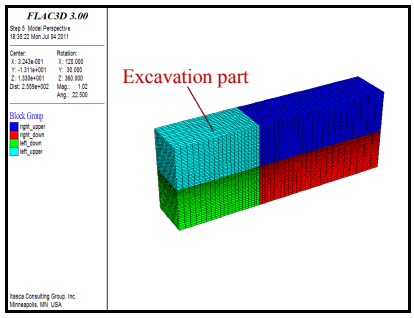

Fig.3 Calculating model

## Basic theories

The interaction effects of cable, grout and rock/soil are investigated by using spring-slider model system. This model can reflect the shear properties of interaction between cable and rock. The maximum shear force robustly depends on the shear stiffness of grout. The shear stiffness $K_g$ of grout for unit thickness can be expressed by:

$$k_g = \frac{2\pi G}{\ln(1 + 2t / D)} \tag{1}$$

where, $G$ is the shear modulus of grout, $t$ is the thickness of grout annular and $D$ is the diameter of anchor cable. The shear force $\tau_g$ of grout intersection can be calculated by:

$$\tau_g = \frac{G}{(D/2 + t)} \frac{\Delta u}{\ln(1 + 2t / D)} \tag{2}$$

where, $\Delta u$ is the relative displacement of grout and rock/soil.

In evaluating the axial forces that develop in the reinforcement displacements are computed at nodal points along the reinforcement axis, as show in Fig. 2. Out-of-balance forces at each node are computed from axial force in the reinforcement, as well as shear forces contributed through shear intersection along the grout annulus. Axial displacements are computed by integrating the nodal accelerations using the out-of-balance axial force and a mass lumped at each node.

**Modelling and parameters**

The height of the model is about 2.1 times of the depth of excavation, while the length of the model is about 3.3 times of the length of excavation. The length of the model is 130m, with the depth of 30m. The length of excavation is 39m, with the depth of 14m, as shown in Fig. 3. Physical and mechanical properties of soils, cables and piles are shown in Tables 1 ~ 3.

Table1 Physical and mechanical properties of soils

| Number | Soil type | Thickness of soil (m) | Modulus of deformation (MPa) | Poisson's ratio | Saturated unit weight ($kN/m^3$) | Cohesion (KPa) | Internal friction angle (º) |
|---|---|---|---|---|---|---|---|
| 1 | plain fill | 1.5 | 13.17 | 0.27 | 19.0 | 10.0 | 10.0 |
| 2 | silt clay | 2 | 20.70 | 0.30 | 19.3 | 26.3 | 19.4 |

| 7 | silt clay | 25 | 30.33 | 0.30 | 19.4 | 45.7 | 22.9 |

Table2 Physical and Mechanical Properties of Anchor Cable

| Num-ber | Type | Density $\rho$ ($kg/m^3$) | Elasticity modulus E(GPa) | Cross-section area A($mm^2$) | Grout cohesion $C_g$(N/m) | Grout stiffness $k_g$(N/m/m) | Grout perimeter $P_g$(mm) | Tensile strength $F_t$ (KN) |
|---|---|---|---|---|---|---|---|---|
| 1 | Freedom segment | 7800 | 195 | 181.37 | 1 | 1 | 471 | 337.35 |
| 2 | Anchorage segment | 7800 | 195 | 181.37 | $2\times10^5$ | $1.75\times10^7$ | 471 | 337.35 |

Table3 Physical and Mechanical Properties of Pile

| Num-ber | Type | Density $\rho$ (kg/m3) | Elasticity modulus E(GPa) | Poisson's ratio ν | Cross-section area A($mm^2$) | Cohesion of pile and soil Pg (N/m) | Interface stiffness $k_g$ (N/m/m) | Friction angle $\phi_g$ | Pile perimeter $P_g$ (mm) |
|---|---|---|---|---|---|---|---|---|---|
| 1 | pile | 2500 | 31.5 | 0.3 | 5024 | 0.96e7 | 1.3e7 | 9.6 | 252 |

## Results and analysis

Figs. 4(a) and 4(b) show the results of bending moment of pile and axial force of anchor cable with varying grid layers in the vertical direction in numerical model. With the increment of grid layer, the bending moment of pile and the axial force of anchor cable increase too. When the number of grid layer exceeds 50, the increment of bending moment and axial force is not remarkable, however, the computing time is increasing significantly. Figs. 4(c) and 4(d) depict the changes of bending moment of pile and axial force of anchor cable under different cohesions of pile and soil. As the cohesion increases, the bending moment of pile and the axial force of anchor cable increase, too. This is because the increasing cohesion results in a better bonding effect of pile and soil, leading to more stress applying on pile. Figs. 4(e) and 4(f) illustrates the variations of bending moment of pile and axial force of anchor cable with increasing stiffness of pile. The increasing stiffness causes the increase of bending moment of pile and decrease of axial force of anchor cable. The reasons may be that with the increase of pile stiffness, the supporting pile would suffer more stress of soil, making the soil suffering less stress and resulting in the increase of bending moment of pile and decrease of axial force of anchor cable.

Fig. 5 and Table 4 present the comparison results of monitoring data and calculated results. The monitoring data shows that the maximum interior bending moment is 158.7kN•m located in $z$ = -10m, while the numerical results are 159.79kN•m located in $z$ = -9.15m. The maximum exterior bending moment of monitoring data is -152.3kN•m in the depth of $z$ = -14m, while the maximum exterior bending moment of calculated results is -139.68kN•m in the depth of z = -14.64m. The monitoring data agree well with the measured data, showing the accuracy and reliability of the numerical simulation.

(d) Axial force of cable (cohesion) (e) Bending moment of pile (stiffness) (f) Axial force of cable (stiffness)

Fig. 4 Bending moments of pile and axial forces of cable with varying grid

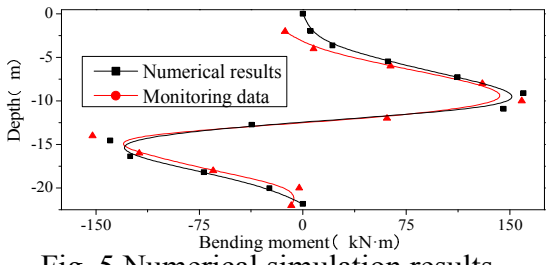

Fig. 5 Numerical simulation results and measured data

Table 4 Measured data and numerical simulation data

| Data source | Max interior bending moment | | Max exterior bending moment | |
|---|---|---|---|---|
| | value（kN•m） | depth（m） | value（kN•m） | depth（m） |
| Monitoring | 158.7 | -10 | -152.3 | -14 |
| Calculating | 159.79 | -9.15 | -139.68 | -14.64 |
| Errors(%) | 0.7 | 8.5 | 8.286 | 4.571 |

## Conclusions

The comparisons of monitoring data and numerical simulations show that when obtaining the reasonable parameters and considering the interaction effects of soil, cable and pile, the numerical simulation is accurate and reliable. The vertical grid layer, the cohesion of pile and soil, the pile stiffness and other parameters can significantly influence on the mechanical behaviors of pile and anchor cable. When excavation is finished, the results show the maximum axial force of anchor cable located in the former part while its value is constant for freedom segment, which agrees well with other researchers' results.

**Keywords:** Failure Condition, Complex Rocks and Soils, Anisotropic, Nonlinear, Engineering Application

**Abstract.** A failure criterion is proposed for complex rocks and soils. Their anisotropic and nonlinear behavior is analyzed theoretically and experimentally. The influence of the intermediate principal stress is taken into account. The nonhomogeneous strength and the effect of geological temperature are also discussed. Many classical failure criteria are special cases of the proposed condition. The criterion is applied in the analysis of the bedrock of Ankang Dam in China. The case study illustrates the potential of the proposed general model in engineering application.

## Introduction

When engineering works are constructed in a soil or rock, two issues need to be addressed. One is whether shear stresses exceed the shear strength of soil so that the soil failure will cause catastrophic collapse of structures. The other is whether consolidation deformations are so large that total or differential settlement will result in damage to structures. In practice, both strength and consolidation should be considered. At this point, soil strength is examined in detail. Soil failure is an essential topic for engineering purposes. It is concerned with bearing capacity of foundations, stability of slopes, earth pressure, etc.

In studying soil strength, a useful method is to establish a failure criterion, which links limiting combinations of stresses and describes behavior of soil strength effectively. In plasticity theory, the Tresca and the Mises criteria are commonly used. However, Tresca's yield condition indicates that the normal stress on slip planes does not affect shear strength. Mises' model states that the hydrostatic stress has no influence on failure. Therefore both the criteria take no account of internal friction of rocks and soils. In soil and rock mechanics, the Mohr-Coulomb criterion is widely used. Nevertheless, this model ignores the intermediate principal stress. This is not true in many cases. Drucker and Prager suggested an extended Mises criterion, in which the octahedral shear stress is a function of the octahedral normal stress. This model is generally employed in the FEM analysis. Basically, all the criteria mentioned above are applicable to homogeneous and isotropic rocks and soils only, and all of them are linear functions in stress space.

In fact, soil and rock behavior is extremely complicated (Xu, 1993; Qian and Yin, 1994) [1, 2]. The authors have conducted constitutive modeling for non-ideal materials involving their evolutionary elastoplastic damage (Ju and Ruan, 2002; Ju, Ruan and Ko, 2004) [3, 4]. Specifically for complex soils, Shen (2000) [5] cited Ruan and Xu's extended strength theory as an analysis basis. Due to vertical consolidation in field, different geological environments, and many other reasons, rocks and soils sometimes behave anisotropic, heterogeneous, and nonlinear. In order to deal with all these characteristics, a comprehensive failure criterion is proposed. This model embraces many advantages of available theories and agrees with experimental data very well.

**General Criterion**

Anisotropic behavior is common for many soils and rocks due to preferred orientation of mineral grains or bedding planes. Strengths parallel and perpendicular to weakness planes are quite different. Donath (1964) [6] performed strength and deformability tests on slate. Here the three principal stresses are denoted by $\sigma_1$, $\sigma_2$, and $\sigma_3$, and it is assumed that $\sigma_1 \geq \sigma_2 \geq \sigma_3$.

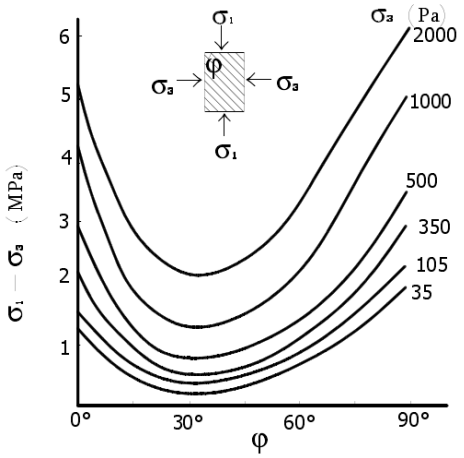

Fig. 1 Triaxial compression test on slate

Figure 1 shows that the limiting stress difference $\sigma_1$-$\sigma_2$ is related to loading direction. When the major principal stress $\sigma_1$ is inclined with bedding planes at an angle of some 30°, the strength reaches its minimum. Jaeger (1960) [7] extended the Mohr-Coulomb criterion for anisotropic rocks. He suggested that the shear strength parameters are expressed as continuous functions of direction. In many cases, the intermediate principal stress $\sigma_2$ cannot be ignored. Hill (1950) [8] developed a model for anisotropic metal as follows

$$F(\sigma_y - \sigma_z)^2 + G(\sigma_z - \sigma_x)^2 + H(\sigma_x - \sigma_y)^2 + 2L\tau_{yz}^2 + 2M\tau_{zx}^2 + 2N\tau_{xy}^2 = 1 \tag{1}$$

where $\sigma_x$, $\sigma_y$, and $\sigma_z$ are the normal stresses in three co-ordinate directions, $\tau_{xy}$, $\tau_{yz}$, and $\tau_{zx}$ are the shear stresses, and $F$, $G$, …, and $N$ are material parameters characterizing anisotropy. In fact, this is a model obtained by generalizing the Mises criterion for anisotropic materials. For anisotropic soils and rocks, a better model is Pariseau's criterion (1972) [9]

$$\left[F(\sigma_y - \sigma_z)^2 + G(\sigma_z - \sigma_x)^2 + H(\sigma_x - \sigma_y)^2 + 2L\tau_{yz}^2 + 2M\tau_{zx}^2 + 2N\tau_{xy}^2\right]^{\frac{n}{2}} = 1 + (U\sigma_x + V\sigma_y + W\sigma_z) \tag{2}$$

in which $U$, $V$, and $W$ are additional parameters describing anisotropy, and $n$ is a nonlinear constant. Considering layered soils, Saada (1973) [10] introduced the Gol'denblat-Kopnov criterion which is written

$$\frac{1}{2}\left[U(\sigma_x + \sigma_y) + W\sigma_z\right] + \left[F(\sigma_x^2 + \sigma_y^2) + H\sigma_z^2 + I(\sigma_y\sigma_z + \sigma_z\sigma_x) + K\sigma_x\sigma_y + 2L(\tau_{yz}^2 + \tau_{zx}^2) + 2N\tau_{xy}^2\right]^{\frac{1}{2}} = 1 \tag{3}$$

In this equation the anisotropy parameters are reduced to eight, namely, $U$, $W$ …, and $N$. The model implies that soils behave transversely isotropic, and their strengths parallel to the $x$ and $y$ axes are the same but that perpendicular to the $z$ axis is different. Both Eqs. (2) and (3) are generalized forms of the Drucker-Prager criterion. They are experimentally confirmed to a sufficient degree of accuracy for some soils. These two failure conditions involve the hydrostatic stress, and state that the compressive strength differs from the tensile strength. Therefore, the models account for internal friction of soil. Including the advantages of the above models, a universal failure criterion is suggested as follows

$$i_1 = U\sigma_x + V\sigma_y + W\sigma_z \tag{4}$$

$$j_2 = F\sigma_x^2 + G\sigma_y^2 + H\sigma_z^2 + I\sigma_y\sigma_z + J\sigma_z\sigma_x + K\sigma_x\sigma_y + L\tau_{yz}^2 + M\tau_{zx}^2 + N\tau_{xy}^2 \tag{5}$$

$$j_2^{\frac{n}{2}} = 1 + i_1 \tag{6}$$

In reality, $i_1$ comes from the expansion of the first stress invariant $I_1$ to anisotropy, and $j_2$ is reached by generalizing the second deviator stress invariant $J_2$. The nonlinear relationship between $i_1$ and $j_2$ is established in the form of power function. This model is used to describe anisotropic and nonlinear behavior of soil. In Eq. (6), $j_2$ is of the anisotropy type of the Gol'denblat-Kopnov (G-K) criterion, and thus it is capable of describing a higher degree of anisotropy than Pariseau's criterion of Eq. (2). The nonlinear relationship between $i_1$ and $j_2$ is in the form of the Pariseau criterion, and therefore this power law illustrates much more potential than the linear G-K model of Eq. (3).

Laboratory and *in situ* tests show that failure lines are nonlinear for certain soils and rocks. Temporarily $\sigma_2$ is ignored. The stress difference $q$ is defined as $q=(\sigma_1-\sigma_3)/2$, and the mean stress as $p=(\sigma_1+\sigma_3)/2$. Based on theoretical and experimental analysis, the power law is presented to depict nonlinear relationship between $q$ and $p$. This model takes the form

$$q^n = A_1 p + B_1 \tag{7}$$

where $A_1$ and $B_1$ are strength parameters.

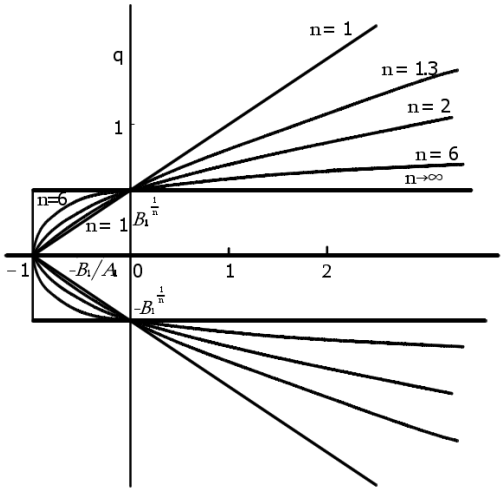

Fig. 2 Failure lines of power law

In Figure 2, nonlinear strength lines are demonstrated in several types of power law. Actually both linear and nonlinear failure criteria are expressed in terms of power function. When $n=1$, Eq. (7) gives a linear criterion. Under the linear condition, Eq. (7) is the Mohr-Coulomb criterion when $A_1 \neq 0$, and it reduces to the Tresca criterion if $A_1=0$. When $n=2$, the failure locus is a parabola. This kind of criterion is sometimes used for soft rocks and soils.

Now the intermediate principal stress $\sigma_2$ is taken into consideration. For isotropic solids, the power function between $p$ and $q$ is extended to the relationship between the first stress invariant $I_1$ and the second deviator stress invariant $J_2$. This model is expressed as

$$J_2^{\frac{n}{2}} = A_2 I_1 + B_2 \tag{8}$$

In Eq. (8), there are also two parameters besides the power $n$. When anisotropic soils are dealt with, Eq. (8) is expanded as

$$j_2^{\frac{n}{2}} = i_1 + 1 \tag{9}$$

This is Eq. (6). $i_1$ and $j_2$ are denoted by Eqs. (4) and (5). Therefore, Eq. (6) is a failure criterion characterizing both anisotropic and nonlinear behavior of soils.

It is common that several types of rock or soil are encountered in a single engineering site. Their mechanical properties are different from position to position. For heterogeneous soils and rocks, strength parameters may be expressed as functions of location. Thus Eqs (4) ~ (6) can be rewritten in terms of co-ordinates

$$i_1 = U(x,y,z)\sigma_x + V(x,y,z)\sigma_y + W(x,y,z)\sigma_z \tag{10}$$

$$j_2 = F(x,y,z)\sigma_x^2 + G(x,y,z)\sigma_y^2 + H(x,y,z)\sigma_z^2 + \cdots \tag{11}$$

$$[j_2(x,y,z)]^{\frac{n}{2}} = 1 + i_1(x,y,z) \tag{12}$$

In practice, the material parameter functions of *U(x,y,z)*, *V(x,y,z)*, … will be determined from tests or observations for various locations. In geological problems, high temperature and high pressure deep in the earth's crust will affect strength and deformability of rocks. Moreover, it is known that geothermal fields are not uniform. A regular variation is that temperature rises with depth. Set

$$t = t(x,y,z) \tag{13}$$

Strength parameters become functions of temperature *t*. Eqs. (10) ~ (12) are rewritten

$$i_1 = U(x,y,z,t)\sigma_x + V(x,y,z,t)\sigma_y + W(x,y,z,t)\sigma_z \tag{14}$$

$$j_2 = F(x,y,z,t)\sigma_x^2 + G(x,y,z,t)\sigma_y^2 + H(x,y,z,t)\sigma_z^2 + \cdots \tag{15}$$

$$[j_2(x,y,z,t)]^{\frac{n}{2}} = 1 + i_1(x,y,z,t) \tag{16}$$

In effect, the influence of non-uniform temperature is the same as that of material heterogeneity. Meanwhile, some other thermal properties of soils and rocks, such as thermal expansion, will also cause stress alteration. This topic will be covered in other relevant research.

**Special Cases of the Proposed Criterion**

The failure criterion of Eqs. (14) ~ (16) is a comprehensive model dealing with heterogeneous, nonlinear, and anisotropic materials. Many classical criteria are its special cases. When the material parameters do not change with position and temperature, Eq. (16) reduces to Eq. (6). It is a nonlinear and anisotropic criterion for homogeneous medium. In Eq. (6), let

$$n = 1 \tag{17}$$

It is simplified into

$$j_2^{\frac{1}{2}} = 1 + i_1 \tag{18}$$

This is the three-dimensional Gol'denblat-Kopnov criterion. In Eqs. (4) ~ (6), assume

$$\begin{cases} I = F - G - H = -2F' \\ J = G - H - F = -2G'' \\ K = H - F - G = -2H \end{cases} \tag{19}$$

Substituting Eq. (19) to Eqs. (4) ~ (6) yields

$$\left[F'(\sigma_y - \sigma_z)^2 + G'(\sigma_z - \sigma_x)^2 + H'(\sigma_x - \sigma_y)^2 + L\tau_{yz}^2 + M\tau_{zx}^2 + N\tau_{xy}^2\right]^{\frac{n}{2}} = 1 + (U\sigma_x + V\sigma_y + W\sigma_z) \tag{20}$$

which is the Pariseau criterion. Now the hydrostatic stress is neglected. That is

$$U = V = W = 0 \tag{21}$$

Eq. (20) becomes the Hill criterion

$$\left[F'(\sigma_y - \sigma_z)^2 + G'(\sigma_z - \sigma_x)^2 + H'(\sigma_x - \sigma_y)^2 + L\tau_{yz}^2 + M\tau_{zx}^2 + N\tau_{xy}^2\right]^{\frac{n}{2}} = 1 \tag{22}$$

When isotropic soil is under consideration, there are relationships in Eq. (20)

$$\begin{cases} F'=G'=H' \\ L=M=N=6F' \\ U=V=W \\ n=1 \end{cases} \tag{23}$$

Substituting Eq. (23) in Eq. (20) gives

$$\left\{\frac{1}{6}\left[(\sigma_y-\sigma_z)^2+(\sigma_z-\sigma_x)^2+(\sigma_x-\sigma_y)^2+6(\tau_{yz}^2+\tau_{zx}^2+\tau_{xy}^2)\right]\right\}^{\frac{1}{2}} = (6F')^{-\frac{1}{2}}+U(6F')^{-\frac{1}{2}}(\sigma_x+\sigma_y+\sigma_z) \tag{24}$$

This is the celebrated Drucker-Prager criterion. Further, the mean stress is ignored, and then

$$U=0 \tag{25}$$

Eq. (24) reduces to

$$\frac{1}{6}\left[(\sigma_y-\sigma_z)^2+(\sigma_z-\sigma_x)^2+(\sigma_x-\sigma_y)^2+6(\tau_{yz}^2+\tau_{zx}^2+\tau_{xy}^2)\right]=(6F')^{-1} \tag{26}$$

It is the famous Mises criterion.

Eq. (26) is applicable to isotropic metal. Eq. (24) is suitable for isotropic soil and rock. Eq. (22) can be used for anisotropic metal. Eqs. (20) and (18) may be employed for anisotropic soil and rock with nonlinear and linear behavior respectively. The criterion of Eq. (16) presented in this paper can be applied for heterogeneous, nonlinear, and anisotropic geomaterials.

## Case Study of the Proposed Model

The Ankang Dam is taken as an example. It is shown how to apply the proposed criterion for actual engineering projects. Rock foundations of the Ankang dam consist of metamorphic rock formed in the Sinian Period. Phyllite and schist are widely distributed. Experimental data show that these rocks exhibit strong anisotropy. Rock specimens are prepared from drill cores. Specimens are made dry, wet, and saturated separately. Unconfined compression tests are carried out. Loads is applied perpendicular, parallel, and inclined to weakness planes of rock respectively. When weaknesses are inclined, the load orientation varies from 10° to 60°. For a transversely isotropic medium, the proposed criterion of Eqs. (4) ~ (6) may be expressed as

$$\left[F(\sigma_x^2+\sigma_y^2)+H\sigma_z^2+I(\sigma_y\sigma_z+\sigma_z\sigma_x)+K\sigma_x\sigma_y+L(\tau_{yz}^2+\tau_{zx}^2)+N\tau_{xy}^2\right]^{\frac{n}{2}} = 1+U(\sigma_x+\sigma_y)+W\sigma_z \tag{27}$$

Here the *z* axis is normal to geological planes. The loading direction changes within the *zx* plane. In this example, $\sigma_y=0$. Substituting into Eq. (27) yields

$$\left(F\sigma_x^2+H\sigma_z^2+I\sigma_z\sigma_x+L\tau_{zx}^2\right)^{\frac{n}{2}}=1+U\sigma_x+W\sigma_z \tag{28}$$

where there are seven parameters totally. The Mohr circle of stress for unconfined compression can be applied in the stress analysis. The stress components with reference to co-ordinates can be calculated using the following

$$\begin{cases} \sigma_x=\sigma\sin^2\theta \\ \sigma_y=\sigma\cos^2\theta \\ \tau_{zx}=\sigma\sin\theta\cos\theta \end{cases} \tag{29}$$

where $\theta$ is the angle between the *z* axis, i. e. the normal to weaknesses, and the load is $\sigma$. Substituting Eq. (29) in Eq. (28) gives

$$\left(F\sigma^2 \sin^4\theta + H\sigma^2 \cos^4\theta + I\sigma^2 \sin^2\theta\cos^2\theta + L\sigma^2 \sin^2\theta\cos^2\theta\right)^{\frac{n}{2}} = 1 + U\sigma \sin^2\theta + W\sigma \cos^2 \tag{30}$$

It has been verified that a parabolic failure curve is applicable to some soft rocks. This is the case for the Anking dam according to investigation. Let $n=2$. Substituting to Eq. (30) and rearranging it yields

$$F\sigma^2 \sin^4\theta + H\sigma^2 \cos^4\theta + I\sigma^2 \sin^2\theta\cos^2\theta + L\sigma^2 \sin^2\theta\cos^2\theta - U\sigma \sin^2\theta - W\sigma \cos^2\theta = 1 \tag{31}$$

In order to determine the six parameters in the above equation, six sets of $\theta$ versus $\sigma$ data are obtained from tests. Saturated phyllite specimens are prepared and tested. The experimental data are shown in Table 1.

Table 1 Unconfined compression test results for Ankang phyllite

| θ(°) | 0 | 45 | 50 | 60 | 70 | 90 |
|---|---|---|---|---|---|---|
| σ(MPa) | 69.167 | 36.250 | 45.700 | 26.500 | 64.150 | 55.025 |

In Eq. (31), the parameters $I$ and $L$ are identical. Therefore, only five sets of experimental data are necessary. Select five groups in Table 1. Substitute to Eq. (31) and solve the system of equations for the parameters. Finally the following results are obtained

$$\begin{cases} F = -8.47450094\times10^{-4} \\ H = -3.30567059\times10^{-4} \\ I + L = -1.41260893\times10^{-3} \\ U = -6.480586986\times10^{-2} \\ W = -3.73229342\times10^{-2} \end{cases} \tag{32}$$

This is the failure criterion for the Ankang rock foundation. The model is applied for stability analysis of the rock masses. The bearing capacity of the foundations, the safety factor of the slopes, and many other solutions for the Ankang project are determined. The elastoplastic analysis using the finite element method containing the present criterion is performed. All the study indicates the proposed criterion displays good potential in application.

## Conclusions

A failure criterion for heterogeneous, nonlinear, and anisotropic geomaterials is proposed. It accounts for the influence of the intermediate principal stress. Anisotropy arising from weakness planes is considered. Nonlinear envelopes to Mohr's circles are involved. Heterogeneous media and non-uniform thermal fields are discussed.

This model is highly comprehensive. It may reduce to the Mises criterion, the Drucher-Prager criterion, the Hill criterion, the Pariseau criterion, and the Gol'denblat-Kopnov criterion. There are totally thirteen parameters in this criterion. They can be determined from conventional tests of unconfined compression, uniaxial tension, biaxial compression, and direct shear.

A case study of the Ankang dam illustrates that the proposed criterion is applicable to actual engineering. It demonstrates good potential in stability analysis of complex soils and rocks.

**Key words**: GSI; P-velocity; Hoek-Brown; Mechanical parameters;

**Abstract.** Rock mass mechanical parameters play a significant role in geotechnical engineering design, slope stability evaluation and numerical simulation, which is commonly determined by GSI method. The simplified method using P-velocity to determine GSI (Geological Strength Index) values is proposed in this study, avoiding the limitations of Hoek-Brown method. The relationship between GSI and P-velocity is established through data collected from several projects in China. Then the dam site of Rumei hydropower station, Tibet, China has been taken as a case study to validate this relationship. This method can be utilized directly in engineering projects since it can meet with the engineering accuracy requirement and reduce the cost.

## Introduction

With the progressive proceeding of hydropower engineering, the determination of rock mass deformation modulus has become more and more important in geotechnical engineering design, rock mass deformation analysis, slope stability evaluation and numerical simulation et al..

The common processes for determining rock mass deformation modulus consist of in situ test method (Rocka and Dasilv, 1970), numerical method (Kawamoto and Ichikawa, 1988) and rock mass classification method (Bieniawski, 1978; Hoek and Brown, 1997). However, some of these methods have large limitations in the following ways. Firstly, it is time consuming and expensive for in situ test; secondly, for numerical method, it is difficult for general engineers to establish the complex constitutive models; thirdly, the selection of training samples is subjective for artificial neural network method. Nevertheless, the rock mass classification method with the properties of simplicity, accuracy and money-saving, has being widely used in engineering practice.

For this reason, many researchers proposed some empirical relations based on the rock mass classification method (Q, RMR, GSI and RQD method) to predict rock mass deformation modulus. Amongst those empirical formulas, the most commonly utilized and effective method is GSI method proposed by Hoek and Brown, since the estimated values can be employed in the practical engineering directly, especially for the closely jointed and heterogeneous rock mass.

Sonmez and Ulusay (1999) proposed an empirical approach for the prediction of rock mass deformation modulus based on the quantitative GSI system and suggested to consider disturbance factors, and then Sonmez and Ulusay (2002) slightly modified the quantitative GSI chart. Marinos and Hoek (2000) suggested adding intact or massive rock into the top row of the GSI system. Hoek (2006) studied to take into account the properties of the intact rock as well as the effects of disturbance due to blast damage or stress relaxation in GSI system. Cai (2007) presented a method to extend the GSI system for the estimation of rock mass residual strength, which is proposed to adjust the peak GSI to the residual GSI value based on the two major controlling factors—the residual block volume and the residual joint condition factor. Russo (2009) put forward a new approach for a quantitative assessment of the GSI values based on the relationship between GSI and

joint parameter used in RMi system. Okay Aksoy (2012) made comparisons of different empirical equations of rock mass deformation modulus including GSI method with numerical model results.

Unfortunately, although the GSI (Hoek-Brown) method has been used widely in recent decades, the disadvantages of this method cannot be ignored especially for those who are short of geological experience, because the GSI values obtained from the chart can only be a range due to the lack of the accurate measurable parameters to describe the characteristics of rock mass structure and the conditions of discontinuities. Meanwhile, the quantitative assessment of the GSI values proposed by some researchers is sometimes complicated and inconvenient for engineering practice. Therefore, it is crucial to find a simplified method to estimate GSI values to meet the need of practical engineering.

The purpose of this study is to propose a new method to determine the GSI values more simply by establishing the relationship between GSI and P-velocity (Vp) using the data collected from several large-scale projects in China. Then the comparisons of the GSI prediction performance between the P-velocity method and Hoek-Brown method were made to validate the accuracy of this relationship through Rumei hydropower station engineering, Tibet, China, which provides the scientific basis for engineering practice.

**Structure of the database**

The data for this study were collected from 14 dam sites in China, namely the Yinpan dam in Wujiang river, the Three Gorges Dam, the Jinshuitan dam, the Gezhou dam, the Longyangxia dam, the Longtan dam, the Tongjiezi dam, the Pubugou dam, the Baozhusi dam, the Manwan dam, the Goupi dam, the Enshi dam, the Maerdang dam and the dam in Lancang river.

Table 1 The statistical evaluations of some parameters provided from the studied locations

| properties | locations | Min | Max | Mean | Count |
|---|---|---|---|---|---|
| GSI | the Yinpan dam | 26.71 | 68.25 | 52.48 | 9 |
| | the Three Gorges dam | 55.86 | 80.87 | 71.08 | 7 |
| | the Jinshuitan dam | 51.76 | 78.76 | 66.56 | 3 |

## The determination of GSI values by utilizing P-velocity

### The qualitative method to determine GSI by Hoek and Brown

The geological strength index (GSI) method was put forward and developed by Hoek and Brown, which can be used to estimate rock mass deformation modulus of different geological conditions, especially for the closely jointed and heterogeneous rock mass, hence, it overcomes the deficiency of RMR method and becomes the widely used method in the world. The GSI values are estimated from the rock mass structure and the discontinuities surface condition, and the deformation modulus can be deduced from formula (1) (Hoek,1997).

$$E_m = \sqrt{\sigma_c / 100} * 10^{((GSI-10)/40)} (GPa) \quad (1)$$

Where $\sigma_c$ is the uniaxial compressive strength of intact rock, $GSI$ is the geological strength index, and $E_m$ is the deformation modulus of rock mass.

### The quantitative method to determine GSI by using P-velocity

Although the GSI method has been utilized widely in recent decades, the drawbacks of this method cannot be neglected. Without the accurate measurable parameters to describe the characteristics of rock mass structure and the conditions of discontinuities, the GSI values can merely be range values from the chart above, which leads to large errors especially for the engineers who are lack of experience. Meanwhile, the quantitative assessment of the GSI values put forward by some researchers is sometimes complex and difficult for engineers to grasp. Therefore, under the condition to meet the need of engineering projects, it is crucial to find a simplified method to estimate GSI values.

In general, the larger the sound wave velocity is, the better the rock mass integrity is, the higher the rock mass quality is, and the larger the corresponding GSI value is. Therefore, both the GSI and P-velocity have the tendency to increase with the increasing of rock mass integrity.

To find the specific relationship between the GSI and P-velocity, the data collected from above were imported into the Statistica software, resulting in the logarithmic relationship presented in Figure 1. The results shows that the fitting relationship is very good.

$$GSI = 76.61 \lg V_p - 216.56 \qquad r^2 = 0.8475 \quad (2)$$

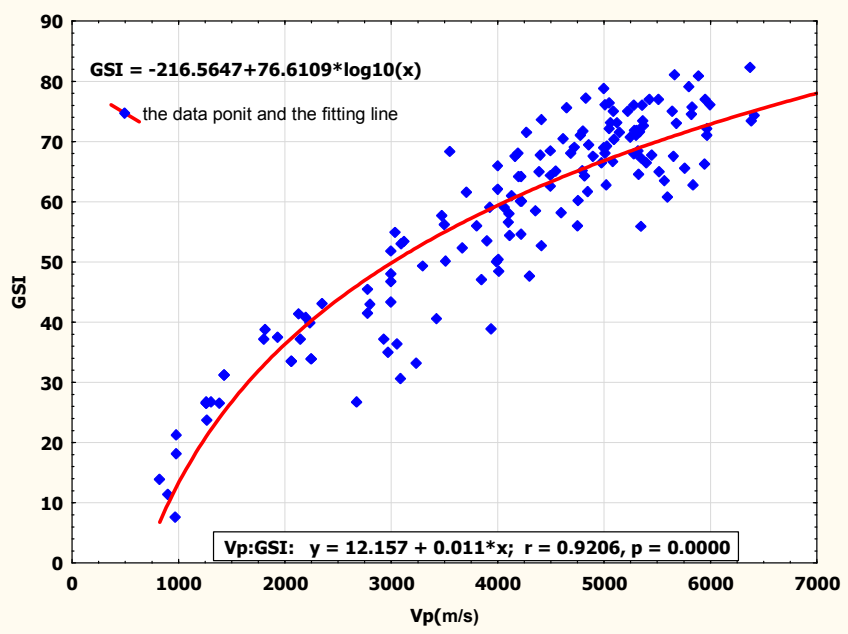

**Figure 1.**The fitting relationship between P-velocity and GSI

## The validation of using P-velocity to determine GSI value

### The research background for engineering project

Rumei hydropower station is located in the Mangkang County, Changdu district, Tibet, China, along Lantsang River. The Rumei hydropower station dam is about 315 m high, the drainage area of Lantsang River is $7.94\times104$ km$^2$, and the average river discharge is 653m$^3$/s.

The dam site encompasses three different formations, namely, the Triassic Series of Zhuka Formation ($T_2z$) for which the predominant lithology is dacite; the Jurassic Series Huakai formation ($J_2h$) for which the lithology includes sandstone and mudstone with the same amount; the Quaternary (Q). The large scale of geological structure observed at the dam site is Zhuka Fault (F), which is located about 0.8 kilometers away from left dam abutment. Gentle dipping advantage discontinuities are developed on both sides of the valley, and secondary discontinuities, small faults and cracks are developed randomly in this area.

In situ tests were carried out on dacite rock mass of Rumei dam site through scientists and engineers from Guiyang Investigation and Design Institute, State Power Corporation, China. The Schmidt hammer test, P-velocity tests and plate-loading tests were conducted to obtain the uniaxial compressive strength of intact rock, P-velocity and deformation modulus of rock mass. The GSI values can be deduced backwards from formula (1).

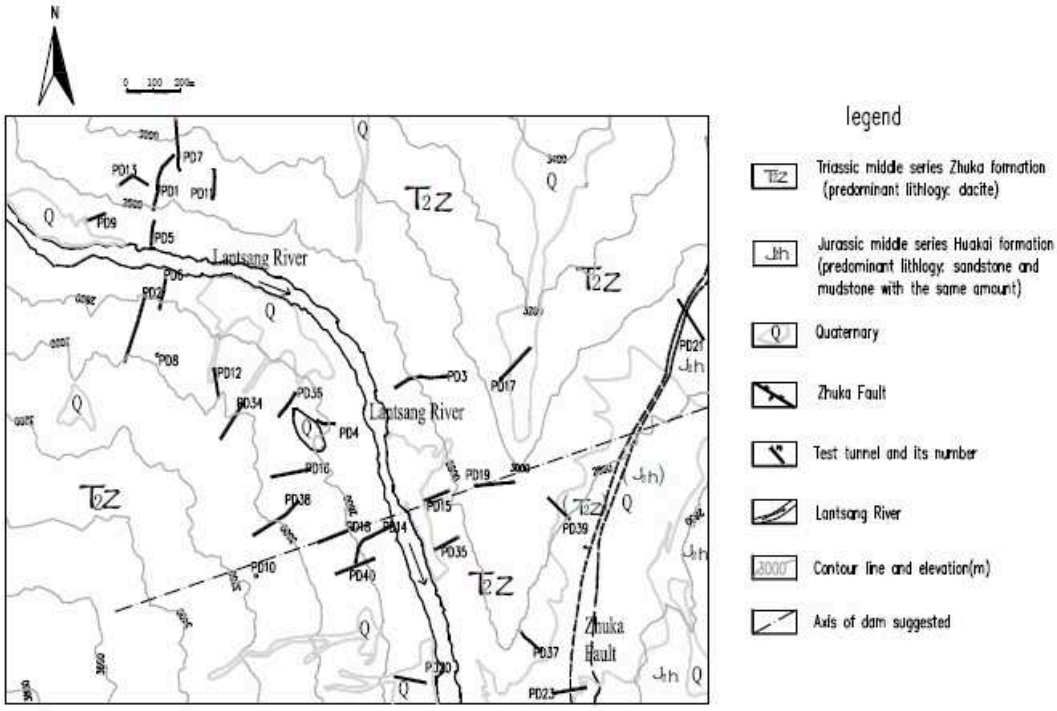

**Figure 2.** The engineering geological figure of this dam site

**Table 2** Rock mass deformation modulus, uniaxial compressive strength and P-velocity results from in situ tests

| | Tunnel number and location of test point (from the tunnel entrance) | Deformation modulus (Em, GPa) | Uniaxial compressive strength (UCS, MPa)* | P-velocity (Vp, m/s) | GSI （Hoek-Brown method） |
|---|---|---|---|---|---|
| 1 | PD17 (22m) | 4.36 | 16.3 | 2506.5 | 51.34 |

| 16 | PD15 (70m) | 22.87 | 42.9 | 5050 | 71.72 |
| 17 | PD15 (98m) | 25.32 | 59.3 | 5415 | 70.68 |

*Note: Uniaxial compressive strength is obtained by rebound apparatus

**The comparisons of GSI values between P-velocity method and Hoek-Brown method**

The GSI values of this dam site based on P-velocity method can be obtained by formula (2), therefore, the results presented in table 3 show that the prediction performance of using P-velocity method to determine GSI values is good when compared with the Hoek-Brown method, meanwhile, the relationship between GSI and P-velocity based on 14 dam site in China is accurate which can be used to determine GSI values for other engineering projects.

**Table 3** The comparisons of GSI values between two methods

| | GSI（Hoek-Brown method） | GSI（P-velocity method） | error |
|---|---|---|---|
| 1 | 51.34 | 43.85 | 0.146 |
| 2 | 56.06 | 44.63 | 0.204 |
| 3 | 59.67 | 56.58 | 0.052 |
| 4 | 62.68 | 52.27 | 0.166 |
| 5 | 62.47 | 66.18 | 0.059 |
| 6 | 66.41 | 62.23 | 0.017 |
| 7 | 66.15 | 60.66 | 0.083 |
| 8 | 65.60 | 60.02 | 0.085 |
| 9 | 63.83 | 68.35 | 0.071 |

| 13 | 66.41 | 62.23 | 0.063 |
| 14 | 66.42 | 64.59 | 0.028 |
| 15 | 65.98 | 68.48 | 0.021 |
| 16 | 71.72 | 67.15 | 0.064 |
| 17 | 70.68 | 69.47 | 0.017 |

**Conclusions**

The simplified method using P-velocity to determine GSI values is proposed and validated in this study.

The relationship between GSI and P-velocity is established through 150 data collected from 15 large-scale projects in China, and the fitting relationship is obtained as GSI=76.61lgVp-216.56 ($r^2$=0.8475). Then the dam site of Rumei hydropower station, Tibet, China has been taken as a case study to validate this relationship. The results show that the error of using P-velocity method and Hoek-Brown method to determine GSI values is small, resulting in the conclusion that the method to determine GSI values by using P-velocity is reasonable.

The P-velocity method overcomes the limitations that the GSI values based on Hoek-Brwon method cannot be obtained accurately in the non- isotropic rock mass of multilayers with different lithology and strength, which provides a new way for this type of rock mass to determine GSI values.

In conclusion, using P-velocity method to determine GSI values provides a feasible, rapid and economical method for the estimation of rock mass mechanical parameters. This method can be utilized directly in engineering projects if the in-situ shear tests are not carried out, since it can meet with the engineering accuracy requirement and reduce the cost.

# Analysis of Engineering Characteristics of Cement Soil with Low Mix Additions

Ai Min Liu

CCCC-Tianjin Port Engineering Institute, Ltd., Key Laboratory of Geotechnical Engineering, Ministry of Communications; Key Laboratory of Geotechnical Engineering of Tianjin, West District, Tianjin, China, 300222

liuaimin1987@163.com

**Keywords:** Low mix additions; cement soil; engineering characteristics

**Abstract.** The mold bag cement soil was used to be as the material of dike core while building cofferdam. So the engineering characteristics of cement soil with low mix additions were analyzed in this paper. It was pointed out the unconfined compressive strength of cement soil is mainly related to the property of soil, water content, cement mixing content and degree of mixing uniformity, but has little to do with curing condition, cement adding way and the property of mixing water.

## Introduction

When building cofferdam and bank revetment in region with soft clay in our country, the riprap mound breakwater and backfilling sand dike are the common structural style. In the region with lacking sand and stone resources, large amount of fund needs to be invested for the procurement and transportation of sand stone materials, which makes the costs for building riprap mound breakwater and backfilling sand dike are very high[1,2]. Therefore, the new cofferdam type has been tried to develop. The successful applications of cement soil cofferdams with low mix additions in Tianjin and Lianyungang have great significance for building cofferdam in region lacking sand and stone materials.

By adopting cement soil with low mix additions as dike core of cofferdam, its engineering characteristics shall be analyzed so as to guide and optimize the design and reduce engineering cost.

## Research Approach

There are many factors to affect the strength of cement soil. The mainly factors are as follows: (1) Cement: the type, mix proportion and mixing content of cement; (2) Soil property: the property of soil in different area is difference, and even for the soil of different type in the same area, there is also relatively large difference; (3) Degree of mixing uniformity: It is the degree of mixing uniformity of cement. These factors will affect the strength of cement soil. Therefore, the tests were done regarding several main influential factors.

## Research Results

Main test materials are soil sample, water and curing agent. The soil sample used in test is from the seabed of Port of Tianjin. They were mainly mucky clay and ultra-soft clay. Table 1 is the main physical mechanical properties of the soil samples. The water used in test is sea water at the place with soil borrowing. And the fresh water for comparative test is from the running water of residents. Cement used in test is P.O.32.5 Portland cement.

**Table 1 Statistical table of main physical mechanical properties of soil sample**

| Description of soil | Water content % | Unit weight kN/m$^3$ | Porosity ration | Plasticity index | Liquidity index | UU strength index | | Coefficient of compressibility MPa$^{-1}$ | Modulus of Compressions MPa |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | | c(kPa) | φ(°) | | |
| Ultra-soft clay | 63.7 | 16.2 | 1.747 | 25.9 | 1.55 | 5.23 | 0.1 | 1.52 | 1.86 |
| Mucky clay | 41.0 | 18.1 | 1.149 | 17.1 | 1.25 | 10.91 | 4.36 | 0.83 | 2.99 |

**Relation between Mixing Amount of Cement and Strength.** As cement is the major material in this test, its consumption has great influence on the cost of project. Thus, it is very important to select a proper mixing proportion which could meet the strength requirement while reducing construction cost to a maximum extent.

In the cement soil cofferdam, the strength of cement soil does not need to be as high as that of ordinary cement mixing soil. Therefore, cement mixing content needn't too high for unnecessary waste, but its strength shall neither be too low, as it will have influence on the stability of mold bag and construction progress. For this purpose, the cement mixing content is 6～10% (mass ratio between cement mixing content and the soil to be mixed). It is resulted that the strength of cement soil is greatly improved comparing with that of previous soft clay, but the strength of cement soil is still very low in case cement mixing content is 6%. When cement mixing content exceeds 7%, the shaping state of cement soil is greatly improved. Thus, the cement mixing content of project site is intended to be 8%. It is because that the operation condition in laboratory test is better than that of project site. The construction effect at site shows about 8% cement mixing content could better ensure the stability of cement soil mold bag and the interval with the filling construction of mold bag of the next layer.

Figure 1 is the relation between unconfined compressive strength and curing period. The laboratory test condition was P.O.32.5 Portland cement, standard curing condition (20±3 ℃, immersed).

It can be seen from the Figure 1 that the larger the cement mixing content is, the higher the strength of cement soil is. The unconfined compressive strength of cement soil with 8% cement mixing content and 11 days curing period is to 0.69MPa.

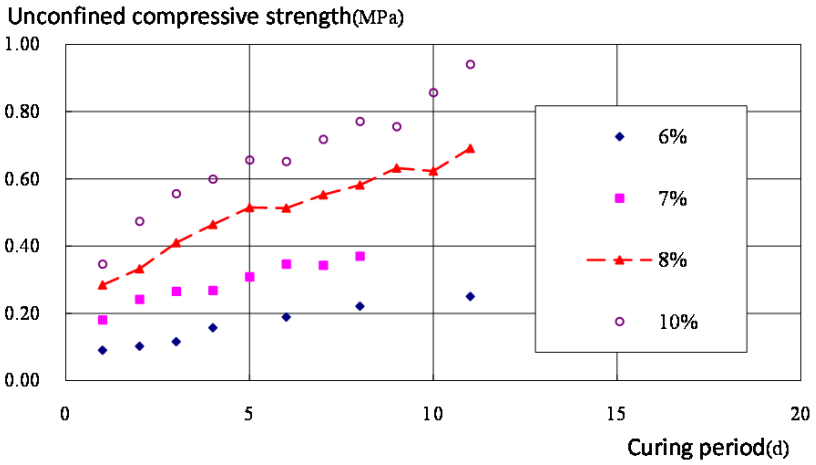

**Fig.1 Strength of cement soil with different mixing contents**
(P.O.32.5 Portland cement , water content is 58%)

**Relation between Water Content of Soil and Strength.** Figure 2 is the correlation curve of strength of cement soil with the same cement mixing content and different water contents. Under the same

curing condition, it is shown that the lower the water content of soil is, the higher the unconfined compressive strength of cement soil with the same cement mixing contents.

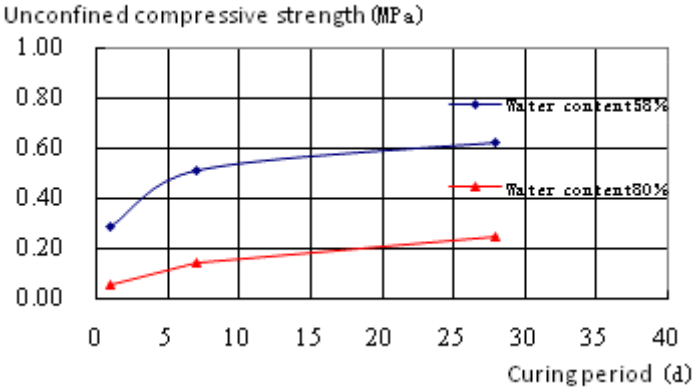

**Fig.2 Correlation curve of strength of cement soil with different water contents**
(8% cement mixing content)

**Relation between Soil Property and Strength.** The comparative tests for cement soil strength of ultra-soft clay, mucky clay, mucky silty clay and silt of Port of Tianjin were done. The results are shown on Figure 3.

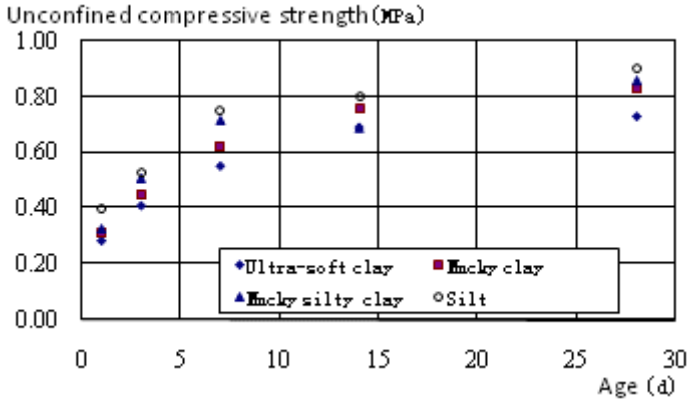

**Fig.3 Strengths of four kinds of soil under the same test condition**
(8% cement mixing content and P.O.32.5 Portland cement)

Test result shows the strengths of cement soil made with mucky silty clay and silt are higher than the strengths of cement soil made with ultra-soft clay and mucky clay under the same cement mixing content. This result is convenient to borrow soil at project site. The soft clay of seabed could be used as wanted.

**Relation between Degree of Mixing Uniformity and Strength.** Generally, the degree of mixing uniformity has a large influence on the strength of cement soil. The better the mixing uniformity is, the higher the strength of cement soil is, while the worse the mixing uniformity is, the lower the strength of cement soil is. Two kinds of cement soil with the same cement mixing content were made, one was uniformly mixed in laboratory and the other was incompletely mixed at project site, and the comparative tests of cement soil strength were done under the different ages and the same curing condition. The result shows the unconfined compressive strength of cement soil (P.O.32.5 Portland cement mixing content is 8%) prepared in laboratory with seabed soft clay could reach 0.69MPa after 11 days, and test condition is standard curing condition (20±3℃, immersed, water content of cement soil is about 58%), see Figure 1. Under the same standard curing condition, the strength of cement soil mixed at site is only 0.243MPa after 14 days (See Figure 4), which is obviously lower than the unconfined compressive strength of cement soil mixed in laboratory. The main reason is the degree of

mixing uniformity at site is relatively low. As there are few test samples of cement soil at site, the formula of relation between site strength and indoor strength cannot be found out for the moment.

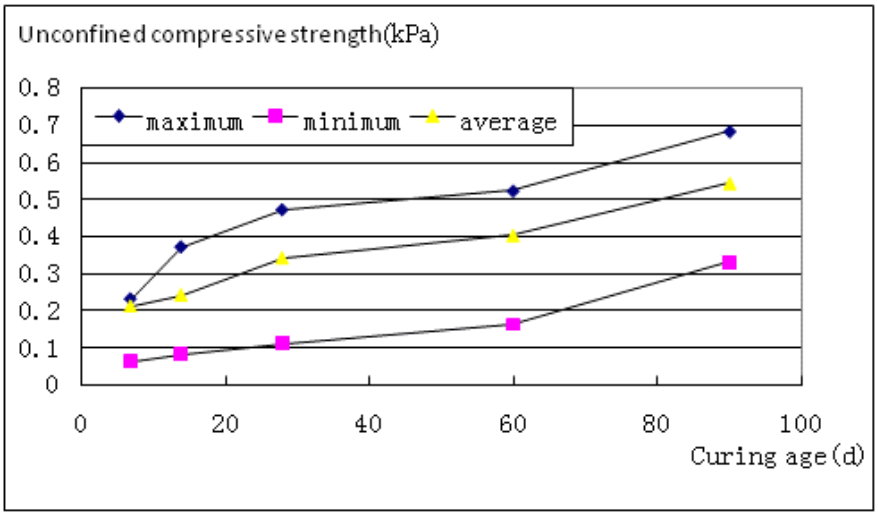

**Figure 4 Strength of on-site shaped cement soil with 8% mixing content under indoor curing condition**

In addition, the laboratory tests were also done for the influence of mixing form of cement, curing condition and test water on strength of low mix addition cement soil. The results show there is no obvious influence on unconfined compressive strength of cement soil whether mixing dry or wet cement, or whether sea water or fresh water. And the influence of the change of curing temperature (10℃～30℃) on strength is also very small.

## Conclusions

(1)The unconfined compressive strength of cement soil is mainly related to the property of soil, water content, cement mixing content and degree of mixing uniformity, while has little to do with curing condition, the mixing form of cement and mixing water.
(2)The unconfined compressive strength of cement soil uniformly mixed in laboratory is far higher than that mixed at site under the same curing condition.

**Keywords:** Brittle rock; failure; energy; high geostress

**Abstract.** Energy transformation in rock failure process is a complicate process, especially in the high geostress conditions. First from the point of energy, analysis and study on the rock deformation and failure process under uniaxial compression and triaxial compression condition. Based on the test results, the deformation failure characteristics and its energy in triaxial compression are analyzed. Reveal the energy dissipation and energy release characteristics in the process, and found the internal causes is stored elastic in rock mass unit can release suddenly and cause rock damaged. Especially in the high geo-stress condition, the compressed engineering rock mass are often faced with the risk of unloading damage. After add anchor, the mechanics performance of specimen after peak period is significantly improved, and can absorb more of the release of strain energy, which is helpful for maintaining the overall stability of surrounding rock.

## Introduction

With the human activity spread to the underground space, more and more underground engineering are constructed in high geostress area. For example, the biggest geostress of lashiwa hydropower station underground workshop is 29.6 MPa, the maximum principal stress value of jinping I hydropower station underground workshop is 37.5 MPa, and the measured the maximum principal stress value of Jinping II long tunnel of hydropower station is as high as 42 MPa. The part west-line project of south-to-north water transfer project in planning will meet 50MPa squeezing stress when excavated. The above projects belong to high geostress underground engineering in reference [1].

In the high geostress condition, unloading rock mass action can cause internal the agglomeration of elastic strain energy release suddenly for excavation, and in the long-term of the geological tectonic movement rock as a kind of inhomogeneous multiphase composite structure material, internal formed a wide variety of scale joints and fissures, and had a random state distribution. When get the outside effect, the internal defects of micro occurring regularly evolution, crack gradually expand, in local form breakthrough area. Along with the increase of external function, these tiny crack development into cracks. Bearing force over the limit, crack extension forward quickly, resulting in rock instability and failure, causing the surrounding rock and pineapple rock burst occurred brittle failure phenomenon, to the stability of surrounding rock and personnel equipment safety brought serious threat, so study under high geostress underground rock destruction of energy to ensure the safety of the engineering characteristics and the stability of the major research value.

## Relationship between failure and energy

Figure 1 is the uniaxial compression stress strain curve, generally, the whole process of the rock deformation can be divided into five stages in reference [2], the five stages corresponding to different energy into form.

1) Compress dense phase (OA) : When rock in compression, the internal defects gradually closed, input in the conversion of energy for rock elastic energy stored in internal; If unload the part of the energy and can be released.

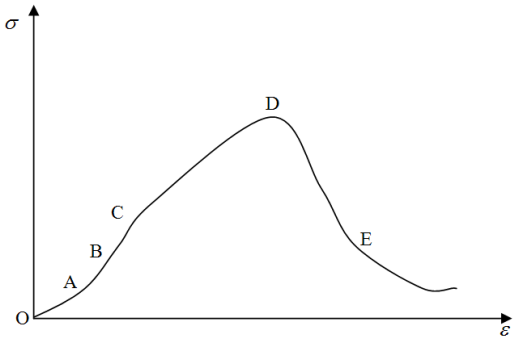
2) Elastic stage (AB) :Rock will produce linear elastic deformation, the outside world can input into the rock elastic energy. If in the range and unloading, energy and can be released, and will not cause damage to the destruction of the rock.

3) Stable cracking stage of development (BC) : After the elastic limit, rock come into the plastic deformation stage,the micro crack began to appear as stress rupture and poor and the increase of development, when the stress remain unchanged, the rupture also stop development. The tester input energy into elastic energy.

4) Unstable cracking stage of development (CD): In this stage micro broken development came a qualitative change, elastic energy storage is abate, due to the rupture process caused by stress concentration effect significantly, and even work stress unchanged, broken still keep progressive development, make the weak link in damage. At this time, body strain to inflation, axial strain rate and lateral strain rate increase accelerated.

5) Strain softening stage (DE): The microcrack join into and produce the macro rock ,which lead to the overall destruction. The storage of elastic energy released, transformation, such as kinetic energy to surface, all kinds of radiant energy increase a lot.

From the above it can be seen in the whole process of rock deformation, the different stage have different ways of energy conversion, the general can think, in the peak intensity D point before the performance for the slow the energy dissipation process, and the peak value point is energy change is sharply after the release of the process.



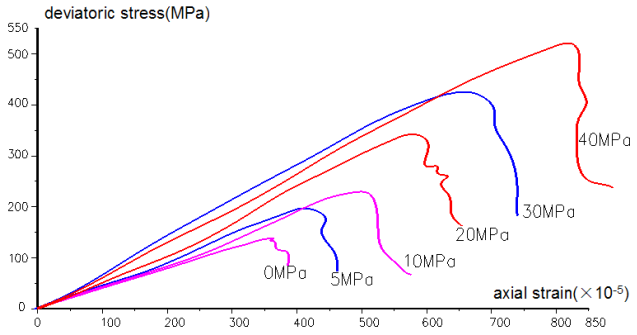


**Fig. 1 Curve of rock stress-strain Fig.2Curve of stress-strain under pseudo triaxial compression**

## Test research on energy characteristic in failure process

This test is developed by rigid pressure in the testing machine. In the experiment, the axial displacement and transverse displacement rate joint control, axial displacement load rate is 0.002 mm/s, and transverse displacement load rate is 0.0005 mm/s (in confining pressure). Processing molding the specimens for cylindrical, a diameter of 50 mm and 100 mm high. The rock specimen is loaded by the axial displacement control loading mode. In the process, the axial displacement of the 5 mm D1117 sensor measuring axial displacement, 100 kN load sensor measuring of the rock axial load, and the testing machine to be automatic conversion into the corresponding strain and stress the output to data collection system. The 5 mm diametral strain of chain sensor record was adopted.

Conventional triaxial compression test confining pressure are chosen 5, 10, 20, 30, 40 MPa. Test the axial displacement control early loading mode; When curve deviates from the straight start segment, the switch as horizontal displacement control loading mode. Begin by hydrostatic pressure conditions on the reservation gradually to the confining pressure value (confining pressure loading using manual control mode, the loading process in two to three minutes to complete), and then keep the confining pressure constant and continuous sinusoidal axial pressure test until the end.

Conventional rock uniaxial compression and triaxial compression test have been mechanical parameters are given in table 1, including confining pressure for rock damage instantaneous confining pressure value, strength in the rock for confining pressure under the condition of the axial load-bearing capacity, and elastic modulus for rock is axial compression curves straight segment of the slope.

**Tab. 1 Rock mechanics parameters**

| NO. | Loading mode | Confining/MPa | Strength/MPa | Elastic modulus/Gpa | Passion ration |
|---|---|---|---|---|---|
| ETD-1 | Unaxial compression | 0.0 | 142.27 | 32.28 | 0.246 |
| ETD-2 | | 0.0 | 143.84 | 33.08 | 0.248 |
| ETD-3 | | 0.0 | 141.39 | 32.08 | 0.244 |
| ETD-4 | | 0.0 | 145.38 | 33.65 | 0.252 |
| ETD-5 | | 0.0 | 138.98 | 31.58 | 0.241 |
| ETD-6 | | 0.0 | 139.24 | 31.89 | 0.245 |
| ETD-7 | | 0.0 | 128.18 | 22.11 | 0.237 |
| ET-1 | Triaxial compression | 5.0 | 198.50 | 32.26 | 0.249 |
| GT-2 | | 10.0 | 229.08 | 33.10 | 0.261 |
| GT-4 | | 20.0 | 343.57 | 35.79 | 0.264 |
| GT-5 | | 30.0 | 418.34 | 36.19 | 0.253 |
| GT-6 | | 40.0 | 519.78 | 37.21 | 0.247 |

## Energy characteristic

The generation of new fracture rock material need energy dissipation, fracture surface of the sliding between to energy dissipation, rock material of the yield of destruction and damage fracture is essentially an energy dissipation process. Axial compression, the initial testing machine is the work done by the energy dissipation of the rock material. But in confining pressure under the action of core distortion, confining pressure also the initial work is done. And derived from [3] in confining pressure the energy dissipation for actual rock is

$$U = \int \sigma_1 d\varepsilon_1 + 2\int \sigma_3 d\varepsilon_3 \tag{1}$$

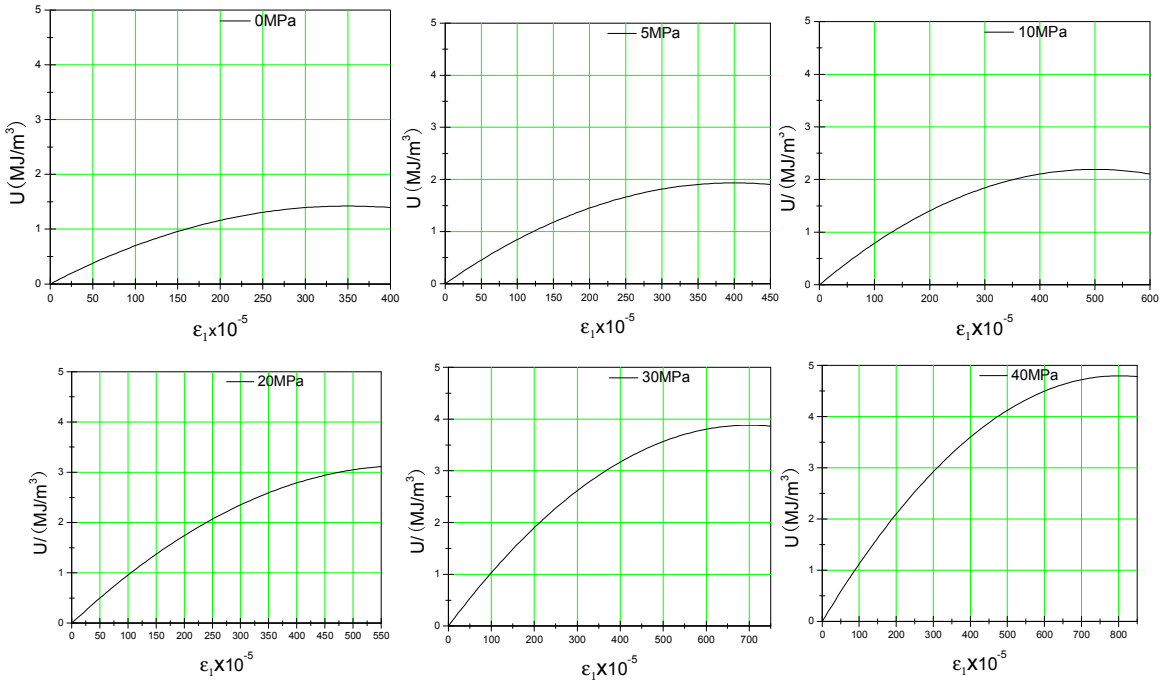

**Fig.3 Energy dissipation properties under different confining pressures**

Figure 5 gives different confining pressure under the effect of axial compression damage of rock energy analysis. The chart shows, online elastic stage, the rock of the actual absorption energy roughly into parabolic increase. Rock began to yield, as the axial stress increase slowly and ring to deformation increase quickly, rock sample of actual absorption energy increase speed slow. After the peak intensity, of the rock deformation change, the absorption of energy with the axial deformation also changes the speed increase further reduced. It is worth noting that, when rock has broken down completely, produce the macro fracture surface, change is shear failure surface friction between the work done. From this may know, is in peak strength of rock after absorbing energy is mainly used to internal material plastic sliding between doing work. And with the increase of confining pressure, absorb energy of rock gradually increase. Low confining pressure when the energy of the actual absorption of rock specimens is very little, and relatively slow increase; But high confining pressure when the energy of the actual absorption of rock specimens is very big, and increase more quickly.

## Summary

The destruction of the rock material and energy is closely related to the changes, especially in the high ground stress conditions. Under the condition of high ground stress in surrounding rock of the damage characteristics of energy, respectively, the deformation and energy surrounding rock the relationship of change, anchor on the influence of the fracture energy and excavation process release of energy and transfer, get the following conclusion:

(1) In the whole process of rock deformation, the different stage have different ways of energy conversion, the general can think, is in peak strength point before the performance for the slow the energy dissipation process, and the peak value point is energy change is sharply after the release of the process. Dissipation to a certain extent inevitable to release the transition, the energy dissipation of strength of rock of that reduce, energy release is a rock reckoning the real cause of the damage.

(2) Rock mass unit stored elastic energy released is a unit of rock mass destruction suddenly internal causes. Especially in the high ground stress condition, for excavation unloading rock mass action can cause internal agglomeration elastic strain can suddenly released, can cause rock destruction, to the stability of surrounding rock and personnel equipment safety brought serious threat;

(3) In three axis of stress state of engineering, and if some of the direction of stress suddenly drops, cause rock in lower stress state damage, so the rock of actual absorption energy is reduced, the original rock stored elastic strain energy release will be foreign, converted to rupture the kinetic energy of rock, rock, rock burst fracture may occur and pineapple brittle failure phenomenon.

**Keywords:** prediction method; shear wave velocity; in-situ test; offshore engineering; GRNN.

**Abstract.** Characterization of the shear wave velocity of soils is an integral component of various seismic analysis, including site classification, hazard analysis, site response analysis, and soil-structure interaction. Shear wave velocity at offshore sites of the coastal regions can be measured by the suspension logging method according to the economic applicability. The study presents some methods for estimating the shear wave velocity profiles in the absence of site-specific shear wave velocity data. By applying generalized regression neural network (GRNN) for the estimation of in-situ shear wave velocity, it shows good performances. Therefore, this estimation method is worthy of being recommended in the later engineering practice.

## Introduction

Values and vertical gradients of shear wave velocity ($V_s$) are important physical and mechanical properties of soils. They are used in both basic and applied engineering geology and civil engineering. They are important in determining the soil dynamic behavior and liquefaction susceptibility, as well as in static loading situations, including site classification, hazard analysis, site response analysis, and soil-structure interaction [1-3]. Many building and geotechnical engineering investigation codes now require consideration of site response when estimating the seismic demand on a structure and rely on a time averaged shear wave velocity $V_s$ to a depth of 20m or 30m for this evaluation. In addition, several geological investigations have recently used correlations between geological parameters and $V_s$ in predicting the foundation properties [4].

The $V_s$ can be measured using different in-situ tests such as seismic cone penetration test, seismic dilatometer test, down-hole test, cross-hole test, suspension logging and spectral analysis of surface wave. Also different empirical correlations have been developed between $V_s$ and cone penetration test data. Baldi et al. correlated $V_s$ in Italian sands with cone tip resistance of cone penetration test (CPT) and the effective overburden stress [5]. Mayne and Rix found that $V_s$ in clays is statistically correlated with cone tip resistance and void ratio [6]. In-situ measurement of $V_s$ has become the preferred method for estimating the small-strain shear properties and has been incorporated into site classifications systems and ground motion prediction equations. The paper presents a new method for estimating the shear wave velocity profiles in the absence of site-specific shear wave velocity data.

The generalized regression neural network (GRNN) is a kind of intelligent algorithms. It has some advantages such as simple design, perfect convergence and high accuracy etc, so it has been widely used for complex nonlinear forecasting model [7]. A model based on GRNN is established to estimate the $V_s$ at the offshore site using the physical and mechanical parameters of samples.

## In-situ test and prediction study

The feasibility of the in-situ test for $V_s$ is studied in both technologically and economically at the offshore wind farm construction site. We used the XG-I suspension logging instrument for testing the shear wave velocity because of low-cost and high-precision. At the same time, the instrument is put

into the drilling hole and it detects $V_s$ point to point from bottom to top. The test site of offshore wind farm and the test instrument are show in Fig. 1.

**Fig.1.** Offshore wind farm construction site and test instrument of shear wave velocity

The conventional estimation methods for shear wave velocity are often using the empirical equations such as regression formulas based on the test data and test depth. However, the different regression formulas present different results even though they are showing the good correlation. We take the part test points for example, the estimation depths for $V_s$=500m/s between power function and polynomial function show that the estimation error is very big (see Fig.2).

In addition, Mayne's equations for estimating the value of $V_s$ based on CPT data are shown as equations (1) and (2). The estimation and comparison results of construction site based on the equations and test data are also shown in Fig.2. As can be seen from the Fig.2, the equation (2) has good applicability. But it is a problem to estimate the values of $V_s$ without the in-situ test results such as the CPT data. We can establish an applicable non-linear mapping relation using the soil parameters and $V_s$ data already known to estimate the new $V_s$ data at other construction site.

$$V_s = 118.8\log_{10}(f_s) + 18.5 \quad (1)$$

$$V_s = [(10.1\log_{10}(q_c) - 11.4]^{1.67}(100 f_s / q_c)^{0.3} \quad (2)$$

where $f_s$ is the side friction of CPT (kPa), and $q_c$ is cone tip resistance of CPT (kPa).

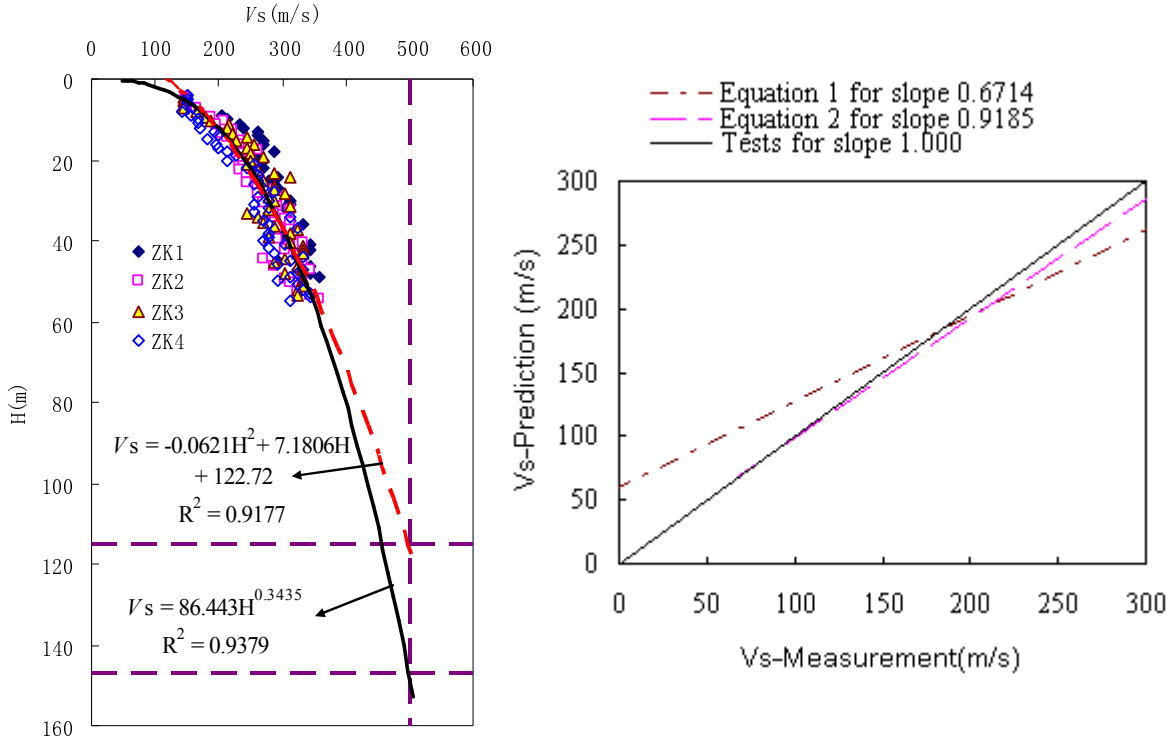

**Fig.2.** Regression method and experienced method for predicting shear wave velocity

**GRNN method and conclusions**

The factors of shear wave velocity of soils in seabed have been studied by statistical analysis. The affecting factors mainly include the physical and mechanical properties of foundation soils, such as standard penetration test (SPT) number $N$, side friction $f_s$ of CPT, cone tip resistance $q_c$ of CPT, depth $z$, void ratio $e$, compression modulus $E_s$, water content $w$, density $\rho$, specific gravity of soil grain $G_s$ and type of soils $T$. Then we use GRNN model to estimate $V_s$. The affecting factors are defined as the input samples and the corresponding $V_s$ as output samples. The minimum error corresponding to spread of GRNN is the final network selected value, which is shown as follows:

$$E(spread) = \frac{1}{n}\sum_{i=1}^{n}(e_i)^2 = \frac{1}{n}\sum_{i=1}^{n}[Y_i(X_i) - Y_i]^2 \quad (3)$$

where spread is the undetermined parameter of the GRNN, $n$ is number of samples, $e$ is corresponding error, $X_i$ is input sample and $Y_i$ is the corresponding output sample of each input sample. With the training samples gathered from the test results before, the optimal value of spread is obtained. Some training samples of input and output data are shown in Table 1.

**Table.1.** Some training samples of GRNN

Considering the excellent classification property of GRNN, the types of soils are introduced to the training samples. The cohesive soils are represented by the number 1, and non-cohesive soils by the number 0. The trained network will automatically make the soils classifications, which as one of the input samples affect the shear wave velocity. For example, when the input number of soil type is 0, the trained GRNN can identify automatically the characteristics of non-cohesive soils and seek the corresponding shear wave velocity. The mechanical and physical parameters of the seabed soils of in-situ test and indoor test from the offshore construction site as the predicting samples, the predicted values of $V_s$ can be obtained based on the trained GRNN. Some predicting samples of GRNN can be shown in Table 2.

Because the GRNN estimation model considering the comprehensive factors, the predicted results show good agreement with the actual values. The example analysis shows that the method has the good forecast precision and useful value. In addition, the estimation of GRNN can offer reference to other engineers and researchers.

**Table.2.** Some predicting samples of GRNN

**Keywords:** marine geotechnical medium; calcareous sand; P-wave attenuation; particle breakage; explosion energy

**Abstract.** Calcareous sand is a special marine geotechnical medium that exhibits interesting physical and mechanical properties resulting from its composition and structure. In the current paper, the blasting compression wave (P-wave) attenuation mechanism of calcareous sand under explosion was studied through explosion experiments. The decay law of the P-wave was obtained based on the earth pressure at different distances from the blast center. The results show that, the broken, compress, and damage zones were formed under the effect of blasting load, many particles were broken near the blasting zone. Calcareous sand exhibits strong absorption and attenuation effects on the P-wave because of its particle breakage characteristics.

## Introduction

Calcareous sand is a special marine geotechnical medium composed primarily of calcium carbonate. The special sedimentary environment of calcareous sand, particularly its deposition process which does not involve long-distance transport, resulted in the preservation of the small pores in the original skeleton[1-2]. Studies have shown that the irregular shape and particle breakage characteristics of calcareous sand account for its engineering properties, which are significantly different from those of other terrestrial sand[3-5].

At present, docks, airport runways, collecting tanks, and other kinds of civil and military infrastructures are constructed on coral reefs because of necessity, as well as for protection and the development of marine resources. These infrastructures potentially cause accidental and man-made explosions. Thus, studies on explosion safety and protection for these buildings are becoming increasingly significant.

Calcareous sand is the most common material medium on coral reefs, and its mechanical properties significantly affect the propagation and attenuation of the explosion wave. In recent decades, extensive studies on the dynamic characteristics of terrestrial sand or soil have been conducted. For example, VAN IMPE W F *et al.* (1989) [6], Gohl W B *et al.* (2000) [7], Dontsov V E *et al.* (2001) [8],WANG Ming-yang *et al.* (2002) [9], Qu Jun-tong *et al.* (2006) [10], MU Chao-min *et al.* (2010) [11]. These studies can be classified into two categories, namely, the experimental method and numerical simulations. The experimental method obtains the relationship between the material medium parameter and the explosion load. For example, different densities, grain compositions, and sand saturation exhibit different characteristics in response to explosions. On the other hand, numerical simulations are mostly performed by establishing physical models based on experimental test results and then using the ANSYS/LS-DYNA software to imitate the explosive process[12]. Studies on the dynamic response characteristics of calcareous sand under explosion are rare. Hence, the

conduct of research on this field is necessary. Understanding the explosion compression wave propagation and attenuation can provide basic information for engineering constructions. In the current paper, the explosion compression wave propagation and attenuation of calcareous sand would be examined through indoor explosion experiments.

## Experiment material

The calcareous sand used in this experiment was sampled from China Nansha Islands. The physical parameters were determined and a granulometric analysis experiment was conducted prior to the indoor explosion experiment. The results show that 50% of the particles have sizes larger than 0.5 mm, and the non-uniform coefficient is 7.83, indicating that the samples could be classified as coarse sand. Table 1 and Fig. 1 show the detailed physical properties of the calcareous sand and the results of the granulometric analysis experiment, respectively:

**Table 1** Physical properties of calcareous sand

| $D_{60}$ (mm) | $D_{30}$ (mm) | $D_{10}$ (mm) | $e_{max}$ | $e_{min}$ | $d_s$ |
|---|---|---|---|---|---|
| 0.876 | 0.579 | 0.112 | 1.405 | 0.766 | 2.76 |

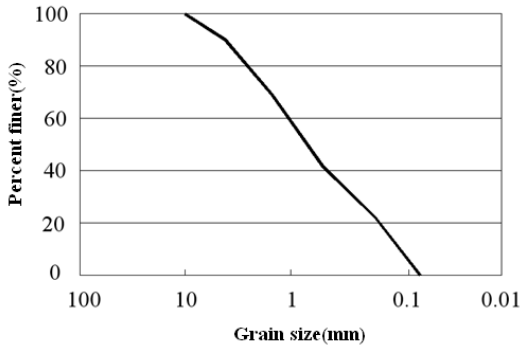

**Fig. 1** Granulometric analysis of calcareous sand

## P-wave attenuation test

High-temperature and high-pressure gas are produced after an explosion and rapidly expands, resulting in a huge energy explosion. This energy acts on the surrounding medium and then spreads in the form of an explosion wave.

Shi Jiao-wang et al. (1992) [13] tested the earth pressure of terrestrial sand after it was subjected to an explosion experiment. The shock wave rapidly attenuated in the impact zone, and the measured waveform basically turned into a compression wave outside the impact zone. The earth pressure increased because of the P-wave compression action. The propagation and attenuation of the explosion compression wave was then obtained based on a complete analysis of the test results.

A 100 cm × 100 cm × 100 cm steel box was used for the mini-explosion experiment. Given that the boundary constraint and stress wave reflection significantly affects the precision of the experiment, a 2 cm thick foam mat was placed around the inside wall of the experiment box for the multiple comparison of experimental data. The results indicate an efficient improvement.

Three earth pressure strain gauge-type sensors were disposed along the horizontal direction of the experiment box at a depth of 40 cm. The distances from the explosion were 30, 50, and 70 cm. Fig. 2 shows the size of the experiment box and the position of the sensors, with TY01 to TY03 representing the three earth pressure strain gauge-type sensors.

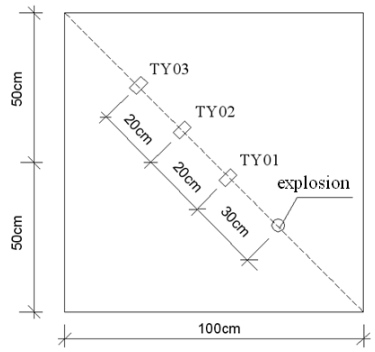

**Fig. 2** Size of the experiment box and the position of the sensors

## Test results

Fig. 3 shows the earth pressure–time history curve of the calcareous sand, in which the overpressure from the explosion reaches a peak value within 1 ms to 6 ms followed quickly by an attenuation and then by a negative pressure.

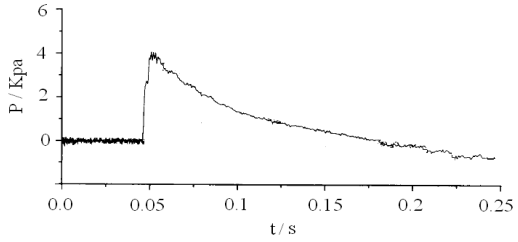

**Fig. 3** Typical earth pressure time–history curve of the calcareous sand

Fig. 3 shows that the maximum earth pressure is 4.13 kPa. However, when the mechanics of the explosion [Eqs. (1) and (2)] are used to calculate the overpressure from the explosion in the water, the water pressure on the same explosive distance is 16.18MPa, which is far greater than the maximum earth pressure of the calcareous sand. These differences indicate that the calcareous sand has greater absorption and attenuation effect. Calcareous sand is a non-continuous medium mainly consisting of loose particles and pore water. Thus, the deformation of loose particles and the effect of the explosive stress wave between the particles can lead to a greater loss on the explosive wave energy.

$$\Delta P_m = 53.3\left[\frac{\sqrt[3]{Q}}{R}\right]^{1.13} \tag{1}$$

$$\Delta P_m = \frac{35.5}{R^0} + \frac{15.5}{(R^0)^2} - \frac{0.024}{(R^0)^3} \tag{2}$$

$$R^0 = \frac{\sqrt[3]{Q}}{R} \tag{3}$$

where $\Delta P_m$ is the overpressure from the explosion, $R$ is the distance from the explosion, and $Q$ is the number of explosives.

**Regression analysis of the P-wave attenuation mechanism**

According to the blast similarity law, when two explosives with the same properties but different quantities explode in the same medium, their stress or deformation field is broadly similar. Thus, the geometry terms can be expressed as the relative distance, as shown in Eq. (4):

$$R_1 / \sqrt[3]{Q_1} = R_2 / \sqrt[3]{Q_2} \tag{4}$$

The explosive pressure can be expressed as a function of the relative distance, as follows:

$$\sigma = f(\sqrt[3]{Q} / R) = \sum_{i=1}^{n} K_i (\sqrt[3]{Q} / R)^{\alpha_i} \tag{5}$$

where $K$ and $\alpha$ are the attenuation parameters associated with the explosive conditions and the wave dissemination media. The first-series solution can be used to establish the experimental formulas, as shown in Eq. (6):

$$\Delta P_m = K \ (\sqrt[3]{Q} / R)^{\alpha} \tag{6}$$

By defining $\rho = \dfrac{\sqrt[3]{Q}}{R}$, and through the logarithmic transformation of Eq. (6), a linear equation is derived, as follows:

$$\lg \Delta P_m = \alpha \lg \rho + \lg K \tag{7}$$

By defining $y = \lg \Delta P_m$, $a = \lg K$, $b = \alpha$, $x = \lg \rho$,

$$y = a + bx \tag{8}$$

$a$ and $b$ can be obtained through a linear regression analysis, and the attenuation parameters ($K$ and $\alpha$) can be obtained. The decay law of the P-wave with the distance can then be calculated using Eq. (9).

$$\Delta P_m = 24.36 \left( \frac{\sqrt[3]{Q}}{R} \right)^{1.76} \tag{9}$$

Fig. 4 shows the fitted curve of the experimental results.

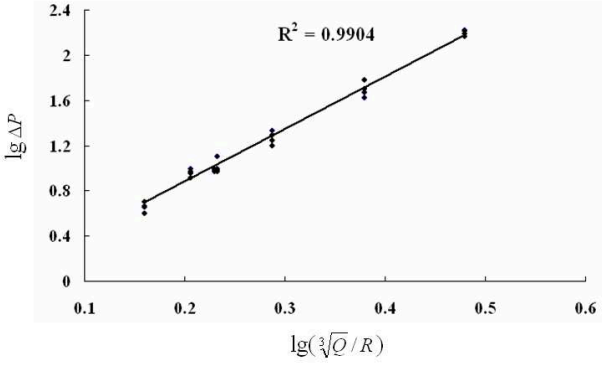

Fig. 4 Decay law of the P-wave through a linear regression analysis

**Conclusions and Discussions**

The attenuation mechanism of the P-wave was examined through blasting test, main conclusions are summarized as follows:

(1) The effects of absorption and attenuation of the compression wave were very strong for saturated calcareous sands. In the current study, the attenuation law was expressed as $\Delta P_m = 24.36\left(\frac{\sqrt[3]{Q}}{R}\right)^{1.76}$.

(2) Under the effect of blasting load, many particles were broken near the blasting zone. The broken, compress, and damage zones are formed, which consume most of the energy and result in an increase in the attenuation effect. The energy for the formation of the broken, compress, and damage zones will be calculated through theoretical method in the later study.

**Key words:** Non-homogeneous Saturated Soil, SH Wave, Dynamic Response, Reflection and Transmission

**Abstract.** Based on the Biot's Theory, the dynamic response of non-homogeneous saturated soil has been studied using Helmholtz vector decomposition principle and Exact Dynamic Stiffness Method (EDSM). Reflection and transmission of SH wave in non-homogeneous saturated soil have also been analyzed in considering the continuous variation of physical and mechanical properties of saturated foundation along the thickness. The general calculation formula about the reflection and transmission coefficients of bedrock and free field on both surfaces was achieved. Assuming that the material properties have an exponential law distribution and gradient variation along the thickness-coordinate, the dynamic response of non-homogeneous saturated soils under incident plane SH wave was discussed by numerical examples. The results show that the incident angle, the thickness and heterogeneity index of saturated soil have significant influences on the ratio of the ground displacement and bedrock displacement.

## Introduction

Dynamical response of soil subjected to earthquake is one of the major considerations in the field of geotechnical engineering and earthquake engineering. Biot's theory has been widely applied in geomechanics to study the wave propagation in fluid-saturated poroelastic medium subjected to seismic wave action [1,2]. Knopoff [3], Gilbert and Backus [4] assumed that the covering soil layers upon bedrock as ideal elastic, homogeneous, isotropic media and then derived the exact dynamic-stiffness matrices for the soil layer and half-space, with that a complete theory for wave propagation in layered soils was derived, and widely been used in civil engineering. Curtis and Redwood [5], proposed a solution for the dispersion characteristics of SH wave in a piezoelectric material and the conditions for the existence of various modes. Buchen[6,7] studied the reflection, transmission, and diffraction of SH waves excited by a line source in layered half space. However, very few studies have considered the influence of non-homogeneous saturated soils. In this paper, SH wave in a layered structure of non-homogeneous saturated soils is investigated under the varying with incident angle, the thickness and heterogeneity index of saturated soil, the numerical results are presented and discussed.

## Theoretical Formulations

The saturated soil foundation model is shown in Fig.1; the thickness of saturated soil above bedrock is $H$, and SH wave is incident from bedrock.

**In Bedrock**. The potential function of bedrock can be introduced here [8] :

$$\Phi = 2B_e \mathrm{e}^{i(k_{1R}x_1 + k_{3R}x_3 - \omega t)} \tag{1}$$

Where $B_e$ , $B_r$ are the amplitude coefficient of incident and reflected SH wave in bedrock, respectively, and $B_e$=$B_r$ ; $k_{3R}=(\omega\cos\theta)/v$ , $k_{1R}=(\omega\sin\theta)/v$ ; $v$ is the velocity of incident SH wave, and $v=\sqrt{\mu/\rho}$ ;

The calculation formula of displacement component is:

$$u_{R2}(x_1,x_3,\mathrm{t})=\frac{\partial^2\Phi}{\partial x_1^2}+\frac{\partial^2\Phi}{\partial x_3^2} \tag{2}$$

Using the stress-strain relations and wave equation, we can get the following forms of function relation between the stress and the potential function,

$$\tau_{R23}=\mu\frac{\partial}{\partial x_3}\left(\nabla^2\Phi\right) \tag{3}$$

Physical quantities of bedrock are:

$$u_{R2}(x_1,x_3)=-2\left(k_{1R}^2+k_{3R}^2\right)B_e\mathrm{e}^{i(k_{1R}x_1+k_{3R}x_3-\omega t)} \tag{4a}$$

$$\tau_{R23}=-2i\mu k_{3R}\left(k_{1R}^2+k_{3R}^2\right)B_e\mathrm{e}^{i(k_{1R}x_1+k_{3R}x_3-\omega t)} \tag{4b}$$

**In Saturated Porous Media.** Assuming that the soil skeleton is uncompressible and the fluid viscosity is incorporated into the dynamic permeability, the control equations for saturated soil [9] are:

$$\mu\nabla^2\mathbf{u}+\mathrm{grad}\left[\left(\mu+\lambda+\alpha^2M\right)e\right]-\mathrm{grad}\left(\alpha M\zeta\right)=\rho\ddot{\mathbf{u}}+\rho_f\ddot{\mathbf{w}} \tag{5a}$$

$$\mathrm{grad}\left(\alpha Me-M\zeta\right)=\left(\rho_f\ddot{\mathbf{u}}+m\ddot{\mathbf{w}}\right)+b\dot{\mathbf{w}} \tag{5b}$$

In the above equations, $u_i$ and $w_i$ are the displacement vectors of the solid skeleton and pore fluid, respectively; $e=u_{i,i}$ , $\zeta=-w_{i,i}$ ; $\lambda$ and $\mu$ are Lame constants of solid skeleton; $\alpha$ and $M$ are the compressibility parameters of the two-phase medium.; $\alpha=1-K/K_s$ , $1/M=(\alpha-n)/K_s+n/K_f$ , $K_f$ is bulk modulus of pore fluid; $\rho$ is total density of the saturated soil, and can be derived by $\rho=(1-n)\rho_s+n\rho_f$ , where $n$ is porosity, $\rho_s$ and $\rho_f$ are density of solid grains and pore fluid, respectively; $b=\eta/k_f$ ; $\eta$ is the fluid viscosity, $k_f$ is the intrinsic permeability; $\nabla$ denotes the Laplace operator.

According to Helmholtz vector decomposition principle, it's convenient to introduce potentials $\varphi_u$ , $\psi_u$ , $\varphi_w$ and $\psi_w$ , then the solid skeleton and pore fluid displacements $u_i$ and $w_i$ can be expressed as:

$$\boldsymbol{u}=\nabla\varphi_u+\nabla\times\boldsymbol{\psi}_u,\quad \nabla\cdot\boldsymbol{\psi}_u=0 \tag{6a}$$

$$\boldsymbol{w}=\nabla\varphi_w+\nabla\times\boldsymbol{\psi}_w,\quad \nabla\cdot\boldsymbol{\psi}_w=0 \tag{6b}$$

Substituting Eq.(6) into Eq.(5), differential equation of S wave can be given as:

$$\mu\nabla^2\boldsymbol{\psi}_u-\rho\ddot{\boldsymbol{\psi}}_u-\rho_f\ddot{\boldsymbol{\psi}}_w=0 \tag{7a}$$

$$\rho_f\ddot{\boldsymbol{\psi}}_u+m\ddot{\boldsymbol{\psi}}_w+b\dot{\boldsymbol{\psi}}_w=0 \tag{7b}$$

Introduced displacement potential function of saturated soil skeleton:

$$\Psi=\left(Ae^{-iv_tx_3}+De^{iv_tx_3}\right)\mathrm{e}^{i(k_1x_1-\omega t)} \tag{8}$$

We can get the following physical quantities of saturated soil:

$$u_2(x_1,x_3)=-\gamma_t^2\left(Ae^{-iv_tx_3}+De^{iv_tx_3}\right)\mathrm{e}^{i(k_1x_1-\omega t)} \tag{9a}$$

$$\tau_{23}=i\mu v_t\gamma_t^2\left(Ae^{-iv_tx_3}-De^{iv_tx_3}\right)\mathrm{e}^{i(k_1x_1-\omega t)} \tag{9b}$$

Where $A$ , $D$ are the amplitude coefficient of transmission and reflection for SH wave in saturated soil, respectively; $k_1=k_{1R}=(\omega\sin\theta)/v$ ; $v_t^2=\gamma_t^2-k_1^2$ ; $\gamma_t^2=-\beta_3/\mu\left(m\omega^2-i\omega b\right)$ ; $\beta_3=\omega^2\rho\left(m\omega^2-i\omega b\right)-\omega^4\rho_f^2$ .

**Propagation of SH Wave in Non-homogeneous Saturated Soil Layer**

According to the different environment, geography and climate conditions, the soil physico-mechanical properties have great difference along the depth. The control equation of non-homogeneous saturated soils is partial differential equations with variable coefficients, and it is difficult to get analytical solutions. To solve this problem, the non-homogeneous saturated soil layer along the thickness is simplified as many homogeneous thin layer of saturated soil, as is shown in Fig.2. The layer number *N* is decided by precision. The wave transmission and reflection of SH wave in the *jth* layer is also shown in Fig. 2.

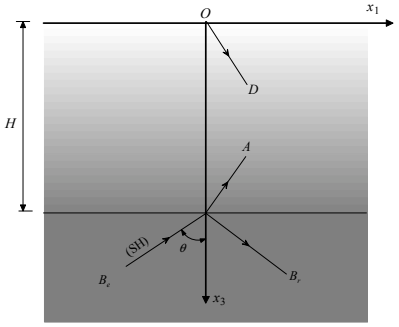

Fig.1 Diagram of non-homogeneous saturated soil foundation

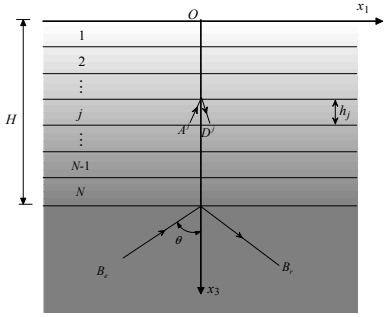

Fig.2 The laminate model of non-homogeneous saturated soil

**Transfer Matrix.** SH wave is incident from bedrock, reflected and transmitted in non-homogeneous saturated soil, from formula (9), and using Exact Dynamic Stiffness Method (EDSM), we get:

$$\mathbf{U}^j = \mathbf{F}^{(j)} \cdot \mathbf{A}^j \cdot \mathrm{e}^{i(k_1 x_1 - \omega t)} \tag{10}$$

Where superscript *j* represents the *jth* layer of non-homogeneous saturated soil; $\mathbf{U}^j = \left(u_2^{(j)} \quad \tau_{23}^{(j)}\right)^T$, $\mathbf{A}^j = \left(A^j \quad D^j\right)^T$, $\mathbf{F^{(j)}} = \begin{bmatrix} -\gamma_t^2 e^{-iv_t x_3} & -\gamma_t^2 e^{iv_t x_3} \\ i\mu v_t \gamma_t^2 e^{-iv_t x_3} & -i\mu v_t \gamma_t^2 e^{iv_t x_3} \end{bmatrix}$.

The formula (10) is applicable to any depth from 0 to *h*. When $x_3 = 0$, we can get the value of displacement and stress component on the top surface of the *jth* layer, and $\mathbf{F}_0^{(j)}$. According to the continuity conditions of boundary surface, The displacement and stress component on the top surface of the *jth* layer are equal with the corresponding values of the (*j-1*)*th* layer on the bottom. In the follow formula, subscript B represents the bottom surface, and subscript T represents the top surface:

$$\mathbf{U}_{\mathrm{B}}^{j\text{-}1} = \mathbf{F}_0^{(j)} \cdot \mathbf{A}^j \cdot \mathrm{e}^{i(k_1 x_1 - \omega t)} \tag{11}$$

From formula (10) and (11), the relation expression of displacement and stress between the *jth* and the *(j-1)th* both on the bottom layer can be obtained:

$$\mathbf{U}_B^j = \mathbf{G}_{h_j}^{(j)} \cdot \mathbf{U}_{\mathrm{B}}^{j\text{-}1} \tag{12}$$

Where, $\mathbf{G}_{h_j}^{(j)} = \mathbf{F}_{h_j}^{(j)} \mathbf{f}_{\mathbf{0}}^{(j)}$; $\mathbf{f}_0^{(j)}$ is the inverse matrix of $\mathbf{F}_0^{(j)}$.

According to the formula (12), we can get recursive relation expression of displacement and stress on the bottom of the *jth* and the *(j-1)th* layer. The displacement and stress of the *(N-1)th* bottom layer are equal with the corresponding values of the *Nth* layer on the top, therefore, the displacement and stress relations on the top of the *Nth* layer and the first layer can be expressed as follows:

$$\mathbf{U}_{\mathrm{T}}^{N}=\mathbf{M}\cdot\mathbf{U}_{\mathrm{B}}^{\mathbf{1}} \tag{13}$$

Where: $\mathbf{M}=\prod_{m=N-1}^{2}\mathbf{G}_{h_m}^{(m)}=\mathbf{G}_{h_{N-1}}^{(N\text{-}1)}\cdot\mathbf{G}_{h_{N-2}}^{(N-2)}\cdot\cdots\cdot\mathbf{G}_{h_2}^{(2)}\cdot$

Consider the displacement and stress of the top and the bottom of the first layer and the *Nth* layer both on the top, we can obtained:

$$\mathbf{F}_{\mathbf{0}}^{(N)}\cdot\mathbf{A}^{N}=\mathbf{M}\cdot\mathbf{F}_{h_1}^{(1)}\cdot\mathbf{A}^{\mathbf{1}} \tag{14}$$

**Boundary Conditions.** At the interface of the saturated soil and bedrock, $u_{R2}=u_2^N$, $\tau_{R23}=\tau_{23}^N$, we get:

$$2\left(k_{1R}^2+k_{3R}^2\right)B_e=\gamma_t^2\left(A^N e^{-iv_t h}+D^N e^{iv_t h}\right) \tag{15a}$$

$$-2i\mu k_{3R}\left(k_{1R}^2+k_{3R}^2\right)B_e=i\mu^N v_t^N\gamma_t^2\left(A^N e^{-iv_t h}-D^N e^{iv_t h}\right) \tag{15b}$$

According to formula (14) and (15), we can establish a system of linear equations:

$$\mathbf{A}\bullet\mathbf{X}=\mathbf{B} \tag{16}$$

Where, $\mathbf{X}$ is the unknown amplitude vector of the first and the *Nth* of saturated soil layer, $\mathbf{X}=\left[A^1\ \ D^1\ \ A^N\ \ D^N\right]^T$; $\mathbf{A}=\left[a_{ij}\right]_{4\times4}$; $\mathbf{B}=\left[0\ \ 0\ \ 2\left(k_{1R}^2+k_{3R}^2\right)B_e\ \ -2i\mu k_{3R}\left(k_{1R}^2+k_{3R}^2\right)B_e\right]$.

Solving the formula (16) when $B_e$=1, we can get unknown amplitude coefficient of the first, the *Nth* of saturated soil layer. Bringing the amplitude coefficient into equation (4) and (9), and $x_3=0$, we can get the displacement ratio of saturated soil and bedrock both on the top surface.

## Numerical Results and Discussion

Considering a saturated soil with a thickness of *H*, assuming the porosity of the saturated soil is varying along the thickness as an analytic function of power law [10] as follows:

$$n(x_3)=\left[n(0)-n(H)\right]\left(\frac{H-x_3}{H}\right)^{\gamma}+n(H) \tag{17}$$

$$k_f=k_{f0}\left(\frac{n}{n_0}\right)^{\kappa},\quad G(n)=G_0\left(\frac{1-n}{1-n_0}\right)^{\kappa} \tag{18}$$

Where $\gamma$ is a non-homogeneous parameter, and different values of $\gamma$ dictate that the material properties have different non-homogeneous distributions along the thickness; $\kappa$ denotes the change in the index of the physical and mechanical properties of the soil with porosity; $G$ represents the parameters of the saturated soil, such as $\mu$, $\rho$ and $\rho_f$; $n_0$, $k_{f0}$ and $G_0$ are the porosity, permeability and the corresponding physical and mechanical parameters at initial state, respectively.

The porosity of the upper surface ( $x_3=0$ ) is $n(0)=0.45$, and other physico-mechanical parameters in saturated soil are chosen as follows: $n(H)=0.25$, $\mu_0=2.70\times10^9\ \mathrm{N/m^2}$, $\rho_0=2100\ \mathrm{kg/m^3}$, $\rho_{f0}=1000\ \mathrm{kg/m^3}$, $k_{f0}=6\times10^{-4}\ \mathrm{cm/s}$. And physico-mechanical parameters of bedrock are presented as: $\mu_R=1.70\times10^9\ \mathrm{N/m^2}$, $\rho_R=2640\ \mathrm{kg/m^3}$. In the example the calculation frequency for the seismic simulation is 5Hz, and the soil is divided into 100 layers.

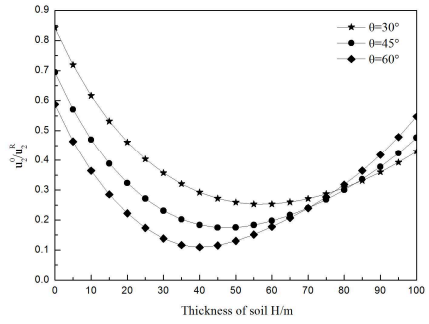

Fig.3 Curves of displacement ratio varying with soil thickness at different incident angles

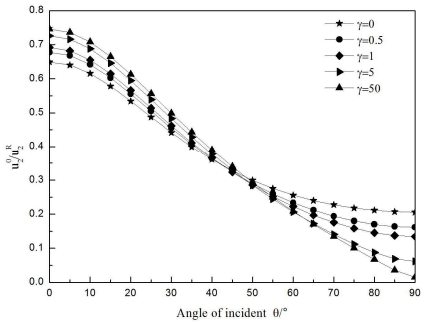

Fig.4 Curves of displacement ratio varying with incident angles at different heterogeneity indexes

Considering the influence of incident angle and soil thickness on the response, the displacement ratio varying with soil thickness under three different inclined angles ($30^\circ$, $45^\circ$, $60^\circ$) is presented in Fig.3 when $\gamma$=1 .The curve ranges parabola, and the displacement ratio gets its minimum varying with soil thickness near 40m. Displacement ratio decreases varying with the incident angle while the thickness is less than 80m; and it increases while more than 80m.

For study the influence of non-homogeneous on the response under the inclined SH seismic wave, displacement ratio with incident angle changing in different heterogeneity index is shown in Fig.4 when the soil thickness is 20m. Displacement ratio decreases varying with the incident angle. Displacement ratio increases varying with the heterogeneity index while the incident angle is less than $45^\circ$; and it decreases while more than $45^\circ$.

## Conclusions

(1) EDSM is applicable to analyzing SH wave propagation in non-homogeneously saturated soil. It has clear formulations and can solve the complex wave equations.

(2) Considering the material properties vary along $x_3$, the incident angle, the thickness and heterogeneity index of saturated soil play an important role on the dynamic response of non-homogeneously saturated soil.

**Key Words:** aeolian sand; compatibility; optimum moisture content; maximum dry density; compactness; compatibility times; lay-down thickness

**Abstract:** The main factors affecting soil compatibility include moisture content, compaction work, soil type, grading and coarse material content etc.. The effects of compaction work are as follows: the stronger compaction work is, the more larger soil dry density is. The optimum moisture content decreases with the compaction work increasing. This paper mainly studies the effect of compaction work to aeolian sand compatibility. Its lay-down thickness is about 30-50cm when we use vibratory roller to compact aeolian sand in practical engineering. This paper analysis's and studies the maximum dry density and the optimum moisture content of aeolian sand in the middle region of Inner Mongolia, and achieves its lay-down thicknesses are 30cm,40cm,and 50cm respectively at the optimum moisture content. We use 85kg vibration-impact rammer instead of YZ 18 vibratory roller to simulate the aeolian sand compaction effect at the optimum moisture content. The specification does not specify the number of compatibility times, but it is generally 3 to 5 times in the actual project .We choose the most suitable compatibility times and lay-down thickness through anglicizing the Aeolian sand compactness for vibration-impact rammer rolling on eloign sand 3 times,4 times, and 5 times respectively at 3 different kinds of lay-down thicknesses. Through the study of the Inner Mongolia area Aeolian sand, it provides a useful reference for highway and railway construction in the desert area as well as the encapsulated layer thickness of reinforced retaining wall, a new type support structure.

## Introduction

Previous technical specification for construction of highway sugared provisions: the highway and a highway should be tested according to lay-down thickness 30cm, to ensure the uniformity of the compacted layer. Now the technical specification for construction of highway sugared rules: each packing lay-down thickness should be determined by test. But for the lay-down thickness in the process of aeolian sand compatibility, specification is not clearly defined. In practical engineering, its lay-down thickness is about 30-50cm. The main factors affecting soil compatibility include moisture content, compaction work, soil type, grading and coarse material content etc. The effects of compaction work are as follows: the more stronger compaction work is, the more larger soil dry density is. The optimum moisture content decreases with the compaction work increasing. This paper studies aeolian sand compatibility in Inner Mongolia area when its lay-down thicknesses are 30cm, 40cm, and 50cm respectively at the optimum moisture content. Due to the limitation of experimental conditions, vibration-impact rammer can not be directly used for aeolian sand compatibility study. In this experiment. We use 85kg vibration-impact rammer instead of YZ 18

vibratory roller to simulate the aeolian sand compaction effect at the optimum moisture content. The number of compatibility times is generally 3 to 5 times in actual project . Vibration-impact rammer is used to roll on aeolian sand 3 times4 times, and 5 times respectively at 3 different lay-down thicknesses in this test. The cutting ring method detects the aeolian sand compactness. Based on experimental results, the most suitable compatibility times and lay-down thickness are selected, which provides a useful reference for highway and railway construction in the desert area as well as the encapsulated layer thickness of reinforced retaining wall, aeolian sand as fillers.

## Experiment with small tamping machine and YZ 18 vibratory roller

2.1 The determination of various parameters of experiment with small tamping machine and YZ 18 vibratory roller

Small tamping machine is used for the test of HCD85-A type vibration shock ramming, the motor power is 30 kW, the quality of 85kg, and the jump height is 40 to 60mm, the impact frequency is 480 to 650 times / min, forward speed is 10 to 14m/min. In order to facilitate the calculation, the average values is selected. The jump height is 50mm, the impact frequency is 565 times / min, forward speed is 12m/min. The lower section size of small ramming machine is 25mm * 27mm. Vibratory roller is a more efficient compatibility machinery, it is widely used in all kinds of highway construction. For earth-rock foundation, technical specifications for construction of highway sugared rule: compatibility machinery should be choused based on the weight of no less than 18 tons of vibration road roller.

2.2 Calculation of key parameters of using small ramming machine to simulate compatibility effect of road roller

In 1 to 2 times of compatibility, the total power consumption of YZ 18 vibratory roller is 87.2 kW. In 3 to 8 times, the total power consumption of YZ 18 vibratory roller is 124.1 kW. And the roller in the process of compatibility, its maximum speed of calculation is the first gear, v=6km/h=1.67m/s. The basic parameters are shown in Reference 1**.** We can control the experiment used small ramming machine's working time to simulate approximately the wet aeolian sand compaction effect of YZ 18 vibratory roller. Rolling section is 25cm * 54cm. The calculation results are shown in Table 1.

**Table 1. Small ramming machine simulated the calculation results of YZ 18 vibratory roller**

| Compactibility times | 3 times | 4 times | 5 times |
|---|---|---|---|
| Rolling area（$cm^2$） | 1350 | 1350 | 1350 |
| Power（kW） | 298.5 | 422.6 | 546.7 |
| Working time（s） | 28.4 | 40.1 | 51.9 |

## Use small ramming machine to simulate the experimental process and result of YZ 18 vibratory roller

3.1 The steps of the experiment

(1) Weighed a sufficient amount of aeolian sand, and added appropriate amount of water to the optimum moisture content and mixed well. In this experiment, the aeolian sand is from the central area of Inner Mongolia, the maximum dry density and optimum moisture content is 1.576g/$cm^3$ and 17% respectively.

(2) Found a flat area as a test site, and poured enough mix of aeolian sand down at the test site, measured and controlled aeolian sand lay-down thickness, its lay-down thicknesses were respectively 30cm, 40cm and 50cm. To flatten the aeolian sand surface, as shown in Figure 1.

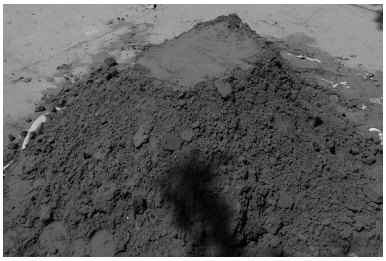

**Figure 1. Aeolian sand-pine lay on the ground**

(3) Small tamping machine rolled uniformly on three kinds of lay-down thicknesses respectively, and stopwatch controlled each small tamping machine's working time. Small tamping machine was used to simulate approximately the YZ 18 vibratory roller 3 times, 4 times and 5 times compaction effect.

(4) Every compatibility was completed, and the cutting ring method was used to measure the compactness. Used the cutting ring to take samples in accordance with the top, middle and bottom order respectively after compacting the aeolian sand. Then flattened the aeolian sand surface and weighed the weight. Recorded the data and calculated the compactness.

(5) Calculation of the compactness. In this experiment, the cutting ring with inner diameter of 61.9mm and height of 20mm, and its weight was 46.6g. The calculation formula of the compactness:

$$\text{Compactness}=\frac{m-46.5}{\pi\times(\frac{6.19}{2})^2\times 2\times\rho_{\max}}$$

Of which: $\rho_{\max}$ refers to the wet density corresponding to the optimum moisture content, take 1.84g/cm$^3$.

3.2 *The compatibility effect for lay-down thickness of 30cm*

Speeded enough wet aeolian sand on the experiment site, and divided the sand into three mounds evenly. The lay-down thickness was 30cm,flattened the aeolian sand surface, Small tamping machine rolled uniformly on three mounds in accordance with 3 times, 4 times and 5 times respectively to simulate approximately the YZ 18 vibratory roller compaction effect Then the cutting ring method was used to measure the compactness of three mounds. As seen from Table 2, when the aeolian sand lay-down thickness is 30cm, its compactness has a downward trend from the top to down, and the bottom compactness is comparatively small. The bottom compactness increases with compatibility times increasing. The number of compatibility times is 5 times, the compactness meets and exceeds the compactness requirements of highway and road to highway sugared. Soil sugared compactness standards are shown in Reference 1.

3.3 *The compatibility effect for lay-down thickness of 40cm*

According to the same experimental steps, spreaded enough wet aeolian sand on the experiment site, divided the sand into three mounds evenly. The lay-down thickness was 40cm.The measured compactness results are shown in Table2. It can be seen from Table 2, the aeolian sand compactness of the top and middle is higher in general than the bottom. And the bottom compactness increases with compactibility times increasing. When the number of compatibility times was 5 times, the bottom compactness reached a relatively large value. At this time, the bottom aeolian sand compactness had reached 96%. This accorded with the compactness requirements of highway and a highway.

**Table 2. The compaction results for lay-down thickness of 30 cm /40cm/50cm**

| Compatibility times | Top compactness （%） | Middle compactness （%） | Bottom compactness （%） |
|---|---|---|---|
| 3 times | 95.8/94.8/92.8 | 92.1/91.1/90.1 | 88.9/85.9/82.9 |
| 4 times | 98.1/97.1/94.1 | 96.2/95.2/91.2 | 95.1/93.6/85.6 |
| 5 times | 99.2/99.5/96.2 | 98.6/97.8/92.4 | 97.2/96.2/86.5 |

3.4 The compactibility effect for lay-down thickness of 50cm

According to the same experimental methods and steps, spreaded enough wet aeolian sand on the experiment site, divided the sand into three mounds evenly. The lay-down thickness was50cm.Small tamping machine rolled uniformly on three mounds in accordance with 3 times, 4 times and 5 times respectively to simulate approximately the YZ 18 vibratory roller compaction effect. Then the cutting ring method was used to measure the compactness's of three mounds. The measured results are shown in Table 2. It can be seen from the experimental data in Table 2, when the aeolian sand lay-down thickness is 50cm at optimum moisture content, its compactness has a downward trend from the top to down, and the bottom compactness is comparatively small than the compactness of the top and middle. According to whether the bottom compactness meets the specification requirements or not, to determine whether the compacted sugared achieves the levels of compactness requirements or not. Table2 shows the aeolian sand bottom compactness and the number of compatibility times curve for lay-down thickness of 50cm. As can be seen from the graph, along with the increase of the number of compatibility times, the compactness is increased. When times is 5 times, the compactness is the largest. But even so, the compactness is only 86.5%, and it can not meet the requirements of the highway sugared compactness.

3.5 Three kinds of lay-down thicknesses comparison

Comparison of Table2 experimental data shows: when the aeolian sand has the same lay-down thickness and compatibility times, the compactness from top to bottom gradually decreased. Regard the number of compatibility times for the 5 times as an example, as shown in Figure 2. And with the decrease of lay-down thickness, the compactness difference between the top and bottom becomes smaller. In this experiment, When the compatibility times is 5 times and lay-down thickness is 50cm, the compactness difference between the top and bottom is 9.7%. When the lay-down thickness is 40cm, the compactness difference between the top and bottom is 3.3%. When the lay-down thickness is 30cm, the compactness difference between the top and bottom is 2%.

The test for three kinds of different thicknesses was studied. We can see from Figure 3: when the lay-down thicknesses are 30cm, 40cm and 50cm, along with the increase of compatibility times, the bottom aeolian sand compactness increases. From the experimental data, when compatibility times is 3 times, three kinds of lay-down thicknesses can not meet the compactness requirements of highway and a highway. When compatibility times is 4 times and the lay-down thickness is 30cm,the wet aeolian sand compactness meets the requirements of two grade highway and approach the requirements of first grade highway.

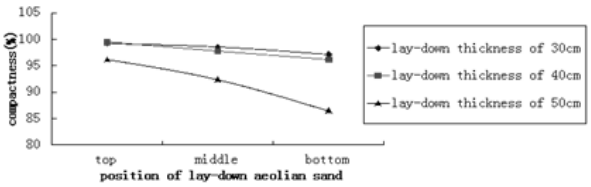

**Figure 2. It is the relationship curve of aeolian sand compactness and position at different lay-down thicknesses when compatibility times is five times**

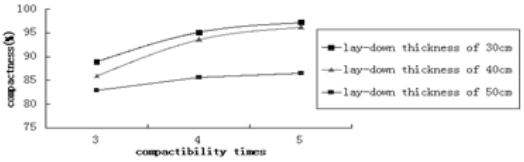

**Figure 3. It is the relationship curve of bottom aeolian sand compactness and compatibility times**

## Conclusion

According to Inner Mongolia region aeolian sand experimental research, The results show that:

(1) The compactness from top to bottom gradually decreased, and with the decrease of lay-down thickness, the compactness difference between the top and bottom becomes smaller. Generally the bottom compactness is the most minimum， which can be used as a reference standard to determine the aeolian sand compactness requirements.

(2) From the experimental data, in three different kinds of lay-down thicknesses, with the increase of the number of the compatibility times, the compaction has varying degrees of increase, namely, the compaction work is stronger, the generated soil compactness is large. And the lay-down thickness is small, and compaction work improves the aeolian sand compactness smelly.

(3) From the experimental data, when compatibility times is three times, three kinds of lay-down thicknesses can not meet the requirements of the compactness. When compatibility times is 4 times and the lay-down thickness is 30cm, the wet aeolian sand compactness meets the requirements of two grade highway and approaches the requirements of highway and a highway. When the compatibility times is 5 times, in lay-down thicknesses of 40cm and 30cm, the wet aeolian sand compactness meets highway and a highway requirements.

(4) From the experimental data and the compaction effect, this paper suggests that wet aeolian sand can be used when its compatibility times is 5 times and lay-down thickness is 40cm.

**Keywords:** Mechanism, Pre-Anchoring, Fissured Stope Hangingwall, Fully-Grouted Cable Bolts.

**Abstract.** The construction techniques and anchoring mechanism of pre-anchoring fissured stope hangingwall of some copper mine in China by fully-grouted cable bolts are explored. The construction stages such as drilling anchor holes, making anchorage cables and cement mortar, grouting, and curing are expounded. A combined action mechanism of pre-anchoring fissured stope hangingwall by fully-grouted cable bolts is presented. The achievements are helpful and beneficial to the design and construction of rock engineering projects which need anchoring reinforcement, such as slopes, tunnels, deep foundation pit, caverns, and underground mining.

## Introduction

The anchoring techniques of fully-grouted cable bolts [1, 2] find a wide application in the reinforcement of slopes, tunnels, deep foundation pit, caverns and underground mine stopes. The construction techniques and anchoring mechanism of pre-anchoring fissured stope hangingwall of some copper mine in China by fully-grouted cable bolts are explored. The embedded depth, horizontal section width along inclined direction, strike length, vertical height, and pitch angle of the studied mine stope are 89.75m, 12.5m, 7m, 32.5m, and 30° respectively. The surrounding rock of the stope hangingwall is fissured granite porphyry [3].

## Pre-Anchoring Construction

Anchor holes in the unstable fissured hangingwall are drilled by YGZ-90 type drilling equipment. The diameter and depth of an anchor hole are 55 mm and 10.5 m respectively. Upward anchor holes in a row form a vertical fan shape. The corresponding anchor holes in two adjacent rows use staggered arrangement. The row spacing is 3 m. Fan-shaped layouts of anchor holes in two adjacent rows are as shown in Fig. 1. Every anchor hole is cleaned with high-pressure water or compressed air.

An anchor cable uses 20 mm diameter steel wire rope with the length of 11 m. 6 ~ 8 strands of steel wires are taken out from one end of steel wire rope and are bent into 5 ~ 10 cm long agnail around the outer wire rope as anchor cable head. Finally the steel bar hook (see Fig. 2) is strapped on anchor cable head with iron wire and the anchor cable is pushed into the bottom of the hole by using pushing rods.

Ordinary Portland cement is used and the largest particle size of sand is not more than 5 mm. Cement mortar is made underground and the mixing weight ratio of cement : sand : water = 1 : 1 : 0.3. For each anchor hole 25 kg cement and 25 kg sand are approximately used. Injection pump is employed for injecting cement mortar into anchor holes.

After grouting, anchor hole orifices are plugged with cork, cotton, or cement bag paper lest mortar outflow from anchor holes. Mortar strength has relation to curing time. To assure quality mortar should be cured for at least half a month and the best curing time is a month or more. The deformation of the unstable fissured hangingwall can be inhibited by the hardened fully-grouted cable bolts combined with fissured hangingwall.

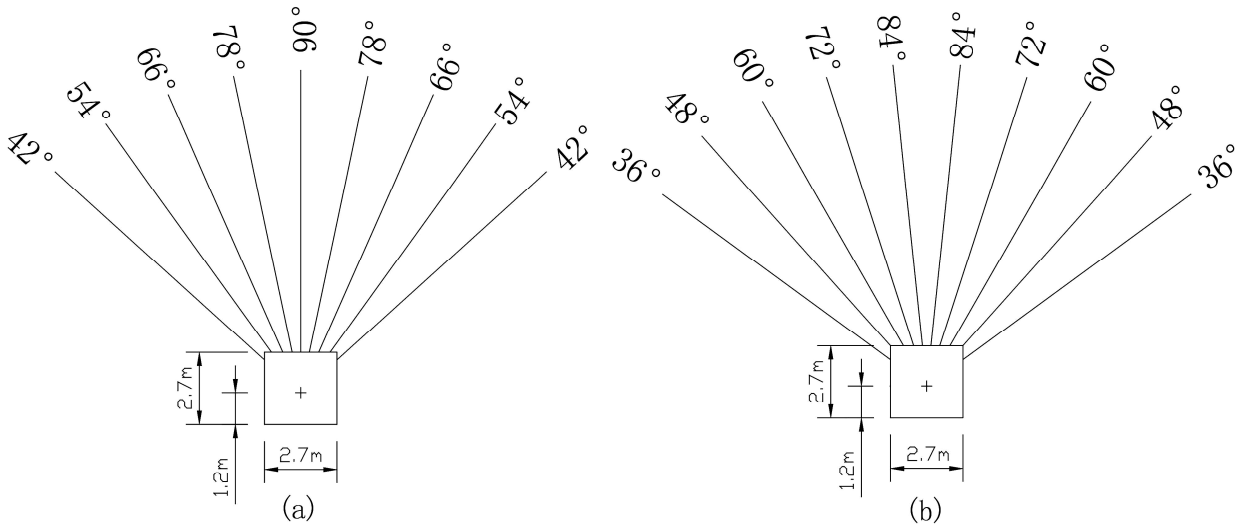

Fig. 1 Fan-shaped layouts of anchor holes in two adjacent rows

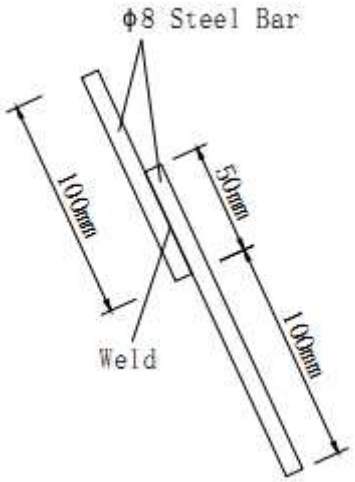

Fig. 2 Steel bar hook

Fig. 3 shows the schematic vertical section of the test mine stope and fissured stope hangingwall pre-anchored by fully-grouted cable bolts along inclined direction.

## Mechanism

The mechanism of pre-anchoring fissured stope hangingwall by fully-grouted cable bolts is a combined action. It includes the following five main effects.

**Hanging Effect.** Cable bolts are different from bolts. The flexibility of cable bolts is something like that of ropes. Action of faults can make a cable bolt become curved or appear a broken line, but its anchoring force still exists. In-situ we have occasionally observed that fully grouted cable bolts hang some unstable rock blocks on the stope hangingwall surface and the rock blocks can not drop.

**Effect of a Laminated Beam.** Fully-grouted cable bolts, which are something like linen thread in the sole of cloth shoes, sew up the rock layers of stope hangingwall together to form a laminated component as a whole. Resisting force between rock layers increases greatly, and the bending strength, shear strength, and rigidity of hangingwall also grow.

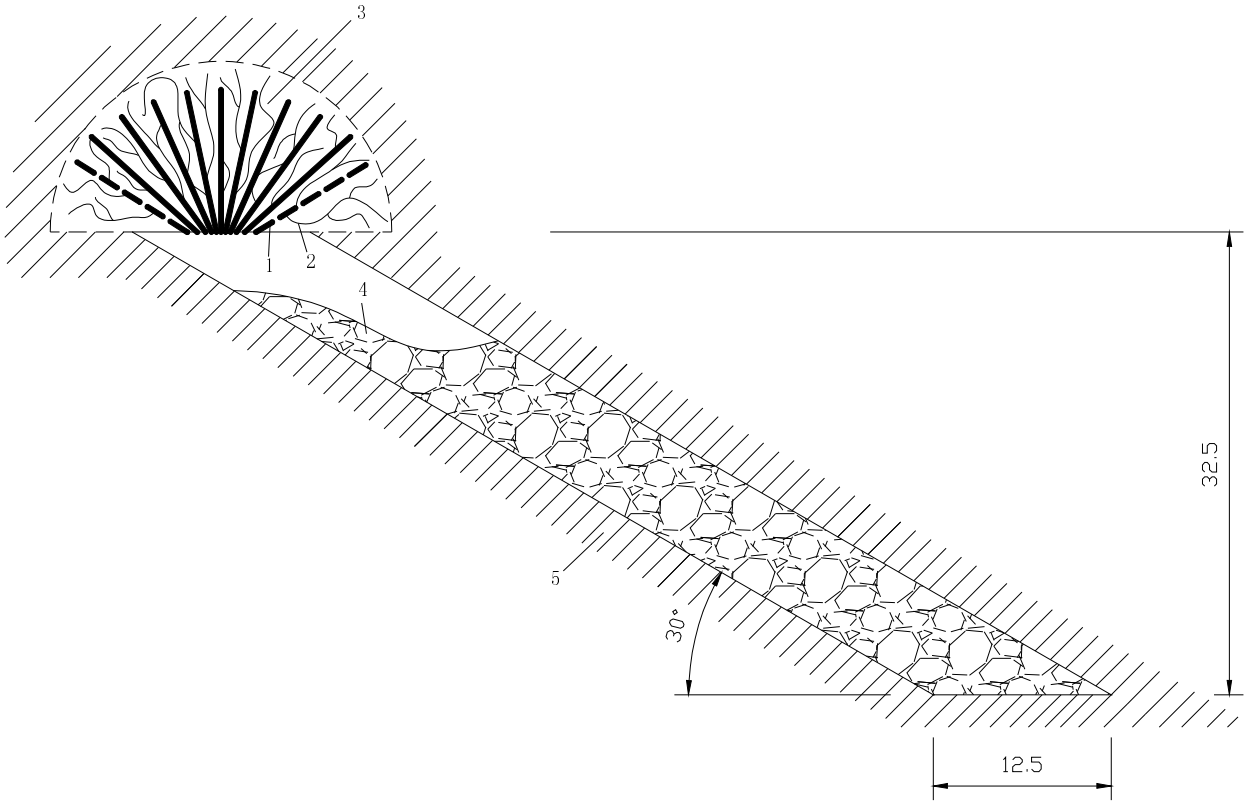

Fig. 3 Schematic vertical section of the test mine stope and fissured stope hangingwall pre-anchored by fully-grouted cable bolts along inclined direction 1) Fully-grouted cable bolts 2) Faults and fissures 3) Fissured mine stope hangingwall pre-anchored by fully-grouted cable bolts 4) Ore 5) Surrounding rock

**Effect of Injection Anchorage.** That cement mortar injects and fills faults, fissures, and cleavages makes rock being in a 1D or 2D stress state become in a more stable 3D one. Injection can also increase the strength and deformation modulus of soft constructional surfaces in surrounding rock. Strip-shaped and pulse-shaped grouting, which is something like the root hair of a tree, wraps fissured hangingwall into a wedge-shaped thing. This wedge wedges the top part of the stope. The space system of forces of the whole stope is balanced, and therefore no hangingwall collapse occurs.

**Waterproof and Impervious Effect.** Injection fills faults, fissures, and cleavages in surrounding rock to form an artificial impervious hangingwall with certain thickness. Influence of water on surrounding rock is alleviated or effectively protected. This waterproof and impervious effect is the same as principles of water-protection, sand-fixation, and water and soil conservation of tree roots.

**Effect of Anchoring in Advance.** Fully grouted cable bolts reinforce stope hangingwall in advance before in-situ rock is disturbed. The strength of surrounding rock itself is maintained and acquires further improvement and enhancement owning to the fact that fully-grouted cable bolts restrain deformation of surrounding rock. It is protected that a 3D stress state of surrounding rock is transformed into a plane stress state in the process of mine extraction. The stability of mine stopes is guaranteed.

## Conclusions

Active support can be formed by pre-anchoring. The mine stope hangingwall pre-anchored by fully-grouted cable bolts can immediately and actively support surrounding rock and bear loads to prevent the further development of rock strata movement when the mined-out space is formed.

During test and production process, persistent safety production of the mine stope pre-anchored by fully-grouted cable bolts is ensured due to the reliable anchorage performance and stable work space. The ore recovery rate and profits of the mine are increased.

A combined action mechanism of pre-anchoring fissured stope hangingwall by fully-grouted cable bolts is presented. The combined action includes hanging effect, effect of a laminated beam, effect of injection anchorage, waterproof and impervious effect, and effect of anchoring in advance. The achievements are helpful and beneficial to underground deep mining, and the design and construction of rock engineering projects which need anchoring reinforcement, such as slopes, tunnels, caverns, and mine stopes.

**Keywords:** foundation engineering; single pile; horizontal load; p-y curve; numerical analysis.

**Abstract.** Understanding the pile behavior and predicting the capacity of piles under horizontal load are important topics in foundation design. In this paper, the mechanical characteristics of single pile under horizontal load is analyzed based on FLAC3D finite difference software, and the load-displacement curve, the bending moment, shear force, soil resistance under all levels of load and the distribution law of p-y curve along the pile shaft are obtained. accordingly the following conclusions can be made: the bending moment of the upper part of pile body is big, the maximum bending moment is at the height of 2~3 meters and it is almost zero below the depth of 9 meters. The bending moment increases with the increase of load, the point of maximum bending moment moves down along the pile body with the increasing of horizontal load. and the location of the point of maximum bending moment moves from 2 meters below the ground to 3 meters below it. The distribution of soil resistance along the pile shaft is a reverse "S", the maximum of pile lateral soil resistance is at the height of about 2~3 meters below the ground.

## Introduction

Pile foundation is widely used as one kind of important foundation forms in civil engineering. With the constant improvement of the level of bridge construction and the development of economic in China, across the strait channel will be built at the Bohai bay, the Taiwan strait and the Qiongzhou strait and sea-crossing bridge is the most competitive solution to the problem of crossing the straits. The application of deep water foundation will be more and more common, the horizontal loadings, such as the wave loading, static dynamic water pressure and wind loading, the ship collision loading, etc. the deep water foundation sustained are much bigger than that of the land building, which makes it have equal importance with the vertical loads[1-4]. In this paper, combined with the engineering geological data, the finite difference method is adopted to study the horizontal bearing performance of single pile and its bearing capacity, which is aimed at providing basis and references for the design of the horizontal bearing pile.

## The numerical calculation model

### Calculation parameters

In this paper, finite difference program FLAC3D based on the fast Lagrangian method is used to calculate and analyze the working traits of single pile under horizontal load. In the calculation, Mohr-Coulomb model is used for the soil , the Elastic model is used for Pile, Pile size (diameter 600 mm, wall thickness 130mm, buried depth 15 m). It is sandy loam and silt of the main aquifers. In the depth of exploration, Quaternary overburden is completely developed with: foundation for artificial accumulation, sandy loam, loam, the foundation strata belongs to Quaternary Holocene alluvial deposits($Q4_{a1}$), and from top to bottom are as follows:①sandy loam;②silt;③clay;④sandy loam;⑤ clay. The physical and mechanical properties of field test area's foundation soil is illustrated in Tab.1.

According to Equation (1) and (2), the bulk modulus and shear modulus can be converted from elasticity modulus.

Bulk Modulus: $$K = \frac{E}{3(1-2\upsilon)} \quad (1)$$

Shear Modulus: $$G = \frac{E}{2(1+\upsilon)} \quad (2)$$

Tab.1 The physical and mechanical properties of field test area's foundation soil

| Soil class | Thickness (m) | ω (%) | $e$ | $\rho$ (kg/m$^3$) | $E_s$ (MPa) | $c$ (kPa) | $\varphi$ (°) |
|---|---|---|---|---|---|---|---|
| sandy loam | 7 | 25.8 | 0.883 | 1960 | 4.93 | 21.0 | 11 |
| silt | 7 | 20.9 | 0.660 | 1970 | 10.65 | 25.0 | 10 |
| clay | 3 | 35.4 | 1. 171 | 1880 | 3.92 | 18.2 | 19 |
| sandy loam | 2 | 24.2 | 0.736 | 1990 | 4.83 | 19.4 | 18 |
| clay | 3 | 21.7 | 0.743 | 2040 | 4.62 | 18.1 | 16.6 |

**Numerical computational model**

Interface command is used in the pile - soil interface, sliding and separation are allowed in it and the normal stiffness and shear stiffness of the interface are 10 times of the equivalent stiffness of the pile[5].Grading one-way maintain load time step control is adopted in the calculation and the top pf the pile is free. Computational geometry model is shown in Fig. 1.

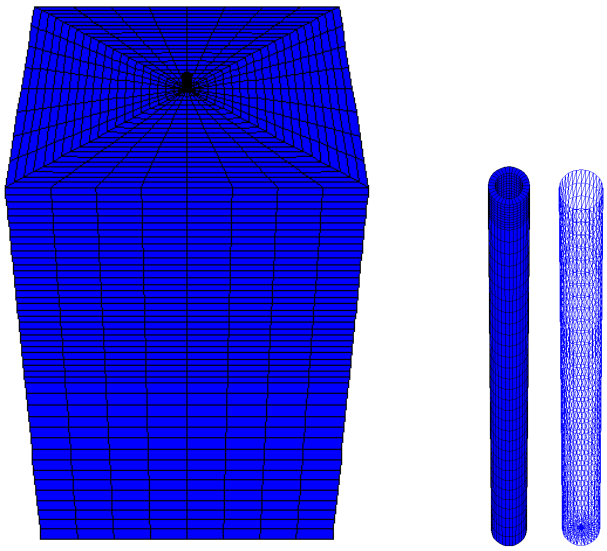

Fig.1 Numerical computational model

**The analysis of numerical calculation results**

The largest single pile load can be forecast according to the regulations. The load increment of per load level is about 1/10 ~ 1/15 of the estimated maximum horizontal load. Therefore, the design load per level is 15kN and there are 10 levels at all. One-way maintain load method is used to applied the load and the loading ends when there is a mutation of the displacement of the pile top.

The curve of horizontal displacement of the pile top under the action of all levels of load is drawn and the result is shown in Fig. 2.

According to the [6], for precast reinforced concrete pipe pile, the horizontal bearing capacity characteristic value of single pile can take 75% of that of the load that causes the horizontal displacement at the earth's surface to be 10 mm, while 6mm for buildings that are sensitive to horizontal displacement according to the results of static load test. It can be known from the horizontal load displacement curve shown in Fig. 2 that the horizontal displacement of 6 mm is corresponding to the load of 98kN while the horizontal displacement of 10 mm is corresponding to the load of 126kN.

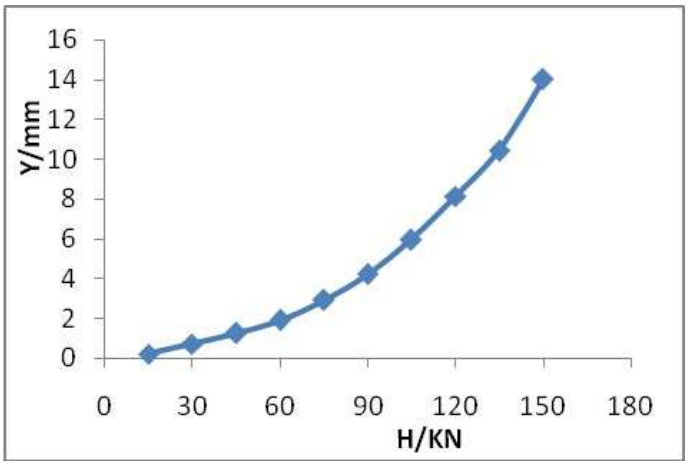

Fig.2 The p-y curve

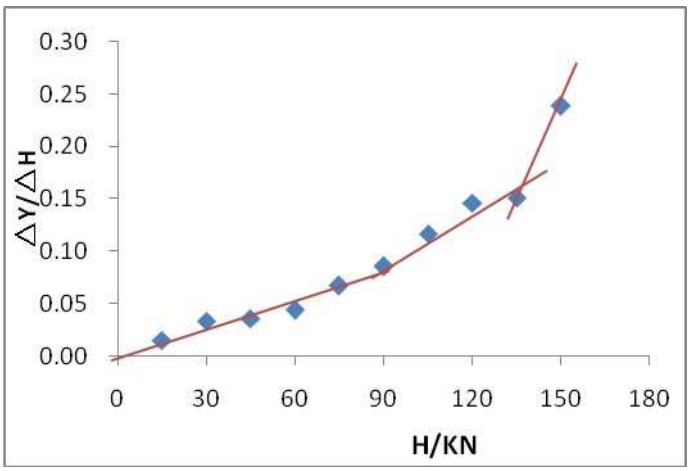

Fig.3 The p-y gradient curve

The determine for the critical load usually based on the result shown in Fig. 3. As the result of numerical calculation shows, the load of the first turning point on the gradient curve which is 90kN is chosen as the horizontal critical load of the single pile, while that of the second turning point as the horizontal ultimate load which is 135kN.

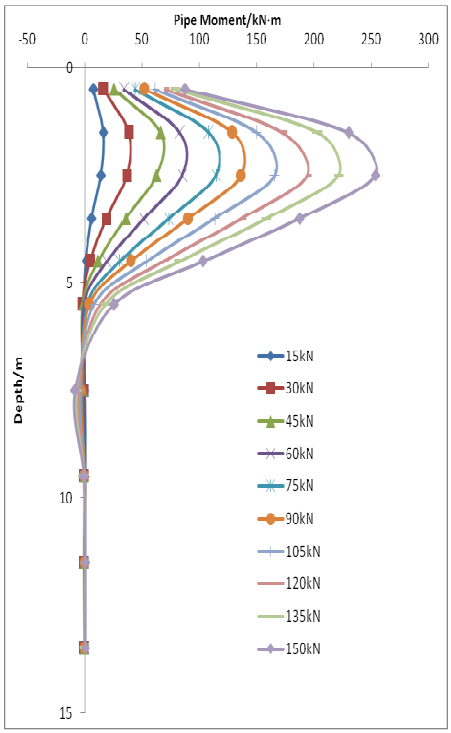

Fig.4 The bending moment of pile

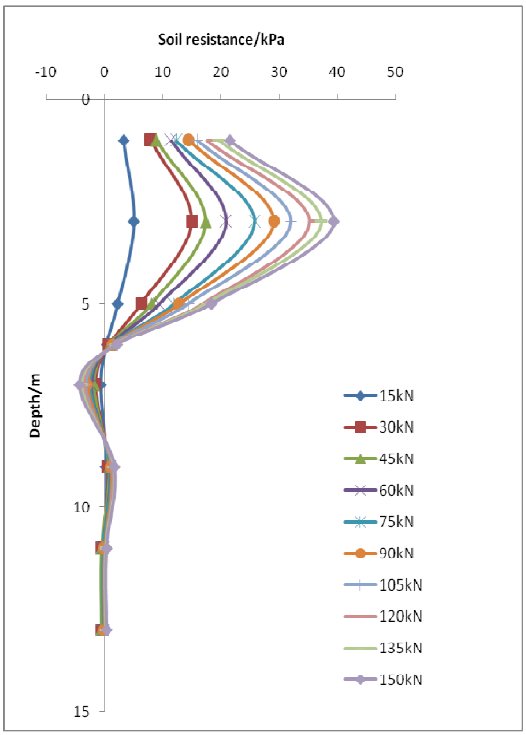

Fig.5 Distribution of soil resistance along the pile shaft

As Fig.4 shows, the bending moment of the upper part of pile body is big, the maximum bending moment is at the height of 2~3 meters, while the bending moment of the lower part of pile body is small and it is almost zero below the depth of 9 meters.

The bending moment increases with the increase of load, the point of maximum bending moment moves down along the pile body with the increasing of horizontal load. As the horizontal load increases from 15kN to 150kN gradually, the maximum bending moment of pile shaft increases from 16.0kN·m to 254.1kN·m, and the location of the point of maximum bending moment moves from 2 meters below the ground to 3 meters below it.

The zero moment point moves down along the pile body as the load increasing, it moves from 5.2 meters below the ground to 7.5 meters with the increasing of load, which indicates that the soil is in the elastic state during the initial state of horizontal loading. With the increasing of load, the soil changes from elastomer to plastomer, the influence depth increases as well, the deeper soil participate in the effect to resist horizontal load.

As Fig.5 shows, the distribution of soil resistance along the pile shaft is a reverse "S", the maximum of pile lateral soil resistance is at the height of about 2~3 meters below the ground, while the negative peak of it is in the middle of the pile shaft, and the absolute value of the negative peak is less than the positive peak of the soil resistance, the pile lateral soil resistance is almost zero below the depth of 9 meters. As the horizontal load increases, pile lateral soil resistance gradually come into operation and point of maximum soil resistance moves down along the pile shaft.

## Conclusions

The paper mainly conducts the horizontal bearing performance of single pile and its bearing capacity, accordingly the following conclusions can be made: the bending moment of the upper part of pile body is big, the maximum bending moment is at the height of 2~3 meters and it is almost zero below the depth of 9 meters. The bending moment increases with the increase of load, the point of maximum bending moment moves down along the pile body with the increasing of horizontal load. and the location of the point of maximum bending moment moves from 2 meters below the ground to 3 meters below it. The distribution of soil resistance along the pile shaft is a reverse "S", the maximum of pile lateral soil resistance is at the height of about 2~3 meters below the ground.

**Keywords:** C# language; simplified Bishop method; slope stability; the factor of safety; the critical slip surface

**Abstract.** A computer program was compiled based on the C# language of Microsoft Visual Studio 2008 and the principle of simplified Bishop method. The program will calculate the minimum factor of safety, and automatically draw the two-dimensional(2-D) critical slip surface after user input the basic parameters. Through testing a lot of examples, the program has good stability, high precision, fast speed and good visibility.

## Introduction

The slope stability problem is an ancient and young subject. During 240 years evolution, slope stability analysis went through a long and hard journey, In general, slope stability analysis methods are divided into three categories: qualitative analysis, quantitative analysis and uncertainty analysis.

Qualitative analysis methods mainly include: historical causes analysis, expert system method and graphical method[1]. These methods have distinct empirical in common, so qualitative analysis can only be used for preliminary and rough assessment.

Quantitative analysis methods are divided into two categories: one is the article points method based on the theory of the rigid body limit equilibrium theory, the other is the numerical analysis method based on the theory of elastic-plastic theory. The origin of the former was very early and withstood the test of practice, and a large number practice have proved that the simplified Bishop method often could get enough precision for homogeneous soil slope. However, the latter's accuracy and reliability is to be measured based on the former.

Uncertainty analysis methods mainly include: the dissipative structure theory, catastrophe theory, etc[2]. These methods consider the uncertainty of the factors, but there are a lot of shortcomings: (1) the theoretical is strong, it's difficult to master them; (2) starting late, the computer program is less;(3) lack of mechanics analysis, focus on the accidental factors.

For the reasons above, the computer program is compiled based on the simplified Bishop method.

## The overview of slope stability analysis software status

At present, the commercial software in geotechnical engineering field are foreign products, such as ANSYS, FLAC, MARC, ABAQUS, MIDAS/GTS, etc. We can obtain the safety factor and the most disadvantageous slide surface nephogram by using them, the criterions include: (1)the characteristics of main parts of displacement mutation. (2) the numerical convergence. (3) the plastic zone through[3].

The advantages of the slope stability analysis by finite element method are: (1) they can give the size and distribution of stress and strain in soil. (2) they don't need to assume the shape and position of sliding surface. But the controversy of this method are: (1) the effectiveness of the slope instability criterion is controversial. (2) factors influence the accuracy are various. (3) the location of the sliding surface could not be determined accurately. (4) they require high quality of science and technology for the user. (5) they generally more expensive.

In contrast, there are more weaknesses and shortcomings for the development of the domestic software: (1) foreign software outshine others, there is no place for domestic software. (2) domestic software in early time more use the process oriented language, the visualization is low and human-computer interaction is relatively poor. (3) few people dare to try programming.

For the reasons above, the purpose of this paper is to use Visual C # language of the Microsoft Visual Studio 2008 to develop a simple, friendly, fast and accurate visualization software, the software can read basic parameters well, obtained the minimum safety factor, and automatically draw the two-dimensional(2-D) critical slip surface.

## The program design

### C # language features

C # is a kind of development language designed specifically for the .Net framework, the characteristics are: (1) fully Object Oriented Programming, and visualization degree is high; (2) programming based on component, and be more likely to achieve modular; (3) the grammar is free and be easy to understand; (4) does not support pointer by default, program safety is high; (5) automatic memory management, save space.

### Program module analysis

Program development uses modular design, according to the calculation principle and personal analysis, the program is divided into five modules: Center of the circle search module, angle calculation module, weight calculation module, safety factor module and the minimum safety factor choose and the most disadvantageous slide surface determines module. Due to the limited space, only the center of the circle search module is analyzed.

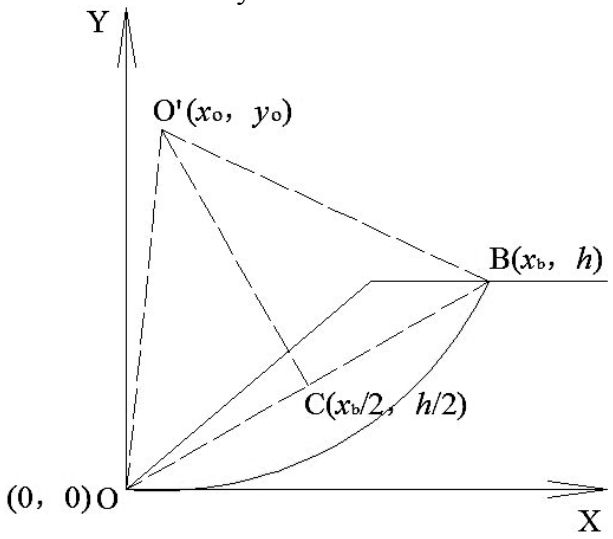

Fig.1. Slope calculation diagram

The XOY rectangular coordinate system is shown in Fig.1. O(0, 0) is the sliding out point, B ($x_b$, $h$) is the falling point, $h$ is the height of slope. O′($x_o$, $y_o$) is the center of arc OB, it must be on the perpendicular bisector of OB. The perpendicular bisector of OB and OB intersect at point C($x_b$/2，$h$/2). The slope of line OB is:

$$K_{AB} = \frac{y_B - y_A}{x_B - x_A} = \frac{h}{x_b}. \tag{1}$$

$$\because OB \perp O'C$$

$$\therefore K_{OB} \cdot K_{O'C} = -1$$

$$K_{OC} = -\frac{x_b}{h}. \tag{2}$$

The equation of O′C is:

$$y - \frac{h}{2} = -\frac{x_b}{h}(x - \frac{x_b}{2}). \tag{3}$$

When determining the scope of $x_o$, we take $h \leq y \leq 3\ h$[4].

When $y_0=h$:

$$x_0 = \frac{x_b}{2} - \frac{h^2}{2x_b}. \tag{4}$$

When $y_0=3h$:

$$x_0 = \frac{x_b}{2} - \frac{5h^2}{2x_b}. \tag{5}$$

And $h>0$，$x_b>0$:

$$\frac{x_b}{2} - \frac{5h^2}{2x_b} \le x_o \le \frac{x_b}{2} - \frac{h^2}{2x_b}. \tag{6}$$

By the Fig.2:

$$x_b \ge h \cdot \cot\alpha. \tag{7}$$

After many trial:

$$x_b \le h \cdot (1 + \cot\alpha). \tag{8}$$

α is the slope angle, so the scope of $x_b$ is:

$$h \cdot \cot\alpha \le x_b \le h \cdot (1 + \cot\alpha). \tag{9}$$

The scope of $x_b$ is determined, then the scope of $x_o$ is determined, and then the scope of the $O(x_o,y_o)$ is also determined, the analysis of the module is over.

After the program running, first, through the "New" command under the "Project" menu, create a new project shown in Fig.2. then click "OK" to enter the engineering interface shown in Fig.3, engineering interface is consist of three parts, the top of the left side is the parameter input window, the bottom of the left side is the data output window, and the right side is graphics output window. After entering the parameters, click the "Calculate" button to calculate, the result will be shown in Fig.3. Click "Save" button, the program will automatically save the results, Through the "History" command under the "Project" menu, you can also view the history.

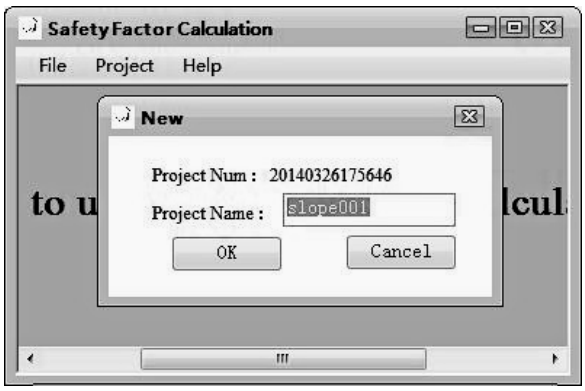

Fig.2. Start Interface

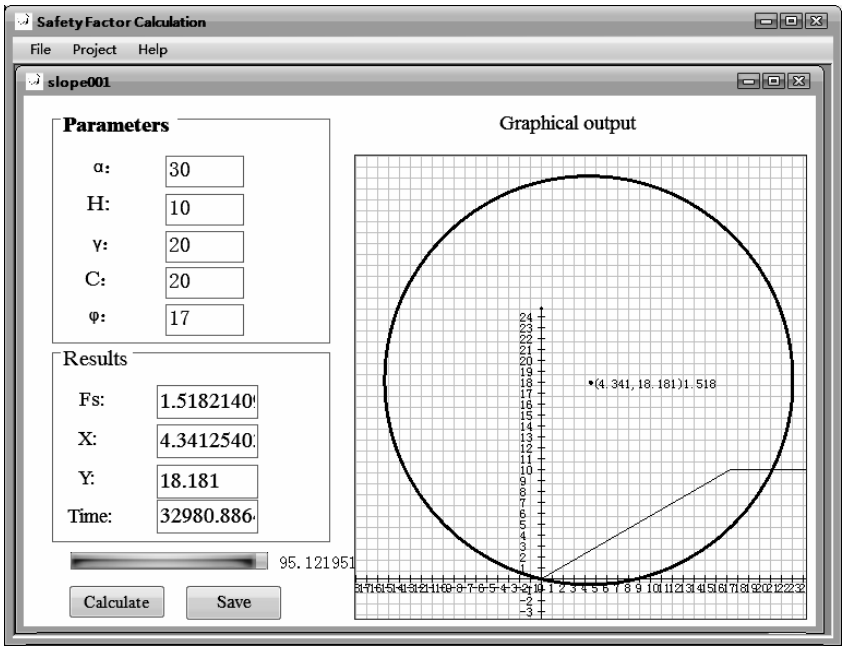

Fig.3. Engineering Interface

**To verify**

In order to test the stability and reliability of the program, a large number of examples are tested, due to the limited space, just list some results shown in table 1, and the most dangerous sliding surface of Num2, Num4 and Num5 are shown in Fig.4, Fig.5 and Fig.6.

## Conclusions

Through the examples above, the programm has the following features:

(1) The calculation accuracy is high, it firstly ensures the practicability and reliability of the program.

(2) The calculation speed is fast, it meets the time requirements for the user.

(3) The operation interface is simple, input parameters quickly, and the output results are abundant and easy to understand.

**Keywords:** Deep soft ground; Non-embedded pile-board structure (NEPBS); Engineering behavior; In-situ test; Over-shallow-embedded metro

**Abstract:** It's the first application of NEPBS crossing over-shallow-embedded metro in deep soft ground on new *Shanghai-Hangzhou passenger dedicated railway* (SHPDR) in China. It's necessary to study the engineering behavior of NEPBS in complex geology field. Long-term observation systems were installed at the typical test sections of SHPDR; Combined with theoretical analysis model, the mechanical properties and deformation laws were analyzed and tested. Measurement results show that the test reinforcement stresses of loading plates and supporting beams are small; the test bending moments agree well with the theoretical bending moments, which are far less than the resistance bending moments; the piles improved the mechanical properties of deep soft ground, so the plate-soil contact stresses are small, the maximum value is 132 kPa; 45 days after the train operation, the post-construction settlement is 1.86 mm; the settlements of individual test points are not yet stable, but they tend toward stability, which can meet the requirements of settlement control of SHPDR.

## Introduction

The new SHPDR is a high standard passenger railway, which intersects Shanghai metro 9 at 87° in zone DK5+344.8~DK5+374.8 in deep soft ground[1]. The embedded depth of metro tunnel is less than 8m, abutment excavation could make the tunnel rise and a lot of existing structures in the subgrade clearances in common subgrade scheme. Therefore, the design department put forward the NEPBS subgrade with strong adaptability in crossing underground pipelines and structures.

NEPBS is a new subgrade form of Ballastless track railway, which has high bearing capacity and good dynamic properties, and it is very economical too. In recent years, NEPBS has been successfully applied in Zhengzhou-Xi'an dedicated passenger railway and many other high-speed railways [2-4]. It's the first application of NEPBS crossing over-shallow-embedded, and the engineering behaviors of NEPBS in complex geology field are not known exactly, thus, it's necessary to study the engineering behavior of NEPBS in SHPDR. Combined with the SHPDR project, the engineering behavior of NEPBS and the tunnel-NEPBS interaction were tested, so as to verify that the NEPBS can meet the construction requirements of high-speed railway, and to provide scientific basis of the application of NEPBS in deep soft ground and other complex geology fields.

## In-situ Test Condition

**Engineering Overview.** The new SHPDR stands on the coastal plain with open flat terrain. The Shanghai metro-9 consists of three parallel over-shallow-embedded shield tunnels, and the surrounding rock is muddy clay. The interval between two tunnels is 10 m. The NEPBS is composed of reinforced concrete loading plates, supporting beams and cast-in-situ bored piles. One

continuous unit of NEBPS is composed of three spans. There are 4 piles on one lateral section, the diameter is 0.8m and the length is 46 m. The supporting beam is on the top of 4 piles with the size of 9.64×1.50×1.60 m. And we set two loading plates on 4 supporting beams with the size of 30.0×4.4×1.0 m (see Fig. 1~3).

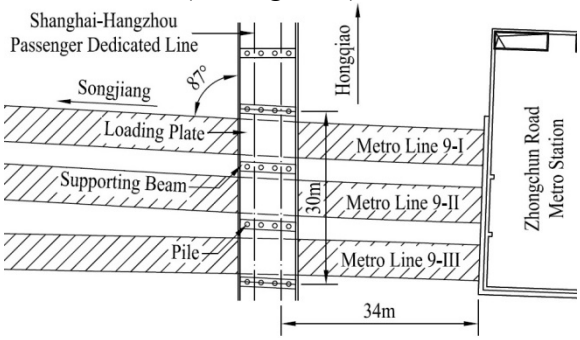

Fig. 1 Layout chart of NEPBS and metro

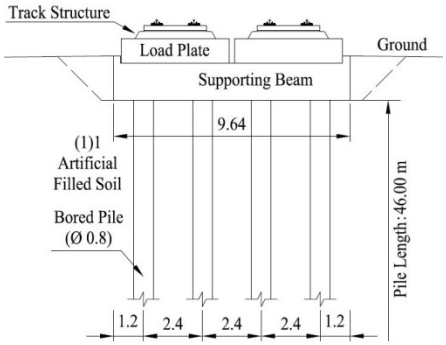

Fig. 2 Layout chart of NEPBS cross section (Unit: m)

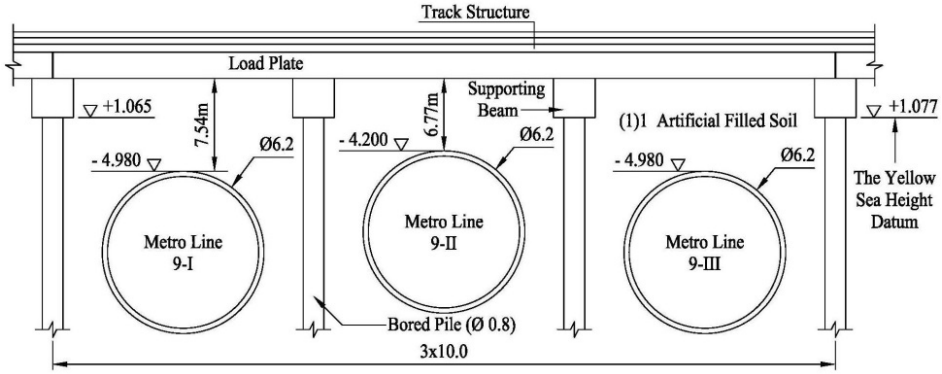

Fig. 3 Layout chart of NEPBS profile (Unit: m)

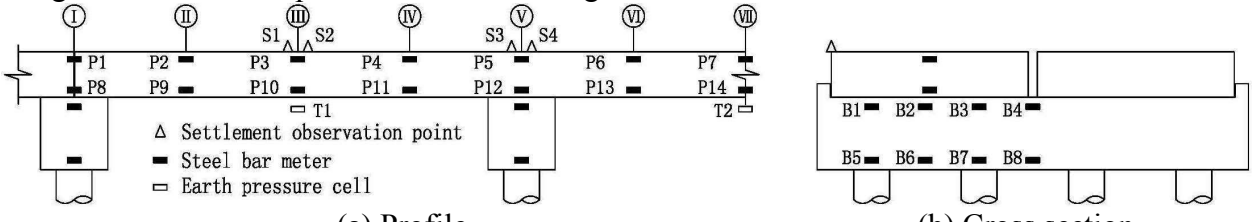
**Physical Mechanical Indexes of Soil.** The main foundation soil is soft clay or silt. According to geological prospecting materials, in the range of 60 m below the ground, the bearing capacity of soil is very low. The physical mechanical indexes of soil are listed in Tab 1.

Tab 1 Physical mechanical indexes (natural soil)

| Soil layer | Name | Thickness (m) | Density (g/cm$^3$) | Void ratio | Bearing capacity (kPa) | Cohesion (kPa) | Internal friction angle (°) |
|---|---|---|---|---|---|---|---|
| 3(1) | Muddy clay | 2.0 | 1.79 | 1.16 | 60 | 9.11 | 6.66 |
| 4 | Muddy clay | 6.6 | 1.80 | 1.13 | 80 | 9.70 | 7.13 |
| 6(1) | Silty clay | 8.4 | 1.99 | 0.72 | 180 | 18.04 | 14.06 |
| 7(1) | Silt | 5.5 | 1.95 | 0.75 | 150 | 12.59 | 17.04 |
| 7(2) | Fine sand | 7.6 | 2.05 | 0.64 | 160 | 19.00 | 22.40 |
| 8(2) | Silty clay | 12.5 | 1.87 | 0.93 | 150 | 15.88 | 12.64 |

**In-situ Testing Scheme.** In order to study and predict the engineering behavior of NEPBS, the in-situ observation systems were established. The test content included the internal force of loading plate and supporting beam, the plate-soil contact stress, and the settlement of plate. The arrangement of test components is shown in Fig. 4.



(a) Profile (b) Cross section

Fig. 4 Arrangement of test components

## Design and Calculation Method

**Design and Calculation Thoughts.** The design methods of NEPBS include allowable stress method (ASD) and limit state method (LSD) at present. LSD is more reasonable than ASD. LSD is better than ASD in theoretically, however, the dynamic properties of NEPBS under the train load are not known enough, therefore, ASD is still being used. NEPBS is a statically indeterminate structure, which can be analyzed by analytical method after being simplified.

**Calculation Models.** Based on equal rigidity, NEPBS can be simplified as lateral and longitudinal plane models because the load is strip load, and the loading plate is a textural one-way slab. The soil has strong transverse effect on piles; therefore, comprehensive rotation rigidity $G$ is introduced in the simplified plane models to describe the ability to resist rotation deformation of piles under the soil-pile interaction [5,6]. The comprehensive rotation rigidity is represented by the following equation:

$$G = \frac{1}{\varphi_0} = \frac{\alpha E_1 I (A_3 B_4 - B_3 A_4)(B_3 D_4 - D_3 B_4)}{(C_3 A_4 - A_3 C_4)(B_3 D_4 - D_3 B_4) + (C_4 B_3 - C_3 B_4)(D_3 A_4 - A_3 D_4)} \tag{1}$$

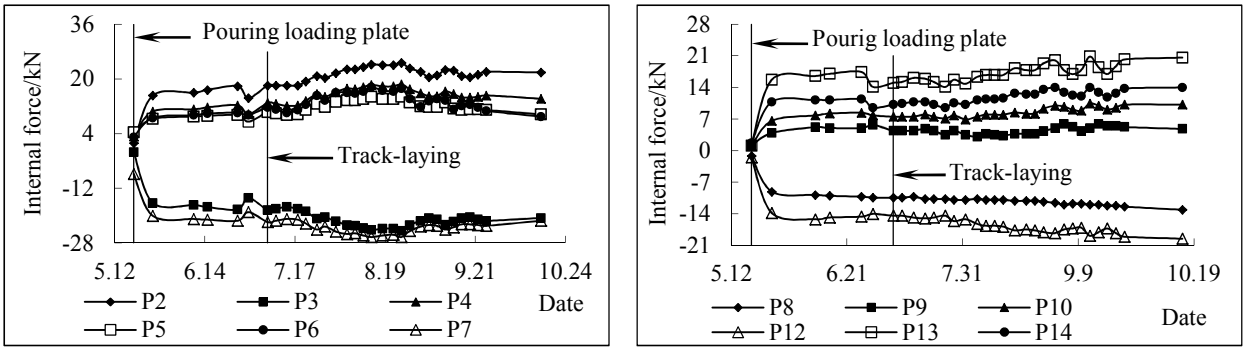
where $\varphi_0$ represent rotation, $\alpha$ represent pile deformation coefficient, $E_1$ is elastic module, $I$ is pile moment of inertia, and $A_3$, $A_4$, $B_3$, $B_4$, $C_3$, $C_4$, $D_3$, $D_4$ are undetermined constants. In order to further simplify the calculation, conversion pile length $h_{\text{con}}$ independent of pile-soil interaction is introduced instead of real pile length. The conversion pile length is represented by the following equation:

$$h_{con} = 3E_1 I / G \tag{2}$$

**Design load.** Construction load and other load in service life should be considered into the design of NEPBS. The design loads include structure weight, train live load, temperature load, centrifugal force, swaying force and so on. In this static test, only the structure weight of NEPBS and the load from track structure were considered to calculate the theoretical internal forces and bending moments when test results were compared with theoretical calculation results.

## Results and Analysis

**Reinforcement Stress.** The load from track structures was transferred to loading plates, then, transferred to supporting beams and soil under plate; the load on the supporting beams was transferred to the pile, then, transferred to the bearing soil stratum. Supporting beam was rigidly connected to pile, and loading plate and supporting beam formed hinged or rigid structure. The measurement results of reinforcement internal force of loading plate and supporting beam are shown in Fig. 5~6.



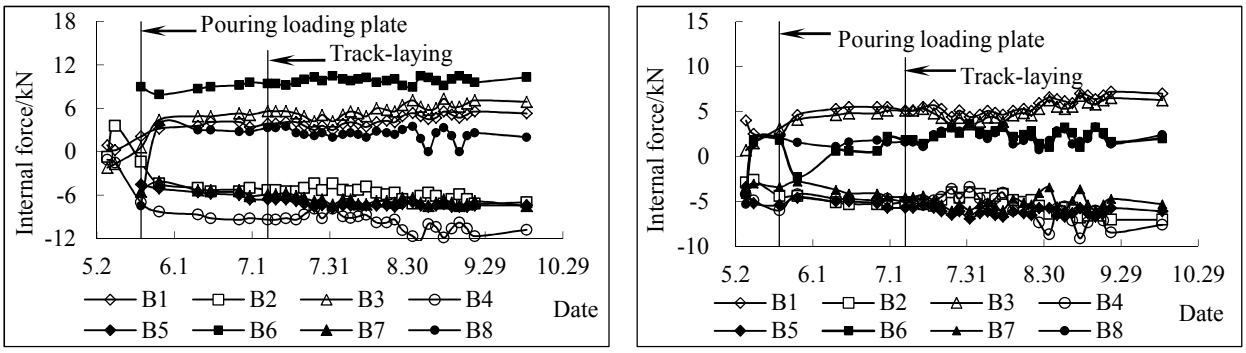
(a)Top (b) Bottom

Fig. 5 Time-history curves of reinforcement internal force of loading plate

After the completion of loading plate pouring, the hydration heat of concrete could make the test values of steel bar meter fluctuate acutely so that the test would not have high precision. The data after temperature stabilized were analyzed, in Fig. 5~6, the positive represent tension, and the negative represent pressure. The loading plates and supporting beams are in the working state of beam with compression steel. The maximum reinforcement tensile stresses of loading plates are

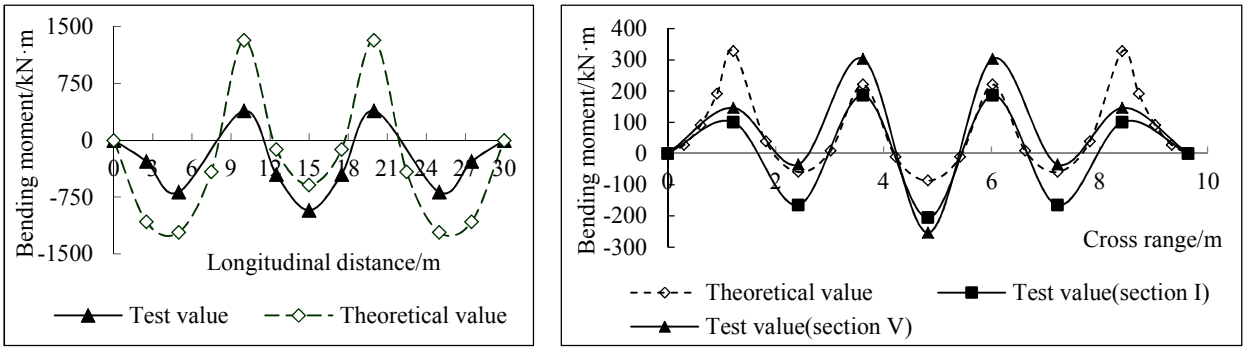
24.0 MPa at the bearing and 22.7 MPa at the span center, and the maximum reinforcement compressive stresses are 31.7 MPa at the bearing and 42.7 MPa at the span center. The maximum reinforcement tensile stresses of supporting beams are 11.9 MPa at the bearing and 17.0 MPa at the span center, and the maximum reinforcement compressive stresses are 12.7 MPa at the bearing and 20.0 MPa at the span center. After the completion of subgrade and track engineering, the test values were tend toward stability because the supporting effect of soil increased with the increase of settlement. The average values of reinforcement stresses at all sections were conversed to the bending moment of loading plate (see Fig. 7).

In Fig. 7, the test bending moment values agreed well with theoretical values of NEPBS which is subjected to the structure weight and the load from track structure. In theoretically, the bending moment at the bearing of side span should be zero, however, the test bending moment values were not zero because the real bearing was not a point but a plane. Therefore, the ends of loading plate need to be designed especially. What's more, the test bending moment values were far less than the design resistance moment values, which showed that the design resistance is safe and reliable.



(a)Section I (b)Section V

Fig. 6 Time-history curves of reinforcement stress of supporting beam



(a)Loading plate (b) Supporting beam

Fig.7 Comparison between test and theoretical bending moment

**Analysis of Plate Soil Contact Stress.** In theoretical design, the supporting effect of soil is often ignored, which is treated as safety margin. The stronger supporting effect of soil becomes, the bigger foundation coefficient is, and the smaller settlement of loading plate is. Foundation coefficient can be back calculated by the plate-soil contact stress. In order to get the plate-soil contact stress, earth pressure cells were set below the loading plate at the center line of the track (represented by *zx*) and one rail (represented by *zz*). The measurement results are shown in Fig. 8.

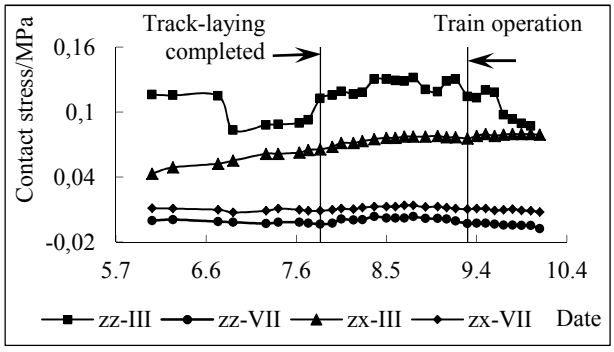


Fig.8 Time-history curves of plate-soil contact stress

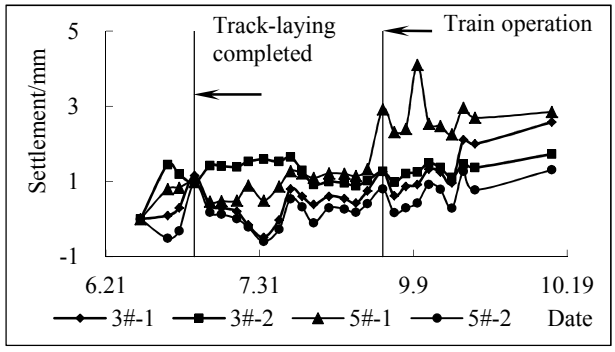

Fig.9 Time-history curves of settlement

The test contact stresses are small, the maximum value is 132 kPa. There is a great rigidity difference between pile and soil, and the supporting effect weakened gradually with the soil-pile interaction so that the upper load was transferred to the top of piles. Moreover, with the settlement increase and long-term interaction of NEPBS and soil, the contact stresses changed a little which can indirectly reflect that the metro tunnels didn't rise basically.

**Settlement Analysis of Pile-Board.** The deformation stability of NEPBS can be verified by the settlement test. The measurement results are shown in Fig. 9. Measured data shows that the initial settlement rate was fast, and then decreased with the lapse of time. After the train operation, settlement increased obviously again. 45 days later, the total settlements of section III and VII were 1.73mm and 2.85mm; and the post-construction settlements were 0.76mm and 1.86mm. The settlement of individual observation points were not yet stable, however, the settlements tended toward stability according to the prediction, and the settlements could be less than 15mm which is the requirement of design code.

## Conclusions

**Mechanical Properties.** NEPBS has the features of stressing definite, reasonable structure, clear path of force transfer and strong anti-disturbance capability, which can improve the bearing capacity of soft soil efficiently.

**Influence on metro.** With the settlement increase, the metro tunnels didn't rise. NEPBS has little influence on metro on SHPDR project, which can guarantee the stability of metro tunnels.

**Safe and reliable design.** The test bending moments agree well with theoretical moments, and they are far less than the resistant bending moment. Some internal forces of loading plates increased first and then decreased because of the supporting effect of foundation soil.

**Contact stress.** Foundation soil has certain supporting effect. The plate soil interaction can make most of load be transferred to the top of piles so that the load on soil would be reduced.

**Settlement.** The total settlements of NEPBS are small, and which has a slow trend of increase. According to the prediction, the settlement can meet the construction requirements of SHPDR using the NEPBS.

**Keyword:** Residue pile, Composite foundation, Bearing characteristic, ANSYS finite element analysis

**Abstract.** The bearing capacity of residue pile composite foundation formed by deep dynamic compaction, shorted for DDC, is calculated and analyzed by ANSYS finite element software. The analysis results show that pile body and soil between piles have a good coordination, residue pile composite foundation is semi-flexible and semi-rigid and the effect of consolidating foundation is obvious. The purpose of foundation treatment should be taken into consideration primarily to provide reference for future similar projects.

## Introduction

The residue pile composite foundation is filled with soil, sand, rock, broken bricks, concrete blocks, industrial wastes and mixtures of inorganic waste solids and formed by deep dynamic compaction method. At present, it is common to study the residue pile composite foundation applied in engineering, while the numerical simulation analysis is rare. This paper calculates and analyzes the bearing characteristic changes of residue pile in different factors, such as bearing characteristic analysis of residue pile, bearing characteristic analysis of soil between piles, elasticity modulus of pile body and soil between piles, pile-soil stress ratio, and pile length. The general bearing characteristic regulation of residue pile composite foundation is analyzed in detail.

## Build the finite element model of residue pile composite foundation

Based on the actual project, the holes diameter of residue pile composite foundation is 1.2m. After deep dynamic compaction, the holes diameter is 1.8m and pile length is 12m. The pile bodies are filled with residue and the properties of soil between piles has been strengthened. Model parameters mainly are come from laboratory soil test and construction experience. Poisson ratio of residue pile and soil between piles is taken from the references [1], and the specific parameters are shown in table 1.

Table 1 Model parameters of residue pile composite foundation

| Materials | modulus of compressibility $E_s$ (Pa) | Poisson ratio $\mu$ | Cohesive strength $c$ (Pa) | Internal friction angle $\varphi$ (°) |
|---|---|---|---|---|
| Pile body | $2.4e^8$ | 0.27 | | |
| Load board | $2e^{10}$ | 0.15 | | |
| mattress | $5.0e^7$ | 0.25 | 0 | 38 |
| soil between piles | $4e^7$ | 0.35 | $3.2e^4$ | 23.2 |

Under vertical load of residue pile composite foundation, it can be regarded as axially symmetric load. Therefore, the space problem of residue pile composite foundation under vertical load can be simplified plane problem in finite element calculation process. The model is symmetric, so take half of single pile composite foundation to carry out numerical simulations. Element type applies for Plane42. In fact, because pile and soil between piles sustain larger top loads within a certain range, refine them on grids. That is to say, divide X axis positive direction by 2.5 percent to achieve the exact solution.

According to contact elements provided by ANSYS finite element software, use surface contact element target169 and contact170 between pile and soil to simulate relative sliding efficiently. Friction coefficient should be determined to make contact analysis. There exists occlusion effect between piles and soil based on the reinforcement mechanism of DDC, the divide is not clear, so friction coefficient is large. The friction coefficient is 0.5 in this paper. Assuming that no relative slip between the piles and mattress when calculating, it applies for coupling connection. Set contact element between piles and soil to simulate the relative sliding effectively.

Before the numerical simulation, there are some assumptions including soil is isotropy; residue piles are elastic material; soil between piles is elastic-plastic material; the effect of history stress, soil displacement and initial stress of soil in pile-forming process are left out.

According to the reference[2] and trial calculation, dimensions of calculation model take 1 time pile length horizontally and twice times vertically. Boundary conditions are side of the model has no horizontal displacement, the bottom is completely fixed and surfaces are free. The finite element model of residue pile composite foundation and mesh are shown in Fig.1.

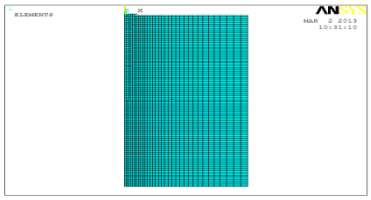

Fig.1 Element partition of residue pile composite foundation

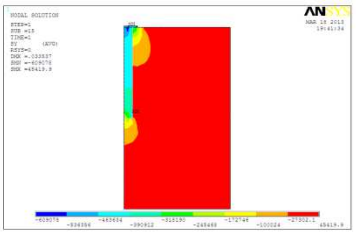
## The analysis on bearing characteristic of residue pile composite foundation

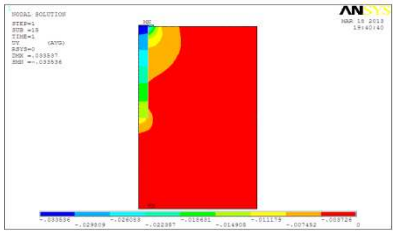
Bearing characteristic of composite foundation lies in coactions of piles and soil between piles, and sustaining top load. By studying the mechanism of reinforcement and load bearing, this paper analyzes the bearing characteristic of composite foundation in the aspects of composite foundation, single residue pile and soil between piles respectively.

**The analysis on bearing characteristic of composite foundation** .From the (a) of Fig.2 below, it can be seen that the effect of vertical pressure stress of residue pile is obvious under the action of superstructure, and the stress is very large leading to stress concentration at the top and tip of piles. Pile stress is 172.7kPa, taking 35.4 percentage of top loads. It is shown from data analysis that pile side resistant of residue pile composite foundation plays a major role which taking 64.6 percentage of top loads.

From the (b) of Fig.2 below, it is found that there is different degrees of sedimentation of piles and soil around piles. Vertical displacement of soil is 18.6mm under load board, and the average displacement of soil around load board is 9.3mm. The compressive deformation of soil is obvious under load board. The sedimentation of composite foundation decreases gradually from top to bottom presenting layer status. It can be seen clearly that piles and soil between piles of composite foundation under load board move down together basically, which means piles and soil between piles play a very good teamwork.



（a）vertical stress nephogram



（b）vertical deformation nephogram

Fig.2 Numerical simulation result of composite foundation at 500kPa

Fig.3 is a curve about load and settlement of composite foundation by numerical simulation. From the curve, it can be seen that residue pile composite foundation changes evenly under the range of 800kPa, and the p-s curve is gentle and smooth. Known from reference[3], for composite foundation filled with soil, sand, rock, residue pile, industrial waste and so on, the load is characteristic value of bearing capacity of single pile corresponded by s/d=0.015. Therefore, the bearing capacity of composite foundation is 380kPa in such conditions.

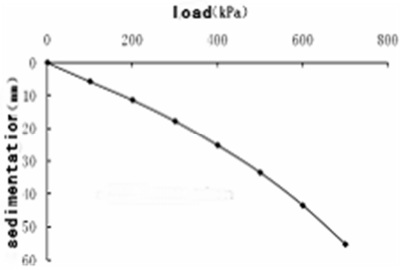


Fig.3 Loading-settlement curve of residue pile composite foundation

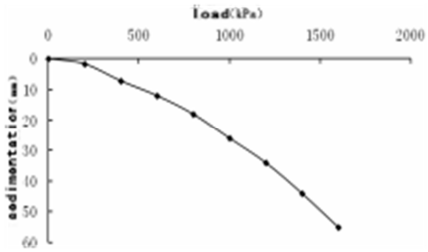

Fig.4 Loading-settlement curve of residue pile

**The analysis on bearing characteristic of residue pile body** .It is controversy to calculate bearing capacity of residue pile composite foundation. In some references, it is calculated by treating as dispersive pile or bonding materials pile in the other references. In the model, length of residue pile is 12m and diameter is 1.8m. Treated as Brauns dispersive piles, ultimate bearing capacity of single pile is 695kPa. While it is 1380kPa treated as bonding materials pile. Fig.4 is p-s curve of residue pile by numerical simulation. From the curve, it can be seen that ultimate bearing capacity of single residue pile is 1400kPa, which is higher than ultimate bearing capacity of dispersive pile. Difference between numerical simulation results and the ultimate bearing capacity by treating as bonding materials pile is small. It indicates that residue piles belong to bonding materials pile, and they are also frictional piles whose lateral friction is larger.

As shown in Fig.5, the difference of stress between top and tip of residue piles is large. With increasing the pile length continually, the stress of pile body decreases gradually due to the existence of the friction along the pile side and resistance of pile body material. And the stress of pile body increases with raising the load. However, load increment of pile top is 200kPa, and load increment of tip of piles is 28kPa. So, load increment of pile top is bigger than load increment of tip of piles. The reason is that the friction along the pile side is larger than tip resistance which is a stable value with increasing of the load.

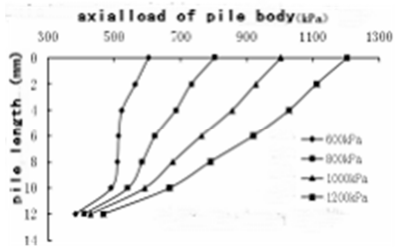

Fig.5 Axial Load distribution curve of pile body

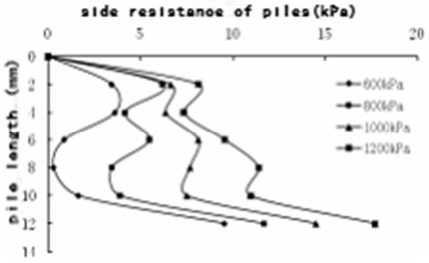

Fig.6 The distribution curve of side resistance of piles

From Fig.6, it can be found that the side resistance of piles has certain regulations along pile body length with increasing top load. From the distribution curve of side resistance along pile body, the changes of side resistance is divided into three a stage roughly. In stage1, the side resistance of top of the piles increases linearly. With increasing load of top piles, the side resistance increases gradually. But the side resistance decreases when top load increases to a certain extent. In stage2, if pile length is 2 to 8 meters, the side resistance decreases gradually after the peak. In stage3, the side resistance has a tendency to sudden increase at the tip piles, which is caused by strengthening effect of the side resistance. Due to diversity of residue pile materials, distribution laws of residue piles are different. However the overall trend is that the side resistance increases gradually as the load increases.

Above all, by theory calculation, comparing numerical simulation and load transmission laws of pile body, the residue pile composite foundation meets bond bearing capacity of friction pile and the reinforcement mechanism. Therefore, the residue piles are adhesive friction piles.

**The analysis on bearing characteristic of soil between piles .**Fig.7 is a relationship curve about stress of soil between piles and load in different depth of burial. It shows that stress of soil between piles enlarges with the increase of load in the same depth of burial, and there is a great difference in different depth of burial that stress of soil between piles decreases with the increase of depth of burial. Stress of soil between piles is lower around tip of piles, which is only about 50kPa.

Fig.8 is a relationship curve about deformation of soil between piles and load in different depth of burial. It show that sedimentation of soil between piles increases as the load enlarges. The deformation curve and stress curve are both gentle, which means soil between piles has better work performance sustaining top loads. From loading-settlement curve of soil between piles, the bearing capacity of soil between piles can reach 250kPa through DDC, which indicates that DDC has a significant effect on reinforcement for soil between piles.

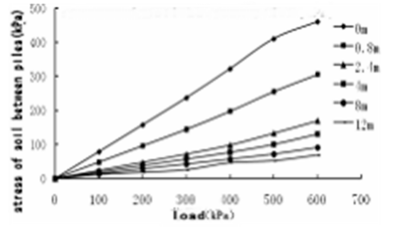

Fig.7 Relationship curve about stress of soil piles and load

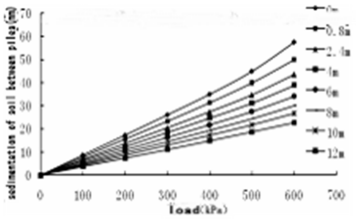

Fig.8 Relationship curve about deformation of between soil between piles and load

**The analysis on pile-soil stress ratio .**From Fig.9, pile-soil stress ratio of residue pile composite foundation changes slightly with the changing of load. Known from the figure above, when pile-soil stress ratio changes between 2.3 to 3, the load fluctuates within a narrow range, which agrees with the properties of dispersive pile composite foundation[4]. In terms of residue pile composite

foundation, the main reason is that the rigidity of residue pile is not very large, belonging to semi-flexible and semi-rigid piles in among bonding materials piles.

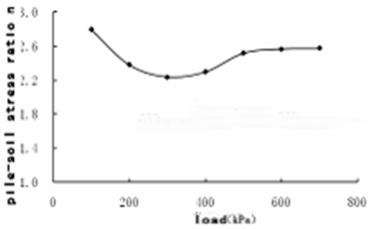

Fig.9 Relationship curve about pile-soil stress ratio and load

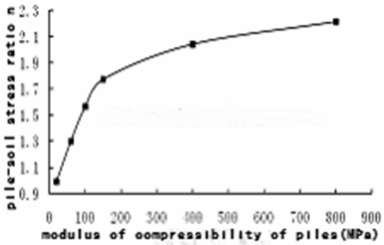

Fig.10 Relationship curve about $E_p$ and n

**The analysis on influencing factors of residue pile composite foundation**

**The effect of modulus of compressibility on bearing characteristic of composite foundation .**From Fig.10, modulus of compressibility of piles has a greater impact on sedimentation of composite foundation. It can be seen from modulus of compressibility of piles and pile-soil stress ratio that pile-soil stress ratio starts from1 when modulus of compressibility of piles and soil between piles is equal, which means that pile-soil stress ratio is about 2.5 with increasing modulus of compressibility of piles when they sustain equal loads.

From Fig.11, sedimentation of composite foundation decreases as modulus of compressibility of piles increases. At the beginning, the sedimentation decreasing is fast. And it is stable when modulus of compressibility of piles reaches to 800MPa. It indicates that increasing the modulus of compressibility of residue pile may enhance bearing properties of composite foundation and reinforcement effect.

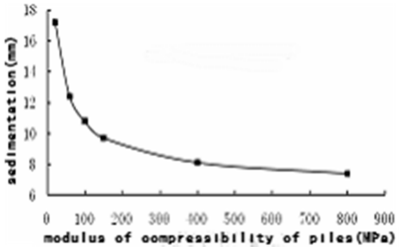

Fig.11 Relationship curve about $E_p$ and sedimentation

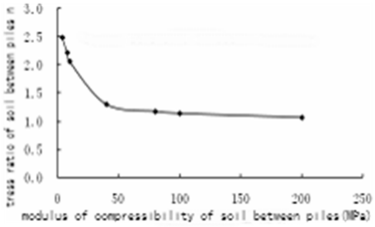

Fig.12 Relationship curve about $E_p$ and n

**Conclusions**

The finite element model about bearing characteristic of residue pile composite foundation is established by applying for ANSYS. By comparing the model and theories, this paper analyzes bearing capacity and mechanism of residue pile composite foundation formed by DDC, and studies the impact of modulus of compressibility of piles and soil between piles on bearing properties of residue pile composite foundation. Using the concept of composite foundation and theories, the article regards residue piles as semi-flexible and semi-rigid piles, which have large differences with dispersive piles. The main contents are given as follows:

The curve about load and sedimentation of single residue pile composite foundation is achieved by numerical simulation, and it is gentle, which means piles and soil have a better cooperation. The bearing capacity of composite foundation is 380kPa, which shows that soft foundation can achieve better reinforcement by choosing residue pile composite foundation.

Calculate the bearing capacity of single residue pile by using the formula of dispersive pile and bonding materials pile, then establish numerical model. It shows that the bearing capacity of single

residue pile is appropriate to bonding materials pile's, and has big differences with dispersive pile. And it can be found that residue pile composite foundation belongs to bonding materials pile. By analyzing the pile-soil stress ratio of residue pile composite foundation, residue piles are semi-flexible and semi-rigid.

The piles and soil between piles of residue pile composite foundation sustain top load together and have good compatibility. Soil between piles works well though DDC, which has reached around 250kPa. It indicates that compactness of soil between piles overcomes natural foundation.

**Keywords:** Dissipation function. Yield function. Yield surface rotation. Saturated sands. Thermodynamics with internal variables.

**Abastract**：Using constitutive modelling principle of thermodynamics with internal variables, the yield surfaces rotation of saturated sands subjected triaxial compression stress state are justified and explained. The explanation for the yield surfaces rotation of saturated sands prove the correctness and feasibility for the principle of thermodynamics with internal variables to construct elastoplastic constitutive relation of saturated soils.

## Introduction

With the thermal-mechanical coupling phenomena research, theory of thermodynamics of continuua has developed a lot since the 80's of the last century. Results of thermodynamics of continuua enriched the constitutive theory of continuum mechanics, and provided new ideas and methods for soil constitutive modelling. Collins and Houlsby *et al.* applied principles of thermodynamics of continuua to geomaterial constitutive modelling, and used two scalar founctions: free energy founction and dissipation founction (or yield founction), in theory of thermodynamics with internal variables, to establish constitutive model. Once the form of the free energy and dissipation potential functions have been specified, the corresponding yield loci, flow rules, isotropic and kinematic hardening rules as well as the elasticity law can be deduced in a systematic manner[1,2].

It is now well understood that whilst volumetric hardening models are normally sufficient to describe the behaviour of clays. It is necessary to additionally introduce shear hardening to model the observed behaviour of sands. It is shown in this paper that in order to keep the thermomechanical models internally consistent, the introduction of shear hardening implies that the yield surfaces must necessarily rotate in stress space and the material response immediately becomes anisotropic. This is, of course, already well recognized observationally and is a feature of a number of recent sand models. This paper provides justification and explanation for the yield surfaces rotation of saturated sands subjected triaxial compression stress state, by constitutive modelling principle of thermodynamics with internal variables(T.I.V). The explanation for the yield surfaces rotation of saturated sands prove the correctness and feasibility for the principle of thermodynamics with internal variables to construct elastoplastic constitutive relation of saturated soils. [3,4].

## The Dissipation Function and Yield Surface of Clay′s Isotropic Models

To specify $\boldsymbol{\alpha} = \boldsymbol{\varepsilon}^p = (\varepsilon_v^p, \varepsilon_d^p)$ an internal variable, $\varepsilon_v^p$ is the volume strain and $\varepsilon_d^p$ is the shear strain of a saturated soil element，the element is in a two-dimensional stress state in triaxial compression test. Use $p$, $q$ to represent the effective mean stress and the effective shear stress, respectively, the stess tensor is then specified by $\boldsymbol{\sigma} = (p, q)$. The dissipation function of isotropic models has the form

$$D(\boldsymbol{\sigma}, \boldsymbol{\alpha}, \dot{\boldsymbol{\alpha}}) = \sqrt{A^2 \left(\dot{\varepsilon}_v^p\right)^2 + B^2 \left(\dot{\varepsilon}_d^p\right)^2} \qquad (1)$$

where $A=a_1p'+a_2q+a_3p_c'$ , $B=b_1p'+b_2q+b_3p_c'$ ; $a_1,a_2,a_3,b_1,b_2,b_3$ are dimensionless coefficients. When $a_1=a_2=b_1=b_2=0,$ the dissipation function is

$$D(\boldsymbol{\sigma},\boldsymbol{\alpha},\dot{\boldsymbol{\alpha}})=p_c'\sqrt{(a_3\dot{\varepsilon}_v^{\mathrm{p}})^2+(b_3\dot{\varepsilon}_d^{\mathrm{p}})^2}$$

According to thermodynamics with internal variables the dissipative stresses are

$$\chi_p=\frac{\partial D}{\partial\dot{\varepsilon}_v^{\mathrm{p}}}=p_c'\frac{a_3{}^2\dot{\varepsilon}_v^{\mathrm{p}}}{\sqrt{(a_3\dot{\varepsilon}_v^{\mathrm{p}})^2+(b_3\dot{\varepsilon}_d^{\mathrm{p}})^2}},\quad \chi_q=\frac{\partial D}{\partial\dot{\varepsilon}_d^{\mathrm{p}}}=p_c'\frac{b_3{}^2\dot{\varepsilon}_{\mathrm{s}}^{\mathrm{p}}}{\sqrt{(a_3\dot{\varepsilon}_{\mathrm{v}}^{\mathrm{p}})^2+(b_3\dot{\varepsilon}_{\mathrm{s}}^{\mathrm{p}})^2}} \tag{2}$$

From Eq.(19) we obtain the yield surface equation in dissipative stress space

$$\left(\frac{\chi_p}{a_3p_c'}\right)^2+\left(\frac{\chi_q}{b_3p_c'}\right)^2=1 \tag{3}$$

this yield surface is shown in Fig. 1. The shift stress is $\boldsymbol{\rho}=(\rho_p,\rho_q)=(\gamma p_c',0),$ so $\chi_p=p-\gamma p_c'$, $\chi_q=q$ , the yield surface equation in true stress space is

$$\left(\frac{p-\gamma p_c'}{a_3}\right)^2+\left(\frac{q}{b_3}\right)^2=p_c'^2 \tag{4}$$

As $a_3=1/2,b_3=M/2,\gamma=1/2$ , where the $M$ is the slope of the critical-state line in the $(p,q)$ plane, Eq.(4) becomes

$$\left(p-\frac{p_c'}{2}\right)^2+\left(\frac{q}{M}\right)^2=(\frac{p_c'}{2})^2 \tag{5}$$

This is the yield surface equation the modified Cam-Clay model given by Burland（1965）in the Cambrige University, the yield surface is shown in Fig. 2.

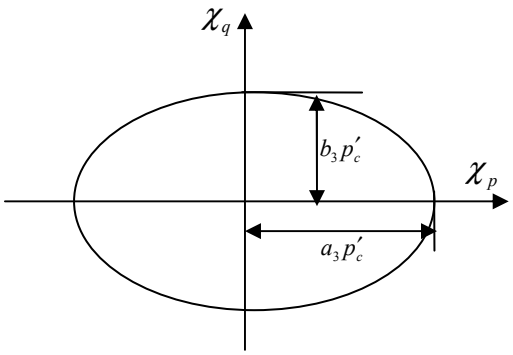

**Fig.1 Yield surface in dissipative stress space**

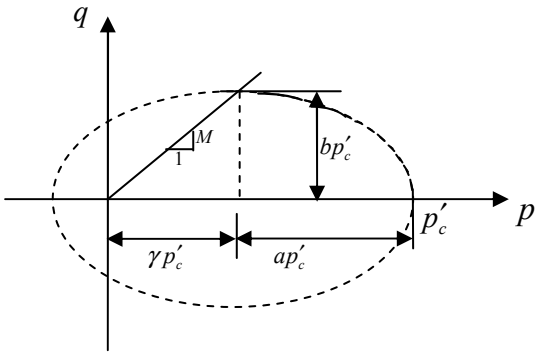

**Fig.2 Yield surface in true stress space**

**The Dissipation Function and Rotational Yield Surface of Sands**

As the dissipation function involves the product of the plastic volumetric and shear strain increment components, the dissipation function becomes

$$D(\boldsymbol{\sigma},\boldsymbol{\alpha},\dot{\boldsymbol{\alpha}})=\sqrt{A^2\left(\dot{\varepsilon}_v^p+\tan\theta_n\dot{\varepsilon}_d^p\right)^2+B^2\left(\dot{\varepsilon}_d^p\right)^2} \tag{6}$$

where, as will be shown, the new parameter $\theta_n$ is the slope of the NCL in the current state of anisotropy. A similar form for the dissipation function was considered, in a micro-mechanical context, by Muhunthan *et al.* [ 5 ]. The dissipative stress components are hence given by

$$\begin{aligned}\chi_p&=\partial D/\partial\varepsilon_v^p=A^2\left(\dot{\varepsilon}_v^p+\tan\theta_n\dot{\varepsilon}_d^p\right)/D\\ \chi_q&=\partial D/\partial\varepsilon_d^p=(A^2\left(\dot{\varepsilon}_v^p+\tan\theta_n\dot{\varepsilon}_d^p\right)\tan\theta_n+B^2\dot{\varepsilon}_d^p)/D\end{aligned} \tag{7}$$

from which it follows that

$$\chi_q-\chi_p\tan\theta_n=B^2\dot{\varepsilon}_d^p/D \tag{8}$$

By eliminating the plastic strain increments between (7)–(8), the equation of the inclined, elliptical yield locus (Figure 3) is obtained as

$$\frac{\chi_p^{\,2}}{A^2}+\frac{(\chi_q-\chi_p\tan\theta_n)^2}{B^2}=1 \tag{9}$$

Inverting (7), the normal flow rule for the plastic strain increments is obtained

$$\dot{\varepsilon}_v^p = D\left[\frac{\chi_p^{\,2}}{A^2}-\frac{(\chi_q-\chi_p\tan\theta_n)\tan\theta_n}{B^2}\right] \quad \text{and} \quad \dot{\varepsilon}_d^p = D\frac{(\chi_q-\chi_p\tan\theta_n)}{B^2} \tag{10}$$

Since the shear strain increment is zero on the current NCL, it follows from Equations (7), (8) and (10) that on this line

$$\chi_p=\pm A \quad \text{and} \quad \chi_p/\chi_q=\tan\theta_n \tag{11}$$

so that $\tan\theta_n$ is the slope of the **NCL** in dissipative stress space, and $(\pm A,\ \pm A\tan\theta_n)$ are the associated dissipative pressures and shear stresses at yield. The **NCL** in dissipative stress space is the chord of the ellipse joining the two points where the normals are in the $\chi_p$ direction, as shown in Figure 3. Similarly the **CSL** is the chord joining the points where the normals are in the $\chi_q$ direction, so that the volumetric strain increment is zero. If the origin in true stress space is to be on all the yield loci, the shift stress components must be related by

$$\rho_q=\rho_p\tan\theta_n \tag{12}$$

It follows that the slope of the NCL in true stress space, is identical to $\theta_n$. If we represent A by the linear function of the basic stress parameters as in the previous section, the pressures at the two ends of the **NCL** are

$$p'=\rho_p\pm A=\rho_p\pm(a_1p'+a_2q+a_3p_c') \tag{13}$$

The positive sign corresponds to $p'=p_c'$, so

$$p'=\rho_p+[a_1p_c'+a_2(\rho_q+(p_c'-\rho_p)\tan\theta_n)+a_3p_c'] \tag{14}$$

whilst, the negative sign gives yield at zero pressure $p'=0$, so that

$$0=\rho_p-[a_2(\rho_q+(p_c'-\rho_p)\tan\theta_n)]+a_3p_c' \tag{15}$$

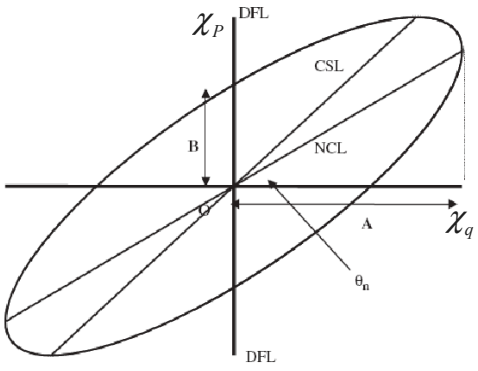

**Fig. 3 Rotated elliptical yield locus in dissipative stress space**

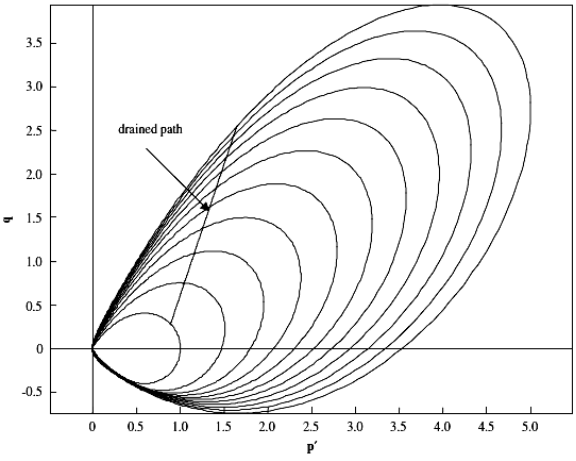

**Fig. 4 Rotational yield loci of a loos sand under triaxial compression**

The shift stress components, and the coefficients of $A$ hence satisfy:

$$\rho_p=\frac{1}{2}\gamma p_c' \quad \text{and} \quad \rho_q=\frac{1}{2}\gamma p_c'\tan\theta_n \tag{16}$$

where $a_1=1-\gamma,\ a_2=0,$ and $a_3=\frac{1}{2}\gamma$.

Since the two components of the shift stress have been found in (16), the equation or the yield locus in true stress space can be written as

$$\frac{(p-\gamma p_c'/2)^2}{A^2}+\frac{(q-p'\tan\theta_n)^2}{B^2}=1 \tag{17}$$

Dimensionless coefficients $b_1$、$b_2$、$b_3$ in $B=b_1p'+b_2q+b_3p_c'$ can be deduced from the slopes of the critical state lines in compression and extension.

Since we are trying to model the effect of shear strain hardening, it is perhaps natural to assume that the rotation angle depends on the plastic shear strain, so that we can write

$$\tan\theta_n=\tan\theta_f\left[1-\exp\left(-\beta\varepsilon_d^p\right)\right] \tag{18}$$

where $\theta_f$ is the ultimate value of $\theta_n$, $\beta$ is a model parameter of the rotational harding law (18).

According to the harding law $(\lambda-\kappa)dp_c'/p_c'=d\varepsilon_v^p+\tan\theta_n d\varepsilon_d^p$, the rotational harding law (18) and Eq.(17), giving a loose sand model parameters $\lambda=0.15,\kappa=0.01,M_c=1.2,M_e=0.86,\gamma=0.4,\alpha=03,\theta_f=30^0$ and $\beta=10$, the rotational yield loci are drawn in Fig.4 with the computer software Matlab.

## Summary

To take $\boldsymbol{\varepsilon}^p=(\varepsilon_v^p,\varepsilon_d^p)$ as an internal variable, when the dissipation function does not include the product of the plastic volumetric and shear strain increment components, the yield surface just shifts from dissipative stress space to true stress space without change of shape. But when the dissipation function includes the product of the plastic volumetric and shear strain increment components, the yield surfaces rotate in dissipative stress space and true stress space, and the material response immediately becomes anisotropic. Principles of thermodynamics of continuua with internal variables present good explanations of yield surface rotation of saturated sands.

**Key Words:** True triaxial stress state; Poisson random distribution; D-P criterion; Constitutive relation

**Abstract**: From the feature of rock micro-unit failure obeys Poisson random distribution, the damage softening statistical constitutive of was established under true triaxial confinement based on D-P criterion, so the impact of the intermediate principal stress on rock deformation and failure was considered in theory, and the actual engineering rock complex stress path evolution was reflected more realistically. Furthermore, according to the geometrical conditions of stress-strain relationship, the theoretical relationship between constitutive model parameters and the stress-strain curve characteristic parameters during the process of rock softening and deforming, which enhance the adaptability of the model. Finally, the rationality of the model verified by the measured data.

## Introduction

The concept of damage was first used by the Soviet Union plastic mechanics Kachanov home in 1958 when the creep rupture studied. In 1976, Dougill first proposed the study of rock material damage mechanics, which introduced the concept of damage to the study of rock [1]. Rock is a porous medium, and its constitutive equation has obvious nonlinear characteristics, thereby, how to create the stress-strain relationship can reflect rock in the process to the damage is one of the hot and difficult rock mechanics studies [2]. To this, the researchers conducted a great deal of research, and made some encouraging research achievements, especially after the introduction of statistical methods, the research of rock damage softening statistical constitutive relations have made great progress[3-5]. In [6] the strain equivalence hypothesis was proposed, and the damage variable D is introduced into the constitutive model of rock, which opened the study of rock damage softening constitutive model. In [4] based on D-P criterion,the three-dimensional rock damage evolution equation and rock damage softening constitutive equations were established , which describes the rock mechanism of damage. In [7] the parameters can reasonably describe rock micro-element strength were introduced based on the assumption that the strength of the rock micro element obeys normal distribution.

However, the above triaxial constitutive theory model mainly focus in the conventional triaxial model without considering the impact of the intermediate principal stress. In fact, a lot of rocks true triaxial compression test results indicate that [8-10], the strength and failure of rock were not only affected by the maximum principal stress and minimum principal stress, but also affected by the intermediate principal stress, namely the so-called intermediate principal stress effect. And the evolution of complex stress path resulted from underground rock excavation can only reflected by true triaxial constitutive model.

In this paper, on the basis of predecessors' research, the true triaxial stress state of rock damage softening constitutive model was established, and the theoretical expression of model parameters was deduced based on the Poisson, and the correctness of established formula finally verified through the test data.

**The established of rock damage statistical constitutive model**

Using the J. Lemaitre strain equivalence hypothesis [6], the basic formula of rock damage constitutive model is

$$\{\sigma\}=[C]\{\varepsilon\}(1-D) \tag{1}$$

where, $\{\sigma\}$ is the nominal stress vector, $[c]$ is elastic matrix, $\{\varepsilon\}$ is strain vector, $D$ is damage variable.

Based on the heterogeneity of rock meso structure [4], the physical property of material internal micro elements are of probabilistic, assuming they obey Poisson statistical distribution. Under the action of load, the gradual destruction of material caused by the micro cracks and micro pore aggregation can represented by the damage of available $D$,its expression is [11]

$$D=1-\left(\left(\frac{\varepsilon}{\varepsilon_0}\right)^m+1\right)\exp\left(-\left(\frac{\varepsilon}{\varepsilon_0}\right)^m\right) \tag{2}$$

where, $\varepsilon$ is the strength of micro element, $m,\varepsilon_0$ are model parameters.

According to D-P failure criterion, $\varepsilon$ is

$$\varepsilon=\left[\frac{\sin\varphi}{\sqrt{9+\sin^2\varphi}}\frac{E(\sigma_1+\sigma_2+\sigma_3)}{\sigma_1-\mu\sigma_2-\mu\sigma_3}+\frac{E\sqrt{(\sigma_1-\sigma_2)^2+(\sigma_2-\sigma_3)^2+(\sigma_3-\sigma_1)^2}}{\sqrt{6}(\sigma_1-\mu\sigma_2-\mu\sigma_3)}\right]\varepsilon_1 \tag{3}$$

where, $E$ is elastic modulus, $\mu$ is poisson ratio, $\varphi$ is internal friction angle, $\varepsilon_1$ is the max principal stress.

Therefore, by Eq. 1and Eq. 2 the statistical constitutive model of rock damage was established

$$\begin{cases}\sigma_1=E\varepsilon_1\left(\left(\frac{\varepsilon}{\varepsilon_0}\right)^m+1\right)\exp\left(-\left(\frac{\varepsilon}{\varepsilon_0}\right)^m\right)+\mu(\sigma_2+\sigma_3)\\ \sigma_2=E\varepsilon_2\left(\left(\frac{\varepsilon}{\varepsilon_0}\right)^m+1\right)\exp\left(-\left(\frac{\varepsilon}{\varepsilon_0}\right)^m\right)+\mu(\sigma_3+\sigma_1)\\ \sigma_3=E\varepsilon_3\left(\left(\frac{\varepsilon}{\varepsilon_0}\right)^m+1\right)\exp\left(-\left(\frac{\varepsilon}{\varepsilon_0}\right)^m\right)+\mu(\sigma_1+\sigma_2)\end{cases} \tag{4}$$

Since the Eq. 4 contains the intermediate principal stress, so the Poisson distribution variables may reflect the impact of the intermediate principal stress on rock strength.

The above derivation based on Poisson distribution function, the damage model of rock was described from a statistical point of view, however, the parameters of the model have not been determined. In previous studies, the majority of the constitutive model parameters were determined by using the test curve fitting method, which has obvious limitations. In order to enhance the adaptability of the model, the theoretical relationship between model parameters and rock deformation and the stress-strain curves characteristic parameters in failure process must be studied, based on it , the expression the model parameters under complex stress state of were established.

**Determine of model parameters**

In this section, we took the Total differential method to deduce the model parameters. Typical triaxial test curve satisfies the following conditions at the extreme points of the geometry

$$\begin{aligned}&(1)\,\varepsilon_1=\varepsilon_c,\sigma_1=\sigma_c;\\ &(2)\,\varepsilon_1=\varepsilon_c,\frac{\partial\sigma_1}{\partial\sigma_2}=0.\end{aligned} \tag{5}$$

The model parameters are (the solution is ignored)

$$\begin{cases}\left(\left(\dfrac{\varepsilon_c}{\varepsilon_0}\right)^m+1\right)\exp\left(-\left(\dfrac{\varepsilon_c}{\varepsilon_0}\right)^m\right)=\dfrac{\sigma_c-\mu\sigma_2-\mu\sigma_3}{E\varepsilon_c}\\ \left(\dfrac{\varepsilon_c}{\varepsilon_0}\right)^m+1=m\left(\dfrac{\varepsilon_c}{\varepsilon_0}\right)^{2m}\end{cases} \tag{6}$$

Let $x=\left(\dfrac{\varepsilon_c}{\varepsilon_0}\right)^m$, then Eq .6, simplified to

$$\begin{cases}(x+1)\exp(-x)=\dfrac{\sigma_c-\mu\sigma_2-\mu\sigma_3}{E\varepsilon_c}\ \text{(a)}\\ x+1=mx^2\qquad\qquad\qquad\text{(b)}\end{cases} \tag{7}$$

The parameter $x$ can be solved from Eq .7(a), then the parameter $m$ can be calculated from Eq .7(b), finally get the value of $\varepsilon_0$, so far the rock damage softening Statistical constitutive model under true triaxial stress state are finally determined.

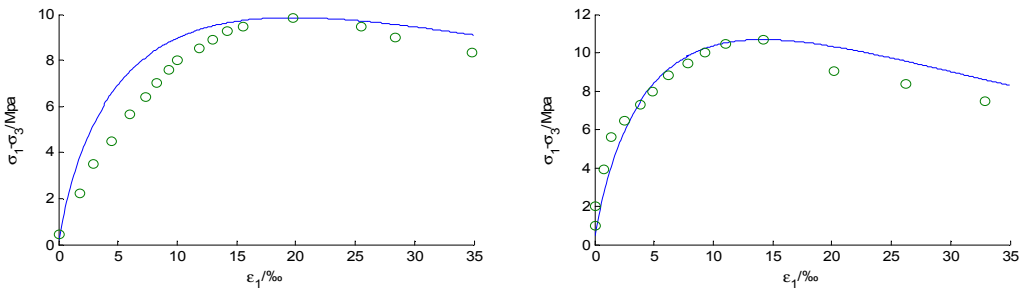
**Verification of model**

The maximum principal stress and maximum principal strain theory curve about different intermediate principal strain under complex stress state can be obtained from Eq .3, Eq .4 and Eq .6, and contrasted it with the test data provided from [9],as shown in Fig.1 The rock elastic modulus $E$=4.866GPa, poisson ratio $\mu$=0.25, internal friction angle$\varphi$=44.70.And Peak point parameters under different intermediate principal stress are shown in Table 1.

Table 1 Sandstone parameters under different intermediate principal stress

| $\sigma_2$/MPa | $\sigma_c$/MPa | $\varepsilon_c$/‰ |
|---|---|---|
| 1.2483 | 10.6359 | 19.7582 |
| 2.2622 | 11.4578 | 14.1821 |

To highlight reflect the impact of the intermediate principal stress on rock failure, especially selected two different intermediate principal strain cases when the minimum principal strain were the same in literature [9]. In Fig.1 (a), $\sigma_3=0.78$MPa, and the ratio of the intermediate principal stress and the minimum principal strain is $\sigma_2/\sigma_3=1.6$; In figure 1 (b), $\sigma_3$= 0.78MPa, and the ratio of the intermediate principal stress and the minimum principal strain is $\sigma_2/\sigma_3=2.9$.



（a）（$\sigma_3$=0.78MPa,$\sigma_2/\sigma_3$=1.6）　（b）（$\sigma_3$=0.78MPa,$\sigma_2/\sigma_3$=2.9）

Fig.1 The verification curves of true triaxial rock theoretical model under different confining pressure

As can be seen from Fig.1, the stress-strain relationship theoretical curve of rock damage constitutive model established in this paper matched with test data, so the rationality of constitutive model were verified.

## Conclusions

1. In this paper, assuming that rock micro element obey Poisson statistical distribution, the rock damage statistical constitutive model was established based on the D – P criterion, which considering the effect of intermediate principal stress on rock failure strength in theory;
2. The theoretical relationship between model parameters and rock deformation and the stress-strain curves characteristic parameters in failure process were established, the Parameter $m, F_0$ can only be determined by using peak point stress and strain information of test curve and rock elastic modulus, poisson ratio, and these parameters can be easy to get in the conventional mechanical properties test;
3. Through the model verification show that the rock damage statistical constitutive model under true triaxial stress state established in this paper matched with test data.

**Keywords:** Threshold, Image segmentation, Degree of membership

**Abstract.** With the development of computer technology, digital image technology is also to grow rapidly. At present, the image processing has become a popular research field. Segmentation is a very important critical step in image processing tasks, which directly affects the subsequent analysis results. Cluster analysis belongs to the category of unsupervised classification and it is not depended on any prior knowledge of the category, so it usually serves as a basic tool to be used for the initial stage of image segmentation. In this paper, we propose a weighted fuzzy threshold algorithm based on fuzzy relations. This algorithm determines the fuzzy membership function according to the similar relationship between pixels, and emphasizes influence of sharpening features of Gaussian function. The new method overcome the drawbacks of clustering algorithms such as, sensitive to the initial value, need to pre-set number of categories. The numerical results show the effectiveness of the new method.

## Introduction

Image segmentation is to divide the input image into a disjoint set of physically meaningful, quasi-homogeneous regions. The partition is made according to some perceptual attributes like color, boundary information, or a certain application-dependent region uniformity criterion. Since it provides the basis and precondition for the further analysis of the image, it is useful for feature extraction and pattern recognition. It has been well studied in the past decades. For example, Ben et al. [1] do the image segmentation by employing the color clustering method. Bu et al. [2] do the image segmentation by employing the Fuzzy cluster method (FCM). However, the image segmentation is till a hot research area as there exists no a common method.

Image segmentation technology is a multi-factor, multi-index classification problem. Lots of the threshold algorithms for image processing ignore some similarities between pixels and are affected by some extent abnormal pixel values. Cluster analysis is an effective tool for dealing with data classification. As it does not depend on any prior knowledge of the category, cluster analysis is an unsupervised classification method. Until now, researchers have proposed lots of clustering algorithms, which can be divided into two categories based on the nature of the general classification algorithm. One is hard clustering method with the representation K-means clustering method and another one is the fuzzy clustering algorithm with representation FCM. However, both categories of cluster algorithms depend on the cluster number which needs to be given first, and they are sensitive to initial conditions. Moreover, the running time depends on the size of the data. In the recent years, many of researchers have focused on improving the cluster methods mentioned above. For example, [3] improved the FCM by introducing the entropy constraint into FCM. On the other hand, the new proposed method still has some drawback of limitations. The methods proposed in [4-5] only perform well when there is a small gap between the actual image and the ideal result. Moreover, the algorithms are very complex. The membership-based threshold segmentation algorithm provided by [6] has ignored the similarity of the image.

In the field of data processing, the received data may be uncertainty. Since the following operation will be affected by the uncertainty, it is very important in the process of analysis. Fuzzy theory is good at dealing with uncertainty and has been widely applied to the field of image processing such as image enhancement, image segmentation. Then we may get stable results if we employ the fuzzy theory in process of data clustering.

In this paper, we propose a weighted fuzzy threshold algorithm based on fuzzy relations, the new method overcome the drawbacks of clustering algorithms such as, sensitive to the initial value, need to pre-set number of categories. The numerical results show the effectiveness of the new method.

## Definition of image segmentation

Image segmentation is proposed in 1992 and its aim is to divide the image into small regions. The mathematical formulations of image segmentation are as what follows. Let R denote the entire area of the image. The image segmentation is to divide R into some sub-areas which satisfy:

1) $\bigcup_{i=1}^{n} R_i = R$ ;

2) $R_i$ is a connection region, for $i = 1,2,\cdots,n$ ;

3) $R_i \cap R_j = \varnothing$ , $i, j = 1,\cdots,n, i \neq j$ ;

4) $P(R_i) = TRUE$ , $i = 1,2,\cdots,n$ ;

5) $P(R_i \cup R_j) = FALSE$ , for any adjacent areas $R_i$ and $R_j$ .

Here $P(R_i) = TRUE$ means that all points in $R_i$ satisfy some given properties and $P(R_i \cup R_j) = FALSE$ means that the adjacent areas $R_i$ and $R_j$ satisfy the different properties.

## The threshold clustering method based on fuzzy theory

Segmentation is a critical step in the image processing as it affects the following steps of segmentation analysis directly. In fact, the image segmentation algorithm can be taken as the clustering method. Due to the intuitive nature and simplicity, the threshold plays a key role in the image segmentation. By taking advantage of the fuzzy membership function, we sharp the impact of singular value to the threshold of the image and strengthen the impact of the similarity to the threshold of the image. The algorithm for calculating the threshold of clustering algorithm based on membership is as follows.

Suppose that there are *m* sample vectors and *n* variables, where $X_i = (x_{i1}, x_{i2}, \cdots, x_{in})$ denotes the *i*-th sample. When estimating the threshold value, we use the Euclidean distance to calculate the similarity between *i*-th and *j*-th sample, that is, $d_{ij} = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2 + \cdots + (x_{in} - x_{jn})^2}$ , $i, j = 1,2,\cdots,m$ .

Step 1.Calculate the similarity of the samples and denote $D_i = \{d_{i1}, d_{i2}, \cdots, d_{im}\}, i = 1,2,\cdots,m$ .

Step 2.Rearrange the elements of $D_i$ , and write by $S_i$ ,

$$S_i = \{d_{ip}, d_{ik}, \cdots, d_{it}\} = \{s_{i1}, s_{i2}, \cdots, s_{in}\}, i = 1,2,\cdots,m, \text{ where } d_{ip} > d_{ik} > \cdots > d_{it}.$$

Step 3.Rearrange the samples based on the order of $S_i$ , write by $S_{X_i}$ ,

$$S_{X_i} = \{X_p, X_k, \cdots, X_t\} = \{X_1^i, X_2^i, \cdots, X_m^i\}, i = 1,2,\cdots,m.$$

Step 4.Construct membership functions $g_{ij} = \exp\{-\frac{(d_{ij} - \overline{d}_i)^2}{\sigma_i^2}\}$, where

$$\sigma_i^2 = \frac{1}{n-1}\sum_{j=1}^{m}(d_{ij} - \overline{d}_i)^2 \text{ and } \overline{d}_i = \min\{S_i\}.$$

Step 5.Calculate the fuzzy center with respect to $i$-th sample and denote them by $C_i = \{c_{i1}, c_{i2}, \cdots, c_{in}\}$, where $c_{ij} = \dfrac{\sum_{k=1}^{m} g_k x_{kj}^i}{\sum_{k=1}^{m} g_k}$, $i = 1,2,\cdots,m,\ j = 1,2,\cdots,n$.

Step 6.Calculate the value of the threshold

$$\theta = \frac{\sum_{i=1}^{m}\sum_{j=1}^{m}\sqrt{(c_{i1}-c_{j1})^2 + (c_{i2}-c_{j2})^2 + \cdots + (c_{in}-c_{jn})^2}}{m^2 - m},$$

specially, $\theta = \dfrac{\sum_{i=1}^{m}\sum_{j=1}^{m} | c_i - c_j |}{m^2 - m}$, if $n = 1$.

Step 7. Split or merge regional clusters.

In our algorithm, Step 1 depicts the similarity to the threshold of the image by a similar distance. This make our algorithm need not provide the cluster number with the lack of the priori knowledge and avoid the influence of the initial value. Step 4 can escape from the affected of the singular values by defining the membership function as $\exp(-\dfrac{(x-\mu)^2}{\sigma^2})$. Step 7 can make the algorithm insensitive to the order of input samples by merging clustering algorithm.

## Two numerical experiments

### A numerical experiment of FCM

We choose ten 2-dimensional samples as in Table 1 and cluster the data by FCM.

Table1 Ten 2-dimensional samples

| Sample | $X_1$ | $X_2$ | $X_3$ | $X_4$ | $X_5$ | $X_6$ | $X_7$ | $X_8$ | $X_9$ | $X_{10}$ |
|---|---|---|---|---|---|---|---|---|---|---|
| $x_1$ | 0 | 0.5 | 0 | 0.5 | 1.5 | 1.5 | 2.5 | 2.5 | 3 | 3 |
| $x_2$ | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |

As FCM need the number of clusters, we test FCM by setting the number of clusters as 2. The result is shown as in Figure 1.

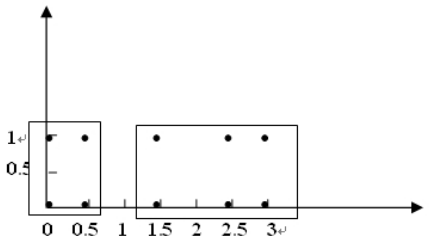

Fig 1 FCM (with 2 clusters)

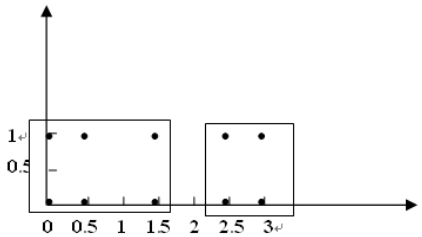

Fig 2 Change in the inputting order

The above numerical experiment shows that we can use FCM to cluster according to the given cluster numbers. If we change the inputting order of the data (see Figure 2), we get the different results, which means that the FCM depends on the order of the inputting of the data.

### A numerical experiment of the new algorithm

FCM depends on the given cluster number. But in general, we can not always know in advance except that we can have a thorough understanding of the data. The proposed method does not need to provide

the cluster number. It can cluster the dada by setting the threshold. Moreover, it does not depend on the inputting order. Next we show the improvement by an actual image example.

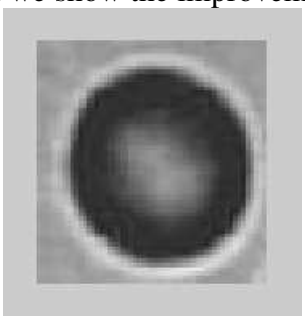

Fig 3 Original image

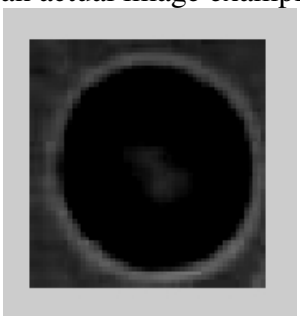

Fig 4 Fuzzy center

The images after segmentation：

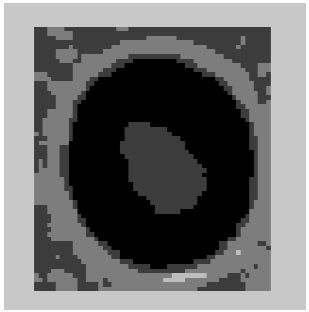

Fig 5 FCM (with 4 clusters)

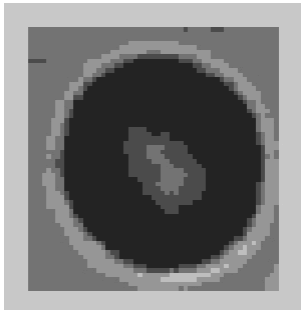

Fig 6 Results of the our method

## Conclusions

In this paper, we propose a weighted fuzzy threshold algorithm based on fuzzy relations. Compared with the existing clustering algorithms dealing with image segmentation, our algorithm can sharp the impact of singular value to the threshold of the image and strengthen the impact of the similarity to the threshold of the image. But with different forms of the membership function, we may get different results. In the future, the algorithm may be improved in this aspect.

# COMPARISON ANALYSIS OF BUILDINGS SETTLEMENT, CALCULATED IN ACCORDANCE WITH RHEOLOGICAL PROPERTIES OF SOILS

## (basedon the geotechnicalconditions of St. Petersburg)

Astafyeva Ekaterina

Russia, Saint-Petersburg State Polytechnical University (Institute of Civil Engineering)

astafyeva.ekaterina@gmail.com

**Keywords:**foundation settlement, soft soils, soil models, Plaxis, Fem-models, rheological model, hardening soil model, field observations, monitoring

Soft soils are well represented as the foundation of buildings all over the world. Settlements of buildings that are built on soft soils are developing over decades and often uneven. This can cause structural damages to constructions and as consequence unplanned repairs or even collapses of buildings in general.

Tojustify the useof different modelsof soil mechanicsit is necessary to carry outtheir verification. Verification of the modelconsists of complianceto the simple laboratoryexperimentsand of theadequacy ofthe field tests description. And the most important thing is that theresults of calculations should be based oncomparison between series of field observations.The principaldifficulty ofcomparingcalculation resultswithfield observationsisthat the actualsoil deformationisdeveloping over a longtime, andmost of thecalculation methods are aimed to obtainfinite values ofdeformations. Comparison between dataof finite deformations and data of field observationsis not quite correct, because, asa rule, in-situ (field)observationsrecordedincompletedevelopment process of deformations but not only the final resultof settlement. Therefore, to comparethese calculationsand observations we should selectcalculation modelsthat canexamine the development ofdeformationsin time.

Based on the above, it is interesting to analyzethe applicability ofthe most commonengineeringmethodsandcalculation models ofthe soils that underlie different calculation programsused in practice.

### Geotechnical engineering software

For calculating settlement geotechnics usually use engineering methods described in the regulatory literature: SNiP[1] and SP [2](Russian norms), Eurocode[3] (EU norms) and standards of other countries.Calculations of buildings settlement are alsocan be done with use ofnumerical methods (software).Manysoftware products, such as«Plaxis», «Ansys», «Abaqus», «Fem-Models», are developed to studythe stress-strain state of grounds. Basically, theseprograms use thefinite element method.

Numericalmethods for determining in-timesettlement are basedon two types oftasks:

1) based onsolvingthe filtrationcomponents (the first type)[4];
2) based onthe rheological modelofsubgrade (the second type)[5].

For solving the first type tasksRussiangeotechnicalengineers usually use calculation software «Plaxis» and for solving tasks of the second type – software package «Fem-models».Mostoftento calculatebuildings settlement Russian engineersuseHardening Soil model(«Plaxis»),as well asElastoviscoplastic (rheological)model («Fem-models»). The Hardening Soil modelallows to estimateonly the finalsettlement,the rheological model – a development of the settlementintensityover time.

**Comparison analysis of settlement calculations: numerical orengineering methods?**

Several historicbuildings were selected in St. Petersburg (Russia): House of Soviets, Krylov State Research Centre. The data offield observationsover about pastseventyyears was collected [6]. For them were made calculations usingnumerical and engineeringmethods for determining in-timesettlement. Finally was made comparison analysis with field observations results.In this paper the House of Sovietsis considered.

Figures 1 and 2 present the main resultsof the calculation in software «Plaxis»for the House of Soviets.The figure 2 showsthat prolongedsettlement ofwesternwing is about 403 mm.

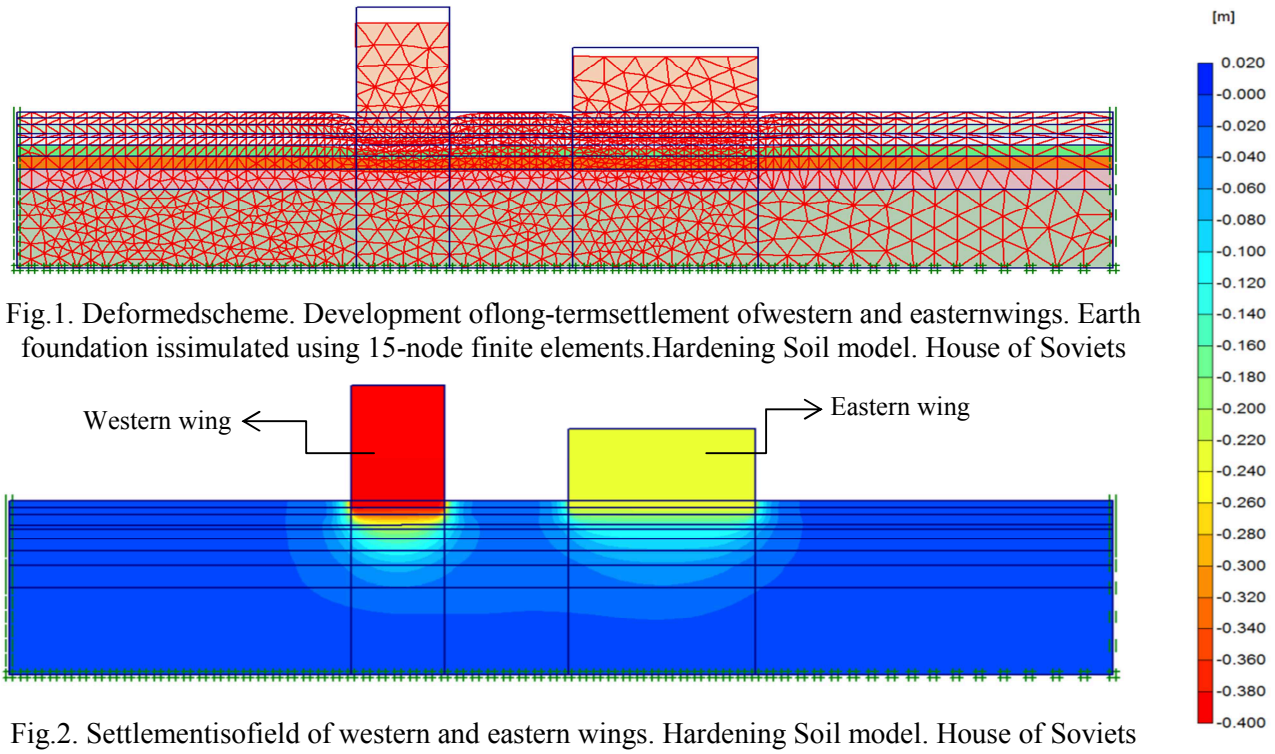

Fig.1. Deformedscheme. Development oflong-termsettlement ofwestern and easternwings. Earth foundation issimulated using 15-node finite elements.Hardening Soil model. House of Soviets

Fig.2. Settlementisofield of western and eastern wings. Hardening Soil model. House of Soviets

A figure 3 showsthe resultsof numerical method using software «Fem-models»[5] for the House of Soviets.Averagesettlement of the most loaded western wing is 398mm.

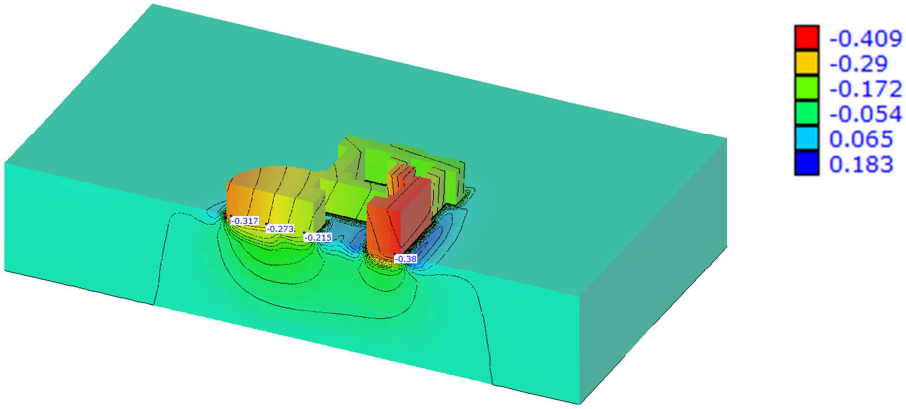

Fig.3. Settlementisofield (m) of the western andeastern wings. rheologicalmodel. House of Soviets

Figure 4 shows theoverlaygraphs of developmentin timesettlementof the western wingfor 70 years, which reached 398 mm in 1967 year,according tofield observationsandthe results ofa numerical calculationsbased onthe simulationofthe «Fem models»rheologicalmodel.

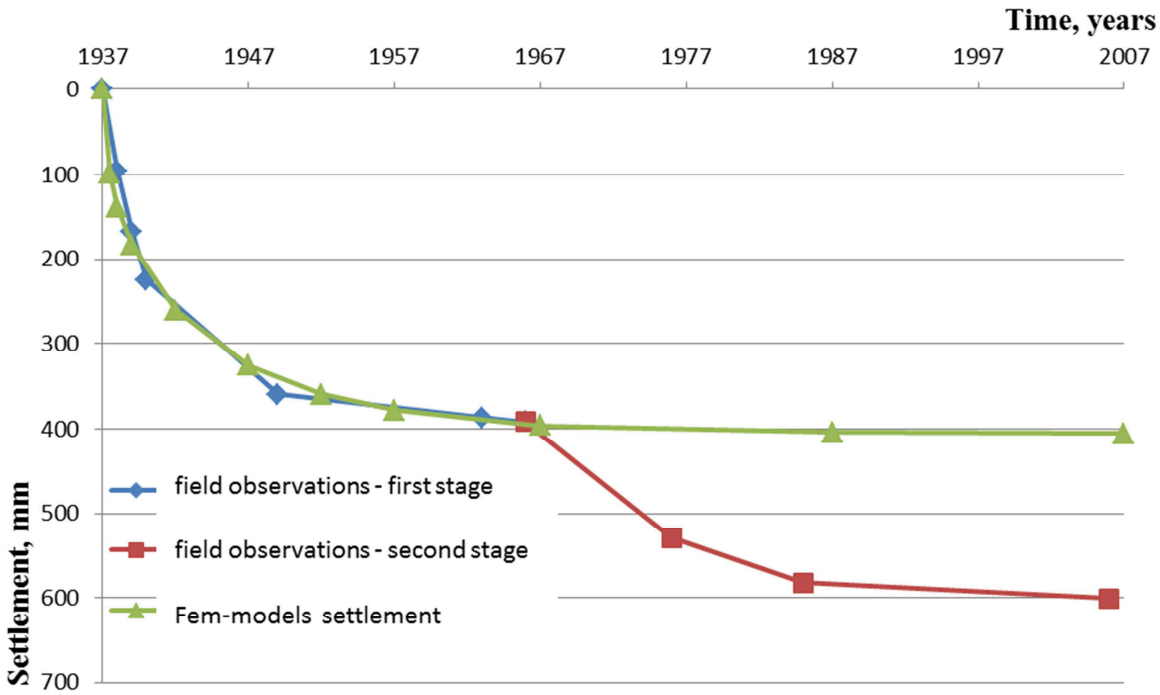

Fig. 4. Graphscomparingthe calculatedsettlement (mm) of the western wing with the results oflong-term observations. Calculationsare based on therheological model. House of Soviets

According to the figure 2and figure 4 following conclusions can be done:

1)The numerical forecast in «Fem-models» fairly accurately correlated with the datum of field observations thatwas 395 mm in 1967 (until possible anthropogenic impact due to which after 1967 the western wing precipitate was further developed).

2) Final settlementof 403 mm, calculated in «Plaxis», is sufficiently close to the observed long-term settlement.

3) Also it may be notedresults match of long-term settlement calculation using Hardening Soil model («Plaxis») and nonlinear Elastoviscoplasticmodel («Fem models»).In Hardening Soil model the developmentof the building settlementwas modeledwithdrainedconditions,in Elastoviscoplastic model–with undrainedconditions.In both cases,identicalresultsare due to the ratherlowshearmoduliof weakclay soils.

Engineering calculations results of final settlement of the western wingwere made using different methods:

1) 360 mmbySNIP 2.02.01-83* [1];
2) 301 mm bySP 22.13330.2011[2];
3) 358 mm by method Egorova [1];
4) 371mm by Eurocode 7 [3].

Results of engineering calculations show thatcurrent standards of engineering calculation methods underestimate the final settlement on more than 10%.

## Conclusions

Usinglong-situ observations in researchis essential, as it allows to evaluate the accuracyof geotechnicalpredictionsusing differentmodelsof soil mechanics:

1) In the case of use «Plaxis» with Hardening soil model (drained working conditions) Russian geotechnics should consider a number offactors and constraints [7].Be aware that themodel was developedfor denseclay andsand soils. Use of Hardening soil modelwithoutcostlystabilometrictestsinvolves administeringactuallyequal tothe shear modulus$E_{50}$odometer$E_{oed}$,thatis not the sameforsoft soils. In addition, deformation modules given in geotechnical investigations reports by Russian geologists are artificially led to the results of stamp tests using coefficient Agishev. Using"table" deformation modulescan belogical forengineering calculationsof settlement, but the use of suchmodulesinnumerical methodsis incorrectbecause it unreasonablyoverstatesthe shearmodulusand, consequently,reduces thesheardeformationdeviatorpart, which in turnreduces the overalldeformationof the soilarray. Accountingof thesefeaturesHardening soil modelprovides a goodconsistency withlong-situ observations.

2)Viscoelastoplasticmodel («Fem-models»), giventhe actual valuesof shear deformationunderundrainedsoilconditions,can achieve results which arecloseto collected innatural conditionsdeformation of buildingsconstructedon soft soils.

3) Engineering calculating methods are not accurate. They need to be deeply researched and developed.

It is necessary to develop existing rheological models which taking into accountlong-termsheardeformationandrelaxation coefficientson the basis of verification between field observations data.

**Keywords:** Mining engineering, underground mining, Gypsum mine, golf, Stability

**Abstract.** According to golf's distribution and occurrence situation of Jinghua Gypsum Mine circumstances in Jingmen city, The golf is divided into general golf, filling golf, then the stability of column and covering layer of the two kinds of golf are analysed. It is shown that: For the general golf, A large range of column is stable within a relatively short period of time in the process of underground mining. it will be unstable for local small column because of it was bore weight of overlying strata. After the column was soaked, its strength will be greatly reduced, and the long term stability of column will not be guarantee. Complementary, the covering layer is basically critical stable state; For the filling golf, A large range of column is stable, and the covering layer is also basically critical stable state. It can promote the control of mining disaster and the protection of ecological environment and similar engineering with a high theoretical and practical value.

## Introduction

The formation of the geological strata structure is changed caused by underground Mining, including drainage and the stress state, which exceeds he natural resilience of the environment, and its impact was far beyond the scope of time and space mines exist. The goaf caused by underground mining is the potential geological disasters [1-4].

Jinghua gypsum mine is located in Hua Zhu Cun of the former Dongbao area Bai Miao Jie, designed annual production capacity is 150000 t in 1982, and the mine design life is 28.64 years, and the mining is due at September 2011.While the relevant departments is no extension. Jinghua Gypsum Mine Gob approximately 0.6 square kilometers, the vertical depth is 70-150 meters from the ground. The golf area caused by mining is large, so it is extremely difficult to deal the golf and restore the geological environment.

## The classification of golf

According to golf's distribution and occurrence situation of Jinghua Gypsum Mine Gob circumstances in Jingmen, The golf is divided into general golf, filling golf

### 2.1 the general golf

When the ore is exploited from the underground mining, no filling or caving process, also did not appear obvious roof fall accident in goaf. According to the relevant data and field survey, the general golf is about 126800 $m^2$ in Jinghua gypsum mine.

After the research of main column and rooms in filling golf of Jinghua gypsum mine,the survey result is described in the following: the general golf of Jinghua gypsum mine(X group), the maximum column is 8.8×5.9m and the minimum is 4.4m×2.2m, so 5.9m×4.3m is regarded as the average size. The maximum space between column is 8.2m×7.9m and the minimum space is 6.0m×3.2m ,so 7.5m×6.0m is regarded as the average space. The maximum height is 9.1m and the minimum height is 6.9m, so 8.0m is regarded as the average height. In consideration of the irregular column size, 5.0m×4.0m is regarded as effective size of column, 8.0m×7.0m is regarded as average space and 8.0m is regarded as average height.

The irregular column or small column in general golf of Jinghua gypsum mine is shown in Figure 1.

Fig.1 The irregular column or small column in ordinary golf of Jinghua gypsum mine

**2.2 the Filling golf**

If the golf is filled by waste rock after mining, calling the filling golf. Relevant information and field surveys show the filling golf total area is about 37,000 $m^2$ in Jinghua gypsum mine, which are mainly distributed in 310,311,312 mining area

After the research of main column and rooms in filling golf of Jinghua gypsum mine, the survey result is described in the following: the filling golf of Jinghua gypsum mine(X group), the maximum column is 6.5m×5.0m and the minimum column is 6.3m×3.0m ,so 6.6m×3.8m is regarded as the average size. The maximum space between columns is 8.2m×7.9m and the minimum space is 6.1m×5.5m, so 7.3m×6.6m is regarded as the average space. The maximum height is 5.0m and the minimum height is 4.0m, so 4.7m is regarded as the average height. In consideration of the protective effect to column by waste rock, 6.0m×4.0m is regarded as effective size of column, 7.0m×6.5m is regarded as average space and 4.5m is regarded as average height.

**Stability analysis of golf**

Surface stability of golf at gypsum mine depends on the stability of column and overlying. Based on the results of the stability study have been made in column, stability is determined by several key parameters in the following:

**3.1 Stability analysis of general golf**

Golf surface stability in gypsum mine depends on the stability of column and overburden [5-8]. Therefore, based on the stability results of the study have been made in golf, stability is determined by two key parameters in the following.

**3.1.1 Stability analysis of column**

When using the room and column method of mining, column strength on the stability of golf plays a big role. Slightly inclined ore and column calculation method is used to estimate the stability of golf. column's relative area of the mine should satisfy the following formula:

$$S_0 / S \geq \gamma hnk / \sigma_0 k_f \tag{1}$$

where $S$ —area of column support($m^2$); $S_0$—column cross-sectional area ($m^2$); $k$—load factor, and relate to the rock property, according to the characteristics of gypsum mine, reference information, take = 1; $\sigma_0 k_f$—uniaxial compressive strength of ore cube specimen(MPa); $n$—safety factor when the column without long-term retention, take 2 to 3, the surface does not allow collapse or require column long-term retention, take 3-5; $k_f$ — column shape factor; $\gamma$—Overburden density; $h$—depth from golfto surface (m).

Safety factor can be obtained when given the size of column and room.

$$n=\frac{S_0}{S}\times\frac{\sigma_0 k_f}{\gamma hk}=\frac{S_0}{S}\times\frac{R_C}{\gamma hk} \tag{2}$$

In consideration of the exist of argillaceous siltstone in the mine roof and its strength is lower than ore, so the compressive strength of the mine roof written as $R_c$ is selected to replace $\sigma_0 k_f$. According to survey data, take $\gamma$=24 $KN/m^3$; $k$=1; $R_c$=27.6Mpa; $h$=40～119m.

Research result shows that in golf of Jinghua gypsum mine(X group), the maximum column is 8.8×5.9m and the minimum column is 4.4m×2.2m ,so 5.9m×4.3m is regarded as the average size. The maximum space between columns is 8.2m×7.9m and the minimum space is 6.0m×3.2m ,so 7.5m×6.0m is regarded as the average space. The maximum height is 9.1m and the minimum height is 6.9m ,so 8.0m is regarded as the average height. In consideration of the irregular column size ,5.0m×4.0m is regarded as effective size of column, 8.0m×7.0m is regarded as average space and 8.0m is regarded as average height.

Thus can calculated the minimum cross-sectional area accounted for 8.5 percent of the column supporting area,and with an average of 14.0 percentage in golf at Jinghua gypsum mine. According to the above formula, the average safety factor range is from 1.4 to 4.0 , and the minimum safety factor is 0.8.

Relevant research results show that the strength of saturated gypsum mine will be greatly reduced, softening coefficient is about 0.8, strength reduction factor due to the rheological is 0.66, thus the average long-term safety factor range is from 0.7 to 2.1, the minimum safety factor is 0.4.

This shows that in the majority golf column in the underground mining process is stable within such a relatively short period of time, some small column can not bear the weight of overlying rock will be unstable. After the underground golf of a certain time, especially after the column saturated, its strength will be greatly reduced, long-term stability of the column will not be protected.

### 3.1.2 Stability analysis of covering layer

Shown in Figure 2, the overlying rock abdc will sink due to gravity after mining, and both sides of the wedge abm and cdn also impose its horizontal pressure force written as P, so friction resistance effect produced by P is happened in planes written as ab and cd, now unit length in mining area (gateway) is taken as the calculational unit body, so the pressure written as Q which is acted on the unit length of the roadway roof is:

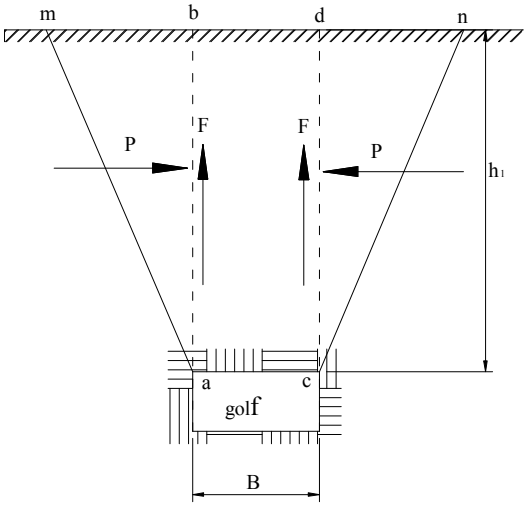

Fig.2 Schematic of depth calculated from golfroof to the surface

$$Q=G-2F \tag{3}$$

Where $G=B\gamma h_1$; $B$-tunnel width(m); $h_f$—depth from roof to the surface(m); $\gamma$-unit weight of overburden,KN/$m^3$.

$$F=p\cdot\tan\Phi \tag{4}$$

Where $p$ - compressive stress in the ab plane or cd produced by wedge abm and cdn; $\Phi$ -Angle of internal friction of rock.

When $p$ is taken as its maximum:

$$P = \frac{\gamma \cdot h_1^2}{2} tg^2(45^\circ - \frac{\Phi}{2}) \tag{5}$$

So $Q = B\gamma h_1 - \gamma h_1^2 tg(45^\circ - \Phi/2)tg\Phi$

From the above equation, when h1 large to a certain depth, the rock layer above the roof can maintain balance and not collapse, at this time $Q$ is zero and $h_1$ is named critical depth written as $h_0$:

$$h_0 = \frac{B}{tg^2(45^\circ - \Phi/2)tg\Phi} \tag{6}$$

The stability of roof can be evaluated by critical depth $h_0$ .When $h_0 < h_1 < 1.5\,h_0$ , the stability of roof is worst; when $h_1 > 1.5\,h_0$ ,the roof is in stable condition.

At Jinghua gypsum mine, the overlying strata of golf are mainly composition by silty mudstonepelitic pelitic siltstone and surface dust producted in Quaternary, as the largest thickness come from siltstone and its friction resistance and weight takes the largest proportion, so siltstone's friction angle written as $\Phi$ is selected. According to related date , $\Phi$ =48.5° ; This formula applies to the stability calculation of the roadway and the roof of golf which is supported bu strip column , due to Jinghua gypsum mine is supported by the point column, so mining width B is selected as 8m which is larger than ordinary ,and $h_0$ = 50m can be obtained when the parameters taken into the above formula. This means when the depth from golfroof to the surface , $h_1$ >75, the roof is stable.

On Jinghua gypsum mine overburden's thickness is 40 ~ 119m, the overburden in golf is in the critical stability condition.

### 3.2 Stability analysis of covering layer of filling golf

#### 3.2.1 Stability analysis of column

After the research of main column and rooms in filling golf of Jinghua gypsum mine, the survey result is described in the following: in filling golf of Jinghua gypsum mine(X group), 6m×4.0m is regarded as the average size; 7.0m×6.5m is regarded as the average space; 4.5m is regarded as the average height and 82~96m is regarded as the depth between golf to the suffice.

Thus can calculated the minimum cross-sectional area accounted for 14.9 percent of the column supporting area,and with an average of 17.3 percentage in the golfat Jinghua gypsum mine. According to the above formula, the average safety factor range is from 2.1 to 2.4 , and the minimum safety factor is 1.8.

Relevant research results show that the strength of saturated gypsum mine will be greatly reduced, softening coefficient is about 0.8, strength reduction factor due to the rheological is 0.66, thus the average long-term safety factor range is from 1.1 to 1.3, the minimum safety factor is 1.0.

So we can make the conclusion that mainly columns in filling golf is safety.

#### 3.2.2 Stability analysis of rocky covering of filling golf

The depth written as $h_0$ between roof and the surface of earth is called critical depth, when the rocky overburden can maintain its balance and not collapse, in addition, Q is just equal to zero.

$$h_0 = \frac{B}{tg^2(45^\circ - \Phi/2)tg\Phi} \tag{7}$$

The roof's stability can be evaluated by critical depth. When $h_0 < h_1 < 1.5\,h_0$ ,the stability of roof is worst ; when $h_1 > 1.5\,h_0$ ,the roof is in stable condition.

At Jinghua gypsum mine, the overlying strata of golfare mainly composition by silty mudstonepelitic pelitic siltstone and surface dust producted in Quaternary, as the largest thickness

come from siltstone and its friction resistance and weight takes the largest proportion, so siltstone's friction angle written as $\Phi$ is selected. According to related date , $\Phi$=48.5° ; This formula applies to the stability calculation of the roadway and the roof of golf which is supported bu strip column , due to Jinghua gypsum mine is supported by the point column, so mining width B is selected as 7m which is larger than ordinary ,and $h_0$ = 43m can be obtained when the parameters taken into the above formula. This means when the depth from golfroof to the surface , $h_0$>65, the roof is stable.

On Jinghua gypsum mine overburden's thickness is 82 ~ 96m, the overburden in golf is in the critical stability condition.

## Conclusions

After studying this article, the following conclusions can be drawn:

(1) According to golf's distribution and occurrence situation of Jinghua Gypsum Mine Gob circumstances in Jingmen, The golf is divided into general golf, filling golf

(2) For the general golf, A large range of column is stable within a relatively short period of time in the process of underground mining . it will be unstable for Local small column because of it was bore weight of overlying strata. After the column was soaked, its strength will be greatly reduced, and the long term stability of column will not be guarantee. Complementary, the covering layer is basically critical stable state.

(3)For the filling golf, A large range of column is stable, and the covering layer is also basically critical stable state

**Keywords:** Coarse particles saline soil, Field test, Salt content, Salt expansion rate.

**Abstract.** Salt expansion was the main diseases of the salty foundation. In order to study the deformation regularity and quantitative description of coarse particles saline soil ground in natural condition, a field test was conducted in Dunhuang area. The exploratory well with 7.5 m depth (deeper then annual temperature change layer) was excavated on site, and the data of salt content \water content \ground temperature \salt expansion rate were collected. From the test it was found that : salt expansion mainly decided by salt content, salt content and salt expansion rate have approximately a quadratic function relationship; the minimum salt content could cause soil expansion is 1.5‰; The salt expansion force was strong, and the gravitational stress could not suppress the deformation.

## Introduction

A lot of construction projects in the Hexi corridor region face the salt expansion deformation problem. In earlier years, the investigation of the engineering properties of this kind ground was not very deep. But now with higher safety standard, the issues of salt expansion became more and more important. We had known that the salt expansion amount of coarse saline soil after repeated freeze-thaw cycles was less than fine-grained soil in an open system[1], and the salt expansion amount was not only associated with the dry density and water content of soil, but also with the pressure and the content of fine particles[2.3], and the sensitive temperature of salt cementation layer between 3~7 $^{o}$C and 12~15 $^{o}$C, but for the loose soil, the sensitive temperature between 0~-7 $^{o}$C [4], and the sand layer exist was very important to form the salt cementation layer[5], and so on. These studies used indoor simulation experiments mostly, and lack field measurement for verification. In order to study the engineering properties of coarse saline soil and quantitative evaluate its characteristics, it was necessary to take in-site experiments. The authors took an in-site experiment in Dunhuang area in winter (from October 19, 2011 to March 7, 2012) and measured the salt expansion amount of ground. It was found that some regularity and quantitative description of salt expansion deformation.

## The condition of experiment

### Purpose and test methods

This experiment aimed to study the salt expansion regularity of coarse particles saline soil. During the test, water content, salt content, ground temperature and salt expansion rate were measured to study the relationship among them.

First of all, a 1.2 m diameter, 7.5 m depth exploratory well was excavated in ground. The schematic of exploratory well was shown in Fig.3, and the stratigraphic column was shown in Fig.4**.** A settlement observation stick placed in the center of well which did not move in vertical. Meanwhile, the horizontal observations sticks were set at different depths to measure the salt

expansion amount of each soil layer. The moisture meter and ground temperature gauge were set next to horizontal observations sticks.

The observation stick used in experiment was $12\times10^{-3}$ m diameter galvanized pipe, and the ground temperature gauge wasYH5000 temperature gauge, and the moisture meter was ST-TW moisture meter.

In order to ensure the compactness and humidity of the soil filled in well was similar with undisturbed soil, we took some watering when fill back.

**Salt and water conditions of the test site**

The ground was divided into eight layers in depth corresponding to the location of observation stick. The soil parameter of each layers was shown in Table 1.This kind of foundation (gravel) had a high permeability, so the content of water was low (most of samples less than 8%), the curve of water content and salt content along depth direction is shown in Fig.1 and Fig.2. From the literature we knew that it could not have frost heaving under this water content. All expansion deformation was caused by salt expansion.

**Tabel.1 The average salt content and water content of the original ground**

| sequence | interval [m] | Anion content [mg·kg$^{-1}$] | | | | Action content [mg·kg$^{-1}$] | | | | salt content [‰] | Water Content [%] |

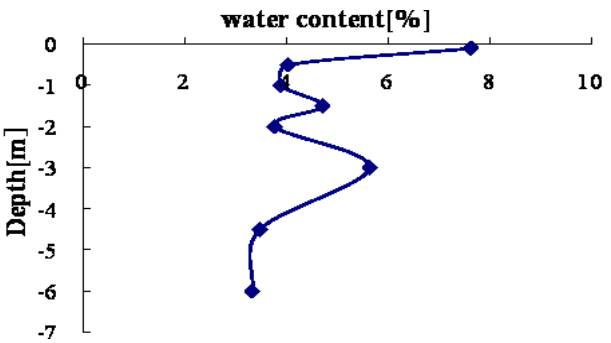

Fig.1 Natural water content curve with the depth

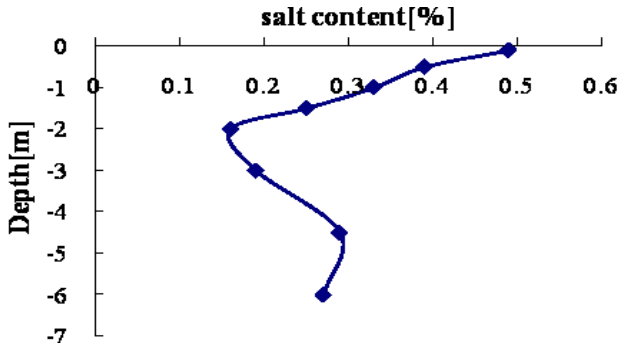

Fig.2 Natural salt content curve with the depth

## Experimental procedure and data

### The condition of ground temperature

The ground temperature curves of each depth were shown in Fig.5. We could know that, 6.0 m depth strata temperature change less than 0.6 $^{o}$C in whole winter, and the depth of zero annual amplitude was about 7.5 m. The minimum temperature of 0.1 m depth was -6.1 $^{o}$C and frozen depth in this region about 1.0 m. The Surface of foundation was frozen about 82 days in winter.

Fig.4 Stratigraphic column

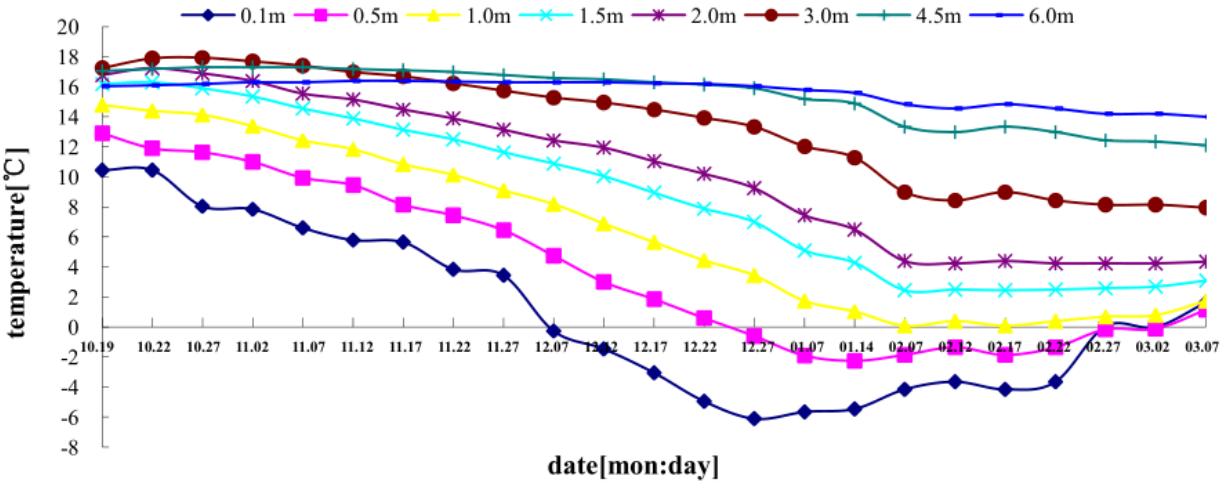

Fig.5 Ground temperature curve

**The effect of salt content on salt expansion rate**

22 group data of strata expansion amount were recorded during the whole experiment period, and the results was shown in Fig.6. Based on above data, we got the average salt expansion amount and salt expansion rate of each stratum which shown in Fig.7 and Fig.8. The amount of salt expansion deformation of every stratum increased in winter. Especially, the expansion amount of 0.5 m and 4.5 m depth were the most prominent. So the curve of salt expansion looks like a bow. This phenomenon was related to the salt content. It proved that salt content, which directly decided the amount of expansion, was the most important affecting factor of expansion deformation. And the temperature, which was the secondary affecting factor, became lower could induce crystallization and expansion among soil particles.

The salt content of 4.5 m depth was more than 2.0 m depth, so it caused the amount of salt expansion was more than 2.0 m depth. But in the later days, the surface ground temperature became lower and lower, so more and more salt migrated from deep to shallow of ground, which was why the expansion amount of 2.0 m depth continued to grow subsequently.

The relationship between salt content and salt expansion rate was shown as formula1 and Fig.9. According to formula **1** we could calculate the minimum salt content of coarse particles saline soil. The minimum salt content of coarse particles saline soil is about 1.5‰, and it was lower than fine-grained soil.

$$\eta=0.4889(\omega)-0.1466 . \quad (1)$$

note：η——salt expansion rate[%].

ω——salt content [‰].

$R^2$——The correlation coefficient of polynomial，$R^2$=0.8043.

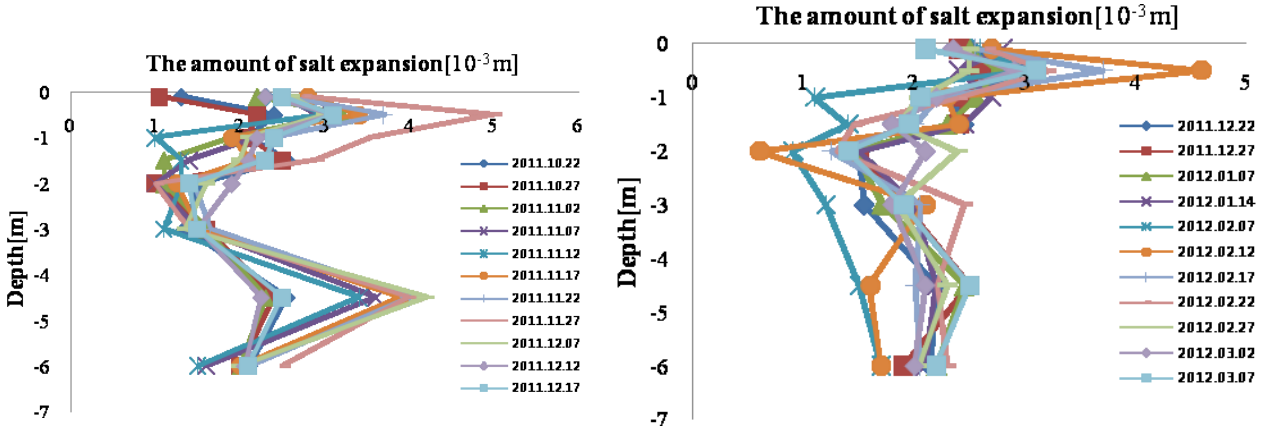

**Fig.6 The salt expansion curves of each stratum**

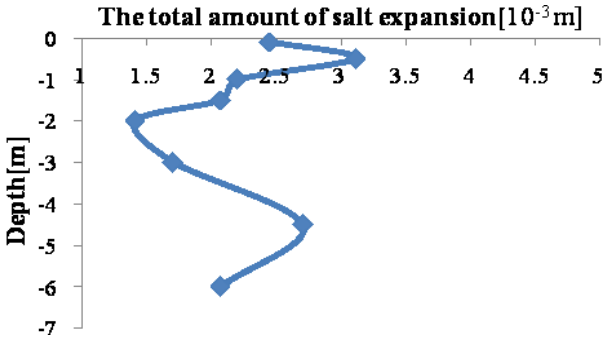

**Fig.7 Measured average salt content curve**

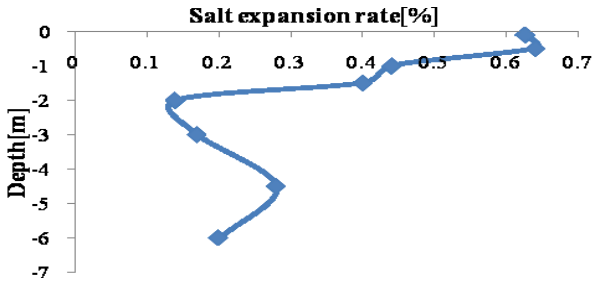

**Fig.8 Measured average salt expansion rate curve**

**The effect between water content and salt expansion rate**

Experiment simulated rainfall, and the amount of watering equivalent to the annual maximum rainfall in this region. According to the experiment recording we found that the rainfall could cause salt expansion indeed. The amount of salt expansion of each stratum increased after rainfall and the average expansion amount reached $2.04\times10^{-3}$ m. Especially, the salt expansion developed very fast in a short time after rainfall. After the water penetrates to deeper location, water content of foundation became lower, the speed of salt expansion slows down. It indicated that when water content was low, it just participated in the process of crystallization, but had almost no effect on the migration of salt. Under this condition, water barely causes salt migrated from deep to shallow. Therefore, water was a necessary condition of salt expansion, but it contribution depended on its amount.

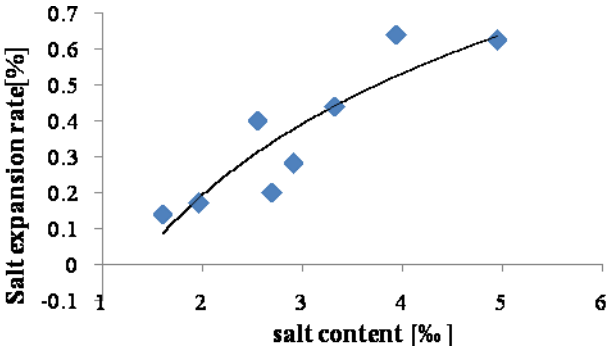

**Fig.9 The salt content and salt expansion rate curves**

## Conclusion

From this experimental observation and data analysis, we could know that:

1. Salt expansion problem does exist in coarse particles saline soil, but the expansion amount was very limited. This experiment discovered that the total expansion amount was about $6.9\times10^{-3}$ m within range of 7.5 m depth in ground. Though this expansion amount was limited, it would happen every year. So this kind of harm to projects will last forever. Meanwhile, this experiment discovered several salt-rich layers within range of 0.1 m~2.0 m depth in ground , it could be considered as direct evidence of salt migrated from deep to surface in ground. The salt migration would last in the future; it was shown that this problem was extremely complex.

2. From data analysis we could know that 1.5‰ salt content was the minimum salt content for coarse particles saline soil, which was lower than Fine- grained soil (almost 3‰~5‰).

3. For coarse particles saline soil, salt content was the most important factor affect salt expansion deformation. There was an approximately quadratic relationship between salt content and salt expansion rate. Water content was hardly affect salt expansion deformation when it was low, while water content increased immediately, the destruction showed a sudden increase in the amount of salt expansion.

4. Since the test conditions was limited, we could not measured the salt expansion force directly. But we measured the salt expansion deformation in 6.0 m depth in ground; it proved that the salt expansion force was very significant.

**Keywords:** Generalized Hoek-Brown criterion; initial geostress field; horizontal ground stress; calculation model of value range

**Abstract.** On the conditions that assuming vertical ground stress and horizontal ground stress are both principal stress, a calculation model of horizontal ground stress value range with depth change in initial geostress field is built by formula derivation, according to the Generalized Hoek-Brown failure criterion, and the reasonability of the calculation model is verified by the geostress measured value. The results show that, there is a good consistency at the distribution range of horizontal ground stress calculated value and horizontal ground stress measured value, it is proved that the the calculation model is reasonable. The calculation model gives new methods and thinking for evaluation of the initial geostress field.

## Introduction

Ground stress is the fundamental forces inducing geological disasters such as landslide, collapse, ground subsidence, rock burst and so on, especially when the balance of initial geostress field has been destroyed by rock mass excavation makes ground stress releasing. So, it has a important implications to prevention and control of geological disasters by a effective evaluation of initial ground stress field. Ground stress can be decomposed into vertical ground stress and horizonta ground stress, vertical ground stress can be estimated by the average unit weight of rock mass times the depth of rock mass [1], however, it is hard to estimate horizontal ground stress by such parallelapproach [2] . So, how to stimate horizontal ground stress is a key point in initial geostress field evaluation.

In this paper, a calculation model of horizontal ground stress value range with depth change in initial geostress field is built by formula derivation, according to the Generalized Hoek Brown failure criterion [3], and the reasonability of the calculation model is verified by the geostress measured value. The results show that, there is a good consistency at the distribution range of horizontal ground stress calculated value and horizontal ground stress measured value, it is proved that the the calculation model is reasonable. The calculation model gives new methods and thinking for evaluation of the initial geostress field.

## The Generalized Hoek-Brown criterion

Hoek and Brown bringed up the Hoek-Brown criterion at 1980[4], and it is widely used in giving joint rock mass strength parameters. The Generalized Hoek-Brown criterion bringed up by E. Hoek and so on, is a correction on the problems founded when the initial criterion has been using, and its specific expression is shown in Eq. 1:

$$\sigma_1 = \sigma_3 + \sigma_c \left( m_b \frac{\sigma_3}{\sigma_c} + s \right)^a \tag{1}$$

$\sigma_1$ and $\sigma_3$ are the maximum and minimum principal stress when rock mass damage; $\sigma_c$ is The rock uniaxial compressive strength; $m_b$ and $s$ are the material parameter related to the characteristics of rock mass; $a$ is the constant of joint rock mass. The computational formulas estimating $m_b$, $s$ and $a$ are respectively shown in Eq. 2:

$$\left.\begin{aligned} m_b &= m_i \exp\left(\frac{GSI-100}{28-14D}\right) \\ s &= \exp\left(\frac{GSI-100}{9-3D}\right) \\ a &= \frac{1}{2} + \frac{1}{6}\left(e^{\frac{-GSI}{15}} - e^{-\frac{20}{3}}\right) \end{aligned}\right\} \tag{2}$$

$m_i$ is intact rock empirical constant; $GSI$ is geological strength index; $D$ is rock mass disturbance parameters, $D$ equals to 0 in initial geostress field.

**Calculation model of horizontal ground stress value range**

Rock mass are most in limit equilibrium state or steady state in initial geostress field. According to Generalized Hoek-Brown failure criterion, if rock mass wants to keep steady, its internal stress field shall meet the conditions are shown in Eq. 3:

$$\sigma_1 \le \sigma_3 + \sigma_c \left( m_b \frac{\sigma_3}{\sigma_c} + s \right)^a \tag{3}$$

Although, $a$ is determined by $GSI$ as shown in Eq. 1, $a$ can be equaled to 0.5 according to the Hoek-Brown criterion for concisely. So Eq. 3 can be changed to Eq. 4:

$$\sigma_1 \le \sigma_3 + \sqrt{m_b \sigma_c \sigma_3 + s\sigma_c^{\,2}} \tag{4}$$

In addition to the near the big fault, vertical ground stress ($\sigma_V$) and horizontal ground stress ($\sigma_H$) are both principal stress as a general rule in the crustal rock mass [1]. There are two stress condition ($\sigma_H < \sigma_V$ and $\sigma_H > \sigma_V$) shall be consider.

1st condition: if $\sigma_H < \sigma_V$, then $\sigma_H = \sigma_3$ and $\sigma_V = \sigma_1$. So, Eq. 4 can be changed to Eq. 5:

$$\sigma_V \le \sigma_H + \sqrt{m_b \sigma_c \sigma_H + s\sigma_c^{\,2}} \tag{5}$$

Solve the inequation Eq. 5 about $\sigma_H$, then Eq. 5 can be changed to Eq. 6:

$$(\sigma_V + \frac{1}{2} m_b \sigma_c) - \sqrt{m_b \sigma_c \sigma_V + \frac{1}{4} m_b^{\,2} \sigma_c^{\,2} + s\sigma_c^{\,2}} \le \sigma_H \le (\sigma_V + \frac{1}{2} m_b \sigma_c) + \sqrt{m_b \sigma_c \sigma_V + \frac{1}{4} m_b^{\,2} \sigma_c^{\,2} + s\sigma_c^{\,2}} \tag{6}$$

2nd condition: if $\sigma_H > \sigma_V$, then $\sigma_H = \sigma_1$ and $\sigma_V = \sigma_3$. So, Eq. 4 can be changed to Eq. 7:

$$\sigma_H \le \sigma_V + \sqrt{m_b \sigma_c \sigma_V + s\sigma_c^{\,2}} \tag{7}$$

If rock mass want to keep steady in the two conditions above, $\sigma_H$ must meet Eq. 6 and Eq. 7 at the same time, so $\sigma_H$ must meet the intersection between Eq. 6 and Eq. 7. Because the right side of Eq. 6 is bigger than the right side of Eq. 7, so the intersection between Eq. 2 and Eq. 7 can be wrtten as Eq. 8:

$$(\sigma_V+\frac{1}{2}m_b\sigma_c)-\sqrt{m_b\sigma_c\sigma_V+\frac{1}{4}m_b{}^2\sigma_c{}^2+s\sigma_c{}^2}\le\sigma_H\le\sigma_V+\sqrt{m_b\sigma_c\sigma_V+s\sigma_c{}^2} \quad (8)$$

Inequation Eq. 7 is the calculation model of horizontal ground stress value range in initial geostress field. According to research content above, $\sigma_V$ can be wrtten as Eq. 9:

$$\sigma_V=\gamma h \quad (9)$$

$\gamma$ is average unit weight of rock mass; $h$ is depth of rock mass. So Eq. 8 can be wrtten as Eq. 10 :

$$(\gamma h+\frac{1}{2}m_b\sigma_c)-\sqrt{m_b\sigma_c\gamma h+\frac{1}{4}m_b{}^2\sigma_c{}^2+s\sigma_c{}^2}\le\sigma_H\le\gamma h+\sqrt{m_b\sigma_c\gamma h+s\sigma_c{}^2} \quad (10)$$

**Calculated values of horizontal ground stress**

The right and left side of inequality sign of Eq. 10 are the lower upper limit values of horizontal ground stress, they are can be written as $\sigma_{H\min}$ and $\sigma_{Hmax}$. So, Eq. 10 can be changed to Eq. 11:

$$\sigma_{H\min}\le\sigma_H\le\sigma_{H\max} \quad (11)$$

In order to verify the calculation model, give $m_i$ a value range of 5~15, give $GSI$ a value range of 52.5~67.5, give $\sigma_c$ a value range of 20MPa~100MPa, give $\gamma$ a value range of 0.02MN/m³ ~0.03MN/m³ .Divide the value ranges of $m_i$, $GSI$, $\sigma_c$ and $\gamma$ into 5 sections, so there are 6 groups values of $m_i$, $GSI$, $\sigma_c$ and $\gamma$, they are shown at table 1.

Table 1. Values of calculation model parameters

| group | GSI | $m_i$ | $\sigma_c$(MPa) | $\gamma$(MN/m$^3$) |
|---|---|---|---|---|
| 1 | 67.5 | 15 | 100 | 0.030 |
| 2 | 64.5 | 13 | 84 | 0.028 |
| 3 | 61.5 | 11 | 68 | 0.026 |
| 4 | 58.5 | 9 | 52 | 0.024 |
| 5 | 55.5 | 7 | 36 | 0.022 |
| 6 | 52.5 | 5 | 20 | 0.020 |

Give $h$ a value range of 0~3000m, substitute the values at table 1 in Eq. 10 to calculate the values of $\sigma_{H\min}$ and $\sigma_{Hmax}$ in every 200m, there are 6 groups of $\sigma_{H\min}$ and $\sigma_{Hmax}$. According to the results above, the calculated values of $\sigma_H$ with $h$ change can be shown in Fig. 1.

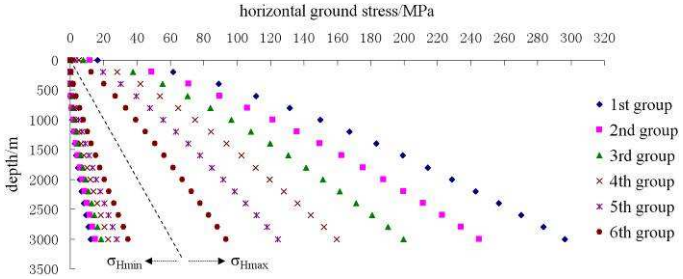

Fig. 1. Calculated values of $\sigma_{Hmin}$ and $\sigma_{Hmax}$ change with depth

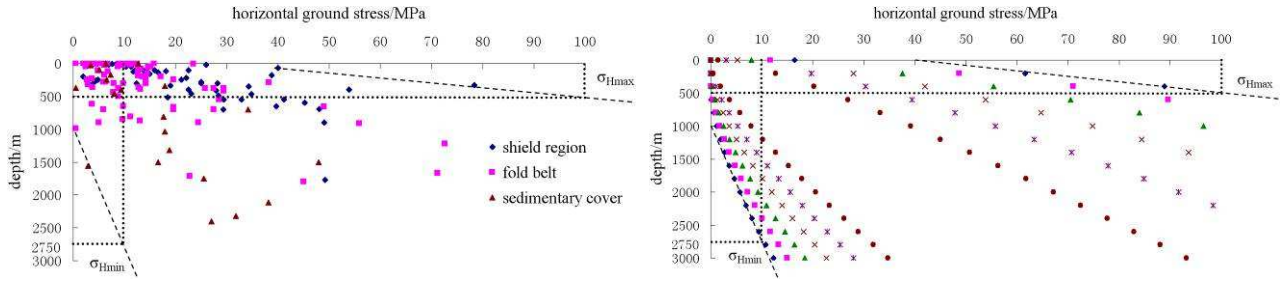
Analyzing the calculated values of $\sigma_H$ in picture 1 can get the conclusion as follows: The value range of $\sigma_H$ is growing bigger from the earth's surface to earth's deep. As the values at table 1 are growing bigger , the growing speed of the value range of $\sigma_H$ is more and more faster.

## Verification of the calculation model

Compare to the measured values of $\sigma_H$ can verify the reasonability of the calculated values. G. Ranalli[4] collected more than 150 measured values of $\sigma_H$ from all of the world, and divided these measured values of $\sigma_H$ into 3 types (shield region, folt belt, sedimentary cover) according to the geological tectonic environment, the research results have been shown in Fig. 2 (a).

In order to compare conveniently, clip the section of picture 1 make the value range of $\sigma_H$ from 0 to 100MPa, shown in Fig. 2 (b). Find two minimum values of $\sigma_H$, and link them to a line as the lower boundary of $\sigma_H$, and then get the upper boundary of $\sigma_H$ using the same method. Link the 6th group of $\sigma_{H\min}$ and $\sigma_{Hmax}$ to lines respectively in the Fig. 2 (b), the line on the left and right are the lower and upper boundary of $\sigma_H$ respectively.



(a) measured values of $\sigma_H$ (b) calculated values of $\sigma_H$

Fig. 2. Comparison between measured values and calculated values of $\sigma_H$

The upper boundary values of $\sigma_H$ are both about 100MPa when $h$ is 500m in Fig. 2 (a) and Fig. 2 (b). The upper boundary values of $\sigma_H$ are both about 10MPa when $h$ is 2750m in Fig. 2 (a) and Fig. 2 (b). Near the surface, the value ranges of $\sigma_H$ are both 0~20MPa in Fig. 2 (a) and Fig. 2 (b). According to the above analysis, there is a good consistency on distribution ranges between measured values and calculated values of $\sigma_H$, and it is proved that the calculation model of horizontal ground stress value range is reasonable.

## Conclusions

The calculation model of horizontal ground stress value range is induced based on the Generalized Hoek-Brown failure criterion, and the reasonability of the calculation model is verified by the geostress measured value.

The results show that, there is a good consistency on distribution ranges between measured values and calculated values of $\sigma_H$, and it is proved that the calculation model of horizontal ground stress value range is reasonable.

The calculation model gives new methods and thinking for evaluation of the initial geostress field.

**Keywords:** deformation, geotextile, optical fiber sensor, reinforced retaining wall

**Abstract.** Geotextiles have been widely used in the reinforced retaining wall, but it is not easy to measure the deformation of the wall during and after construction. To assess the deformation stability of the reinforced retaining wall, an optical fiber sensor was used in geotextile. Based on the measurement accuracy of strain for the sensor geotextile, an actual geotextile-reinforced retaining wall was studied using the fiber sensor geotextile. The experimental results were compared with the results from a numerical procedure, which employs the Mohr-Coulomb yield criterion and an initial stress method and determines the plastic displacement at collapse represented by the distribution of yield elements. The comparison shows that the numerical results have a good agreement with the corresponding measurement values. The result shows the possibility that the procedure gives the realistic evaluation of long-term deformation of reinforced retaining wall.

## Introduction

Due to cost-saving, ease of construction and ability to improve the visual appearance, the geosynthetics has been widely applied in the embankment construction. With the development of reinforced soil, a number of recent papers have examined different aspects of their design and behavior [1,2]. A lot of literatures proved that the reinforced have the merit of high bearing capacity [3,4]. However, geotextile play the role of reinforcement when reinforced soil occurs a certain amount of deformation. To analyze the deformation behaviors of geosynthetics applied to a reinforced soil structure, the load-elongation properties of the geosynthetics and local deformation measurement data are required.

Field observation for the geotextile is carried out to assess the stability of the reinforced retaining wall during and after construction. The deformation of the geosynthetics installed in soil was usually evaluated through strain gauge. Leshchinsky and Fowler have suggested using silicon to attach strain gauges to the woven geotextile [5]. Strain gauges can be attached directly to woven geotextiles and geogrids, however, the local deformation of nonwoven geotextile is difficult to measure with strain gauges. Huang used a method of attaching strain gauges to the surface of non-woven geotextile composed of a core layer of knitted textile and needle-punched double layer of non-woven geotextile, by using gauge cement [6]. Won et al. proposed a strain-gauge attachment method [7] to attach strain gauges to geogrid, woven geotextile or nonwoven geotextile using an adhesive, results in less resistance against tension stress, due to its ductile and elastic properties, and it also prevents the water rising from below. But no matter what, the strain gauge is difficult to install and provides only local measuring points because of it lacking durability.

To measure the strain of geosynthetics for long term periods, an optical fiber sensor is used to geotextile reinforcement [8,9].The accuracy of the sensor geotextile on strain measurement had been confirmed through a laboratory tensile test by Tsuji et al [10]. Application of the sensor geotextile to

actual reinforced retaining wall showed that the deformation of the reinforced soil wall can be evaluated continuously during and after construction, and for long term maintenance operations. It proves that the assessment system using the sensor geotextile is useful to evaluate the stability of the wall.

Based on Mohr-Coulomb yield criterion and an initial stress method, a numerical procedureis proposed to evaluate the stability of retaining wall. Compared with the case study, it showed the possibility that the procedure gives the realistic evaluation of stability assessment of reinforced retaining wall.

## Optical Fiber Sensor Geotextile and Measure Method

**Optical Fiber Sensor Geotextile.** To measure the strain of reinforced soil wall in one direction for long term periods, an optical fiber sensor geotextile was applied. The optical fiber sensor geotextile is manufactured by inserting a single-mode optical fiber sensor with a diameter of 0.9 mm longitudinal into the geogrid. As shown in Fig. 1, the geogrid includes a core of optical fiber sensor surrounded by light-weight and high-strength synthetic fiber which is covered by high-density polyethylene resin.

**Strain Measure Method.** Employing the Brillouin Optical Time Domain Reflectometry (BOTDR) system through the optical fiber sensor inserted in geogrid, the strain distribution of geogrid and deformation of reinforced earth wall was measured.

When strain occurs in the optical fiber sensor, the peak frequency of the Brillouin scattered light changes in proportion to the magnitude of the strain of optical fiber sensor. According to the linear relationship between the frequency distribution of Brillouin scattered light with the strain of optical fiber, the strain distribution along the entire length of the geogrid was monitored by the BOTDR system. Moreover, the position of the strain can also be identified by measuring the return time with the BOTDR system.

In the actual field, the initial value of strain can be measured after the optical fiber sensor geotextile is installed in the way as normal geotextile.

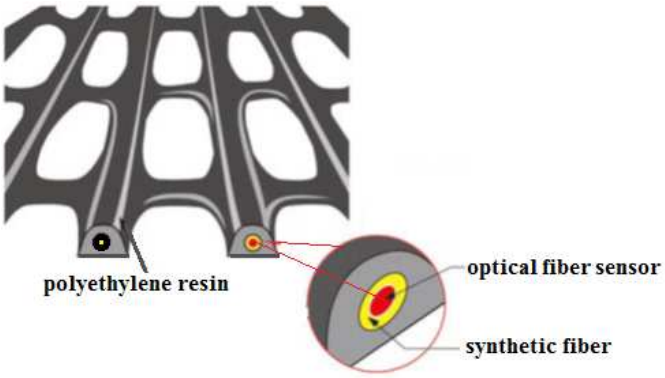

**Fig. 1** Diagrammatic sketch of optical fiber sensor geotextile

## Numerical Procedure

The stability of reinforced retaining wall is also estimated by a numerical procedure to compare with the measurment results. Wang et al. concluded that the slope failure occurs when the cumulative plastic displacement exceeds a certain critical value at collapse [11]. To estimate the critical value at collapse, a numerical procedure which considers the stiffness and strength of materials is proposed to evaluate the stability of reinforced retaining wall.

Employing Mohr-Coulomb (Eq. 1) and Coulomb (Eq. 2) yield criteria to vertical fill and friction interface respectively.

$$F_M = \{(\sigma_x - \sigma_y)^2 + 4\tau_{xy}^2\}^{1/2} - \{(\sigma_x + \sigma_y)\sin\phi + 2c\cos\phi\} = 0 \quad (1)$$

$$F_C = /\tau_{xy}/ - c - \sigma_t \tan\phi \quad (2)$$

where, $\sigma_x$, $\sigma_y$ and $\tau_{xy}$: stress components, and $\sigma_t$ and $\tau_{st}$: normal and shear stresses in friction interface, c: cohesion and $\phi$: internal friction angle.

In actual ground, when applying further $\sigma_3$ or $\sigma_n$ after yield point A, the stress state will move along the yield surface as seen in Fig. 2. At the elasto-plastic state from point A to B shown in Fig. 2, we employ a simple non-associated flow rule, where $F_c$: yield function; $Q_c$: plastic potential; $\{\delta\varepsilon_p\}$: increment of plastic strain. Here, we employ the simple plastic potential $Q_M$ and $Q_c$ as defined by Eqs. (3) and (4) respectively for Mohr-Coulomb and Coulomb material.

$$Q_M = \{(\sigma_x - \sigma_y)^2 + 4\tau_{xy}^2\}^{1/2} - 2g = 0 \quad (3)$$

$$F_C = /\tau_{xy}/ - g = 0 \quad (4)$$

where g: a hypothetical parameter which is not cited actually because plastic potential Qc and $Q_M$ are used only by the differential form. By applying the initial stress method described later, all elements of fill are assumed to bear no tensile stress, and reinforcement material is assumed to sustain no compression stress.

To evaluate the stability analysis of vertical fill mainly by its final state as treated in the limit equilibrium analysis. The distribution of yield elements calculated by the initial stress method presented by Zienkiewicz et al. [12] is relatively accordance with the final collapse pattern of slope. Two types of nonlinearity (nonlinear stress-strain relationship and no tension) are well treated by the initial stress method. To apply the initial stress method at only one loading stage as shown in Fig. 3, the fundamental flow diagram of calculation is shown in Fig. 4.

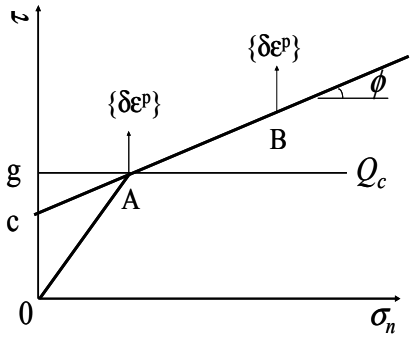

**Fig. 2** Flow rule along yield line

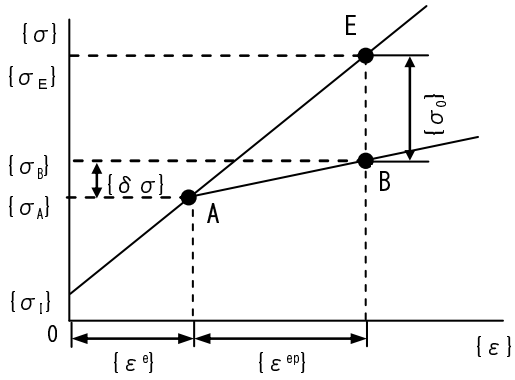

**Fig.3** Initial stress method

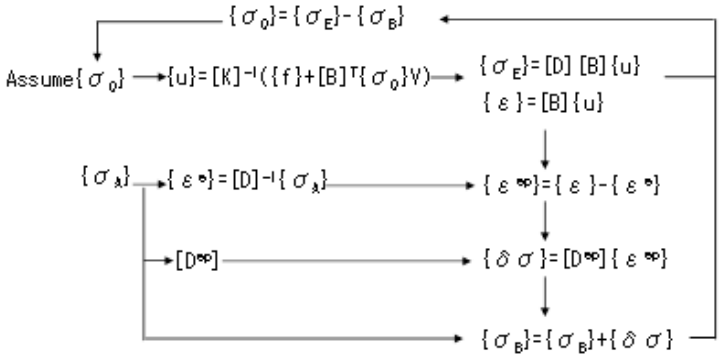

**Fig. 4** Flow diagram of iteration

### Case study of Application Geotextile of Sensor Gegeotextile

A cross-section of the geotextile- reinforced retaining wall is shown in Fig. 5, in which configuration of geotextile and measuring sensors is also shown. The wall was 9.5m high and the overburden backfill was constructed to a height of 30m with gravelly sandy with fines as shown in Table 1. Particle size distribution of backfill: 37.7% Gravel, 53.0% sand and 9.3%. In the actual field, the installation and type of geotextile changes along the height of fill according to limit equilibrium method. The properties of geotextile are also shown in Table 1.

From the laboratory tensile tests, the relationships between strain and tensile strength for the two types of geotextile used in the reinforced wall are given in Fig. 6. The horizontal displacements of wall surface after completing the construction are compared with numerical results respectively in Fig. 7. Both the measuring and numerical results show a shape of horizontal displacement that curves outward. Fig. 8 compares the strain distributions measured using optical fiber sensors with numerical results in different time point of construction. It is obvious that the optical fiber sensor can measure a continuous strain distribution in a geotextile. The strain is largest near the wall in Geotextile A, which is located close to the bottom of the wall, and in the middle the strain close to the rear on geotextile B.

**Table 1** Properties of Case study

| Density [g/cm$^3$] | Dry Density [g/cm$^3$] | Maximum Dry Density [g/cm$^3$] | Optimum Water Content [%] | C [kN/m$^2$] | φ [ °] |

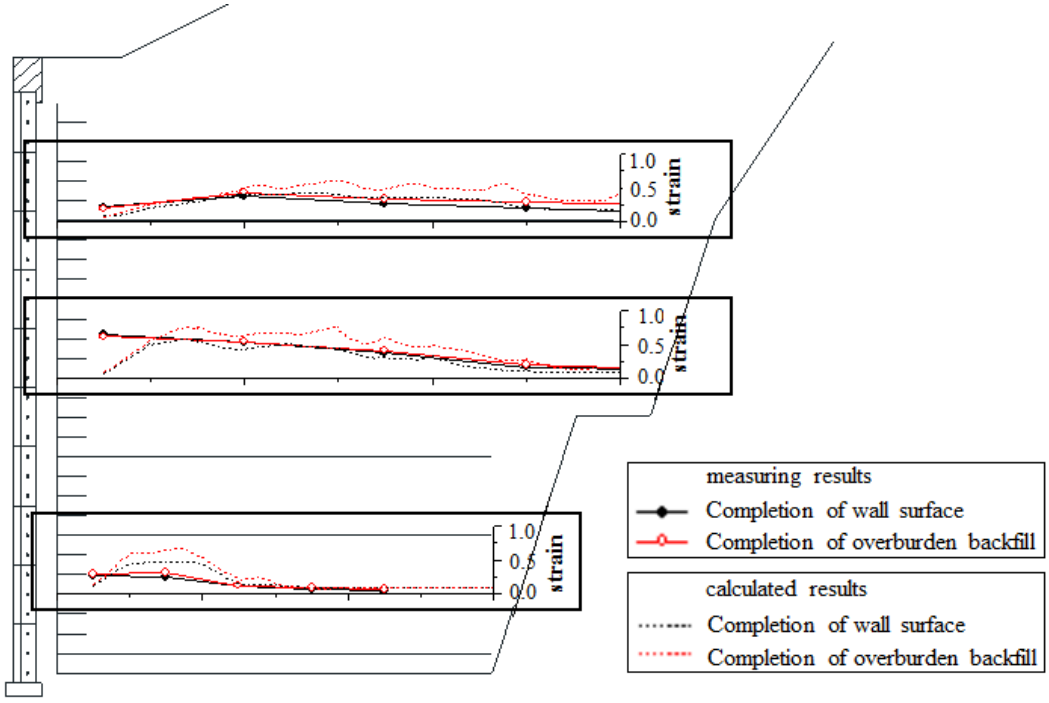

**Fig. 8** Strain distributions

## Discussions

Fig. 6 shows the tensile characteristics and the design tensile strength of the two types of geotextile respectively. The design tensile strength is based on maximum tensile strength considering the reduction of creep, durability and installation damage factors. The strain corresponding to the design tensile strength of geotextile is about 2.0 % to 2.5 %, as shown in Fig. 6. Based on the limit value of strain, the stability of reinforced retaining wall can be evaluated by the measured strain. The reinforced retaining wall is considered to be stable when the measured strain is less than 2.0 %, which represents the tensile force acting in the geotextile less than the design tensile strength. When the measured strain is greater than 2.5 %, the corresponding tensile force of the geotextile is greater than the design tensile strength, the reinforced retaining wall is considered unstable.

For the actual reinforced retaining wall using sensor geotextile, as shown in Figs. 7 and 8, the calculated result agree fairly well with the measured one. The maximum value of strain during and after construction of reinforced retaining wall, either in measurement or numerical procedure, is below 1 % for Geotextile B and C and about 0.6 % for Geotextile A, which shows that the tensile strength induced in the geotextile is less than the design tensile strength. Correspondingly, the wall is considered stable.

## Conclusions

To evaluate the stability of reinforced retaining wall during and after construction, an optical fiber sensor geotextile was used to measure the strain of geotextile embedded in the soil and a numerical procedure was applied to calculate the strain of geotextile. The following conclusions can ne drived from the experimental and numerical results in this paper:

1) The application of optical fiber sensor geotextile to an actual case showed that the optical sensor can measure a continuous strain distribution in the geotextile and enable to provide the strain distribution close with the numerical result.
2) The proposed procedure used a simple model which only requires a small number of soil parameters and provided reasonable results in the critical state, in which the collapse mode is represented by the distribution of yield elements.
3) According to the critical value of strain, the case study proved that the stability of the geotextile reinforced retaining wall can be evaluated by the maximum strain.
4) Case study showed the possibility that the proposed procedure gives the realistic evaluation of stability of reinforced retaining wall and provides a useful engineering tool for the design of reinforced retainig wall.

**Keywords:** reclamation, soft soil, existing pipeline, settlement of foundation, platform on piles

**Abstract.** At coastal beach soft soil area, reclamation projects may have great effect on the deformation of the existing underground pipeline. In this paper, the engineering specification method and the finite element method are used respectively for the pipe deformation calculation of the application of platform on piles to handle such underground pipeline deformation control. The results show that the application of platform on piles can effectively diminish the settlement deformation of the existing underground pipe. Co mparing the two calculation results and the monitoring results, the finite element calculation results are more in line with the actual. By appropriately increasing the width of the platform and the pile spacing, the initial design program can achieve a more optimal solution.

## Introduction

At coastal beach soft soil area, it is widely distributed underground pipeline which have strict deformation control requirements. Reclamation project may have effect on the deformation of the existing underground pipeline. Pile foundation is a very commonly used in industrial and civil engineering infrastructure. But it pours rare that platform on piles of the engineering project is built above the protection target and shares the upper-loading. The problem is how to calculate the deformation of the pipe for the platform on piles treatment, whether this treatment is effective and how to fix the specific dimensions for the platform and the piles.

## Project overview

The length of the cofferdam is 12.2 km; the area of the reclamation is 6395 mu. There 6 existing underground pipelines are distributed through the body of the cofferdam. The pipe tube center elevation is -6.5m, all of which were laid underground with pipe jacking method. The main material of the cofferdam is sandbag. The crest elevation is 7.3m and the original ground elevation is about -0.43m. Levee foundation widely distribute compression larger heavy silt loam and silty clay silt . The main foundation soil physical and mechanical parameters are showed in Table1.

Table 1 The main foundation soil physical and mechanical parameters table

| Layer No. | Soil Classification | Basic Physical Indicators | | | | Consolidation Fast Shear | Consolidation Test |

**Pipe Deformation Control Analysis of platform on Piles Program**

As the existing water pipeline with steel material, its strength, stability has a larger surplus. But related specifications have strict requirements on the longitudinal strain of the pipelines. According to the relevant regulatory requirements, the largest settlement of the pipeline project should be controlled in less than 18cm. Thus, this requirement proposed pipe cap reinforcement program are as follows:

Drive caisson pile φ800 on both sides of the pipeline. According to the upper load and sedimentation control requirements pile length segments using 38m, 28m and 18m in three sizes. On top of the pile design longitudinal pile capping beam, with width of 1m, height of 0.8m. Cast unidirectional platform plate on the pile beam in situs, with board thickness of 1m and board top elevation of 0.00. The cofferdam was constructed on the area of the platform board. Consider subsidence space reserved between platform and the ground, and the sand leak holes were also reserved in the platform board. After the foundation settlement stable, fill sand in the space between platform and the ground through the sand leak holes reserved before. The platform on piles reinforcement program layout is showed in Fig.2.1.

There are many methods to calculate the foundation settlement, most of them can be categorized into theoretical formulation method based on Terzaghi' s consolidation theory, simulating three dimensional consolidation theory and Biots consolidation theory, and numerical computing method based on finite element theory. Therefore, these two methods will be used to do analysis as follows.

**3.1 Engineering Specification method**

3.1.1 Assuming Boundary Conditions

(1) Take the cofferdam as load

As the analysis concerns the settlement of foundation not the deformation of the cofferdam, to simplify the calculation model, take the cofferdam as an external load.

(2) Soil uniaxial compression

The calculation model (one-dimensional model) only considers a vertical compression without considering lateral deformation.

(3) Pipes have the same nature with the soil layer where it placed

To simplify the calculation model, not consider the differences between the water pipes and the soil where it placed and take the pipe and the foundation soil the same nature to calculate.

(4)Take the settlements of the soil below pipes as the settlements of pipes

Assume the pipes together with the settlement of the pile, without considering the longitudinal stiffness of pipes, nor consider the relationship between the pipes, soil and rigid pile.

3.1.2 Calculation method

Settlement deformation is calculated by using relevant formula from "Building Pile Technical Specifications". As the pile spacing of this project is about 6 times the pile diameter, for the sake of caution, the calculation methods of clustered pile foundation (pile spacing less than 6 times pile

diameter )and sparse pile foundation (pile spacing more than 6 times pile diameter) are taken respectively and adopt the greater result.

For the pile spacing of not more than 6 times the pile diameter pile , the final settlement adopt using Boussinesq's solution, according to the sum of physical stratification method of deep foundation. For the pile spacing of more than 6 times the pile diameter pile, the bottom soil of the platform not share the load and the subsidiary stress caused by piles is determined by the Mindlin's solution. Adopt one-way compression method to calculate the sum of stratified soil subsidence, by the superposition calculation of the subsidiary stresses caused by all the piles in the horizontal range of the calculation point, taking into account the pile compression.

#### 3.1.3 Calculation Result

According to calculations, the maximum settlement of the platform is 0.05m; the maximum settlement of the pipe is 0.05m. Considering the reserved settlement differences between the platform and the ground, the settlement of pipes will be very small, almost zero.

### 3.2 Finite Element method

#### 3.2.1 Assuming Boundary Conditions

(1) Take cofferdam as area load.

(2) Take the influence depth calculated by regulation formulation as the lower boundary and the 2 times influence depth as the horizontal boundary. The bottom boundary apply 3-dimention displacement constrains, and the border boundary apply normal displacement constrains.

(3) Use shell elements to simulate pipe body.

(4) Use solid elements to simulate ground foundation. Apply DP model comes with ANSYS to do the calculation. The DP model is an ideal elastic-plastic model, which compliance with Drucker-Prager criterion based on M-C criterion presented by D.C Drucker and W.Prager. It is needed to input 3 parameters, cohesion force c, internal friction angle φ, and expansion angle φf which is to control the expansion. As the main soil type of this project is sandy clay, normally consolidated or unconsolidated soil, which would occur only shear compression, expansion angle φf is zero.

(5) Use solid elements to simulate pile, applying concrete material model.

(6) Add contacting elements (no separation type) between ground soil and pipes, allowing sliding without friction occur in a small area.

(7) Add contacting elements (Frictional type) between ground soil and pipes, allowing the two contacting surfaces transfer a certain shear stress before relative sliding occurs. As long as the shear stress come over this value, the relative sliding will occur between the two contacting surfaces.

Fig.1 shows the finite element model.

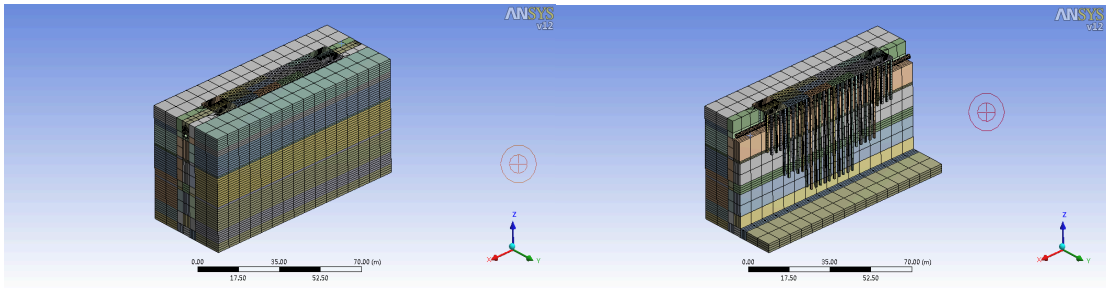

Fig.1 Finite element model

3.2.2 Calculation Result

The settlement of pipe foundation is 0.16m; the maximum vertical deformation of pipe is 0.15m, as the maximum radial deformation is 0.001m. The vertical deformation of pipe is controlled under the values specification allows, but is far more than the result calculated by specification method.

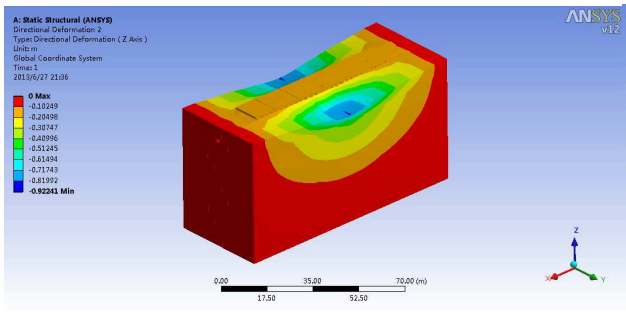

Fig.2 Foundation deformation diagram

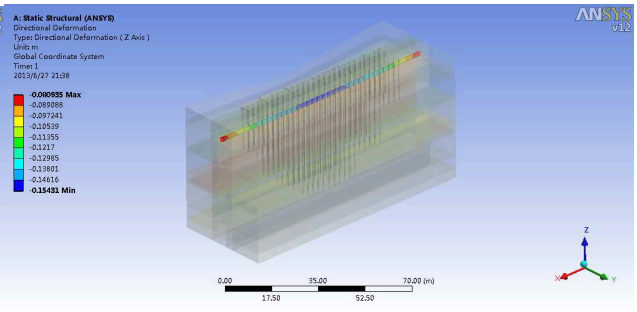

Fig.3 Water pipe deformation diagram

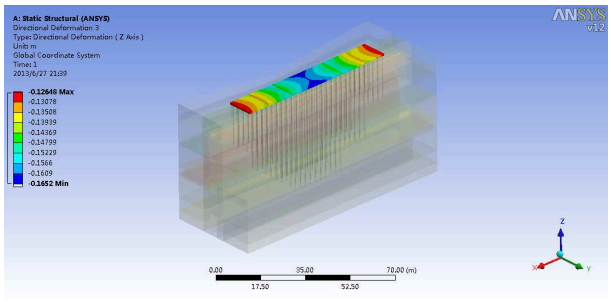

Fig.4 Platform deformation diagram

Fig.2 and Fig.3 show that the foundation treatment of platform on piles has significant effect on settlement control. Fig.4 shows that, the reserved settlement differences between platform and ground is surplus. As the differences of settlement between piles and the soil around are great, the leakage channel is more likely to be formed.

### 3.3 Results Analysis

The calculation result of finite element method is larger than the specification method. Analyzing the reasons, there may be several factors as below:

Factor 1: The specification method assumes the pipe, pile and the soil between piles subside together. The settlement deformation is comprised of the settlement deformation of soil under the piles and the pile compression which is very small because of the large pile stiffness.

Factor 2: The specification method not takes effect from the lateral loads into consideration.

Factor 3: The specification method cannot calculate the negative friction force caused by the differences of settlement between pile and the soil around it.

The main factors are factor 1 and factor 2. Comparing to the general calculation, it is very different cases that the protected object is located under the platform. Due to the limited width, the platform can only share the load directly to the upper part of the cofferdam, and the edge loads would have a greater impact to the soil among piles.

Factor 3 is also very important. Because of the less settlement of the piles and the more settlement of the soil around piles, it would generate large negative friction force. The more densely arranged in piles, the greater its negative friction force.

The pile platform and pipes of this project are arranged monitoring facilities, according to the monitoring results at completion of this project, the maximum settlement of the pipe is 47 mm, the maximum settlement of the steel concrete caisson pile is 49 mm. According to the experience of

similar projects in the past, it can be expected that, within 50 years of engineering use fixed number of year, the final settlement of the water pipe will be about 100 mm. The results are greater than the results calculated by engineering specification method and slightly smaller than the finite element method. The monitoring results show that the settling amount of the pipe is approximately the same as that of the caisson pile at completion of the project, which is very different from the engineering specification method calculation results. So the finite element method calculation results are more in line with the actual.

According analysis of the calculation and the monitoring results, the initial design of the platform on piles can also be optimized from the following several aspects:

(1) Appropriate increase cap width

It can be seen from the calculation results, the edge loads are the most important factors to generate vertical deformation of the pipe. The platform can only reduce the shallow foundation stress, where is under the platform and above the pipe. With increasing depth, the foundation stress increases rapidly until almost the same with the same depth of soil, at the meantime the protection effect of the platform is weakened and exhausted. But as the increase width of the platform the investment increase, the platform can be of different design programs for the width election to achieve the optimal design.

(2) Appropriate increase pile spacing

According to the results, the pile strength is still surplus. By increasing pile spacing, especially to increase the distance between the pile and the pipes can save investment, while also reducing the effects of pile lateral friction to the pipes. At the same time, as the loads of single pile increasing, settlement of the pile would increase. But it can be solved by increase the reserved gap between the platform and the ground.

## Conclusions

In the coastal reclamation projects, applying platform on piles design can effectively solve the settlement problem of existing pipeline caused by the upper large area loading. By appropriately increasing the platform width and the pile spacing, it can achieve a more optimal solution. In accordance with regulatory requirements, while increasing the pile spacing, it must guarantee the pile bearing capacity not exceed its ultimate bearing capacity. When the pile bearing capacity exceeds its ultimate bearing capacity, the result is the soil at the bottom of the pile would occur plastic damage and the pile would continue to subside, but it is impossible to subside unlimitedly. To some deep, the stresses would achieve a re-balance. It is necessary to do further analysis for the stress-strain state of the foundation soil while increasing the pile spacing, which can create a greater space for the design optimization.

**Keywords**: Hot Dry Rock, Heating,Fracture storage layer, Water temperature change

**Abstract**. Hot dry rock(HDR) provides heat through fracture storage layer. The purpose of research on water temperature change of hot dry rock fracture is to study that whether heat energy can satisfy five months winter heating or not. Research method is establishing model of hot dry rock fractured storage layer by means of numerical simulation software FLUENT according to the rock physical properties in Shenyang region. The depth of drilling is 4000m and the water flow rate is 1cm/s. Research principle is high temperature underground rock transfer heat to medium water in the fracture by coupling. Conclude water temperature change equation every two weeks. The results of the study is that fracture water temperature distribution can be approximated taken as linear distribution. According to the slope K, we can conclude water temperature change formula(3.10), and we can use it to infer fracture water temperature.

## Introduction

In the Shenyang area, winter heating consumes a lot of mineral fossil fuel for five months. The burning products critically affect air quality and undermine the sustainable development. Hot dry rock has obtained more and more people's attention.Because the enormous pre-development costs, the research work is still in the theoretical stage[1]. In this paper, we study water temperature change of fracture storage layer. It is critical step in the development of hot dry rock heating system.It directly affects the prime cost of hot dry rock research.It is also the basis of studying the fracture storage layer rock temperature distribution.

## Working mechanism of hot dry rock heating system

Hot dry rock heating system consists of injection wells, extraction wells and artificial fracture storage layer. Fractured storage layer is located between the injection wells and the extraction wells. Fracture storage layer is built by massive hydraulic fracturing technology. Its working mechanism is injecting high-pressure water through the injection wells to the high-temperature rock. The high-pressure water is heated in a boiling state through the fractured storage layer. Then the high-temperature water is transmitted through the extraction wells.The low-temperature water is injected into injection wells for recycling.Fracture storage layer is the place where medium water and high-temperature rock exchange heat energy and thermal conductivity [3,4].Environmental conditions of artificial fracture storage layer play an important role to analysis energy absorption. Working Mechanism diagram is shown in Figure 1.1.

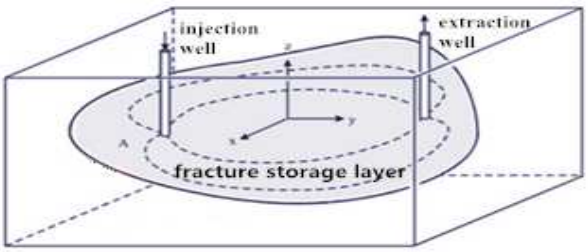

Fig1.1 Working mechanism diagram of HDR

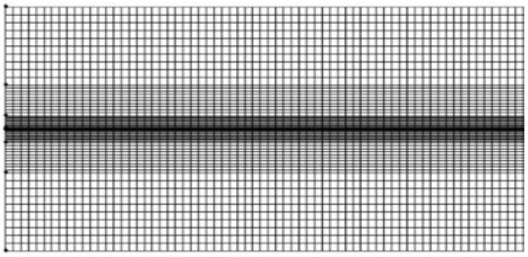

Fig 2.1 HDR retention layer crack model

**Assumptions.** Rock blocks are intended to simplify homogeneous and isotropic continuum models. Fracture is simplified fractured media model. Water storage and water permeability of rock are negligible. Because of the high-pressure, water vaporization does not occur. The model can be considered saturated with water. The density of water is 1.0g/cm$^3$ all the time. Rock transfer heat by conduction, convection, radiation. And the radiation component of hot dry rock model is negligible. Water flow rate only relate to the pressure difference between the injection wells and production wells. To simplify the mathematical modeling, model can be seen a rotating body as the axis of fracture, according to the assumptions. Thereby simplifying the model into a two-dimensional calculation model [2,3]. The model is shown in Figure 2.1.

**Fracture water temperature control equation.** In the HDR system, the movement of water is mainly controlled by the pressure difference between the injection wells and the production wells, and the free convection caused by the temperature change is generally negligible. Thus the heat transfer equations and fluid motion equations can be independently solved. Therefore, forced convection is the only factor to consider in the heat transfer equation [5].According to the norm of conservation of energy, quantity of heat of per unit area along the axis direction is $Q_1$

$$Q_1 = -\lambda_w \nabla T \tag{2.1}$$

The effect of fluid movement, control body of per unit area along the axis direction is $Q_2$

$$Q_2 = c_{vw} \bullet \rho_w \bullet v_i \bullet T \tag{2.2}$$

The heat conduction from the rock to fracture water is $Q_3$

$$Q_3 = -\frac{\lambda_r}{\delta}(T_{rb} - T_w) \tag{2.3}$$

Therefore, according to the norm of conservation of energy infer the heat transfer equation

$$c_{vw}\rho_w \frac{\partial T_w}{\partial t} + Q_1 + Q_2 + Q_3 = 0 \tag{2.4}$$

Putting(2.1 ~ 2.3) into (2.4) can infer

$$c_{vw}\rho_w \frac{\partial T_w}{\partial t} = \lambda_w \nabla^2 T - c_{pw} \bullet \rho_w \bullet \nabla(v_i \bullet T_w) + \frac{\lambda_r}{\delta}(T_{rb} - T_w) \tag{2.5}$$

The seepage of water obeys Darcy's law, can infer

$$v_i = q_i = k_f \nabla p \quad i = x, y, z \tag{2.6}$$

Therefore, putting the formula (2.6) into (2.5) can get complete fracture water temperature field equations

$$c_{vw} \frac{\partial(\rho_w T_w)}{\partial_t} = \lambda_w \nabla^2 T - c_{pw} \bullet \nabla(\rho_w \bullet k_f \bullet \nabla p \bullet T_w) + \frac{\lambda_r}{\delta}(T_{rb} - T_w) \tag{2.7}$$

In the equation: $\lambda_w$ is the thermal conductivity of water, $c_{vw}$ is constant volume specific heat of water, $c_{pw}$ is constant pressure specific heat of water, $\rho_w$ is density of water, $\lambda_r$ is thermal conductivity of rocks, $\delta$ is 1/2 slit width, $T_{rb}$ is crack rock edge temperature, $T_w$ is water temperature, $v_i$ is water flow rate, $q_i$ i290s ratio of flow rate, $k_n$ is seepage coefficient.

**Water temperature change in fracture storage layer**

In order to research the water temperature change in entire fractures. Research on the fracture water temperature distribution during different time periods. Calculate and analysis the data of system every two weeks. Concrete analysis of the situation is as follows:

From Figure 3.1, we can summarize temperature distribution of water in the fracture after the 2 weeks' running of system. The line of cracks in the first 200m range extent straightly. Temperature of water in fracture distributes linearly. Within the range from 200m to 500m, the image is curve state. After the system runs two weeks, the temperature distribution of the fissure water can not be accurately expressed the relationship linear distribution.

From Figure 3.2, we can summarize temperature distribution of water in the fracture after the 4 weeks' running of system. The image of fracture linearly extend in the front 300m range, fissure water temperature changes linearly distributed. Within the range of 300m to 500m, the image is bent. Four weeks after the system runs, the fissure water temperature distribution can be summarized as the range of linear increase than two weeks ago,but the overall linear relationship is still not accurately expressed.

From the Figure 3.3 can summarize fracture water temperature distribution after system runs six weeks.Fracture water temperature change trend is close to linear. The linear equation can be approximately defined as:

$$T = T_0 + 0.09L \tag{3.1}$$

In the equation: $T_0$ is the injection water temperature. $T$ is the temperature of random point in the crack. $L$ is the distance from fractured to the injection wells.

The hot dry rock system fracture water temperature distributions of eight weeks and ten weeks can be summarized from the Figure 3.4 and Figure 3.5. Compared to the water temperature distribution of six weeks, change trend of fracture water temperature is closer to linear. The linear equation can be approximately defined as:

$$T = T_{_0} + 0.08L \tag{3.2}$$

$$T = T_0 + 0.076L \tag{3.3}$$

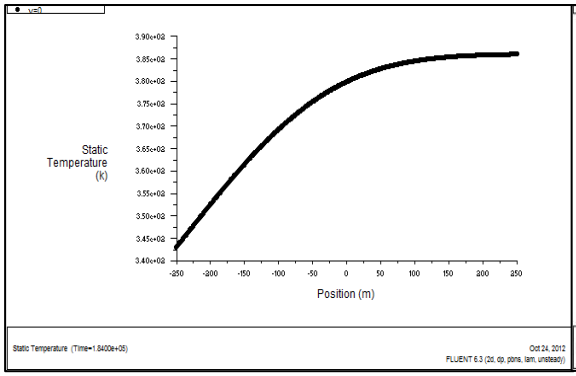

Fig 3.1 Cracked after two weeks the water temperature distribution 4000m 1cm/s

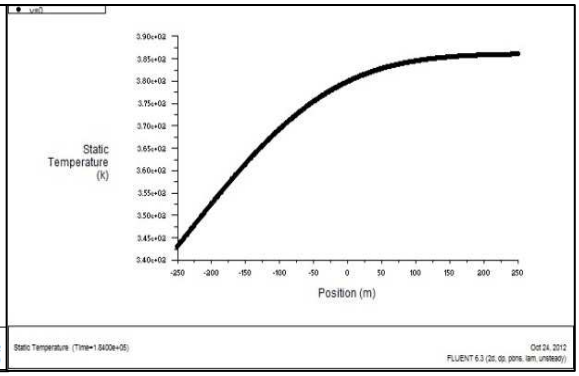

Fig 3.2 Cracked after four weeks the water temperature distribution 4000m 1cm/s

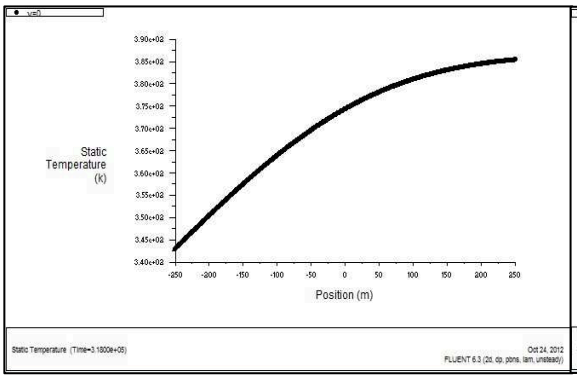

Fig 3.3 Cracked after six weeks the water temperature distribution 4000m 1cm/s

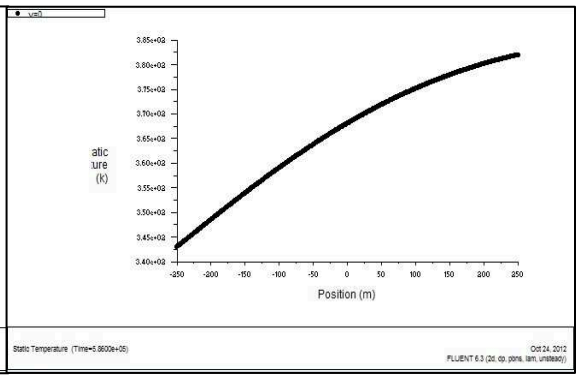

Fig 3.4 Cracked after eight weeks the water temperature distribution 4000m 1cm/s

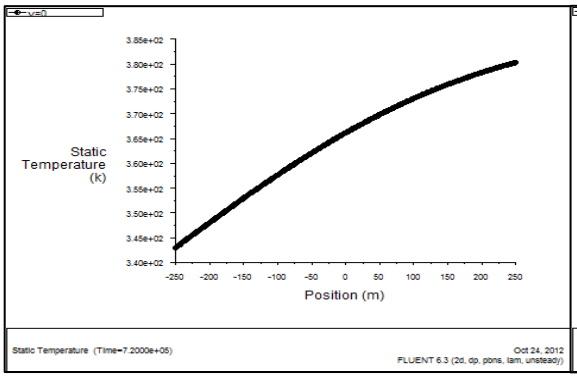

Fig 3.5 Cracked after ten weeks the water temperature distribution 4000m 1cm/s

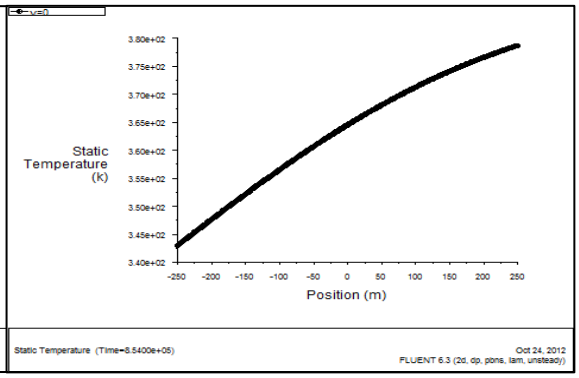

Fig 3.6 Cracked after 12 weeks the water temperature distribution 4000m 1cm/s

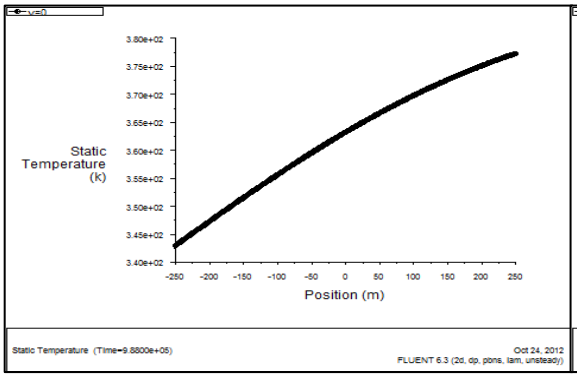

Fig 3.7 Cracked after 14 weeks the water temperature distribution 4000m 1cm/s

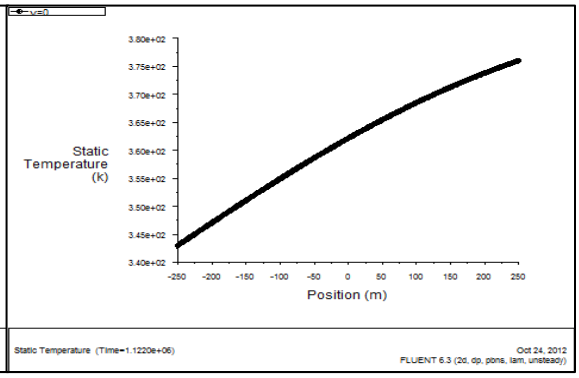

Fig 3.8 Cracked after 16 weeks the water temperature distribution 4000m 1cm/s

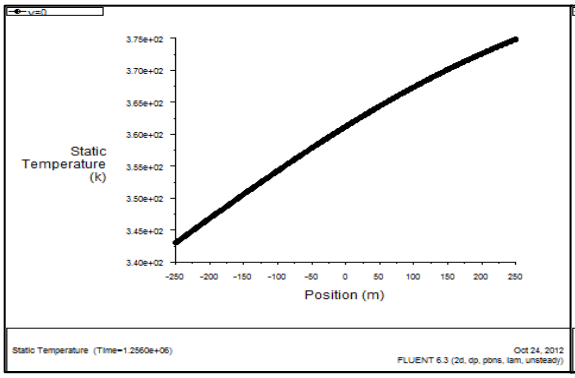

Fig 3.9 Cracked after 18 weeks the water temperature distribution 4000m 1cm/s

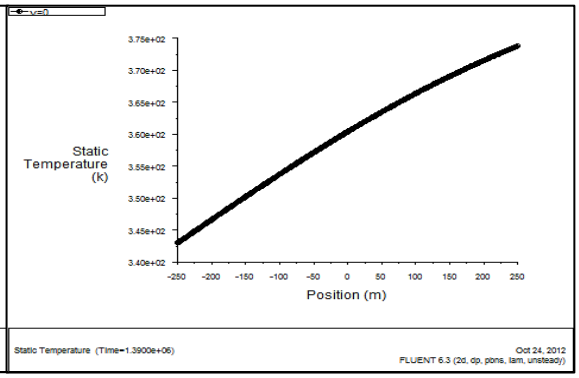

Fig 3.10 Cracked after 20 weeks the water temperature distribution 4000m 1cm/s

The hot dry rock system fracture water temperature distribution of twelve weeks, fourteen weeks, sixteen weeks, eighteen weeks, twenty weeks can be summarized from the Figure 3.6~Figure 3.10,The linear equation can be respectively defined as equation(3.4) ~ (3.8) :

$$T = T_0 + 0.072L \tag{3.4}$$

$$T = T_0 + 0.07L \tag{3.5}$$

$$T = T_0 + 0.068L \tag{3.6}$$

$$T = T_0 + 0.064L \tag{3.7}$$

$$T = T_0 + 0.062L \tag{3.8}$$

Table 3.1 Slopes calculated from Fig 3.3 to Fig 3.10

| Time | 6 | 8 | 10 | 12 | 14 | 16 | 18 | 20 |
|---|---|---|---|---|---|---|---|---|
| Slope | 0.09 | 0.08 | 0.076 | 0.072 | 0.07 | 0.068 | 0.064 | 0.062 |

Fig 3.11 shows the tendency of change of slope with time goes by

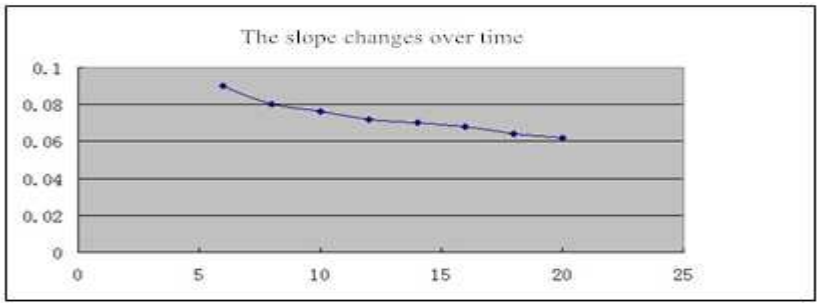

Fig 3.11 The slope changes over time

We can infer the equation 3.9 which the change of slope K with time goes by. The equation can be approximately defined as:

$$k = 0.092 - 0.0015t \tag{3.9}$$

In the equation: $k$ is water temperature slope of the curve variation with time. $t$ is the running time of the hot dry rock system. The unit is weeks.

Thus, the equation of water temperature variation with the time is equation 3.10.

$$T = T_0 + (0.092 - 0.0015t) \bullet L \tag{3.10}$$

In the equation:$T$ is the water temperature in different fracture locations. $T_0$ is injection water temperature. $t$ is the time of the hot dry rock system runs. $L$ is the distance from the injection wells.

**Conclusions**

(1) With the system running, the rate of change of water temperature distribution gradually tends to change linear.
(2) When the system runs five months, fracture water temperature distribution can be approximated as linear distribution.
(3) With the system running, the rate of change of temperature distribution of water in the fracture decrease following the increase of the length of crack.
(4) The depth of drilling is 4000m and the water flow rate is 1cm/s. We can use the equation (3.10) to study and predict fracture water temperature

$$T = T_0 + (0.092 - 0.0015t) \bullet L \tag{3.10}$$

In the equation: $T$ is the water temperature in different fracture locations. $T_0$ is injection water temperature. $t$ is the running time. $L$ is the distance from the injection wells.

**Keywords:** silty clay; $k_0$ consolidation; triaxial drained creep test; creep coefficient;

**Abstract：** The creep characteristic of saturated silty clay was studied by triaxial drained creep test through two stress paths of axial loading and lateral lightening. According to test data, some conclusions were submitted. First, the axial creep laws between the two stress paths were consistent on the drainage conditions. Volume strains were much smaller than axial strains. Volume strains presented shear dilatancy along with lightening confining pressure. The silty clay creep coefficient was put forward and its variation law was summarized. The silt soil creep coefficient was closely related to the deviatoric stress level. The two had a linear relationship. The silt soil creep coefficientincreased with deviatoric stress level and had no matter with the confining pressureand loading path.

## Introduction

The deformation of soil is not just a transient, but also increases with a certain speed, and it has some creep characteristics.The experimental studies on creep characteristics of soil most based on conventional undrained consolidation triaxial test, without considering drained conditions effects on the soil creep characteristic. There were many researches about silty clay's creep properties [1-2]. But the drainage creep characteristics of silty clay were seldom studied on the condition of preconsolidation state. The purpose of this paper is to study the creep characteristic of saturated silty clay with triaxial test by $k_0$ consolidation and drainage conditions, and to explore differences of the soil creep properties through two stress paths of axial loading and lateral lightening.

## Triaxial Drained Creep Test

The triaxial drainage creep tests of saturated remoulded soil with axial loading or lateral unloading were carried on by takinga certain amount of silt soil. The previous $k_0$ consolidation was completed according to the sampling depth before the creep tests. In this paper, the $k_0$ value was 0.45. Test apparatuseswere the modified stress controlling triaxial apparatuses. The creep tests scheme was shown in table 1.

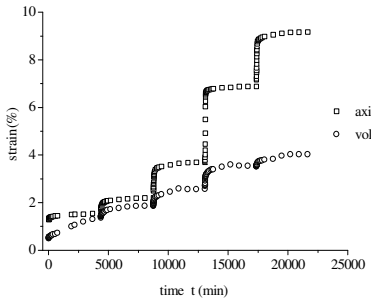
Table 1 The loading scheme of silt soil creep test

| Loading paths | Consolidation pressure （kPa） | | Creep paths |
|---|---|---|---|
| Axial loading | Confiningpressure | 50 | Confining |
| | Axial pressure | 111 | pressure is |

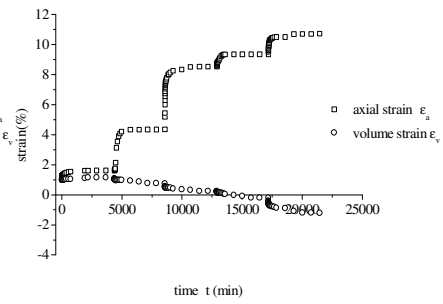
| | | | |
|---|---|---|---|
| | Confiningpressure | 100 | constant, and |
| | Axial pressure | 222 | Axial pressure is |
| | Confiningpressure | 250 | increasing step by |
| | Axial pressure | 555 | step |
| Lateral lightening | Confiningpressure | 50 | Axial pressure is constant, and Confining pressure is decreasing step by step |
| | Axial pressure | 111 | |
| | Confiningpressure | 100 | |
| | Axial pressure | 222 | |
| | Confiningpressure | 250 | |
| | Axial pressure | 555 | |

**Analysis of Test Results**

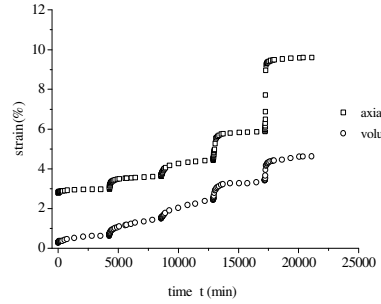
It was shown from fig.1 that axial strain and volume strain were consistent between axial loading and lateral unloading conditions. It was shown that from the trend of the curve the creep strain increment increased with stress levels, and the accelerated creep did not appear for the two strains. Regardless of high or low stress levels, both were degenerative patterns. There were no uniform creep and accelerated creep. The volume strain showed much difference between axial loading and lateral unloading conditions. When $\sigma_3 = 250\text{kPa}$ with lateral unloading, it showed shearing shrinkage tendency and was the same as the axial loading conditions. But with increasing of shear stress levels, this increment in volume deformation gradually decreased. From fig.1 (f) showed that volume deformation increments of the two lateral levels were fewer than the first two levels. When $\sigma_3 = 100\text{kPa}$ with lateral unloading, it showed tendency of shear shrinkage after shear dilatancy. But When $\sigma_3 = 50\text{kPa}$ with lateral unloading, it showed shear dilatancy tendency beginning at the first level. This showed that under the condition of lateral load shedding, silty clay creep has a certain volume dilatancy characteristics, and with the decrease of consolidation confining pressure, the dilatancy properties were more obvious.



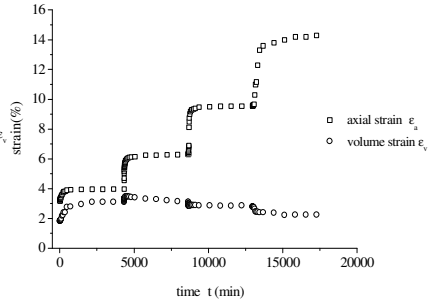
(a) $\sigma_3 = 50\text{kPa}$ withaxial loading



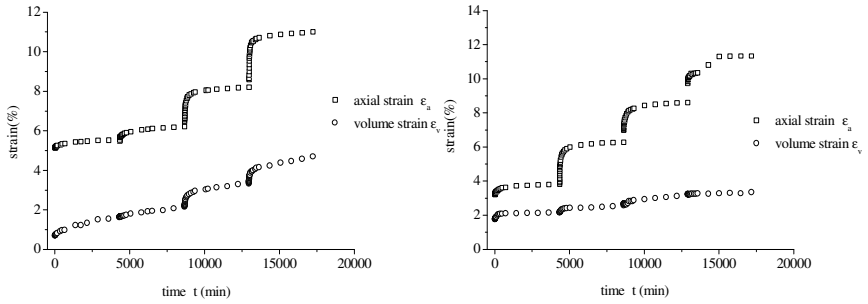
(b) $\sigma_3 = 50\text{kPa}$ with lateral lightening



(c) $\sigma_3 = 100\text{kPa}$ withaxial loading



(d) $\sigma_3 = 100\text{kPa}$ with lateral lightening



(e) $\sigma_3$ = 250kPa with axial loading (f) $\sigma_3$ = 250kPa with lateral lightening

Fig.1 Creep strain curves of silt soil with triaxial drained creep test

## Creep Coefficient

For one-way consolidation compression test, coefficient of secondary compression was used to describe the creep properties of soil. After pore pressure dissipate, the characteristic quantities used void ratio changes to represent creep deformations under effection of effective stress. Similarly, concept of creep coefficient for triaxial drained creep test was defined as the gradient between creep strain and logarithmic time. The expression is shown as Eq.(1):

$$C_\varepsilon = \frac{\varepsilon - \varepsilon_0}{\log(t / t_0)} \qquad (1)$$

For Eq.(1): $t_0$ is creep starting time of soils, $\varepsilon_0$ is creep value for creep starting time. The value was 80 min here.

The relationship curves between axial strain and logarithmic time under different deviatoric stress was shown in Fig.2. The slope factor of fitting line represented the creep coefficient, which increased with stress levels from Fig.3. All creep coefficients of six soil samples under different stress levels were plotted out in Fig.3. According to Fig.3, it showed that regardless of confining pressure and loading path, creep coefficients increased up with stress level, and basically the relationship line was a straight line. Under the same loading path and the same deviatoric stress level, the creep coefficient changed unobviously with consolidation confining pressure. The relationship curves of the two creep path with axial loading and lateral unloading was similar. The conclusion was that creep coefficients of soil sample was closely related to deviatoric stress levels, but had little relationship with consolidation confining pressure and creep loading path.

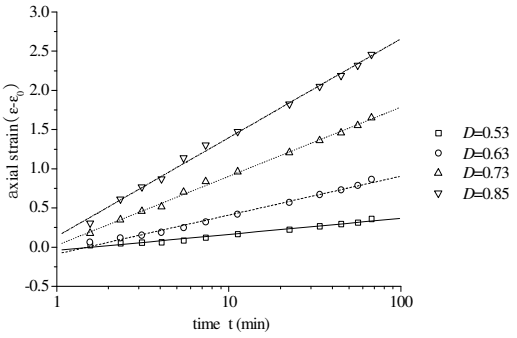


Fig.2 Relationship between axial creeps and logarithmic times at $\sigma_3$ =250kPa with axial loading

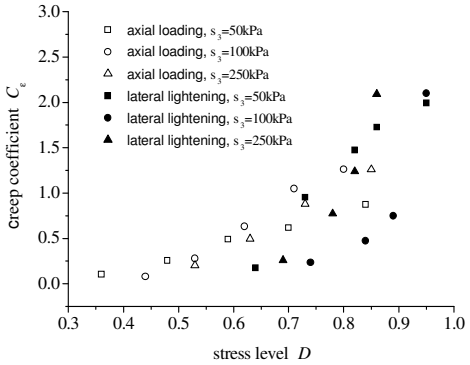

Fig.3 Relationship between stress levels and creep coefficients of six soil samples

## Conclusions

There were many researches about silty clay's creep properties. The drainage creep characteristics of silty clay were studied by the paper on condition of preconsolidation state. The conclusions from experimental results and related analysis were as follows:

(1) Volume strains were significantly less than axial strains. For the two stress path of axial loading and lateral unloading, the creep laws were fundamentally consistent in triaxial drained creep test.

(2) Volume strains showed much difference between axial loading and lateral unloading conditions. Volume strains presented shearing dilatancy characteristic. The lower consolidation confining pressure was, the more clearly shearing dilatancy characteristic was.

(3) Concept of creep coefficient was drew up. According to test data, creep coefficients of soil sample were closely related to deviatoric stress levels, but had little relationship with consolidation confining pressure and creep loading path.

**Keywords:** bentonite-sand mixtures; soil-water characteristic curve; moisture balance method; suction

**Abstract:** A series of tests on the soil water characteristic curve through moisture balance method were conducted to study the effects of temperature, sand mix ratios and dry density on the soil water characteristic curve of bentonite-sand mixture. The test results show that with the increase of temperature, the water retention capacity of the mixture significantly decreased. Within the test control suction range, sand mix ratios at the low suction had obvious effects on the soil water characteristic curve and at high suction the effects gradually decreased. Dry density had no effects on the soil water characteristic curve of bentonite-sand mixture. In accordance with the test data, an experience model of soil water characteristic curve of bentonite-sand mixtures considering temperature and sand mix ratios is established.

## Introduction

With the development of the use of nuclear energy and nuclear engineering, safe disposal of the (high-level radioactive waste) is raising the concern of the world as well as the use of nuclear energy. At present, deep geological disposal is universally recognized as a viable solution placing the high-level radioactive waste solidification down to 500-1000 meters in the underground repository, to achieve the purpose of isolation from living environment of mankind. Buffer/backfill material used in the construction of an underground repository is one of the important aspects, and the bentonite sand mixed buffer/backfill materials have become popular around the world. As Canada mixed Avonseal bentonite and sand at a proportion of 5:5; Japan add 30% quartz sand into Kunigel V1 as the preferred buffer/backfill material[1]. China, after a comprehensive studying, has preliminarily identified the Inner Mongolia GMZ bentonite as our preferred buffer/backfill material.

Soil water characteristic curve shows the relationship between the unsaturated soil suction, water content and saturation. scholars have done a lot of work on the soil water characteristic curve of bentonite and mixtures. For example, G.X.Tang et al.[1] studied the soil water characteristic curve, through the filter paper method, of the mixture with sand mix ratios of 50% at different temperatures. A.C.Jacinto et al.[2] studied water retention curves of MX-80 bentonite of different temperatures and dry density and then used them in the analysis of the thermal-hydraulic-mechanical coupling. E.E.Alonso et al.[3] using the vapor balance method, studied the soil water characteristic curve of compacted FEBEX bentonite with different temperatures and dry density. G.F.N.Gitiranar et al.[4] studied impact factors of the equation of soil water characteristic curve of the bentonite. Ye et al.[5] studied the impact of temperatures and free expansion in unconfined condition on highly compacted pure GMZ bentonite SWRC under high suction. Zhang et al.[6] using the pressure plate and the vapor balance method studied the GMZ bentonite under different initial saturation conditions at room temperature, the significant influence of saturation, sand mix ratios and the dry density of bentonite-sand mixture on the water retention capacity. Studies above on soil water characteristic curve of bentonite and the mixture of bentonite and sand are carried out under normal temperature, therefore studies on buffer/backfill material under different temperature, sand mix ratios and dry

density and its water retention capacity under the influence of residual radiant heat by geological disposal of high level radioactive waste have practical importance both in theoretical analysis and engineering.

This paper studies soil water characteristic curve of the mixed buffer/backfill material of bentonite with sand through the vapor balance method, analyzed the influence of temperature, sand mix ratios and dry density on soil water characteristic curve of the compacted mixture and establishes empirical model that can predict reference to the soil water characteristics curves of mixture of different sand mix ratios and temperature.

## Preparation of test specimens and the test methods

### 1.1 Test materials and preparation of sample

Bentonite used in the test is produced from Gaomiaozi area in Inner Mongolia, and quartz sand aggregate is the manually processed local quartz sand. The basic performance of the bentonite is presents a liquid limit of 318%, a plastic limit of 38%, a grain weight of 2.66[7], and the sand is presents grain size of 49.72% within 0.6~0.3mm and 45.64% within 0.3~0.15mm. Sand mix ratios is defined as the ratio of dry sand to dry bentonite. Fully stir and mix the bentonite with the initial water content of 12.59% and dry quartz sand with sand mix ratios at 0, 10, 20, 30, 40, 50 and 60% and leave them alone for one week. Samples of the mixture are made by statically compacted to a cylinder with diameter of 20mm and height of 10mm through specialized sample preparation apparatus, with dry density, respectively 1.7, 1.8, 1.9 and 2.0g/cm$^3$. After that, put samples in small aluminum boxes, and measured their weight.

### 1.2 Test procedures and determination of soil water characteristic curve

The samples placed in the aluminum capsule are placed in the moisturizing vessel with saturated salt solution at the same time, the samples are on the humidor aperture ceramic board, and the prepared saturated salt solution is placed at the bottom. Saturated salt solution is used to control soil suction and the relative humidity (RH) relationship can be determined according to the thermal dynamics, the following relationship exists between the suction and relative humidity[8]:

$$\psi = -\frac{RT\rho_w}{\omega_v}\ln(RH) \quad (1)$$

Temperature is controlled according to test requirements, and samples are weighted by high-precision electronic balance (with accuracy of 0.0001g) every one to two weeks. When two consecutive weight remains unchanged (two measurements within the range of 0.001g), the exchange of water vapor between the soil samples and steam is considered to reach a equilibrium, at this time the weight of test sample can be recorded and final moisture can be calculated. Elevated temperatures can significantly shorten the time to reach the final balance during the test. Tests are conducted at the temperature of 20, 40, 60 and 80℃ respectively in a incubator with an accuracy of ± 0.5℃. The whole process lasts for three months. Saturated salt solution, and their corresponding suction values under different temperatures are shown in Table 2. Relative humidity translation are cited from DEAN J. A. et al.[9]. Suction balance of tests in this paper mainly relies on free diffusion of water vapor.

## Analysis of test results

### 2.1 Influence of temperature on the soil water characteristic curve of the mixture

Figure 2 gives Influence of temperature on the soil water characteristic curves of bentonite-sand mixture. It can be seen from figure 2 that under the same sand mix ratios(30%) and dry density(1.80g/cm$^3$), when the temperature increases, water retention capacity of the mixture decreases. To observe and analyze better, fitted soil water characteristic curves of mixture of various temperatures are given, in the semi log coordinate, soil water characteristic curves of various temperatures are roughly parallel. When the temperature was raised from 20℃ to 80℃, the controlled suction of the saturated salt solution increased from 4MPa to 367MPa, while the water content of the

mixture decreased from 33.2% to 1.0%. Due to space limitations, Figure 2 lists the soil water characteristic curve of a sand mix ratio (30%) at different temperatures, under other sand mix ratios, as the temperature increases, the behavior of the mixture of soil water characteristic curve is consistent. The finding above is consistent with literature[3-5]. This is because, soil suction is controlled in the suction vapor equilibrium method, and the total suction is equivalent to the free energy of the water in the soil; for higher suction, the dominate factor of adsorption of soil transited from capillary action into the water retention. With increasing temperatures, free energy of water molecules increases freely, with more adsorbed water molecules escaped, the moisture content is decreased.

**2.2 Influence of dry density on soil water characteristic curves of the mixture**

Impact of dry density on soil water characteristic curves of bentonite mixed with sand of are shown in Figure 3. As can be seen from Figure 3 test, the suction controlled with the same sand mix ratios (40%) and under the conditions of temperature (60℃), soil water characteristic curves of the mixture at the different dry density coincidence. It can be seen that the dry density had no effect on the moisture content of the mixture. Scholars who studied FEBEX bentonite[3,4], GMZ bentonite[5,6] observed a similar phenomenon in the test, that the dry density of the soil water characteristic curves of the mixture had no effect. This is because the water in the soil is mainly adsorbed on the mineral surface, while compaction is difficult to change the impact of mineral water adsorption capacity. Suction controlled in the test is within high suction condition, and the dry density has no effect on the soil water characteristic curves of the mixture.

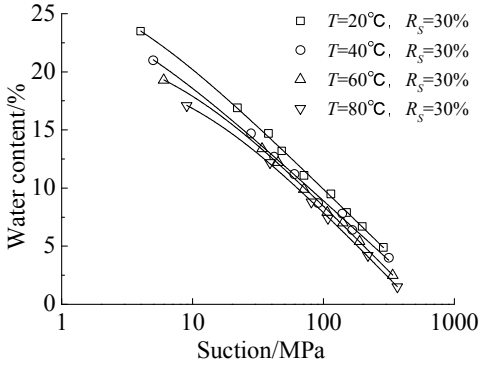

Fig.1 Influence of SWCCs on bentonite-sand mixtures at different temperature

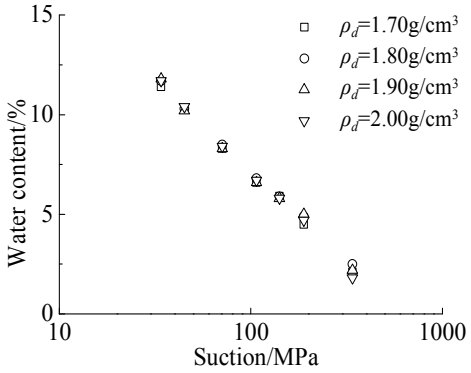

Fig.2 Influence of SWCCs on bentonite-sand mixtures under different dry densities

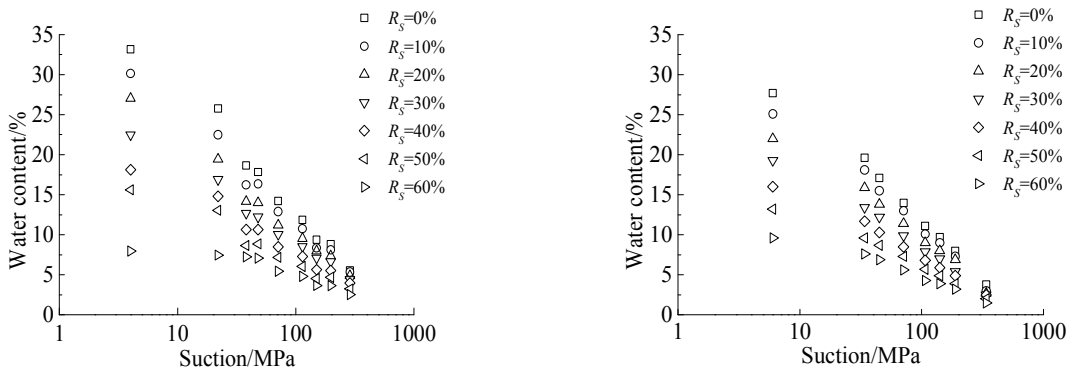
**2.3Influence of sand mix ratios on the soil water characteristic curves of the mixture**

Soil water characteristic curves of bentonite-sand mixture of sand mix ratios at different temperatures (20℃, 40℃, 60℃and 80℃) and under the conditions of the same dry density (1.80g/cm$^3$) are shown in Figure 4 (soil water characteristic curves of mixture at 20℃ and 60℃ are listed). At the same temperature (see Figure 4 (a) and Figure 4 (b)), as sand mix ratios increases water retention capacity of a mixture significantly reduces, within the suction range of the test control, and a low power segment, water content of sand mix ratios of a mixture are significantly affected; When the suction increase under different sand mix ratios, water content of the mixture decreases. It is the same in the performance of soil water characteristic curves of the mixture at other temperatures. This is mainly because the contact manner between the bentonite particles is changed, in the compacted sample, at this test of lower suction; soil suction is caused by capillary action. the void between the structure in the soil particles affect the soil water characteristic curves; For higher suction, the free energy of soil water can be increased, thus reducing soil adsorption of water, a mixture of different sand mix ratios would lose a large amount of water, then the suction is the main factor of water retention curves. The law, found by Zhang et al.[6], of soil water characteristic curves of GMZ mixture of different mixing sand ratios is consistent with what is found by vapor balance method under normal temperature conditions.



（a）SWCCs on bentonite-sand mixtures at 20℃ （b）SWCCs on bentonite-sand mixtures at 60℃

Fig.3 Influence of SWCCs on bentonite-sand mixtures under different sand mix ratios

## The construction of empirical model of soil water characteristic curve

### 3.1 Empirical model

According to the test data to be analyzed in the semi log coordinate system within a range of test controlled suction, when the suction increases, the moisture content of the mixture shows a decreasing trend. Different temperatures and mixing sand ratios under the conditions of moisture and suction followed the relationship:

$$\omega_T = a - b\ln(\psi + c) \quad (2)$$

Where, $\omega_T$ is the water content of the mixture at different temperatures; $\psi$ is the suction corresponding to different temperatures; *a, b, c* are equation coefficients.

To fit the experimental data under different temperatures, get the series fitting equation by analyzing under different conditions of temperature and sand mix ratios. With the increase of sand mix ratios, the average of parameters shows a decreasing trend, the test parameter c shows an increasing trend with the temperature. A relationship can be found between equation coefficients a, b and mixing sand ratio, presented in (3) and (4).A relationship also exists between the equation coefficient c and temperature，presented in (5).

$$a = k_1 R_s + \lambda_1 \quad (3)$$

$$b = k_2 R_s + \lambda_2 \quad (4)$$

$$c = k_3 e^{\alpha T} \quad (5)$$

Where， $k_1, k_2, k_3$ are 0.49, -0.08, and 1.49; $\lambda_1, \lambda_2$ are respectively 44.58, 6.95; and $\alpha$ is 0.01. Incorporate (3), (4) and (5) into (2), we obtain the equation of soil water characteristic curve of mixture in any temperature and sand mix ratios:

$$\omega_T = k_1 R_s + \lambda_1 - (k_2 R_s + \lambda_2)\ln(\psi + k_3 e^{\alpha T}) \quad (6)$$

### 3.2 Validation of empirical model

Validation of soil water characteristic curve model of mixture under any temperature and sand mix ratios is considered below. Temperatures are taken at 20℃, 40℃, 60℃ and 80℃, sand mix ratios are 0, 20, 40 and 60%, respectively; validation of the established empirical model of soil water characteristic curves of a mixture is carried out. The predicted curve is shown in Figure 5: the forecast curve with the experimental data fits better.

## Conclusion

(1) Within the scope of this article, the dry density has no effect on the soil water characteristic curves of the mixture; impact of temperature, sand mix ratios on oil water characteristic curves of the mixture is obvious; as the temperature increases, water retention capacity of the mixture decreases. For lower suction, when mixing sand ratio increases, the water retention capacity decreases

significantly. For higher suction the impact of the increasing sand mix ratios on the water retention capacity of the mixture is not obvious.

(2) In the semi log coordinates, different temperatures, sand mix ratios are considered, and empirical model of soil water characteristic curve, of a mixture is obtained. The empirical model is used to predict soil water characteristic curves of the mixture of different temperatures and sand mix ratios. Predicted results and experimental data agree with each other well.

**Keywords:** Transformation of open-pit to underground mining; Deformation and failure of slope; Method of limit equilibrium.

**Abstract.** The Yanqianshan iron mine is preparing to transform from an open-pit mine to an underground mine. We adopt the non-pillar sublevel caving approach to exploit the particularly thick steep ore bodies within the range from -183 m to -500 m from top to bottom. According to the features of ore body distribution and the approaches of exploitation, we expect that underground mining will result in the loss of stability on the northern slope of the open pit, causing traction-type landslides. Moreover, along with increasing the depth of the mining operation, the range of slope failure will continue to expand and further affect the safety of drainage features and roads distributed on the north side of the open pit. For this purpose, we select four sections along the trending direction of ore bodies and apply the limit equilibrium method to predict the failure process and characteristics on the northern slope according to the stratified mining process.

## Introduction

The Yanqianshan iron mine was founded in 1960 under open-pit mining practices, which were halted in September 2012. The resulting open pit is 1,410 m long in the east-west direction and ranges from 570 m - 710 m wide in the north-south direction. The elevation of the closed loop is 93 m, and the eventual elevation of the bottom of the open pit is -183 m (Figure 1). The ore bodies of the iron mine are located in the middle of the open-pit, and the trending direction is approximately east-west, tipping in the northeast or southwest directions at a dip angle of 70°-88°, and partially upright. According to the distribution features of ore bodies and the mining methods, we predict that underground mining will result in the loss of stability on the northern slope of the open pit, causing traction-type landslides as a result.

To solve the problem of pit slope deformation and failure caused by the transformation from open-pit to underground mining of metal mines, scholars mainly adopt numerical simulation, model experiment, and on-site monitoring methods. Liu et al. used 2D-Block to study the impact of the transformation of open-pit to underground mining on the slope in the Shizishan mining area of the Daye iron mine [1]. Zhao et al. combined the GPS monitoring data of surface rock movement and FLAC3D numerical simulation to study the impact of the transformation of open-pit to underground mining in the Longshou mine on the stability of rock on the slope, investigating the movement and deformation of wall rocks, the distribution of stress fields, and the failure mechanism [2]. Yang et al. applied FLAC to analyze the displacement field and stress field of the slope during the transformation of open-pit to underground mining in the Nanfen iron mine, in addition to the possible regions of instability [3]. Wang et al. combined PFC and a similar material experiment to study the failure regularity and disaster mechanism of slopes due to the transformation of open-pit to underground mines [4]. Some scholars used similar material model tests to study the failure mechanism of rock layers during the transformation of open-pit to underground mining and the regularity of slope deformation and failure. Sun et al. combined the results obtained for a model test and measurements of mine exploration to investigate the mechanisms of deformation and failure of rock bodies during

the transformation of open-pit to underground mining [5]. Zhang et al. studied the Longshou mine in Jinchuan and analyzed the mechanism of deformation caused by the transformation of open-pit to underground mining in the high-stress area dominated by horizontal tectonic stress, according to the GPS measurement data [6].

To predict the process and regularity of pit slope failure caused by the transformation of open-pit to underground mining and to avoid the loss of personnel and property caused by sudden failure, we apply the limit equilibrium approach and investigate the process and characteristics of failure on the northern slope of an open-pit caused by underground mining according to the actual underground mining process underway in this location. We carry out our study by following the procedure of cyclic analysis as a "simulation of the underground mining-computation of the slope stability-simulation of landslide." Hence, we are able to determine the range of failure on the ground and provide a basis for the layout of drainage and road systems.

## Geology of the mining area and an overview of mining

The Yanqianshan iron mine is located 5 km northeast of the Qianshan scenic area in Anshan City, Liaoning Province, and is 22 km to the west of the center of Anshan City. The southern slope of the iron mine is mainly distributed with mixed rock formations, including gneissic mixed rocks, and granite-like mixed rocks. The basic structural pattern in the mining area is a steep monoclinic structure trending in the direction of 270°-300°, with a dip direction in the northeast or southwest and a dip angle of 70°-88°; that is, the structure is partially upright. The faults in the mining area can be divided into strike faults, oblique faults, and transverse faults, which destroy the integrity of the ore bodies; the main faults are F13, F20, F19, and Fm-1 (Fig.1). The overall trending direction of the ore bodies is 270°-300°., which includes three ore bodies, i.e., Fe1, Fe2, and Fe3; the composition is dominated by ore body Fe1, which is 1,600 m long in the east-west direction and ranges from 55-194 m wide in the north-south direction (Fig.1).

In May 2012, the Yanqianshan iron mine began mining the ore bodies on the eastern and western slopes. The range of mining on the western slope includes the ore bodies to the west of exploration line XIV with an elevation in the range of 21 m to -183 m, and the range of mining on the eastern slope includes the ore bodies to the east of exploration line VII-50 with an elevation in the range of -47 m to -183 m. After mining the eastern and western slopes, the underground ore bodies will be mined, and the range of underground mining includes the ore bodies between exploration lines XVI-IX+100 with elevation in the range of -183 m to -500 m (Fig. 1). The mining activity on the eastern and western slopes and the underground exploration have adopted the non-pillar sublevel caving method, proceeding from the top to the bottom in a horizontal layer approach with an inter-lay thickness of 18 m.

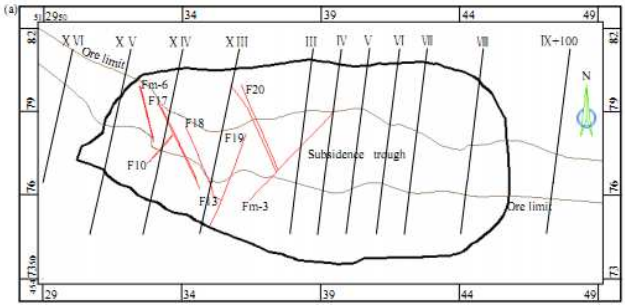

Fig. 1 The geological plan of Yanqianshan iron mine.

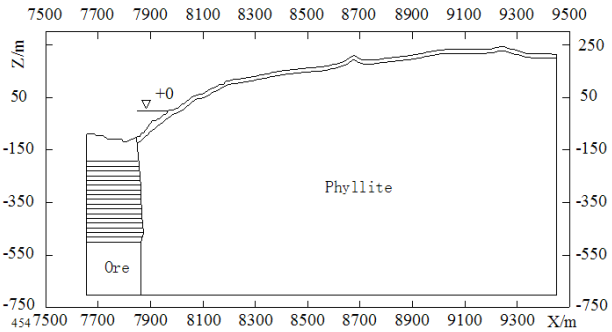

Fig. 2 Computational model of section IV.

## Prediction of the failure process on the northern slope caused by underground mining

**Methods of analysis.** Based on the distribution features and mining methods of ore bodies, we predict the rock movement and failure process caused by the underground mining as follows: (1) After commencing the underground mining practices on the eastern and western slopes, a collapse groove

will appear in the open pit along the trending direction of the ore veins, and the collapse groove will grow increasingly deeper with mining progress on the eastern and western slopes and underground. (2) Along with the deepening of the collapse groove, the rock bodies adjacent to both sides of the collapse groove will displace and begin to slide toward the collapse groove. (3) The collapse of rock bodies adjacent to the two sides of the collapse groove will then cause the loss of the stability of the northern and southern slopes of the open pit, resulting in traction-type landslides. (4) The aforementioned movement and failure of the rock layers will happen repeatedly as the increase of the mine depth, and the range of rock movement and failure caused by underground mining will continue to expand.

In contrast to the conventional analysis of slope stability, during the mining process, the slope of the open-pit discussed in this paper is subject to continuous landslides and collapse that continuously develop into the deeper layers of rock, causing the range of surface failure to undergo continued expansion. Therefore, we select profiles III-VI (Fig. 1) as the typical profile of the northern slope, and we apply the limit equilibrium method to investigate the process and characteristics of failure on the northern slope of the open-pit caused by underground mining. We carry out our analysis in accordance with the actual process of underground mining by following the procedures of cyclic analysis as a "simulation of the underground mining-computation of the slope stability-simulation of landslides." The detailed analytical processes performed for each profile are as follows.

Step 1: According to the stratified process of underground mining, modify the calculation model and simulate the horizontal mining from the current layer downward to the next layer, with a stratified thickness of 18m.

Step 2: Apply the limit equilibrium method to calculate the slope stability after the exploration of one layer, and search and draw the potential sliding surface that corresponds to different safety coefficients.

Step 3: If a sliding surface exists with a safety coefficient smaller than 1.0, cut off the sliding bodies along the minimum sliding surface, and carry out the simulation of landslides and collapse during the mining process.

Step 4: Continue the previous step until there is no remaining sliding surface with a safety coefficient smaller than 1.0.

Step 5: Repeat the procedures of Step 1-Step 4 until the exploration reaches the level of -500 m.

**Determination of the physical mechanical parameters of rock bodies.** In this paper, all of the computation profiles are located in the same partition, and a given type of rock body can use the same physical mechanical parameters. According to the survey report, we determined the physical mechanical parameters for different types of rock bodies, as shown in Table 1.

Table 1 The physical mechanical parameters of rock bodies.

| Rock | Density [g/cm$^3$] | Cohension [Mpa] | Fraction angle [°] |
|---|---|---|---|
| Phyllite | 26.8 | 500 | 40 |
| Ore | 32.7 | 1300 | 41 |

**Model of calculation.** Fig. 2 is the calculation model for profile IV. In the model, the direction of the X-axis points from south to north, and the direction of the Z-axis points from low elevation to high elevation. The range of the computation model is specified as follows: the coordinates of the northern boundary are X = 4, 549, 450 m, and the south side extends to the southern boundary of the ore veins. The Z coordinate for the bottom of the model is -700 m, and the upper part reaches the ground surface. The mining activity in the first step reaches the elevation of -194 m; then, mining proceeds layer-by-layer in 18-m increments, before eventually reaching the elevation of -500 m. The calculation model used for the other profiles is similar to that of profile IV and, hence, is not reiterated here.

**The process of slope failure and an analysis of the characteristics.** With the method of analysis described in section 3.1, we analyze the process and characteristics of failure on the northern slope (profiles III-VI) of the open-pit. The procedures for the analysis of underground mining, the computation of slope stability, and the simulation of landslides are the same for different computation profiles. However, due to the difference in the geometric morphology of the slopes, there is also a difference in the relationship between the slope failure process and mining depth and the position of the most dangerous sliding surface. Fig. 3(a)-(d) give the relationship between the minimum safety coefficient and mining depth for the slopes with profiles III-VI, and Fig. 4(a)-(d) give the relationship between the position of the most dangerous sliding surface and the mining depth for profiles III-VI. In the following, we use profile IV as an example, and we present details about the slope failure process while carrying out the underground mining practice.

Before the underground mining practice is initiated, the minimum safety coefficient of the slope with profile IV is 1.891, and the slope is in a stable state. According to the relevant designs, mining advances to the elevation of -194 m at the first step and then continues for 17 steps, with a mined layer measuring 18 m at each step. To facilitate the narration, we use $\lambda$ to represent the horizontal distance from the intersection between the most dangerous sliding surface and the ground surface to the northern margin of the model. The process and characteristics of failure for the slope with profile IV are as follows.

(1) When the mining activity reaches the elevation from -194 m to -212 m, the slope is in a stable state without landslides, but the minimum safety coefficient of the slope decreases to 1.004. Additionally, the most dangerous sliding surface of the slope moves northward, and the $\lambda$ value is 1, 540 m.

(2) When the mining activity reaches the elevation from -212 m to -230 m, the minimum safety coefficient of the slope is 0.909, and $\lambda$ is 1, 540 m. We cut off the landslide along the sliding surface of the slope that corresponds to the minimum safety coefficient, and then, we calculate the stability of the slope, where the safety coefficient of the slope reaches 1.056. The stability of the slope after a landslide increases, and the most dangerous sliding surface moves northward by 52 m.

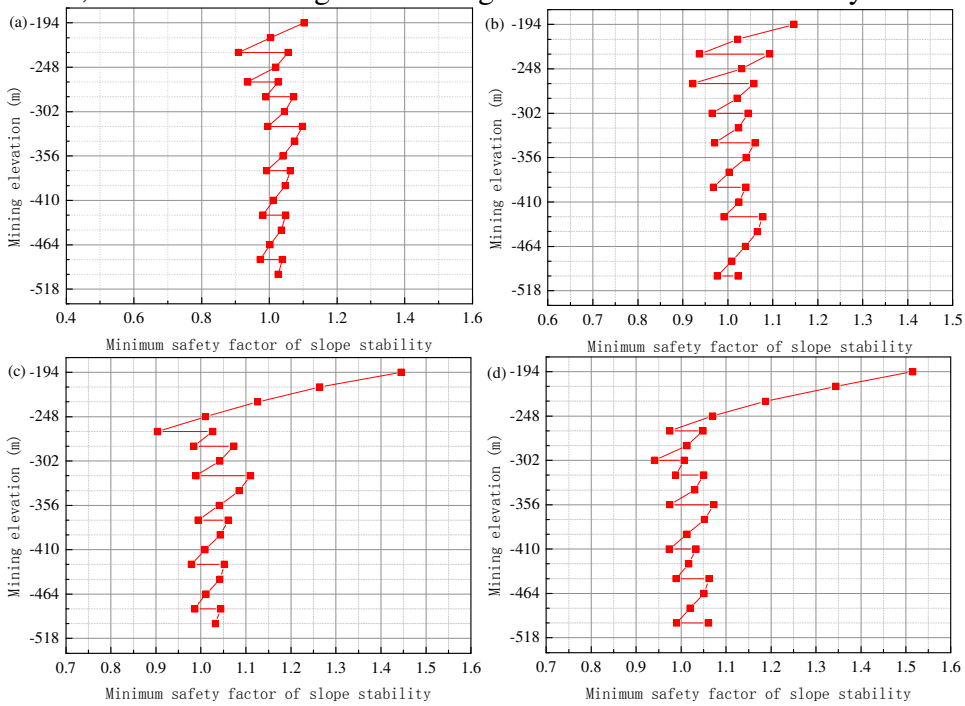

Fig. 3 Relationships between slope failure and mining depth at different sections: (a) Sec. IV, (b) Sec. III, (c) Sec. V, (d) Sec. VI.

(3) When the mining activity reaches the elevation from -230 m to -248 m, the minimum safety coefficient of the slope is 1.017, and $\lambda$ increases from 1, 488 m to 1, 505 m. This indicates that after the first simulation of slope cutting, the stability of the slope increases, and the most dangerous sliding surface moves slightly southward.

(4) When the mining activity reaches the elevation of -266 m, the minimum safety coefficient of the slope is 0.936, and $\lambda$ is 1, 425m. After performing slope cutting on the corresponding sliding surface according to the minimum safety coefficient, we again calculate the stability of the slope, finding that the minimum safety coefficient increases to 1.026 and that the $\lambda$ value becomes 1, 492 m. This indicates that after the second slope-cutting event, the stability of the slope increases again, and the most dangerous sliding surface continues to move northward by 67 m.

(5) When the mining activity reaches the elevation of -284 m, the minimum safety coefficient of the slope is 0.990, and $\lambda$ is 1, 342 m. After performing slope cutting on the corresponding slide surface according to the minimum safety coefficient, we calculate the stability of the slope. The minimum safety coefficient increases to 1.072, with a $\lambda$ value of 1, 434 m. This indicates that after the third landslide simulation, the slope again reaches a stable state, and the most dangerous sliding surface moves significantly northward by 92 m. When the mining activity reaches from -284 m to -302 m, the minimum safety coefficient of the slope is 1.050, and the variation of $\lambda$ is very small. At this time, the slope is in a stable state.

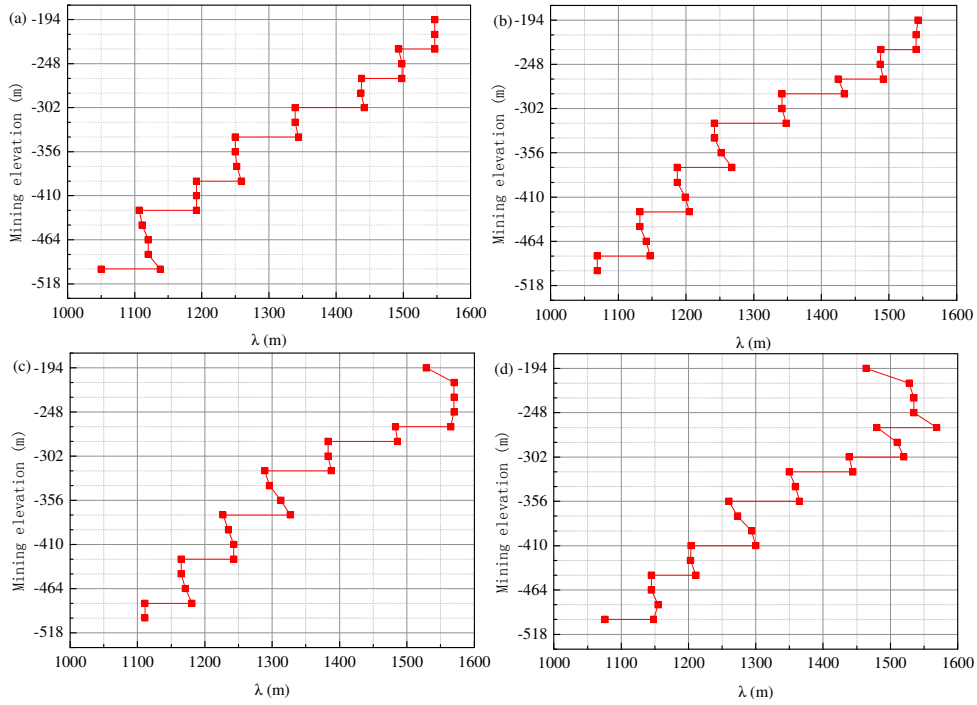

Fig. 4 Relationship between most dangerous sliding surface and mining depth at different sections: (a) Sec. III, (b) Sec. IV, (c) Sec. V, (d) Sec. VI.

(6) When the mining activity continues, reaching the elevation of -320 m, the minimum safety coefficient of the slope is 0.996, and $\lambda$ is 1, 242 m. After the landslide simulations, the minimum safety coefficient is 1.098, and $\lambda$ changes to 1, 348 m. This indicates that when the mining activity reaches the elevation of -320 m, the implementation of a fourth simulated landslide causes the slope to reach a stable state, and the most dangerous sliding surface again moves significantly northward by 106 m. When the mining continues to -338 m, the minimum safety coefficient of the slope is 1.075, without significant change in the most dangerous sliding surface, and the slope is still in a stable state. When the mining activity reaches from -338 m to -356 m, the minimum safety coefficient of the slope is 1.040, and the most dangerous sliding surface again moves slightly southward, with the slope in a stable state.

(7) When the mining activity reaches the elevation of -374 m, the minimum safety coefficient of the slope is 0.992, and $\lambda$ is 1, 187 m. Again, we perform the slope cutting along the sliding surface that

corresponds to the minimum safety coefficient, and we derive the minimum safety coefficient to be 1.062. This indicates that after the fifth simulated landslide, the minimum safety coefficient increases, and the stability of the slope also increases. As a result, the most dangerous sliding surface moves northward by 81 m, and $\lambda$ is 1, 268 m. When the mining activity continues to -392 m, the minimum safety coefficient of the slope is 1.047, without significant change in the most dangerous sliding surface, and the slope is still in a stable state. When the mining reaches from -392 m to -410 m, the minimum safety coefficient of the slope is 1.010, and the most dangerous sliding surface again moves slightly southward, with the slope in a stable state.

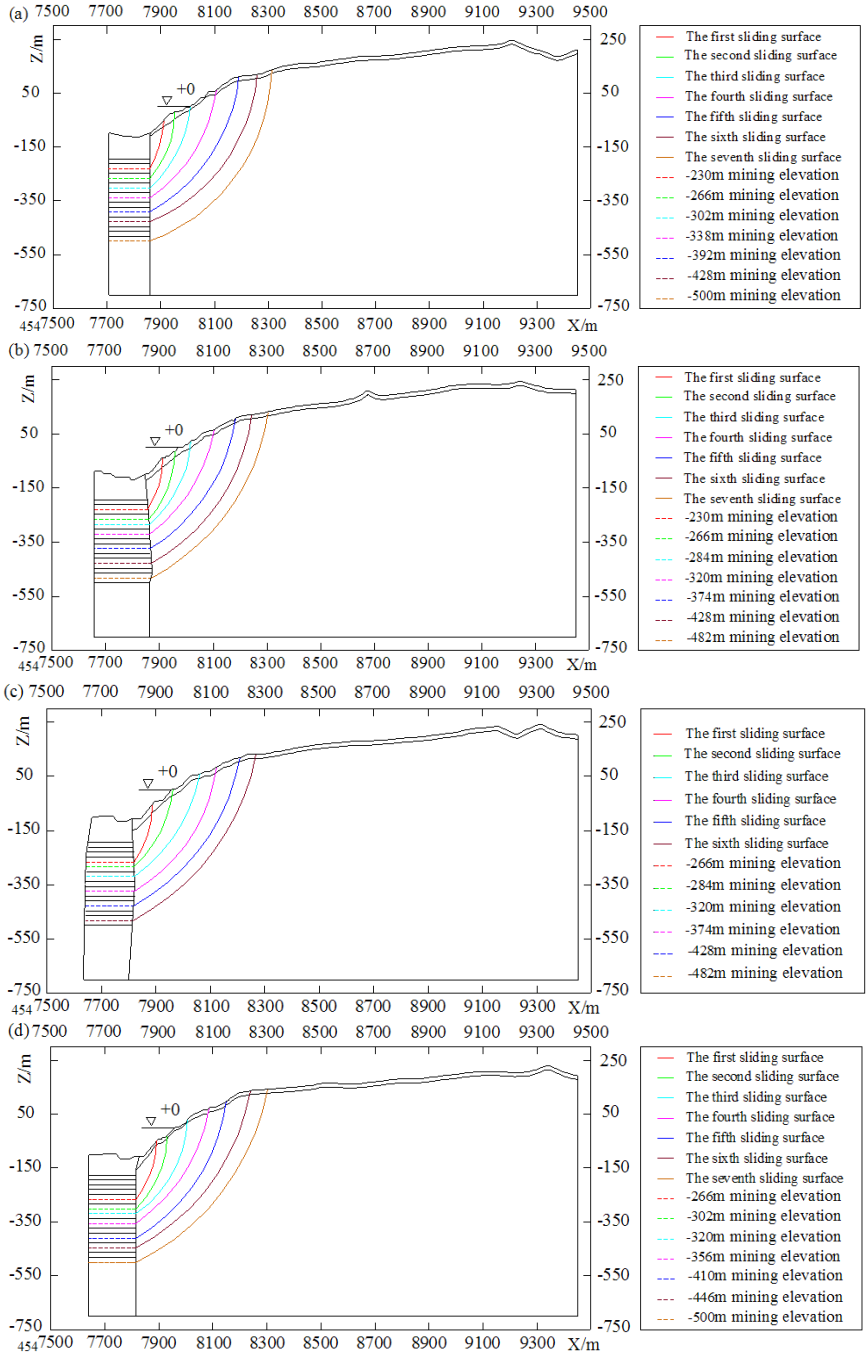

Fig. 5 Relationship between most dangerous sliding surface and mining depth: (a) Sec. III, (b) Sec. IV, (c) Sec. V, (d) Sec. VI.

(8) When the mining activity reaches the elevation of -428 m, the minimum safety coefficient of the slope is 0.981, and $\lambda$ is 1, 132 m. After slope cutting, the calculated minimum safety coefficient is 1.048, and $\lambda$ becomes 1, 205m. It can be seen that when the mining reaches the elevation of -428 m, after the sixth simulated landslide, the minimum safety coefficient increases, and the stability of the slope also increases, and the most dangerous sliding surface moves northward by 73 m. When the

mining activity continues to the elevation of -446 m, the minimum safety coefficient of the slope is 1.036, without a change in the value of $\lambda$; hence, the slope is still in a stable state. When the mining reaches from -446 m to -464 m, the minimum safety coefficient of the slope is 1.020, and the most dangerous sliding surface again moves slightly southward.

(9) When the mining activity reaches the elevation of -482 m, the minimum safety coefficient of the slope is 0.974, and $\lambda$ is 1, 069 m. The minimum safety coefficient with the simulation of slope cutting is 1.039. That is, after the seventh landslide simulation, the minimum safety coefficient increases, as does the slope stability; furthermore, the most dangerous sliding surface again moves northward by 78 m, and $\lambda$ is 1,147 m. When the mining reaches -500 m, the position of the most dangerous sliding surface experiences an insignificant change.

Fig. 5 (a)-(d) give the position of the most dangerous sliding surface with a safety coefficient smaller than 1.0 for profiles III-VI during the mining process. From these figures, it can be seen that during the underground mining activity, seven landslides occur for profile III. After the final landslide, the minimum safety coefficient of the slope is 1.023; a total of seven landslides occur for profile IV, and the minimum safety coefficient of the slope is 1.039; a total of six landslides occur for profile V, and the minimum safety coefficient of the slope is 1.044; a total of seven landslides occur for profile VI, and the minimum safety coefficient of the slope is 1.061.

## Conclusions

(1) The Yanqianshan iron mine is preparing to transform from open-pit exploration to underground mining practices. According to the distribution features of ore bodies and the method of exploration, underground mining will cause the loss of stability on the southern and northern slopes of the open-pit, resulting in traction-type landslides. Moreover, in addition to increasing the depth of the mine, the landslide will continuously occur on the northern and southern slopes of the open-pit, and the range of failure will continuously expand, endangering the nearby buildings and facilities on the surface.

(2) In this paper, we select profiles III, IV, V, and VI for the northern slope of the open-pit as the typical profiles, and we apply the limit equilibrium method to investigate the process and characteristics of failure on the southern slope of the open-pit caused by underground mining. We carry out our investigation according to the actual process of underground mining by following the procedures of cyclic analysis as a “simulation of the underground mining-computation of the slope stability-simulation of landsides.”

(3) We establish the minimum safety coefficient and relationship between the location of the most dangerous sliding surface on the slope and mining depth for the slope of each typical profile. Additionally, we predict the process of slope failure, and we analyze the impact of the range of slope failure on the buildings and facilities on the ground surface.

**Key words:** squeezed branch pile; combined load; bearing properties; model test

**Abstract.** In this article, we design an experiment about model piles to study their bearing capacity and deformation properties under uplifting load of different angles, model piles include the equivalent-diameter pile, the squeezed branch pile with single plate and the squeezed branch pile with two plates. The test shows, the bearing capacity of squeezed branch pile is higher than the equivalent-diameter pile, and its plates can resist the horizontal load on the top of pile better.

In the actual project, pile foundation often bears various loads, such as vertical load, horizontal load and bending moment, etc. The bearing properties of squeezed branch pile under one-way load have been studied many times, but the study of bearing properties under combined load has not been reported almost. In this article, we carry out a model experiment of the squeezed branch pile under vertical load and horizontal load together to increase access to its bearing properties.

## The brief test introduction

There are 3 model piles in this experiment, no.1 is the equivalent-diameter pile, no.2 is the squeezed branch pile with single plate and no.3 is the squeezed branch pile with two plates, as shown in Figure 1. The pile shaft is a steel pipe with 50mm in diameter and 60mm in length, and the plate is a steel plate with 120mm in diameter and 20mm in thickness. In order to increase the model pile's surface roughness, we brush a layer of cement slurry on the steel pipe. We carry out this experiment in the soil tank of Geotechnical Laboratory of our college, its plane dimension is 0.6*1.5m and its depth is 0.85m, the test soil sample is generic homogeneity silt from Xiasha Hangzhou. We bury the three model pile into the soil tank in place and tamp the test soil sample in layers before the experiment, the place as shown in Figure 1.

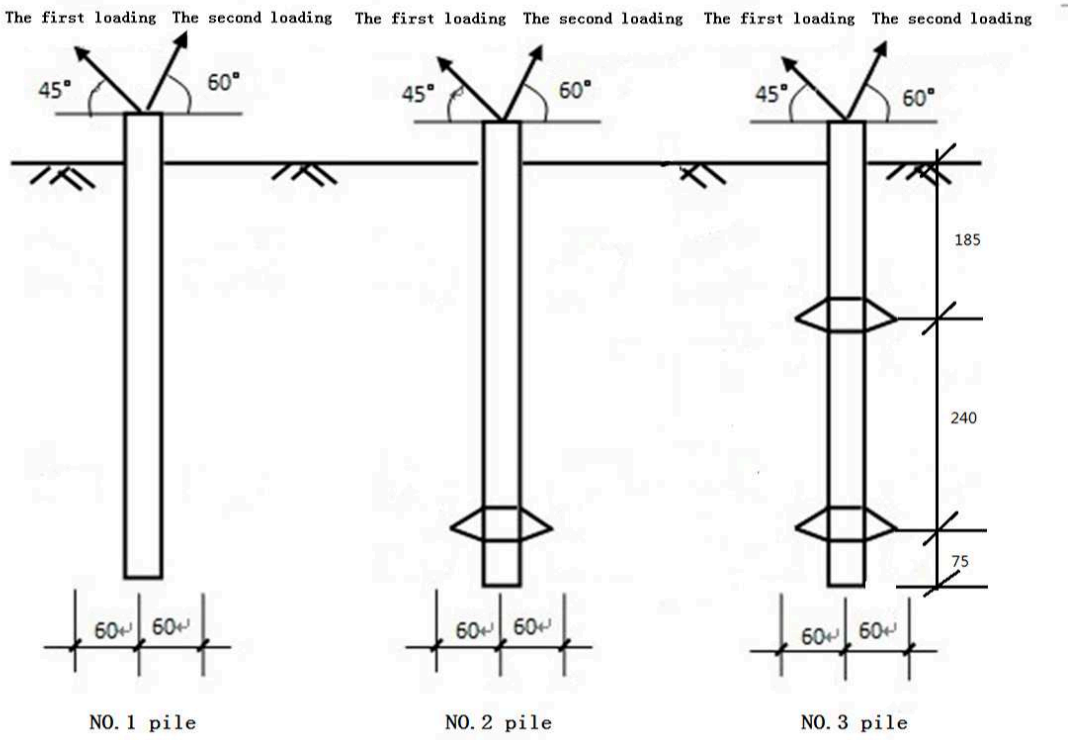

Fig.1 The model piles and loading schematic diagram

For comparison, two groups of loading are be designed in this experiment, in the first group, three piles are studied under uplifting horizontal load of 45 degree angle, in the second group, three piles are studied under uplifting horizontal load of 45 degree angle.

## Q-S curve analysis

According to the load and horizontal displacement measured by experiment, we can get the Q-Sv curve as shown in the figure below:

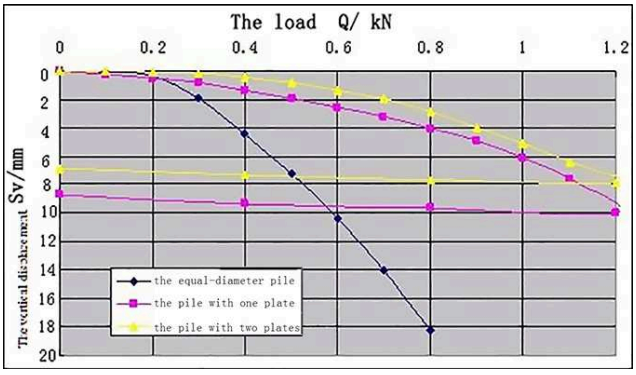

Fig.2-1 The Q-$S_v$ curve when the load inclination is 45 degree

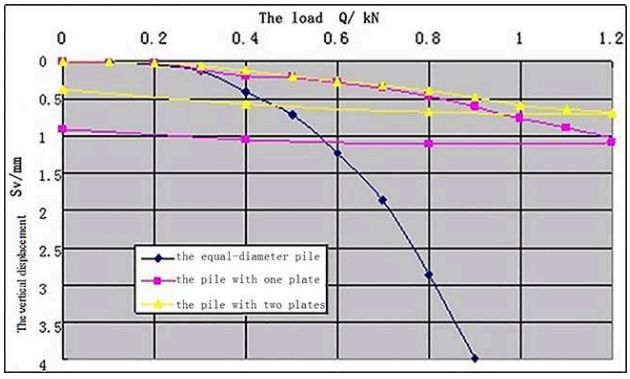

Fig.2-2 The Q-$S_v$ curve when the load inclination is 60 degree

According to the load and horizontal displacement measured by experiment, we can get the Q-Sh curve as shown in the figure below:

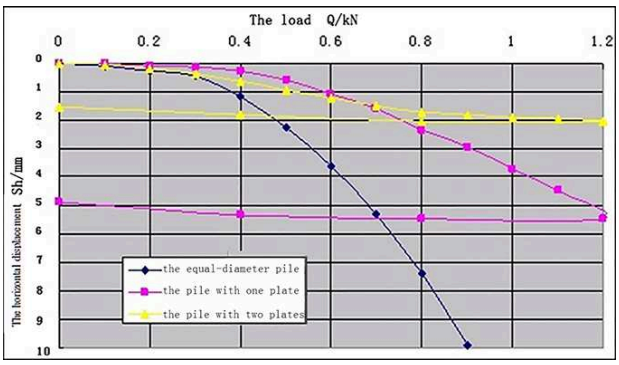

Fig.2-3 The Q-$S_h$ curve when the load inclination is 45 degree

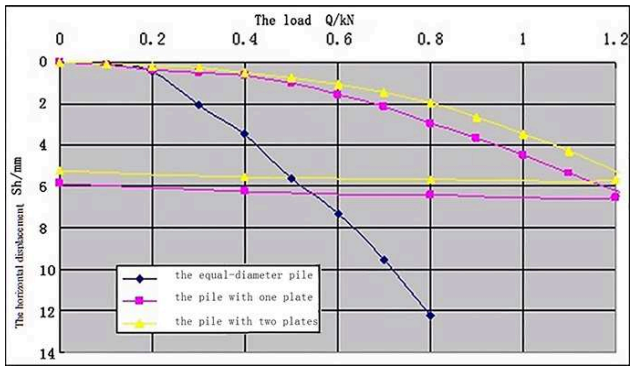

Fig.2-4 The Q-$S_h$ curve when the load inclination is 60 degree

To analyze the curve features above-mentioned, we can get the following results:

1) According to the analysis of figure 2-1~2-4, we find the Q-Sv curve and Q-Sh curve of the squeezed branch pile is more flat without steep drop, compared with general equivalent-diameter piles, under inclined load. If determine the bearing capacity with the equal displacement, we can find the bearing capacity of squeezed branch pile is higher than the general pile's, which fully embody the advantage of the squeezed branch pile's bearing capacity.

If take horizontal deformation of 4 mm as a control condition of bearing capacity, we find the bearing capacity of the equivalent-diameter pile is about0.62kN and of the squeezed branch pile with single plate is about 1.03kN when 45 degree load inclination. The bearing capacity of the squeezed branch pile with single plate increase by 66%, compared with the equivalent-diameter pile, and the bearing capacity of the squeezed branch pile with single plate is much higher(because the displacement of two plates pile do not load to 4mm, it is not strictly comparable).

When 60 degree load inclination, the bearing capacity of the equivalent-diameter pile is about 0.43kN and of the squeezed branch pile with single plate is about 0.94kN, compared with the equivalent-diameter pile, the bearing capacity of the squeezed branch pile with single plate increase by 119%

2) To displacement, when the load inclination is 45 degree and the load is 0.8kN, the vertical displacements of three piles are 2.86mm, 0.47mm, 0.39mm, we can find the displacements of the single plate pile and two plates pile are 16 and 14 percent of the equivalent-diameter pile's. Meanwhile, the horizontal displacements of three piles are 7.39mm, 2.37mm, 1.72mm, and the displacements of the single plate pile and two plates pile are 32 and 23 percent of the equivalent-diameter pile's displacements. So the squeezed branch pile has the better capability to resist deformation caused by horizontal load and uplifting load, and the more plates, the more favorable.

3) Different load angles, that is to say, the proportion of horizontal load and vertical load is different, have an effect on the load-bearing performance of piles. For the equivalent-diameter pile, when 45 degree load inclination, its Q-Sv curve is no obvious steep fall, but when 60 degree load inclination,

the steep fall point is obvious. According to the phenomenon, we can assume that when the load horizontal component is larger, the friction increases as the increase of pressure on pile-soil interface, thus the uplift bearing capacity increases.
For squeezed branch piles, the phenomenon of high uplift bearing capacity caused by large horizontal load is obvious, especially the pile with two plates, there appear a inflection point in its Q-Sv curve, when the load increase to a value, the deformation of piles with two plates is insensitive to load, it is called “uplifting stamina”.

4) According to the test data when the load inclination is 45 and 60 degree, we can get the ratio $S_v/S_h$ between the vertical and horizontal displacement as shown in the table below:

Table.1 The ratio $S_v/S_h$ when the load inclination is 45 degree

| The pile mark | NO.1 pile | NO.2 pile | NO.3 pile |
|---|---|---|---|
| $S_v/S_h$ | 0.39 | 0.2 | 0.23 |

Table.2 The ratio $S_v/S_h$ when the load inclination is 60 degree

| The pile mark | NO.1 pile | NO.2 pile | NO.3 pile |
|---|---|---|---|
| $S_v/S_h$ | 1.5 | 1.37 | 1.44 |

From the above tables, we can assume that the load inclination is sensitive to the deformation in both directions when the pile foundation bears the uplifting and horizontal load. When the load inclination is 45 degree (the load ratio is 1:1 in vertical and horizontal directions), the horizontal displacement of three piles is larger than the uplifting. But when the inclination increase 15 degree to 60 degree (the load ration is 1.73:1 in vertical and horizontal directions), the horizontal displacement of three piles is less than the uplifting displacement.

So in the actual project, we should consider that the combined load composed of uplifting and horizontal load is sensitive to the displacement variation. For example, when it requires high level for deformation control in one direction, we should emphasize to strengthen the anti-deformation design of pile foundation in the direction.

**Conclusions**

1) Compared to the equivalent-diameter pile with the same length and diameter, the load bearing behavior of squeezed branch piles under uplifting inclined loads is similar with the behavior loaded in one way(horizontal or vertical direction), and There is a significant increase in the bearing capacity of squeezed branch piles, especially the piles with two plates.

2) The squeezed branch pile has a better capability to resist deformation caused by horizontal and uplifting loads, and the more plates, the more favorable.

3) When the proportion of horizontal load and vertical load is different (the load inclination is different), there is an effect on the load-carrying properties of piles. The appropriate horizontal load can increase the pressure on pile-soil interface, and increase the friction force, and enhance the uplifting bearing capacity.

4) The experiment shows that the combined uplifting inclination is very sensitive to the deformation in two directions.

**Keywords:** Combustible ice, Marine sediments, Triaxial test, Mechanical property

**Abstract.** Combustible ice is a kind of efficient and clean energy that has the potential to be exploited in the future, exploiting combustible ice needs to understand its mechanical properties. Combustible ice is another important feature of soil which is different from soil, in order to correctly understand the distinction, this paper using soil mechanics triaxial test method, to study the mechanical properties of combustible ice. Different from previous study, this article put forward the concept of simulated combustible ice, namely through baking powder, sodium chloride, and Marine sedimentary soil to simulate flammable ice, explore a new method for sample preparation to study the mechanical property of combustible ice.

## Introduction

Combustible ice is a kind of cage ice crystals generated by gas and water in a range of high pressure and low temperature conditions, so is also called gas hydrate. It widely distributed in the mainland, deep sea and some inland lake. It is a new energy with huge reserves [1-2]. According to statistics, the total energy of gas hydrate in the world is about 2~3 times more than coal, oil and gas, 27% of the mainland and 90% of the sea containing gas hydrate [3]. As the world's energy dried up, Combustible ice has got more and more attention as a kind of clean energy. In recent 10 years, combustible ice is known as the crown of 21st century new energy [4].

Before exploiting gas, we must carry on the experiments of gas hydrate research. Research on simulation test, Hyodo [5] and Clayton [6] created the integration of triaxial test apparatus. Experimental study on the mechanical properties of hydrate sediments at home and abroad work started relatively late, so the literature of hydrate sediments mechanical properties research reports is limited to the laboratory test results of Winters, Hyodo, Masui and Clayton et al. The study of hydrate sediments stress-strain relationship and strength characteristics need to be further [7].

It is tedious and expensive to improve equipment and prepare simulated sample in the study of combustible ice. That goes against the fundamental research of combustible ice. Relative to the complex equipment modification and sample preparation, this paper proposes a new idea, simulated combustible ice which means using conventional materials to simulate the structure form of combustible ice, get the mechanics performance through triaxial test and analysis the geological problems may encounter in the process of exploit combustible ice.

## Test introduction

Domestic experts agreed in three basic aspects about the study on combustible ice [8-10]: ①Macroscopic mechanical properties of combustible ice difference is mainly caused by the different methods of its formation; ②Combustible ice strength characteristics associated with test conditions, such as confining pressure, initial porosity and so on; ③The strength of combustible ice is associated with the particle properties of sediments. At home and abroad for the simulation of combustible ice is used more high voltage equipment simulated conditions of combustible ice generated at low temperature, at the same time, take advantage of highly visual equipment to observe the formation and decomposition of combustible ice. But for the mechanics characteristic test, these test conditions are not important. Therefore, the author thought that as the key models of combustible ice is mainly

focused on three aspects: ①The choice of skeleton particles; ②The cellular structure of sediment; ③The simulation of combustible ice crystal particles.

**Skeleton Particle.** Skeleton particles of test sample preparation using Marine sedimentary soil. Marine deposit refers to the Marine environment by Marine dynamic process to produce a series of deposits, including debris from land and Marine biological bone and debris, ash and cosmic dust, etc, with a series of lithologic features and biological characteristics of Marine environment. Marine sediments is the breeding of oil and gas, selected areas of Hainan island coastal deposition by dry sieving to make combustible ice soil sample can suit the requirements of triaxial test.

**Cellular Structure.** Cellular structure is due to leave the sediment space after the release of crystals gas. The cellular structure is accomplished by baking powder. The acid salt in baking powder can react with carbonate and control the speed of gas velocity. Carbonates are hydrolyzed in water balance:

$$HCO_3^- + H_2O \Leftrightarrow H_2CO_3 + OH^- \quad (1)$$

$$H_2CO_3 \Leftrightarrow H_2O + CO_2 \uparrow \quad (2)$$

Reaction to the right to produce large amounts of gas when the system of ph or temperature changes. Acidic salt by hydrolysis or ionization effect change system of ph in the reaction process, thus affecting the carbonate gas.

**Crystal Particle.** The most common type of combustible ice crystal structure form is six sides cube. In order to achieve the simulation test under atmospheric pressure, select properties of stable and crystal particles with six sides of the cube sodium chloride is most appropriate.

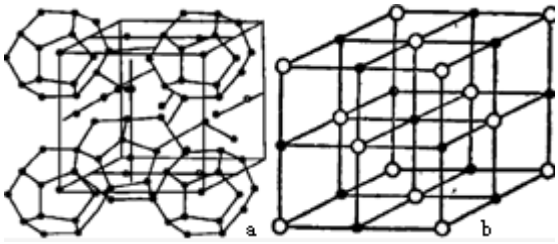

Fig. 1 Comparison of Gas hydrate and Sodium chloride

(a-Gas hydrate the diamond cubic structure diagram; b-Sodium chloride cubic structure diagram). As can be seen from the figure 1 both gas hydrate and sodium chloride are six sides cube. Experiment chose the sun sea water to prevent crystallization of large granular sodium chloride crystals test of sodium chloride in the process of early into the soil.

**Test Set.** Combustible ice is another important characteristic of soil and different from the soil. Triaxial test can correctly understand the difference. Triaxial test set to three kinds: consolidation test; consolidation undrained test; not consolidated undrained test. Simulations of combustible ice exploit process in different project environment.

## Combustible Ice Sample Triaxial Test

**Consolidation-Drainage Triaxial Test (CD).** Consolidation drained shear test set $\sigma_3 = \sigma_c$, five consolidation pressures $\sigma_c$ rank: 0kPa; 50kPa; 75kPa; 100kPa; 150kPa. Reverse pressure saturated samples first, then consolidated under $\sigma_c$, drainage shear keep $\sigma_3 = \sigma_c$ at last. Each level cell pressure 1 set of tests are carried out, sample size: $\phi 50 \times 100$.

The stress strain curve is shown in figure 2. From figure 2 we can see sample of combustible ice present plastic damage, the higher confining pressure, the greater intensity.

**Consolidated-Undrained Triaxial Test (CU).** The strength index of consolidated undrained can be used for seabed combustible ice under the water level change suddenly during exploit. Test set five cell pressures: 0kPa, 50kPa, 75kPa, 100kPa, 150kPa. Each level cell pressure 1 set of tests are carried out, sample size: $\phi 50 \times 100$.

The stress strain curve is shown in figure 3. From figure 3 we can see sample of combustible ice present plastic damage, the higher confining pressure, the greater intensity.

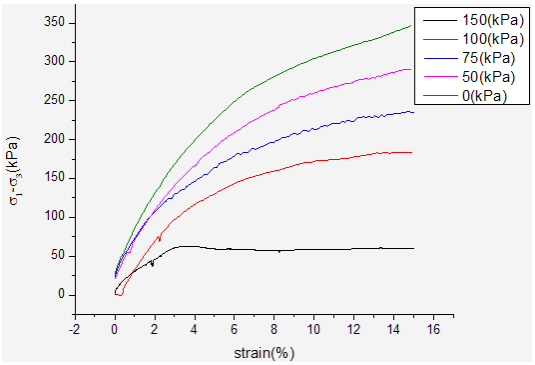

Fig. 2 The stress-strain diagram of CD

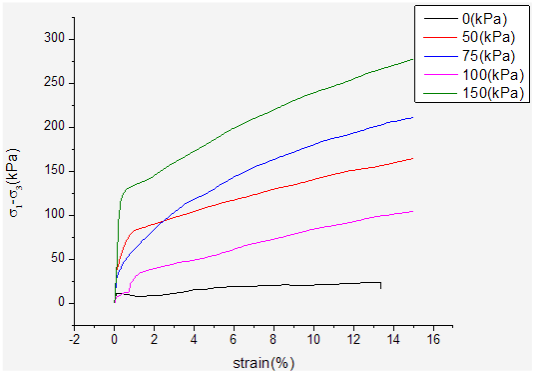

Fig. 3 The stress-strain diagram of CU

**Unconsolidated-Undrained Triaxial Test (UU).** Undrained strength is used to the pore water pressure dissipation caused by load increase and density not remains the same. If the viscosity of combustible ice carrier soil is big and permeability is little, we should use this strength when drainage condition is poor. This test is divided into two groups, a set of crystal content 5%, and another group of crystal content 10%. The group of 5% has five cell pressure levels: 50kPa; 100kPa; 150kPa; 200kPa; 300kPa. The group of 10% has four cell pressure levels: 50kPa; 100kPa; 150kPa; 200kPa.

Crystal content 10% obtained a set of test stress strain curve as shown in figure 4 and crystal content 5% obtained a set of test stress strain curve as shown in figure 5.

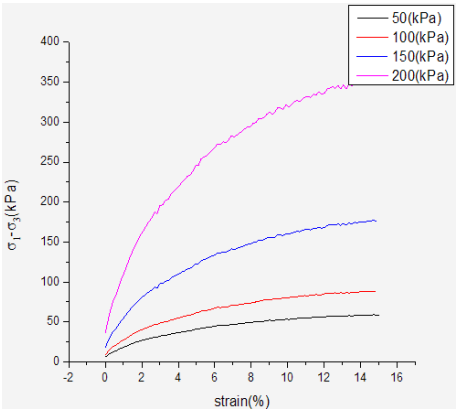

Fig. 4 The stress-strain diagram of UU (10%)

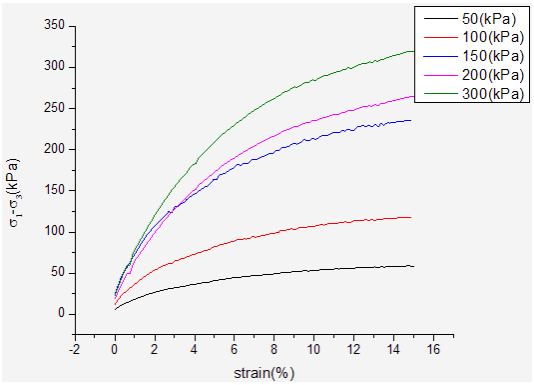

Fig. 5 The stress-strain diagram of UU (5%)

By comparing the figure 4 and figure 5 can be learned, the peak compressive strength difference of combustible ice sample with different crystal content under same cell pressure is very big, to compare the same cell pressure with different contents of crystal to analyze the crystal content on the compressive peak as combustible ice peak compressive strength of Marine sediment sample, draw the table 1:

Table 1 The same cell pressure the comparison of different crystal content compressive peak

| Cell pressure | Peak strength（5%） | Peak strength（10%） | Strength added(kPa) |
|---|---|---|---|
| 50kPa | 58.68 | 63.72 | 5.04 |
| 100kPa | 88.02 | 117.36 | 29.34 |
| 150kPa | 176.04 | 234.72 | 58.68 |
| 200kPa | 264.25 | 352.08 | 87.83 |

Table 1 illustrates that peak strength of combustible ice sample increased along with the increase in crystal content under the same cell pressure. At the same time, the peak strength of combustible ice sample increased along with the increase of cell pressure. This is because the crystals in combustible ice sample played the cementation in traxial shear compression process and the greater the cell pressure cementation, the more obvious.

## Conclusion and Outlook

Using baking powder, sodium chloride and Marine sedimentary soil to simulate combustible ice sample is feasible. Compared the CD and CU test, crystal affect little to the internal friction angle of

combustible ice sample, mainly because of the cementation of pore water pressure and crystal of combustible ice sample's cohesive force. The cellular structure produced by baking powder generated gas to combustible ice sample peak compressive strength effect remains to be further research. Different skeleton materials combustible ice samples should be studied by means of triaxial test in response to the kinds of geological environment during exploiting combustible ice.

# Weak Form Quadrature Element Analysis of Diaphragm Walls

Ye Li[1,a], Hongzhi Zhong[1,b]

[1] Department of Civil Engineering, Tsinghua University, Beijing 100084, China

[a]superl_y@sina.com, [b]hzz@mail.tsinghua.edu.cn

**Keywords:** weak form quadrature element; diaphragm wall; Rankine's earth pressure theory

**Abstract.** In combination with Rankine's earth pressure theory, a weak form quadrature element formulation is established for analysis of diaphragm walls. Results are compared with those of Paroi2, a finite element software package for diaphragm walls, to demonstrate the effectiveness and the advantages of the present formulation. Accurate results are obtained with only a few weak form quadrature beam elements, contrasting with dense finite element division that is needed for complex load distributions over the diaphragm wall.

## Introduction

For large-scale suspension bridges, the entire loads on the girder are transmitted to the tower through cables. As a result, the main cable usually bears large force. In order to provide a strong constraint at the end of the main cable, an anchorage is designed effectively to transmit the cable force to the basis.

Depending on the attachment of cables, there are two-types of suspension bridges: self anchored and earth anchored; while the earth anchored suspension bridges are further classified into rock anchor bridges and gravity-type anchor bridges. A gravity-type anchor balances the main cable tension with the anchorage gravity, and bears most action of gravity during construction. The anchorage with diaphragm wall is an important type of gravity-type anchor. Yangluo Yangtze River Bridge [1] and Humen No.2 Bridge both use diaphragm wall anchorage foundation.

Diaphragm walls, buried deeply in the ground, usually form a circular or rectangular cross section envelope of anchor. It ensures the stability of the structure during layerwise excavation inside the diaphragm wall and adding support on the inner side of the diaphragm wall at the same time. After the formation of foundation trench, cylindrical or cubic shape of mass concrete anchorage foundation would be built by placing concrete inside and capping.

It is important to ensure the serviceability of diaphragm walls all the time. Not only during normal operation phase but also during the construction is the analysis of diaphragm wall integral to its reliability. With the continual excavation of one side soil and adding support, the stress of the diaphragm wall varies from time to time. Therefore, engineers need to calculate the bending moment envelope curve of diaphragm walls and design parameters accordingly.

## Diaphragm wall and soil pressure

As shown in Fig.1, each section of diaphragm wall is simplified into a strut [2]. For cylindrical anchorage foundation, the diaphragm walls form a circular ring. Normally a section of diaphragm wall deforms in the radial direction and lateral sides of the section are constrained. In calculation, the lateral constraint is simplified as additional distributional stiffness acting on the diaphragm wall.

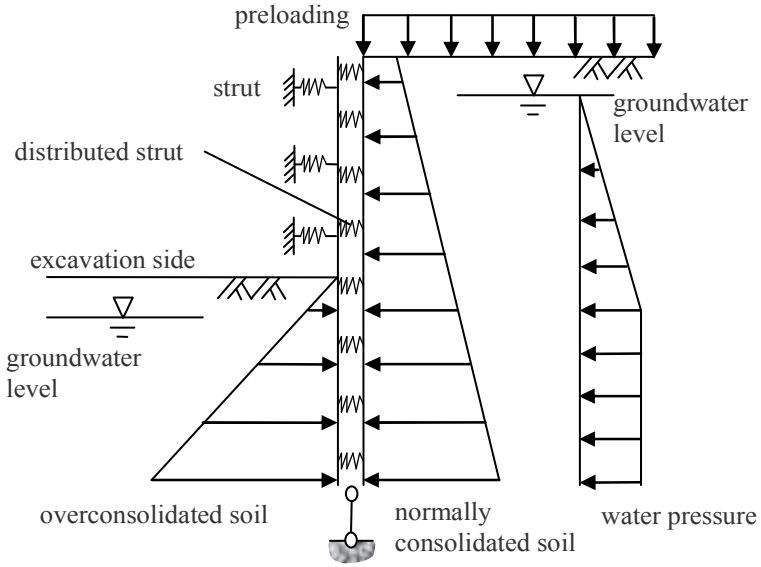

Fig 1. Strut model of diaphragm wall

Before excavation, there is a certain preloading on the ground. With progress of excavation, the groundwater level of the excavation side declines at the same time. Water and soil are treated separately to gain the force exerted on the wall. Static pressure is taken as water pressure, disregarding the impact of seepage. Soil stress is calculated based on Rankine's earth pressure theory [3] for which the stress-strain relationship is shown in Fig 2. On the excavation side, over consolidated soil model is used while normally consolidated soil model is used on the other side.

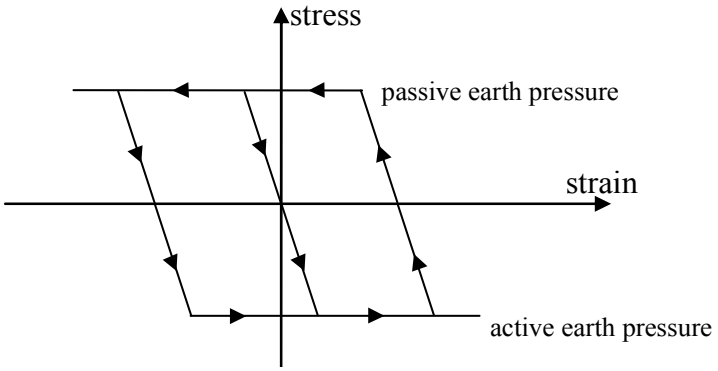

Fig. 2 Stress-strain relationship of soil based on Rankine's earth pressure theory

Paroi2 is a specific finite element software package for analysis of diaphragm walls which is currently used in some bridge design institutes. Usually, the finite element beam element is only suitable for uniform additional stiffness and load. Consequently, large result errors may arise if coarse finite element mesh is used in the case of nonlinearly distributed soil pressure.

In contrast, weak form quadrature beam element has shown its advantages in dealing with complex load distribution in previous studies [4-8]. In addition, weak form quadrature element analysis can achieve accurate simulation with sparse element division.

**A quadrature element for diaphragm wall**

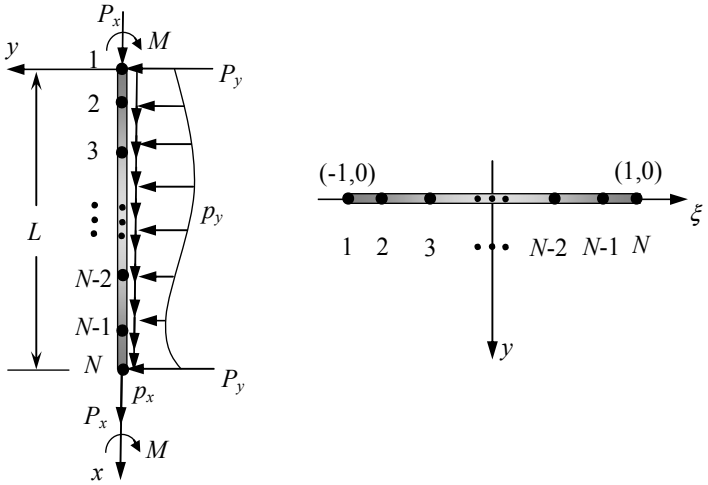

Fig 3. Quadarture element and integration points

As shown in Fig 3, a quadrature element, an abbreviation for weak form quadrature element, is mapped onto the normalized coordinate before analysis. Coordinate transformation formula is chosen as [8]

$$\xi = x/S - 1, S = L/2 . \tag{1}$$

The black dots in Fig 3 are integration points. There are two translational degrees of freedom at every integration point, while each end point is endowed with a rotational degree of freedom additionally.

The element displacement vector can be expressed as

$$\mathbf{d}^{(\mathrm{e})} = \left[\mathbf{d}_1^{\mathrm{T}} \quad \mathbf{d}_N^{\mathrm{T}} \quad \mathbf{d}_2^{\mathrm{T}} \quad \cdots \quad \mathbf{d}_{N-1}^{\mathrm{T}}\right]^{\mathrm{T}} \tag{2}$$

$$\mathbf{d}_i^{\mathrm{T}} = \begin{cases} \left[u_i \quad v_i \quad \left(\dfrac{\mathrm{d}v}{\mathrm{d}\xi}\right)_i\right], & i = 1, N; \\ \left[u_i \quad v_i\right], & i = 2, ..., N\text{-}1. \end{cases} \tag{3}$$

The strain vector is given as

$$\overline{\boldsymbol{\varepsilon}}(x) = \begin{Bmatrix} \varepsilon \\ \kappa \end{Bmatrix} = \begin{Bmatrix} \dfrac{\mathrm{d}u}{\mathrm{d}x} \\ \dfrac{\mathrm{d}^2 v}{\mathrm{d}x^2} \end{Bmatrix} \tag{4}$$

which is related to the strain vector in the normalized coordinate through

$$\overline{\boldsymbol{\varepsilon}}(x) = \mathbf{D}\boldsymbol{\varepsilon}_0(\xi) \tag{5}$$

where

$$\mathbf{D} = \begin{bmatrix} \dfrac{1}{S} & 0 \\ 0 & \dfrac{1}{S^2} \end{bmatrix}, \ \boldsymbol{\varepsilon}_0(\xi) = \begin{Bmatrix} \dfrac{\mathrm{d}u}{\mathrm{d}\xi} \\ \dfrac{\mathrm{d}^2 v}{\mathrm{d}\xi^2} \end{Bmatrix}. \tag{6}$$

The quadrature element formulation is established based on the virtual work principle. The expressions of external and internal virtual work can be given as

$$\delta U_{\text{ext}}^{(\text{e})} = -S\int_{-1}^{1}(p_x\delta u + p_y\delta v)\mathrm{d}\xi - (P_x\delta u + P_y\delta v + \frac{M}{S}\frac{\mathrm{d}v}{\mathrm{d}\xi})\Big|_{\xi=\pm1} \tag{7}$$

$$\delta U_{\text{int}}^{(\text{e})} = S\int_{-1}^{1}\delta\overline{\boldsymbol{\varepsilon}}^{\mathrm{T}}\mathbf{R}\mathrm{d}\xi + S\int_{-1}^{1}k_y v\delta v\mathrm{d}\xi + K_y v\delta v\Big|_{\xi=\pm1} \tag{8}$$

The soil pressure is taken into account in external virtual work, and the effect caused by soil pressure is included in internal virtual work. In Eq. (8), $\mathbf{R}^T=[N(\xi)\quad M(\xi)]$ is section internal force vector; $k_y$ is distributional additional stiffness resulting from variation of soil pressure and lining support; $K_y$ is elastic support stiffness at ends. It is noteworthy that repeated calculation of elastic support at ends should be avoided.

Lobatto quadrature with $N$ sampling points is used to evaluate the integrals in Eqs. (7) and (8) which are rewritten as

$$\delta U_{\text{ext}}^{(\text{e})} = -\delta\mathbf{d}^{(\text{e})\mathrm{T}}\mathbf{F}^{(\text{e})} \tag{9}$$

$$\delta U_{\text{int}}^{(\text{e})} = S\sum_{i=1}^{N}W_i\delta\overline{\boldsymbol{\varepsilon}}_i^{\mathrm{T}}\mathbf{R}_i + S\sum_{i=1}^{N}W_i k_{yi}v_i\delta v_i + K_{yi}v\delta v\Big|_{\xi=\pm1} \tag{10}$$

where $W_i$ are the weighting coefficients for Lobatto quadrature.

The virtual work principle states

$$\delta U_{\text{ext}}^{(\text{e})} + \delta U_{\text{int}}^{(\text{e})} = 0 \tag{11}$$

which gives the equilibrium equations. To find the solution of the equilibrium equations, an incremental form of the equilibrium eqautions is needed, which can be written in matrix form as

$$\delta\mathbf{F}^{(\text{e})} = \mathbf{K}^{(\text{e})}\delta\mathbf{d}^{(e)} \tag{12}$$

where $\mathbf{K}^{(\text{e})}$ is the tangent stiffness matrix given by

$$\mathbf{K}^{(\text{e})} = S\sum_{i=1}^{N}W_i\mathbf{B}_{0i}^{\mathrm{T}}\mathbf{D}\mathbf{k}_i\mathbf{D}\mathbf{B}_{0i} + \overline{\mathbf{K}}_a \tag{13}$$

where $\overline{\mathbf{K}}_a$ is a diagonal matrix representing the additional stiffness matrix, i.e.

$$\overline{\mathbf{K}}_a = diag\left(\mathbf{K}_{a1}\quad 0\quad \mathbf{K}_{aN}\quad 0\quad \mathbf{K}_{a2}\quad \mathbf{K}_{a3}\quad \cdots\quad \mathbf{K}_{a(N-1)}\right) \tag{14}$$

$$\mathbf{K}_{ai} = \begin{cases}\left[0\quad SW_i k_{yi} + K_{yi}\right], & i=1,N;\\ \left[0\quad SW_i k_{yi}\right], & i=2,...,N-1;\end{cases} \tag{15}$$

and

$$\begin{aligned}&\mathbf{B}_{0i} = \left[\mathbf{B}_{0i,2}\quad \tilde{\mathbf{B}}_{0i,1}\quad \mathbf{B}_{0i,N+1}\quad \tilde{\mathbf{B}}_{0i,N+2}\quad \mathbf{B}_{0i,3}\quad \cdots\quad \mathbf{B}_{0i,N}\right]\\ &\mathbf{B}_{0i,j} = \begin{bmatrix}C_{i(j-1)}^{(1)} & 0\\ 0 & G_{ij}^{(2)}\end{bmatrix}, \tilde{\mathbf{B}}_{0i,j} = \begin{bmatrix}0\\ G_{ij}^{(2)}\end{bmatrix}\end{aligned} \tag{16}$$

where $C_{ij}^{(1)}$ and $G_{ij}^{(2)}$ are the weighting coefficients for the differential quadrature analog and the generalized differential analog [8], respectively. The section stiffness matrix of the element is given by

$$\mathbf{k}(x)=\begin{bmatrix} EA & 0 \\ 0 & EI \end{bmatrix}. \tag{17}$$

**An example**

The anchor of Humen No.2 Bridge is examined here to verify the quadrature element formulation. The anchor is in the shape of a circular cylinder with 90m in diameter and 27m in depth. It is a reinforced concrete structure.

The diaphragm wall under consideration consists of 4 soil layers: mucky soil, gravelly sand, strong weathered shaly sandstone and weathered sandstone. The parameters of the soil are taken from the geological exploration report. It is 36m from the ground plane to the bottom of the diaphragm wall. During construction, the foundation trench is excavated for 9 times with 3m excavating depth each time.

Paroi2 and the quadrature beam element are used to calculate the internal forces respectively and results are compared. In analysis with Paroi2, the diaphragm wall is divided into 27 segments and 5 elements per segment. In quadrature element analysis, the diaphragm wall is modelled with 13 beam elements, each with three integration points.

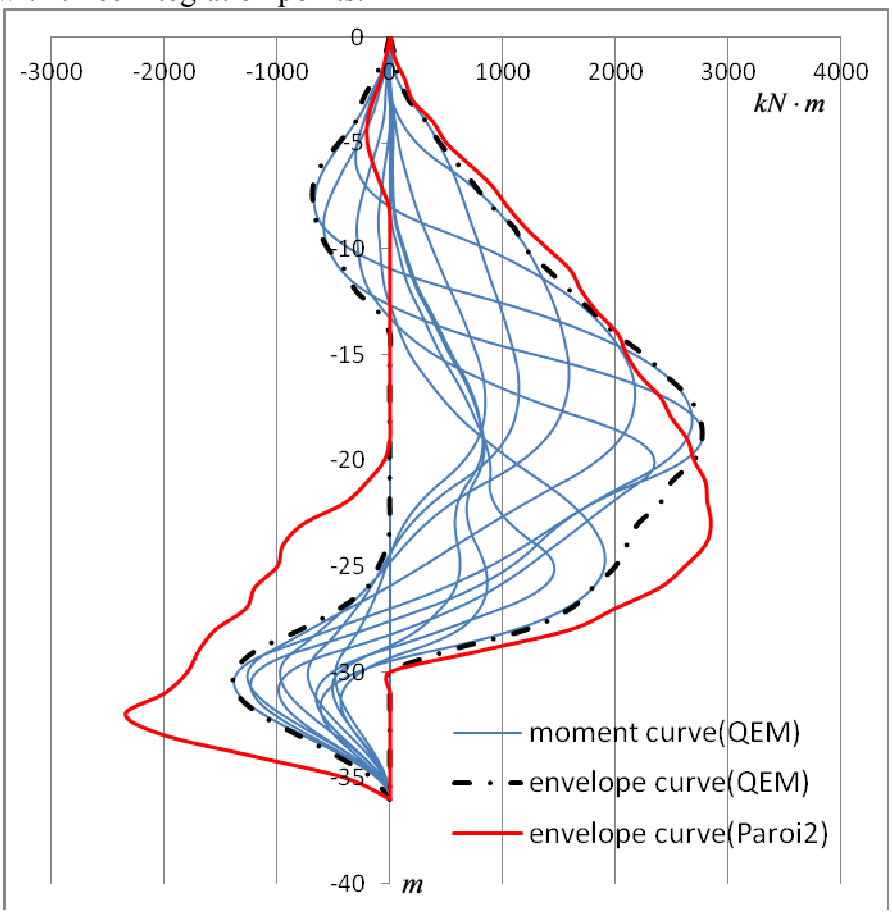

Fig 4. Envelope of bending moment

The envelop curve of the bending moments at all excavation stages is obtained as shown in Fig 4. It is seen that the quadrature element result conforms to that of Paroi2, indicating that it is effective to calculate the diaphragm wall with the quadrature beam element. Paroi2 uses 135 beam elements to acquire convergent results, contrasting to 13 elements in quadrature element analysis.

The maximum bending moment is found to be $2819\,\mathrm{kN\cdot m}$ from Paroi2 runs, while $2769\,\mathrm{kN\cdot m}$ is obtained for the quadrature element analysis, there being a 1.8% difference. However, the deviation of the negative moment of the diaphragm wall of Paroi2 from that of quadrature element analysis is relatively larger.

The difference between the results is believed to come from the modeling difference. Loads and additional stiffness are treated differently in Paroi2 and the quadrature element formulation. As less simplification is introduced in the present quadrature element formulation, the results of quadrature element analysis are believed to be more reliable.

## Conclusions

It has been shown that quadatrture element is effective in analysis of diaphragm walls in combination with Rankine's earth pressure theory. Compared with finite element analysis, quadature element analysis can offer accurate results with fewer elements.

**Keywords:** Sandstone, chemo-mechanical coupling, constitutive model,pH

**Abstract.** In this paper, we present a numerical modeling of chemo-mechanical behaviour of sandstone. An internal variable is introduced in this model for the purpose of describing pH effect on elasto-plastic properties. A new chemo-elasto-plastic model is proposed for sandstone. The proposed model is applied to predict material responses in triaxial compression tests of sandstone after soaking in different pH acidic solutions. We concluded with good agreement between numerical simulations and experimental data.

## Introduction

In recent years, research interest in the chemo-mechanical behavior of soils and rocks has been enhanced, as a result of the increasing geomechanical problems evolved due to the chemical effects. Many applications based on the study of chemo-mechanical behaviour can be found in the practice, especially for corrosion due to industrial waste water and acid rain, petroleum drilling,etc. A large number of experimental investigations involving in-situ tests and laboratory tests have been performed[1-5]. Based on these experimental results, similar conclusions have been drawn. Chemical degradation induces an increase in material porosity, which ultimately causes the deterioration of mechanical properties, especially the acidic environment has an influence on the elastic properties as well as the plastic properties and induces the yield limit to shrink with increase in concentration of acid.

A good understanding and prediction of these mechanisms, therefore, is necessary for the performance of fully coupled chemo-mechanical numerical analysis. Different numerical models taking into account chemical effects have been proposed [6,7]. These models deal with the chemo-mechanical coupling problem by damage statistics model or mathematical models. However, these models lack of mechanical meaning.

In this study, a new chemo-elasto-plastic model is presented in order to describe the chemo-mechanical behaviour of sandstone. An internal variable is introduced in this model to describe the pH effect to sandstone in acidic solution; the numerical results are given in the paper.

## Modeling of chemo-mechanical behavior of Sandstone

In this part, the variable $\theta$ denotes the change in pH of acidic environment with respect to a reference value:

$$\theta = \frac{pH}{7} \tag{1}$$

In order to take into account the chemical effect of plastic deformation, an internal state variable called chemical hardening variable, noted by $\gamma_\theta$ is proposed; this variable physically represents the

concentration of $H^+$ in acidic solution induced by change of microstructure of material. In consideration of chemo-mechanical coupled behavior, we assume that $\gamma_\theta$ can be defined by:

$$\gamma_\theta = \frac{pH}{7} \cdot \left( \frac{\sigma_c}{p_0} \right)^3 \quad (2)$$

Where pH represents the concentration of $H^+$ in acidic solution, $\sigma_c$ is the confining pressure. The fixed reference pressure $p_0$ =1MPa is used to make the parameter $\gamma_\theta$ dimensionless.

In this work, a quadratic function is used to describe plastic yielding and failure surface [8], the yield function is expressed as below:

$$f = q^2 + A\alpha_p (p - C_0) = 0 \quad (3)$$

Where $p$ is the mean stress, $q$ is deviatoric stress .The parameter $C_0$ represents the material tensile property and $A$ represents the frictional angle. The fixed reference pressure $p_0$ =1MPa is used to keep the parameter $A$ dimensionless. The plastic hardening is described by the increasing function $\alpha_p$ of the generalized plastic shear strain $\gamma_p$ and chemical internal state variable $\gamma_\theta$ . Based on the experimental data obtained from the tests on sandstone [9,10], we use the following form:

$$\alpha_p(\gamma_p, \gamma_\theta) = \alpha(\gamma_\theta) \left[ \alpha_p^0 + (1 - \alpha_p^0) \frac{\gamma_p}{B + \gamma_p} \right] \quad (4)$$

$$\gamma_p = \int \sqrt{\frac{2}{3} de_{ij}^p de_{ij}^p} \quad (5)$$

The parameter $B$ determines the plastic hardening rate.

The function $\alpha(\gamma_\theta)$ is introduced here for the description of chemical effect on the evolution of material mechanical property. In the absence of relevant data and for the sake of simplicity, a quadratic functions is used:

$$\alpha(\gamma_\theta) = a\gamma_\theta^{\,2} + b\gamma_\theta + c \quad (6)$$

$a$ , $b$, $c$ are the parameters related to the chemical hardening of material, and can be obtained from fitting the experimental data.

Here we use a non-associative plastic flow rule. Taking into account the chemical effect on the material friction coefficient, the following plastic potential is used:

$$g = q + A\eta\alpha(\gamma_\theta)(p - C_0) \ln\left( \frac{p - C_0}{I_0} \right) \quad (7)$$

By using this potential, the stress space is divided into two zones, which are plastic compressibility and dilation. The boundary between these two zones is defined by the condition $\partial g_\sigma / \partial p = 0$ and this boundary can be approximated by a linear function[8]:

$$f_d = q - A\eta(p - C_0) \quad (8)$$

The parameter $\eta$ is the slope of the boundary line between compressibility-dilation zones.

**Numerical simulations of triaxial compression tests on Sandstone with chemical corrosion**

In this section, the proposed model is used to simulate the triaxial compression tests of sandstone under different confining pressures(4MPa and 6MPa) after soaking in three solution with different pH values (pH =3 and 7) [2]. Totally, the proposed model contains 10 parameters to describe the chemo-elasto-plastic behavior of sandstone, which can be entirely determined from interpretation of tri-axial compression tests. The initial elastic constants ($E_0$ and $\mu_0$) can be obtained from the linear part of stress–strain curves in a tri-axial compression test. We use the average values obtained from

various tests. The parameters $A$ and $C_0$ can be deduced by drawing the locus of peak stresses in $p$–$q$ plane, while the parameter for the initial yield surface $\alpha_p^0$ is captured from the locus of stresses at onset of inelastic strains. We can obtain the value of parameter $\eta$ by identifying stress points corresponding to $\partial g_\sigma / \partial p = 0$ on stress–strain curves. The plastic hardening parameter $B$ can be obtained by drawing the function $\alpha_p$ versus plastic deviatoric strain $\gamma_p$, the parameters $a$, $b$ and c for the description of chemical effect in $\alpha(\gamma_\theta)$ can obtained by drawing the function $\alpha(\gamma_\theta)$ versus plastic deviatoric strain $\gamma_\theta$.

In order to evaluate the performance of the proposed model, the parameter sensibility of pH to the mechanical response is carried out. Different values of pH (pH=7,5,4,1) are used in the simulation while the confining pressure is fixed at 6 MPa. The comparison of simulation results are shown in Fig.3. It is noticed that the strength increase with the increasing value of pH.

By fitting the experimental data by above methods, we have obtained the following values of parameters shown in Table 1:

**Table 1**. Representative values of parameters for sandstone

| Elastic parameters: | Plastic parameters: | |
|---|---|---|
| $E_0$=3.65MPa | $A$=52 | $a$= -2.10e-5 |
| $\mu_0$=0.45 | $C_0$=8 | $b$=0.00788 |
| | $\alpha_p^0$=0.19 | $c$= 0.339 |
| | $B$=0.00075 | |
| | $\eta$=-0.022 | |

By using these parameters, numerical simulations of tri-axial compression tests of sandstone soaked in the solutions bearing different pH values (pH=3 and 7) were performed. The relation between deviatoric axial stress and axial strain is simulated.

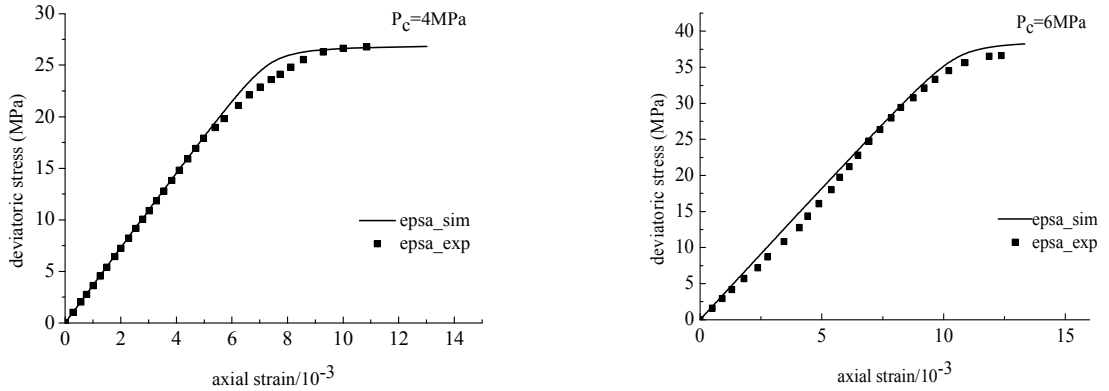

**Fig.1**. Simulations of triaxial compression tests on sandstone under different confining pressures at pH=7.

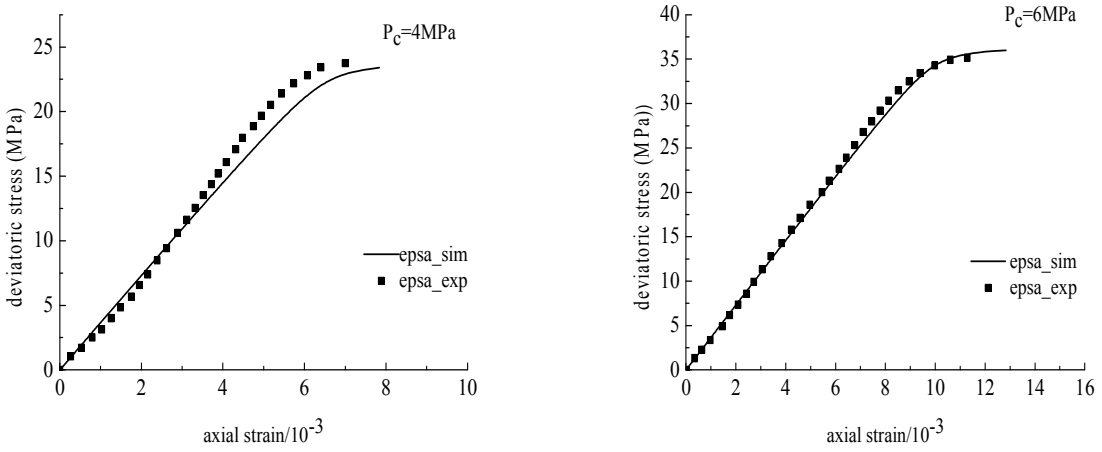

**Fig. 2**. Simulations of triaxial compression tests on sandstone under different confining pressures at pH=3.

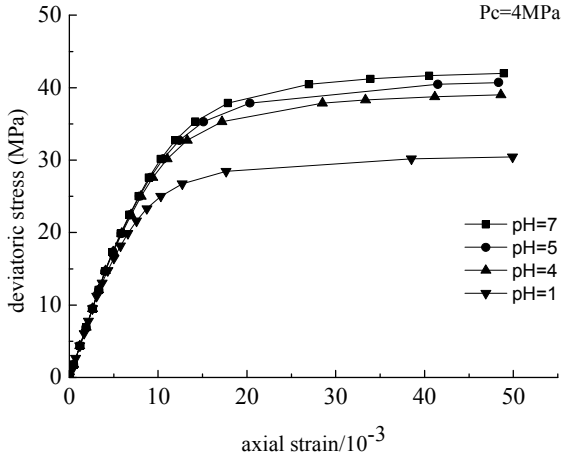

**Fig. 3**. Simulations of triaxial compression tests on sandstone under different pH at confining pressures fixed at 6 MPa.

Fig.1,2 and 3 show the comparisons between test data and numerical simulations. From the figures, with the increase in confining pressure and pH value, the strength increase. It seems that the model can well describe the feature. Moreover, in spite of simplifications and assumptions used, a general good agreement is obtained between the experimental data and simulation results for the stress-strain relationships. Qualitatively, the proposed model can correctly describe the general trend observed in the test data.

## Conclusions

In this study**,** numerical modeling of the chemo-mechanical behavior of sandstone is presented. The evolution of microstructure due to chemical effect is quantified through an internal variable, taking into account the effect of pH of acidic solution on the mechanical properties of sandstone. A quadratic function is used to describe the plastic yielding and failure surface. The triaxial compression tests on sandstone soaked in different pH (pH=3, 7) solutions are simulated. In spite of limited data available, the proposed model seems to describe well the main features observed in experiments. However, the proposed model should be verified by other experimental data and this will be done in the further study.

**Keywords:** Landslide, rainfall, critical line, rainfall intensity, accumulated rainfall.

**Abstract.** This paper developed a critical-line-based method for predicting the occurrence of landslides using two rainfall indices, the rainfall intensity and the accumulated rainfall, based on four landslide case histories recorded in a county. Specifically, the rainfall records of the four cases were used to compute the 60-minute rainfall intensity and accumulated rainfall prior to the occurrence of landslides. Although the meteorological and geological conditions as well as other crucial factors are not considered in the development of the intended model, the analysis results indicated that the developed critical-line-based predictive model can reasonably identify the boundary between occurred and non-occurred zones. The developed model has the potential to be a useful tool for predicting the occurrence of landslides according to the rainfall conditions.

## Introduction

Taiwan is a mountainous country and located in the routes of typhoons in southeastern Asia. Landslides are occasionally triggered by the heavy rainfall during typhoon or Mai-yu seasons and caused tremendous damage and lost in Taiwan. According to the records by the SWCB [1], the number of landslides recorded every year increases after the 1999 Chi-Chi earthquake. This means that slopes may be disturbed and the factor of safety of stability may be reduced. Over the past decades, many methods have been developed for predicting the landslide occurrences using meteorological factors all over the world [2-6]. It is desirable to develop a local predictive model for landslides in Taiwan.

Landslides may be caused by a large number of various factors such as meteorological factors, geological factors, vegetation, construction of roads, earthquakes, and so on. However, the rainfall factors are generally recognized to be ones of most crucial factors causing landslides. According to the past studies, the intense rainfall has been recognized as the primary factor to trigger landslides. In addition, accumulated rainfall is commonly recognized as a secondary landslide-triggering meteorological factor [7]. Therefore, the objective of this study is to develop a simplified model for predicting the occurrence of landslides with use of two rainfall indices, the rainfall intensity and the accumulated rainfall.

## Collection of landslide cases

The SWCB [1] delivered the reports annually to record and analyze the slope failure events in Taiwan, including landslides and debris flows. Based on the annual reports by the SWCB, the present study collected four landslide case histories occurred in Renai Township, Nantou County, Taiwan in various years. Specifically, two of them occurred in Datong Village in 2006 and 2007, while the other two occurred in Cueihua Village in 2006 and 2008. All the four landslide cases were triggered by the heavy rainfall. Detailed information such as location, rainfall history (as shown in Fig. 1), rainfall station name, time of landslide occurrence, hydrogeology conditions, vegetation condition, description and in-situ photos of failure, and so on, were collected for each of the four landslide cases.

Overall, the four landslide cases are located in a relatively small region and the use of them to develop the simple model for predicting the occurrence of landslides intends to reduce the effect of other influence factors on the landslides as much as possible.

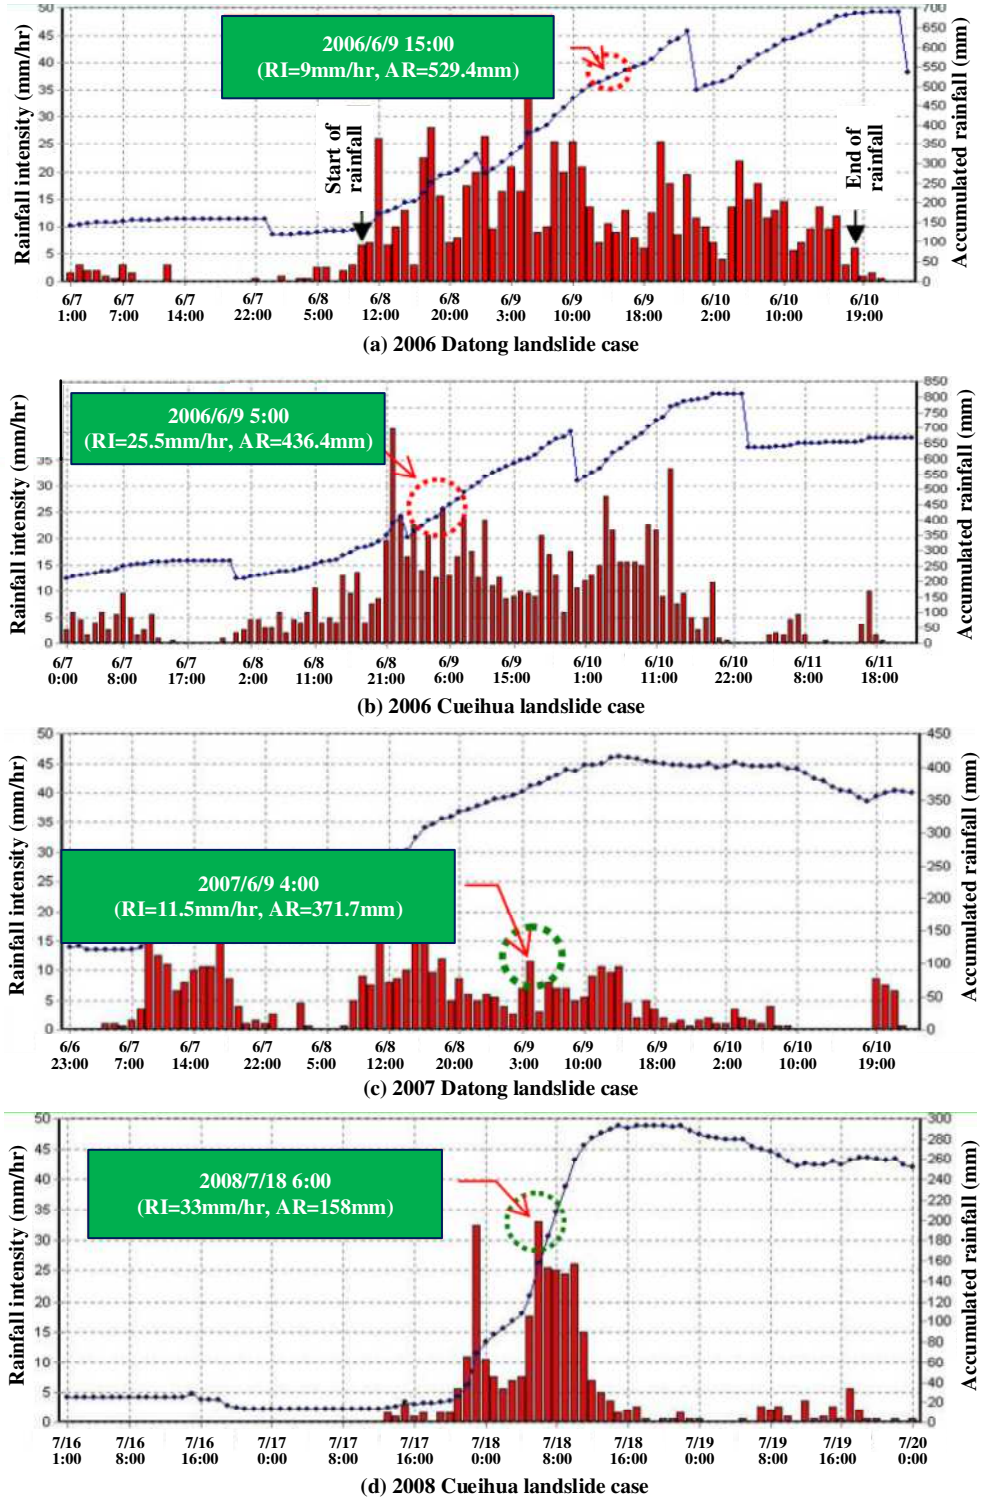

Fig. 1 Rainfall records for the four landslide cases collected.

## Calculation of rainfall indices

For the calculation of the rainfall intensity and the accumulated rainfall, the following definitions are employed: (1) the sum of rainfall within 60 minutes is called the rainfall intensity, and (2) the rainfall accumulated from the start of the rainfall event to a certain time is named as the accumulated rainfall.

With these definitions, the rainfall intensity and the accumulated rainfall at every hour can be obtained prior to the occurrence time of landslides for each of landslide cases. It should be noted that the rainfall records after the occurrence of landslides were not employed in this present study. Then, all the data points (the combination of the rainfall intensity and the accumulated rainfall) calculated are employed together to develop the critical line for predicting the occurrence of landslides.

**Analysis results**

Figure 2 reveals the analysis results of four landslide case histories. The solid points represent the values of the rainfall intensity and the accumulated rainfall when the landslide occurred, while other hollow points are hourly data calculated prior to the occurrence of landslide with respect to various time. It should be noted that the data after the occurrence time of landslides are not incorporated into the figure. Based on those data points, a critical line for predicting the occurrence of landslides in Renai Township, Nantou County was established. As mentioned previously, the critical line is the boundary for identifying the occurrence of landslide. The scenario that hollow points are located inside the critical line and solid points are located outside the critical line represents the capacity of the critical line for estimating the occurrence of landslides is good. On the contrary, the critical line established is not satisfactory provided the hollow points are located outside the critical line and solid points are located inside the critical line.

As shown in Fig. 2, only five hollow points are outside the critical line as well as only one solid point is inside the critical line. This means the developed critical line may be capable of identifying the boundary for predicting the occurrence of landslide by using two indices, the rainfall intensity and the accumulated rainfall. However, it is desirable to incorporate more landslide data to validate the capacity of the developed critical line. In addition, the critical line developed in Fig. 2 is only valid to Renai Township, Nantou. The simple methodology exhibits a high potential to be employed in other vulnerable area to develop the critical line for predicting the occurrence of landslides.

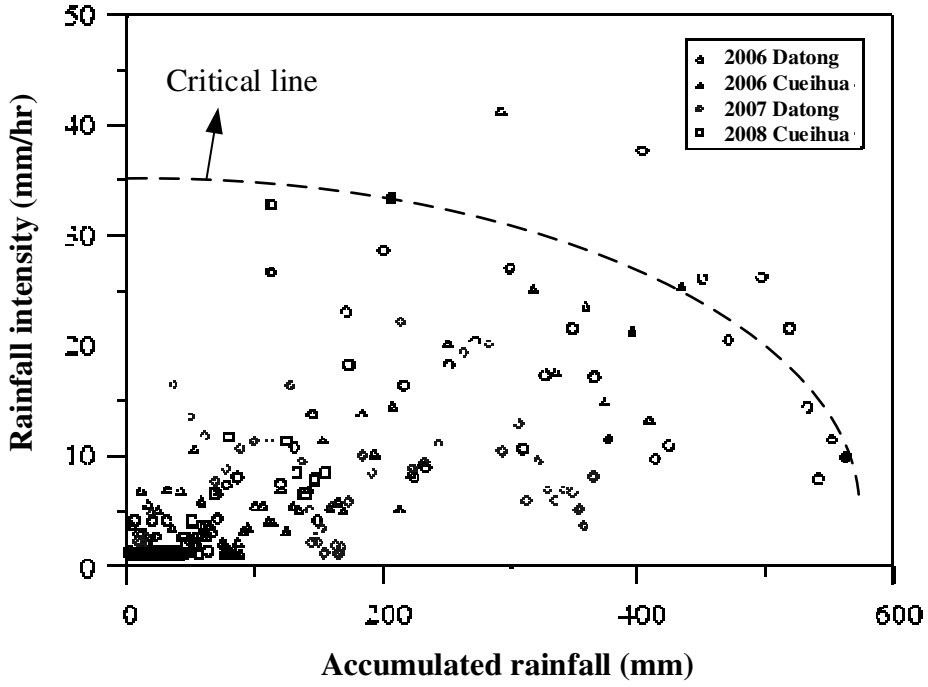

Fig. 2 The developed critical line using two rainfall indices for prediction of landslides in Renai Township, Nantou County

**Summary**

This study collected four landslide case histories occurring in Renai Township, Nantou County in various years to develop a critical-line-based model for predicting the occurrence of landslides. The analysis results displayed that the developed critical line is capable of identifying the boundary for predicting the occurrence of landslide based on two rainfall indices, the rainfall intensity and the accumulated rainfall. The results of the present study indicated that the critical-line-based model established based on the data of landslide case histories located within a small area, e.g., 5km×5km or 10km×10km, could be applicable to predict the occurrence of landslides. Although additional studies are required to validate the developed predictive model, it has the potential to be a useful tool to predict the occurrence of landslides.

**Keywords:** soft clay, deep excavation, finite element, back-analysis from measured displacement, dynamic prediction, process control.

**Abstract.** Mechanisms of the distortion of deep excavation in soft clay are recommended on the beginning. Plane FEA method is combined with back-analysis from displacement on this paper to establish a dynamic prediction system of the distortion of deep excavation, which is proved to be viable by practice. Combining with the idea of process control, a process control model of the distortion of deep excavation is established on this paper. It is divided into three parts: advance control, observation and dynamic prediction, process control in the construction.

## Introduction

With the rapid development of urban construction, more and more underground space is applied, after what lots of deep excavation produced. With the increase in scale and depth of excavation, a series of challenges are put forward to the design and construction of the pit currently.

The excessive deformation of excavation will cause uneven settlement or cracking of the surrounding buildings, roads, pipelines and other important facilities [1], furthermore it will affect the normal use function. Therefore, the deformation control has become an important link of design and construction of deep foundation pit engineering, especially in the construction of deep foundation pit in soft soil area, the environmental effects caused by excavation is more obvious, the deformation control of deep excavation in soft soil is particularly important.

## Deformation Mechanism of Deep Excavation in Soft Clay and Finite Element Analysis

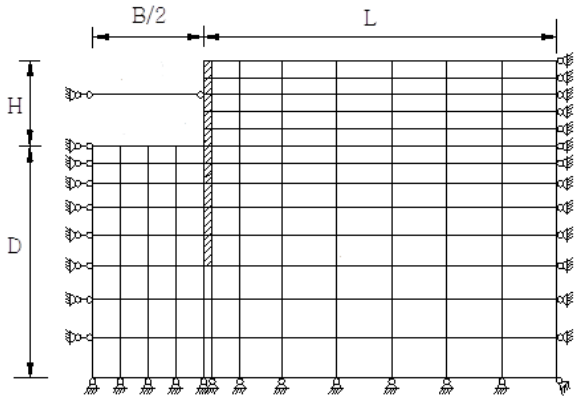
**Deformation Mechanism.** Excavation deformation consists of three parts, which are the wall deformation, the bottom uplift and the surface settlement around foundation pit. Pit excavation process is unloaded process of the excavation of soil. The process not only leads to mainly upward displacement produced by the bottom of the soil, but also causes horizontal deformation of the enclosure wall, which results in plastic uplift of the bottom soil. The two parts are also main causes of the surrounding ground movement.

**The Time-Space Effect of deep Excavation in Soft Soil.** Earth pressure on the supporting structure is changing, the deformation of foundation pit also changes with time. In addition to soil properties and supporting structure parameters, the deformation of foundation pit is also related to

excavation method, time, excavation sequence, space, and so on. This is the rule of space-time effect of deep the deformation of foundation pit.

**The Finite Element Analysis Model of foundation pit.** It is divided into plane model and 3-D model. For the long strip pit, we usually use the first model. Due to the existence of large space effect obviously, we use the other one to the foundation pit which has complex shapes.

The plane finite element model is as follows. In consideration of symmetry between the shape and excavation of the foundation pit, one side of the symmetry axis is usually taken as the computational domain during the plane finite element analysis in deep foundation pit. The influencing width is three to four times longer than the depth, and the influencing depth is two or four times longer than the depth or as long as the depth between the surface and the hard soil of the bottom of the foundation pit, as shown in Fig.1.



H—The depth of excavation B—The width of excavation
L—Width range D—Depth range

Fig.1 The plane finite element model

3-D finite element model is as follows. In the establishment of 3-D finite element model, when layout of the supporting structure and excavation method are satisfied with the condition of symmetry, we can choose a half or a quarter of the side of symmetry axis as the computational domain. The determination of the overall size is same as the model of plane finite element.

**Simulation of the Interaction between Retaining Structure and Soil.** The contact can be divided into two types in ANSYS, which are the rigid-flexible contact and the flexible-flexible contact. There are three ways to simulate contact, which are the point to point, the point to surface and the surface to surface.

The contact between pile and soil contact is the rigid-flexible contact. The pile is defined as the target body, while soil is defined as the contact body. These two surfaces together are regarded as a contact pair. By defining a lot of contact pairs, the simulation of the pile-soil contact can be come true. Each contact pairs is recognized by a set of constants alone, as shown in Fig.2.

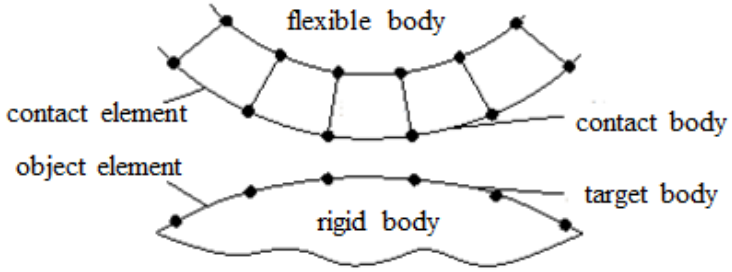


Fig.2 Simulation of surface-surface contact in ANSYS

**Consideration of the Initial Stress.** There are two ways to consider self-weight stress in ANSYS [2]. The first one is to regard the weight as the load and impose it on the ground. The ground emerge displacement under its own weight. While continuing to analyze the subsequent construction, the results of displacement is the accumulation of the initial displacement, while in reality the initial displacement is long over. Therefore behind each construction stage analysis of the displacement field, we need to subtract the initial displacement field. The second one is to apply weight first and obtain the initial stress field. The results will be saved as a file. During analysis of excavation, the initial stress will be read directly into the soil element, so that the displacement field is zero under self-weight stress. Then the result is the actual displacement field.

**The Simulation of Excavation and Support Processes.** These processes can be effectively simulated by using the "life and death" technique of unit in ANSYS [2]. During the excavation of deep foundation pit, we can directly select the soil element that is removed and "kill" it, in order to simulate the excavation. When erecting support, we can “active” the corresponding part that is killed in the excavation. The unit should become zero when it is activated. It is important to note that these units that input initial strain in form of real constant are not affected by birth and death element options.

## Dynamic Prediction for the Deformation of Foundation Pit based on Anti-Analysis

In geotechnical engineering, the certain physical quantities which are obtained by field measurement to reflect the system mechanical behavior can be used to calculate various parameters or some initial parameters of the system. We usually call this method anti-analysis.

**Target Parameters Selection of Anti-Analysis.** The target parameters are unknown parameters that to be solved in the process of anti-analysis. Different constitutive model of soil can be used in finite element analysis，which resulted in different target parameters of anti-analysis. The details are shown in Table1.

[Table 1 Selection of target parameters in anti-analysis]

| Constitutive model of soil | Target parameters of anti-analysis |
|---|---|
| Elastic model | Elastic modulus and Poisson's ratio |
| Elastic-plastic model | Elastic modulus, Poisson's ratio μ, Cohesion and Internal friction angle |
| Viscoelastic model | Elastic constants and Viscous constants |

**Objective function based on the relative displacement.** Before establishing the objective function, displacements calculating by the finite element analysis should be conducted. the calculated displacements of each points should subtract the calculated displacements from the bottom of points, then a relative displacement could be obtained, after that we can establish the objective function through the relative displacement which measured by taking the bottom of the tube as a fixed point. The equation is shown in Eq.1.

$$J=\sum_{i=1}^{m}(U_i-\triangle U_i^*)^2 \tag{1}$$

In the formula: $m$ —The total number of measurement points;

$U_i$ —The measured displacements of the point i;

$\triangle U_i^*=U_i^*-U_m^*$ —Relative displacement by calculation.

**Optimization and solution of the objective function.** Selected the appropriate way to optimize and solve function optimization can greatly improve the convergence speed of the objective function, so as to improve the efficiency of back analysis. Here mainly introduce two common methods.

Firstly, the golden section method in single-parameter solution is as follows. The interval (a, b) should be divided and supposing breakpoints are c and d. The equation is shown in Eq.2.

$$\begin{cases} c = (1-\alpha)a + \alpha b \\ d = \alpha a + (1-\alpha)b \end{cases} \quad (2)$$

In the formula, $\alpha$ =0.618. After calculating the values of this function in c and d, we should do the following comparison.

（1）If f(c)< f(d), then the interval (a, d) is used as the new interval ($a_1$,$b_1$).

（2）If f(c)>f(d), then the interval (c, b) is used as the new interval ($a_1$,$b_1$).

We should continue to compare the values of the function at all points by using segmentation method, namely it is not until the minimum meet the accuracy requirements that the interval can be stopped shortening, by doing what we can calculate the similar minimum.

Secondly, Modified simplex algorithm [3] is as follows. The basic idea is as follows. Establishing an n-dimensional space, in which we can compare the values of the function in these n+1 points and remove the point which makes the objective function get the maximum and is replaced by a new point. The new simplex replaces the old one constantly by iterated operation and is designed to close to the minimum of J(x). In the process, the power continues to shrink automatically, and get the minimum point finally.

**Deformation Dynamic Forecast based on the Anti-Analysis Method.** Taking comprehensive parameters obtained from anti-analysis into normal analysis and predicting internal force and deformation in the excavation process can not only help to test anti-analysis, but also improve the accuracy of it. The flow chart is shown in Fig.3.

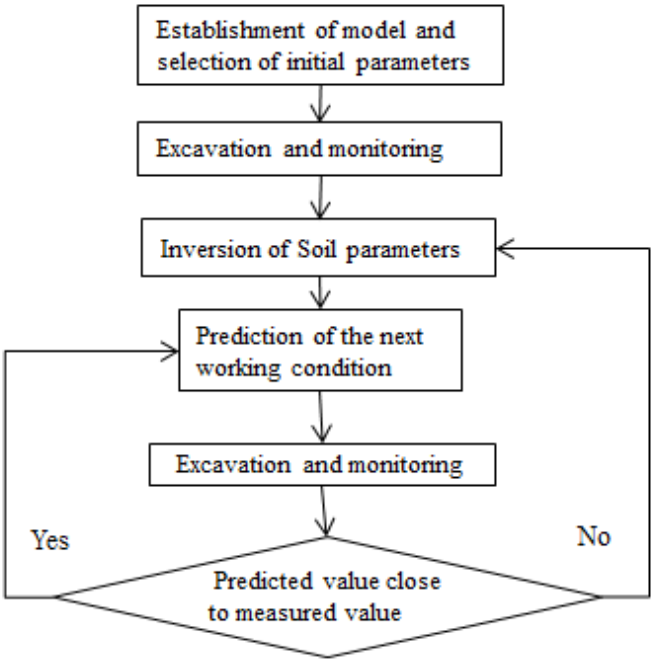

Fig.3 Flowchart of dynamic prediction for pit deformation

**Process Control for Deformation of Deep Excavation in Soft Soil**

Process control for deformation of deep excavation in soft soil can be divided into three parts, which are prior pre-control, construction monitor and dynamic forecast and construction control.

**Identify of Deformation Control Objectives.** Before deciding the objective of deep excavation deformation control, we should make a careful investigation of the engineering geological conditions and the surrounding environmental conditions, then study and calculate the allowable deformation of surrounding buildings, structures and pipelines, on this basis, determine the allowable value of deformation for the supporting structure caused by excavation and settlement of surrounding ground, finally we regard it as the deformation control objective of deep excavation.

**Construction Supervision.** The content of excavation monitoring can broadly divide into three parts that are displacement monitoring, stress monitoring and auxiliary monitoring. In early excavation, information acquisition cycle can be longer. With the depth increasing, the deformation scale of exterior-protected construction increases, then the acquisition cycle should be shortened. After collecting all kinds of information, we should input the computer for data processing promptly and draw the curves. At the same time, we should analyze bad data to find out causes and make improvements timely. After processing the information, it should be feedback to the designer, builder, superior and developer and submitted monitoring report timely.

**Measures of Process Control during Construction.** The first one is Construction measures considering time-space effect. The main construction parameters are lift height, intermediate dimension, excavation time and exposure time without the support. The determination of lift height and intermediate dimension should consider the location of strut and soil conditions. During excavation, we should make full use of their own strength and let excavation alternates with strut. If the excavation time or the exposure time is too long, the deformation will also be increased. Therefore, it is necessary to reduce the excavation time. After excavation, we should set up the strut timely and inflict the pre-stress to avoid long exposure time without the support.

The second one is add axial force of strut and adjust the position of strut.

The third one is tracking the grouting reinforcement.

The last one is emergency measures in construction Cantilever excavation depth caused by excessive horizontal displacement of pile top is too large. The details are shown in Table2.

[Table2 Common problems of deep foundation pit in soft soil and emergency measures]

| Types and causes of danger | Measures |
|---|---|
| Long depth of Cantilever excavation leads to long horizontal displacement of pile top | Unloading outside the pit and setting support immediately |
| Leakage of waterproof curtain leads to large settlement of ground | Grouting plug and setting recharge wells |
| Shallow embedment depth results in pile introversion or skirting instability | Unloading, heaping pile foot and reinforcing soil of passive zone |
| Excessive excavation leads to large deformation of the supporting structure | Stopping digging and setting strut immediately |
| Long exposure time causes deformation increasing | Setting strut immediately or refilling pre-stress |

## Conclusions

Deformation problems of deep excavation in soft soil have been attracted much attention for a long time, which is a focus and difficulty in excavation engineering. This paper combines the anti-analysis technology of displacement and method of finite element analysis and analyzes the deformation of supporting structure caused by excavation, which is also an important trend in the deformation analysis of foundation pit. From the finite element, selection of constitutive model and related parameters is still a problem, which needs a further study in the future. The anti-analysis model used in this paper is based on the elastic plane finite element model, but it cannot consider local deformation caused by soft soil rheology.

Deformation control of deep excavation is a complex process, this paper analyzes its control method and basic process from the technical aspects only, it needs a further study in the application and promotion in practical engineering.

## Acknowledgements

This paper is completed under the careful guidance of teacher Li, so I want to say thank you to him firstly. At the same time, I want to thank you the author of all references and teachers and friends providing help for thesis writing.

**Keywords:** Foundation Pit, Supporting Structure, Soil Anchor, Soil Pressure

**Abstract.** This paper analyzes an engineering in an area of China which was processed by vacuum preloading technology in the silt soft soil. This engineering was used rigid supporting structure technology of piles in row and bolts for large area of deep foundation pit supporting. It compared the realistic measure soil pressure and theoretical concluded soil pressure, and got the soil pressure distribution mode which is suitable for silt soft soil processed in this way. The conclusion can provide a reference for similar supporting structure system to calculate earth pressure.

## Introduction

Foundation pit engineering is a very complex system engineering, with a strong regional, comprehensive, practical and risk. Excavation structure is a complex structure with the interaction of structure and surrounding soil. The ways of supporting include using structural obstructing soil, using materials reinforced soil and retaining structures obstructing soil, using retaining structures and anchored rock reinforcing soil. Supporting structure, no matter what methods, it's forces are all complex and it's analytical methods all involve the problem of retaining structures and geotechnical cooperative work. This paper analyzes an engineering in an area of China which is processed by vacuum preloading technology in the silt soft soil. This engineering is used rigid supporting structure technology of piles in row and bolts for large area of deep foundation pit supporting. Combined with the monitoring results of axial tension and earth pressure, this paper analyzes the interaction of of soil and the pile anchor supporting system and the deformation of foundation pit for soil pressure. It provides some reference for complex conditions of large area deep foundation pit supporting engineering's design and construction.

## Project Overview

A building site into various high-rise housing complex, located in an province. Its original coastal geomorphic units are stacked landscape. The main building of the proposed project from 11 to 32 floors, above ground level 41~100m, with 2 floors basement. ±0.00 elevation equivalent to an absolute elevation 4.90m. Bottom elevation of the basement floor is -5.60m. Cushion thickness is 0.20m. Actuality ground elevation is 2.00~2.50m. Considering cap excavation depth is 0.50m. The foundation pit's perimeter of this project is about 1054 meters. The foundation pit's design depth is 8.30~8.80m. The security level is level 1. The importance factor of excavation sidewalls is 1.1. The groundwater level of proposed site has great differences Buried underground water depth ranged from 0.10 to 1.20 meters , equivalent to 0.89 to 2.60 meters above sea level. The site has been processed by vacuum preloading technology.

According to the results of the survey report, the name, thickness, physical properties indicators of soil which are related to excavation of foundation pit are in Table 1 from top to bottom.

**Table 1. Physical Properties of Soil Indicators**

| Number | Soil Name | Strata Thickness (m) | Severe ($kN/m^3$) | Floating Severe ($kN/m^3$) | Cohesion (kPa) | Internal Friction Angle ($^0$) |
|---|---|---|---|---|---|---|
| ① | Plain Fill | 8.50 | 18.5 | - | 14.0 | 14.0 |
| ② | Plain Fill | 1.20 | 18.4 | 8.5 | 14.0 | 14.0 |
| ③ | Silt | 3.80 | 16.5 | 6.5 | 6.7 | 3.1 |
| ④ | Silt | 5.80 | 16.1 | 6.1 | 5.3 | 2.9 |
| ⑤ | Silt | 9.95 | 16.1 | 6.1 | 5.2 | 2.7 |
| ⑥ | Gravelly Sand | 1.50 | 19.0 | 9.0 | - | - |
| ⑦ | Strong Weathered Rock | 0.72 | 19.5 | 9.5 | - | - |
| ⑧ | Strong Weathered Rock | 3 .50 | 20.0 | 10.0 | - | - |
| ⑨ | Middle Weathered Rock | 15.60 | 21.0 | 22.0 | - | - |

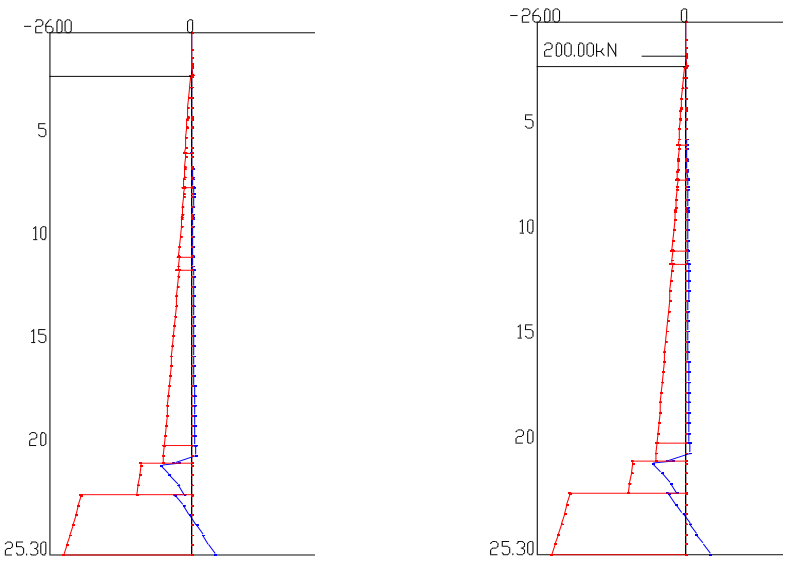
## Foundation Pit Supporting Program

This project's foundation pit designed according to the principles of economic, safety, easy of construction, using rigid supporting structure form of piles in row and bolts. Piles in row are constructed by rotary digging pile machine or auger drill (red). Pile's diameter is 1.20m and spacing is 1.50m. Clear distance between piles is 0.30m, using 0.60m diameter high pressure jet grouting pile to check water between piles between piles. Top elevation of crown beam is 1.30m. Concrete strength grade of pile is C35 and reinforcement is HRB400; stirrups is HRB300. Rock bolts are compose of high strength steel wire mesh, using a dedicated machine bolt into the hole , and the use of the casing wall holing. Bore diameter is 150mm, steel strand is $\Phi^s$ 15.2mm. The tensile strength of the standard value is 1860 N/mm. Grouting materials used 42.5R ordinary portland cement paste, adding the amount of cement 0.3% FDN superplasticizer.

## Analysis of Retaining Structure and Soil Interaction

### *Computed Result of Retaining Structure's Soil Pressure*

There are five sectional supporting on the south side pit. The perimeter of foundation pit is 150 m. Each level of excavation is divided into one, two , three , etc. drill excavation. Excavation must be balanced stratified open digging, digging depth should not exceed bolt on each storey 20cm. After the excavation, each layer of anchor bolt should be constructed and prestressing force should be brought to bear, of and prestressed anchor. Earth pressure is the side thrust that applied to the soil structure, and also the main load bared by retaining structures. The construction of soil pressure value of the working condition of each role in supporting anchor structure is calculated by Leading deep foundation pit construction design software. The model of soil pressure calculating used elastic soil pressure model and classical soil pressure model. The results are shown in Figure 1.



**Condition 1 ( excavation 4.6m)** **Condition 2 ( excavation 6.6m)**

**Fig. 1. Distribution of calculation soil pressure (kN/m)**

As can be seen from the figure the value of earth pressure distribution over the use of theoretical calculations are always on the small great.

### *Analysis of Calculation Soil Pressure Retaining Structure and Measured Results*

The pit sets 28 observation points in total, using resistance strain gauges to test the pit active soil pressure. Measured anchored piles' soil pressure distribution is shown in Figure 2. In the figure, The measured soil pressure distribution approximation a triangle that up and down small and middle large. For the pile anchor supporting structure, because that rock bolts are all prestressed bolts, bolts' prestress have changed soil pressure distribution, made the soil pressure that near bolts increasing, at the bottom of pit decreasing.

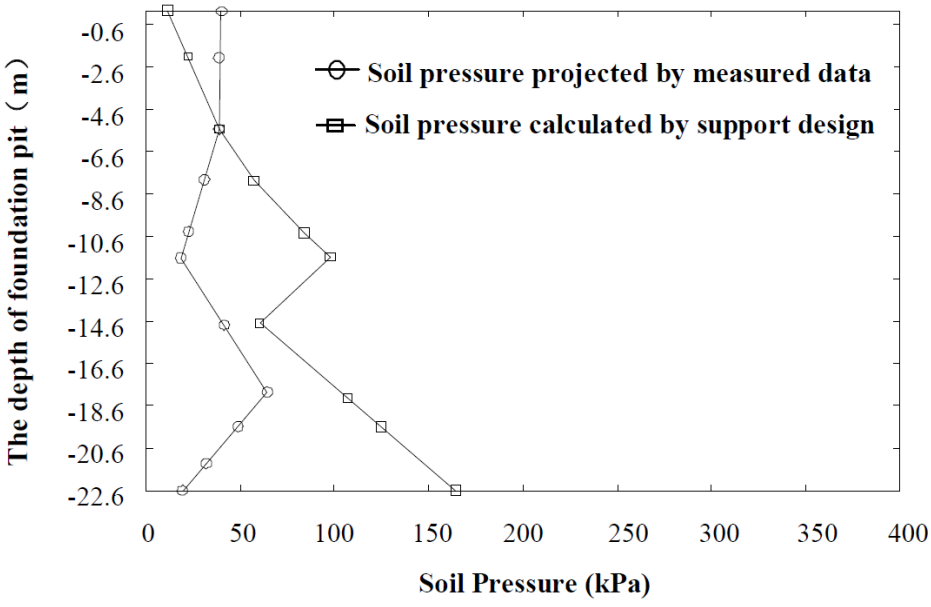


**Fig. 2. Realistic measure soil pressure and theoretical concluded soil pressure compare**

## Conclusions

- Via this engineering example, it proves that in the silt soft soil foundation using vacuum preloading for large area of deep excavation , piles in row and bolts pit supporting structure technology is feasible.
- In the supporting system, soil piles and anchors are complementary and mutually reinforcing.
- The measured soil pressure distribution approximation a triangle that up and down small and middle large. It can be corrected by theoretical formula when design calculating.

# Calculation for Earth Pressure of Cavity Expansion Considering Displacement

WUMEI ZHANG[1, a], XIN HUANG[2,b]

[1,2]School of Transportation Science and Engineering BUAA, Beihang University, 37 Haidian Street ,Beijing, 100191, P. R. China

[a]may3718@163.com, [b]hx2000@buaa.edu.cn

**Keywords:** finite element method; passive earth pressure; cavity expansion.

**Abstract.** Most of the studies on cavity expansion are about the analytical solutions of the stress distribution, and not related to the effect of soil properties on earth pressure. Aiming at the problem, the change law of passive earth pressure is analyzed by using the Mohr-Coulomb model, and the formula of earth pressure is summarized. The error value of calculation and simulation is small that the formulas can be directly used in practical engineering.

## Introduction

Cavity expansion has been widely used in many geotechnical engineering such as underground excavation and pile foundation. The classical earth pressure theories are used in calculation of the limit state of soil, without considering the change of earth pressure with the displacement. The process of the displacement magnitude of the retaining structure under the condition of plane displacement has been researched [1-4]. The earth pressure is related to the displacement mode of the retaining structure. It is static earth pressure when the displacement is zero. With the increasing of displacement, the earth pressure becomes the passive earth pressure until it reaches a maximum passive earth pressure. The analytical solutions of the stress distribution due to the cavity expansion have also been studied, without the formula of passive earth pressure [5-7].

In this paper, the variation trend of passive earth pressure of soft soil with initial aperture will be simulated by using the finite element software of ABAQUS. The change law of passive earth pressure is analyzed by calculation qualitatively and quantitatively in the process of displacement loading on the soil, and the formula of passive earth pressure in the expansion process is summarized.

## Calculation method and numerical model

The existing studies have indicated that the passive earth pressure will increase when the displacement increases gradually until it reaches the passive state of limit equilibrium. At present, the constitutive model of rock and soil are mainly divided into the theory of elasticity, viscoelastic and viscoelastic plasticity theory and elastic-plastic theory. And elastic-plastic model is the most consistent with the characteristics of soft soil which is the main research object of this paper. The commonly used yield criteria of ideal elastic-plastic model are the D-P model, the Mohr-Coulomb model and the Cam-Clay model. The Mohr-Coulomb model is widely used, and it has fewer parameters which are easy to identify. The analysis of soil is using the Mohr-Coulomb model and the parameters of soft soil can be searched in engineering geology manual. Take different parameter

value in the range into numerical simulation model, extract and process the data from the models, and summarize the change trend between the earth pressure and the parameters.

Building finite element model includes building apart, input parameters, input load, establish grid. The displacement load is applied to enlarge the aperture of the soil, so axial symmetric model is chosen, and the depth and width of model should not affect the calculation results of different depth and aperture of the hole, and the depth of 20m, width of 40m can meet the conditions. 36 models were established, the depth of hole $H$ are 5, 6, 7, 8, 9, 10m and the initial radius of hole $r$ are 0.06, 0.07, 0.08, 0.09, 0.1m respectively. Without considering the friction effect between the soil units and retaining structure, the input material parameters includes: gravity of soil $\gamma$ (KN/m$^3$), elastic modulus $E$ (KPa), soil cohesion $c$ (KPa), Poisson ratio $\mu$, frictional angle $\varphi$(º), void ratio $e$, Saturation $\omega$, osmotic coefficient $k$ (cm/s), and each parameter selects 4 or 5 different number, assuming the distance between a point on the wall of the hole and the ground is $h$ (m), initial radius of the hole is $r$ (m), the expansion displacement of the wall is $x$ (m). The establishment of the grid has great influence on the results of finite element analysis, aiming at the problem, the grid properties of various models are same, and decrease the grid density until effect of grid on the earth pressure can be neglected, and the grid density is 0.25m.

The earth pressure formula summarized principles: 1. The various parameters are derivative to approximate a function. 2. To reduce the complexity of the formula, parameters with negligible effect on the final data will be ignored. 3. Each parameter's dimension will be regardless, KPa is the unit of earth pressure $\sigma$.

**Numerical analysis and earth pressure formula summary**

The main purpose is to calculate the passive earth pressure of the cavity expansion. Therefore, data extracted from the models are the node force $F$, which is horizontal direction on the wall. $F$ is the horizontal resultant of the scope of the nodes of the elements.

$$F=\sigma\times 0.25\times 2\,\pi(r+x) \tag{1}$$

The formula of $F$ must be summarized before the formula of the earth pressure is summed up. Passive earth pressure is a function associated with the parameters.

$$F = f(\gamma, E, c, \varphi, e, \omega, k, h, r, H, x) \tag{2}$$

In order to simplify the model, linear Function is used to fit the curve, all the terms in the formula of $F$ are of the first degree. When calculating the passive earth pressure, the Equation. 2 should be derivation and decomposition.

$$F = f_x' x + f_1(\gamma, E, c, \varphi, e, \omega, k, h, H, r)$$

$$F = f_{xE}'' xE + f_2\ (\gamma, c, \varphi, e, \omega, k, h, H, r)x + f_{1e}'(\gamma, c, \varphi, e, \omega, k, h, H, r)E + f_3\ (\gamma, c, \varphi, e, \omega, k, h, H, r)$$

…… (3)

And so on, the various parameters derivation of the formula of the passive earth pressure is achieved, and put the solution into the formula, and some parameters have less influence on calculation, those will be ignored for simplification.

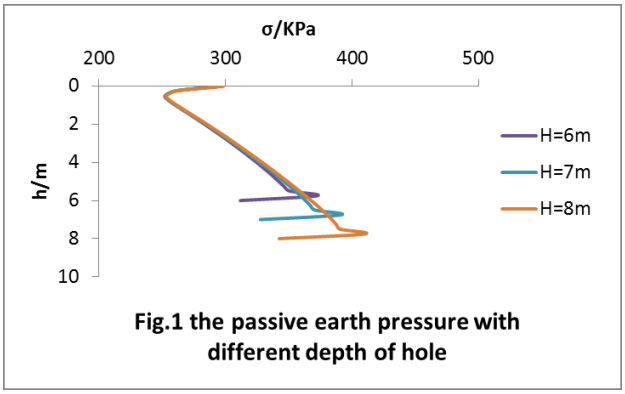

Fig.1 the passive earth pressure with different depth of hole

In Figure 1, the passive earth pressure in same conditions is almost the same except the soil near the top and bottom of the hole, the earth pressure of the soil near the top and bottom is irregular unlike the middle, because the constraints are different. Therefore, the formula of the passive earth pressure is only suitable for the middle part of the soil and the pressure is unrelated to the depth of hole.

By changing the parameter values, it can be learned that void ratio $e$, Saturation $\omega$, osmotic coefficient $k$ and Poisson ratio $\mu$ do not affect the formula. When $h$ and $r$ is unchanged, with the increase of $x$, $E$, $c$, $\gamma$ and $\varphi$ have large effect to the passive earth pressure.

Figure 2-5 are the curves of relationship between earth pressure and displacement with different single parameter under the same other conditions respectively. The earth pressure can be considered as two stages, the elastic stage that the pressure raises rapidly and the elastic-plastic stage that the pressure increases slowly. In the elastic stage, elastic modulus $E$ is the main effect and the other parameters are quite opposite. Therefore, the passive earth pressure is only related to $E$, $x$, $h$, $r$, that it increase when those parameter increase.

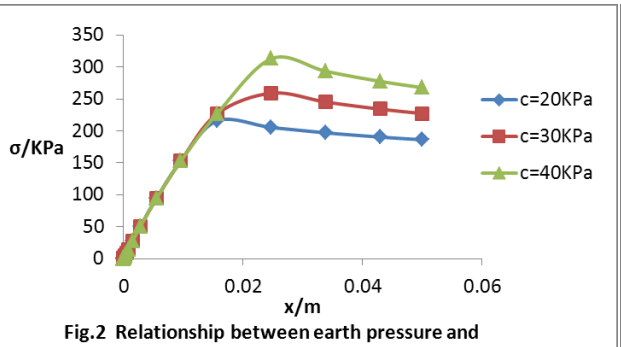

Fig.2 Relationship between earth pressure and displacement with different c

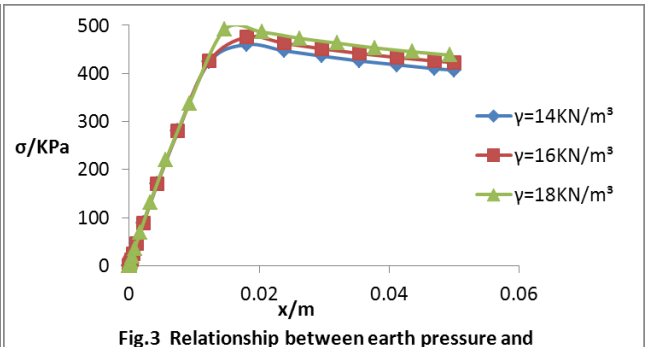

Fig.3 Relationship between earth pressure and displacement with different γ

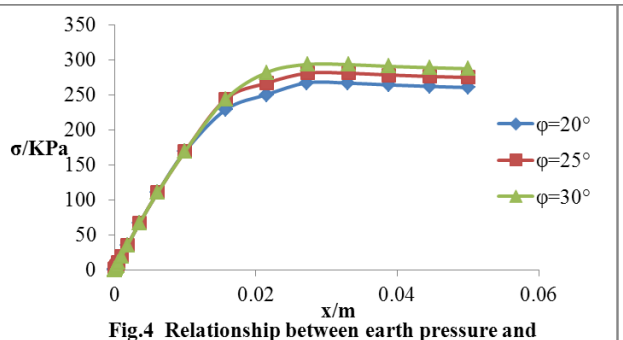

Fig.4 Relationship between earth pressure and displacement with different φ

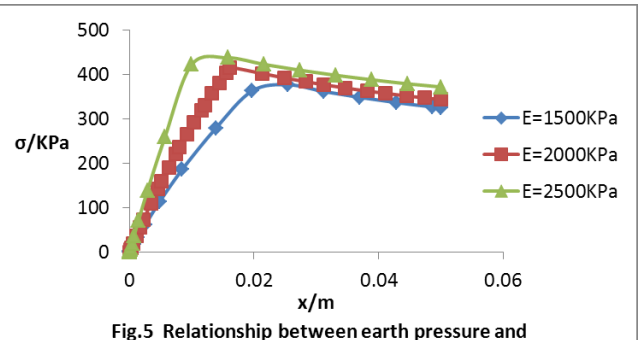

Fig.5 Relationship between earth pressure and displacement with different E

After calculation and summarizing, passive earth pressure in elastic stage should be in calculated in accordance with Equation 4.

$$\sigma=[(1.3081E+249hr+12.h-15r+1)x+3\times10^{-5}]/0.5\pi(r+x) \quad KPa \tag{4}$$

In the elastic-plastic stage, the passive earth pressure changes slowly, and each parameter has impact on it, passive earth pressure in elastic-plastic stage should be in calculated in accordance with Equation 5.

$$\sigma=[(0.0044rhE+22.015rh+0.0007Eh+0.1201rE-21.3713r+1.3973h+0.00266E)x-0.00011\gamma\varphi ch+0.008\gamma\varphi h+0.0013\gamma ch+0.07657\gamma\varphi c-0.1101\gamma+0.00206,.c\varphi h-0.059\varphi h-0.03953ch+0.00264\varphi c+0.67c-0.088\varphi-0.24h+1.9802]/0.5\pi(r+x) \quad (KPa) \tag{5}$$

Random selections of parameters are putted into Equation 4-5, and the results are compared with finite element simulation results in Table 1, there are a few differences between the results. Therefore, the passive earth pressure can be directly calculated according to the formula.

Table.1 Comparison between calculation and simulation with different parameters

| parameters | $\gamma$=18, r=0.08, h=2, e=1500, c=50, $\varphi$=30°, x=0.466, H=6 | $\gamma$=18, r=0.08, h=2.75, e=1500, c=50, $\varphi$=30°, x=0.466, H=8 | $\gamma$=18, r=0.08, h=2, e=2000, c=40, $\varphi$=25°, x=0.0138, H=8 |
|---|---|---|---|
| calculation(KPa) | 269.22 | 283.3 | 316.28 |
| simulation(KPa) | 274.34 | 290.37 | 318.36 |
| error amount | 1.86% | 2.43% | 0.65% |

## Conclusions

(1) The earth pressure can be considered as two stages, the elastic stage that the pressure raises rapidly and the elastic-plastic stage that the pressure increases slowly. In the elastic stage, the passive earth pressure is only related to *E*, *x*, *h*, *r*, and in the elastic-plastic stage, each parameter has impact on the value of pressure.

(2) By simulation, the formulas of the two stages are summarized, and the error value is small, formulas can be directly used to calculate the earth pressure except the soil near the bottom and the top. The earth pressure is not compared with the actual ones due to the lack of real data, but considering the numerical simulation and the formula derivation method is reasonable, the formulas of earth pressure can be applied to practical engineering.

**Keywords:** Red clay;Triaxial test;Engineering property;moisture content;shear strength

**Abstract:** Red clay belongs to region special soil.It has engineering geological properties that are different from general soils.The natural red clay has high ratio void ratio,high moisturecontent,low density and so on.But red clay has non-corresponding high strength,bearing capacity of foundation and low compressibility. With the high speed development of China economy,the main soil named red clay in South is used as bearing stratum of many building foundations.However,when red clay is used as foundation,it is regarded as gerenal clay to consider its bearing capacity of foundation.So this will cause two disadvantages.First,potential is not given full play,resulting in considerable waste.Second,red clay has some special properties,such as high woid ratio,softening in water.These properties will bring hidden troubles,causing some bad accidents.These are caused by lacking of knowledge to engineering properties.Xiamen locates in southeast of China,and red clay is widely distributed.It is formed by accumulation through laterization of granites and basalts.So it is essential to study red clay.In this article,literatures of red clay in Xiamen are collected.Indoor conventional geotechnical tests are done,some engineering property parameters are obtained.

## Introduction

Red clay belongs to region special soil,formed in tropical and sub tropical zones.It experiences different degree of laterization.It is rich in iron,aluminum oxide and much clay content,not containing base composition[1-3]. Engineering properties of red clay are different from that of general soil.Red clay under native state generally has high void ratio,high moisture content,low density and so on. But red clay has non-corresponding high strength,bearing capacity of foundation and low compressibility[4-7].

In our country,distribution of red clay is very extensive.According to preliminary statistics,there are more than 2 million square kilometers that are converd by red clay in our 9.6 million square kilometers.Its range is roughly from Changjiang River to Hainan,from Taiwan and the Penghu Islands to Yunnan-Guizhou Plateau and Hengduan Mountains.It refers to 14 provinces and regions.It is one of the most extensively distributing soils[8].It is observed from distributing regions that almost the South region is covered by red clay.I t is a parlance in China that is north of the loess,south red soil.

Xiamen locates in southeast in China.And it is extensive distribution of red clay in Xiamen.The land area of Xiamen is 1565 square kilometers,belonging to subtropical climate.

With the high speed development of China economy, the main soil named red clay in South is used as bearing stratum of many building foundations. However,when red clay is used as foundation,it is regarded as gerenal clay to consider its bearing capacity of foundation.So this will cause two disadvantages.First,potential is not given full play,resulting in considerable waste.Second,red clay has some special properties,such as high woid ratio,softening in water.These properties will bring hidden troubles,causing some bad accidents.These are caused by lacking of knowledge to engineering properties.So it is essential to study the red clay.

On the basis of collecting literatures,reading literatures and analysizing literatures in this article,study on shear strength of red clay in Xiamen is done.The main works are following.

(1) Reading literatue of red clay.

literatures about red clay are collected,read and analysed.

(2) Laboratory experiments of engineering characteristics of red clay.

It is regarded red clay in each region of Xiamen as the object of study.Samples of red clay are taken,the physico-mechanical indexes,such as moisture contents,are obtained by common physical experiments.

(3) doing Triaxial experiments of red clay.

Through triaxial experiments(triaxial consolidation draining shear test(CD), triaxial consolidation undraining shear test(CU), triaxial unconsolidation undraining shear test(UU)).Shear parameters of $c$ and $\varphi$ in Xiamen are determined.

**Routine laboratory experiments of red clay in Xiamen**

In order to know shear parameters of red clay in Xiamen,disturbed soils are sampled in some regions of Xiamen and moisture content experiments are done.

Table 1 Moisture content experiment

| Name | Testing samples | Teams |
|---|---|---|
| Sample1 | 1-9 | 3 |
| Sample2 | 1-9 | 3 |
| Sample3 | 1-9 | 3 |

In order to measure moisture content of disturbed samples exactly,sampling should obey priniples which is far from ground surface,keeps soils wet,and decreases evaporation of water as far as possible.

**Experimental methods and equipments**

Experimental methods of moisture content mainly have oven drying method,alcohol burning method,frying dry method,specific gravity method and so on.In this testing, oven drying method is used.9 specimens are sampled in each site,and are dryed for 8hours under 105-110°C,and the average value of 9 moisture contents are taken for moisture content of specimens

testing equipments:oven box which is heated by electricity and can keep 105-110°C;balance that its accuracy is 0.01g; small aluminum box and so on.

**Experimental datum**

moisture contents of specimens are obtained through meticulously experiments.The main datum are in the following table.

Table 2 Moisture content of specimens

| Name | Team | Quality of aluminum box(g) | Quality of soil and aluminum box(g) | Quality of dry soil and aluminum box (g) | moisture content (%) | The average value of moisture contents of each team(%) | The average value of moisture contents of each sample(%) |

| | | 9.557 | 22.845 | 20.114 | 20.552 | | |
| | | 9.287 | 23.359 | 20.565 | 19.855 | | |
| | 3 | 9.570 | 19.043 | 17.118 | 20.321 | 20.121 | |
| | | 9.559 | 20.911 | 18.681 | 20.206 | | |
| | | 9.573 | 22.862 | 20.226 | 19.836 | | |

**Analysis of testing datum**

From above table,it is concluded that the difference of moisture contents of specimens is bigger.The moisture contents of three samples are 16.599%, 26.131%, 20.202% respectivlely.

**Triaxial shear experiments of red clay in Xiamen**

Triaxial shear experiment is a method of testing shear strength.Generally 3-4 cylinder specimens are used in this experiment.Ttrixial compression(difference of principal stress $\sigma_1$-$\sigma_3$) is loaded under constant confining compression(minor principal stress $\sigma_3$) to shear until break.Then according to Mohr-coulomb theory, parameters of shear strength are obtained.

Triaxial experiments are divided into triaxial consolidation draining shear test(CD), triaxial consolidation undraining shear test(CU), triaxial unconsolidation undraining shear test(UU).In this experiment,these three experiments are done successively.

**Introduction of triaxial apparatus**

TSZ micro-control triaxial testing apparatus uses newest technology,gathering machine,electronic technique,automatic control technology,sensor automatic measurement technology and computer technology.Basic equipment could do routine stress-strain unconfined test,UU,CU,CD and so on.Different equipments of test vessels and control modules could do Ko consolidation test,static lateral pressure coefficient,triaxial test of multiple stress path,tensile test,elasticity modulus test,bearing ratio test and so on.If consolidation modules are equiped,step loading test and continuous loading testing are done.If vibration modules are equiped, micro-control vibration triaxial testing could done.

Fig. 1 TSZ micro-control triaxial testing apparatus

**Testing method**

Triaxial testing is composed of specimen preparation,specimen installation,consolidation stage,shear stage.

**Specimen consolidation**

(1) Confining compression is applied through control cabinet,and when it approachs to setting value,it is started.

(2) open drain valve.

(3) Pore water is drained through confining pression until pore water pressure decreases more than 95%.

(4) consolidation finishs and drain valve is closed.

**Analysis of testing datum**

Three testings are done to specimens: triaxial consolidation draining shear test(CD), triaxial consolidation undraining shear test(CU), triaxial unconsolidation undraining shear test(UU).The datum are following.

Testing results of triaxial unconsolidation undraining shear test(UU)

Table 3 UU testing datum

| Name | Team | value of C | average value of C | Value of $\varphi$ | average value of $\varphi$ |
|---|---|---|---|---|---|
| Sample 1 | 1 | 59.20 | 61.07 | 15.00 | 14.6 |
| | 2 | 61.10 | | 15.10 | |
| | 3 | 62.90 | | 13.70 | |
| Sample 2 | 1 | 12.70 | 15.80 | 19.90 | 19.73 |
| | 2 | 15.70 | | 19.90 | |
| | 3 | 19.30 | | 19.40 | |
| Sample 3 | 1 | 40.70 | 38.90 | 4.00 | 3.97 |
| | 2 | 32.80 | | 5.30 | |
| | 3 | 43.50 | | 2.60 | |

Testing results of triaxial consolidation undraining shear test(CU)

Table 4 CU testing datum

| Name | Team | value of C | average value of C | Value of $\varphi$ | average value of $\varphi$ |
|---|---|---|---|---|---|
| Sample 1 | 1 | 53.20 | 53.50 | 18.50 | 19.57 |
| | 2 | 56.30 | | 19.60 | |
| | 3 | 51.00 | | 20.60 | |
| Sample 2 | 1 | 12.70 | 16.10 | 19.90 | 19.73 |
| | 2 | 19.90 | | 19.40 | |
| | 3 | 15.70 | | 19.90 | |
| Sample 3 | 1 | 41.00 | 51.50 | 8.70 | 7.30 |
| | 2 | 57.00 | | 6.30 | |
| | 3 | 56.50 | | 6.90 | |

Testing results of triaxial consolidation draining shear test(CD)

Table 5 CD testing datum

| Name | Team | value of C | average value of C | Value of $\varphi$ | average value of $\varphi$ |
|---|---|---|---|---|---|
| Sample 3 | 1 | 19.40 | 42.43 | 23.50 | 21.73 |
| | 2 | 61.90 | | 20.10 | |
| | 3 | 46.00 | | 21.60 | |

Analysis of testing datum

It is concluded from table 6 and table 7 that parameters of shear strength will change with the change of testing method.Draining mode and consolidation mode have unconspicuous influence law to cohesions,but have conspicuous influence law to frictional angles.With improvement of consolidation and draining conditions, friction of soil increases showing the increasement of effective indexes of soil.This coincides with practical engineerings.

Table 6 Changes of cohesion C（KPa）under three testing conditions

| | UU | CU | CD |
|---|---|---|---|
| Sample 1 | 61.07 | 53.50 | |
| Sample 2 | 15.80 | 16.10 | |
| Sample 3 | 38.90 | 51.50 | 42.43 |

Table 7 Changes of frictional angle $\varphi$(°)under three testing conditions

| | UU | CU | CD |
|---|---|---|---|
| Sample 1 | 14.60 | 19.57 | |
| Sample 2 | 19.73 | 19.73 | |
| Sample 3 | 3.97 | 7.30 | 21.73 |

**Conclusions**

On the basis of collecting literatures,reading literatures and analysizing literatures in this article,study on routine experiments and shear strength experiments of red clay in Xiamen is done.The main conclusions are following

(1) moisture content relates to distributing sites of soil.

Difference of moisture content of samples is bigger.The moisture contents of samples are 16.599%, 26.131%, 20.202% respectively.

(2) Laboratory experiments of engineering properties of red clay.

It is regarded red clay in each region of Xiamen as the object of study.Samples of red clay are taken,the physico-mechanical indexes,such as moisture contents,are obtained by common physical experiments.

(3) doing Triaxial experiments of red clay.

Through triaxial experiments(triaxial consolidation draining shear test(CD), triaxial consolidation undraining shear test(CU), triaxial unconsolidation undraining shear test(UU)).Shear parameters of $c$ and $\varphi$ in Xiamen are determined. Parameters of shear strength will change with the change of testing method.Draining mode and consolidation mode have unconspicuous influence law to cohesions,but have conspicuous influence law to frictional angles.With improvement of consolidation and draining conditions, friction of soil increases showing the increasement of effective indexes of soil.This coincides with practical engineerings.

**Keywords:** failure mechanism, geotextile-reinforced soil, deformation, bearing capacity

**Abstract.** Several laboratory model tests were carried out on the bearing capacity of strip footings on reinforced soil foundation and reinforced slope. Compared with unreinforced cases, the deformation and failure of reinforced earth in different foundation conditions were monitored and analyzed. In order to visualize a failure mechanism when the ground reaches the state of limit equilibrium, a new numerical procedure was proposed. Assuming an elastic-perfectly plastic model, a smeared shear band approach and a modified initial stress method enable the proposed procedure to create an explicit collapse mode by the stress yield condition. On the basis of the development of failure mode and deformation of foundation, the bearing capacity of strip footings can be significantly increased by the inclusion of geotextile. And because the procedure considers the stiffness and deformation of the material, it may be applied to complex stability problems.

## Introduction

The technology of geosynthetics reinforced soils is applied more and more in recent geotechnical engineering practice. Among the possible applications, the beneficial use of foundation reinforcement to improve the bearing capacity has attracted a great deal of attention, and there have been numerous studies on this subject [1, 2]. These investigations have demonstrated that both the ultimate bearing capacity and settlement performance of shallow foundation can be improved by the inclusion of geosynthetics in the ground, and have proven the reinforced soil foundation to be a cost-effective foundation system.

When a footing is rested on sloping ground, the bearing capacity of footings may be significantly reduced. Yoo presented a possible measure of reinforcing the sloping ground with layers of geogrid to improve the bearing capacity [3]. To design a footing on a reinforced slope requires a thorough understanding of the mechanical behavior in addition to the bearing capacity behavior of the reinforced slope.

Most of previous studies concerning the design methods for the reinforced soil foundation and reinforced slope are based on the limit equilibrium which represents kinematical conditions only by using the mechanically reasonable shape of failure [4, 5]. However, the limit equilibrium-based stability analysis often tends to become uncertain and unreliable for a soil stratum which consists of multiple layers, or which includes materials having quite different stiffness like earth reinforcement material. This is because this method evaluates the material properties only by its final strength, and does not explicitly allow considering the stiffness and deformation of materials which may play an important role for evaluating earth reinforcement, and which may affect the globe failure mechanism. Although numerical analyses such as the finite element or finite difference analysis have become popular in design practice, no rational evaluation for the failure and deformation stability for determination of ultimate bearing capacity on reinforced foundation. Many researches show that the classical FEM does not necessarily provide a reasonable failure mechanism [6].

This study aims at establishing a rational method to examine the effect of geosynthetics on improvement of bearing capacity behavior based on the formation of failure collapse and deformation stability and to estimate the stability of rigid strip footing on reinforced soil ground and reinforced

slope. Firstly, several laboratory model tests were carried out to investigate the failure and deformation behavior of rigid strip placed on level ground and on top of slope with and without layers of geotextile. Then, combined a smeared shear band approach with a modified initial stress, a numerical procedure based on FEM was proposed to create a failure mechanism by stress yield condition. In addition, the proposed numerical procedure employs requires a small number of soil parameters to reduce the numerical efforts and to be applied directly to practical design works. Finally, the mechanical behavior of reinforced soil is discussed and analyzed by comparing the location and collapse of failure and deformation of reinforced earth with the unreinforced cases.

## Laboratory model tests

**Test configuration.** A series of laboratory model tests were executed in a test box made of a steel frame, having inside dimension of 70×10mm in plane and 55mm in height. The two sidewalls of the test box were constructed using transparent glasses marked in grids with side length of 5cm size for ease of monitoring the deformation and failure mechanism during testing. In addition, a rough base condition of a 0.15m model footing made of steel prepared at the bottom of the footing. Since the walls of the test box were firmly held in position by steel melting and the wall friction was kept to the minimum by using a thin rubber membrane smeared with a thin layer of silicon grease on the surface of sidewalls, plane strain conditions were considered for all model tests. In order to observe the experimental behavior, a hardened glass is fixed on one side of the soil stratum. Fig. 1 shows different parts and locations of testing apparatus for the case of slope, while the model footing and Bellofram cylinder used for applying the loading pressure to the footing should be rested on the middle of surface of ground.

All tests of slope were conducted with an artificially made slope of 1(V): 1.73(H). The model strip footing was located on the edge of slope, with the length of the footing equal to the full width of the soil tank in order to maintain the plane strain conditions. The two ends of the rigid model footing were polished smooth to minimize the end friction effects. A rough base condition was provided by rough sand paper on the bottom of model footing. The model tests considering the effect of reinforcement material were also performed. For the case of level ground, only one layer of geotextile is placed 130 mm deep in the ground according to the calculated position of active wedge below the model footing. For the case of sloped ground, the effect of reinforced soil was discussed through the two cases setting up one layer and two layers of reinforced material respectively, as shown in Fig. 2, besides Case 1 for natural unreinforced one.

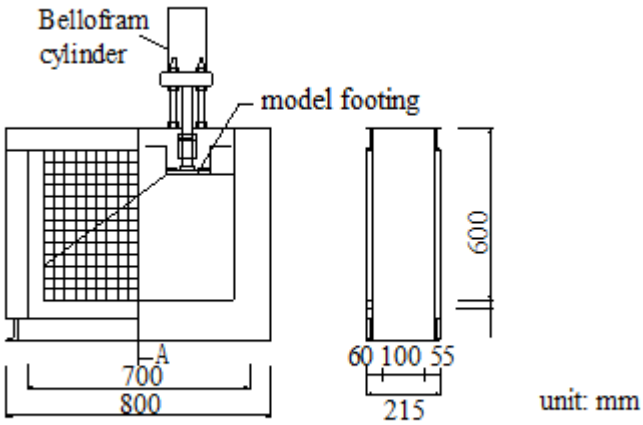

**Fig. 1** Schematic view of experimental apparatus

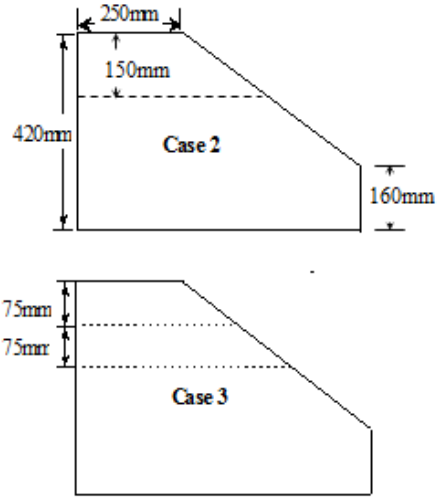

**Fig. 2** Arrangement of reinforced slope

**Materials used for the testing.** The sand used in the model ground was mountain sand taken from Mikuni region of Fukui in Japan. The soil parameters are shown in Table 1, in which c, φ: Mohr-Coulomb strength parameters, E: Young's modulus of the soil stratum, γ: unit weight of soil,

and μ: Poisson's ratio. In the experiments, c and φ were obtained by a direct shear test. E is back calculated by the footing settlement observed. Note that because of different locations of soil sample in two tests for level ground and slope, the parameters taken from soil test were different. Considering the effect of reinforcement material, one type of woven geotextile is used to the reinforced subsoil. Table 2 shows the properties of the woven geotextile.

**Test results.** Test relationship between load pressure and settlement of footing on natural level ground is compared with the reinforced case in Fig.3. The test results show that the bearing capacity and settlement is considerably improved by use of geotextile. The test results for three cases of sloping ground are shown in Fig. 4. Compared with Case 1 of natural subsoil without reinforced material, Case 2 with one layer of geotextile or Case 3 with two layers of geotextile has a higher failure load and a lower settlement respectively.

**Table 1** Soil Parameters

| Case | c (kpa) | φ (°) | E(kPa) | γ (kN/m$^3$) | μ |
|---|---|---|---|---|---|
| Level ground | 12.25 | 30.96 | 3924 | 15.66 | 0.33 |
| Slope ground | 7.85 | 15.9 | 5886 | 14.03 | 0.33 |

**Table 2** Properties of Geotextile

| length (mm) | width (mm) | thickness (mm) | E (MN/ m$^2$) | strain at tensile failure | tensile strength (kN/m) | mass (g/ m$^2$) |

| 900 | 200 | 0.21 | 4900 | 19% | 950 | 130 |

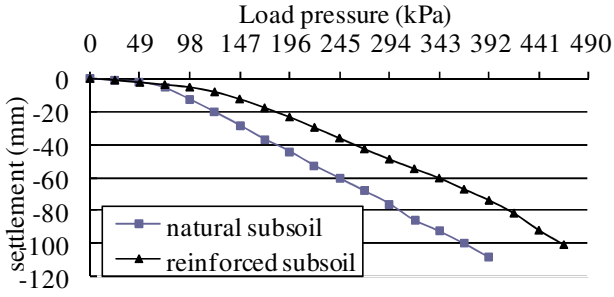

**Fig. 3** Load pressure-settlement relationship (Level ground)

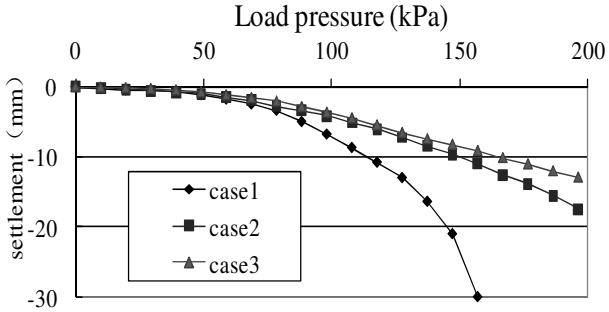

**Fig. 4** Load pressure-settlement relationship (Sloping ground)

## Numerical modeling

To relate the proposed procedure to conventional stability analysis, Mohr-Coulomb and Coulomb yield criteria were employed respectively to soil mass in plane strain condition and to the interface between the footing and the ground surface. To explain the effect of geosynthetics on improvement of bearing capacity and deformation behavior, a numerical procedure enables to get a definite failure mechanism was proposed. To obtain a rational failure mechanism analogous to that assumed in limit equilibrium method, three assumptions are followed [7]: 1) Assume an active wedge below footing; 2) Assume the yield element as a stratified material based on the smeared shear band approach; 3) Perform a nonlinear FEM based on the modified initial stress method [10].

**Numerical analysis.** Applying the numerical procedure to the laboratory model tests, the footing is modeled by beam elements and represented by its elastic modulus $E=2.1\times10^7$kPa, cross area $A=0.012m^2$ and moment of inertia $I=1.44\times10^{-7}m^4$. The shear modulus G of interface elements is given as $E/2(1+\mu)$ by using E and μ of subsoil. Many experimental researches have observed actually the active wedge developing below footing. However, when a footing rested on the slope the active wedge may be changed based on the relationship between major principle and direction of shear band rather than the most fundamental expression.

**Numerical results.** Due to the assumption of the smeared shear band for yield element, it may create an estimated slip surface by the distribution of yield element. Figs. 5 and 6 shows the yield regions given by the proposed procedure, in which a solid line in some finite element represents the correspongding element has yielded and shows the direction of shear band. In this study, the failure mechanism can be defined when the yield elements are connected to form a continous slip surface, accordingly the corresponding load $q$ determined as ultimate bearing capacity. Figs. 7 and 8 shows the numerical relationships between load and settlement for all cases in comparison with the test results, in which solutions of bearing capacity are shown supported by the formation of failure mechanism.

## Discussions

For the case of level ground, Fig. 7 illustrates the earth reinforcement effect on the bearing capacity in comparison with natural subsoil. FE meshing and material parameters are the same as those on unreinforced cases except the geotextile is practiced by truss material. The results show that the geotextile improves the bearing capacity because the geotextile restrict the extension of yield regions for reinforced subsoil in Fig. 5 which also contains a conventional slip surface presented by Prandtl .

For the case of slope, Fig. 6 compares the distribution of yield elements when the foundation reaches the ultimate bearing capacity $q$ for three cases. Because the position of geotextile in Case 2 is much deeper than the region of failure mode in Case 1 as shown in Fig. 6 (a), the geotextile little improves bearing capacity. While the geotextile of upper layer in Case 3 largely improves bearing capacity, for its position rather restricts the expansion of failure surface. Because the yield elements are mainly concentrated on the region upper the geotextile, the bearing capacity and deformation of reinforced soil foundation is improved, as shown in Fig. 8. In addition, it can be found that the bearing capacity of slope is less than the level ground because the failure surface cut through the side of slope prior to the surface of ground.

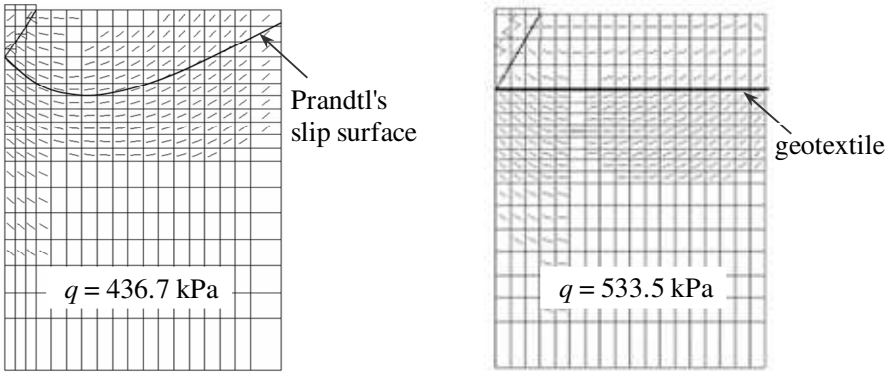

**Fig. 5** Failure collapse and yield regions for right half partof level ground: (a) unreinforced case (b) rienforced case

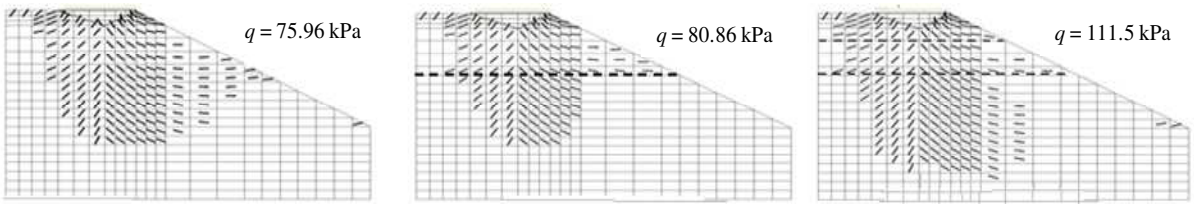

**Fig. 6** Filure collapse and yield regions of sloping ground: (a) Case 1 for natural slope (b) Case 2 for slope with one layer of geotextile (c) Case 3 for slope with two layers of geotextile

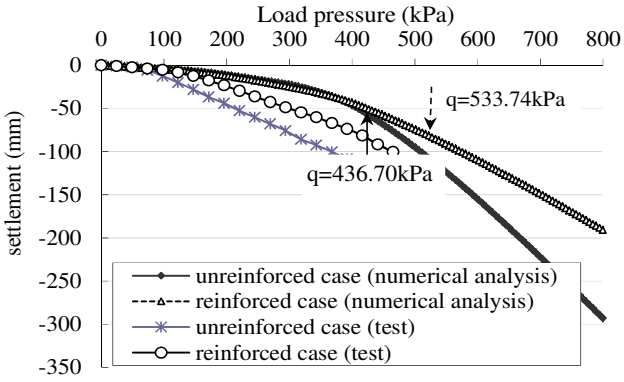

**Fig. 7** Load pressure - settlement relationship (Level ground)

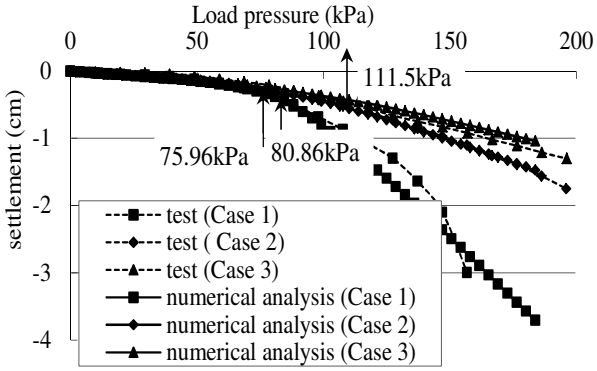

**Fig. 8** Load pressure-settlement relationship (Sloping ground)

## Conclusions

On the basis of the development of failure mode of foundation, the bearing capacity behavior of strip footings on reinforced soil was discussed. The following conclusions can be derived :

1) In order to fill a gap existing between limit equilibrium method and classical FEM, a numerical procedure was proposed to provide a reasonable failure mechanism in the course of design. Because the procedure considers the stiffness and deformation of the material, it may be applied to deal with the reinforced soil problems.
2) The bearing capacity can be determined by the failure collapse represented by yield elements; in any case the earth reinforcement gives much larger bearing capacity and restricts the settlement of foundation because the collapse mode is observed to be restricted to a narrow limit and to restrain the unconstrained plastic flow by geotextile especially by the upper geotextile.
3) In all cases the bearing capacity and failure collapse provided by the proposed procedure agrees fairly well with the test results. The results show that the geotextile placed different positions improve the bearing capacity behavior in different degrees, which agrees well with the experiment.

**Keywords:** GFRP bars; PC Strand; Supporting Piles; Engineering Field Test; Horizontal displacement; Energy principle.

**Abstract.** GFRP bars and PC strand composite pile is a new supporting piles, according to the engineering field test and analysis of experimental data prove that there is a significant effect on the control aspects of the horizontal displacement of supporting piles. Principle energy method can calculate the horizontal displacement of pile foundation pit in theory, by comparing the size of the horizontal displacement of the supporting piles of ordinary reinforcement, to demonstrate the feasibility of using GFRP bars and PC strand combination of techniques to reduce the horizontal displacement of excavation, provide reference for future engineering practice.

## Introduction

In recent years, with the accelerated progress of urbanization, urban population continues to gather, as land resources are very limited, the city would like the building height and depth inevitable. Along with high-rise buildings, large-scale development and construction of municipal facilities and underground space, the project site appears a lot of deep excavation, in order to ensure safety during construction excavation site and the surrounding environment, the horizontal displacement of foundation pit structure is not can be too much, so how to limit lateral excavation engineering practice structure is an urgent problem to be solved.

## GFRP bars and PC strand combination technique

**GFRP bars characteristics compared to ordinary steel.** Glass fiber reinforced (GFRP bars) as a new wire, used in China has just started. GFRP bars by using multi-strand continuous glass fibers as the polyethylene resin, epoxy glue, through a special pultrusion die. GFRP bars compared with ordinary steel, the main features are: (1) GFRP bars tensile strength than ordinary steel; low (2) shear modulus, ease of removal after the end of engineering support piles; (3) bulk density of small , is about 25% of the ordinary steel; (4) good corrosion resistance. Between these characteristics, GFRP bars replace bar in the supporting structure is entirely feasible, but it is reasonable.

**Combination technique of GFRP bars and PC strand in the supporting piles.** The use of low shear strength of GFRP bars, brittleness easy removal and post-tensioned steel noose recyclable characteristics, reduce excavations abandoned after the difficulty and cost of demolition, environmental protection, green construction has significance.

GFRP bars and PC strand combination pile that is configuration GFRP bars in the compression zone of the general pile, in the tension zone configuration PC strand. Pile construction is completed and before the excavation, applied partially prestressed for the tension zone of PC strand, so that GFRP bars in tension, with the excavation pit, GFRP bars tendons pulling force gradually reduced; When the excavation to a certain depth, the second prestressed steel strand so until the excavation is completed. In summary, the technology features is GFRP bars, concrete piles, PC strand all in tension. This makes full use of the concrete compression performance, GFRP bars and PC strand tensile good performance characteristics.The GFRP bars arranged on the pressure side of the row of piles, PC

strand disposed in pit row piles in tension side, shown in Figure 1, Figure 2. The use of pre-stressed technology, making the total cross section of the concrete is always compressed state (no tension zone), while the GFRP bars and the strand is always in tension, and through hierarchical prestressed GFRP bars tensile stress remains under control status, you can give full play to the advantage of material, making the material properties into full play, for material savings, lower costs of practical significance.

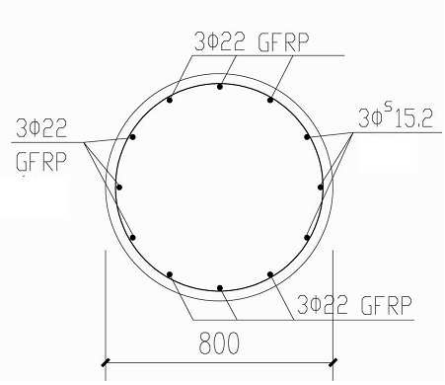

**Figure 1 Portfolio section pile reinforcement** **Figure 2 Combination trailer coupling**

## Energy Method Principle

**Energy Act introduced**. In static structural analysis, can be applied directly equilibrium conditions, geometric deformation conditions and physical conditions for solving the structure of the internal forces and displacements, which is generally static method, according to the most general case, its calculation of a total 15 unknown amount, there is the corresponding 15 equations, even for a simplified plane problem is, there are still six unknowns, ie there are six equations to be solved, the difficulty of solving these equations are equations without saying and Yu. If the equilibrium conditions or conditions with the corresponding geometric deformation energy principle instead solution as the basis for the establishment of the energy method is called. There are two basic methods in the static method, namely displacement method (to shift the basic structure of an unknown quantity) and power law (in some internal forces as the basic unknowns). Correspondingly, the energy principle also has two basic principles: the displacement method corresponds to the principle of minimum potential energy (potential energy in value theorem), and the corresponding force method is the minimum complementary energy principle. Algorithm on the horizontal displacement of the supporting piles mentioned below uses a minimum potential energy theorem, namely the potential in value theorem.

**Principle of stationary energy.** The total potential energy of the system by the criteria used to determine whether the structure of the stable equilibrium state. Energy criterion contains two common energy principle for the principle of stationary potential energy and minimum potential energy principle. Principle of stationary potential energy is when the system is in equilibrium, the total potential energy of a first-order change into zero, that is the total potential energy of this system is a stationary value:

$$\delta \prod = 0$$

Where in the total potential energy of the system has indicated that it is the strain energy and force potential U and W.

## Engineering Field Test

**Project Overview.** Golden Plaza project is located in Huaian City at the southwest corner of the word dam. The project set a floor basement. This is a basement excavation works. Engineering ± 0.00 equivalent absolute elevation 10.00m, excavation area 42000m$^2$ about pit perimeter around 1000m.

Natural ground level within the site about 8.50m, ± 0.00 equivalent absolute elevation 10.00m, Bottom elevation -7.00m, so the actual excavation of the pit depth 5.50m. The excavation depth of 5.50m, the environment in general, support the design level of safety to take two, namely the importance of the coefficient γ= 1.0.

**Engineering Hydrogeological Conditions.** ① Miscellaneous fill: taupe, gray-yellow, mainly clay, more than 30 years backfill time, the layer of soil audience distribution, thickness 4.00 ~ 8.10m. ② Silty clay: gray, soft plastic, widely distributed field area, thickness 3.70 ~ 8.00m. ③ Clay: brown, plastic, widely distributed field area, thickness 0.60 ~ 4.50m.

Each soil calculation parameters are shown in Table 1.

**Table 1 Calculation parameters for each soil**

| Layer No. | Strata Title | Severe | Solid fast direct shear | | Permeability coefficient recommended value |
|---|---|---|---|---|---|
| | | | Cohesion | Angle of internal friction | |
| | | γ | C | ϕ | K |
| | | KN/m$^3$ | KPa | Degree | (cm/s) |
| ① | Miscellaneous fill | 17.3* | 6.0* | 17* | 3e-4 |
| ② | Silty clay | 17.5 | 26.0 | 12.0 | 6.2e-5 |
| ③ | Clay | 19.2 | 49.0 | 18.3 | 3e-6 |
| Remark | In the table ,C, φ is the standard value, the rest is the average and marked with * are empirical values. | | | | |

**Test data processing.** According to the experimental data obtained pit displacement drawn through the measured data shown in Figure 3. After analysis, the true and reliable experimental data, through PC strand tensioning graded approach is applied to the control pit displacement effect is obvious, GFRP bars and PC strand combination supporting piles experiment was successful basically successful, can be used for further study.

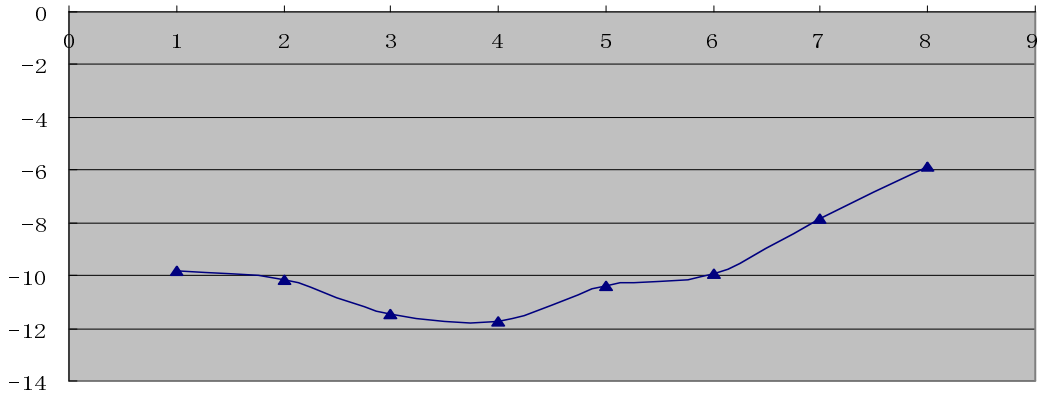

**Figure 3 The map of pit displacement**

## Using the energy method to calculate the lateral supporting piles

In order to reduce the horizontal displacement of the pile excavation, pile on the Strand in the tension zone of prestressing. After the excavation, in the role of supporting piles of earth pressure and prestressed re-equilibrium. Here in value theorem using the potential energy method to recalculate the amount of horizontal displacement after prestressing supporting piles.

By substituting the data and calculated: lateral reinforcement piles under normal circumstances occurred to 17cm, the maximum rear sway prestressed piles happen to 12cm, can be seen through the GFRP bars and prestressing strand combination of technology, the amount of horizontal displacement pile excavation reduction compared to ordinary reinforcement in the case of about 30%, and with the increasing depth of the excavation carried out repeatedly applied prestressing, the lateral row of piles will decrease to some extent.

## Conclusion

GFRP bars and PC strand combination of technology in the excavation of the theory is still in the research stage, by using the principle of energy method for the actual maximum lateral displacement of the pile calculation of the amount, and excavation pile comparison proved the feasibility of reducing the horizontal displacement of the pile excavation GFRP bars and PC strand combination technique. GFRP bars and because of low shear modulus characteristics, structure excavation as a temporary structure after the demolition of the construction problems have been resolved, not only reduced the waste, to achieve green building, but also for the future of the surrounding buildings construction brought convenience.

**Keywords:** slope stability; factor of safety; socketed pile length; strength reduction method.

**Abstract.**Piles are used widely for stabilization of landslides. To stabilize a slope settled on bedrock with piles the required factor of safety must be checked, and pile should be designed properly. Piles should be socketed into firm rock to prevent uprooting or overturning .In this research it is aimed to look into the socketed length of pile in bedrock. Therefore the parameters that affect the factor of safety of slope/pile system such as location, length, spacing and diameter of piles are analyzed. The effect of socketed length of pile in rock on pile behavior is investigated by plotting the shear force and bending moment diagrams along pile. The optimal pile position is found to be located slightly upper of the middle of the slope. The minimum socketed length after which the factor of safety will be remained constant is found to be 0.12L where L is pile length.FLAC3D computer code based on finite difference method is used to simulate the slope/pile system.

## Introduction

Anti-slide piles are utilized for the stabilizing of unstable slopes, and have been established as efficient stabilizing technique. The piles employed in stabilization of slopes and landslides are regarded as passive piles since they are generally subjected to lateral force developing from the horizontal movements of the surrounding soil. The Problem in the case of passive piles is complicated because the lateral forces acting on the piles are dependent on the soil movements, which are in turn affected by the presence of the piles. A pile will serve by its shear strength, which is different from an anchor or soil nail. [1]

For slopes with great depth between ground surface and stiff stratum or stable layer (bedrocks), the solution is impractical to embed piles into bedrock or a stable layer (infinite pile length assumption). Thus, the embedded length of piles is an issue and attracts great attention. Many studies have analyzed the embedded length of piles due to lateral soil movements. Ito et al. investigated the design method for a row of piles in a slope with a fixed slip surface, and analyzed the effect of pile length above the slip surface on the factor of safety of pile-slope system[2][2]. Poulos[3] introduced a design method of piles to reinforce slopes by a computer program ERCAP, and examined the impression of embedded length on resistance of piles. Chen and Poulos et al. [4] described a series of laboratory tests on single-instrumented model piles embedded in calcareous sand undergoing lateral soil movements, and analyzed the effect of the ratio of embedded pile length in the upper "unstable" sand layer to that in the lower "stable" sand layer on the maximum bending moment. Griffiths et al. [5] uses two-dimensional plane strain to examine the influence of pile reinforcement on stability of slopes by numerical analysis, and presented the effects of pile length on stability and factor of safety of slope; the uses of two dimensional plane strain would not reflect the actual pile-slope interaction.

Guo and Qin [6] developed an experimental setup to look into the behavior of vertically loaded free-head piles in sand subjected lateral soil movements.

The embedded length of piles subjected to lateral soil movements or in unstable slopes has been referred to either by model tests or by numerical simulations. However, only two parameters, the embedded pile length above the slip surface and the ratio of embedded pile length in the upper "unstable" layer to that in the lower "stable" layer, have been analyzed. More systematic studies are needed to better understand the pile-slope interaction. In the present study, the socketed length of pile in stable rock layer is analyzed, and the influence on safety factor and pile behavior is analyzed with three-dimensional elastoplastic shear strength reduction method.

**Analysis method**

The stability of slopes reinforced with one row of piles is commonly estimated using pressure or displacement based methods, applying an assumed or measured pressure or displacement distribution on piles according to experiences or in-situ measured values caused by lateral soil movements. But it cannot describe the actual coupled pile-soil interaction, and may cause some inaccuracies. Alternatively, the shear strength reduction finite element/finite difference methods can be a good choice, because it cannot only simulate the coupled pile-slope interaction but also calculate the global factor of safety conveniently. The definition of global factor of safety of slopes reinforced with one row of piles in shear strength reduction method is identical to the one in limit equilibrium method. The reduced shear strength parameters, $c_{rd}$ and $\phi_{rd}$, are defined as

$$C_{rd} = \frac{C}{FOS} \tag{1}$$

$$\phi_{rd} = \tan^{-1}(\tan\phi / FOS) \tag{2}$$

Where $C$ and $\phi$ are the actual shear strength parameters of the sliding soil layer; and FOS is the SSRM reduction coefficient; it is considered as the global safety factor of the pile stabilized slope.

**Slope reinforcement system**

**3.1 Model Geometry and Meshing**

The construction of three-dimensional finite difference models is processed using ANSYS 14.5 because it is accurately creating a refine meshed models. The generated meshed model is transferred to FLAC3D using special code written using C++ language. The FEM mesh in ANSYS is well fine-tuned at the pile zone and the near region to enable a closer examination of the state of stresses and displacements of the pile. The selected size of the pile element is 0.40 m and 0.50 m at the adjacent zones of sliding soil and rock layer. The maximum element size in the model does not exceed 2.0 m .In order to minimize the effect of boundaries; the least distant left at both sides back and front the anti sliding pile is 10 times pile diameter . The basic model was reinforced with a row of piles socketed into rock with different socketed length.

**3.2 Constitutive model and parameters:-**

The constitutive behavior of soil continuum is modeled using Mohr-Coulomb model. The Mohr-Coulomb strength criterion has been widely used for geotechnical materials. The position of a stress point on this envelope is controlled by a non-associated flow rule for shear failure, and an associated rule for tension failure. Constitutive behavior of anti slide pile and stable rock layer is considered as isotropic elastic model. The principal parameters of the base model are selected to let

the slope model at verge of failure (FS=1.0). The main parameters required in model calculation are shown in table1.Slope angle was selected to 35° while S/D is selected to be 3 in the base model and the anti slide pile diameter is 2.0 m.

Table 1. Material Properties required in the model computations

| Material Properties | Antislide Pile | Sliding soil | Rock |
|---|---|---|---|
| Density (Kg/m$^3$) | 2500 | 2000 | 2200 |
| Elastic Properties | | | |
| Young's Modulus (Mpa) | 1.04E+06 | 2.00E+02 | 2.39E+04 |
| Poissison's Ratio | 0.2 | 0.3 | 0.2 |
| Strength Properties | | | |
| Cohesion (Kpa) | | 20 | |
| Friction Angle(°) | | 10 | |

For slope-pile analysis, the use of interface elements is essential; the use of them allows relative movements between the soil and the pile, and between sliding and stable soil layers. The apparent stiffness of an element in the normal direction ( kn ) is

$$kn = ks = 10 \times \max\left[ (K + \frac{4}{3}G) \Big/ \Delta Z_{\min} \right] \tag{3}$$

Where : $K$ = bulk modulus of the stiffest neighbouring element

G =shear modulus of the stiffest neighbouring element

$\Delta Z_{\min}$ = smallest dimension of an adjoining element in the normal direction

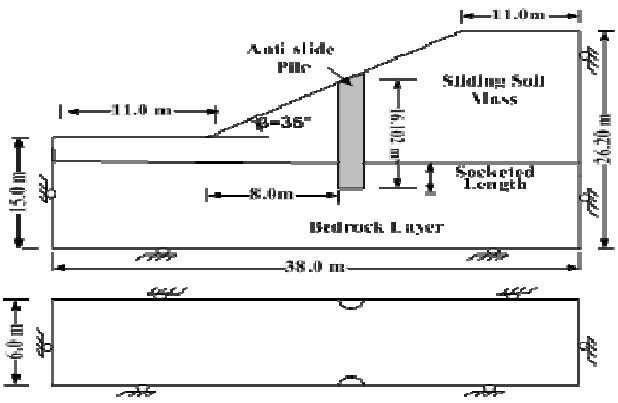

Fig. 2 Model Layout

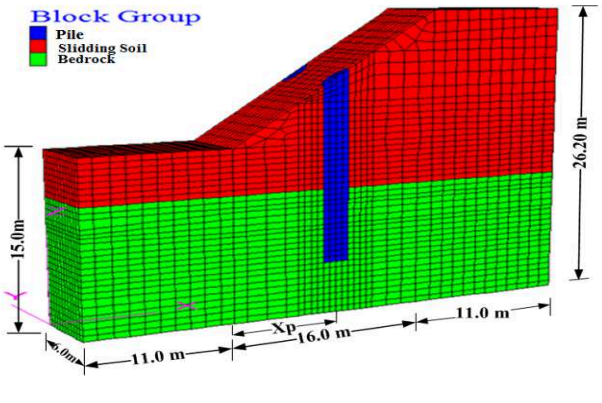

Fig. 1 Slope Model and Finite Difference mesh

## Results and discussions

### 4.1 Effect of pile location

In slopes and landslides stabilized with the piles, the location of the pile has an important role in the stability of slopes reinforced with piles. Many authors studied and investigated the effect of the pile location; they apply using different analysis techniques. As presented in Fig. 2, the pile location in the slope is determined by utilizing a dimensionless ratio ( $x_P/X$ ) where ( $x_P$ ) is the distance from the slope toe, and ( X ) the horizontal length of the slope.

Previous studies on one layer slopes have shown that the optimal pile location is not dependent on the distance between the piles[1]. Consequently, the location of a pile (S=3D) will be employed to find of the optimal location of the piles in a three-dimensional analysis.

The variations of the pile location with the factor of safety of reinforced slope for different slope angles are shown in Fig. 3. The embedment length in rock is considered large enough so that the maximum factor of safety can be obtained at each location. The results show that the maximum value of factor of safety is obtained when the stabilizing piles are installed in the upper middle part of the slope and this result is the same as results of other studies that have been carried out using shear strength reduction method. For the purpose of determination of the exact optimal location of pile, more models with different slope angles with different pile location are analyzed.

From the results shown in Fig. 3 the location of optimal position the pile tended to be within the upper middle of the slope for the different slopes. The optimum location of the pile tends to be towards the upper middle with the increase of slope angle (SA). All Slopes presented in Fig. 3 has factor of safety of 1.0 before installation of pile, consequently after pile installation the maximum factor of safety ranged from 1.49 to 1.53 and $X_P/X$ ranged from 0.53 to 0.59.

Xinpo et.al [7] used FLAC two-dimensional plane strain model found that the exact optimal location of the pile for slopes when the $X_P/X$ is 0.53. Won et al.[8] employing FLAC3D found the optimum pile location for slope when $X_P/X$ is 0.51, however, Hassiotis et al.[9] used the friction circle method to conduct the couple effect found the optimum $X_P/X$ to be 0.72. Hence, the results obtained in the present study are close to the findings from the authors who used FLAC3D to conduct such as a problem.

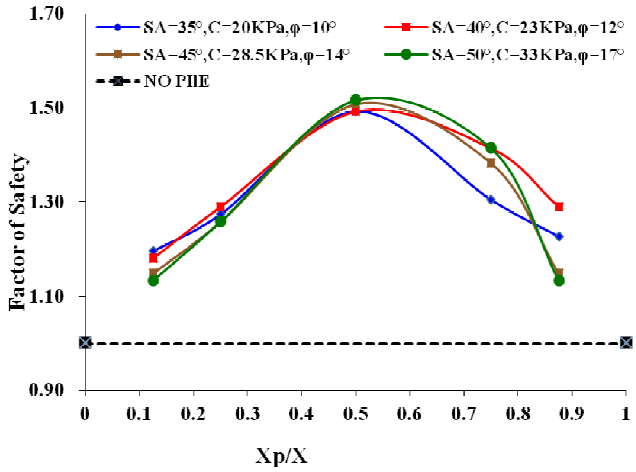

Fig. 3 Effect of Pile location on Safety Factor

**4.2 Effect of socketed pile length in stable layer (Sliding soil Thickness):-**

The impression of the coupled effect of The Stabilizing pile and soil can alter the depth of sliding surface. In effect, the thickness of sliding layer varying for slope to and another and at the same time, there is no determined pile length to be used in all slopes since it is dependent on the proportions of the slope and the depth of the critical slip surface. Therefore, in order to evaluate the effect of socketed length of the pile in stable layer the ratio $L_R/L$ ( $L_R$ , Length of Socketed length of the pile portion in stable layer, $L$ , length of piles) is used for the piles located at the middle of the slope.Fig. 4 shows the effect of the socketed ratio on the factor of safety of the reinforced slope. As expected, the results show that the factor of safety of the reinforced slope will increase with increasing of the socketed ratio. However, after a specified socketed ratio which is termed as the critical socketed ratio, the factor of safety will be remained constant. These results are similar to the results obtained by Griffith and Yang for the slope of one soil layer reinforced with one row of pile [5] . Thus, assumption of unlimited pile length in analysis is excessive and will make the designers to conduct an uneconomic design.

The results of analyzed models for different pile socketed lengths at the spacing of 2D are shown in Fig. 5 as the pile socketed length decreases; the pile deflection at the failure mode of slope will be increased, and comes to fully failure when the socketed length decreases as shown in displacement. The displacement of the pile along its length is relatively increased as shown when SR=0.0 and 6.0% consequently. It should be noted that when the pile socketed ratio is less than the critical socketed length; the deflection increases almost linearly with the depth. It emanated from less anti-slide force provided by the bottom of the piles and increase of sliding soil area in the top parts above the socketed portion.

It is observed that the bending moment of the piles as presented in Fig. 5 is increased in the socketed portion with the reduction of the socketed ratio. The position of the maximum bending moment is always slightly above the contact surface between sliding and stable soil layers, and whenever this surface move up or down the position of the maximum moment moves correspondingly. The distribution of the pile shear force as shown in Fig. 5c has two peak points. In the sling soil layer where the negative portion of the pile shear forces distribution, it is observed that the pile shear force increases with decreasing pile socketed ratio, and the point of the maximum shear force moves correspondingly with the move of the surface between sliding and stable layer until the pile socketed ratio less than the critical value. When the socketed ratio below the critical socketed length the shear force and bending moment in the pile are showing big reduction, in other words, the pile seems malfunction compared to the status where the socket ratio is greater than the critical value.

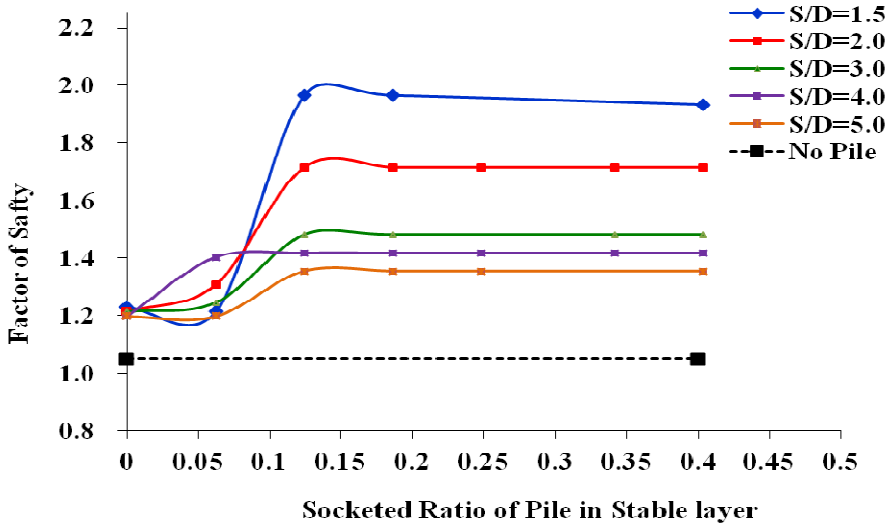

Fig. 4 Effect of Socketed length on factor of safety

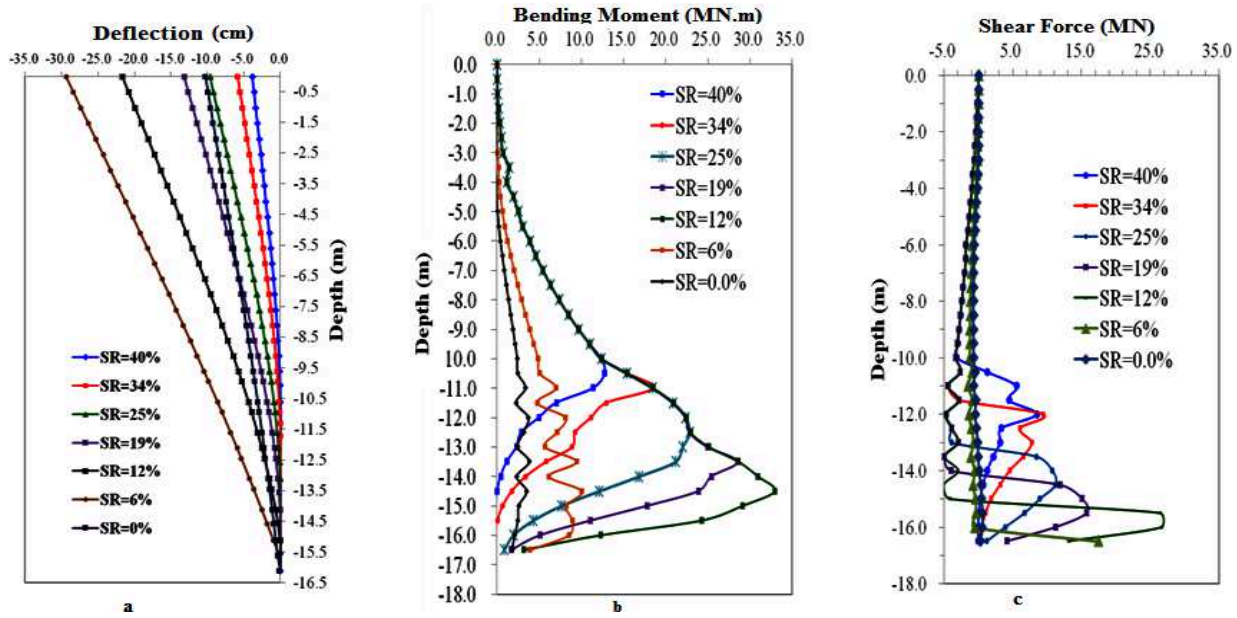

Fig. 5 Effect of socketed ratio on pile behavior

### 4.3 Effect of pile spacing

The influence of pile spacing on factor of safety with socketed ratio is present in Figure , it is noticed for smaller socketed ratio less than the critical $SR$ the effect of $S/D$ is small whereas the factor of safety for variant pile spacing was close together while the effect is considerable after the socketed length become greater than the critical SR and factor of safety show no increase after the critical socketed ratio. The effect of pile spacing on the factor of safety of reinforced slope for the piles installed where $x_P/x$ is equal to 0.5 is shown in Fig. 6. As anticipated, the factor of safety is reduced with increasing pile spacing. Similar curves have also been obtained by Cai and Ugai [10] and Jeong et al. [8] using coupled and uncoupled analyses, respectively. As shown in Fig. 6 ,at the beginning, as the pile interval increased the factor of safety decreases rapidly but the increase of the pile spacing contributes to a gradual decrease in the factor of safety. When the spacing of piles is $5.0D$ the factor of safety is 1.3, which is slightly greater than the recommend value by the Chinese code. Since, in practice, the pile spacing usually is not taken a very large value, regarding a small range for the pile spacing is enough in the analysis.

Fig. 7shows the effect of the socketed pile spacing on the pile behavior for the reinforced slope. With the reduction of pile spacing, the behavior of piles are more like to a continuous materials and the consequence of soil arching and load sharing of the pile turns to be more apparent so that the soil with a big displacement is arrived into the limit state. The behavior of the pile can be manifested by the deflection of piles at the failure mode of the slope for different pile spacings Fig. 7.a. The bending moment Fig. 7.b and the shear force of the piles for different pile spacings are shown in Fig. 7.The results show that with increasing pile spacing, the bending moment of the piles' increases and the position of the maximum bending moment is slightly above the surface between the sliding and stable soil layer. In other words, with increasing pile spacing, the value of the maximum bending moment increases. The same tendency also occurs within the shear force distribution of the piles. This can be explicated by the fact that the loading zone of each pile, impressed by lateral movements of soil (Sliding), is consequently increased with the increase of spacing between piles. It is also detected that the rate of change in the behavior of piles with small spacings is faster than piles with large spacings. This is in a well agreement with the results formerly obtained about the factor of safety of the reinforced slope for various pile spacings and also the results obtained by Yang et al.[5].

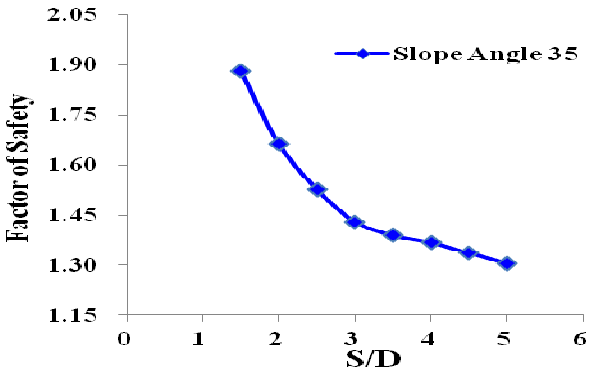

Fig. 6 Effect of S/D on Factor of safety

## Conclusions

The Socketed length of anti-slide pile used in slopes overlaying bedrock is analyzed employing three dimensional shear reduction method .From the result of the numerical model following conclusions can be drawn.(1) Pile position significantly affects the factor of safety of reinforced slope; the optimum position was found to be within the upper middle of the slope; when the slope angle increased the optimum pile location is prompting slightly up.(2) The socketed length is affecting safety factor of the slope; the minimum socketed length to gain the maximum safety factor was found to be 12% of the pile length.(3) Pile behavior is affect by socketed length with the increase of socketed length the maximum bending moment and shear force are increased, the position of peak value always located slightly above the bedrock layer.(4) Bending moment and shear force is increased with the increase of pile spacing due to the extension of loading zone of each pile.

**Keywords:** Bridge Engineering, Bearing Characteristics, Numerical Simulation, Rock-socket pile, Side Friction

**Abstract.** Wujiang Bridge is located on the Wujiang River in Chongqing Province in China. Based on test method of numerical simulation, the bearing characteristics of this large-diameter rock-socket pile with super-thick pile caps have been analyzed, including pile foundation load-bearing characteristics, pile-soil load sharing, and stress flow analysis of thick pile caps. The results indicated that Q-s curve of this kind of pile is approximate to linear. Under the action of ultimate load, the main load was supported by pile end résistance. And according to main stress distribution of pile cap, there is an obvious spatial truss effect phenomenon in it.

## Introduction

With the development of large span bridge structure, the large diameter rock-socket pile has been widely used in bridge engineering [1, 2]. The mechanism research on stress and deformation is more and more at present, but the research about the mechanism of super-large diameter rock-socket pile is comparatively rare, and lack of the necessary reference data. The main research methods are field test and laboratory tests [3, 4]. Based on the Wujiang bridge pile foundation project, the finite element analysis method is used to study the load bearing characteristics in this article.

## Project Overview

Wujiang Bridge, which is 630m length, is located over the Wujiang River at the Fuling of Chongqing Province in China. The structural style is twin towers and double cable plane cable-stayed bridge as shown in figure 1. The main beam is 26.9m width, and 2.73m high. The high span ratio is 1/117.2. On the west side of river the tower is 206.3m height, east tower is 198.3m height. The concrete strength of the pylon is $C_{50}$, The large diameter group pile foundation, using $C_{40}$ concrete poured, is used in this project. The cap size is 20m×16.4m×7.5m. The four piles under the cap is cast-in-place pile, which is 4.0m diameter, 38.5m length. The bearing layer at the tip of pile is weathered limestone.

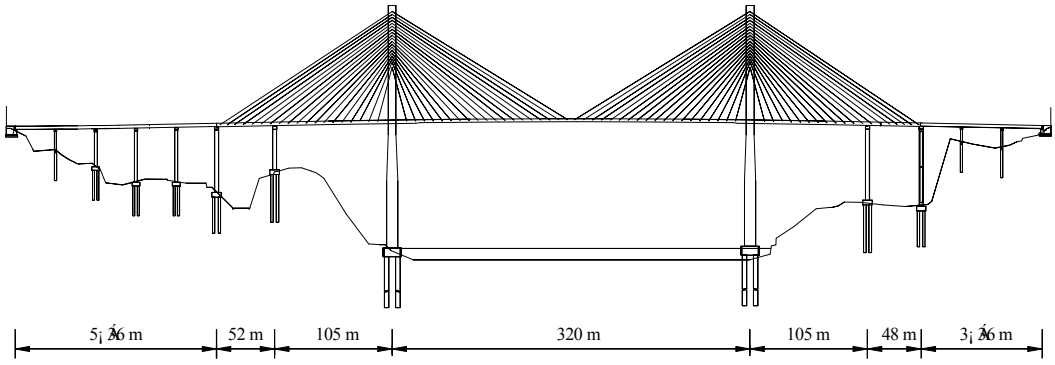

Fig.1 Schematic diagram of Wujiang Bridge

## Established the finite element model

**Model unit.** Numerical simulations of soil, pile cap, pile are used in 3D modeling in this paper. Considering the restrictions of computing speed and accuracy of the results, the C3D8R unit is selected in the modeling. Soil are divided into about 100000 grid units, the four piles are divided into 15000 grid units and pile cap is divided into 9000 grid units. The number of the grid can ensure the accuracy of numerical analysis enough.

**Material parameters of the model.** The material of pile and pile cap is reinforced concrete, the isotropic elastic model, its parameters as shown in chart 1. The soil around the piles is used in Mohr - Coulomb model. Due to the more soil can bring more inconvenience to contact calculation, soil is simplified into three layers according to the geological exploration report, and its parameters are shown in chart 2.

Chart1 Elastic Parameters of Pile Model

| name | elasticity modulus (MPa) | Poisson's ratio | density (kg/m$^3$) |
|---|---|---|---|
| concrete | 30000 | 0.22 | 2500 |

Chart2 Physical and Mechanical Parameters of Soil

| layer | elasticity modulus (MPa) | Poisson's ratio | Cohesion (kPa) | internal friction angle | Density (kg/m$^3$) |
|---|---|---|---|---|---|
| soil-1 | 7 | 0.30 | 22 | 35 | 1950 |
| soil-2 | 10.9 | 0.30 | 0.025 | 35 | 1950 |
| rock | 455 | 0.25 | 690 | 51 | 2200 |

**Model size and boundary conditions.** According to the modeling of the relevant engineering experience, the soil model is 77 m length, 60 m width, and 80 m depth, as shown in figure 2.

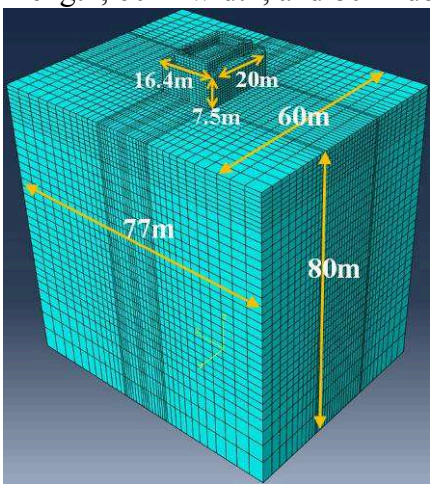

Fig.2 Model for the numerical simulation

## Numeric Simulation Results and Analysis

**Pile foundation load-bearing characteristics.** In order to learn the transfer mechanism of pile-pile caps- soil system, the vertical ultimate load for 67800 T, which is provided by designing institute, is selected to impose on the model. Under the vertical load the stress and displacement cloud charts as shown in figure 3 and 4.

From the perspective of the stress cloud charts of z axis, under the action of ultimate load, it can be seen that the soil at the bottom of the pile and soil-pile friction beard the upper load, side friction was more noticeable.

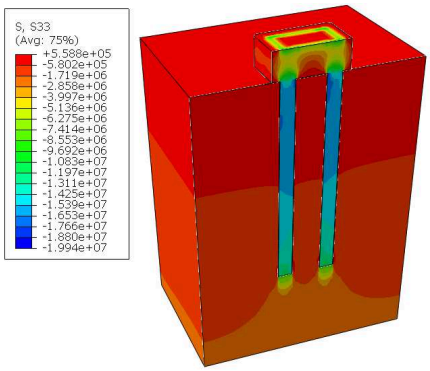

Fig.3 Stress cloud maps of z axis

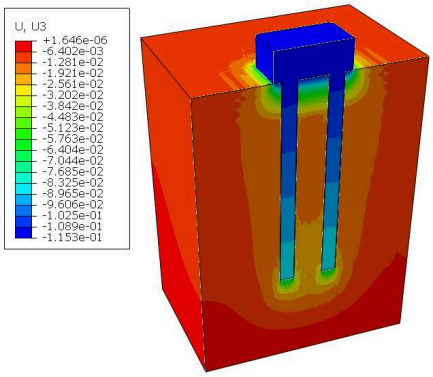

Fig.4 Displacement cloud maps of z axis

The load-settlement relationship of pile is shown in figure 5. As shown in the picture, load-settlement curve is gentle, which is approximate to linear. The reason is that the pile foundation of Wujiang Bridge is rock-socketed pile, its diameter and length is deeper. So its bearing capacity is high and the settlement is less. Besides, its bearing layer is weakly weathered limestone, which can effectively reduce the settlement. The relative stiffness of pile caps is bigger than pile. It has good coordination ability to differential settlement of pile.

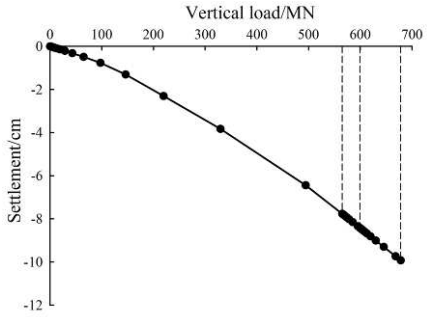

Fig.5 Load - settlement curve of group Piles

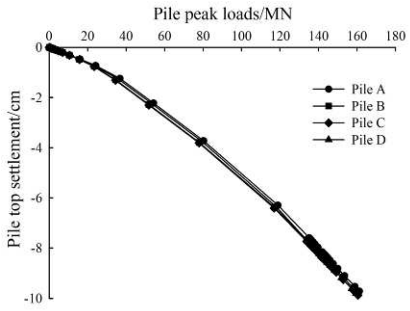

Fig.6 Load - settlement curve of each pile

From figure 5, the curve has not been a turning point. This is because with the load increasing, the elastic slip between pile and rock wall get increasing, the upper load shall be done by the pile end. Under the pile end is full of high strength of rock, so the curve does not appear obvious turning point.

**Load-settlement curve of each pile.** Q-s curve of single pile in group pile as shown in figure 6. With the increase of load on pile caps, the settlement of pile top has been increased too. The curve presented a linear relationship. When load added to limit state, there are still no obvious turning points. This shows that the bearing capacity of pile foundation has a high security reserves. From the settlement of each pile, it can explain the ultra thick pile cap has very good coordination ability to differential settlement. It is also a very important control parameter in the process of bridge construction.

**Analysis of Pile-soil load sharing.** With the load at the top of the cap increase, the pile tip resistance and pile side resistance and soil at the bottom of the pile caps has changed as shown in figure 7.

From the diagram it can be seen that, at the beginning of loading, side friction sustained majority of the load, while the rest of load was supported by the rock of pile end. The load, shared by the soil at the bottom of the pile caps, is small. With the increase of load, pile side friction began to increase slowly, and reached limit value, the load, which the soil at the bottom of the pile caps sustained, would increase slowly, however, the quantity is very limited. By contrast, the bearing capacity of pile end was increased dramatically.

The load sharing ratio is shown in figure 8. It can be seen clearly the proportion relationship among the pile tip resistance and pile side resistance and soil at the bottom of the pile caps in the process of loading. We can draw a conclusion that the load is mainly composed of pile side friction and pile end resistance, the load which soil at the bottom of the pile caps bear is small, it can be neglected in large diameter super thick pile caps in pile foundation system.

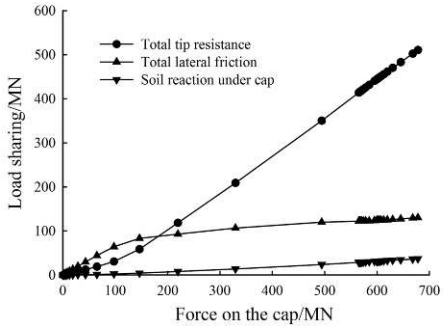

Fig.7 Load sharing

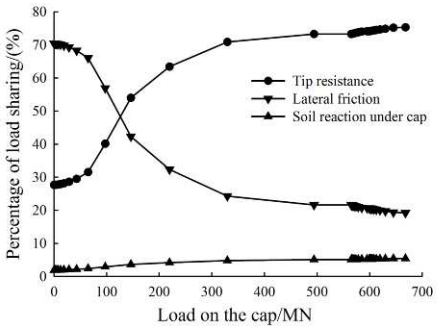

Fig.8 Percentage of load sharing

**Load transfer stress flow analysis of thick pile caps.** In the process of load transfer of pile foundation, thick pile caps can appear the obvious effect of thick pile caps. In order to be more intuitive understanding of its mechanical characteristics, the finite element data was processed, and entity graph of internal compressive stress flow on pile caps is shown in figure 9.

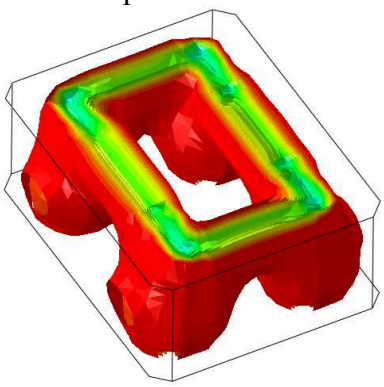

Fig.9 Entity graph of ompressive stress flow

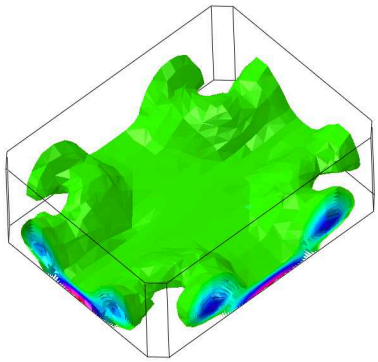

Fig.10 Entity graph of tensile stress flow

It can be seen from the figure 9. a compressive stress arch will be formed between two adjacent piles. Upper load pass directly to the pile top through stress arch foot. The entity stress flow graph is shown in Figure 10. Through the picture it can be clearly seen the area where the tensile stress distributed in the process of force transmission. The main distribution was at the bottom of the thick pile caps. According to main stress distribution of pile cap, we can know where reinforced should be set up in pile cap design. This not only ensures the safety of the structure, but also save material, avoids waste in the whole cross section of encryption.

## Summary

In pile foundation system of large diameter super thick pile caps, the load is mainly supported by side friction and pile end resistance, the load which soil at the bottom of the pile caps bear is small. According to main stress distribution of pile cap, there is an obvious spatial truss effect phenomenon in it. This is completely different to the general pile caps.

**Keywords:** Support Vector Machines, Markov Chain, Displacement Time Series, Particle Swarm Optimization.

**Abstract.** A new displacement time series predicting model was proposed by combining the Support Vector Machines and the Markov Chain, which was named as Support Vector Machines and Markov Chain (SVM-MC) model. Through studying the measured displacement, SVM optimized by particle swarm optimization (PSO) was used to forecast the trend of macro development in roll. Markov chain was applied to compute State Transition Probability Matrix. By classifying system state and calculating absolute error and relative error between measured value and SVM fitting value, the predicting results are improved. The model was used on predicting displacement time series of a high slope of a permanent lock. The engineering case studies indicated that the model was scientific and reliable, and there was engineering practical value for displacement time series forecasting.

## Introduction

The rock mass displacements show some characteristics of random fluctuations for both the internal factors (geological structure, the nature of the rock, rock structures, etc.) and external factors (excavation, blasting, rainfall, etc.). The prediction of the displacement timing of geotechnical engineering could be used to accurately predict the deformation of rock and soil with the monitoring data collected. Thus the feedback is helpful in adjusting the construction program and taking urgent measures. Currently the major modeling methods used to predict the timing of displacement are time series analysis methods and intelligent rock mechanics methods. However, there are defects in all of these methods[1-2].

SVM (support vector machines, SVM) is a kind of machine learning techniques based on structural risk minimization principle, which can solve the practical problems of small samples, nonlinearity, high dimension and local minima. Applicable to volatile random time series forecasting, the Markov Chain (markov chain, MC) system can better reveal the performance randomly generated influenced by a variety of complex factors. In order to improve the prediction result, obtaining a more accurate timing of displacement, the two algorithms is proposed to be integrated and the support vector machine - Markov chain model (SVM-MC) is proposed.

## SVM-MC Model Building

**Support Vector Machines.** Given the training sample set $(x_i, y_i)_{i=1}^{l} \in R^n \times R$, $x_i$, $y_i$ is the input and output variables respectively, $l$ is the sample number. SVM [3] uses the linear regression function to fit the sample set as follows:

$$y(x) = w\phi(x) + b\,. \tag{1}$$

Where, $w$ is the weight vector, $b$ is the bias, $\phi(x)$ is the non-linear mapping. Assume that all training samples within the precision $\varepsilon$ is error-free fitting using linear function. Considering the existence of the fitting error, the non-negative slack variables $\xi_i$ and $\xi_i^*$ are introduced. Using duality theory, turned the optimization problem into the following optimization problem:

$$\max\{-\frac{1}{2}\sum_{i=1}^{l}\sum_{j=1}^{l}(\alpha_i-\alpha_i^*)(\alpha_j-\alpha_j^*)K(x_i,x_j)-\varepsilon\sum_{i=1}^{l}(\alpha_i-\alpha_i^*)+\sum_{i=1}^{l}y_i(\alpha_i-\alpha_i^*)\}$$
$$St\sum_{i=1}^{l}(\alpha_i-\alpha_i^*)=0(\alpha_i,\alpha_i^*\in[0,c]) \quad . \tag{2}$$

Here, $K(x_i,x_j)$ is the kernel function. According to KKT theorem, $\alpha_i,\alpha_i^*,b$ can be obtained for the SVM:

$$f(x)=\sum_{i=1}^{l}(\alpha_i-\alpha_i^*)K(x_i,x)+b\,. \tag{3}$$

Here, the kernel function $K(x_i\cdot x_j)=\phi(x_i)\phi(x_j)$. The Gaussian radial basis function is used in this paper.

**Particle Swarm Optimization.** PSO uses the velocity - position search model. Each particle represents a candidate solution of the solution space. A fitness function is defined to evaluate each particle solution. The velocity $v_i=\{v_{i1},v_{i2,}\cdots,v_{in}\}$ determines the $i$ th particle's distance of each iteration in the solution space. A group of random particles is initialized, among which the location of $i$ th particle in the $n$ -dimension solution space could be represented by $x_i=\{x_{i1},x_{i2},\cdots,x_{in}\}$. Particles update their velocity and position through tracking the individual extreme values $f_i=\{f_{i1},f_{i2},\cdots,f_{in}\}$ and the global ones $g=\{g_1,g_2,\cdots,g_n\}$ dynamically. The formula is as follows:

$$\begin{aligned} v_{id}^{k+1}&=wv_{id}^k+c_1r_1(f_{id}^k-x_{id}^k)+c_2r_2(g_d^k-x_{id}^k)\\ x_{id}^{k+1}&=x_{id}^k+v_{id}^{k+1}\end{aligned} \quad . \tag{4}$$

Where, $w$ is the inertia weight factor; $r_1,r_2$ present the random number uniformly distributed in the interval $(0,1)$ ; $c_1,c_2$ are the learning factors; $i=1,2,\cdots,N$ , $N$ is the number of particles; $v_{id}^k,x_{id}^k$ are the $i$ th particle's $d$ -dimensional component vector of the velocity vector and the position one respectively; $f_{id}^k,g_d^k$ are the $i$ th particle's $d$ -dimensional component vector of the optimal individual location and the global optimization one, $d=1,2,\cdots,n$ ; $n$ is the dimension number.

**Dynamic Trend Forecast.** The first step of dynamic trend forecast is to prediction the $p$ time series $\{x_m,x_{m+1},\cdots,x_{m+P-1}\}$ after $m$ using $m$ time series $\{x_i,x_{i+1},\cdots,x_{i+s}\}$ $(i=0,1,\cdots,\ m-s-1)$ , $m-s$ group time series. With the $p$ time series obtained, $\{x_0,x_1,\cdots,x_{P-1}\}$ is replaced by the $p$ time series. The new $m$ time series is used in the $p$ time series prediction next time, and so on[4].

When using SVM modeling, the selection of penalty factor $C$ and kernel function parameter $\sigma^2$ directly affect the prediction accuracy. PSO is induced to optimize its parameters.

**Improvement of Prediction by Markov Chain.** The displacement time series is divided into several states with the different upper and lower thresholds of the relative error $\Delta$ between the displacement measured value and support vector machine fitting results chosen as the criteria for classification denoted $S1,S2,\cdots,Sn$ . $n$ is the number of states. Assuming the probability of the sequence number $Si$ in the displacement state is $m_i$ . The probability of state $Si$ transferred to state $Sj$ after $k$ steps is $m_{ij}(k)$ . The probability of the state $Si$ transferred to state $Sj$ of displacement sequences after $k$ steps is:

$$P_{ij}^{(k)}=\frac{m_{ij}(k)}{m_i}(i,j=1,2,\cdots,n) \quad . \tag{5}$$

Since the last state of displacement timing shift is uncertain, so the last $k$ timing data is to be removed.With the transition probabilities calculated, the displacement time state transition matrix is created.Giving state transition matrix established, the trend of the system can be predicted by examining the state transfer matrix $P(k)$. Preparation table is enquired before forecast.

Determining the future steering of the displacement time series, the variation range of SVM prediction value is determined. The most likely predicted value may be the midpoint of the interval:

$$F(x) = (1+\overline{\Delta}) f(x) = (1+\overline{\Delta})(\sum_{i=1}^{n} (\alpha_i - \alpha_i^*) K(x_i \cdot x) + b) \ . \tag{6}$$

Where, $\overline{\Delta} = (\Delta_{up} + \Delta_{down})/2$ is the average relative error, $\Delta_{up}, \Delta_{down}$ respectively presents the upper and lower limits of the interval; $F(x)$ is the improved predicted value by Markov chain; $f(x)$ is the predicted value of support vector machine. The variation range of the predicted value is $(1+\Delta_{up}) f(x) \sim (1+\Delta_{down}) f(x)$. Equation (6) is the SVM-MC model .

## Project Applications

The permanent ship lock in a project is huge, technically complex. And it comprehensive benefits significantly. A lot of monitoring instruments is settled in the south, the northern slope and central pier for real-time monitoring of the deformation of the slope. The monitor displacement of observation points outside the lock TP/BM27GP02 from 14 January 1998 to 14 May 2001 were analyzed using the proposed method. Monitoring interval is one month, with totally 41 steps.

**Displacement timing fitting by SVM.** After SVM trial, select $C = 62.43$, $\sigma^2 = 7.98$, $s = 10$, $p = 1$, take the first 37 time steps to construct 27 learning samples, while the last four steps as the test samples. Table 1 lists the measured displacement value of 27 learning samples, fitted values of support vector machines , absolute error, and relative error.

Table 1 Measured value and fitting value of SVM

| Time Step | Measured Value / mm | SVM Fitted Value / mm | Absolute Error / mm | Relative Error (%) | State | Time Step | Measured Value / mm | SVM Fitted Value / mm | Absolute Error / mm | Relative Error (%) | State |

| 21 | 30.51 | 30.15 | 0.36 | 1.18 | *S*3 | 35 | 34.76 | 34.25 | 0.51 | 1.47 | *S*3 |
| 22 | 31.70 | 31.03 | 0.67 | 2.11 | *S*4 | 36 | 34.76 | 34.99 | -0.23 | -0.66 | *S*2 |
| 23 | 32.21 | 31.52 | 0.69 | 2.14 | *S*4 | 37 | 32.90 | 35.02 | -2.12 | -6.44 | *S*1 |
| 24 | 31.28 | 31.12 | 0.16 | 0.51 | *S*3 | | | | | | |

**Improvement of Displacement Timing by Markov Chain.** Divided state based on the relative error $\Delta$ of the measured value and the displacement values support vector machines fitted. Taking into account the convenience of calculation the timing displacement is divided into four states (Table 2). According to Table 2, in which the state of learning samples is divided( Table 1).

Table2 The state division standard

| Status codeS | *S*1 | *S*2 | *S*3 | *S*4 |
|---|---|---|---|---|
| State numeric limits (%) | [-8,2) | [-2,0) | [0,2) | [2,8] |

After a number of steps to the state according to Table 1, may be determined for each state, but also can determine the number of state occurs.

According to the distance from the forecast step, numbers of shift steps are set 1,2,3,4. In the transition matrix corresponding to the shift steps, the row vectors of the initial state is selected to form a new probability matrix. Sum the new column vector. The state corresponding to the shift steps with the largest sum is the steering state of the system. Table 3 shows the results of the states the 38'th step is in. Seen from Table 3, in the total column, the possibility state $S1$ and $S2$ appear is the largest and nearly equal, which means that the error of the measured and predicted values of the 38'th step is most likely in the range constituted by $S1$ and $S2$. Therefore, the error of the midpoint of the range is taken as the possible errors of predicted values. According to formula (6) it is obtained

$$F(x) = (1+\bar{\Delta}) f(x) = (1+{}^{(-8)}\!/_{2}\,\%) \times 35.95 = 34.512$$

In this case, the measured value is 34.60mm. The predictive value using support vector machine model is 35.95mm. SVM-MC effectively improve the prediction accuracy.

Table 3 The table of state forecasting of the 38th time step

| Time step | Initial Status | Shift Steps | *S*1 | *S*2 | *S*3 | *S*4 |
|---|---|---|---|---|---|---|
| 37 | *S*1 | 1 | 0.667 | 0 | 0 | 0.333 |
| 36 | *S*2 | 2 | 0.143 | 0.428 | 0.286 | 0.143 |
| 35 | *S*3 | 3 | 0 | 0.428 | 0.428 | 0.144 |
| 34 | *S*4 | 4 | 0.333 | 0.333 | 0.167 | 0.167 |
| | Total | | 1.143 | 1.189 | 0.881 | 0.787 |

When the measured value of the 38'th step ia obtained, deleting the data of the first time step, add the data of the 38'th time steps, and form learning sample of fixed length, ensuring the latest observational data is used in each prediction. Seen from Table 4, SVM-MC predicted values and the measured ones are in good agreement, the error is small, and the prediction accuracy has been greatly improved compared with SVM.

Table4 Comparison of the measured value and predicted value of displacements

| No. | Measured Value /mm | SVM Predicted Value/mm | SVM Relative Error （%） | SVM-MC Predicted Value /mm | SVM-MC Relative Error (%) |
|---|---|---|---|---|---|
| 38 | 34.60 | 35.95 | -3.902 | 34.52 | 0.254 |
| 39 | 35.78 | 36.98 | -3.354 | 35.50 | 0.783 |
| 40 | 34.53 | 36.86 | -6.748 | 34.87 | -0.985 |
| 41 | 33.99 | 37.04 | -8.973 | 35.02 | -3.030 |

## Conclusions

Combining SVM and MC, SVM-MC for displacement timing prediction is proposed. SVM-MC boasts both advantage of SVM and MC. SVM is adopted to predict the macroscopic development law of the timing displacement. The state transition probability of MC is applied to characterize the microscopic fluctuations feature of the timing displacement, thereby improving the accuracy of prediction. Project application shows that the model is feasible, enhancing the single prediction accuracy of SVM model. Thus the mode could be promoted in displacement timing analysis.

# Project Design of Dewatering for Deep Foundation Pit in Dalian

Bailiang Guo[1, b],Hongbin Liu[1,a]

[1] School of Civil Engineering, University of Science and Technology Liaoning, Liaoning, China

[a]binbinliu999@126.com, [b]908663979@qq.com

**Keywords:** Deep Foundation Pit, Dewatering Design, Well-Points Dewatering

**Abstract.** Tube well dewatering is widely applied in deep foundation pit for its large water discharge, good dewatering effect, simple equipment and easy maintenance. In this paper, rube well dewatering is designed for the temporary project of foundation pit according to the engineering characteristics and stratum and underground water distribution with the deep foundation pit engineering as the background. The required parameters and design process of well tube dewatering are illustrated, and experience of applying tube well dewatering in evacuation of deep foundation pit is accumulated, which will be of certain referential significance for similar projects.

## Introduction

With the continuous rapid development of economy, the construction of underground urban space develops at an unprecedented speed. As a result, substantial foundation pit engineering occurs, and its depth increases constantly. The security of foundation pit turns to be extremely significant, while the construction of foundation pit is usually below the underground water, For avoiding the quick sand, piping and sudden surge at the bottom of pit, and preventing the earth from collapsing. As a result, it is quite necessary to conduct dewatering design for the foundation pit. In this paper, combining certain foundation engineering in Dalian, the tube well dewatering technology of foundation pit is introduced.

## Project overview and geological site condition

### Project overview

Locating in the northeast side of Gangwan Square of Zhongshan District in Dalian, this project is consisted of a high tower and low skit building. The tower is about 244 meters in height, with 4 underground floors and 51 above-ground floors. Its structural system is steel reinforced concrete frame-tube formed by concrete shear wall, inner shear wall, concrete filled steel tubular column, and overlapped incline support. It is tube-in-tube structure, with 18 meters of depth.

### Geological site condition

The main stratum structure of this site is that the overlaying soil is miscellaneous fill and sludge, while the underlying bedrock is strong and intermediary weathered sandstone. There is no active fault structure around the site. The lithology, depth and thickness parameters of each soil layer are shown in table 1.

Table 1 Lithology, depth and thickness of each soil layer

| number | Soil layer name | Layer top elevation [m] | Average thickness [m] |
|---|---|---|---|
| 1 | Miscellaneous fill | 3.25~6.57 | 5.8~11.4 |
| 2 | Muck | -2.17~7.27 | 0.40~1.20 |
| 3 | Completely weathered rock slate | -2.47~-7.77 | -5.68~16.60 |
| 4 | Strongly weathered slate | -1.37~16.60 | 1.0~11.20 |
| 5 | Weathered slate | -3.67~19.6 | 26.6 |
| 6 | Weathered gray-green rock | -34.8 | |

The underground water type of this site is the quaternary system pore water and bedrock fissure water. The buried depth of groundwater is about 2.8 m. The basal water is the fill stratum, sludge and complete weathering slate and intense weathering slate. The underground water is mainly filled by the atmospheric precipitation and ditch permeation. The thickness of the water-bearing stratum is about 26m.

**Dewatering project design**

The total precipitation area of this site is $9873.5m^3$, with the osmotic coefficient $1.4 m/d$. In the deep foundation pit, two approaches are adopted for dewatering. One is surface dewatering, and the other is the tube well dewatering [1]. According to the groundwater buried depth and excavation depth of this site, the tube well dewatering is adopted. Considering the economic factors, the tube well dewatering method with relatively low cost is employed. Tube wells with certain water are arranged around the foundation pit, and the underground water shall be extracted. The underground water around the foundation pit will flow into the foundation pit, so that the underground water level decreases by 0.5m below the excavation face, as shown in Fig. 1.

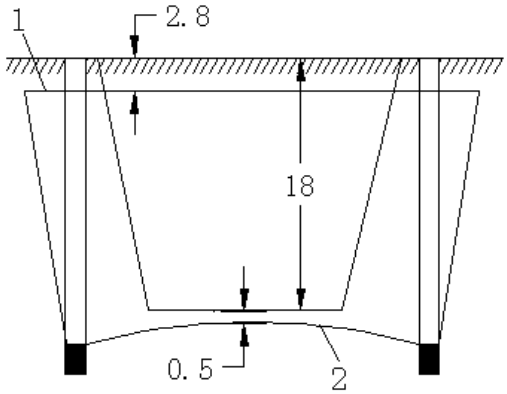

Fig.1. Water level schematic diagram

**Precipitation influence radius**

When the cone of depression is basically stable, the precipitation influence radius is related to the designed drawdown, permeability coefficient, and thickness of water-bearing stratum. The calculation Eq. 1[2] is:

$$R = 2S\sqrt{KH} = 2\times 15.7\times\sqrt{1.4\times 26} = 189.4m \tag{1}$$

In which, R is the precipitation influence radius, S is the designed drawdown, K is the permeability coefficient, and H is the thickness of water-bearing stratum.

**Equivalent radius of foundation pit**

$r_0$ is the illusion radius, and it is related to the excavation area and form of the foundation pit. The calculation Eq. 2[4] is:

$$r_0 = \sqrt{A/\pi} = \sqrt{9873.5/3.14} = 56m \tag{2}$$

In the equation, $r_0$ is the equivalent radius of the foundation pit, and A is the excavation area.

**Water inflow of the foundation pit**

It employs fully penetrating well, and the water inflow can be calculated with large well method, and the calculation Eq. 3[4] is:

$$Q = 1.366K\frac{(2H-S)S}{\lg R - \lg r_0} = 2060.3\, m^3/d \tag{3}$$

In which, $Q$ is the water inflow of the foundation pit, $K$ is the permeability coefficient, $H$ is the thickness of water-bearing stratum, $S$ is the designed drawdown, $R$ is the precipitation influence radius, and $r_0$ is the equivalent radius of foundation pit.

**Single-well water yield**

The single-well water yield is determined by the well with maximum interference in group well dewatering, and the calculation Eq. 4[2] is:

$$q = 120\pi r_s l\sqrt[3]{K} = 120\pi \times 0.3 \times 2.5 \times \sqrt[3]{1.4} = 87\, m^3/d \tag{4}$$

In which, $q$ is the maximum water yield of single-well well casing, $r_s$ is the radius of the filter, $l$ is the length of the filter, and $K$ is the permeability coefficient

**Number of well point required**

Elements such as blocking shall be considered when calculating the well points, and as a result, it should multiply by 1.1, and the calculation Eq. 5[3] is:

$$n = 1.1\frac{Q}{q} = 1.1\frac{2060.3}{87} = 26.04 \tag{5}$$

Therefore, 27 wells will be arranged.

In which, $n$ is the number of well points, $Q$ is the water inflow of the foundation pit, $q$ is the maximum permitted water yield of single well tube.

**Well point pipe spacing**

The well points are arranged in equal-gap method, and the calculation Eq. 6 is:

$$a = \frac{(L_1 + L_2 + B_1 + B_2)}{n} = 14.8m \tag{6}$$

In which, $a$ is the inter-well gap, $L_1$ is the upper base of the trapezoid foundation pit, $L_2$ is the lower base of the trapezoid foundation pit, $B_1$ and $B_2$ are the two sides of the trapezoid foundation pit.

**Design of precipitation well**

The Eq. 7[5] for calculating the depth of the precipitation well is:

$$\begin{aligned} H_W &= H_{W1} + H_{W2} + H_{W3} + H_{W4} + H_{W5} + H_{W6} \\ &= 18 + 0.5 + 6 + 1 + 2.5 + 1.5 \approx 30m \end{aligned} \tag{7}$$

In the equation, $H_W$ is the depth of the precipitation well, $H_{W1}$ is the depth of the foundation pit, $H_{W2}$ is the distance of the precipitation water level from the required depth, $H_{W3}$ is $ir_0$, $i$ shall be within the precipitation distribution range of the water conservancy, $1/15 \sim 1/10$, $r_0$ is the equivalent radius of the rainfall distribution or $1/2$ of the inter-well gap, $H_{W4}$ is the range of stage during dewatering period, $H_{W5}$ is the working length of the filter of the precipitation well, and $H_{W6}$ is the length of sand setting tube.

The diameter of the tube well is 0.3m, the diameter of the filter tube is 0.168m, 1.5 m sand setting tube is set, and it is filled by the natural gravel, while the mater convolvulus is sealed by clay. The structure is shown in fig. 2.

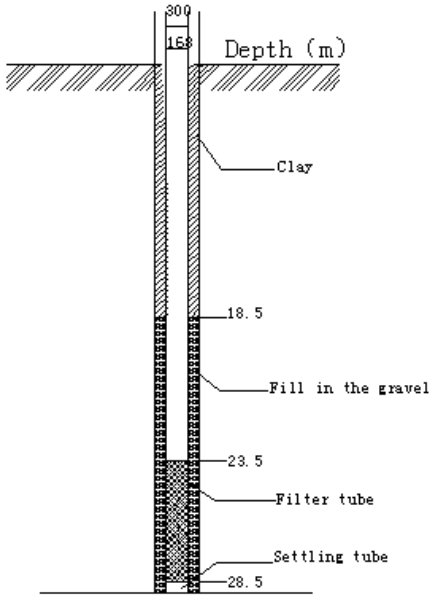

Fig.2. Precipitation well structure diagram

**Arrangement of precipitation well**

The precipitation well is arranged in circle about 1m distant from the side boundary of the foundation pit, and 27 wells are set. Meanwhile, two observational wells shall be set in the center of the foundation pit. The arrangement plan is shown in Fig. 3.

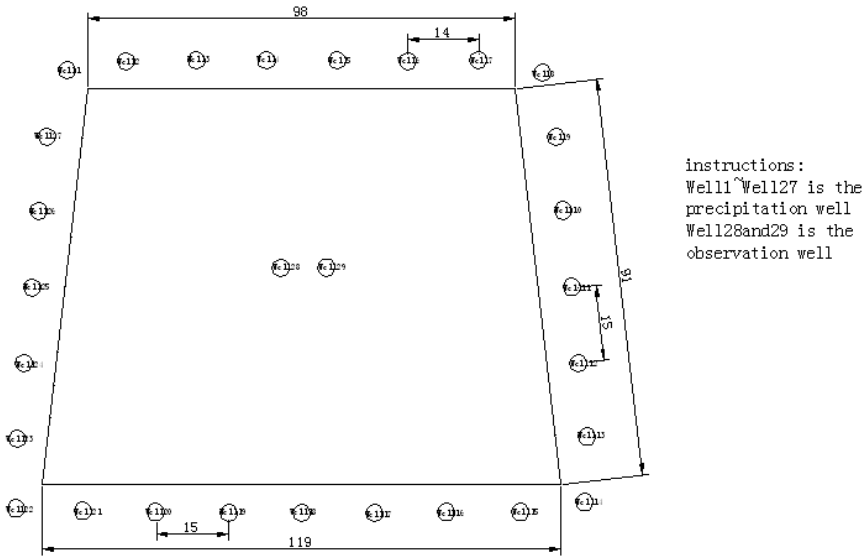

Fig.3. Precipitation well layout

**Verification of drawdown**

After the number of tube well, gap and arrangement method are determined, the fully penetrating well of the foundation pit can be taken advantage of for predicting the depth of foundation pit with Eq. 8[6].

$$S = H - \sqrt{H^2 - \frac{Q}{1.366K}\left[\lg R - \frac{1}{n}\lg(r_1 \cdot r_2 \cdot r_3 \cdots r_n)\right]} \tag{8}$$

In which, $S$ is the water level drawdown, $H$ is the thickness of the water-bearing stratum, $R$ is the precipitation influence radius, $Q$ is the water inflow of the foundation pit, $K$ is the permeability coefficient, $r_1 \cdot r_2 \cdot r_3 \cdots r_n$ is the distance from the foundation pit center to each well point.

Substitute it into the above equation, and it is concluded that $S = 18.6 > 15.7$, satisfying the requirements of drawdown.

**Control over the land subsidence caused by the precipitation**

During the dewatering process, with the decrease of underground water, it may give rise to the deformation of ground or land subsidence. In this project, filling method is employed for preventing the ground settlement, as shown in Fig. 4.

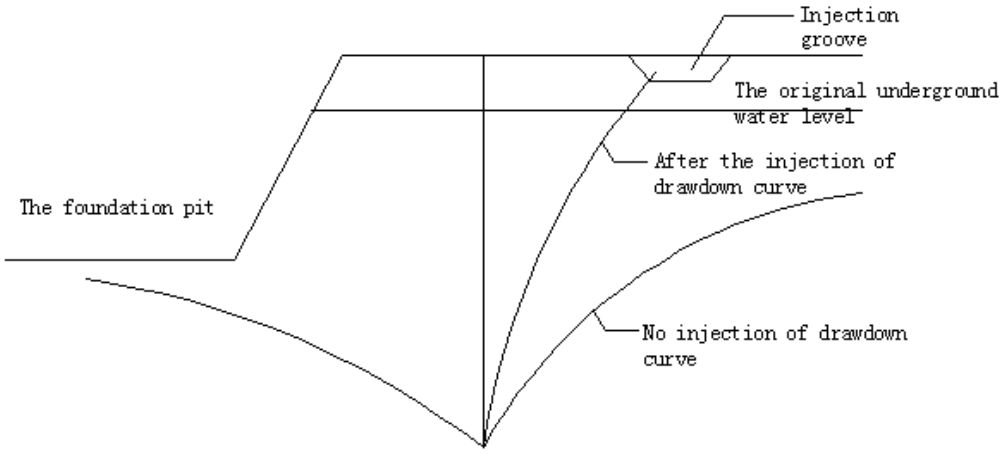

Fig.4. Injection method of schematic diagram

**Conclusion**

After calculation, there are 27 precipitation wells arranged around the foundation pit, about $30m$ in depth, and $300mm$ in diameter. The water outflow of single well is $87 m^3/d$, and two observational wells are set. According to the calculation result, it satisfies the requirements of the foundation pit.

The preliminary precipitation design plan is workable. In order to guarantee the construction security of the foundation pit, the precipitation effect shall be monitored. If it cannot satisfy the requirements, future optimization design shall be conducted.

**Keywords:** Bolt technology; Bedding Rock Slope; Stability of Slope; Reinforcement

**Abstract.** Discrete element software is used to simulate the excavation of a rock slope in Puli-Xuanwei Expressway in Yunnan Province. Through monitoring displacement development characteristics in different positions of slope, the result shows that the minimum horizontal displacement under excavation exists in the top of the slope, meanwhile the maximum horizontal displacement occurs in the foot and waist of the slope, and the maximum vertical displacement occurs in the top of the slope. Comparing rock slope in such conditions as different stratum angles, directions, rock characteristics and thickness, it concludes possible failure modes of slope and the variation law of safety coefficient under different conditions. This paper is instructive and offers reference for the practical engineering.

## Introduction

The slope locates on the right of K3+580, it is 26.6m high, there is tectonic denudation canyon and karst landform in line area. Terrain slope ranges from 15° to 24°, the earth's surface is Quaternary holocene diluvial clay and consist of clay limestone gravels and rubbles, rubbles present angular shape and the diameter ranges from 3 to 86 mm; underlying bedrock is limestone, and its colors present gray and dark gray, the core of the rock disintegrates, which is the main characteristic in line area. The type of groundwater in line area is mainly pore phreatic water in loose rock mass and the water forms in rainy days and disappears in sunny days, so there is no uniform water level in line area.Slope has its structural surface,and the angle of dip is 36°, importance should be attached to the slope with structural surface, and appropriate support shold be taken. At home and abroad the most common way for slope reinforcement is mainly bolt technology, pre-stressed anchor cable and slide-resistant pile. These method play a role and are widely used in practical engineering.

## Selection of Calculation Parameters

According to the engineering geological survey data, Rock and soil parameters of slope are as follows: density of limestone rock is 24KN/m, angle of internal friction $\varphi$=22°, cohesion equals to

55KPa, concrete C30 is used for slope reinforcement, design value of the bond strength between mortar and reinforced bar $f_{bi}$=2400kPa, bond strength between bolt and rock $f_{rb}$=180kPa.

**Calculation of bolt design**

Limit equilibrium method is used for checking the safety factor of slope $k$, when $k$ is greater than or equal to 1, the slope is thought to be safe but according to design requirements from highway embankment design specifications, safety factor $k$ should be greater than or equal to 1.3. The following formula is used to calculate $k$ in limit equilibrium method:

$$k = \frac{R}{T} \quad , \quad R = N \cdot \tan\varphi + c \cdot L \tag{1}$$

In the equation, $R$ and $T$ represent sliding resistance force and slide force (KN) in the direction parallel to the surface structure; $N$ represents positive pressure on structure surface(KN); $c$ represents cohesion on structure surface(KN/m$^2$); $\varphi$ represents friction angle of structure surface; $L$ represents the length of structure surface(m).

In calculation, the gravity of slope is considered but earthquake and groundwater impact is out of consideration. After calculating by limit equilibrium method, total slide force is 2975.6 KN, total sliding resistance force is 3430.4 KN, security coefficient is 1.153. Calculation model is shown in figure 1, the slope is basically stable but the coefficient does not meet the requirements of design specifications, so reinforcement measures are needed to be taken on the slope and bolt technology is used in the engineering.

Firstly the state of slope under gravity is discussed and then the supporting force of bolt on slope is analyzed.

$$T = T_1 + T_i \, , \qquad N = N_1 + N_i \tag{2}$$

**A. calculation of slope gravity**

$$T_1 = W \cdot \sin\alpha \, , \quad N_1 = W \cdot \cos\alpha \, , \quad W = \sum A_i \cdot \gamma_i \tag{3}$$

In the equation, $N_1$ and $T_1$ represent two component forces of gravity (KN) in the directions of vertical and parallel to the structure surface; $W$ represents gravity of sliding body; $\alpha$ represents dip angle of structural plane; $A_i$ represents the total area (m$^2$) of rock stratum $i$; $\gamma_i$ represents the density (kN/m$^3$)of rock stratum $i$.

**B. calculation of bolt anchoring force**

The two component forces of bolt vertical and parallel to the structure surface $N_t$ and $T_t$ are calculated according to Equation 4.

$$T_t = \sum T_{ti} \quad , \qquad N_t = \sum N_{ti} \tag{4}$$

The two component forces of each installed bolt vertical and parallel to the structure surface $N_{ti}$ and $T_{ti}$ are calculated according to Equation 5.

$$N_{ti} = R_{mi}\sin(\alpha+\theta_i) \quad , \quad T_{ti} = -R_{mi}\cos(\alpha+\theta_i) \tag{5}$$

In the equation, $\theta_i$ represents incidence angle of installed bolt $i$; $R_{mi}$ represents anchorage (KN) of installed bolt $i$, its value equals to the minimum among uplift bearing capacity $R_{mi1}$, tensile resistance of steel bar $R_{mi2}$, pullout resistance of steel bar and mortar $R_{mi3}$. $R_{mi} = \min\{R_{mi1}, R_{mi2}, R_{mi3}\}$

$$\begin{cases} R_{mi1} = \xi_1 \dfrac{\pi D_i \sum q_{sik} L_{ia}}{s_{ix}} \\ R_{mi2} = \dfrac{\xi_2}{\gamma_0} \cdot \dfrac{n_i \cdot \pi \cdot d_i^{\,2} \cdot f_{yi}}{\gamma_s \cdot 4 s_{ix}} \\ R_{mi3} = \dfrac{\xi_3}{\gamma_0} \cdot \dfrac{n_i \cdot \pi \cdot d_i \cdot f_{bi} \cdot L_{ia}}{\gamma_s \cdot s_{ix}} \end{cases} \tag{6}$$

In the equation, $D_i$ represents the diameter (mm) of anchoring segment $i$; $n_i$ represents steel $i$; $q_{sik}$ represents friction resistance (KPa) of rock and bolt $i$; $L_{ia}$ represents length of effective anchorage section $i$; $\gamma_s$ represents coefficient of load component; $s_{ix}$ represents horizontal spacing of bolt $i$; $d_i$ represents the diameter of the steel bar in bolt $i$; $\gamma_0$ represents importance coefficient of slope; $\xi_1$, $\xi_2$, $\xi_3$ separately represents applying condition coefficient in bond of anchor body and formation, tensile of steel bar in bolt and bond of steel bar and mortar; $f_{bi}$ represents the bond strength (KPa) of steel bar and mortar; $f_{yi}$ represents tensile strength of steel bar ($N/mm^2$).

The excavation body was broken like before support of slope, there is a slip down trend along the surface structure, bolt support belongs to an active support technology. Not only can this support technology control anchored slope sliding along structure surface, but it can also conduct the overall control on broken crack-like slope, so it maintains the integrity of the slope.

Based on dates from geological survey information and considering dip angle of the structure surface, a space layout as up-wide and down-narrow forms in the slope. The length of bolt in the upper part is 12 meters, in the middle and lower part is 10 meters, so as to make bolt pass through the structure of the surface. Deformed steel bar HRB335 is used in the bolt and the diameter of the steel bar is 28 mm, the diameter of anchoring segment is 91 mm, bolts are layer in 3.0×3.0 square shape in spatial distribution of slope, the angle of bolt with the horizontal plane is 20°.

After calculating by limit equilibrium method, total slide force of slope under bolt supporting is 2779.5 KN, total sliding resistance force is 36391KN, security coefficient is 1.309.The resistance

each bolt bearing is 49 KN, bolt supporting structure and calculation model is shown in Fig.1, the result shows that the slope is in a stable state, and this proves that bolt plays an important role in supporting slope.

**Analysis on the effect of bolt**

Assume the other things keep constant, then change the incidence angle of bolt ranges from 0~40°, it can be found that when the incidence angle increase from 0~10°, FOS of slope has an increasing trend and it reaches the maximum at 10°; when the incidence angle increase from 10~40°, the coefficient has an decreasing trend, the relation between the incidence angle and FOS is shown in Fig.2, it proves that the incidence angle has a great impact on the effect of slope reinforcement.

Assume the other things keep constant, then change the diameter of drilling anchor from 30~120mm. It can be found that when the diameter is less than 70 mm, safety coefficient of slope increases with the increasing of the diameter; when the diameter is greater than 70 mm, safety coefficient keeps constant. It proves that there is an extreme value to bolt diameter, the relation between slope safety factor and drilling anchor diameter is shown in Figure 3. It plays a key role in determining drilling anchor diameter meanwhile ensure slope stability and it takes a good effect on controlling the project cost.

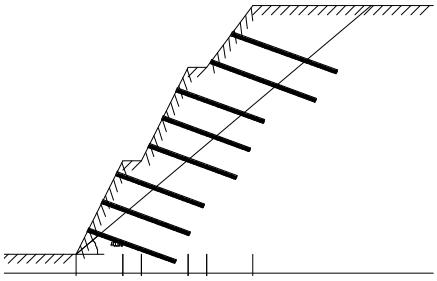

Fig.1 Cross-sectional of slope under bolt support

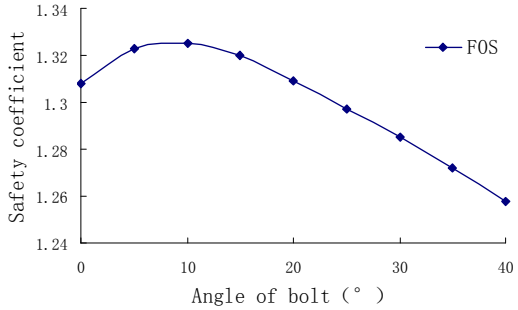

Fig.2 Relation of slope FOS and angle of bolt

Assume the other things keep constant, then change the diameter of bolt from 16~32 mm. Safety coefficient of slope increases in a second-order parabola with the increasing of the diameter, the relation is shown in Fig.4. In the control of slope stability, the diameter of bolt can be chosen according to practical engineering so as to improve the stability of slope.

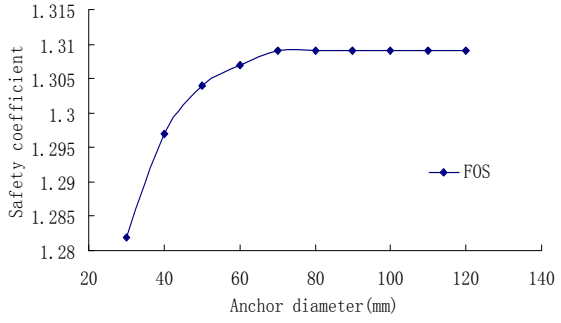

Fig.3 Relation of FOS and drilling anchor diameter

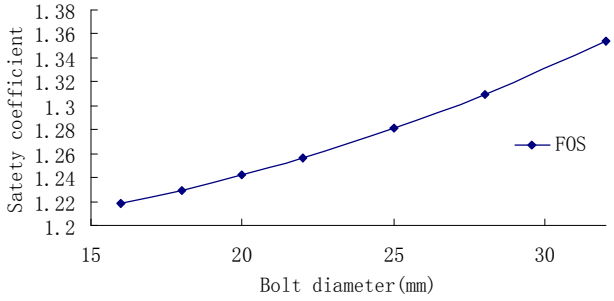

Fig.4 Relation of slope FOS and bolt diameter

**Summary**

By calculating stability of slope on the right of K3+580 locating in Puli-Xuanwei Expressway in Yunnan, the result shows that the safety coefficient does not meet the requirements of design specifications when there is not any support for slope. Such measure as bolt supporting is proposed

to improve the stability of slope, and the effect of bolt on slope reinforcement is proven. After changing the parameter of bolt , following conclusion can be reached:

（1）Different incidence angle has impact on the effect of slope reinforcement, and the optimal incidence angle should be taken into consideration in order to take the optimal supporting effect.

（2）In bolt construction diameter of the drilling anchor significantly affected the stability of slope, and when the diameter reaches a certain value, safety coefficient keeps constant. The critical value should be applied in the engineering so as to take optimum efficiency on slope reinforcement.

（3）The diameter of bolt plays an important role in slope stability, so the diameter can be limited in a certain range to ensure the stability of slope in practical engineering

By calculating and contrast above, bolt reinforcement takes some effect on slope stability. After analyzing the change rule among different parameters, the relation between safety coefficient and parameters can be determined and it has significance in guiding slope reinforcement.

**Keywords:** grain size distribution, forming method, curing age, strength influencing factors

**Abstract.** The compressive strength of cement stabilized macadam base is an important index to evaluate the quality of road construction. In this paper, investigation and field sampling were conducted on roads in Shenyang city, and, indoor experiment study was then adopted to analyze effects of particle grade, cement dosage, molding method, compaction and curing age on compressive strength. The results show that rational particle grade greatly enhances the strength. Strength of vibration molding sample is closer to the field sample strength and is 0.6 times bigger than that of static pressure molding sample. 1% increment of construction compaction degree will induce 10% increment of compressive strength. Increment of cement dosage and curing age will induce increment of compressive strength, but the effect is limited. Studied in paper can provide a theoretical basis for site construction in Shenyang area.

## Introduction

The cement stabilized macadam base with its high strength, good board, good erosion resistance, and economy becomes the main structure of our country highway semi-rigid base, standard requirements for 7 days on the base of the cement stable class unconfined compressive strength to achieve 2.5 ~ 4.5 MPa in China[1]. However, there are many and complex factors which can affect the strength of cement stabilized macadam roadbase.

## Raw material properties

Table 1 Raw material sampling

| Number | Mixing station | Construction route | Particle size composition(cm) | Stone origin |
|---|---|---|---|---|
| 1 | Shenbeicui gongbao | Pingwang route,Nongwang engineering | 1~3,1~2,0.5~1;attle | Tieling |
| 2 | Shenyan | Shenyan route | 1~3,1~2,0.5~1;attle | Fushun |
| 3 | Xinmin | Jiangzhang route | 1~3,0.5~1;attle | Tieling |
| 4 | Hunnansifang | Xinlibao route | | |
| 5 | Hunnanlixiang | Shenli route, Yonghong route | mixture, attle | Liaoyang |
| 6 | Liaozhong | Gaonen route | | |

## Analysis of the formation mechanism of the strength of cement stabilized gravel

Table 1 shows. Under the pressure of mechanical compaction, the gap between coarse aggregate in the mixture is filled with a mixture of cement and fine aggregate, the air in the pore is discharge; Cement and gravel particles close to each other, so as to achieve solid state[2].Subsequently, the formation of its strength mainly depends on the cement hydration and hardening. The cement hydration generating have cementation ability of hydration products of hexagonal $Ca(OH)_2$, C-S-H, square plate hydrated calcium aluminate. The hydration products of cement hydration, intertwined overlap, the aggregate particles wrapped together to form the skeleton structure[3].

**The influence of particle gradation for strength**

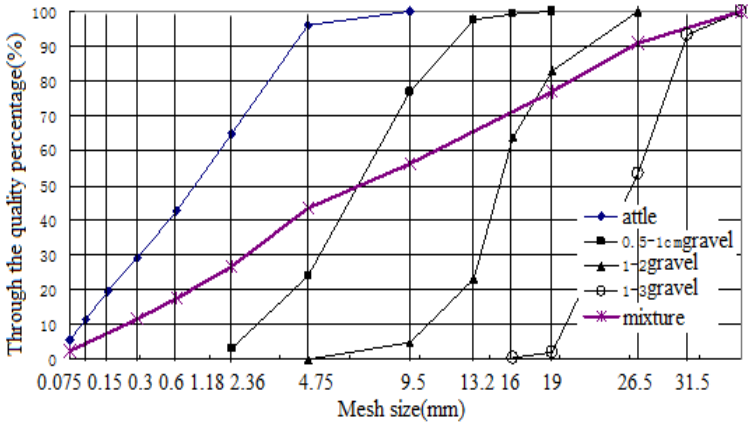

Fig.1 Nongwang engineering of the particle size sieving curve

Figure 1 shows. Construction mixture gradation curve reflects in less than 2cm of coarse particles, 1-2cm grain accounts for larger proportion, through the quality percentage is low, particle partial thick; Greater than 2cm of the gradation curve is located in the middle of the upper and lower curves. So the above mix proportion mixing mixture has not been a skeleton structure, the content of fine particles on the pore filling is less. Although the gravel composed of 3-4 grade according to the standard[4], but the average value is 2.9MPa, mixture gradation needs to be optimized.

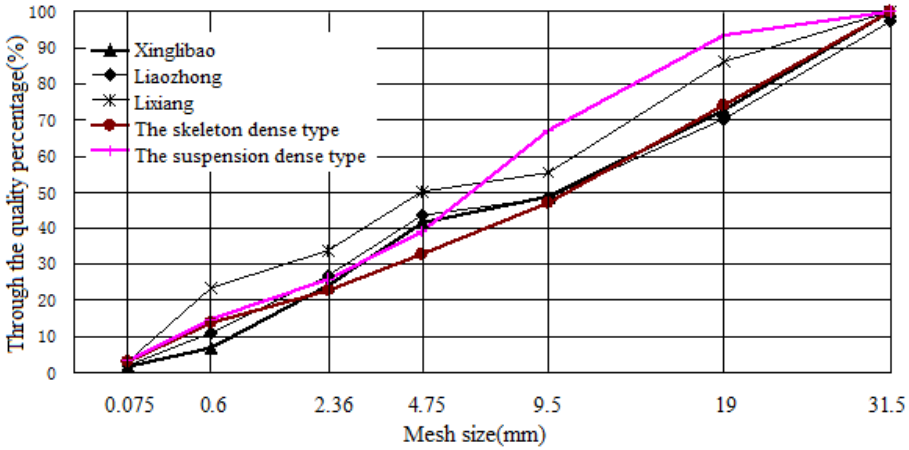

Fig.2 Mixture gradation curve distribution characteristics of Liaozhong, Xinlibao, Lixiang

As shown in figure 2, Liaozhong and Xinlibao mixture gradation curve at greater than 9.5mm larger particles part close to the skeleton dense type curve, the mixture of the coarse particle content is larger, more than 9.5mm particles above 50%; Mixture in 4.75mm~9.5mm particle quality is less than 10% of the total. Because of the pore filling between the skeleton is not real, so improve the strength of the effect is not obvious, and the specimen prone to segregation and cellular phenomenon. In Lixiang, mixture content of fine particles less than 4.75mm, reached 50% of the total, the larger particles content of more than 20mm smaller than other mixing station mixing scheme, less than 15%, gradation curve closer to suspended dense type grading curve.

**The influence of cement dosage for strength**

To investigate the cement dosage effect on the strength of the cement stable macadam mixture, adopting Lixiang mixing station mixing ratio, cement dosage by 4%, 4.5% and 5%, and indoor experiments, the results are shown in table 2.

Table 2 Different cement dosage on the influence on the strength of cement stabilized gravel base

| Number | Mixture ratio | Cement dosage（%） | Molding method | Unconfined compressive strength of the average value（MPa） | | |
|---|---|---|---|---|---|---|
| | | | | 7d | 28d | 90d |
| 1 | gravel：attle =1:1 | 4.0 | static pressure | 3.41 | 3.88 | 5.86 |
| 2 | gravel：attle =1:1 | 4.5 | static pressure | 3.68 | 3.95 | 6.03 |
| 3 | gravel：attle =1:1 | 5.0 | static pressure | 3.86 | 4.04 | 6.24 |

From table 2 shows, the degree of compaction and distribution under the same conditions, the cement dosage had no significant effect on the compressive strength, When the cement dosage increased by 1%, the compressive strength of the 7 d growth is 0.45 MPa, the growth rate is 13%, the 28 d compressive strength growth is 0.16MPa, the growth rate is 4%, the 90 d compressive strength growth is 0.38 MPa, growth rate of 6.4%.Visible cement dosage effect on the strength is not obvious, and with the increase of age, strength increase value and ratio is to reduced compared with early strength. Therefore, considering the shrinkage cracks and other factors, suggestions appropriate to reduce the dosage of cement in engineering.

**The influence of molding methods impacting for strength**

Take the gravel materials from Lixiang mixing stations , according to the construction mix stirring the mixture, the dose of cement is 4.5%, use static pressing and vibration molding specimens respectively, standard of the compacted degree is of 97%. Among which vibration molding uses two molding time which are 75s and 100s , obtaining the results of 7d unconfined compressive are shown in Table 3.

Table 3 Comparison of 7d compressive strength of different molding methods (MPa)

| Isostatic pressing $R_{cj}$ | Vibration molding (75s) $R_{cz1}$ | Vibration molding (100s) $R_{cz2}$ | Core sample at site $R_{cx}$ | $R_{cj}/ R_{cx}$ | $R_{cz1}/ R_{cx}$ | $R_{cz2}/ R_{cx}$ |
|---|---|---|---|---|---|---|
| 3.68 | 5.87 | 8.06 | 6.14 | 0.60 | 0.97 | 1.31 |

Table 3 shows that the average intensity value of isostatic pressing is 3.68MPa, the average of vibrating 75s is 5.87MPa, increasing 60% compared to isostatic pressing; The average of vibrating 100s is 8.06MPa, increasing 119% compared to isostatic pressing; The intensity of 7 d of vibration time which is 75s is closest to core samples strength, the value of the site is 0.97 times the field strength of the core sample, showing vibration molding is greatest similarity for construction process of the rolling process.

**Analysis of effects of the degree of compaction on the strength**

Based on previous research, on the conditions of meeting the standard of compact degree, for static pressing specimens, the degree of compaction is increased by 1%, the corresponding 7d unconfined compressive strength is increased by 0.2 ~ 0.3MPa and is about 10% of the measured values[5]. If you do not meet the requirements of the degree of compaction,when degree of compaction is reduced by 1% for each , the decreased value of intensity will be greater than 0.3MPa. With increasing age, the strength of cement stabilized gravel affected by the degree of compaction shows a decreasing trend.

**Analysis of effects of age on the strength**

For the analysis of the relationship between cement stabilized macadam mixture curing age and compressive strength, and in the testing process, respectively parts, conserve 7d, 28d and 90d, test unconfined compressive strength.

Table 4 Compressive strength test value in different age

| Num | Route | Mixture ratio | Cement dosage | Compressive strength R(Mpa) 7d | 28d | 90d | R7/R28 (%) | R7/R90 (%) |
|---|---|---|---|---|---|---|---|---|
| 1 | Jiangzhang route | 1-3cm:0.5-1cm: attle=25:25:50 | 5% | 3.4 | 4.4 | 4.7 | 77.3 | 72.3 |
| 2 | Xinlibao | Attle:gravel (mixture)=45:55 | 5% | 2.7 | 3.5 | 3.8 | 77.1 | 71.1 |
| 3 | Shenyan route | 1-3cm:1-2cm: 0.5-1cm:attle=10:25:20:45 | 5% | 2.3 | 3 | 3.4 | 76.7 | 67.6 |
| 4 | Nongwang engineering | 1-3cm:1-2cm: 0.5-1cm:attle=20:20:20:40 | 5% | 2.9 | 3.7 | 4.4 | 78.4 | 65.9 |
| 5 | Shenli route | Gravel:attle=50:50 | 5% | 3.5 | 4.4 | 5 | 79.5 | 70.0 |
| average value | | | | 2.96 | 3.8 | 4.26 | 77.8 | 69.4 |

Table 4 shows, with the increase of age, the compressive strength of cement stabilized gravel increases, the slope of the intensity distribution curve decreases, indicating that the growth rate of the compressive strength decreases. The average of 7d compressive strength is 77.8% of 28d compressive strength , is 69.4% of 90d compressive strength. Mix in tests of five groups, the average of 7d compressive strength is greater than 65% of 90d compressive strength values. Because cement stabilized gravel is relatively quick in the cement hydration process, so the early strength is higher. Therefore, in the construction process roadbed should focus on early conservation in order to the cement hydration and then promotes the formation of early strength of cement stabilized macadam. Meanwhile, the problem of shrinkage cracks should be considered fully, early strength should not be too high and should be controlled in a reasonable range.

## Conclusions

In plurality of cement stabilized macadam mixing plant of Shenyang region (involving more than one route), project team samples for laboratory tests to analyze the development of the rule and impact factors of compressive strength in Shenyang, the following conclusions:

(1)The mix of laboratory test used is construction mix and cement dose is 4% -5%. The average of the laboratory tests of 7d unconfined compressive strength is more than 2.0MPa, meeting the indicator of secondary and the following secondary road base which are provided by(highway subgrade technical specifications).

(2)Mixture gradation is an important factor of 7d compressive strength, in the construction the gradation which is used is close to a lower limit of gradation range which is in the specifications, but part of the particle content of the mix is less and not yet form a gradation of a skeleton dense. So the integrity of the specimen decreases and the intensity values reduces.

(3)The impact of doses of cement on strength is small, in laboratory tests 4.0% of dose of the cement mix of 7d unconfined compressive could meet strength values of regulatory requirements, so in the project considering the shrinkage cracks，project cost and other factors may appropriately reduce the dose of cement.

(4)Forming method has a greater impact on the strength of cement stabilized crushed stone, 75s vibration compaction intensity used in the experiment is closest to the measured values. The intensity value of 75s indoor vibration is about 170% of isostatic pressing and this shows vibration molding methods make the strength greatly improved.

(5)The degree of compaction is a key indicators which ensure the strength of cement stabilized macadam base, when the degree of compaction is reduced by 1%, the strength is reduced by about 10%, so the standards of compact degree should be strictly controlled in the construction.

(6)With the age increasing, the strength of cement stabilized macadam base increases, the rate of early strength increases rapidly, the rate of late strength decline. 7d compressive strength is above 65% of 90d compressive strength, early conserve should be paid great attention to ensure the growth of early strength in the construction.

**Keywords:** cyclic triaxial test; dynamic modulus; damping ratio; tailings.

**Abstract:** In this paper, the dynamic characteristics for three different kinds of copper tailings are studied through a series of cyclic triaxial tests. It is found that under confining pressure 200 and 300 kPa, elastic modulus raises with the increasement of coarse grain content to a certain degree and then declines, and the maximum elastic modulus corresponds to good gradation. While, as for confining pressure 100 kPa, elastic modulus raises with the increasement of fine grain content. It is also found that elastic modulus raises with the increasement of confning pressure. And, damping ratio raises with the increasement of shear strain and finally to a stable value. Finally, the fitting $G_d/G_{dmax} \sim \gamma$ curve for three kinds of tailings shows the reasonableness of test results.

## Introduction

Mine mining ore through beneficiation process to select the valuable ore. Tailings, the remaining waste is discharged through the water head processed to form slurries and stored in the storehouse lastly. There're are over 2,700 tailings existing in China, most of which are constructed in upstream method and because of inadequate drainage system the invasion line of the dams is very high [1]. These tailings in the dams usually in saturated and loose state. Tailings deposition from coarser below to finer is regular, the upper mostly fine sand, silty sand and sub-sand mostly in central and bottom is mud tailings which are quite different from ordinary clay and mechanical properties are very complex, especially in the earthquake they are easily liquefaction and destructive deformation [2-3].

Current researches related to the dynamic characteristics of tailings dam are still relatively small, the results of researches are very limited. It is mainly because of the experiment of dynamic characteristics has high requirements on equipment and it needs a long experimental time. In this paper, basing on a copper in Shenyang, we focus on dynamic characteristics of different particle size of tailings. The past experiment mainly studies the affect of density, consolidation ratio, confining pressure on the dynamic characteristics of tailings, while, different tailings on the particle size distribution are very different, which also affects the dynamic characteristics. Basing on the law of tailings deposition, we configure three kinds of tailings namely tail fine sand, tail silty sand and tail floury soil to study their dynamic characteristics under cyclic loading.

## Laboratory instruments and solutions

This experiment uses VJT5010 bidirectional dynamic triaxial test system which produced by Vjtech company, the sample size is $\phi 39.1 \times 80mm$. Exicitation frequency of cyclic loading is 1Hz, the wave of vibration is sin wave.

Tailings material used in the experiment taken from a copper mine in Shenyang and considering representative samples, physical experiment and particle size analysis experiment carried out on the samples. The maximum diameter of copper mine tailings is no more than 2mm, nonuniformity coefficient Cu = 4.1 ~ 11.0, coefficient of curvature Cc = 2.0 ~ 5.2, which are poorly graded tailings. According to the data in this experiment, we configure three kinds of tailings material, namely 1 # tail fine sand, 2 # tail silty sand and 3 # tail floury soil. Physical properties of three kinds of tailings are shown in table 1.

The experiment uses dry packing method and hierarchical compaction according to the dry density measured in the site. After preparation, placing the specimen to the vacuum device, pumping and then passing into the degassed water from the bottom to make the specimens saturated, so that the pore water pressure coefficient B reaches 0.95. After saturation, samples drainage consolidates under confining pressure 100, 200 and 300 KPa. Consolidation ratio Kc = 1. Then the dynamic stress is applied under undrained conditions. According to the relevant specification when generally elastic strain and plastic strain of the sample reaches to 5%, the sample is damage [4].

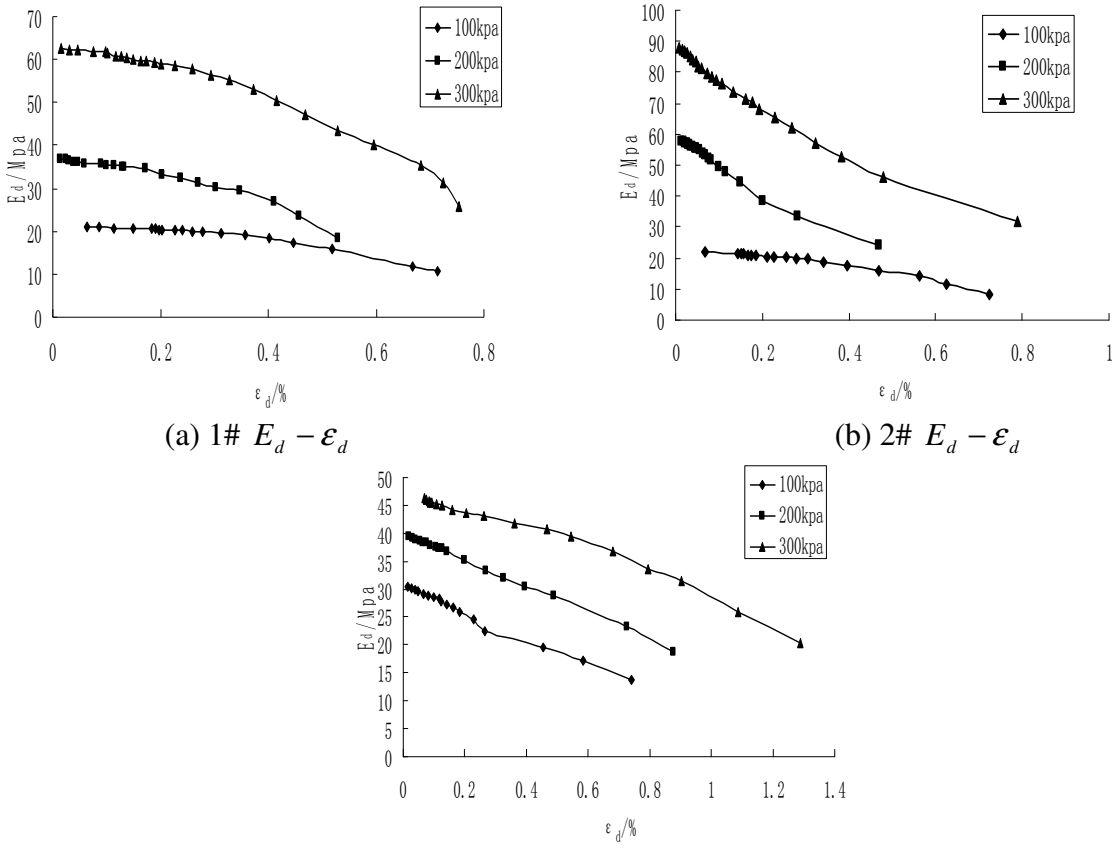
Table 1 Physical properties of three kinds of tailings

| Number | Soil type | Composition | $d_s$ | e | w | $\rho_d$ | $c_u$ | $c_c$ |
|---|---|---|---|---|---|---|---|---|
| 1# | Tail fine sand | >0.075mm 85%<br><0.075mm 15% | 2.98 | 0.861 | 28.4% | 1.68 | 4.2 | 2.18 |
| 2# | Tail silty sand | >0.075mm 64%<br><0.075mm 36% | 2.96 | 0.858 | 27.8% | 1.64 | 3.8 | 5.0 |
| 3# | Tail floury soil | >0.075mm 19%<br><0.075mm 81% | 2.92 | 0.856 | 28.1% | 1.63 | 3.9 | 2.3 |

## Experimental results and analysis

### Curve analysis dynamic elastic modulus and dynamic strain

At confining pressure 100, 200 and 300kPa, relationship between dynamic modulus and strain curves of the three Tailing's dynamic triaxial tests are shown in Fig.1.



(a) 1# $E_d - \varepsilon_d$ (b) 2# $E_d - \varepsilon_d$

(c) 3# $E_d - \varepsilon_d$

Fig.1 Dynamic elastic modulus - dynamic strain relation curves

By the curve, we can see that:

（1）With the increasing of strain, dynamic modulus decreases. In the same consolidation ratio, when the confining pressure is200 or 300KPa, dynamic modulus of Silty sand is bigger than fine sand; dynamic modulus of fine sand is bigger than Floury soil. This is because silty sand not only contains coarse particles but also contains a certain amount of fine particles, the two particles working with each other, forming a good gradation, which is better to resist the elastic deformation. While the particle content of fine sand and floury soil is relatively simple, so the ability to resist deformation is weak. At the same time because of the sbility of the coarse particles to resist deformation is larger than fine particles, so elastic modulus of fine sand whose main composition is coarse particle is greater than floury soil. By contrary, when the surrounding pressure is 100KPa, dynamic modulus of floury soil is bigger than the others, the reason is the floury soil has a certain amount of fine particles. So when the surrounding pressure is little this will make it even more easier to squeeze particles.

（2）Dynamic modulus has a certain relationship with confining pressure. In the same strain, the elastic modulus of soils under surrounding pressure of 300KPa is bigger than the soils under surrounding pressure of 100 and 200KPa. This is because the surrounding pressure will apply bond stress on the tailings material, making it more dense, and consequently the ability to resist deformation improves.

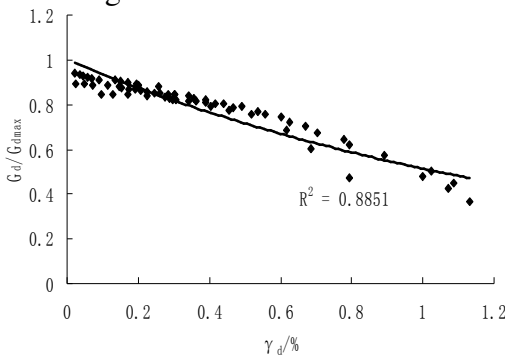
**$G_d/G_{dmax}\sim\gamma$ line fitting and comparative analysis**

We experimentally measured dynamic triaxial dynamic elastic modulus axial and axial dynamic strain, according to the translation of the relationship, we can obtain dynamic shear strain and dynamic shear modulus.

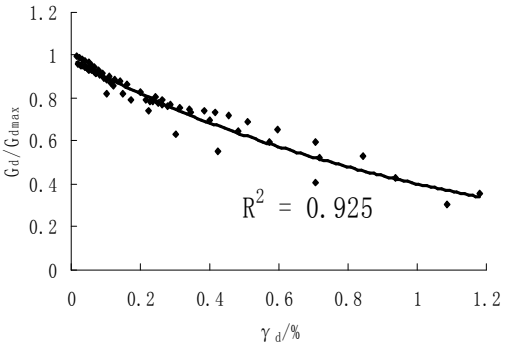
$$\gamma_d = \varepsilon_d(1+\mu) \tag{1}$$

$$G_{\mathrm{d}} = E_d / 2(1+\mu) \tag{2}$$

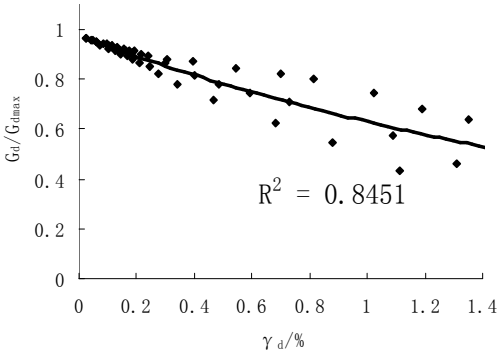
The experiment was carried out in 100,200 and 300kpa confining pressure on tailings and then three kinds of data integration together confining pressure curve fitting. $G_d/G_{dmax}\sim\gamma$ relation curves are shown in Fig.2.



(a) 1# $G_{\mathrm{d}} / G_{d\max} - \gamma_d$



(b) 2# $G_{\mathrm{d}} / G_{d\max} - \gamma_d$



(c) 3# $G_{\mathrm{d}} / G_{d\max} - \gamma_d$

Fig.2 Dynamic shear modulus ratio – dynamic shear strain relation curves

For fine sand,

$$G/G_{d\max} = 0.9983e^{-0.6645\gamma} \tag{3}$$

For silty sand,

$$G/G_{d\max} = 0.9825e^{-0.8964\gamma} \tag{4}$$

For silt,

$$G/G_{d\max} = 0.9732e^{-0.4337\gamma} \tag{5}$$

From the curves we can see that:

（1）For fine sand, data distribution is relatively concentrated, while, it is discrete when the shear strain is larger.

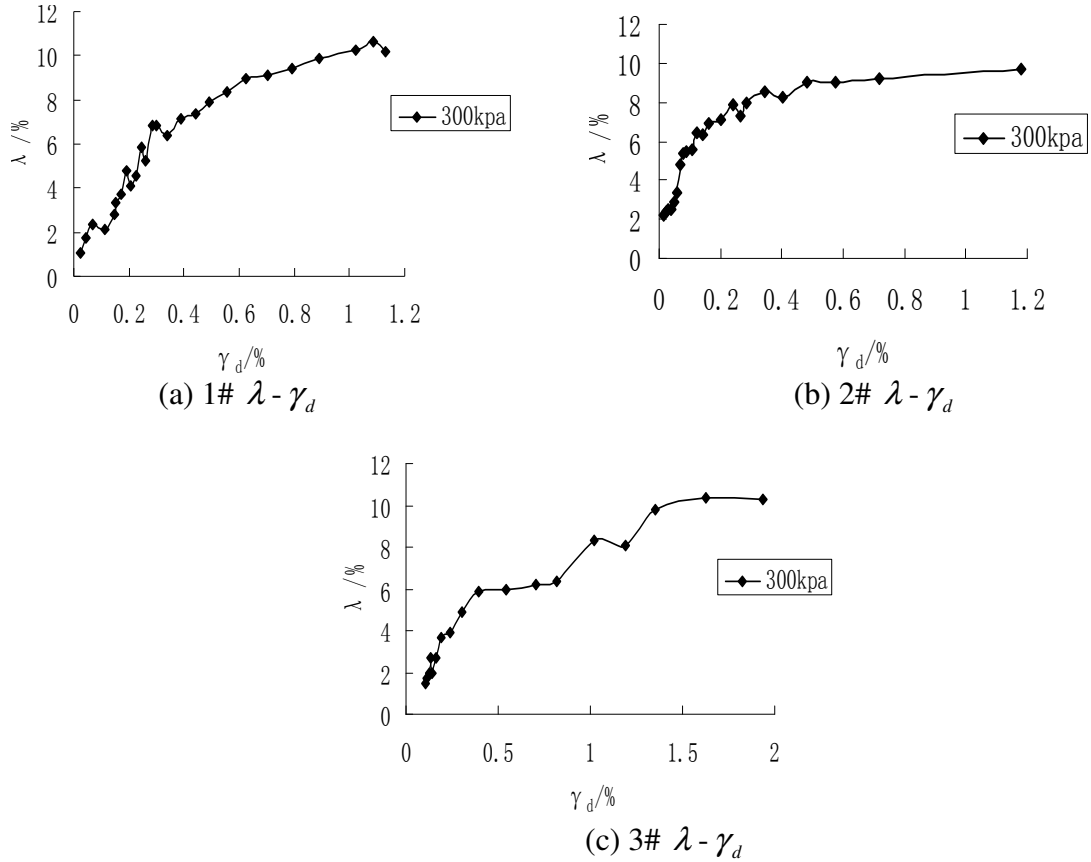
（2）For silty sand and floury soil, data distribution is concertrated when the shear strain is less than 0.4%, while, data distribution is discrete when the shear starin is more than 0.4%.

（3）Shear modulus increases with decreasing shear strain and, because with increasing shear strain, the ability to resist deformation of the specimen decreases.

（4）Exponential fitting may well reflects the relationship between the shear modulus and shear strain. From the viewpoint of the limit, when the shear strain tends to infinity the shear modulus ratio tends to zero. From this point of view, realistic exponential is fitting.

**Analysis of damping ratio and dynamic shear strain curve**

Due to the presence of the damping ratio, In the process of vibration, the change of the stress strain is slower than the change of the stress state , we also called it hysteresis. The relationship between damping ratio and dynamic shear strain is shown in Fig.3.



(a) 1# $\lambda$ - $\gamma_d$ (b) 2# $\lambda$ - $\gamma_d$

(c) 3# $\lambda$ - $\gamma_d$

Fig.3 Damping ratio - dynamic shear strain relation curves

From the chart we can see that:

（1）With the increasing of the shear strain, the damping ratio increase, which is worth noting that when the strain is small, the damping ratio increases rapidly with the increasing of strain, after that the rate of increasing slows down.

（2）There is no significant increase in the damping ratio when the shear strain increases to a certain value, in fact, it is gradually approaching a certain fixed value. That is to say the lag of stress relative to strain has a limit value.

## Conclusions

In this paper, by applying cyclic loading on three kinds of tailings which include fine sand, silty sand and floury soil, analyzing the dynamic parameters of elastic modulus and damping ratio, we obtained the following conclusions:

（1）With the increasing of the strain, the dynamic modulus decreases. In the same consolidation ratio, when the confining pressure is 200 or 300KPa, dynamic modulus of Silty sand is bigger than fine sand; dynamic modulus of fine sand is bigger than Floury soil, when confining pressure is 100Kpa, the dynamic modulus of Floury soil is greater than the other two.

（2）Dynamic modulus have a certain relationship with confining pressure. With the same shear strain, the higher the confining pressure, the greater dynamic modulus.

（3）According to the experimental data, fitting out three Tailings $G_d/G_{dmax}\sim\gamma$ curve. When the shear strain tends to infinity the shear modulus ratio is zero, this fits fact.

（4）Damping ratio increases with increasing shear strain, there is no significant increase in the damping ratio when the shear strain increases to a certain value, in fact, it is gradually approaching a certain fixed value.

# Experimental Study on Engineering Characteristics of Basalt Residual Soil on High Slope

Kai Cui[1, a], Ye Yang[2, b]

Department of Civil Engineering, Southwest Jiaotong University, Chengdu, Sichuan, 610031, China

[a]acuikai@swjtu.cn, [b]86352218@qq.com

**Keywords:** BiWei Highway, Basalt Residual Soil, Engineering Characteristics.

**Abstract.** The basalt residual soil of high slope of BiWei highway in Guizhou province belongs to regional special soil. Comprehensive and systematic evaluation for engineering geologic characteristics of residual soil on basalt is necessary to the construction in this area and geological engineering investigation. Kaolinite is dominant in clay mineral of this soil, which has a higher clay particle content. The special material composition and structural morphology make it have the physical properties of high porosity, low density and high water content. But it has mechanical properties of higher strength. The soil has a low expansibility and weak water-resistance. Moreover, the soil is sensitive to environmental factors such as temperature and humidity. The mechanical properties become weak after soaking, leading to a larger collapse deformation and a heavy disintegration. Therefore, it is important to focus on the engineering disasters caused by rain water for example.

## Introduction

The basalt residual soil has characteristics such as low density, high water content, high saturation, high void ratio, high compressibility, low capacity, maldistribution, and unstable properties. The Permian basalt is widely distributed in Guizhou province and rock joints and fractures develop in the indexing lot where it exists. The rock broke into pieces after weathering and then become residual soil. It is widely overlying strata and it has greater thickness [1,2]. It will lead to the collapse of slope, heavy slumping, large-scale landside [3] and other geological hazards [5,6], which is a serious threat to the country's economic construction and people's lives and property safety. In-depth study on the engineering mechanical properties of the highway building in basalt residual area is important to elevate the highway construction technology in basalt residual area. Scholars have researched on physical and mechanical index [7-10], permeability [11,12], strength [13], disintegrative [7,14], mineral composition [15] and microstructure [16]. The previous studies indicate that different basalt residual soils of varioius regions show the similar engineering mechanical properties and also their respective regional characteristics. In view of the above situation, in this paper, the basalt residual soil in high slope in BiWei highway K86+700-+960 was studied. The engineering mechanical properties of the basalt residual soil in this area was studied through a lot of experiments, consolidation test, direct shear test, permeability test, and disintegration test. And then the strength and deformation characteristics of the basalt residual soil is analyzed, which can provide some theoretical support for the guidance of highway construction and the prevention of geological disasters in the region.

**Physical properties of basalt residual soil**

The basalt residual soil in this area has high water content (33%), low natural density (1.6g/cm$^3$), and big pore. It is between hard plastic and waxiness in the natural state. The basalt residual soil particle size distribution curve showed that the soil clay has large content, non-uniform coefficient $c_u$ is 31, the curvature coefficient $c_c$ is 2.33, belonging to good gradation. Mineral composition analyzed by X ray showed that kaolinite minerals is a main component with the basalt residual soil clay minerals.

**Mechanical properties of basalt residual soil**

The WG-4 portable consolidation apparatus is used to determine the compressibility. The test method is uniaxial consolidation compression test. The results showed that BiWei basalt residual soil compression coefficient $a_{1\text{-}2}$=0.3MPa$^{-1}$, belongs to medium compressible soil.

The remolded soil is used to conduct the direct shear test. Remolded soil is compounded according to bulk density of undisturbed soil, divided in six water content grades including 20% (dry state), 33% (natural water content), 45% (saturated state) and three middle values. Each water is graded with three samples, each sample of the void ratio is controlled in natural void ratio (1.2), and peak strength $c$, $\varphi$ and residual strength $c_r$, $\varphi_r$ of M-C model are determined by repeated shear test. The test results showed that the high cohesion of the residual soil is similar to cohesive soil and the high internal friction angle is similar to silty soil. It showed that in the natural state, although the structure of soil is lost, the coupling force between soil particles is still strong. The soil has better mechanical characteristics. At the same time, like other types of basalt residual soil, the soil becomes wet when it encounters water, which leads to soil degradation. Before and after the basalt residual soil is saturated, by comparing the changed strength, we can find that the variation amplitude of cohesion is significantly greater than the internal friction angle, the soil deterioration is caused by the decrease of particle cohesion. In addition, the residual strength significantly reduced compared with the peak strength, the $c$ decreased by 50%-70% with the $\varphi$ value of decline 2°-8°. Fig. 1 and Fig. 2 show that the relationship curves of cohesion and residual cohesion change with the water content. Fig. 3 and Fig. 4 show that the relationship curves of internal friction angle and residual internal friction change with the water content. The figures show that cohesion is influenced obviously by the change of water content. The general tendency is that it reduces obviously with the increase of water content. Also, residual cohesion also decreases with the increase of water content, but the trend is relatively slow. The internal friction angle and residual friction angle have a downward trend with the increase of water content, but the change is slow.

Basalt residual soil has poor water resistance, so it is easy to be disintegrative in a certain state. After immersion in water, the original basalt residual soil is not to be disintegrative in 24 hours. After soaking in water 24h and 3 to 4 cycles of wetting and drying, the original basalt residual soil begin to be the small block disintegration, and the disintegration is in a matter of chunky, with weak disintegration under natural state. The test also shows that the degree of disintegration and rate of disintegration is higher than undisturbed soil. While the temperature and humidity cycle will also accelerate the disintegration, the disintegration of basalt residual soil is influenced importantly by the changes of water content. In general, the disintegration of clayey soil and clay rock is caused by the structure of destruction, which is composed of soil surface water hydration expansion. But kaolinite mineral is the main components of the BiWei basalt residual soil mineral, which has poor hydrophilicity and expansion. Mineral composition should not be the main reason of this kind of soil disintegration. We believe that the main factors of different state of disintegration of basalt

residual soil is not the same. The disintegration under natural soil is the fracture expansion, and the disintegration phenomenon is caused by the original structure defect expansion, because the majority of fine pores in soil are bigger than surface area. The adsorption effect, the air of soil fissure and structural flaws is pressed by the water, to produce super tension. Residual soil is sensitive to cycles of wetting and drying process. Dehydration in a dry environment, cementing material bonding of particles occur dehydration hardening. Although it may become quasi crystalline or crystalline iron oxide in certain circumstances, to form aggregates coated surface coverage, enhance the agglomeration degree, but the whole structure is loose structure, the connection of the structure strength turns weak. At the same time, the electrostatic repulsion between the surface of clay particles turns weak by the concentration of colloidal iron oxide, when it turns wet again, the harden condensation water can not be restored to the original state, it causes the cement performance of particles turns weak, structure strength turns weak. When the water immerses, the micro structure of soil is disturbed and damaged, strong disintegration phenomenon is happened, therefore, the disintegration of remolded soil and dry-wet cycling soil are dispersed disintegration.

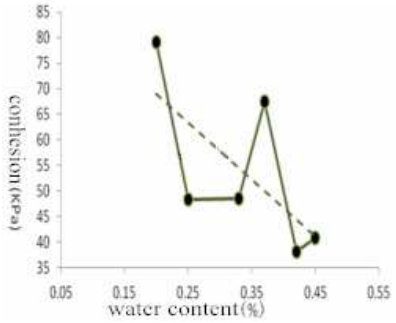

Fig. 1 Cohesion-water content relationship curve

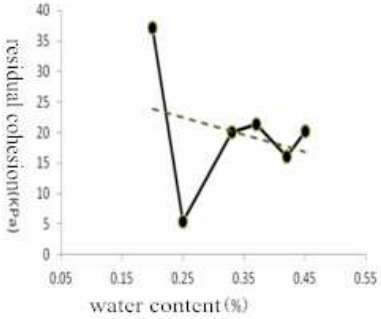

Fig. 2 Residual cohesion-water content relationship curve

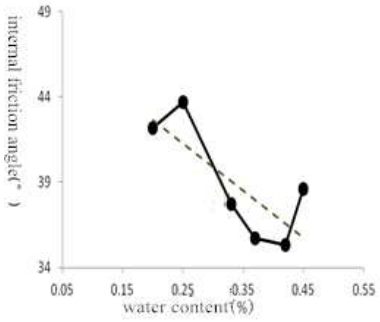

Fig. 3 Internal friction angle-water content relationship curve

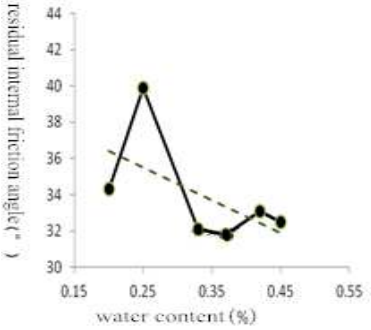

Fig. 4 Residual internal friction angle-water content relationship curve

The permeability coefficient of soil samples at 20℃ is determined by TST-55 varying-head permeameter. The average of permeability coefficient $K_{20}$ of the basalt residual soil is $2.49\times10^{-4}$cm/s, belonging to the high permeability. This is mainly because kaolinite mineral is the main component of basalt residual soil clay minerals, hydrophilic is weak, water molecules are easy to pass through the soil, and permeability is strong. In addition, in the process of penetration test, obvious swelling phenomenon is not found.

## Conclusions

The high slope of BiWei highway basalt residual soil was a kind of special regional soil with poor physical characteristics (high porosity, low density, high water content)and better mechanical properties(high intensity).

BiWei highway basalt residual soil was sensitive to water, and the characteristics of water resistance were poor. After soaked and saturated the mechanical properties deteriorated significantly, which also led to disintegration, especially when the structure suffers disturbance and dry-wet cycle, the phenomenon is enhanced. Construction should focus on the engineering disaster caused by rain.

**Keywords:** TSC pile, ultimate flexural capability, cross section parameter, mid-span deflection

**Abstract.** Precast thin-wall steel and spun concrete composite pile (TSC pile) is a kind of new type of steel-concrete composite pile whose bearing performance is between steel pile and concrete pile. This article adopted FEM software to set up 3D TSC pile model to analyze its performance. Through the comparison with actual pure bending bearing experiment results, the model's reliability was verified and the results showed that the model was reliable. Then lots of bending bearing capacity contrast calculations were conducted by using different cross section parameters (outside diameter, concrete pipe's wall thickness and steel pipe's wall thickness), and the influences of these parameters on bending resistance of TSC pile were discussed. The results showed that: with the increase of outside diameter, concrete pipe's wall thickness and steel pipe's wall thickness, TSC pile's ultimate flexural bearing capacity increased. The influences of different parameters were not the same, outside diameter was the most important parameter, then concrete pipe's wall thickness, and the last one was steel pipe's wall thickness.

## Introduction

Precast Thin-wall Steel and spun Concrete composite Pile (the abbreviation is TSC pile[1]) is a kind of new type of foundation pile which is made by pouring concrete into the curl formed steel pipe, made by Q235B or Q345B steel plate (steel belt), and then centrifuging in centrifuge to form the shape. Concrete compression strength is not lower than 80MPa, which can bear large vertical load and horizontal load. TSC pile is a new type of steel-concrete composite structure whose bearing performance is between steel pile and concrete pile, and it owes the advantages of steel pile and concrete pile, and can avoid the defects of these two kinds of piles when they are used alone: outside steel pipe's stability will be increased by inside concrete pipe; Inside concrete pipe's compression capacity will be greatly increased by the "lock ring effect" of outside steel pipe, which turn the stress state of concrete pipe from one-way to three-dimensional stress state[2]. TSC pile owes lots of advantages: high anti-hammering capacity, high penetrating power, fast driving speed, good endurance quality, good forming equality, low material cost and so on[3].

TSC pile has already successfully been used in practical engineering projects in industry, electricity power, transportation and some other field [4]. Harbor engineering projects usually use piles with large diameter, and commonly, the pile obviously bears the effect of wind, wave and some other horizontal loads effect, which need high flexural capacity. Now, there were already many scholars studied the flexural performance of TSC pile through laboratory tests method[5], the results showed that TSC pile's flexural capability is good, and also indicated that cross section properties of pile had a greater impact on its bending performance, but the specify influence degree of each parameter was not clear. Model test and numerical computation are the most effective methods to study the pile loading behavior[6-8]. For the fully play of performance of steel pipe and concrete material in TSC pile, optimizing cross section parameters, and then improve its bending resistance capacity, this article simulated TSC pile with varied cross section parameters (outside diameter, wall thickness and steel pipe's wall thickness) to discuss the influence of different parameters on the bending performance of TSC pile, the results were valued for TSC pile's designing and producing.

## Analysis methods

Large-scale FEM software Abaqus was used in the analysis. Abaqus is one of the most efficient and reliable nonlinearity software in the world now, and owes obvious advantages in solving varied nonlinearity problems in civil engineering projects, and provides many material constitutive models.

Based on the pure bending test date, the analysis model's rationality was verified. The laboratory test loading diagram is shown in Fig.1.In laboratory test, TSC pile's diameter is 1000mm, pile length is 13m, total wall thickness is 130mm, the outside steel pipe uses Q235 steel and its wall thickness is 10mm, inside concrete is C80 concrete. The loading sketch map of prototype is showed in the figure 1. L is pile's length (value in test is 13m), *a* is 1/2 loading span (value in test is 0.5m). In the numerical simulation, concrete damage plasticity model was used to display the characters after pile material entering into the plasticity status, and the steel adopted elastic-plastic model.

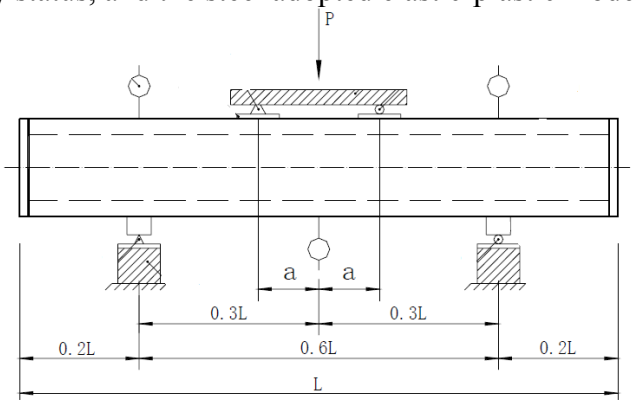

**Fig. 1 Laboratory test loading diagram**

Fig. 2 shows load-mid-span deflection curves which measured in test and calculated in FEM method. The figure indicates that the numerical modeling results are close to the test measured results. This numerical modeling can better show the elastic status, elastic-plastic status and plastic status of the pile under the effect of bending moment, which shows that the FEM used in this study is reliable. The ultimate flexural bearing capacity calculated by this numerical modeling is 5687 $kN \bullet m$.

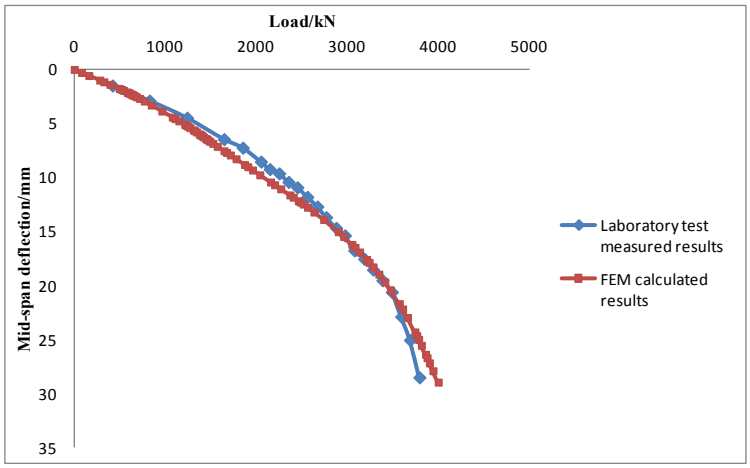

**Fig. 2 Load-mid-span deflection curve of TSC piles**

The below are TSC pile's numerical analysis with varied cross section parameters, different cross section properties are discussed to analyze their influences on the bending resistance performance of pile. The pile uses C80 concrete and Q235 steel. Through numerical modeling method, different cross section parameters (outside diameter, concrete pipe's wall thickness and steel pipe's wall thickness) are used respectively in comparison calculations, the calculation length of pile is 15m, and specific parameters can be seen in table 2.

**Table 1Calculation parameters for numerical modeling comparison**

| sorts | Parameters/(mm) |
|---|---|
| Pile outside diameter | 600,800,1000,1200 |
| Concrete pipe's wall thickness | 110,120,130,150 |
| Steel pipe's wall thickness | 8,10,16,20 |

## Analysis of calculation results

**Influence of pile's outside diameter on the bending resistance performance.** Fig. 3 shows the influence of varied pile outside diameters on the load-mid-span deflection. In the comparison calculations, the same cross section total wall thickness, same steel pipe's wall thickness, same pile length (t=100mm, ts=10mm, L=15m) are used and pile material is also the same. The figure indicates that load-mid-span deflection curves of piles with different outside diameters are similar to each other, deflection changes linearly under small load, and the pile begins to enter into the plastic status with the increase of load, finally, regional pile material enter into plastic yield status, the pile reaches its ultimate flexural bearing capacity, mid-span deflection begin to increase greatly. With the increase of outside diameter, under the same load, the mid-span deflection decrease obviously. Even when the load is small, diameter variation will cause bigger variation of mid-span deflection, this is because that, with the increase of load, the pile gradually enters into the plastic status, which indicates that diameter has a great impact on bending resistance capacity of TSC pile.

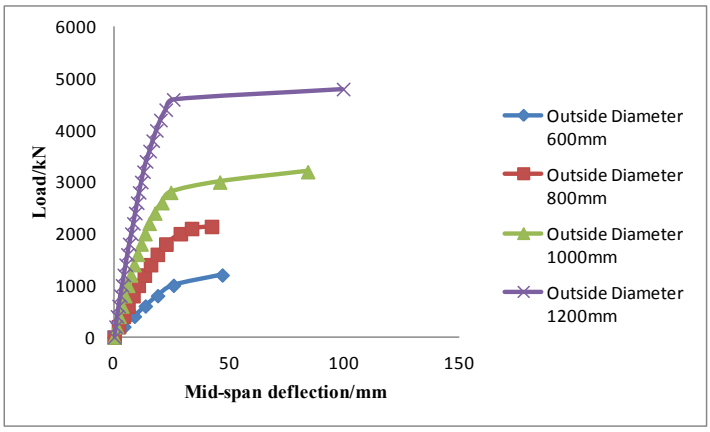

**Fig. 3 Load-mid-span deflection curves of piles with different outside diameters**

**Influence of concrete pipe's wall thickness on the bending resistance.** Fig. 4 shows that influence of different concrete pipe's wall thickness on the load-mid-span deflection of pile. In the comparison calculations, the pile's outside diameters, steel pipe's wall thickness, pile's length are the same (D=1000mm, ts=10mm, L=15m) and also the material. The actual changed parameter is the wall thickness of concrete pipe. Figure 6 shows that the variation trends of piles, when concrete pipe's wall thickness changes, are closed to each other, and the variation trend is basically linear when the load is small; With the increase of load, the pile gradually enters into plastic status, the curve doesn't change in linear; With the increase of load, material's plastic zone continuously extend, the deflection begins to increase greatly. With the increase of concrete pipe's wall thickness, under the same load, the mid-span deflection is decreased. When the load is small, the influence of concrete pipe's wall thickness is small, with the increase of load, the mid-span deflection of pile with small concrete pipe's wall thickness will increase dramatically, this is because that, with the increase of load, the pile begin to enter into plastic deformation status.

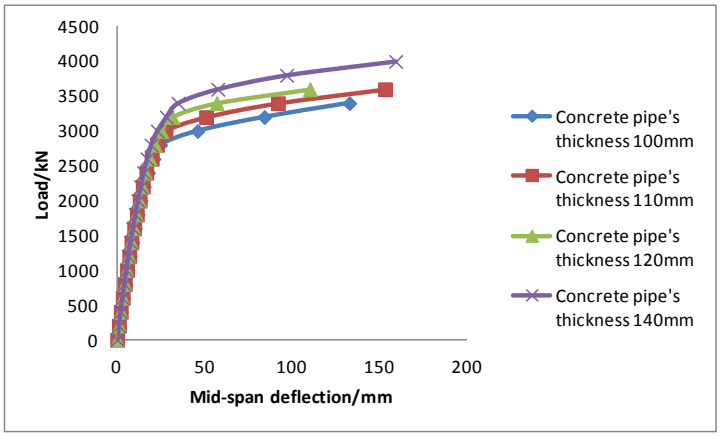

**Fig. 4 Load-mid-span deflection curves of piles with different concrete pipe's wall thickness**

**Influences of steel pipe's wall thickness on the bending resistance.** Fig. 5 shows the influences of steel pipe's wall thickness on load-mid-span deflection. In the comparison calculations, the total wall thickness, outside diameter, the length of pile are all the same (D=1000mm, t=130mm, L=15m), and also the pile material, steel pipe's wall thickness is the only changed parameter. The figure indicates that load-mid-span deflection curves' tracing pattern do not change when steel pipe's wall thickness change, and the pile also experiences three main status, linear status, plastic status and plastic yield status. When pile material enters into plastic yield status, the mid-span deflection changes dramatically. With the increase of steel pipe's wall thickness, under the same load, mid-span deflection decreases obviously. When the load is small, the influence of steel pipe's wall thickness on the deflection is small, with the increase of load, the mid-span deflection of pile with thin steel pipe will increase dramatically, this is mainly because that, with the increase of load, pile with thin steel pipe will first enter into the plastic deformation status till plastic yield status.

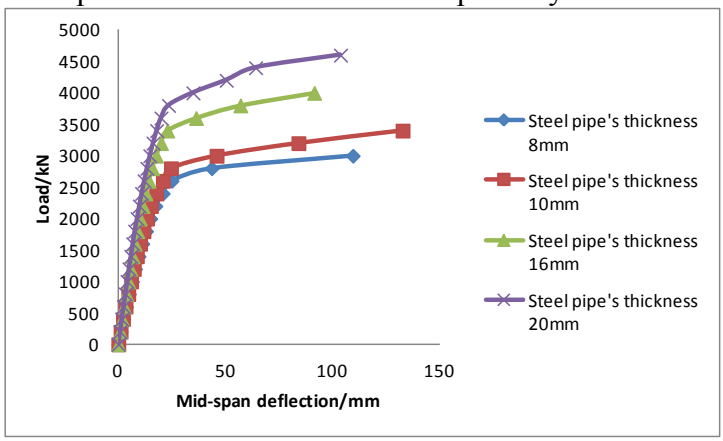

**Fig. 5 Load-mid-span deflection curves of pile with different steel pipe's wall thickness**

## Conclusions

Through numerical modeling, the bearing characteristics of TSC pile under the effect of bending moment are discussed, different cross section parameters (outside diameter, total wall thickness and steel pipe's wall thickness) are chosen in the comparison calculations, and the influences of different parameters on the bending resistance performance are analyzed, the main conclusions are as follows:

(1) Through the comparison with the laboratory test date, the feasibility of finite element model for analyzing the ultimate flexural capability of pile is verified.

(2) With the increase of outside diameters, mid-span deflection decreases obviously, the ultimate flexural capability of pile increases dramatically. But the varying patterns of piles' mid-span deflection with different outside diameters were similar. Each pile experiences three status, elastic deformation status, plastic deformation status and plastic yield status.

(3) With the increase of concrete pipe's wall thickness, under the same load, the mid-span deflection is decreased, and the pile's ultimate flexural capability is increased. When the load is small, the influence of concrete pipe's wall thickness on the mid-span deflection is small, with the increase of load, the influence becomes obviously gradually. With the increase of concrete pipe's wall thickness, the increase trend of ultimate flexural capability of pile becomes gently gradually.

(4) With the increase of steel pipe's wall thickness, under the same load, the mid-span deflection is decreased, and the ultimate flexural capability is increased. With the increase of steel pipe's wall thickness, the ultimate flexural capability of pile increase in linear trend.

**Keywords:** expansive soil; roadbed; swell shrink mechanism; treatment

**Abstract.** This paper elaborate the bad geological characteristic and the huge disaster caused by expansive soil. When constructing the road or railway in expansive soil area, the roadbed disease such as slope stability failure, roadbed settlement, mud pumping, ballast bag and so on is elaborated. The expansion and shrinkage mechanism of expansive soil has been studied from such aspects as physical-chemistry-mechanics effect, material composition, external influencing factors and so on. In expansive soil area, such expansive soil treatment and reinforcement methods as physical improvement, chemistry improvement, biological improvement are summarized and proposed.

## Introduction

There are more than 35 countries where exists the expansive soil which spreads six continents. In China, the expansive soils create the extremely huge harm, the loss that the expansive soil creates is double more than the loss sum created by such disasters as flood, hurricane, earthquake and so on in American, the economic loss for the expansive soil question approximately amounts to $20 billion every year. In China railway engineering the expense used for treatment the expansive soil foundation reach ten million Yuan each kilometer. Therefore, treatment research of expansive soil geological disasters has the significant economic significance and project practice value [1,2].

## Engineering Characteristic and Swell Shrink Mechanism

*1). Engineering Characteristic.* Expansive soil distribute broadly, is one kind of more crevasses and having remarkable swell-shrink characteristics geologic body, its distribution are very widespread. The expansive soil's clay ingredient is mainly composed by the strongly hydrophilic mineral and other clay mineral, as one kind of high plastic clay which is sensitive to the environment moist-heat change, its chief feature is that the expansive soil is rich water affinity clay , richly big the liquid limit, big swell-shrink characteristics, absorbing water swell and softening, dehydration shrink and hard crack, more crevice, distortion repeatedly and so on, in the soil body the crevasse disorderly distribute, and do the special harm to all kinds of shallow light engineering construction[2,3].

*2). Swell Shrink Mechanism of Expansive Soil.* The swell-shrink of expansive soil, in fact, are the soil body mechanics characteristic change caused by the soil water “gain and loss”. It is the quite complex physical-chemistry-mechanics effect action process, it is not only decided by its material composition and microstructure characteristic, but also having close relation with the environmental condition in which it locates. The expansive soil swell-shrink mechanism's explanation theory mainly includes the crystal lattice expansion theory, the double-electrode layer theory, the microstructure theory and so on.

The physical mechanics theory about expansive soil includes mainly effective stress theory, capillary vessel theory, elastic theory and so on. These theories thought that the swell of the expansive soil is caused by the physical mechanics effect which produced by the water-soil interaction under certain external process. After fractional saturation expansive soil absorbing water, the soil pore water pressure and the effective stress will change, the capillary vessel potential energy and the surface tension change accordingly, and caused the pellet elasticity effect, thus caused the volume of the expansive soil to increase.

**The Roadbed Failures in Expansive Soil Area**

In road or railway engineering, because of surface layer weathering effect, swell with wet and shrinkage with dry effect, as well as the insufficient compaction or protection and so on, many roadbed is distressing [4].

Under the wet cyclical effect in the dry season and the rainy season, in addition the vehicles travel load's action, the expansive soil roadbed which is not be replaced or sealed treatment will be caused superficial relaxation. Thus causes the roadbed to produce mud pumping phenomenon. The roadbed mud pumping phenomenon often is followed by the roadbed bigger settlement and the pavement wave distortion, therefore, it seriously influence traffic safety and even cause the traffic interruption.

After roadbed soil sliming, base course's crushed stone and so on is easy to fall into or is pushed in foundation bedding soil and forms the saccate structure. The ballast pouches will cause the pavement structure to destroy, at the same time, become the water seepage channel and water carrier in the roadbed, further cause deep soil body wet and sliming, thus intensify the ballast pouch's development, finally result in the vicious circle.

Usually, because of the mechanical roller compaction not arriving the road border section, the later settlement of road border become bigger, and also because of its free face, it is specially sensitive to the atmospheric physics action, therefore after water loss the shrinkage strain of road border is far bigger than that of dike body under the alternation of wetting and dry action. Road border longitudinal crack phenomenon occurs more in the dry season. After the road border has the longitudinal crack, although it does not immediately influence road's security of service, but if it is not repaired promptly, the longitudinal crack forms the seep channel of roadbed, causes the surface water very easily permeate roadbed, thus easy to cause the road border collapse.

**Roadbed Treatment Methods of Expansive Soil**

According to the improvement mechanism, the methods of expansive soil improvement may divide into three types, one is physical property improvement methods, for example to add coarse sand filling materials and so on, the other is chemistry improvement methods, for example to add lime, cement, gypsum, sodium silicate and so on, the next other is biological improvement methods, in order to reduce or permanently control disease.

*1). Physical property improvement methods*

The physical improvement methods include such many methods as soil replacement method, humidity control method, compaction control method, totally closed method, mixing sand method, Geo-cell or Geo-grid reinforcement method, Geo-textile reinforcement method, soil nail wall reinforcement method, the pile foundation reinforcement method and so on[4~5].

a) Humidity control method includes two methods, pre-wetting method and maintaining stable water content method. In order to control the change of expansive soil water content, to maintains water content little evaporation and prevent rain water to permeate in the roadbed slope or the foundation soil during construction, some necessary measures should be adopted, for example, in the construction process reserving covering layer, before lining soaking the expansive soil and

controlling critical humidity and so on, sometimes using the plastic membrane or the asphalt to cover on expansive soil slope face.

b) Soil replacement method is to dig out the part expansive soil and enclosed with the un-expansive cohesive soil or coarse-grained soil. The replacement roadbed soil thickness should consider the soil water content rapid change zone's depth which is caused by rain. The road slope protection effect of soil replacement is closely related with such construction factors as the soil water content, dry unit weight, soil type, soil block size, laying soil thickness, rolling quality and so on. If the quality of replacement soil meets each technical specification requirement and some supporting measures are taken, this method is really effective to the roadbed stability of slope.

c) Totally closed method is also named cover method, is to fill in the expansive soil in the core of bank and encircle the dike body with the non-swelling earth. The thickness of cover soil layer should not be smaller than 1m, and the cover soil layer should be built tightly and totally close the expansive soil in order to restrict the temperature' change in the dike, namely waterproof and preservation moisture, but the side slope spot is often the construction roller compaction weak spot. If the closed soil layer and the embankment soil are constructed in layered filling and roller compaction together to reach the similar compactness, then the treatment effect will be better.

d) Compaction control method is to make the expansive soil's compaction to the request density. The method can reduce effectively the swell of expansive soil when it is in low dry density and high moisture content, but the high water content's expansive soil is very difficult to gain compaction, when soil body roller compaction is under the volume weight, the strength of it is smaller. Similarly, it cannot meet the engineering need. The compaction control method has low expense, but has certain sphere of application, generally it is suitable for the weak expansive soil ground. After expansive soil compaction its dry density will increase, moreover the cohesion and the angle of internal friction will also increase, ground bearing capacity will enhance.

e) Mixing sand method is to do the expansive soil improvement through adding non-expansive coarse sand filling materials and so on, the main role is to change the constitutive property, particle combination of the natural or disturbed expansive soil, and make the expansive soil to become the non-swelling earth or to reduce its swell-shrink characteristics. If mixed the sandy gravel in the lime to synthetically treat expansive soil embankment, the swell shrink characteristics of expansive soil is eliminated in chemistry, the grain composition is optimized in physics and its compaction character and bearing capacity is improved. Before applying mixing sand method, the reasonable mixture ratio of mixed material must be determined, and the construction technology feasibility must be demonstrated.

f) Geo-cell or Geo-grid reinforcement method is that through laying the level Geo-cell or Geo-grid in the expansive soil embankment of construction, to make the best of the friction force and the snap-in force between Geo-net and filling soil, to increase the shearing strength of the soil body, to restrict expansive soil' swell distortion, and finally to achieve the stable roadbed the goal. Because expansive soil embankment's weathering depth is generally in 2m, adding Get-net length in the soil is within limits slope surface certain scope, and the construction is convenient. It is a kind of method which is worth using and promoting.

*2). Chemistry improvement methods*

Using chemical methods to improve expansive soil, it includes the following methods[6].

a) Lime stabilization method is the most commonly-used improvement methods in engineering practice. The lime solidification appears as a result of the base exchanges, the cementation, interaction of clay particle and lime. The reinforcement mechanism of lime stabilization foundation soil is mainly because expansive soil contains major content dissociation aluminum silicon ions,

after mixed with lime, the expansive soil carry on the cation exchange action, aggregation, solidification like the cement effect, after the curing the plastic limit of the soil may be enhanced greatly and its plasticity index may be reduced great degree, finally the swell-shrink behavior of expansive soil is eliminated. The lime action on earth level relates to the lime dose, degree of grinding of soil and lime, mixing uniformity, age and so on.

b) Chemical improvement fluid method, through the microscopic analysis and the physical mechanics experiment to the soil mass improved by modifier, we know that Certain organic positive ion compound can change the charge distribution of the montmorillonite mineral crystal structure, weaken the negative electricity repulsion, and stop hydrone to enter the crystal layer and the granule, increase adsorption and the cementation between the loose particle, keep down the swell-shrink distortion of the expansive soil. After improvement the expansive soil's shearing strength parameter also has comparatively large degree enhancement. Simultaneously, the organic chemistry grouting material is one kind of non-toxic, tasteless, odourless liquid. After chemistry solution is firmly adsorbed by earth, it will not drained and not create the environment pollution.

c) Fly ash, cement, lime mixed modification method. The fly ash, cement, lime mixed modification method is one kind of quite ideal improvement method, the proportion of additives should be decided according to the improvement earth’s request. In this kind of mixed chemical additive, the lime obviously reduces the earth expansion rate and the cement increases the earth the strength characteristic. After fly ash and the quicklime mixed, under certain moisture content condition they has a series of hydration reaction, and produce such compounds which is water-fast stable crystallization resultant as hydrated Calcium silicate, hydrated Calcium aluminate, as well as hydrated Calcium ferrite and so on, these compounds may harden gradually in the air and water, and play the reinforcement role to expansive soil so as to limit its expansibility.

d) Mixing cement improvement method, The cement chemical composition is mainly Tricalcium silicate, Dicalcium silicate, Tricalcium aluminate and so on, after these mineral of clinker in the cement meeting the water, they have the chemical reaction, hydrated reaction, and produce such main hydrated products as Calcium silicate hydrate, Calcium hydroxide, hydrated Calcium aluminate, hydrated Calcium ferrite, hydrated Calcium sulphoaluminate and so on.. When the cement content increases, the improvement earth's expansion ratio reduces, the reducing reason is similar to the lime, but the cement will have the bigger condensation which transforms the clay into the even more granular earth, thus cause the expansion rate to decrease, but lime is more effective than cement with aspect to reducing the expansion rate.

e) Mixing slag composites improvement method. Such composites as expansive soil, slag, cement, lime, sand and so on is called “the slag composites earth” which is put into mortar as slope protection material. The expansive soil improved by slag composite may basically lose the expansibility. The slag composites earth’s strength changes with the age, the strength of age one year is 3-8 times of age 28d, moreover the slag composites earth have good property to resist swelling with wet and shrinkage with dry[6].

f) The pressure injection grouting improvement method is to apply the lime white or the cement mortar injection scheme to reinforce expansive soil slope, under the high pressure the lime white enters the earth from lateral and longitudinal direction of grouting hole, along the soil body crevasse or the new fracture face caused by grouting precipitate and form many lime arteries or the lime thin layer. Using jet grouting, directional jet grouting or sprinkler irrigation, the grout under high pressure form not only the pulpous state structure, but also may form the lime or soil cement coagulation bodies which have certain structure and shape, or forms the boards and piles composite anti-slide body which can adapt to the bigger distortion.

*3).* Biological *improvement methods*

Physics-chemistry improvement reinforcement method is applying both physical and chemical effect to improve the expansive soil. It is refers to according to the certain proportion mixing expansive soil with lime, cement, fly ash, slag as well as the mixture of them, and adding ration active catalyst to promote modifier and earth to react each other, and finally achieving the goal to stabilize expansive soil.

The biological improvement method is to make use of the biology surface active agent to attach on the clay mineral surface, so it can reduce the liquid level tension, cause the clay mineral surface hydrophobization, break down mineral surface hydration shell or cause it to become thin, thereby cause the intergranular cohesive force to increase, enhance the earth shearing strength, and finally reduce the swell-shrink characteristic of expansive soil.

## Summary

In expansive soil area, the roadbed disease such as slope stability failure, roadbed settlement, mud pumping, ballast bag and so on is elaborated emphatically. Expansive soil treatment and reinforcement methods as physical improvement, chemistry improvement, biological improvement are summarized and proposed. But on the part of the expansive soil treatment technology, many further deep researches need to be done, aiming at the key question of expansive soil embankment fill, based on preserving moisture and anti-seepage, carry on the expansive soil embankment filling technology deep study. In order to determined the best mixed dosing and effective construction technology of expansive soil distribution area. The expansion and shrinkage mechanism of expansive soil has been studied from such aspects as physical-chemistry-mechanics effect, material composition and external influencing factors and so on.

**Keywords:** Foundation pit in Soft Soil, Stand column bulge, Additional bending moment.

**Abstract.** In the excavation process of Foundation Pit in Soft Soil area, it will cause the large uplift of stand column, and may cause the instability and failure of foundation pit in case of being serious; but the additional internal force of support system caused by the uplift and sinking of stand column currently has no practical calculation model in the foundation pit design. This article discusses the reason and mechanism for uplift of stand column in the foundation pit, proposes the simplified calculation method of estimating the additional bending moment of inner support through uplift of stand column in allusion to two main influence factors of bottom heave and vertical load caused by the excavation of foundation pit, inversely calculates the permissible additional bending moment of inner support based on this, verifies by combining the monitoring data for uplift of stand column in the actual project, and finally, further proposes the project measures corresponding to the uplift of stand column, hoping to provide beneficial reference for the similar project.

## Introduction

In recent years, our rail transit construction has been rapidly developed, the safety and stability problem of foundation pit of metro station is also increasingly concerned by people, and the deformation size and change rule of foundation pit is not only related to the safety of foundation pit, but also to the safety of surrounding building and underground pipeline. The foundation pit of many metro stations in the soft soil is used inner structural support system; and in the foundation pit project design and construction, the overall stability of foundation pit project, horizontal deformation of retaining structure and internal force are calculated and studied. But there are few studies on the vertical displacement of stand column pile in the foundation pit [1]; and if the vertical displacement amplitude of stand column is too big, it may enlarge the lateral displacement of retaining structure of foundation pit, intensify the uplift of bottom soil of foundation pit, and increase the vertical displacement of stand column, thus causing the vicious cycle, causing the adverse effect to the environmental protection around, and then causing the project accident. This article discusses the reason and mechanism for uplift of stand column in the foundation pit, analyzes the additional bending moment produced by vertical displacement and influence for overall stability of foundation pit, proposes the method and standard of calculating the permissible vertical displacement of stand column, and finally verifies by combining the some project cases.

## Reason and Mechanism for Vertical Displacement of Stand Column

In all factors impacting on the vertical displacement of stand column, the bottom heave and vertical load of foundation pit are main two aspects [2]. The direct action of earth excavation in the foundation pit causes the uplift and deformation of soil layer below the excavation face, and the bottom heave will cause the floating of stand column pile; and the vertical load mainly causes the sinking of stand column pile. Sometimes, the design considers the effect of vertical load, but the stand column pile still has displacement upward, the reason is that the condition of foundation pit during the construction is relatively complicated and the actual variability of used vertical load value and condition of

geological soil layer is relatively big. When the foundation pit is excavated, the stress of bottom is released, the soil in the pit is rebounded, the upper part of pile body is born the positive frictional resistance upward, and the stand column pile is lifted; and the deep soil of foundation pit prevented the lifting of pile, and produces the frictional resistance downward to the pile to prevent the lifting of pile. The lifting of pile will prompt the stress release of soil of pile tip, the soil of pile tip will also produce the uplift, the pile will also be lifted, but the continuous loading of upper structure and construction load with big variability will cause the sinking of stand column, therefore, it can be seen that the mechanism for vertical displacement of stand column is relatively complicated. Therefore, it is relatively difficult to calculate and forecast whether the stand column pile is lifted or sunk finally through data, and it is more difficult to calculate the final displacement quantitatively, which can be controlled and adjusted through monitoring in real time only.

## Harm for Vertical Displacement of Stand Column

If the vertical displacement amplitude of stand column is too big, it may enlarge the lateral displacement of retaining structure of foundation pit, intensify the uplift of bottom soil of foundation pit, and increase the vertical displacement of stand column, thus causing the vicious cycle, causing the adverse effect to the environmental protection around (which is shown in the Figure 1). The nonuniformity of vertical displacement of stand column will cause the differential displacement of all points of support system on the vertical plane and plane, and finally cause the support to produce bigger secondary stress (this part of stress is not considered generally in the support structure design), and if there is bigger differential settlement among the stand columns or between the stand column and underground diaphragm wall, it will cause the eccentric compression of support system and even instability, and then cause the project accident [3].

The change for shaft force value obtained before and after the stand column has vertical displacement is not big, the shaft force in most of the bars is increasing trend, but the absolute amount increased is not big. But because the additional bending moment of support caused by the vertical displacement of stand column is relatively big, the bending moment is even several times before the stand column has displacement. For the bending component, it should check and calculate its stable condition in the plane of bending moment effect and outside the same respectively according to the code for design of steel structures; for the component like 609 steel pipe of which the second moment of area of two directions is same, this problem is very serious; but for the I-steel and other components, it should pay special attention, to prevent the occurrence of local instability; for the inclined strut close to the retaining wall, it should pay special attention; and for the component of which the change of bending moment is relatively big, it should check and calculate separately, to prevent its instability, and impacting on the normal work of whole support system.

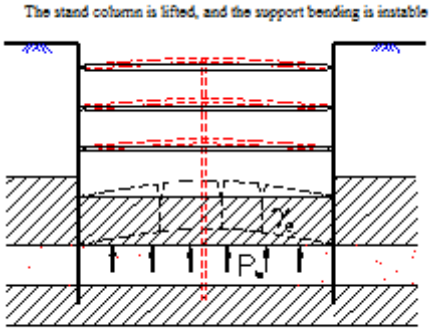

Fig.1 Sketch for retaining instability caused by uplift of stand column

## Discussion for Additional Bending Moment and Permissible Displacement

**Calculation method of additional bending moment.** Due to the reason of analysis above and effect of confined water head pressure of bottom, it is easy to produce the floating phenomenon of stand column pile, and then drive the support to float, in this way, it will produce the additional bending moment to support. The difference deflection of support will change the stress state of support, which is very easy to cause the instability and failure of support. For the reinforced concrete support, the floated and deformed additional bending moment can use the calculation model shown in Fig.2, the differential deformation of support and underground diaphragm wall is equivalent to the beam fixed at two ends, and the support base will produce the vertical deflection. It can obtain the bending moment produced by deflection according to the method of structural mechanics, shown in Fig.2.

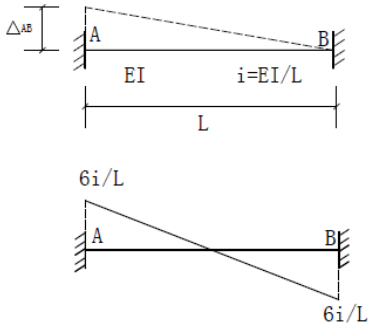

Fig.2 Calculation model for additional bending moment of support with differential settlement

Maximum bending moment of supported after deflection

$$M_{\max} = 6EI\Delta_{AB} / L^2 \quad (1)$$

Except the additional bending moment produced by floating the stand column, the foundation pit support is compression member, and the additional bending moment will also be produced due to the pressure effect, which can be obtained by the following formula

$$M_N = N \cdot \Delta_{AB} \quad (2)$$

In the formula, N——Support shaft force;

$\Delta_{AB}$——Support deflection value

The maximum additional bending moment produced by uplift of stand column is in the middle part of support and at endpoints of two ends, of which the value is

$$M_{总} = M_{\max} + M_N = \frac{6EI\Delta_{AB}}{L^2} + N \cdot \Delta_{AB} \quad (3)$$

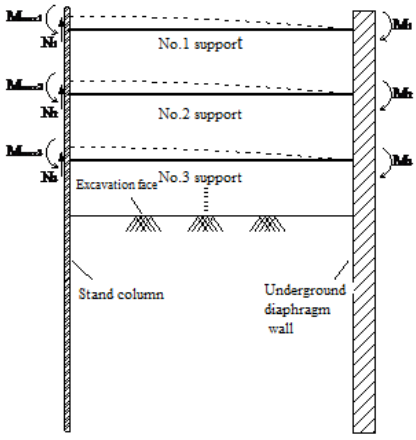

Fig.3 Calculation chart for floating force of stand column

The floating force acted on the stand column can be calculated through $M_{\max}$

The force acted on the stand column according to the principle of theoretical mechanics is

$$N_{总}=\sum_{i=1}^{n} N_i = \sum_{i=1}^{n} \frac{M_{\max i}}{L} \quad (4)$$

In the formula, n——floating support number.

**Ultimate bending moment of support and permissible differential settlement.** The calculation formula of ultimate bending moment of concrete support is as follows

$$M_u = f_y b h_0^2 \rho (1-0.5\rho \frac{f_y}{f_{cm}}) \quad (5)$$

In the formula: $f_y$—— Bending compressive strength of steel bar;

b—— Width of section;

$h_o$—— Effective height of section;

ρ ——Reinforcement ratio of longitudinal tensile reinforcement;

$f_{cm}$ ——Bending compressive strength of concrete.

Since the bending moment caused by eccentricity is smaller than the bending moment caused by lifting stand column, it can ignore the bending moment caused by eccentricity conservatively, and the maximum permissible differential settlement shall be inversely calculate with ultimate bending moment.

$$\Delta_{AB} = \frac{M_u \times L^2}{6EI} \quad (6)$$

**Estimation for vertical displacement of stand column.** Assuming that the underground diaphragm wall is not sunk and controlled through the differential settlement of each support, thus, the permissible lifting amount of stand column of each support is equal to $\Delta_{AB}$ + lifting amount of stand column and underground wall settlement when the support is completed. The minimum in the permissible lifting amount of each support is taken as the limit value of uplift of stand column.

## Project Case

Some foundation pit has length of 174.08m at the east side and 62.53m at the west side, and has width of 22.30m; and the excavation depth H of standard section is 38m (wherein the end well is 41.2m), and the retaining wall is underground diaphragm wall of which the thickness is 1200mm, of which the depth is 65m.

Since the depth of foundation pit is deep and the risk is big, all foundation pits use 9 concrete supports during the construction, and the middle part of foundation pit is equipped with bearing support of stand column pile. The stand column pile uses the cast-in-place pile of which the pile diameter is 1200mm, of which the depth is 75m. Since the depth of foundation pit is deep and the risk is big, the construction process is monitored in all directions; and in addition, the upper part has much unloading and the substratum has confined water, so the uplift of strand column becomes a main monitoring content, which should pay close attention. Up to September 15, 2006, the lifting amount and differential settlement of each support is shown in Table 1 according to the monitoring data.

Table 1 Lifting amount and differential settlement of each support

| Support No. | Lifting Amount of Support/mm | Differential Settlement/mm | |
|---|---|---|---|
| | | Left Wall | Right Wall |
| No.3 | 24.92 | 20.06 | 16.76 |
| No.4 | 23.39 | 18.44 | 15.22 |
| No.5 | 19.85 | 14.88 | 11.07 |
| No.6 | 17.92 | 12.93 | 9.74 |
| No.7 | 8.4 | 4.3 | 2.1 |
| No.8 | 1.5 | -4.03 | -7.25 |
| No.9 | -2.7 | -7.55 | -10.80 |

For this project, the support uses the reinforced concrete support,E= $3.25\times10^{10} N/m^2$, $I=\frac{bh^3}{12}$, L=22.3/2=11.15m, $\Delta_{AB}$ is shown in the Table 1; and the additional bending moment produce by floating the stand column of foundation pit is calculated according to formula (1), shown in the Table 2. The ultimate bending moment of concrete support calculated by formula (4) and reinforcement of reinforced concrete support are shown in the Table 3: the interface size of each support and permissible differential settlement value calculate by formula (5) are shown in the Table 4. The limit value of uplift of stand column calculated according to the permissible lifting amount of stand column is equal to $\Delta_{AB}$ + lifting amount of stand column and underground wall settlement when the support is completed. Thus, it can obtain that the limit value of uplift of stand column is the minimum of each permissible lifting amount, 42.251mm; and the limit value of differential settlement is: 42.251-5.41 =36.841mm. According to the principle above and calculation process, the bending moment and floating forced of each support can be obtained when the lifting amount of stand column is 30mm, shown in the Table 6. The measured duration curve of stand column lifting is shown in Fig.4 and Fig.5.

It can be known through the calculation that, in this case, the uplift of stand column does not exceed the maximum permissible uplift amount, but has been relatively close, which should be concerned and taken the corresponding project measures.

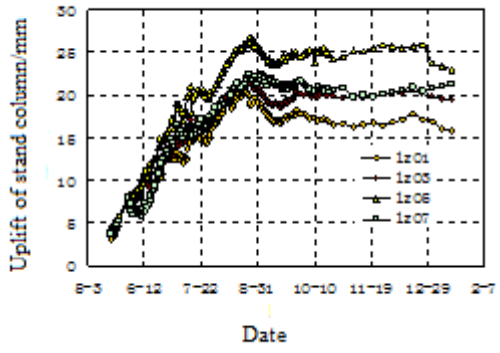

Fig.4 Changing curve for measured value

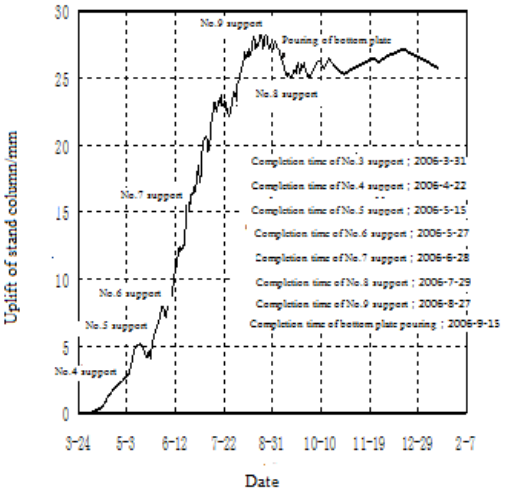

Fig.5 Curve for uplift of stand column Z04 with time

**Construction measurement of reducing deformation of stand column**

In the normal state, the vertical deformation of stand column can be effectively controlled by taking measures from the following aspects according to the reason and mechanism that the stand column produces the vertical displacement:

- For the bottom heave has big influence to the stand column lifting, the reduction of bottom heave can reduce such influence.
- The stand column and retaining structure of underground diaphragm wall shall be subjected to the settlement estimation according to the construction state, on this basis, coordinating the excavation of foundation pit or applying the load on the stand column, so that the differential settlement among the stand column, underground diaphragm wall and other retaining walls meets the requirement of structural design.
- Form the entity with big rigidity between the stand column and support and among the support, underground diaphragm wall and other retaining structure, and coordinate the non-uniform deformation jointly.

- Consider reducing the settlement through enlarging the bearing capacity of stand column pile.
- The frictional resistance of pile soil interface will have direct influence to the stand column pile lifting, therefore, it can reduce the influence of the excavation of foundation pit to the stand column pile lifting through reducing the frictional resistance above the stand column pile.
- Strengthen the settlement observation of stand column, support, underground diaphragm wall and others, and feed back to guide the information construction.
- Displacement control of stand column caused by temperature change and other factors.

## Conclusion

With deeper and deeper depth of foundation pit, the uplift of stand column in the foundation pit becomes a problem which is not ignored. It occasionally happens the accident of foundation pit brought that the retaining structure of foundation pit is damaged due to the uplift of stand column. This article obtains the following conclusion through analyzing the harm of uplift of stand column to the foundation pit project:

- The mechanism for uplift of stand column is relatively complicate. The main influence factors have bottom rebound, confined water and upper load. The soil rebound and confined water cause the stand column to uplift upward, and the continuous load of upper structure and construction load with big variability will cause the settlement of stand column, therefore, at current, it is very difficult to calculate the final displacement of stand column quantitatively, and the best method is still depended on the field monitoring and real-time feedback to guide the construction.
- Analyze the additional bending moment of support caused by the uplift of stand column, and propose the calculation formula of calculating the permissible deflection of stand column according to the ultimate bending moment of support.
- Strengthen the statistical analysis of monitoring data of uplift of stand column, and summarize the change rule and calculation method appropriate for the vertical displacement of stand column of Foundation Pit in Soft Soil from mass data.

**Keywords:** Slope Stability, Slope Early Warning System, Early Warning Criterion, Warning Thresholds.

**Abstract.** Early warning thresholds for slope instability were discussed in this study by means of rheological tests and field measurements due to availability and effectiveness of the data. Five warning levels were specified to take proper measures in different emergent cases. The left bank slope of Jinping I hydropower station was studied as an instance to implement the strategies introduced in the study. The surface displacement thresholds were obtained by analyzing long-term observed displacements (the former three warning levels) and the rheological tests on the rock mass (the last two levels). The results gave out that the thresholds of surface displacement rate for different warning levels were 0.30mm/d, 1.15mm/d, 3.00mm/d and 5.00mm/d. These results could be potential references for other projects.

## Introduction

The slope warning system was put forward to manage the safety of these slopes. The slope early warning system was consisted of several parts in this study: the data acquiring modulus, the data processing modulus, the forecasting modulus, the early warning modulus. The first three parts were not included hereby despite the need for further research.

Research on slope forecast and monitoring alarm for landslide disaster had been a worldwide challenge. The US Geological Survey and US Weather Bureau had collaborated to establish the real-time regional landslide warning system by means of long-term statistics of relationship between landslide occurrence and the precipitation[1]. In China, research on geologic hazard system survey and monitoring warning system for slopes had been entirely started round the Three Gorges Reservoir Area since the late 1990s, and had obtained some valuable achievements[2]. The top key issue on forecast and warning of slopes to prevent instability hazards was the analysis and identification of critical warning criterion[3]. In the slope warning stage, the warning thresholds for the warning criteria were often the top key issues accounting for the accuracy and reliability of the slope warning system. So far, researchers had been doing intensively on surface features and the inducing factors of slope failures from different aspects, like the deformation capacity, crack of slopes, precipitation, seism, underground water and so on[4] although research on this issue was under exploratory stage.

The work hereby was closely related to the left bank slope of Jinping I hydropower station. It was aimed to develop a reliable approach to specify the thresholds of the slope early warning criteria with multiple warning levels. It first presented the guide lines for selection of the slope warning criteria. And then gave the framework of five level warning for the safety of high-steep slopes. The surface displacement and the precipitation of the area were specified as the two key warning indicators for the slope safety warning. Afterwards, the threshold values of the warning criteria were discussed. The work could provide references for slopes with similar conditions.

## Slope Early Warning System Design

The purpose of slope early warning was to warn people before the potential slope hazards and so as to keep them and the properties from suffering. It can be implemented through the slope early warning system. As described above, slope early warning system was consisted of four stages: data collection, data processing, forecasting and early warning, which was shown in Fig.1.

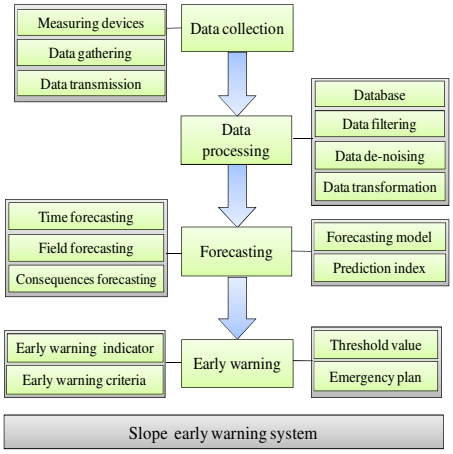

Fig1. The composition of slope early warning system

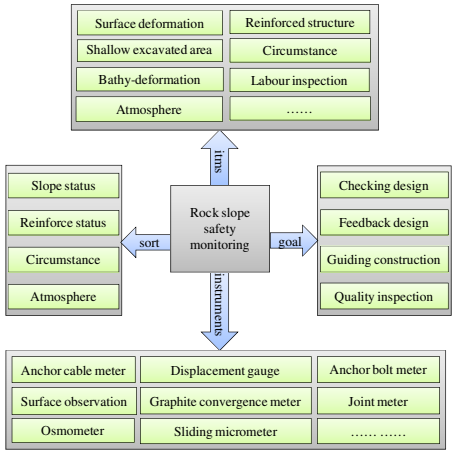

Fig.2 Monitoring design of the rock slope

Data collection was the beginning of slope early warning. It involved data acquiring instruments and measuring technologies. Also, some data gathering devices may be needed in this stage to obtain sufficient data. Then data transmission technologies need be applied to transmit data gathered by measure devices to the data collection devices which could be recognized by working staffs. The stage of data processing was the construction of data base and execution of data pre-processing for the slope safety analysis downwards. Data base was firstly needed to manage the huge amount of data collected in the stage of data collection. Afterwards, some pre-processing technologies were needed to reduce the influences of the random errors or the potential measuring faults. The data collected by the apparatus could be affected by many factors, such as the temperature, human activities and other kinds of uncertain causes, thus data filtering should be executed to remove the "fake" data component collected during the process of data collection. Also, there may be noise in the initial data collected and in this way "data de-noising" was needed to remove the affection of noise. Meanwhile, the process of data transformation was often needed to translate data into other forms. Sometimes, the accumulative displacement was needed, and in other cases the deformation rate may be the focus.

As to the "forecasting" stage, it had plenty of usage since it can tell people in advance the event of slope instabilities about the occurring time, location and potential consequences to human beings and their properties. Time forecasting was to tell the time of slope movement before its occurrence with some forecasting techniques like the forecasting model and the prediction index. Field forecasting was to broadcast the location where slope instabilities would happen or the region that would be affected by the slope instabilities. In this way, human activities within the region would be avoided. Massive of works had been done on the movement of landslide for forecasting the occurring time. Mainly, the forecasting model and prediction index were the two key issues for the forecasting of landslide events. With the proper forecasting model, the monitoring data collected can be organized in a rational way in order to obtain the expected results to pre-tell the occurrence of slope hazard, like the landslide and rock fall.

Early warning stage was designed for proper management of slope instability events. It aimed to not only tell people the occurrence of slope instabilities, but also to provide or propose pre-designed policies and measures for disaster prevention and mitigation when these disasters happened. Also, it can design different warning levels and thus can give different suggestions in variant emergent situations.

## Warning Criteria and the Thresholds

The first step in the early warning stage was to identify the early warning criteria that could be used as the standard to label the stability status of the slope. The process of identifying the warning criteria may be involved many aspects of the slope conditions. The research aim on slope warning criteria is to identify the threshold values for early warning indexes on different warning levels. It was difficult

and complex for identification of slope warning criteria and the thresholds since that the potential evolutionary process of rock slope was unforeseen and difficult to reveal desperately so far. That's to say, the principles for slope evolution were uncovered implicitly at present. Many works[5] had contributed differently on the warning criteria of landslide performance for forecasting landslide event. The works showed that it would be unpractical at present to completely discover the rules of slope evolution especially for those high-steep slopes with complex conditions. These effects were the external feedback of the potential evolutionary process of high-steep slopes. Slope displacement was the most common one among the entire monitoring index and thus it was used mostly often for analysis of slope stability. In this way, slope displacement was adopted as the main indicator to execute early warning of high-steep slopes.

**The Five-level Early Warning Method.** In the five-level early warning method, slope early warning was designed with five warning levels. Each level was represented as a basic status of slope stability. The relationship of the five-level warning design with the stage of slope stability evaluation and the warning signals were shown paralleled in Table 1. To this end, the five-level early warning design could be accord with the results of slope stability evaluation and can be represented easily with a suitable warning signal which could be recognized by people without academic background. It should be stated that the five-level warning design concerned nothing with the form of the warning criteria. It was proposed for each warning criterion with five ranges of values and thus there were four thresholds to be specified as shown in Table 1. The thresholds $a_i (i = 1, \cdots 4)$ denoted the critical value of a criterion which indicated that the slope stability status would involve to the $i$ th warning level.

Table1 The five-level early warning design for early warning

| Stability Status | Highly Stable | Stable | Average Stable | Unstable | Extremely Unstable |
|---|---|---|---|---|---|
| Warning Level | V | IV | III | II | I |
| Warning Signal | Green | Blue | Yellow | Orange | Red |
| Thresholds | $[0,a_4]$ | $[a_4,a_3]$ | $[a_3,a_2]$ | $[a_2,a_1]$ | $[a_1,\infty]$ |

The process of slope early warning could be carried out with the method introduced in this study in the following ways. Let denote the present value of the warning criterion and $s_i^*$ be the threshold value corresponding to the $i$ th warning level. If satisfied

$$s_{i-1}^* (s_{i+1}^* < s_i^*, i = 4,3,2) or \quad s > s_i^* \quad (i = 1) \quad or \quad 0 \le s < s_{i-1}^* \quad (i = 5). \tag{1}$$

Then, it indicated that the slope system would execute the ith warning level. The output of Equation (1) indicated that the larger value of the criterion, the more unstable of the slope. These were suitable for most criteria, for example the accumulative displacement, the strain rate level of the slope material and the precipitation of the region. While, there may be the criteria with the opposite effect of their value, like the reinforced strength and the strength of the rock mass. It could be transferred easily to the other kind with the normalization method for these kinds of criteria (the larger of the value the safer of the system).

**Slope Introduction.** Jinping I hydropower station located in Yalong River and situated in Yanyuan and Mulu of Liangshan District, Sichuan Province, southwest of China. The concrete dam was an arch dam with double curvature and was the top highest arch dam worldwide so far with the height 305m. In the dam site, the mountain was tremendous with high steep valleys and bareness basement. It was a typical V-like deep valley with relative height difference more than 1000m. The tendency of rock formation was general in accord with the direction of the river. The left bank slope was escarpment slope with none large profound gully. The main rock formations exposed were marble and green schist. The thickness of marble was about 600m and lay into valley slope under the height of 1820m and the river bed. Many weak geological structure surfaces were exposed in the rock slope, such as the faults, the dike X and deep seated crack. Several kinds of structural planes crossed mutually and there were several potential slipping blocks and sliding patterns [6].

**Slope Monitoring Design.** The safety monitoring system of the rock slope was installed to check the design and guide the construction activities. The monitoring of the excavated slope of the left abutment was aimed to firstly check the slope designs and provide data for feedback analysis, and

secondly guide the construction and confine its quality. Constructing supports would be strengthened according to the monitoring results to safeguard the project. Meanwhile, the data obtained by the monitoring system can reveal the comprehensive information related to the deformation and stability of the slope which was affected assembly by the external triggering factors and the geological factors. The composition of the monitoring system was shown in Fig.2.

**Thresholds of Surface Displacement**. The evolution process of rock slope from initial steady status to its failure divided into five stages from the view of creep theory[7]. The goal hereto was to identify the threshold values for each of the five warning levels shown in table 1. Firstly, the statistical analysis on the monitoring information of the slope was carried out to obtain the threshold values for the warning level IV in the term of an interval. Secondly, the rheological experiments were taken to reveal the thresholds for warning level III, II and I, i.e. the thresholds. The procedure was given as follows.

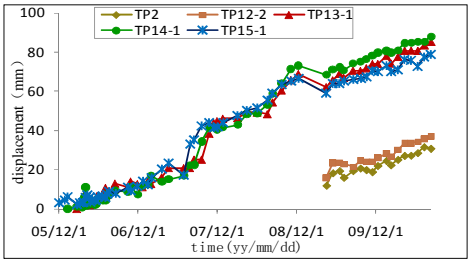

Fig.3 Monitoring results of slope surface displacement

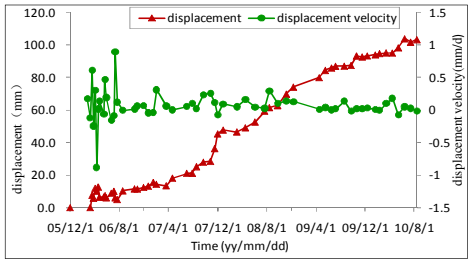

Fig.4 Deformation curves of monitoring point TP14-1

The displacements obtained from five monitoring points were shown in Fig.3. It can be noticed that the rules and trends were mainly the same for the five different monitoring results. Thus statistical analysis could be taken to analyze the monitoring information for each typical monitoring point. Here we chose, TP14-1, the one with the largest accumulative displacement. The deformation features of monitored point TP14-1 were shown in Fig.4 with the accumulative displacement and the displacement rate. As to obtain the thresholds, we firstly rejected the noisy data by "3σ-rule" in the deformation series which were shown at the beginning of the curves, and then selected the displacement rate as the warning criterion. In this way, the problem was settled to identify the threshold values of different warning levels.

It can be found from the figures that the maximum displacement rate of TP14-1 was 0.30mm/d. And the mean and the variance of the displacement rate were 0.07 and 0.22 respectively. Two different formulas were set to calculate the thresholds of warning level IV.

$$a_3 = \max\left\{V_1, V_2\right\}(V_1 = V_{\max} + 2\sigma, V_2 = \overline{V} + 5\sigma)\,. \tag{2}$$

Where, $V_{\max}$ denoted the maximum displacement rate; $\overline{V}$ and $\sigma$ represented the mean and variance of the displacement rate, respectively. The threshold was specified as the maximum value of historical data of the monitoring displacement rate. To this end, the interval $[a_4, a_3]$ was obtained as $[0.30, 1.15]$.

As for the interval thresholds $[a_2, a_1]$, other method must be applied to identify the values as we could not foresee the instability process of the slope. In this study, the rheological experiment was tried to reveal the whole deformation features of the rock mass of the slope. We carried out the whole rheological test in the rock automatic tri-axial rheological servo apparatus to obtain the features during the whole process of the rock mass from loading until its failure. The lateral strain and strain rate were recorded during the whole test. In this way, the deformation rate could be obtained as the reference for determination of threshold values.

The results of lateral accelerating rheological and rheological rate of marble and greenschist were shown in Fig.5 and Fig.6. It can be drawn from the figures that the lateral strain of the rock mass had evolved the stage of initial rheology, steady rheology and boosting rheology before its failure. Also it could be noted that the rheological rate of deformation at the beginning of boosting stage was about

1.0mm/d. In the primary period of boosting rheology it was between 1.0mm/d to 2.5mm/d, while in the later period it reached about 2.5mm/d to 5.0mm/d, and over 5.0mm/d in the failure period. Encouraged by the results and by reference to the creep theory, the threshold values of the warning level II were specified as 2.5mm/d and 5.0mm/d. Thus we obtained $a_2$ = 2.5mm/d , $a_1$ = 5.00mm/d . Therefore the thresholds $a_4, a_3, a_2, a_1$ have all been obtained.

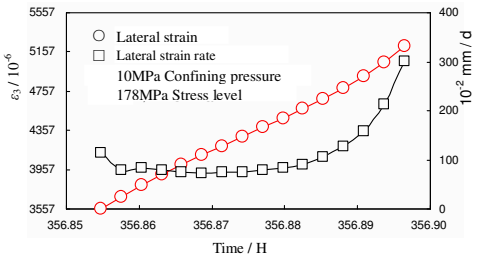

Fig.5 Results of the rheological test for marble

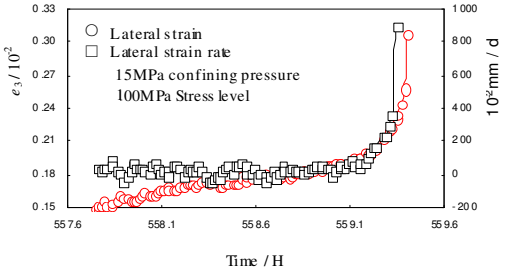

Fig.6 Results of the rheological test

## Conclusions

Slope safety early warning can be analyzed in different warning levels to take different measures in variant emergent situations. Slope early warning system was an efficient method to safeguard slope stability with multiple source data like the field monitoring and laboratory test.

Slope early warning could be executed with the five-level warning method on condition that the warning criteria were efficient to label the safety status of the slope and the data could be obtained properly. Surface displacement rate was studied as the major warning indicator in this study and was specified as a criterion for execution of slope early warning. Threshold values of slope surface displacement rate for different warning levels were determined as 0.30mm/d, 1.15mm/d, 3.00mm/d and 5.00mm/d for left bank slope of Jinping I hydropower station, respectively.

**Keywords:** Slope, Stability, Projection Pursuit, Particle Swarm Optimization, Logistic Curve Function.

**Abstract.** Evaluation of slope stability is a complex system problem with uncertainties. Based on the Projection Pursuit (PP), the Particle Swarm Optimization (PSO) and the Logistic Curve Function (LCF), a new model for evaluation of slope stability is developed, which is referred as Projection Pursuit based on Particle Swarm Optimization (PSO-PP). The model, on the one hand, uses PSO to optimize the projection index function and the parameters of LCF. Thus it would ensure the accuracy of the parameters used in the model. On the other hand, the nonlinear relationship between projection values and empirical grades is established according to LCF. The test results of the model show that the model has a very good precision. In this study, the evaluation results obtained by applying the model developed here into Jinping I site hydropower plant are well consistent with the practice situation. It indicates that the model here is feasible and effective in the evaluation of slope stability.

## Introduction

The stability of the slope is affected by many factors internal and external that is fuzziness, randomness and variability. Thus the slope stability evaluation is a complex system of uncertain. This paper attempts to combine projection pursuit algorithm (Projection Pursuit, PP), particle swarm optimization (Particles Swarm Optimization, PSO) and a logistic curve function (Logistic Curve Function, LCF) in one model, that is, Projection Pursuit based on Particle Swarm Optimization, PSO-PP, to conduct the slope stability evaluation. The principles, algorithms and steps of the mode is put in detail. Then the new model is applied to a project.

## Projection Pursuit Model PSO (PSO-PP)

**Projection Pursuit.** The basic idea of Projection Pursuit [1] (PP) is to projected high-dimensional data onto low-dimensional subspace ones through computer technology. The projection index function is used to evaluate the possibility of a projection structure for projection configuration. The minimization of projection index function helps in seeking the optimal projection value, based on which the structure and characteristics of the original high-dimensional data is analyzed. Besides the prediction value and the scatter diagrams could also be used to establish regression model to predict the system.

**Particle Swarm Optimization.** PSO uses the velocity - position search model. Each particle represents a candidate solution of the solution space. A fitness function is defined to evaluate each particle solution. The velocity $v_i = \{v_{i1}, v_{i2,} \cdots, v_{in}\}$ determines the $i$ th particle's distance of each iteration in the solution space. A group of random particles is initialized, among which the location of $i$ th particle in the $n$ -dimension solution space could be represented by $x_i = \{x_{i1}, x_{i2}, \cdots, x_{in}\}$. Particles update their velocity and position through tracking the individual extreme values $f_i = \{f_{i1}, f_{i2}, \cdots, f_{in}\}$ and the global ones $g = \{g_1, g_2, \cdots, g_n\}$ dynamically. The formula is as follows:

$$v_{id}^{k+1} = wv_{id}^{k} + c_1 r_1 (f_{id}^{k} - x_{id}^{k}) + c_2 r_2 (g_d^{k} - x_{id}^{k}); \quad x_{id}^{k+1} = x_{id}^{k} + v_{id}^{k+1}. \tag{1}$$

Where, $w$ is the inertia weight factor; $r_1, r_2$ present the random number uniformly distributed in the interval $(0,1)$ ; $c_1, c_2$ are the learning factors; $i = 1, 2, \cdots, N$ , $N$ is the number of particles; $v_{id}^{k}, x_{id}^{k}$ are

the $i$ th particle's $d$ -dimensional component vector of the velocity vector and the position one respectively; $f_{id}^k, g_d^k$ are the $i$ th particle's $d$ -dimensional component vector of the optimal individual location and the global optimization one, $d = 1, 2, \cdots, n$; $n$ is the dimension number of the solution dimension.

**Logistic Curve.** Mathematical equation of logistic curve is:

$$x(t) = K / (1 + e^{a-rt}) . \tag{2}$$

Where, $x(t)$ is the predicted value of the time $t$; $K$ is the saturation limit for the predicted value; $r$ is the growth rate; $a$ is integration constant..

**The PSO-PP Model of Slope Stability Evaluation.** The process of PSO-PP modeling is as follows:

Step 1, generate the projection data. Establish sample sets $(x_{ij}^*, y_i)$ $(i = 1, 2, \cdots, n; j = 1, 2, \cdots, m)$ based on the index of slope stability evaluation. $x_{ij}^*$ is the evaluation index and $y_i$ presents the level of experience evaluation. $n$ is the number of samples. $m$ is the evaluation value of indicators.

Set the strength of slope stability criteria are: the number of slope level increases with the stability of slope, level one is the most stable, level $N$ stage the most unstable. Establish PSO-PP mode of the slope stability evaluation is to establish the nonlinear relationship between $x_{ij}^*$ and $y_i$. To realize dimensionless $x_{ij}^*$ is normalized to $x_{ij}$ by the following formula:

$$x_{ij} = (x_{ij}^* - Ex_j) / Sx_j \, (i = 1, 2, \cdots, n; j = 1, 2, \cdots, m) . \tag{3}$$

Where, $Ex_j$ is the expectation value of the $j$ th evaluation index and $Sx_j$ is the standard deviation.

Step 2, calculate of the projection values. Set the vector $\vec{a} = (a_1, a_2, \cdots, a_m)$ as the projection direction. Then PSO-PP project $m$ dimensional evaluation index $x_{ij}$ onto $\vec{a}$ to obtain projected $z_i$.

$$z_i = \sum_{j=1}^{m} a_j \cdot x_{ij} , (i = 1, 2, \cdots, n; j = 1, 2, \cdots, m) . \tag{4}$$

Step 3, establish the projection index function. During integrated projection, it is required that the projection value $z_i$ is set as close as possible to the variability information of the evaluation index, that is, the standard deviation $S_z$ of $z_i$ should be as large as possible and the local density $D_z$ of $z_i$ reaches a maximum at the same time [2]. Thus, the projection index function $Q(a)$ is:

$$Q(a) = S_z \cdot D_z ; S_z = [\sum_{i=1}^{n} (z_i - E_z)^2 / n]^{1/2} ; D_z = \sum_{i=1}^{n} \sum_{j=1}^{n} (R - r_{ij}) f(R - r_{ij}) . \tag{5}$$

Where, $E_z$ is the mathematical expectation of $\vec{a}$ 's projected value; $r_{ij} = \left| z_i - z_j \right|$ is the sample distance; $R$ is the density window breadth, $(\max(r_{ij}) + m / 2) \le R \le 2m$; unit step function is:

$$f(R - r_{ij}) = \begin{cases} 1 & , \quad R > r_{ij} \\ 0 & , \quad R \le r_{ij} \end{cases} . \tag{6}$$

Step 4, optimize the projection index function. As projection index function $Q(a)$ change with $\vec{a}$, reflect the structure of the data type. The most optimum projection direction $\vec{a}$ is the most possible to reveal a structure's projection direction of high-dimensional data of. The optimal projection direction could be determined by solving the optimization formula (7):

$$\max Q(a) = S_z \cdot D_z \quad S.t. \sum_{j=1}^{m} a_j^2 = 1 . \tag{7}$$

It is difficult to solve the problem by conventional methods unless using PSO.

Step 5, establish PSO-PP regression model. Set the best projection direction $\vec{a}^*$ obtained from step 4. The optimum projected value $z_i^*$ is generated by substituting $\vec{a}^*$ into equation(5) . The corresponding mathematical model is established based on the scatter $z_i^*$ and $y_i$. Research shows it is suitable to apply the logistic curve to describe the relationship between $z_i^*$ and $y_i$, that is,

$$y_i^* = N / (1 + e^{a - r \cdot z_i^*}) . \tag{8}$$

Where, $y_i^*$ is the calculation of the sample $i$ th slope grade value; $N$ is the number of slope stability classification, which is the upper limit of the curve as well; $a$ is the integration constant of the logistic curve function and $r$ is the increase rate parameters. $a$ and $r$ is determined by the following minimization problem:

$$\min F(a, r) = \sum_{i=1}^{n} (y_i^* - y_i)^2 . \tag{9}$$

PSO is used for the optimization whose process refers to step 4.

## Project Applications

**Select Evaluation Index and Determine Slope Grade.** The Factors affecting slope stability is very complex among which the most important one is the rock and soil type and its nature, geological structure, hydro geological conditions. From the aspects like terrain features, rock features and monitoring status, eight factors are selected as evaluation index of slope stability. They are the slope height ( $H$ ), slope angle ( $\phi$ ), cohesion ( $C$ ), internal friction angle ( $\varphi$ ), rock quality index ( $RQD$ ), rock integrity coefficient ( $K_V$ ), slope deformation rate ( $V$ ), anchoring force growth anchor proportional ( $P$ ):

By referring to the relevant literature [3-4], and with reference to five slope stability system, stable (I), relatively stable (II), basically stable (III), unstable (IV) extremely unstable (V). Each index's classification criteria are listed in Table 1. Taking into account that calculated value of PSO-PP is continuous real number, that there might be certain errors near the endpoint value of the level classification zone, and that the output value of PSO-PP is in a threshold range, the "rounding" rule is applied and the threshold averaged if a slope level is between two categories. Set the level threshold of slope stability as follows in Table 2.

Table 1 Classification standard for the discrimination indices of slope stability

| Evaluation index | Stable （I） | Relatively stable （II） | Basically stable （III） | Unstable （IV） | Extremely unstable （V） |
|---|---|---|---|---|---|
| $H$/m | 0~30 | 30~45 | 45~60 | 60~80 | >80 |
| $\phi$/° | 0~20 | 20~35 | 35~45 | 45~60 | >60 |
| $C$/MPa | >0.22 | 0.22~0.12 | 0.12~0.08 | 0.08~0.05 | 0.05~0 |
| $\varphi$/° | >37 | 37~29 | 29~21 | 21~13 | 13~0 |
| $RQD$ | >90 | 90~75 | 75~50 | 50~25 | 25~0 |
| $K_v$ | 1~0.75 | 0.75~0.55 | 0.55~0.35 | 0.35~0.15 | 0.15~0 |
| $V$/mm/m | 0~2 | 2~3 | 3~5 | 5~8 | >8 |
| $P$/% | 0~8 | 8~15 | 15~20 | 20~25 | >25 |

Table 2 Classification threshold value of PSO-PP

| Slope level | I | II | III | IV | V |
|---|---|---|---|---|---|
| PSO-PP Result | <1.50 | 1.50~2.50 | 2.50~3.50 | 3.50~4.50 | >4.50 |

**Engineer Applications.** Zone I Slope of Left Bank Slope, the Hydropower Station I, Jinping, Yalong river is 90 meters high. The slope angle is 63.5 ° deduced from excavation breaking rate 1:0.5. Seen from the deformation and stability analysis of the left bank slope and the safety monitoring analysis of left bank slope[5], the relevant parameters of slope zone I is: slope height is 90m, slope angle is 63.43°, cohesion is 0.07*MPa*, internal friction angle is 22.8°, *RQD* is 89, rock integrity index is 0.78, deep deformation rate is 0.32mm / m, the proportion of anchor that anchoring force increases is 7%. The projection value obtained by PSO-PP is -0.265. So the calculation result of slope level is 1.97. Seen from Table 2, the stability of the slope is between stable (I) and relatively stable (II), and is finally determined level II. Similarly, the stabilization level discrimination of other slopes are in Table 3. Discrimination results are consistent with the three-dimensional limit equilibrium calculations. In the pre-set guideline "the better slope stability, the lower the levels", the district of the slope is sorted from high to low as follows: zone II, zone I, zone I.

Table 3 Grade discrimination of left bank slope of Jinping I site hydropower station

| Slope No. | Projection value | PSO-PP result | Level |
|---|---|---|---|
| Zone I | -0.265 | 1.97 | II |
| Zone II | -0.311 | 1.86 | II |
| Zone III | -0.235 | 2.04 | II |

## Summary

Combining PP, PSO and logistic curve, the mode Projection Pursuit based on Particle Swarm Optimization (PSO-PP) is established. PSO is used to realize the global optimization of the logistic function parameters. The logistic function described the relationship between scatters of projection value and experience one.

Taking advantage of the superior capacity of PSO optimization, the accuracy of the projection direction and logistic curve parameters is guaranteed, ensuring the reliability and objectivity of the PSO-PP evaluation.

Based on PSO-PP result and slope stability criteria set in advance, the stability of slope from the same level could be compared, enhancing the accuracy of the analysis.

# Stability Analysis of Tower Foundation for Transmission Line

Zhen Chen

School of Electromechanical and Architectural Engineering, Jianghan University, Wuhan, Hubei, 430056, China

184139321@qq.com

**Keywords:** Transmission Line, Tower Foundation, Stability Analysis.

**Abstract.** On basis of geological hazard survey for dangerous tower foundations of transmission line in the sphere of influence of some goaf, stability analysis is conducted for dangerous towers by use of statistical approach in accordance with relevant regulations, to propose recommended treatment measures. The method suggested in this paper can provide references for stability analysis on dangerous towers of transmission lines. The recommended measures can be served as a reference for actual projects.

## Introduction

Due to mineral resources development and other human activities, part of transmission line tower position may suffer impacts of geological disasters such as landslides, mudslides, collapse, ground subsidence, ground fissures and so on to cause tower base collapse, power failure and other accidents so that power supply for surrounding areas will be affected. In this paper, impacts of mining subsidence in tower position stability are evaluated by use of statistical approach in accordance with relevant regulations on basis of geological hazard survey for dangerous tower section of some transmission line. Dangers of geological disasters such as ground subsidence and ground fissures caused or intensified by coal mining on towers are analyzed to propose recommended treatment measures for protection of line sections and tower bases subject to impacts and damage.

## Overview of Evaluation Area

**Meteorological and Hydrological Conditions.** Survey area is located in the Pearl River Basin. Designed line tower positions are higher than maximum flood level of surface rivers in the area, the towers are less affected by surface rivers. There is no large surface water body but some seasonal creeks in the area which is recharged mainly by atmospheric precipitation and largely affected by climates. In accordance with observational data from local weather bureau, annual rainfall is not even in the area where rainy season accounts for 77% of annual rainfall while dry season only 10% of annual rainfall, with maximum temperature of 30℃ and minimum temperature of -5℃.

**Geomorphic Feature and Structure.** Lines in the area need to run through mountains. Tower site is mainly subject to denudation landform of lower-medium and medium-high mountains and has a terrain of valleys between mountains. Vegetation mainly consists of miscellaneous trees and bushes and some of cultivated lands are distributed in gentle slopes and low-lying areas.

Exposed strata include Permian Longtan Formation (P3l), Lower Triassic Feixianguan (T1f) and Quaternary (Q). Rock strata near towers are of monocline structure with attitude of 190∠66°. There are reverse faults about 250m west of 009 tower for I circuit in the strike of S37~40°W, tendency of

SE, dip angle of 54 ~ 46 °, horizontal fault displacement of 20 to 90m and vertical fault displacement of 20 to 60m.

In accordance with the Zoning Plan of Chinese Seismic Response Spectrum eigenperiod and Zoning Plan of Chinese Ground Motion Peak Acceleration Area, the area reaches the seismic response spectrum eigenperiod of 0.35 to 0.40s, ground motion peak acceleration of 0.05g and seismic basic intensity of below VI.

**Engineering Geological Conditions.** Based on mechanical properties of rocks, lithology and composition relationships, rock strata in the survey area can be classified into soft and loose engineering geology rocks.

Main human activities in the area mainly include coal mining and road construction. Coal mining has a long history in the area where small coal mines and old caves ate distributed complexly to largely affect tower base of ground lines.

The coal mine at dangerous towers which seam dip is 43~50° adopts inclined shaft development and retreat mining along strike long wall. Its mining elevation is 1600~1400m and it applies full falling roof management mode. For coal seam outcrops and shallow coal seam zone, small coal mines have a long history with a general mining depth of 30 to 60m to cause fragmented goafs. 1 coal seam is mainly mined and it has been mined to the elevation of 1445m between F54 and F57.

## Stability Analysis of Dangerous Tower Section

**Safe Mining Depth of Coal Mines.** In accordance with Literature [1] and people-oriented geological disaster prevention principle, 220kV and 500kV transmission lines have ground facilities at protection class of Ⅱ and security coefficient of K=150. Safe mining depth is calculated based on the formula (1):

$$H_{\delta} = M_n \cdot K \tag{1}$$

Where, Hδ is the safe mining depth, Mn is the coal seam mining height or combined action thickness, and K is the safety coefficient(K=150).

**Surface Movement and Deformation Expectation**. Surface movement and deformation in the tower position can be predicted by use of probability integration method and empirical formula[2].

$$W_{(x)} = \frac{W_0}{2}[1 + \mathrm{erf}(\sqrt{\pi}\frac{x}{r})] \tag{2}$$

$$U_x = W_{(x)} \cdot \left(b + \eta \cdot \mathrm{tg}\alpha - \frac{h}{H}\right) \tag{3}$$

$$\varepsilon_x = \frac{dU_x}{dx} \tag{4}$$

$$T_x = \frac{dW_{(x)}}{dx} \tag{5}$$

Where, $W_{(x)}$ is the subsidence of any point, $U_x$ is the horizontal displacement of any point, $\varepsilon_x$ is the horizontal deformation of any point, $T_x$ is the inclination of any point, r is the major radius of influence, h is the average thickness of soil layer, H is the average mining depth, b is the horizontal movement factor and $b = 0.3 \times (1 + 0.0086\alpha)$, α is the seam dip, and η is the subsidence factor(taking 0.7).

**Building Damage Level.** Building damage in the goaf is classified into four levels[2], shown in Table1.

Table 1. Building damage level

| Level | Possible Maximum Settlement (mm/m) | Horizontal Deformation (mm) | Inclination (mm/m) | Damage Level |
|---|---|---|---|---|
| Ⅰ | - | ≤2.0 | ≤3.0 | Slight |
| Ⅱ | - | ≤4.0 | ≤6.0 | Minor |
| Ⅲ | - | ≤6.0 | ≤10.0 | Moderate |
| Ⅳ | 200 | >6.0 | >10.0 | Serious |

**Coal Mine Overview.** The coal mine is located above Triassic Feixianguan formation as an immediate roof of coal-bearing stratum. There are more than 10 faults, most of which are reverse

faults. The area is of anticline structure with a stratigraphic dip of 30° to 50 °. The coal seal is inclined with a thickness of 1.4 to 3.0m and mining elevation of 1600 to 1400m and mined by use of inclined shaft development and retreat mining along long wall, of which roofs are managed by full falling method. Existing production scale of the coal mine is 210,000 t / year. For coal seam outcrops and shallow coal seam zone, small coal mines have a long history with a general mining depth of 30 to 60m to cause fragmented goafs. 1 coal seam is mainly mined and it has been mined to the elevation of 1445m between F54 and F57 faults.

**Geological Disasters Near Towers.** No geological disasters such as collapse, landslides and ground subsidence are found along the transmission line. Small coal mines have a long history to cause small goafs. There are surface cracks of 1 to 2m long and 5 to 15cm wide near the towers, but they are covered with agricultures. Tower base has two cracks of 4 to 5cm wide.

**Safe Mining Depth of Coal Mines.** Combined action thickness of coal seam mining is calculated as shown in Table 2. As shown from formula (1), the coal mine has an existing average mining depth of 212m and future average mining depth of 234m, much smaller than the safe mining depth of 2505m, and overlying rocks of the goaf are poor in the stability.

Table 2. Combined action thickness of coal seam mining

| No. | Workable seam | Seam thickness M1(m) | Seam mining height M(m) | Seam spacing H(m) | H/M | C | Combined action thickness $M_n$(m) |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 2.42 | 2.42 | 0.0 | 0.00 | 1.00 | 2.2 |
| 2 | 5 | 1.98 | 2.20 | 20.0 | 9.09 | 1.00 | 4.4 |
| 3 | 6 | 1.51 | 2.20 | 11.6 | 5.27 | 1.00 | 6.6 |
| 4 | 10 | 3.00 | 3.00 | 34.0 | 11.33 | 1.00 | 9.6 |
| 5 | 12 | 3.10 | 3.10 | 16.1 | 5.19 | 0.75 | 11.9 |
| 6 | 17 | 2.90 | 2.90 | 33.0 | 11.38 | 1.00 | 14.8 |
| 7 | 19 | 1.40 | 2.20 | 35.0 | 15.91 | 0.85 | 16.7 |

**Determination of Coal Mining Range of Influence.** Lithological rocks in the area mainly comprise the upper Permian Longtan coal measures ($P_3l$), Triassic Feixianguan ($T_1f$) argillaceous siltstones, fine sandstones and silty mudstones, belonging to medium hard overlying rocks. The coal seam has a dip angle of 43° to 50 °, 47 ° on average, so it is an inclined coal seam. Unconsolidated formation bears water with a thickness of 0 to 20m, 10m on average. Considering importance of transmission lines, weak foundation and other conditions, surface influence range shall be delineated to the maximum extent. Downhill boundary angle of $\beta_0$= 44° is taken by graphical method based on Literature [2] and mining influence radius.

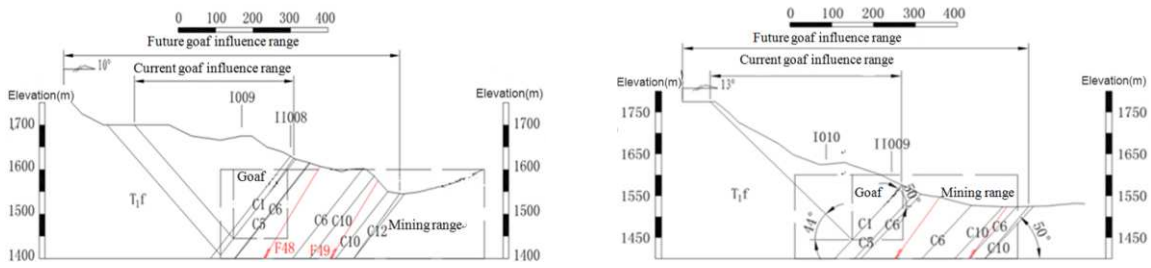
**Tower Stability Evaluation.** The coal mine has an existing average mining depth of 212m and future average mining depth of 234m respectively with a mining depth-thickness ratio of 86 and 14, much lower than safety coefficient K=150 of surface facilities at protection class of II.

By using probability integral method[2], possible maximum settlement, horizontal deformation, horizontal deformation, inclination and damage in the position of dangerous towers under existing goaf conditions can be calculated, as shown in Table 3.

Table 3. Stability of dangerous tower positions

| Tower | Profile | Position | Maximum Subsidence (mm) | Horizontal Deformation (mm/m) | Inclination (mm/m) | Damage Level |
|---|---|---|---|---|---|---|
| I009 | Fig.1 (a) | Inside Goaf | 1042 | 0.3 | 0.2 | Serious Damage |
| I010 | Fig.1 (b) | Outside Goaf 42m | 1066 | 1.6 | 1.4 | Serious Damage |
| Ⅱ 008 | Fig.1 (a) | Outside Goaf 8m | 1050 | 1.3 | 1.1 | Serious Damage |
| Ⅱ 009 | Fig.1 (b) | Inside Goaf | 1048 | 0.4 | 0.3 | Serious Damage |

All the above tower sections are located within the influence range of future mining surface subsidence. With further mining of coal mines, goaf influence range will be expanded to possibly cause geological disasters such as surface cracking, subsidence of ground and so on. Under existing conditions, tower position stability is poor where towers may suffer geological disasters with large possibility, risk and hazard. It is suggested to change transmission lines and ensure a distanced of 200m from future goaf influence range [3,4].



(a) (b)

Figure 1. Tower section

**Suggested Prevention Measures For Dangerous Tower Sections**

To prevent geological disasters, including surface cracking, ground subsidence as well as resulting landslide and collapse, from causing tower base collapse, line power failure and even power supply problem affecting surrounding areas, the following prevention measures are suggested based on stability of dangerous tower sections (Table 3):

(1) All tower sections are within the influence range of future mining ground subsidence, they may suffer geological disasters at a higher level of influence, risk and hazard. Tower base is poorly stable and suffer serious safety hazards. It is suggested to change route of the above tower sections and ensure a distanced of 200m from future goaf influence range[5].

(2) Associated with future mining of coal mines around towers, coal mining is highly possible to cause and intensify surface cracking, ground subsidence and other geological disasters. Towers and foundation have no significant deformation. It is suggested to strengthen monitoring and change routes if tower and foundation deformation exceeds the allowable value[6].

(3) Old goafs affect towers outside the goaf influence range. It is suggested to strengthen monitoring.

(4) During coal mining, security coal pillars must be reserved near the tower base according to relevant requirements of Literature [2] to ensure existing tower base is protected from geological disasters.

(5) Appropriate measures shall be taken to ensure adjacent tower base is not affected when a tower base is collapsed to cause power failure in extreme cases and even the collapsed tower base can be recovered as soon as possible.

(6) Future line construction shall avoid coal mining influence areas to the greatest extent.

# Study on Sheltering Effect of Underground Building to Horizontal Displacement of Retaining Wall of Foundation Pit

Yan Liu[1a], Junyan Liu[1,b] Shanbing Cai[1,c]

[1]School of Civil Engineering and Architecture, University of Jinan, Shandong Jinan 250022

[a]liuyan322@163.com, [b]liujunyan@vip.sina.com,[c]treasure168@126.com

**Keywords:** Foundation pit, Displacement field, Underground building.

**Abstract.** Due to the existence of underground building, the distribution of displacement field of adjacent foundation pit is obviously different from that of general foundation pit, and it is of great significance to correctly understand the sheltering effect of underground building to displacement field for determining the protection class of foundation pit while supporting design of foundation pit, and protecting the safety of metro station built near and surrounding buildings during the construction. Relying on the foundation pit project of metro station and combining the sensitivity theory through mechanism analysis, this article discovers that the sheltering effect is most obvious when the spacing between the underground building and retaining wall of foundation pit is 0.5H, and the sheltering effect can be ignored when the distance is more than 2H.

## Introduction

With the extension and development of rail transit network, more and more foundation pits near the underground building had (such as metro station, basement and the like) are excavated. There have been many studies on the influence of excavation of foundation pit to adjacent underground building currently, and many advanced construction technologies of foundation pit to adjacent construction are also developed. During the construction, the horizontal displacement for retaining wall of foundation pit will also be strictly controlled in general, to reduce the influence to the station, but it does not say that the nearer the distance from the underground building to foundation pit is, the stricter the control displacement is, instead, there is a sensitive area, however, the study on this is not perfect [1].

## Mechanism for sheltering action of underground building to displacement field of foundation pit

The foundation pit is excavated to unload the retaining wall body to displace towards the pit, and when the insertion ratio is not big enough, the soil behind the wall will also have the plastic flow towards the pit, both of which will cause the ground loss behind the wall; and the upper soil will compensate the loss behind the wall in the effect of self weight, thus causing that the soil behind the wall is displaced horizontally and vertically. Due to the large horizontal integral rigidity, the old station behind the wall will produce reversed sheltering action to the soil displacement, thus reacting on retaining wall of foundation pit and uplift in the pit [2-4].

This sheltering action will make the horizontal displacement of retaining wall body of foundation pit is much less than the displacement value of those without underground building.

**Project background.** The new station is located at the south side of station operated in parallel, the parallel spacing of the second floor underground of two stations is about 5m, and the foundation pit is excavated with one underground diaphragm wall in the first floor underground totally. The station has length of 241.2m, the main structure has width of 20.6m, the maximum burial depth of bottom plate of end well is 16.59m, and the buried depth of bottom plate of standard section is 14m, which are in the double column three-span underground two-tier architecture. The retaining structure of station is underground diaphragm wall of which the thickness is 800mm and the depth is 26m. The

finite element model shall be built to analyze the sheltering action of underground building, shown in the Figure 1.

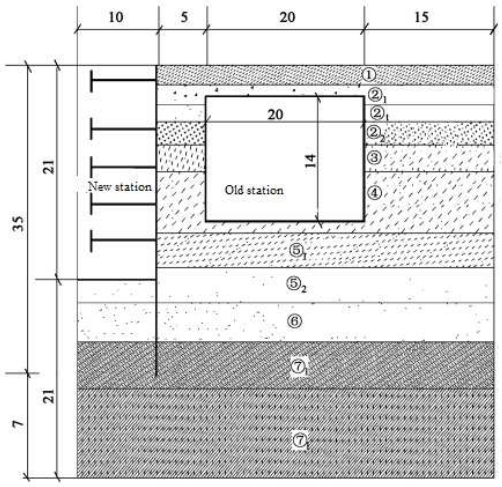

Fig.1 Calculation Model

**Analysis for sheltering effect of different spacings.** Fig.2 (a)-(e) is the deformation diagram of retaining structure in the different working conditions and soil widths.

6m and 9m of curve in Fig.2 (a)-(e) respectively indicate that the distance from the underground structure to foundation pit is 6m and 9m, we indicates that others are similar in case of no

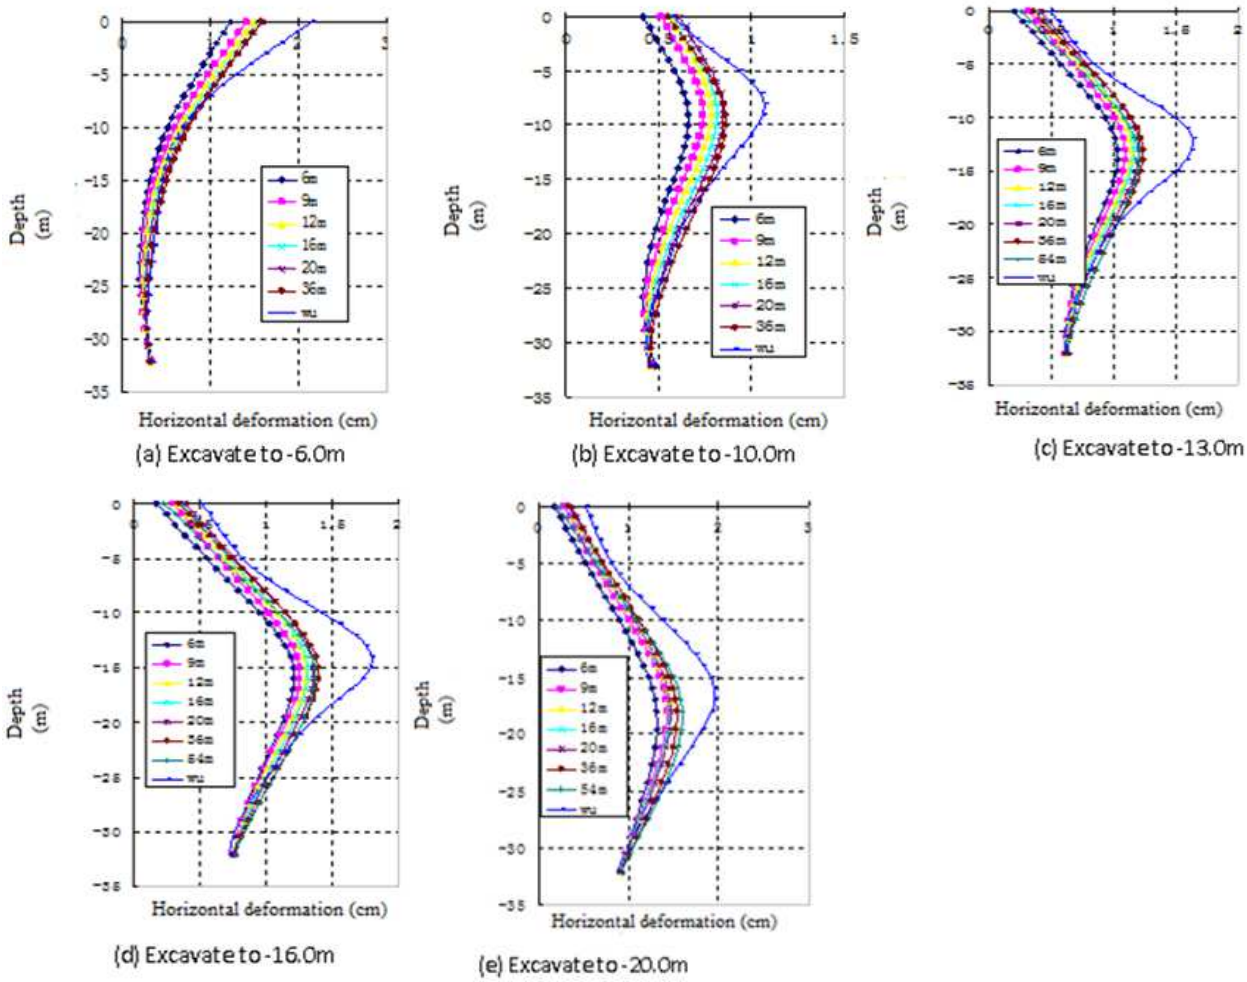

Fig.2 Deformation diagram of retaining

It can be seen from the figure that the existence of underground building has certain influence to the horizontal deformation of retaining structure of foundation pit, and especially, the influence for maximum deformation value of supporting structure is relatively big. The distance from the

underground building to the supporting structure of foundation pit is inversely proportional to the sheltering effect of underground building and proportional to the horizontal displacement produced by the retaining structure.

Respectively taking the spacing from the old station to wall of foundation pint is 0m, 5m, 10m, 15m, 20m, 30m, 40m and 50m, the relation between its spacing and maximum horizontal deformation of wall of foundation pit while excavating to the bottom (20m) is shown in the Figure 3.

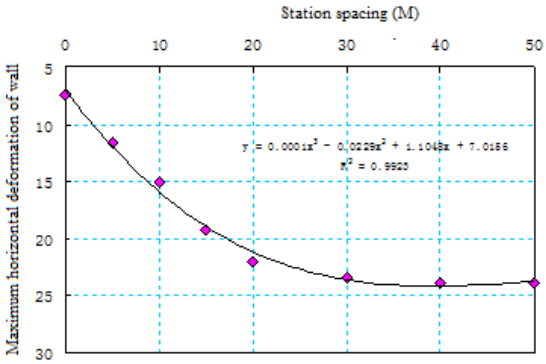

Fig.3 Relation diagram for maximum horizontal deformation and spacing of wall of foundation pit

**Sensitivity Analysis of Spacing to Horizontal Deformation of Retaining Wall**

In virtue of sensitivity analysis method in the system analysis, seek the sheltering effect of old station with changed spacing to the wall deformation of foundation pit.

Set a system, of which the system characteristic P is mainly decided by the n factors, i.e.

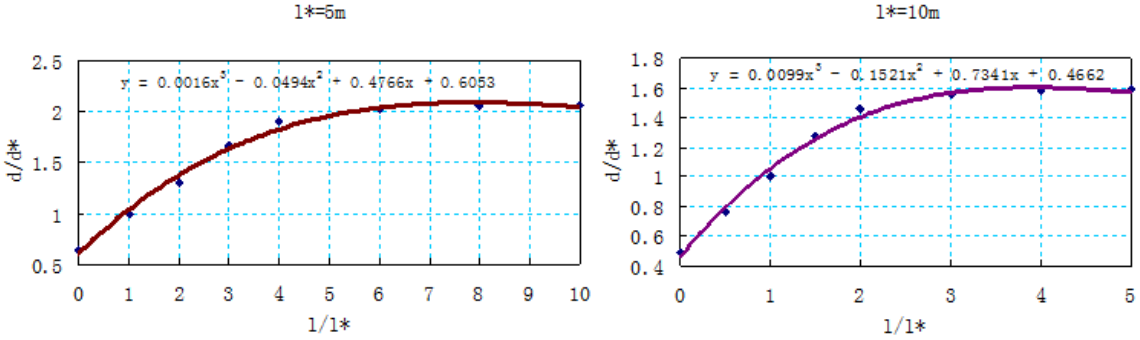
$$P = f(a_1, a_2, ...a_n) \qquad (1)$$

In some a reference state , the system characteristic is P*. Respectively order that each factor is changed within its possible range respectively, and analyze the trend and degree of system characteristic P while deviating the reference state P* due to the change of these factors, such analysis method is called as sensitivity analysis [5,6]. The sensitivity function [5] can be defined after each physical quantity is subjected to the dimensionless method:

$$S(k) = \frac{\left(\frac{|\Delta P|}{P^*}\right)}{\left(\frac{|\Delta a|}{a_k^*}\right)} \qquad (2)$$

$$P^* = f(a_1^*, a_2^*, ..., a_n^*) \qquad (k = 1, 2, ..., n) \qquad (3)$$

It can be seen from the formula above that the calculation of sensitivity function is closely related to the reference value. By taking the reference value $l^*$ of spacing from the wall of old station to that of new foundation pit is 5m, 10m,15m, 20m ,30m, 40m and 50m, it can obtain the relation of $d_{\max} / d_{\max}^*, l / l^*$ , shown in the figure 4 respectively.



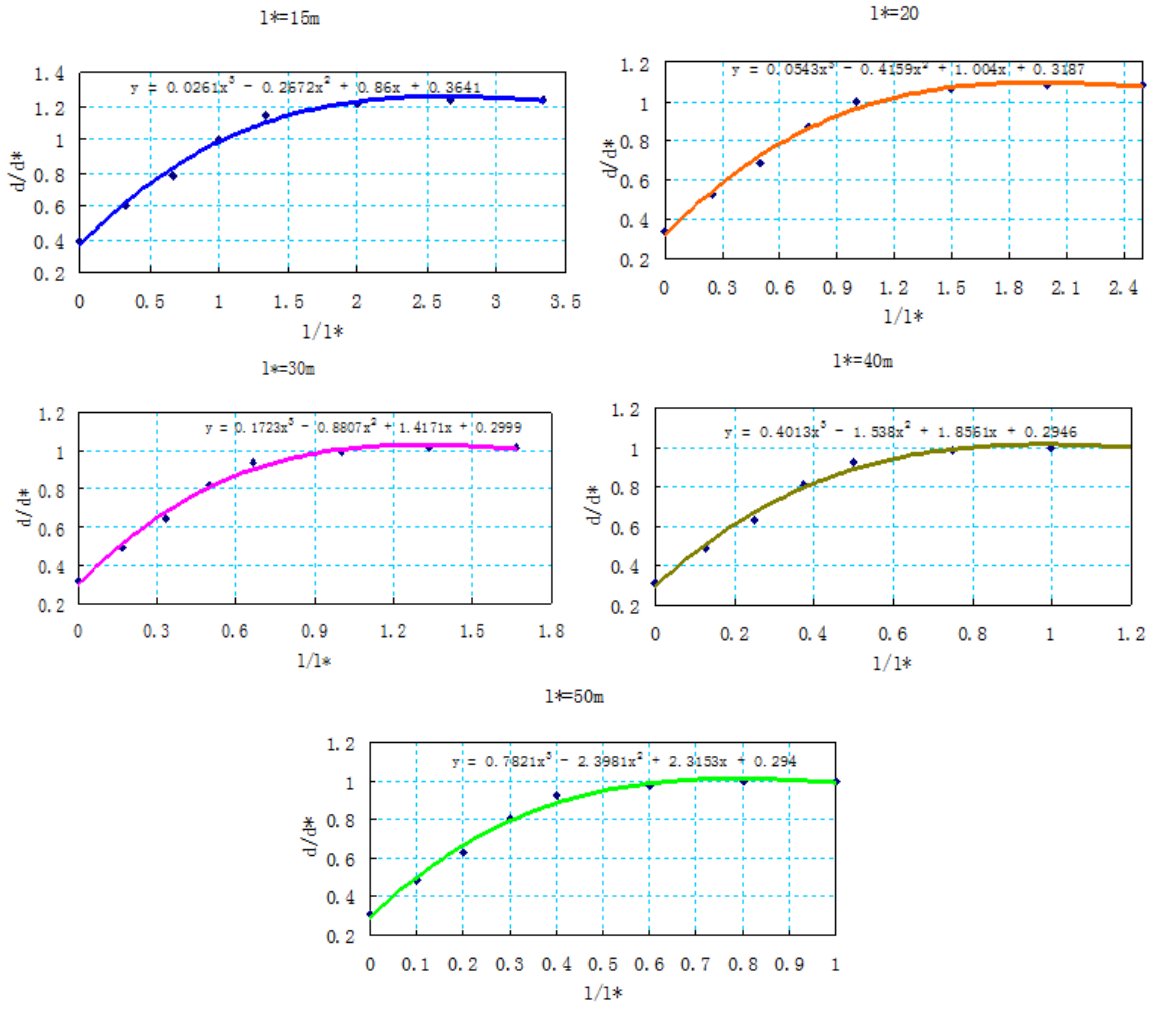


Fig.4 Relation of $d_{\max}/d^*_{\max}, l/l^*$

In the figure, when is 5m, it can obtain from the curve fitting:

$$y = 0.0016x^3 - 0.0494x^2 + 0.4766x + 0.6053 \quad (4)$$

Thus, it can obtain that the sensitivity function of is

$$S(l) = \left|y'\right| = \lim_{\Delta\to 0}\left|\frac{\Delta y}{\Delta x}\right| = \lim_{\Delta\to 0}\left|\left(\frac{\Delta d_{\max}}{d^*_{\max}}\right) \Big/ \left(\frac{\Delta l}{l^*}\right)\right| = \left|0.0048x^2 - 0.0988x + 0.4766\right| \quad (5)$$

It can be know from the formula above that the sensitivity factor of is S ($l^*$) = 0.3826 when $l^*$ is 5m, meaning that the relative error d of parameter will cause that the relative error of maximum horizontal displacement of station is 0.3826d. Similarly, it can be obtained that the sensitivity factors of are 0.4593, 0.4039, 0.3351, 0.1726, 0.0819 and 0.1346 when $l^*$ takes 10, 15, 20, 30, 40 and 50m.

Table 1 Sensitivity Factor of Different Reference Values

| | l*=5m | l*=10m | l*=15m | l*=20m | l*=30m | l*=40m | l*=50m |
|---|---|---|---|---|---|---|---|
| Influence coefficient of horizontal displacement | 0.3826 | 0.4593 | 0.4039 | 0.3351 | 0.1726 | 0.0819 | 0.1346 |
| Influence coefficient of wall settlement | 0.5033 | 1.6507 | 0.9020 | 0.2620 | 0.5856 | 0.0762 | 0.1794 |

When $l^*$ is 40m, the sensitivity factor of parameter is the smallest, so it can think that when the spacing from the wall of old station to that of new foundation pit is more than 40m, the influence of underground structure to the foundation pit can be ignored, thus, it can take 2H (which is excavation depth of foundation pit) as boundary recommended value for the existence of underground structure

to vertical displacement of foundation pit. And when the distance is 0.5H, the sheltering effect of underground station to the horizontal deformation of retaining wall of foundation pit should be the most obvious.

## Conclusion and Prospect

It is not hard to see though the analysis above that when then spacing from the underground building to the retaining wall of foundation pit is 0.5H in the soft soil area, the sheltering action is the most obvious, therefore, at this time, in the excavation process of foundation pit, it should strictly control the deformation of retaining wall body, reasonably determine the construction alarm value, and reasonably determine the design grade of foundation pit.

When the distanced is more than 2H, the sheltering effect of underground building to the retaining wall body of foundation pit can be ignored.

It shall need the further study for considering the design mode of foundation pit of such sheltering action.

# Study on the stress and strain of EPS silt light-weight soil by laboratory test

Yong Feng [a] , Yubin Pei [b]

School of Civil Engineering,Henan University of Technology,Zhengzhou ,Henan,China

[a]51433719@qq.com, [b]874769620@qq.com

**Keywords:** EPS silt mixed lightweight soil; Stress and strain; Laboratory test

**Abstract.** EPS is silt mixing light-weight soil by expanded polystyrene, curing agent, mixture mixing and has a certain strength, lightweight synthetic packing. This article is based on laboratory test, using the uniaxial and triaxial compression test on the relationship between stress and strain, research has shown that the strain values are greatly influenced by the EPS content ratio, strength is mainly composed of cement mixing ratio control. Triaxial test results show that only when the cement mixing is larger, mixed soil shear strength characteristics with general soil has a great deal of similarity.

## Introduction

EPS technology silt mixing light-weight soil from a new point of view that the sludge as a resource, by adding the waste foamed polystyrene, curing agent, mixture mixing and has a certain strength, lightweight synthetic packing. due to its stable physical properties, won't produce the soil pollution problem, at the same time, the technology can be abandoned foamed material and silt into high quality filling construction materials, To waste recycling is the environmental geotechnical engineering is on the rise and development of one of the main research direction.

This article mainly USES the indoor experiment study of the stress-strain relationship, is the purpose of the study for EPS silt mixed lightweight soil engineering application provides reasonable geotechnical parameters, for the selection, preparation has a clear service engineering properties of EPS silt mixing light-weight soil, can be widely applied to facilitate the green technology.

## Under the conditions of uniaxial compression of light-weight soil stress-strain relationship

### Different EPS content of light-weight soil stress-strain relationship analysis

Fig.1 is the changing rule of the stress of the lightweight soil with strain. In the figure 5 curve we can see that every curve has obvious peak stress strain curve for processing softening type curve, it shows that the formation of lightweight soil is of obvious structural.

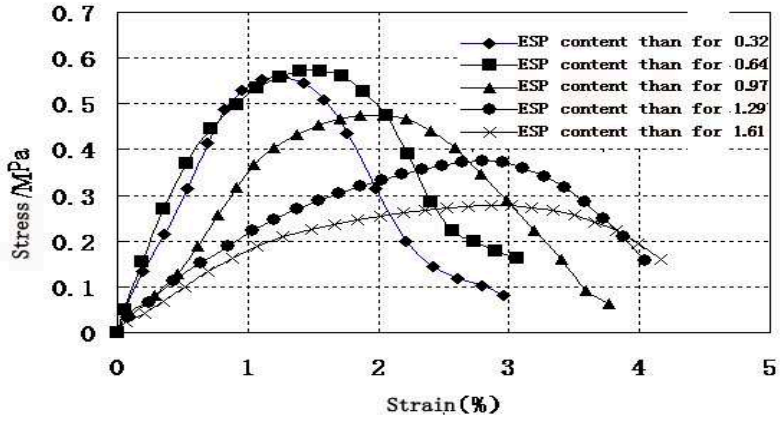

Fig.1 Different EPS content of light-weight soil stress-strain relationship

The whole stress-strain relationship curve is divided into three stages. Line segment, the first stage is the initial load time, increases with the strain, stress increasing, before reach the yield stress, stress-strain relationship is close to linear relationship, but the short line segment. Linear

relationship suggests that samples in the elastic state, samples, there is no obvious cracks deformation basically can be restored. The second phase of material plastic yielding phase, with the increase of load, a new crack sample, the original cracks is also improved, soil by contraction to inflation, the growth of strain growth speed is greater than stress, stress-strain relationship clearly into curve, stress increases to the peak. Sharp decline in the third stage is the failure stage, stress, and that the slope of the curve to become negative.

Although different EPS content than the case of light-weight soil stress-strain relationship characteristics are consistent, but there is a big difference strain values. Can be seen from the diagram, the strain value increases with the increase of the ratio of the mixed quantity of EPS, and the plastic zone range is obviously increased, but lower strength.

**Different cement mixing ratio of light-weight soil stress-strain relationship analysis**

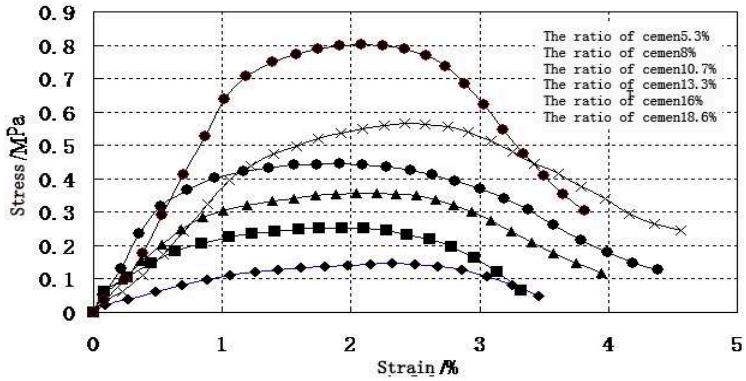

Fig.2 Different cement dosage of light-weight soil stress-strain relationship

Fig.2 for cement ratio 5.33 to 18.6% of light-weight soil stress-strain curve, we can conclude that the changing rule of the stress and strain are the same as shown in Fig.2, presents the processing softening type curve. Different cement ratio stress-strain relationship characteristics of lightweight soil is relatively consistent, but at different curve. Cement ratio is high, the stress strain curve is steep, high stress strength, failure strain is small, about 2%, mainly brittle failure; Than low dosage of cement, the stress strain curve and stress intensity is low, failure strain, about 3%, plastic damage is given priority to. Both strain values were similar, therefore, can not consider the effect of cement content on strain value.

**Triaxial compression under the condition of the light-weight soil stress-strain relationship**

**Triaxial compression test comparative study on the stress and strain**

Uniaxial compression test is still not fully reflect the characteristics of lightweight TuShiYang stress and strain, so the triaxial tests are needed to further study and discussion.

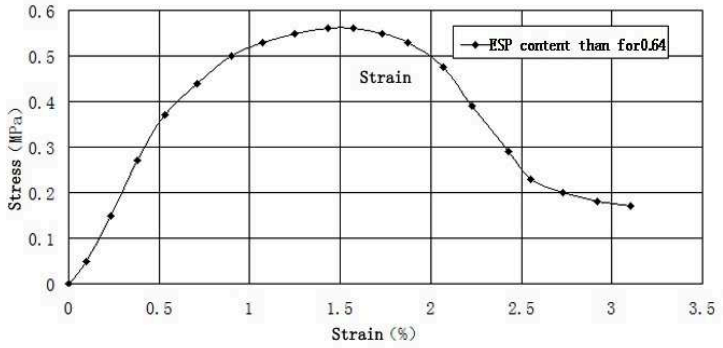

Fig.3 Typical mixing light-weight soil stress-strain relationship curve

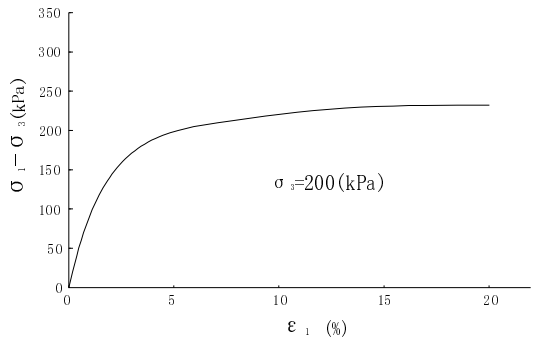
EPS of silt mixing light-weight soil triaxial stress strain curve as shown in Fig.3, under the condition of confining pressure is 200 kPa, for mixing water, 20% of cement is 13%, the density of 0.823 g/cm3, age 28 days sample separately not consolidated undrained stress-strain test and consolidated undrained stress-strain test, to conduct comparative analysis.

Fig.4 and Fig.5 shows the mixed lightweight soil triaxial stress strain curve has the same rule, namely the characteristic of nonlinear and hardening characteristics of obvious. At the initial stage, the main differential stress and axial strain relationship curve of the initial phase of approximate to linear, show that hybrid lightweight soil in the elastic state, when the stress reaches a critical value, the stress-strain relationship is nonlinear, and proved that there are lightweight soil mixed plastic deformation. At the same time, in the process of loading, material after entered the stage of elastic-plastic deformation, stress and constantly improve, with the increase of strain curve, no obvious peak hardening characteristics of stress - strain relationship is obvious.



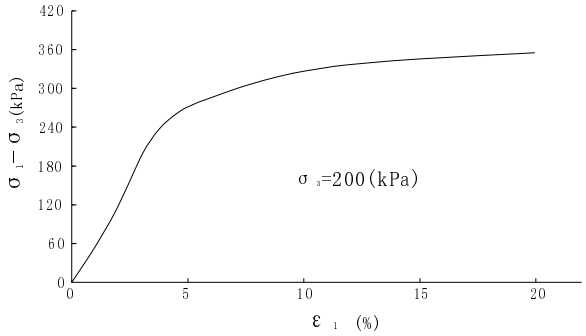


Fig.4 No consolidation undrained stress-strain curve Fig.5 Consolidated undrained stress-strain curve

At the same time, the comparative Fig.4 and Fig.5, you can see that consolidation undrained stress strain test of maximum principal stress difference is greater than consolidation undrained stress-strain test, and also compared with high yield stress.

Respectively under the consolidated undrained triaxial compression test and consolidated undrained triaxial compression test respectively to investigate and analysis the characteristics of stress and strain.

**No consolidated undrained triaxial compression test stress and strain characteristics**

EPS particles in silt mixing lightweight soil soil cohesive action mainly depends on the cement bonding between the degree of shear process can be considered as a lightweight structure failure process of soil itself. When the cement dosage is small, weak bonding effect, the higher the confining pressure, the extent of damage, the greater the light-weight soil and the lower the strength. When the cement dosage is bigger, bonding effect is strong, its high strength, lightweight soil with a relatively low confining pressure effect on lightweight soil, the characteristics of lightweight soil is close to the general characteristics of soil.

Cement mixing ratio of 16% and 22%, the same confining pressure conditions, the principal stress difference along with the confining pressure increases. Accordingly, when the cement mixing ratio of 10% and 13%, under the same confining pressure, the principal stress difference is small, the main differential stress decreases with increasing confining pressure.

Experiment also found that when the cement mixed with more hours, no obvious effect on the size of the principal stress difference, when the cement mixing is larger, influence on the size of the principal stress difference is obvious. Principal stress difference and gradually increase with the increase of cement mixing ratio, the high stress approximate linear increase

**Consolidated undrained triaxial compression test stress and strain characteristics**

In the consolidated undrained triaxial compression test, the extraction of sample saturated, sample density in the range of 0.823 to 0.987 g/cm3, 10-22% cement mixing ratio, mineral water, 20% (28 days, respectively in confining pressure 50 kPa, 100 kPa, 200 kPa and 300 kPa under the action of the stress strain curve of sample.

Obviously found in the process of test, with the continuous development of axial strain, principal stress difference increasing, confining pressure is greater than 50 kPa, the stress strain curve for strain hardening; Principal stress difference increases with the increase of confining pressure on, this of conventional triaxial compression test results of soil with general similar.

Found in the experiment: cement mixing ratio within a certain range, confining pressure, respectively, in the 50 kPa, 100 kPa, 200 kPa and 300 kPa, under the action of EPS silt mixed lightweight soil stress - strain curve has obvious nonlinear features and hardening. With confining pressure increasing, the stress strain curve in the initial period of linear degree and the tangent slope gradually decreases, and when the strain hours, confining pressure is higher, the initial elastic modulus and principal stress difference is small; When large strain, high confining pressure, the principal stress difference increasing, hardening characteristics more obvious.

Experiment also found at the same time, the cement mixing ratio of beads has greater effect on the size of the principal stress difference, the main differential stress increases with the increase of cement mixing ratio, the high stress approximation of linear increase relation, but compared with not consolidated undrained triaxial compression test, the smaller of absolute value of the slope.

## Conclusion

Strain values increase with the increase of the ratio of the mixed quantity of EPS, and the plastic zone range is obviously increased, but lower strength. Situation of different cement lightweight soil stress-strain relationship characteristics are consistent, and the small strain values, the maximum stress when the strain value is about 2%.

Through the consolidated undrained triaxial compression test results of analysis, the EPS of silt mixing light-weight soil shear strength properties. Shear strength index of the internal friction Angle and cohesive force of the cement mixing ratio, density, and varies according to age, only when the cement mixing is larger, mixed soil shear strength characteristics of great similarity with general soil. Experiment also found that the cement mixing ratio has a certain influence on the size of the principal stress difference, the difference of principal stress that increases with the increase of cement mixing ratio, the high stress approximate linear increase.

# The Analys of Stability of Composite Soil Nail

Yong Zeng[1,a]

[1]Jiangxi Transport Consultation Company,Nanchang,330008,China

[a]14263330@qq.com

**Keywords**：Composite soil nailing technology; New technology; Main form of structure; Main principle

**Abstract.** Composite soil nailing technology is a new technology which developed on the basis of the soil nailing supporting technology. This new technology has a very important practical significance to the construction, for which the scale is larger and larger, the condition is more and more complex and the excavation of foundation is more and more deep. Composite soil nailing technique is mainly introduced in this paper by its main form of structure and the main principle, which draw a conclusion that different forms of the combination of support types have different effects on the stability of structure, by analyzing the support stability. This thesis shows that we should adjust measures to local conditions, choose the right organic combination. At the same time it also provides the basis for the practical application of engineering support.

## Introduction

Along with the construction of high-rise buildings, municipal engineering of underground space development unceasingly, in order to meet the requirements of building's using function, meet the requirements of excavation depth and area of growing demand, support technology must be improved to a certain height. Composite soil nailing supporting construction gets more and more favor of engineering application, due to its economical, safe and reliable features. There is no formal definition about the composite soil nail. According the reference experience and theory[1,2] we can get that: the composite soil nailing technology is a support technology which takes the soil nail as a solidified body, allying with the other ground treatment technology to support the soil pressure. Because composite soil nailing technology can be applied to the complicated geological conditions[3,4], it can save project investment, and has a good application prospect. So far the composite soil nailing technology is widely used. However, there are still few research reports about the theory and experimental research of composite soil nailing support, working mechanism and design calculation .the design and analysis method of composite soil nailing technology is still very lack. Although there have been some research, and have provided a certain theoretical basis, there is no analysis method that has been agreed about the composite soil nailing technology. And we also have not enough acknowledge about the working performance of the composite soil nailing support technology, we needs further research. Recently , with the support of natural science , the civil engineering department of Tsinghua university are doing some research about the working mechanism and design theory of the composite soil nailing support technology, and will hopefully get a series of achievements in the past two or three years.

## Main types of composite soil nail

In the existing engineering examples, there are mainly the following categories about the composite soil nail.

1) Soil nailing and waterproof curtain composite support

When the water table is high or the foundation pit is in anti-seepage requirement. (to prevent ground subsidence caused by the large decline of the water table) , in the weak soil stratum, we can use the

technology of soil nailing and waterproof curtain composite support. This support technology solves the issues of water seepage after the excavation of soil and the soil instability, basement high, piping problem caused by the decrease of strength of soil. Meanwhile, as a result of the foundation pit supporting in a timely manner, the slope is vertical flat and dry, when the support completes.

2) The soil nailing with micro pile composite supporting

When the water table is deep or there is no requirement about water seepage, we can adopt the technology of soil nailing with micro pile composite supporting. This supporting technology is available to prevent the basement from uplifting and from the local lane in the process of the excavation. Generally use the root pile or micro column steel tube, sometimes using a stake.

3) The soil nailing and the pre-stressed anchor composite supporting

Pre-stressed anchor is a useful and effective form in the composite soil nail supporting, especially when the foundation pit is deep ,the geological conditions, the surrounding environment is complex, and we have a strict requirement for the deformation of the foundation pit, it will show its advantage. Its main characteristic is governing the deformation displacement of side wall by applying pre-stressed. There are two kinds of the supporting, one is implanted in a row or two rows of pre-stressed anchor; the other is that A pit bottom with pre-stressed anchor, the anchor rod arranged on the bottom.

4) Soil nailing and waterproof curtain, steel pipe pile composite supporting

Cement mixing pile can stop water seepage, and the advanced micro pile has large stiffness. In order to give full play to the advantages of both, we can combine the two, together with the soil nailing to form a kind of new composite soil nailing support type ------ a soil nailing and waterproof curtain, steel pipe pile composite support. If we have a strict requirement in displacement of excavation in the practical engineering, we can join the pre-stressed anchor; If required the displacement and settlement of excavation, we can exert a certain pre-stress on soil nailing.

**The mechanism of action of composite soil nail**

1)The mechanism of the waterproof curtain

The water curtain often consists of cement mixing pile. In the application of cement-soil mixing pile, the width of the single pile is 0.5 m, width of double row piles is 1.0m. According to the soil conditions and the depth of excavation, we will decide to adopt the single row pile or double row pile. There are two aspects about the mechanism of the water curtain: (a) Get the problems of self-stability and seepage of pit side solved. When the water content of side wall is large, the net shotcrete layer is not easy to bond together with the soil, if spray layer spray directly on soil-cement mixed pile, it's easy to bond together.(b) because of the better work performance of the cement soil than the undisturbed soil, when the cement-soil pile set in the basement below a certain depth(the grave ratio between 0.7~1.0), play an important role to resist the uplift of the basement and piping.

2)mechanism of the advanced micro pile

Advanced micro pile is grouted by steel pipesφ48-φ108 or drill pipe, and spacing of 0.5-1m, This kind of micro pile can not form waterproof curtain, but can increase the self-stability of each layer soil in case of uplifting the basement. Meanwhile, it also plays a very important role for the stability of the supporting system.

3)The mechanism of the pre-stressed soil nails and pre-stressed anchor

There is a difference in structure between the pre-stressed soil nail and common soil nail. The body of pre-stressed soil nail is twisted steel atφ20-φ32 and total length of grouting. At the free period, add a sleeve on the steel body. We need take some measures of grouting seal before adding a sleeve. Covering a panel on the head of nail and tighten with nuts. The pre-stress was applied to implement by locking the nut. This kind of pre-stress was often small, less than 50KN. The place of

soil nail has a role of group nail and the construction technology is common with soil nail. This type of pre-stressed soil nail can be placed according to the actual conditions, like setting few rows above or the overall layout or interval setting. While the pre-stress applied is lesser, the density is bigger, and avail the deformation of side wall. This kind of soil nail will show its superiority for the soil of low bond strength. If we use the pre-stressed anchor to reinforce the soil, the pre-stress is bigger and the anchor is easy to pull out to failure.

**Analysis on stability of soil nail**

3.1 The calculation principle of stability of composite soil nail

Based on engineering application situation and the research methods of analysis on stability of composite soil nailing, we get the conclusion that the main consideration should be given to determine the stability safety factor of slope, the determination of the most dangerous slip surface, the calculation on stability of the supporting, the stability in construction process, the influence of the water in the soil, the effect of pre-stressed anchor, the role of soil-cement mixing pile retaining wall and nano-pile, etc.

3.2 The calculation of slope stability safety coefficient

At present, there are two types of calculations about the slope stability safety coefficient. One is calculated by the torque, the other is calculated by the strength. The former is Peterson ke. Petteson calculation method and phelan Newcastle (W.F ellenius) calculation method I[5], the latter is phelan Newcastle (W.F ellenius) calculation method II[6]. Although the two methods both get the same expression about the safety coefficient, the meaning is different. The method of according to the strength to calculate slope stability safety coefficient explains the safety of the anti-sliding force reserves, which is obtained by the moment balance, implying static unbalance; the method of according to the torque to calculate slope stability safety coefficient is static balance, implying moment unbalance, and explains the safety reserve of the anti-sliding moment reserves.

3.3 The determination of the most dangerous slip surface

In order to study the most dangerous sliding surface of the soil, we usually assume that the most dangerous sliding surface is a circular arc. When we use the circular arc method to determine the slid surface, the key is how to determine the center of the circular arc in the circle. Now there are two kinds of methods to determine the center of the circular arc: the traditional method and the geometrical parameters control method[7-9].

The most important method in the traditional method is exhaustion and search method. As shown in fig.3-1, the specific search method is: first to determine the slope toe point O, then slip arc destruction endpoints P can be extended from the top point A extends outward along the direction of A to B in the step length of 0.05H. Finally determine the center F of the slip circle arc fracture surface, the center when the safety factor is Minimum is the most dangerous slip surface circle center. Geometric parameter control method, as shown in fig. 3-2, the specific method is: set a sliding surface after A and B, A is in the foundation pit slope toe (the toe that dig each layer of slope or the time of completion of the excavation slope toe), B is the point of intersection with the top surface. Connect line AB, Over A,B as a circular arc and tangent to the vertical line after B. The relative height between A and B is H, draw a line parallel X axis in the point where is H/2 and intersect AB at D, intersecting the circular arc at F. The most dangerous sliding surface can only exist between the AB line and AFB arc. If the soil is plain soil, the most dangerous sliding surface can be determined by the formula (1)

$$F_s = \frac{M_R}{M_s} = \frac{\sum (C_i L_i + W_i \cos\theta_i tg\phi_i)}{\sum W_i \sin\theta_i} \quad . \tag{1}$$

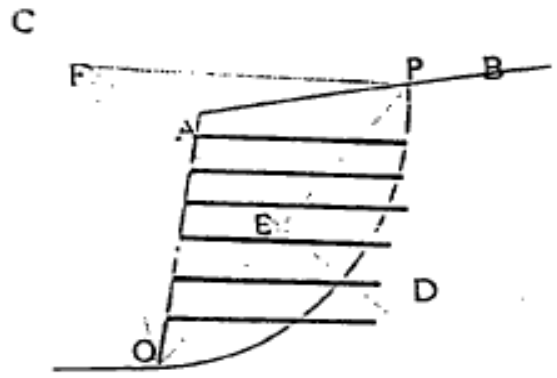

Fig.3-1.The most dangerous sliding surface determined by exhaustion and search method

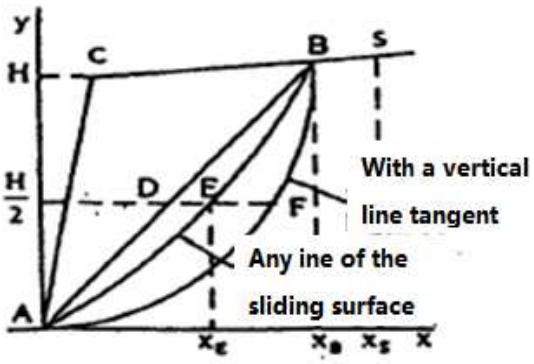

Fig.3-2. The most dangerous sliding surface determined by geometrical parameters control method

**The influence factor of stability of composite soil nailing support**

4.1 The influence of water

At present, there are many forms of composite soil nailing but the literature is rare. The stability ultimately depends on the organic combination of the composite form. In addition, water is also an important factor in the complex geological conditions, also has an important influence on the stability of foundation pit. The influence of water on soil is expressed by the effective stress principle that studying the difference between the stress between grains and pore water pressure in saturated soil and the relationship between the both and total pressure; total stress method and the effective stress method is that the proper strength index C and $\phi$ got from the different trials and the influence on strength that the pore water pressure has in the specific circumstance; select the fair use of shear strength parameters and bond strength indicators reasonably, and use tri-axial test and direct shear test to analyze the effect of water on the slope stability. No matter which method to choose, the key of stability analysis is to select appropriate shear strength index.

4.2 The effect of pre-stressed anchor rod (rope)

The palisade structure of the pre-stressed anchor rod and the traditional plate, pile, wall support, which mainly bear the soil pressure and water pressure exerting on envelope, anchoring force of stable soil is used to maintain the stability of the supporting structure and soil. The stability analysis also included the overall stability of soil. Due to instability of slope or the action of load, the foundation bottom of the wall will slide and push out, the whole system will slide down along the surface, and the soil will uplift from the outside corner of the wall, the whole soil anchor is within the deep slip surface of soil, causing overall instability. The article stability analysis can be used in Sweden point method, and stability safety coefficient is not less than 1.5. Internal stability refers to the stability calculation on deep slip surface of soil anchor and the wall foundation between the imaginary fulcrum, the usually calculation method is Kranz stability analysis.

4.3 The effect of Cement soil mixing pile retaining wall and the advanced micro pile

Cement-soil mixing pile retaining wall usually used in soft soil, high water table of foundation pit supporting, and play an important role in seepage prevention, resistance to uplift and resistance to

horizontal slip and to overthrow, allying the soil nailing, also plays an important role in the internal stability of foundation pit. Meanwhile, it also solved the problem that the nit-suspended spray on the surface is not easy to bond. If the internal stability checking of combined support system can meet the requirements of resistance, the bottom of slide and resistive overturning safety factor is enough. The combination of the advanced micro piles with soil nailing plays an important role for the internal stability of soil.

## Conclusions

The composite soil nailing developed at the base of soil nailing has mainly several types. Such as advanced micro pile composite soil nailing support, soil nailing + pre-stressed anchor rod composite soil nailing support, soil nailing + advanced micro piles + pre-stressed anchor rod composite support, soil nailing + soil-cement mixing pile waterproof curtain composite support, Soil nailing + cement soil mixing pile water stop curtain (including single pile and double pile) + pre-stressed anchor (cable) composite support, Mechanism of action on the composite soil nailing is mainly about the soil nailing, according to different soil conditions, engineering environment, with the help of cement soil mixing pile water stop curtain, advanced micro pile and pre-stressed anchor and other components of the joint action to stabilize the soil and slope. Stability of composite soil nailing analysis show that the slope stability safety coefficient, the most dangerous slip surface and waters in the soil, setting up advanced micro pile, adding pre-stressed anchor has significant effect on the stability of slip plane. At present, the composite soil nailing technology building its application in many areas of foundation pit supporting in China, but in the mountain slope reinforcement and under complicated geological conditions, such as supporting engineering in soft soil area, it is not very wide. However, it has a very long term application of significance. In the future research, we can try to perfect the supporting theory, improve the construction technology, and make it develops in a direction of gradually replacing the traditional supporting technology.

**Keywords:**data processing, rheological experiment, Origin software, curve fitting.

**Abstract.** The rheological experiment is one of main methods in studying rock's long-term mechanical properties, with the characteristic of mass data and numerous relevant parameters. In this paper, the data of surrounding rock's rheological experiment in Zhuji Coal Mine roadway is processed by Origin software, including drawing the creep experiment curves, taking derivatives of curves and then drawing the curves of creep rate and acceleration, curve fitting and parameter estimation, etc. The results show that the data it does not need to programme when using the software to process and it is convenient and time-saving with high precision and is worthy of popularization and application.

## Introduction

The rheological experiment is one of main methods in studying rock's rheological features. Compared with other general experiments, it has the characteristic of mass data and numerous relevant parameters, and has to face the issues of drawing the creep experimental curves, taking derivatives of curves and nonlinear constitutive equation model fitting and parameters estimation, etc. In order to solve those problems, MATLAB software requires users to have the ability of calculation and programme to deal with the data in the process, and the adjustment of software needs some necessary time and energy. However, users of Origin do not need to programme and they could process data directly and draw curves conveniently.

Origin is the data analysis and draw software exploited by American company OriginLab, and also the advanced data analysis and drawing tool often used by researchers and engineers. The data analysis of Origin includes various perfect mathematical analysis functions such as curve fitting, sorting, adjustment and computing, statistics, spectrum transform, and it could draw dozens of two-dimensional and three-dimensional graphs based on the template. People get rid of the process of operating directly on the computer hardware resources by using Fortran and C programming language, professional software such as MATLAB provide rich resources of function, which frees the programmer from tedious program code, and Origin does not need users to write any code but brings users the most direct and simple data analysis and drawing environment.

This paper takes the surrounding rock's rheological experiment in Zhuji Coal Mine roadway as an example to introduce the specific application of Origin8.0 in the data processing of rheological experiment, mainly including data imputing, graph exporting, drawing curves, the derivation of curves, and function fitting, etc.

## Main functions of Origin

The window of Work Sheet and input of data

When users start Origin or create a new file, the default setting is to open a worksheet window, in which there are two columns named A(x), B(y), representing independent variable and dependent variable respectively. Clicking on the Column's Pull-down Menu or Add New Columns of the right mouse button, users can add the required number of columns. Double clicking on the top of columns,

users could change names and set types of columns, and then they could import the data in the Excel files or directly input data or copy and paste the data from Excel files into worksheet.

Drawing and modifying graph

Origin offers the drawing templates including alignment chart, scatter diagram, point plot and pole coordinates, etc. When users draw graph, they could pick the drawing area directly in the worksheet, then click on the orders such as line, symbol to draw alignment chart and scatter diagram, or click on the drawing order first, picking coordinate axis, drawing area in the pop-up message, and then click OK to finish graph.

Users also could click on the generated graph to pop-up dialog box, and then click the "independent" in the message box to modify each line gradually or follow the default "dependent" to finish all curves linear and color changes.

Curve fitting

Origin software provides the orders such as linear fitting, nonlinear curve fitting, and a custom function fitting. Firstly, users should activate drawing window Graph where the data curve to be fitted is, then choose the menu Analysis→Fit…to get the corresponding fitting. After fitting finished, the fitting curve will appear in the graph window and give the fitting model function and parameters.

The output of graphics

Origin has two ways to put Graph graphs into the word file: one of them is saving Graph graphs as images and then inserting them into various files. Choosing File→Export page, and then selecting parameters of type of files and others according to needs, users could save the graphs in the specified path, then open the word file and insert picture to finish the whole process. The other way is taking graph as the Origin file to paste it in the Word page. In the Origin page, users choose File→Export page, and copy the graph in the Graph window to the clipboard, then click right mouse button to choose "Paste" or "Paste Special" to finish the whole process. When using the "Paste Special", if users want to choose graph in the importing of Origin graph object, all they need to do is to double click the graph and then enter Origin Page to reedit the graph. After modifying, users could directly save the changed graph into the source file through closing Origin.

## Main tasks in the data processing of surrounding rock's rheological experiment in Zhuji Coal Mine road way

Zhuji Coal Mine is located in the junction of Panji and Huaiyuan districts in Huainan city, Anhui Province, which is around the area of Wuqian and Qilong villages. Its coal-bearing stratus are Carboniferous system and Permian system, in which the Shanxi Formation in the Permian system and the upper and lower Shihezi Formation are main coal-bearing layers. The main mineable layers immediate roof and seam floor both consist of mud rock. RQD of mud rock is between 0.74 and 1.27, and the average number is 0.95. The rock mass quality is generally medium, and minority is good, which belongs to the range of instability to moderation. Especially the roof and floor are carbonaceous mudstone and mudstone containing carbon, with small thickness and low compressive strength, most of which belong to soft rock with low to medium stability. In the process of engineering, unstable situation such as floor heave happens a lot, so it is necessary to study the rheological features of mudstone.

The purpose of rock creep experiment is to study rock's character of deformation under the long-term load. Through the study of damage condition of rock sample and measured creep curves, researchers could confirm the rheological model, using regression analysis to identify the rock creep experimental curves, and then get the corresponding rheological mechanical parameters. The main tasks of creep test data processing are: To draw strain-time curve under the condition of a certain load and observe the change rule of strain; To take derivatives of curves, drawing curve of strain rate changing over time, and study strain's rate of convergence and mechanical property of rock sample to confirm mechanical components and the corresponding model in constitutive model; To do the curve fitting, then confirm the mechanical parameters and establish the creep equation.

## The Application of Origin in the Data Processing of Rock Rheological Experiment

This paper takes the sample single-shaft axial rheological experiment of mudstone roof of the Zhuji coal mine roadway named "roof 2/6-7" as an example to do data processing. The load continuously loads in classification and computer collects data automatically in the process of experience. For the limitation of this paper, the forth grade load is taken as an example to do the data analysis, and its stress is 44.9MPa, the sample interval is 0.5h, ignoring the instantaneous deformation when it is loading, the data of axial direction strain are shown in the table 1.

Tab. 1 Axial direction strain when the stress is 44.9MPa

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Time (h) | 0.123177 | 0.624305 | 1.125694 | 1.626909 | 2.211632 | 3.214236 | 4.216666 |
| Strain1 (%) | 0.657360 | 0.660019 | 0.661371 | 0.663309 | 0.664466 | 0.666156 | 0.667320 |
| Time (h) | 5.219097 | 6.221527 | 7.223958 | 8.224926 | 9.224946 | 10.224966 | 11.224986 |
| Strain1 (%) | 0.668387 | 0.669303 | 0.670122 | 0.670600 | 0.670900 | 0.671100 | 0.671400 |
| Time (h) | 12.225006 | 13.225026 | 14.225046 | 15.225066 | 16.225086 | 17.225106 | 18.225126 |
| Strain1 (%) | 0.671600 | 0.672000 | 0.672400 | 0.672600 | 0.672900 | 0.673200 | 0.673400 |
| Time (h) | 19.225146 | 20.225166 | 21.225186 | 22.225206 | 23.225226 | 24.225246 | |
| Strain1 (%) | 0.673600 | 0.673900 | 0.673900 | 0.674200 | 0.674400 | 0.674600 | |

Drawing curves of axial direction creep

Importing the data form Excel files, saving accumulated measurement time in column A and measured value of axial strain in column B, setting the time column's name is time and the unit is h, naming strain column "strain", the unit is %, and the annotation is "stress 44.9MPa", after selecting time column and strain column, users only need to click on "scatter" to draw scatter diagram, as shown in Figure 1.

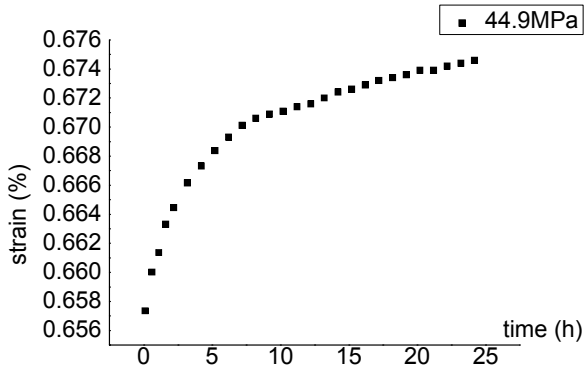

Fig. 1 Scatter diagram of axial strain creep experiment

Drawing curves of creep rate and creep acceleration

When study of rock's rheological properties, researchers need to confirm the mechanical properties and the form of constitutive model through creep rule reflected by the change of creep rate and creep acceleration. The curves of rock creep rate and creep acceleration are first derivative and second derivative curves of creep to time. There are two conditions of creep rate: $\varepsilon'=0$, which means the deformation is stable; $\varepsilon'>0$, which means the deformation is increasing. And there are three conditions of creep acceleration: $\varepsilon''<0$, the creep rate is decreasing, and the rock is in the period of creep attenuation; $\varepsilon''=0$, creep rate is a constant value, and the rock is in the period of creep stability; $\varepsilon''>0$, the creep rate is increasing, and the rock is in the period of creep acceleration, and it will be damaged soon.

After drawing the creep curve, click the graph window, select differentiate in mathematics of the analysis menu, and then open differential window to set the proper parameters. If users want the number of creep rate, input "1" in derivative order; if want that of creep acceleration, input "2", and then click OK to return to book window, users could see there is a new-added data column of differential results, and use this column data to draw graph, as shown in Figure 2 and 3.

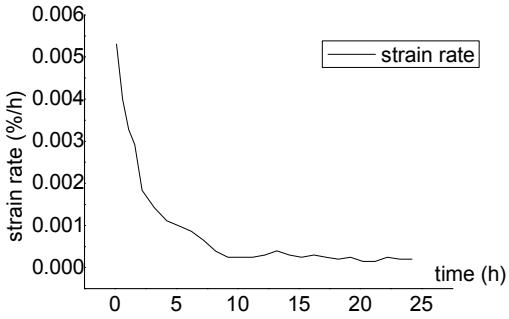

Fig. 2 Curve of axial creep rate

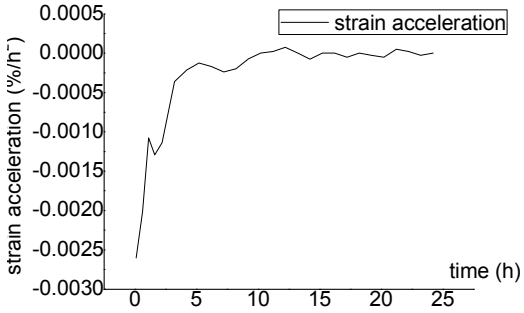

Fig. 3 Curve of axial creep acceleration

From Figure 2 and Figure 3, when axial direction stress is 44.9MPa, in the first 1 hour of load, the creep rate ε' changes a lot, when ε"<0, the creep rate decreases rapidly, and the rock is in the period of creep attenuation; then the change speed of ε" become stable, within 2 hours, the creep rate decreases to a non-zero value. When ε"=0, creep rate is a constant value and the rock is in the period of creep stability. Therefore, the constitutive equation could choose model burgers. Model burgers are made up by Maxwell and Kelvin in series, which could describe two periods of rock creep, namely, rock creep attenuation and rock creep stability.

If ε">0, and the creep rate ε' is increasing gradually and the rock is in the period of creep acceleration, researchers should choose nonlinear viscous component model.

Axial direction creep curve fitting

There are various rheological models and different rock materials should take diverse models with various forms and parameters. In order to get the proper parameters, users should use optimization algorithm such as simple algorithm, genetic algorithm to do programming calculation. And Origin software could solve the problem of programming calculation and use the custom function of nonlinear curve to do the fitting.

The creep equation of Burgers model is:

$$\varepsilon = \frac{\sigma_c}{E_1} + \frac{t}{\eta_1}\sigma_c + \frac{\sigma_c}{E_2}\left(1 - e^{-\frac{E_2}{\eta_2}t}\right). \tag{1}$$

In order to input parameters easily, order $A=\sigma_c/E_1$, $B=\sigma_c/\eta_1$, $C=\sigma_c/E_2$, $D=-E_2/\eta_2$, $x=t$,$y=\varepsilon$, then the creep equation becomes:

$$y = A + Bx + C(1 - e^{Dx}). \tag{2}$$

After drawing the creep curve, click the analysis→fitting→nonlinear curve fit in the menu and open the NLFit message box. In the settings, select new in drop-down menu of "Function", it will pop up Fitting Function Organizer, which is the Fitting function editor. Input parameters in the editor: the name of function is Burgers, the names of coordinate are X and Y, the Function parameters are A, B, C, D, the form the function is origin c, the inputting function expression is y=A+B×x+C-C×exp(D×x) according to the C programming language rule. Then click on the upper right red arrows in the function edit box to enter the compiling page, and check whether the edition is successful or not by clicking "Compile".

After successful editing, click right "save" and "ok" in order to exit function editor until get to the NLfit message box. Then click on "Parameters" to set the initial values, inputting the initial values in the value column in turn, choosing "Fitting to the convergence", then the software begin to do the fitting, to calculate the parameters and draw the fitting curve.

Please notice that the biggest difficulty in using custom function to do the fitting in the nonlinear fitting box is the confirmation of parameters' initial values. If the setting values are not proper, it would be hard to get the satisfied fitting results. For instance, the initial values of A, B, C, D are all the

same: 0, the similarity of fitting is just 0.81627, and the fitting results is too large, which means the fitting curve is not matching the experimental curve. If users set the initial values in this way: A=0.2,B=0.000,C=0.02,D=-0.2, the similarity of fitting is 0.99874, the standard errors are all small, which matches the fitting results, and the fitting curve is close to the experimental curve. Therefore, researchers should do the preliminary estimation of parameters first when they begin the fitting.

After fitting, users could see that on the base of scatter diagram in the drawing window, the fitting curve is added, and the window also provide the fitting similarity and the main parameters and standard errors of them, as shown in the Figure 4. the fitting results are: A=0.65706, B=0.000236172, C=0.01195,D=-0.38153, therefore $E_1$=68.33470MPa, $\eta_1$=190115.67840MPa.h, $E_2$=3757.32218MPa, $\eta_2$=9848.03862MPa.h.

The equation after fitting is:

$$\varepsilon = \frac{\sigma_c}{68.33470} + \frac{t}{190115.67840}\sigma_c + \frac{\sigma_c}{3757.32218}\left(1 - e^{-\frac{3757.32218}{9848.03862}t}\right) \tag{3}$$

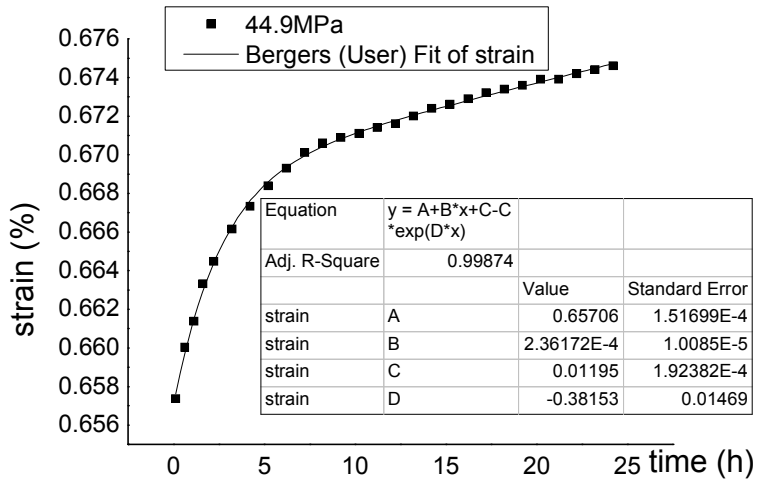

Fig. 4 Fitting Curve and Main Parameters

## Conclusion

Origin software has powerful function of data analysis, calculation and drawing. Through the data processing of creep experiment of rock sample in the Zhuji Coal Mine roadway when the stress is 44.9MPa, the results show that this software could drew creep curve, take derivatives of curves and do the curve fitting and parameters estimation without programme, which is easy to operation, has quick speed and high efficiency, and is worthy of popularization and application.

# The experimental study of the influence of the matric suction on the unsaturated soil strength

CuiRan Liu

Luoyang Institute of Science and Technology,China

liucuiran@163.com

**Keywords:** unsaturated soil, matric suction, triaxial apparatus, shear strength

**Abstract.** With modified unsaturated soil triaxial apparatus, unsaturated soil shear strength of the tests under the condition of different water contents are done. Experimental results show that the matric suction exist in unsaturated soil and increases with the decrease of moisture content. And the shear strength of unsaturated soil is higher than that of saturated soil. Shear strength of unsaturated soil varies as the matric suction and water content. The shear strength increases when the matric suction increases. when soil tend to be saturated, the matric suction will tend to be zero. And the shear strength of unsaturated soil values gradually close to the strength of the saturated soil.

## Introduction

The strength of the soil is one of the important mechanical properties of soil. The strength of the unsaturated soil is more complex [1] than that of saturated soil largely due to the presence of matric suction. The matric suction is capillary part of the free energy of water in soil. It is determined by the equivalent suction through the measure of vapor pressure which balances water in soil. It can be thought for the difference values of the pore air pressure and pore water pressure. It is the essential feature of unsaturated soil which differs from the saturated soil. There exists a close relationship between saturated soil and unsaturated soil at the same time and they can be reciprocally transformed with the changes of water content in the soil pore.

## Unsaturated soil strength theory

So far, the shear strength research of unsaturated soil has a history of more than forty years. Generally, the strength parameters are selected on the basis of the Mohr-coulomb strength theory of saturated soil. Several different shear strength formulas were put forward from different perspectives and point of view combined by studying the properties of soil. At present, the following two shear strength formulas have been widely accepted by people.

(1) Bishop (1960) shear strength the theoretical formula

$$\tau_f = c' + (\sigma - u_a)_f tg\phi' + \chi(u_a - u_w)_f tg\phi' \tag{1}$$

Bishop proposed his unsaturated soil shear strength formula combining his effective stress principle [2] of unsaturated soil with Mohr - Coulomb failure criteria. The $\chi$ is a parameter which is related to saturation, soil category, dry-wet circulation and loading paths. It is difficult to determine, the formula is not widely applied.

(2) DG. Fredlund (1978) effective shear strength formula

$$\tau_f = c' + (\sigma_f - u_a)_f tg\phi' + (u_a - u_w)_f tg\phi^b \tag{2}$$

Fredlund formula was put forward with presence of double stress principle [3]. When $(\sigma - u_a)$ is fixed and $(u_a - u_w)$ can be changed, different $\tau$ can be obtained. So the $\varphi^b$ can be obtained from the $\tau \sim (u_a - u_w)$ figure. Ten different test results compiled by Fredlund show that the $\varphi^b$ is smaller than $\phi'$.

**Triaxial shear test of unsaturated soil**

(1) The experimental principle and method

Triaxial test is one of the most commonly used method indoor measuring soil shear strength. According to the drainage, triaxial strength test of unsaturated soil can be divided into: consolidation drainage experiment, constant moisture content test, consolidated undrained tests, undrained tests and the unconfined compression test. According to the practical drainage situation of unsaturated soil, the drainage consolidation test method is adopted in this paper. It can respectively control and measure pore air pressure and water pressure and can accurately measured volume change of samples in the test. In order to avoid vaporization of measurement of pore water pressure system, axis-translation technology is adopted in test process [4-5]. In test, dry density of the specimens is controlled as 1.51 kg/cm$^3$ and water content was respectively controlled as 5%, 10%, 15% and 20%. The specimens are cylindrical and the diameter is 6.18 cm with 12.5 cm height. Under confining pressure is respectively controlled as 100KP$_a$, 200KP$_a$, 300KP$_a$ and 400KP$_a$ during test. The matric suction is controlled and measured.

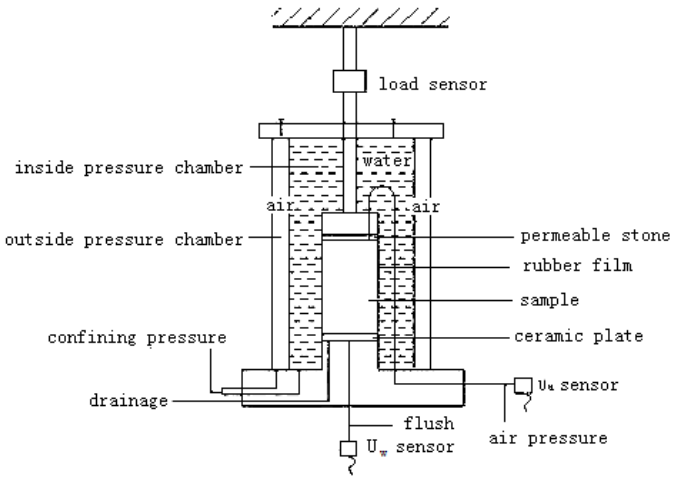

Fig.1 Triaxial Pressure Chamber of unsaturated soil

(2) Test results

According to the test results, stress-strain curves and strength envelopes of unsaturated soil with water content of 5%, 8%, 10%, 15% and 20% are obtained. Due to the limited space, only stress-strain curves and strength envelopes of water content 5%, 10%, 20% are listed in this article as figure2～4.

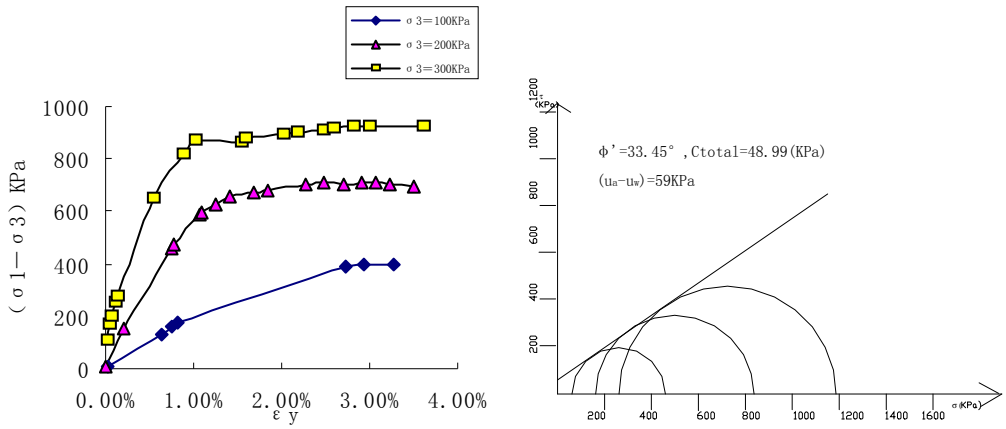

Fig. 2 The stress-strain and Mohr-Coulomb curves of unsaturated soil with 5% water content.

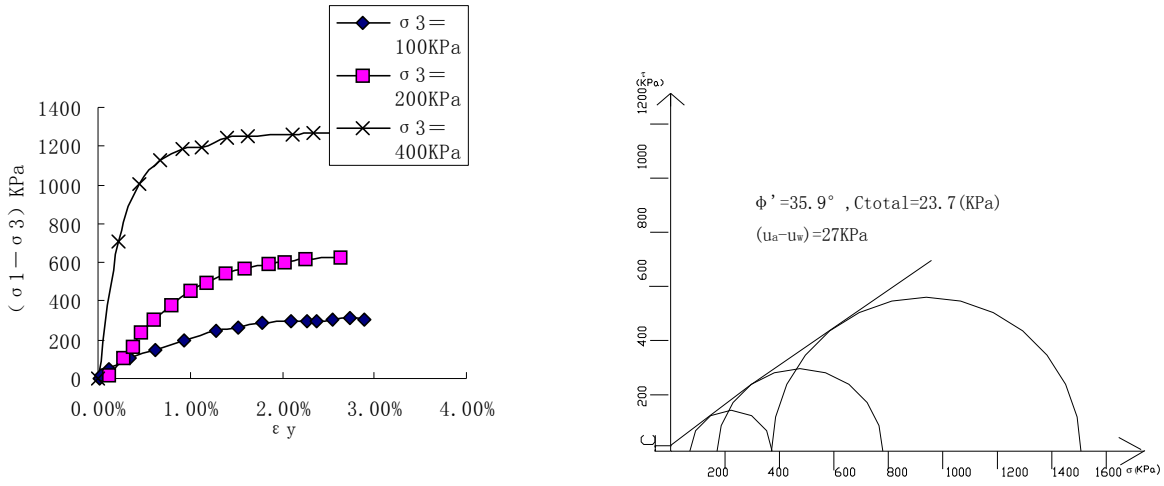

Fig.3 The stress-strain and Mohr-Coulomb curves of unsaturated soil with 10% water content.

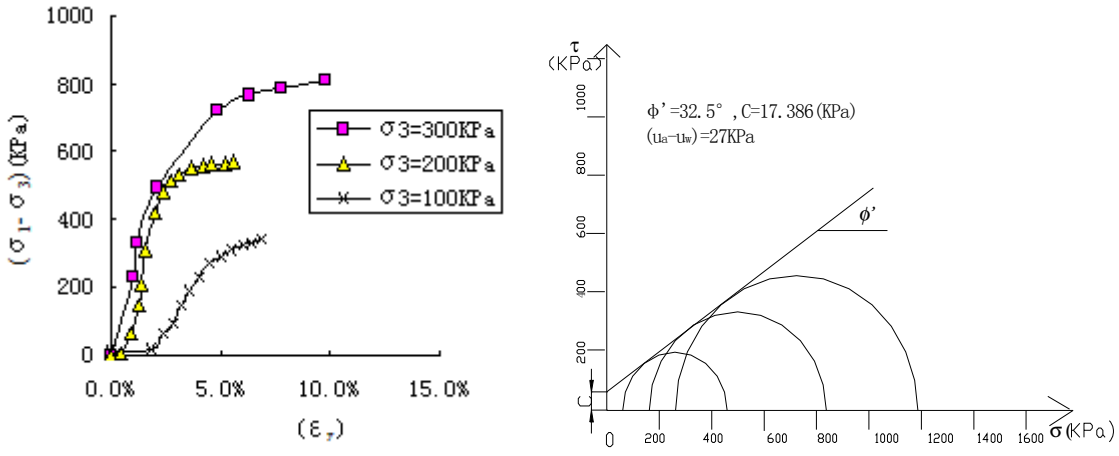

Fig.4 The stress-strain and Mohr-Coulomb curves of unsaturated soil with 20% water content.

(3)Strength formula of unsaturated soil

According to shear test, the Parameters of shear strength of unsaturated soil are obtained as in table 1.

Tab.1 Parameters of shear strength of unsaturated soil

| Moisture content | Matric suction | Internal friction Angle | Total cohesion | Saturation |
|---|---|---|---|---|
| w | Us（KPa） | φ（°） | $C^{'}$（KPa） | Sr |
| 5% | 59 | 33.44848 | 48.990201 | 16.39% |
| 10% | 27 | 35.89876 | 19.744096 | 32.78% |
| 15% | 25 | 32.67281 | 17.366 | 49.20% |
| 20% | 11 | 33.2952 | 17.052282 | 65.59% |

The unsaturated soil shear strength formula is fitted as (formula3) according to the test data using the least squares method.

$$\tau_f = (\sigma_f - u_a)_f tg\phi + \exp(a + b/(u_a - u_w) + c\ln((u_a - u_w))) \quad (3)$$

A, b, c are fitting coefficients and respectively is 3.86, 23.90 and 23.90 in the formula.

(4) The relationship between the matric suction and shear strength Unsaturated soil

From table 1, effective friction angle value calculated by the unsaturated soil test results is slightly affected by water content. Therefore, the author thinks that the effective friction angle of some specific unsaturated soil can be thought of as a fixed value. But because of the matric suction, the total cohesion is strongly influenced by water content. When the matric suction is larger, the greater the

total cohesion becomes and the shear strength of unsaturated soil increase accordingly. But the relationship between the shear strength and matric suction is not linear and is unstable. Using the data in the table 1, the scatter diagram between total cohesion and matric suction is drawn as figure 5.

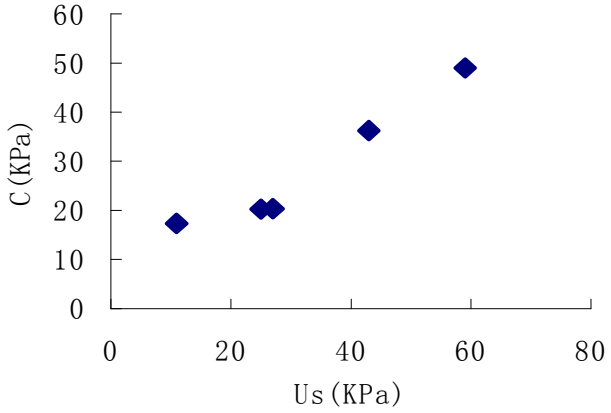

Fig. 5 The curve of relationship between matric suction and total cohesion

## Conclusion

(1) Due to the existence of adsorption frictional force of unsaturated cohesive soil skeleton, the strength of the unsaturated cohesive soil is generally greater than that of the saturated cohesive soil. Its value is not affected by the influence of applied stress, but is greatly influenced by water. When the water content reaches a certain value, the adsorption frictional force decreases rapidly. So contribution of the matric suction to unsaturated soil shear strength is a limit value and unstable.

(2) Effective internal friction Angle of unsaturated cohesive soil saturated cohesive soil is not affected by external forces and suction, its value depends on the mineral composition of soil and stress history.

**Keywords:** Cement fly-ash gravel pile composite foundation, Resilience-recompression, Consolidation settlement, Settlement analysis.

**Abstract.** This paper analyzes the causes of larger differences of final settlement calculated value of cement fly-ash gravel pile (CFG pile) composite foundation of Baotou with actual observed result of it. On the basis of analysis on a number of practical engineering data of Baotou, we modify the settlement formula of the CFG pile composite foundation and gain the modified coefficient applied to the settlement calculation of the CFG pile composite foundation of Baotou. The modified formula and coefficient proposed in this paper have a positive effect on the accurate settlement calculation of puting forward a more accurate correction formula and coefficient of the calculation of the CFG pile composite foundation of Baotou.

## Introduction

In recent years, high-rise buildings in Baotou area are increased year by year, and the the CFG pile composite foundation has been widely used. However, a large number of engineering practices of Baotou show that there are large differences between the calculated value of the final settlement of the CFG pile pile composite foundation of Baotou and actual observed result of the settlement according to the formula recommended by the standards. The research of the CFG pile composite foundation conducted by many scholars is mainly concentrated in the pile side resistance, load transfer of piles and soil [1~ 6], the common stress of soil and pile and the performance of material in pile body, there are only a few researches on the settlement deformation of the CFG pile composite foundation. While the researches on the settlement deformation of the CFG pile composite foundation of Baotou are still a blank.

The causes of larger differences between the calculated value of the final settlement of the CFG pile composite foundation of Baotou and actual observed result of the settlement mainly consist two aspects: First, the final settlement of the CFG pile composite foundation should include settlement deformation of the springback recompression when the foundation embedded deeper, while the specification does not consider this; Second, the correction coefficient of the settlement calculation of the CFG pile composite foundation directly comes from the specification, while the compression modulus value of the settlement calculation of the CFG pile composite foundation of Baotou by the depth range beyonds the scope of coefficient values given by specification, resulting in the bias of correction coefficient of the settlement calculation of the CFG pile composite foundation of Baotou.

In regarding to the two points presented in this paper, according to the settlement mechanism of the CFG pile composite foundation and the basis of analysis and research on a number of practical engineering data of Baotou, we modify the formula of the final settlement of the CFG pile composite foundation of Baotou and gain the modified coefficient applied to the settlement calculation of the CFG pile composite foundation of Baotou.

**The problems in the application of the of the settlement deformation formula of the CFG pile composite foundation recommended by the norm**

The geological conditions in Baotou area are good, when building foundations are buried shallowly, it can be used as supporting layer of the natural foundation, and it does not need to do ground treatment. So the technology the CFG pile composite foundation of Baotou can be used when the building foundations buried deeply. However, the final settlement formula of the CFG pile composite foundation is applied to the conditions that the building foundation is embedded shallowly. The formula which recommended by the specification takes the consolidation settlement deformation into consideration which is produced by the average additional stress $p_0$ [7,8], but does not consider the settlement deformation of the springback recompression. However , when the building foundation is embedded deeply, from the excavation of the foundation ditch to the use of buildings, the final settlement of the foundation consists of the settlement deformation produced by the springback recompression and the consolidation settlement in the foundation. Some high-rise buildings in the basement have 3 ~ 4 layers (or even more layers), the total load $p$ may be equal to or less than the weight $p_c$ of the overlying soil, the settlement deformation of the high-rise building foundation will be only decided by the deformation of the compression deformation. Therefore, when calculating the final settlement deformation of high-rise building foundation, the deformation of the compression deformation is more important in the total settlement and should attached importance to it and considered.

**Correcting and deducing the computational formula of final settlement of the CFG pile composite foundation**

When the building foundation in Baotou area is buried deeply, the excavation of the foundation ditch will unload the foundation and cause the springback deformation of foundation soil (Fig. 1 (a)). With the external load $p$ in the upper structure gradually increasing , when the external load $p$ is less than or equal to the gravity $p_c$ of the foundation pit soil , the settlement deformation $s_1$ of the springback recompression in the CFG pile composite foundation will occur (Fig. 1 (b)). When the external load $p$ is increasing and will be greater than the weight of foundation pit soil $p_c$, the consolidation settlement deformation $s_2$ in the the CFG pile composite foundation also will happen (Fig. 1 (c)). So the final settlement of the CFG pile composite foundation $s = s_1 + s_2$ ($p > p_c$).

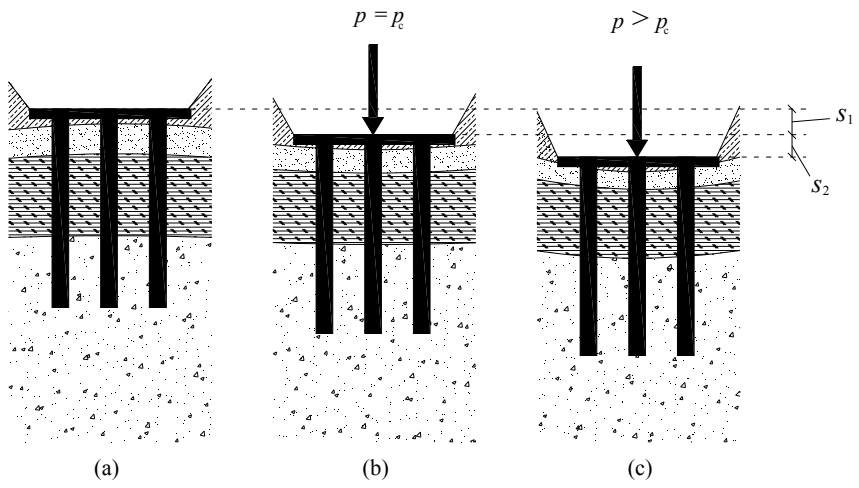

Fig.1 The settlement calculation of the CFG pile composite foundation

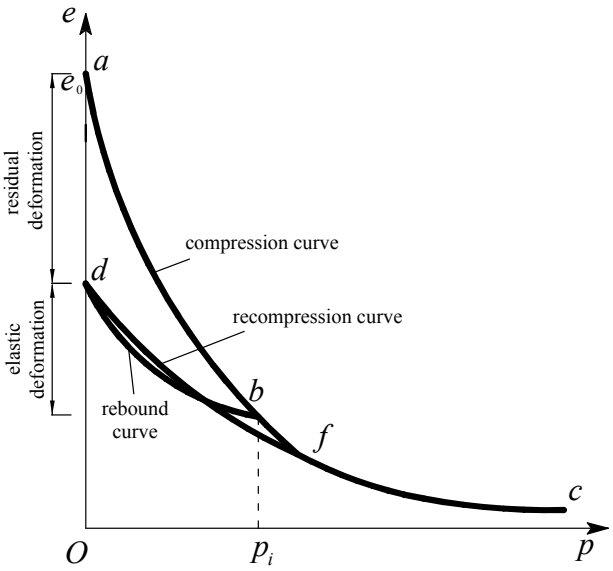

Fig.2 The springback recompression in the soil body and compression curve

The springback recompression in the soil body and compression curve in Fig.2 shows that the rebound curve of the soil body can not coincide with the original compression curve. The slope of recompression curve is much smaller than the original compression curve. After the deformation of the soil unloading $p_i$ becoming stability, then exert external load $p_i$ again, at this point the void ratio of recompression curve of soil is less than the void ratio of the compression which exerted the same loading pi, thus the settlement deformation of springback recompression $s_1 > 0$.

This article uses the layer-wise summation method, and takes the continuous process of settlement deformation of the springback recompression and consolidation settlement deformation in the CFG pile composite foundation into consideration, and introduces a new correction coefficient $\psi'_{sp}$ of the final settlement calculation in the CFG pile composite foundation, then modifies the standard formula, finally deduces the modified formula of the final settlement calculation in the CFG pile composite foundation when considering the situation that the foundation is buried shallowly.

$$s = \psi'_{sp}\{[\sum_{i=1}^{n}\frac{p_c}{E'_{spi}}(\overline{\alpha}_i z_i - \overline{\alpha}_{i-1}z_{i-1}) + \sum_{i=n+1}^{m}\frac{p_c}{E'_{si}}(\overline{\alpha}_i z_i - \overline{\alpha}_{i-1}z_{i-1})] + [\sum_{i=1}^{n}\frac{p_0}{E_{spi}}(\overline{\alpha}_i z_i - \overline{\alpha}_{i-1}z_{i-1}) + \sum_{i=n+1}^{m}\frac{p_0}{E_{si}}(\overline{\alpha}_i z_i - \overline{\alpha}_{i-1}z_{i-1})]\} \quad (1)$$

Where:

$n$ —— the soil layers within the scope of the CFG pile composite foundation

$m$ —— the total soil layer within the depth range of the settlement calculation in the CFG pile composite foundation

$p_c$ —— be equivalent to the base pressure of gravity in the soil of the upper pit depth (kPa)

$E'_{spi}$ —— the modulus in the i-th layer of the composite soil in the CFG pile composite foundation affected by the external load (the gravity in the soil of the upper pit depth) (MPa), $E'_{spi}=\xi E'_{si}$

$E'_{si}$ —— the modulus in the i-th layer below the composite soil in the CFG pile composite foundation affected by the external load (the gravity in the soil of the upper pit depth(MPa)

$z_i$, $z_{i-1}$ —— the distance from the bottom of foundation to the first layer and to the i-1 layer of soil background (m)

$\overline{\alpha}_i$ , $\overline{\alpha}_{i-1}$ —— the average coefficient of additional stress within the bottom of foundation to the first layer and to the i-1 layer of soil background

$\xi$ —— the increased coefficient of the compression modulus in the composite soil which located in the CFG pile composite foundation $\xi = f_{spk} / f_{ak}$

$\psi'_{sp}$ —— the modified coefficient of the final settlement in the CFG pile composite foundation

**The value analysis on the modified coefficient of the final settlement calculation in the CFG pile composite foundation when the foundation is buried deeply**

With the modified formula (not including the modified coefficient)of the final settlement in the CFG pile composite foundation mentioned above, we calculate five typical engineering examples in different areas of the Baotou area, and obtain the five engineering total settlement value before the five engineering settlement values are amended. With the value and the analysis of the observed settlement results, we get the modified coefficient value of the final settlement in the CFG pile composite foundation when considering the influences of settlement deformation of the springback recompression . The correction coefficient of the values are shown in Table 1.

Table 1. The modified coefficient table of the final settlement of the CFG pile composite foundation in the engineering examples

| Serial number | The equivalent value of the compression modulus $\overline{E'}_s$ | The final settlement before the method of calculation is modified S(mm) | The actual final settlement S′ (mm) | $\psi_{sp}' = S'/S$ |
|---|---|---|---|---|
| Case 1 | 55.312 | 52.0 | 9.9 | 0.178 |
| Case 2 | 41.151 | 115.0 | 19.3 | 0.168 |
| Case 3 | 37.446 | 190.9 | 36.5 | 0.191 |
| Case 4 | 51.078 | 195.8 | 35.4 | 0.176 |
| Case 5 | 87.133 | 71.8 | 12.4 | 0.173 |

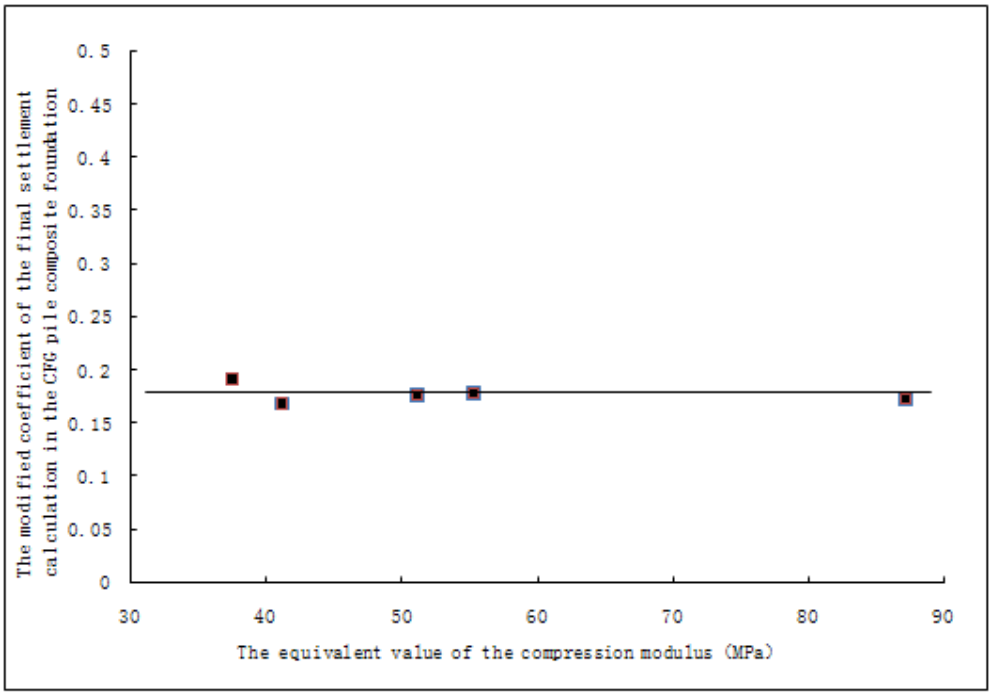

Fig.3 The distribution diagram of modified coefficient of the settlement calculation

The relation of the modified coefficient of final settlement calculation in the CFG pile composite foundation in the engineering examples of Baotou is shown in Fig.3.

Fig.3 shows that the approximate distribution of the modified coefficient of the final settlement calculation in the CFG pile composite foundation is on both sides of $\psi'_{sp} = 0.178$ when the equivalent value of the compression modulus in five engineering examples $\overline{E'_s}$ >35Mpa. We can get $\psi'_{sp} = 0.178$ when $\overline{E'_s}$ >35Mpa in Baotou area.

**The tests on the modified calculation formula and the correction and applicability of modified coefficient proposed in this paper**

By separately using the calculation proposed in this paper and the formula recommended by the norm, we calculate the settlement in another practical engineering examples chosen in Baotou area (example 6), and compare with the observed data in an engineering practice. In an engineering example, the soil physical and mechanical indexes in various soil layer and the parameters of the settlement calculation in foundation are shown in Table 2. The calculation results of the final settlement are summarized in table 3.

Table 2. The soil physical and mechanical indexes and the parameter table of the settlement calculation in foundation

| Soil layer | Thickness $h_i$(m) | Severe $\gamma$(kN/m$^3$) | compression modulus $E_s$ (MPa) | Limit shaft resistance $q_{si}$ | Ultimate tip resistance $q_p$ | Comprehensive vale of bearing capacity $f_{ak}$ (kPa) |
|---|---|---|---|---|---|---|
| ①miscellaneous fill | 0.45 | 17 | 3 | | | |
| ② collapsible silt | 1.43 | 17.3 | 6 | | | 160 |
| ③gravel sand | 3.81 | 20 | 30 | 60 | | 280 |
| ④silty clay | 6.73 | 19.7 | 7 | 60 | | 180 |
| ⑤silty clay | unrevealed | 19.7 | 8 | 70 | 1200 | 190 |

Table 3. The summary sheet of final settlement in the CFG pile composite foundation

| Characteristic value of loading capacity of single pile (kN) | Characteristic value of loading capacity of Composite foundation (kPa) | The equivalent value of the compression modulus (Mpa) | The final settlement calculated by normative formula (mm) | The final settlement calculated by modified formula (mm) | The actual observed final settlement (mm) |
|---|---|---|---|---|---|
| 2931.5 | 512.3 | 38.3 | 25.7 | 34.3 | 36.0 |

The Table 3 shows that the final settlement calculated by the modified formula proposed in this paper is very close to final settlement in the engineering practice, the error is within 5%,. However, there is a large difference between the final settlement calculated by the formula which is recommended by the norm and final settlement in the engineering practice. Thus, the modified formula of the final settlement calculation in the the CFG pile composite foundation proposed in this paper and it is correct. The modified formula and coefficient proposed in this paper will have a positive effect on the refined calculation of the final settlement in the CFG pile composite foundation of Baotou.

**Keywords:** Braced excavation, Lateral displacement , Distance, Pile stiffness, Axial load.

**Abstract.** Using the explicit finite difference code FLAC3D, the behavior of pile adjacent to braced excavation is investigated. The Modified-cam clay constitutive model was employed to model the non-linear stress-strain soil behavior, and the pile was assumed to have linear elastic behavior. The interface model incorporated in FLAC3D code was used to simulate the soil/pile contact, The built-in 'fish' language was used to calculate the data demanded. The pile response such as pile deflection, bending moment and lateral soil pressure were studied, and it is shown that the pile response is different from that caused by the excavations which are unstructted. In "standard" problem, the effect of different pile head constraints on the pile response was investigated, the effect of lateral displacement of the wall, distance from the excavation face, pile stiffness, pile length and axial load on the pile response are also investigated when the pile head is constrained from deflection. The research finding was compared with other published case history and reasonably good agreement was found between them.

## Introduction

In dense urban environments where land is scarce and buildings are closely spaced, deep excavation for basement construction and other underground facilities is unavoidable. Deep excavation work for a new building would result in soil movement behind the retaining structure. The soil movement might induce considerable bending moment and deflection on the pile foundations supporting existing structures nearby. As pointed out by Poulos, the lateral soil movement is considered to be more critical for adjacent piles, especially concrete pile, as piles are often not designed to sustain significant lateral loading.

This problem has been investigated extensively by many authors. For example, Yang and Zhou(2005)[1] employed the three-dimensional elastic-plastic finite element method to study the pile response due to unstructted excavation-induced soil movements. Zheng and Yan(2007) [2]performed a field measurement and the influences of various parameters on pile response due to adjacent excavation were studied with three-dimensional finite element mode. Chen and Wang(2008) [3]used the geotechnical finite element numerical analysis software Plaxis 8.2 to simulate the effect of many factors on the behaviors of adjacent piles. Poulos and Chen(1996, 1997) [4,5]used two-stage analysis involving the finite-element method and the boundary-element method to study the pile response due to excavation-induced lateral soil movement and design chart for estimating the pile moments and deflections were presented. A. T. C. Goh and K.S. Wong(2003) [6] carried an actual full-scale instrumented study to examine the behavior of an existing pile due to nearby excavation activities resulting from the construction of a 16m deep cut-and -cover tunnel. C. F. Leung, Y. K. Chow and R. F. (2000) [7], D. E. L. Ong, C. E. Leung and Y. K. Chow (2006) [8]carried out centrifuge model studies to investigate the effect of the excavation-induced soil movement on adjacent single pile in sand and clay.

Although lots of numerical studies were carried out, some disadvantage still existed, such as the ideal elastic-plastic model was employed for the excavation simulating and the pile was modeled

using beam element. In this paper, using the commercially available three-dimensional code FLAC3D, the behavior of the pile adjacent to excavation is investigated, this code used an explicit finite difference program to study numerically the mechanical behavior of a continuous 3D medium as it reaches equilibrium or steady plastic flow, the explicit Lagrangian calculation scheme and the mixed-discretization zoning technique used in FLAC3D ensure that plastic failure and flow are modelled very accurately.

## Details of Numerical Model

For simplifying the numerical analysis, the model was cut out from a rectangular foundation pit. The length of the model is only 20m, only 1/2 model was conducted for symmetry, as is shown in Fig. 1. The thickness of the diaphragm wall is 0.8m and the height is 26m. The width of the foundation pit is 10m(1/2 model) . The boundary conditions for the soil are as follows: the nodes at the top face are free to move, the nodes at the bottom face of the soil are fixed vertically, and the nodes at other faces are fixed horizontally. A total of 37200 elements and 43582 nodes were used for this analysis.

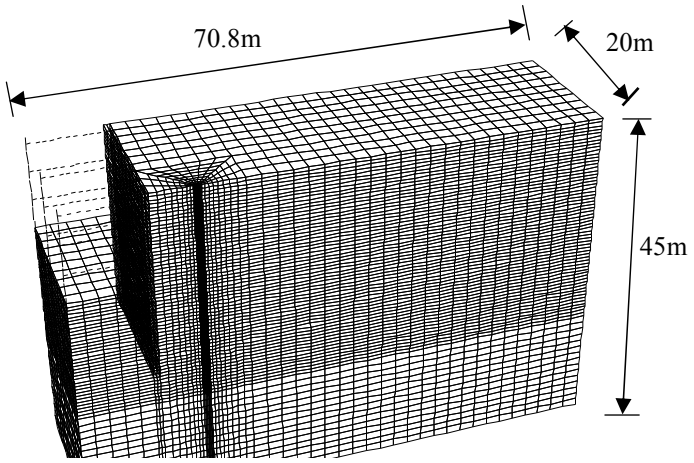

Fig.1. Three dimensional finite difference model

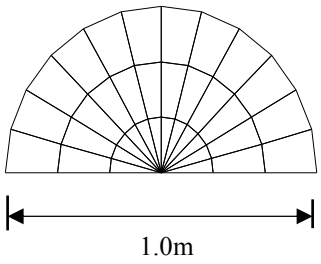

Fig. 2. Cross section of pile

The modified-cam clay constitutive mode was employed to model the non-linear stress-strain soil behavior. Total stress analysis with undrained conditions was assumed with the following soil parameters: the unit weight of the soil $\gamma$=1.9kN/m$^3$, the void ratio e=0.62, the coefficient of earth pressure at rest $K_0$=0.5, $\lambda$=0.09, $\kappa$=0.0093, M=0.90, poisson's ratio $\mu$=0.35, and over consolidation ratio OCR=1. The parameters of the soil is equal to the 5th layer soil of Tianjin , which is modified by considering the structural property of the soil(Meng, 2009) [9].

The solid elements used for modeling the pile were assumed to have linear elastic behavior. Poisson's ratio of $\mu$=0.3 was used. The diameter of the pile is 1.0 m, the adopted mesh of the pile section is shown in Fig. 2.

The calculation steps of the numerical model are presented in Table 1.

Table 1. Calculation Steps of Excavation

| Step | Construction Conditions |
|---|---|
| 0 | Compute the initial ground stress |
| 1 | Excavate to -1.5m and install the first level struts |
| 2 | Excavate to -5.5m and install the second level struts |
| 3 | Excavate to -9.5m and install the third level struts |
| 4 | Excavate to -13.0m |

## Results and Discussions

In general, the response of the pile adjacent to excavation is relevant to the lateral wall displacement, which was related to the relative stiffness parameter EI/h$^4$(EI is the bending rigidity of the wall, h is

the vertical space of the structs)and other factors . In "standard" problem, the maximum lateral displacement of diaphragm wall was 0.30%H(H is the maximum excavation depth ).

In the following analyses, a "standard" problem with constant "standard" parameters is analyzed first, and then some key parameters are varied to investigate their influence on pile response. The parameters defining the "standard" problem are as follows: X=6m, distance from the excavation face; Lp=30m, pile length; Ep=30GPa, modulus of elasticity of the pile; $\delta_{hmax}$=0.3%H, the maximum lateral displacement of the diaphragm wall.

Because three pile head restraints condition are used, the pile response for "standard" problem are shown in Fig. 3, Fig. 4 and Fig. 5. A negative value of deflection indicates that the deflection is moving towards the excavation face, A positive value of bending moment indicates that the side of the pile which is far away from the excavation is in tension, and a positive value of lateral soil pressure indicate the lateral soil pressure acted on the side of pile which are far away from the excavation. Pile deflection is monitored at the centre of the pile elements. The forces per unit length acting on the pile node are calculated by summation the component of the normal forces acting on the interface nodes and the shear drag forces around the pile shaft in the direction of soil displacement at the same level of pile length.

**Result for "standard " problem.** The pile response under different head constraints for 4 stages of the excavation are shown in Fig. 3, Fig. 4 and Fig. 5. It can be seen that the pile response increase with increasing excavation depth.

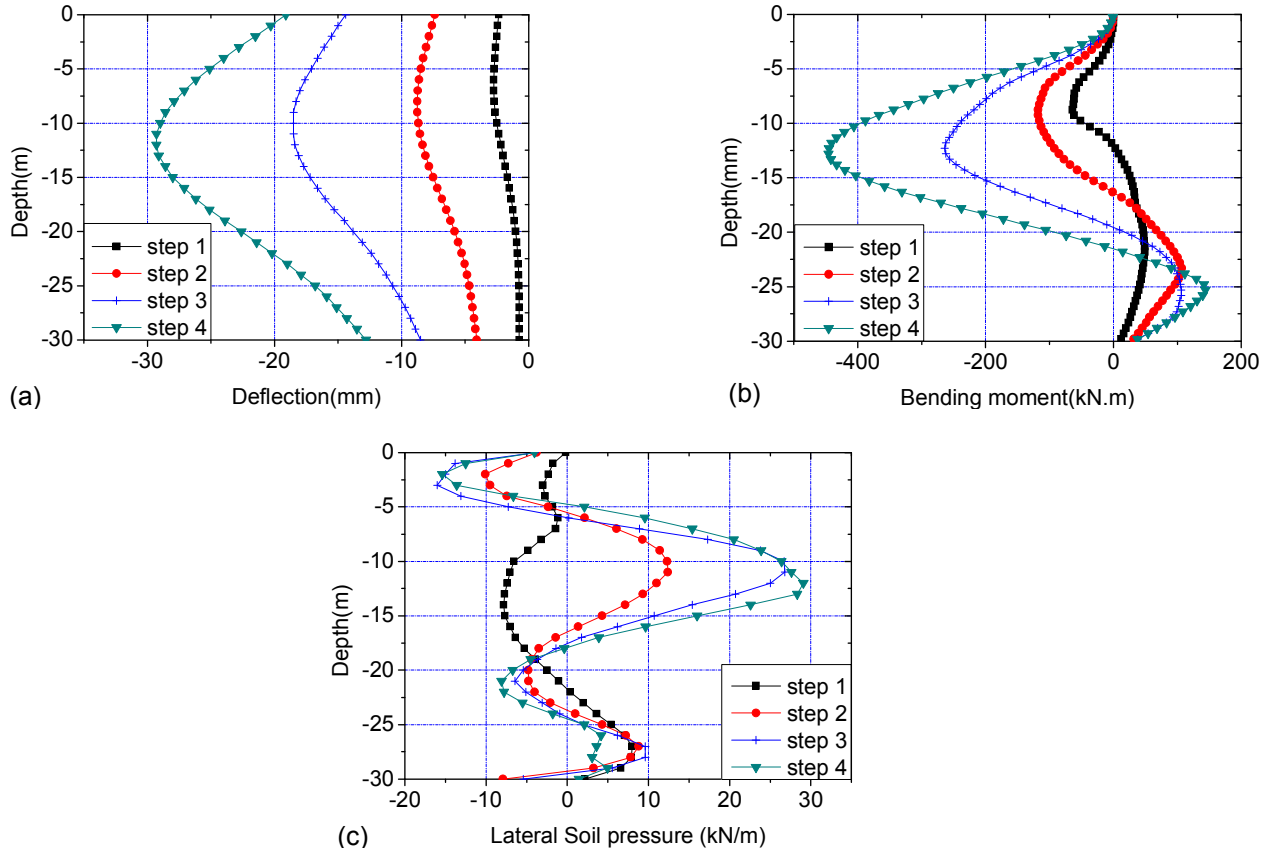

Fig. 3. Pile response for "standard" problem (free-headed)

Fig. 3 shows the pile response under free head condition(free-headed). For braced excavation, the movement of the top of pile was slightly larger than the surface lateral soil movement, so a 'negative' soil pressure is introduced on the upper part of the pile shaft, i.e. soil pressures acting on the opposite side of the pile on the top of the pile. With the depth increasing, the 'negative' soil pressure on the upper part of the pile shaft turned to 'positive' soil pressure in the middle part of the pile.

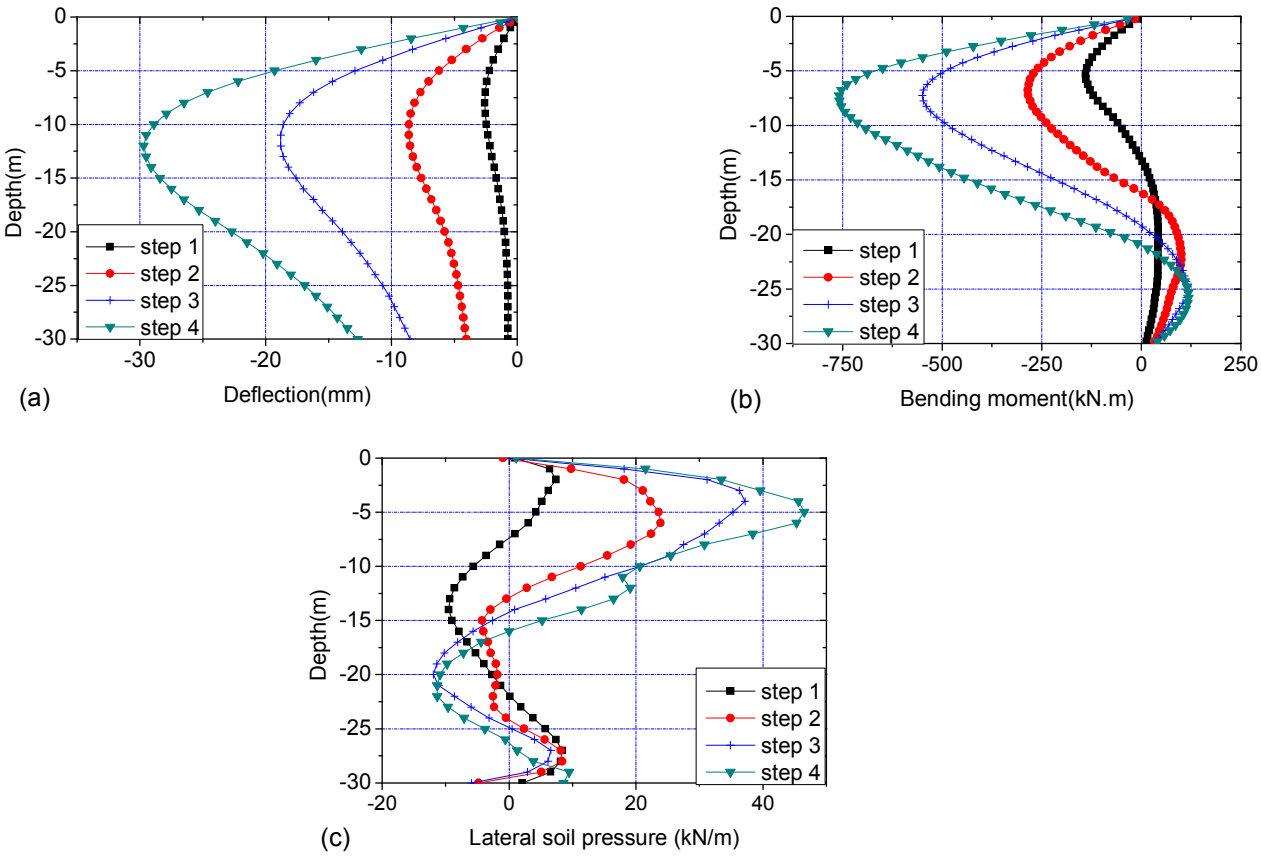

Fig 4. Pile response for "standard" problem(fixed deflection-free rotation)

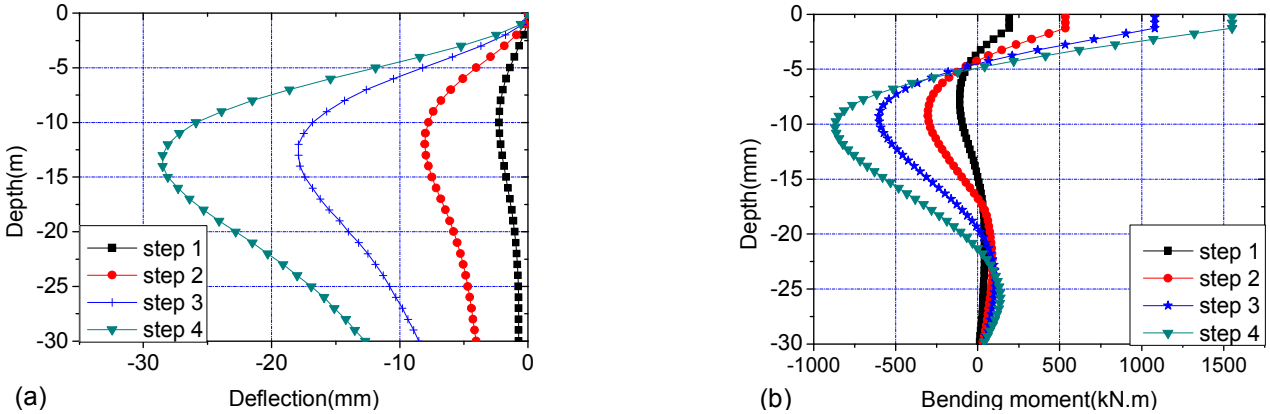
Fig. 4 shows the pile response when the pile head is constrained from deflection. But the rotate is allowed(fixed deflection-free rotation). This corresponds to the situation that the single pile supporting superstructure columns connected by tie beam to enhance the overall foundation stability, The tie beam are usually long and slender with the main function of providing lateral support to the individual piles without much restriction on the pile-head rotation, thus connection between the tie beam and the piles maybe approximately assumed as a hinge connection. The pile head deflection is effectively eliminated, no bending moment developed at the pile head, but the negative moment and the lateral soil pressure along the upper pile shaft have a remarkably increase, the depth of the maximum negative moment is -7m, that is higher than -12m which is the depth under free head condition.

Fig.5 shows the pile response when the pile head is fixed against both deflection and rotation(fixed-fixed condition), which is likely to correspond to the situation where a massive pile cap is restrained by ground beams, or when the pile is part of pile raft foundation for a large structure, A signification positive bending moment developed at the pile head due to the constraint in rotation besides the pile head deflection is effectively eliminated. The lateral soil pressure on the pile shaft is the largest among the three constraints cases.



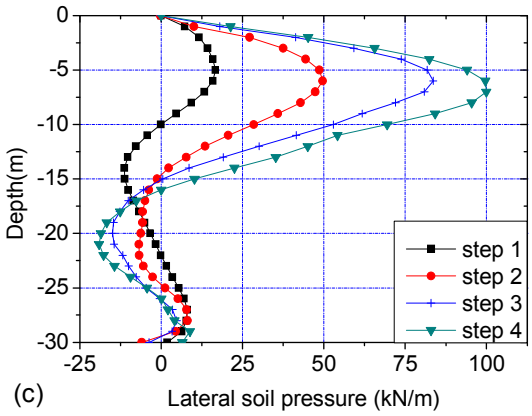


Fig. 5. Pile response for "standard" problem(fixed-fixed )

**Influence of the lateral displacement of the wall.** In engineering practice, the lateral displace--ment of the wall may vary in large scope. The influence of lateral displacement of the wall on the pile response for maximum excavation depth is shown in Fig. 6， the maximum lateral displacement of the wall is respectively be 0.28%H, 0.3%H, 0.35%H and 0.45%H(H is the maximum excavation depth ).

The pile head condition is constrained from deflection and the distance from excavation face is 6m in this case. It can be seen that the deflection, the bending moment and the lateral soil pressure all significantly increase with the increasing lateral displacement of the wall.

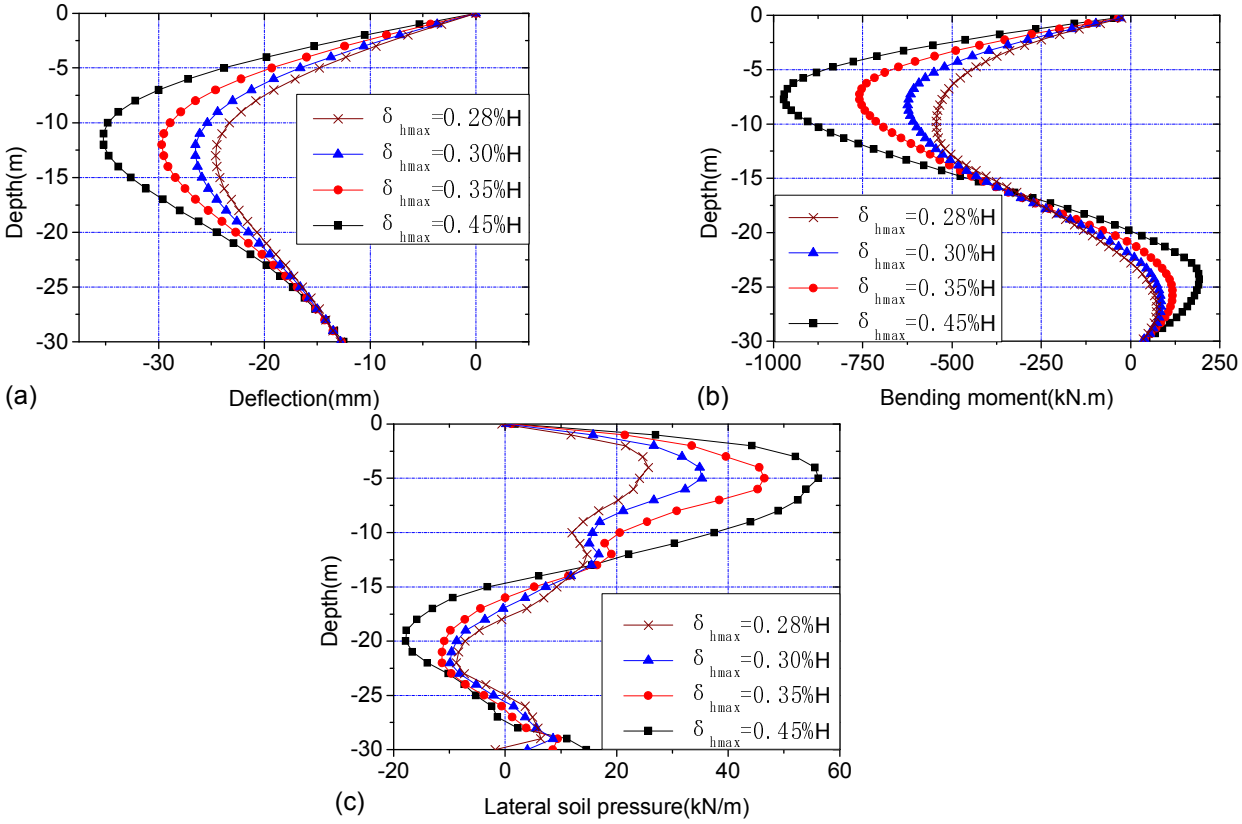

Fig. 6. Effect of retaining wall stiffness on the response of pile

**Influence of the distance from the excavation face.** When the pile head only constrained from deflection(fixed deflection-free rotation), the influence of distance on the pile response for maximum excavation depth is shown in Fig. 7. The distribution of the deflection, bending moment and lateral soil pressure are quite similar in shape at various distance, but the maximum value decreases with the distance increasing.

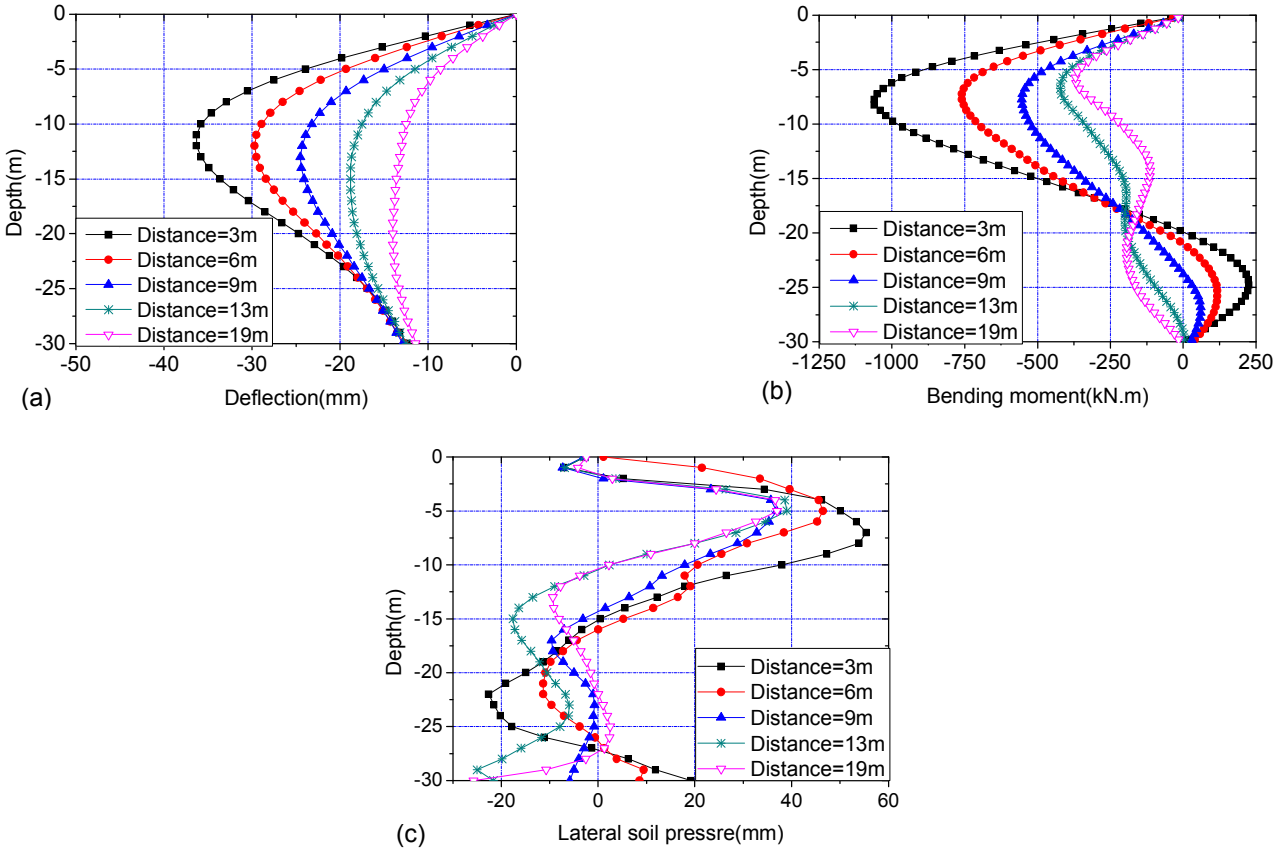

Fig. 7. Effect of distance from excavation face on the response of pile

**Influence of the pile stiffness.** When the pile head only constrained from deflection(fixed deflection-free rotation), the influence of pile stiffness on the pile response for maximum excavation depth is shown in Fig. 8. Only the young's modulus of pile stiffness is varied. It can be seen that the pile deflection decreases with the pile stiffness increases, and the pile bending moment and lateral soil pressure increase greatly with the pile stiffness increases.

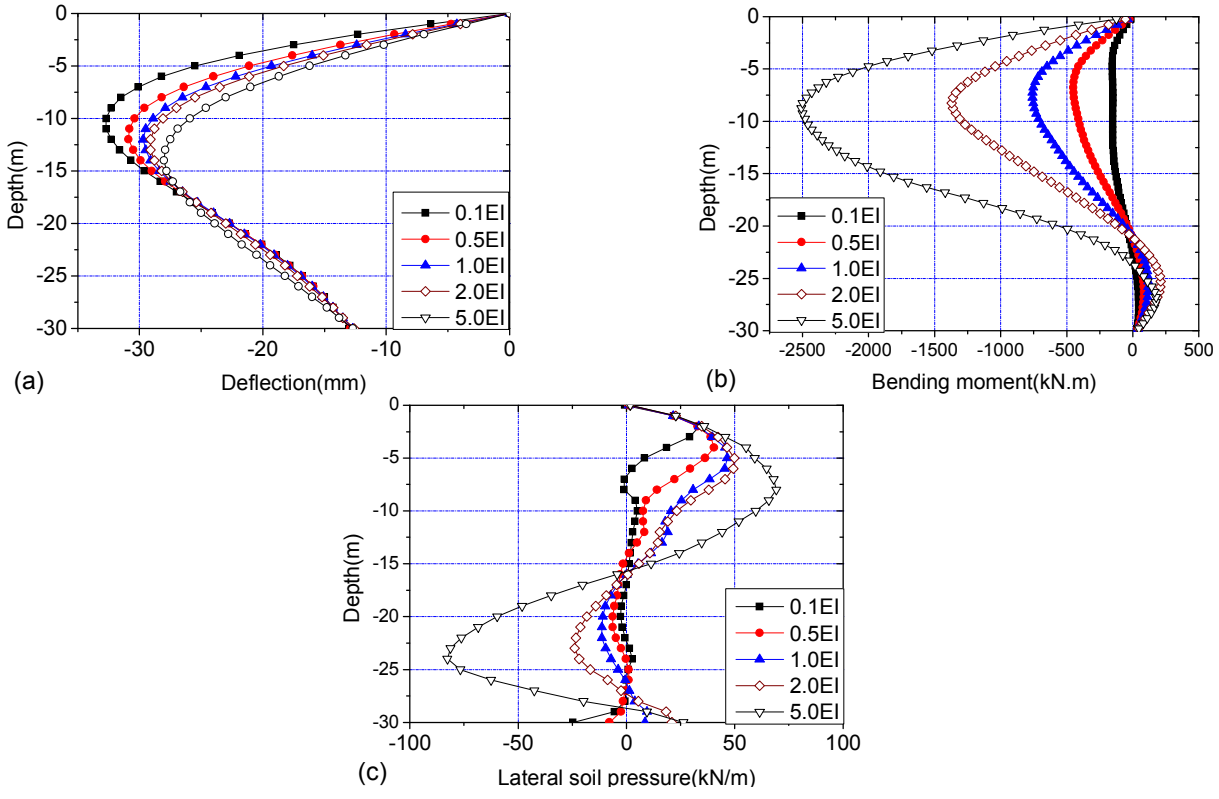

Fig. 8. Effect of pile stiffness on the response of pile

**Influence of pile length.** A cases of pile(pile head only fixed deflection) have been studied. The pile behavior is quite similar when the pile length is more than 22 m. When the pile length is less than 10 m, the deflection of the pile is near to a straight line, and the bending moment of the whole pile is negative.

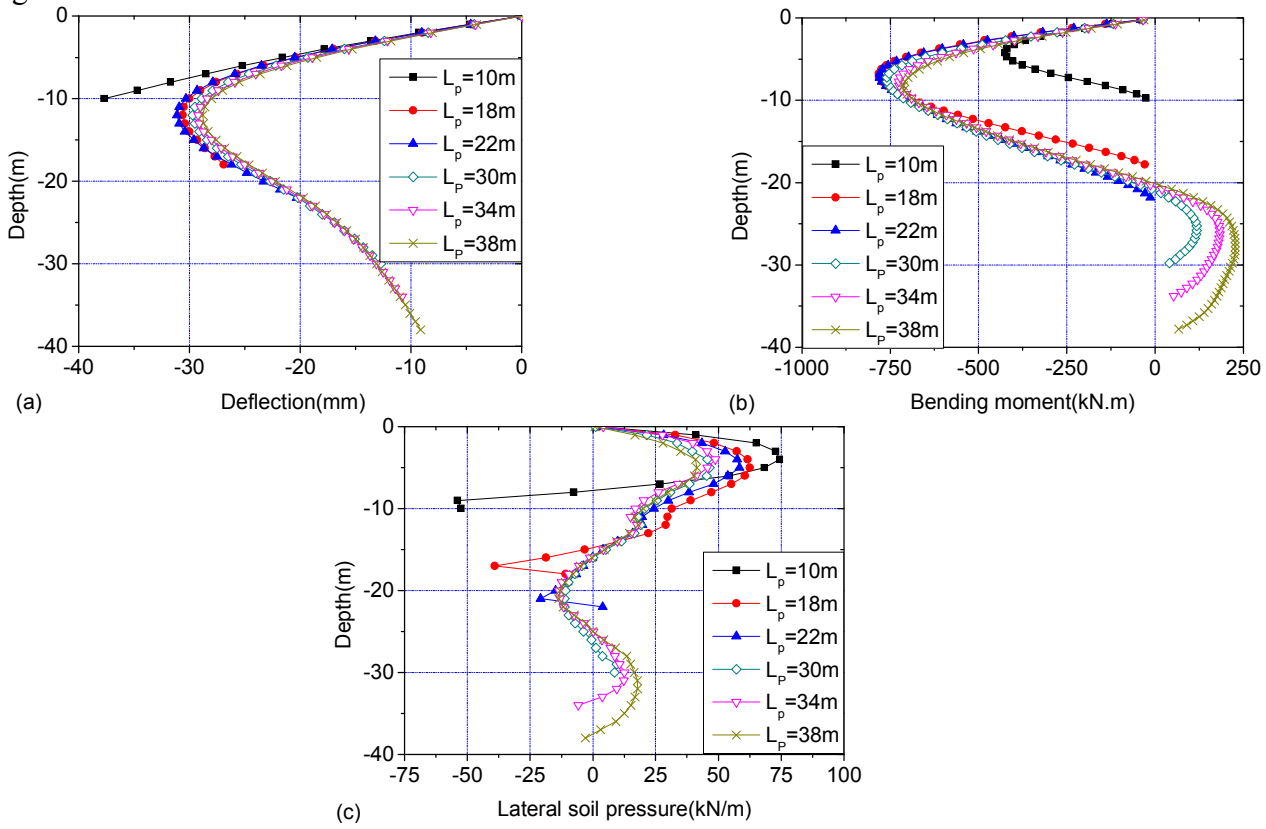

Fig. 8. Effect of pile length on the response of pile

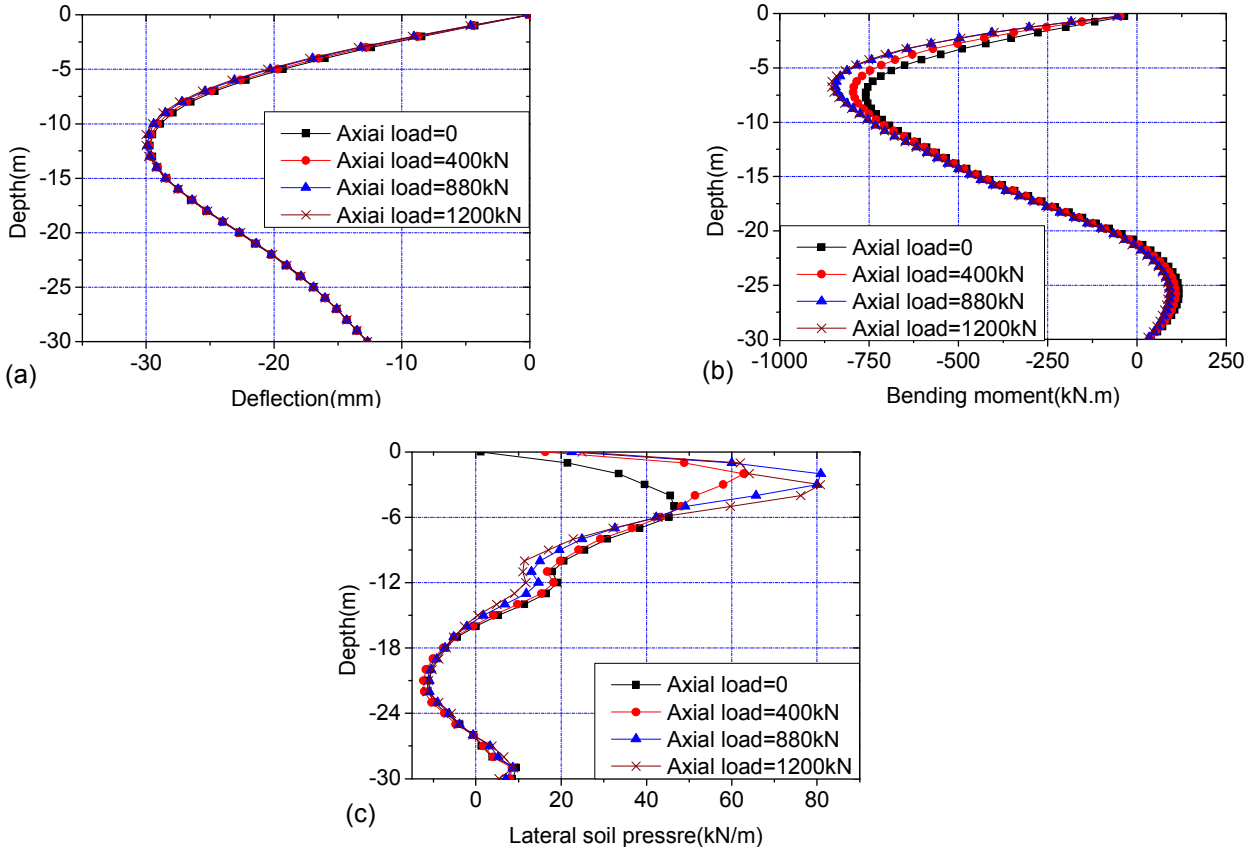

Fig. 9. Effect of axial load on the response of pile

**Influence of axial load.** The effect of axial load on pile response for maximum excavation depth is shown in Fig. 9, Only the pile head in the fixed deflection-free rotation case is introduced. It can be seen that the pile deflection, bending moment, and lateral soil pressure increase with the axial load increases, but the increase is very small due to the constraint of the surrounding soil. This shows little difference with Guo and Ghee (2006)[10], but the effect of the axial load is less than that of Guo and Ghee (2006).

## Conclusions

The influence of braced excavation on adjacent pile was studied by numerical analysis, the distribution of deflection, bending moment and lateral soil pressure along the pile is significantly different from that caused by unstructted excavation[11], but the laws of the influence of some parameter on pile response are similiar. The results given by the numerical analysis indicate that the pile response increase with the increasing excavation depth and the increasing lateral displacement of the wall. With the increasing distance from the excavation face, the pile response decrease. With the pile stiffness increasing, the pile deflection decrease, the pile bending moment and lateral soil pressure increase. The pile response increase with the axial load increasing, but the increase is very small.

**Key words:** High steep rock slope; 3D finite element numerical analysis; Stability analysis.

**Abstract.** Due to the high steep rock slope stability analysis its complex geological conditions and other factors, its stability calculation has been a technical problems the field of slope engineering, in this paper, 3D finite element calculation software Midas GTS for side slope surface topography and slope internal faults, weak structural plane of complex three-dimensional geological modeling, it overcomes the complex slope geological modeling problem and simulates rainfall, earthquakes and other factors affecting the stability on the slope, calculated results more in line with reality, and the software calculates is in accordance with fact, it provides a useful reference for slope engineering.

## Introduction

Stability analysis of high steep rock slope has been a technical problem in the fields of engineering, if the slope stability can be calculated accurately, that is not only can predict slope failures or not, and the calculated results provides a scientific basis for later design and monitoring. However, due to the complex geological conditions, accurate analysis for its stability is not easy, this paper is on the basis of actual slope stability assessment project, Midas GTS finite element numerical simulation software is used for three-dimensional modeling of complex slope geological structure and analyzes the stability of the slope.

## Overview of high steep rock slope engineering

There was a rock slope engineering in Guangdong Province, the height is about 130m and length is about 302m, according to engineering survey data show that the overburden of bedrock is artificial fill soil and slope residual soil, its thickness is 2.30 ~ 8.45m, the lithology of bedrock are: shale, sandstone, geological conditions is complex, rock boundaries, fractures, weak structural plane are staggered, and there are another two through fractures $F_1$ and $F_2$, $F_1$is major fracture, trending toward is NE9°, the tendency is NW279°, the average angle is 78°; $F_2$ fault: trending toward is NW316°, the tendency is SW226°, dip 78°.

## 3D modeling of high steep rock slope

Midas GTS is an excellent finite element method (FEM) 3D numerical simulation software in engineering field which has fast and intuitive three dimensional modeling, rapid and very powerful ability in mesh generation, professional geotechnical analysis capabilities and intuitive analysis results, etc., it has been applied to the field of geotechnical engineering widely.

As the geological conditions of this rock slope is very complicated, rock boundaries , faults, weak structural plane are staggered , so three dimensional modeling is difficult, but Midas GTS is used to geometric modeling and mesh generation of slope geological and structural, focused divided slope complex surface, geography, stratified structure of rock, faults , weak structural plane , crush belt and son on, making it be closer to the actual three dimensional simulation geometry and spatial

distribution of slope ,it can more realistically simulate a three dimensional stress state and reflect rock and soil slope of actual slope, the calculated results are more in line with reality, and then using the finite element method to calculate the slope stability, specific process of three dimensional modeling is as follows:

**Three dimensional surface and geography generation of slope generated**. Using Midas GTS software terrain generator modules (TGM), import 3D DXF CAD in line (with real elevation contour lines, shown in Figure 1), the points is sampled as much as possible, because the more sampling points, the higher precision, and then it generates complex slope terrain and surface. (Shown in Figure 2)

**Using generated surface to segmentation entity to get slope model**. It is to ensure the boundaries of a solid model are level. On the basis of the solid model, according to the rock slope three dimensional coordinates of points, spatial distribution, fault strike, dip, spatial location of weak structural plane to generate a three dimensional curved surface and divided solid model, carved out of rock units, faults, weak structural plane, (Shown in Figure 3).

**Solid mesh is divided.** Generally it is divided tetrahedral mesh, the meshing size is smaller, the accuracy is higher, but the spent time calculating is longer, for some important key parts, such as faults, weak structural plane, bottom of slope and so on should be divided a little fine mesh to ensure its accuracy (Shown in Figure 4).

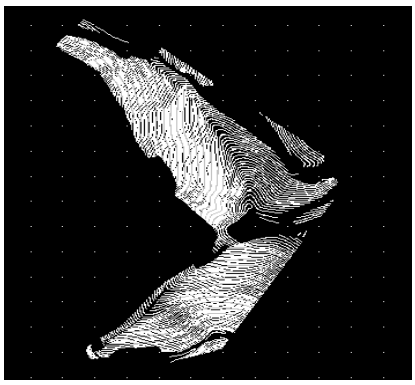

**Figure 1. Slope contour map**

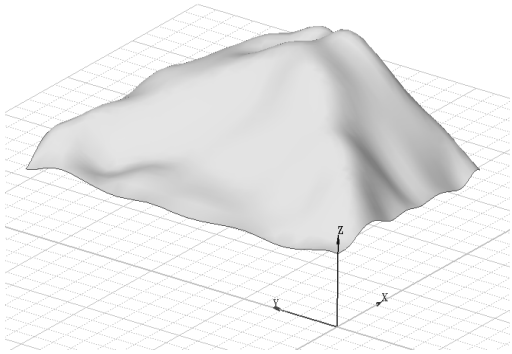

**Figure 2. Generated slope surface and geography**

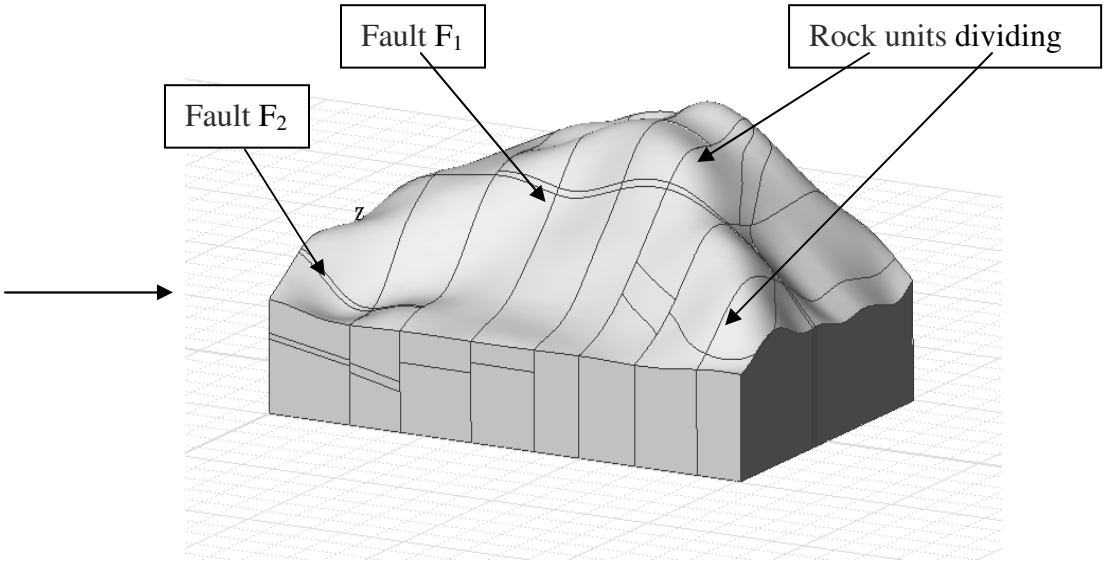

**Figure 3. Solid mesh of rock units, faults is divided**

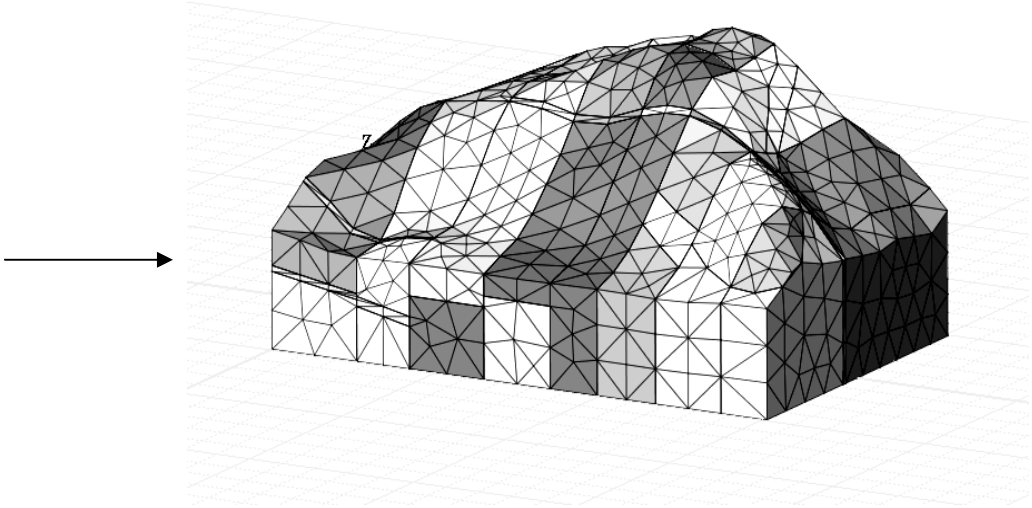

**Figure 4. Solid mesh is divided**

**Slope stability calculation**

**The rock unit calculation parameters.** Mechanical parameters of rock units are shown in Table 1.

**Table 1. Rock unit calculation parameters**

| Rock level | Rock unit classes and code | | Gravity Density (kN/m$^3$) | Shear Strength | |
|---|---|---|---|---|---|
| | | | | Angle of internal friction (°) | Cohesion (MPa) |
| Ⅳe | Good combined N5 | | 26.00 | 31.15 | 0.147 |
| Ⅴd | General combined N4 | | 25.50 | 29.00 | 0.120 |
| Ⅴc | Bad combined N3 | N3-3 | 25.00 | 19.00 | 0.080 |
| | | N3-2 | 25.00 | 18.50 | 0.070 |
| | | N3-1 | 25.00 | 18.00 | 0.060 |
| Ⅴb | very bad combined N2 | | | 13.00 | 0.035 |
| | | | | 18.00 | 0.030 |
| | | N2-2 | 24.50 | 12.50 | 0.045 |
| | | N2-1 | 24.50 | 12.00 | 0.040 |
| Ⅴa | extreme bad combined N1 | N1-5 | 22.00 | 8.55 | 0.033 |
| | | N1-4 | 23.00 | 8.55 | 0.030 |
| | | N1-3 | 24.00 | 8.50 | 0.030 |
| | | N1-2 | 20.50 | 13 | 0.030 |
| | | N1-1 | 23.50 | 8.45 | 0.030 |

## Engineering conditions analysis

**Groundwater level and rainfall.** According to the water table for each drill hole sectional view of survey data, a cross section water line is drawn, while the groundwater pressure is as external load, directly on the slope structure, it is in order to achieve a common effect of rainfall and the water table. According to the national weather station records of local rainfall condition, it is shown that local maximum 24 hours rainfall is 213.1 mm, there time is August 2, 1997 (statistical life :1956-2013 year). In finite element model, this is achieved by node flow of 2.5e-6m3 / s in slope model.

**The seismic fortification intensity.** According to《Seismic Design Code》（GB50011-2010）, local seismic intensity is 6 degrees, the design peak of acceleration is 0.05g. The project site conditions is rock, hence the earthquake seismic waves using class Ⅰ site seismic waves of GTS software, adjust amplitude reaches 0.05g, while duration is 24.96s,acquisition time interval is 0.01s, the seismic process is shown in Figure 5.(Ordinate is acceleration values (g), abscissa is time (s))

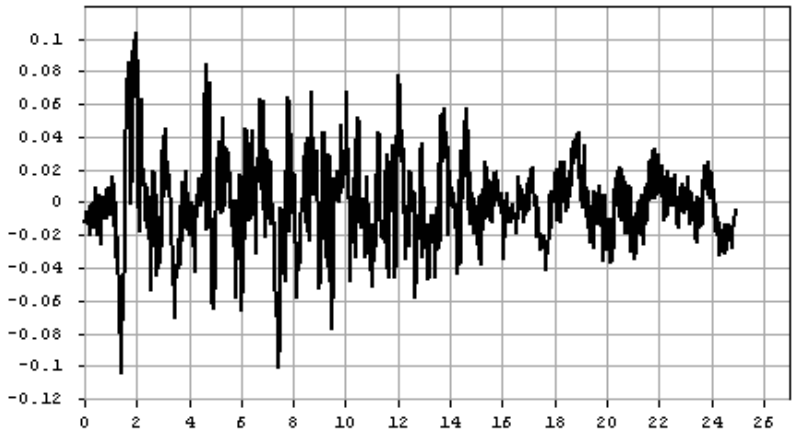

**Figure 5. Earthquake time curve**

Using the strength reduction method, rock slope is three dimensional analyzed under its own weight, heavy rainfall, earthquake three conditions effect, obtained the safety factor, the maximum shear strain (potential slip surface) of slope, shown in Figure 6～10.

## Numerical calculation results

### Under the action of gravity

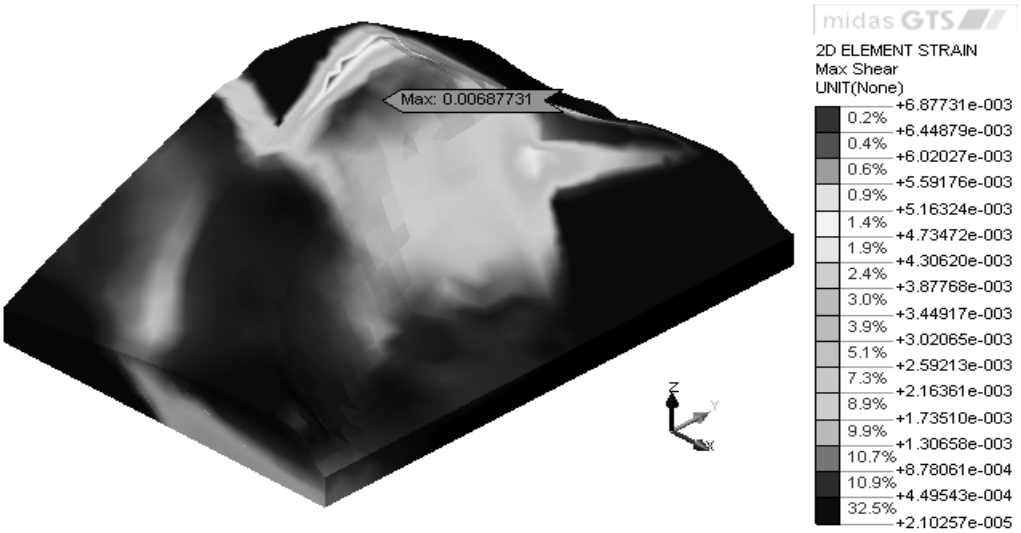

**Figure 6. The maximum shear strain**

**Under rainfall infiltration**

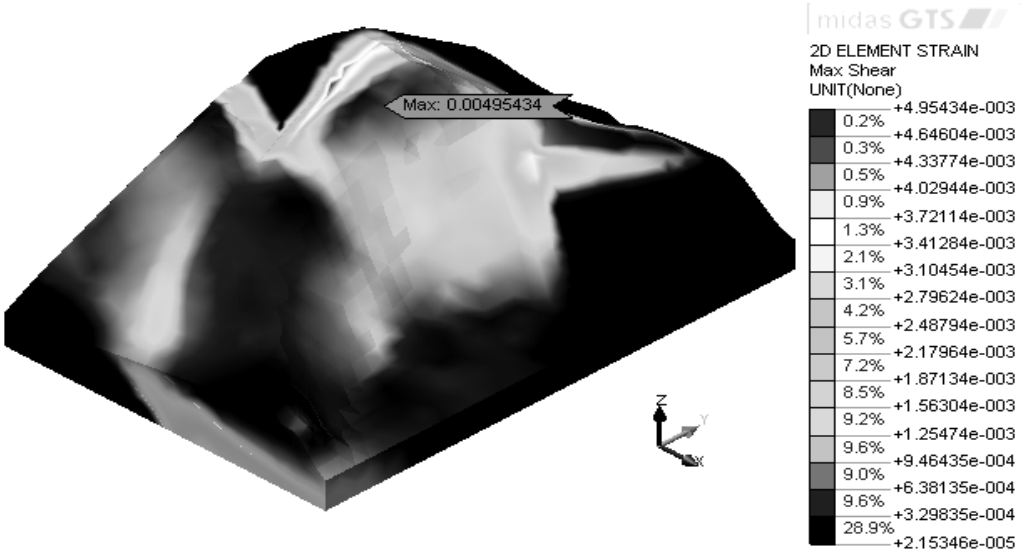

**Figure 7. The maximum shear strain**

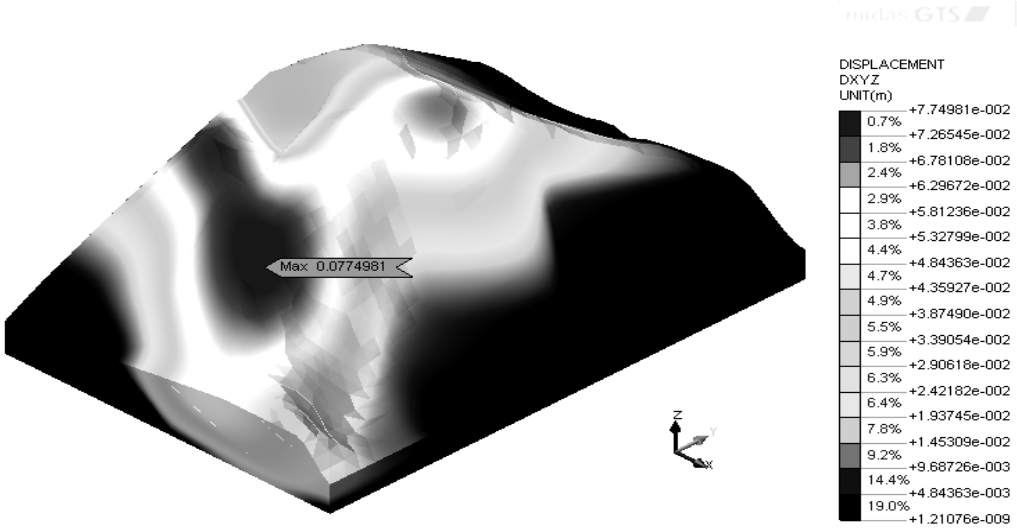

**Figure 8. Displacement**

**Under the action of earthquake**

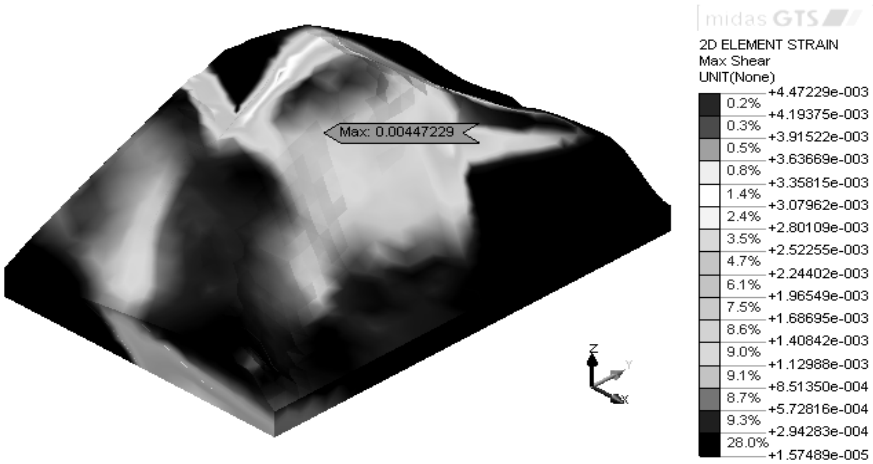

**Figure 9. The maximum shear strain**

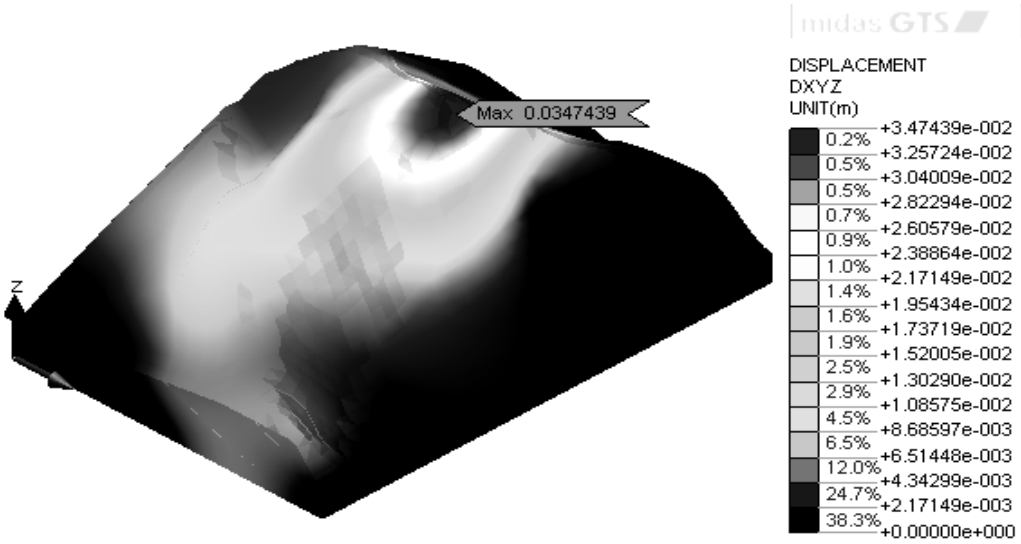

**Figure 10. Displacement**

**Stability calculation results**

**Table 2 Stability calculation results**

| Conditions effect, | Safety Coefficient | The maximum displacement (m) | The maximum limit yield stress （KPa） | The maximum Shear strain |
|---|---|---|---|---|
| Under the action of gravity | 1.2125 | —— | 1179.07 | 0.0033 |
| Under rainfall infiltration | 1.0875 | —— | 1114.39 | 0.0013 |
| Under the action of earthquake | 1.1625 | —— | 1126.71 | 0.00257 |
| Displacement under the action of gravity | —— | 0.158 | 1042.04 | 0.0035 |
| Displacement of Seismic time history analysis | —— | 0.0677 | 180.57 | —— |

**Based on the above calculated results:**

The slope is generally stable under action of gravity, but stability is bad in local section.

Three-dimensional analysis for large displacement and shear deformation of slope residual soil are main factor affecting slope safety.

Safety coefficient is reduced about 20%, the maximum displacement reaches 158mm under heavy rain seepage, under seismic safety factor is reduced about 15%, the maximum displacement reached 67.7mm, so in heavy rain and earthquakes, the slope is instable. The maximum stress occurs in the vicinity of the rupture zone, the security is determining the distribution of stress field across the slope here.

Verified by actual monitoring data show that the calculated results are accordance with reality.

## Conclusion

In this paper, Midas GTS finite element calculation software is used for complex geological bodies 3D modeling such as geological terrain and surface, internal faults, weak structural plane, it overcomes the difficult problem of slope complex geological modeling, and slope stability is calculated under simulating rainfall, earthquakes and other factors affecting, the results are accordance with reality, it provides a useful reference for slope engineering.

**Key words:** Foundation pit support, soil nailing wall, supporting, construction.

**Abstract.**We adopt the supporting scheme of soil nailing wall by comparison and selection combining engineering geological conditions and surrounding buildings load situations. And introduce focally its supporting principles and major parameters and main construction points. The scheme meets the engineering requirements proved by the construction acceptance inspection with its safe and rational design and construction convenience.

## Introduction

The soil nailing wall is a supporting technique strengthening slope and excavation soil stability developing in resent two or three decades [1].It is a self stabilization and retaining-soil behind the wall supporting structure. By a combined action of top-bottom slender and dense soil nailing in situ soil, steel mesh reinforced shotcrete and reinforced soil mass. And the wide applications of the structure in slope enhancing and foundation pit supporting at home and abroad benefited from its characters of non pollution, low noise, stability and reliability, obvious social effect and economic effect comparing with other structures. The technology applies in parts above groundwater level or artificial fill, cohesive soil and weakly consolidated sand after artificial precipitation [2] [3].

## Project profile

### Brief Introduction

It is a geotechnical engineering reconnaissance task in detail survey delegated by China IPPR International Engineering Corporation for proposed Baotou Steel Xinxingshuian garden engineering. It is located in east of Kunriver road, north of Qingnian road, and south of Baiyan road. It is a flat terrain, Lower from north to south, of ground level from 1066.38～1068.59m, alluvial fan front edge of Kun river, and rich in quaternary sediment in thickness. The site with 65m length and 5.5m height in 2m north of D business district was sloped 1: 0.3 due to the location limits. But it partial collapsed in rain flood season because of simple laying of Φ8@200 steel mesh and thinner C20 concrete than <50mm.So we proposed soil nailing wall for re-supporting considering the engineering conditions and technical and economical factors.

### Engineering Geology and Hydrological Conditions

Besides artificial miscellaneous fill(thickness of 0.2～0.4m)in surface in the engineering investigation, It is Holocene rushed diluvia all above 35.0m depth range and stated according lithology and engineering properties:

The First layer is a little wet and dense collapsible silt, with mica and white stripe and macroporous structure, and soaking collapsibility. Its thickness is between 1.7～5.3m, layer level is between 1061.05～1064.98m.

The second layer is tawny fine sand of feldspathic and quartziferous, a little wet and dense to middle dense in natural state. Its thickness is between 0.3～4.2m, layer level is between 1059.02～1063.74m.The third level is variegated gravelly sand of feldspathic and quartziferous, with good grain composition and a little grait. Its thickness is between 14.9～19.7m, layer level is between 1040.55～1046.58m.The third[1] level is tawny silty clay of mica and iron oxide, plastic state in natural state, Its thickness is between 0.3～4.4m, layer level is between 1049.58～1053.57m.

The forth level is silt and part silty clay of feldspathic and quartziferous, tawny to taupe, with feldspathic and quartziferous granular mineral, middle dense in natural state. Its thickness is between 0.3～4.7m, layer level is between1040.23～1046.55m.The fifth layer is taupe grit and partial fine sand and silt clay interlayer or lenticle of feldspathic and quartziferous, saturation and middle dense in natural state. And we don't expose the layer in the reconnaissance. he initial underground water level is 25m in the location reconnaissance, and didn't measure the stable underground water level because of the mud counterfort in exploitation.The stable underground water is hidden 20m under the earth surface and is phreatic water according existing data of nearby regions. We can ignore the influence of underground water due to its depth and take 10kPa for surrounding load.

The table below of definite soil layers and mechanical characteristics for slope supporting and construction range according to the location reconnaissance:

Table 1 Soil layers and parameters in construction range

| Layer | Average depth (m) | gravity density $\gamma(kN/m^3)$ | cohesion c(kPa) | internal friction angle $\varphi(^\circ)$ | cohesive τ(kPa) |
|---|---|---|---|---|---|
| artificial miscellaneous fill ① | 1.2 | 19.0 | 5 | 10 | 16 |
| collapsible silt ② | 3.7 | 16.5 | 13 | 30.3 | 80 |
| gravelly sand ③ | 0.6 | 19.0 | 0 | 18 | 130 |

## Pit Supporting Method Selection and Design

### Selection

The slope protection range is on the east of the 10th building, 65m longitude 2m north of D business district, and 12.5m in the northeast corner with average 5.5m height of "┘"shape.The top and bottom slope lines are all certain in the excavation. We proposed initially soil nailing wall or anchoring for supporting comparing with location limitations, security and economic problems of gravity retaining wall and the sheet pile supporting. We decided the soil nailing wall for its low cost, fast construction speed, simple equipment, convenient operation, less noise and the owners' requirements of quick supporting engineering finish for the end of construction of the 10th building and D business district.

### design of soil sailing wall

For location limitation, the soil nailing wall lever pitch is $\beta = 73.3^\circ$ （1: 0.3slope）,soil nailing and horizontal plane angle is $\alpha = 15^\circ$,soil nailing horizontal spacing is $s_x = 1.2m$,vertical spacing is $s_y = 1.4m$, the artificial borehole aperture is 110mm.

(1) the soil nailing lateral pressure: $\sigma_{ai} = (q + \gamma_i h_i)K_{ai} - 2c_i\sqrt{K_{ai}}$ .

in the equation: $q$ —The ground overload from simple work shed

So: $\gamma_i$ —the soil weight of the layer I row soil nailing in

$h_i$ —the distance between the I row soil nailing and slope top

$K_{ai}$ —The coefficient of active earth pressure in the layer the I row in, $K_{ai} = \tan(45^\circ - \frac{\varphi_i}{2})$ ,

$\varphi_i$ is the internal friction angle of the I row soil

$c_i$ —the soil nailing cohesion of the layer the I row in

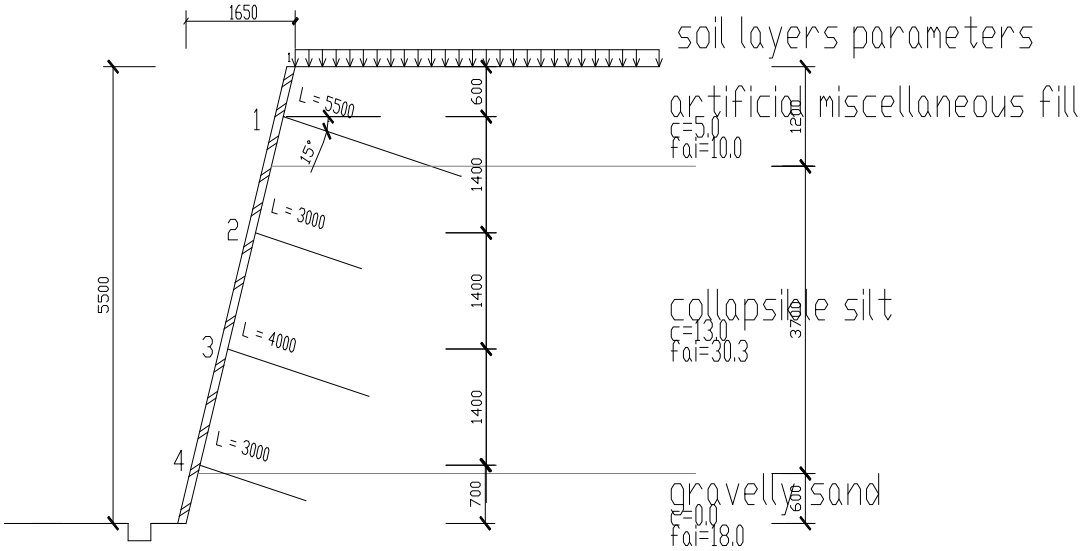

Fig1 Calculation diagram

(2) The reduction coefficient of active earth pressure

$$\xi_1 = \tan\frac{\beta - \varphi_1}{2}[\frac{1}{\tan\frac{\beta + \varphi_1}{2}} - \frac{1}{\tan\beta}] / \tan^2(45° - \frac{\varphi_1}{2}) = 0.722$$

$$\xi_2 = \tan\frac{\beta - \varphi_2}{2}[\frac{1}{\tan\frac{\beta + \varphi_2}{2}} - \frac{1}{\tan\beta}] / \tan^2(45° - \frac{\varphi_2}{2}) = 0.583$$

$$\xi_2 = \xi_3 = \xi_4 = 0.583$$

(3) the standard tensile load values $T_i = \xi_i \sigma_{ai} s_x s_y / \cos\alpha$

(4) tensile load design value,the important factor of the foundation pit side wall $\gamma_0 = 1.0$

(5) soil nailing length design

①effect length of anchoring end

$l_j = \frac{T_{uj}\gamma_s}{\pi d_j \tau_i}$ pulling safety coefficient $\gamma_s$=1.3,drilling diameter of the j row soil nailing $d_j$=110mm

$\tau_i$ —soil cohesive strength of the I layer

② free segment length

$L_{fi} = \frac{H - Z_i}{\sin\beta}\sin(\beta - \frac{\beta+\alpha}{2}) / \cos(90° - \alpha - \frac{\beta-\alpha}{2})$,

slope height H=5.5m, $Z_i$ —height of slope top and soil nailing in I row

③ $L_i = l_i + L_{fi}$ the whole soil nailing length

(6) bolt diameter calculation

$As = \frac{kTmax}{fy_k} = \frac{1.3\times 54430}{335} = 211.2mm^2$, secondary steel of 20mm diameter

$As = 314mm^2$, secondary steel of 20mm diameter for vertical stress, surface concrete thickness of 80mm and Φ8@200×200mm steel shed.

Table 2 Values according layer coefficients

| Row No. | Lateral pressure （kPa) | reduction coefficient | standard tensile load values (kPa) | tensile load design value (kPa) | whole soil nailing length (m) | Practical soil nailing length(m) |
|---|---|---|---|---|---|---|
| 1 | 6.68 | 0.722 | 8.39 | 10.49 | 5.37 | 5.5 |
| 2 | 0.21 | 0.583 | 0.21 | 0.26 | 2.07 | 3 |
| 3 | 33.72 | 0.583 | 34.19 | 42.74 | 3.25 | 4 |
| 4 | 42.95 | 0.583 | 43.54 | 54.43 | 2.97 | 3 |

(7) interior pulling check calculation

$L_{fi} + \frac{F_{sd}T_{ui}}{\pi d\tau_i} < L_i$ and the value is ,partial stability safety coefficient of soil nailing $F_{sd}$=1.3

(8) check calculation of stability against sliding

$E_{\alpha x} = s_x s_y \sum[(q + \gamma_i h_i)k_{ai} - 2c_i\sqrt{k_{ai}} = 130.76kN$

$F_t = (w + qB)s_y \tan 18° = 191.5kN$; so: $Kn = \frac{F_t}{E_{ax}} = \frac{191.5}{130.76} = 1.46 > 1.3$, meets the requirements of stability against sliding.

(9) check calculation of stability against overturning, moment against overturning $M_w = (w + qB)s_y \frac{B}{2} = 1178.8kN \cdot m$ ,overturning moment $M_0 = \sum[(q + \gamma_i h_i)k_{ai} - 2c_i\sqrt{k_{ai}}]s_x s_y \frac{H}{3} = 239.75kN \cdot m$

so: $K_q = \frac{M_w}{M_0} = 4.92 > 1.3$ , meets the requirements of stability against overturning.

So: $K_q = \frac{M_w}{M_0} = 4.92 > 1.3$

**Conclusions**

(1) And we got the geological coefficients based on detailed geological survey report in the design of soil nailing wall. But we took the conservative coefficient of artificial miscellaneous fill according to local experience because of its complex and various properties and influences of environment, human and seasons

(2) We adopted 2m width of Reinforced concrete flanging and Φ6@200×200mm steel shed to ensure slope stability due to the 1m thick artificial miscellaneous fill in the slope top.

(3) The whole supporting system is rational and reliable according to the monitoring results of horizontal displacement less than 14mm,vertical less than 16mm and no obvious crack.

(4) We should give priority to the soil nailing wall for a narrow location and tense construction period by comparison other supporting systems.

**Keywords**: accumulative, landslide,expansivesoil,micro pile,failure mode,design technique

**Abstract.**This paper studies the micro pile technology for the accumulative landslide reinforcement of expansive soil, putting forward the three failure modes of the micro pile strengthening accumulative landslides of expansive soil and design principles of the micro pile, and then illustrating its calculation methods. Those finding have been applied into 22 landslide disasters for the micro pile design, landslide treatment engineering in south mountainous area of Shaanxi Province in China, which attaches theoretical and practical importance to the design and treatment of micro piles reinforcing the same type of landslide.

## Introduction

Accumulative landslides are widely distributed in China, and there were 6535 landslides in the south mountainous area of Shaanxi Province according to the geological survey, in which the accumulation landslides accounted for about 92.3% in total, and shallow landslides with thickness less than 6m were made up for 51%, therefore those landslides has provided a broad space for the use of miniature piles[1-4].In China, the formula for micro pile can be roughly divided into three categories--- General theoretical method to calculate anti-slide pile, Cantilever pile calculation method and Equivalent calculation method.

Technically from the aspect of General theoretical method to calculate anti-slide pile, slope load is borne by the body of micro pile, and its effect is equivalent to the ordinary anti-slide pile without taking into account of the anti-sliding function for the soil between piles, which could turn into a conservative calculating result. The cantilever pile calculation suggests that the micro diagram of the micro pile is equivalent to cantilever structure anchoring below the sliding surface, and technology personnel is more likely to use this method due to its simple calculation, but the hypothesized landslide thrust and distribution condition of anti-sliding resistance before piles are not accurately assumed, so there exists a huge difference between the calculating results and the actual monitoring results of the spots. Based on Equivalent calculation method, the pile spacing is small, and micro pile and its surrounded soil form an integrated structure to share load, which could serve as a composite structure equivalent to the soil retaining structure in traditional way, then deducing the results according to the calculating method of the soil retaining structure. The last method is the combination of theory and experience, but the thickness of the retaining soil is often difficult to estimate, therefore it is difficult to avoid the errors in design and calculation. So far, our country has not yet developed a set of sound and systematic calculation theory and design method of miniature piles, impacting the wide application and development of micro piles.

The design techniques for the micro pile reinforcement of accumulative expansive soil landslide are studied based on laboratory research, field monitoring and miniature pile reinforcement practical operations for 22 landslides in the southern region of Shaanxi Province.

## Micro pile reinforcement of slope failure mode

Studies have shown that the failure mode of micro pile reinforcement accumulative landslide consists of three types—the overall failure of the micro pile, the single pile failure of the micro pile and the local failure of the micro pile[1,5,6].

**The overall failure of the micro pile.**In the landslide reinforcement engineering, the composite structure of micro pile is often formed by the single piles in rows according to certain combination. The test research indicates that the overall failure mode are basically same as that of a single tiny single pile, showing that in the surrounded sliding surface, there exist the cutting deformation of failure, and bending of pile body within the destructive areas, many oblique cracks, basically being vertical of pile's anchoring section, loaded pile tilting towards front edges of slides, different bearing force in rows of piles , the destruction decreasing in line with the sliding orientation, as the result, the shear calculation is used to calculate for the design of micro pile.

**The single pile failure of the micro pile**.In the process of using micro pile to reinforce expansive soil landslide, the maximum bending moment and shear force is close to the sliding surface, and the single pile failure is often characterized by shear fracture caused by inadequate shear carrying capacity of single piles, and the destruction area of the piles roughly ranges 60 cm or so in the slip surface.

**The local failure of the micro pile.**Due to uneven distribution for the soil nature, there is loose soil between piles in certain area of micro pile reinforcement engineering, with relative large spacing between piles, under the effect of sliding force, the soil body between piles slip away; in the destructive area, the bearing shear force for a number of micro piles close to the sliding surface exceeds the shear strength, and results in shear failure, or excessive deformation of pile body. The occurrence makes the micro pile composite structure seriously damaged in certain area or loses bearing ability of anti-slope slide, leading to the destruction of the local structure, or the failure as a whole eventually .

## Design principles[1,7,8,9,10]

(1)Miniature pile supporting system belongs to the interaction of piles and soil, and the design must take the pile-soil interaction problem into consideration.

(2)In the reasonable arrangement of piles, even if only a tiny relative displacement of piles and soil takes place, the shapes of arching soil look similar under irregularly distributed load, with different pile-soil load sharing ratio, pile bearing 80%, while soil accounting for 20% .

(3)With reasonable pile spacing for micro pile composite structure , anti-resistance to slide force of pile in rows is of difference, and the design should be took consideration about different resistance of pile in rows, with load sharing ratios of 1:0.7:0.6 respectively for the first row, the second one and the third row of piles

(4)In the process of arrangement, it is advisable to leave pile spacing to (8 ~ 10) d, pile row distance to (5 ~ 10) d, pile of anchoring depth to (1/3 ~ 2/5) L.

(5)Micro pile group is often designed for multiple pile body, and the top of pile shall be designed for coupling beam, which pile efficacy can be adjusted to a certain extent to control and avoid the displacement of pile top.

(6)In the working process, the maximum bending moment and shear force of micro pile are near the sliding surface, and their moment and shear force values are taken as the design basis for micro pile to guarantee the bending and shear strength of pile body as a whole.
(7)It is crucial to design a perfect drainage system on the micro pile reinforcement of accumulation of expansive soil landslide. Intercepting drains, torrent gutter, side ditches, drainage and build-in slope pipes in the slope, etc should be jointly considered and developed with project situations.
(8)The cracking or fracture disturbed in the slope surface should be filled solidly, reducing water infiltration into the slope, to control cracking and fracture, to adjust the soil stress state, to improve the soil strength, and to avoid generation of secondary sliding surface.
(9) Micro steel pile should be set up by open-off cut to have pressure grouting in certain depth of sliding surface, in order to reinforce the sliding zone of pile and soil strength. Experience about engineering and project has shown that the ratio of grouting is around between 1.6 ~ 3.5.

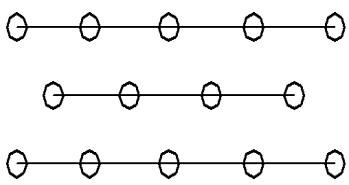
**The design calculation method of micro pile reinforcement**

**Design concept.**Micro pile reinforcement system is the interaction of piles and soil body, landslide load is shared by piles and soil on pro rata basis, and bearing capacity of piles in rows is not identical in group. In the micro pile design, the resistance of soil between piles should be fully considered according to the different pile-soil load share ratio and different bearing capacity of piles in rows. With reasonable spacing pile design, down force of the landslide is allocated to the group micro piles and the soil between piles in the proportion 8:2, and the total assigned load on bearing should be distributed in the proportion 1: 0.7:0.6to the piles in rows. The pile body is under the uniform distributed load, acting on the piles above the sliding surface. Given to the pile anchoring end as the fixed bearing, we may simplify micro pile and beam connection by rigid connections to generate the calculation of the internal force of each item based on structure internal force calculation method, to check reinforcement system in the terms of the overall damage, the destruction of the local structure and single pile failure modes.

**Arrangement patterns and drainage design:**

(1) The layout

Expansive soil landslide failure forms of performance failure for shallow slip, in order to prevent the shallow slip of Expansive soil form landslide failure and to guarantee the effect of micro pile the reinforcement. We often use laterally linear connection to reinforce the single slope, or equip the single piles in vertical and horizontal (longitudinal and cross)frame structure, as shown in Figure 1. & 2.



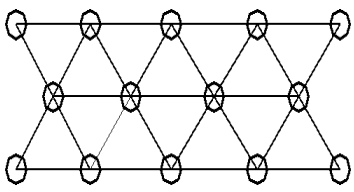


**Fig.1 Single pile lateral connection form Fig.2 Single pile lateral and longitudinal connection form**

(2)Drainage design

Accumulative landslide of expansive soil induced by rainfall erosion and water infiltration in southern Shaanxi will seriously affect the stability of the slope, so measures must be adopted to

protect the sliding surface, such as, intercepting drains, torrent gutter, side ditches, drainage and build-in pipes in the slope to be set up in the certain depth of the slope body to drain off the water in time.

**Design calculation method:**

(1)Calculation assumption

1)Assuming landslide thrust of micro pile composite structure above sliding surface is a uniformly distributed load;

2)Stating the micro pile below the surface as the fixed end set in the bedrock;

3)Calculating the length of each micro pile approximately from the top of the pile to the sliding surface at L/3 below;

4)The stress of the each single pile of the same row being same ;

5) Assuming the connection between each micro pile and connecting beam for the fixed one, while compared with the pile ,the beam structure member being regarded as a rigid one;

6)Letting the connecting beam be only horizontal displacement and horizontal displacement of the pile tops being equal in the connecting beam.

(2)A sketch of calculation

According to the above calculation assumption, the calculating model of expansive soil micro pile as shown in figure 3:

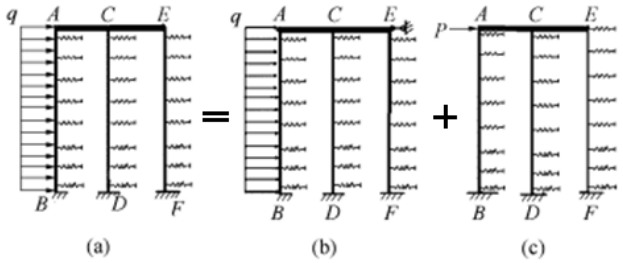

**Fig.3 The calculation model for landslide reinforcement with micro pile**

(3)The landslide thrust calculation

There are multi-formula to compute the landslide thrust to compute. The transfer coefficient method is simple, and we assume that the direction of the force between the bars parallels to the ground, not taking the specific form of landslides destruction into account, and could derive the force in accordance with the transfer coefficients. Landslide thrust by the transfer coefficient calculation method is shown in Figure 4.The calculation is assumed as the follow: 1) we assert the landslide body to slide down as the whole but incompressible based on the assumption of no extruding deformation between the bars or plates; 2) there is no cracking or fracture between the bars or plates, so no pulling force is transmitted only for the thrust; 3) the thrust between the bars is inferred to function at the midpoint of the interface; 4) we may take the sliding body as the calculation item with formulating 1.0 m of length unit on a central axis at the sliding surface without considering shaft or side resistance.

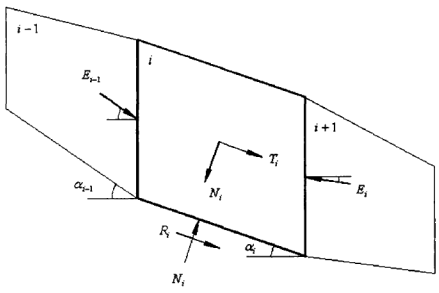

**Fig.4 Transfer coefficient method to calculate the landslide thrust**

From the above pictured, we may take the Separated Slider i for example, and the inclined forces are resolved into different components on the sliding surface:

$N_i=W_i\sin\alpha_i$

$T_i=W_i\cos\alpha_i$(1)

Based on the equilibrium conditions, the left force of the Separated Slider i will be inferred as follows:

$E_i= W_i\sin\alpha_i- W_i\cos\alpha_i\tan\varphi_i-c_il_i+\psi_iE_{i-1}$(2)

In the Formula: $\varphi_i$ for the angel of internal friction ($^O$) ; $C_i$ for the cohesive force of Separated Slider i on the surface of the sliding body (kN/m) ; $L_i$ for the length of the sliding surface of the landslide mass (m); $\psi_i$ for the Transfer coefficient;

$$\psi_i=\cos(\alpha_{i-1}-\alpha_i)-\sin(\alpha_{i-1}-\alpha_i)\tan\varphi_i \quad (3)$$

We may calculate the landslide thrust to ensure landslide stability. If the thrust of the last slider is positive, the landslide is unstable; If the thrust value of some piece is less than or equal to zero, then the landslide turn into more stability in geotechnical engineering. Due to full consideration about the stability of landslide in an actual engineering project, so we are supposed to assume the safety coefficient of slope stability to calculate the landslide thrust, so the safety coefficient could be defined as the ratio of overall anti-sliding resistance of the Slider i to the sliding-down force or the thrust through the effect of gravity.

$$F_s=\frac{E_i+W_i\cos\alpha_i\tan\varphi_i+ c_il_i-\psi_iE_{i-1}}{W_i\sin\alpha_i} \quad (4)$$

In the Formula: $F_s$ for safety coefficient, usually ranging 1.05 ~ 1.25.

So the landslide thrust could be concluded as follows:

$$E_i=F_sW_i\sin\alpha_i-W_i\cos\alpha_i\tan\varphi_i-c_il_i+\psi_iE_{i-1} \quad (5)$$

In addition, if the calculated interface containing reverse slopes, the value of $W_i\sin\alpha_i$ is negative, thus $W_i\sin\alpha_i$ being a resistance, and then we will not multiply safety coefficient at this time.

(4) Determined landslide thrust of row piles

We conduct the uneven distribution coefficient of thrust force being as 1:0.7:0.6 based on the numerical analysis, physical model tests, field monitoring tests and the previous findings, which derives from a comprehensive analysis.

(5) Single pile reinforcement calculation

Steel piles are widely used into micro pile reinforcement engineering, and the reinforcement calculation would be determined and generated as the followings:

Firstly, the landslide thrust and sliding resistance are calculated. Setting the horizontal component for the landslide thrust of the first row pile to be $E_n$, the sliding resistance for the last row pile being $P_n$,of horizontal component in the calculation unit, the lateral force of the micro pile group should be $T_n$ , as shown below:

$$T_n = E_n - P_n \tag{6}$$

Then based on the assumption of landslide thrust distributed evenly on the pile, the cross section As of each row steel pile reinforced area for per calculated width is indicated as follows.

$$A_s = \frac{T_n}{n \cdot f_v} \tag{7}$$

In the Formula: fv for reinforcement value of shear strength; Tn for lateral force of micro pile; n for row number of micro pile arrangement.

As heterogeneity reflected in the design of pile stress, uneven distribution coefficient of a landslide thrust should be introduced , and the resulting revised reinforcement area of row pile for per calculated width goes below:

$$A_{si} = \eta \cdot A_s \tag{8}$$

In the Formula: Asi for the actual reinforcement area of row pile ranking i; As for the average of micro pile reinforcement area;ηfor 1:0.7:0.6(inferred on the basis of the numerical analysis, physical model experiment, field monitoring and previous research findings after a comprehensive analysis ), that is to say, the ratio of the row pile landslide thrust for the No. 1 row, No.2 row and the No. 3 row respectively .

(6)The determination of pile length and pile spacing

Miniature pile length can be obtained by the following formula (determined the total length for the length of each micro pile above the sliding surface plus with the pile anchorage length at L / 3 below the sliding surface):.

$$L = L_1 + L_2 \tag{9}$$

$$L_2 = \frac{A_c \sigma_R}{\pi d \tau_2 10^2} \tag{10}$$

In the above Formula: $L_1$ stands for pile length from sliding line to slope surface (m); $L_2$ is for pile length of anchored section (m);$\tau_2$ is for the weighted average of cohesive force ($N/cm^2$) between the pile and the soil mass under the calculated sliding line; d means a micro pile diameter (cm); $A_c$ is for cross section area of micro pile ($cm^2$); $\sigma_R$ refers to compressive stress acted on the cement mortar ($N/m^2$).

In the engineering, the expansive soil micro piles are arranged in different rows and groups toensure the effectiveness of spacing effect . In order to guarantee the soil mass not flow around single piles, this kind of composite structure can play a normal role effectively. Some scholars assume that the estimated value of friction resistance acted upon between soil mass and side pile is greater than the landslide thrust to commonly determine the anti-slide pile spacing, and other scholars calculates the pile spacing through the strength of the soil arch conditions. But these two methods have advantages and disadvantages. The former failed to give full consideration to the strength of the soil arching conductive to be conservative in calculation, while the latter ignored the static equilibrium conditions produced by the interaction between the pile shaft resistance and landslide thrust, though soil arching strength was considered. The estimation of pile spacing for the micro pile composite structure is practically expected to be as (8 ~ 10) d in the reasonable way.

(7)Micro pile composite structure calculation

Miniature single pile calculation. In the landslide reinforcement project, , three conditions should be met with to maintain the stability of the composite structure simultaneously: no sliding failure in the whole body, no general shear failure on the sliding surface of soil, no general shear for the single rank of piles

1) The safety coefficient to calculate the anti-sliding stability of pile composite structure is not less than 1.25

2) Shear capacity for the micro pile composite structure is no less than the landslide thrust to satisfy the general shear on the sliding surface:

$$R=n[\tau]A>E_i \tag{11}$$

In the Formula:[τ] stands for shear strength of steel pipe (125Mpa); n means the number of miniature pile per meter arranged; A is for cross-sectional area of steel tube.

3) When local failure of micro pile composite structure occurs, the main reason is to blame for low mechanic parameters of soil mass between piles not enough to form effective soil arching or too large pile spacing, whereas spacing of micro pile in expansive soil is generally accepted as (8 ~ 10) d , not feasible for the larger one .

(8)Engineering applications

The anti-slide technology for micro piles are applied into the design of 22 small-scale landslides control engineering in southern mountains of Shaanxi Province for 5 years since 2009, which have gained lots of social and economic benefits. The practical application shows that micro pile reinforcement technology is an effective control method of expansive soil landslide.The practice of landslides monitoring, such as Mu-Shang Village landslide, Kimcheon Temple landslide, a landslide took place at Lao-dao-si , and landslides at the Town of New Street yangjiawan village, reaching a conclusion, we can appropriately enlargement of the pile spacing and row distance to get better technical advancement and economic benefits in other similar engineering design.

## Conclusions

(1) The micro pile composite structure of accumulative landslide is under reinforcement system with space force, so spatial structure can be transferred to a flat or level steel structure embedded in the rock and soil mass under the certain calculation assumptions. We may simplify anchored pile as the fixed support, micro pile and beam connection by rigid connections to draw the calculation.

(2) The three failure modes of micro pile are determined , respectively, for the overall destruction, destruction of single pile and local damage, to carry on the corresponding calculation.

(3) Micro single pile layout should be arranged in the Quincunx shape (conventionally in three rows), pile spacing composed as the (8 ~ 10) d rows to lay out, the pile row distance used in accordance with (5 ~ 10) d to arrange , and anchoring depth of pile being (1/3 ~ 2/5) L of the length of the pile

(4) Anti-slide pile- soil interaction should be taken into account in the reasonable pile design and arrangement. When calculating the internal force for each row pile, downslide thrust force should be acted upon by the external force on the whole structure in the rectangular distribution.

(5)Reinforcement technology of micro pile anti-sliding composite structure , its design thoughts, approaches and procedures are given.

**Keywords:** Expansive Soil, Anti-seepage measure, Subgrade engineering, Water content, Numerical analysis

**Abstract.** Deformation of expansive soil subgrade depends on moisture content. Anti-seepage measure of unsaturated expansive soil was carried out using ABAQUS as for the influence of atmosphere. The results show that there is large change in water content using anti-seepage measure measure. After using anti-seepage measure, range of water content decreases. At the same time, range of water content value obviously decreases with the increase of the depth of seepage control. Therefore, damage of pavement caused the deformation can decrease by seepage control measure. The results could be used for engineering design and numerical calculation.

## Introduction

Moisture content changes of expansive soil casue expansion, contraction, intensity changes and also influence slope stability. With the growth of moisture content of expansive soil, the expansive force grows gradually. When the expansive force exceeds the upper loads, the subgrade will appear serious disintegration partial collapse, uplift and crack. When the moisture content of the expansive soil subgrade reduces, the road will crack. In case of rain or snow, water seeping into the soil, the soil will lose bearing capacity. [1-3]

Hefei is one of typical expansive soil coverage region in our country. Moisture content changes casued by rainy season, monsoon and temperature. Facts proved that, the moisture content of the expansive soil shifted and transformed with climate, geological environment and construction activities. The effective cohesion of the soil was declined by cycle dry shrinking and wet expanding, and lead to reduce the strength of soil. [4]

In this paper, we adopt the finite element software ABAQUS to simulate the effect of rainfall. Through application of the software, we can analysis the difference between using anti-seepage measure and no anti-seepage about moisture content changing in Hefei. We can use ABAQUS to analysis the effect of speeage and the influence of seepage depth to moisture content. The results could be used as reference for engineering designing and numerical calculation.[5-6]

## Unsteady seepage finite element analysis

(1)Anti-seepage scheme and geometric model

Figure 1 is the geometric model of numerical calculation. There are two kinds of anti-seepage scheme. The seepage depth are 500mm and 1000mm.

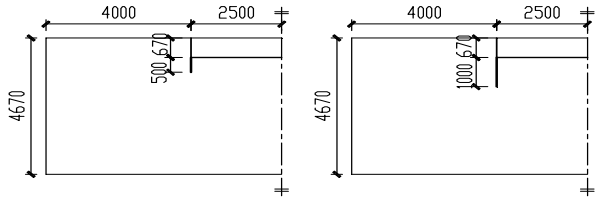

Fig. 1 The geometric model of anti-seepage measure

Divide the unit after the finite element model, as shown in figure2.

(2) Material parameters and boundary conditions

(a) physical property Initial water content 25%;initial void ratio 0.75;density 1.92g/cm3;permeability coefficient 3.06×10-8m/s.Expansive soil subgrade soil water characteristic curve are shown in figure 3 below.

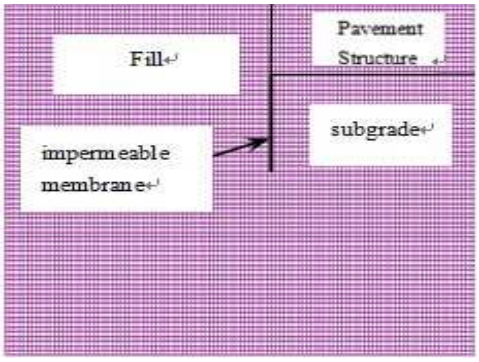

Fig.2 Diagram of finite element

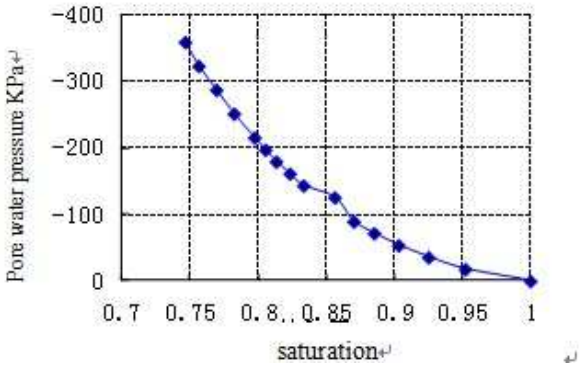

Fig.3 Soil water characteristic curve

(b) boundary of flow

Reference to the expansive soil area construction technical specification, July is the largest rainfall in Hefei area, the rainfall is 181.5 mm. Considering the largest rainfall month, we can take the precipitation of heavy rain in July. Assuming that there are 5 days of precipitation, then the precipitation is 181.5÷5 = 36.5 mm/d. Because of the low soil permeability, we can use two kinds of boundary condition; The first is that we can use flow boundary condition before surface pore pressure approach 0. The precipitation is: 0.0365÷24 =0.00152m/h. The second is using head boundary condition after the surface pore pressure approach 0 : the surface matrix suction is 0.

2 Anti-seepage calculation results and analysis

In this paper, the ABAQUS software is used to conduct 3 kinds of caculation about moisture content changes. These three kinds of situations are no seepage measure, anti-seepage measure 0.5 m and anti-seepage measure 1.0. Figure 4 is different location node marker in subgrade. The saturation distribution map of three schemes are showed in figure 5 to 7.

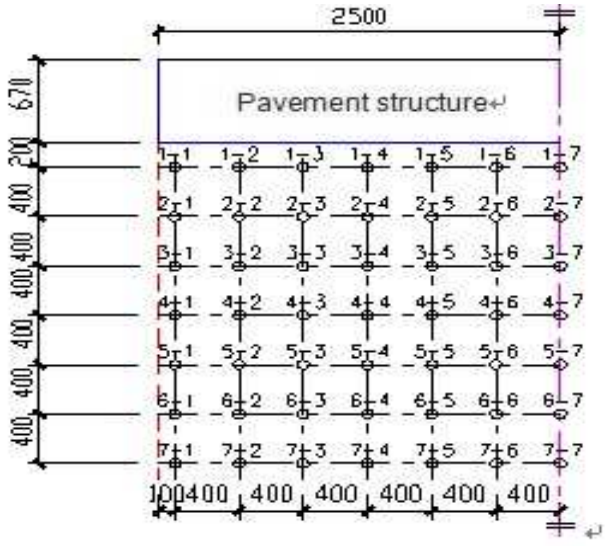

Fig.4 Different location node diagram in subgrade

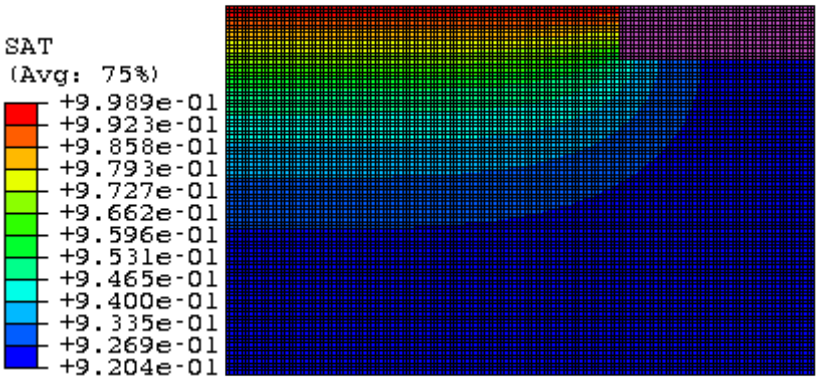

Fig. 5 Water content after no anti-seepage measure

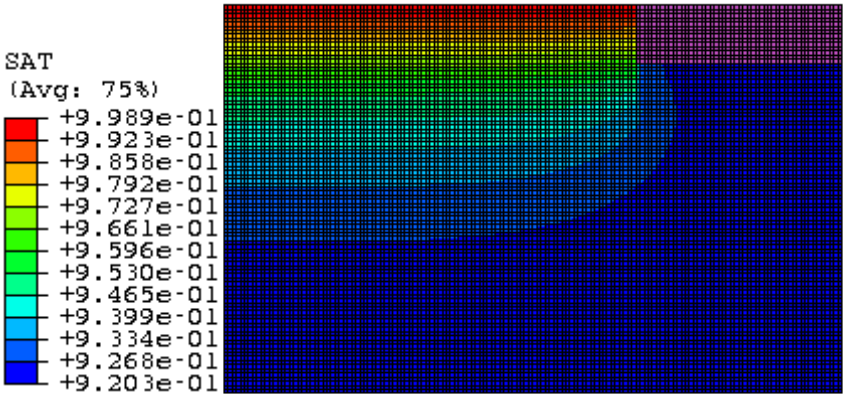

Fig. 6 Water content at 0.5 m after anti-seepage measure

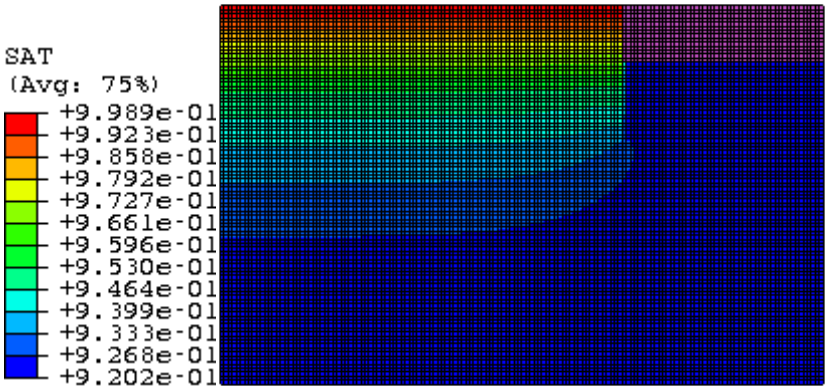

Fig. 7 Water content at 1.0 m after anti-seepage measure

Figure 5 is no anti-seepage measure. Changes of water content caused by rainfall have directly effect on roadbed, which will lead to remarkable expansion deformation. Figure 6 ~ 7 are anti-seepage measure. The moisture content changes occur under the seepage film. With the increasing of seepage depth, the infiuence of roadbed will be reduced.

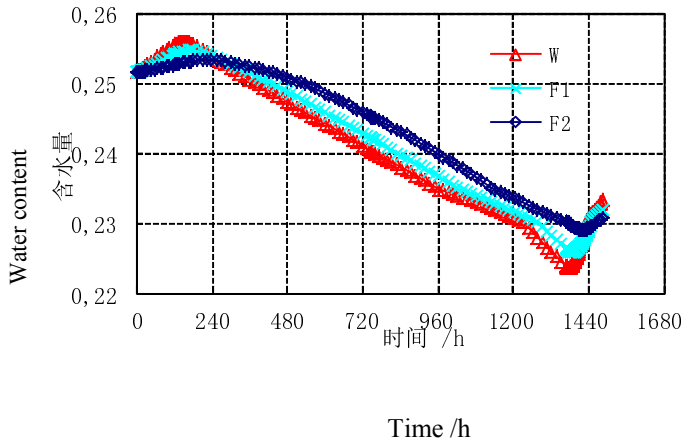

Fig. 8 Curve of water content at 2-2 section in subgrade

Figure 8 is subgrade of node 2-2 ( in figure 4) moisture content curve. The W means no seepage control scheme, F1, F2 refer seepage control scheme 1, 2 respectively. As it showed in figure 8, after take anti-seepage measure, the curve is more smooth.Seepage scheme can reduce the deformation of expansive soil.

## Conclusions

Through the above analysis, we can draw the following conclusions:
(1) Expansion and deformation of subgrade soil depends on the distribution and changes of moisture content, anti-seepage measures can reduce the extent and inhomogeneity of water content in subgrade soil.
(2) Anti-seepage measures can reduce the non-uniform deformation of subgrade soil. Therefore, the non-uniform deformation of pavement structure will be reduced after take anti-seepage measures.
(3) Moisture content in subgrade soil are significantly declined after using anti-seepage measure under rainfall. Because of water seepage channel was obstructed by anti-seepage measures, and the effect of anti-seepage measures are more obvious with the improvement of seepage depth.

**Keyword**: soft rock roadway; deformation; mechanical mechanism; support technology

**Abstract:** The deformation and support technology of soft roadway is a very important problem in mine. Based on the roadway's deformation of Jian Xin Mine of Jiangxi Fengcheng Mining Bureau, the mechanics mechanism and reasons of the soft rock roadway deformation are analyzed. And the three kinds of support technologies which are suitable for soft rock roadway are put forward. The support technologies have been used in the soft rock roadway of coal mine and have achieved good results. The research has important reference value for soft rock roadway supporting technology and its stability maintenance.

## Introduction

In recent years, the pressure control and supporting problem of soft rock mine roadway is more and more brought to the attention of the experts with the increasing of mining depth [1-3]. In our country, many mines have great difficulty in soft rock roadway supporting and become the main factors that influence the mine development and the economic benefit [4]. The buckling deformation of soft rock roadway excavation happens easily, and it shows as floor heave and two roadsides crowded and folded, roof causes layer off the top or roof fall, etc by fracture and abscission. When using the traditional supporting of soft rock roadways, it results in roadway maintenance difficulties, disrepair seriously, high maintenance costs for many times, low mine production efficiency [5-6]. The depth of Jiangxi Jian Xin Mine is -700m at present, thereby the pressure is high, the litho logy is poor and the roadway had several large deformations. Combined with the actual situation of Jian Xin Mine, this paper describes support technology of deep soft rock roadway briefly, provides support and references for mining for deep coal rock roadway excavation safety.

## Project overview

Jian Xin Mine is located in the north of Qujing syncline in Xianguling Mine. The overall structure of the mine is monoclinic, the strata is the North-East and East-West, dip direction is South and Southeast and the inclination angle is 8° to 10°.The mine develops a structural anticline—Xiufangshan anticline, it is located in the secondary level West Wing mining area, axial is between N40°-60°E, the inclination angle is 0° to 8°,the local rises, south west inclines, exposes in the western mountain and Xiufangshan line, east wing rock strata dips and the dip angle is small, the west wing steepens and dip is 12°- 25°。

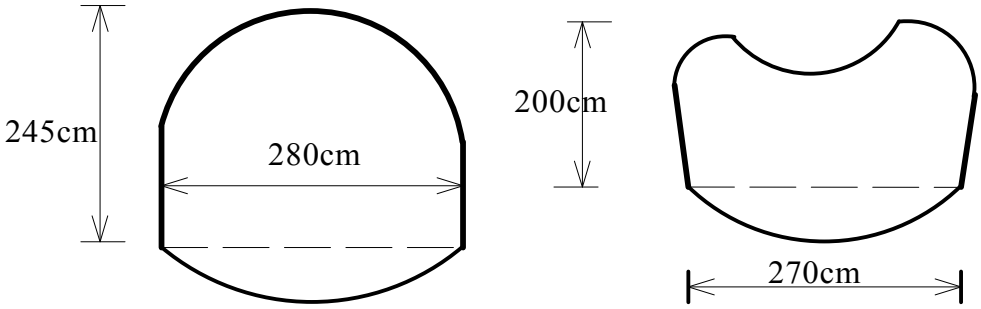
## Deformation and mechanics mechanism

### 3.1 Deformation

Due to deep mining and poor geological conditions, many roadways deform in Jian Xin Mine. The typical is the 7 # in the central panel of the wind roadway, the deformation of the roadway is shown in Fig. 1. Field test demonstrates that the original arch turns to concave, arch point sink

generally and the maximum arch deformation of the most serious transverse section is about 60 cm, as shown in Fig.2.

Fig.1 Deformation of the roadway



（a）design pattern （b） deformation pattern

Fig.2 Design chart of the roadway

**3.2 Gravity stress of Rock mass**

With the roadway depth increasing, the internal elastic energy stored in rock mass increases. When roadways be excavated, rock mass stress state disturbances, the original stable three dimensional stress field to unstable two-dimensional stress field and release huge strain energy which can lead to deformation and failure of roadways. Especially for deep soft rock roadways, this situation is more obvious. Buried depth on the surrounding rock affects deformation of roadway strongly; it may cause damage because of large deformation fast and instability if not take effective support timely.

**3.3 Geological condition**

The stability of the roadway not only depends on the strength of the rock itself, more important is on the geological conditions of roadway. This includes the development situation of rock mass, groundwater, etc. Generally, the more the geological structure of surrounding rock develops, the worse the integrity of the surrounding rock is and the more serious the deformation and failure of roadways are under the same pressure load. In addition, the groundwater is the important factors influencing the deformation of soft rock roadway excavation. Because the soft rock mostly contains minerals such as kaolinite, montmorillonite and others, it not only produces expansion strain and stress, causes uneven internal stress of rock mass, reduces the strength of the rock and leads to deformation serious when water molecules in rock mass.

**3.4 Environment disturbance**

The deep soft rock roadway excavation deformation is highly affected by the external disturbance. construction in adjacent roadways, mine moving on working face and so on change the size of soft rock’s stress, cause the non-uniform deformation of roadway and even instability.

**Support technology**

**4.1 Anchor combined support technology**

Anchor bolting is regarded surrounding rock as active supporting body and roadways anchor before the large deformation of roadway surrounding rock. By making full use of the bearing capacity of surrounding rock itself, taking variable load as the supporting body and making the whole of the surrounding rock formation to be a larger rigidity, abscission layer extension is prevented and reduced[7-8]. For further improving the stability of soft rock roadway excavation, bolt is often applied to bolt-mesh-spurting technology and bolt-grouting technology. In bolt mesh spurt technology, bolts anchor on no damage of rock mass to prevent surrounding rock loose deformation and failure, shotcrete is used closing surface of surrounding rock and the supporting bolt of surrounding rock in lays to prevent surface rock caving and the steel mesh laid in the spray layer increases the strength and flexible of the shotcrete layers and improves the integrity of the support. Anchor combined anchor, concrete spray layer and steel fabric closely with the surrounding rock bear the weight together, it gives full play to the bearing capacity of surrounding rock, provides timely resistance in the process of deformation with the surrounding rock together and limit excessive deformation of surrounding rock to maintain the stability of roadway.

Bolt-grouting support is closing the surrounding rock of roadway with shotcrete to prevent further weathering of surrounding rock after the roadway excavation, and then putting bolt-grouting anchors into the surrounding rock grouting for reinforcement. Bolt-grouting anchor has both the characteristics of bolt support and grouts through this bolt grouting to surrounding rock. Through grouting, grout filling and pressure dense fissure space, the unconstrained loose state of the surrounding rock before grouted into joint support system adapted to the complex state of stress and strain (compression, shear, tensile)with the combined action of the rock, slurry and the surrounding rock.

Jian Xin Mine's roadways are buried deeply, complicated geological conditions, long service life and the serious deformation. In roadways repair reinforcement, it effectively control the deformation of surrounding rock by using the above technology, ensure the stability of roadway, achieve good socioeconomic benefits.

**4.2 U-shape compressible support and wall backfilling technology**

Its greatest advantage is that when the surrounding rock pressure reaches a certain value, the u-shaped bracket occurs to yield reduction and a result of yield is decreasing surrounding rock pressure acting on the support, avoiding the support destruction caused by the surrounding rock pressure is greater than the bearing capacity of the stent and ensuring the normal use of roadway. But new roadway surroundings are uneven and cause stress concentration because it contacts the smooth u-shape support unevenly. In order to reduce the uneven contact, between u-shape flexible support and roadway wall, it often packs some adhesive materials to make the force uniform. After filling in the back of the wall, the interactive system of roadway surrounding rock and support changes from the "support - surrounding rock" system without wall backfilling into the trinity function system of "support –filling layer-surrounding rock". Support and filling layer makes up the composite support structure and it makes the change from the effect alone of support on filling layer without wall after filling into the interaction of the support and filling layer together on surrounding rock. Through the wall pack will support and surrounding rock couplet one, form the joint bearing, more advantageous to play since the bearing capacity of surrounding rock. After wall filling with concrete jet u-shape set direct injection filling, filling is close-grained, not only effect is good, and construction craft simple, the technical main point easy to grasp, greatly reduces the labor intensity of workers, to speed up the advance. U-shape Steel support wall backfilling with concrete spraying machine grouting directly and filling is filling density and good effect, and the construction process is simple, the technical essentials is easy to master, greatly reduces the labor intensity of works and accelerates the driving speed.

### 4.3 Secondary coupling support technology

In general, with soft roadway having the features of deforming speedily, large deformation and long creep duration, etc, therefore roadway is quick to pressure, pressure big, low success rate of one supporting after roadway excavation. According to the principle of the combination of supports and surrounding rock, control technology of soft rock roadway's surrounding rock is used with a certain deformation of the flexible supports and carries on the secondary support. One flexible supporting depressurization leads to the rock stress reaching the mechanical equilibrium under lower deformation rate, and it gives full play to the bearing capacity of surrounding rock. The stiffness of secondary support reduces the deviatory stress of rock mass of roadway, decreases the tangential stress of surrounding rock of roadway relatively, increases the radial stress relatively and promotes the stress stability of surrounding rock. Flexible support is anchor support, bolt-grouting support or the combined support of anchor and metal net, the stiffness of support is used stone arch or u-shaped bracket supporting method, etc.

## Conclusions

The supporting technology of soft rock roadway excavation is a complicated work, especially in the poor condition called "three high and one disturbance" after the deep mines transfer. And the stability of surrounding rock of roadway is the important premise of the mine economic benefits and the security situation. Therefore, it is necessary to study the deformation mechanism of deep soft rock roadway excavation and determine the reasonable way of supporting technology are the. Under the condition of deformation mechanism of soft rock roadway excavation in the specific analysis, Jian Xin Mine gets the ideal supporting effect with the supporting technology combined a variety of techniques.

[c]email: dennis19900828@gmail.com

**Keywords:** Contaminant Extraction; Smear Effect; Analytical Solution; Well Injection Depth Extraction (WIDE)

**Abstract.** The smear zones are usually caused by the installation of vertical drains in fine-grained soil. An analytical solution for contaminant extraction using well injection depth extraction (WIDE) system considering the smear effect was developed. The injection rate was assumed to be equal to the retrieval rate to maintain full saturation and steady-state seepage flow. The results obtained by the proposed analytical solution agree well with those obtained from the finite element method. An illustrative example was presented to show the influence of the smear zones and results reveal that the smear zone can have a great influence on the contaminant extraction from soils. The 500-hour base concentration of acetone in the middle of the contaminated soil increases by a factor of approximately 1.9 when the effect of the smear zone is considered in the model.

## Introduction

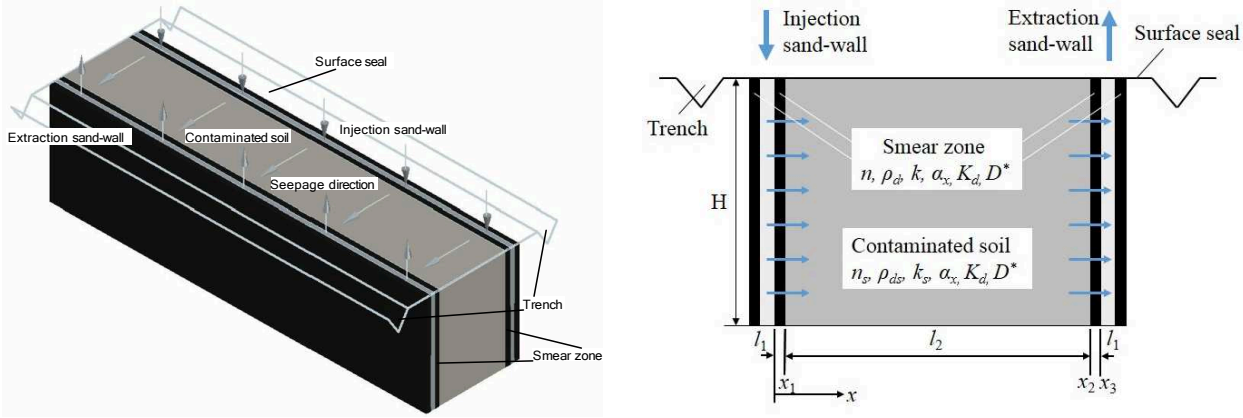
Well injection depth extraction (WIDE) is an improved pump-and-tread system in which prefabricated vertical wells (PVW) installed in a relatively close spacing shorts the flow path. It is demonstrated to be effective for depth-specific removal of contaminants in fine-grained soils [1-3]. Welker et al. [1] developed MODFLOW with MT3D method to numerically model the bench-scale PVD remediation system. Sharmin et al. [2] analyzed the impact of the extraction process of WIDE technology on the groundwater head distribution and contaminant transport using the finite element model. Although many sophisticated problems must be solved numerically, simplified analytical solutions are still an economical and efficient alternative to the numerical models. Gabr et al. [3] presented the analytical solution for contaminant extraction through an axisymmetric model.

The installation of vertical drains by means of a mandrel causes significant remolding of the subsoil, especially in the immediate vicinity of the mandrel [4-6]. The characteristics of the smear zone investigated using a large-scale consolidometer are found with reduced permeability, decreased water content and increased compressibility [4, 5]. Therefore, it is of great importance to research the smear effect on contaminant extraction in contaminated soils.

In this paper, an analytical solution of 1D contaminant extraction using WIDE system considering the smearing effect is obtained under conditions of steady-state flow. In order to simplify the sophisticated problem and emphasize the smear effect on contaminant extraction, the PVWs are substituted by sand-wall (Fig. 1). The presented model is described as an idealized three-zone model, where the smear zone is the disturbed region in the immediate vicinity of the sand-wall, and the middle zone is the intact region. The results obtained by the proposed method are compared with those obtained by the finite element method (FEM). An illustrative example is performed to investigate the smear effect based on the proposed analytical solution.

**Mathematical model**

As shown in Fig. 1, the flushing solutions are injected through a row of sand-wall, and retrieved through another row of sand-wall that runs parallel to the injection sand-wall, and the rate of the injection which remains constant is equal to the rate of the extraction. The model mainly includes the sand-walls, the smear zones, and the undisturbed contaminated soil which are considered to be homogeneous and fully saturated. The co-ordinate x has its origin at the border of the injection sand-wall, and its direction is parallel to the ground surface. It is assumed that the piezometric heads in the injection sand-wall and extraction sand-wall are steady. Based on Darcy's law, the flow of the flushing solution can be occurred only in the x direction and if the piezometric heads in the injection sand-wall and extraction sand-wall are fixed, the seepage velocity must be invariable.



(a) Spatial pattern (b) Analysis scheme

**Fig. 1** Schematic diagram of contaminant extraction considering smear zones.

The governing equation for solute transport through the smear zones and the undisturbed contaminated soil at a particular distance $x$ and time $t$ is:

$$R_{di}\frac{\partial C_i(x,t)}{\partial t}=D_i\frac{\partial^2 C_i(x,t)}{\partial x^2}-\frac{1}{n_i}\frac{q_x\partial C_i(x,t)}{\partial x}\quad (i=1,2,3). \tag{1}$$

where $R_{d1}$, $R_{d3}$ are the retardation factors of the smear zone; $R_{d2}$ is the retardation factor of the undisturbed soil; $C_1$ is the contaminant concentration in the smear zone near the injection sand-wall; $C_2$ is the contaminant concentration in the undisturbed soil; $C_3$ is the contaminant concentration in the smear zone near the extraction sand-wall; $D_1$, $D_3$ are the coefficients of the hydrodynamic dispersion of the smear zone; $D_2$ is the coefficient of the hydrodynamic dispersion of the undisturbed soil; $n_1$, $n_3$ are the porosity of the smear zone, i.e. $n_s$; $n_2$ is the porosity of the undisturbed soil, i.e. $n$; and $q_x$ is the seepage velocity in the contaminated soil. Based on the Darcy's law, $q_x$ is determined as

$$q_x=k_H\frac{\Delta h}{L}=\frac{l_1+l_2+l_3}{l_1/k_s+l_2/k+l_3/k_s}\frac{\Delta h}{L}. \tag{2}$$

where $k_H$ is the horizontal equivalent permeability coefficient; $k_s$, $k$ are the permeability coefficients of the smear zone and the undisturbed soil, respectively; $\Delta h$ is the water head difference between the injection sand-wall and extraction sand-wall; $l_1$, $l_3$ are the width of the smear zone; $l_2$ is the width of the undisturbed soil; and $L$ is the span between the injection sand-wall and the extraction sand-wall.

Using the Henry's law, $R_{di}$ can be represented as follows:

$$R_{di} = 1 + \rho_{di} K_d / n_i \quad (i = 1, 2, 3) . \tag{3}$$

where $\rho_{d1}$, $\rho_{d3}$ are dry bulk density of the smear zone, i.e. $\rho_{ds}$; $\rho_{d2}$ is dry bulk density of the undisturbed soil, i.e. $\rho_d$; and $K_d$ is the equilibrium distribution coefficient. For the soil type of the smear zone and undisturbed zone are same, $K_d$ in both smear zone and undisturbed soil are assumed to be the same.

Based on Eq. (2), $D_i$ can be determined by

$$D_i = D^* + \alpha_x k_H \frac{\Delta h}{n_i L} . \tag{4}$$

where $D^*$ is the effective diffusion coefficient; and $\alpha_x$ is the dispersivity of the x direction, likewise, $D^*$ and $\alpha_x$ in both regions are assumed to be the same.

The initial condition is

$$C_i(x, 0) = C_0 \quad (i = 1, 2, 3) . \tag{5}$$

where $C_0$ is the initial contaminant concentration in the contaminant zone.

For the left boundary, the contaminant concentration of the flushing solution is zero:

$$C_1(0, t) = 0 . \tag{6}$$

The Neumann boundary condition is considered at the right boundary:

$$\frac{\partial C_2(x, t)}{\partial x}\Big|_{x=L} = 0 \tag{7}$$

The contaminant concentration at the interface of the smear zone and the undisturbed zone are the same, and the continuity of the contaminant flux must be obeyed as well:

$$-n_i D_i \frac{\partial C_i(x_i, t)}{\partial x} + q_x C_i(x_i, t) = -n_{i+1} D_{i+1} \frac{\partial C_{i+1}(x_i, t)}{\partial x} + q_x C_{i+1}(x_i, t) \quad (i = 1, 2) . \tag{8}$$

$$C_i(x_i, t) = C_{i+1}(x_i, t) \quad (i = 1, 2) . \tag{9}$$

**Analytical solution**

Similarly to the problem of one-dimensional consolidation of layered systems, the method of separation of variables is applied. The solution to the governing Eq. (1) satisfying the boundary conditions given by Eqs. (6), (7) and the continuity conditions given by Eqs. (8), (9) can be expressed as follows:

$$C_i(x,t) = C_0 e^{\frac{q_x x}{2n_i D_i} - \frac{q_x^2 t}{4n_i^2 R_i D_i}} \sum_{m=1}^{\infty} \xi_m g_{im}(x) e^{-\beta_{im} t} \quad (i = 1,2,3) \tag{10}$$

where

$$g_{im}(x) = A_{im} \sin\left(\mu_i \lambda_{im} \frac{x}{l_1}\right) + B_{im} \cos\left(\mu_i \lambda_{im} \frac{x}{l_1}\right), \qquad \lambda_{im} = l_1 \sqrt{\frac{R_{d1}\beta_{im}}{D_1}}, \qquad \mu_i = \sqrt{\frac{R_{di} D_1}{R_{d1} D_i}},$$

$$\xi_m = \frac{e^{\frac{q_x x_1}{n_1 D_1} + \frac{q_x x_2}{n_2 D_2}} \int_0^{x_1} g_{1m}(x) e^{-\frac{q_x x}{2n_1 D_1}} dx + \frac{R_{d2} n_2}{R_{d1} n_1} e^{\frac{q_x x_1}{n_2 D_2} + \frac{q_x x_2}{n_2 D_2}} \int_{x_1}^{x_2} g_{2m}(x) e^{-\frac{q_x x}{2n_2 D_2}} dx + e^{\frac{q_x x_2}{n_3 D_3} + \frac{q_x x_1}{n_2 D_2}} \int_{x_2}^{L} g_{3m}(x) e^{-\frac{q_x x}{2n_3 D_3}} dx}{e^{\frac{q_x x_1}{n_1 D_1} + \frac{q_x x_2}{n_2 D_2}} \int_0^{x_1} g_{1m}^2(x) dx + \frac{R_{d2} n_2}{R_{d1} n_1} e^{\frac{q_x x_1}{n_2 D_2} + \frac{q_x x_2}{n_2 D_2}} \int_{x_1}^{x_2} g_{2m}^2(x) dx + e^{\frac{q_x x_2}{n_3 D_3} + \frac{q_x x_1}{n_2 D_2}} \int_{x_2}^{L} g_{3m}^2(x) dx}$$

The coefficients $A_{im}$ and $B_{im}$ can be determined by the following recurrence equation:

$$\left.\begin{aligned} &\left[A_{1m} \quad B_{1m}\right]^T = \left[1 \quad 0\right]^T \\ &\left[A_{(i+1)m} \quad B_{(i+1)m}\right]^T = S_{im} \left[A_{im} \quad B_{im}\right]^T \quad (i = 1,2) \end{aligned}\right\}. \tag{11}$$

in which:

$$S_{im} = \zeta_i \begin{bmatrix} E_{im}F_{im} + \eta_i G_{im}H_{im} & E_{im}H_{im} - \eta_i G_{im}F_{im} \\ G_{im}F_{im} - \eta_i H_{im}E_{im} & G_{im}H_{im} + \eta_i E_{im}F_{im} \end{bmatrix}, \quad E_{im} = \sin\left(\mu_{i+1}\lambda_{(i+1)m} \frac{x_i}{l_1}\right), \quad F_{im} = \sin\left(\mu_i \lambda_{im} \frac{x_i}{l_1}\right),$$

$$G_{im} = \cos\left(\mu_{i+1}\lambda_{(i+1)m} \frac{x_i}{l_1}\right), \quad H_{im} = \cos\left(\mu_i \lambda_{im} \frac{x_i}{l_1}\right), \quad \zeta_i = e^{-(\frac{q_x}{2n_{i+1}D_{i+1}} - \frac{q_x}{2n_i D_i})x_i}, \quad \eta_i = \frac{n_i \lambda_i}{n_{i+1}\lambda_{i+1}} \sqrt{\frac{D_i R_{di}}{D_{i+1} R_{d(i+1)}}}$$

The determinant of the following which is equal to zero yields the values of $\lambda_{im}$:

$$\left| S_3 \cdot S_2 \cdot S_1 \cdot \left[1 \quad 0\right]^T \right| = 0 \tag{12}$$

in which

$$S_3 = \begin{bmatrix} \frac{\lambda_{3m}}{l_1} \sqrt{\frac{R_{di} D_1}{R_{d1} D_i}} H_{3j} + \frac{q_x}{2n_3 D_3} F_{3j} \\ -\frac{\lambda_{3m}}{l_1} \sqrt{\frac{R_{di} D_1}{R_{d1} D_i}} F_{3j} + \frac{q_x}{2n_3 D_3} H_{3j} \end{bmatrix}^T, \quad \lambda_{1m}^2 = \lambda_{3m}^2 = \lambda_{2m}^2 + (\frac{q_x^2}{4n_2^2 R_{d2} D_2} - \frac{q_x^2}{4n_1^2 R_{d1} D_1}) \frac{l_1^2 R_{d1}}{D_1}$$

**Comparisons with the finite element method**

To demonstrate the method is reasonable and verify the analytical solution gives the correct results, the proposed analytical solutions are compared with the finite element method (FEM) provided by

GeoStudio 2007. The width of the sand-wall is assumed to be 4cm and smear zone is taken to be 0.1m, which is 2.5 times the width of the mandrel based on large-scale consolidation studies, as described by Sathananthan et al. [4]. The porosity and permeability in the undisturbed contaminated soil and the smear zone are extracted from Indraratna et al. [5, 6]. Toluene is chosen to represent the contaminant in the soil, and the initial constant concentration of toluene is assumed to be 1mg/L. The material and chemical properties of the soil are taken directly from Foose et al. [7] for the similar property of the compacted clay liner from Foose et al. [7] and the clay used in Indraratna et al. [5]. The properties of the undisturbed zone and smear zone are shown in Table 1.

The comparisons of contaminant concentration profiles in contaminated soil consisting of two smear zones and an undisturbed zone obtained by the presented analytical solution and GeoStudio 2007 are shown in Fig.2. The presented analytical solutions are agreed with the results obtained by the finite element method excellently. This result further validates the proposed analytical solutions.

**Table 1** Parameters of the model for comparison with GeoStudio 2007

| **Soil type** | $n_s$ | $n$ | $\rho_d$[g/cm$^3$] | $\rho_{ds}$[g/cm$^3$] | $k$[cm/s] | $k_s$[cm/s] |
|---|---|---|---|---|---|---|
| Clay | 0.52 | 0.55 | 1.25 | 1.30 | $3.36\times10^{-7}$ | $2.7\times10^{-8}$ |
| **Contaminant** | $K_d$[ml/g] | $D^*$ [cm$^2$/h] | $\alpha_x$[m] | $\Delta h$[m] | $l_1$, $l_3$[cm] | $l_2$[cm] |
| Toluene | 1.0 | $7.34\times10^{-3}$ | 2.0 | 12 | 10 | 80 |

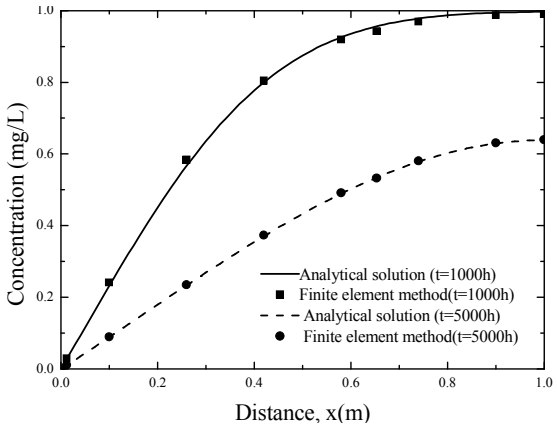


**Fig. 2** Comparisons of the analytical solution with the finite element method

## Results and discussion

An illustrative example is presented to show the influence of the smear zones. Acetone is selected to represent the contaminant in the soil. The initial constant concentration of acetone is assumed to be 1mg/L. The diffusion and distribution coefficients of the clay are from Kalbe et al. [8]. The properties of the smear zone and the undisturbed zone are extracted from Indraratna et al. [5, 6]. The material and the chemical properties of the undisturbed zone and smear zone are summarized in Table 2.

**Table 2** Parameters of the model for analysis

| **Soil type** | $n_s$ | $n$ | $\rho_d$[g/cm$^3$] | $\rho_{ds}$[g/cm$^3$] | $k$[cm/s] | $k_s$[cm/s] |
|---|---|---|---|---|---|---|
| Clay | 0.52 | 0.55 | 1.25 | 1.30 | $3.9\times10^{-8}$ | $3.4\times10^{-9}$ |
| **Contaminant** | $K_d$[ml/g] | $D^*$ [cm$^2$/h] | $\alpha_x$[m] | $\Delta h$[m] | $l_1$, $l_3$[cm] | $l_2$[cm] |
| Acetone | 0 | $1.22\times10^{-2}$ | 2.0 | 12 | 10 | 30 |

Two conditions are considered for this discussion. The comparison of the concentration profile for the case considering the effect of the smear zone and that assuming no smear zone is shown in Fig. 3.

Both concentration profiles of the two cases are obtained on the basis that the water head difference is maintained at 12m, and correspondingly the seepage velocities of the two cases are $6.49\times10^{-6}$m/h and $3.37\times10^{-5}$m/h respectively. The 500-hour base contaminant concentration at the distance of 0.25m decreases from 0.88 for the case considering the smear zone to 0.46 for that assuming no smear zone. Meanwhile, the contaminant concentration at the distance of 0.5m decreases from 0.996 to 0.66 when the smear zone is not considered in the model. The results suggest that the smear zone has a great effect on the contaminant extraction from contaminated soils.

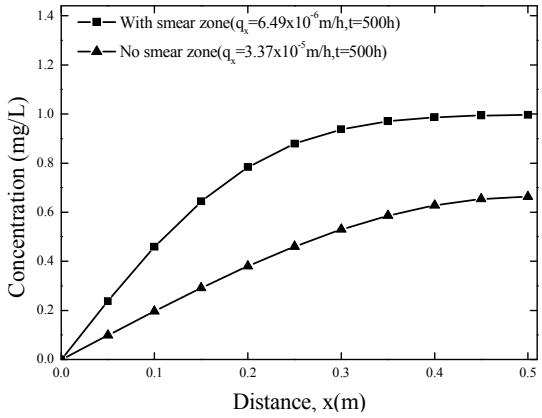

**Fig. 3** Effect of smear zone on contaminant concentration profiles.

## Conclusions

An analytical solution for one-dimensional contaminant extraction considering the effect of the smear zone is presented in this paper. The results obtained by the proposed analytical solution agree well with those obtained by the finite element method. The results suggested that the smear zone can have a great influence on the contaminant extraction from contaminated soils. The 500-hour base concentration of acetone at the distance of 0.25m increases by a factor of approximately 1.9 when the effect of the smear zone is considered in the model.

**Keywords:** Fuzzy logic, ANFIS, Slope stability prediction.

**Abstract.** An artificial intelligence tools, Adaptive Neuro Fuzzy Inference System (ANFIS), was used in this study to predict the stability of slopes. Data used in this study were 300 various designs of slope. Those designs were created by using Slope/W which calculated factors of safety using various limit equilibrium methods (LEM) such as Bishop, Spencer and Morgenstern-Price. The input parameters consisted of height of slope, H (1–10 m), unit weight of slope material, $\gamma$ (15-22 kN/m$^3$), angle of slope, $\theta$ (11.31°-78.69°), coefficient of cohesion, c (0-50 kN/m$^2$) and internal angle of friction, $\phi$ (20°- 40°) and the output parameter is the factor of safety. To build the fuzzy inference system, 243 rules were used at 60 epochs. The number of membership function for the any input was three and the type of membership function for output was linear. ANFIS obtained regression square ($R^2$) of one for Bishop, one for Janbu, one for Morgenstern-Price and one for Ordinary. The result proved that ANFIS may possibly predict the safety factor with good precision and nearly to the target data.

## Introduction

An exposed ground surface that stands at an angle with the horizontal is called slope. Slope stability problem has been an important issue in geotechnical engineering. Slope failure is a common natural disaster which takes place around the world. The evolution of slope stability analyses in geotechnical engineering has followed closely the developments in soil. Geotechnical engineers have to pay particular attention to geology, ground water and shear strength of soils in assessing slope stability. Therefore, slope investigation and classification are important for the community [1,2,3,4,5].

Geotechnical engineers frequently use limit equilibrium methods (LEM) of analysis when studying slope stability problems. The methods of slices have become the most common methods due to their ability to accommodate complex geometrics and variable soil and water pressure conditions. During the past three decades approximately one dozen methods of slices have been developed. They differ in (i) the statics employed in deriving the factor of safety equation and (ii) the assumption used to render the problem determinate [6,7,8,9].

System modeling based on conventional mathematical tool is not well suited for dealing with ill-defined and uncertain systems. By contrast, a fuzzy inference system (FIS) employing fuzzy if-then rules can model the qualitative aspects of human knowledge and reasoning processes without employing precise quantitative analyses. This fuzzy modeling or fuzzy identification, first explored systematically by Takagi and Sugeno, has found numerous practical applications in control, prediction and inference. However, there are some basic aspects of this approach which are need of better understanding. More specifically (i) no standard methods exist for transforming human knowledge or experience into the rule base and database of a fuzzy inference system, (ii) there is a need for effective methods for tuning the membership functions (MFs) so as to minimize the output error measure or maximize performance index [10,11,12,13,14].

Fuzzy if-then rules or fuzzy conditional statements are expressions of the form *IF A then B*, where *A* and *B* are labels of fuzzy sets characterized by appropriate MFs. Due to their concise form, fuzzy if-then rules are often employed to capture the imprecise modes of reasoning that play an

essential role in the human ability to make decisions in an environment of uncertainty and imprecision. Another form of fuzzy if-then rules, proposed by Takagi and Sugeno, has fuzzy sets involved only in the premise part. Both types of fuzzy if-then rules have been used extensively in both modelling and control. Through the use of linguistic labels and MF, a fuzzy if-then rule can easily capture the spirit of "rule of thumb" used by humans. From another angle, due to the qualifiers on the premise parts, each fuzzy if-then rule can be viewed as local description of the system under consideration [10,15,16,17].

Fuzzy inference systems (FIS) are also known as fuzzy-rule-based systems, fuzzy models, fuzzy associative memories (FAM), or fuzzy controllers when used as controllers. Basically a fuzzy inference system is composed of five functional blocks: (1) a rule base containing a number of fuzzy if-then rules, (2) a database which defies the membership function of the fuzzy sets used in the fuzzy rules, (3) a decision-making unit which performs the inference operations on the rules, (4) a fuzzification interface which transforms the crisp inputs into degrees of match with linguistic value, (5) a defuzzification interface which transform the fuzzy results of the inference into crisp output. Usually, the rule base and the database are jointly referred to as the knowledge base [10].

Depending on the types of fuzzy reasoning and fuzzy if-then rules employed, most fuzzy inference systems can be classified into three types: (1) the overall output is the weighted average of each rule's crisp output induced by the rule's firing strength and output MF, (2) the overall fuzzy output is derived by applying "max" operation to the qualified fuzzy outputs, (3) Takagi and Sugeno's fuzzy if-then rules [10,15,18,19,20].

The power of Artificial Intelligent (AI) becomes more authoritative when the system is programmed to cater the need of complex applications. Adaptive Neuro-fuzzy Inference System (ANFIS) Model using neuro adaptive learning techniques which are similar to those of neural networks was originally presented by Jang. Given an input/output data sets, ANFIS constructs FIS whose MF parameters are adjusted using back propagation algorithm or other similar optimization techniques. Hence, the advantages of a fuzzy system can be combined with a learning algorithm [21,22,23,24].

## Methodology

The methodology for this study could be divided into three steps; (i) Designing slopes. Height of slope (H), unit weight of soil (γ), angle of slope (θ), coefficient of cohesion (c) and internal angle of friction ($\phi$) were used as input parameters. To design the slopes, many possibilities were considered for the input parameters by fixing some of them and changing the others. The angles of slope were calculated by considering horizontal and vertical length of the slope, (ii) Calculation of safety factors. Slope/W which applied limit equilibrium methods i.e. Bishop, Janbu, Morgenstern-Price and Ordinary, was used to compute factors of safety for 300 different designs. The comprehensive formulation of the software made it possible to easily analyze both simple and complex slope stability problems using a variety of methods, (iii) Adaptive Neuro-Fuzzy Inference Systems (ANFIS) prediction. After carrying out the stability analyses, ANFIS was used to formulate the mapping from a given input to an output. For this research, linear output and 243 rules were used for generating fuzzy inference system (FIS). For training the FIS, 60 epochs, hybrid method and zero errors tolerance were used. The mapping then provided a basis from which decisions could be made.

## Results and Discussion

The result of this research can be divided into three parts; (i) Designed slopes. In this research, 300 different designs of slopes were established. Different variables including height of slope (H), unit weight of soil (γ), angle of slope (θ), coefficient of cohesion (c), and internal angle of friction ($\phi$) were used as the input parameters for designing, (ii) Factors of safety. The results of the calculated

safety factors can be classified as (1) less than one, (2) greater than one, and (3) greater than 1.5, (iii) Prediction by Adaptive Neuro Fuzzy Inference Systems (ANFIS). By using 300 training data, ANFIS model was used as a function of different parameters. Prediction using ANFIS produced average percentage error of 0.0915 for Bishop, 0.0928 for Janbu, 0.0917 for Morgenstern-Price and 0.0935 for Ordinary. Figure 1 until 4 show the comparison of calculated factors of safety using LEM and predicted factors of safety using ANFIS. In addition, ANFIS obtained regression square ($R^2$) of one for Bishop, one for Janbu, one for Morgenstern-Price and one for Ordinary.

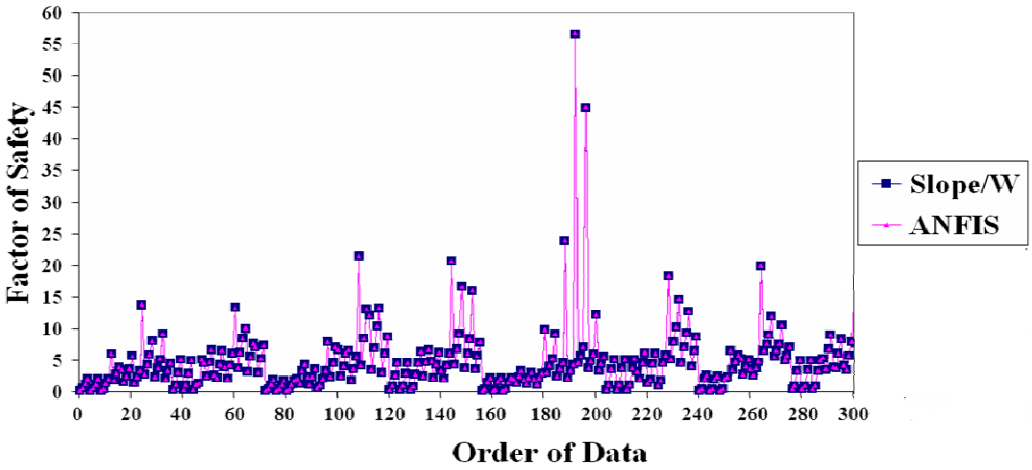

Fig.1 Comparison of calculated factor of safety using Bishop and predicted using ANFIS

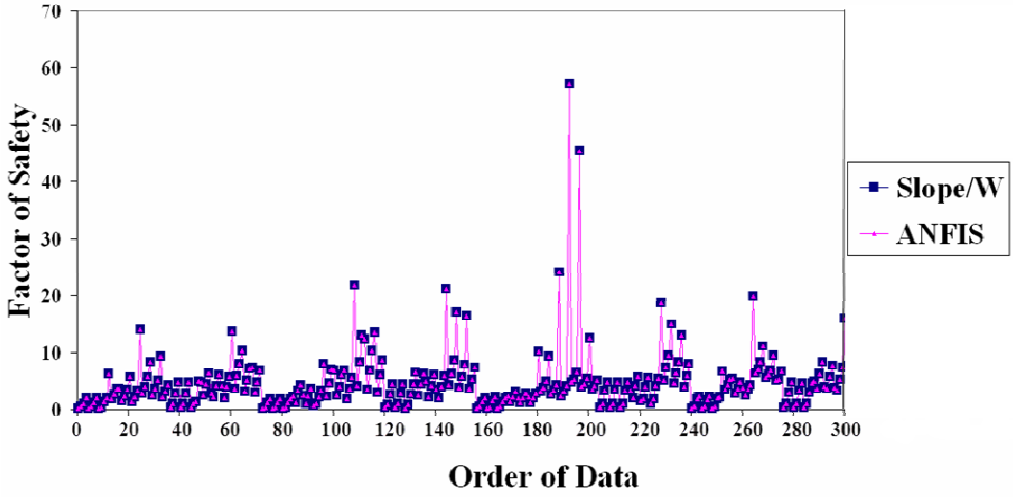

Fig.2 Comparison of calculated factor of safety using Janbu and predicted using ANFIS

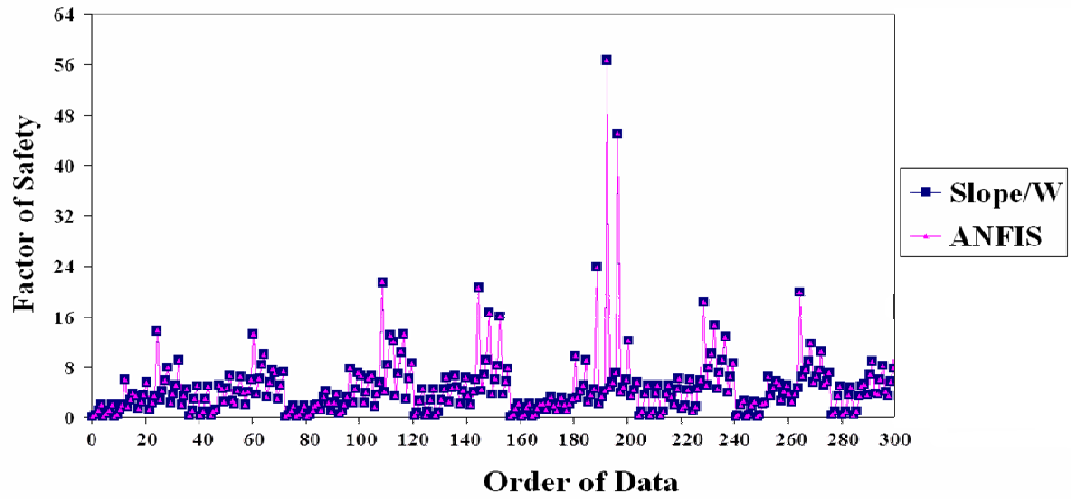

Fig.3 Comparison of calculated factor of safety using Morgenstern-Price and predicted using ANFIS

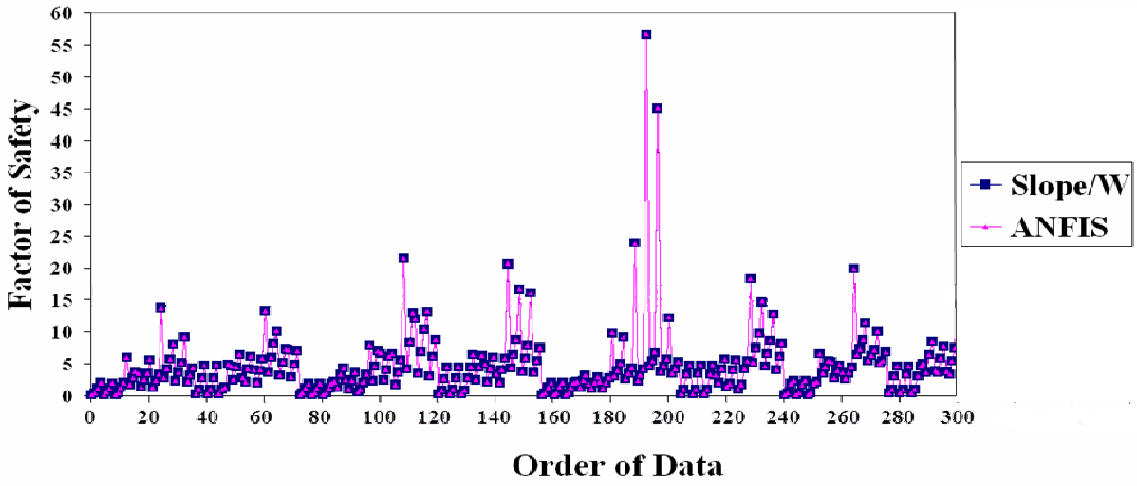

Fig.4 Comparison of calculated factor of safety using Ordinary and predicted using ANFIS

## Conclusion

As a conclusion, this research has achieved all the desired objectives. The results of this study can be considered as a major contribution to the field of knowledge since the use of Adaptive Neuro Fuzzy Inference Systems (ANFIS) for prediction of slope stability as carried out in this research has not been conducted before. The results show that ANFIS could really predict the factor of safety very well since the values of $R^2$ for all cases are very close to one and could predict the safety factors with high accuracy compared with other methods. Thus, ANFIS could be a suitable tool for predicting the stability of slope in future research.

**Keywords:** distributed optical fiber, post-grouting filling pile, bearing character

**Abstract.** The Static load test of the post-grouting filling pile in Zhengzhou city's third ring road rapidness project, uses strain gauge and distributed optical fiber to track and monitor the evolution rule of load-settlement, pile body stress, pile side resistance, etc., interprets bearing properties of large diameter post-grouting filling pile, contrasts and analyzes the monitoring data obtained by optical fiber and strain gauge at the same time. The result shows that, the monitoring effect of the pile body stress obtained by distributed optical fiber technology is superior to the strain gauge, but the data of them still needs to verify each other.

## Introduction

In recent years, with the development of optical fiber technology, the distributed optical fiber technology is widely used in geotechnical engineering and underground engineering [1-8]. Compared with the strain gauge, the measuring point of the distributed optical fiber is simple to embed, a higher monitoring precision and automatically collecting data, the ability to monitor continuously in a complex environment. So far the monitoring technology is mainly used to monitor the internal force of tunnel structure in geotechnical and underground engineering, rarely used in ground treatment. Thus, Through Zhengzhou city's third ring road rapidness project, the distributed optical fiber technology is applied to the large diameter post-grouting filling pile load test, analyzing the bearing character of the large diameter post-grouting pile and comparing with the monitoring data obtained by the strain gauge to discuss the applicability of the technology.

## Overview of Test

This test depends on the Zhengzhou city's third ring road rapidness project. Test area is located at crossing of Hanghai road and Jingguang road. The district is mainly the quaternary alluvium and the soil geotechnical properties are shown in Table 1.

Table 1 Soil physical and mechanical index

| Soil layer number | Soil | Depth (m) | Bearing capacity basic allowable value [$f_{a0}$] (kPa) | Pile flank friction force standard value $q_{ik}$ (kPa) | Soil layer introduction |
|---|---|---|---|---|---|
| ② | Floury soil | 15.30～18.20 | 200 | 50 | The most shallow buried, structural is poorer, engineering properties of groundwater is sensitive, not as foundation bearing layer of the project |

| | | | | | |
|---|---|---|---|---|---|
| ③$_1$ | Floury soil | 8.40～16.80 | 240 | 70 | No significant difference engineering properties, structural, not easily affected by groundwater are bearing layer can be used as a basis |
| ③$_2$ | Silty clay | 3.30～11.70 | 390 | 80 | |
| ③$_3$ | Floury soil | 7.60～21.20 | 220 | 70 | |
| ③$_4$ | Silty clay | | 410 | 80 | |

The single pile static load test was divided into six groups, one group of the piles was conducted without post-grouting, two groups were conducted post-grouting at the bottom of the pile, three groups were conducted composite grouting between the bottom of the pile and the side of the pile. Loading method is anchor-pile method. Maximum loading of test pile is 22000kN, the diameter of test piles is 1.2m, anchor-piles (using composite post-grouting) diameter is 1.5 m, the strength grade of the concrete is underwater C30, the length of the piles is 38m, and the depth inserted into the soil is 40 m. Before grouting, ultimate bearing capacity of the single pile is 9900kN. The plane position of the test pile and scene photos is shown in Fig. 1 and Fig. 2.

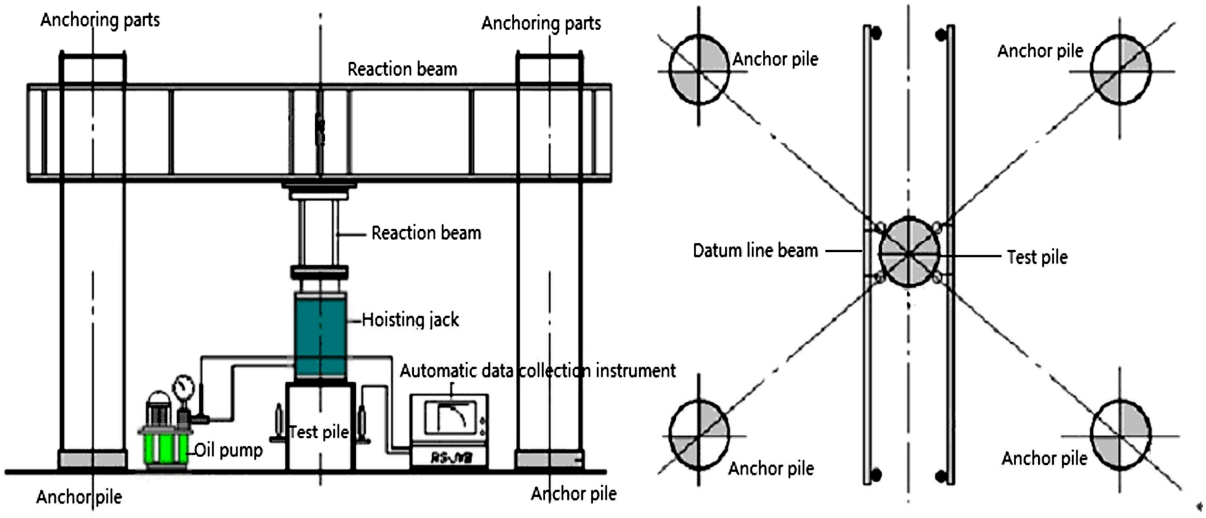

Fig. 1 The piles arrangement

Fig. 2 The scene photos of the static load test of single pile

**Monitoring of Distributed Optical Fiber**

**Basic Principle** Brillouin scattering is affected by strain and temperature at the same time. When the temperature along optical fiber changes or axial strain exists, the light frequency of the optical fiber in the back of the Brillouin scattering will drift, the degree of the frequency drift and the change of optical fiber strain and temperature had a good linear relationship, so by measuring the degree of the frequency drift of the back on to the natural optical fiber Brillouin scattering light can retained the information of the optical fiber temperature and strain distribution.

**Method of Embedding Optical Fiber Sensor** In the test, before lifting the first section of reinforcing cage, two relatively main reinforcements of steel cage were selected as distributed optical fiber's attachment objects, along the main reinforcements inside of the steel cage from bottom to up began tie the optical fiber, and maintain fiber straight when tying, close to the main reinforcement inside of the reinforcing cage, used nylon cable to tie every 100 mm to 150 mm to fix the optical fiber to ensure the uniform deformation of fiber and concrete. In order to avoid the adverse effect on the distributed optical fiber like break points in the pouring and construction process in the later stage at the same time. The optical fiber was protected with metal corrugate pipe when laying, then cling the bellows to reinforcing rib at the bottom of reinforcement cage to form "U" glyph circuits. Nylon cable ties were used to assemble in every 100mm and waterproof tape was adopted to waterproof. At the junctions of the main reinforcements and the reinforcing ribs of reinforcement cages, namely the transitions of the optical fiber from the main reinforcements to the reinforcing ribs and from the reinforcing ribs to the main reinforcements, where the hollow area was formed and optical fibers were easily damaged when pouring concrete, triangle plastic foam is adopted to fill in these areas and the foam is tied with waterproof tape in order to avoid water and cement paste flowing into the area when pouring concrete or post grouting and negative effect on the optic fiber, The photos of optic fibers banging are shown in Fig. 3 and Fig.4.

Lay the optical fiber at the head of pile. The protection tube of the pile is made of steel plate welded whose thickness is 5mm, the inner diameter 1200mm, the length 1.2 m. In order to avoid the damage when making the head of pile in later stage, the optical fiber shall be protected by metal corrugate pipe in a distance of 3.0m to the top of the pile, sealed with waterproof tape and loaded in PVC plastic pipe whose length is about 2.0m, fixing the PVC plastic pipe on steel cage's main bars with iron wires. The optical fibers above PVC plastic tube head were treated with waterproof tape and put them all in nylon bag and marked beside pile and buried them in the soil for protection.

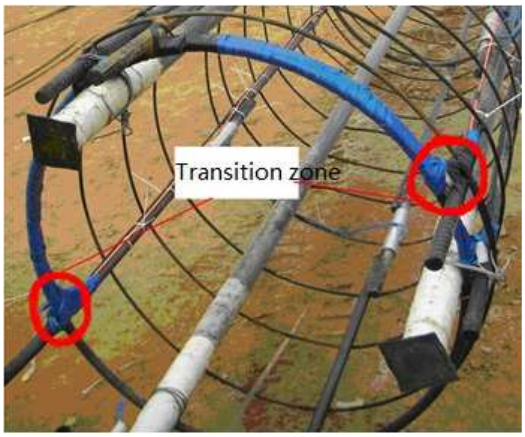

Fig. 3 Optic fibers laying at the bottom of the steel cage

Fig. 4 Optical fibers banging in the steel cage

After finishing the pile body concrete pouring, curing was asked for 28 days. Before the static load test of pile foundation, the optical fibers buried in the soil in the earlier stage were found out according to the mark to be butted joint to the optical fibers whose functions were just sensing with PCF fusing machine. Then circuit testing was conducted with BOTDR optical fiber strain analyzer to determine the effect of optical fiber welding quality.

**Data Collection** BOTDR instrument tracked and monitored the loading and unloading process of the test piles. The test of each stage of loading starts before the time when the displacement observation is stable 10 minutes. Next stage of loading was loaded (unloaded) after the data was collected. The initial strain value of the pile foundation load can be forecasted and obtained before the experiment and the strain can be considered to be the initial strain in free state. The difference between the strain produced by each stage of loading and the initial strain could be taken as the strain value in this stage of loading.

## Results Analysis of the Experiment

This experiment data is selected every 0.4 m. Pile 4 # (composite grouting in the side and bottom of pile) was taken as the analysis object. The data of composite grouting pile settlement, pile body parameters such as strain, stress and axial force were analyzed respectively, comparing the strain and the optical fiber strain data at the same time.

**P-s Curve** As is shown in Fig. 5, with the load increasing, the settlement of pile top increases gradually. The ultimate bearing capacity of single pile is 20000 kN.

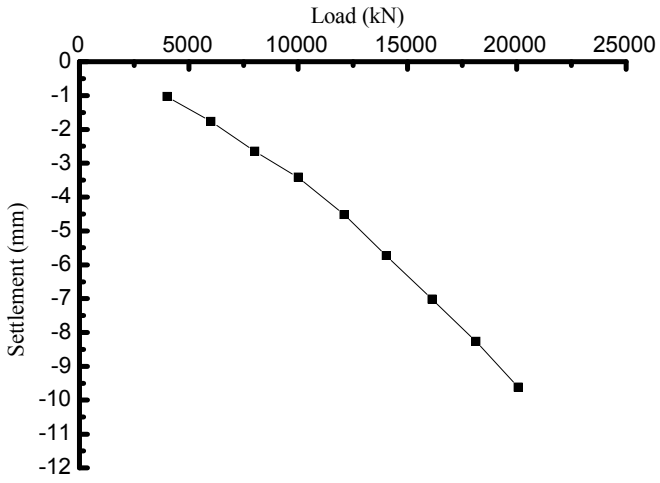

Fig. 5 The p - s curve of test pile 4#

**Pile Body Stress** Fig. 6 shows that, with the increasing of upper load, pile body stress increases gradually. The principle of stress variation is consistent with the strain of the pile. The reduction of pile stress fluctuates from the top of the pile to the bottom of the pile.

The main factors to induce the monitoring data fluctuation include the change of the pile diameter, monitoring accuracy, embedment method, construction technology and so on. Increasing the diameter of the pile made the pile stress reduce under the same axial force. Material changes in temperature affected the monitoring accuracy of the optical fiber sensor and data transmission error occurred. When pouring concrete, temperature changes of different depths of concrete hydration heat affected the monitoring results. Since the fiber was flexible material, there would be local bend in laying and it would also affect the accuracy of the monitoring to some extent. After grouting, side friction resistance of the pile increased in the test and pile stress reduced relatively with the same axial force.

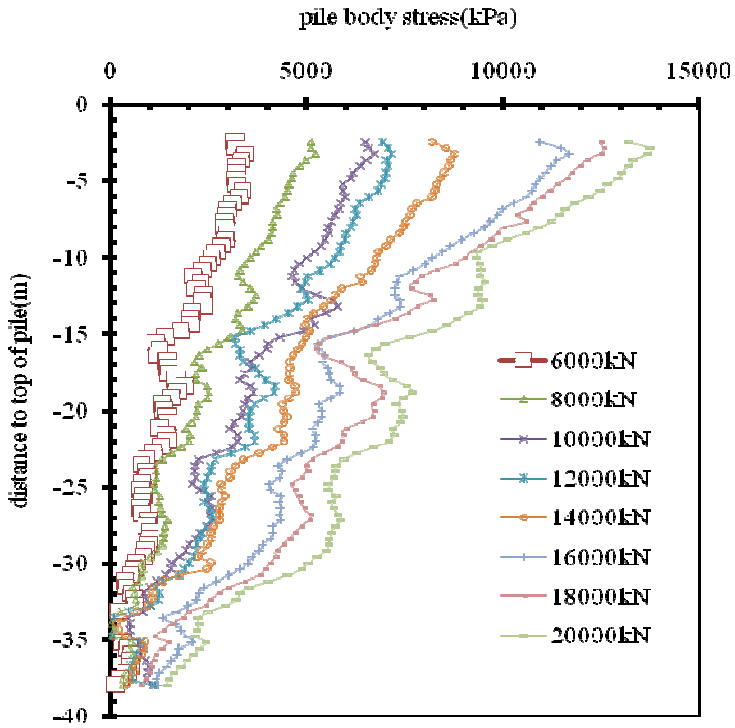

Fig. 6 The pile body stress curve of test pile 4#

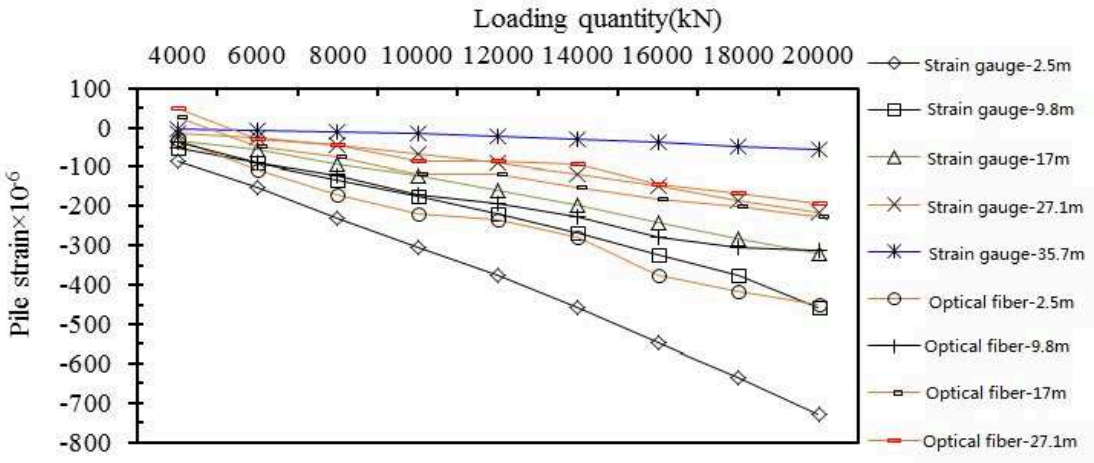
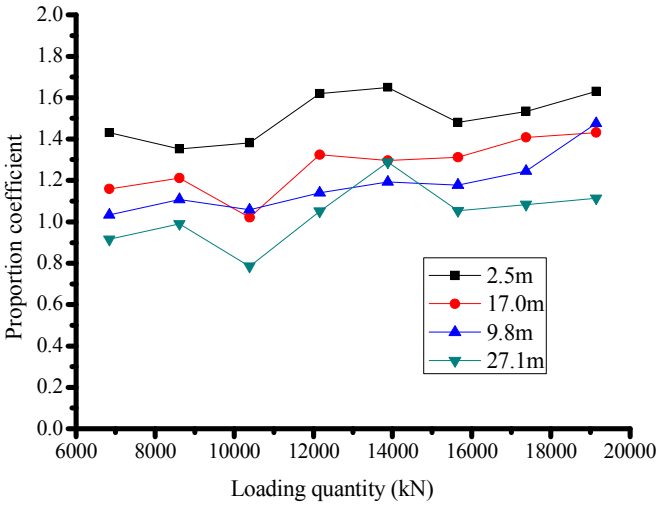
**Comparison Analysis of the Strain Measured with two Methods** In the test, the strain gauges and optical fibers were embedded at the same time, the data obtained from two methods was in contrast and analyzed. The results are shown in Fig. 7.



(a)



(b)

Fig.7 Strain data contrast curves of test pile 4# of the strain gauge and optic fiber

As is shown, at the same location, two kinds of data have the same evolution law: with the load increasing, the strain increases gradually and it presents a linear growth, the ratio of strain measured by two methods between 0.9~1.6.

## Conclusions

The experiment of post-grouting filling pile in Zhengzhou city's third ring road rapidness project, study the evolution of large diameter and post-grouting filling pile about the settlement of pile top and pile body stress. Contrast and analyzing the data of strain gauge and optic fiber, the main conclusions are as following: With the upper load increasing, pile strain, pile stress and pile axial force increases gradually. The test data accuracy will be affected by the change of pile diameter, monitoring accuracy, embedment method, construction technology, temperature change of material, etc. Strain ratio measured with optical fiber and strain gauge at the same position is 0.9~1.6. With the load increasing, difference of the strain data measured with the two methods increases gradually. Distributed optical fiber measurement can be applied to monitor the pile body stress continuously and has obvious advantage in monitoring pile axial force, pile stress, pile strain, pile side resistance and so on over strain gauge. But the data needs to be modified with the strain gauge data.

**Keywords**：analytic calculation;flexibility matrix;field experiment;finite element numerical calculation

**ABSTRACT**： In accordance of the principles of stress continuousness and displacement coordination, the interactions model of pile and pile, pile and soil are set up； Accoring to the symmetry of the models,1/4 of the models are extracted to set up three-dimension multipile composite foundation models.The flexibility matrix of the three reinforcements are modified to build a global flexibility matrix with the consideration of cushion's compression； Interaction coefficients of the analytic calculation are lower than those of the finite element when pile lengthen is diversity.The comparison between the on-site measured data from the literature review and results of the analytic calculation shows the settlements in the analytic calculation are smaller than those in the measured data, and the model measurements are very close to the curves from the analytic calculation. All these prove that the analytic methods proposed by this research are accurate and may function as a reference to engineering.

## Introduction

Pile-net composite foundation is made of reinforced sand-pile-soil,they coundertake embankment loads and traffic loads.The methods about the joint actions of pile and soil include:load transfer-method[1][2],shearing displacement method[3],elasticity theory,numerical calculation.The paper adopt shearing displacement method to analy the coactions of group piles-nets-soil-cushion under the embankment loads.

## Basic assumption

Due to the coactions mechanism of the piles-soil-cushion is complex,the minor factors are neglected in analytic calculation,material properties are assumpted,the assumptions are ut infra:

(1) Pile-net-cushion-soil are homogeneous,isotropic,ideal elastic mass;
(2) The bearing of net is neglected;
(3) Relative displacement of frictional resistance of pile side are ideal elastoplasticity ;
(4) The actions of soil around piles are neglected when the coactions among piles are analyzed.

## Flexibility matrix of the bearing system

The matrix of displacements and loads about group piles is:

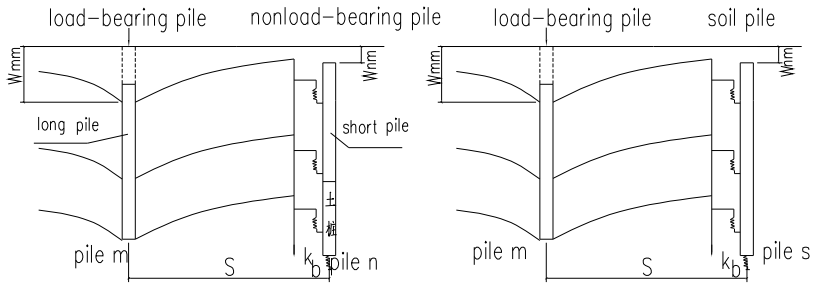
$$\{w\}=[\delta]\{P\} \quad (1)$$

In formula (1), $[\delta]$ is the flexibility matrix of the bearing system,partitioned matrix is represented

$$[\delta]=\begin{bmatrix}\delta_{mm} & \delta_{mn} & \delta_{ms}\\ \delta_{nm} & \delta_{nn} & \delta_{ns}\\ \delta_{sm} & \delta_{sn} & \delta_{ss}\end{bmatrix} \tag{2}$$

3.1 Softness factor of coactions about piles

Material,physical dimension of piles are ipentity,according to the action model of piles were deduced by Mylonakis and gazetas[4] ,as shown in Fig.1:



(a) Interact model of piles (b) Interact model of pile and soil

Fig.1 Interact model of load-bearing pile and nonload-bearing pile

Pile body shear stress of load-bearing pile m is created by applied load $\sigma_p$, Shear stress is transferred along radial,arrive the soil around piles,settlement of the soil is

$$w_s=\psi(s)_{mn}w_{mm} \tag{3}$$

$$\psi(s)=\frac{w_s(s,z)}{w_s(r_p,z)}=\begin{cases}\dfrac{\ln r_m-\ln s}{\ln r_m-\ln r_p} & r_p\le s\le r_m\\ 0 & s>r_m\end{cases} \tag{4}$$

Directed pile n,relative displacement of pile depth z is $w_{mn}-w_s$, According to Winkler model,the pile side resistance of pile n is $k_{zn}(w_{nm}-w_s)$, Vertical unit differential of pile n is

$$A_{pn}E_{pn}\frac{d^2w_{nm}(z)}{dz^2}-k_z[w_{nm}(z)-w_s(z)]=0 \tag{5}$$

Assumpt $\lambda_m=\sqrt{\dfrac{k_{zm}}{A_{pm}E_{pm}}}$, subscript m of $\lambda_m,k_{zm}$ represent pile m load transfer coefficient and pile side Winkler coefficient, $w_{mm}(z)$ is displacement of pile body due to the own load of pile cap,according to the displacement formula of the single pile $w_p(z)=C_1e^{\lambda z}+C_2e^{-\lambda z}$ ,the solution of formula (5) is:

$$\frac{d^2 w_{nm}(z)}{dz^2} - \lambda_n^2 w_{nm} + \lambda_n^2 \psi(s)(c_1 e^{\lambda_m z} + c_2 e^{-\lambda_m z}) = 0 \quad (6)$$

According to formula (6),obtain pile body displacement $w_{nm}(z)$ ,substitute into $P(z) = -E_P A_P \frac{dw(z)}{dz}$ The axis force of pile body $p_{nm}(z)$ is ,

$$w_{nm}(z) = \frac{\lambda\psi(s) z(-D_1 e^{\lambda z} + D_2 e^{-\lambda z})}{2} + D_3 \cdot z \cdot e^{\lambda z} + D_4 \cdot z \cdot e^{-\lambda z} \quad (7)$$

$$P_{nm}(z) = \frac{\lambda\psi(s)}{2} A_P E_P [D_1(1+\lambda z)e^{\lambda z} - D_2(1-\lambda z)e^{-\lambda z}] + A_P E_P \cdot \lambda(D_3 e^{\lambda z} + D_4 e^{-\lambda z}) \quad (8)$$

Integration constant $D_1, D_2$ are drawn from the terminal condition of pile m:

$$D_1 = \frac{P_{bm} - A_{pm} E_{pm} \lambda_m P_{bm} / k_{bm}}{-2A_{pm} E_{pm} \lambda_m e^{\lambda_m l_m}}, \quad D_2 = \frac{P_{bm} + A_{pm} E_{pm} \lambda_m P_{bm} / k_{bm}}{2A_{pm} E_{pm} \lambda_m e^{-\lambda_m l_m}} \quad (9)$$

When the pile depth $z = l_n$ , $w_{bnm}(z) = w_{bnm}(l_n)$ , $P_{bnm}(z) = P_{bnm}(l_n)$ ; When $z = 0$, $P_{nm}(0) = 0$ , The relation of the end resistance $P_{bnm}(l_n)$ and the end displacement $w_{bnm}(l_n)$ is

$$P_{bnm}(l_n) = k_{bn} w_{bnm}(l_n) \quad (10)$$

$$D_3 = -\frac{\psi(s)}{2} \frac{-P_{mm} l_n + l_n k_m w_{mm} l_m - \frac{l_n k_{bn}}{A_p E_P} P_{mm} l_n - \frac{P_{mm}(0) e^{-\lambda l_n}}{A_p E_p \lambda}(k_{bn} - A_P E_P \lambda)}{e^{\lambda l_n}(k_{bn} + A_P E_p \lambda) + e^{-\lambda l_n}(k_{bn} - A_P E_P \lambda)} \quad (11)$$

$$D_4 = \frac{\psi(s)}{2} \frac{-P_{mm} l_n + l_n k_m w_{mm} l_m - \frac{l_n k_{bn}}{A_p E_P} P_{mm} l_n + \frac{P_{mm}(0) e^{-\lambda l_n}}{A_p E_p \lambda}(k_{bn} + A_P E_P \lambda)}{e^{\lambda l_n}(k_{bn} + A_P E_p \lambda) + e^{-\lambda l_n}(k_{bn} - A_P E_P \lambda)} \quad (12)$$

are deduced[5].

When the load $P_{mm}(0) = 1$ ,affect the pile cap m,numerical displacement of nonload bearing pile n is the softness factor $\delta_{nm}$ is: $\delta_{nm} = \frac{w_{nm}(0)}{P_{mm}(0)} = \frac{D_3 + D_4}{-A_p E_p \lambda(D_1 - D_2)}$ (13)

3.2 The interaction of pile and soil

The interaction of pile and soil can change to the action of pile and soil pile,The interaction model of pile and soil as shown in Fig.1(b),that is

$$A_{Ps} E_{Ps} \frac{d^2 w_s(z)}{dz^2} - k_z w_s(z) = 0 \quad (14)$$

The displacement equation of soil pile is obtained according to formula(6),in formula(15), $w_s(z)$ is the answer to the formula(3).When we solve formula(14),the flexibility coefficient of adjacent soil pile $\delta_{sm} = \psi(s) \cdot \delta_{mm}$ (15)

According to the reciprocal displacement law,when the load bearing pile is soil pile,the relation about flexibility coefficient of the affected pile is $\delta_{nm} = \delta_{mn}$ (16)

3.3 Flexibility coefficient $\delta_{ss}^{`}$ of soil pile

When exert load to the soil surface, $\delta_{ss}^{`}$ is the self-displacement under the unit load.Suppose it is Winkler foundation model to analy the interrelation of soil piles:

$$\delta_{ss}^{`}=\begin{cases}\frac{1}{c} & i=j\\ 0 & i\neq j\end{cases} \tag{17}$$

When it is the soil around pile,c is Winkler bedding coefficient ; When it is pile end soil,according to $P_b=k_b w_b$ ,c is $c=k_b=\frac{P_b}{w_b}$.

3.4 The simulation of cushion action

Due to the depth of cushion is thin,we regard it is distributed spring,rigidity of spring is $k_c=\frac{EA}{h_c}$, revised flexibility matrix is

$$\delta=[\delta]=\begin{bmatrix}\delta_{mm} & \delta_{mn} & \delta_{ms}\\ \delta_{nm} & \delta_{nn} & \delta_{ns}\\ \delta_{sm} & \delta_{sn} & \delta_{ss}\end{bmatrix}+\begin{bmatrix}\frac{h_c}{EA} & 0 & 0\\ 0 & \frac{h_c}{EA} & 0\\ 0 & 0 & \frac{h_c}{EA}\end{bmatrix}=\begin{bmatrix}\delta_{mm}+\frac{h_c}{EA} & \delta_{mn} & \delta_{ms}\\ \delta_{nm} & \delta_{nn}+\frac{h_c}{EA} & \delta_{ns}\\ \delta_{sm} & \delta_{sn} & \delta_{ss}+\frac{h_c}{EA}\end{bmatrix} \tag{18}$$

## 4. Contrast verification

We contrast such analytic formula and finite element numerical calculation and field test data,to verify the rationality of these analytic solution.

4.1 Contrast with finite element numerical calculation

Consider symmetry ,we give 1/4 part model to numerical calculation,symmetry restrain is applied to 1/4 boundary, normal restrain to the cross-section are applied to the other two side,fixed end restrain are applied to the end.1/4 part pile is pile m,the other pile is pile n.Diagrammatic sketch and finite mesh are shown in Fig.2 and Fig.3.

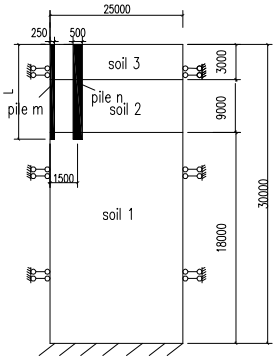


Fig.2 Calculation model diagrammatic sketch

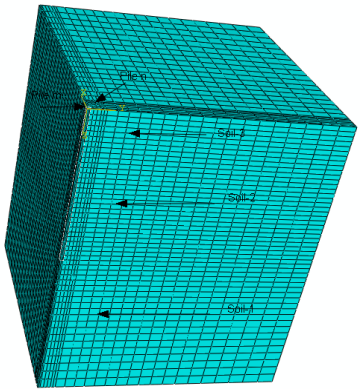

Fig.3 Finite mesh of 1/4 double piles

Unit load is respectively applied to pile m and pile n.We count the settlements of pile cap and soil among pile,the interaction coefficients are shown in table1.

Table 1 Pile length affect to the interaction coefficients

| pile length /m | finite element numerical calculation | | | | | | Analysis of the thesis | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | $\delta_{mm}$ | $\delta_{mn}$ | $\delta_{ms}$ | $\delta_{nm}$ | $\delta_{nn}$ | $\delta_{ns}$ | $\delta_{mm}$ | $\delta_{mn}$ | $\delta_{ms}$ | $\delta_{nm}$ | $\delta_{nn}$ | $\delta_{ns}$ |
| 8 | 0.95 | 0.95 | 1.02 | 0.95 | 0.95 | 1.02 | 0.87 | 0.865 | 0.99 | 0.865 | 0.87 | 0.99 |
| 15 | 0.696 | 0.777 | 1.01 | 0.695 | 0.779 | 1.01 | 0.68 | 0.679 | 0.96 | 0.679 | 0.68 | 0.96 |
| 20 | 0.598 | 0.597 | 1.00 | 0.6 | 0.6 | 1.00 | 0.56 | 0.554 | 0.95 | 0.554 | 0.56 | 0.95 |

4.2 Contrast with field experiment

In order to study the interact coefficient of piles under work load,Cooke[6] took a series of experiments to obtain measured value about interact coefficient.The test respectively drive three steel tubular piles,their lengthen are 4.5m,outside diameter is 168mm,wall thickness is 6.4mm,pile space is three times as much as pile diameter.The paper assume the elastic modular ratio of steel tubular pile is $2.1\times10^5$MPa,the Poisson ratio of soil is 0.5.When the load is 20KN,the settlement of pile A is 0.153mm.Literature 6 gave the measured value of interact coefficient when the pile space is 3d and 6d(d is pile diameter),individual is: $\delta_3$ =0.22 and $\delta_6$=0.1.In order to test the accuracy of the interact coefficient in the paper,the paper determine the revise coefficient by the foundation shear modulus from the literature[6],when l/d is 25, the interact coefficients of different pile space are obtained,as shown in Fig.4.

From Fig.4,the results of numerical calculation is close to the analysis which is put forward by the text.When s/d is identical,the coefficient of the numerical calculation and the analysis of the paper are somewhat greater than the site measured values.That is when the pile was driven in soil,the soil was compacted,intensity of the soil was intensifying.But we ignore the intersity,so the measured value of interact coefficient is less than the other two.

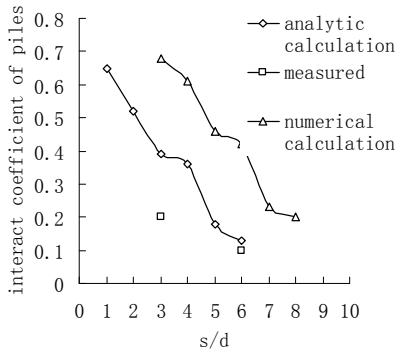

Fig.4 Comparison of interact coefficient

## Conclusions

Generally,the analytic solution is less than the finite element results.Contrast the results of site test and analytic solution,the settlement of analytic calculation is lower than the measured settlement,these maybe ascribe to analytic calculation ignore the group piles effect.

**Keywords:** No sand cushion; Ultra soft soil; Vacuum preloading; Surface-layer improvement; Cone tip resistance.

**Abstract.** No sand cushion vacuum preloading method is one of the construction technology for treating the ultra soft soil formed with hydraulic fill at present. The practice is ahead of the scientific research work, as the effect detection technology of the surface-layer improvement is still in the stage of exploration. In this paper, the cone penetration test (CPT) is used to detect the effect of the surface-layer improvement of the ultra soft soil based on one case in Zhejiang province in China. The result shows that the cone tip resistance is at the range of 0.08 ～ 0.40MPa and the thickness varies about 1.5 to 2.2 m of the treated ultra soft soil. The cone tip resistance along the depth has two kinds of curve shape and four zones.

## Introduction

Tianjin, Zhejiang, Fujian and other coastal areas in China have formed a large number of land space by reclamation, whereas the ground elevation cannot satisfy subsequent development requirements for factories, industrial, road and other constructions. One preferred solution is to fill the ground up to the required elevation with the ultra soft soil transporting from the near sea. At the same time, the traditional vacuum preloading method with sand cushion is difficult to excute in the ultra soft soil, so no sand cushion technology is developed to meet the requirements of the reality [1]. As a new construction technology, no sand cushion vacuum preloading method is still in the stage of exploration, so the treatment effect need to detect and analyze at present. This paper tries to analyze the treated effect of the ultra soft soil by the cone penetration test (CPT), and to provide reference of technology applicability and guidance of process improvement and detection technique development.

The CPT has been widely used as an important field test in geotechnical engineering where penetration is possible[2, 3, 4]. The CPT provides near-continuous penetration test datu to draw test curve and determine soil type and soil mechanical properties and analyze space changing law.

**Table 1 Particle size, moisture content and depth of the initial ultra soft soil**

| Soil layer number | moisture content | Particle size | | | | | Depth |
|---|---|---|---|---|---|---|---|
| | ω(%) | | $d_{60}$(mm) | $d_{50}$(mm) | $d_{30}$(mm) | $d_{10}$(mm) | H(m) |
| 0-1 | 126.9 | Max | 0.011 | 0.007 | 0.003 | 0.002 | ≤2m |
| | | Min | 0.005 | 0.003 | 0.002 | 0.002 | |
| | | Average | 0.007 | 0.005 | 0.002 | 0.002 | |
| 0-2 | 92.1 | Max | 0.012 | 0.008 | 0.004 | 0.002 | 2～2.5m |

| | | Min | 0.008 | 0.005 | 0.002 | 0.002 | |
| | | Average | 0.010 | 0.007 | 0.003 | 0.002 | |

## Description of the case

The case is located on one coastal areas of east Zhejiang in China. The reclamation ground has a certain slope and covers an area of 125000 $m^2$. First, fill the reclaimed area with the sedimentary soil from the near sea. Then no sand cushion vacuum preloading method was applied to improve the ultra soft soil. The soil characteristic parameters of the ultra soft soil before improvement as shown in table 1.

The CPT was applied to detect the improvement effect of the ultra soft soil after vacuum preloading treatment, and the test points were arranged in square layout with 50 m x 50 m, and the total test point number was 50.

## Curve shapes of the cone tip resistance

Due to the difference of the vacuum pump position and the transferring effect of the vacuum pressure in horizontal direction and depth direction and the phenomenon of soil column surrounding the vacuum drainage channel, etc., the improvement effect may be different in each test point and lead to form the different curve shapes of the cone tip resistance. The test curve of the cone tip resistance to depth can be divided into two kinds of shape, namely uniform shape and peak shape, and the peak shape can be divided into unimodal shape and bimodal shape.

The uniform shape curves as shown in fig. 1, the cone tip resistance changes within a small range along the top and middle of the vertical direction. The unimodal shape curves as shown in fig. 2, the cone tip resistance has a bulge in the middle of the vertical direction. The location of the bulge has a wide range in the depth direction, and the peak value also changes in some degree. The bimodal shape curves as shown in fig. 3, the cone tip resistance has two bulges in the middle of the vertical direction. The bimodal shape is a variant of the unimodal one.

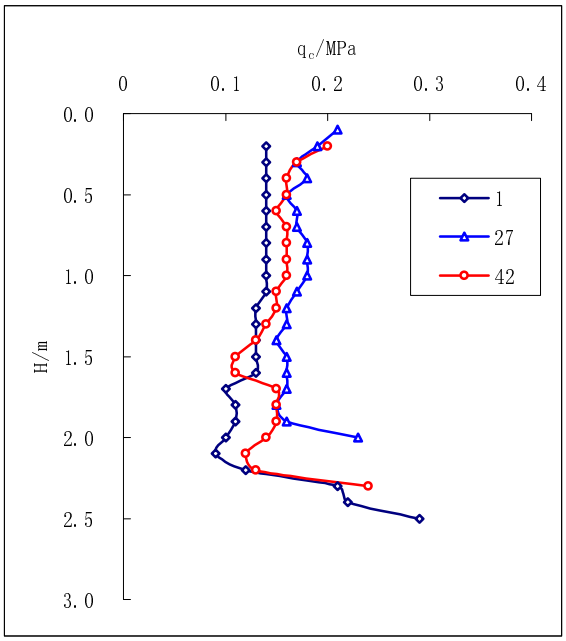

Fig. 1 The uniform shape curves

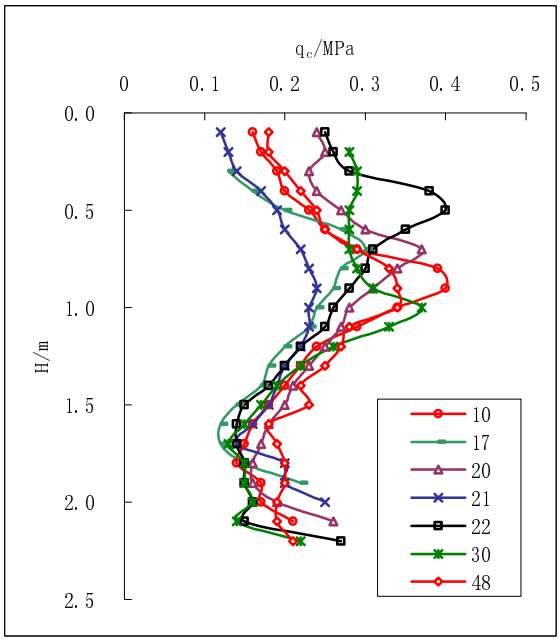

Fig. 2 The unimodal shape curves

## The thickness of the improved ultra soft soil

The junction between the bottom of the ultra soft soil and the natural soil is a weak zone with vacuum preloading treatment, where the cone tip resistance of the ultra soft soil is smaller and the cone tip resistance of the natural soil is bigger. So the changing trends of the cone tip resistance with depth can reflect the thickness of the improved ultra soft soil. The cone tip resistance to depth curves related to the maximum thickness and the minimum thickness of the test points as shown in fig. 4, the minimum

thickness is about 1.5m in test point No.3 and the maximum thickness is about 2.2m in test point No.5, namely the range of the thickness of the improved ultra soft soil is about 1.5 ~ 2.2 m. The result is corresponding with the initial ground slope.

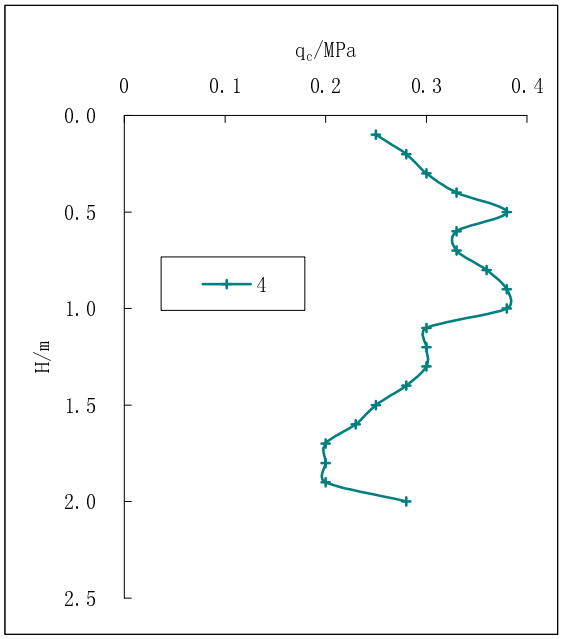

Fig. 3 The bimodal shape curves

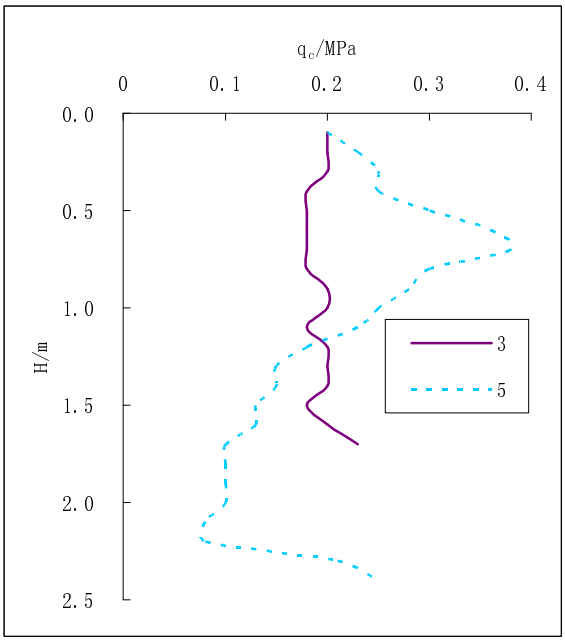

Fig. 4 The $q_c$ – H curves related to the maximum and the minimum thickness of improved soil

**The change laws of the cone tip resistance**

The scatterplot of the cone tip resistance to depth as shown in fig. 5. There are four bandwidth zones of the cone tip resistance down the depth.

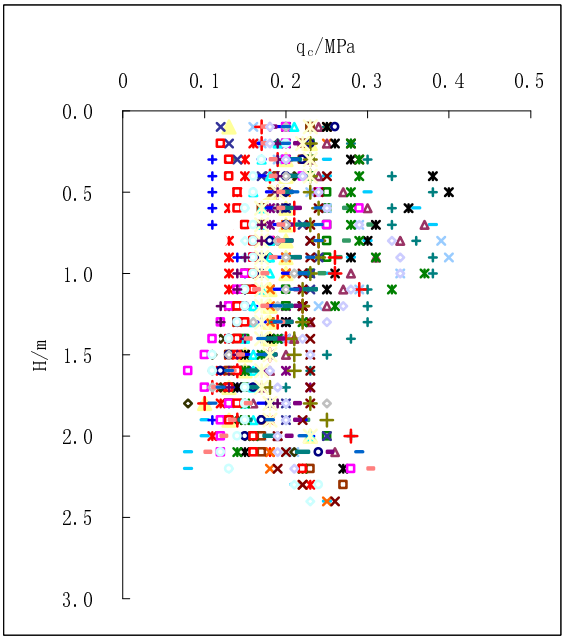

Fig. 5 The scatterplot of the cone tip resistances

At the surface, there is a monotonic increase bandwidth zone of the cone tip resistance down the depth within 0～0.4 m, where the minimum value varies between 0.11 and 0.12 MPa and the maximum value varies between 0.26 to 0.40 MPa. In the upper middle, there is a uniform bandwidth zone of the cone tip resistance down the depth within 0.4～1.0 m, where the minimum value varies

between 0.11 and 0.13 MPa and the maximum value varies between 0.38 to 0.40 MPa. In the lower middle, there is a monotonic decline bandwidth zone of the cone tip resistance down the depth within 1.0～1.5 m, where the minimum value varies between 0.10 and 0.13 MPa and the maximum value varies between 0.25 to 0.38 MPa. At the bottom, there is a uniform bandwidth zone of the cone tip resistance down the depth within 1.5～2.2 m, where the minimum value varies between 0.08 and 0.10 MPa and the maximum value varies between 0.19 to 0.25 MPa.

## Conclusions

Following the analysis, there are some interesting things:

According to the detection result of the CPT, it can be obtained that the thickness of the ultra soft soil after vacuum preloading varies about 1.5 to 2.2 m in the case of east Zhejiang in China.

The cone tip resistance curves along the depth can be divided into two kinds of shape, namely uniform shape and peak shape as the later mainly belongs to the unimodal shape.

Due to the difference of the vacuum pump position and the transferring effect of the vacuum pressure in horizontal direction and depth direction and the phenomenon of soil column surrounding the vacuum drainage channel, etc., the improvement effect may be different in each point.

According to the test scatterplot, the cone tip resistance can be divided into four zones, namely monotonic increase bandwidth zone down the depth at the range of 0 ~ 0.4 m and uniform bandwidth zone at the range of 0.4 ~ 1.0 m and monotonic decline bandwidth zone at the range of 1.0 ~ 1.5 m and uniform bandwidth zone at the range of 1.5 ~ 2.2 m.

**Keywords:** low strain method, bored pile, error analysis

**Abstract:** Based on the field test of bored piles at wharf detected by low strain reflection wave method, time-history curve features and defect position of intact piles and defective piles contrastively analyzed, with verification of on-site drilled core testing. The reason for discrimination error between specific defect position and actual data when processing low strain reflection wave method are derived, based on the analysis of effect of defective piles strengthened by pressure grouting method retested by low strain testing, practical measures of on-site low strain reflection wave testing are purposed to improve detection accuracy.

## Introduction

The bored pile is refers to pile that first forms borehole with drilling machine, steel tube or artificial excavation, then proceed with reinforcing cage placing and concrete casting. With the development of construction technology, due to advantages of low noise, small vibration, high load capacity and broad applicable scope, bored pile is used widely in infrastructure engineering such as pavement, railway, bridge and wharf, etc. [1-4]. However, as a kind of concealed work, 5% - 20% of the bored piles appear different levels of quality problems. Therefore, it could effectively avoid quality accidents if the testing to foundation pile is enhanced in construction stage, also contemporaneous remedy could be adopted to reduce economic loss [5-10].The low strain dynamic testing is regarded as an effective testing method, with advantages of convenience, expeditiousness, low cost and wide coverage [11-13].

Based on engineering example of defect detection to bored piles at wharf tested by low strain reflection wave method, testing waveform of intact piles and defective piles are analyzed and discriminated, to compare the results of core samples drilled from defective piles, the reason for to occur error on the defective interface during actual defect position discrimination is proposed. Based on large number of practical experience, the method to strengthen quality of signal acquisition is also proposed, which aims to improve discrimination accuracy of low strain reflection wave testing. However, during the low strain reflection wave testing to foundation pile, discrimination to testing data often meets error problems. Hence, testing technology should be enhanced, the ability of data analysis should be upgraded, and consequently the accuracy of testing data discrimination is improved.

## Engineering background

The project is bored piles in a port engineering, low strain reflection wave method is used for discriminating pile structure integrity.

The project is located in ground surface with stratum in Beihai Fm, middle Pleistocene and Eopleistocene largely outcropped, whereby Beihai Fm stratum is a set of littoral facies deposit, which is the main stratum constituting low terrace on both sides of harbor banks. The Eopleistocene stratum is a set of river delta facies deposit that sand interbeds with caly, with mottled caly layer, laterite layer and ferruginous cementation layer on top. As the erosion surface showing, the Eopleistocene stratum has a unconformable contact with Beihai Fm stratum, also it often outcrops near the high tidal mark and on the bottom of gulf bank. On the top of borehole drilled in waters, mottled clay and silty clay are exposed as Beihai Fm stratum. On the lower part of borehole, grey clay, grey clay interbedded with sand, grey sand layers(silty fine sand, medium coarse sand, gravelly sand) are exposed as Eopleistocene stratum, while the soft soil layers or loose sand layers exposed on the upper part of borehole, what refers to silt, silty soil, silt mixed with sand, sand mixed with silt, silty fine sand, medium coarse sand with grey or grayish yellow belong to stratum in Holocene of Quaternary.

The drilling soil layers distribution is shown as：①Plain fill, grey to grayish yellow, abandoned dredged fill, mainly consists of flowing mud, silt, cohensive soil and medium coarse sand, 1.03m average layer thickness. ②Medium coarse sand, grey to grayish yellow, saturated and loose, minor shellgrit contained. Lens in distribution, 3.24m average layer thickness. ③Sand with cohensive soil mixed (interbedded), grayish yellow, grayish white to purplish pink, saturated, loose to slightly dense, mainly medium coarse sand, partially interbedded with cohensive soil, 2.88m average layer thickness. ④Clay, rey, wet, plastic to hard plastic, partially interbedded with multi-thin-layer silty sand, minor rotten wood fragment contained, 11.42m average layer thickness. ⑤ Medium coarse sand, grey to light grey, saturated, medium dense to dense, poor sorting features, partially interbedded with cohensive soil, 1.86m average layer thickness. ⑥Clay, grey, slightly dense and wet, hard plastic, partially hard, partially interbedded with multi-thin-layer silty sand, minor rotten wood fragment contained, 6.04m average layer thickness. ⑦Medium coarse sand, grey, light grey to grayish white, saturated, medium dense to dense, partial extreme dense, poor sorting features, partially minor cohensive soil and rotten wood fragment contained, 6.34m average layer thickness. ⑧ Clay, grey, wet, hard plastic to hard, partially plastic, partially minor silty sand contained, or interbedded with multi-thin-layer silty sand, 9.03m average layer thickness.

The wharf uses 3-storey frame structure that gross area is approximately 800m$^2$, bored piles are selected for the foundation design, the design strength grade of concrete is C35, design pile bearing capacity is 3400kN, the diameter and length of pile is respectively 1.0m and 43m, the bearing stratum is clay. The piles pertain to ultra long pile engineering in soft soil area.

## Principles and apparatus of testing

Generally, foundation pile low strain dynamic testing is applied to pile integrity and concrete quality testing, preliminary inspection of pile bearing capacity, later the foundation pile quality is evaluated. The Principles of foundation pile low strain dynamic testing is principles of reflection and refraction that strain wave propagates in elastomer. As the pile bolck subjecting to temporary mechanical vibration, particle on pile will be extruded and vibrates along pile shaft to propagate strain wave downward. When the strain wave encounters abrupt interface, such as pile end, mud layer, fracture or serious expanding, refraction wave will appear immediately. The quality data including reflection signals will be recorded by high sensitive sensor placed on pile block, then converted to digital signals by high speed A/D converter. Based on the features of waveform, the change of wave impedance can be determined that pile integrity will be discriminated too. The testing standard or testing basis is applied according to Specification for Dynamic Testing of Piles in Port Engineering, JTJ249-2001.

The testing apparatus adopts PIT-Collector foundation pile integrity tester produced by Pile Dynamics, Inc.

Assuming the pile is one-dimensional linear elastic bar, whose pile length is *L*, cross sectional area is *A*, elastic modulus is *E,* mass density is $\rho$ and generalized impedance is $Z = A\rho C$ ; The one-dimensional wave equation can be obtained as

$$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} - \frac{R}{\rho \cdot A} \tag{1}$$

where *R=R(x,t)* is soil resistance activated by hammer percussion per unit length along pile axis, $C = \sqrt{E/\rho}$ is elastic wave velocity of pile.

$$x = \frac{1}{2} \bullet \frac{c}{\Delta f_i} \tag{2}$$

Assuming impedance somewhere in the pile has changed, when strain wave moves from mediator I（$Z_1 = \rho_1 \bullet C_1 \bullet A_1$） to mediator II（$Z_2 = \rho_2 \bullet C_2 \bullet A_2$）, it will produce velocity reflection wave $V_r$ and velocity transmission wave $V_t$.

To let pile integrity coefficient $\beta = Z_2 / Z_1$ , then

$$V_r = V_i \cdot \frac{1-\beta}{1+\beta} \tag{3}$$

$$V_t = V_i \cdot \frac{2}{1+\beta} \tag{4}$$

where incident wave $V_i$， transmission wave $V_t$ and reflection wave $V_r$ are values in the interface between mediator I and mediator II. Influenced by damping of pile material and pile shaft soil resistance, both the amplitude of incident waves and reflection waves received from pile bolck and interface are different, while the corresponding phases are the same. Pile shaft defects position is calculated by equations below

$$x = \frac{1}{2000} \bullet \Delta t_i \bullet c \tag{5}$$

$$x = \frac{1}{2} \bullet \frac{c}{\Delta f_i} \tag{6}$$

In low strain testing, pile integrity types should be synthetically discriminated with consideration of defect depth, test signal attenuation, pile type, stake technology, geological condition, construction condition and test signal features in time domain or frequency domain. According to *Specification for Dynamic Testing of Piles in Port Engineering,* the pile integrity are classified to 4 types. According to response signals from sensor, wave train figure is plotted. Considering the phase of incident wave and reflection wave in wave train figure, vibration frequency and relevant wave arrival time, pile integrity type can be discriminated. When performing testing analysis, reflection signal at pile end should be found first, if the signal is weak, processing signal can be zoomed in appropriately until clear signal emerges, then to discriminate waveform through contrastive analysis. If the waveform is regular, no defect reflection occurs in pile, the reflection at pile end is clear, the pile should be classified as type I. If the waveform is basically regular, small defect reflection occurs in pile, the reflection at pile end is basically clear, the pile should be classified as type II. If the waveform occurs serious defect reflection wave or periodic reflection wave and no reflection occurs at pile end, or due to serious defect at upper part of pile, low frequency vibration of waveform decays sharply, no reflection occurs at pile end, the pile should be classified as type IV. If there is obvious defect reflection wave in time domain signal, other features intervene type II and type IV, the pile could be classified as type III.

## Testing results

In the pile integrity testing, bore piles at wharf in the project are tested by low strain reflection wave method, the reflection wave time-history curves of testing results are shown in Fig. 1and Fig. 2.

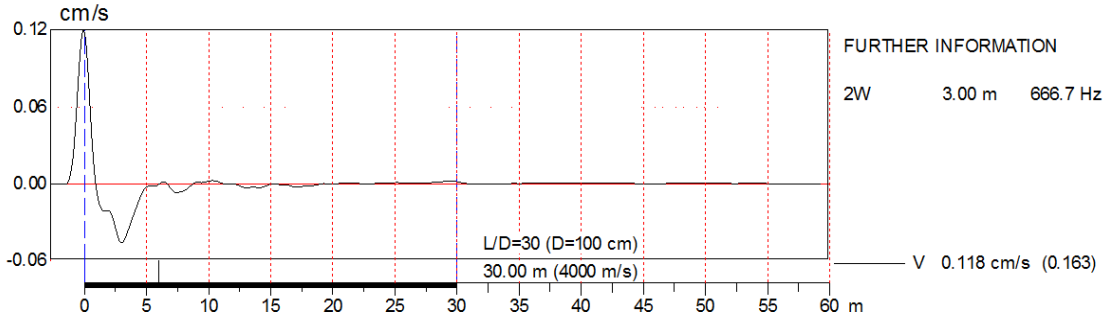

**Figure 1 Reflection wave time-history curve of intact pile**

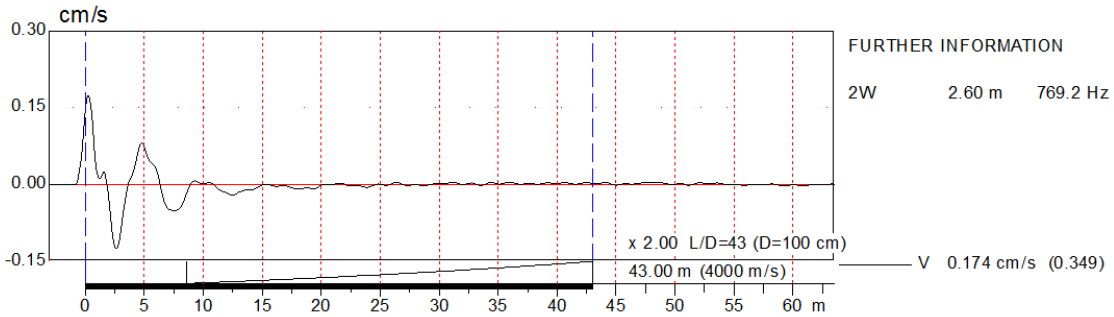

**Figure 2 Reflection wave time-history curve of defect pile**

According to the reflection waveform time-history curve shown in Fig. 1, reference wave velocity is 4000m/s. The peak of incident wave occurs in the position of 0m, pile length is 30m. It has clear wave train and regular waveform, no abnormal reflection occurs, that means wave velocity is normal and no defect occurs in pile. Hence, the pile should be classified as type I. The piles belong to super-long piles in soft soil area, strain wave in piles generally occur sharp attenuation, what leads to detection difficulty of reflection wave signal at pile end. Therefore, not only reflection signal at pile end, but also the testing results of drilled core method and high strain method, construction records should be taken into account to discriminate pile integrity.

According to the reflection waveform time-history curve shown in Fig. 2, there are obvious anomalies revealed through the curve, that means clear synclastic reflection wave peak occurs in the position of 5m, manifesting as necked-in defect. Furthermore, the signals at pile end is weak, so the defective pile should be classified as type III.

For the defective pile tested by reflection wave method in Fig. 2, drilled core method is applied for detection. The drilled core method is a concrete strength testing method that to drill core sample from foundation pile by dedicated drill, the thickness of sinking slag at pile end and bedrock strength also can be tested with application of the method. Drilled core method has the advantages of intuition, reliability, high precision, but the cost is relatively high. The pictures of core samples drilled from bored piles are shown in Fig. 3.

As shown in Fig. 3, the core samples appear as fragmentized in the position of 8m, with length of about 3m, it has poor cementation near the fragmentary part, voids and pits occurs on the side face of core samples, fracture on piles are in good agreement and appear as prismatic, part of the samples are trenched and compact, thus, the piles can be discriminated as defective piles. The results tested by drilled core method is basically in accordance with those tested by low strain method, however, there are some error in the discrimination of exact position of the defect, the result of drilled core appears to be about 8m, while the result of waveform time-history curve is 5m, which is 3m shallower than actual depth.

**Figure 3 Core samples drilled from defect bored piles**

According to the engineering example mentioned above, there are certain limitations for low strain reflection wave method. When testing pile integrity with the method, the initial exciting wave received by station varies from different distance that the station away from exciting point, that leads to various degree of lag occurs when compared with the exciting point. However, he time that reflection wave at pile end from each point reaches pile bolck is identical，that causes smaller time difference between incident wave and reflection wave on interface, so the predicted pile length or position of defect interface is shallower than actual situation. Hence, the error analysis of defect discrimination should be noticed in actual application of low strain method.

According to the results of low strain testing data and on-site core drilling, serious defect occurs in the pile, certain remedy needs to be adopted. After full discussion among quality supervision department, supervision unit and construction unit, pressure grouting method is adopted to strengthen the defect part in pile. Based on high pressure, cement slurry is forced to diffuse to poor cementing part of concrete and seepage discretion occurs, after the cement becomes solid, process to grout under the pressure, and then retest the strengthened pile. In order to verify the strengthening effect of pile treated by pressure grouting method, low strain reflection wave testing are adopted for detection, as shown in Fig. 4.

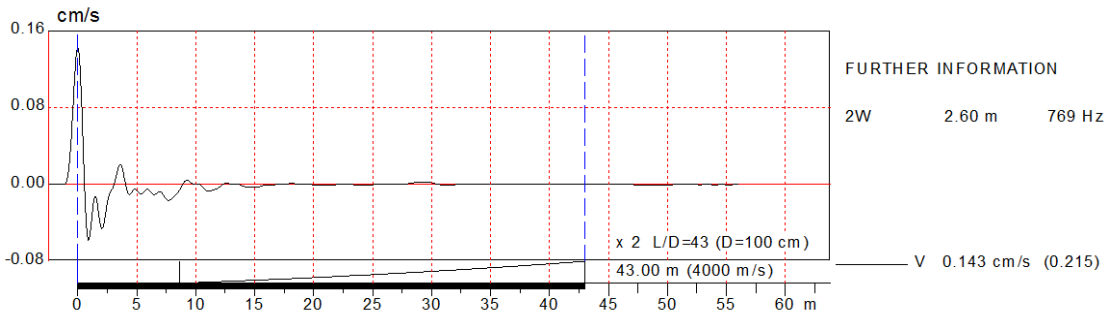

**Figure 4 Reflection wave time-history curve of intact pile after pressure grouting**

It can be discerned from the waveform time-history curve of strengthened piles shown in Fig. 4, that the waveform degenerates in a regular way with normal wave velocity, slightly defect of incident wave occurs in the position of 4m, that means slightly defect occurs in pile, the piles can be classified as type II and used as engineering piles.

The results of low strain reflection wave testing show that pressure grouting is a effective way to dispose of quality defect such as breaking piles, serious segregation and loosening of concrete, and bottom sediment. With the advantages of simple construction process, low cost, short construction period, convenience in execution and quality control, the application of pressure grouting technology is more widely than other reinforcement methods. Therefore, it can be regarded as a reference to similar projects.

## Testing measures

In foundation pile testing, low strain reflection wave is a semi-direct testing method (nondestructive testing method) that is able to detect foundation pile integrity thoroughly and effectively, it has an important effect on detecting quality of piles. However, the use of low strain dynamic testing of foundation pile is unilateral, the analysis results of testing curve are influenced by plenty factors such as pile concrete uniformity, compactness, accuracy of parameters of pile length, size effect, frequency response and excitation energy, etc.

As for the discrimination of abnormal piles, not only defect in pile causes irregularity of curve，but also test results are affected by external test condition, it still confined to qualitative analysis at present. Hence, on the premise that accuracy of data is ensured, pile integrity types should be analyzed and discriminated with consideration of the depth of defect position, attenuation characteristics of test signal, pile type design, stake technology, geological condition, construction situation, measured time domain or amplitude frequency signals， etc. In order to avoid safety and quality accidents in construction caused by misjudgment, to improve the accuracy of testing, alternative testing method should be adopted for contrast verification, if necessary, which favors adopting targeted remedy promptly and reducing unnecessary economic loss caused by misjudgment.

Based on the experience of massive low strain testing, actual operation process of low strain reflection wave method is concluded empirically to improve the accuracy of foundation pile low strain dynamic testing.

For site sampling, the selection of sampling parameters are different under varied field and weather conditions, this is because electric apparatus leakage happened in rainy humid weather and excessive vibration in piling field interfere with sampling accuracy, that leads to misjudgment of defects in piles. Hence, weather factor is ineligible on site sampling.

Usually, it will produce the inferior laitance part on the top of engineering pile during construction, so station must be positioned on dense part of concrete and preferably in the middle of reinforcing cage.

To avoid quality problems on the top of testing piles, laitance should be cleaned up and pile head should be leveled off in case of porosity. The connection between sensor and concrete generally is bonded with plaster powder or grease, there is a huge strength difference between plaster powder and concrete, so the dosage of plaster powder needs to be considered carefully. During site test, the concrete mark of engineering piles all around the field should be discriminated accurately, because the speed wave in concrete is determined by concrete strength grade, which will affect the results of pile length testing and defects position discrimination.

During the foundation pile testing, try to make the force acts perpendicular to pile head when doing the percussion, it is conducive to suppress particle lateral vibration and avoid secondary pulse ，thereby preventing from the subsequent wave interference. It is a good choice to percuss with short-handled impact hammer or impact bar. Short-handled impact hammer is easy to make the force acts perpendicular to pile head, while the magnitude of every percussion is hard to control that causes poor waveform repeatability；With impact bar free falling at a certain height, the force exerted on pile head reveals verticality and uniformity, also fine signal repeatability is obtained, whereas secondary pulse is easy to appear.

## Conclusions and suggestions

With applying low strain reflection wave method to test the bored piles，conclusions below are obtained through defects discrimination and error analysis.

(1) The view that geological condition of soft soil and excessive pile length can lead to low reflection effect at the bottom of pile is raised, after analyzing the time-history curve of reflection wave in bored piles low strain test and comparing characteristics curve and defect positions between intact piles and defective piles.

(2) In low strain reflection wave testing, various degree of lag occur at initial exciting wave and exciting point received from measuring point at varied distance, which leads to error in actual location and experimental data of the defective piles.

(3) According to the low strain retest result of defective piles strengthen by pressure grouting, fine strengthening effect is verified.

(4) The actual operation of low strain reflection wave method on bored pile at construction site is proposed, that both accuracy and quality of testing are enhanced.

**Keywords:** composite supporting, double-row piles, anchor, soil nailing, numerical simulation

**Abstract:** Zhengzhou East Green high-speed rail block D6 site supporting of deep foundation pit engineering, double row pile composite retaining structure design and data analysis. Through specific examples of projects, based on the measured data shows that support form of the rationality and practicality.

## 0Introduction

As the city construction land increasingly nervous, more and more high-level, high-rise building, the excavation of foundation pit depth increases gradually, technology requirements for design and construction of supporting structure growing, is composed of a single form of multiple compound supporting system of foundation pit supporting in China gradually become the main development direction and research hot spot.

Double row pile composite anchor as a new type of composite retaining structure, double row pile and anchor by the reasonable design consists of a whole, the formation of double row pile composite bolt support system, give full play to the double row pile and anchor their technical advantages, technical and economic benefit is remarkable.

All manuscripts must be in English, also the table and figure texts; otherwise we cannot publish your paper.

## Project summary, geological hydrology conditions

### 1.1Project summary

High-tech development zone green high iron D6 block including two 36 class an office building and attached three layers such as commercial podium. The main building foundation pit depth of 17 m, podium, underground garage foundation pit depth is 16 m. D6 plot on the east side, the south 5 m for land red line, land outside the red line, respectively for the two urban trunk road; Red line on the west side, north of 5 m for land, land outside the red line is 20 m wide green belts.

### 1.2Geological and hydrological conditions

According to the geotechnical engineering investigation report, the green high iron D6 plot field of geotechnical engineering information is as follows:

1) Geological conditions

(1) Topography site for cultivated land, basic flat terrain, ground geomorphic units for the Yellow River flood plains, and the whole field within the scope of the investigation found no bad geological phenomenon.

(2) According to the litho logy and mechanics characteristics of foundation soil layer from top to bottom is divided into 12. Design USES the soil parameter is as follows:

2) Hydrological conditions

Groundwater types is diving, stable water depth of 10.2 ~ 11.0 m.

**Double row pile supporting scheme and the calculation model for software of FLAC3D**

**Table 1 Soil design parameters**

| soil | geotechnical category | soil thickness/m | severe/kg/m$^3$ | angle of internal friction / ° | cohesion/KPa | anchor side resistance/KPa | compression modulus/MPa |
|---|---|---|---|---|---|---|---|
| 1 | silty soil | 3.01 | 18.0 | 23 | 12 | 57 | 7.1 |
| 2 | silty soil | 1.98 | 17.8 | 25 | 13 | 66 | 9.7 |
| 3 | silty soil | 1.66 | 18.2 | 24 | 18 | 60 | 6.6 |
| 4 | silty clay | 1.46 | 18.2 | 16 | 18 | 72 | 6.2 |
| 5 | silty soil | 1.04 | 18.0 | 26 | 18 | 75 | 10.2 |
| 6 | silty clay silt | 1.30 | 18.0 | 11 | 15 | 66 | 6.8 |
| 7 | silty soil | 1.34 | 19.0 | 26 | 14 | 78 | 11.2 |
| 8 | silty clay | 3.7 | 18.2 | 10 | 15 | 60 | 7.2 |
| 9 | silt | 1.22 | 18.5 | 28 | 4 | 87 | 23.0 |
| 10 | fine sand | 6.76 | 18.8 | 30 | 2 | 114 | 34.0 |
| 11 | silty clay | 2.70 | 19.5 | 19 | 24 | 102 | 12.7 |
| 12 | fine sand | 3.96 | 19.0 | 32 | 2 | 120 | 35.0 |

## 2.1 Double row pile supporting scheme

The foundation pit adopts the upper slope, lower double row pile composite bolt support scheme. Support plan section diagram is shown in figure 1. Pile diameter 800 mm, 1500 mm longitudinal spacing, double row pile row distance 2700 mm. Anchor adopted three rows, from top to bottom length of 26 m respectively, 22 m, 22 m, is apart from the pile top is 1 m, 4 m, 6.5 m respectively. Upper part put slope using soil nail and soil nail length is 12 m, soil nail spacing is 1.0 m, the longitudinal spacing is 1.3 m.

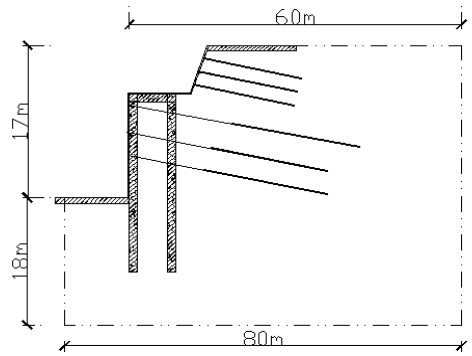

**Figure 1 Double row pile composite bolt support structure profile sketch**

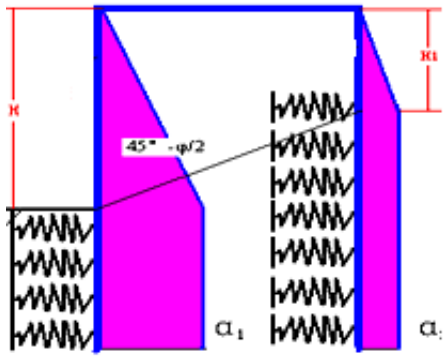

**Figure 2 Is double row pile design calculation software model**

## 2.2 Richard software for double row pile design calculation model

This project adopts the principle is the foundation pit design software to calculate, before the calculation according to certain earth pressure model is given. Calculation model diagram as shown in figure 2, The H1 for equivalent excavation depth, Has the excavation depth。

## 2.3 FLAC3D software double row pile design calculation model

Selected by FLAC3D and the boundary the conditions, the definition of foundation pit excavation presents point as the origin of coordinates, excavation length direction along the Y axis is outspread, width along the X axis is outspread, excavation the depth along the Z axis negative stretch. The Analysis calculation, the model around four symmetry constraint, which is restricted to the X and Y respectively to the below of foundation pit at the bottom of the fixed constraint.

FLAC3D finite difference software analysis of foundation pit excavation calculation model diagram as shown in figure 3 to figure 5:

**Richard software and FLAC3D numerical results contrast analysis**

Calculation process because of the two kinds of software, using two kinds of software of double row pile composite anchor and lateral bending moment calculation results contrast analysis to better understand the performance of double row pile composite anchor.

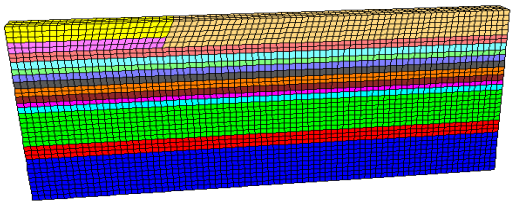

**Figure 3 Not when excavation of double row pile composite bolt support structure model diagram**

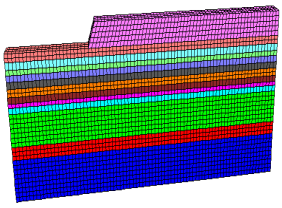

**Figure 4 Slope excavation supporting model diagram**

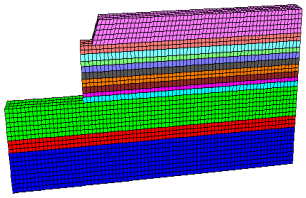

**Figure 5 Excavation on the supporting model diagram**

Reason is the calculation results show that before and after double row pile lateral and bending moment diagram in the form of expression is significantly different. In front of the deformation of the pile for curved scissors, back row pile characterized by pure bending shape, only the last step when Before and after row pile lateral trend to show the consistent, illustrate a few steps before the deformation of the excavation Before and after double row pile, only to the last step before and after double row pile show good work mechanism.

Before and after double row pile bending moment diagram of the first three steps in applying bolt and the last step is obvious different, mutation happened when excavation bottom, especially the back pile bending moment diagram. Whether in theory or the measured before and after double pile bending moment should show the gradient, as to why in excavation on deformation and bending moment are why, unlike before a few steps, worth exploring.

In view of the above two problems, we should start with double row pile soil pressure calculation model considering. Reason is the earth pressure calculation model is shown in figure 6.

Double row piles is only active earth pressure calculation, consideration of the soil on earth pressure between piles of transference, normally in front of the pile and the back pressure of piles and soil is different. In the front row piles on the soil pressure according to the actual excavation surface, and the rear pile as defined by the equivalent excavation surface soil pressure.

1. Equivalent depth excavation face

$$L_O = H\tan(45° - \varphi/2) = 5.78 \tag{1}$$

Because $L_0 > L$

$$H_1 = H - \frac{L}{\tan(45° - \varphi/2)} = 6.39 \tag{2}$$

so

$$\varphi = \frac{\sum_{i=1}^{n} h_i \varphi_i}{\sum_{i=1}^{n} h_i} \tag{3}$$

Type:

$H_1$ - The back pile equivalent excavation depth (m);

$H$ - The foundation pit excavation depth (m);

$L$ - Front of the pile row distance (m);

$L_0$ - Sliding surface extends to the surface to the edge of the foundation pit horizontal distance (m);

$\varphi$ - Internal friction Angle of soil, a weighted average of the values for the excavation surface above the soil.

Front and back row pile soil pressure

Double row piles is calculated according to their equivalent Front and back row pile excavation surface when the value of earth pressure calculation their Ea, then share multiplied by the coefficient of Front and back row pile respectively, have effect on Front and back row pile soil pressure, when decorate a form for rectangular double row piles is calculated as follows:

$$\alpha = \frac{L_0}{L} < 1 \tag{4}$$

$$\alpha = \frac{2L}{L_0} - \left(\frac{L}{L_0}\right)^2 = 0.716 \tag{5}$$

Front of the pile $P_A = \alpha e_a 0.716 \mathrm{E}_a$ (6)

Back row pile $P_B = (1-\alpha)E_a = 0.284E_a$ (7)

Reason is that the calculated results of the distribution of earth pressure and calculation. And adopt some assumption, which is associated with the project, double row piles without considering any slope, slope line up from behind the double-row piles; In front of the resistance of pile elastic range from excavation face downwards, back row pile resistance elastic range from H1 face downwards; Back row pile equivalent above the excavation surface soil before the passive earth pressure.

Can be seen from the used FLAC3D calculation results from the front of the excavation to the beginning of the excavation before and after double row pile deformation are identical. The change of various working conditions in the process of excavation is gradient, no obvious mutation, the third and fourth largest lateral at the top of the pile, compared to a few steps behind the main reason is that the excavation depth is small, but by carefully observe the deformation of the overall trend and a few steps behind the fact is the same.

Constantly, is a dynamic soil pressure, So any form of distribution is appropriate in advance, only the measured is reliable, but the actual is to get after excavation, only feedback adjustment, and can be measured to the true earth pressure is also very difficult. And when is obtained by using the FLAC3D is modeled according to the actual situation, not in front of the excavation to the size of the earth pressure, but let it automatically generated in the process of excavation to the role of supporting structure, the actual situation and is consistent, the precision of calculation is higher also.

**Monitoring result analysis**

Foundation pit safety level to level. Groundwater types for diving, stable water level is 10.2 ~ 11.0 m. Foundation pit supporting the main way is: the top 5 m by soil nail wall, bottom and even beam with double column piles and anchor rope combined support.

Building foundation pit engineering monitoring technical specification requirement level of foundation pit does not exceed the maximum lateral value of 50 mm, when the excavation is one of the biggest lateral value of 25.7 mm specification requirements is far less than 50 mm and satisfies the requirement of monitoring. Show that composite bolt support structure with double-row piles meet the requirements of the foundation pit engineering.

From the monitoring result analysis, before and after double row pile deformation trend is consistent, roughly from start construction to the excavation to the end, no mutation and achieve value. The same condition, the back pile the maximum lateral value is greater than the front pile, but

before and after double row pile basically equal on the top of the pile lateral values, give full play to the role of coupling beam, make Front and back row pile forced deformation of the pile is coordinated. Different condition, the back pile of pile top lateral value is the same, maximum lateral gradually increases with the increase of excavation depth, but the maximum point remains unchanged. Again, in front of the pile displacement of pile top is basically remain unchanged, from pile head to 5 m strength of pile lateral value is nearly equal, the reason is that the bolt through the waist beam direct effect on the front row piles, equivalent to three rows of supporting pile in the front row, this and FLAC3D calculations in front of the pile deformation curves are very similar.

From the measured values shows that Front and back row pile deformation trend is roughly similar, show that double row pile composite the wholeness of the anchor supporting form is very good, always maintain coordination double row pile deformation, and work together. Overall Front and back row pile deformation monitoring data and calculation result of finite difference software, verify the accuracy of FLAC3D numerical model.

Monitoring results show that the deformation of the measured values is less than the calculated value, fully achieve the desired goal. In a word, the principle is, though cannot be accurately according to the actual earth pressure for the design of supporting schemes, but this kind of calculation method of design guide the construction is safe and reliable. Practice proved that is feasible.

## Summary

1) Double row pile composite supporting structure for anchor supporting of foundation pit lateral, can satisfy the requirements of specification, and in construction process found no crack is not conducive to the construction of more obvious.

2) The principle is the software, though cannot be accurately according to the actual earth pressure for the design of supporting schemes, but this kind of calculation method of design is used to guide the construction is safe and reliable;

3) The use of double row pile composite bolt supporting of foundation pit lateral capacity, under the same conditions is less than the pure double row pile and pile anchor support.

# Experiment research of rock anchor foundation on sandstone ground in transmission line

Yan Zhang[1, a*], Weifeng Zheng[1,b]

[1]China Electric Power Research Institute 100192, China

[a]zhangyan2009@gmail.com, [b]zhengweifeng1977@126.com

**Keywords:** transmission line; rock anchor foundation; sandstone ground; ultimate uplift bearing capacity; failure mode

**Abstract.** Rock anchor foundation can be widely used for the practical transmission line engineering in mountain areas. On strong-weathered sandstone ground, ten sets of uplift static load test of single rock anchor foundation were carried out. Based on the testing results, the typical failure modes and the ultimate uplift bearing capacity of foundations were obtained. Internal force distribution and effective anchorage depth were investigated through stain measurements. Design parameters of rock anchor foundation on sandstone ground were proposed, which can provide a reference for transmission line engineering design.

## Introduction

Rock anchor foundation is a new type of transmission tower foundation which consists of anchor rod and pile caps [1]. Because of taking full advantage of the mechanics performance of original rock mass, rock anchor foundation has excellent pull-out bearing performance. Compared with regular foundation, rock anchor foundation can reduce excavated volume, concrete dosage and project cost significantly which make it an environmental protection foundation type.

Under uplift load condition, the load transfer mechanism of rock anchor foundation is very complicated and ambiguous. In order to investigate the failure characteristics and load-bearing mechanism of rock anchor foundation systematically, this paper will analyze the load-displacement relation and the law of internal force distribution of rock anchor foundation based on uplift field load test on sandstone ground.

## General situation of test

**Engineering geological conditions.** This field test site is located in Lingwu City of Ningxia Hui Autonomous Region. The surface of ground is silty sand layer which is about 0.5m~1.5m thick. The bottom of ground is strong-weathered sandstone layer with more than 10m thickness. According to the result of point load test, the hardness degree of sandstone can be defined as relatively hard rock. The physical and mechanical properties of sand and rock mass are shown in Table1.

Table1. Physical and mechanical properties of sand and rock mass

| Lithology | Thickness [m] | Natural unit weight [kN/m$^3$] | Cohesion [kPa] | Internal friction angle [°] | Shear strength [kPa] | Eigenvalue of bearing capacity [kPa] |
|---|---|---|---|---|---|---|
| Silty sand | 0.5~1.5 | 15.0 | 0 | 15 | / | / |
| Sandstone | >10 | 21.0 | 0 | 55 | 20 | 400 |

**Experimental foundation design scheme.** Ten sets of single rock anchor foundation are designed for field static load test. The diameter of anchor bar is 36mm. The material of anchor bar is HRB400. The diameter of anchor hole is 100mm. The strength grade of fine stone concrete is C30. The depth and quantity of single rock anchor foundation are shown in Table2.

Table2. Depth and quantity of single rock anchor foundation

| Serial number | D0.5 | D1.0 | D1.5 | D3.0 | D4.5 |
|---|---|---|---|---|---|
| Depth [m] | 0.5 | 1.0 | 1.5 | 3.0 | 4.5 |
| Quantity | 2 | 2 | 2 | 2 | 2 |

**Loading device and testing system**. The loading device consists of reaction force steel beams and hollow tension jack. The counterforce device consists of wood block and natural ground. The test devices are RS-JYC static load meter and DH3816 strain gauge. The uplift loading system is shown in Fig1.

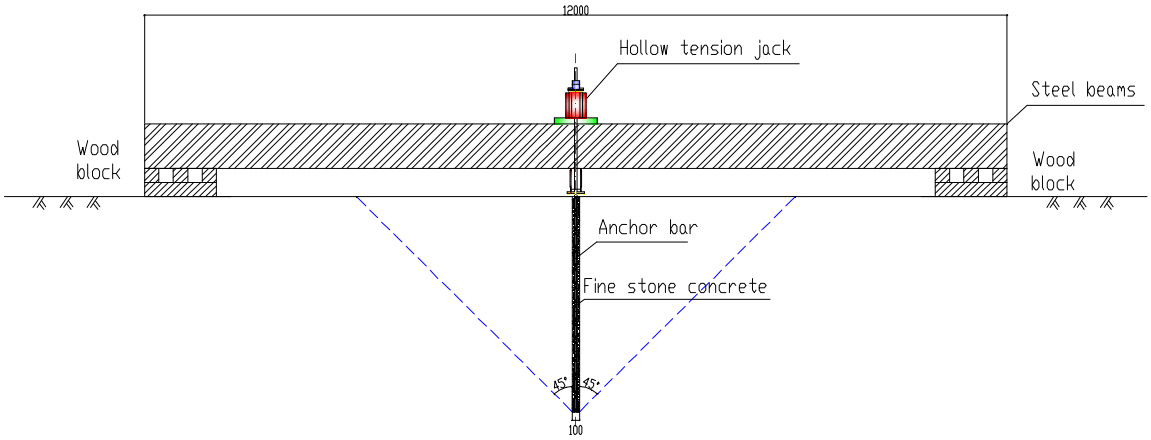

Fig1. Sketch of uplift loading system of single rock anchor foundation

**Loading method.** According to relevant technical standard [2], static load test adopts slow maintenance loading method. Uplift load is applied on foundation step by step. The step number of load cannot be less than 8. The maximum uplift load must be greater than 2 times of design load. The displacement of rock anchor foundation should be recorded right after each loading step immediately. The test data should be recorded every 5 minutes till the deformation is less than 0.01 mm 4 times in a row.

## Analysis of test results

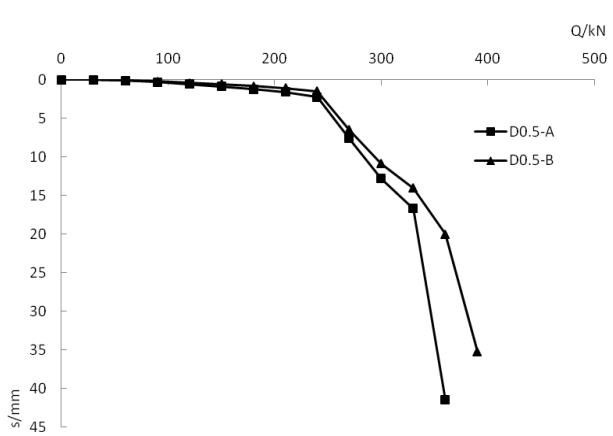
**Typical failure mode.** The failure mode of foundation is the macro performance of the reaction between anchor and rock ground. The failure mode which can reflect the load-bearing characteristics directly is also one of important basis of design parameters. Under uplift load, single rock anchor foundation has four kinds of potential failure modes which are anchor bar tensile failure, anchor pile pull-out failure, anchor bar pull-out failure and rock mass shear failure depending on the depth of anchor, anchor bar features, properties of rock mass and construction quality. Anchor bar tensile failure and anchor pile pull-out failure are the main failure modes of this field test. The failure photos of this field test are shown in Fig2.

**Analysis of uplift bearing capacity of single rock anchor foundation.** The load-displacement relations of single rock anchor foundation of different anchorage depth are shown in Fig3.

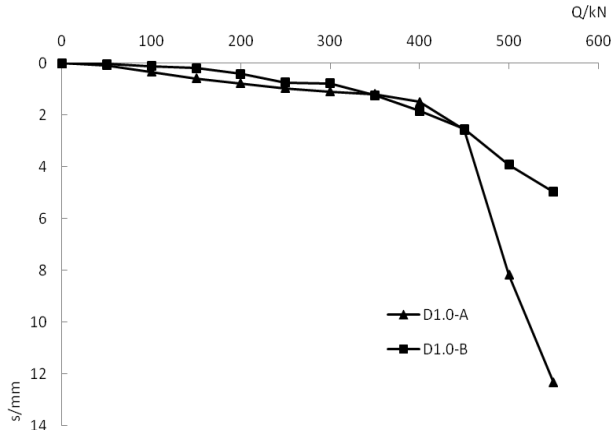
The displacement of single rock anchor foundation refers to the displacement of top of anchor bar. Learn from Fig3, the ultimate uplift bearing capacity of foundations of different anchorage depth are 240kN, 450kN, 450kN, 465kN and 475kN respectively. The ultimate uplift bearing capacity of 0.5m deep foundations is less than the foundations of other anchorage depths obviously. This is because the failure mode of 0.5m deep foundations is anchor bar tensile failure while the failure mode of foundations of other anchorage depth is anchor pile pull-out failure.

(a) Anchor bar tensile failure (b) Anchor pile pull-out failure

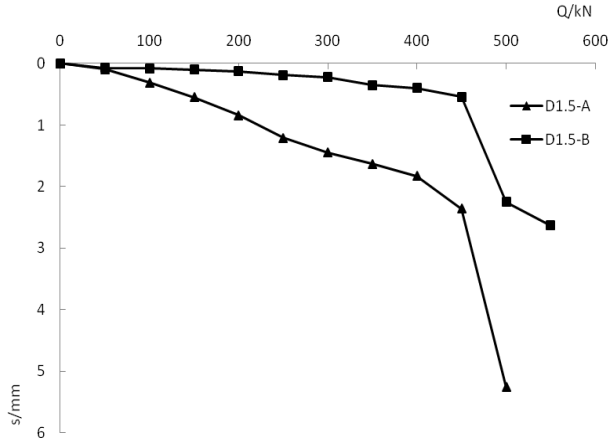
Fig2. Two kinds of failure photos



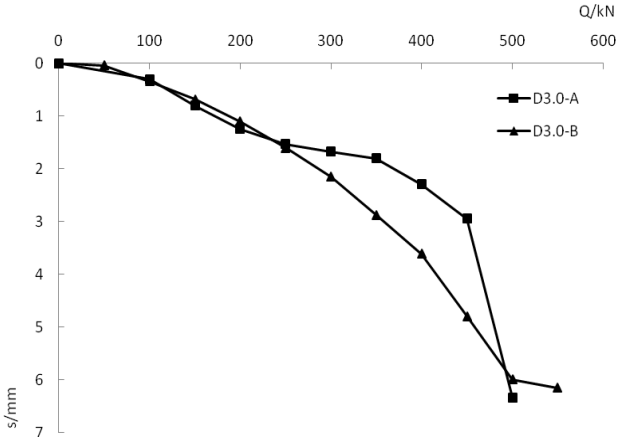
(a) Anchorage depth=0.5m



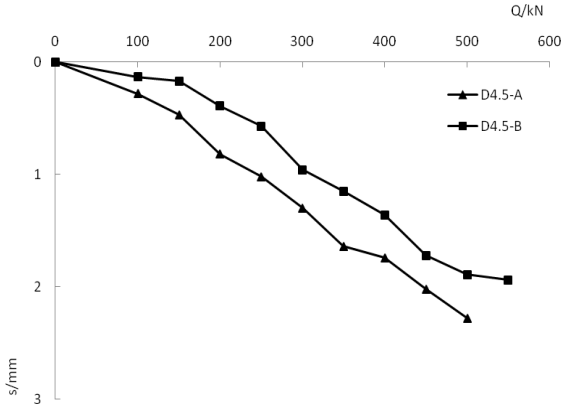
(b) Anchorage depth=1.0m



(c) Anchorage depth=1.5m



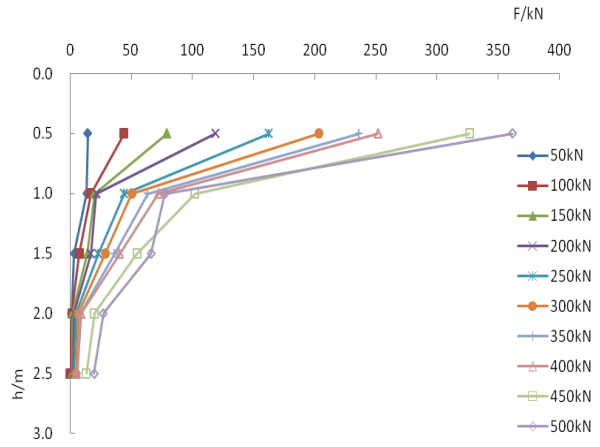
(d) Anchorage depth=3.0m



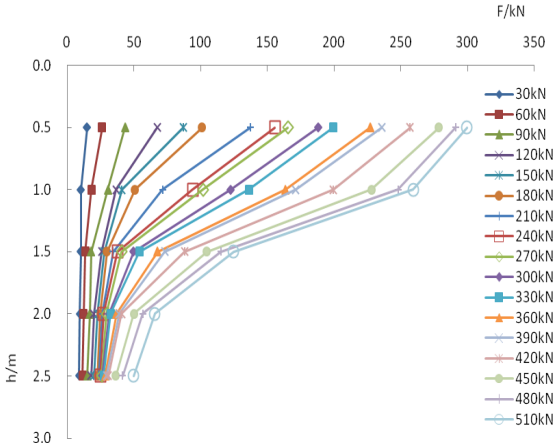
(e) Anchorage depth=4.5m

Fig3. The load-displacement relations of single rock anchor foundation

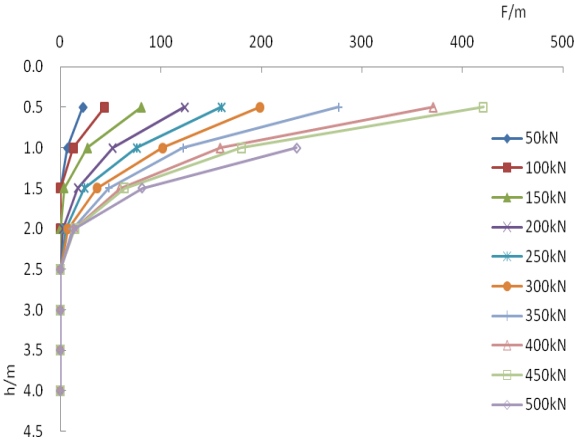
**Analysis of internal force distribution of anchor bar.** Based on stain measurement results of anchor bar in loading process, the internal force distribution along the depth of anchor bar is shown in Fig4.



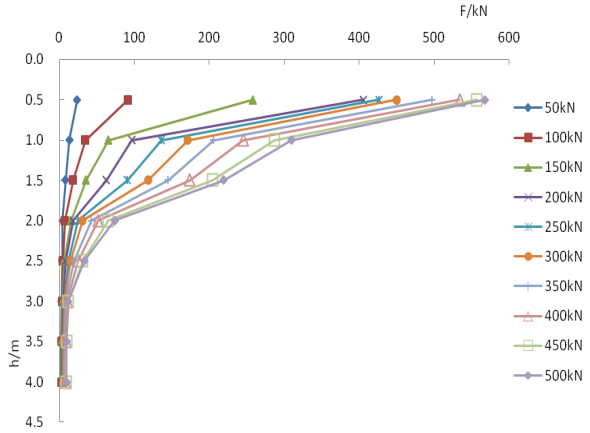
(a) Anchorage depth=3.0m



(b) Anchorage depth=3.0m



(c) Anchorage depth=4.5m



(d) Anchorage depth=4.5m

Fig4. The internal force distribution of anchor bar

Learn from Fig4, the internal force distribution of anchor bar increase with load and decrease with increasing depth. When the depth is larger than 2.5m, the internal force of anchor bar is less than 10% of current load. Therefore, the effective anchorage depth can be considered as 2.5m.

**Analysis of design parameters of rock anchor foundation.** According to the test result of single rock anchor foundation of 0.5m depth, the bond strength between anchor pile and rock mass can be calculated by Eq. 1 directly. Where $T_u$ is the ultimate uplift bearing capacity; $D$ is the diameter of anchor pile; $h_0$ is effective anchorage depth. Internal force distribution and effective anchorage depth are obtained.

$$\tau_b = \frac{T_u}{\pi D h_0} = \frac{240}{3.14 \times 0.1 \times 0.5} = 1528 \quad \text{kPa} \tag{1}$$

## Conclusions

On basis of the uplift static load test of single rock anchor foundations on strong-weathered sandstone ground, this paper analyzes the typical failure modes and the ultimate uplift bearing capacity of foundations. The bond strength between anchor pile and sandstone rock mass is proposed

# Experimental Studies on Acoustic Emission of Different Damaged Concrete

Hongguang Ji [1,a], Xurong Li[1,b], andChenglin Song[1,c]

[1]School of Civil and Enviromental Engineering,University of Science and Technology Beijing, Beijing,China

[a]jihongguang306@ces.ustb.edu.cn, [b]lixr0911@163.com,[c]lianyi6789@163.com

**Key words:** Concrete; Damage; Acoustic emission signal.

**Abstract.** Through to conduct uniaxial compression test on concrete of suffering sulfate attack, the frequency characteristics of acoustic emission signal are analyzed in the corrosion concrete failure process. The results show that: the acoustic emission ringing counts show phases developmental rule with the relative stress increased.When the relative stress is low, acoustic emission signal of the damaged concrete $S_1$ is intensive and large amplitude, while the acoustic emission signal of the no damage concrete $S_0$ is active - relative quiet - active - relative quiet and the acoustic emission signal of the damaged concrete $S_2$ is active - quiet - active.

## Introduction

For the corrosion concrete materials, the failure process of concrete and the internal micro crack evolution process are consistent. Concrete cracking is mainly the initial expansion of the internal micro crack. It produces the acoustic emission phenomenon because generation and propagation of micro cracks cause the stress relaxation and the part energy stored suddenly released in the form of stress wave [1,2]. Frequency characteristic of acoustic emission signal is an important aspect of acoustic emission signal analysis [3,4].The relationship of the frequency characteristics of concrete material acoustic emission and the mechanical parameters of concrete material is an important basis of sensor selection, effective characteristic selecting and signal analysis in the testing of the concrete material acoustic emission [5,6,7,8].Developing research of characteristics of acoustic emission signal in the corrosion concrete failure process and revealing the relations between the failure process of concrete and acoustic emission characteristic parameters are helpful for understanding the failure mechanism of the corrosion concrete. In order to study the relationship between the mechanical parameters of corrosion concrete material and the frequency characteristics of the AE signal, uniaxial compression tests are conducted on the no damage concrete and the damage concrete immersed in sulfate solution in 9% after seven months.

## Experimental Design

In order to study the relationship between the mechanical parameters of the corrosion concrete and the frequency characteristic of the acoustic emission, the C30 concrete specimens were made. The specimen size is 100mm*100mm*100mm. Specific parameters of the mixture ratio of the concrete material can be seen in table 1. Sulfate solution of sodium sulfate and magnesium sulfate mixed of the 9% sulfate ion concentration was compounded. Concrete was stirred in forced action mixer and was vibrated compacting in shaking table. The forms of the concrete specimens were removed after twenty-four hours then they were standard cured in standard curing room. Three concrete specimens were directly put into the sulfate solution after curing 28 days, labeled as $S_0$.Three concrete specimens were pressurized to 50% of the ultimate load then unloading, then put they into sulfate solution, labeled as $S_1$.Three concrete specimens were pressurized to 70% of the ultimate load then unloading, then put they into sulfate solution, labeled as $S_2$.Uniaxial compression test and acoustic emission testing are conducted on all the specimens of soaking in sulfate solution after seven months.

Table 1 Mix proportion of concrete

| Concrete mark | Water-cement ratio W/C | Water [kg/m$^3$] | Cement [kg/m$^3$] | Sand [kg/m$^3$] | Stone [kg/m$^3$] | Water Reducer [kg/m$^3$] | Nacl [kg] | $NaNO_2$ [kg] | Trolamine [kg] |
|---|---|---|---|---|---|---|---|---|---|
| C30 | 0.49 | 196 | 400 | 620 | 1224 | 34.20 | 4 | 4 | 0.2 |

**Appearance Features**

The surface of the concrete appears variation of different degree with increasing corrosion time after the concrete was corroded by sulfate solution. These specimens have no obvious changes in the first one month then the color of the concrete is slightly pale over the next few months. The concrete's surface appears slightly sand phenomenon and some parts of the specimen which were exposed to the air began to produce crystal in the sixth month. The concrete specimens have slight spalling in the seventh month. The surface of the concrete specimens after being taken out from the solution gradually appears a lot of white crystals of salt in the dry process. Because of the crystalline absorption effect of concrete in the air, the drying time of the specimen is relatively long, and there are a large number of salt on the surface of the concrete and some have entered the concrete surface area( see figure 1).

**Concrete Acoustic Emission Parameters and Corresponding Relation between Stress and Strain**

Through uniaxial compression test on corrosion concrete, using acoustic emission detection system, conducting the acoustic emission signal waveform acquisition and stress-strain observation in a whole process, the acoustic emission ring counts that corresponding to each time period are obtained in uniaxial compression process of the corrosion concrete. Combined with the process of the stress of corrosion concrete, by using data from the press, stress,strain and time corresponding relationship of the corrosion concrete can be obtained. When the stress value is converted into the corresponding relative stress value, after finishing, the corresponding relationship can be obtained on the relative stress and AE counts and the strain and acoustic emission counts.

Acoustic emission ring refers to the time-domain graphics of the acoustic emission wave, transducer each shocking one time, the output of a pulse called "ring". Acoustic emission ring count is number that acoustic emission signal exceeds a certain threshold. The relative stress is defined as the ratio that the stress value of a certain point of time in the compressive process and the maximum stress value that concrete bears, expressed as a percentage. The reference of corresponding stress level, which have a more clear understanding of the concrete in the loading process stage.

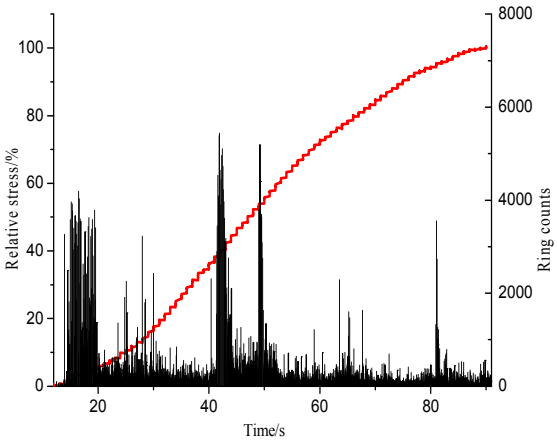

Fig.2 9%-$S_0$ Concrete relative stress -time-ring count diagram

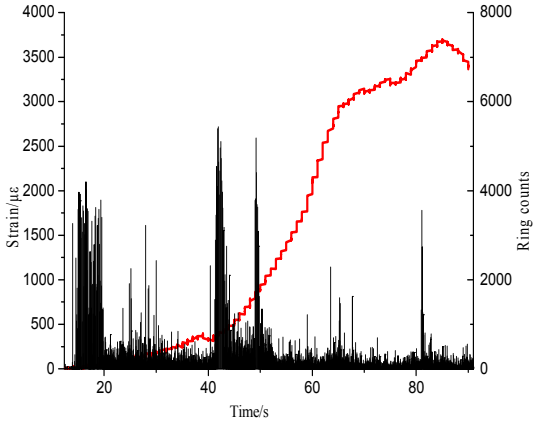

Fig.3 9%-$S_0$ Concrete strain-time-ring count diagram

From figure 2 and figure 3 can be seen, no damage concrete specimens were corroded in sulfate solution after seven months, which acoustic emission mainly occurs in 10% of the relative stress and 40% of the relative stress in the process of uniaxial compression. The acoustic emission counts decrease during the late stage of the specimen deformation.

Analysis reasons: because no damage concrete specimens were corroded by sulfate solution, the main reaction products are gypsum and ettringite, which the micro internal structure changes. The deformation of the concrete is not obvious in the initial loading stage, but acoustic emission counts are relatively high because of the effect of ettringite.

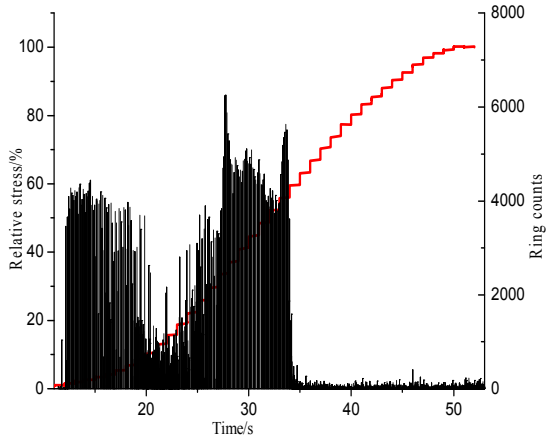

Fig.4 9%-$S_1$ Concrete relative stress -time-ring count diagram

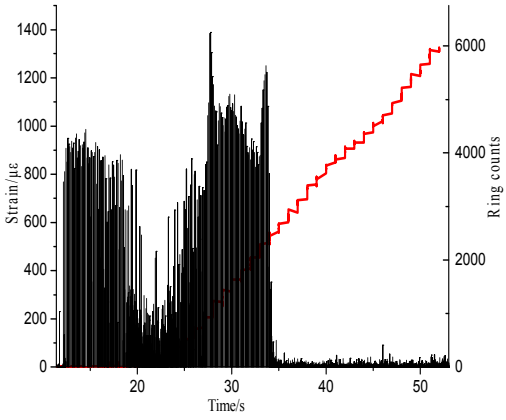

Fig.5 9%-$S_1$ Concrete strain-time-ring count diagram

From figure 4 and figure 5 can be seen, damage concrete specimens $S_1$ were corroded in sulfate solution after seven months, which acoustic emission mainly occurs in 5%-10% of the relative stress and 20%-50% of the relative stress in the process of uniaxial compression. The acoustic emission counts also show a downward trend and calm in the late stage of the specimen deformation.

Analysis reasons: the gypsum and ettringite of reactive formation are more because the number that sulfate ions get into the concrete is more after the concrete suffered damage and sulfate erosion. Furthermore, the early acoustic emission counts are relatively high and relatively dense because the gypsum and ettringite are belong to the brittleness material.

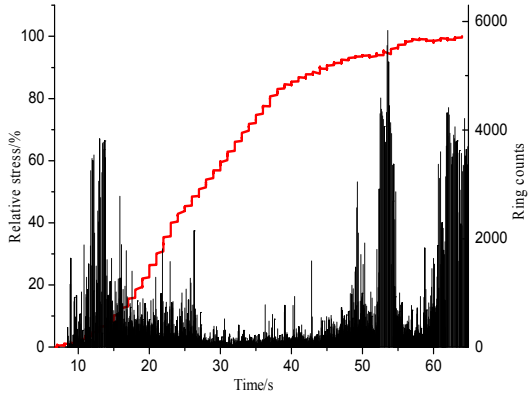

Fig.6 9%-$S_2$ Concrete relative stress -time-ring count diagram

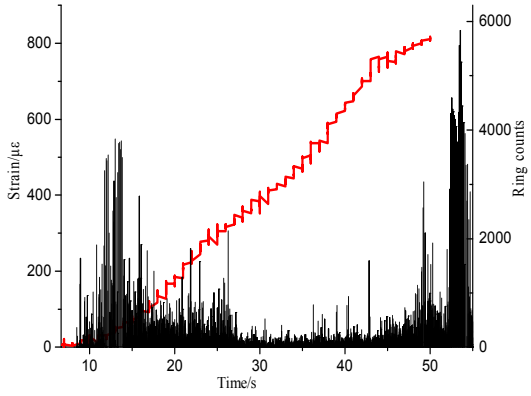

Fig.7 9%-$S_2$ Concrete strain-time-ring count diagram

From figure 6 and figure 7 can be seen, damage concrete specimens $S_2$ were corroded in sulfate solution after seven months, which the acoustic emission process is divided into three stages, namely initial stage, quiet period and active period in the process of uniaxial compression.

Analysis reasons: the internal concrete is density because the concrete specimens have been loaded 70% of the ultimate load in the initial stage. The sulfate ion is not easy to enter the concrete and produce the gypsum and ettringite so that the initial deformation of the corrosion concrete is not too large. The acoustic emission counts of the concrete specimen $S_2$ decreased relative to the acoustic emission counts of the concrete specimen $S_1$. Acoustic emission signal seems relatively calm in the middle of loading. The corrosion concrete performance is more brittle and acoustic emission activity is enhanced sharply when it reached the ultimate load.

## Conclusions

(1). Frequency characteristics of the acoustic emission signal is not very dense for no damage concrete specimen $S_0$ in the whole uniaxial compression process. Initial AE activity is stronger than the late AE activity.

(2). Initial acoustic emission signal of damage concrete specimen $S_1$ are stronger than that of the concrete specimen $S_2$, and performance is obviously very dense. The acoustic emission process of the damage concrete specimen $S_2$ is divided into three stages, namely the initial stage, calm stage and active stage.

# Experimental study on post-peak failure behavior of rock masses with persistent joint

Lei Wang[1, a], Jiang Yu [1, b], Xue Hua[1, c],

[1]PLA Institute of Engineering Corps, Xuzhou, Jiangsu 221004, China

[a]wljdd@foxmail.com, [b]yj20051202@163.com, [c]huaxue@163.com

**Keywords:** transfixion joint; post-peak; joint inclination angle; uniaxial compression

**Abstract.** The uniaxial compression test on pre-existing persistent jointed rock cylindrical standard specimen made by high stiffness servo control testing machine, systematic researched the relationship between jointed rock post-peak stress-strain curve, the destroy form of rock masses with dip angles of persistent joints. And the results reveal that: (1) The post-peak stress - strain curves of specimens with joint inclination angle of 15°and complete specimens are basically the same, but the difference of post-peak stress - strain curves of specimens with the joint inclination angle from 30°to 60°and complete specimens is vary greatly; (2) The post-peak failure modes of specimen change with different joint inclination. The research result can reflect mechanics and deformation and damage characteristics under uniaxial compressive loading in the phase of post-peak of rock masses with different dip angle pre-existing persistent joints.

## Introduction

Rock mass are mostly containing multiple irregular joints. In underground engineering surrounding rock is despite the destruction, many joints and even rupture state is more serious, but the failure of surrounding rock after mostly remained relatively stable, especially in Anchorage under the action of the stress field around the change, can form a stable structure and rupture the suitable, so studying the jointed rock after peak strength and deformation characteristics, is practical for the current project. Currently there are studied by means of mathematical calculations [1] [2], numerical analysis [3] [4], field testing and laboratory model tests.

Model test carried out in the laboratory is the better method. Because the rock is a complex containing much messy joint body, research ideas we can make to the process with a plurality of joints of rock from the intact rock into single jointed rock gradually carried out research on [5].

Domestic and foreign scholars regarding the mechanics of jointed rock compression through many experiments[6]-[9], but the study for post peak characteristics of jointed rock is few, for this paper, several groups through the joints of precast standard specimens containing different angle uniaxial compression tests carried out, through a systematic study of the uniaxial compression joints under different inclination failure mode peak after peak after the apparent relationship between the Poisson's ratio-strain curves - and post-peak stress.

## Experimental methodology

**Preparation of specimens.** Specimens for high 100mm diameter 50mm standard specimens, see Figure 1. Values were 15 °, 30 °, 40 °, 45 °, 50 °, and 60 °.

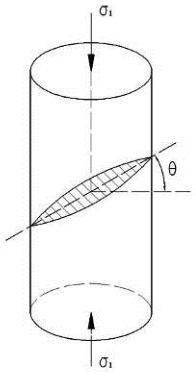

Fig.1 Schemes of jointed specimen

The cement mortar samples were produced by mixing of 425R OPC, sand and water at the ratio 1: 2.6: 0.35, respectively, by quality. To ensure the maximum possible homogeneity and isotropy of the overall compound, the OPC and silica sand were initially mixed together prior to the addition of water. Subsequently, water at room temperature was added to the dry mix of the constituents and thoroughly remixed. Grooves were cut on the two longer sides of the mold to insert thin galvanized sheets (0.1mm thick) in between them to create persistent (through-going) joints inclined angle which is 15°, 30°, 40°, 50°and 60° before initial setting, in order to simulate prefabricated through the fractured joints.

After the initial setting and final setting, the block will automatically make the fracture aperture closed to ensure that prefabricated fractured joints have certain cohesion. Each sample was kept under room temperature for 24 hours after being taken out of the mold, and then placed for 28 days, before cylindrical specimens with diameter 50 mm were cored from them. Individual cores were cut with a diamond saw to produce a set of cylindrical cement-mortar specimens 100 mm in height.

**Testing procedure.** Uniaxial Compressive Strength tests were carried out for the testing programme described below. All experiments were performed at TAW-2000 microcomputer control high stiffness servo testing machine. Methodologies utilized for the experimental work followed the ASTM specified standards for UCS testing.

## Results

**The post peak stress - strain curve.** The joint angle, the axial stress - strain curve shown in figure 2. The graph shows the difference of stress strain curve of the 15 ° joint angle specimen and complete specimen is very small. Great influence and joint angle from 30 °, 40 °, 50 °, 60 °, stress strain curve. As can be seen, the specimen in comparison with integrity, including joint angle at 30 ° to 60 ° between the specimen, the stress-strain curve from a single peak curve into a multi peak curve.

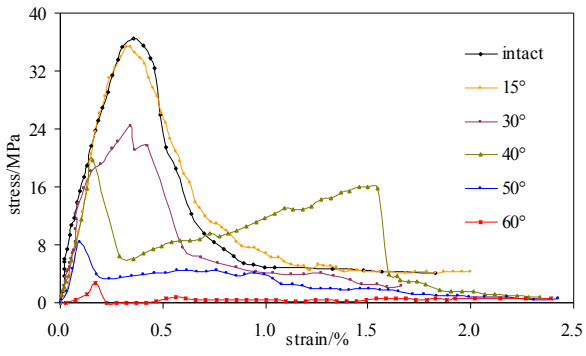

Fig.2 Axial stress-strain curves for specimens with different joint inclination angles

**Post peak failure mode.** Through the joint angle $\theta$ =15°, damaging effects of joints on the specimen is very weak, the specimen is still in accordance with the splitting failure. Through the joint angle $\theta$=30°to $\theta$=50°until failure forms of joint angle, the size of the specimen has great influence $\theta$=30°, the joint surface sliding failure and specimen overall splitting failure is almost the same time; =40°, first along the joint plane sliding failure, then produce overall splitting failure; $\theta$=45°, is still the first along the joint plane sliding failure, then produce overall splitting failure; $\theta$ =50° destruction, just along the joint surface sliding, does not produce splitting failure. Through the joint angle $\theta$=60°, along the joint plane sliding failure phenomenon is more obvious, there is no splitting failure.

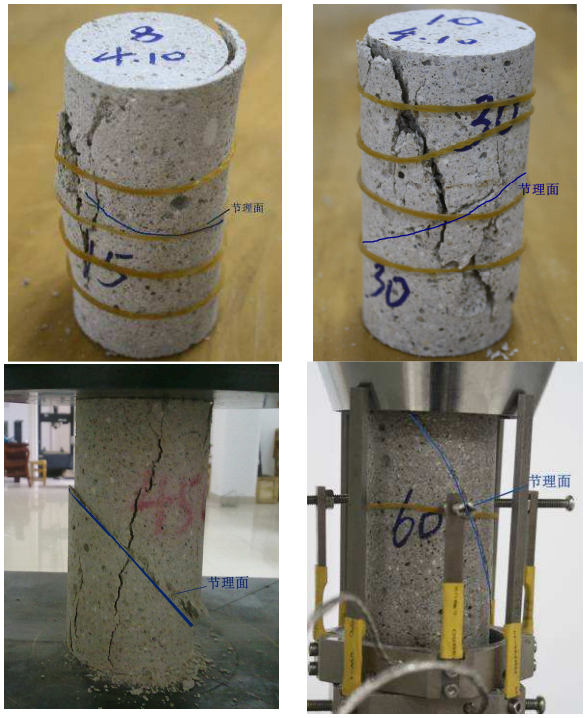

Fig.8 Post peak damage morphology of jointed rocks in turn with the joint inclination from 15°, 30°, 45°to 60°

## Discussion

When $\theta$=30°, 40°, 45°, stress-strain curve appeared multi peak phenomenon =30° time curve remains and complete curve similar, just after the strength peak curve has a small fluctuation of second small peak; but after $\theta$=40°, 45° stress-strain curve is greatly change the first peak, then there will be second, third or even more of the peak, the peak strength of will and the back is greater than the first peak intensity value. The first peak is the specimen damage in the joints, and the peak is due to the specimen had a splitting shear failure and produced, $\theta$=40°, 45° specimen easily along the joint surface damage, as the pressure increases further the two part separated off specimen is further compression (main factors at joints has not influence), which reached second peak, and this season will have a sliding surface, so the stress began to decline, but with the specimen is further compressed, pressure drop to the bottom and the gradually increased, it will repeat the last action, this is the reason why $\theta$=40°, 45°when there are multiple peak. 60°$\geq\theta\geq$50°, direct shear failure along the joint plane. To achieve greater angle this paper does not research.

Through jointed rock specimen failure with the different point of view, we can see the damage in the form of joint angle of peak after the main factors. The joint angle at $\theta$=15° when damage is splitting, the joint surface almost no effect, its failure forms and complete specimens were similar; $\theta$=60° failure is mainly shear failure, the failure is the main failure along the joint surface; $\theta$=30° and $\theta$=45° is splitting and shear failure mode, first damage along the joint surface, with the pressure increase joint friction is relatively stable, and began to produce specimens of splitting failure.

## Discussion

In this paper, a different angle of prefabricated jointed rocks through uniaxial compression test specimens were studied through joints inclination on the stress - strain curves and forms of destruction. From the experimental results obtained:

(1) With the change of joint angles, the post peak stress - strain curve significantly, jointed inclination $\theta$= 15° stress - strain curves and complete specimen similar, jointed inclination from 30°, 40°, 45°, 50°, 60° , the stress - strain curves and complete specimen obvious differences, stress - strain curves produce multiple peak after peak phenomenon, particularly evident at 40°.

(2) Different angle joints, different specimens after the peak phase of the failure mode. After the dip $\theta$= 15° when the specimen failure mode for the peak splitting, inclination $\theta$= 50°, 60° when the specimen after the destruction of the peak shear, angle of $\theta$= 30°, 40°, compared with 45°, splitting and shear cut the hybrid model.

**Keywords:** The seepage force; Phenomenological characteristics; Soil clod analysis; Soil particle analysis

**Abstract:** Soil mechanics has been developed for a long time and its concept system is basically complete. But there are still some concepts not being defined clearly. The unclear concepts of seepage force are stated from three phenomenological characteristics aspects in this paper. The difference between loaded object and calculated range is cleared. The contact rule of solid phase and liquid phase is illustrated. The mathematical meaning of seepage force is clarified. Though judging the critical hydraulic gradient of soil flow on surface of cohesionless soil, the difference and correlation of the soil particle and clod analysis based on the phenomenological characteristics will be illustrated.

## Introduction

Soil mechanics has developed for nearly 90 years since Terzaghi put forward the effective stress principle and one dimensional consolidation theory as the foundation of this subject. Water is important in the status of soil mechanics. Its influences on consolidation, strength, permeability, and many other theories have been caused wide attention and discussion in science and engineering. As the intersection of hydraulics and soil mechanics, the researchers in different disciplines have different understanding in the concepts and application of seepage. The concept of seepage force, for instance, has not been used in the hydraulic field because the main research object of which is a fluid. However, there are still some unclear and inoperable explanations in soil mechanics, which is especially disadvantage for beginners understanding and application of the knowledge. At present, the concept of seepage force which is defined by Chinese current soil mechanics teaching material[1]-[11] can be generally divided into the following two categories: (1) Seepage of water in the void of soil cold will drag on it. The stress and strain of soil can be changed by this force. The drag force on soil particles in the unit volume of soil is called seepage force; (2) While groundwater flow in the soil, head pressure will change due to the resistance of soil particles. From the point of the principle of action and reaction, the flow will surely exert a force on soil particles. For convenience, this force on unit volume in soil particles is named as seepage force.

Physically, the forces under seepage should be consisted of the normal water pressure on the surface of soil particles and the tangential force caused by viscosity of water. This kind of description also has been referred in hydraulics[12]. But in soil mechanics, viscous tangential force does not appear in the description of seepage force. And it is classified as the drag of water on soil particles or the soil particles' resistance to flow. Literally, the description of seepage comes from the angle of the water movement but not according to the objective existence of force itself, which will puzzle beginners. For example, whether the seepage force can be equated to the flow viscous tangential force which is mentioned in hydraulics? If it does, how can it be calculated?

In order to clarify the concept of seepage force and apply it to engineering, some phenomenological characteristics in the concept of seepage force will be explained first. The concept of loaded object and calculated range, solid-liquid contact rules, and the mathematical meaning of the drag force will be made clear. The domestic soil mechanics teaching material is draw to descript abstract concept of seepage force, which is the drag force of seepage flow applied to soil particles in unit soil.

**Explanation of the phenomenological characteristics in the seepage force concept**

So-called phenomenological characteristic is concluded from the study of surface phenomenon, which can explain the phenomenon but is not the accurate intrinsic reason of these phenomena. It is particularly prominent for the phenomenological characteristics in the concept of seepage force. The following will focus on the triple phenomenological characteristics in the concept of seepage force.

**(1)Disunity of loaded object and calculated range**

In order to understand the concept of seepage force, the loaded object and calculated range of research must be understood first. By definition, the loaded object is the soil particles in soil while the calculated volume range is the unit of the whole soil in the case of seepage. On the surface, it is unreasonable to establish such mathematical model for seepage force. When the seepage force was analyzed from a macroscopic perspective, the object analyzed is the general soil rather than the soil particle. It will not create a big impact on the final result in actual application based on the model and is convenient to apply theory to practice.

Similar ways of expression might be found in many concepts of soil mechanics. For example, the permeability coefficient is defined as the flow water cross the unit in the section of the soil. Actually, the section includes the cut surface of the soil particle and the pore. The seepage can only happen in the pore among the soil particle but not the whole section. In another word, seepage can only happen in the pore while the calculated object is the whole section. From this point of view, the definition of the permeability coefficient also reflects the disunity between actual analysis object and calculated one.

**(2) Contact rules of solid phase and liquid phase**

When setting up the mathematical model of the seepage, the mutual contact soil particles and water also should be taken into consideration besides considering applying object and forced object. The contact rules means: In the case of regarding the saturated soil clod unit (including soil particles and water in the pores of the soil particles) as the modeling object, it must be sure that the internal soil particles contact external soil particles and internal water contacts external water. That is to say the internal soil particles will not contact the external water or internal water will not contact the external soil particles at the contacting surface between clod units. To put it simply, there is no contact between different phases (as shown in Fig. 1).

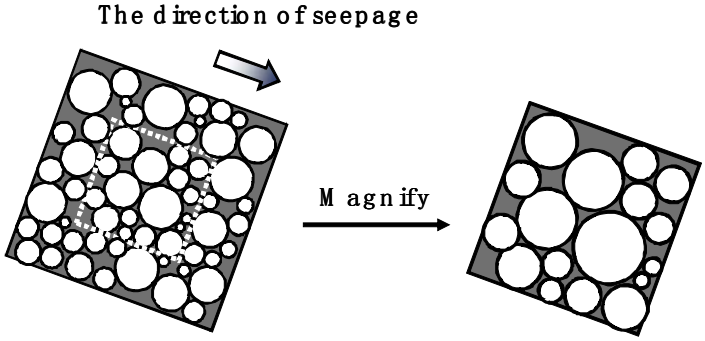

**Fig. 1 Solid-liquid phase contact in soil clod**

Physically, the contact between different phases certainly exists. The rule only caters to the modeling characteristics of a special classification method. There are several purposes as follows:

First, the resistance which soil particles put on the flow water can be solved under the condition of the model when regarding water as the analyzed object, thus the seepage force which is the reaction of resistance can be obtained;

Second, as the object of study, pore pressure is only generate between the water-water touching surface for soil cold. And this rule is in agreement with the calculating premise that pore pressure cannot cause the deformation of soil skeleton. It stays the same with the modeling of the effective stress principle.

Third, the viscous shear stress which is vertical to the pore pressure (that means the direction is tangent to soil particle surface) will not appear. The shear stress will only arise when solid is in contact with solid, and the water pressure will only arise when water contact with water.

**(3) The mathematical clarity of seepage force**

The drag in the definition of seepage force emphasizes the force which water applies on the soil particles under the condition of flowing. Due to the loaded object in the seepage force mathematical model is soil particle, the soil particle under the condition of static water is only loaded by buoyancy force. And the soil particle is also loaded by the reacting force of water resistance under the condition of seepage in addition to the buoyancy of water. Thus, the so-called drag force is the part of acting force of water flow on the soil particles except buoyancy. In addition to the seepage force and buoyancy, there is no more force imposing on the soil particles.

Saying from the physics, the force stressed by flow on the soil particle is the result of superposition of pore pressure and viscous force, or also can be seen as the result of superposition of seepage force and buoyancy(as shown in Fig. 2). The "force" in the two groups can not appear at the same time. Because the researchers are very clear to the method of the seepage force calculating, this kind of system is more inclined to adopt in the actual calculation. Although buoyancy and seepage force are not of real objective existence.

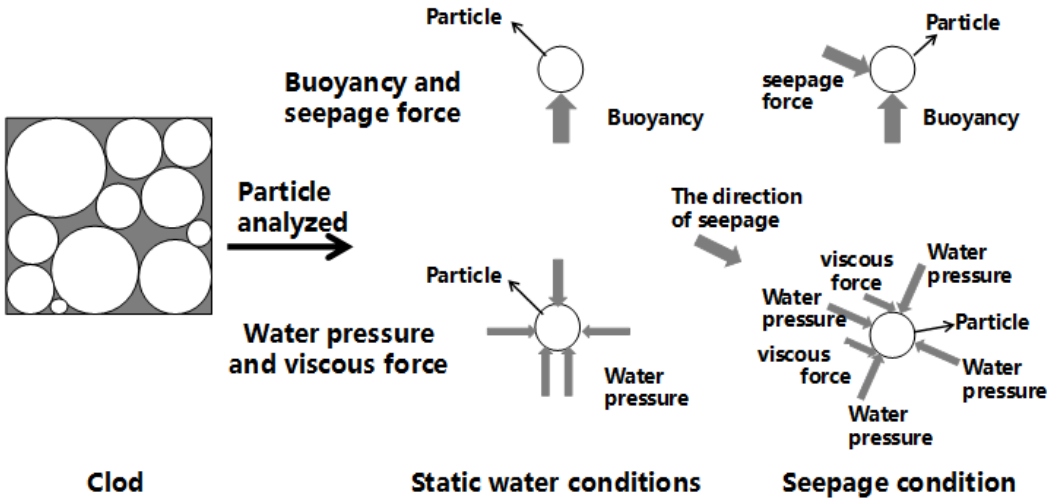

**Fig. 2 Two kind of force stressed on the soil particle**

To sum up, the definition of seepage force is put forward based on the above stating: Under seepage condition (or flowing condition) the water would load on the soil particles. Such load in the unit volume of soil cold consists of two parts. The buoyancy is the one part, and the seepage force is the rest part.

## Soil particle and soil clod analysis based on the phenomenological characteristics

Based on three layers of phenomenological characteristics mentioned above, water in soil mechanics shows two ways of the effect on the different mechanical objects while stress analysis was carried out on the soil particles or the clods. The third layer of phenomenological characteristics can help analysis the force of water putting on the soil particle in the system consist of buoyancy and seepage force when regarding soil particle as the research object. And the second phenomenological characteristics according to the above can help study the force condition of soil clod with pore pressure and effective stress analysis. The difference and correlation of the two methods will be illustrated with a simple example. It is the judgment of critical hydraulic gradient of soil flow on surface of cohesionless soil.

**(1) Seepage force analysis method with soil particles as the study object**

Seepage force analysis is used for studying soil particle under the soil flowing condition. As shown in Fig. 3, when the vertical upward seepage happens in soil, the soil particle in the soil clod is forced by the vertical gravity and vertical upward buoyancy put on. At the same time, due to the effect of

seepage water, soil particle will inevitably suffer the vertical seepage force. The two components together with the effective stress of soil particles are balanced. According to the mathematical model of seepage force in the volume of soil cold, the soil particle stress vertical balance can be set up:

$$\sigma' A = W_s - F_b - J = G_s V_s \gamma_w - V_s \gamma_w - i\gamma_w V = \gamma_w V[(G_s - 1)(1-n) - i] \quad (1)$$

Where: $\sigma'$—— Effective stress loading on the particles;

$A$——Area of the end of the infinitesimal clod;

$W_s$——Gravity of particles in the infinitesimal soil clod;

$F_b$——Buoyancy of particles in the infinitesimal clod;

$J$——Seepage force of particles in the infinitesimal clods;

$G_s$——Proportion of soil particles;

$V_s$——Volume of soil particle;

$\gamma_w$——Specific gravity of water;

$i$——Hydraulic gradient of infinitesimal clod;

$V$——Volume of infinitesimal clod;

$n$——Porosity of infinitesimal clod.

When the soil flowing occurs, the effective stress is zero. The critical hydraulic gradient can be easily got through the relevant formula translation:

$$i_{cr} = (G_s - 1)(1-n) \quad (2)$$

Where: $i_{cr}$——Critical hydraulic gradient of soil.

The third layer of phenomenological characteristic help deriving the balance. Through the analysis, the soil is the calculated range while the soil particle is the real loaded object.

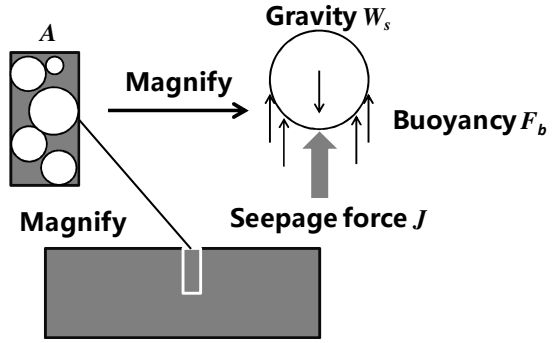

**Fig. 3 Effective stress analysis method based on the soil particle**

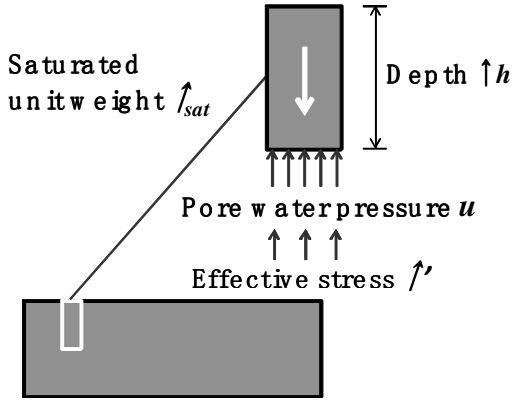

**Fig. 4 Effective stress analysis method based on the soil clod**

**(2) Effective stress and pore pressure analysis method with soil clods as the study object**

Similarly, the critical hydraulic gradient also can be analyzed with effective stress on soil clod.

There is a soil clod in the soil surface as shown in Fig. 4 being regarded as the analysis object. Its depth is $\Delta h$, which is very close to zero in the numerical value. The clod can be seen as an infinitesimal volume. The total stress $\sigma$ at the bottom is $\gamma_{sat}\Delta h$, the pore pressure $u$ is $\gamma_w \Delta h + i\gamma_w \Delta h$. When vertical seepage occurred, at the condition of soil damage critical state, the effective stress is zero, which means that the pore water pressure is equated with the total stress at the bottom. That is:

$$\gamma_{sat}\Delta h = \gamma_w \Delta h + i\gamma_w \Delta h \quad (3)$$

Through some formula translations, the critical hydraulic gradient can be expressed as the ratio of effective weight of soil to specific weight of water:

$$i_{cr} = \frac{\gamma'}{\gamma_w} \quad (4)$$

Where: $\gamma_{sat}$——Saturated specific gravity of Infinitesimal clod;

$\Delta h$——Height of infinitesimal clod;

$u$——Pore water pressure of the infinitesimal clod of by at the bottom of it;

$\gamma'$—— Effective specific gravity of infinitesimal clod.

Although (4) and (2) type is different in form, but the same result can be got by comparing the nature indicators of soil:

$$i_{cr} = \frac{\gamma'}{\gamma_w} = \frac{\frac{(G_s - 1)\gamma_w}{1+e}}{\gamma_w} = \frac{(G_s - 1)}{1+e} = (G_s - 1)(1-n) \tag{5}$$

Where: $e$——Void ratio.

From stating above, the hydraulic gradient can be got with the different ways with effective stress analyzing. Although the form is different, the result is unified. Also, the effective stress and pore pressure analysis method with soil particle or clod as the study object is feasible can be approve

## Conclusion

The three layers of phenomenological characteristics in the concept of seepage force system are stated above. In this paper, the acting force of water flow is clearly distinguished in the modeling of soil mechanics. And the assumption of single-phase contact is emphasized, when the soil clod is the analyzed object. The assumption guarantees that the effect of water flow only performance on the pore pressure, thus the modeling system of pore pressure and effective stress can be established. Based on the perspective of soil particle, the effect of water flow can be divided into two components including buoyancy and seepage force. And then the mathematical significance of seepage force from soil mechanics is explained. The correlating analysis not only strengthens the understanding of soil mechanics concepts but also promote the maneuverability of calculation in seepage.

# Finite element analysis of rock bolt foundation in metallurgical industrial plant

Mengxi Tan[1b] Hongbin Liu [2a]

[1] China University of Geosciences, beijing,China

[2] School of Civil Engineering, University of Science and Technology Liaoning, Liaoning, China

[a]binbinliu999@126.com, [b]441670016@qq.com,

**Keywords:** Rock bolt foundation; Foundation design; Static load test; finite element simulation

**Abstract.** Based on the application of Rock Bolt Foundation in metallurgical industrial plant foundation design, this paper utilized bolt deformation formulas that derived by Gu Shuancheng and others to calculate deformation of rock blot. The result is consistent with the experimental value, the authors can further verify the experimental and theoretical calculation value eventually by finite element analysis software ANSYS, which provides a reference for practical application of rock bolt foundation in metallurgical industrial plant.

## Introduction

Industrial plant is located in the seaside of Bayuquan Development Zone, which is a steelmaking continuous casting plant, rocks of this region possess a layer structure of shale. Large in density and slight slope, the bearing capacity of the bedrock is relative high. These plants adopt whole steel structure, its building area is approximately 150000 square meters, the height of plants can reach 65 meters, the converter charging span of crane beam is defined as heavy duty, which lifting load is 450 tons. According to practical condition of site, suppose that the foundations of plant employ the technique of traditional design into column foundations, however, it will inevitably lead to a waste of bearing capacity for rock subgrade. A large quantity of experimental date and analysis show that it is available to employ rock bolt foundation. In this case, rocks are taken as load bearing stratum, anchor erected in foundation base. Moreover, bedrock and foundation are connected into entirety to bear the moment so as to reduce the size of base and buried depth, which can save project cost.

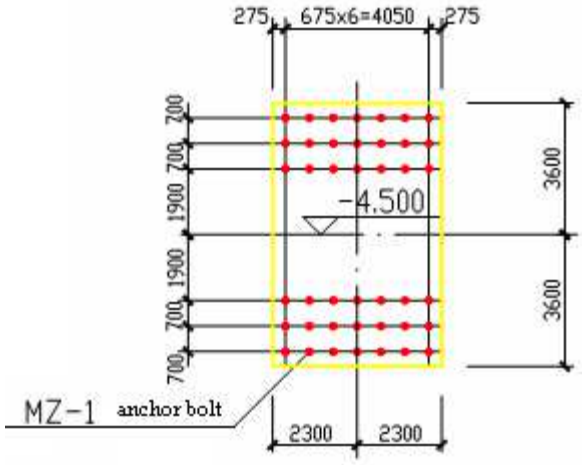

Fig. 1 Arrangement diagram of anchor bolt.

**Rock bolt foundation treatment**

Due to the plant structure is influenced by moment. Compared with others plans, the bolt can exert a better function when it is settled at the edge of foundation (Figure.1). Although calculation of bolt tension in the "Code for design of building foundation GB50007-2011" and "Code for design of high-rising structures GB50135-2006" accord the same set of formulas to obtain uplift capacity, calculations proceed without considering the force interaction between foundation and bedrock calculation, while actual bedrock owns a higher bearing capacity, one can ignore the compressive capacity of bolt. Therefore, the formula is applicable for the foundation with anchor bolt. Assignment of bolt for this project is relative unreasonable so that the author takes reaction of bedrock into account, which is reliable for the model.

**Single anchor uplift static load testing and theoretical analysis**

**Program of bolt detector and arrangement.** This static load testing commences with a ZY-50 type radial bogie, its operations are as follows: 1.Connecting the radial bogie with anchor bolts that to be measured, in addition, work-table of the hydraulic cylinder and bolts should be adjusted appropriately to make sure that bolts tolerate vertical load.2.Placing the value in the middle and it should be connected with pipe, then unscrewing the cover of hand pump.3. Pressing digital pressure gauge switch and adjusting to following state.4.Ensuring that all instruments are feasible, then the valve switch is placed in the "load" and "unload" position, which conducts pre-loading and unloading experiments.5.Since there is no issue, one can commence with the test of anchor bolt.6.It is desirable to turnoff gauge switch so that service life of battery can be prolonged after the test.7.Overloading is forbidden, digital pressure gauge can not exceed the maximum range.

In this construction the bedrock is mainly composed of moderate weathering rock, to reach its design elevation, bedrock is filled with 100~2000 mm concrete C15 as cushion. Bolt adopt two-stage Φ 32 hot rolled ribbed bar (HRB335), which diameter is 100mm and design depth of anchor rock is 4.0 m, afterward, pouring micro hole perfusion GJ type of secondary grouting material to guarantee the eigenvalues of a single anchor uplift loading is 130KN.

According to extract 5% of the total number for bolt, specify its position and check the site elevation for design of the foundation, bolts to be inspected in three days after perfusion.

**Bolt detector and theoretical calculation.**It is difficult to confirm uplift capacity and deformation of the bolt in engineering, furthermore, body material, rocks around the bolt, geometry characteristics of interface and physical properties of the bolt also effect its mechanics. At present, anchor design is still in state of experience and semi-empirical, for the acknowledge of mechanism in rock bolt is vague, it is especially complicated to estimate of the deformation and rigidity.

In this paper, the author employs the formula deduced by Gu Shuancheng, the total displacement of anchor S is divided into free section elastic displacement S1 and interface of relative shear displacement S2, expressed in a formula, the relationship can be written as $S= S_1+S_2$. Based on local deformation of theory, one can conclude ideal elastic-plastic load transfer model as the instruction, when drawing force is increased to a certain extent, surface of anchored rock and soil will gradually appear to current plastic condition. Before the capacity of anchor reach its ultimate capacity, the anchor rod section remains elastic. After a series of the deduction, the deformation of anchor bolt can be denoted by

$$S=[\frac{4L_1}{\pi E_s d^2}+\frac{4}{\pi D^2 E_a \beta}(\frac{1}{\beta L_b}+\frac{\beta L_b}{3})]p \qquad (1)$$

In which, P is the tension of the bolt, the freedom length of the bolt $L_1$ is 1.6m, the anchored segment of bolt $L_b$ is 4m, the diameter of anchorage D is 100mm, the interface tension of anchor in elastic limit is $p_e$, $E_s=2.06\times10^5 MP_a$, $E_r=3.25\times10^4 MP_a$.

$$\beta=\sqrt{\frac{4K_s}{DE_a}};E_a=\frac{E_r(D^2-d^2)+E_Sd^2}{D^2};K_s=\frac{3DE_a}{3\pi D^2E_a[S/P_e-4L_1/(\pi E_Sd^2)]L_b-4L_b^2}$$

On the basis of calculation, deformation of bolt can be figured out when the load applied to 52 kN, 78 kN ,104 kN, 130 kN ,156 kN, 182 kN ,208 kN, 234 kN and 260 kN. By extracting ten pillars of 34 bolts, one can make a comparison of its theoretical and experimental value.

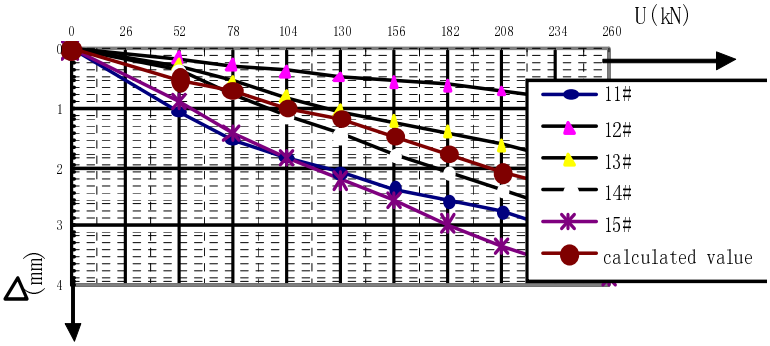

Fig.2 11-15# the curve of theoretical and experimental value U~Δ

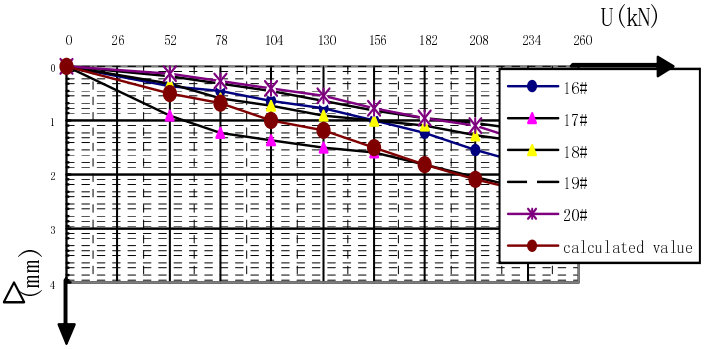

Fig.3 16-20# the curve of theoretical and experimental value U~Δ

By contrast the result obtained is in agreement with the experimental value, due to the distribution of shear stress along the anchor rod is uneven, anchor solid and rock interface between the limit of the shear strength and stiffness of bolt will generate a direct influence for stress distribution law, based on the factors as has been noted, it is difficult to determine bolt deformation directly by theory, bolt deformation formula inquires to be further improved. Meanwhile, specifics are to specific analysis, only by combination of theory with practice can ensure the safety of project.

**ANSYS finite element analysis**

The anchor bolt employs the element of LINK, Micro-swelling agent utilizes the element of PLANE42. Geometric parameters as follows: Freedom length of the bolt is 1600mm, anchored segment of bolt is 4000mm, diameter of anchorage is 100mm and its aperture is 32mm, diameter of the rock is 300mm. Mechanical parameters: Elastic modulus of rebar is $3.25\times10^4$MPa, the Poisson's ratio is 0.3, the strength of GJ Micro-swelling agent is equivalent with concrete C40, which elastic modulus is $2.06\times10^5$MPa, the Poisson's ratio is 0.27, elastic modulus of rock is $15\times10^9$MPa, the Poisson's ratio is 0.25. Graphs below plot the deformation of anchor after calculation:

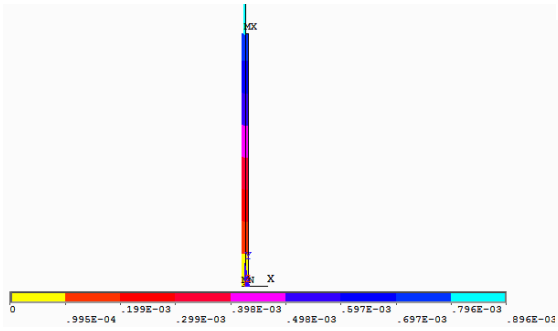

Fig.4 Y-Component of displacement ,Y=104KN

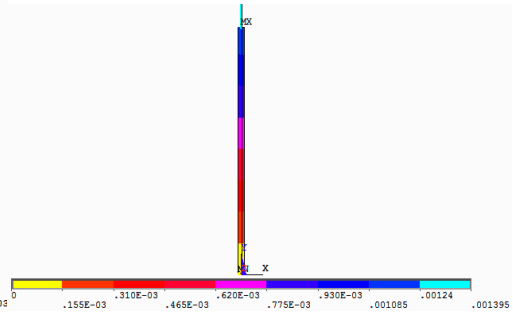

Fig.5 Y-Component of displacement,Y=156KN

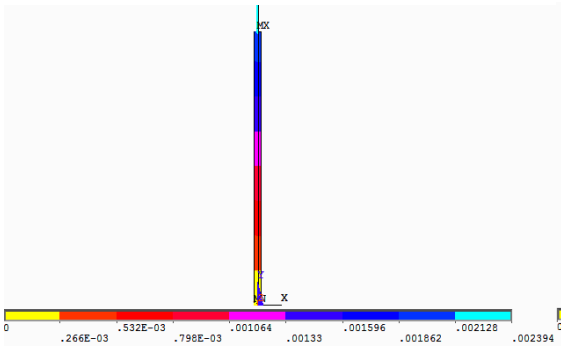

Fig.6 Y-Component of displacement ,Y=208KN

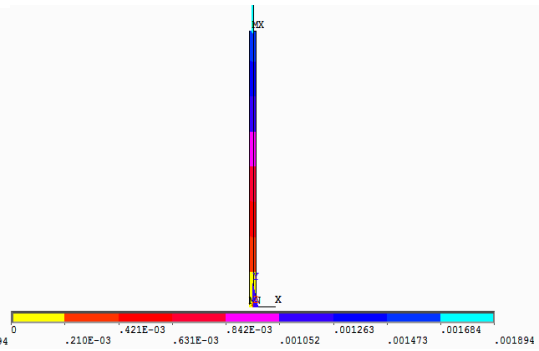

Fig.7 Y-Component of displacement ,Y=260KN

Through contrast one can conclude that the consequence fits into the computer simulation because of discreteness, reading error and initial eccentricity. Finite element analysis employs a simplified model, it is impossible to accurately simulate the stress of anchor rod, the main reason is that bonding effect between bolt and micro expansion agent is difficult to measure.

## Conclusion

The displacement of anchor bolt is a complex problem, there are many factors that can influence its deformation. These uncertain factors cause difficulties of simulation, to accurate calculation of the bolt deformation, either from theory or from practice are not possible. In this paper, result of the theoretical calculation is in line with the deformation value performed by ANSYS, moreover, the safety of anchor bolt is verified that provides a valuable reference for practical engineering. While bonding effect between bolt and micro -swelling agent are difficult to calculate and simulate, which deserves further research.

**Keywords:** Impact Load, Coal Failure, Acoustic Emission, Monitoring and Prediction

**Abstract.** To simulate the fracture of the coal under impact load, uniaxial pressure test of coal which retrieved from KongZhuang coal mine-DaTun coal and electricity Company of China coal group was done in the manner of strain control which rest with a function of uniform variable acceleration. Through researches on the stress-strain relationships and acoustic emission characteristics, the relationship between ring count rate and time series was founded, and the process before failure of coal was divided into four stages: low-level ringing count rate, higher level, highest level and peaceful period. Through the comparison and analysis, it is founded that acoustic emission characteristics in the stage of higher level of ringing count rate can be regarded as a basis for the prediction of coal fracture. According to three obvious rise stages of acoustic emission signal in the process before failure of coal, growth factor of climbing speed $\mu$ is introduced and the values are calculated between 2 to 4, and it is conferred that the value of $\mu$ is proportional to compressive strength of coal and loading rate. It is of great significance for the prediction of coal fracture by acoustic emission characteristics in the stage of new cracks.

## Introduction

The rock acoustic emission is a phenomenon that rocks release strain energy in pulse wave forms when its creek is extended. Since American scholar Obert discovered this phenomenon in the 1930s, study on acoustic emission is gradually developed and it is also applied in the structure engineering and mine monitoring in foreign countries. Chinese scholars conducted many studies on the technology of rock acoustic emission since 1980s. Because of its low technique requirement, simple and intuitive analysis mode, fast analysis, good real-time performance, easy master and operation, the technology of rock acoustic emission has been widely used in the mine ground pressure research and it has become one of the main means in the modern engineering monitor.

The signals of rock acoustic emission are always obtained through conventional uniaxial or triaxial pressure test, which contain abundant information includes rock damage and rupture. In engineering practice, the coal seams at the working face of deep mine usually bursts due to the impact which is caused by high stress disturbance on the top of the face. Study on the coal acoustic emission is widely developed in recent years and varieties of research thinking and analysis methods are adopted. So, plenteous research achievements are achieved. However, not so many scholars study on the effect of impact to coal, and existing prediction of coal burst caused by surge pressure in engineering are more depends on the experience. The failure of coal at working face caused by surge pressure is simulated approximatively through the coal specimen uniaxial pressure test under variable accelerative control. It has vital significance in the coal seam failure monitor and prediction to analyze the acoustic emission signals and to resolve the failure process and characteristics of signals.

**The coal specimen acoustic emission test under uniaxial pressure**

The diameter of the cylindrical coal specimen is 48mm and more details can be seen in Table.1.

Table.1 Numbers and heights of specimens

| Number | Height（mm） |
|---|---|
| Coal 01 | 100 |
| Coal 02 | 90 |
| Coal 03 | 76 |

In the test, the coal specimen is loaded through SAW-2000 Electro-hydraulic Servo- controlled Rock Mechanics Testing System and the acoustic emission signals are received by AE21C Acoustic Emission Instrument.

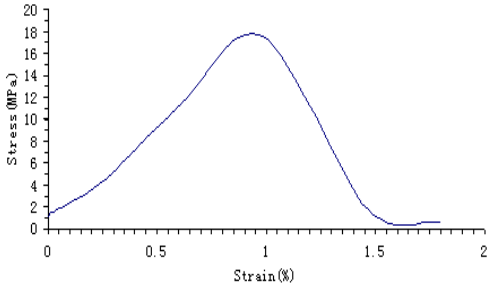
In the uniaxial pressure test, the specimen is under a dead load at first and then, to simulate the actual coal seam failure under surge pressure in the engineering by the strain-controlled method of ramped acceleration function. First, the coal specimen is applied a constant load in 2kN to simulate the dead load state of coal seam in stable period. From the first 30 seconds, the strain is changed based on the variety of the $\varepsilon = \frac{1}{6}\alpha t^3$ function. That is to say, the designed strain is changed in a ramped acceleration way at the acceleration $a = \alpha t$.

The controlling coefficient $\alpha$ of the coal sample01, 02, 03, is 0.003, 0.002 and 0.002 separately and all of them are under variable accelerative strain control to simulate the impact approximatively.

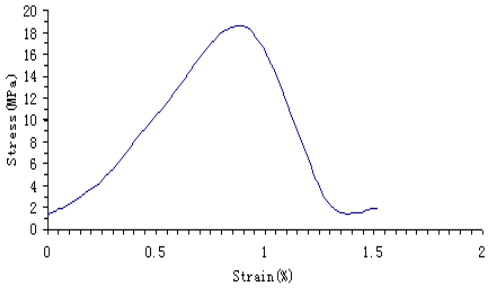
**The result and analysis of the coal dynamic response test**

At the beginning of the 30 seconds before the set function works, the constant load value is 2kN, the strain value is 0 and acoustic emission signal is not produced. During the period, time from the beginning of the strain controlled load to the damage of the specimen is very short. The dynamic load value gets the highest at almost 12s, 13s and 14s, and the specimen is damaged.

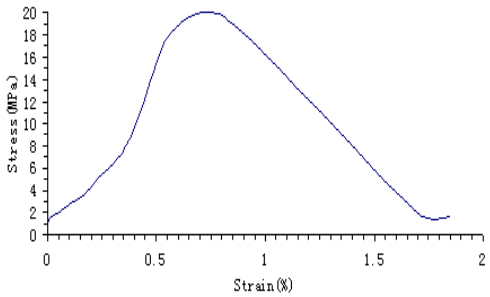
**The strain-stress relationship.** As is shown in Fig.1, the strain-stress relationship of the specimen follows the typical rock strain-stress relationship law.



(a) coal01



(b) coal02



(c) coal01

Fig.1 Relations of strain-stress for coal

According to the conversion formula provided from *Concise Handbook of Engineering Geology*, the uniaxial compressive strength value of non-standard specimen is corrected and the translated values can be seen in Table.2.

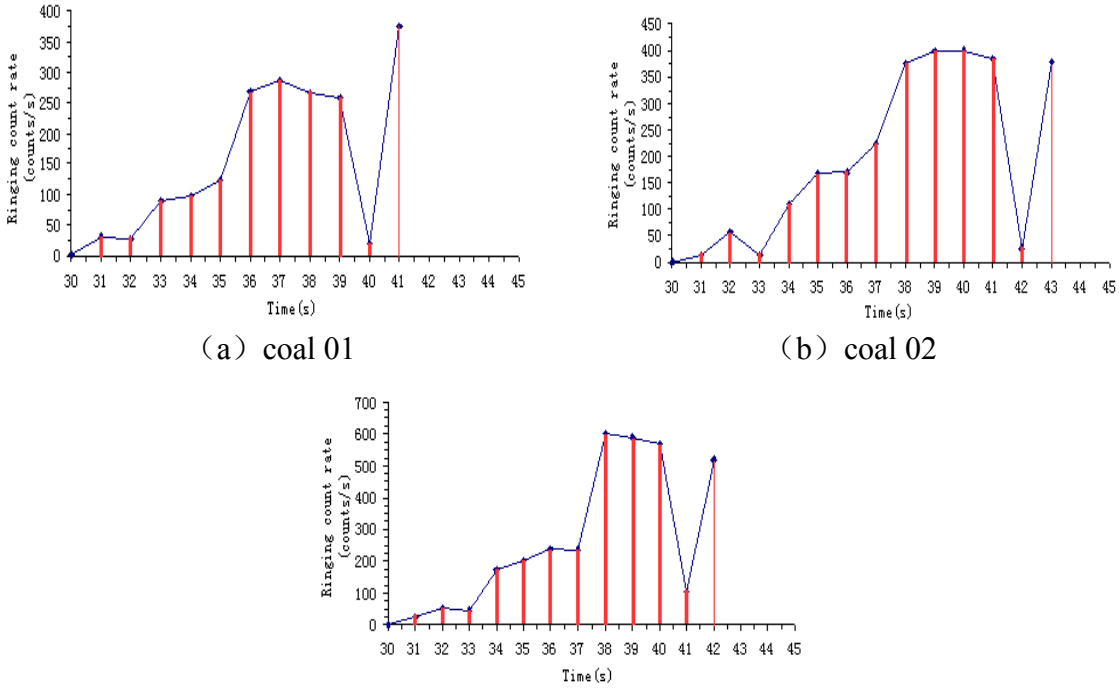
Table.2 Compressive strength of standard specimens

| Number | Coal 01 | Coal 02 | Coal 03 |
|---|---|---|---|
| Compressive strength (MPa) | 18.1 | 18.3 | 19.3 |

It can be inferred from the relationship of the compressive strength value and the strain value at the peak point of the stress that, the quantity of the internal cracks of coal 03 is the smallest and the degree of the joint is the lowest and it is the hardest. The crack development degree of coal 01 and coal 02 is close.

**The relationship of the ring count rate and the time series.** In the application of the acoustic emission techniques, the ring count is considered to be a parameter that can best reflect the variation of the material property in a variety of parameters. In the forecast of rock break, the monitor and prediction are achieved through parameter changes with time series. So, it is analyzed mainly through the relationship of ring count and time series. The results are as follows:

When the load maintains in 2kN, there is little acoustic emission or not and it can be considered that there is no acoustic emission produced. The ring count- time series curves before the specimen damaged are depicted in Fig.2.



（a）coal 01 （b）coal 02

（c）coal 03

Fig.2 Changes of ring-down accumulation counts over time for coal prior failure

The ringing count rate-time series curves of three specimens are quiet similar and four obvious stages are founded: ring count low level stage, higher level stage, highest level stage and peaceful stage. Thus, the typical ring count- time series cure can be described in Fig.3.

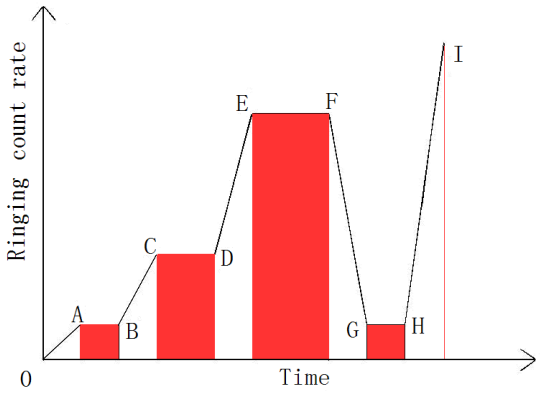


Fig.3 Diagram of typical changes of ringing count rate over time for coal under impact load

In the application of engineering prediction, the signals at peaceful stage are not suitable to regard as a characteristic signal to predict the coal damaged because coal is destroyed very soon after peaceful stage. If regard the signals at low level stage as monitoring signals, it may lead to false alarm. This is because the signal level is low and duration is very short, and the signals can be disturbed by the messy and irrelevant ones easily. According to the comprehensive analysis of the signal characteristics and time series, it is reasonable to regard signals at higher level as basis of coal failure prediction. During this period, the ringing count rate begins to appear continuous signal, maintains a lower level after rise, and rises up to a higher level after a short time. This time could be regarded as forecast period.

**The analysis of growth rate of acoustic emission signal.** The coal is damaged very soon after the peaceful stage and before this stage, the curve of ring count rate and time series has three obvious upward phrases. The mean upward rate of each phrase is defined as $k_1$, $k_2$, $k_3$ by the time order. The $k$ value calculated by test data can be seen in Table.3.

Table.3 Rates of mean in different rise stages

| | $k_1$ (counts·s-2) | $k_2$ ( counts·s-2) | $k_3$ ( counts·s-2) |
|---|---|---|---|
| Coal 01 | 29 | 61 | 145 |
| Coal 02 | 28 | 64.5 | 104 |
| Coal 03 | 26.5 | 127 | 365 |

It can be known from Table.3 that the $k$ value double increases with time, i.e., the ring count rate double increases at each stage. Average growths $\mu$ of each specimen can be seen as follows: $\mu_{01} = 2.239$, $\mu_{02} = 1.958$, $\mu_{03} = 3.832$. The interval of the $\mu$ value is (2, 4) and this means each stage ring count rate is 2 to 4 times to its previous one.

Combined with compressive strength of each specimen and the analysis of loading rate, conclusion can be inferred as follows: for the coals have the same compressive strength, the higher loading rate, the bigger $\mu$ value; for the coals under the same loading rate, the bigger compressive strength, the bigger $\mu$ value. That is to say, the compressive strength and loading rate have direct ratio relation with $\mu$ value separately.

Due to the limitation of the numbers of specimen and the loading rate, deep relationships of the growth multiple $\mu$, coal compressive strength and the loading rate need to be studied further.

## Conclusions

(1) The simulant impact test of coal is achieved through variable accelerative strain controlled method and it is more consistent with practical engineering situation.

(2) The characteristics of acoustic emission signals are analyzed and four obvious stages before coal damaged are founded: Ringing count rate's low level stage, higher level stage, highest level stage and peaceful stage. And the relationship of coal ringing count rate and time under variable acceleration load is gained.

(3) The ringing count rate at higher level stage can be regard as forecast basis of coal failure. The ringing count rate begins to appear continuous signal, maintains a lower level after rise, and rises up to a higher level after a short time and maintains stable. This time could be regarded as forecast period.

(4) The growth multiple $\mu$ of acoustic emission signal rate is introduced and the interval of the $\mu$ value is (2, 4). It can be inferred that the $\mu$ value has direct ratio relation with the compressive strength and loading rate separately. This is of great significance to predict the coal failure through ring count rate at higher level stage.

# Mechanical model of pile-soil work together

Sujuan Zhang

Civil Engineering School, Shandong Jiao Tong University, Jinan, Shandong, 250023, China

Zhangsujuan2007@sina.com

**Keywords:** pile-soil-foundation, mechanical model, the analytic method

**Abstract.** Come up with of pile-soil-(foundation) pile cap interaction grounded upon penetration deformation of pile ends and compression of soil between piles. Hyperbolic model is adopted to simulate the development of tip resistance and side resistance in accordance with deformation to reflect the nonlinearity of pile-soil work, Boussinesq solution is utilized to calculate the stresses generated in soil by foundation (pile cap)plate, Mindlin stress solution is used to calculate the stress produced in the soil between piles by side resistance and end resistance, and the stress of soil is the superposition of the two solutions.

## Introduction

## The play function of tip resistance and side friction with the change of penetration deformation

In view of previous scholars' research results, this paper use hyperbolic function to simulate the development of side resistance, compared with the relative displacement of pile-soil, and the development of pile tip resistance with normalized penetration deformation.

(1)Normalized settlement curve of pile tip resistance:

$$q_{cal} = \frac{K_p\left(\frac{s}{d}\right)}{n + m\left(\frac{s}{d}\right)} \tag{1}$$

In this formula: $K_p$ is correction coefficient, $s$ is amount of pile tip penetration, $d$ is diameter of pile, $m$ is the reciprocal of ultimate pile tip resistance $m = 1/q_{pcal}$ , $n = (s/d)_{ref}/q_{pcal}$ ,in most cases, median is more acceptable, namely, $(s/d)_{ref} = 0.235$, it can also be determined by fitting formula through experiment measuring. Without measured data, it may also be determined by making the following formula as a reference in standard value of pile end tip resistance.

$$q_{cal} = K_p\left\{\frac{\left(\frac{s}{d}\right)}{0.30+\left(\frac{s}{d}\right)}\right\}^{\frac{0.44}{0.33}} q_{s\tan dard} \qquad \frac{s}{d} \le 0.2 \tag{2}$$

(2) Similar to pile tip resistance, hyperbolic function is adopted to simulate the play of side resistance with pile-soil relative displacement:

$$f = \frac{K_S z}{a_f + b_f z} \tag{3}$$

In this formula: $K_s$ is correction coefficient, $f$ is frictional resistance, $z$ is pile-soil relative displacement, $a_f, b_f$ is constant. $b_f$ is reciprocal of ultimate frictional resistance of pile side $b_f = 1/f_{uit}$ , parameter $a_f$ is reciprocal of stiffness of initial tangent, the value is usually dependent upon measured data, on Hirayama's advice, the value can be $a_f = z_{reff} / f_{uit}$ ,and $z_{reff}$ can be 0.004Ds(Ds is diameter of pile); it can also be determined by fitting formula through test results.

**The determination of stress in soil**

2.1 The distribution assumption of foundation (pile cap) in sharing the stress

Assume that soil stress distribution of calculation unit in calculated foundation (pile cap) is rectangular footing with uniform distributed loading.

2.2 Layered property of soil and distribution assumption of side friction

Similar to load transfer method, the pile is divided into several segments, each of which is a calculation unit. Considering different soil properties, adopting different calculation parameters, the soil layers in calculated areas are set as calculated areas accordingly. when calculating, in accordance with the different soil properties in each calculated layer, we choose calculation properties of different soil properties. For the sake of analysis, two soil layers are considered, soil layers between piles and bearing course at pile end. As for the soil layers under the surface of pile end, they also receive stratified treatment when calculated.

2.3 The determination of additional stress in soil

Soil stress consists of three parts, namely, additional stress generated in soil by the load-sharing of foundation (pile cap), additional stress produced in soil by side friction and that brought out by pile tip resistance in soil. Elastic solution is still used to analyse the stress in soil layers in the situation of pile-soil interaction.

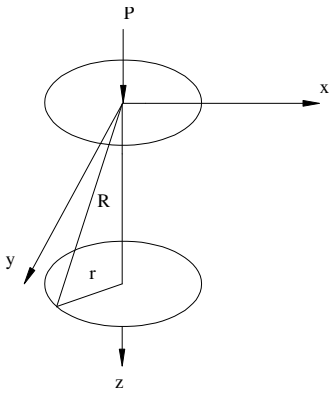

Fig. 1, Schematic analysi diagram for the surface stress of semi-infinite body

2.3.1 The solution of additional stress produced by bearing sheet in soil

Calculate the additional stress generated by foundation (pile cap) in soil, (Bossinesqsolution[1]) is used, which can calculate the vertical concentrated forces imposed on the elastic surface of semi-infinite body. See Fig. 1, under the action of vertical force, the stress components of additional stress in vertical direction is:

$$\sigma_z = \frac{3P}{2\pi} \frac{Z^3}{\left(r^2 + Z^3\right)^{\frac{5}{2}}} \tag{4}$$

The stresses of each point under foundation(pile cap) can go through integral solution with above formula, then additional stress in soil produced by foundation(pile cap) is defined.

2.3.2 The solution of additional stress generated by side friction and pile tip resistance in soil

(1) Geddes stress solution

To calculate the stress and settlement under soil layers of a single pile and piles, Geddes stress solution, integral expression of Mindlin stress solution, is employed. Geddes stress solution assumes that soil is a semi-infinite body which is isotropic, uniform and elastic, Geddes holds that the load on pile top of a single pile p consists of three parts, see See Fig. 2,

$$P = P_b + P_\gamma + P_t = P_b + P_\tau \tag{5}$$

$$P_b = \alpha P \tag{6}$$

$$P_\tau = \beta P \tag{7}$$

$$P_t = (1-\alpha-\beta)P \tag{8}$$

In this formula:

$P_\tau$ is aggregate side friction, $P_\gamma$ is side friction of rectangular distribution（kN）, $P_t$ is resultant force of triangular distribution side friction(KN); $\alpha, \beta$ is load distribution coefficient of pile tip resistance and rectangular distribution side friction respectively.

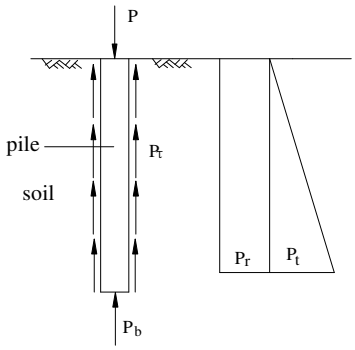

Fig. 2, Schematic analysis diagram of a single pile stress

Under action of the above internal forces, vertical additional stress of any point M(r,z)in soil can be solved according to the following formula, see Fig. 3,

$$\sigma_z = \sigma_{zb} + \sigma_{zr} + \sigma_{zt} = \frac{P_b}{L^2} I_b + \frac{P_r}{L^2} I_r + \frac{P_t}{L^2} I_t \tag{9}$$

In this formula:

$L$ is embedded depth of pile, $I_b, I_\gamma, I_t$ is additional stress coefficient of any point in soil under action of pile tip resistance, frictional resistance of rectangular distribution and frictional resistance of triangular distribution respectively. Geddes also gives the vertical additional stress coefficient in soil.

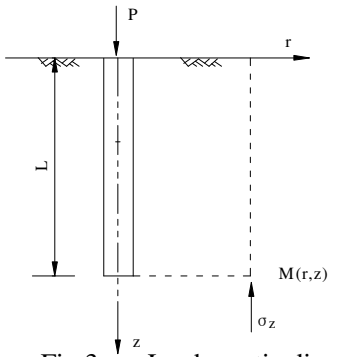

Fig.3, r,z,L schematic diagram

(2)additional stress produced by side friction in soil

The intensity of side friction can be fixed with the formula (3). Suppose side friction is evenly distributed in the calculated pile, pile-soil relative displacement is determined by the middle point of calculation unit of pile and that of the corresponding calculated soil layer.

Adopting integral expression of Geddes on Mindlin stress solution to solve the additional stress produced by pile in the soil, because the given side friction is the average side friction of each pile,

when using the formula, superposition is imperative, see Fig. 4, pile is divided into n units, top depth of the unit k is ht, k, bottom depth is h, k, then additional stress produced by the frictional resistance of unit k in points of the soil is $M(h_t,k)$-$M(h_b,k)$.

Function M (h) indicates the pile with the length, the pile side resistance of which is the additional stress generated by the average frictional resistance of unit in points of the soil, and additional stress generated by side friction of the whole pile in points of the soil is

$$\sum_{i=1}^{n} M\left(h_{t,i}\right) - M\left(h_{b,i}\right) \tag{10}$$

In this formula:

M (h) can be solved by Geddes based upon side friction influence coefficient formula of Mindlin solution.

(3)additional stress set off by pile tip resistance in the soil

Formula (1) is used to determine the intensity of pile tip resistance. As for the additional stress set off by pile tip resistance in the soil, integral expression of Geddeson Mindlin stress solution is used.

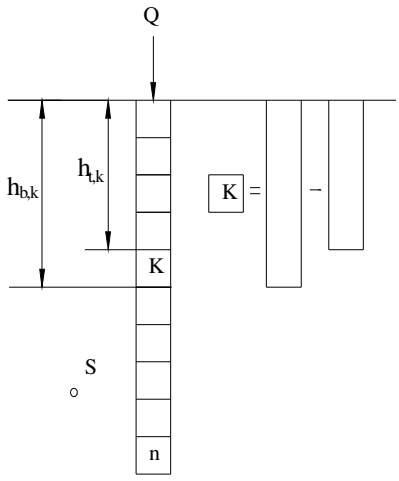

Fig. 4, K additional stress calculation produced by side friction of a single pile in points in soil

**Determination of soil deformation**

After additional stress of soil is fixed, additional stress layer-wise summation method is used to determine soil deformation. Compression modulus, which is defined according to e～p curve, is helpful in reflecting the nonlinearity of soil.

**Summary**

This paper puts forward stress model based upon micro pile-soil-foundation (pile cap) interaction, analyzes different stress stages and calculation method of foundation sedimentation value in each stage. Based upon penetration deformation theory, related calculation program is developed in accordance with pile-soil interaction.

# Mechanics analysis of flexible base Pavement Structure

Liya Su

Architecture and Civil Engineering School, Inner Mongolia University of Science and technology, Baotou, 014010, China

suliya1@.imust.cn

**Keyword:** Asphalt pavement; Flexible base; Elastic modulus; Reasonable thickness

**Abstract.**With the rapid development of traffic cause in our country, the operating requirement of driving load factors to pavement structure become higher and higher. The Semi-rigid base asphalt pavement structure exposed some defects and shortcomings, so the study of flexible base asphalt pavement structure is put on the agenda under the circumstances.Based on the research achievements at home and abroad of the existing asphalt pavement structure , choosing different elastic modulus and thickness to calculate and analyze the flexible base by ANSYS, gaining the law and trend of mechanics response (the vertical displacement and tensile stress) about pavement structure for the flexible base pavement of each layer foundation to provide the design reference.

## Introduction

The semi-rigid base asphalt pavement structure of domestic traditional appear constantly early damage problems such as local network crack, pavement crack and push, which affect seriously the our country development of transportation and economy, so flexible base have good development and application prospect [1], and the basic types pavement structure has been used widely. According to foreign experience, it has the some advantages but the semi-rigid base is not ,and overcome some shortcomings of the semi-rigid base, but domestic research has just started in this field. For that reason, further systematic research the flexible base asphalt pavement structure for our country development of road pavement structure has the profound significance [2].

## Establishment the finite element model of flexible pavement

Pavement structure is actually a three-dimensional engineering structures can bear any form load, so the best model describing the road system work is the 3D model [3] as shown in Fig.1. The concrete form of flexible base pavement have many kinds, which can be roughly divided into surface course, base course, subbase and soil matrix.

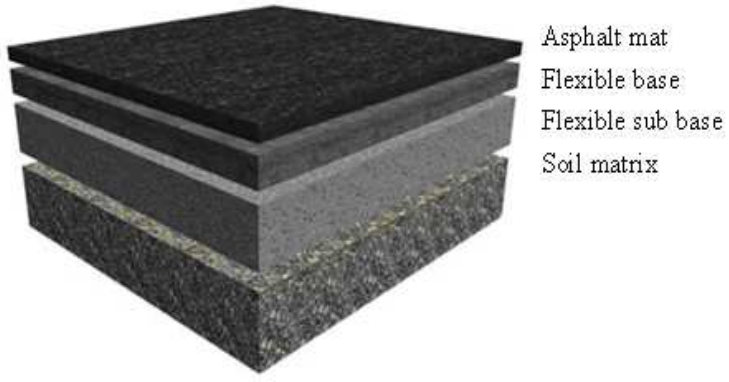

Fig.1 A typical flexible base asphalt pavement structure

In order to apply the above calculation model and finite element method to analyze the force mechanism of flexible base asphalt roadbed by ANSYS, the material properties and the structure characteristics of the model for the following assumptions: the layers are continuous, completely

elastic, homogeneous and isotropic; the next layer is infinite in the horizontal direction and vertical direction; layers contact condition for completely continuous; and the weight of each layer was Ignored[4].

Model geometry size and the actual size is similar, the road width for 6m, the base thickness for 6 m and the length along road direction for 7m. According to the design specifications of highway asphalt pavement (JTGD50-2006) [5] known that standard axle load for BZZ -100, the tire ground pressure for 0.7MPa, when the radius of circle for 10.65cm, two rounds of center distance for1.5cm*10.65cm. In order to calculate conveniently, the wheel load is simplified to square uniformly distributed load for19 cm*19 cm, contact area for 361 square centimeters and double center distance for 32 cm. The entity model after the mesh as shown in Fig.2.

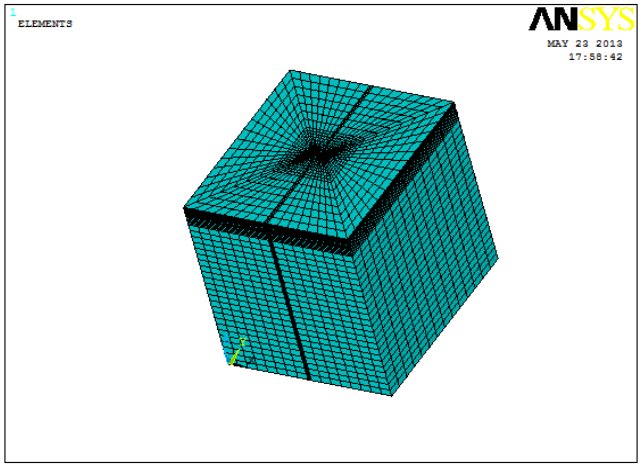

Fig.2 Grid Meshing by ANSYS

**Mechanics effect of Elastic modulus for pavement structure**

Changing the elastic modulus to study the change rules of deflection value and stress under the condition of the flexible base thickness unchanged,the rustle as shown in Tab.1, Fig.3 and Fig.4.

Tab.1 The structural parameters of the flexible base for asphalt pavement

| | elastic modulus(MPa) | thickness (cm) |
|---|---|---|
| asphalt concrete pavement | 1400 | 17 |
| flexible base | undetermined | 23 |
| flexible subbase | 800 | 30 |
| soil matrix | 60 | 600 |

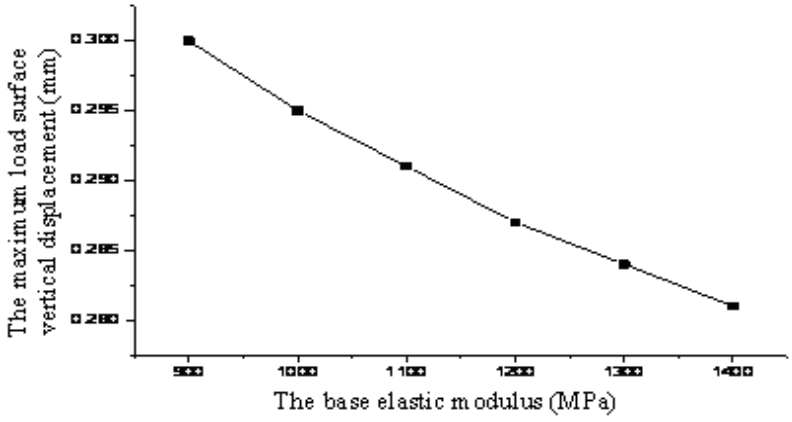

Fig.3 The relation of base elastic modulus and maximum load surface vertical displacement

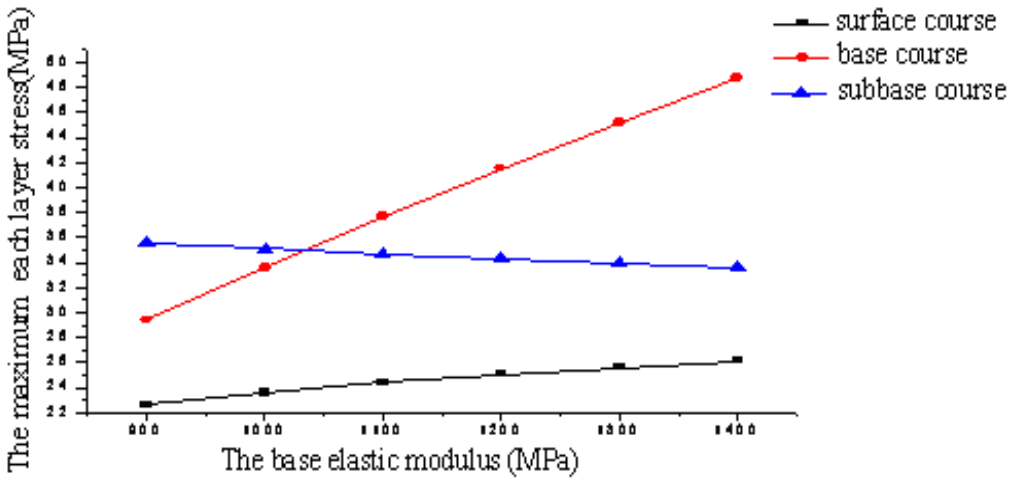

Fig.4 The relation of base elastic modulus and maximum each layer stress

The deflection value of road surface and the elastic modulus of flexible base meet to linear relationship. With the increase of elastic modulus about flexible base materials, the deflection value of road surface decreases gradually as shown in Fig.3. The tensile stress increased by 15.4% at the bottom of the surface layer, tensile stress increases 0.93 times at the bottom of base layer, and tensile stress decreases by 6.8% at the bottom of the subbase as shown in Fig. 4.

**Mechanical effect of the basic thickness for pavement structure**

Changing the flexible base thickness to study the value of deflection and stress under the condition of the elastic modulus unchanged, the result as shown in Tab.2,Fig.5 and Fig.6.

Tab.2 The structural parameters of the flexible base for asphalt pavement

| | elastic modulus(MPa) | thickness (cm) |
|---|---|---|
| asphalt concrete pavement | 1400 | 17 |
| flexible base | 1200 | undetermined |
| flexible subbase | 800 | 30 |
| soil matrix | 60 | 600 |

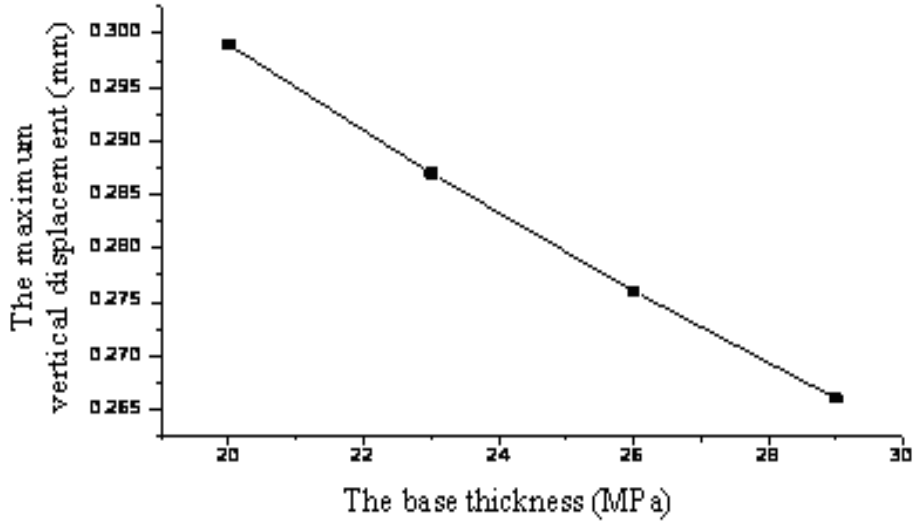

Fig.5 The relation of base thickness and maximum vertical displacement

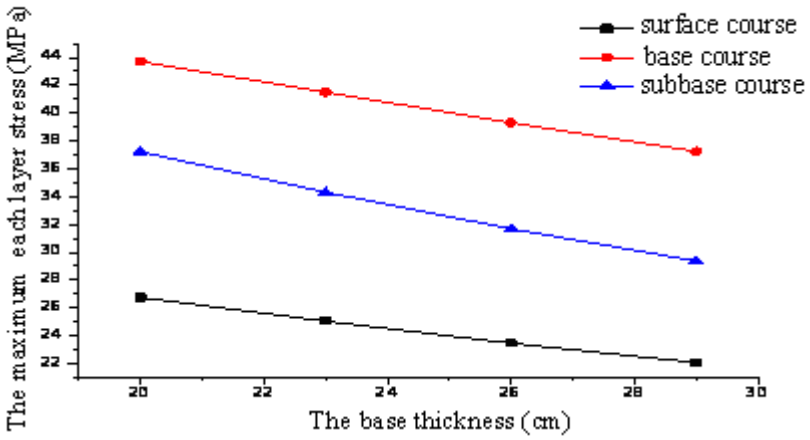

Fig.6 The relation of base thickness and maximum each layer stress

Fig.5 shown that the influence of flexible base thickness and the influence of elastic modulus to road surface deflection is the same, and Fig.6 shown that the increase of base layer thickness will make the tensile stress decrease in different degree at the bottom of each layer.

## Conclusion

Mechanics analysis of flexible base asphalt pavement structure by the ANSYS. When select different elastic modulus and thickness of flexible material, analysis and checking calculation the mechanical response of various design parameters on pavement under the traffic load (stress and displacement component).Through calculation and analysis get the following conclusions:

The influence of structural base elastic modulus for the mechanics index is obvious, The increases of base elastic modulus lead to the maximum vertical displacement reduced,which indicate the bigger the material modulus, the smaller the deflection value. In order to make the large deformation of pavement structure was not produced , the use of materials need have enough modulus.Because the changes of base modulus can affect the tensile stress at the bottom of each layer, the increased of base modulus will make tensile stress at the bottom of base layer increase.

The increase of the base thickness lead to the value of pavement structure deflection depress, and the base thickness increase also can make the tensile stress have the different reduction at the bottom of each layer.

**Keywords:** deep foundation pit; deep horizontal displacement; deformation control; monitoring analysis

**Abstract.** The horizontal displacement of pit top and horizontal displacement in deep soil of underground garage deep foundation pit in Radio and TV centre of Shandong province was analyzed. Combing the deformation control value of foundation pit, we thought that the supporting structure was safe and reliable. The supporting structure could not only meet the strength requirements but also meet the deformation control requirements. This deep foundation pit was a successful case under complex conditions. Analyzing the variation rules between monitoring data and construction time, the instructive conclusions were obtained. The deformation of foundation pit external corner was largest. The external corner should be avoided in foundation pit. The dynamic loads around foundation pit had a great influence on the safety and stability of pit. The rainfall was disadvantage factors, so the construction of foundation pit should keep away from the rainy season. The foundation pit floor could limit soil deformation and improve the safety of pit. The pit floor should be constructed as early as possible.

## Introduction

In the recent twenty years, the foundation pit engineering has become a hot issue and difficult problem in the field of geotechnical engineering [1]. The foundation pit engineering is a comprehensive system engineering. It is related to not only the soil strength and stability but also the collaborative work of soil and supporting structure. The design and construction of foundation pit is to ensure the safety and stability of supporting structure, but also to ensure the safety of the surrounding buildings and facilities [2-4]. At present, a lot of dangerous accidents have happened in the foundation pit engineering. In many accidents, the collapse of foundation pit has brought destructive impact on the surrounding buildings and facilities and caused incalculable losses [5, 6]. The accidents have a lot to do with the complex and imperfect design theory of foundation pit engineering. Based on the present situation, the monitoring analysis of foundation pit engineering and typical engineering experiences have become very important. The underground garage deep foundation pit in Radio and TV centre of Shandong province is a deep, large, complex engineering. Combing with the monitoring data of this engineering, the deformation of pit soil and surrounding buildings with foundation pit construction has been analyzed, and the safety and stability of the pit engineering has been evaluated. Some instructive conclusions are obtained, and these conclusions can provide references for similar engineering.

## Project Overview and Reinforcement Scheme

The underground garage deep foundation pit in Radio and TV centre of Shandong province is located in north-west corner of intersection of Youth East Road and Jingshi Road in Jinan. The surroundings around foundation pit are complex. There are buildings and underground pipelines near the foundation pit. The foundation pit excavation depth is 17.9m, the width is about 30m, and the length

is about104m. Because of the deep excavation depth, the complex surrounding environment and the restriction of excavation site, the supporting structure of foundation pit is required. According to the engineering geological and hydro-geological conditions, combing with the surrounding environment, the safety grade of the foundation pit shall be class A. The lateral wall of foundation pit is vertical, the steel pipe piles and pre-stressed anchors are used to support foundation pit. The diameter of steel pipe pile is 200mm, the effective length of pile is 20.5m, and the spacing of pile is 600mm. The rod body material of anchor is 2φ28 steel bars. The anchored length of pre-stressed anchors is 13m, and the free length is 7m. The horizontal spacing of anchors is 1.5m, and the vertical distance is 2.5m. Reinforced shotcrete is used for surface protection.

## Monitoring Scheme of Foundation Pit

The safety grade of the foundation pit is class A. The working time of foundation pit is 18 months. According to the regulations of Technical Code for Monitoring of Building Foundation Pit Engineering, monitoring items of the foundation pit engineering should include: the horizontal and vertical displacement of pit top, the horizontal displacement in deep soil, the settlement of surrounding buildings, the internal force of supporting pile structure, etc. Because of the limited space of this article, only the horizontal displacement of pit top and the horizontal displacement in deep soil were analyzed in this paper. Fig.1 is the monitoring plane layout of foundation pit.

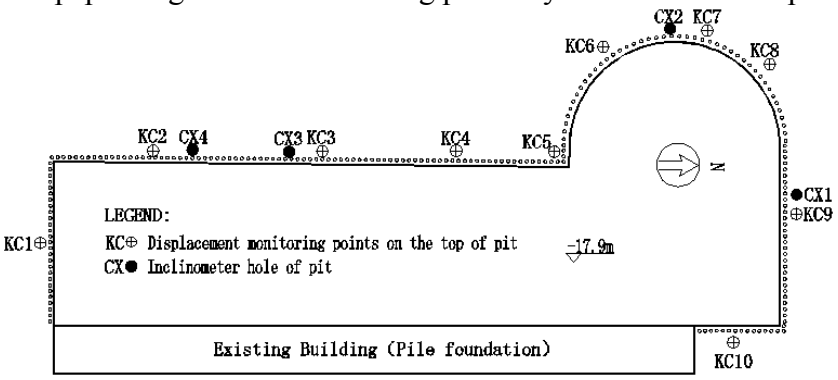

Fig.1 Monitoring plane layout of foundation pit

## Monitoring Results and Analysis

**Corresponding Relations between Key Time and Construction Content.** From the pit excavation to the construction of underground garage structure is a longer period of time, and a large number of monitoring data is gained. Analysis of all of the monitoring data is very difficult and not easy to find out the rules. Therefore, the monitoring data of several key time was analyzed. In order to obtain the instructive monitoring conclusions, the corresponding relations between the key time and the foundation pit construction content should be clear firstly. Table 1 is the corresponding relations between key time and foundation pit construction content.

Table 1 Corresponding relations between key time and construction content

| Key time | Construction content and related events | Cumulative time / d |
|---|---|---|
| April 13, 2011 | Set monitoring point, Install inclinometer tube, excavate earthwork | 0 |
| July 10, 2011 | Excavate to -5.5m, install the first and second rows of pre-stressed anchor | 88 |
| September 15, 2011 | Excavate to -11m, install the third and fourth rows of pre-stressed anchor | 155 |
| November 15, 2011 | Excavate to -16m, install the fifth and sixth rows of pre-stressed anchor; continuous and heavy rain | 216 |
| December 20, | Excavate to the final depth -17.9m | 251 |

| | | |
|---|---|---|
| 2011 | | |
| March 25, 2012 | Complete the construction of the cushion and floor of underground garage | 346 |
| September 15, 2012 | Complete the construction of underground garage; ready to backfill | 460 |

**Horizontal Displacement of Pit Top.** Fig.2 is the correlation between horizontal displacement of pit top and cumulative time. The positions of monitoring point KC1, KC3, KC5, KC7 and KC9 are marked in Fig.1. The horizontal displacement of pit wall is negative, which indicates the deformation of foundation pit is towards inside. In order to analyze the monitoring datas, the details of some monitoring points are as follows: KC5 is located in west external corner position of the foundation pit; KC7 is located in west internal corner position of the foundation pit; KC9 is located in the north central position of the foundation pit, there are dynamic loads in the vicinity.

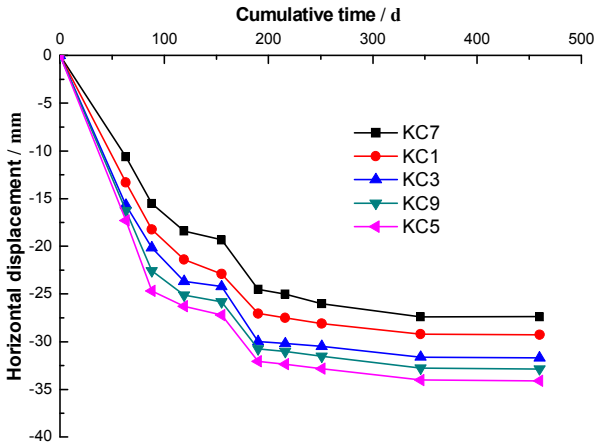

Fig.2 Correlation between horizontal displacement and cumulative time

The horizontal displacement of monitoring point KC7 is the smallest, and the ultimate displacement value is -27.39mm. The horizontal displacement of monitoring point KC5 is the biggest, and the ultimate displacement value is -34.13mm. The horizontal displacement of foundation pit external corner position is far greater than the internal corner position. Therefore, external corner should be avoided in the design of foundation pit. The horizontal displacement of monitoring point KC9 is relatively large and close to the control value, and the ultimate displacement value is -32.85mm. This shows that the dynamic load on the north side of foundation pit has great influence on the safety of the foundation pit. In the cumulative time from 155 days to 216 days, there has been a bigger increase in the horizontal displacements of all five monitoring points. Considering the rainfall in this period, rainfall has a great influence on the safety of foundation pit. In the cumulative time from 251 days to 346 days, the horizontal displacement increases continuously, while the horizontal displacement remains unchanged in the cumulative time from 346 days to 460 days. This shows that foundation pit floor is very important to the safety of foundation pit.

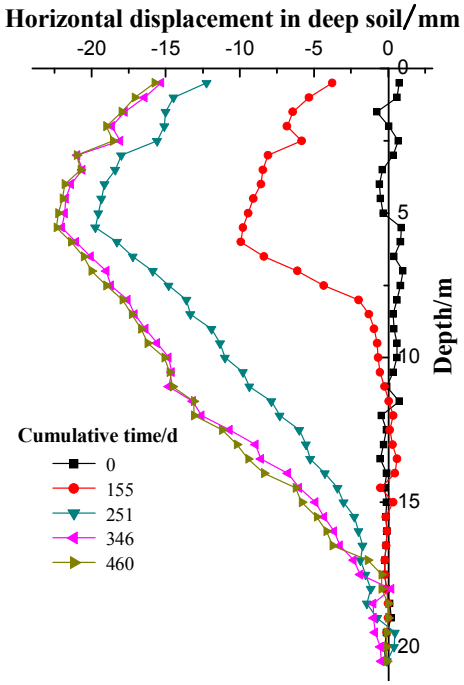

Fig.3 Correlation between CX1 horizontal displacement and depth

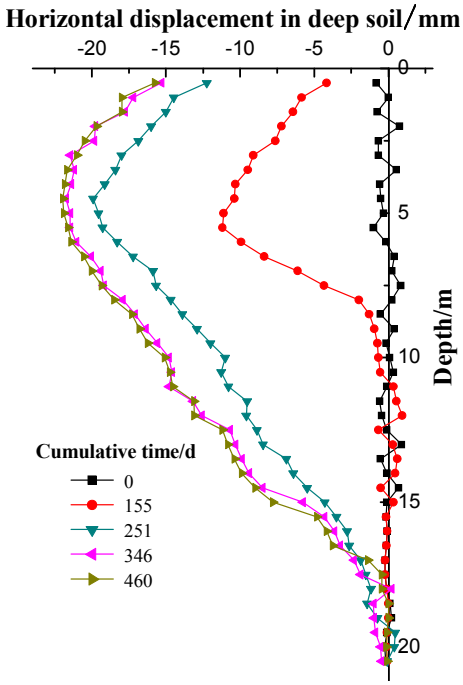

Fig.4 Correlation between CX1 horizontal displacement and depth

**Horizontal Displacement in Deep Soil.** The inclinometer is a device used for monitoring the horizontal displacement in deep soil. It can monitor the magnitude and direction of horizontal displacement. The project provided four inclinometer holes, their position are shown in Fig.1. Fig.3 and Fig.4 is the relationship curve between deep horizontal displacement and depth of CX1 and CX3. The variation rule of the deep horizontal displacement is consistent basically in Fig.3 and Fig.4, but it is worth noting that: (1) in the cumulative time from 155 days to 251 days, the horizontal displacement has more than doubled. Considering the rainfall in this period, rainfall has a great influence on the deep horizontal displacement of foundation pit. (2) Comparing the three curves of cumulative time 251 days, 346 days and 460 days, we find that the horizontal displacement of deep soil has not change after the completion of foundation pit floor, while the soil displacement is still increasing before the completion of foundation pit floor. This indicates that foundation pit floor is favorable factors for the safety of foundation pit.

## Summary

After finishing the analysis of the foundation pit monitoring data, we find that foundation pit supporting structure is safe and reliable. The supporting structure can control soil deformation effectively. It is a successful deep foundation pit case under complex conditions. Further analysis of monitoring data variation, we get the following instructive conclusions: (1) the deformation of foundation pit external corner is the largest; and the external angle should be avoided in the foundation pit. If the external corner can not be avoided, the supporting structure should be strengthened and the monitoring frequency should be increased. (2) Dynamic load around foundation pit has a great influence on the pit safety. If the dynamic load can not be avoided, enough safe distance should be provided. (3) The rainfall is disadvantage factors for the safety and stability of foundation pit engineering. The construction of foundation pit engineering should avoid the rainy season; otherwise the monitoring frequency should be increased. (4) The pit floor can limit soil deformation and improve the safety of pit. Therefore, the pit floor should be as soon as possible constructed.

**Keywords:** borehole camera, geological survey, coral reef, rock mass integrity.

**Abstract.** At present, relatively few drilling surveys have been conducted on coral reefs, and comprehensive geological info on coral reefs is difficult to obtain. However, research of coral reef is of great importance to our development and exploitation of maritime resources. The survey of Chenhang Island in Paracel (Xisha) Islands saw China's first usage of digital borehole camera technology, which resulted in a large amount of first-hand geological data. We have utilized the rock mass integrity index (RMDI) method in our analysis of coral reef integrity, and with reference to the rock mass classification standard, formulated the correlation between RMDI values and coral reef intactness, enabling the engineering evaluation of coral reef integrity. Through statistical analysis of camera data gathered along the CK2 borehole's approx. 1km length, we performed an integrity evaluation of the entire borehole length using the RMDI classification, and created a coral reef stratum development diagram which is consistent with the actual cores. The results indicate: (1) the classification system based on RMDI is feasible in the integrity evaluation of coral reefs; (2) the coral reef integrity values obtained using the RMDI method are accurate; (3) borehole camera survey and statistical analysis are of great utility in the study of coral reefs.

## Introduction

Coral reefs are rock and soil structures formed by the remains of scleractinian corals (refer with: Fig. 1) after long-term geological effects[1]. They can be found widely and prominently around islands and certain coastlines in South China Sea. They may function as symbols of China's sovereignty over its territory, and valuable sites for exploitation of maritime resources and construction of airborne and seaborne transportation facilities in South China Sea. As the history of corals spans from the Paleozoic Era to the present, they can also be used as important indicators for stratum designation and analysis of past climate and geography. Coral reefs are affected by crust movements. They are generally formed in shallow areas 50m below low tide line, with reefs above sea level indicating an upward movement of crust or lowering of sea level, and lower reefs indicating a downward crust movement. Coral reefs are also often found near abundant oil and natural gas resources. Coal, bauxite, manganese ore and phosphate rock have been found in the sediments of coral reefs and their lagoons, and strata-bound mineral deposits with multiple metals including copper, lead and zinc have been found through the rudaceous rocks of reef bodies. The coral limestone can be used as a raw material for lime and cement, the corals can be used as decorations, and many coral reef regions have been developed for tourism. In summary, the study of coral reefs is of great significance.

The main component of coral reef rock mass is calcium carbonate (CaCO3). As shown in Fig.2, it is porous and brittle, low in both hardness and strength. Drilling is an indispensable method in the background survey of coral reefs, but due to characteristics of their structure and limitations of technology, such as mechanical disturbances which may result in low or even zero coring rates, the geological info obtained is often incomplete, rendering traditional analytical methods inaccurate. As coral reef rocks tend to shatter under high pressure, it is easy for the drilling process to damage the intactness of coral rocks, which is impossible to determine through rock cores. Therefore, a singular reliance on drilling would affect the accuracy of coral reef research and even cause erroneous results. A better evaluation of their rock mass would require a combination of drilling and other complementary techniques. The digital borehole camera[2,3,4] system has integrated digital video

and computer control by using optical sensors for close observation of rock mass inside the borehole. The acquired information is processed with computer to generate digital column-shaped image of the borehole walls (refer with: Fig. 3), solving the integrity and accuracy problem of geological info acquisition in coral reef boreholes.

Fig. 1—Remains of scleractinian corals.

Fig. 2—Rock cores obtained from coral reefs.

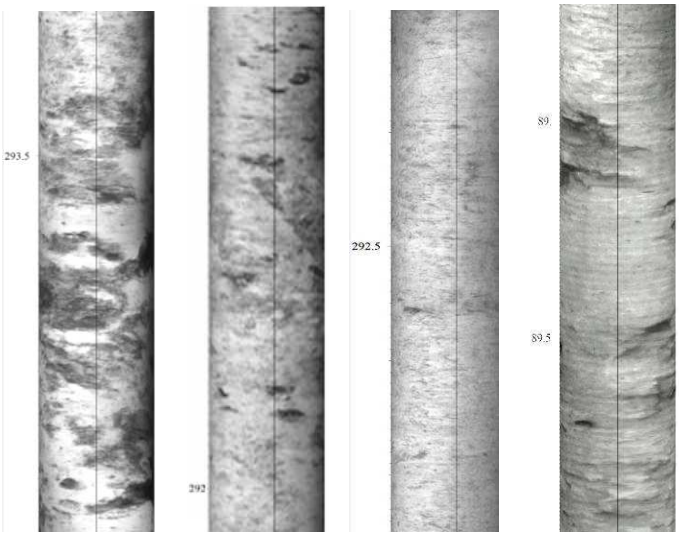

Fig. 3—Borehole camera images.

The basic quality of a rock mass is an inherent fundamental property that affects its stability in engineering projects. It depends on internal factors of the rock structure, of which rock mass integrity is a controlling factor. The borehole camera system has enabled us to evaluate the geometric (macroscopic) intactness of a rock mass. RMDI method is used in evaluation of coral reef integrity, but there is not a detailed standard of evaluation. Hence, this paper provides an in-depth comparison between results of RMDI method and actual engineering, by comparing the RMDI values acquired from borehole CK2 at Chenhang Island, Xisha (Paracel) Islands with geological info obtained using other methods. The rock mass classification standard is then used to help determine the corresponding degrees of rock mass intactness for the RMDI values.

**Borehole Camera**

The key to the digital panoramic borehole camera system lies in breakthroughs of panoramic (reflector on the conical surface) and digital (digital video and imaging) technologies. The panoramic technologies enable a 2-dimensional representation of the 360° borehole wall, which is overlayed with directional info, creating a panoramic image; digital technologies allow the digitization of videos, which are processed with inverse transformation algorithms to construct a model of the borehole wall and generate a digital vertical image. The borehole camera image is an intuitive representation of the cavities and other geological info from the borehole wall. By processing this info, a complete database can be generated, which can be used to statistically determine the number and sizes of visible cavities in the image. Fig.4 is a schematic diagram of borehole camera imaging.

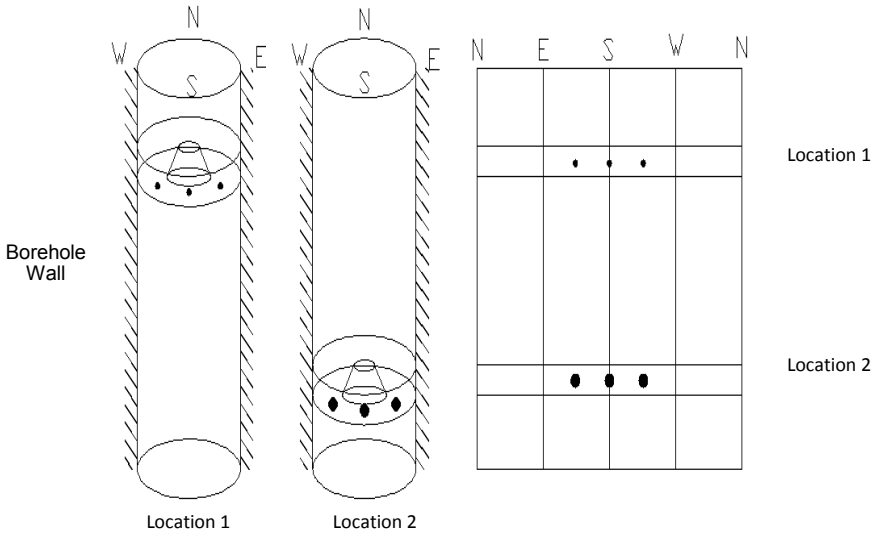

Fig. 4—Schematic diagram of borehole camera imaging.

**RMDI Method Overview**

**The Lumpiness Function**. The formation of coral reef rock mass is affected by multiple factors. Its special characteristics caused the rock mass to have multiple sections of intact rocks in addition to multiple hollow and broken sections. For the purpose of evaluating the maximum value of intact rock height within a unit depth, we establish the lumpiness function $\ell(z)$, expressed as

$$\ell(z) = L/H. \quad (1)$$

Where H is the depth to be measured; L is the maximum height of intact rock within the depth to be measured; generally $0 \le L \le H$. If the value of the lumpiness function $\ell(z)$ is zero, it indicates the given section of rock mass is hollow.

**The DIDF Function**. Since the coral reef rock mass is a complex entity formed from geological structures of the coral reef, the integrity shown in borehole images or lack thereof depends directly on its geological structures. For instance, a very small number of tiny cavities have little effect on the rock mass integrity, and its image shows even distribution of colours, which is an indication of high integrity; a relatively high number of large cavities break up the rock mass, causing its image to show great variation in colours and signs of fragmentation. We establish a single-variable function that varies along the borehole axial direction, the rock mass integrity index density function (DIDF)[5], represented as f(z) where z is depth, expressed as

$$\alpha = \ell(z). \quad (2)$$

Where 0≤α≤1. If the value of f(z) is 1 or approximating 1, it indicates the rock mass at the given depth has high integrity; the smaller the f(z) value is, the lower the integrity is, and the more fragmented the rock mass appears.

**The Coefficient α.** The coral reef rock mass integrity is affected by the size effect of lumpiness. The coefficient α in the DIDF represents the effect, with their relations expressed as

$$\alpha = \ell(\mathrm{z}). \tag{3}$$

**The RMDI Value.** The coral reef rock mass integrity index density function DIDF is a reflection of rock mass intactness along borehole axial direction. The rock mass integrity index (RMDI)[5] refers to the proportion of intact rock bodies within a given range, expressed as a percentage, where the given range can be a part of the borehole or the entire depth. If the given depth range is [h1, h2], the RMDI can be expressed as a definite integral of DIDF within the range, expressed as

$$\mathrm{RMDI} = \frac{\int_{h_1}^{h_2} f(\mathrm{z})\mathrm{dz}}{\int_{h_1}^{h_2} 1\mathrm{dz}}. \tag{4}$$

## Correlation Between RMDI and Rock Mass Intactness

**Classification of Rock Mass Intactness.** Rock mass intactness refers to the extent of development of various geological interfaces, mainly the fissures and faults. It is a generalized representation of the rock mass structures, and is determined by many factors including the shearing of structural planes, the sizes of structural bodies, and the cementation between bodies. A high-intactness rock mass has fewer faults, and a low-intactness rock mass contains more faults. It is one of the most important signifiers of rock mass quality, used in rock engineering as an overall indicator. Thus it is significant for rock engineering to find methods that allow simple and scientific evaluation of rock mass intactness.

The various classification schemes for rock mass, whether focusing on qualitative classification or quantitative assessment, all must take integrity into account, as it is an important signifier for rock mass strength and transformative properties. China's engineering geologists have always used properties of joints and fissures (which directly affect rock mass integrity) to describe the engineering characteristics of rock mass, especially the distances between joints and fissures. Table 1 shows the classification standards based on joint spacing by China's "Code for investigation of geotechnical engineering", "Technical code of railroad engineering geology", "Code of engineering geological survey" and "Code for hydropower engineering geological investigations", and the joint spacing standard recommended by International Society for Rock Mechanism[6,7,8,9]. Table 2 shows the qualitative classification from "Standard for engineering classification of rock masses" (GB50218-94)[10].

Table 1—Classification based on rock mass joint spacing.

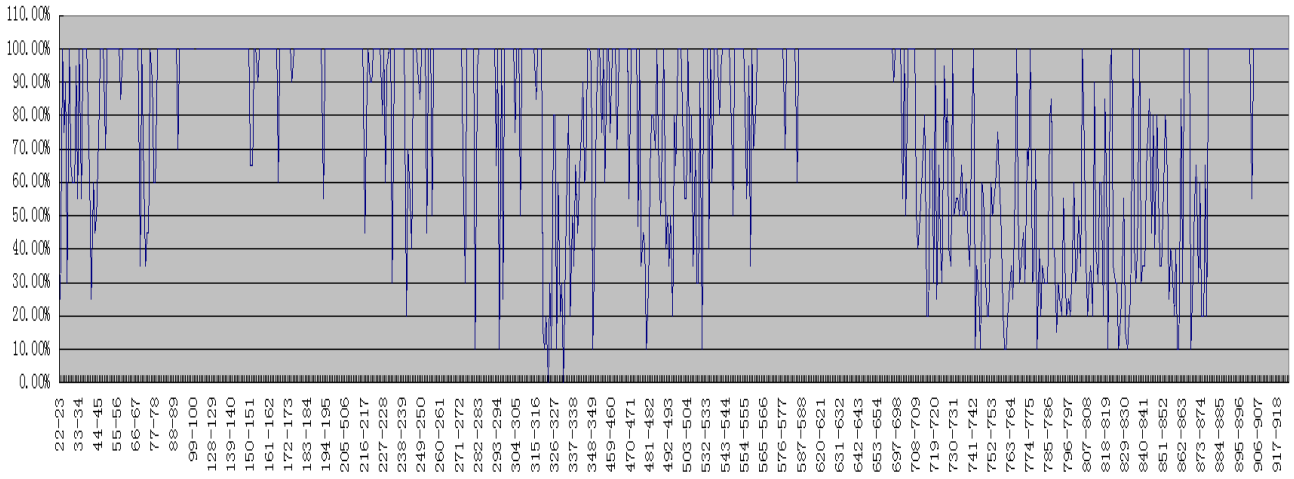
| Standard | Structure Type | | | | |
|---|---|---|---|---|---|
| | Intact | Lumpy | Bedded | Fragmented | Granular |
| Code for investigation of geotechnical engineering GB50021-2001 | >1.0m | >1.0m<br>>0.4~1.0m | 0.4~1.0m<br>0.2~0.4m | 0.2~0.4m<br>≤0.2m | |
| Technical code of railroad engineering geology TBJ12-85 | >1.0m | >0.4m | <0.4m | <0.2m | |
| Code of engineering geological survey ZBJ14003-89 | >1.0m | 0.5~1.0m | 0.3~0.5m | <0.3m | |
| Code for hydropower engineering geological investigations GB50287-2006 | >1.0m | 0.5~1.0m | 0.3~0.5m | 0.1~0.3m | <0.1m |
| ISO/TC182/SC/WGI0 | >0.6m | | 0.2~0.6m | <0.2m | |

Table 2—Qualitative classification of rock mass intactness.

| Name | Development of Structural Planes | | Cementation of Main Structural Planes | Types of Main Structural Planes | Corresponding Structural Types |
|---|---|---|---|---|---|
| | No. of Groups | Mean Spacing | | | |
| Intact | 1~2 | >1.0m | Strong or average | Joints, fissures, beddings | Intact or very thick bedded structure |
| Moderately intact | 1~2 | >1.0m | Weak | Joints, fissures, beddings | Lumpy or thick bedded structure |
| | 2~3 | 1.0~0.4m | Strong or average | | Lumpy structure |
| Moderately fragmented | 2~3 | 1.0~0.4m | Weak | Joints, fissures, beddings, minor faults | Fissured lumpy or medium thick bedded structure |
| | ≥3 | 0.4~0.2m | Strong | | Mosaic fractured structure |
| | | | Average or weak | | Medium & thin bedded structure |
| Fragmented | ≥3 | 0.4~0.2m | Weak | Various types | Fissured lumpy structure |
| | | ≤0.2m | Average or weak | | Fractured structure |
| Highly fragmented | Disordered | | Very weak | | Granular structure |

As the standards differ with regards to classification of rock mass intactness, and no prior examples exist for coral reef rocks, grading their intactness can be difficult. With the comprehensive geological info acquired by borehole camera system, we attempted to conduct the rock mass integrity evaluation of coral reefs using the RMDI method, and explored the correspondence between the RMDI values and rock mass intactness.

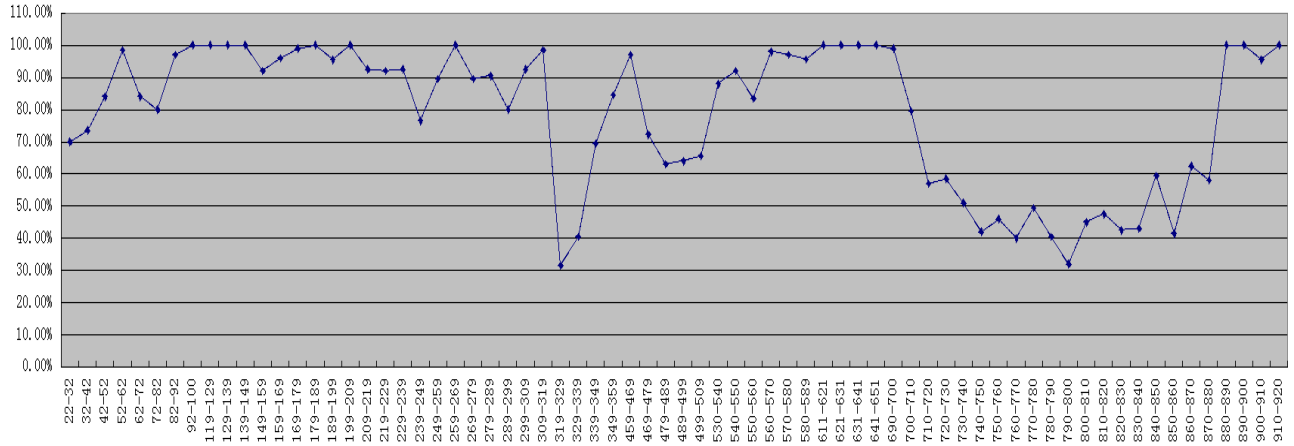
**Correlation between RMDI and Rock Mass Intactness.** During the geological survey on coral reef islands in the central northern parts of South China Sea, a panoramic digital camera survey was completed along the full length of the CK2 borehole in Chenhang Island, with the depth of the survey ranging from 22 to 924m. An info database was created through acquisition of info from borehole walls, which was processed by computer to generate the borehole image. The sizes and numbers of visible cavities in the image were statistically analysed, and the DIDF value of the rock mass was calculated using Equations 1, 2and 3, as shown in Fig.5:



depth (m)

Fig. 5—Coral reefs integrity index density function (DIDF).

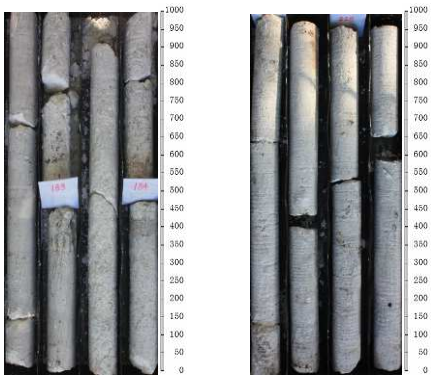
As the CK2 is a relatively deep borehole approximating 1km in length, we choose 10m as the basic unit to simplify the calculation and assessment of RMDI (refer with: Fig. 6).



depth (m)

Fig. 6—Coral reef rock mass integrity index (RMDI).

As shown in Fig.6, the RMDI stays relatively high in the segment from CK2 depth 82 to 229m, at values above 0.85. Based on drilling log and rock core photos (refer with: Fig. 7), the rock cores of the segment are intact. Moreover, the intact cores from this segment are all longer than 1m (the cores shown in the figure have been broken up for the purpose of storage). We treat the length of intact cores to be the spacing between joints or structural planes, therefore this segment corresponds to the "intact" type in the qualitative classification of rock mass intactness from Table 2. Thus we consider the segment of coral reef rock mass to have high intactness.



129~133m 169~173m

Fig.7—Some cores from coral reef rock mass.

At the segment from depth 319 to 339m, the RMDI is below 0.4. Based on drilling log and rock core photos (refer with: Fig. 8), the cores obtained from this segment are more fragmented, the heights of intact cores are less than 0.2m, and the structures display weak cementation. These cores correspond to the "highly fragmented" type in the qualitative classification, thus we consider the segment to have low intactness.

324~329m 333~338m

Fig.8—Some cores from coral reef rock mass.

At the segment from depth 469 to 509m, the RMDI is between 0.55 and 0.75. Based on drilling log and rock core photos (refer with: Fig. 9), the intact cores from this segment have an average length around 0.5m. The cores display medium thick bedded structures, with average cementation, which corresponds to the "moderately fragmented" type in the qualitative classification. Thus we consider the segment to have average intactness.

475~479m 505~509m

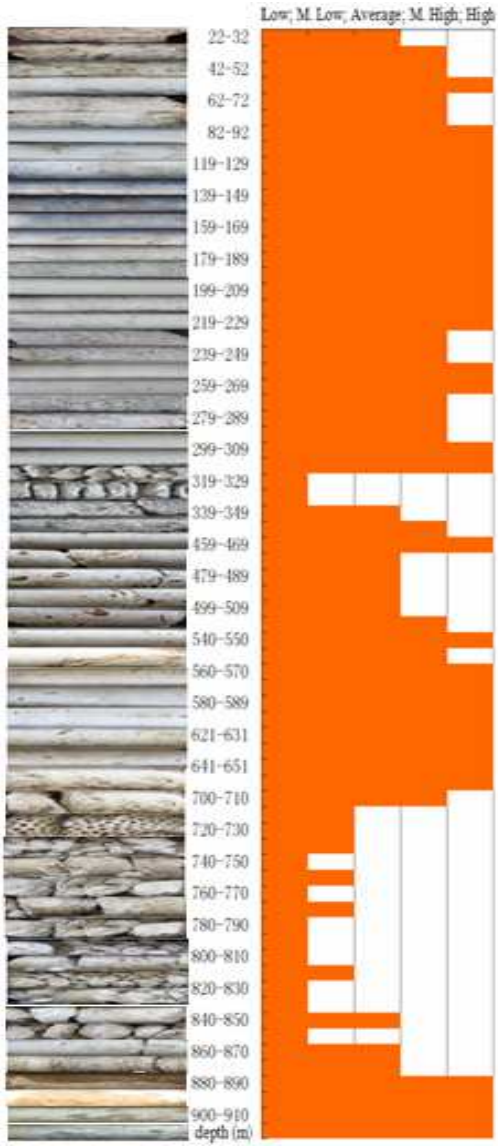
Fig.9—Some cores from coral reef rock mass.

The feasibility and accuracy of the RMDI method has already been established in prior studies on coral reef rock mass integrity evaluation. Through the comparison between RMDI and other data shown above, with reference to the classifications based on joint spacing (refer with: Table 1) and qualitative classification of intactness, the correlation between coral reef RMDI and rock mass intactness can be formulated (refer with: Table 3).

**Evaluation of the CK2 Borehole.** Based on the correlation between RMDI and intactness from Table 3, an evaluation of intactness throughout CK2 can be made. The intactness of coral reef rock mass can be deemed to be the degree of cementation in the coral reef. A comprehensive coral reef stratum development diagram can be constructed using RMDI, as shown in Fig.10(b).

TABLE 3—Correlation between RMDI and coral reef rock mass intactness.

| Intactness | High | Moderately high | Average | Moderately low | Low |
|---|---|---|---|---|---|
| Homogeneity | 1.00~0.85 | 0.85~0.70 | 0.70~0.55 | 0.55~0.40 | <0.40 |



(a) (b)

(a) Selected photos of rock cores

(b) Diagram of coral reef stratum development

Fig. 10—Comparison of rock cores and RMDI evaluation results.

A comparison of actual rock cores and results of RMDI-based assessment (refer with: Fig. 10) shows that the RMDI results are generally consistent with actual cores. Through the evaluation of rock intactness throughout the CK2 borehole, we discovered that the intactness in coral reef is alternately interleaved along the depth. The 82 to 229m, 560 to 700m and 880 to 924m segments have high intactness, with strong cementation in the corresponding cores, high coring rates, and more intact cores; the 319 to 349m and 740 to 860m segments have low intactness, with weak cementation, low coring rates, and fragmented cores. The construction of coral reef development stratum structures will be of great significance to the identification of geological stratums and investigation of past climates and geography.

## Conclusion

Through detailed comparative analysis of RMDI values and info from the entire approx. 1km length of the CK2 borehole, and with reference to the rock mass classification standards, we formulated the correlation between RMDI values and coral reef rock mass intactness, conducted an integrity evaluation of the CK2 borehole, and constructed a coral reef development stratum structure diagram. The results of RMDI evaluation also prove generally consistent with other evaluation methods. It can be concluded that: (1) the classification system based on RMDI is feasible in the integrity evaluation of coral reefs; (2) the coral reef integrity values obtained using the RMDI method are accurate; (3) borehole camera survey and statistical analysis are of great utility in the study of coral reefs.

**Keywords:** soft sub-grade; settlement prediction; Hyperbolic model; Logistic curve model

**Abstract.** Both Hyperbolic model and Logistic curve model have certain applicability to settlement prediction of soft sub-grade. Based on the observational settlement data of soft sub-grade in an industrial zone, the features of Hyperbolic model and Logistic curve model are studied. By using curve fitting methods with Origin software to predict the sub-grade settlement value and analyze the simulation results, compare these two models to determine which one is more reasonable. The results show that the Logistic curve model is more accurate and reasonable, it has the value of popularization and application in engineering.

## Introduction

Soft soil is characterized by features of high compressibility, high water content, low strength and poor permeability. It's deformation is quite complex in the soft sub-grade treatment works. The deformation is related to its own characteristics, in addition, it's influenced by filling traits, filling speed and soft foundation treatment methods. So, the study of soft sub-grade settlement issues has important significance.

Engineering practice situations indicate that accurate calculation of soft sub-grade settlement, especially prediction of settlement after construction is the key issue in engineering construction. While the measured data of settlement is the standard of testing calculation results, it's important to analyze the measured data of settlement. It's of great value in project to use the settlement data observed during pre-construction sufficiently and rationally to find out settlement regularity, thus we can predict the settlement during post-construction and after completion according to settlement regularity.

The commonly used method to predict soft soil sub-grade settlement according to measured data is to assume that sub-grade settlement regularity obeys some kind of mathematical model form. Determining the undetermined coefficient of model dynamically by using measured data samples, thus after construction settlement and final settlement can be predicted. Such mathematical model are mainly two types, one which regards Logarithmic model and Hyperbolic model(He et al., 2009). as representative to predict after construction settlement, the other which contains the growth curve model(GOMPERTZ B., 1825) and Weibull model to predict the whole process. The growth curve generally contains Logistic curve equation and Gompertz(Zai et al., 2000) curve equation.

This paper relies on a filling project of soft soil area road at an industrial zone. By using its settlement observation data, we can predict the settlement value of this road with origin software(Xiao et al., 2009) which based on analysis of Hyperbolic model and Logistic curve model, in order to verify the scientificalness and rationality of models and determine the optimal prediction method of settlement value in projects.

## Building and Analysis of Settlement Prediction Model

**Hyperbolic Model.** Hyperbolic model is an empirically derived method which assumes the average speed of sinking resumes in the form of hyperbolic. Expression is expressed as,

$$s_t = s_a + \frac{t - t_a}{\alpha + \theta(t - t_a)} \qquad \text{(a)}$$

Formula (a) can be rewritten as formula (b),

$$\frac{t-t_a}{s_t-s_a}=\alpha+\theta(t-t_a) \qquad \text{(b)}$$

In formula(a) and formula(b), $t_a$ and $s_a$ are respectively the time and settlement value of fitting calculation starting reference point, t and $s_t$ are the time and settlement value of any point on the fitting curve, α and θ are the coefficients obtained from the measured value which respectively represent intercept and slope of lines.

When $t\rightarrow\infty$ ,we can get the final settlement value formula(c),

$$s_\infty=s_a+\frac{1}{\theta} \qquad \text{(c)}$$

**Logistic Curve Model.** Logistic curve belongs to growth model curve, it's S-curve shape and found by a German mathematician, biologist P.F.Verhus in 1837 when he studied population.

Jinmin Zai etc (Zai et al., 2000) consider that the process of things reflected by growth model curve happen, develop, mature, then reach a certain limit is similar to the process of sub-grade loading progressively infliction with corresponding settlement gradually occurrence. Settlement increases linearly in the initial stages when immediate settlement mainly occurs. After the first turning point occurs, settlement rate increases along with the increase of land filling height, at this time main consolidation settlement mainly occurs. Another turning point appears after that, the settlement rate slows down gradually to a steady value which is named the final settlement, during this stage, secondary consolidation settlement mainly occurs. The whole process of settlement curve is an anti-S shape. So, we can use this curve to fitting the whole process soft soil sub-grade settlement and predict final settlement.

The Logistic curve equation is,

$$S_t=\frac{A_1-A_2}{1+(t/t_0)^p}+A_2 \qquad \text{(d)}$$

In this equation, $s_t$ represents the cumulative settlement value at time t, $A_1$, $A_2$, p and $t_0$ are fitting parameters.

According to this equation, when the Logistic curve function is fitted by measured S-t data, if $t\rightarrow\infty$, $S_\infty\rightarrow A_2$,it means that parameter is the predicted final settlement value.

A typical Logistic curve is shown (in Figure. 1)

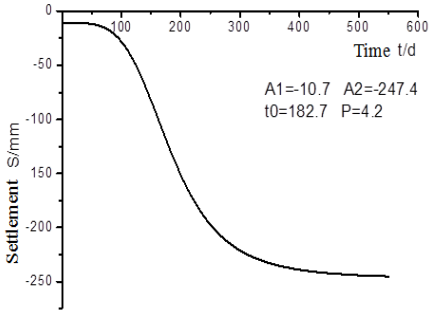

Figure1 Typical Logistic Curve Model

**Engineering Case Analysis.**

Soft soil sub-grade distributes widely in an industrial zone. In the construction of municipal roads, to control the settlement value of sub-grade, the sub-grade is reinforced by equal load preload, DJM, and geogrid. Among them, the observed values of some observation points in this industrial area are showed in (Table. 1), sub-grade is dealt by preload. The settlement is observed between May 17 to September 30, totally 136 days, the embankment is divided to 9 grades, the cumulative land filling height is 4.3m.

Table1 Settlement Observation Data

| Observation time | Time interval *t*/d | Cumulative time *t*/d | Cumulative settlement *S*/cm | Land filling height *H*/m |
|---|---|---|---|---|
| May 17 | 0 | 0 | 0.0 | 0.0 |
| May 24 | 7 | 7 | 5.7 | 0.3 |
| May 30 | 6 | 13 | 10.0 | 0.9 |
| June 7 | 8 | 21 | 13.3 | 1.5 |
| June 14 | 7 | 28 | 16.1 | 2.0 |
| June 21 | 7 | 35 | 17.9 | 2.6 |
| June 27 | 6 | 41 | 19.1 | 3.0 |
| July 3 | 6 | 47 | 20.0 | 3.4 |
| July 13 | 10 | 57 | 20.6 | 4.0 |
| July 20 | 7 | 64 | 21.1 | 4.3 |
| July 27 | 7 | 71 | 21.8 | 4.3 |
| August 5 | 9 | 80 | 22.2 | 4.3 |
| August 19 | 14 | 94 | 22.3 | 4.3 |
| September 1 | 13 | 107 | 22.5 | 4.3 |
| September 16 | 15 | 122 | 22.6 | 4.3 |
| September 30 | 14 | 136 | 22.6 | 4.3 |

**Rationality of Comparative Model.**Hyperbolic curve and Logistic curve are used to predict the settlement of this road, results are shown in (Figure. 2),

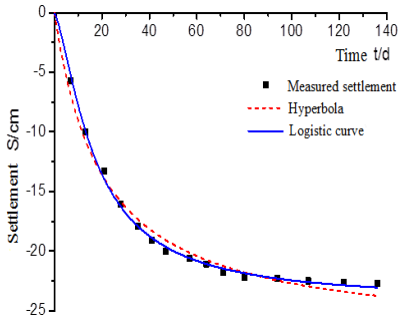

Figure2 Prediction of Settlement by Hyperbolic and Logistic Curve

It's can be seen from (Figure. 2) that both of Hyperbolic model and Logistic curve model can reflect the development regular pattern of sub-grade settlement. However , comparing with measured settlement value, the predicted value of Hyperbolic model appears a phenomenon of large early value, small medium value and large late value. The "S" development mode of Logistic curve model fits with measured settlement curve at any stages, this indicates that Logistic curve model can reflects the sub-grade settlement accurately than Hyperbolic model.

The predicted values of two methods in (Figure. 2)are summarized and compared as Table2 shows. According to the predicted results of settlement in (Table. 2), the predicted settlement values of both Hyperbolic model and Logistic curve model are larger than measured settlement value. According to the error of settlement value, the error of predicted settlement value of Logistic curve model is less than Hyperbolic model for about 13.6%. According to the standard error which is used to evaluate model prediction accuracy indicators, Logistic curve model is smaller than Hyperbolic model, means that the predicted accuracy is more exact. To sum up, the predicted settlement value of Logistic curve model is more accurate.

Table2 The predicted results of Hyperbolic and Logistic curve model

| Simulation Model | Curve Equation | Standard Error | Predicted Settlement $S_t$/cm | Measured Settlement S/cm | Settlement Error /% |
|---|---|---|---|---|---|
| Hyperbolic Model | y=P1*x/(P2+x) | 0.62986 | 27.24 | 22.6 | 20.5 |
| Logistic Curve Model | y=A2+(A1-A2)/(1+(x/x0)^p) | 0.32519 | 24.17 | 22.6 | 6.9 |

**The Effectiveness Analysis of Curve Model.**There are 16 actual numbers of observation among the given data in (Table. 1). Taking three types of prediction of 1-8times, 1-12times and 1-16times, namely using Hyperbolic model and Logistic curve model respectively to predict the observational data within 47d, 80d and 136d. Comparing predicted results, the results are shown in (Table. 3),.

Table3 The Effectiveness Analysis of Settlement Prediction

| Categories | Categories | Cumulative Time | Predicted Settlement $S_t$/cm | Measured Settlement S/cm | Settlement Error/% |
|---|---|---|---|---|---|
| Hyperbolic Model | Point8 | 47d | 34.14 | 22.6 | 51 |
| | Point12 | 80d | 29.74 | 22.6 | 31.6 |
| | Point16 | 136d | 27.24 | 22.6 | 20.5 |
| Logistic Curve Model | Point8 | 47d | 29.16 | 22.6 | 29 |
| | Point12 | 80d | 25.58 | 22.6 | 13 |
| | Point16 | 136d | 24.17 | 22.6 | 6.9 |

It's can be seen from the effectiveness analysis of settlement prediction(Table3):

(a).The settlement error of Logistic curve model is always smaller than the settlement error of Hyperbolic model by comparing settlement error at any same monitoring time and monitoring data of two types of curve model, namely it's more accurate. The accuracy of Hyperbolic model needs more monitoring time and monitoring data.

(b).From the predicted results analysis of Logistic curve model, it's can be seen that the predicted value has a large difference with measured settlement value at point8, the predicted values are close to measured results at point12 and point16. It showed that it's insufficient to meet the characteristic of curve model and the prediction accuracy is not enough when measured data are not enough. Only taking enough measured data(at point12 or point16), can we achieve good prediction effectiveness. (Xu et al., 2007)

## Conclusion

(a).Establish Hyperbolic model and Logistic curve model, analyze the application in predicting settlement value of two models.

(b).Compared with Hyperbolic model, Logistic curve model can reflect the laws of sub-grade settlement change accurately, have more accurate prediction results and higher prediction accuracy.

(c).To achieve a certain prediction accuracy, Hyperbolic model needs more monitoring time and monitoring data than Logistic curve model. The more measured data to fitting, the more accurate predicted results are.

**Keywords:** Overload; Reinforced ground; Bearing capacity; Settlement; Model test

**Abstract.** Concrete blocks were arranged on both sides of the strip foundation to simulate overload. Model tests with overload or not were conducted, for four test programs including pure sand ground, single plate reinforced ground, double plates reinforced ground and single plate with two anchorage ends reinforced ground. The influence of overload on bearing capacity and settlement of ground, earth pressure and strain of FRP was analyzed. The test results showed that overload can enhance the bearing capacity, and reduce the ground settlement in a certain extent, with the beneficial effects of overload on reinforcement effect being decreased while the amount of reinforcement was increased.

## Introduction

Fiber reinforced polymer (FRP) material has good performance such as corrosive resistance, water resistance, high temperature resistance, high strength, high modulus of elasticity, light weight, and so on, so it's application is more and more widely in civil engineering and hydraulic engineering. FRP material can be used to improve reinforcement effects significantly and improve durability of traditional reinforcements.

In recent years, the reinforcement mechanism has been in–depth studied by domestic and foreign scholars. Wei has discussed the size and distribution of internal force of reinforcement [1]. Huang believed that the reinforcement mechanism being diffusion mechanism and deep foundation mechanism [2, 3]. Yamanouchi has analyzed lateral pressure effect and tension membrane effect of geogrid [4]. Patra has researched the effect of embedment depth of strip foundation on the bearing capacity [5]. Li proposed the bearing mechanism of reinforced aeolian sand [6]. Huang considered stress diffusion effect from friction of reinforcement and earth as reinforcement mechanism [7]. Du has researched settlement and slope stability of embankment reinforced with CFRP [8].

Tests on a pure sand ground program and three reinforced ground programs were completed, with overload or not. Influence law of overload on reinforcement effect was analyzed.

## Experiment overview

Loading tests were completed in the model box which was made of the steel box embedded by 1.5cm thick transparent organic glass plate along walls. The length, height and underside width of strip foundation were 46 cm, 14 cm and 10 cm respectively. Stress-strain curve of FRP was a straight line approximately. The fine sand screened from dry sand was made as ground.

There were four test programs, including pure sand ground (program *a*), single plate reinforced ground (program *b*), double plates reinforced ground (program *c*) and single plate with two anchorage ends reinforced ground (program *d*), with overload or not for each program. "N" was used to mark no overload program.

The size of plate and arrangement of strain gauge were shown in Fig. 1, with shaded area being anchoring ends. There were no anchoring ends for program *a*, *b*, *c*. Width and height of each anchoring end were 2cm and 1.2cm respectively. Placement of reinforcement and earth pressure gauge was shown in Fig. 2. There was no reinforcement for program *a*.

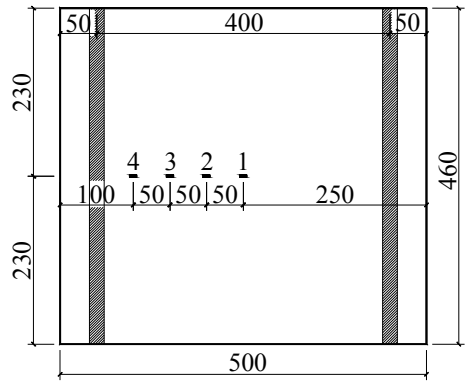

Fig. 1 Arrangement of strain gauge

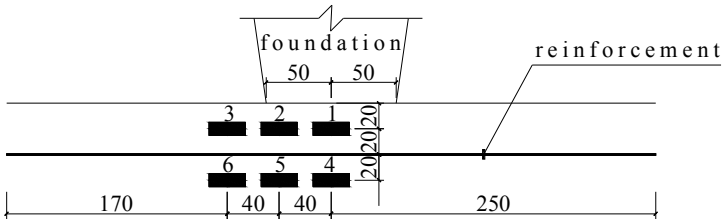

Fig. 2 Reinforcement and earth pressure gauge

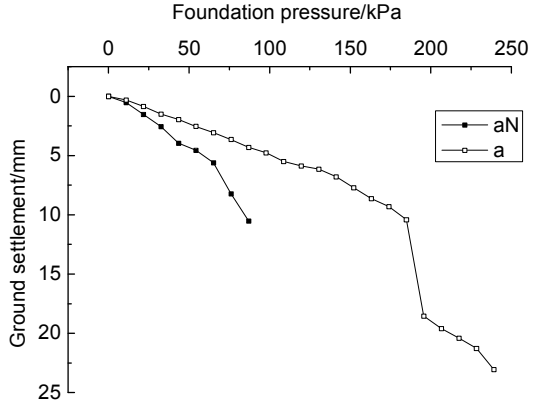
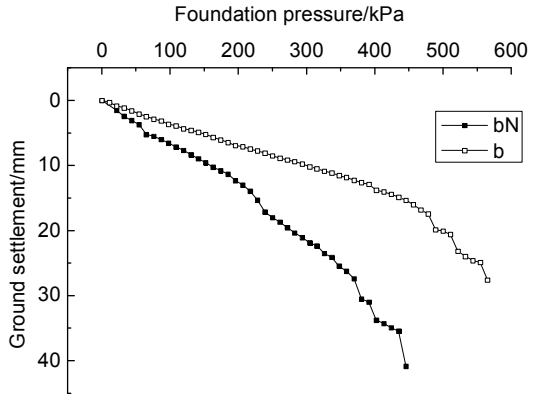
## Test results and analysis

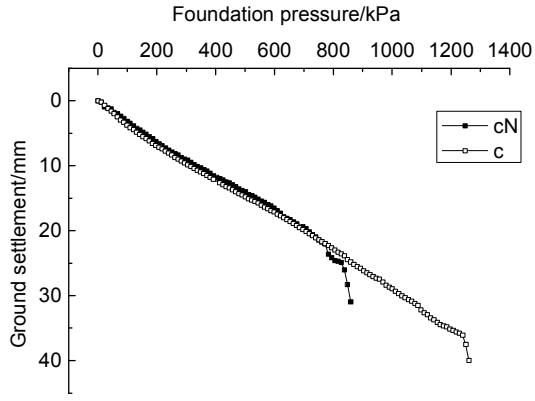
**Contrast for Curves of load and settlement.** Contrast for curves of foundation pressure and ground settlement was shown in Fig. 3. The results showed that overload can increase the bearing capacity and reduce ground settlement for program *a*, *b*, *d*. Overload can both increase bearing capacity and ground settlement for program *c*. There was earth shear failure for unreinforced ground, and there were reinforcement extrusion and earth shear failure for reinforced ground.



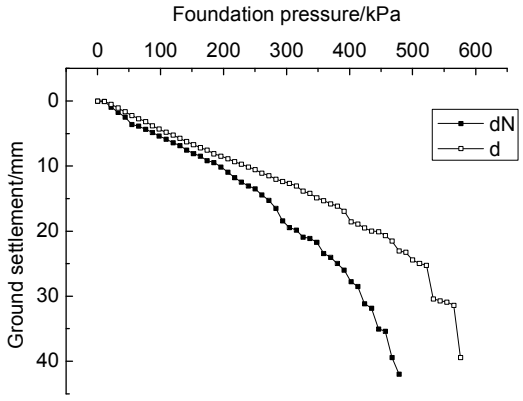
(a) program *a*



(b) program *b*



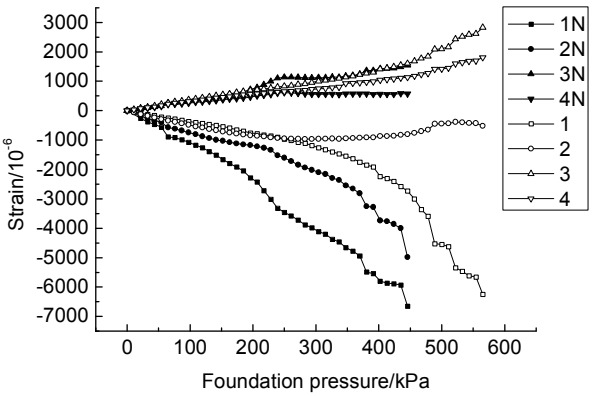
(c) program *c*



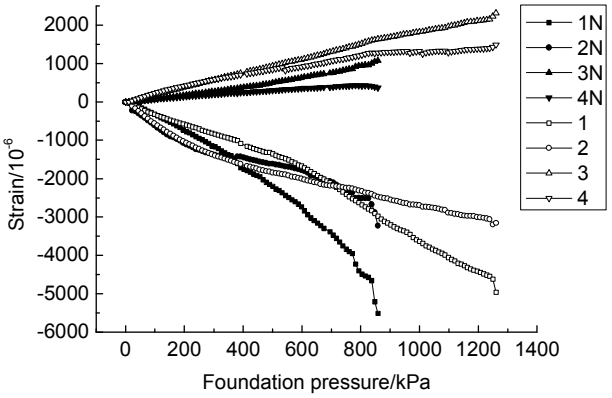
(d) program *d*

Fig. 3 Contrast of pressure-settlement curves

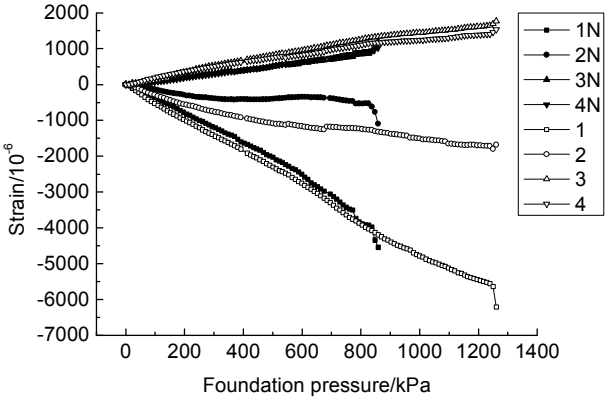
**Contrast for Curves of load and strain of reinforcement.** Contrast for curves of foundation pressure and strain of reinforcement was shown in Fig. 4 for reinforced programs. We can saw that overload can reduce strain value of 1 and 2 measuring points for program *b* and *d*, and the influence of overload on strain value for program *c* was small.



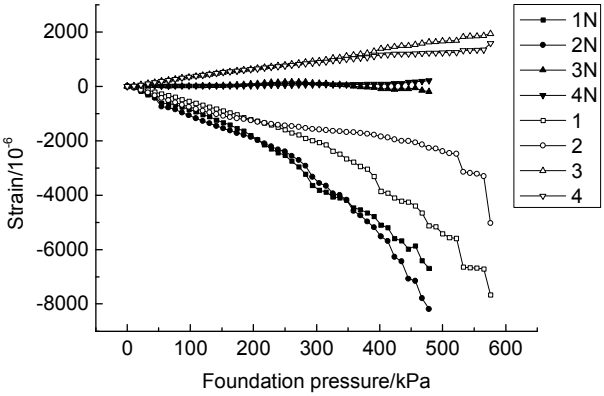
(a) program *b*



(b) upper layer reinforcement of program *c*



(c) under layer reinforcement of program *c*



(d) program *d*

Fig. 4 Contrast for curves of foundation pressure and strain

**Contrast for Curves of load and earth pressure.** Contrast for curves of foundation pressure and earth pressure was shown in Fig. 5. Earth pressure value of 3 and 6 measuring points was small, so the remaining four points were shown in Fig. 5. The comparison result showed that there was no influence of overload on distribution of earth pressure nearly.

## Conclusions

Earth shear failure emerged for unreinforced ground, and reinforcement extrusion and earth shear failure emerged for reinforced ground. Overload can enhance the bearing capacity of ground, and can reduce the settlement of ground and the deformation of reinforcement in a certain extent, but the overload had little effect on the distribution of earth pressure. The beneficial effects of overload on reinforcement effect were decreased while the amount of reinforcement was increased.

**Keywords:** Relative density, Shear strength, Permeability.

**Abstract.** This article aims at assessing the influence of relative density on the hydraulic conductivity and shear strength of two sands, denominated S01 and S02, derived from different regions and formation processes. S01 is wind-blown and S2 alluvial. The results of characterization and hydraulic conductivity in constant head tests were presented for both samples. The results of direct shear tests with sand S01 prepared with 5 different void ratios were also presented, for a vertical stress of 100kPa. The S02 sample was prepared with 4 different void ratios and these underwent direct shear testing with vertical stresses of 25kPa and 150kPa. This sample was prepared with the maximum and minimum void ratio and submitted to strength tests at CD triaxial compression with confining stresses of 50kPa, 100kPa and 200kPa. Results showed that even with different grain sizes, and under different density conditions, there were no significant variations in the permeability of the materials. With respect to shear strength, sand S01 obtained higher angle of friction values than sand S02, even though the latter had a higher percent coarse fraction. Sand S02 was relatively similar in terms of friction angle values obtained in direct shear and triaxial compression strength tests.

## Introduction

Relative density is a function of the void ratio of the soil that interfere in the strength of a granular soil. It provides an indication of the state of compactness of a mass of natural or compacted soil. A number of properties used in engineering can vary with the state of soil compactness, These include shear strength, compressibility and permeability of a soil. However, different soils in the same state of compactness can exhibit differences in these properties. Thus, it is important to accurately relate engineering properties to this ratio. [1] and [2], among others, conducted strength tests on compact and loose sands. [3] show that the lower the shear strength of a sand the greater the tendency to dilatancy (expansion) in the shear phase. [4] underscores that the lower the confining stress applied to compact sand, the greater the expansion during shear.

This study aims at assessing the influence of relative density on the hydraulic conductivity, compressibility and shear strength of two sands, one wind-blown from the city of Natal, Brazil, denominated S01, and the other alluvial from the city of São Carlos, Brazil, denominated S02. Moreover, we intend to compare compressibility behavior and angle of friction values of sample S02 obtained in direct shear and CD triaxial compression tests.

## Materials and Methods

Granulometric analysis [5], maximum [6] and minimum [7] void ratios and the specific gravity of solids [8] were conducted to characterize these sands. To determine the hydraulic conductivity of the 2 samples, permeability tests [9] were carried out at constant head in the maximum and minimum state of compactness. Sand S01 underwent direct shear testing with a normal stress of approximately 100kPa, for samples with void ratios (e) of 0.45, 0.55, 0.64, 0.75 and 0.88 respectively.

Sand S02 was submitted to direct shear testing with normal stresses of 25kPa and 150kPa, when void ratios (e) were 0.53, 0.55, 0.60 and 0.63 respectively. In this sample, for the direct shear tests, these

parameters were grouped according to the following nomenclature: Group A (e = 0:53 and normal stress of 25kPa and 150kPa), Group B (e = 0:55 and normal stress of 25kPa and 150kPa ), group C (e = 0.60 and normal stress of 25kPa and 150kPa) and group D (e = 0.63 and normal stress of 25kPa and 150kPa). Furthermore, this sample was subjected to two stages of CD triaxial compression strength tests, with 3 tests in each stage. In the first series of assays the test specimens were molded under maximum relative density, that is, with a minimum void ratio. The second series of tests was performed in test specimens molded under minimum relative density. A strain rate of 0.5mm/minute was used in all the tests.

## Results

### Characterization

Figure 1 shows the particle size distribution curves of the 4 samples, and Table 1 summarize the characterization test results of the samples as well as their classification according to Unified Soil Classification (USC). Table 2 presents the permeability test results of the 4 samples.

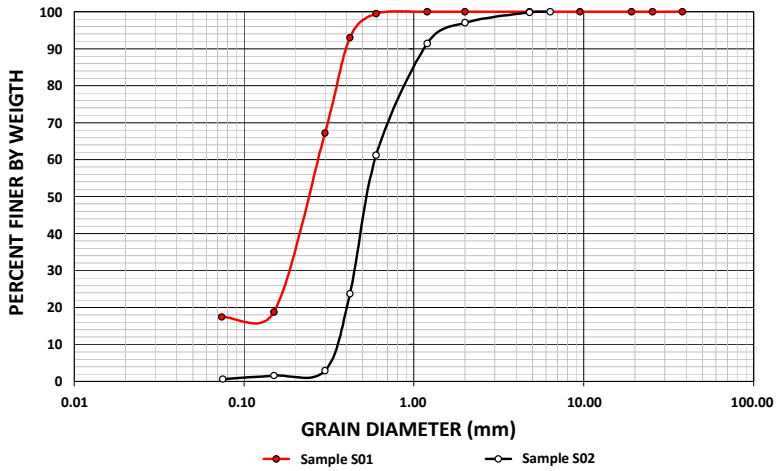

Figure 1: Particle size distribution curves of the 2 samples.

Table 1: Particle size characteristics of the 2 sands.

| Samples | Gravel (%) | Coarse Sand (%) | Medium Sand (%) | Fine Sand (%) | $C_u$ | $C_c$ | $\rho_s$ (g/cm³) | $e_{max}$ | $e_{min}$ | Classification - USC |
|---|---|---|---|---|---|---|---|---|---|---|
| **S01** | 0.0 | 1.1 | 68.9 | 30.0 | 1.53 | 0.90 | 2.65 | 1.10 | 0.35 | Medium to fine sand - **SP** |
| **S02** | 3.0 | 36.0 | 59.0 | 2.0 | 1.71 | 0.96 | 2.67 | 0.75 | 0.50 | Medium to coarse sand - **SP** |

Table 2: Permeability test results of the 2 samples

| Samples | S01 | S02 |
|---|---|---|
| **k (cm/s) - $e_{max}$** | $8.9 \times 10^{-2}$ | $1.2 \times 10^{-1}$ |
| **k (cm/s) - $e_{min}$** | $1.2 \times 10^{-2}$ | $5.4 \times 10^{-1}$ |

Direct Shear Tests: S01

As mentioned above this series of tests was conducted under normal stress of 100kPa. Figures 2 and 3 show the results obtained by [2]. With these results the angle of friction was determined for each sample. Figure 4 exhibits the angles of friction as a function of the variation in void ratio in the samples [2].

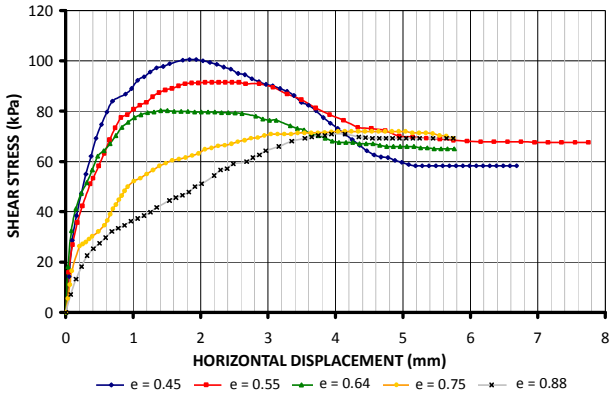

Figure 2: Shear stress x horizontal displacement – Sand 1. [2]

Triaxial Compression Strength Tests – CD Test: S02

Figures 9, 10, 11 and 12 show the results of these tests. Figure 13 exhibits the envelopes in terms of the s x t diagram of this series of tests, as well as angles of friction of the soil, with respect to the Mohr-Coulomb envelope.

## Analysis of Results

Sands S01 and S02 were classified according to USC as medium to fine and coarse to medium sand, respectively, both poorly graduated. The coefficient of permeability obtained for S01 sand was around 10 times smaller than that obtained for S02 sand. Relative density did not significantly influence the permeability of the samples.

With respect to shear Strength of sand S01, a well-defined peak can be observed in tests with void ratios between 0.45 and 0.64. In these tests there was a slight tendency to compression, followed by volumetric expansion (dilatancy) during the test (Figures 2 and 3). It is hypothesized that the critical void ratio for this material under these conditions is between 0.64 and 0.75. In this series of trials the angle of friction ranged from 35.5º, in a less compact state, to 46.8º, in the denser state (Figure 4). These values corroborate the limits established by [10] and [11].

Sand S02, for the series of direct shear tests, with vertical stress of 150kPa, showed no tendency to an increase in shear strength with a rise in relative density. This is evidenced, for example, when the shear strength of Group B, which, as previously mentioned, has 65% relative compactness, is compared with that obtained by Groups C and D.

The results of tests with 25kPa of normal stress showed no discrepancies. The initial condition of the samples, for this level of vertical stress, seemingly did not influence their shear strength (Figures 5). The angles of friction for this sample ranged from 36.6º to 40.5º (Figure 8). It is hypothesized that the divergent results are related to the lack of uniform testing. A tendency to compression was observed in all the tests of this sand (S02), followed by dilatancy, from 2 millimeters of horizontal displacement onwards (Figures 6 and 7).

The triaxial tests conducted with sand S02 showed greater deviatory stress with both an increase in confining stress and a rise in relative density (Figures 9 and 11).

As depicted in Figure 10 regarding the behavior of the material in terms of volumetric variation with an increase in axial deformation, test specimens molded with a minimum void ratio show a tendency to compression followed by dilatancy of test specimens. This dilatancy increased with a decline in confinement level. In tests where test specimens were molded with relative density in terms of maximum void ratio, confining stresses of 100kPa and 200kPa showed expansion followed by compression, whereas in the test with confining stress of 50kPa expansion only occurred in the shear phase (Figure 12).

The effective angles of friction for the sample in states of minimum and maximum compactness obtained from triaxial tests were 35.4º and 40.7º respectively. These values are similar to those obtained from the direct shear test in this sample. [12] reported the similarity of angles of friction obtained from direct shear and drained triaxial tests. He states that for practical purposes the direct shear test can be used to determine the angle of friction of sands.

If the angles of friction for the two samples are compared in their maximum and minimum states, it can be observed that in the loose state, the angle of friction of the samples is similar, while in the compact state, the angle of friction at peak strength of sand S01 is around 7 times higher than in

sand S02. In regard to critical values, this difference is less than in samples with lower relative density, as illustrated in Figures 2, 5 and 11, where after resistance peak, the residual strength was somewhat similar.

## Conclusion

According to the results of this study, it is concluded that an increase in relative density in the sands did not significantly influence their permeability.

A rise in relative density generally results in greater interaction between grains of sand, which has a direct effect on the shear strength of a material and, in turn, on the angle of friction of the samples. Irrespective of the tendency to increased strength as a function of relative compactness, if the highest and lowest angle of friction values found for sand S01 and S02 are compared, it can be observed that the values obtained for sand S01 are significantly higher than those of sand S02, which contrasts the notion that grain size determines the strength of a granular material.

The results of triaxial compression tests show a tendency towards increased strength, with both a rise in confining stress and an increase in relative density. Under conditions of maximum compactness, as expected, it was found that the lower the confining stress, the higher the tendency of the material to expand during the shear phase. Under conditions of minimum compactness, the behavior of dense sand was observed in the test with 50kPa of confining stress and loose sand in confined samples with 100kPa and 200kPa.
