Where $\beta$ is concrete surface heat transfer coefficient, $T_a$ is environment temperature, $n$ is the normal-to-wall direction, $\lambda$ is thermal conductivity.

Through dispersing dam concrete, we can get finite element control equation of quasi stable temperature field , it is as follows

$$\left(\boldsymbol{H} + \frac{1}{\Delta \tau_n}\boldsymbol{R}\right)\boldsymbol{T}_{n+1} - \frac{1}{\Delta \tau_n}\boldsymbol{R}\boldsymbol{T}_n + \boldsymbol{F}_{n+1} = 0 \tag{4}$$

where $\Delta\tau_n$ is calculation step; $\boldsymbol{H}$ , $\boldsymbol{R}$ is heat conduction matrix and heat capacity matrix respectively; $\boldsymbol{T}$ is node temperature array; $\boldsymbol{F}$ is boundary temperature load array; $\boldsymbol{n}$ is the number of time intervals .

**Projects**

Take a high concrete arch dam which is under construction in southwest as an example, in order to reduce the dam concrete temperature to sealing temperature , the process of cooling circulation can be

divided into three stages:the first cooling circulation, the second cooling circulation and the third cooling circulation .

**Three-dimensional Finite Element Model.** Finite element model. In order to research the influence of environment temperature to temperature rebound of the irrigated area, This paper selects two riverbed dam sections and their corresponding foundations to establish three-dimensional finite element model with the eight-node hexahedral isoparametric elements, 7092 units ,among the units there are 5652 units in the dam, three-dimensional finite element model is shown in Fig. 1.

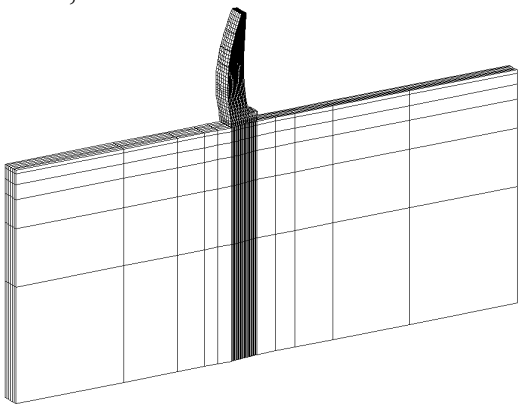

**Fig. 1** Three-dimensional FEM model

**Calculating Parameters.** Assuming the concrete surface is bare, the exothermic coefficient is $1005\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$; assuming concrete surface is covered with 3cm insulation benzene board, the exothermic coefficient is $95.52\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$; assuming concrete surface is covered with 5 cm insulation benzene board, the exothermic coefficient is $58.56\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$;beside, coefficient of concrete conduction is $184.9\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$; concrete density is $2663\,kg/m^3$; concrete specific heat capacity is $860\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$; bedrock thermal conductivity is $184.9\,\mathrm{kJ/(m^2\cdot d\cdot ℃)}$; bedrock density is $2663\,kg/m^3$; bedrock specific heat capacity is $860\,\mathrm{J/(kg\cdot ℃)}$.

**Initial Conditions**.The initial dam temperature is 13˚C.

**Boundary conditions.**This model takes all sides of bedrock and transverse joints as insulated boundary, takes rock bottom as ground temperature boundary(it is 20˚C), the rest of the boundary is the third boundary condition.The expression of annual average temperature is $T_a = 19.79 + 8.04\cos(2\pi(t+153)/365)$ ,taking the effect of solar radiation into consideration, environment temperature is annual average temperature plus 3˚C.

**Calculated Cases.** Case 1: thermal conductivity is equal to 0.8 times the given design value without taking any measures; Case 2: thermal conductivity is equal to the given design value with 3cm benzene board ; Case 3: thermal conductivity is equal to the given design value with 5cm benzene board ; Case 4: thermal conductivity is equal to 0.8 times the given design value with 3cm benzene board; Case 5: thermal conductivity is equal to 1.2 times the given design value with 5cm benzene board ;

## Calculation Results Analysis

Temperature field simulation calculation results are shown in Fig. 2 and Fig. 3 and Table 1.This paper selects three different heights—34.5m( the thickness along the river is 58m) , 130.5m ( the thickness along the river is 48m) , 235.5m ( the thickness along the river is 30m)， all of which are using foundation surface as a standard.And average temperature rebound in table 1 refers to the average temperature rebound of all the nodes at 130.5m height at a particular time .

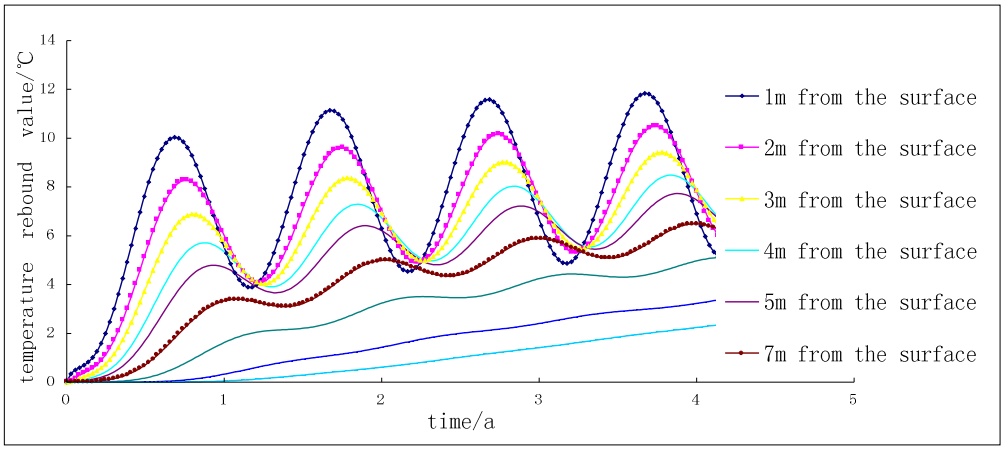

**Figure. 2** Temperature rebound process line of the section of 130.5m high above foundation surface of case 2

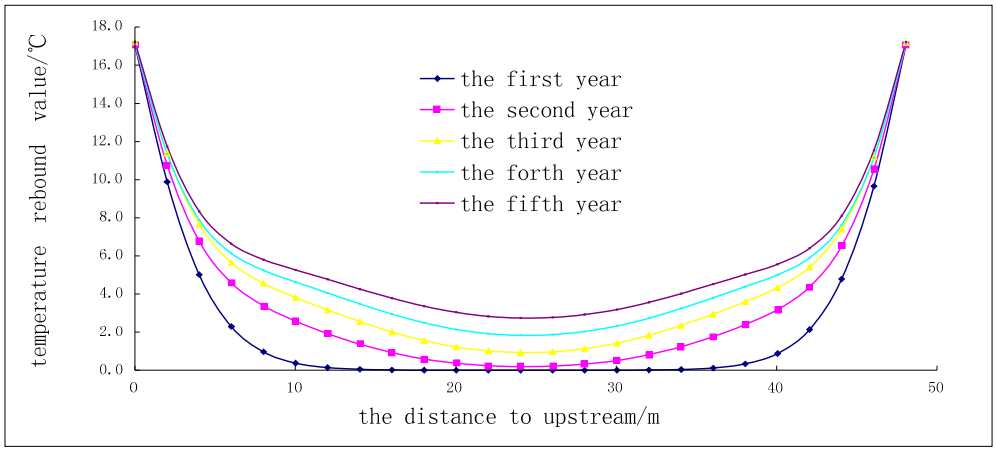

**Figure.3** Temperature rebound distribution along the river direction of section 130.5m high above foundation surface at the highest temperature moment of case 2

**Table.1** Average temperature rebound of the section of 130.5m high above foundation surface

| Time | 1year | 2years | 3years | 4years | 5years |
|---|---|---|---|---|---|
| Case1 | 2.27 | 3.31 | 4.18 | 4.81 | 5.35 |
| Case2 | 1.88 | 2.90 | 3.73 | 4.38 | 4.94 |
| Case3 | 1.63 | 2.60 | 3.40 | 4.04 | 4.60 |
| Case4 | 1.72 | 2.64 | 3.39 | 3.98 | 4.48 |
| Case5 | 1.72 | 2.78 | 3.63 | 4.33 | 4.92 |

## Conclusions

(1)During construction period, upstream dam has not yet been filling, because there exist differences between joint grouting temperature and environment temperature in irrigated area, so environment temperature would cause the temperature of irrigated area increasing slowly.The closer to the concrete surface , the bigger the temperature rebound will be and the more dramatic the environment temperature fluctuations will be, what's more ,temperature rebound of the irrigated concrete Shows a upward trend of cycle fluctuation when environment temperature changes.As is shown in figure. 2, when the distance is 1m far away from the concrete surface, temperature fluctuation reaches up to

6.69˚C,when the distance is 4m far away from the concrete surface, temperature fluctuation is only 1.31˚C.

(2)It can be learned from several selected sections that the smaller the thermal conductivity is, the slower the temperature rebound speed will be, on the contrary, the quicker the temperature rebound speed will be.Taking the cross section of 130.5m as an example, with 3cm benzene board covered in concrete surface , and thermal conductivity is respectively equal to given design value and 0.8 times given design value, when the joint irrigation is done for 5 years, average temperature rebound is respectively equal to 4.28˚C and 3.84˚C;while with 5cm benzene board covered in concrete surface, and thermal conductivity is respectively equal to given design value and 1.2 times given design value, when the joint irrigation is done for 5 years, average temperature rebound is respectively equal to 3.99˚C and 4.32˚C.

(3)Due to environment temperature would cause the temperature of irrigated area increasing slowly., benzene board insulation can reduce concrete temperature recovery rate , besides, the heat preservation effect of 5 cm benzene board is better than the heat preservation effect of 3 cm benzene board .Just as figure. 1 shows, when concrete surface is respectively covered with no benzene board insulation, 3 cm benzene board insulation and 5cm benzene board insulation, the average temperature rebound is respectively equal to 5.35˚C, 4.94˚C and 4.60˚C after joint grouting for 5 years.

**Keywords:** the micro-pressure inner loop reactor, numerical simulation, mixture model

**Abstract.** The treatment of the urban sewage and the Organic industrial wastewater has been transformed from removing of the organics to the Removal of organic matter and nitrogen, phosphorus. According to the deficiency of the Traditional wastewater treatment process，the micro-pressure inner loop reactor is put forward to solve the Anaerobic, anoxic and aerobic environmental issues in this paper. Aiming at the newly development of the micro-pressure inner loop reactor, based on the methods of Computational Fluid Dynamics, using the methods of computational fluid dynamics, By analyzing the velocity distribution field, flow lines, the gas volume fraction and other factors, the result shows that the reactor Meets the actual needs of the project, and provides a theoretical basis for practical engineering equipment.

## Introduction

The Urban sewage discharge and the Wastewater in industrial production has become a major pollution source of the urban water[1][2]. So, in the current and future, the treatment of the urban sewage has been the most important thing of the Urban Water Conservation and Urban water environmental protection. At present, the batch reactor and continuous reactor have been mainly used in The Treatment process of the Municipal sewage and industrial wastewater. By separating the three reactors of Anaerobic, anoxic and aerobic, the Continuous reactor solves the Oxygen environment issues; by separating the three stages of Anaerobic, anoxic and aerobic, the Batch reactor solves the Oxygen environment issues[3][4]. Some achievements have been achieved by the two types of reactors in the Sewage treatment. But, in the 21st century, due to the change of sewage water quality and the treatment of the urban sewage and the Organic industrial wastewater has been transformed from removing of the organics to the Removal of organic matter and nitrogen, phosphorus. The Traditional processors will face a serious shortage[5][6]. For example, the Continuous reactor makes the Microbial flora of various function not conduct fully biochemical reactions in the whole environment, to solve the problem of carbon source, by using the method of reflux can also cause reflux power consumption. Batch reactor also has the issue which the Microbial flora of various function cannot conduct all biochemical reaction[7].

Aiming at the new problems, which are encountered in the treatment of city sewage and industrial wastewater, the micro-pressure inner loop reactor has been put forward and built in this paper. By using the method of Computational fluid dynamics[8], Micro pressure of inner loop reactor flow field velocity field, pressure field and phase change are simulated by using the multiphase flow model, And Provides a reference basis for The further optimization and industrial equipment.

## The Micro-pressure Inner Loop Reactor

Micro pressure internal circulation reactor is proposed based on the traditional reactor, the top of the reactor is almost closed and the reactor internal is at a micro pressure. Under the effect of the aeration, The Mixed liquid of wastewater with microorganisms (activated sludge)stay mixed circulating inside the reactor, the concentration of dissolved oxygen is gradually increased from the

reactor center outward, respectively forming the area of hypoxia, anaerobic and aerobic. In the hydrodynamic action, the concentration of activated sludge is gradually decreasing from the center of the reactor outward, realizing all the reaction of the three kinds of functional bacteria.(See Fig.1 and Fig.2)

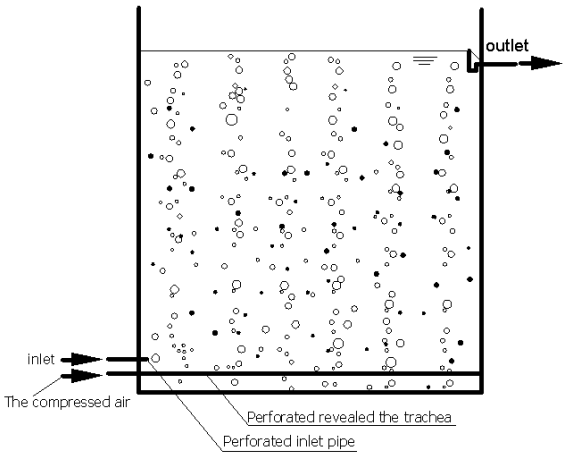

Fig.1 Traditional reactor

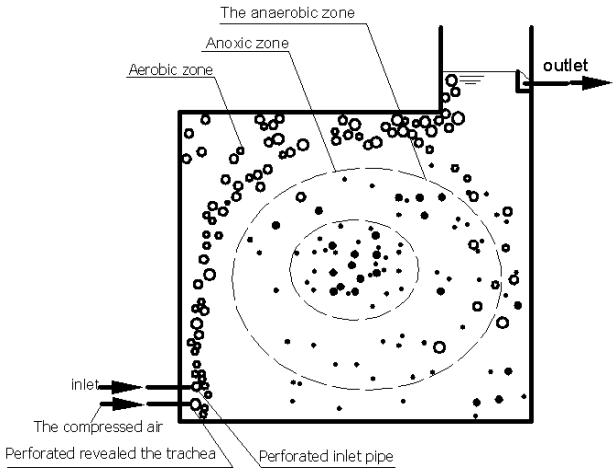

Fig.2 Micro pressure internal circulation reactor

**The control equation**

The Fluid flow of the micro-pressure inner loop reactor is a little more complex, it belongs to the multiphase turbulent flow. The basic equation for hybrid model mainly includes the following.

The continuity equation: $\frac{\partial}{\partial t}(\rho_m)+\nabla\cdot(\rho_m\vec{v}_m)=\dot{m}$

The Momentum equation is got though the summation of all respective phase momentum equation, it can be represented as the following:

$$\frac{\partial}{\partial t}(\rho_m\vec{v}_m)+\nabla\cdot(\rho_m\vec{v}_m\vec{v}_m)=-\nabla p+\nabla\cdot\left[\mu_m\left(\nabla\vec{v}_m+\vec{v}_m^T\right)\right]+\rho_m\vec{g}+\vec{F}+\nabla\cdot\left(\sum_{k=1}^{n}\alpha_k\rho_k\vec{v}_{dr,k}\vec{v}_{dr,k}\right)$$

The relative speed is defined as the second phase: $\vec{v}_{qp}=\vec{v}_p-\vec{v}_q$

The relationship between the relative speeds and the drift velocity can be represented by the following formula:

$$\vec{v}_{dr,p}=\vec{v}_{qp}-\sum_{k=1}^{n}\frac{\alpha_k\rho_k}{\rho_m}\vec{v}_{qk}$$

The equation of volume fraction:

$$\frac{\partial}{\partial t}(\alpha_p\rho_p)+\nabla\cdot(\alpha_p\rho_p\vec{v}_m)=\nabla\cdot(\alpha_p\rho_p\vec{v}_{dr,p})$$

**Numerical Simulation**

The micro-pressure inner loop reactor which is used in this model is shown as the figure 3, The length of the container is 80 cm, The height of the container is 60 cm, The width which is located at the top of the right side of the tube is 8 cm, and the height is 30 cm, it is connected with the atmosphere. The G pipe is a Burst pipe; the Value of gas detonation in the calculation is 1.4m3/h, the Specific size of the G pipe is shown in Figure 2. The quadrilateral non-uniform structured grid is used in the whole area, It generates 5253 nodes, and The number of the grid unit is 5075, to improve the accuracy, encrypting the grid around the Burst pipe. The meshing is shown in the figure 4.

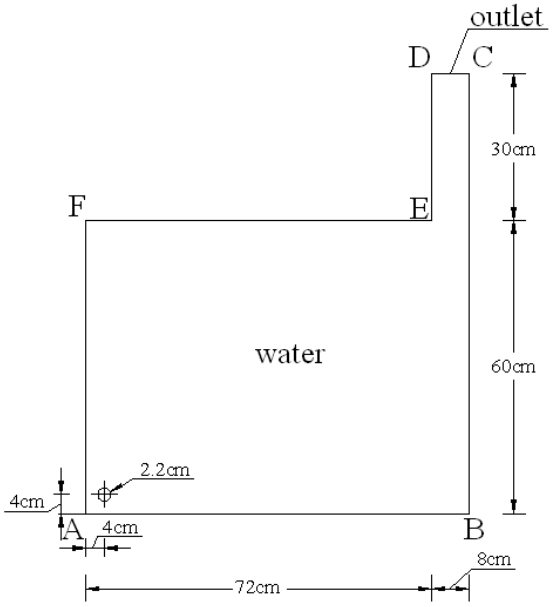

Fig.3 The model size of reactor

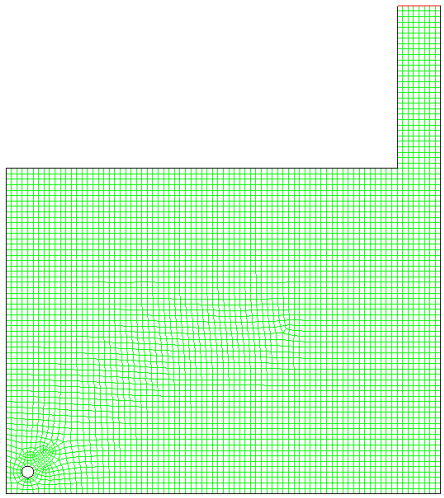

Fig.4 The mesh diagram of reactor

**Boundary conditions**

There mainly are three kinds of boundary conditions in this model, including the Inlet boundary, the Outlet boundary and the solid wall boundary. The conditions of Speed import are calculated by the turbulent kinetic energy (k) and the turbulent dissipation rate(ε).

The intensity of turbulence (I) is $I = \frac{u'}{u} = 0.16\left(\mathrm{Re}_D\right)^{-\frac{1}{8}}$

The turbulent kinetic energy (k) is $\kappa = 1.5\left(\bar{u}I\right)^2$

Turbulent energy dissipation rate( $\varepsilon$ ) is $\varepsilon = C_\mu^{3/4}\frac{\kappa^{3/2}}{l}$

The outlet is set as the turbulent full development of free export pressure; the pressure of the outlet is the atmospheric pressure. The solid wall boundary is set as the solid wall boundary.

**The Simulation Results and Discussion**

By calculating, we can get the velocity distribution field; trace the whole calculation domain and the volume fraction of air, the calculation results are shown in the figure 4 to figure 7. (1)The figure 4 is a velocity vector diagram of the hybrid model, the boundary of the contact with the atmospheric outlets meets the reality, because the gas which is squeezed out constantly can cause the velocity of gas-liquid mixing, and the velocity vector is Sometimes positive, sometimes the reverse. The enlarge figure circular pipe is shown in the figure 5. (2) The calculation of the whole flow field of the region is shown in the figure 6, due to the shot of the gas, the stillness of the water in the whole area is affected and begins to flow, at the same time because of the influence of gravity flow, making the streamline approximate an oval, that conform to the actual situation. (3) When the gas shouts into the water from the pipe, because of the smaller gas density, and the pipe is close to the left wall, the gas in the water will soon get close to the left wall and move up along the wall; The volume fraction of the gas will continue to increase due to the gas gathering on the wall, this is consistent with actual situation.

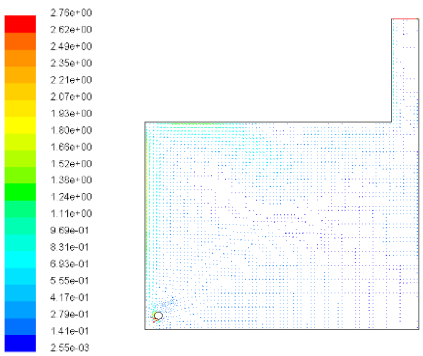

Fig.4 Velocity profile(m/s)

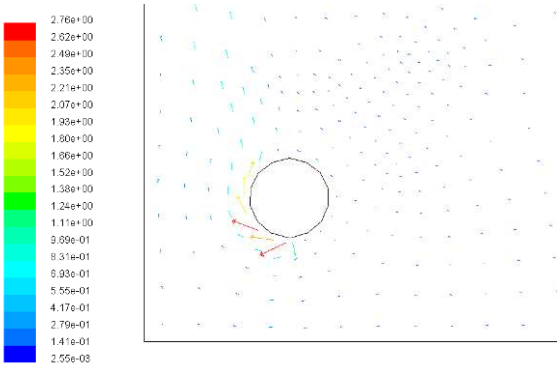

Fig.5 Enlarged drawing on outlet

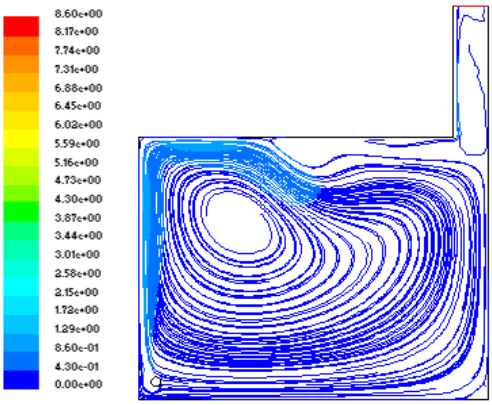

Fig.6 Path lines colored by velocity magnitude (m/s)

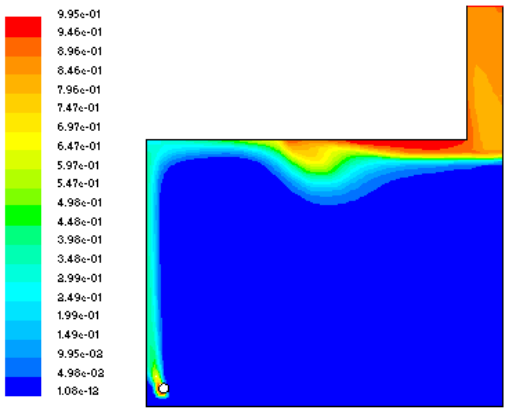

Fig.7 Contours of volume fraction of air

## The Conclusion

Aiming at the new questions that the treatment of the urban sewage and industrial wastewater, the micro-pressure inner loop reactor is put forward and built in this paper, under the action of aeration, the interior of the reactor is at the state of mixing cycle, that can form anaerobic, anoxic and aerobic zone respectively. The aeration problems of the micro-pressure inner loop reactor are simulated by the methods of the hybrid model of multiphase flow, which is based on computational fluid dynamics. The gas volume fraction, the velocity vector distribution and flow field which are acquired from the whole area, we can see that, the calculation result is in conformity with the actual situation. The numerical experiments show that, the micro-pressure inner loop reactor meet the water treatment requirements and it provides a theoretical basis for practical engineering equipment production.

# Vibration Analysis and Human Comfort Evaluation of Underground Hydropower House

Dan Fu [1, a], Hegao Wu [1, b]

[1]State Key Laboratory of Water Resources and Hydropower Engineering Science, Wuhan University, Wuhan 430072, China

[a]303960788@qq.com, [b]wbf1988@vip.sina.com

**Keywords:** Hydraulic structure; main powerhouse; vibration; human comfort; pressure fluctuation; finite element method

**Abstract:** Human comfort is of great importance to main powerhouse and vibration level should be controlled below the human comfort limit. Comparison of ISO2631/1-1985 and ISO2631/1-1997 was performed firstly in this study. It points out that weighted root-mean-square acceleration is basic variable for vibration evaluation. The reduced comfort boundary of 2 hours (0.260m/s$^2$) in 1985 version is very close to the comfort threshold (0.315m/s$^2$) in 1997 version. Above two values were selected as human comfort standard in this paper. After that, 3D dynamic finite element model of HongPing pumped storage station was established and vibration analysis under pressure fluctuations was conducted using time history method. The calculation results indicated that vibration of generator floor was mainly caused by the multiples of runner blade number frequency. Vibration level of generator floor would not lead to human discomfort.

## Introduction

As a place to transform hydraulic energy to electric energy, structural vibration in hydropower house is unavoidable. Harmful results due to structural vibration can be summarized into three aspects: (a) Long-term severe vibration may lead to damage and fatigue in powerhouse's components which affects the normal usability and durability of structures. (b) Vibration is disadvantageous to the performance of electric equipments and instruments. (c) Operating personnel would feel uncomfortable in strong vibration condition which is also harmful to their health if accumulated working time is too long. In addition, if vibration leads to obvious human discomfort, vibration level may be considered as unacceptable even though it has no essential effect to structure and electronic equipment. Currently, insufficient importance has been attached to human comfort in vibration analysis and evaluation for hydropower house. Research on vibration evaluation method and standard has been unfortunately lagged behind. In fact, the work to study human ride comfort with literature [1-3] in public transport is very active.

In this paper, the new standard (ISO2631-1997) and the old version (ISO2631-1985) for human exposure to whole-body vibration were compared firstly. Vibration evaluation method applied to main powerhouse was proposed through above comparison. Based on the dynamic FE model of powerhouse structure of HongPing pumped storage station, vibration analysis under fluctuation pressure using dynamic time history method was performed. At last, vibration evaluation of main powerhouse was conducted using the stated evaluation method.

**ISO2631/1-1985 standard**

Vehicle, mechanical equipment and industrial activity can all make human body be exposed to vibration environment that affects human comfort and normal activity, even health and safety. Therefore, it is of great importance to scientifically evaluate the negative effects from whole-body vibration.

Based on sufficient research achievements about human whole-body vibration, ISO formulated the earliest vibration evaluation standard (ISO2631/1-1985). Now related evaluation literature for hydropower house in China are all put forward by referencing it [4-6]. This standard provides three kinds of vibration exposure boundaries: health and safety boundary, reduced work efficiency boundary and reduced comfort boundary. Evaluation methods include frequency spectrum method and frequency-weighed acceleration method which is stricter than the former in most cases. Only if the whole vibration energy focus on one octave, two methods are equivalent. When frequency spectrum method is taken, this standard provides a specific value of reduced comfort boundary corresponding to a certain vibration frequency *f* and period *T*. Health and safety boundary and reduced work efficiency boundary can be determined by multiplying the comfort value by 6.30 and 3.15 respectively. For the other method, ISO2631/1-1985 provides frequency weighting curves in three directions that are applicable to all evaluation contents and body postures. Weighted root-mean-square acceleration $a_{\mathrm{w}}$ can be calculated according to equation (1) or (2). Then $a_{\mathrm{w}}$ should be compared to the minimum value of reduced comfort boundary for the purpose of human body's comfort evaluation. The evaluation of health and safety or reduced work efficiency can be performed in the same way.

$$a_{\mathrm{w}} = [\frac{1}{\mathrm{T}}\int_0^{\mathrm{T}} a_{\mathrm{w}}^2(\mathrm{t})\mathrm{dt}]^{\frac{1}{2}} \tag{1}$$

$$a_w = [\sum(W_i a_i)^2]^{\frac{1}{2}} \tag{2}$$

Equation (1) is the form in time domain and $a_{\mathrm{w}}(\mathrm{t})$ is weighed acceleration as a function of time *t*. Equation (2) is the form in frequency domain and $\mathrm{W_i}$ and $a_{\mathrm{i}}$ are weighted factor and root-mean-square acceleration in the ith one-third octave respectively. ISO2631/1-1985 points out that if vibration amplitude in two or three directions are close, vector sum $a_{\mathrm{v}}$ of them should be calculated according to equation (3). Then the vector sum $a_{\mathrm{v}}$ should be compared to the minimum value of three kinds of boundaries in Z direction.

$$a_{\mathrm{v}} = \sqrt{\mathrm{k_x^2}a_{\mathrm{wx}}^2 + \mathrm{k_y^2}a_{\mathrm{wy}}^2 + \mathrm{k_z^2}a_{\mathrm{wz}}^2} \tag{3}$$

In equation (3), $k_x$, $k_y$ and $k_z$ are the directional factor. The evaluation standards according to IS2631/1-1985 are listed in Table 1 in which the numbers in bracket are vibration period. Considering that the possibility of accumulated vibration time of operating personnel surpassing 8 hours in main powerhouse is very low, so the reduced comfort standards corresponding to 2 hours are also presented in Table 1. The values of 8 hours are more suitable for central control room where operating personnel stays relatively long.

Table 1 ISO2631/1-1985 evaluation standard

| Boundary | Variable | Evaluation standard/(m/s$^2$) | |
|---|---|---|---|
| | | Vertical（Z） | Horizontal（X, Y） |
| Health and safety | $a_{\mathrm{wx}}, a_{wy}, a_{wz}$ | 0.63(8h), 1.07(4h) | 0.44(8h), 0.69(4h) |
| | $a_v$ | 0.63(8h), 1.07(4h) | |
| Reduced work efficiency | $a_{\mathrm{wx}}, a_{wy}, a_{wz}$ | 0.32(8h), 0.54(4h) | 0.22(8h), 0.35(4h) |
| | $a_v$ | 0.32(8h), 0.54(4h) | |
| Reduced comfort | $a_{\mathrm{wx}}, a_{wy}, a_{wz}$ | 0.10(8h), 0.26(2h) | 0.07(8h), 0.18(2h) |
| | $a_v$ | 0.10(8h), 0.26(2h) | |

**ISO2631/1-1997 standard**

ISO2631/1-1997 aims to evaluation of human exposure to whole-body vibration for four aspects: health, comfort, perception and motion sickness. Compared to 1985 version, the concept of reduced work efficiency due to vibration has been deleted. For evaluation method, weighted R.M.S acceleration $a_{\mathrm{w}}$ is specified as the basic variable with condition that crest factor is less than 9 and the frequency spectrum method has also been eliminated in 1997 version. If crest factor is greater than 9, additional evaluation methods including running R.M.S method or fourth power vibration dose method should be adopted. ISO2631/1-1997 provides six frequency weighting curves for different evaluation contents and body postures. The curves in three directions corresponding to original version have also been modified slightly. The biggest difference between two versions is that the concept of exposure period has been eliminated in 1997 version for human comfort evaluation. ISO2631/1-1997 suggests that there is no consequent relation between subjective comfort with vibration period. What's more, no exact reduced comfort boundary is presented because same vibration level may leads to different results for different persons. The actual feeling depends on many other factors (individual condition, activity type, etc.). New standard gives approximate indications of likely reactions to various magnitudes of overall vibration values in public transport. There are six sections with various feelings and Table 2 lists two of them. For hydropower house, it's basically reasonable to reference the vibration standards in 1997 version with the reason that in powerhouse and in public transport people can both tolerate some degree vibration. No reading and resting activities exist in powerhouse, so acceptable vibration level may be higher than that in public transport.

For human health evaluation, 1997 version points out the maximum of weighted R.M.S accelerations in three directions should be used as the evaluation variable. Vector sum $a_{\mathrm{v}}$ of directional weighted R.M.S accelerations should also be calculated as the evaluation variable if vibration magnitudes in different directions are close. In Table 2 eVDV is estimated vibration dose value which is used be the auxiliary variable. Similar to 1985 version, evaluation variable for human comfort is vector sum $a_{\mathrm{v}}$ of directional weighted R.M.S accelerations. The evaluation variable for perception is the maximum of weighted R.M.S accelerations (Max $\{a_{\mathrm{wx}}, a_{wy}, a_{wz}\}$) in three directions. Additional evaluation method is recommended if the condition of basic method is not met, but the standard does not give detailed information for additional method. Details summarized from ISO2631/1-1997 are given in Table 2.

Table 2 ISO2631/1-1997 evaluation standard

| Content | Variable | Standard/(m/s$^2$) | Period |
|---|---|---|---|
| Health | $a_v$ | 0.45～0.80 | 8 hours |
| | eVDV | 8.5～17/(m/s$^{1.75}$) | 8 hours |
| Comfort | $a_v$ | Less than 0.315 | not comfortable |
| | | 0.315～0.63 | a little uncomfortable |
| Perception | Max$\{a_{\mathrm{wx}}, a_{wy}, a_{wz}\}$ | 0.01～0.02 | 0.015 is median value |

For main powerhouse, making an attempt to limit structural vibration to be below perception level is not necessary and unpractical. Considering the low possibility of accumulated vibration time surpassing 8 hours in main powerhouse, recommended health limits listed in Table 1 and Table 2 can be amplified properly. In engineering practice, vibration level is likely assessed be unacceptable while it leads to human discomfort, thus the definition of human comfort is significant. However, there is no specific comfort standard for hydropower house in China. The practical experiences from pumped storage projects indicated that if vibration level can meet the reduced comfort boundary in ISO2631/1-1985, other else requirements can all be met for main powerhouse. However, related literature did not demonstrate the vibration period corresponding to above mentioned comfort boundary. Considering that 1985 version has been applied for a long time in China, this paper still takes it as a major reference. As stated before, vibration period *T* is an essential variable in 1985 version. The reduced comfort boundaries for 2 hours and 8 hours are respectively 0.26m/s$^2$ and 0.10m/s$^2$ in Table 1. For main powerhouse, adopting the value of 2 hours is more reasonable than that of 8 hours while the former is very close to the human comfort threshold 0.315 m/s$^2$ in 1997 version.

## Engineering project

### Calculation condition

Four reversible hydroelectric generating sets with 300MW unit capacity are installed in HongPing pumped storage station. Rated speed is500r/min and number of runner blades is 9. The form of one joint for one unit is taken in this station. This study established a 3D dynamic FE model for 2# main powerhouse and rock range the FE model contained equaled three times of the span of main powerhouse. Sketch map of 3D dynamic FE model is shown in Fig.1 and model of powerhouse is shown in Fig.2. Main powerhouse was concreted attaching to the excavation surface and joint bars were set between rock and structure, therefore in FE model elements of rock and structure shared the same nodes on boundary B. Viscous-elastic artificial boundary was set on boundary C to simulate the dynamic stiffness of infinite rock. Concrete grade of powerhouse is C25. Material of spiral case, stay ring and liner of draft tube and generator pit is steel. Material parameters adopted in this paper are listed in Table 3. In the global coordinate system of the model, Z-axis is vertical with the positive direction moving upward and Y-axis is horizontal with the positive direction along water direction, X-axis is horizontal, specifically perpendicular to Y-axis.

Table 3 Material parameters

| Material | Density/(kN/m$^3$) | Young's modulus/GPa | Poisson's ratio |
|---|---|---|---|
| Concrete(C25) | 25.0 | 28.0 | 0.167 |

| Rock | 27.0 | 10.0 | 0.23 |

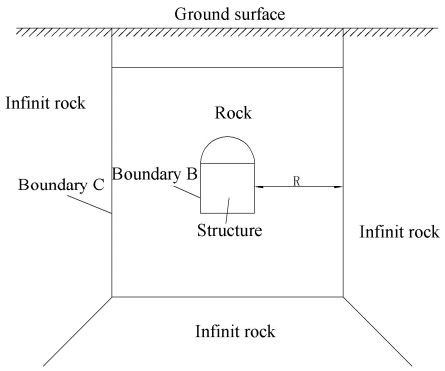

Fig.1 Dynamic model of underground powerhouse

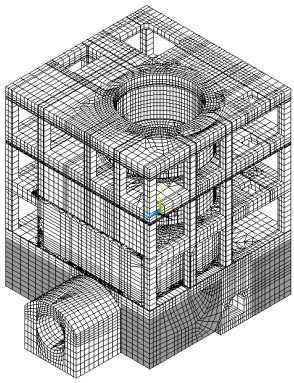

Fig.2 Finite element meshes for powerhouse structure

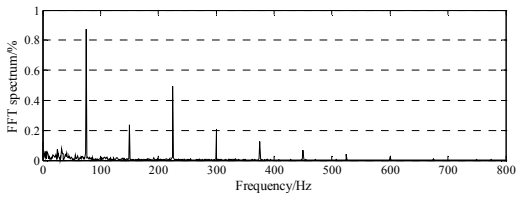
Model tests of hydraulic turbine were accomplished by turbine manufacturers. Pressure fluctuation tests under eleven different kinds of output conditions at maximum head 565m, rated head 540m and minimum head 520m were performed. For the measurements of the pressure fluctuations, dynamic pressure transducers were installed at the following locations: spiral case inlet, vaneless space, between head cover and runner crown, between bottom ring and runner band, draft tube cone and draft tube elbow. Sampling frequency is 4800Hz and sampling time is 10s.

In this paper, rated power at rated head was selected for vibration analysis of main powerhouse. Pressure fluctuation signals of model were transposed to prototype conditions by referencing literature [5]. Spectral characteristic of vaneless space point and draft tube cone point in prototype condition are shown in Fig.1 and Fig.2. As seen in two figures, dominant frequencies in vaneless space are runner blade number frequency and multiple frequencies of it. Dominant frequencies of draft tube cone are 66Hz and the rated rotation frequency 8.33Hz. Characteristic amplitude of pressure fluctuation in draft tube is significantly less than that in vaneless space.



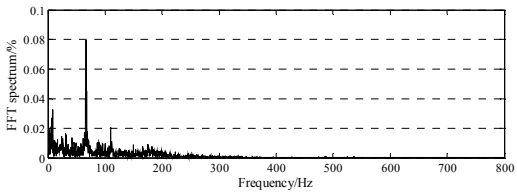


Fig.3 Pressure fluctuation FFT spectrum in vaneless space Fig.4 Pressure fluctuation FFT spectrum in draft tube cone

**Vibration analysis and evaluation of generator floor**

Root-mean-square of vertical acceleration (RMSVA) of generator floor is shown in Fig.5. Vector sum of root-mean-square of accelerations (VSRMS) in three directions is shown in Fig.6. The difference between two figures occurs at stair hole where RMSVA is 0.1m/s$^2$ and VSRMS is 0.3m/s$^2$. It indicates that at stair hole horizontal acceleration is relatively big. RMSVA and VSRMS

are almost at the same level in the rest region of generator floor, it demonstrates vertical acceleration is the major component. The maximum value of VSRMS locates at bottom right corner and the value of this point is 0.825m/s$^2$. This point is selected as the vibration feature point of generator floor.

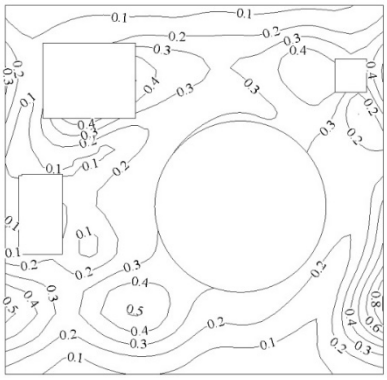

Fig.5 R.M.S of vertical acceleration of generator floor（m/s$^2$）

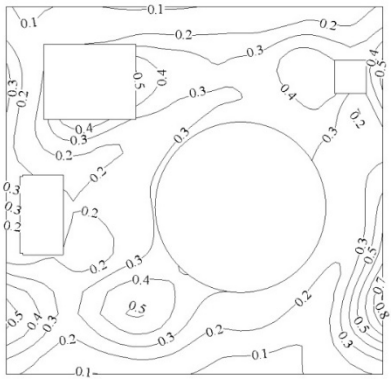

Fig.6 Vector sum of R.M.S of accelerations（m/s$^2$）

Feature point's vibration time history signal and FFT spectrum in three directions are shown in Fig.7~Fig.12. The initial 1s or 1.5s of time history signal is captured out for showing. From these figures we know, peak acceleration in X direction is below 0.2m/s$^2$ and the dominant frequencies includes 75Hz, 150Hz and 225Hz corresponding to runner blade number frequency, double and triple of it. Peak acceleration in Y direction is below 0.3m/s$^2$ and dominant frequencies are similar to that of X direction, but FFT spectrum of 150Hz and 225Hz in Y direction is bigger than that in X direction. Peak acceleration in Z direction is 1.588m/s$^2$ and the dominant frequency is 75Hz while the pressure fluctuation of 66Hz in draft tube has a little contribution to feature point's vibration response. Above statements indicate that vibration of generator floor is mainly caused by pressure fluctuation in vaneless space, dangerous frequencies for generator floor are multiples of runner blade number frequency.

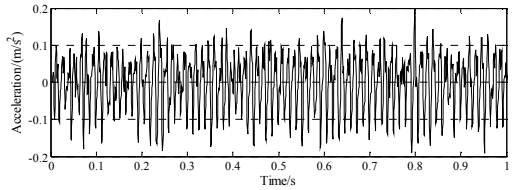

Fig.7 Acceleration time history in X direction

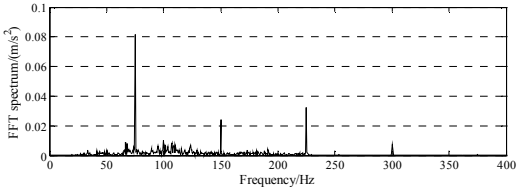

Fig.8 Acceleration FFT spectrum in X direction

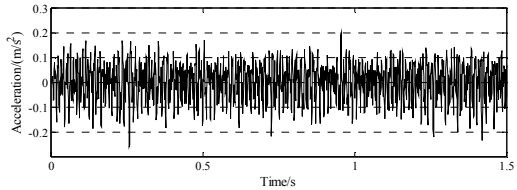

Fig.9 Acceleration time history in Y direction

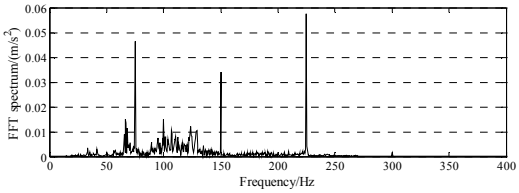

Fig.10 Acceleration FFT spectrum in Y direction

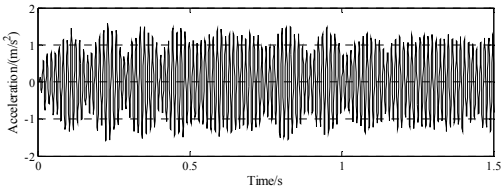

Fig.11 Acceleration time history in Z direction

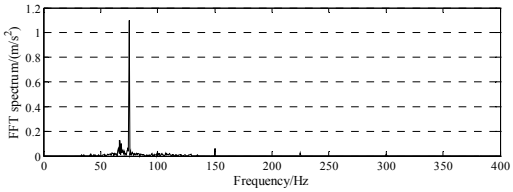

Fig.12 Acceleration FFT spectrum in Z direction

Table 4 Feature Point's vibration evaluation parameters

| Evaluation variable | Direction | | | Vector sum |
|---|---|---|---|---|
| | X | Y | Z | |
| Root-mean-square of acceleration /(m/s$^2$) | 0.0731 | 0.0738 | 0.8195 | 0.8260 |
| Weighted root-mean-square of acceleration /(m/s$^2$) | 0.0016 | 0.0012 | 0.1226 | 0.1226 |
| Crest factor | 2.73 | 3.56 | 1.94 | |

Feature point's root-mean-square of acceleration and weighted root-mean-square of acceleration in three directions are listed in Table 4. In addition, crest factors in three directions are also listed. Frequency curves used in calculation are from ISO2631-1997 and the calculation is performed by MATLAB. Power spectrum of acceleration signal is calculated in the first step, then weighted root-mean-square value is carried out according to equation (4) which is equivalent to equation (2). In equation (4), $P_i$ is power spectrum density of the ith octave.

$$a_{\mathrm{w}} = [\sum w_i^2 P_i \Delta f]^{\frac{1}{2}} \quad (4)$$

As listed in Table 4, feature point's crest factors in three directions are all less than 4, so basic evaluation method in ISO2631-1997 is feasible. Taking no account of frequency weighting, vector sum of root-mean-square of three directional accelerations (VSRMS) is 0.8260m/s$^2$ which exceeds reduced comfort boundary of 2 hours (0.260m/s$^2$) in ISO2631-1985 and comfort threshold (0.315m/s$^2$) in ISO2631-1997. It even exceeds health evaluation standard of 8 hours in both standards. But if frequency weighting is considered, vector sum of weighted root-mean-square accelerations in three directions is 0.1226m/s$^2$ which exceeds perception threshold (0.01m/s$^2$~ 0.02m/s$^2$) but is less than reduced comfort boundary of 2 hours in ISO2631-1985 and comfort threshold in ISO2631-1997. It indicates that under rated power at rated head, human would feel obvious vibration but vibration level would not lead to human discomfort. Vibration of generator floor is acceptable in the view of human body comfort.

**Summary**

Weighted root-mean-square acceleration should be used as basic evaluation variable. Additional evaluation method should be taken if crest factor of vibration acceleration signal exceeds nine. For main powerhouse, vibration level should be controlled under the human comfort limit. ISO2631/1-1985 contains vibration period concept and the comfort boundary of 8 hours is some stricter for main powerhouse. In fact, the comfort boundary of 2 hours (0.260 m/s$^2$) is close to the comfort threshold (0.315m/s$^2$) in ISO2631/1-1997. Above two values are selected as human comfort standard in this paper.

Vibration analysis of HongPing main powerhouse indicated that vibration of generator floor is mainly caused by the multiples of runner blade number frequency. Evaluation results showed that vibration level of generator floor would not lead to human discomfort. At last, we must realize that it is necessary to formulate a specialized standard for human exposure in hydropower station because of main powerhouse's particularity.

**Keywords:** Gravity dam, Anti-arch dam segment, Working performance, Deformation, Stress.

**Abstract.** The working performance of a gravity dam with an anti-arch shape differs from that of conventional gravity dams. To understand the working performance of the anti-arch segments on the bank slope of Xiangjiaba dam, linear and non-linear finite element methods were used to analyze the deformation, stress, the state of transverse joints, and cracks during operation. The anti-sliding stability coefficient of each dam segment and the safety degree of the dam were also calculated. Results show that under non-grouting of transverse joints and well grouting of cracks, deformation rules are consistent in all investigated segments and are in accord with those of conventional gravity dams. The dam heel and dam toe are subjected to compressive stress. During cold seasons, a tensile stress region is observed on top of the dam body, wherein tensile stress is smaller than tensile strength. Transverse joints are opened, whereas cracks are generally stable and closed under compression. The anti-sliding stability coefficient and safety degree of each dam segment are above 3.0, which satisfies the design code.

## Introduction

A gravity dam, which is one of the most important dam types, typically has a linear layout. Such dam maintains stability and satisfies the strength requirement through its dead weight. In some special cases wherein topographical or geological constraints are salient, a broken-line or curved-line layout is observed. For example, Danjiangkou Dam [1] and Xiangjiaba Gravity Dam [2] have a counter-arched shape in several segments. Force distribution varies with the specific layout of a dam, thus further influencing the working performance of a dam [3]. Based on monitoring data and research results [4], the following situations may occur when Danjiangkou Dam has no transverse joint or has an extremely narrow transverse joint. 1) Deformation. The counter-arched segments tend to deform downstream during summer and upstream during winter. The displacement of the dam top exhibits a contrary annual variation trend compared with a linear-type dam segment. The deformation value is closely related to the joint configuration. 2) Stress. The water level is generally high during summer. Moreover, the dam body exhibits a downstream deformation under high temperature. The superposition of these two effects tends to aggravate dam heel stress. When the water level is low during winter and the dam body exhibits an upstream deformation, dam toe stress deteriorates. Hence, the kerf concept is adopted during later stages. 3) Transverse joint. The state of the transverse joint varies with joint width, grouting elevation, and bedrock, thereby influencing the deformation and stress of the dam; 4) Stability. The anti-sliding stability of a counter-arched dam segment also differs from that of a conventional gravity dam. Under the same hydraulic thrust, large dam body results in high anti-sliding coefficient. Based on these situations, the working performance of the counter-arched segment obviously differs from that of a conventional gravity dam. Information on various aspects of gravity dams with a linear layout is abundant. However, counter-arched gravity dams have not been intensively studied. Existing literature has focused on the qualitative analysis of monitoring data and on the partial stress analysis of dam heels, which affects judgment of the overall safety of the project.

The Xiangjiaba Hydraulic Power Station is located between Yibin County in Sichuan Province and Shuifu County in Yunnan Province. This gravity dam has a maximum height of 162 m. The slope dam segments on the left bank, which consist of 12 pieces, have a total length of 199.92 m. The highest section of the dam is 122 m. The six dam segments from left segment 7 to 12 along the riverbed are arranged in an arch shape on the plane view, with the sum of the central arc angle being 54°. The six dam segments from left segment 13 to 18 along the slope are arranged in a linear pattern. Figure 1 shows the layout of the slope dam segments, and Figure 2 shows the cross-sectional view of a typical dam. The left segments exhibit the following features. 1) The slope dam segments on the left bank are counter-arched, thus making them significantly different from conventional gravity dams. 2) The base elevation and height of different segments differ significantly, which influences dam working performance. 3) The dam heel is close to the free face of the foundation, which is not completely stable. 4) Several cracks appear on the dam during construction. These cracks may affect structural integrity to certain extent. Based on these features, conducting an in-depth analysis on the left segments of Xiangjiaba Dam is necessary to further understand the working performance of the dam, including deformation, stress, anti-sliding stability and safety degree. This work provides technical support for dam operation and subsequent engineering designs.

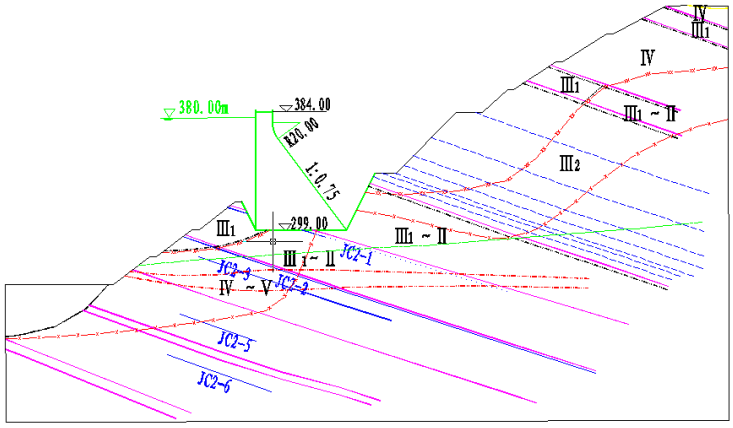

Fig. 2 Cross-sectional view of the dam

## Analysis method and model

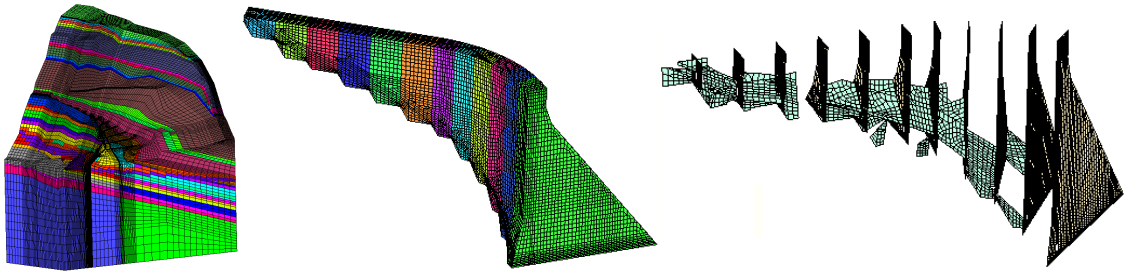
**2.1 Analysis method.** Normal working performance is calculated via linear elastic finite element analysis [5]. The dead weight of the dam body, hydrostatic pressure, silt pressure and temperature load are considered. Temperature load is calculated with the following method [6]. The mean temperature of the dam site over the years is taken as the initial temperature of the dam body and the bedrock. The monthly mean air temperature over the years is taken as the boundary condition to calculate the temperature fields of the dam body and the foundation in the future years. The temperature field in October which is close to the annual mean temperature is used as the initial temperature field. The quasi-steady temperature fields of the dam body and the bedrock after several years of impoundment

are obtained by considering boundary conditions such as air temperature and reservoir water temperature. The differences in the temperature field during winter (January) and summer (July) relative to the temperature field in October are considered as temperature drop and temperature rise loads, respectively.

Anti-sliding stability is calculated by using the material mechanics analysis method specified in the design code [7]. The safety degree of the dam body is obtained through non-linear finite element analysis [8]. The Durcker-Prager yield criterion is adopted for the bedrock, whereas the Mohr-Coulomb yield criterion is adopted for the dam concrete and the weak intercalated layer. The model is assumed as an ideal elastic-plastic model.

Transverse joints and cracks are simulated as contact elements. Three states are involved in the calculation, namely, opened, in contact and bonded (the state after grouting). There is no transmission of force when a joint or crack is opened. The contact state enables a transmission of compressive and shears forces with certain values. The bonded state allows withstanding tensile, compressive and shears forces. Once the bonding element yields under tension, the stress acting on the element is adjusted. Then, tensile stress shifts to adjacent elements. Under the compressive-shear state, an element yields and softens when the shear stress exceeds shear strength. Cohesive force also disappears. The element can only withstand friction. The excess part of stress shifts to the adjacent element. After adjusting the stress on the element, the yield criterion for the element under stress is rejudged until the judgment is completed for all contact elements. All finite element analyses are performed by Saptis software for multi-field simulation and non-linear analysis. This software was developed by the Department of Structure and Materials, China Institute of Water Resources and Hydropower Research [9, 10].

**2.2 The model.** According to topographical and geological conditions, dam body structure and material zoning, a calculation model that can objectively and accurately simulate the dam structures and geological structures is established. The model involves the concrete and bedrock zones, weak intercalated layer of dam foundation, dominant joints, compressive rupture zones, transverse joints, cracks, and main corridors. The model has 364,283 nodes and 413,343 elements, as shown in Figure 3.

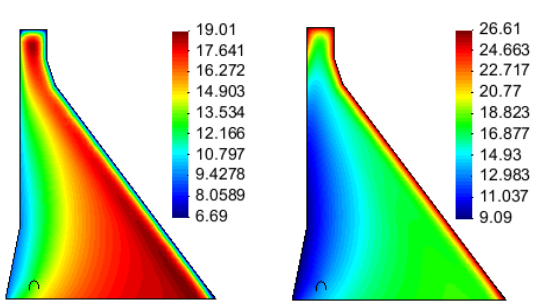


a. Foundation b. Dam c. Transverse joints and cracks

Fig. 3 The model

## Working performance

**3.1 Temperature.** After impoundment, the dam gradually achieves the quasi-steady temperature field under the joint actions of earth temperature, air temperature and water temperature. After 30 years of impoundment, the temperature field of the structure under the normal water level is shown in Figure 4. Meanwhile, Figure 5 shows the temperature variation curves at different elevation points. Based on these figures, the temperatures of the underground portion of the upstream face and the interior of the dam remain basically unchanged. Meanwhile, the temperature of the downstream face and the top section change periodically with air temperature. The lowest and highest temperatures are 7℃ and 26.5℃, respectively.



Winter Summer

Fig. 4 Temperature field of the dam

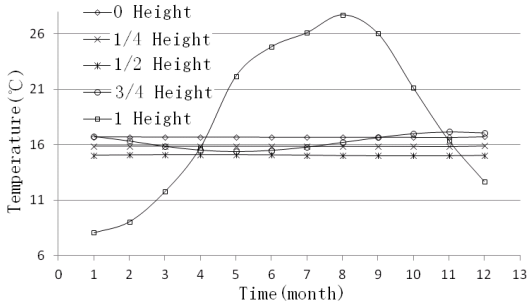


Fig. 6 Temperature curve of different heights

**3.2Deformation.**In calculation, the cracks are considered well grouted and its strength is equal to the test result, while the transverse joints are not grouted. The radial and tangential displacements of the midpoints of the upstream face at the top of dam segments for typical water levels at different seasons are obtained, as shown in Table 1. The radial deformations of all dam segments point downstream, while the tangential deformation points toward the middle of the riverbed. Therefore, the structure generally exhibits deformations downstream and toward the middle of the riverbed. Temperature change has a significant effect on dam deformation. The temperature of the upstream face is constant under the influence of the water temperature of the reservoir. By contrast, the downstream face has a fluctuating temperature because of the influence of air temperature. Therefore, the downstream face contracts during winter. Moreover, the dam basically exhibits downstream deformation. During summer, the downstream face expands and the dam exhibits upstream deformation. The non-grouting of transverse joints illustrates that the deformation of the dam segments is similar to that of conventional dams, and that no adverse effect is posed on the dam.

Table 1 Radial and tangential deformations of the dam under different working conditions (mm)

| Deformation | Working conditions | Left 7# | Left 8# | Left 9# | Left 10# | Left 11# | Left 12# |
|---|---|---|---|---|---|---|---|
| Radial | Normal water level + winter | 25.97 | 25.73 | 24.29 | 21.72 | 14.53 | 12.34 |
| | Normal water level + summer | 20.95 | 20.55 | 19.15 | 16.77 | 9.59 | 7.56 |
| | Dead water level + winter | 17.9 | 17.28 | 16.08 | 14.29 | 8.49 | 6.56 |
| Tangential | Normal water level + winter | 13.02 | 12.31 | 11.26 | 9.87 | 9.71 | 8.64 |
| | Normal water level + summer | 10.86 | 10.45 | 9.69 | 8.6 | 6.31 | 5.13 |
| | Dead water level + winter | 10.41 | 9.59 | 8.62 | 7.45 | 5.62 | 4.09 |

**3.3 Stress.** The vertical stress of the dam heel and dam toe on each dam segment according to the results of the finite element analysis is shown in Table 2. Under the action of dead weight, hydraulic pressure, silt pressure, slag pressure at the back and temperature, the dam heel and the dam toe are in a compressive state. The magnitude of the compressive stress on the dam heel and the dam toe is related to the height of the dam segment, upstream water level and temperature. The stress generally increases with increasing dam height. At high water level and low air temperature, the compressive stress of dam heel decreases. At low water level and high air temperature, the compressive stress of the dam toe decreases.

Figure 6 shows the stress nephograms of the upstream and downstream faces of the dam at different seasons and water levels. The dark color indicates the tensile stress region. When temperature is low during winter, a tensile stress region is observed above the water level of the upstream face and downstream face. Tensile stress is smaller (typically less than 0.3 MPa) at low water levels. In some sites, tensile stress is 0.3MPa - 0.6 MPa, which falls within the allowable range of concrete tensile strength. When temperature is high during summer, nearly no tensile stress is observed to affect the overall safety of the structure.

Table 2 Vertical stress on the dam heel and the dam toe (MPa, negative is compressive)

| Dam segment | Dam heel | | | Dam toe | | |
|---|---|---|---|---|---|---|
| | Normal water level + winter | Normal water level + summer | Dead water level + winter | Normal water level + winter | Normal water level + summer | Dead water level + winter |
| 12# | -0.58 | -0.96 | -1.38 | -1.75 | -2.13 | -1.3 |
| 11# | -1.36 | -1.69 | -2.1 | -1.09 | -1.82 | -0.83 |

Fig. 6 Stress nephograms at different seasons and water levels (0.01MPa)

**3.4 State of transverse joints and cracks.** After impoundment, upstream hydrostatic pressure radially acts on the upstream face of the dam segment. Segments left 7 to 12 are arranged in a counter-arched shape. Thus, there is the trend of disintegration and deformation. Transverse joints are generally opened without contact. Each dam segment withstands load independently, which is consistent with the deformation rule of conventional dams.

The cracks of the dam are mainly distributed in the upstream curtain grouting corridor, as well as scattered in the transverse joint corridor and several drainage galleries. Most cracks run parallel to the dam axis or form a small angle with the dam axis. Therefore, the cracks are subjected to compressive stress under normal water loads and a tensile region does not exist. The magnitude of normal stress varies regularly. Compressive stress gradually decreases from left to right and from low to high elevation. The distribution pattern of shear stress resembles that of normal stress. Shear stress gradually decreases from right to left and from low to high elevation. The magnitude of shear stress also decreases from the downstream to the upstream face. Compressive stress is generally below 2.0 MPa, or above 4.0 MPa in some positions. Shear stress is mostly smaller than 0.7 MPa in cracks on the upstream face, whereas the maximum shear stress of the downstream face is below 1.8MPa. Shear stress of the cracks on the corridor is less than 1.4 MPa. In Calculating strength after grouting, the friction coefficient of 0.75 and the cohesive force of 0.60 MPa are used for analysis. Cracks are generally in a bonded state after grouting. Except for some elements that yield at the cracks on the corridors of left segments 9, 10 and 18 corridors, as well as those on the upstream face of left segment 12 and 13, all other elements are in a bonded state. Thus, cracks are generally stable.

## Safety analyses

**4.1 Anti-sliding stability.** Checking calculation is performed via the using material mechanics method for each left segment. Table 3 shows the anti-shear and anti-sliding stability coefficients at the foundation plane of each dam segment. Under the existing load and other parameters, the anti-sliding stability coefficients of the foundation plane of each left non-overflowing segment are above 3.0. Load increases and stability coefficient decreases with increasing dam height. The counter-arched segments from left segment 7 to 11 have anti-sliding stability coefficients larger than 3.0. The stability coefficients of the dam segments beyond left segment 12 are large and satisfy the design code requirements.

Table 3 Anti-sliding stability coefficients

| No. of dam segment | Bottom elevation | Anti-sliding stability coefficient | No. of dam segment | Bottom elevation | Anti-sliding stability coefficient |
|---|---|---|---|---|---|
| 7# | 262m | 3.44 | 13# | 330m | 4.53 |
| 8# | 274m | 3.06 | 14# | 339m | 5.62 |
| 9# | 286m | 3.1 | 15# | 347m | 8.4 |
| 10# | 299m | 3.14 | 16# | 355m | 9.12 |
| 11# | 311m | 3.53 | 17# | 360m | 11.64 |
| 12# | 323m | 4.06 | 18# | 371m | 48.23 |

**4.2 Safety degree.** Safety degree analysis is performed via the overloading method. Therefore, the upstream water level is regarded as the normal water level. Then the unit weight of water is constantly increased for non-linear calculations. According to the overload coefficient $\lambda$, the ratio of the calculated unit weight of water to the actual unit weight is used to evaluate the overall safety of the arch dam. The non-convergence of calculation is considered as final safety degree [11]. Two models are used for the calculation: the single dam segment model and the overall model. In the former, only one dam segment is considered, and its interaction with other dam segments is ignored. Therefore, the overload capacity varies from one dam segment to another. In the latter, contact with other dam

segments at the site of transverse joints is observed. Such contacts lead to interactions. If calculation is impeded by the low overload capacity of a particular dam segment, then calculation cannot be done for other dam segments either.

Figure 7 shows the deformation curves of each dam segment in the single dam segment and overall model. Figure 8 shows the yielding process of a typical dam segment. It is obvious that the deformation of the dam and the yielding degree increase with increasing overload. Deformation at the early stage increases linearly, and the overall structure is in an elastic state. Deformation mutation occurs at later stage. This phenomenon happens earlier at higher sections of the dam segments than at lower sections. The deformation increases rapidly, and so does the yielding degree. The overall structure is in the plastic stage. The deformation increases rapidly at constant load or increasing load. The structure is on the verge of total failure. The calculation results from single dam segment model and overall model are inconsistent. The result varies for each dam segment in the single dam segment model. However, the result from the overall model depends on the dam segment with the lowest safety degree. In addition, the interaction between the dam bodies also influences the calculation result, and not to the extent of affecting the final safety evaluation. The safety degree calculated by the overall model is 3.8. The lowest safety degrees (3.4) are obtained for the left segment 7 and 8 in the single dam segment model. The safety degrees from left segment 9 to 15 are in the range of 3.8 to 7.8. The safety degrees of left segment 16 to 18 exceed 8.0, which are the highest among all dam segments.

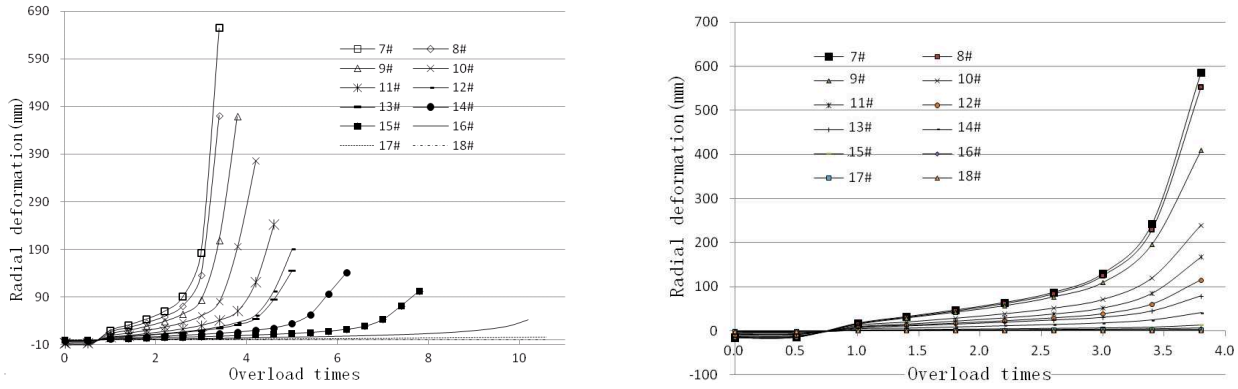

Fig. 7 Maximum deformation curves of each dam segment under different overload times

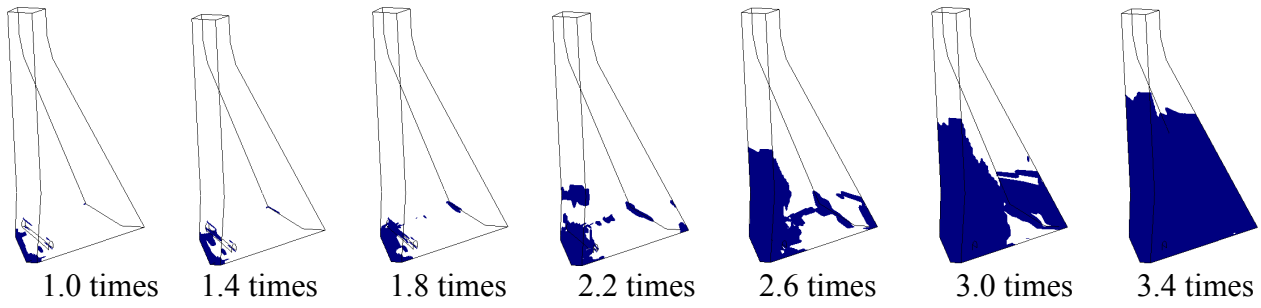

Fig.10 Yielding process of typical dam segments under different overload times (dark color: yielding)

## Conclusion

The left segments (7 to 12) on the slope of Xiangjiaba Gravity Dam with a counter-arched shape were analyzed in detail to assess the working performance of the dam. The results include dam temperature, deformation, stress, state of transverse joints, cracks, coefficient of anti-sliding stability, and safety degree. The results show,

With proper arrangement, the transverse joints of counter-arched dam segments are all opened after normal impoundment. Moreover, these joints are basically dependent on each other. Deformation, stress distribution and change rule are consistent with those for conventional gravity

dams, and no adverse effect is produced. The dam heel and the dam toe are subjected to compressive stress in each left segment. During cold seasons, a tensile region is observed on top of the dam. However, tensile stress is generally below 0.3MPa. The maximum tensile stress is approximately 0.6MPa, which is smaller than the tensile strength of concrete.

Grouting of the cracks in the dam is performed. Base on the analysis at 0.75 friction coefficient and 0.6MPa cohesive force, the cracks are generally in a compressive state. Except for local yielding at the base of cracks in several dam segments, cracks are mostly stable.

The anti-sliding stability coefficients and safety degrees of each dam segment are above 3.0, which satisfy the design code requirements.

**Key words:** leakage of reservoir area; bank stability; Yellow River water diversion and irrigation; saline; seismic liquefaction

**Abstract:** Engineering geology survey was carried out on the reservoir engineering of Yellow River water diversion and irrigation area, main engineering geology problem including leakage problem of reservoir area, shore stable and siltation problem around the reservoir, siltation problem of storehouse district, connected the river course and the pilot, water leakage river course, earthquake liquefication and immerse and salinification were analyzed and appraised, the corresponding project measure was proposed against the infiltrates of the storehouse district.

## Engineering Survey

A Yinhuang irrigation reservoir engineering is 6.15km from East to West, and 1.10km from north to south. The planning area is 3.20 $km^2$, which is divided into east reservoir and west reservoir. The reservoir is the plain reservoir formed by artificial excavation. The ground elevation is 51.50 ~ 51.80m. The planning water area is 3.51 $km^2$, lead, with water channel surface area of 0.26 $km^2$. The normal water level of the reservoir is 51.00m; the maximum water depth is 6.00m. Reservoir strata structure is the type of adhering sand multilayer structure. There is the horizontal leakage problem after impoundment of reservoir. This paper makes analysis and evaluation of the main engineering geological problems for the irrigation reservoir project area.

## Geological Survey

The site is located in the North China Plain. The geomorphic units belong to Yellow River alluvial plain, with flat terrain. The west is slightly higher than the east, with local residual sand dune. Reservoir formation is mainly composed of Quaternary Holocene (Q4) and the upper Pleistocene (Q3) alluvial sandy loam, silty sand clamp, heavy silt loam and silt clay strata. The reservoir distribution features are as follows. The upper strata is composed by the first layer of sandy loam, the second layer of silt loam silty sand, and the third layer of silty sand and sandy loam, which is excavation layer for reservoir formation. The thickness of the first layer of sandy loam is 3.7 ~ 7.5m, with uneven soil. The thickness of the second layer is 0.3 ~ 4.2m. The third layer of silt sand and silt loam: the thickness of silt sand is 7.2 ~ 9.0m, the sandy loam is 0.5 ~ 5.6m, with large variation of thickness and uneven soil. The middle stratum is composed by the 4th layer of silty clay and the fifth layer of fine sand, which is the reservoir foundation and substratum. The thickness of the fourth silty clay layer is of 1.3 ~ 7.2m; the distribution is not continuous, which belongs to the micro-low permeability, can be used as a relatively impermeable layer. The thickness of the fifth layer of fine sand is 5.5 ~ 18.0m, with high thickness and sandy inequality. The thickness of the sixth layer of heavy silt loam is 4.3 ~ 13.3m, with sandy loam, light silty loam and fine sand lens; the layer is of micro - low permeability, can be used as a relatively impermeable layer.

**The main engineering geological problems in reservoir area and the evaluation**

**3.1. Leakage problem of the reservoir**

The average digging depth is about 6.0m. The dike is 5 ~ 7.5m higher than the reservoir bottom. Reservoir strata structure is adhesive multilayer structure types; the lithology is in sandy soil, clip with heavy silt loam and silty clay layer. The first layer of sandy loam soil is of medium permeability; the second layer of silt loam is of low permeability in general; local parts are general permeable; the third layer of silt is in the medium permeability; the third layer of silty clay is with micro - low permeability. It has the horizontal leakage problem after impoundment of reservoir.

The reservoir bottom is composed of the layer of silt loam, the third layer of silty sand, sandy loam, the fourth layer of silty clay, the fifth layer of fine sand and the sixth layer of heavy silt loam and the seventh layer of fine sand. Sandy loam soil is with medium permeability generally; powder and fine sand is with moderate to high permeability; silty clay and silty loam is with micro - low permeability. The fourth layer of silty clay is with low permeability, which can be used as relative water- resisting layer. But the space distribution is not continuous, some or most of the section is lack of the layer. The third layer of silty sand and sandy loam and bottom fifth layer of silty sand are moderately permeable, which is directly connected with the stratum, thus forming the leakage path. It has the vertical leakage problem after impoundment of reservoir.

**3.2 Bank stability and deposition problems of the reservoir**

Reservoir's excavation depth is 6 ~ 7m. The surrounding ground height is of about 1m, the bank slope height is about 7 ~ 8m. According to the above analysis of soil layer, the first layer of sandy loam soil has medium dense, with moderate permeability, low strength, and poor anti erosion ability; the second layer of silt loam has loose structure, with weak permeability, local parts with medium permeability; the stability is poor; the third layer of sandy loam and silty sand is in a little dense shape, with moderate permeability, low strength, poor anti erosion ability. The reservoir stratum, under the reservoir conditions, is prone to reservoir bank collapse. To sum up, the surrounding bank slope's stability is poor. It should take appropriate protection measures. The surrounding bank slope rate can be set to 1:2.5 to 1:4.0.

**3.3 siltation problems of reservoir, connecting channel and river water diversion channel**

The lithology of the upper strata of field was mainly sandy soil, storage water was carried out in the reservoir, connecting channel and river water diversion channel, because the sandy loam and silty sand have the characteristic of medium permeability, low shear strength and poor anti-erosion ability, under the water erosion and scour effect, sandy soil slope collapse and reservoir sedimentation were easily happened. According to the design data, Silt content of reservoir can reach 1~2kg/m3, which can also make the reservoir and river sedimentation, so the sedimentation of reservoir and river should be taken corresponding measures.

**3.4 Earthquake liquefaction problem**

Seismic basic intensity of field was VII, seismic peak acceleration was 0.15G. Site 20m soil layer under the ground is the fourth recent (Q4) formation. In addition to the first layer of silty clay and clay content was greater than 17%, the rest of the layer clay content is less than 17%,

Through calculating the shear wave velocity, combining the measured average hear wave velocity, according to engineering geological survey specification of water hydropower (GB50487-2008)， soil liquefaction was preliminary judged, The fourth layer of silty clay was a non liquefied soil, The first layer of sandy loam, the second layer of silt, the third layer of silt and the fifth layer of fine sand soil were probably liquefied soil, so soil liquefaction should be judged again. Which should be done according to building seismic design specification (GB50011-2010), standard penetration blow number method was adopted. Liquefaction of saturated sand soil under 20m range was existed, with a serious liquefaction rank, so the corresponding measures should be taken.

### 3.5 Immersion and salinization problem

According to the codes on water conservancy and hydropower engineering geological survey (GB50487-2008) and appendix D, submerged groundwater threshold values were calculated. Three dimensional seepage calculation analysis indicated that, without seepage measures, The water table around the reservoir within 100m groundwater level was 50~51m, groundwater deep was 0.3~1.5m, which was smaller less than critical value of immersion groundwater, so immersion and salinization problem were existed, thereby which led to foundation conditions deteriorated near village, the substation, and new community. so the corresponding anti-seepage measures should taken.

### 3.6 anti-seepage measures

The fourth layer of silty clay has low permeability, which can be used as relative water-resisting layer, But the space distribution is continuous in the western region, only part of the section is lack of the layer. which has certain sedimentary thickness and can be used as the impervious curtain lower. But the east reservoir layer distribution was not continuous, sedimentary thickness varied greatly, which could not be used as relative water- resisting layer, The thickness of the sixth layer of heavy silt loam was large, stable distribution was continuous, only sandy soil skylight was existed in local area. the layer was of micro-low permeability, can be used as a relatively impermeable layer deposition. so the reservoir anti-seepage curtain or wall should be bound to the surface, and the lower limit should be 0.5 ~ 1.0m in the sixth layer of heavy silt loam.

## Summary

Through the investigation of Yinhuang irrigation reservoir engineering, it was finded that the reservoir seepage problems, reservoir bank stability and sedimentation, river water diversion, connection and siltation problems, seismic liquefaction, immersion and salinization and other engineering geological problems were existed in the reservoir, especially the of reservoir leakage problem was the most prominent, this paper gave the treatment measures of reservoir leakage problem.

# Research on the Calculation Method of Earth Pressure on the Back Side of Large Cylinders

HE Jialong[1, a]

[1] Hohai University, College of Water Conservancy and Hydropower Engineering, Nanjing, China

[a]815356713@qq.com

**Keywords:** Large cylinders,earth pressure,arch effect,calculation method.

**Abstract.** The study on calculation method of earth pressure around the circle of large cylinders will be deduced in this paper. The arch effect of soil is introduced into study. Considering the soil arch effect, different stress sections appear in the soil between two cylinders due to the change of stress state. Equations are established respectively in these sections and the analytic solutions to the equations are obtained.

Large cylindrical structure are brought in China in recent decades, and it began to promote as a new type of port [1]. This paper focuses on the distribution of large cylindrical structure plane earth pressure on the back side of large cylinders.

Currently earth pressure on the back side of large cylinders widely used formula is Levacheve formula [2], and the premise of the formula is put forward as there is no interaction between adjacent cylinder. But it works in practice and experimental studies [3] were found, after filling the cylinder will form soil vaulted arch [4]. In this paper, the different extents are proposed in the research process calculation formula of soil pressure: limit state sector, the pressure arch sections and loose state sector, as shown in Figure 1.

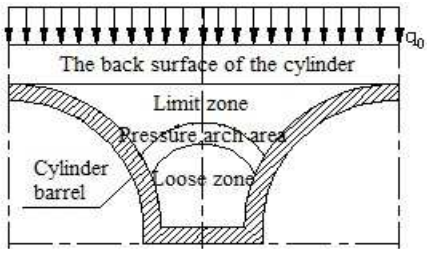

Fig.1 Three Stress Sections Distribution

## Earth pressure of limit state sector

This paper avoid pressure arch arch axis characterization studies directly, and a situation made some assumptions based on the state of the soil in the limit to derive formulas limit state soil earth pressure.

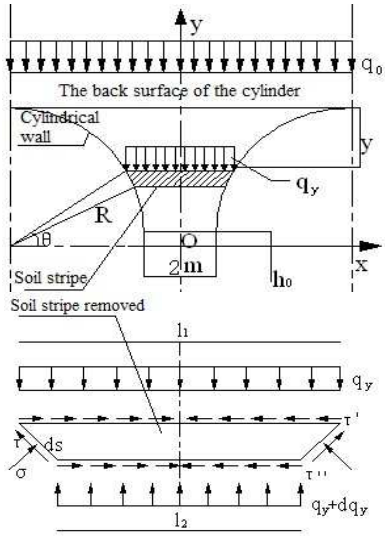

Fig.2 Earth Pressure Calculation Model

As is shown in figure 2 . There are $\sum Y_i = 0$ , mean that: $q_y l_1 - (q_y + dq_y) l_2 - 2\sigma \sin\theta ds - 2\tau \cos\theta ds = 0$

$\sigma$ - radial cylindrical shell reaction force, $\tau$ - reaction force to cut the shell column, $r$ - cylinder diameter, $m$ - cylinder interface slot width, $\theta$ - central angle.

So: $a = 1 + m/r$ , there are: $dq_y = \dfrac{q_y \sin\theta - \sigma \sin\theta - \tau \cos\theta}{a - \cos\theta} d\theta$ .

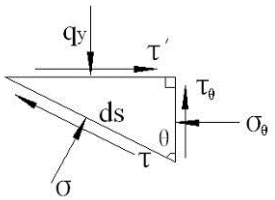

Fig.3 Differential Element

Remove an adjacent differential unit cell shown in Figure 3. There are:

$\sum X_i = 0$, mean that

$$\sigma \cos\theta + \tau' \sin\theta = \tau \sin\theta + \sigma_\theta \cos\theta \tag{1}$$

$\sum Y_i = 0$, mean that

$$q_y \sin\theta = \tau_\theta \cos\theta + \tau \cos\theta + \sigma \sin\theta \tag{2}$$

So: $$\sigma_\theta = K_i q_y \tag{3}$$

$K_i$ - soil lateral pressure coefficient;When $\dfrac{\pi}{2} - \delta \le \theta \le \dfrac{\pi}{2}$ ,i=1; When $0 < \theta < \dfrac{\pi}{2} - \delta$ ,i=2;

The value is not the same $\theta$ , the friction contact surface of the cylindrical wall are different.

At that time $\dfrac{\pi}{2} - \delta \le \theta \le \dfrac{\pi}{2}$ ($\delta$ of external friction angle of the soil), the soil on the slope triangular element is self-steady state, the friction can not reach the limit, it can be assumed:

$$\tau = \sigma c \tan\theta \tag{4}$$

Consolidated (1) (2) (3) (4), the solution of basic differential equations can be obtained as follows:

$$q_y = C_0[a - 1 + (a+1)\tan^2\frac{\theta}{2}]^{\frac{-K_1 a^2}{a^2-1}} \times (\tan\frac{\theta}{2})^{\frac{K_1}{a-1}} \times (1 + \tan^2\frac{\theta}{2})^{K_1} \quad , \quad \frac{\pi}{2} - \delta \le \theta \le \frac{\pi}{2} \tag{5}$$

$C_0 = q_0 (2a)^{\frac{K_1 a^2}{a^2-1}} (2)^{-K_1}$ .

At the time $0 < \theta < \dfrac{\pi}{2} - \delta$ , assuming the friction reach the limit, mean that:

$$\tau = f\sigma \tag{6}$$

$f$ - the soil and the friction coefficient of the tube wall, $f = \tan\delta$.

The (6) into (1) (2) finishing available $\sigma = \varphi(\theta) q_y$ ,

$$\varphi(\theta) = \frac{K_2 \cos^2\theta - \sin^2\theta}{\cos 2\theta - f \sin 2\theta} \tag{7}$$

$$K_2 = \tan^2(\frac{\pi}{4} - \frac{\delta}{2}) \tag{8}$$

Comprehensive (7) (8) we can get the solution: $q_y = (a - \cos\theta) \cdot e^{-d \cdot \varphi_1(\theta)} \cdot e^{-fd \cdot \varphi_2(\theta)}$

$d = \dfrac{\cos\delta}{\sin\delta + 1}$; $\varphi_1(\theta) = \int \dfrac{\sin(b+\theta)\sin\theta}{\cos(b-\theta)(a-\cos\theta)} d\theta$; $\varphi_2(\theta) = \int \dfrac{\sin(b+\theta)\cos\theta}{\cos(b-\theta)(a-\cos\theta)} d\theta$ .

**Earth pressure pressure arch section**

The load decreasing trend makes a zone between the soil to form a single barrel characterization arch axis alone bear the remaining external loads is possible.

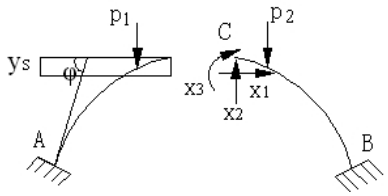

Fig.4 Pressure Arch Model

As is shown in Figure 4, we have a matrix expression:

$$\begin{Bmatrix} M \\ Q \\ N \end{Bmatrix} = \begin{bmatrix} 1 & -x & y-y_s \\ 0 & \cos\varphi & -\sin\varphi \\ 0 & -\sin\varphi & -\cos\varphi \end{bmatrix} \begin{Bmatrix} X_1 \\ X_2 \\ X_3 \end{Bmatrix} + \begin{Bmatrix} M_P \\ Q_P \\ N_P \end{Bmatrix} \tag{9}$$

Surface of the internal forces of any length of arch: $M_P = \frac{-q}{2}x^2$ , $Q_P = qx\cos\varphi$ , $N_P = -qx\sin\varphi$ .

$$\begin{bmatrix} \delta_{11} & 0 & \delta_{13} \\ 0 & \delta_{22} & 0 \\ \delta_{31} & 0 & \delta_{33} \end{bmatrix} \begin{Bmatrix} X_1 \\ X_2 \\ X_3 \end{Bmatrix} + \begin{Bmatrix} \Delta_{1p} \\ \Delta_{2p} \\ \Delta_{3p} \end{Bmatrix} = \{0\} \tag{10}$$

To enable $\delta_{13} = \delta_{31} = 0$, move some extra binding action point C along the $y$ axis distance $y_s$ , making integration $\int_s \frac{\overline{M}_1 \overline{M}_3}{EI} ds = 0$ . Simplification can be obtained by: $y_s = \int_s \frac{yds}{EI} \Big/ \int_s \frac{ds'}{EI}$.

Equation (10) simplifies to: $\begin{bmatrix} \delta_{11} & 0 & 0 \\ 0 & \delta_{22} & 0 \\ 0 & 0 & \delta_{33} \end{bmatrix} \begin{Bmatrix} X_1 \\ X_2 \\ X_3 \end{Bmatrix} + \begin{Bmatrix} \Delta_{1P} \\ \Delta_{2P} \\ \Delta_{3P} \end{Bmatrix} = \{0\}$

So: $[X_1 \quad X_2 \quad X_3]^T = -\begin{bmatrix} \frac{\Delta_{1P}}{\delta_{11}} & \frac{\Delta_{2P}}{\delta_{22}} & \frac{\Delta_{3P}}{\delta_{33}} \end{bmatrix}^T$; $\delta_{11} = \int_s \frac{ds}{EI} = \frac{-2a}{EI}\left[-\frac{1}{8a^2}\ln(2al - 2aB) + \frac{l}{2}B\right]$

$B = \sqrt{l^2 + \frac{1}{4a^2}}$ ; $\delta_{22} = 0$ ; $\delta_{33} = \int_s \frac{(y-y_s)^2 ds}{EI} + \int_s \lambda \frac{\sin^2\varphi ds}{GA} + \int_s \frac{\cos^2\varphi ds}{EA}$ ; $\int_s \frac{\cos^2\varphi ds}{EA} = \frac{-2a}{EA}\left[\frac{-1}{8a^2}\ln 2a(l-B) + \frac{Bl}{2}\right]$

$\int_s \frac{(y-y_s)^2 ds}{EI} = \frac{a^2}{EI}\int_{-l}^{0} x^4\sqrt{1+4a^2x^2}\,dx + \frac{4a^2(y_s - c)}{EI}\int_{-l}^{0} x^2\sqrt{\frac{1}{4a^2} + x^2}\,dx - \frac{2a\left(c^2 - 2y_s c + y_s\right)}{EI}\int_{-l}^{0}\sqrt{\frac{1}{4a^2} + x^2}\,dx$ ;

$\int_s \lambda \frac{\sin^2\varphi ds}{GA} = \frac{2a\lambda}{GA}\left[\ln 2a(l-B) + \frac{l}{B}\right]$ ;

Free term is: $\Delta_{1P} = \int_s \frac{M_p ds}{EI} = \frac{qa}{EI}\left[\frac{1}{128a^4}\ln 2a(-B+l) + \frac{l}{8}KB\right]$

$K = 2l^2 + \frac{1}{4a^2}$ ; $\Delta_{3P} = \int_s \frac{(y-y_s)M_p ds}{EI} - \int_s \frac{\sin\varphi Q_p ds}{GA} - \int_s \frac{\cos\varphi N_p ds}{EA}$ ; $\int_s \frac{\sin\varphi Q_p ds}{GA} = \frac{2a\lambda}{GA}\int_{-l}^{0} \frac{qx^2 dx}{\sqrt{1+4a^2x^2}}$ .

$\int_s \frac{(y-y_s)M_p ds}{EI} = \frac{-qa}{2EI}\int_{-l}^{0} x^4\sqrt{1+4a^2x^2}\,dx - \frac{q(c-y_s)}{2EI}\int_{-l}^{0} x^2\sqrt{1+4a^2}\,dx$ ;. $\int_s \frac{\cos\varphi N_p ds}{EA} = \frac{q}{EA}\int_{-l}^{0} \frac{x^2}{\sqrt{\frac{1}{4a^2} + x^2}}dx$

**Loose soil pressure status section**

Silo pressure formula can be used to calculate the earth pressure value of the section.

As is shown in Figure 5, which acts on: sheet body weight $\gamma Fdy$ ; sheet body facing the top of the vertical pressure $q_y$ ; pressure of the bottom surface upward $q_y + dq_y$ ; periphery of the sheet body frictional resistance $\mu dyq_y Kf$ . Then: $\gamma Fdy + Fq_y - F(q_y + dq_y) - \mu dyq_y Kf = 0$ ; $dy = \frac{dq_y}{\gamma - fK\frac{\mu}{F}q_y}$

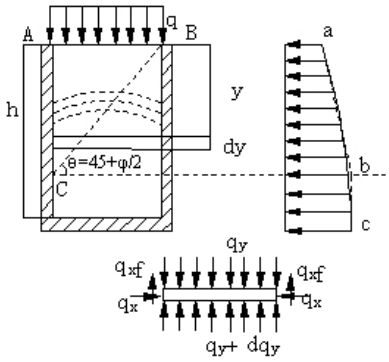

Fig.5 Inner Earth Pressure Calculation Model

So: $q_y = \frac{\gamma F}{fK\mu}(1-\exp\left(-\frac{fK\mu y}{F}\right)) + q\exp(-\frac{fK\mu y}{F})$; $q_y$ - silo filler surface from a depth of packing pressure on the $y$ section; $\gamma$—Severe filler; $q$—Uniform load on the filler surface; $F$—Cross-sectional area of the silo; $\mu$—Circumference of the inner wall of the silo.

Applied to the horizontal position of the side wall of pressure: $q_x = q_y K$.

**Discussion and Levacheve earth pressure formula**

Given the role Levacheve radial force on the cylinder wall and tangential force formula is:

When $\frac{\pi}{2}-\delta<\theta<\frac{\pi}{2}, \sigma = q_y \sin^2\theta$ ; $\tau = 0.5q_y \sin 2\theta$ ;When $\theta<\frac{\pi}{2}-\delta, \sigma = q_y \frac{\sin\theta\cos\delta}{\sin(\theta+\delta)}$ ; $\tau = q_y \frac{\sin\theta\sin\delta}{\sin(\delta+\theta)}$.

If $\frac{\pi}{2}-\delta \le \theta \le \frac{\pi}{2}$ so $K_1 = 0$, mean that lateral pressure $\sigma_\theta = K_1 \cdot q_y = 0$ . The lateral pressure into the basic differential equations (5), we have: $q_y = q_0$ $(\frac{\pi}{2}-\delta \le \theta \le \frac{\pi}{2})$

The $\sigma_\theta$ into (1) (2), we have: $\sigma = q_0 \sin^2\theta, \tau = 0.5q_0 \sin 2\theta$.

So, the expressions Levacheve recommended formula obtained above is consistent.

Similarly, when $0<\theta<\frac{\pi}{2}-\delta$ , taking $\tau' = 0$, then: $\sigma = q_0 \frac{\sin\theta\cos\delta}{\sin(\theta+\delta)}; \tau = q_o \frac{\sin\theta\sin\delta}{\sin(\theta+\delta)}; q_y = q_0$.

The actual effect of external loads due inward squeeze, the influence of the cylinder adjacent soil arching effect will appear. Thus, this article assumes done more in line with inter-tube real stress state of the soil, it seems more reasonable in theory, but also from a more general applications.

**Summary**

This paper introduce soil arching barrel earth pressure calculation of large cylindrical structures, depending on the stress state of the soil behind the cylinder body, the partition segments earth pressure calculation.

**Keywords:** Penchala River, water quality modelling, GIS.

**Abstract.** The quality of river water has been an important issue, due to its significant important function to the human being. In Asia, Malaysia is considered as one of the most speedily urbanizing countries and it's facing huge environmental challenges. An increased pressure on urban areas has been generated by rapid manufacturing especially in the Penchala River Basin. Penchala River originates from Kiara Hill and passes through several important townships as it flows through residential and industrial areas before meeting with Klang River. Although the river is relatively short, with an approximately 12 km in length with a catchment area of 28 kilometer square, this catchment is noted to be under environmental stress emanating from storm water pollution, solid waste, sedimentation and micro-pollutant. To study the water pollution issue, it is always best if it is tied up with the geographic information system. The objective of this study is to use the GIS for preparing and organizing the geometric data to satisfy the water quality model requirements. As a result of this study, a digital map for Penchala River has been created.

## Introduction

Water is considered as an important element in the keep up of all forms of life, most living organisms can only survive for short periods without water. Therefore, any change in the distribution quality of the natural and water has an environmental effects that can be devastating [1, 2]

The water quality management has been an important issue for decades nevertheless the current situation of the water quality management in the world is quite far from satisfactory [3-5]. This is due to the increasing of the population as well as the economic development [6-11].

In term of water resources management, the water quality modeling was often employed as a supporting tool for the aquatic environment assessment, and the calculated results provided valuable information for improvement water quality management [12]. Although the mathematical models have been used by the scientists to assess river water quality, however, the application of these models in risk assessment and environmental management is quite limited due to the difficulty in preparing the input data and explaining the model output. Previous studies have shown that the water quality modeling can be coupled with geographical information system (GIS) to determine the strategy for the water resources management [13, 14]. GIS are a strong tool for understanding, modeling, and managing complex stream water problems [15]. GIS are increasingly used to process spatial data representing pollution factors and to study how vulnerable a particular area is to the pollution of groundwater or the potential risk of contamination of surface waters [16-18].

## Study Area and Methodology

**Study Area.** Malaysia, one of the most rapidly urbanizing countries in Asia, faces major environmental challenges. Penchala River which flows through the south-western parts of Petaling Jaya in Selangor, Malaysia, is one of the most polluted river in the Klang valley. The Penchala River catchment covers an area of about 28 $km^2$ passing through the urban areas. The main river

length is about 12 km. Industrial & residential areas are the major land use in the river basin, and almost 70% of river length has been concrete-lined when it passes through residential and industrial area [19].

As Penchala River runs through the city, its water quality is greatly affected by the land use and activities of the area. Urbanization has been linked to the degradation of the urban waterways, which has produced an adverse effect on the quantity and quality of the water resources. In view of the urgency to minimize and control the water quality degradation, the state government has chosen Penchala River in "One State One River" program in keeping the river clean [20]. The "One State One River" program has been launched in 2002 by the Department of Irrigation and Drainage Malaysia (DID), with the objective to restore the selected rivers in each state to a minimum water quality class of II by the year 2015. The idea of this program is to involve everyone into the managing of a selected river in each state and collect all the resources to rehabilitate and protect that river [21].

**Topographic map and DEM.** Fig. 1 shows the topographic map of Penchala River basin with a scale of 1:250,000. The map has been processed using the techniques of the GIS to produce the digitized river network. Thus, the length of each reach can be measured using the GIS techniques to satisfy the river model.

The Digital Elevation Model (DEM) for the study area has been obtained and from this model the elevations and slopes can be calculated to fulfill the river model requirements.

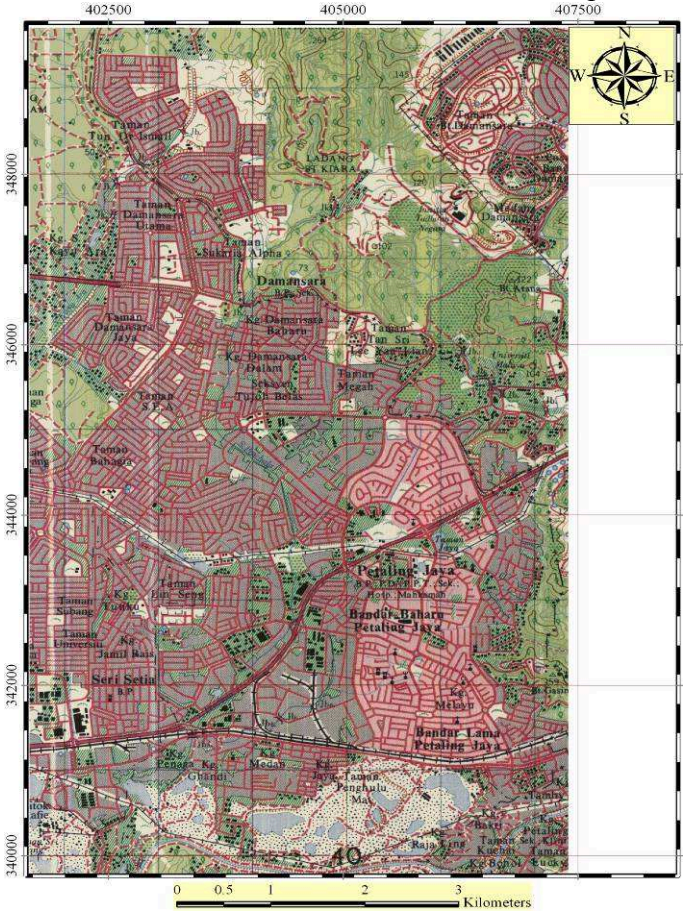

Fig. 1: The topographic map of Penchala River basin

**Monitoring, sampling stations and sources of pollution.** Beside the geometric data, the hydrological, hydraulic and water quality data are also required to satisfy the water quality model requirements. Thus, water quality monitoring and sampling stations along the river are also needed to satisfy the water quality model. Eight water quality monitoring stations have been set up along Penchala main river and its tributaries.

In addition, the spatial location of the pollution sources along the Penchala River basin has been collected in a digital shape file format. These are essential to identify the locations and loadings of the effluent form the point sources that are discharging into the river.

## Results

All the shape files have been imported into the GIS environment. As a result, the digital map for Penchala River basin has been created to assess the running of the river water quality model. As shown in Fig. 2, the generated digital map represented in the GIS environment in three feature types; points, lines and polygons. For instance, the main river and its tributaries represented as line features, while the sampling stations represented as point features. The created map is a physical map which means that it can be edited and modified any time according to the phenomenon changes along the river basin. It can be clearly seen that most of the point sources are concentrated at the downstream of Penchala River.

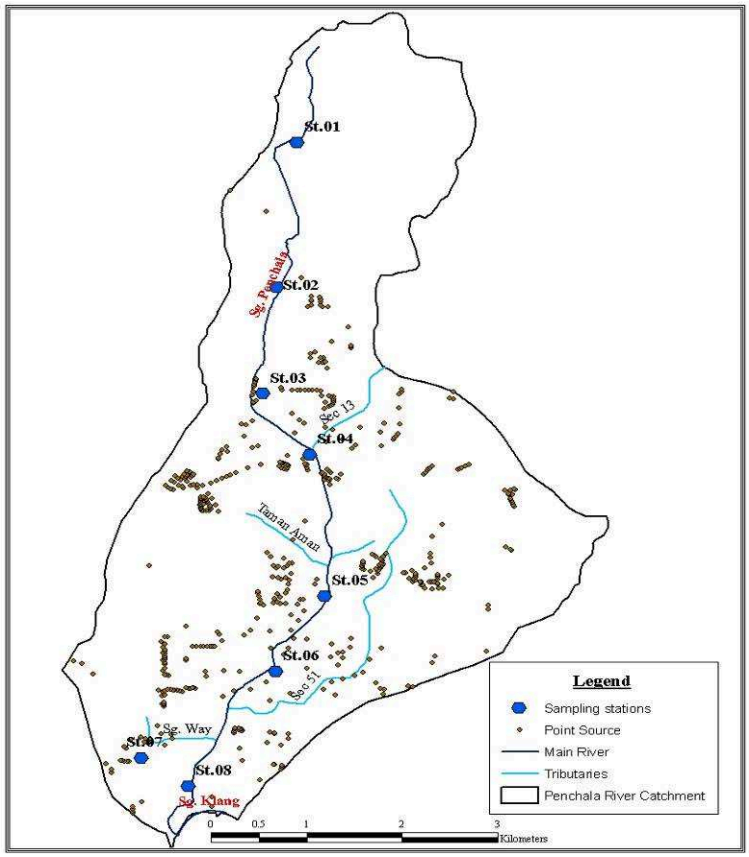

Fig. 2: The digital map for Penchala River basin showing the sampling stations and point sources

## Conclussions

The current study represents the spatial data of Penchala River basin that can be used to assess the monitoring and assessment of the river water quality. The GIS tools and techniques were applied to acheive the objectives. The study shows the importance of GIS applications in the managements of the river water quality.

## Acknowledgements

The authors highly appreciate the finanicial support by LRGS (203/PKT/6720004) and (RG244-12AFR) for the study. The authors are greatly indebted to the Department of Environment Malaysia, Department of Irrigation and Drainage Malaysia for their support on this study. We are most grateful and would like to thank the reviewers for their valuable suggestion, which led to a substantial improvement of the article.

**Keywords:** the K-means clustering, ARIMA model, water utilization efficiency, target decomposition, Shandong province

**Abstract.** Data mining model is the most important technical basis of the control target decomposition for the most stringent water resources management of Shandong province. K-means clustering model is adopted to analysis the water withdrawal of industrial added value per ten thousand yuan in 2010. Based on the yearly industrial water consumption trend from 1995 to 2010 of 17 municipal-level cities in Shandong province, the ARIMA (p, d, q) model is established through a lot of fitting and optimization and then the regional industrial water demand and water utilization efficiency in 2015 were forecasted. According to the proposed principal and technical route of target decomposition, the industrial water utilization efficiency target in 2015 of the whole province and 17 municipal-level cities are defined respectively.

## Introduction

To promote the most stringent water resources management system and ensure to realize the main goal of development, utilization, saving and protection of water resources, the General Office of the State Council issued "the most stringent water resources management assessment method" (the General Office of the State Council, [2013] Reference No. 2), requires the provinces, autonomous regions, and municipalities directly under the central government assess the implementation of the most stringent water resources management. The water utilization efficiency control target is stipulated in the assessment method, and the water withdrawal of industrial added value per ten thousand yuan in 2015 should be 25% lower than in 2010.

## Statistical Analysis of Data Mining Model[1]

Data mining model is widely used in statistical analysis techniques such as correlation analysis, regression analysis, variance analysis, cluster analysis, discriminant analysis, time series analysis method, etc. In all of the data mining technology, the statistical model of data mining tools is one of the most mature technology in the data mining, and has been widely used. Clustering analysis and variance analysis can be used in the classification of different business behavior and characteristics in water resources management, thus the different business groups can be determined and the government can implement distinguish management mode. Correlation analysis can be used in finding the relationship between various influencing factors in the complex water resources system. Regression analysis and time series analysis can be used to predict the regional water resources in the future, also can be used in short-term, mid-term and long-term water consumption forecasting. K-means clustering and Autoregressive Moving Average Time Series Model (ARIMA) are mainly used in this article for data statistical analysis, forecasting.

**K-means clustering [2]-[3].** The term k-means was first used by James MacQueen in 1967 and the method has been successfully used in various topics, ranging from market segmentation, computer vision and geostatistics. K-means algorithm process is as follows:

Step 1: Given a set of observations $(x_1, x_2, x_3, \cdots, x_n)$, where each observation is a d-dimensional real vector， set $I$=1 and initialize the center of the $k$ clusters $Z_j(I), j = 1, 2, \cdots, k$;

Step 2: Calculate the distance of each data object and the centroid.

$$D(x_i, Z_j(I)), i = 1, 2, \cdots, n, j = 1, 2, \cdots, k \tag{1}$$

If $D(x_i, Z_k(I)) = \min\left\{D(x_i, Z_j(I))\right\}, j = 1, 2, \cdots, k$, then $x_i \in C_k$;

Step 3: Set $I = I + 1$, calculate the new means to be the centroids of the observations in the new clusters.

$$Z_j(I+1) = \frac{1}{n}\sum_{i=1}^{n_j} x_i^{(j)}, j = 1, 2, \cdots, k \tag{2}$$

And also calculate the Sum of Squares Estimator (SSE).

$$E(I+1) = \sum_{j=1}^{k}\sum_{p \in C_k}^{k} \left\| p - Z_j(i) \right\|^2 \tag{3}$$

Step 4: Discriminant: if $\left\|E(I+1) - E(I)\right\| \geq \varepsilon$, then $I = I + 1$ and return to step(2), else the algorithm is ended.

**Autoregressive integrated moving average (ARIMA) Model [4]-[5].** In statistics and econometrics, and in particular in time series analysis, an autoregressive integrated moving average (ARIMA) model proposed by Box and Jenkins is a generalization of an autoregressive moving average (ARMA) model. ARIMA model can be generally expressed as follows.

$$x_t = \varphi_1 x_{t-1} + \varphi_2 x_{t-2} + \cdots + \varphi_p x_{t-p} + \varepsilon_t - \theta_1 \varepsilon_{t-1} - \theta_2 \varepsilon_{t-2} - \cdots - \theta_q \varepsilon_{t-q} \tag{4}$$

Where $\varphi_1$， $\varphi_2$,…， $\varphi_p$ are autoregressive coefficients, p is the order of regression, $\theta_1$， $\theta_2$,…， $\theta_q$ are the average moving coefficients, $p$ is the moving average order; $\{\varepsilon_i\}$ is a white noise series. If $d$ is the representation of difference order, then the model can be abbreviated as ARIMA ($p,d,q$).

## Process of Regional Target Decomposition of Water Resources Utilization Efficiency

**Principles and technical route.** According to the provincial status of water utilization efficiency in 2010 and the control target which the nation decomposed to Shandong Province; considering the regional water resources characteristics, economic and social conditions as well as the industrial water development in the future; adhere to the principles such as promoting the improvement of water utilization efficiency and benefit, promoting the change of water utilization pattern and economic development pattern, and promoting the monitoring and management of water utilization. The technical route of the target decomposition for water withdrawal of industrial added value per ten thousand yuan is shown in the Fig. 1.

**K-means clustering analysis.** Using the variable “water withdrawal of industrial added value per ten thousand yuan” the 17cities of Shandong province can be divided into six categories. The clustering result is shown in Table 1. Table 1 shows that Qingdao, Weihai city, Yantai city are relatively high in industrial water utilization efficiency; Yantai city is the highest, and Laiwu city is the lowest. Table 2 shows that the probability P corresponding to statistics F is 0.000, and there is significant difference in the six categories for the mean of variable “water withdrawal of industrial added value per ten thousand yuan”. Based on the clustering result and the whole target of the province that the water withdrawal of industrial added value per ten thousand yuan in 2015 should be 25% lower than in 2010, the target decomposition (the declining ratio of water withdrawal of industrial added value per ten thousand yuan) program of 17 cities in 2015 can be preliminarily proposed in six categories which is shown in Table 3.

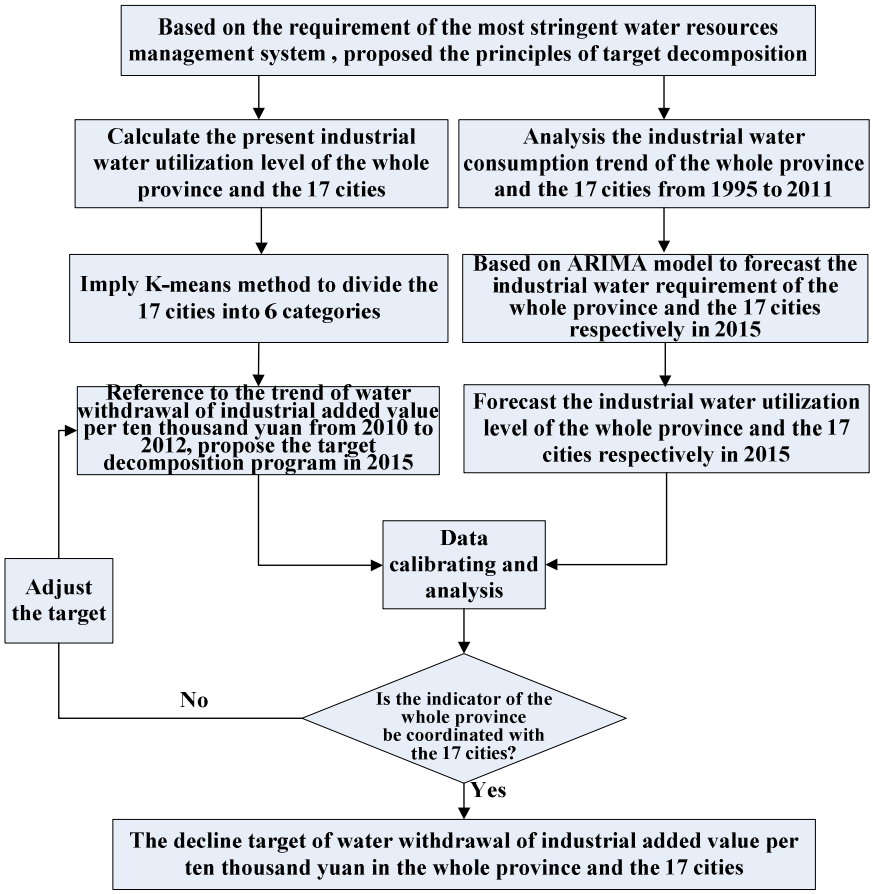

Fig. 1 Technical route of the target decomposition for water withdrawal of industrial added value per ten thousand yuan

Table 1 The clustering result

| category | administrative region | water withdrawal of industrial added value per ten thousand yuan ($m^3$) | the final superior cluster center |
|---|---|---|---|
| 1 | Qingdao City | 7.07 | 6.2 |
| | Yantai City | 5.01 | |
| | Weihai City | 6.53 | |
| 2 | Dongying City | 9.62 | 9.62 |
| 3 | Jinan City | 18.71 | 18.27 |
| | Zaozhuang City | 16.41 | |
| | Weifang City | 16.96 | |
| | Jining City | 17.68 | |
| | Rizhao City | 19.35 | |
| | Linyi City | 18.56 | |
| | Dezhou City | 18.71 | |
| | Liaocheng City | 19.74 | |
| 4 | Zibo City | 14.98 | 14.14 |
| | Taian City | 14.53 | |
| | Binzhou City | 12.81 | |
| 5 | Heze City | 22.85 | 22.85 |
| 6 | Laiwu City | 37.61 | 37.61 |

Table 2 Calculation result of the clustering statistics

| | clustering | | deviation | | F | Sig. |
|---|---|---|---|---|---|---|
| | mean squared deviation | df | mean squared deviation | df | | |
| water withdrawal of industrial added value per ten thousand yuan（$m^3$） | 179.367 | 5 | 1.19 | 12 | 151.16 | 0 |

Table 3 The preliminarily proposed target decomposition program in 2015

| category | administrative region | water withdrawal of industrial added value per ten thousand yuan（$m^3$） | declining ratio (2010-2015) |
|---|---|---|---|
| 1 | Qingdao City | 7.07 | 10% |
| | Yantai City | 5.01 | |
| | Weihai City | 6.53 | |
| 2 | Dongying City | 9.62 | 18% |
| 3 | Jinan City | 18.71 | 25% |
| | Zaozhuang City | 16.41 | |
| | Weifang City | 16.96 | |
| | Jining City | 17.68 | |
| | Rizhao City | 19.35 | |
| | Linyi City | 18.56 | |
| | Dezhou City | 18.71 | |
| | Liaocheng City | 19.74 | |
| 4 | Zibo City | 14.98 | 20% |
| | Taian City | 14.53 | |
| | Binzhou City | 12.81 | |
| 5 | Heze City | 22.85 | 30% |
| 6 | Laiwu City | 37.61 | 35% |

**Based on ARIMA model to forecast the industrial water requirement.** Implying the exponential smoothing method, ARIMA model and artificial neural network method to analysis the industrial water consumption trend of the 17 cities from 1995 to 2011, the results show that the data series are not smooth change data series, and the catastrophe point occurred around 2004. Therefore, ARIMA model is adopted to simulate the nonstationary sequence difference processing and respectively forecast the industrial water demand of 17 cities in 2015, then get the industrial water utilization efficiency of 17 cities in 2015. The forecast result is shown in table 4.

Table 4 The forecast result of industrial water demand and utilization efficiency in 2015

| administrative region | ARIMA *(p,d,q)* | industrial water demand in 2015 (ten thousand $m^3$) | industrial added value in 2015(forecasted by the rate of increase method)( one hundred million Yuan) | water withdrawal of industrial added value per ten thousand yuan in 2015 ($m^3$) |
|---|---|---|---|---|
| Jinan City | (3,2,0) | 30608 | 2129 | 14.38 |
| Qingdao City | (3,2,0) | 23005 | 3606 | 6.38 |
| Zibo City | (3,1,0) | 30408 | 2480 | 12.26 |
| Zaozhuang City | (3,1,1) | 13111 | 1164 | 11.27 |
| Dongying City | (3,0,1) | 20293 | 2480 | 8.18 |
| Yantai City | (3,0,1) | 15104 | 3407 | 4.43 |
| Weifang City | (3,2,1) | 32205 | 2390 | 13.48 |
| Jining City | (3,0,1) | 24085 | 1818 | 13.25 |
| Taian City | (3,2,1) | 17759 | 1396 | 12.72 |
| Weihai City | (3,2,0) | 9314 | 1520 | 6.13 |
| Rizhao City | (3,0,1) | 10548 | 727 | 14.5 |
| Laiwu City | (2,2,1) | 10845 | 458 | 23.69 |
| Linyi City | (3,0,1) | 22370 | 1553 | 14.4 |
| Dezhou City | (3,0,1) | 18205 | 1217 | 14.96 |
| Liaocheng City | (3,2,1) | 17549 | 1331 | 13.19 |
| Binzhou City | (3,0,1) | 14316 | 1127 | 12.7 |
| Heze City | (3,2,1) | 14186 | 822 | 17.25 |
| Shandong Province | | 323910 | 29625 | 10.93 |

Table 4 shows that the provincial industrial water demand will reach 3.2391 billion m³ by 2015. Combined with the prediction of industrial added value, the derived water withdrawal of industrial added value per ten thousand yuan was 10.93 m³ in 2015, slightly more than 10.67 m³ (the industrial water utilization efficiency goals in 2015, decline 25% compared with 2010). Therefore, the goal that the whole provincial water withdrawal of industrial added value per ten thousand yuan shoud be 25% lower than in 2010 will be realized with the province promoting of water-saving society construction, by adjusting the product structure and improving the production process.

**Data calibrating and target decomposition program adjusting .** According to the forecasted result of industrial added value and the preliminarily proposed target decomposition program in 2015, the industrial water demand of 17 cities can be derived respectively and thus the whole provincial industrial water demand which is the sum of the 17 cities' is about 3.16238 billion m³. But based on the forecasted result of industrial added value and the industrial water utilization efficiency goals in 2015 (10.67 cubic meter per ten thousand yuan ) the whole provincial industrial water demand will be 3.16099 billion m³. The two results of the provincial industrial water demand have slight difference. Therefore the preliminarily proposed target decomposition program in 2015 should be adjusted. The adjusted target decomposition program in 2015 is shown in Table 5. After calibrating again the whole provincial industrial water demand is coordinated with the 17 cities', that is the indicator of the whole province is coordinated with the 17 cities'.

Table5 The adjusted proposed target decomposition program in 2015

| administrative region | the adjustde decline ratio of water withdrawal of industrial added value per ten thousand yuan (2010-2015)(%) | water withdrawal of industrial added value per ten thousand yuan ($m^3$) |
|---|---|---|
| Jinan City | 25 | 14.03 |
| Qingdao City | 17 | 5.87 |
| Zibo City | 19 | 12.13 |
| Zaozhuang City | 39 | 10.01 |
| Dongying City | 23 | 7.41 |
| Yantai City | 10 | 4.51 |
| Weifang City | 23 | 13.06 |
| Jining City | 23 | 13.61 |
| Taian City | 17 | 12.06 |
| Weihai City | 10 | 5.88 |
| Rizhao City | 15 | 16.45 |
| Laiwu City | 29 | 26.7 |
| Linyi City | 22 | 14.48 |
| Dezhou City | 30 | 13.1 |
| Liaocheng City | 25 | 14.81 |
| Binzhou City | 17 | 10.63 |
| Heze City | 30 | 16 |
| Shandong Province | 25 | 10.67 |

## Conclusions and suggestions

Implying the data mining model in regional target decomposition of industrial water resources utilization efficiency can provide scientific and effective technical support to the most strict water resources management in Shandong province. Therefore according to the data characteristic of water resources management and information needs, using a efficient statistical model algorithms, extracting useful information and knowledge from plenty of water resources data can provide a new analysis method and scientific decision support to solve the problems in the field of water resources management.

**Keyword:** overload analysis arch dam RCC.

**Abstract.** It does numerical analysis on the overload of RCC arch dam named wanjiakouzi, through the analysis, we try to find the damage process of the dam. It does elastic-plastic analysis by FEM. Result shows that the horizontal cracks are usually a very important clue, it means the dam will reach its ultimate capacity.

## Introduction

Due to the high safety and less cost of arch dam, it is built all over the world [1], Arch dam is one kind of important dam type, because of material strength's full display, large load bearing capacity, small body, convenient flood discharge arrangement, potential high safety, perfect earthquake resistance performance and so on; it receives domestic and foreign engineers' favor. Because arch dam has a strong overload capacity, auto-regulation characteristic and low project construction cost, over one half of the world dams, which are above 200m high, are arch dam [2]. The largest number of arch dam has been built in China [3]. It can be quickly and simply constructed, uses less concrete per unit, and generates less heat, so engineers pay much attention to it. Arch dam's height will be much higher in the future, safety analysis becomes a key problem. Safety analysis research of arch dam has achieved much by scientific research institute and university, but there are still many questions for further study. The paper does researches on the overload analysis of the highest RCC dam of the world named wanjiakouzi.

## Basic Theory

The yield criterion of materials is the Drucker-Prager criterion - the yield cone surface is through outside vertices of yield hexagon in the following calculations. Plastic flow rule is the orthogonal flow rule. The yield function of Drucker-Prager model is

$$F = \alpha I_1 + \sqrt{J_2} - k = 0 \tag{1}$$

Where $\alpha$, $k$ = parameter of material, $I_1$ = the first stress tensor invariant, $J_2$ = the second stress tensor invariant. They can be got from the following equation.

$$I_1 = \sigma_x + \sigma_y + \sigma_z \tag{2}$$

$$J_2 = \frac{1}{6}\left[(\sigma_x - \sigma_y)^2 + (\sigma_y - \sigma_z)^2 + (\sigma_z - \sigma_x)^2\right] + \tau_{xy}^{\ 2} + \tau_{yz}^{\ 2} + \tau_{zx}^{\ 2} \tag{3}$$

$$\alpha = \frac{2\sin\phi}{\sqrt{3}(3 - \sin\phi)} \tag{4}$$

$$k = \frac{6c^{'}\cos\phi}{\sqrt{3}(3 - \sin\phi)} \tag{5}$$

Where $\sigma_x^{\ 2}, \sigma_y^{\ 2}, \sigma_z^{\ 2}, \tau_{xy}^{\ 2}, \tau_{yz}^{\ 2}, \tau_{zx}^{\ 2}$ = stress component $\phi = tg^{-1}f^{'}$.

Stress-strain relationship of concrete is linear before the failure in the tensile, the matrix which describes it is list below.

$$[D_c^{ck}] = \frac{E}{(1+v)(1-2v)} \begin{bmatrix} (1-v) & v & v & 0 & 0 & 0 \\ v & (1-v) & v & 0 & 0 & 0 \\ v & v & (1-v) & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{(1-2v)}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{(1-2v)}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{(1-2v)}{2} \end{bmatrix} \quad (6)$$

Where: E = young's modulus for concrete ν = poisson's ratio for concrete

**Modeling of a crack**

The presence of a crack at an integration point is represented through modification of the stress-strain relations by introducing a plane of weakness in a direction normal to the crack face. Also, a shear transfer coefficient βt is introduced which represents a shear strength reduction factor for those subsequent loads which induce sliding (shear) across the crack face. The stress-strain relations for a material that has cracked in one direction only become:

$$[D_c^{ck}] = \frac{E}{1+v} \begin{bmatrix} \frac{R^t(1-v)}{E} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{(1-v)} & \frac{v}{(1-v)} & 0 & 0 & 0 \\ 0 & \frac{v}{(1-v)} & \frac{1}{(1-v)} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\beta_t}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\beta_t}{2} \end{bmatrix} \quad (7)$$

If the crack closes, then all compressive stresses normal to the crack plane are transmitted across the crack and only a shear transfer coefficient βc for a closed crack is introduced. Then the matrix can be expressed as

$$[D_c^{ck}] = \frac{E}{(1+v)(1-2v)} \begin{bmatrix} (1-v) & v & v & 0 & 0 & 0 \\ v & (1-v) & v & 0 & 0 & 0 \\ v & v & (1-v) & 0 & 0 & 0 \\ 0 & 0 & 0 & \beta_c \frac{(1-2v)}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{(1-2v)}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \beta_c \frac{(1-2v)}{2} \end{bmatrix} \quad (8)$$

The stress-strain relations for concrete that has cracked in two directions are:

$$[D_c^{ck}] = E \begin{bmatrix} \frac{R^t}{E} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{R^t}{E} & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\beta_t}{2(1+v)} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{\beta_t}{2(1+v)} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\beta_t}{2(1+v)} \end{bmatrix} \quad (9)$$

If both directions reclose,

$$[D_c^{ck}] = \frac{E}{(1+v)(1-2v)} \begin{bmatrix} (1-v) & v & v & 0 & 0 & 0 \\ v & (1-v) & v & 0 & 0 & 0 \\ v & v & (1-v) & 0 & 0 & 0 \\ 0 & 0 & 0 & \beta_c \frac{(1-2v)}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \beta_c \frac{(1-2v)}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \beta_c \frac{(1-2v)}{2} \end{bmatrix} \quad (10)$$

The stress-strain relations for concrete that has cracked in all three directions are:

$$[D_c^{ck}] = E\begin{bmatrix} \frac{R^t}{E} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{R^t}{E} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{R^t}{E} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\beta_t}{2(1+\nu)} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{\beta_t}{2(1+\nu)} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\beta_t}{2(1+\nu)} \end{bmatrix} \tag{11}$$

The open or closed status of integration point cracking is based on a strain value $\varepsilon_{ck}^{ck}$ called the crack strain. For the case of a possible crack in the x direction, this strain is evaluated as

$$\varepsilon_{ck}^{ck} = \begin{cases} \varepsilon_x^{ck} + \dfrac{\nu}{1-\nu}\varepsilon_y^{ck} + \varepsilon_z^{ck} & \text{if no cracking has occurred direction} \\ \varepsilon_x^{ck} + \nu\varepsilon_y^{ck} & \text{if y direction has cracked} \\ \varepsilon_x^{ck} & \text{if y and z direction has cracked} \end{cases} \tag{12}$$

Where: $\varepsilon_x^{ck}$, $\varepsilon_y^{ck}$, $\varepsilon_z^{ck}$ =three normal component strains in crack orientation. The vector $\{\varepsilon'\}$ is computed by: $\{\varepsilon^{ck}\} = [T^{ck}]\{\varepsilon'\}$ where: {ε'} = modified total strain (in element coordinates), {ε'}, in turn, is defined as: $\{\varepsilon'\} = \{\varepsilon_{n-1}^{el}\} + \{\Delta\varepsilon_n\} - \{\Delta\varepsilon_n^{th}\} - \{\Delta\varepsilon_n^{pl}\}$, where: n = substep number $\{\varepsilon_{n-1}^{el}\}$ =elastic strain from previous substep, $\{\Delta\varepsilon_n\}$ =total strain increment, $\{\Delta\varepsilon_n^{th}\}$ ,=thermal strain increment, $\{\Delta\varepsilon_n^{pl}\}$ =plastic strain increment. If $\varepsilon_{ck}^{ck}$ is less than zero, the associated crack is assumed to be closed. If $\varepsilon_{ck}^{ck}$ is greater than or equal to zero, the associated crack is assumed to be open. When cracking first occurs at an integration point, the crack is assumed to be open for the next iteration.

Finite element model is 230 meters wide, 270 meters long, 360 meters high, it is shown in Fig. 1, Parameters are listed in Table 1.

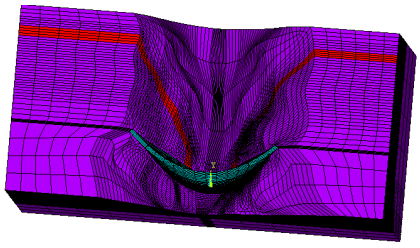

Fig. 1 Finite element model

Table. 1 Material parameters

| Location | Young's modulus (Gpa) | Density ($KN/m^3$) | Poisson's ratio | Cohesive force(Mpa) | Friction angles (°) | Coefficient of thermal expansion($10^{-6}$) |
|---|---|---|---|---|---|---|
| Dam | 18 | 2350 | 0.167 | 2 | 56 | 4.87 |
| Abutment | 14 | 2730 | 0.25 | 0.9 | 45 | |
| Base | 11 | 2700 | 0.27 | 0.7 | 42 | |
| Unconformity | 3 | 2660 | 0.3 | 0.35 | 35 | |

Abutment force is got by integral of node stress of arch dam. The force direction of abutment and coordinate system is coincident. Moment direction complies with right-hand rule.

## Conclusions

The numerical simulation results (Fig. 2) show that the initial cracks appear at the bottom of the dam, where are strongly constrained. The cracks are usually vertical. They are developing from bottom to the up of the dam along the foundation surface. When the dam nearly reaches its ultimate capacity of overload, the horizontal cracks appear on the top arch ring, which begin from two sides of arch ring to the middle. It is calculated by strength reverse method. It means that when the material strength reduces, the top arch ring and the base face will be damaged first. The result is a little different from that by water specific gravity overcharge method and water-level overcharge method. The main reason it that the loads are different. The load of strength reverse method is much the same with a arch dam in operation. The material strength reduces after a long work period. The numerical calculation by this method may be much the same with the real case.

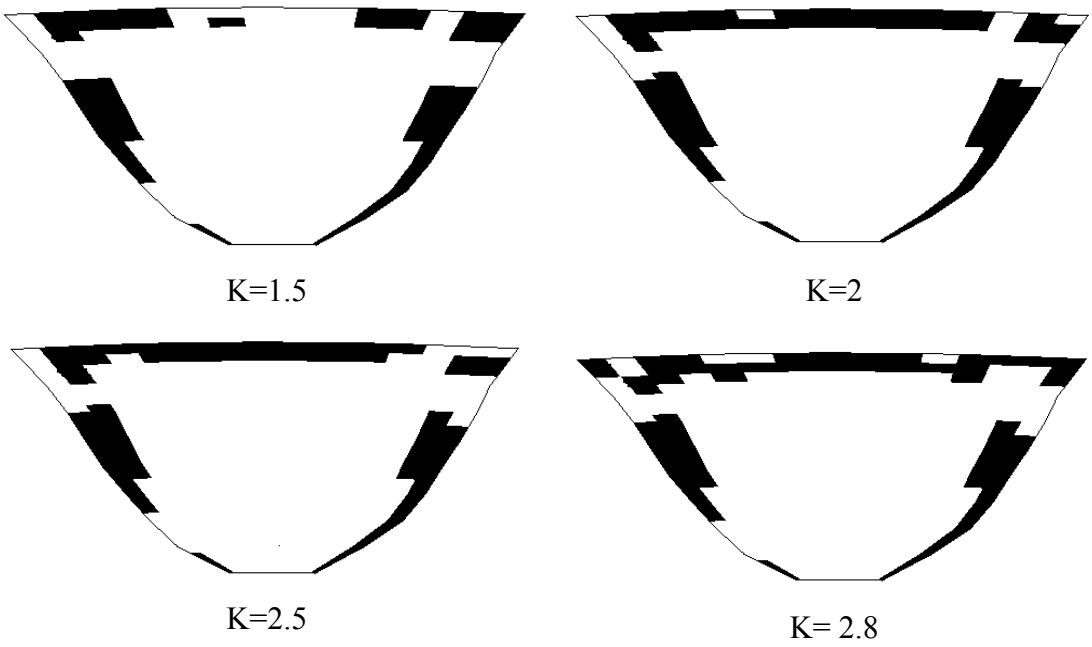

Fig. 2 Overload calculation by strength reverse method ( k=overload factor )

**Keywords:** gravity dam, damage evaluation, extreme disaster, earthquake, slide surge

**Abstract.** It is possible for hydraulic engineering located in high intensity earthquake area under the action of extreme disaster induced by earthquake and secondary slide surge. Several impact action models of slide surge were introduced and the damage evolution of concrete gravity dam subjected to combined action of different sequences of earthquake and secondary slide surge were studied based on nonlinear numerical analysis. The effects of different time sequences of combined earthquake and slide surge were compared and the safety performance analysis was performed. The results show that the combined form has great effects on the damage evolution law of concrete gravity dam.

## Introduction

Generally speaking, seismic safety of water retaining structure and reservoir slope stability are the most critical problems of hydraulic engineering located in high intensity earthquake area. However, the potential reservoir landslide will be in an alternate state of wetting and drying for a long time under the influence of water level fluctuation caused by reservoir operation, which can decrease the anti-sliding stability of potential landslides. At the same time, the ground motion is random and unpredictable, the reservoir slope reinforcement measures will show aging and performance degradation under the action of earthquake, heavy rain and other environmental conditions, so there is a real possibility that landslides slid into the reservoir and cause huge landslide surge when reservoir slopes lose its stability in the process of earthquake, under the influence of aftershocks after the strong shock or heavy rain. It seriously threaten the security of the people's lives and wealth near the landslides area and downstream area if a high dam subjected to extreme combined action of high head surge pressure and ground motion increase its crash risk. There is no lack of some tragic accidents that large-scale landslides surge lead to devastating disasters to the security of the people's lives and wealth near downstream area: 1972 Shimabara, Japan; 1934 Tafjord, Norway and 1963 Vaiont Italy, all of them caused different degrees of personnel casualties.

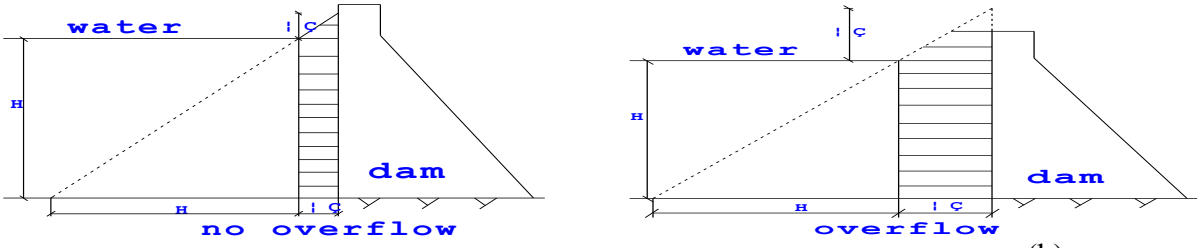
At present, the study of landslides surge disasters at abroad and China mainly focus on surge height and its influence on the reservoir bank, the major research approach are model test, empirical formula and statistical regression analysis, which basic idea is that some important factors selected firstly, then combined with model test and analyzed by the statistical regression method, and finally the empirical equation is concluded [1]. However, there have been a few studies with the impact height and pressure of surge to the dam of finite height, especially there have been almost no researches on the dam damage situation under the action of different times combination of earthquake and landslides surge, which include different distance from the landslides to the dam and landslides occurs at different times during or after the process of ground motion. In consequence, it is of great significance to carry out researches on this field for exploring the seismic safety and bearing capacity of concrete gravity dam located in high intensity earthquake area under extreme conditions and providing references on the risk management and emergency measures for the hydraulic complex.

## The impact model of surge

The impact model of surge is the most important among a large number of studies on landslide surge. There are very few data on the impact model of surge against the dam at this stage, so usually

many researchers refer to the static model of wind-wave pressure on the straight wall water retaining structure mentioned in the《Specifications for load design of hydraulic Structures》 or 《Code of Hydrology for Sea Harbour》[2]. However, landslide surge and wind-wave have different mechanism, so they shall have different corresponding impact model of pressure.

In fact, reservoir water subjected to the combined action of high-speed impact and squeezing at the same time while the large reservoir landslide slid into reservoir at high speed, which makes the invasion depth water subjected to shock pressure and the combined action throughout the whole reservoir water from top to bottom and then the surge occurs , when the surge is blocked by the dam in the process of propagation, it will have dynamic impact pressure on the dam in the range of reservoir water depth. This idea is confirmed in the model test[3] , it showed that the dynamic model of surge impact pressure on the upright surface of dam is vertical distribution under the static water level with the amplitude of impact pressure head is about 1.77～1.89 times the height of surge, which is very different from the model of wind-wave pressure. So in this paper, we take the amplitude of impact pressure head under the static water level 1.9 times the height of surge, while consider that the amplitude of impact pressure in the range of 1.9 times surge height along the dam above the static water level is applicable to hydrostatic pressure distribution form. Sometimes any water mass can overflow the dam crest after the surge impact the dam under the combination of different reservoir water level and surge height, therefore, the distribution model of surge pressure can be divided into no overflow and overflow accordingly, as shown in Figure 1: H as the reservoir water depth, h as the height of surge and η as the height of surge climb along the dam is 1.9 times the height of surge.



(a) (b)

Fig.1 The distribution model of surge pressure: (a) no overflow (b) overflow

On the other hand, the impact pressure of surge is a kind of dynamic and short-lived load, we can conclude that an impulse period of surge is 0.6s-1.5s according to the model test of landslide surge[4], in one period, the process of the impact pressure is similar to a half sine-wave. In this paper, we take the impact period of surge for T as 1s and the amplitude process of impact pressure as a half sine-wave. The emergence of surge is due to the exchange of reservoir landslide and water mass on kinetic energy and its process of propagation is first a sharp attenuation, then a slow attenuation. once the process of landslide is completed, there will no more new kinetic energy exchange to the reservoir water so that it will be unable to provide a steady stream of power for surge to impact the dam with a consistent high pressure head for a long time, so we can only discuss the impact of a period of initial surge height against the dam.

## The effects of earthquake and surge on the dam

In this paper, the model of Koyna dam is selected as a calculation object, its geometry as shown in Figure 2. We take the Koyna seismic wave as the ground acceleration and set its peak acceleration as 0.4g. The dam material use the elastic-plastic damage model of concrete[5,6] and take the elastic modulus as 31GPa, density as 2643Kg/m³, Poisson's ratio as 0.2, dilation angle as 36.3, initial compressive strength as 13MPa, ultimate strength as 24.1MPa and tensile strength as 2.9MPa. The finite element mesh of dam choose the structured quadrilateral mesh and the geometry of elements are no more than 2m as shown in Figure 3, the bottom border of dam is fixed.

In March 1961, the scale of Tangyanguang landslide occurred in Hunan Zhexi reservoir is 1.65×106m³, it caused 21m high surge; in June 1985, the scale of Hubei Three gorges Xintan

landslide is 3×107m³ and the height of surge it caused was as high as 40m. The height of surge will have attenuation in the process of propagation to the upstream and downstream area, so this paper takes the height of surge in front of the dam as 10m, and analyses the effects of surge and earthquake combined under different times on the dam. Simulation analysis and calculation are performed on 5 working conditions as shown in Table 1.

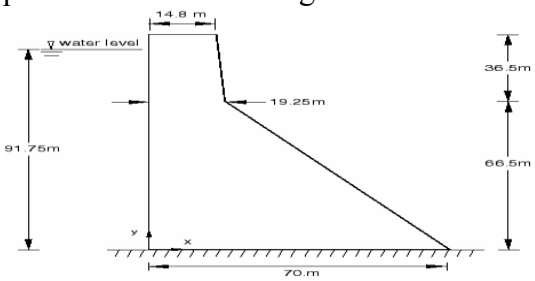


Fig.2 The geometry of Koyna dam

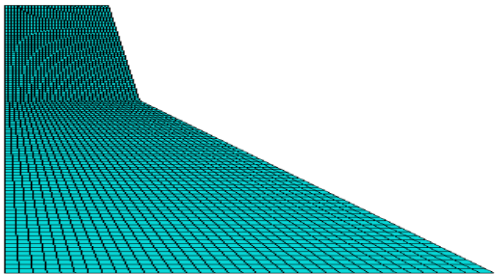

Fig.3 The dam element mesh

Table.1 Combination of surge and earthquake under different times

| Condition 1 | Condition 2 | Condition 3 | Condition 4 | Condition 5 |
|---|---|---|---|---|
| Static+ seismic | Static+ seismic+ surge | Static+ seismic (surge peak acts at 2.81s) | Static+ seismic (surge peak acts at 3.24s) | Static+ seismic (surge peak acts at 4.18s) |

Static load includes the hydrostatic pressure and gravity of the dam, it works in all steps, the surge step is 1s and the earthquake step is 10s. For condition 2 is just a surge step more than condition 1 at the end of earthquake step, so the calculation results of condition 1 included in condition 2, the relative displacement of dam crest and the plasticity and damage dissipation energy of dam body under condition 2 as shown in Figure 4 and Figure 5.

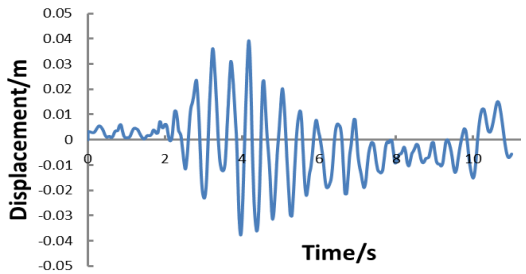

Fig.4 Displacement of dam crest

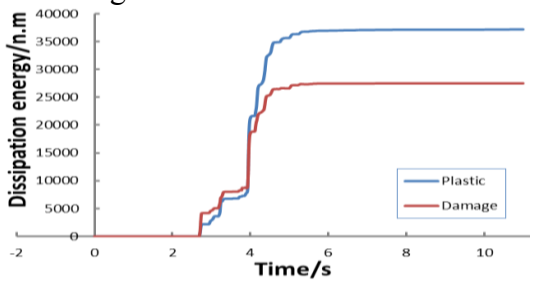

Fig.5 Dissipation energy

We can consider that superpose the surge peak time to the times when the plastic damage of upstream surface increase sharply due to the surge have an adverse effect on the upstream surface, and then explore the effects of the most unfavorable combinations on the dam. It can be seen that these moments at which the dam's dissipation increase sharply corresponding to the amplitude positive relative displacement of dam crest are 2.81s, 3.24s, 4.18s from Figure 4 and Figure 5. If we select these three moments for the surge peak work at, the combination of surge and earthquake will have more effects on the dam. Taking working conditions under these moments as condition3,4 and 5, the relative displacement of dam crest under working condition1,3,4 and 5 as shown in Figure 6.

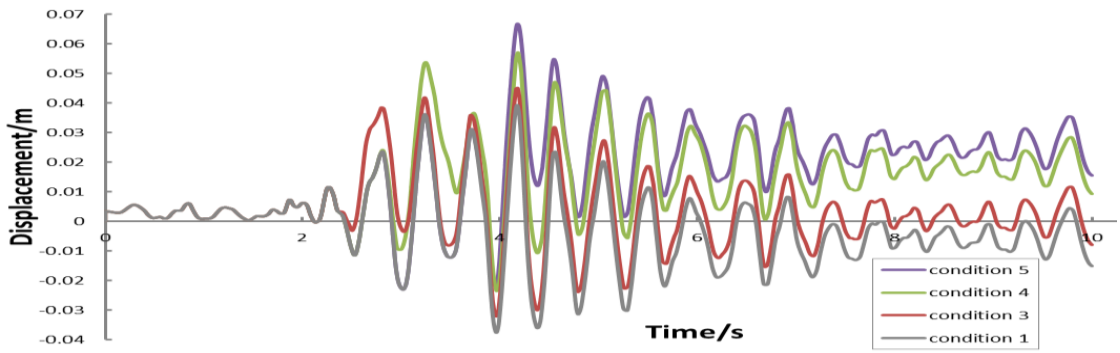

Fig.6 Relative displacement of dam crest under 4 conditions

It can be seen from Figure 6 that the positive relative displacement of dam crest under working condition3, 4 and 5 are all increase sharply at each moment of surge peak than condition1 and reach the peak value in each process of earthquake, while these displacement are all less than condition1.

This paper hold the idea that surge has good effects on the positive relative displacement of dam crest, which makes the upstream surface more likely to be damaged. The positive peak inertia force of ground motion combine with the surge peak at different moments have different effects on the upstream surface, the more seriously the upstream surface damaged, the greater decrease in the strength of dam anti-positive motion and the larger positive relative displacement of dam crest in the subsequent ground motion. The upstream surface damage increase sharply provides a larger space for dam releasing stress in the subsequent motion, and reduces the stress concentration area of the downstream surface which makes the dam still have a large strength of anti-negative motion, so the negative relative displacement of dam crest decreases in the subsequent motion.

## Conclusions

This paper selects a reasonable model of surge pressure and explores the effects of combined action of surge and earthquake on the dam. Surge can occurs at any moments in the process of earthquake (some of unfavorable conditions are analyzed) and concludes that combined action of surge and earthquake at some moments has much more effects on the dam.

**Key words:** anti-sliding stability; strength reserve coefficient method; rigid equilibrium limit method; reinforce; concrete cogging; XiangJiaba Hydropower Station

**Abstract:** By two-dimensional nonlinear finite element strength reserve coefficient method and the rigid body limit equilibrium method respectively, a comprehensive study of the stability of the 12th sluice section of XiangJiaba hydropower station is made and some conclusions of the instability mode and the lack of safety are reached. The reinforcement measures, which set up concrete cogging at the dam heel and put up additional drainage holes at the stilling basin,are proposed and calculated by the strength reserve coefficient method and the rigid body limit equilibrium method respectively again,Results show that the dam foundation safety meets the code's standards if the . reinforcement measures are adopted.

## Introduction

XiangJiaba Hydropower station is the last one of the step electric stations on Jinsha River. It is one of the key power points among China's West-East Electricity Transmission Projects. The total capacity is 6000MW. The foundation bedrock mainly consists of Trias marshes of the XuJiahe formation of fluvial facies sandstone, mudstone and coal-bearing stratum. The lithology and lithofacies vary, and the cross bedding develops. The quality of rock masses is mainly II and III, there are local III2 or IV kinds. A 2km length of geniculate bend coal serves as the skeleton which has obliquely penetrated at the dam site. The core of the dam obliquely crosses between the sluice section and the dam axis, and dips steeply to the downstream. As a result, it forms a steep fracture zone which is narrow in the upstream and wide in the downstream. 11 local small faults distributes in the dam foundation of the river bed. The angle of the joints and fissures are mostly in a steep and medium dip. Low angle joints develop in strata fracture zones of a steep dip to a certain extent. The combination of these negative factors has formed the geological background of XiangJiaba Dam's deep slide.

Anti-sliding stability of gravity dams is one of the key techniques in dam designing. To confirm the dams' safety and put forward related reinforcement measures in relation to demand are important parts in gravity dams designing, especially for significant dams and complex dam foundations. According to the actual geological conditions and the designers' suggestions, this paper took the 12th sluice section of XiangJiaba as a typical example to make a comprehensive analysis on the stability of the dam foundation and put forward structure reinforcement schemes. The nonlinear finite element strength reserve coefficient method and the rigid body limit equilibrium method were used in this paper.

**Nonlinear finite element analysis**

**Characteristics of the dam and distributions of the structural surface of the dam foundation.**The 12th sluice section of XiangJiaba Hydropower Station has a height of 154m. Dam crest has a width of 50m, and bottom width of 166m. The $T_3^{2-3}$ and $T_3^{2-5}$ rock formations with soft lithology are distributed in the bedrock. The top and bottom surface of the bedrock are fracture zones with a width of 0.2m, and they have better continuity (as the Pn layer shown in Figure 1. Moreover, there are intercalary strata from JC2-5 to JC2-8, with a specific distribution shown in Figure1.

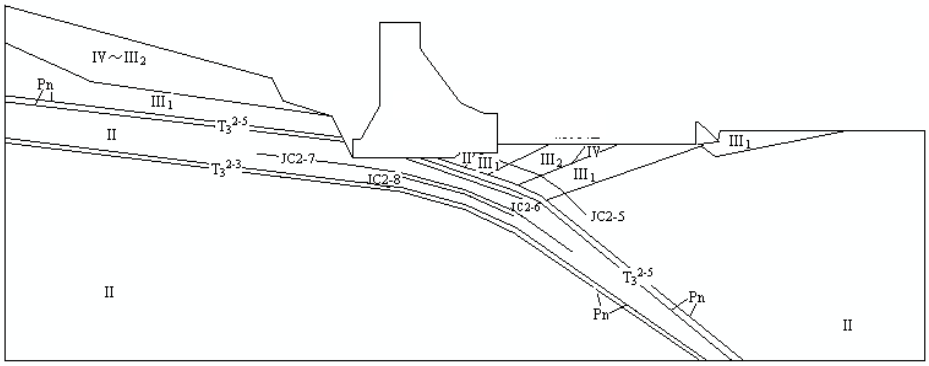

Fig.1 Surface distributions of the rock mass structure of the 12th sluice section

**Ranges and conditions of the calculation.**The calculation range of the two-dimensional finite element model extends from the dam heel 398m to the upstream, about 2 times longer more than the dam's height, and extends from the dam site 490m to the downstream, about 3 times longer more than the dam's height. Foundation depth extends below 231m from the building surface, about 1.5 times higher of the dam's height. Normal restraints are adopted for the upstream and downstream boundary of the dam foundation. The normal impounded level in the upstream is 380m, and 265.8m is the tailwater level in the downstream. The calculation loads included water pressure in up and down stream, silt pressure, uplift pressure, seepage pressure and dead weight. The casting work of the gravity dam is divided into 12 steps. Ideal elastic-plastic model was adopted in the material constitutive relation. Mohr-Coulomb criterion which is in conformity with the related flowing rule was used in yield criterion.

**Structure surfaces simulation.**Intercalary strata JC2-5 to JC2-8, $T_3^{2-3}$ layer, $T_3^{2-5}$ Pn layer and the bearing surface are thin, and they have obvious anisotropy. So these layers were simulated by jointed material model with anisotropy. General isotropic unit elements were adopted in the other parts. Parameters of the material calculation are shown in Table1.

Table 1 Material parameters

| | density [KN/m$^3$] | Elastic modulus [GPa] | Poisson's ratio | Friction coefficient | cohesion [MPa] |
|---|---|---|---|---|---|
| concrete | 24 | 25.5 | 0.167 | | |
| Ⅱ | 26.0 | 20.0 | 0.22 | 1.2 | 1.4 |
| Ⅲ1 | 26.0 | 11.75 | 0.25 | 0.99 | 1.0 |
| Ⅲ2 | 26.0 | 9.25 | 0.28 | 0.865 | 0.8 |
| Ⅳ | 26.0 | 4 | 0.30 | 0.65 | 0.45 |
| T32-3 | 26.0 | 1.28 | 0.28 | 0.45 | 0.175 |
| T32-5 | 26.0 | 1.28 | 0.30 | 0.45 | 0.175 |
| Pn | 26.0 | 1.28 | 0.40 | 0.35 | 0.1 |
| Intercalary strata JC | 23.0 | 0.72 | 0.40 | 0.42 | 0.14 |

**Analysis of the unstable models and the stability of the dam foundation.**Based on the nonlinear finite element strength reserve coefficient method, the analysis of the dam foundation stability was carried out by reducing the structure surfaces or the strength parameters progressively in possible sliding channels. Then we could obtain the progressive failure process, as well as the whole safety degree of the foundation stability. Therefore this paper intends to confirm the unstable modes and the whole safety degrees by studying the development processes of the yield zones.

As is shown in Fig.2, when the strength reserve coefficient reached 1.0, the crack rock at the dam heel came to yield, communicated with the interlayer JC2-7. Soft rock $T_3^{2-3}$ and $T_3^{2-5}$ appeared yield regions in a certain range. When the strength reserve coefficient reached 1.9, the crack rock at the dam heel penetrated through the interlayer JC2-7 and communicated with the soft rock $T_3^{2-3}$. Soft rock $T_3^{2-3}$ and $T_3^{2-5}$ were almost yield entirely. Each JC interlayer also appeared faster and various degrees' development. A small amount of compression zones appeared at the resistance body of the tail rock. When the strength reserve coefficient reached 2.4, the layer JC2-7 of shallow low-angle dip fully penetrated through the site. JC2-5 and JC2-6 layers almost penetrated through the site. The tail rock resistance block had formed yield zones of compression and shear force with an angle of 23°~27°, and it had connected with the upper yield zone of soft rock $T_3^{2-5}$, forming a sliding channel which leaded to instability of the dam.

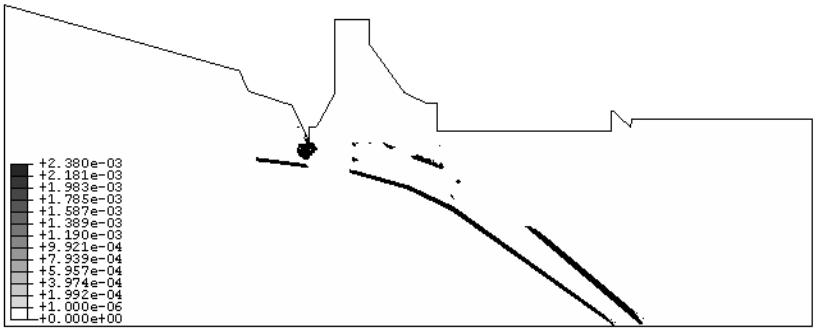

Fig.a The distribution of the yield zones when the strength reserve coefficient is 1.0

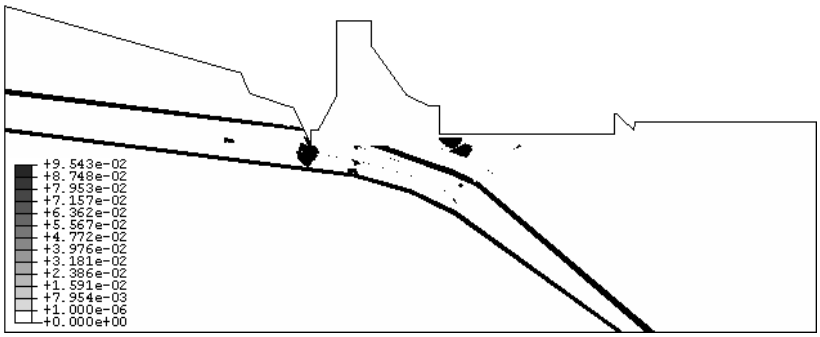

Fig.b The distribution of the yield zones when the strength reserve coefficient is 1.9

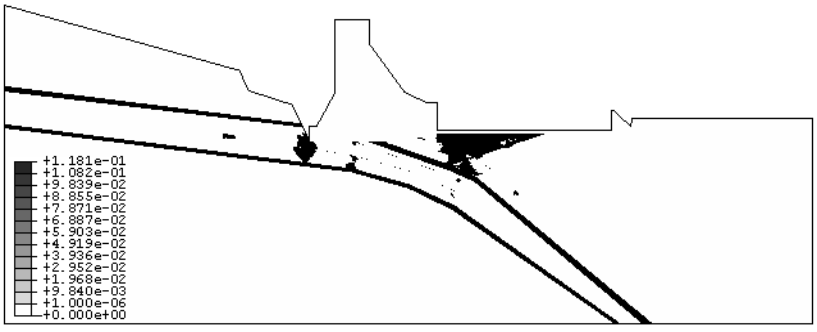

Fig.c The distribution of the yield zones when the strength reserve coefficient is 2.4

Fig.2 Development of the yield zones of dam foundation

The research on the development of the dam foundation yield zones indicated that, with the increase of the strength reserve coefficient, the strength parameters of the dam structure surface and tail rock resistance block reduced. The dam and its bedrock slid along the layer JC2-7 or the soft rock $T_3^{2-3}$ and the Pn mudded interlayer on top and bottom. When the strength reserve coefficient reached 2.4, the tail rock resistance block would lead to instability of the dam foundation because of the lack of resistance. Therefore the strength reserve coefficient of the dam safety degree should be 2.4.

The nonlinear finite element method has considered the deformation of the rock mass properties such as sliding and yield, compared with the rigid body limit equilibrium method which takes the sliding rock mass as a rigid body, so it would weaken the strength of the rock material. What's more, supposing the common boundary of the two sliding bodies as a vertical line in the calculation of the safety factors of the double sliding plane by the rigid body limit equilibrium formula is ill grounded. It will get a much higher safety factor, leading to a unsafe results. Above all, the factors mentioned above would all lead to a smaller strength reserve coefficient calculated by the nonlinear finite element method than the one of the rigid body limit equilibrium method. So the strength reserve coefficient that meets the safety requirements should be less than the standard 3.0 by the nonlinear finite element method. But there is no safety evaluation standard so far. It is still difficult to judge whether the dam is stable. We should double-check the dam's safety by the rigid body limit equilibrium method.

**Analyses of the rigid body limit equilibrium method**

When analyzing the dam foundation stability of the 12th sluice section of XiangJiaba by the rigid body limit equilibrium method according to the nonlinear finite element analyses and the geological conditions of the dam foundation, we can generalize the instability models of the dam foundation as the double sliding surface and formulate the slipping boundary and calculation conditions as follows:

The major sliding plane: From the perspective of the structural plane distributions, the interlayer JC2-6,JC2-7,JC2-8 and soft rock $T_3^{2-3}$ , $T_3^{2-5}$ and Pn layer on top and bottom all can serve as the potential sliding surfaces. But the major sliding plane searched by the nonlinear finite element analyses turned out to be the interlayer JC2-7 or soft rock $T_3^{2-3}$ and Pn mudded intercalation on top and bottom. The results illustrated that these three factors are more dangerous than any other potential major sliding planes. Therefore we can assume interlayer JC2-7 and soft rock $T_3^{2-3}$ Pn layer (Because of the soft rock $T_3^{2-3}$ and Pn mudded intercalation on top and bottom distributes in a narrow band region continuously. It is safe to simplify the two layers as Pn mudded intercalation.) as the potential major sliding planes to carry out the rigid body limit equilibrium analyses. The connectivity rate of the crushing Pn silt layer is 100%. The comprehensive shear strength parameters of the interlayer were defined with area weighting factor method.

The profile of the sliding shear: $III_1$,$III_2$,IV kinds' rock mass had developed surfaces resisting the slide after yield to pressure and shear. The angle of the surface is 23°~27°according to the finite element analysis. This paper adopts 23°as the angle of the sliding surface. The comprehensive shear strength parameter would be adopted according to the categories of the rock mass in relation to rocks' quality division graph.

Direction of resistance block: The direction of resistance block has a large effect on the safety factor. It should be demonstrated before putting into use as the standard required. The second failure surface had passed through part of $II_1$,$II_2$ layers and soft rock $T_3^{2-3}$ ,so the sliding friction coefficient of the second failure surface reached 0.93 in weighted calculation and the K reached 3.5. The angle

of the resistance block direction is 15°according to the empirical formula. What's more, the angle between the principal stress of resistance block and horizontal plane was about 20°on the basis of finite element analyses. The angle of the resistance block direction should be 15°for caution's sake.

The rigid body limit equilibrium method was adopted to carry out the analysis of the stability of the 12th sluice section on the basis of the sliding boundary and calculation conditions. The calculation results are shown in Table2.

Table 2 Deep sliding stability analysis of the 12th sluice section

| Major sliding plane | Comprehensive shear strength parameter of the major sliding plane | | Comprehensive shear strength parameter of the profile of the sliding shear | | Safety factor |
|---|---|---|---|---|---|
| | *f'* | *c'/MPa* | *f'* | *c'/MPa* | |
| JC2-7 | 0.43 | 0.15 | 0.87 | 0.82 | 2.65 |
| $T_3^{2-3}$Pn layer | 0.35 | 0.1 | | | 3.01 |

Table 2 shows that The safety factor in relation to the sliding mode which put layer JC2-7 as the major sliding plane was 2.65. Layer JC2-7 and layer $T_3^{2-3}$ Pn are more dangerous than any other potential sliding planes, so we can confirm that the safety factors of other potential major sliding planes are larger than the standards required 3.0 except the one of layer JC2-7. The safety factor that represents the whole safety degree of gravity dam is 2.65. The figure doesn't meet the standard requirements. Measures should be taken to the reinforcement.

**Research & Assessment of reinforcement measures**

The control conditions of dam foundation stability should be confirmed before designing reinforcement measures. The calculation results of the strength reserve coefficient method and the rigid body limit equilibrium method show that, the dam and part of the bedrock were sliding along layer JC2-7, extruding the tail rock resistance block near the dam toe. The tail rock resistance block lost its balance for lack of enough resisting force. Therefore, increasing the anti-sliding ability or the tail rock resisting force could be the methods to enhance the stability of the dam foundation. Otherwise, reducing the uplift pressure of the building surface also benefits the foundation stability.

As is shown in Fig.1, the major sliding surface JC2-7 shallow buried at the dam heel. The deep cutoff trench can be set up at dam heel in the case of not affecting the project's time limit. It can not only increase the anti-sliding ability of layer JC2-7 but also work as a diaphragm wall. Moreover, the work of setting up cutoff trench would link up with curtain grouting, and the work's excavation volume is small. For the above-mentioned considerations, this paper intends to adopt some measures to reinforce the foundation. Setting up concrete trench to cut off the layer JC2-7 and putting up additional drain holes at the stilling basin are useful measures. The design of the cogging reinforcement scheme is shown in Fig.3.

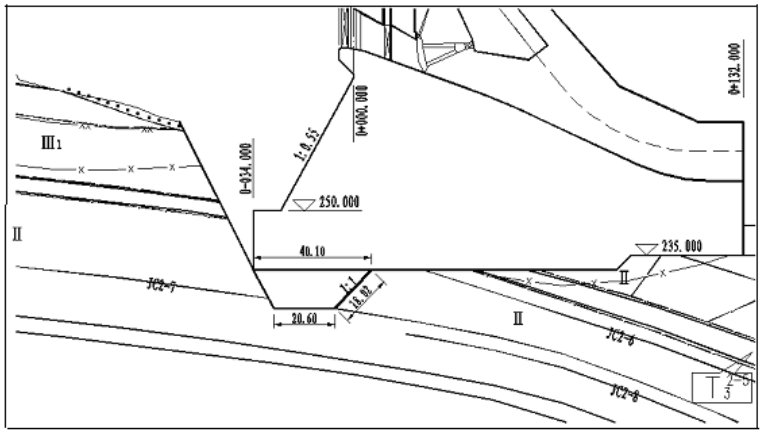

Fig.3 The deepened profile of the cogging at dam heel of the 12th sluice section

In view of the reinforcement schemes suggested, the strength reserve coefficient reached 2.8 which was calculated by the strength reserve coefficient method, and the safety factor reached 3.01 which was calculated by the rigid body limit equilibrium method. The results meet the standard requirements.

## Conclusions

[1] In order to find out the failure mechanism and the safety degree of the 12th sluice section of XiangJiaba hydropower station, this paper has carried out the analysis of the stability by the two-dimensional nonlinear finite element strength reserve coefficient method and the rigid body limit equilibrium method separately. The nonlinear finite element analyses indicated the instability mode. The dam and its bedrock slid along the layer JC2-7 or the soft rock $T_3^{2-3}$ and the Pn mudded intercalation interlayer on top and bottom, extruding the tail rock resistance block and leading to instability of the dam foundation. The strength reserve coefficient 2.4 characterizes the safety degree of dam foundation. The minimum of the safety factor turns out to be 2.65 by the rigid body limit equilibrium method. The corresponding major sliding plane is layer JC2-7. All the factors mentioned above are smaller than the standard required 3.0. So it is necessary to adopt reinforcement measures.

[2] This paper has put forward reinforcement schemes according to the instability mode of dam foundation. To set up concrete trench to cut off the layer JC2-7 and put up additional drain holes at the stilling basin. The calculation results of the two methods indicated that the stability of dam foundation increased after the reinforcement to a certain degree. The strength reserve coefficient has increased from 2.4 to 2.8, and the safety factor has increased from 2.65 to 3.01. Consequently, the results meet the standard requirements.

**Keywords:** experimental investigation, grain size distribution, landslide dam, particle segregation.

**Abstract:** Large landslides usually dam lakes that may easily fail and then result in catastrophic flood threatening the population downstream. The grain size composition within landslide dams is considered as a vital factor that impacts the timing of failure and the resulting magnitude of flood. Therefore, experiments were conducted to investigate the features of size distribution in accumulation bodies. The results indicate that the grain size distribution varies in different parts of the deposits. The inverse grading phenomenon can be observed. Grains in the front of the deposit are coarser, while grains in the rear are finer. For the front of the deposit, the grains in the middle are finer than the other two sides. The grain size segregation is believed to be the governing mechanism that contributes to this special distribution. The speculations of the grain size distribution inside the landslide dam are presented.

## Introduction

Landslide lakes occur once landslides block natural river flows and form landslide dams. Usually, the structure of landslide dams is weak and unstable, especially when water level rises high. It will easily fail due to piping or overtopping. Its breach may lead to catastrophic flood threatening the lives and properties of people living downstream. On May 12, 2008, an earthquake of magnitude 8.0 took place at Wenchuan, Sichuan Province, China. According to the preliminary investigation, 257 earthquake induced landslide lakes formed, 32 of which may cause flood disaster [1]. Tangjiashan Landslide Lake was the most dangerous one at that time, with maximum water storage of 320 million $m^3$. The landslide dam was approximately 124 m and 90 m high on the left and right sides, respectively and its volume is about $2.437\times10^7 m^3$. The potential breach posed a severe threat to 1.2 million people as the lake site was just 5km upstream from Beichuan County Seat [2].

In the sample of documented landslide dam failures, overtopping and piping are respectively the first and second common causes of dam failures [3]. As one of the most important characteristics of landslide dams, the grain size composition plays a key role in deciding the erodibility, permeability of the dam materials, thereby impacting the timing of failure and the resulting magnitude of flood in both failure modes. Because of this, some dam failure models, e.g., Breach, a widely used model for earthen dam failure [4], require grain sizes as crucial parameters of computation.

The grain size distribution of landslide dam materials may have special features. According to the researches of granular materials, the movement of granular materials will lead to particle size segregation, that is, larger particles tend to move upward to the top layer of the granular flow [5-7]. The dry landslide debris slips down the mountain at a high speed before forming a landslide dam. During this process, materials of the landslide dam may segregates, which probably contributes to special size distribution. Moreover, field investigations reveal that there indeed exist some typical features of grain size distribution of rock avalanche deposits and landslide dams [8-11]. However, since most of landslide dams will breach within a short period of time, for example, 60% of the landslide dams induced by Wenchuan Earthquake failed within a month [12], there are only a few opportunities to make field investigations on landslide dams, which is far from enough. Therefore, experimental investigation needs to be conducted to study the forming process of landslide dams, which contribute to a better understanding of its grain size distribution.

## Methodology

We use a steel slope shown in Fig.1 to study the mechanism of the accumulation and segregation of landslide debris. The slope is 5.40m long, 3.24m high and 2.50m wide, with 5cm high walls on both left and right sides of the slope. The surface of the slope is a plane, without any special treatment to make the slope smoother or rougher, that is, the coefficient of friction of the slope is the same as normal steel. The slope is set on horizontal ground, with enough space in front of the slope allowing the experimental material to accumulate. A bulldozer is used to carry and pour the experimental material from the top of the slope, shown in Fig.2. The experiment material should be poured continuously in an appropriate speed.

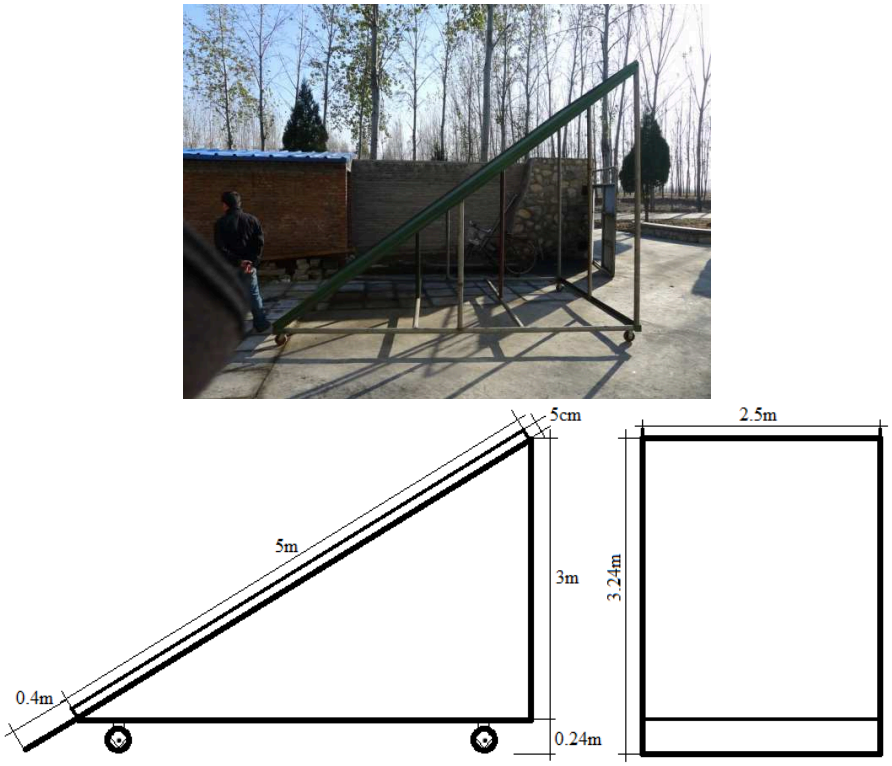

Figure 1 Photo and dimensions of the steel slope.

The experimental material is a homogeneous dry mixture of a certain amount of pebbles, coarse sands and fine sands, as shown in Fig.3. About 0.45m$^3$ experimental material is used in each experiment. Before experiment, about 1 kg material will be taken as an initial sample. After material being poured down the slope, another 11 samples will be taken from different positions of the deposit, as shown in Fig.4. Then all of the 12 samples are analyzed using standard gradation test. A series of geotechnical sieves is utilized, with the diameters of sieve pores being, respectively, 10mm, 6mm, 4mm, 3mm, 2mm, 1mm, 0.8mm and 0.6mm.

Figure 2 Bulldozer carrying experimental material.

Figure 3 Experimental material.

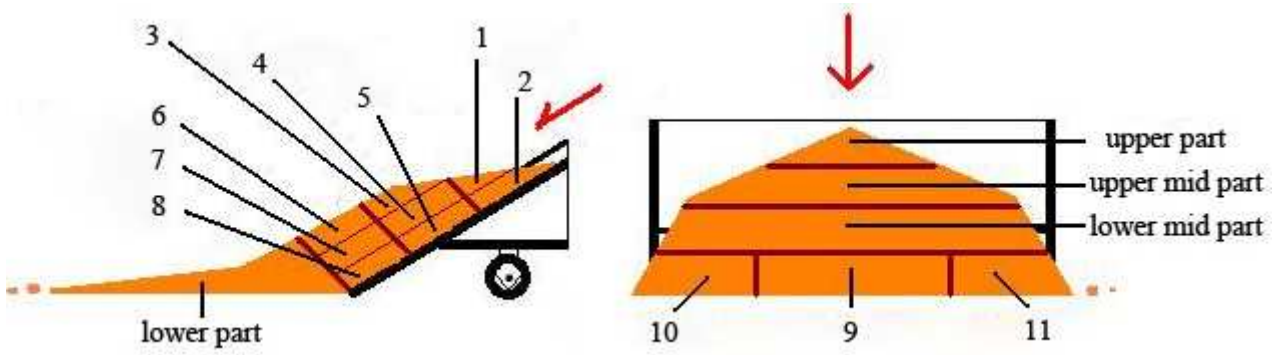

Figure 4 Sampling locations: 1) top layer of upper part, 2) bottom layer of upper part, 3) top layer of upper middle part, 4) middle layer of upper middle part, 5) bottom layer of upper middle part, 6) top layer of lower middle part, 7) middle layer of lower middle part, 8) bottom layer of lower middle part, 9) middle foot part, 10) right foot part, 11) left foot part.

## Results

Five experiments were conducted. In each experiment the initial grain size distribution of experimental material and the initial speed are slightly different.

The shape of the deposit is close to a triangle cone, as shown in Fig.5a. From the detailed view given in Fig.5b, inverse grading, which is an evidence of particle size segregation, can be observed.

We analyzed 60 samples from the 11 selected locations in the 5 experiments by sieving method. The results are shown in Fig.6.

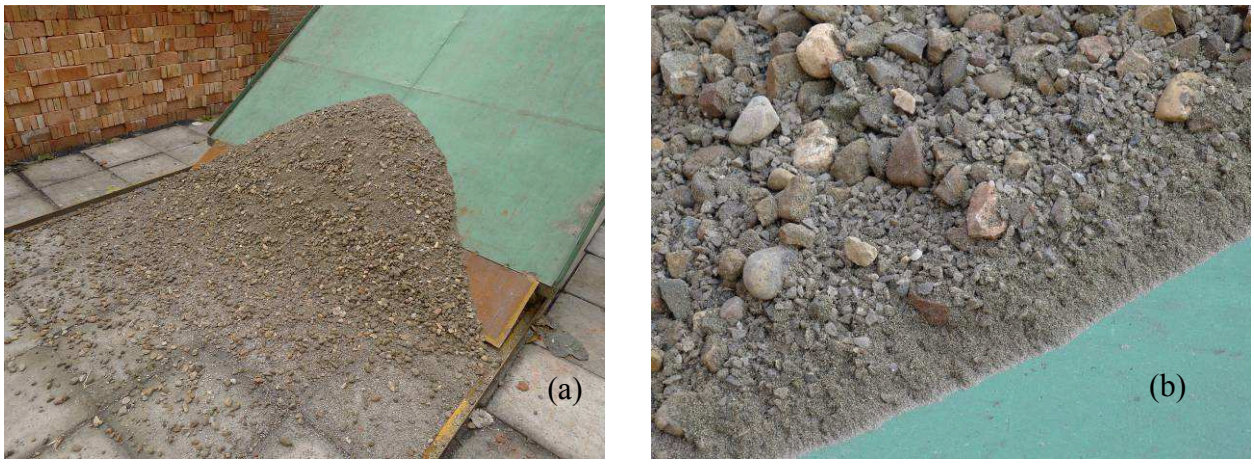

Figure 5 Shape and detailed view of the deposit.

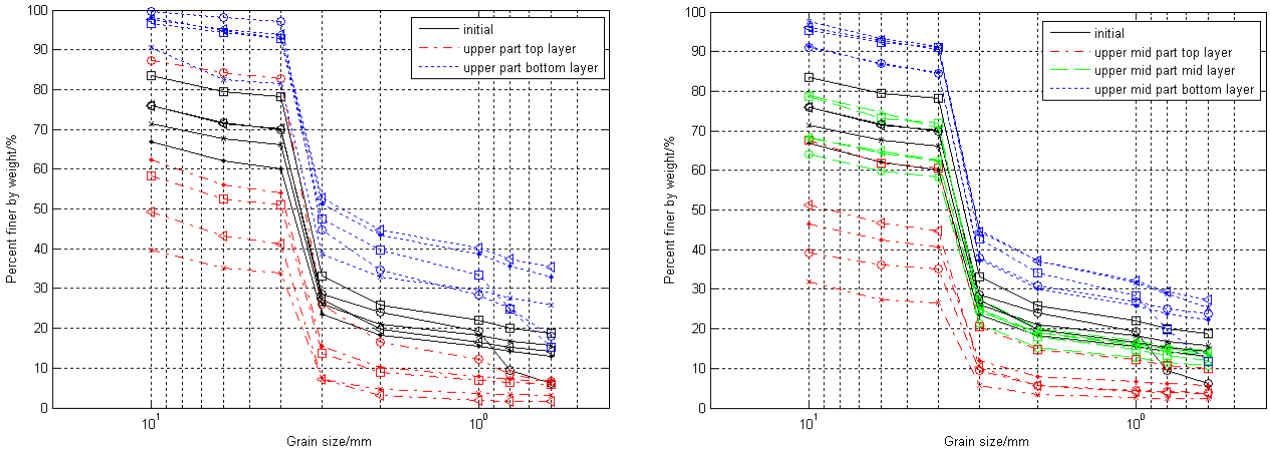
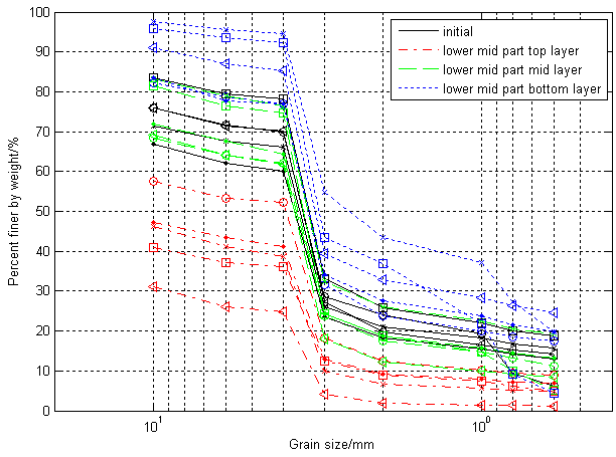
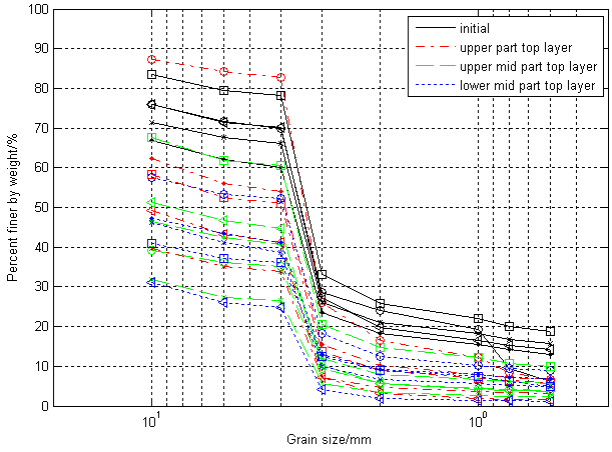


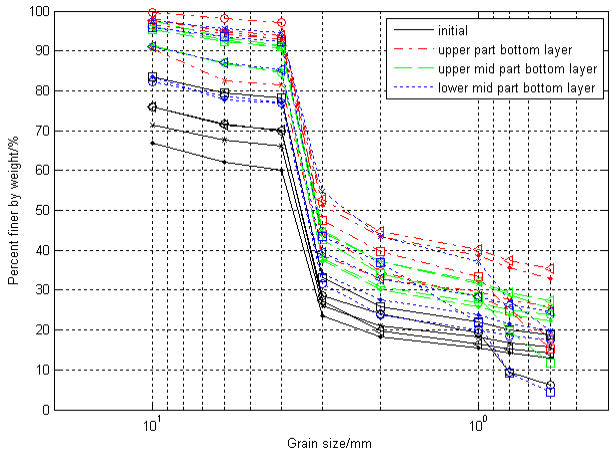
(a) upper part (b) upper middle part



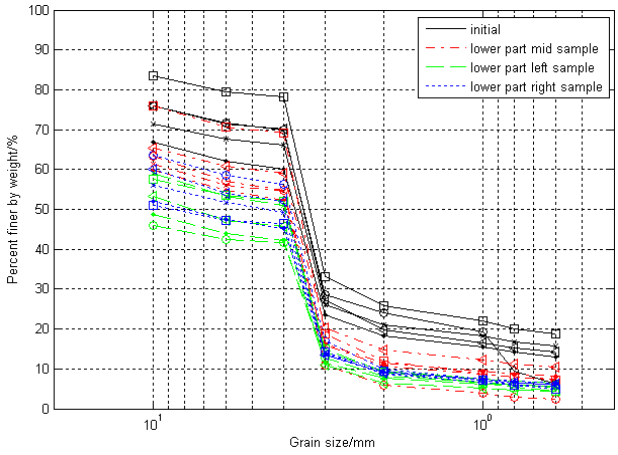
(c) lower middle part



(d) top layers in different parts



(e) bottom layers in different parts



(f) lower part

Figure 6 Grain size accumulation curves of selected locations of the deposit.

Fig.6a to Fig.6c show the difference between different layers. It is shown in Fig.6 that the grain size of bottom layer is much coarser than those in top layer and initial sample. In most samples of top layer of upper part, 40% of the material is larger than 10 mm, and there are almost no grains $<2$mm. In contrast, about 95% of the material in bottom layer consists of grains $<4$mm. The same feature can also be seen in upper middle part and lower middle part, as shown respectively in Fig.6b and Fig.6c. Besides, the grain size of middle layer is between the sizes of top layer and bottom layer and is close to the size of initial sample. These are all the features of inverse grading.

Fig.6d and Fig.6e show the variation of grain size distribution in different parts, i.e., the upper part, the upper mid part and the lower mid part. Comparing the distributions with each other, no remarkable regularity can be obtained. The results in different experiments are diverse. However, for the grain size of top layers, in most of the experiments, the grain in upper part is finer than in both upper middle part and in lower middle part, while there is no relation noticed between distributions of upper middle part and lower middle part. And for the grain size of bottom layers, although the size distributions of different parts are close to each other, the grain size of upper part tends to be finer than other two parts.

Fig.6f shows the grain size distribution of lower part. Lower part is thinner and quite different from other parts. It is obvious that grain size in lower part is coarser than initial sample. Moreover, we can notice that grain size in the middle is finer than in the left and right.

## Conclusions

Experiments were conducted to investigate the grain size distribution within landslide dams. The results indicate that the grain size distribution varies in different parts of deposits. To be more specific, the phenomenon of inverse grading is obvious. Grains in the front of the deposit are coarser, while grains in the rear are finer. For the front of the deposit, grains in the middle are finer than the other two sides. Particle size segregation is convinced to be the governing mechanism that contributes to this special distribution. Meanwhile, according to the experimental results, we speculate the grain size distribution within land slide dams. The speculations are partly consistent with field investigations. Moreover, limitation of our experiments is discussed and suggestions for further study are proposed.

**Keywords:** Finite element method, Relaxation, Limit tensile strain, Jinping Ⅰ hydropower station

**Abstract.** The arch dam of Jinping Ⅰ hydropower station is on obvious high ground area, and the foundation rock masses may relaxed while excavating. Limit tensile strain is put forward to be relaxation criterion. By three-dimensional elastic-plastic finite element method analyzing, and imitating the dam excavating steps, the maximum principle strain of the dam foundation rocks is obtained. The research indicates that the maximum principal strain of upstream side is greater than that of downstream side commonly, and some area would relaxed, with 41m maximal relaxed depth. By engineer analogical research with Xiaowan arch dam foundation rock mass, which have relaxed while excavating, the calculate method and criterion of this paper are reliable, and they can provide reference for engineer design.

## Introduction

In high ground stress area, due to unloading relaxation effect, rock masses rebound deformation orientation the free face, with the ground stress reduce in superficial and concentration in a larger extend in deeper place of the slope. In the stress adjustment process, relaxation crack produced or original crack expand, which cause rock masses relaxation and weaken the rock masses [1, 2, 3]. For the important function of rock masses in arch dam foundation plane, it possess important value in theory and engineering practical to bring forward reasonable unloading relaxation criterion and analyzing the unloading relaxation scope.

Jinping Ⅰ hydropower station is locates on Sichuan province, which is an important cascade hydropower station. The installed capacity is 3600MW, and the dam type is concrete double curvature arch dam, with 1885m crest elevation and 305m dam height, which is the highest arch dam in the world. The dam site is a typical V shaped canyon, with strongly geology structure action. The bed rocks are mainly metamorphic rock, in addition, there is a small amount of lamprophyre vein(X), and some unfavorable geological structures exist, mainly are f2, f5, f8, f13 and f14. The rock masses are mainly weaken weathered. The ground stress measured on site indicates that first principal stress of more than 70% positions exceed 20MPa, with a few exceed 40MPa, which is of obvious high ground stress area. The geology structure of both banks slope is complex. Affected by stress releasing, gravity and other factors, the slope obviously rebound toward the free face.

## The finite element model and computation condition

The finite element model is constructed according to the geological condition and excavation steps. Along and transverse the stream are X and Y direction respectively, while Z direction is vertical upward. The calculation scope is 800m along the stream, 500m transverse the stream of both banks, and the elevation of the model bottom is 1300m. The model before excavation is shown in Fig.1, and the model after excavation is shown in Fig.2. There are 132686 nodes and 294057 elements, in which 63681 elements would be excavated. Developmental faults such as f2, f5, f8. f13, f14, lamprophyre vein(X) and superficial strong and weak unloading area are constructed in the model.

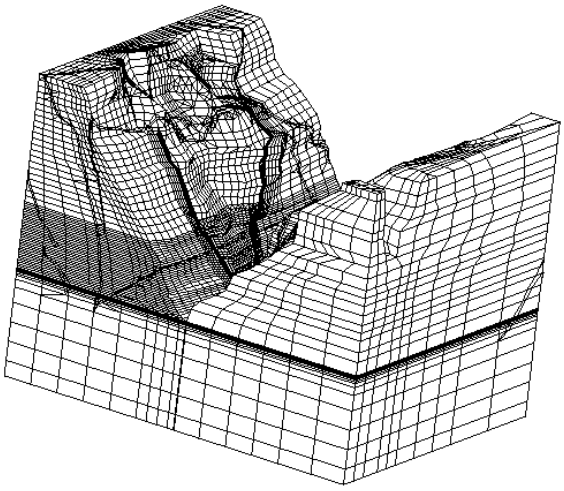

Fig.1 The FEM model before excavation

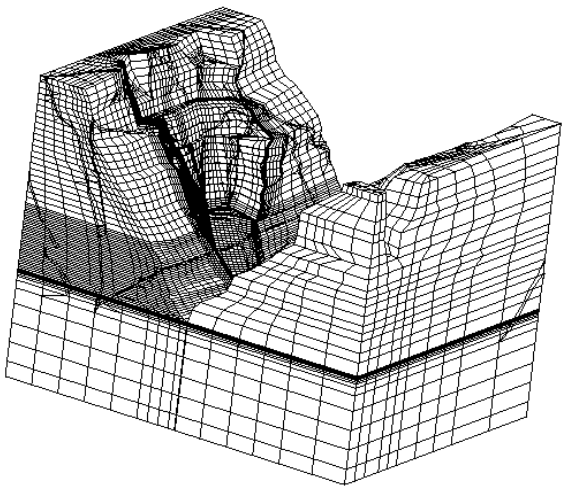

Fig.2 The FEM model after excavation

On the basis of the geological exploration on site and designers' suggestions, material parameters are as Table 1.

Table 1 Material parameters

| Material classification | Deformation modulus (GPa) | Poisson ratio | Unit weight ($MN/m^3$) | Cohesion strength (MPa) | Angle of internal friction ($^o$) |
|---|---|---|---|---|---|
| II | 26 | 0.22 | 0.0280 | 2.0 | 53.5 |
| III1 | 12 | 0.25 | 0.0278 | 1.5 | 46.9 |
| III2 | 8 | 0.27 | 0.0274 | 0.9 | 45.6 |
| IV1 | 3 | 0.30 | 0.0270 | 0.6 | 35.0 |
| IV2 | 2 | 0.30 | 0.0265 | 0.4 | 31.0 |
| V | 0.4 | 0.35 | 0.0265 | 0.02 | 16.7 |
| faults | 0.4 | 0.35 | 0.0265 | 0.02 | 16.7 |

The initial ground stress field is obtained by regression analysis based on measured stress on site. The load is mainly dead weight. Because the natural underground water level is low and the rocks are porous, the seepage field is not taken into consideration. The computation software is self-making FEM [4, 5, 6], which is based on elastic-plastic theory and bolted jointed rock masses model. The software had been successfully used in many major hydropower engineering.

According to the designed construction order of the arch dam foundation rock masses, 27 excavation steps are divided to simulate the excavation process. The yield criterion is D-P equivalent circle criteria, whose degree of safety is between the inscribed circle and the circumscribed circle.

Currently, there is no maturity unloading relaxation criterion for arch dam foundation rock masses. The physical quantities those used are mainly displacement, stress, point safety degree, strain, and so on. While excavating, the rock masses with larger displacement, massive stress reduce, minor point safety degree probably be relaxed. But these are just relative qualities. We consider the reason why the rock masses relaxed is strain exceed the limit tensile strain of the material in some direction, thus lamellar fractures appeared perpendicular to the direction. The limit tensile strain can be obtained by testing. So limit tensile strain is adopted to judge rock masses relaxation. By consulting the designers, the limit tensile strain of foundation rock masses( except exposure faults and their influence areas) of Jinping Ⅰ hydropower station is 0.0002. It should pay attention that the strain here is not strain increment while excavating, but total strain, which contains both initial strain caused by initial ground stress and strain increment while excavating.

**Relaxation analysis**

The maximum principal strain contour map is shown in Fig. 3, and the maximum principal strain contour map of typical cross section of the foundation, which is along the arch dam axis, is shown in Fig. 4.

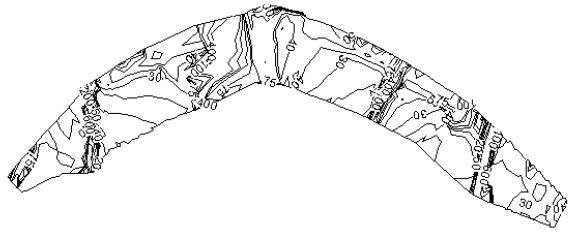

Fig.3 The maximum principal strain contour map

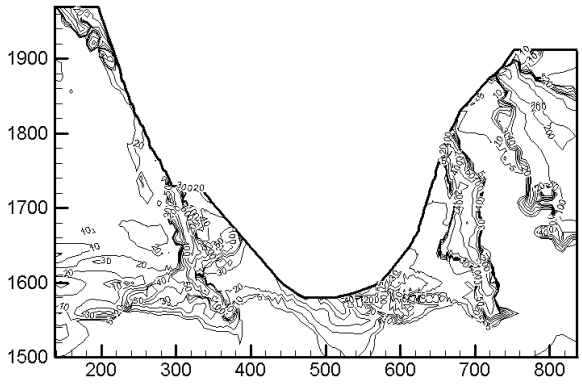

Fig.4 The maximum principal strain contour map of typical cross section

It can be seen from the figure that: (1) the maximum principal strain of upstream side is greater than that of downstream side commonly; (2) while 0.0002 is adopted as the limit tensile strain of the foundation rocks, the areas that would relaxed are shown by thick lines in Fig. 5; (3) if the limit tensile being lager than 0.0004 is adopted as criterion for strongly relaxation, the areas would be strongly relaxed are shown by thick lines in Fig.6; (4) the relaxation depth of the left bank is 22.5m in the elevation of 1610m, 17.5m in the elevation of 1590m, and 26.5m in the elevation of 1580m; the relaxation depth of the middle riverbed is 41m in the elevation of 1580m, and rock masses in the elevation of 1670m of the right bank would not relaxed. Being affected by locational faults or fracture zone, relaxation depth of rock masses in these places cannot be analyzed.

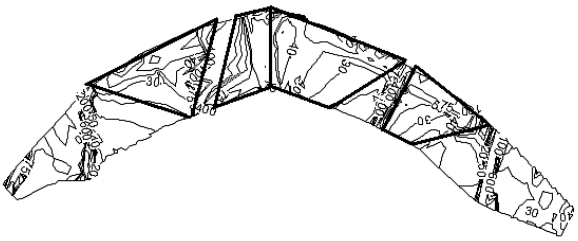

Fig.5 Foundation areas that would relax

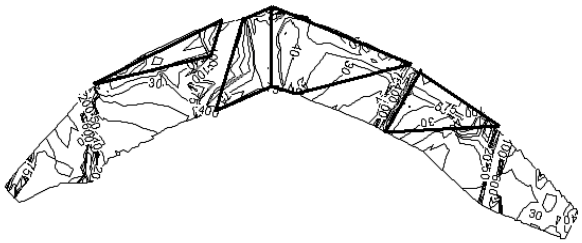

Fig.6 Foundation areas that would strongly relax

**Engineering analogical research**

Considering that there is no enough proven on relaxation criterion of arch dam foundation rock masses, Xiaowan arch dam, which is similarly high arch dam in high ground stress area, is adopt as example of analogy engineering and engineering analogy analysis is carried out. Lower foundation rocks of Xiaowan dam are mainly weak weathered or fresh granite gneiss, with no exposed large fault. By consulting the designers, the limit tensile strain of the rock masses is 0.00015.

After calculate on Xiaowan project by the same computation method and relaxation criterion, we can conclude that (1) the foundation rock masses under the elevation of 990m on the left bank and 975m on the right bank would relaxed; (2) the relaxation depth of the left bank is 8.5m in the elevation of 990m, 8.5m in the elevation of 975m, and 8.0m in the elevation of 953m; the relaxation depth of the right bank is 8.5m in the elevation of 953m, 2.0m in the elevation of 975m; the relaxation depth of the middle riverbed is 9.0m in the elevation of 953m.

The foundation rock masses of Xiaowan arch dam relaxed while excavating. Compared with the actual foundation rock masses relaxation while excavating Xiaowan arch dam foundation, the calculated relaxation scope and depth are consistent. So, it indicates that the above calculate method and relaxation criterion are reliable. According to the analogical research results, the foundation rock masses of arch dam of Jinping Ⅰ hydropower station would probably relaxed after excavation.

## Conclusions

Rock masses excavating in high ground stress areas would relaxed. Limit tensile strain is put forward to be relaxation criterion in this paper. Three-dimensional finite element model of dam site of Jinping Ⅰ hydropower station is constructed. By elastic-plastic finite element method and imitating the excavating process, the maximum principle strain is obtained. The analyses indicate that the maximum principal strain of upstream side is greater than that of downstream side commonly. After compared with limit tensile strain of the rock masses, which obtained by consulting the designers, the maximum principal strain of rock masses in some area is larger than the limit tensile strain of it. So the rock masses in some area may relax. By analyzing the typical section, the maximum relax depth is about 41m. Xiaowan arch dam was adopt as example of analogy engineering and engineering analogy analysis was carried out. It indicates that the calculate method and excavation criterion are reliable. According to the analogical research results, the foundation rock mass of arch dam of Jinping Ⅰ hydropower station would probably relaxed.

The research of this paper is preliminary, and the theory of rock masses unloading relaxation is complex. There are following shortages remain which need further researching: (1) rock masses is usually bolted while excavation and unloading relaxation is varied with time, which are not taken in consideration in this paper; (2) the unloading relaxation criterion of limit tensile strain have not applied commonly, which need to be proven in more engineering practices.

# Research on the Influence of Diking in Shallow Sea of Tangdao Bay on Marine Environment

Yun Hai Xu[1, a], Xiao Hui Hao , Xin Mei Dong

[1]Li Shan Road 125, JiNan China

[a] xuyunhai1963@163.com

**Keywords:** TangDao Bay, Marine Environment, Flow Filed, Numerical Simulation

**Abstract.** In the process of comprehensive treatment for the Tangdao Bay in Qingdao,the dikes need to be constructed firstly and then the construction for treatment can be started,in this paper,the author uses the two-dimensional mathematical model to analyze the change of the flow field in the water area of Tangdao Bay before,during and after the diking construction in simulation and analyze the influence on the marine environment after diking.By use of the diking method of throwing sand in jute bags,the new secondary pollution caused in the diking construction process can be prevented effectively and nice economic and social benefits can be obtained.

## Introduction

Tangdao Bay extends from the northeast to southwest with the depth of 4.5 km and width of 2.5 km,The bay is in narrow long pocket shape with the area of 17km$^2$ and coastal line of about 23.9 km.Niu Dao is located in the middle of the bay with the area of 0.2km$^2$.In the low tide,it can be connected to the continent. In recent years,the sludge accumulation is very serious in the water area of the bay,which affects the sailing line and environment of water body.Recently,the comprehensive treatment project for the Tang Dao Bay includes sludge clearance,wharf,port pool and sailing line construction,etc.,of which the area of sludge clearance section is 2.602 million m$^2$and the total volume of sludge excavation is 7.132 million m$^3$.However,there are thousands of acres of mariculture farm in the open sea area of NiuDao and the farm is connected to the sludge clearance area.If no engineering measures are taken in the construction,a lot of sludge, sand and contaminated water will surge into the open sea from the south side and north side as the tide rises and falls,causing the whole TangDao Bay and even the open sea become muddy.Consequently, not only the farm is severely affected,but also the natural ecological resources of the sea are damaged. According to the natural conditions and construction requirements, to protect the farm in the open sea from being affected,maintain the natural ecological resources of the sea, the treatment area needs to be isolated from the open sea to prevent causing new secondary pollution in the diking construction process and provide good environment for the treatment engineering. After technical and economic comparison,the scheme of diking in the shallow sea is used.In this paper, the author analyzes the influence of diking on marine environment by the numerical simulating calculation to the flow field in the bay before and after dike is built.

## Calculation and Analysis for Change in the Flow Field before and after Diking

2.1 Features of TangDao Bay Area

The water is shallow in the Tang Dao Bay. According to the topographic map for the interior part of TangDao Bay, the relation between the water level and water area, water storage volume inside the bay is as shown in the table 1.

Table 1 Relation between the Water Level and Water Area, Water Storage Volume inside the Bay

| Water Level (m) | -2.42 | -1.48 | -1.08 | -0.3 | 0.5 | 1.08 | 2.08 |
|---|---|---|---|---|---|---|---|
| Water Area (Ten thousand m$^2$ ) | 35 | 70 | 240 | 550 | 630 | 680 | 690 |
| Water Volume (Ten thousand m$^3$ ) | 80 | 130 | 192 | 500 | 972 | 1352 | 2037 |

### 2.2 Overview for Diking Engineering

The dikes newly built are located in the south side and north side of NiuDao and divided into the south dike and north dike with the length of 809.1 and 605m respectively,the maximum height of 11.7 m； The width at the top of the dikes is 5 m and the backpressure platform of 5～15 m is set at the either side.The material used for building the dikes is the jute bags filled with sand.Before the erection and water blocking in the engineering, the sea water freely accesses into the bay area for treatment; According to the construction organization and design,a posterior built section of diversion gap is set at the trench of the south dike with the length of 150～200 m and the filling elevation 0.5～1.0 m lower than other dike sections.The flow rate and flow regime of sea water at the reserved gap and entrance are uniform and also easy to be observed and controlled.When the whole dikes are built above the designed high water level,the horizontal closure and erection are performed and the diking task is completed.

### 2.3 Hydrological Computation Data

#### 2.3.1 Designed Wave Height

Because NiuDao is located at the northwest～southeast direction of NiuDao, only the designing wave factors at different recurrence interval for the section of NiuDao～ancient pier in the high tide need to be calculated. According to the forecasting method regulated in the *Technical Code for Port Engineering* , it is calculated the designed wave height of one occurrence in ten years for the section of Niu Dao is 1.40 m.

#### 2.3.2 Tide and Tidal Current

Results of statistics and harmonic analysis indicate the main amplitude rate between the solar and lunar semidiurnal constituent for Tang Dao Bay is 0.25,The tidal current of TangDao Bay belongs to the semidiurnal constituent, and the movement form of tidal current is reciprocating flow pattern.

According to one-month tide data and the synchronous data of big port, it is calculated that the mean duration for tide rising in the bay is 5h 45min, the mean duration for tide falling is 6h 39min, the mean monthly maximum tide water level is 1.08 m, the mean monthly minimum tide water level is -1.48m and the mean monthly seal level is -0.19m.

The possible maximum flow rate of tidal current and the possible maximum movement distance of water particles in the bay are about 1.1m/s and 11.3km respectively.

### 2.4 Numerical Simulation Calculation

2.4.1 Establishment of Numerical Model

Because the water is shallow in TangDao Bay, the two-dimensional mathematical model is used for simulation. The equation set for the mean shallow water with the two-dimensional depth is:

$$\frac{\partial \zeta}{\partial t} + \frac{\partial (Hu)}{\partial x} + \frac{\partial (Hv)}{\partial y} = 0 \tag{1}$$

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} - fv + \frac{\tau_{bx} - \tau_{ax}}{H} + g\frac{\partial \zeta}{\partial x} = 0 \tag{2}$$

$$\frac{\partial v}{\partial t} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} + fu + \frac{\tau_{by} - \tau_{ay}}{H} + g\frac{\partial \zeta}{\partial y} = 0 \tag{3}$$

$$H = h + \zeta \tag{4}$$

In the equation set: t is time; ζ is the water level; H is the overall water depth; h is the depth of undisturbed water depth; μ and ν are components of flow rate of sea water along x, y directions respectively; f is Coriolis coefficient; g is accelerated speed of gravity; τhx, τhy are components of frictional force along x, y directions respectively; τax, τay are components of wind-stress along x, y directions respectively.

Calculating the boundary conditions:

The normal flow rate at the closed boundary is 0 and the tide equation at the open boundary is:

$$\xi = \sum_{i=1}^{N} f_i H_i \cos[\sigma_i t + (V_{ot} + V_i) - G_i] \tag{5}$$

In the equation, N is the number of constituent, fi, σi, (Voi+Vi) are intersection point factor, angular frequency and initial phase of tidal constituent no. i respectively; Hi, Gi are amplitude as well as late angle adjusting and constant of tidal constituent no. i respectively.

The influence of overland runoff increased by the rainfall is not taken into account.

The initial condition is set as 0, namely: μ=ν=ζ=0

The ADI method is used for the array of difference. The gridding distance in x direction is set as 75 m and the gridding distance at y direction is set as 92 m.

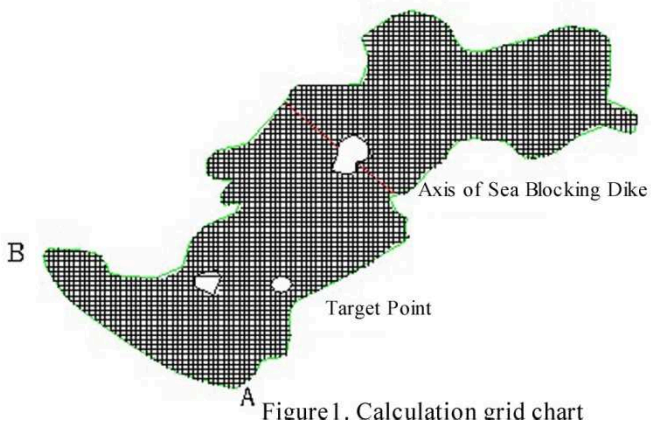

Figure 1. Calculation grid chart

The step length of calculation is set as 6 seconds.

Calculation grid chart is shown in Figure 1.

2.4.2 Change of Flow Rate, Water Level before and after Diking

The section A-B is selected to predict the change of the tide surging volume. The calculation indicates the tide surging volume is $2.99\times10^7 m^3$ before diking and the tide surging volume is $2.73\times10^7 m^3$ after diking, reducing by $3.6\times10^6 m^3$ compared with the one before diking. Figure 2 is the calculation result of the change of flow rate at the representation point in the target sea area. From the figure 2, it can be seen that the change of flow rate before and after the diking is within ±0.22m/s, increasing or decreasing by 25% compared to the original one; it indicates the diking has certain influence on the tide field of the bay.

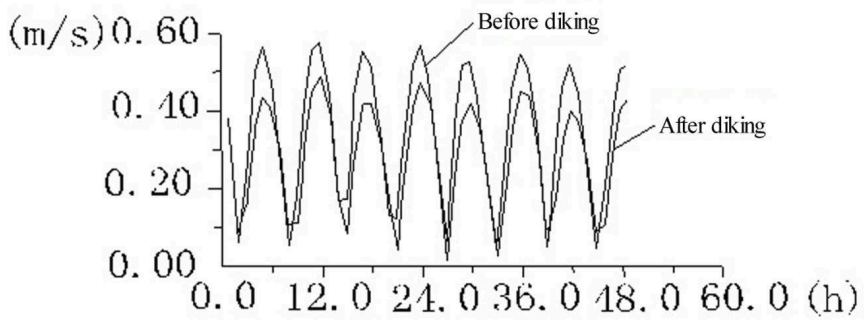

Figure 2 Change of Flow Rate as Time at Some Representation Point before and after Diking

In the process of dikes construction, the calculation and analysis for the change of water flow is: In the process of erection in the construction of dikes, the change of water level and flow rate at the closure gap is large; thus, the hydraulic power is calculated according to the following formula:

$$Q = \sum b_i \varepsilon m \sqrt{2g}\,(H_{\text{outer}} - H_{\substack{\text{elevation of the bottom} \\ \text{of sluice and entrance}}})^{3/2}\,\sigma$$

In the formula, Q is the flow passing through the closure gap; ∑bi is the overcurrent width; H is the water depth; σ is the submerging coefficient.

Figure 3 and figure 4 are the change of water level as the time when the overcurrent width is 100m and 50 m respectively. According to the water level, the maximum flow rate is calculated to be 2.8m/s.

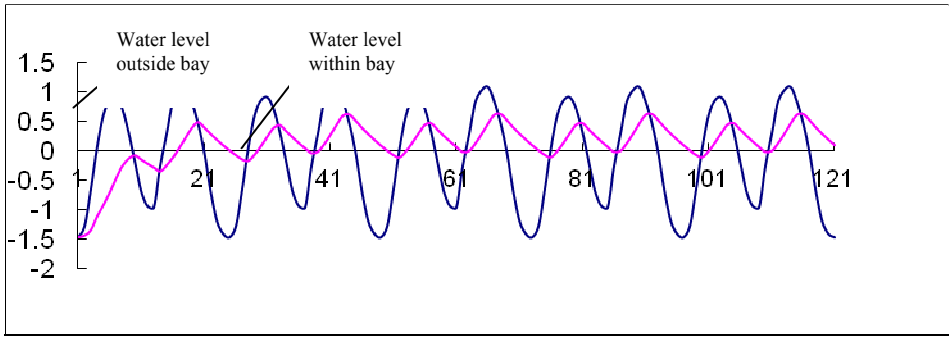

Figure 3 Change Process of Water Level When the Overcurrent width is 100 m

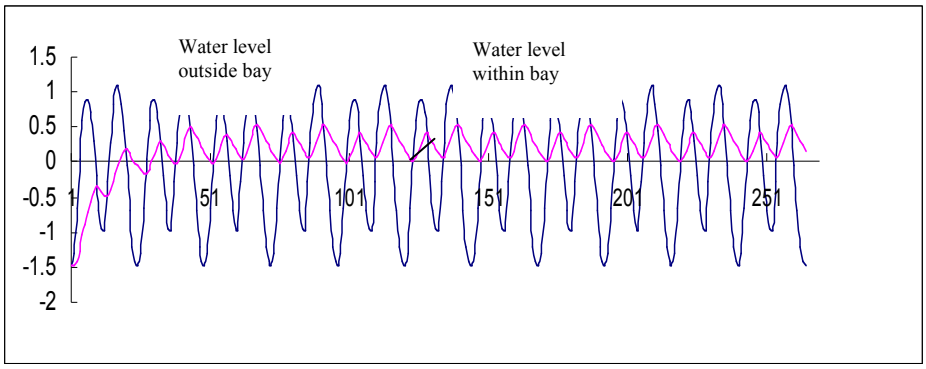

Figure 4 Change Process of Water Level When the Overcurrent width is 50 m

### 2.5 Analysis for Change of Flow Field and Engineering Measure

From the calculation results, it can be seen that change occurs at the flow field of the bay in comparison before diking and after diking. Generally, the flow rate is reduced somewhat and water exchange weakens, however, it doesn't cause great influence on the water environment in the bay; In the diking process, the flow cross-section at the erection opening, the flow rate is nearly increased by two times and the movement distance of water particles is nearly increased by tow times accordingly, so it is liable to cause pollution to the open sea and affect the engineering effect if no measures are taken.

In the erection for diking, the engineering measures to be taken include replacing the diking by the jute bags filled with sand with diking by throwing sand in jute bags, and the sand is pure medium sand; controlling the clay content within 1.5%. Because the measures above are taken,no new secondary pollution is caused in the construction, achieving the expected objective.

## Summary

From the calculation results, it can be seen that change occurs at the flow field of the bay in comparison before diking and after diking；Generally, the flow rate is reduced somewhat and water exchange weakens. By use of the diking method of throwing sand in jute bags, the new secondary pollution caused in the diking construction process can be prevented effectively and good economic and social benefits can be obtained.

**Keywords:** Coastal Levee Construction; Quality Accident; Monitoring System; Quality Inspections; Early Warning System.

**Abstract:** The phenomenon of the actual situation leave the design index is very common during the civil project construction especially in the coastal levee construction. As the way to reduce the probability of diseases occurrence, from the aspect of quality accident analysis, construction quality monitoring moisture, quality inspection and accident early warning system, the paper studied the levee construction quality control monitoring system deeply and advanced some useful conclusion.

## Introduction

Recent years, the design theory and quality control theory has made great progress in coastal moisture levee construction, but still some shortcoming, mainly reflected in the comprehensive knowledge of many quality affecting factors, quality control systems are imperfect, and so on, resulting in frequent quality accidents during the project construction especially in the coastal levee construction.

In response, some scholars have conducted targeted research. Liu Ying-xin[1] think we can do project quality comprehensive evaluation and control from the physical quality of proposed projects, quality assurance data, design quality, environmental factors and other aspects. Li Xu-hui[2] emphasized the emphasis of quality control is the "cause" control. Li Hua-ming[3] proposes using the Gray Markov model to predict the quality and optimal cost. Liu Hui-ming[4] proposed the standardized criteria of seawall proof. Wang Ke-qin[5] studied height elevation of land formation, embankment and wave retaining wall by analysis the design principles, moisture-proof system division, moisture standards.

## Coastal Levee Quality Accident Analysis

A．Levee stability

Landslide is the disease phenomenon when the levee slope instability. The Cracks began to appear at the top of the levee or the levee slope, with the development of cracks the landslide formed. For the prevention and treatment of stability problems, the participation unit of the project should strengthen the genesis of key sections of the site inspection and monitoring, forecasting the danger timely. And focusing on the levee analysis and cracks monitoring, clarify the cause of the cracks.

B．Levee seepage

Water or other fluids flow in the rock medium such as pores or fissures, referred to as seepage. Moisture seepage control is very important to ensure the security and stability of the levee, if the seepage problem cannot be resolved, will lead to an immeasurable loss. The levee seepage damage mainly includes piping, seepage loopholes, pit (or nest, collapse pits) and so on.

C．Crack

Crack is the common danger in the levee construction and operation; sometimes it may be a harbinger of other dangers. From the aspect of parts appear, the cracks can be divided into surface

cracks and internal cracks; from the causes of the cracks it can be divided into uneven subsidence cracks, landslides and cracks, shrinkage cracks and vibration cracks.

D. Storms scour

Moisture levee embankment will be storms during its construction, if the phenomena cannot be controlled timely, along with the development of scour, it will endanger the safety of the levee.

## Quality Accident Relationship

The relationship of the upper quality accident is very complex, from a macro aspect, it can be predigest as Fig.1.

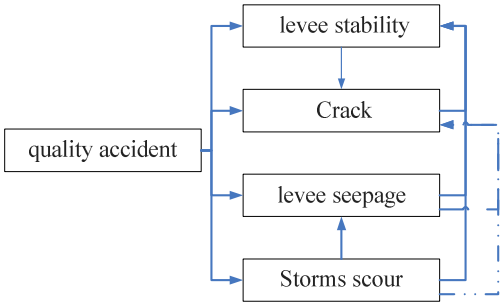

Fig.1 The relationship of the quality accident

## Quality Monitoring System of Coastal Ievee

Controlled by a large number of uncontrollable factors, the actual construction process of the quality indicators often deviation from the expected case. The purpose of monitoring in the process of the project construction is done by setting a series of on-site monitoring program, with the help of modern means of monitoring to identify the actual state of the construction quality.

## Monitoring Items Analysis

Current levee monitoring items always including labor inspection, surface subsidence monitoring, deep horizontal displacement monitoring, pore water pressure monitoring, slope horizontal displacement monitoring, crack monitoring, soil pressure monitoring. The results of surface subsidence monitoring can be used for the evaluation of the levee settlement. The deep horizontal displacement, crack monitoring, pore water pressure monitoring primarily reflects the steady state. The earth pressure monitoring is used to reflect the stress state of the earth structures, levee soil pressure inside the levee.

A. Monitoring Systems Design

Based on the actual situation of one levee construction project, the monitoring system can be designed as Fig.2.

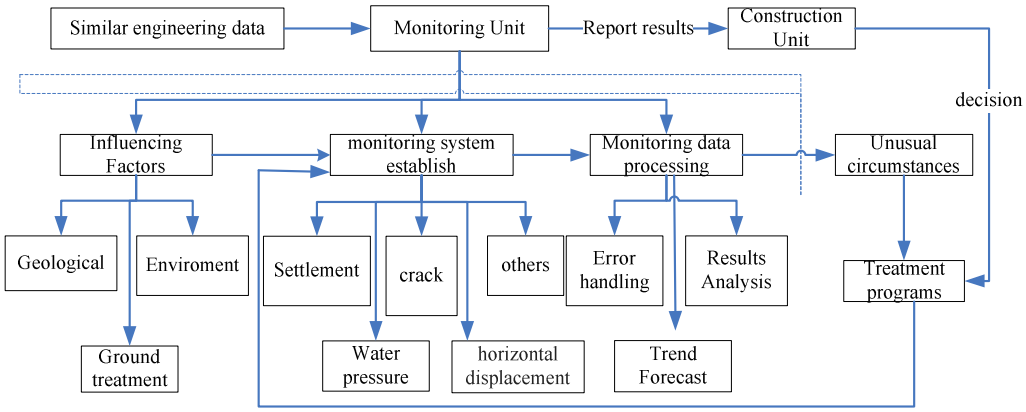

Fig.2 Monitoring system of levee construction project

## Coastal Levee Construction Quality Inspections

As the way to ensure the quality of levee construction, some projects often need to inspect the engineering quality based on the actual situation of the project and related specifications testing.

A. Slope engineering inspection

Content slope engineering testing including: concrete revetment thickness, strength of concrete, concrete samples described, cushion thickness and particle analysis and so on.

B. Revetment engineering inspection

The main content of revetment engineering inspection is to detect the underwater riprap section line.

C. Building quality inspection

The content of building quality inspection includes: Detection the variety of raw materials, mainly test the physical and mechanical properties of materials; Concrete testing, take the on-site sample to do some laboratory test.

D. Seepage engineering quality inspection

The content of seepage engineering quality inspection include: the on-site detection of various materials' (including cement, admixtures, sand, stone, etc.) physical and mechanical properties on-site detection; cutoff wall quality testing, including the wall material quality testing and integrality detection of wall .

## Establishment of Accident Early Warning System

System for the quality control of levee construction not only according to the specification and design requirements for the engineering quality control, also according to the field monitoring, detection data, factor analysis, risk assessment, which can be helpful to make an accurate analysis of the accident trend and accident state.

A. Function analysis of early warning system

The function of levee engineering quality early warning system mainly manifests into three aspects, namely the alarm function, emergency function and recovery function.

(1) Alarm function

Alarm function includes the monitoring, feature recognition, diagnosis and alarm of the construction management and disease status. It does this by setting the boundaries of various diseases, and forecasting the behavior of some possible diseases or phenomena that may arise to the imbalance state, which can be useful to standardize the construction process.

(2) Emergency function.

Emergency function is according to the alarm information and risk trend, take preventive measures in advance to prevent the occurrence of diseases and ensure project quality.

(3) Recovery function.

The recovery function refers to the alarm control failure, engineering accident occurs, a passive remedial action taken. It is in accordance with the project monitoring data and information related to the accident, decision analysis, to determine the appropriate remedial measures which can helpful to ensure the engineering loss at a minimum.

B. Warning implementation process

According to the security early warning theory, combined with field monitoring data and test results, the levee project early warning process consists of identifying alert, looking for the alert source, analyzing the warning signs, warning and alarm response decision-making. The useful early warning process is shown in Fig.3:

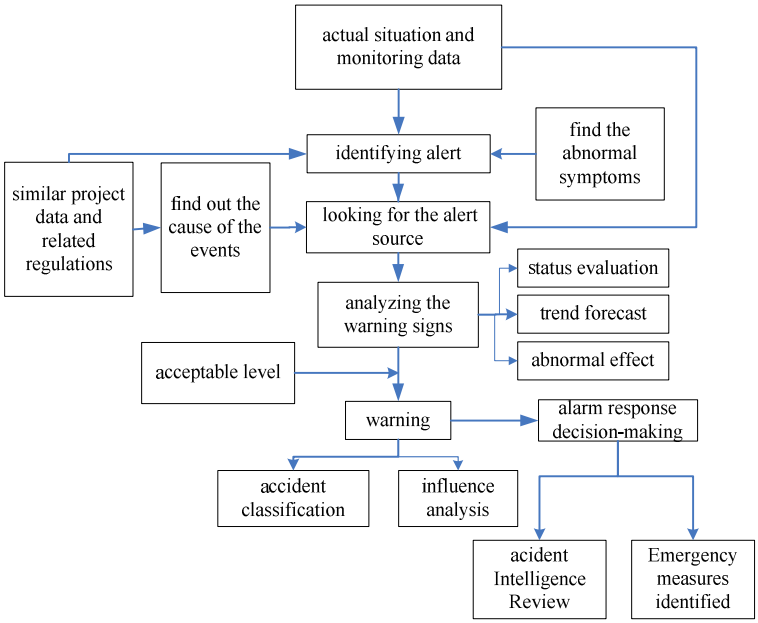

Fig.3 Early warning process sketch of levee project

## Summary

Combined with the actual situation and the researches of levee construction, the paper studied the levee construction quality control monitoring system from the aspect of quality accident analysis, construction quality monitoring moisture, quality inspection and accident early warning system, get the following conclusions:

A. In order to improve the quality of the project, the construction unit should pay more attention on the possible accident and establish reliable monitoring and inspection system during the construction process.

B. Reasonable set of project monitoring and detection systems are very helpful to improve the construction quality and reduce the probability of occurrence of disease.

C. Timely and accurate warning for variety possible exceptions is most important measure to reduce the occurrence of disease during the levee construction.

**Keywords:** Supertanker, Steel line, Cable force, Mooring manner, Experiment Research

**Abstract.** At present, many oil tank wharfs of 300,000DWT which taken the maximum of 450,000DWT supertanker into account had been built in our country. In this paper, through the physical model test on 450,000DWT supertanker, the mooring line tension with different mooring arrangements, cable diameters and cable materials were studied and the wave condition for the supertanker safety operation was given. The results showed that: on the same wave condition, to increase the steel cable's diameter could reduce the ship's movements, which could enhance the ability to operation. In addition, using the combination cable on the same diameter instead of the steel cable could reduce the tension of mooring line and increase the working ability effectively. The research results can provide reference and guidance for the future of supertankers mooring operation.

## Introduction

With the rapid development of the international petroleum sea transportation, the scale and the capacity of the oil tanker were increased quickly. Now the main large oil tanker in active service is 300,000DWT[1]. Since 2002, South Korea's Daewoo heavy industries build four 450,000DWT supertankers with double hull, then the capacity of the oil tanker was developed to 450,000DWT supertanker gradually. For this purpose, many domestic wharf structure of 300,000DWT oil tanker was designed for the 450,000DWT supertanker. Such as 300,000DWT crude oil wharf of Qingdao port, 300,000DWT crude oil terminal of Caofeidian port, 300,000DWT fuel oil wharf of Ningbo, 300,000DWT crude oil wharf of Quanzhou and so on. Based on the experiment of mooring manner and the safety operation condition for 450,000DWT supertanker carried out by the combined action of wind, wave and current, it can be shown that the different cable diameter and cable material had the influence of the ship movements and line tensions, and the wave condition for the supertanker safety operation was given. The research results can provide reference and guidance for the future of supertankers mooring operation, which has the great realistic significance and research value.

## Experimental Condition

**Vessel Parameters.** The vessel size information and the dynamic parameters of the 450,000DWT supertanker were shown in table1.

**Design Layout Plan of Terminal.** The terminal is composed of one working platform, two fender dolphins and six mooring dolphins with the butterfly layout. The berth length is 455m. Every fender dolphin installed two C3000H standard rubber fender with a drum a board, the designed reaction force is 4400kN.

**Arrangement and Parameters of Mooring Lines.** There were three kinds of cable specifications:

The steel cable of the diameter 44mm, which break force was 1070kN.

The steel cable of the diameter 52mm, which break force was 1470kN.

The combination cable of the diameter 52mm, which break force was 1470kN. The combination cable mainly for the steel cable and the hook joint with 15m long nylon cable of the diameter 100mm.

The arrangements of steel cable of the diameter 44mm and 52mm were 3-4-4-3, the arrangements of combination cable of the diameter 52mm was 4-3-3-2, the different arrangements were showed in Fig.1a and Fig.1b.

Table 1 450,000DWT supertanker parameters

| Vessel Scale | | | | | |
|---|---|---|---|---|---|
| Length overall (m) | | Breadth (m) | | Depth (m) | |
| 380 | | 68 | | 34 | |
| dynamic parameters | | | | | |
| Loadage | Displacement(t) | Draft(m) | Gravity Center High(m) | Buoyant Center High(m) | Rolling Period(s) |
| Full Load | 555527 | 24.5 | 23.03 | 13.45 | 16.31 |
| Ballast | 176145 | 10.74 | 20.71 | 6.62 | 9.36 |

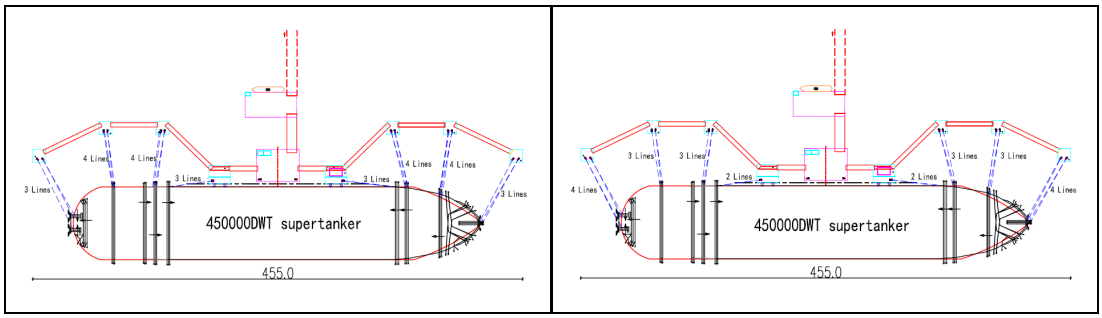

Fig.1a Mooring lines arrangements (3-4-4-3) Fig.1b Mooring lines arrangements (4-3-3-2)

**The standards of vessel safety operation.** According to the guidelines of OCMIF and the experience of past tanker mooring test[2,3], the standards of the large tankers ship operation are shown that the surging ≤±2.0m, the swaying ≤±2.0m, the heaving ≤±0.5m, the rolling ≤±2°, the maximum line tension did not exceed 50% of the line break force, the maximum impact force on fenders did not exceed the designed reaction force.

## Experimental Method

**Equipment and Measuring Instrument.** The testing was carried out in the wave basin of 60m in length, 40m in width, and 1m in depth. The measuring instrument include data acquisition system, wave height transducer, six degree freedom meters, fenders and cable force instrument, and ADV.

**Model Scale.** Following the gravitational similarity and the Wave Model Test Regulation (JTJ/T234-2001)[4], the geometric scale of the model is 1:60.

**Model of Vessel.** The vessel model (seeing Fig2a) and prototype were satisfied with similarity conditions as Geometric similarity, Gravitational similarity and Dynamic similarity.

**Fender simulation.** The simulation for fender should make sure the reaction force-deflection curve and absorbed energy curve were similar to the prototype (seeing Fig2b).

**Mooring Line simulation.** To make sure that the length and elasticity of mooring line in test was similar to prototype (seeing Fig.2c). The line force ~ elongation curve was according to the formula in Wave Model Test Regulation.

**Wave simulation.** The wave was calibrated at the berth with the JONSWAP spectrum.

Fig.2a Model of vessel

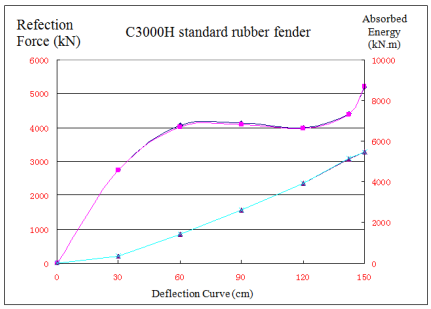

Fig.2b Fender simulation

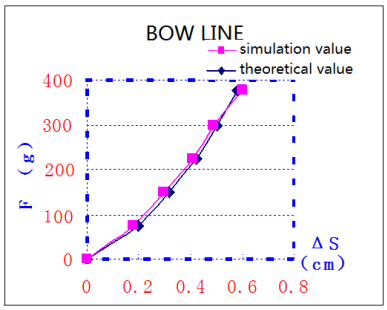

Fig.2c Mooring Line simulation

## Test Results

In the general ship mooring test, the influence on the mooring ship on the beam sea was greater than the following and quartering seas by the same wave condition. The combination of the ship's loadage with water level, the full load with low water level and the ballast with high water level were the most adverse condition in ship mooring test. According to the relevant regulations of "Design Code of General Layout for Sea Port" in our country, the permitted wave height，wave period and wind for large oil tanker safety working were $H_{4\%}$≤1.5m, T≤8s and wind speed was less than 6 grades. So the experiment used the condition of the beam sea and beam wind, which the wave height was $H_{4\%}$=1.2m, 1.5m and the wave period was T=7s, 8s. The test conditions and schematic diagram were shown in table 2 and Fig.3 respectively.

Based on the above test conditions, the swaying and the rolling of six degree freedom, the maximum line tension and the maximum impact force on fenders were discussed in the paper.

Table 2 Mooring test condition of 450,000DWT supertanker

| Loadage | Water level | Wave | Wind and Current |
|---|---|---|---|
| Full load | DLWL 0.68m | Beam sea $H_{4\%}$=1.2, 1.5m，T=7, 8s | Offshore wind with13.8m/s Flood current with 0.85 m/s |
| | | | Onshore wind with13.8m/s Ebb current with 1.0 m/s |
| Ballast | DHWL 7.06m | Beam sea $H_{4\%}$=1.5m，T=7, 8s | Offshore wind with13.8m/s Flood current with 0.85 m/s |
| | | | Onshore wind with13.8m/s Ebb current with 1.0 m/s |

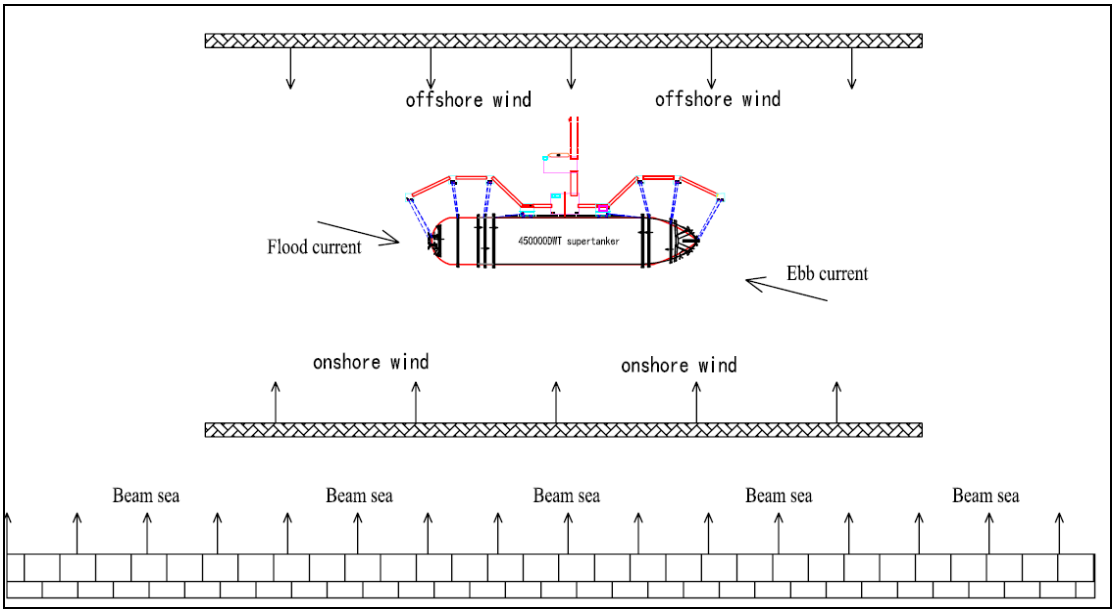

Fig.3 Test working schematic diagram

The test results of steel cable with 44mm and 52mm were shown in table 3 and table 4, the test result of combination cable with 52mm was shown in table 5.

Table 3 Test results of steel cable with 44mm（mooring lines arrangements with 3-4-4-3）

| test conditions | Wind and Current | Wave condition | swaying（m） | rolling（°） | maximum line tension（kN） | maximum impact force on fenders（kN） |
|---|---|---|---|---|---|---|
| the full load with low water level | Offshore wind and Flood current | $H_{4\%}$=1.5m T=7s | 0.84 | 0.29 | **652** | 3016 |
| | | $H_{4\%}$=1.2m T=7s | 0.65 | 0.29 | **566** | 1249 |
| | | $H_{4\%}$=1.5m T=6s | 0.53 | 0.16 | 425 | 971 |
| the ballast with high water level | Offshore wind and Flood current | $H_{4\%}$=1.5m T=7s | 0.95 | 1.59 | **694** | 3008 |
| | | $H_{4\%}$=1.2m T=7s | 0.73 | 0.79 | **590** | 1251 |
| | | $H_{4\%}$=1.5m T=6s | 0.68 | 0.65 | 529 | 1114 |

Table 4 Test results of steel cable with 52mm（mooring lines arrangements with 3-4-4-3）

| test conditions | Wind and Current | Wave condition | swaying（m） | rolling（°） | maximum line tension（kN） | maximum impact force on fenders（kN） |
|---|---|---|---|---|---|---|

| | | $H_{4\%}$=1.5m T=7s | 0.36 | 0.26 | 369 | 4318 |
| the ballast with high water level | Offshore wind and Flood current | $H_{4\%}$=1.5m T=8s | 0.82 | 1.56 | **1018** | 3889 |
| | | $H_{4\%}$=1.5m T=7s | 0.74 | 1.38 | 725 | 3408 |
| | Onshore wind and Ebb current | $H_{4\%}$=1.5m T=8s | 0.64 | 1.33 | 687 | **4459** |
| | | $H_{4\%}$=1.5m T=7s | 0.55 | 1.08 | 502 | 3376 |

Table 5 Test results of combination cable with 52mm（mooring lines arrangements with 4-3-2-2）

| test conditions | Wind and Current | Wave condition | swaying（m） | rolling（°） | maximum line tension（kN） | maximum impact force on fenders（kN） |
|---|---|---|---|---|---|---|
| the full load with low water level | Offshore wind and Flood current | $H_{4\%}$=1.5m T=8s | 1.04 | 0.24 | 547 | 2955 |
| | Onshore wind and | $H_{4\%}$=1.5m T=8s | 0.63 | 0.38 | 336 | **4507** |

| | | | | | | |
|---|---|---|---|---|---|---|
| | Ebb current | $H_{4\%}$=1.5m T=7s | 0.54 | 0.25 | 328 | 4327 |
| the ballast with high water level | Offshore wind and Flood current | $H_{4\%}$=1.5m T=8s | 1.09 | 2.00 | 777 | 3536 |
| | Onshore wind and Ebb current | $H_{4\%}$=1.5m T=8s | 0.61 | 1.72 | 306 | 4364 |

**Remarks:** The bold data in the table above was exceeding the ship safety operation conditions.

According to the test results, on the ballast condition when mooring line arrangements was 3-4-4-3, and under the combined action of the wave ($H_{4\%}$=1.5m, T=7s), offshore wind and flood current, the maximum swaying and line tension of the steel cable with 44mm were 0.95m and 694kN which was exceeded 50% of the line breaking force. When increased cable diameter to 52mm, the maximum swaying was 0.74m and the maximum line tension was 725kN. Although the line tension was bigger, the value was not exceeding the 50% of the line breaking force. So to increase the steel cable's diameter could enhance the vessel's ability to operation.

In addition, on the ballast condition and under the combined action of the wave ($H_{4\%}$=1.5m, T=7s), offshore wind and flood current, the maximum swaying, rolling and line tension of steel cable with 52mm were 0.82m, 1.56°, and 1018kN. When using the combination of cable with the line arrangements of 4-3-3-2, the maximum swaying, rolling and line tension were 1.09m, 2.0°, and 777kN. The reason was that the elastic deformation of combination cable was large, so the ship's swaying was increased, but the cable's number and the tension was reduced, which enhanced the vessel's operation ability relatively.

## Conclusions

It can be seen from the mooring test results of the 450,000DWT supertanker that on the combined action of wind, wave, current of different water level and loadage. The safety operation wave condition by using steel cable with 44mm was $H_{4\%}\leq$1.5m, T≤6s under the mooring lines arrangements of 3-4-4-3. The safety operation wave condition by using steel cable with 52mm was $H_{4\%}\leq$1.5m, T≤7s under the mooring lines arrangements of 3-4-4-3. And the safety operation wave condition by using combination cable with 52mm was $H_{4\%}\leq$1.5m, T≤7s under the mooring lines arrangements of 4-3-3-2.

Furthermore, by increasing the steel cable's diameter did not reduce the line tension, but could reduce the ship's movements, enlarge the line breaking force and enhance the ship operation ability. Compared with the pure steel cable, the vessel's movements increase with the increment of elastic deformation of composite cable. However the cable's number and the line tension was reduced with the improvement of vessel's operation ability relatively.

**Keywords:** large caisson, positioning, movement, cable force, experiment and research.

**Abstract.** The traditional method of the offshore caisson positioning and installing is using the barge or floating crane, but for the large caisson with 26,000 tons, the method is unable to achieve apparently. In this paper, the offshore location and installation of the large caisson with mooring line system and anchor cable system are studied. The research gets the wave and flow conditions results as well as the related and advertent items, which provide the reference for large caisson positioning and installation as well as the similar engineering construction technology.

## Introduction

At present, the caisson was widely used in the port engineering construction in our country, such as the harbor wall, piers, breakwaters, and lighthouses, etc. The caisson weight was development from hundreds of tones to tens of thousands of tones with the development of port construction to deepwater. For example, the large caisson with 26,000 tons was used in the main cable tower foundation of the Bridge of Dalian South Binhai Avenue engineering [1]. The caisson's size, weight and area was far more than the traditional scale, which was the first in china. As to the construction technology for the large caisson, It was concreted on the shore or in dock, then was floated to the engineering sea area for positioning and sink to the rubble-mound foundation smoothly by filling water.

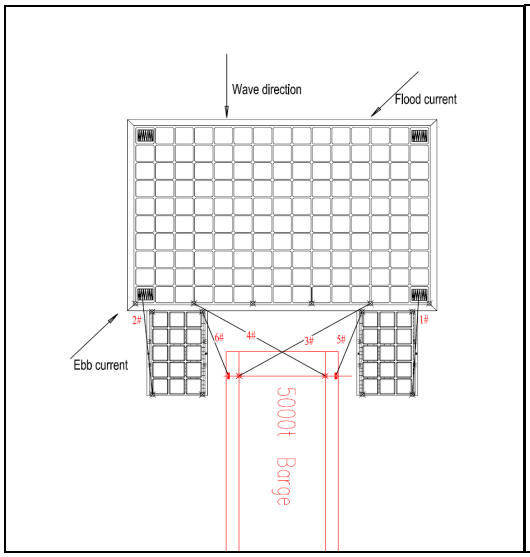
In the whole process of the construction, the stage of positioning and sinking at sea was the most difficult and critical. The traditional construction method was using the barge, but for the capacity of large caisson, this method was difficult and high risk. On this study, two positioning method was adopted. One was using cable system to position, which was similar to the vessel docking on port, on this method, two small caissons was set in advance in the engineering area, the large caisson was docking on the small caisson, through adjusting the cable to marine positioning and sinking,( seeing in Fig. 1). Another method was using anchor system to position, on this method, six anchors were set up in advance in engineering area, the large caisson was moored on the anchor, through adjusting the tightness of the anchor cable to marine positioning and sinking, (seeing in Fig. 2).

## Physical Model Test

**Caisson Model.** The large caisson with 26,000 tons was tested in the study[2], which basic size was shown in table1.

**Cable Simulation.** The nylon rope with the diameter of 80mm was used in the positioning with cable system, which breaking force was 900 kN.

The steel line with diameter of 44mm and length of 240m was used in the positioning with anchor system, which breaking force was 1070 kN.



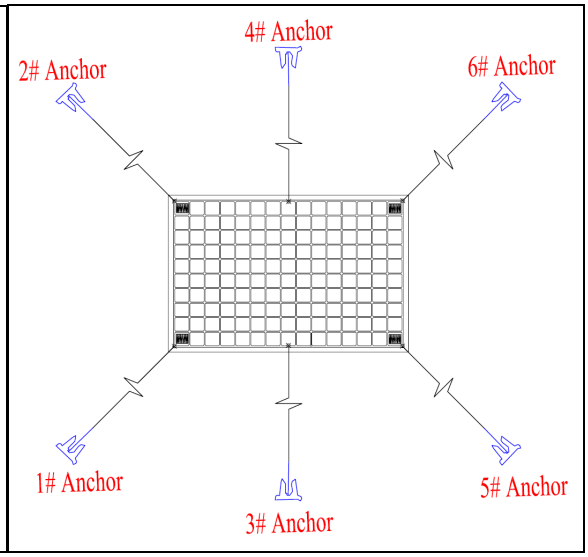


Fig.1 Positioning with cable system Fig.2 Positioning with anchor system

Table1 The basic size of the caisson (Scale:1:40)

| basic size | length（m） | width（m） | height（m） | draft（m） | displacement（t） |
|---|---|---|---|---|---|
| Prototype value | 69.0 | 44.0 | 17.0 | 8.29 | 26000 |
| Model Values | 1.725 | 1.10 | 0.425 | 0.207 | 0.406 |

**Wave Condition.** The nature water depth of the offshore area was 18m and the water depth of the foundation bed was 15m. The wave condition was shown in table2.

Table2 Wave condition

| | |
|---|---|
| Wave condition | Wave direction was positive for caisson long axis (seeing figure 1 and figure 2). |
| Wave spectrum | Code for seaport hydrology spectrum of China |
| Positioning with cable system | $H_{13\%}$=1.0m， T=5.0s, 6.0s |
| Positioning with anchor system | $H_{13\%}$=0.8m~1.2m， T=6.0s~8.0s |

## Test Results for Positioning with Cable System

**Test Program.** The installation process of cable system to position was that: firstly, two small caissons were set in advance in the engineering area, a 5,000 tons barge was stop behind the small caissons[3], the front two rope of barge were moored on the small caissons and the back two rope of barge were anchored in the sea. There were four ropes on the large caisson to make it docked on the small caisson, two were moored on the small caissons and two were moored on the barge. Through adjust the cable to make the large caisson marine positioning and sinking.

**Test Content.** The movements and the cable force under the different draft (d=8.29m,14.5m) and the conditions of wave ($H_{13\%}$=1.0m, T=5s, 6s) and current (V=0.5m/s, 0.2m/s) were given[1] (seeing figure 1). The movement was given the swaying and rolling of the large caisson, and the cable force was given the maximum value of the cables. The test photos were shown in figure 3 and the test results were shown in table 3.

Fig.3 Testing photos for Positioning with cable system

**Test Analysis.** It can be seen from the test that:

(1) Under the wave action, the bigger the caisson draft, the smaller the swaying and rolling, each cable force was relatively uniform, the largest cable force did not exceed 200kN.

(2) Under the combination of spring tide and waves, the large caisson was docked on the small caisson and had drift on the length wise direction, due to which the cable forces on large caisson were not uniform as well as the large impact force on the small caisson.

(3) Under the combination of ebb tide and waves, the large caisson was left from the small caisson and the impact force on the small caisson was 0kN. Each cable force was relatively uniform; the largest cable force did not exceed 200kN when the flow velocity did not exceed 0.2m/s.

(4) According to the large caisson positioning by cable system, the impact force on small caisson was very large on the condition of spring tide, so we should select the better wave condition with slack current or the ebb tide of less velocity for positioning. The wave and flow conditions on positioning were the $H_{13\%}$ less than 1.0m, T less than 6s and the ebb velocity less than 0.20m/s. If the velocity was bigger, it was sensible to enhance the strength of cable or increase the number of cable, but the velocity of ebb should not be more than 0.50 m/s.

Table3 The test results of the large caisson positioning with cable system

| Draft | Wave | Current | Swaying (m) | Rolling (°) | Impact force on small caisson (kN) | The maximum cable force (kN) |
|---|---|---|---|---|---|---|
| 8.29m | $H_{13\%}$=1.0m T=6s | none | -1.04~0.26 | -1.48~1.82 | 8073 | 194 |
| | | Flood with 0.50m/s | -0.99~0.31 | -0.90~1.09 | 10000 | 427 |
| | | Ebb with 0.50m/s | -0.55~0.84 | -1.09~1.25 | 0 | 215 |
| | | Flood with 0.20m/s | -0.65~0.12 | -0.98~1.06 | 8301 | 129 |
| | | Ebb with 0.20m/s | -1.03~0.24 | -0.92~1.18 | 0 | 195 |
| 14.5m | $H_{13\%}$=1.0m T=6s | none | -0.80~0.31 | -0.27~0.18 | 7942 | 99 |
| | | Flood with 0.50m/s | -0.59~0.04 | -0.32~0.42 | 9025 | 562 |
| | | Ebb with 0.50m/s | -0.42~0.36 | -0.23~0.20 | 0 | 286 |
| | | Flood with 0.20m/s | -0.54~0.05 | -0.21~0.39 | 8213 | 182 |
| | | Ebb with 0.20m/s | -0.86~0.38 | -0.35~0.36 | 0 | 190 |

Remarks: swaying is positive in the wave direction, negative in inverse wave direction

## Test Results for Positioning with Anchor System

**Test Content.** The Schematic plot of Caisson positioning with anchor system was shown in Fig. 2. The caisson's swaying, rolling and the maximum value of cable tension were given in the test results. The test photos were shown in Fig. 4 and the test results with different waves ($H_{13\%}$=0.8m~1.0m, T=6s~8s) and drafts (d = 8.29 m, 10.5 m, 13.0 m, 14.0 m, 15.0 m) were shown in Fig. 5.

Fig.4 Test photos of positioning with anchor system

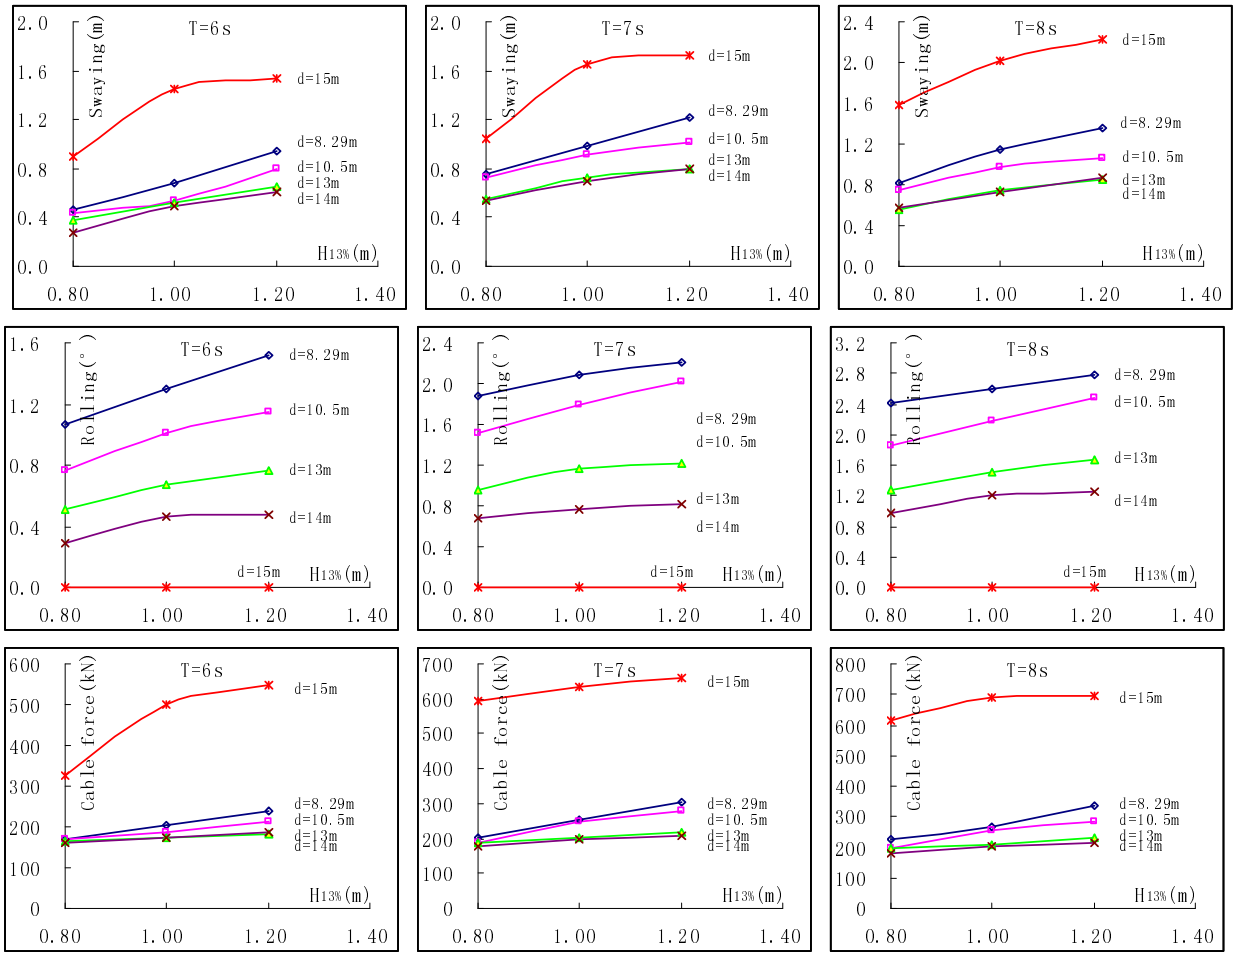

Fig.5 Testing results for positioning with anchor system

**Test Analysis.** It can be seen from the test that:

(1) The large caisson moved back and forth following the wave before it was located on the foundation. The swaying, rolling and anchor cable forces were increased with wave height and period, but were decreased with drafts. Along with the rising of the drafts, the stability of the caisson was better.

(2) When the caisson was just located on the foundation (d = 15.0m), the swaying and anchor cable forces under the wave action were much bigger than other drafts. Mainly because there was still the displacement under the wave action, however due to the friction on the bottom of the foundation bed,

this displacement was no longer the back and forth movement, which swaying was increased gradually, and the cable forces on the sea side were gradually increasing. Eventually the anchor system was built up a new balance.

(3) According to the test results, it's better to increase the caisson draft appropriately when the large caisson was positioned with anchor system. The most dangerous stage was the caisson near or just located on the foundation bed, it was necessary to take some corresponding measures to prevent the caisson moving on the foundation bed, for example assisted by tug, at the same time increased the caisson's gravity as soon as possible, or using barge lifting the enough weight on the caisson, to ensure the stability of caisson.

## Conclusions

In this paper, two methods of the large caisson offshore positioning were introduced, and the movements and the cable tension under wave action were given by the physical model test. According to the research results, when the large caisson was positioned by cable system, it should choose the better wave condition when the ebb current velocity was little or slack. If the flow was large to enhance the strength of cable or increase the number of cable. When the large caisson was positioned by anchor system, it's better to increase the caisson draft appropriately. To ensure the stability of caisson, it should take some corresponding measures to prevent the caisson moving on the foundation bed when the caisson near or just located on the foundation bed.

**Keywords:** Two-Dimensional finite element, seawall, numerical analysis, constitutive models

**Abstract:**Two-Dimensional finite element analysis was used to investigate the performance of seawall construction over weak subgrade soil using artificial base layer material consisted of cemented sand cushion comprising geosynthetics materials. Two types of base layer materials pure sand and cemented sand comprising husk rich ash and two types of geosynthetics materials geogrid and geotextile were used. Constitutive models were used to represent different materials in numerical analysis. The competence of two-dimensional numerical analysis was compared with experimental results. Numerical results showed a superior harmony with the experimental results. Finite element analysis model proved to be a great tool to determine the parameters that are difficult to measure in laboratory experiments. In addition, finite element analysis has the benefit of cost and time saving when compared to experimental investigation work. Numerical results showed strain induced in geosynthetics eliminated beyond a distance approximately equal six times of footing width.

## INTRODUCTION

Numerical analysis based on a method of finite element is a powerful tool for studying the performance and characteristics of different earth work applications. Applying finite element analysis can determine the complicated parameters that would be difficult to measure in experimental work. In addition, finite element analysis is used as a good alternative process for laboratory investigation studies especially in case of large physical models, which leads to saving the time and costs associated with construction of physical models. Several investigators, including Duowen and Hargrove (2006), Chandra and Khaled (2005), Mauricio (1998), Rodrigues (1998), Hashem et.al (2000), Ahmed (2004), Hassona et.al (2005) and Love et.al (1987) investigated the performance of reinforced soil system using numerical analysis based on finite element analysis method. Finite element code called DSC-SST-2D was used to predict the field behavior of reinforced soil based on advanced constitutive models (Chandra and Khaled, 2005).

The main objective of this study is develop a methodology to predict the performance of pavement structure underneath the contact area of wheel over weak subgrade seawall layer using artificial cemented sand layer comprising husk rice ash reinforced with geosynthetics materials using numerical analysis based on finite element method in two dimensional analysis. A comparison between numerical and experimental results is presented. The parameters investigated in this research include the thickness of the base layer sand or artificial cemented sand, type of geosynthetics, position of geosynthetics within base layer thickness and type of base layer materials. The comparison is also verified using previous experimental studies related to this study area as a comparison between numerical and experimental to evaluate the validity of numerical analysis.

## NUMERICAL PARAMETERS

As mentioned above the main four different materials used in the experiment are soft clay, sand, artificial cemented sand and geosynthetics. Modified cam model, hyperbolic model, linear elastic model and slip surface model were used to represent soft clay soil, layer of sand or artificial cemented materials, geosynthetics and the interface between different materials surfaces respectively. These parameters are presented in Table 1.

To obtain a complete set of non-linear elastic-plastic, that called hyperbolic, model parameters, unconsolidated drained Traixial compression tests were conducted on representative sand and cemented sand samples. Two modules are used in this method, the initial modules Ei and the tangential modules, Et are calculated as per the following.

Table 1. Numerical parameters of modified cam clay model

| Property | Value | Property | Value |
|---|---|---|---|
| Over-consolidation ratio (OCR) | 1.00 | Nu (ν), (Specific volume) | 1.94 |
| Lambda (λ) | 0.21 | Kappa (κ) | 0.04 |
| Gamma (Γ) | 0.80 | Mu (M) | 0.28 |
| Pre-consolidation pressure (Pc) | 0.31 | Unit weight, ( γ ) | 17.9 kN/m2 |

$$E_i = K_L P_a \left( \sigma_3 / P_a \right)^n \tag{1}$$

$$E_t = \left[ 1 - \left\{ R_f (\sigma_1 - \sigma_3)(1 - \sin\phi) \right\} / \left\{ 2C(\cos\phi) + 2\sigma_3 \sin\phi \right\} \right]^n \times E_i \tag{2}$$

Where, Ei= initial insitu modules as a function of confining pressure (σ3) and atmospheric pressure (Pa), KL= loading modules number, Pa= atmospheric pressure (used as a normalizing parameter),

σ3= confining pressure, n= exponent for loading behaviour, Et= Tangent modules, ϕ= Friction angle of soil, RF= ratio between the asymptote to the hyperbolic curve and the maximum shear strength, σ1= major principal stress and σ3 = minor principal stress.

The parameters describing the young's modules based on a hyperbolic fit to the stress-strain curve are K, n, C, ϕ and Rf. The different numerical parameters of hyperbolic model for different features of sand cushion layer used in this research to represent in finite element analysis are presented in Table 2.

Table 2. Numerical parameters of hyperbolic model for different sand features

| Property | Value | |
|---|---|---|
| | sand | Cemented sand |
| Friction angle, $\phi$ | 34.00° | 38° 15' |
| Cohesion, C kN/c2 | 0.00 | 13.00 |
| Failure ratio, Rf | 0.73 | 0.72 |
| Modulus exponent, n | 0.06 | 0.33 |
| Modulus number | 380 | 487 |

The interaction characteristics between the soil mass and any different material type can be modeled by introducing interface elements models that called slip surface model as mentioned above. The different values of shear stiffness are tabulated in Table 3.

Table 3. Shear stiffness values for different interface composite materials

| Interface Surface | K shear (N/mm) | Interface Surface | K shear (N/mm) |
|---|---|---|---|
| Clay-sand | 12.00 | Sand-geotextile | 88.00 |
| Clay-cemented sand | 13.00 | Sand-geogrid | 112 |
| Clay-geotextile | 6.00 | Cemented sand-geotextile | 46.00 |
| Clay-geogrid | 5.10 | Cemented sand - geogrid | 53.50 |

Numerical model analysis configuration

Two-dimensional plain strain finite element analysis was used to simulate a width of footing that is representing the contact stress area of wheel vehicle in the field over seawall construction underlying weak subgrade soil layer. Only half of the physical model is considered in numerical analysis due to an axisymmetric at the center of the footing. The configuration alignments of finite element mesh in y-vertical and x-horizontal directions is shown in Figure 1. For mesh installation, different elements types are used 8-nodes quadrilateral element to signify modified cam clay and hyperbolic models, 4-nodes quadrilateral element to signify linear elastic and slip surface models, and 6-nodes triangular element to signify transition process in different area sizes of elements.

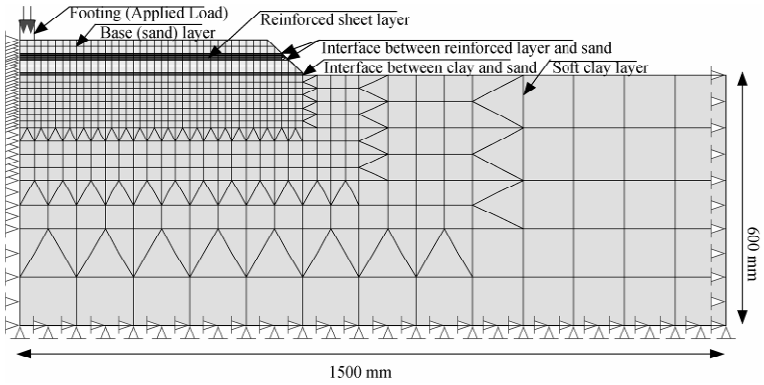

Figure 1. Configuration alignments of finite element mesh in two-dimensional

## RESULTS AND ANALYSIS

Stress pattern mechanism

Parameters investigated herein include the thickness of base layer, type of base material, geosynthetics type and position of geosynthetics sheet within base layer thickness. Stress distribution mechanism is a very important output of finite element analysis in case of earthwork construction analysis because it has used as a judge for the performance of seawall construction over weak subgrade layer in case of introducing stabilization techniques. Vertical stress contour lines in case of base layer thickness H = B, H is the base layer thickness and B is the width of footing, for different types of base layer materials of sand and artificial cemented sand over soft clay soil are shown in Figure 2. From these figures, it is clear that when cemented sand material introduced to the system the depth of stress bulb shifted up comparing with case of sand material alone. Therefore, existing cemented sand cushion in the system has a good resistance for stresses and the stress bulbs have a little extension within soft clay soil, which lead to increasing the bearing capacity of subgrade soil to sustain more loads comparing with case of sand cushion only.

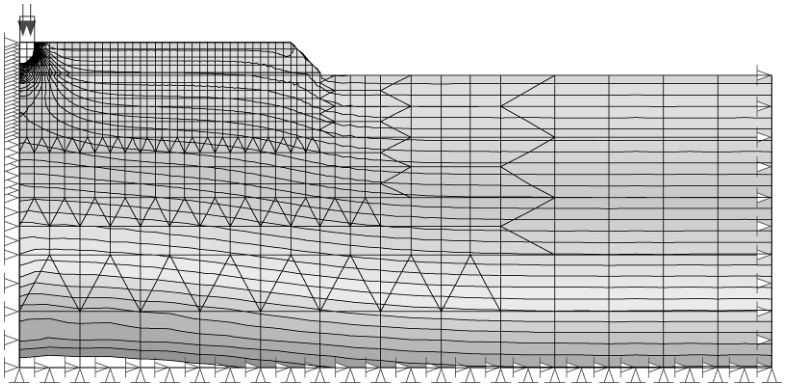

Figure 2. Vertical stress distributions contour lines in case of sand alone without additives for base layer thickness H=B

Figure 3 show the stress distribution contour lines in case of samples comprising one layer of geosynthetics located above clay directly and another layer within the mid of sand layer respectively for case of sand thickness H=B . From these figures, it is noticed that when

geosynthetics materials are applied, the stress bulbs squeeze and seems flatter in longitudinal direction before reaching the subgrade layer. Therefore, seawall stabilization, for two cases of base layer materials is increased when geosynthetics materials introduced to the system. This can be explained on the light of the following reasons: Firstly, most of stresses are cutting before to reach the subgrade layer. The second reason, the stress distributed over a large area that followed by decreasing in the stress values reaching to the subgrade layer. The third, when vertical stress applied to geosynthetics sheet, the stress adsorbed by geosynthetics and shifted to horizontal stress resisted by these materials, so the stability of seawall is increased and the resistance against applied loads is also increased.

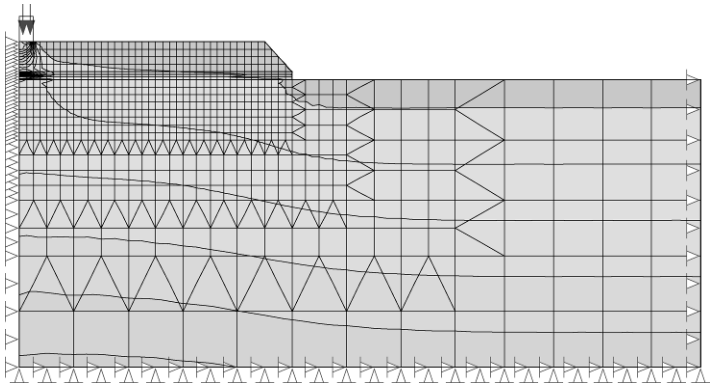

Figure 3. Stress distribution contour lines in case of sample H=B comprising one sheet of geogrid above clay layer

Displacement pattern mechanism

Deformations distribution pattern mechanism one of the important numerical analysis outputs to study the performance of seawall stabilization with different base layer materials. Deformed mesh is representing the deformation and corrugation happened within seawall mass after completing the process of loading. Figure 4 show the deformations in the mesh for sand and cemented sand layers. These figures indicate that the deformation pattern in case of sand layer is higher than the deformation in case cemented sand layer. These results confirm that the performance of seawall when cemented sand layer introduced is much pronounced than pure sand layer.

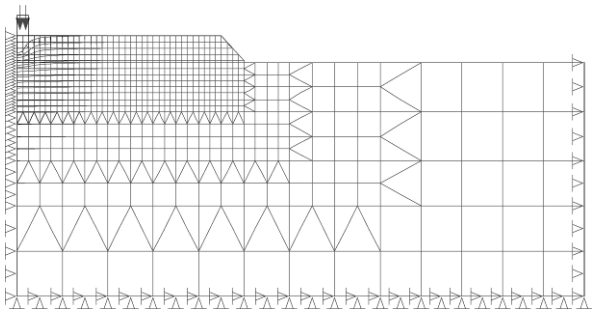

Figure 4. Mesh deformation in case of using sand for base layer thickness, H=B

Variation in Y-strain against horizontal distance along geogrid sheet at different positions for geosynthetics, the first position above clay layer directly and the second position in the mid of base layer are shown in Figure5.

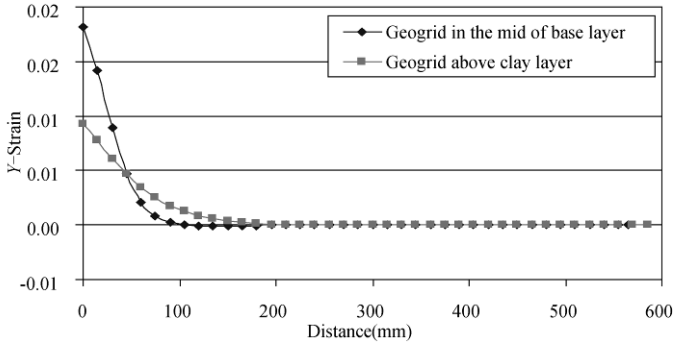

Figure 5. Variation in Y-strain against horizontal distance induced on geogrid sheet within base layer thickness in case of base layer thickness H=B

Deformations appear clearly beneath the footing and is gradually reduce until a distance that is approximately three times the width of the footing, it means six times of footing width because the problem solved as axisymmetric. It can be explained this results, when geogrid placed near to the footing affected early with stress comparing with geogrid placed at a deep distance from the footing. So when geogrid sheet placed near to the footing a high performance is obtained because the stress cutting early before to reach the weak clay layer and this result agree with experimental results for stress-settlement relationships.

## CONCLUSIONS

Based on above results the following conclusions can be drawn:

Two-dimensional finite element analysis is a good powerful too to study the performance of reinforced earth works.

Numerical results showed that artificial cemented sand is a good technique in seawall stabilization especially when geosynthetics introduced to the system comparing with identical sample having sand material. Increasing the thickness of base layer for both materials used enhancing the performance of stabilization.

Performance of geosynthetics in both of sand and cemented materials is a good while geogrid is much pronounced than geotextile. Numerical results indicated the best performance for geosynthetics is obtained when reinforced sheets are located nearest to the footing.

Vertical strain induced in geogrid is less than induced in geotextile and the effect of strain within geosynthetics mass eliminated after a distance equal six times of footing width.

Finite element analysis method gave good satisfactory results comparing with experimental results. In addition, a good agreement between these results and previous study results investigated the same way of parameters.

## ACKNOWLEDGEMENTS

# Accuracy Comparison for the Ocean Tide Models in EstuarineTidal Prediction, the Pearl River Estuary

Lei Zhu[1, a], Xiaoling Yin[1,b] and Liao Jiang[1,c]

[1]School of Civil Engineering and Transportation, South China University of Technology, Guangzhou, China

[a]juneyylei@gmail.com, [b]arxlyin@scut.edu.cn, [c]jiang18986015121@163.com

**Keywords:** ocean tide model, tidal prediction, RMS misfits, Pearl River Estuary

**Abstract.** Ocean tide models with satellite altimetry can simulate global ocean tides conveniently and accurately. However, it was not sure for them to have a same good performance in estuaries and coastal zones. To assess their accuracy in the Pearl River estuaries, tidal elevations were computed respectively by three models NAO.99b, OTPS and WWT, and compared with the hourly observed data. RMS misfits were calculated and the results suggest that the models are competent to demonstrate the basic time features of tides and the accuracy is not lower than that of traditional methods in some certain periods and areas. The models behave better in the mouth zones, especially in the open area outside, but in the upstreams have differences between dry season and flood season. At the entrances, compared with the river-dominated estuary, the models indicate more accurate estimations for the tide-dominated estuaries. WWT is recommended among these three models.

## Introduction

Ocean tides primarily influence ocean surface variation. Ocean tidal prediction is of critical importance for industrial and agricultural production, water conservancy, transportation and ecological environment. Furthermore, numerical simulation relative to estuarine hydrodynamic process usually needs ocean tides as boundary conditions [1]. The traditional methods of tidal prediction can be classified into two categories: regression analysis and harmonic analysis [2], though some other methods have also been proposed by the scholars [3,4]. The predictive error of these traditional methods is usually 20-30cm and it is difficult to use them properly in the areas lack of observational data [5]. Although hydrodynamic models can have more advantages, the computation is complex and strenuous [6].

A finite element method derived from hydrodynamic equations can estimate ocean tides [7] and has developed into a global ocean tide model in 1990s. Thanks to satellite altimetry, nowadays ocean tide models can have an accuracy of 2-3cm RMS (root-mean-square) error in deep ocean [8,9]. However, their uncertainties usually inflate significantly in estuaries, coastal zones and shallow seas [10,11]. Nevertheless, some researches indicated that the model accuracies in both China Sea and northwest Pacific Ocean are comparable to that in deep ocean [12-14]. As they are developing increasingly and become a convenient and available method for tidal prediction, we need to know how accurate they are for a particular estuary.

Pearl River Delta has a complicated river net system and three main estuaries: Lingdingyang Bay, Modaomen Estuary and Huangmaohai Sea. To assess the accuracy of ocean tide models in these estuaries, NAO99b, OTPS and WWT are used to predict the hourly tides at the points where the tide gauges have been set up, and the RMS misfits to the observed data are calculated and compared according to different locations, seasons and estuary types.

## Ocean tide models

Satellite altimetry is an active remote sensing technique introduced in 1970s, which makes it available to observe global ocean surface height [15]. In recent years, global or regional ocean tide models,

which are derived either by assimilating altimetry data only or in combination with tide gauge data into hydrodynamic models, have a variety of application in scientific researches and engineering.

In this article, the following three models are involved:

(1) NAO.99b

NAO.99b [16] is developed by assimilating about 5 years of T/P altimeter data, representing major 16 constituents with a spatial resolution of 0.5°. Compared with measured data of 200 tide gauges distributing along China Sea coast, the prediction of NAO.99b shows a better agreement than many other models, such as GOT4.7, FES2004, EOT10a and TPXO7.2 [8,17].

(2) OTPS

OTPS has a spatial resolution of 1/30° owing to combining altimeter data of T/P and Topex Tandem and being validated by 61 coastal and shallow tide gauges' data. Nine principle tidal constituents (M2, S2, N2, K2, K1, O1, P1, Q1 and M4) can be predicted, which is based on global and/or regional barotropic inverse tidal solutions obtained with OTIS [18].

(3) WWT

Tidal elevations and hydrograph in given period and location can be obtained easily on the official website of WWT (http://worldwidetide.com/). WWT's prediction is also based on OTIS, but has some improvement on computation [19].

## Comparison and analysis of prediction accuracy

We applied the three models in the places of tide gauge installation in the Pearl River estuary. But we noticed that the models had their playing scopes, i.e. S6 in Fig.1 was beyond. Thus the locations of these places concerned are shown in Fig. 1. The hourly tides obtained from the models were then compared with the measured values via the gauges.

To assess the modeling accuracy, the RMS misfit of tidal elevations are calculated, which is defined as:

$$\mathrm{RMS} = \left[\frac{1}{n}\sum_{i=1}^{n}\left(L_p^i - L_m^i\right)^2\right]^{1/2} \tag{1}$$

where $L_p^i$ and $L_m^i$ are tide levels at time *i* of ocean tide model and tide gauge data respectively, and *n* is the total number of times.

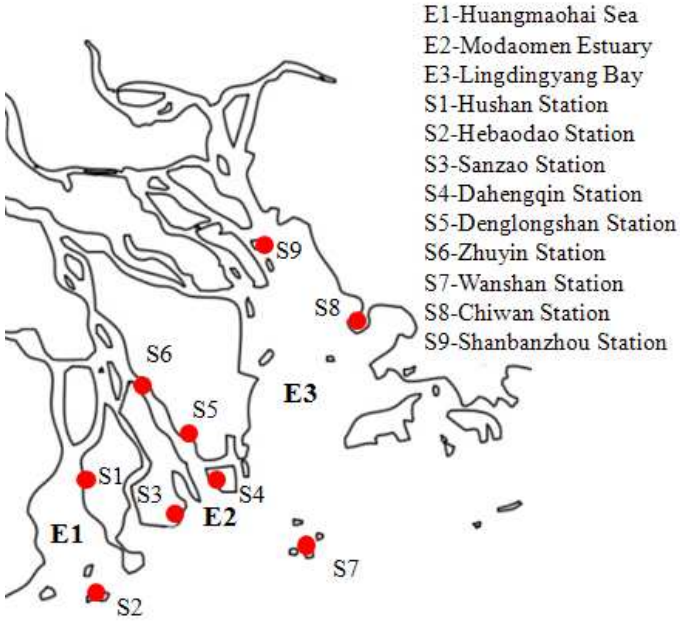

Fig. 1. Location of the tide gauges in Pearl River Estuary

**Comparison of time features of the tides.** The predicted tides compared with measured data during Feb. 2001 at Sanzao Station are shown in Fig. 2. The tidal curves of each model are generally in accordance with measured data except for a few individual moments with about one-hour errors, which suggests that the models are competent to the basic time characteristics of the tides.

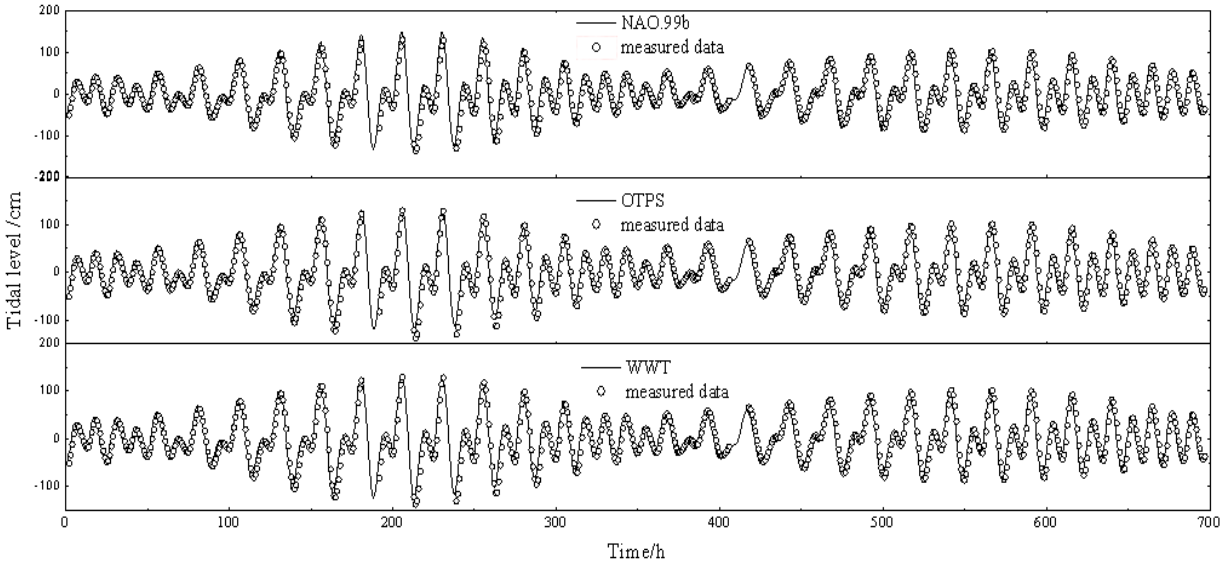

Fig. 2. The tidal curves of each model and measured data during Feb. 2001 at Sanzao Station

**Accuracy comparison at different locations in the same estuary.** The tides were predicted at Denglongshan, Dahengqin and Sanzao Station in or near Modaomen Estuary during Jan. 2006 and 2007. The result of RMS misfits is shown in Tab 1.

Tab 1. The RMS misfits at different stations in Modaomen Estuary. Note that "/" indicates the location is beyond model's coverage and italic letters represent the least RMS in a row. [cm]

| Tide gauge | Period | RMS misfit | | | |
|---|---|---|---|---|---|
| | | NAO.99b | OTPS | WWT | Average value |
| Sanzao | 2006.01 | 10.80 | 9.94 | *9.24* | 9.99 |
| | 2007.01 | 14.84 | 14.23 | *13.45* | 14.17 |
| Dahengqin | 2006.01 | 14.42 | 11.43 | *11.07* | 12.31 |
| | 2007.01 | 14.89 | 12.26 | *11.92* | 13.02 |
| Denglongshan | 2006.01 | 25.11 | / | *19.59* | 22.35 |
| | 2007.01 | 24.54 | / | *19.68* | 22.11 |

In Tab 1, at Sanzao and Dahengqin which are near the entrance, the RMS misfits of the three models are less than 15cm and the average is about 12cm, but at Denglongshan in the upstream the values are about 22cm. It can be seen that the RMS misfits increase gradually as the location moves from estuarine entrance to upstream in a specified estuary. Even so, the accuracy at estuarine entrance is higher than traditional methods'. Accordingly it can be assumed that a better accuracy can be gained in the area far outside from estuary.

**Accuracy comparison during flood and dry seasons.** Upstream runoff which is different during dry and flood seasons has an impact on tidal propagation in estuary. To evaluate the influence of runoff on model accuracy, the tidal levels at Sanzao, Dahengqin, Denglongshan and Shanbanzhou Station during both flood and dry seasons were predicted by the three models, with Tab. 2 showing the result.

From Tab 2, the average RMS misfits of the three models during flood and dry seasons are both 8.45cm at Sanzao Station. In contrast, compared with dry seasons, the RMS misfits during flood seasons are much larger at Dahengqin, Denglongshan and Shanbanzhou Station. Besides, the average RMS misfits at Shanbanzhou Station are larger than 30cm regardless of the season. As shown in Fig. 1, Sanzao Station lies in the open area outside Modaomen Estuary, suffering from little influence of runoff. By contrast, Dahengqin and Denglongshan Station are located inside Modaomen Estuary which has a substantial runoff during flood season. Shanbanzhou Station is in the upstream area of

Lingdingyang Bay, influenced by the runoff of Humen and Jiaomen Gate. As a result, the RMS misfits are immense and the difference between flood and dry season is obvious. Hence it is recommended that the predicted position had better deviate from the direction of runoff especially during flood season.

Tab 2. The RMS misfits during flood and dry seasons. Note that "/" indicates the location is beyond model's coverage and italic letters represent the least RMS in a row. [cm]

| Tide gauge | Period | | RMS misfit | | | |
|---|---|---|---|---|---|---|
| | | | NAO.99b | OTPS | WWT | Average value |
| Sanzao | dry | 2004.01 | *8.63* | 9.80 | 8.75 | 8.45 |
| | | 2001.02 | 7.25 | 7.70 | *6.39* | |
| | | 2007.02 | 8.73 | 10.39 | *8.41* | |
| | flood | 1998.07 | 7.91 | 7.82 | *6.84* | 8.45 |
| | | 2006.09 | 10.56 | 10.99 | *9.59* | |
| | | 2001.10 | 7.86 | 7.68 | *6.77* | |
| Dahengqin | flood | 2004.07 | 22.03 | 19.82 | *18.96* | 20.27 |
| Denglongshan | flood | 2004.07 | 38.20 | / | *33.70* | 35.95 |
| Shanbanzhou | dry | 1979.03 | / | 44.93 | *26.96* | 35.94 |
| | flood | 1978.07 | / | 50.86 | *34.01* | 42.44 |

**Accuracy comparison of different estuaries.** Pearl River Estuary is known for its different kinds of sub-estuaries. Huangmaohai Sea and Lingdingyang Bay belong to tide-dominated estuaries while Modaomen Estuary is a river-dominated estuary [20]. The accuracy comparison of different estuarine areas is shown in Tab 3.

Tab 3. The RMS misfits in different estuaries. Note that "/" indicates the location is beyond model's coverage and italic letters represent the least RMS in a row. [cm]

| Estuary | Period | Tide gauge | RMS misfit | | | |
|---|---|---|---|---|---|---|
| | | | NAO.99b | OTPS | WWT | Average value |
| Modaomen | 2006.01 | Dahengqin | 14.42 | 11.43 | *11.07* | 12.31 |
| | | Delongshan | 25.11 | / | *19.59* | 22.35 |
| Huangmaohai | 2001.01 | Hebaodao | 10.44 | 9.72 | *9.29* | 9.81 |
| | | Hushan | 30.63 | *25.18* | 26.11 | 27.31 |
| Lingdingyang | 2001.01 | Wanshan | 8.07 | *8.00* | 11.02 | 9.03 |
| | | Chiwan | *27.19* | 40.75 | 43.05 | 37.00 |

According to the RMS misfits in Tab 3, the average value of Danghengqin Station (12.31cm) is larger than that of Hebaodao and Wanshan Station (<10cm). At the entrances, hence, the models indicate more accurate estimations for tide-dominated estuaries. However, the RMS misfits at Denglongshan Station inside Modaomen Estuary are less than that of the stations inside Huangmaohao Sea and Lingdingyang Bay. So it is not appropriate to compare the accuracies of an estuary as a whole. The accuracy at a specified location inside an estuary is influenced by many factors such as the distance from entrance, local bathymetry, and hydrodynamic processes besides estuarine type.

Compared with the other two models, WWT has a higher accuracy in overall, especially in the entrance area, and a larger applying coverage.

## Conclusions

As the predictive accuracy of ocean tide models is considered unsure sometimes in coastal zones, to assess their performances in Pearl River Estuary, the RMS misfits of tidal levels generated from three ocean tide models (NAO99b, OTPS and WWT) against measured data were calculated. The comparison and analysis suggest that (1)ocean tide models are competent to demonstrate the basic time features of tides, and the accuracy of tidal levels is not lower than traditional methods' in some

certain periods and areas. (2)The models behavior better in the mouth zones, especially in the open area outside.(3)The accuracies in upstream have a certain difference between dry season and flood season. (4)At the entrances, compared with the river-dominated estuary, the models indicate more accurate estimations for tide-dominated estuaries. There is no clear conclusion inside the estuary because of more influencing factors. (5)WWT is recommended among these three models.

Ocean tide model is a convenient and available tool for tidal prediction in estuarine area. To obtain a better accuracy, it is recommended that the predicted position had better deviate from the direction of runoff and keep away from upstream as much as possible especially during flood season.

**Keywords:** Numerical Model, Finite Volume Method, Hydrodynamic Impact, HZM Bridge.

**Abstract.** In this paper, a 2D model for the simulation of shallow water flow by convection and diffusion over variable bottom is presented, which is based on the FVM (finite volume method) over triangular unstructured grids. The format of Reo's approximate Riemann is adopted to solve the flux terms. And the bed slope source term is treated by split in the form of the flux eigenvector. For the diffusion terms, the divergence theorem is employed to obtain the derivatives of a scalar variable on each triangular cell. The numerical model is adopted to simulate the hydrodynamic impact from HZM (Hongkong-Zhuhai-Macao) bridge on Pearl River estuary. The simulated results show that the HZM bridge has little influence on the distribution of hydrodynamic environment in the Pearl River estuary.

## Introduction

The shallow water equation has been experienced in FDM (Finite Difference Method), FEM (Finite Element Method) and FVM (Finite Volume Method) usually In the numerical discretization method,. The Finite Volume Method is an improved Finite Difference Method with a combination of Finite Element Method, and it can be strictly satisfied to physical quantity conservation through integral of each control volume[1]. Simulated by Finite Volume Method based on unstructured mesh, the numerical solution research of shallow water equations has gone from one-dimensional, two-dimensional to three-dimensional, where the boundary flux calculation between cells became the emphasis in solving shallow water equations. However, in shallow water, the diffusion motion is mostly not taken into account about the impact of shallow water equations. As the diffusion motion is an indispensable item of equations, and it's an important factor in the stability of numerical solution of shallow water equations in simulating actual flow movement [2]. Therefore it's necessary to conduct special studies of the numerical solution of shallow water equations combining with FVM based on unstructured grids.

The calculation of numerical flux is a very important part of solving shallow water equations with Finite Volume Method based on unstructured mesh. There are a lot of solutions to the numerical flux, such as Roe's approximate Riemann solver [3], HLL, as well as arithmetic average schemes and so on. The source terms treatment is also critical in shallow water equations, the simple treatment may lead to still water flowing over variable topography. The usual method is splitting source terms according to the decomposed form of eigenvectors of convective terms feature matrix [4]. The diffusion motion contains partial differential quadratic term, and the surface integral is translated into line integral after integrated over the calculating element, but there is still a differential term, which is one of the main reasons that diffusion motion isn't easy to deal with in solving shallow water equations [5]. In this paper, the diffusive flux in the interface is calculated by average of element interface, and it's treated similar to the Finite Element Method for the differential terms, so it can achieve numerical solution of shallow water equations with diffusion motion. Then the flow pattern around a pillar in tank are simulated, the result is present the model could be applied to simulate the complicated current structure in the water area around the hydraulic construction.

**Governing Equation**

When the size of plane is much larger then the vertical, two-dimensional shallow water equations can be used to describe the flow motion of calculated water area. Taking turbulence into account, flow governing equation can be expressed as formula (1).

$$\frac{\partial U}{\partial t}+\nabla E=S+\nabla E^{d} \tag{1}$$

with $U=(d,du,dv)^{T}$, $d$ is the total water depth, $d=h+\eta$ ($h$ is the water depth under horizontal plane, $\eta$ is the surface fluctuation, figure 1), $E=(F,G)$, and

$$F=\begin{pmatrix} du \\ du^{2}+gh^{2}/2 \\ duv \end{pmatrix},\quad G=\begin{pmatrix} dv \\ duv \\ dv^{2}+gh^{2}/2 \end{pmatrix} \tag{2}$$

where u and v are the velocity along the x and y coordinates, respectively.

The turbulent diffusion of equation is expressed as: $E^{d}=(F^{d},G^{d})$, where

$$F^{d}=\begin{pmatrix} 0 \\ \varepsilon_{x}d\partial u/\partial x \\ \varepsilon_{x}d\partial v/\partial x \end{pmatrix},\quad G^{d}=\begin{pmatrix} 0 \\ \varepsilon_{y}d\partial u/\partial y \\ \varepsilon_{y}d\partial v/\partial y \end{pmatrix} \tag{3}$$

and $\varepsilon_{x}$、$\varepsilon_{y}$ are the kinematic edd viscosity coefficients along the x and y coordinates, respectively, here isotropy is taken, then $\varepsilon_{x}=\varepsilon_{y}=\varepsilon$, $\varepsilon$ can be expressed as $\varepsilon=kdU_{*}$, where $U_{*}$ is the shear velocity, and it can be expressed as $U_{*}=\dfrac{n\sqrt{g(u^{2}+v^{2})}}{d^{1/6}}$.

The source term $S$ is written as formula(4).

$$S=S_{0}+S_{f}=\begin{pmatrix} 0 \\ gd(S_{0x}+S_{fx})+fv \\ gd(S_{0y}+S_{fy})-fu \end{pmatrix} \tag{4}$$

where $S_{ox}$ and $S_{oy}$ are bed slopes along the $x$ and $y$ coordinates, respectively, $S_{0x}=-\partial z_{b}/x$, $S_{0y}=-\partial z_{b}/y$, $z_{b}$ is the bottom level, and $S_{fx}$, $S_{fy}$ are the friction losses in terms of the Manning's roughness coefficient $n$:

$$S_{fx}=-\frac{n^{2}u\sqrt{u^{2}+v^{2}}}{d^{4/3}},\quad S_{fy}=-\frac{n^{2}v\sqrt{u^{2}+v^{2}}}{d^{4/3}} \tag{5}$$

The superscript $f$ is Coriolis force, $f=2\omega\sin\phi$, $\omega$ is the Earth's rotation speed, $\phi$ is the geographical latitude.

**Numerical Solution**

To be convenient for calculating, the computational domain is discrete using triangular grids, the variables are located herein at the geometric centers of the cells, and each grid cell represents a control volume. The formula (1) is integrated over computational domain, Gauss's theorem applied to integral given as follow formula (6).

$$\frac{\partial}{\partial t}\int_{\Omega}U d\Omega+\oint_{\partial\Omega}(E\cdot n)dl=\int_{\Omega}S d\Omega+\oint_{\partial\Omega}(E^{d}\cdot n)dl \tag{6}$$

the integral of each unit can be written as formula(7)

$$\frac{\partial U_i}{\partial t} A_i + \oint_{\partial \Omega_i} (E \cdot n - E^d \cdot n) dl = \int_{\Omega_i} S d\Omega_i \tag{7}$$

Where $Ai$ is the area of the cell $\Omega_i$ , $l$ is the boundary of triangle, the boundary integral of each cell is approximated by a summation over the triangle edges.

$$\oint_{\partial \Omega_i} (E \cdot n - E^d \cdot n) dl = \sum_{k=1}^{3} (E_k \cdot n_k - E^d{}_k \cdot n_k) l_k \tag{8}$$

The format of Reo's approximate Riemann is adopted to solve the convective numerical fluxes through one edge of triangle (such as the edge $l$ between adjacent cells $i$ and $j$ , $R$ and $L$ are the both sides of $l$ , respectively), the calculated type is as follow formula (9).

$$E \cdot n = \frac{1}{2}[(E \cdot n)_R + (E \cdot n)_L - \Delta E^*] \tag{9}$$

where $(E \cdot n)_R$ and $(E \cdot n)_L$ are numerical fluxes on both sides of interface, $\Delta E^*$ is the corrected value of flux on both sides and it's written as formula (10).

$$\Delta E^* = \sum_{k=1}^{3} \alpha_k |\lambda_k| e_k \tag{10}$$

where $\lambda_k$ and $e_k$ (k=1,2,3) are the eigenvalues and eigenvectors of convective characteristic matrix $A$ , it satisfies $\Delta E = A \Delta U$ , matrix form as follow formula (11).

$$A = \frac{\partial (E \cdot n)}{\partial U} = \begin{bmatrix} 0 & n_x & n_y \\ \left(\bar{c}^2 - \bar{u}^2\right) n_x - \bar{u}\bar{v} n_y & 2\bar{u} n_x + \bar{v} n_y & \bar{u} n_y \\ -\bar{u}\bar{v} n_x + \left(\bar{c}^2 - \bar{u}^2\right) n_y & \bar{v} n_x & \bar{u} n_x + 2\bar{v} n_y \end{bmatrix} \tag{11}$$

The $\bar{u}$ , $\bar{v}$ and $\bar{c}$ in matrix are calculated by mass-weighted average, they are expressed as follow formula (12).

$$\bar{u} = \frac{u_R \sqrt{d_R} + u_L \sqrt{d_L}}{\sqrt{d_R} + \sqrt{d_L}}, \quad \bar{v} = \frac{v_R \sqrt{d_R} + v_L \sqrt{d_L}}{\sqrt{d_R} + \sqrt{d_L}}, \quad \bar{c} = \sqrt{\frac{g(d_R + d_L)}{2}} \tag{12}$$

The eigenvalues of $A$ are present as formula (13).

$$\lambda_1 = \bar{u} n_x + \bar{v} n_y + \bar{c}, \quad \lambda_2 = \bar{u} n_x + \bar{v} n_y, \quad \lambda_3 = \bar{u} n_x + \bar{v} n_y - \bar{c} \tag{13}$$

The corresponding eigenvectors are shown as (14).

$$e_1 = \left(1, \bar{u} + \bar{c} n_x, \bar{v} + \bar{c} n_y\right)^T, \quad e_2 = \left(0, -\bar{c} n_y, \bar{c} n_x\right)^T, \quad e_3 = \left(1, \bar{u} - \bar{c} n_x, \bar{v} - \bar{c} n_y\right)^T \tag{14}$$

The corresponding coefficients of each term are respectively formula (15) and (16).

$$\alpha_{1,3} = \frac{\Delta d}{2} \pm \frac{1}{2\bar{c}} \left[\Delta(du) n_x + \Delta(dv) n_y - (\bar{u} n_x + \bar{v} n_y) \Delta d\right] \tag{15}$$

$$\alpha_2 = \frac{1}{\bar{c}} \left(\left[\Delta(dv) - \bar{v} \Delta d\right] n_x - \left[\Delta(du) - \bar{u} \Delta d\right] n_y\right) \tag{16}$$

where $\Delta(\bullet) = (\bullet)_R - (\bullet)_L$ .

**Hydrodynamic Impact from HZM Bridge**

The HZM(Hongkong-Zhuhai-Macao) bridge connects Hongkong, Zhuhai and Macao district, and it strctchs across the Pearl River estuary. A lot of piers and three large artifical islands would have some impact on the hydrodynamic environment in the Pear River estuary.

The isoline of velocity variation in water area nearby the bridge before and after engineering is showed in Figure 1. From the amplitude and range of the velocity variation in engineering waters in the process of flood and ebb tide we can see the east and west artificial islands in main navigable area and the man-made islands on Macao port are still main area of velocity variation, and the velocity of waters on upstream and downstream face is decreased after the brige constructed. Because the island and piers narrowed overcurrent section, the velocity of the main navigable waters between the eastern and western islands and the water area between the pier is increased when the bridge finished. If taking 0.02m/s as discriminant criteria of velocity variation, the coverage impacted by the artificial islands is within 5.0km upstream and downstream the bridge location, and the coverage of none-navigation area is within 1.0km water area up and down the bridge axis.

Fig1. Flow velocity change before and after HZMB in Lingding sea

## Conclusions

The numerical model of the shallow water flow is introduced to simulate the hydrodynamic impact from HZM (Hongkong-Zhuhai-Macao) bridge on Pearl River estuary. The shallow water equation is based on the FVM (finite volume method) over triangular unstructured grids. The format of Reo's approximate Riemann is adopted to solve the flux terms. And the bed slope source term is treated by split in the form of the flux eigenvector. For the diffusion terms, the divergence theorem is employed to obtain the derivatives of a scalar variable on each triangular cell. The computed results show that the HZM bridge has little influence on the distribution of hydrodynamic environment in the Pearl River estuary.

# The Research of Flow Resistance Property in the Tugging and Mooring of Tube Segment

Qiu Zhengzhong [1, a *] and Min Dong [2,b]

[1] CCCC Second Harbor Engineering Co., Ltd, Wu Han, Hu Bei, 430040

CCCC Water Transportation Consultants Co., Ltd, 100007

[a]bqiuzhengzhong@126.com, [b]117043742@qq.com

**Keywords:** fluent; tugging; mooring; resistance coefficient; numerical simulation

**Abstract.** The tube tugging and mooring is the key step in the process of the immersed tunnel, and the most important theoretical is the calculation of water flow force. According to the numerical simulation and physical model of the tube in the Pearl River, the difference value of the flow resistance coefficient can be calculated. The fluent software is used to simulate the process of the tube tugging and mooring. On the basis of the empirical data of the tube experiment in the Pearl River, the flow resistance coefficient is obtained in the process of the tube tugging.

## Introduction

By now, more than 100 immersed tunnels have been built at home and abroad and the construction technology has been maturing. In the process of immersed tunnel, the most important theoretical is the calculation of water flow force. By the related data analysis, the water flow force consists of frictional resistance, wave-marketing resistance and viscous pressure resistance. The frictional resistance is due to the effect of water viscosity, which makes the hull surface friction force. For the wave-marketing resistance, when the vessel motions in the static water, there will be a pressure area at the ship bow and a suction area at the stem. That will prevent the vessel due to the pressure difference in the motion direction of the vessel. The viscous pressure resistance is due to the viscous effect of water caused by the pressure resistance of the pressure difference front and back of the vessel. The water resistance coefficient in the process of the tube floating is studied in the paper[1-3].

## Numerical calculation of the flow resistance coefficient in the Pearl River

**parameter specification.** Calculate the difference value of the flow resistance coefficient between the numerical simulation and physical model of the tube in the Pearl River at the same boundary conditions. According to the book “design and construction of immersed tunnel”, the boundary conditions are introduced as follows.

The immersed tube length 2m, width 0.674m, height 0.156m, draft 0.136m

The numerical mesh: 200m×6m×0.17m

Sea-water density: 1.0×103kg/m³, viscosity: 1.003×10-3pa*s

When horizontal anchor, the velocity is 0.15m/s; when Longitudinal floating, the velocity is 0.302m/s

**The numerical simulation model.** The fine calculation model 1:1 is set up to describe the change of the flow field around the tube accurately and reduce the calculation errors. The tetrahedral mesh is adopted to the three-dimensional flow field in the channel and foundation trench.

Define origin of coordinates on the free surface, just center of poor upper surface. The water flows along the x-axis. As the distance between the bottom of the tube and the bed is relatively short, the flow velocity will be rapidly magnified when the tube incident flows. To obtain better calculation accuracy, the mesh spacing of the tube underside is 0.01, growth factor 1.1 and the maximum interval 0.05. In the end the total number of units is 1874740, with 389228 nodes. The model is shown as follows.

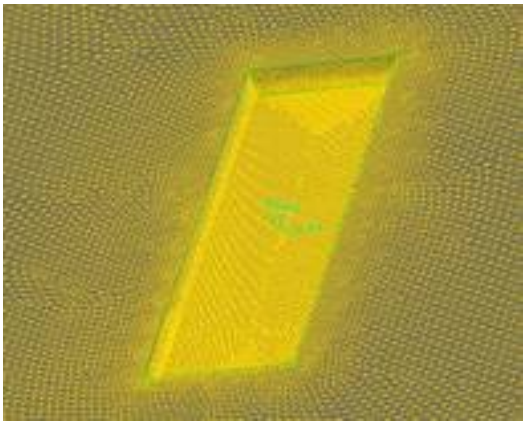

Figure1 Sketch map of tube mesh encryption

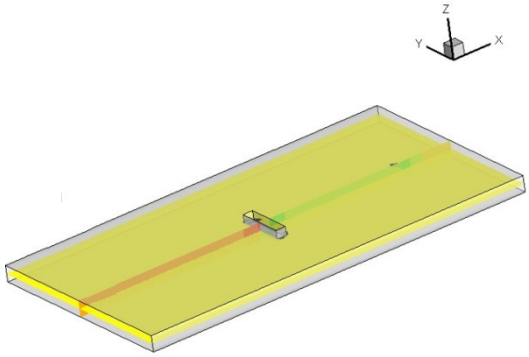

Figure 2 Sketch map of model section

**The calculation value of numerical simulation and physical model.** Comparing to physical model, the calculation value of the numerical simulation is increased by about 18% at the same operating condition seen from table 1. The reason of that are pretreatment processes, boundary layer setting and limits of the grid computing capacity of the fluent software.

Table1 Calculated Value of Numerical Simulation and Physical Model of the Tube in the Pearl River

| NO. | Tube Condition | Flow Velocity | Depth Draft Ratio | Resistance Coefficient | Amplification |
|---|---|---|---|---|---|
| 1 | horizontal anchor | Physical Model Value | 1.06m/s | 1.25 | 18.6% |
| | | Numerical Simulation Value | 1.06m/s | 1.25 | |
| 2 | Longitudinal floating | Physical Model Value | 2.135 m/s | 1.25 | 18% |
| | | Numerical Simulation Value | 2.135 m/s | 1.25 | |

## Analysis of computing result on the flow resistance coefficient of certain project tube

**Calculate purpose.** According to the data of the immersed tube tunnel, the calculation of the most unfavorable conditions that the least depth draft ratio of 180m standard tube sections is chosen. When the tube in the foundation trench wanting for sinking, the depth draft ratio of 180m standard tube sections is among 1.55~3.71 of the minimum design level -1.63m. The least depth draft ratio of 180m standard tube sections is chosen as the maximum resistance coefficient tube and the maximum capacity of the software fluent6.3 is chosen to calculate the resistance coefficient[4].

**Parameter specification.** Calculate the flow resistance coefficient of the numerical simulation at the preset boundary conditions. The boundary conditions are introduced as follows.

When horizontal anchor

The channel, width 200m, depth 13m

The numerical mesh: 1000m×200m×13m

The flow velocity is 1.5 m/s perpendicular to the face of tube incident flow.

When Longitudinal floating

The immersed tube length 180m, width 38m, height 11.4m, draft 11.4m

The numerical mesh: 1000m×760m×18m

The flow velocity is 1.5 m/s perpendicular to the face of tube incident flow.

**Result of calculation model.** The fine calculation model 1:1 is set up to describe the change of the flow field around the tube accurately and reduce the calculation errors. The tetrahedral mesh is adopted to the three-dimensional flow field in the channel and foundation trench.

Define origin of coordinates on the free surface, just center of poor upper surface. The water flows along the x-axis. The mesh spacing of the tube underside is 1.0, growth factor 1.2 and the maximum interval 3. The mesh spacing of the tube side is 2, growth factor 1.2 and the maximum interval 3. In the end the total number of units is 2095773, with 448338 nodes.

From figure 3-4, more than one vortex in the horizontal direction comes into being in the two sides of tube that incident flow and tail end. Seen from figure 4, because of groovy, the flow section is larger and the flow velocity is smaller. There is no vortex in the vertical direction of tube tail end.

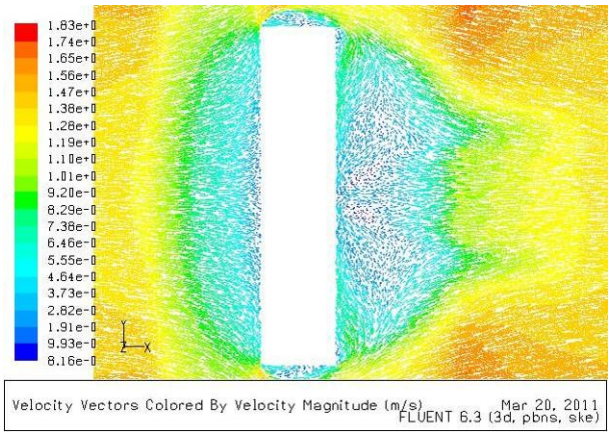

Figure 3 Flow field velocity vector of cross section

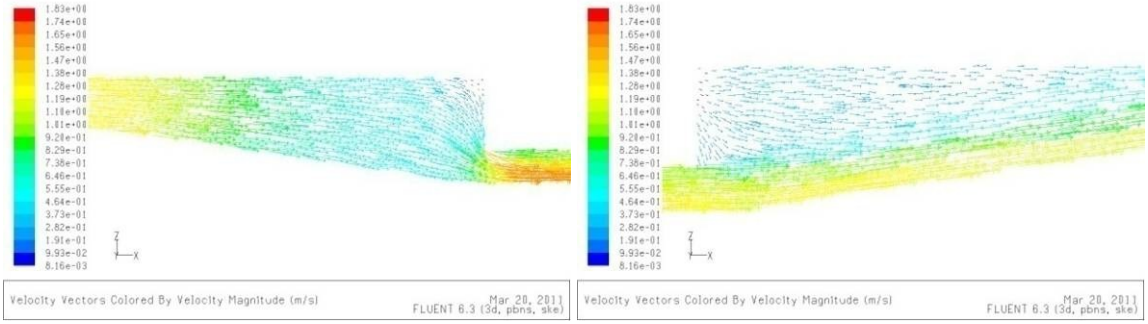

Figure 4 Flow field velocity vector (front end and tail endlongitudinal section)

**The calculation value of numerical simulation.** The flow velocity changes as the flow section changes. There is no vortex in the vertical direction in the tail end and very large flow separation in the horizontal direction[5].

The drag coefficient also has some relationship to the discharge capacity in the bottom of the tube. This also means depth draft ratio has some influence on the resistance coefficient

Table2 The calculated value of three-dimensional numerical simulation of the tube

| Tube Condition | Flow Velocity | Tube size | Depth Draft Ratio | Resistance Coefficient | remark |
|---|---|---|---|---|---|
| horizontal anchor | 1.5m/s | 180×38×11.4m | 1.55 | 2.31 | Turbulent flow |
| Longitudinal floating | 1.5m/s | 180×38×11.4m | 1.14 | 1.45 | Turbulent flow |

## Conclusions

By means of the comparison of calculated value between the numerical simulation and physical model of the tube in the Pearl River, the value of numerical simulation is larger by about 18% than the value of physical model under both horizontal anchor condition and longitudinal floating condition, which indicates that the software fluent is reliable.

According to the reliability of software fluent, the resistance coefficient of certain project when tube mooring is 1.96, as the value of numerical simulation is 18% larger than the value of physical model. In a similar way, when tube floating, the resistance coefficient of certain project is 1.23.

**Keywords:** Numerical simulation, Mild-slope model, Long wave, harbor resonance

**Abstract.** The general development plan of Tieshan port is designed to be long and narrow, for which the long wave induced resonance may be problematic. Within the present work, a numerical study on the effects of this kind of resonance is conducted. The simulations are performed with the use of the mild-slope model developed in Ref. [1], which was further validated in the present work to be able to predict reasonable results for the harbor resonance. To evaluate the wave resonance for the plan of Tieshan port, 71 offshore wave conditions with the period ranging from 50*s* to 400*s* have been calculated. The rationalities of the numerical solutions are analyzed through comparisons with the theoretical ones, and the general agreement is seen to be reasonable. Some preliminary results for the harbor resonant modes, the resonant periods and the corresponding amplification factors for the plan of Tieshan port have been presented.

## Introduction

Tieshan port is situated in Tieshan Bay, as seen in Fig. 1 (a), a southeast bay which is located in the northeast of Beibu Gulf, South China Sea, This port is being planed. Fig. 1 (b) shows the general development plan of Tieshan port, from which we see that the configuration of this plan consists of four rectangular harbors, with Harbor 1 (2840*m*×1000*m*) facing to the south-southeast, and with Harbor 2 (2100*m*×1000*m*), Harbor 3 (2700*m*×1000*m*) and Harbor 4 (7700*m*×1000*m*) connecting at the mouth, facing to the south-southwest. Within this general development plan, the long wave induced resonance might be problematic. This will be investigated numerically in the present work by using the mild-slope model developed in Ref. [1].

Harbor oscillations have been regularly observed in specific sea around the world, for example, the Longkou Harbor, China [2], the Hualien Harbor, Taiwan [3], the Port of Long Beach, USA [4], and etc. A harbor has certain resonant frequencies, or periods, depending on its size, geometry and water depth. If the period of the incident wave coincides with the harbor's resonant period, then this wave will be seized and amplified in the harbor. Sometimes, the amplification factor of the maximum wave height within the harbor relative to the wave height outside the harbor was so large that it would endanger the cargo loading and unloading activities, hamper the ship accommodations and damage the mooring facilities. Therefore, during the design stage, to avoid any undesirable resonant mode which may be close to the resonant periods of the ship-mooring system, it is important for the designers and planners to know the characteristics of the harbor oscillations, including the resonant mode, the resonant period and the amplication factor.

In previous, analytical, numerical and physical models are typical means used to determine the resonant characteristics of a harbor [5-7]. Nowadays, with the development of computer resources and numerical techaniques, numerical models, such as the mild-slope models [3, 8-9] and the Boussinesq models [10-11], have been more and more applied to this problem. Although the Boussinesq model can describe the nonlinear wave transformation behaviors, the higher order derivatives containing in the governing equations make the model's application to relative large areas very time-consuming. Therefore, in the present work the mild-slope model was chosen as a means to study the wave resonant characteristics of the plan of Tieshan Port.

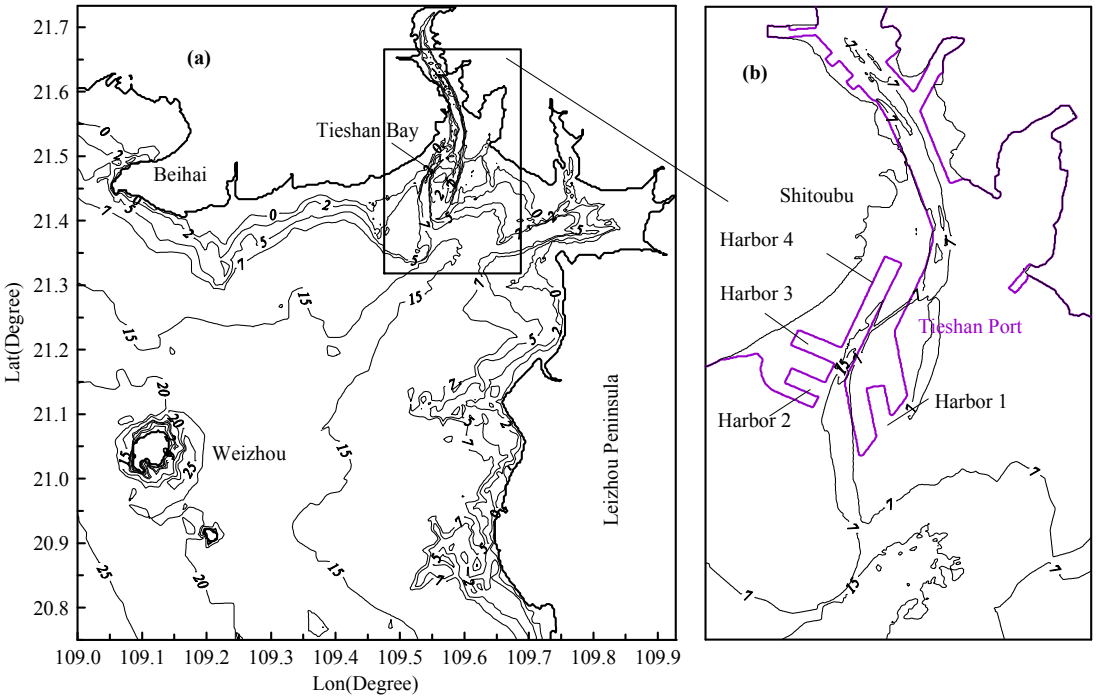

Fig. 1 The general development plan of Tieshan Port.

**Mathematical Foundations of the Mild-slope Model**

The numerical model used in this work is the mild-slope model that was developed in Ref. [1]. Some different numerical techniques for the wave generation and absorption have been introduced to this model. These will be briefly described in this section.

The governing equation of the mild-slope model is the time-dependent mild-slope equation that accounts for the energy dissipation and the internal wave generation, written as:

$$\frac{\partial^2 \zeta}{\partial t^2} + \sigma f_s \left(\frac{k}{k_c}\right)^2 \frac{\partial \zeta}{\partial t} - \left(\frac{\sigma}{k_c}\right)^2 \nabla^2 \zeta = S^*, \tag{1}$$

where $\zeta$ is the effective wave displacement; $\sigma$ is the wave frequency; $f_s$ is the wave energy dissipation coefficient; $k$ is the wave number, and it can be related to the wave frequency $\sigma$ by the linear wave dispersion relation; $k_c$ is the effective wave number, and it can be expressed as:

$$k_c{}^2 = k^2 - \nabla^2 \left(\sqrt{cc_g}\right) \Big/ \sqrt{cc_g}\,, \tag{2}$$

where $h$ is the local water depth; $C$ and $C_g$ are the wave velocity and the wave group velocity, respectively.

$f_s$ is the dissipation term that describes the wave energy dissipation in a sponge layer. According to Lee and Yoon [12], this term can be expressed as:

$$f_s = \begin{cases} 0, & x > x_s \\ \dfrac{\sigma^2}{k^2 cc_g}\left(\dfrac{e^{d/s}-1}{e-1}\right), & x < x_s \end{cases} \tag{3}$$

where $d$ is the distance from the point to the begining of the spone layer; $s$ is the width of the sponge layer; and $x_s$ is the begining location of the sponge layer.

$S^*$ is the source term that describes wave generation, and it can be expressed as:

$$S^* = \left(\frac{\sigma}{k_c}\right)^2 \frac{S}{g\sqrt{cc_g}}, \tag{4}$$

where $S$ is the internal wave generation funtion. According to Kim, *et al.* [13], $S$ can be expressed as:

$$S(x,y,t) = 2gc_g \delta(x - x_s)\cos(\theta)\eta_i, \tag{5}$$

where $\delta(x-x_s)$ is the Direclet function; $\theta$ is the angle of the incident wave direction relative to the generation line; $\eta_i$ is the incident wave free surface. According to the linear wave theory, $\eta_i$ can be expressed as:

$$\eta_i = \frac{H_i}{2}\cos\left(k_x x + k_y y - \sigma t\right), \tag{6}$$

where $k_x$ and $k_y$ are the wave number respectively in $x$ and $y$ direction; $H_i$ is in the incident wave height.

Eq. (1) is a time-dependent partial differential equation, which can be solved by a finite difference scheme developed in Ref. [1]. Setting the physical variables ($\zeta$, $k_c$, $C$, $C_g$ , $f_s$ and $S^*$) at the grid nodes, the finite difference scheme for Eq. (1) with constant space step $\Delta x$ , $\Delta y$ and time step $\Delta t$ can be described as:

$$\begin{aligned}&\frac{\zeta_{i,j}^{n+1}-2\zeta_{i,j}^{n}+\zeta_{i,j}^{n-1}}{\Delta t^2}+\sigma f_s\left(\frac{k}{k_c}\right)^2\frac{\zeta_{i,j}^{n+1}-\zeta_{i,j}^{n-1}}{2\Delta t}\\&=\left(\frac{\sigma}{k_c}\right)^2\left(\frac{\zeta_{i+1,j}^{n}-2\zeta_{i,j}^{n}+\zeta_{i-1,j}^{n}}{\Delta x^2}+\frac{\zeta_{i,j+1}^{n}-2\zeta_{i,j}^{n}+\zeta_{i,j-1}^{n}}{\Delta y^2}\right)+S^{*n}\end{aligned} \tag{7}$$

Re-arranging Eq. (7), we can obtain

$$\zeta_{i,j}^{n+1} = a_0\zeta_{i,j}^{n-1} + a_1\zeta_{i,j}^{n} + a_2\left(\zeta_{i+1,j}^{n}+\zeta_{i-1,j}^{n}\right) + a_3\left(\zeta_{i,j+1}^{n}+\zeta_{i,j-1}^{n}\right) + \frac{\Delta t^2}{a}S^{*n} \tag{8}$$

where $a_0 = -\left(1-\sigma f_s\left(k/k_c\right)^2\Delta t/2\right)/a$, $a_1 = 2\left(\frac{1}{a}-a_2-a_3\right)$, $a_2 = \left(\sigma\Delta t/\left(k_c\Delta x\right)\right)^2/a$, $a_3 = \left(\sigma\Delta t/\left(k_c\Delta y\right)\right)^2/a$, and $a = 1+\sigma f_s\left(k/k_c\right)^2\Delta t/2$. For the detailed calculation process of Eq. (8), one can see Ref. [1].

**Validation of the Mild-slope Model**

The above Mild-slope model has been validated in Ref. [1] through three benchmarks, including (1) the combined refraction and diffraction over a submerged elliptic shoal on a slope, (2) the resonant Bragg reflection of monochromatic waves from a sinusoidal ripple patch, and (3) the wave transformation near a shore parallel breakwater.

In this work, in order to validate the model's capacity to simulate the harbor resonance phenomenon, the wave transformation in a fully rectangular basin with a constant depth connected to the open-sea was numerically computed.This is a classical case of harbor resonance that has been widely studied by many researchers [3, 6, 8-9]. Analytically speaking, such a case is relatively simple to handle, but numerically it is complicated to simulate, because the numerical results are somewhat sensitive to the extent of the infinite ocean in the simulation. Fig. 2 shows the computational domain for this case. Here, the infinite ocean was approximated by a finite rectangular region $400m\times150m$. The geometry of the rectangular basin is $6m\times31m$, and the water depth is $25.73m$. The up side, the right side and the left side of the outer domain were all treated as the passing through boundaries, and these were attrived by arranging the sponge layer with width of $2.5L$ ($L$ is the wave length) along each of them. While for the inner basin's boundary and its perimeter, the total reflection boundary conditions were specfied. In order to capture the respond curve of the harbor, 23 different incident wave conditions with period ranging from $5.0s$ to $14.0s$ were numerically simulated. These waves were generated internally at $y_s$=$181m$, and the generated wave height $H_i$ was $0.1m$. The space grid is set as $\Delta x = \Delta y = 1.0m$ , and the time space is $\Delta t = 0.04s$ . The model runs until the waves in the computational domain reach the steady state.

Referring to Fig. 3 and Fig. 4, where the computed time series of the normalized free surface displacement ($\eta/H_i$) at the harbor mouth (position A) and at the harbor end (Position O) for $T$=$11.3s$ and $T$=$5.5s$ are presented, we can find that the numerical results are stable. The relative wave height

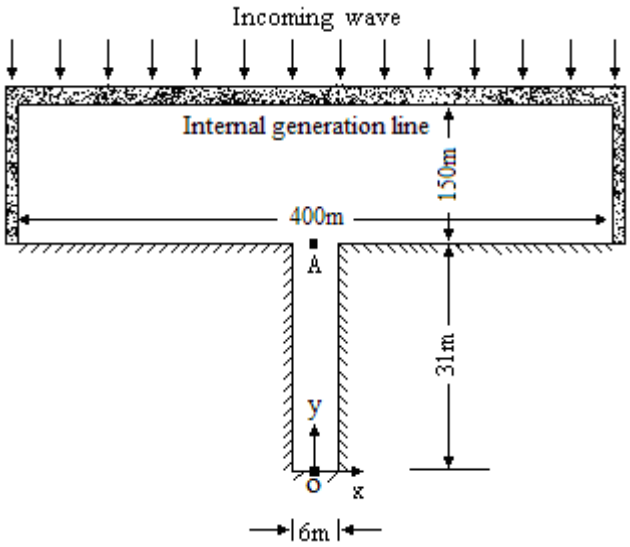

Fig.2 Computational domain for a fully-open rectangular harbor

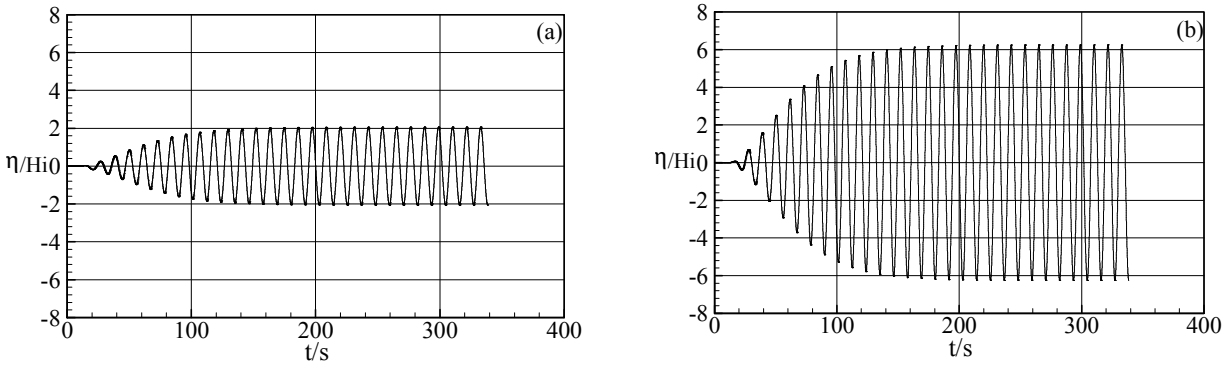

Fig. 3 Time series of the surface displacement for the case of $T$=11.3$s$. (a) surface displacement at Point A, and (b) surface displacement at Point O

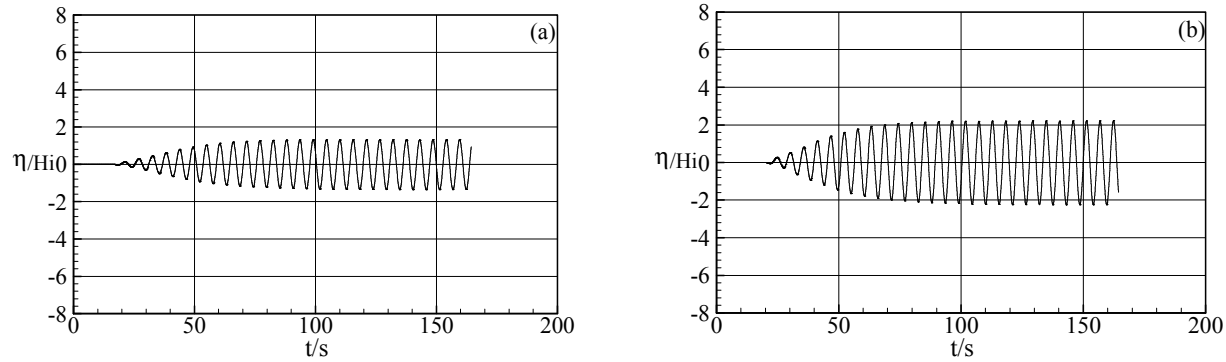

Fig. 4 Time series of the surface displacement for the case of $T$=5.5$s$. (a) surface displacement at Point A, and (b) surface displacement at Point O

dirtributions inside and outside the rectangular harbor for $T$=11.3$s$ and $T$=5.5$s$ are, respectively, ploted in Fig. 5 (a) and (b), showing that for the case of $T$=*11.3s*, the value of the relative wave height increases from 4.1 at $y$=31.0$m$ to 12.6 at $y$=0.0$m$, while for the case of $T$=5.5$s$, the relative wave height in the harbor has a peak value of about 4.6 at approximately $y$=0.0$m$ and $y$=24.0$m$, the relative wave height reachs the minimum of about 0.16, at about $y$=12.0$m$. As for the nearly semi-circular patterns of the wave height contours near the mouth shown in Fig. 5, we should refer this to the scatter waves propagated outward from the harbor entrance.

The computed response curve of the rectangular harbor is presented in Fig. 6, where the abscissa is the normalized harbor length $kl$ ($k$ is the incident wave number, and $l$ is the length of the harbor), and

the ordinate is the normalized wave height at the harbor end ($H_O/2H_i$). If the rectangular harbor does not exist, the wave height would be doubled due to the specified total reflection boundary condition.

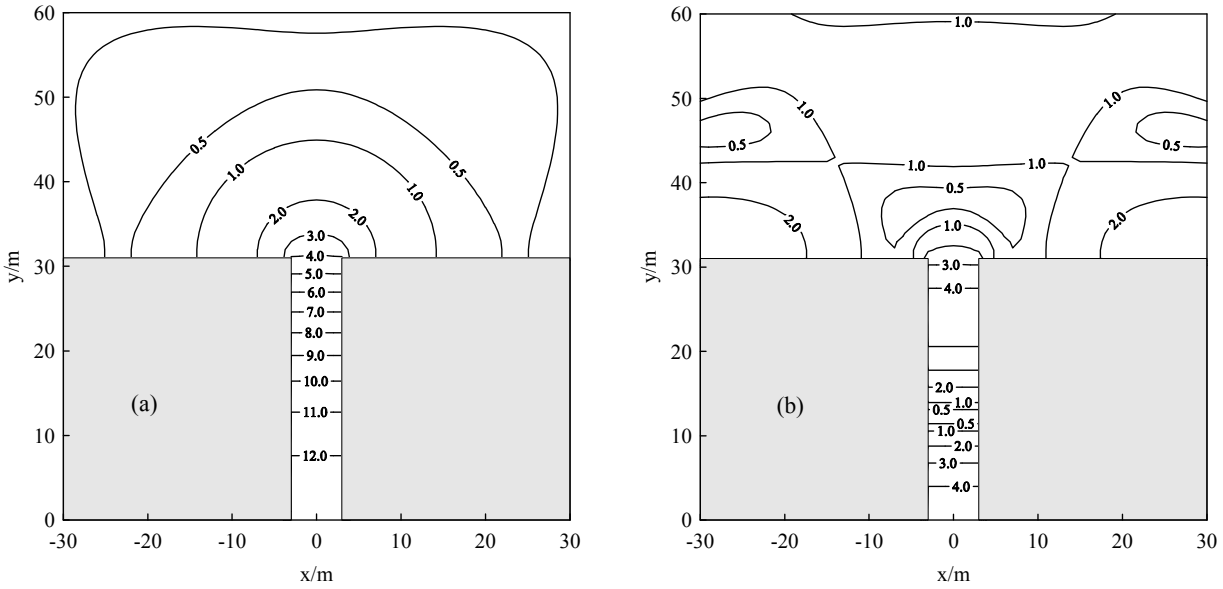

Fig. 5 Computed relative wave height ($H/H_i$) distributions inside and outside the harbor. (a) the relative wave height contour for $T$=11.3$s$, and (b) the relative wave height contour for $T$=5.5$s$

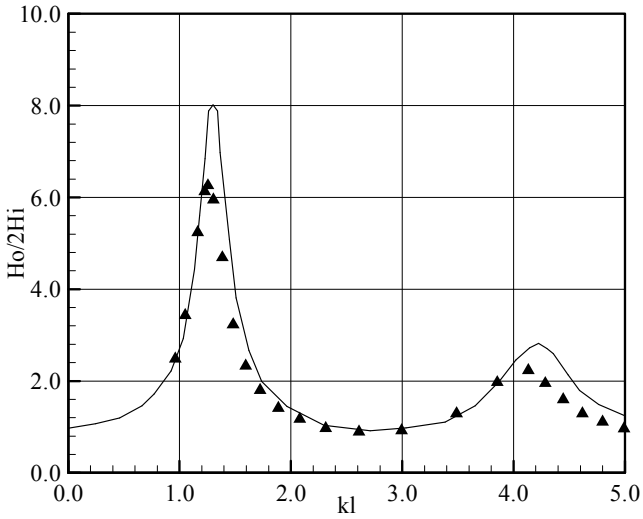

Fig. 6 Comparisons for the normalized wave height between the numerical results (▲▲▲) and the analytical ones (——) at the harbor end (Position O).

Therefore, the doubled wave height $2H_i$ is used to normalize the calculated wave height. From this fiture, we can see that the wave height relative to the standing wave at the harbor end is very large, as high as 6.3, when the period is about 11.3$s$. This is the first mode of the harbor resonance. We can also detact the second resonant mode at about $T$=5.5$s$, and the relative wave height for this mode is about 2.3. The analytical response curve of this harbor given by Lee [6] was also ploted in Fig. 6 for comparison conveniences, from which we can see the numerical results are in agreement with the theoretical ones, indicating that the mild-slope model can be applied to the simulation of the harbor resonant phenomenon.

**Evaluation of the Long-wave Induced Resonance for the Plan of Tieshan Port**

In order to study the resonant responses of Tieshan Port, nearly 71 offshore wave conditions in the SSW direction with period ranging from 50$s$ to 400$s$ were calculated. These waves were generated internally in the computational domain, and the generated wave height $H_i$ is 0.1$m$. Since the resonant

periods of a harbor depends mainly on its size, geometry and depth, therefore we donot consider the depth variation outside the port, and the outside depth was set the same as the inside of the port. Considering the numerical results might be affected by the size of the computational domain, we choose a large area of 45*km*×24 *km* (see Fig. 7) to conduct the numerical computations. The grid size of 25*m*×25*m* is selected for the computational domain. On the one hand, the 25-*m* grid resolution can accurately describe the harbor geometry. On the other hand, this resolution can also garantee to accuratly simulate the wave fiel even for the case of the minimum wave length. The time step is set as 1.0*s*. This time step is small enough to garantee the stability of the numerical calculations even for the case of the longest wave length. The shoreline boundaries and the four computational domain boundaries were all set as the open boundary conditions, and to further minimize the effects of the pseudo-reflected waves, the sponge layers with width of 0.5*L* were also used with the combination of the open boundary conditions. As for the inner and outer harbor boundaries, the total reflection conditions were specified. This is because, even for the slope structures, the structure dimension of O(100*m*) is relatively small compared to the wave length dimension of O(1000*m*) in the present study.

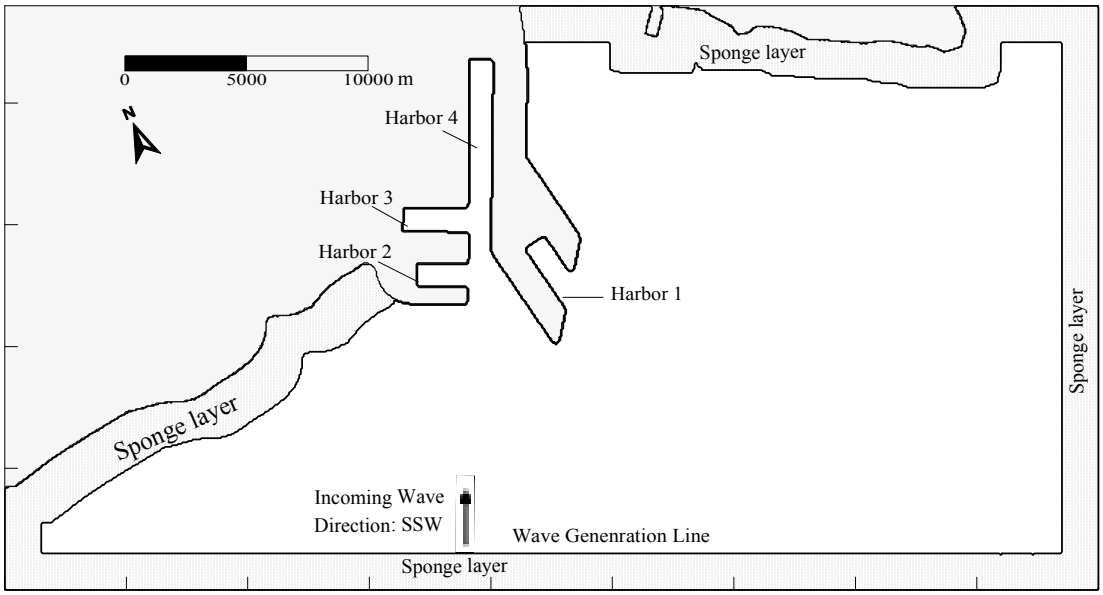

Fig. 7 Computational domain for calculating the long-wave induced resonance in Tieshan port

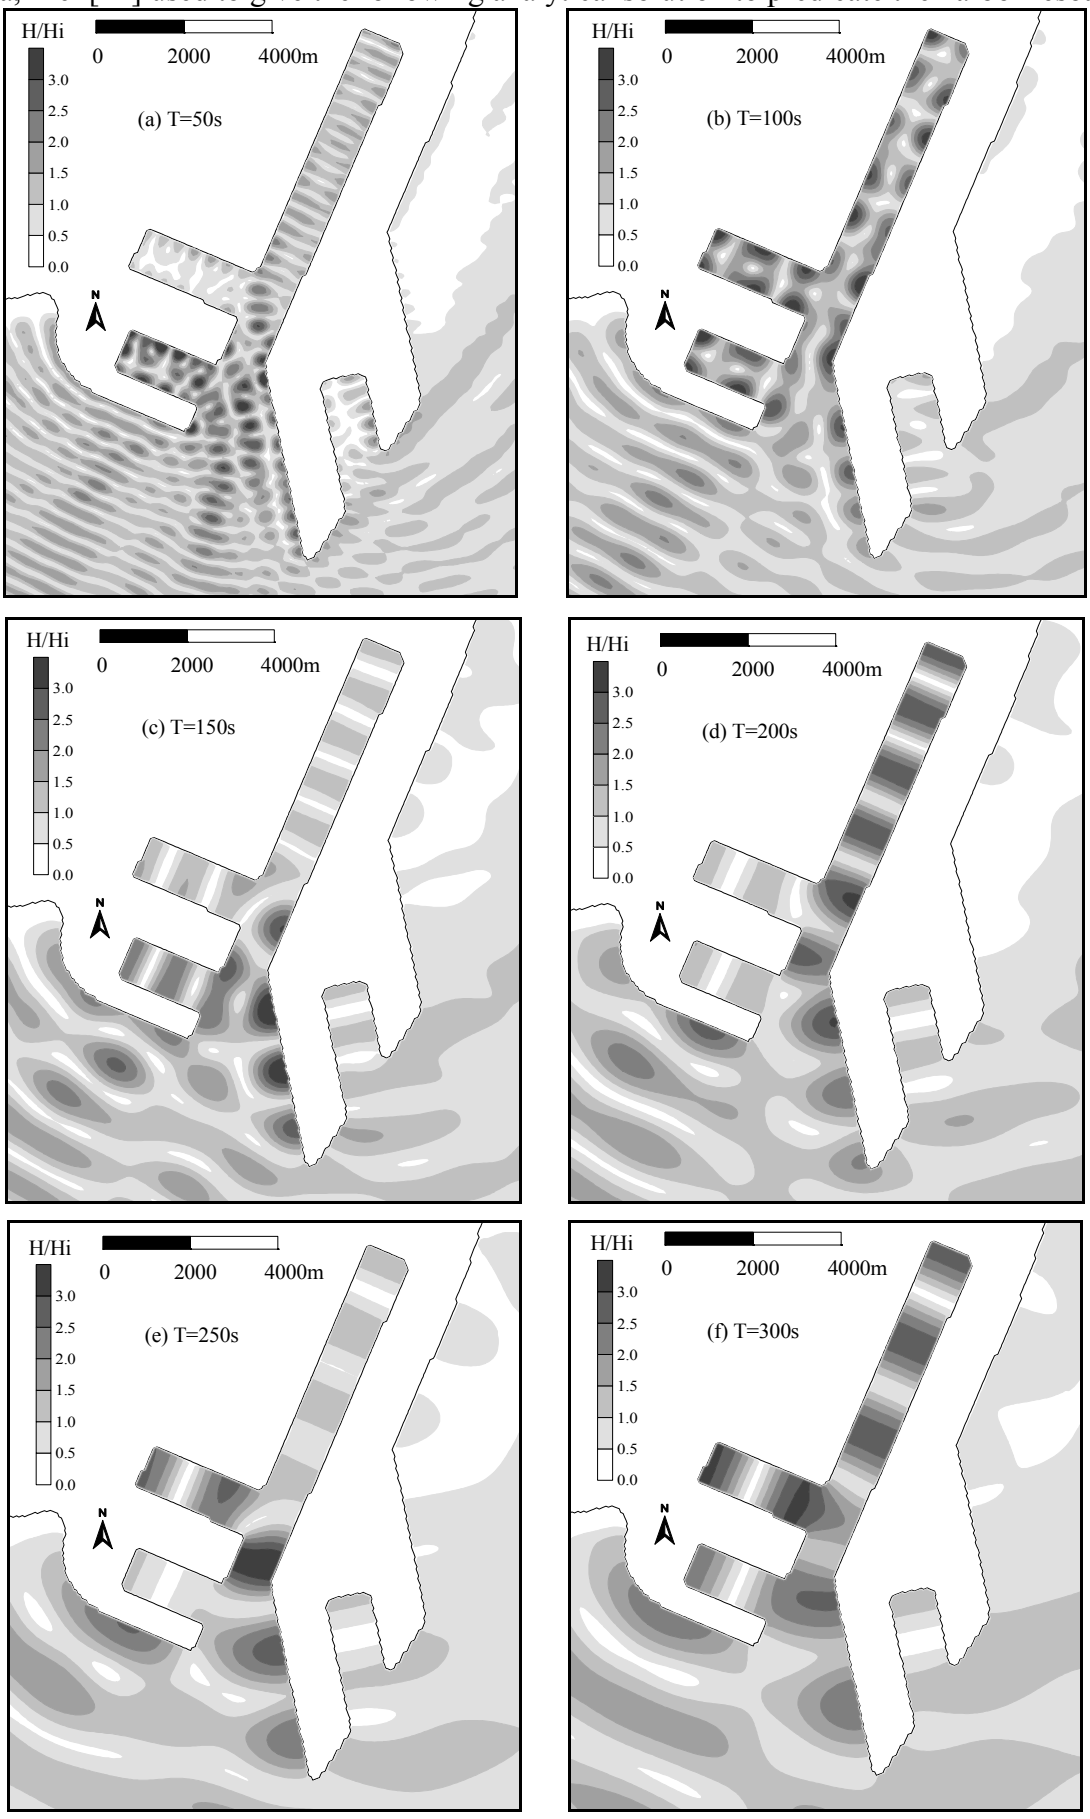
Fig. 8 (a) to (h) respectively shows the distributions of the computed relative wave height ($H/H_i$) for different wave periods inside and outside Tieshan port. From these figures, we can see that the wave height distributions inside the port for the periods smaller than 150*s* all exhibit two dimensional characteristics, with apparent node and anti-node regions generating alternatively inside the four harbors. While for the periods larger than 150*s*, the wave height distributions inside the four harbors all behave to be one dimensional, with the node and anti-node line nearly parallel to the harbor's transverse axis. Besides that, we can also see some high energy regions along the east perimeter of the port, which should be attributed to the oblique wave reflection. The number of these high energy regions decreases with the increase of the incident period, and their strength increases with waves penetrating into the inside of the port.

When the wave resonance occurs, the node and anti-node regions like standing waves would be formed in the harbor, and the locations of these node and anti-node regions would be different for different incident wave periods. Hence, instead of wave height at the harbor's backwall, we choose the maximum relative wave height and the mean relative wave height of each harbor to study their resonant responses. Fig. 9 (a) to (c) respectively shows the respond curves of the mean relative wave height and the maximum relative wave height for Harbor 2, Harbor 3 and Harbor 4. From these fitures, we can see that the responce of the mean relative wave height behaves the same as that of the maximum relative wave height, and they both fluctuate with the incident wave period. For some

certain periods, there exist the extreme values, indicating that harbor resonance might occurs when these periods are achieved. As for the problem of a long rectangular harbor connecting to an infinite open sea, Mei [14] used to give the following analytical solution to predicate the harbor resoance:



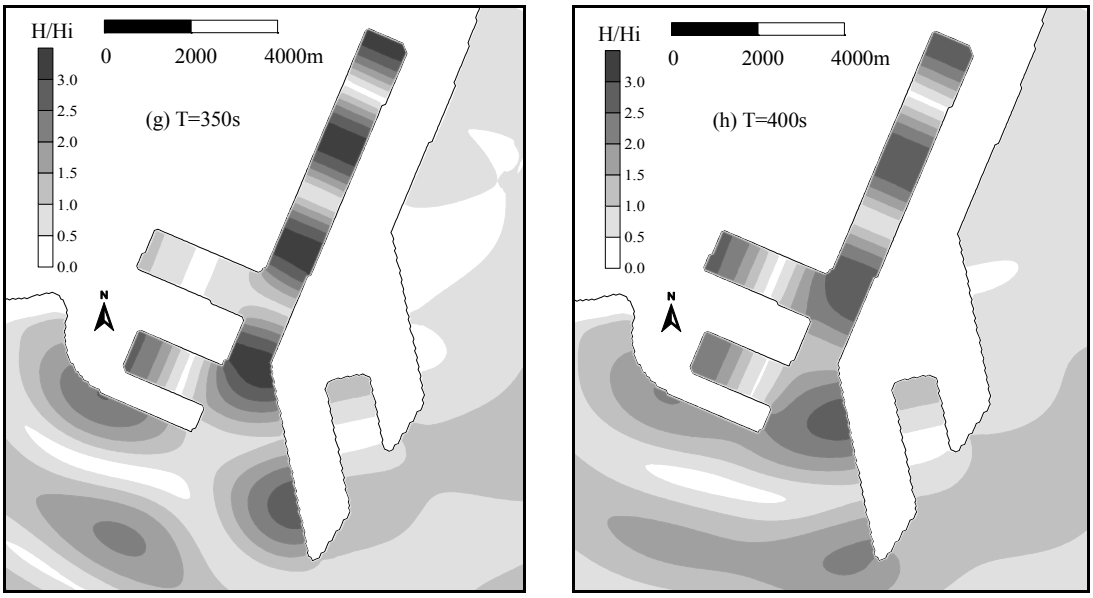


Fig.8 Distribution of the computed relative wave height $H/H_i$ for different incident wave period

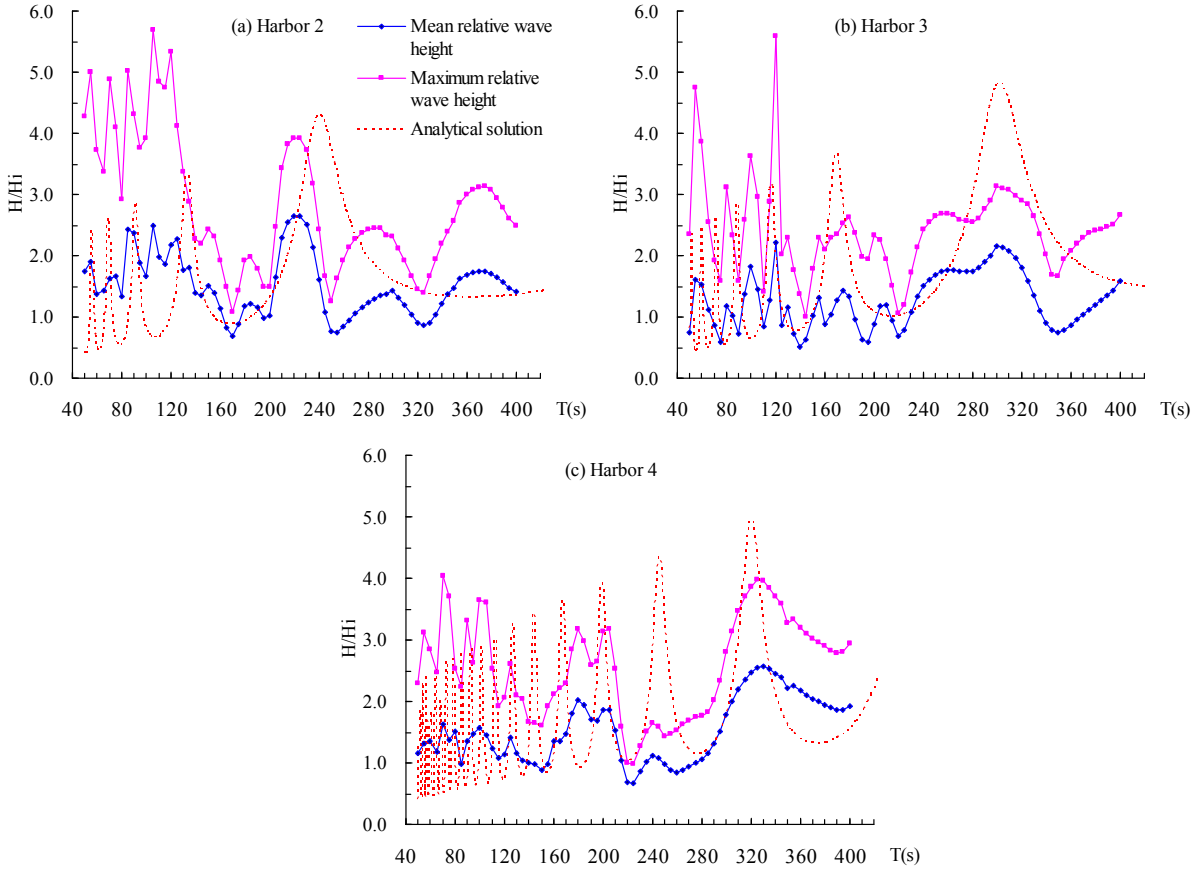

Fig.9 Response curves of the mean relative wave height and the maximum relative wave height for Harbor 2 (a), Harbor 3 (b), and Harbor 4 (c)

$$\vartheta = \left[ \cos kl + \frac{2ka}{\pi} \sin kL \ln \frac{2\gamma ka}{\pi e} - ika \sin kl \right]^{-1} \tag{9}$$

where $\vartheta$ is the amplification factor relative to the standing wave height; $l$ and $a$ are respectively the length and half width of the harbor; and $\ln \gamma = 0.5772157$ is the Euler constant.

Here, Eq. (9) was used to estimate the resonant periods and the corresponding amplification factor for Harbor 2, Harbor 3 and Harbor 4. For conveniences of comparisons, these analytical results were also ploted in Fig. 9 as the dashed lines. Comparing the numerical results with the analytical ones, we

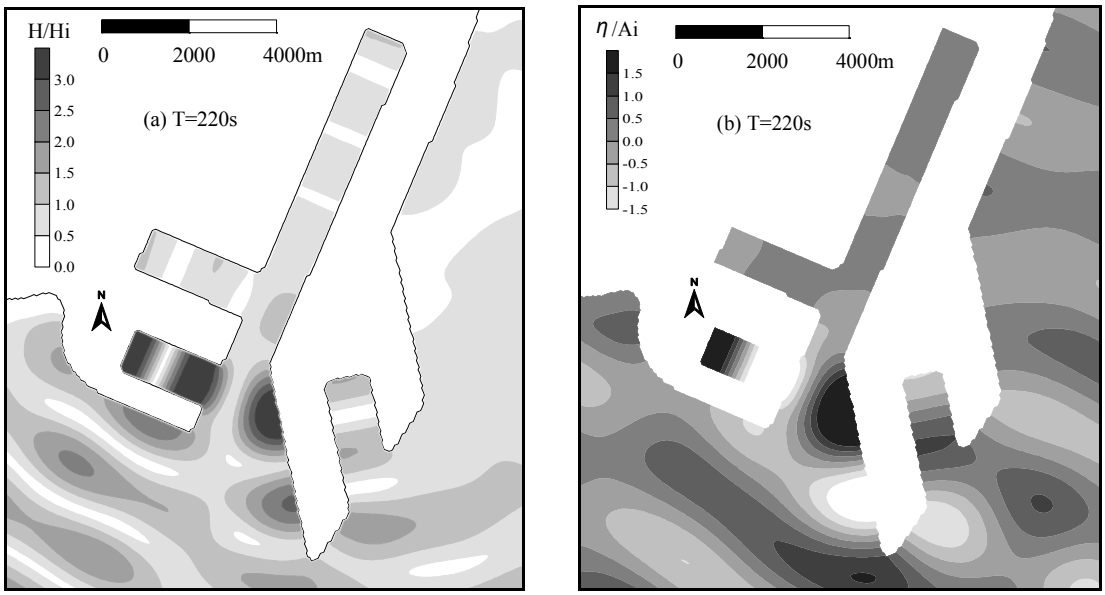

Fig.10 Distribution of the relative wave height $H/H_i$ (a), and the relative free surface $\eta/A_i$ (b), when the wave period is $T$=220$s$. Note that the resonance of the second mode occurs in Harbor 2.

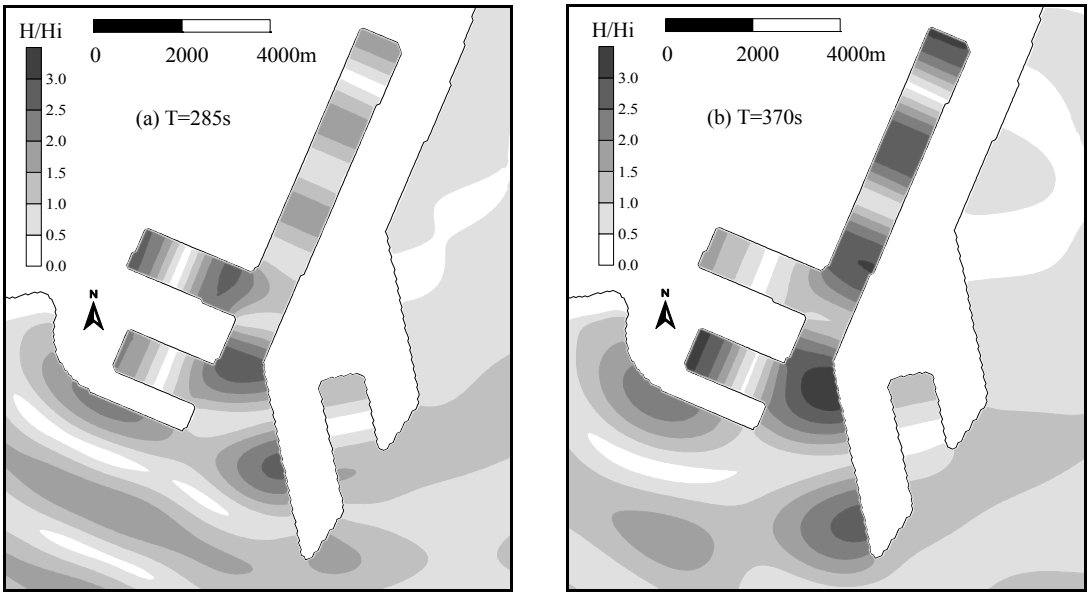

Fig.11 Distribution of the computed relative wave height $H/H_i$ for $T$=285$s$ (a) and $T$=370$s$ (b). Note that for the two periods the resonance of the second mode occurs in Harbor 2.

can see that most of the resonant periods for the three harbors predicated by Eq. (9) have been captured by the numerical models, and the predicated resonant periods by the analytical and numerical models agrees fairly well. As for the amplication factor, when the higher resonant modes occur, i.e., the resonant periods smaller than 150$s$, the numerically predicated amplication factors appear obviously to be higher than the analytical ones. This should be attributed to the fact that the higher resonant modes occuring in the harbor mainly behave to be two dimenssional: the longitudinal resonance and the tranverse resonance are both intrigered in the harbor (see Fig. 8a and 8b). These phenomena cannot be predicated by the analytical theory. While for the lower resonant modes, i.e., the resonant periods larger than 150$s$, the numerically predicated amplication factors agree with the analytical ones. This is because for the lower resonant mode, the wave height patterns in the harbor mainly behaves to be one dimensional (see Fig. 8c to 8h), i.e., the longitudinal resoncance is seen to be the main exhibitions. Further analyzing the numerical and analytical results, the following characteristics for the resonances of the plan of Tieshan port can be obtained.

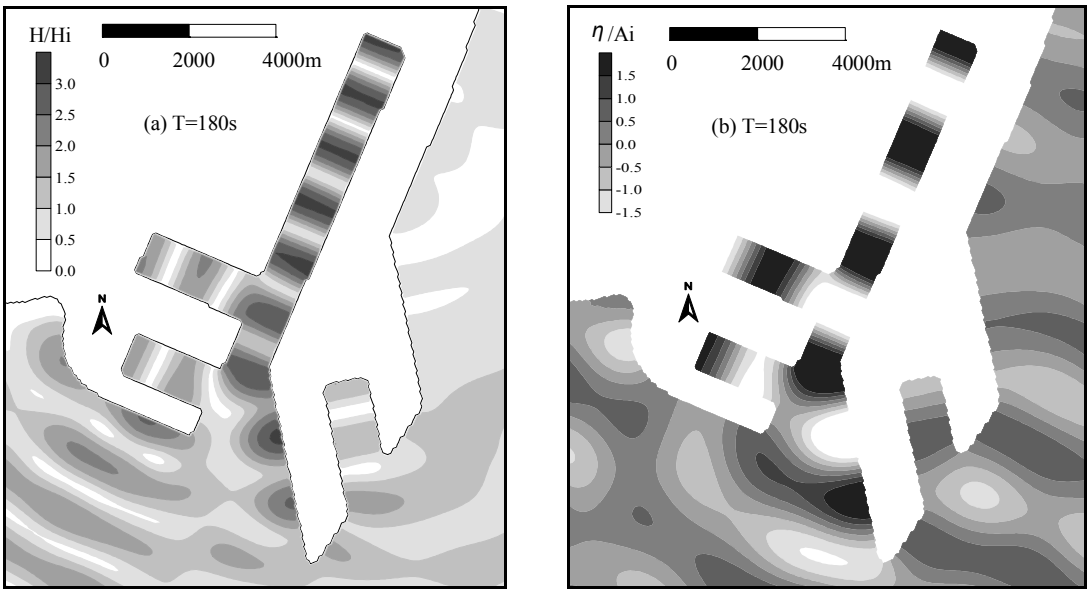

Fig.12 Distribution of the relative wave height $H/H_i$ (a), and the relative free surface $\eta/A_i$ (b), when the wave period $T$=180$s$. Note that while the resonance of the third mode occurs in Harbor 3, the resonance of the seventh mode also occurs in Harbor 4.

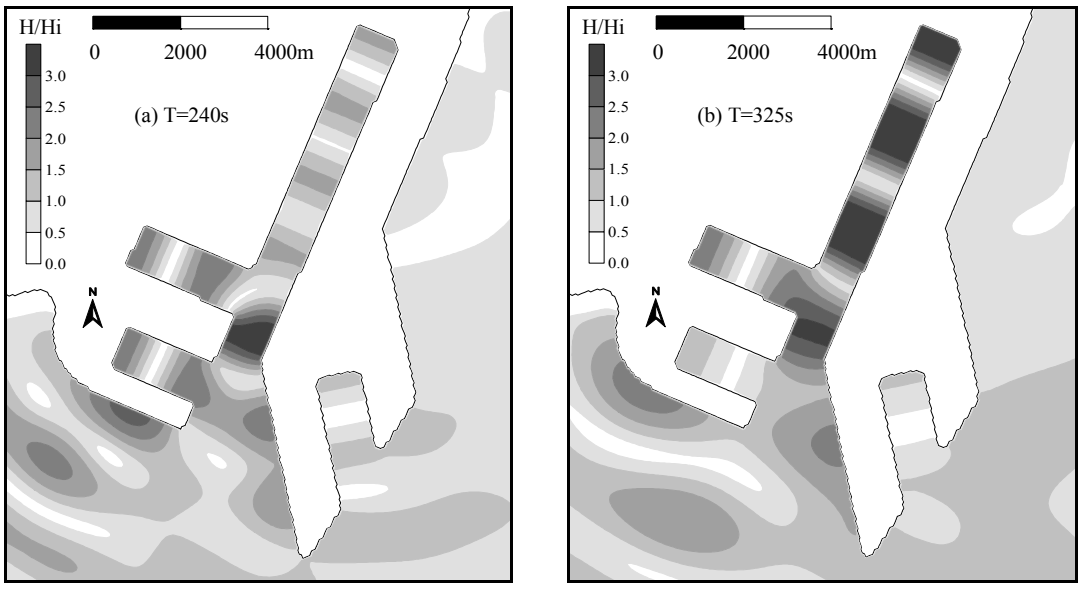

Fig.13 Distribution of the computed relative wave height $H/H_i$ for $T$=240$s$ (a) and $T$=325$s$ (b). Note that for the two periods, the resonance of the fifth mode and the fourth mode, respectively, occurs in Harbor 4.

(1) The numerical results of Fig. 9 (a) shows that one of the main resonant period for Harbor 2 is $T$=220$s$, and the corresponding maximum relative wave height inside this harbor is about 4.0. As for this case, Fig. 10 (a) to (b) respectively shows the relative wave height and the relative free surface distributions inside and outside the port. Examining the patterns of the wave height and the free surface distributions in Harbor 2, we can see that the resonance occurring at this period exhibits to be one dimensional, and there obvously exist the scatter waves radiated out of the harbor mouth. The two node regions and the three anti-node regions existing in Harbor 2 mean that the resonance occurring at this period is of the second mode. The numerically predicated resonant period $T$=220$s$ agrees well to the analytical one $T$=240$s$. In addition, the numerical results of Fig. 9 (a) also shows another two resonant periods $T$=285$s$ and $T$=370$s$ that donot captured by the analytical ones. As for the relative wave height distributions for these two periods, one can see Fig. 11 (a) to (b). Examining the wave

height distributions shown by Fig. 11, we see that the wave climates in Harbor 2 are obviously influenced by the scatter waves propagated out of Harbor 4. Further counting the numbers of the node and anti-node regions, we know that the resonances of these two periods are both of the second resonant mode, which should be caused by the scatter waves that propagate out of Harbor 4.

(2) From the numerical results shown in Fig. 9 (b), we see that the 180-*s* and 300-*s* periods are the two resonant periods of Harbor 3, and the corresponding maximum relative wave height for these two resonances are respectively 2.6 and 3.2. Referring to the distributions of the relative wave height and the relative free surface for $T$=180*s*, one can see Fig. 12 (a) to (b). While for the relative wave height distributions for $T$=300*s*, one can see Fig. 8 (f). Counting the number of the node and anti-node regions, we know that the resonances occurring at these two periods are respectively of the third resonant mode, and of the second resonant mode. Furthermore, the numerically predicated resonant periods (170*s* and 300*s*) agrees fairly well with the analytical ones (180*s* and 302*s*). Comparing the numerically predicated amplification factor of the second mode of Harbor 2 with that of Harbor 3, we can see that even the length of Harbor 2 is smaller than that of Harbor 3, the amplification factor of the former is a bit larger than that of the latter. This should be attributed to the fact that Harbor 3 is sheltered a bit more than Harbor 2. In addition, when the third resonant mode occurs in Harbor 3, the seventh resonant mode was also excited in Harbor 4.

(3) From the numerical results of Fig. 9 (c), we know that when the incident wave period occur at 180*s*, 200*s*, 240*s* and 325*s*, the resonances will be excited in Harbor 4, and the corresponding resonant modes are respectively of the seventh mode, the sixth mode, the fifth mode and the fourth mode. These numerical resonant periods agrees well with the analytical ones (167*s*, 200*s*, 250*s* and 320*s*). Further comparing the strength of the four resonances in Harbor 4, one can see that the fourth resonant mode is the largest. For the relative wave height distributions of the seventh mode and the sixth mode of Harbor 4, one can see Fig. 12 (a) and Fig. 8 (d), respectively. While for the fifth mode and the fourth mode occurring in Harbor 4, one can see Fig. 13 (a) to (b), respectively. All of these figures show that when the resonances occur in Harbor 4, the scatter waves radiated out of this harbor will eventually influence the wave height climates both in Harbor 2 and in Harbor 3. An obvious case is that the 285-*s* and 370-*s* resonant periods of Harbor 2 should be excited by the scatter waves that propagate out of the mouth of Harbor 4.

## Summary

In this paper, a numerical study on the long wave induced resonance has been conducted for the plan of Tieshan port. The simulations were performed with the use of the mild-slope model which was developed in Ref. [1], and further validated through a classical benchmark to examine its ability to predict the wave resonance phenomenon in a harbor. To evaluate the resonance period and the corresponding amplification factor for the plan of Tieshan port, 71 offshore wave conditions with the period ranging from 50*s* to 400*s* have been calculated. The rationalities of the numerical results were examined through comparisons with the theoretical ones. It is shown that the resonances induced by the waves with period larger than 150*s* are quite different from those induced by the waves with period smaller than 150*s*. The resonance occurring at the period larger than 150*s* is seen to be nearly one dimensional, mainly behaving to be longitudinal. While the resonance occurring at the period smaller than 150*s* is seen to be two dimensional, both the longitudinal and transverse resonances existing in the port. After carefully examining the numerical results, the resonant period, the amplification factor and the corresponding resonant mode for each harbor of the plan of Tieshan port have been given.

**Keywords:** Wave Kinematics and Pressure fields, Bichromatic Bi-Directional Waves, Third-Order Theory, Nonlinear Dispersion Relation, Ambient Currents, Finite Water Depth

**Abstract.** Based on the third-order theory for bichromatic bi-directional waves in water of finite depth, a set of explicit formulas for the state-of-the art quantities of wave kinematics for horizontal and vertical particle displacements, velocities and accelerations, and wave pressure field is developed, and would be much more accurate and realistic in the design of harbor, coastal and offshore structures and their structural members.

## Introduction

Strictly speaking, the ocean surface waves are never monochromatic and monodirectional, they are nothing but multi-chromatic and multi-directional. The latter is, however, much less theoretically studied [1-4] because of its dramatic increased complexity, let alone its wide range of applications in engineering. In fact, the former is most dominant in existing wave models, such as famous Stokes theory [5],short-crested waves [6,7] and mild-slope equations [7,8], thus leading to all kinds of applications [9,10] which have inevitably gives rises to a variety of marine problems concerned with how to compute loads on harbor, coastal and offshore structures and how the structures respond to these loads.

The solutions given in [2,4] for bichromatic bi-directional water waves propagating over a horizontal bottom provide the basis for applications to a variety of problems of engineering interest. In particular, the water particle kinematics and the pressure field within the wave are directly related to the calculation of forces on bodies. For the purposes of this study, this paper is devoted to a third-order explicit solution with the phase functions, $\theta_n = \omega_n t - \boldsymbol{k_n}\cdot\boldsymbol{x}$, for the water particle displacements, $(\zeta_x,\zeta_y,\zeta_z)\equiv(\boldsymbol{\zeta_x},\zeta_z)$, velocities, $(u,v,w)\equiv(\boldsymbol{u},w)$, accelerations, $(a_x,a_y,a_z)\equiv(\boldsymbol{a_x},a_z)$,and the pressure field $p$.

## Particle Displacements

$$\begin{aligned}\zeta_x = \int \boldsymbol{u}(\boldsymbol{x},z,t)\,dt = \boldsymbol{U}t - \varepsilon[\sum_{r=1}^{2}\frac{\boldsymbol{\kappa}_r F_r}{\omega_{1r}+\boldsymbol{U}\cdot\boldsymbol{\kappa}_r}\cosh\kappa_r(z+h)(a_r\sin\theta_r - b_r\cos\theta_r)]\\ -\varepsilon^2[\frac{(\boldsymbol{\kappa_n}\pm\boldsymbol{\kappa_m})F_{n\pm m}}{(\omega_{1n}+\boldsymbol{U}\cdot\boldsymbol{\kappa_n})\pm(\omega_{1m}+\boldsymbol{U}\cdot\boldsymbol{\kappa_m})}\cosh\kappa_{n\pm m}(z+h)(A_{n\pm m}\sin\theta_{n\pm m} - B_{n\pm m}\cos\theta_{n\pm m})\\ +\sum_{r=1}^{2}\frac{\boldsymbol{\kappa}_r F_{2r}}{\omega_{1r}+\boldsymbol{U}\cdot\boldsymbol{\kappa}_r}\cosh\kappa_{2r}(z+h)(A_{2r}\sin 2\theta_r - B_{2r}\cos 2\theta_r)]\\ -\varepsilon^3[\frac{(\boldsymbol{\kappa_n}\pm 2\boldsymbol{\kappa_m})F_{n\pm 2m}}{(\omega_{1n}+\boldsymbol{U}\cdot\boldsymbol{\kappa_n})\pm 2(\omega_{1m}+\boldsymbol{U}\cdot\boldsymbol{\kappa_m})}\cosh\kappa_{n\pm 2m}(z+h)(A_{n\pm 2m}\sin\theta_{n\pm 2m} - B_{n\pm 2m}\cos\theta_{n\pm 2m})\\ +\frac{(\boldsymbol{\kappa_m}\pm 2\boldsymbol{\kappa_n})F_{m\pm 2n}}{(\omega_{1m}+\boldsymbol{U}\cdot\boldsymbol{\kappa_m})\pm 2(\omega_{1n}+\boldsymbol{U}\cdot\boldsymbol{\kappa_n})}\cosh\kappa_{m\pm 2n}(z+h)(A_{m\pm 2n}\sin\theta_{m\pm 2n} - B_{m\pm 2n}\cos\theta_{m\pm 2n})\end{aligned}$$

$$+\sum_{r=1}^{2}\frac{\boldsymbol{\kappa}_r F_{3r}}{\omega_{1r}+\boldsymbol{U}\cdot\boldsymbol{\kappa}_r}\cosh\kappa_{3r}(z+h)(A_{3r}\sin 3\theta_r - B_{3r}\cos 3\theta_r)$$

**Summary**

Including the nonlinear third-order dispersion relation and the effects of an ambient current, this paper obtains a series of perturbation formulas for bichromatic bi-directional wave kinematics and pressure field in water of finite depth. The formulas are both an extension of the common Stokes waves [5, 7-10] from monochromatic monodirectional to bichromatic bi-directional waves and an extension of [6,7] from monochromatic to bichromatic short-crested waves, thus probably providing the state-of-the art in harbor, coastal and offshore engineering [9,10].

**Keywords:** Floating breakwater; catamaran raft; wave-attenuating and oscillation-inhibiting device

**Abstract.** This paper briefly introduces the design, construction and wave attenuation effect test of a kind of floating breakwater sheltering deep water aquaculture. This novel floating breakwater structure is composed of 28 standard modules and corresponding anchoring systems, and each standard module comprises a catamaran raft and a wave-attenuating and oscillation-inhibiting device, with a length of 30 m, a width of 7 m, a depth of 2 m and a draft of 1.1 m. Each catamaran raft employs a box-shaped multi-ribbed beam-and-slab structure, and was constructed using high-performance concrete and ferrocement materials and internally filled with polystyrene foam plastics. Each wave-attenuating and oscillation-inhibiting device uses a detachable split box-shaped structure and was pre-fabricated using high-performance concrete, with a length of 2 m, a width of 1.638 m and a height of 2 m. Each standard module is anchored using 6 anchor chains, each of which has an on-floor length of about 25 m. After construction, this floating breakwater system was tested for wave attenuation effect, and the data analysis results show that the floating breakwater system has a wave attenuation effect of up to 50 %.

## Introduction

As a major marine aquaculture province in China, Fujian Province is currently dominated by offshore shallow water aquaculture, but the offshore shallow water aquaculture threatens the safe operation and oceanic water environment of existing ports. Therefore, there is a movement to transfer marine aquaculture from offshore areas to open sea areas, to promote the development of the oceanic economy, to drive good circulation of ecosystems, to ensure quality and safety of aquatic products and to push ocean exploitation from shallow sea areas to deep sea areas. However, large waves in the open seas threaten the deep water aquaculture in the marine aquaculture industry, and good shelter facilities [1] need to be established so as to provide shelter for the deep water aquaculture.

This paper introduces a kind of novel floating breakwater, which is composed of 28 standard modules and corresponding anchoring systems. Each standard module comprises a catamaran raft and a wave-attenuating and oscillation-inhibiting device. Through model and pilot testing in 2011–2013, this floating breakwater system was constructed in the sea area to the east of Fujian Province, preliminarily forming an artificially sheltered water area with a given range, to provide a relatively safe production site for deep water aquaculture with a good ecological environment. After the construction was completed, the wave attenuation effect of the floating breakwater system was tested using acoustic wave and current (AWAC) acoustic Doppler current profilers (1 MHz, AWAC) imported from Norway, and the test results indicate that the wave attenuation effect is good, reaching 50 %. This paper briefly describes the design, construction and wave attenuation effect test of this floating breakwater system.

**Design overview.**

**Main body structure.** This floating breakwater system is composed of 28 standard modules and corresponding anchoring systems, as shown in Figure 1. The standard modules constitute the main structure of the floating breakwater system, and each standard module comprises a catamaran raft [2] and a wave-attenuating and oscillation-inhibiting device, as shown in Figures 2 and 3. The figures show that there are a total of 6 tether piles provided at both ends and in the middle of the main deck, corresponding to which anchor chain pipes are set up between the main deck and the bottom plate. There is an inspection hole provided in the main deck of each anti-sinking compartment, which is closed in normal times to prevent sea water from entering the compartment.

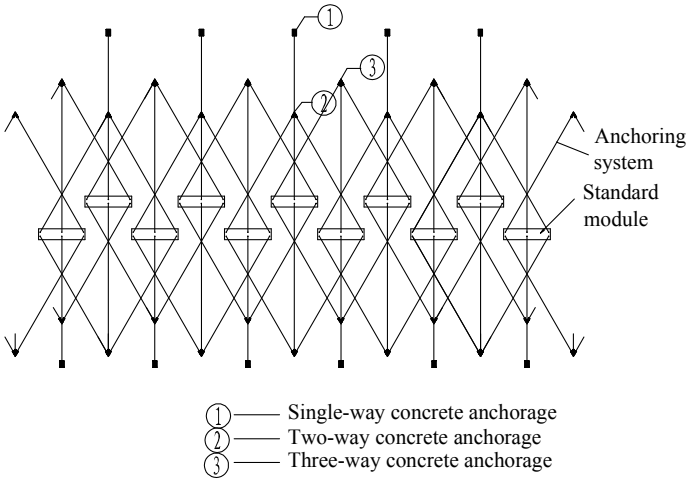

Fig. 1 Floating breakwater layout diagram

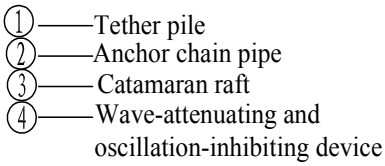

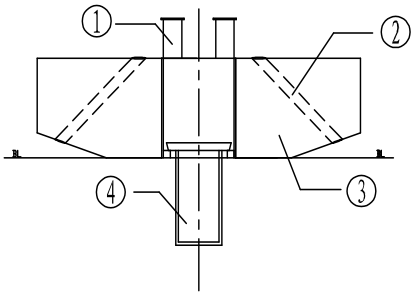

Fig. 2 Cross-sectional view of standard module

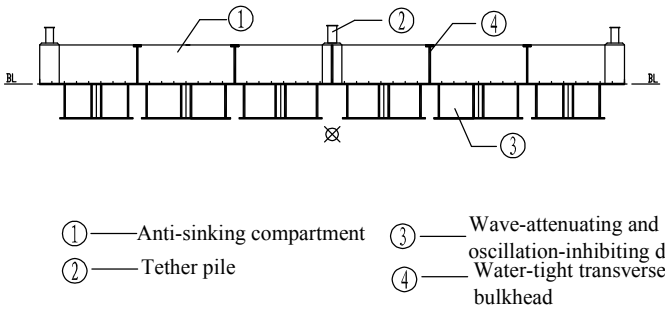

Fig. 3 Side view of standard module

A catamaran raft is one body formed of two fully-enclosed units connected with head and tail closing plates, a middle baffle plate, a web beam and a bottom traverse. Each unit has an overall length of 30.00 m, a molded breadth of 2.50 m and a molded depth of 2.00 m, the unit spacing is 2.00 m, and the design draft is 1.1 m. Each unit is provided with 6 anti-sinking compartments under the main deck, so one catamaran raft has a total of 12 anti-sinking compartments, to meet the requirement that if any two compartments are damaged with water entering, the catamaran raft will not sink. According to need, waste foam plastics in the aquaculture zone and floating materials on the water surface can be filled into each anti-sinking compartment to effectively reduce the quantity of water entering the compartments after the anti-sinking compartment is damaged, and thus to improve the anti-sinking performance; onsite polymer foaming technology can also be used to fully fill the internal space of each anti-sinking compartment so that the raft becomes an all-weather anti-sinking floating body, to ensure the unsinkability of the main body structure in any damage case. Under the main deck of each unit of a raft, there are 6 anti-sinking compartments divided by 5 water-tight transverse bulkheads; each unit has a box-shaped

multi-ribbed beam-and-slab structure to fully exert the mechanical properties of different structural materials, and to increase the strength and rigidity of the main body structure under the effect of waves. The internal rib frame and longitudinal members in each unit are ferrocement thin-wall members, to decrease the deadweight of the structure and the consumption of main materials; the side plates and head and tail closing plates are shaped vertically using high-frequency grouting of composite material ferrocement, as they are the places easiest to corrode under the direct wave impact and wave-splashing alternating dry-wet effect. The deck and bottom plate facilitate good construction operating conditions and a convenient module disassembly operation, and they are formed with high-performance ship-making concrete. In addition to paint coating, sufficient corrosion allowance is reserved for the steel members of the catamaran raft, which are in direct contact with sea water, so that their useful life is as consistent as possible with that of the main body structure.

The wave-attenuating and oscillation-inhibiting device is located below the baseline of the catamaran raft, to increase the dipping depth, underwater side projection area and water-carrying mass moment of inertia of the main body structure, and thus to improve the wave-attenuating and oscillation-inhibiting effect. This device has a detachable split box-shaped structure, and is prefabricated using high-performance concrete, with a length of 2 m, a width of 1.638 m and a height of 2 m. Bevel faces are provided on both sides of the top, which are connected with an elastic supporting device for the longitudinal bottom and fixed via embedded stainless steel bolts and clamp plates. Each catamaran raft and corresponding wave-attenuating and oscillation-inhibiting device can move synchronously under the effect of waves, with some micro-displacement allowed. According to need, there is a piece of fixed ballast added above each wave-attenuating and oscillation-inhibiting device, to adjust the height of the center of gravity and swing period of the standard module.

Each standard module is located by two vertical chains and four inverse cross chains; ends of each anchor chain are connected to an anchorage and a tether pile, respectively, and the on-floor length of each anchor chain is about 25 m. The tether piles are set up at both ends and in the middle of the catamaran raft. The tether piles in the middle are used as fixing devices for two vertical chains, while the tether piles at both ends are used as fixing devices for the four inverse cross chains. The anchor chain pipes corresponding to tether piles are set up between the deck and the bottom plate of two units of each raft, and the areas around each anchor chain pipe, under the deck and above the bottom plate, are locally reinforced using reinforced concrete. Each anchor chain passes through a corresponding anchor chain pipe and enters the water from the bottom of the raft. The size and species of anchor chain, and the form, dimensions and functions of anchorage, are determined through analysis and calculation according to the design operating conditions and considering relevant model test results and sea-floor geological conditions [3,4].

**Model test.** The model test was carried out in a wind wave current tank of No. 708 Research Institute China State Shipbuilding Corporation, and the movement of the standard module, the anchor chain force, and the wave parameters of the water zone sheltered by the wave-attenuating system were determined under specified wind, wave and current effects, to provide a basis for design and use of floating breakwaters. Figure 4 is schematic diagram of the layout in the model test.

The test tank was 9 m wide and 28 m long, with a maximum water depth of 2 m (adjustable using a false bottom), and the overall flow rate in the tank was a maximum of 0.3 m/s. The floating breakwater model was formed by alternately arranging 5 standard modules. The test water depth was 1.0 m, the flow rate was 0.2 m/s with a flow direction identical to the wave direction, and the test wind velocity was 6.0 m/s and 10.4 m/s with the wind direction identical to the wave direction; wind machines were used to simulate wind field and wind velocity. In the regular wave test, about 10 different wavelengths were used, and regular waves with a height of about 0.05 m were created. The irregular wave spectra used were ITTC double-parameter spectra [5]; and the spectrum equation is as follows:

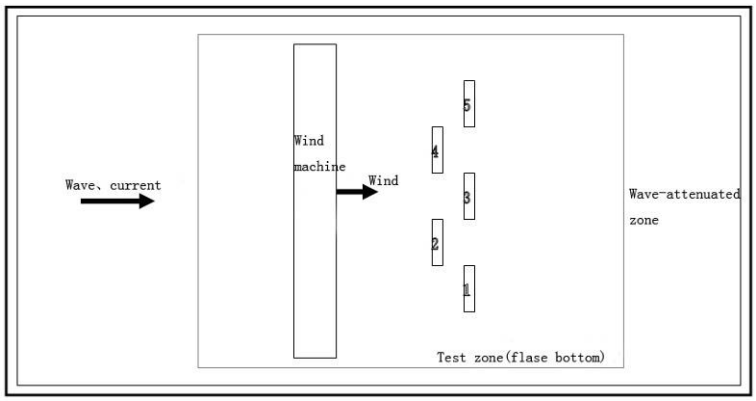

Fig. 4 Schematic diagram of layout in model test

$$S(\omega)=\frac{173H_S^2}{T_1^4\omega^5}\exp\{-\frac{691}{T_1^4\omega^4}\}. \quad (1)$$

where $\omega$ is the circular frequency of the waves, $H_s$ is the effective wave height, and $T_1$ is the spectral centroid period of the waves. The relationship between $T_1$ and spectrum peak period $T_p$ is $T_1=0.772T_p$. For this test, the irregular waves were taken as: effective wave height $H_s$=14cm, spectral centroid period $T_1$=1.24s; and effective wave height $H_s$=18cm, spectral centroid period $T_1$=1.54s. Irregular waves equivalent to actual 120 minutes (24 minutes in the model test) were created in the tank. Both regular and irregular waves were transverse waves.

Figure 5 shows pictures of the model test. The model test results indicate that the floating breakwater with this structure has a relatively good wave attenuation effect on short waves with a period of less than 4 s and long waves with a period of more than 12 s; with the wave period in the operation sea area as a reference, the standard module can be appropriately broadened to achieve the wave attenuation effect on relatively long waves. Under the wind and wave effects, the wave attenuation effect of the floating breakwater can reach 50 % without mutual collision between all standard modules. For the detailed model test results, see the Model Test Report of Floating Wave Attenuating System in Mariculture Area [6].

Fig. 5 Pictures of model test

**Construction overview.** Through uniform planning and arrangement, two floating breakwaters, one oriented from south to north and the other oriented from east to west, were set up in a sea area, about 3 km from the coast, to the east of Dinghai Village, Xiaocheng Town, Lianjiang County, Fujian Province, using natural sheltering conditions of Taiyu Island, to constitute a wave-attenuating facility with an overall length of 2.32 km, forming a sheltered water zone for deep water aquaculture with an overall area of about 1.3 $km^2$. The overall layout diagram of the constructed floating breakwaters is shown in Figure 6.

Fig. 6 Schematic diagram of overall layout of constructed floating breakwaters

Based on actual situations in the construction sea area, different arrangement and combination methods were used for the standard modules of the floating breakwater system. The floating breakwater on the east side in a strong wave direction is double-rowed, and that on the south side in a secondarily-strong wave direction is single-rowed. The floating breakwater on the east side is composed of 18 standard modules, with longitudinal spacing of 60 m and transverse spacing of 30 m, and which, together with Taiyu Island, have an overall length of 1,350 m. The floating breakwater on the south side is composed of 10 standard modules, longitudinally arranged in a single row, with spacing of 60 m, which, together with Taiyu Island, have an overall length of 974 m.

At present, the fabrication and anchor locating of the floating breakwaters have been completed, and Figure 7 shows the double-row floating breakwater on the east side in the strong wave direction.

Fig. 7 Pictures of floating breakwater on the sea

**Wave attenuation effect test.** After the floating breakwaters were constructed, two AWAC acoustic Doppler current profilers (1 MHz, AWAC) were arranged in front and behind the floating breakwater on the east side in the strong wave direction, to monitor the wave height at those positions in real time. The AWAC acoustic Doppler current profilers were arranged in front and behind the middle module of the floating breakwater, at 9 m from each corresponding edge of the standard module; Figure 8 shows the arrangement orientation. The onsite installation and layout of

the AWAC acoustic Doppler current profilers are shown in Figure 9. Synchronous monitoring during the typhoon season was conducted from August 8, 2013 to October 20, 2013, when 9 major typhoons, including Utor, Trami, Kong-rey, Usagi and Fitow, occurred, and the test results indicate that the main body structure of this floating breakwater was not damaged during the typhoon season with wind speeds up to level 12, and that the wave attenuation effect can reach 50 %. The specific test results will be published in later papers.

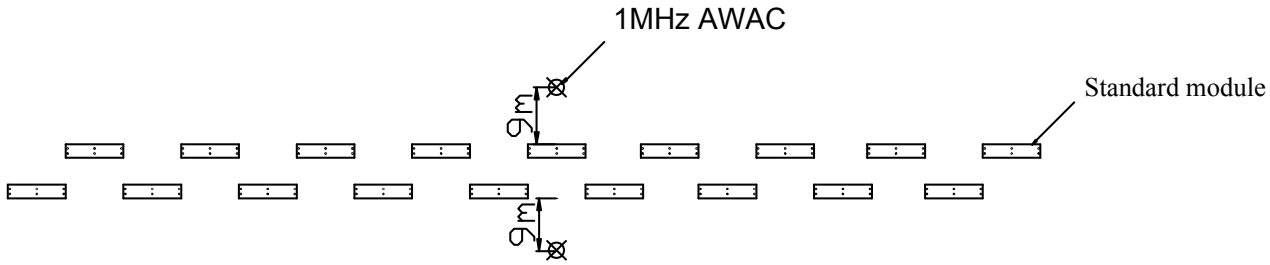

Fig. 8 Arrangement orientation diagram of AWAC acoustic Doppler current profilers

Fig. 9 Installation and layout of AWAC acoustic Doppler current profilers

**Conclusions.** This paper briefly introduces the design, construction and wave attenuation effect test of a kind of floating breakwater sheltering deep water aquaculture. This novel floating breakwater structure is composed of 28 standard modules and corresponding anchoring systems, and each standard module comprises a catamaran raft and a wave-attenuating and oscillation-inhibiting device, with a length of 30 m, a width of 7 m, a depth of 2 m and a draft of 1.1 m. Each catamaran raft employs a box-shaped multi-ribbed beam-and-slab structure, and was constructed using high-performance concrete and ferrocement materials and internally filled with polystyrene foam plastics. Each wave-attenuating and oscillation-inhibiting device used a detachable split box-shaped structure and was pre-fabricated using high-performance concrete, with a length of 2 m, a width of 1.638 m and a height of 2 m. Each standard module was anchored using 6 anchor chains, each having an on-floor length of about 25 m.

The wave attenuation effect test was conducted for the floating breakwater system during typhoon season, and the test results from data analysis indicate that this floating breakwater system can survive level 12 wind speeds, and that its wave attenuation effect can reach 50 %.

This project is a model project for marine aquaculture development for offshore areas to deep sea areas, and this technology also provides technical support for construction of deep water wharves in open sea areas.

# Analysis of Gravity Foundation for Offshore structure under Cyclic Loads

GAO Rui [1,a] , YANG Ling Qiang [1.b], and Wang Yan[1,c]

[1]School of Civil engineer and architecture, University of Jinan, Jinan, Shandong province, China

[a]cea_gaor@ujn.edu.cn,[b]cea_yanglq@ujn.edu.cn, [c]cea_wangyan@ujn.edu.cn

**Keywords:** Offshore structure ; Cyclic Loads; Uncertainty analysis.

**Abstract.** Cyclic characteristic of offshore environmental load may cause the accumulation of foundation settlement and excess pore pressure in the subsoil. This may lead to conditions that jeopardize the structural stability and operability of the wind turbine. This paper discusses the analysis steps of the responses of non-cohesive subsoil under cyclic loads for a gravity base foundation system.

## Introduction

Two of the main design criteria for an offshore wind turbine foundation are the structural stability and operability during its designated service life. These include the stability of subsoil and the settlement of the foundation. A critical[1] factor for the operability of the wind turbine is the tilting of the structure, which can be caused by uneven settlement of the foundation.

In the common design practice for civil structures, the structural stability is proven for several preselected singular static loads[2]. This approach is in general accepted for structures which only experience monotonic loading condition. However, it is still questionable whether this approach is applicable for structures which constantly experience dynamically changing loading condition. In reality, the loading history and sequence play a significant role in the subsoil response and the overall structural stability, particularly due to the influence of pore fluid and permeability of the subsoil.

## Eqivalent Load

Direct analysis of irregular cyclic load in geotechnical field, where the subsoil properties actually changes due to the loading itself will require an advanced constitutive model. The challenge will be even greater when the analysis is required for a high number of cycles. One way out from this problem will be to replace the irregular loads with equivalent uniform cyclic loads. The soil behavior under uniform cyclic load can be described in a simpler way. The high cyclic accumulation model[3] (Niemunis, 2000) for example is developed for uniform cyclic loads.

Equivalent load can be understood as the uniform cyclic load with a certain number of cycles, which gives the same effects as the irregular cyclic loads. From geotechnical point of view, these effects are the cyclic settlement and development of the excess pore pressure. However, it is actually unlikely to find the equivalent load concerning the subsoil response. Every different load level transferred through the foundation footing also possesses a different range of affected subsoil area. It is only possible to determine the cyclic load which gives the closest possible approximation to the actual subsoil response. Furthermore, equivalent load is only appropriate to represent regularly recurring loads. For analysis of extreme load level, it is better to use the real load sequence. Loads acting on gravity base foundations for offshore wind turbines are the superposition

of wave, current, wind and machinery forces. The result is irregular cyclic load sequences (cf. Fig. 1). This irregular load sequence can be simplified by decomposing the loads into predefined groups of cyclic loads. Each group of cyclic load is represented by a certain average level and amplitude. The number of occurrence corresponding to each group can be determined using the rainflow counting method (Clormann, 2001)[4]. The information about the chronological load sequence is however lost in the process.

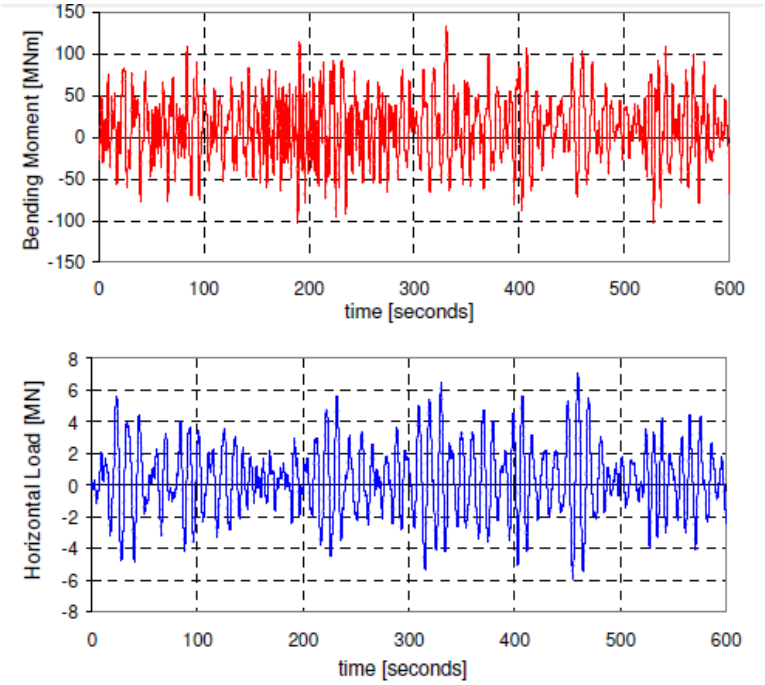

Fig. 1 Typical load sequence acting on foundation for offshore structure

**Case study**

an analysis of the subsoil response under a gravity foundation during a peak wave of a storm is presented. The effect of the preloading is however not considered. The purpose of this calculation is to analyze the pore pressure development and its effect to the overall stability of the foundation under an extreme load. The analysis is carried out in a three dimensional finite element calculation with the finite element program *Tochnog Professional* and the Hypoplastic material model. To consider the effect of the pore fluid, the pore pressure is coupled with the stress of the soil skeleton in element.

The gravity foundation is a cross shaped box girder made of prestressed reinforced concrete with four separated plates at the ends of the boxes and an effective dead weight of approximately 80 MN. The concrete structure is modeled as a linear elastic material. In order to simplify the analysis, the skirt under the plates is not included. The whole model has about 61000 elements and 66000 nodes (see Fig.2 ).

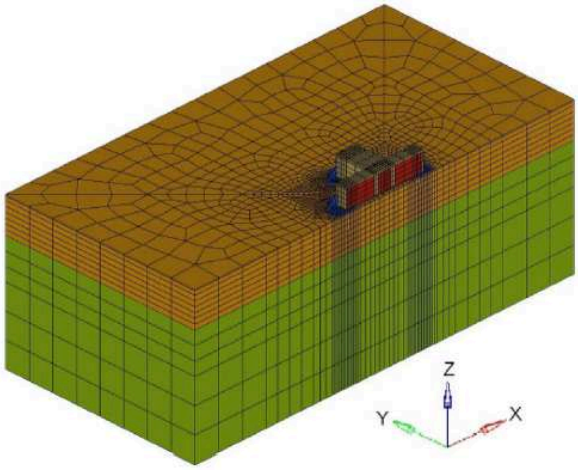

Fig. 2 Finite element mesh of the gravity base foundation and subsoil

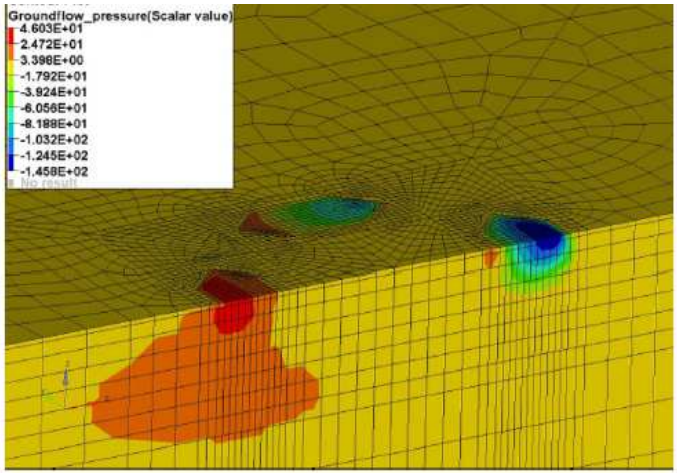

Fig. 3 Excess pore pressure at the moment of the maximum load (t = 37.75 seconds)

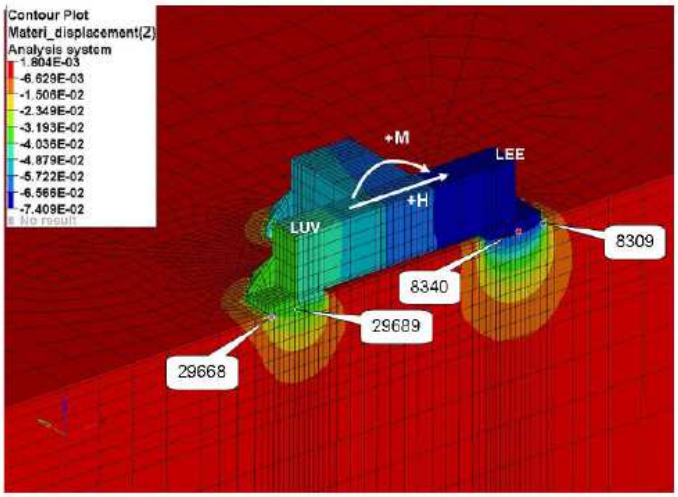

Fig.4 Contour plot of the vertical deformation

The excess pore pressure during the maximum load (t = 37.75 seconds) is shown in Fig.3. Excess of pore pressures occur under the plate at LEE side (away from direction of load) and a negative excess pore pressure at the LUV side (facing the direction of load).The settlement are shown in Fig. 13 (t = 37.75 seconds) and Fig.4. The average vertical displacement at the end of the load sequence is about 11 cm. For a wind turbine structure the tilting is crucial in the foundation design. The maximal tilting reaches about 0.055° to the Left side during the maximal load level at t = 37.75

seconds. The remaining tilting at the end of the load sequence is however only about 0.01° to the Right side. The allowable differential settlement is usually specified by the wind turbine manufacturer. A typical design requirement for an offshore wind turbine given by DNV-OS-J101 as an example is that the permanent accumulated tilt should not exceed 0.25°at seabed.

## Conclusions

A practical method to determine the equivalent load for application in a more complex numerical analysis is presented in this paper. An analysis concept for the foundation of an offshore wind turbine which experiences a high number of cyclic loads has also been proposed. This concept will be proven through back analysis of load simulation which is currently performed on a full-scale gravity base foundation.

# Application status and development trend research of ecological revetment in Jiangsu inland waterway

Zhang Jian[1,2],Zhai Jian-feng[1,2],Wang xian-mei[1,2],Chen Jie[1,2]

[1.] Jiangsu Provincial Communications Planning and Design Institute Co., Ltd., Nanjing 210005，China

[2.]Aquatic transportation center, Nanjing 211100, China

**Keywords:** inland waterway; ecological revetment; structural style; technique feature

**Abstract:** With the development of social economy and acceleration of constructions of inland waterway transportations, the adverse impacts on ecological environment are gradually known by people. Under the circumstance of protecting the environment we live, the generalization of technology of ecological bank revetment will be an irresistible trend of the development of inland waterway. Combining the examples of constructions of ecological bank revetments in inland waterways in Jiangsu Province, this thesis presents us the discussion on the structural style, technique features, as well as the application principles of ecological bank revetments, meanwhile puts forward the prospects of technology of ecological bank revetment.

## Introduction

Hard revetments were adopt in most of ttraditional inland waterway, which excessive emphasis on the function of transporting, less considering the ecological effect and environmental effect.Hard revetment cut off the matter and energy between river and bank, reduced the purification of the river. With the development of social economy and inland waterway transporting, people not only to require the safe of waterway, but also integrate the factors of natural landscape and ecological environment protection. In order to meet the need of new situation, the inland waterway should not only satisfy the requirements of strength, stability, durability and safety, also give full consideration to coordinated development between people and nature. Then, inland waterway revetment technology also turn from pure engineering technology to the ecological engineering technology development, and the ecological revetment technology increasingly widespread attention

## The main types and technology characteristics of ecological revetment in Jiangsu province

The ecological revetment is new types of bank revetment which use plants with combination of civil engineering. The ecological revetment set of landscape function, ecological function and self-purification functions into an organic whole, which on behalf of the development direction of bank protection. The main types and technical characteristics of ecological in Jiangsu province are introduced in this paper, which provided the basis for widely used of ecological revetment.

(1) Ecological bag revetment

Fig.1 Ecological bags

Ecological bags have filter function, which not only prevent loss of filler, but also realize normal moisture communication in the soil. Ecological bag can provides plenty of moisture and let the plant through bag body. The roots pass into soil of the engineering foundation, like countless of anchors which stable bag bodies. Further achieve the goal of building permanent stability slope and greatly reduces the maintenance cost.

(2) Gabion revetment

Fig.2 Gabion revetment

This kind of revetment structure can be well fusion with local natural environment, and voids between filler can provides good channels for moisture and nutrient, which provide growing space for aquatic life. This kind of structure have a strong ability of anti-washout and a high strength of flood fighting, which could be applied to fast velocity river. In addition to this, this kind of structure have a low cost such as slurry masonry structure.

(3) Precast block revetment

Fig.3 Precast block revetment

Precast block revetment have a high adaptability to small deformation and strong ability of anti-washout. This kind of revetment have a better effect of planting grass because of high porosity and good permeability, which improve ecological environmental by forming a natural revetment and reinforce the slope by the roots.

(4) Box-type revetment

Fig.4 Box-type revetment

The advantage of box-type structure lies in saving loss of concrete material, and the cavity reserved along length direction can be filled with non-fine concrete, stone etc. This kind of revetment have an effective treatment to waste soil, and a low project cost. In additional to this, structure of box-type revetment is simple and stress condition is good, and resistance to overturning moment is improved because of force of friction between concrete and wall.

(5) Self-embedded revetment

Fig.5 Self-embeded revetment

Blocks between lumps of self-embedded revetment without mortar and other consolidation measures, which have characteristics of good stability, fast construction, low cost and adaption to soft ground etc. With the optimizing of self-embedded structure, self-embedded greening revetment is generated. This kind of structure consist of embedded block, plastic stick, filter and soil, which wall surface and body could be planted. When applied in water environment, underwater structure could be planted aquatic plants and provided survival space for fish, given a better interpretation to ecological revetment.

**Application principles of inland waterway revetment in Jiangsu Province**

Although ecological revetment has widely used in inland waterway construction and achieved a good results, but suitability of the type of revetment still not have a clear guidance. Construction of ecological revetment should choose suitable structure according to the characteristics of engineering, some principles of application are introduced in following.

(1) The principle of adjust measures to local conditions

Construction of ecological revetment are affected by town planning, site condition, geological condition etc. Therefore, the selection of ecological revetment should be fully researched the prominent factors and considered other factors.

(2) Principles of Hydrodynamic

Restricted channel should consider alternate arrangement of revetment type because of section coefficient is small and the influence of ship wave is bigger. In section of which coefficient is smaller and hydrodynamic is stronger, the hard revetment can be used. And in section of straight which coefficient is bigger, ecological revetment can be widely used.

(3) Principles of construction and easy maintenance

Because of revetment engineering is not converged on a point, but along the layout. Reducing maintenance work and ensuring operation will be of great important in operation period, so it should consider life-cycle cost in selection process.

## Conclusions

(1) Ecological revetment sets of landscape functions, ecology functions and self-purification functions into an organic whole, which is development trend and requirements of construction in present and future. The structure of ecological revetment is varied, which should be considered according to the characteristics of waterway. Ecology notion also should be integrated into design, promoting ecological construction of inland waterway.

(2) Application of ecological revetment should well considered surrounding environment and hydrodynamic characteristics, and pay attention to joint use of ecological revetment and hand revetment.

(3) Concept of life cycling and resource saving should be integrated into design and construct of ecological revetment. We should using ecological method to solve the ecological problems and carrying out ecological concept of sustainable development. The inland waterway in the future will not only being a main transport passage, but also a green and environmental ecological corridor.

**Keywords:** Buttressed Quay, Floor, Internal Force, Finite Element Method (FEM).

**Abstract.** In the design and construction code for gravity quay, the inner floor of multi-ribbed buttressed quays generally is divided into two parts to calculate. The part within 1.5 times the rib spacing is as a three fixed edges and one simply-supported slab. The restriction effect of the three fixed edges is the same. However, because of the difference in thickness between vertical plate and rib with the change in the vertical direction of the flow, the effect of them is not the same. It will lead to the result deviating. Sometimes, there will be a phenomenon that the maximum bending moment of inner floor is smaller than the mid-span moment. Finite element software ANSYS was used to make a 3D numerical simulation on a buttressed quay in this paper. Shortcomings in the current code are addressed by comparing the calculation results. This can provide references for engineering design.

## Introduction

Buttressed quay is a reinforced concrete structure which consists of vertical plate, floor and rib. It has advantages of simple structure, rapid construction, mature technology and low cost compared with other gravity quays [1]. Currently, in the design and construction code for gravity quay, the calculation of floor's internal force by following provision: on the floor of multi-ribbed buttressed quay, divide the inner floor into inner and outer part in the location of 1.5 times the rib spacing. The inner part is as a slab whose three edges are fixed and one simply-supported, while the outer part is as continuous [2]. When using this method assumes that the restriction effect of vertical plate and rib on the floor is the same. However, because of the difference in thickness between the vertical plate and rib with the change in the vertical direction of the flow, the effect of them is not the same. It will lead to the result deviating. Besides, when the force on the floor becomes more complex, there will be a phenomenon that the maximum bending moment of inner floor is smaller than the mid-span moment. This paper took another simplified method to calculate the internal force of the floor. In order to make the buttressed quay structure design more reasonable, the finite element software ANSYS was used to calculate the floor's internal force as well. Making an analysis of the calculation results of three methods and provide guiding suggestions on the practical project design.

## Engineering example

The quay of the example is a multi-ribbed buttressed structure, as show in Fig.1. The length of each structural segment is 13m, thicknesses of the ribs are all 0.6m, the spacing of the rib is 3.6m and the length of the cantilever is 1.1m.

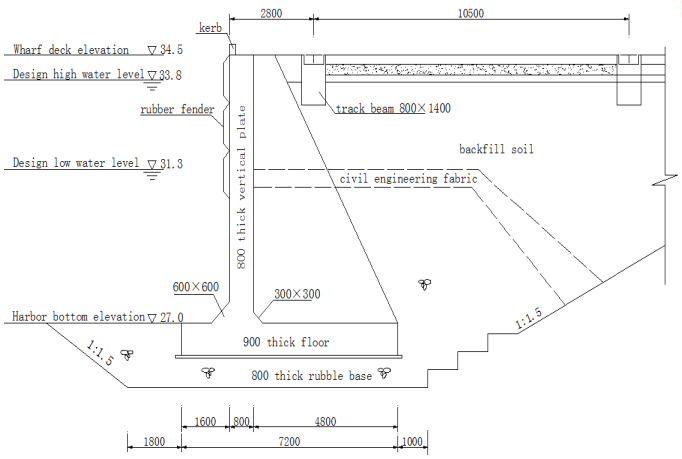

Fig.1 Cross-section of the buttressed quay

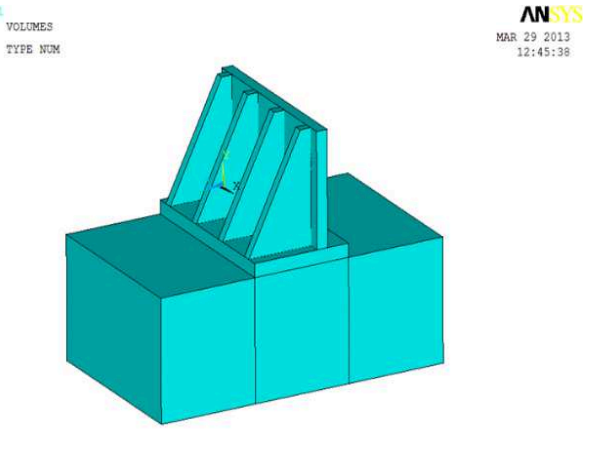

Fig.2 Finite element model of buttressed quay

## Calculation of the floor's internal force

**Design loads and load combination.** Active earth pressure caused by self-weight of backfill soil calculated with the Rankine formula [3]; foundation reaction force calculated with the formula of eccentric compression. Research on the floor of buttressed quay during the completion period, then the remaining water pressure, uplift pressure, ship impact force and surface load can be ignored. So load combination is structural weight + earth pressure.

**The common calculation method.** On the inner floor of multi-ribbed buttressed quay, the inner part is as a slab whose three edges are fixed and one simply-supported, while the outer part is as continuous. The front toe of floor is as a cantilever structure [2].

When use three fixed edges and one simply-supported slab to calculate the internal force of floor, the force acting on the floor can be decomposed into uniform load and triangular load, middle floor moment (Mx, Mz), the maximum moment (Mxmax, Mzmax), bearing moment (Mx0, Mz0) with the action of uniform load and triangular load can be calculated by using the static structural calculation handbook. Then the two calculation results can be superimposed (hereinafter referred to as the method 1) [4]. When the force on the floor becomes more complex, sometimes in order to simplify the calculation, the triangle load can be taken the mean value as a uniform load to calculate the floor's internal force (method 2) [5]. The calculation results according to the above two methods are shown in Table 1.

Table 1 Floor moment calculation results (kN·m)

| moment | Mx | Mxmax | Mz | Mzmax | Mz0 | Front toe |
|---|---|---|---|---|---|---|
| FEM | 23.2 | 26.65 | 23.81 | 24.78 | -24.6 | 280.7 |
| method 1 | 3.61 | 0.8 | 9.98 | 9.78 | -20.9 | 296.5 |
| method 2 | 4.16 | 4.88 | 8.84 | 9.06 | -19 | 296.5 |

**Finite element model.** In order to accurately reflect the internal force of floor, three-dimensional numerical model has been established by finite element software ANSYS 10.0. The finite element model of buttressed quay and foundation soil were created with soild-45 unit (the eight-node element), as show in Fig.2. This paper mainly studies the structure as a whole buttressed its floor's internal force distribution. Therefore, for the active earth pressure of backfill soil, the paper used Rankine earth pressure formula simplified earth pressure as the horizontal static force acting on the vertical plate. The vertical earth pressure on the floor directly took soil weight on the floor surface.

**Inner floor calculation result.** Extracting the bending moment of inner floor in FEM calculation results, and compared with the simplified calculation. The results are shown in Table 1.

As can be seen from Table 1, both positive and negative results are consistent, and the trend is also consistent. However, FEM results significantly larger than simplified calculation results, main reasons:

(1) Foundation reaction force distribution is different in the FEM and simplified calculation method.

(2) There are some problems to the simplified calculation method. In this paper, the thickness of the vertical plate and rib is different, so the restriction effect of both of them on the floor is different. Besides, the size of rib along the vertical direction of flow is changing. This allows the restriction effect of rib on the floor is also changing. However, the restriction of three fixed edges is the same in the static structural calculation handbook.

(3) FEM considering the deformation and stress of buttressed plate as a whole; simplified calculation method only considering the load in the region of inner floor, and then calculate the internal force of floor with the static structural calculation handbook. This also lead to a large deviation between two calculation results.

In addition, it can be seen in Table 1, Mx, Mz larger than Mxmax, Mzmax in the method 1 calculation results. The reason is that the external forces acting on the floor are broken down to a downward uniform load and an upward triangle load in the calculation process, then separately calculate the internal force of the floor under the action of them, and superimpose the two results. However, the maximum bending moment of inner floor in a downward uniform load is positive; the maximum bending moment in an upward triangle load is negative. And generally they do not appear at the same point, directly overlay them allows the maximum reduced. Thus causes this problem.

**The influence of rib spacing on the floor's internal force.** Change the rib spacing, respectively for L=3.2, 4.0, 4.4m, to observe the change of foundation reaction force and internal force of floor.

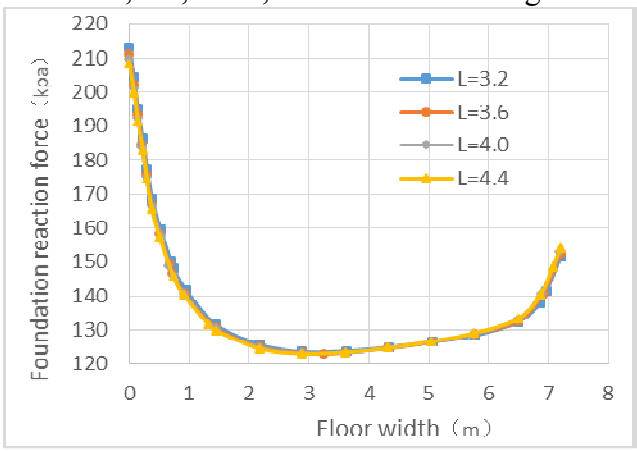

Fig.3 With the foundation reaction force change in different rib spacing

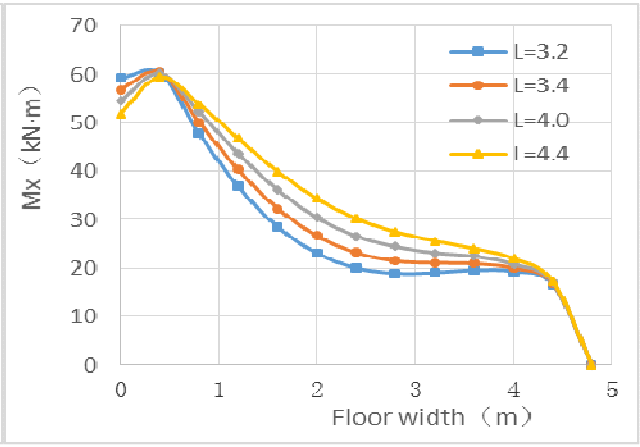

Fig.4 The floor moment Mx

As can be seen from Fig.3, foundation reaction force distribution is almost no change with the increase of rib spacing. Extracting the floor moments: Mx, Mz, Mz0. Observing the bending moment changes with the rib spacing:

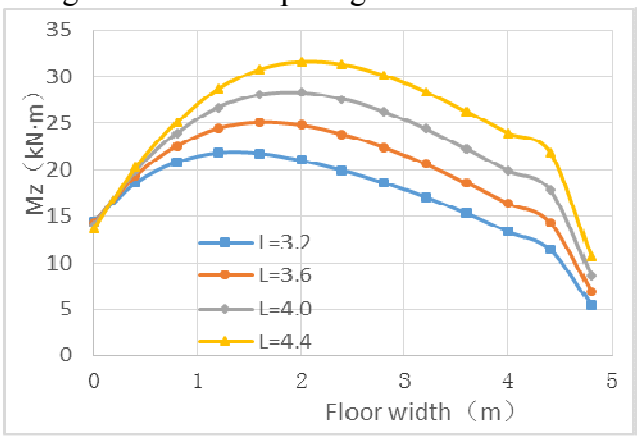

Fig.5 The floor moment in the middle ribs Mz

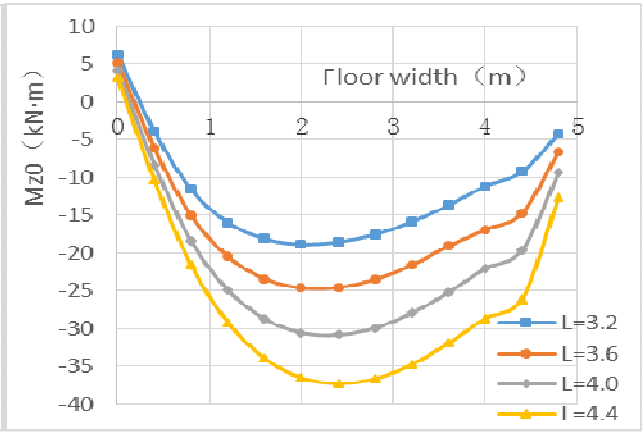

Fig.6 The floor moment in the floor junction with ribs Mz0

Fig.4, Fig.5 and Fig.6 reflects the bending moment changes with the distance of ribs. It is shown that foundation reaction force is basically unchanged with the increase of rib spacing. The bending moment increased with the increase of rib spacing, and the moment changes more and more obvious. Meanwhile, the internal force of floor was calculated with two simplified calculation methods. Get the floor's internal force in different rib spacing as shown in Table 2.

Table 2 Calculation results of floor's internal force in different rib spacing (kN·m)

| rib spacing | 3.2m | | | 3.6m | | | 4m | | | 4.4m | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | FEM | Method 1 | Method 2 | FEM | Method 1 | Method 2 | FEM | Method 1 | Method 2 | FEM | Method 1 | Method 2 |
| Mx | 20.06 | 2.33 | 2.84 | 23.2 | 3.61 | 4.16 | 26.62 | 5.3 | 5.71 | 30.23 | 8.13 | 7.67 |
| Mxmax | 23.07 | -0.65 | 3.61 | 26.65 | 0.8 | 4.88 | 30.41 | 3.03 | 6.33 | 34.34 | 5.65 | 7.96 |
| Mz | 19.93 | 8.26 | 7.52 | 23.82 | 9.98 | 8.84 | 27.62 | 11.58 | 9.95 | 31.32 | 13.23 | 10.88 |
| Mzmax | 21 | 7.47 | 7.71 | 24.78 | 9.78 | 9.06 | 28.31 | 11.72 | 10.17 | 31.61 | 13.51 | 11.11 |
| Mz0 | -18.6 | -16.9 | -15.8 | -24.6 | -20.9 | -19 | -30.8 | -24.7 | -22 | -37.3 | -28.2 | -24.7 |

Comparative analysis of the calculation results in Table 2. The calculation results of method 1 and 2 are less than FEM, and Mx, Mz larger than Mxmax, Mzmax in the method 1 calculation results. This shows that when superimpose on the maximum bending moment calculated by the uniform load and triangular load in the opposite direction, because of the maximum bending moment do not appear at the same point, and therefore it cannot be directly superimposed. So it is partial to the danger if they are forced to overlay in engineering design. While the calculation results of method 2 which simplify triangle load as a uniform load are very close to method 1, and can reflect the maximum bending moment of inner floor. It can provide a reference for engineering design.

## Conclusions

(1) Through the comparative analysis of results with three kinds of methods including two simplified calculation methods and one FEM, using the FEM for spatial simulation is feasible.

(2) Because of the difference in thickness between the vertical plate and rib with the change in the vertical direction of the flow, the restriction effect of three fixed edges is not the same. All reasons lead to the calculation results tending to smaller, so the calculation result of two simplified methods should be amended appropriately for the safety of the engineering.

(3) When the force on the floor becomes more complex, and the direction is opposite after simplified to uniform load and triangular load. There will be a phenomenon that the maximum bending moment of inner floor (Mxmax, Mzmax) is smaller than mid-span moment (Mx, Mz) in method 1. At this point the triangle load can be taken the mean value and simplified as a uniform load which is method 2 in this paper. Whichever is greater as the design value in the calculation results of two simplified methods.

# Research of sediment transport trend and erosion-deposition characteristic of Yangma Island sea area

YingWang[1, a], WeiYe[2,b] , and Mingchang Li[3,c]

Tianjin Research Institute for Water Transport Engineering, M.O.T,Tianjin, China

ruozhu1106@163.com

**Keywords:** Yangma Island; sediment transport; erosion-deposition; numerical simulation.

**Abstract.** The article adopts the methods of long shore sediment transport calculation, historic chart comparison and numerical simulation of ECOMSED and analyses erosion-deposition characteristic of the Yangma Island sea area. Research shows that the deposition-dominating areas are located at the southwest of study area, while the beach between Xin'an River and Yuniao River shows slightly erosion trend.

## Introduction

Yangma Island is located in the northern part of Shandong Peninsula and 9 km away from Muping District, Yantai City [1]. Its geographical position is shown in Fig1. It is the third largest island in Jiaodong Peninsula.

The tidal condition of Yangma Island sea area is under the control of north yellow sea tidal wave system. Its tide type belongs to regular semidiurnal tide. By the harmonic analysis of survey data on March 19 and 20, 2009, the current is mostly in the rectilinear current movement. The tidal current type is composed of regular semi-diurnal tide and irregular semidiurnal tide. According to the statistical data，often wave direction for the whole year are N, NNW and NW and the strong wave direction is N. The max wave height is 4.7m.

## Analysis of sediment transport trend

### 2.1 sediment characteristics

The coastal type of Yangma Island is the bedrock coast. Coarse sand , silty sand and silver sand are the main bottom sediment types. The sediment characteristic and distribution range are shown in Fig2.

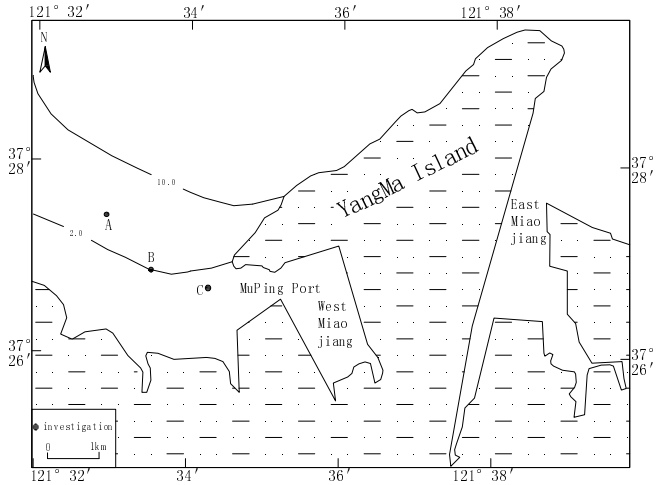

Fig.1 The position of Yangma Island

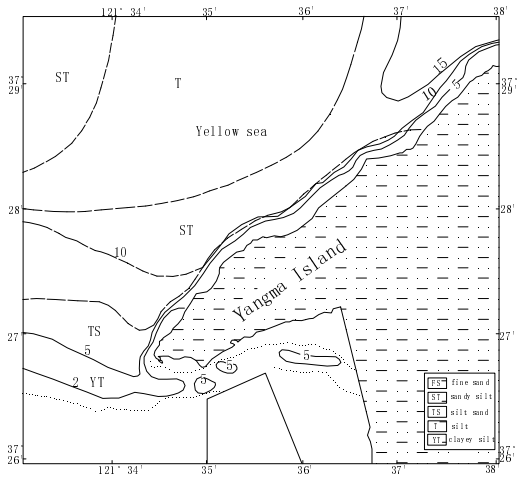

Fig.2 Sediment distribution of study area

### 2.2 sediment source

The main sediment sources are from river sediment and longshore sediment transport.

**River sediment transport**

There is no big river flowing into the study sea area, only two seasonal rivers which are Xin'an River and Yuniao River. Yuniao River is 14.5 km long, there is a reservoir upstream. Xin'an River with annual sediment discharge $2\times10^5$ t is 40 km long, which river runoff and sediment runoff are increasingly reducing .

**Longshore sediment transport**

1. The active depth of sand

The paper adopts experience formula[2] to calculate the active depth of sand.

The coastal types is sandy coast in southeastern Mou Ping port. Due to the influence of the topography, specially impact of NW, NNW, NNE, N, NE, ENE and E wave, 90% of sands are actived in the zone of wave breaking. According to the calculation results of formula[4],we know the active depth of sand is 0.62m-2.14m under general wave conditions. While the $H_{1/3}$ wave height (4.9m) appears in heavy sea, the active depth can reach 2.14 m. The calculation results are shown in table1.

Table 1 The active depth in action of wave

| wind direction | significant wave height（m） | period (s) | active depth (m) |
|---|---|---|---|
| NW | 1.76 | 4.4 | 0.86 |
| WNW | 1.92 | 4.6 | 0.94 |
| NNW | 2.4 | 5.0 | 1.15 |
| NNE | 2.4 | 5.1 | 1.17 |
| N | 4.9 | 4.9 | 2.14 |
| NE | 1.92 | 4.7 | 0.93 |
| ENE | 1.6 | 4.1 | 0.77 |
| E | 1.3 | 3.6 | 0.62 |

Seabottom slope: tanβ=0.01

2. The motion depth of sand

Jiaju Liu[3] considered that the motion depth of sand is less than 4 m in the zone of wave breaking. Due to the impact of offshore wind and waves, the sand was active easily under wave action and then transport following tidal current movement. The coarse particle was active hardly when the depth reached 4m. The paper applies Komar's and Miller's formula [4] to calculate the active depth of sand. The calculation results are shown in table2.

Table 2 The initiate depth in action of wave

| significant wave height（m） | the motion depth (m) | | | | |
|---|---|---|---|---|---|
| 1.76 | 1.32 | 1.98 | 3.30 | 3.30 | 3.30 |
| 1.92 | 1.56 | 2.34 | 3.90 | 3.90 | 3.90 |
| 2.4 | 1.62 | 2.43 | 4.06 | 4.06 | 4.06 |
| 4.9 | 1.38 | 2.07 | 3.45 | 3.45 | 3.45 |
| 1.92 | 1.32 | 1.98 | 3.30 | 3.30 | 3.30 |
| 1.6 | 1.56 | 2.34 | 3.90 | 3.90 | 3.90 |
| 1.3 | 1.62 | 2.43 | 4.06 | 4.06 | 4.06 |
| grain size(φ) | 1 | 2 | 3 | 4 | 5 |

3. Longshore sediment transport

On sandy coast longshore sediment transport occurred in the zone of wave breaking [5]. There are the close relation to morphological evolution and longshore sediment transport on Yangma Island coast.

Now Yangma Island has become a peninsula. Longshore sediment transport from west of Muping Port and northwestern coast of the island is important to balance to erosion-deposition of study sea

area. Coastal type of northwestern island belongs to bedrock coast, which grain size is coarser and sediment discharge along wave coast is very small. So the western coast of Muping Port's longshore sediment transport calculation is very important to the whole sea area.

The paper uses the wave data of ocean station of Zhifu Island for longshore sediment transport calculation. The America CERC formula [6] is applied in the calculation. Result shows that direction of sand transport is from west to east in western Muping Port and amount of sediment transport is $4.2\times10^5 m^3/a$. The calculation results are shown in table3.

Table 3 The results of longshore sediment transport（unit：$\times10^5 m^3/a$）

| Wave direction | N | NNW | NW | WNW | Sed discharge |
|---|---|---|---|---|---|
| Sed discharge | +1.81 | +1.62 | +0.872 | −0.06 | +4.25 |

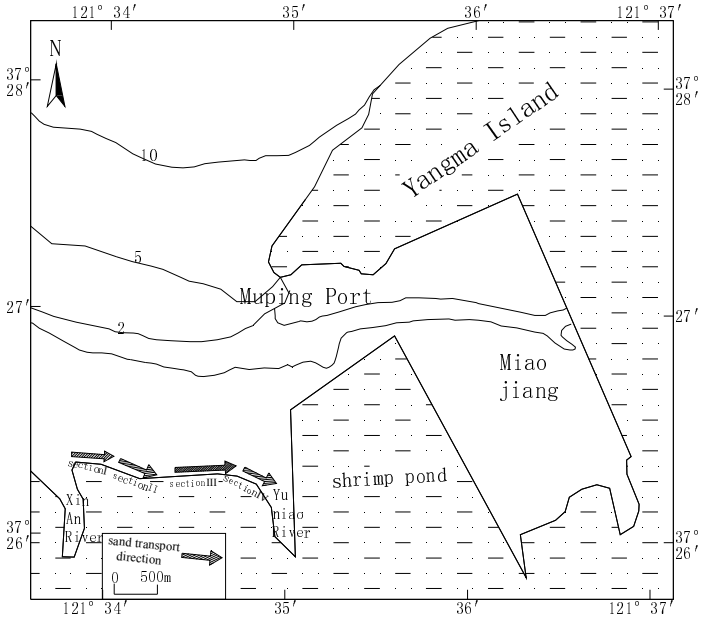

Fig.3 The direction of longshore sediment transport

**sed transport trend**

The sediment supply of the study area is mainly from river and longshore sediment transport. Amount of sediment transport is $4.2\times10^5 m^3/a$. Due to the barriers of Yangma Island and sea wall, the fastest sed deposition amount is located near the channel of Muping Port. However, because this part is in the wave shadow zone of island, the deposition trend will continue to exist.

## Numerical simulation

### 3.1 research method

The method of ECOMSED [7] numerical simulation is applied to obtain the seafloor evolution situation of the Yangma Island sea area.

### 3.2brief introduction

The sediment scouring and deposition model equation.

$$\frac{\partial C_k}{\partial t}+u\frac{\partial UC_k}{\partial x}+v\frac{\partial VC_k}{\partial y}+\frac{\partial (W-W_{s,k})C_k}{\partial z}$$

$$=\frac{\partial}{\partial x}\left(A_H\frac{\partial C_k}{\partial x}\right)+\frac{\partial}{\partial y}\left(A_H\frac{\partial C_k}{\partial y}\right)+\frac{\partial}{\partial z}\left(K_H\frac{\partial C_k}{\partial z}\right)$$

Where: $C_K$ is the concentration of $k$ sediment suspension, in which $k$ = 1, 2, respectively representing the sticky and non-sticky deposits; $A_H$ is the horizontal diffusion coefficient; $K_H$ is the vertical eddy viscosity coefficient; $E_k$ and $D_k$ are the scouring and deposit functions of $k$ sediment

suspension; $\eta$ is the sea surface fluctuations; H is water depth; $W_s$ is the settling velocity of suspended sediment.

### 3.3 numerical simulation

**Analysis of numerical simulation of erosion-deposition**

Under normal weather, the erosion-deposition characteristic of seabed around Yangma Island is shown in Fig4. It can be seen from the Figure that the whole study area show the laws that coastal area of Yangma Island slightly eroded and offshore area deposited entirely. The maximum deposition thickness is within 15cm/a and maximum erosion thickness is 1cm/a. The southwestern coastal area of Yangma Island has always been slight deposition. The deposition thickness is within 1cm/a. The southwest sea area of Yangma Island has been deposition and its deposition thickness is between 0.5cm/a to 5cm/a. The place which has fastest deposition amount is located near the channel of Muping Port. The beach between Xin'an River and Yuniao River shows slightly erosion trend and its erosion thickness is within 1cm/a.

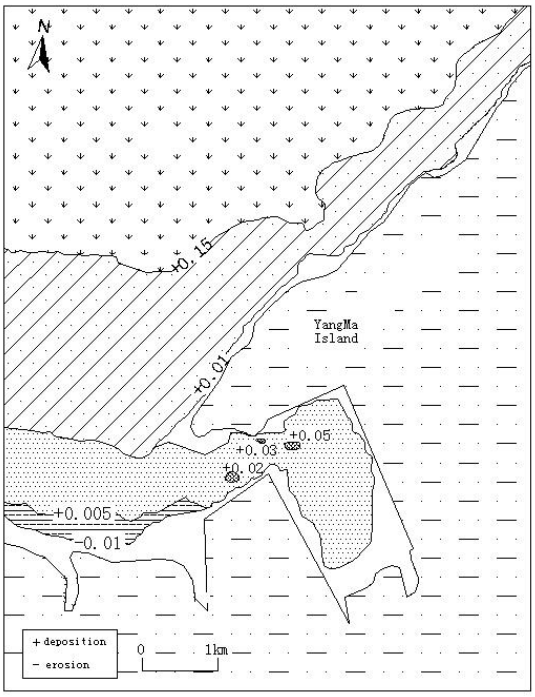

Fig.4 Annual erosion and silting height under normal climate（unit：m）

**Model validation**

For the accurate results of numerical simulation, the application of software of AutoCAD and Suffer, language of Visual basic and historic chart comparison(form 1976 to 2009) are adopted. Results are shown as follows.

In the northwestern coastal area of Yangma Island the coast type is bedrock coast, between the area of 2m depth contour shows slightly deposition trend.The depth contour moves less than 20m and its deposition thickness is within 1cm/a.

The depth contour between Xin'an River and Yuniao River moves slightly to land and its erosion trend is not obvious. There are two major aspects for the erosion. Reducing the coast sediment source leads to erosion directly. The other is related to the tidal current. During flood tide, the sediments on the northeastern side and southwestern side of Yangma Island are transported to its southern sea are with the flood tide. Current velocity declines caused sediments deposition in this area. During ebb tide, the sediments in strong current area of on southwestern entrance of Yangma Island is transported to the adjacent sea area outside the entrance. The flow velocity declines rapidly and the sediments then caused obvious deposition.

In southeastern sea area of coastal area of Yangma Island, the 2m depth contour and 5m depth contour moves outside obviously. That is to say: deposition occur in the area. The main deposition

changes were located near channel of Muping Port. However, because this part is in the wave shadow zone of island, the deposition trend will continue to exist. But annual deposition amount is extremely small. In addition the increase of land reclamation and weakened tide dynamic are the main reasons of fine grained sediment deposition here.

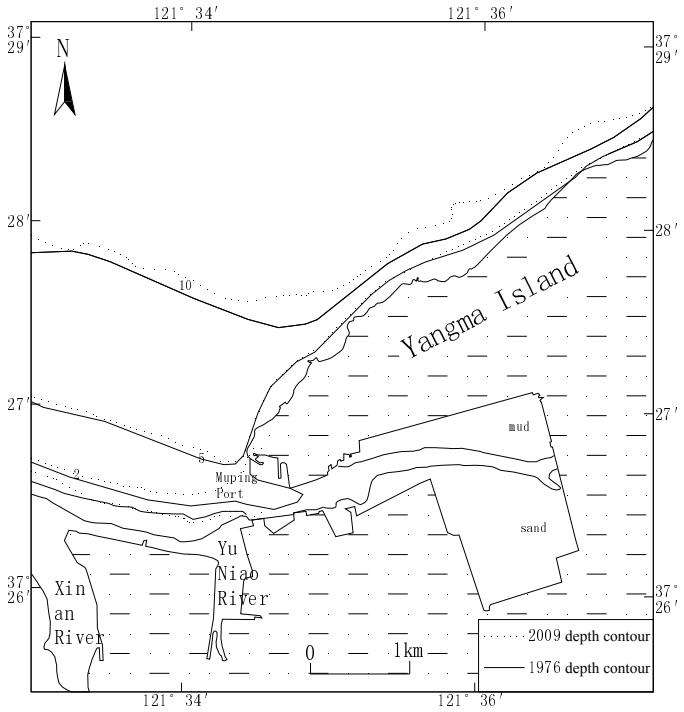

Fig.5 Comparison chart of fathom line form 1976 to 2009

## Conclusion

1.The river and longshore sediment transport are the main sediment source in sea area of coastal area of Yangma Island ;

2.The southwest coastal area of Yangma Island has always been slight deposition and its deposition thickness is between 0.5cm/a to 5cm/a ;

3.Historic chart comparison(form 1976 to 2009) shows the simulation of ECOMSED can precisely reflect the erosion-deposition characteristics in area of Yangma Island.

# Study on the evolution of artificial beach in Xiamen

Guanglu Wang [1, a]

[1] Tianjin Research Institute for Water Transport Engineering, Tianjin 300456,China;

[a]wglas4@163.com

**Keywords:** beach restoration, beach evolution, monitoring.

**Abstract.** Taking Xiamen Xiangshan-changweijiao beach project as an example, study the technology of beach restoration. Xiangshan-changweijiao beach locates at the SE of Xiamen Island, which has already been eroded out. The restoration project was finished by the first step and the beach showed better performance than history after one year evolution. By analyzing the environment of shore, designing beach factors, technology of beach fill placement, study the beach restoration and evolution of artificial beach, inquiry the theory of beach nourishment in China.

## The natural conditions of artificial coast

Xiangshan - Changweijiao artificial beach project is located in the eastern coast of Xiamen Island, with a total length of 1.5km, is currently the largest artificial beach. Kinmen Island and many small islands are around the east and south sea area, and the Shoreline towards NNE. Out side waves are difficult to spread in the area, which is possible to bring the longest wind and wave field around the project. The underwater topography of the project sea area is more complex. In the mean sea level contour to 5m deep seabed topography is irregular, distribution alternates with tidal channel and shallows. Both sides of the coast north and south are respectively protected by the Xiangshan and Changweijiao rock headland, the coastline is north-south asymmetry concave arc. According to the site survey and the existing information, geomorphic units of restoration area includes laterite plateau coast, bedrock headland coast, artificial embankment, intertidal beaches, underwater shoal, deep grooves and so on.

## Artificial beach restoration

The coastal function is clear that the east coast of Xiamen is an important tourist area. in order to reduce the impact on the other part of coast ,the restoration shoreline was designed base on Dynamic equilibrium, and the shoreline was arranged as possible to perpendicular to ordinary wave direction. So the shoreline was designed into two arcs towards northeast.

The fill may be placed well above the shoreline as dune nourishment, on the dry beach and near the waterline, across an extended portion of the profile that stretches from the dry beach to well offshore, or completely offshore as a sand bar. The fill with medium-coarse sand of 0.5mm median diameter, was placed on the dry beach and near the waterline in this project. Once sand is placed on the beach, waves and currents redistribute the material offshore and alongshore until a stable configuration is achieved. Depending on local conditions, a nourished beach may take several months or years to reach the equilibrium condition. [1].

## Beach stability analysis

Grain size grading of the ‘native’ and ‘borrow’ material is necessary for assessing the feasibility of a beach nourishment project. The application of the beach fill model involves calculation of two factors, an overfill factor RA and a renourishment factor RJ, where: RA = the estimated number of cubic meters of fill (nourishment) material required to produce 1 cubic meter of beach material when the beach is in a condition compatible with the native material. It is used to estimate the initial quantities of nourishment required; RJ = the ratio of the rate which borrow material will erode to the

rate at which the native beach material is eroding. It is used to estimate how often renourishment may be required [2, 3]. The values of RA and RJ are determined graphically based on the knowledge of the mean grain size and sorting characteristics of the native and borrow materials. Figure 7 shows isolines of the overfill factor RA and renourishment factor RJ, where: $M_\Phi$= the mean diameter of the grain size distribution in phi units; $\sigma_\Phi$= the standard deviation of the grain size distribution in phi units (a measure of sorting); subscript b refers to borrow material; subscript n refers to native material

The survey of Chinese bay [4] and the report of Xiamen Xiangshan-Changweijiao beach restoration project, showed that $M_\Phi n$=1.22, $M\Phi b$=1.44, $\sigma_\Phi n$=0.78,$\sigma_\Phi b$=0.55. Based on the data as shown in Figure 1, the sands, generally, are not too fine or too well sorted, which would result in the nourishment between unstable and stable.

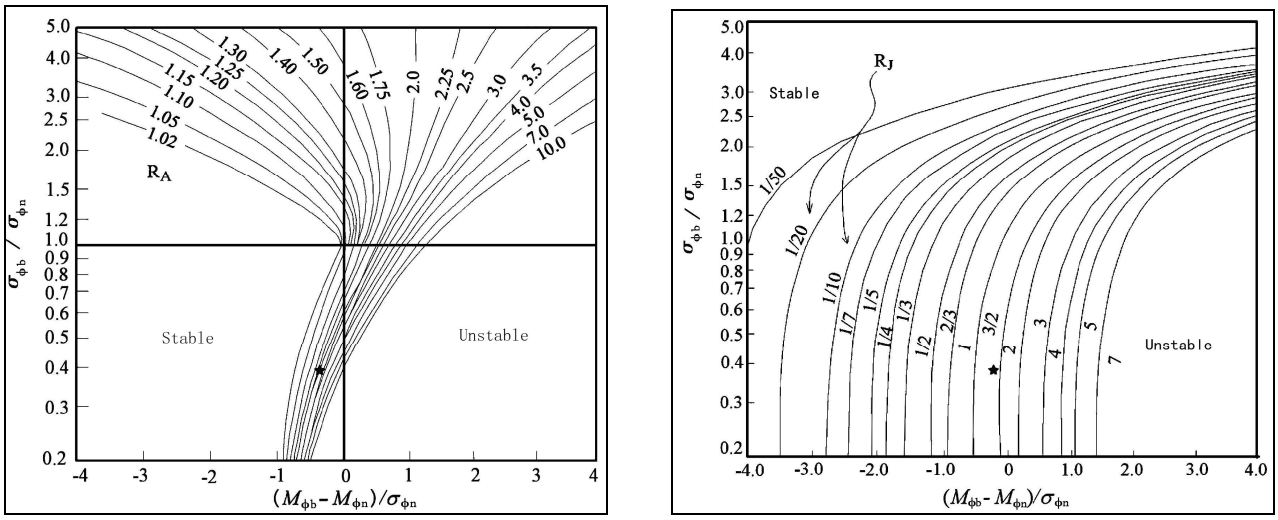

Fig.1 (a) Isolines of the adjusted overfill factor, RA, for values of Phi mean difference and Phi sorting ratio (b) Isolines of the renourishment factor, RJ, for values of Phi mean difference and Phi sorting ratio

**Evolution of artificial beach**

After fill placement, the beach still needs evolution for several years. According to Dean, base on many artificial beach of America, it needs nourishment every 5~7 years, the half period beach is Negative Correlation with the near shore effective wave and coast line corrosion rate, but positive Correlation with the length of beach [4 - 15 ] . According to Combe and Soileau, there is erosional"Hot Spots" that corrosion rate are quicker than beside part. Erosional"Hot Spots" is helpful for estimating the period of beach [16 - 17]. It's convenient for monitoring and renourishment to make clear character in different period of beach, so the study gives an ideal evolution of artificial beach, which is no renourishment and guarding, shown in table 1.

Tab.1 The evolution stages of artificial beach

| types / stages | pocket beach and beach adjacent to Inlets) | long straight beach and seawall beach |
|---|---|---|
| Primary period (less than 1 year) | Shoreline is same as the fill placement; beach face is narrow and steep, with thick sediment and coarse grain, a banding distribution. | Shoreline shape is same as the fill placement, mostly along the coast. |
| shaping period (1-2 years) | Shoreline shape change continuously ,beach face becomes wide ,with erosional"Hot Spots", beach berm becomes narrow, and beach sediment is fine. | Offshore sediment transports obviously, the beach sands spread to Downstream, with erosional"Hot Spots". |

| | | |
|---|---|---|
| maturity period (2-6 years) | Shoreline shape has a suitable arc, with special Landforms, beach face very Broad and gentle, and sediments become fine from land to sea. | none |
| Decline period (more than 6 years) | Shoreline is back off greatly, beach face become steep, sediments are coarser, beach volume reduces. | Shoreline turn to the status before fill placement, coarse grains remnant. |

**Post-project monitoring**

After the fill placement, the beach shape was as shown in figure 2.the monitoring was followed immediately.

(Before) (After)

Fig.2 Satellite photos before and after the beach project

Well-planned performance monitoring allows for verification and future improvement to project design and modeling, as well as justification of project necessity and renourishment intervals. Sufficient project monitoring is a necessity, particularly in chronically eroding locations that pose a challenge to coastal engineering practitioners.

The wind waves are most toward NE～E in winter of Xiamen. After one winter's monitoring, it's shown that beach profiles became gentle from north to south, and beach face became wide. In the middle part of beach, there was a islets which turned into a erosional"Hot Spots". The south part of beach with no shelter and open, eroded most. Tidal zone sediments became fine, especially in middle zone. From the above characters, it's sure that the beach was during shaping period.

**Conclusions**

Artificial beach in Xiamen discussed in the papers, was filled with medium-coarse sand of 0.5mm median diameter, base on the theory it's just between stable and unstable. By the profile, the sediment and the planform, the evolution of artificial beach can be divided into four stages. According to monitoring, it is clear that plan form adjustment began immediately after nourishment and that the relatively high-energy wave events following both the initial and repair nourishments resulted in profile equilibration. Both profile and plan form adjustment can occur rapidly given the appropriate site conditions and energy levels. The beach discussed has come into shaping period just one year.

# Three Dimensional Physical Model Study on Penang Fishing Port Project

Ciheng Zhang[1, a], Baolei Geng [1, b]

[1] Key Laboratory of Engineering Sediment of Ministry Communications, Tianjin Research Institute for Water Transportation Engineering; No.2618, Xingang Erhao Road, Tianjin, 300456, China

[a]zchfirestrom@126.com, [b]gbl@tiwte.ac.cn

**Keywords:** Three Dimensional, Physical Model Test, Fishing Port Project, Wave.

**Abstract.** A three-dimensional physical model was used to study the wave distribution around breakwater in Malaysia Penang. Model tests were carried out by using the L-type action absorption directional wave generator in a 45m×40m wave basin at TIWTE in Tianjin China. The incident wave conditions were checked first in the laboratory and a series steps were introduced to construct the bathymetry and breakwater structure. By comparing the test results, the improved top elevation of breakwater is +4.5m, and the recommendation length of northern part of breakwater is 65m.

## Introduction

A three-dimensional physical model study was carried out, on the proposed design for the breakwater system. The objectives of this study is to ascertain the sheltering effect of the breakwater on the berthing and mooring area, and to achieve optimization of the design. The project site is located at the north-eastern coast of Peninsular Malaysia. A location plan is shown in Fig. 1. For implementation of the project, two training walls, two outer breakwater and one navigation channel will be constructed, the layout plan is shown in Fig. 2.

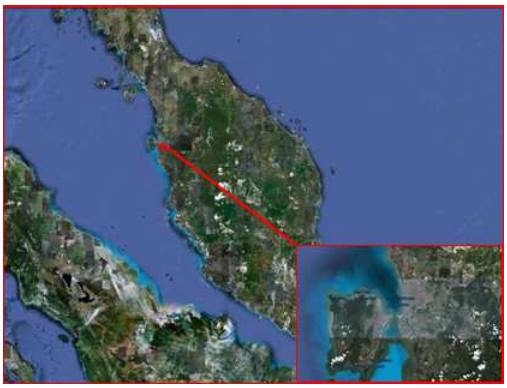

Fig. 1 Location plan of project site

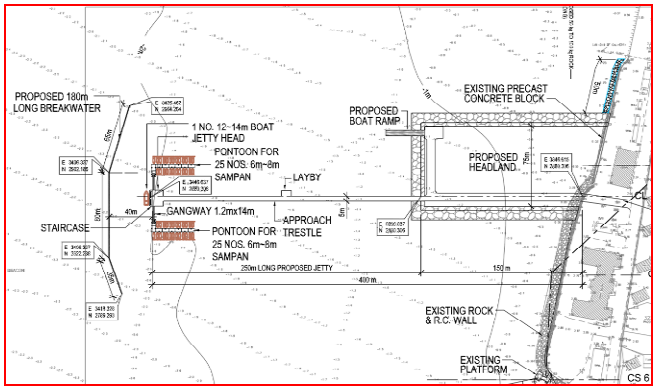

Fig. 2 The layout plan

## Test Conditions

**Wave and Water Level Conditions** The tests were carried out for three offshore wave direction which namely 240ºN, 270ºN and 300ºN at offshore; Three water levels which namely Design water level for model test (DWL) at +3.315m CD, Mean high water spring (MHWS) at +2.69m CD and Mean lowest low water spring (MLWS) at +0.72m CD; 100 years return periods is considered in this paper.

The position of the wave gauges for model is shown in Fig 3. In calibration test, wave gauges $S_4$ to $S_6$ are located at -3m isobaths, as the $P_1$ to $P_3$ in provided condition. The wave height distributions of DWL are shown in Fig. 4.

**Breakwater Structure** The length of breakwater is 180m, northern part is 65m, middle part is 80m, southern part is 35m. The top elevation of piled breakwater is +3.6m. The structure of piled breakwater is shown in Fig. 5.

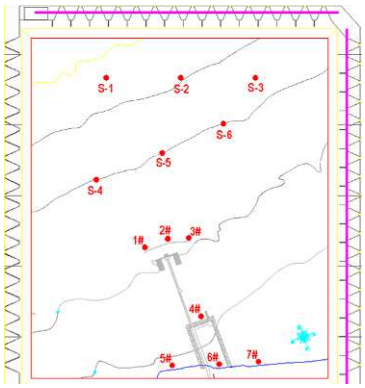

Fig. 3 Positions of wave gauges in model

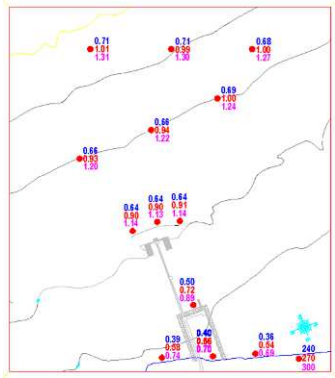

Fig. 4 Wave height result of 100yrs wave under DWL

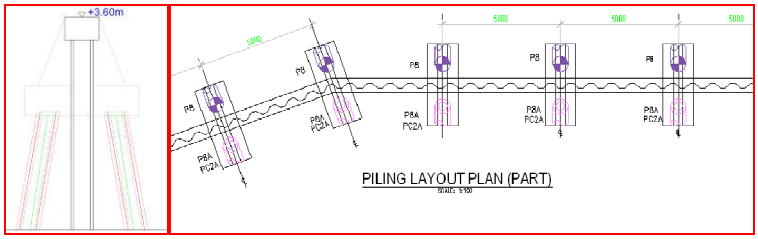

Fig. 5 Structure of Piled Breakwater

## Model Scale

The model is constructed to a linear length scale of 1:30 undistorted. As gravity and inertia forces are the dominant forces in the present model, the Froude similarity law is applied for conversion of the model measurements to prototype values. The following scales apply accordingly:

Length scale: $1:\lambda = 1:30$

Time scale: $1:\sqrt{\lambda} = 1:5.48$

Velocity scale: $1:\sqrt{\lambda} = 1:5.48$

Force scale: $1:\lambda^3 = 1:27000$

Mass scale: $1:\lambda^3 = 1:27000$

## Model Construction

The model study is performed in another wave basin which is 38m length and 34m width. Fig. 6 illustrates the model bathymetry construction process.

Fig. 6 Construction of Model Bathymetry

The bathymetries of the piled breakwater models are constructed to a linear length scale of 1:30, as a fixed bed in accordance with the bathymetry charts provided by project consultants. The model breakwater construction process is illustrated in Fig. 7.

Fig. 7 Construction of Model Breakwater

**Test Equipment** The waves of 3D model are generated by an L-type action absorption directional wave generator, which is an advanced wave generator by international standards. The wave basin is 45m length, 40m width and 1.0m height. The longer side of L-type wave generator is 38m long with 77 wave generating elements. The shorter side of L-type wave generator is 33m long with 67 wave generating elements. The model wave conditions are simulated by the irregular wave generator system. The maximum wave generating capability is 40cm and the maximum wave period is 5.0s.

The wave height is measured by the Hydrodynamic Data Collection System SG2008, using capacitance-type wave gauges, which can automatically collect and analyze the wave heights and wave periods, fitted with built-in temperature compensation. The wave gauges have a wave height measurement range of 0.1~40cm, an accuracy of ±0.5% of the measured value, and sampling rate (output) of 1~200Hz.

## Test Results for Original Design

Wave gauge layout for piled breakwater is shown in Fig. 8. Based on the wave distribution result, the wave height at most extraction point at mooring area are less than 0.3m, but the wave height at 6 points are more than 0.3m, the maximum wave height is 0.41m. The wave distribution results after construction of model are shown in Fig. 9. The test photography is shown in Fig.10.

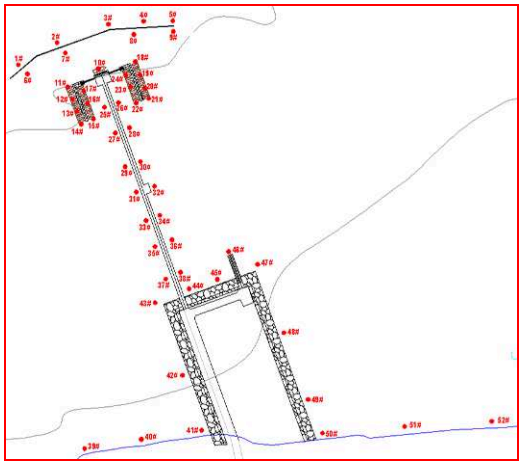

Fig.8 Wave gauge layout

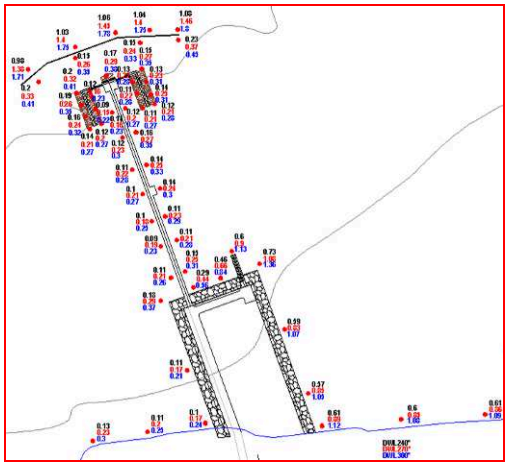

Fig.9 Wave distribution results for 100yrs

Fig.10 Test Photography of Original Design (DWL, 300ºN, 100yrs)

## Test Results for Optimization Design

Based on test result of original design, the most important influence elements of wave height at mooring area are overtopping and diffraction wave. Increasing the top elevation of breakwater can decrease the overtopping, and extend the length of breakwater can decrease the diffraction wave. The improved top elevation is +4.0m, +4.2m and +4.5m, and the improved length of northern part breakwater is 70m, 75m, 80m and 85m.

For top elevation increasing, when the breakwater length is 180m, the wave height result is adopted, and for breakwater length extend, when the top elevation is +4.5m, the wave height result is adopted. For different top elevation, under 100yrs (DWL, 300ºN) wave action, the amount of overtopping wave is shown in follow: +3.6m: 23%; +4.0m: 15%; +4.2m: 10%; +4.5m: 4% wave splashing.

And based on the comparison result of different top elevation, the wave height at mooring area is decreased with the top elevation increasing, about 10% decrease from +3.6m to +4.5m. But for the comparison result of different breakwater length, the wave height at mooring area is decreased with the length extend, but not obvious.

Above all result, the improved top elevation of breakwater is +4.5m, and the recommendation length of northern part of breakwater is 65m. It can be considered as recommendation design.

**Keywords:** Panel, Estuary, High-pile Wharf, Wave Force.

**Abstract.** The high-pile wharf near estuary under wave subjects to great wave force. The wave force can cause destruction of the wharf superstructure. Current research focuses on the case where the forward direction of the wave is perpendicular to or inclined to the wharf front line and mostly applied physics modelling experiments. This paper is to study the case where the wave is parallel to the front line of the high-pile wharf. Take a high-pile wharf near estuary as a model and use the finite element software Ansys to establish the space model. Analysis of internal forces and the destruction of high-pile wharf are made. Meanwhile, the preliminary solution depending on the destruction are proposed, providing references for projects.

## Introduction

The wave force must be considered in high-pile wharf structural design as an important external load, especially to the wharf without the cover. It is closely related to the safety of wharf structures, such as beams, slabs & pile foundations, but its running and working mechanism is very complex [1]. Current research focuses on the case where the forward direction of the wave is perpendicular to or inclined to the wharf front line, and mostly applied physical modelling experiments [2]. This paper mainly studies the case where the wave's forward direction is parallel to the wharf front line. Taking a high-pile wharf near estuary engineering [3].as an example, use finite element software Ansys to build its space model [4] and take its internal forces& deformation for the analysis to investigate the effect of wave force to high-pile wharf structures.

## Engineering example

**Dimension parameters.** This project structure belongs to the high-pile wharf with beams and slabs. Its platform's length is 213m and width is 20m. Each structure segment consists of eight lateral bents and the length is 53.2m. The lateral bent's length is 7m. The wharf top elevation is 4.35m, while pile bottom elevation is -48.30m and mud surface elevation is -5.85m. The pile length is 50m.

**Wind regime.** The wind speed in different return periods is determined by the frequency analysis to the annual maximum series measured by weather station nearby. Specific measurement values are shown in Table 1.

Table 1 Wind speed(m/s)

| return period (year) | wind group | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | N-NNE | NE-ENE | E-ESE | SE-SSE | S-SSW | SW-WSW | W-WNW | NW-NNW |
| 100 | 25.7 | 35.5 | 40.5 | 27.3 | 23.6 | 21.2 | 46.6 | 33.7 |
| 50 | 23.6 | 33.3 | 37.5 | 25.1 | 22.0 | 20.1 | 41.1 | 31.1 |
| 20 | 20.7 | 30.4 | 33.3 | 22.3 | 19.8 | 18.5 | 34.0 | 27.6 |

**Wave paremeters.** The project is in the southeast coast of Zhejiang monsoon region. In this region, Northerly winds prevailing in winter and southerly winds prevailing in summer, the spring and autumn are in the alternate period. Through observation, winter waves mainly northerly, the

frequency of occurrence in the north-northeast is approximately 53% -59% and the east-southeastern is 35% -38%. Summer waves mainly east-southeasterly, the frequency is approximately 69% -72%. Spring waves also mainly east-southeasterly, the frequency is approximately 55% -67%. September waves is like the Summer,while October&November is like the winter. Under the influence of Ao River, wind and wave has almost equal frequency. Wave paremeters are shown in Table 2.

Table 2 Wave paremeters

| Wave direction | Water level | $H_{1\%}$(m) | $H_{4\%}$(m) | $H_{5\%}$(m) | $H_s$(m) | $\overline{H}$(m) | $\overline{T}$(s) | L(m) |
|---|---|---|---|---|---|---|---|---|
| E | 4.97 | 3.69 | 3.20 | 3.11 | 2.66 | 1.76 | 15.5 | 141.8 |
| ESE | 4.97 | 3.51 | 3.04 | 2.95 | 2.52 | 1.66 | 15.5 | 132.1 |
| SE | 4.97 | 3.39 | 2.92 | 2.84 | 2.42 | 1.59 | 15.5 | 132.1 |

**Model building.**This paper made the model in the following order: upper structure of the wharf; pile foundation; contact with pile and soil. Using the Spring simulates the interaction of soil and pile and the Spring's stiffness is calculated by "m" method. Using coupling connects the upper structure and pile foundation. The finite element model of high-pile wharf are shown in Figure 1.

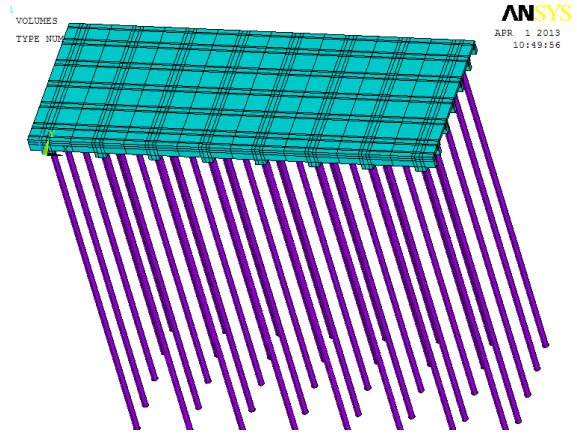

Figure 1 The finite element model of high-pile wharf

**Load.** Loads acting on the wharf include structural weight, ship mooring force, ship impact force, current force. By comparison, using Guoda's formula [5] calculates the wave uplift force and using Shenzuyin's formula [6] calculates the wave horizontal force. When design high water level is 3.85m, uplift force calculation results on the high-pile wharf panel are shown in Table 3 and horizontal force calculation results are shown in Table 4.

Table 3 Uplift force calculation results on the high-pile wharf panel

| return period | direction | $K_1$ | $K_2$ | n | α | π | η | γ | H | L | d | P(Pa) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 100years | E | 4.2 | 1.4 | 2.5 | 0.2 | 3.1 | 5.8 | 9.8 | 3.4 | 133.0 | 8.0 | 214.8 |
| | ESE | 4.2 | 1.4 | 2.5 | 0.2 | 3.1 | 5.1 | 9.8 | 3.3 | 124.1 | 8.0 | 188.3 |
| | SE | 4.2 | 1.4 | 2.5 | 0.2 | 3.1 | 4.9 | 9.8 | 3.2 | 124.1 | 8.0 | 180.9 |

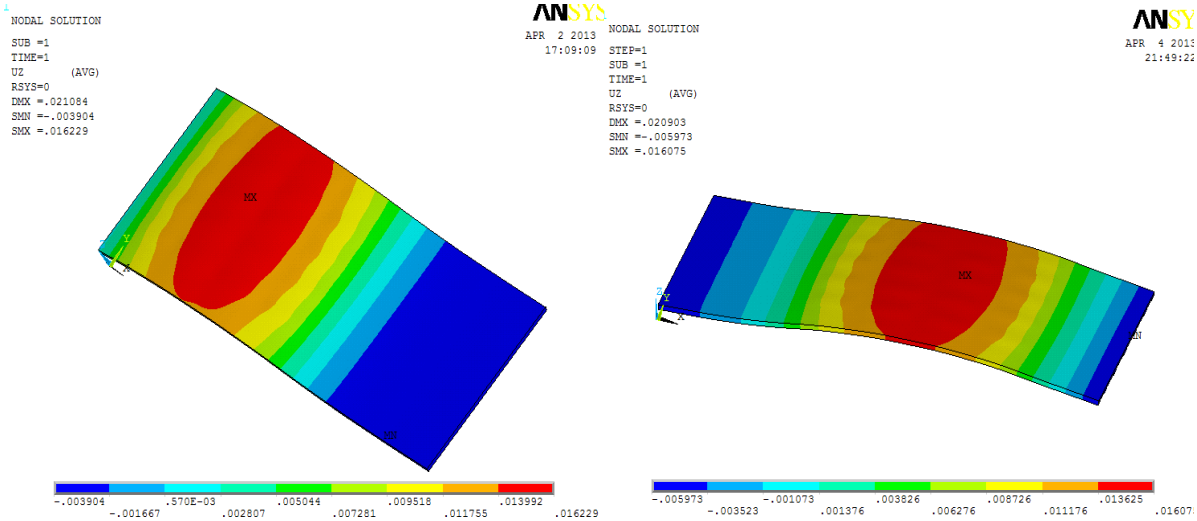
Table 4 Horizontal force calculation results on the high-pile wharf panel

| return period | direction | water level | D (m) | H (m) | L (m) | T(s) | eflectional coefficient Kr | reflected wave height Hr(m) | ho (m) | wharf apron average pressure p(kN/m$^2$) |
|---|---|---|---|---|---|---|---|---|---|---|
| 100 years | E | 5.0 | 10.8 | 3.7 | 141.8 | 14.5 | 1.5 | 5.5 | 0.4 | 5.8 |
| | ESE | 5.0 | 10.8 | 3.5 | 132.1 | 14.5 | 1.5 | 5.3 | 0.3 | 5.2 |
| | SE | 5.0 | 10.8 | 3.4 | 132.1 | 14.5 | 1.5 | 5.1 | 0.3 | 4.9 |

**Results and analysis.** Displacement and the first main stress of the high-pile wharf in two conditions are analyzed. In condition one, the wave cresh is just completely into the bottom of high-pile wharf. In condition two, wave cresh acts in the middle.

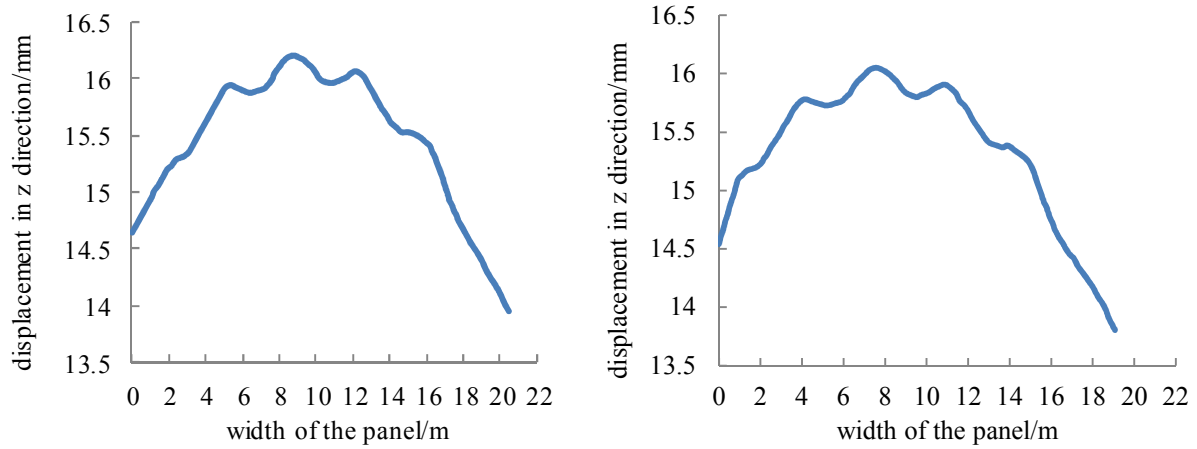
**Displacement analysis.** The displacement results are shown in figure 2~figure 4. From them it can be knew that because the panels and stringers formed a mutual restrain, the maximum displacement

of panel in the z direction is basically occurred in the middle position of the width direction and Z-direction displacement of the panel has a local mutation in the variation process of the width direction. This is in line with reality. Meanwhile, as the crest moving, the uplift forces on the panel also moved and the deformation in the z direction basically coincides with the position of the crest, usually the maximum displacement occurring at the center of the peak. Comparing the results in different varying directions, Changes of panel z-direction displacement in the longitudinal direction are smoother than that in the width direction.



(a) condition one (b) condition two

Figure 2 The displacement in the z direction of the panel



(a) condition one (b) condition two

Figure 3 The displacement in the z direction varying with the width of the panel

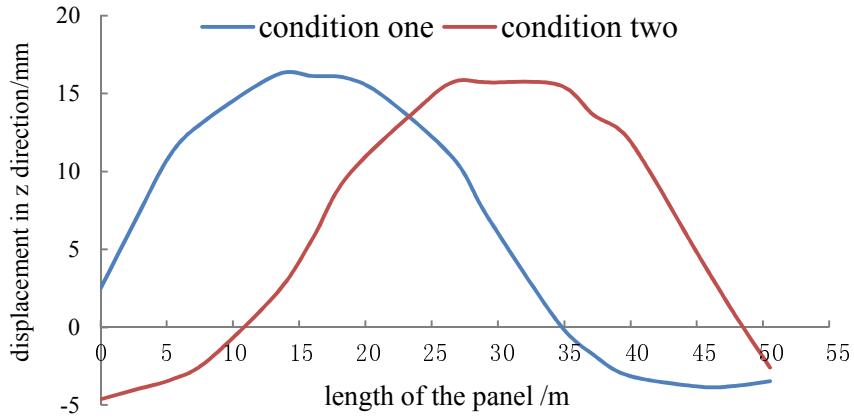


Figure 4 The displacement in z direction varying with the length of the panel

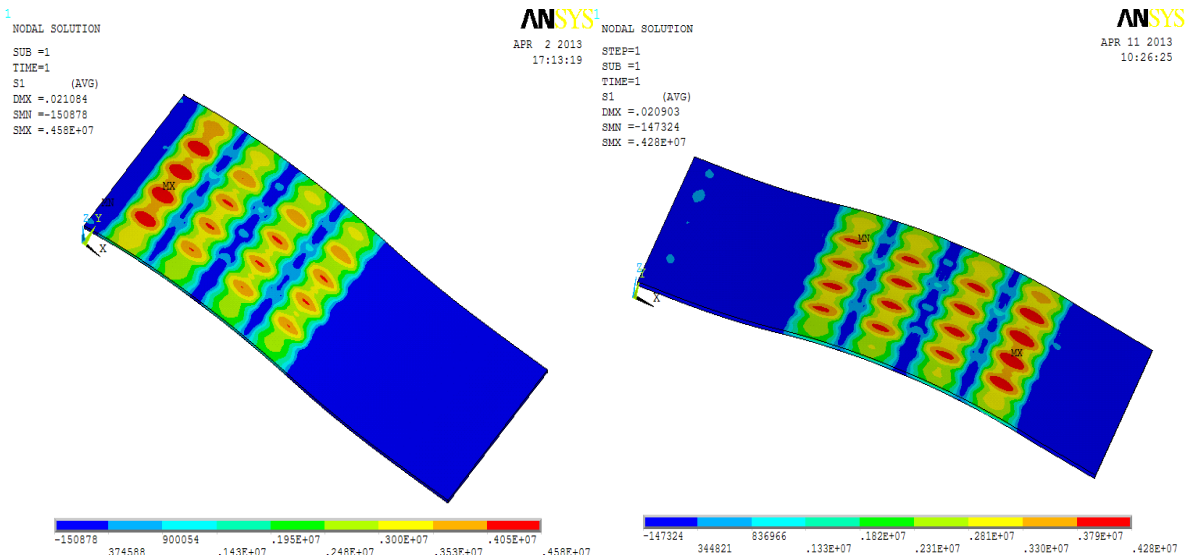

(a) condition one (b) condition two

Figure 5 The Ansys analysis results of the first main stress on the panel

**Stress analysis.** As can be seen from the figure 5, the maximum stress in condition one is 4.58 MPa, the maximum stress in condition two is 4.28 MPa and these stresses belong to the tensile stress. When the wave acts on the wharf, the local stress of panel is large and concentrated in the center. Meanwhile, the tensile stress of panel concentrates at the panel surface, while the compressive stress occurs at the bottom. In most cases, the tensile stress is much greater than the compressive stress, so the crack may appear on the panel, then local failure will occur. Sometimes the panel may be thrown by the waves or cause a large-scale destruction, so there will be great hidden for the security of this condition. Therefore, if there is a greater wave acting on the wharf. a wave dissipation facilities or wharf partially perforated panels must be considered to reduce the impact of waves on the role of the panel to prevent its damage.

## Conclusions

Under the action of the wave, the large displacement and tensile stress of the panel occurred which may cause local failure, even severely destroy to the wharf superstructure, leaving a great hidden for the security of the wharf, especially in the peak position. Therefore, if there is a greater wave acting on the wharf, a wave dissipation facilities or wharf partially perforated panels should be considered to reduce the impact of waves on the role of the panel to prevent its damage.

# Appropriate Jackup Selection in Disturbed Wellsite by Pile Inserting and Pulling in Offshore Oilfield

Yongning An[1,a,*], Qingfeng Song[2] and Jing Li[1]

[1]Tianjin Research Institute for Water Transport Engineering, M.O.C, Tanggu, Tianjin, China

[2]Zhejiang Engineering Prospecting Institute, Ningbo, Zhejiang, China

[a]17106241@qq.com

**Keywords:** Offshore Oilfield. Pile inserting and pulling. Wellsite. Jackup. Pile ultimate bearing capacity. Punch-through analysis.

**Abstract.** Pile inserting and pulling activities may occur for many times in some wellsite in Offshore Oilfield, that resulted in serious stratum disturbance and complex strength change, it's difficult to select appropriate jack-up drilling platform in the workover process latterly. By applying American Petroleum Institute <API RP 2A-WSD> norms, calculating the pile bearing capacity of two typical jackup, combing with the actual data of jackup emplaced, this paper analyzes and compares the suitability of various type of jackup in place in seriously disturbed wellsite by pile inserting and pulling, and then offers a proposal on how to select the appropriate jackup in such wellsite as a reference.

## Introduction

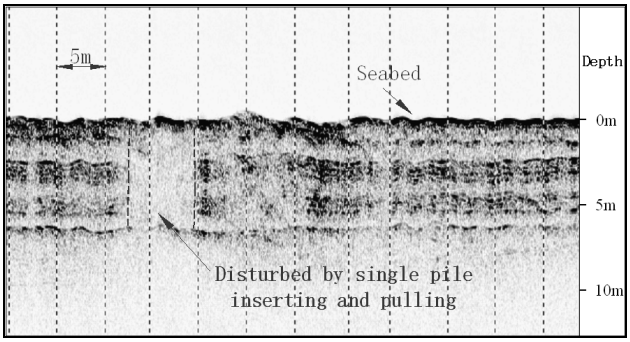
Marine engineering geophysical survey revealed that pile inserting and pulling activities may occur for many times in some wellsite in Offshore Oilfield, that resulted in serious stratum disturbance and complex strength change, it's difficult to select appropriate jack-up drilling platform in the workover process latterly. This paper used an offshore oil wellsite as a typical example to investigate how to select an appropriate jackup in disturbed wellsite by pile inserting and pulling.

## Typical Wellsite Overview

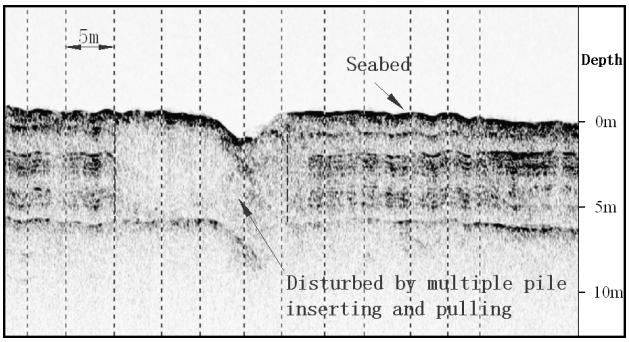
There had been many times pile inserting and pulling activities of Jack-up drilling platform in some offshore oil wellsite and the activities would lead to serious stratum disturbance and complex strength change which had impact on inserting piles activities of workover jackup[1-2]. According to explanation of high resolution shallow seismic profile , pile inserting and pulling disturbance is divided into three categories,single pile inserting and pulling disturbance, location overlapping multiple pile insertion and pollout disturbance,location adjacent multiple pile inserting and pulling disturbance(fig.1).

As can be seen in fig.1, pile inserting and pulling disturbance's influence depth is 7m around.The pile pits formed in site after pile inserting and pulling and the amplitude of the reflected wave is weak which reflected the difference between its internal components and surround because of pile pits destroyed the original formation structure and new sedmiment was filled into pile pits. The plane infuence scope of single pile inserting and pulling disturbance is about 8~10m(fig.1a) larger than common pile pits. The plane infuence scope of location overlapping multiple pile insertion and pollout disturbance is about 20m(fig.1b) which were formed in pre-pile pits. The plane infuence scope of location adjacent multiple pile inserting and pulling disturbance is about 40~70m(fig.1c), which were formed in adjacent location in the same period and the short distance between each pile pits leaded to original stratum collapse so joined together.

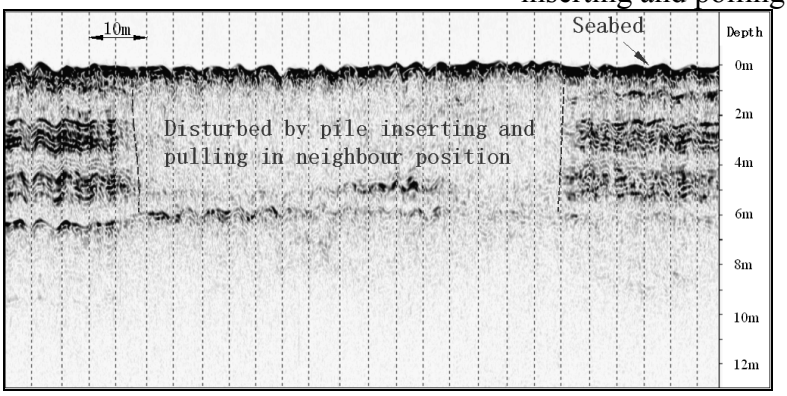
As can be seen in fig.1, pile inserting and pulling disturbance's influence depth is 7m around.The pile pits formed in site after pile inserting and pulling and the amplitude of the reflected wave is weak which reflected the difference between its internal components and surround because of pile pits



(a) disturbed by single pile inserting and pulling



(b) disturbed by overlapping multiple pile inserting and polling



(c) disturbed by location adjacent multiple pile inserting and pulling

Fig.1 Seismic profile of inserting and pulling disturbance in typical wellsite

destroyed the original formation structure and new sedmiment was filled into pile pits. The plane infuence scope of single pile inserting and pulling disturbance is about 8~10m(fig.1a) larger than common pile pits. The plane infuence scope of location overlapping multiple pile inserting and polling disturbance is about 20m(fig.1b) which were formed in pre-pile pits. The plane infuence scope of location adjacent multiple pile inserting and pulling disturbance is about 40~70m(fig.1c), which were formed in adjacent location in the same period and the short distance between each pile pits leaded to original stratum collapse so joined together.

In terms of topography on sea level, single pile inserting and pulling and location adjacent multiple pile inserting and pulling's seabed surface were gently because of long time filling by hydrodynamic scouring action.And the filling substance consolidation degree was high. There was big pile pits in the seabed where occurred location adjacent multiple pile inserting and pulling disturbance that reflect the occurrence of shorter pile inserting and pulling and the pile pits was not filled. Reflection amplitude is different in the stratum below the pile pits demonstrating the components or materials strength different and the carrying capacity is the most complex.

Drilling data reveals the pile hole inside and outside layer composition and strength as follows.

The original stratum outside of the pile pits: (1) Silt, brown, medium dense, layer bottom depth of 4.2m. (2) Mucky silty clay, gray and black, soft plastic, layer bottom depth of 5.8m. (3) Silty clay, gray and black, plastic, layer bottom depth of 7.1m. (4) Silt, gray and black, medium density, layer bottom depth of 9.0m. (5) Silt, light gray, dense, layer bottom depth 10.2m. (6) Silt, brown, dense, maximum depth of 16.0m.

Disturbed stratum inside of the pile pits: (1) Silt, brown, dense ,layer bottom depth of 3.2m. (2) Silty clay, taupe, hard plastic, layer bottom depth of 5.8m .(3) Silt, brown, dense, maximum depth of 10.0m.

**Working Jackup Emplacement and Process Analysis**

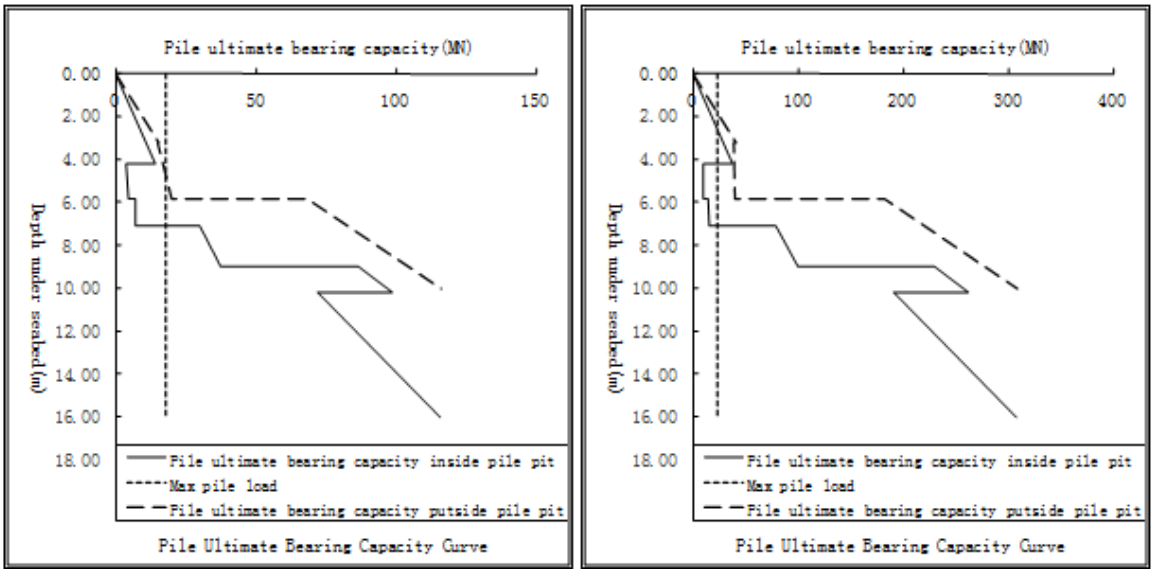
The wellsite experienced two twice inserting and pulling emplacement. The diameter of Jackup No.1 pile shoe is 5.7m, single pile ultimate bearing capacity is 17920kN, did not insert to a predetermined depth when emplacement. The diameter of Jackup No.2 pile shoe is 8.5m, single pile ultimate bearing capacity is 23415 kN.

The two stern piles of Jackup No.1 inserted to a predetermined depth 7.1m and bow pile inserted to 4.0m. After analysis that may be encountered in stratum disturbed by the early pile inserting and pulling. Engineering geophysical results indicated that a number of pile pits widely distributed in wellsite, specifically around the bow pile. When the formation strength inside the pile pits is higher than outside, inserting depth will be less than that calculated based on the original formation.

Table 1 Pile strength parameters inside and outside pile pits in typical wellsite

| stratum outside of the pile pits | | | | | stratum inside of the pile pits | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Layer No. | layer bottom depth (m) | undrained shear strength $C_u$(kPa) | pile-soil friction angle δ(°) | ultimate bearing capacity factor $N_q$ | layer No. | layer bottom depth (m) | undrained shear strength $C_u$(kPa) | pile-soil friction angle δ(°) | ultimate bearing capacity factor $N_q$ |
| 1 | 4.2 | / | 20 | 12 | 1 | 3.2 | / | 23 | 16 |
| 2 | 5.8 | 18 | / | / | 2 | 5.8 | 80 | / | / |
| 3 | 7.1 | 28 | / | / | 3 | 10.0 | / | 30 | 40 |
| 4 | 9.0 | / | 23 | 16 | | | | | |
| 5 | 10.2 | / | 29 | 37 | | | | | |
| 6 | 16.0 | / | 27 | 27 | | | | | |

At the same time, considering the stratum inconsistency inside or outside of pile pits, recalculated the single pile ultimate bearing capacity of Jackup No.1 and Jackup No.2 and to evaluate the suitability of the pile emplacement and safety of piercing damage (fig.2).



(a) Calculated result of Jackup No.1 (b) Calculated result of Jackup No.2

Fig.2 Pile Ultimate Bearing Capacity Curve

When Jackup No.1 re sitting, its theory insert depth is not unified because of inhomogeneity of bearing stratum. The theoretical insert depth of the two stern piles of jackup which was outside of pile pit was same to predicted 7.1m. The theoretical insert depth of the bow pile of jackup which was inside of pile pit was 4.8m shallower than predicted .

The theoretical inserting depth of jackup No.2 was 1.9m inside of pile pits. The soft stratum would occurred piercing damage when the inserting depth was 2.3m outside of pile pits though the ultimate bearing capacity could meet the requirements. It is safe when the inserting depth is7.1m.

In the case of the surface covered by a thick silt, the stratum strength is higher than original stratum after long time later of the pile pits forming. In a decade or even more time, waves, currents, storm surges, cold, earthquakes and other geological forces had been continuously or intermittently to play the role, so that silt filled inside the pile pits drainage consolidation [3-6], thereby becoming dense. However, the pile pits formed by insertion of jackup No.1 was only less than 2 months without the full action of geological forces.. Only pile toe was compacted by pile shoe and the pile side solid collapsed after pulling should be deemed remolded and the stratum strength was lower than original stratum. Therefore, in calculating two stern piles of Jackup No.1, depth7.1m above could be calculated according to reshape, the following parts could be calculated according to reshape original stratum.

After analysis, although plug-in depth of each leg of jackup No.2 was inconsistent, but had been inserted to stabilize bearing stratum, the difference insertion can be used in re sitting. In this case, it should be noted self-stable of jackup [7].

## Conclusion

(1) In general, stratigraphic strength inside pile pits after pile inserting and pulling is larger than that in original stratum. For example, when the seabed is covered with thick silt, a long time later after the pile inserting and pulling, the strength inside the pile pits would be larger. However, after a relatively short time, the strength inside the pile pits would be smaller.

(2) When the jackup is emplaced, it is difficult to prejudge the pile is inserted inside or outside the pile pits. If it is planned to insert to a dense stratum inside the pile pits but actually insert to outside, the pile will go on insert to deeper, it's unsafe if the inserting depth is larger than allowed. If it is planned to insert to stratum outside the pile pits but actually not, the pile will be inserted to a shallower depth and the inclining of jackup increased.

(3) If the surface layer is thick and dense silt, there's always a little change occurred inside the pile pits after pile inserting and pulling. It's suitable to emplace a jackup with big pile shoe that will not insert too deep, a piercing damage check should be done previously.

(4) When it's seriously and unevenly disturbed in the upper stratum, it's NOT appropriate to emplace a jackup with small pile shoe. For each leg is more easily to insert to different strength stratum, that will lead to inconsistent inserting depth, thus increasing the risk of self-stability of jackup. In addition, the actual strength in disturbed stratum is difficult to investigate accurately, it also increases the risk of jackup emplacement.

**Keywords:**CSFRC, SFRSCC, Bending test, Inductive test, Fibre orientation, Fibre distribution

**Abstract:**Many researches have been conducted in past decades for promoting the application of steel fibre reinforced concrete (SFRC), either conventional or self-compacting. However, the differences of post-crack behaviour and the properties of these two types of concrete remains unclear. The objective of this paper is to analyse such differences in terms of flexural behaviour, fibre orientation and contribution as well as the fibre content. For that, an extensive experimental campaign was carried out. In total 3 mixes of self-compacting and 3 mixes with traditional concrete were produced with the nominal fibre contents of 30kg/m$^3$, 45kg/m$^3$ and 60kg/m$^3$. In each series, specimens were produces and characterized bythree point bending test (code EN 14651) and inductive test. The results illustrate how fibre orientation and distribution justify the differences in the mechanical behaviour of the materials and the scatter of the bending test results.

## Introduction

Many studies were performed in past decades to promote the application of steel fibre reinforced concrete (SFRC)[1,2,3].The introduction of steel fibres in the concrete matrixproduces several advantages, such as increase inthe energy absorption capacity and in the post-cracking flexural tensile strength of the material. Moreover, fibres could behave as alternative of conventional reinforcement so that the passive reinforcementcould be removed total or partially from concrete.

With the reduction of skilled construction workers, it is more and more difficult to build good quality structural elements. In order to mitigate this thorny issue, self-compacting concrete (SCC) appeared in 1988 [4]. Since then, a lot of studies were devoted to the development of the material, leading to reduction of manpower or time required for construction, as well as safety improvements and noise reduction.

By introducing steel fibres in SCC on may combine the advantages from both types of concrete. In this matter, research about steel fibre reinforced self-compacting concrete (SFRSCC) has been highlighted since it was first put into use in real structural elements [5,6].

In order to ensure the quality of SFRC, it is important to characterize the post-cracking behaviour and to evaluate the fibre content. On one hand, the characterization of post-cracking residual tensile strength is usually performed through three point or four point bending test. On the other hand, the fibre content is estimated according to the procedure established in [7]. For that, specimens must be either crushed or fresh concrete should be washed in order to separate the fibres that are then weighed. These tests not only demand a lot of time of execution but also are expensive and environmentally unfriendly. In addition to that, limited number of tests that may be performed per day compromise both the statistical representativeness of the results and the effectiveness of the quality control system.

The objective of this paper is to propose an alternative to the traditional quality control system used for SFRC. First, study on conventional steel fibre reinforced concrete (CSFRC) and SFRSCC by conducting three point bending test to characterize e their post-cracking behaviour will be presented. Then a non-destructive test “inductive test” would be carried out on cubic specimens and

extracted samples to estimate the fibre content and fibre orientation and distribution within the specimens. Finally, further analysis of post-cracking behaviour according to bending and inductive test will give an objective evaluation of the material tested.

## Materials

The compositions of the mixtures used in the experimental programme are presented in the Table 1. It is necessary to point out that GLENIUM TC1425 is a water-reducing admixture based on the high activity behaviour of polycarboxylate, and X-SEED is a suspension of CSH nanoparticles, which acts as crystallization nucleus to activate the cement hydration, thus increasing the resistance of concrete at the initial stage.

The low carbon hooked end steel fibre used in the experimental campaign was the MasterFiber 502, supplied by BASF Chemical Company. The main characteristics of the fibre are shown in Table 2.

Tab.1: Mix composition of CSFRC and SFRSCC [in kg/m$^3$]

| Mixtures | CSFRC | SFRSCC |

## Experimental study

### 3.1. Specimens

Three batches of concrete with the fibre content of 30 kg/m$^3$, 45 kg/ m$^3$ and 60 kg/ m$^3$ were produced in concrete plant both for CSFRC (numbered as CSFRC-30, CSFRC-45, CSFRC-60) and SFRSCC (numbered as SFRSCC-30, SFRSCC-45, SFRSCC-60). For each batch of concrete, the fresh state properties were tested.All of them met the requirements of [8,9,10,11].

### 3.2. Tests

In order to evaluate the mechanical properties SFRC at hardened state, compression test and 3 point bending test were carried out in accordance with thestandards [12,13].Additionally, inductive test was carried out to estimate the amount and distribution of fibres within the specimen.Table 3 shows the detail information respect to different tests for each dosage.

Tab.3: Concrete tests performed at hardened state

| Test type | Regulation | Variable | Nº of specimen | Dimension (mm) |
|---|---|---|---|---|
| Compression Test | UNE-EN 12390-3 | fc | 9 | ϕ150×300 |
| 3 Point Bending Test | UNE-EN 14651 | $f_L$ $f_{R,1}$ $f_{R,2}$ $f_{R,3}$ $f_{R,4}$ | 3 | 150 x150 x 600 |
| Inductive Test | | Fibre content and orientation | 8+6 | 150 x 150 x 150 |

Taking into account that, the amount and the orientation of fibres in the SFRC are directly related to its mechanical behaviour. The inductive test proposed by Torrents et al [14] and improved

by Cavalaro et al [15]is used to quantify the amount and the distribution of fibres in SFRC specimens. It presents a high accuracy, robustness and allows assessing a big volumes of material in a short time.

The inductive test is composed by a coil and a LCR impedance analyser. The coil receives an electric current and generates a magnetic field in its interior. Variations of the field due to the modification of the magnetic permeability inside the coil are measured. These modifications are induced by the introduction into the environment of elements with different permeability than the air, as is the case of SFRC. The introduction of a SFRC specimen into the system generates an inductance change which can be measured [14].

In this experimental programme, two types of cubic specimens with 150 mm of side were characterized to evaluate the differences that might exist depending on the nature of the sample. The first type consisted of specimens cast in moulds whereas the second type were cubes extracted from the beams once the bending test was completed. Figure 1a depicts the zones of the extractions of the cores. The first cut was performed respecting a 75 mm distance from the extremities of the beams, with the intent of reducing the influence wall-effect that exist close to the moulds. In total, 8 moulded cubes and 6 extracted cores were obtained per mix.

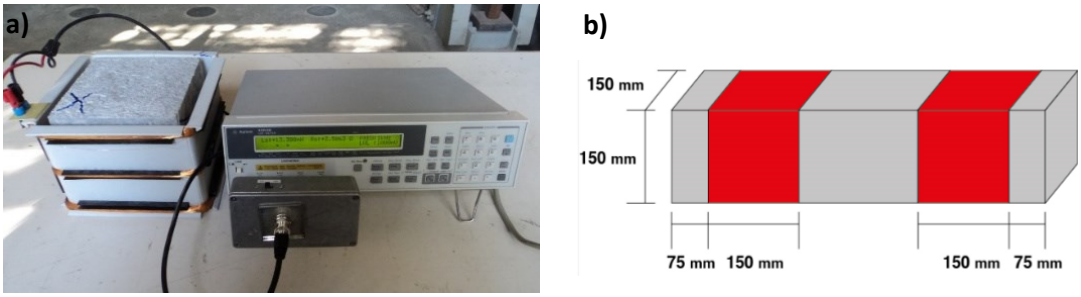

Fig. 1: a) Inductive test set-up and b) Extracted cubic sample

The summed inductance value measured in each specimen for the axes X, Y and Z is related with the fibre content, while the proportion between measurements provide information about the fibre orientation. For that, however, the values of inductance should be calibrated. Therefore, four specimens from different series were crushed after inductive test. This was done by first compressing the specimens to complete failure. Then the chunks were fed into a grinding machine. Once the specimens were reduced to rubble, the fibres were retrieved by a magnet and weighed by a scale with the accuracy of 0.0001kg. A linear regression was applied to correlate the summed inductance change and the fibre content ($C_f$), as shown in Fig. 2. As observed in previous works [14,15], a linear relation exists between both parameters.

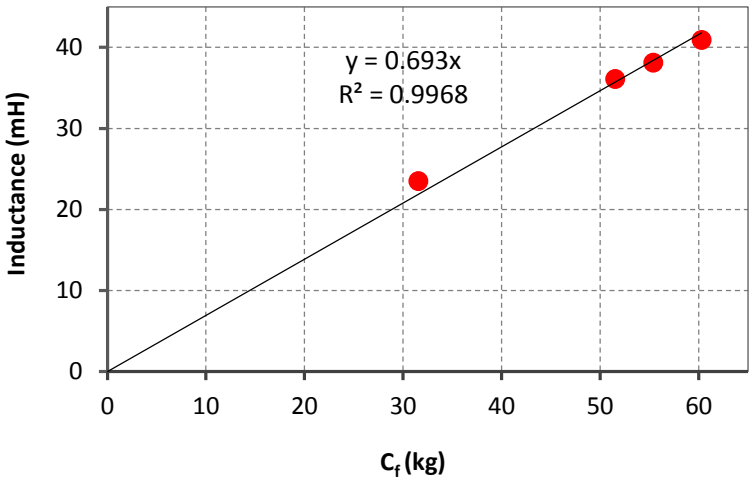

Fig. 2: Inductance-$C_f$ relationship based on inductive test

## Results and analysis

### 4.1 Compression test

The results obtained are shown in Table 4, together with its average strength and CV (coefficient of variation). For CSFRC, the average compressive strength at 28 days is 64.7 MPa, whereas the SFRSCC is 67.5 MPa, slightly higher than CSFRC.

Tab.4: Compressive strength [in kN/mm$^2$] and C.V

| Series | Day 1 | | Day 7 | | Day 28 | |
|---|---|---|---|---|---|---|
| | Mean | C.V (%) | Mean | C.V (%) | Mean | C.V (%) |
| CSFRC-30 | 20.2 | 1.2 | 54.4 | 1.8 | 65.1 | 0.3 |
| CSFRC-45 | 19.7 | 2.4 | 54.6 | 0.8 | 63.9 | 1.5 |
| CSFRC-60 | 21.5 | 1.5 | 54.8 | 0.2 | 64.9 | 1.9 |
| SFRSCC-30 | 25.4 | 2.1 | 56.1 | 2.9 | 70.5 | 1.2 |
| SFRSCC-45 | 18.3 | 0.8 | 55.2 | 1.8 | 66.3 | 1.3 |
| SFRSCC-60 | 17.1 | 1.5 | 53.4 | 1.3 | 66.7 | 4.2 |

As may be seen in Table 4, the increase in the fibre dosage did not lead to a significant difference in the compressive strength. This is consistent with the studyfrom [16]. Likewise, the fibre dose does not affect the scatter in the compressive strength, which at 28 days at 1.13MPa for the CSFRC and 2.65MPa for SFRSCC.

### 4.2 Three point bending test

Figure 3 shows the Load - CMOD curves obtained from three point bending test as the average value recorded for each series.

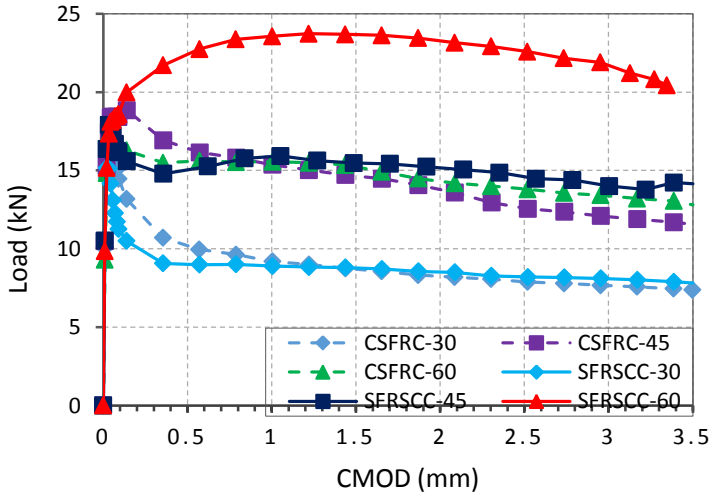

Fig. 3: Load - CMOD relationship curves obtained from three point bending test

A similar tendency is observed in all curves. Initially, the concrete shows a linear behaviour until the first-crack appears. Then a sudden drop due to stiffness decrease of specimen occurs. After a certain crack opening, the fibres bridging the crack become active and provide a residual resistant capacity. According with Figure 3, the SFRSCC shows a better post-crack behaviour than the CSFRC. This is especially evident in the series with 60 kg/m$^3$. In this case, the mix with SFRSCC shows a hardening behaviour while the mix with SFRC presents softening behaviour.

Table 4 shows the average limit of proportionality (LOP) and residual flexural tensile strength ($f_{R,i}$) of different series of beams.

All mixes show similar values of LOP, except for the ones with 30 kg/m$^3$ that present the smallest values. On the other hand, the $f_{R,i}$ increases with the fibre dosage for both types of concrete. As expected, the use of a higher dosage leads to an increase in the number of fibres that bridge the crack and contribute to the residual strength.

Tab.5: Three point bending test results [in kN/mm$^2$] and C.V

| Series | LOP | | $f_{R,1}$ | | $f_{R,2}$ | | $f_{R,3}$ | | $f_{R,4}$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Mean | C.V (%) | Mean | C.V (%) | Mean | C.V (%) | Mean | C.V (%) | Mean | C.V (%) |
| CSFRC-30 | 5.17 | 1.1 | 3.15 | 8.4 | 2.7 | 2.5 | 2.44 | 1.8 | 2.22 | 6.4 |
| CSFRC-45 | 5.76 | 3.82 | 5.06 | 20.28 | 4.54 | 22.02 | 3.89 | 22.18 | 3.6 | 22.7 |
| CSFRC-60 | 5.49 | 12.4 | 4.81 | 19.25 | 4.71 | 21.89 | 4.26 | 22.12 | 4 | 22.63 |
| SFRSCC-30 | 4.99 | 9.94 | 2.85 | 28.37 | 2.79 | 32.11 | 2.61 | 32.67 | 2.47 | 34.96 |
| SFRSCC-45 | 5.8 | 8.48 | 4.72 | 1.91 | 4.86 | 3.66 | 4.67 | 5.84 | 4.33 | 5.79 |
| SFRSCC-60 | 5.89 | 2.66 | 7.13 | 17.23 | 7.54 | 16.64 | 7.12 | 11.56 | 6.41 | 11.76 |

The results show again that, for the same fibre dosage, the mixes SFRSCC presents a higher residual strength ($f_{R,2}$, $f_{R,3}$ and $f_{R,4}$) than the equivalent mixes with CSFRC. Such trend becomes more evident as the fibre content increases. The improved behaviour of SFRSCC might be attributed to a more favourable orientation of fibre regarding the cracking plane. The high flowability achieved in this type concrete provides more freedom of movement to the fibres. In this context, fibres tend to align perpendicular to the casting direction that coincides with the cracking plane. On the contrary, the lower consistency of CSFRC restrict the movement of fibres, which assume an orientation not as favourable. Notice that this trend is not observed for $f_{R,1.}$ The main reason for that may lay in the influence of the concrete matrix failure for small crack openings. In other words, the more favourable orientation of the fibres in the case of SFRSCC is not perceived since for small crack openings some of the fibres are not activated and the response of the concrete matrix might affect the results.

As shown in Figure 3, a general similar tendency could be observed in all curves, it mainly consists of three stages. Initially, the concrete shows a linear behaviour until the first-crack appears; then there is a sudden drop due to stiffness decrease of concrete, in this phase, the plain concrete lost workability and the steel fibres haven't started to make contribution to the concrete matrix. After a short adjustment, the fibres bridge in the crack work as the reinforced bars to bare the flexural tensile strength, and makes the concrete maintain substantial load until reaching final failure.

To study the post-crack behaviour of the concrete comprehensively, it can be seen from the Figure 3, systematically, the SFRSCC shows a better post-crack behaviour than the CSFRC, especially in the series which has 60 kg/m$^3$. Moreover, there is no significant difference in terms of the load for the first-crack either in CSFRC or SFRSCC. This reveals that by adopting the 3 point bending test, on the condition of with same dosage of fibres, the type of concrete makes slight influence on the limit of proportionality (LOP).

It is worth to point out that, for both type of concrete with 60 kg/m$^3$ steel fibres show a slight different behaviour after the first-crack appears. This phenomenon called concrete bending hardening, which refers to the situation where the post-crack flexureal tensile strength is higher than the first-crack flexural tensile strength. It usually occurs at the concrete with fibre dosage above 50 kg/m$^3$ with relative high aspect ratio [16].

### 4.3 Inductive test

Figure 4 shows the contribution of the fibres in the 3 axes calculated according with the formulations by Cavalaro et al. [15] with the results from the inductive test for moulded (a and c) and extracted (b and d) specimens.

It is known that the addition of steel fibres could reduce the workability of the concrete matrix. However, it is still not ascertained if the fibre orientation and distribution will be affected by the increment of fibre content. Therefore, it is of interest to evaluate the influence of fibre content on the fibre orientation and distribution within the concrete.

As shown in Figure 4, the contribution of fibres in the X and Y axes are always bigger than in Z axis. Precisely, no matter how much the amount of steel fibre is, the orientation number and the contribution of steel fibres in each axis keep a similar ratio. Consequently, based on the results obtained, the fibre dosage does not affect the orientation inside the concrete.

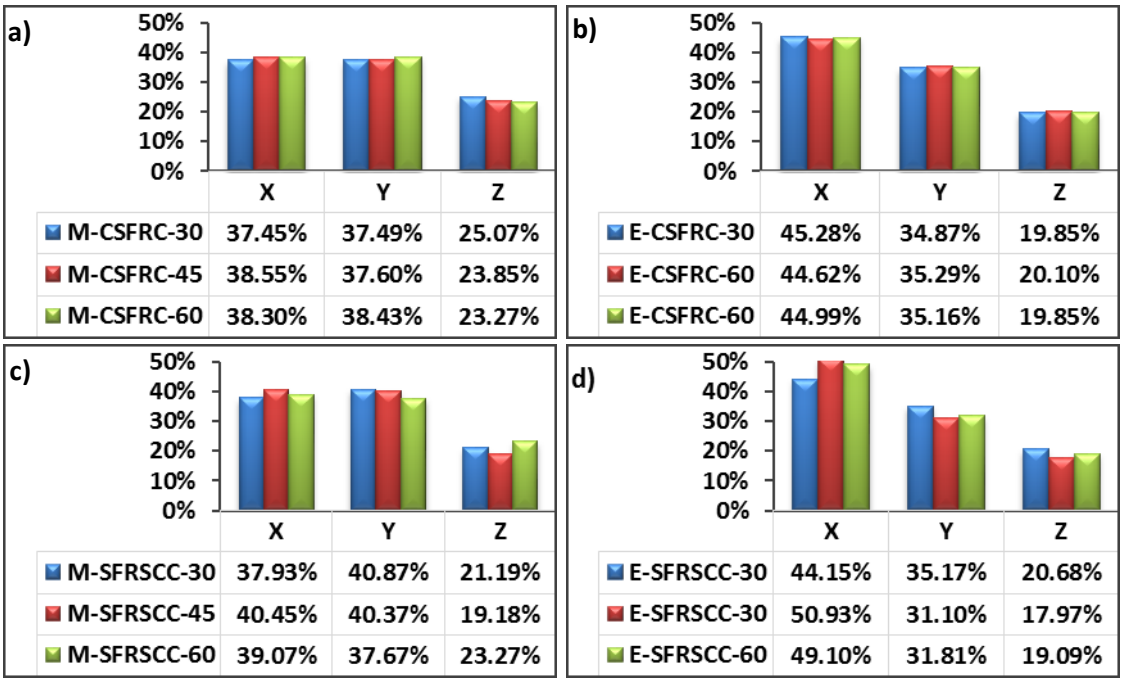

Fig. 4: Contribution of fibres in different axes obtained from inductive test

Additionally, the proportion of the contribution of steel fibres in X, Y and Z approximates 4:4:2 for moulded specimens. On the other hand, this proportion changes to 4.5:3.5:2 approximately in the case of extracted specimens as a result of the influence of the concrete flow.

Moreover, the Figure 4 indicates that the contribution of fibres percentage in X axis in extracted samples are bigger than in the moulded specimens, whereas in Y axis the opposite conclusion was obtained. This observation illustrates that, for both type of concrete, steel fibres are more likely to align parallel to the longitudinal direction of the prismatic beams.

Moreover, the mixes of SFRSCC with 45 kg/m$^3$ and 60 kg/m$^3$ show higher proportion of fibres aligned with the X axis than the equivalent mixes of CSFRC. This is consistent with the better performance in terms of residual strength of SFRSCC and the explanation provided in the previous section.

## Conclusions

The following conclusion can be drawn from this research programme:

- The residual flexural tensile strength$f_{R,i}$is proportional to the fibre dosagefor both type of concrete.
- The SFRSCC shows a better post-crack behaviour than CSFRC in the premise of the same fibre dosage.
- Combining the analysis results of 3 point bending test and inductive test results, it is feasible to evaluate the post-crack behaviour of SFRC with a high reliability.
- The inductive test presents a high accuracy and robustness to predict the fibre orientation and distribution within the concrete, as well as to detect differences in the fibre content.

**Keywords:** Tension Fixture, Pre-stress FRP Sheet, Non-destruction, Quantify Tension.

**Abstract.** Traditional pre-stress FRP sheet tension fixture must have the beam of the bridge slotted to reduce the cross-section of the beam. Besides, stress on the FRP sheet is irregular with local stress concentration. Its indirect load pre-stress, as well as quantitative criterion of pre-stress born by FRP sheet is not accurate. To solve the above problems, a newly-developed self-balanced type pre-stress FRP sheet tension fixture has been introduced. Such a tension fixture consists of welded steel frame, a mechanical jackscrew, a dynamometer and a strain gauge. It is able to give specified stress onto the FRP sheet accurately while not damaging the beam cross-section. At the same time, with the combination of ANASYS Workbench and UG8.0 Software, also states the simulation analysis of the new type tension fixture, including its stress under practical work and deformation state, which initially proves the scientific and economic usefulness of such tension fixtures.

## Introduction

At present, the main method of reinforcing the concrete of the beam is to tension the pre-stressed FPR sheets, that is to say, through slotting on the beam of the bridge and changing the position of the fixture in the slot, the pre-stress is able to be controlled, as shown in Fig.1 [1-3]. Such a method is easy with simple technology. However it has the following problems:

Reducing the cross-section of the existing beam: To make the installation of fixture convenient and simple, the slot is always chosen in the middle of the beam, while such position has the largest bending moment. Slotting in this position will definitely reduce the cross-section of the beam, which unquestionably worsens the stress state of the beam [4, 5].

Damaging the protective layer of the existing beam: Beams reinforced with pre-stressed FPR sheets need follow-up reinforcing because of their old age and insufficiency in carrying capacity. Slotting on the beam will damage the concrete protective layer. Thus the working environment of existing steel bars goes worse and worse.

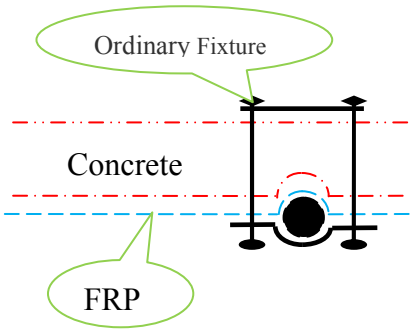
Uncertainty of stress determined by FRP sheet: As shown in Fig.2, FRP stress is controlled indirectly through the changing of fixture position in the slot. The pre-stress is influenced by the displacement of the fixture as well as the friction between the concrete and FRP sheets. Local stress concentration will easily occur and FRP sheet is easily to be destroyed. Standard pre-stress determined by FRP sheet cannot be measured and guaranteed [6-7].

Aiming at solving the above problems, a newly-developed pre-stressed FRP sheet tension fixture is introduced in this paper. The new type fixture tensions the FRP sheets without hurting the existing cross-section of the girder. Besides, it makes the measurement of pre-stress determined by FRP sheet more accurate and precise. Thus, it possesses broad application prospects and practical value in the field of pre-stressed FRP sheet reinforcing the beam.

## Design of the new-type pre-stressed FRP sheet tension fixture

The new-type tension fixture takes self-balancing system. To improve the rigidity of the fixture under tension stress and reduce loss of pre-stress caused by the deformation of the fixture, the

tension fixture is designed to consist of an overall welded steel framework. To satisfy the quantitative control requirement of pre-stress determined by FRP sheet, the friction between FRP sheets and the fixture will be reduced by pulley blocks and trolley system. At the same time, the tension of FRP sheet is controlled by the mechanical jackscrew; the strain gauge is installed at the bottom left of the fixture while the dynamometer is at the right side with one end fixed.



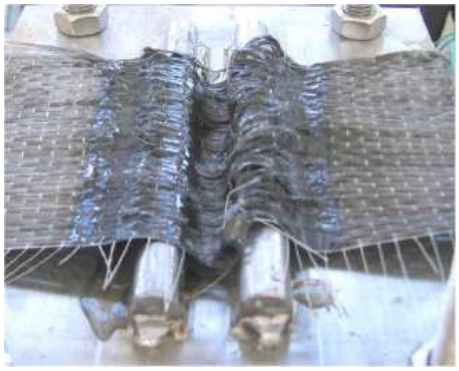


Fig.1 Ordinary Pre-stress FRP Fixture Fig.2 Ordinary Pre-stress FRP destroy

During the operation, put the pre-stressed FRP sheet onto the top of the tension fixture; the two ends of the FRP sheet, along the trolley, shall be fixed on both sides of the fixture. Turn on the jackscrew; the steel wire ropes are pushed by the jackscrew and the pulley will drive the left-side fixture to tension the FRP sheet. When the dynamometer on the right side reaches certain value, the strain gauge shall be reset. Then go uploading until there is a correspondence relation between the tension and deformation. Pay attention to the value shown on the dynamometer and make sure the accurate and precise of the pre-stress. The 3D model of the integrated design and the main design size indexes are shown in Fig.3. Length of the main girder: 2450(mm); width350 (mm); height 600(mm). The main beam is made up of 8#cjannel steel and is constructed through welding; the thickness of the soldering block is 15mm; the material of the welding assembly is 20# steel. The secondary beams and supports are connected with the main beam by M8 high-strength bolts. The supports on both sides of the fixtures are 45mm processed thick steel plates which are connected by bolts and truckles to make sure the maneuverability of the fixtures.

## Analysis on the deformation of the new-type tension fixture

The new-type fixture belongs to 3-dimensional high-order statically indeterminate tensioning system; to verify the feasibility of such fixtures in actual work, its finite element model has been developed with the help of ANASYS Workbench and UG 8.0 Software to analyze its stress state and deformation degree under design load. Deformation analysis on the fixture is achieved by finite element method:

Finite element analysis progress: First, by applying UG 8.0 Software, transform 2D design plan made with CAD to 3D design data archived in IGS files, then by the ANASYS Workbench Geometry model reads design data in up IGS files，and achieves the calculate by ANASYS Mechanical model.

Finite element analysis parameters: Element Type：8 nodes Solid 183; Typical Element Size: 200mm; Boundary conditions：Four groups of fixed fixture (the fixture applies self-balancing system; uploading can be carried out after fixing the fixtures on the ground under the beam). Load conditions: upload 100 KN stress symmetrically both in horizontal and vertical (maximum designed tension) on trolleys of both sides. The stress is assumed to be the reactive force by the FRP sheet which is most unfavorable to the fixtures.

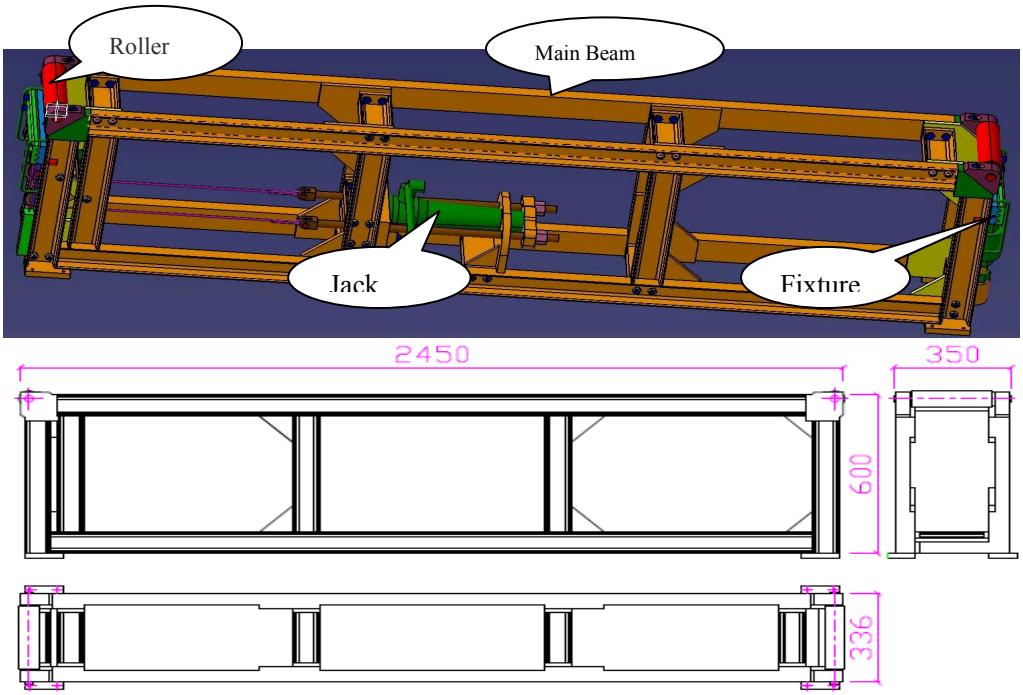

Fig.3 New Type Fixture Design Pictures Unit (mm)

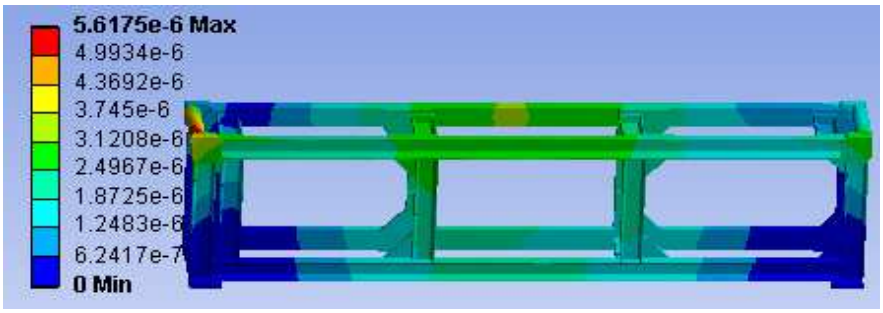

Fig.4 New Type Fixture Total Deformation

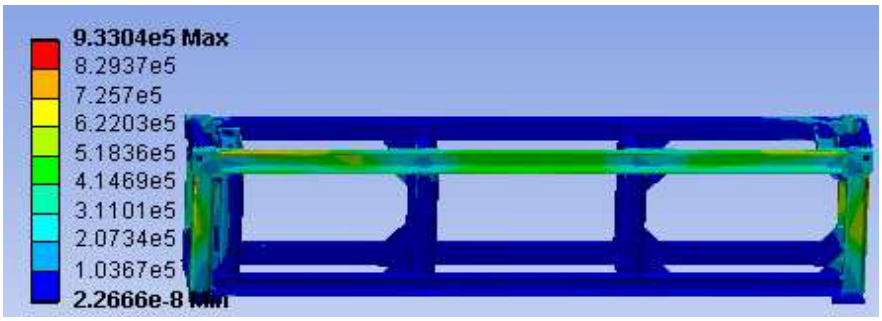

Fig.5 New Type Fixture Equivalent Stress

Finite element analysis results: The fixture total deformation is on the Fig.4, and the equivalent stress on the Fig.5. From Fig.4 we can see that deformation mainly occurs around trolleys of the fixtures, the total deformation is 0.5mm, the max strain is 5E-6; from Fig.5 we can infer that and the max stress is 0.83Mpa. The above data shows that under the design load, the new type tension fixture is in flexible working conditions. Loss of pre-stress caused by the deformation of the fixtures can be ignored in the whole tension system.

## Conclusion

Through statements and analysis in the thesis, the following conclusion can be drawn:

The new-type tension fixture is self-balancing so it can operate without counter-force facilities and more adaptable in practical work. At the same time, it possesses advantages such as easy handling and high adaptability. It also can be recycled to lower the cost of the engineering.

Through the dynamometer on the fixture, the value of pre-stress determined by FRP sheet can be accurately achieved, which provides technical guarantee for pre-stressed FRP sheet reinforcing the beam.

By reading the strain gauge at the end of the fixture, deformation degree of the fixture under various pre-stress can be achieved precisely.

By using the new-type tension fixture, there's no need to slot on the girder, so there will be no damage to the girder. Meanwhile, the pre-stress determined by the FRP will be regular and even without local stress concentration.

**Keywords:** formwork support, node connection, ANSYS, semi-rigid joint

**Abstract.** Fastener-style steel pipe formwork support is currently the most widely used form of template support during the domestic construction. At present, there are many models for the node connection pattern. This paper used ANSYS to build different connection pattern models of formwork support and draws the conclusion that the connection pattern of semi-rigid nodes is the most conform to the actual working conditions. This provide the basis for the theoretical research on fastener-style steel pipe formwork support.

## Introduction

Since fastener-style steel pipe formwork support belongs to the time-varying structure and is often recycled. However, academe has biggish difference between rigid joint [1] and hinged join for right-angle fastener node. There is a large difference between the calculation results of two ways.

A series of finite element model on perfectly rigid hinged and semi-rigid joint were established apart to analysis on impact of the node connection pattern of formwork support to its stable bearing capacity [2-5]. By comparing the results of the stable bearing capacity under different conditions with those known on the actual working conditions, node connections pattern that best meet the actual working conditions are obtained. Thus, reference points are provided for the theoretical research on fastener-style steel pipe formwork support.

## Calculation Model

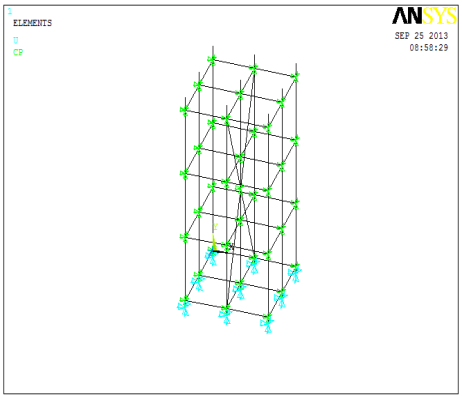
Referring to the test, five groups of calculation model were set up. Steel pipe's outer diameter was 0.048 m, wall thickness was 0.003 m, elastic modulus was 2.06 e11, Poisson's ratio is 0.25. The models were shown in table 1. Test 1 set a bracing. Test 2 set two bracing. The others didn't set bracing.

**Table1** Model parameter

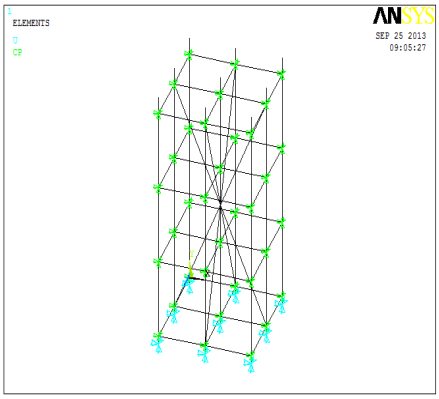
| parameter / Number | longitudinal spacing (mm) | departure spacing (mm) | drawing pace (mm) |
|---|---|---|---|
| 1 | 1200 | 1200 | 1800 |
| 2 | 1200 | 1200 | 1800 |
| 3 | 1200 | 1200 | 1800 |
| 4 | 1200 | 1200 | 900 |
| 5 | 900 | 900 | 900 |

## Establishing Finite Element Model

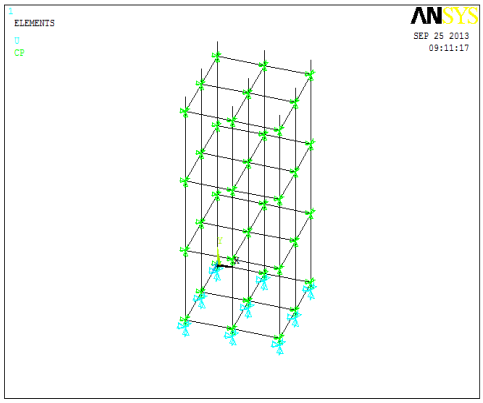
ANSYS was used to build the calculating model. Beam4 unit was choose for vertical tube and horizontal tube[6]. Link8 element was used to simulate the vertical bracing and horizontal bracing [7]. Combin14 element was choosen to simulate joint [8]. The finite element models were shown in fig 1.



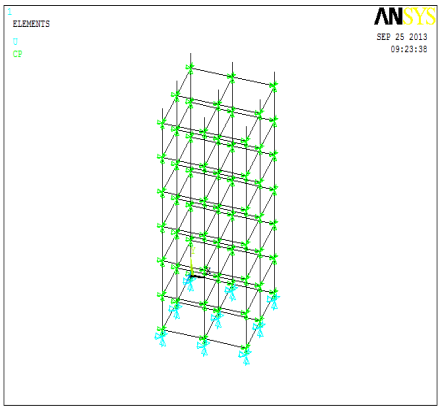
Test 1 Finite element model



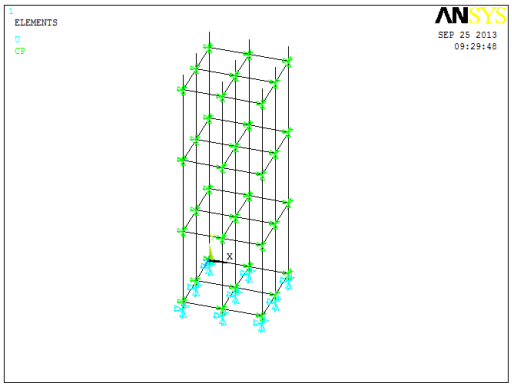
Test 2 Finite element model



Test 3 Finite element model



Test 4 Finite element model



Test 5 Finite element model

**Fig. 1** The finite element models

## Finite Element Analysis

With the resort on ANSYS we have performed the eigenvalue buckling analysis, compare ultimate bearing capacity under the condition of various model types with the experimental values of stability bearing capacity. Those types are the models considering perfectly rigid and hinged joint, semi-rigid joint that initial stiffness is10000, 20000, 50000, 80000and1000000. Analyse the various factors that affect the stability of formwork support and find the regularity.

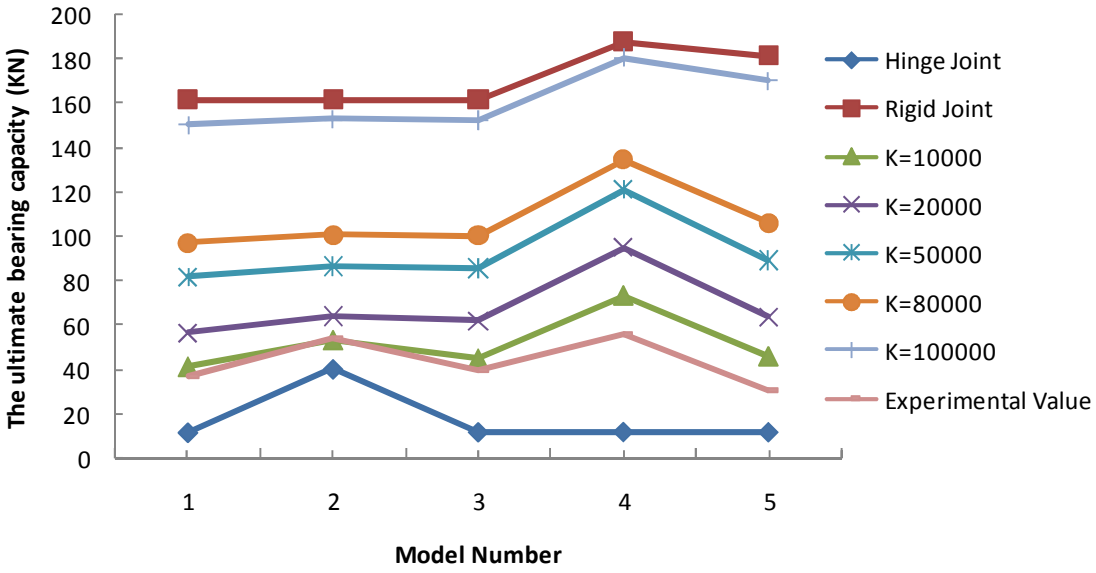


**Fig. 2** The ultimate capacity of formwork support in all simulation conditions

It can be seen from fig 2 that the bearing capacity of the vertical tube do not reach the theoretical calculation value of material strength in all tests. The destruction form of vertical tube is buckling failure.

The experimental values of stability bearing capacity are simply located quite far away from the ultimate bearing capacity of perfectly rigid and hinged model. But, the experimental values have accordance well with the ultimate bearing capacity of the model. Initial stiffness is 10000 in the model. This shows that the node at the intersection of horizontal tube and the vertical tube is close to the semi-rigid join that transfers part of the bending moment.

With the increase of initial stiffness, ultimate bearing capacity of the model is gradually increasing. The size of the initial stiffness has an impact on ultimate bearing capacity with the semi-rigid nodes in mind. The bigger the initial stiffness is, the greater ultimate bearing capacity is. Fastener tightening moment is the direct influencing factor for initial stiffness. Therefore, in theory, the greater fastener tightening moment is, the better whole stable bearing capacity is and the greater the ultimate bearing capacity is. This shows that the tightening extent of fastener has a big influence on whole stable bearing capacity.

## Conclusions

By simulating the model under three kinds of situations, perfectly rigid, hinged and semi-rigid joint, it can be concluded that the results of model under the semi-rigid join have accordance well with the experimental results.

The tightening extent of fastener has a big influence on whole stable bearing capacity for formwork support. With the increase of fastener initial stiffness, ultimate bearing capacity of the model is dramatically increasing. To ensure fastener torque value is the key to guarantee the structure stiffness of formwork support. Therefore, the fastener tightening moment should be strictly inspected to ensure the safety of the formwork support during the construction.

**Keywords:** ABAQUS, high-formwork, bridging, deformation

**Abstract.** Setting bracing is conducive to stabilize formwork support in high-formwork system. ABAQUS was used to build the calculating model of high-formwork system to simulate and analyse lateral deformation of high-formwork in different column's spacing of bridging. The results show, increasing column's spacing of bridging can add the whole lateral displacement of high-formwork, but, it is not obvious. Increasing appropriately column's spacing can save material during construction.

## Introduction

Along with the improving requirement of high and tall across the space on the industrial and civil building, the high-formwork is used more and more frequent, the usage requirements are also more and more high during construction[1].Since high-form belongs to the time-varying structure[2-4], it is easy to cause global or local buckling, it may cause the collapse of the whole high-formwork system when the situation becomes serious, and thus many accidents happen[5-6]. Therefore, whole stability of the high-formwork system plays an important role in construction safety.

It is urgently needed that researching on high-formwork to provide favorable data of calculation theory of high-formwork system, facing hidden danger easily caused by high-formwork design and control during construction.

In this paper, ABAQUS was used to build the model of high-formwork system to simulate lateral deformation of high-formwork in different column's spacing of bridging. Based on the analysis of column's spacing of the formwork support erected by continuous vertical bridging mentioned in the code[7],and this provide the theoretical basis for the design of construction scheme and the revision of the Safety Technical Code for Building Construction Template JGJ162—2008.

## Calculation Model

According to the code requirements, high-formwork calculation models were designed: Spacing of vertical tube was 1.2m, the pace was1.8m, the distance between the bottom transom and the ground was 0.2m, the length of the top horizontal tube extending from top was 100mm, the height of the formwork support was 14.4m, the area of it was 24m×24m. Continuous vertical bridging were used around the formwork support and horizontal bridging were set at the top, middle and bottom of the formwork support. Analyze separately the whole lateral displacement of high-formwork in the case that column's spacing of bridging was 8m,10m,12m,14m. The type of tube was Q235, its specification was Φ48×3.5mm. The specific parameters were shown in table 1 and 2.

**Table1** Pipe section properties

| d[mm] | t[mm] | A[$cm^2$] | I[$cm^4$] | W[$cm^3$] | i[cm] |
|---|---|---|---|---|---|
| 48 | 3.5 | 4.89 | 12.19 | 5.08 | 1.58 |

**Table2** Pipe material parameters

| EX[pa] | μ | f[pa] |
|---|---|---|
| $2.06\times10^{11}$ | 0.3 | $2.05\times10^{8}$ |

## The Finite Element Model

ABAQUS was used to build the calculating model of high-formwork system. The calculating element was linear beam element [8-9]. The node at the intersection of horizontal tube and the vertical tube was processed to rigid connection [10]. The high-formwork finite element model was shown in fig 1.

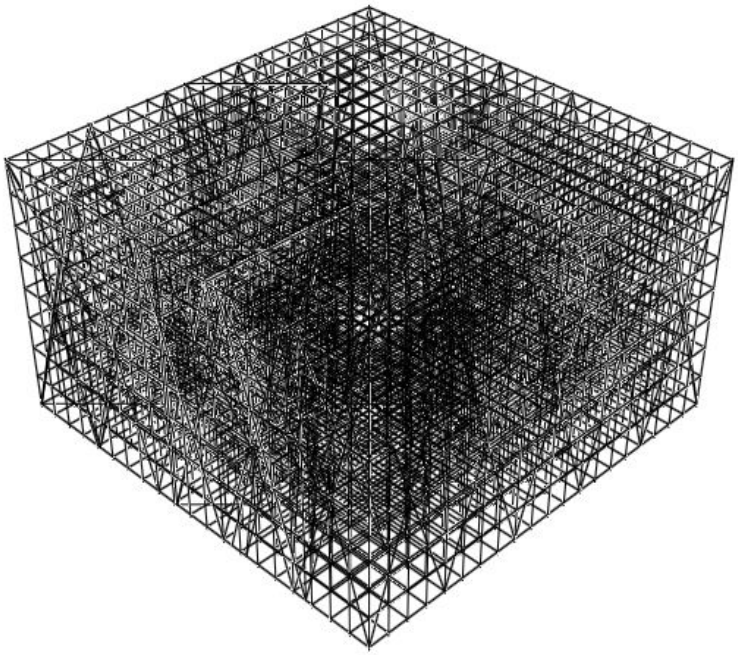

**Fig.1** The finite element model of high-formwork system

Applying concentrated force at the node of the upper of the formwork support by the creat load command in the load module and adding the boundary condition at the bottom of the formwork support by the creat boundary condition command to make that U1,U2,U3,UR1,UR2andUR3 were equal to zero, namely, the bottom was consolidated.

## Finite Element Analysis

This paper got deformation nephogram of the model, using post processing of ABAQUS. The column's spacing of bridging was 10m in the model. The deformation nephogram was shown in fig 2. The variation of the column's spacing of bridging and the whole displacement of high-formwork system was shown in fig 3.

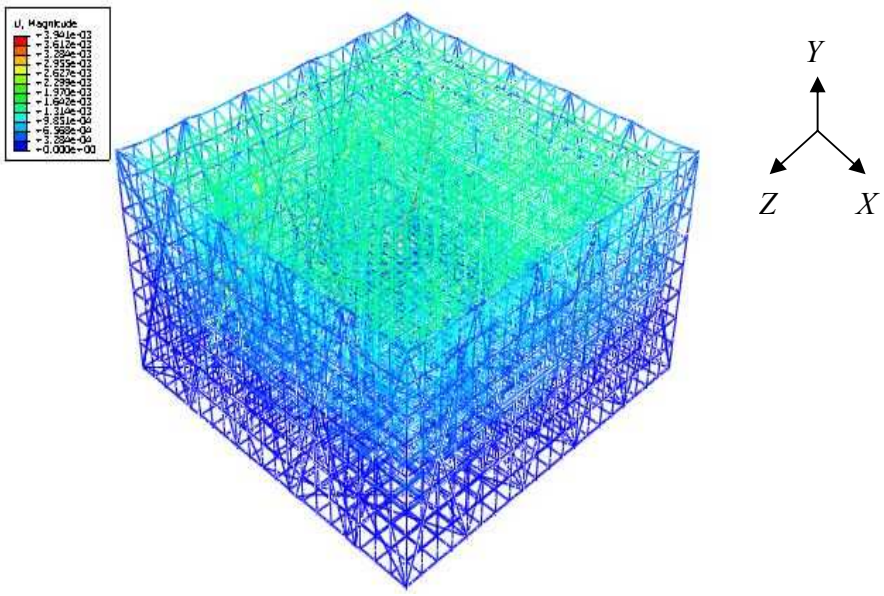

**Fig.2** Deformation nephogram of 10m model

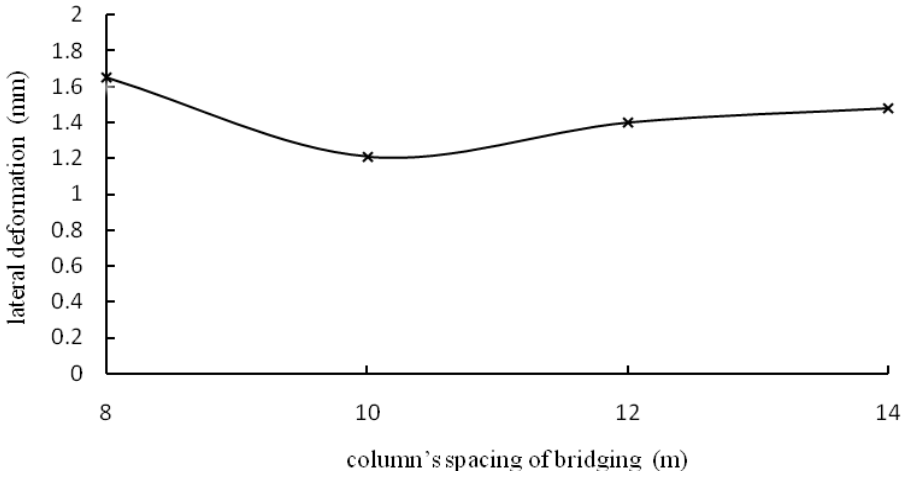

**Fig.3** Variation of the lateral deformation t with the change of column's spacing of bracing

It can be seen from fig 2 that the upper lateral displacement of high formwork system is larger than the lower lateral displacement under symmetrical loading. Lateral displacement near the bottom of the fixed end is minimum.

As can be seen from fig 3, the values of lateral displacement of high formwork system is 1.21mm when the column's spacing of bridging is 10m, which is required for the code. With the increase of the column's spacing of bridging, the lateral displacement of frame body is gradually increasing. When the distance increased from 10m to 14m is increased by 25%, the lateral displacement is increased from 1.21mm to 1.48mm. It is increased by 22%.

The difference between the two lateral displacement is very small. The one is 10m required for the code, the other one results from appropriate increase of the column's spacing of bridging. Therefore, column's spacing of bridging can be properly relaxed.

In addition, the change of the internal force of horizontal bracing is regularity. The internal force of horizontal bracing at the top is maximum. The internal force of horizontal bracing is gradually reduced with the height of high-formwork system decreasing. The internal force at the bottom is minimum. This is because mechanical behavior of vertical tube at the top are bigger, internal force of vertical tube is partly shared by horizontal tube, horizontal bridging has restraining effect on it, when the high-formwork system forces.

## Conclusions

The upper lateral displacement of high formwork system is larger than the lower lateral displacement under symmetrical loading.

Increasing the column's spacing of bridging have little impact on lateral displacement of high-formwork system. Based on the practice, column's spacing of bridging can be properly relaxed so as to save material during construction.

**Key words**: high-formwork, bridging, lateral migration, arrangement location

**Abstrac**t. Bridging play a important role in guarantee the stability of the high-formwork support system as a whole, its arrangement location will affect the force of the frame body. This paper used the finite element analysis method to compare the bridging arrangement location under the beam with the bridging under the board which was arranged according to certain modules. the results show, the arrangement spacing of the bridging under the beam is greater than the bridging under the board, but its frame body lateral migration is smaller, sharing part of the axial force of beam bottom rod at the same time, that means the bridging under the beam is more beneficial for the stability of high-formwork support system.

## Introduction

With the increasing demand of industrial and civil construction on height-span space, tall template support system requirements are increasingly high. Tall template system is different from the common template support system, during the construction process, the frame body is more prone to total or partial structural instability ,even cause the collapse of the entire template system when the situation becomes serious, form a vicious accident loss. Thus, the overall stability of the tall template becomes an important factor related to construction safety. In recent years, domestic and foreign scholars [1-3] studied the template support system, but there are many factors affecting the overall stability of tall template, the stress and deformation of the support frame body is influenced by many factors during the process of construction, it is comparatively complicated process. this article we compared the bridging arrangement under the beam with the bridging under the board which was arranged according to certain modules by the finite element analysis method, the results show, the bridging arrangement spacing under the beam is greater than the board, but its frame body lateral migration is smaller, The conclusion provides theoretical basis for the current specification revision and the construction scheme design.

## Calculation Model

According to the actual conditions, design calculation model of high-formwork body, thickness of the plating was 120mm, space between upright tubes was 1.2m, horizontal bar spacing step length was 1.8m, the template erection height was 16.2m,erection area was 19.9m×4.4m,the size of each beam were: 1 # 1.0m×1.8m; 2 # 0.6m×1.2m; 3 # 0.24m×0.72m, the distance between the bottom horizontal tube and the ground was 200mm, the height of the top horizontal tube extending to the pole tip was 100mm.Model of Planar graphs were shown in Figure 1.

Based on the calculation model, established two different bridging arrangement model, respectively: (1)At the bottom of each 1#,2#,3#beam arranged a vertical bridging;(2)Along the direction of the frame body parallel to the beam arranged a vertical bridging under the board every

3.6m. Continuous vertical bridging were arranged around the formwork support according to the requirement of standard.

High-formwork support system model was built by ABAQUS[4-7] finite element analysis software, the calculating unit of the calculation model select linear beam element, the scale of the beam element was greater in a certain direction significantly than the scale of the other direction, And choose the bearing longitudinal based structure for simulation. Selection of beam unit based on the following assumptions: structural deformation can be determined by all along the beam length direction position function ,when define a beam element, the different between the solid element and shell element is that the solid element should firstly establish cross-sectional size and geometry shape, define the beam section characteristics and material parameters. The node at the intersection of horizontal tube and the vertical tube was processed to ideal rigid connection [8].

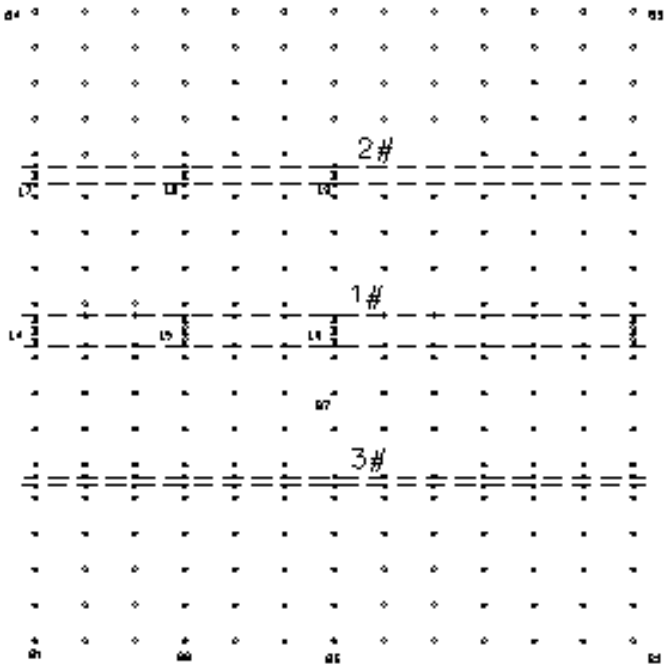

**Fig.1** The plan of the model

**Finite Element Analysis**

**The analysis of bridging arrangement location on the lateral migration of high-formwork support system**. By applying the same symmetry load on the two different arranged bridging position of high-formwork support system, the results indicate: when the vertical continuous bridging were arranged under the beam, the maximum displacement of high formwork support system is 1.01mm,the overall lateral migration of the frame decreases in turn from top to bottom, near the bottom of the fixed end displacement is minimum, its value is almost zero. Its lateral migration value from top to bottom followed by 1.01mm, 0.93mm, 0.82mm, 0.71mm, 0.62mm, 0.57mm, 0.44mm, 0.36mm, 0.19mm, 0.09mm ; when the bridging are arranged under the board, the maximum overall displacement of high formwork support system was 1.27mm,with reducing of the height of the bracket ,its lateral migration value were 1.87mm,1.52mm,1.38mm,1.24mm,0.97mm, 0.81mm,0.74mm,0.67mm,0.49mm,0.31mm,0.23mm,0.17mm.

The bridging arrangement spacing under the board was smaller than the beam, but the frame body lateral migration of beam is 0.86mm shorter than the bridging arrangement under the board, indicating that the bridging under the beam is more beneficial for the stability of high-formwork support system. The bridging spacing under the beam was 4.4m, it's spacing was smaller than the

bridging spacing under the board, but its lateral migration of the frame body is still smaller than the board, the whole stability is good.

**The analysis of bridging arrangement location on the beam bottom rod internal forces.** Discuss separately the influence of the two bringing arrangement location on the axial force of 1#-3# the beam, axial force of beam under different bridging arrangement location are shown in table 1

**Table 1** Axial force of beam under different bridging location

| Pole-axis force [KN] / location | 1# | 2# | 3# |
|---|---|---|---|
| Under the beam | 6.21 | 1.36 | 0.87 |
| Under the board | 8.42 | 3.03 | 2.49 |

Thus, the axial force of the beam decreased when the bridging under the beam. Take 1 # beam for example, the axial force of the beam is 2.21kN smaller than the bridging under the board . It is due to axial force of the opposite pole of bridging under the beam plays a role of constraints, sharing part of the axial force of the pole, and the beam bottom belong to high risk section of the high-formwork supports system at the same time, therefore the bridging under the beam is beneficial to relieving dangerous cross section.

## Conclusions

To sum up, Bridging arrangement location have a considerable influence on the frame body force, the arrangement spacing of the bridging under the beam is greater than the bridging under the board, but its frame body lateral migration is smaller, while sharing part of the axial force of beam bottom rod, the bridging arrangement under the beam is conducive to the overall stability of high-formwork support system, is advantageous to the construction safety, and can save materials, has a good economic characteristics.

**Keywords:** High-formwork, finite element analysis, concrete pouring sequence, stability

**Abstract.** ANSYS finite element analysis software is used to simulate the changes of maximum lateral displacement of the high-formwork support system in different sequences of pouring concrete. In the condition of loading which was applied from one side to the other side, the maximum lateral displacement of the frame had a sudden increase in each loading process. In the condition of loading which was applied symmetrically, the maximum lateral displacement of the high-formwork steadily rising nearly straight with the load applied. So the symmetrical pouring concrete ways is better for the whole stability of the high-formwork.

## Introduction

With the development of modern cities, there appeared more and more large engineering, high formwork support system was applied more widely. In recent years, high formwork collapse accidents had occurred, some of them had led to serious consequences and caused irreparable damage to the country and people's life and property [1-3]. Therefore, the overall stability of formwork support is one of important factors which must be considered in the construction. There are many factors that affect the stability of formwork support. The study found that the sequence of concrete pouring was usually ignored in the process of construction. In order to make the operation convenient, they often poured concrete from one side to the other side and caused serious accidents in the concrete pouring stage [4]. This paper got a conclusion after studied the concrete pouring sequence through the finite element analysis. It is that pouring sequence of concrete can't be ignored and pouring symmetrical can make high-formwork more stability. The conclusion provide a reliable basis for the revision of high-formwork support system design and the current code, provide the reference for the construction plan, reduce incidence of collapse accident, to ensure high-formwork support system use safely.

## Calculation Model

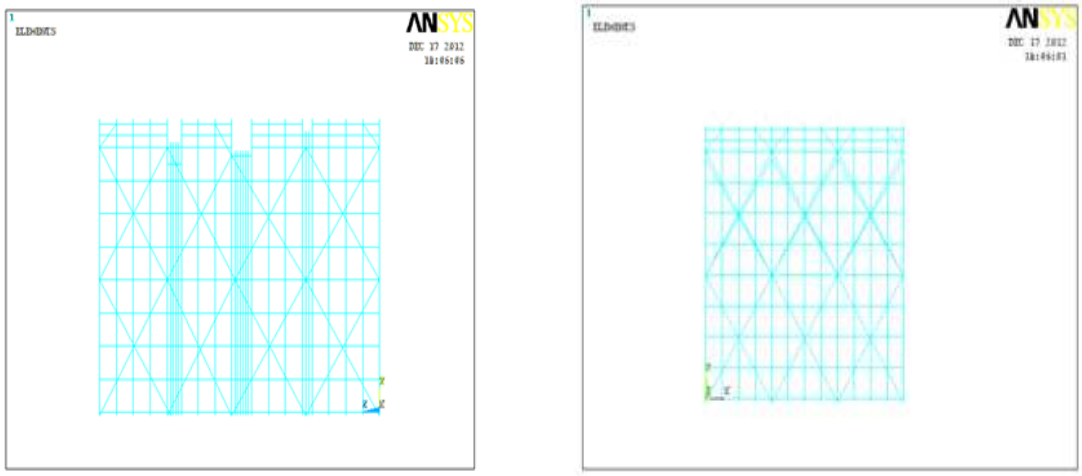
The height of high-formwork erection was 16.2m, the area was 19.9 x 14.4 m, the spacing of vertical pole was 1.2m, the pace of horizontal pole was 1.8m. The section area of the middle beam was 1.0m× 1.8m.The remaining two beam in the left and right sides were 0.6m × 1.2m and 0.24m × 0.72m. The type of the steel pipe was Q235, its specification was Φ48×3.5mm.

The high-formwork was arranged around the continuous vertical bridging and the bottom of beam was also set vertical bridging. The sweeping rod, the top rod was arranged horizontal bridging, The middle part of the high-formwork were respectively arranged two bridging. Regardless of wind load, seismic load and the dynamic load in the process of calculation.

## High-Formwork Finite Element Simulation

**Element Selection and Node Processing.** In this paper, ANSYS was used to simulate the model of high-formwork system. BEAM4 was used to simulate the vertical pole and horizontal pole. The BEAM4 was uniaxial stress element which could bear pulling, pressing, bending moment, torque. The element had six degrees of freedom for each node: X, Y, Z linear displacement in three directions and angular displacement rotate around the X, Y, Z three axis. And it could be used to calculate the stress hardening and large deformation. The Link8 was used to simulate the vertical bridging, horizontal bridging. To simulate "semi-rigid" connection through combin14, it was spring damper element and can be applied to simulate one-dimensional, two-dimensional or three-dimensional elastic damping effect in longitudinal or torsional.BEAM4 was used to simulate the the vertical pole and horizontal pole. BEAM8 and combin14 were used to simulate bridging and the connection of the fastener node [5-7]. Establishing "semi-rigid" model whose initial stiffness was K=50000N · m/rad to compare.

The external diameter of the steel pipe was 48mm, the wall thickness was 3.0mm, the sectional area was 4.24cm$^2$,the Elastic Modulus was $2.06\times10^{11}$pa, the Poisson's ratio was 0.25, the yield strength was $2.05 \times 10^8$pa.The finite element model of high-formwork was shown in fig 1.



The Y-Z elevation drawing The X-Y elevation drawing

Fig. 1 The finite element model of high-formwork

**Loading Scheme.** In the calculation model, beam loaded seven times and plate loaded three times, to calculate the load value of each beam and plate in each loading process, to assign the load value to each vertical pole. To simulate concrete pouring through different loading sequence, the load was applied on the vertical pole which under beam and plate. There were two loading sequence in each loading process, loading from one side to the other side and from middle to both sides,comparing the stability of High-formwork Support System in different loading sequence.

**Influence of Concrete Pouring Sequence on the Stability of the Frame.** Lateral changes in symmetrical loading process were shown in fig 2. Lateral changes in asymmetrically loading process were shown in fig 3.

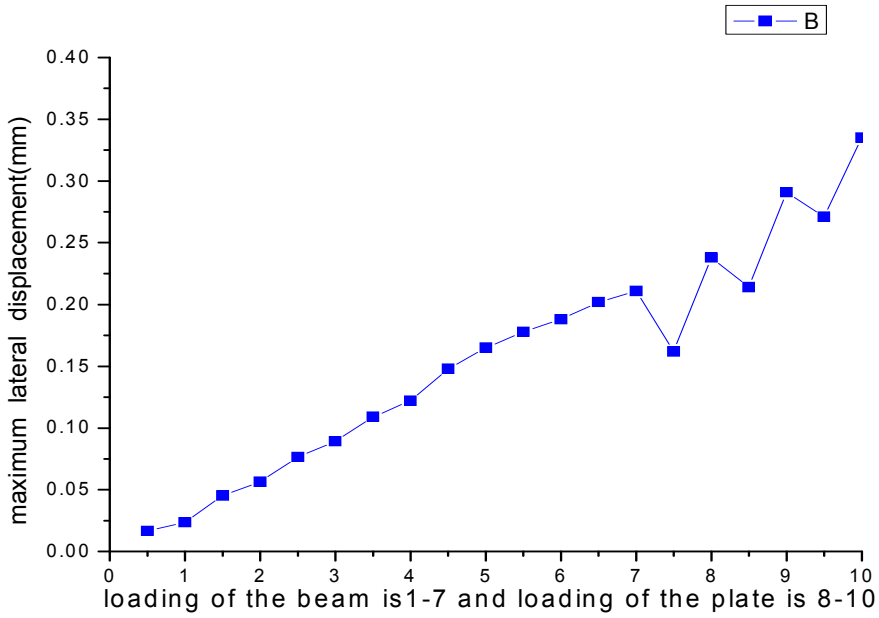


Fig.2 Middle to both sides maximum lateral changes in loading process

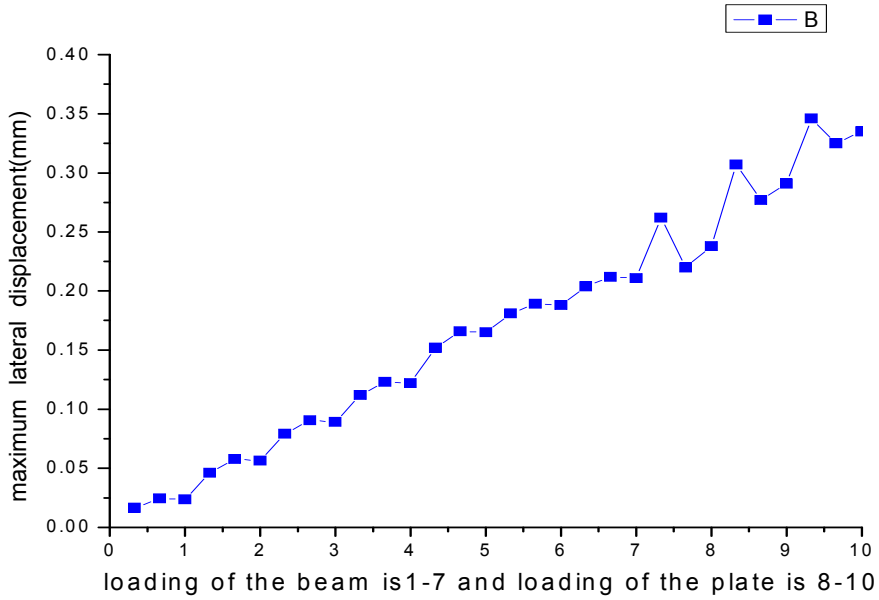

Fig. 3 One side to the other maximum lateral changes in loading process

It can be seen from fig 2and fig3, the maximum lateral displacement of the high-formwork steadily rising nearly straight with the load applied from the middle to both sides. when loaded on plate, the maximum lateral displacement had a sudden increase in the loading process, the reason is that the lateral displacement was produced by the load which applied on the plate offset some of the lateral displacement was produced by the load which applied on the beam. In the condition of loading which was applied from one side to the other side, the maximum lateral displacement of the high-formwork had a sudden increase in each loading process when applied on the beam. This was due to more force was distributed on one side of the beam,lead to the lateral displacement was too large. Loading on plate, due to the force also tilted to one side, the maximum lateral displacement increased. The sequence of pouring concrete from the middle to the sides should be adopted, so that we can avoid the lateral deformation of high-formwork is too large in the concrete pouring stage.

## Conclusions

To sum up, in the process of High-formwork Support System construction, if the way of pouring concrete from one side to the other side of the beam was adopted, the lateral displacement of the high-formwork would have a sudden increase in the concrete pouring stage, Thus the overall stability of high-formwork would be impacted and the probability of malignant accident would be increase. However, if the way of symmetrical pouring concrete was adopted, lateral displacement would rise more smoothly, the overall structure would more stable. Therefore, In order to reduce templates collapse accident, it is appropriate to use the way of symmetrical pouring concrete.

# The Integration of New Technology Research on Composite Inorganic Fiber Acoustic Insulation Spray in Engineering Construction

Junyi Shao [1, a], Dong Wang [2, b]

[1]Qingdao Technological University, China

[2]Qingdao Technological University, China

[a]qdlgdx@163.com, [b]15589808134@163.com

**Keywords:** Composite inorganic fibers; Hybrid nozzle; Sector coverage; Multiple mixed nozzle; High-strength interfacial agent;

**Abstract.** Composite inorganic fiber spray technology was based on high-strength interfacial agent, then sprayed an appropriate mixed proportion of ultrafine diameter (D <4μm) composite inorganic fibers, adhesives, cement and other raw materials through a dedicated spray equipment on the building roof (ceiling)or flank, which formed a homogeneous, porous, durable and eco-friendly cover layer. The key technology is combined composite inorganic fiber sprays' adhesive, mixing, porous, insulation and acoustic fireproof mechanism with three key technology working principles " high-strength interfacial agent sector coverage ", " composite inorganic fibers + adhesive multiple mixed spray " and " continuous overall seamless fireproof insulating layer ", to achieve integrate engineering effects of insulation, fastness, energy-efficient, sound-absorbing and homogeneous coverage. The new technology solves acoustic insulation problems of public buildings with fireproof requirements as: underground garage ceiling, elevator shafts and fire passage, etc.

## Introduction

Composite inorganic fiber insulation, fireproof and sound absorption spray is a new construction technology. Raw materials utilized ultrafine glass wool or rock wool(D <4μm) and sprayed into building roof (ceiling) or sidewalls with adhesives and cements through a dedicated spray equipment, which could achieve integrate effect of fireproof, insulation , sound absorption and waterproof. Currently, composite inorganic fiber spray can be applied to various types of buildings and public buildings sound-absorbing, acoustic ceiling and curtain wall insulation works, especially for the underground garage ceiling, elevator shafts, fire passage [1]. But there existed some problems in the construction process:

1) The selection of spray gun is unreasonable and the spraying is too concentrated. The situation will lead to non-uniform spray interface and waste fiber materials in the construction process.

2) All kinds of raw materials are not fully mixed through the spray gun. The condition leads to spray on the surface of uneven thickness, which affects the use function.

3) Interfacial agent adhesive is ineffective and spraying method is unreasonable. This condition causes the phenomenon of inorganic fiber shedding.

## Features of composite inorganic fiber

1) High-quality: the ultrafine and low-density of composite inorganic fiber mixed with spray by one-step modeling. The layer quality is uniform and has good thermal insulation, noise-absorption properties [2].

2) Security: the mixture of composite inorganic fibers and adhesive sprayed into grassroots interfacial agent through gun muzzle, forming a whole seamless insulation, anti-crack and fireproof layer, which quality is reliable and stable.

3) Eco-friendly: interfacial agent with good adhesion, mixed spraying with low loss, fiber composite inorganic is pollution-free and dust-free with a lifetime as long as the building itself and has good environmental protection function.

4) Economy: raw materials are mass production in the domestic, and construction process is simple and easy to operate with low construction costs and high construction efficiency.

**Composite inorganic fiber spray integrate new technical principle**

1) High adhesion principle

Using specially formulated high-strength interfacial agent forms a highly viscous boundary layer, which provides good conditions for inorganic fiber insulation layer construction; Detail in Fig1.

2) Uniform coverage principle

The high-strength interfacial agent sprays by dual-port, cross-forms sector cover with uniform coverage, high efficiency and materials-saving; Detail in Fig2.

3) Homogeneous and equal thickness principle

The multiple mixed spray technology of composite inorganic fibers and adhesive allows ultrafine inorganic fiber mixes with uniform, sprays with high-quality, loss with low, easily control with spray thickness;

4) A lifetime as long as the building principle

Composite inorganic fibers coordinated with cement, water and high-strength interfacial agent, formulate scientific and rational, bond solid and reliable, form fireproof insulating layer together with ceiling or wall, which can be a lifetime as long as buildings in an indoor environment.

**Fig.1:** Hybrid nozzle

**Fig.2:** High-strength interfacial agent sector coverage

**Composite inorganic fiber spray operation technical points**

**Construction Process**

Composite inorganic fiber acoustic insulation spray construction process includes: construction preparation; base surface treatment; measuring(positioning , screeding);high-strength interfacial agent spray; (steel reinforcement); composite inorganic fiber multi-mix spraying; surface rolling smooth integration; protective layer spraying; checking (repairing); site clean-up ;acceptance.

**Operating technical points**

**Construction preparation**

1) Checking with the drawing to determine spray portion and non-spray portion;

2) Evacuating compressed cotton fibers, continuously filling spray cotton into the sprayer and keeping adequate fiber material inside;

3) The person was responsible for diluting adhesive liquid with water under the ratio in the ingredients jar equipped with high-speed blender;

**Base surface treatment**

1) Using compressed air or water fully sprays base dust and dirt;

2) Checking hanging pieces and embedded parts solidity, loose parts should be fastened;

3) Checking base surface quality, if the primordial surface has been damaged or have serious cracks, it should be repaired and meet regulatory requirements.

**Pre-spray primer at the base surface**

After the base surface cleaning, using well high-strength interfacial agent spray adhesive aqueous which acts as pre-spray interfacial agent treatment for base surface, the dose should be appropriate and uniform, not expose at the end, not flow. Detail in Fig3.

**Fig.3:** Hybrid nozzle construction work

**Composite inorganic fiber spray**

1) Spraying equipment commission

In strictly accordance with the equipment instructions test spraying host pressure, plastic pump pressure and feeding device, through template test spray, measurement of glue flow and the amount of cotton, gradually adjust air pressure range and feed mixing speed, until the fiber spraying status is stable, glue and cotton meet process requirements.

2) Placing thickness control points partition

Each5m$^2$area set up a standard aerated concrete block (15mm × 15mm × spray thickness).

3) Spray insulation layer construction

Adjusting working pressure and feeding device to ensure fiber feed uniform, stirring speed of 30 ~ 45r/min; regulating the ratio of water and glue, stirring together evenly, along with the spray to the base surface. Spray gun away from the base surface is preferably 400mm ~ 600mm, spray cotton content appropriate for the 0.8kg/min ~ 1.25kg/min each spray thickness of 30mm or less, which should ensure continuous evenly sprayed on the grassroots, cannot reveal at the end.

4) If the spray thickness less than standard, fill spray should be carried out in a timely manner, forms homogeneous spray insulation.

**Spray layer surface shaping**

After half an hour later for spray insulation layer dry on the surface, using a dedicated tool for surface processing according to the different requirements of insulation or sound absorption engineering. In general, dedicated platen should be pressed down 5mm; corners should be dealt with smooth, keeping right angles to form a continuous insulating seamless layer.

**Spraying protective layer**

Leveling directly through spraying hydrophobic agent or insulation mortar to form a protective layer at the surface of shaped product; spraying waterproof coating, waterproofing agent to the insulating layer, forming a waterproof protective surface layer.

**Enhanced a3nchorage**

When the ceiling (roof) spray thickness>60mm or sidewalls spray thickness>80mm, alkali-resistant fiberglass mesh or galvanized steel mesh should be used to lay reinforced. After leveling with mortar in spray layer, using expansion bolts fixed insulation layer together with steel mesh reinforcing layer on the substrate surface.

**Construction site cleanup**

Construction site should be cleaned after spraying, clearing the rebound material and removing protective enclosure, scaffolding.

**Spray product protection and precautions**

1) Avoid drilling, chiseling in the base after the completion of spraying, installing various pipelines, ducts and other equipment hanging pieces in advance;

2) Avoid mechanical impact or water erosion in the early dry-cured;

3) For susceptible to mechanical impacts parts，sticking fiberglass cloth or other protective material to protect fiber layer surface ;

4) Avoid dusty polluting surface layer, keep spray area cleaning environment;

**Applications and examples**

Composite inorganic fiber acoustic insulation spray technology successfully applied in several projects in Qingdao Economic and Technological Development Zone. First used in the underground garage ceiling acoustic insulation projects, the area of composite inorganic fiber spraying approximately 15,210 $m^2$. Engineering Practice has proved that the technology achieves the performance targets as follows:

1) High-strength interfacial agent water -screen sector coverage technology owns good uniformity, low loss (≤ 5%), high shear bond strength (≥ 0.5MPa);

2) Composite inorganic fiber + adhesive multi-mixing gun spraying technique owns smaller mixing ratio error (≤ 1%), a uniform thickness control (≤ 1mm);

3) Continuous whole seamless fireproof insulating layer technology owns lower thermal conductivity≤ 0.040W / m • k, good compactness, pit depth ≤ 2mm, no cracks, no peeling.

**Economic benefit analysis**

From the perspective of current market material price, the operator costs, construction ancillary costs and other costs, compared the unit square project cost with composite inorganic fiber spraying in the process, the technology has a larger profit margin which pre-tax profit reach around 15%.

**Social benefit analysis**

Inorganic fiber composite spray insulation, fireproof, sound-absorb is a new technology, compliance with national industrial policy "energy savings ", which is insulation engineering and fire proof engineering technology.

## Conclusions

The integration of new technology research on composite inorganic fiber acoustic insulation spray set in engineering practice, repeatedly demonstrated the difficulties and key construction process in the construction process. Through a combination of theoretical analysis and engineering experience, integrate fireproof, sound-absorbing, insulation with energy-saving, firmness. Practice has proved that the paper proposes three key technology " high-strength interfacial agent sector coverage ", " composite inorganic fibers + adhesive multiple hybrid spray " and " continuous overall seamless fire insulating layer combination form", achieve the optimization of building fireproof insulation, energy-saving and durable. The new technique can be widely used in the construction of basement and underground garage. The resistance of acoustic insulation to ensure class A fireproof quality; bonding firm and no cracking, eliminates the security risks which reduces labor costs and achieve a high-quality, economical and environmentally friendly construction goals.

# The Technology Innovation of Green Soft Ground Handling Based on Squeezing and Consolidation Composited

Junyi Shao [1, a], Xiao Zhang[2, b]

[1]Qingdao Technological University, China

[2]Qingdao Technological University, China

[a]qdlgdx@163.com, [b]402159264@qq.com

**Keywords:** Life-cycle environmental load evaluation techniques, cement mixing pile, spiral pump pressure CFG pile, squeezing and consolidation composited technology;

**Abstract.** In this paper, we sorted soft foundation treatment technology by quantifying based on evaluation technique of life cycle environmental load and choose cement mixing pile which life-cycle environmental load is small and spiral pump pressure CFG pile which carrying capacity is high to integrate. It not only improved soil compaction effects, but also solved the problems of other technologies in the foundation process, such as low carrying capacity, reduced diameter, broken pile, virtual pile and so on. Besides, it has reduced the cost of the project and the application prospects are broad.

## Introduction

At the present stage, the schemes of soft foundation treatment technology are numerous. For the same project, there may be many technologies meeting its safety indicators such as carrying capacity, settlement and so on. Under the constraints of energy conservation and environmental protection how to choose a foundation treatment technology which both ensures the construction period and is affordable is one of the hot in the field of architecture and foundation engineering.

## Process principle of innovative technologies

Based on life-cycle environmental load evaluation techniques, first we implanted the factors of technology, economy, environment and period, and then we sorted soft foundation treatment technology by quantifying, as shown in Fig.1. Such sorting results are more in line with the principles of green construction.

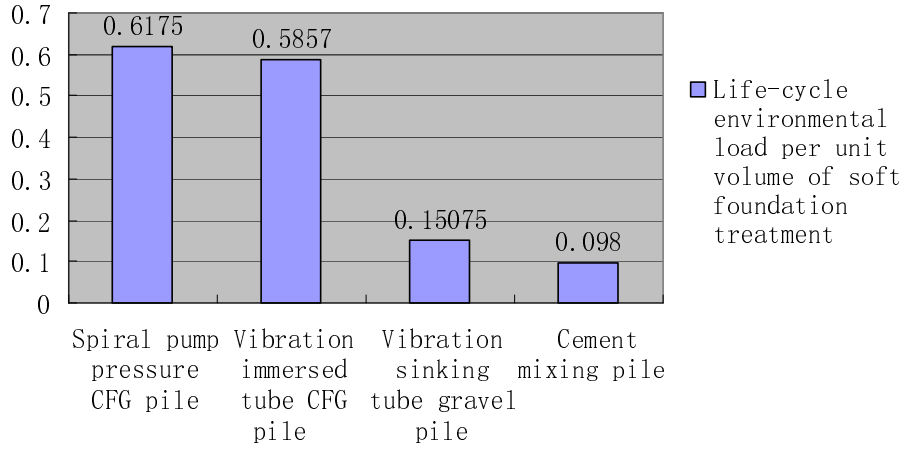

Fig.1: Life-cycle environmental load per unit volume of soft foundation treatment technology

Cement mixing pile is inexpensive and its construction is simple, but the foundation bearing capacity is limited; Environmental load of gravel pile is small, while soil compaction pressure is big and easily breaks pile; spiral pump pressure CFG pile can form high strength composite foundation by squeezing soil between the piles, while life-cycle environmental load is large.

Using the above two methods to integrate, first fix soil between piles by cement mixing pile , then squeezing soil between piles by spiral pump pressure CFG pile. It enhances the effect of compaction and improves the bearing capacity, at the same time; it reduces the cost and environmental impact of the project and provides a complementary and optimized combination for foundation treatment.

**Process flow**

Squeezing and consolidation composited technology of spiral pump pressure CFG pile and cement mixing pile, construction process as shown in Fig.2:

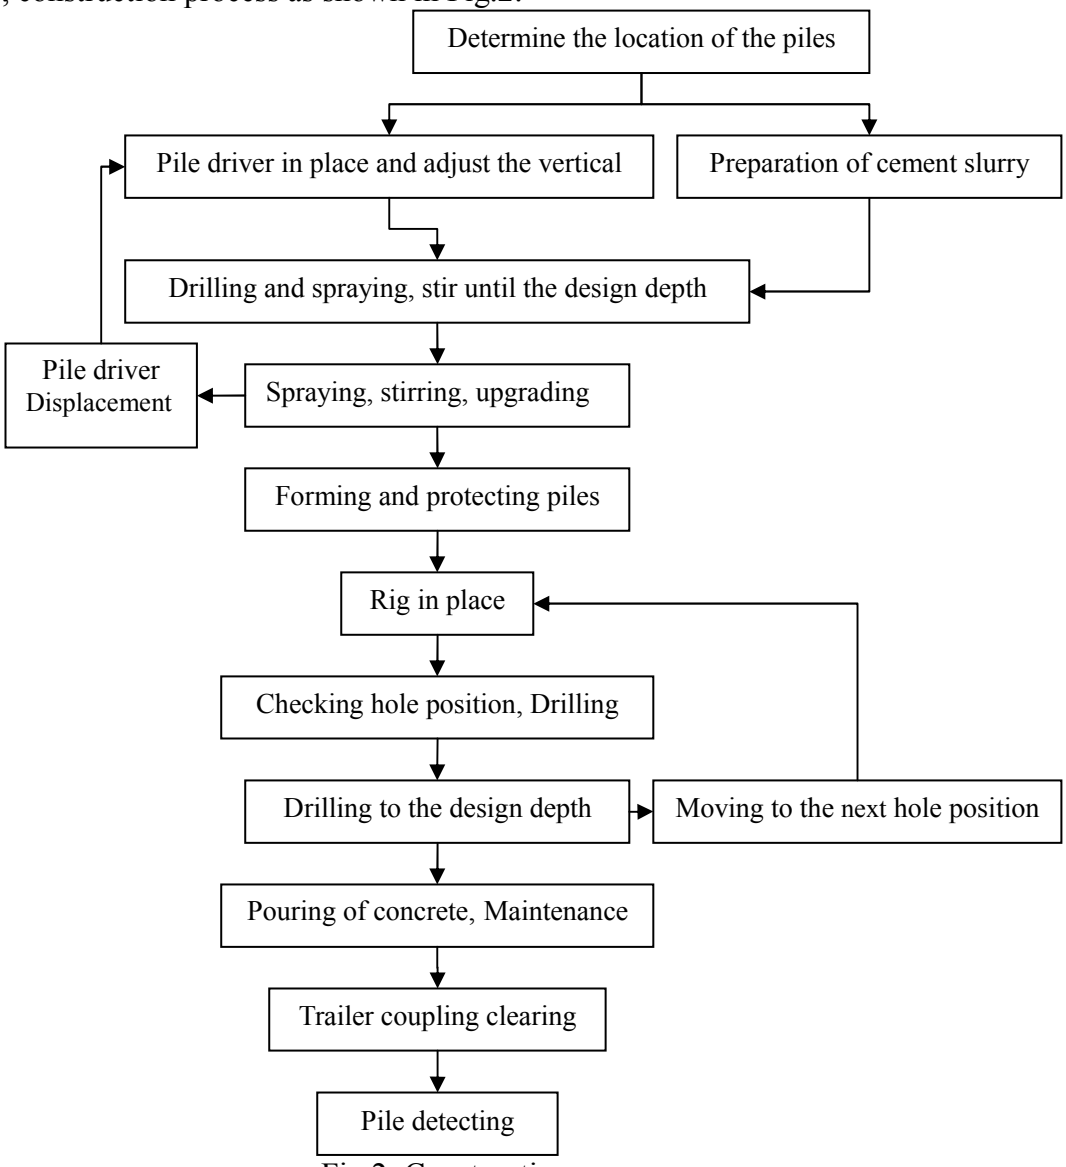

Fig.2: Construction process

**Scope of application**

Squeezing and consolidation composited technology of spiral pump pressure CFG pile and cement mixing pile has the features with large carrying capacity and small ground deformation. It is suitable for soft clay, silt, sand and other ground handling. Besides, it is also suitable for high requirements of noise and mud pollution.

**Application Example**

Qingdao, a regional transformation and resettlement housing, Building E 3, 4, 5, 9, 10, construction area is 120000 $m^2$, 1 basement and ground floor is 30. Make Foundation bearing capacity not less than 300KPa by foundation treatment.

**Carrying capacity calculation** if all use cements mixing piles, the calculation results are as follows:

Pile diameter: $d = 550mm = 0.55m$ $A_P = \pi \cdot (\frac{d}{2})^2 = 0.237m^2$ single pile bearing:

$$R_a = \eta \cdot f_{cu} \cdot A_P = 0.3 \times 3000 \times 0.237 = 213.3KN \quad (1)$$

Area displacement ratio:

$$m = \frac{f_{spk} - \beta \cdot f_{sk}}{\frac{R_a}{A_p} - \beta \cdot f_{sk}} = \frac{300 - 0.3 \times 120}{\frac{213.3}{0.237} - 0.3 \times 120} \times 100\% = 30.6\% > 30\% \quad (2)$$

It is unreasonable, so it should not use cement mixing pile single.

In the formula, $\eta$ --------Pile strength reduction factor,

$f_{cu}$ [2]-----Cube compressive strength of the average at 90d age of interior reinforced soil test block which is at the same ratio of cement-soil of cement mixing pile body,

$f_{spk}$ [2]----Capacity eigenvalues of composite foundation (KPa),

$f_{sk}$ [2]-----Carrying capacity eigenvalues of soil between piles (KPa),

$\beta$ --------Carrying capacity reduction factor of soil between piles (KPa).

If all use spiral pump pressure CFG piles, the calculation results are as follows:

Pile centric axial compressive loading ultimate strength:

$$q_c = \mu \cdot q_{cu} = 0.64 \times 10000 = 6400KN \quad (3)$$

Ultimate bearing capacity of single pile:

$$p_{pf} = q_c \cdot A_P = 6400 \times 0.237 = 1516.8KN \quad (4)$$

Allowable bearing capacity of single pile:

$$p_{pc} = p_{pf} / K = 1516.8 / 2 = 758.4KN \quad (5)$$

Area displacement ratio:

$$m = \frac{f_{spk} - \beta \cdot f_{sk}}{\frac{R_a}{A_p} - \beta \cdot f_{sk}} = \frac{300 - 0.3 \times 120}{\frac{758.4}{0.237} - 0.3 \times 120} \times 100\% = 8.3\% < 30\% \quad (6)$$

It meets the requirements of the replacement rate.

While, due to the high life-cycle environmental load of spiral pump pressure CFG pile, as shown as Fig.1, we should minimize the spiral pump number of CFG pile during the construction process. In this example, we select the cement mixing pile and spiral pump pressure CFG pile to use compositely.

Cement mixing pile and spiral pump pressure CFG pile composite foundation:

Calculate according to the number ratio of 7:3 of cement mixing piles and spiral pump pressure CFG piles:

Allowable carrying capacity of single pile:

$$R_a = 0.7 \times 213.3 + 0.3 \times 758.4 = 376.83KN \quad (7)$$

The composite area replacement rate:

$$m = \frac{f_{spk} - \beta \cdot f_{sk}}{\frac{R_a}{A_p} - \beta \cdot f_{sk}} = \frac{300 - 0.3 \times 150}{\frac{376.83}{0.237} - 0.3 \times 150} \times 100\% = 16.5\% < 30\% \quad (8)$$

It meets the design requirements.

The test verified, cement mixing pile and spiral pump pressure CFG pile combined used in accordance with the ratio of 7:3 can meet the requirement of final foundation carrying capacity.

Pile spacing calculation:

The total area of piles: $16.5\% \times 850 = 140.25 m^2$ the number of piles: $140.25 \div 0.237 = 593$ (Excluding stockades), arranged by type of quincunx as shown as Fig.3, excluding stockades, assuming pile spacing was x, y, then:

$$(\frac{35.15}{x}+1)\times(\frac{23.25}{x}+1)+\frac{35.15}{x}\times\frac{23.25}{x}=593 \tag{9}$$

Namely, $x = 1.7117m$ $y = \frac{\sqrt{2}}{2} \times 1.7117 = 1.2104m$

During construction in accordance with integrated technology, we shall be in accordance with the "first the peripheral later center" construction sequence for construction, piles detailing of the site layout as shown as Fig.3 (excluding stockades).

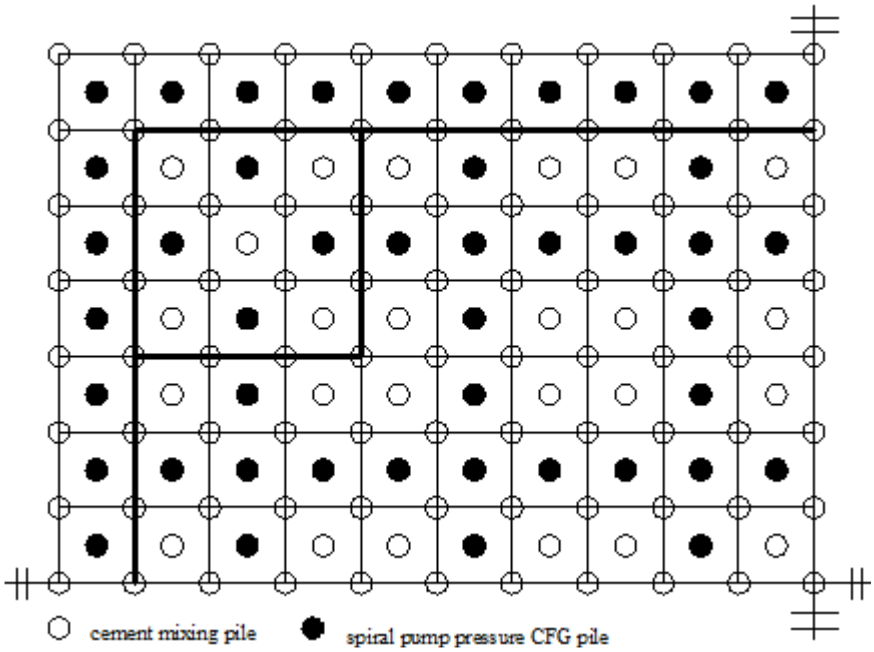

Fig.3: General arrangement drawings of integrated technology

After sampling inspection of a wide range, single pile bearing meets the requirements.

**Cost calculation.** If all use cement mixing piles, the calculation of direct costs as follows:

$$n_1 = \frac{m \cdot A}{A_P} + 50(\text{stockades}) = \frac{0.306 \times 850}{0.237} + 50 \approx 1148 \tag{10}$$

Project amount: $V_1 = 1148 \times 8 \times 0.237 = 2176.608 m^3$

According to 2011 construction price list of Shandong Province, the base price is 1388.4 *Yuan* per $10\,m^2$, so the cost of cement mixing piles: $2176.608 \div 10 \times 1388.4 = 302200.25$ *Yuan*.

If all use spiral pump pressure CFG piles, the calculation of direct costs as follows:

$$n_2 = \frac{m \cdot A}{A_P} + 50(\text{stockades}) = \frac{0.083 \times 850}{0.237} + 50 \approx 348 \tag{11}$$

Project amount: $V_2 = 348 \times 0.237 \times 8 = 659.808 m^3$

According to 2011 construction price list of Shandong Province, the base price is 2011.21 *Yuan* per 10 $m^2$, so the cost of spiral pumps pressure CFG pile: $659.808 \div 10 \times 2011.21 = 132701.24$ *Yuan*.

Cement mixing pile and spiral pump pressure CFG pile composite foundation:

Cost calculation of composite foundation:

The number of cement mixing pile:

$$n_3 = \frac{m \cdot A}{A_p} + 50(\text{stockades}) = \frac{0.7 \times 0.165 \times 850}{0.237} + 50 \approx 465 \tag{12}$$

The number of spiral pumps pressure CFG pile:

$$n_4 = \frac{m \cdot A}{A_p} = \frac{0.3 \times 0.165 \times 850}{0.237} \approx 178 \tag{13}$$

The pile length: $l = 8m$

Project amount of cement mixing pile: $V_3 = n_3 \cdot A_P \cdot l = 465 \times 0.237 \times 8 = 881.64m^3$

Project amount of spiral pump pressure CFG pile:

$$V_4 = n_4 \cdot A_P \cdot l = 178 \times 0.237 \times 8 = 337.49m^3 \tag{14}$$

According to 2011 construction price list of Shandong Province, the total cost of composite foundation:

$$881.64 \div 10 \times 1388.4 + 337.49 \div 10 \times 2011.21 = 190283.22 \ \textit{Yuan} \tag{15}$$

**Economic benefit analysis**

To meet the request of the foundation bearing capacity, the cement mixing piles and spiral pump pressure CFG piles construct with the ratio of 7:3 in the project example, its cost is 190283.22 *Yuan*. If we use a single foundation treatment method to construct, the cost of cement mixing pile is 302200.25 *Yuan*; the construction cost is too high. While, the cost of spiral pump pressure CFG pile is 132701.24 *Yuan*, but the environmental load is too high, so we use cement mixing pile and spiral pump pressure CFG pile to integrate for construction, it not only solve the problem of foundation carrying capacity, but also control costs and reduce the environmental load effectively and provide reference basis for the foundation treatment scheme selection and integration.

Compared with cement mixing pile, only a building foundation (approximately 995m$^2$) can save 111917.03 *Yuan*.

**Conclusion**

This is the first use of environmental load evaluation techniques for soft foundation treatment plan to sort comprehensively by quantifying. It provides a more scientific basis for technology scheme comparison. Used cement mixing pile and spiral pump pressure CFG pile to integrate, first fixed soil between piles by cement mixing pile, then squeezed soil between piles by spiral pump pressure CFG pile, it not only improves soil compaction effects, but also solves the problems of other technologies in the foundation process, such as low carrying capacity, reduced diameter, broken pile, virtual pile and so on. It can eliminate liquefaction, unconfined stiffness of composite foundation defects. It satisfies the requirement of the large tower structure complicated foundation treatment and used for soft sticky, sandy, silty ground. The subsidence and deformation meet the specification requirements.

# Causes and Solutions for the Common Problems in Rotary Drilling Cast-in-place Pile Construction

Zhaoyin Zhou[1,a], Changyou Zhang[1,b]

[1]School of Civil Engineering and Architecture, Chongqing University of Science and Technology, Chongqing, 401331, China

[a]zzy2485@126.com, [b]zcy56@126.com

**Keywords:** Rotary Drilling Cast-In-Place Pile, Construction Craft, Quality Control, Measures

**Abstract.** Quality control in the rotary drilling cast-in-place pile construction is of great difficulty. Once a quality problem occurs, it would have an impact on the quality of the whole project. The text mainly analyzes the causes for the common problems in rotary drilling cast-in-place pile construction and gives some corresponding measures to solve them combined with engineering cases.

## Introduction

Rotary drilling cast-in-place piles to adopt a rotary drilling rig to pierce and form a pile. According to the methods of piercing, it could be divided into rotary drilling cast-in-place pile in dry operation, rotary drilling cast-in-place pile in damp operation, all steel casing and protective wall of rotary drilling cast-in-place pile. In recent years, rotary drilling cast-in-place pile construction has been a new-type construction method for pile foundation, which is employed in bridge and building engineering projects and has a broad application prospect.

Take Chongqing area as an example, manual cast-in-place pile construction has been eliminated due to the lack of operational safety assurance for workers and the low efficiency during the process. Given the rock high fill mountainous geological conditions of Chongqing area, rotary drilling cast-in-place pile is the first choice for pile foundation. But in the application process, many quality problems occur, such as hole pull collapse, bottom sediment, reinforcing cage float, and localized necking in the pile hole. They have caused a profound influence on the quality of the rotary drilling cast-in-place pile. If the problem could not be solved in time, it would have detrimental effects on the quality of the entire project. Therefore it requires engineering staffs' high attention during the construction.

## The common problems in rotary drilling cast-in-place pile construction and cause analysis

**1.1 Water emitting of steel casing.** The outer wall of the steel casing emits water. The more serious cases will induce foundation subsidence, incline and displacement of the steel casing, which will cause pile hole deviation. Even it is hard to go on the construction. The main reason is that the earth around it is not dense enough when it is embedded, or the water level in the steel casing varies largely, or the bit hits it when it rises and falls.

**1.2 Slow drilling or no drilling footage.** Drilling is slow in hard plastic clay layers. Generally, it takes 8 to 10 hours, which accounts for 60% to 70% of the penetration time for on pile. It is mainly for the reason that the type of bit is incorrect, setting angle for the alloy cutter is improper, the depth of earth cut by a cutter is too shallow, the bit counterweighs, and the bit is thoroughly coated with clay.

**1.3 Collapse of the wall of pile hole.** After and during the piercing, the wall collapses in varying degree. Bubbles appear constantly in the emitted mud. Sometimes the water level decreases suddenly. All of them are the harbingers of collapse. The main reasons are that the earth is lax, the mud protective wall is not good enough; the embedding of the steel casing is bad, the inner water level is not high; the speed of the bit is too fast or its idling time is too long are causes for the bottom collapse. Or waiting and perfusion time after piercing is too long.

**1.4 Localized necking in the pile hole.** Localized necking means that localized hole size is smaller than the designed size. Poor performance and large water loss of mud causes water swelling of plastic layer or form lax honeycomb thick mud cake; improper distance between neighboring pile constructions, the stresses in the layers of soil has not been diffused, soft clay creeps in new holes, or the bit size wears excessively are the main causes.

**1.5 Displacement and incline of pile hole.** Great vertical deviation or bends appear after piercing. The main causes are that the installation of the drilling rig is not flat or the virtual earth under the platform causes uneven sinking; pile holder is unstable, drill pipe guide inclines, underground barriers like old foundation or big rocks, heterogeneous foundations or bedrock inclines.

**1.6 Too much sediment in the bottom.** Silting in the bottom; extremely thick residual mud sandy or the collapsed walls drop into the bottom. It mainly due to the fact that the hole is not completely cleaned, the percentage of mud is low or it is replaced by clean water in the cleaning process; the hanging position of steel reinforcement cage is not directed at the center; the earth scrubbed drops into the bottom; concrete pouring is not in time after cleaning the hole which causes the mud sediment and there is no unify bottom elevation which measures the thickness of sediments.

**1.7 Steel reinforcement cage floats.** Steel reinforcement cage floats, apart from the obvious reason that catheter raises the hook, the main reason is that the surface of concrete is right to the bottom of steel reinforcement cage, the bottom of catheter is 2 to 3m below the bottom of steel reinforcement cage, the speed of concrete pouring is fast so that the dropped concrete strokes upward, its buoyancy is more than the gravity of steel reinforcement cage.

## Control measures for common problems occurred in rotary drilling cast-in-place pile construction

**2.1 Guarantee embedding quality of steel casing.** Choose and tamp clay which has the optimal water content when embedding the bottom and walls of steel casing; dig a hole in the proper height in the steel casing so as to retain 1-1.5m water head height within it; prevent the bit from hitting the steel casing in rise and fall; fill and tamp the steel casing with clay when it emits water for the first time. If it falls or displaces seriously, it should be reworked and embedded again.

**2.2 Change bit in time according to the soil condition.** Change or improve the bit, rearrange the setting angle, shape, and orientation of the cutter, increase weights, reinforce sediments emission, reduce mud percentage or use drilling method, adopt reverse circulation drilling method.

**2.3 Adjust the percentage of mud in time, and careful manipulation to prevent the collapse of hole.** Deeply embed steel casing in lax soil layer, tamp the soil, use high grade mud, increase the percentage and viscosity of mud, raise the steel casing, add mud after well completion, keep the required water head height, guarantee the manufacturing quality of steel reinforcement cage, prevent transformation; align with the hole in hoisting, hang direct and guide, sink slowly, prevent hitting the wall; after the piercing, pouring concrete in time, the interval is no more than 3 hours and quicken the speed and reduce the time as much as possible; before placing the steel reinforcement cage in the hole, backfill the cement mortar, clay composite to the place which is 1-2m below the collapsed hole depth, or backfill and tamp the whole hole and then clean the bottom of the hole with the original bit and high grade mud. In the case that a slight collapse caused the steel reinforcement cage, use the bit, of which the size is shorter than that of steel reinforcement cage and high-grade mud or catheter to clean the hole.

**2.4 By adjusting the percentage of mud and adopting excavation method to assure that no contractive necking occurs.** When you have predicted or the necking has happened, you should use high-grade mud, control the share and viscosity of mud and reduce water loss. When the designed distance between two piles is less than 4D, you should construct in every two or three piles; the construction of a new pile should be started 36 hours after the piling of its neighboring pile; choose a double guide gauge protection cage bit; use mud and full-scale bit to clean the hole and finish concrete-filled steel tube after cleaning the hole as soon as possible.

**2.5 Ensure that the drilling rig has been installed to the right position, check and adjust in time during the construction.** The installation should be upright, flat, stable, three points: front edge tangent point, swing center and steel casing center should be in the same surface and same line; steel casing does not incline, drill pipe is not bend, drive rod keeps upright; add guide frame, control and hang the swivel; adopt collar to pressurize where is possible; clean underground barrier; except the adaptation of light reduction and slow shift technique parameters in soft and hard layers, from the soft plastic clay layers, especially when enter the hard plastic clay layer from flowing plastic clay layers and sand layer or from soft soil layer to bedrock, the taper guide bit in the bottom should be changed into flat guide bit or bit without a guide; adopt open caisson or pile hole digging to clean underground barriers; when the inclination occurs in the hard plastic clay layers, use the mixture of sand and soil to backfill the area 1-2m higher than the targeted area, when it becomes dense enough, use flat alloy bit to have a light reduction and slow shift on the inclination; when the bedrock inclines, throw rubbles, of which the size is from 20-40mm, to the area which is a little bit higher than the inclination area, when it is dense enough, use flat alloy bit, rolling bit or flat calyx bit to correct it.

**2.6 Assure the quality of hole cleaning.** Raise the bit by 10-20 cm from the bottom after piercing, keeps slow steering and more than 30 minutes'' cycle time; use high-grade mud in cleaning hole, control the share and viscidity of mud and do no replace mud with clean water directly, steel reinforcement cage should be put on the bottom slowly and horizontally; the thickness of sediment is accounted from the bottom surface of the hole; raise the impact of concrete on the bottom of the hole in the first pouring, the distance between the bottom of catheter and the bottom of the hole should be controlled within 30 to 40cm.The amount of concrete in the first pouring should satisfy the requirement that the end of the catheter could be embedded more than 1.0m in the concrete, use interval blocking and concrete to clean the residual sediment.

**2.7 Slow down the concrete pouring speed and reduce the floating of steel reinforcement cage.** To prevent the floating of steel reinforcement cage, you need to slow down the concrete pouring speed when the end of the catheter is lower than the bottom of the steel reinforcement cage by 2 to 3m and the surface of the concrete is within 1m higher or lower than the bottom of steel reinforcement cage. The fastest speed permitted by the drilling rig is related to the size of the pile. When the concrete surface has been higher than the bottom of the frame by 4m, raise the catheter to the height, which is 2m higher than the bottom of the frame, and then get back in a normal pouring speed. Except for the above-mentioned method, steel reinforcement cage itself should be accounted for. The common method is to weld and fix the frame on the steel casing, or to reduce the amount of stirrup below the steel reinforcement cage to a proper amount (within 2m below it); or to extend the four main reinforcement in the frame to the bottom of the hole; or to install one or two stiffening reinforcement, of which the size is no less than that of the main reinforcement, and weld proper traction reinforcement on the bottom of the steel reinforcement cage. When the floating of steel reinforcement cage occurs, the pile driver stops pouring concrete immediately, control the steel reinforcement cage with the help of some equipment like steel casing and drilling rig. When the floating is little, slow down the pouring speed when it has been controlled; when the floating height is large, the pile could not satisfy the requirement of design, you need to draw the steel reinforcement cage, clean the hole and re-pour concrete.

## Conclusions

Rotary drilling cast-in-place pile is a new type of building foundation pile construction craft, which can be applied to all kinds of complicated geological conditions like flowing mud, soft soil, gravel and quicksand in the rotary drilling pile construction. Because of fast speed of drilling bit, high degree of automation, accurate locating, less labor cost, good environmental performance, high working efficiency and low construction cost in the construction process, its value attracts more and more attention. However, in real rotary drilling construction, there are still many above-mentioned problems. In order to have better control over the pile quality constructed through the rotary drilling

cast-in-place pile method, the following several points should be attached importance to in the construction:

3.1 Get prepared before drilling. Such as, understand the geological condition, placement of the field, and mud preparation.

3.2 Keep record and analysis in time during the drilling process, ready to know the geological condition, check indexes like inclination of the hole, percentage of mud frequently, find out problems and adjust immediately.

3.3 When the depth and size of the hole has reached the requirement of design, clean the hole and hang the steel reinforcement cage in time. When the steel reinforcement cage is in position, recheck the thickness of sediment in the bottom and clean the hole for the second time.

3.4 Take proactive measures to prevent the floating of steel reinforcement cage, and adjust the percentage of concrete to guarantee the quality of concrete.

With rotary drilling cast-in-place pile construction craft becoming more mature, all areas make their local standards. Its construction craft and method get more application. During the construction process, professional technicians' strict control and master of technology key points are needed, constant experience accumulation, further absorption of advanced technology and craft, guarantee construction quality, and ensure the process of a project and its economic profit.

**Keywords:** Construction of buildings, mobility, system, labour force, material and technical resources, stages, organisations, buildings, moved, permanent constructions, intensity.

**Abstract.** The present article examines the principles and aspects of building degree of mobility systems, the parameters defining the mobility. The dependences of determining the degree of mobility for different periods of construction.

Mobility is a key feature of the building system that characterizes the industry's ability to carry out a rapid concentration of manpower and material resources in the area of construction (reconstruction) in order to implement the planned commissioning of facilities and production capacity.

This property is connected to the constant mobility of labor resources, relocation from one object to the construction of machines and mechanisms, delivery structures and materials, the use of mobile buildings. Each object contains erected mobile elements that provide the necessary production and social conditions for workers, and for every construction organization has an extensive range of items such as sets of machines and mechanisms, mobile sets of buildings and structures, etc [1].

In remote and underdeveloped regions, except the above mobile elements, to create a mobile base of construction, industrial and technological base configuration, shift and basic residential settlements, as well as necessary engineering infrastructure for the sustenance of the mobile units.

Thus, the degree of mobility in the construction industry is the straight line, depending on the development of the areas and places of permanent deployment of construction organizations. So for most regions of Siberia, the Far East, rural , mountain and desert and semidesert areas, where the decisive factors are difficult climatic conditions and lack of database construction industry, the mobility of the construction industry is significantly increased through the creation of autonomous functioning industrial, social and engineering spheres.

Should distinguish between two aspects of the building system for mobility: moving the elements of production in the area of construction and their concentration to the desired level [2].

The first aspect characterizes the parameters of a mobile construction organization - range of mobile elements, their number in the kit, duration of delivery, the costs of dismantling, transportation, etc.

These elements are formed separately for a period of pioneering development of the territory, and for the preparatory and main periods of construction replaced or supplemented by new ones (Table 1).

In this part of the resources of a construction company belonging to the category of stationary (permanent buildings and structures, machinery equipment, etc.) are not eligible for relocation to new areas.

Table 1
Distribution of mobile elements by period of construction

| Types of elements | Periods of construction | | |
|---|---|---|---|
| | pioneering | preparation | principal |
| Labor resources | H | H | H |
| Machinery and equipment | H, P | H, P | H |
| Motor transport | H, P | H, P | H |
| Mobile buildings and constructions | P | P | H |
| The power tool | H, P | H, P | H |
| Mounting accessories | H, P | H, P | H |
| Inventory means scaffolding | H, P | H, P | H |

The table H - elements that are not migrating to other periods of construction, P - the elements going over different periods of construction. Consequently, the mobility of the construction company can be determined by the ratio of items moved to the construction site to the total number of elements on the balance of the construction company:

$$\hat{E}_{\tilde{n}} = \frac{\sum_{i=1}^{7} \cdot \sum_{j=1}^{n} \cdot R_{iJ}^{M}}{\sum_{i=1}^{7} \cdot \sum_{j=1}^{n} \cdot R_{ij} + \sum_{k=1}^{m} \cdot R_{k}^{P}}$$

where $R_{iJ}^{M}$ -number of displaced j-th of mobile elements i-th group in the new construction area;

$R_{iJ}$ - number of j-th of mobile elements i-th group in the construction of the organization;

$R_{k}^{P}$ - the number of fixed elements of a construction company.

The second aspect of the concept of mobility building system reflects the values of mobility in the construction of the object (the length of deployment capacity, compliance with these capacities calculated volumes of work, etc.). These parameters characterize the intensity of the construction works. Here we have in mind the intensity of the manufacturing processes of work, creating a building product and intensity of providing for their respective industrial and social conditions - building industry, industrial and technological base configuration, power plants, boilers, cooling towers, etc. In this context, the degree of mobility in the construction of the object is recommended to set the ratio of intensity of work and services, requiring the construction of mobile elements to the intensity of work on the project as a whole:

$$K_{c} = \frac{\sum_{l=1}^{L} J_{l}^{M} + \sum_{p=1}^{P} J_{p}^{EM}}{J_{0}}$$

where $J_{l}^{M}$ - the intensity of the *l*-th construction and assembly work requiring of mobile elements;

$J_{p}^{EM}$ - the intensity of the *p*-services;

$J_o$- construction of intensity.

$$J_0 = \frac{V}{T}$$

where $V$ - volume of construction works;

$T$ - duration of construction.

The above expression determining the degree of mobility in the construction of the object is integral. For certain periods of construction degree of mobility is set by the corresponding parameters of the period:

pioneer period:

$$\hat{E}_{o}^{H} = \frac{\sum_{l=1}^{L_1} J_l^M + \sum_{p=1}^{P_1} J_p^{EM}}{J_H}$$

where $J_н$- the intensity of the pioneer period of construction work;

$L_1$ - number of species of pioneer work period;

$P_1$ - number of types of services in the pioneer period;

preparatory period:

$$K_{o}^{P} = \frac{\sum_{l=L_1+1}^{L_2} J_l^M + \sum_{p=P_1+1}^{P_2} J_p^{EM}}{J_P}$$

where $J_n$ - the intensity of the construction work of the preparatory period;

$L_2$ - the number of species of the preparatory period;

$P_2$ - is the number of types of services during the preparatory period;

basic period:

$$K_{o}^{o} = \frac{\sum_{l=L_2+1}^{L} J_l^M + \sum_{p=P_2+1}^{P} J_p^{EM}}{J_3}$$

where $J_3$ - the intensity of the construction works of the main period;

$L$ - number of basic types of work period;

$P$ - number of types of services during the main period.

Compliance with degree of mobility in the construction of the object and the degree of mobility of the building organization characterizes the organizational and technical level of the building system and its commitment to achieving this goal.

Calculations show that the minimum degree of mobility of a construction company can not be less than 0.2. Such organizations are working on a very limited area, such as in large cities, maneuvering mainly labor and technical resources. The beginning of a zone of high mobility should be considered as the mobility of the order of 0.8.This area is typical for construction companies, usually leading work on a rotational form of labor organization and possessing besides labor and technical resources appropriate mobile manufacturing bases, shift camps and engineering units.

Graphical interpretation of the relationship exponents mobility construction industry is shown in Fig. 1. It should be borne in mind that the relationship between the degree of mobility is given one object and one building organization without loss of productivity in the facility and related costs. In the case of the construction of the object by several organizations in the index of mobility $K_0$ allocated respective shares for each building organization.

Promotion of mobility of the construction industry, which is closely connected with the need to reduce labor costs for construction sites, has several lines. Key areas for reducing labor costs, especially important for the development of new areas not only provide the highest possible degree of prefabrication construction products, but also increase labor intensity, the formation of rational composition of workers and improve working conditions. A special place in mobile construction takes industrialization as the basic foundation of the industry.

The first direction contains mainly technical and technological factors reducing the complexity. The second direction is basically provides maximum utilization of labor resources in time and skill. In addition, this area includes measures to maximize the use of mechanization, quality of work, the elimination of various losses, strengthen labor discipline, etc. The third and fourth directions, being content mainly organizational, solved, usually on pre-production phase and implemented over a long period of time.

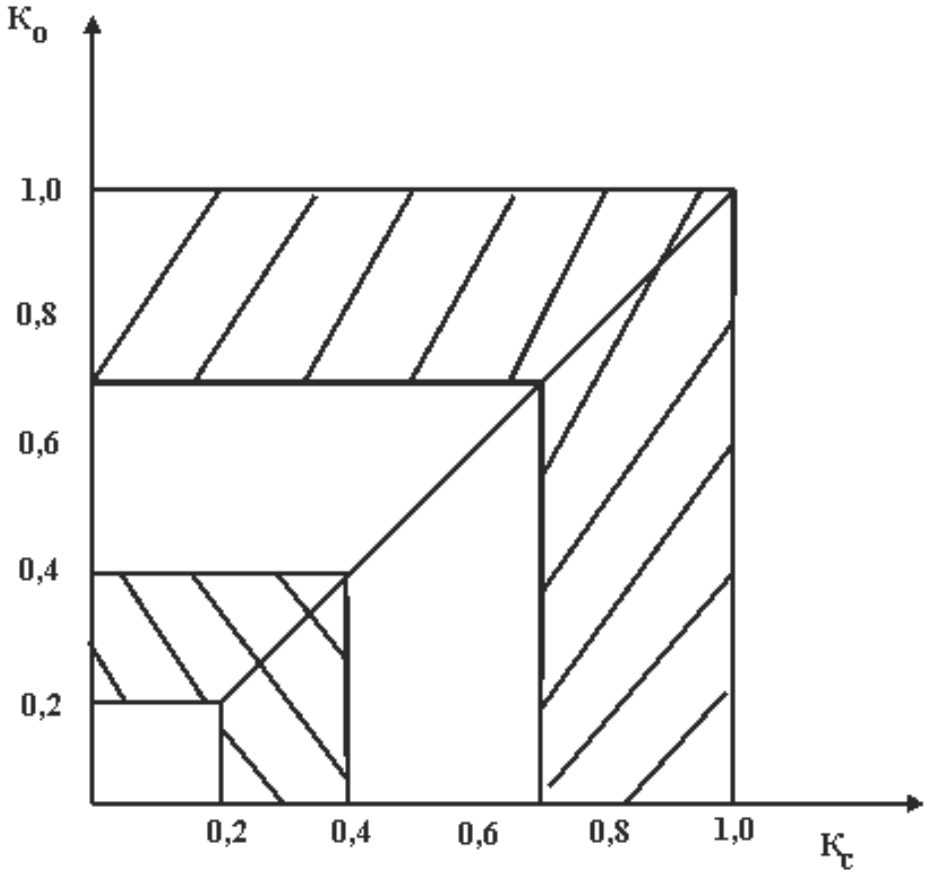

Fig.1.Relationship between mobility exponents Kc and Ko.

Thus one of the basic principles of construction of mobile systems as a result of consideration of the relationship is to achieve the integrity of the mobile building system in relation to the adequacy of the degree of mobility of construction companies and the degree of mobility in the construction of facilities. Besides providing the necessary mobility of building production can be carried out by grouping elements and forming the basis of this work, industrial, commercial, and engineering fields.

**Keywords:** Residential industrialization, Assembly integral shear wall structure, prefabricated components, prefabricated composite wall, grouting sleeve connection technology, exterior walls

**Abstract.**With the implement of policies which are to accelerate the transformation of economic development mode and go to a new road of industrialization, the industrialization of residential construction has entered a new stage of development. This paper lists the structure engineering example which is Beijing holidays landscape D1, D8#floor and discusses the key technologies of engineering examples and application status of precast assembly integral shear wall structure in the residential industrial engineerings, then propose some difficulties and challenges in the process of the housing industrialization .

## Introduction

With the development of national macro economy and science, the construction of residential industrialization of our country has already entered a new stage of development, and has shown good momentum of development. In the residential industrialization process, the core technology is the selection of structure system. it is difficult to realize the residential industrialization, not to study and solve the main structure technology. Any kind of industrialization of residential design and structure of the system are limited by the technical, economic and certain conditions corresponding to a certain level of industrialization. Industrialized housing system should use the most common structure. At present, the main structure system of our country industrialized housing is frame structure, shear wall structure and frame shear wall structure[1]. But the frame structure is not suitable for industrialized residential requirements due to existing standard constraints and highly restricted , so the shear wall structure system is currently used in industrialized residential structure. Harbin town Rock 18 layers of precast concrete shear wall structure and the Beijing holiday scenery D1, D8# floor assembly integral shear wall structure are two important pilot of residential industrialization in our country, as shown in Fig.1 and Fig.2.

Figure.1 Harbin Rock town 18 layer structure of prefabricated concrete shear wall

Figure.2 Beijing holiday scenery D1, D8# floor assembly integral shear wall structure

Some domestic leading enterprises developed some own features of industrialized housing system by constantly exploring and innovating based on the reference and the introduction of foreign advanced technology in the industrialization of residential roads. As the focus of the assembly integral shear wall structure system, the part or all of concrete structure adopt the load-bearing precast wall panels, form reliable transmission mechanisms by connecting joints, and meet the bearing capacity and the deformation ability, the shear wall structure is called as the assembly type shear wall structure[2]. Assembly integral shear wall structure with precast concrete shear wall panel component and cast-in-situ concrete shear wall is vertical and horizontal structure of the lateral force resisting members, form a connected by integral of a reinforced concrete shear wall structure, the structure of the system so that the structure has good overall rigidity and bearing capacity. More and more popularization, structure system widely used in domestic residential industrialization pilot in the current.

Assembly integral shear wall structure can be divided into precast concrete shear wall structure and some precast shear wall structure. Because the more prefabricated components, the requirements of production and construction requirements will be higher. We can not reach the level that all the members are pre production in the current industrialization level and the level of construction technology , so the current industrialization pilot project mainly uses the precast wall, staircase, balcony, wall cast-in-situ or inner wall prefabricated part of cast-in-situ structure system. In recent years, various provinces and cities nationwide have started the industrialization of residential pilot and promotion work, and have built a batch of pilot project. Assembly integral shear wall structure system is introduced from abroad with the domestic situation is improved and has been gradually recognized and applicated in the process of industrialization. Application status of D1, D8# building in Beijing holiday scenery as an example of assembly integral shear wall structure in the housing industrialization in this paper.

## Introduction of the engineering situation

The project is located in Beijing Fengtai District Village No. 108. D1# floor,the building area is 11396.5 square meters. There are 4 units, of which 1 underground floors, the ground layer 15; the height of the building is 44.25 meters; D8# floor, the building area is 21141 square meters. There are 7 units, of which 2 underground floors, the ground layer 15; the height of the building is 44.25 meters.

## The project system assembly integral shear wall structure system

This project is the first industrialized residential pilot project in beijing. The main structure system of this project is the assembly type shear wall structure, where in the inner wall is the wall of cast-in-place reinforced concrete shear wall, exterior walls for assembly. Each unit has 31

components, including: external wall plate 6 blocks, window 6 blocks, fireproof board 1 block, balcony wall 1 block, balcony decoration 1 board, laminated floor 12 blocks, balcony block 2 boards, stairs block 2 boards. Prefabricated rate is about 25%. See Fig.3 ,there are a prefabricated wallboard and prefabricated stair boards in the project. Thermal insulation materials and structural materials (steel reinforced concrete) of the external wall and the bay window on the north and South outside wall are combined into a whole. These components are produced in the factory, and then installed in the field, more than three layers begin assembling construction.

Fig. 3 Prefabricated wallboard and prefab stair boards

**The connection technology of assembly integral shear wall structure**

Along with the advance of the housing industrialization in China and the continuous improvement of assembly integral shear wall structure system, the grouting sleeve connection technique ,as one methed of the concrete prefabricated ,is naturely paid more and more attention. Grouting sleeve connection is a new type of steel structure due to the needs and technology development and engineering practice, the connection mode has been used to make up the deficiency of the traditional steel structure connection (including welding and bolt connecting). Principle of grouting sleeve is that steel connected through the hollow sleeve casting from the two opening into the sleeve, it doesn't need to overlap or welding, steel sleeve and filled with high strength micro expansive structural mortar to complete the connection between the steel bar[3].It strengthens the positive interaction between it and the sleeve mainly by means of mortar by sleeve confining effect, plus itself has the property of micro expansion. The reinforcement can transfer the stress of steel bar bar with the positive force and the friction of surface roughness. This method is much researched and applicated because of its simple operation.New cement grouting sleeve developed by Beijing Jianmao group and China Metallurgical Construction Research Group are used in Beijing holiday scenery D1, D8# building project based on this technology ,it has optimized the reinforcement structure of wall panel, and reduced the difficulty of steel binding.So this technology has become a breakthrough technology in the process of housing industrialization. Fig.4 shows the cement grouting reinforcement sleeves in this project.

Fig. 4 Cement grouting reinforcement sleeves in this project

Cement grouting reinforcement joint used in this project is composed of reinforced one end of the threaded ,sleeve ,the other one with ribbed steel bar and non-shrinkage cement mortar. The diameter is between with 14- 20. Before in use, the first, one end of a steel bar will be made into straight thread, then connect with the sleeve threaded end, and prefabricate in precast concrete components. In construction site, another prefabricated would be inserted adapter sleeve of the member, the gap between the cement mortar and steel sleeve fill up with the cement mortar to harden, The two bars are connected together. This new type of cement grouting reinforced joint grouting has many advantages.For example,it is easier, the structure of filling cavity and threaded hole is more advanced, high machining precision, ensure the joint performance, especially for accurate positioning of steel sleeve in the production of precast reinforced, and the concentricity of the steel bar is more accurate than the joint of two ends with filling in cement mortar.

**Construction technology of wall panels**

With the speeding up of "building industrialization, housing industrialization", the external wall panels have come true integrate production at the factory with Bearing, insulation, decoration, etc at the same time[4,5]. The precast facade of this engineering is the sandwich type, as illustrated in Fig. 5: its inner is structure layer stress, the thickness is 200mm according to the structure stress calculation ;It is the insulation layer in the middle, the material is glass fiber connector with heat resistance to ensure that the insulating layer and the structure have the same life, and to avoid thermal bridge and improve the effect of heat preservation.The outermost layer is protective layer with 50mm thick, but also the decoration layer with the clear water concrete, giving person with plain and natural the appearance of the lasting appeal.

Fig. 5 The prefabricated composite wall in Beijing holiday scenery D1, D8# building

Although the external wall thermal insulation technology has been used in the pilot project of residential industrialization, the problem of external wall thermal insulation life still is a problem need to solve in the process of housing industrialization. Generally,the life of subject structure require fifty years or more, how to realize the prefabricated insulation wallboard and main structure with the same life is still in research and discussion.

**Waterproof technology of wall panels**

In the assembly structure, there are inevitably level or vertical cracks between the precast wall panels with the main structure and the precast wall panels in the assembly process,the waterproof problem of wallboard and these cracks has not been properly resolved.That is the fundamental reason restricting the development of China's housing industrialization in a certain extent. Therefore, the seepage prevention system of the project is more advanced, more reliable. There are four heavy protection system: First, the vertical joint adopts the structure self waterproofing, using

cast-in-place concrete in joints of two block wall, which make All blend into one harmonious whole.; Second, horizontal seam adopts structure waterproof, there are prefabricated groove on the top and bottom panels to prevent water into the room. Third, waterproof materials(modified silicone rubber) are used in the joints of exterior wall. Fourth, it has formated decompression cavity at the seams inside and set the exhaust pipe every three layers to the exclusion of water vapor.

**Fire prevention technology and its advantages of the wall panels**

Precast wall panels have many advantages: Firstly, the production, processing and storage of Insulation materials are all completed in the factory, it can minimize the probability of fire occurrence as long as the management and production is scientific .Secondly, To take some measures in the production process to improve the overall fire performance of precast wall panels. Such as the weatherability sealant, fireproof sealing strip (not burning ) are used to prevent fires in the horizontal joints and vertical joints in this project, it is more effective to set the fire separation zone.Finally, the precast wall panels as a whole to be installed and the whole process does not contact the insulating layer, ensured the safety of construction.

**Conclusions**

The Residential industrialization of our country has entered a new stage of development from a relatively extensive stage,although we have achieved good results in the aspect of connecting technology , there are many problems to be solved in practice. In this project, such as D1# D8# floor, only North and south wall is prefabricated, east-west gable is still cast-in-place because of unresolving the issues of buried pipelines and just avoiding the pipeline integration problems by adjusting the electrical position. Therefore, only part of the room floors are precast, the others including corridor, kitchen, bathroom all are cast-in-place,the advantages of laminated floor are limitted. So the pipeline integration problems will be inevitable in the process of industrialized residential; Because the bay window is overweight, up to 5 tons, the wall can not be precasted ,resulting in prefabricated composite wall are not continuous, so it is impportant to reduce the weight and the depth of bay window.

# Features and Construction of Prefabricated Buildings

Yuhong Zhao [1, a]

[1] Sichuan College of Architectural Technology, Department of Civil Engineering, Deyang, Sichuan, China 618000

[a]540895565@qq.com

**Keywords:** Prefabricated, Features, Production and Transportation, Lifting, Connections

**Abstract.** Prefabricated buildings have the advantages of convenient construction, low cost, energy saving and environmental protection, etc., it is suitable for industrial production of buildings, lifting and connections of prefabricated components are key to construct the prefabricated buildings.

## Introduction

Prefabricated construction refers to the method that transport the main components and accessories manufactured by factories, such as girders , boards, pillars, walls and stairs, balconies and others to the construction site with the use of industrial production, use crane to lift the components and accessories to the designed location, then connect the components and accessories as well as nodes together by using the ways of reserving poles for planting reinforcing bars, pressure grouting, concreting after the production of keyways or post concreting.

1.1 Features of Prefabricated Buildings

1.1.1 Industrial Production and Easy Installation

Prefabricated building is a kind of environmental building with functions of energy-saving, land-saving, water-saving and materials-saving, steel components, building claddings and wallboards have achieved industrial production with quick and easy on-site installation. Components can be constructed in an assembly line with high industrialization. Prefabricated wallboards can satisfy the individual needs of designers and building developers to create styles of Chinese, Continental, American, Japan, Korea and others. Wallboards and finishes can be completed simultaneously and succeed one time, as shown in Figure 1 and Figure 2.

Fig 1. Exterior Wallboards with Windows and Exterior Wall Paint

Fig2. Exterior Wallboards with Exterior Wall Tiles

1.1.2 Reduction in Costs and Convenient Construction

Steel consumption of prefabricated buildings is only 30-40kg/m2, saving 30% -40 % of construction steel. Prefabricated components are on-site assembled after processed in the factory, reducing the turnover materials and tools as well as their leasing expense, the construction speed of part of the buildings has increased by 4-6 times, the economic benefits gained due to the shortening of construction period is considerable.

1.2.3 High Degree of Mechanization and Reduction in Equipments of on-site Construction Staff

Prefabricated buildings use a lot of finished and semi-finished components for installation and construction, the labor intensity is greatly reduced, the number of on-site construction staff has fallen more than 30%, which also leads to a corresponding decrease in the number of on-site construction management staff, thereby reducing labor costs.

1.2.4 Features of Thermal Insulation and Superior Performance

Prefabricated buildings can organize walls with different thicknesses and structures according to climate and temperature in different regions. Its energy-saving effect can achieve the current national energy-saving requirements. Data show that when the prefabrication rate of residence reaches to 37%, it can save water by 36%, electricity by 31%, reducing construction waste by 83%, simultaneously, achieving 60% reduction in material consumption and 50% in energy consumption.

1.2.5 Environmental Protection and Good Economy

Prefabricated buildings are prefabricated and semi-prefabricated, which greatly reduces the on-site wet construction, the great reduction in construction of mould boards and cast-in-site concrete helps to reduce the impact of construction on the surrounding environment, dust and noise pollutions have been effectively controlled. Prefabricated components have flat surfaces, good appearance and accurate size, they can integrate the functions of decoration, heat preservation, thermal insulation, layout of water pipeline and wires, thus to bring sound technical and economic benefits.

1.2.6 High Quality Assurance Rate

The construction of prefabricated buildings can achieve fully automated production and modernized control. The component size is highly precise and is manufactured according to a very rigorous testing standard, which brings a high quality assurance rate and an enhancement in seismic resistance. After the "5.12" Wenchuan earthquake, the factory buildings of Dong Qi in Han Wang, which locates in a strong earthquake area, whose brick walls had already collapsed, but the external prefabricated wallboards are still hanging in the pillars( see in figure 3 ).

Fig 3. Factory Buildings of Dongfang Turbine Co. Ltd. in Hanwang after the Earthquake

## Factory Production and Transportation of Prefabricated Components

2.1 Casting & Compacting and Maintenance of Concrete

Before casting the prefabricated concrete components, the mold, release agent brushing, reinforcement cage quality, control measures of protective layers, reservation for pores, accessories and other items should first be hidden and then checked and accepted, only if they satisfy all of the requirements, concrete casting and compacting are permitted; the height of concrete feeding should be less than 500mm and evenly laid; after the forming of concrete, it requires to use plug-in vibrator for jolt ramming, the jolt ramming should be conducted tightly row by row, vibrator should not contact with reinforcement cage, tiles and embedded parts: concreting should be carried out continuously, and simultaneously observe the mold, door frames, embedded parts to avoid deformation and displacement. Anything unusual requires for timely reinforcement and corrective measures.

When casting and compacting of prefabricated concrete components are completed, they need timely maintenance. Steam curing is adopted to ensure the quality of prefabricated components.

2.2 Stack of Prefabricated Components

Stacking methods are divided into horizontal stack and vertical stack, in principle, wallboard adopts vertical stack, floor boards, roof boards and pillar components adopt both of the two methods, girder components adopt horizontal stack. Ground laying should be compacted or concreted, pads are necessary when the grounds are stacked one on top of the other.

2.3 Transportation of Prefabricated Components

In order to prevent the occurrence of cracks, damages and deformations etc. in components, the appropriate transport vehicles and transport bench should be selected, be careful when loading and unloading, the cushioning materials need to be placed between the transport bench and carriages. During the transportation, it requires to use steel wires or fixture to sufficiently fix the components, make sure safe driving and prevent the phenomenon of over speed driving or sudden braking.

## On- site Construction of Prefabricated Components

3.1 Lifting of Prefabricated Components

The lifting of prefabricated components is a very important aspect of the construction of prefabricated buildings, it is mainly divided into dry system and wet system, the difference between the two system is that the lifting time and connect ways of prefabricated exterior wallboards are different.

Wet System: The lifting of wallboards is conducted before the floor grouting. The lifting process of wet system is: lofting → lifting of the prefabricated pillars → lifting of the big prefabricated girders → lifting of the small prefabricated girders → floor lifting → exterior wall lifting → balcony board lifting → stairs lifting → cast-in-site structural engineering and electromechanical piping → floor grouting.

The installation of a wet wall system is: reserve the anchoring bars on the upper wall, then insert them into the folded cast-in-site layer. When casting the floor, the upper wallboards and structure are cast together with cast-in-site concrete technique, the lower wallboards are connected with iron parts, there is a certain space to slide, which makes it easy to shake following the earthquakes (including wind).

Dry System: Wallboard lifting is carried out when the whole structure is completed. There is no need to reserve anchoring bars in the folded layer of wallboard; the top part and bottom part of wallboard are connected by 4 iron parts for bearing and adjustment. Its lifting process is: lofting → lifting of prefabricated pillars → lifting of the big prefabricated girders → lifting of the small prefabricated girders → floor lifting →balcony board lifting → stairs lifting → cast-in-site structural engineering and electromechanical piping → floor grouting → complete the structure → exterior wall lifting.

3.2 Connection of Prefabricated Components

Connection of prefabricated components is another important aspect of the construction of prefabricated buildings. The joint's quality directly determines the integrity and seismic resistance of prefabricated buildings.

3.2.1 Welding Connection

Connection of steel plates, connection of steel plate and reinforcing bars as well as connection of reinforcing bars are completed by welding. Welding should reasonably select welding method, conditions, order and preheating and other measures, try to minimize welding stress and welding distortion.

3.2.1 Mechanical Connection

The prefabricated pillars are connected by sleeve connector, cast with high-strength non-shrink cement mortar. Reinforcing bars connected by mortar from sleeve connector, whose yield strength

should not exceed 500 MPa and tensile strength should not exceed 630 Mpa. Strength of high-strength non-shrink cement mortar should reach more than 80 MPa (Figure 4).

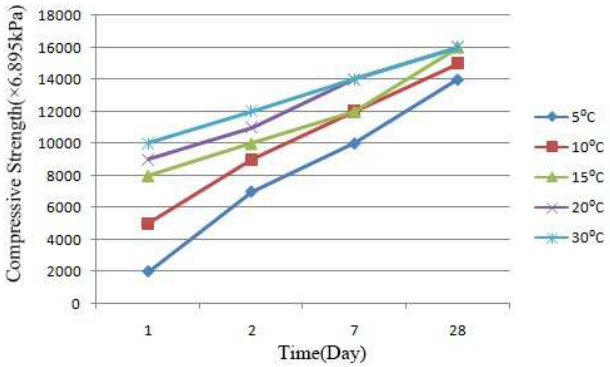

Fig 4. Statistics of Changes in Compressive Strength of Non-shrink Cement Mortar

3.2.2 Connection of Cast-in-site Concrete

Relatively narrow joints such as joint of prefabricated girder and prefabricated pillar, vertical joints of shear walls are connected by the using of cast-in-site concrete technique. In order to prevent the cement grouting from surface of prefabricated component and connection surface of mould board, the mould board should be tight and secure.

3.2.3 Connection of Mortar

Seams, component joints of wallboard or floor board, fillings or facings of metal accessories for connection as well as parts needed to guarantee the durability and fire resistance are mainly connected by mortar. First, clean the surface of the components, and then wet it with water. When constructing with mortar, it is necessary to ensure the laying width of mortar is the same with that of components, and mud trowel is needed for shaping mortar, make sure the laying height of mortar is 1.5 times of that of construction seam ( adjust the height of the material in horizontal direction).

**Summary**

Prefabricated building is applied in several projects in Nanjing, it is obviously fast, simple, energy-saving and good, which makes it the development direction of China's industrialization of construction, in accordance with the green building concept; it is particularly applicable to residential buildings with wide range and large amount.

# Connecting Passage Construction for the Foundation Pit under Existing Optical Fiber Cable

Hanqing Cao[1, a], Nan Lou[1,a] and Weijiu Cui [1,2,b]

[1] Shanghai Construction CO.,LTD, Shanghai, China

[2] School of Civil Engineering, Tongji University, Shanghai , China

[a]hanki0901@163.com, [b]897835249 @qq.com

**Keywords:** Connecting passage, optical fiber cable, construction technology, finite element modeling.

**Abstract.** Puli center project protects the original soil with pipe roof technology through combining the field analysis and finite element modeling while constructing the connecting passage of foundation pit under the existing optical fiber cable, so as to avoid the optical fiber cable from producing too big settlement to cause the adverse effect, and then constructs the connecting passage of foundation pit. After field monitoring, the maximum settlement of pipeline conforms to the deformation control standard of optical fiber cable, and this technology has certain innovation, which can provide reference for the similar project.

## Introduction

With the urbanization process and increasing tension of construction land, our underground urban complex, air defense project and metro are emerged constantly; and the development and utilization of underground urban space have been entered into rapid development period [1]. The construction of connecting passage seems especially important to build the underground communication network, so that the various underground spaces form convenient traffic.

Ranging from underground tunnel to pipeline channel, the connecting passage has wide application range. The early construction technology of connecting passage is mostly derived from the municipal engineering, and the underground municipal pipeline excavates the pipe trench with open cut technology, and then paves the pipeline. But the open cut will have impact on the above-ground building use and road traffic, therefore, in recent years, the dark cutting technology is used widely, such as pipe-jacking operation technology, etc. [2,3].

In this article, the common channel in the underground connecting passage and municipal engineering is different, and this channel is used for passing the optical fiber cable of communication being used at the top, the deformation control standard [5] of optical fiber cable is high, and the conventional construction technology is difficult to guarantee the requirement of deformation control, therefore, it should perform the careful demonstration and study. One the one hand, the subject study can solve the design and construction difficulties of connecting passage, and on the other hand, can enrich the building technology of connecting passage, so as to provide the reference for the similar project.

## Project Profile

**Overview of connecting passage.** This channel is the channel between the subcellar for eastern skirt building and subcellar of western main building of Jinan Greenland Center, the two north-south optical fiber cables is passed on the channel, the ground elevation is 32.35m-32.58m, the elevation of optical fiber cable is 31.47m-31.52m, and the buried depth of optical fiber cable is 0.83m-1.09m. The section of channel is rectangular and its width is 9.0m; and the roof elevation is -5.80m, and the elevation of bottom plate is -11.0m. The main building and skirt building of this project are excavated respectively, the eastern foundation pit is supported with bond angle of cast-in place pile, the high

grouting pile is applied among the pile and is lapped with the supporting pile to form curtain for cutting of water; and the western foundation pit is supported with the underground diaphragm wall and concurrently used as curtain for cutting of water.

**Geological conditions.** Within the range of exploration depth, the site stratum consists of quaternary artificial layer filling, quaternary Holocene to upper Pleistocene diluvium, quaternary eluvium and cretaceous diorite weathering zone. The main soil layer is: miscellaneous fill, silt, silty clay, clay, residual soil, rubble and weathering diorite.

During exploration, the depth of groundwater of site measured is 3.45-5.04m, and the elevation is 27.20-28.57m. The western river to the groundwater level of site (which is mainly quaternary upper pore water has small influence to rangeability. But in case of flooding the rainy season, the river water can surge over the river, so it has certain influence to construct the west of site, and especially foundation pit of main building. The groundwater exposed by site is quaternary upper pore and bedrock weathering fissure water, which have slight bearing pressure.

## Deformation Analysis and Control Measure of Optical Fiber Cable

**Distribution of optical fiber cable.** This project mainly protects the cable, and the strike of two cables is shown the Figure 1. The protection cable area is also equipped with inspection well, wherein the bottom elevation of inspection well is +29.75m to +30.36m. Before the formal construction, the detecting instrument will be used for further confirmation, to guarantee the safety.

**Deformation analysis of optical fiber cable.** The optical fiber cable is paved in ---times of the last century, and its outer side is protected with precast concrete block and the joint is not subjected to any treatment, so in case of not producing the differential settlement, it will produce big shear force, cause the break of optical fiber cable easily, and bring the huge loss. In the construction process of foundation pit project, the main reason causing the deformation of optical fiber cable is as follows:

- Land subsidence caused by soil loss produced in the construction process of pipe-jacking and retaining pile.
- Land uplift caused by the large-scale jet grouting pile construction and untimely stress release.
- Land subsidence caused by reducing the groundwater substantially for a long time.
- Retaining body deformation and land subsidence around caused by unbalanced force produced while the excavation of foundation pit, big deformation produced by soil and water and soil loss outside the pit.

**Deformation control measure of optical fiber cable.** After the expert argumentation, the settlement deformation of optical fiber cable is set at 20mm temporarily according to the spefication. The following measures are taken to reduce the pipeline deformation:

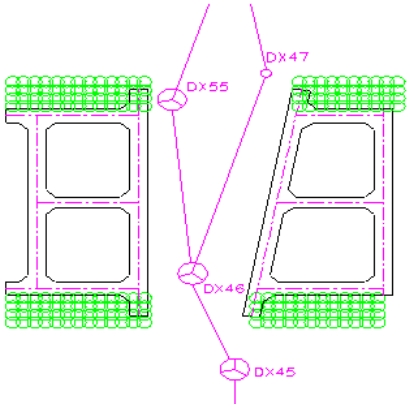

Fig. 1 Distribution figure of optical fiber cable

- Verify the strike of pipeline before construction.
- Take the reasonable construction measure, and finally determine the pipe-jacking construction.
- Perform the information construction according to the monitoring data.

## Finite Element Modeling

**Analysis method.** The software Plaxis of professional large geotechnical engineering finite element analysis is use for performing the simulation analysis to the pipe-jacking construction according to the finite element method of plane strain continuous medium. This project uses the Hardening-Soil model to simulate the constitutive relation of soil, and this model is an improved model of simulating the rock-soil behavior. HS model has 11 parameters totally, part of which is parameter of model itself, part of which can be obtained from the geotechnical engineering exploration report, and another part of which is obtained by inverse analysis through the monitoring data of many similar projects.

**Calculation and analysis.** This project takes the north-south profile for analysis, and the pipeline is pipeline DX45-DX5 nearest to the steel pipe and is considered according to the flexible pipeline. The steel pipe is dragged back after the steel pipe is hole-formed, the influence for drilling diameter of pipeline is relatively small during the construction, and the hole position far away from the pipeline has little influence to it, so this considers the influence of five steel pipes hole-forming respectively to central pipeline while calculation.

Model calculation area: Take 30m in the vertical range and 50m in the horizontal range.

Structure parameter: The elasticity modulus of steel is 2.1×104MPa, the Poisson's ratio is 0.31, and the severity is 25kN/m3. The specific parameter is shown in the Table 1.

Totally, divide into 6 working conditions through the “Element Birth and Death” technology simulation, wherein the specific working condition is as follows:

- Working condition I: Generate initial ground stress field.
- Working condition II: Construct the first hole, including the slurry retaining wall.
- Working condition III: Drag the steel pipe back after the first hole is constructed completely; and lead hole for the second hole, and perform the slurry retaining wall.
- Working condition IV: Drag the steel pipe back after the second hole is constructed completely; and lead hole for the third hole, and perform the slurry retaining wall.
- Working condition V: Drag the steel pipe back after the third hole is constructed completely; and lead hole for the fourth hole, and perform the slurry retaining wall.
- Working condition VI: Drag the steel pipe back after the fifth hole is constructed completely.

The maximum vertical displacement after forming hole through simulation is 9.84mm, the maximum horizontal displacement is 2mm, and the maximum vertical deformation is steel pipe is 5mm, shown in the Figure 2, Figure 3 and Figure 4.

The maximum shaft force of steel pipe is 29KN/m, its maximum shear force is 10.6KN/m, and its maximum bending moment is 1KNm/m, shown in the Figure 5.

After simulation, it can reach the corresponding requirement through protecting optical fiber cable with pipe-jacking operation.

Table 1 Table for analytical element type and constitutive model

| Object | Element Type | Number of nodes | Constitutive Model |
|---|---|---|---|
| Soil | Triangle | 15 | HS model |
| Pipeline | Beam element | 3 | Linear elasticity |
| Steel pipe | Beam element | 3 | Linear elasticity |
| Contact surface of pile and soil | Contact surface element | 15 | Coulomb criterion |

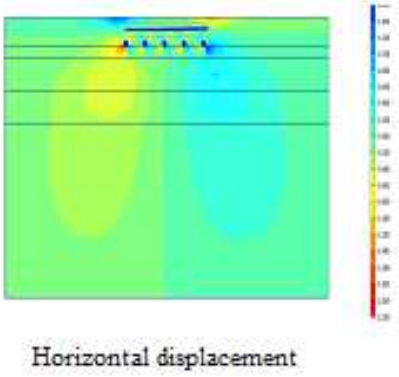

Fig.2 Overall horizontal displacement fringe after hole-forming

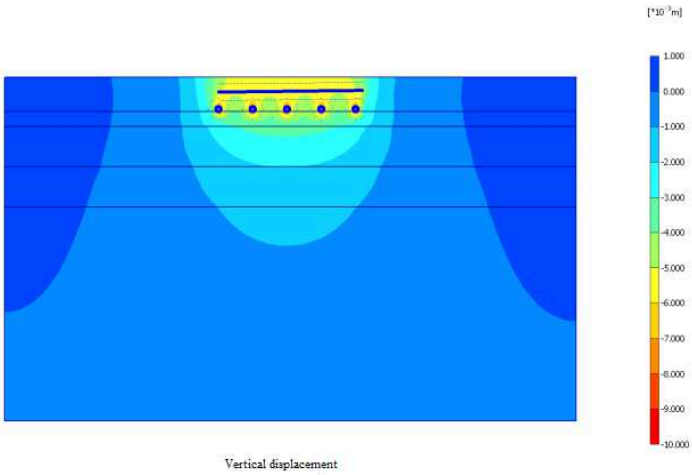

Fig.3 Overall vertical displacement fringe after hole-forming

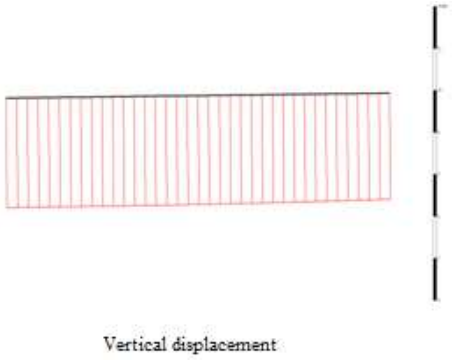

Fig.4 Overall vertical displacement fringe of pipeline after hole-forming

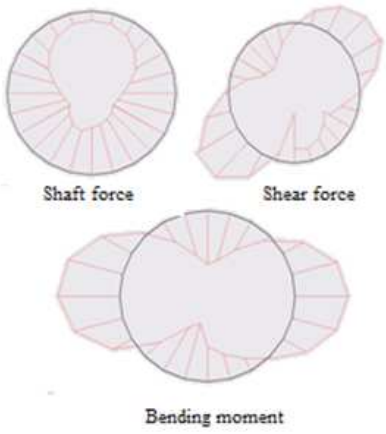

Fig.5 Internal force diagram of steel pipe

## Key Technology of Connecting Passage Construction

**Construction technology process of connecting passage.** The construction technology process of connecting passage is shown in Fig.6.

**Innovation measure in construction .**The pipe-jacking operation uses Φ426 steel pipe, of which the length is measured according to the drawing; and the relation of pipe roof and pipeline is shown in the Figure 7.

The engineering technicians put heads together and take many innovation measures of project technology, to overcome the difficulties in the construction process of connecting passage.

- Take the measure of hitting one every three to reduce the disturbance of drilling to soil and influence of adjacent hole passage, namely, the construction sequence of hole-forming is “1, 4, 7”, and “2, 5, 8”; and cycle the operation until the hole-forming is complete.
- Perform many hole-forming to the drill with different diameters, and change the jacking into pulling back. Since the construction of underground structure at two sides of channel is completed and the remaining space cannot meet the requirement of jacking of steel pipe once, this project constructs with the form of dragging back the steel pipe after leading hole. In order to reduce the disturbance of construction to soil, the drill of which the diameter is 100mm is used for drilling in the hole-forming operation process, drill of which the diameter is 200mm

is used for drilling, drill of which the diameter is 300mm is used for drilling, and then drill of which the diameter is 400mm is used for drilling, so as to complete the construction.

- Adjust the angle of drill rod, and guarantee hole-forming quality. If the length of drill rod is too long, its deflection will have impact on the hole-forming quality. Adjust the angle of drill rod, and finally determine the drilling angle of drill rod through testing continuously, to guarantee the hole-forming at two sides is on the same line.
- Arrange the slurry pouring jacket. Due to forming hole horizontally while forming hole, the slurry is easy for losing. Considering that part of slurry at the pipe roof hole-leading stage and back enlarge stage is lost, which may cause the formation of hole wall, the slurry pouring jacket is arranged, to guarantee that the slurry level in the hole is always located above the hole location, and the hole wall is stable.

Main structure of pouring jacket: arrange 1000×600 steel cover box, of which the wall thickness of pouring jacket is 10mm; arrange U-shaped groove at the drill rod position, of which the groove width is 100mm; and arrange rubber seal plate of which the thickness is 10mm and rubber pressing plate outside the pouring jacket. The pouring jacket is shown in the Figure 8.

The pouring jacket plays big role of guaranteeing the slurry level and guaranteeing the efficiency and quality of forming groove.

**Construction effect.** The monitoring items are arranged according to the specification [4], to guarantee the safety in the construction process. The final monitoring result shows that: the maximum vertical displacement of soil is 12mm, which is close to simulated data, stating that the construction technology effect is relatively good, and can guarantee the project safety.

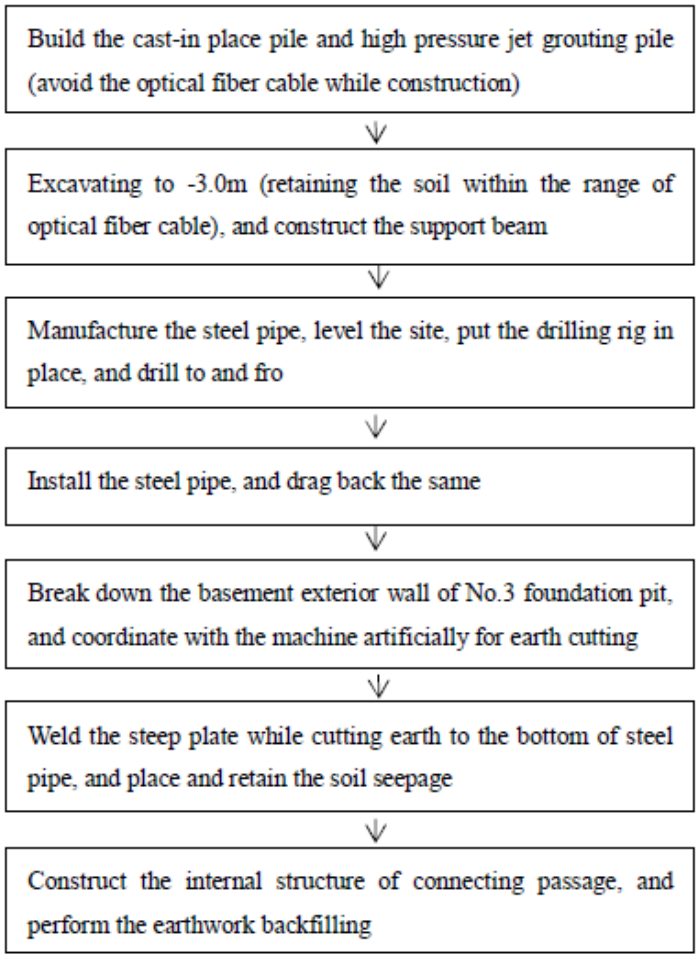

Fig. 6 Construction technology process diagram

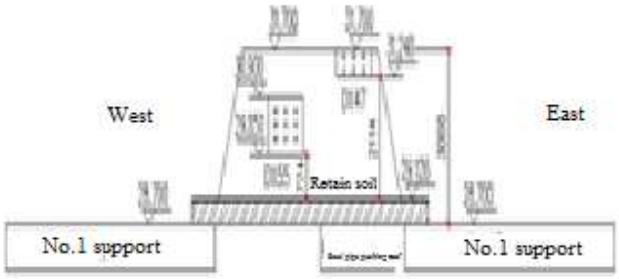

Fig.7 Relational graph of northern pipeline and steel pipe of foundation pit

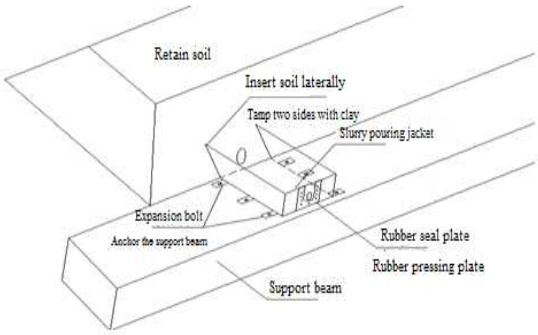

Fig.8 Aerial view of pouring jacket

## Conclusion

In this construction technology, the final land settlement monitoring is 12mm, which plays the role of protecting the optical fiber cable, and has innovation, being worthy of popularization and application.

The angle of drill rod can guarantee the hole-forming level while drilling in from one side and out from the other side, to avoid the error influence of hole-forming due to deflection of drill rod.

The pouring jacket has positive effect for guaranteeing the slurry level, to guarantee the hole-forming quality and efficiency, and be convenient for manufacture and installment, and therefore, it can be used as the auxiliary equipment of slurry level of horizontal hole-forming.

**Keywords:** vibratory pile driving; soil sample; efficiency of vibratory pile driving; experimental research

**Abstract.** Vibratory pile driving is a common application method of piles foundation construction. A test bed was designed and built according to the principle of vibratory pile driving. The test bed is composed of excitation system, machinery parts and signal acquisition system. At first soil samples with different relative compactness and different saturation were made. Then tests of vibratory pile driving have been done by using the soil samples and the test bed. For each soil sample, time of pile sinking to the bottom of the container was recorded respectively under the condition of the exciting force with same amplitude. The time represents efficiency of vibratory pile driving. The former is shorter and the latter is higher. Relationships between efficiency of vibratory pile driving and exciting frequency, relative compactness of soil, saturation of soil were researched respectively by single factor method. The experimental results have guide meaning to vibratory pile driving construction.

## Introduction

Pile foundation is the part of a structure used to carry and transfer load of the structure to soil or rock with strong hardness and small compressibility, which located at some depth below ground. Pile foundations possess of many properties, including its high bearing capacity, good stability, small and uniform settlement, low sedimentation rate and fast convergence speed [1]. In addition, pile foundation is constructed easily by machinery. Its construction method also has a variety of ways: hammer piling, static pressure pile driving, and vibratory pile driving, etc [2]. Hammer piling is to press the pile into the soil with the force provided by pile head under the impact of the pile hammer. The disadvantage of this method is that a lot of noise will be produced at the moment when pile hammer impacts pile and pile tip is easy to damage. Static pressure pile driving is to press the pile into the soil by strong static pressure. In this construction method a little noise is produced and the pile head is protected from damage. At the same time, being equipped with more weight, heavy work will be finished in assembling and transportation when static pressure pile driver transfers workplace. Therefore it is not only a long construction period and high costs but also high bearing capacity requirement of the construction site [3]. In process of vibratory pile driving, the pile generates a longitudinal vibration of a certain frequency under the action of periodic excitation force generated by vibration pile hammer. Meanwhile the soil around the pile moves in a forced vibration state. Then the side friction resistance of the pile from the soil will be greatly reduced. Under the action of gravity of pile and hammer pile, and exciting force of pile hammer, the pile sinks into the soil after overcoming the soil resistance [4]. This kind of construction method has a lot of outstanding advantages such as strong penetration force, high efficiency of pile driving, good quality, less damage to pile head in the process of pile driving, low noise, simple operation etc [5,6].

**Design of a test bed for vibratory pile driving**

A test bed for vibratory pile driving is composed of excitation system, machinery part and signal acquisition system. Its composition diagram is shown in figure 1. The test bed built for vibratory pile driving as shown in figure 2.

Excitation system provides an excitation force for the pile, which frequency and magnitude can be adjust. It consists of a signal generator, a power amplifier and an electric vibrator. In experiment of pile driving, the signal generator generates a sine signal and the power amplifier magnifies power of the sine signal. Then the amplified sine signal is input to the electric vibrator. Finally, the vibrator outputs excitation force varied by sine curve which can realize the function of vibratory pile hammer.

Vibration pile hammer and pile move in vertical direction. The pile sinks straight down into the soil. Machinery part is used to implement the relative motion of the pile and soil, namely, pile driving movement. The signal acquisition system is used to collect the magnitude of the vibration force from the vibrator.

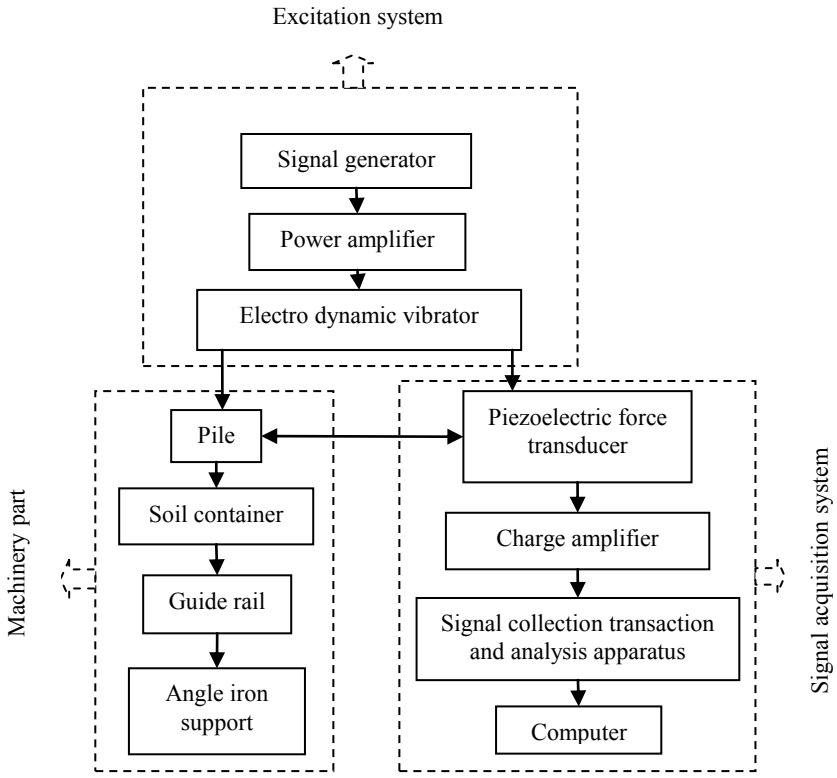

Fig.1 Sketch map of a test bed for vibratory pile driving

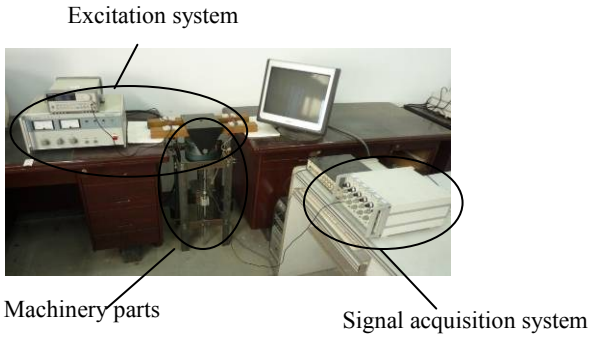

Fig.2 A set up for vibratory pile driving

### Making of soil sample

In following experiment, sandy soil is used to make sample of soil. The minimum dry density $\rho_{dmin}$ and maximum dry density $\rho_{dmax}$ of the sandy soil are 1.27 g/cm$^3$ and 1.66 g/cm$^3$ respectively, which are obtained via measurement of relative density of sandy soil [7]. In process of making sample of soil, at first ratio of water and the dry sandy soil were determined via match calculation. Then we put right amount of water and the sandy soil in a container and mixed them up until smooth. Finally soil sample was compressed to the designed volume by an electric stripper.

In order to study the impacts of different relative compactness of soil on the process of vibration pile driving, two kinds of relative compactness ($D_r$) of the soil sample were prepared for the follow experiment. Their relative compactness ($D_r$) of the soil sample were 40% and 60% respectively.

In order to study the impacts of different saturation of soil on the process of vibration pile driving, two kinds of saturation ($S_r$) of the soil sample were prepared for the follow experiment. Their relative saturation ($S_r$) of the soil sample were 20% and 40% respectively.

### Test contents of the process of vibratory pile driving

More detailed research on the process of vibratory pile driving was conducted for different physical properties of soil samples in the test bed shown in figure 2. Excitation frequency can be divided into three bands: low-frequency stage (15Hz, 20Hz), middle-frequency stage (40Hz, 50Hz) and high-frequency stage (60Hz, 80Hz). Test contents are as follows:

- Research the relationship between soil saturation and efficiency of vibratory pile driving under the same condition of excitation force, excitation frequency and the relative compactness.
- Research the relationship between relative compactness and efficiency of vibratory pile driving under the same condition of excitation force, excitation frequency and soil saturation.
- Research the relationship between excitation frequency and efficiency of vibratory pile driving about different physical properties of soil.

### Results and analysis of the test

In the test, in order to ensure that the amplitude of excitation force output from vibrator is same in each test, settings of the signal generator and power amplifier are as follows. Rapidly increase the amplitude of sine voltage signal from 0.000Vpp to 3.000Vpp by adjusting knob of signal generator. Put power amplifier in "high impedance" working mode and adjust the scale line of potentiometer knob always located in the intermediate position of the scale line of the “gain”. For a soil sample, time of pile sinking to the bottom of the container is recorded in given excitation frequency. It represents efficiency of vibratory pile driving. The former is shorter and the latter is higher.

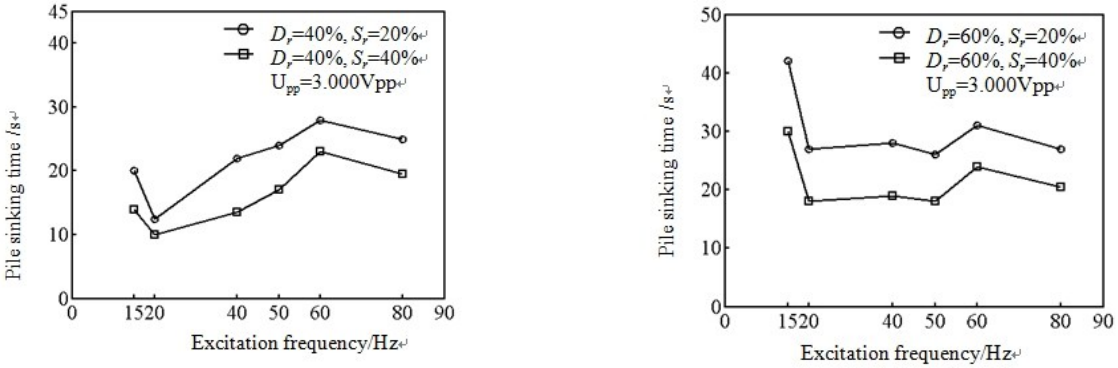
**Relationship between soil saturation and efficiency of vibratory pile driving.** Two groups of soil sample are prepared and each one has two kinds of soil samples which have same relative compactness and different saturation.

For one group of soil sample, their relative compactness ($D_r$) is 40%, and saturation ($S_r$) is 20% and 40% respectively. The time of pile sinking to the bottom of the container is recorded in different excitation frequency and same amplitude of excitation force and the result is shown in figure 3a. It shows that at the same excitation frequency the pile need more time to sink to the bottom of the container when saturation ($S_r$) is 20% than it does when saturation ($S_r$) is 40%.

For another group of soil sample, their relative compactness ($D_r$) is 60%, and saturation ($S_r$) is 20% and 40% respectively. Settings of signal generator and power amplifier remain unchanged and record the time of pile sinking to the bottom of the container, the result is shown in figure 3b. It shows that at the same excitation frequency the pile need more time to sink to the bottom of the container when saturation ($S_r$) is 20% than it does when saturation ($S_r$) is 40%.

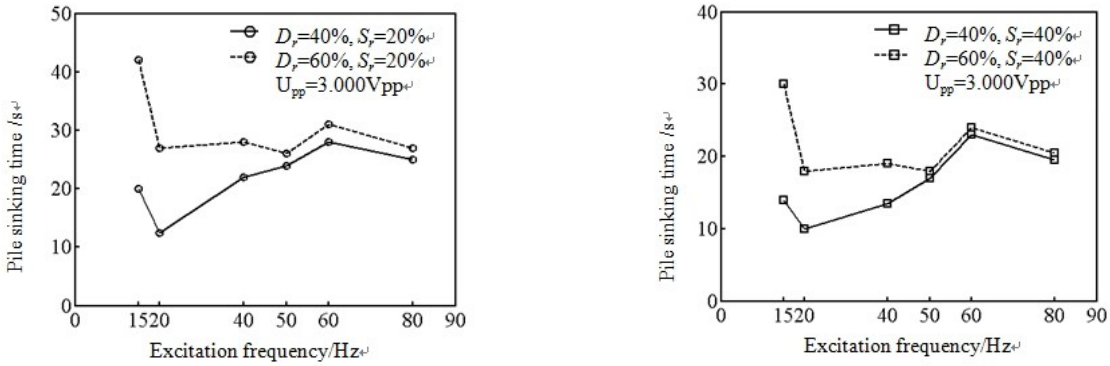
As a result, under the condition of exciting force and exciting frequency, the higher the degree of soil saturation, the higher efficiency of vibratory pile driving for soil sample with same relative

compactness. Therefore, vibratory pile driving method is suitable for construction of the soil with high saturation.



a) $Dr$ = 40% b) $Dr$ = 60%

Fig.3 Relationship between saturation of soil and pile sinking time



a) Sr = 20% b) Sr = 40%

Fig.4 Relationship between relative compactness of soil and pile sinking time

**Relationship between relative compactness of soil and efficiency of vibratory pile driving.** In the same manner test result of relationship between relative compactness and efficiency of vibratory pile driving is shown in figure 4a and figure 4b. It indicates that the pile need more time to sink to the bottom of the container when compactness ($D_r$) is 20% than it does when compactness ($D_r$) is 40% at the same amplitude and frequency of excitation force for two group of soil sample which saturation is 20% and 40% respectively. As a results, under the condition of same exciting force and exciting frequency, the lower degree of soil compactness, the higher efficiency of vibratory pile driving for soil sample with same saturation. Therefore, vibratory pile driving method is suitable for construction of the soil with low degree of compactness.

**Relationship between excitation frequency and efficiency of vibratory pile driving.** Make soil samples with required saturation and relative compactness and then conduct the test of vibratory pile driving at the exciting force with same amplitude and different frequency. Time of pile sinking to the bottom of the container is shown in table 1. It shows that when exciting frequency in low frequency band the efficiency of the vibratory pile driving is the highest for soil sample with low relatively compactness. While exciting frequency is in middle frequency band the efficiency of the vibratory pile driving is the highest for soil sample with high relatively compactness.

By comparing figure 3a and 3b, we find that the distance between two lines is large in middle and high band. It indicates that time of vibratory pile driving changes bigger when the saturation of soil sample changes in this frequency band. While comparing figure 4a and 4b, we find that the distance between two lines is little in middle and high frequency band. It means that time of vibratory pile driving changes smaller when the relatively compactness of soil sample changes in this frequency band. Thus it can be seen that the relative compactness of soil has less effect on the efficiency of vibratory pile driving and the change of saturation of soil has more impact on the efficiency of

vibratory pile driving when the vibration frequency of the vibratory pile driving in middle and high frequency band.

Table 1 Corresponding exciting frequency of the highest efficiency of vibratory pile driving

| Physical properties of soil sample | Amplitude of sine vibration signal($V_{PP}$) | Excitation frequency (Hz) | Shortest time of pile driving（s） |
|---|---|---|---|
| $D_r = 40\%$，$S_r = 20\%$ | 3.0 | 20 | 12.5 |
| $D_r = 40\%$，$S_r = 40\%$ | 3.0 | 20 | 10 |
| $D_r = 60\%$，$S_r = 20\%$ | 3.0 | 50 | 26 |
| $D_r = 60\%$，$S_r = 40\%$ | 3.0 | 50 | 18 |

## Conclusions

Experimental research on the process of vibratory pile driving has done on the test bed made by own. Some conclusions are as follows:

- Under the condition of the same vibration force, vibration frequency and relative compactness of soil, the higher the degree of saturation of soil, the higher the efficiency of vibratory pile driving. Under the condition of the same vibration force, vibration frequency and the saturation of the soil, the lower the relative compactness of soil, the higher the efficiency of vibratory pile driving. Therefore, vibratory pile driving method is suitable for the construction of soil with high saturation, low relative compactness.
- When the vibration frequency of the vibratory pile driving in middle and high frequency band, the relative compactness has less effect on the efficiency of vibratory pile driving, but saturation has more impact on the efficiency of vibratory pile driving.
- For soil with lower relatively compactness, efficiency of vibratory pile driving is highest when exciting frequency of the vibratory pile driving in low frequency band. For soil with higher relatively compactness, it is highest when exciting frequency of the vibratory pile driving in middle frequency band.

# The study about anti-seismic structures stirrup construction blanking length theory calculation

Huiling Li[1,a*],Xuxiang Cui[1,b],Yuhan Zhao[1,c]

[1.]Management Institute, Shenyang Jianzhu university, Shenyang, China

[a]Lihuiling092@163.com, [b]cuixroll0418@live.cn, [c]376299780@qq.com

**Keywords**: stirrup; construction; blanking length; new norm;empirical calculation method

**Abstract:** According to the new norm's requirements and regulations for stirrup and related construction , deducing the theoretical calculation formula of stirrup blanking length of anti-seismic component in different levels. And analyzing it and the three empirical calculation methods comparatively, to find out the application conditions and scope of the empirical calculation method.

## Introduction

With the rapid development of China's high-rise buildings, the demand for steel is growing incessantly, and occupying a large proportion in engineering materials.Currently, there is no uniform standards and calculation rules between beams stirrup length calculation methods and blanking budgets length calculation methods when calculating the steel engineering quantities.The empirical calculation methods are often used[1]. But some methods will bring lots of construction issues on stirrup blanking length and thickness of concrete cover, which affected the safety and anti-seismic performance of components and structure.The problem about finding a method which is both accurate and fast will be discussed in this paper,combined with the new《Design of Concrete Structures(GB 50010-2010)》and《Earthquake Resistant Design Code(GB 50011-2010)》(hereinafter referred to as the new norms) in theory.

## Theoretical calculation of stirrup blanking length[2]

Stirrup blanking length should be calculated with the size of the center line of the bending stirrup. The thickness of concrete cover is defined according to the new norm.As shown in Fig.1.

Stirrup blanking length=Outsourcing size- Measure the difference+ The added value of hook

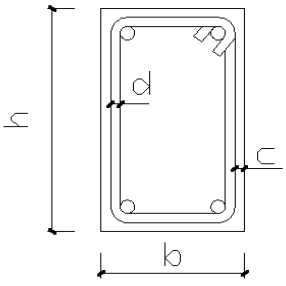

Fig.1 Stirrup theoretical calculation of blanking length

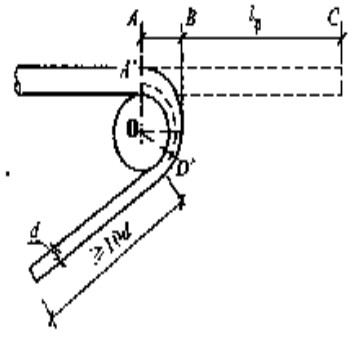

Fig.2 Stirrup bend 135 $^{o}$ hook growth calculation diagram

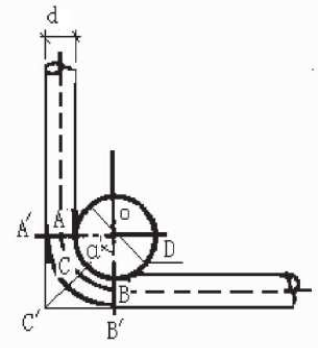

Fig.3 A measure of the central stirrup bending 90° difference calculation diagram

**The stirrup outsourcing Size.**Outsourcing size is the outer contour size indicated in construction drawing, and it also refers to the size of steel skin fold line. According to Fig.1, the stirrup outsourcing size can be calculated as follows:

$$\text{Outsourcing size} = 2*(b+h)-8c \quad (1)$$

**The added value of stirrup end of 135° bend hook.**The calculation diagram Fig.2 shows:

The added value of 135 ° hook = $A'D'$-AB+$l_p$=$135^0$ /$360^0$* $\pi$ *(D+d)-(D/2+d) +$l_p$

$$=0.678D + 0.178d+l_p \quad (2)$$

D in the equation refers to diameter of the curve center, the value shown in Table 3;d refers to diameter of stirrup;$l_p$ refers to the straight length of stirrup hook;In the anti-seismic design, the value of the straight length is max(10d, 75).

Substituting D =2.5d(level I) and D =5d(level II) into the equation above, the added values of stirrup end of 135° bend hook of this two levels are 1.87d +$l_p$ and 3.75d +$l_p$.

**Measure the difference of 90° stirrup bend hook.** The result of different intensity level of steel is listed in Table 1.

Measure the Difference of 90° =$A'C'$+$B'C'$ -arc ABC= 2（D/2+d）- $\pi$ （D+d）$90^0$/$360^0$ (3)

Table 1 Stirrup $90^0$ measurement difference table

| Intensity levels of stirrup | Angle of Bend | Curved inside diameter D | Measure the difference |
|---|---|---|---|
| HPB235 | $90^O$ | D=2.5d | 1.75d |
| HRB335 | $90^O$ | D=5d | 2.29d |

**Theoretical calculations of stirrup blanking length of anti-seismic structure**

Theoretical calculated value of stirrup blanking length L= outsourcing size -3*measure the difference of 90° +2*the added value of 135° stirrup hook (4)

Substituting the results of equation(1), (2), (3) into equation(4), and the new calculation results are shown in Table 2.

Table 2 Stirrup theoretical calculation of blanking length value table

| Stirrup types | Curved inside diameter D | Stirrup diameter | L |
|---|---|---|---|
| HPB235 | D=2.5d | ≥8 | 2*(b+h)-8c+18.5d |
| | | 6 | 2*(b+h)-8c+1.87d*2+150-1.75d*3 |
| HRB335 and above | D=5d | ≥8 | 2*(b+h)-8c+20.6d |
| | | 6 | 2*(b+h)-8c+3.57d*2-2.29d*3+150 |

2*(b+h) -8c means the outsourcing perimeter. When the diameter of stirrup is larger than 8, the theoretical calculation of stirrup blanking length equation can be simplified as follow:

Outsourcing perimeter +21d (5)

According to the new norm,concrete protective layer thickness value fo beams, pillar stirrup is 20mm. After calculating the blanking length of different diameter of anti-seismic stirrup, the results are listed in the Table 3.

Table 3 Stirrup anti-seismic structure simplified calculation of blanking length table (mm)

| Steel level | Curved inside Diameter D | Diameter of stirrup | | | | |
|---|---|---|---|---|---|---|
| | | 6 | 8 | 10 | 12 | 14 |
| Level Ⅰ | D=2.5d | 2(b+h)-20 | 2(b+h)-15 | 2(b+h)+25 | 2(b+h)+65 | 2(b+h)+100 |
| Level Ⅱ and above | D=5d | 2(b+h)-10 | 2(b+h) | 2(b+h)+50 | 2(b+h)+90 | 2(b+h)+130 |

2(b+h) is the section perimeter. According to Table 3, blanking length of different diameter stirrup can be got only by knowing its section perimeter.

**The analysis of calculation of stirrup blanking length in new norm**

The thickness of the concrete protective layer in new norm is the distance from the outermost layer of steel to the surface of concrete. But in the old, the thickness of the concrete protective layer is the distance from the outer edges of stress longitudinal steel to the surface of concrete. Therefore, the outsourcing size of stirrup in the old norm can be expressed as:

$$\text{Outsourcing size} = 2(b+h) - 8c + 8d \tag{6}$$

Compared with equation.1, the thickness of the concrete protective layer in new norm increase a little, but the blanking length decrease. Table 4 shows the results comparatively.

Table 4 Anti-seismic structure under the old and the new norm stirrup blanking length calculation (mm)

| Steel levels | Equation in new norm(anti-seismic) | Equation in old norm (anti-seismic) |
|---|---|---|
| HPB235（Level Ⅰ） | 2(b+h)-8c+18.5d | 2(b+h)-8c+26.5d |
| HRB335 （Level Ⅱ） | 2(b+h)-8c+20.6d | 2(b+h)-8c+28.9d |
| Protective layer | c=20 | Beam c=25, Pillar c=30 |

**Comparative analysis between the theoretical calculation of stirrup blanking length and the empirical ones**

**The commonly used empirical calculation of stirrup blanking length.** The first empirical method: Budget stirrup length =section perimeter of component =2(b+h)[3]; the second empirical method: Stirrup blanking length =perimeter of stirrup +adjusted value of stirrup =2(b+h) -8c+ adjusted value of stirrup[4](To simplify the stirrup blanking length, the adjusted value of stirrup is got by merging the added value of stirrup hook and measure the difference. And the adjusted value is listed in Table 5).

Table 5 Stirrup adjustment value table(mm)

| Stirrup measuring methods | Diameter of stirrup | | |
|---|---|---|---|
| | 6 | 8 | 10～12 |
| Outsourcing size | 50 | 60 | 70 |
| Insourcing size | 100 | 120 | 150～170 |

The last one: Budget stirrup length =outsourcing perimeter +the added value of hook =2(b+h) -8c+the added value of hook[5]

b, h, c represents the width, height and the thickness of the protective layer of beams and pillar.

**Example of calculation conditions.** The beam section of anti-seismic frame 300mm*600mm. Intensity level of concrete is C30. Environment level of concrete is first grade. diameter of stirrup is 6, 8,10,12. Thickness of protective layer is 20mm. Stress longitudinal steel using four 22mm diameter of HRB335 ordinary steel. Double stirrup, solve the blanking length L of single stirrup.

Table 6 is got by substituting the diameters in the example into Table 3 and three empirical methods.

Table 6 Three types of stirrups blanking length calculation method of analysis and calculation comparison table

| length / method / diameter | Theoretical calculation mm | First empirical method mm | Second empirical method mm | Third empirical method mm |
|---|---|---|---|---|
| 6 | 1790 | 1800 | 1690 | 1804 |
| 8 | 1800 | 1800 | 1700 | 1858 |
| 10 | 1850 | 1800 | 1710 | 1912 |
| 12 | 1890 | 1800 | 1710 | 1967 |

It can be known from Table 6. When stirrup diameter is 6 or 8, the first empirical method can be used to calculate the stirrup blanking length for its small error rate; When stirrup diameter is 10 or 12, the results of this method is less than theoretical calculation. So it's not applicable. For he second method is deduced from non-seismic stirrup hook, the blanking length it calculated are all negative deviation and not meet the conditions. The results of the third method is larger than the theoretical calculation, error rate is less than 5%. So it is more suitable for calculating the quantity of construction stirrup budget.

## Conclusion

It is simple and fast to get the stirrup blanking length by looking up Table 3,and the calculation of stirrup blanking length in old norm can be continue used. Compared with theoretical calculation, when stirrup diameter is no less than 8, the first empirical method can be used to calculate the stirrup blanking length. The second empirical method is only applicable for non-seismic design. The last one has an reasonable rate of deviation and can be used as the stirrup budget length.

# Components and guidance for constructional rearrangement of buildings and structures within reorganization cycles

Volkov Andrey, prof., DSc.[1,a], Chulkov Vitaliy, prof., DSc., [2,b], Kazaryan Ruben, prof., DSc.[3,c], Fachratov Muhammed, prof., DSc.[4,d], Kyzina Olga, PhD.[5,e], Gazaryan Robert, Ph.D.[6,f],

**Keywords:** visual (infographic) modeling; assignment and documenting of models; technologization, organization, computerization and intellectualization of activity and control over it, integrated documenting.

**Abstract:** constructional rearrangement is a special case of «Rearrangement» phase in reorganization cycle. It is a set of measures, works and solutions implemented to improve operating characteristics of a construction facility. The main goal of CR objects is to bring them to the condition meeting the needs of users or requirements of regulatory documentation using the methods of architectural, planning and functional transformation.

The need in CR is related to many factors (need to increase the affordability of housing, improvement of housing stock operating quality, refinement of urban-planning, architectural and environmental approaches to forming living environment, implementation of energy-conserving systems, etc.) [1].

CR is an aggregate of nomenclature, structure and interrelations of constructional rearrangement characteristics which are never implemented simultaneously.

Guidance for CR include: visual (infographic) modeling [2,3]; assignment and documenting of models; technologization, organization, computerization and intellectualization of activity and control over it.

Activity co-organization processes and technologies include: integrated documenting, infographics, screening, scoping, diagnostics, monitoring, outsourcing, facility management, outstaffing, logistics, coaching, engineering, consulting and a series of other well-known and innovative activity technologies.

CR components:

- working processes organization principles;
- constructional rearrangement processes;
- types of works performed;
- construction materials and structures;
- employed mechanical and transportation means;
- principles, technologies and parameters for assessing quality and comfort of human habitation within rearranged HME system.

CR types:

- well-known, time-proved and publicly recognized (repair, re-construction, restoration);
- emerged in our practice during «perestroika» variants of CR of facilities and areas (as well as innovative terms defining these variants: renovation, recomposition, reversal, etc.), which are at their «development», «careful study» and «approval» stages in construction, directive and regulatory documentation and there-fore requiring certain explanation.

In the course of CR of urban infrastructure facilities the difficulties occur related to referring certain types of rearrangement works to the corresponding CR type in order to qualify the functional activities of construction organizations and complexes correctly.

For instance, capital repairs will not increase the cost of construction facility, but its reconstruction will. The costs for repairing property assets can be recognized when calculating the profits tax immediately after the works have been completed. But reconstruction will increase the book value of property and will be written-off via depreciation allowance. It is more favorable for an organization to formalize CR as repairs, but it's often difficult to distinguish capital repair from reconstruction.

An accountant not familiar with construction cannot do this in most cases, if the term «reconstruction» is not expressly specified in the contract. However, reconstruction is mentioned in the contracts very rarely. Usually, a simple term «repair works» is used. The term «reconstruction» is specified only when CR works are of great significance. Therefore many firms, without going into particulars, charge the costs under such contracts to the prime cost at once. However, what is written in the contract may have little importance, and during the review the tax officers will be mainly examining the nature of works performed but not the contract itself. Upon identifying a violation they will additionally impose profits tax and property tax.

Therefore, slowly but surely, CR specialists come to the following conclusion: to increase the efficiency of implementation of CR plans and programs for buildings and structures, it is reasonable to single out innovative types of CR from the general «crusty» boundaries of reconstruction and repair.

When rationalizing the need: single out a local component of a known CR type and assign it with a status of a new separate CR type; form a directive and administrational documentation support for an new CR type; make this CR type a multiversion business object; form the variety of its organizational and technological subtypes; rate activity processes, indicators and performance levels of such new CR type. For example, execution of alteration works which, according to the current regulations are referred to reconstruction, can be transformed to a separate innovative CR type called «recomposition».

Lots of modern innovative CR subtypes are open, it means that as reasonable interests and various types of demands emerge, new innovative CR subtypes can be created.

Presently, the group of innovative subtypes includes the following:

Renovation - forced vacation of territory (demolition of buildings and structures, retrieval of utilities from underground, etc.) to provide a possibility for new construction depending on the extent of preservation of the structures located in such territory (term by Vedeneyev N.S. and Maklakova T.G. was applied to CR by Resin V.I. in directive documents by Moscow Government).

Recombination (recomposition, restructurization) arrangement of com-ponents in a new order with the elements of innovation and increase of habi-tation comfort on a new technical basis (term by Schreiber K.A. was applied to CR by Ginsburg A.V. and Kuznetsov S.V.);

Reversation - alteration of designated purpose, legal status and owner-ship pattern of a facility being rearranged (term by Chulkov V.O. was applied to CR by Golubeva N.N.).

Retrivation (from retrieve - restore, find) - bringing a facility being rear-ranged into a good repair by way of annexing to the old functional system of the building a new system providing for local or entire repla-cement of elements of such new system (using assembly/disassembly principle) and ensuring elimination of obsolescence of the building and normal operation of the facility (term by Kuzina O.N. was applied to CR by Chulkov V.O. and Kuzina O.N.). The old functional system is the main bearing structure of the building, the new system - add-on systems of buildings, structures and internal premises finishing.

The structure of «Retrivation» CR is given on fig.1.

Technical rehabilitation (sanitation) - complex of measures aimed at restoration of operating prope-rties and refurbishment of buildings and structures which bring them to a new condition, maximally complying with the cur-rent requirements. Such measures can also be taken to increase energy-conserving properties of the structures and in case of impossibility of demolition and

eviction. An integrated reha-bilitation means an overall refurbishment of the building, including utilities, however, without alterations. It is larger than capital repairs but smaller than reconstruction.

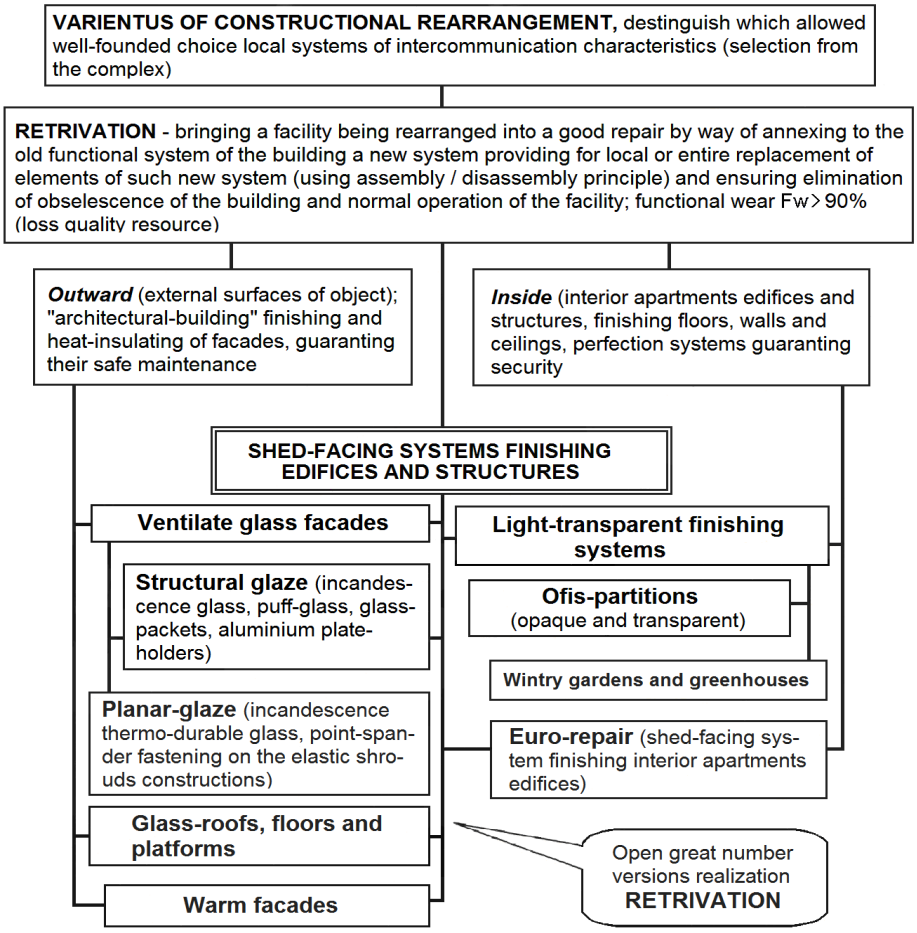

Figure 1. Structure of «Retrivation» CR

When further construction or CR of a facility is impossible or unfavorable, but the improvements of market conditions or company's financial situation are expected in future, such facility under construction undergoes a preservation process. Upon the expiry of preservation the measures on depreservation of facility under construction can be performed, it means the working processes can be resumed. Preservation is used in cases when a facility needs to be «frozen» for a period over 6 months.

The set of measures to preserve a facility:

- preparation of a plan including all organizational and legal measures and construction works on preservation of the facility;
- elaboration of method statement for the works required to preserve the facility under construction;
- management of organization and execution of all construction works related to presservation of the facility.

The preservation of a facility consists of the following stages:

- inventory of construction facilities;
- check of availability and accuracy of all technical documentation (drawings, cost estimates, construction journals and other documents);
- examinations and inspection measurements.

The following types of works should be carried out:

- works protecting the building structures and equipment of the facility against aggressive environmental exposure;
- fire protection of the facility;
- enclosure of excavation pits and through holes in slabs);

- reinforcement of the walls;
- fixation of all moving elements of building structures.

Research and design of system «man - technology - environment, MTE» predetermined the integ-ration of technics and sciences about man and his working activity, led to emergence of a new psycho-physiological terms of reference.

These tasks are related:

first, to description of characteristics of a human and his activities within the management systems;

second, to development of new resources for activities, mainly concerned with provision of inte-raction between human and machines in certain environmental conditions and with requirement of quantitative assessment, measurement and monitoring of the human comfort level at performance of certain activities;

third, to allocation of functions between operator and machine, to arrangement of cooperation thereof.

Currently, there is a long-felt need and finally became possible in principle comprehensively to study labor activity basing on all sciences, which scope of research is human being as the subject of labor, knowledge and communication.

It is easy to see that failure of labor activity currently includes not only a distortion of human physiological functions, but also failure of any of his functions such as labor, knowledge (informative function) and the function of communication. At intersection of psychology, physiology and engineering, has appeared a new science about principles of labor process - it is ergonomics. Ergonomic analysis of normal and pathological state is a fascinating and faintly studied problem of modern psychology, biology, medicine, and antropotechnics.

The living conditions of modern humans became significantly different from those in which happened a formation of human being and human society. Large number of new factors arising from scientific, technological and social progress impact humans. Ionizing radiation, all kinds of toxic substances, noise, vibration, excessive mental stress, intensification of work are becoming the hallmarks of civilization.

Furthermore, the human body is widely influenced by consumption of food products, undergone various types of processing, as well as mass taking of antibiotics, sulfanilamides, hormonal, and other highly active pharmaceuticals.

In this regard, study of issue of human adaptive capacity is of particular importance because morphological and physiological characteristics of man, formed over a long period of evolution during millions of years, may not change with the same speed as technological processes and environment chan-ging. That particular comprehensive approach to the issue will afford to over-come the common perception of the standard permanence. Only such a synthetic approach may ensure an adequate knowledge of normal human development, otherwise there will always arise paradoxical points of view about childhood as «immature», «abnormal» adultness and about relativity of standard definition.

**Keywords:** Precast fabricated structure, Composite wallboard, Mold-unloading-lifting; Construction checking.

**Abstract.** Take composite wallboard of residential parts as object of study, use investigation and theoretical calculation to check unfavorable conditions of Mold-unloading-lifting and lifting-transportation in industrial production. mold-unloading coefficient and dynamic coefficient value are researched according to summarize domestic and foreign standard, and give out suggested dynamic coefficient values of construction checking of lifting-transportation for composite wallboard. It can provide reference of production and development of residential parts.

## Introduction

Modernization of housing industry has been gradually put on the agenda with the emerge of reform of the wall, building energy efficiency project and other relevant policies. Fabricated structure residential has been more popular and taking increasingly proportion among individuals for its advantages such as on-site assembly, green environmental protection, and convenient for industrial and standardizing production.

But industrialized construction technology research and applications is still in its infancy, production technology is not well developed and with low level of industrialization, industrialized building system occupies low shares in construction market of our country. There are still many issues must be resolved such as the construction checking of mold-unloading-lifting and lifting-transportation of residential parts. The paper take composite wallboard of residential parts as object of study, use investigation and theoretical calculation to check unfavorable conditions of mold-unloading-lifting and lifting-transportation in industrial production. It can provide reference of production and development of residential parts.

## Embedded hanging pieces

Through the investigation of prefabricated member manufacturers found that the common hanging pieces have rings and dedicated embedded hanging pieces.

The rings is to embed HPB300 reinforced in the specified location in composite panels (welding together with main reinforcement). Besides, it cannot be cold treatment. Because the load of the ring is normally dynamic load. If the flexibility is inadequate, the ring will occur brittle fracture easily, yet the ductility and toughness of the reinforced will decreased after cold treatment. It shown in Fig. 1.

The form of special embedded hanging pieces has embedded nuts, embedded boom and reserved lifting holes, and using the combined dedicated spreader to achieve lifting. The buried nuts are the most common. It is with the use of high-strength bolts. When it is being used, embedded nuts into the specified location in composite panels. When lifting, screw the bolts and nuts together, and hang on the lug bolt with hook. And then, it can be lift. It shown in Fig. 2.

Fig. 1 Composite panels embedded rings

Fig. 2 Composite wallboard embedded nut and bolts

In practical engineering applications, because of low design strength and anchorage length, the rings made by hot rolled round steel bars may consume more and having bad economy. Meanwhile, when the Installation is complete, the exposed parts of the rings must be cut off. Otherwise the appearance quality and durability of precast member will be influence. So there are many component factories begin to use dedicated embedded hanging pieces, embedded nuts are the most common. No matter what component is chosen, it must meet the requirement of being lifting safely under the effect of self weight. (Steel rings are calculated in reference of GB50010-2010[1]).

## Construction checking of mold-unloading-lifting

To consider the influence of the adsorption force, we can introduce mold-unloading adsorption coefficient to recheck when composite wallboard receive adsorption force from mold on the surface of concrete structures during mold-unloading-lifting.

The component values are multiplied by the weight of the standard mold-unloading adsorption coefficient as equivalent load standard value. Mold-unloading adsorption coefficient is related to components and mold surfaces' condition and it can be determined by testing.

Table 1 is some commonly used prefabricated mold-unloading coefficient specified by PCI Design Handbook[2] of the USA.

Table 1 Mold-unloading coefficient in PCI design handbook

| type of component | mold surface conditions | |
|---|---|---|
| | exposed aggregate, mold release agent coating | smooth surface, oiled |
| Flat without active side mold and slot, slot edge | 1.2 | 1.3 |
| Flat with active side mold and slot, slot edge | 1.3 | 1.4 |
| Flat with Chute(Such As T-Shaped Plate, Double-T Board) | 1.4 | 1.6 |
| Flat with Carved Face | 1.5 | 1.7 |

In our country, the construction standard mold-unloading adsorption coefficient takes 1.5 based on domestic practical engineering experience.

**Examples of checking:**

A composite wall, plate length b = 3600mm, plate height a = 2850mm, thickness t = 330mm, using level lifting on 4 points, to make positive moment between lifting points and negative moment at lifting point roughly equal, referring to the United States' PCI design Handbook[2] and determine the position of lifting points, shown in Fig. 3. Before mold-unloading, the compressive strength has been measured with the concrete conditions of test cubes conservation and the value is 18.5Mpa, now checking whether mold-unloading-lifting is satisfied.

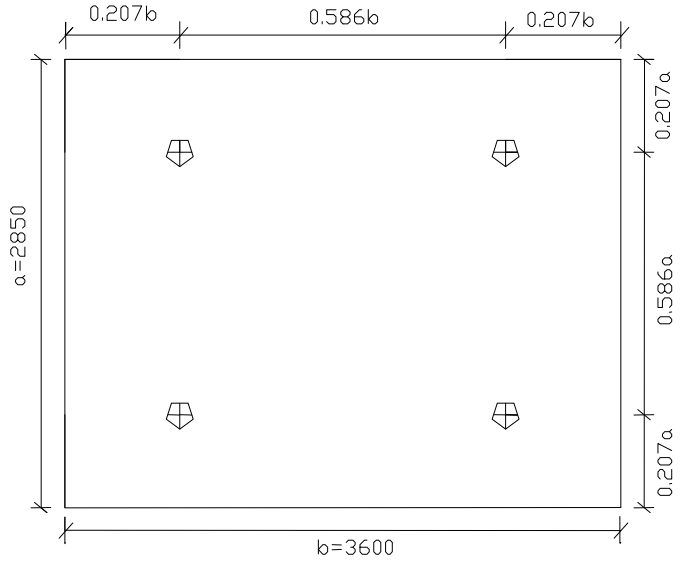

Fig. 3 Lifting point diagram

Solution: Known $f_{cu}$ = 18.5Mpa, $f_{tk}$ =1.46Mpa(according to standard GB50010-2010[1]);

Reinforced concrete density takes $25\times10^{-6}$ N /mm$^3$;

mold-unloading adsorption coefficient takes 1.5;

the equivalent uniform load q= $330\times25\times10^{-6}\times1.5 = 12.4\times10^{-3}$ N/mm$^2$;

owing to 0.5a =0.5×2850=1425mm ＜15t = 15×330 =4950mm, the calculate width takes 0.5a;

Then the biggest moment of maximum: $M^{+}_{\max} = M^{-}_{\max} = \frac{1}{2}\times\frac{1}{2}a\times q\times(0.207b)^2$, maximum tensile stress: $\delta_{\max} = \frac{M_{\max}}{at^2/12} = 0.19Mpa$.

There $\delta_{\max} < f_{tk}$, it is requirement and can be lift.

**Construction checking of lifting-transportation**

Lifting-transportation means is lifting and placing the prefabricated components into specified site, including lifting, transportation and field erection. When checking, field personnel should consider the impact of the dynamic load and the wallop generated in the process of lifting. Generally by pull-in dynamic coefficient to consider the dynamic load, the weight standard value of component multiplied by dynamic coefficient as the equivalent standard value. Table 2 is the current domestic and foreign standards for dynamic coefficient value[3-5].

The complexity and importance of the lifting process should be taken into consideration, and the lifting checking dynamic coefficient is suggested that taks1.5 as possible; when there are any reliable experiences, power coefficient can be adjusted according to actual stress situation.

Table 2 The dynamic coefficient in domestic and international current standards

| standards | dynamic coefficient |
|---|---|
| 《Code for design of concrete structure》GB50010-2010 | 1.5 |
| 《Assemble large residential building design and construction code》JGJ1-91 | 1.5 |
| 《Technical standard for reinforced concrete lift slab structure》GBJ130-90 | 1.2 |
| 《Code for design of concrete structures of railway bridge and culvert reinforced and prestressed》 | 1.2 |
| U.S.A《PCI Design Manual》 | 1.2 |
| Hongkong《Standard for construction of precast concrete》 | 1.2 |

## Conclusions

This paper describes the types of embedded hanging pieces (rings and embedded nut). By an example using mold-unloading coefficient check calculating unfavorable conditions of mold-unloading-lifting of composite wallboard in industrial production. And summarize domestic and foreign standard, give suggested dynamic coefficient values of check lifting-transportation.

# Discussions on Foundation Pit Construction Scheme of Large Building in Mountain Area

Mengjie LIN[1,a]

[1]Hunan Communication Polytechnic, Hunan Changsha 410004, China

[a]Email: lindalux@qq.com

**Key words:** Large building; Foundation pit; Groundwater control; Slope stability

**Abstract:** Based on the analysis of the engineering geology and the hydrology data of a large construction project along the river in Hunan province, according to the engineering design requirements and the local construction conditions, the paper analyzed in-depth on deep excavation, groundwater control and high slope treatment schemes. The results can provide a reference for similar engineering problems.

## Introduction

With the rapid development of the city and utilization of underground space, the theories and research on pit projects have also become increasingly sophisticated. Because various factors often cause some technical problems in the process of pit excavation, leading to numerous damages to the surrounding environment and the building structure. Therefore, the construction program must be technologically advanced, safe and reasonable to ensure the stability and safety of the building itself and the surroundings roads and underground facilities. So the foundation pit engineering has strong regional characteristics, and the past experiences have important reference value.

The pit supporting structure should be designed be by the limit state method expressed by partial coefficients. Meanwhile, the design should consider the horizontal deformation of the structure, and identify the limit deformation of the supporting structure according to the surrounding environment. In addition, the methods for controlling pit groundwater can be divided into dewatering, collection, recharge, cutoff and so on. When the dewatering scheme may affect the stability and security of the pit and its surroundings, the recharge method should be applied. As to the cutoff scheme, the dewatering method should be adopted when the pit water amount or the water pressure is great [1].

## Project overviews

A large building along the river locating in the mountainous area with high slope areas, takes the way of large excavation, according to one of the principles of engineering design requirement to minimize the demolition of houses and farmland occupation to the greatest extent. The pit is 121.7m along the flow direction, 76.3m wide and the bottom elevation is about -9.10m. The geological environment, and the climatic and hydrological conditions of the area are complex. According to the project arrangements, the storm season and the seepage may affect the slope stability and cause uneven subsidence during the excavation construction of the foundation pit.

The geological conditions of pit areas are shown in Table 1. The excavation mainly involves 10 different geological sub-layers with 2~4m thick silt clay. The layers of ③-3、④-1 and ②-5 are the main aquifer, with the vertical and horizontal permeability $K=A\times10^{-5}\sim A\times10^{-4}$cm/s, belonging to weak aquifer. The cohesive soil layers of ⑤ and ③-2 with groundwater horizontal motion has

good horizontal bedding, whose K (vertical) =A×$10^{-7}$cm/s, K (level) = B×$10^{-5}$cm/s. The peat layer is between ②-2 and ②-3, with high compressibility, soft, low intensity. Under the effect of groundwater flow, ④-1 and ③-3 composed of light sandy loam layer may produce quicksand.

**Table 1 Geological parameters of foundation pit**

| Layer | Soil bottom elevation / m | Natural Moisture | Consolidation | | Permeability coefficient （20°C）/(cm/s) | Allowable Bearing |
|---|---|---|---|---|---|---|
| | | | c/kPa | φ/(°) | | |
| ①-1 | 2.0～4.4 | — | 16/8 | 31/30 | 4.1×$10^{-6}$（6.0×$10^{-5}$）(Vertical) | |
| ②-2 | 0.3～1.8 | 36.7 | 13/10 | 23/20 | 3.2×$10^{-6}$（9.5×$10^{-6}$）(Vertical) | 84 |
| ②-3 | 0.1～-4.7 | 48.9 | 15/11 | 17/15 | 8.5×$10^{-6}$（2.7×$10^{-5}$）(Vertical) | 63 |
| ②-5 | -5.0～-5.2 | 35.3 | 11 | — | 3.0×$10^{-5}$（2.8×$10^{-5}$）(Vertical) | 119 |
| ③-1 | -2.4～-3.1 | 26.9 | 40/28 | 21/19 | 1.1×$10^{-7}$（3.6×$10^{-7}$）(Vertical) | 361 |
| ③-2 | -3.3～-8.5 | 30.2 | 31/21 | 22/20 | 4.2×$10^{-7}$（9.2×$10^{-7}$）(Vertical) | 149 |
| ③-3 | -6.8～-8.6 | 32.2 | 5/5 | 37/34 | 1.4×$10^{-4}$（1.9×$10^{-4}$）(Level) | 118 |
| ④-1 | -9.0～-11.6 | 33.1 | — | — | 6.6×$10^{-4}$(Vertical) | 123 |
| ⑤ | -3.2～-15.1 | 34.9 | 17/13 | 18/16 | 4.1×$10^{-7}$（1.6×$10^{-4}$） | 110 |
| ⑤` | -4.9～-15.8 | 35.6 | 12/5 | 29/26 | 1.3×$10^{-6}$（2.5×$10^{-6}$） | 112 |
| ⑥ | -17.6～-20.1 | 23.3 | 56/46 | 24/21 | 1.7×$10^{-7}$（6.2×$10^{-6}$） | 298 |

**Note：①The former in the permeability coefficient value column is the arithmetic average of the values, and in parentheses are the average large-value；②In the "Consolidation fast shear" column, the left of the slash is the arithmetic average and the right is the small value average.**

**Comparison of excavation schemes**

(1)To reduce the damage caused by the river-side seepage to the pit, the 24cm-thick 130m-long 19.2m-deep underground continuous diaphragm wall was set, relatively embedded in about 0.4 ~ 0.6m depth of the impervious bed.

(2) Preliminarily design 1m and 2m-wide bridleway respectively at 3.7m and 2.5m height, where the inlet and drainage pipes and the intercepting ditch were arranged in the 3.7m-wide bridleway. Based on the slope stability calculation, the upper limit of the excavated slope elevation is 3.7m corresponding to the slope 1:1.5, and at 2.5~3.7m elevator is 1:2.5, at-2.5m is in 1:2.5. Thus the total excavation is 198,000$m^3$.

The dewatering and drainage plan and slope cut program are the two key issues of high slope areas along the river.

① There were three slope grading scheme. The design found two possible sliding planes, namely layer ⑤ and layer ②-3, and the latter one is in the middle of the slope.

Table 2 shows the three design conditions, working conditions, results and proposals.

**Table 2 Comparison of excavation schemes**

| Program code | A | B | C |
|---|---|---|---|
| **Engineering Level** | Temporary buildings 4 | | 10-year return flood control requirements |
| **Side slope safety factor** | K≥1.05 | K≥1.15: Well point dewatering effective. | K≥1.2 |

| | | | |
|---|---|---|---|
| **requirements** | | K≥1.05:Well point dewatering failure | |
| **Shear strength index** | Direct fast shear minimum average | K≥1.15: Consolidation fast shear minimum average. K≥1.05: Direct fast shear mean | According to geological conditions, sum up the design value |
| **Drainage** | Normal groundwater levels : -2.1m; 10m from slope top to the bottom: linear change | Well point dewatering | Light well in 3.5m height; Injection well in -1.0m height. |
| **Calculation Method** | Swedish Arc Method, self compiled program. | Slope stability analysis computer program | Arc sliding method |
| **Results** | Three platforms:5m+5m+5m. Slope 1:2.5. $K_{up}$=1.453, $K_{down}$=1.082 | Slope 1:1.5, K=1.292 Slope 1:2.5, K=1.06 | Slope 1:1.5, 1:2.5; 1:2.0, K=1.26 |
| **Proposal** | Set 5m wide bridleways at 3.90m, 0.00m, -4.10m elevation; slope 1:2.5 | Above ②-3: Slope 1:3; Blow ②-3: Slope 1:2. | Set 3 m bridleways at 3.60 m elevation and 2 m bridleway. at -1.20 m elevation; slope 1:1.5, 1:2.5, 1:2.0. |

② Use ditches and diving pool to collect rainwater and groundwater into catchment.

The key point of the dewatering and drainage program is groundwater pumping, where the water level should be lowered below the pit base, in order to ensure the smoothly concrete pouring and foundation pit excavation.

The pumping geological experiments on the confined aquifer at 3.31m~3.52m elevator showed that this layer has a moderate permeability, and the permeability coefficient is K = 2.25 × 10-4cm / s. When the groundwater was lowered down to 3.4 ~ 3.7m elevator, the radius of influence is 35m. To make the gushing at 240 ~ 360$m^3$ / day, the groundwater level should be controlled at -9.1m.

Set the deep test wells at the northeast corner of the pit, diameter φ800mm, bottom elevation 17.0m, depth 25m and make ensure the pressure water head at -9.1m after the dewatering. Finally, the multilayered-ring light well point dewatering gained acceptance.

(3) Above all, the excavation program was determined as follows:

① There are two most unfavorable circular sliding planes: the deep arc sliding above the hard soil layer along the -12.6m elevation⑥ and the sliding plane above the top local hard soil with the elevation-0.2m ③-1, where the former one was taken for slope design.

② According to the relevant specifications, the slope stability coefficient is taken as1.20. And according to the design specifications in Shenjiang, the slope stability safety factor is 1.44. Take the arithmetic mean of the consolidation fast shear peak as the standard value of the soil shear strength at the sliding plane. And the excavation depth exceeds 10m, belonging to the first level pit [2].

Comprehensively considering the above three programs, due to reserve sufficient width of soil to ensure the stability of the continuous wall, the paper proposed an annular arrangement of four wells and three-point grading scheme bridleways, and chose different sliding stability indicators for slope calculation. In Table 3, According to the circular slip calculations, it can meet the specification requirement K = 1.20. when the slope is 1:2.5 with three bridleways, $K_{min}$ = 1.47. According to the Shenjiang specifications, $K_{min}$ = 1.85(＞1.44). However, the total failure of dewatering wells should be considered to make sure the grading scheme appropriate, not conservative.

**Table 3 Results of slope stability calculation (slope 1:2.5)**

| Well point / Type of safety coefficient | Completely valid | | Failure | |
|---|---|---|---|---|
| | $K_{up}$ | $K_{down}$ | $K_{up}$ | $K_{down}$ |
| Mean of small values of consolidation fast shear | 1.46 | 1.92 | 1.22 | 1.06 |
| Arithmetic mean of fast shear consolidation | 1.88 | 2.18 | 1.53 | 1.4 |

**Key points of excavation process**

During the excavation process, there was about $20\times10^4m^3$ soil taken out from the foundation. In the actual implementation process, considering the protection of the pit bottom and the construction of the deep cement mixing pile, the excavation was divided into two phases.

After the first phase of the excavation, the bottom elevation was about-6.3m or so; and at the second phase the bottom elevation was excavated to -9.1m through miniature backhoe digging machines and manual excavation. Furthermore, the protection measures have adopted as follows:

① After the light well point played the role controlling water, the excavation of the stage can start and should strictly follow the principle of "dewatering first, excavation later".

② Drainage ditches should be set at the top of the slope and each platform, and then collect water drained by pumps in order to ensure a good drainage system on the construction site.

③ To strengthen the slope protection, the geotextile should be prepared for the soil slope protection in rainy season except plasterring plain concrete on the lowest layer.

④ To guide the construction, the professional staff should be entrusted to monitor changes in groundwater level, settlement, inclinometer and other aspects during excavation..

⑤ Prohibit the upright excavation deeper than 2m, and strengthen the management and control of the construction site.

⑥ Solutions to emergency:

a. When the excavation was close to the design base elevation, local wing walls appeared the phenomenon of fine sand stream. Then the technicist increased the drainage and speeded up local construction, thus completing the bottom sealing as soon as possible.

b. The tilt and the deformation of an observation point in the northwest slope exceeded the specification in one day's time. So the local construction was suspended for four days and did not take any measures until the slope regain stability [3].

**Conclusions**

(1) The terrain-geological and hydrology-weather conditions should be accurately grasped to make appropriate countermeasures for groundwater control and slope treatment. Furthermore, make contingency plans for unexpected problems is needed.

(2) Because of the significant shear indicator of the slope, the most unfavorable results should be introduced to calculate, and the slope design should consider the impact of precipitation.

(3) Close attention should be paid to the deformation and stability of the main pit structure and the surrounding buildings, and strengthening the monitoring and measurement and performing informationization construction are important guarantee for safe and effective excavation.

**Keywords:** construction site, a combination of milestones, the intensity of work

**Abstract.** The basic scheme of intensive implementation preparatory work, the general form of the formulas for determining the structure and amount of preparatory work performed prior to the start of construction.

A prerequisite for the planned deployment of construction works is the performance of preparatory work in the volume providing an implementation of the construction of the specified rate [1, 2]. In this context, the main task of choosing effective solutions organization of the preparatory period is to determine:

structure and the amount of work necessary and sufficient for the timely opening of the front work on the construction of buildings and structures ;

structure and the amount of work performed in accordance with the basic construction and installation works .

Currently available theoretical positions to implement the Preparatory works are inconclusive solve the above problem. Moreover, in the construction industry organization theory there is no clear methodology for the development of preparatory work in time and space, taking into account the totality of the factors influencing a variety of techniques and building facilities [3, 4].

Basic provisions on the organization of engineering site preparation should include:

advancing the construction of permanent utilities and facilities for the construction of water, heat , steam, compressed air and electricity ;

Ahead of off-site and intra- device roads for use in the construction process;

anticipatory lining of engineering networks for transport communication, , assembly and storage areas ;

lining combined with the construction of engineering networks of underground hour children of buildings and structures ;

combined gasket different kinds of utilities outside the zones and under construction projects mounting and storage areas ;

organization of production and living conditions on construction sites for the erection of mobile systems from the inventory of buildings, construction in the preparatory period and the use of permanent buildings for the needs of the construction of the existing buildings .

These provisions are implemented adequately provided subdivision construction site on homogeneous sites on functional characteristics of the work. Such homogeneous sites organized into ten groups (tab. 1).

Table 1 Systematization of homogeneous regions by functional signs

| Group number | Functional features |
|---|---|
| I | Land, land construction site, to be clearing with the demolition of buildings |
| II | Land, land construction site, to be planning ensuring runoff |
| III | Land construction site intended for organize mobile (inventory) of buildings and their complexes |
| IV | Land with communications, providing needs construction site in energy resources (water, heating, electricity, etc.) |
| V | Areas with transport routes (roads, railways) used in the construction process, and areas of communications, traceable under them |
| VI | Land with communications within storage sites, assembly and consolidation of structures and equipment |
| VII | Land with communications within the mounting zones construction of buildings and structures |
| VIII | Land for advancing the construction of buildings and structures, used for construction needs |
| IX | Land with utilities and foundations of buildings and structures combined with earthy grooves |
| X | Land with communications is mounting zones construction of buildings |

It is necessary to consider the following:

- Work in groups I - VIII (denoted by the volume of these works $V_{\text{П}}^{'}$) is - are crucial for the opening of the front main construction and installation of the works and should be fully executed prior to the construction of the object ;

- Work on group IX ($V_{\text{П}}^{''}$) must be carried out simultaneously with the device of foundations (underground parts) buildings and structures;

- Work on the group X ($V_{\text{П}}^{'''}$) does not hinder the opening of the front main construction works.

Thus, the amount of preparatory work for each direct object under consideration can be represented as :

$$V_n = V_{\text{П}}^{'} + V_{\text{П}}^{''} + V_{\text{П}}^{'''}, \quad (1)$$

where $V_n$ - amount of preparatory work (thousand RUB; man-days).

Number of homogeneous sections and the amount of work on them depend on the density of the object settings for synthesizing the entire set of influencing factors : the size and area of the territory ; availability of production , transport and engineering communications; cooperation of the main and auxiliary facilities; composition commissioning of new systems and queues. Meanwhile housing density change significantly even within the same industry. For example, enterprises of mining and chemical industry are building density 28% and the production of synthetic fibers - 50%. For light industrial building density is 21-61% , vehicle construction - 13-65 %, etc.

We introduce a factor as the ratio of the density of buildings:

$$p = \frac{F}{S}, \quad (2)$$

where: $F$ - building area;

$S$ - area of the enterprise within the enclosure.

Then the expression (1) can be determined as a function of density for the settings :

$$V_n(p) = V_{\text{П}}^{'}(p) + V_{\text{П}}^{''}(p) + V_{\text{П}}^{'''}(p) \quad (3)$$

But, on the other hand, the amount of preparatory work can be expressed through and the amount of work performed prior to the construction of the object $V_{\Pi}^{C}(p)$ :

$$V_{\Pi}(p)=V_{\Pi}^{D}(p)+V_{\Pi}^{C}(p) \tag{4}$$

As noted earlier, prior to the construction of the object in full compliance with the scope of work - $V_{\Pi}^{'}(p)$, and in combination with the basic construction and assembly pa - bots - the amount of work $V_{\Pi}^{''}(p)$. As for the scope of work $V_{\Pi}^{'''}(p)$, then the density of the development company , which tends to zero $p \to 0$ , the number of sites is mounting zones construction of buildings occupies a significant part of the territory of the construction site, and the amount of work in these areas tends to $V_{\Pi}^{'''}(p)$. At the same time, with increasing housing density $p \to 1$, the number of such sites and theoretically reduced their volume is equal to zero when $p = 1$. Therefore, when the development density coefficient from *0 to 1* is " transfusion " volumes $V_{\Pi}^{'''}$, in $V_{\Pi}^{'}$ and volume $V_{\Pi}^{''}$ . And as the site-specific portion of the volume all the preparatory works are permanent $V_{\Pi}^{'}, V_{\Pi}^{''}, V_{\Pi}^{'''} \to const$, then the pattern changes in the structure and scope of the preparatory period under review is presented as a function of the density of buildings :

$$V_{\Pi}^{'''}(p)=V_{\Pi}^{''',D}(p)+V_{\Pi}^{''',C}(p), \tag{5}$$

where: $V_{\Pi}^{''',D}(p)$- amount of preparatory work for the groups X, executed before the main construction works;

$V_{\Pi}^{''',C}(p)$ - amount of preparatory work for the group X, performed in combination with the main building and construction and installation works (CIW).

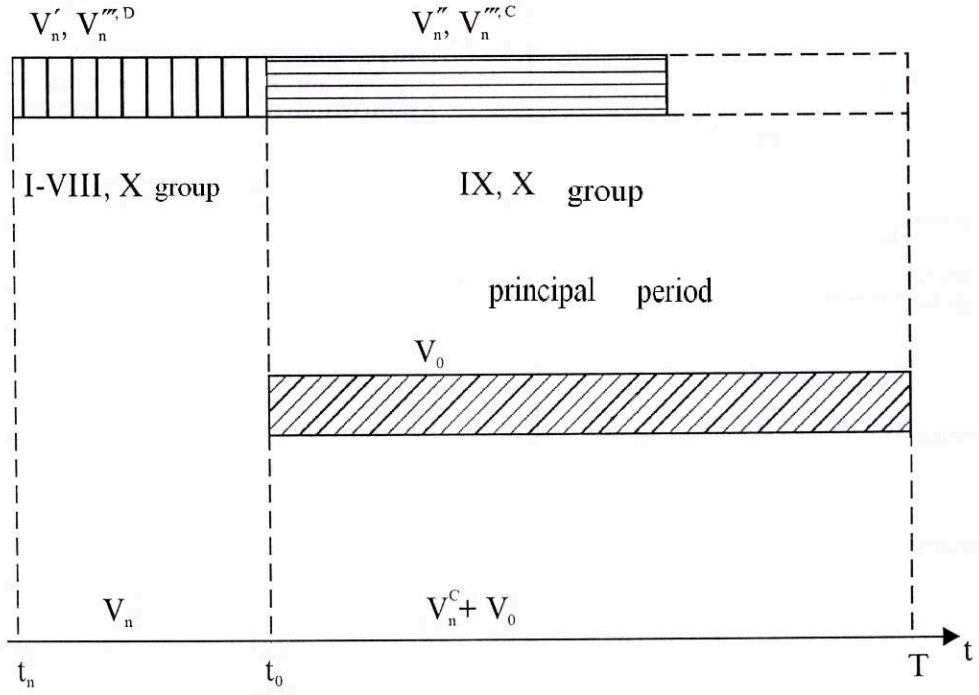

Fig.1. Schematic diagram of the intensive implementation spadework

This provision is essential and allows all the variety of options for the implementation of organizational solutions preparatory work reduced to a single diagram (Fig. 1).

Thus, the calculations necessary to use the general form of the formulas for determining the structure and volume of preparatory work performed prior to the construction of the object:

$$V_{\Pi}^{D}(p) = V_{\Pi}^{'} + V_{\Pi}^{'''',D}(p) \tag{6}$$

in combination with CIW:

$$V_{\Pi}^{C}(p) = V_{\Pi}^{''} + V_{\Pi}^{'''',C}(p) \tag{7}$$

Analysis of statistical data and the calculations showed that the subject:

$p \le p_0$ - Are as preparatory work performed prior to elevated of the object, and the preparatory work carried out in combination with the main building and construction works;

$p \succ p_0$ there are only preparatory work performed prior to elevated of object, ie $V_{\Pi}^{III,C}(p) = 0$

The simulation of the workload, it was found that $p_0$ = 0.71 (Fig. 2). Calculation formulas $V_{\Pi}^{D}(p)$ and are $V_{\Pi}^{C}(p)$summarized in Table 2 .

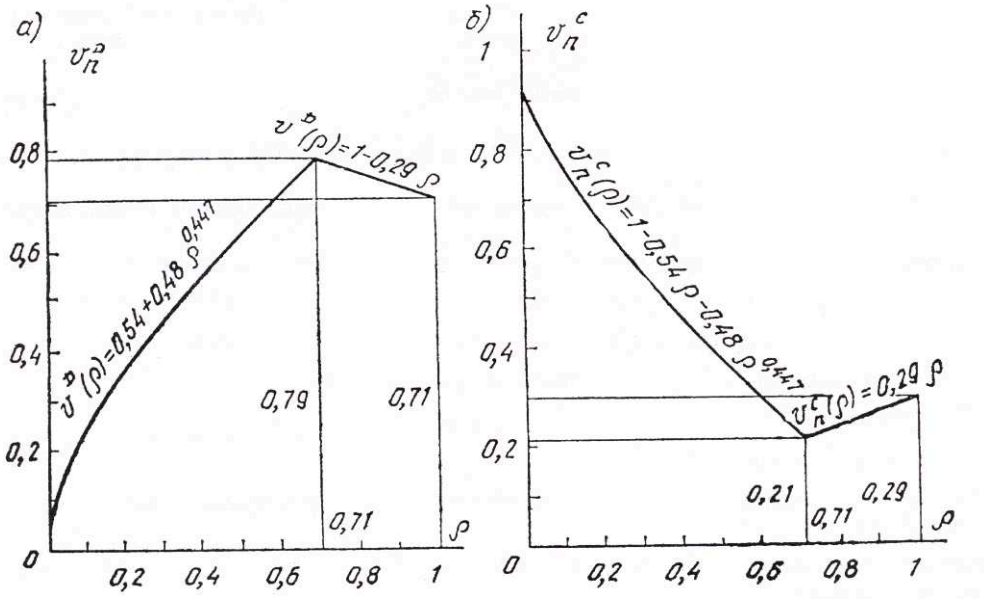

Fig. 2. Dependence volume distribution preparatory work performed:
prior to the construction of the object; b) in combination with the basic CIW

Table 2. Summary table of the estimated volume of rationing schemes preparer

| Design scheme | density ratio building | Volume of preparatory work performed: | |
|---|---|---|---|
| | | prior to construction object: $v_{\Pi}^{D}(p)$ | in combination main CIW, $v_{\Pi}^{C}(p)$ |
| 1 | $p \le 0,71$ | $(0,54p - 0,48p^{0,447})V_{\Pi}$ | $(1- 0,54p - 0,48p^{0,447})V_{\Pi}$ |
| 2 | $p > 0,71$ | $(1 - 0,29)V_{\Pi}$ | $0,29p\ V_{\Pi}$ |

Scheme 1 includes changes to the curvilinear law on the interval [0; 0.71] = 0 to 0.79.

Scheme 2 seems to be linear law of variation $v_{\Pi}^{D}(p)$ in the interval ( 0.71, 1.0 ) from $v_{\Pi}^{D}(p \succ 0,71) \prec 0,79$ to $v_{\Pi}^{D}(1,0) = 0,71$.

For the case of the distribution volume of preparatory work carried out in combination with the basic construction and installation works, there is a specular reflection function $v_{\Pi}^{D}(p)$ followed by the amount of shift $\Delta$ = +1.

Values of the functions $v_{П}^{'}$, $v_{П}^{''}$, $v_{П}^{'''}$, $v_{П}^{''',D}$, $v_{П}^{''',C}$, $v_{П}^{D}$, $v_{П}^{C}$ depending on changes in housing density $p$ increments $\Delta p = 0{,}05$ are given in Table 3 and represent the corresponding fraction of the volume of preparatory work. In this

$$V_{П} + V_{П}^{II} + V_{П}^{III} = 1$$

Table 3. Distribution function of the volume of preparatory work

**Abstract.** For researching principle and production line state of steam curing of composite wallboard, the art have been conducted through actual investigation and field test. Based on the influence of steam curing on the strength of high performance concrete, durability and volume stability, put forward suggestions of steam curing system; Several problems have been raised for steam curing in the actual production, then some correlative improve measurements are given. Provide the reference for the production and development of the residential part in our country.

## Foreword

With the implementation of the policy on wall innovation and energy saving, housing industry modernization is on the agenda gradually. Prefabricated housing structure has becoming increasingly popular for its advantage of environment protecting, convenient for factory production and standardization production, field assembly. Use ratio has become higher and higher[1]. As one of the most rapid development materials[2], composite wall panel has the advantage of light weight, high strength, heat preservation and sound insulation, especially the same lifespan of insulating layer as the structure comparing to the ordinary wall materials. At present, the prefabricated housing system is still in its infancy, whose the technology is not perfect enough, especially the research of industrial production is very rare, techniques of production is laggard, industrialization level is low.

The found from the actual investigation are that curing time and curing conditions are not uniform is the main factors that restrict the assembled composite wallboard production efficiency and increase the cost. With the precast production change rapidly, research on the steam curing technology in China still remained in the last century. Backward technology, maintenance and monitoring is only determined by experience, no innovation, no improvement. When the production number is large, appear that steam curing can not keep up with the other processes of the rhythm, leading to low efficiency, increase the cost. So it is urgent need to improve the steam curing plan.

## Steam curing equipment for the industrialized production of composite wall panel

Steam curing is a kind of ordinary pressure and wet and heated curing, which a curing technique that could accelerate the hardening of concrete when the medium temperature does not exceed 100, and the RH is above 90%. Steam curing can be divided into four period, procuring, heating period, constant temperature period, cooling period. Currently there are three kinds of common steam curing equipment, curing cover, vertical curing kiln, horizontal tunnel curing kiln[3].

**Curing cover:** It is apply to fixed horizontal curing kiln, which the steam pipe lays under the pedestal in advance. Canvas puts on the components directly ,and open the steam pipe valve to start steam curing. Curing cover is poorly equipped, and poor heat preservation effect. The operation is a waste of time and energy. It shown in Fig. 1.

**Vertical curing kiln:** It is apply to assembly line production mode. There are two lines in kiln ,up and down. The product raises layer by layer on one side of the kiln, and move to the other side by the

small flat car, then descend layer by layer, Kiln has been divided into three rising phase, stabilization phase, decreasing phase by the theory that high temperature steam up ,the low temperature air flow down. Vertical curing kiln has the advantage of saving the workshop area, easily continuous operation, less consumption of steam. But the investment is large ,and the equipment is hard to repair. It shown in Fig. 2.

**Horizontal tunnel curing kiln:** It is apply to assembly line production mode. The products go through the kiln from one end, pass by the rising phase, stabilization phase, and decreasing phase and go out from the other end of the kiln. The advantage is continuous flow process, but it is hard to divide the three phases, the temperature and humidity are hard to control, In addition, steam will leak because the kiln is hard to close. It shown in Fig. 3.

Fig. 1. The Curing cover

Fig. 2 The vertical curing kiln

Fig. 3. Horizontal tunnel curing kiln

## The determination of steam curing system

It is known that parameter such as rest period, heating/cooling rate, constant temperature time could not be increased or decreased separately. For example, although extend the rest period could enhance the strength of concrete, durability and volume stability, but too long rest period could affect the production efficiency, so strength, durability, volume stability, and the demand of production cycle must be considered when selecting parameters[1~5].

By the contrast analysis of “Code for production construction and quality acceptance of concrete member in assembly integrated precast building” in Shanghai, “The design and construction technical guide for framed concrete structure”provided by Kajima Corporation in Japan, “Production and acceptance procedures of precast concrete component” in Liaoning province, and consider the problems in the actual production process, this paper has given the steam-system, which the rest period should be less than 2 hours, 3 hours is suggested to ensure the performance of the component development without affecting the production efficiency(the rest period is determined by environment temperature, which is concluded by the experimental results of influence of stop time on

concrete performance under different environment temperatures),method such as covering membrane, humidification should be taken to keep the components humid, the temperature in plant should not be less than 5℃, heating rate should be between 10℃~20℃/h, the maximum curing temperature should be no more than 55 ℃.The maximum temperature should be reduced appropriately, considering the water loss too fast would cause the cracking on concrete surface and XPS deformation by heat .Constant temperature time should be no less than 4 hours, which is vary depending on the plant maintenance equipment and local temperatures, etc. As shown in Figure 3.1 is the proposed steam curing system by this paper.

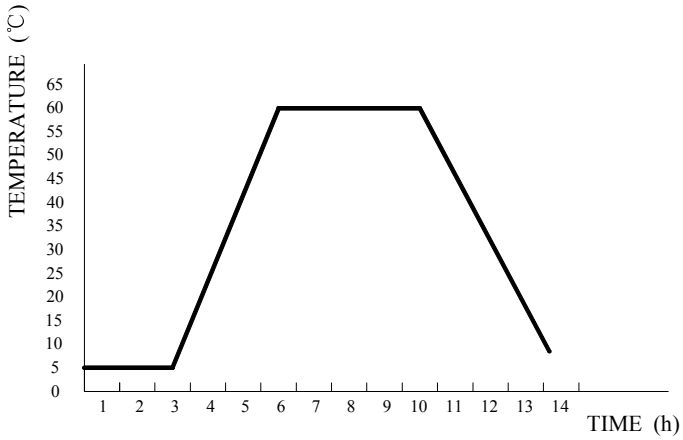

Fig. 3.1 Steam curing system

**The current situation and problems for the industrialized steam curing of composite wall panel**

Four problems have been summarized by reviewing the related literatures [1~5]and field survey of several prefabricated concrete factories in Shenyang:

(1) When the production is low, assembly line production mode is a waste time and energy, production efficiency is low, at this time, fixed horizontal curing kiln should be used, then the kiln in assembly line has been leaved unused.

(2) When the production is high, steam curing procedure is too slow comparing to other procedures, reduce the production efficiency.

(3) The technical study for the steam curing of composite wall panel is. few .The research in our country still stay at the end of last century. The research of pros and cons is not enough, curing monitor can be only determined only by experience.

(4) Some domestic manufacturers have just introduced dynamic model production lines, but automation level has been reduced because the research is so few. Cost has been increased for the long time of curing.

**Proposed scheme of Improved steam curing**

Considering the problems above, some suggestions for improving steam curing have been provided:

(1) Shorten the rest period to improve production efficiency: the rest time could be optimized by demoulding strength and strength and volume stability of 28 days curing after steam curing. the high the temperature is ,the shorter time the rest period is ,but there would always have a shortest rest period in different environment temperatures. Shenyang Yuhui factory uses the secondary curing to shorten the rest period, the products have been put into curing kiln in rest period time, which could help the products get the early strength in advance. And consequently shorten the rest period, practice has proved that time could be shorten by half.

(2)Adopting temperature-gradient method or variable speed temperature rise: most of the steam curing use one time heating up method, one time heating up method is a common method of steam curing .But the curing time is too long. Temperature-gradient method could make the concrete

strength increase gradually at low temperature ,until it could resist the damage caused by second phase fast heating-up, then temperature rise to constant temperature rapidly. This method could reduce the damage caused by heating up. It could also reduce the rest period, and curing time as well.

(3) Fixed horizontal curing kiln is the traditional production mode, which is discouraged by its resource utilization, huge waste of energy and resources. But since the fabricated structure of our country is in its initial stage. Component demand is not so much, the factory production is not stable, so this method has become safer mode of production. The curing equipments like vertical curing kiln and horizontal tunnel curing kiln have been put on hold even though they could save lots of time and energy. So it is necessary and meaningful develop a flexible production line which could not only make the most of curing equipment but also ignore the limit of the production.

## Conclusions

Based on the influence of steam curing on the strength of high performance concrete, durability and volume stability, put forward suggestions of steam curing system; Several problems have been raised for steam curing in the actual production, then some correlative improve measurements are given. The research of this article is to promote the industrialization of modern construction progress, which not only meet the demand of the national development strategy, but also is an inevitable choice for modern building industrial upgrading. Provide the theory support for the enterprise and the reference for national standards. And improve the quality of the fabricated composite wall panel, large-scale industrial production and labor productivity.

# Temperature cracks of concrete engineering analysis and treatment measures

GENG ZHANG

Department of civil engineering , Xinjiang Construction Vocational Technology Institute ,Urumqi 830026 ,China.

260021488@qq.com

**Keywords:** concrete temperature cracking temperature stress treatment measures.

**Abstract.** In the building construction project occupies an important position in the concrete , cracks appeared in the concrete work is more common , the cause of cracks in the concrete temperature control and crack prevention measures such as on-site concrete temperature were analyzed .

## Introduction

Concrete works , the temperature stress and temperature control is important. This is mainly due to two reasons . Concrete temperature cracks often appear in the construction , affect the integrity and durability of the structure . During operation , the temperature change has a significant impact on the stress can not be ignored state structure . We encountered mainly construction temperature cracks , this article on the causes and treatment measures in construction of concrete cracks were analyzed.

## Organization of the Text

### 1 Cause crack

There are several reasons for the concrete cracks , that the changes in temperature and humidity during hardening of the concrete release large cement hydration heat , the internal temperature rising to the surface due to tensile stress . Late in the cooling process , or due to constraints based on the old coagulation , will appear in the tensile stress in the concrete . Reduce the temperature of the concrete surface will cause a lot of tension stress . When these tensile stresses exceed the capacity of the concrete cracking , cracks will appear . Many internal concrete humidity changes or changes little slower , but larger changes or surface moisture may change dramatically . Such as conservation ill , when dry wet surface deformation constrained internal shrinkage of concrete, often leads to cracks. Concrete is a brittle material , the compressive strength of tensile strength 1/10 , ultimate tensile strain just short loading time (0.6 ~ 1.0) × 104, when the limit position of the long-term loading deformation extends only ( 1.2 ~ 2.0) × 104. Since the raw material is uneven, unstable water-cement ratio , and transportation and pouring during segregation , in the same piece of concrete tensile strength is uneven , there are many low tensile strength , easy cracks weak site. In concrete , the tensile stress is mainly borne by the reinforced concrete to withstand compressive stress only . In the plain concrete or reinforced concrete on the edge of the site if there is a tensile stress within the structure , the concrete shall rely on their own commitments. General design requirements in both the tensile stress does not occur or occurs only to a small tensile stress . But in the construction of the concrete by the maximum temperature is cooled to a stable temperature during operation , often causing considerable tensile stress in the concrete . Temperature stress can sometimes exceed other stresses caused by external loads , and therefore grasp the temperature variation of the stress is extremely important for the structural design and construction reasonable .

### 2 Analysis of temperature stress

According formation temperature stress can be divided into the following three phases:

( 1 ) Early : pouring concrete from the beginning to the end of basic heat cement , usually about 30 days . Two features of this stage , first emit a lot of heat of hydration of cement , the second is the

dramatic changes in coagulation and elastic modulus . Since the change in the elastic modulus , residual stress formed during this period in the concrete .

( 2 ) Interim: from basic cement exothermic effect until the end of the concrete when cooled to a stable temperature only, this time , the temperature stress is mainly due to cooling and external temperature changes caused by concrete , the stress and the early formation of residual stress superposition , little changed in the meantime on the elastic modulus of coagulation .

( 3 ) Late : Concrete completely cooled after operation period. Temperature stress is mainly caused by external temperature changes , these stresses and residual stress of the first two phases of superposition .

Depending on the cause of stress caused by temperature can be divided into two categories:

( 1 ) Stress of the : without any constraints or boundary structure completely still , if the internal temperature distribution is non-linear due to the structure itself bound to each other appears and temperature stress. For example , a bridge pier , the structure size is relatively large, while the concrete cooling surface temperature is low, the internal temperature is high, the surface tensile stress , compressive stress occurs in the middle.

( 2 ) stress constraints : all or part of the boundary of structures is outside the constraints are not free of stress caused by the deformation . As concrete box girder roof and concrete fence .

Both temperature and shrinkage of concrete stress is often caused by stress joint action .

**3 Measures to crack Temperature control and prevention**

To prevent cracks , reduce temperature stress can proceed from the constraints of controlling the temperature and improve two aspects .

Measures to control the temperature as follows:

( 1) Heavy unreinforced concrete or less muscle mass , the total does not exceed 20% admixture of large stones , reduce the amount of concrete in order to reduce the heat of hydration of cement and conservation purposes .

( 2 ) improving reinforcement . In order to ensure that the upper and lower layers are each pouring temperature tendons , the proposed design will be distributed tendons make the appropriate adjustments . Temperature distribution should be fine ribs , usually with ϕ 8 steel , bi- reinforcement , spacing 15 cm. Such temperatures can enhance the ability to resist stress .

( 3) The aggregate gradation improvement in mass concrete is generally used in grit or coarse sand , fineness modulus is generally about 2.3 to 3.0. Gravel particle size generally require the use of a continuous gradation of coarse aggregate to the preparation of concrete , should try to use a larger diameter well-graded gravel . With dry concrete , mixed mixes, plus air-entraining agent or plasticizing agent in concrete measures to reduce the amount of cement ; reduce the heat of hydration of cement and deformation , or use low heat of hydration heat of hydration of cement in concrete preparation such as slag cement , pozzolana Portland cement, fly ash cement , composite cement , etc.

( 4 ) when mixed with a certain amount of mixing fly ash concrete admixtures can replace part of the cement , concrete and can improve viscoplastic . Improve pumpability , reduced heat of hydration of concrete , improve late strength ; adding water or gravel with water cooling to reduce the temperature of the concrete pouring ;Decrease when pouring concrete

( 5 ) days of pouring hot thickness , the use of heat pouring level ;

( 6 ) pipes buried in concrete , pass into the cold water to cool ;

( 7 ) the conservation of mass concrete and the internal temperature is monitored to measure the surface temperature and the internal temperature of the concrete after pouring through technical measures for the temperature control requirements within the scope of the design , when the design is no specific requirement when temperature should not exceed 25 ℃. Set reasonable removal time , when temperatures plunged surface insulation , concrete surface in order to avoid the occurrence of sharp temperature gradient ;

( 8 ) the construction and long-term exposure to pouring concrete block surface or thin-walled structures , insulation measures taken during the cold season ;

Improvements constraints are:
( 1 ) reasonably parting block ;
( 2 ) to avoid excessive fluctuations basis ;
( 3 ) reasonable arrangements for the construction process , to avoid excessive height and lateral long-term exposure ;

In addition, to improve the performance of concrete , improving crack resistance and strengthen conservation , prevent surface shrinkage , particularly to ensure the quality of concrete is very important to prevent fractures , special attention should be avoided through the cracks appeared to be restored after its structural integrity it is very difficult , so the construction should be to prevent the occurrence of cracks penetrating dominated .

( 1 ) improve the constraints , reducing temperature stress . Stratified block or pouring concrete, a reasonable set of horizontal or vertical construction joints , or in the appropriate location set construction pouring belt to relax the constraints extent , reduce the length of the heat storage capacity of each pouring to prevent the accumulation of heat of hydration reduce temperature stress . Between massive concrete foundation and concrete cushion Heavy sliding layer settings , such as the use of flat- poured asphalt or paved membrane. In the vertical plane , keyway site set up buffer layer , such as the laying of asphalt after 30 ~ 50 mm polystyrene foam board or wood wool to remove embedded solid role in the release of restraint stress .

( 2 ) improve the ultimate tensile strength of concrete . Following the coarse aggregate with a good choice , and strictly control the clay content , strengthen vibrated concrete, concrete density and tensile strength , reduced shrinkage deformation , to ensure construction quality. Take the second feeding method , the second vibration method , and remove surface water after pouring , enhance early conservation , improve early age or the corresponding tensile strength and modulus of elasticity of concrete . The temperature setting is necessary on the basis of mass concrete reinforcement inside , the turning point in the cross section deformation and , at the end, the turning point of the roof and walls , holes and around the corner to increase the diagonal structure reinforcement to improve the stress concentration to prevent cracks .

In concrete construction , in order to increase turnover template , often require new cast concrete form removal as soon as possible . When the temperature is higher than the temperature of the concrete should give due consideration to the removal time , so as not to cause cracks in the concrete surface early . New cast early form removal , surface caused great tensile stress, a " thermal shock " phenomenon. In the early concrete pouring , because distributing heat of hydration , causing considerable surface tensile stress , when the surface temperature of the high temperature compared , then removal of the template , the surface temperature dips, would inevitably lead to a temperature gradient , resulting in an additional surface tensile stress , thermal stress superposition hydration plus concrete shrinkage , tensile stress surface a large value , there is a risk of cracks , but if the insulation material is promptly covered with a light at the surface after removal of the template , such as foam sponge , the concrete surface to prevent excessive tensile stress has a significant effect.

Reinforced stress has little effect on the temperature of mass concrete , because the rate of muscle mass concrete containing very low . Just reinforced concrete impact on the general . At a temperature below the yield stress is not too high and the limit conditions , the performance of steel is stable regardless of the state of stress , time and temperature. Linear expansion coefficient of linear expansion coefficient of steel and concrete difference is small, the internal stress between the two occur only small changes in temperature . Since the elastic modulus of the steel is 7 to 15 times the modulus of elasticity of concrete , when the stress reaches the tensile strength of the concrete cracking , steel stress will not exceed 100 ~ 200kg/cm2 ..... So , you want to use in concrete reinforced to prevent small cracks very difficult. But the cracks in the reinforced structure generally becomes more than the number of small spacing, width and depth of the smaller . And if the bar diameter thin and dense spacing , good crack resistance of concrete to enhance the effect . Surface of the concrete and reinforced concrete structures are often thin and shallow cracks occur , most are shrinkage cracks .

Although such cracks are generally shallow , but the strength and durability of its structure is still some impact.

To ensure the quality of concrete work to prevent cracking and improve the durability of concrete , proper use of admixtures is also one of the measures to reduce cracking . Use water-reducing agent, such as crack , practice, summed up its main role is to :

( 1 ) the presence of a large number of pores in the concrete road, the capillary force generated in the capillary after the evaporation of water , drying shrinkage of the concrete . Increasing the diameter of the pores can be reduced capillary surface tension , but will reduce the strength of concrete .

( 2 ) water-cement ratio is an important factor affecting concrete shrinkage , the use of water-reducing agents can crack the concrete to reduce water consumption by 25%.

Important factors

( 3 ) the amount of cement concrete shrinkage also doped water subtraction concrete cracking agent under conditions to maintain the strength of concrete can be reduced by 15 percent the amount of cement , aggregate usage by increasing its volume to add.

( 4 ) water-reducing agents can improve the cracking grout consistency and reduce bleeding of concrete , reduce shrinkage deformation sink .

( 5 ) improve adhesion grout and aggregate to improve the crack resistance of concrete .

( 6 ) to be bound by concrete shrinkage during tensile stress, the tensile stress when the crack is generated is greater than the tensile strength of concrete . Water-reducing agent can effectively improve the cracking of the concrete tensile strength, a substantial increase in crack resistance of concrete.

( 7 ) allows the mixing of concrete admixtures dense , and can effectively improve the anti-carbonation of concrete, reducing carbonation shrinkage .

(8 ) mixed with water reducing agent for concrete crack retarding the appropriate time in the effective prevention on the basis of cement hydration heat quickly , avoid plastic shrinkage due to cement long-term non-condensable brought increased.

( 9 ) mixed with good workability of concrete admixtures , easy to touch the flat surface , the formation of micro- film to reduce water evaporation , reduce drying shrinkage .

Many retarding admixtures have increased workability, improve the function of plasticity in engineering practice should be more research into the experimental comparison and , simply by improving external conditions , may be more simple than the economy.

## 4 Early concrete curing

Practice has proved that the common concrete cracks , most of surface cracks at different depths , mainly due to the temperature gradient caused by the sudden drop in temperature in cold areas also easy to form cracks. So, to say the insulation on the concrete surface to prevent early cracks especially important.

From the viewpoint of temperature stress , thermal insulation should meet the following requirements:

( 1 ) prevent the temperature difference between the inside and outside of concrete and concrete surface gradient , to prevent surface cracks.

( 2 ) prevent the concrete super cold , should try to try to make the construction period of not less than the minimum temperature of the concrete using a stable temperature of the concrete .

( 3 ) to prevent the old concrete too cold to reduce the constraints between old and new concrete .

Early curing of concrete , the main purpose is to maintain proper temperature and humidity conditions in order to achieve the effect of two aspects, one of the concrete from adverse temperature and humidity deformation of the invasion, prevent harmful shrinkage and shrinkage . On the one hand the cement hydration smoothly to achieve strength and crack resistance design.

Optimum temperature and humidity conditions are interrelated . Coagulation on insulation measures often have the effect of moisture .

Theoretically, the water contained in the newly poured concrete fully meet the requirements of more than cement hydration . However, due to evaporation and other factors often cause water loss ,

delay or interfere with cement hydration , the easiest and the concrete surface directly affected by such adverse effects . So the first few days after concrete pouring conservation is a critical period in the construction must pay attention to . You can take specific measures to deal with :

( 1 ) According to the plan layout , check the temperature before pouring the concrete situation and prevent damage to the point of laying pouring the facility , and to establish an initial value measurement points . Before the initial setting of concrete , the implementation of secondary bleeding treatment , overcoming early due to cracks caused by dehydration , and the amount of water covering film , the insulation measures and implement .

( 2 ) According to Shi group requirements, strict measures to check the insulation of concrete implementation . Concrete pouring process and the conservation period, the concrete should be closely monitored during temperature changes . Since when pouring from 1 ~ 7 d, measured every 1 h time ; Section 8 ~ 14 d, measured every 4 h. Control temperature difference of concrete, when the temperature difference exceeds 25 ℃ should supervise the construction side to further strengthen the implementation of insulation measures

( 3 ) large volume concrete is generally less than 7 d, the strength of concrete block and concrete conservation center of the plate according to the same conditions of temperature change and determine the curing cycle. Curing Concrete should heat, moisture and technical measures to cool slowly , usually when pouring in thickness greater than 3 m, requires consideration of measures to cool the cooling water circulation inside the concrete, set the cooling water , and through the concrete temperature measurement and control center the temperature inside the concrete surface or the cooling water temperature is controlled within 25 ℃.

## 5 Conclusion

The above construction of the relationship between the temperature of the concrete and the cracks were on the theory and practice of preliminary study , although the causes of academia and calculation methods for concrete cracks have different theories , but for specific advice for prevention and improvement measures is relatively uniform , while applying the effect in practice is relatively good , concrete construction is up to us seeing much comparative , multi- analysis problems, and more summary , combined with a variety of preventive treatment measures, concrete cracks are completely avoidable.

**Key words:**energy efficiency, heat balance equation, cold attic, roof covering, icicle, ice-dam.

The following article deals with the problem of icicles formation on the roofs and the elimination methods. The attic roofs with pitched roofing are highly susceptible to this negative phenomenon.

In work warming of garret overlappings as a method of prevention of formationice-dams on roofs of buildings in the operation, being characterized is in detail considered by the lowest temperatures of external air.

## Introduction

The last winters were remembered not only with mass snowfalls butwithnumerous victims of icicles. Every wintermany people suffer from the icicles falling from roofs. According to Agency of medico-social information on February 26-28, 2010 in St. Petersburg 56 people suffered from iciclesin only three days. Thus it is limited not onlyto physical injuries. People get to hospitals, remain disabled people, lethal outcomeoccur. Besides, falling of icicles does also material harm. The icicles fall commonly enough on the cars parked near buildings. Moreoverformation of icicles causesdestruction of eaves and drainpipes. Ice in the frozen drain blocks outflow of thawed snow, thawed snow can leak on walls, under a roof and in rooms, yielding more considerable damages [1].

Most often icicles are formed on acting sites of a facade of the building on eaves, balcony peaks, roof edges. At necessary for process of formation of an icicle conditions, in one days its weight can considerably will increase. The weight of some icicles can reach 300 kg, and length more than a meter. Icicles can be broken off and fall down, damaging everything that meets to them on a way.For obvious reasons, the problem of the formation of ice dams is relevant.

If the gravity operating on an icicle, as a result of growth of its weight exceeds strength of ice in a point of the beginning of growth, the icicle will collapse. At the termination of intake of thawed snow growth of an icicle stops, and at a temperature over zero there is a reduction of the sizes and mass of an icicle due to thawing.

At a roof with a small bias it is rather difficult to avoid formation of frost on it at various options of external conditions.

## The overview

Petrichenko M.R. in works proposed procedure that makes it possible to assign the rate of drop in water level in the upper pool, which eliminates failure of earthen structures [20-21]. Petrichenko M.R in works [22-23] offered to replace the traditional Dupuis formula by the condition of the minimum of the functional reflecting the average quadratic norm of the departure of the curvilinear profile of the free surface from a straight line.

Petrichenko M.R. revealed that successful plotting of the depression curve for the plane problem of filtration in homogeneous soils can solve many engineering problems of hydrotechnical construction while organizing surface drawdown, or maintaining a difference in the levels of a filtering embankment. In solving this problem, it is important to have a representation of the actual position of the depression surface to evaluate the stability of soil masses subject to filtration action. Determination of the position of the depression curve is based on use of Dupee's hypothesis for average filtration rate, and integral formulas for the flow rate through a homogeneous soil mass. It is readily demonstrated that the equation of nonuniform motion is a required condition of the minimum for F(h) (in uniform motion, F(h) = 0). Dupee's depression curve has minimum length and maximum free-surface gradient [24-25].

Petrichenko M.R. derived an energy-balance equation for an integral flow with a variable flow rate over a particular length. The equation was applied to the confluence of flows [27-28]. Unsteady heat and mass transfer in combustion chambers of internal combustion (primarily Diesel) engines are analyzed and experimental data are reviewed. A stable correlation is found to exist between the instantaneous local heat transfer coefficients and the thermal resistance of the pseudolaminar boundary layer on the chamber wall. Other governing factors are also analyzed [29]. Petrichenko M.R presented [30-31] an algorithm for the problem of flame propagation rate in combustion of a homogeneous fuel-air mixture in the cylinder of an internal combustion engine. It is assumed that the mixture is not 'overturbulized' and that the flame front is spherical. The model used for the phenomenon is based on a turbulent transport mechanism. In the near-wall region the combustion mechanism follows a fine-scale mechanism, but in the core, a large-scale mechanism. Experiments permitted determination of the character and numerical value of coefficients which consider the effect of turbulence on flame front propagation in the combustion chamber of a ZMZ-4021 engine. The principles presented can be used as the basis of an algorithm for heat liberation rate in an internal combustion engine with external mixture formation.

Possibilities of utilizing quasi-stationary techniques in calculating flows through exhaust ducts of internal combustion engines have been discussed in some studies [32] with two major assumptions entertained: gas parameters obey laws and relations prevailing in fully stationary flow, in circumstances of quasi-stationary flow, and pressure remains the same throughout the entire volume of the internal combustion engine system at any fixed instant of time. An approximation analysis is conducted.

The paper [33] discusses problems concerning the formation of an oil film in the clearance between a piston ring and the internal combustion engine cylinder liner. An expression is derived for the lift force of the piston ring. The variation of the lift force with piston speed and the speed of the radial movement of the ring is shown. The results of calculation of oil film thickness under the sealing piston ring in 1ChN16/17 type diesel engines are presented.

The purpose of work [34] is to obtain a description of the fluctuation for component of the induced difference of the scalar potential in transducers of correlation flowmeters and to refine the limits of the inductionless approximation and possibilities of meeting the requirements imposed on transducers.

Gorshkov A.S., Vatin N.I.,Urustimov A.I. and Rymkevich P.P. in the scientific work consider the reason of formation of icicles on roofs of buildings.Insufficient thermal insulation and lack of appropriate ventilation of a garret cause heating of a roofing covering to above-zero temperature and snow fusion above a dam while temperature on a roofing plumb remains lower than zero [38].

New experimental data are presented [35] on nonstationary and transient operating conditions of closed liquid metal loops with MHD pumps. The investigations were made by utilizing the automated system of experiment staging, ″control system - experiment″. It is shown that the type of the transient process as well as the type of external characteristics of pumps are determined by the magnitude of the system drag coefficient. Characteristic ranges of flowrate and pressure pulsations, both as regards the amplitude and frequency of transient processes as well as the nonlinear effects connected with the startup of high-capacity pumps in a liquid metal loop, are noted.

The measurement of volumetric flow rate of a liquid-metal heat transfer agent in heat transfer loops is a serious technical problem, which may be solved by applying correlation methods of measurement. The object of the present study is to derive an equation describing the change in the space-time correlation functions of the velocity fluctuation components on increasing the spatial separation and to solve this equation for a well-developed turbulent flow of a conducting liquid with axisymmetric mean velocity profile [36-37].

**Method of controlling ice dams on the roof**

The most widespread way of fight against icicles in the Russian Federation is a manual mechanical removal of frost by means of shovels [1], that is industrial climbers come and start forcing down icicles from a roof simply. Naturally, all this creates certain problems for people: sidewalks and that people weren't run over by cars are blocked, bypassing the blocked foot zones, isblocked also part of the road. One more minus of such way of fight against icicles: the high cost of services of industrial climbers - municipal services try to save on them.

Recently try to force down icicles and by means of the pneumatic weapon. But this way doesn't look very reliable.

One more method of fight is a removal of icicles by ultrasound. This method is based on formation in the special device of a powerful ultrasonic impulse which influences the formed icicles and bringing to destruction and the subsequent controlled falling of icicles on a sidewalk surface. At the described method there is a lot of shortcomings. Most important - the big initial cost of system on 1 running meter of the protected eaves, reaching 200 Euros.

The method of cable heating is based on protection of a surface of a roof and a drain, by heating, by means of a special heatallocating (heating) electrocable. Necessary parts of a roof and drain are warmed - where the congestion of snow, formation of ice and icicles is possible. The positive side at such decision doesn't raise doubts: on a roof and a drain icicles and noticeable quantities of ice that protects both a roof, and a drain from any damages aren't formed and guarantees long service of modern roofs.

The main lack of such anti-freezing system, the realizing method of cable heating is the considerable cost of a heating cable and control units and big consumed electric power that demands noticeable costs of payment of the electric power [3].

Having carried out the short review of existing ways of fight against icicles, it is possible to draw a conclusion that the problem needs be not to solved, and to warn [4-7, 16-18].

**The formation of ice dams**

It is widely known that ice is formed of water at a temperature less than zero degrees Celsius. Snow on roofs thaws even in the coldest weather because of heat getting from an attic and from solar radiation. Water flows down to the roof edge where, contacting to the cold surface blown by air, freezes [2]. All snow which has thawed on a roof at the subzero temperature of external air turns into ice on eaves and gutters as on these sites of a roof heat from the house doesn't arrive. On formation of ice on a roof, icicles, such factors, as the steepness of a slope and her roughness influence. If the slope corner (depending on a roughness) more than 40 - 60 degrees, at snowfall snow cover on a roof isn't formed [11,14].

The thermal stream arriving through a roof at the expense of heat conductivity and an infiltration, is spent for heating of snow cover. In certain cases it is enough this thermal stream for melting (thawing) of snow on a surface of a roof and formation of water. At ambient temperature fall the part of a liquid phase hardens and ice is formed. Receipt of warmth from a surface of a roof leads to that the two-phase system the water ice divided by a contact surface is formed.

Process stylization the such. Let the axis x>0be directed from the roof having temperature of $T_h$, surpassing temperature of melting ($T_h$>273K). The area x>0consists of two parts divided by the contact x0 plane. In area x<x0 environment temperatureT is more than temperature of phase transition $T_0$ ($T>T_0$), is more right than the contact plane, in area $x>x_0$, temperature of the

environment is lower than temperature of phase transition. In other words, there is a hot phase (water)more to the left of the contact plane, there is a cold phase (ice)more to the right of the contact plane. Phases are divided by the contact plane. On the plane of contact there is a spasmodic change of phases,water turns into ice on an interval of zero length. Actually, of course, transformation of phases happens on some set of the values x filling the eutectic niche; otherwise, there is a vicinity of a point of $x_0$, ($x_0$-δ, $x_0$+δ)in which both phases, liquid and firm, water and ice, are in a condition of thermodynamic balance.

Let:

1. Temperature in section x>0 is equal to $T_h$ and remains not less $T_0$ in between $0<x<x_0$, i.e. $T=T_h>T_0$
2. Heat diffusivity coefficient on an interval $0<x<x_0$ is equal to $a_h$,on an interval $x> x_0$ is equal to $a_c$.
3. For water (approximately): $a_h=5*10\text{-}7m^2/s$; for ice (approximately): $ac=10\text{-}7m^2/s$. In any case $a_h>a_c$.

Then:

1. Temperature distribution in the space occupied by mix of water and ice has an appearance:

$$T = T_h erfc\left(\frac{x}{2\sqrt{a_h t}}\right), 0 < x < x_0;$$

$$T_0 = T_h erfc\left(\frac{x_0}{2\sqrt{a_h t}}\right); \quad (1)$$

$$T = T_0 erfc\left(\frac{x - x_0}{2\sqrt{a_c t}}\right), x_0 < x < \infty;$$

2. Length of the eutectic niche is:

$$2\delta = \frac{x_0}{2}\left(\frac{1}{\sqrt{a_c t}} - \frac{1}{\sqrt{a_h t}}\right) \underset{t\to\infty}{\to} 0 \quad (2)$$

3. Speed of movement of the contact $x=x_0$ plane dividing water and ice is equal:

$$c := \frac{dx_0}{dt} = \frac{x_0}{2t} \quad (3)$$

4. Then the instant provision of a contact surface is equal:

$$x_0 = x_0^{'} \ln\sqrt{\frac{t}{t_0^{'}}} \quad (4)$$

$x_0^{'}$ – initial values of coordinate

$t_0^{'}$ – initial values of time

5. The stop of a contact surface occurs when the thermal stream extending from a surface of a roof in area x>0, is insufficient for ice melting. Otherwise, the thermal stream going from water, on a surface of contact has to surpass a thermal stream in ice.
   Density of a thermal stream is more left than the contact plane is:

$$\dot{q_h}(x_0 - 0, t) = T_h\sqrt{\frac{\lambda_h \rho_h C_h t}{\pi}} \exp\left(-\frac{x_0^2}{4a_c t}\right) \quad (5)$$

λ, ρ, c -heat conductivity coefficient, density and a water thermal capacity.

Density of a thermal stream is more right than a contact surface is:

$$\dot{q}_c(x_0+0,t)=T_0\sqrt{\frac{\lambda_c\rho_c C_c t}{\pi}} \tag{6}$$

If thermal streams on both sides of contact coincide, movement of a contact surface stops. Otherwise, approximately:

$$\frac{T_h}{T_0}=\sqrt{\frac{\lambda_c\rho_c C_c}{\lambda_h\rho_h C_h}}>1 \tag{7}$$

Also, one of the defining factors influencing education in the winter of icicles on roofs and eaves are parameters of heattechnical properties of a roof (warming), and also ventilation of subroofing space [7].

This method of fight against frost on roofs was taken as a basis by specialists of the St. Petersburg polytechnical university, City Service and PAROC Group management company. The warming of garret overlappings which is conducted by means of new technology - inflatable cotton wool (Figure 1) was offered. Inflatable cotton wool, first of all, is specially intended for thermal insulation of overlappings and hard-to-reach spots. Use of inflatable cotton wool is the alternative solution of isolation of subroofing space. Installation of this material requires the special equipment - the vozudokhoduvny car. Of carrying out such works is result seamless, Thermotechnical a uniform layer of a heater of the subroofing space, providing preservation of a necessary difference of temperatures no more than 2 degrees between temperatures in and outside of an attic. Both the frost, and icicles for lack of temperature differences aren't formed [12].

Fig. 1. Inflatable cotton wool.

The necessary component of the described constructive decision is a wind-shelter design which isolates connection between an external wall and a ceiling beam from external air and provides ventilation in garret space.

It turns out that the roof is better warmed, the smaller thermal stream resembles through it, therefore, snow on it thaws in smaller quantity. Thus the thick snow cover on a roof is some kind of heater. The thermal insulation of a roof is better made and the snow layer is thinner, the at smaller subzero temperature thawing of snow [13] will stop.

Such improvement of warming of a roof not only saves heat and energy resources, but also reduces quantity of being formed ice on eaves and drains of a roof [15]. The organization of ventilation of subroofing space external air gives more considerable effect. The ventilation is better, the it is more effect. In this case, the roofing carpet is cooled with cold external air, and snow thawing on a roof doesn't happen.

The cost of processing of garret overlapping on this technology will cost 820 rubles for 1 sq.m.

Now works on renovation of subroofing spaces on four buildings are carried already out, all is up to the end planned to warm garret overlappings of six more houses of old construction. The total area of the warmed subroofing space will make eight thousand square meters. During the whole heating period for an independent expert assessment of a heater of PAROC complex monitoring

will be carried out. It includes visual research of a condition of garrets, determination of the actual heat conductivity of a heater, measurement of temperature and humidity of air in rooms, an assessment of technical condition of a roof, rafter system and garret overlappings, and also photofixing and thermovision inspection [12].

**Key words:** high-rise buildings; construction technology; safety management

**Abstract.** The construction of high-rise building has a lot of features such as large capital investments, narrow operation face and long construction period. This puts forward higher requirements for technology. Characteristics of high-rise building construction, the construction quality controlling and construction safety managements were analyzed in this paper.

With the rapid development of high-rise buildings, the construction engineering structure becomes a variety, increasing scale and gradually towards the direction of building exterior complication and difficulty in construction of large comprehensive development. Aiming at these phenomena in this paper, the related high-rise building construction technology was analyzed and explored.

## High-rise Building Construction Characteristics

(1) High-rise building construction period is long, layer number of buildings, the work high above the more, the construction difficulty is high, the big workload and complicated technology. As a result, the vertical transport, high safety, fire prevention, communications, water, and the processing of construction waste problems become one of the characteristics of the high-rise building construction [1].

(2) In order to ensure the overall stability of high-rise building construction, needs to be buried deep under the ground 5 m, a layer or two layers of building construction, in improving the reliability of the foundation at the same time can be auxiliary equipment layer and the garage, etc.

(3) High-rise building construction period is generally long, the huge manpower, material consumption, seasonal span construction is inevitable, the staff and the engineering quality put forward higher requirements.

(4) High-rise building construction land tensions, surrounding environment is complex, in order to ensure the normal conduct of engineering equipment, the proper use of the material, need to arrange the site temporary facility engineering, as far as possible reduce the storage in the high-rise building construction materials, equipment, make full use of the goods and prefabricated components and semi-finished materials.

## High-rise Building Construction Quality Control

(1) To control the construction scheme in the high-rise building. If the construction scheme is not appropriate, will be prone to the safety of the foundation pit collapse accident. Once foundation pit depth more than 5 m, it must please have rich experience and professional knowledge of the expert group to carry on the deep foundation pit project demonstration, only through expert argumentation support plan to continue to organize the construction[2].

(2) The quality of the high-rise building need accurate measurement and elaborates construction. The measurement is the most crucial parts of the high-rise building is the building axis, elevation, verticality control, and the accuracy of the measurement data will directly affect the quality of the whole building construction, must go through strict measurement for many times.

(3) High-rise buildings appear cracks in construction process; the corresponding control measures must be taken. Construction in the high-rise building concrete amount is larger, the intensity is high, the concrete crack needs to prevent in advance. For new pouring concrete, it is necessary to control the component moisture curing, avoid surface moisture to evaporate quickly, make the internal force is too large, lead to cracking. For water after concrete internal temperature difference to control within the 20 ℃, avoid the ambassador from the internal cracking of concrete temperature difference.

## High-rise Building Construction Technology

### 3.1 Deep foundation construction technology

Deep foundation construction technology is the building structure, one of one of the most important technology in the construction, and the construction technology is more complex, easy to cause the construction of key parts of the accident. So in the construction should be very specific, ensure construction safety.

**(1)** In details for the whole process of foundation construction engineering should limit detection and analysis, and puts forward some corresponding solutions. To vigorously promote the information construction, a lot of specific construction example can prove that, for the construction quality and safety is a very effective and necessary protection methods and means is to analysis the whole process of deep foundation construction and monitoring.

**(2)** About how to solve the problem of groundwater, to take reasonable method. According to the different situations, such as: the state of groundwater, depth, and soil of different take different approaches. More commonly used the method of lowering groundwater has deep well, Ming set face, adopt the method of single stage and multistage or injection well point, so that it can effectively prevent groundwater impact on infrastructure construction and the foundation pit. Also need to be aware of is that when the groundwater is abundant, precipitation impeded relatively difficult time should adopt the corresponding cutoff appropriate measures to form a water curtain.

**(3)** For foundation pit supporting structure, should according to the natural conditions and the conditions of the equipment management. Such as environment, geology, hydrology, takes a different approach. Inverse arch wall, soil nail wall, such as the underground continuous wall, pile, etc., at the time of application should be combined with the basement of the relevant situation, try to reduce the cost of investment. For the soil body around, want to further on the soil of the foundation pit, should take deep mixing method, grouting, compaction, so that you can prevent the soil slope instability caused by the collapse accident.

### 3.2 The transformation layer construction technology

Engineering structure construction when need to make some decorate, contrary to common building stiffness is used in upper class need larger shear wall, and the lower stiffness to switch to smaller frame column. Want to realize such the structure of the way, you need in the arrangement of the transformation layer structure floors.

**(1)** Template support system construction. The main purpose of the high-rise building conversion layers is used to convert the fluctuation of the load of high-rise building and balance. Its construction is very complex and difficult. In order to ensure the construction of high-rise building structure. Need to choose a suitable template support system, it can be a supporting system for the

load transfer method or one-time molding supporting system, can also be combined with casting method supporting system, etc. Specific support system to choose or according to the scene of the construction environment and construction characteristic to the appropriate configuration. In the template configuration and support system design. First of all have to draw a diagram. To the construction of relevant personnel of detailed interpretation of the template construction process, support, disassembling and arrangement method, etc. In counting parts and template site, it is forbidden to use inferior and does not conform to the provisions of the fittings and template, fundamentally guarantee the mould and the quality of the material[3].

**(2)** Transformation layer of steel construction. In order to ensure the transformation layer construction quality, in the construction of the transformation layer reinforced materials to make a turn, accurate, this request must be careful about design idea, documents and relevant regulations. Also, accurate arranged reinforcement in place the order. Transformation layer reinforced joint is generally arranged in taper thread connections or cold pressing sleeve and flash butt welding, and to solve the problem of the rotation of the elbow reinforcement, generally adopt the method of nipple. Because transformation layer for the construction of the need to install a large amount of reinforcement and big diameter, beam-column node. Steel bar colligation and in place of the difficulty is bigger, so under the reinforced material must be conducted in strict accordance with the order of the row of reinforcement, thus reduced the difficulty of the steel binding and in place, and guarantee the construction quality of steel. In the reserve reinforced positioning control to ensure that in the transformation layer section is greater than the reserve of steel reserve the accuracy of the reinforcement. Ensure floor pay-off shear wall in the positioning line and control line, girder projection line and control line are released. Ensure that all reserved inserted reinforcement layout construction has carried out in strict accordance with the design standards. After final review on measuring accurate, will provide fixed on the original steel reinforcement.

### 3.3 Concrete construction technology

**(1)** High-rise building construction concrete consumption is big, should try to use ready-mixed concrete and pump concrete.

**(2)** Rainfall distribution on 10-12 in areas such as the high strength concrete is suitable for high-rise building bottom column, but unfavorable use should be paid attention to in the construction of high strength concrete, lest cause shrinkage.

**(3)** After concrete pouring should be timely maintenance, especially pay attention to not ignore the concrete wall, column and other body parts vertical concrete. To choose water should be developed according to the season and the engineering characteristics, steam, composite heat storage, electric heating, curing methods, such as film and cover and other insulation materials.

**(4)** Standard layer of floor slab concrete structures of tall building, the strength level of the beam are generally consistent, and the strength level of the plate and beam intensity lower than that in column, and bottom-up gradually reduced, thus node intensity difference exists, is not conducive to the construction operation, so effective measures should be taken to ensure the construction quality.

**(5)** Post-cast strip shall be proposed by the design unit of pouring time and location, and consult with the contractor; The early appropriate chooses of post-cast strip, compensating shrinkage concrete pouring. Before pouring concrete, clean up the surface of post-cast strip, after casting also covers maintenance should be carried out on the surface.

### High-rise Building Construction Safety Management

Too much attention to the construction enterprises improve product quality, improve the economic benefit, often ignored the security problems in site construction, for enterprise's quality department should give full play to its functions, Ann is content with professional safety knowledge, with administrative reward, laws and regulations as the means, comprehensively enhance the safety awareness of construction personnel, constantly improve the self safety of construction personnel.

Must not blindly pursue the progress of the construction process, construction speed should be safe as guarantee, construction before and want to do a good job of supervision and management in the construction process, and to find potential safety hazard in time and exclusion, establish the safe production responsibility system, perfect the security system.

## Conclusion

High-rise building with the constant development of the socialist modernization has become the important symbol of urbanization today, the structure of the high-rise building and high-rise building construction process of an important component of the construction process, to people's production and the work has a very important influence, so the construction technology of high-rise building engineering construction structure becomes very meaningful.

# Research on the characteristics and status of recycled concrete filled steel tube

Bing Wang [1, a], Xiao Liu[1, b], Xiao Yu[1,c]

[1]School of Architectural and Civil Engineering, Shenyang University, Shenyang, 110044, China

[a]liuxiao19740701@sina.com, [b]489298344@qq.com , [c]283292935@qq.com

**Keywords:** Concrete filled steel tube, Recycled concrete, High temperature resistant.

**Abstract.** Utilization of waste concrete has a great significance for environmental protection; concrete filled steel tube is a way of utilization of waste concrete. At the same time, the recycled concrete on the center tube has a "hoop" function, can compensate for the deviation of mechanical properties of recycled aggregate concrete. This paper introduces the characteristics of steel recycled concrete, and introduces the research status of domestic experts and scholars on it, based on the above; the future application of the recycled concrete in steel pipe is presented.

## The characteristics of steel tube filled with recycled concrete

The mechanical properties of recycled concrete compared with ordinary concrete fell and variability increased mostly are used for non-structural system of road. In order to make better use of recycled concrete, some scholars from the view of combined structure the recycled concrete is poured into the steel tube concrete formed steel tube filled with recycled concrete, the use of the function of ferrule(constraint) of steel tube for the core of recycled concrete so that the core of recycled concrete in the state of pressured from three direction to improve recycled concrete compressive strength and resistance to deformation, and the core concrete can enhance the stability of steel tube so that the mechanical properties of recycled concrete are improved, and the mechanical advantage of steel and concrete to play their respective, provides an important way for the resource utilization of waste concrete. The steel tube recycled concrete as a new type of structural members, the present research about this aspect is still in the immature stage.

The steel tube recycled concrete is a composite material which be formed by filling recycled concrete into the pipe, it can give full play to the existing advantages of steel tube filled with concrete, and give a solution to the enormous pressure that waste concrete to ecological environment, also, for the material of recycled concrete , because it has very good high temperature performance, its mechanical properties are rarely influenced by temperature, the increase of temperature did not significantly decrease the mechanical properties, the properties that make up the shortcomings of low resistance to fire performance of steel, which makes the high temperature for steel recycled concrete applied to concrete filled steel tubular structure, and for the application of recycled concrete provided broad prospects in structural engineering. Therefore, research on steel pipe concrete attached importance by more and more countries（As show Figure1.

Fig.1 The engineering examples of steel tube filled with recycled concrete

**High temperature resistant performance of steel tube filled with recycled concrete**

In the disasters that people faced, fire is the one which has highest frequency of occurrence and the largest span of time and space. In all sorts of disaster, fire is the most often and common one of the main disasters threatening public safety and social development. Fire damage to buildings is very large, steel reinforced concrete structure at the time of the fire, because the concrete protective layer thickness is small, resulting in a fire occurs, the high temperature will through concrete protective layer to affect the internal reinforced steel. Experiments show that, when the temperature exceeds 300 ℃, steel will lost the ability to load. At the same time, concrete under certain temperature will decompose into lime and carbon dioxide which not have adhesive force, causing the floors collapsed, the building suffered catastrophic destruction. According to the statistics, since twenty-first Century, the building fire accounted for about 80% of the total number of fire. For example: the evening of 9 February 2009 21 am, in the construction of the CCTV new site park and cultural center catastrophic fires, building fire, smoke over an area 21,333 square meters, of which 8,490 square meters burned area, causing direct economic losses of 16383 million (Figure 2a);At 14:00 on November 15, 2010, a high-rise apartment Shanghai Jiaozhou Road, Yuyao Road caught fire, the fire led to 58 people were killed (Figure 2b).

(a)

(b)

Fig.2 Building fires occur

With the development of modern architecture, people's requirement of function structure form are increasing, the ground structure to the large span, tall and complex forms of development, to the development of multilayer three-dimensional underground structure. When the column at a higher axial pressure, if adopt to ordinary concrete column, the column cross-sectional dimension must be designed bigger. And with the increase of column section size, will not only take up the use of the

building space, but also the formation of small shear span ratio of the short column, easy to cause the brittle failure, it is not allowed to exist in the design; If use the steel structure, cross section area of the column member although diminished, but the member under pressure, the member's overall buckling and local buckling often precede the section strength and failure, and fire resistance performance is poor. For example, the 911 terrorist attacks on the United States is due to the steel used, resulting in a fire when the temperature exceeds the fire resistance of steel, resulting in huge economic losses and casualties.

Steel tube concrete structure due to the absorption of recycled concrete has strong ability, at high temperatures, the ductility and strength decreased, but due to buckling, internal core concrete filled steel tube can effectively delay the steel under high temperature. Therefore, steel tube concrete structure at the time of the fire is better compared with the fire resistant performance of ordinary reinforced concrete structure and the fine steel structure.

**Research Status of steel tube filled with recycled concrete**

The sit-ting room is the family activity center with large area, and suitable for placing big plant in the corner or the sofa, generally in large foliage plants, and beside the window, we can place four season flowers, or hang the small plants on the wall as the decoration. But place too many plants, otherwise it will appear to be too vulgar to be endured.

Hallways and other room area is lesser, and is suitable to place some small plant, or hang plants in the space for decoration. We should take the plants of general room concentrated in a corner or the place in our sight. If we feel a bit monotonous, we can consider that divide them into one or two groups to decorate.

In addition, in the current structure of the bedroom, it inevitably exists concave and convex, so that, we'd better use plant green decorative to remedy or have a balance. If we plant ivy on the surface of the column, we can get poetic sentiment.

**Considering the position of the view line**

From the beginning of the last century, the world gradually began working on steel tube filled with recycled concrete after high temperature regeneration; China also began to study the relevant aspects of strength. Domestic and foreign researchers have mechanical properties of recycled concrete and recycled concrete members conducted in-depth research, but also began to reinforced concrete structures or components manufactured from recycled concrete research, but because of the performance limitations of waste concrete itself, is currently recycled concrete in the actual project is also largely confined backfill and other non-structural forces or by the use of a smaller force, the application of recycled concrete is on relatively low levels. In order to make concrete waste be more reasonable used, in recent years, our country scholars at home and abroad research and application is still in the model of initial stages of combined the concrete filled steel tube structure and the utilization of recycled concrete. The study has the following several aspects:

He Dong, Qiu Cichang, Wang Qingyuan [1]analyzed the whole process of load-deformation curve of steel tube filled with recycled concrete on the different substitution ratio when it under axial compression, and done the experimental study, got the load of steel tube concrete under axial compression deformation curve and the load changing trend, the numerical results are in good agreement with the experimental results.

Ye Xin, Yang Youfu [2]studied on the steel tube concrete flexural members, and studied the 4 square steel tube concrete member and the 4 steel tubes for pure bending test of recycled concrete member, observe and analyze the failure modes and mechanical properties, take the calculation method of fiber model to verify the test results, the results show that: steel tube filled with recycled concrete bending members with similar mechanical properties of common concrete filled steel tube, steel tube filled with recycled concrete pure bending stiffness and flexural capacity decrease with recycled concrete replacement rate increase.

Li Weining, Xu Jinjun, Chen Zongping [3]studied the interface bond slip performance of steel tube filled with recycled concrete, designed 10 square steel tube concrete specimens, by changing the three parameters of testing rate, concrete strength grade and buried depth of substituted recycled concrete, got the load slip curves between recycled concrete filled square steel core and interface, and analyzes the ultimate bond strength and bond strength of sliding effects parameters, results show that: load slip curve is divided into non slip stage, stress rising stage, mutation and decline phases four stages, the bond strength by the substitution rate of the minimum, the embedded length of time is least, the influence of concrete strength is maximum.

Hou Rui[4] has studied the constant high temperature steel mechanical properties of recycled concrete columns of the shaft , test design 40 different temperature, different sizes of aggregate replacement ratio, different cross sections specimens, and analysis of the constant high temperature steel recycled concrete axial compressive failure mode, the interaction between the section and working mechanism the stress distribution and the core concrete and the steel tube with ABAQUS, studied the factors influencing coefficient of compressive strength and elastic modulus of the influence factors, and put forward the constant high temperature steel simplified recycled concrete axial compression bearing capacity and modulus of elasticity formula.

## The prospect of steel tube filled with recycled concrete

Existing research results show that steel tube filled with recycled concrete has similar mechanical properties with steel pipe concrete, which not only has the common advantages with concrete filled steel tube, but also has some unique advantages: the fire resistance performance of recycled concrete is better than ordinary concrete, which helps to improve the recycled concrete as the core concrete of concrete filled steel tubular members durability. Steel tube concrete member having good ductility and the later bearing capacity, good mechanical properties, is a kind of structure form which is more promising. The steel tube recycled concrete can achieve waste resources' reuse, save natural resources, conducive to the Protect environment, its ecological significance is important.

**Keywords:**Mass concrete,Temperature crack,Shrinkage crack,Countermeasures

**Abstract.** Combined with practical engineering，this paper analyzes the mechanism of mass concrete temperature and shrinkage cracks, from raw material selection, structure design, construction, monitoring and management five aspects,the author respectively gives the countermeasures on temperature and shrinkage crack of mass concrete, reference for engineers.

## Introduction

As built object shape is increasing, the corresponding structural scantlings is bound to increase.For concrete structure, when the volume of a component or larger area to produce larger temperature stress in the reinforced concrete structure and components, such as not to take special measures to reduce the temperature stress is bound to lead to concrete cracking.The cracking of the temperature is not simple construction method, also involves structural design, structural design, material selection, material composition, constraint condition and the construction environment, and many other factors. The current industry standard JGJ55-2000" the mix proportion design of ordinary concrete regulation"is defined as:" concrete structure entity minimal size is equal to or greater than 1 m, or is expected to be caused by cement hydration heat of concrete internal and external temperature difference is too large and cause of concrete crack."

## The Causes of Cracks

The section size of large mass concrete structure, the possibility of cracks caused by external load is small, but in the hydration reaction of cement hydration heat release a large amount, due to the large volume, not easy to heat, causing significant temperature rise, leading to increased volume.When the deformation is not constrained, won't produce stress of concrete structure.But in fact the deformation would be constrained, there are two kinds of constraints.One is external constraint, and the other is the internal constraints.Concrete pouring on rocks or on old concrete, its volume change will be bound by external rocks and old concrete, due to cement early hydration heat up sharply, volume expansion, under pressure, but because of the concrete elastic modulus is low, the compressive stress is very small;Heat coming from the later period of cement hydration heat is reduced, greater than the hydration heat, the temperature is reduced, the volume contraction, are in bondage to the rock and concrete by into tensile state of stress, so the concrete elastic modulus increased large tensile stress is produced.Internal constraints are caused by the heat of hydration of cement produced inside the concrete is not easy to send out, the surface is easy to send out, so the surface temperature is lower than the interior., in contrast, the expansion of the internal volume by surface constraints in compression state, the surface of the volume contraction (especially the temperature drop or water) by the internal constraints, tensile stress is produced.Because concrete is a brittle material, low tensile strength, ultimate tensile strain is small (less than $1 \times 10^{-4}$).When the deformation temperature, deformation is restrained its internal cause tensile stress is very easy to exceed the ultimate tensile strength and cracks.

**The Countermeasures on Crack of Mass Concrete**

**Material selection**

**Using low heat of hydration of cement.**Because of the different size of mineral composition and admixture of cement hydration heat differences.Tricalcium aluminate and silicate high calcium content, high hydration heat;Admixture of cement hydration heat is low.So choose low hydration heat or in the concrete hydration heat of cement varieties, such as slag Portland cement, fly ash cement, composite cement, etc.Unfavorable use early strength cement.

**Reduce the dosage of cement and the amount of water.**Cement hydration heat temperature changes of mass concrete is the primary sources of lead to volume change.Wet and chemical change will cause the volume change, but are usually far less than the volume change produced by the hydration heat of cement.Except by hydration heat low thermal cement, therefore, to reduce the temperature deformation, there should be one thousand to reduce the dosage of cement, reduce the dosage of the water.According to the test every 10 kg of cement, reduce the hydration heat will make the temperature of the concrete corresponding lift 1 ℃.This requires:

- On the premise of meet the structural safety, try to reduce the strength of the design requirements.
- Mixed with fly ash.The heat of hydration of the fly ash is much less than the cement, 7 days is about 1/3 of the cement, 28 days is about half of the cement.Reduce the dosage of cement mixed with fly ash can effectively reduce the hydration heat.The strength of the mass concrete usually require lower, allowed to take part in more fly ash.In addition, small water demand of high quality fly ash, water reducing effect, can reduce the unit water use of concrete and cement dosage;Can also reduce the volume shrinkage of concrete, some still a slight expansion, is beneficial to crack.Mixing fly ash can restrain alkali - aggregate reaction and prevent the resulting cracks.
- The mixed water reducing agent.Mixing water reducing agent can effectively reduce the unit water use of concrete, thus reducing the cement dosage.Retarded type water reducing agent and inhibitory effect of cement hydration, can reduce the hydration temperature rise, is beneficial to crack.Adding of mass concrete is mainly calcium lignosulphonate water reducing agent, which has obvious dispersion effect of cement particles, can effectively increase the liquidity of concrete mixture, and can make the cement hydration is fully, improve the strength of the concrete.If the concrete strength unchanged, can save 10% of cement, which can reduce the hydration heat, can obviously delay the hydration heat release rate at the same time, heat peak also corresponding delay.

**Using micro expansive cement.**Using micro expansive concrete, the purpose of expansion is when the temperature and shrinkage of concrete, shrinkage compensation, to prevent the cracks.But currently using micro expansive cement, most early, the concrete expand on heating and cooling has been expanding when finished, also started to shrink, can only make up of compressive stress increases slightly, the effect of shrinkage compensation.So you should use the expansion of the late

**The linear expansion coefficient of the aggregate.**Concrete is composed of cement paste and aggregate, the linear expansion coefficient of linear expansion coefficient for cement paste and aggregate of the weighted average (volume) of the concrete.The coefficient of cement slurry is 11 ~ 16 x $10^{-6}$ / □;The linear expansion coefficient of aggregate depending on the type of parent rock.The linear expansion coefficient of different rocks difference is very big.Aggregate volume accounted for more than 75% in mass concrete, the linear expansion coefficient of aggregate on the reduction of concrete linear expansion coefficient, and the function of decreasing temperature deformation is very significant.

**Strengthen the structure design**

To prevent the mass concrete temperature crack, in improving the boundary constraint and structural design, also can take some technical measures.Such as reasonable poured subsection, setting sliding layer, the reasonable configuration of reinforced, buffer layer, avoid stress concentration, etc.

**The measures to eliminate external constraint**

- Rock can spread a thin layer of sand gravel;
- On the old concrete paving asphalt linoleum, usually with a blanket a oil practice;

- Side of rock or the old concrete, can be separated with asphalt felt.

**Reasonable configuration of reinforced.**Set up necessary temperature reinforcement in the concrete, the variable cross-section and the turning point, such as turning point and the hole bottom, the roof and wall corner, etc., add diagonal structure reinforcement, in order to improve stress concentration.

**Adopting reasonable construction method**

**In low temperature season, at low temperature of casting.**In addition to the cement hydration temperature rise, the temperature of the concrete itself is the cause of volume change.Conditional should try to avoid casting in the summer.If they can't do that, you should avoid in high temperature at noon pouring.

**Reduce the concrete temperature.**When mixing concrete mixing water can be added in ice (can reduce 3 ~ 4 ℃) and cooling aggregate (can reduce more than 10 ℃).Within the structure of buried pipes, through the low temperature water cooling, cooling of high efficiency, small cold energy loss.Casting piece not too thick, can be used on the surface of water cooling, also has a good effect.

**Surface heat insulation protection.**Crack of mass concrete, especially the surface crack, mainly due to the large temperature difference between inside and outside.After casting, the cement hydration temperature rise of concrete, the surface easy to cooling temperature is low, internal cooling temperature is higher, not easily relatively surface shrinkage internal expansion, surface shrinkage is governed by internal tensile stress is produced.But the tensile stress is small, usually not more than concrete tensile strength and cracks.Only encounter cold air attacks at the same time, or excessive ventilation, cooling or water cooling the surface when the fracture occurs (5 ~ 20 days after casting) most likely to happen.Surface heat insulation protection to prevent surface cooling is too large, reduce the temperature difference between inside and outside, is the effective measures to crack.

**Control the concrete into the mold temperature.**In order to reduce the total mass concrete temperature rise, reduce the temperature difference between inside and outside structure, coagulation of mould temperature control measures is very important.People die temperature, closely related to the temperature of the machine, also with the number of transport, the distance, transport, construction of climate related.About the concrete into the mold temperature control, all countries have clear rules.Our country should be no more than 25 ℃, the United States ACI construction manual regulation is less than 32 ℃, Japanese architectural society reinforced concrete construction regulations in mud is not more than 35 ℃.According to the experience of the engineering practice in our country, it is recommended that the coagulation on the highest one mould temperature should be controlled below 32 ℃.

**Slow cooling rate of concrete.**After mass concrete casting, enhance its surface heat preservation, moisture curing, plays an important role in prevent concrete cracks.The effect of heat preservation and maintenance has three: first reduce the coagulation on the temperature difference between inside and outside, to prevent surface crack;The second is to prevent the concrete surface is too cold, avoid to produce cracks, the third is the slow cooling rate on the coagulation, to cut new and old concrete on the lower level constraints.Moisture curing can reduce the drying shrinkage on the coagulation, makes a concrete cement hydration smoothly, to improve the ultimate tensile strength on the coagulation, has positive effect to control cracks.Insulation materials commonly used wood pattern, sack, sawdust, dry sand, etc.After the final set of concrete, adopts the water storage curing is a very good method, not only has the effect of heat preservation and heat insulation, but also can delay the coagulation and the cooling rate, reduce the center and surface of the concrete temperature difference value.

**After setting up reasonable pouring belt**

Using the method of "latter pouring belt", the concrete structure is divided into several segments, concrete pouring concrete of the reoccupy after 30 ~ 40 d closed. "Latter pouring belt" is the construction design, during the period of temporary temperature and shrinkage deformation cracks, it can effectively reduce the temperature stress and shrinkage stress on the coagulation.Under normal construction conditions, space between "latter pouring belt" is generally 20 ~ 30 m, width is about 0.5

~ 1.0 m.In structure stress concentration areas, appropriate and anti-crack reinforcement to make local enhancement processing, in must be horizontal construction joint position of the section construction, increasing the number of dark beam to prevent crack propagation.

**To strengthen the construction monitoring work**

The mass concrete temperature monitoring is an important technical measures, it helps to grasp the situation, timely and accurate provide scientific basis for handling measures.Monitor the temperature inside the concrete, concrete temperature measurement is commonly used in data recorder, it attached to printing system, each measuring point temperature can be printed on the record paper, can also direct reading.According to the temperature of each measuring point. Can be timely to map the concrete internal temperature change curve, control concrete theoretical calculation value, analysis of existing problems, and targeted to the corresponding technical measures are taken.

**An engineering example**

A three layers of the earth, the underground engineering, construction area of 17968.26 m2, foundation slab length 84.5 m, 53.4 m wide, 1.8 m thick, C30 concrete strength grade, permeability grade for the S8, mass concrete.In the engineering construction in the central floor, setting post-cast strip width 1 m, concrete grade, C35 mixed UEA expansive admixture, wet curing 20 days before casting.The structure of post-cast strip as shown in figure 1.

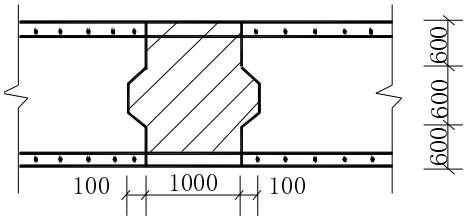

Fig.1 The Structure diagram of latter pouring belt

In order to ensure the concrete strength and integrity to meet the design requirements, try to reduce the dosage of cement, reduce caused by cement hydration heat of concrete temperature difference between inside and outside.Reduce secrete water in the process of concrete pouring and curing shrinkage, reduce the external restraint degree to prevent cracks, determine the strength grade 52.5 Portland cement, adding fly ash ( Ⅱ type) and micro expansive agent UEA double mixing of concrete technology.Adopted in construction are described in this article the method of strengthening temperature monitoring, not present any floor cracks and leakage.

## Conclusions

Above all, to prevent the cracks of mass concrete, one of the key: use the cement of low hydration heat, reduce the dosage of cement, as far as possible choose small linear expansion coefficient of aggregate, adopting reasonable construction method, good cooling and surface heat insulation protection, eliminate or reduce the external constraints, improve the concrete tensile ability.

**Key words:** foundation reinforcement, soft soil, composite foundation

**Abstract.** Soft soil's properties including low bearing capacity and large deformation leads to the necessity of reinforcement of foundation when it is made of soft soil. This article illustrates the features and applications of different methods, through the comparison of them.

## Project Profile

Soft soil foundation has remarkable structural, rheological, properties as well as high compressibility, low shear strength, low permeability and low bearing capacity. It also has a very long duration before the completely consolidation under the self-weight of soil layer or external load. It is unqualified to bear large building load without any extra processing, or there will be a risk of local shearing and whole sliding and even possible large building settlement or differential settlement. For the long time consumed before the stabilization of settlement—several years or even tens of years on thick soft soil, the deformation and stabilization requirements cannot be satisfied, so the reinforcement processing is indispensable. We choose different programs depending on the difference of the conditions of engineering, geological conditions of foundation or composition of soil. Generally, perfect foundation processing method does not exist. We have to act appropriately to the situation to ensure the realization of the processing. [1]

## Methods

## Compacting

**CFG pile method.** CFG piles and cement-flyash-stone piles, through hydrated reaction of cement and pozzolanic reaction of fly ash, or can help gravel pile to replace and reinforce the foundation by compacting, so that the consolidation is achieved. The pozzolanic reaction mechanism is like the following. [2]

$$XCa(OH)_2 + SiO_2 mH_2O = xCaOSiO_2 nH_2O$$

In the chemical equation, x is the kind of composite material and lime, the proportion of active silicon oxide, environment temperature and the duration of reaction. The settled gravel pile reinforcement is a good drainage channel, which also bears the loads together with the soil, forming a composite foundation.

CFG pile composite foundation improves the bearing capacity of composite foundation by the combined action of CFG piles and adjacent soil. Its strength and compression modulus are relatively even, which is beneficial to the superstructure considering stress and structure seismic. Flexible cushions can also be put between CFG piles and foundation, which artificially meets the condition for piles to penetrate into the cushions from the top, and the cushions can to a certain degree compensate the differential settlement of foundation. In this way, the problem of relative deformation can be adjusted or even solved so that effective contact stress of adjacent soil is increased and the shear strength and bearing capacity of piles are improved.

**Sand-gravel pile compacting.** This method reinforces the foundation in two ways: compacting and replacement. Compacting is to place sand-gravel piles into the foundation so the foundation soil is compacted during the formation of the piles, and the adjacent soil and piles form a composite foundation. Replacement is to replace foundation soil by the same volume of large-diameter, compacted sand-gravel piles, so that the piles and adjacent soil form a composite foundation, and then bear the upper load together, increasing the bearing capacity and stability of soil. It also helps the drainage and its consolidation works well, so it is widely applied.

## Preloading

It can be achieved by surcharge loading or vacuum preloading. Surcharge preloading is to stack the raw materials on the foundation in the purpose of preloading consolidation, in which the strength of foundation is improved. It properly suits the area with convenient transportation and abundant raw materials. Surcharge preloading leads to positive pore stress. The preloading effect goes better when the soil permeability coefficient in the reinforcement region is larger. The processing details are as followings. Pave a $50cm$-thick sand cushion on the surface of foundation to be reinforced. The cushion will act as horizontal drains. Then let sand wicks or plastic drainage boards squeeze into soil body to be vertical drains. Pave airproof thin films on the cushion above the soft soil to be reinforced. Keep the edges of the films buried into the soil. Get the soil under the film exhausted to vacuum with the help of the pipelines buried in the cushion. The vacuum soil is extended downward through plastic drainage boards so the plastic drainage reaches a level of vacuum, which spreads through sand pores so that a vacuum gradient occurs. Then the pore water goes out through sand well and plastic boards, which leads to consolidation. The decreasing of $u$ will increase $\sigma'$ to achieve the consolidation.

$$\sigma' = \sigma - u$$

where $\sigma'$ — the effective stress of soil particles, （$kPa$）

$\sigma$ — the total stress of soil , （$kPa$）

$u$ — the pore water pressure （$kPa$）.

During reinforcing the soft foundation of expressway, surcharge and vacuum preloading can be combined, which is called surcharge-vacuum combined preloading. We can shorten the construction duration by using roadbed filled soil as load. Then we can take the advantage of both and solve the problems of earth filling speed caused by the surcharge method and ultimate load caused by vacuum method.

## Chemical Reinforcement

**Deep stirring.** Its mechanic is to stir the mixture of cement and saturated soft soil, which caused the hydrolysis and hydration reactions of cement, and then a stable structural integrity occurs. The hydrolysis and hydration reactions strengthen the cement soil. The local stirring and mixing of solidified agent and origin foundation soil utilize the origin soil to the maximum. The side extrusion force upon adjacent soil and soil outside the piles is low during stirring, so there is hardly any effect toward the buildings around. Meanwhile, there is no vibration, noise and pollution, so execution downtown or in an area of high building density is acceptable. Other advantages are like the flexibility of design and low cost.

**Vibroflotation.** It is economical but time consuming, so not appropriate for time-limited projects. We can either wet or dry vibroflotation. The wet one is to pound the soil by water pressure, leading to the rearrangement of soil particles so the number of pores reduces and the compacting is realized. At this point, fill crushed stones into the pounded holes to form a composite foundation, which improves the bearing capacity. The dry one is not feasible downtown because a large amount of slurry comes out during the execution of vibroflotation, which will pollute the environment. So it does not suits projects downtown.

**High pressure jet grouting.** This method is suitable for soft soil layer, such as the alluvial layer and eluvium layer of Quaternary Period. It widely suits different kind of conditions and is easy to execute. We can also control the shape of consolidation. Both vertical and oblique jetting are available. It asks for simple equipment, easy management and low cost but supplies high durability so is a good choice of permanent projects. We drill injection pile, which has a jet, into a predetermined depth of the soil layer with the help of drilling machine. Then spray the mud or water out of the jet with a pressure of $20-40kPa$, producing a squirt flow to destruct the soil layer. A proportion of tiny particles emit out to the ground with the mud, while other soil particles mix with the mud and rearrange, forming a composite foundation. This method is applied in sandy soil, cohesive soil, loess and mucky soil.

**Dynamic compaction.** The properties are simple equipment requirement, easy processing, favorable strengthening effect, wide application, low operation stuff request, fast execution, low cost and no consumption of cement or steel. The foundation bearing capacity will take a 1-5 times increase and the reinforced depth is generally $5-10$ meter. The shortages are drastic vibration, noise so it's hard to be used in the high-building-density area downtown. Dynamic compaction asks for strictly control of some construction parameters such as cushion thickness, tamping potential energy. It also has a high demand for the geological conditions of the area to be reinforced, which determines the depth. And this method works well for floury soil and sandy soil.

Dynamic compaction replacement can be used to process deep thick soft soil foundations, which is a new foundation replacement method developed from dynamic compaction reinforcement in the recent years. Both pile replacement and integral replacement are available. We fill in crushed stones and dynamic compact simultaneously so we get crushed stone piers in the foundation, which, together with soil and crushed stone cushion, forms a composite foundation and bears the upper load so the foundation settlement is reduced and the bearing capacity is increased. The mechanic is like follows. When the soft soil is compacted, the space for organic matter decomposition in the soil is compressed and gas goes outward, causing instantaneous deformation of soil and pore water pressure increase. Under the repetitive impact force, local liquidations take place in the foundation and the soil structure is destroyed when the pore water pressure approaches the adjacent soil overburden pressure. At the same time, the compacting-caused shock wave spreads in the soil and rearranges the stress in the soil. When the tensile pressure at a point in the soil surpassed the tensile strength, there will be a crack as well as a change of the permeability of soil. Afterward the pore water overflows and the soil consolidates continually. As the consolidation going, pore water pressure decreases and thixotropic phenomenon is under control.

## Conclusions

**The combination of reinforcement methods.** We have plenty of methods, but none is omnipotent and everyone has its own application scope and limitations. We should combine some of them when necessary, in order to get the expected result.

In the reinforcement project of the podium foundation of Shanghai Yang Guang Ming Di, six columns along the same vertical axis between the 2nd and the 6th layer of the podium were removed for the request of utilization, resulting in shortage of pile foundation bearing capacity. What's more, the foundation soil mainly consisted of cohesive soil, silt soil and sandy soil so it was difficult to deal with the underground water. A method of grouted bolts and static pressing steel pipe piles, combining the theories of grouting and pile foundation, was applied. In detail, there were three solid-drawn steel pipe piles under each column, and after pressing the piles, injection pipes are inserted for grouting. A combined bond between solidified body and piles, foundation and baseboard was constructed. It worked well and saved money and time. [3] A seven-floor brick-concrete residential building in Qinhuangdao, whose ground floor was 0.15 meters above outdoor floor due to the high underground water level, consumes much money because the precast pile must be into peddle bed 1.2-1.5 meters. The situation was not ideal even after reinforcing the saturated silt soil by dynamic compacting: there was not an enough increase in bearing capacity

after the processing, the compacting effective depth was small and the foundation soil showed obvious discreteness. Vibroflotation of gravel piles was also suitable on account of long duration, difficulties in pollution discharging and high cost. Then the solution became dynamic compacting of gravel piles, which overcame the shortages of dynamic compacting and the high cost and long duration of grouting pile and vibroflotaion pile. Eventually, the bearing capacity of composite foundation significantly went up.

**Applications of new materials.** Based on the origin method, we can also change the construction equipment or use new materials. The engineering geological condition of the run way of an airport is like follows. The upper part was sandy silt with good permeability and high strength, while the substratum was mucky soil which was waterproof and had low strength. The constructors used plastic drainage board surcharge preloading method, setting deep drainage board to remarkably improve the drainage condition of the substratum. It was able to meet the designed consolidate requirement timely so the settlement problems of the run way was thoroughly solved. [4] Though it spent more money and time than dynamic compacting, the implement was simpler, easier more widely available. The demand of geological condition of area to be reinforced was loose as well. The plastic drainage board surcharge preloading method worked well in reinforcing, especially for the soft layer in substratum, in which the residual settlement after processing was effectively controlled. So the execution was well-off with a satisfying result.

# Bending Resistance of a Slender Plate Girder With Longitudinal Stiffener

Stefan I. Gutiu[1, a*], Catalin Moga[2,b]

[1,2] Faculty of Civil Engineering, Technical University of Cluj-Napoca, 400020, Romania

[a]stefan.gutiu@infra.utcluj.ro, [b]catalin.moga@dst.utcluj.ro

**Keywords:** slender plate girder, stiffener rigidity, bending resistance, Eurocode 3

**Abstract.** This paper presents an analysis regarding the bending resistance of a slender plate girder having a longitudinal stiffener in the compression zone of the web.The influence of the longitudinal stiffener rigidity on the bending resistance of a slender girder of Class 4 section is analyzed, starting from the hypothesis that the transversal stiffeners are infinitely rigid.

## Introduction

Steel plate girders having the webs made by thin plates which are of Class 4 sections are frequently utilized in steel structures because they are economically efficient.

Because some part of the web is buckled when the limit stresses are reached, this zone becomes ineffective but it remains important with regard to the girder rigidity. By disposing one or more longitudinal stiffeners the girder web will be divided in sub panels of a lower section class so that the ineffective zones can be diminished or eliminated.

In this paper we carry out a comparative analysis regarding the bending resistance of a Class 4 steel plate girder: of a girder without longitudinal stiffener versus the same girder with a longitudinal stiffener of different compression stiffness. A simplified method to evaluate the girder bending resistance, useful in pre-design is proposed.

## Theoretical Basis. Simplified Method to Evaluate Bending Resistance of a Stiffened Girder

According to [1] and [2] the resistance to pure bending of a steel plate girder is determined as: $M_{c.Rd} = (W_{eff.min} f_y)/\gamma_{M0}$ (for class 4 cross sections) or $M_{c.Rd} = (W_{el.min}\sigma_{lim})/\gamma_{M0}$ (for stress limits). Stress $\sigma_{lim}$ is the limiting stress of the weakest part of the cross section in compression.

In case of a stiffened web with one longitudinal stiffener located in the compression zone, Figure 1, this stiffener is considered a strut supported on an elastic foundation.

For the calculation of $A_{s\ell}$ and $I_{s\ell}$ the gross cross section of the column should be taken as the gross area of the stiffener and adjacent parts of the plate. For the stress distribution, as shown in Figure 1.b, the "column" cross section is given in Figure 1.c.

The elastic critical buckling plate of the stiffener can be calculated as follows:

$$\sigma_{cr.s\ell} = \begin{cases} \dfrac{1.05\ E}{A_{s\ell}} \dfrac{\sqrt{I_{s\ell}\ t^3\ b}}{b_1\ b_2} & -\text{if } a \geq a_c = 4.33\ \sqrt[4]{\dfrac{I_{s\ell}\ b_1^2\ b_2^2}{t^3\ b}} \\ \dfrac{\pi^2 E\ I_{s\ell}}{A_{s\ell}\ a^2} + \dfrac{E\ t^3 b\ a^2}{4\pi^2\left(1-\upsilon^2\right)A_{s\ell}\ b_1^2\ b_2^2} & -\text{if } a < a_c = 4.33\ \sqrt[4]{\dfrac{I_{s\ell}\ b_1^2\ b_2^2}{t^3\ b}} \end{cases} \quad (1)$$

The elastic critical force of the longitudinal stiffener is:

$$N_{cr} = \sigma_{cr.s\ell} \cdot A_{s\ell} \quad (2)$$

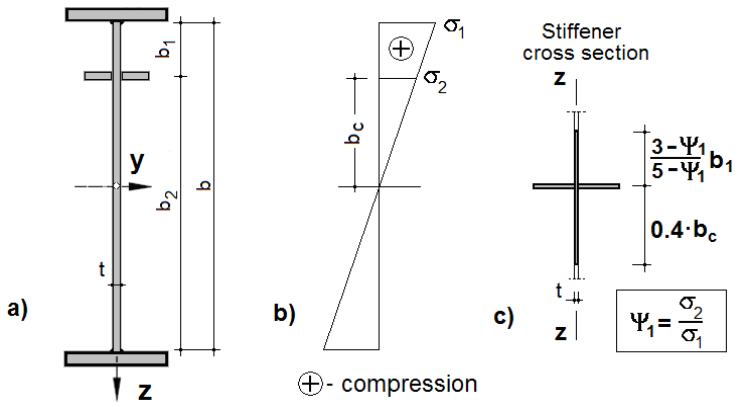

Figure 1. Girder with longitudinal stiffener

An accurate calculation regarding the bending resistance of the stiffened girder should be made as specified in [3], §4.5 and Annex A, by taking into account the interaction between plate and column buckling to evaluate the stress limit. For the girder pre-design a simplified design method is proposed as follows:

1. Knowing the critical force $N_{cr}$, the compression buckling resistance of the longitudinal stiffener can be determined:

$$N_{c.Rd} = \chi \cdot \frac{A_{s\ell.eff} \cdot f_y}{\gamma_{M1}}, \quad \text{where}: \ \chi = \chi\left(\bar{\lambda}_c = \sqrt{\frac{A_{s\ell.eff} \cdot f_y}{N_{cr.s\ell}}}\right) \tag{3}$$

2. The bending resistance of the girder can be approximately evaluated with the following relations:
   Upper subpanel Class 1 or Class 2:

$$M^r_{c.Rd} = \chi \cdot M_{c.Rd} \tag{4.a}$$

   Upper subpanel Class 3 or Class 4:

$$M^r_{c.Rd} = \begin{cases} M_{c.Rd} & -\text{if}: \Psi_1 \le \chi \\ K \cdot M_{c.Rd} & -\text{if}: \Psi_1 > \chi \end{cases} \tag{4.b}$$

where: - $M_{c.Rd}$ is the bending girder resistance considering that the stiffener is perfectly rigid;

- K is a reduction coefficient determined in such a way that the stresses $\chi \cdot f_y$ (Figure 2) should not be exceeded in the stiffener area: $K = f_y^{/} / f_y = \chi / \Psi_1$.

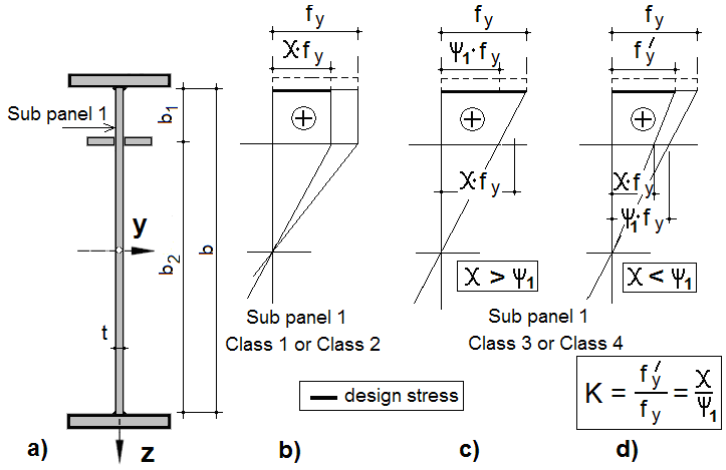

Figure 2. The reduction factor K

**Analysis example**

A comparative analysis regarding the pure bending resistance of a plate girder with a longitudinal stiffener located in the compression zone of the web is performed in this worked example. The following cases are subject to analysis: Case 1 - Girder without stiffener; Case 2 - Girder with a very rigid longitudinal stiffener in the compression zone; Case 3 - Girder with a flexible longitudinal stiffener; the stiffener is not considered as active part of the girder cross section; Case 4 - Girder with a flexible longitudinal stiffener; the stiffener is considered as active part of the girder cross section; Case 5 - Girder is working in the elasto – plastic domain.

**Design data:** Girder cross-section: web 2600x12 mm, flanges 650x30 mm; the girder stiffeners are at the distance of 2500 mm and have sufficient stiffness to create nodal lines for the buckled web; steel S355 for all girder elements.

The synthesis of the comparative analysis is presented in Table 1 & Table 2.

Table 1. Case 1 & Case 2 – Effective Cross Sections and Girder Bending Resistance

| **Case 1**. Girder without stiffener | **Case 2**: Girder with a very rigid longitudinal stiffener in the compression zone |
|---|---|
|  |  |
| $M_{c.Rd} = 20\,054$ kNm | $M_{c.Rd} = 22\,090$ kN · m |

Table 2. Case 3 & Case 4 – Effective Cross Sections and Girder Bending Resistance

| **Case 3**: Girder with a flexible longitudinal stiffener; the stiffener is not considered an active part of the girder cross section | **Case 4**: Girder with a flexible longitudinal stiffener; the stiffener is considered an active part of the girder cross section |
|---|---|
|  |  |
| $M_{c.Rd} = 22\,090$ kN · m | $M_{c.Rd} = 22\,386$ kN · m |

**Case 5**: Girder is working in the elasto – plastic domain

If two or more longitudinal stiffeners will be used, the girder cross section will be of Class 2 or of Class 1 and the girder bending resistance is:

$$M_{c.Rd} = (W_{pl} \cdot f_y) / \gamma_{M0} = 25\,404 \text{ kN} \cdot \text{m}$$

## Conclusions and Final Remarks

Steel plate girders having the webs made by thin plates which are of Class 4 sections are frequently utilized in steel structures because they are economically efficient.

Because some part of the web is buckled when the limit stresses are reached, this zone is ineffective but it is still important in what concerns the girder rigidity.

By disposing a longitudinal stiffener, the girder web is divided in two sub panels and thus the ineffective zones can be diminished or eliminated.

The increase of the girder bending resistance is more significant if the longitudinal stiffener is considered as an active part of the girder cross section.

In Table 3 the analysis results are centralized.

Table 3. Analysis results

| Case | Girder Type | Bending Resistance $M_{c.Rd}$ [kN · m] | Efficiency Factor $C = \frac{M_{c.Rd}}{M_{c.Rd}^{gr.w.stiffener}}$ |
|---|---|---|---|
| **1** | Girder without stiffener | 20 054 | 1.00 |
| **2** | Girder with a very rigid longitudinal stiffener in the compression zone | 22 090 | 1.10 |
| **3** | Girder with a flexible longitudinal stiffener; the stiffener is not considered an active part of the girder cross section | 22 090 | 1.10 |
| **4** | Girder with a flexible longitudinal stiffener; the stiffener is considered an active part of the girder cross section | 22 386 | 1.12 |
| **5** | Girder is working in the elasto – plastic domain | 25 404 | 1.27 |

# Processing status and utilization of construction waste in China and the West

Fengjun Liu[1, a], Feifei Suo[1,b]

[1] School of Civil Engineering, Henan University of Science&Technology, 471023, Henan Luoyang, P.R.China

[a]lfjhaust@163.com , [b]prettysophie@sina.com

**Keywords**: Construction waste, Resource utilization, Processing status

**Abstract.** With the rapid development of economy and urbanization, more and more construction waste is produced. The construction waste consumes lots of space and pollutes the environment. Therefore，how to deal with it well is attracted more and more attention and research. The legal system and the treatment processes for construction waste resource utilization between china and the west are compared. Furthermore, considering the fact that a few deficiencies appear in construction waste resource utilization in china, some pertinent suggestions are put forward.

## Introduction

With the rapid development of economy and urbanization, construction waste is hard to avoid. According to their generation source, construction waste can be divided into building and demolition construction waste. As its name implies, building waste, is solid waste produced in building, rebuilding or expansion projects. Demolition waste generates thanks to demolished buildings, or met irresistible factors (such as volcanic eruptions, earthquakes, floods, war, etc.). Construction waste, a misplaced resource, not only takes up a lot of spaces but also pollutes the environment. The construction waste resource utilization is a method to solve this thorny problem which must be taken into account. Although there are several differences between China and the West, the purpose of the construction waste resource utilization is the same.

## Technology and Legal System in China and Abroad

The construction waste recycling starts earlier in the United States and forms a set of system in aspects of related policies and practical applications. In 1980, the *Superfund Law* was made. It stipulated: “Any company producing industrial waste must properly handle it by themselves, and is not allowed to freely dump industrial waste” [1]. In 1965, the *Solid Waste Disposal Act* was enacted. Information disclosure, reporting, resource recycling, regeneration demonstrations, technology development, recycling standards, economic stimulus and the use of priority, occupational protection, civil litigation and other solid waste recycling policies were included in this act. After several revisions, the laws and regulations related to construction waste in the United States have been gradually improved.

Germany is the first country in the world to carry out the circular economic legislation. Germany has developed several laws and regulations such as the *Waste Disposal Law, the circular economy and waste disposal law* and so on, to deal with construction waste since 1978. [1]. Compared with other countries, the legislation is rigorous in Germany, which is conformity with its reality.

After the Second World War, due to the support of the United States and other western countries, Japan's economy developed rapidly. But Japan, as an island country, saw the contradiction between economic development and land resources had been becoming increasingly prominent. As a result, the construction waste management started in the late 1960s. The corresponding laws, regulations, policies and measures to promote the transformation and utilization of construction waste were formulated, which included *Recycled Aggregate and Recycled Concrete Norms*, *Recycling Law*, *Building Recycling Law*, *Construction Materials Recycling Law*, *Green Purchasing Law* [1].

In China, the construction waste management is based on the *Urban Construction Waste Management Regulations* promulgated by the Ministry of Construction. The regulation came into effect in June 1, 2005, which required any individual or organization was not allowed to dump and bury building waste at random.

At present, the domestic legislation system is not perfect in China. Experiences about the related laws, regulations and management could be learned from the western countries, which results in fewer detours. Moreover, a large amount of construction waste would be avoided, and negative effects on the environment would be reduced.

## Construction Waste Treatment Technology in China and Abroad

**Foreign Technology in Construction Waste Management.** American construction waste utilization can be divided into three levels [1] [2]. Low-level utilization, for example, on-site sorting using and general backfilling, accounts for 50% ~ 60% of construction waste. Intermediate utilization is accounting for about 40% of construction waste. For example, base materials of buildings and roads, which is processed into aggregates by treatment plants, and then made into a variety of building bricks and so on. High-level utilization is little, a typical example of which is construction waste could be reduced into cement and asphalt.

Germany is the first country in the world to implement environmental labeling. Each region has a large comprehensive construction waste reprocessing plant. In Berlin there are more than 20 plants [2]. The technique of using construction waste to reforge recycled aggregate is leading the way in the world. The comprehensive and advanced production technology is formed due to long-term practice, continuous improvement and support of the corresponding mechanical equipments.

Fig.1 shows that the construction waste treatment process is widely used in developed countries [3].

Japan has already built a number of construction waste processing plants. Construction waste recycled products are eventually accepted by the market, which ascribes to a long period of production operations, continuous improvement of production processes and equipment. Currently, the basic ideas of construction waste in Japan are the same with Germany. However, the unique features in the treatment of construction waste are that its each step has a higher degree of refinement, and the device is more advanced. Its process equipments include the conventional separation equipment, electromagnetic separation equipment, fuel rotary separation equipment, incombustibles sorting equipment and other advanced equipment [1].

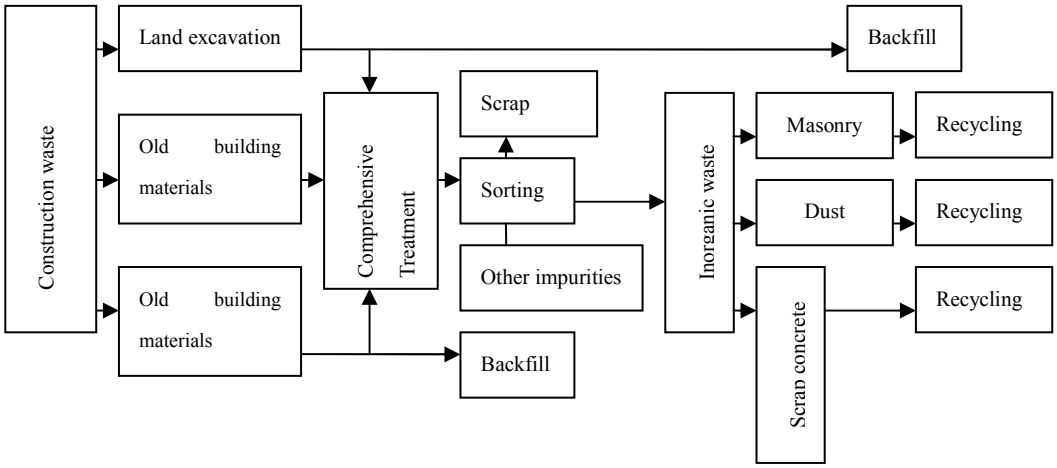

**Fig.1 Construction waste treatment process widely used in developed countries**

**Construction Waste Treatment Technology in China.** Waste building concrete and bricks could be made into new coarse and fine aggregate, which could be used to produce such products of the corresponding strength grade as concrete, mortar or wall panels, floor tiles and other building materials products [4]. When some curing agents added, the reforged aggregate could be used as road pavement base as well.

Waste residue could be applied to road construction, fillers, foundation, etc. It could be used directly without crush because of its relatively small particle. Therefore, construction waste treatment costs relatively little, and the use of waste residue is more convenient.

Waste timbers without apparent damage could be used to reconstruct the building, while badly damaged wooden components could be used as renewable raw materials of paper, mosquito coils, composite sheet, energy, home improvements and so on.

Scrap steel and other metal scrap materials could be directly reused or reforged. In general, the recovered steel is returned to steelworks, where it is remade, its impurities removed, and then it is made into various types of steel products before flowing into the market again [4].

Fig.2 shows that the construction waste treatment process is used in China [3].

As is shown in Figure 1, the circulation operation mode is used in the construction waste treatment process in advanced countries such as America, Germany and Japan. Construction waste can be recycled and applied to building spaces as renewable resources. Figure 2, operated by the linear model, shows that single treatment process is widely used in China. However, if analysis is made on construction waste treatment process of China and the West, disparities are presented evidently.

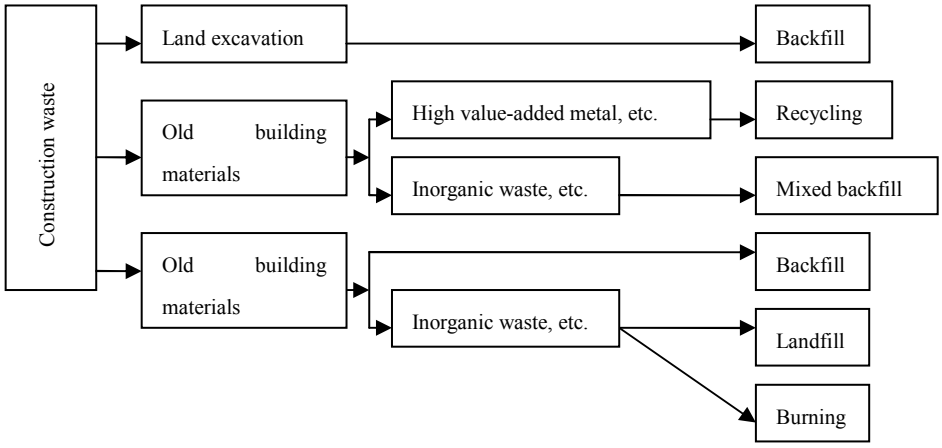

**Fig.2 Construction waste disposal process used in china**

## Countermeasures for China's Construction Waste Resource Utilization

**Several Problems about China's Urban Construction Waste Treatment** [5]**.** The level of construction waste classified collection is low. Most construction waste could only be collected as a mix.

The rate of construction waste recycling utilization is low.

The technology of construction waste treatment and resource utilization in China is backward. Construction waste in urban always is dumped into some landfills directly, which not only occupies a lot of land spaces, but also pollutes the environment.

Little investment is spent in urban construction waste treatment, policy measures are still not perfect, and the construction worker's environmental awareness is quite weak.

The enforcement of relevant policies, laws and regulations are not strong enough, and the standardization degree of construction waste treatment is low.

**Construction Waste Resource Utilization Should be Started with the Following Aspects.** Adopt the full life cycle management mode. Take the building cycle management model into the whole process, break the traditional linear model of the "building materials - building - building rubbish", and form the circular economic model of the "building materials - building - construction waste - recycled materials"[2].

Strengthen the legislation work for construction waste recycling. In the recycling of construction waste, the relevant government department should formulate special laws and regulations to prohibit landfilling available construction waste. What's more, the rules for construction waste sorted collection and storage should be stipulated. And, apply economic levers to regulate the disposal of construction waste [2] [6].

Carry out scientific research on construction waste recycling.

Strengthen education on construction waste resource utilization. Widely publicize the construction waste is a kind of available resources, improve environmental consciousness of construction workers, and introduce the latest technology and methods of construction waste utilization to the related units and individuals.

## Conclusion

Compared with China, construction waste resource utilization is at a higher level in many developed countries. It starts late in China, and there is a large gap behind of the advanced

international level. In order to realize the utilization of construction waste, China's national conditions should be taken into consideration. It should be started with such aspects as legal, management, technology and others, to promote the process of construction waste comprehensive utilization. Only in this way, can China effectively solve the problem of construction waste, develop the recycling economy, build a conservation-minded society and promote the sustainable development.

**Keywords:** tomato;irrgation amount;yield;quality

**Abstract.** In order to determine the proper irrigation amount of summer tomatoes,taking drip irrigation in green house,5 irrigation volume including 990 $m^3/hm^2$, 1485 $m^3/hm^2$, 1980 $m^3/hm^2$(CK), 2475 $m^3/hm^2$, 2970 $m^3/hm^2$ were set,and the effects of different irrigation amount on the yield and quality of tomato in greenhouse were studied. The results showed that with the increase of irrigation amount,the soluble solid content,titratable acid content,Vc content and irrigation water use efficiency of tomato decreased. In treatment T1, T4, T5 ,yield decreased by 26.3%, 6.5%, 15.8%. In treatment T2 , the yield decreased by 1.9%,while the irrigation water use efficiency increased by 20.8%,and the soluble solids content,titratable acid content and Vc content increased.It was concluded that the optimum irrigation amount was1485 $m^3/hm^2$.

## Preface

Tomato is one crops of the common important vegetable,in recent years, scholars have done a lot research in the irrigation amount.Many scholars discussed effects of different irrigation amount in different growth stage on yield and quality of greenhouse tomatoes.Irrigation amount and effect on yield and quality of the relationship showed the same changes [1-5] , Guo Haitao [6] believed in tomato fruit flowering period, reducing the amount of irrigation will increase yield,but there was less irrigation amount research on tomato from planting to harvest.The experiment considered 5 different irrigation amount,try to find the yield and fruit quality difference between 5 treatment,aiming to provide a reference for water management of tomato.

## Materials and Methods

1.1Experiment material

Tomato variety:Oudun.

1.2 Experiment methods

Experiment was conducted in the greenhouse from March to July,the greenhouse was located in experiment field of school of Horticulture and Plant Protection,Yangzhou University. The size of greenhouse is 30m×6m,15 plots whose size is 6m×1m were set,in each plot there were two lines of tomatoes,arrangement is shown in Figure 1. Tomatoes was planted in March 8th,the distance between lines is 60cm, while the distance between plants is 30cm.Irrigation started from March 11th, five irrigation volume including 990 $m^3/hm^2$, 1485 $m^3/hm^2$, 1980 $m^3/hm^2$(CK), 2475 $m^3/hm^2$, 2970 $m^3/hm^2$ were set, each treatment is repeated three times.The water was irrigated by drip under membrane.

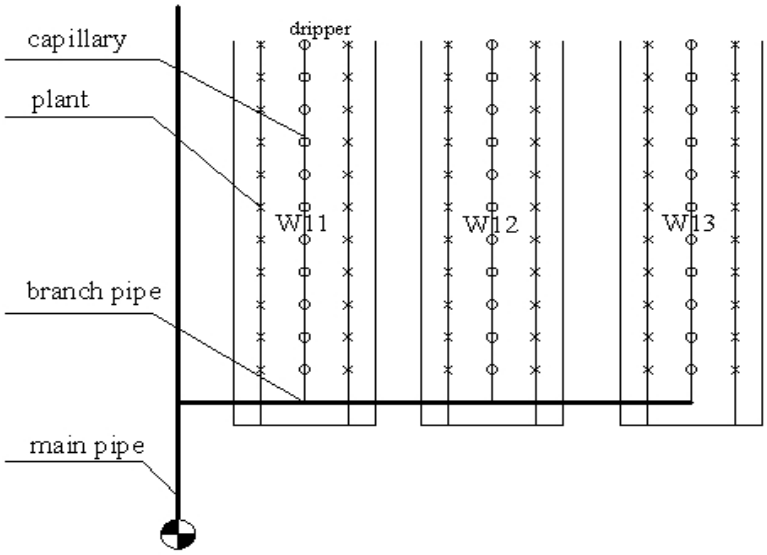

Figure1 Schematic Diagram of Tomatoes

1.2 Experiment methods

Experiment was conducted in the greenhouse from March to July 2013 ,the greenhouse was located in experiment field of school of Horticulture and Plant Protection,Yangzhou University. The size of greenhouse is 30m×6m,15 plots whose size is 6m×1m were set,in each plot there were two lines of tomatoes,arrangement is shown in Figure 1.

Tomatoes was planted in March 8th,the distance between lines is 60cm, while the distance between plants is 30cm.Irrigation started from March 11th, 5 irrigation volume including 990 $m^3/hm^2$, 1485 $m^3/hm^2$, 1980 $m^3/hm^2$(CK), 2475 $m^3/hm^2$, 2970 $m^3/hm^2$ were set, each treatment was repeated three times.The water was irrigated by drip under membrane.

1.3 Measurement items and methods

Quality of tomatoes: Measure quality of fruits in the flourishing period.

Soluble solids content (RHBO-90) was measured by a handheld refractometer,titratable acid content was measured by acid-base titration,Vc content was measured by spectrophotometry.

Yield:Pick fruits when they are mature and calculate the production.

## Results and analysis

2.1 Effects of different irrigation amount on quality of tomatoes

2. 1. 1 Effect on soluble solids content

With the increase of the irrigation amount, soluble solids content of tomatoes decreased,difference between 5 treatments is not significant(Table 1).The results showed that with the increase of irrigation amount，the soluble solid content decreased,which is consistent with former scholars' conclusion [7].

Table 1 Effects of different irrigation amount on fruit quality of tomato

| Treatment | soluble solids content （%） | titratable acid content （%） | Vc content （mg/kg） |
|---|---|---|---|
| T1 | 4.71 a | 0.46aA | 12.87Aa |
| T2 | 4.75 a | 0.41bB | 12.10Aa |
| T3 | 4.65 a | 0.41bB | 10.60bB |
| T4 | 4.46 a | 0.35bB | 9.46BC |
| T5 | 4.40 a | 0.34aA | 8.26Bc |

2. 1. 2 Effect on titratable acid content

With the increase of the irrigation amount, titratable acid content of tomatoes decreased. Treatment T2 and T4 had no significant difference with CK,but all the significance <treatment T1 and T5.The results showed that with the increase of irrigation amount,titratable acid content decreased,which is consistent with former scholars' conclusion [8].

2. 1. 3 Effect on Vc content

With the increase of the irrigation amount,Vc content of tomatoes decreased. Treatment T4 and T5 had no significant difference with CK,but all the significance <treatment T1 and T2. The results showed that with the increase of irrigation amount, Vc content decreased.It is concluded that decrease of irrigation amount will increase the quality of tomatoes.

2.2 Effect of different irrigation amount on yield and irrigation water using efficiency

With the decrease of the irrigation amount,yield of tomatoes decreased.Treatment T2 reduced by 1.9% compared with CK,while treatment T1 and T5 reduced by 26.3% and 15.8%, the differences have reached a significant level(Table 2). The results showed that irrigation amount has significant impact on yield, but less impact on T2 and T4.So it is concluded that the proper irrigation amount is treatment T2.

Table 2 Effects of different irrigation amount on yield and irrigation water use efficiency

| Treatment | irrigation amount （m3） | Yield （kg） | water use efficiency （kg/ m3） | Compared to CK （%） | |
|---|---|---|---|---|---|
| | | | | yield | water use efficiency |
| T1 | 1.095 | 49.566 bB | 45.27 | -26.3 | 68.8 |
| T2 | 1.8808 | 65.927aA | 35.05 | -1.9 | 20.8 |
| T3(CK) | 2.5062 | 67.216 aA | 26.82 | - | - |
| T4 | 3.0567 | 62.843 aA | 20.56 | -6.5 | -23.3 |
| T5 | 4.9147 | 56.615cb | 11.52 | -15.8 | -57.0 |

## Conclusion

The research show that with the increase of irrigation amount, the soluble solid content,titratable acid content,Vc content and irrigation water use efficiency of tomato decreased.Compared to CK,either increase or decrease the amount of irrigation,the yields declined [7] . In the treatment T2,although the yield slightly declined, but soluble solid content，titratable acid content,Vc content increased,besides water use efficiency significantly improved.Therefore it is considered that appropriate irrigation amount of tomatoes in the spring and summer is 1485 $m^3/hm^2$.

**Key words:** emergencies, emergency situation, crisis situation, contingency plan, emergency preparedness plan, replacement, emergency water supply.

**Abstract.** The article deals with the ways of dealing with the concept of drinking water supply in the event of emergencies and crisis situations. The contribution defines concepts related to crisis planning, describes preventive measures to ensure a prompt resolution of a situation, solution to minimize the damage caused by the incident and, last but not least, the possible ways of ensuring the supply of drinking water in emergency situations.

## Introduction

Occurrence of emergency situation in the production and distribution of drinking water can never be excluded. The probability of their occurrence increases with the increasing influences of the civilization. The cause of an emergency situation can often be the action of natural phenomena, whose intensity and frequency is induced by a number of natural laws, and in some cases even the humans. The most significant natural influencing phenomena manifesting in water management are floods. The influences of civilization then include, for example, various types of industrial accidents. Since that incident can not be ruled out, it is necessary to eliminate the negative consequences to an acceptable level. To eliminate the effects of such emergencies, the government creates its own security system. [1]

Timely and adequate readiness of the state and the stakeholders for a potential incident is then the decisive factor in managing emergencies at the optimal time and with minimal consequences. In the water sector, which is part of the critical infrastructure of the state, contingency planning is a necessity, especially because of its complete linkage to civil life and operation of public infrastructure.

## Emergencies and crises

Emergencies may represent natural effects, negative effects caused by human activity, accident threatening human health, property, goods and, ultimately, the environment.

An emergency situation arises, when the sovereignty and territorial integrity of a country is directly threatened, hence the operation of the economy, trade and industry, state and local governments, international commitments, lives and health of the population, property, goods, environment, etc., and such a threat can not be prevented by normal activities of administrative bodies, local government bodies, armed forces, rescue squads, emergency and other services, as well as the consequences of these situations can not be eliminated by common practice of these bodies and institutions.

A crisis situation can be understood as a form of emergency which is induced by a violation of one of the segments of critical infrastructure. In this case, a state of crisis is usually declared, i.e. a state of emergency, state of danger or a state of national emergency. [2,3,4]

## Contingency planning in water management

Contingency planning is a form of preventive measure in case of emergency and crisis situations to ensure minimized damage caused by the crisis and especially a plan that helps to quickly deal with the situation. These especially include the situations arising mainly by natural influences,

while their timing and duration can not be accurately determined. Similar are some situations caused by human activities, which can not be assumed. A typical representative of an emergency caused by natural phenomena are floods, which can have a very negative impact on water management. Likewise, an event of emergency can be induced by industrial accidents, which are a typical representative of emergency caused by human activity. It should be noted that the emergence of such situations in water management can not be ruled out and therefore it is necessary to be able to face these situations and minimize negative impacts to an acceptable level. Such situations are addressed today by contingency planning, as only a high-quality and timely readiness of stakeholders for any incident can provide a fast and efficient mastery in minimal time and with minimal consequences. Part of these preventive measures are incorporated in the contingency plan itself for the relevant territory or local government unit and plan of emergency preparedness of the institutions and bodies involved. [1,5,6]

The contingency plan is a set of documents containing a description and analysis of threats, summary of emergency procedures and measures in case of a situation of crisis. This plan is prepared by the competent authority, such as municipality, county, or state as one of the preventive measures in case of a crisis situation. It consists of two parts, namely basic part containing mainly the subject of potential sources of risk and threat analyses, a list of organizations and entities providing measures given by the contingency plan and characteristics of those organizations and entities of crisis management. The second part of the contingency plan is the annex part incorporating in particular the list of critical resources and measures for different types of crises, plans of the necessary supplies, connections, medical support, material and technological support and the like. The annex part of the contingency plan includes agility plan containing the response of the processor of the contingency plan for the declaration of the state of emergency and its readiness to fulfil the tasks set by contingency plan, such as the location of the planned or emergency sites of crisis staffs, including an overview of their equipment, list of people who will be working the crisis staff, the manner of convening the crisis staff and also the protection itself in case of threat to the crisis staff. [1,2,3,7]

Upon the actual processing of the crisis plan, the processor includes various cooperating agencies and organizations, such as the competent authority included in the contingency plan of emergency supplies of drinking water in the event of a crisis using services of an organization operating water supply systems. In this case, the organization is obliged to participate in addressing the crisis situations. The competent authority therefore concludes a contract with such organization, such as a contract on securing emergency water supplies and technical assistance under a crisis situation and the organization must provide a plan of emergency preparedness. Emergency preparedness plan itself serves the purpose of the organization involved in the crisis plan and comprises especially the very functioning of the organization in crisis situations and ways of securing and performing of the tasks outlined by the contingency plan. [1,3]

**Replacement and emergency water supply**

Replacement water supply is an activity whose purpose is to ensure the drinking water supply of the required quantity and quality for all users in the event of an outage of drinking water supply from the public water supply main due to emergencies or possible repairs. This is followed-up by emergency water supply, which is the way in which, in case of emergencies, replacement securing of the necessary amount of drinking water of the required quality is addressed, if the current drinking water supply system is partially or completely non-functional.

In the case of outage of a water source, non-compliance with the required values for drinking water quality at the outlet of the water treatment plant or an emergency in on drinking water feeder for the points of consumption or a fault on the distribution network it is sometimes necessary to cut off the entire system of public water supply in the consumption site. In this case, there is need for replacement and emergency drinking water supplies, which normally greatly complicates the living conditions in the given area and usually does not solve the water supply for the operations of the technical and technological operational units where there is a permanent supply of the required

quantity of water and often at the necessary pressure required to run the entire operation. At the same time the failure of the supply of drinking water also completely eliminates fire water supply from public water mains throughout the territory. It is therefore necessary that stakeholders are prepared for such incidents and be able to handle the situation at optimal time and with minimal consequences. [1]

For such situations, the operator of public water supply shall ensure replacement drinking water supply, which is performed according to his plan of emergency preparedness and this supply is ensured in reachable distance and in the extent for necessary personal use. The method of securing replacement water supply stems mainly from the technical possibilities and conditions under which it is possible to use several methods to provide for the supply of drinking water. The easiest way to provide a replacement of drinking water supply is the trucking of drinking water in truck tanks or stable tanks that are refilled as needed. Another source may be the functionally fixed aboveground or underground hydrant in reachable distance, which is equipped with a hydrant extension for the withdrawal of drinking water. [4]

*Fig. 1 Discharge stand for emergency water supply* [8]

Alternatively, functional and accessible aboveground or underground hydrants can also be used for direct connection to the internal water system of the given facility. Other ways to ensure the supply include the cut-off of the section which is the subject of failure and then replace it with the temporary ground pipeline, possibly connecting the site to an alternative source of water supply.

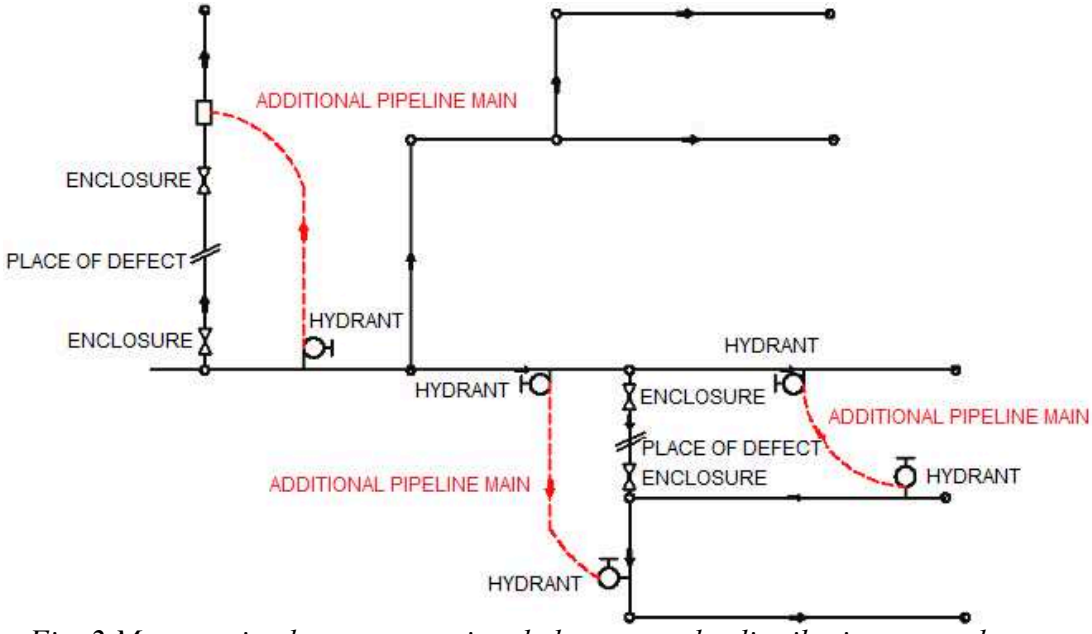

*Fig. 2 Means to implement operational changes to the distribution network structure*

It may thus be for example a connection to another functional water supply pressure zone, provided that the supply of drinking water will be either of higher or lower pressure condition, a temporary water supply connection for example led along the road surface at the distant functional above-ground or underground hydrant or a connection to another alternative source of raw water,

such as public well, in which case it is necessary to equip the temporary water supply with mobile water treatment plant facility.

Complications in these methods may occur in the event of adverse weather conditions when temperatures can fall below freezing point and there is a risk of water freezing. In these cases the preferred method is the distribution of drinking water with tank trucks or stable tanks located in heated areas. [4]

## Summary

Due to the ever increasing global population going against the gradual reduction of drinking water, we can also expect greater problems in the field of water management and the inherently related emergencies. The crisis situations arise naturally, therefore not only due to human activities, and therefore it is important to be prepared for such a contingencies, since the lack of water carries a particular risk to the health and life of the population and therefore can be fatal, especially in large populated areas. [1]

It is therefore important that especially the state authorities, water authorities and organizations are prepared in the long term for such facts, since being able to handle such a crisis requires advance preventive measures set in advance, such as contingency plans, including not only the relevant legislative requirements, but also the overall evaluation of all sources of water, including the allocation of strategic reserves, preparation of technical equipment for an emergency, training of rescue teams, as well as technical means of communication between the entities affected by the crisis and, last but not least the preparation of the plan of fire protection of urban areas in crisis caused by the situation of water scarcity. If we adopt the above measures and take possibly some further actions, we get a real chance to handle emergency situations and thereby reduce the potential damage caused by the same.

**Keywords:** raw water; eutrophication; evaluation; GIS; entropy weight method.

**Abstract.** To do a research about raw water eutrophication of water plants in Hangzhou, samples of raw water in Jiuxi, Xiangfu, Nanxing, Qingtai Plant were collected and analyzed to get more than 10 water quality indexes. Turbidity, DO, COD, TN, $NH_3$-N and CHL-a serving as example. supported by GIS, integrated fuzzy evaluations of raw water eutrophication in July and December were completed applying entropy weight method. The result shows that in terms of the nutrient degree, Xiangfu is the most qualified while the least one is Qingtai. Overall, raw water in December is of higher quality than July.

## Introduction

Although China's economy is rapidly developing, environment and health problems, however, are becoming increasingly serious. How to guarantee water quality in urban and rural areas becomes a major problem. The latest hygienic standard for drinking water came out in July, 2012. The range of water quality inspection expanded a lot. There were only 35 indexes of water quality testing before the standard came out, which fell far behind the developed countries. Then the new standard's indexes increased to 106, which almost reached the international advanced level and could guarantee the tap water to be drunk without extra process. With the new standard, water quality was improved a lot. The water plants in cities supply residents with safe tap water, and undertake the task to purify raw water of rivers. When the ability to process raw water and the processing water yield is certain, the raw water quality will exert a significant impact on water treatment technology, equipment, operating efficiency and so on.

## Review of Study

**General situation of Study Area.** Hangzhou Water Industry Group administers 5 water plants, Qingtai, Xiangfu, Nanxing, Jiuxi and Chishanfu (the first four plants are studied), whose scope of water supply covers main urban area of Hangzhou, part of Yuhang and Xiasha. And the turbidity of processed water is under 0.2NTU. The designed water supply capacity can come to 1700,000 m3.

**Data Collection.** Samples of raw water were collected from water inlet of Jiuxi, Nanxing, Xiangfu and Qingtai in July and December, 2012. After the collection, the samples were taken to laboratory immediately to be analyzed. The analyzation covered more than 10 indexes, and Turbidity, DO, COD, TN, NH3-N and CHL-a were chosen to be studied.

**Research Method.**

**Geographic Information System.** GIS collects, saves, calculates and illustrates the data with computer technology based on the geographic data of earth surface [1]. The water quality evaluation used to process data manually or apply certain software, the results of evaluation only come out in the form of chart. However, these traditional methods hardly reflect the spatial distribution, and are not able to express the information vividly[2]. Then GIS offers some relevant methods. The ability of spatial analysis is the most pivotal and strongest function of GIS, also the difference between GIS and other computer aided software; spatial analysis makes quantitative description of spatial matters, making consequences more objective and accurate[1]. Based on the electronic map whose accuracy is 2 km, the map was input into ArcMap, in which the positions of these four water plants were marked

as points, the water front of the West Lake and Qiantang River was marked as lines, the water supply area of each water plant, the West Lake, and Qiantang River were marked as polygons. And the geographic information of each element was input into the attribute table. Necessary annotation was added on the picture as well. After editing, a manipulable GIS digital map came out.

**Entropy Weight Method**. Entropy is suitable for the measurement of amount of valid information and systematic level of disorder that known data contains and determining the weight at the same time. Entropy weight method determines the weight of each index according to the difference between each monitoring index, and is widely applied in water quality fuzzy evaluation as an objective method of determining weights[3]. The theory of entropy weight method is to quantify and assess comprehensively the information of every unit to be evaluated. Determining weight of each factor with entropy weight method could simplify the assessment process and enhance the accuracy of integrated fuzzy evaluation of raw water eutrophication. When certain index value of every object varies a lot from one to another, the entropy is small, indicating that the amount of information it provides is big, and its weight ought to be big; on the contrary, when certain index value of every object varies a little from one to another, the entropy is is big, indicating that the amount of information it provides is small, and its weight ought to be small; when certain index value of every object is exactly equal, it means that the index's information is useless and could be removed from the evaluation system[4].

## Integrated Fuzzy Evaluation of Eutrophication

### Step of Entropy Weight Method.

**Normalize the Matrix of Original Data.** Define the original matrix that consists of $m$ evaluation indexes and $n$ evaluation objects as $A=(a_{ij})_{m\times n}$. $a_{ij}$ is the $j$th original data of object $i$[3]. Apply different normalization formula to index that is better when it is bigger and index that is better when it is smaller. The normalized matrix is $R=(r_{ij})_{m\times n}$.

To index that is better when it is bigger such as DO, the normalization formula is

$$r_{ij}=\frac{a_{ij}-\min\limits_{j}\{a_{ij}\}}{\max\limits_{j}\{a_{ij}\}-\min\limits_{j}\{a_{ij}\}}. \tag{1}$$

To index that is better when it is smaller such as TN, the normalization formula is

$$r_{ij}=\frac{\max\limits_{j}\{a_{ij}\}-a_{ij}}{\max\limits_{j}\{a_{ij}\}-\min\limits_{j}\{a_{ij}\}}. \tag{2}$$

**Define the Entropy.**

$$h_i=-k\sum_{j=1}^{n} f_{ij}\ln f_{ij},\quad f_{ij}=\frac{r_{ij}}{\sum\limits_{j=1}^{n} r_{ij}},\quad k=\frac{1}{\ln(n)},\ \text{when } r_{ij}=0,\ f_{ij}=0. \tag{3}$$

**Define the entropy weight.**

$$w_i=\frac{1-h_i}{m-\sum\limits_{j=1}^{m} h_i},\ (0\le w_{ij}\le 1,\ \sum_{1}^{m} w_i=1). \tag{4}$$

**Figure out integrated weighted nutrition state index $m_{ij}$.**

$$m_{ij}=\sum_{i=1}^{n}(a_{ij}\times w_i). \tag{5}$$

**Integrated Fuzzy Evaluation in July.** Four water plants and six indexes consist the original matrix of water quality evaluation. The four water plants are Jiuxi, Xiangfu, Nanxing and Qingtai. Six evaluation factors are Turbidity, DO, COD, TN, NH3-N and CHL-a.

$$A=\begin{bmatrix} 22.60 & 5.30 & 77.30 & 60.20 \\ 5.26 & 4.70 & 3.64 & 5.46 \\ 1.65 & 3.41 & 1.77 & 1.76 \\ 0.74 & 1.32 & 1.60 & 1.38 \\ 2.26 & 2.87 & 2.70 & 2.17 \\ 0.0006 & 0.0006 & 0.0018 & 0.0029 \end{bmatrix}, \text{ then } R=\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0.233 & 0.887 & 0.047 & 0.091 \\ 0.927 & 0.357 & 0.977 & 0.971 \\ 0.967 & 0.751 & 0.979 & 0.977 \\ 0.900 & 0.459 & 0.965 & 0.964 \\ 1 & 1 & 1 & 1 \end{bmatrix}.$$

$$H=\{h_i\}=[0 \quad 0.628 \quad 0.955 \quad 0.995 \quad 0.973 \quad 1]$$
$$W=\{w_i\}=[0.690 \quad 0.257 \quad 0.031 \quad 0.003 \quad 0.019 \quad 0]$$
$$M=\{m_j\}=[17.04 \quad 5.03 \quad 54.38 \quad 43.04]$$

$m$ is the integrated embodiment of the six indexes. The smaller $m$ is, the better is water quality.

**Integrated Fuzzy Evaluation in December.**

$$A=\begin{bmatrix} 16.00 & 9.00 & 42.00 & 16.00 \\ 7.43 & 8.01 & 6.76 & 6.57 \\ 3.04 & 2.29 & 3.24 & 3.16 \\ 0.20 & 0.02 & 0.28 & 0.72 \\ 3.83 & 3.91 & 4.61 & 4.26 \\ 0.0037 & 0.0003 & 0.0067 & 0.0038 \end{bmatrix}, \text{ then } R=\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0.464 & 0.890 & 0.161 & 0.410 \\ 0.810 & 0.746 & 0.923 & 0.803 \\ 0.988 & 0.998 & 0.993 & 0.955 \\ 0.761 & 0.566 & 0.890 & 0.734 \\ 1 & 1 & 1 & 1 \end{bmatrix}.$$

$$H=\{h_i\}=[0 \quad 0.892 \quad 0.740 \quad 1 \quad 0.991 \quad 1].$$
$$W=\{w_i\}=[0.731 \quad 0.079 \quad 0.190 \quad 0 \quad 0.007 \quad 0].$$
$$M=\{m_j\}=[12.89 \quad 7.67 \quad 31.88 \quad 12.84].$$

**Evaluation of Raw Water Eutrophication Based on GIS.** Spatial analysis function was applied to analyze the integrated value of raw water nutrient degree in the water supply area in order to find the demarcation point. Then raw water nutrient degree was divided into 4 levels: medium-nutrient, light-eutrophic, meso-eutrophic and hyper-eutrophic, as shown in Fig. 1.

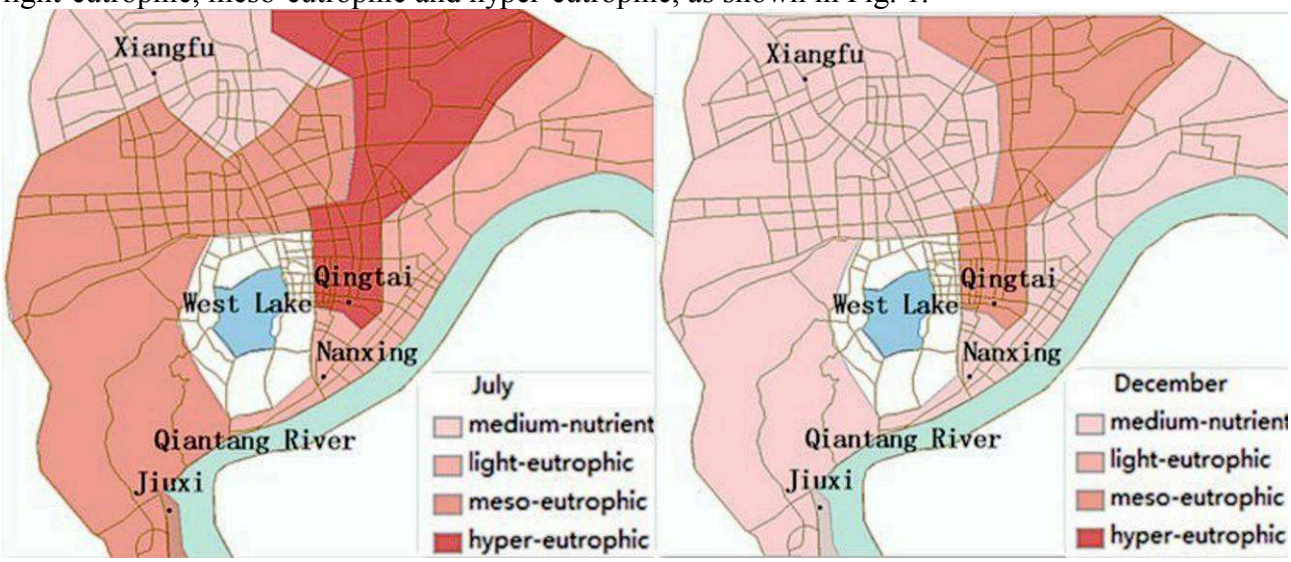

Fig. 1 Distribution Map of Nutrient Degree

As is shown in Fig. 1, in July, raw water nutrient degree in Xiangfu is the lowest, graded as medium-nutrient; raw water nutrient degree in Nanxing is graded as light-eutrophic; raw water nutrient degree in Jiuxi is graded as meso-eutrophic; raw water nutrient degree in Qingtai is the highest, graded as hyper-eutrophic. While in December, except that raw water nutrient degree in

Xiangfu remains to be medium-nutrient, raw water nutrient degree in other three water plants all drops. Raw water nutrient degree in Nanxing drops from light-eutrophic to medium-nutrient; raw water nutrient degree in Jiuxi drops from meso-eutrophic to medium-nutrient; raw water nutrient degree in Qingtai drops from hyper-eutrophic to meso-eutrophic.

**Analysis of Research.** Raw water nutrient degree in December drops to some extent compared with that in July. One of the factors is DO, whose content is in close relation to oxygen partial pressure of atmosphere and water temperature. Under the natural condition, oxygen content of atmosphere hardly changes, so water temperature is the main factor. The lower water temperature is, the higher DO is. Another factor is that raw water that water plant gets is usually deep water. Algae blooms in summer, shades and isolates the air, thus destroys the balance of oxygen exchange between oxygen in water and air. Photosynthesis of plants under water is limited as well. In the meantime, oxygen is consumed greatly by respiration, reducing the content of DO in deep water substantially.

Due to the fact that Xiangfu gets raw water from Dongtiao River, its raw water nutrient degree is lower than the other three water plants, which reflects the fact that Qianjiang River's water quality is not good. Because China is the largest exporter of textiles, and Zhejiang's capacity could account for 50 percent. There are many textile printing and dyeing enterprises in industrial parks in Xiaoshan and Shaoxing, which discharge sewage that is not up to standard into Qiantang River.

## Summary

Supported by raw water data, raw water quality was analyzed and evaluated in the eutrophication reaearch based on GIS. In July, raw water nutrient degree in Xiangfu is the lowest, followed by Nanxing, Jiuxi and Qingrai, ranging from low to high. In December, raw water nutrient degree in Jiuxi, Nanxing and Qingtai all drops. On the whole, raw water nutrient degree in Xiangfu is the lowest and water quality is the best; raw water nutrient degree in Qingtai is the highest and water quality is the worst. According to the raw water quality in Jiuxi, Nanxing and Qingtai, there is eutrophication in water body of Qiantang River and the water quality is not good.

**Keywords:** Biological treatment, biofilter, feed, contact time, waste water, reconstruction, treatment plants, integrated waste water treatment.

**Abstract.** The paper deals with the calculation of the contact time of waste water in the body of feed in the biofilter to determine the optimum settings.

## Introduction

There are a lot of biofilration treatment plants nowadays that work with overloading capacity and pollution values, so the issues of modernization of such plant are of the top priority.

Biofilters are widely used for the waste water treatment plants of a small capacity, in Moscow region it means about 70% of overall biofilter use. A Majority of them demands reconstruction and intensification of treatment processes, because most of them can provide only insufficient biological waste water treatment with discharge is BOD -30 mg/l. [1]

## Research of hydrodynamics of biofilter

Reconstruction allows avoiding solid capital costs comparing with new construction and meanwhile can show significant improvement in treatment quality.

Definition of optimal flow, hydraulic load and choice of efficient feed is important for a biofilter maintenance, and this can be done by means of reconstruction.

Feed of biofilters can be of volumetrical and surface type. The last one is of the big interest due to its lower weight and significant porosity. When designing new types of feed it is strongly needed to make it durable, rigid, chemically, biologically and frost-resistant, with a developed surface, low volume weight and high porosity. [2]

The research was made to define contact time of wastewater with surface feed in biofilter body because of the fact that this parameter has a significant influence at biochemical oxidation e.g. intensity and efficiency of biochemical treatment depends among other on length of the path, that drops of waste water pass on surface of feed.

The experiment was decided to be carried out using surface rigid feed. Polymer samples can suit for these purposes especially light weight that is another advantage. There were crimped cuts of polyethylene pipes chosen (fig.1) for this research. Mass of one element – 1.51 g, unit weight – 191 g per cubic meter.

Fig. 1. The surface feed

There is a solutuion of non-oxidized dye (red, E124, 1.5 g diluted in 200 ml of distilled water) to pass through cylindrical laboratory model of biofilter (that consists of a 60 liter cistern with a pump to supply waste water to the upper part of the biofilter , a distribution system for steady waste water supply and the model of biofilter made of perspex ,circular in plan, 2 meters high, 0, 1 in diameter, feed is 1,9 metres high) with fixing of color change in the discharge water by means of photocolorimetry.

There are three modes of flow set – 58 l/day, 108 l/day, 173 l/day. Dye solution (25 ml) was put instantly together with inlet water. Samples of discharge water were taken within fixed time intervals from dye input and until entire vanishing of colour.

Afterwards these samples were investigated for transparency by means of photocolorimetry. The investigation resulted in diagrams that show the dependence of colour intensity to the sample collection time. This diagram is compared with the curve drawn according to the optical density of a dye with various concentrations.

The experiment #1 on the method above was made with a flow 57,89 l/sec.

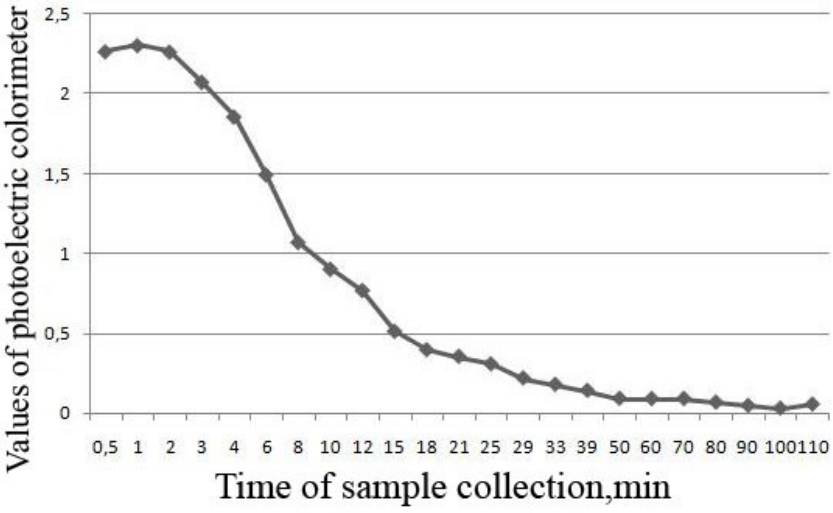

Fig.2. The diagram showed the dependence of colour intensity to the sample collection time (flow 57,89 l/sec.)

The experiment #2 was made with a flow 172,8 l/sec, afterwards a curve was drawn.

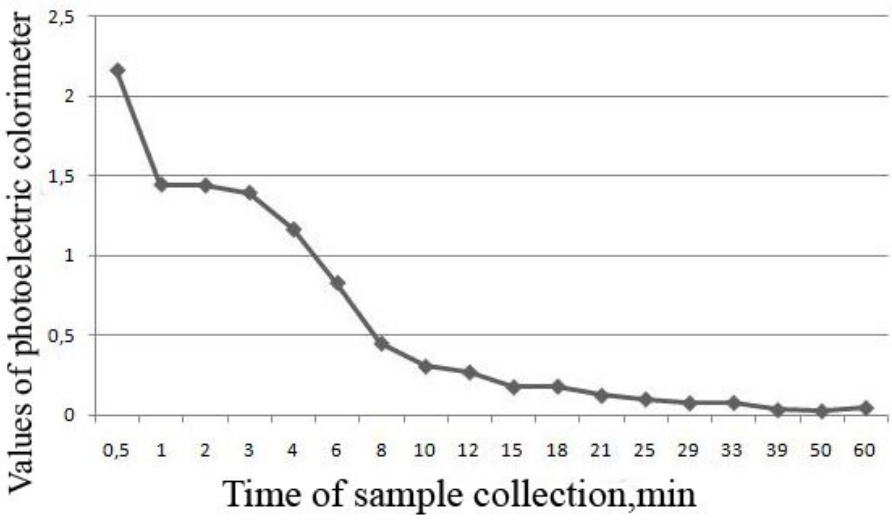

Fig.3. The diagram showed the dependence of colour intensity to the sample collection time (flow 172,8 l/sec.)

The experiment #3 was made with a flow 108 l/sec, afterwards a curve was drawn.

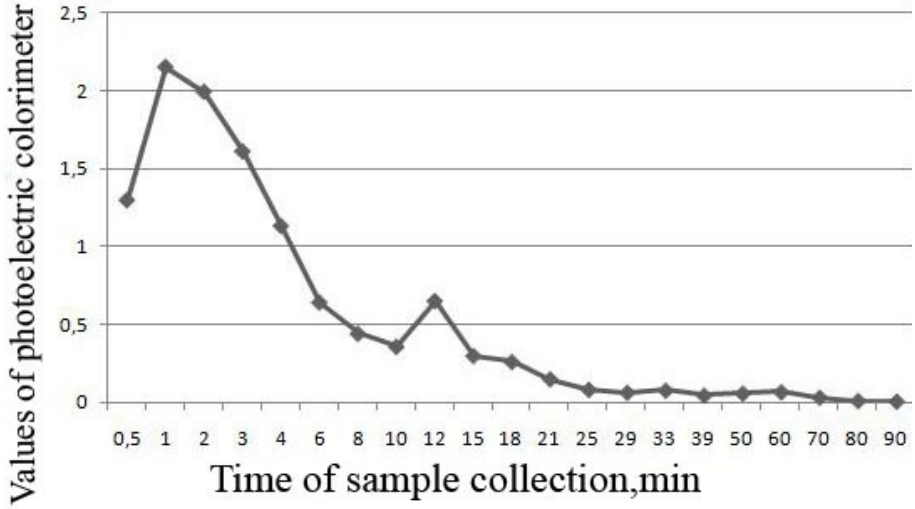

Fig.4. The diagram showed the dependence of colour intensity to the sample collection time (flow 108 l/sec.)

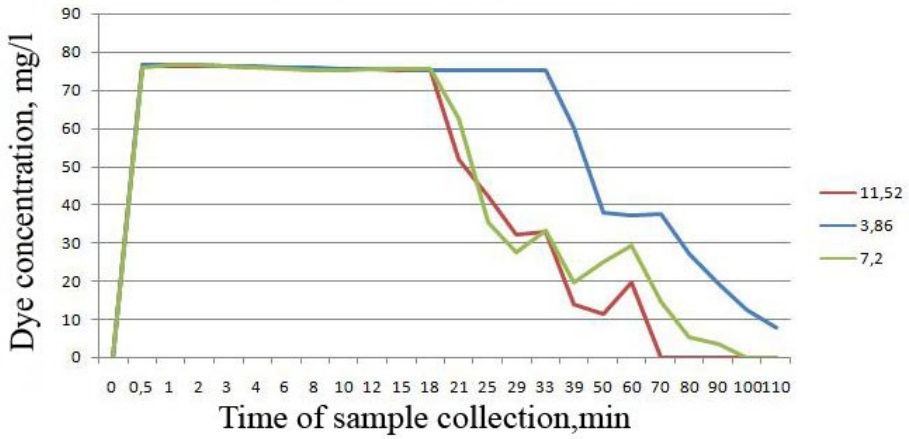

Fig.5. Diagram of dye concentration change depending on treatment time in biofilter body with various hydraulic loads

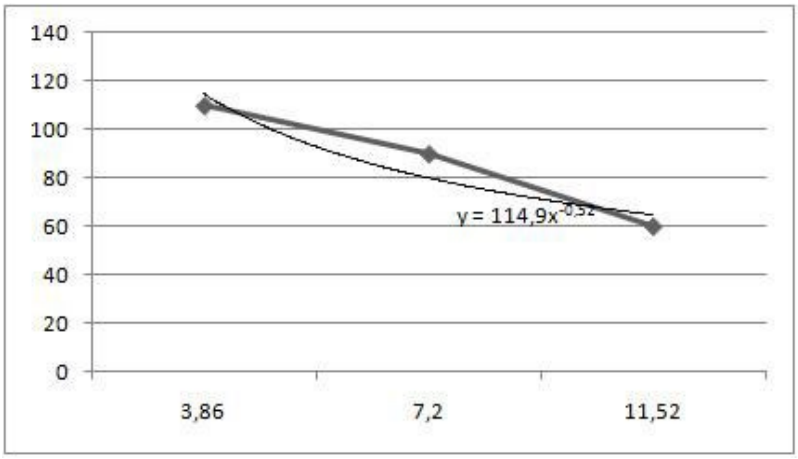

Fig.6 The diagram was made based on fig.5.

Average time of the water stay in the biofilter can be expressed as follows

$$t = \frac{C \times H}{q^n}$$

H –height of the feed,
Q – hydraulic load,
C and n – constants, that are depended on the surface of biofilm in a uint of feed volume, on viscosity of liquid and construction of a feed.

When H is 1.9 m the equation is

$$t = 114{,}9 \times 1{,}9 \times q^{-0{,}52}$$

After putting values of hydraulic load we get 108.2, 78.2 and 61.25 correspondingly.

**Conclusions:**

Overall experiment showed that this type of feed has features needed for the optimal work of biofilter for all tested flows and suits for WWTP reconstruction including integrated treatment.

# Research On UV/$TiO_2$ Photocatalytic Oxidation of Organic Matter In Drinking Water and Its Influencing Factors

Jinhui Zhao

(College of Environmental, Nanjing University of Technology, Nanjing, P R China)

zjh-huaxian@163.com

**Keywords-** drinking water; photocatalysis; organic matter; removal efficiency

**Abstract—**UV/$TiO_2$ photocatalytic of filtrated water are conducted in S waterworks which take Yangtze River as its source water in Nanjing. Self-made glass supported nano-$TiO_2$ film and photocatalytic reactor are used for the experiment. Results show that TOC removal efficiency can reached 45% -63% within 2h-3h, Organic matter removal efficiency is positively related with the • OH generated in photocatalytic process. The influence factors on TOC removal efficiency follows the sequence: light intensity, dissloved oxygen, reaction time and pH. Changes of UV absorption characteristics in photocatalytic process indicate that the saturation of organic matter increase significantly, this is conductive to control the risk taken by disinfection by-products. Results proved that UV/$TiO_2$ photocatalytic is a promising technology for the removal of organic pollutants in drinking water, it can improved the chemical safety of drinking water.

## Introduction

In recent years, the chemical safety of drinking water caused by organic pollutants in water has become one of the main problems. Sanitary Standards for Drinking Water (GB5749-2006) set higher quality standard for drinking water. Facing the deteriorating source water quality, conventional water treatment process can't fully meet the new standards [1]. Domestic and foreign research and practice indicate that the conventional coagulation, sedimentation and filtration processe can only remove 20% -30% organic matters from water. How to strengthen the traditional treatment process and develop new drinking water treatment process to control organic pollutants has become an urgent problem.

UV/$TiO_2$ photocatalytic advanced oxidation technology is receiving more and more attention in drinking water treatment. In 1972, Fujishima and Honda reported that the radiation of $TiO_2$ can induce sustainable oxidation reduction reaction of water in the photocell and generate hydrogen[2]. Since then, scholars have conducted much researches on the removal effect of photocatalysis on priority pollutants [3], humus [4, 5] and algal toxins [6] in water. Moreover, some scholars further studied the photocatalytic oxidation kinetics of organic matter [7]. However, there still lack systemic research on the removal efficiency and influencing factors of UV/$TiO_2$ on the organic substance in drinking water.

## Equipments and Methods

### Experimental equipments

A self-made photocatalysis reactor are made with glass-supported $TiO_2$ film adhered inside (Fig.1), A 18w ultraviolet germicidal lamp in a 6cm-diameter quartz socket tube are used in the reactor as UV light source, the major wavelength of the lamp is 253.7nm.

XRD analysis shows that the $TiO_2$ film crystal morphology is anatase. The surface morphology of the film is studied by a Veeco Autoprobe CP–R model atomic force microscopy, AFM image shows that the average particle size is 13.2 nm. The average film thickness is 14.88 nm and the relative surface roughness is 15.5% (Fig. 2).

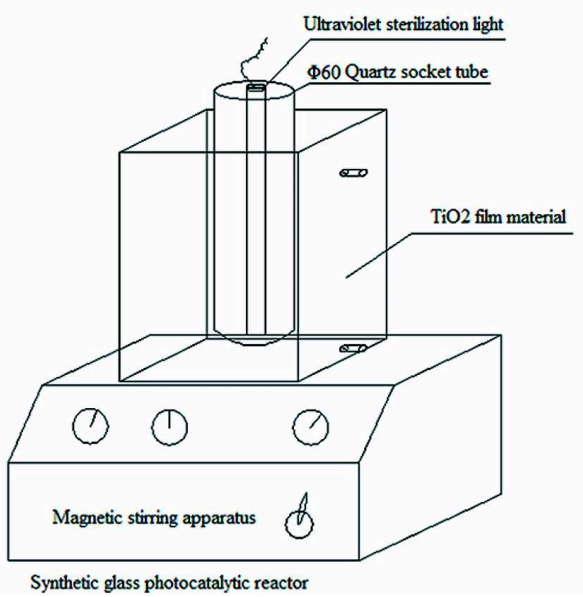

Fig.1 Experimental equipment of photocatalytic

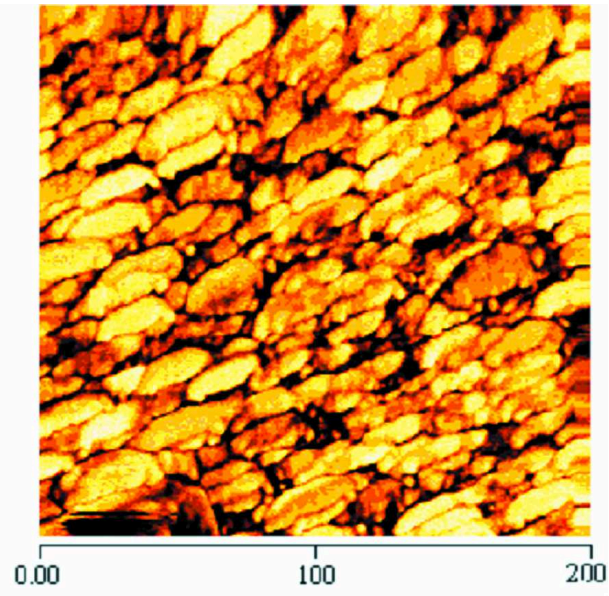

Fig.2 AFM image of $TiO_2$ film

## Experimental Methods

Take TOC as a characteristic index for organic matters, removal efficiency of UV/$TiO_2$ photocatalysis on trace organic matters in filtered water are studied, relationship between TOC removal efficiency and the amount of •OH generated are studied by correlation analysis. In addition, the influence of UV light intensity, reaction time, pH, dissolved oxygen are analyzed through $L_9$ ($_3^4$) orthogonal experiments.

Photocatalytic experiments of filtered water are conducted under the optimal conditions determined by the above orthogonal experiments, transformation of organic matter in photocatalytic process are studied by comparing spectral scanning characteristics and changes of SUVA value of water sample before and after photocatalysis.

The determination methods of conventional water quality indexs listed in Table 1 all adopt the national standard method [8]; UV intensity is determined by a UV-B dual-channel ultraviolet irradiation made by Beijing Normal University; TOC is determined by analytikjena AG Multi N/C2100 TOC analyzer; DO is determined by a Shanghai Leici JPB-607 type magnetic dissolved oxygen meter; absorption spectrum scanning characteristics are analysied by a general T6 new century UV/Vis spectrophoto meter.

• OH is determined by the photometry method which use salicylic acid as molecular probes [9]. Specific methods are: prepare 150mg/L salicylic acid, place it in the photocatalytic reaction system, determine the amount of hydroxylation-2, 3-dihydroxy benzoic acid produced by the absorbance under 510nm.

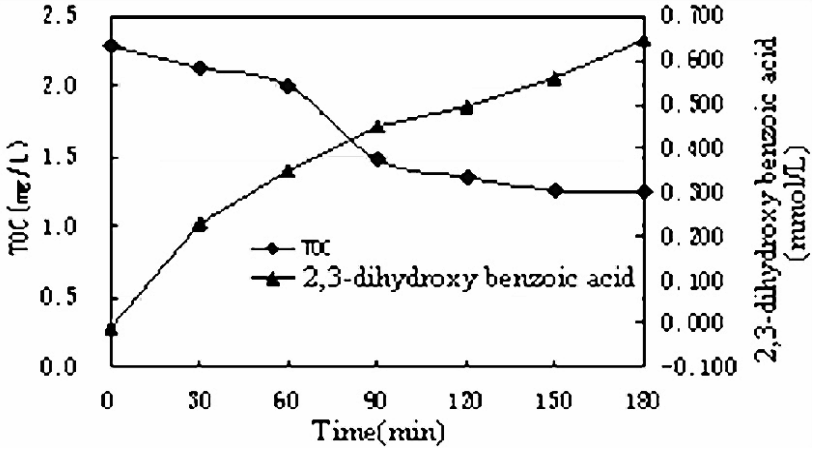
## Results and Discussion

### Removal efficiency of UV/$TiO_2$ photocatalysis of organic matter in water

The content of organic matter in raw water of S waterworks is relatively low, most of the organic matters are dissolved organic matters. The DOC content in source water is 2.86mg/L and accounting for 82.52% of TOC. After coagulation, sedimentation, and filtration, DOC content can be reduced to 2.14mg/L and the corresponding removal rate is 25%, it is proved that the removal effect of organic matter by conventional process is limited.

Under the UV intensity of 0.25mw/$cm^2$, static photocatalytic experiments are conducted in the self-made photocatalytic reactor, the variation of TOC and • OH during photocatalysis are shown in Fig. 3.

Results shows that the TOC content in filtered water decreased from 2.284mg/L to 1.255mg/L within 180min, the corresponding removal efficiency is 45.05%. The content of 2, 3- dihydroxy benzoic acid generated is 0.647mmol/L. Supposing that a • OH attacks a salicylic acid molecule forms a 2, 3 -dihydroxy benzoic acid molecule, thus, the captured • OH is 0.647mmol/L. The removal efficiency of photocatalysis on organic matter in filtered water is significantly proportionate to the amount of • OH generated, results indicate that • OH is the main active substance leading to the mineralization of organic matter, thus, optimizing the reaction condition to maximum the generation of • OH is the key to improve removal efficiency.



（T=22℃，DO=5.34，pH=6.85）

Fig.3 Removal effeciency of TOC by static photocatalysis

**Research on influencing factors of UV/$TiO_2$ photocatalysis of organic matter**

**Orthogonal experiment results of UV/$TiO_2$ photocatalytic**

UV light intensity, dissloved oxygen, reaction time, and pH value are selected as four main influencing factors according to our former reaserch. The dissolved oxygen content in filtered water is 3.55mg/L under the experimental conditions, the stable value of dissolved oxygen in the reactor are 5.58 mg/L, 7.21 mg/L when the aeration amount are 50L/h and 150L/h respectively.

Results of the orthogonal experiment are shown in table 1.

The values of R in table 1 show the importance of several factors, the importance of the four factors follows the sequence: light intensity, dissloved oxygen, reaction time and pH. Light intensity and dissolved oxygen are main factors that affect removal efficiency of UV/$TiO_2$ photocatalytic on organic matter in filtered water.

It can be seen from the orthogonal test results that the group-6 test (light intensity = 3.3 mw/$cm^2$, DO = 7.21 mg/L, time = 60min, pH = 5.0) reaches the highest TOC removal rate-53.2%. Because pH is not the important influencing factors, in addition, pH of filtered water is about 7 and it is unlikely to regulate pH of drinking water in production practice. Therefore, additional experiments are conducted by improving the level of light intensity, DO and reaction time. light intensity is increased to 4.2 mw/$cm^2$, dissolved oxygen reaches to 7.48 mg/L under the aeration amount of 200L/h, reaction time is extended to 3h. Results show that TOC has declined from 1.826 mg/L to 0.665mg/L and the corrsponding removal efficiency is 63.58%. Therefore, increase light intensity, DO, reaction time in a certain range can improve oxidation effect, but further increase of the level of influencing factors can only increase removal efficiency slightly. Studies have shown that under lower radiation flux condition, the reaction rate(r) is linearly dependent to the radiation flux ($\Phi$); under moderate radiation flux condition, r is linearly dependent to $\Phi^{1/2}$; under high radiation flux condition, r is irrelevant with $\Phi$[10]. As the surface of the $TiO_2$ thin film is limited, high light intensity will lead to lower efficiency of photons, which is not economic; higher levels of dissolved oxygen will increase energy consumption; long reaction time will increase the volume of treatment facitilty and increase the project costs. Therefore, the level of influencing factors should

be reasonably controlled from the point of cost, it is suggested that the reasonable light intensity should be controlled in 2-3 mw/cm$^2$, while suitable reaction time is 2-3h.

Table 1 $L_9$（$3^4$）orthogonal experimental results of UV/ $TiO_2$ photocatalytic

| Experimental arrangements | UV Light intensity(mw/cm$^2$) | dissloved oxygen (mg/L) | reaction time (min) | pH | TOC removal ratio（%） |
|---|---|---|---|---|---|
| 1 | 1.3 | 3.55 | 30 | 5.0 | 18.1 |
| 2 | 1.3 | 5.58 | 60 | 7.0 | 28.9 |
| 3 | 1.3 | 7.21 | 120 | 9.0 | 38.3 |
| 4 | 2.5 | 3.55 | 60 | 9.0 | 38.1 |
| 5 | 2.5 | 5.58 | 120 | 5.0 | 42.1 |
| 6 | 2.5 | 7.21 | 30 | 7.0 | 48.5 |
| 7 | 3.3 | 3.55 | 120 | 7.0 | 41.3 |
| 8 | 3.3 | 5.58 | 30 | 9.0 | 42.2 |
| 9 | 3.3 | 7.21 | 60 | 5.0 | 53.2 |
| M1 | 28.433 | 33.500 | 36.267 | 37.800 | |
| M2 | 42.900 | 37.733 | 40.067 | 39.567 | |
| M3 | 45.567 | 46.667 | 40.567 | 39.533 | |
| R | 17.134 | 14.167 | 4.300 | 1.767 | |

**Transformation of organic matter in the process of UV/$TiO_2$ photocatalysis**

Light intensity in the reactor are controlled to be 2.5mw/cm$^2$ during photocatalytic treatment of filtered water, take water samples at the react time of 1 min, 60 min, 90 min, 120min respectively. Measure spectral scan characters of the water sample between wavelengths from 190 to 450nm.The results are shown in Fig. 4.

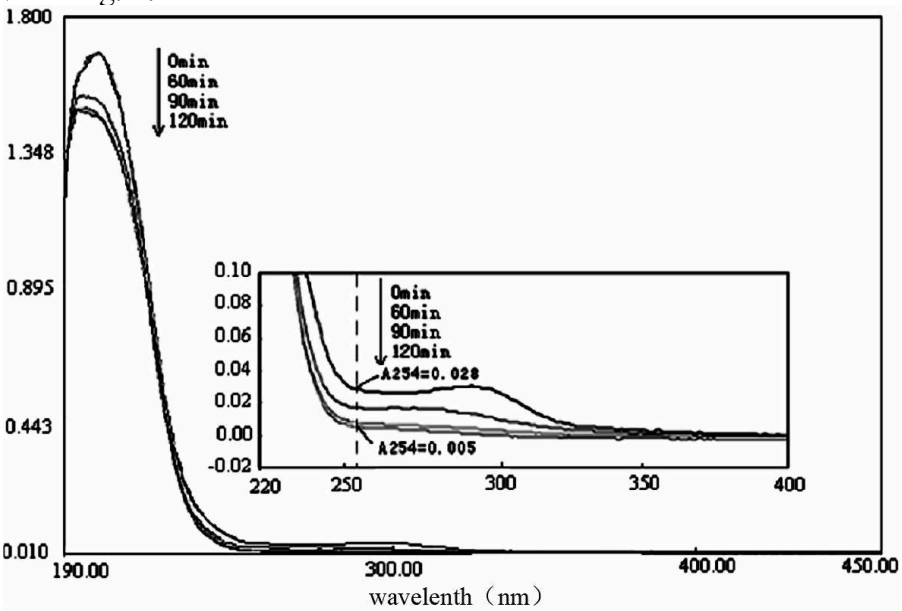


Fig. 4 Spectral scanning curve of filtered water by photocatalytic process

It can be seen that filtered water show an apparent absorption characteristics within the range of 190-240nm, this indicate that double-bond olefin compounds exists in water. In addition, there is an obvious absorption characteristics within the range of 250-320nm, this indicate that conjugated system organic exists in water. Experiment shows that the absorbance within the two intervals decreases significantly, which indicates that the photocatalytic process has a good removal effect on those types of organic matters, for example, $UV_{254}$ decrease 82.14% within 2h. Such kinds of substances in water are mainly human substances as well as organic matters with unsaturated

structure, these substances usually have high chlorine reactivity and also regarded as the main precursors of disinfection by-products—THMs. So, it can be deduced that photocatalysis has a sound removal effect on disinfection by-products precursors and improve chemical safety of drinking water.

## Conclusions

Following conclusions can be get by the research on UV/$TiO_2$ photocatalysis of filtered water:

(1) The glass supported nano-TiO2 photocatalysis has a good removal effect on trace organic pollutants in drinking water; it can greatly improve the chemical safety of drinking water. Organic matter removal efficiency is positively correlated to the amount of • OH generated in the process.

(2) Orthogonal tests on influencing factors show that the importance sequence of influencing factors are as follows: light intensity, DO, reaction time, pH. DO act as electron acceptor and have an obvious impact on photocatalytic effect. Enhancing the level of each factors is conductive to improving TOC removal efficiency, however, under the comprehensive consideration of TOC removal efficiency and cost, it is suggested that light intensity should be controlled in 2-3 mw/$cm^2$, and the reaction time should be controlled within 2-3h.

(3) UV/$TiO_2$ photocatalysis has a good removal effect on double-bond olefin compounds and the organic compound with conjugated system. Its removal efficiency on $UV_{254}$ is higher than the removal efficiency of TOC; this is conductive to control the risk of disinfection by-products and improve drinking water safety.

# The Development of Prestressed Concrete Cylinder Pipe in China

Zhang Hongyu[a], Peng Hua[b], Chen Xiang[c]

College of Civil Engineering, Wuhan University, Wuhan 430072, P.R.China

[a]ptlemoon@163.com, [b]huapeng904@163.com, [c]119345020@qq.com

**Keywords:** Prestressed Concrete Cylinder Pipe; Development Survey; Water Supply; Pipeline Manufacturing

**Abstract.** *Prestressed Concrete Cylinder Pipe* (PCCP) consists of a steel cylinder lined with concrete, then helically wrapped with a wire and coated with a dense mortar. PCCP has excellent structural properties, so it is widely used in various water-transportation projects around world. This paper presents a review of development of PCCP in China, which was summarized as three stages: *the period of exploratory development*, *the period of cooperative development*, and *the period of independent development*. The development process of design and production technique, the application in China, the construction and development prospect of PCCP were made a detailed discussion in each stage.

## Introduction

Prestressed concrete cylinder pipe, PCCP for short, is a kind large-diameter composite pipe of high pressure resistance, corrosion resistance and good anti-seepage performance. PCCP combines the tensile properties of high-strength steel wire, compressive strength of concrete and impermeability of steel cylinder, gives full play to the physical and mechanical properties of various materials. So it was widely used in large amount of water projects around the world[1, 2].

The first PCCP pipeline was produced in 1939 in Paris, France. The engineer Bonna designed a 1800mm-diameter PCCP based on prestressing technique and prestressed concrete pipe, and installed in Clombes water pipe network of Paris. The pipe was design within the water pressure 0.35MPa, and with full-length of 1500m. During the same period, the United States Company LookJoint had also developed a similar PCCP, after which PCCP had entered a rapid development period[3-10]. After 70 years of development PCCP has been widely used in various large-scale water projects of the world, such as: Libya's *Great Man-Made River Water Project* is the world's largest PCCP project, which has a total length of over 5000 km, and is hailed as "the eighth wonder of the world." PCCP was introduced into China in the eighties of the last century. After 30 years of development, it has formatted a certain application and production scale. There were detailed descriptions of PCCP's development history in China from the beginning of PCCP entering China in this paper. It could be figered out that the development of PCCP in China fell into three stages: the period of exploratory development, the period of cooperative development, and the period of independent development. The PCCP development process in China could also be the technological advances and improvements of PCCP in the process. By this paper, the researchers were able to clearly understand the technology development process of PCCP, to carry out more further research to accelerate the development and application of PCCP in China.

## Period of exploratory development (1980s)

In the eighties of last century, after the reform and opening up, some of Chinese research institutes and enterprises had begun to introduce, digest and absorb the advanced technologies of American PCCP pipeline. In 1984, Suzhou Research Institute of concrete and cement products cooperated with the pipe plant of Yingkou water company, using simple methods developed and produced a diameter of 600mm lined prestressed concrete cylinder pipe (PCCPL), which was used in water projects. In the same time, in 1985, cement pipe plant in Nanjing cooperated with the Beijing Research Institute of

Municipal Engineering, produced PCCPL of 600mm and 1200mm diameter using self-stressing concrete, which was installed in Jianyang Hydropower Project, Fujian and Nanjing water supply pipelines. It could be figered out that most of research institutes and enterprises in china would rather find their own way in PCCP production technology research in this period. It could be calles exploratory development phase, in which PCCP had a simple method of manufacturing, a relatively small diameter, and less production.

**Period of cooperative development (1990s)**

With the in-depth reform and opening up, and under the guidance of reform and opening up policy, some foreign advanced technology and information of PCCP through various channels accessed to the Chinese market, so that Chinese enterprises could introduce, digest and absorb foreign advanced technology and critical equipment. Thus the development of PCCP producing and applying was accelerated in China.

Shandong Electric Power pipeline Engineering Company (SEPPEC) introduced some key technology and equipment from the U.S. PCCP company Ameron in July 1986, such as: welding machine for spirally rolled steel cylinder, socket production equipment, pipe mold of 2600mm diameter, connectors and spreader. Basis on these equipments, it produced the first batch of PCCPE with 2600mm diameter as the plant circulating water pipe in June 1990. That filled the blank of PCCP producing and applying in China. Meanwhile, Hangzhou Research Institute of Mechanical Design (HRIMD) in the supporting of the national electricity company, researched and designed the vertical differential reeling machine and the vertical roller spray machine, and produced the welding machine for spirally rolled steel cylinder with 1600mm diameter mandrel on the basis of mapping Ameron's mandrel. So that a well-equipped , advanced technology and large-diameter PCCP production line was built, and produced PCCPE of1600mm diameter for Yellow River Diversion Project Zibo section. In 1998, SEPPEC introduced a welding machine to produce PCCP with 1200mm diameter below, thus it can produce PCCP with a variety diameter below 2600mm, and became a PCCP pipeline manufacturing company with relatively sound equipments in China.

Wuxi Huayi Pipeline Co. prepared to establish PCCP production plant from 1990. Then Huayi Pipeline Co. introduced a welding machine and socket production equipment from Ameron Company of the United States, and improved the vertical differential reeling machine and the vertical roller spray machine and spreaders by HRIMD. So that the company built a well-equipped production lines and put into operation in April 1995, and produced a number of PCCPE with 1400mm diameter, followed by producing 15km PCCP with 1200mm diameter for Suzhou Singapore Park. Shenzhen sun pipeline Company was founded in 1992, and introduced a complete set of production equipment from Price Brothers Company of the U. S. in the same year. its production line can produce a diameter of 900 ~ 2600mm of PCCP. In 1999 a vertical differential reeling machine which can produce PCCP with 3000mm diameter was provided by HRIMD and Heda Mechanical Engineering Co. Ltd.

By the turn of the century, the first three companies which had introduced PCCP production line produced a total of over 700 km, from 600 to 3000mm diameter PCCP pipeline, which was applied in more than 80 projects. During this period, Chinese companies assisted by foreign (mainly U.S.) PCCP advanced production technology, meet the needs of domestic projects through the introduction of foreign mature PCCP production lines and self-developed key production equipment simultaneously. It was a critical stage in which China PCCP industry started to take off.

**Period of independent development (the 21$^{st}$ century)**

In the 21st century, with the rapid launch of China's infrastructure construction, the Chinese PCCP industry experienced a wave of PCCP manufacturing plant construction boom to adapt to market demand off. In addition to the initial three PCCP production enterprises, there had been more than a dozen PCCP production plants emerged After 2000, such as Sichuan Jinwei, Xinjiang Guotong, Zibo Longquan, Jilin Electric Power, Beijing Heshan, Hohhot Wanlian Jiangsu Zhongyi, etc. According to

incomplete statistics, there have been more than 40 PCCP manufacturing enterprises, and more than 50 PCCP production lines up to now. It is showing a thriving scene. Among these plants, someof them are new constructions, others are converted by factories producing prestressed concrete pipe (PCP). Some PCCP production lines' products are already being used in the practical project. According to the statistics in 2010, the annual PCCP designed production capacity of China had reached more than 1000 km, the pipe's diameter ranged from 400mm ~ 4800mm, and the applicable operating pressure ranged from 0.2 to 2.0MPa, and the maximum covering soil reached deep of 10m above.

In order to promote the construction and development of China's water engineering technology, Hangzhou Reacher Institute of Mechanical Design digested and absorbed of Ameron's PCCP manufacturing technology, and developed PCCP production equipment and production technology for the Chinese conditions. Its subsidiary Heda concrete mechanical Engineering Co. Ltd is an excellence enterprise developed by itself, which can provide a full set of PCCP manufacturing equipment and technology. Heda can produce key equipment of PCCP manufacturing, such as: welding machine, reeling machine and spray machine, which can produce pipe with diameter range from 500mm to 4000mm. Now, many Chinese enterprises have chosen PCCP manufacturing equipments which were produced by Heda Company, so that not only the cost is saved, but also the construction speed is speeded up. Thereby the competitiveness of Chinese companise is increased, while the development of Chinese PCCP industry is also beneficial.

More and more PCCP plants were built in China, and most of them had choosen domestic production facilities indicated that China's PCCP production and manufacturing had been completely free from dependence on foreign technology. It can rely on the country's own forces, rather than rely on imported equipment. All indications are that PCCP industry development in China has entered a brand new phase. There are a number of PCCP production line are still preparing to build or already under construction, which shows that PCCP production and application in China is in a good momentum of vigorous development. However, how to ensure that these manufacturers can produce qualified PCCP, and guarantee the quality of PCCP in the practical projects, is the key to the healthy development of China PCCP production. That is definitely a very important task.

## Application of PCCP in China

Currently, PCCP has been widely used in various fields in China, such as: water conservancy, electricity, municipal, water supply and drainage, and also successfully used in the Guangdong Ling'ao Nuclear Power Station. In particular, PCCP has an unique advantage in the long-distance and high-volume water diversion projects, such as: the connection project of Yellow River Diversion Projec in Wanjiazhai of Shanxi Province is about 138.6km long, of which from Fen River reservoirs to Taiyuan Huyan water plant was in the use of PCCP with the diameter of 3000mm, length of 43.2km, working pressure of 0.6 ~ 1.0MPa, and deep of 2m ~ 8m covering soil. The Huiningzhuang - Daning section pipeline, which is a section of Middle Route Project of South-North water diversion from Beijing to Shijiazhuang emergency project, has a length of 56.4km,and use double pipes of large diameter PCCP. The maximum diameter is 4000mm, working pressure is from 0.6 to 1.0MPa, and the maximum covering soil reached deep of 10.5m. In addition, there are some other projects, such as: Xinjiang Irtysh River Diversion Projec lead the water from Irtysh river to Urumqi. The 2800mm diameter PCCP was used in three large inverted siphon project, which were in a total length of 10km. The pipeline with double parallel arrangement had a working pressure of 1.6MPa, a deep of 4m covering soil, and a single length of 7.25km. The project was completed in 2006, but because of the project's specific location, complex ground conditions, bad weather and construction conditions, it can be regarded as the most difficult of PCCP project in China comprehensively. Yangling water Supply Project is located in Shanxi Province. The pipeline with double diameter of 1200mm PCCPE has a length of 17.86km, the maximum working pressure of 1.4MPa, the maximum deep of 16m covering soil. Due to the Guanzhong economic zone and Guanzhong urban belt ,where the project

located, Yangling water Supply Project has to cross with rails, roads, rivers, and channels. It makes the project even more difficult in construction.

PCCP also has extensive applications in the electric power system. Such as: The PCCP produced by Shandong Electric Power pipeline company was used for water supplemental system, water recycling system and water delivery system. The effect turned out to be great. After nearly 30 years of development, PCCP is widely used in the circulating water system of various power plants for its outstanding ability to resist internal pressure. In the area of municipal water supply and drainage, PCCP is more widely used. The largest PCCP application was Shanghai Sewage treatment Project, which embedded 3.91km PCCP with 3600mm diameter in coastal soft foundation. It created a typical case of minimal disturbance to the environment and fast construction speed.

## Summary

The development and application of PCCP have been more than 70 years of history. Although China started relatively late, but the starting point is quickly established on the basis of introducing and absorbing foreign latest technology, and thus it‘s a relatively high starting point. The application of the technology was closed with the foreign advanced degrees. PCCP has many advantages of its own feature, therefore increasingly being used in a variety of projects. According to incomplete statistics, it has been installed more than 700 km PCCP and operated through the implementation in China. With the rapid development of China's industry and the continuous improvement of people's living standards, the demand for water is in the fast-growing, and so as the demand for large diameter pipe. Therefore it requires more specialized manufacturing equipment, transportation and installation equipment to meet the requirements. In consideration of this, we need to accelerate research and development process, and promote the development and application of PCCP in China.

[a]GoginaES@mgsu.ru, [b] Gulshin-dii@yandex.ru

**Keywords:** Wastewater, ecology, treatment plants reconstruction, deep biological wastewater treatment, nitrification, denitrification.

**Abstract.** The paper investigates the optimal parameters of the single-sludge denitri-nitrification system and their compliance with the existing wastewater treatment plants in Russia

Ecological status of water resources is causing great concerns of the population of the Russian Federation. The pollution of fresh water – rivers and lakes – is a result of the dumping of wastewater. In Russia the standards for wastewater discharge have increased in the nineties of the twentieth century. So the main question was the removal of nutrients (nitrogen and phosphorus compounds). In recent years there have been many studies of developing new methods of wastewater treatment, and of transferring Western technologies to Russian treatment plants. But the main problem now is that most of the stations in Russia were built more than thirty years ago. And now they are in need of renovation. It takes a lot of financial resources, but the possibilities are limited. Therefore it is necessary to carry out the reconstruction with minimal monetary costs, maximum usage of existing tanks and equipment, and satisfactory quality of wastewater treatment to the standards [1].

In Moscow State University of Civil Engineering there are extensive researches in the field of biological wastewater treatment, including the removal of nutrients. The results of the researches were used for constructions and reconstructions of treatment plants in Russia.

Technological Scheme "Deep biological ammonium-nitrogen removal activated sludge system", which was developed and patented in MGSU, treats wastewater biologically in the aeration tank, which is divided into a sequence of alternating anoxic and aerobic zones. Reconstruction of biological treatment under this Scheme is possible with minimal cost, and quality of treatment satisfies the modern standards (table 1).

**Table 1**. Parameters of the biological wastewater treating systems.

| Parameters of wastewater treatment | Different technologies of wastewater treatment | The basic technology of wastewater treatment, developed in MGSU |
|---|---|---|
| BOD in effluent, mg/l | 10 - 15 | 4 - 6 |
| Ammonium NH4 – N in effluent, mg/l | 0,6 - 1,5 | Less than 0,39 |
| Phosphate PO4 – P in effluent, mg/l | 0,8 - 1,5 | 0,4 - 0,6 |

Nowadays in the Russian Federation there are about sixty two percent of the plants with aeration tanks, thirty three percent of biofiltration plants, and five percent of the plants with only mechanical treatment. The main objective of the present study was to investigate the possibility of applying the single-sludge denitri-nitrification system in reconstruction of wastewater treatment plants in the Russian Federation. Only plants with aeration tanks were studied, because only they can be reconstructed with the Scheme.

The study included fifty three treatment plants of various Russian cities. According to the questionnaires has been received data for each treatment plant about the influents and the effluents, the features of the construction and the operation of structures at the station and data about the cost of aeration in the aeration tanks and so on. The location of the studied treatment plants is on the map (figure 1).

**Fig. 1.** The location of the studied wastewater treatment plants.

From the initial data were calculated the basic parameters of the aeration tanks, including the amount of air required for denitrification and nitrification. The calculation of the required amount of air has been produced by the method developed in MGSU. This method includes both normative calculations and practical experience of operating the aeration tanks (working with the single-sludge denitri-nitrification scheme) [2]. The results of the calculations were compiled for further analysis (table 2).

**Table 2**. Some of the data resulting from research.

| Technological parameters | Minimal value | Average value | Maximal value |
|---|---|---|---|
| Food to Microorganisms ratio mgBOD/day | 60 | 256 | 725 |
| Flow rate, m3/day | 144 | 162876 | 500000 |
| Treatment time, hour | 8 | 8,2 | 14 |
| Volume of the aeration tank, m3 | 46 | 26782 | 164900 |
| Q of air without the reserve, m3/hour | 48 | 15916 | 95900 |
| Q of air with reserve, m3/hour | 72 | 28874 | 143855 |
| Q of air in fact, m3/hour | 35 | 27557 | 167000 |

According to the analysis, sixty five percent of the studied wastewater treatment plants may be reconstructed according to the single-sludge denitri-nitrification scheme. It will greatly enhance the quality of wastewater treatment.

It is important that the calculations were made on the basis of the amount of air that is produced by the existing station`s blowers. Therefore reconstructions don`t require replacements of blowers and can be done in stages.

**Keywords:** Compound micro-polluted groundwater, contact oxidation filtration, iron, manganese

**Abstract.** The compound micro-polluted groundwater was treated by three-stage contact oxidation filters with total 1.5m ceramic layer. The filtration rates, in accordance with the time sequence, were respectively 1m/h, 1.5m/h, 2m/h, 3m/h and 4m/h. The result indicated that, in the condition of sufficient dissolved oxygen, the effluent concentration of iron, manganese, ammonia nitrogen and $COD_{Mn}$ can met the National Drinking Water Standards. Under the range of filtration rates the average effluent concentration was respectively that 0.073 mg/L, 0.278 mg/L, 0.229 mg/L, 0.172 mg/L and 0.199mg/L for iron; 0.150 mg/L, 0.180 mg/L, 0.110 mg/L, 0.150 mg/L and 0.359 mg/L for ammonia nitrogen. The average concentration of manganese was 1.828mg/L with dropping aeration only, compare with that 0.323mg/L with strengthening aeration under filtration rate 1m/h. And the manganese concentration was 0.061mg/L, 0.062 mg/L, 0.084 mg/L and 0.071 mg/L, respectively under the range of filtration rates of 1.5-4m/h by strengthening aeration. Because of the biological system in filter layer no perfect, humic acid and low temperature, the average removal rate of $COD_{Mn}$ was only 16.10% under the 1m/h filtration rate. Then when the rates were up to 1.5m/h-3m/h, effect of $COD_{Mn}$ removal increased and the water treated met the Standard with the maturity of filter layer. But under the rate 4m/h $COD_{Mn}$ concentration of effluent was exceed the Standard. Meanwhile, in the range of 1m/h-3m/h, consumption of dissolved oxygen respectively were 19.26mg/L, 14.73mg/L, 13.99mg/L and 13.99mg/L.

## Introduction

For geological reasons, the concentration of iron and manganese in groundwater exceeds the national Drinking Water Standards in some areas. In recent years, the groundwater is contaminated due to the infiltration of surface water pollution into the underground. The polluted groundwater is called compound micro-polluted groundwater (CMPG, for short). It is worth attention that the ammonia nitrogen and organic pollutants in the groundwater, make the water treatment harder[1,2]. Bio-contact oxidation filter has the advantage that can remove iron and manganese in the same filter layer at the same time[3]. In some condition, bio-contact oxidation filter can remove the iron, manganese, ammonia nitrogen and organic pollutants in the CMPG[3,4]. The bio-filter layers not only contains autotrophic bacteria (including Iron Bacteria, Manganese Bacteria, Nitrobacteria), but also has heterotrophic bacteria, which are trained by the CMPG[4]. The competition for dissolved oxygen (DO) among the microorganisms is one of the important factors to removing effect. Three-stage aeration bio-contact oxidation filter is used to treat CMPG for drinking water.

## Experimental Method

**Experiment Apparatus.** The experiment apparatus is composed of same three pice of plexiglass columns filled with ceramsite as filter layer. The inner diameter of the column is 47 mm, 700 mm in height, and the layer height is 50 mm, supporting layer for 50 mm. The overflow port is set for 50 mm above the filter layer. H\The ceramsite size are from 1.25 to 1.25 mm. As shown in figure 1.

The experiment time was 270 days in total. Specific plan was as shown in table 2. Water dropping into columns above the inlet 50 cm is for aeration. In 95th day one aeration device is set in the second column above the filter layer for strengthening aeration.

**Water Used.** Experimental water is comprised of groundwater, humic acid, urea, starch, $NH_4Cl$, $MnSO_4 \cdot 5H_2O$ and $FeSO_4 \cdot 7H_2O$. Table 1 is for water quality.

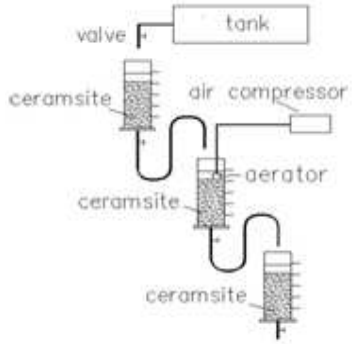

Fig.1 Schematic of apparatus

| $NH_3$-N | Nessler's reagent spectrophotometry | spectrophotometry | | | |

## Results and Discussions

The range of filtration rates was shown in tab.3. Under 1m/h, include drop aeration stage and increasing aeration stage, namely 1-fist and 1-second.

**Iron Removal Effect.** The result is shown in fig.2. With 1m/h, 1.5m/h, 2m/h, 3m/h and 4m/h, the average concentrations of effluent were respectively 0.073mg/L, 0.278mg/L, 0.229mg/L, 0.172mg/L and 0.199mg/L. Because ferrous ion is easily oxidized, the lower the filtration rates are, the better the removal efficiency is. When the rate was up to 1.5m/h, the results were worse. The reason may be that filter layer was saturated. After backwashing, the filtration rate up to be 1.5m/h, microorganism needs certain time to adapt to the new environment. When the filtration rate is 2-3 m/h, microorganism would have been adapted to the new environment. When the filtration rate up to be 4m/h, and after running four days, it need backwashing. After that, the removal effect of iron ion is stable. Thus proved that biological membrane is mature, can effectively remove the iron ion in the MPCG.

**Manganese Removal Effect.** The result is shown in fig.3. the effluent concentrations of manganese were 1.828mg/L, 0.323mg/L, 0.061mg/L, 0.062mg/L, 0.084mg/L and 0.071mg/L respectively under 1m/h-first, 1m/h-second, 1.5m/h, 2m/h, 3m/h, 4m/h. A number of studies have demonstrated that temperature and DO are a key factor for biological filter to remove manganese. Because of the stronger absorption, during the early stage of device operating, the treatment effect is also better. Due to the higher concentration of ferrous ion, in oxidation sequence of manganese lags behind the $NH_3^-$-N, and all bacterium are aerobic bacteria. Therefore, only when DO condition is adequate, the treatment effect can reach the Standard. At the 95th day aeration device was set in the second filter inlet. DO concentration changes are shown in table 4. The effluent concentration of manganese was 1.83mg/L(under 1m/h by drop aeration only), as contrast, the effluent concentration is 0.32mg/L(increasing aeration device) and still have a downward trend, and finally will reach the

Standard. Compared with before, the concentration of DO increased 3.10mg/L, and the consumption in the filter was 14.13mg/L. Obviously, the average removal rate raised by 57.78%. In fact, the growth of bacteria in filter layer is a decisive factor on removing manganese. Iron ion in the MPCG stimulated oxidation activity of manganese removal bacteria. For the entire device, the three-stage filter provides plenty of places for microorganisms to reproduce, so the filter had higher biomass, and logically has the very good removal effect on manganese. Continue to improve the filtration rate to 1.5-4m/h, effluent concentration of manganese was low. In the filtration rate up to be 1.5m/h and 4m/h respectively, device was backwashed. When finish backwashing, the data in the figure can be seen that no matter how to change the filtration rates, the treatment effect was not affected.

**Tab.4 The DO average concentration** (mg/L)

| Time | First filter | | Second filter | | Third filter | |
|---|---|---|---|---|---|---|
| | Inflow | effluent | Inflow | effluent | Inflow | effluent |
| 1-94d | 9.05 | | 5.00 | | 5.80 | |
| 95-270d | 7.85 | 0.82 | 8.10 | 1.90 | 5.97 | 5.07 |

**Ammonia Nitrogen Removal Effect.** As shown in fig.4, when filtration rate range is 1m/h-4m/h, the removal effeciency of NH4+-N is obvious. The initial average concentration of ammonia nitrogen in MPCG was 3.5mg/L, the average effluent concentration of it was 0.15mg/L. Nitrifying bacteria through nitrification to remove ammonia nitrogen, because nitrifying bacteria is aerobic bacteria, enough content of DO is key role for ideal treatment effect.

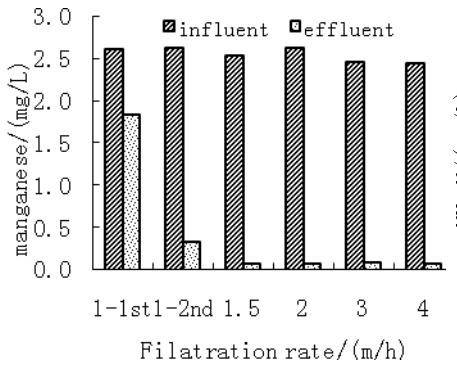

**Fig.3 The manganese removal effect**

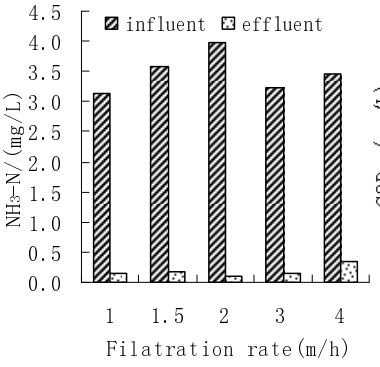

**Fig.4 The $NH_3$-N removal effect**

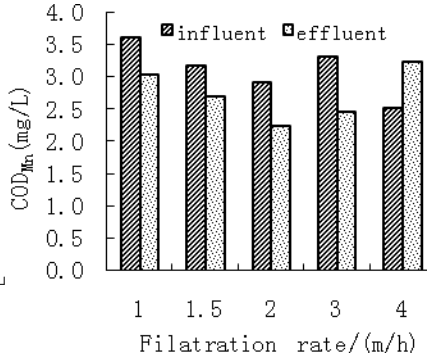

**Fig.5 The $COD_{Mn}$ removal effect**

The reason why it is suitable for the growth of nitrifying bacteria which need long time generating is due to non-uniform granular, that will lead to the inner surface and the concave part of ceramsite produced relatively thick and stable biofilm formation, and also less affected by hydraulic conditions. After succeeding at biofilm formation, denitrifying bacteria can thrive in low organism environment, then multiply much faster than heterotrophic bacteria, nearly be superiority strains. Since the 95th day, it added the aerating device to ensure adequate dissolved oxygen. Nitrification is much better than before, ammonia nitrogen removal efficiency obviously. Under the scale of filter speeds was 1-4m/h, removal rate of it respectively was 95.22%, 94.97%, 97.24%, 95.38%, 89.64%. Although the removal rate was the lowest under 4m/h, but still can meet the Standard. Therefore, the filtration rate changes do not affect stability biofilm to remove ammonia nitrogen with filtration rate no more than 4 m/h.

**$COD_{Mn}$ Removal Effect.** As shown in figure 5, the $COD_{Mn}$ average concentrations of CMPG were 2.39-3.60mg/L. Under the range between 1m/h to 4m/h, the average concentrations of effluent respectively were 3.02mg/L, 2.69mg/L, 2.23mg/L, 2.46mg/L and 3.2 mg/L and the removal rate respectively were 16.10%, 14.99%, 23.15%, 25.88% and 28.49%. The concentrations of effluent were under 3 mg/L than is the limited concentration of the Standard with the filtration rates of 1.5m/h-3 m/h. Generally the removal rate is low. It is because of the test device short running time, low room temperature(under 12˚C) in early time, then the biological systems in the filter layer is not yet perfect. The most important is because of the humic acid in MPCG and the competition between all kinds of microorganisms in the filter layer. Humic acid is macromolecular organics. Microorganisms can't capture it, and also wouldn't be able to degrade it. Therefore, it only was

removed by microorganisms' extracellular enzyme and biological membrane flocculation and adsorption. In addition, humic acid is easy to chelate iron and manganese, and then generate clathrate which is difficult to dissolve in water. The result indicated that among iron, manganese, ammonia nitrogen and $COD_{Mn}$ in MPCG, $COD_{Mn}$ is difficult to remove by contact oxidation filter. But with the extension of the running time and temperature (18˚C-22˚C） increase, the removal rate increased. And the $COD_{Mn}$ concentration met the Standard. From 247th to 270th days, the filtering rate was 4 m/h with temperature of 18˚C-14˚C, and in this period was 5m/h for three days. The filtration rate increases too fast in a short time and the temperature dropping, so that made the treatment effect of abnormal. In addition the large amount of organism accumulated before, even to the extent that the effluent concentration higher than influent. Humic acid is decomposed by microorganisms into simple organic compounds that are more easily to detect by potassium permanganate, this also is one of the important reasons for the poor treatment effect. So this method for MPCG to remove organic pollutants, needs to be further in-depth study. further

**Dissolved Oxygen Consumption.** The result is shown in table 5. With increasing aeration and the filtration rate of 1 m/h, the removal rate of iron, manganese, $COD_{Mn}$ is in higher levels(compared with drop aeration only). In particular, the average removal rate of manganese increased by 57.78%. And when filtration rate was 1-3m/h, DO consumption and filtration rate are inversely proportional. This is consistent with a rule, that the lower filtration rate, the more consumption of DO. Because of increasing filtration rate, MPCG will stay in the filter for a shorter time, and then the biological membrane contact oxidation time is shortened too, so the consumption of DO will be less. But the biofilm has been mature in the filter, no matter how to change filtration rates, the results (including iron, manganese and ammonia nitrogen) do not change. With filtration rates within 4m/h, the removal effect is obvious and stable for iron, manganese and ammonia nitrogen.

**Tab.5 DO consumption and average removal rate of each index**

| Filtraton rate (m/h) | DO consumption (mg/L) | Average removal rate | | | |
|---|---|---|---|---|---|
| | | Fe | Mn | $NH_3$-N | $COD_{Mn}$ |
| 1(Drop aeration only) | — | 96.86% | 29.89% | 88.27% | -3.09% |
| 1 (Increasing aeration) | 19.26 | 95.17% | 87.67% | 94.52% | 9.25% |
| 1.5 | 14.73 | 86.37% | 97.59% | 94.97% | 14.99% |
| 2 | 13.99 | 88.96% | 97.63% | 97.24% | 23.15% |
| 3 | 13.99 | 91.80% | 96.57% | 95.38% | 25.88% |
| 4 | — | 90.24% | 97.19% | 89.16% | -10.31% |

## Conclusions

(1) For the iron, manganese and ammonia nitrogen，the treated water can meet the national Drinking Water Standards by three-stage under the filtration rates as 1 m/h, 1.5 m/h, 2 m/h, 3 m/h and 4 m/h. And the effect is also stable. For $COD_{Mn}$ the filtration rate should not exceed 3m/h.

(2) Sufficient dissolved oxygen is necessary for effective treatment of MPCG. With the increase of filtration rate, consumption of dissolved oxygen decreased slightly.

**Key words:** ultra-high-rise-building，water supply and drainage system，fire fighting system，middle water tank

**Abstract:** With the rapid development of chinese economy,to speed up the modernation of the society more and more ultra-high-rise-building rise abruptly.This article as Liuhe square project in Shengzhen city an example,elaborated the water supply system, drainage system,and fire fighting system design in water supply and drainage system design.

## Introduction

High-rise building of the international conference in 1972 the high-rise building has been divided into four classes, including a fourth category that building height of more than 100m high-rise building construction is called ultra-high-rise-building. In recent years , the level of economic and social development by leaps and bounds , with the process of urbanization, building height of 100m above the high-rise building continued to increase , particularly in compensation for the use of land , urban centers of the scarcity of land , building height is constantly increased. Rapid economic development in China has brought the rise of raising building and construction technology , construction is moving in the direction of ultra develop . This will not only be able to solve the congestion caused by the urban population living and working environment , but also to ease the current tension in urban land pressure , therefore , the development of high-rise buildings is the future trend of building development. High-rise and ultra-high-rise-building designed with the general theoretical and computational methods and low-rise multi-storey building designs, but because of the multi-layered architecture , multi-functional, structural complexity and difficulty of the depth of its design are relatively increased. Many difficulties with increasing height , building water supply and drainage design to bring , unlike high-rise building high-rise building , the presence of multiple water supply system partition , fire systems requirements, pipe drainage system , the interface has strict requirements and other issues. This article as Liuhe square project in Shengzhen city an example,describes the design of super high-rise building water content.

**Project Summary**

Liuhe commercial plaza located in Shenzhen Plateau montainous area , located in the hinterland of Pegasus Plaza (Plateau montainous Square ) which the core point of Plateau montainous, Liuhe commercial plaza is the only real estate development projects, but also first change change old project of Plateau montainous ,was designated by the government in Plateau montainous district urban renewal of demonstration projects. The project covers an area of 39084m2, with a total construction area of 214750 m2. This project has nine of 26-42 layer business-living buliding near the ground, there are seven high-rise residential , a ultra-high-rise multiple-use building, one super high-rise residential , underground 2 floors. Among them the seven high-rise residential each of 12 layer, ultra-high-rise multiple-use building have 36 layer, building altitude is 139.8 m, ultra-high-rise residential 39 layer, building altitude is 151.8 m, underground 2 floor is garage and equipment room, garage for the underground layer 2 local at ordinary times, for civil air defense in wartime.

**Lifing Water Supply System Design**

This water supply water source project chooses urban tap wate, from this plot of land on the east and west on both sides of the municipal water feeding respectively introduced a DN200 feed pipe for the project life, fire water, and outside a circular pipe network, water supply pressure is 0.2 Mpa.

**Daily water consumption**

The project of residential living water rationing takes 300L / person • day, business of 5 L/m2 • d, the maximum daily life of the project water consumption is 1699m3; unforeseen maximum daily water consumption of water by 10 percent, the total water consumption to 18689 m3.

**Feedwater system partition**

In order to ensure water security , combined with architectural features, water district the project are as follows :

Ⅰ Area : Underground 2 floors - 4 floors , directly from the municipal water supply pipe network .

Ⅱ Area: Middle Ⅰ area in 5-14 layer, due to the low zone 2 floors underground life water pump room variable frequency pumps by the pressure reducing valve for water supply after decompression.

Ⅲ Area: Middle Ⅱ area in 15-24 layer, from underground 2 layer life water pump room of the central frequency conversion pumps by the pressure reducing valve for water supply after decompression.

Ⅳ Area : High Ⅰ area in 25-29 layer, water pump room by 2 floors underground life high area of variable frequency pumps by the pressure reducing valve for water supply after decompression.

Ⅴ Area : High Ⅱ area in 30-39 layer, high water pump room by 2 floors underground life zone of variable frequency pump up to the roof water tank and then directly by the water tank water supply, namely adopt the combination of water pump, water tank.

**Life water pump and water tank**

According to the use of functional division and convenient management in the future, the project of commercial and residential in the use of water meter set separately, separate measurement, and set up the independent life pool and pressurized equipment, frequency conversion for water pump

group. According to the working principle of water pump, the smaller the difference between the peak flow and low flow, water pumps in high efficient area of the running time is longer, the more conducive to energy conservation. The project more than 8 layers for high-end residential traffic, tend to be more uniform, so choose frequency conversion water supply way.
The project life and fire the pool set apart, near J negative on the second floor of the basement, which pools the effective volume of residential life is 250 cubic meters, two lattice; Business is 100 cubic meters.

**Sewer System Design**

Sewer system uses rain and sewage seprate system . Indoor uses sewage , waste diversion system, set up specific vent stack, namely three vertical pipe drainage system.

**Sewage System**

The highest daily displacement of this engineering is 1529 m3. After centralized sewage produced food grease trap grease into the basement finished by supporting the sewage lifting unit extraction outdoor sewage pipe network ; ground floor small shops catering waste requires users to set up before being discharged to the sewer network outdoor grease trap treatment; the remaining wastewater is discharged to the outdoor gravity sewer network , and then discharged into the septic tank treatment municipal sewage pipe network. Flush water through underground garage submersible sewage pump sewage pipe network upgrade to outdoor access municipal sewer .

**Rainwater System**

Adopt an organized drainage, roof rainwater collection and outdoor rain after confluence , the nearest into the municipal storm sewer system . Shenzhen storm rainfall intensity calculated using the formula, the formula is:

$$q = 9.194 \times (1 + 0.460 \lg P)^{0.555} /(t + 6.840) l / s \cdot ha$$

Among them the recurrence interval : five-year senior roofing , outdoor venue by two years , according to the entrance ramp to the underground garage for 50 years .
Duration of rainfall : roofing by 5min, outdoor venues by 10min.

**Condensed Water System**

Air conditioning condensation water in the bottom of the indirect drainage works at the podium roof can be discharged to the nearest water bucket or drain and ensure the outlet from the ground 150mm, pipe layer nearest the door to the outside row gullies .

**Fire Fighting System Design**

**Fire fighting water consumption**
According to “the code for fire protection design of tall buildings” in this project indoor fire hydrant water consumption of 40 L/s, outdoor to 30 L/s, fire duration for 3 h. According to " code of design for sprinkler systems " by the underground garage and commercial grade Ⅱ dangerous level design , design of water taken 30L/s, fire duration is 1h. According to the "fixed artillery fire extinguishing system design specifications," water cannon system to take water 40L / s, fire duration takes 1h. Water hydrant , automatic sprinkler water and fire water cannons water of this project as shown in **Table 1**.

**Table 1 Fire water consumption**

| Fire range | Fire fighting system | Design of water/（L/s) | Fire life/h | A fire water consumption /m3 |
|---|---|---|---|---|
| Indoor | Fire hydrant | 40 | 3 | 432 |
| | Automatic sprinkler | 30 | 1 | 108 |
| | Fire monitor | 40 | 1 | 144 |
| Outdoor | Fire fighting | 30 | 3 | 324 |

**Refuge floors and roof fire water tank**

The project is set up on the roof 18 m3 of water tank and pressurization voltage regulation equipment, reserve fire early fire consumption of 10 min. Among them,the 13 and 29 layer of the ultra-high-rise multiple-use and residential buliding, while also offering the device layer ..

**Hydrant system**

According to “the code for fire protection design of tall buildings” in this project indoor fire hydrant water consumption of 40L / s, Outdoor is 30 L / s, fire duration of 3h; calculated the project 's fire water hydrant system volume 650m3, two grid , where fire hydrant water is 432m3, fire pond water from the municipal water supply .

Indoor hydrant system uses a temporary high-voltage systems, indoor is equipped with special fire hydrant pipes.System is divided into three zones for the low zone underground 2 floors – 3 layer , District 4 layer to 30 layers, high zone 31 layer to 39 layer. The lower zone system and underground pump room fire hydrant 2 layer after decompression supply pressure pump by a roof high water tank through the valve regulator ; high zone system from the ground layer 2 double outlet hydrant pressure pump supply by roof Fire high water tank be regulated ; fire hydrant at the mouth of the water pressure is more than 0.5Mpa using vacuum regulator hydrant . Fire standpipe arrangement to ensure the same level of two adjacent hydrants gun enrich the water column can be protected at the same time to reach any part of the range . Fire hydrant enrich the water column is not less than 13m, in addition to the hydrant Fire elevator room , the rest are equipped with Fire hydrant reel . In addition to A, B, C, D, E, F, G ( four or more ) , the other at the ground hydrant boxes need to configure a fire hose reel , hose length of 25m. Are located outside the high , medium and low zones hydrant pump adapter 3 sets of water to the interior of each system .

**Automatic sprinkler system**

The project is set in the ground three 540m3 reinforced concrete fire water pressure pump and automatic sprinkler , sprinkler water storage room 108m3, indoor fire water 432 m3, two fire water grid ; roof set 18 m3 of reinforced concrete Fire a water tank .

( 1 ) Set the location and device . The layers of super high-rise projects , among asylum , both commercial and underground garages with automatic sprinkler systems.

( 2 ) The automatic sprinkler system works vertically divided into two zones , the system uses a temporary high repression. Low Zone : 3 -storey underground to 28 layers , 29 layers to 39 layers of underground high zone . Low area consists of 3 floors underground pump room supply pressurized sprinkler pump pressure , high roof by fire water tank through the valve regulator ; high zone

system consists of three levels of underground sprinkler pump room supply pressure pump by roof high water tank and regulator device regulation.

( 3 ) nozzle level requirements . The super high-rise residential projects of public walkways decorated with concealed sprinklers ; garage , equipment room using orthostatic nozzle ; Business section in addition to commercial atrium , lobby , function rooms and theaters using spray nozzle type lower ceiling , the rest are used in commercial establishments upright sprinklers K = 80. Underground garage, water density mall is 8L/min.m2, active area 160 m2; spray strength in other parts of the floor area is 8L/min.m2, active area 160 m2. Using closed nozzle 93 ℃ glass ball on commercial catering kitchen stove , using the rest of the glass ball 68 ℃ closed nozzle .

( 4 ) sprinklers installed. Nozzle diameter were taken over DN15mm, in contact with the water distribution pipe diameter DN25mm. Sidewall sprinklers takeover diameter DN20mm, in contact with the water distribution pipe diameter DN32mm, while the upper sidewall sprinklers located Poly hot plate .

( 5 ) has a pump room in the basement and ultra- high-rise residential roofing wet automatic alarm valve , each alarm valve pressure does not exceed 1.2Mpa, the number of nozzles is generally not responsible for more than 800 .

( 6 ) are located outside the high and low zone automatic sprinkler system pump adapter to the indoor water systems , including high zone 2 sets of pump adapter , the lower zone 4 sets pump adapter .

**Fixed artillery fire extinguishing system**

According to the specification requirements in clear height of more than 12m commercial atrium to set a fixed artillery fire extinguishing equipment , the project in the ultra- high-rise 15-storey complex building has an atrium , in this layer set two fixed fire water cannons . This system uses automatic scanning ZDMSO.8/20SYA shoot water at high altitude water cannons , each muzzle diameter of DN65mm, working pressure is 0.8Mpa, single shot flow 20L / s, protection radius 50m. Fixed fire artillery temporary water supply system for the high-pressure system , negative two fire pump room located on the ground floor fixed fire artillery fire pumps , fire water tank with a high roof to ensure the system is connected through the valve to maintain the most negative point pressure water cannon .

**Extinguishers provided**

Residential : A ~ G are light hazard class A class configuration 2 2Kg ammonium phosphate fire extinguisher in each fire box office . H, J Building is a serious risk of grade A class configuration 2 5Kg ammonium phosphate fire extinguisher at each hydrant , and to ensure maximum protection from the location of fire extinguishers does not exceed 15m, the distance over protection should be added two 5Kg ammonium phosphate fire extinguisher . Commercial : Commercial belongs to the class A dangerous level , configuration 2 4 Kg ammonium phosphate fire extinguisher at each hydrant , and to ensure maximum protection from the location of fire extinguishers does not exceed 20m, the distance over protection should be added two 4Kg ammonium phosphate fire extinguisher .

Underground Garage: underground garage by dangerous Class B Class design , set 2 4 Kg ammonium phosphate fire extinguisher at each hydrant fire hydrant in the middle position and the adjacent , and to ensure maximum protection from the fire extinguisher does not exceed 12m, more than protection from the position should be added two 4Kg ammonium phosphate fire extinguisher.

## Conclusion

In recent years, the rapid development of high-rise buildings , high-rise buildings of the design of the drainage system requirements also put forward higher requirements. In building water supply , drainage , etc., to be developed , the problem is still a lot of innovation and research . As a building drainage design staff, should be based on technical , security, economic principles , in practice, to innovation , to find the best drainage design programs to meet the new requirements of architectural design development to meet the continuous improvement of people's material cultural requirements, is to embark on the basis of sustainable development and protection.

# Treatment of raw water in Yangtze Chenhang Reservoir by Diatomaceous Earth Precoat Filtration

Wenqi Zhou[1, a], Dong Zhang [1], Hui Ye[1], Zheng Wang[1], Zheng Yang [2], Chunlin Zhang[2]

[1] National Engineering Research Center of Urban Water Resources, Shanghai 200082, China;

[2]Shanghai Safbon water service Co. Ltd., Shanghai 201716, China;

[a]email: zwqbati@163.com

**Keywords:** diatomaceous earth; precoat filtration; turbidity; drinking water treatment

**Abstract.** Taking the raw water of Yangtze Chenhang Reservoir as the research object, the characterization of diatomaceous earth, and the removal efficiency of $COD_{Mn}$, turbidity by precoat filtration process were investigated by pilot experiment in this paper. The results showed that diatomaceous earth patterns having porous structure and the pure silica peak at 2θ angles 21.980, 36.080, 31.460 and 28.430 in XRD analysis. Precoat filtration has a good stability to remove solid suspended particle, effluent turbidity was remained about 0.05NTU. Precoat filtration had no effect on removing $COD_{Mn}$. The pressure of 50KPa could be defined as a critical point in this experiment. Beyond the critical point, the devices should be stop and backwash, to resume operation pressure. Overall, precoat filtration can be defined as a filtration technique for relatively low turbidity raw waters.

## Introduction

During World War II, the US Army needed a portable, efficient filter to remove Entamoeba histolytica, a protozoan parasite prevalent in the Pacific war zone, from drinking water. The army developed precoat filtration, which successfully removed the cysts. Since 1949, precoat filtration has been used in the filtration of sugar syrups, fruit juices, wine, beer, and water. Now, precoat filtration is a US Environmental Protection Agency (US EPA) accepted filtration technique for potable water treatment [1]. More than 170 potable water treatment plants using precoat filtration have been constructed. As a new water treatment technology, diatomaceous earth precoat filtration could remove suspended particles without adding chemicals [2]. The main objectives of this study were to evaluate the feasibility of the application of precoat filtration enhance the turbidity removal in Yangtze Chenhang Reservoir raw water.

## Material and method

**Raw water.** The main feature parameters of experimental raw water were shown in Table 1.

Table 1 Water Quality of Raw water

| parameter | $COD_{Mn}$ mg/L | Turbidity NTU | $UV_{254}$ $cm^{-1}$ | Conductivity μS/cm | Fe mg/L | Mn mg/L |
|---|---|---|---|---|---|---|
| value | 1.4-2.7 | 5-45 | 0.027-0.103 | 280-860 | 0.33-1.04 | 0.002-0.58 |

**Pilot process parameters.** Pilot-scale was $6m^3/h$. Coagulant used PAC (alumina content 10%) and the dosage was about 20mg/L. After coagulation and sedimentation, raw water were flowing into sand filtration ($3m^3/h$) and precoat filtration ($3m^3/h$). The filter area was $1.5m^2$. The dosage of precoat was 0.9kg, turn on the precoat pump to bring the diatomaceous earth to the filter. When all the filter media is on the filters, change the valving to bring raw water and body-feed to the filter. Dosage of body-feed was 4.32mg/L.

**Materials and Physical characterizations.** The diatomaceous earth sample was provided by Lin Jiang Imerys Diatomite Co, Ltd. A Rigaku D/Max 2500 powder diffractometer (Cu *Kα* radiation) was used to obtain powder XRD patterns. The surface textures of the samples were observed using scanning electron microscopy (SEM) with a JEOL JSM-6700F (JEOL Co., Japan) apparatus.

## Results and discussion

**Characterization of diatomaceous earth.** SEM micrographs of diatomaceous earth (DE) are shown in Fig.1 [3,4]. The porous structure of DE can be clearly seen in Fig.1 (b). The filtering medium used in precoat filtration is composed of fossil-like skeletons of microscopic water plans called diatoms, which range in size form under 5 to more than 100 micrometers. These algae have the capability of extracting silica form water to produce their skeletal structure. We could see in Fig.2, that the XRD patterns having the pure silica peak at 2θ angles $21.98^0$, $36.08^0$, $31.46^0$ and $28.43^0$. These peaks are consistent with the report in literature. Diatomaceous earth is distinguished not only by the Diatom species, but also by its purity of $SiO_2$. Most of the constituents of diatomaceous earth are practically inert. The soluble portion of diatomite is very low(less than 1%). The chemically inert characteristics mean that diatomaceous earth could safely be used for filtration of water, beverage, or other liquids for human consumption.

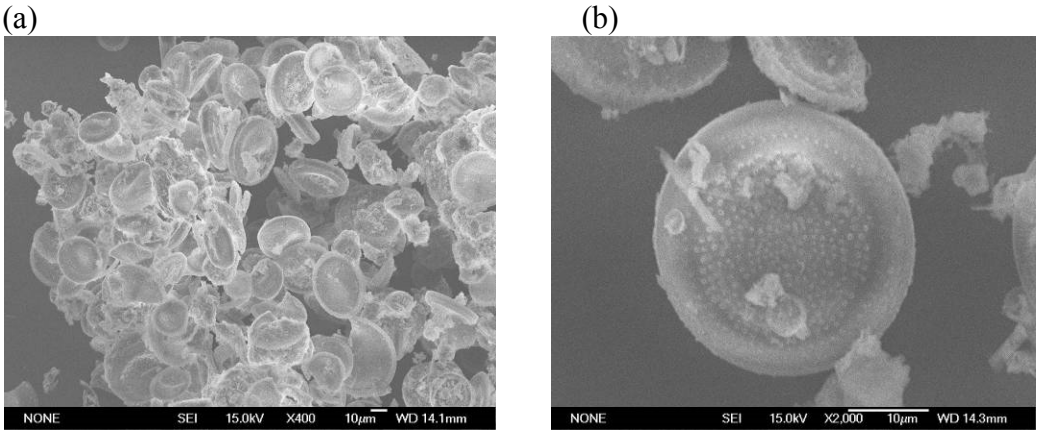

Fig.1 SEM photographs (×400 and ×2000) of diatomaceous earth

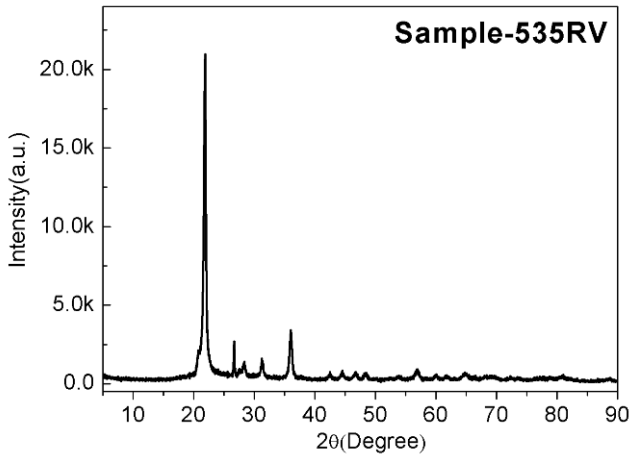

Fig.2 XRD patterns of the diatomaceous earth sample(535RV)

**Turbidity removal.** The turbidity of different process was shown in Fig.3, within 32 hours of running time, effluent turbidity of precoat filtration was remained about 0.05NTU, the removal rate of turbidity was more than 90%. Compared with the precoat filtration process, the effluent turbidity of sand filtration was affected by the filtration rate, sedimentation tank sludge period, and other factors.

The effluent turbidity of sand filtration was changed form 0.05NTU to 0.25NTU, even though the removal rate of turbidity in sand filtration was more than 88%, which indicate that precoat filtration has a good stability to remove solid suspended particles. Diatomaceous earth (DE or diatomite) filtration can be defined as a filtration technique for relatively low turbidity waters, generally below 10 turbidity units (NTU). A survey of direct filtration practice, including precoat filtration plants, indicated that 80 percent of the plants had an average source water turbidity of 5 NTU or less. The maximum turbidity at 80 percent of the plants was 40 NTU or less[2].

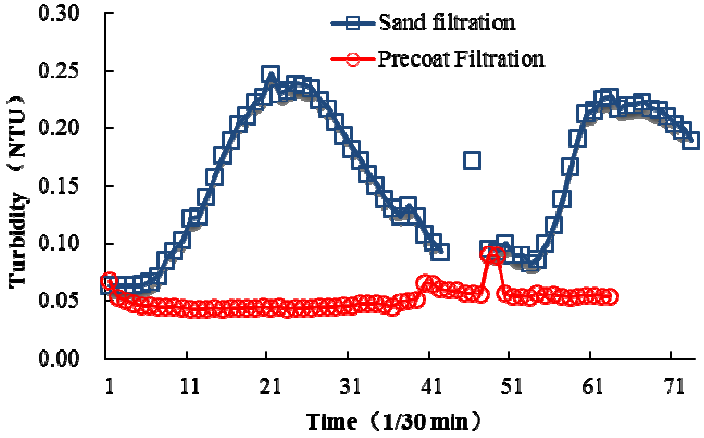

Fig.3 The effluent turbidity of sand filtration and precoat filtration

**$COD_{Mn}$ removal.** As shown in Fig 4, under different operation conditions, the effluent $COD_{Mn}$ of precoat filtration was 1.38 mg/L, which was closer to the effluent of sedimentation (1.36 mg/L) and sand filtration (1.32 mg/L). It was showed that precoat filtration had no effect on removing $COD_{Mn}$. The removal of organics combined process mainly depends on the process of coagulation and sedimentation. Therefore, in order to make the effluent quality meet the national drinking water standard (GB5749-2006, less than 3 mg/L), the production units should use coagulation and sedimentation, or other pre-oxidation process to ensure the effective removal of organic matter in raw water.

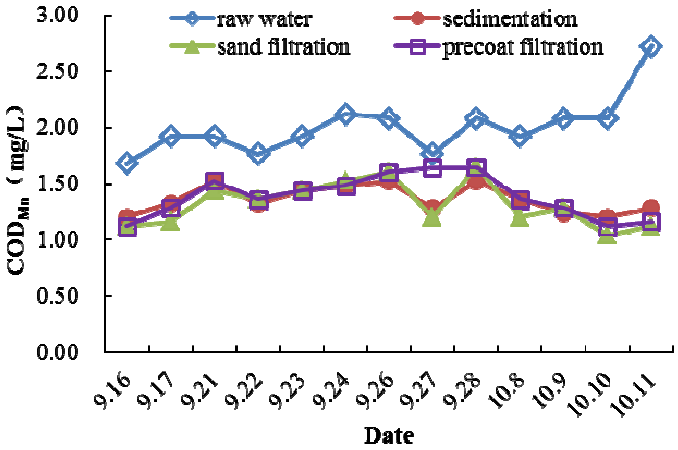

Fig.4 The effluent $COD_{Mn}$ of different process

**Hydraulics.** The hydraulics of precoat filtration process was investigated in Fig.5. By analyzing flow and pressure data during the operation, the hydraulics of the device was changed. It was showed that when the pressure up to 50KPa, the effluent flow dropped from the $3m^3/h$ to $2.9m^3/h$. For the devices used in this experiment that the actual operating pressure must not exceed 50KPa, otherwise it will

lead to decline in effluent flow. Thus, the pressure of 50KPa could be defined as a critical point. Beyond the critical point, the devices should be stop and backwash, to resume operation pressure.

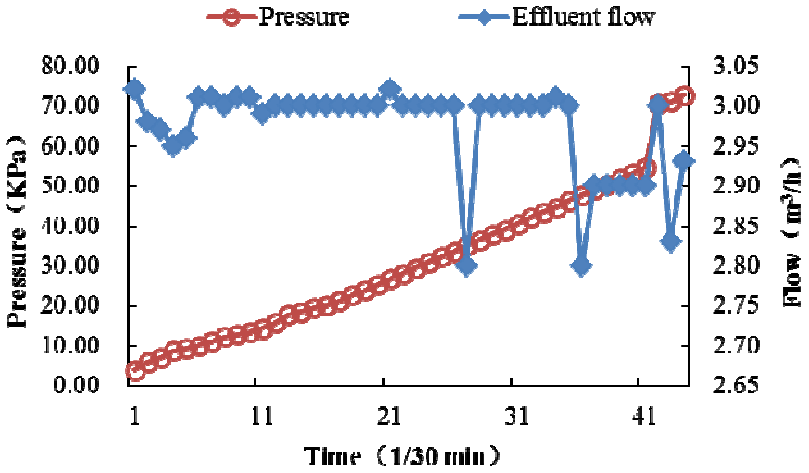

Fig.5 The hydraulics of precoat filtration process

## Conclusions

Diatomaceous earth patterns having porous structure and the pure silica peak at 2θ angles 21.980, 36.080, 31.460 and 28.430. Precoat filtration has a good stability to remove solid suspended particle, effluent turbidity was remained about 0.05NTU. Precoat filtration had no effect on removing $COD_{Mn}$. The pressure of 50KPa could be defined as a critical point in this experiment. Beyond the critical point, the devices should be stop and backwash, to resume operation pressure. Precoat filtration can be defined as a filtration technique for relatively low turbidity raw waters.

# Choosing an optimal trenchless renovation method for pressure and non-pressure pipes

Vladimir Orlov[1, a], Ilya Averkeev[1, b]

[1]Moscow State University of Civil Engineering, Department of Water Supply, Yaroslavskoye sh. 26, 129337, Moscow, Russia

[a]orlov950@yandex.ru, [b]ilji4.msk@gmail.com

**Keywords**: trenchless renovation, pressure pipes, non-pressure pipes, pipelines network

**Abstract.** The paper presents the innovative decision of the problem of choosing the most effective pipe renovation method among the wide range of them. To solve this problem a computer program called "Repair 2012" was developed. The factors influencing the selection process of optimal renovation method for pressure and non-pressure pipes and the theoretical base for creating a computer program are described. The program algorithm based on weighted analysis of these factors. Weighting coefficients for each factor are calculated using arithmetical mean for all concerning trenchless methods. The income and outcome user information, the sequence of the process of working with the program are represented in the article. The process and results on determining an optimal renovation method are shown as an example.

## Introduction

The use of trenchless technologies for infrastructure network rehabilitation makes it possible to accelerate the repairing processes with an opportunity to reach high ecological and economical factors, which are the most important ones for effective operation of urban area.

Trenchless technologies used for pipelines network renovation have to provide energy, resources and costs savings and to prevent (reduce sharply) leakages into the environment as well. A variety of trenchless methods for pipe network rehabilitation exist in the modern market, therefore municipal services got confused with question of using the most effective renovation method in certain cases. This fact makes scientists, designers and constructors decide to use a wide range of techniques or strategies for the selection of optimal renovation method. Most modern studies are devoted to choosing the optimal techniques for pipe laying [1-5], in a less degree – to rehabilitation woks [6-8]. Different researches use available software (ExpertChoice [5]) or computer-based information system (DSS [4]) as well as self-developed programs [1, 3]. The municipal service in large cities such as Moscow and Sankt-Petersburg need an efficient tool to create strategy of pipe network renovation.

## Theory

The selection of renovation methods starts with assessment of some critical factors. The primary importance have: costs (marked as C), technological duration of the process (D), mean lifetime (T), technical (B) and hydraulic (H) factors. In order to take into account all these factors it is necessary to reveal an average one, which may become the main criteria for choosing an optimal renovation method. For this purpose lots of information needs to be processed. In this case it is more convenient to process all this information in the computer program using weighted factors calculation.

Cost factor (C) means building and repairing works cost for one meter of a pipe for a specified trenchless method and diameter (Eq. 1). Weighted cost factor is:

$$K_C = \frac{C}{C_W}, \qquad [1]$$

where $C_w$ is an arithmetical mean value of costs of all concerning trenchless methods.

Technological factor (T) means the duration of the entire working cycle (in days) on a section of 100 m in length for specified trenchless method and diameter (Eq. 2). Weighted value is:

$$K_D = \frac{D}{D_W}, \quad [2]$$

where $D_w$ is an arithmetical mean value of duration of all working cycles for specified trenchless method.

Lifetime factor (T) means the frequency of carrying out rehabilitation process (times/year) for specified trenchless method rehabilitation – it is the inverse value of renovated pipe lifetime (Eq. 3). Weighted lifetime factor is:

$$K_T = \frac{T}{T_W}, \quad [3]$$

where $T_w$ is an arithmetic time mean of frequency of carrying out the rehabilitation process of all concerning trenchless methods.

Technical factor (B) means diameter loss (in percents) after carrying out the specified trenchless rehabilitation method (Eq. 4). Weighted technical factor is:

$$K_B = \frac{B}{B_W}, \quad [4]$$

where $B_w$ is an arithmetical mean value of diameter loss for all concerning trenchless methods.

Hydraulic factor (H) is the inverse value of the main criteria of waste water pipelines – Chezy coefficient (for gravity-flow pipelines) or ratio of hydraulic friction λ (pressure pipes).

Total weighted factor for certain trenchless method is the sum of all factors (Eq. 5):

$$\sum(K_C + K_T + K_D + K_B + K_H). \quad [5]$$

The minimal total weighted factor means the priority of given method among the others. An algorithm for computer program was based on theoretical considerations mentioned above.

The algorithm contains the income and outcome forms, which includes the following data:

- information about the repair section with particular data about the specific water flow (pressure or gravity), diameter and material, damage level and failure characteristics;
- information about methods for trenchless rehabilitation according to the pipe type.

Boundary conditions (cycles) are installed in the algorithm of calculating optimal parameters:

- the external cycle, which serves to extract those trenchless methods, which are used with an optimal diameters that differ from the repairing one;
- the first internal cycle, which divides trenchless methods according to their materials (metal/nonmetal);
- the second internal cycle, which divides trenchless methods according to defect characteristic;
- the third internal cycle which deals with minimal total weighted ratio of 5 optimization factors.

**Results and discussion**

As one of results the developed program called “Repair 2012” gives us the printouts of outlet information and designs a graph to illustrate weighted factors of optimal trenchless method for pipe renovation. The program is worked out as a database of all trenchless technologies, which can be used for water supply and sewer networks. The program includes four inserts to illustrate passport data and other information, such as: water flow behavior, pipe diameter, material and failures (Fig. 1 and 2).

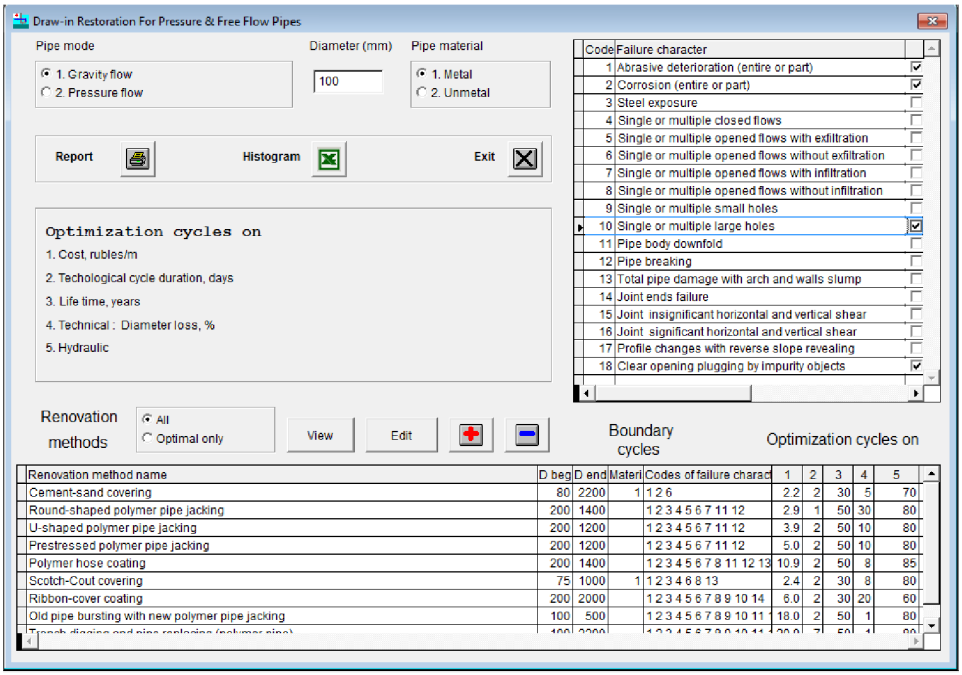

Fig. 1. The example of the first dialog box for non-pressure pipe.

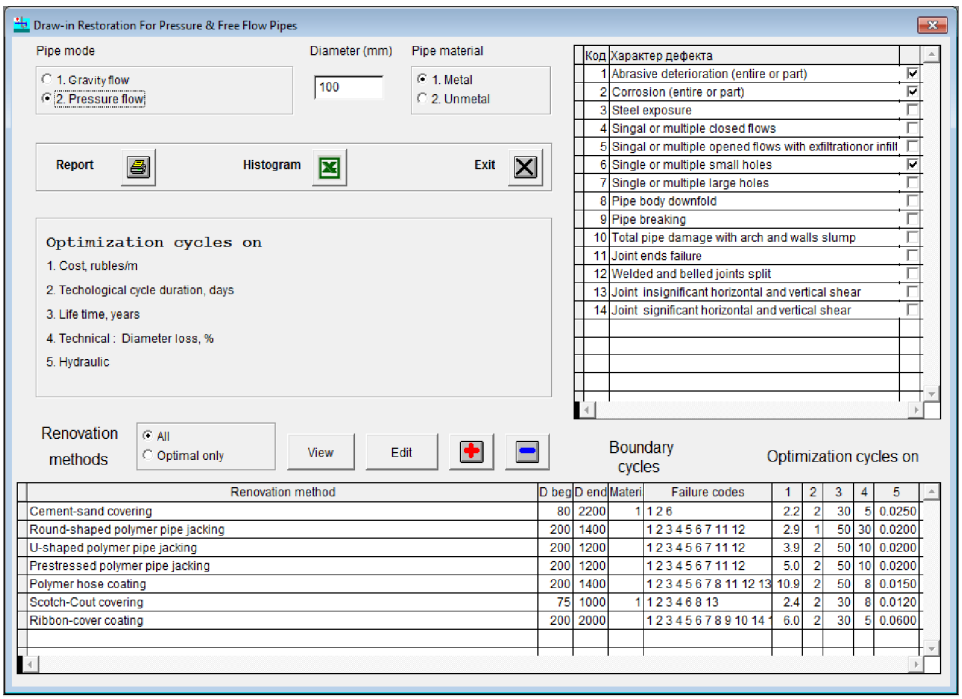

Fig. 2. The example of the first dialog box for pressure pipe.

Optimization cycles are placed hear to divide 5 positions according to criteria factors: C (1), D (2), T (3), B (4), H (5).

The information given in the lower part of the box includes the list of all trenchless methods with boundary parameters used for each method (diameter range, material codes and the type of defects, which can be removed by certain method), including the data on optimization factors (1-5).

There are “Show”, “All methods” and “Only acceptable”, “Change”, “+” and “–“ buttons above the methods data. These buttons make it possible to enter the particular method, change its parameters or delete lines in the box. The typical defect lists for pressure and non-pressure pipes are represented in dialog boxes (Fig. 1 and 2).

The operation process during the work with the given program is represented below.

At first user should input the following data: flow mode of pipe network (pressure or gravity), diameter of the existing pipeline, pipe material (metal/nonmetal) and pipe defects (as a code).

After data input the program automatically generate some changes:

- the 5th line in the "Optimization cycles on:" shows Chezy coefficient, $m^{1/2}/s$ (for non-pressure pipes), or hydraulic friction ratio λ (nondimensional quantity);
- the method titles with all the input data in lines as they also depend on flow dynamics;
- the defects list according to the chosen flow type.

It is also possible to make manual changes for the failure nature (quality factor) as well as their quantity (quantity factor).

The program also allows to user to input changes and additions in renovation methods list. Prior to operating changes and additions, it is necessary to push the buttons "All" and "Show". In order to change information in particular method line or to add a new method (database changing mode) it is necessary to use "Correct" button. Thereafter user checks the exact method to get the possibility to verify new information. In order to confirm changes user should press the button "Apply". Filling the data in cells "Boundary cycles" and "Optimization cycles on" provided by entering the start and final diameters, code of pipe material, which can be renovated by specific method (1 – metal, 2 – nonmetal, 0 – the others), failures codes, data concerning described above five factors.

In order to add a new method into the database, the "+" button should be pressed to get a new line called "New method"; the "–" button is used to delete any method in line.

The work with the program ends using buttons "All" and "Output form".

In you want to display only valued methods for this particular case study, user may press the button "Only valued" and then again "Output form".

Table 1
Final results on automated analyze and choosing an optimal renovation method

| **D = 600 mm** | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| **Renovation method** | **Factors** | | | | | | | | | | |
| | Cost C [rubles/m] | Weighted cost $K_C=C/C_W$ | Technological, cycle duration D [days] | Weighted technological $K_D=D/D_W$ | Time (opposite the life time) T [1/year] | Weighted time $K_T=T/T_W$ | Technical (diameter looses) B [%] | Weighted technical $K_B=B/B_W$ | Hydraulic ratio H | Weighted hydraulic $K_H=H/H_W$ | Total |
| 1. Cement-sand covering | 3.2 | 0.3988 | 2 | 0.7619 | 0.0333 | 1.4286 | 5 | 0.5479 | 0.0250 | 1.2739 | 4.4111 |
| 2. Round polymer pipe jacking | 4.0 | 0,4984 | 1 | 0.3810 | 0.0200 | 0.8571 | 30 | 3.2877 | 0.0200 | 1.0191 | 6.0433 |
| 3. U-shaped pipe jacking | 4.5 | 0.5607 | 2 | 0.7619 | 0.0200 | 0.8571 | 10 | 1.0959 | 0.0200 | 1.0191 | 4.2948 |
| 4. Prestressed pipe jacking | 5.0 | 0.6231 | 2 | 0.7619 | 0.0200 | 0.8571 | 10 | 1.0959 | 0.0200 | 1.0191 | 4.3571 |
| 5. Cured in place pipe | 2.5 | 0.3115 | 2 | 0.7619 | 0.0200 | 0.8571 | 8 | 0.8767 | 0.0150 | 0.7643 | 3.5716 |
| 6. Scotchkote covering | 5.0 | 0.6231 | 2 | 0.7619 | 0.0333 | 1.4286 | 8 | 0.8767 | 0.0120 | 0.6115 | 4.3017 |
| 7. Trench excavation and pipe replacing (polyethylene pipes) | 20.0 | 2.4922 | 5 | 1.9048 | 0.0200 | 0.8571 | 1 | 0.1096 | 0.0200 | 1.0191 | 6.3828 |
| 8. Trench excavation and pipe replacing (ceramics and cast iron pipes) | 20.0 | 2.4922 | 5 | 1.9048 | 0.0200 | 0.8571 | 1 | 0.1096 | 0.0250 | 1.2739 | 6.6376 |

It is also possible to print out a histogram, which reveals the dynamics of optimization process.

Table 1 represents an example of such a printout on choosing an optimal renovation method for a section of non-pressure pipeline. Fig. 3 represents a histogram for this case. Such histograms help users and designers to estimate and compare optimization parameters in order to determine an optimal method.

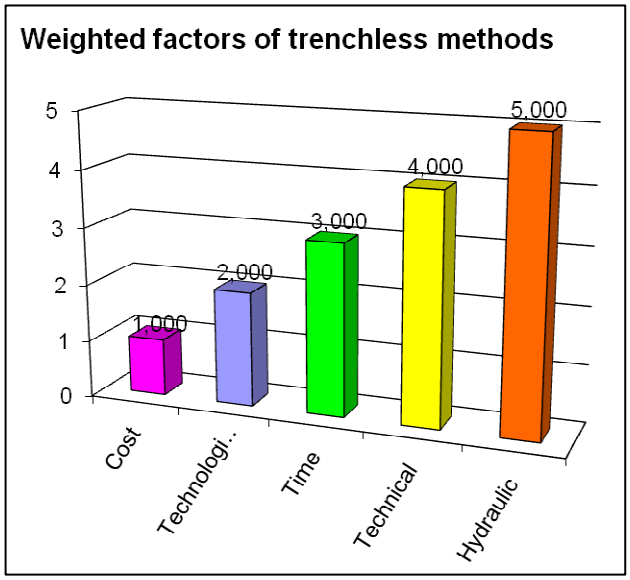

Fig. 3. The example of the histogram for optimal method for non-pressure sewer network.

## Conclusions

1. A computer program for selection an optimal renovation method for trenchless rehabilitation of pressure and gravity water supplying and water disposal pipelines is developed for specialists and engineers from the design and operating organizations.
2. As a result the program displaying a histogram for each particular case study, which reveals proportions of operating costs, technological duration of renovation works, lifetime, technical and hydraulic factors of optimal renovation trenchless method, which has the minimal weighted factor.

**Keywords:** GIS, water supply network, System development, maintenance

**Abstract.** Urban water supply systems are the primary guarantee for life and enterprises to work orderly, according to the requirements of water resource department and the technical feasibility for the management system, the water supply pipe-network information system was designed and developed. The system was developed in C # language and SuperMap Objects as secondary development components. The applicability and weaknesses of the system was analyzed in order to provide better service for the water conservancy work digitally.

## Introduction

Urban water supply pipe network systems composed of a series of structures and distribution pipe network are critical infrastructure for urban economic development and that are the primary guarantee for life and enterprises to work orderly[1]. With the development of production, the city gradually expanded and the city's water supply network continuously updated. Water supply network becomes a lifeline of the city and it is closely related to the normal life of the city residents. Urban water supply systems were built underground with the hidden, large-scale, huge dada and complex characteristics. The traditional management methods by drawings and diagrams were difficult to manage and utilized a large number of constantly updated urban water supply pipe network information effectively. GIS is a computer assisted system for the capture，organization，storage，retrieval，query，update，analysis and display of spatial data[2]. GIS with the specific function of Visualization and spatial analysis can meet the requirements mentioned above, as an advanced technology used in the field of urban water supply. GIS has a positive effect on urban water supply planning, information inquiry, quick repairs, accurate positioning, optimal allocation of staff, etc [3-6]. This system was developed for a city in North China by C # language and SuperMap Objects as secondary development components, in order to provide better technical services for the city's water management and transport.

## Requirement analysis

The system designed based on customer demand analysis and the water management department as the service object, it should have the functions as following:

To display the information of all kinds of water supply network in the city, providing information query and search quickly for the user, that conducive to management and scheduling range.

Basic on the information of the water supply pipe network, user can position the damage valves exact location timely in order to determine which valves need closed and how to channelize.

Basic on the existing layout of the city's water supply network, the system provided basis for the new water supply network pipeline.

## General design of the system

**Design of the system main flow.** The user can user this water supply network geographic information system after login. When user enter the main interface of the system， they can monitor and manage the information of the urban water supply network, including editing, query, maintenance analysis, displaying of water delivery mode, calling the Symbol Selector and various kinds data entering. In addition, the system also provides other assist functions such as particular location marked of the water pipeline, different levels of valves marked and map production output. The flowchart of the system main flow was shown in Fig.1.

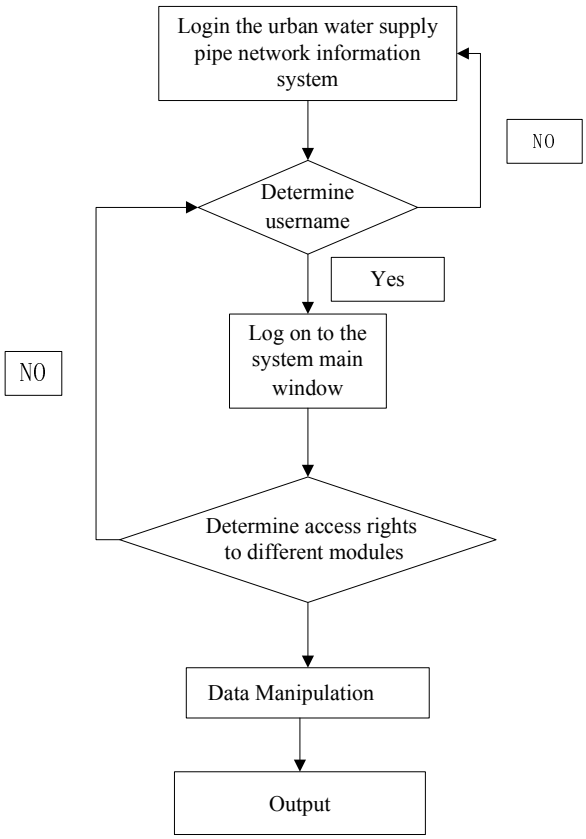

**Fig.1** The flowchart of the system main flow

**Data Storage.** Development of urban water supply network geographic information system needed the strong support of database system. And given urban water supply network information was different from other relevant spatial geographic information, there were two kinds of database those were attributes database and spatial database for storage and management of data. The system design mainly uses SQL Server and the SDB data engine of SuperMap Objects for data processing.

**Design of the system main function modules.** Combined with the actual situation of the city, the main function modules of the management system can be divided into data editing of the pipeline, the water supply network information query and map making. Each main function module has different sub-modules of function shown in Fig.2.

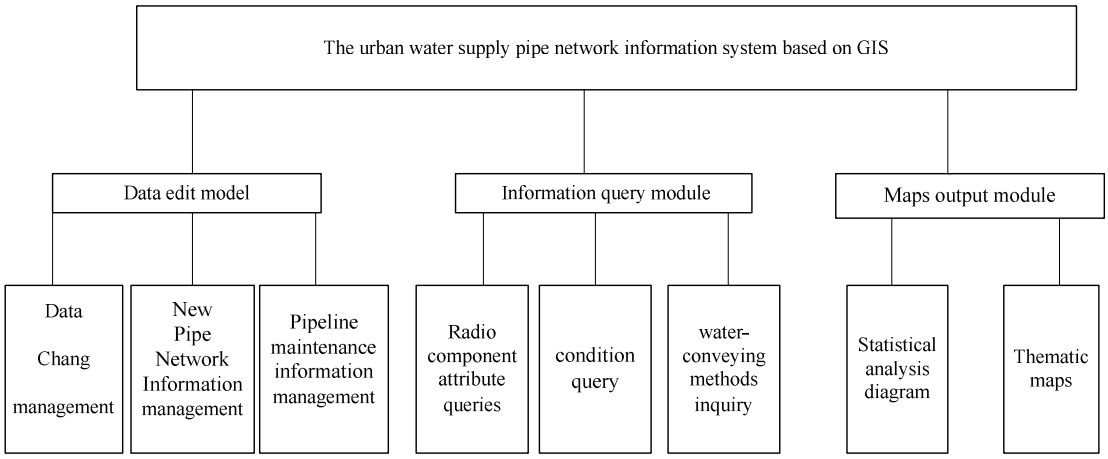

**Fig.2** The flowchart of the system main flow

## Detailed design of the system

**The water supply pipe network information editing module.** That was mainly to adapt to the development of water supply network or create constantly changing in the city, the relevant data can be update on the map in real time via the system. The main pipeline data editing module fulfils three main functions those were data change management, new pipe network information management, management of pipeline maintenance information and decision analysis based on the above information. The function module diagram was shown in Figure 3.

**The water supply pipe network information query module.** That mainly in order to facilitate user to query information of the city water supply pipeline. Its features include a radio component attribute queries, condition query (such as location, water supply) and water-conveying methods inquiry. The function module diagram was shown in Figure 4.

**Maps output module.** User can make some Statistical analysis diagram and specific module maps by map making model，including a compass, scale, coordinate grid, diagram generation for water supply, etc.

## System implementation

**Main interface.** The main interface provided a window for user interact with the information system, it reflects the overall layout of the system, can directly express the most function of the system. It reflected the overall layout of the system and expressed the most function of the system directly. An operating interface of the system with intuitive, concise, friendly characteristics can greatly improve the operation efficiency. The system minimized redundancy controls on interface and number and distribution of child windows were designed reasonable to maximize the efficiency for user.

**The menu bar and toolbar.** Accurate classification for the system menu made user stick out a mile to the program function and improved operation efficiency. The system menu bar includes the following functions:

File: open, create, add data, load CAD, save as, and exit.

Editor: copy parallel, split, rotate, extend, trim, fillet, add bookmarks, labeling features, etc.

View: zoom, pan, full size, clear screen and the layout view and map view.

System toolbar includes some commonly tools, such as open, save, zoom, etc, to facilitate users.

**Right-click menu function.** Attribute table of right click menu showed the attributes data in an elected layer and displayed in another window, recorded the total number of attribute data. Right click menu is convenient for user to add data, opening and closing layer, select elements and map view in the map window.

**Map Global Display.** Global map display is primarily a thumbnail map and user can change its area in the view by changing the position of thumbnail map border.

**Comprehensive query and analysis.** The system provides four queries by SoDatasetVector.QueryEx of SuperMap Objects that can help users to accurately retrieve the information they need.

Service area queries: The main function is to query service area, numbers of population of the water supply pipeline and water station through the buffer analysis in different conditions.

Water station query: That was a kind of map query, it convenient for the user to capture the spatial and attribute data those they need about water station and positioned the location.

Water pipeline component query: User can query target position of water supply pipeline and valve according to different conditions.

Water-conveying methods query: User can find out the water-conveying methods was branched, cyclic or others through this function to scheduling and emergency better.

On the basis of the information above mentioned the system design analysis capabilities that can provide decision support for users.

**Maintenance analysis.** User can analyze and optimize the water maintenance of water supply network through the system; it was the effective method to troubleshooting when the valve trouble happened. There were two kind of maintenance analysis i.e. valve maintenance analysis and pipeline maintenance analysis.

Valve maintenance analysis: The position of valve damaged can be to determine the position of valves which should be closed and which spare valve should be opened. Steps of valve maintenance analysis as following: Maintenance analysis - valve maintenance analysis - select the type of valve damaged and its properties - analysis and get conclusion.

Analysis of Water supply pipeline maintenance: The location of damaged pipeline and area which was serviced can be found by this system to adjust water supply scheduling timely. Steps of v Analysis of Water supply pipeline maintenance as following: Maintenance analysis - analysis of Water supply pipeline maintenance - select the type of pipeline damaged and its properties - analysis and get conclusion.

**Map production.** User switch to Layout view then in the layout view adding a command button, compass, grid, scale, coordinate grid network, then you can map production output.

## Conclusions

The water supply geographic information systems of a city in north China was designed and development basic on the analysis of existing distribution information of the city. The system implements the functions included comprehensive query and analysis, maintenance analysis, map production and some basic functions such as the menu bar and toolbar, right-click menu function, etc. The system has friendly interface, simple operation, good compatibility, strong function, can provide fast and efficient service for water management. The system relied on the mathematics, graphics, computer science and other disciplines, so there was better practicability and comprehensive.

**Keywords:** Water Distribution System; Hydraulic Model; Uncertainty Analysis; Random Sampling

**Abstract.** This research analyzed the operation characteristics of the urban water supply network, the space and time change rule of water consumption and the micro modeling process. Using typical simulation software and the corresponding computer environment, the authors took a simple network, e.g., the pipe network model parameters, and under the conditions of variables uncertainty. and created a new Hydraulic Model. Corresponding uncertainty quantitative techniques of water supply network computer model technology were put forward, and new integration software was developed on that basis.

## Introduction

Computer simulation is the foundation of the planning, design and operation of the pipeline network of a water supply network system. A lot of engineering of mathematical model describe the system behavior with the certain method. However, all real-life problems in some way are accompanied by uncertainty. In the process of network modeling, uncertainty may come from parameter measurement, parameter estimation process, mathematical certainty and uncertainty. These contradictions will seriously affect the reliability of the simulation and optimization results[1].

Since the beginning of the 1970s, when the idea of uncertainty of the model was proposed, study in this area has created extensive interest of different background researchers, thus pushing the discussion and fusion of the process identification theory, filtering theory, time series analysis and sensitivity analysis method in the applications of the environment system, and created the feasible tools of uncertainty analysis[2].

If each input parameter in the model of probability distribution is independent of each other, then the probability distribution of the output parameters can also seek but, in most cases, the function relation of input and output parameters can't be expressed using an analytical equation, and therefore other methods have to be used, such as sensitivity analysis (SA), Monte Carlo simulation method (MCS) and Latin super cubic sampling method (LHS), fuzzy sets method and random sampling simulation method, etc. Random sampling method is a favorable method to study the random variables using a digital computer, and it is a kind of uncertainty analysis method [3].

This paper using random sampling preliminary quantified the uncertainty interval of the model result caused by the uncertainty of the model parameters, puts forward the new proposals evaluation model accuracy, technical route of model uncertainty analysis.

**Setting of parameters interval.** Take pipe C value as an example, the original each tube C value is fixed, before simulation the value of C needed to be input, such as a new line of cast iron pipe (without inner liner) C a value for 130, but the actual condition is probably 125 or 135, so set an uncertainty interval [125, 135], also can be set to a [120, 140], the lower interval can be set by yourself according to the actual situation, every time when all the pipe from the simulation of C value interval randomly an integer modeling.

**Interval setting of state variable.** Take water demand at the nodes (nodal demand) as an example, the original water demand every moment of each node is fixed value, such as 10 l/s, basic water demand and demand pattern must be input in the dynamic model, basic demand model of water each time multiplied by the amount of water coefficient is the water each time, need before simulation prior input, because users maters are read every two months or one month, it is hard to know exactly water

use volume of each node a certain time, so it needs to set a numerical interval, such as [5, 15], the lower interval according to the actual situation of their input, every time when simulation from all the interval randomly a numerical modeling.

**Control of interval numerical precision.** Pipeline roughness coefficient C value generally is integral, Take [120, 140] interval as an example, the interval of integer 21, respectively for 120,121... 139,140, each time to take a random integer for simulation; The amount of water needed to node precision interval define your own, as a decimal or two decimal places, with the [5, 15] interval as an example, if take a decimal numerical precision, the interval but random numerical including 5.0, 5.1, 5.2,..... 14.9, 15.0; If take two decimal places of numerical precision, the interval but random numerical including 5.00, 5.01, 5.02,..... 14.99, 15.00.

**Stability control of the results.** Each a sampling simulation, get a simulation results, two sample after the simulated results of simulation to get the lower interval, after a sampling each simulation, the modification of the corresponding the lower interval. As the first sample simulation results node pressure for 1 is 20 m, and the second sampling simulation node pressure for 1 is 21 m, the node output interval for 1 [20, 21], if the third sampling simulation of pressure for nodes 1 is 22 m, the modification of the output of node 1 interval for [20, 22], the fourth sampling simulation node pressure for 1 is 19 m, the modification of the 1 output node interval for [19, 22], the more sampling simulation, the more stable interval can be get. Different scale of the network simulation test sample, and concludes that the simulation results interval to the basic stability simulation times, as the basis of simulation times set, so as to different scale, the different sections of the numerical precision sampling simulation Settings reasonable termination conditions.

## Case Study

Put this simple system for double headwater system, node 1 and 7 for water source node, the flow from 1 to the pipeline network is10 l/s, from 7 to the pipeline network is 20 l/s, the node flow for 3, 4, 5, 8 is 7 l/s, 5 l/s, 5 l/s, 13 l/s, node 2 and 6 for transmission node, node flow is zero. The pressure of node 1 is known, the head is 20 m, and the specific properties, see table 1. According to above pipe and node data hydraulic adjustment with, that all the pipe flow and node pressure, seen in table 2.

Table 1. Pipeline and Nodes Properties of Network Deterministic Model

| Pipe | Length (m) | Diameter (mm) | C-value | Node | Demand (*l*/s) |
|---|---|---|---|---|---|
| 6-4 | 1000 | 300 | 170 | 1 | -10.00 |
| 4-2 | 650 | 300 | 50 | 2 | 0 |
| 2-3 | 110 | 150 | 60 | 3 | 7.00 |
| 2-1 | 400 | 200 | 145 | 4 | 5.00 |
| 4-5 | 500 | 200 | 100 | 5 | 5.00 |
| 6-8 | 400 | 250 | 100 | 6 | 0 |
| 6-7 | 1000 | 300 | 170 | 7 | -20.00 |
| 3-8 | 500 | 200 | 100 | 8 | 13.00 |

Table 2. Calculation Results of Network Deterministic Model

| Node | Pressure [m] | Pipe | Flow [*l*/s] |
|---|---|---|---|
| 1 | 20.00 | 6-4 | 5.32 |
| 2 | 19.79 | 4-2 | -4.68 |
| 3 | 19.41 | 2-3 | 5.32 |
| 4 | 19.70 | 2-1 | -10.00 |
| 5 | 19.56 | 4-5 | 5.00 |
| 6 | 19.72 | 6-8 | 14.68 |
| 7 | 19.92 | 6-7 | -20.00 |
| 8 | 19.43 | 3-8 | -1.68 |

Hypothesis model parameters in table 3 ， the uncertainty in the interval is normal distribution, random sampling among those the middle value can get great probability, take out medium on both sides of the small probability. 100 times the random sampling results of simulation see table 4. Finally, using the method of probability and statistics, statistical results of interval probability density distribution (table 4 of 4-5 pipe flow simulation results of interval for [3.5, 6.5].

Table 3. Node Properties of Network Uncertainty Model

| Node | Demand [l/s] | Pressure [m] |
|---|---|---|
| 1 | [-10.2, -9.8] | [19.5, 20.5] |
| 2 | 0 | |
| 3 | [4.9, 9.1] | |
| 4 | [3.5, 6.5] | |
| 5 | [3.5, 6.5] | |
| 6 | 0 | |
| 7 | [-20.4, -19.6] | |
| 8 | [9.1, 16.9] | |

Table 4. Calculation Results of Network Uncertainty Model

| 2-1 | [-10.20, -9.80] | 4 | [19.16, 20.24] |
| 4-5 | [3.50, 6.50] | 5 | [18.92, 20.16] |
| 6-8 | [11.71, 17.59] | 6 | [19.19, 20.25] |
| 6-7 | [-20.40, -19.60] | 7 | [19.39, 20.45] |
| 3-8 | [-3.85, 0.71] | 8 | [18.80, 20.04] |

**New Suggestions For Accuracy Evaluation**

Considering the uncertainty of the model parameter, uncertainty interval of the simulation results can be preliminary quantified by random sampling simulation, node pressure and the simulation results of the pipe flow has some uncertainty, therefore, model checking is no longer the simulation results and the measured curve scatterplot comparison, but look at the proportion of the field observation point fall in the interval of the simulation results (seen in Fig.1).

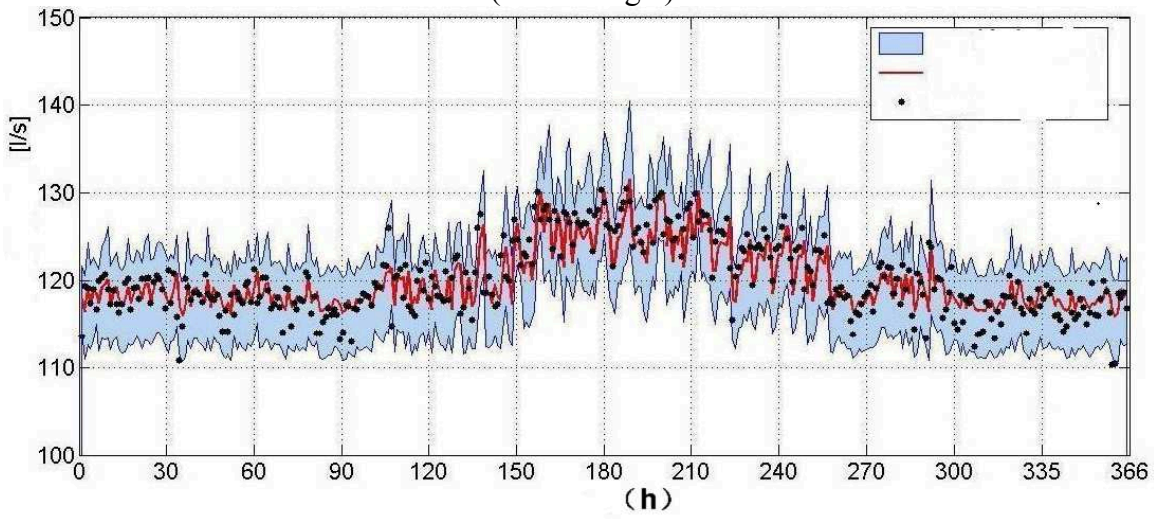

Fig.1 The checking result of the model

The author used to make a comprehensive comparison of the pipe net certainty model accuracy of every international research institutions, and put forward the pipe network model accuracy suitable for China's national conditions[4]. However, with the deepening of the uncertainty research, the simulation results not only, but in certain interval. Through the example analysis of the pipe network model parameters and state variables from the uncertainty of the simulated results of uncertainty, and the simulation method based on random sampling of preliminary quantify the simulation results of the uncertainty of the interval, is put forward based on the analysis of the uncertainty model checking precision analysis new method, the Suggestions model has 90% scattered point fall in the simulation results in the interval for precision of the model.

Water supply network model checking standard belong to the technical requirements and methods of the engineering construction acceptance, with the lack of unity still technical requirements. Because the model checking standard depends on the purpose of the modeling, different uses of the model with a different precision, so a lot of practice can unified technical requirements to the pipe network model checking.

## Conclusions

Water supply network model accuracy evaluation has been no unified technical specifications or standard, the simulation results of the node pressure, for example, proposed 100% pressure monitoring stations measured and simulation value of no more than 2 m or error 3 meters, which is based on static model. For dynamic model, no boundary for all the time to meet the above requirements and average value meet the demands, because most of the time there will be no more than two meters or 3 meters error, but there are a few time beyond this range. In this paper based on the analysis of uncertainty evaluation model has new ideas overcome the defects, and can be used as a reference, but also needs a large number of modeling practice.

**Keywords**: computer program, renovation, trenchless technologies, non-pressure pipes, sewer network

**Abstract.** Operative and planned rehabilitation of old pipe networks, including water disposal systems, is a relevant objective of modern city. It is especially difficult to make pipeline reconstruction works in large cities with high construction area density, transport moving intensity, also full of multifunctional both underground and above-ground infrastructure. All these factors set a lot of restrictions for open excavation methods of pipelines repair and reconstruction. That is the reason why trenchless technologies are becoming more popular among the engineers. A wide range of trenchless techniques provides people with convenient method of fast and effective reconstruction processes in comparison with durable and inconvenient open excavation. This fact leads to a necessity of creating a strategic planning of pipeline rehabilitation. This article presents how to operate the first step of such strategic planning – choosing the priority pipe section for sewer network renovation. The most convenient way for choosing one specific section from a great range is to use a program package based on mathematical algorithm that takes into account a quantity of different factors. This paper presents such a program created by authors and describes its interface, date input and processing.

## Introduction

The process of sewerage renovation includes three interrelated problems: choosing the priority pipe section for reconstruction; finding out an optimal renovation method (trenchless methods take great advantages under the common open excavation methods); providing hydraulic compatibility of existent pipes and new sections in regard with the whole system [1]. Successive and careful systematization and analysis of pipe defects are needed to solve the first problem. For this purpose inventory and television diagnostic research are used in order to determine the main external influence factors. The use of special computer programs allows us to make the process of carrying out all these investigations easier.

The deep investigations concerning this problem including international experience resulted in facing the fact that there is still no finished strategy of choosing the priority object for renovation [2-5]. There are some complicated approaches using artificial neural networks to estimate pipeline network conditions but they are difficult to implement in practice [6, 7]. The process of solving this problem, regarded with the similar conditions but with the use of different techniques, comes to the results, which significantly differ from each other. It happens because of subjective factors prevalence and ways of thinking and making decisions in each strategy are various. Some cities still don't have any strategy of wide-scale failures removing. The regional operating organizations of such cities use so-called «fire-brigade» and «patching the holes» methods. There are some megalopolises where pipe renovation strategy is still under development [7].

## Application example

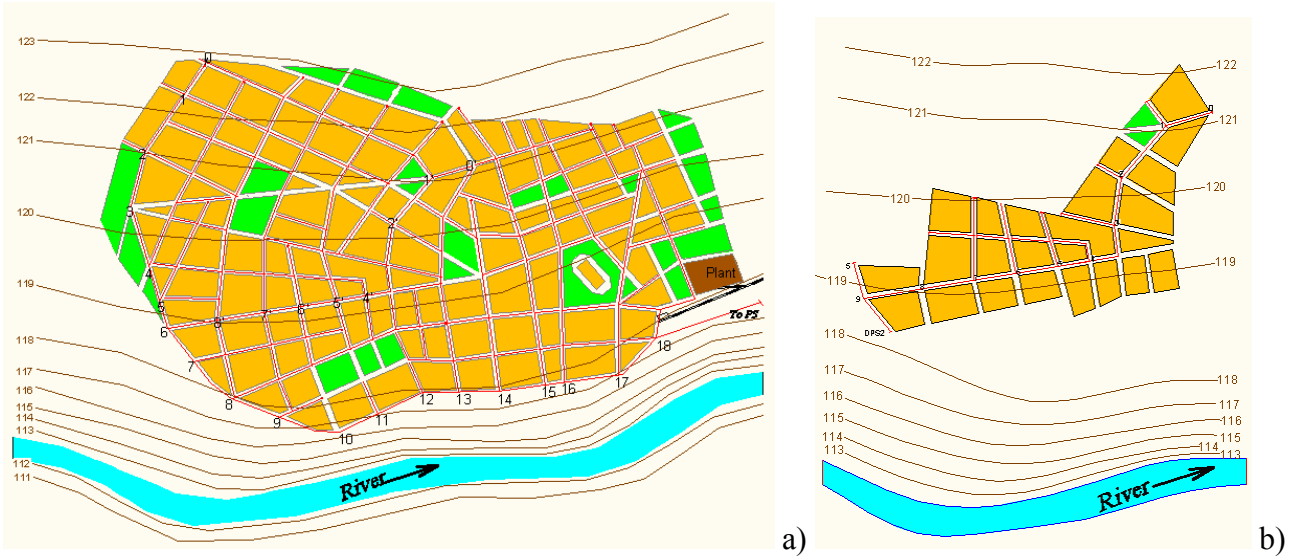
The developed by authors program automates the process of determining the priority object for renovation with taking into a consideration all factors, which destabilize the pipe network. This program will allow specialists from other countries to carry out the complex analysis of pipe

network condition. In other words, this innovative project makes a great contribution to advancement of trenchless technologies worldwide.

Moreover, without a system of selection the priority renovation objects the increasing of accident condition of the whole pipeline network can't be excluded. The absence of rehabilitation work planning leads to accident frequency increase which in turn results in carrying out immediate off-schedule undesirable rehabilitation work resulting in substantial operational costs. Moreover all these reconstruction and repair operations have a great influence on ecology and social costs. The use of proposed program gives an opportunity to significantly reduce this influence.

It's important to stress, that this project is economically advantageous, because the use of this program doesn't need additional financial investments.

The imaginary town is taken as a basic example (Fig 1a) to show how the program works. Sewer system of this town has been being under operation for 20 years.



a) b)

Fig. 1. City plan with sewer network (a) and selected fragment (b)

According to the relief of this area, the sewerage scheme was designed as crossed one with one sewerage basin. The pipeline system serves 112 blocks, that is why it is difficult to represent the whole information about it. In order to minimize the number of network sections to examine, a specific fragment was selected (Fig. 1b).

This fragment includes 12 blocks, which are served by the part of the whole sewer network, coming across the center of the town. For the whole system, including the researching fragment, pipe diameters and materials are known. The prevalent pipe material is ceramics.

In given example a complex estimation work was carried out for determining the technical condition of sewerage network. This work was based on taking to a consideration the number of external factors, which have a greatest influence on pipe condition and accident-free work efficiency. All this factors are evaluated on point scale. According to developed algorithm the most worthless condition has the section, which has gained maximum amount of points.

The key factors, which considered to be the most destructive for pipeline systems, include: pipe diameters and materials, water quality, hydraulic characteristics, the setting year and the laying depth of pipes, soil condition, ground water presence and character [1, 8]. These and others factors are represented in rating passports of different sections.

Fig. 2 illustrates the example of such passports. According to the sewer chambers, each pipe section has its own number.

In order to fill in all the positions in this passport, one should use the information from hydro-geological map of the area (Fig. 3), geological map (Fig. 4), the map of transport moving intensity (Fig. 5), including design data and teleinspection results with all pipe failures.

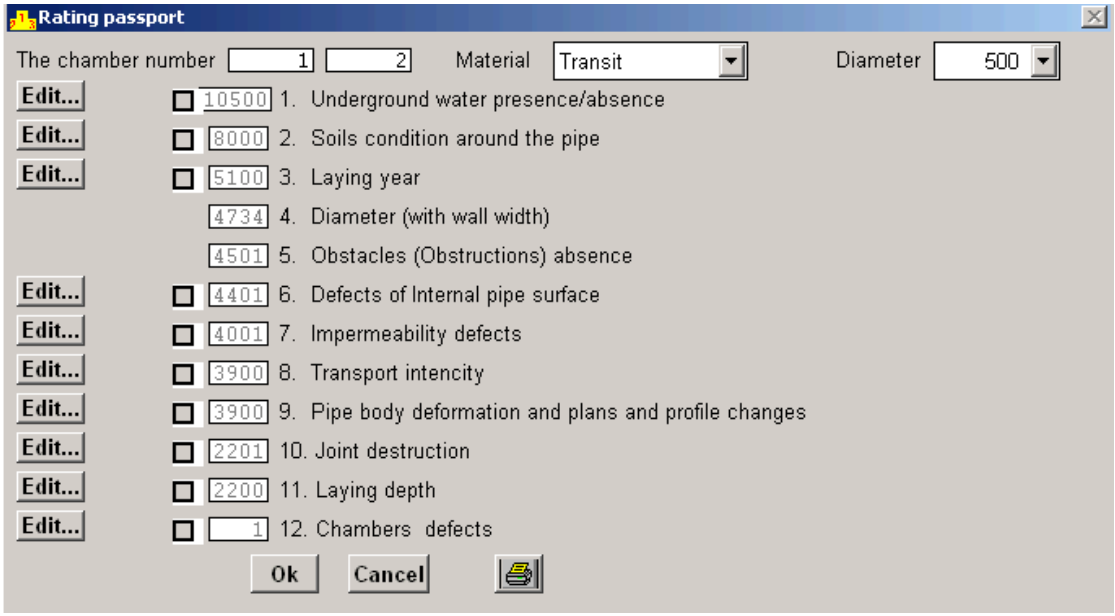


Fig. 2. The example of rating passport for section number 1-2.

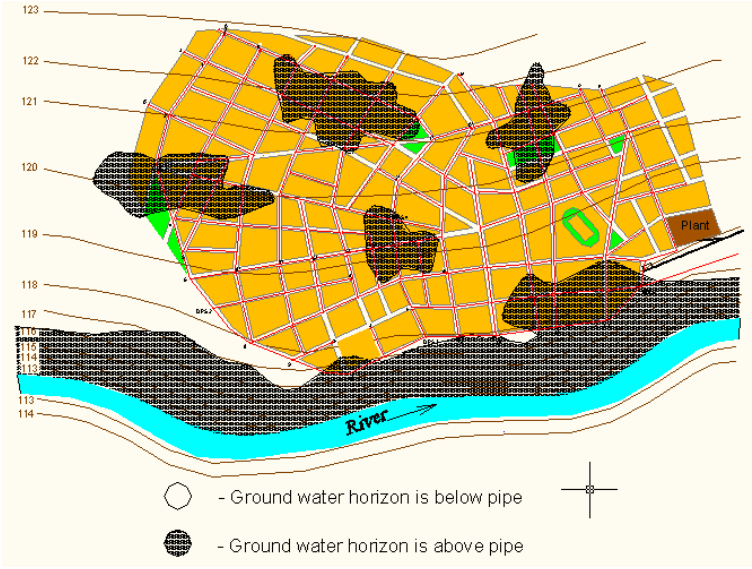

Fig. 3. Hydro-geological map

Fig. 4. Geological map

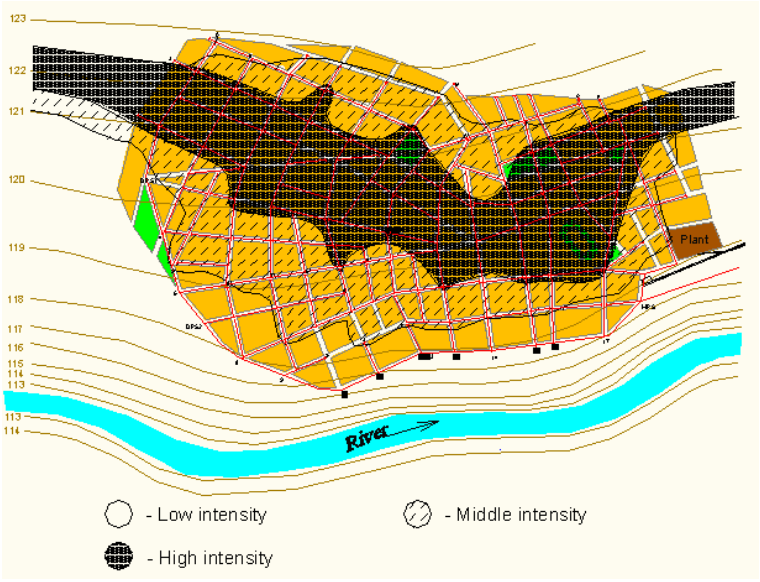

Fig. 5. The map of transport moving intensity

The work of this computer program results in assignment a certain amount of points to each section of the system. According to these points, all sections of concerned fragment can be divided into 2 parts: the priority renovation sections and sections for perspective renovation.

Table 1
The final results of pressure-free sewerage pipes rating

| Chambers | Points | Diameters, mm | Material |
|---|---|---|---|
| 4-5 | 52824 | 400 | C |
| 3-4 | 52574 | 300 | C |
| 2-3 | 52227 | 250 | C |
| 7-8 | 48066 | 600 | A |
| 1-2 | 47866 | 200 | C |
| 0-1 | 47859 | 200 | C |
| 6-7 | 47675 | 500 | A |
| 8-9 | 46574 | 600 | A |
| 5-6 | 47403 | 500 | A |

Material: C (ceramics), I (iron), A (asbestos-cement), P (polyethylene)

The final results (Table 1) represent the rating of studied sections. Having analyzed this table, we can make a conclusion, that the section, limited with the chambers number 4 and 5 (400 mm in diameter, ceramics), which is situated at the top of the table, has the maximum amount of points, so that is why it should be recommended for priority renovation. The section number 5-6 has the minimum amount of points. According to the data obtained, the diagram renovation priority has been made, where each section is represented with its own priority points (Fig. 6).

The diagram also illustrates two possible periods of renovation: the priority renovation area (sections number 4-5, 3-4, 2-3) and the area of perspective renovation (sections number 7-8, 1-2, 6-7, 8-9, 5-6).

## Conclusions

Operative and planned rehabilitation of old pipe networks is a relevant objective of modern city. The computer program was developed to help engineer with planning of renovation priority of sewer networks. The renovation priority based on complex estimation of pipe technical condition compared with all other ones.

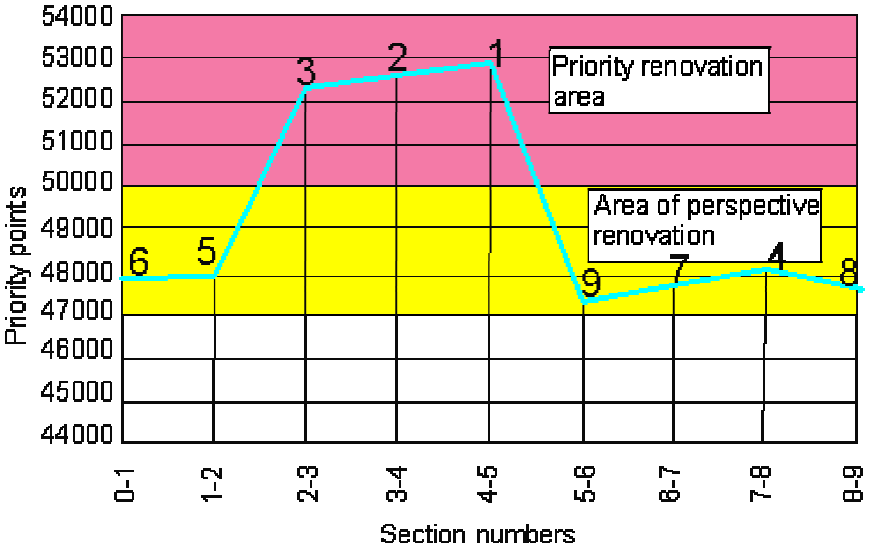

Fig. 6. Diagram of renovation priority

In conclusion it is important to stress, that the data obtained in this program, can't give the final decision about the object which should be renovated first. The printouts serve as the basic materials for specialists (engineers), who ought to make the final decision on renovation of any particular object. In other words, human factor has preferences, while computer program make it possible to carry out the detail complex analysis of pipeline network condition.

# Hydraulicsoflooping

Julia Zolotova[1, a *]

[1]Polytechnicheskaya str.,29, Saint-Petersburg, Russia

[a]yszolotova@gmail.com,

**Key words:** looping, pressure loss, hydraulic resistance, the actual distribution of expenses, energy efficiency

**Abstract:**This article describes the urgency of studying the reduction of hydraulic loss in terms of energy efficiency.

*Looping* is a section of the pipeline, which is laid in parallel with the main pipeline. Distribution of expenses on Looping`s branches in the valid movement minimizes dissipation in the flow and, consequently, reduces the energy losses in the piping network.

Literature describes the calculation of a system of parallel lines through quite cumbersome calculations. The purpose of this work is to create a method of simple and quick calculation of looping.

The article describes the simplest case of the connection: every branch does not contain any nodes, neither a source nor wastewater. Testing calculation of looping is represented in three conditions: looping`s resistance coefficient shown, partial expenses` calculation is transformed to rotating circulants and looping`s statics equations coincide with necessary condition of a minimum.

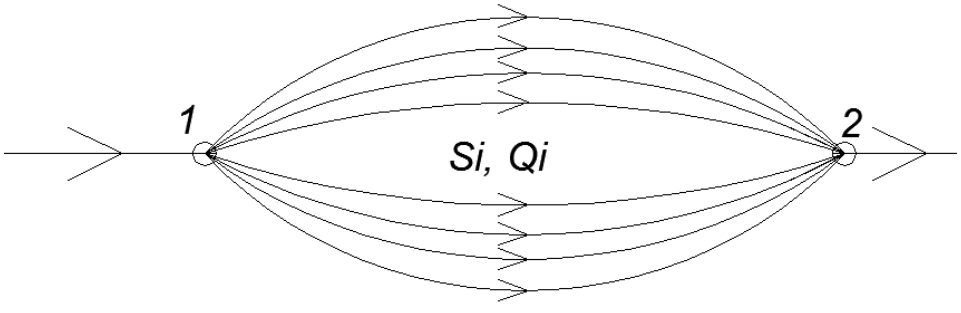
## Introduction

Nowdays energy efficiency is the main strategic objective of the energy policy of all countries and Russia as well. Of course it entails the development of the legal framework that is proved by emergence of Federal law of November 23, 2009 N 261-FZ «On energy saving and increasing energy efficiency and about modification of separate acts of the Russian Federation»and of standard GOST R 50001 «Energy management systems. Requirements and guidelines». As a result, the market of energy-saving materials and technologies is rapidly developing. However, there are not enough solutions for reducing energy losses in the piping network, caused byviscous friction, so-called pressure losses.

Considering that the operation of pumps and fans spends up to 80 % of electricity in life-support systems of building, reduction of hydraulic losses will reduce the power inputs of the buildings.

This article is dedicated to a construction, which can be regarded as part of a package of energy efficiency measures – looping. It is a parallel joint of downstream conduit, widely used in hydraulic networks for division and connection of streams of hot and cold water or air. The flow of transported product in the main pipeline is reduced in the area oflooping. That reduces the total loss of pressure at overcoming the hydraulic resistance. Therefore, capacity ininvariable pressure pipeline increases the more significant the more cross-sectional area of looping is.

Settlement scheme of looping is shown on picture 1. Flow separation is in point 1 (site - source) and connection of flows occurs in point 2 (site - runoff).



Pic. 1 Scheme of looping

In the elementary case, which is considered in the article, it is supposed that every branch ($S_i$, $Q_i$) doesn`t contain joints, sources, nor runoffs.

**Literature review and research objective:**Today great attention is paid tothe question of reducing of pressure losses [1-26].

However, a review of material related specifically to the application looping showed almost no sources.

The purpose of this work is to test a simple method of calculation of systems of parallel lines (looping).

According to that authors were faced by the following tasks:

1. Transformation of partial expenses` calculation to rotating circulants
2. Development of simple algorithm of variation in any order

**Research description:** Pressure loss [26-27] in every branch is calculated by the formula

$$h_r = S_i Q_i^2, \tag{1}$$

where $Q_i$ –partial expense in i-th branch, $S_i$ - resistance coefficient in i-th branch, which is defined by this formula

$$S_i = \left(\frac{\lambda_i}{D_i} \cdot l_i + S_i\right) \cdot \frac{1}{2g \cdot A_i^2}, \tag{2}$$

where $\lambda_i$ - coefficient of hydraulic friction, $D_i$ - diameter of cross-section, $l_i$ –length of the branch, $A_i$ - area of cross-section.

For hydraulically long pipeline

$$S_i = \frac{l_i}{K_i^2}, \tag{3}$$

where $K_i$ - resistance module.

Then method of calculation of looping can be represented by the following 3 theorems:

1. Looping`s resistance coefficient will be:

$$S = \frac{1}{\left(\sum_{i=1}^{n} \frac{1}{\sqrt{S_i}}\right)^2} \leq \min(S_i)_i^n = 1. \tag{4}$$

Actually, if

$$h_r = S_i \cdot Q^2, \tag{5}$$

and

$$Q = \sum_{i=1}^{n} Q_i, \tag{6}$$

then

$$\sqrt{\frac{h_r}{S}} = \sum_{i=1}^{n} \sqrt{\frac{h_r}{S_i}}. \tag{7}$$

The inequality is obviously a consequence of an inequality of Cauchy. Looping`s coefficient of resistance doesn't surpass resistance of the branch with the maximum throughput (with the minimum resistance).

2. Partial flow [28] is :

$$q_i = \frac{Q_i}{Q} = \frac{\sqrt{S_{\alpha i} \cdot S_{\alpha i+1} \ldots S_{\alpha n-1}}}{\sum_{j=1}^{n} \prod_{j=1}^{n-1} \sqrt{S_{\alpha j} \cdot S_{\alpha j+1} \ldots S_{\alpha j+n-1}}}, \tag{8}$$

where $\alpha_{i,\ldots}$ , $\alpha_{n-1} \neq i$, $n \geq 2$.

For example, for looping that consists of 4 branches :

$$q_1 = \frac{\sqrt{S_2 S_3 S_4}}{\sqrt{S_1 S_2 S_3}+\sqrt{S_2 S_3 S_4}+\sqrt{S_3 S_4 S_1}+\sqrt{S_4 S_1 S_2}}, \quad (9)$$

$$q_2 = \frac{\sqrt{S_3 S_4 S_1}}{\text{denom}}, \quad (10)$$

$$q_3 = \frac{\sqrt{S_4 S_1 S_2}}{\text{denom}}, \quad (11)$$

$$q_4 = \frac{\sqrt{S_1 S_2 S_3}}{\text{denom}}, \quad (12)$$

where$\text{denom} := \sqrt{S_1 S_2 S_3} + \sqrt{S_2 S_3 S_4} + \sqrt{S_3 S_4 S_1} + \sqrt{S_4 S_1 S_2}$.

It easy to notice, that there is a cycle of combinations of n by n-1 numbersin the denominator and a cycle of combinations of n-1 – numbers (that do not contain an index i) in numerator.

3. In the actual motion we can use Kelvin`s principle of minimum dissipation [29-32], that is described by the formula:

$$\sum_{i=1}^{n} S_i q_i^3 \rightarrow \min, \sum_{i=1}^{n} q_i = 1, \quad (13)$$

Formula of Lagrange satisfies that condition (13):

$$L_\lambda(\vec{q}) = \sum_{i=1}^{n} S_i q_i^3 + \lambda \cdot \sum_{i=1}^{n} q_i, \quad (14)$$

On achievable partial expenses works such equality for all i ϵ 1(1)n:

$$S_i q^2 + \frac{\lambda}{3} = 0, \quad (15)$$

It means, that all $S_i q^2$ are equal andthis leads to the 1st and 2ndtheorems . So the actual distribution of expenses along the branches of looping brings to the smallest value of dissipation in the flow, that crosses looping.

This 3rd theorem is used by K.I. Strahovich for calculation of pipeline systems [34].

**Conclusion:**

Thus much easier and less labor-consuming calculation looping has been tested. Itsalgorithmcanbedividedinto 3 conditions:

1. Looping`s coefficient of resistance doesn't surpass resistance of the branch with the minimum resistance.
2. Calculation of partial flow is reduced to calculating fractions.
3. Looping`s statics equations coincide with necessary condition of a minimum.

# The Water Usage Method and Spatial Structure Type of Spring Village in Northern China

Yawei Kong[1, a]

[1]College of Architecture and Urban Planning, Shandong Jianzhu University,

Jinan, P. R. China, 250101

[a]kywnd@163.com

**Keywords:** Spring village, water usage, spatial structure, type, conservation

**Abstract.** Spring village is a widely existing type of human settlement in northern China, the spring water usage with natural environment is the main factor of the heterogeneous spatial structure in spring village. By the analysis for hierarchically usage of multi-kind values, this paper introduces the spatial structure and feature of typical villages under the views of living, manufacture, ecology and landscape. Meanwhile, based on the combination of modern function requirement and spring water usage, the settlement-spatial conservation, which relies on natural environment, is seen as the essential way for the sustainable development of spring settlement.

## Introduction

As the living area by adapting and utilizing nature, human settlement not only provides various spaces for living and relaxing etc., but is the place for manufacture. [1] In the development period, local nature environment decides the eternal form and internal space of settlement. Especially the area with spring water became the first choice for ancient people to living. Through the activities of living, manufacture and social communication, spring settlement has been one of typical settlement for combining spring water with topography.

In northern China, for the widely existing karst groundwater system, most villages in which people live and produce with spring water are built for the wisdom of utilizing nature resources. Through the integrated research of the water usage and spatial structure in spring village, the conservation strategies which ensure the optimizing use of spring water and sustainable development of spring village, are provided to satisfy the multiple requirement of living, manufacture and landscape.

## Basic Principle

In northern China, the emerging areas of spring water are always in mountains or on the plains near mountains, the distribution of spring villages thereby is determined, [2] the emerging amount of spring water is determined by the water-collection area of supplying and the pressure. While at the top of mountain slope, for the less area and pressure, the limit spring water only satisfies living of small village. Near the valley or beach, to avoid the latent danger of fluid or humid, the villages are built on the high spaces and wells are excavated for water supply, the areas near spring are utilized for farm or cultivation. The best situation is the spring water emerges on the foot of mountain, in the alley and on the plain close to mountain, different kinds of spring villages are appeared for the various combinations between spring-emerging forms and local environments.

The emerging forms of spring water are decided as punctiform well, linear stream and regional pond for the form of water, also as the static collecting water area and the dynamic overflowing stream. In reality, the layouts and forms of villages are determined by the different emerging ways and various drawing methods. In Fig. 1, with static well or less-overflowing pond, the spring water always becomes the center of villages, as well as be utilized only for living, meanwhile the larger ponds appear the effects of regulating the micro-climate and beautifying the environment. If the spring emerging amount reaches certain scale, shown in Fig. 2, various dynamic spring water forms,

such as pond with overflowing water and stream, come into being, the structure of villages always becomes linear form by the overflowing water, the spring water is utilized not only for living, but for irrigation, cultivation, production and other manufacture ways, as well regulating climate, beatifying environment and other ecological and landscaping requirement.

## Water Usage and Space Structure

**Living.** The space structure of villages, in which the living value of spring water appears, is determined by the emerging form of spring water. As Fig. 3 shown, the emerging forms of spring water that influence the space structure of this kind villages rely on present three kinds as static water without overflowing, static water with overflowing and dynamic stream with overflowing. Towards the static water, two situations are presented as out of village and in village. Therefore, dynamic stream with overflowing is always combined with village tightly, and treated as the main influent fact for the space structure of village.

| Spring Form | Location | Usage Method | Space Structure | Typical Case | Diagram |
|---|---|---|---|---|---|
| Well (Static water) Without overflowing water | In village | Directly drinking and washing, in modern, using piper and pump for water. | Spring as the center of village, public place around spring water. | Xichexaing Village (Zhangqiu Town, Jinan City) | |
| | Out of village | Taking water by hand or piper, terrace farmland along the lane. | The main road along the lane of taking water, buildings around the road. | Heilongyu Village (Licheng Town, Jinan City) | |
| Well or Pond (Static water) With overflowing water | In village | Emerging water for drinking, overflowing water for washing. | Static water as the center, the main part of village along overflowing water. | Yuhequan Village (Licheng Town, Jinan City) | |
| | Out of village | Hidden piper for taking water by height difference or pump, overflowing water for landscape. | Linear space structure along overflowing water. | Xilihu Village (Zhangqiu Town, Jinan City) | |
| Stream (dynamic water) With overflowing | In village | Dynamic water utilized besides living. | Village along the stream or overflowing water. | Nanduo Village (Zhangqiu Town, Jinan City) | |
| Legend | village farmland pond road water piper spring | | | | |

Fig. 3 The space structure of villages in which the spring water is utilizing for living

**Manufacture.** The manufacture-value of spring water is influenced mostly by the emerging amount, after living usage; the rest spring water is taken mainly for farm or cultivation, otherwise for producing or industry. In Fig. 4, because of the higher requirement of land in manufacture, the producing area is parallel arranged with village, the emerging point of spring water becomes the major factor to influence the space structure of village. Meanwhile, the space of village is influenced by dynamic water which appears in the village.

| Usage | Location | Usage Method | Space Structure | Typical Case | Diagram |
|---|---|---|---|---|---|
| Farm | In village | Overflowing water passing farmland with additional living and landscape value. | Spring and overflowing water in the middle of village and farmland. | Touquan Village (Jingxing Town, Shijiazhuang City) |  |
| | Out of village | Overflowing water passing farmland directly, pumping station for water. | Spring along the village, part of the village along overflowing water. | Zhongtao Village (Dongping Town, Taian City) |  |
| | | Spring water taken by piper or pump for farming, landscape value appearing. | The emerging point of spring water as the center of village and farmland. | Xincheng Village (Taian District, Taian City) |  |
| Culti-vation | In village | Cultivation along the overflowing water with additional landscape value. | Less influence of spring water for the space of village, the space around overflowing appearing flexible. | Shangquan Village (Daiyue District, Taian City) |  |
| | Out of village | Taking spring water to pond by channel, for cultivation as planting lotus or feeding pig and fish. | Spring water separated from village. The space structure of village appearing Checkerboard form. | Zhifang Village (Daiyue District, Taian City) |  |
| | | Huge emerging amount of spring water for large area fishing pond. | The road connecting spring water and village influencing the space structure of village. | Potou Village (Jingxing Town, Shijiazhuang City) |  |
| Produce | In village | Canning drinking wate. | Spring emerging point as the center of village and static water. | Longquan Village (Yicheng District, Zhumadian City) |  |
| | Out of village | Better quality for spring water. | Spring water besides village with less influence. | Jiunvquan Village (Dongping Town, Taian City) |  |
| Industry | In village | Gold industry poplar in history, and influencing village space and custom. | Spring water as the center of village and farmland. | Tongjing Village (Yinan Town, Linyi City) |  |
| | Out of village | Abundant spring water for pottery industry. | Spring water influencing lowly the space structure of village. | Hongshan Village (Jiexiu Town, JiInzhong City) |  |
| Legend | village farmland pond road water piper spring | | | | |

Fig. 4 The space structure of villages in which the spring water is utilizing for manufacture

**Landscape**. Emerging forms, which include punctiform well, linear stream and regional pond, are the first influent factor for the ecological and landscaping values of spring water. In Fig. 5, Temples and trees are always arranged in the social area of punctiform well which is the main source of

water, but the ecological value is not outstanding. While near the dynamic overflowing stream or static gathering pond, on the one hand constant-temperature spring water appears important ecological value of regulating temperature, eliminating dust and protecting species diversity, on the other hand the landscape environment of spring character appears in the practice of utilizing the synthetical values of spring water.

| Emerging Form | Spring Form | Usage Method | Space Structure | Typical Case | Diagram |
|---|---|---|---|---|---|
| Punctiform well | Wells part of which connecting overflowing water | Spring as the public area and core of landscape, with less ecological value | Spring as the center of village, coexisting springs as the muiti-center of same village | Xiaosi Village (Zhangqiu Town, Jian City) |  |
| Linear stream | With overflowing water or several springs | Higher ecological and landscaping values, important effects for living and manufacture | Space structure along the overflowing water, part of village around the water | Yuhequan Village (Changqin Town, Jian City) |  |
| Regional pond | Large area pond with overflowing | Higher ecological and landscaping values for farm and cultivation | Gathering water as the center of village and land, spring as the core of public place | Nanmi Village (Linzhou Town, Anyang City) |  |
| Legend | village farmland pond road water piper ● spring | | | | |

Fig. 5 The space structure of villages in which the spring water is utilizing for landscape

Especially in typical villages, such as Niangziguang Village in Yangquan City and Huangsi Village in Xingtai City, more than two emerging kinds of spring water exist, meanwhile the living, producing, ecological and landscaping values appear, the space structure presents typical features of spring village. [3]

## Conclusion

"Dwelling by spring water" is the wisdom of ancient people to living with nature, while special natural environments induce abundant space structures of spring villages. [4] As special case of utilizing nature, the practices of utilizing synthetical values of spring water, create different special structures of spring villages; reflect the ecological wisdom of living with nature, and present higher values of history and culture. Under the pressure of modern life, the values of spring water are ignored; the style and features of most spring villages disappear in modern construction. For ecological civilizing construction becomes one of the basic national strategies, it is urgent to protect spring villages with ecological wisdom, the essential way for the sustainable development, presents as the conservation of space structures and features by not only combining modern requirement with values of spring water, but utilizing spring water according of natural environment.

**Keywords:** Double Skin Facades, Thermal Performance, CFD, Comprehensive Heat Transfer Coefficient, Thermal Channel

**Abstract.** Simulation and analysis of heat transfer process in internal recycle double skin facades(DSF) of the established standard model were carried out by computational fluid dynamics(CFD). Comprehensive heat transfer coefficient under the condition of different ventilation rate of DSF with and without blinds was studied. The results show: the increase of the ventilation rate can not only improve the comprehensive heat transfer coefficient, but also improve the temperature of inner surface of the inner curtain wall. Double skin facades can improve the comfort level of the indoor environment, reduce the energy loss of the palisade structure and reduce energy consumption.

## Introduction

The glass curtain wall is used more and more widely in high-rise building in recent years. Its thermal performance is a important indicator about the energy saving effect of the whole building. Double skin facades can stabilize the temperature and illumination of the indoor environment and strengthen the function of ventilation and air change on the one hand; and can improve the thermal insulation ability, reduce the noise outside and save energy on the other hand. So the DSF will become one of the new development direction of environmental protection and energy saving. Technology.

Most DSF studies now are based on CFD simulation. Many researchers (Stec 2003, Howell 2001, Safer 2005, Manz 2004, Tanaka 2009, Gratia 2004, 2007) have studied the ventilation and the thermal performance of the DSF. The DSF has good engineering application value and good market prospect. As the more and more using of the DSF, accurate analysis on the performance of the DSF and determination of its economic performance and energy saving effect have become the urgent need of social development.

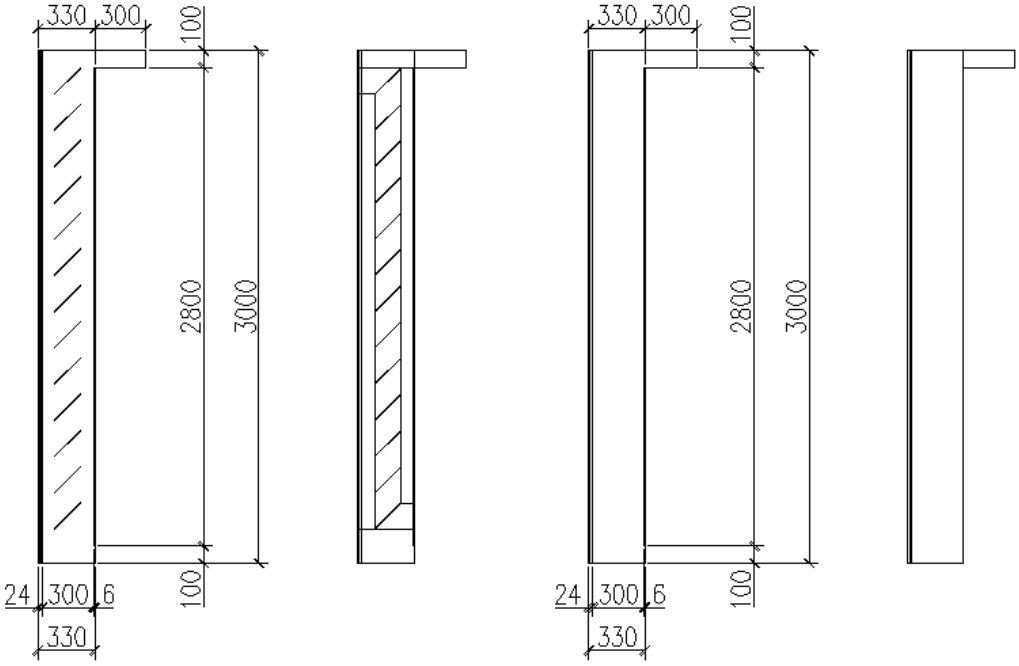
Simulation and analysis of DSF of the established standard model were carried out by using the software Fluent. The performance of the DSF under the condition of different ventilation rate was studied.

## Analysis model

**Structure and parameters.** The standard model of the paper is internal recycle DSF, the schematic diagram of it is shown in Fig. 1. The Fig. 1 (a) shows the detalis of the cross section about DSF with blinds and the dividing of the cross section which can be imported to the Gambit as areas to be mapped. The Fig. 1 (b) shows the detalis of the cross section about DSF without blinds and the dividing of the cross section which can be imported to the Gambit as areas to be mapped.

**Dimension details.** Plate size is 1500mm×3000mm. The width of the thermal channel is 300mm. The cross sectional dimension of outlet, which is in the middle position at the top of the DSF, is 100mm×100mm.

**Physical model.** The outer glass wall is insulating glass, the inner of which is air. The thickness of the outer glass wall is 6mm+12mm+6mm. The inner glass wall is 6mm thickness full tempered glass. The aluminum blind is 3mm thickness.



(a) (b)

Fig. 1 Standard model of the internal recycle DSF

**Boundary conditions.** The temperature of indoor and outdoor air are 20°C and -20°C respectively. The convective heat transfer coefficient of indoor and outdoor air are 3.6W/($m^2$•°C) and 16W/($m^2$•°C) respectively. The wind speed of outlet is 1.35m/s.

**Steps of analysis.**

(1) The standard model is established by AutoCAD as Fig. 1 (a). The model is seperated as quadrangles and the quadrangles are transformed to surface units, which are shown in Fig. 1 (b). Then the standard is exported and saved as *.sat file.

(2) Through software Gambit, the*.sat file is imported and all the surface units are meshed as structured grids which are extruded to 1500mm form a standard volumn.

(3) The cell zone conditions and boundary conditions are defined through software Gambit, and the *.mesh file is exported.

(4) The *.mesh file is imported in Fluent and the relevant parameters are defined. Then the calculation of the standard model is carried out and the post processing is made.

## Results and analysis

**Flowing of air layer.** The flowing of the air layer in the DSF is an important characteristic about the DSF and is the key indicator about the thermal performance, ventilation and energy saving. The velocity distribution of the middle section of the internal recycle DSF with blinds and without blinds are shown in Fig. 2 and Fig. 3, respectively.

It can be seen that: (1) the air flows out throuth the fan under the action of airflow, and in order to keep balance, it need the air flows in the air layer. This process can discharge the indoor heat, reduce the indoor temperature and improve the indoor comfortableness. (2) The air speed near the top of air inlet of inner and outer glass wall is faster than other space. (3) Because of the existence of blinds, there is reverse flow between the blinds. (4) The velocity of the DSF with blinds (4.65 m/s) is larger than the DSF without blinds (3.18 m/s). (5) The velocity distribution of the DSF without blinds is much more regular than the DSF without blinds.

From the above, the air flow in the air layer can bring the indoor heat into the air layer of the DSF, which can stabilize the temperature in a certain range. So the double skin facades have great thermal performance and can improve the comfortableness of the indoor environment.

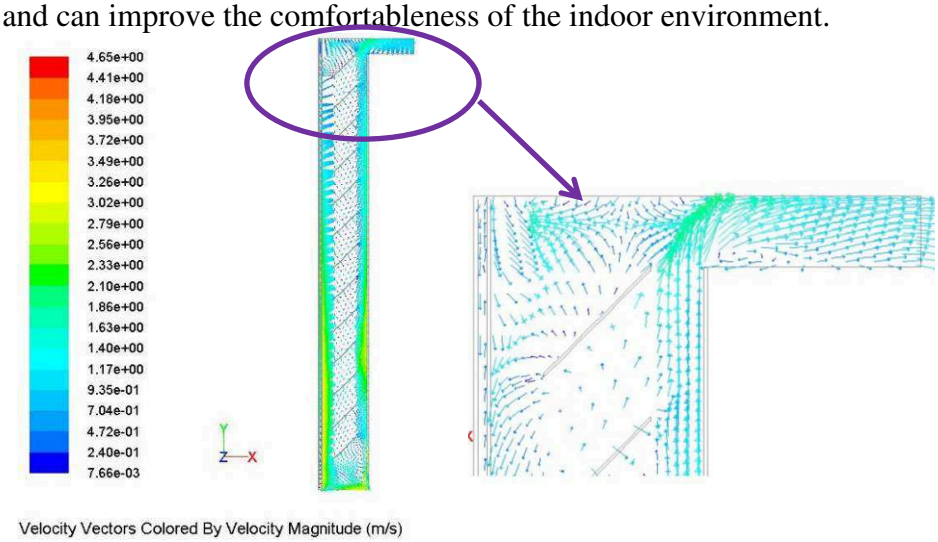


Fig. 2 The velocity distribution of the DSF with blinds

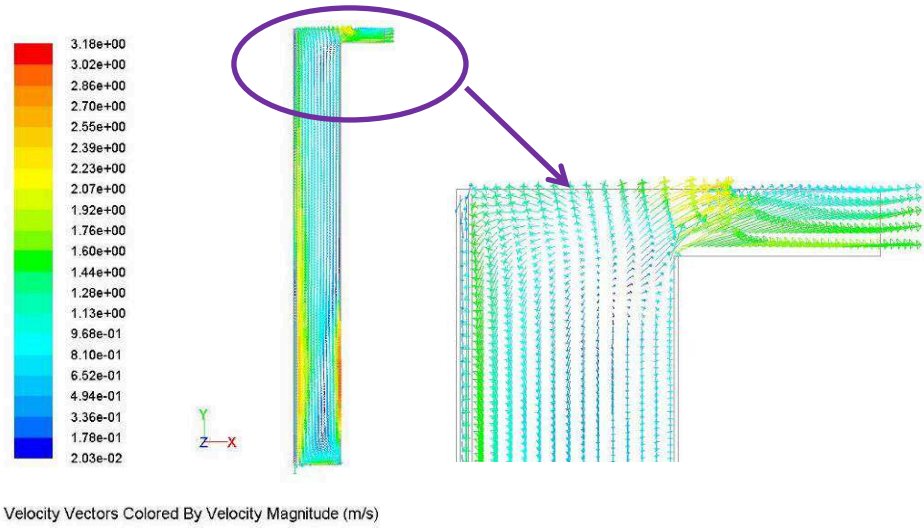

Fig. 3 The velocity distribution of the DSF without blinds

**Temperature field.** The temperature distribution of the middle section of the internal recycle DSF with blinds and without blinds are shown in Fig. 4 and Fig. 5, respectively. The temperature distribution can more intuitive reflect the ventilation and thermal properties of the DSF. The temperature of internal surface of inner glass wall is an important parameter of the indoor environment comfortableness and building energy consumption. The temperature of internal surface of inner glass wall is higher, and the temperature difference between it and indoor air is smaller in winter, the energy loss through the envelop enclosure is litter and the thermal radiation from glass surface to indoor air is much more.

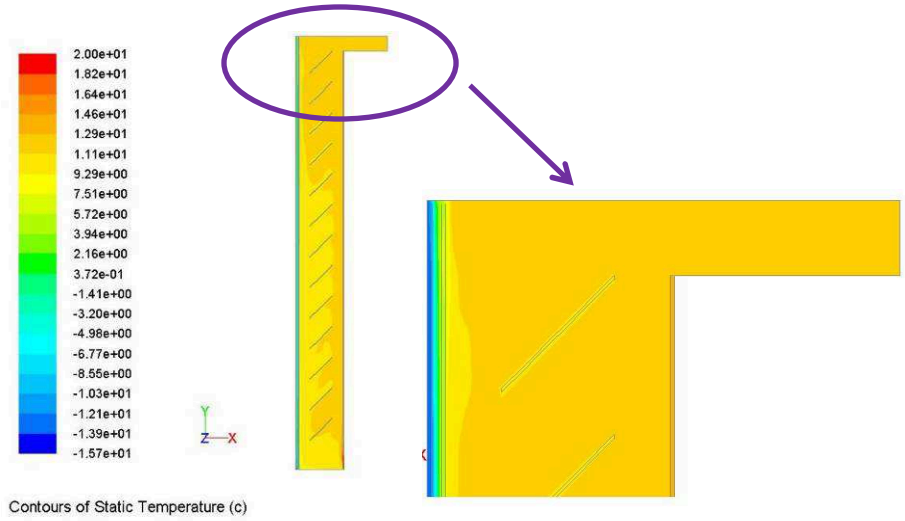

Fig. 4 The temperature distribution of the DSF with blinds

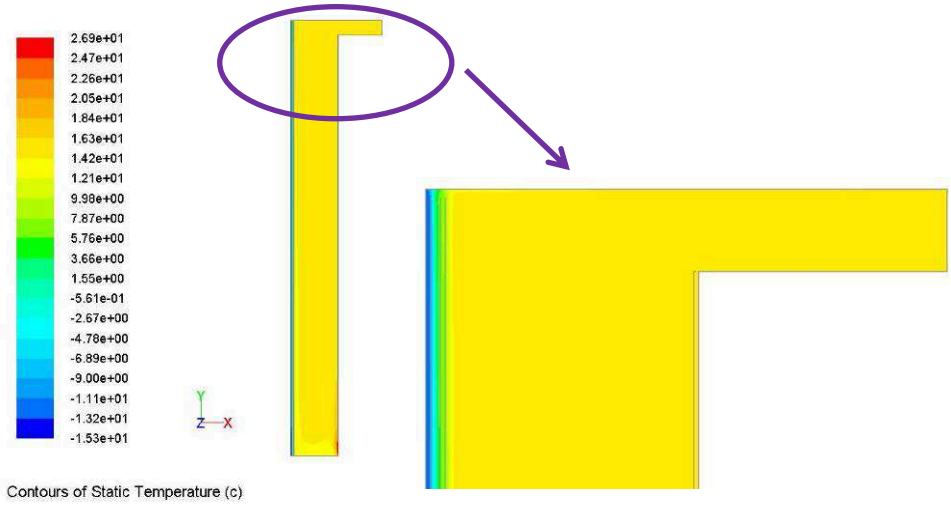

Fig. 5 The temperature distribution of the DSF without blinds

**The influence of ventilation rate of the DSF.** The direct influencing factor of the ventilation rate of the DSF is air speed of the outlet.

$$Q=V\times A \tag{1}$$

In eq. (1), Q is the ventilation rate, V is the air speed of the outlet and A is the sectional area of the outlet.

The temperature of internal surface of inner glass wall, the comprehensive heat transfer coefficient and comprehensive heat transfer resisitance of the different analysis model with blind and without blinds of different air speed of outlet are shown in Table 1 and Table 2, respectively.

Table 1 The results of different analysis model with different air speed of outlet (with blinds)

| Air speed of outlet (m/s) | Internal surface temperature (°C) | Comprehensive heat transfer coefficient (W/(m$^2$•°C)) | Comprehensive heat transfer resisitance ((m$^2$•°C)/W) |
|---|---|---|---|
| 0.5 | 11.93 | 1.012 | 0.988 |
| 1.0 | 13.42 | 0.817 | 1.224 |
| 1.35 | 13.59 | 0.797 | 1.255 |
| 1.5 | 13.66 | 0.788 | 1.269 |
| 2.0 | 13.84 | 0.766 | 1.305 |

From Table 1, it can be seen that: (1) as the increasing of air speed of outlet, the temperature of internal surface of inner glass wall increases, the comprehensive heat transfer coefficient decreases and comprehensive heat transfer resisitance increases. (2) The thermal properties of the DSF improve significantly when the air speed of outlet increases to 1.0 m/s from 0.5 m/s. (3) When the air speed of outlet increases from 1.0 m/s to 2.0 m/s, the thermal properties does not improve obviously.

Table 2 The results of different analysis model with different air speed of outlet (without blinds)

| Air speed of outlet (m/s) | Internal surface temperature (°C) | Comprehensive heat transfer coefficient (W/(m$^2$•°C)) | Comprehensive heat transfer resisitance ((m$^2$•°C)/W) |
|---|---|---|---|
| 0.5 | 14.75 | 0.656 | 1.524 |
| 1.0 | 15.33 | 0.585 | 1.709 |
| 1.35 | 15.85 | 0.521 | 1.919 |
| 1.5 | 16.37 | 0.458 | 2.183 |
| 2.0 | 17.43 | 0.327 | 3.058 |

There are almost the same regularitide in Table 2 as in Table 1. When the air speed of outlet of DSF with blinds is the same as the DSF without blinds, the internal surface temperature and comprehensive heat transfer resisitance of DSF with blinds are less than these of DSF without blinds. This is because the material of blinds is aluminum alloy and the heat transfer coefficient of the blinds is much large than the air's.

## Conclusions

Through the simulation and analysis of the DSF using CFD method, the conclusions can be get as follows:

(1) Relatively stable continuous flow field can be obtained through DSF. The air flow in the air layer can bring the indoor heat into the air layer of the DSF, which can improve the comfortableness of the indoor environment and reduce energy consumption.

(2) As the increasing of air speed of outlet, the temperature of internal surface of inner glass wall increases, the comprehensive heat transfer coefficient decreases and comprehensive heat transfer resisitance increases.

(3) The ability of energy saving of double skin façade is much better than single glass curtain wall. The results of standard model in this work can be applied to other environmental types.

(4) The DSF, which is a form of energy conservation and ecological envelop enclosure, has a broad prospect of engineering application.

**Keywords:** Ground source heat pump, Heat recovery, Annual cost, Whole life cycle, Economic analysis.

**Abstract.** Economic performance of investment capital, operational costs and supplying costs of domestic hot water for different scenarios of ground source heat pump system (GSHPS), which designed for a hotel located in the hot summer and warm winter area, have been analyzed using the dynamic annual cost method. The results show that the investment capital decreased while the operational costs increased first and then decreased with the ratio of waste heat recovery of GSHPS increased. The comprehensive benefit of GSHPS with waste heat recovery is distinct compared with conventional GSHPS. When the ratio of waste heat recovery is 50%, the dynamic annual costs of GSHPS are minimum and achieve the optimization of energy-saving effect.

## Introduction

Energy is an important basic material for human survival and development. With the booming of the economy, energy consumption has increased sharply. In the future, the world's energy supply must become more sustainable. In China's energy consumption structure, the proportion of building energy consumption reached to 32% of total amount, while the energy of HVAC has reached about 60% of building energy consumption [1], which is the dominated. Therefore, it becomes essential necessary to take measures to reduce the energy consumption of HVAC.

Currently, to explore energy-efficient air-conditioning system has already become the industry's research focus. The ground source heat pump is one of promising means of reducing the consumption of fossil energy resources, and hopefully reducing the cost of delivered energy for residential heating [2]. The ground temperature is relatively stable in the whole year, which is higher than ambient temperature in winter and lower than ambient temperature in summer. The characteristic makes its energy efficiency is much more than the traditional system. With little premium energy (electric energy) input, ground source heat pump transfers low temperature thermal energy into high temperature thermal. That is to say, getting the heat from ground supply heating to indoor space in winter, and the recycles are revised in summer.

In the hot summer and warm winter area, cooling period is generally longer for 1 to 2 months, than that of the heating period, and the cooling load intensity in summer greater than that of the heating load intensity in winter. Therefore, the amounts of heat extracted from and injected to the ground are not balanced. This unbalance requires either extra ground loop heat exchanger or some mechanisms for assisting the system by rejecting excess heat. The cost of installing the extra ground heat exchangers (GHE) may be excessive, and the operational efficiency of heat pump will be declined due to the soil temperature increment [3]. How to avoid heat pump's operating efficiency drop caused by the amount unbalance of heat between extracted from and injected to the ground, and utilizing the waste heat of condenser has become the focus of engineering applications. Combining with a commercial hotel located in Zhenjiang, Jiangsu Province, which provides 24 hours hot water, this study puts forward the ground source heat pump system to meet the building heating/cooling demand, the gas boiler or the heat-recovery of condensation provides four kinds of design scenarios to make

domestic hot water. Economic performance of capital cost, operational cost and supplying cost of domestic hot water for different scenarios of GSHPS have been analyzed using the dynamic annual cost method.

## Description of the Project and the Design Scenarios

**Description of the Project.** To evaluate the performance of GSHPS, the system was installed in a commercial hotel located in Zhenjiang, Jiangsu Province. The hotel has a living area of 32630m$^2$, air-conditioning area of 24470m$^2$, 340 standard rooms, with an average occupancy rate of 70%, namely 476 people living in. The hotel's air conditioning system is designed for cooling in the summer and heating in the winter, 24h domestic hot water supply throughout the year. According to state regulations [4], the heat load of 65℃ domestic hot water for star hotel is about 1565kW, average hourly heat consumption of 813kW, the amount of hot water consumption is 95 tons per day (T/day). The total design cooling and heating load for the building is 4160kW and 1792 kW, respectively, calculated by the Dest software [5]. Consequently, to recover the heat from condenser can meet the needs of energy to heat the domestic hot water. In the present study, an economic analysis was performed to determine the performance of ground heat pumps.

**Description of the Design Scenarios.** The conventional ground source heat pump injects condensation heat into the ground in summer, which will lead to heat accumulation, and waste a great quantity high-grade energy. To give a brief definition, heat recovery technology is the heat pump recovers and recycles the waste heat when the system is operating by some ways. Recovery of waste heat by heat pump system could decrease the discharge of urban waste heat, protect environmental and save energy. Figure 1 shows the principle of heat recovery system.

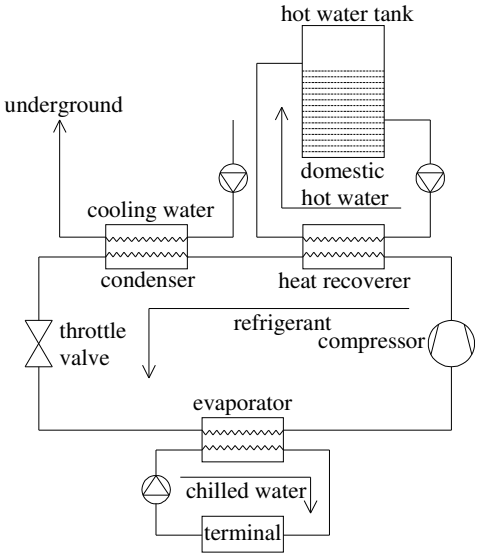

Fig. 1 The principle of heat recovery system

This study selected four kinds of economic and effective solution to analysis on account of the hotel's demand.

1) Scenario 1: ground source heat pump system in combination with gas boiler

The air conditioning is made up of three water source heat pump units. The cooling capacity and cooling power is 1308kW and 215kW, respectively. The heating capacity and heating power is 1420kW and 315kW, respectively. The hot water is supply by a gas boiler with hot water load of 800kW.

2) Scenario 2-4: ground source heat pump system with waste heat recovery system

The air conditioning of the scenario is consisted of three water source heat pump units. The cooling capacity and cooling power is 1416kW and 257kW, respectively. The heating capacity and heating

power is 1526kW and 347kW, respectively. The GSHPS is used for hot water supply. In summer, the systems of scenario 2-4 recover 813kW (the ratio of waste heat recovery is 20%), 1248kW (the ratio of waste heat recovery is 30%) and 2080kW (the ratio of waste heat recovery is 50%), respectively. Other seasons, heat pump units are set to the mode of making hot water in order to provide the required domestic water.

## Calculations of Buried Pipe Length

The performance of GSHPS depends on the design of GHE. Furthermore, the main fee of ground source heat pump project is drilling costs and buried pipe fee, accordingly the calculation of buried pipe length is extremely important.

The length of buried pipe was calculated base on geological conditions and pipe thermal performance from the references [6-10]. The design principles for buried pipes met the standards issued by the International Ground Source Heat Pump Association (GSHPA) [11].

In summer, the length of GHE was calculated based on the cooling load and hot water load, i.e.

$$L_c = \frac{1000Q_c\left(R_P + R_S \cdot F_c\right)}{\left(T_{\max} - T_\infty\right)} \frac{COP_c + 1}{COP_c}. \quad (1)$$

In winter, the length of GHE was determined by the heating load and hot water, i.e.

$$L_h = \frac{1000Q_h\left(R_P + R_S \cdot F_h\right)}{\left(T_\infty - T_{\min}\right)} \frac{COP_h - 1}{COP_h}. \quad (2)$$

Specific symbol in the above equations listed in reference [12]. The calculated results of the pipe's length are shown in table 1.

## Economic Analyses of the Design Scenarios

To obtain profound insight into the project investment capital and operational costs, in this work, the investment capital is calculated by multiplying prices of the apparatus with their installations costs, and the operational costs are assessed based on the investigated thermal loads of the borehole heat exchangers.

**Investment Capital Analysis.** The investment capital of the GHE is assessed by the amount of money invested for accomplishing the project. Prices of the components such as U-tube and hot water devices are the main difference of the systems.

The length of GHE can be formulated as (1)-(2). It is obvious that the main parts of the GHE costs for installation of the GSHP system are the drillings and grouting material, which is about 100 RMB/m. The investment capital of hot water mainly include hot water tank, heat water pump, gas boiler and the difference cost between the heat recovery unit and the conventional unit. The investment capital of the scenarios is listed in Table1.

Table 1 The investment capital of the scenarios

| Scenarios | GSHPS with gas boiler | GSHPS with waste heat recovery | | |
|---|---|---|---|---|
| | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 |
| Costs of hot water devices [RMB] | 181440 | 60400 | 74600 | 80650 |
| Length of GHE [m] | 98810.0 | 80150.3 | 72956.5 | 58612.9 |
| Costs of GHE [RMB] | 9881000 | 8015030 | 7295650 | 5861290 |
| Total costs [RMB] | 10062440 | 8075430 | 7370250 | 5941940 |
| Per area costs [RMB/m$^2$] | 308.4 | 247.5 | 225.9 | 182.1 |
| The fraction [%] | — | 19.7 | 26.8 | 40.9 |

As can be seen from the table, the investment capital of GSHPS with waste heat recovery is less than the conventional GSHPS with gas boiler. The results show that the investment capital of hot water system increased and the GHE costs decreased with the ratio of waste heat recovery of GSHPS increased. The total costs depend on the hot water system and the length of GHE. Because the drillings investment of this research is high, the investment capital of the project decreased with the ratio increased of GSHPS' waste heat recovery. Compared with scenario 1, the investment capital of scenario 4 decreased by 126.3 RMB/$m^2$, and the fraction is 40.9%.

**Operational Costs.** The operational costs in air conditioning mode and in hot water mode are the main operational costs components.

1, the system operates in air conditioning mode

In summer, the energy consumption of compressor and the load of building inject to the underground, which is the cooling load of the GHE. In winter, the heat transform between GHE and ground is equal to the load of building subtracts the compressor's energy consumption.

When the ground source heat pump operated individually, the COP of system and the load of GHE in summer is 2.8 and 5656.57kW, respectively. In winter, the COP of system and the load of GHE is 4.19 and 1364.32kW, respectively. When the ratio of waste heat recovery is 20% (832kW), the load of BHE decreased to 4824.57kW, the COP in summer increased to 3.44. Due to the length reduction of buried pipe, the COP in winter decreased to 4.10. The power of hot water pump is 10.8kW. When the ratio of waste heat recovery is 30% (1248kW), the load of GHE decreased to 4408.57kW, and the COP in summer increased to 3.5. Due to the reduction of buried pipe length, the COP in winter decreased to3.96. The power of hot water pump is 16.2kW. When the ratio of waste heat recovery is 50% (2080kW), the load of GHE decreased, the COP in summer, the COP in winter and the power of hot water pump is 3576.5kW, 3.66, 3.7 and 24.3kW, respectively. This study has analyzed the annual energy consumption of the different scenarios, which is listed in table 2-4. Table 2 and 3 shows the operational costs of air conditioning and hot water, respectively. The total costs are shown in table 4.

Table 2 The operational costs of air conditioning

| Scenarios | GSHPS with gas boiler | GSHPS with waste heat recovery | | |
|---|---|---|---|---|
| | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 |
| Operational time in summer [h] | 3312 | 3312 | 3312 | 3312 |
| Energy consumption in summer [kWh] | 4920685.7 | 4005209.3 | 3936548.6 | 3764459.0 |
| Operational costs in summer [RMB] | 4428617.1 | 3604688.4 | 3542893.7 | 3388013.1 |
| Operational time in winter [h] | 2520 | 2520 | 2520 | 2520 |
| Energy consumption in winter [kWh] | 1077766.1 | 1101424.4 | 1140363.6 | 1220497.3 |
| Operational costs in winter [RMB] | 969989.5 | 991282.0 | 1026327.3 | 1098447.6 |
| Total operational costs [RMB] | 5398606.6 | 4595970.3 | 4569221.0 | 4486460.7 |
| Per area operational costs [RMB/$m^2$] | 165.4 | 140.9 | 140.0 | 137.5 |
| The fraction [%] | — | 14.9 | 15.4 | 16.9 |

In terms of operational costs, only the operational costs of air conditioning were accounted. While the labor, equipment maintenance, management costs and other expense were not took into account. In summer, the efficiency of system increased and the operational costs increased, meanwhile, the operational costs of auxiliary equipments such as water pumps increased because of the heat recovery. In winter, the efficiency of system decreased and the operational costs increased with the length of

GHE decreased. It can be seen from table 2, the operational costs of air conditioning decreased with the ratio of waste heat recovery of GSHPS increased. Compared with scenario 1, the air conditioning operational costs of scenario 4 decreased by 27.9 RMB/$m^2$. The fraction is 16.9%.

2, The operational costs of hot water

This project is a hotel building, which has hot water demand annually.

Table 3 shows the hot water operational costs of heat recovery are less than gas boiler. The operational costs increased with the ratio of heat water increased. This finding indicates that the smaller the ratio is, the less the cost is. Compared with scenario 1, the hot water operational costs of scenario 4 decreased by 37.6 RMB/$m^2$. The fraction is 58.4%.

Table 3 The operational costs of hot water

| Scenarios | GSHPS with gas boiler | GSHPS with waste heat recovery | | |
|---|---|---|---|---|
| | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 |
| Operational time in summer [h] | 2880 | 2880 | 2880 | 2880 |
| Energy consumption in summer [kWh] | — | 31104.0 | 46656.0 | 69984.0 |
| Operational costs in summer [RMB] | — | 27993.6 | 41990.4 | 62985.6 |
| Operational time in other seasons [h] | 5580 | 5580 | 5580 | 5580 |
| Energy consumption in other seasons [kWh] | — | 812956.1 | 841697.0 | 900843.2 |
| Operational costs in other seasons [RMB] | — | 731660.5 | 757527.3 | 810758.9 |
| Total operational costs [RMB] | 2102237.3 | 759654.1 | 799517.7 | 873744.5 |
| Per area operational costs [RMB/$m^2$] | 64.4 | 23.3 | 24.5 | 26.8 |
| The fraction [%] | — | 63.9 | 62 | 58.4 |

Table 4 The total operational costs

| Scenarios | GSHPS with gas boiler | GSHPS with waste heat recovery | | |
|---|---|---|---|---|
| | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 |
| Total operational costs [RMB] | 7500844.0 | 5355624.4 | 5368738.7 | 5360205.2 |
| Per area operational costs [RMB/$m^2$] | 229.9 | 164.1 | 164.5 | 164.3 |
| The fraction [%] | — | 28.6 | 28.4 | 28.5 |

It is obvious that the total operational costs of GSHPS with waste heat recovery are less than GSHPS with gas boiler. The results show that the operational costs increased first and then decreased with the ratio of waste heat recovery of GSHPS increased. And the fraction is 28.5%.

**Economic Analysis.** The investment capital and the operational costs are different economic indicators, which only reflect one aspect of economy. While the comprehensive benefit of GSHP requires a comprehensive economic indicators. The dynamic annual cost method is a powerful tool, particularly when it is used in the analysis and design of experiments. Economic performance of investment capital and operational costs for different scenarios has been analyzed using the dynamic annual cost method [13]. Thus, the annual cost (AC) is calculated by

$$AC = \frac{i(1+i)^n}{(1+i)^n - 1} \times C_0 + C \,. \tag{3}$$

Where, $i$ is the interest rate, 10%, $n$ is the service life, in this study, the life of GSHPS and boiler is assumed to be 50 and 10 years, respectively, $C_0$ is the investment capital, RMB, $C$ is the annually operational costs, RMB. Table 5 shows the economic analysis for each scenario.

Table 5 The economic analysis for each scenario

| Scenarios | GSHPS with gas boiler | GSHPS with waste heat recovery | | |
|---|---|---|---|---|
| | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 |
| Investment capital [RMB/m$^2$] | 330.6 | 247.5 | 225.9 | 182.1 |
| Annually operational costs [RMB/m$^2$] | 229.9 | 164.1 | 164.5 | 164.3 |
| AC [RMB/m$^2$] | 262.9 | 188.9 | 187.1 | 182.5 |

Dynamic annual cost method, when used in the initial planning phase of a project, can identify such situations and save the project money and embarrassment. It is obvious that GSHPS with waste heat recovery is more economic than GSHPS with gas boiler. As can be seen in table 5, tiny difference is between the dynamic annual costs of scenario 2 and 3. The costs of scenario 4 are minimum. Therefore, scenario 4 is the most effective system with regards to energy and economics.

## Conclusions

Economic performance of investment capital, operational costs and supplying costs of domestic hot water for different scenarios of GSHPS, which is designed for a hotel located in the hot summer and warm winter area, have been analyzed using the dynamic annual cost method. From the analysis of the results, the following conclusions can be drawn:

1) In the area with hot summer and warm winter, the combination of heat pumps and hot water system, as in system scenario 3 and 4, with the heat pump to produce domestic hot water is effective. The production of hot water can reduce the over-reliance on the boiler, electric heaters and other energy-consuming heating equipment. Meanwhile, with the heat recovery of condensation, the condensing temperature decrease, and the heat pump system becomes more efficient and the investment capital is less because the system consumes less power.

2) According to the investment capital and the annually operational costs, ground source heat pump system with suitable heat recovery ratio is more economical than the conventional ground source heat pump system with gas boilers. In addition, the investment capital decreased while the total operational costs increased by a small margin with the ratio of waste heat recovery increased.

3) Considered on the total costs, which including the investment capital and the operational costs after $n$ years operated, the comprehensive benefit of GSHPS with waste heat recovery is distinct compared with conventional GSHPS. When the ratio of waste heat recovery is 50%, the dynamic annual costs of GSHPS are minimum and achieve the optimization of energy-saving effect.

**Keywords:** cleanroom, non-unidirectional airflow, particles removal

**Abstract.** Efficient airflow delivery is key to achieve effective contamination control for a high-performance cleanroom. The influence of airflow organization on effect of particles removal in cleanroom with non-unidirectional airflow was investigated in this paper. A series of experiments were conducted on a cleanroom experimental platform with different airflow organization modes and supply air volume variation by frequency converter ( 40 to 50 Hz, 5Hz interval) on air-supply fan unit. The results showed that higher cleanliness could be gained at local area in cleanroom with radial airflow organization. Moreover, the outcomes from these experiments indicated that particle concentration at measuring points appeared more orderly when the cleanroom operated with radial airflow organization. The conclusion can be drawn that radial airflow can benefit contamination control at local area for cleanroom operation with non-unidirectional airflow when compared with ceiling-supply and wall-return airflow organization.

## Introduction

Effective contamination control attributes to efficient airflow in high-performance cleanroom. An efficient airflow system may not only reduce initial costs, but also help cleanrooms achieve operation reliability.[1,2]

Air-recirculation system with ceiling supply and wall-return airflow is traditionally used in non-unidirectional airflow cleanroom. While in the traditional airflow cleanroom, locations and layouts of the production lines affect much on particle diffusion.[3] with the demond for better contamination control in engineering applications to achieve higher cleanliness, it is important to optimize airflow design to meet cleanliness requirements and to achieve effective particle removal.

Airflow organization and air-supply volume are major factors determining particle removal effect in cleanroom, then a series of experimental investigations need be conducted to better understand particle distribution in non-unidirectional airflow cleanroom affected by airflow organization mode.

## Experimental methods

The experimental investigations were conducted in cleanroom2 of a multi-zone experimental platform. Fig.1 shows the schematic diagrams of the platform, in which cleanroom1 is designed as ISO5 cleanliness, cleanroom2 is designed as ISO6 cleanliness class with two airflow organization modes can be chosen, one is Radial airflow pattern with top-aside-radiation supply and down-aside wall-return airflow path (Valve2 open and Valve1 closed), the other is traditional airflow pattern with ceiling-supply and wall-return airflow path (Valve1 open and Valve2 closed).

Electronic frequency converter is configured in air-supply fan unit. During the experiments, the comparison of particle removal effect between radial airflow pattern and traditional airflow pattern in cleanroom2 with different send air volume can be investigated.

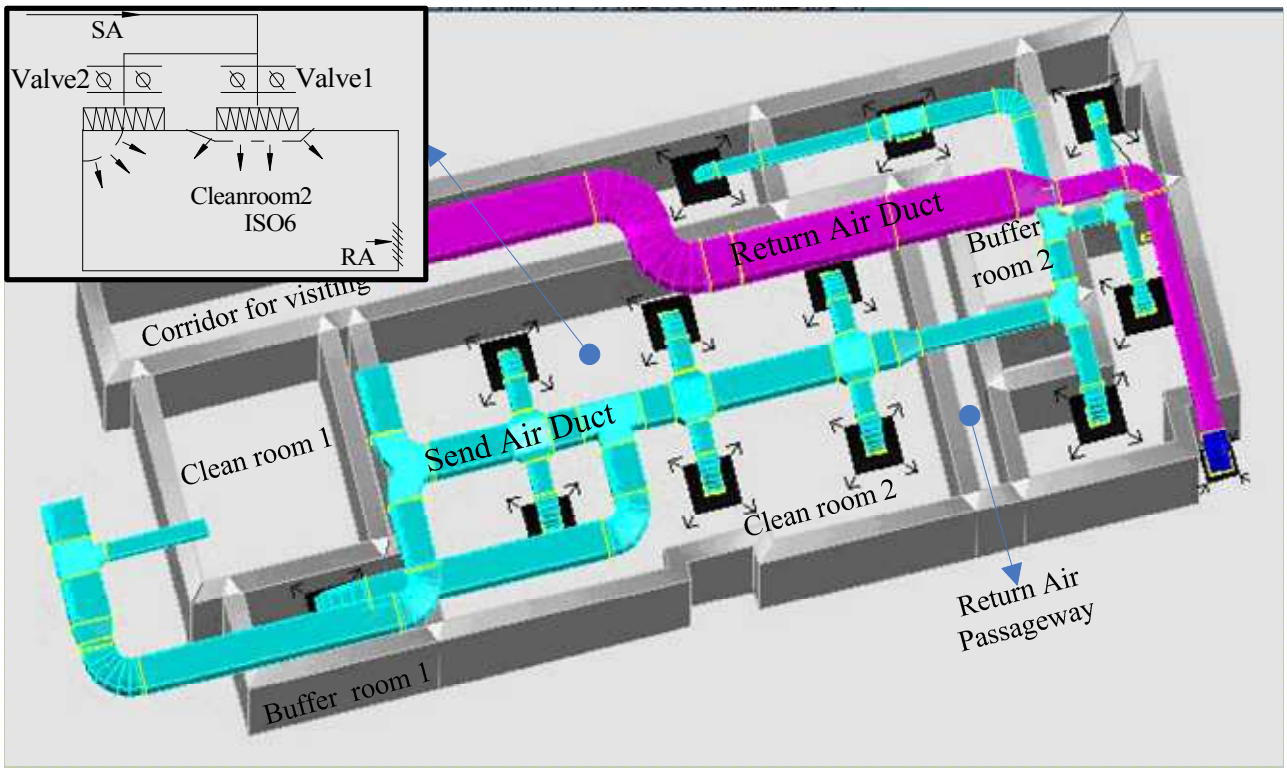

Fig.1 Schematic of airflow path in the cleanroom experimental platform

Judging by design code for clean room and acceptance code for ventilation works[4,5], the measuring points is arranged in cleanroom2, as shown in Fig.2. Laser particle counter is employed to measure particle concentration level in the investigated zone.

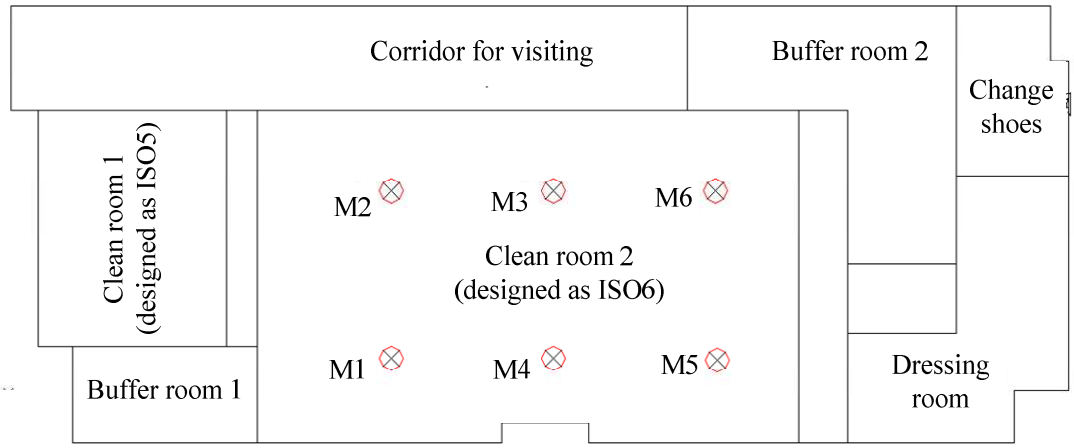

Fig.2 Schematic of measuring points in the investigated zone

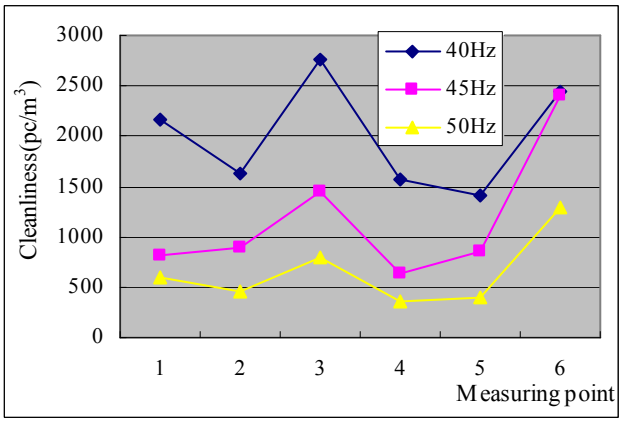
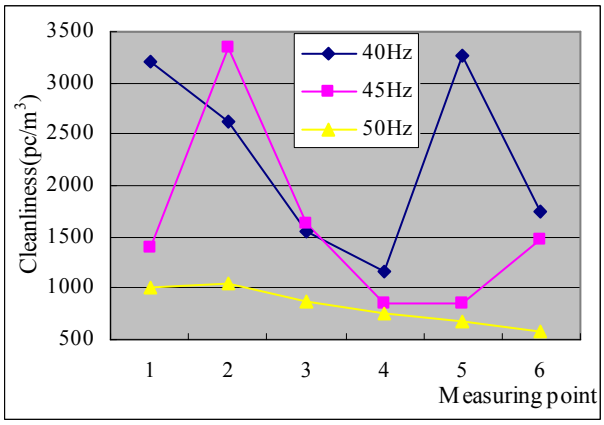
## Results and discussions

Particle distributions in cleanroom2 measured during experiments are shown in Fig.3 and Fig.4. The characterization of minienvironment in cleanroom2 appeared to be effective in maintaining particle-concentration levels well below what was designated (ISO6-cleanliness-class).

Fig.3 reveals concentrations of particles at points M1-M6 decrease consistently with the increase of air-supply (frequency converter varied from 40Hz to 50Hz) when cleanroom2 operated with radial airflow, and particle-concentration levels at points M1-M5 in cleanroom2 with radial airflow well below what appeared in cleanroom2 with traditional airflow, while concentrations of particles at points1-6 trend to uniformity till air-supply fan working at 50Hz. It indicates that local cleanliness are effectively controlled under radial airflow during cleanroom operation.



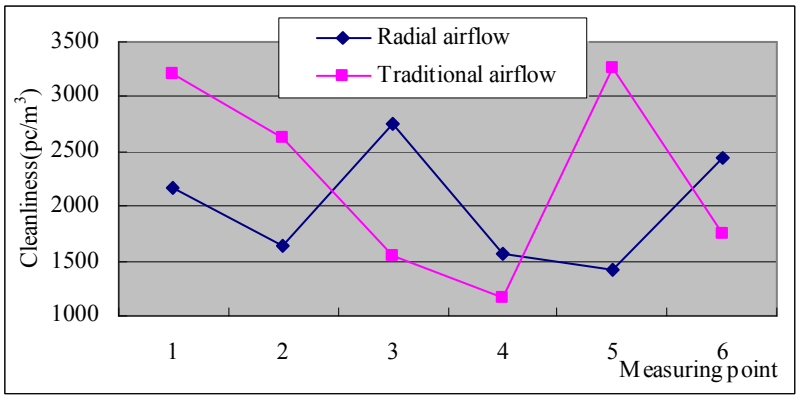
(a) Operation with radial airflow



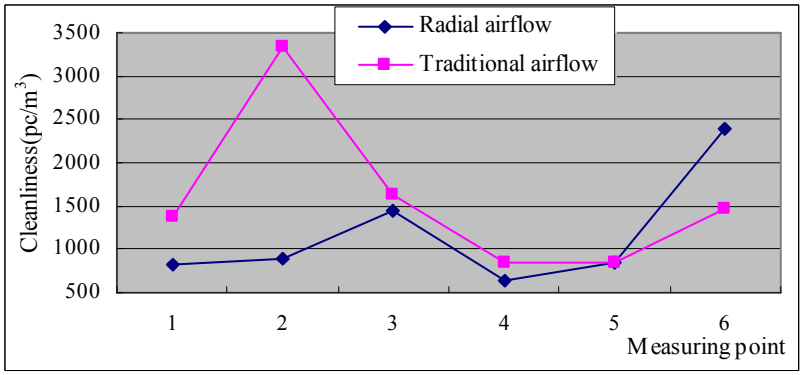
(b) Operation with traditional airflow

Fig.3 Comparison of particle distribution between two airflow patterns

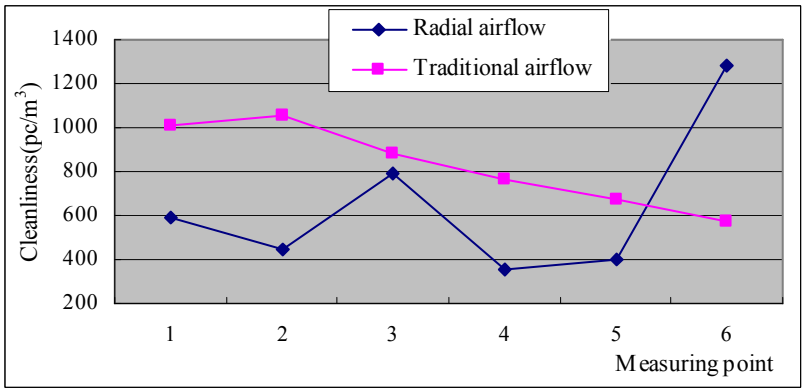
Fig.4 reflects that particle removal comparison between two airflow patterns under different air-supply conditions. It is shown in Fig.4(a) that particle distributions appear irregular in cleanroom2 with either radial airflow or traditional airflow when air-supply fan working at 40Hz. It can be seen from Fig.4(b) and Fig4(c) that particle concentrations near air inlet such as M1 and M2 when air-supply fan working at 45Hz are almost at the same level as what in cleanroom2 with air-supply fan working at50Hz. Then the conclusion can be drawn that radial airflow not only benefit particle removal but also achieve energy-saving for air-supply system when sufficient air are delivered into cleaning zone for maintaining cleanliness requirement.



(a) air-supply fan working at 40Hz



(b) air-supply fan working at 45Hz



(c) air-supply fan working at 50Hz

Fig.4 The influence of air-supply fan operational state on particle distribution

## Conclusions and recommendations

Based upon measurements and comparisons of particle distribution in the non-unidirectional airflow cleanroom with different airflow organizations, the following conclusions are drawn:

·Cleanliness measurements in the cleanroom with radial airflow operation appeared to be more effective in particle removal than what was appeared in the cleanroom with traditional airflow operation.

· Particle distribution appears similar with air-supply variation when radial airflow is employed in the non-unidirectional airflow cleanroom, which is suitable for reasonable layouts of production lines and tool equipment in cleanroom operation and benefit operational energy-saving.

The experimental investigations provide quantitative data to characterize particle removal effect in non-unidirectional airflow cleanroom that were in operation at as-built state. Additional investigations would be need for further evaluating acceptable air-supply volume and air-change rates in cleanroom with radial airflow organization.

**Keywords:** mathematical expectation; gravity head coefficient; operation regulation; design supply and return water temperature

**Abstract:** This paper presented a method of mathematical expectation to calculate gravity head coefficient, and this method was applied to calculate the value of gravity head coefficient of some selected cities in China in different operation regulation mode and different design supply and return water temperature. The results show that gravity head coefficient calculated by this method reflects the average value during the whole heating period. It has more representative significance. When the temperature of design supply and return water in heating system is reduced, the gravity head coefficients change very little. In different operation regulation modes, the gravity head coefficients change larger. The gravity head coefficients have a certain difference in different areas.

## Introduction

In the two-pipe hot water heating system, although gravity head was a limited proportion in the total cycle power, it is one of the important reasons to produce vertical imbalance. It must be considered in designing hydraulic calculation of the system. The gravity head cannot be selected by 100% of the value of design conditions. The reason is that operation regulation will be conducted according to the outdoor temperature change in the actual operation. That is, in different stages of heating, the temperature of supply and return water varies. Thus the gravity head will be reduced at the beginning and end of the heating season. Therefore, when calculating the gravity head, a relatively eclectic coefficient (the ratio of calculated gravity head to designed gravity head) will be selected to ensure that the change of indoor temperature does not affect human comfort.

Ref. [1] describes that gravity head under the outdoor temperature corresponding to the gravity head coefficient should be selected. The outdoor temperature can represent a long duration of the heating period. According to this theory, there are currently two methods to calculate gravity head coefficient. One is that the design value of gravity head coefficient is the ratio of the outdoor mean air temperature during heating period $t_p$ corresponding to gravity head and designed gravity head. The reason is that, all over the country, duration hours of less than or equal to $t_p$ accounts for almost 50% of total hours during heating period. This method is called the $t_p$ algorithm. Another is that a certain outdoor temperature interval is selected, which can represent a longer duration hours during heating period. Then an average value of the outdoor temperature corresponding to the gravity head coefficient in the temperature interval can be calculated. For example, in the Ref. [2], the relative heat load ratio is 0.8 ~ 0.5 during more than 70% of the whole heating period. Then the relative heat load ratio for heating within the range of 0.8 to 0.5 corresponding to the gravity head coefficient can be calculated. Then the average value is calculated. The average value is the design value of gravity head coefficient.

From the perspective of probability, mathematical expectation method is adopted to calculate the gravity head coefficient. And this method is applied to calculate the value of gravity head coefficient of some cities in China in different operation regulation modes and different temperatures of design supply and return water.

**Definition and calculation of the expectation of gravity head coefficient**

Gravity head coefficient is the ratio of calculated gravity head to designed gravity head. Its expression is:

$$B=\frac{\Delta P}{\Delta P'} \quad (1)$$

In formula, $B$ is the gravity head coefficient; $\Delta P$ is calculated gravity head, Pa; $\Delta P'$ is designed gravity head, Pa.

Without considering water pressure generated by water cooling in the circulation line, gravity head in radiator heating system is the result of joint action of the density difference between supply and return water of system and the vertical height difference between radiator cooling center and heating center. Its expression is:

$$\Delta P = gh(\rho_h - \rho_g) \quad (2)$$

In formula, g is the acceleration of gravity, 9.81 m/s$^2$; h is the vertical height difference between radiator cooling center and heating center, m; $\rho_g$ and $\rho_h$ are the supply and return water density of system, kg/m$^3$.

When the system is determined, the variables are $\rho_g$ and $\rho_h$ in Eq. (2). Because of incompressible water, $\rho_g$ and $\rho_h$ are related to $t_g$ and $t_h$, which are the supply and return water temperature of the system. The supply and return water temperature of heating system changes with the outdoor temperature $t_w$ change. Its variation is related to the mode of heating operation regulation. From Eq. (1) and Eq. (2), B is a function of $t_w$. It is set to $B(t_w)$.

The outdoor temperature interval $t_{w,i-1} < t_w \le t_{w,i}$ at heating period corresponding to the average duration hours can be got by the table of the average duration hours of outdoor temperature $t_w \le t_{w,i}$ in some cities[3]. The outdoor temperature interval $t_{w,i-1} < t_w \le t_{w,i}$ at heating period can be taken as a uniform distribution. The more duration hours of the interval are, the greater the corresponding probability $P(t_{w,i-1} < t_w \le t_{w,i})$ is. Probability density $f(t_w)$ of an interval $(t_{w,i-1} < t_w \le t_{w,i})$ can be obtained.

$$f(t_w) = \frac{P(t_{w,i-1} < t_w \le t_{w,i})}{t_{w,i} - t_{w,i-1}} \quad , \quad t_{w,i-1} < t_w \le t_{w,i} \quad (3)$$

The function expression of mathematical expectation is that:

$$E[B] = \int_a^b B(t_w)\, f(t_w) dt_w \quad (4)$$

In formula, $E[B]$ is the mathematical expectation of gravity head coefficient during whole heating period; $a$ represents outdoor design temperature for heating $t_w'$, ℃; $b$ is the outdoor temperature at the beginning and end of the heating season, typically 5℃; $B(t_w)$ represents the gravity head coefficient B when the outdoor temperature is $t_w$; $f(t_w)dt_w$ represents the probability when the outside temperature is $t_w$.

Integral expression of gravity head coefficient expectations is too complex. When $\Delta t_w$ is very small (take $\Delta t_w$= 1℃here), Eq. (4) can be simplified as:

$$E[B] = \sum_{j=a}^{b} B(j) f(j) \times 1 = \sum_{j=a}^{b} B(j) f(j) \quad (5)$$

In formula, j is the outdoor temperature $t_w$ at heating period, ℃; $B(j)$ represents the gravity head coefficient B when the outdoor temperature is j; $f(j)$ represents the value of probability density when the outside temperature is j. When j is discontinuity point of $f(j)$, $f(j) = \frac{f(j^+)+f(j^-)}{2}$.

**Calculation of practical examples**

Take Tianjin as an example to calculate the expectation of its gravity head coefficient using the method above.The average duration hours of outdoor temperature $t_w \le t_{w,i}$ at Tianjin is shown in Table 1.

Table 1 The average duration hours of outdoor temperature $t_w \leq t_{w,i}$ at Tianjin

| $t_w$ | -10 | -8 | -6 | -4 | -2 | 0 | 3 | 5 |
|---|---|---|---|---|---|---|---|---|
| hours | 69 | 127 | 330 | 700 | 1235 | 1833 | 2465 | 2928 |

When +3℃<$t_w$≤+5℃, the average duration hours is 2928-2465=463h. P(+3℃<$t_w$≤+5℃) =463/2928=15.81%. According to probability density function of uniform distribution, f($t_w$)=15.81%/2=7.9%, +3℃<$t_w$≤+5℃. Similarly, the probability density values of other interval can be obtained, the results are shown in Figure 1.

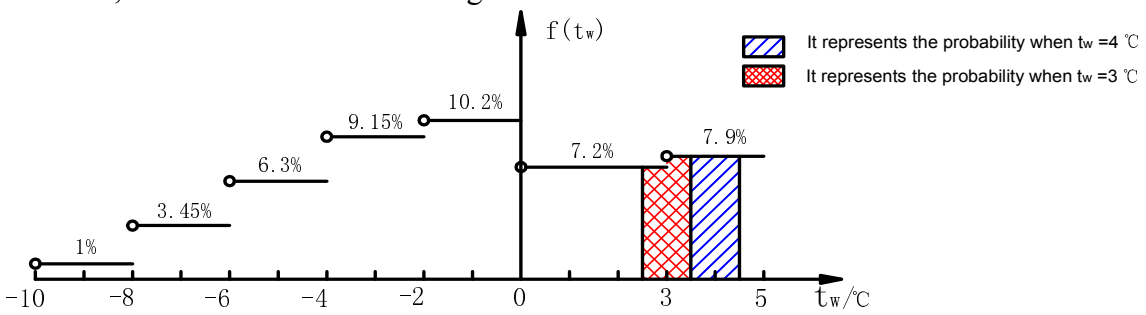

Figure 1 The distribution of f($t_w$) at Tianjin

From the Figure 1, f(+5℃)=(7.9%+0)/2=3.95%, f(+4℃)=7.9%, f(+3℃)=(7.9%+7.2%)/2= 7.55%.And so on,different outdoor temperatures for heating corresponding to the probability density values f(j) of Tianjin can be calculated. If the operation regulation mode for heating system is quality regulation and design supply and return water temperature for heating system is 75/50℃, different outdoor temperatures for heating corresponding to gravity head coefficients B(j) can be calculated. f(j) and B(j) are shown in Table 2.

Table 2 The different outdoor temperatures for heating corresponding to f(j) and B(j) at Tianjin

| $t_w$ | 5 | 4 | 3 | 2 | 1 | 0 | -1 | -2 | -3 | -4 | -5 | -6 | -7 | -8 | -9 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| f(j) | 3.95 | 7.90 | 7.55 | 7.20 | 7.20 | 8.70 | 10.20 | 9.68 | 9.15 | 7.73 | 6.30 | 4.88 | 3.45 | 2.23 | 1.00 |
| B (j) | 0.40 | 0.41 | 0.48 | 0.52 | 0.56 | 0.61 | 0.64 | 0.68 | 0.73 | 0.77 | 0.81 | 0.84 | 0.90 | 0.95 | 1.00 |

E[B] can be calculated from the Table 2, $E[B] = \sum_{j=a}^{b} B(j)f(j) = 0.628$. The expectation of gravity head coefficient at Tianjin is 0.628. Under the same conditions, in other words, when design supply and return water temperature for heating systems is 75/50℃ and the operation regulation mode for heating system is quality adjustment, the gravity head coefficient calculated by $t_p$ algorithm is 0.64. From the results of two methods, it can be seen that gravity head coefficients between the two methods have little difference.

Duration hours curves of the same outdoor average daily temperature of some cities in China is relatively flat, no obvious peak. Duration hours curves of the same outdoor average daily temperature in Russia has obvious peak interval. When design supply and return water temperature for heating systems is 95/70℃ and the operation regulation mode for heating system is quality regulation, the gravity head coefficient calculated by $t_p$ algorithm is 0.36. But the gravity head coefficient calculated by the algorithm of this article is 0.43.

The above analysis show that when duration hours of the same outdoor average daily temperature have smaller change, the result of the algorithm of this article is relatively close to the result of $t_p$ algorithm. However, when duration hours of the same outdoor average daily temperature have larger change, the result has a slight deviation. The result of the algorithm of this article is closer to the true value of 0.4. The reason is that the result of $t_p$ algorithm is a reflection of 50% time of heating period, but the expectation reflects the average during the whole heating period, which has more representative significance.

**The values of E[B] in some cities**

**The basic formula of operation regulation for heating system.** Operation regulation modes of centralized heat-supply in hot water heating system include quality regulation, flow regulation, quality regulation with flow varied by steeps, quality - flow optimization regulation and intermittent regulation. Since the major consideration of this paper is that supply and return water temperature for heating system changes with the outdoor temperature change. Three operating regulation modes will be discussed. They are quality regulation, quality regulation with flow varied by steeps and quality - flow optimization regulation respectively.

The formula of quality regulation is:

$$t_g = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} + 0.5(t_g' - t_h')\overline{Q} \quad (6)$$

$$t_h = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} - 0.5(t_g' - t_h')\overline{Q} \quad (7)$$

In formula, $t_g$ is supply water temperature of heating installation,℃; $t_h$ is return water temperature of heating installation,℃; $t_n$ is indoor design temperature for heating, taking 20℃ here; $t_g'$ is design supply water temperature for heating, ℃; $t_h'$ is design return water temperature for heating, ℃; b is the radiator cooling index, available from manuals and samples, typically 0.3; $\overline{Q}$ is relative heat load ratio for heating, $\overline{Q} = \frac{t_n - t_w}{t_n - t_w'}$ .

The formula of quality regulation with flow varied by steps is:

$$t_g = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} + 0.5\frac{(t_g' - t_h')}{\varphi}\overline{Q} \quad (8)$$

$$t_h = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} - 0.5\frac{(t_g' - t_h')}{\varphi}\overline{Q} \quad (9)$$

In formula, $\varphi$ is the flow ratio, 0.75 here. The remaining symbols and the symbols of quality regulation formula are the same.

The formula of quality - flow optimization regulation is[2]:

$$t_g = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} + 0.5(t_g' - t_h')\overline{Q}^{1-m} \quad (10)$$

$$t_h = t_n + 0.5\left(t_g' + t_h' - 2t_n\right)\overline{Q}^{1/(1+b)} - 0.5(t_g' - t_h')\overline{Q}^{1-m} \quad (11)$$

In formula, *m* is flow optimization regulation coefficient. Its physical meaning is the percentage that flow regulation accounted for heating regulation in optimization regulation of system under the premise of ensuring the normal operation of system. *m* is taken 1/3 in two-pipe heating system. The remaining symbols and the symbols of quality regulation formula are the same.

**The formula of B .**From Eq. (1) and Eq. (2), it can be obtained that:

$$B = \frac{\Delta P}{\Delta P'} = \frac{\rho_h - \rho_g}{\rho_h' - \rho_g'} \quad (12)$$

$t_g$ and $t_h$ under a certain outdoor temperature can be calculated from Eq. (6) and Eq. (7). Then check the table of the relationship between the density and temperature of water[3]. $\rho_g$ and $\rho_h$ can be obtained. Thereby B can be calculated in different operation regulation modes and different design supply and return water temperature. The method of quality regulation with flow varied by steps and quality-flow optimization regulation are the same.

**The values of E[B] in some cities and their analysis.** The design supply and return water temperature for heating system is set for 95/70 ℃, 85/60 ℃ and 75/50 ℃. Calculation results are tabulated in Table 3.

From the table, it can be seen that. When design supply and return water temperature for heating system is reduced, the gravity head coefficients change very little. The reason is that when design supply and return water temperature for heating system are 95/70 ℃, 85/60 ℃ and 75/50 ℃ respectively. The density differences are 15.89 kg/m$^3$, 14.59 kg/m$^3$ and 13.185 kg/m$^3$ respectively.

From the formula of operation regulation, different design supply and return water temperature corresponding to supply and return water temperature with outdoor temperature change is different. Consequently the density difference between supply and return water is different. Thus B varies from Eq. (12). Why do they change little? Ref. [1] describes, for the low-temperature water heating system, when the pressure was constant, the density difference between supply and return water and the temperature difference between supply and return water has a linear relationship whose slope is 0.64. In other words, $\frac{\rho_h-\rho_g}{t_g-t_h}=0.64$. Bringing the value into Eq.(12). $B=\frac{t_g-t_h}{t_g'-t_h'}$ can be got. Bring operation regulation formula into this formula. Since the temperature difference between design supply and return water is constant, B is relevant to $\overline{Q}$ and it has nothing to do with design supply and return water temperature. Due to the linear relationship of the density difference between supply and return water and the temperature difference between supply and return water is fitted and is not exact, B changes little in different design supply and return water temperature.

Table 3 The E[B] values of some cities in China

| city | Quality regulation | | | quality regulation with flow varied by steps | | | quality - flow optimization regulation | | |
|---|---|---|---|---|---|---|---|---|---|
| | 95/70 | 85/60 | 75/50 | 95/70 | 85/60 | 75/50 | 95/70 | 85/60 | 75/50 |
| Beijing | 0.63 | 0.64 | 0.63 | 0.74 | 0.74 | 0.73 | 0.70 | 0.70 | 0.69 |
| Tianjin | 0.63 | 0.64 | 0.63 | 0.75 | 0.75 | 0.74 | 0.70 | 0.70 | 0.69 |
| Harbin | 0.56 | 0.57 | 0.55 | 0.62 | 0.63 | 0.60 | 0.64 | 0.64 | 0.62 |
| Changchun | 0.56 | 0.57 | 0.55 | 0.63 | 0.64 | 0.61 | 0.64 | 0.64 | 0.62 |
| Urumqi | 0.59 | 0.59 | 0.58 | 0.66 | 0.66 | 0.64 | 0.66 | 0.66 | 0.64 |
| Shenyang | 0.57 | 0.57 | 0.56 | 0.65 | 0.65 | 0.63 | 0.64 | 0.65 | 0.63 |
| Hohhot | 0.57 | 0.57 | 0.56 | 0.65 | 0.65 | 0.63 | 0.65 | 0.65 | 0.63 |
| Yinchuan | 0.58 | 0.59 | 0.58 | 0.68 | 0.68 | 0.67 | 0.66 | 0.66 | 0.64 |
| Xining | 0.62 | 0.62 | 0.61 | 0.71 | 0.72 | 0.70 | 0.69 | 0.69 | 0.68 |
| Taiyuan | 0.62 | 0.63 | 0.62 | 0.72 | 0.72 | 0.70 | 0.69 | 0.70 | 0.69 |
| Lanzhou | 0.65 | 0.65 | 0.65 | 0.75 | 0.75 | 0.74 | 0.72 | 0.72 | 0.71 |
| Shijiazhuang | 0.66 | 0.66 | 0.66 | 0.77 | 0.77 | 0.76 | 0.73 | 0.73 | 0.72 |
| Xi'an | 0.69 | 0.69 | 0.69 | 0.84 | 0.83 | 0.83 | 0.75 | 0.76 | 0.75 |
| Zhengzhou | 0.67 | 0.67 | 0.67 | 0.82 | 0.82 | 0.81 | 0.74 | 0.74 | 0.74 |
| Jinan | 0.65 | 0.65 | 0.64 | 0.78 | 0.78 | 0.77 | 0.71 | 0.72 | 0.71 |

The gravity head coefficients change greatly in different operation regulation modes. The B ranges from 0.55 to 0.69 in quality regulation. The B ranges from 0.62 to 0.84 in quality regulation with flow varied by steps. The B ranges from 0.62 to 0.76 in quality-flow optimization regulation. The reason is that circulating flow- rate is constant in quality regulation at the whole heating period. The smaller flow-rate is remained at the stage of higher outdoor temperature in quality regulation with flow varied by steps. The flow-rate is 75% of design circulating flow- rate. There are quality regulation and flow regulation in quality - flow optimization regulation at the whole heating period. Quality regulation accounts for 67% of the share and flow regulation accounts for 33% of the share. Therefore, the modes of operation regulation for heating system are different, the range of B values are different.

The gravity head coefficients have a certain difference in different area. The reason is that $\bar{Q}$ and f(j) are the two factors that affect gravity head coefficient. When $t_w'$ is same and different outdoor temperature corresponding to the values of probability density f(j) are similar, the calculated gravity head coefficient is same. For example, $t_w'$ are both -9℃ at Beijing and Tianjin. Their f(j) are similar. The calculated gravity head coefficient is same. When $t_w'$ is same and different outdoor temperature corresponding to the values of probability density f(j) are not similar, the calculated gravity head coefficient is not same. For example, $t_w'$ are both -9℃ at Xi'an and Zhengzhou. Their f(j) are not similar. The calculated gravity head coefficient is not same.

## Conclusion

A method using mathematical expectation to calculate gravity head coefficient was presented. The calculated results reflect the average value during the whole heating period. When duration hours of the same outdoor average daily temperature have larger change, this method is still applicable.

When design supply and return water temperature for heating system is reduced, the gravity head coefficients change very little. In different operation regulation modes, the gravity head coefficients change greatly. The gravity head coefficients have a certain difference in different areas.

# Study on the Current Situation of Economic Analysis of Ice Storage Air-conditioning System

Li Yuna, Wang Sifu, Lv Tuzhai, Lang Shaofei

Zhengzhou Electric Power College, Zhengzhou, 450004, China

yah0133@163.com

**Key words:** Ice Storage Air-conditioning System; Economic Analysis; Evaluating Methods

**Abstract:** Ice storage air-conditioning system has incomparable advantages than a lot of of conventional air -conditioning system example for "peak shifting and valley filling". The ice storage air-conditioning systems on the research states of the economic analysis are summed up from the building of economic analysis model,the introduction of the special systems , as well as the impact of economic factors in this paper. This paper outlines several main methods about economic evaluation of the ice storage air-conditioning systems,points out some issumes in the course of the study and some places needing to improve.

## Introduction

With China's rapid economic development, the improvement of people's living, air-conditioning system spreads rapidly, so the electricity consumption of air-conditioning increases day by day, the electricity consumption of air-conditioning in Shanghai has reached the total building electricity with more than 40% , Jiangsu, Shanghai city didn't allowed air-conditioning entering the family on account of the lack of electric power . At present, the ice storage air-conditioning system can realize the merits of "peak shifting and valley filling" ,which caused by the attention of electric power department. Ice storage air conditioning system has more advantages , but the initial investment is more than conventional air-conditioning , so economic research of the ice storage air-conditioning is the premise of popularization and application of ice storage air-conditioning technology. In this paper, the author summarizes the recent economic analysis of ice storage air-conditioning system , on the basis of existing research points out some problems and areas for improvement about the ice storage cold economic , meanwhile hopes that it can promote application and popularization of the ice storage air-conditioning system in China.

## Research Situation of Economy on Ice Storage Air-conditioning

Generally Ice storage system includes the charging cycle and cooling cycle, it can be divided into cold storage, ice storage, eutectic salt storage and gas hydrate cold storage four ways according to the storage medium. Because the cold storage capacity of ice storage system is large, the volume of ice storage tank is greatly reduced, and easy to realize the standardization and seriation of cold storage equipment; at the same time, ice storage tank also can be produced on site, its request is not high, that can save a lot of money . Economy is the foundation of the survival of ice storage air-conditioning , there are many evaluation of the ice storage system about its economy by domestic researchers and engineers from many aspects , summarized as follows:

### 1.1 the Establishment of Economic Analysis Model for Economic Analysis

Establishment of ice storage economy analysis model for economic analysis is a very effective method. Some researchers at home and abroad establish the economic analysis model of ice cold storage system from the different angle, and come to a conclusion by combined with example.

The literature [1]John Wiley et al. give the typical lexamples through establishing analysis,model of the exergy and comparing with the traditional energy analysis model, finally state that the exergy analysis model have great practical significance in the economical evaluation of ice storage air-conditioning system. The literature [2] establishes economic model through the annual,cost index respectively during the life period, the initial investment and the annual operating cost , and analyse the economic for example with a construction area of Harbin of ice storage air-conditioning system, that explain it had unmatchable advantages. The literature [3] establishes economic model respectively from initial investment, operating cost and peak power consumption, but also come to two economic indicators taking an ice storage air-conditioning system for example, by compared with the conventional air conditioning , one is the reduction of peak power of air-conditioning ; two is recovery period of the increase investment of use . The literature[4] establishes model about saving year electricity , obtain five indicators about a comprehensive evaluation of the ice storage air-conditioning system of economic and social benefits, such as recovery period of the increase investment, the transfer coefficient of performance, rate of peak power, the reducing rate of performance,rate of refrigerator, capacity ratio of refrigerator and cool storage rate of air-conditioning's load.

### 1.2 Economic Analysis on Special Forms of Ice Storage System

With the development of the ice storage technology, pure ice storage system has been unable to meet the economic demand of user , so a special ice storage system arises.

The research on these aspects has a lot: ice storage system combined with low temperature air supply system is introduced respectively from the initial investment and running costs in the literature [5],results show that this system can greatly reduce the size of the wind pipe, pump power, so to reduce initial investment and running costs, at the same time to save space, and improve this system competitiveness. the literature [6] has operation cost as the indicator by aiming at three conditions (refrigeration, heating,ice) heat pump unit, and compile analysis software, then concludes energy consumption of heat pump unit and cold storage device under different load conditions by simulating cooling load of a air-conditioning period and operation of heat-pump,takes the effects of initial investment into account, finally calculates the cost in different cold storage operation scheme.

### 1.3 Using Engineering Examples for Economic Analysis

At present, many domestic scholars analyse its economy respectively from two aspects of initial investment and operation cost through the typical engineering examples, and explain that ice storage air-conditioning system is better than conventional air-conditioning system [7] [8]. On the basis of the coupling relationship among building function, price and other factors, The author analyses its economy aiming at the typical functional building in Shanghai are, and put forward a set of ice storage air conditioning system scheme in the literature [1].

### 1.4 Economic Influencing Factors of Ice Storage Cooling System

#### 1.4.1 Price of Electricity

Ice storage system is the product of the national electricity policy, therefore, the structure of price of electricity becomes the direct factors that affect the economy of the ice storage cold from the social benefits.

#### 1.4.2 Operating Mode and Operating Strategy

For the ice storage system, its economy mainly depends on the initial investment cost and operation cost. However, the selection of its running mode is the precondition of the selection of cold storage equipment capacity, because the rational system mode can determine the appropriate storage device's size, thus saving the initial investment cost; and saving operating costs as far as possible from the aspects of perfecting the operation strategy of the ice storage system.

#### 1.4.3 Ice Packing Factor

In the ice storage air-conditioning system, ice packing factor of ice storage tank is the direct factors influencing the economical performance of ice storage air-conditioning system. Ice packing factor refers to the ratio of ice's quality in the ice water mixture. It marks the volume unit of storage in the cold ice storage tank, its size has no ground for blame role in initial investment, operating cost and life cycle cost .

The literature [9] points out the suitable range of changes in the proportion of cold storage rate; the literature [10] points out the best selected range of storage rate ; the literature [11] put forward different view to definition and optimization of cool storage proportion; the literature[12] illustrates the relationship between rate of ice storage and ice storage air-conditioning factors of economy from different angles; the literature [13] introduces the calculating method for optimizing the storage rate; the literature [14] combines with a typical project, analyzes the effect of cold storage system on the economic, obtains curve relationship between the storage rate and among initial investment, annual operating cost , investment recovery period, on the basis of economy analysis method of the traditional storage cooling system.

### Economic Evaluation Method of Ice Storage Cold Air-conditioning System

There are many methods for the economic evaluation of the ice cold storage,at present simple static economic evaluation method and dynamic economic evaluation method are the most commonly used[15-17].

### 2.1 Single Static Economic Evaluation Method

The evaluation index of this method is investment recovery period. Investment recovery period of ice storage cold air-conditioning is that its increased investment divides by its operating costs of annual savings . After the recovery period of investment, operating cost of annual savings is economic benefit that the users net .

i. Calculation of initial investment cost increasing of ice storage air conditioning system

$$\Delta I = I_s - I_c \quad (1)$$

In the type: $I_s$ stands for initial investment of ice storage air-conditioning system (yuan); $I_c$ stands for initial investment of conventional air-conditioning system (yuan); $\Delta I$ stands for initial investment of increasing of the ice storage air-conditioning system (yuan).

ii. Calculation of saving operating cost throughout the year of ice storage air conditioning system

$$\Delta P = P_s - P_c \tag{2}$$

In the type: $P_s$ stands for total electricity running throughout the year of ice storage air conditioning system (yuan)； $P_c$ stands for total electricity running throughout the year of conventional air-conditioning system (yuan); $\Delta P$ stands for the amount of the annual power consumption saving of ice storage air-conditioning system (yuan).

iii. Calculation of investment recovery period

$$n = \Delta I / \Delta P \tag{3}$$

In the type: $n$ stands for investment recovery period (years).

Simple static economic evaluation method is the most simple and intuitive when using. But this method is generally believed that if the investment recovery period is less than 5 years that the system is economically feasible. When the investment recovery period is longer, we should adopt the dynamic economic evaluation method, so as to make the evaluation more practical.

### 2.2 The Dynamic Economic Evaluation Method

The dynamic economic evaluation is more perfect and precision than the single static economic evaluation method . It can be divided into dynamic payback period analysis and life cycle investment analysis method.

#### 2.2.1 Analysis Method of Dynamic Investment Recovery Period

i. If only considering the effect of the time value of money , computational formula of dynamic investment recovery period is as follows:

$$\sum_{n=0}^{N} \frac{E_n}{(1+R_0)^n} = \sum_{n=0}^{k} \frac{I_n}{(1+R_0)^n} \tag{4}$$

In the type: N stands for dynamic investment recovery period (years)； $R_0$ stands for the standard discount rate；k stands for the ending year of investment； $E_n$ stands for the net earnings of N years； $I_n$ stands for the investment of N years.

ii. In addition to consider the time value of money, but also consider factors such as energy prices are affected by inflation, then computational formula of the dynamic investment recovery period is as follows:

$$N = \frac{\log\{1-(i-c-e)\frac{I_s - I_c}{P_c - P_s}}{\log\{\frac{1+e}{1+i-c}\}} \quad (5)$$

In the type: N， $I_s$， $I_c$， $P_s$， $P_c$ with the above； $i$ stands for interest； $c$ stands for the rate of prices rising； $e$ stands for the rate of energy costs rising.

### 2.2.2 Analysis Method of Life Cycle Investment

This method is also called the net present value method. It analyzes economy coming from the using life cycle of the whole equipment .Life cycle investment includs all life cycle cost, energy consumption cost of the building, equipment purchase, installation, maintenance, replacement cost, and other expenses related to the investment.

When all the money is transformed into the net amount, it has to consider the past and the future funding of equivalence

$$NPV = \sum_{N=1}^{L}\{\frac{E_n}{(1+R)^n}\} - I_c \quad (6)$$

In the type: NPV stands for the net present value； $E_n$ stands for the net income of N years；R stands for the discount rate； $I_c$ stands for a one-time investment；L stands for economic life.

When the net present value (NPV)> 0, it means the project scheme is feasible.When using the net present value to evaluate several schemes, if the service life of the scheme is the same, the optimal net present value is the highest scheme. So,the economic life and the discount rate must be carefully selected. Economic life of equipment is the length of time that the equipment can continuously use.For cold storage equipment, although cool storage tank may last longer, but the biggest economic life is thought to be 20 years. The discount rate represents the return on investment that the people would expect.

## The Existing Problem and Needs to be Improved of Ice Storage Air-conditioning System in the Process of Economic Evaluation

The economic evaluation of ice storage air-conditioning system is for a system's engineering, needs to make concrete analysis to specific ngineering, comes to the reasonable conclusion. In evaluating the ice storage system and establishing the model, we need to pay attention to the built model can fully reflect the initial investment and operating cost of this system, so that economic evaluation is more objective and fair. Most of the literature when narrating economy influence of ice storage rate of the ice storage air-conditioning system, just give roughly best cool storage rate scope, and there is no specific instructions, which remains to be further research. Economical analysis of ice storage air-conditioning system is more complex, some people design the relevant software of economic analysis, but whether software itself really evaluate the economy of ice storage system, we still should do further research, so as to make it perfect.

## Conclusions

This paper summarizes the research status of economic analysis of ice storage air-conditioning system from four aspects, and shows economy analysis of research work has made some progress in the ice storage air conditioning system in our country. Also it pointes out that the model of the ice storage air-conditioning system, the optimal cool storage rate and efficiency analysis software of ice storage and so on need further in-depth study, so as to promote the development of ice storage air-conditioning system in our country.

# A CFD Simulation of Indoor Natural Ventilation of a Residential District In Zhuzhou

Zhiyong Wang[1,a], Shunfu Yang[1,b*], Changrong Liu[1], Tianyu Zhang[1], Na Cui[1]

[1]School of Civil Engineering, Hunan University of Technology, Zhuzhou, Hunan, China, 412007

[a]zywang668@126.com, [b]ford_young@163.com

**Keywords:** natural ventilation; CFD; numerical simulation; residential district

**Abstract.** With the promotion of building energy conservation, many residential areas are closely link with energy saving in design phase, and natural ventilation becomes the key to reduce building energy consumption. Thus, house design and building distribution of residential district is particularly important. Computational fluid dynamics (CFD) get rapid development in recent 20 years, especially in architectural design. This text established a model of part of a residential district in Zhuzhou based upon ANSYS FLUENT CFD software, and used numerical simulation method to simulate the condition of indoor natural ventilation under typical summer climate when the doors and windows of buildings were opened. The distribution regularities of indoor velocity field and pressure field and etc have been gotten. These data provide a theoretical basis to evaluate the building distribution of residential area.

## Introduction

Nowadays residential energy consumption accounts for more proportion of building energy consumption in China. Compared with mechanical ventilation and air conditioning, natural ventilation show the remarkable advantages of energy saving and environmental protection on the premise to meet the requirements. The main purpose of applying natural ventilation is to make full use of natural wind to take away the indoor quantity of heat and reduce the service time of air conditioning when the outdoor temperature is benefit to room draught in transition season. It is possible to achieve the goal of energy saving by this way. But there are some limitations on layout in a few constructions. The indoor comfort of some rooms in these constructions is greatly influenced by the poor effect of natural ventilation. Therefore, studying the law of indoor natural ventilation becomes the most important premise of indoor environment design.

## Architectural overview and meteorological conditions

The plane sketch of simulating region in this residential district is shown in Fig. 1. Building A to E has the same house type. They have a total of 30 floors and there are 4 households in each storey. The floor height of building A to E is 3.3 meters. The structure of each house type is shown in Fig. 2. Building F to J are single-family villas, they all have the same house type. These villas have three floors which height could arrive at 3.3 meters. Our research mainly focused on the third floor, the structure is also shown in Fig. 2. This residential district is in Zhuzhou city where is located in the subtropical monsoon climate zone which mainly prevail south wind and northwest wind in summer. We operated this simulation on the condition that the outdoor temperature was at 27℃ and chose 2.2m/s as the south air velocity.

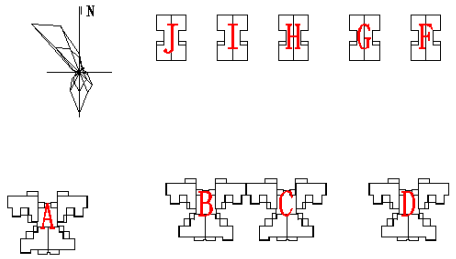

**Fig. 1. The plan sketch of simulated building in the residential district**

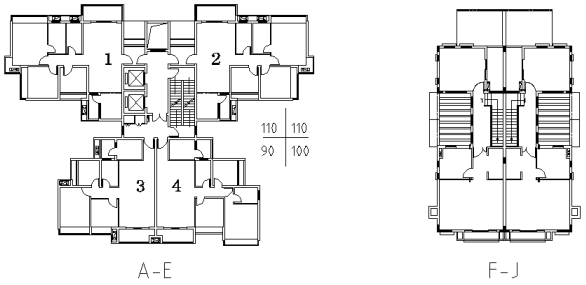

**Fig. 2. The standard floor layout of each building**

## Mathematical and physical model

At present, most commercial CFD software select finite volume method to solve the calculation. We calculated the indoor natural ventilation by regarded it as the stationary flow of incompressible turbulent flow. Chose RNG $k$-$\varepsilon$ model as the turbulence models, and assumed that the airflow meet the continuity equation; momentum conservation law and the law of conservation of energy.

In the RNG $k$-$\varepsilon$ model, the effect of small-scale was reflected by large-scale movement and the revised viscosity item. Thus, the small-scale movement could be systematically removed from the control equation. After some changed, the $k$ equation and epsilon equation we got as follow was very similar to the standard $k$-$\varepsilon$ model.

$$\frac{\partial(\rho k)}{\partial t}+\frac{\partial\left(\rho k u_i\right)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\alpha_k \mu_{eff}\frac{\partial k}{\partial x_j}\right]+G_k+\rho\varepsilon \tag{1}$$

$$\frac{\partial(\rho\varepsilon)}{\partial t}+\frac{\partial(\rho\varepsilon u_i)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\alpha_\varepsilon \mu_{eff}\frac{\partial \varepsilon}{\partial x_j}\right]+\frac{C_{1\varepsilon}\varepsilon}{k}G_k-C_{2\varepsilon}\rho\frac{\varepsilon^2}{k} \tag{2}$$

Where $\alpha_k = \alpha_\varepsilon = 1.39$; $\mu_{eff}$ is the sum of turbulent viscosity coefficient and kinetic viscosity coefficient; $C_{1\varepsilon}$ and $C_{2\varepsilon}$ is the empirical constant; $G_k$ is a item of $k$ which represent turbulent kinetic energy caused by average velocity gradient.

The continuity equation is expressed as:

$$\frac{\partial\rho}{\partial t}+\nabla(\rho\boldsymbol{u})=0 \tag{3}$$

Where $\rho$ is the density; $t$ is the time; $\boldsymbol{u}$ is the velocity vector of fluid.

The momentum conservation equation is defined as:

$$\frac{\partial(\rho u)}{\partial t}+\nabla(\rho u\boldsymbol{u})=\nabla(\mu\,\mathrm{grad}\,u)-\frac{\partial p}{\partial x}+S_u \tag{4}$$

Where $u$ is a component of the velocity vector $\boldsymbol{u}$ in the x direction; $p$ is the pressure on the infinitesimal body of fluid; $S_u$ is the generalized source term of momentum conservation equation.

The energy conservation equation can be written as:

$$\frac{\partial\rho T}{\partial t}+\nabla(\rho\boldsymbol{u}T)=\nabla\left(\frac{k}{c_p}\mathrm{grad}\,T\right)+S_T \tag{5}$$

Where $c_p$ is the specific heat; $T$ is the temperature; $k$ is the heat transfer coefficient of fluid; $S_T$ is the viscous dissipation term.

**Model building and meshing**

The simulation was on the condition that it was natural ventilation when all the doors and windows indoor were opened. Considering the computer's memory and operating speed, we simplified the actual buildings into two-dimensional model and simulated the natural ventilation in people main activity area of third floor and tenth floor. The area is 1.5 meters high from the local ground. In order to accurately simulate the air moving in and out of the room, researchers selected a region which is 300 meters in length and 200 meters in width as the simulation area. The buildings to be simulated were put in the middle of the area. We chose unstructured grids for computational domain and defined the indoor grid size as 400 millimeters for the purpose to obtain a more accurate calculation results. Due to few influence on indoor simulation, the external grid was gradually increasing from indoor to outdoor with an amplification factor of 1.12.

**Set of boundary conditions**

Inlet boundary conditions: There is a gradient wind in the vertical direction because of the friction caused by the ground. Gradient wind is distributed on the basis of the law of boundary layer. The computational formula is shown below:

$$\frac{v}{v_s}=(\frac{z}{z_s})^{\alpha} \tag{6}$$

Where $v$ and $z$ represent average air velocity and height respectively; $v_s$ and $z_s$ represent average air velocity and height at standard height respectively (most countries often take 10 meters); $\alpha$ is the ground roughness coefficient, it is generally take 0.3 for downtown area which have dense and higher buildings. Chose velocity inlet as the inlet boundary conditions, the wind speed at different heights were calculated by Eq. 6.

Outlet boundary conditions: outflow boundary.

On both sides of the fluid domain: moving wall boundary.

Building envelope: no slip wall boundary.

**The results and analysis of numerical simulation**

**The simulated results and analysis in people main activity area of third floor**

Fig. 3 to Fig.6 shows that the rooms on the windward side of building A to E got excellent indoor ventilation effect; the air velocity can reach to 1 to 2.5 m/s. People in the room can feel the wind flow. Meanwhile, the wind can take away the quantity of heat in the room and reduce the energy consumption of air conditioning.

As to the rooms on the leeward side, the ventilation effect varies from building to building. The air velocity in house type 1 of building A and B is maintained below 1 m/s, it's indoor temperature is higher than other rooms, the ventilation effect is poor and the age of air is greater than 100 seconds. The reason is that the incoming flow blocked by the house type 3 and it formed a separation zone in which the incoming flow bypass house type 1 and moving backwards. These rooms should rely on air conditioning to assist the interchange of air inside the room in summer.

As a result of blocked by elevator shaft, the ventilation effect is also less obvious in house type 2 of building E. There is almost no air circulation in most rooms except sitting room which has an air velocity about 2 m/s at the entrance. The age of air in these rooms is greater than 120 seconds and the temperature is relatively high. Thus, they also need air conditioning to assist the interchange of air in the summer.

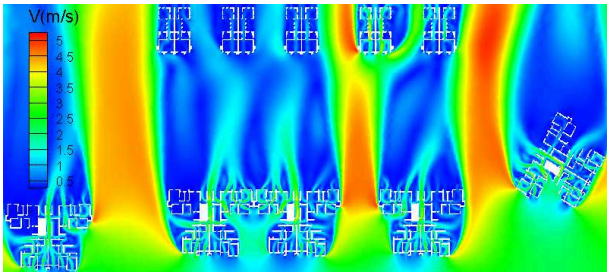

**Fig. 3. Contours of the velocity**

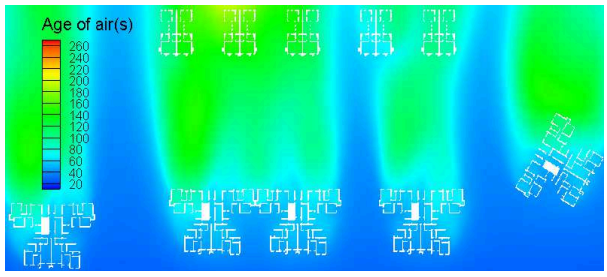

**Fig. 4. Contours of the age of air**

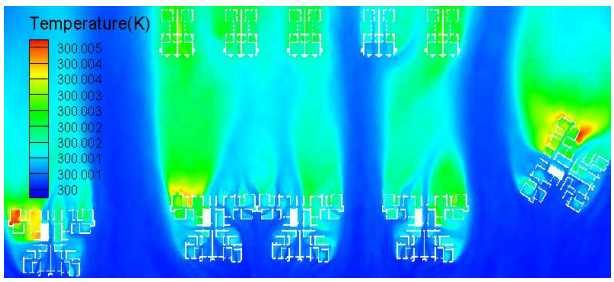

**Fig. 5. Contours of the temperature**

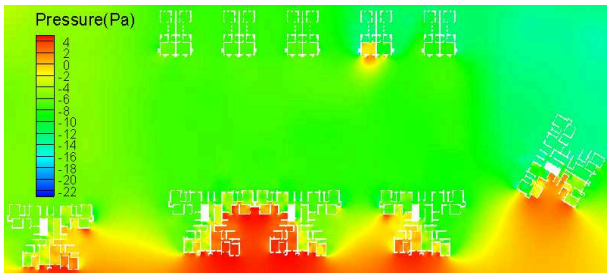

**Fig. 6. Contours of the pressure**

Incoming flow suddenly blocked between building B and C for the small spacing of two buildings and formed a strong wind pressure in this region. The pressure contribute to the natural ventilation in house type 2 of building B and house type 1 of building C. Maximum air velocity of indoor can reach up to 3.5 m/s, it gives people a sense with the breeze caress the cheeks.

For the height of building A to E is nearly 100 meters, it form a cavity area on there backfaces. The wind velocity in this area is rather small. Then, a wake zone which extend to a distance at several times of the building height is formed because the kinetic energy loss of airflow. Building H to J just located in the wake zone of building B to D. Though the wind is weak and the wind direction is not stable in this area, building F to J has an unobstructed indoor structure which can help to generate cross ventilation in the north and south direction. So, there are two obvious air channel appear in building H to J, the air velocity in channel can reach to 1.5 to 2 m/s.

Building G is out of the wake zone. The incoming flow get through between two tall buildings, this increase the air pressure and air velocity and form a wind tunnel at last. It ensures building G a perfect ventilation effect; the maximum indoor air velocity can reach up to 4 m/s, and the age of air is also maintained a level below 100 seconds. Building G is able to keep a good indoor thermal comfort completely by natural ventilation.

**The simulated results and analysis in people main activity area of tenth floor**

Fig. 7 to Fig. 10 shows that the speed of incoming flow on tenth floor was faster than third floor, it is because of the gradient wind. These improve the natural ventilation of several rooms. For example, house type 1 of building B get a maximum air velocity at 2 m/s along with the strengthening of natural ventilation, and the age of air is kept below 70 seconds. The quantity of heat in rooms is taken away by natural ventilation.

There is a slightest change on ventilation in house type 1 of building A and house type 2 of building E, the indoor air velocity is still at a slow level, the temperature is relatively high, these rooms still need the help of air conditioning to meet the indoor air quality.

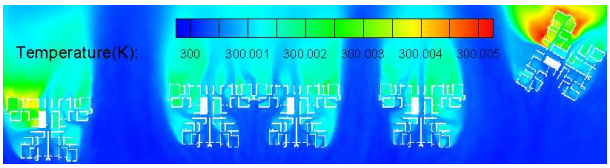

Fig. 9. Contours of the temperature

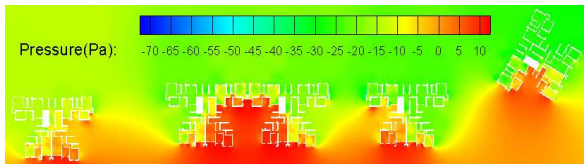

Fig. 10. Contours of the pressure

## Conclusions

The study shows that using CFD software to simulate indoor ventilation has an important value of engineering application, for it can reduce the research and development (R&D) cost and guarantee the feasibility and reliability of design. Many detail data and graphics have been gotten from this numerical simulation, such as air velocity, air age, temperature and pressure of architecture. It can be found from these results that it is reasonable of most architectural design except a small part need to be improved. A majority of rooms can make the most of natural ventilation to eliminate indoor quantity of heat and satisfy the requirement of comfort and energy saving.

**Keywords:** ice storage system, internal-melt ice-on-tube, numerical simulation, enthalpy method.

**Abstract.** The numerical simulation is widely used in study of the ice storage system. The model about melting is established and solved by using enthalpy method. Natural convection of the melted water in the course of melting is studied. Effects on the performance of heat-exchange, caused by variation of velocity of the refrigerant, inner diameter of the tube, initial temperature of the external water and inlet temperature of the refrigerant, are simulated and analyzed.

1. As the increase of cryogen inlet temperature, the influence of natural convention is more and more in the process of melting heat transfer.
2. Under the conditions of the different cryogen velocity, the different diameter of tube and the different initial temperature of ice layer, the effect of natural convention also is different in the process of melting heat transfer.

## Introduction

The ice storage system is widely used because of its simple design and obviously economy. The overseas study of the ice storage system starts in 1930s and now the technique is already mature [1,2,3]. The domestic study of the ice storage system starts in1990s and is still in underway stage. The studies focus on the melting and icing models [4,5], and the experiments of the ice storage system [6,7].

It is more complicated to analyze the heat transfer process when melting because it always goes with phase change. So the academic studies of melting always neglect the natural convection. But in fact the influence of natural convection is very great and can not be neglected. In the paper, the melting process of the ice storage tube is calculated by using enthalpy method, Natural convection is considered. The effects of some initial parameters on natural convection have been simulated and analyzed.

## Physical Model

When setting up the melting model which chooses the glycol as cryogen under considering natural convection, make the following assumptions to simplify the problem:

1) Because the length of the tube is much more than its diameter, so neglect the radial heat transfer and polar heat transfer of the cryogen.
2) The initial temperature of the ice in the groove is uniform and is a constant temperature , $T_{ice} \prec 0^{\circ}C$;
3) During the whole process of the heat transfer, properties of glycol, ice and water always keep the same; however, when dealt with volume stress in the momentum equation, water density was considered as variance, other ones was still considered as constant;
4) The thickness of the ice storage tube wall is very thin, and thermal conductivity is great. Therefore, the thermal resistance can be neglected;
5) The thermal insulation capability of groove wall is strong. Therefore, the heat loss to the surroundings can be neglected;

6) Viscous dissipation of water is neglected;
7) Volume change caused by phase change is neglected.

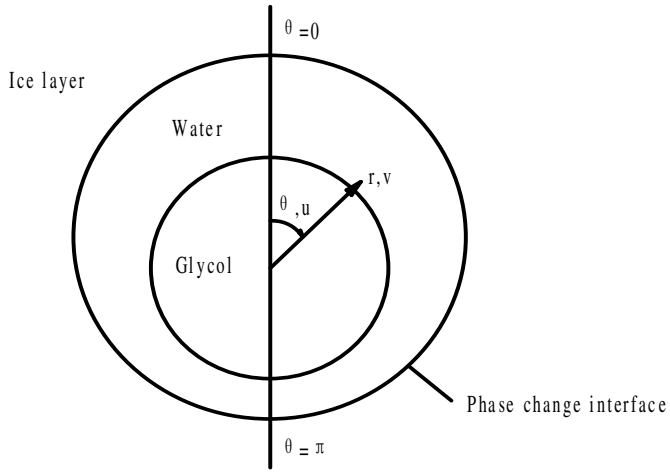

Figure.1 Physical model and coordinate system

## Mathematicl Model and Solution Method

Fig 1 shows the physical model of the section which is vertical to the axis in the ice melting process under natural convention and the polar coordinate system. According to the physical model, mathematical model can be conducted as follows:

**Continuity equation**

$$\frac{1}{r}\frac{\partial}{\partial r}(rv)+\frac{1}{r}\frac{\partial u}{\partial r}=0 \tag{1}$$

**Momentum equation**

Radial direction *r*

$$\rho\frac{\partial v}{\partial \tau}+\frac{\partial}{\partial r}(\rho vv)+\frac{1}{r}\frac{\partial}{\partial \theta}(\rho uv)-\frac{\rho u^2}{r} = \rho g\beta(t-t_{\mathrm{ph}})\cos\theta-\frac{\partial p}{\partial r}+\frac{1}{r}\frac{\partial}{\partial r}(r\mu\frac{\partial v}{\partial r})+\frac{\mu}{r^2}\frac{\partial^2 v}{\partial \theta^2}-\frac{2\mu}{r^2}\frac{\partial u}{\partial \theta}-\frac{v}{r^2} \tag{2}$$

Polar angle direction $\theta$

$$\rho\frac{\partial u}{\partial \tau}+\frac{\partial}{\partial r}(\rho vu)+\frac{1}{r}\frac{\partial}{\partial \theta}(\rho uu)-\frac{\rho uv}{r} = -\rho g\beta(T-T_{\mathrm{ph}})\sin\theta-\frac{1}{r}\frac{\partial p}{\partial \theta}+\frac{1}{r}\frac{\partial}{\partial r}(r\mu\frac{\partial u}{\partial r})+\frac{\mu}{r^2}\frac{\partial^2 u}{\partial \theta^2}+\frac{2\mu}{r^2}\frac{\partial v}{\partial \theta}-\frac{u}{r^2} \tag{3}$$

**Energy equation**

$$\rho c_{\mathrm{p}}[\frac{\partial T}{\partial \tau}+\frac{\partial}{\partial r}(vT)+\frac{1}{r}\frac{\partial}{\partial \theta}(uT)] = \frac{1}{r}\frac{\partial}{\partial r}(rk\frac{\partial T}{\partial r})+\frac{1}{r}\frac{\partial}{\partial \theta}(\frac{1}{r}k\frac{\partial T}{\partial \theta})+\frac{\partial}{\partial z}(k\frac{\partial T}{\partial z}) \tag{4}$$

**Energy equation of enthalpy method**

Using enthalpy method, energy equation (4) can be converted as follows:

$$\frac{\rho}{c_{\mathrm{p}}}\frac{\partial h}{\partial \tau}+\frac{\partial}{\partial r}(\rho vT)+\frac{1}{r}\frac{\partial}{\partial \theta}(\rho uT) = \frac{1}{r}\frac{\partial}{\partial r}(r\frac{k}{c_{\mathrm{p}}}\frac{\partial T}{\partial r})+\frac{1}{r}\frac{\partial}{\partial \theta}(\frac{1}{r}\frac{k}{c_{\mathrm{p}}}\frac{\partial T}{\partial \theta})+\frac{\partial}{\partial z}(\frac{k}{c_{\mathrm{p}}}\frac{\partial T}{\partial z}) \tag{5}$$

Where:

$$t - t_{ph} = \begin{cases} (h - h_s^*)/c_s & h < h_s^* \\ 0 & h_s^* \le h \le h_l^* \\ (h - h_l^*)/c_l & h > h_l^* \end{cases} \quad (6)$$

$$\rho = \begin{cases} \rho_s & h < h_s^* \\ \rho_l & h > h_l^* \end{cases} \qquad k = \begin{cases} k_s & h < h_s^* \\ k_l & h > h_l^* \end{cases} \quad (7)$$

Meanings of the above symbols:

| | | | | | |
|---|---|---|---|---|---|
| $\theta$ | polar coordinate | $(m)$ | $r$ | radial coordinate | $(m)$ |
| $z$ | axial coordinate | $(m)$ | $v$ | radial velocity | $(m/s)$ |
| $u$ | peripheral velocity | $(m/s)$ | $\rho$ | density | $(m^3/kg)$ |
| $\mu$ | kinetic viscosity | $(Pa \cdot s)$ | $\tau$ | time | $(s)$ |
| $g$ | acceleration of gravity | $(m/s^2)$ | $\beta$ | volume expansion coefficient | (1/℃) |
| $k$ | heat conductivity coefficient | $(w/[m \cdot °C])$ | $c_p$ | specific heat | $(kJ/(kg \cdot K))$ |
| $T$ | temperature | $(K)$ | $ph$ | phase change point | |
| $h$ | normal specific enthalpy | $(kJ/kg)$ | $h_s^*$ | ice specific enthalpy | $(kJ/kg)$ |
| $h_l^*$ | water specific enthalpy | $(kJ/kg)$ | $c_s$ | ice specific heat | $(kJ/(kg \cdot K))$ |
| $c_l$ | water specific heat | $(kJ/(kg \cdot K))$ | | | |

**Solution of The Governing Equation**

\In this paper, the solution domain is dispersed by using inside-node method. Governing equations are integrally dispersed using the control volume method and the staggered grid technology. The discrete equations are solved using SIMPLE algorithm. Because of the nonlinear coupling relationship of each variable, during the process of applying SIMPLE algorithm, sub-relaxation iteration method is used to accelerate converging of the nonlinear problem [8].

**Simulation Result and Analysis**

The shape of the ice storage box is considered as columniation, basic parameters for calculation are given in Table 1.

Table 1 Basic parameters for calculation

| | | | |
|---|---|---|---|
| Fluid specific heat | 3.85 kJ/(kg·℃) | Ice heat conductivity | 2.215 W/(m·℃) |
| Fluid density | 1030 kg/m$^3$ | Ice density | 916 kg/m$^3$ |
| Fluid heat conductivity | 0.5 W/(m·℃) | Ice specific heat | 2090 J/(kg·℃) |
| Fluid kinetic viscosity | 1.77 mPa·s | Water heat conductivity | 0.551 W/(m·℃) |
| Fluid velocity | 0.5 m/s | Water density | 1000kg/m$^3$ |
| Fluid inlet temperature | 20 ℃ | Water specific heat | 4187 J/(kg·℃) |
| Inside diameter of tube | 17 mm | Ice-water phase change temperature | 0 ℃ |
| Outside diameter of tube | 20 mm | Ice-water phase change Latent heat | 335kJ/kg |
| Inside diameter of box | 0.4m | Initial temperature of ice | -0.5℃ |
| Outside diameter of box | 1m | | |

In order to analyze the influence of different initial parameters to natural convection, we define $r_{in\text{-}out}$ as follow:

$$r_{in-out} = \frac{r_{in-top} + r_{out-top}}{2} \quad (6)$$

$r_{in-top}$ top melting radius of the intake (m)

$r_{out-top}$ bottom melting radius of the exit (m)

Simulation result and analysis as follows:

Figure.2 shows the influence of different intake temperature to natural convection. At the initial of melting, natural convection is very weak because there is little water, so the influence is little. But along with the quantity of water increasing, natural convection become more and more strong, and the influence will become strong gradually. The higher temperature and the stronger natural convection, this is because that the increase of the liquid intake temperature causes the increase of the difference in temperature, and then the increase of the difference in temperature causes the increase of natural convection.

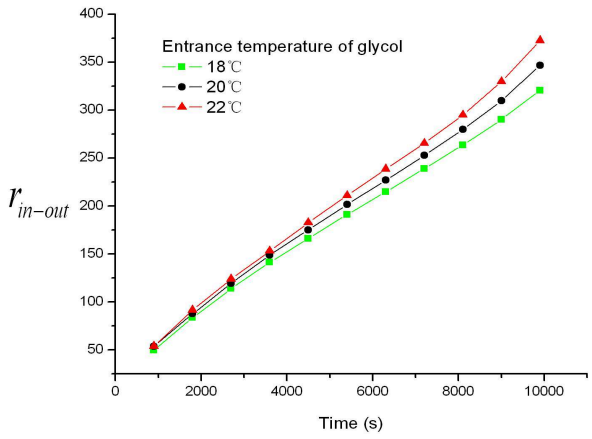

Figure.2 Influence of glycol entrance temperature on $r_{in-out}$

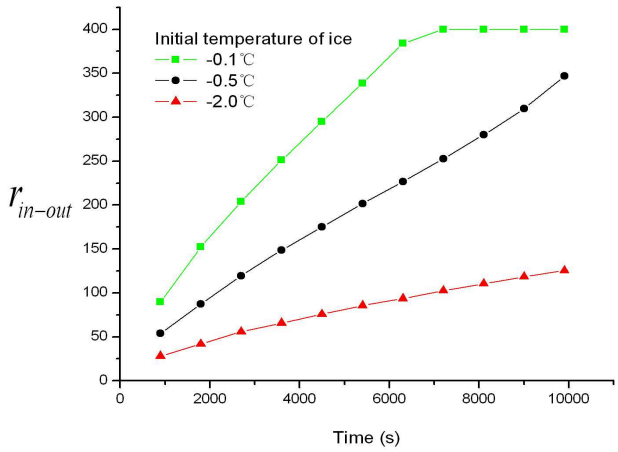

Figure.3 Influence of initial temperature of ice on $r_{in-out}$

Figure.3 shows the influence of different ice initial temperature on natural convection. From the above chart we can find that the intake temperature of ice influence natural convection very greatly. The lower ice temperature and the weaker intensity of natural convection, this is because that the ice needs more quantity of heat if the ice temperature becomes lower, and accordingly natural convection will occur even later. At one time we also find that the influence of the ice temperature will become stronger along with time going. This is because that if the ice temperature is higher, the quantity of the melted water is more, accordingly the intensity of natural convection will be stronger at the same time.

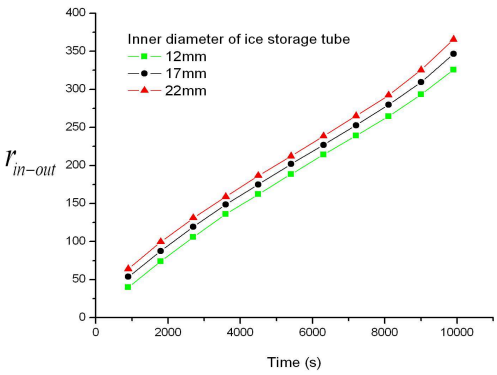

Figure.4 Influence of inner diameter of ice storage tube on $r_{in-out}$

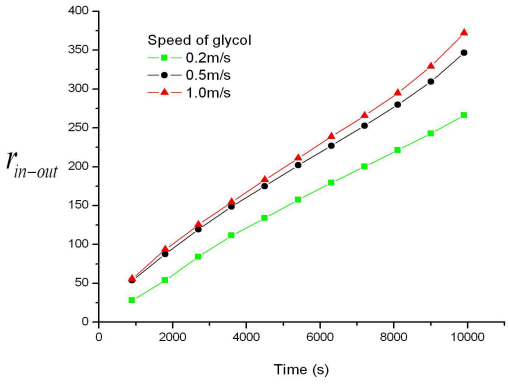

Figure.5 Influence of velocity of glycol on $r_{in-out}$

Figure.4 shows the influence of different tube inner diameter to natural convection. From the above chart we can find that the influence of the inner diameter is almost linear. This is because that the change of the inner diameter mainly influences the quantity of the cryogen which drills through the tube, but the influence to the temperature field is smaller, so the influence of the inner diameter is almost linear.

Figure.5 shows the influence of different cryogen velocity to natural convection. From the above chart we can find that the influence of cryogen velocity will gradually become stronger along with time. This is because that the heat exchange between cryogen and water will increase along with the increase of the cryogen's velocity, so the temperature grade of water will increase and natural convection will increase. At the same time, we can find that the grade of natural convection intensity will descend along with the increase of the cryogen velocity. This is because that grade of the heat exchange between cryogen and water will descend along the cryogen velocity.

## Summary

1. The influence of the inner diameter of the storage tube is almost linear.
2. The influence of the cryogen initial temperature, the cryogen velocity and the ice initial temperature on natural convection will increase along with time.

**Keywords:** ground source heat pump; flow velocity; system operation; power consumption

**Abstract.** The heat pump system by using earth energy is increasing very rapidly. In this paper, by studying the underground heat exchanger heat transfer mode, the computing platform for ground source heat pump system was established. Through a engineering case, the influence character of the circulation flow velocity in ground heat exchangers on the fluid temperature, the heat pump power consumption, and the length of system were analyzed, which provide an approach for system engineering design and operation prediction, and for the thermodynamic analysis of performance of system year by year and prospective study to guide the engineering practice.

## Introduction

Despite the certain development of ground source heat pump（GSHP）and related underground storage technology, some work still should be strengthened, such as the influence law of the circulation flow velocity in ground heat exchangers, which is one important problem for system operation. In fact, in unbalance load area, the longer application of the large scale GSHP engineering has caused underground energy decay and system efficiency decline, and become bottleneck and obstacle to the sustainable application, so complex science and technical question in large-scale heat pump system by using earth energy need to be researched, to provide the reference and analysis method for improving the operation reliability in different regions and the evaluation analysis of long-term operation efficiency on system, which can be used to guide engineering applications, to ensure the progress of science and technology and healthy development in earth energy utilization technology[1].

In the paper, through a engineering case, the influence character of the circulation flow velocity in ground heat exchangers on the fluid temperature, the heat pump power consumption and the length of system were analyzed, which provide an approach for system engineering design and operation prediction.

## The ground heat exchange model

In the paper [2] [3]**,** it systematically explored the establishment of modules, module scarf and coupling call based on Matlab/Simulink calculation control platform, established the basic analysis method of heat pump system. The calculation diagram is shown in Fig.1. Eskilson developed an approach to determine the temperature distribution around a borehole based on a hybrid model combining analytical and numerical solution techniques called G function[4] [5]. The theory of G

function of ground heat exchanger is used to compute the borehole temperature and the thermal resistance of borehole by entering relevant parameter of ground heat exchanger and thermophysical property date of ground, and output of the fluid temperature at the outlet of ground heat exchanger, the heat pump power consumption and the length of system.

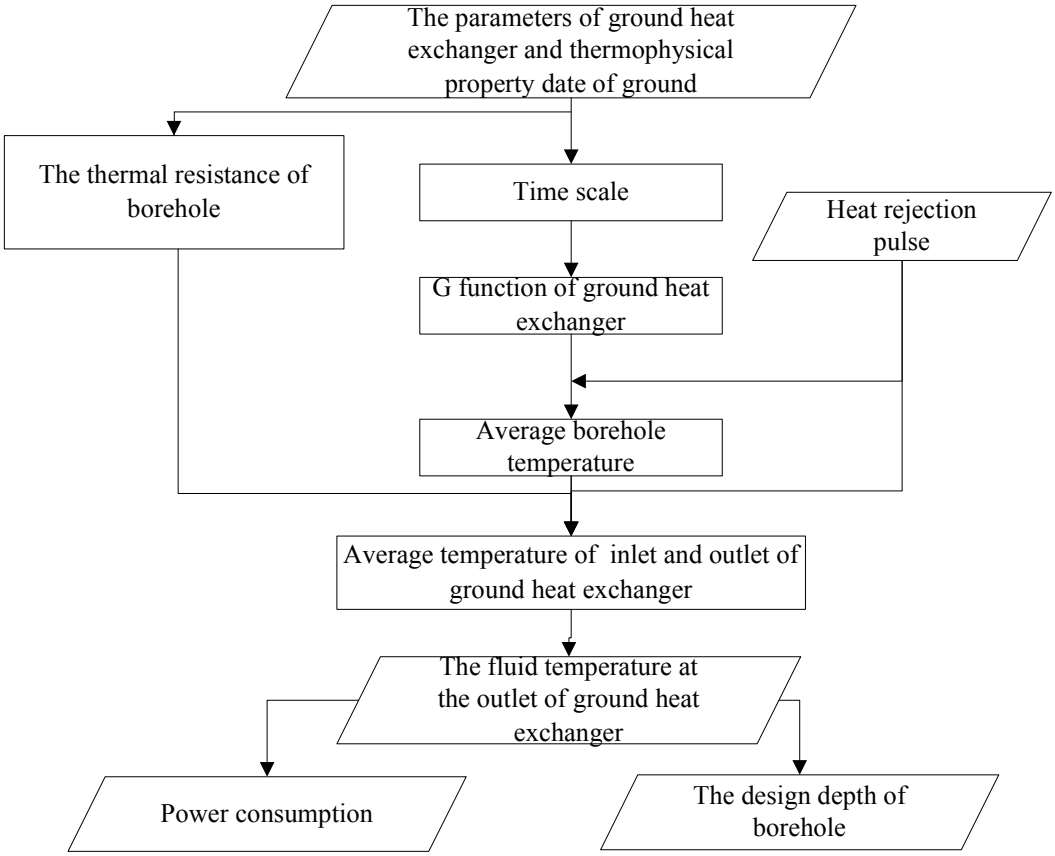

Fig. 1 The calculation diagram

This provided hourly data for the space heating loads or cooling loads for the building in Changchun, China, a summary of the loads are shown in Fig.2. The purpose of this case is to research the influence character of the circulation flow velocity in ground heat exchangers on the fluid temperature, the heat pump power consumption and the length of system for the space heating loads or cooling loads for 20 years. It is very important for proper flow velocity in ground heat exchangers. The research on the influence law of the circulation flow velocity ($v_1$=0.13m/s, $v_2$=0.26m/s, $v_3$=0.52m/s, $v_4$=0.78m/s) in ground heat exchangers on system operation.

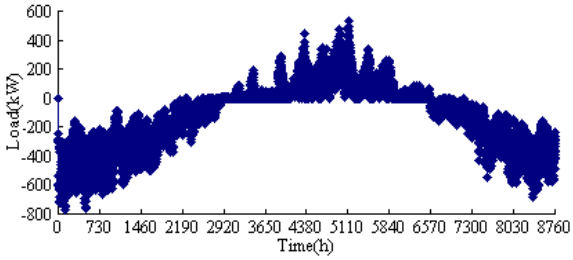

Fig. 2 Building loads

**Results and discussion.**

**The outlet fluid temperature of GHE (ground heat exchanger).** As can be seen from the Fig.2, in Changchun, the heat load significantly greater than cooling load annual and the average fluid temperature of GHE declines year by year. In 20 years operation time, the outlet fluid temperature of GHE can be calculated in Fig.3. As the same loads, the higher outlet fluid temperature of GHE in summer and the lower temperature in winter when the higher circulation flow velocity and quantity,

because of the smaller difference temperature between cycle fluid and the underground. The outlet fluid temperature of GHE change is significant when flow rate increase from $v_1$=0.13m/s to $v_2$=0.26m/s, but little difference when flow rate increase from $v_1$=0.52m/s to $v_2$=0.78m/s.

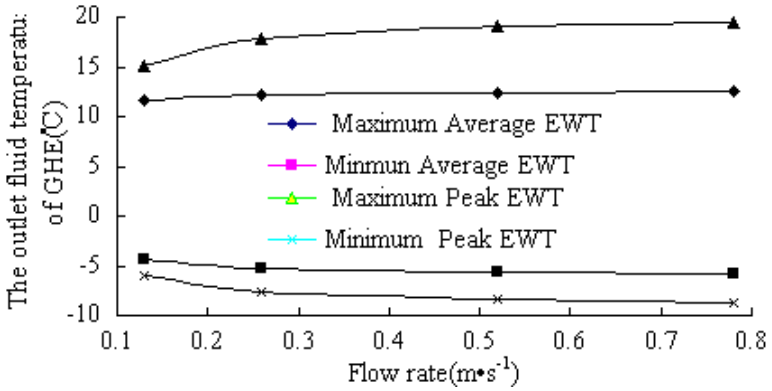

Fig. 3 The fluid temperature of GHE

**Power consumption.** The power consumption for heat pump can be calculated in four situations in Fig.4. In Changchun, the power consumption for heat pump is increase due to the fluid temperature is decrease year by year. With higher circulation flow velocity, the energy consumption is apparent increase. The power consumption increase 48912.16kWh when flow rate increase from $v_1$=0.13m/s to $v_4$=0.78m/s, in 20 years. When flow rate is 0.78m/s, because of the imbalance of heating and cooling load, the average fluid temperature of GHE decreases year by year, power consumption for heat pump rises 6.18% for 20 years.

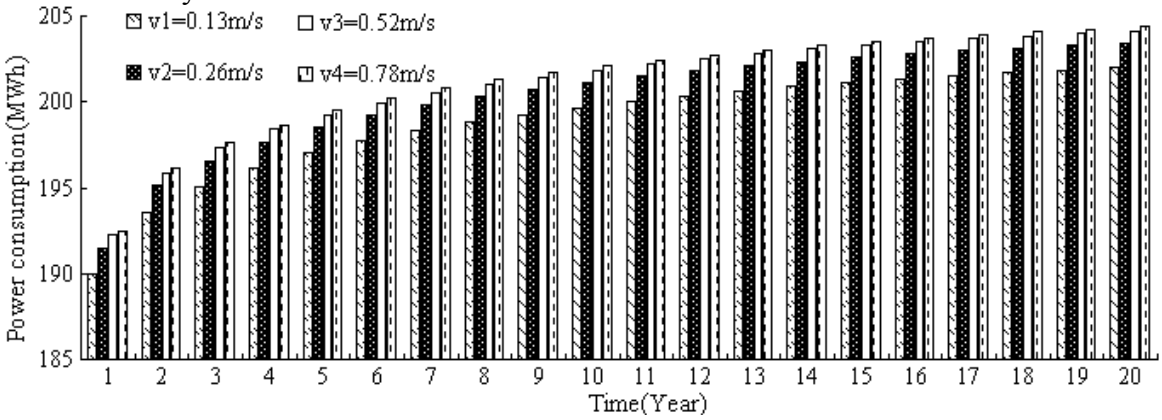

Fig. 4 Power consumption

**The design depth of borehole.** The design depth of borehole is limited to the minimum fluid temperature at the outlet of ground heat exchangers, and it decides initial cost and the life of project directly. In this case, we select the minimum fluid temperature at the outlet of ground heat exchangers is -6℃. The deepest depth of borehole and biggest initial cost are caused by the increment of the flow velocity in the ground heat exchangers. In the Fig.5, a relationship diagram for the depth of borehole and flow rate in the ground heat exchangers. Under this design conditions, we have to redesign the system for optimal solution for the flow velocity. The design depth of borehole rises 20.01% from 100.28m to 120.35 when flow rate increase from $v_1$=0.13m/s to $v_4$=0.78m/s.

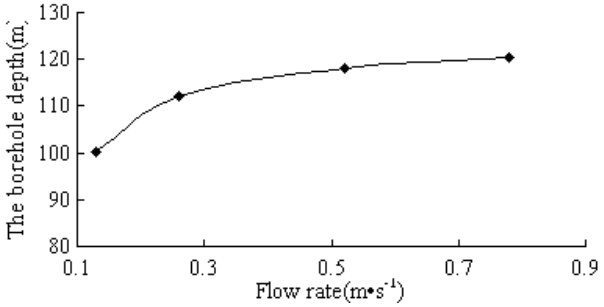

Fig. 5 The depth of borehole

## Conclusion

In the paper, it is to study of underground heat exchanger heat transfer mode and calculate fluid temperature at the outlet of ground heat exchangers. Through a engineering case, the influence character of the circulation flow velocity in ground heat exchangers on the fluid temperature, the heat pump power consumption and the length of system were analyzed, which provide an approach for system engineering design and operation prediction.

# Energy saving design of a training center in Dongguan

LAI Xue -jiang[1,a],DU Zhi-heng[2,b], ZHANG Zhen-qin[2,c]

[1]School of Engineering, Guangdong Ocean University, Zhanjiang, China

[2]Architectural design research Institute of SCUT, China

[a]Laixuejiang1@21cn.com, [b]dzh1981@126.com, [c]443575560@qq.com

**Keywords:** Building energy-saving design; Air conditioning system energy-saving design; Lighting system energy-saving design;

**Abstract.** A training center design as an example, the impact of building energy-saving design on building energy consumption are showed. Energy-saving design options of air conditioning system and refrigerator are given. Lighting power density of the lighting system energy-saving design and the project of energy-saving design are provided.

## Introduction

Building energy consumption refers to energy consumption of residential buildings and public buildings in using process. Heating, air conditioning, ventilation, lighting, hot water supply, cooking, all kinds of electrical appliances, elevators and other aspects of energy consumption are comprised. At present, for the annual energy consumption of public buildings, heating and air conditioning system is accounted for 40%~50%, lighting energy consumption is accounted for 30%~40% and other energy consuming equipment is 10%~20%. In the heating and air conditioning energy consumption, the energy consumption causing by the high heat transfer coefficient of building's exterior-protected structure is accounted for 20%~50%[1]. Therefore, to meet energy-saving demands, mainly at design time three ways should be implemented: Improvement of thermal performance of building's exterior-protected structure; Improving the energy efficiency of heating and air conditioning equipment; Limiting the lighting power density.

## Building summary

The training center is located in Dongguan city, the total construction area is 19828 $m^2$. Built-up area is 9810$m^2$, the building layer is 3 layer aboveground and 1 layer underground. Building height is 21 m, the conditioning area is 5510 m². The building construction heads for South. Garage, chiller rooms are in underground layer. Auditorium, service rooms, reception rooms and awards gallery are at the first floor. Service rooms and discussion rooms are at the second floor. Discussion rooms, training classrooms and seminar rooms are at the third floor. Architectural drawing are presented in Fig. 1~ Fig. 4.

1.1 Reinforced concrete buildings parameters

External wall thermal parameters are shown at table 1.

Tables1: External wall thermal parameters

| position | Name of the main materials of the wall's construction | Thickness（mm） | λ(W/m.k） | Total area（$m^2$） | K（W/$m^2$.k） | Dm |
|---|---|---|---|---|---|---|
| Packed wall | cement mortar | 25 | 0.93 | | | |

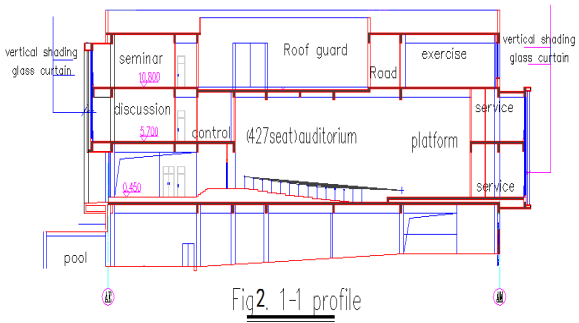

Fig2. 1-1 profile

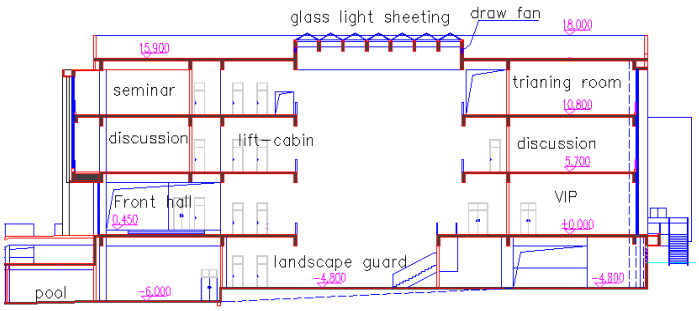

Fig3. 2-2 profile

The construction head facing south's building is advantage to natural ventilation in architecture. Building entrances are designed in staggered arrangement which is advantage to air flow. There is the middle courtyard which has not proof, which is advantage to hot air discharge up.

2.2 Buildings' insulated sun-shading design

Buildings' insulated sun-shading has the roles which are to prevent the heat and to cool down the air and to prevent glare and UV. There are sun-shading elements, roof gardens ,glass light sheeting, aluminum grille in the building.

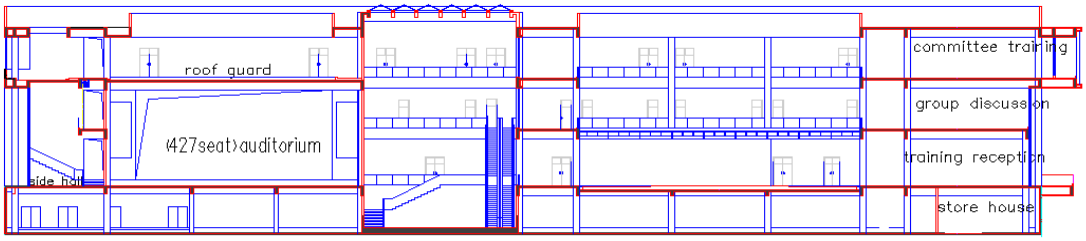

Fig4. 3-3 profile

The 427-seat auditorium located in the northwest corner of the building is the maximum heat load of this building. The service rooms at the first and second floor have the radiant gain heat's exterior-protected structure from fig.2 and fig.1. The north exterior-protected structure of the service rooms is glass curtain wall which has K=1.8W/m$^2$.K heat transfer coefficient and has vertical sun-shading, so the north exterior-protected structure radiant gain heat is reduced largely. The 427-seat auditorium's roof is roof garden. From JGJ-75-2003 *《Design standard for energy efficiency of residential buildings in hot summer and warm winter zone》* , as calculating the total thermal resistance of the roof, the equivalent thermal resistance value of planting roof is 0.5m$^2$.K/W, the auditorium roof heat transfer coefficient calculation process is as follows:

Total thermal resistance of the planting roof shall be determined by the following formula:

$$R_0 = R_i + R + R_e + R_h \quad (1)$$

formula: $R_0$—— Total thermal resistance of the planting roof.

$R_i$—— Inner face heat transfer resistance, $(m^2 \cdot K/W)$;$R_i = 0.11$.

$R_e$——Outer face heat transfer resistance, $(m^2 \cdot K/W)$; $R_i = 0.06$.

$R_h$——The equivalent thermal resistance value of planting roof, $(m^2 \cdot K/W)$;$R_h = 0.5$

R---Roof structures resistance of the heat transfer; $(m^2 \cdot K/W)$

$$R = \sum_{i=1}^{n} R_i \quad (2)$$

$$R_i = \frac{\delta_i}{\lambda_i} \quad (3)$$

Table 2 parameters are substituted (1) to (3), calculate $R_0 = 2.01(m^2 \cdot K/W)$.

The heat transfer coefficient of the planting roof is $K = 1/R_0 = 0.498(W/m^2 \cdot K)$;

After increasing the planting guard on the roof ,heat transmission coefficient has fallen down (0.67-0.498)/0.67=25.7%,so the planting roof's radiant gain heat is reduced largely. The side hall is at the west side of the auditorium, there is no direct radiation of heat, so the radiant heat gain of the auditorium's exterior-protected structure is less, air conditioning energy consumption is significantly reduced.

From fig.1 it can be seen that the south face of awards gallery increasing the vertical metal plate at outer of the glass curtain wall which effects the vertical sun-shading roles. Increasing vertical shading, overall sun-shading coefficient is reduced from 0.38 to 0.238. so the glass curtain wall 's radiant gain heat is reduced largely. Light colored blinds at the upper of the glass curtain wall and at the bottom of the glass curtain wall also help ventilation.

**Air conditioning system energy saving design**

3.1 Design parameters of air-conditioning system

The energy-saving building is a training center which collecting office and training. Air-conditioned rooms' interior design parameters are different that varying with different rooms' function. The air-conditioned rooms' interior design parameters are shown in Table 3.

Table 3 Air-conditioned rooms' interior design parameters

| room | summer temperature(℃) | summer relative humidity (%) | fresh air($m^3$/h.P) |
|---|---|---|---|
| The first floor auditorium | 26 | 40~60 | 20 |
| The rest room | 26 | 40~60 | 30 |

3.2 Summer air conditioning loads, refrigerating system

The air conditioning load per unit area (KW/$m^2$) is smaller than the design estimates unit area air conditioning cooling load (KW/$m^2$) from Table 4 shows, energy-saving design works.

3.3 Programmer narrative for air conditioning system energy saving design

Due to the rooms' different functions, used time is not the same, so refrigerating systems are adopted the following methods:

Table 4 .Summer air conditioning loads, refrigerating system and lighting power density values

| location | air conditioning area（$m^2$） | air conditioning loads（KW) | unit area air conditioning cooling load （W/$m^2$） | design estimates unit area cooling load （W/$m^2$） | refrigerating systems | lighting power density value （W/$m^2$） |
|---|---|---|---|---|---|---|
| small auditorium and service | 560 | 90 | 160 | 269 | VRF | 15 ( auditorium) 9(service） |

| group discussion | 1410 | 246 | 174 | 235 | VRF | 9 |
| awards gallery | 370 | 70 | 189 | 200 | VRF | 9 |
| seminar rooms | 460 | 75 | 163 | 235 | VRF | 9 |
| large exercise and training room | 875 | 164 | 187 | 200 | VRF | 9 |
| training room and front hall | 485 | 75 | 155 | 191 | VRF | 9 |
| large auditorium and service | 1670 | 380 | 228 | 269 | Air cooled scroll chiller | 15(auditorium) 9(service） |

VRF= VRF air conditioner

（1）Large auditorium and auxiliary rooms are sent cooling-air by the full-air low speed blower way. Cabinet type air conditioners are set in the air conditioning machine room that send cooling-air through the duct to indoor. The air conditioning ducts are located in floor ceiling. The splitters sends the air downward . Return air through the air ducts hided in ceiling from the air conditioning machine room with negative pressure to door hinge air ports backs to the rooms. Other service rooms are mounted the fan-coil system. Hided horizontal fan coils are mounted ceilings of the rooms, which air flow line is upward sending and upward return way, sending air mode adopts side sending air mode. Refrigerating system is the air cooled scroll chillers, the air cooled scroll chillers and cold circulating pump are mounted on the roof floor. Choose typical air-cooled scroll chillers: cooling capacity 212KW, power consumption 71KW, COP 3.0. Meet COP≧ 2.6 (scroll type) specifications.

(2) Other conditioning rooms: Each floor is divided into two to four units, each unit has a set of commercial VRF air conditioning machines (cold), selection of frequency conversion adjustment, or digital scroll air conditioning unit. Outdoor units are mounted in roof floor. Four-sides block-top indoor units send the cooling air by the upward sending and upward return way. Select the typical VRF air conditioner: cooling capacity 123.5KW, power consumption 38KW, COP 3.0. Meet COP≧ 2.3 (According to the joint dust selection) specifications.

(3) Air conditioning water systems' transportation energy efficiency ratio: transportation energy efficiency ratio ER=0.002342H/(ΔT.η) ,designing water pump head H=25m，difference in temperature of the feed pipe and return pipe ΔT=5℃, Pump efficiency in designη=75%，so ER=0.0156, Meet ER≤0.0241 specifications.

(4) The high efficiency and low power consumption air conditioning and ventilation products are used in designing, room temperature control designing is used.

（5）A grid line foil laminated glass wool felt is used in the air conditioning system duct insulation, The thickness of the grid line foil laminated glass wool felt is 30mm, the density is 40Kg/$m^3$, the transmission coefficient is $\lambda \leq 0.033$W/m.K , the thermal resistance value is R=0.857 $m^2$.K/W, Meeting the specification which is the minimum thermal resistance of the duct's thermal insulation materials $\geqq$ 0.74 $m^2$.K/W.

**Energy-saving design of lighting system**

The International Commission on illumination lighting principles:

(1)According to room's function designing illumination;
(2)With meeting the illumination requirements, energy-saving lighting design is used;
(3)Meeting the color demonstrating requirements, using efficient lighting units;
(4)Low glare and efficient lamps are used;
(5)Highly reflective materials are used in indoor designing;
(6)Designing the effective circuit loop;
(7)Setting the energy management device;
(8)Using artificial lighting and natural lighting;
(9)Regular cleaning and maintenance of lighting apparatus are needed.

There are the side light, the top light, the middle courtyard light of the natural lighting form of the building. According the building's own characteristics, proceeding from the practical operability, the lighting power density values of each rooms are shown in table 4. Energy-saving design of lighting system are used as follow:

(1) For general lighting the small diameter straight tube fluorescent lamps are used. Low wattage ceramic metal halide lamps are used in importance lighting area

(2)Lighting is controlled by sound and light control unit in public area, so the unnecessary lighting is reduced.

(3)Selection rational line path, line length is shorten as far as possible ,so line loss is cut down.

(4)Installing human body movement sensors in the bathroom and lounge, the lighting is automatically turned off when there are no people in these areas. The outdoor road lighting adopts photoelectric control and controls by band reduced light at different periods. Adopting sound and light control for the lighting at indoor passages and other parts of the public areas, minimum illumination requirement is met and the energy-saving effect is achieved.

**Summarize**

For the public buildings, energy consumption is more. If energy-saving design is considered ,building energy consumption is reduced surely. Therefore, design of construction energy-saving should be designed as part of the design of architecture.

**Keywords:** Energy efficiency,DCS, Direct burial cooling pipe, Maximum length

**Abstract.** Formula of the maximum length of direct burial cooling pipes used in the district cooling system(DCS)was derived, by means of establishing the mathematical relationship between the maximum temperature rise of the pipe, under which the energy efficiency of the refrigeration unit would not decrease, and the thermal equilibrium of the pipe. And an engineering application with DCS in Zhuzhou was analyzed. The results showed that the insulation measures should be applied to the directly buried cooling pipes in engineering applications, appropriately with a thermal insulation layer of 0.04m.

## Introduction

The district cooling system is characteristic of energy conservation, environmental protection, easy operation and management and so on. However, if the system is not appropriately designed, these advantages cannot be fully exhibited. It has been reported by Hui Rongna[1] that the economical effects of the DCS in Beijing Zhongguancun Village are far from satisfaction due to the bad match during the design. In addition, the economical effects of the DCS in Guangzhou University City is not satisfactory as a result of the excess cooling load of the system. In order to make full use of the advantages of the DCS, key parameters of the system have to be determined during the design, in terms of the characteristics of cooling technology of the DCS. Among these parameters, the length of direct cooling pipe is directly related to the temperature rise of chilled water, which further affects the energy efficiency of refrigeration unit and the pipe transportation.

A series of regulations concerning the energy efficiency of refrigeration unit and the transportation energy efficiency ratio of the cooling pipes have been put forward in the Design standard for energy efficiency of public buildings [2]. As a result, the length of pipes must meet the national energy-saving requirement. Applying the principle of minimum overall energy consumption, conclusion was obtained that the best cooling area is determined by the characteristic of thermal power unit, as well as heating parameters, structure and functions of the buildings and the local meteorological conditions[3]. In addition, conclusion was obtained by Zhujijun and Liujin that the energy efficiency ratio during a whole year could reach a higher grade with a small investment and high reliability, if the cooling radius is not greater than 1000m[4]. However, a length of 650m was considered to be the ideal cooling radius for energy conservation purpose by other researchers, such as Zhangsi Zhu and Yangjun. Moreover, they concluded that the maximum cooling radius of the DCS in engineering applications should not exceed 960m[5].

Although there have been a lot of researches on the design of the DCS, however, studies on the calculations of the maximum length of direct burial cooling pipes of the DCS are rare at present, and the theories to guide the design of the DCS are actually in short. In this work, a method is introduced to determine the maximum length of direct burial cooling pipes of DCS.

**Determining the maximum length of direct burial cooling pipes with the insurance of the non-decreasing of the energy efficiency grade of the refrigeration unit**

Fundamental of this method is explained as follows. Assuming the refrigeration unit has a certain energy efficiency grade before incorporating into the pipelines, the grade will decrease after connecting to the pipelines, due to the requirement of the lower temperature of the chilled water(as a result of heat loss, there is an increase of the chilled water), to ensure the power of the terminals.

The maximum temperature difference resulting in the decrease of the energy efficiency grade of the refrigeration unit, is the maximum allowed temperature rise of the chilled water, which is caused by power loss of the pump and the heat loss of the pipe. Based on the analysis above, the maximum length of direct burial cooling pipes of DCS can be determined by establishing the heat balance equations.

*Allowed temperature rise of the chilled water*

Energy efficiency grade coefficient of refrigeration unit can be defined with Eq.1 according to the Lorenz Cycle's Circulation principle,

$$COP_i = k_i \times \frac{T_0 + 2\Delta t_{ij}}{T_k - \left(T_0 + 2\Delta t_{ij}\right)} \quad j \geq i, i = 1,2,3; j = 1,2,3 \tag{1}$$

where $COP_i$ is the energy efficiency's grade coefficient of the refrigeration unit. $T_0$ and $T_k$ indicate the cold source temperature and hot source temperature in Kelvin, respectively. As to the value of $T_k$, 313K is an appropriate choice if the Freon refrigeration unit is adopted in the system. $k_i$ is the comprehensive correction coefficient, considering the effects of internal structure of *i*-grade energy efficiency of the refrigeration unit on heat transfer and the effects of cooling pipes on the performance of refrigeration units due to heat loss.$\Delta t_{ij}$ is temperature rise in Kelvin of the chilled water of the one-way cooling pipes of refrigeration unit when energy efficiency in *i* grade drops to *j*. Therefore$\Delta t_{ii}=0$. Finally, $2\Delta t_{ij}$ denotes the temperature rise of the chilled water of double-way cooling pipes of refrigeration unit when energy efficiency in *i* grade falls to *j*.

If $T_0$ in Eq.1 is replaced by the outlet temperature of the refrigeration unit, $t_m$, Eq.1 can be expressed as Eq.2.

$$COP_i = k_i \times \frac{\left(t_m + 2\Delta t_{ij}\right) + 273}{T_k - \left[\left(t_m + 2\Delta t_{ij}\right) + 273\right]} \tag{2}$$

Provided that the allowed maximum temperature rise of the chilled water is$\Delta t_{ij}$ when the energy efficiency grade decreases by one grade, the value of$\Delta t_{ij}$ can be derived by substituting the energy efficiency grade coefficient of the i+1grade into Eq.2.

$$t_{ij} = \frac{k_i\left(t_m + 273\right) - COP_{i+1}\left(T_k - t_m - 273\right)}{-2\left(COP_{i+1} + k_i\right)} \tag{3}$$

If the result is less than 0, the chilled water(outlet water temperature of the unit) has to be reduced.The energy efficiency grade coefficient of refrigeration units varies with the type and the cooling capacity. For a refrigeration unit with a cooling capacity greater than 1163kw, the value of $k_1$ and $k_2$ approximate 0.72 and 0.66, respectively. Substituting these values into Eq.3, the result turn out to be $\Delta t_{12}$=-1.31℃, $\Delta t_{23}$=-1.43℃, $\Delta t_{13}$=-2.84℃.

*Heat loss of the chilled water of DCS and the thermal balance*

There are mainly two reasons for the temperature rise of the chilled water in water pipelines of DCS. One is the heat loss caused by the heat exchange between chilled water and the surrounding environment outside the pipe; the other is that heat loss caused by the friction heat of the chilled water pumps.

*a) Reason one*

Generally speaking, outdoor pipelines of the DCS are directly buried. Therefore, heat loss due to the heat transfer between the chilled water in the pipe and the environment outside the pipe can be obtained according to Eq.4,

$$\Phi = \frac{\pi l\left(t_w - t_g\right)}{\frac{1}{d_1\alpha_n} + \frac{1}{2\lambda_1}\ln\left(\frac{d_2}{d_1}\right) + \frac{1}{2\lambda_2}\ln\left(\frac{d_3}{d_2}\right) + \frac{1}{d_3\alpha_w}} \tag{4}$$

where $\Phi$ is the heat loss of direct buried pipe in *W*. And *l* means the length of the pipes in *m*. $t_w$ is the ambient temperature outside pipe insulation, and its value is often thought to be 24℃. $t_g$ is chilled water temperature in Celsius inside the pipe. $d_1$ and $d_2$ are the inner and outer diameter of the pipes. And $d_3$ is the total outer diameter of the pipe including the thermal insulation layer. Namely $d_3=d_2+2\delta$, where $\delta$ is the thickness of the insulation layer. $\lambda_1$ and $\lambda_2$ are the thermal conductivity coefficient of the pipe and thermal insulation material, respectively. $\alpha_n$ is the convective heat transfer coefficient of the chilled water inside the pipe, usually with a value of 6000W/($m^2$.K). And $\alpha_w$ means the convective heat transfer coefficient outside the pipe. Moreover, the value of $1/(d_3\alpha_w)$ is usually be neglected if the pipe is buried directly.

*b) Reason two*

According to related studies, the heat loss caused by friction heat of the pump accounts for 80% of the total power consumption of the distribution networks[6]. The result can be obtained according to Eq.5 as below.

$$Q_b = 0.8\frac{\gamma GH}{\eta} \tag{5}$$

In Eq.5, $Q_b$ is the heat loss caused by the friction heat generated by the pumps. And $\gamma$ is the density of the chilled water. *G* is the volume flow rate of chilled water, and $G=\pi d_1^2 v/4$ where *v* is the velocity of chilled water. *H* denotes the lift head (in *m*) of the pumps, and $H=1.1(2\times 1.4R_0l/\gamma)$ where $R_0$ is specific frictional resistance of pipe(in Pa/m). $\eta$ means the efficiency of chilled water pumps.

*c) Deduction of the thermal balance equation*

The Temperature rise of the chilled water per unit time in the pipe is equal to the heat transferred to the pipe and the increased internal energy caused by the friction heat caused by the water pumps. According to the analysis above, the thermal balance equation can be expressed as below,

$$C\rho G\left|\Delta t_{ij}\right| = \Phi + Q_b \tag{6}$$

where C is the specific heat capacity of chilled water and ρ is the density of chilled water.

*Calculation of the allowed maximum length of the directly buried cooling pipes*

Substituting Eq.4 and Eq.5 into Eq.6, meanwhile replacing *l* with $l_{1ij}$, the formula can be obtained as Eq.7.

$$l_{1ij} \prec \frac{\left\{\frac{1}{d_1\alpha_n} + \frac{1}{2\lambda_1}\ln\left(\frac{d_2}{d_1}\right) + \frac{1}{2\lambda_2}\ln\left[\frac{\left(d_2+2\delta\right)}{d_2}\right]\right\}\cdot\eta\rho C v d_1^{\,2}\left|\Delta t_{ij}\right|}{4\eta\left(t_w - t_g\right) + 2.464R_0 v d_1^{\,2}\cdot\left\{\frac{1}{d_1\alpha_n} + \frac{1}{2\lambda_1}\ln\left(\frac{d_2}{d_1}\right) + \frac{1}{2\lambda_2}\ln\left[\frac{\left(d_2+2\delta\right)}{d_2}\right]\right\}} \quad j \geq i, i = 1,2,3;\ j = 1,2,3 \tag{7}$$

In Eq.7, $l_{1ij}$ corresponds with$\Delta t_{ij}$, namely the allowed maximum length of directly buried cooling pipes in refrigeration unit, under which the energy efficiency grade of the unit will not decrease.

## Analysis on an engineering application

*Initial parameters and the calculation of the allowed maximum length of the directly buried pipes*

Initial parameters of the DCS in Shennong town in Zhuzhou are listed in table 1.

Tab.1 Initial parameters

| Parameter | Description | value |
|---|---|---|
| Rated power | Centrifugal chiller | 1614 KW |
| $\eta$ | Efficiency of the Chilled water pump | 0.7 |
| $t_w$ | Soil temperature in summer | 24℃ |
| $\lambda_1$ | Thermal conductivity of the pipe wall | 45W/(m.K) |
| $\lambda_2$ | Thermal conductivity of the insulation layer | 0.033W/(m.K) |
| $d_1$ | Inner diameter of the pipe | 350mm |
| $v$ | Velocity of the water flowing in the pipe | 1.66m/s |
| $\delta$ | Thickness of the insulation layer | 70mm |
| $t_g$ | *T*emperature of the chiller water | 7℃ |
| $R_0$ | specific frictional resistance of the pipe | 85.69Pa/m |
| $\alpha_n$ | Convectional heat transfer coefficient inside the pipe | 6000W/(m$^2$.K) |

Substituting $\Delta t_{12}$=-1.31℃, $\Delta t_{23}$=-1.43℃ and $\Delta t13$=-2.84℃ into Eq.7, the results turn out to be $l_{112}$=14870m, $l_{123}$=16233m and $l_{113}$=32238m.

*Analysis on the maximum length of the directly buried pipe*

Defining all the parameters in Eq.7 as fixed values, except $\delta$, and regarding the maximum length of the pipe as a function of the thickness of the insulation layer, $l_{1ij}=f(\delta)$,the variation of the maximum length with the thickness of the insulation layer can be obtained, which are illustrated in Fig.1 and Fig.2.

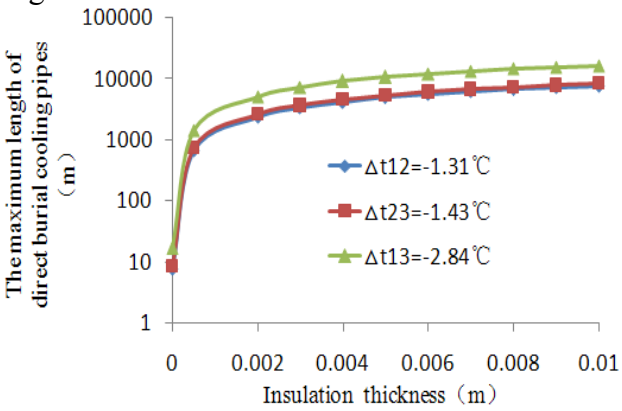

Fig.1 Relationships between the maximum length of directly buried cooling pipes and the thickness of the insulation layer

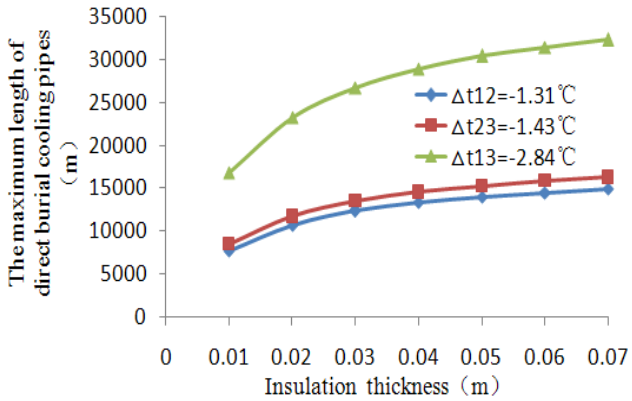

Fig.2 Relationships between the maximum length of directly buried cooling pipes and the thickness of the insulation layer

As is shown in Fig.1, on condition that the energy efficiency grade does not decrease, when the thickness of the insulation layer is less than 0.0005m, the allowed maximum length decreases rapidly. And when $\delta$=0, the maximum length can just reach tens of meters. Even when $\delta$=0.0005m, the allowed maximum length is only hundreds of meters. However, the maximum length can reach 2000 meters when $\delta$=0.002m, which suggests that thermal insulation measures should be taken in the directly buried pipe in DCS.

In addition, as indicated in Fig.2, the maximum length of the pipes increases with the thickness of the insulation layer. The maximum length can reach up to 13300 meters when a 0.04-m insulation layer is applied. However, the increment of the pipe maximum length changes insignificantly thereafter. Therefore, thermal insulation layer with a thickness of 0.04m is usually regarded to be appropriate in engineering applications.

## Conclusions

The calculation of the maximum length of directly buried cooling pipes adopted in DCS is of great significance. In this work, formula of the maximum length of directly buried cooling pipes used in the district cooling system was derived. And an analysis on the engineering application in Shennongcheng town project was conducted. The results showed that thermal insulation layer with a thickness of 0.04m is appropriate in engineering applications.

# Discussion on Ventilation Requirement for Meeting Indoor Air Quality

Mengjie LIN[1,a], Qinqin LIU[1] and Zimao PENG[1]

[1]Hunan Communication Polytechnic, Hunan Changsha 410004, China

[a]Email: lindalux@qq.com

**Keywords:** Indoor air quality; Pollutant concentration; Ventilation

**Abstract:** Based on the calculation method and the analysis method of the ventilation requirement, the paper discussed the necessary ventilation referring to the standard of the allowed indoor $CO_2$ concentration, the necessary ventilation with oxygen as the standard and the calculation method and correction method of the full amount of required ventilation to remove the waste heat or wet. According to the pros and cons of the methods described above, the paper proposed the corresponding countermeasures to meet the indoor air quality and the fresh air needed by indoor personnel.

## Introduction

The indoor air quality is a complex issue involving multi-disciplinary. There are a variety of pollutants affecting air quality which can be summarized as toxic and harmful gases, tobacco smoke, dust production and fungi and other microbial contamination. In industrial ventilation and dust design, the common method is to use the appropriate equipment and technology to control the concentration of pollutants and indicators of pollution within the allowable range. The pollutants in the residential buildings and office building are different to that of industrial buildings, such as the sources of indoor pollutants contained the personnel exhaled carbon dioxide, the building decoration materials, the cleaning agents volatiles, the furniture, the smoking fumes and so on, while the main pollutants in the office buildings are the carbon dioxide and the odoriferous of the devices (Table 1). For a long time, because people lack of knowledge on the health effect of low concentration of indoor air pollution, especially the impact of the unnoticeable indoor air pollution, leading to a long time involving in low concentration pollutant and pythium odor, people's physical and mental health have been affected severely.

**Table1 Source of indoor air pollutants and its influencing factors [1]**

| Pollutant sources | Specific factors |
|---|---|
| Indoor environment | Pattern of life, building renovation, personnel density, etc. |
| Outdoor environment | Surrounding environment, community planning, architectural |
| Air conditioning and ventilation systems | New wind, air, pipeline, operation and management, etc. |

In order to solve the above problem of indoor air pollution, people often use the ventilation method to achieve the acceptable indoor air quality, or use the introduction of new air dilution method, which not only can control the concentration of pollutants in the air below the harmful concentration limit determined by the norms, but also can make the indoor air quality accepted by most people and effectively avoid the adverse effects on health [2]. But in the current ventilation process, the ventilation volume is always short of in-depth consideration, based on which this paper analyzed the calculation method of the required indoor ventilation.

**Methods of ventilation**

Based on the purpose of eliminating waste heat or wet and diluting the harmful substances, the conventional ventilation calculation method can respectively calculate the amount of needed ventilation, and takes the maximum as the design ventilation. The research methods of ventilation are as follows:

**1）The calculation method of provisions**

Because the pollution associated with personnel and buildings is superimposed considering the effect on the human feelings, the required ventilation is the sum of the corresponding amount of ventilation for the two parts. The calculation equation is as follow [3]:

$$G = R_P P_D D + R_b A_b \tag{1}$$

Where: $G$—design needed fresh air, L/s or $m^3/h$; $R_P$—personal minimum fresh air, $m^3$; $P_D$—number of persons in the room; $D$—variation coefficient; $R_b$—minimum fresh air required per unit area, $L/m^2$; $A_b$—indoor building area, $m^2$.

Consider the following two different situations: when the indoor pollutants have not mutually influence，the individual new ventilation can be respectively calculated to achieve the required standards of fresh air, and then take the maximum as the ventilation requirement, which has been used for the current fresh air standard; when the certain indoor pollutants may have mutually influence, the maximum method can't be applied to calculate the necessary fresh air, while the reasonable method should be summed up to obtain the desired indoor fresh air. To ensure the number of ventilators, the personal total air volume should not be less than 7.5L/s [2].

**2）Analysis and calculation method**

Not only because of the need to eliminate the indoor thermal and wet load of the indoor ventilation, but also to ensure the indoor air quality, for the high indoor pollution or the strong contamination existing in construction, the indoor air quality can be calculated with the mass balance method, such as equation (2) [3]:

$$Q = \frac{N}{(C_y - C_j)E_y} \tag{2}$$

Where: $Q$—amount of ventilation required to ensure indoor air quality, L/s or $m^3/h$; $N$—indoor pollutants generated within unit time, $\mu_g$ /h; $C_y$—allowable indoor pollutant concentration, $\mu_g$ / $m^3$ ; $C_j$—pollutant concentration of entering the building, $\mu_g$/ $m^3$; $E_y$—ventilation efficiency.

The method of calculating fresh air need to consider the type and the nature of pollutants, the dissemination speed, the allowable concentration values and other factors, and conducts the calculation comprehensively. The two methods for calculating the ventilation are based on multiple indicators, and the algorithm is more accurate, while in some office buildings and civil buildings, the ventilation calculation often considers only one or a few main pollutants, such as the necessary ventilation to the standard of the allowable indoor $CO_2$ concentration and the allowable necessary ventilation of total volatile organic compound (TVOC) concentration and so on.

**Necessary ventilation of allowable indoor $CO_2$ concentration**

Because human body can exhale a large amount of $CO_2$ in the metabolic process, and the concentration of $CO_2$ is associated with other air pollutant caused by human metabolism, so the indoor $CO_2$ concentration is often used as an important indicator for indoor air quality [4]. The $CO_2$

generation of human body is concerned with the energy metabolism and body surface area. The amount of $CO_2$ and necessary fresh air under different activity intensity is shown in Table 2.

**Table2 Product of $CO_2$ and necessary fresh air [4]**

| Activity intensity | Amount of $CO_2$ occurs [$m^3$/(h· person)] | Necessary fresh air to be different $CO_2$ allowable concentration [$m^3$/(h· person)] | | |
|---|---|---|---|---|
| | | 0.1% | 0.15% | 0.2% |
| Sit still | 0.0144 | 20.6 | 12 | 8.5 |
| Very light | 0.0173 | 24.7 | 14.4 | 10.2 |
| Light | 0.023 | 32.9 | 19.2 | 13.5 |
| Medium | 0.041 | 58.6 | 34.2 | 24.1 |
| Heavy | 0.0748 | 106.9 | 62.3 | 44 |

Some experiments and research on controlling the concentration of carbon dioxide as an indicator of ventilation systems show that the calculation method can not only ensure the indoor air quality, but also save energy. In recent years, studies have shown that the indoor pollutants include carbon dioxide in addition to other pollutants, such as the above-mentioned pollutants generated by the interior decoration, furniture and building materials, pollutants generated by the conditioning system itself. The high concentration of these pollutants can make people feel uncomfortable, and some pollutants can have direct harm on people's health, so the indoor pollutants generated by nonhuman factors has been put forward to quantitatively describe the problem, which is because the ventilation system of simple indicators to control the carbon dioxide is difficult to eliminate their influence on the indoor air quality. Therefore, the method is applicable to teaching architecture, building of high-density populations, or other environment with the carbon dioxide as the main indoor pollutants. Meanwhile, solving the ventilation can only depend on the concentration of carbon dioxide as an indicator without causing large ventilation errors.

**The required ventilation to eliminate heat or wet** [3]

The required ventilation to eliminate the waste heat or wet can be calculated with equation (3):

$$G = \frac{Q}{c(t_n - t_w)} kg/s \tag{3}$$

Where: $G$—full ventilation, kg/s; $Q$—indoor waste heat, kg/s; $C$—specific heat of air quality, 1.01KJ/(kg•℃); $t_n$—exhaust-air temperature, ℃; $t_w$—entering-air temperature, ℃.

The required ventilation to eliminate the remaining wet can be calculated by equation (4):

$$G = \frac{W}{d_n - d_w} kg/s \tag{4}$$

Where: $W$—indoor remaining wet content, g/s; $d_n$, $d_w$—respectively the moisture content of the exhaust air and the entering air, g / kg.

The fresh air of air-conditioning system should not be less than 10% and not less than the greater of the following two values: (1) the local exhaust volume to supplement the room and the fresh air needed to keep the interior pressure; (2) ensure personal fresh air per hour required to meet the health requirements.

**Necessary ventilation of the required oxygen**

The fresh air should be able to provide enough oxygen to meet the breathing of indoor personnel in order to maintain the normal physiological activities. The oxygen demand for human body depends

on the levels of energy metabolism. According to the theoretical analysis[4], it can be obtained that the oxygen required in very light activities is approximately 0.0187 $m^3$ / (h • person), which shows that the required fresh air of breathing oxygen is not great, and could be satisfied under normal ventilation condition.

**Ventilation correction**

The calculated result of the fresh air and ventilation needs to be corrected combining with the actual situation. If the building facilities increase or decrease, or the use of building has changes, the required ventilation may changes accordingly, so it needs for building contamination correction. If the person in the room changes and the number of working hours is changed, and the room is part of the load state, the fresh air should be changed accordingly and need for dynamic process correction. If there are people who do not accept the indoor air quality, it is needed to carry out unacceptable correction by increasing the fresh air on the basis of the original population.

Based on the above-mentioned calculation method, the total wind can be obtained for the buildings. However, the deficiency is that the formulas can not identify how much amount of fresh air of indoor personnel is needed in the total amount of wind and how much is necessary for the sewage and breathing. Moreover, people often neglect the improvement significance of the indoor air quality by increasing the new wind. Some field tests and research show that simple increase in airflow can't completely solve the problem of indoor air quality [5], so which means that it is necessary to study the effective indoor fresh air of ventilation effectiveness.

The ventilation effectiveness consists of two parts: one is to ensure the adequate fresh air; another is the fresh air which can directly delivery into the breathing zone and rapidly discharge the indoor air pollutants through some organizational forms of airflow. The ventilation effectiveness should be comprehensively studied based on the calculation method combined with the law of human metabolism.

**Conclusions**

(1) When the indoor pollutants have not mutually influence on each other，each individual ventilation can be calculated to achieve the required standards of fresh air, and then take the maximum value as the indoor required ventilation; When certain indoor pollutants may have mutually influence, the fresh air needed to exhaust various pollutants should be summed to obtain the desired indoor required ventilation.

(2) It is needed to modify the calculated results of the fresh air and the ventilation considering with the actual situation.

(3) The simple increase in airflow can't completely solve the problem of indoor air quality, the comprehensive analysis of the ventilation effectiveness should be conducted according to the calculation method mentioned above and combined with the law of human metabolism.

**Keywords:** pure electric vehicles, ultra-low temperature, heat pump, simulation

**Abstract:** In view of high discharge temperature of compressor, the heating performance attenuated seriously, even unable to work properly and other issues of normal heat pump air conditioning system for electric vehicles under low temperature conditions, a gas-mixing heat pump air conditioning system for pure electric vehicles is designed. Based on the first law of thermodynamics and coupling properties among all components, the mathematical model of this system is established. The analog computation of main performance parameters of this system is carried out by this model, having a better match in comparison with experimental results. By simulation, the results show that the system can effectively solve the problems of high exhaust temperature from compressor and heating performance attenuation seriously of non-gas-mixing heat pump air conditioning system for pure electric vehicles under low temperature condition.

## Introduction

Oil-fueled automotive heat pump air conditioning system (HPACS) used the waste heat of the engine as the heat source in winter, while electric vehicles heat can only rely on PTC heating electric heating and other ways, due to the heat source is limited, which would further increase the consumption of battery power and reduce the car battery's capacity. In order to solve this problem, HPACS as well as solar assisted and other different forms[1] was put forward by related scholars. For the electric vehicles, the heating efficiency of the heat pump system is far greater than other heating methods. when outside ambient temperature below 10˚C, the heating capacity of normal system which used medium temperature refrigerant R134a attenuate seriously, compressor discharge temperature is too high due to the compressor suction pressure is too low and the heat pump system cannot work normally. Related scholars concerned with $CO_2$ as the refrigerant in the heat pump system, the system performance is better than R134a heat pump system, $CO_2$ has a very good thermal performance especially in the low temperature, and $CO_2$ is more environmentally than R134a as a natural refrigerant [2]. But the pressure of $CO_2$ heat pump system is too high and go against the reliability and security of the system, automotive air conditioning parts need to be redesigned and the cost is too high. For this series of problems, combined with the characteristics of low temperature heat-pump technology and automobile air conditioning system, a gas-mixed heat pump system for pure electric vehicle with R134a as refrigerant is designed by our research group.

The article is based on previous research, establish mathematical model for every part of the system according to the coupling characteristics among the components, each component model will be connected to form a mathematical model which can predict the performance of the system, and the performance of the system is simulated under variable condition.

**Mathematical model of gas-mixing heat pump system for pure electric vehicle**

The flowchart of gas-mixing heat pump system for pure electric vehicle is shown in Fig 1, the system model primarily focused on the thermodynamic cycle of the whole system, as well as coupling calculation among the each component model. Mathematical model of the system mainly includes: mathematical models of low pressure injection scroll compressor, internal and external heat exchanger, gas-mixing heat exchanger, electronic expansion valves and thermal physical parameters of refrigerant R134a.

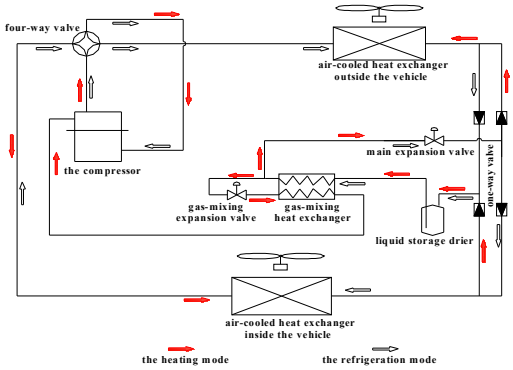

Fig 1 Schematic of gas-mixing heat pump system for pure electric vehicle

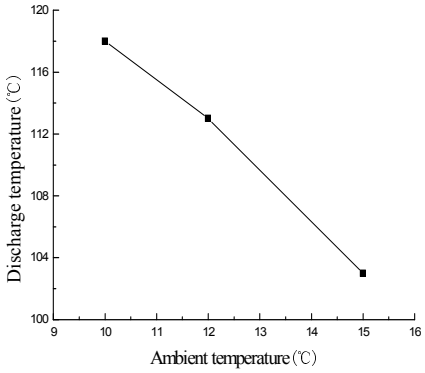

Fig 2 Compressor discharge temperature variation with respect to Outside ambient temperature

**2.1. Mathematical model of system components**

Thermo physical parameter of refrigerant R134a in this system adopts Cleland thermodynamic property models, the model is simple and practical and the amount of calculation is smaller[3]. Compressor in this system is low pressure gas-injection type scroll compressor, its mathematical model is mainly divided into two parts when set up, first, refrigerant mixture model in suction chamber is established, and then mathematical model of compressor compression process is established, in order to calculate refrigerant flow and compressor power and other parameters that affect the system's performance.

As the system simulation requires a certain precision, and stability and running speed, the internal and external heat exchanger model using separated-phase lumped-parameter dynamic models. According to the different state of refrigerant, condenser divides into superheat region, two-phase region, and supercool region[4]. The cell division of superheat region and supercool region is based on temperature drop of refrigerant, two-phase region according to enthalpy of refrigerant. Similarly, the evaporator can be divided into two-phase region and superheat region, the cell division of two-phase region in accordance with the enthalpy value, and superheat region according to the temperature drop. Parallel flow heat exchanger used by the system is a micro channel heat exchanger, according to the structural characteristics of the air side finned tube; the air side heat transfer coefficient adopts the experimental correlations of WangC.C et al.[5]. Condenser and evaporator refrigerant side of the single-phase region heat transfer coefficient adopts the heat transfer correlation of Gnielinski[6]. The heat transfer coefficient of condenser refrigerant two-phase region adopts correlations of Akers[7]. The heat transfer coefficient of evaporator two-phase region adopts the experiment correlation which is presented by Kandlikar and suitable for micro-channel boiling heat transfer[8]. For the main refrigerant cycle gas-mixing, heat exchangers corresponds to condensers, in which refrigerant supercool further, the cell division in accordance with the temperature drop; for the auxiliary cycle, gas-mixing heat exchanger is equal to the evaporator, the cell division of two-phase region is based on the enthalpy value, and superheat region is based on temperature drop. Electronic expansion valve through the stepper motor to make the valve core has the continuous displacement, changing the refrigerant flow area, and then the mathematical model is established according to the momentum equation and energy conservation. The known parameters of the heat exchanger model

calculation process are heat exchanger structure parameters, the refrigerant and air inlet parameters, according to the known parameter calculate the heat transfer performance of heat exchanger.

### 2.2. System mathematical model

The mathematical model of gas-mixing heat pump system for pure electric vehicles is established based on various parts of the system model and the thermo physical parameters model of refrigerant R134a. The model connects internal and external heat exchanger, electronic expansion valve, and mixed-air heat exchanger into an organic whole. Under variable conditions, dynamic performance parameters were simulation when the system is stable, the heating capacity and the energy efficiency ratio (EER) of system can be obtained by calculating.

### Simulation analysis

According to the model of gas-mixing heat pump system for pure electric vehicles established above, When the air side temperature of internal condenser remained 20˚C, with the air side temperature of external evaporator are 10˚C, 5˚C, 0˚C, -5˚C, -10˚C, -15˚C, assuming that the condensing temperature is 45˚C, 50˚C and evaporator outlet temperature is the outside air temperature, calculate the main performance parameters of the system.

### 3.1. Simulation error analysis

In order to verify the reliability of the system model, table 1 is comparison between simulation value and experiment test value result when ambient temperature is 10 ˚C, 5 ˚C, 0 ˚C, - 5 ˚C, -10 ˚C, -15 ˚Cand the condensation temperature is 45 ˚C. It can be seen from the table, the error of the simulation results and the experimental results within 10%, it shows that the system model can be used to analyze performance of the system[9]. Main causes of the error: the heat transfer coefficient used in the simulation calculation is empirical formulas fitted by experimental results, although it has been amended, still has some limitations for different operating conditions. In the calculation process of the compressor model, the compression process is based on the ideal isentropic compression, ignoring the irreversible loss of the clearance volume and other aspect, so will cause errors.

Table 1 Comparison between simulation model and experimental result ($T_k$=45 ˚C)

| Performance ($T_k$=45˚C) | Discharge temperature（˚C） | | | Heat capacity（W） | | | EER | | |
|---|---|---|---|---|---|---|---|---|---|
| Ambient temperature（˚C） | Simulation | Experiment | Error（%） | Simulation | Experiment | Error（%） | Simulation | Experiment | Error（%） |
| 10 | 72.6 | 75.4 | 3.7 | 5383 | 4962 | 8.5 | 3.38 | 3.10 | 9.2 |
| 5 | 70.7 | 74.3 | 4.8 | 4622 | 4336 | 6.6 | 3.01 | 2.81 | 7.7 |
| 0 | 69.1 | 73.1 | 5.6 | 4051 | 3779 | 7.2 | 2.71 | 2.48 | 8.5 |

*$T_k$: Condensing temperature

### 3.2. Results analysis

The experimental test performance of the non-gas-mixing heat pump system under low temperature condition are shown in Fig 2, Fig 3. It can be seen from Fig 2, the compressor discharge temperature rise from 103˚C to 118˚C as the ambient temperature decreases from 15˚C to 10˚C. When the ambient temperature continues to drop, the compressor discharge temperature will exceed the allowed maximum discharge temperature 120˚C, the system cannot continue to run. It can be seen from Fig 3, the heating capacity decreased rapidly with the ambient temperature reduced, This is due to suction

pressure of system reduced with the ambient decreased, and the specific volume of refrigerant R134a increased gradually while the suction vortex of scroll compressor was invariant, causing the refrigerant mass flow of the system reduced, so the heating capacity decreased gradually. It can be seen from the above data, when the ambient temperature was below 10˚C, the compressor discharge temperature will exceed the allowed 120˚C in normal heat pump circulation system for pure electric vehicle, so the system cannot run normally.

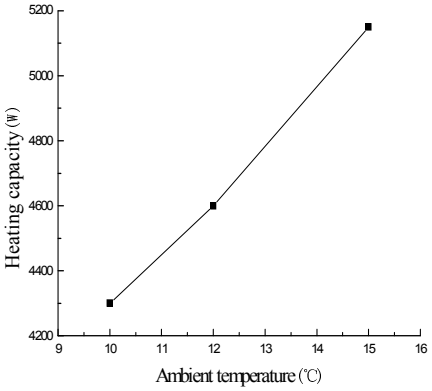

Fig 3 Heating capacity variation with respect to Outside ambient temperature

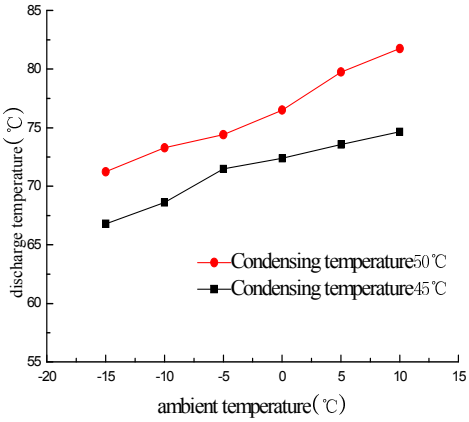

Fig 4 Compressor discharge temperature variation with respect to Outside ambient temperature

Under different condensing temperatures, the compressor discharge temperature in gas-mixing HPACS for pure electric vehicle varies with the outside ambient temperature is shown in Figure 4. It can be seen from the figure, the compressor discharge temperature lower with the reduction of the outside temperature under different condensing temperatures. Because refrigerant of the auxiliary cycle pass gas-mixing heat exchanger, then enter the mixing chamber of the compressor to mix adiabatically with refrigerants in the main cycle, the degree of superheat of refrigerant absorbed by compressor is reduced, the discharge temperature decrease after isentropic compression of compressor. The compressor discharge temperature is 71˚C at -15˚C, much less than the allowed maximum discharge temperature 120˚C, the system can operate normally.

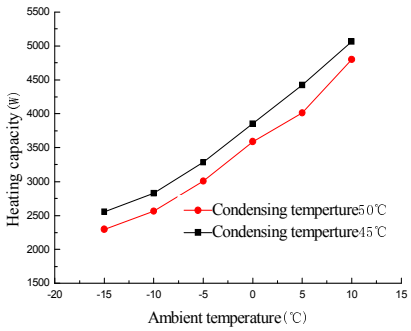

Fig 5 Heating capacity variation with respect to Outside ambient temperature

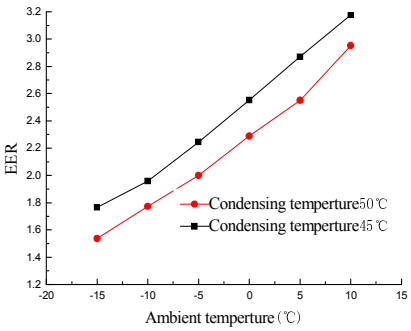

Fig 6 EER variation with respect to Outside ambient temperature

As shown in Fig 5, the heating capacity of the gas-mixing HPACS for pure electric vehicle reduced gradually with the decrease of outside ambient temperature. The system can run normally and the heating capacity improved greatly with respect to the non-gas-mixing HPACS for pure electric vehicle. When the ambient temperature is 10˚C, the heating capacity of the gas-mixing HPAC is 5383W, while the normal HPAC is 4200W, the heat capacity increases about 28%. Because after adopting gas-mixing HPACS, refrigerants from the auxiliary cycle mixed with refrigerants from the main cycle in compressor suction chamber reduce the degree of superheat of compressor suction, the specific volume of working fluid decreases and the mass flow increase, the heating capacity of the

gas-mixing HPACS will be greatly improved respect to normal HPACS. The evaporation pressure of external heat exchanger decreases with the reduction of ambient temperature, so it cause a reduction of the compressor suction pressure, the refrigerants specific volume increase. when the outside ambient temperature decreased from 10˚C to -15˚C, the heating capacity of the gas-mixing HPACS is reduced by 50%. the heating capacity slightly down with the rise of the condensing temperature, as the rise of condensing temperatures causes evaporating temperature of outside heat exchanger rising, the refrigerants specific volume increase, refrigerant mass flow lower. When the outside ambient temperature is 10˚C, the heating capacity reduces from 2620W to 2296W with the condensing temperature increases from 45˚C to 50˚C.

As shown in Fig 6, the heating efficiency of the system is about 1.7 when the ambient temperature is -15˚C, which is still greater than the efficiency of PTC heating methods used by electric vehicle normal HPACS when the outside ambient temperature is below 10 ˚C.

## Conclusions

This paper establish the model of gas-mixing HPACS for pure electric vehicle, and simulation the discharge temperature, the heating capacity and EER of the system under different condensing temperatures and outside ambient temperatures. The results show that after the use of mixed gas, the compressor discharge temperature of heat pump system is decreased about 40.5%, the heating capacity of the system increases by about 28% under low temperature; the system EER increases by more than 70% compared with normal HPACS for electric vehicle; solving some problems that the discharge temperature is too high , and attenuation of heating performance of non-gas-mixing HPAC under low temperature condition, it has a positive role in promoting the application of the heat pump technology in the pure electric vehicles.

One of the most important topic of 21th century is energy savings, and many countries create enterprises which develop standards and codes for construction, repairs and building renovations, including a realistic, cost-effective recommendation aimed at making city buildings become cleaner and more energy efficient. For example, one of these enterprises is C 40 Cities Climate Leadership Group.

This group is a network of the world megacities taking action to reduce greenhouse gas emissions, to increase energy efficiency of municipal services and to adapt to climate change.

In this regard, we consider the application of engineering systems of the building automation aimed at energy savings. So, substantial part of the energy consumption in the building intended for public use is heating ventilation and air-conditioning (HVAC) systems.

In this article HVAC systems in public catering will be considered, since many factors should be taken into account while designing. For example, the imbalance between the dining room and the kitchen ventilation systems can prevent kitchens smells getting to dining room area.

For air quality to remain at the highest level, HVAC systems should include several supply and exhaust systems, and to achieve greater economic and energy efficiency recuperation and recirculation systems should be applied and variable-frequency drive (VFD) should also be used.

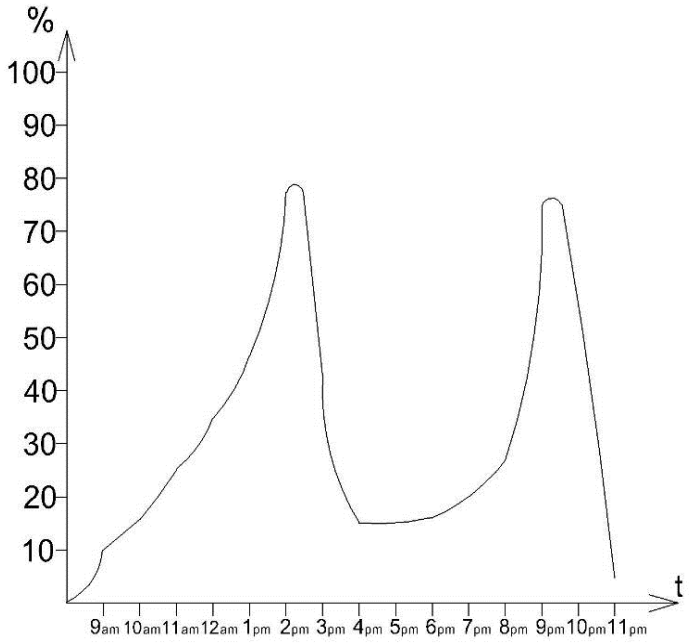

Fig.1 Graph of the volume of visitors on the time

The recirculation system is applied to mix high quality air, which is processed by supply ventilation, with the outdoor air. Air quality is monitored by carbon dioxide sensor, which is located in the exhaust air duct.

A carbon dioxide sensor or CO2 sensor is an instrument for the measurement of carbon dioxide gas. The most common principles for carbon dioxide sensors are infrared gas sensors (NDIR) and chemical gas sensors. Measuring carbon dioxide is important in monitoring indoor air quality and many industrial processes.

This system is particularly effective when there is a large temperature difference between the outdoor and indoor air, because less energy is consumed for heating or cooling.

Figure 1 shows the number of visitors on the time. This graph shows that recirculation will be working from 9am to 1pm and from $3^{30}$pm to $8^{30}$pm, when number of the visitors is less than 60%.

However the recirculation has some restrictions on sanitary and hygienic standards. Smell from the kitchen could spread to dining room, therefore the use of this system in public catering is undesirable.

In this case recuperative heat exchangers are widely used. Heat recovery ventilation, also known as HRV, is an energy recovery ventilation system using equipment known as a heat exchanger which employs a counter-flow heat exchanger (countercurrent heat exchange) between the inbound and outbound air flow.

Recovery ventilation efficiency reaches up to 70%, and it generally saves heating energy during winter period. It also depends on several factors. A thermal wheel is the most effect. A thermal wheel, also known as a rotary heat exchanger, or rotary air-to-air enthalpy wheel, or heat recovery wheel, is a type of energy recovery heat exchanger positioned within the supply and exhaust air streams of an air handling system, or in the exhaust gases of an industrial process, in order to recover the heat energy. But for public catering recuperator, or cross plate heat exchanger, is more suitable, because thermal wheel can bring unwanted odors.

A recuperator is a special purpose counter-flow energy recovery heat exchanger positioned within the supply and exhaust air streams of an air handling system, in order to recover the waste heat.

In HVAC, recuperators are commonly used to re-use waste heat from exhaust air normally expelled to atmosphere. Devices typically comprise a series of parallel plates of aluminium, plastic, stainless steel, or synthetic fibre, alternate pairs of which are enclosed on two sides to form twin sets of ducts at right angles to each other, and which contain the supply and extract air streams. In this manner heat from the exhaust air stream is transferred through the separating plates, and into the supply air stream.

The recuperator's drawback is that condensation can become frozen in the cold periods. In order to control the icing, the differential pressure switches (DPS) are used, and apply a bypass of supply duct. DPS - is a form of switch that closes an electrical contact when a certain set pressure has been reached on its input. The switch may be designed to make contact either on pressure rise or on pressure fall.

So, principle of operation is that when the icing reaches a maximum level, DPS sends a signal to the controller. Then controller sends a signal to the damper actuator and opens the bypass, and exhaust air heats the recuperator and condensate is drained into a special hole. Also, it is recommended to use a heat exchanger at a temperature not lower than -30$^{o}$ C. in this case, the supply air passes through the bypass.

According to my research, with the use of recuperator in public catering efficiency reaches 54% in winter, and 46% in summer. The recuperator is located in supply and exhaust system of the dining room. Net dining room area is 112 square meters.

Through economic analysis, we conclude the following:

$Q = 0.278 \bullet \mathrm{Ca} \bullet \mathrm{Ga} \bullet (t_K - t_H)$ – amount of heat calculation to air heating, watt (1)

$$\mathrm{Gw} = \frac{(3.6 \bullet Q)}{\mathrm{Cw} \bullet (\mathrm{t1} - \mathrm{t2})}$$ – consumption of a heat-transfer agent kg/h, (2)

provided that the temperature indoors is 16 $^{o}$C, according RCC 2.08.02–89, and mean air temperature -1,8$^{o}$C, according RCC 23-01-99*. In my variant the city is St. Petersburg. RCC– is Russian Construction Code (SNIP).

All data obtained from diploma paper.

Gw = 997.40 kg/h - this is a consumption of a heat-transfer agent, before applying of recuperator, after applying the consumption is 435,856 kg.

Sh.w. = Ah.w. $\bullet$ Ph.w . – expenditures for hot water, RUB/year, (3)

where Ah.w.– is annual hot water consumption ton/year, Ph.w. – price ton of water RUB/t, according as heating season is 220 days.

Sh.w.= 256,199.2 RUB/year – this are expenses for hot water before applying recuperator, and after its applying the expenses reduce to 112, 727. 65 RUB/year.

Also one of the very important device to energy saving is variable-frequency drive (VFD). VFD (also termed adjustable-frequency drive, variable-speed drive, AC drive, micro drive or inverter drive) is a type of adjustable-speed drive used in electro-mechanical drive systems to control AC motor speed and torque by varying motor input frequency and voltage.

VFDs are used in applications ranging from small appliances to the largest of mine mill drives and compressors. However, about a third of the world's electrical energy is consumed by electric motors in fixed-speed centrifugal pump, fan and compressor applications and VFDs' global market penetration for all applications is still relatively small. This highlights especially significant energy efficiency improvement opportunities for retrofitted and new VFD installations.

Over the last four decades, power electronics technology has reduced VFD cost and size and improved performance through advances in semiconductor switching devices, drive topologies, simulation and control techniques, and control hardware and software.

Use them necessary almost on all fans in ventilation systems, to change motor speed. If not applied VFD, fans will working in full power, and hence is not energy efficient. Depending on time of day number of customer is different, this means that air exchange should change. Figure 1 proves it, the graph shows VFD's working.

Trough economic analysis we conclude the following:

$$Sel.en. = \Sigma Ni \bullet Tyear \bullet Pel.en. \bullet Ce \text{ – electricity costs,} \quad (4)$$

where ΣNi – total power of used electromotors (kW). Tyear - operating time per year. Pel.en. - price of electricity 1kW*hour. Ce – coefficient of ancillary costs to electricity.

In my diploma paper 2 supply and 4 exhaust ventilation systems were applied. VFD was used with all fans. Total power of used electromotors is 12.8 kW.

$$Sel.en = 12{,}8 \bullet 5040 \bullet 3{,}6 \bullet 1 = 232{,}243.2 \text{ RUB\year}$$

Used graph which located in Fig.1, I calculated total power of fans, with applying of VFD, and total power decrease about 2,5 times.

$$Sel.en = 4.77 \bullet 5040 \bullet 3{,}6 \bullet 1{,}15 = 99{,}528.91 \text{ RUB\year}$$

Therefore, applying VFD decreased power consumption more than two times.

As already mentioned the fan speed depends on carbon dioxide content in the room. This rule will be used with all rooms except kitchen, there will be extract hoods over hotplates and in washing place will be applies. Also fan speed control cannot be used with the light detector and temperature sensor, because regulation cannot be exact, and optimal conditions will not be achieved if misregulated.

In my diploma paper I tried to keep optimal conditions. I controlled the fan speed which is located in the kitchen's exhaust system by amount of activated burners, located in the cooker. That means relay was installed on each control knob for burners, and relay contact closes when burners turn on, after that relay signal is send to the controller. Then analog signal the logic of controller is send to the VFD, and depending on the number of activated burners, the fan speed will be changed.

For example, if one burner is activated the fan will be working by 20%, if two burners are activated the fan will be working by 40 %, and if all the burners activated the fan will be working full power. Fan schedule is almost similar to Fig. 1.

Although kitchen's exhaust system is not controlled by carbon dioxide sensor, the system has to be related with other systems. In order to do it, it is necessary to install a set point in controller, whereby the imbalance between dining room and kitchen would be observed.

Thus, applying recuperation system, variable frequency drive, and most importantly the right automated approach, we make comfortable conditions for visitors and staff, also we save heat and energy recourses, which in turn can save the money.

**Keywords:** new air system, healthy housing

**Abstract:**
As the continual improvement of human living standards, healthy housing became a hot topic and was attached more and more emphasis whatever from the profession or the public. Professionally, better ventilation is one of the most important facets of the healthy housing. Compared with the traditional ventilation system, this paper illustrates the new air system that makes a full use of natural resources, directly and simply changes the normal traditional housing to the healthy housing, through the concept, philosophy, typology and property of the new air system. Additionally, it takes the "*Dong Ya Shi Ji Cheng*" in Batou as typical example of healthy housing, in order to demonstrates the advantages of the new air system more clearly.

## The background

A myriad of previous research indicate that the air pollution level of indoor is 5-20 times higher than the outdoor one, and people stay indoor much longer than outdoor. On the other hand, more respiratory diseases resulted from the indoor air pollution, for instance the air pollution caused by the interior decoration, and people inhales the floating bacterial particles due to the closed transom prevents the natural ventilation. Especially as the emergence of SARS and avian influenza, the quality of indoor air condition became a inescapable issue of healthy housing.

Modern society promotes healthy housing which maximize the people's better physical and psychological experience. Therefore, the quality of indoor air condition is undoubtedly an important indicator of the comfortable living condition. In general, the traditional ventilation methods could be summarized as follows:

(1) Traditional window: it could exchange the air quickly, but causes several problems particularly for the high-rise buildings. When the widow open, the sand dust and cold air will come inside of the room. It often caused air floating particle, air turbulence and noise problems as well.

(2) Ventilator: the exhaust volume is huge, but the noise problem will increase while the longer you use it. It is only positive for the shortly and partly exhaust without rational organized flowing path. In fact, its effect is negative which could not be considered as the real air exchange.

(3) Large central air condition system has the New air systems. However, this system is very complex and has poor operability. The traditional design of positive pressure ventilation has the disadvantage to exclude the polluted air. The air hose is the place easily accumulate with dust and bacterial, the most corner is breeding ground for the infecting organisms.

(4) small domestic central air condition system : it has the ventilation hole, but it can't completely exchange the air from outside. The fresh air can't be sent into the room without the exhaust system, and the bad smell can't go out either. It is impossible to fundamentally change the inside air quality.

In north Europe, the VMC has been invented fifty years ago. Spanish have already equipped their new houses with VMC in the 1970s. French introduced new regulation on ventilation in 1958, and the VMC were used widespread in 1969. In 1989, American ASHRAE drew up “Indoor air quality ventilation specifications”. In Germany, residential ventilation systems have become an indispensable part of their lives. In 2000, EU unified the standards on residential ventilation. With the improving of building air tightness, it caused “new house disease” and other diseases accompanied with the chemicals, polluted air and inadequate ventilation. So Japan put Mechanical Ventilation Facility into “Basic Architecture” as enforcement. In accordance with these regulations, every building has to ventilate all day, and the ventilation should reach 0.5 times per hour. However, VMC as a new ventilation system in China has been stepping into our lives.

**The concept and philosophy of the new air system**

The new air system is constituted of four parts: fans, inlet, vents and various pipes. A series of pipes connects the fans and vents. The fans installed in the ceiling could exhaust the polluted air through vents, created the air pressure difference. Therefore, the fresh air could come into the room through inlet which guarantees the air circulation. In reality, a series of rational organized air flow and continual low wind energy design (100 $m^2$ housing only use a kilowatt hour per three days) promise the inside fresh air condition.

We take the second phase of "*Dong Ya Shi Ji Cheng*" in Baotou as an example. It uses a new air system of Panasonic which is a diversified ventilation system based on three principles of mechanical ventilation system and natural ventilation system. The fans is installed in the ceiling, the inlet is on the window frame. Most of the exhaust pipes are installed in the ceilings of aisle and toilet, while the inlet doesn’t need pipeline to occupy the space in the ceiling. The room where people stay for more than three hours should provide 30 $m^3$fresh air per hour, the master bedroom is 50 $m^3$ per hour and the other bedrooms are 30 $m^3$ per hour, while the places don’t stay can be laid aside to provide fresh air, such as the kitchen, the bathroom and the equipment room. Based on the principles above, this system determines the area to supply fresh air, the air volume and the duration to ventilate in the different rooms. This system divides the house into two areas, one is positive pressure area and the other is negative pressure area. The positive one includes bedrooms and the living rooms. while the negative one includes kitchens, bathrooms and aisles. The fresh air is brought in from the clean area and force the polluted air going out from the filthy area, which makes sure that the inhabitant can enjoy the fresh air all day.

This system named as Thermal Comfort Ventilation which could keep the fresh air inside and exchange the polluted air to the outside. It can increase the body’s heat dissipation to prevent the sick caused by the moist skin. This kind of ventilation is also named as the cooling-house ventilation, because it can cool the building when the temperature is higher than the outside.

Furthermore, "*Dong Ya Shi Ji Cheng*" is known as “the breathing house”. It has these advantages as follows:

(1) the house could breathe the fresh air.

(2) It’s benefit for human's mental and physical health, and has moisture proof and disinfection effect.

(3) The guarantee of the power engine is five to eight years, and it saves energy. The motor power is 38W, 90 $m^2$ room only need 1 kWh electricity per day.

(4)National standards for noise defined that the day time is 40 db, the night 30 db. The fresh air system is less than 30 db low-noise system.

(5)Through adjust the controller, it could control the temperature according to the weather. Therefore, the air exchange might not change the inside temperature.

**The property and Types of Fresh Air System**

The fresh air system is divided into three types based on the property :

(1)Single-pass Fresh Air System

It uses the natural air supply and mechanic exhaust system. The rationale is when the system is running, the organized air flow will continuously exhausted the stagnant air to the outside from the most polluted areas, and then the outside fresh air can be led into the room through the air inlet from the most active place into the room, maintaining indoor air fresh. The route of airflow is that the fresh air enters from the living room and then exhaust from the bathroom and kitchen.

The advantage of Single-pass Fresh Air System is that the preliminary investment is low and the indoor pipelines are relatively less. Because the fresh-air-supply of Single-pass Fresh Air System is through pressure difference between the room and outside. Hence it is heavily impacted by the quality of atmospheric air, and is not able to filter or disinfect the incoming air. It will take indoor heat and cold away during the exhausting procedure, which wastes the energy.

(2)Two-way Fresh Air System

The Two-way Fresh Air System is a supplement to the Single-pass Fresh Air System in certain aspects. It is composed of two sets of systems. One is mechanic exhaust system, the other is mechanic air supply system. Compared to natural supply, the difference between mechanic air exhaust system and Single-pass Fresh Air System is that the fresh air gets into the room through the pipes of supply system. The arrangement of pipes is the airflow paths, which is better to the airflow organization. Meanwhile, the fresh air can be improved, such as dehumidification, humidification, disinfecting and heating, according to the requirements. It is suitable for the rooms with special requirements of the air quality. It is able to make the room being in a state of micro-pressure, which can effectively isolate invalid air from entering through the gap of doors.

Two-way Fresh Air System uses the mechanical ventilation, so the fresh air can be filtered and disinfected effectively. But the cold or heat will be discharged outdoors during the procedure of supplying and exhausting, which will cause the energy waste. Furthermore, it needs much more pipes and the preliminary investment is higher.

(3)All-air Heat Recovery Exchanger Ventilation System

The advantage is it has a heat exchange module which combines the supplying and exhausting. The structural components consist of fresh air host, inlet, outlet, pipe network and speed switch etc. The host is usually set in the balcony, kitchen, bathroom, ceiling or storage rooms. It has the same operational principle with Single-pass Fresh Air System. When it works, the indoor polluted air and particulates are discharged outside by the exhaust pipe. Meanwhile, fresh air is coming in through the ventilator. But the difference is the heat recycle ventilation system which is improved from the Single-pass Fresh Air System, could absorb and supply heat. In the heat exchange module, the heat of exhaust air will be exchanged with the supplying fresh air. Therefore, it can achieve the goals of recycling cold in summer and heat in winter, which can save energy and improve the indoor air quality.

All-air Heat Recovery Exchanger Ventilation System uses the mechanical ventilation, so the fresh air can be filtered and disinfected effectively. In the process of supply and exhaust, it is able to recycle the energy of exhaust air, saves energy. But it needs more pipes and the priliminary investment is quite higher.

**The Limitation of The New Air System**

(1) Limitation of installation. For instance, the new air system should be installed in the ceiling with other pipeline.

(2) Regional Limitation. Anti-frost wind measures should be considered in Cold regions to use the new system

(3) Limitation of Energy saving. The new wind load will reach 30% of heating in the cold areas.

(4) Requirements of Multifunction. For instance, the room requires air purification, humidification, dehumidification, sterilization.

(5) Requirements of Technical and economic. It needs comprehensive consider the Run-time investment costs, use effect systems, maintenance fees to control costs.

**The Advantages of The New Air System**

(1) Ventilation. People could not only enjoy the natural fresh air, but also filter indoor air, cleared the long-term harmful gases caused by interior decoration, and conducive to human health without opening the window.

(2) Avoiding "Air-condition disease".

(3) Large electricity distribution capacity can no longer be considered; Partly exhaust equipment in kitchen, bathroom can be cancelled; Window screen is not necessary; Only the bottom of the door in kitchen and bathroom needs screen; Main engine could put in the ceiling of kitchen or bathroom; the exhaust port is flexible, and the area of the pipe shafts are reduced.

**Conclusion**

Currently, China's building energy saving should based on the sustainable development of the energy value promoting model. For instance, the solar air system as the auxiliary heating system in winter is a new fresh air system combined the solar energy and technology of changing thermal storage. The solar energy could heat the fresh air, while the additional solar energy could be stored in the thermal storage device, used for bad weather. In this case, it maximizes the use of solar energy, and guarantees the long time work of the new air system.

Only the low energy consumption of heath building could create the sustainable living environment. The new air system is just on the way towards to the promising. Healthy housing, energy conservation and other development concepts have laid a solid foundation for the widely application of new ventilation system in the residential buildings and other public buildings.

# Research on the construction technology of radial underground heat exchanger and its heat exchange performance

Ronghui Wang, Qinghua Wang, Ye Feng

(Construction engineering college of Jilin University, Changchun, Jilin Province, 130061)

**Key words**: Radial heat exchange wells; Buried tube heat exchanger；Heat exchange performance

**Abstract**：5 radial heat exchange wells were designed, and the different angle drilling, drilling pipe, and grouting backfill construction technology was studied. In addition, the heat transfer performance of the buried radial heat exchange wells was tested. The results show that, design of pipe equipment is feasible, construction is convenient, and the ratio of backfill material is reasonable; the heat transfer performance of 90 °buried tube is the best. The smaller the angle with the ground heat exchanger, the greater the heat exchange performance is affected by the surface temperature.

## Outline

Ground source heat pump engineering both domestic and abroad, a single U or dual U type vertical tube HDPE is usually used as underground heat exchangers. But when the ground-source heat pump technology developed rapidly in the city and buried pipe region adjacent to the road, bridge or other buildings, land constraints make heat well spacing decreases, the low efficiency of heat exchange, or the heat transfer well depth increase project cost. Therefore, by inclined way to alleviate or solve this problem, the road or green slope to the building foundation and the surrounding has been paved, neither destroy the building or bridge structure, and can save a lot of buried pipe construction land.The buried heat exchanger can be composed of HDPE tube of multiple sets of double U or single U, heat exchange wells according to different direction and angle are arranged radial. Radial heat exchange wells covers an small area, saves the land resources, high heat exchange efficiency, is a new type of ground source heat pump system of outdoor heat exchanger.

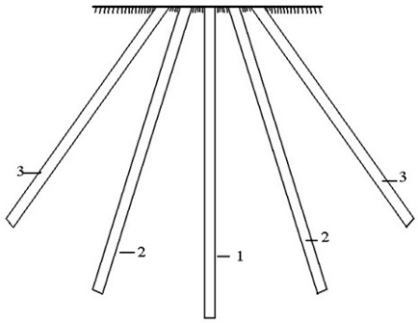

Figure 1 Radial heat exchange wells

Based on the problems, this paper designs 5 radial heat exchange wells and research the heat transfer performance and construction technology. Shown in figure 1, 5 wells are symmetrically arranged, angle with the ground are 90 °, 60 ° and 30 °, length is 100m. HDPE tube of single U is placed in hole, which diameter is 32mm.

**Construction of radial heat exchange wells**

Use the hydraulic pressure driving head of JDZ-5 ground coring drilling rig developed by Jilin University. Drill the radial wells, drilling diameter is180mm.

After the construction of radiation wells, began the decentralization of underground pipe. Because the inclined of the borehole, the commonly pipe decentralization method can not be used, therefore, a special down tube apparatus had been designed, the apparatus comprising a fixed hollow hammer with tip head, the end of pipe placed in the empty weight core, then poured into the hollow core of the concrete, after the concrete was hardened ,underground pipe can be fixed with the hammer ,as shown in Figure 2. The hammer can play a protective role of underground during placing down the pipe tube , also can increase the weight of the pipe, and made the decentralization of underground pipe more smoothly into the borehole. After the decentralization of the tube, filled with backfill material, and connected the underground pipe to the interior through horizontal pipe.

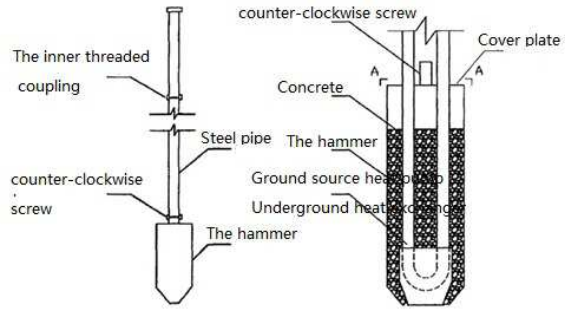

Figure 2 Schematic diagram of tube laying device the structure of heat exchanger buried underground

The heat transfer performance of buried tube strongly depends on the quality of backfill process. Some projects often use mixture of 80%-95% bentonite and 5%-20% cement. In this paper, through the indoor test of the heat transfer performance of the backfill material, several more ideal backfill material are obtained, which are shown in table 1.

Table 1 The backfill material

| Serial number | The backfill material proportion | | |
|---|---|---|---|
| | Sand | Cement | Bentonite |
| 1 | 0 | 20% | 80% |
| 2 | 20% | 0 | 80% |
| 3 | 10% | 20% | 70% |
| 4 | 20% | 0 | 80% |

The plunger mud pump is used to backfill. To prevent backfill material solidification, the process of grouting interval time should not be too long. If considering it is in winter, the temperature is low, it can increase the grouting pump alternating grouting.

**Heat transfer performance testing of radial heat exchange wells**

A portable ground thermal response test instrument, developed by Jilin university, is suffered an underground irrigation thermal test, used to simulate the heat pump units in summer cooling exchanger and heat transfer situation of formation. Test has three stages that include the cycle of reactive power, constant heat flux test and constant temperature. Five radial heat wells of thermal are tested in July 2011. Test time is shown in table 2, and test related conditions are shown in table 3. Among them, the number of buried tube heat exchanger respectively are: 1 # is 90°, 2 # and 3 # is

60°, 4 # and 5 # is 30°. On the basis of test, on the basis of linear source model[1], combining with the parameter estimation method[2], using matlab programming fitting to calculate the coefficient of thermal conductivity of 1 # well to 5 # well and other thermal physical property parameters, and the calculate according to test data per linear meter for heat and so on are shown in table 4.

Table 2 Test time of hot filling

| No. | No power cycle time | The stage of constant heat flux | The stage of constant temperature | Total time on test |
|---|---|---|---|---|
| 1# | 4h6min | 51h50min | 37h22min | 93h19min |
| 2# | 1h15min | 55h16min | 37h50min | 93h7min |
| 3# | 1h21min | 50h58min | 45h55min | 98h26min |

| No. | The stage of constant heat flux | The stage of constant temperature | | Thermal parameters | | |
|---|---|---|---|---|---|---|
| | Per meter for Quantity of heat W/m | Import well circulating water temperature ˚C | per meter for Quantity of heat W/m | The heat conduction coefficient λ W/(m·K) | Drill hole thermal resistance Rb （mK/W） | Thermal diffusion coefficient α 10-6m2/s |
| 1# | 43.51 | 5.41 | 90.51 | 2.8358 | 0.3037 | 0.7405 |
| 2# | 43.98 | 5.08 | 85.52 | 2.8166 | 0.3783 | 0.7456 |
| 3# | 43.16 | 4.08 | 67.04 | 2.9141 | 0.5015 | 0.7206 |
| 4# | 43.64 | 5.68 | 89.44 | 2.9246 | 0.2702 | 0.7180 |
| 5# | 43.56 | 5.21 | 83.06 | 2.2859 | 0.3636 | 0.9187 |

As can be seen from table 2 to table 4:

The initial ground temperature of 4 #, 5 # (30 °) heat exchange wells has difference of only 0.07 ˚C, are basically the same; During the test, the flow keep stable. Compared with the set value, deviation does not exceed 0.005m ³ / h; temperature difference compared with the set value does not exceed 0.02˚C; get results of heat exchange per meter from calculation of flow and temperature difference, in constant flux phase were 43.64W/m, 43.56 W/m, with difference of only 0.08W/m, In the constant temperature stage into the wells were 89.44W/m, 83.06 W/m, with difference of only 6.38W/m, we can take the average of # 4 and # 5 as heat exchange under the conditions.

The initial ground temperature of 2 #, 3 # (60 °) heat exchange wells has difference of only 0.04 ˚C, are basically the same; During the test, the flow keep stable. Compared with the set value, deviation does not exceed 0.009m ³ / h; temperature difference compared with the set value does not

exceed 0.03 ˚C; get results of heat exchange per meter from calculation of flow and temperature difference, in constant flux phase were 43.98W/m, 43.16 W/m, with difference of only 0.82W/m, In the constant temperature stage temperature difference were 5.08˚C, 4.08˚C, with difference of only 1˚C.The calculated heat exchange per meter were 85.52W/m, 67.04 W/m, with difference of 18.48W/m. The heat exchange of 3 # is less, because the temperature difference of recycled water is less.

The initial ground temperature of 1 # (90 °) heat well and other well temperature has difference of 0.3 ˚C, are basically the same; at the stage of constant temperature difference of 0.3 ˚C, are basically the same; at the stage of constant temperature testing, its heat exchange performance is higher than other heat well，so vertical buried tube heat transfer performance is the best.

## Conclusion

Through the heat injection test of underground heat radiating exchanger, the following conclusions can be drawn:

(1) Pipe device of radial tube heat exchanger design is feasible, construction is Convenient; the ratio of backfill material is reasonable.

(2) The heat transfer performance of 90 ° buried tube system (Take cold capacity) is the best, can be 90.51 W/m. The taking cold capacity of 60°and 30° buried pipe is closed, Respectively are 85.52W/m, 86.25 W/m. Buried pipe heat exchanger performance will be affected by the surface temperature in a certain extent.

(3) The difference of circulating water temperature directly affects the size of per meter of heat exchange. The greater the temperature difference is, the greater the heat will be.

**Key words:** acid fracturing; fracture parameter; construction parameter

**Abstract:** This paper recommends the application of acidic fracturing technology for horizontal wells in Yubei region basing on its fractured reservoir's characteristics, and the numerical simulation method is used to optimize the parameters of acidic fracturing. According to the results of optimization, the proper acid system is selected, and the construction parameters of acidic fracturing are optimized. According to the results of numerical simulation, we recommend the fracture half-length to be 120m, the fracture conductivity to be 30D.cm, and the fracture number to be 5. According to the properties of reservoir in Yubei region and the optimization results of fracture half-length and fracture conductivity, the alternative injection of crosslinked acid and ordinary gelled acid is recommend. The injection rate of crosslinked acid is $5m^3$/min, with volume $300m^3$. The injection rate of ordinary gelled acid is $6m^3$/min, with volume $300m^3$.

## Introduction

The Yubei oilfield of Tarim develops natural fractures, and the reservoir heterogeneity is strong, so that it is suitable to use acidic fracturing technology on the horizontal wells in this area. Usually, the multi-stage fracturing is needed because the horizontal wells are long, and the fracture parameters should be optimized in this process. Since the temperature of the reservoir is high, and fractures are developed, and the reaction rate of the acid and the rock during the acidic fracturing is high, the acid filtration during the acidic fracturing construction is serious, which negatively affects the acidic fracturing effect. In this regard, the acid system should be carefully chosen, and measures should be taken to reduce the acid filtration. This requires the optimization of the construction parameters of acidic fracturing. The oil production and the construction efficiency will be significantly improved by optimizing the fracture parameters and the construction parameters during the acidic fracturing.

This paper investigates the geological characteristics in Yubei region, so that the proper acidic fracturing technology can be determined. The Eclipse software was used to simulate the fracturing process, and the orthogonal analysis method was applied on the studying of effects of different fracture parameters on the productivity, so that the half-length, the conductivity and the numbers of the fractures were optimized in this process. Then, according to the half-length and the conductivity that were optimized, the FRACTPROPT software was used to optimize the injection rate and the volume of the acid system during the construction process, so that the best construction method can be obtained.

**The optimization of fracture parameters**

In this paper, the Yubei 1-3 horizontal well was the target well. The Eclipse software is used to optimize the fracture parameters. The basic geological parameters are as follows:

Table 1 Basic geological parameters

| Depth of the top face (m) | Avera-ge poro-sity | Average vertical permea-bility (mD) | Average horizontal permea-bility (mD) | Surface oil density (g/cm3) | Surface water density (g/cm3) | Volume factor of crude oil | Oil viscosity (mpa.s) | Water saturation |
|---|---|---|---|---|---|---|---|---|
| 5770 | 1.5% | 0.37 | 3.58 | 0.93 | 1.07 | 1.105 | 8.35 | 0.2 |

Table 2 Compressibility factor of crude oil

| Pressure （MPa） | Compressibility factor(1/MPa) |
|---|---|
| 54.03~50 | $8.49\times10^{-4}$ |
| 50~40 | $9.76\times10^{-4}$ |
| 40~30 | $10.28\times10^{-4}$ |
| 30~20 | $11.31\times10^{-4}$ |
| 20~10 | $12.30\times10^{-4}$ |

Input the parameters of reservoirs and wells into the Eclipse software, and the dual-porosity medium model was used.

**The optimization of fracture half-length.**Select the fracture half-length as 20m, 35m, 50m, 65m, 80m, 95m, 110m, 125m, 140m, the Eclipse software was used to calculate the corresponding cumulative oil production under different fracture half-length. Put the nine cumulative oil production curves together to compare and analyze, graphics are as follows:

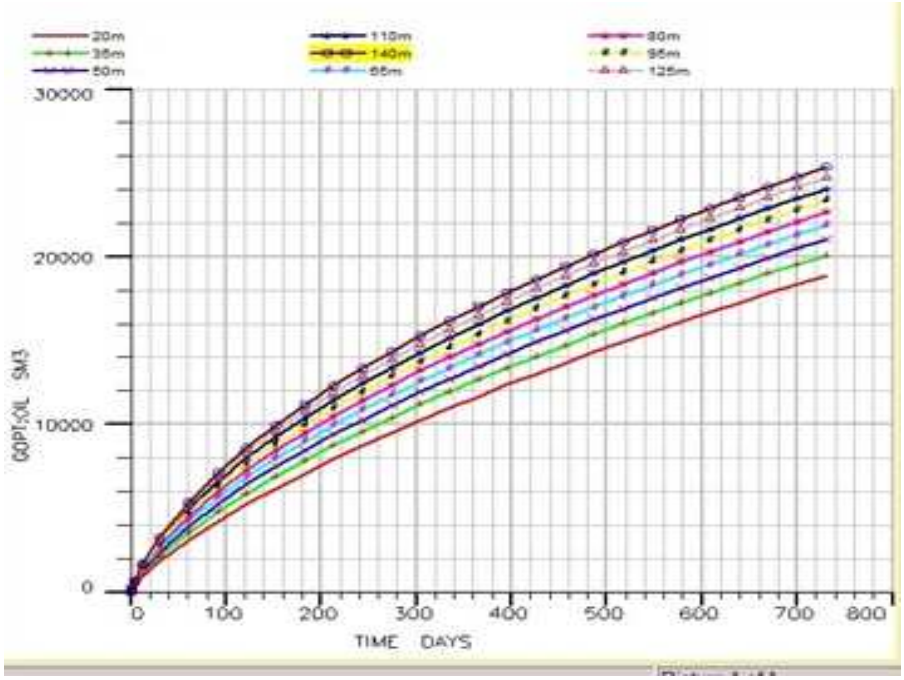

Figure 1 Cumulative oil production under different fracture half-length

As can be seen from the figure, with the increasing of the fracture half-length, the cumulative oil production is increasing, when the fracture half-length increases to about 120m, with the increasing of fracture half-length, the increasing rate of cumulative oil production is small. Considering economic factors, it is not economical to continue to increase the fracture half-length, so we take 120m as the optimal fracture half-length.

**The optimization of fracture conductivity.**Select the fracture half-length as 120m, and then select the fracture conductivity as 10D.cm，20D.cm，30D.cm，40D.cm，50D.cm. After running the program, the cumulative oil production under different fracture conductivity is obtained. Put the 5 curves together and analyze, the results are as follows:

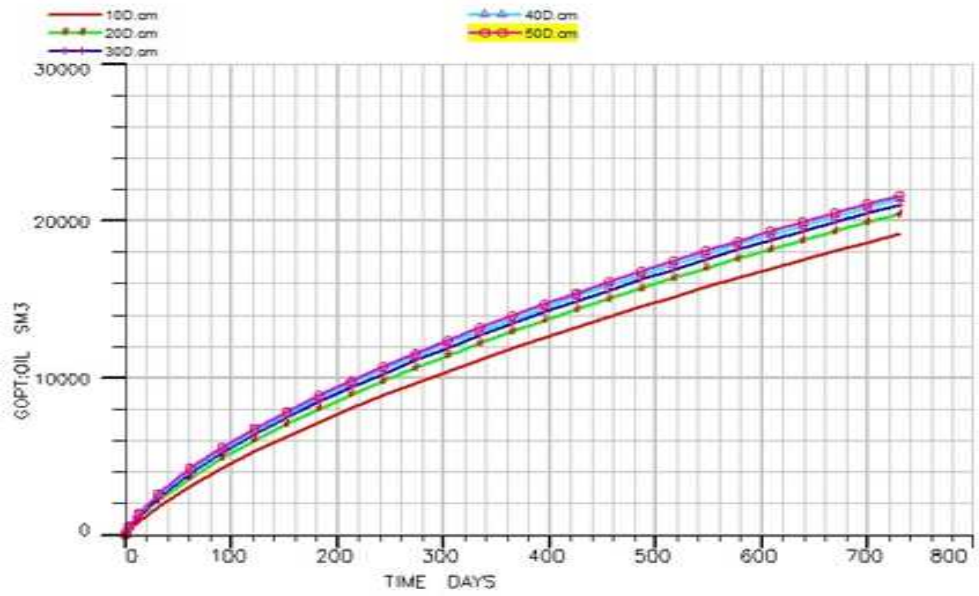

Figure 2 The cumulative oil production under different fracture conductivities.

As can be seen from the figure, with the increasing of fracture conductivity, the cumulative oil production is increasing. When the fracture conductivity increases to 30D.cm, the effect of fracture conductivity on the cumulative oil production is small (almost equals to zero). Considering economic factors, the optimal fracture conductivity is 30D.cm.

**The optimization of fracture number .**Select the fracture half-length as 120m, and the fracture conductivity as 30D.cm, and found 5 models with the same parameters except for the fracture number. Select the fracture number as 2, 3, 4, 5, 6. After running the program, the cumulative oil production under different fracture numbers is obtained. Put the 5 curves together and analyze, the results are as follows:

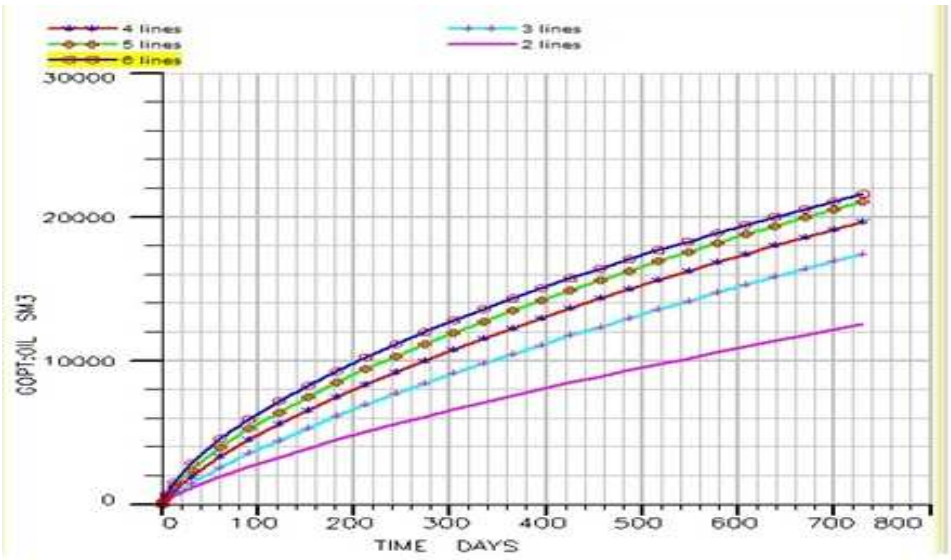

Figure 3 Cumulative oil productions under different fracture numbers

As can be seen from the figure, with the increasing of the fracture number, the cumulative oil production is increasing. When the fracture number increases to 5, the effect of fracture number on the cumulative oil production is small. Considering economic factors, the optimal fracture number is 5.

**The selection of acid system**

The selection of the acid system is based on the reservoir temperature, rock type, rock composition, the optimization result of fracture parameters, and the impacts of acid viscosity on the height of the fracture. Since the reservoir temperature of Yubei1-3 horizontal well is high, and consists a large proportion of carbonate, the calcite content is very high, and there is plenty of limestone and dolomite, it can be designed to alternatively inject the crosslinked acid and the gelled acid. According to the optimization results of the fracture parameters, the fracture conductivity is 30D.cm. Though field tests, the corresponding fracture heights under different acid viscosities are shown as follows:

Table 3 Fracture heights under different acid viscosities.

| Acid viscosity mPa·s | Inject rate $m^3$/min | Volume $m^3$ | Fracture height m |
|---|---|---|---|
| 51.2 | 5 | 700 | 46.59 |
| 107 | 5 | 700 | 53.71 |
| 159.5 | 5 | 700 | 57.95 |
| 195 | 5 | 700 | 60.48 |
| 238.7 | 5 | 700 | 63.34 |
| 317 | 5 | 700 | 69.13 |
| 358.9 | 5 | 700 | 70.05 |
| 380 | 5 | 700 | 71.13 |

Considering all the factors, the crosslinked acid is selected as the main acid type, hydrochloric acid is used to make crosslinked acid, the concentration of hydrochloric acid should be at around 20%.When the acid system is determined, we can begin to simulate the acid fracturing construction by using FRACTPROPT software, and optimize the construction parameters.

**The optimization of construction parameters**

**The optimization of injection rate.**The acid etched fracture length is affected by the acid filtration and the acid-rock reaction. The acid filtration is affected by the characteristics of the reservoir and the acid system. The injecting rate determines the flooding rate of acid in the fracture. Lower flooding rate means more acid filtration near the wellbore, so that the active acid seepage distance can be increased by increasing the injection rate. Considering the need to increase the active acid seepage distance, the high injection rate should be selected. However, the injection rate is limited by the friction, the device performance, and the network pressure. This paper mainly studies the acid injection rate.

Select the fracturing fluid viscosity as 200mpa.s. The viscosity of the crosslinked acid is selected as 205mPa.s. The viscosity of the gelled acid is 40mpa.s. Respectively input the injection rate $3m^3$/min，$5m^3$/min，$7m^3$/min，$9m^3$/min into the FRACTPROPT software and run the program. Observe the change in fracture length, fracture conductivity under different injection rates. The simulation results are as follows.

Table 4 Fracture length under different injection rates

| Injection rate (m3/min) | 3 | 5 | 7 | 9 |
|---|---|---|---|---|
| Dynamic fracture length(m) | 92.6 | 138.7 | 133.2 | 130.4 |
| Acidic erosion fracture length(m) | 83.4 | 129.41 | 126.60 | 121.71 |

Comparing the tables and figures above, when the injection rate is $5m^3$/min, the fracture conductivity decline is smooth. When the fracture half-length reaches to 120m, the fracture still possesses conductivity to some degree. In this view, the optimal injection rate is $5m^3$/min.

**The optimization of acid volume.**The acid unevenly etches the fracture surface, so that the fracture will possess conductivity. The acid volume determines the fracture conductivity and effective length. Because of the acid filtration and the high speed of the acid-rock reaction, the effective half-length of the fracture will not increase in proportion to the increase of the acid volume. In order to obtain the optimal 120m fracture, different acid volumes are used to realize to optimization of acid volume.

The injection rate has been determined as $5m^3$/min, and the main acid is crosslinked acid with viscosity 204mPa.s, input the acid volume $300m^3$, $500m^3$, $700m^3$ into the FRACTPROPT software. Then, run the program, so that we can obtain the fracture length and fracture conductivity under different acid volumes. The simulation results are as follows.

Table 5 Fracture length under different acid volume

| Acid volume (m3) | 300 | 500 | 700 |
|---|---|---|---|
| Dynamic fracture length (m) | 92.4 | 142.8 | 185.0 |
| Acidic etched fracture length(m) | 85.01 | 129.4 | 161.5 |

According to the tables and figures above, when the acid volume is $300m^3$, the fracture conductivity is too small. When the acid volume is $700m^3$, the fracture conductivity curve becomes steep. When the acid volume is $500m^3$, the fracture still possesses conductivity to some degree when the fracture length reaches to 120m. Considering all the factors, the optimal acid volume is $500m^3$.

**Pump injection program.**Alternatively inject the gelled acid and the crosslinked acid into the reservoir. The injection rate of crosslinked acid is $5m^3$/min, and the volume of crosslinked acid is $300m^3$. The injection rate of gelled acid is $6m^3$/min, and the volume of gelled acid is $300m^3$. According to the simulation, the dynamic fracture length is 163.3m, the acid etched fracture length is 148.7m. The fracture configuration is as follows:

Then, we can compare the fracture conductivity after alternative injecting and only using crosslinked acid, the results are as follows:

According to the tables and figures above, alternatively injecting 300m3 crosslinked acid and 300m3 gelled acid has better effect than injecting 500m3 crosslinked acid only. Therefore, the optimal crosslinked method is alternative injection method.

## Conclusions

1. The acidic fracturing technology can be applied in Yubei region.
2. The optimal fracture half-length is 120m, the optimal fracture conductivity is 30D.cm, and the optimal fracture number is 5.
3. The optimal injection method is alternatively injecting crosslinked acid (with volume $300m^3$ and injection rate $5m^3$/min) and gelled acid (with volume $300m^3$ and injection rate $6m^3$/min).

**Keywords:** pressure gradient; permeability; $CO_2$ flooding; pressure gradient

**Abstract:** This paper mainly studied the influence of starting pressure gradient in $CO_2$ flooding. The capillary pressure of low permeability reservoir is much larger than the ordinary reservoir, so that the influence of starting pressure gradient can not be ignored. Since $CO_2$ flooding will be widely used in the development of low permeability reservoirs, it is necessary to study the influence of starting pressure gradient. This paper mainly used Runge Kutta Fehlberg Method and Adams Fourth-order Predictor-Corrector to solve the black oil model, which was founded to study the process of $CO_2$ flooding. These two methods considered the starting pressure gradient during the $CO_2$ flooding, and the influence of reservoir permeability and crude oil density were studied by founding black oil model and use these two methods to solve the model. We have compared the production rate with staring pressure gradient and without starting pressure gradient.

## Introduction

In China, water flooding is widely used in almost all the oil field. However, in low permeability reservoir, the effect of water flooding is bad. Because of the low permeability, it is hard for water to flow in the reservoir. In this case, $CO_2$ flooding technology in low permeability reservoir is developing rapidly. The numerical simulation of $CO_2$ flooding technology is playing an important role in the application of $CO_2$ flooding in the real oil field. Normally, the Eclipse software is used to simulate the process of $CO_2$ flooding, and black oil model or compositional model were founded to study characteristics of oil production with this technology. Unfortunately, the starting pressure gradient can not be considered in the Eclipse software, which is one of the main short-comings of Eclipse software. We will be too positive when we estimate the oil production rate without considering the starting pressure gradient. This may be dangerous when we decide some project plans according to such estimation, so that it is necessary to consider the starting pressure gradient when we simulate the process of $CO_2$ flooding in low permeability reservoirs.

## Theoretical model

**Black oil models.**In this project, black oil model was founded to simulate the process of $CO_2$ flooding in low permeability reservoirs. The seepage flow mathematical model and computer software for black oil is called black oil model. In traditional definition, black oil is non-volatile compared with light volatile oil, and it is heavy and dark. Now, the definition of black oil model is much wider, which are models with there features stated below:

(1) Contain three phases: oil phase, water phase, gas phase.
(2) Oil phase contains two components: oil component and gas component.

**Numerical method.**Runge-Kutta Method of Order Four can be described as:

$$w_0 = \alpha$$

$$k_1 = hf(t_i, w_i)$$

$$k_2 = hf(t_i + \frac{h}{2}, w_i + \frac{1}{2}k_1)$$

$$k_3 = hf(t_i + \frac{h}{2}, w_i + \frac{1}{2}k_2)$$

$$k_4 = hf(t_{i+1}, w_i + k_3)$$

$$w_{i+1} = w_i + \frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4)$$

## Basic geological information

## Result from Eclipse

**Reservoir permeability's influence on oil production.**We has chosen different reservoir permeability. After running the program, we obtained different oil production rates. Then, the relationship between reservoir permeability and oil production rate can be expressed as the curve below:

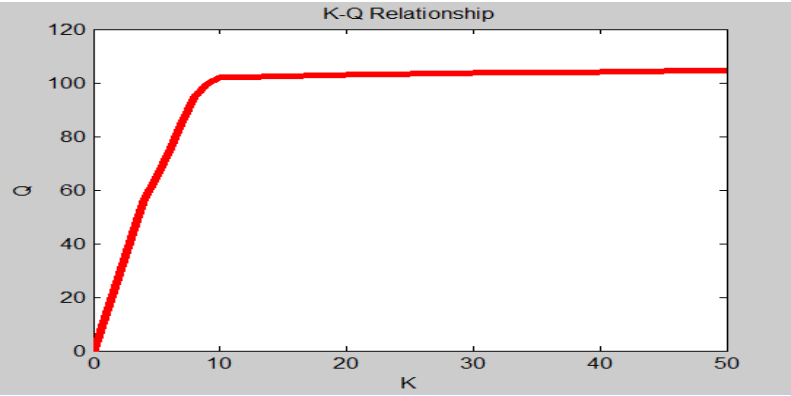

Figure 1 Relationship between permeability and oil production rate

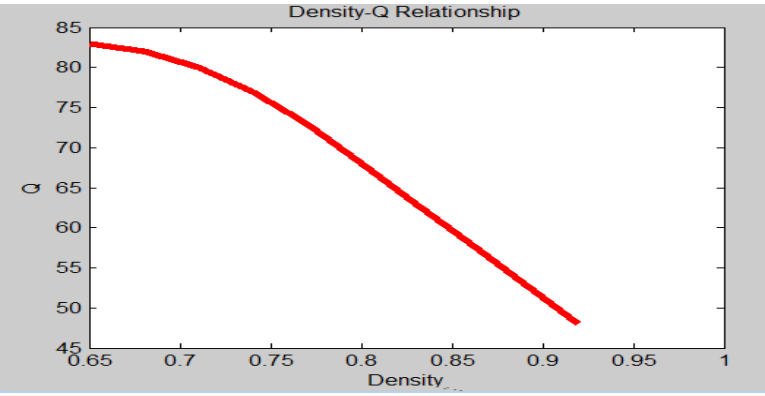

Figure 2 Relationship between oil density and oil production rate

**Results from numerical analysis methods**

A significant short-coming of Eclipse software is that the starting pressure gradient can not be considered when founding a black oil model. In this case, we will positively estimate a much higher production rate than the real one. In low permeability reservoirs, because of the low porosity and low permeability, the capillary pressure in these reservoirs are much higher than other ordinary reservoirs, and the interfacial tension in the capillary also causes significant resistance to the fluid flow. Obviously, it is necessary to consider the starting pressure gradient when simulating the $CO_2$ flooding in the low permeability reservoir. In this paper, Runge Kutta Fehlberg Method and Adams Fourth-order Predictor-Corrector were used to found the $CO_2$ flooding black oil model. Both methods have three main steps: match the reservoir permeability –oil production curve and the crude oil density-oil production curve obtained from Eclipse; consider the starting pressure gradient and modify the codes, so that we can get the modified reservoir permeability-oil production curve and crude oil density-oil production curve; compare the two curves, and analyze the influence of starting pressure gradient.

**Match the curves from Eclipse**

**Runge Kutta Fehlberg Method.**First, we use Runge Kutta Fehlberg method to found the numerical model of the low permeability reservoir. Program 1, program 2 and program 3 was created in this process to match the relationship between the permeability and oil production rate and the relationship between the crude oil density and the oil production rate with the results from the Eclipse.

Change the permeability in program 1, the corresponding production rate will be obtained.Table 4 shows the relationship between reservoir permeability and oil production rate according to the results from program 1.

Table 4 Relationship between reservoir permeability and oil production rate

| i | K(md) | Q(m3/s) |
|---|---|---|
| 0 | 0 | 0 |
| 1 | 1 | 9.519283 |
| 2 | 2 | 20.88549 |
| 3 | 3 | 29.88468 |
| 4 | 4 | 39.7442 |
| 5 | 5 | 53.31579 |
| 6 | 6 | 60.26761 |
| 7 | 7 | 67.30559 |
| 8 | 8 | 81.99021 |
| 9 | 9 | 99.1983 |
| 10 | 10 | 1.03E+02 |
| 11 | 20 | 103.5 |
| 12 | 30 | 104 |
| 13 | 40 | 104.7 |
| 14 | 50 | 105 |

Then, according to the data in Table 4, program 2 was created to do interpolation. After running program 2, we got figure 3, which reflects the relationship between the reservoir permeability and the oil production rate. We can compare figure 3 with figure 1.

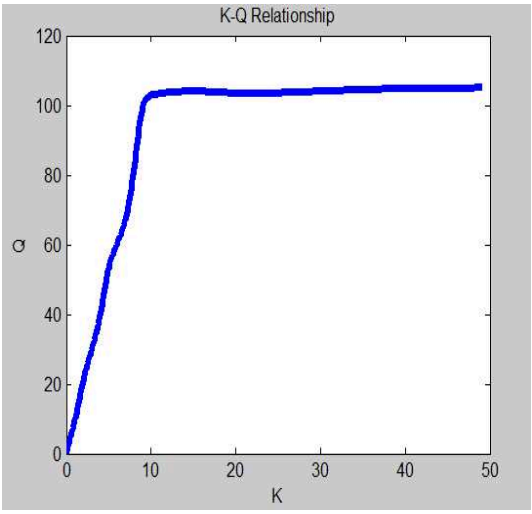

Figure 3 Results from Matlab

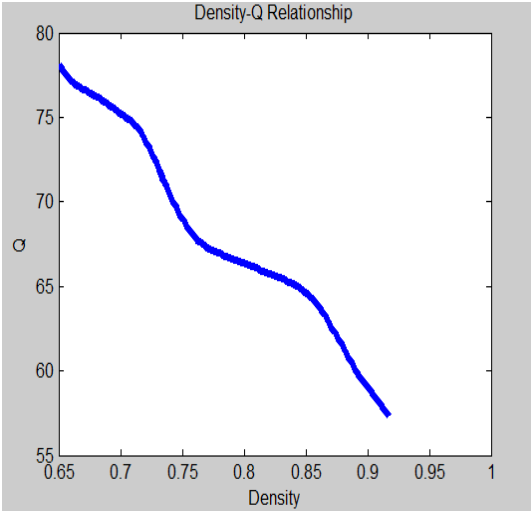

Figure 4 Results from Matlab

By comparing the results from the Matlab and the results from Eclipse, we can see the maximum relative error of the calculated permeability-oil production rate by using Runge Kutta Fehlberg method is about 16.7 %.( we assume the results from Eclipse is accurate in this case).

Then, let the reservoir permeability remain the same, and change the oil density in program 1. After running the program 1, we will get the corresponding oil production.

After running program 3, we got figure 4, which reflects the relationship between the oil density and the oil production rate. We can compare figure 4 with figure.

By comparing the results from the Matlab and the results from Eclipse, we can see the maximum relative error of the calculated oil density-oil production rate by using Runge Kutta Fehlberg method is about 8.2%.(We assume the results from Eclipse is accurate in this case).

## Conclusions

1. It is practical to use numerical analysis method to improve black oil model when solving the problems in petroleum engineering, such as considering the starting pressure gradient in the numerical simulation of injecting $CO_2$ to develop low permeability reservoirs.

2. Runge Kutta Fehlberg Method can effectively simulate the black oil model, but the oil production rate will diverge when we use Adams Fourth-order Predictor-Corrector to solve the same equation. Obviously, it is better to use Runge Kutta Fehlberg Method to solve the similar problems in petroleum engineering.

3. In low permeability oil reservoirs, the influence of starting pressure gradient is significant, while in high permeability oil reservoirs, the influence of starting pressure gradient is weak.

4. With the increasing of oil density, the influence of starting pressure gradient on oil production rate will decrease. However, in low permeability reservoirs, the effect of starting pressure gradient will still remain in a high value even if the oil density is high. The effect of starting pressure gradient can never be ignored in low permeability reservoirs.

5. From the result of Eclipse, we can conclude that the oil production rate will increase with the increase of reservoir permeability, and the oil production rate will decrease with the increase of oil density.

**Keywords:** pressure gas and water; spray; effective range ; droplet size; parameters

**Abstract.** In order to find out the factors influencing self-suction spraying with pressure gas and water performance, the working principle of the spray was analyzed, orthogonal experiments were conducted, in which influenced of different air flow, bronchia- nozzle distance, nozzle diameter as well as the diffusion angle on the effective rang and spray particle size were tested, the optimal matching of parameters was obtained. The results showed that, the optimal configuration parameters could be obtained by orthogonal test of self-suction spraying with pressure gas and water, to provide data support for the design of efficient spraying device.

## Introduction

Industrial dust exists in many industries and fields, such as mining industry, metallurgy industry, manufacturing industry, which has been a serious threat to the safety production and staff occupational health. As an effective measure of water spraying dust control technology, it is widely used. However, the conventional spray has deficiency (lower dust removal efficiency and higher water consumption), to solve the problems effectively, the self-suction spraying with pressure gas and water technology was put forward, and related experimental study was made.

## Principle of self-suction spraying with pressure gas and water structure

Self-suction spraying with pressure gas and water is characterized by the mixture of high pressure on gas water as the jet medium and the suction power, seen as the combination of compressed air water spray and suction spray.

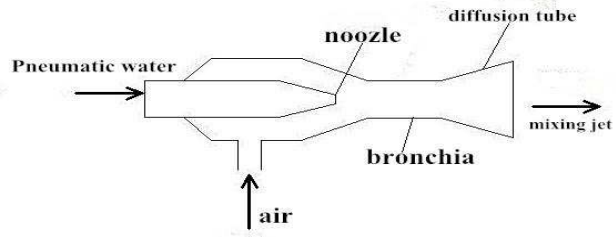

**Figure 1** Structure of self-suction spraying with pressure gas and water

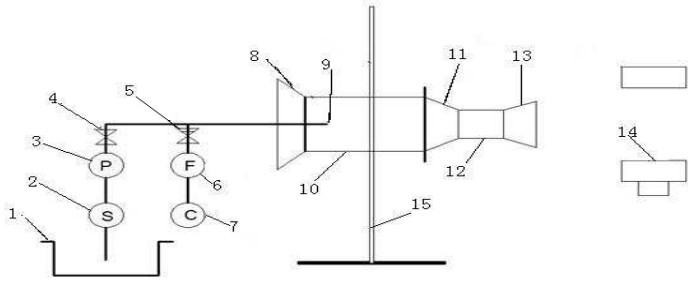
Self-suction spraying with pressure gas and water is what shown in figure 1 .With the mixture of low pressure water and high pressure air flow through the nozzle jet at a high speed, external effect of air makes the water jet airflow disordered and broken, big diameter droplets are developed. High-speed jet momentum transformation with air at the same time makes part of kinetic energy into the jet pipe pressure, leading to the decreases of pipe pressure, and thus forms certain pressure

difference between inside and outside, sucking the air outside in [1].Mixing jet goes into the bronchia in a high speed, as a result of the bronchia diameter becoming smaller. The jet flow is certain and will be at a higher speed through the bronchia, leading to a continuous fluid breaking into droplets. Droplets with particle size larger will be further broken into smaller droplets under the action of air flow. When mixing jet runs into diffusion section, the interaction of gas and droplets will form a small bubble, which has the very high speed due to the effect of air flow, breaking as the surrounding pressure decreasing at the same time, the droplets are further broken.

The suction spray can reduce the spray droplets size effectively and improve the atomization effect. It also has characteristics of self-priming spray, the high-speed mixed gas water jet as the suction power, which can further improve the atomization effect. Due to the use of high pressure air as power of the spray, low water supply pressure can meet the needs of the spray and that reduces the demand on water pressure, to a certain extent, saves the water resource.

**The test system and the solution**

The main devices were shown in figure2. Experimental water was tapwater from municipal network water supply, aspirated into water supply line by high pressure water pump and controlled by the valve.



1 - water tank; 2 - high pressure water pump; 3 - pressure gauge; 4,5- the one-way check valve; 6 - flowmeter;7 - air compressor; 8 – wind collector 9 - nozzle;10 - suction chamber; 11 - reducer; 12 - bronchia; 13 - diffusion tube; 14 - particle size measuring instrument; 15 stents

**Figure2** Self-suction spraying with pressure gas and water system

The main parameters of structure of the sprayer were as follows: wind collector inlet diameter of 140 mm, the wind collector length of 30 mm; suction chamber diameter of 80 mm, length of 115 mm; reducer contraction half Angle of 18 °; bronchia diameter of 70 mm, length of 5 mm; diffusion tube angle alpha took 30 °, 45 ° and 60 ° respectively; bronchia- nozzle distance could be adjusted to 50 mm and 67 mm, 84 mm; the nozzle diameters were 2 mm, 3 mm, 4 mm respectively.

The spray particle size SMD (Sautur Mean Diameter) value and the effective range (L) [2] were chosen as spray performance index, spray particle size was tested by Winner318 laser particle size analyzer, the range was measured directly with metric scale [3].

The experiment used the orthogonal design method [4]. Test factors and levels were shown in table 1, four levels were randomized.

**Table1** Factors and levels

| level | A compressed air flow ） | B (nozzle aperture ) | C (diffusion angle ) | D （bronchia-nozzle distance） |
|---|---|---|---|---|
| 1 | 15 $m^3$/h | 2 mm | 30° | 50 mm |
| 2 | 20 $m^3$/h | 3 mm | 45° | 67 mm |
| 3 | 25 $m^3$/h | 4 mm | 60° | 84 mm |

Testing scheme with $L_9$ ($3^4$) orthogonal table arrangement, the test results were shown in table 2. Just nine times experiment was carried out to understand the corresponding factors which affected the performance of spray.

**Table 2** Experimental plan table and results

| NO. | A compressed air flow | B nozzle aperture | C diffusion Angle | D bronchia-nozzle distance | performance index | |
|---|---|---|---|---|---|---|
| | | | | | range (m) | SMD (μm) |
| 1 | 1 | 1 | 1 | 1 | 1.50 | 71.1 |
| 2 | 1 | 2 | 2 | 2 | 2.0 | 53.9 |
| 3 | 1 | 3 | 3 | 3 | 1.85 | 66.4 |
| 4 | 2 | 1 | 2 | 3 | 2.00 | 68.2 |
| 5 | 2 | 2 | 3 | 1 | 1.86 | 39.9 |
| 6 | 2 | 3 | 1 | 2 | 2.40 | 63.0 |
| 7 | 3 | 1 | 3 | 2 | 2.35 | 73.0 |
| 8 | 3 | 2 | 1 | 3 | 2.44 | 44.7 |
| 9 | 3 | 3 | 2 | 1 | 2.32 | 58.3 |

**Test result and analysis**

The test data in table 3 was analyzed, the average level of various factors $K_{ij}$ was obtained, corresponding to different factors of poor $R_i$ (see table 3). Poor reflects the influence of various factors on the target size. As shown in table 3, in terms of effective range, $R_A > R_D > R_B > R_C$ ;in respect of the spray particle size (SMD), $R_B > R_D > R_A > R_C$. So the order of the four factors impact on the effective range was: compressed air flow > bronchia-nozzle distance > nozzle aperture > diffusion angle; The order of the influence on the spray particle size was: nozzle aperture > bronchia-nozzle distance > compressed air flow > diffusion angle.

**Table 3** Data analysis

| Program | | A | B | C | D |
|---|---|---|---|---|---|
| range (m) | $K_{Ij}$ | 5.35 | 5.85 | 6.34 | 5.68 |
| | $K_{2j}$ | 6.26 | 6.30 | 6.32 | 6.75 |
| | $K_{3j}$ | 7.11 | 6.57 | 6.06 | 6.29 |
| | $\overline{K_{1j}}$ | 1.78 | 1.95 | 2.11 | 1.89 |
| | $\overline{K_{2j}}$ | 2.09 | 2.10 | 2.10 | 2.25 |
| | $\overline{K_{3j}}$ | 2.37 | 2.19 | 2.02 | 2.10 |
| | Rj | 0.59 | 0.24 | 0.09 | 0.36 |
| SMD (μm) | $K_{Ij}$ | 191.40 | 212.30 | 178.80 | 169.30 |
| | $K_{2j}$ | 171.10 | 138.50 | 180.40 | 189.90 |
| | $K_{3j}$ | 176.00 | 187.70 | 179.30 | 179.30 |
| | $\overline{K_{1j}}$ | 63.80 | 70.77 | 59.60 | 56.43 |
| | $\overline{K_{2j}}$ | 57.03 | 46.17 | 60.13 | 63.30 |
| | $\overline{K_{3j}}$ | 58.67 | 62.57 | 59.77 | 59.77 |
| | $R_j$ | 6.77 | 24.60 | 0.53 | 6.87 |
| | $K_{Ij}$ | 86064 | 82615 | 113778 | 107508 |

| | | | | | |
|---|---|---|---|---|---|
| Complex (L/SMD) | $K_{2j}$ | 114038 | 138309 | 106226 | 107393 |
| | $K_{3j}$ | 126572 | 105750 | 106670 | 773 |
| | $\overline{K_{1j}}$ | 28688 | 27538 | 37926 | 35836 |
| | $\overline{K_{2j}}$ | 38013 | 46103 | 35409 | 35798 |
| | $\overline{K_{3j}}$ | 42191 | 35250 | 35557 | 37258 |
| | $R_j$ | 13503 | 18565 | 2517 | 1460 |

Levels mean reflected the level of the various factors affect index . The level of the four factors average size in the effective range of sorting, respectively: $\overline{K_{3A}} > \overline{K_{2A}} > \overline{K_{1A}}$ , $\overline{K_{3B}} > \overline{K_{2B}} > \overline{K_{1B}}$ , $\overline{K_{1C}} > \overline{K_{2C}} > \overline{K_{3C}}$ , $\overline{K_{2D}} > \overline{K_{3D}} > \overline{K_{1D}}$; In the aspect of the spray particle size sorting, respectively : $\overline{K_{1A}} > \overline{K_{3A}} > \overline{K_{2A}}$ , $\overline{K_{1B}} > \overline{K_{3B}} > \overline{K_{2B}}$ , $\overline{K_{2C}} > \overline{K_{3C}} > \overline{K_{1C}}$ , $\overline{K_{2D}} > \overline{K_{3D}} > \overline{K_{1D}}$.

Can be concluded from this, in terms of effective range, when the air flow rate, nozzle aperture, diffusion angle and bronchia nozzle distance of 25 $m^3$ / h respectively, 4 mm, 30 ° and 67 mm, spraying worked as the best effective range; In terms of the spray particle size SMD, when the air flow rate, nozzle aperture, the diffusion Angle and bronchia nozzle distance of 20 $m^3$ / h respectively, 3 mm, 30 °, and 50 mm, spray particle size SMD was minimal.

Since the greater the effective range, the better, and the spray particle size as small as possible (the reciprocal of the spray particle size the more the better). So the ratio of two indicators (L/SMD) was a comprehensive index to select the optimal model. Still can use intuitive analysis it was concluded that the mean level of various factors ($K_{ij}$) and their corresponding poor $R_i$ (see table 3) : $R_B > R_A > R_C > R_D$, $\overline{K_{3A}} > \overline{K_{2A}} > \overline{K_{1A}}$ , $\overline{K_{2B}} > \overline{K_{3B}} > \overline{K_{1B}}$ , $\overline{K_{1C}} > \overline{K_{3C}} > \overline{K_{2C}}$ , $\overline{K_{3D}} > \overline{K_{1D}} > \overline{K_{2D}}$.Can be concluded that the four factors influencing the comprehensive efficiency from big to small order: B>A>C>D,and the optimal combination model for $A_3B_2C_1D_3$, so eventually want to choose the optimal combination model was compressed air flow for 25 $m^3$ / h, nozzle aperture of 3 mm, the diffusion Angle of 30 ° and bronchia-nozzle distance was 84 mm.

## Discussion

From the above analysis, in the effective range and the SMD of best combination factors C and D levels in the critical level[5], in order to understand the critical level of the index, the influence of the factors to the level of the mean as the ordinate, analysis of four factors index (see table 2).

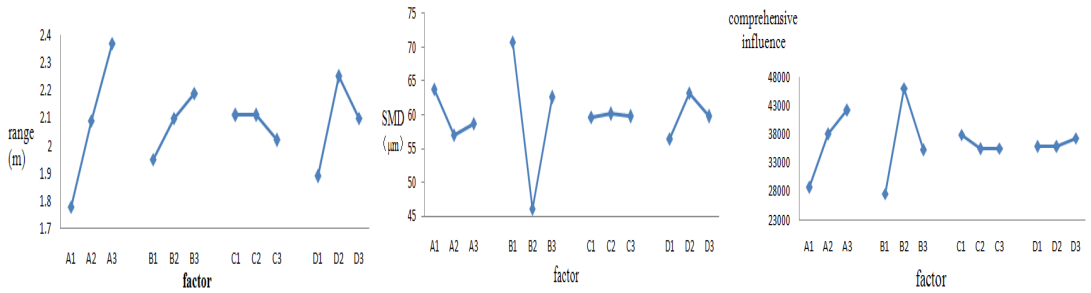


**Figure 3**. Factors and index analysis

(1) Compressed air flow When the value changed from 15 to 20 $m^3$/h, the effective range and the comprehensive factors significantly increased, and the spray particle size decreased obviously; Flow from 20 $m^3$/h to 25 $m^3$/h, increased significantly, while the spray particle size increase, the effective range of the comprehensive factors. Suggesting that take factors A between at 20 ~ 25

$m^3/h$, spray particle size of optimal value, the factors of A greater than 25 $m^3/h$ level had increased the effective range and the comprehensive factors would also help.

(2)Nozzle aperture When the size changed from 2 mm to 3 mm, the effective range and comprehensive factors increased rapidly, while the spray particle size decreased significantly; but from 3 mm to 4 mm effective range and the spray particle size increases the comprehensive factors which showed that B near the 3 mm was better.

(3) Diffusion angle When angle changed from 30 to 45 degrees, the spray particle size increased, the effective range was almost the same as significant reduction in the comprehensive factors; but from 45 degrees to 60 degrees spray particle size was reduced, effective range fell while the comprehensive factors raised slowly which suggests that the good was less than 30 degrees.

(4) Bronchia- nozzle distance Which can be found from the factor index analysis diagram, bronchia nozzle distance from 50 mm to 67 mm.The effective range and the spray particle size were both rising, and comprehensive factor index falling. When the bronchia nozzle distance from 67 mm to 84 mm ranges and the spray. Particle size was decreased effectively, comprehensive factor index would be on the rise. This showed that take factors D greater than 67mm can make comprehensive factors larger increase.

This conclusion was under the condition of this experiment, the results of other conditions remain to be further studied.

## Conclusion

In this paper, the self-suction spraying with pressure gas and water technology related technology was researched, and through the orthogonal experiment preliminarily determining the compressed air flow, the structure of the nozzle aperture and spray on the range of a self-suction spraying with pressure gas and water and spray particle size effects. Study showed that the four factors influence on the effective range of the order was: compressed air flow from>nozzle aperture>diffusion angle> bronchia-nozzle distance, and the order of the influence on the spray particle size was: nozzle aperture> bronchia nozzle distance> air flow diffusion Angle, to the order of the comprehensive factors were: nozzle aperture>compressed air flow>diffusion angle > bronchia-nozzle distance.

**Keywords:** surface deformation; tectonic-stress-type mining; FLAC3D; shift line

**Abstract.** Analysis of the surface deformation law in mines can provide a significant guide to safety operation of important structures around. For mental mine, field monitoring and simulation are the major methods to study its surface deformation. Chengchao iron mine is a typical mental ore. Taking it as background engineering, the Flac3D is used to simulate its engineering geology condition and mining technology, and study its surface deformation law. It turns out that the simulation results are very close to the field monitoring data. With the mining on, important structures such as ore dressing workshop and new auxiliary shaft will go into the shift line range. It is necessary to adjust the mining program for the safety of the important structures.

## Introduction

Metal mining is very different from coal mine in strata structure, morphology of ore body, occurrence conditions and mining methods. In mental mine, surface deformation from underground mining can be considerably complicate for varied facts. The forecast of shift angle and sink angle is always inaccurate, which makes the mine's construction planning often improper and land acquisition and residents relocation scope too small. Sever economic lost has been caused and serious threat has been made to the safe operation of mine [1, 2]. So, it is a significant issue to do research on the surface deformation law from underground mining in mental mine.

Chengchao iron is of tectonic stress type and has complicate engineering geology conditions. The underground mining has made the surface deform severely and collapse time after time [3, 4]. This paper aims at studying the surface deformation law of western area of Chengchao iron, by employing FLAC3D to simulate its engineering geology and mining technology. Finally, the change of shift line in the process of mining and the deformation of ore dressing workshop and new auxiliary shaft are known.

## Engineering background

Geology situation

Chengchao iron [5, 6] is located in Ezhou city Hubei province, which belongs to hilly area. The major strata include granite, sandy shale, marble and diorite.

The preferred tectonic tracks in mine are faults and joints. The most important fault is Chengchaobei fault whose dip direction is 190° and dip angle ranges from 47 degree to 80 degree. The hanging wall is marble and the downthrown block is granite. The preferred joints include two groups, whose strike directions are 330 degree and 30 degree respectively, and dip angles are both 70 degree.

Before mineralization, Chengchao iron had experienced intense tectonic movement repeatedly, in which the tectonic stress is considerable complicate. According to the field stress tests, the present orientation of major principal stress is parallel to the ore body strike. In granite, the principle compressive stress is 18.63 Mpa, azimuthal angle is N87°W which is close to the east-west direction. The ratio of horizontal stress to the vertical one is 1.4.

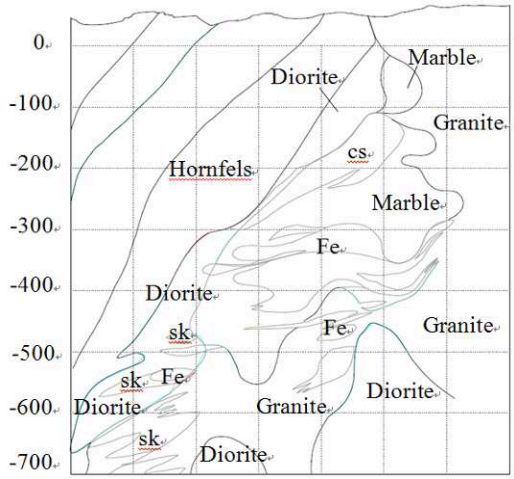

Fig.1 Geological profile of section No.35

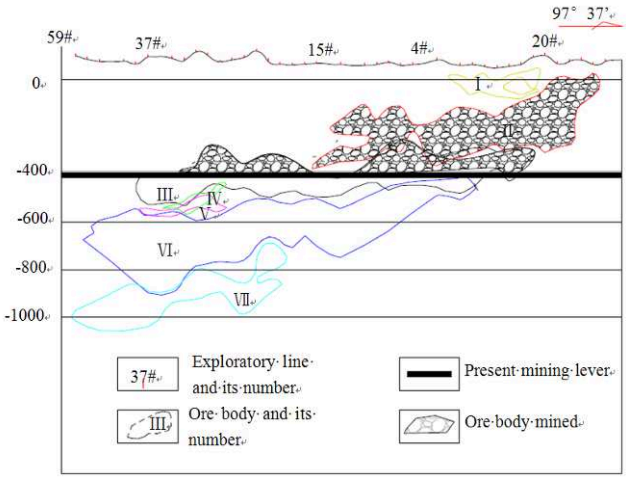

Fig.2 Geological section showing longitudinal map projection of ore bodies

Brief introduction of mining

The ore deposit is divided into two parts east and west by the 15th exploratory line. The western mine has four ore bodies, namely Ⅲ, Ⅳ, Ⅴ, Ⅵ, Ⅶ. Now, Ⅲ ore is being mined. For Ⅲ ore, the east-west length is 850m, the south-north length ranges from 120m to 450m.

In Chengchao iron, the ore is always mined with sublevel caving method and no sill pillar. The finished levels in Ⅲ ore include -290m, -307.5m, -325.5m, -342.5m, -358m and -375.5m. Both of -395m and -410.5m are now being mined. The golf perimeter of the finished level is shown in fig.3.

Fig.4 Model meshing

**Numerical simulation with Finite difference method**

With finite difference method FLAC3D, study the surface deformation law of western area of Chengchao iron, by simulating its engineering geology conditions and mining technology. Determine the change of shift line in the process of mining and the deformation of ore dressing workshop and new auxiliary shaft.

Description of computing model

The scope of model should be set larger than the estimate range of influence. Besides, considering the occurrence of ore body, the model scope was determined. Take the ore body as geometry center, set the vertical direction from surface to underground -1000m level, east-west length 3000m, south-north length 2000m. The mesh model is shown in fig. 3.

The lithology and geological structure simulated in model have been simplified. The granite and granite porphyry are grouped the same category and the scatter altered skarn, dioritic porphyrite and chloritization diorite. Choose their average parameter as the calculated one. For geology structure, only Chengchaobei fault and the preferred joint whose occurrence is 238° ∠60° are taken into account.

Boundary conditions

The side faces of model, including front, back, left and right faces, are applied slide constraints restraining their normal displacement. And the bottom is fixed without displace in all direction. The horizontal tectonic stress is applied, which makes the $\sigma_{xx}$ is 1.28 times of $\sigma_{zz}$, $\sigma_{yy}$ is 0.48 time of $\sigma_{zz}$.

Parameters for calculating

The rock constitution is of ubiquitous-joint type and the mechanical parameters of rock and joint are shown in table 1 and table 2 respectively.

Table 1 Rock mechanical parameters

| Lithology | γ kN/m$^3$ | E GPa | μ | φ Deg | c MPa | $\sigma_t$ MPa |
|---|---|---|---|---|---|---|
| Hornfels | 22.3 | 3.0 | 0.23 | 31.8 | 1.84 | 0.7 |
| Iron ore | 43.3 | 5.3 | 0.31 | 38.1 | 2.48 | 0.25 |
| Anhydrite | 28.3 | 2.1 | 0.26 | 23.9 | 1.24 | 0.12 |
| Marble | 26.7 | 2.6 | 0.28 | 30.2 | 1.70 | 0.17 |
| Granite | 24.7 | 2.0 | 0.27 | 29.6 | 1.61 | 0.16 |
| Diorite | 26.3 | 1.9 | 0.27 | 31 | 0.8 | 0.16 |
| Fault | 25.9 | 1.3 | 0.35 | 27 | 0.55 | 0.1 |

Table 2 Joint mechanical parameters

| Lithology | Kn GPa | Ks GPa | φ deg | c MPa | $\sigma_t$ MPa |
|---|---|---|---|---|---|
| Hornfels | 7.0 | 5.5 | 27 | 0.74 | 0.18 |
| Iron ore | 9.0 | 7.0 | 35 | 2.0 | 0.20 |
| Anhydrite | 5.0 | 4.5 | 22 | 1.2 | 0.12 |
| Marble | 6.5 | 5.0 | 19 | 0.26 | 0.03 |
| Granite | 6.0 | 4.3 | 25 | 0.48 | 0.05 |
| Diorite | 7.0 | 5.5 | 21 | 0.2 | 0.02 |

Set of calculating conditions

From -270m to -412.5m, the mining method simulated is sublevel caving method without sill pillar while below -412.5m, it was changed to be sublevel caving method with sill pillar. In the process, the mining time, mining location and mining method are all simulated in system.

According to the mining record, the mining activity is simulated for each 17.5m. From -290m to -500m, there are 13 sections. The detailed sets are shown in table 3.

Table 3 Mining conditions

| Number | Level | Thickness/m |
|---|---|---|
| 1 | 270～290 | 20 |
| 2 | 290～307.5 | 17.5 |
| 3 | 307.5～325 | 17.5 |
| 4 | 325～342.5 | 17.5 |
| 5 | 342.5～360 | 17.5 |
| 6 | 360～375.5 | 17.5 |
| 7 | 375.5～395 | 17.5 |
| 8 | 395～412.5 | 17.5 |
| 9 | 412.5～430 | 17.5 |
| 10 | 430～447.5 | 17.5 |
| 11 | 447.5～465 | 17.5 |
| 12 | 465～482.5 | 17.5 |
| 13 | 482.5～500 | 17.5 |

## Analysis of calculation

When the calculation finished, the results were compared with the field monitoring data. The major information will be shown as follows.

(1) The simulation before -395m lever is very close to the monitoring data in the whole deformation law and trend, except that there are a few differences in value. And the two history collapses around 2006 can be found corresponding phenomena in the simulation. It proves that the simulation is effective and the results are of guidance significance to the next mining.

(2) From the settlement contour map of 2cm shown in fig. 4(a) and total displacement contour map of 4cm fig. 4(b), the shape of critical deformation extension line in footwall mining area is like a saddle with the middle point between the new auxiliary shaft and skip shaft no northern displacement. The phenomenon can also be found in monitoring contour, which proved the validity of the simulation.

(3) The center of surface deformation moved with the shift of underground mining. When mining from -342.5m to -360m level, the center of surface deformation moved 140m eastward. When mining from -377.5m to -395m level, the center of surface deformation moved 140m in NEE. When mining from -412.5m to -430m level, the center of surface deformation moved eastward 50m again.

(4) With mining developing deep and goaf area extending, the important structures will be influenced gradually. In -342.5-360 mining stage, surface deformation extended fastest, with 290m east-west-ward and 120m south-north-ward. The new auxiliary shaft, measures shaft, ore dressing workshop and other important structures except skip shaft all go into surface deformation of 2cm. In -360-377.5 mining stage, surface deformation extended the most slowly, with 40m east-west-ward and 30m south-north-ward. In the next stage, the major direction of surface deformation is east-west. And the extending velocity is 88m per level. The shape of critical deformation range will change from ellipse to saddle.

(5) From the simulation results, the surface deformation of the place where important structures such as new auxiliary shaft locate will increase with mining developing deep. It is necessary to adjust the mining program for the safety of the important structures.

## Conclusions

The finite difference method FLAC3D has been used to study surface deformation law of western Chengchao iron by simulating the engineering geology condition and mining technology. Comprehensive analysis has been done to the calculation results, and some important conclusions have been got.

(1) The simulation results are very close to the monitoring data in the whole deformation law and trend, except that there are a few difference in value. It proves that the simulation is effective and the results is of guidance significance to the next mining.

(2) With mining developing deep and goaf area extending, the important structures will be influenced gradually.

(3) Surface deformation of place where important structures such as new auxiliary shaft locate will increase with mining developing deep. It is necessary to adjust the mining program for the safety of the important structures.

**Keywords:** Conglomerate reservoir; polymer;; static adsorption; dynamic retention.

**Abstract.** In the process of polymer flooding in porous media, polymer was detained due to interactions between surface adsorption and polymer molecules， and this could lead to negative effects on oil displacement. For polymer adsorption in Xinjiang conglomerate reservoir, HPLC analysis was adopted to study the static and dynamic laws. Results have showed that the adsorption process could be divided into 3 stages: rapid growth, slow growth and stable state. With the loss of polymer molecular weight, equilibrium adsorption quantity reduces gradually. The adsorption amount is different for the same polymer on four types of oil sands. For equilibrium adsorption, the maximum value is argillaceous sandstone, followed by conglomeratic sandstone.The third is argillaceous gravel, and the minimum is sand gravel. For polymer flooding in conglomerate cores, the dynamic retention amount of seriate conglomerate is much greater than that of fine particle conglomerate. These data have provided reference for project design of polymer flooding in conglomerate reservoir.

## Introduction

During the course of polymer flooding in porous media, polymer solution would be diluted by formation water, and it was stranded due to surface adsorption, mechanical capture, hydrodynamic trap and the interactions between polymer molecules[1]. It is certain that this retention could lead to negative effect on oil displacement.

For the polymer on surface of core particles, adsorption amount are affected by many factors, which are the types of polymer, molecular weight, degree of hydrolysis, salinity, rock composition, surface properties of particles, environmental temperature and so on. Compared with small molecules for solid-liquid adsorption, macromolecule polymer solution has many traits[2]. Nowadays, there are a lot of research on application of polymer flooding in sandstone reservoir. For polymer in sandstone, adsorption is in keeping with the Langmuir isotherm adsorption law. Rarely research has focused on polymer adsorption in conglomerate reservoir. No comparison study has been published currently about sandstone and glutenite.

## Experimental conditions and methods

**Experimental material** These adsorption experments are correlated with four types of polymer, whose molecular weight is 10 million, 15 million, 20 million and 25 million respectively. Xinjiang oilfield has provided the products of polymer. The hydrolyzing degree is 25%, and the solid content is 91.2%. Formation water and injected water were simulated by medicals, and the specific ion content were shown in table 1. In these experments, oil sand particles could be divided into four types, which are argillaceous sandstone ,conglomeratic sandstone, argillaceous gravel and sand gravel. All oil sands and core samples had came from Qidongyi block in Xinjiang oilfield.

**Table. 1 Salinity of formation water and injected water for Qidongyi Block in Xinjiang oilfield**

| Category | $HCO_3^-$ | $Cl^-$ | $SO_4^{2-}$ | $Ca^{2+}$ | $Mg^{2+}$ | $K^+$ and $Na^+$ | Salinity |
|---|---|---|---|---|---|---|---|
| Injected water(mg/L) | 146.7 | 103.0 | 33.8 | 58.0 | 8.4 | 55.3 | 405.2 |
| Formation water(mg/L) | 3407.0 | 5168.0 | 68.0 | 94.0 | 17.0 | 4525.0 | 13279.0 |

## Experimental procedure

**Static adsorption** Firstly, a series of polymer solution were conducted with the known concentration to get criterion concentration curves,, then it is need to determine the relationship of concentration with optical density by high performance liquid chromatography (HPLC) analysis[3]. Oil sand particles were mixed with polymer solution which were deployed with different concentration. The weight of oil sand is 2.0 gram for each test sample, and solid to liquid ratio is 1：9. The mixture was put in water-bathing constant temperature vibrator for 24 hours at 34.3℃[4]. The mixture was separated by high-speed centrifuge after oscillation to get solid and liquid respectively. Concentration can be got by using HPLC after adsorption of oil sands in polymer solution. According to optical density of test samples, their polymer concentration can be computed by standard curves[5]. Adsorption was calculated by fomula (1).

$$\Gamma = \frac{(C_0 - C_1) \times V}{1000G} \tag{1}$$

Where，$\Gamma$ is static adsorption capacity,mg/g；$G$ is quality of oil sands, g；$C_0$ and $C_1$ are polymer concentration before and after adsorption respectively, mg/L，$V$ is the volume of solution, mL.

**Dynamic retention** After selection of cores, it is also need to get the quality of each core. These cores were put in a vacuum for 8 hours, then they were saturated by formation water. Parameters such as porosity and permeability are available by relevant experimental instruments. Polymer solution was injected into cores after being kept in thermostat for 1 hours at 34.3℃. Collected at export of displacement device, polymer solution was analysed by HPLC to get the specific cconcentration[6]. When the concentration of injected polymer is equal to that of effluent, it is time to stop injecting polymer and to end this experiment. Dynamic retention was computed by equation (2).

$$A_r = \frac{C_0 V_f - \int_0^{V_t} C dV}{1000W} \tag{2}$$

Where, $A_r$ is the retention capacity of polymer,mg/g；$C_0$ is the concentratin of injected polymer, mg/L；$V_f$ is the volume of injected polymer,mL；$C$, $V$ are the concentration and volume of polymer

of effluent samples separately,mL; $V_t$ is the total volume of injected polymer and water,mL; $W$ is the weight of core, g.

## Experimental results and analysis

**Static adsorption** Four kinds of oil sands were employed in these experiments, and they were argillaceous sandstone , conglomeratic sandstone, argillaceous gravel and sand gravel. Argillaceous sandstone and conglomeratic sandstone contain a certain amount of clay and gravel respectively. Argillaceous gravel and glutenite refer to the conglomerate having a small quantity of mud and sand separately.

The results of polymer static adsorption experiment were showed in figure 1. With the increase of polymer concentration, the adsorption quantity also enhanced gradually for one unit quality of oil sands. As surface coverage fraction (solute on the surface of the oil sand particles) increasing, the adsorption of particles gradually reached equilibrium status when the polymer concentration is about 700 mg/L. The whole adsorption process can be divided into three stages:

Stage I: With the increase of polymer concentration, individual molecule accelerates to the surface of adsorbent, and the number of polymer molecules increases quickly on surface of oil sands. It also shows that the thread size of a single polymer molecule is small in the dilute solution, so the activated adsorption bits occupied by individual molecule are relatively less.

Stage II: Adsorption quantity increases slowly. When the adsorption of polymer on the adsorbent has reached a certain degree, a few of adsorption bits exists on the surface. Adsorption volume changes slowly with the increase of polymer concentration, and monolayer adsorption is basically saturated.

Stage III: State of dynamic stable equilibrium. Saturated by monolayer adsorption, parts of surface have adsorbed two or more layers of molecules. On the surface of adsorbent, polymer in the solution would act on molecules which had been adsorbed by particles, so polymer may be associated together. When the concentration reaches critical associating point, a structure of dynamic physical crosslinking network was formed by polymer's mutual combination. In the solution, individual polymer molecule was impacted by both of adsorbed molecules and association aggregation. Adsorption of particle surface is in the state of dynamic stable equilibrium.

Because of interactions of ions and molecules in the solution, rates of adsorption and desorption are differrent. The adsorption on surface of various particles is different for the same polymer at adsorption equilibrium. For equilibrium adsorption, the maximum value is from argillaceous sandstone, followed by conglomeratic sandstone.The third is argillaceous gravel, and the minimum is sand gravel.

Under the condition of same quality of oil sands, larger surface area is beneficial to the adsorption of polymer at active point. Take 25 million molecular weight for example, both the surface area of argillaceous sandstone and the adsorption activity point are the maximum, and the adsorption quantity is 5.6 mg/g for argillaceous sandstone. For conglomeratic sandstone, argillaceous conglomerate and sand gravel, the adsorption are 3.2 mg/g, 3.0 mg/g, and 2.8 mg/g respectively.

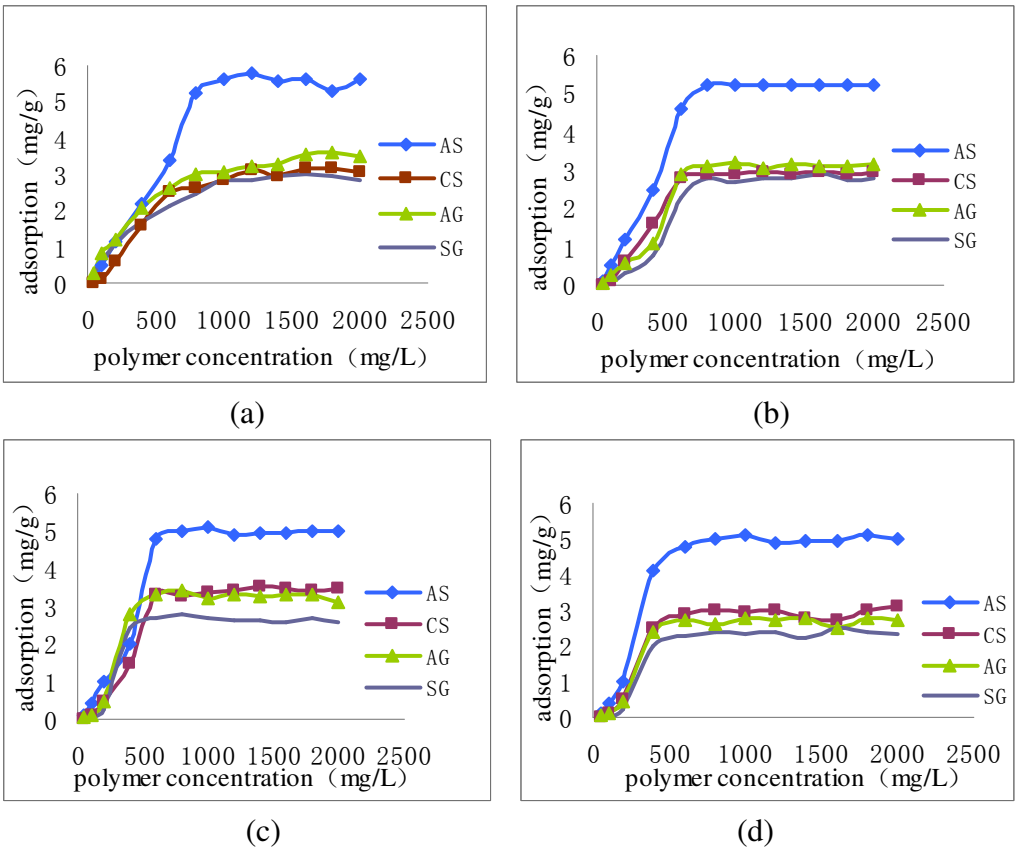

**Fig. 1 Static adsorption of polymer on oil sands**

(a, b, c, d are the polymer of molecule weight 25 million, 20 million, 15 million and 10 million respectively, these abbreviations of AS, CS, AG and SG are argillaceous sandstone, conglomeratic sandstone, argillaceous gravel and sand gravel separately)

These curves of adsorption isotherm presented "L" type. The polymer adsorption is in keeping with the Langmuir isotherm law. Under the same polymer concentration, due to the extension of molecular chains, small molecular weight of polymer has more freedom. It is easy to contact with adsorption activity bits for smaller molecule. At the same time, smaller molecular weight polymer is more likely to deviate from the sands' surface for less chance of association and more freedom, so the adsorption for small molecule is much more than that of high molecule.

**Dynamic retention** When polymer flows in porous media of reservoir, hydrodynamic trapping and mechanical capture would occur on the rock surface due to its pore structure and permeability heterogeneity[7]. It is generally considered that four mechanisms have caused the polymer retention, and they are surface absorption, mechanical capture, capture of fluid dynamics and interactions between polymer molecules[8]. Dynamic retention experiments have simulated the retention phenomenon when polymer flows through the conglomerate reservoir. These cores can be divided into two categories, fine particle and seriate conglomerate. These experiments involved gravel particles whose diameter is between 0 and 4 mm. The fine particle conglomerate's diameter is in uniform distribution of 0 to 1 mm, while the seriate conglomerate' particle diameter is in uneven distribution between 0 and 4mm.

**Table.2 Dynamic retention capacity of polymer in different cores**

| Core numbers | Category | Water permeability(mD) | Molecule weight (million) | Concentration (mg/L) | Retention capacity(mg/g) |
|---|---|---|---|---|---|
| 1 | Fine particle conglomerate | 12.1 | 1500 | 1200 | 0.66 |
| 2 | Fine particle conglomerate | 43.2 | 1500 | 1200 | 0.61 |
| 3 | Fine particle conglomerate | 145.2 | 2500 | 1200 | 0.67 |
| 4 | Seriate conglomerate | 413.0 | 2500 | 1500 | 0.75 |

For core numbers of 1,2,and 3, dynamic retention of fine particle were 0.66 mg/g, 0.61 mg/g and 0.67 mg/g separately. The difference of quantity is very small in polymer dynamic retention. The dynamic retention for core number 4 is 0.75 mg/g, which is significantly greater than that of fine particle conglomerate in table 2.

In seriate conglomerate cores, more adsorption activity points, pore throat structure and particle surface are beneficial to the adsorption retention. In the process of core flowing, polymer solution does not go along with the wall of hole. It is difficult to spread to areas with small permeability for polymer solution in the cores, so value of dynamic retention is much smaller than that of static adsorption.

## Conclusions

1. The static adsorption process could be divided into 3 stages: rapid growth, slow growth and stable state. Due to differences from composition of sand particle, surface areas and adsorption activity points, the maximum value of equilibrium adsorption is from argillaceous sandstone, followed by conglomeratic sandstone. Argillaceous gravel is less than conglomeratic sandstone, and the minimum is from sand gravel.
2. Multilayer adsorption and intermolecular association would occurred on the surface of oil sands. Polymer adsorption for 25 million molecular weight is the largest, followed by 20 million molecular weight. The third is 15 million molecular weight, and the minimal adsorption is 10 million molecular weight. Determining the allocation of pore throats, particle size distribution has a significant impact on polymer retention. The dynamic retention for seriate conglomerate is significantly greater than that of fine particle conglomerate.

# Analysis on Permeability of High Permeability Layer-penetration Oil Influencing Factors

FANG Yu [1, a]

[1] Anhui expressway holding group Co., LTD, Hefei, China 230088

[a]506155526@qq.com

**Keywords:** permeability condition, penetrating agent, emulsifier, permeation resistance, high permeability permeate layer emulsification asphalt

**Abstract:** This article from the permeability condition, half-rigid base type, material requirements, penetrating agent and emulsifier choice, permeation resistance, etc., through the analysis of the factors affecting the permeability of permeable layer of emulsified asphalt, and guided by the factors above, we developed and prepared a new high permeability permeate layer emulsification asphalt, the tests showed that it has good permeability.

## Introduction

According to Technical specification for construction of highway asphalt pavement (JTG F40-2004): All kinds of asphalt pavement's base have to splash layer-penetration and it can't be omitted when lower seal coat is installed above the base. But in the practice of engineering, permeable layer of emulsified asphalt penetration results is unsatisfactory to meet regulatory requirements[1]. Factors affecting the permeability of the permeable layer of emulsified asphalt in this article did a more detailed analysis, and based on the principles identified in the analysis, research and development of new high-permeability emulsified asphalt.

## Penetration of the layer-penetration oil condition

**Wetting function.** Therefore, after the semi-rigid regimen, grass surface must be cleaned not leave dust, mud, debris, etc., and be napping treatment. In order to increase the contact area with the primary emulsion surface, the grass-roots aggregate surface should be exposed to reach better wetting.

**Permeation.** Since the semi-rigid base is a porous structure, emulsified asphalt through the first primary surface under gravity and slowly penetrate the grassroots interior. Wetting effection and penetration are closely related. Emulsified asphalt first wetting base material and then penetrate to the base material , the smaller the wetting angle on the material surface to form, the emulsion is more easily extended in the base material and penetrate to the grass roots. The greater difference between surface tension of the emulsion and grassroots and the smaller the wetting angle emulsion formation, the smaller the penetration resistance, so the more easy to penetrate.

**The role of penetrating agent.** In the infiltration process, emulsified asphalt surface tension is relatively large, so adding penetrant is a feasible and applicable method so that it can reduce the surface tension, enhance the role of grassroots infiltration and can diffuse into the grass.

Typically, there are two ways of penetrant incorporation, one is adding quantitative emulsifier firstly, and then melt the asphalt and join the colloid; another one is added quantitative penetration to the already produced emulsified asphalt. Experience has indicated that the first way better dispersion, the property is more uniform, because penetrant with asphalt and emulsifier in sufficient shear and grind in colloid.

In the process of study, a mixed mode is used, namely the osmotic agent is added to hot asphalt, and then join the colloid mill with emulsifier solution through the preparation of oil layer. The test proved that this approach can promote the asphalt emulsion to obtain a better stability of emulsified asphalt compared to other ways, suitable for the preparation of high permeable transparent layer oil.

Gasoline, kerosene, diesel and other permeable material is often used to dilute bitumen, now kerosene is generally incorporated in the high penetration emulsified asphalt as penetrative solvent. In this study, a novel penetrant is used to improve the performance of asphalt and to promote asphalt emulsion, this penetrant non-volatile, substantially non-polluting to the environment.

## Characteristics of semi-rigid base

**Semi-rigid base type.** According to the literature[3], semi-rigid base material classified by type of structure can be divided into suspension dense structure, the skeleton structure and the skeleton dense pore structure, as shown in Figure 1 to Figure 3

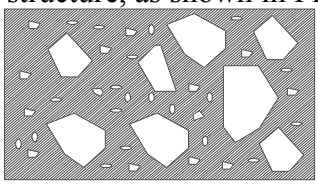

Figure1 Suspended solid structure

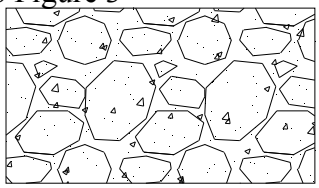

Figure 2 Framework-dense structure

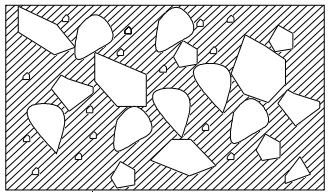

Figure 3 Framework-pore structure

In order to ensure adequate strength of the material and infiltration capacity,of transparent layer of oil and have some anti-erosion properties and crack resistance, semi-rigid material skeleton dense structure mix is more desirable transparent layer of oil on the material has a certain ability to penetrate

**Half-rigid base course surface aggregates.** Ease of emulsified asphalt into semi-rigid base is directly related to not only the bitumen droplets own intrinsic viscosity, but also the primary material composition the fine powder materials. the greater penetration resistance, the harder penetration.

Porosity, roughness and humidity and other factors of Aggregate surface also directly affect the material to absorb water in emulsion, thus affecting the emulsion breaking speed. When the surface of porous aggregates rough or loose surfaces, the water emulsion will soon be absorbed by the aggregate, to speed up the demulsification of emulsion; But on the other hand, large pore and number for emulsion infiltration.

## Analysis of factors affecting the penetration resistance

**Base surface and interface tension.** Tension between the liquid and gas phase interface is called surface tension. Tension between liquids and liquids, liquids and solids is collectively referred to as the interfacial tension. While layer-penetration material of surface tension and half rigid base material of surface tension poor value more hours, two species material between of interface tension more big, layer-penetration oil more not easily to base penetration; that base material and layer-penetration material contact area is small, and base surface voids smaller, formed of interface will tension very big , led to asphalt particles cannot in gravity role through into grass-roots. Emulsified asphalt in the penetration resistance of a half-rigid surface is mainly from the interfacial tension.

**Layer-penetration of viscosity of emulsified asphalt.** Viscosity is a major indicator reflects the quality of emulsified asphalt, construction primary control targets, directly affects the size of the viscosity of emulsified asphalt emulsion liquid. Asphalt emulsion evaporation residue content is the main factors affecting the viscosity of emulsified asphalt, evaporation residue content, the higher the greater the viscosity of emulsified asphalt; lower evaporation residue content, viscosity of emulsified asphalt will be smaller. Asphalt emulsion evaporation residue on penetration of a direct relationship between speed and depth, lower evaporation residue content, then penetrate better. Therefore, in order to ensure the osmotic effect, lower viscosity requirements are met as far as possible on the basis of modified asphalt emulsion evaporation residue content.

To explore the evaporation residue content on priming effect of emulsified bitumen viscosity and penetration, anion-crack slow emulsifier used in the study, add the appropriate amount of highly adhesive and penetrant agent, different priming emulsion evaporation residue content on half-rigid asphalt Distributor, observes its penetrant effect, as shown in table 1.

Evaporation residue levels on priming effect of layer-penetration of viscosity of emulsified asphalt Table 1

| Evaporation residue content/% | 40.5% | 42.7% | 44.5% | 45.1% | 46.8% | 47.9% | 49.2% |
|---|---|---|---|---|---|---|---|
| Viscosity of EngueraE25 | 1.68 | 1.81 | 2.0 | 2.10 | 2.21 | 2.27 | 2.41 |
| Storage stability | Good | Good | Good | Good | Good | Good | Good |
| Penetration depth /mm | 10 | 8 | 7 | 6 | 5 | 3 | 1 |

Table 1 reveals that with the increase in evaporation residue content, viscosity increases, penetration depth decreases; when the evaporation residue content of 40%,, stability is still very good, mainly due to the high viscosity of the join, better make the bitumen particles suspended in the aqueous solution, when evaporation residue content of about 40~45%, and layer-penetration oil work well

**Demulsification of layer-penetration emulsified asphalt speed.** At the time of construction, it played its bonding capabilities of emulsified asphalt, tar particles from separating aqueous, asphalt emulsion dispersion of particles gathered in knots, in aggregate or combined form a continuous cover film on the road. The developing process is shown in Figure 2-6. From a permeable layer of emulsified asphalt infiltration perspective, its emulsion speed should not be too fast.

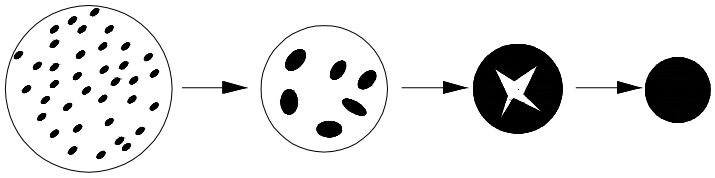

Figure 2-6 General process of decomposition of emulsion

Demulsification mechanism of cationic and anionic is a difference [4], this difference is mainly caused by Yang and anionic emulsifiers are different in nature.

Cationic emulsified asphalt emulsion through hydrophilic emulsifier molecules-amino good affinity with the aggregate surface, adsorption, forming bridges, asphalt-microspheres by emulsifier molecule this bridge reach the aggregate surface, and film formation and aggregate exposure. At the moment of filming, film of asphalt and aggregates produce larger extrusion force, moisture squeezed out of aggregate surface, making it volatile quickly. Therefore, cationic emulsified asphalt emulsion, condenses, forming quickly.

Anionic emulsified asphalt emulsion is by adhesion between asphalt and aggregate wrap aggregates. Emulsifier molecules themselves and aggregate surface compatibility, poor absorption and therefore did not play a bridge role, filming cannot occur when you squeeze the moisture out, and uniform distributions bituminous membrane surface moisture through the asphalt and aggregate bead gaps between the increasingly volatile. At the same time, due to the hydrophilic emulsifier molecules with more atoms of oxygen hydrogen-bonding association formed a solid combination of water, water evaporation is slow, time required is longer, after the moisture completely volatile, asphalt films to fully wrap aggregates. Therefore, anion emulsified asphalt emulsion, condenses, forming a long time.

**High permeability type layer-penetration oil material requirements**

For asphalt materials must be made of high quality asphalt, such as Donghai 90# asphalt. Emulsifier, demulsification and slower due to priming requirements, to make emulsion better penetration, plus decided demulsification mechanism of cationic emulsion speed too fast, this article recommends the use of slow-crack slow clotting anionic emulsifiers. Additives, in order to guarantee the new layer of asphalt emulsion to have certain character must be added with a certain volume of high viscosity to

ensure grass-roots good bonding with the surface to ensure its structural stability. In order to make emulsions with high penetration ability must be added with a certain volume of penetrating agent. This paper in order to overcome the traditional penetrating agent (such as kerosene, diesel) defects will pollute the environment, uses a new type of non-volatile, its molecular weight close to the penetration of the kerosene solvent in order to set this new layer of emulsified asphalt used as part of protecting the environment.

Based on the analysis above, select several emulsifier which emulsion slow, Donghai 90# asphalt, emulsified asphalt water-oil ratio of 45:55, not high viscosity, adding a certain amount of penetrating agent. Half-rigid specimen, judging permeability of emulsified asphalt, to filter criteria for emulsifiers, test results are shown in table 2.

Influence of emulsifier on permeability of emulsified asphalt Table 2

| Emulsifying agent type | Cationic | | Anionic |
|---|---|---|---|
| | A | C | B |
| The emulsifying process | Smooth | Smooth | Smooth |
| Emulsion speed | Mild-breaking | Slow-breaking | Slow-breaking |
| Viscosity of EngueraE25 | 2.01 | 1.98 | 1.86 |
| Amount of emulsifier /% | 1.5 | 1.4 | 1.5 |
| Evaporation residue content /% | 42.3 | 41.5 | 42.8 |
| Storage stability | Good | Good | Good |
| Penetration depth /mm | 0 | 1 | 5 |

As can be seen in Table 2, emulsified asphalt which is produced by cationic emulsifier B and anionic emulsifier C has certain permeability in the semi-rigid member, but the penetration effect of the anionic emulsifier cationic emulsifiers C is significantly better than the cationic emulsifier B. Previous engineering experience also shows that in the cement, lime, fly ash semi-rigid, since the material is highly alkaline, cationic emulsified asphalt is difficult to penetrate, the anionic emulsified asphalt material should be adopted as a transparent layer.

## Conclusions

In this paper, the layer of emulsified asphalt material, penetrating agent, emulsifier choice and requirements, semi-rigid type of aggregate penetration factors were analyzed, and then the selection of requirements is pointed out ; According to the analysis result, permeability test shows that penetration effect of high infiltration emulsified asphalt in this paper is good.

**Abstract:** Based on complex adaptive systems (CAS) theory, using the method of case studies to explore the Shaanxi Province magnesium industry cluster knowledge innovation behavior. Based on the complexity stimulus—response rules, build the knowledge innovation system of metallic magnesium industry cluster main body behavior patterns; Based on complex adaptive - learning, building the overall behavior pattern of magnesium metal industry cluster knowledge innovation system; and based on the complex level—emerge theory, build the magnesium industry cluster evolution behavior pattern of knowledge innovation system. Use CAS theory to solve the problem of knowledge innovation in industrial cluster, which offers a basis for realize the sustainable and health development of industry cluster better.

## Introduction

The important driving force of human society's development is the innovation of industry, including technological innovation and knowledge innovation. Potter [1] believes that industry cluster is a group of geographically close and interconnected companies and associated institutions, they are in the same specific industry areas. Due to the commonality and complementary, they have the industry links and affect each other. Ji-ci Wang believes that industrial cluster is a group of businesses and organizations that are geographically adjacent and interconnected, they have industry contacts and influence each other[2]. We can consider industrial cluster is industry agglomeration in geographic economic geography phenomenon because of the need for economic development in a certain region [3]. The knowledge innovation system of industrial cluster is a complex nonlinear system, there are a lot of feedback and emergence of the problem that reductionism cannot be used to explain and study. When the university of Michigan's professor Holland[4] put forward Complex Adaptive System (Complex Adaptive System, hereinafter referred to as CAS) theory, let a person find everything new and fresh. Also aroused the home and foreign scholars' study enthusiasm, they use CAS theory in their field of study. Foreign theorists have begun to use CAS theory of enterprise technology innovation cluster study the issue and began to focus on the phenomenon of innovation clusters. But overall is still in its beginning and exploring stage, the study of knowledge innovation clusters are relatively small.

## Research methods

This study uses case study method, tries to take a comprehensive view of industry cluster in Shaanxi Province, and metal magnesium based on the actual situation, in-depth study of the

knowledge innovation behavior of industrial cluster based on CAS theory. On the other hand, knowledge innovation of industrial clusters should consider industry characteristics and regional characteristics and different development phases. Based on CAS theory, the research on knowledge innovation of magnesium and other non-ferrous metal industrial cluster has not appeared basically. And the foreign and domestic research achievements can't be directly applied to the knowledge innovation of nonferrous metal industry cluster. The case study is particularly applicable to the field of new or existing insufficient research field, it is suitable for the explanatory and exploratory research[5].

**Based on the complexity stimulus—response of operation mechanism of knowledge innovation main body behavior patterns of industrial cluster**

According to the theory of Holland, stimulus - response model is used to describe the different performance of adaptive principal way of unification, it illustrates the main body ability to respond to the environment in different times. This model mainly includes three parts: detector set, IF/THEN rule set, and effecter set. Using industry cluster of magnesium which in Shanxi as an example for discuss.

Based on the analysis of the factors of the complex adaptive features of knowledge innovation of industrial cluster and influence, establishes the knowledge innovation of industrial cluster stimulus -- response model. As shown in Figure 1. The model intended to describes the shanxi magnesium industry cluster behavior and reflect the main body of knowledge innovation from the micro level behavior, and reveals the essence characteristic and the behavior mechanism of knowledge innovation .

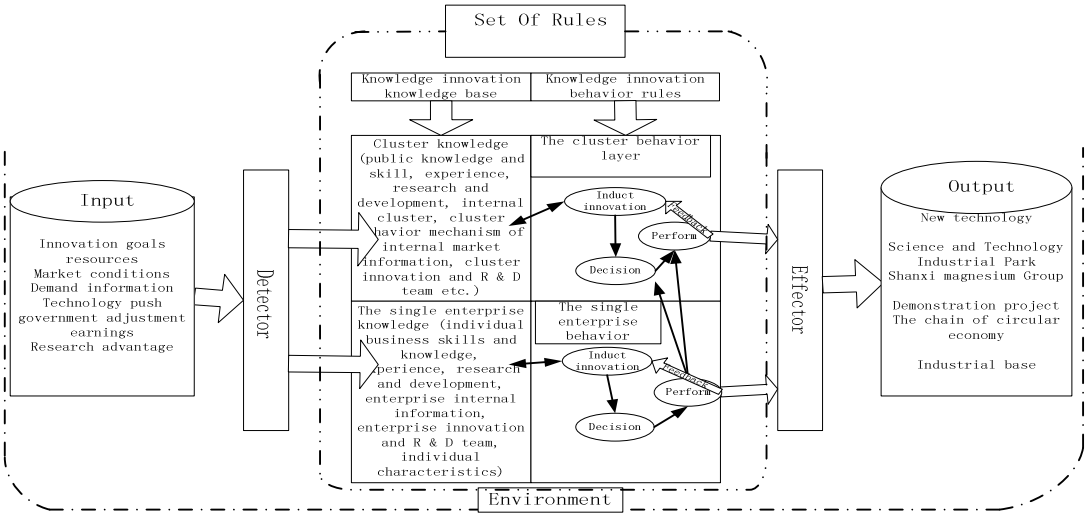

Figure 1 Shanxi metal magnesium industry clusters innovation stimulus-response model

Industrial cluster knowledge innovation influenced by four factors ,which are the front of the market pull, technology driven, enterprise internal uncertainty, government macro support. Innovation environment including enterprise innovation goals, within the cluster resource condition, metal magnesium at home and abroad market conditions, market demand, technology, the government macroeconomic regulation and control, enterprise or the entire industry profitability, development advantage. These factors of any changes will stimulate the knowledge innovation of industrial cluster, the whole environment and knowledge innovation is inseparable relationship. IF environment changes, THEN subject will through their own rules of conduct or behavior mechanism for knowledge innovation. Can be seen in the figure1, the target detector transmitted

goals to the cluster knowledge innovation subject, subject try to innovation based on existing knowledge. Since the knowledge innovation clusters are geographically close, and many companies which together form the industrial advantages, so in the process of knowledge innovation clusters will appear subject knowledge innovation and individual enterprises. Knowledge innovation of individual enterprises can't be ignored, it will serve the cluster of knowledge innovation. As a complex adaptive features of identification, flow, building block. In single enterprise cluster has its own characteristics, advantages and disadvantages, while the single enterprise knowledge innovation, information will be passed to the industry cluster, new technology and new knowledge new achievements of multiple enterprise gathers together can promote the overall development of the industry cluster, strengthen the competitiveness of the whole industry. Every achievement will feedback to the knowledge base, so as to accumulate experience for knowledge innovation in the next.

**Operation mechanism of knowledge innovation of industrial cluster overall behavior patterns based on Adaptive - learning**

Shanxi metal magnesium industry cluster as a whole is the highest level of main body of knowledge innovation system, remove the technology reform, technology research and development, self organizing group, subsystem level such as the main body to gather effect, more important is the overall model of behavior reflected Shanxi magnesium industry cluster innovation network in the industry or economic system or the international and domestic the higher level. To maintain Shanxi unique industrial clusters of metal magnesium, it is necessary to adaptive learning continuous and ongoing process of adaptive learning and knowledge innovation behavior of industrial clusters. CAS theory, the main body of adaptive learning is knowledge innovation cluster system to external changes in the environment of reaction. The reaction is subject cluster knowledge innovation system with the accumulation of experience, by changing their behavior rules, thus improving its ability to fit for the environment. Cluster body rule knowledge innovation system transformation is through the rules of local search and global search and the new rules of the discovery process [6].CAS theory attaches great importance to the active adaptation of the individual, the system still isolated individuals is almost meaningless, Only through individual and individual, individual and environment, mutual influence, interaction between system to active and appear new features, thus increasing the diversity and complexity of the whole, to provide a steady stream of power for the continuous improvement of the overall. And cluster complex adaptive learning ability of whole namely cluster behavior main body of knowledge innovation. The key for Knowledge innovation system to adapt to the dynamic changes of external environment, to achieve continuous innovation is cluster complex adaptive learning subject of knowledge innovation. So, must improve its complex adaptive learning ability in order to improve the cluster knowledge innovation ability. Based on the analysis above, the adaptive -learning mode operation of Shanxi magnesium industry cluster mechanism of knowledge innovation system which shown in figure 2.

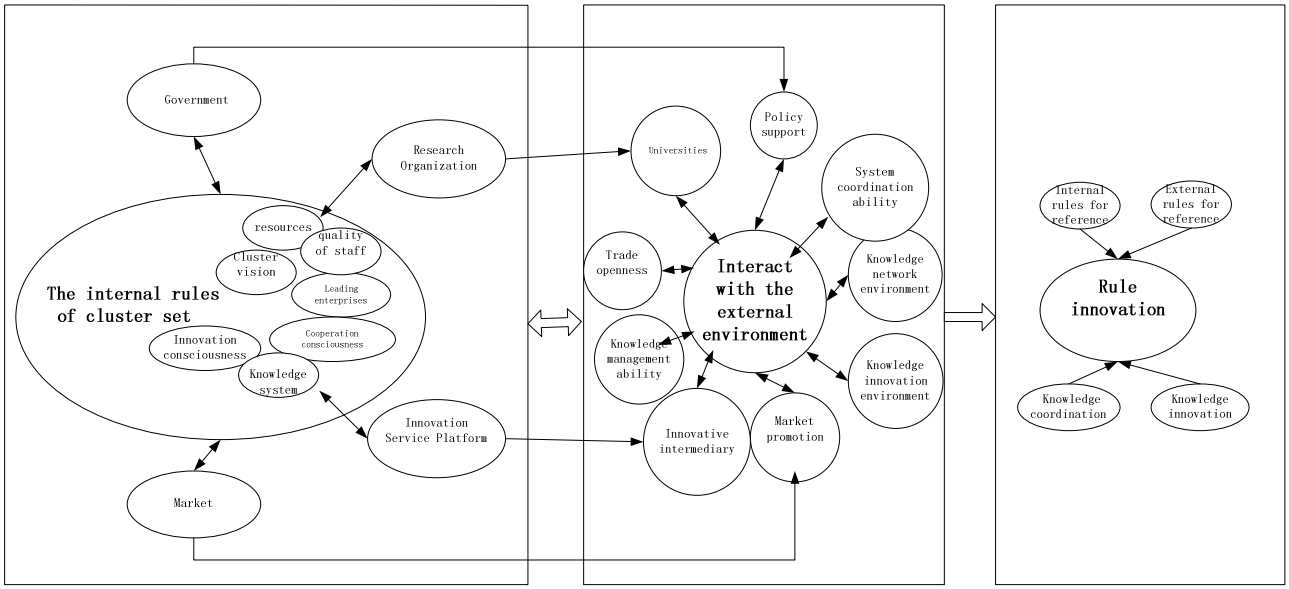

Figure 2 The adaptive – learning mechanism in Shaanxi Province metal magnesium industry clusters innovation overall pattern of behavior

**The operation mechanism of evolution patterns of behavior level- emerging knowledge innovation system based on Industrial Clusters**

The CAS theory, complex adaptive-learning of metal magnesium industry clusters innovation system will produce feedback. Positive feedback can strengthen the industrial cluster learning function, while the negative feedback is eliminated. On the one Hand, low level subject to survive within the cluster, must timely adjust, change the mode of thinking and behavior of enterprise development business and positively associated with high levels of body communicate and work together to achieve the goal. Industry cluster in the system, on the other hand, collaborative mechanism between the main body, make each level subject mutual influence, interaction, mutual constraints, have the same or similar to adapt to the learning activity (i.e., imitation). When a certain level of emergent phenomena, levels of emergent phenomena and the same will also produce, which are called "synergistic effect". With interaction and mutual influence between different level sunder the impetus of the nonlinear characteristic, produce the phenomenon of the emergence of a higher level. So, knowledge of industrial cluster innovation system with the steps of the emergent properties to evolve.

The magnesium metal industry cluster knowledge innovation system will produce three levels of emergence according to the search and selection of Shanxi Province magnesium industry cluster knowledge innovation system evolution in the scope of the rules and the way. Self-development : As you can see in the adaptation-learning model ,the first step in the search of industry cluster rule is the rules of Local Search, and start from the internal Shanxi magnesium metal industrial cluster, and make copies of itself if the rules are effective , while eliminate the rules which are invalid. This can lead to failure if search effective rules is unsuccessful. Or successfully find the effective rules but we did not create a successful application, it can also lead to the failure . Dynamic mock: After local rules' Searching and copying successfully then will form emergence, by the rules of globally search , when found the successful rules , then following the the dynamic imitation rules and eliminate weak imitation dynamic rules. If the dynamic imitation is not successful, it will lead to an unsuccessful knowledge innovation. Innovation emergence: when find the effective rules in the course of generally searching rules, we not only imitating and learning but also using it as base to reorganize rules. With the emergence of level growth in Shanxi magnesium industry cluster

knowledge innovation system , the adaptability and level complexity of Shanxi magnesium industry cluster knowledge innovation system appear to be on the rise. Based on the above analysis, we can construct the hierarchical emergence model of Shaanxi Province magnesium industry cluster knowledge innovation system evolution and show it in Figure 3.

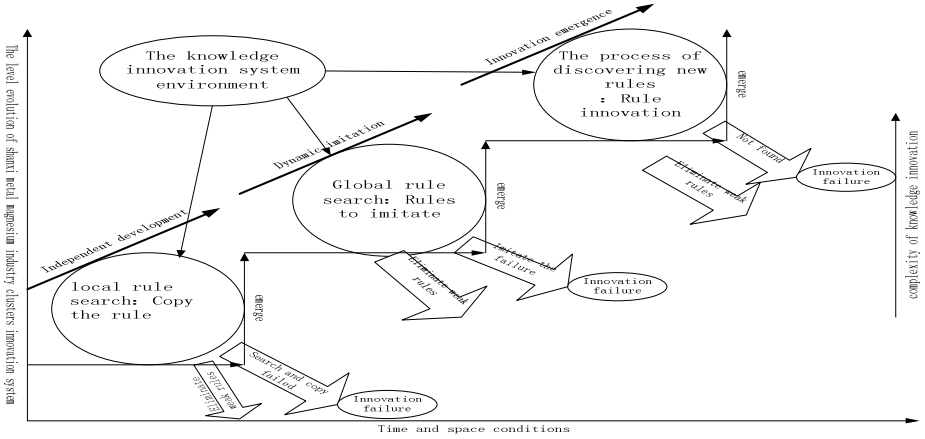

Figure 3 Shaanxi metal magnesium industry clusters innovation system level emerging patterns

## Conclusion

Knowledge innovation is a dynamic process. Knowledge innovation often appears to be uncertainty and emergent properties. The study of knowledge innovation and complex adaptive will be filled with new content with the transformation of time and space. Knowledge innovation theory and complex adaptive will constantly improved in the development.

The use of CAS theory on the research of magnesium industry clusters innovation behavior mode is a new perspective. In order to analysis and solve the problem of shanxi magnesium industry cluster's knowledge innovation, first is the innovation of individual subject behavior, then the whole. Most critical is level –emerging.

Using CAS theory to solve the problem of knowledge innovation in industrial cluster, which offers a basis for realize the sustainable and health development of industry cluster better.

# Research on Construction Technology of The High Permeability Type Layer-penetration Oil Production

HU Gang[1, a]

[1] Anhui expressway holding group Co., LTD, Hefei, China 230088

[a] 975267082@qq.com

**Keywords:** high permeability layer-penetration oil Penetration depth

**Abstract:** Current specification, does not specify the full construction process. In practice, the majority of construction units according to their own experience, hard to get reliable assurance of construction quality. In the early development of new and the high permeability type layer-penetration oil on the basis of construction of the test section of this article relies on permeable layer, oil on high permeable layer construction process, quality testing, and control indicators complete process was studied, test construction and achieved good results.

## Introduction

Asphalt concrete pavement and cement stabilized crushed stone and lime-fly ash bound macadam semi-rigid base course for interlaminar bond quality, is one of the most important factors affecting the service life of the asphalt concrete pavement, if integration between the two is not good, opening under load and rain, prone over asphalt pavement early damage. Now widely recognized, the layer-penetration oil seep into the grass-roots level in some depth, can improve the basic ability to resist water erosion, reducing water damage to the grass-roots, are important factors in reducing asphalt pavement over [1]. Thus, the layer-penetration as an important bonding of asphalt concrete pavement with semi-rigid base layer is essential and permeable layer surface of semi-rigid base materials can penetrate a certain depth, enhanced integrity of the grass-roots bonding interface and form the most important [2].

Is not stated in the specification as the existing asphalt pavement construction of concrete construction procedure and requirements, most of the construction company didn't have the experience of successful construction of the layer-penetration, so it is necessary to combine a number of successful construction projects, construction steps and points to the layer-penetration in a systematic study. Main problems of current construction of the layer-penetration as the following [3]: ① spraying oil hard penetration with base deep enough (around 5mm); ② normal solids content less concentration of 30%~35%, a spray of more than 1.2kg/m2 easily flowing surfaces along the cross slope or gradient at the grassroots level. If two spraying, the asphalt penetrate into the base level at the second time. ③ semi-rigid cleaned is not clean; ④ spread unevenly; ⑤ when the air temperature is low, due to the duration and other reasons, cannot be completely breaking; ⑥ permeable layer of construction equipment and vehicles damaged. Therefore, during the construction process should be avoided and overcome these problems in the construction of oil. Construction technique of transparent layer of oil block diagram shown in Figure 1.

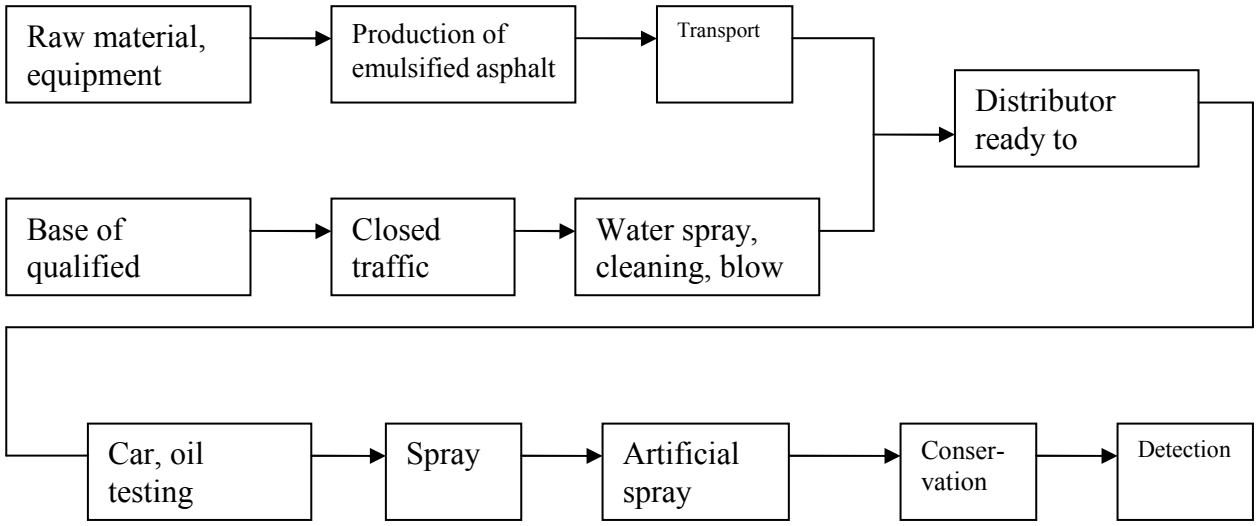

Figure 1 The high permeability type layer-penetration oil spray technology

**Preparation for construction**

**Pavement Base to prepare.** (1) Prior to construction, be obtained from the construction section "Pavement Base acceptance from".

(2) After the primary health 3~5d, brushes, dehairing machines for surface or grass-roots local "mirror" site, as far as possible so that top surface of cement stabilized crushed parts of coarse aggregate exposure and then spreading through the layer of oil.

(3) Air compressor base surface clean, cannot remain airborne particles.

(4) Before the spreading oil, must block the curbs and artificial structures, to avoid contamination.

**Select the appropriate job segment length.** As far as oil production capacity, taking into account the tanker transport distance, selecting the suitable for spreading of the day length.

**Combinations of equipment and construction personnel.** Each construction work surface should be equipped with the appropriate amount of air compressors, water truck, bituminous distributor, before the Spraying oil, should be preheated and fix the nozzle, ensuring uniformity of penetration oil spray, insulation oil tankers and command vehicle (traffic control, test) and configured with 2 sets of temperature, the amount of spray test equipment, total construction staff of about 20 people per class.

**Test sections of the construction**

Used oil contains no kerosene, test section of the 200m spreading to achieve the following objectives:

(1) To qualify for construction layer-penetration oil spray volume and blending ratios;

(2) To determine the spreading speed of the vehicle;

(3) Examination of the depth of oil penetration (≥ 5mm) and a reasonable spread of time;

(4) Determine the appropriate length of each work surface;

(5) To determine the standard construction method of priming.

Use of raw materials, construction machinery, construction method and test section of test projects are in line with the provisions of,confirmation by the supervision inspection qualified, Experimental Section Construction Summary can be written as above, reviewed by Director approval and after the company approved, starting the construction of 1km standard. 1km standard escalation summary report at the end, as declared officially started based on a large area.

**Spray time**

Penetration depth and layer-penetration oil spray time had a close relationship. Tests and practice has proved that the pervious layer of oil in semi-rigid base has not yet hardened when spraying, the penetration depth of the largest, growth and strength increases with age, oil is increasingly difficult to penetrate. Semi-rigid base after the semi-rigid materials have not been due to consolidation, base close to graded, priming oil easily penetrate half rigid base, but with the increased strength of semi-rigid materials, its internal structure will be more and more dense, and oil penetration will become increasingly difficult. Therefore, layer-penetration oil spray at the base should be laminated after forming as soon as possible.

States to the layer-penetration oil spray time rules are basically the same [4], for example, the United Kingdom specification states that for base course of cement stabilized, turbine oil should be laminated after forming an hour later at the base level as soon as possible; United States highway construction norm of base course of cement stabilized, the layer-penetration oil should be carried out immediately after the final pressure; Technical code for construction of Highway asphalt pavement provides, for permeable layer of half-rigid base oils should be immediately rolled back slightly at the base level to dry up, but have not been spraying case hardening.

However, spray priming prematurely, likely to affect the strength of the surface layer of half-rigid base, so spreading on permeable layer of half-rigid base oil, preferably after the paving of semi-rigid 3~5d sprays, which can guarantee the layer-penetration oil penetration depth, while also ensuring the strength of the surface layer of half-rigid base.

**Spraying dosage**

The layer-penetration oil spray shall be adopted according to the degree of semi-rigid surface rough trying to sprinkle OK. Distributor shall travel at a constant speed 30km/h speed, start time as short as possible, get to spread rate, running at the same time must be straight and stable. For ensuring a permeable layer asphalt distributor fully and evenly, achieves the proper penetration effect, spray to spraying dosage the back does not form an apparent runoff for the standard, the spreading quantity control in 0.8~1.2kg/m2, large engineering practice should be taken into account. Requires closed the distributor circuit on time when spraying end, so as to avoid residual oil film formed.

Distributor after the job is complete, timely organization assisted jobs, clear spray excessive amount of spilled oil runoff or uneven parts, parts of the film occurs promptly clean up to remove, when artificial spray sprayer.

**Spreading measures**

Layer-penetration oil asphalt distributor truck spraying should be used, speed and select the appropriate nozzle, spray and spray, and remained stable. After layer-penetration oil methods and measures for standard data identified, the asphalt layer can be made sprinkle, but distributor for actual construction was sprinkle, due to the large amount, it must be according to the paving area, standard content and per unit area of bitumen emulsion, calculated with reasonable accuracy synthesis of emulsion, and calculates spray distributor of road speed; a sprinkler success, does not fill as far as possible. When emulsion sprinkling, taking the following a series of measures to ensure the quality of the spray.

(1) To clean the surface of the base. First use broom to clean it twice, and then rinse with water gun, make pit slot dips dust discharge with the current roadbed.

(2) To ensure that the surface of the emulsion at the grass-roots moist (but not the water) state sprinkles in order to increase the amount oil seepage. Primary flushing of water has dried on the surface, to be carried out before the sprinkler.

(3) Strict control emulsion breaking time and the interval time of paving on the surface. Ensure that layer-penetration oil in front of the emulsion asphalt infiltration 70% complete, asphalt firmly

embedded within the grassroots, pending demulsification infiltration process, after the water evaporates, paving layer. Paving layer at the earliest time after waiting for 24h, but also not easy clearance is too long, with no more than 3d advisable.

**The layer-penetration conservation**

Layer-penetration up to seal (if any) shall be closed before the end of construction traffic; after the end of the conservation, cannot cut off the transport case, appointed commanding vehicles slow (less than 20km/h).

After spreading, generally require closed 24h traffic; if you need timely sealing job, requires demulsification and 8h may be carried out. Spray priming oil after strict traffic controls, traffic is strictly prohibited until the priming oil full penetration.

**The Penetration depth**

Technical Code For Construction of Highway Asphalt Pavement (JTG F40-2004) explicitly requested through the depth of the layer-penetration oil penetration should be no less than 5mm. If you are not into grass-roots just spilled on the surface to form an oil film, it does not play the consolidation, stability, adhesion and waterproof functions. Because the bonding layer is too thin to pavement process, the oil film is easy with grass-roots off, or is punctured by coarse aggregate for structural layers below.

**Testing method of construction quality and controlling index**

**Inspection methods**. (1) Spraying dosage detection: aluminum trays placed on the primary receiving oil, electronic weighing scales, according to pallet back-calculate the size of each square of the spray volume.

(2) Detection of penetration effect: After spreading 48h to conduct penetration testing, the drill core samples measure the penetration height shall prevail.

(3) Detection of adhesion between layers: Bonding between layers of permeable layer should include two requirements: one is layer-penetration oil and grass-roots bonded well formed turbine oil demulsification of spreading a thick layer of asphalt film, requires this layer bituminous membrane, even in the absence of shed-skin cloth and chip cases, vehicle passage would bring bitumen membrane, making a round of the India. Second, asphalt concrete layer after completion of construction, the following also to excellent adhesion between the layer and the grass-roots level and requested that the following layer and the grass-roots level drill-core samples to be joined together into a whole.

**Control indexes.** Layer-penetration with the high permeability type layer-penetration oil, major technical indicators are shown in table 1.

High permeability type oil technical requirements Table 1

| Test items (unit) | | Unit | Technical requirements | Test method |
|---|---|---|---|---|
| Demulsification velocity | | | Slow crack | T 0658 |
| Particle charge | | | - | T 0653 |
| Sieve residue on sieve (1.18 mm) | | % | ≥0.1 | T 0652 |
| Viscosity | Viscosity of Enguera E25 | | 1~4 | T 0621 |
| Evaporated residue | Residue content | % | ≤40 | T 0651 |
| | Needle penetration | 0.1mm | 100~300 | T 0604 |
| | solubility | % | ≤97.5 | T 0607 |
| Room temperature storage stability | 1d | % | ≥1 | T 0655 |
| | 5d | % | ≥5 | |

During the construction of oil, shall be as provided in table 2 and table 3, inspection of turbine oil.

Frequency of detection of oil raw material quality Table 2

| Project | Inspection frequency | Detection method |
|---|---|---|
| Viscosity | After the first approach of determining material sources, abnormal, a full set of tests, the construction of each class testing viscosity, evaporation residue 1 time | |
| Evaporated residue | | |
| Water content | | |

Construction process quality inspection requirements Table 3

| Project | Quality or allowable deviation | Inspection frequency | Detection method |
|---|---|---|---|
| Spraying dosage （kg/m2） | 0.8~1.2 | 1/paragraph per job | With cardboard weigh |
| Distributing uniformity | Uniformity | At any moment | Visual inspection |
| From the next operation the construction interval (h) | ≥24 | 1/paragraph per job | With the watch |
| Depth of penetration （mm） | ≥5 | 1/paragraph per job | Core, feet |
| Demulsification and base surface adhesion | Thicker bitumen film, not wheels belt, leaving only the round print | Spraying 48h | Visual inspection |
| Interlayer bonding | Base and below layer bonded to a whole | After paving layer below | Linger-sometimes constantly sampling |

**Construction equipment and testing instruments**

**Main machine in construction of prime coats**

Machinery equipment parts table Table 4

| Serial number | Device name | Number | Notes |
|---|---|---|---|
| 1 | Intelligent emulsifying asphalt distributor | 1 | Spray quantity does not change with speed |
| 2 | Small milling machines or dehairing machines | 2 | To meet construction requirements |
| 3 | Powerful sweeper | 1 | |
| 4 | Road sweeper | 1 | |
| 5 | Air compressor | 4 | |
| 6 | 8tWater truck | 2 | |

**Construction quality testing equipment for layer-penetration**

Layer-penetration quality testing devices Table 5

| Serial number | Instruments and equipment name | Quantity |
|---|---|---|
| 1 | Ruler or measuring tape | 1 |
| 2 | core drilling machine | 1 |

**Environmental protection measures**

(1) The layer-penetration material production, the self-system should be set up in the factory's waste disposal and sewerage facilities, in order to avoid water pollution.

(2) Prior to spraying oil, such as curbs, bridge and culvert structures must be covered, to avoid contamination.

(3) The layer-penetration oil spray volume should meet the requirements, does not cause the massive flow of slopes, farm, and pollution.

(4) Spray oil section must carry out a traffic control to avoid crosstalk with other processes in order to stop construction and transportation pollution.

**Points for attention in layer-penetration construction**

(1) Oil preferably at asphalt distributor truck spraying evenly, before the spray oil, should be preheated and dredge nozzle, nozzles should be used according to the priming oil viscosity select and ensure uniform spray, uneven asphalt distributor truck spraying times switched to hand-sprayed asphalt Distributor. A graying omission should be artificial to sprinkle, sub-skin cloth and immediately spray excessive amount of suction of dust or sand, if necessary, properly compacted.

(2) Spray layer-penetration oil to clean the road, shielding protective curbs and artificial structures to avoid contamination.

(3) The layer-penetration oil spray process should ensure that penetration oil spray volume spraying personnel shall not adjust or change.

(4) Keeping time after layer-penetration oil spray priming variety and climatic conditions is determined by testing, ensure that volatile thinners put in liquid asphalt, infiltration and evaporation of emulsified asphalt and paving asphalt surface as soon as possible to prevent vehicle damage.

(5) Temperature is below 10℃ or in case of strong wind or rain penetration shall not be sprayed.

# Research on High Permeability Layer-penetration oil production

GUAN QIN[1]

[1] Anhui expressway holding group Co., LTD, Hefei, China 230088

[a]809251326@qq.com

**Keywords:** High permeability layer-penetration oil emulsifying machine oil-water ratio

**Abstract:** Domestic and foreign road construction for many years of practical experience shows that pavement early damage and between the base and the surface layer of oil related to the quality of construction, the quality of life of the future road surface layer has a major influence[1]. In order for the preparation of high-permeable dialysis oils heavy investment in production, combined with permeable layer of oil in the production of enterprises, taking into account the conditions and existing equipment of enterprises, the paper layer on oil production, put forward the requirements for equipment, processing parameters, control indicators.

## High permeability type layer-penetration oil material requirements

High permeability layer-penetration oil using the Donghai 90# asphalt and removing acidic residue salts, kerosene is not included, and added a new type of infiltration solvent and high viscosity. Based on actual laboratory tests combined with mass production needs, presented highly permeable strata oil production scale of the main components, as shown in table 1. Suppliers can be combined with the actual situation in this range adjustment to good production stability of layer-penetration oil.

Table 1 Production scale of Various materials in the high permeability type layer-penetration oil

| Main ingredients | Scale | Notes |
|---|---|---|
| High adhesive | 0.3%~0.4% | Growth over time, the binding effect is getting better and better |
| Penetrating agent | 8%~10% | Non-kerosene diluent, non-volatile, pollution-free, on the grass-roots level without damage |
| Emulsifier | 1.4%~1.6% | Anionic emulsifier |
| Water | 52%~56% | Tap water or ground water |
| The Donghai 90# asphalt | 28%~32% | Various performance indicators than other asphalt emulsion |
| Salt-removed acid slag | 4%~5% | Recycling of asphalt modification, improve the performance of emulsified asphalt |

## The production process and control conditions

### 1.1 The choice of production equipment

Higher production in the high permeability type layer-penetration oil emulsifier is the most crucial equipment. Mechanical emulsion effects mainly on the size and evenness of the asphalt emulsion particles[2]. The ideal emulsifying machine should make the asphalt emulsion particles small, uniform, in order to enhance the stability of the emulsion. Emulsification machine is complete asphalt liquid scattered broken device. Its performance quality has important influence on the quality of the emulsion. Commonly used mulser have agitator emulsifying machine, the homogenizer mulser, colloid mill several forms of the emulsifying machine adopt more is colloid mill type emulsifying machine. Can be correctly chosen emulsifying machine equipment, will directly affect the quality of the emulsified asphalt. All kinds of emulsifying machine principle and characteristics are shown in Table 2.

Table 2 Principle and characteristics of various kinds of the emulsifying machine

| Emulsifying equipment | Principle | Characteristic | Disadvantages |
|---|---|---|---|
| Stirrer machine | Through the high speed rotating blades, cut mixing, great cut effect on melting asphalt, bitumen particles dispersed into many small, evenly dispersed throughout the emulsion to form dark brown asphalt suspension | simple and practicable | Poor uniformity of bitumen particles |
| Homogenizer class | Motor drive gear pump with high speed rotation, the input of liquid asphalt and emulsion by gear pump and reciprocating cycle of injection dispersion. Chemical injection mouth diameter is small, from gear pump to piping under a lot of pressure, from the head of a small note the asphalt emulsion and liquid mouth spewed a lot of cutting force, making it a mixture of fog. Iterative multiple times, by mechanical and hydrodynamic effects make the asphalt of asphalt into very fine particles, and are evenly dispersed in the emulsion, forming a stable asphalt emulsion | Homogenization head part is no rotating parts manufacturing processes more easily. Emulsification effect is better than that of agitator emulsification | Easy to jam, use the first requirement of asphalt and emulsifier aqueous solution carefully filtering |
| Colloid mill class | Rotation in the stator, rotor, the mixture from imported into, in under the action of centrifugal force, through the gaps between the rotor and stator, liquid asphalt in the gap by the effects of the centrifugal force and friction force of rotor, is ground into very fine particles, flow from exports | Emulsion is a high degree of refinement, good storage stability, emulsification effect is better than that of homogenizer emulsifying machine | |

As can be seen in the table: category colloid mill emulsion machine for emulsified asphalt emulsion advantage a lot, and be able to make the bitumen particles evenly, storage stability,the high permeability type layer-penetration oil production more favourable. Therefore, recommended enterprises using high permeability emulsified colloid mill class machines-oil production.

### 1.2 The oil-water ratio control

Asphalt emulsion oil and water than typically 60:40 or 50:50. For the high permeability type layer-penetration oil production, oil-water ratio control in 45:55, solid content can be as low as necessary to 40%. Enterprise on-site monitoring of oil production than the main methods: one is the observation with the naked eye, according to the worker's experience, General color is Brown, takes the form of a fluid, liquid; the second is to field test it, determination to adjust oil evaporation residue ratio, its oil-water ratio error not exceeding ± 5%.

Oil and water temperature is one of the important indicators of emulsified asphalt production. Emulsion temperature control between 55 ° c ~70 ° c, temperature control of asphalt between 120° c~135° c. Production, the temperature of the asphalt and liquid soap, according to the weather control with flexible production times. In principle the difference between oil and water temperature below 85 ° c, and less than 200 ° c oil temperature of. Prevent aging of asphalt on the asphalt temperature is too high, preventing excessive water temperature causes evaporation, water vapor and temperature too high possible cause and expansion tank.

### 1.3 Preparation of emulsifying agent solution and its temperature control

Preparation of emulsifying agent solution is directly related to high osmotic priming oil quality is good or bad. Through laboratory tests found that the emulsifier amount control in 1.2%~1.6% are relatively modest, when preparation of emulsions generally is added emulsifier in a fixed container, plus the amount of water, then adding quantitative high viscosity, the container is best installed mixer, emulsifier and high-viscosity fully soluble in water, emulsifying agent solution mix.

Preparation of high permeable dialysis due to oil emulsifier, sensitivity to the temperature of the water is relatively high, therefore, need to be adjusted according to the ambient temperature, summer high temperatures at around 50 ℃ temperature control of emulsion, spring and emulsion temperature at 60 ℃, winter temperature, latex at about 70 ℃ for temperature control. Note: when the water temperature is low (especially in winter), you should add the water temperature to 30 ℃ then add emulsifiers, for faster dissolution of the emulsifier, increase its solubility, making it fully dissolved.

### 1.4 The mix asphalt proportions and temperature control

Preparation of the high permeability type layer-penetration oil chose to remove acid residues of salt and the Donghai 90# asphalt mixing, removes the acidic residue of salt mixed into the Donghai 90# asphalt bituminous mix, through laboratory studies, the Donghai 90# removal of acidic residues of salt mixed asphalt and quality control between 7:1~6:1.

To the Donghai 90# asphalt heated to 100, desalt acidic slag when heated to a molten state mixed into the Donghai 90# asphalt, and through the blender mixing, mixing heating temperature control at about 125.

### The penetrating agent added

The laboratory test found that penetrating agent added in the mixed asphalt effect is better. Penetrating agent is a kind of thick liquid, can be directly added to the asphalt mixture, under normal temperature. If there is a phenomenon of solidification in winter, it can be heated slightly and add to the asphalt mixture, and a mixing device in the mixture in container and heating device, the mixing, and heated to the temperature of the emulsified asphalt in asphalt need, is about 125 ℃, penetrating agent adding quantity control at 8% ~ 10%.

### 1.5 The production process

Before the high permeability type layer-penetration oil production, check all valves and pipes, and the temperature of diesel preheat to 80 ℃ or so, start the diesel pump, preheat emulsification ball mill, and relevant asphalt heating pipes, after being emulsified surface hot mill and pipe heat stop heating. Control valves, joined the high adhesive with good emulsifier solution, heating the mixture of asphalt and penetrating agent to the specified temperature, start the mulser, restart the asphalt pump, adjust the oil-water ratio, can be emulsified asphalt production. In the process of emulsification, still need to be careful observation, according to the test of oil content to fine-tune.

### Adjustments and improvement of the production equipment

The high permeability type layer-penetration oil production has four links: First is the configuration of emulsifier aqueous solution; scond is through the emulsified oil production through layer; three is highly adhesive to add; Fourth, through oil product storage and use.

In this paper, the research and development of the high permeability type layer-penetration oil of asphalt materials adopted two kinds of asphalt mixture, joined the desalt acid slag, so the preparation technology with conventional through layers of oil product is different. According to this topic based on a projection of the specific conditions of the production equipment, put forward in the production

of high permeability type layer-penetration oil need to make the following improvements in the production equipment: (1)Add a small heating function, storage containers, storage need to add the material of waste tire pyrolysis tar; (2)Add a small storage container, to store the added penetrating agent; (3)Conventional asphalt containers to increase mixing features, make it mix evenly. Due to the high permeability type layer-penetration oil raw materials for Donghai 90# waste tire pyrolysis of asphalt mixture of asphalt and asphalt materials, and removes the acidic slag and penetration of salt spray into the asphalt container and stir to make it mix; (4)Emulsion between emulsion flow meter and emulsifying machine install the check valve in the pipeline. To prevent thermal pressure is greater than the emulsion asphalt, and rushed to dilute liquid jar; (5)Liquid tank installed on the device, easy mixing emulsifier solution and solution; (6)Due to good emulsified asphalt production also need to add a certain amount of high adhesive, and make its mixing, therefore, the transparent layer of oil product storage tanks to increase the mixing function.

## The production processes and its condition control

### 4.1Production precautions

(1) Before asphalt, aqueous solution entering the mulser must use fine mesh filter, lest production block; (2)Before the emulsification machine starting, must be conducted with hot diesel cleaning after use; (3)The emulsion storage containers must be sealed, in order to avoid clutter and into rain. Produce a good product should be stored in sealed container, minimize the finished product is exposed to air, to avoid the surface crust or demulsification floe; (4)Before emulsification machine and asphalt pump start-up, should first dial the pulley and shaft coupling with the hand, less because of the presence of asphalt solidification in the machine and all of a sudden start motor to burn out; (5)When you start the emulsification and there must be "water supply, oil supply after" stop the emulsion must be "just closed after oil and water".

### 4.2 The preparation works before production

(1)Transparent layer of oil production equipment in accordance with the requirements of emulsified asphalt production equipment to be checked. To ensure operated of the equipment normally, the timely processing of all kinds of problems and ensure smooth production; (2)To confirm the number required for the production of transparent layers of oil, various quantities of raw materials to ensure adequate; (3)Heating the raw material to the specified temperature: ①Advance according to the proportion of water added to the production equipment emulsifier blending tank and adds an emulsifier to the provisions of the mark, after the incorporation of the quantitative high viscosity, heated to a predetermined temperature and stir well; ②Asphalt is heated to around 100℃ in storage tanks, waste tire antipyretic asphalt is heated to around 100℃, remove the acid residue of salt and osmotic agent joined Donghai 90# asphalt container in proportion, and stir well and heat it to about 125℃.

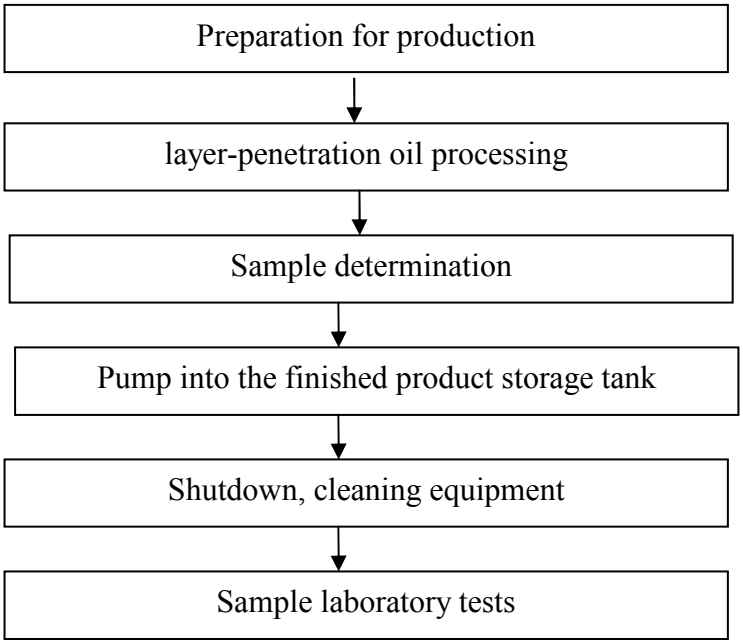

Fig.1 The high permeability type layer-penetration oil production

After the temperature of various raw materials up to standard, to begin production: (1)Asphalt outlet valve open, opens a blending of emulsifying agent tank outlet valve; (2)Start the emulsification machine, simultaneously closes emulsifying machine heat conducting oil heating system; (3)Start the emulsion pump, adjust speed, until the emulsion stability outflow; (4)Start the asphalt pumps, adjust the speed; (5)According to experience, adjust and asphalt emulsion pumping speed; (6)Probably to reach a suitable proportion, sampling determination of content, and adjust the machine according to the results of the determination; (7)Start finished taking the pump, the emulsion production pump into the finished product storage tank.

### 4.4 Production completed requirements

(1) After the outage, order in contrast to boot. Asphalt pump close, shedding all emulsifier emulsion solution, emulsion pump stopped, finally closed colloid mill; (2)Emulsified asphalt production after the cleaning equipment; (3)Sample laboratory tests; (4)Long time no longer produced, closed heat-conducting oil heating system.

### 4.5 The high permeability type layer-penetration oil storage

After the high permeability type layer-penetration oil produced should be stored in a closed container to minimize exposure to air and emulsified asphalt to avoid breaking the surface of the crust caused by or occur flocculation; emulsion to prevent separation of the mixing device may be provided in the container , but not involved in the air.

## Conclusion

This requirements for permeable layer of emulsified asphalt production equipment, production processes, process control, product storage, and so did the study, has been highly permeable strata oil production process. According to the results of this research, and successfully applied in engineering practice, making road construction quality has been improved.

[a]tsliangbing@126.com

**Key word:** hematite, griding aids, griding efficiency, mechanism of action

**Abstract:** In this paper, the effect of citric acid on the hematite was studied and the mechanism was analyzed. The results indicated that under the condition of the optimal grinding medium, compared with the result without citric acid added, with citric acid added at the mass of 0.10% of the hematite, the content of -0.074mm of grinding production was increased by 7.11%; physical adsorption and chemical adsorption which were on the surface of hematite produced by citric acid can reduce viscosity of grinding pulp, change surface potential of the hematite, and reduce the hardness on the surface of the hematite. Therefore citric acid can improve the grinding efficiency of the hematite.

Our country can use in industry of the iron ore types, including hematite ore accounted for 18%, mainly occurs in the sedimentary type, weathering leaching type and metamorphosed sedimentary type, and the volcano intrusive activities related to iron ore deposits, which belongs to the refractory mineral, mainly distributed in Liaoning, Hebei, Hubei, Hunan, Sichuan and Inner Mongolia province (area). The characteristics of China's hematite ore is: large reserves, low grade, fine particle size distribution, complex composition, mineral processing technology economics etc.

Because of the ore of fine-grained dissemination, in the -0.01mm grade, hematite accounted for 36%, -0.02mm accounted for 54.6%, and the gangue minerals quartz, biotite and clay minerals is more, grinding process prone to mud, therefore, plays an important role in grinding process.

This article with citric acid as the grinding agent, with reserves of 2.3 billion a hematite in Hebei province as an example to carry out the fine grain of lean hematite grinding efficiency, combined with grinding pulp viscosity, hematite surface potential index and the characteristics of adsorption mechanism of grinding aid are studied.

## Test materials and test methods

### 1.1 Preparation and properties of the sample

Hematite ore sample used in the test taken from Hebei LuanXian Sijiaying iron ore plant. Broken to below 2 mm, the sample after smashing blending division, a per 1kg, for subsequent grinding test and study.

#### 1.1.1 Multi-elementanalysis of ore

Table 1 Ore multi-element analysis (%)

| Element | TFe | FeO | $SiO_2$ | CaO | $Al_2O_3$ | MgO |
|---|---|---|---|---|---|---|
| Content(%) | 29.14 | 4.04 | 46.63 | 0.89 | 2.12 | 1.46 |
| Element | S | P | $K_2O$ | $Na_2O$ | MnO | $TiO_2$ |
| Content(%) | 0.083 | 0.053 | 0.41 | 0.086 | 0.090 | 0.073 |

According to the analysis results, the iron grade of 29.14%, the main impurity in the ore is $SiO_2$ and $Al_2O_3$, followed by MgO and CaO, S and P content is relatively low. $(CaO+MgO)/(SiO_2+Al_2O_3)=0.048 < 0.5$ for the acid ore.

**1.1.2 Phase analysis of iron ore**

Table2 Ore iron phase analysis results(%)

| Mineral name | Fe of magnetic minerals | Fe of Hematite, limonite iron minerals | Fe of iron carbonate minerals | Fe of iron silicate minerals | Fe of iron sulfide minerals | Total Fe |
|---|---|---|---|---|---|---|
| Content（%） | 6.34 | 22.09 | 0.35 | 0.05 | 0.12 | 29.14 |
| Iron distribution rate（%） | 21.32 | 75.66 | 1.20 | 0.15 | 0.45 | 100.00 |

The analysis result shows that full iron phase the sample average is 29.14%, compared with normal selected ore grade is high, but the deviation is small. Useful iron mineral in ore are mainly hematite and limonite iron minerals, the iron distribution rate was 75.66%, followed by the distribution of the magnetic iron accounted for 21.32%, the sum of hematite, limonite iron and magnetic accounts for about 96.98% of the iron, the ratio of other iron minerals is smaller, the content of iron carbonate accounted for 1.2% and also contains a small amount of iron sulfide and iron silicate.

**Effect of citric acid on the grinding efficiency**

Mill test specifications for XMQ-67 type 240×90cone ball mill, the effective volume of 6.65L.

Experimental grinding agent is anhydrous citric acid, also known as folic acid. The molecular formula is $C_6H_8O_7$. At room temperature, citric acid is a colorless transparent crystal or white granules or white crystalline powder, odorless, slightly deliquescent in wet air.

A lot of experiments and Optimization testing in the early, to determine the best ratio of steel ball medium in the grinding process is Φ31mm: Φ26mm: Φ19mm=12.18%: 26.00%: 62.98%, material ball ratio is 1.20, the grinding time is 3min. Each test selection of testing sample is 1kg.

**2.1 Reagent dosage and concentration test**

Experiments were carried out in citric acid grinding concentration each difference of 10%, get a reagent dosage and the grinding efficiency, the specific relationship as shown in figure 1.

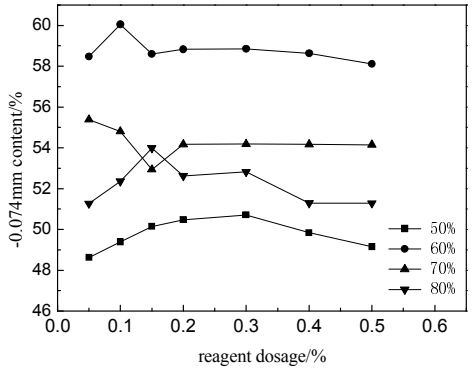

Fig. 1 The relation of amount of citric acid and -0.074mm content of products

We can see from Figure 2, under different concentration, amount of citric acid corresponding to -0.074mm content of products is different. At the concentration of 50%, the grinding efficiency as been gradually increases and increases to a maximum at0.05%~0.3%, but the grinding efficiency is 2.22% lower than no dosing, therefore low concentration is not suitable for grinding. At the

concentration of 60%, the amount of reagent concentration of 0.1% reached the maximum grinding efficiency, grinding mineral content increased in -0.074mm 7.11% higher than when no dosing, reagent rate between 0.1% ~ 0.15% when its production rate of 0.074 mm trend is flat and slightly lower. At the concentration of 70%. When the grinding concentration is 80%, adding agent has no grinding effect, but inhibited slightly. According to the test results, the final determination of citric acid optimum amount is 0.10%, the concentration of 60%.

## Mechanism analysis

### 3.1 Citrate adsorption characteristics of hematite surface

Add citric acid and not add citric acid grinding infrared spectrum diagram as shown in figure 2.

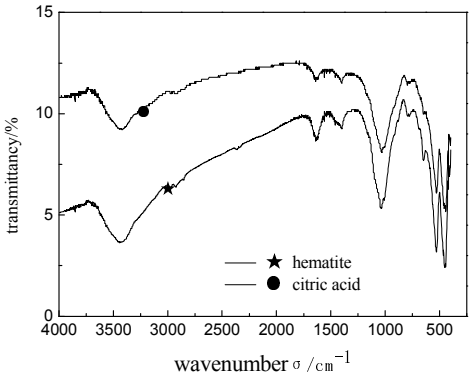

Figure 2 IR spectra of hematite and hematite in presence of citric acid

Solid star infrared spectral curves of hematite, solid round infrared spectrum curve for adding grinding agent hematite. As you can see from Figure 3, the role of micro-fine hematite and citric acid, -OH stretching vibration absorption peak moved from 3431.80cm-1 to 3423.50cm-1, while the peak surface width significantly, indicating the possible formation of hydrogen bonds, the chemical adsorption, adsorption layer is formed on the mineral surface, increases the space repulsion. The characteristic peak of 2975.58cm-1 move to 2967.28cm-1, the characteristic peak of 1635.94cm-1 move to 1631.80cm-1, the characteristic peak of 1403.69cm-1 move to 1399.54cm-1 and the characteristic peak of 1034.56cm-1 move to 1026.27cm-1, this shows the effect of hematite and citric acid, the surface has a physical adsorption or chemical adsorption, reaction with the metal cation generated hydrophilic group, enhanced the dispersion of suspended particles in the pulp, and then to reduce the effects of pulp viscosity.

### 3.2 Effect of citric acid on the viscosity of the slurry

The amount of citric acid is not at the same time, the change of pulp viscosity as shown in figure 3.

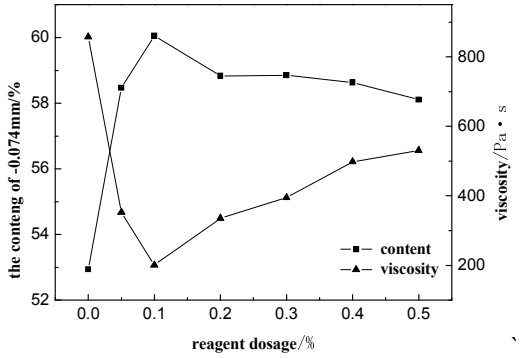

Fig.3 The influence of the citric acid on the viscosity and the -0.074mm content

As can be seen from the figure 4, the changing rule of the slurry viscosity is inversely proportional to the rate of mineral grinding. The viscosity of the slurry itself is 857.5 Pa·s. When the citric acid 0.05%, pulp viscosity decreased rapidly; When increase the amount of citric acid to 0.1%, the viscosity of pulp reached a minimum limit of 201.7 Pa·s; Then continue to increase the amount of citric acid, slurry viscosity is rising trend but not growth. Also can be seen, the addition of citric acid increased from 0.2% to 0.5%, the slurry viscosity change a little. Through the comparison of the two map, can determine the viscosity of the slurry and the grinding efficiency is a certain link under certain conditions, reduce the slurry viscosity is beneficial to improve the grinding efficiency of mill at high concentration.

**3.3 Effect of citric acid on pulp potential**

Hematite and joined citric acid hematite surface potential changing with the solution pH value as shown in figure 4.

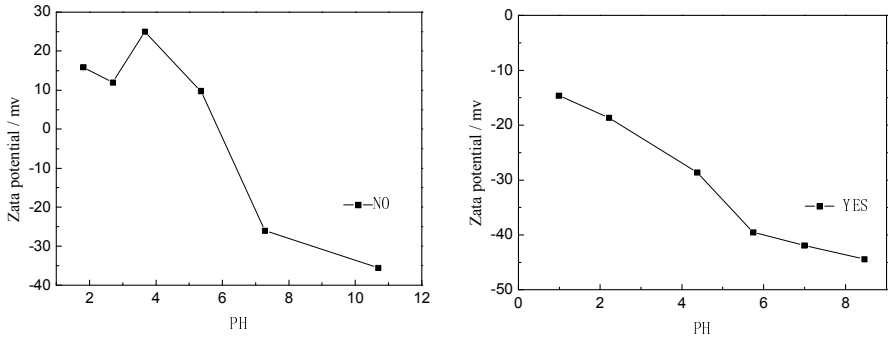

Fig.4 Relationship between before and after adding citric acid surface potential of hematite and the pH value of the solution.

As you can see from Figure 5, naturally the microgranular hematite pH value is 6.9. When adding agen, the matite electric potential from -26mV decreased to -73mV, negative ζ zeta potential of mineral surface is higher, particle electric potential absolute value is larger, strengthened the mutual repulsion between particles, enhanced the dispersion of suspended particles in the pulp, prevented re-condensation of the particles after crushing and mineral adhesive to barrel wall and so on. This is consistent with the previous slurry viscosity experiment, the dispersion strengthening, its relative pulp viscosity decreases, the flow becomes strong, reduce the grinding effects between particles.

**Conclusion**

Due to the Hebei area have more Anshan type hematite ore, its main characteristic is the dissemination size is fine, dissociation is difficult, so the grinding aid is one of the effective measures to improve the grinding efficiency and reduce the energy consumption of grinding.

In the process of hematite grinding using citric acid. In the optimal experimental conditions, add the equivalent of hematite mass fraction 0.10% citric acid compared with no added, can make the content of 0.074mm in grinding increased by 7.11%.

Citric acid form hydrogen bond on surface of hematite, the physical adsorption and chemical adsorption, reducing the grinding pulp viscosity, changed the potential on the surface of the hematite, reducing the hardness on the surface of the hematite. Through the above factors work together, to improve the grinding efficiency of hematite.

**Keywords:** Blasting face, Drive speed, Blasting parameters, Air column interval charging structure

**Abstract:** The paper studied the driving blasting mechanism and blasting parameters in working face, in order to improve the advance rate of blasting mining face in Liangzhuang mine. The research results show that taking the air column interval charging structure can reduce the peak pressure on the borehole wall, change the distribution ratio of explosion energy, decrease the smash district radius and increase the effect of secondary stress wave. To improve the energy utilization efficiency was improved in this structure, the consumption was reduced by 35.3%, the cyclical footage from 0.8m to 1.2m and crushing effect is obvious.

## Introduction

In mining engineering, almost all ore are cutting and crushing with blasting method and blasting operations account for almost 1/4 ~ 1/3 of the whole production operation cycle. In mine exploiting, the basic tunneling method is utilizing blasting excavation [1-2]. In order to speed up the advance rate of coal rock roadway, deep hole blasting method was adopted in coal seam roadway. Choosing a good cut blasting parameters, determining the loose circle, improving the utilization rate of perforation and decreasing unit consumption are became increasingly important [3]. In this paper, the scope of the demolition loose zone was determined and explosive energy was used efficiently through researching the blasting theory and blasting parameter, obtaining a good blasting effect in field industrial test.

## Engineering situation

The test coal seam was located in Liangzhuang Mine 11310 working face of Xinwen mining area, occurrence condition of the thirteenth layer coal is relatively complex, immediate roof of roadway is four gray, basic roof are four ash and sandstone, direct floor is fine sandstone and the coal bed is silty sand rock. The coal seam entrained the unequal thickness coal gangue and some places also mingled with relatively hard pebbles, physical and mechanical parameters of coal and coal gangue are shown in Table 1.

Due to the impact of these factors, in Liangzhuang Mine, production difficulty of the thirteen coal layer mining faces is large; Hole utilization rate is low, the arrangement is unreasonable, the unit explosive consumption is high and circulating footage is small. It also increase the workers' labor intensity and reduce the output of coal. According to the basic conclusion of theory analysis and laboratory model test, this paper puts forward a set of effective feasible blasting parameters, which is on the basis of a large number exploratory industrial test from the hole diameter and hole arrangement. It is also in view of the complex coal seam with coal gangue. By adopted the parameters, it is improved the production process, the construction speed and quality, achieving the high yield and efficiency goal of thin coal seam.

Table 1 Physical and mechanical parameters of coal and coal gangue

| | Bulk density $\rho$(kg/m$^3$) | Compressivestrength $\sigma_t$(MPa) | Tensile strength $\sigma_t$(MPa) | Elastic modulus E(MPa) | Poisson ratio $\mu$ | Internal friction angle(°) | Cohesion c(MPa) | P wave propagation (m/s) |
|---|---|---|---|---|---|---|---|---|
| Coal | 1470 | 11.3 | 2 | 2800 | 0.30 | 17 | 1.6 | 1380 |
| Gangue | 2600 | 63.7 | 5 | 12000 | 0.25 | 32 | 12 | 2150 |

Note: in order to describe the convenient, original blasting scheme called "plan 1", the improved blasting scheme called "plan 2".

## Experimental method

The field experiment is using coal blasting method, known as blasting mining, which is a common coal drop method in coal mine. It can be applied to all kinds of complicated geological changing conditions. The manufacturing process of coal blasting method includes drilling, charging, plugging and shooting. In order to ensure the safety in production, improve the effect of coal drop, cut down the consumption of materials and get the appropriate blasting fragmentation, it should make coal drop to transport as much as possible and improve the loading rate of blasting, trying to increase the number of each blasthole to save time. At the same time, decorating blasthole and charge weight reasonably and reducing the consumption of explosives and detonator, which are also important.

## The original blasting technical scheme

**Blasthole arrangement.** Blast hole arranged three blossom cup. The layout diagram of blast hole in working face is shown in Fig. 1. The blast hole parameters as shown in Table 2.

Table 2 Blast hole feature table

| Names | Hole-space(m) | Location | | Angle | | Hole depth (m) | Charge weight (kg) |
|---|---|---|---|---|---|---|---|
| | | From the bottom (m) | From the top(m) | Elevation, depression (°) | Level(°) | | |
| Up hole | 0.8 | 1.2 | 0.3 | 10~15 | 85 | 1.3 | 0.6 |
| Down hole | 0.8 | 0.3 | 1.2 | 10~15 | 85 | 1.3 | 1.1 |

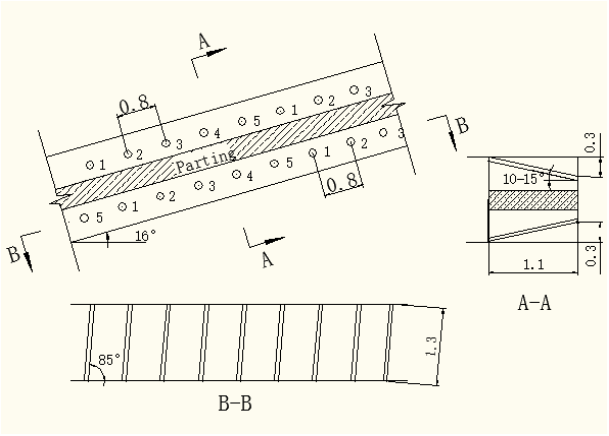

Fig. 1 Original hole layout Unit: m

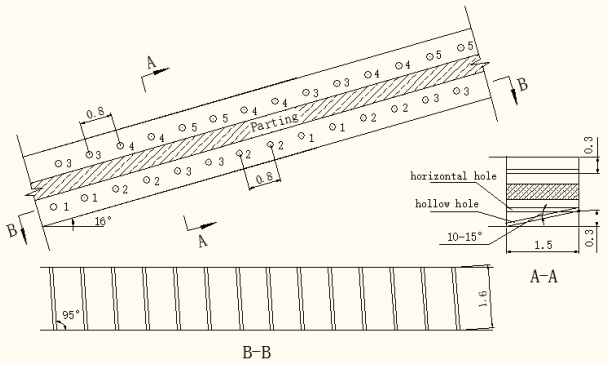

Fig. 2 Optimizing perforation plan Unit: m

**Blasting method.** Using SMZ - 1.2 portable electric drill to drill and choosing wet drilling type, diameter of the hole is φ42, the depth is 1.3m and row spacing is 0.8m. Using φ36 cartridge emulsion explosive and 1~5 millisecond delay electric detonator blasting, taking the positive charge structure series shooting. Set the explosive used water mud blast and mud blast, each charge is 25 explosives and each charging needs one-time initiating.

**Calculation of specific charge.** With each 10.0m is a unit of length calculation, hole for counting formula is N=0.5L/a. Computing available: a total of the up and down two rows is 25 blasthole, which under each row has 12.5 holes on average. The table 2 shows that each hole charge of the up row is 0.6kg, each hole charge of the bottom row is 1.1kg, a total of 21.25kg. Within the unit length blasting volume is 16.5m$^3$. Consumption calculation formula of the blasting is q=M/V, type: q-optimal charge quantity, kg/m$^3$, M-total drug consumption, kg, V-the original rock blasting volume, m$^3$. The practical unit consumption of blasting scheme is 1.288 kg/m$^3$.

The specific charge of underground caved ore related to many factors, such as ore property, explosive performance, mining amplitude width, blast hole diameter and blast hole depth. In general, the narrower the amplitude width is, the deeper the blast hole is, and the larger the specific charge is. The physical and mechanical parameters of the thirteenth coal and coal gangue as shown in Table 1. It can be seen that the universal applicable coefficient f are less than 8, so this plan remains to be improved.

**Blasting effect.** Based on field monitoring, the average circulation blasting footage is around 0.8m, the rate of residual eye is up to 39% after the blasting, and explosives consumption is relatively high (1.288kg/m$^3$) and the rate of prop wrecking is 36%, coal toward the direction of the gob throw excessive, thus increasing the labor intensity, material costs, labor-consuming, and time-consuming, not to mention efficient production.

## Test on Optimization of Blasting Parameters

**Problems.** Through field condition and the observation and analysis of blasting effects, in order to increase production and efficiency, to achieve the purpose of high-yield in thin seam, the major problems working face need to be resolved include: improve circulation footage; control throwing volume; reduce consumption of explosives.

If the top and the bottom eye explosion at the same time, the charge weight is proportional to the displacement of conveyor and the number of Collapse down pillars, in order to improve circulation footage and control the amount of coal drop, The general practices to achieve the goal are increasing the free surface, reducing consumption and improving explosives utilization ; using loose blasting, full use of explosives energy and prolong explosive stress wave and duration of action of coal will play a good role. The program intends to optimize the axial direction of linear charge, blast hole space, initiation sequence, the air column interval and so on.

**Test Scheme.** On the basis of exploratory tests, through comparative analysis, we began a formal test after obtaining obvious results. Through theoretical analysis and lots of experiment groping, summed up the blasting parameters suitable for thirteenth layer coal of Liangzhuang mine, as shown in Table 3.

Table 3 Blast hole feature table

| Names | | Hole space(m) | Location(m) | | Angle(°) | | Hole depth (m) | Charge weight | |
|---|---|---|---|---|---|---|---|---|---|
| | | | From the bottom | From the top | Elevation, depression | Level | | Vol | Kg |
| Up hole | 3#,5# | 0.8 | 1.2 | 0.3 | 0 | 95 | 1.6 | 3.0 | 0.6 |
| | 4# | 0.8 | 1.2 | 0.3 | 0 | 95 | 1.6 | 2.5 | 0.5 |
| Down hole | horizontal | 0.8 | 0.3 | 1.2 | 0 | 95 | 1.6 | 4.5 | 0.9 |
| | hollow hole | 0.8 | 0.3 | 1.2 | 10~15 | 95 | 1.6 | 5.0 | 1.0 |

In order to fully utilize the energy blast, at the bottom and top of blast hole, respectively, plus set an "empty pipe" to achieve the air column spacing, the length according to the nature of the coal seams, according to the nature of the coal mine, take the air column length of 0.1 ~ 0.15m. Use emulsion explosives Φ36 drug volume produced by Xinwen Mining Bureau and use of 1 to 5ms extension segment given electric detonators guns blasting, Dan arrangement is shown in Fig. 2. Fig. 2 shows that it is a positive charge, shooting series.

**Explosives consumption calculation.** Referring 4.3 formula to calculate the length of 10.0m as a unit, there were two rows up and down the borehole 25, both the up hole and the down hole has 12.5.Within 10m range of total drug 18.75kg. Within 10m range blasting volume of 22.5m$^3$, blasting consumption is 0.833kg/m$^3$. Explosives consumption value within the allowable range.

**Test results.** After a number of experiments, by improving existing technology and blasting parameters, and gradually expand the scope of the experiment, and achieved remarkable results, explosives consumption to reduce 0.455kg/m$^3$, and is within the allowable range. Circulating footage reached 1.2m, a 12% reduction in the collapse of the pillars, coal toward the direction of the gob reducing the amount of 80%, well shaped Muck pile, no tentacles, no nose, no residual eye, made a good technical and economic benefits.

## Conclusion

Experimental results show that the scheme two is very suitable for this coal seam.

Blasting effect is obvious by using air column interval charging structure. Coal gangue crushing significantly and achieve better crushing effect, reducing the damage to the roof and reducing vibration.

Muck pile has been effectively controlled within the design range. Reducing the workload of shovel coal, reduce labor intensity. Muck pile in tests showed ideal parabolic shape, the whole muck pile move forward, the coal toward the gob decreased by 80%.

Reducing the consumption of explosives. Since changing the charging structure, so that the energy can be effective and rational used, making consumption reduced by 35.3%.

Improved utilization of the embrasure by changing the parameters of the original blasting technology and to improve the utilization of the embrasure, making cycling footage from the original 0.8m up to 1.2m.

**Keywords:** Stopping line; Numerical simulation; Security coal pillar; Stability of surrounding rock

**Abstract.** The surrounding rock deformation of pedestrian roadway was serious under the influence of the working face. And it has affected the safety and normal use of roadway. To ensure the long-term stability of the pedestrian roadway surrounding rock and increase the coal recovery rate of working face, the paper studied the position of stopping line of 1203 working face by numerical simulation. The results show that setting 115m wide of security coal pillar between 1203 working face and pedestrian roadway that the area of stress concentration near the working face has less effect on the pedestrian roadway could better control the surrounding rock stability of the pedestrian roadway and meet the need of the long-term normal production use. It narrows the width of security coal pillar, increase the coal resources recovery rate and achieve the better economic benefits.

## Engineering Situation

The length of pedestrian roadway in Shuguang mine which is development roadway of mining area is 1500m and service life is long. And the section shape of roadway is vertical wall-round arch. Since the pedestrian roadway excavation, the surrounding rock has a certain deformation under the influence of the working face. And it has threatened the life safety of workers and affected the normal use of roadway. On the premise of ensure the stability of roadway, the paper studied the position of stopping line of 1203 working face by numerical simulation for lengthening the distance of stopping line of working face, increasing the coal resources recovery rate to achieve better economic benefit.

## Setting Initial Model

**Establish Basic Model.** The selection of FLAC3D model range is directly related to the correctness of the calculation results.Model range is too big, computer energy spent in vain,Otherwise the calculation results will be distorted and cannot give guidance for practical engineering , so it is crucial to choose a reasonable range of the model [1]. According to rock mechanics principle, influence range of stress after roadway driving is about 3 to 5 times the width of the roadway, Considering the size of the roadway, The shape of the pedestrian roadway cross-section is straight wall semicircle, and roadway height 3.5m, width 3.8m, so The length, width and height of the model is 258.2m×10m×86.6m respectively. Once you determine the size of the calculation model,a corresponding number of calculation grid is determined, In the program in order to reduce the error caused by meshing, length-width ratio of grid should not greater than 5, For the key research,the grid can be more intense.To sum up, in order to as far as possible consistent with the the geological condition at the same time, considering the modeling is convenient and reasonable. Model is shown in Fig. 1. And the x-direction is divided into up to 134 mesh, y direction is divided into up to 5 mesh, z direction is divided into 53 grids,A total of 22,320 units. The entire model from top to bottom in turn for sandy mudstone, fine sandstone, mudstone, coarse sandstone, mudstone, siltstone and fine sandstone, siltstone, sandstone, mudstone, fine sandstone, sandy mudstone, fine sandstone, sandy mudstone, fine-grained sandstone, mudstone, 1# coal, silty mudstone, fine sandstone, mudstone,

sandy mudstone, sandstone, 2# coal, siltstone, silty mudstone, 3# coal, shale, siltstone, sandstone, fine sandstone and sandy mudstone, pedestrian roadway located in the 2# coal and sandstone layers.

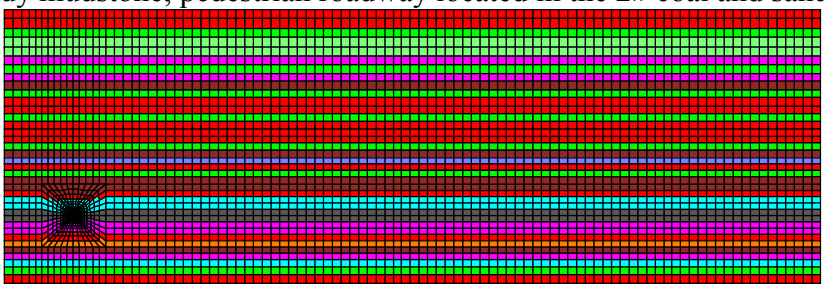

Fig. 1. Initial model

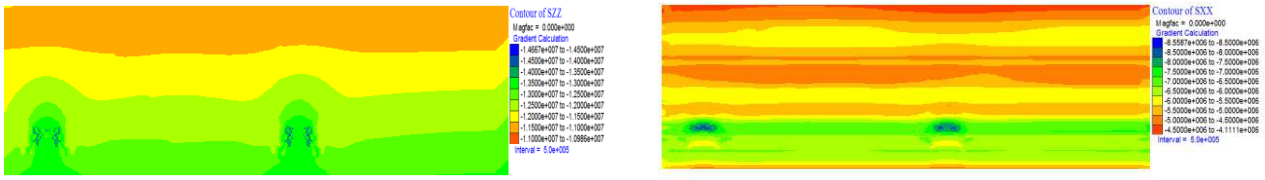
**Select the Constitutive Model.** Constitutive relation of rock and soil is defined by a number of experiments to test small amount of rock, soil elastic-plastic stress - strain curves, and then through the soil plasticity theory and the assumption with certain necessary supplementary conditions, and then promote the results of experiment to the complex stress and composite state to calculate the stress and strain of universal relations; The stress-strain relationship expressed in mathematical expressions, which is called constitutive relation of rock and soil. According to the analysis of rock mechanics, combined with information obtained from the field test, this numerical analysis use Morh-Coulomb constitutive relation

**Generation of Initial Stress.** There is no real force boundary conditions in FLAC3D, stress in the model can only balance stress with gravity stress through stress redistribution. The initial stress field is gravity stress field, and that accord with actual situation of shallow underground projects initial stress field. Main pedestrian roadway of Shuguang Mine and 1203 working face are at depth of -500m. They belong to general underground roadway engineering. The ground stress law is almost same to that of general underground engineering, mainly because horizontal stress is smaller than vertical stress. The initial ground stress field of this kind of project is generated by rock and soil gravity, $\sigma_{zz} = \rho g z$ , $\sigma_{xx} = \sigma_{yy} = \frac{\sigma_{zz} v}{1 \quad v}$. Besides, due to elastic solution, when the system reached equilibrium, yield area does no generate in the rock and soil mass [2-3].

Initial stress of model in this way is shown in Fig. 2. Fig. 2 shows that the vertical stress is about 14.67MPa, and horizontal stress is about 8.56MPa. The result meets with theoretical analysis and field test.



a Vertical stress b Horizontal stress

Fig. 2. Initial stress of model

## Stability Analysis of Main Pedestrian Roadway

Considering the actual geological conditions, the stopping line of 1203# face is differentially set 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 105, 110, 115, 120, 125, 130, 135, 140m from the main pedestrian roadway in the numerical simulation, so as to confirm best position that feasible for technology and reasonable for economic.

The rock vertical deformation nephogram when the coal pillar set at 115m is shown in Fig. 3. Different color present different deformation and deformation decreased from blue to red. Fig. 3 shows that the roof almost collapses, and maximum roof subsidence of working faces is about 4.2m. The rock deformation section of pedestrian roadway when the coal pillar set at 115m is shown in Fig. 4. After mining stop of 1203#, the surface deformation damage of main pedestrian roadway increased,

the stress concentration area transfers to deep area, especially right side destruction area and degree of damage increase than ever before. Fig. 4 shows that maximum movement of left side is 74.65mm, maximum movement of right side 94.65mm, maximum roof deflection 36.81mm, which is compared to that before stoping, surfaces deformation increase, left side -6.78mm, right side 12.54mm, roof -8.38mm. It shows that working face stoping has greatest influence to right side of main pedestrian roadway.

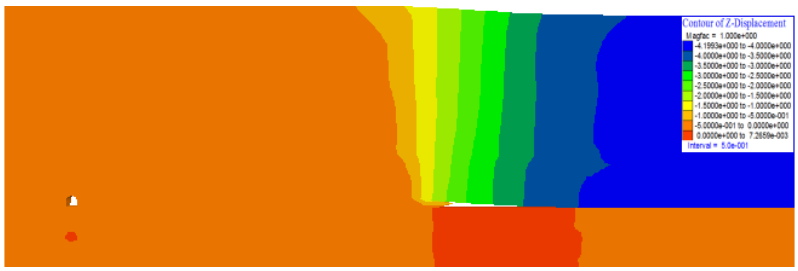


Fig. 3. Rock vertical deformation nephogram when the coal pillar set at 115m

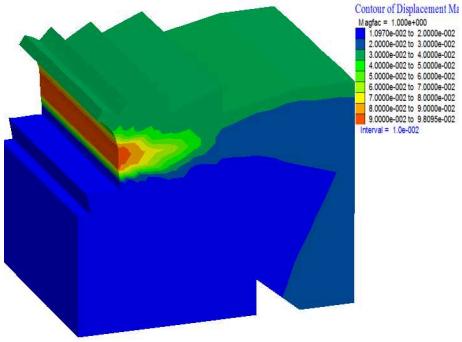

Fig. 4. Rock deformation section of pedestrian roadway when the coal pillar set at 115m

The rock vertical stress nephogram when the coal pillar set at 115m is shown in Fig. 5. Different color present different stress and deformation decreased from blue to red. Fig. 5 shows that the area of stress concentration was formed near goaf due to roof subsidence of 1203 working face. But it has less effect on the pedestrian roadway. The area of stress concentration was in the deep of surrounding rock of roadway sides because the ground stressare mainly vertical stress.

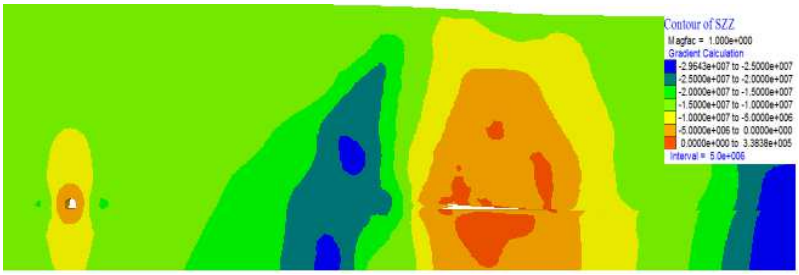

Fig. 5. Rock vertical stress nephogram when the coal pillar set at 115m

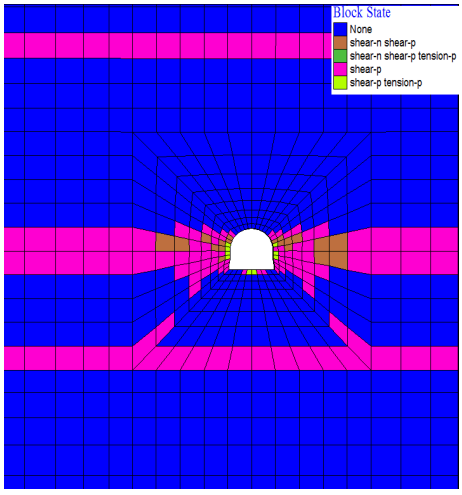

Fig. 6. Rock plastic zone distribution maps when the coal pillar set at 115m

The rock plastic zone distribution maps when the coal pillar set at 115m is shown in Fig. 6. Fig. 6 shows that the surrounding rock stress state in the two sides of roadway is obvious poor to the roof and floor of roadway. The surrounding rock surface of roadway has different degree of tensile failure, including two sides, roof and floor of roadway. The shallow surrounding rock plastic tensile fracture scope increased obvious. And the thickness of tensile plastic zone is about 0.42m. The shear failure area is in the deep of surrounding rock. And the thickness of plastic zone in the floor is 0.42m. The scope of plastic zone is throughout between the sides of roadway and security coal pillar of 1203 working face.

The increase rate of deformation of pedestrian roadway to 1203 working face no stopping when setting different width of security coal pillar after stopping mining of 1203 working face in Shuguang mine is shown in Fig. 7. Fig.7 shows that the pedestrian roadway surrounding rock surface deformation is increased obviously under the influence of 1203 working face mining when the security coal pillar width is less than 75m. And the deformation is reduced in the left side and roof, is

increased in the right side when the security coal pillar width is more than 75m. The deformation in the right side is changed less and the deformation of pedestrian roadway could meet the requirements of production safety. The position of stopping line of 1203 working face could be considered to set at the distance to pedestrian roadway 115m.

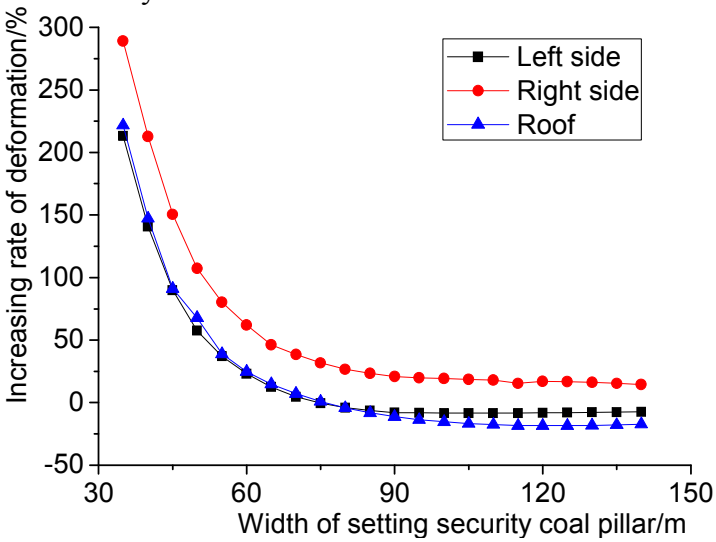

Fig. 7. Increase rate of deformation of pedestrian roadway to 1203 working face no stopping when setting different width of security coal pillar

## Conclusions

Through studying the position of stopping line of 1203 working face by numerical simulation, it shows that setting 115m wide of security coal pillar between 1203 working face and pedestrian roadway that the area of stress concentration near the working face has less effect on the pedestrian roadway could better control the surrounding rock stability of the pedestrian roadway and meet the need of the long-term normal production use. It narrows the width of security coal pillar, increase the coal resources recovery rate and achieve the better economic benefits.

**Keywords:** Outburst; Drilling field; Borehole; Gas prsssure; Drainage rate

**Abstract.** 3# coal seam of Daning coal mine is outburst， thus severely restricting the safe production. Based on the analysis of gas emission sources and the logical drainage parameters, firstly, Daning coal mine arranged some drilling fields, then utilized the VLD-1000-type rig to drill boreholes, achieving the integrated gas drainage of the coal seam and goaf. Finally, there is a test on the drainage result. The results showed that, through this kind of integrated gas drainage technology, the highest value of gas pressure in the coal seam reduced to 0.63MPa from 1.95MPa after twelve months' drainage, and the gas drainage rate of the whole mine reached 77.6%, achieving efficient use of gas clean energy.

## Introduction

Every year, gas disasters cause huge casualties and property losses, and it is a long way for the prevention and management of gas disasters. In recent years, the technology of gas drainage has become a major measure for gas control [1-3]. In the mining process of Daning coal mine, the gas emission is up to 25.94 $m^3$/t, which is a typical outburst mine. In order to solve the problem of gas outburst, according to gas condition and development system of the mine system of the mine ,Daning coalmine make a choice that it adopts a integrated gas drainage method used in the coal seam and grob. Based on the rational choice of gas drainage parameters, it uses the world-leading VLD-1000-type drilling machine that can drill a directional one-thousand meters deep drilling to drain the gas of the coal seam and goaf , reducing the amount of gas emission in the mining process , achieving safety and efficient production.

## Mine overview

Daning coalmine belongs to the management of Yangcheng County, Jincheng City, Shanxi Province, located in the region of high gas distribution in the Qinshui coalfield. Consequently, it belongs to the high gas coalmine. At the same time , it is designed to possess the production capacity of 4 million t/a. In the whole coalfield, there are two stable coalseams, 3 # seam of Shanxi group and 13 # seam of Taiyuan group. But, for Daning coalmine, currently it is approved of mining 3 # coalseam. In addition, the average thickness of 3 # coalseam is 4.5m, and for the coalseam roof, it is constituded of siltstone mudstone or sandstone, and for the bottom, it is constituded of shale or siltstone.

The whole mine are divided into five mining districts, and they are under the order of first district, third district, second mining district, fourth and fifth districts. For the mining technology, it adopts fully-mechanized mining and tunneling. Currently, the first mining district is largely finished, and the second mining district is mainly mining object, and the third mining district is under the preparation. When first mining district was mined, the maximum of gas emission reached 25.94 $m^3$/ t, bringing a serious threat to mine safety.

**The performance and applications of VLD 1000 meters rig**

The platform of LID-1000 rig uses a design of crawler-piece, and at the same time it is equipped with AMT, MWD, DGS, MECCA guidance system (MWD directional guidance system). Be based on design requirements of gas drainage, it can achieve a directional drilling with the specified target.

Daning mine uses LID-1000 rig mainly for three applications: (a)the pre-pumping of next coalface, mainly by arranging borehole along coal seam in the ventilation roadway of earlier coalface; (b) the gas drainage of the caving zone above goaf, mainly in the ventilation of the coalface, by arranging face-up borehole to reach the gas gathering zone above goaf; (c) the gas drainage through crossing boreholes arranged in the roof or floor.

**The research of gas drainage methods**

According the analysis of the composition of gas emission in Daning coal mine, the amount of gas emission in the coal seam and goaf is larger than that in the excavation face, and the proportion of adjacent layers is the smallest. As a result, Daning mine chooses a way of integrated gas drainage method that is applied in the coal seam and goaf. The methods of gas drainage in the coal seam are following, including gas drainage of the longwall mining coalface , gas drainage of excavation face, and rock roadway drainage. The methods of gas drainage include semi-enclosed gas drainage of goaf and fully enclosed gas drainage of goaf [4].

**Methods of gas drainage in the coal seam.**For the long-wall coalface, there are two types of gas drainage methods that one is draining gas with no-relief( pre-pumping ) and the other is draining gas while mining. Within the range of underground mining, regarding mine development and mining districts, some drilling fields in the tailentry of $3^{\#}$ coalseam should be arranged to vertically fix up directional drilling boreholes into next coalface and developing roadway , and this kind of pre-pumping should be finished before next coalface is mined. At last ,there is a test on the result of pre-pumping. When the result meets the demend, the coalface can be mined. Drainage is continuously carried on while the mining is doing, thus increasing the rate of gas drainage , reducing the amount of gas emission, forming the gas drainage plan of coalface. The arrangement of drainage is shown in Figure 1.

Boreholes along the tailentry of earlier mingning face are arranged to conduct pre-pumping of development roadway in next mining face. At last ,there is a test on the result of pre-pumping, then when the result meets the demend, the roadway can be excavated. It is shown in Figure 1

When there is a rock roadway above or below the seam , drilling field are arranged in the rock roadway, then make use of one-thousand meters rig to carry out gas drainage of coal seam by crossing boreholes. This method is shown in Figure 2.

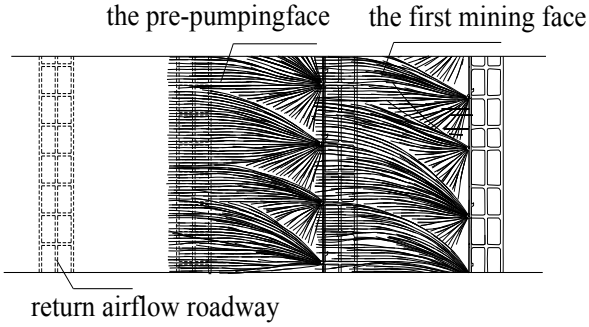

Fig. 1 The gas drainage of the coal seam

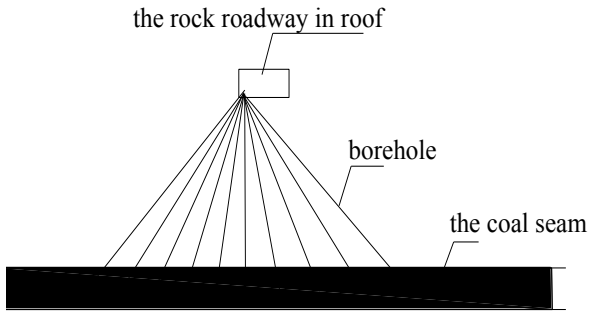

Fig. 2 The gas drainage by rock roadway

**Methods of gas drainage of goaf.** According to the condition of goaf, methods of gas drainage vary, and mainly can be divided into gas drainage of semi-closed goaf and gas drainage of closed goaf.

semi-closed goaf is that it is behind the mining face and continuously exsits with the advance of mingning face. In addition, with the continuous mining, the range of semi-closed goaf is increasing. Since this kind of semi-closed goaf is connected to the ventilating network, with the difference of

ventilation pressure, gas originating from all aspects is flowing into the goaf, then is exhausted through return air. When the amount of gas emission from goaf is larger, the state of gas of coalface up-corner and return air is under overrun level. Especially, when the roof caving causes that the amount of gas is suddenly increasing, it brings a big threat to the safe production.

Therefore, according to the roadway arrangement, there are mainly two methods of gas drainage of semi-closed goaf that one is drilling high-position boreholes above caving zone, and the other is burying drainage pipes. In the term of arranging high-position crossing boreholes above roof, this method is that drilling field are firstly arranged in the ventilation roadway of mining face, then crossing boreholes in drilling field are carried out to capture gas of destroyed zone. In addition, it is also used to drain accumulated gas of goaf [5-6]. This method is shown Figure 3. In the term of burying horizontal excavation pipes in advance, this method is that drainage pipes are embedded before roof cave or conducted in the goaf to drain gas. In order to obtain a better drainage effect, pipes embedded should be designed to have some small holes in the front of the pipes ,and at the same time, these pipes should be located in the zone of higher gas concentration that is above coal seam. This kind of drainage result is not as effective as that of high-position borehole drainage, but the low cost and simple construction. It is shown in Figure 4

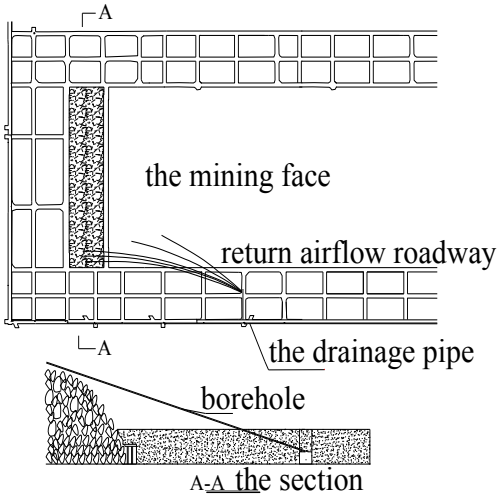

Fig. 3 Arranging crossing boreholes

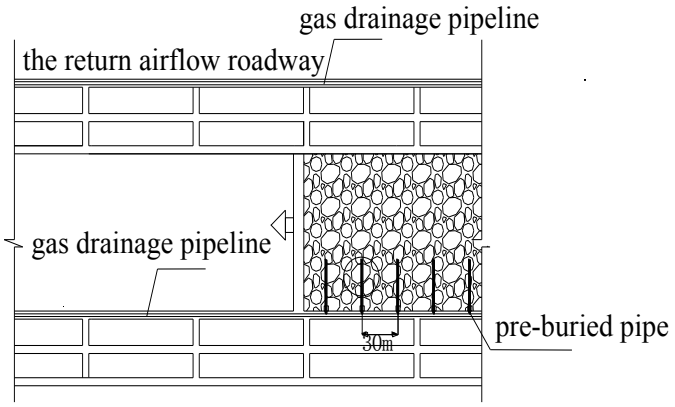

Fig.4 Burying horizontal drainage pipes in advance

closed goaf is that face (or mining area, mine) has completed been mined and is totally closed, also known as the old goaf. Although it is isolated from the ventilation network of whole mine, it is often filled with a lot of high density gas. Gas is still possible to escape out through the crack of isolated coal pillar, thus increasing the burden and unsafe factors to the mining. Daning mine designed a method of making roadway closed to draina gas of goaf. This method is that a hermetic wall is constructed in the roadway to drain gas, with pipes inserting the wall. It is shown in Figure 5.

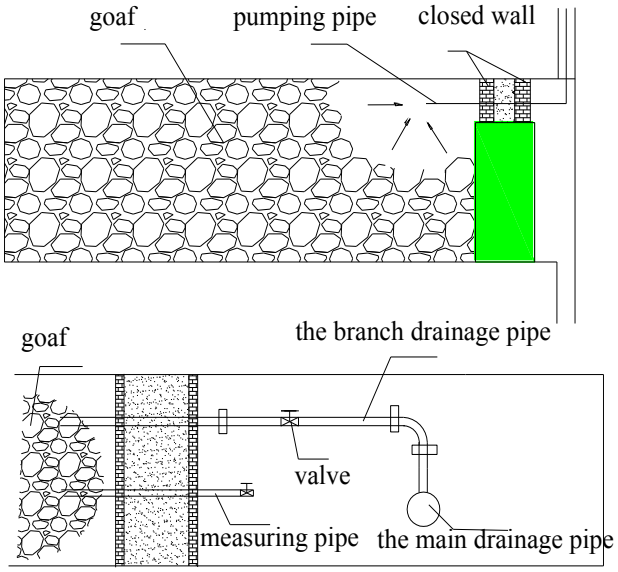

Fig.5 The closed goaf gas drainage

**Determination of drillin field and borehole parameters.** Drilling field should avoid the minging effect and geological tectonic. Meanwhile, it is easily constructed and maintained [7]. And, it should make best use of existing development roadway, preparation roadway, and gateway so that it is easily arranged. For example, drilling fields are arranged in the gateway, and the distance of between them is 120m. Its supporting adopts bolting with wire mesh and cross-section is rectangular with width 5.5m, height 3.8m, and depth 5.5m, as shown in Figure 6.

The main borehole parameters are made of diameter, length, and spacing.

Daning mine applys five sets of VLD-1000-type directional rigs into the use of gas drainage. Drilling method of rig is rotary, and final hole diameter is φ100mm.

Daning Mine utilizes the VLD-1000-type directional rig to obtain boreholes , a longer length. Based on the number of mingning face covered by a borehole, the length of pre-pumping borehole is determined. When the borehole covers a mining face, its length is the sum of mining face length, ventilation roadway width, and transportation roadway width, generally 330-390m. When covering two mining face, the length is generally 650-710m [8-9]. When the roadway in the coal seam is being excavated and the boreholes are arranged along the direction of the roadway, the borehole length is determined by the time of reserved gas drainage. When the roof rock roadway is existed, the length of floor crossing borehole is generally 30-60m, and the end of borehole pass through the floor of coal seam with 0.5m.

The beginning distance of between two boreholes along coal seam is generally 0.4-0.6m, and the terminal distance is 5-8m. The beginning distance of between two roof crossing boreholes or floor crossing boreholes is 0.3-0.5m, and the terminal distance is 3-5m.

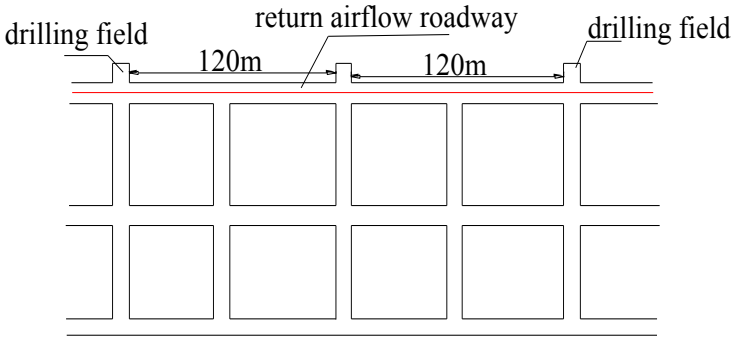

Fig. 6 The drilling field arrangement

## Effect of gsa drainage

**The effect of the coal seam drainage.** In order to analyze the effect of gas drainage, we take 301 full-mechanized mining face as a example. Firstly, some drilling fields in the ventilation roadway of 303 full-mechanized mining face were constructed. Then, boreholes are carried out in the drilling field to drain gas of 301 mining face. Finally, there are a result that after a year's drainage time, gas content of 301 coalface reduces to 7.01$m^3$/t from 17.5$m^3$/t, and gas pressure reduces to 0.63MPa from 1.95MPa. Meanwhile, drainage efficiency of the coal seam is up to 60%. With the changes in drainage time, gas drainage efficiency and gas pressure in the coal seam are shown in Figure 7.

As can be seen from Figure 7, with the extension of drainage time, gas drainage efficiency is progressively increasing, but the growth rate is slower. When the the drainage time reach a year, the drainage rate is up to 60%, and simultaneously the residual gas pressure reduces to 0.63 MPa below outburst value.

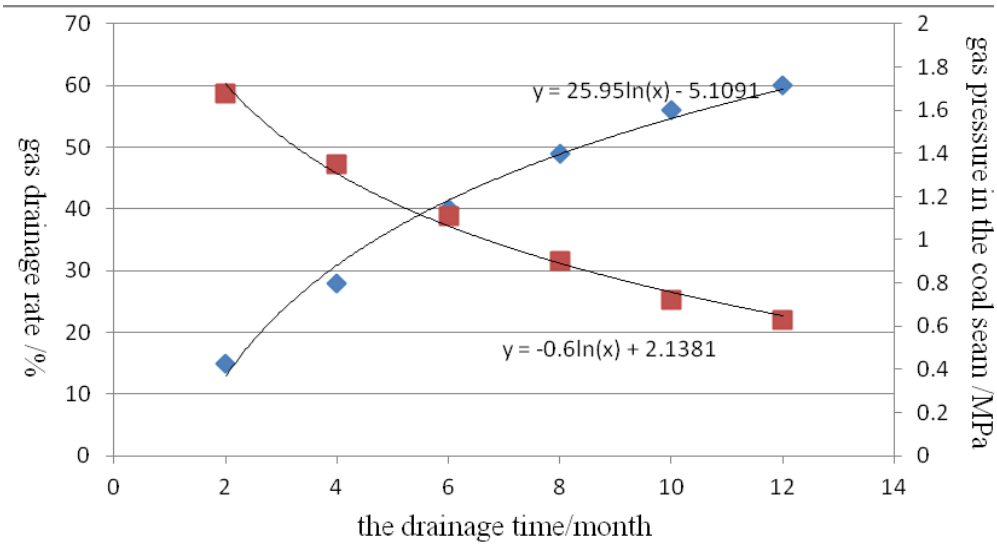

Fig. 7 Gas drainage rate and gas pressure in the coal seam with different drainage time

**The effect of goaf gas drainage.** When the coal face is being mined, large amount of gas will flow out. In this case, Daning mine consider the semi-closed goaf as a critical region where a lot of gas generate. In order to drain semi-closed goaf gas, Daning mine employs two kinds of measures that one is crossing boreholes above roof and the other is burying horizontal drainage pipes in advance. Finally, by monitoring related drainage data, there is a conclusion that the drainage rate in semi-closed goaf is up to 30%. In production, it will produce a lot of closed goaf. If any measure is not taken, safety production will be impossible. As a result, Daning mine determined to construct a closed wall to drainage gas coming from closed goaf. At last, by monitoring drainage data, the drainage rate is up to 25%.

**The effect of the whole mine gas draina.** According to the ventilation report table, by calculating the drainage rate, there is a conclusion that the whole mine drainage rate is up to 77.6%.

The drainage rate formula is,

$\eta=100\%A/(A+B)$

where the value of A is 212.99 and the value of A is 61.31.

## Conclusion

by utilizing the VLD-1000 directional rig to drill boreholes to conduct gas drainage of 301 full-mechanized mining face, after a year's gas drainage, there is a significant effect that the gas drainage efficiency of 301 mining face is 60%, and the coal seam pressure reduced to 0.63MPa, achieving the demand of safe mining. In the semi-closed goaf, by carrying out high-position boreholes above caving zone and burying horizontal excavation pipes, the gas drainage efficiency is 30%. In the

closed goaf, by employing the technology of closed wall, the drainage efficiency is 25%. Obviously, the gas drainage effect is significantly outstanding. By adopting gas drainage of the coal sea and gas drainage of goaf, the drainage efficiency of the whole mine is 77.6%, achieving efficient utilization of gas resources, protecting the natural environment.

**Keywords:** Hilly terrain, Tall buildings, Wind-induce vibration, Wind tunnel test, Wind speed.

**Abstract.** The responses of tall buildings under wind loads in hilly terrain are remarkably different from that in flat terrain. Wind load codes can't work efficiently or directly to calculate the wind-induced vibration of tall buildings in hilly terrain. Utilizing some wind tunnel test results of wind field in hilly terrain and pressures on tall buildings, the access to response of tall buildings on hilly terrain were provided. Some effects from hill characteristics to building responses were discussed.

## Introduction

As the development of metropolis in hilly terrain, wind-induced vibration of tall buildings in hilly terrain is becoming notable by structural engineering. In most design code, wind load of tall building was derived from vertical profile of mean and fluctuating wind in atmospheric boundary layer, which cannot be applied to hilly terrain directly. Many codes specify hilly terrain correction factors, but only mean wind was concerned while fluctuating wind was ignored.

In order to get wind-induced response of tall buildings, the characteristics of wind filed in hilly terrain must be get first. From 1970s, Jackson [1], Taylor [2], Weng [3], and so on carried out some wind tunnel tests and computational simulations to study mean wind velocity in hilly terrain. In these studies, some formulae to calculate wind velocity in hilly terrain were acquired. Some wind tunnel test researches about tall buildings in hilly terrain were finished. In these researches, mean and fluctuating wind velocity model and wind load spectrum model of tall buildings in hilly terrain were obtained.

In this paper, based on researches of wind tunnel test [4-5], wind-induced responses in along-wind and across-wind direction of tall buildings were calculated in frequency-domain calculation. Some relationship between hill parameters and wind-induced response were discussed.

## Wind tunnel tests

*Tests on wind filed in hilly terrain* [4]

A series of hill models, including different slope and height, were made to get wind field in hilly terrain. In each model, wind velocity in different location and height were get and analyzed. The characteristics of wind field in hilly terrain were discussed, which provide basic conditions to get wind load on tall buildings

The tests were carried out in wind tunnel F-11 in China Aerodynamics Research & Development Center. The size of cross section is 1.4m×1.4m. A pressure measurement system was utilized to probe fluctuating wind velocity in hilly terrain. The cosine model was take to make the hill outline. The scale ratio was 1:1000. Totally, 10 models, with height from 50 m to 200m, were made. Fig. 1 shows a case of test.

After these tests, wind field characteristics in hilly terrain were get. Furthermore, computing method of mean and root-mean-square velocity of fluctuating wind were raised, which becomes the foundation of wind load calculation of tall buildings in hilly terrain.

***Tests on wind load on tall buildings***

A series of wind tunnel test were carried out on wind pressure on tall buildings. Mean and fluctuating wind load of tall buildings on each direction was obtained. In this approach, wind load of any tall building in hilly terrain could be got.

Totally 9 models of tall building were made, including different cross section, height-to-width ratio and width-to-thickness ratio. The scale ratio was 1:500. Mean and fluctuating wind load in every layer of tall buildings can be calculated by integration of wind pressure from 220 pressure holes in surface of models. Fig. 2 shows a tall building model in wind tunnel.

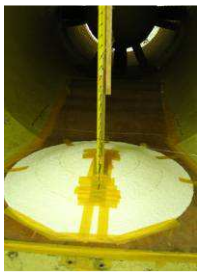

**Fig. 1 Wind tunnel tests on wind field in hilly terrain.**

**Fig. 2 Wind tunnel tests on pressure on tall buildings.**

## Basic assumptions and algorithm in frequency-domain

***Basic assumptions***

(1) No coupling existed in 3 modes of vibration.

(2) Only first mode of vibration was taken into concern in caclulation. Ye Feng 6 made discussion on influence from number of modes of vibration to background and resonant responses. The results showed that calculations only from the first mode could make the results accurate enough.

(3) The first mode of vibration in each direction was linear. Vickery 7 believed that although the actual mode may far away from linear, the error from mode was usually limited to 1%~3%. By this reason, affection from nonlinear mode might be ignored.

(4) Assumptions of coherence function of wind loads in every direction. Coherence function of fluctuating wind velocity was taken to be coherence function of wind load in along-wind direction. Coherence function of vortex shedding was taken to be coherence function of wind load in cross-wind and torsional direction 8. The coherence functions is given by

Along-wind direction:

$$\mathrm{coh}(z_1, z_2, f) = \exp\left(-7f\frac{|z_1 - z_2|}{U}\right) \tag{1}$$

Cross-wind and torsional direction:

$$\mathrm{coh}(z_1, z_2, f) = \exp\left(-f\frac{|z_1 - z_2|}{HL_w}\right) \tag{2}$$

where $z_1$ and $z_2$ are height of two layers, and f is frequency, and U is the mean value of mean wind velocity of 2 layers, and H is height of a building, and Lw is the ratio of size related to vortex shedding to typical width of structures, which could be 1 usually.

***Calculation steps of wind-induced fluctuating response of tall buildings in hilly terrain***

(1) To determine the mean and fluctuating wind speed profile of the building location in hilly terrain.

(2) To determine wind load of each layer.

(3) To calculate the generalized power spectrum density of wind load, by

$$S^*_{P\alpha}(\omega) = \frac{1}{H^2}\sum_{i=1}^{m}\sum_{i'=1}^{m} S_{P\alpha}(z_i;\omega)S_{P\alpha}(z_{i'};\omega)\mathrm{coh}(z_i, z_{i'};\omega)z_i z_{i'} \tag{3}$$

(4) To calculate the fluctuating wind-induced response, by

$$\sigma_\alpha(z) = \sqrt{\int_0^\infty \frac{z^2|H_{\alpha 1}(i\omega)|^2 S^*_{P\alpha}(\omega)}{H^2 M^{*2}_{\alpha 1}}d\omega} \tag{4}$$

**Wind-induced responses of tall buildings in hilly terrain**

In this calculation, class of ground roughness was D in Chinese wind load code. The turbulent density profile in height in given by

$$I(z) = 0.1\left(\frac{z}{H_g}\right)^{-\alpha-0.05} \tag{5}$$

Ten different locations were numbered in the Fig. 3.

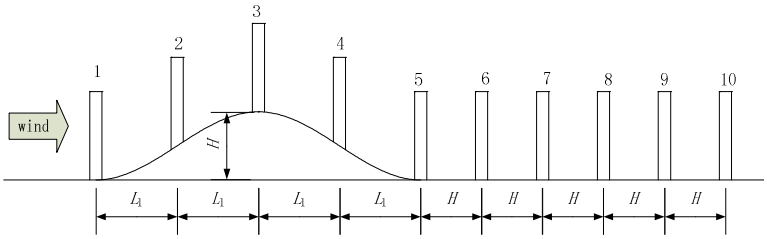

**Fig. 3 Schematic diagram of numbering of location in hills.**

Some other parameters were set as: the building section was square, with 300m high, 60m width and 5s period. The damp ratio of first vibration mode was 0.01 and the reduced density was 190Kg/m$^3$. The wind speed in 10m high was 30m/s, and air density was 1.25 Kg/m$^3$.

***Effect from different slope of hills***

Ten hill models with same height and different slopes were made. The geometry was shown in Tab. 1, where $H$ shows the height and $L_1$ shows the diameter in half height.

**Tab. 1 Geometry of hills of different slopes.**

| | $H$(m) | $L_1$(m) | $H/L_1$ |
|---|---|---|---|
| 1 | 150 | 150 | 1.00 |
| 2 | 150 | 200 | 0.75 |
| 3 | 150 | 250 | 0.60 |
| 4 | 150 | 300 | 0.50 |
| 5 | 150 | 350 | 0.43 |
| 6 | 150 | 400 | 0.38 |
| 7 | 150 | 450 | 0.33 |
| 8 | 150 | 500 | 0.30 |
| 9 | 150 | 550 | 0.27 |
| 10 | 150 | 600 | 0.25 |

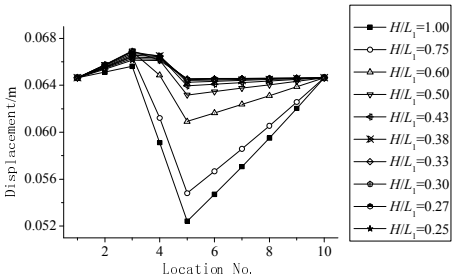

**Fig. 4 Effect of slope of hills on along-wind static response of displacement.**

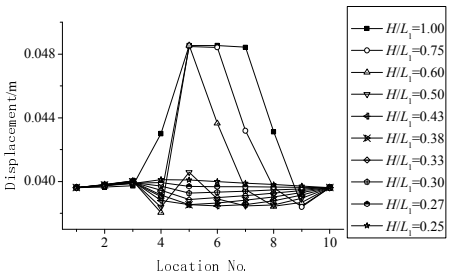

**Fig. 5 Effect of slope of hills on along-wind RMS fluctuating response of displacement.**

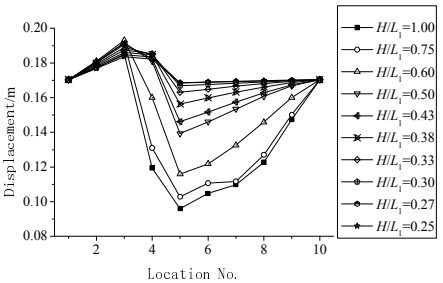

**Fig. 6 Effect of slope of hills on across-wind RMS fluctuating response of displacement.**

Fig. 4 shows the along-wind static response of displacement in the top of tall buildings in different location of different hills. Along direction of wind, the response increases from the hill foot (location 1) in windward side, and reaches to the maximum value at hilltop (location 3). After hilltop, the response becomes to decrease, and get to the minimum value at hill foot in leeside (location 5). After that, the response begins to increase, and recover to be the same with in flat ground (location 1) in location 10.

The speed-up effect is most remarkable in the top, but the maximum speed-up ratio is generated in the height near the ground. With height increases, speed-up ratio decreases rapidly with power law. As a result, speed-up effect doesn't contribute a lot to mean response of displacement.

Fig. 5 shows the along-wind RMS fluctuating response of displacement in the top of tall buildings in different location of different hills.

At the hill top, the fluctuating wind keeps almost the same with in flat ground, while increasing of mean wind contribute little to the generalized wind load and fluctuating response. At the hill foot on leeside, mean wind decreases and fluctuating wind increases. As a result, fluctuating response increases in larger slope hills and decreases in less slope hills.

Fig. 6 shows the across-wind RMS fluctuating response of displacement in the top of tall buildings in different location of different hills. A notable situation is that, the across-wind fluctuating responses are larger than along-wind fluctuating responses.

***Effect from different height of hills***

Four hill models with same slope and different height were made. The geometry was shown in Tab. 2.

**Tab. 2 Geometry of hills of different slopes.**

| | $H$(m) | $L_1$(m) | $H/L_1$ |
|---|---|---|---|
| 1 | 50 | 100 | 0.50 |
| 2 | 100 | 200 | 0.50 |
| 3 | 150 | 300 | 0.50 |
| 4 | 200 | 400 | 0.50 |

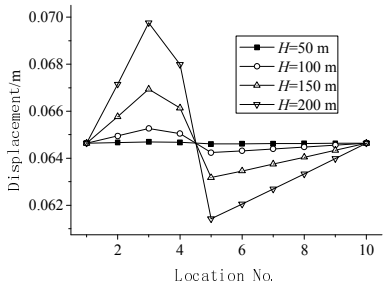

**Fig. 7 Effect of height of hills on along-wind static response of displacement.**

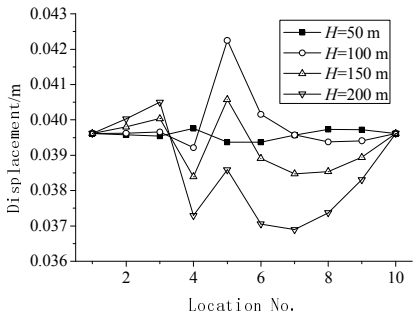

**Fig. 8 Effect of height of hills on along-wind RMS fluctuating response of displacement.**

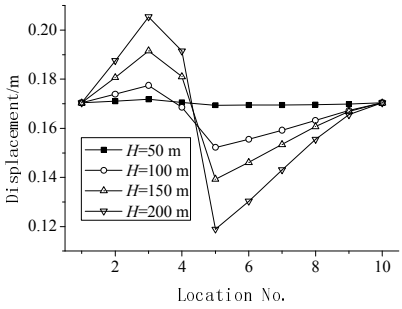

**Fig. 9 Effect of height of hills on across-wind RMS fluctuating response of displacement**.

Fig. 7 and Fig. 8 show the effect of height on along-wind static and fluctuating response of displacement. In hill with low height of 50 m, along-wind displacement of each location keeps almost the same with that in flat terrain. In hill foot of lee side, large fluctuating wind induced to large fluctuating displacement. Fig. 9 shows the across-wind RMS fluctuating displacement, which has the similar shape with the along-wind static displacement.

## Conclusions

(1) Mean and fluctuating wind speed model, wind load model of tall buildings, the Davenport coherence function in along-wind direction and the vortex-shedding coherence function in across-wind and torsional direction could be utilized to get the generalized load spectrum, response spectrum, mean and RMS response of tall buildings in hilly terrain.

(2) In the hill top, small changes of response happen in different slope. In the hill foot of leeside, static response on along-wind direction and fluctuating response on across-wind direction

dramatically reduce with the enlargement of slope, while the fluctuating responses on along-wind increase with the enlargement of slope.

(3) With the height of hill increase, static responses on along-wind direction and fluctuating responses on across-wind direction increase in hilltop and decrease in hill foot of leeside. Fluctuating response on along-wind direction increases notably in hill foot of leeside.

**Keywords:** impingement component; bumps; numerical analysis; different configurations; energy absorption characteristics

**Abstract.** For the effective prevention and control of mine bumps, or to a certain extent, to reduce the loss the losses caused by impact ground pressure accident,thin-walled components are proposed to be applied as a scaffold components in roadway supporting. Components impingement is reflected in the component crushed process ,in which the impacting energy absorption and crushing space provide certain amount of energy to free up space. The energy absorption characteristics of different configuration thin-walled components has been simulated with ABAQUS finite element, such as the conventional square,regular hexagon, round and origami square, regular hexagon etc,.and the results showed that: (1) The problem of conventional components is larger load fluctuation coefficient. Origami component is a kind of perfect impingement components ,as it can reduce peak loads and the load fluctuation coefficient effectively. (2) Under different ratios width-to-thickness, components can have different deformation modes, but the relationship of peak load and wall thickness is near linear and has nothing to do with the deformation modes. (3) The component can have a relatively lower crushing peak load and load fluctuation coefficient and relatively higher specific energy absorption,if given a suitable diamond concave angle. impingement components using combined with existing supports can make the existing supports to become top beam impingement support , mudsill impingement support ,two sides impingement support and impingement hydraumatic support and so on.

## Introduction

Our country is rich in coal resources, but most of the coal reserves in deep, the coal resource under the depth of 1000m made up 53% of the total coal resources. With the increase of mining depth, the rock burst occurs more and more frequently[1-2], causing great threat to people's life and property[3]. The occurrence of rock burst has the characteristics of instantaneousness， abruptness and destructiveness, a lot of energy release at the same time , the impact energy can reach up to 103MJ[4-5] . The impact energy plays a major role in the two parts, one part acts on the coal causing the coal and rock broken causing the breakage of coal and rock while another part acts on the roadway support structure. The huge impact can cause the destruction of coal and rock roadway and its support structures. At present, the main methods of the anti-chock support mainly include bolt, U steel, shotcrete support, shed-cable cooperative support. The roadway system satisfied the safety requirements under the static mine pressure, but there is the problem that the ability resisting the impact load is poor.

In today's world, the number of vehicles is increasing, and the speed is more and more fast, collision accidents often occur, which causes serious loss of life and property every year. Therefore, many countries gave high attention on car collision in more than half a century, scientists and engineers was encourage to improve energy absorption device performance[6-8] and the crashworthiness of cars, ships, aircraft and other vehicle[9]. The main evaluation index of the structure crashworthiness is the absorption and dissipation of the impact kinetic energy, a well-designed crashworthiness structure must absorb energy in a controlled manner[10]. With its excellent energy

absorption effect[11-13], the metal thin-walled structure as the energy absorption device has been widely used in aircraft, cars, ships, aerospace, machinery, bridges and other fields[14-18], but the application in the mining areas has not been reported.

If the metal thin-walled structure as supporting components was used in the roadway support structure to absorb impact energy, whether the rock burst can be prevented effectively, or to a certain extent to protect the roadway and the supporting structure? Because the anti-shock components used in mine need large crushing force, there is a need to simulate the bearing capacity and energy absorption properties of the conventional thin-walled components with circular cross -sections, square cross-sections, hexagonal cross-sections and the thin-walled components with folds of square and hexagonal cross-sections.

## Mine Impingement Thin-walled Components Design

**Essential Characteristic of Mine Impingement Thin-walled Components.** The anti-component need to meet the strength that the hydraulic support or supporting structure is not crushed under the normal working state on one hand, while the strength also can't be too big, or it has on effect of energy absorption and anti-shock. On the other hand, the components need to absorb energy as large as possible in the process of deformation and crushing, the space crushing occupied should be as small as possible, in other words, the effective distance of components should be as large as possible under the same height. The effective compression distance is defined as the distance that from the start of compression to the peak crushing load, which shows that components should have the following basic characteristics: The crushing peak load should be higher than a threshold and lower than another threshold; the deformation mode is regular and repeatable, which has high energy absorption, low cost and is easy to install.

The component preventing rockburst is mainly manifested in the following two aspects: the component itself can absorb some of impact energy in the process of crushing; the energy releasing space was provided after the components are crushing, which is equal to the components absorbing some of impact energy once again. This will greatly reduce the impact force effects on the support, which can protect the supporting system better.

Component generally installed on the upper surface of support beam, the bottom surface of the set sill, the top of the hydraulic prop, The bottom of the hydraulic prop or the top beam and the bottom beam, etc. the upper surface of support beam and the bottom surface of the set sill can be installed with a plurality of components, which can make the existing support to be the anti-shock top beam support, the anti-shock set sill support, the anti-shock two sides support and the anti-shock hydraulic prop.

**Impingement Components Geometry Structure Design.** According to the basic characteristics and the main mounting position of impingement components, the length and width of components are designed as 120 ~ 200mm, and the height around 350mm is better. So a thin-walled steel plate with an area of 720mm × 360mm is chosen to make the following five types of components: (1)The circular thin-walled components with radius of 114mm, height of 360mm. (2)The square thin-walled components with side length of 180mm, height of 360mm.(3)The regular hexagon thin-walled components with side length of 120mm, height of 360mm. (4)The square origami thin-walled components with side length of 180mm, height of 352mm.(5)The regular hexagon origami thin-walled components with side length of 120mm, height of 354, 356, 357, 358, 359 mm.

The square origami thin-walled component consists of two modules, which are "stacking" in the axial direction. Each corner region of a individual module has a diamond shape concave angle, which can form preformed crease lines. The surface of a individual module consists of eight congruent triangular faces and eight congruent trapezoidal faces. The module can be developed into a plane, when cut along the middle of the side, which is shown in Fig.1.The composed of origami thin-walled component is shown in Fig.3, in which the dotted line stands for concave angle.

The regular hexagon origami thin-walled component consists of two modules, which are "stacking" in the axial direction. The six corner regions of a individual module all have a diamond shape concave angle, which can form preformed crease lines.The surface of a individual module

consists of twelve congruent triangular faces and twelve congruent trapezoidal faces. The module can be developed into a plane, when cut along the middle of the side, which is shown in Fig.2. The composed of origami thin-walled component is shown in Fig.4, in which the dotted line stands for concave angle.

Both of the square and regular hexagon origami thin-walled components can define the individual modules with three independent geometric parameters: Module width a, module length L and module concave angle width b.Diamond concave angle 2θ is determined by b and L,satisfying the equation,where N is the number of edges.

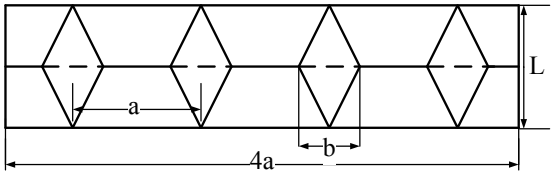

Fig .1 A quadrilateral module unfolds into a plane

**Numerical Simulation of the Mine Impingement Thin-walled Components**

**Energy Absorption Performance Evaluation of Impingement Components.** The crushing peak load F max,load fluctuation coefficient Δ,specific energy absorption SEA and compression efficiency SE are used to evaluate the performance of impingement components.

The crushing peak load F max reflects the situation of overload or maximum overload. And F max can be received through the crushing force - distance curve of thin-walled components.

Load fluctuation coefficient Δ can make a effective evaluation for the stationarity of loads in the cushing process of thin-walled components. it is clear that the load fluctuation coefficient should be as small as possible for thin-walled components, which is defined as formula (1).

$$\Delta = \frac{F_{\max}}{\frac{1}{\delta}\int_0^{\delta} F(s)ds} \quad (1)$$

Where F (s) denotes the force , when the compressed distance of thin-walled components is s; δ denotes the compressed effective distance of thin-walled components .

The specific energy absorption SEA is the energy absorbed by unit mass in the effective crushing distance of components, which is defined as formula (2).

$$SEA = \frac{\int_0^{\delta} F(s)ds}{m} \quad (2)$$

Where m denotes the quality of thin-walled components.

The compression efficiency SE is used to measure the deformability of compression efficiency energy absorption structures, which is defined as formula (3).

$$SE = \frac{D}{H}100\% \cdot \tag{3}$$

Where D denotes the effective distance of the compression; H is the height of components.

**Geometry Size Selection of Impingement Components.** Components with different configurations, different thicknesses and widths of module concave angle selected, according to impingement components geometry structure design, as shown in Table 1.

Table 1 The geometry size and the energy absorption characteristics of thin-walled components

| Number | a [mm] | b [ mm] | L [ mm] | 2 θ [°] | Thickness [ mm] | $F_{max}$ [kN] | $F_{mean}$ [kN] | Δ | E [kJ] | SE [%] | SEA [kJ.kg$^{-1}$] | H [mm] |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 120 | 45 | 180 | 172 | 8 | 4402 | 2138 | 2.06 | 620 | 81 | 38.09 | 359 |
| 2 | 120 | 60 | 180 | 169 | 8 | 4305 | 2390 | 1.80 | 707 | 82 | 43.46 | 359 |
| 3 | 120 | 75 | 180 | 167 | 8 | 3962 | 2421 | 1.64 | 663 | 77 | 40.76 | 358 |
| 4 | 120 | 90 | 180 | 165 | 8 | 3608 | 2643 | 1.37 | 703 | 75 | 43.20 | 357 |

**The Finite Element Model Impingement Components.** The paper adopts the algorithm of dynamic display, chooses S4R element, takes 5 integration points along the thickness direction of the shell, and uses the default value of the software itself to hourglass and bulk viscosity control of the material to set up finite element mode with the finite element software ABAQUS. Besides, in the moding, the primarily elements of the thin-walled component are quadrilateral elements, and only a few triangular elements it has. Thin-walled structures crushing process uses two rigid plates to conduct, namely using a rigid plate to support the bottom of the component and another rigid plate to load on the top of the component. The contact between rigid plates and thin-walled components is defined as the surface -surface contact between components, and the inside and outside surface of components is set as self-contact during deformation. Both of the friction coefficients of two contacts are 0.25. Mechanical Parameters adopt steel T700L parameter model with the density of 7850kg/m3, the elastic modulus of 210GPa, Poisson's ratio of 0.3, the yield strength of 720MPa, ultimate strength of 780MPa. In addition, the test of the mesh density and analysis time is conducted, from which we obtained a satisfactory result with the mesh size of 5 mm, the compression distance of 300mm and the analysis time of 0.03s .

## Numerical Simulation Results Analysis

The axial compressive-deformations of components with different configurations are shown in Fig.5, and the crushing force-distance curves are shown in Fig.6. The axial compressive-deformations of components with different thicknesses are shown in Fig.7, and the crushing force - distance curves are shown in Fig.8. The crushing force - distance curves of components with different angular widths are shown in Fig.9.The simulation results of components are shown in Table1.

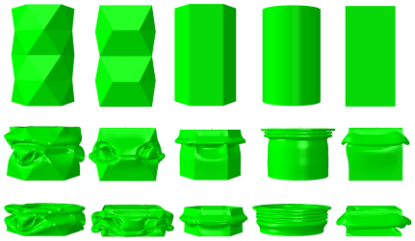

Fig.5 The axial deformation of components with different configurations

Fig.7 The axial deformation of components with different thicknesses

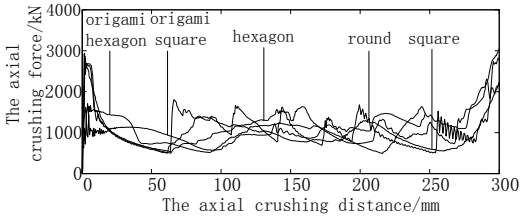

Fig.6 The crushing force - distance curve of components with different configurations

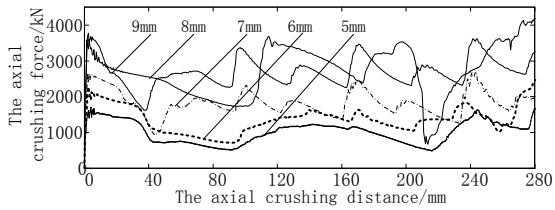

Fig. 8 The crushing force - distance curve of components with different thicknesses

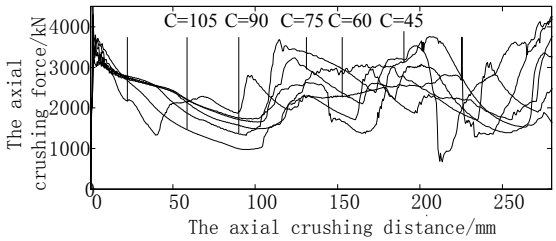

Fig.9 The crushing force - distance curve of components with different angular widths

**Comparison of Components With Different Configurations.** As can be seen from Fig.6: When applyed axial compression loads to components with different configurations, The axial crushing force increased with the deformation rapidly and reached a peak, then decreased to a stable platform for the regular waves of area, finally stepped into the stage of compaction structure and the crushing force increasing rapidly. The regular waves of load is formed by folding components continuously in the stable buckling stage, and each wave represents a partial folding process.

From Table 1,the performance indicators of conventional square, regular hexagon and round thin-walled components with same material (No. 12, 13, 14) is similar to each other ,and the regular hexagon is the best relatively and square relative worst. Compared with conventional components, the origami square and regular hexagon have a lower peak load and load fluctuation coefficient.

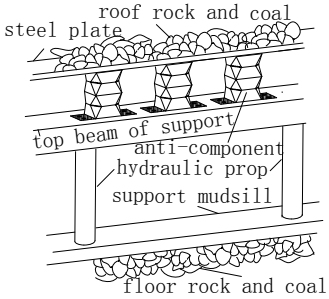
**Performance Analysis of Origami Components with Different Thicknesses.** The effect of wall thickness on the energy absorption of components is analyzed, keeping the module width a, module concave angle width b, module length and component height consistent (No. 6-10 components).

As can be drawn from Table 1: The crushing peak loads of wall thicknesses of 6, 7, 8, 9mm are increased by 33%,56%,91%,122% respectively than wall thinckness of 5mm; specific energy absorptions are increased by 10 %, 33%, 41%, 51%; load fluctuation coefficients are reduced by 0.6%, 13.7%, 12.5%, 17.3%; and compression efficiencys are increased by 0%, 3.8%, 2.5%, 2.5%. The relationship between crushing peak load and wall thickness is nearly linear, and a few other

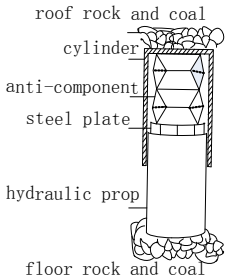
indicators in the case of wall thickness greater than 7mm and less than 7 mm have changed greatly. As can be seen from Fig. 7,it is mainly because the deformation patterns of the wall thickness 7mm have changed, the failure mode of wall thickness less than 7mm is diamond failure mode, and wall thickness greater than 7mm is axisymmetric failure mode.

**Performance Analysis of Origami Components with Different Angular Widths.** Under the conditions of keeping the module's thickness, width a,length L coincident, The effect of module concave angle width b (diamond concave angle) on the energy absorption of components is analyzed (No. 1-6 components).

As can be drawn from Table 2 and Fig. 9 : the crushing peak load is reduced with the module width increasing or concave angle decreasing, but the specific energy absorption , the load fluctuation coefficient and the compression efficiency don't simply increase or decrease. It shows that module concave angular width (diamond concave corner) selection is particularly important for the performance of components. there is a relatively low crushing peak load and load fluctuation coefficient and a relatively high specific energy absorption, when the module concave angular width is 90mm(No. 4 components).



(a) The top beam support of impingement



(b) The hydraulic prop of impingement

Fig .10 The component combined with the support diagram

## Conclusions

For the effective prevention and control of mine bumps, or to a certain extent, to reduce the loss the losses caused by impact ground pressure accident, thin-walled components are proposed to be applied as a scaffold components in roadway supporting. Partial function of components using combined with stents is shown in Fig. 10.

The energy absorption characteristics of different configuration thin-walled components has been simulated with ABAQUS finite element, such as the conventional square, regular hexagon, round and origami square, hexagonal etc, and the results showed that:

(1) The performance indicators of conventional square, regular hexagon, round thin-walled components are similar to each other, and a same problem of them is larger load fluctuation coefficient. Origami components can reduce peak loads and the load fluctuation coefficient effectively.

(2) Under different ratios width-to-thickness, the deformation modes of components will change, but the relationship of peak load and wall thickness is near linear and has nothing to do with the deformation modes.

(3) The module concave angular width selection (diamond concave corner) is particularly important for the performance of components. The component can have a relatively lower crushing peak load and load fluctuation coefficient and relatively higher specific energy absorption, if given a suitable diamond concave angle.

If supporting 100 brackets in the impact pressure roadway and installing 5 impingement components (No. 5) on the top beem of each support, the device can absorb 320MJ energy when the impact ground pressure happens and prevent and control coal mine bumps effectively, or to a certain extent, to reduce the losses caused by impact ground pressure accident.

**Keywords:** Freezing damage, Frame structure, Ice pressure, Structure design

**Abstract.** Frame structure building is widely used for its advantages of flexible space, light weight, saving material, building plan can be flexibly arranged and so on. However, researches on frame structure built in the water in cold areas, under horizontal ice pressure, are very few, and there is also no ice pressure calculation method for this structure form. Combining with the damage phenomenon of Jintaizi fishing floor engineering, analyzed the causes of freezing damage from ice pressure, temperature joint, structure form, and put forward a concept of ice pressure influence width for frame structure under the effect of ice. This article provides a reference for ice pressure calculation and the design of frame structure buildings which built in the water.

## Introduction

Jintaizi fishing floor is located in Shibei reservoir, in Fuyu, Jilin province, which was founded in 2012. It was a single-story building, built in the water, and its form is frame structure. Area of the building is 1600 $m^2$, and this building can be used either for fishing, but also can be used as landscape architecture. According to local meteorological bureau of statistics analysis, the average annual temperature in this region is 4.5°C , and the monthly average temperature difference is 42.1°C. Water in reservoir began to freeze in late October or early November. In winter, the average thickness of the ice is 0.95m. Reservoir ice begins to melt between in late March and early April.

The structural diagram of fishing floor is shown as Fig.1. The plane shape of the building looks like a semicircle, which was designed according to the idea of a bow. The span of the bowstring is 142.8m, and perpendicular to bowstring the span is 69m. This engineering adopted prefabricated pile foundation with reinforced concrete, and the pile bearing capacity is 210kN. Frame columns' section dimension is 400×400mm. The height of columns is 3550mm, and the thickness of slab is 120mm. Frame columns' concrete strength grade is C30, the same to frame beams and floor. The part of bowstring arch close and parallel to the shore; bow arm towards the middle of lake.

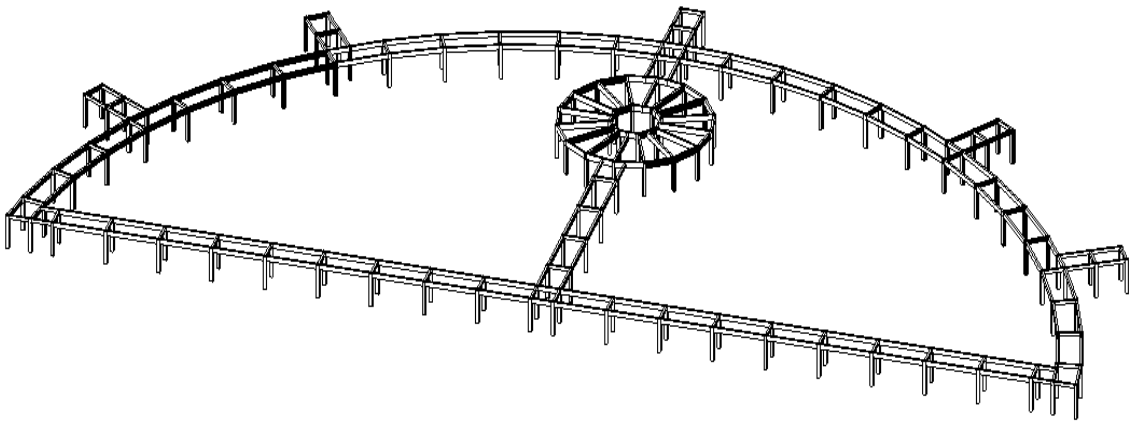

Fig.1.Structural diagram of fishing floor

When ice began to melt, we found that the structure of the overall leaned to the shore suddenly in 2013. More seriously than that, cracks appeared at the position of beam-column joints, especially at

the ends of the bowstring. The inclination of frame columns which near the shore side is more obvious. Phenomena of structural damage are shown as Fig.2.

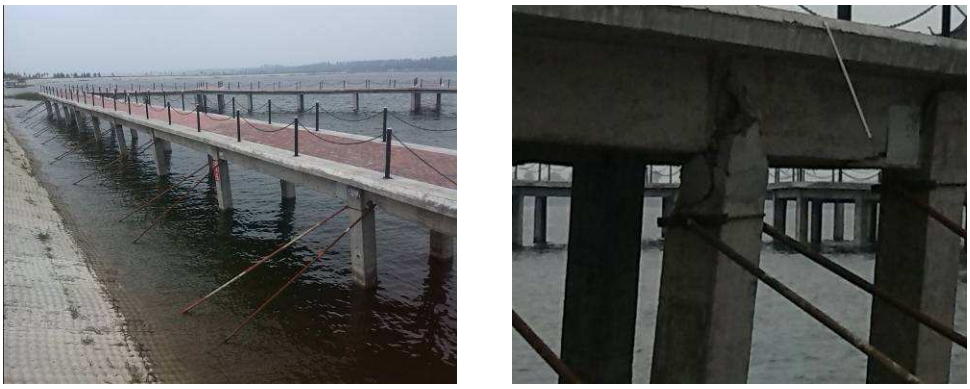

Fig.2. Phenomena of structural damage

**Reasons of Freezing Damage**

Through field measurement of fishing floor and finite element analysis, it is concluded that the main reason made the building leaned to the shore is horizontal ice pressure. Additionally, the floor of the building did not set up temperature joints and the structure form was unreasonable. Under horizontal ice pressure, it increased damage degree of the building, and it is also a significant factor that made the joints badly broken.

**No Consideration of Horizontal Ice Pressure in Structure Design**

Static ice pressure refers to the pressure that ice imposes on static buildings, which can be divided into swelling pressure, ice thrust under the influence of wind and flowing water, and thermal expansion pressure[1]. Thermal expansion pressure is one kind of static ice pressure generated by a 9% volume expansion from water to ice under the building's restraint . However, swelling pressure's impact on buildings is quite minimal and shall not be taken into account. Ice thrust under the influence of wind and flowing water also imposes no notable impact. On the contrast, thermal expansion pressure can do great damage to buildings under varying temperatures as the heated-and-then -expanded ice layer can generate huge thrust, which is the so called ice pressure.

Weak lateral stiffness is one of the disadvantages of frame structure. As a result, the building can not resist the effect of horizontal ice pressure and damages happened. Static ice pressure is influenced by environment, and there is no calculation methods for frame structure buildings which built in the water. Therefore, horizontal ice pressure was ignored in the process of the structure design. There are several different formulas to calculate ice pressure, *Code for Design of Hydraulic Structures against Ice and Freezing Action* provides a simple method by making a comprehensive analysis of them. This method needs to know the thickness of the ice, and the way to get the value is shown as Table 1.

Table 1. Value of Ice Pressure

| Thickness of Ice （m） | 0.4 | 0.6 | 0.8 | 1 | 1.2 |
|---|---|---|---|---|---|
| Ice Pressure （kN/m） | 85 | 180 | 215 | 245 | 280 |

The thickness of ice in Table 1. should be choose from average maximum for previous years , and the value can be interpolated for different thickness of ice[2]. The average ice thickness for previous years in this region is 0.95m, then the value of ice pressure is 237.5kN/m according to Table 1. The width of frame columns is 0.4m, so the ice pressure load on each frame column is 95kN. However, through the analysis of finite element software, the destroy degree of structure was lower under ice pressure. The maximum normal stress on frame columns is 5.6N/mm$^2$, less than compressive strength of C30 concrete, whose design of value is 143N/mm$^2$. Meanwhile this ice pressure cannot cause cracks on the building. Therefore, the ice pressure value calculated by *Code for Design of Hydraulic*

*Structures against Ice and Freezing Action* is small, and this calculation method do not apply to frame structure which in the water.

Ice is continuum. It can cover the frame columns and form a block. Therefore, the ice pressure on frame columns not only includes the impact of ice that has contact area with the frame columns but also that of the ice covering both sides of the frame columns.While calculating the horizontal ice pressure, static ice pressure should multiply a wider distance, ice pressure impact width, which is related to and shall stand between the width of frame column and the span of frame columns. After many trial tests based on the frame structure, it is concluded that the reasonable width shall range from 2m to 4m.

Additionally, according to the statistics of Bureau of Metrology of Jilin Province, 2012 witnessed extreme cold weather, featuring by an unprecedented lowest temperature of -39.8°C. Accompanied by severe weather are thicker ice layer, more remarkable temperature fluctuations and ice volume expansion which leaded to greater static ice pressure. The extremely cold weather, as one of the factors impacting static ice pressure, increased the damage to fishing floor.

**No temperature Joints**

The temperature joints, also called expansion joints, are set in case of the possible fissure on the building under the temperature variations. Surrounded by the lake, this floor experienced remarkable temperature changes more than 70 °C from summer to winter. No temperature joints are set in the building which is slim in shape. This may lead to expansion and contraction of the building under temperature variations and temperature stress of the floor. With the restrain of frame columns, frame columns are imposed impact while the concrete are easy to breach. The coefficient of thermal expansion is 0.00001. The span of bowstring is 142.8m and the length of the bow's back is 219m. Thus, the maximal expansion amounts of bowstring and bow's back are as following.

$$\Delta l_1 = l_1 \times \alpha \times \Delta t = 142480 \times 0.00001 \times 70 = 99.74\text{mm}. \quad (1)$$

$$\Delta l_2 = l_2 \times \alpha \times \Delta t = 219480 \times 0.00001 \times 70 = 153.3\text{mm}. \quad (2)$$

As can be seen from the calculation, bowstring and back of bow have greater expansions and exert significant impact on the building. While the temperature rises, it moves toward the ends of bowstring and back of bow, bringing both horizontal and vertical temperature stress to the frame columns at the sides of bowstring which then slide in both directions. This is consistent with the fact. The width of expansion joint usually stands between 20mm to 30mm and the largest span of the expansion joint in cast-in-place reinforced concrete is 35m[3].Standard temperature joints should have been set in the floor. No temperature joints also contribute to the damage of the building.

**Unreasonable Structure Form**

At first, as can been seen from Fig. 1, the plane graph of the fishing floor can be simplified as an arch structure featuring of generating horizontal impact on the arch toes, under the impact of vertical loads. Horizontal ice pressure can be simplified as the even loads distributed equally in the vertical direction of arch axis. The frame columns have to undertake the impact of the horizontal impact as there are no supports at the arch toes, which leads to movement of the columns via the horizontal direction to the lake. Meanwhile, the joints under the impact of the ice pressure, temperature stress and arch thrust, the ultimate strength of the joints is surpassed and then it does great damage to them. Taking consideration of the comprehensive impact of the ice pressure, the part of joints should be strengthened while section size of beams and columns should be expanded.

Secondly, the fishing floor is a one-span frame structure which shall not be applied in design while the horizontal impact exists. One-span frame structure is difficult in transmitting force and bending moment under horizontal impact， and it is easy to make beam-column joints destroyed. In terms of degrees of freedom, one-span structure is redundant structure with less redundancies and may be damaged totally once one joint is damaged. If double-span or multi-span were applied in design, the

degree of statical indeterminacy will increase and once several constraints out of work will do less damage to the overall structure.

Thirdly, the size of cross section is small which leads to small lateral stiffness and slide of structure under impact of horizontal ice pressure.

## Conclusion

Less lateral stiffness and direct ice pressure are the main reasons that lead to the freezing damage to the fishing floor. Temperature joints shall not be overlooked in cold areas. Neither shall we apply a one-span structure under the influence of horizontal impact. Moreover, the calculating method of ice pressure cited from *Code for Design of Hydraulic Structures against Ice and Freezing Action* is not applicable, and the concept of ice pressure influence width shall be taken into consideration. More researches and discussions need to be taken to find out specific evaluation method. To sum up, ice pressure, larger section size, reasonable temperature joints and two-span or multi-span structure shall be taken into account in designing frame structure in water in cold areas. At present, the fishing floor is out of service and shall be consolidated.

**Keywords:** steel structure; monolayer cable net; glass curtain wall; fire disaster; mechanical properties; critical temperature.

**Abstract:** The developing trend of large scale curtain wall structure system is monolayer cable net glass curtain wall, so it's important and necessary to study the corresponding calculation method and mechanical properties under fire conditions. The changing rule of the displacement and the maximum cable force with the temperature was analyzed by making series of numerical calculations, and the principle for determining critical temperature was deeply discussed upon the basis of the numerical simulation results. The critical temperature table considering different spans, grid dimensions and cable diameters is given, and the influence on critical temperature has also been studied when initial prestressed force of vertical cable is relatively small. Some suggestions are proposed finally.

## Introduction

The prestressed cable system used high strength steel in monolayer cable net glass curtain wall has a small structural section can avoid the shortcoming of point-supported glass curtain wall, such as could not satisfy the architectural design requirements of large-scale curtain wall structure for use the rigid structural system like steel frame and truss. The monolayer cable net glass curtain wall represent the trends of large scale curtain wall structure [1] can achieve the elegant appearance, simple structure and convenient construction requirements for large space structures.

In recent years, the monolayer cable net glass curtain wall has quickly spread in our country. However, the elastic modulus and yield strength of high strength cables will significantly reduce under high fire temperature. Even that have an obviously influence on the structural mechanical properties. It is difficult to take fire prevention measures on cables and there is glass blowout dangerous. Thus, the mechanical properties and fire resistance calculation methods [2] for monolayer cable net glass curtain wall under fire condition are urgently need.

## Mechanical properties for high strength cables

It should to make clear that the high strength cables material mechanical property parameters changing situation with the temperature rise under fire condition for research the monolayer cable net glass curtain wall mechanical properties under high fire temperature. The high strength cables have many differences with common steel in material properties for the different processing technology [3].

The elastic modulus of structural cables is in range of 147～170 kN/mm$^2$ and the linear expansion coefficient is $3.9\times10^{-6}$ / ℃ [4] at room temperature. Based upon the commonly used cables, normal elastic modulus E take 150kN/mm$^2$, breaking strength fu take 1570MPa and linear expansion coefficient take $3.9\times10^{-6}$ /℃.

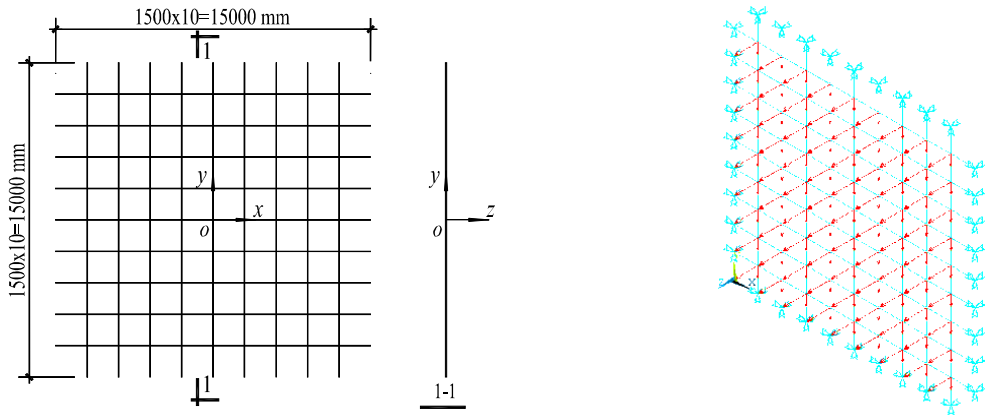
There is no domestic and foreign scholars do system research on material properties under high fire condition for various types of cables. The elastic modulus reduction coefficients [5] of cables under high temperature are shown in Tab.1.

**Tab.1 The elastic modulus reduction coefficients of high-strength cables under high temperatures**

| Temperature（℃） | 20 | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | 900 | 1000 | 1100 | 1200 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| $E_T/E$ | 1.00 | 1.00 | 0.87 | 0.72 | 0.56 | 0.40 | 0.24 | 0.08 | 0.06 | 0.05 | 0.03 | 0.02 | 0.00 |

In the following research, the high strength cables will be taken as the linear elastic material for theirs high yield strength and the little strength reserve after yield, and only consider the elastic modulus with temperature changes. The cables are considered failure when the cable stress higher than the yield strength under the temperature at that time.

## Finite element method analysis



**a)** Geometric model b) Finite element model

**Fig.1 Calculation model of monolayer cable net structure**

The synergism of the glass and cable net has a certain influence on the mechanical properties of the monolayer cable net glass curtain wall at room temperature [6]. But even at the room temperature, it is not easy to determine the connection stiffness of the glass and the cable net nodes. The mechanical of no matter claw or glass cement will be some changes in node connection parts under fire condition, so it is harder to ensure the simulation method. This paper will first conservatively research the structural mechanical performance under fire condition when do not consider the contribution from the glass stiffness, but put the weight of the glass and fittings on the cable net.

The monolayer cable net structure analysis model is established shown in Fig.1a. The size of cable net is 15 m×15 m, the grid size of glass compartment is 1.5 m×1.5 m, the horizontal and vertical cables are adopt φ16 steel strand, and the section area A is 151 $mm^2$. To simplify the calculation, the bearings take fixed end and do not consider the effect of its stiffness on the structure system. The dead weight of the curtain wall fittings takes 0.2 $kN/m^2$, and the horizontal load is 1.0 $kN/m^2$ uniform load which is perpendicular to the glass panel.

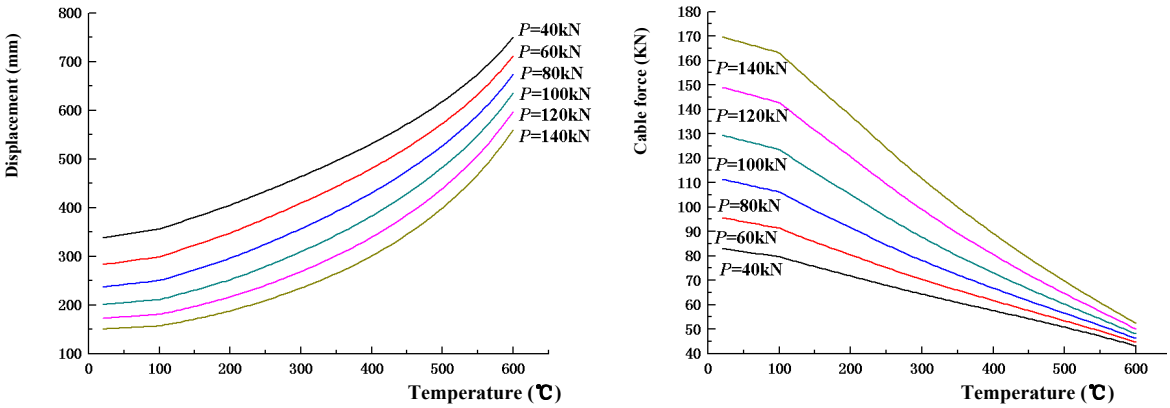
The calculation models were established by ANSYS to conduct non-linear analysis on cable net structure under fire condition. LINK10 element was used to simulate cables. Only take the structural maximum deformation and cable force of the calculation results for the space limitation.

The temperature distribution in large space structure is not uniform under fire condition. The monolayer cable net glass curtain wall often can not be applied fire retardant paint for the small cables section, and the intersections of each cable are connected by metal fixture so that the temperature in cables soon able to reach thermal equilibrium and uniform distribution. This consideration is emphasis on safe, so this paper will calculate according to scheme of cables even temperature-increasing.

The initial temperature of cable net is 20 ℃, then uniformly heat to 600 ℃. The horizontal and perpendicular cables are all applied the same initial prestress in the same calculation model. The initial prestress P is range from 40 kN to 140 kN for its value is about 30％of cable breakage stress in engineering practice.

The calculation result changing situation of the monolayer cable net structural maximum displacement and cable force in temperature heating process is shown in Fig.2. The structural maximum displacement of all calculation models are increasing with the temperature rise and the change curves are approximately parallel under different initial prestress. While, as the temperature increases the cable prestress are all obvious relaxation. When cable temperature is lower than 100 ℃

the prestress relaxation speed is slower, but when it higher than 100 ℃ the prestress relaxation speed is obviously faster and the larger initial prestress the faster relax speed.



a) The maximum displacement curve b) The maximum cable force curve

**Fig.2 The monolayer cable net maximum displacement and cable force curve varies with temperature**

## Calculation method of critical temperature

According to Point Supported Glass Curtain Wall Engineering Discipline[7], the relative deflection of point supported glass curtain wall supporting structure is can not more than l/300 (l is span of supporting structure ) under composite action, such as wind load. The flexible supporting structures like monolayer cable net have a big different from normal rigid supporting structures, so if use the existing norms to control deflection have distinct irrationality.

Sun Fen, Tsinghua university, discuss the deflection limits of monolayer bi-directional flexible cable glass curtain wall structure based on Beijing New Poly Plaza [8]. The research shows that if the large flexible glass curtain wall structures meet the limit condition of relative deflection is not greater than l/300 need to apply a great prestress on the cable net. It will lead to the additional inner force on the main structure even more than the influence of external load, thus make the members section coarser and the main structure unbearable. Based on the consideration of the ability to adapt to deformation, permeability and economic of point supported glass curtain wall, the vertical deformation of the curtain wall control in l/50 under the effect of the most unfavorable load

Through the previous calculations are not hard to find that the cable net deformation will increase with the temperature rising, but excessive deformation will cause glass twist or broken for too much squeeze. However, it is difficult to simulate the glass collapse in finite element numerical simulation. Based on the engineering practice, we think the deformation of general monolayer cable net glass curtain wall can not over l/50 under the worst combination of loads condition, otherwise easy to cause the glass broken and structural damage [9] finally. This paper determines the monolayer cable net glass curtain wall displacement limit can not more than l/50.

The difference between monolayer cable net glass curtain wall and other large space steel structures is that glass will burst and lead to the destroy of the curtain wall under high temperature condition. The research of glass burst under high temperature is very few in domestic, so this paper adapts the research results of scholars like Hassani [10]. The results are that the burst temperature of 6mm thickness glass is 450 ℃ and should not more than 450 ℃ in order to ensure the integrity of the glass curtain wall.

In addition, cables will have a degree of relaxation for thermal expansion and decrease of the elastic modulus. The cables relax speed under the vertical load combination without consider wind load condition will faster than wind load condition. If the cable tension decreases to zero, it will also cause the structure damage. However, by finite element analysis found that when apply the same prestress on both horizontal and vertical cables in the range of 450℃, the cable tension would never decrease to zero even if the cable stress has a great decrease.

Above all, the monolayer cable net glass curtain wall, applied the same prestress on both horizontal and vertical cables, will take the smaller value between 450℃ and the temperature makes

the maximum displacement reach to l/50 as its critical temperature, and take it as the judgment basis of fire resistant design.

## Calculation for critical temperature of fire-resistant

The monolayer cable net glass curtain wall practical critical temperature table for fire resistant design can be obtained by calculating a large number of numerical models, as shown in Tab.2. This critical temperature table including a more comprehensive range of monolayer cable net glass curtain wall in engineering practice, such as the cable span between 10m and 50m, the aspect ratio is 1.0～2.0, the grid size is 1.0 m～2.5 m, the cable diameter is 12 mm～36 mm, the glass weight is mainly considered based on the commonly used (12 mm+12 mm) insulating glass curtain wall, and the weight of the curtain wall fittings take 0.2 kN/m$^2$.

Based on the usual practice, the cable initial prestress uniformly take the 30％of the breakage stress and the horizontal loads take 1 kN/m$^2$, this will be more safe than a majority cases. The critical temperature table given in this paper can be help structural designers to estimate the fire resistant capacity of monolayer cable net glass curtain wall and quickly to get the highest allowable temperature in fire disaster. This has a good practical significance.

**Table 2 Critical temperatures for monolayer cable net glass curtain wall under fire conditions (℃)**

| Curtain wall geometry size | Grid size | Cable diameter (mm) | | | | | |
|---|---|---|---|---|---|---|---|
| | | 12 | 16 | 22 | 26 | 30 | 36 |
| 10m×10m | 1.0m×1.0m | 329 | 450 | 450 | 450 | 450 | 450 |
| 10m×20m | 1.0m×1.0m | 204 | 373 | 450 | 450 | 450 | 450 |
| 15m×15m | 1.5m×1.5m | -- | 197 | 385 | 450 | 450 | 450 |
| 20m×20m | 1.0m×1.0m | -- | 227 | 405 | 450 | 450 | 450 |
| 20m×20m | 2.0m×2.0m | -- | -- | 201 | 308 | 360 | 450 |
| 20m×40m | 1.0m×1.0m | -- | 195 | 354 | 432 | 450 | 450 |
| 20m×40m | 2.0m×2.0m | -- | -- | 201 | 244 | 303 | 407 |
| 30m×30m | 1.5m×1.5m | -- | -- | -- | 263 | 321 | 425 |
| 30m×45m | 1.5m×1.5m | -- | -- | -- | 202 | 265 | 377 |
| 40m×40m | 2.0m×2.0m | -- | -- | -- | -- | 115 | 206 |
| 50m×50m | 2.5m×2.5m | -- | -- | -- | -- | -- | 76 |

However, vertical cables are mainly bear the glass and fittings weight in engineering practice, so put a low prestress on the vertical cables and only meet the situation that not appear relaxation under room temperature and the most unfavorable load combination condition. Thus , the following will put a low prestress on the vertical cables and calculate the critical temperature under fire condition, and make a compare with Fig.2.

The size of the calculation model is 15m×15m, the grid size is 1.5m×1.5m, the cable diameter is 16mm, and the initial prestress of the horizontal cable is 80KN. The vertical cable prestress is 10%～50% of the horizontal cable, the glass weight is mainly considered based on the commonly used (12 mm+12 mm) insulating glass curtain wall, the weight of the curtain wall fittings also take 0.2 kN/m$^2$, and the calculation results are shown in Tab.3. At this time, take the lowest temperature among the cable temperature when the structure displacement is over l/50 under the load combination with consider wind load condition, the cable temperature when a cable prestress decreases to zero under the load combination without consider wind load condition and 450℃.

Through the comparative analysis, it can be known that when the vertical cable prestress is lower the structure bearing capacity will reduce and lead to the decrease of the structural critical temperature. In general, the displacement transfinite is faster than cable relaxation.

Above all, the low vertical cable prestress has a significant influence on the critical temperature, so can not use the critical temperature table shown in Tab.2. This paper has not give the corresponding fire resistance critical temperature calculating table for the space limitation, but the same calculation method can be used to get the different critical values when the horizontal and vertical cables have a different prestress ratio.

**Table 3 Critical temperatures when lower prestresse in vertical cables (℃)**

| | Prestress ratio of horizontal and vertical cables | | | | | |
|---|---|---|---|---|---|---|
| | 10% | 20% | 30% | 40% | 50% | 100% |
| Displacement transfinite | -- | 24 | 69 | 107 | 128 | 228 |
| Cable relaxation | 112 | 217 | 315 | 420 | 518 | -- |
| Critical temperature | -- | 24 | 69 | 107 | 128 | 228 |

## Summary

1) The structure maximum displacement will increase with the temperature rising of monolayer cable net glass curtain wall, and the relaxation speed of the large initial prestress cable will greater than the lower one.
2) When the horizontal and vertical cables applied the same initial prestress, take the smaller value between 450℃ and the temperature makes the maximum displacement reach to l/50 as the structure critical temperature. When the vertical cable prestress is low, take the lowest temperature among the cable temperature when the structure displacement is over l/50 under the load combination with consider wind load condition, the cable temperature when a cable prestress decreases to zero under the load combination without consider wind load condition and 450℃as the structure critical temperature.
3) Based on a plenty of numerical analysis, the critical temperature table which can be applied to different span, grid size, and cable diameter has been obtained and including a more comprehensive range of monolayer cable net glass curtain wall in engineering practice.

**Keywords:** Chair-Shaped Cataclinal Bank Slopes, Rock Landslides, Pregnant and Sliding Mechanism, Mechanical Model, Groundwater Pressure, Prevention Measures.

**Abstract.** The pregnant and sliding mechanism was firstly compared between Vajont and Qianjiangping large rock landslides, which happened in the chair-shaped cataclinal bank slopes. And then the essence of the landslides occurred was deduced. The pregnant and sliding process of the landslides was showed two stages. First, after the first impoundment of the reservoir, the soil and shallow rock at the front of the landslides were slipped and then caused posterior margin of the deep latent sliding surface cracks. So the groundwater supply condition was significantly changed. Second, with the rapidly increase of the groundwater recharge, its pressure on the front of the landslides was also rapidly rise to the critical value which the landslides occurred. Afterwards, the stability mechanical model of the chair-shaped cataclinal bank slopes and critical value formula of the groundwater pressure were established on the basis of the stability mechanical model of general chair-shaped cataclinal slopes, added reservoir water level which was a dynamic load. While working procedures to determine the groundwater pressure was put forward. Last, the theory was certified validity take Liangshuijing rock landslide of the Three Gorges Project area as an example and the monitoring methods and control measures for the landslide were proposed.

## Introduction

In the world, there were two large catastrophic rock landslides caused by reservoir make engineering, rock mechanics and engineering geology academic community shock and concern. The one was Vajont reservoir rock landslide occurred on Oct.9, 1963 in Italy, the other was Qianjiangping rock landslide occurred on Jul.13, 2003 in China's Three Gorges Project reservoir bank.

Since Vajont reservoir rock landslide occurred, many scholars all over the world studied on the landslide and published numerous thesis for decades. After Qianjiangping rock landslide occurred, the case was also. But so far, there is no consensus to germination and sliding mechanism of the large rock landslides [1-7], especially no one put forward the quantify criterion of the landslides prediction. Therefore, a little tentative work was done in this thesis or it could play a valuable role to further understanding these large landslides.

Both Vajont and Qianjiangping rock landslides happened in the chair-shaped cataclinal slope. This cataclinal slope is a kind of easily slipping structure. Chair-shaped cataclinal slope is such cataclinal slope [8], that upper slope angle less than penetrative discontinuities angle, meanwhile penetrative discontinuities angle greater than dip angle causing slide, under slope angle great than penetrative discontinuities angle, meanwhile penetrative discontinuities angle less than dip angle causing slide. Rock stratum angle of upper slope is steep, so the rock declining power will undoubtedly increase. Rock stratum angle of under slope is gentle, so the slip resistance increase, but it avail penetrative

discontinuities leading edge form an effective freeing surface. In view of this, the overall stability of the chair-shaped cataclinal slope depends on the hydrogeological structure and syntagmatic relations of length, height, and angle change of the upper and under slope. It were published by Xichang Chen(2009) that mechanical model of common chair-shaped cataclinal slope and fundamental calculation formula of the rock landslide hydraulic start critical value [9]. On this basis, the special mechanical model of chair-shaped cataclinal reservoir bank slope stability will be established, and forecasting and early warning criteria of the large rock landslides will be put forward in this thesis.

**Vajont Reservoir Rock Landslide**

On 22:39 (GMT) October 9, 1963, The Vajont reservoir rock landslide with a volume of more than $2.4\times10^8 m^3$ rock and gravel occurred in Italian, at the maximum speed of 30m/s. As a result, The Vajont reservoir was scrapped and nearly 3,000 people were killed. It was the worst landslide accident of hydraulic architectural history in Italy [2].

Vajont reservoir was built in Vajont valley, which in the Alps mountains in northern Italian. Vajont valley was formed by deep canyons and two-stage U-shaped glacial valleys. Near the Vajont reservoir dam it was a asymmetric syncline, which the south wing (left bank) steep and the north wing slowed down. The dam built on the upper Jurassic limestone stratum in the raise ends of the syncline. The limestone stratum were gently and a tendency to the upper reaches. So the engineering geological conditions of the dam was quite satisfactory. But near the dam, both sides of the reservoir bank were chair-shaped cataclinal bank slope, and formation of two-stage flat mesa on the slope through the glacial and river erosion. The flat mesa were covered with glacial outwash soils, alluvial soils and ancient slumping mass, etc. The underlying bedrock dip angle of the chair-shaped cataclinal slope was about 40° at upper and middle limestone stratum, and it was nearly horizontal at the bottom of the river valley (Fig. 1).

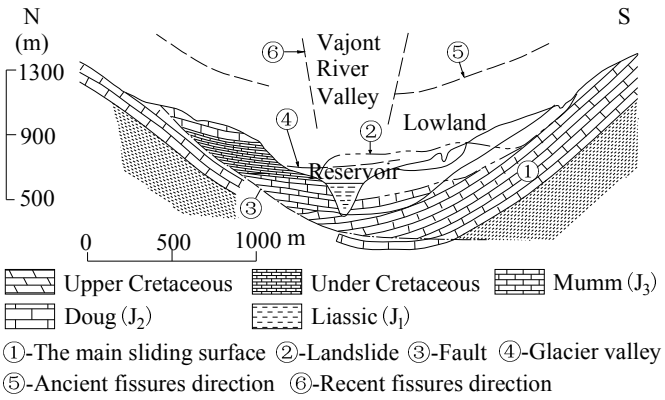

Fig. 1 Geological profile of Vajont valley in Italy (According to Kiersch,1964)

On October 1960, when the initial water level of the Vajont reservoir reached to 642m, close to the below flat mesa on the slope, the rear of the above flat mesa appeared tensile fractures and extended to the eastward. When the water level reached to 652m, the front of the above flat mesa happened collapses and landslides. Obviously, this was due to the uplift pressure of the reservoir water reduced the rock and soil anti-slide force of the front slip resistance section of the above flat mesa. In December 1960 to October 1961, the water level of the Vajont reservoir dropped below 600m, and the displacement rate of rock and soil quickly dropped below 0.3cm/d, and remained stable. But in November 1961, the reservoir water level began to rise again to more than 600m, and with the water level rose, the displacement rate of rock and soil was gradually increased. On November, 1962, when the water level rose to 700m, the displacement rate of rock and soil exceeded 1cm/d. On December 1962 to March 1963, the water level was dropped to 650m, the displacement rate also declined. During this period, the displacement of rock and soil may be partial elastic deformation and show the changes of water pressure intensity. The real landslide (including creep) did not happen during this

period. While After April 1963, the water level began to rise again, and rose to 700m or more in June. At this point, the displacement rate increased progressively, it was to no avail even if the water level was adjusted. And the large rock landslide shocked the world finally happened.

So, what were the key factors that the landslide occurred? The following analysis was divided into three phases to the germination and sliding process of the landslide.

Before reservoir impoundment (Fig. 2). The bank slope was chair-shaped cataclinal slope, which was controlled by the slope structural form, and formation of two-stage flat mesa through the glacial erosion effect. There piled moraine and alluvial on the two-stage flat mesa. On the above flat mesa, moraine was dominated, and there was geomorphological conditions that surface water come together. Because of moraine on the above flat mesa was impermeable, surface water can not infiltrate, so the fissure water internal the slope was relatively poor due to lack of supply. In addition, lay and fissure located front of the slope were easily blocked in the leaching process. Therefore the underground water level near the river bank of the large rock landslide can only remain in place near the river level. So the bank slope was long-term relatively stable.

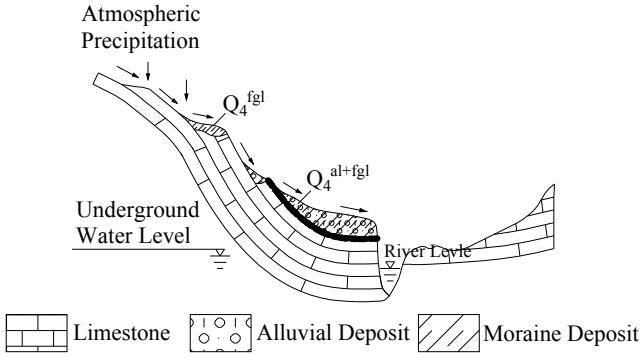

Fig. 2 Geological profile of the Vajont reservoir bank slope before impoundment

Initial stage of reservoir impoundment (Fig. 3a, Fig. 3b). When the water level of the reservoir to 642m ~ 652m, soil and rock at the front of the slope was submerged and shallow soil-rock aggregate landslides were occurred by the reservoir water pressure and uplift force. In the affect of drag and unloading of shallow landslides, it was destroyed that the closed condition, which the top of latent sliding surface of the Vajont reservoir bank landslide. So the tension crack was appeared on the above flat mesa and the groundwater supplementary amount was showered, as well as the groundwater dynamic variety range. Although the slope loads and normal stress imposed on the latent sliding surface was rose with the rise of the reservoir water level, but it was also raised that the drainage datum of the shallow phreatic water and uplift force and dynamic water pressure imposed on the shallow soil and rock. Soil and rock at the front of the slope submerged, that not only induced shallow soil-rock aggregate landslides, but also formed the large easily slipping hydrogeological structure in the rocky slope. Although both rainfall capacity and the reservoir water level was reached higher values, but because of its short duration, so the underground water level (hydrostatic pressure imposed on the front section of the latent sliding surface) in the rocky slope not yet reached the critical value which caused The Vajont reservoir rock landslide. The large rock landslide had not slid. Thus, comply with Pascal principle and hydrostatic pressure formula, it was showed in Fig.3b that groundwater pressure which imposed on the latent sliding surface.

Sliding of the large rock landslide (Fig. 4a, Fig. 4b). After June 1963, due to abundant rainfall, not only the water level of the reservoir continued to rise, it was also rapidly increased that the groundwater level on the latent sliding surface, which infiltration conditions of surface water had been significantly altered. And the rising speed of groundwater level was faster than the speed of the reservoir water level because of large supplementary amount and small hydraulic conductivity and storage space. The rainy season rainfall in 1963 was too large, especially the continuous heavy rain during September 28 ~ October 9. The continuous heavy rain caused the groundwater level on the latent sliding surface continued to rise further. And Finally, groundwater pressure on the latent sliding

surface leading edge reached the critical value that caused the rock landslide slid. So the large catastrophic rock landslide, called Vajont reservoir rock landslide, was occurred. It was a testament to the first slide of the front section stratum of the landslide that the stratum was not crushed and tiled in the Vajont reservoir.

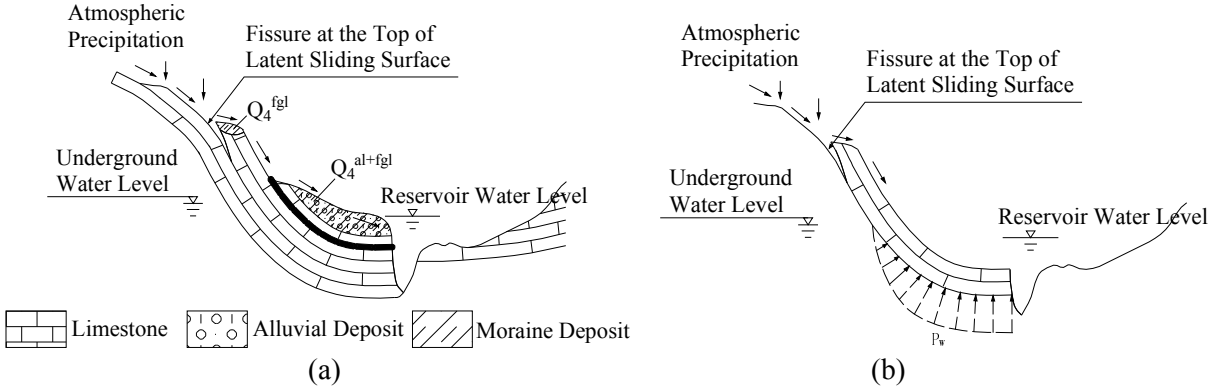

Fig. 3 (a) Geological profile of the Vajont reservoir bank slope in the initial stage of reservoir impoundment and (b) the groundwater pressure distribution

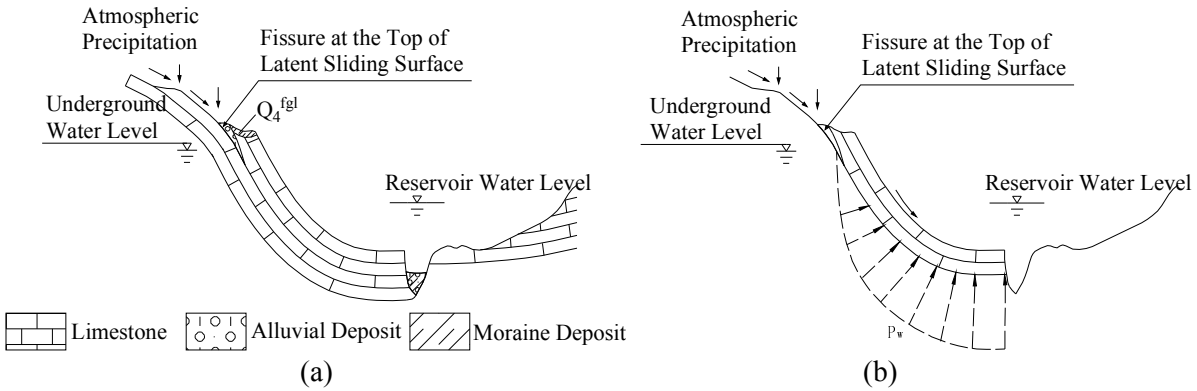

Fig. 4 (a) Geological profile of the Vajont reservoir bank slope and (b) the groundwater pressure distribution of the latent sliding surface at the landslide slid

From the above three phases discussion, it can be seen that germination and sliding process of Vajont reservoir rock landslide was a staged chain reaction. Because of the shallow landslide caused by initial impoundment of the reservoir changed the hydrogeological structure of the chair-shaped cataclinal rocky bank slope, the supply conditions of the latent sliding surface groundwater was improved. So the groundwater pressure that applied to the front part of the rocky bank slope reached to the critical value that the landslide occurred. However, the soil slippage at the front part of the Qianjiangping rock landslide, in the following illustration, may be mainly happened under the water.

**Qianjiangping Rock Landslide**

At 0:20 on July 13, 2003, a landslide with a volume of more than $1500\times10^4 m^3$ occurred on the left bank of the Qinggan River, Shazhenxi Town, Zigui County, Hubei Province, China. This was called Qianjiangping rock landslide. This landslide caused houses collapse, plant destroyed, traffic stop, rivers clogged, 28 people died, 22 fishing boats overturned, 14 fishermen killed. In addition, this landslide also caused 10 people missing and 19 people injured, 1200 people homeless. After the disaster, domestic authorities were extremely concerned about this landslide. One after another experts and scholars were sent to the landslide scene to participate in the disaster relief. And the landslide was carried out detailed investigation and research, and numerous research papers were published on the causes of the landslide. Here the genetic mechanism of the landslide was be analyzed based on existing data and site survey to the landslide.

**Regional Geological Environment and Slope Structure of the Qianjingping Landslide Region.** The Qianjingping landslide was just located in the reverse composite position of the NE-trending Zigui syncline, Xinhua fracture and NW-trending Liuleiguan anticline. Zigui syncline and Xinhua fracture are both component of Huaiyang tectonic system, and mainly finalized in the indosinian period. While Liuleiguan anticline is belong to the Sichuan-Hubei fold belt in the new cathaysian, which finalized in the Yanshanian period. The overall direction of the Sichuan-Hubei fold belt is the NNE to NE, but the Liuleiguan anticline located in the northeast terminal is be turned to NW because of the obstruct of Huaiyang tectonic system. In addition, Xinhua fracture is deep fracture, cutting through before sinian system strata, and has significantly activity in the recent period. The southern extension direction of Xinhua fracture is envisaging Qinggan river, where the front of the landslide take a sharp turn. So, the southern extension direction of Xinhua fracture is likely to pass along the bottom of the landslide failure surface and extend along Luogutong river. This tectonic position and its geological history also formed geologic environment and the structure type of the slope in the area of Qianjingping landslide region. There were many landslides in the Xinhua fracture and its south extension line, such as Liuleiguan landslide ($2600\times10^4m^3$), Shuitianba slump group (160 ~ $1250\times10^4m^3$) and Majiaba landslide ($2882\times10^4m^3$). Therefore, correct understanding of regional geological structure is of great significance for discovering easily slipping structure of the slope in time.

Qianjiangping landslide locate in plunging wing of the Liuleiguan anticline. The strata is amaranthine mudstone and shale interbedded with feldspar quartz sandstone of Niejiashan groups in Jurassic systerm ($J_{1\text{-}2n}$). The strata tendencies is the same as the slope. The strata dip angle is 25°~ 40° above the elevation 180m (upper section), it is 15°~ 20° below the elevation 180m, it is 10°~ 13° at the front of the slope [3-5] (Fig. 5). Obviously Qianjiangping landslide is a rock landslide happened in the chair-shaped cataclinal bank slope, the gully (whether for branch fault in dispute) and fault as its east and west boundaries. The Triassic strata mainly locate in the area of the landslide up to the ridge, as well as the Liuleiguan anticlinal axis. The geomorphic conditions is conducive to pooling the atmospheric precipitation, and converge to the upper of the landslide.

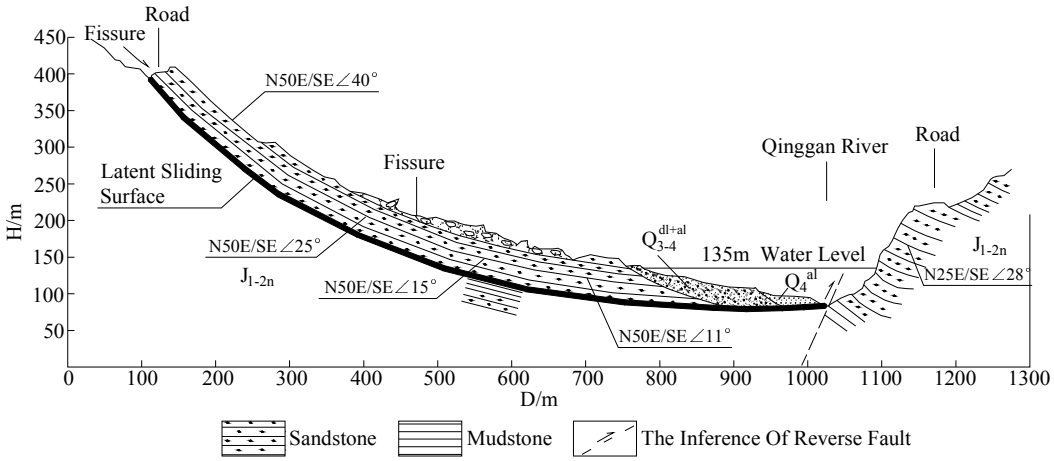

Fig. 5 Diagrammatic section of Qianjiangping landslide on the sliding threshold

**Sliding Process of the Qianjiangping Landslide.** The Qianjiangping landslide located in the left bank of the Qinggan river which is a primary tributary of the Yangtze river, less than 2 km away from the estuary and about 50 km away from the Three Gorges Project dam site. The landslide slid at the 33 days after the 135 m elevation water storage of the Three Gorges reservoir. The Qinggan river elevation was 95 m and the riverbed elevation was 92 m before the Three Gorges reservoir impound. On June 13, 2003, three days after the Three Gorges reservoir impoundment to 135m, intermittent tension cracks began to appear at the position of 400 m elevation. On June 21 to July 11, 2003, the heavy rainfall occurred in the landslide area, with a total rainfall of 162.7mm. Since July 1, 2003, fine cracks were appeared on the silicon factory road about 200m elevation. On July 12, the cracks were

arced and penetrative, open about 2m. On July 12 at 11 PM, there were many obvious cracks on the bank slope and sharply open. About 1:00 the next day, the landslide occured at high sliding speed of approximately 17.6 m/s for 1 minute, then small-scale landslides occurred at the upper edge and sides, five minutes after, the landslide stopped. The shear outlet of the landslide was 100m ~ 110m.

**Pregnant and Sliding Mechanism of the Qianjiangping Landslide.** Modern, there was no obvious indication of deformation and damage in the Qianjiangping landslide area, and there was no history of landslide disasters. However, the landslide incident, as well as the Vajont reservoir rock landslide, showed that can't use pure rock and soil mechanics point of view to treat with bank slope stability problems, which has complex evolution history and environmental conditions, especially not analyze pregnant and sliding mechanism of the landslides just from the mechanical properties of rocks or sliding surfaces. Now pregnant and sliding mechanism of the Qianjiangping landslide was revealed by analyzed the corresponding relationship of the slope structure, dynamic change of the landslide main inducing factors and each part deformation and failure of the slope on the sliding threshold.

First, although the rock slope of the Qianjiangping landslide area was chair-shaped cataclinal bank slope, with free face at the front of penetrative discontinuities, but belonged to the alluvial coast in the rising district during the recent period. Therefore before the Three Gorges reservoir impounded, it was growing and heavier that the soil on the front of sliding resistance segment, with gently dip angle, although the soil also suffered heavy rain, groundwater and flooding erosion, but its overall stability was to a better direction.

On June 1 ~ 10, 2003, the water level of the Three Gorges reservoir reached 135 m elevation, only three days later, intermittent tension cracks began to appear at the position of 400 m elevation. At the moment, the mechanical properties of latent sliding surface itself of the Qianjiangping landslide is unlikely to have a big change. Because the latent sliding surface in the river incised period had experienced 135m ~ 100m elevation change, and also suffered heavy rain, groundwater and flooding erosion, and sliding resistance segment, with gently dip angle, was certainly shorter and thinner than the time of the landslide slid, that through shear strength of the latent sliding surface was more difficult to maintain stable in that time. With the river incision, there had been surface sliding in the free face of slope and accumulated to the front edge, causing the river to the other side and the sliding resistance segment growth. However, these alluvium and colluvium at the gentle slope mesa and the foot of the slope were the modern (from a geological time) to add, so they were easily sliding part or all by flooded and submerged of the Three Gorges reservoir water while the water level rise again to 135 m elevation. Uplift pressure was stressed on the submerged rock at the front of the slope (especially shallow sandstone above river bed mudstone layer) by the reservoir water, so that normal stress on the latent sliding surface was decreased and unloading and drag effect by the sliding of rock and soil landslides was also stressed on the submerged rock. Both of these make the sliding resistance of the front section of the slope further reduce, and lead to the upper steep dip rock adjustable sliding downward with intermittent cracks on the road located in the rear of the landslide. So groundwater recharge conditions above the latent sliding surface was larger changed.

Another effect that the Three Gorges reservoir water level rise was raised groundwater drainage plane, Even under the condition of supplementary amount invariable, the underground water level was also increase correspondingly and easily caused shallow rock and soil slid. However, whether the landslide slid mainly depend on the underground water supply conditions of the deep latent sliding surface.

But very unfortunately, June 21 ~ July 11, 2003, heavy rainfall occurred in the landslide area. At this stage, the tension cracks on the back steep wall of the landslide had been more conducive to the land surface water infiltration and groundwater levels raise rapidly, thus greater groundwater pressure stressed sliding resistance segment of the landslide which resistance forces reduced. However, due to the dynamic changes of the groundwater (especially deep latent sliding surface groundwater) lag behind in rainfall and surface water, two days after the end of the continuous heavy rain, that July 12 ~ 13, 2003, the groundwater level and its pressure on the sliding resistance segment was increased to

the critical value of the landslide slid. When July 12, 2003, the cracks in the back steep wall of the landslide were arced and penetrative, July 12 at 11 PM, there were many obvious cracks on the slope and sharply open, about 1:00 the next day, the rock landslide overall finally slid downward rapidly.

**Revelation of Contrast Analysis and Study between the Vajont Reservoir Rock Landslide and Qianjiangping Rock Landslide**

Pregnant and sliding process of the large rock landslides, such as Vajont reservoir rock landslide and Qianjiangping rock landslide, showed two stages. First, under the influence of initially impoundment of the reservoir, the soil and shallow rock at the front of the slope was slid downward, caused unloading and drag effect, this effect caused posterior margin of the deep latent sliding surface cracks, and then surface water was easy to infiltration to supplying the groundwater. Second, with the rapidly increase of groundwater recharge, its pressure was also rapidly rise to the critical value which caused the landslides. The interval of these two stages, generally may be a few days or a few years, depended on the structure elements of the latent sliding surface, the change degree of the groundwater supply conditions and the recharge growth rate of the groundwater. Tangyanguang landslide occurred in Tuoxi reservoir in 1961, in Hunan province. The slope which the Tangyanguang landslide occurred in was also chair-shaped cataclinal slope. Due to the dip angle of the upper steep sand slate was reached 45°, and the loose layers at the front of the slope was thick, the two stage was just 12 hours apart.

Through analysis the pregnant and sliding process of Vajont reservoir rock landslide, an important understanding can be concluded that with the reservoir water level rise the normal stress on the latent sliding surface was increased and the groundwater supply conditions of the latent sliding surface was changed by the unloading and drag effect, which caused by the submerged soil and shallow rock at the front of the slope slid downward. Often the latter effect was revealed more prominently in the second stage. That was, after hydrogeological structure of the slope changed, inducing factors dynamically had only the possibility of starting the landslides, groundwater pressure would become main mechanical mark which caused the rock landslides. Also known as that the groundwater pressure on the front section of the latent sliding surface reached the critical value, the rock landslides occurs. In addition, it was easy to see that the emergency measures to reduce the water level of the Vajont reservoir adopted by the staff was incorrect, because at that time it was urgently needed to reduce the groundwater level rather than the reservoir water level. Seepage rate of the underground water is far lower than the flow velocity of the reservoir water, so they are impossible to synchronize decline. Through the reservoir level lower rapidly, the pressure difference between reservoir water and groundwater was widen and normal stress and friction on the latent sliding surface was reduced, thereby the landslides sliding was accelerated. Meanwhile, because of rapidly drainage, the flow condition of the reservoir water was complex, even partial vacuum and negative pressure was formatted in the latent sliding surface. As a result, to reduce the water level of the Vajont reservoir was actually added fuel to the fire, accelerated the Vajont reservoir rock landslide slid.

Therefore, detailed investigation and study to the typical landslides case was basis and premise that understand pregnant and sliding mechanism of the reservoir bank landslides, established mechanics model of the reservoir bank slope stability and the critical value formula of the landslide sliding, determined the quantitative marks of prediction and forecasting landslide. Simple rainfall or rise and fall of the reservoir water cannot become iconic factor of the landslides slid, while it was to find the real cause of the rock landslides slid that only to understand the dynamic change of groundwater (especially the groundwater pressure change) before the landslides slid. However, in the three years monitoring of Vajont reservoir rock landslide, it was precisely lack of the dynamic monitoring of groundwater, and therefore it was fail to succeed for lack of a final effort. The incident also exposed many problems of the previous monitoring methods and equipments.

Qianjiangping rock landslide, as well as Vajont reservoir rock landslide, had easily slipping structure of chair-shaped cataclinal slope. Both of the two landslides were occurred under the force of

the successive coupling that the landslide weight force, the reservoir water uplift pressure, unloading stress and drag force by the sliding of front rock and soil landslides and groundwater pressure. When it was the groundwater pressure that final breakthrough stability limit and causing landslides. Although the magnitude of the forces on the slope was different at each place, but specifically for each bank slope section, these forces were measured and can be calculated. Therefore the mechanical model of chair-shaped cataclinal slope stability was established, and the value of hydraulic induced the landslide was calculated. So that correctly regulate or engineering measures adopted in order to improve the stress state of the latent landslide, to achieve the purpose of disaster prevention.

## Stability Mechanical Model of Chair-Shaped Cataclinal Bank Slope and Critical Value of the Rock Landslide Sliding

**Mechanical Model and Critical Value Formula of the Rock Landslide Sliding.** For easy to comparison and understanding, the mechanical model of general chair-shaped cataclinal slope stability in reference [9] (Fig. 6a) was also attached.

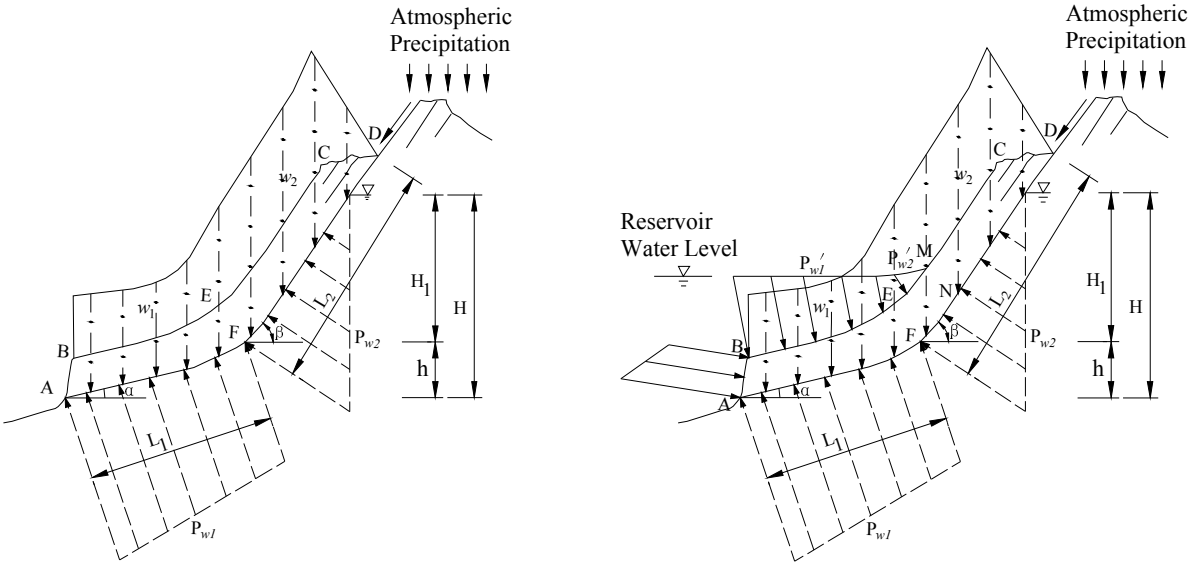

Fig. 6 The pressure diagrammatic section of the unit width of (a) the general chair-shaped cataclinal slope and (b) the chair-shaped cataclinal bank slope (In accordance with the Vajont reservoir bank slope)

In the Fig. 6, – · → gravity vector of the latent sliding body, — — ► interstitial hydraulic pressure vector of the latent sliding surface, ⟶ reservoir water pressure vector of the surface of latent sliding body, $w_1$ —— the per unit area gravity of ABEF section latent sliding body at the gravity center position, $w_2$ —— the per unit area gravity of ECDF section latent sliding body at the gravity center position, $p_{w1}$ —— the per unit area interstitial hydraulic pressure of ABEF section latent sliding body at the pressure center position, $p_{w2}$ —— the per unit area interstitial hydraulic pressure of ECDF section latent sliding body at the pressure center position, $p_{w1}'$ —— the per unit area reservoir water pressure of ABEF section latent sliding body at the pressure center position, $p_{w2}'$ —— the per unit area reservoir water pressure of EMNF section latent sliding body at the pressure center position, $L_1$ —— the length of ABEF section latent sliding surface, $L_2$ —— the length of ECDF section latent sliding surface, $H$ —— elevation difference of the underground water level to A point, $H_1$ —— elevation difference of the underground water level to F point, $h$ —— elevation difference of A point to F point.

After the reservoir water level rise to flat mesa of the slope lower section, water pressure is actually exist perpendicularly to the front free face of the slope, as shown in fig. 6b. But in view of the reservoir water easy mobility and hydraulic connection with the bank slope groundwater, so it is

difficult to resist the slide of the bank slope. For this reason, the reservoir water pressure on the front free face of the slope was not considering in the mechanical model of chair-shaped cataclinal bank slope stability and critical value of the rock landslide sliding. And when the reservoir water level continues to rise to more than the slope turning point of the steep section to flat section, because of the surface covering layer is scattered and thin, even if fall, the unloading and drag effect is often very small, so it can be also ignored. Longitudinal pressure of the reservoir water is perpendicular to the slope surface, it can rough as a normal stress on the latent sliding surface only the dip angle of the slope surface very small differ to the latent sliding surface, otherwise it need to conversion. Although the load of the reservoir water pressure, dynamic variation between the level of dead water and normal high water, had been added to the mechanical model of chair-shaped cataclinal bank slope stability, but its variation range and way is also limited for each specific reservoir bank slope.

From fig.6 it is not hard to see that the slope front section of the penetrative discontinuities smooth (ABEF section) is sliding resistance. The applied forces on the ABEF section have rock mass gravity, interstitial hydraulic pressure, reservoir water pressure, also have total surplus sliding force (*Pr*) of upper dipping section (ECDF section) of the slope. So the hydraulic starting critical value of the landslide is the start value of the total latent sliding body. In order to make calculation formula not too multifarious, the amount of forces had been expressed, their corresponding symbols also use capital letters. So, the mechanical model of chair-shaped cataclinal bank slope stability had been established on the basis of the mechanical model of general chair-shaped cataclinal slope stability. Its computation formula was as follow,

$$K = \frac{(W_1 \cos\alpha + P_{W1}^{'} - P_{W1} t_{w1}) tg\varphi_c}{W_1 \sin\alpha + P_r \cos(\beta - \alpha)} \tag{1}$$

While $K$=1, the critical value of groundwater pressure on the landslide sliding threshold was educed as follow,

$$H_{critical} = \frac{\sqrt{b^2 - 4ac} - b}{2a} + h \,. \tag{2}$$

$$a = \frac{\gamma_w t_{w2} tg\varphi_c \cos(\beta - \alpha)}{2\sin\beta} \,. \tag{2-1}$$

$$b = \gamma_w L_1 t_{w1} tg\varphi_c \,. \tag{2-2}$$

$$\begin{aligned} c = {} & W_1(\sin\alpha - \cos\alpha tg\varphi_c) + W_2 \cos(\beta - \alpha)(\sin\beta - \cos\beta tg\varphi_c) + \gamma_w L_1 h t_{w1} tg\varphi_c / 2 - \gamma_w h_1 l_1 tg\varphi_c / 2 \\ & - \gamma_w h_2 \left[ 2l_1 + l_2 \cos(\beta - \alpha) \right] tg\varphi_c / 2 \end{aligned} \,. \tag{2-3}$$

In the above formula, $\varphi_c$ —— comprehensive internal friction angle of the penetrative discontinuities (latent sliding surface) in the absence of water pressure effect, $t_{w1}$ —— water seepage rate of ABEF section of the penetrative discontinuities (latent sliding surface), $t_{w2}$ —— water seepage rate of ECDF section of the penetrative discontinuities (latent sliding surface), $\gamma_w$ —— unit weight of water, $l_1$ —— distance of B point to E point, $l_2$ ——distance of M point to E point, $h_1$ —— elevation difference of B point to E point, $h_2$ —— elevation difference of M point to E point. The determination method of the $\varphi_c$ and $t_w$ had been introduced in reference [9], it can be constantly improved and supplement in practice in the future.

**Procedures and Methods Determination of Critical Value of The Bank Rock Landslide Sliding.** First of all, according to field investigation data, it was determined that whether there was easily slipping hydrogeological structure. The so-called easily slipping hydrogeological structure, simply speaking, should have at least the following three conditions. The first, the steep section of the chair-shaped cataclinal rock bank slope is close to or even longer than the flat section, and the upper

of the steep section has geographic and geomorphic conditions for surface water collection or has possible leakage drainage engineering. The second, it has aquifer in the slope with good water-resisting top and bottom. The third, the front and side ditch of aquifer may be blocked or covered, so it go against groundwater discharge, and is conducive to groundwater accumulation and its level rise. This stage work is the premise and foundation of later work, it need more geological basic theoretical knowledge and experience of field to identification, and should pay attention to the basic requirement of the engineering geological survey. It must not "do a rough work with outstanding method" (Albert Einstein).

According to the upper rock outcrop of the rock bank slope and the highest crack pulled by shallow rock and soil sliding, the possible highest level of groundwater could be to determine. And the critical value of groundwater pressure on the landslide sliding in low reservoir water level could be to calculated using the Eq. 2. Comparison the two value of number above, to determine whether the rock bank landslide slides. If possible, the landslide stability will be calculated step by step according to the coupling effect of different reservoir water level and groundwater level using the Eq. 1.

Both of the reservoir water level and groundwater level are variable, and it has transformation process from the reservoir water gravity to normal stress and sliding pressure on the latent sliding surface, which is Influenced by the geometry of the surface. Computational process of the critical value of groundwater pressure on the landslide sliding is very complicated, so it can use the matrix method for numerical simulation, and it can calculate under the coupling effect of different reservoir water level and groundwater level with the aid of computer. As a result, the critical value of the landslide most easily slides will be determined. This value is the quantitative mark of landslide prediction and forecasting and reliability evaluation of landslide control measures.

The critical value of groundwater pressure on the landslide sliding threshold was layered calculated with multilayer aquifers of easily slipping hydrogeological structure of the chair-shaped cataclinal bank slope.

**Instance Analysis**

Liangshuijing landslide was formerly known as the Biaoganshang in the reference [8] attached fig.1. The landslide located in Guling town, Yunyang country, on the right bank of the Yangtze river, which was 38 km away from the Yunyang county. When the Three Gorges reservoir water level rise to 172m, the landslide began to appear deformed since the November 2008. According to the monitoring data of geological environmental monitoring station in the Yunyang country, the landslide was increasing deformation at a speed of 1 cm every day, since March 10, 2009. To April 1, the penetrative tension cracks were appeared in the back scarp of the landslide, about 150 m length and 10 cm ~ 25 cm width. The elevation was 105 m at the front of the landslide and 289 m at the back cracks. The landslide was 250 m to 370 m length, 200 m ~ 370 m width, about 35 m of average thickness, with about $360\times10^4 m^3$ total volume. The back scarp of the landslide had been dropped 45 cm ~ 60cm, with 45cm plane displacement.

Liangshuijing landslide was also occurred in the the chair-shaped cataclinal rock bank slope and its stability had been successfully predicted prior to the Yangtze river Three Gorges Project construction. When the reservoir level rise to 172 m, the shallow sliding was occurred at the front of the slope and caused the Yangtze river closure of navigation. It is monitoring that whether or not the landslide occurs through the deep penetrative discontinuities. The monitoring methods of the landslide are mainly displacement monitoring using tiltmeter, but lack of quantitative marker. So, the quantitative evaluation method of whether or not the landslide slides is advised, which adopt the critical value formula of the rock landslide sliding put forward in this paper. And the monitoring of groundwater pressure is strengthen, especially the front section of the landslide. At the same time, to seal of cracks of the landslide back scarp and find out whether other penetrative discontinuities was pulled in order to handle in time. Both of the methods can prevent the landslide slides caused by the groundwater pressure, one is truncation of surface water supplement, the other is drainage decompression to the

deep latent sliding surface at the strata dip angle turn. Meanwhile, the drainage holes and the connecting beams at the top of drainage hole can also prevent shallow rock and soil landslides. Under the condition of the appropriate location and structure, the drainage holes can also be used to monitoring the stability of reservoir rock bank. The monitoring result can also be graded warning according to the mechanical model of chair-shaped cataclinal bank slope stability and critical value of the rock landslide sliding in this paper added the necessary safety.

## Conclusions

Based on study between the Vajont reservoir rock landslide and Qianjiangping rock landslide, it was obtained that the fundamental laws and generality of structural conditions, inducing factors, deformation and failure characteristics of the landslides which occurred in the chair-shaped cataclinal rock bank slope. And it was preliminarily revealed that the pregnant and sliding mechanism of the landslides which showed two stages. The groundwater supply condition of the latent sliding surface was changed by the shallow rock and soil landslide in initial period of the reservoir impoundment. This also created the structure premise that the groundwater pressure on the latent sliding surface rise to the critical value of the rock landslides slid.

Based on the mechanical model of general chair-shaped cataclinal slope stability, it was established that mechanical model of chair-shaped cataclinal bank slope stability and computational formula and work procedures and methods of the rock landslides caused by the groundwater pressure on the latent sliding surface. This provides quantitative criteria of monitoring and early warning for rock landslides and provide design basis of landslides control measures.

After the groundwater levels reached the critical value, the sudden conversion of the hydrodynamic pressure and hydrostatic pressure caused the landslides. So the key to the landslides prevention is timely to intercept groundwater supply and drain the groundwater of latent sliding surface. Meanwhile, it is a more accurate and reliable method that monitoring and warning using of the dynamic changes of the groundwater pressure.

In view of the complexity of this problem, the author would like to see more colleagues took a different understanding to participate in discussion of this issue.

**Keywords:** rough set; expert scoring; dump landslide; weight calculation

**Abstract.** To combine expert scoring and rough set two kinds of subjective and objective methods, avoiding the indicator weight value is zero, making the expert scoring more efficient, objective. Using the expert scoring method based on rough sets in determining evaluation indicator weights of open-pit dump landslide. Slope density, cohesion, internal friction angle, slope angle, slope height, pore pressure ratio were selected for evaluation indicators of dump landslide. First of all, according to the landslide data collected, to calculate the importance sort of evaluation indicators of the dump landslide based on rough set theory. Then, scores of each indicator corresponds to a certain interval, five relevant experts were selected for scoring. Finally, the weight of each indicator was determined based on the average score. We can know from results, slope angle has the biggest influence on the dump landslide, followed by pore pressure ratio .Slope height and slope density have the minimal impact, which is coincidence with the actual situation of the dump, it shows that the method is more rational and effective .

## Introduction

Currently, the method for determination of the indicator weight includes subjective and objective weighting method. Subjective weighting method is simple, but it requires higher personnel evaluation experience which is influenced by their knowledge and experience; Objective weighting method can effectively convey the data information and differences of the evaluation. The evaluation results are objective and scientific, but sometimes weighting coefficient is unreasonable. In the process of determining the weights, if we can consider both objective and subjective factors, the indicator weight will be more in line with the actual situation, and the assessment accuracy will be improved.

Rough set theory was proposed by the academician Pawlak fron Warsaw University of Technology, in the early 1980s, the theory is about data analysis and reasoning [1-3]. In the process of introducing the rough set theory to China, professor Liu Qing [4], professor Zeng Huanglin and other scholars have made a relatively large contribution.. As the rough set theory can fully reflect the objectivity of the data, without providing any prior knowledge other than the data information, many scholars have studied the weight determination method based on rough set theory. In recent years, the method has been applied in many fields. "Investigation of method for determining factors weights in evaluating slope stability based on rough set theory" is published by Guangyue Wang, Haili Cui and Qian Li in 2009[5]. *"Index weight determination of construction enterprises' social responsibility estimation based on rough set"* is published by Yongshi Pang, Ying Wang in 2012[6]. *"Impact factor weighting analysis of volcanic debris flow of Changbai mountain based on rough set theory"*is published by Yumeng Wang, Chunhong Zou, Han Lv in 2013[7]. However, there is a problem in the indicator weights based on rough set theory: the weight value may be zero, which is not consistent with the actual situation, and the accuracy of the evaluation results is also influential. This paper presents an expert scoring method based on rough set theory. The method combines two methods, which not only can play the advantages, but also avoid the deficiencies, and the weights are more realistic.

## Overview of Rough Set Theory

**Concept of Rough Set.** Definition 1: Command $X \subseteq U$ , when $X$ can be exactly described by attributes subset $B$ (That is the union of attributes subset $B$ of and identified set $U$) $X$ is definable to $B$ , otherwise $X$ is not definable to $B$. Definable set $B$ also called accurate set $B$. Cannot be defined set $B$ is also known as imprecise set $B$ or $B$ Rough (without confusion, it is referred to as $B$ Rough Set) [4].Definition 2: For each concepts $X$, the biggest definable sets that no clear relationship $B$ is contained by $X$ or the smallest definable sets that contain $X$, are able to be determined in accordance with $B$. The former called lower approximation of $B$ (denoted by $B_(X)$), the latter called upper approximation of $X$ (denoted by $\bar{B}(X)$) [4].Definition 3: Set $BN_B(X) = \bar{B}(X) \setminus B_(X)$ is called $B$ boundary of $X$; $POS_B(X) = B_(X)$ is called $B$ positive region of $X$; $NEG_B(X) = U \setminus B_(X)$ is called $B$ negative region of $X$ [4].

**Indiscernible Relationship.**Set theory domain for $U$, $P$ for a subset of condition attributes $C$ , the indiscernibility relation $IND(P)$ determined by $P$ is: $IND(P) = \{(x, y) \in U \times U / \forall a \in P, f(x,a) = f(y,a)\}$ Where: $f(x,a)$ represents the values of theory domain element $x \in U$ about attribute of a; The indiscernibility relation $IND(P)$ constitutes a category of $U$ , denoted by $U / IND(P)$ [5].

**Knowledge Reduction.** Knowledge reduction is the core of rough set theory. As we all known, the knowledge of knowledge base (property) are not equally important, or even some of them are redundant. The so-called knowledge reduction is to keep the classification ability of the knowledge base same, and to delete irrelevant or unimportant knowledge. $R$ is an equivalence relation, $r \in R$, if $IND(R) = IND(R - \{r\})$, r is called the knowledge can be deleted in R ; if $P(R - \{r\})$ is independent, $P$ is a reduction of $R$ [5].

**Attribute Importance.** Order $P$ and $Q$ are a subset of condition attributes $C$ and decision attributes $D$ respectively. Then, the formula $K = \gamma_p(Q) = \frac{|POS_p(Q)|}{|U|}$ indicates that the knowledge $Q$ depends on the knowledge $P$ of degree $K$, denoted by $P \Rightarrow_K Q$ . Wherein: $|U|$ represents a base of $U$ , that is the number of elements in $U$ ; Similarly , $|POS_p(Q)|$ represents the number of elements in $POS_p(D)$ .The importance of subset of attributes $C_i \subseteq C$ about D is defined as $\sigma_D(C_i) = \gamma_c(D) - \gamma_{c-c_i}(D)$ , The larger the value of $\sigma_D(C_i)$ , the greater the importance of the corresponding attribute indicates ; Conversely , the smaller the importance is[5].

## Expert Scoring Method to Determine the Weight Based on Rough Sets

**Expert Scoring Method and its Characteristic.** Expert scoring method refers to consult experts by anonymous methods, then deal with expert opinions, synthesize most experts experience and subjective judgment objectively, and make a reasonable estimate for a large number of factors that is difficult to quantitative analysis, after several rounds of consultation, feedback and adjust, obtaining the final result. Its advantages are simple, intuitive and strong, simple calculation and larger choices, it can consider all evaluation items whether can be quantitative evaluation or not. Its shortage is that the weight is cannot be calculate likely, if experts opinions cannot achieve unity, after consulting experts opinions in multiple rounds. Alone expert scoring method is prone to inconsistent feedback,even after many adjustment, it is difficult to achieve unity, moreover expert scoring method based on rough set can analyze data information objectively by means of rough set theory， and have a objective sort for the importance of weights of evaluation indicators,experts give subjective experience scores based on this objective sort, it can well avoid the situation that experts opinions is difficult to achieve unity[8].

**Steps of Expert Scoring Method to Determine the Weight Based on Rough Sets.**The method to determine the weighting based on rough set theory is entirely according to the objective data, making data mining for the original data, on the basis of the discrete data, and translating weight problems into the problem of attribute importance in rough set; the expert scoring method is entirely according to experts' subjective knowledge and experience, then several rounds of scoring and finally determine the indicator weight; the expert scoring method based on rough set theory is to combine both methods well, mutually to make up their deficiencies, giving full play to the advantage of the subjective and objective methods. Steps of expert scoring method to determine the weight based on rough sets are as follows.

First of all, the rough set method needs to make continuous attribute discrete, namely the continuous attribute domain is divided into a number of interval, different codes for different intervals.

Second, the discrete attribute values form a two-dimensional table, each line describes an object, each column to describe a condition attribute of an object, the last one or two is decision attribute.

Then, to have knowledge reduction, to delete the object with same attribute values, namely repetitive data lines, to make equivalence partitioning for discourse domain according to the condition attributes and decision attributes, after getting rid of some properties, if the change of relevant classification is bigger, it indicated that the properties importance is higher; On the other hand, it shows that the properties importance is lower.

Finally, according to the importance ranking of condition attributes, each condition attribute have each score interval, select a number of experts to give the score for condition attribute, scoring is conform to the prior division score range, then calculating the average value, and normalization, and getting the final weight value.

## Case Study

The open-pit mine dump, a place as acceptance waste rock of open pit mine, is a permanent engineering construction which is indispensable to the open-pit [9]. As our country dump has serious phenomenon such as large capacity, high pile height, insufficient attention to the foundation, disorderly dig the foot of the slope mining brings risks to the stability of the dump, leading to the dump landslide disasters have become increasingly prominent. Dump landslide is the most common occurrence and the highest frequency in dump disaster, however, there are many factors to affect the stability of dump slope, on the basis of both research results and data information from references, to select slope unit weight, cohesion, internal friction angle, slope angle, slope height, Pore pressure ratio as landslide evaluation indicators of opencast mine dump.

There are 25 sets of circular landslide collected in table 1 [10], in this information table, the discourse domain is $\{1, 2, 3,... 25\}$, the condition attribute set is $\{C_1, C_2, C_3, C_4, C_5, C_6\}$, the decision attribute set is $\{D_1, D_2\}$, including: $C_1$ as slope unit weight, $C_2$ as cohesion, $C_3$ as internal friction angle, $C_4$ for slope angle, $C_5$ for slope height, $C_6$ for pore pressure ratio; $D_1$ for stability coefficient, $D_2$ for slope condition. To calculate the attribute importance of indicators in above procedure, the discrete data processing, the selection of discrete values refer to reference 5, the discrete data table is shown in table 2; then the simplified data table is shown in table 3.

| 16 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |
| 17 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 |

The data table of knowledge reduction, according to the condition attributes and the decision attributes table, is classified as follows:

$U/IND(C)=\{\{1\},\{2,4\},\{3\},\{5\},\{6\},\{7\},\{8\},\{9\},\{10\},\{11\},\{12,14\},\{13\},\{15\},\{16,17\}\}$

$U/IND(D)=\{\{1,4,10,11,13,14,15,16\},\{2,3,5,6,12,17\},\{7,8,9\}\}$

The knowledge classification which have been remove a condition attribute respectively is as follows:

$U/IND(C-C_1)=\{\{1\},\{2,4\},\{3\},\{5\},\{6\},\{7\},\{8\},\{9\},\{10,11\},\{12,14\},\{13\},\{15\},\{16,17\}\}$

$U/IND(C-C_2)=\{\{1,2,4\},\{3,6\},\{5\},\{7\},\{8\},\{9\},\{10\},\{11\},\{12,14\},\{13\},\{15\},\{16,17\}\}$

$U/IND(C-C_3)=\{\{1\},\{2,4\},\{3\},\{5\},\{6\},\{7,8\},\{9\},\{10\},\{11\},\{12,13,14\},\{15\},\{16,17\}\}$

$U/IND(C-C_4)=\{\{1\},\{2,4\},\{3\},\{5\},\{6\},\{7\},\{8,10,11\},\{9\},\{12,14\},\{13,16,17\},\{15\}\}$

$U/IND(C-C_5)=\{\{1\},\{2,4,5\},\{3\},\{6\},\{7\},\{8\},\{9\},\{10\},\{11\},\{12,14\},\{13\},\{15\},\{16,17\}\}$

$U/IND(C-C_6)=\{\{1,3\},\{2,4,6\},\{5\},\{7\},\{8,9\},\{10\},\{11\},\{12,14\},\{13\},\{15\},\{16,17\}\}$

The importance analysis of each condition attribute for decision attribute is as follows:

$POS_{C_1}(D)=\{1,3,5,6,7,8,9,10,11,13,15\}$

$POS_{C-C_1}(D)=\{1,3,5,6,7,8,9,10,11,13,15\}$

$POS_{C-C_2}(D)=\{3,6,5,7,8,9,10,11,13,15\}$

$POS_{C-C_3}(D)=\{1,3,5,6,7,8,9,10,11,15\}$

$POS_{C-C_4}(D)=\{1,3,5,6,7,9,15\}$

$POS_{C-C_5}(D)=\{1,3,6,7,8,9,10,11,13,15\}$

$POS_{C-C_6}(D)=\{5,7,8,9,10,11,13,15\}$

$$\gamma_C(D)=\frac{|POS_C(D)|}{|U|}=\frac{11}{17}$$

$$\sigma_D(C_1)=\gamma_C(D)-\gamma_{C-C_1}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C-C_1}(D)|}{|U|}=\frac{11}{17}-\frac{11}{17}=0$$

$$\sigma_D(C_2)=\gamma_C(D)-\gamma_{C-C_2}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C_2}(D)|}{|U|}=\frac{11}{17}-\frac{10}{17}=\frac{1}{17}$$

$$\sigma_D(C_3)=\gamma_C(D)-\gamma_{C-C_3}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C_3}(D)|}{|U|}=\frac{11}{17}-\frac{10}{17}=\frac{1}{17}$$

$$\sigma_D(C_4)=\gamma_C(D)-\gamma_{C-C_4}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C_4}(D)|}{|U|}=\frac{11}{17}-\frac{7}{17}=\frac{4}{17}$$

$$\sigma_D(C_5)=\gamma_C(D)-\gamma_{C-C_5}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C_5}(D)|}{|U|}=\frac{11}{17}-\frac{10}{17}=\frac{1}{17}$$

$$\sigma_D(C_6)=\gamma_C(D)-\gamma_{C-C_6}(D)=\frac{|POS_C(D)|}{|U|}-\frac{|POS_{C_6}(D)|}{|U|}=\frac{11}{17}-\frac{8}{17}=\frac{3}{17}$$

Therefore, the importance sorting of indicators attribute is $C_4 > C_6 > C_2 = C_3 > C_1 = C_5$:

Namely: slope angle> pore pressure ratio> cohesion = internal friction angle> slope density= slope height

We select five experts which are related to the slope field, they give the indicators score based on sort of attribute importance, each indicator corresponds to a score range, results of experts scoring are shown in Table 4.

**Table 4 Experts scoring table of landslide indicators**

| indicators | score range | experts scoring | | | | | |
|---|---|---|---|---|---|---|---|
| | | expert 1 | expert 2 | expert 3 | expert 4 | expert 5 | average score |
| $C_4$ | 75-100 | 90 | 85 | 80 | 85 | 80 | 84 |
| $C_6$ | 50-75 | 75 | 70 | 65 | 60 | 70 | 68 |
| $C_2$ | 25-50 | 50 | 45 | 35 | 45 | 30 | 41 |
| $C_3$ | 25-50 | 45 | 40 | 30 | 25 | 35 | 35 |
| $C_1$ | 0-25 | 25 | 25 | 20 | 15 | 20 | 21 |
| $C_5$ | 0-25 | 20 | 15 | 10 | 15 | 20 | 16 |

According to expert scoring conditions, the weight value of slope angle C4 is: 84 / (84 +68 +41 +35 +21 +16) = 84/256 = 0.317

Similarly, the weight values of slope unit weight, cohesion, internal friction angle, slope angle, slope height and pore pressure ratio are respectively: 0.079, 0.155, 0.132, 0.317, 0.06, 0.257.

As can be seen in the impact indicators of open pit mine landslide, the largest influence is slope angle; the second is pore pressure ratio; cohesion force and the friction angle is relatively small, the influence of slope density and slope height is minimal. In terms of slope protection, we should focus on the impact of the major factors.

## Conclusion

1) Rough set theory is completely depart from the objective data, without any subjective impact, the weight value may be zero by the calculation of rough set theory, which is not consistent with the actual situation; and expert scoring method is entirely based on the subjective experience; and is short of objective theoretical guidance, the weights not only need several rounds of feedback and scoring to get, but also difficult to achieve unity. Expert scoring method based on rough set theory could well avoid defects of two methods, and play the advantages of subjective and objective weighting method.

2) The method is used in the weight determination of landslide indicators in open-pit dump; we select five indicators from the dump landslide factors. We finally get indicator weights of open-pit dump landslide by calculating 25 group of objective data, thus to provide a certain basis to protection and governance of the dump, which is more conducive to the safety management of mine enterprises.

3) Since the calculation of rough sets attribute importance is more complicated, a large number of data samples are not suitable for hand calculations, in order to improve the efficiency and accuracy of the computational in future studies, we should consider the rough set software to calculate.

# Study on Ignition Time of Radiation Cargo in Irradiation Room under Stuck Radioactive Sources

Xiaolin Yao[1,2, a]

[1]Luzhou Vocational and Technical College, Luzhou, Sichuan, 646005, China

[2]Faculty of Geosciences and Environmental Engineering, Southwest Jiaotong University, Chengdu, Sichuan, 610031, China

[a]firesafety@qq.com

**Keywords:** Irradiation room, Radioactive sources, Stuck radioactive sources, Time to ignition.

**Abstract.** Ignition temperatures of common radiation cargo in irradiation room were measured through the experiments, minimum ignition temperature is 210 ℃. In order to discuss the temperature variation and temperature field under stuck radioactive sources, the fire scenario was presented and simulated by FDS. The results show that temperatures rise rapidly when stuck radioactive source broke out within an hour. As the growth of the time, temperatures in irradiation room are rising, but the rising rate is slowing. The temperature field in the irradiation room tends to be the same after three hours. The stuck radioactive source occurred after 2.4 days later, local temperatures can reach 210 ℃, and radiation cargo may be ignited.

## Introduction

With the development of the economic and the society, the irradiation facilities are widely used in irradiation processing, food preservation and sterilization [1]. According to incomplete statistics, there are more than 200 irradiation facilities in our country, of which about 20 are more than one million Ci [2]. If a radiation accident occurs, it will cause significant economic and social impact.

Stuck radioactive sources means that the radioactive sources are stuck in the process of back to source well, not able to reach the design position. Cargo in irradiation room are irradiated for a long time, temperatures constant rising, it may cause a fire, and than lead to a radiation accident. So we must care about the when cargo to be ignited under stuck radioactive sources. Combined with the domestic and foreign research present situation, FAN brought forward some safety measure [3]. QIAO analyzed the reason for the radioactivity fire, and some suggestions for the treatment were presented [4]. XIAO introduced two incidents of stuck radioactive sources. The lessons learned from these events are summarized [5].

Researchers in related fields have only made a rough analysis and research on radioactivity fire. Until recently, there is some lack of sophisticated quantitative analysis about ignition time under stuck radioactive sources. In this paper, typical 60Co irradiation room of hanging chain conveyor has been taken as a research subject. The ignition temperatures of common radiation cargo in irradiation room were measured by the DW-02 ignition point detector. Considering the most disadvantage condition of the irradiation room, the fire scenario was simulated to research the fire risk assessment by FDS under stuck radioactive sources. Ignition time for irradiation room of hanging chain conveyor under stuck radioactive sources was studied by numerical simulation and experiments.

## Model of Irradiation Room

**Irradiation Room Description.** This paper is aimed to research the fire risk assessment on typical $^{60}$Co irradiation room which is located on the ground floor. The room is 15 m long, 7 m wide, 4.6 m high as shown in Fig.1. The thickness of the concrete wall is 2 m. Irradiation room transports cargo through the hanging chain conveyor. There are three doors, one for slings in, one for slings out, and the other one for personal access, with the window closed. The room is equipped with mechanical

ventilation system under normal operating conditions. Radioactive sources are arranged on the shelf uniformly which is about 5 m long, 2 m high, 0.1 m thick, and 1 mm thick aluminum plate wrap around the shelf.

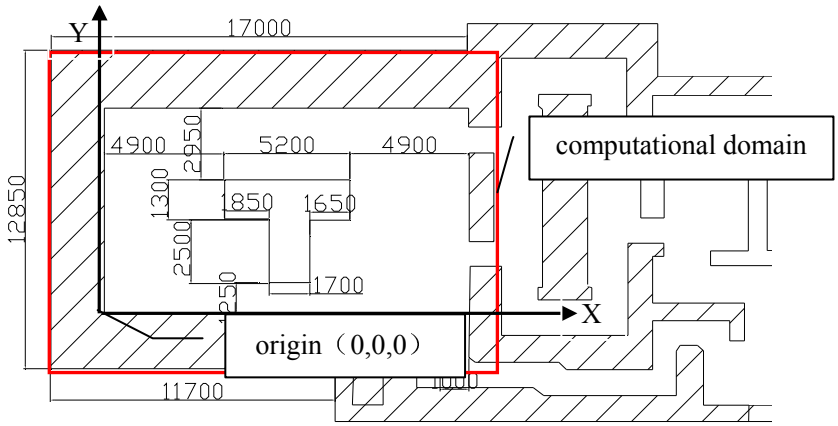

Fig.1 The plans of the irradiation room

**Fire Model of Irradiation Room.**

(1) Analysis of fire risk.

Through the analysis, irradiation room has two major fire risks. One is lead to a fire because the cargo in irradiation room is irradiated for a long time, temperatures constant rising. And the other is destruction of structural member due to high temperature in the room. Through referring to literature at home and abroad, concrete strength is not changed obviously while temperatures are below 300 ℃. Concrete strength decreases and its external surface have cracks when temperature varies between 600-700 ℃. The spalling of concrete might occur and its strength is close to zero when temperature varies between 800-900 ℃ [6]. Ignition temperatures of common radiation cargo are much lower than concrete failures temperature. Therefore ignition temperatures of common radiation cargo are taken as the criterion of fire risk.

In order to analyze fire risk clearly under stuck radioactive sources, ignition temperatures of common radiation cargo should be determined exactly. Regularity of a change in temperature is obtained under typical fire scenarios through the theoretical analysis and the numerical stimulation calculation, and sums up the ignition time, that is, the less time it will take to troubleshoot stuck radioactive sources.

(2) Fire model.

In order to analyze fire risk clearly under the most disadvantage condition, this paper makes the following assumptions:1) $^{60}$Co source releasing heat continuously is equal to the ignition source under stuck radioactive sources. 2) The ventilation system can not work properly. 3) The irradiation room becomes an enclosed space while the exits and entrances are quickly capped by cargo.

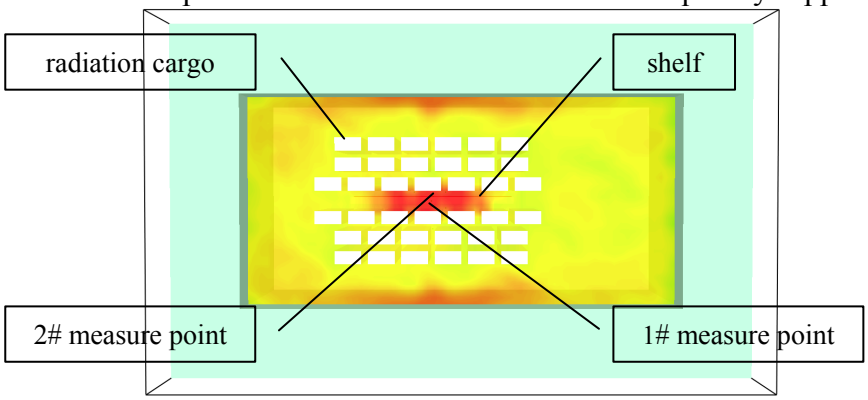

Fig.2 Model of FDS

Fire simulation software FDS widely adopted at home and abroad is used to simulation calculation. Thermal conductivity of concrete wall is 0.72w/m•k. Simulation time is set to six hours because of a long time computation. Model of FDS was built as shown in Fig.2.

Table 1 List of fire scenario

| activity of $^{60}$Co source (Ci) | heat power (kW) | coordinates of 1# measure point | coordinates of 2# measure point |
|---|---|---|---|
| three million | 46.2 | (7.5, 5.3, 2.0) | (7.5, 5.2, 3.5) |

(3) Fire scenarios.

Activity of $^{60}$Co irradiation facilities above one million Ci is not uncommon. According to relationship between activity of 60Co source and heat power, 1000Ci is roughly equivalent to 15.4w. The activity of 60Co source is three million Ci and coordinates of measure points are set up as shown in Table 1.

According to results of linear fitting between 1h and 6h, we can determine whether the temperatures could be ignition point and when to ignition based on the numerical simulation results. This method can calculate accurately and conservatively.

**Experiment of Ignition Temperatures**. The ignition temperatures of common radiation cargo in irradiation room were measured by the DW-02 ignition point detector according to national standards GB4610-84<Test for flammability of plastics temperature test >, as shown in Table 2.

Table 2 Experimental results of ignition temperatures

| **radiation cargo** | **selected reasons** | **ignition temperatures (℃)** |
|---|---|---|
| chili powder | ignited in the radioactivity fire in Qi county of Henan province, typical food | 210 |
| corrugated paper | typical packing materials, lower ignition temperature | 230 |
| toilet paper | typical commodity | 240 |
| gauze | typical medical supplies | 290 |

## Analysis of Simulation Results

**Simulation Results of Temperature Curve**. Three million Ci is equivalent to 46.2kW in the fire scenario. Simulation time is set to six hours as well because of a long time computation. The temperature variety curve in irradiation room is drawn as shown in Fig.3.

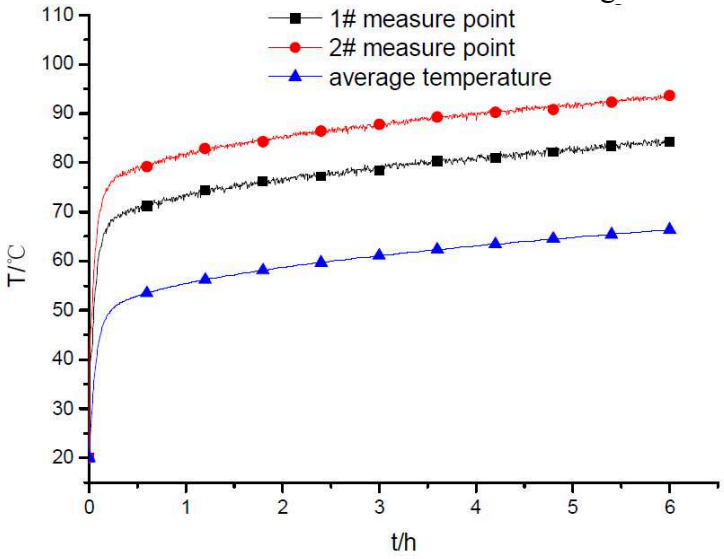

Fig.3 Temperature variety curve of every measure point

The temperatures of computational domain increase to 80℃ rapidly from 0 to 1h. The fire risk of 2#measure point is the largest one on account of the highest temperatures. The liner fitting formula of

temperature for 2#measure point is T=2.2358t+80.6610 as shown in Fig.9. The ignition point of chili powder is 210℃ through experiment. By analysing the simulated result of the liner fitting formula, the time to reach ignition point is about 2.4 days. The radiation cargo in irradiation room may be ignited to cause a radioactivity fire.

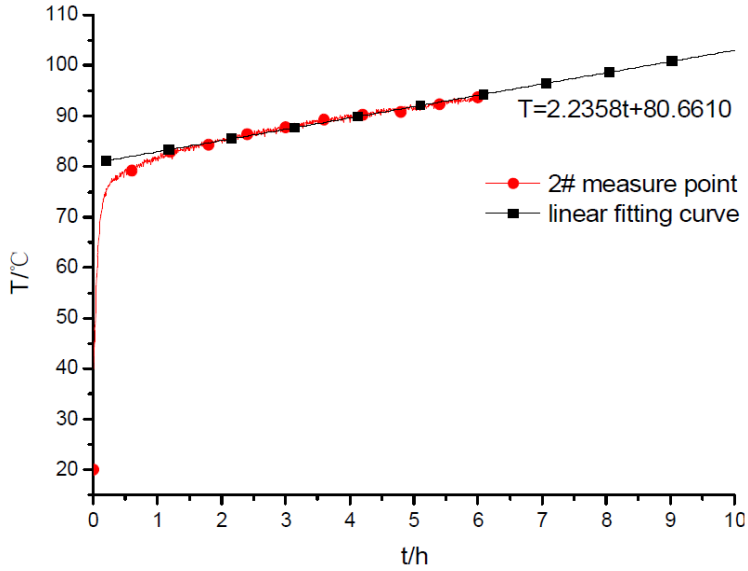

Fig.4 Liner fitting curve of temperature for 2#measure point

**Simulation Results of Temperature Field.** The distribution of temperature field at the height of 3.6 m is presented at different times as shown in Fig.5 Fig.6 and Fig.7. The local space formed by stacking radiation cargo is a relatively closed environment. The increase of temperatures near by the shelf is faster than somewhere else in irradiation room when stuck radioactive source broke out within three hours. The temperature field in the irradiation room tends to be the same after three hours.

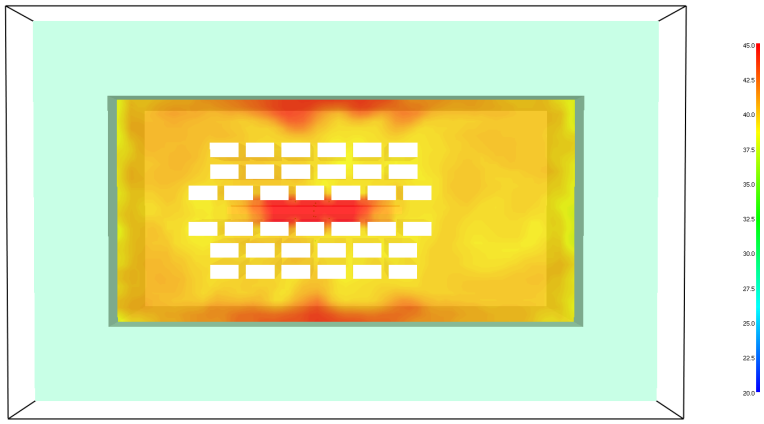

Fig.5 The distribution of temperature field at 2h

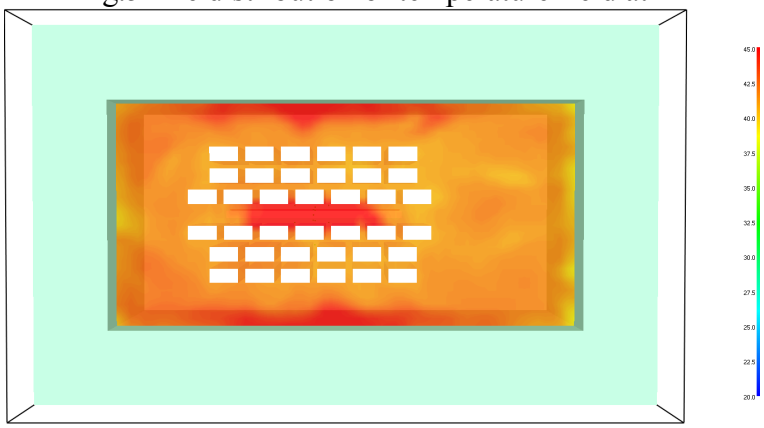

Fig.6The distribution of temperature field at 4h

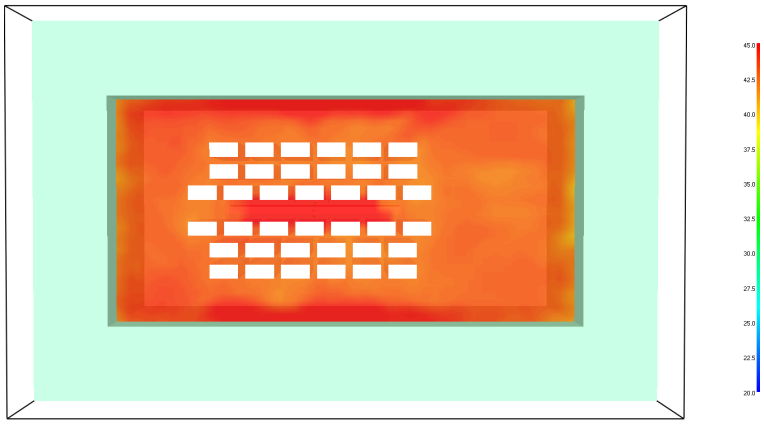

Fig.7 The distribution of temperature field at 6h

## Conclusions

In this paper, typical $^{60}$Co irradiation room has been taken as a research subject. Considering the most disadvantage condition of the irradiation room, the methods combining qualitative and quantitative analysis are used to research the radioactivity fire by numerical simulation and experiments. This paper draws the following conclusions:

(1) The radiation cargo in irradiation room has a low ignition point. The ignition temperatures of chili powder, corrugated paper, toilet paper and gauze are 210 ℃, 230 ℃, 240 ℃ and 290℃ measured by the experiment.

(2) The temperatures of computational domain increase rapidly from 0 to 1h. With time growing, slower growth of temperatures is presented gradually from 1h to 6h. The fire risk of 2#measure point is the largest one on account of the highest temperatures. The liner fitting formulas of temperature for 2#measure point can be obtained in the fire scenario. The irradiation room may be caused a radioactivity fire after 2.4 days under stuck radioactive sources.

The possibility of the radioactivity fire caused by stuck radioactive source is not zero although it is small. The combustibles should be taken away from the irradiation room as soon as possible once the incidents of stuck radioactive sources occur. In order to decrease the temperature of irradiation room, the ventilation system must function correctly to avoid the radioactivity fire.

**Keywords:** CFS column; fire resistance; Rankine approach; shear bond; high temperature.

## ABSTRACT

The Rankine approach has been extended to predict fire resistance of steel, reinforced concrete and concrete filled steel tube (CFS) columns. The conventional Rankine method ignores the coupling interaction and leads to a lower bound prediction compared with actual failure loads, especially for CFS columns. This paper develops a rational and straightforward approach to predict the fire resistance of CFS columns considering the shear bond effect. The method hinges on concept of modified buckling coefficient, and applicable to both axially and eccentrically loaded columns. It shows that the proposed approach predicts the failure load more accurately compared with the traditional Rankine approach. Four case studies comprised of 118 CFS columns from different labs are analyzed to verify the proposed approach. Material deterioration at elevated temperature with regard to the strength and stability of columns is also quantified.

## Introduction

Several of simplified approaches to predict fire resistance of steel, RC and CFS columns have been developed by different researchers. However, most of the approaches are based on the finite element method (FEM) and empirical formulas. The conventional Rankine approach can be expressed as [1]:

$$\frac{1}{P_R} = \frac{1}{P_p} + \frac{1}{P_e} \tag{1}$$

where $P_p$, $P_e$, $P_R$ represent the plastic collapse load, elastic critical load and Rankine load, respectively.

The Rankine formula based interaction approach has been applied to predict the fire resistance of steel columns and frames first by Tang et al. [2]. Their approach divides a column into two hypothetical sub-columns, assuming the two sub-columns act independently of each other and ignore the coupling interaction. In reality, the two sub-columns are deformed together and mutually restricted. The coupling interaction is termed “shear bond”, which increases the ultimate capacity of the column. Yao et al. [3] suggest that the modified approach can predict failure load of RC columns under fire condition more accurately by incorporating the coupling interaction effect into the Rankine formula.

In current work, a modified Rankine approach is proposed to predict the fire resistance of CFS columns by combining the shear bond effect. The coupling interaction effect and the physical meaning are discussed. The effect of shear bond is adapted to predict fire resistance of 118 CFS columns from four laboratories with different column slenderness ratios, concrete covers, cross-sectional areas and fire exposure times. The results show that the developed approach can predict the failure load of CFS columns more accurately compared with conventional Rankine approach.

## Theoretical Model

In order to extend the Rankine approach to predict fire resistance of CFS columns, the authors adopt Eq. 2. For columns subjected to axial load, $P_p$ can be expressed as [4]:

$$P_p = 0.85\beta_c(t)f_c'(20°C)A_c + \beta_{yr}(t)f_{yr}(20°C)A_{sr} + k_y^{tube}(t)f_y(20°C)A_s \quad (2)$$

where $f_c'(20°C)$, $f_{yr}(20°C)$, $f_y(20°C)$ are the cylindrical compressive strength of concrete, yield stress of steel reinforcement and yield stress of steel tube at ambient temperature, respectively; $A_c$, $A_{sr}$, $A_s$ stand for the area of concrete section, steel reinforcement and steel tube; $\beta_c(t)$, $\beta_{yr}(t)$, $k_y^{tube}(t)$ represent the strength reduction of concrete, steel reinforcement and steel tube at elevated temperature.

The elastic critical load $P_e$ can be determined by Eq. 3 [4]:

$$P_e = \frac{\pi^2[0.2E_c(20°C)I_c + E_{sr}I_{sr}]}{(kl)^2} \quad (3)$$

where $k = 1, 0.7, \text{and } 0.5$ for pinned-pinned, pinned-fixed and fixed-fixed end, respectively. $E_c(20°C)$ and $E_{sr}$ are the elastic modulus of concrete and steel reinforcement. $I_c$ and $I_{sr}$ are the second moment of concrete and steel reinforcement area.

To predict fire resistance of CFS column, the original Rankine formula is modified to consider the effect of shear bond:

$$\frac{1}{P_c} = \frac{1}{P_p} + \frac{1}{P_e} - \frac{1}{P_s} = \frac{1}{P_R} - \frac{1}{P_s} \quad (4)$$

where $P_s$ is the effect of the shear bond.

The difference $\Delta_p$ between the Rankine failure load $P_R$ and the actual failure load $P_c$ can be calculated by:

$$\Delta_p = P_c - P_R = \frac{P_R^2}{P_s - P_R} \quad (5)$$

In order to define a general failure curve, the following formula is proposed instead of the original linear interaction equation [3]:

$$\frac{1}{P_c^n} = \frac{1}{P_p^n} + \frac{1}{P_e^n} \quad (6)$$

Eq. 6 represents a modified Rankine approach which incorporates the shear bond effect into the failure interaction. The modified formulas for axially loaded PCFS and RCFS under fire condition can be expressed as:

$$P_c = \frac{P_p P_e}{\sqrt[n]{P_p^n + P_e^n}} \quad (7)$$

The modified formulas for eccentrically loaded RCFS under fire condition can be expressed as:

$$P_c = \frac{[u_{pr}^{core}P_p^{core}(t) + u_{pr}^{tube}P_p^{tube}(t)]P_e}{\sqrt[n]{[u_{pr}^{core}P_p^{core}(t) + u_{pr}^{tube}P_p^{tube}(t)]^n + P_e^n}} \quad (8)$$

## Physical Meaning of the Modified Rankine Approach

Accuracy of the Rankine approach varies with column slenderness ratios, defined by the ratio of the effective length of a column to the least radius of gyration of its cross-section, and the fire exposure time. For CFS columns under fire conditions, the reduction of $P_e(t)$ is much more rapid than $P_p(t)$ due to greater deterioration of $E_cI_c$ and $E_{sr}I_{sr}$ compared with $f_c'$ and $f_{yr}$. For stocky and slender CFS columns, the cross-sectional area of the hypothetical columns is relatively small,

and the effect of shear bond is small. However, for intermediate columns, the values of $P_p(t)$ and $P_s(t)$ are close to each other, and the shear bond effect is large and the prediction of Rankine approach tends to be conservative.

On the other hand, the conventional Rankine approach assumes that two hypothetical sub-columns act independently and ignores the coupling interaction effect. However, there is always some difference between the two failure modes in practice. In reality, the failure modes of two hypothetical sub-columns are deformed together and mutually restricted as the result of shear bond. Thus, the interaction always exists and the conventional Rankine approach tends to be conservative. The accuracy of the Rankine approach depends on the compatibility between the two failure modes of sub-columns. With greater incompatibility between the two failure modes, stronger shear bond will be generated. For this case, the authors propose modified Rankine approach and employ different n values to consider the incompatibility effect between the two failure modes for CFS columns.

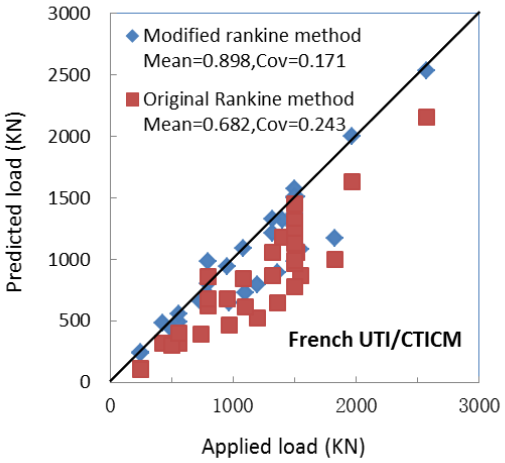
## Case study

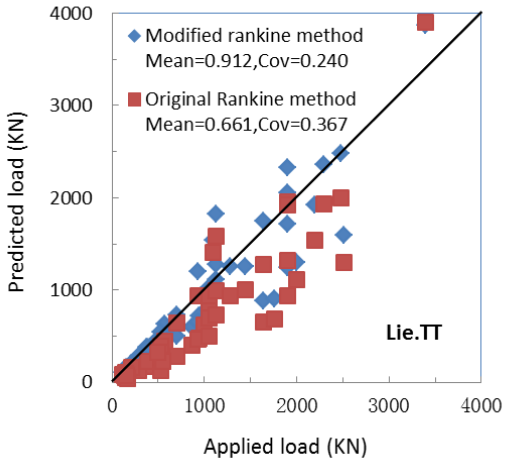
In current study, a group of 118 CFS columns from four laboratories (Canadian National Research Council Tests, French UTI/CTICM, French CSTB, and UK Borehamwood) [5,6] with different slenderness ratios, tube thickness, concrete covers, cross-sectional areas and fire exposure times are compared with proposed approach and finite element analysis. The object of the case study is to benchmark the accuracy of the modified Rankine approach and investigate the influence of different engineering design factors to fire resistance of CFS columns.

Based on the case studies and the physical meaning of shear bond, the *n* values for columns with different slenderness ratios and fire exposure times are recommended in Table 1. One-hundred and eighteen CFS column tests including both PCFS and RCFS from four different laboratories were used for comparison, the results are shown in Fig. 1. It shows that the modified Rankine approach gives more accurate predictions compared with the original one.

**Table 1: The Recommended *n* Values**

| | $\lambda \geq 44.5$ | $37 \leq \lambda < 44.5$ | $26 \leq \lambda < 37$ | $\lambda < 26$ |
|---|---|---|---|---|
| $t \leq 36$min | | 1.3 | 2.2 | |
| $36 < t \leq 68$min | | 2.2 | 1.3 | |
| $t > 68$min | | 3 | 3 | |
| $t \leq 48$min | 3 | | | 1 |
| $48 < t \leq 86$min | 1 | | | 3 |
| $t > 86$min | 1 | | | 1 |





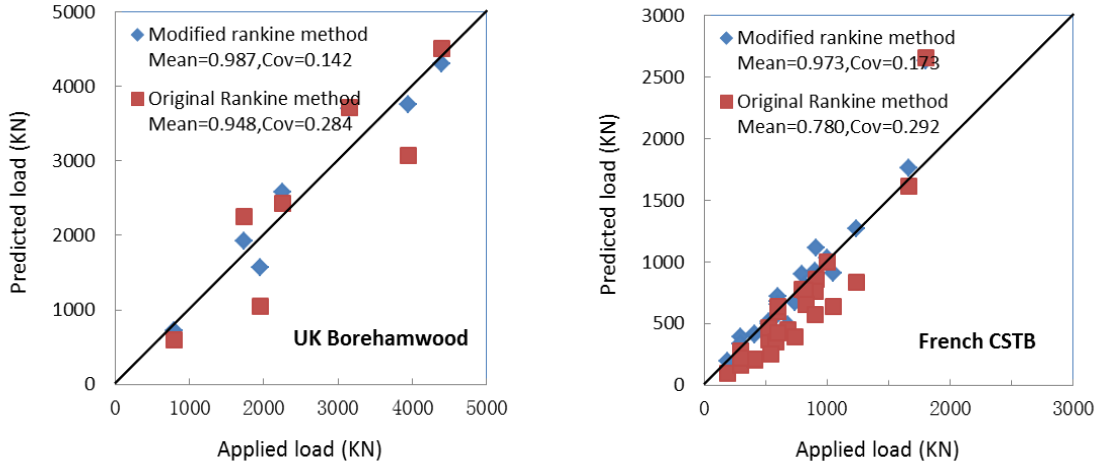


**Fig. 1 The load capacity predicted by modified Rankine approach for four case studies**

## Conclusion

A modified Rankine approach is developed to predict fire resistance of CFS columns under ISO-834 fire conditions, the effect of shear bond is considered in the developed approach. Theoretical basis and the physical meaning of shear bond are discussed. For columns with different slenderness ratios and fire exposure times, the limitations of the original Rankine approach are investigated. Four case studies comprised of 118 CFS columns from different labs are analyzed to verify the proposed approach. It is found that the modified Rankine approach can predict the fire resistance of CFS columns more accurately compared with the original one. In general, the modified Rankine approach is a simplified and straight forward approach to predict fire resistance of CFS columns.

**Keywords:** High-rise civil buildings; Fire risk evaluation tree; The unascertained evaluation system design; The visual basic(VB) technology.

**Abstract:** The study purpose is to design a comprehensive and visual fire risk evaluation system for high-rise civil buildings. Firstly, according to the characteristics of high-rise civil buildings, based on the hazards identification, combined with the international building fire codes, by using the typical accident causation analysis and other methods, the various uncertain factors affecting high-rise civil building fire are analyzed, and a fire risk evaluation tree for high-rise civil buildings was built. Then the unascertained theory is introduced, and a new visual fire risk evaluation system is designed for high-rise civil buildings based on the unascertained C-clustering model and the visual basic(VB) technology. At last, take the fire survey data of China 8 typical high-rise civil building as example, to make an empirical analysis. The research results can provide a reliable decision support system for the high-rise civil building fire risk management.

## Introduction

High-rise buildings are the inevitable product of the city development, but their fire safety issues are always a difficult problem in the world. At present, take China as example, the fire ladders can reach the height of generally not more than 100 meters, so once fire, the high-rise building often suffered heavy losses(Adam C. et al., 2013). So make scientific evaluation on the high-rise building fire risk, to accurately determine their fire risk level, have very important and practical significance to minimize the high-rise building fire accident occurrence.

The international study on building fire safety evaluation began in 1970s, the main methods and models are the U.S. building fire evaluation method(BF-SEM), the Australia risk assessment model (RAM), the Japanese integrated building fire safety design method, Canada FIRECAM method, and so on. In practical application, those evaluation methods each exhibit some advantages, but there are also some problems(Hao C. and George V. H., 2011).

The building fire safety research started late in China, the representative research results such as WeiCheng Fan discussed the theoretical framework of building fire integrated simulation evaluation. Lixin Yi, etc. established the risk assessment model by using fault tree analysis method and the Markov models model of random process. Hongbing Du, etc. used the fuzzy evaluation method to evaluate the building fire risk. Min Xu, etc. introduced the artificial neural network into the building fire risk assessment, et al. (RING Z.X. et al., 2011; HU B.Q et al., 2004 ).

The above research has made some achievements, but in the study of high-rise building fire risk assessment theory and method, there are still some obvious deficiencies. For example, the high-rise building fire risk evaluation index system differences, some are too complex, some are too simple, have brought many difficulties to the fire risk assessment. The risk evaluation index system targeted not strong, there is no explanation for what kind of high-rise buildings. And the lack of a visual

evaluation system results in the index calculation is more complicated and subjective defect, and so on.

So in this study, according to the characteristics of the high-rise civil building fire, a more scientific risk evaluation tree is built, and also a visual fire risk evaluation system is designed for the high-rise civil buildings based on the unascertained C-clustering algorithm and the visual basic technology.

## The comprehensive and visual evaluation system design

### 2.1 The construction of fire risk evaluation tree for high-rise civil building

Based on the three types hazard identification, combine with the related literatures(Hao C. and George V. H., 2011; RING Z.X., 2011; George V.H. and Noureddine B., 1999; China State Bureau of technical supervision and China Ministry of construction, 2005), use the accident causation analysis and other methods, this study builds the fire risk evaluation tree for high-rise civil buildings(shown in table1).

Table1 The fire risk evaluation tree of high-rise civil buildings

| first level index | second level index | third level index | $x_1$ | $x_2$ | $x_3$ | $x_4$ | $x_5$ | $x_6$ | $x_7$ | $x_8$ |
|---|---|---|---|---|---|---|---|---|---|---|
| the fire protection ability U1 | the building general layout U11 | the fireproof distance U111 | 94 | 72 | — | 94 | 95 | 67 | 68 | 91 |

### 2.2 The unascertained evaluation system design

Due to the uncertainty of the high-rise civil buildings fire occurrence, so through the unascertained modeling to evaluate the fire risk condition of high-rise civil buildings is feasible. The basic ideal of the unascertained C-clustering can refer to literature (LIU K.D et al., 2004; ZHAO C.M. et al., 2004). The modle implementation steps:

(1)Set the sort number K, the system error $\varepsilon$, and the counter $t=0$;

(2)Apply initial classification to $n$ samples, and determine the cluster center vector $m_k^{(0)}(k=1\sim K)$ of each sort;

(3)Calculate the unascertained measure $\mu_{ik}(t)(i=1\sim n,k=1\sim K)$ that sample $x_i$ belongs to the $k$-sort;

(4)Compute $m_k(t+1)=\sum_{i=1}^{n}\mu_{ik}\cdot x_i \Big/ \sum_{i=1}^{n}\mu_{ik}$ ; $k=1$, 2,…,K; get the sort center after the first iteration: $m_1^{(1)},m_2^{(1)},\cdots,m_C^{(1)}$;

(5)Compute $err=\sum_{k=1}^{K}\left\|m_k(t+1)-m_k(t)\right\|$ , if $err\le\varepsilon$ , count the unascertained measure $\mu_{ik}(t+1)(i=1\sim n,k=1\sim K)$ that sample $x_i$ belongs to the $k$-sort, stop iteration and switch to (6); otherwise, set $t=t+1$, and switch to (3);

(6)Output the class Center $m_k^{(t+1)}(k=1\sim K)$ of $K$ , the unascertained measure $\mu_{ik}(t+1)(i=1\sim n,k=1\sim K)$, and apply classification:

Set the reliability as $\lambda$, if $k_0=\min_k\left[(\sum_{l=1}^{k}\mu_{il})\ge\lambda,k=1,2,\ldots,K\right]$

That means $x_i$ belongs to $k_0$.

Based on the fire risk evaluation tree and the unascertained C-clustering model, through Matlab programming, and by using the VB technology, a visual fire risk evaluation system is designed for high-rise civil building in the study, shown in Fig.1.

### Example

In order to verify the feasibility and effectiveness of the fire risk evaluation system established in this study, take the fire survey data of China 8 typical high-rise civil buildings as example, to make an empirical analysis. The 8 typical high-rise civil building are the Shan-xi information building($x_1$)， A high-rise civil building in Jiang-xi province($x_2$), the Vittoria Hotel in Xin-xiang city ($x_3$), the 2# teaching building of NCIST($x_4$), the teaching-laboratory building of NCIST($x_5$), the Yan-jiao cultural plaza($x_6$), the 11# building of Dongmao international residential community($x_7$) and the Yanda international hospital($x_8$).

The survey data is shorwn inTable1, the first three sample data($x_1$ ,$x_2$ ,$x_3$) are direct consulting or indirect conversion data from the literatures(GAO Y., 2010; CAO Y., 2008), the other five sample data ($x_4$, $x_5$, $x_6$, $x_7$, $x_8$) are 5 experts scoring and averaged results.

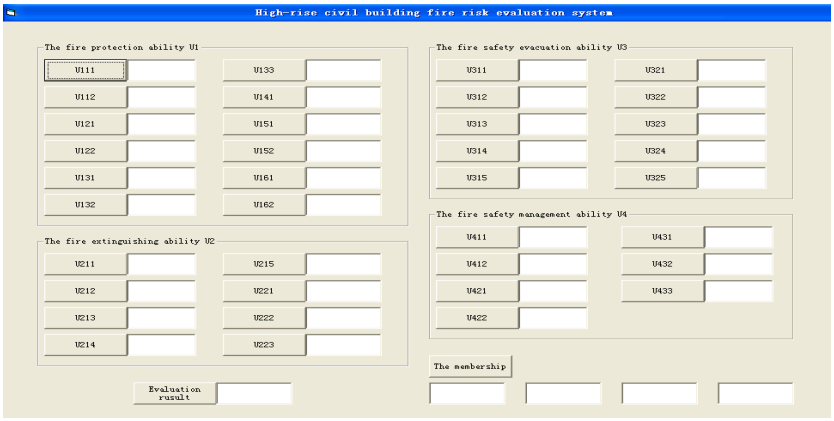

Fig.1 The evaluation system interface

(1) Data complete

For the missing attribute values, the study adopts the mean completer algorithm to filled, for example, for the fireproof distance attribute of sample $x_3$ (the Victoria Hotel), the mean results of other 7 samples in the fireproof distance attribute score is 83, so use "83" to supplement the omission attribute value of sample x3. Similarly, the other missing attribute value can be completed with the same method.

(2) Fire risk evaluation

Firstly, standardized the data in table1, the process omitted. Then input the the normalized data into the evaluation system to classify, let $\lambda$ =0.7, $\alpha_i = 1, \delta = 0.001, \varepsilon = 0.01$, divide the fire risk situation of the 8 samples into four types, that is very dangerous, danger, general and safety. Take sample2 as example, after 34 iterations, the final classification results as shown in Fig.2, the classification error 0.0009761. Similarly, the classification results of all samples seen in Table2.

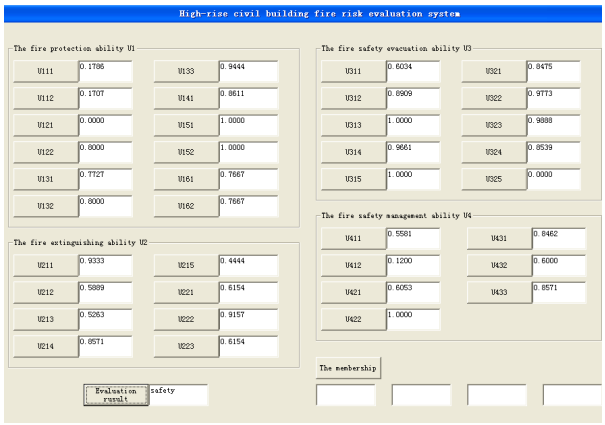

Fig.2 The classification result of sample 2

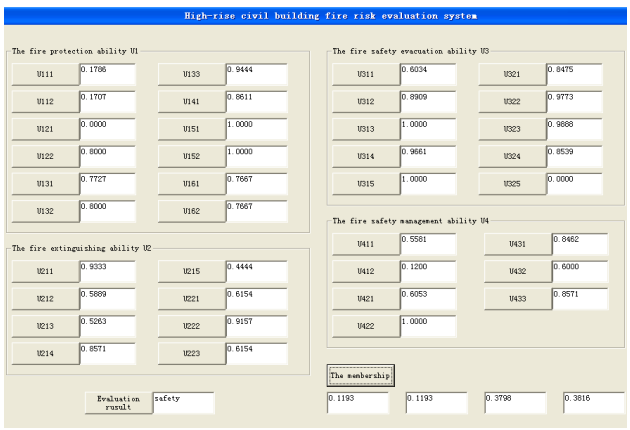

Fig.3 The membership sample 2

Table2 The classification results of all samples

| sample | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|---|---|---|---|---|---|---|---|---|
| classification results | safety | safety | general | danger | safety | danger | danger | safety |

The classification results showed that the fire risk level of the sample $x_4$, $x_6$, $x_7$ are danger, the the fire risk level of the sample $x_3$ is general, and the fire risk level of the sample $x_1$, $x_2$, $x_5$, $x_8$ are safety. The classification results of sample $x_1$, $x_2$, $x_3$ are consistent with the literature research results, but the

evaluation process in this study is greatly simplified, the classification results of sample $x_4$, $x_5$, $x_6$, $x_7$, $x_8$ in line with the actual situation.

At the same time, the evaluation system can not only achieve the evaluation results, but also the membership of the sample belongs to each category. For example, the membership sample 2 belongs to various classifications shown in Fig.3, similarly, the membership each sample belongs to various classifications seen in Table3.

Table3 The membership each sample belongs to various classifications

| sample<br>risk level | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|---|---|---|---|---|---|---|---|---|
| very dangerous | 0.1296 | 0.1193 | 0.3406 | 0.3569 | 0.1201 | 0.3661 | 0.3783 | 0.0765 |
| danger | 0.1296 | 0.1193 | 0.3406 | 0.3568 | 0.1201 | 0.3661 | 0.3782 | 0.0765 |
| general | 0.3692 | 0.3798 | 0.1598 | 0.1434 | 0.3790 | 0.1342 | 0.1221 | 0.4211 |
| safety | 0.3716 | 0.3816 | 0.1590 | 0.1429 | 0.3807 | 0.1336 | 0.1215 | 0.4259 |

## Conclusions

Through the empirical analysis of the 8 typical high-rise civil building fire statistic data, the results showed that, the visual fire risk evaluation system for high-rise civil buildings based on the fire risk evaluation tree and the unascertained C-clustering method, relative to the literature studies often assessment with the second-grade indexes, the system evaluate with the third-grade indexes, the evaluation result is more objective, and the evaluation process greatly simplified, so the system is more practical. Also the system can not only give accurate evaluation results, but also give the membership of the sample belongs to each category, the research results can provide a reliable decision support system for the high-rise building fire risk process management.

**Keywords:** Storm surge, Risk evaluation index, Risk mitigation

**Abstract.** Natural disasters refer to casualties, property damage and social instability. Coastal urban areas with a high population density coupled with the construction of man-made structures are particularly subjected to storm surge hazards, which have become an increasingly urgent problem. In this paper, we try to set up a risk index system, including risk indicator, vulnerability indicator and prevention and mitigation capability index. Each of the risk components has large number of variables and quantities. Through displaying losses and characteristics of the four natural disasters, we put forward suggestions for better disaster mitigation. So that a better understanding of storm surges risk profile and early disaster warning measurement could be achieved.

## Introduction

Storm surge is an abnormal rise of water generated by a storm, over and above the predicted astronomical tide. Storm surge is caused primarily by the strong winds in a hurricane or tropical storm. [1]According to the weather system characteristics induced storm surge, it is usually divided into a typhoon (hurricane) storm surge and extratropical storm surge. [2, 3]Densely populated coastal areas are particularly vulnerable to natural hazards as increasing coastal development has positioned large numbers of people and infrastructure in close proximity to the coast. The tsunami of 26 December 2004 killed more than 220,000 people in 13 countries around the Indian Ocean, and the 11 March 2011 tsunami devastated a whole region in Japan. In 2005, Hurricane Katrina left the United States with a bill of some US$ 125bn (Fig. 1). In Europe, Winter Storms Kyrill (January 2007) and Xynthia (February 2010) cost US$ 10bn and US$ 6.1bn, respectively, the latter claiming 41 lives due to storm surge. Europe reached highest storm surge death toll since 1962, when more than 300 people were killed in Hamburg. Bangladesh (2007) and Myanmar (2008) were hit by tropical cyclones that left thousands dead and vast areas destroyed by wind and flood. Australia's east coast was beleaguered by four consecutive storms, in June 2007 that brought wind, rain, snow and high waves, and drove one large vessel onshore. Only in the case of Africa does one have to go back a few more years to the last major coastal disaster, with the exception of the 2004 Indian Ocean tsunami mentioned above (which killed about 300 people in Somalia, Kenya, Tanzania, Seychelles and Madagascar): namely to 2000 and 2001, when large parts of countries in the south-east of the continent were hit by a number of cyclones. [4]In China, Hainan province has also suffered from storm surge in recently years (Fig.2). Hurricane Sandy occurred in 2011 which affected many areas (Fig.3). In 2013, Typhoon Haiyan attacked Taiwan and many other cities (Fig.4). Here are four pictures about the disaster.

## The Current Storm Surge Risk Research

### 2.1 The research status abroad

Early natural disaster risk assessment is mainly used in the project; put more emphasis on the possibility of the occurrence of natural disasters. In recent years, with the rise of interdisciplinary, analysis and assessment of natural disasters not only focus on their own research, but also combine with the social and economic characteristics. Human factors are playing an enormous role. Good results have also been achieved. Tun Lin Moe [5] proposed a set of effective natural disaster risk management framework and approach through the study of public facilities. Vassilis Tsoumas [6] suggested the natural disaster risk management should move towards automation direction. Michael K. Lindell [7] put forward the continuity model about the impact of natural disasters and the consequences. Charles Kelly [8] preliminary evaluated the impact of natural disasters on the environment. Gary W. Barrett [9] explored post-emergency response to natural disasters assessment work.

### 2.2 The research status in China

Lihua Feng [10] proposed quantitative indicators of the degree of disaster according to casualties and property losses caused by the storm surge. Qiwang Xu [11] et al. conducted a preliminary study based on direct economic losses and two indicators. Wen Ye [12] used the perception algorithm to discriminate the disaster level, using data of storm surge from Zhanjiang and Guangdong Province.

## Risk Evaluation Index

Based on the understanding of disaster risk, some theoretical frameworks for risk assessment were established. For example, ISDR (International Strategy for Disaster Reduction) (2005) considered the history of the disaster, disaster risk analysis, hazard vulnerability analysis, and risk evaluation consisted of disaster risk evaluation system. IRGC(International Risk Governance Council)

suggested disaster risk assessment, including hazard identification, hazard assessment, disaster bearing system diagram, vulnerability assessment, as well as demographic and economic loss risk assessment and other aspects (ITC, 2009). Zhane Yin (2009) proposed to include risk identification, risk analysis and risk assessment only. Based on the results of previous studies of storm surge disaster risk evaluation, a risk evaluation index could be figured out with risk indicators, vulnerability indicators, disaster prevention and mitigation capability indicators.

### 3.1 Risk indicators

The size of the risk caused by storm surge is a direct factor in the disaster, mainly refers to the intensity of the storm surge disasters, including storm surge own activity intensity and frequency. Therefore, identification of the storm surge hazard index for predicting storm surge disasters and mitigation is important.

(1) The strength of storm surge is the degree of storm surge intensity .The higher intensity can cause stronger waves and a larger increase in the water surface level. In this case, the risk of disasters will cause severe effects.

(2) Maximum surge, tide and waves are direct characterizations of the sea change when the storm surge coming .The greater of its value indicates that the greater variation and thus the greater the risk of disaster bring by storm surge .These changes threaten to exacerbate storm surge risk by increasing the sea penetration, which could lead to coastal flooding and inundation.

(3) Central pressure, wind speed and wind radii, are the direct factors causing variation in sea water. The higher pressure, the greater wind speeds, the larger the radius and the higher wave height will result in higher risk.

(4) Landing sites related to the disaster areas are affected by the storm surge. If it lands in a developed economy with dense population and infrastructure region, it bounds to lead to larger losses and the greater risk as well.

### 3.2 Vulnerability indicators

Vulnerability of hazard is the susceptibility of both biophysical and social systems to a hazard. The length of the coastline, the coastal topography and geographic location and the average altitude terrain, potentially affected areas directly relates to the size of the disaster caused by storm surge. The stretches of coastline, flat terrain, near to the coast, under the average altitude of the regions are more vulnerable to the impact of storm surges. Therefore, the regions possess a higher degree of vulnerability.

Population density, per capita GDP and urban population proportion is also related to the storm surge. The population density is the number of units of square kilometers of the population, per capita GDP represents the degree of economic development in the region. If the proportion of urban residents in the area accounts for a large part, it will have a larger population density and a more developed economy. Then storm surge will cause losses of life and property.

Low proportion of housing, which means the number of potentially affected areas is another factor. Because compared to buildings, cottage is subjected to storm surge. So if the ratio is large, then the extent of the damage to the area housing is higher.

Primary/secondary industry GDP ratio or the ratio of the second industry and the total GDP of the area of primary industry is also the cause. Its value indicates the contribution of agriculture and industrial economy of the area. When storm surge hits the area from time to time, it will cause serious economic losses and bring risk of vulnerability as well.

### 3.3 Disaster prevention and mitigation capability index

Capacity building is the ability of people to deal with storm surge characteristics and features of hazard bearing body outside, including storm surge early warning of disasters, disaster recovery and reconstruction. Its specific indicators are as follows:

Coastal observation stations, dam project number and the average heights of the dam are the direct manifestation of the potential disaster area forecasting ability, the ability of disaster prevention. The

fact that people are living in areas endangered by storm surge is ignored, or eventually forgotten. If we grasp the sufficient data about coastal storm data, the risk of disaster can reduce largely.

Disaster emergency management capabilities include the number of storm surge disaster emergency shelters, relief materials reserve and the number of emergency rescue personnel.

The education of Storm surge risk knowledge is also critical. If everyone can realize the potential risk and the government do the relevant training work, the losses can be reduced to a large extent.

## Improvement Suggestions for Disaster Mitigation

### 4.1 Analysis and Comparison

Indicators about the storm surge in last 10 years are shown in Table 1. Accordingly, we include that some measures should be done in aspect of disaster prevention and mitigation.

| Indicators | | Hurricane Katrina | Typhoon Morakot | Hurricane Sandy | Typhoon Haiyan |
|---|---|---|---|---|---|
| | | 2005 | 2009 | 2011 | 2013 |
| Risk indicators | Affected area | USA, Bahamas, Cuba | Philippines, Japan, China, Taiwan Province of China, South Korea, North Korea | USA, Haiti, Cuba, Bahamas, Dominica, Canada, Jamaica | Marshall Islands, Guam, Philippines, Vietnam, Laos, China, Taiwan Province of China, Hong Kong |
| | Average wind speed (km/h) | 280 | 150 | 185 | 315 |
| | The lowest pressure(hpa) | 898 | 945 | 940 | 890 |
| Vulnerably indicators | The property loss (billion) | 108 | 6.2 | 65.5 | 0.83 |
| | The loss of life | >=1833 | 734 | 268 | >=7986 |

### 4.2 Suggestions for better disaster mitigation

Early warnings and preventions can reduce losses. Preparedness and Planning is the most important procedure. First of all, it should be in the form of land-use regulations for a given coastal area that has a high potential storm surge risk, keeping in mind particularly those areas that are known to have sustained damage in the past. Storm surge hazard perception should be introduced to the people of a coastal area for mitigating loss of life and damage to property. Hazard perception by the public is based on a technical understanding of the phenomenon. The next step could be to learn from historical experience and identification of vulnerable areas with reference to risk of potential loss of life, damage to property and related infrastructure. Prepare a vulnerability atlas that will show areas vulnerable to disaster and determinations of run-up level, which will help in coastal zone plan. The local government should formulate a policy of strategy to manage the disaster and enforce modern construction practice and planning in coastal settlements.

Finally, local residents should get more education for natural disaster prevention to a large extent. They should have knowledge of the mitigation and evacuation procedures when a warning is issued. Above all, people should be educated not to panic after the disaster and wait patiently until the issued warning is waved off or wait for the rescue teams to arrive.

## Discussion

Storm surge disaster risks have dynamic characteristics which reflect storm surge tide conditions (storm surge, astronomical tide and wave surge superimposed) in the intensity and frequency of different design scenarios. The extent of exposure (including disaster prevention engineering measure and non-structural measures) spatial and temporal variation also influences the extent of the storm surge. In recent years, it has been proved that sea level rise will likely increase risk in many coastal areas and will potentially create risk where it was not before. Climate change has also the potential to increase the risk of storm surge hazard due to the enhanced greenhouse effect. We should focus on dynamic assessment of storm surge disaster risk when setting up risk evaluation index system.

## Conclusions

We analyze and summarize the evaluation index system of storm surge risk. The main risk indicators include risk indicators, vulnerability indicators and mitigation of vulnerability index. The government agency can better analyze the impact of storm surge factors and make homologous measures. But with the rapid urban development, the coastal city gathered more people and property. How should we grasp the risk characteristics of the new stage, how to improve disaster mitigation and how to expand multidisciplinary field of urban disaster management will be the subject of future research.

**Keywords:** Storm surge, natural hazard, risk assessment, modeling

**Abstract.** Storm surge causes severe casualties and commercial losses to the habitant living within the range of it frequently, and has been one of the most harmful and prevailing hazards that attacks coastal areas. This paper is dedicated to reviewing and analyzing the methodologies and models that are generally used to assess the storm surge risk. Firstly, by means of analyzing the existing models of hazard risk assessment, indicating the purpose, process and methodologies. Secondly based on the analysis a comparison of the basic profile has taken into practice, and the advantages and limitations of the models are discussed. Finally, associating with the impacts of storm surges that affect China, we bring up a research direction that leads to further studies.

## Introduction

### 1.1 Recent storm surges and the losses

Storm surge is an abnormal rise of water generated by a storm, over and above the predicted astronomical tide. The storm surge is primarily caused by the strong winds of a hurricane or tropical storm. [1] The inundation that brought to coastal areas is the main negative affection coming from storm surges. The destructive power, the regional orientation and the predictability are the main characteristics of storm surges.

Storm surges lead to more casualties and economical losses when comparing to other natural disasters (e.g. volcano eruption, earthquakes, floods or droughts). Table 1 shows the cases that cause considerable losses in the last 10 years.

Table 1 Summary of global cases that cause considerable losses in the last 10 years

| Time | Name | Affected Area | Loss of life(missing people included) | Economic Losses (billion dollars) |
|---|---|---|---|---|
| 2005 | Hurricane Katrina | USA, Bahamas, Cuba | >=1833 | 108 |
| 2009 | Typhoon Morakot | Philippines, Japan, China, Taiwan Province of China, etc. | 734 | 6.2 |
| 2011 | Hurricane Sandy | USA, Haiti, Cuba, Bahamas, Dominica, Canada, Jamaica | 268 | 65.5 |
| 2013 | Typhoon Haiyan | Philippines, Vietnam, Laos, China, Taiwan Province of China, etc. | >=7986 | >=0.83 |

The countries and regions affected are mainly distributed in the west and south of Pacific Rim, and in Caribbean Region.

Since the storm surge is primarily caused by the strong winds of a hurricane or tropical storm, and the disasters can be observed through meteorological satellite, the model of the storm surge can be simulated. Furthermore, after the assessment of the topographical and geographical condition of the coastal area, regions of higher risk and higher vulnerability with respect to storm surge can be found out. We may believe that the hazard of storm surge possesses a characteristic of predictability.

1.2 Storm surge is one of the dominant natural hazards in China

China possesses a coastline as long as more than 32 thousands kilometers (18-thousand-kilometer-long mainland coastline and 14-thousand-kilometer-long island coastline respectively). [2] As located near by the Western Pacific Ocean, China suffered from the frequently occurred typhoons and tropical storms, mainly in the coastal areas in the southeast. Therefore storm surge has become one of the most dominant natural hazards in the coastal areas in China.

In 2012, it is storm surge that causes the most severe economic losses among all sorts of marine hazards and a relatively high percentage of loss of life. (Table 2)

Table 2 Losses of marine hazard of different categories in 2012 [3]

| Category of marine hazard | Loss of life (missing people included) | Percentage of loss of life | Direct economic losses (billion) | Percentage of direct economic losses |
|---|---|---|---|---|
| Storm surge | 9 | 13.24% | 126.29 | 81.35% |
| Wave | 59 | 86.76% | 6.96 | 4.48% |
| Sea ice | 0 | 0 | 1.55 | 1.00% |
| Tsunami | 0 | 0 | 0 | 0 |
| Red tide | 0 | 0 | 20.15 | 12.98% |
| Green tide | 0 | 0 | 0.30 | 0.19% |
| Fluctuation of sea level | 0 | 0 | -- | -- |
| Coastal erosion | 0 | 0 | -- | -- |
| Intrusion of tidal saltwater | 0 | 0 | -- | -- |
| Total | 68 | 100% | 155.25 | 100% |

1.3 Current statement of the risk assessment of storm surge

More and more frequent and severe casualties and commercial losses have been caused by storm surge to the countries and/or regions affected in recent years. Policy makers start to figure out the significance of the research on storm surge. Risk assessment of storm surge provides the basis for risk mitigation and related decision making.

However, there has been few generally adopted approach, let alone well-developed common methodology or guideline to assess storm surge risk. The approaches of storm surge risk assessment models available are divided into three categories according to the analytical level, i.e. qualitative, semi-quantitative, and quantitative approaches. As the precondition of the decision making of risk mitigation, risk assessment model plays an important role during the process of risk management. Nowadays, countries and/or regions affected by storm surge dedicate to establishing their exclusive risk assessment model respectively. But the models do not have connections and are lack of consistency in space and time (e.g. Hurricane Sunday causes enormous losses in US especially New York in 2011, only two years later after a comprehensive assessment on storm surge in New York).

The main purpose of this paper is to compare and analyze different risk assessment models, in order to figure out the proper application to different models. In the following section typical paradigms of different kinds of risk assessment models and brief introduction of the methodologies and the process applied is brought out. Analyses of models are summarized in a table which shows the characteristics of the models mentioned. The advantages and limitations of each model are discussed. And the methodologies applied and a general process of storm surge risk assessment is reviewed according to the studies. Last but not least, vista of future work in assessment, management and mitigation of storm surge risk is discussed.

**Risk Assessment Models**

Storm surge risk assessment is a relatively new and growing discipline that is coming from general approaches, which are usually applied to the general field of risk assessment (e.g. industrial risk and other natural risk such as floods, tsunamis or earthquakes). [4, 5] As an interdisciplinary research, the study on storm has greater complexity and difficulty. Comparison and analysis is carried out to the existing risk assessment models as follows.

2.1 Introduction and comparison of the common used models

**1) Data-based risk assessment models**

Among different kinds of assessment models, some simulation results are based on historical data of specific regions. Apparently, this kind of model tents to be quantitative.

Sufficient historical data with respect to storm surge is a prerequisite to establish data-based risk assessment model. There is only relatively short history that people record the hydrologic information in coastal areas. So it is the reason why few researchers are keen on carrying on risk assessment in a historical data-based way. In order to introduce the data-based method, a paradigm is brought, which is used for risk assessment of tsunamis.

An international project was carried out to assess the risk of tsunamis on the shorelines of Australia and its island territories. [6] The historical record from 1788 to 1995 is applied to the approach of quantitative and qualitative definition of the hazard and the vulnerability, and then these elements are integrated into a comprehensive risk assessment. Risk is considered as the product of hazard multiplies vulnerability. Where hazard is a comprehensive concept relative to historical tsunami data, potential tsunamigenic sources, relevant parameter determinations, probabilistic estimates and tsunami travel time charts. And vulnerability delineates the buildings and natural environments and possible effects thereon from tsunami and the human element. [6]

There are four steps in this model, i.e. 1) hazard assessment, 2) vulnerability assessment, 3) risk assessment and 4) policy making for tsunami warning. In the first step, the study involved the collection, collation and analyses of instrumental data (e.g. tide-gauge records), anecdotal information and published scientific papers and reports. By means of quantification of "Tsunami Hazard Zones" (which differs the hazard level into high, medium and low zones), a tsunami hazard map is established for Australia and its territories. And 4 classes of potential tsunamigenic sources have been identified, i.e. earthquake, submarine volcanoes, submarine landslides and extra-terrestrial impacts. The second step is vulnerability assessment which is defined in quantitative terms as the integration of the existing state of and the uncertainty of the future development in the coastal areas and the islands. According to the occurrence of generic elements such as built environment (e.g. major ports, harbors, fishing industry, etc) and natural environment (e.g. significant coastal geography, tourist areas, etc), vulnerability levels (divided into high, medium and low) are given to the coastal areas and the islands. In the third step, the potential risk levels as Zones A to E which is determined by a comprehensive analysis are presented in a tsunami risk assessment zoning map for the study areas. The final step is a governmental behavior, related to tsunami warning and response system, and is beyond the range of this paper.

It is inevitable that differences between tsunami and storm surge risk assessment model are exist. The differences mainly focus on: 1) source identification; 2) propagation of the wave; 3) forecast and warning. But the process of the assessment such as hazard assessment and vulnerability assessment are pretty similar. So this paradigm can be a reference in storm surge risk assessment.

Because of the shortage of specific data in the study field around the world, it is a great challenge to implement the data-based approaches.

**2) Model -based risk assessment**

Data-based risk assessment models need sufficient historical data when they are put into effect. But few countries or regions possess sufficient scale of successive historical data about storm surge. So risk assessment applies model-based approach can be widely used.

Qualitative risk assessment models e.g. scenario-based ones, and statistical risk assessment model are mainstream approaches to realize risk assessment.

A scenario-based tsunami risk approach is implemented by Nadim and Glade in the West coast of Thailand whose geographical position is familiar with China. [7] This approach considers a series of plausible extreme scenarios causing by a tsunami-generating earthquakes, and involves the following steps:

1. Definition of scenarios for tsunami-generating earthquakes,
2. Computing the tsunami inundation levels,
3. Estimation of tsunami risk for the different scenarios, and
4. Comparison of the estimated risk with tolerable or acceptable risk levels.

The risk is considered as the expected value of loss (human life, economic loss, reputation loss, and so on), and is calculated using the following general expression. (Eq.1)

$$E[loss] = \sum_{S} \sum_{\underline{C}} \underline{C} \times P[\underline{C}|S] \times P[S] \tag{1}$$

Where E[loss] stands for the expected value of loss e.g. of human life, economic loss, reputation loss, etc; C is the particular set of losses; S is the particular scenario; P[S] is the probability of occurrence of scenario; P[C|S] is the conditional probability of losses set C given that scenario S has occurred.

This approach mainly focuses on the loss of human life. The affected population could be divided into three groups according to the probability of the occurrence. Other researchers applied scenario-based model as well, such as Tinti et al. carried out a scenario-based approach for both small and large tsunamis, [8] Pruttipong Apivatanagul et al. applied an optimization probabilistic scenario method to estimate the long-term regional hurricane wind and storm surge hazard. [9]

N. Lin et al. carried out a statistical/deterministic storm surge risk assessment associated with the hydrodynamic model SLOSH (sea, lake, and overland surges from hurricanes) and ADCIRC (advanced circulation model) for New York City. [10] This methodology makes it possible to assess the storm surge risk for data-scarce regions. Implementation steps are as follow:

1. The hurricane model and the SLOSH model (with a relatively coarse grid) are coupled to generate a large number of synthetic surge events around a site of interest.
2. Statistical analysis can then be carried out to estimate the probability density function (PDF) of storm surge heights for the site.
3. Combining the PDF of storm surge heights and the annual storm frequency, which may be estimated from the hurricane model, mean return periods of surge heights can be predicted.
4. Using the ADCIRC model (with a high-resolution grid), an evaluation has been carried out to the “most dangerous storms” of the SLOSH simulations to ensure the accuracy of SLOSH model.

Also statistical analysis of the simulation results was carried out in a large scale. They concluded that storm surge may be well correlated with the wind speed parameters at the site of interest. And the characteristics of the highest storm surges are described as follow: high intensity (i.e. high maximum wind speeds, large pressure deficits, and relatively compact structure) when passing by the site; Slow moving velocity, etc. It is different from some assessment models that the results of the model focus on the annual storm frequency and the mean return period of the storm surge heights. They mentioned that it is meaningful to combine the estimated storm surge caused by hurricanes with other components of coastal flood level in risk assessment for further studies.

Similar paradigms applying statistical approaches are widely used: Jarvinen et al. evaluated storm surges by means of SLOSH simulation model; [11] the work of Pickands et al. is useful for estimating the probabilities of future extremely large observations (including storm surges). [12]

## 2.2 Model Comparison

After reviewing the risk assessment models, we can find some general facts. The calculation of the risk is usually carried out in a statistic or a deterministic (i.e. scenario-based or synthetic) approach depending on the availability of historical data. The consequences of the negative incidents refer to

the elements at risk and the vulnerability of them. The vulnerability assessment mainly focuses on the loss of population and property. However the description of the concept of risk has not been unified, more and more researchers acknowledge it as the product of hazard and vulnerability. And the understanding of hazard and vulnerability differs from each other.

The model types are roughly divided into two groups, i.e. data-based models and model-based ones. The application scope comes into national or regional scale. Although process of every model differs from each other, a general process can be summarized, which will be introduced later on. The output of the models is expressed in various methodologies. (Table 3)

All these commonly applied models possess distinct characteristics of advantages and limitations.

Data-based models possess advantages of convincing evident, the persuasion and a larger research area. However, because of the shortage of the source of historical data, research area can not cover all lately developed regions.

Scenario-based models solved the problem when assessing storm surge risk in data-shortage areas. And a relatively precise simulation can be carried out in research region. The limitations of these models are the effectiveness depends on the consistency of the simulated events and the real ones, and the research area usually very limited.

Statistical models solved the data-shortage problem too. Researchers can obtain specific characteristics of the simulated storm surge. And the model is in favor of a detailed risk mitigation plan. But the accuracy is in proportion to the calculation.

Table 3 Summary of the risk assessment models

| Source | Model type | Application scope | Analysis process | Output |
|---|---|---|---|---|
| Jack Rynn & Jim Davison | Data-based | National | 1) Hazard assessment,<br>2) Vulnerability assessment,<br>3) Risk assessment, and<br>4) Policy making for tsunami warning. | Tsunami hazard map, tsunami risk zonation map |
| Nadim & Glade | Model-based | Regional | 1) Definition of scenarios for tsunami-generating earthquakes,<br>2) Computing the tsunami inundation levels,<br>3) Estimation of tsunami risk for the different scenarios, and<br>4) Comparison of the estimated risk. | Expected value of loss |
| N. Lin et al. | Model-based | Regional | 1) Generate a large number of synthetic surge events,<br>2) Statistical analysis to estimate the probability density function (PDF) of storm surge heights,<br>3) Risk assessment by means of combining the PDF of storm surge heights and the annual storm frequency, and<br>4) Ensure the accuracy of SLOSH model through an ADCIRC evaluation. | Mean return period of the storm surge heights |

Therefore when people choose the risk assessment model, they need to suit to the specific conditions they study.

## Methodologies

The methods applied in the risk assessment models are divided into 2 groups according to the quantitative level. In quantitative approaches, contour lines, thematic risk maps and F-N curves play important roles in quantifying the distribution of storm surge risk in space and time. And statistical analysis and event simulation (e.g. ADCIRC and SLOSH) functioned well in statistical approaching risk assessment model. Otherwise risk matrix (which can be further translated into a thematic risk map in a GIS environment) or empirical approaches such as scoring by experts can be used.

Similarities are found in the general steps of risk assessment. This can be explained by the generic origin of natural risk assessment approaches. The general framework deriving from the reviewed models can be summarized as follow:

1. Definition of the issue. Define the characteristic of the problem and confirm the purpose of the analysis including the research area, level of details, and the quantitative level.

2. Hazard analysis. Define the severity and frequency of the storm surge. The output may involve in this step: probability distribution of the occurrence of a storm surge of various return period, hazard map, risk zoning map, etc.

3. Vulnerability analysis (or consequence analysis). It includes the identification of the elements at risk with respect to the potential storm surge, and the vulnerability of the effected elements. The output may involve in this step: distribution maps of specific elements at risk (population, property, infrastructures etc.); thematic maps of the societal, physical or environmental vulnerability.

4. Risk estimation. Integrate the outcomes from hazard and vulnerability analysis in a quantitative way or a qualitative way or a semi-quantitative way depending on the historical data sufficiency of the research area.

5. Risk evaluation. Compare with the available risk criteria, and determine the acceptability of the risk. If necessary, risk mitigation will be put into effect.

6. Early warning system and emergency plans as well as reconstruction and sustainable disaster management.

## Discussion

Storm surge is one of the most devastating coastal disasters which caused about 80% of marine damages in China. Due to the long history of recording natural disasters in coastal areas, which can dated back to Han Dynasty in 48 BC, [13] historical data-based approaches can be used to assess the risk of storm surge. However, the vulnerability has increased dramatically along with the fast urban development. There is an urgent need to assess the risk. [8] Further research on risk assessment in China can associate model-based models with data-based models to form a complementary effect.

Under the influence of global climate change, temperature may be increasing and sea level may be rising, the occurrence of extreme events turns to be more frequent. On one hand, increasing temperature causes more storm surges nowadays; On the other hand, rising of the global sea level leads to a higher occurrence possibility of storm surge and more severe at the same time. [14] Therefore, hazard, as a potential loss, which is a determining factor when assessing disaster risk, has been more complicated. Storm surge risk mitigation faces a more complicated situation around the world.

Vulnerability is another important part of risk assessment. It is easier and easier to have extreme events happen during 1990 to 2009 based on calculation and estimation to the vulnerability of 11 coastal located provinces or metropolises. And it relates to the higher temperature as well. [13]

When hazard and vulnerability increase, higher risk is expected. It is necessary to have a more thorough research on the risk assessment model. Future studies might be done in context of climate change and sea level raise. Modeling should be associated with astronomic tide and sea wave; synthesis risk mitigation should be taken based on risk assessment of multiple coastal disasters such as coastal subsidence and urban inundation.

## Conclusions

This paper reviews the existing storm surge risk assessment models after an introduction of recent statement of storm surge risk assessment including basic information of storm surge, storm surge in China and the current statement of the risk assessment of storm surge. Comparison among the typical models concerning model type (data-based model, scenario-based model and statistical model), application scope, analysis process and outcome were carried out accordingly. We analyze the advantage and limitations of the models reviewed. Some methodologies applied in risk assessment models are presented. General steps for storm surge assessment are brought out performing as a guideline on storm surge risk assessment. Last but not least, aiming at improving risk assessment in China, we discuss a probable trend of storm surge risk and give a research direction on future study. This paper is a threshold of our research, further study will be continued.

**Keywords:** Strom Surge; Risk assessment; Numerical Modelling; Extended Kalman Filter (EKF)

**Abstract.** A new approach to risk assessment of storm surge and prediction problems was suggested. The model is based on the Extended Kalman Filter (EKF) equations, which simply linearises all nonlinear models so that the traditional Kalman filter can be applied. Key factors describing storm surge disasters are considered in the model. Numerical simulations were carried out and tested with some actual observations of recent storm surge events and related damages in coastal regions of China. The results show a reasonable fit for storm surge disaster prediction and encourage the possibility of using the method for future studies.

## Introduction:

The recent devastating impact by Typhoon Haiyan (2013) associated with record wind speed (105 m/s), heavy rainfall again showed Southeast Asia, as well as coastal regions in China is among the most vulnerable areas to storm surge and coastal flooding around the globe, in terms of both the probability of being hit by major storm surges and the potential consequences. [1] Although wind speeds were extreme, the major cause of property damage and loss of life appears to have been storm surge. People in Asia coastal regions are recognizing the impacts of tsunami after the events of 2004 in Indian Ocean and 2011 in Japan; however, they have little knowledge of storm surge risk, let alone risk mitigation and climate adaptations measures, such as an early warning system [2, 3].

Fast industrial developments with densely populated coastal areas in China are particularly vulnerable to these hazards. While planning, early warning and mitigation for these hazards is an ongoing and continuous process, significant challenges lie ahead for central and local government in China tasked with planning for the potential impacts of climate change on the magnitude and frequency of coastal hazards [3, 10].

Previous studies dedicated to different storm surge modeling efforts based on general circulation models (GCMs) and hydrodynamic models to predict the maximum winds and rainfall rates. [4, 6, 7] The models are either based on the historical maximum storm surge sea level and time distribution or statistical analysis with presumed scenarios. These models found useful applications in risk assessment for storm surge hazards by hurricanes in the East coast in US. [5]

However, risk assessment efforts have substantial uncertainty in some areas with few historical records. In such cases, it may be more reasonable to use simplified approaches for an operational storm surge real-time forecast systems. Despite the complexity nature of storm surge phenomena, the direct disaster impacts are coastal flooding i.e. the maximum sea surface level and its distribution of time which results inundation near coastal regions. [8, 9]

The main objective of this study is to set up a simple forecast model and to quantitatively examine the risk of sea level rise and related damages duo to storm surge based on the observational data.

## Modelling

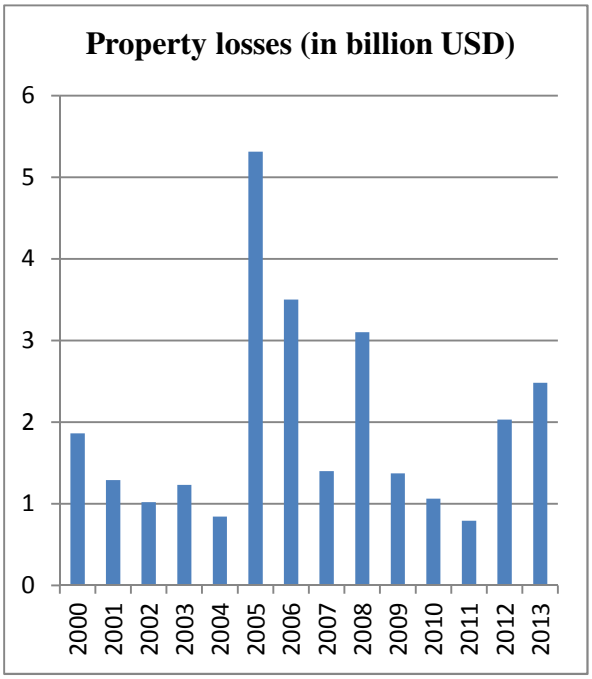
The key factors taken into account influencing coastal urban storm surges include: 1) rainfall: **r** (mm); 2) protective object distance off shore: **d** (m); 3) wind speed: **V1** (m/s); 4) wave height: **h** (m); 5) wave propagation speed: **V2** (m/s). Storm surge hazard forecast indicators come from these key influencing factors are as follow:

1) Risk severity of storm surge: **R**, which divided into 4 Categories based on return period: I: 1000 years, II: 100 years, III: 10 years, IV: 1 year.

2) Property losses: **P** (in billion USD)

3) Loss of lives: **L** (in person).

Fig.1 and Fig.2 illustrate the property and population losses caused by storm surge in recent years in China.



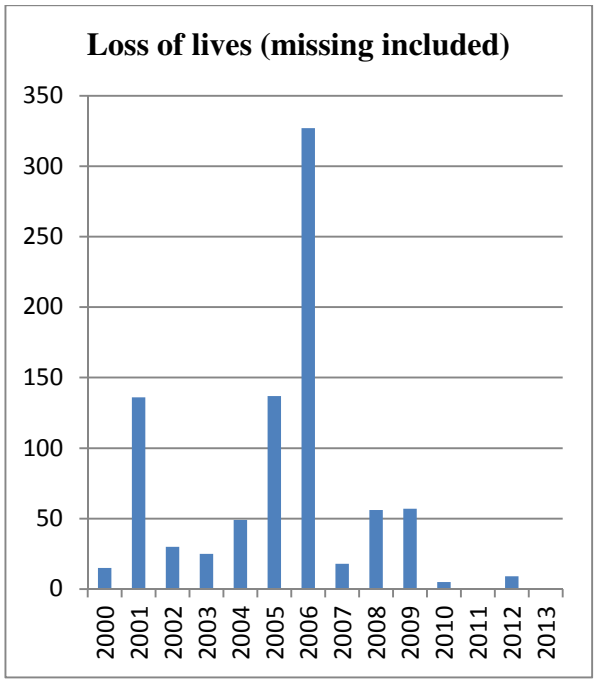


**Fig.1** Property losses caused by storm surge

**Fig.2** Loss of lives caused by storm surge

**Storm surge disaster forecast approaches for coastal cities based on Extended Kalman Filter**

This section analyzes the storm surge disaster influencing factors. We present a simple approache to establish a forecast model. The test the validity of the model is also discussed.

**(1) Methodology**

Recently, Extended Kalman Filter (EKF) approach has been applied widely in disaster forecast and assessment. [10, 11] However, traditional Kalman Filter model only fits on simple linear system models, the real disaster system models tend to be more complicated nonlinear system models. An EKF approach is aimed to establish a real time forecast associated with the basis and modeling advantages on information theory and signal processing.

Based on the key influence factors of urban inundation and storm surge disaster in coastal cities, this approach established a quantitative description on the key influence factors. Because of the fact that EKF is a recursive algorithm and the calculation and storage amount is small, dynamic tracking instantaneity of storm surge inundation and flood could have been realized.

**(2) Model establishment and risk assessment based on EKF**

State vector is shown as:

$$\mathbf{X}(k)=\begin{bmatrix} R(k) \\ P(k) \\ L(k) \end{bmatrix} \tag{1}$$

Observed value:

$$\mathbf{Z}(k)=\begin{bmatrix} r(\mathrm{k}) \\ d(k) \\ V1(k) \\ h(k) \\ V2(k) \end{bmatrix} \tag{2}$$

When system is unstable, state will mutate, and then state equation will be nonlinear. State equation is established as follow:

$$\mathbf{x}(k+1)=\Phi(x(k),k)+\mathbf{w}(k) \tag{3}$$

$$\mathbf{z}(k)=\mathbf{h}(x(k),k)+\mathbf{v}(k) \tag{4}$$

Where, $\Phi(\cdot)$ and $h(\cdot)$ are nonlinear functions respectively, w(k) is dynamic noise, z(k) is observed value, v(k) is measurement noise.

Practical functions are based on data condition. Recursion formula according to the model above is established as follow:

$$\hat{x}(k/k)=\hat{x}(k/k-1)+K(k)\tilde{z}(k/k-1) \tag{5}$$

$$K(k)=P(k/k-1)C^{T}(k)R_{L}^{-1}(k) \tag{6}$$

$$R_{L}(k)=C(k)P(k/k-1)C^{T}(k)+R(k) \tag{7}$$

$$\tilde{z}(k/k-1)=z(k)-h(\hat{x}(k/k-1),k) \tag{8}$$

$$\hat{x}(k/k-1)=\Phi(\hat{x}(k-1/k-1),k-1) \tag{9}$$

$$P(k)=(I-K(k)C(k))P(k/k-1) \tag{10}$$

$$P(k/k-1)=A(k,k-1)P(k-1)A^{T}(k,k-1)+Q(k-1) \tag{11}$$

Where, $C(k)=\dfrac{\partial h(k)}{\partial\hat{x}(k/k-1)}$, $A(k,k-1)=\dfrac{\partial\Phi(k-1)}{\partial\hat{x}(k-1/k-1)}$

After system set up the initial values of $\hat{x}(0)=E\{x(0)\}$ and P(0), recursion will continue until the arithmetic meets the convergence conditions. Then the state estimation will be the storm surge hazard forecast indicators we are looking for.

**(3) Simulation results**

Based on data from available records, [12] simulated observation value of the vectors is presented in Table 1. There are simulated data of 20 years, which can be used to compare the simulated results with the risk level of real storm surges and resulted losses.

Risk of storm surge outputs in 4 levels based on return period: I: 1000 years, II: 100years, III: 10 years, IV: 1 year. In order to be easy to display, R is taken into logarithm, value of 4 levels becomes 3, 2, 1, and 0 respectively.

Based on the observed data, the identification method is established as follow:

$$\dot{x}=\begin{bmatrix} \alpha R(\mathrm{t}) \\ \beta P(\mathrm{t})R^{2}(\mathrm{t}) \\ \gamma R(\mathrm{t})\sqrt{L(\mathrm{t})} \end{bmatrix}+w(\mathrm{t}) \tag{12}$$

$$z(\mathrm{t})=\begin{bmatrix} 3.2\sqrt{R(\mathrm{t})}+0.4\,\mathrm{P(t)}+10L(\mathrm{t}) \\ 54/P(\mathrm{t})+11/L(\mathrm{t}) \\ R(\mathrm{t})/20+4.3\sqrt{P(\mathrm{t})}+6L(\mathrm{t}) \\ \sqrt{R(\mathrm{t})}/5+0.2P(\mathrm{t})+0.3L(\mathrm{t}) \\ 6.4\log_{10}R(\mathrm{t})+2.2P(\mathrm{t})+3L(\mathrm{t}) \end{bmatrix}+v(\mathrm{t}) \tag{13}$$

Simulated values applying EKF and real values are shown in Fig.3, Fig.4 and Fig.5. Fig.3 shows the estimate risk; Fig.4 shows the comparison results between estimate losses and the real one; Fig.5 shows the comparison results between estimate tolls and the real ones.

**Table1** Simulated data of r, d, V1, h and V2

| Year | r | d | V1 | h | V2 |
|---|---|---|---|---|---|
| 1 | 4 | 226 | 8 | 2 | 5 |
| 2 | 3 | 313 | 6 | 2 | 3 |
| 3 | 4 | 227 | 8 | 2 | 5 |
| 4 | 2 | 401 | 4 | 1 | 3 |
| 5 | 0 | 3056 | 0 | 0 | 0 |
| 6 | 15 | 65 | 30 | 10 | 19 |
| 7 | 4 | 244 | 8 | 2 | 5 |
| 8 | 0 | 1635 | 1 | 0 | 0 |
| 9 | 5 | 180 | 11 | 3 | 6 |
| 10 | 6 | 149 | 13 | 4 | 8 |
| 11 | 0 | 6237 | 0 | 0 | 0 |
| 12 | 3 | 252 | 7 | 2 | 4 |
| 13 | 2 | 377 | 5 | 1 | 3 |
| 14 | 2 | 396 | 5 | 1 | 3 |
| 15 | 3 | 320 | 6 | 2 | 3 |
| 16 | 8 | 113 | 17 | 5 | 11 |
| 17 | 3 | 329 | 6 | 2 | 3 |
| 18 | 13 | 76 | 26 | 8 | 16 |
| 19 | 5 | 196 | 10 | 3 | 6 |
| 20 | 4 | 231 | 8 | 2 | 5 |

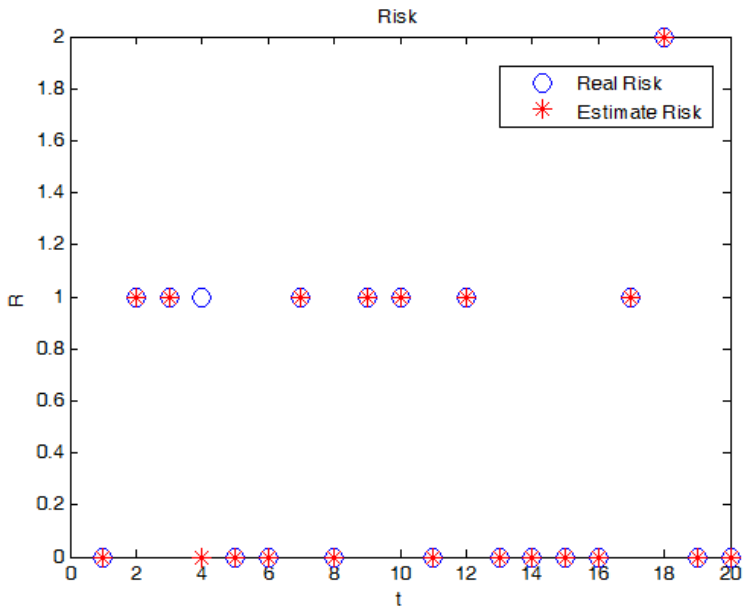

**Fig. 3** Estimate risk estimation level
X axis stands t for year, Y axis stands R for Risk level

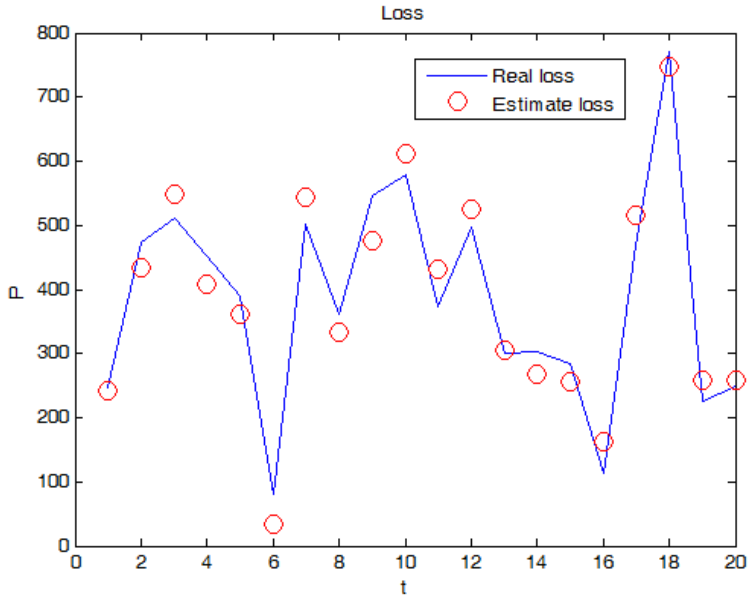

**Fig. 4** Estimate property losses
X axis stands t for year, Y axis stands P for Property loss (in millions RMB)

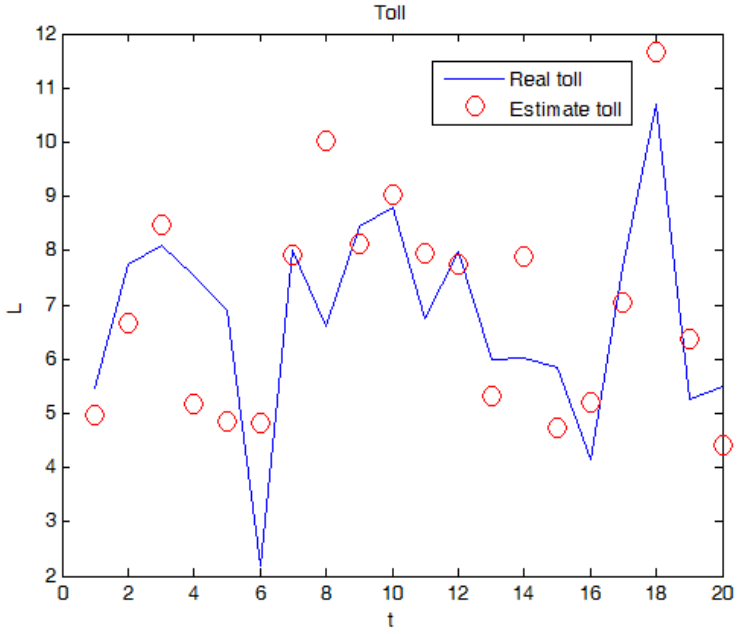

**Fig. 5** Estimate loss of lives
X axis stands t for year, Y axis stands L for loss of lives

The simulated results proved the validity of the EKF based forecast approach for storm surge risk level, property losses and loss of lives. According to the results in Fig.3, only in the 4th year, there is a deviation of ±1 level between the estimate level and the real one. The other estimate values correspond to the real values. A conclusion could be made that the forecast storm surge risk level matches the reality in a reasonable fit. Furthermore, it will be more corresponding to the reality after an adjustment of the parameters when more data would be available. Results from Fig. 4 show a consistency between the estimate loss and the real one, and then show a validity of the EKF when forecasting the property losses. Estimate loss of lives in Fig.5 shows a small deviation to the real value (<=3 persons). Based on the analysis above, it is effective to forecast storm surge risk level, property losses and loss of lives utilizing EKF. Especially, the forecast results are not only within the error range, but also have a high consistency with the reality. It is encouraging to follow the studies and develop more applicable systems in practice of storm surge forecast.

**(4) Arithmetic Advantages**

After looking into the arithmetic model i.e. EKF, the fact EKF reflects most of the real system is found. Through piece-wise linearization, we can solve a major class of problem. So as long as the modeling is reasonable, simulated objects will adapt this arithmetic. Therefore, if we identify the model structure and parameters associated with the system identification method, and apply EKF to dynamic tracking and forecast, we will solve practical issues more conveniently.

From the operation and calculation of the arithmetic, we can conclude that EKF only need to store the estimate values from the earlier year and the observation values of the year, so the calculation and the storage decreases in a large scale, which satisfying the real-time requirement. The urban disaster forecast system consists of a large number of factors and observational data, so it is meaningful to have an arithmetic method with low complexity for a quick response system.

From the arithmetic theory, based on the current observation data, the arithmetic can obtain not only the current estimate value but also the later forecast value of the storm surge and flood disasters. It makes the real-time quantitative forecast possible; thereby disaster forecast will be more convenient using this arithmetic.

## Summary and Conclusions

Disaster preparedness and prevention, prediction measures are the integrated procedures in disaster management. We have developed a simple approach of numerical model to estimate and forecast the key factors of storm surge hazards based on some historical data. The model is based on the Extended Kalman Filter (EKF) equations, which are extensively used to determine the uncertainties in the system. Preliminary results show that it is feasible to estimate and forecast the value of the disaster based on the arithmetic after quantifying the key factors influencing coastal urban storm surges. Thereby a more sophisticated forecast system plan could be set up. Once one of the key influencing factors dominated, there would have been a specific forecast plan and a relevant response. Thus a risk optimizing system associated with simulation and reality could be set up accordingly. This model can extend to other practical field as well, e.g. analysis of the unstable and nonlinear effect from rainstorm and hurricane. In this case, state equation could be improved to quantify the dynamic process. Similar studies are ongoing in our research team.

# Survey of Fire load in building furniture store

Jinping Wang

China Academy of Building Research, Beijing 100013, China

wangjinping@126.com

**Keywords:** building furniture store; fire load; survey.

**Abstract.** There are many combustible materials in building furniture stores with complex people traffic and high risk of fire disaster. Fire load as the represent of flammable material, and the building fire risk can be grasped by the data obtained. Through investigation and statistics on the fire load density value of building furniture store, it is convenient for performance fire safety design. According to the survey, fire load density average value is determined of 382.71 $MJ/m^2$ , the standard deviation is of 143.46 $MJ/m^2$ . After fitting the survey data, the data distribution do not refuse to obey the extreme-value Ⅰ distribution, so this distribution can be the basis of fire design in other corresponding building furniture stores.

## Introduction

Along with China's social economic progress, and the improvement of people's living standard, more and more luxury decoration is appeared in domestic, and building furniture materials market has developed rapidly in the country, so far kinds of building furniture materials market has grown to more than 4000. The good and bad building materials market and merchants are intermingled, resulting in the occurrence of high fire rate in the world, and building materials market have many goods, so fire will cause a great loss of property. The fire happened in largest building materials trading center in northern Thailand has to be estimated the loss of nearly 3,000,000,000 baht.

(a)Decoration Condition

The area of large building materials market is mostly more than 50,000 square meters to 80,000 square meters, and the floor height can reach 4 ~ 5 layer, usually with underground, and adjacent to several blocks. The product categories are among with decoration materials, home furnishing supplies and accessories, such a long industrial chain and all of home decoration products.

Large building materials market in general will be installed of spray, alarm system and fire shutter, a plurality of fire safety export, and goods partition layout.

In china building materials market the ceiling is usually not burning gypsum board, and the ground for marble and other non-combustible material, but in the counter area will generally be twice decorated into wood floor. Fire hazard in small building furniture store is more serious, such as electrical wiring production and processing of inconsistent specifications, and market buildings did not take fire department, and illegal structures occupy fire prevention space, and paint shop in the building furniture store without business license of dangerous goods, etc.

(b) Fire characteristics

Fire characteristics of large building materials stores is as follows: there is many flammable goods and large fire load, so the fire is generally larger than other place; space span is large and upper and lower connectivity, so the fire spread quickly and easily lead to large three-dimensional combustion; electrical lighting equipment is always too much to cause more fire, and small fire is more frequently happened in the store.

## Investigation of Fire Load

### Fire load investigation of building furniture stores

There are many commodity types in large building furniture market, and distribution of fire load is very uneven. Stone, sanitary ware area has less combustible material, but the curtain, furniture and other areas have large number of combustibles, so fire load density values will appeared to be very large, and fire danger will be higher. So the furniture area is chose as the building materials market fire load statistics place, mainly because of the more flammable items, and goods is very concentrated and expensive, so the fire load is larger than other area of the market. In the fire design the larger value is used may decline the fire hazard.

In the statistical process floor area method is used to add total calorific value of one brand, and divided by the brand area. In the investigation one brand area has large regional area among 79 square meters to 324 square meters, which made the statistical work great, but such practices decrease the margin of error and make the data more representative. In the total investigation more than 10,000 square meters floor area is done.

Combustible mainly focused of furniture, such as wardrobe, bookcase, bed and mattress, desk, chair, sofa. So wood is the main fuel material. The polymer products are in small amount. For large furniture it is hard to weigh, so it is determined by the method of density multiplied by the volume which is called inventory method in NFPA 557.

(a) One store in Taiyuan with the business area of 60,000 square meters is surveyed, decoration materials, modern furniture, classical furniture, decoration material are all concentrated in the building materials shopping center.

Fig. 1 Taiyuan spring store of Easyhome

Fig. 2 Beijing shilihe store of Easyhome

(b) One store on the Shilihe located in Beijing is surveyed, with the business area of 51,000 square meters.Unexpectedly the store is to provide home furnishing design and decoration materials, furniture and home furnishing accessories for customers, with a total of four venues, including one to three building "decoration materials hall ", 4 as "furniture hall ". The furniture building is a four floor building and one floor is under ground.

(c) Another store in Beijing is surveyed, with the total building area of more than 50,000 square meters, which is divided into hardware, decorative materials, modern furniture, sofa, children's furniture and other regions.

### Results of the survey and statistical

According to the investigation of the three building materials market 72 valid data is obtained, although the number is small but the area is great so the data is also typical. The maximum value is of 708.97 $MJ/m^2$, and the minimum value is of 83 $MJ/m^2$, through the data group it can be seen the mostly data are between 200～300 $MJ/m^2$ and the statistical parameters are obtained, the mean

value is of 382.71 $MJ/m^2$, and the standard deviation is of 143.46 $MJ/m^2$. The fire load density histogram figure is as follows in fig.3.

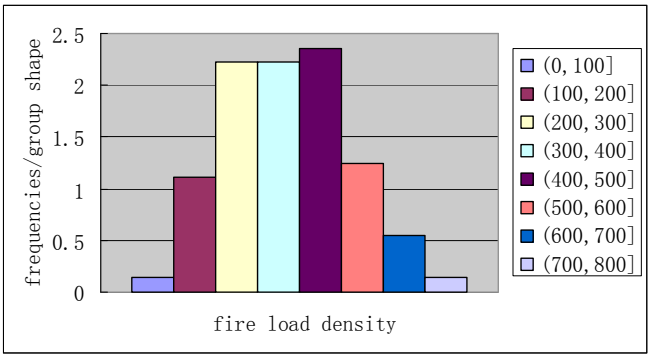

Fig. 3 Fire load histogram

Then analysis of statistics is progressed. To fit the data group, normally distributed, logarithmic normal distribution, the distribution of extreme value type Ⅰ, generalized extreme value, generalized Pareto distribution were processed [4]. After the calculation, the data distribution is not refused to obey the extreme value type I distribution, and its distribution can be expressed by the formula:

$$F(x) = \exp\{-\exp[-0.0089(x-318.15)]\}$$

The maximum value probability distribution during the period of design basis distribution as follows:

$$F_{iT} = \exp\{-\exp[-0.0089(x-493.67)]\}$$

Statistical parameters of $F_T(x)$ for the design basis period of T are as follows:

$\mu_{LT} = 558.23$

$\sigma_{LT} = 143.35$

According to the group preliminary work [3], there carried out calculation of fire load standard value to the exhibition building, the standard value is as follows:

$u_k = 897.96 MJ/m^2$

## Conclusions

The fire load standard value of building furnishing stores values slightly smaller than residential value, this is mainly because of the furniture in home furnishing stores is often vacant, although furniture is placed compactly, but which still decrease the content of fire load.

In the survey it is found that organic gas release rate in home furnishing stores is high, which relates to poor air quality in the store, therefore in the fire toxic gas is extremely easy to cause higher fire hazard, so in the fire design the value of home furniture store should be designed lower for fire load security, so as to decrease the release damage of harmful substances.

# The research on structure fire resistance test of fire retardant rigid polyurethane

Jinping Wang

China Academy of Building Research, Beijing 100013, China

wangjinping@126.com

**Keywords:** rigid polyurethane foam; fire safety; fire resistance test

**Abstract.** The developed rigid polyurethane foam is added several inorganic materials, which made the polyurethane foam release less poisonous gases in fire. The oxygen index value can reach more than 32 percent, and under the standard heating curve the retardant rigid polyurethane foam can present the performance of 1h fire resistance test.

## Introduction

Rigid polyurethane foam with excellent physical and chemical properties, which thermal conductivity is lower than the polystyrene foam and natural insulation materials, and it can be site casting or spray molding, combined with other materials into one constructure, making the insulation, sealing better, all of these advantages make this material widely used in the world. Its fire safety is a huge security risk, because the polyurethane foam containing flammable hydrocarbon chains, low density, large surface area, and the oxygen index value of 17 percent, so polyurethane foam in the air can burn, and decomposition will produce large amounts of toxic fumes. Through the horizontal burning test, it can be found poor thermal stability, and be classified as combustible.

Because of the fire happened in insulation field frequently in china, from March 2011 to December 2012 the Ministry of Public Security issued a document prohibited the use of materials below Class A fire performance. In the inner decoration, number of fire caused by the polyurethane foam is also huge, it shows that the polyurethane foam used widely domestic, but the current dilemma mostly due to the illegal use of the factory and constructionm worker. China has been very concerned about the fire caused by combustible materials, rigid polyurethane foam fire resistant performance has become the important technical indicators of being building materials, there is developed a flame retardant rigid polyurethane foam, and carried on fire resistance test.

## Testing Method

Structural fire resistance test used of flame-retardant polyurethane foam, the choice of several inorganic retardants used in conjunction with best flame-retardant effect, and the oxygen index can reach 39 percent, and the foam's physical and chemical properties are excellent.

Oxygen index, horizontal burning method, vertical burning method, smoke density test, construction fire test are carried on the fire retardant rigid polyurethane foam. It is found that the fire retardant polyurethane foam can reach 32 percent of the oxygen index value, smoke density value of 50-90, the polurethane foam can go through the horizontal and vertical test.

In the structural fire resistance test, the size of the test components reference *GB23864-2009 firestop material*, concrete block size is 800mm*600mm*120mm, rectangular hole size is 510mm*110mm*120mm. In the hole it is filled with flame retardant rigid polyurethane foam prepared, the oxygen index of the polyurethane foam is 35 percent. In the experiment, the concrete block back surface to fire was placed two thermocouples, foam back face and adjacent to concrete block are placed two thermocouples respectively, in the test if the test piece back fire surface or hot gas flow is the loss of integrity, thermocouple temperature rise to 180℃ for the specimen lose heat insulation.Figure 1 shows specimen installed, Figure 2 shows the test is terminated.

Figure 1 Installed foam

Figure 2 Test terminating

In the figure 2 the polyurethane foam reached fire limit and it maintained a fire touched face throughout the experiment, the furnace temperature rise in accordance with the standard temperature curve, the curve of the standard curve and the furnace temperature state as follows in figure 3.

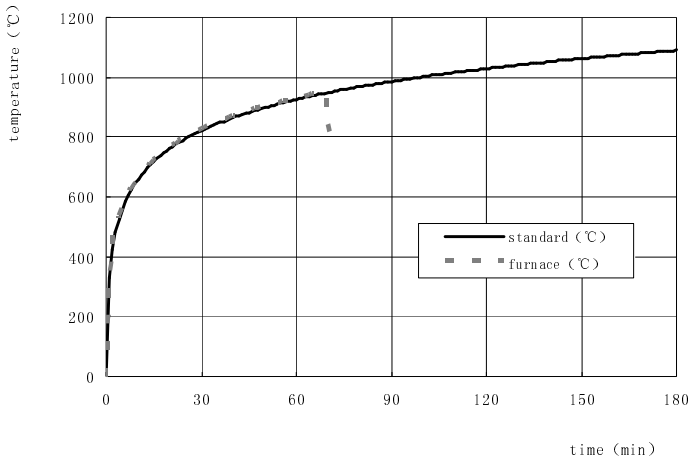

Figure 3 The curve of the standard curve and the furnace temperature

## Results

The following table 1 lists the value of the thermocouple temperature during the experiment.

Table 1 The thermocouple temperature value during the experiment

| Test time | Foam tempera-ture | Foam tempera-ture | Foam tempera-ture | Foam tempera-ture | Construction temperature | Construction temperature |
|---|---|---|---|---|---|---|
| 1 | 0.6 | 0.7 | 0.7 | 0.6 | 0.4 | 0.5 |
| 15 | 0.9 | 0.9 | 0.9 | 0.9 | 0.7 | 0.7 |
| 30 | 2.2 | 2.1 | 0.9 | 0.8 | 6.3 | 4.7 |
| 45 | 11.1 | 11.5 | 1.7 | 1.5 | 28.2 | 21.9 |
| 60 | 42.1 | 32.7 | 2.8 | 3.1 | 49.1 | 47.2 |
| 66 | 59.5 | 48.1 | 4.7 | 6.3 | 54.3 | 54.1 |
| 70 | 137.2 | 64.5 | 4.1 | 6.4 | 148.5 | 60.2 |

Test specimen lost integrity ended, specimen shrinkage, and gas leakage. It can be seen from the above thermocouple data, after lose the integrity, the thermocouple temperature of rigid polyurethane foam remains lowly, which good insulation effect will still be able to prevent temperature rising of side unexposed to fire and good flame-retardant effect of 1h fire resistance.

The polyurethane foam with excellent thermal insulation properties, and in the foam the expanded graphite and porous flame-retardant materials such as aluminum hydroxide, Ammonium polyphosphate, melamine are used, which will be inflated by fire, so polyurethane foam release the gas concentration is smaller than the ordinary foam in the test.

Figure 4 Underside surface in fire

Figure 5 The side opposite fire

Fig. 4 of flame-retardant polyurethane foam claims that although as a thermosetting material there is still a little bubble contraction, and the formation of cracks resulting in leakage of flue gas. The charred solid maintain a good bonding state by observing its combustion products.

The developed polurethane foam demonstrate the excellent characteristics of thermosetting materials, flame retardants added to enhance the fire resistance, the test proved that the foam can promote the use in a large number of building through preventing the spread of fire.

## Conclusions

The inorganic compound flame retardant materials added to the polyurethane rigid foam, which is easy to operate, and more environmentally friendly, reasonable price, the technology is easy to promote, develop low smoke direction of the flame-retardant rigid polyurethane foam, which will greatly reduce the fire hazard of polyurethane foam.

The structural fire resistance test proved that the fire retardant polyurethane foam with excellent thermal insulation properties, maintain a good fire performance to achieve 66min fire resistance under the temperature rise in the standard curve state.

For flame-retardant polyurethane industry we should continue to strengthen the importance of the flame retardant properties, and focus on reducing the toxic fumes, and promote the quality of construction supervision to ensure the material meets the national standard.

# Tornado hazard loss of nuclear power plant building during design service period

Tuo Song [a], Lingyi Lu [b]

School of Civil Engineering, Southeast University, Nanjing 210096, China

[a] longjun_expert@163.com, [b] lylu@seu.edu.cn

**Keywords:** tornado; hazard; fragility; LCC; Markov model; nuclear power plant

**Abstract.** Based on the concept of Life Cycle Cost, we propose a methodology to evaluate the expected economic loss of building caused by tornado disasters during design service time and this methodology is examined by applying to a simplified nuclear power plant main house model.

## Introduction

Tornado is common natural disaster that can be observed frequently. Nuclear power plant buildings are expected to perform their high level of safety and continuous service of their intended function when encountering extreme tornado disaster during their service life[1]. As these structures aging or deterioration with time, their bearing capacities decrease year by year, but the annual probability of tornado hazard occurance may seem to be relatively stable from probabilistic viewpoint. Thus, the structure deterioration level and total economic loss that caused by nature hazard may increase with time. Nature hazard loss contains cost of damage and repairment, meanwhile, risk and loss due to tornados can be reduced by strengthening existing structures and improving their ductility. To decide an optimized strategy for reducing total cost from existing structures' reinforcement, it is necessary to consider total economic loss of nuclear power plant buildings during their design life. For this purpose, we use the concept of 'Life Cycle Cost (LCC)' to evaluate the expected loss caused by tornado disasters during the planned service time of structures and this methodology is applied to an example of nuclear power plant main house .

## Tornado hazard estimation

Tornado intensity is usually measured by Fujita's F scale, from F1 to F5[1]. In this paper, tornado maximum wind speed (MWS, m/s) is employed to represent tornado intensity. MWS lower bound of a tornado that in scale F$M$ is calculated by Eq.(1):

$$V_{\mathrm{F}M} = 6.30\left(M+2\right)^{1.5} \quad M = 1, 2, \cdots, 5 \tag{1}$$

Tornado observation record is generally indicated as the number of tornadic occurrence within a period of time at specific geographic location. If $N$ is the total number of tornadic occurrence at a certain zone and $n_0$ to $n_5$ represent the number of tornados that observed corresponding to F0 to F5 Fujita scales, the probability relation between tornado intensity distribution and tornado observed data can be illustrated as Eq.(2):

$$P\left(V < V_{\mathrm{F}M}\right) = \sum_{i=0}^{M\text{-}1} n_i / N \qquad M = 1, 2, \cdots, 5 \tag{2}$$

Comparing different types of probability distribution that often used in meteorology, it shows that observed tornado intensities can be much better described by Weibull distributions. The cumulative distribution function (CDF) of Weibull distribution is given by Eq.(3):

$$F(x) = \begin{cases} 1 - \mathrm{e}^{-(x/\alpha)^k} & \mathrm{x} \geq 0 \\ 0 & \mathrm{x} < 0 \end{cases} \tag{3}$$

Taking the logarithm twice from Eq.(3), we obtain Eq.(4):

$$\ln\left[-\ln\left(1-F(x)\right)\right]=k\ln x - k\ln\alpha \tag{4}$$

This has the form $Y$=B$X$+A, where $X=\ln x$ and $Y=\ln[-\ln(1-F(x))]$. Linear regression then yields B=$k$ and A=$-k\ln\alpha$. Then the Weibull parameter $\alpha$ is determined by formulas of B and A.

Eq.(3) represents tornado hazard estimation of $N$ years observing time. To get the annual tornado intensity distribution $F_1$ ($V$), we suppose that the CDF $F_1$ ($V$) obeys the same distribution and the random variable $V$ is independent every year. For a deterministic value $V_C$, the relation between $F_N$ ($V_C$) and $F_1(V_C)$ is shown as Eq.(5):

$$\begin{aligned} F_N(V_C) &= P_N\{V \le V_C\} \\ &= \prod_{i=1}^{N} P_1\{V \le V_C\} = \left[F_1(V_C)\right]^N \end{aligned} \tag{5}$$

The annual occurrence probability of a tornado at nuclear power plant site should be evaluated through tornado risk analysis. However, it's not an easy task and many parameters to conduct this analysis are not known exactly. To evaluate the tornadic occurrence that the MWS ranges from very low (<10m/s) to very high (>100m/s), the meteorological concept of return period is used. If tornadic return period of a region is estimated to be $S$ years, the annual occurrence probability is therefore computed by Eq.(6).

$$P_{\mathrm{OCC}}^{1}=1/S \tag{6}$$

**Deterioration model of structure**

Building's bearing capacities will decrease as the structure deterioration with time. It is important to treat such deterioration as stochastic process and to evaluate the probability of damage to structures taking into account the effect of deterioration.

A Markov chain model that the future condition of structures is depend only on the present state and is independent on the past stat is employed to express the deterioration process. Knowing the present state of structure, the future state can be predicted through the multiplication of present state vector and the transition probability matrix as shown in Eq.(7):

$$\boldsymbol{S}(t+1)=\boldsymbol{S}(t)\cdot\boldsymbol{P} \tag{7}$$

where $\mathbf{S}(t)$ is a state vector which consist of the probability that the condition lies in state $i$ at time $t$, and $\boldsymbol{P}$ is the transition probability matrix. They can be written as Eq.(8) and Eq.(9):

$$\mathbf{S}(t)=\{s(1,t) \quad s(2,t) \quad , \quad \cdots \quad s(k,t)\}, \qquad \sum_{i=1}^{k} s(i,t)=1 \tag{8}$$

where $k$ is the number of deterioration levels.

$$\boldsymbol{P}=\begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1k} \\ 0 & p_{22} & \cdots & p_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & p_{kk} \end{bmatrix} \qquad \sum_{j=1}^{k} p_{ij}=1 \quad i=1,\cdots,k \tag{9}$$

Considering the deterioration of structure material with time, the relation between time $t$ and bearing capacity $\varphi(t)$ of steel structure can be expressed by Eq.(10) and Table 1 to Table 3[3]:

$$\varphi(t)=1-\left[0.7\times\left(t-t_c\right)^3/10000\right]\times 0.04\times\alpha\times\varepsilon \tag{10}$$

**Table 1 Selection of parameter $t_c$**

| Rot proofing condition | Value of $t_c$ |
|---|---|
| No proofing | 0 |
| Basic proofing (Painting) | 5 |
| Medium proofing (Hot galvanizing) | 10 |
| Advanced proofing (Composite coating) | 15 |

**Table 2 Selection of parameter $\alpha$**

| Ordinary steel | Weathering resistant steel |
|---|---|
| 1 | 0.7 |

**Table 3 Selection of Parameter $\varepsilon$**

| Air condition | Value of $\varepsilon$ |
|---|---|
| Clean and dry air in suburb | 0.6 |
| Urban air | 0.75 |
| Ocean air | 0.8 |
| Polluted air | 0.85 |
| Severely polluted air | 1 |

**Fragility analysis of structure**

Hazard curve and fragility curve are tools that often used in natural disasters research. Tornado hazard curve represents the relation between tornado intensity and the exceeding probability at a concerned area; meanwhile, fragility curve represents the relation between tornado intensity and failure probability of a given structure. It is important to evaluate damage probability to a structure due to tornado strike by the numerical integration in Eq.(11):

$$P_f = \int_0^{\infty} F_{\mathrm{H}}(V) \frac{dF_R(V)}{dV} dV \tag{11}$$

where $F_H(V)$ denotes tornado hazard curve of a concern zone and $F_R(V)$ denotes fragility curve of buildings that locates at the zone. By definition, tornado hazard curve can be obtained conveniently from tornado intensity distribution, however, computing structure fragility curve is not an easy task and often through the way of stochastic finite element analysis.

**Assessment of tornado hazard loss**

To estimate the tornado hazard loss of NPP building during its service time, the loss of structure hazard damage $C_{\mathrm{D}}$, the loss of temporary shutdown of NPP $C_{\mathrm{S}}$ and the cost of build repairment $C_{\mathrm{R}}$ should be determined. $C_{\mathrm{D}}$ is usually defined corresponding to each deterioration level and will increase with annual inflation rate $\gamma$. To define $C_{\mathrm{R}}$, the assumption is needed that the cost of repairment will not exceed the cost of damage and is equal to the damage. Thus, considering the traffic, labor and equipments cost, $C_{\mathrm{R}}$ chooses the value of $1.5C_{\mathrm{D}}$. However, the most difficult to estimate is the loss of temporary shutdown $C_{\mathrm{S}}$, because the huge influence to society and may cause enormous economic loss. For simplification, $C_{\mathrm{S}}$ chooses the value of $10C_{\mathrm{D}}$ which seems to be large enough but may be conservative in truth. Now, the expectation of tornado hazard loss of NPP building during its $N$ year service time can be evaluated by Eq.(12), where $n$ represents the deterioration level of building and $P_f^1$ represents annual damage probability caused by tornado risk.

$$\begin{aligned} HL^N &= \sum_{t=1}^{N} P_{\mathrm{OCC}}^1 \left[ \sum_{i=1}^{n} S(i,t) P_{fi}^1 \left( C_{\mathrm{D}i} + C_{\mathrm{S}i} + C_{\mathrm{R}i} \right) \right] (1+\gamma)^t \\ &= 12.5 P_{\mathrm{OCC}}^1 \sum_{t=1}^{N} \left[ \sum_{i=1}^{n} S(i,t) P_{fi}^1 C_{\mathrm{D}i} \right] (1+\gamma)^t \end{aligned} \tag{12}$$

**Application to nuclear power plant main house**

A simplified steel frame model of nuclear power plant main house is taken for tornado hazard analysis. FEM model of the main house is showed in Fig. 1. The size of the frame is: 72m (length), 50m (width) and 30m (height). Structural material uses Chinese Q235B steel (columns：HA800×400×16×25; beams: HA600×400×16×25) and Chinese C30 concrete (floor thickness: 120mm). Material elastic modules are considered as log-normal random variables for fragility analysis. The design life of the structure is 50 years. Tornado observation record in F-scale from 1949 to 1999 at nuclear power station site is listed in Table 4.

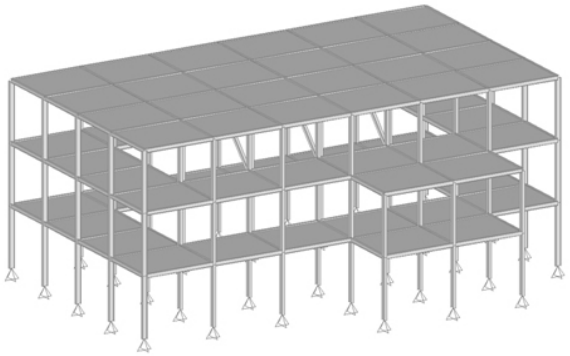

**Fig. 1 FEM model of NPP main house**

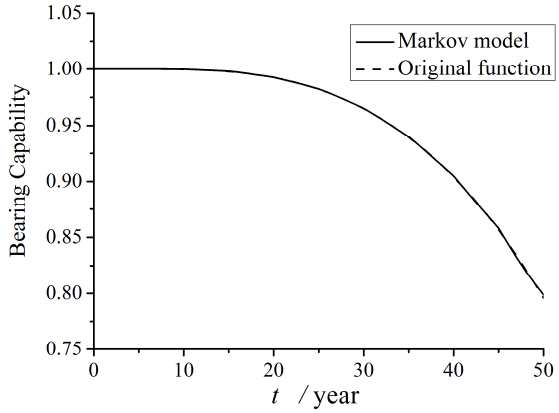

**Fig. 2 Comparison of Markov model expectation and original function**

**Table 4 Observation records of tornado in F scales**

| Event | $V$ /(m/s$^{-1}$) | Number | $P$ ($V$<$V_{FM}$) |
|---|---|---|---|
| F0 | <33 | 111 | 0.464 |
| F1 | 33~49 | 67 | 0.745 |
| F2 | 50-69 | 47 | 0.941 |
| F3 | 70-92 | 13 | 0.996 |
| F4 | 93-116 | 1 | 1.000 |
| F5 | 117-140 | 0 | 1.000 |

Based on the tornado observation records, the tornado intensity distribution of Weibull was derived by linear regression that introduced in previous chapter and the result is shown in Eq.(13), where $V$ is tornado MWS and $F_{50}(V)$ is tornado intensity distribution of 50 years.

$$F_{50}(V)=\begin{cases}1-\mathrm{e}^{-(V/36.964)^{1.834}} & V\geq 0\\ 0 & V<0\end{cases} \tag{13}$$

For Markov model evaluation, we choose $t_c=10$, $\alpha=1$, $\varepsilon=0.8$ and the $\varphi(t)$ curve are plotted in Fig. 2. To determine the transition matrix $\boldsymbol{P}$, we consider a four levels deterioration model for structure and a group of objective functions are established to evaluate elements of $\boldsymbol{P}$ in a short period (5 years):

$$\text{Minimize}\sum_{t=5i-4}^{5i}\left|\varphi(t)-E(t,\boldsymbol{P})\right| \qquad i=1,\cdots,10 \tag{14}$$

Solving these objective functions in Matlab software and computing resistance expectation of the structure in 10 short periods by Eq.(15), the comparison of curves between Markov model and original function that computed from Eq.(10) is shown in Fig.2.

$$E(t,\boldsymbol{P})=\boldsymbol{S}(t)\cdot[1,0.9,0.8,0.7]^{\mathrm{T}} \tag{15}$$

Structure fragility curves corresponding to each deterioration level can be obtained by SSFEM analysis[4] or MonteCarlo simulation. The results of annual tornado hazard curve and fragility curves

corresponding to different levels are shown in Fig. 3. Thus, the annual damage probabilities of different deterioration levels are calculated by Eq.(11) and the results are listed in Table 5. At last, the expectation of tornado hazard loss during service period can be evaluated in Table 6.

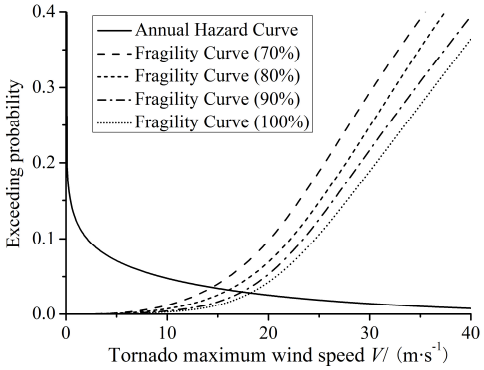

**Fig. 3 Fragility curves of deterioration levels and annual hazard curve**

**Table 5 Annual tornado damage probability of structure**

| Bearing capability level | Level 1 (remain 100%) | Level 2 (remain 90%) | Level 3 (remain 80%) | Level 4 (remain 70%) |
|---|---|---|---|---|
| Annual damage probability $P_{fi}^{1}$ | 0.0856 | 0.0959 | 0.1097 | 0.1291 |

**Table 6 Examples of tornado hazard loss evaluation**

| | Example 1 | Example 2 |
|---|---|---|
| Tornado return period (year) | 50 | 100 |
| $C_{D1}$ (ten thousand yuan) | 800 | 500 |
| $C_{D2}$ ( ten thousand yuan) | 1000 | 700 |
| $C_{D3}$ ( ten thousand yuan) | 1500 | 1000 |
| $C_{D4}$ ( ten thousand yuan) | 2000 | 1200 |
| Annual inflation rate $\gamma$ | 0.02 | 0.03 |
| $HL^{50}$ ( ten thousand yuan) | 2193.3 | 975.1 |

## Conclusions

We propose a methodology to evaluate the expected tornado hazard loss of building during its design service time. This methodology is applied to an example of nuclear power plant main house for examining its applicability. Although there are many assumptions of data used in this paper, result of this analysis is relatively credible after changing assumptions to investigative data.

**Keywords:** Transmission tower, wind load, computation parameters, comparison.

**Abstract.** Wind load computation formula for transmission tower of 《Technical code for the design of tower and pole structures of overhead transmission line》and《Design of latticed steel transmission structures》 are studied in this paper. The differences of basic wind speed, height variation factor of wind pressure, shape factor and wind load factor are compared in detail, respectively. The results show that the wind load defined in the Chinese code is little different from the American code. However, some parameters are still worthy of further discussion. The analysis results can be a reference for the design of transmission tower.

## Introduction

With the growing development of transmission line projects in the international market, more and more overseas projects require the use of foreign codes for design. In order to make the design companies in a strong position in the competition, it is necessary for designers to comprehend and master the similarities and differences between domestic and foreign standards. In the field of the design for high voltage transmission tower,《Guidelines for electrical transmission line structural loading》[1] (ASCE74—2009) is one of the important transmission line code in the world, which is widely applied and used for reference in 《Technical code for the design of tower and pole structures of overhead transmission line》[2-3].

Wind load is the control load for transmission line. For safe and reliable operation of transmission lines, the differences of specifications on the wind load between these two codes need to be fully understood and the wind load calculation method must be mastered accurately.So, this paper selects the 《Technical code for the design of tower and pole structures of overhead transmission line》（DL/T5154-2012） and the 《Design of latticed steel transmission structures》[4]（ASCE10-97）to compare. The calculated values of relative parameters including basic wind speed, height variation factor of wind pressure, shape factor and wind load factor are compared in detail.

## The Basic Formula

The standard value of the Chinese wind load shall be taken as follows:

$$W_s = W_0 \bullet \mu_z \bullet \mu_s \bullet B_2 \bullet A_s \bullet \beta_z \tag{1}$$

where, $W_s$ is the standard value of wind load. $W_o$ is the standard value of reference wind pressure. $\mu_z$ is the height variation factor of wind pressure. $\mu_s$ is the shape factor; $\beta_z$ is the wind load factor. $B_2$ is the enhancement coefficient of wind load under ice accretion. $A_s$ is the area projected on a plane normal to the wind direction.

The design value of the American wind load shall be taken as follows:

$$F = \gamma_w Q K_z K_{zt} (V_{50})^2 G_t C_f A \tag{2}$$

where, F is the wind force in the direction of wind unless otherwise specified. $\gamma_w$ is the load factor to adjust the force F to the desired return period. Q is numerical constant (0.613 metric units). $K_z$ is the velocity pressure exposure coefficient, which modifies the basic wind speed for various heights above ground and for different exposure categories. $K_{zt}$ is the topographic factor. $V_{50}$ is basic wind speed, 50-year return period, 3-sec gust. $G_t$ is the gust response factor for structures. $C_f$ is the force coefficient values. A is the area projected on a plane normal to the wind direction.

## The Computation Parameters

**Basic wind speed.** Basic wind speed is defined by prescriptive landform and height. The specific comparison is shown in table 1.

Table 1 The comparison of the Chinese and American basic wind speed

| Codes | Standard Height | Standard Landforms | Time Duration | Return Period | Wind Speed Limit | Samples of Maximum Wind Speed | Linear Distribution of Maximum Wind Speed |
|---|---|---|---|---|---|---|---|
| China | 10m | B | 10min | 110～330 kV 30-year<br>500～750 kV 50-year | 23.5 m/s<br>27 m/s | year | The distribution curve of extreme value for type I |
| America | 10m | C | 3s gust | 50-year | 31.3m/s | year | The distribution curve of extreme value for type I |

**Height variation factor of wind pressure.** The Chinese height variation factor of wind pressure is given in the following form:

$$u_z^B = \left(\frac{z}{10}\right)^{0.32} \tag{3}$$

where, z is the height to the center of each tower section.

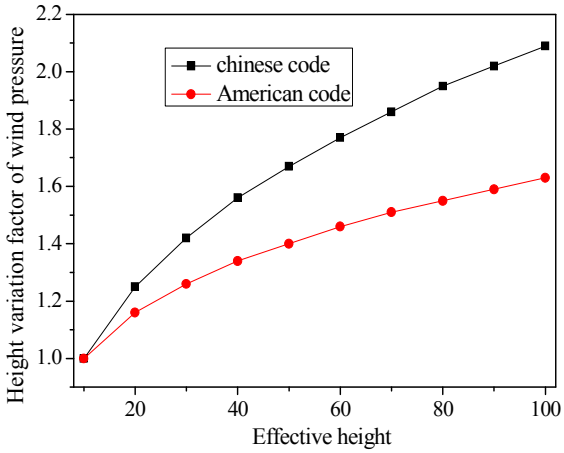

Fig. 1 Contrast curves of the height variation factor of wind pressure

The American height variation factor of wind pressure is given in the following form:

$$K_z = 2.01\left(\frac{z_h}{z_g}\right)^{\frac{2}{\alpha}}, \quad 10\text{m} \le \mathbf{z}_h \le z_g \tag{4}$$

where, $z_h$ is the effective height. $z_g$ is the gradient height. α is the power law exponent.

The height variation factors of wind pressure are calculated in the range of 100m height from Chinese and American codes. Fig. 1 shows the contrast curves of the height variation factor of wind pressure between the Chinese and American codes. It can be seen from the Fig. 1 that the height variation factor of wind pressure in the Chinese code should be less than the American code, and the difference in value is gradually increasing with the increase of height.

**Shape factor.** The Chinese shape factors of towers made up of the steel members is 1.3×(1+η) and the round-section members is (0.7～1.2)×(1+η). η is the lee sid reduction coefficient.

According to the cross-sectional shape of the latticed truss structures which is divided into the square and triangle, the force coefficient can be available from the table in the American code. For towers with round-section member shapes, the force coefficients must multiply the correction factors.

Choose the square-section angle steel towers and steel tube towers as the research object. According to the Chinese and American codes, the shape factors can be calculated easily.The comparison curves of the angle steel towers' shape factors are showed in Fig. 2 and the comparison curves of the steel tube towers' shape factors are showed in Fig. 3. It can be seen from the figures that the American shape factor is always greater than the Chinese code. When solidity ratio is 0.6 or higher, the Chinese shape factors remain the same, but the American shape factors grow as the solidity ratio increases.

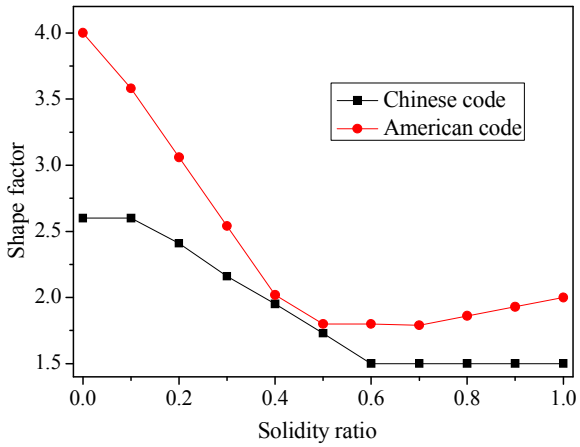

Fig. 2 Comparison curves of the angle steel towers' shape factors

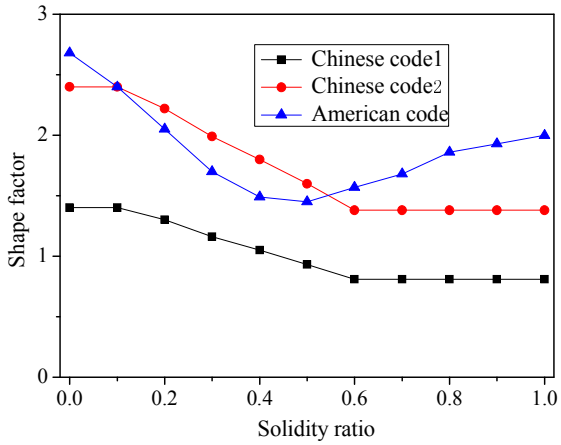

Fig. 3 Comparison curves of the steel tube towers' shape factors

**Wind load factor (Gust response factor).** In the Chinese code, the tower whose height is not more than 60m has only one wind load factor.This factor can be checked from the tables of the Chinese code.

The gust response factor in the American code shall be taken as follows:

$$G_t = \frac{1+2.7E\sqrt{B_t}}{K_v^2} \tag{5}$$

$$E = 4.9\sqrt{\kappa}\left(\frac{33}{z_h}\right)^{\frac{1}{\alpha_{FM}}}, \quad B_t = \frac{1}{1+\frac{0.56z_h}{L_s}} \tag{6}$$

where, $z_h$ is the effective height. $K_v$ whose value is 1.43 is the ratio of the 3-sec gust wind speed to the 10-min average wind speed,. $\alpha_{FM}$ is the power law exponent of the sustained wind. $\kappa$ is the surface drag coefficient. $L_s$ is the turbulence scale.

Fig. 4 shows the contrast curves of the Chinese and American wind load factor. It can be seen in the Fig. 4 that when the height is small, the Chinese wind load factor is less than the American code. With the increase of the height, the wind load factors are gradually approaching.

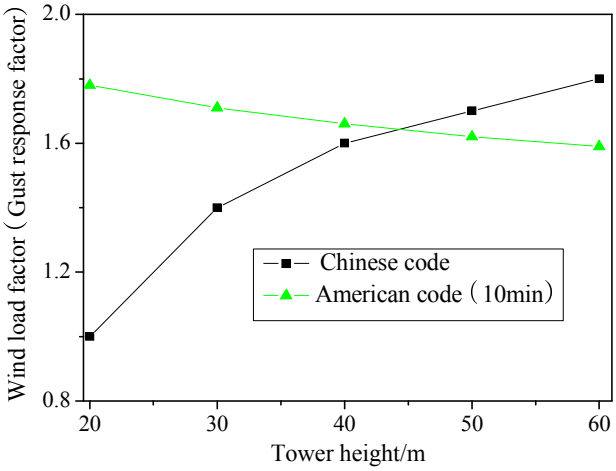

Fig. 4 Contrast curves of the Chinese and American wind load factor

## Conclusions

The comparison between the wind load of transmission tower of the Chinese and American codes are studied in the paper. The differences of basic wind speed, height variation factor of wind pressure, shape factor and wind load factor are researched, respectively. Based on the above results, the following conclusions are drawn:

(1) The differences about the basic wind pressure are on the definition of the wind speed's time duration. The ratio of American 3s gust wind speed to Chinese 10min average wind speed is 1.43:1. It can be seen that the American wind speed is greater than the Chinese code.

(2) If the tower height is less than 60m, the effective height in Chinese code is the height to the center of each tower section, but in American code, it uses too-thirds of the total structure height for the effective height. The height variation factor of wind pressure in Chinese code should be less than the American code, and the difference in value is gradually increasing with the increase of height.

(3) The Chinese and American shape factors are all related with the solidity ratio. While the solidity ratio is greater, the shape factor gets smaller. The American shape factor is always greater than the Chinese code.

(4) With increasing height, the Chinese wind load factor increases. On the contrary, the American gust response factor reduces as the height increases.

**Keywords**:analytic hierarchy process; information value; landslide; susceptibility zonation

**Abstract**: Landslide susceptibility zonation is one of the research hotspots in the field of landslide research. It is important in the process of disaster prevention and land planning. Select Wan Zhou as study area;it is one portion of the Three Gorges Reservoir Area.According to existing landslide statistical data, select lithology, slopegradient, slope structure and reservoir gradeas impact factors. Useanalytic hierarchy process andinformation method to calculate weighted value of each factorrespectively, and then combine them.The landslide susceptibility zonation was done by ArcGIS. This method can unite the advantages of the disaster data and expert experience.According to statistics, resultaccuracy rate is 90.3%.The key areaof landslide disaster prevention can be obtained from the landslide susceptibility zonation map.

## Introduction

Landslide susceptibilityzonationis the comprehensive study which involves the occurrence and development of landslide hazard and thelandslide disastersdistribution.The divided result is the sciencebasis, correct and timely forecasting landslide hazards [1]. According to different research objectives and targets,the methods can be divided into two categories: qualitative methods, quantitative methods. Qualitative methods are expert scoring method, AHP methodand so on. The quantitative methods are deterministic method, artificial intelligence method,information methodand so on.Many scholars have done a lot of job on this research [2-4].

Above described methods are widelyusedin practice, but they have significant differences and disadvantages in the weight value. Qualitative method has a direct relationship with the expert experience, and quantitative methods influenced by the training data. In the other hand,complementationcan also be found on the two methods. Therefore, the combination of analytic hierarchy process and information model is applied on the land susceptibilityzonation. The research area is Wan Zhou,which is one portion of the Three Gorges Reservoir Area.

## Basic Principles

### AnalyticHierarchy Process

AHP (analytic hierarchy process)basic principleis: make the various elements relating to the evaluation system are decomposed into three levels, which are goals , guidelines and programs, then make decision by qualitative and quantitative analysis on this basis[3, 5]. This approach analyzes the actual decision-making problems from the expert experience angle, and then use a

littlequantitative information digitalized decision-making process. It is a digital qualitative approach reliedon experience. The methodsteps as follows: First, establishing a hierarchy according to the problem, and then constitute a judgment matrix, use judgment matrix to calculate the weight vector, and do the consistency test.

**Information Model**

The theoretical basis of information model is information theory.It uses entropy decreasein the process of geological disasters to characterize geological disasters occurred. The factors togeological disasters have uncertainty degree. The average reduction of uncertainty degree equal to the entropy changes in the geological disasters system[4], equationisshown in Eq1:

$$I(Y, x_1x_2 \cdots x_n) = ln\frac{P(Y,x_1x_2\cdots x_n)}{P(Y)} \quad (1)$$

$I(Y, x_1x_2 \cdots x_n)$ isthe landslide information value, which provided by factorscombination$x_1x_2 \cdots x_n$, $P(Y, x_1x_2 \cdots x_n)$is the probability of the landslide occurrence under the set of factors $x_1x_2 \cdots x_n$,$P(Y)$is the landslide occurrenceprobability[6].

In the actual calculation, use the area ratio to calculate the information value, and overall information value in a single evaluation unit as this landslides unit comprehensive index.The higher the value, the landslide more likelyoccurrence, unit landslide risk is also higher.

## The example analysis

**Study area overview**

Wan Zhou locateson the eastern margin of the Sichuan Basin, northeastern edge of Chongqing. It locates at longitude 107 ° 55'22" ~ 108 ° 53'25", latitude 30 ° 24'25" ~ 31 ° 14'58". It is the typical geological disaster-prone area in the Yangtze River. The main geological disasters are landslides and collapse.Wan Zhou belongs to warm and humid subtropical climate zone, mild climate, abundant rainfall. Rainfall is mainly accounted from May to September;daily rainfall can up to 100mm or more.The main geomorphic units of Wan Zhou haveerosion and deposition of river floodplain, terraces, tectonic denudation,low mountains and hills.Wan Zhou locates in eastern Sichuan fold belt, Iron Mountain anticline north, Fangdoushan anticline south, eastern Sichuan fold belt towards the north east[7].

**Factor layer**

Landslide is the result of various factors'comprehensive function. According to study arearegularitysummary, select lithology, slope gradient, slope structure and reservoir gradeas impact factors.Use the existing geological map 1:10000, 1:50000 contours, remote sensing data, can get impact factor layers, which aremade by ArcGIS software. In order to unifycalculation, all the layers are converted into raster; the size is 10 m × 10 m.

(1) Lithology

In order to simplify calculation, lithology formations will be divided into three categories: soft rock, hard rock,alternate with soft and hard, is shown in Table 1.

(2)The slope structure

Slope structurecontrols the landslide development intensity. Slope with different structure has different landslide properties, characteristics and developmentextent.Consequent slope is prone to form large or giant rock landslide. Reverse slope is easy to form soil landslide. Transverse slope is not developed or less developed to landslide. According to the space relationships of slope gradient, aspect, underlying rock dip direction and inclination angle, slope structure is divided into the followingtypes: massive rock, nearly horizontal layered slope, consequent slope (including Floating

inclined slope, Stacked slope and Steep Inclined slope), slant slope (including Forward inclined slope, Contrary inclined slope) , Backward slope, Transverse slope [8].

**Table1 Lithology classification**

| Stratigraphic names | Lithology classification |
|---|---|
| Lower Jurassic Pearl Chong group | soft rock |
| Mid Jurassic Shang Sha-xi Temple group | soft rock |
| Mid Jurassic Xin-tian-gougroup | soft rock |
| Middle-Lower Jurassic Zi-liu Well group | soft rock |
| Upper Triassic Xu-jia-he group | alternate with soft and hard |
| Mid Triassic Ba-dong group | alternate with soft and hard |
| Upper Jurassic Peng-lai town group | alternate with soft and hard |
| Upper Jurassic Sui-ninggroup | alternate with soft and hard |
| Lower Triassic Jia-ling rivergroup | hard rock |

(3)The slope gradient

Terrain gradient is closely related to the landslidespatial distribution;it also affects thesoil thickness, hydrological conditions and lithological characteristics.It is an important factor of controlling landslide occurred. Through statistical relationship between the study area and terrain slope landslide, the study area slope gradient is divided into four levels : 0 ° ~ 15 °, 15 ° ~ 30 °, 30 ° ~ 45 °,> 45 °

(4)The reservoir grade

Periodicity change and erosion of reservoir's water level is an important factor to landslide. This paper proposes a method to determine reservoir waterscope, which is combine statistical analysis and engineering geologic analogy. After statistics, if landslide has the front edge's altitude from 60m to 110m, its average elevation D-value is 255.58m from front to rear edge. If altitudevalue over 110m,its average elevation D-value is 143.91m. Based on these data, the reservoir water affected area will be divided into four intervals: 60m-110m, 110m-253.91m, 253.91m-365.58m,> 365.58m. This is the natural state, the water level in the Three Gorges reservoir is 145m-175m after store water, according to the same method and rounding, the reservoir water scope will be divided into four intervals : 145m-175m (fluctuation zone ), 175m-320m ( strongly affected zone ), 320m-430m (medium affected area ),> 430m ( weakly affected zone ).

**Weight calculation by AHP**

Establish landslide hazard zonation hierarchy structure model in study area,isshown in Figure 1.

**Construct the judgment matrix and eigenvectors calculations**

According to the hierarchy structure model of study area, construct Wan Zhou landslide hazard judgment matrix, is shown in Eq2.

$$k = \begin{bmatrix} 1 & 1/5 & 1/7 & 1/7 \\ 5 & 1 & 1/3 & 1/3 \\ 7 & 3 & 1 & 1 \\ 7 & 3 & 1 & 1 \end{bmatrix} \tag{2}$$

According $k$ ,calculating normalized eigenvector $\omega = (0.04829, 0.1645, 0.3936, 0.3936)^T$ , $\lambda_{max} = 4.075$,and calculates$I_C = \frac{\lambda_{max}-n}{n-1} = 0.025$， $R_I = 0.8931$,$R_C = \frac{I_C}{I_R} = \frac{0.025}{0.8931} = 0.028 < 0.1$， so this matrix satisfy consistency. The feature vector ωcan be regard as AHPweight vector.

**Information value calculation by Information model**

According to the statistical landslide of Wan Zhou data, create landslide data layer, which overlay lithology, slope structure, slope gradient and reservoir graderespectively. Then calculate each impact factor layer's information value, is shown in Table2.

**Table2 Information Value and action indexof each impact factor**

| Impact factor | Classification | Information value | Actionindex |
|---|---|---|---|
| Reservoir grade | fluctuation zone | 1.225783 | 0.9 |
| | strongly affected zone | 0.873626 | 0.9 |
| | medium affected zone | 0.201298 | 0.5 |
| | weakly affected zone | -1.31837 | 0.3 |
| Lithology | Soft rock | 0.213647 | 0.5 |
| | hard rock | -10 | 0.1 |
| | alternate with soft and hard | -0.9084 | 0.95 |
| Slope structure | Nearly horizontal layered slope | 0.394681 | 0.5 |
| | Floating inclined slope | -0.78095 | 0.8 |
| | Stacked slope | -10 | 0.1 |
| | Steep inclined slope | -0.28216 | 0.4 |
| | Forward inclined slope | -0.48066 | 0.6 |
| | Transverse slope | 0.387899 | 0.3 |
| | Contrary inclined slope | -0.21696 | 0.3 |

**Combine method**

According to outdoor surveys and data analysis, judge the action index of each impact factor in AHP on the basis ofimpact factor classification in this article. Thenstandardize each data, which normalize between 0 and 1, detailsare shown in Table 2on the right.

Multiply AHP's weight value and action index ofimpactfactor then add information value, this isthe final risk index.Equation is shown in Eq3:

$$B_L = \sum_{i=1}^{n}(\omega_i n_i + I_i)/2 \quad (3)$$

$B_L$isrisk index of each unit , $\omega_i$ is the weight of AHP each factor, $n_i$ is the action index of each factor , $I_i$ is the information value.

According to the calculated risk index, landslide susceptibility study area will be divided into four zones:extremely high risk zone, high risk zone, danger zone andlow risk zone by using natural breakpoint method (Natural Break).

**The results**

Select 20% of past landslidedataas validated sample, the rest participate used as the training data. Thesum of hazard point as validated is 53, accuracy rate is 90.3% (extremely high risk zoneaccounted for66.4%, high-risk zone accounted for 14.9 %, 9.1% in the danger zone), is shown in Figure2.So the key areaof landslide disaster prevention is the extremely high risk zone,high-risk zone and danger zone can have reference selection. Low risk zone is not as focused on prevention.

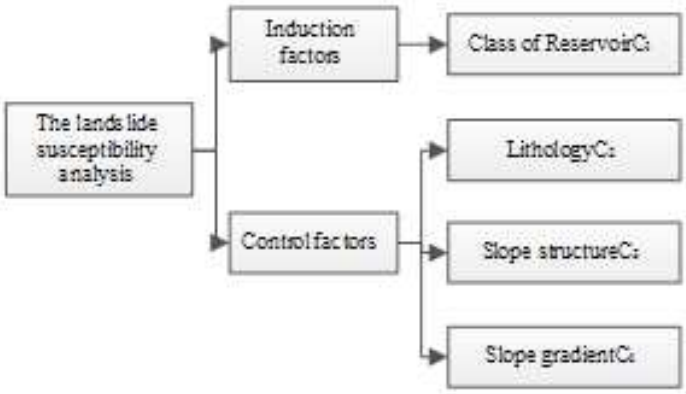

**Fig.1 Hierarchy structure modelof study area**

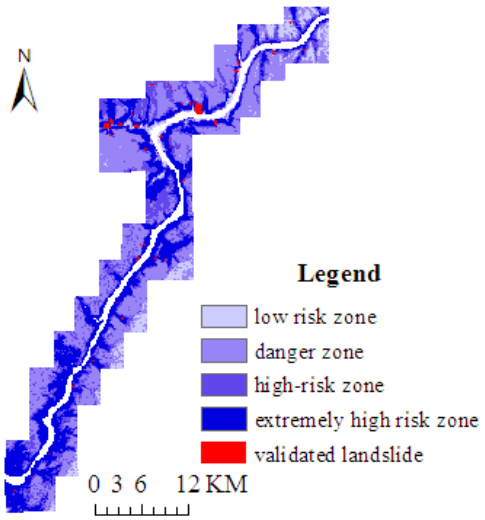

**Fig.2 The landslide susceptibility zonationmap of Wan Zhou**

## Conclusion

Information method evaluates landslide susceptibility uncertainty for each factoris greatly influenced by the existing landslide data.AHPis influenced by experience. So theyare complementary. According to this paper's test, combine information method and AHP could be more reasonable to weights,and get better result. However, this method still used grid evaluation unit, split the landslideintegrity; Secondly , the final risk index is to take a simple average value of the two methods, did not consider further detail, can be improved in the future.

**Keywords:** Evacuation, Cellular automaton, Human behavior

**Abstract.** Emergency evacuation is an important issue in fire safety. In this study, a cellular automaton (CA) model in which the human behaviour termed 'flow with the stream' is considered is proposed to simulate the procedure of emergency evacuation. Based on the CA model, the influence of the number of guiders to the evacuation from a large compartment is analyzed through numerical test. The result shows that the proposed CA model is a promising tool that may be used in fire safety design.

## Introduction

In the light of homeland security, simulation of evacuation from a compartment of fire origin to a safe refuge is attracting more and more attention. In the past decades, quite a number of approaches have been developed for the modelling of evacuation, among which CA is widely used [1]. As a useful class of numerical tools for the simulation of complex system, CA has been successfully applied to simulate various complex systems, such as theoretical biology [2], computability theory [3], fluid dynamics [4], earthquakes and traffic flow, etc. The development of CA can be traced back to 1940s when Neumann [5] studied biological reproduction and crystal growth. Basically, CA is a discrete model, which consists of a regular grid of cells, each cell in one of a finite number of states.

## Cellular automaton model

When CA is used in evacuation simulation, the space is normally discretized into uniform grid, and the time domain can be discretized into a series of finite time steps $t_1$, $t_2$,…, and $t_i$. In a CA model, each cell is vacant or occupied by an evacuee. A specific evacuee makes his/her decision based on the states of his/her neighboring cells at the last time step.

It is well known that a CA model is constructed from basic rules. The research focuses on the simulation of crowd movement after all the occupants start to evacuate from a smoke-filled room. The rules in the proposed model include:

(a) Each evacuee stays within one CA cell at time $t_i$.

(b) Each evacuee selects an exit to move towards.

At the current position, the evacuee has $N$ choices since there are $N$ exits. However, this evacuee can only select one exit at each time step based on the consideration of spatial distance and occupant density [6]. In this study, the movement direction of the evacuee is determined by probability analysis. For instance, the probability of exit $i$ to be selected at $t_k$ is given by:

$$P_i = \frac{\alpha P_{i-S} + \beta P_{i-D}}{\alpha + \beta} \tag{1}$$

where $\alpha$ and $\beta$ are two constants. The terms $P_{i-S}$ and $P_{i-O}$ be calculated by Eq. 2.

$$P_{i-S} = \frac{1}{R_i \cdot \sum_{j=1}^{N} \frac{1}{R_j}}, \quad P_{i-O} = \frac{1}{D_i \cdot \sum_{j=1}^{N} \frac{1}{D_j}} \tag{2}$$

where $R_i$ is the distance from the evacuee to Exit $i$ and $D_i$ is the occupant density at Exit $i$. It can be proved that $\sum_{i=1}^{N} P_{i-S} = 1$ and $\sum_{i=1}^{N} P_{i-O} = 1$. The expressions of $\alpha$ and $\beta$ are given by:

$$\alpha = \frac{\theta}{N} \cdot \sum_{j=1}^{N} \left| 1 - \frac{N}{R_j \cdot \sum_{k=1}^{N} \frac{1}{R_k}} \right|, \quad \beta = \frac{(1-\theta)}{N} \cdot \sum_{j=1}^{N} \left| 1 - \frac{N}{D_j \cdot \sum_{k=1}^{N} \frac{1}{D_k}} \right| \tag{3}$$

Obviously, it can be approved that $\sum_{i=1}^{N} P_i = 1$ since $\sum_{i=1}^{N} P_{i-S} = 1$ and $\sum_{i=1}^{N} P_{i-O} = 1$. In Eq. 3, the term $\theta$ is used to adjust the influence of spatial distance and occupant density. It is a constant which varies in $[0, 1]$.

(c) After the movement direction has been determined, each evacuee will only select one cell among all adjacent cells surrounding the current one as the potential position at time $t_{i+1}$. The evacuee perceives the new selected cell to be safer than the current one.

(d) If a cell is chosen by several evacuees at the same time step, it will be randomly assigned to one of the evacuees. The other evacuees who have no cell to move in have to wait within their current cells until the next time step.

(e) All evacuees update their positions at time $t_{i+1}$, and then based on the new situation, choose new exits and cells for themselves at time $t_{i+2}$.

'Flow with the stream' is regarded as a kind of human behavior. This phrase is usually used to describe the psychological phenomenon that people intend to follow the lead of other people and react to their opinions or actions passively. During emergent evacuation, if it is hard to an individual to make a decision forthwith, for instance, he cannot see the exit in a smoke-filled compartment and he does not know where to move, he may decide to just follow the other people who are near to him. To simulate 'Flow with the stream', the proposed CA model is modified based on Fig. 1.

In Fig. 1, the cells represent cellular automaton grid. The visible domain of an evacuee at cell $O$ is defined as the area surrounded by a circle with a radius denoted by $R_V$. It must be mentioned that $R_V$ may not be constant in the course of time since it may be affected by smoke concentration in a fire compartment. To simulate 'flow with the stream', it is assumed that this evacuee cannot see the exit since it is out of his visible domain. It is also assumed that there are $M$ evacuees within his visible domain, including a typical evacuee denoted by $i$. It is defined that an evacuee at cell $O$ has eight movement directions denoted by $d_1 \sim d_8$ at each time step. Among all the $M$ occupants, the $k^{th} (1 \le k \le M)$ occupant is defined as a guider because he always knows the location of the exit even though he may not able to see the exit due to limited visibility. The evacuee at $O$ determines his movement direction by following the rule:

(1) At time $t_i$, check the status whether the evacuee at cell $O$ can see the exit. If it is true, the evacuee will move towards the exit by comparing the importance of spatial distance and occupant density. Otherwise, proceed to the next step.

(2) Check if there is a guider among the $M$ occupants. If it is true, the evacuee at $O$ just follows the guider to move. Otherwise, proceed to the next step. If there are two or more guiders within the visibility domain, one of them will be chosen randomly to follow.

(3) Based on the state at time $t_{i-1}$, count the number of evacuees who are within the visibility domain and divide them into groups according to their movement directions. Since there are eight possible directions around the cell $O$, the maximum number of groups is also eight. Each group consists of several evacuees who are moving in the same direction.

(4) The group which contains most evacuees is defined as the leading group. The movement direction of the leading group is defined as the principal direction. If there are two or more leading groups (principal directions) around cell $O$, one of them will be chosen randomly to be followed by the evacuee at cell $O$.

The way for the evacuee at $O$ to follow a guider or a group is described below:

(1) Select a target that might be followed, using the way provided in the four steps for 'flow with the stream'. The target can be a guider or a leading group.

(2) Once the target is fixed, the evacuee has two options: a) a probability (value=$\eta$) is set for the evacuee to give up following the target and moves along a direction selected randomly. b) a probability (value=$(1-\eta)$) is set for the evacuee to follow the target.

(3) If the evacuee decides to follow the selected target, a probability with value of $\lambda$ is given to him to make himself closer to the target. When the target is a guider, the evacuee will move towards the guider, but if the target is a leading group, the evacuee will approach the center of this group. As a result, a probability with the value of $(1-\lambda)$ is given to him to just move along the movement direction of the target. In this situation, he will not intend to shorten the distance between him and the target.

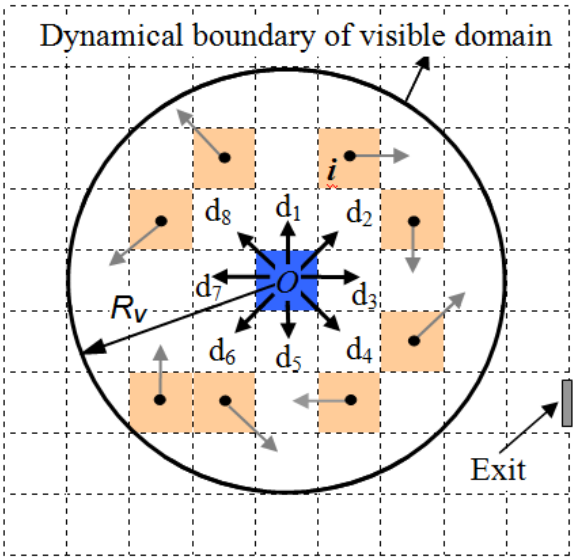

Fig. 1. Illustration of the determination of an evacuee's movement direction

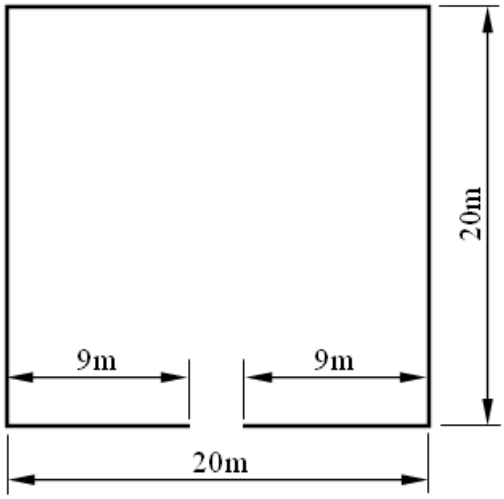

Fig. 2. Dimension of a single square room with an exit

**Numerical example**

As an example, the evacuation from a compartment shown in Fig. 2 is modelled by the proposed CA model. Intuitively, the number of guiders (NOG) will play a key role in the evacuation. To investigate the influence of NOG, it is assumed that 300 evacuees are randomly distributed in the compartment before an evacuation starts. In total, six scenarios are simulated for the case that the visibility range is 2m. Without loss of generality, each scenario has one trial run and the results are depicted in Fig. 3. The NOG in the simulation varies from 0 to 40 (denoted by G0~G40 in Fig. 3).

Fig. 3 shows that NOG does affect the evacuation procedure significantly. The curves indicate that the greater the number of guiders, the more the evacuees evacuated within 300 time steps. However, it can also be seen that the corresponding curves become very similar when NOG varies from 30 to 40.

For further investigation, 10 trial runs are conducted for each case of various scenarios and the average results are depicted in Fig. 4. From this figure, one knows that the gradient of the curve becomes smaller as NOG becomes larger. This reveals that the evacuation procedure is more sensitive to NOG when it is small. Moreover, the curve in Fig. 4 has an obvious platform, which shows that the change of NOG does not affect the evacuation significantly when $30 \le \text{NOG} \le 40$. This finding is very useful to fire safety design.

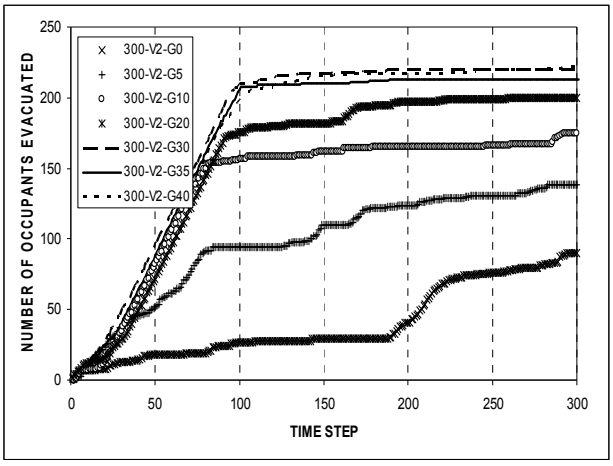

Fig. 3. Evacuation procedures under various NOG and $R_v = 2$m

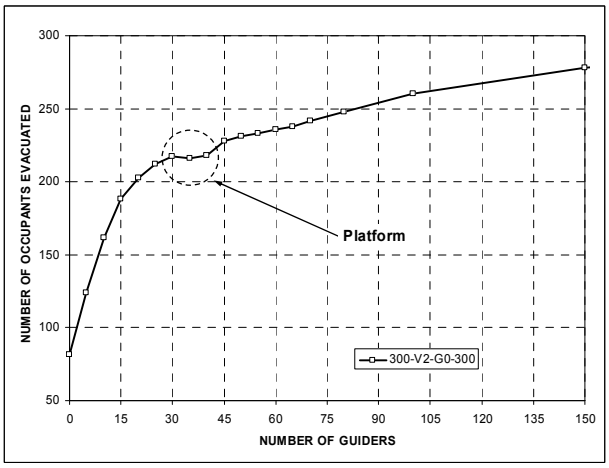

Fig. 4. Effect due to number of guiders

## Conclusions

In this study, a CA model is developed for the simulation of an evacuation from a large compartment where the visibility range is limited. Numerical example proves that the proposed model can be used to model the psychological phenomenon termed 'flow with the stream'. Numerical investigation reveals that the number of guiders can affect the evacuation duration significantly. Meanwhile, the reasonableness of the numerical results indicates that the CA model is a promising tool which may provide quantitative analysis for fire safety design.

**Keywords:** underground; confined space; ghosting fire; numerical simulation; FDS

**Abstract.** The phenomenon of ghosting fire development in underground confined space is simulated to analyze the impacts of ghosting fire generation via some conditions -- different air vent sizes and different fire source areas. FDS is used to establish a physical model of underground fire laboratory in Northeastern University, the simulation is conducted by setting two parameters, the air vent size and the fire source area. The fire heat release rate, temperature, concentration of CO, $O_2$ are measured to analyze the case of ghosting fire generation in underground confined space with different air vent sizes and different fire source areas. It's most likely to generate ghosting fire when the simulating parameter is that the air vent size is 0.4m × 0.4m and the fire source area is 0.96$m^2$. The conclusion is that increasing the air vent size is not a simple ascending and descending relationship with the occurrence time and duration time of the ghosting fire. Increasing the fire source area can improve the fire heat release rate effectively, and promote the formation of ghosting fire.

## Introduction

Ghosting fire is a special phenomenon, which can be seen easily in the confined space. Because of poor ventilation, low content of $O_2$ is caused by continuous combustion, and fire smoke contains large amounts of combustible ingredients because of incompletely burning of fuel. Combustible composition and $O_2$ concentration exist in the confined space, which leads to the flame far from the fuel surface and has been appearing in the other areas beyond the flame area[1] . Sugawa etc.[2] used small size of closed cabin compartments to conduct ethanol pool fire experiments, and they pointed out that ghosting fire was a kind of unstable combustion phenomenon which had an influence on the mass burning rate. Pearson[3] increased the height of the fire source to make the vents below the fire and observed similar flame travel in experiments. In their opinion, the result of the ghosting fire was that the speed of premixed flame is faster than the speed of natural convection. Utiskul etc. [4-5] proposed the determination case of appearing ghosting fire, the concept of the global equivalent ratio (GER) was introduced as a determination case judgment of appearing ghosting fire. Changhai Li etc. [6] conducted the heptane pool fire experiments in the enclosed space of 17.55$m^3$ without opening, and they found that forming the ghosting fire was not a monotonous increasing relationship with simply to improve fire source location. In this paper, FDS was used to simulate and analyze flame walk, and the calculation of the smoke and the heat of fire transfer process was studied to analyze the impact of air vent size and fire source area for the ghosting fire.

## The Underground Fire Laboratory Model

1.1 **Establishment of Geometric Model.** The model is established on the basis of the underground fire laboratory of Northeastern University, which is divided into two parts. The ground part sets three air supply outlets(4.8m × 1.6m) with 1.5m/s velocity and two opens(4.0m × 1.6m), and the ground wind field which is affected by the surrounding buildings was simulated to make the simulation more real and reliable. The main building of the underground part is 18 m (L) ×6.9 m (W) ×2.9 m (H), a natural air vent was set 9 m far from the fire source, heptane is used as the fuel, the simulation time is 1000s, the initial temperature was set to 18 ℃. Specific arrangement is shown in figure.1.

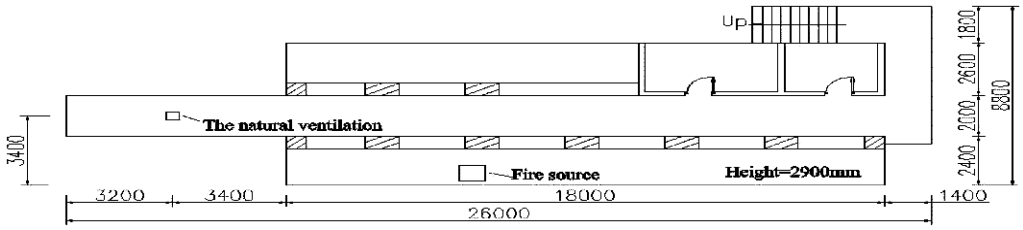

Fig.1.The vertical view of underground fire laboratory

**1.2 Simulation Cases.** The fire behavior in the underground fire laboratory was simulated through changing the size of natural air vent and the fire source area. Nine cases are simulated while the natural air vent size is set to 0.2m×0.2m, 0.4m ×0.4m, 0.6m×0.6m and the fire source area is set to $0.32m^2$, $0.64m^2$, $0.96m^2$. The mechanism of ghosting fire is analyzed and judged through the comparison of the nine cases data with ghosting fire or not. The simulation cases are shown in Table 1. Audouin etc.[7] found that the flame from the fuel surface moved to air vents and became stable near them until the end of the experiment. Around the natural air vent where ghosting fire occurred very easily, a series of measuring points were set to extract data of the temperature and the average value of CO, $O_2$ concentration along with time in each case.

Table.1
Simulation cases

| Cases | Fuel | The natural ventilation | Fire area | Ghosting fire occurs time |
|---|---|---|---|---|
| One | Heptane | 0.2m×0.2m | 0.32 ㎡ | Unhappen |
| Two | | | 0.64 ㎡ | 580s |
| Three | | | 0.96 ㎡ | 236s |
| Four | | 0.4m×0.4m | 0.32 ㎡ | Unhappen |
| Five | | | 0.64 ㎡ | 466s |
| Six | | | 0.96 ㎡ | 206s |
| Seven | | 0.6m×0.6m | 0.32 ㎡ | Unhappen |
| Eight | | | 0.64 ㎡ | Unhappen |
| Nine | | | 0.96 ㎡ | 269s |

**Analysis on the trend of development of fire under different cases**

The numerical simulation in nine cases of fire model in underground fire Laboratory shows that stable suspension of ghosting fire occurred in the natural air vent in case two ,case three, case five ,case six and case nine; while there is no ghosting fire in case one, case four, case seven and case eight during the simulation and fire gathered around the surface of fire source. Specific time that ghosting fire occurred were listed in Table.1. In case two, case five, and case eight, the fire area was the same($0.64m^2$), the natural air vent had three different sizes(0.2m × 0.2m, 0.4m × 0.4m, 0.6m × 0.6m), ghosting fire appears first in the case five. When the fire area is set to the $0.32m^2$, burning intensity of fire was weaker than other cases and no ghosting fire occurred. However, when the fire area was set to the $0.96m^2$, the fire burn more fiercely compared with other cases, and in the underground space there were sporadic ghosting fires, but the ghosting fire in the natural air vent is the most stable, as shown in Fig.2.

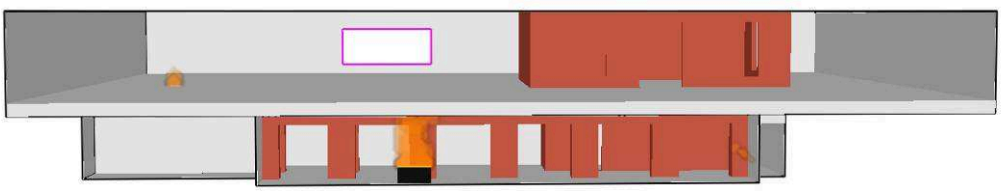

Fig.2.Ghosting fire profiles in underground lab fire

**2.1 Influence of natural ventilation opening size.** The fire area was the same in case two, case five, case eight. The data of these three cases were used to analyze the effects of different air vent size to

the ghosting fire. Figure.3 is the heat release rate curve diagram for case two, case five and case eight. The curve diagram indicates when ghosting fire occurred, the fire power peak was all at 1.1MW in three cases. As the fire developed to a certain time, because of the weak ventilation case, the heat release rate of case two and case five decreased (case two at 525s, case five at 650s), but case eight is not the situation.

Figure.4 is the volume concentration curve of $O_2$ in the underground laboratory natural air vent at case two, case five and case eight. From Figure.4, when ghosting fire occurred, the volume concentration curve of $O_2$ is 13% at case two, 13.7% at case five. The volume concentration curve of $O_2$ reached a minimum value of 12.4% at 525s, then increased, finally tends to be stable at case two and reached a minimum value of 12.4% in 650s, then increased, finally tends to be stable at case five, too. The decreasing speed of $O_2$ concentration in the combustion process is the slowest at 0.6m × 0.6m opening of case eight. Finally, the $O_2$ concentration at three cases is all between 14%~15%, reaching to stuffy quenching concentration of the heptanes in the inner space of underground laboratory. Figure.5 is the volume concentration curve of CO varying with time at case two, five and eight. From the CO content, the changes in content of combustible component in the hot flue gas can be observed. When ghosting fire occurred, the CO volume content at case two was 208ppm, 190ppm at cases five. From Figure.5 it can also be seen that when CO volume concentration reaches for the peak at case two and case five , and the heat release rate curves begin to fall . Figure.6 is temperature curve diagram at three cases affected by the decreasing of heat releasing rate. The temperature at case two and case five also showed a downward trend. When the natural ventilation opening at case eight increased to 0.6m×0.6m, the underground chamber is well ventilated; the combustion process is little affected by ventilation control counter effect, the heat release rate, temperature, $O_2$ and CO concentration at the stage of ventilation control has been in a steady state.

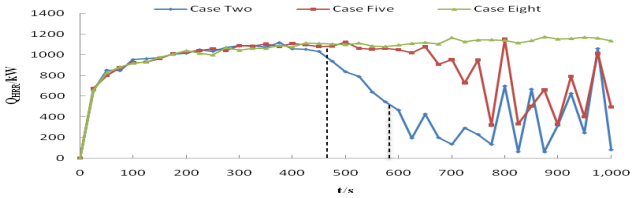

Fig.3.The heat release rate curve of fire source

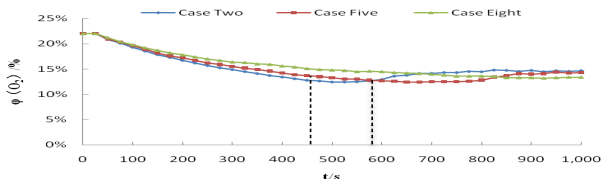

Fig.4.The oxygen concentration

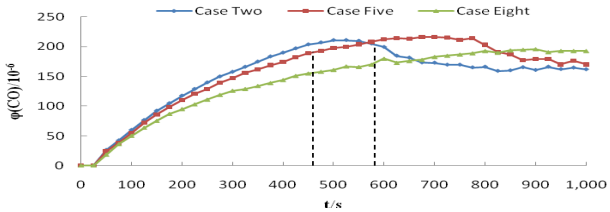

Fig.5.The carbon monoxide concentration curve

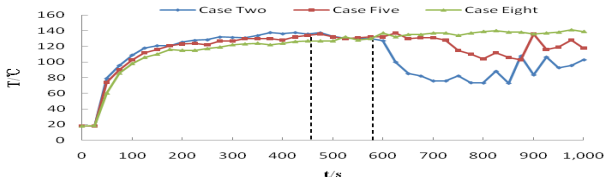

Fig.6.The temperature curve

By comparing these three cases, undersize natural air vent size, such as case two, a weak state of ventilation was caused in underground. In the process of combustion, $O_2$ volume concentration near the fire source rapidly reduces, which leads to the incomplete burning of fuel, and finally the oxygen concentration influenced the combustion intensity, the heat release rate decreased, following by a series of changes of $O_2$, CO, temperature. Because of the 0.6m×0.6m natural air vent at case eight, there was no ghosting fire during simulation. The underground laboratory is well ventilated, so the combustion process is less affected by ventilation control counter effect, the heat release rate and the temperature at the stage of ventilation control has been in a stable growth, $O_2$ concentration tends to a slow decrease until being stable, CO concentration has slow growth. The natural air vent size is not a simple ascending and descending relationship with the occurrence time of the ghosting fire, an undersized natural air vent, resulting in low $O_2$ concentration. While oversized natural air vent led to the more sufficient combustion, the combustion process reduced the generation of CO.

**2.2 The influence of fire source area for the ghosting fire.** Three kinds of parameters were designed in the simulation (0.32m$^2$, 0.64m$^2$, 0.96m$^2$). In these cases, the area of 0.32 m$^2$ fire heat

release rate peaks are 0.4 MW, 0.64 $m^2$ fire heat release rate peaks are 1.1 MW, 0.96 $m^2$ fire heat release rate peaks are 1.9 MW. The cases four, case five, case six have the same natural air vent size, the data of these three cases was used to analyze. The larger of the fire source area, the bigger of the fire heat release rate peak ,the sooner the ghosting fire appeared. The larger of the fire source area, the bigger of the fire heat release rate peak, and at the same time the temperature of the underground laboratory rise sharply, the accumulation of CO content will be accelerated, which accelerate to relight the combustible components in natural vent. Increasing the fire source area has played a significant role in promoting affection for the ghosting fire to occur.

## Conclusions

The change of the natural ventilation is not a simple ascending and descending relationship with the formation of the ghosting fire. An undersized nature air vent restricts the $O_2$ content in the formation. And the oversized natural air vent restricts the CO content, which slows the growth of the temperature of in natural air vent. Therefore, the formation of the ghosting fire is affected by these factors. And increasing fire area improves the fire heat release rate effectively, promoting the formation of ghosting fire in confined underground space. Weak ventilation situation exists in the confined underground space, once a high intensity fire occured, the ghosting fire would occur easily. In the process of the formation of the ghosting fire, the whole underground laboratory fire ceiling temperature reached 200℃, it is easy to cause another fire behavior "flashover" in this situation. Ghosting fire and flashover will be explored whether there is some kind of inevitable connection in the future.

**Keywords:** High Temperature; Quasi-Static; Seismic Performance; Hysteretic Curve; Skeleton Curve

**Abstract.** Super early-strength composite fiber concrete has been widely used. Seismic Performance of super early-strength composite fiber concrete columns needs to be known after high temperature, quasi-static tests under different high temperatures are experimented. The experiment showed that: the downtrend of hysteretic curves and skeleton curves are consistent, but reductions for both hysteretic curves and skeleton curves are diverse after different duration.

## Introduction

China is a many earthquakes nation.The fire often takes place following destructive earthquake. The fire often takes place following the destructive earthquake.Structure safety is the important obje ctive of performance-based seismic design and fire resistant. Column is an important load-bearing element of construction. When the buildings affected by the fire after earthquake, the inner member may be formed of non-uniform distribution of temperature field, material properties will be change, which leads to the structure bearing capacity decreased. Therefore it supplies a basis for the calculation of remainder load bearing capacity and evaluate of damage about the Super early-strength composite fiber concrete structure post fire and earthquake.

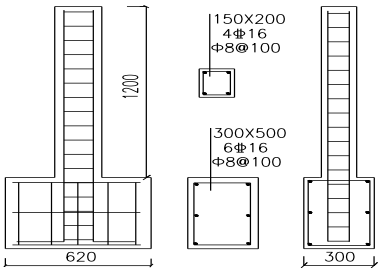
## Experiment and Related Parameters

**Experimental Axial Compression Ratio.**In the experiment, axial compression ratio of experiment is 0.4, axial compression ratio [1] is defined below. $N$ is force; $f_{ck}$ is axial compressive strength standard value; $A$ is area.

$$n' = \frac{N'}{f_{ck} \times A} \tag{1}$$

According the impact of the design specifications of concrete structure [2] and the permanent load factors, which can get the design axial compression ratio is 0.672.

**Specimen Design.**Duration of high temperature has significant effect on hysteretic behavior and remainder load bearing capacity. Therefore, duration of high temperature is the most important factor on concrete columns of super early-strength composite fiber seismic performance. In this experiment, the main parameters of columns are shown in figure 1.



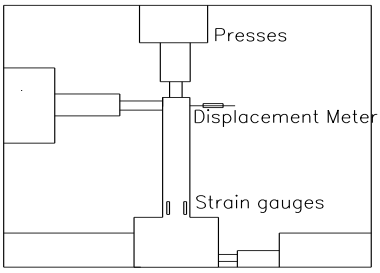


**Fig.1** Main parameters of the specimen **Fig.2** Diagrammatic of experimental device

**Parameters.** The main parameters are shown in table1.

**Tab. 1** Test parameters of specimens

| Specimen | temperature | high temperature duration | axial compression ratio | load |
|---|---|---|---|---|
| Z-1 | 600℃ | 30 | 0.4 | repeated |
| Z-2 | 600℃ | 60 | 0.4 | repeated |

## Specimens Yield Experiments

**Yield Test Apparatus and Loading System**. First, 200t hydraulic jack applies the vertical force, then 60t hydraulic jack applies horizontal force, in the test, force control method is used, Horizontal force is controlled from 10kN to 40kN by 5kN increment[3], it is stop until the turning point appears[4]. Data acquisition is finished by EIC-300 logger type IMP. The experimental apparatus is shown in Figure 2.

**Experimental Phenomena and Hysteretic Curve.** Specific experimental phenomena and the hysteretic curve are shown in the figure 3 and 4.

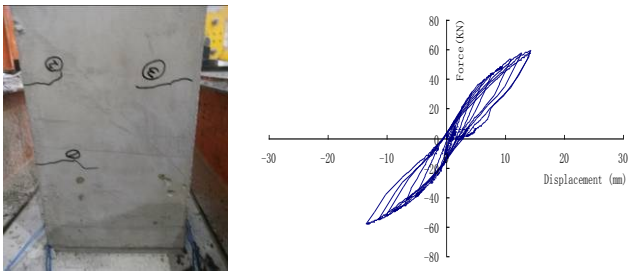

**Fig.3** Z-1 failure pattern and hysteretic curve

**Fig.4** Z-2 failure pattern and hysteretic curve

## Fire Test

**Yield Test Apparatus and Loading System.** In the experiment, fire-resistant cotton wraps the position of top column and column pier. Specimen are put into the heat treatment device which controls temperature to 600℃ for 30min or 60min [5]. Finally, the specimens are cooled to room temperature. The experimental device uses electric heating method.

**Experimental Phenomena.** During the heat treatment, a small amount of visible water vapor spill from the top of the gap. After experiment, the specimen surface are appeared noticeable color, the width and number of surface cracks increased obviously, experimental phenomena is shown in figure 5.

**Fig.5** Z-1, Z-2 The color change of the specimens after high temperature

**After the Multi-hazard Seismic Experiment**

**Experimental Phenomena and Hysteretic Curve.** Specific experimental phenomena and the hysteretic curve are shown in the figure 6 and 7.

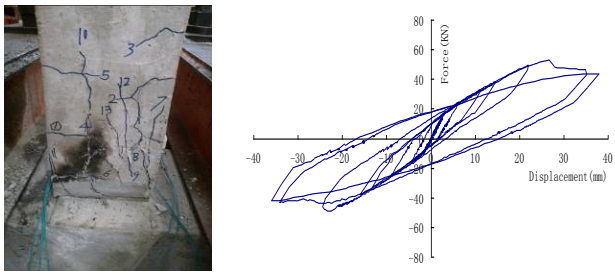

**Fig.6** Z-1 failure pattern and hysteretic curve

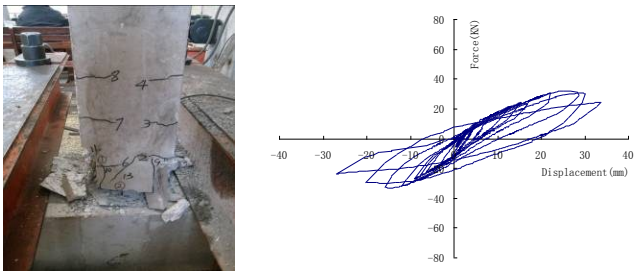

**Fig.7** Z-2 failure pattern and hysteretic curve

Load-Displacement curve can be analyzed about the structure of remainder load bearing capacity, ductility of the columns. Conclusion and suggestion are summarized below.

(1) At the beginning of loading, the columns are in the elastic phase, the latter, load bearing capacity will gradually descend, slope of the curve is reduced, high temperature and cyclic load are the reasons of material strength reduction.

(2) Displacement control is used in experiment at second stage, strength and stiffness of the specimen decline noticeably, load bearing capacity is reduced.

**Skeleton Curve.** As the skeleton curve can be analyzed variation of the bearing capacity and ductility detailed，it can be assessed the seismic performance objectively, skeleton curve is shown below8.9.

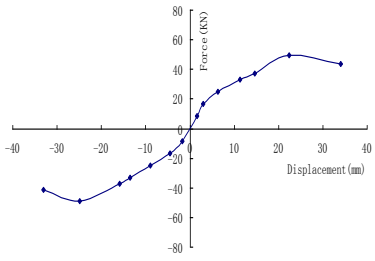

**Fig.8** Z-1 skeleton curves

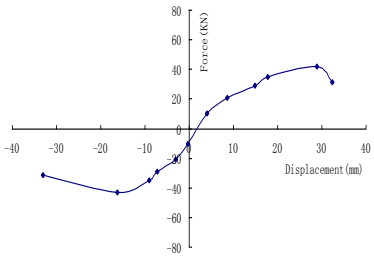

**Fig.9** Z-2 skeleton curves

We can Analysis the skeleton curve above that:

(1) At the beginning of loading, specimen still maintain some elastic state. With load increasing, it appears plastic deformation, cracking phenomenon is very serious.

(2)The longer of the duration high temperature lasts, the more serious material damaged. The damage phenomenon is more obvious

**Ductility Factor.** Specimen damage appearances the ductility deformation [6]. It is often used ductility factor to reflect the ductility index of the specimen, which is defined formula [7].

$$\mu_{\Delta} = \frac{|\Delta_{+u}| + |\Delta_{-u}|}{|\Delta_{+y}| + |\Delta_{-y}|} \quad (2)$$

Use the formula, ductility factor can be got in the table 2.

**Tab.2** Specimen ductility factor

| Specimen | Z-1 | Z-2 |
|---|---|---|
| $\mu_{\Delta}$ | 2.27 | 2.02 |

## Conclusion

(1) Hysteretic curves, skeleton curves, ductility factor can better reflect the specimen seismic performance;

(2) The longer of the duration high temperature lasts, the more serious material damaged. The damage phenomenon is more obvious;

(3) The duration of high temperature is the key indicator effect on seismic performance of the specimen.

**Keywords:** Post-fire, concrete filled double skin steel tubular, Seismic performance, Hysteretic behavior, Displacement ductility.

**Abstract.** In recent years, frequent fires and earthquake make the buildings damage badly, and it causes huge economic loss. Concrete filled double skin steel tubular(Hereinafter referred to as CFDST)as a new member of structure, its mechanical properties are similar to concrete filled steel tubular, at the same time has better fire performance and seismic capacity. Based on this background, the paper expounds study the mechanical performance of CFDST is very important, the hysteretic behavior is the main mechanical indexes of the seismic performance of CFDST after exposure to fire. The study of it will fill the new component in the blank of seismic performance research.

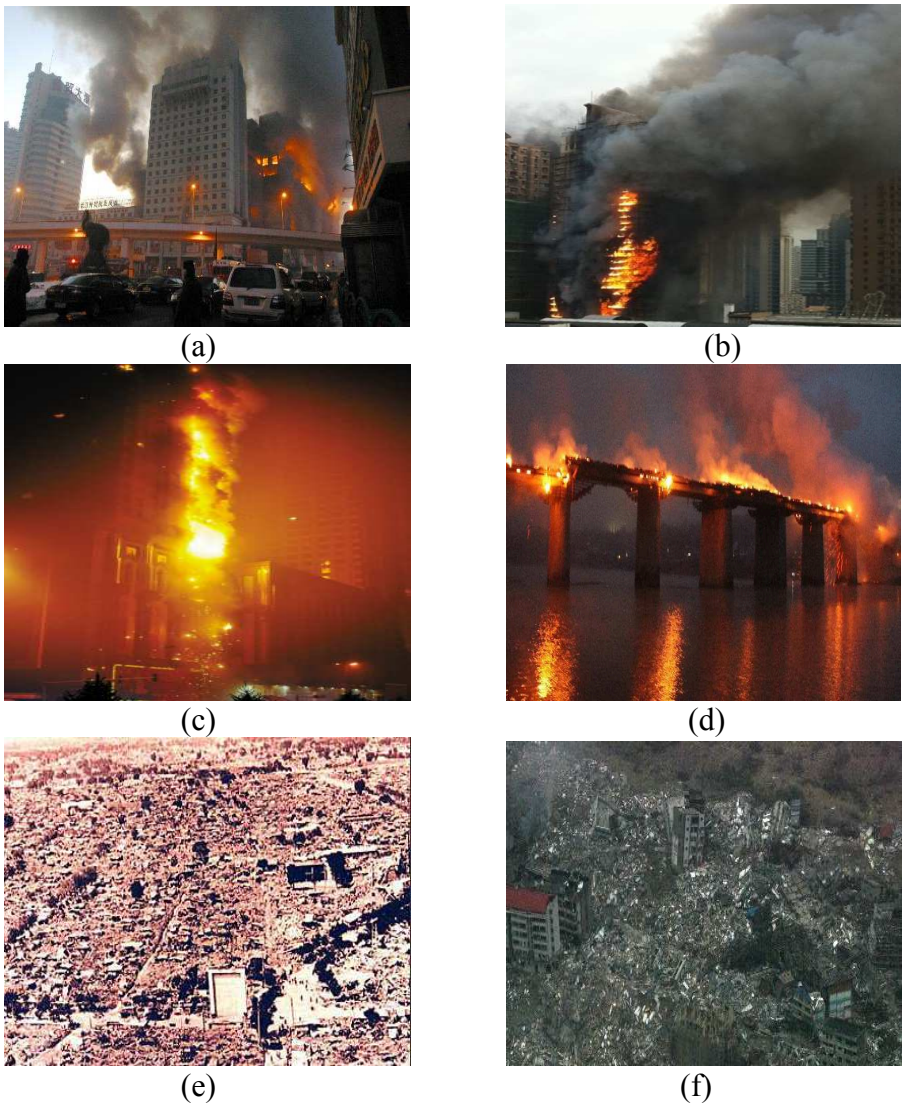
## The research background of the project

Fire refers to the time or space out of control caused by combustion of the disaster, in our country fire happened frequent, and in recent years showed a rising trend, it happened up to 130000 per year on average, in current, our country building fire problem has also become a social problem, according to incomplete statistics, from 2000 to 2010, fire has happened 3237 times in high-rise building in total, more than 10000 persons lost their lives in fire, direct economic losses as high as 35.83 billion of yuan.In recent years, the frequent fires caused great loss to human society, such as on December 25, 2000, fire happened on dongdu commercial building of Luoyang, it has caused 309 deaths and 7 injured, on February 15, 2004, fire happened on zhongbai commercial building of Jilin province and it caused 54 people died(As shown in Fig.1 a), on December 25,2005, fire happen on Liaoyuan central hospital of Jilin province, which caused 40 people died, on November 15,2010, in Shanghai yuyao road jiaozhou road, there has fire happened on a high-rise building(As shown in Fig.1 b), this accident caused 58 deaths, on February 3, 2011, the dynasty in Shenyang wanxin fire accident caused property losses of 3 billion yuan(As shown in Fig.1 c), on November 28,2013, fire has happened on a "Asia's first covered bridge" which located in qianjiang of Chongqing (As shown in Fig.1 d), on the bridge, all wooden buildings were burned out, and this fire caused great economic losses.

In the same time , our country is a earthquake-prone country, China is in the Circum-Pacific seismic belt and seismic zone of the Himalayas, in our country, the earthquake greater than magnitude six happened four times per year on average, the earthquake greater than magnitude seven happened two times per three years on average, such as on July 28,1976,a magnitude 7.8 earthquake struck Tangshan of Hebei province, this accident caused 242000 people lost their lives and direct economic losses more than 10 billion yuan,( As shown in Fig.1 e), on May 28,2008,a magnitude 8 earthquake happened in Wenchuan county of Sichuan province, it caused 69172 and 374159 injured, and direct economic losses more than 14.08 billion yuan(As shown in Fig.1 f),on April 14,2010, a magnitude 7.1 earthquake happened in Yushu of Qinghai province, it caused 2220 people lost their lives, and direct economic losses more than a few billions of yuan.

With the development of economic and the acceleration of urbanization, the following thing is people to the requirement about functions and forms of architectural are continue to increasing, the structure on the ground towards to tall even super-tall, large span and complicated structure body development, the structure underground from the original layer toward multi-level, three-dimensional

development.In these towering structures, the length of the column will be increased, and become longer and thinner. When these towering structures want to withstand wind loads and relatively large horizontal seismic force, it requires the columns have a large horizontal bearing capacity and a good level of flexural rigidity[1].In the range of the medium long column the main factors that determine the bearing capacity of the column is the stability of the column. Its carrying capacity is mainly controlled by the stiffness. But neither the reinforced concrete nor the concrete filled steel tubular cannot be fully expressed their section bearing capacity of strength, and the CFDST have a very good flexural rigidity and a high bearing capacity, so the CFDST has a great advantage when it used in the filed of resistance to earthquake[2].



(a) (b) (c) (d) (e) (f)

Fig .1 Architectural disasters occur frequently

A fire in the high-rise building is increasing, it makes the analysis of hysteretic behavior of concrete filled double skin steel tubular after exposure to fire become a very challenging thing. After the fire, the structure also has a bearing capacity. So the research in hysteretic behavior of CFDST after exposure to fire and insure its mechanical properties such as strength, stiffness, ductility and energy dissipation capacity is very important.

**The characteristics of concrete filled double skin steel tubular**

CFDST refers to the two concentric placed between the steel tubes filled concrete composite structures, concrete filled double skin steel tubular is a new type of composite components which is developed on the basis of concrete filled steel tubular. Not only concrete filled double skin steel tubular has the laminate what concrete filled steel tubular has, such as, a high carrying capacity, good ductility, fire resistance, easy construction and good economic results[1]-[6], but also it has the advantage what the concrete filled steel tubular did not have.

**(1)Light weight and good earthquake resistance**

A large number of experiments and theoretical studies have show that under the condition of reasonable in design, CFDST has a greater carrying capacity than concrete filled steel tubular which has a same size and same cross, and concrete filled double skin steel tubular is a special hollow structure, in the case of same size, the weight of CFDST is lighter than the weight of concrete filled steel tubular and reinforced concrete, so in the practical application, we can design the CFDST which has a very high carrying capacity and good earthquake resistance.

**(2) Section unfold, flexural stiffness great**

The same weight of CFDST, because of its hollow structure, the section unfold is better. At the same time due to its section unfold, the flexural stiffness of CFDST become greater, if under the larger bending moment, it can give full play to the mechanical of materials, and it becomes more economic and reasonable.

**Conclusion**

So far research on mechanical properities of CFDST after exposure to fire and after high temperature have:In 2005, Yang Youfu, and Han Linhai [7] under the terms ISO-834 and GB/T9978-1999 standard temperature curve of CFDST columns under warming a study of the mechanical properties. In 2008, Yang and Han[8] study on mechanical properties of CFDST members after exposure to fire. In 2009 experimental research on mechanical properties of six circular CFDST after exposure to fire by Yuxin and Tao zhong[9]. To date on mechanical properties of CFDST was rarely report, and the hysteresis behavior of concrete filled double skin steel tubular after exposure to fire and after high temperature was not report, so it should research on hysteretic behavior of concrete filled double skin steel tubular after exposure to fire. In order to lay the foundation for application of CFDST in engineering practices.

**Keywords:** Emergency; Emergency logistics; Emergency Logistics System; Information Platform System

**Abstract.** This paper, based on the analysis of the characteristics of emergency logistics and the problems existing in its development, proposes hierarchical structure and the basic framework of the emergency logistics system, and explains the specific content of each subsystem. In addition, this paper constructs intelligent and multilevel collaborative information platform system, which is oriented to the emergency logistics system, and expounds its main functions to provide technical support for the operation of emergency logistics system.

## Introduction

With the rapid development of modern society, all kinds of emergencies happen more and more frequently. In general, emergencies have many characteristics such as suddenness, urgency, uncertainty, severity of consequences [1]. The outbreak of the emergencies tends to produce large amounts of aid needs. In dealing with the emergency, logistics has played a vital role, and if an emergency is mishandled, it will have large negative effects on economic and social life. Whether emergency logistics system can guarantee the need of relief supplies in time will directly affect the efficiency of emergency disposal. The frequent occurrence of emergency makes logistics management become a research focus in the social management, and the research on emergency logistics has become a new field.

When all kinds of public emergencies occur, it is an urgent and critical task, in the first time, to deliver appropriate quantity and quality of emergency supplies to destination in a reasonable way, which has a great significance to guarantee the safety of people's lives and property, quickly return the country to the normal order of social life, reduce all kinds of losses and minimize the negative impact on the social economy and politics as far as possible. In the practice of dealing with all kinds of major emergencies, China has had a certain support capability of emergency material. But in most cases, it is difficult to ensure the supply of emergency materials in the first time as a whole. The reason is mainly due to the construction of emergency logistics system lags behind [2]. The degree of development and improvement of emergency logistics system directly determines the support capability of emergency supplies, and the lag of construction of emergency logistics system is shown as: the relative lag of infrastructure construction, the organizational mechanism is not perfect, serious shortage of emergency logistics companies, emergency materials reserve system is not reasonable, etc.

Responding to emergencies has to enable emergency logistics. Emergency logistics system is an open complex giant system, and provides powerful support for emergency management. Only through the bridge of logistics can emergency supplies provide uninterrupted supply of materials for on-site assistance. Emergency logistics is an important force in national security system. When emergencies occur, they need a lot of emergency supplies within a short time, which largely depends on the capability of emergency logistics. Perfect emergency logistics system can continuously supplement consumption of relief materials, restore the relief strength, and it gradually becomes an important force in the national security system [3]. In order to promote the construction and development of emergency logistics in China, we must strengthen systemization, standardization and informatization in the construction of emergency logistics.

This paper, based on the characteristics of emergency logistics and the problems in its development, puts forward Chinese emergency logistics system framework, in order to realize the optimal allocation of social resources and improve the efficiency of the operation of emergency logistics. At the same time a kind of intelligent information platform system is proposed for the system, providing technical support for the emergency logistics system.

## The concept and basic characteristics of emergency logistics

### (1)The concept of emergency logistics

Emergency logistics is a special logistics activity, which can meet the urgent needs of emergency goods and materials, personnel and funds in response to sudden natural disasters, public health events, public security events and military conflicts and other emergencies, in order to pursue the greatest time benefit and the least loss of disaster[4].

Emergency logistics system is a complex giant system, which is composed of all kinds of subsystems, and every subsystem has mutual contacts and interactions, in order to complete the task of emergency logistics [5].

### (2)The characteristics of emergency logistics

1) Strong timeliness

The most prominent feature of emergency logistics, triggered by unexpected incidents, is the timeliness of the logistics activity. A large number of emergency supplies must be quickly delivered to where needs in a very short period of time. Due to the requirement--strong timeliness of the emergency logistics, the operation mechanism of general logistics is difficult to meet the needs in the state of emergency logistics [6].

2) Unpredictability

Emergency leads to uncertainty of emergency logistics in flow direction (the spatial distribution of the supply and demand places), and quantity of flow (the amount and type of emergency supplies). So it is difficult to predict emergency logistics demand accurately, and the emergency logistics system cannot make plan in advance.

3) Diversity of demand

After the incident, a lot of emergency materials, from special rescue equipment, medical equipment, communications equipment to articles for daily use, are needed in a short period of time. At the same time, the deterioration of logistics environment is often associated with emergencies. In addition to needing to complete the required items in time, the items also need to be delivered timely, which is a very serious test for emergency logistics system.

4) Weak economy

General logistics system emphasizes that effective management can help achieve the best economic benefit, so it makes efforts to reduce costs on the premise of guaranteeing service quality. While the emergency logistics system has the characteristic of weak economy, then it pays more attention to public welfare, and focuses on the social benefit. Therefore, in many cases, emergency logistics obtains the logistics benefit through the realization of the efficiency of logistics.

## The existing problems in the development of emergency logistics

The development of emergency logistics in China is still in its infancy, our country passed 《Emergency Response Law of the People's Republic of China》 in 2007, and in 2009 《Logistics Industry Restructuring and Revitalization Plan》 was issued by the State Council, which lists the construction of emergency logistics as one of the nine key projects[7]. In recent years, the government and the society gradually realize the importance of emergency logistics.

But various emergencies that happened in recent years in our country, such as the South Snow Disaster, Wenchuan Earthquake, Yushu Earthquake, exposed that the emergency logistics system exists many problems in China.

(1) Insufficient predictability. It manifests that the supply of relief materials cannot meet the demand, causing serious imbalance between supply and demand.

(2) Lack of a unified command. No professional and dedicated permanent emergency organs in China, hence there lacks unified management and control in emergency logistics management.

(3) Departing from market. When emergency occurs, the government is responsible for forming a temporary emergency organization, without making full use of existing logistics enterprises in the market.

(4) Informatization level is relatively low. Our country has not yet set up a sound information platform system for publishing and sharing information, causing that the source of information is not detailed and the information is reported not timely, and affecting the efficiency of the operation of emergency logistics.

## The construction of emergency logistics system framework

Systematism is one of the core ideas of emergency logistics, namely global optimization. To make the whole emergency logistics system form a large system that can run efficiently, we should, from an overall point of view, coordinate construction and development of emergency logistics. Emergency logistics system is a new strategy for emergency physical management. There are three kinds of flow--fund flow, material flow and information flow-- in the process of emergency logistics, and the three flows are integrated together in the larger sense. By the optimal allocation of internal resources, the system achieves global and dynamic optimization.

**(1)The principles of the construction of emergency logistics system**

On the basis of summarizing the results of previous studies, we get the corresponding principles in the construction of emergency logistics system. These principles are shown in Table 1.

Table.1 The principles of the construction of emergency logistics system

| | principles | details |
|---|---|---|
| 1 | leading by government, civil-military integration | The system should be led by government, and make full use of the two systems: the military logistics and the local logistics |
| 2 | focus on the emergency, balance at ordinary and urgent times | Not only meet the demand of emergency, but also achieve normalized construction of emergency logistics, then balance urgent time with peacetime. |
| 3 | on the basis of existing , use while building | Integrate the existing resources, improve the ability and level of emergency, and use while building. |
| 4 | improve efficiency, focus on economic costs | Emergency logistics has the characteristic of weak economy, so we should pay attention to the social and economic benefits while improving the emergency capability. |
| 5 | from a global perspective, demand-oriented | From an overall point of view, we take the demand of responding to emergencies as direction, promoting the systematism development of emergency logistics. |

The construction of emergency logistics system takes emergency needs as direction, which is based on advanced information technology, takes modern logistics technology as support, takes administrative system, laws and regulations and public policy as the background, to build integrated, high efficient and fast logistics system. The details of the hierarchical structure are shown in Figure 1.

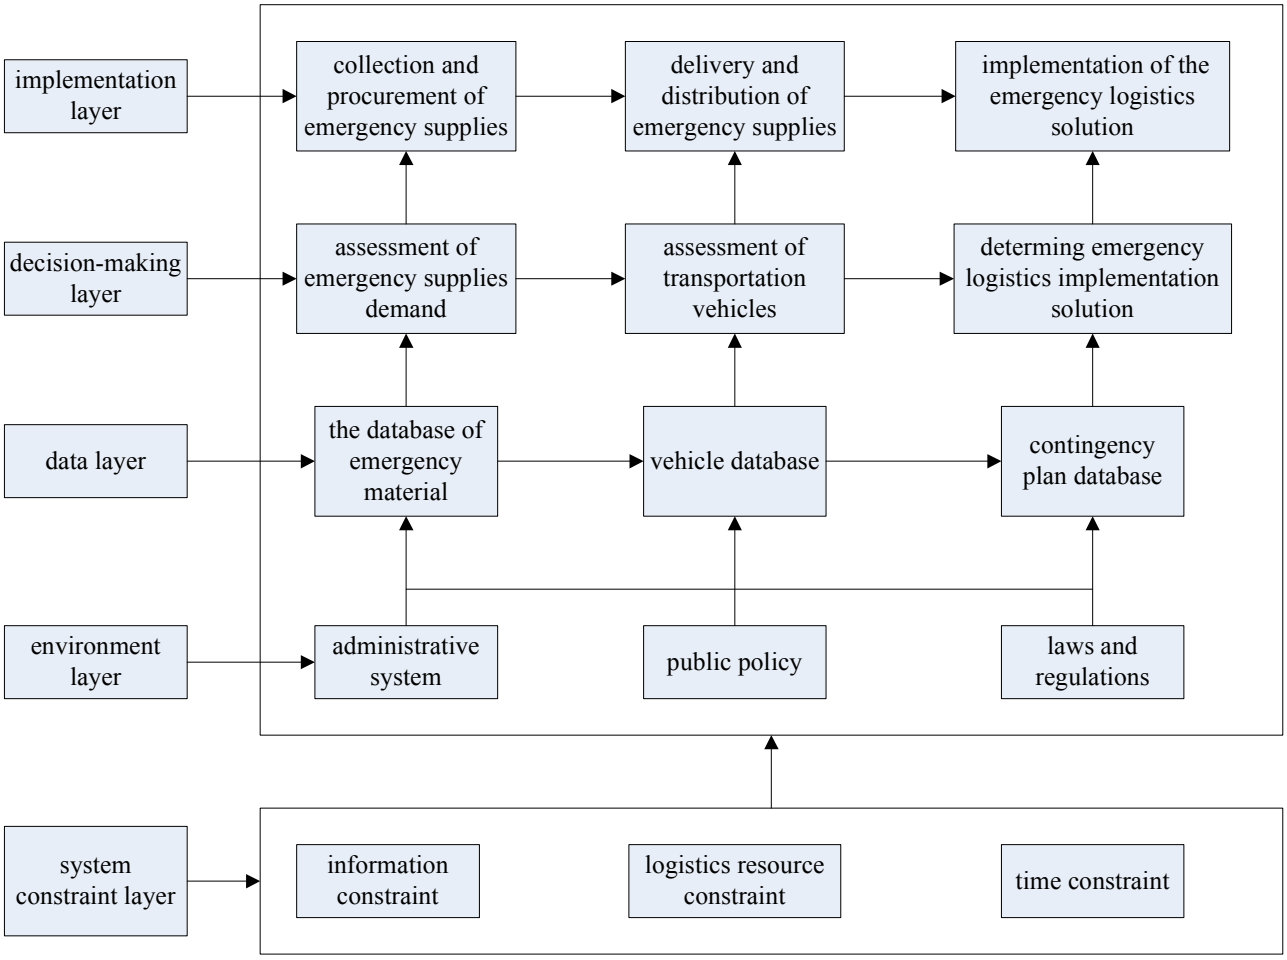

Fig. 1 The hierarchical structure of the emergency logistics system [8]

**(2)The constraints of emergency logistics system**

In the construction and operation of emergency logistics system, many objective conditions limit the realization of the goals of emergency logistics system. The main constraints are as follows: 1) Information constraint. Due to the uncertainty of emergency, it is difficult to get the full grasp of demand information of emergency logistics in a short time, thus possibly resulting in mistakes in prediction and decision-making. 2) Logistics resource constraint. Resource constraints include many aspects, such as material resources, transportation resources, and infrastructure resources. 3) Time constraint. Emergency logistics task should be implemented in a certain time, otherwise it will affects the efficiency of emergency logistics management.

**(3)The composition of the emergency logistics system**

The composition of this system includes emergency supplies subsystem, organizational subsystem, command subsystem, information subsystem, distribution subsystem and support subsystem, which are related to and constrained by each other, as shown in Figure 2. Every subsystem is an important part of the emergency logistics system, and play a key role in distributing emergency supplies accurately and timely and reducing emergency logistics cost.

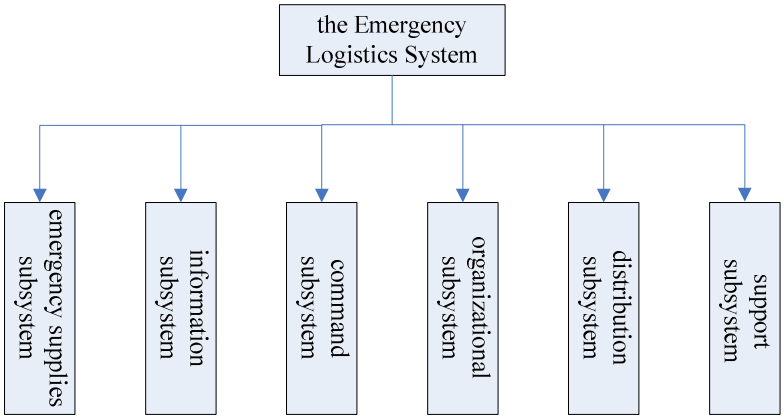

Fig. 2 The composition diagram of emergency logistics system

1) The emergency supplies subsystem. It, as the object of action of the emergency logistics system, is composed of breed structure, quantity and scale, layout form, production capacity, existing state of emergency supplies and other related elements. At present, a reasonable scale of emergency supplies reserves is of great significance for the construction of emergency supplies system. We should follow "the state, the army, the local, market and family" this reserve form to build emergency materials reserve system.

2) The information subsystem of emergency logistics. Information subsystem should be established and keep close contact with command center, even with each subsystem, relevant government departments, and logistics enterprises who takes part in. And in this way it can improve the timeliness and effectiveness of commanding and decision-making of emergency logistics. In addition, the system is an effective channel for the government to publish official news and the masses to provide feedback information.

3) The command subsystem of emergency logistics. Command subsystem refers to a special logistics command center in the government's response to various emergencies, which is established to make good preparations for raising, scheduling, distributing, transporting emergency supplies and other work. Our country should, according to the structure of government and the process of logistics operation, establish a permanent and professional emergency command center, which is dedicated to rescue as an important guarantee for the efficient operation of the emergency logistics.

4) The organizational subsystem of emergency logistics. It should be composed of four elements: decision-making body, emergency response administration, monitoring organization, executing agency.

5) The distribution subsystem of emergency logistics. The ultimate achievement of the goals of emergency logistics system depends on whether the emergency supplies are delivered directly to disaster area timely and accurately. We constantly consider that under both these aspects: the government signs agreements with the domestic professional logistics enterprises in the form of market and gets their help, ultimately integrates social resources effectively; A new emergency logistics mode, namely civil-military logistic integration, should be applied to optimize the allocation of resources.

6) The support subsystem of emergency logistics. It includes infrastructure support and legislative guarantee. We should strengthen the legislation of emergency logistics, to make settlement body, responsibility and power distribution and the source of funds more clear when an emergency occurs. The laws for emergency logistics management can help ensure that emergency logistics moves in the right direction.

**The information platform system of emergency logistics**

**(1)The structure of information platform system**

Building a good information platform system is the key to the construction of emergency logistics system, and the premise of ensuring efficient operation of emergency logistics system. In our country, there is not a good emergency logistics information platform system, and information-based level is

low, causing information transferred irregularity. Based on the emergency needs and the needs of logistics cooperation, this paper proposes the overall framework of information platform system. In this way, we can activate the emergency logistics system through the information technology and then realize the information sharing and collaborative communication among different participants. The structure of the information platform system is shown in Figure. 3.

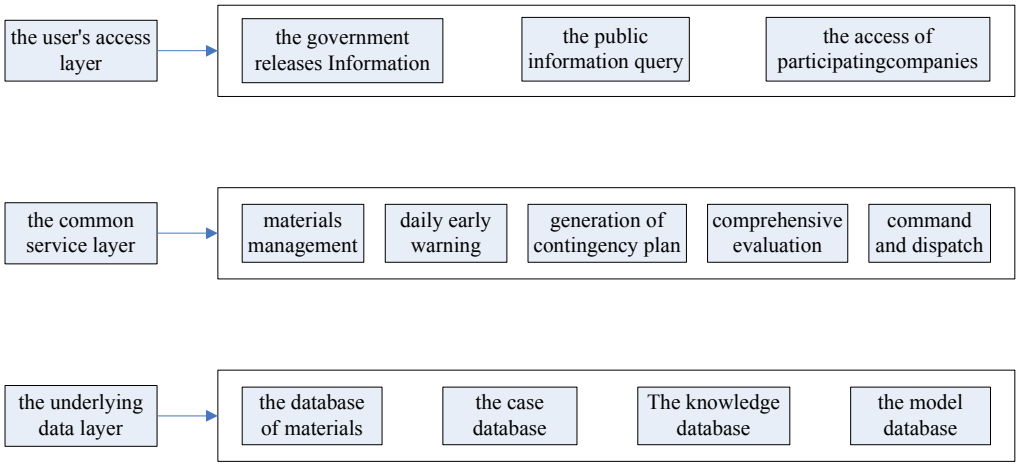

Fig. 3 The structure of information platform system [9]

**(2)Functions of information platform system**

The public information platform system of emergency logistics is divided into underlying data layer, the common service layer, the user's access layer, the three layers are joined together and interact with each other, and they have many functions as the follows:

1) It can collect the supply and demand information of emergency logistics, and achieve accurate perception of emergency logistics demand.

2) The second one is making this information platform system, the existing public logistics information platform and commercial logistics information platform be linked into network, to integrate the emergency logistics resources effectively.

3) It matches emergency logistics participants with relevant information, such as the manufacturer and the demander of emergency supplies, logistics center and logistics enterprise which joins in, in order to avoiding unbalance between supply and demand of emergency supplies and capacity.

4) It can provide useful information of decision-making and supervision for leaders at all levels of emergency logistics, which helps manage the collection, transportation, warehousing, distribution of emergency supplies effectively in the process of the whole operation.

5) It also provides real-time information for relevant departments, such as earthquake, meteorology, health and epidemic prevention and transport departments, which helps to improve the relationship with other subsystems of emergency logistics.

6) The information platform system, as the effective channel for emergency management department to release information to the public timely and the masses to provide real-time feedback information, on the one hand improves the efficiency of the emergency logistics, on the other allows the functions of emergency logistics management system into full play.

## Conclusion

Based on the in-depth analysis of the characteristics of emergency logistics and the existing problems in its development in China, this paper puts forward the hierarchical structure of emergency logistics system, and builds its integrated framework. Then an intelligent and multilevel collaborative information platform system oriented to the emergency logistics system is constructed. This research promotes the systematization and informationization development of emergency logistics management, and provides theoretical references for realizing spatial information service resources share and interoperation. Finally it achieves efficient allocation of social resources in the process of emergency logistics management.

**Keywords:** vulnerability assessment; strain energy; damage demand; local damage; damage scenario.

**Abstract.** The method of structural vulnerability assessment presented in this paper is closely in accordance with the definition based on two aspects, strain energy of structure and damage demand of members. The search process of damage scenarios was carried out by an example of truss structure, and the results of analyses included importance factor of members, damage scenarios with the minimum number of killed members, and local damage occurred in advance. The influence of loading on member importance factor and vulnerability index was discussed and it showed that though with the agreement of general trend, the rank of importance factor or *VI* index under a specified scenario varied greatly. The analysis could be utilized as the proof of measures to enhance structural capacity to meet the extreme event.

## Introduction

With the maturity of structural design principals and the development of advanced computational tools, engineers have more and more knowledge about structural performance, while they still face huge challenges in structural design due to some manmade extreme accidents or terrorist attacks.

Generally, the property that disproportionate damage occurs easily in the structure under extreme events is regarded as the vulnerability, which is the opposite of robustness. Currently researchers have proposed several methods to evaluate the vulnerability of a structure which could be roughly divided into two categories [1], 1) based on structural attributes, 2) based on structural performance. Researchers from University of Bristol [2] proposed assessment method based on structural topology among which structures are regarded as the combination of rings and clusters, and the influence of structural formation under different damage scenarios was utilized to identify the weak point. Ye etc. [3] proposed an index, Generalized Stiffness ($K_{stru}$) with loads in consideration to give structural assessment, which was based on both the stiffness matrix and loading condition, and reflected the ability of structural deformation under specified loads. The methods based on structural performance include deterministic and probabilistic method. Among the deterministic methods, bearing capacity of the system[4, 5], the development level of damage[6], structural deformation energy[7] were selected as the assessment index while the probability of structural failure[8] and the risk [9]are more common utilized in probabilistic methods.

Without consideration of loading distribution path, methods proposed from the structural topology or stiffness matrix for structural vulnerability assessment did not reflect accurately the influence of members on stress redistribution. Structural vulnerability has close link to structural attributes and geometric topology while structural damage shows different patterns under different loading conditions. Currently no assessment index or method has reached general consent among the world though a bunch of scholars have conducted researches on the identification of weak point and significant member among the system.

The method proposed in this paper is based on the strain energy of the system as well as the damage demand under different damage scenarios. Member removal is utilized to simulate the member failure while the selection of damaged members is arbitrary combination to consider the random of initial failure under extreme events. The strain energy in critical condition is normalized by

strain energy under normal loading condition which is regarded as structural performance parameter, and the damage demand is defined as the work done to destroy isolated member. Among single member removal scenarios, the normalized strain energy reflects the member significance; among multi-member removal scenarios, significant members and weak part in the system is obtained through comparison of vulnerability index under different damaged scenarios while regression to geometric mechanism is regarded as structural failure.

**Vulnerability Assessment Method**

The method proposed in this paper is based on the assumptions following:

1. The initial failure is replaced by member removal while the subsequent failure development is regarded as the internal force redistribution among different members.

2. The loads are assumed as the normal loading combination under the service period without change after the initial failure. The force caused by member drop or impact is not considered in this paper as well as the dynamic influence of forces.

3. The structure is assumed as the conservative system without energy dissipation.

Among the conservative system, the work done by the external force is transformed totally to the structural strain energy. The external force is denoted by $\{F\}=F_{max}\{v\}$ in which $F_{max}$ is the maximum value in force vector and $\{v\}$ is the force distribution vector. The work done by the external force is,

$$W_{ext}=U_{sys}(F)=\sum U_i=\sum\int U_i^d(F)dV \tag{1}$$

where $U_{sys}(F)$ denotes structural strain energy and $U_i^d(F)$ denotes strain energy of member I under loading $F$.

In this paper, structural strain energy is obtained from finite element analysis realized in the FE software ANSYS. The material attribute is defined as bilinear model to consider both elastic and plastic deformation. The first load step is specific to the intact structure while the damaged members are killed in the second load step. The strain energy is normalized as,

$$E_r=\frac{E_{sys}^d-E_{sys}^0}{E_{sys}^d}=1-\frac{E_{sys}^0}{E_{sys}^d} \tag{2}$$

where $E_{sys}^d$ is for the damaged system and $E_{sys}^0$ is for the intact system.

The normalized strain energy could reflect the structural performance under a specified damage scenario. The structure has better performance and is less vulnerable to this damage scenario if $E_r$ is small. When $E_r$ is less than zero, it shows that the structure is stable enough.

Currently most evaluation methods are designed to identify the sensitivity to initial failure by comparing the performance of a single structure under different scenario while they seldom could be applied to the performance comparison of different structures. England etc. [10] built the risk level map under damaged scenarios, which realized the generalization of vulnerability assessment.

Different structures have different level of redundancy according to structure importance level. If $E_{sys}^0$ for the intact system is defined as the loading condition of normal loads $\{F\}$, the critical point at the boundary in the risk level map will be different for a specified system due to different level of initial redundancy. It is proper to define $E_{sys}^0$ as the strain energy under a limit state which could be applied to any structure.

During the service period, the stress of member in the truss meets the following requirement,

$$\begin{aligned}&\beta_i^+=\sigma_i^+/\sigma_i^0\le 1.0\\&\beta_i^-=\left|\sigma_i^-\right|/\left(\mu_i\sigma_i^0\right)\le 1.0\end{aligned} \tag{3}$$

where $\beta_i$ is the stress factor, $\sigma_i^0$ is the ultimate tension stress and $\mu_i$ is the stability coefficient under the compression. In this paper, $E_{sys}^0$ is specified in the limit state that the maximum $\beta_i$ of all the members in the system reaches 1.0.

The damage demand is a measure of the effort required to create a deteriorating event, where a deteriorating event is the result of actions which would cause damage to the structure. The damage demand is the actual work causing failure of a member under a specific limit condition like buckling,

tension or bending, and the measure from the member level is determined from the area under the force v.s. the displacement curve.

The damage demand is normalized as,

$$D_r = \frac{D^f}{D^{sum}} = \frac{\sum D_i^f}{\sum D_j} \tag{4}$$

where $D^{sum}$ is the sum of actual work required for failure for all members included in the structure, $D^f$ is the sum of actual work required for failure for all damaged members in a specified damage scenario. The value of $D_r$ is among 0 and 1, while $D_r = 0$ represents no failure member and $D_r = 1$ represents that all members are failed initially.

The damage demand of a single member is obtained from finite element analysis in the FE software ANSYS. The process is that 1) build the member model pinned at both ends, and apply compression force, 2) define the critical state as that the deflection at the middle point reaches 1/200 of the whole member length, and 3) calculate the actual work done at the critical state.

From the definition of structure vulnerability, we could predict that the vulnerability index should be higher if the structural performance is greatly sensitive to the local failure. The vulnerability index is in direct proportion to structural strain energy while it is inversely proportional to damage demand. Based on this, the vulnerability index is defined as,

$$VI = \frac{E_r}{D_r} \tag{5}$$

where $VI$ is the vulnerability index, $D_r$ is the normalized damage demand, and $E_r$ is the normalized strain energy. If $VI$<0, it means that the initial failure is under the redundancy rate.

## Searching of Damaged Scenarios

The initial local failure could cause the change in loading distribution and structure performance, and the structure will undertake progressive failure if current loading is out of the bearing capacity of the damaged system. The combination of initial damaged members is regarded as damage scenario and among each scenario sequence of member failure is out of consideration.

For the truss structure, the system failure could be defined as the loss of geometric stability. That means in truss structure the determinant of stiffness matrix for the damaged system is below zero.

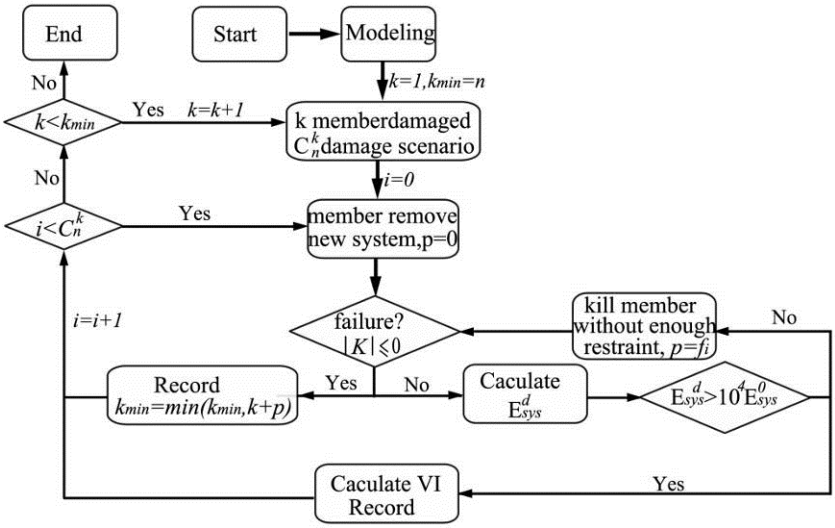

Fig. 1 Searching process of damage scenarios

The searching process is illustrated in Fig. 1, and the main steps are as follows,

1. Build the finite element model in ANSYS, find the specified limit state and calculate $E_{sys}^0$,

2. Define the initial value, $k$=1, $k_{min}$=$n$ (the total number of members included in the truss),

3. Remove the members failed in the damage scenario $i$, and set the number of members without enough constraint $p$=0,

4. Calculate the stiffness matrix of the damaged truss, and judge the geometric stability,

a) if the *det*(K)>0, calculate the strain energy of the damaged truss. Judge whether the value of $E_{sys}^{0}$ is abnormal (extreme large); if $E_{sys}^{d} > 10^{4} E_{sys}^{0}$, kill the member without enough constraints, and re-judge the geometric stability; else calculate the vulnerability index VI, and record the combination of damaged members followed by a new start ($i$+1).

b) if the *det*(K) ≤0, record the combination of damaged members and damaged members in the shortest failure path is $k_{min}$=min($k_{min}$, $k$+$p$).

5. When $i$ reaches $C_n^{k_{\min}}$, the searching reaches the end.

## Example

The structure analyzed in this paper is a 2-storey, 2-bay plane truss in reference [10]. The geometric model and member number are illustrated in Fig. 2, and the member section attributes and damage demand of each member are in Table 1.

The loads are from Reference [11]: DL=3.0 $kN/m^2$, LL=2.0 $kN/m^2$, and for the static analysis, the vertical load set is Load=2(DL+LL), a bit higher than the designed loads. For the beam, the loading width out of the plane is 4 m and the external force is illustrated in Fig. 3.

Table 1 Section of members and damage demand

| Type | No. | Length | Area | $I_{yy}$ | $I_{zz}$ | Stability | $Pu$ | Damage Demand |
|---|---|---|---|---|---|---|---|---|
| Column | 1-6 | 3 | 19.82 | 812 | 89.7 | 0.270 | 181 | 277.8 |
| Beam | 7-10 | 4 | 54.51 | 6490 | 677 | 0.395 | 692 | 1782.6 |
| Brace | 11-18 | 5 | 19.82 | 812 | 89.7 | 0.130 | 64.6 | 114.8 |

Note: the type is just the division from the member position, while each member is pinned at both sides.

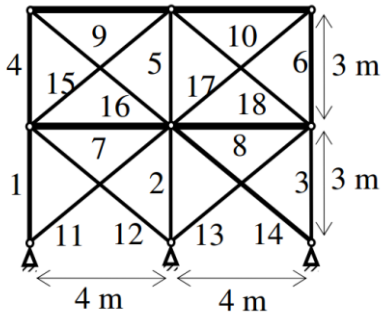

Fig. 2 An example of 2-bay plane truss [10]

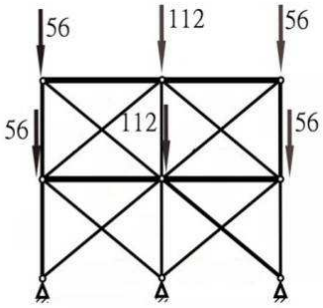

Fig. 3 Loads in the truss (unit: kN)

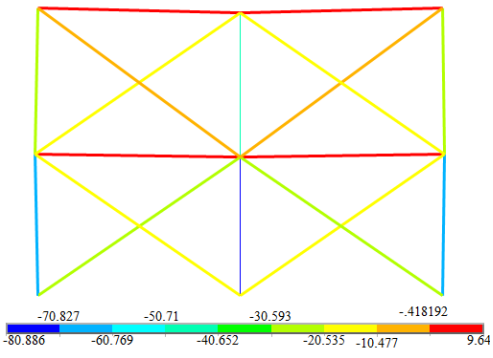

Fig. 4 Stress diagram under critical state (intact)

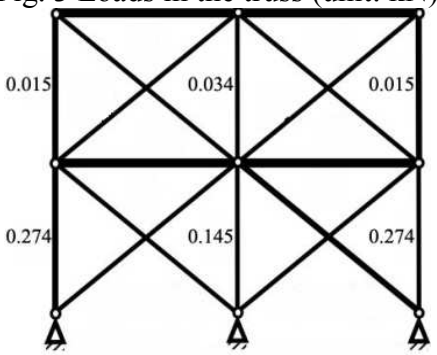

Fig. 5 Member importance factor $E_r$

Note: for uncharted members, $E_r$ is close to 0.

In order to find the specific loading state to calculate $E_{sys}^{0}$, gradually increase the force vector in the truss until the maximum stress index reach 1.0. While reaching the critical state, the principle stress is illustrated in Fig. 4. In the critical state, the compression stress of middle column at the 1st floor reaches 80.9 MPa, ranking 1st among all the members, while the load index is 1.16 and the strain energy is 3.57e-2$J$.

### Importance Factor of Members

The normalized strain energy $E_r$ under single member removal scenario reflects the importance of the member. The member with a higher $E_r$, is more important in the intact system and has a bigger influence on the structural performance; When $E_r$ is close to zero, the removed member is less important to the structure and the damaged system is safe enough. The member importance factor is illustrated in Fig. 5 and it shows that 1) the 1st-floor side column has the largest contribution to structural performance followed by the 1st-floor middle column, 2) the importance of the 2nd-floor column is less than that of the 1st-floor column, 3) after the removal of a single member like a beam or a brace, the influence on the structural performance is not that obvious and the damaged structure is still safe enough. Table 2 shows the change of principal stress in several members after the removal of the 1st-floor side column ( Member No. 1): the largest compression stress is existed in the 1st-floor middle column reaching 100.4MPa; compression stress in another 1st-floor side column ( Member No. 3) decreased from 63.2MPa to 25.7MPa.

Table 2 Principal stress change after the removal of Member No. 1

| Member No. | Principal stress in intact | Principal stress in damaged |
|---|---|---|
| 1 | -63.230 | -- |
| 2 | -80.886 | -100.380 |
| 3 | -63.230 | -25.469 |
| 4 | -30.445 | -16.623 |
| 5 | -45.619 | -62.143 |
| 6 | -30.445 | -14.794 |

Table 3 Analysis result of damage scenario ($k$=2)

| Scenario No. | Member Set | $E_r$ | $D_r$ | $VI$ |
|---|---|---|---|---|
| 2-1 | (1,12)/(3,13 | 0.62 | 0.040 | 15.46 |
| 2-2 | (1,11)/(3,14) | 0.45 | 0.040 | 11.370 |
| 2-3 | (5,15)/(5,18 | 0.45 | 0.040 | 11.197 |
| 2-4 | (2,3)/(1,2) | 0.58 | 0.057 | 10.211 |
| 2-5 | (3,5)/(1,5) | 0.55 | 0.057 | 9.736 |

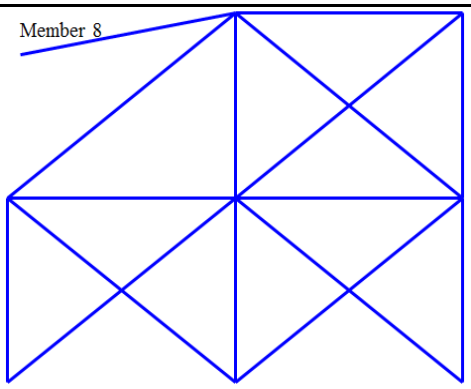

Fig. 6 Local mechanism in damage scenario (4,16)

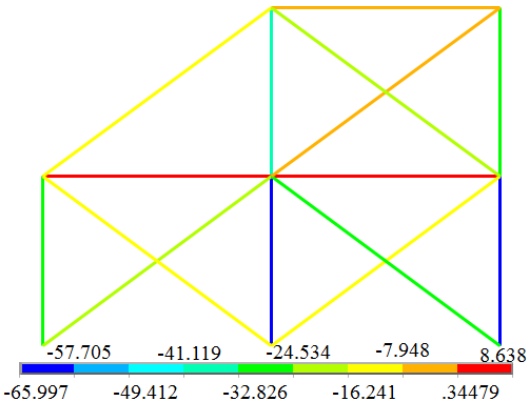

Fig. 7 Principle stress of the residual system after the removal of member 8

### Damage Scenario with the Initial Failure of Two Members

Among damage scenarios with the failure of two members, the local mechanism is existed when removing members linked 2nd floor side node, including removal member set (4,9), (4,16), (9,16) or the symmetric (6,10), (6,17), (10,17). In the damage scenario with removal member set (4,16), member 8 does not have enough restraint showed in Fig. 6. If considering the influence of local mechanism like the dropping of member and additional loads, it is hard to predict the structural safety. If the influence of local mechanism is out of consideration, the residual system works well after the removal of member 8, and the principle stress figure is showed in Fig. 7.

Among other damage scenarios with the failure of two members, when $E_r$ is larger than the maximum member importance factor (0.274), the removed members must include at least one member 1, 2, 3, 5(1st floor column, 2nd floor middle column). Table 3 gives the 5 most vulnerable scenarios among 2-member failed scenario: the first three scenarios are member set of column and brace while the 4th and 5th scenarios is member set of two columns.

### Damage Scenario with the Initial Failure of Three Members

Among damage scenarios with the failure of three members, a new local mechanism is existed in the 2nd floor middle node. As showed in Fig. 8, when removing member set (5,15,18), member 9, 10 lack enough restraint. If the removal of member 9, 10 has no side influence on the residual system, it works well and the principle stress figure is in Fig. 9.

Among other damage scenarios with the failure of three members, the 15th most vulnerable scenarios showed in Table 4, are the member set of (2 columns+1 brace) or (1 columns+2 brace) while the initial failed members do not include any beam member; the 6th most vulnerable scenarios are the member set of (1st floor side column + 2 braces).

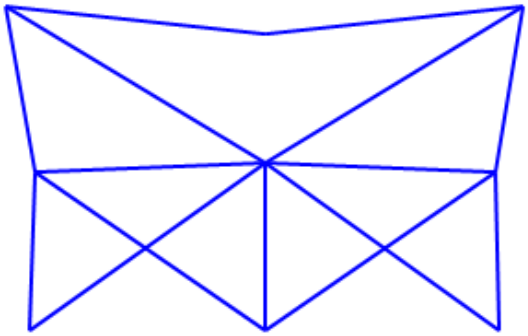

Fig. 8 Local mechanism in damage scenario (5+15+18)

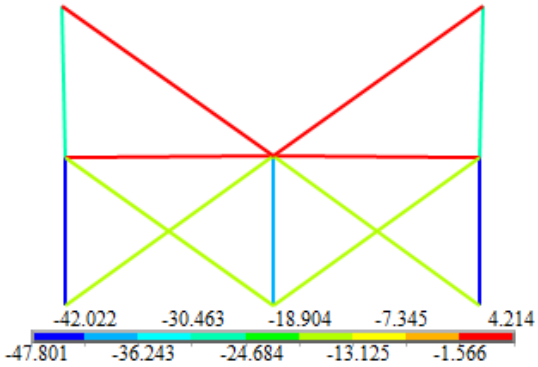

Fig. 9 Principle stress the residual system

Table 4 Analysis result of damage scenario ($k$=3)

| Scenario No. | Member Set | $E_r$ | $D_r$ | $VI$ |
|---|---|---|---|---|
| 3-1 | (3,13,17)/(1,12,16) | 0.704 | 0.052 | 13.476 |
| 3-2 | (1,12,17)/(3,13,16) | 0.703 | 0.052 | 13.459 |

| 3-13 | (4,5,15)/(5,6,18) | 0.721 | 0.069 | 10.446 |
| 3-14 | (5,15,16)/(5,17,18) | 0.533 | 0.052 | 10.215 |
| 3-15 | (2,4,15)/(2,6,18) | 0.696 | 0.069 | 10.083 |

### Damage Scenario with the Initial Failure of Four Members

The truss is 4th statically indeterminate structure, so a bunch of damaged structures after the removal of four members lose the geometric stability and the index $VI$ goes to infinity. Some failure scenarios are listed in Table 5. For member set 4-1 (1,2,11,12), the deformation of new system is showed in Fig. 10, and the system is going to collapse.

### Influence of Load Distribution

A specified member has different contribution to the bearing capacity of the structure under different loading conditions, and the level of loading re-distribution is different as well. So it is necessary to

discuss the difference of vulnerability index under different loading conditions. The load set mentioned in the previous section is defined as LS1, while the load set of LS2 is illustrated in Fig. 11.

Table 5 Damage scenario ($k$=4)

| Scenario | Member Set | Scenario | Member |
|---|---|---|---|
| 4-1 | (1,2,11,12) | 4-6 | (1,5,7,17) |
| 4-2 | (1,2,11,13) | 4-7 | (1,5,15,18) |
| 4-3 | (1,2,12,14) | 4-8 | (1,7,9,12) |
| 4-4 | (1,5,6,7) | 4-9 | (1,7,9,15) |
| 4-5 | (1,5,7,10) | 4-10 | (1,9,12,15) |

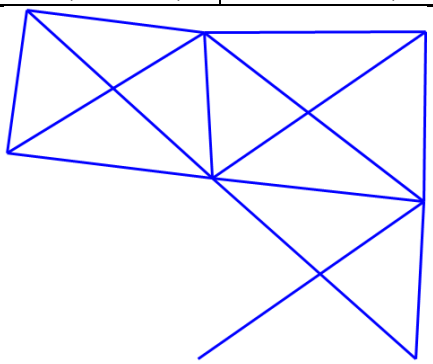

Fig. 10 Deformation of new system under member set 4-1

Table 6 Comparison of importance factor

| LS1 | | LS2 | |
|---|---|---|---|
| Member No. | $E_r$ | Member No. | $E_r$ |
| 1 | 0.274 | 1 | 0.358 |
| 3 | 0.274 | 3 | 0.358 |
| 2 | 0.145 | 4 | 0.115 |
| 5 | 0.034 | 6 | 0.115 |
| 4 | 0.015 | 2 | 0.024 |
| 6 | 0.015 | 5 | 0.000 |

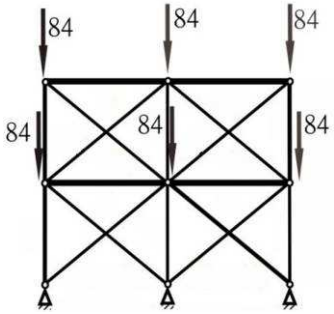

Fig. 11 Load set of LS2(unit: kN)

This section is to discuss the importance factor and VI index under 2-member removal scenario. Table 6 gives the importance factor of member under two loading conditions. The similarity is that the 1st floor side column is the most significant member and makes the largest contribution to structural safety.

The difference includes: 1) In LS1, the rank of most important members is 1st floor side column>1st floor middle column>2nd floor middle column>2nd floor side column>beams & braces, while in LS2, the rank of most important members is 1st floor side column>2nd floor side column >1st floor middle column>2nd floor middle column & beams & braces; 2) The largest importance factor $E_r$ in LS1 is 0.274 while that in LS2 is 0.358, much larger than the former one; 3) The importance factor of 2nd floor middle column in LS1 is 0.034 while that in LS2 is 0, which means the removal of 2nd floor middle column under the load set LS2 is under the structure redundancy and has little influence on structure safety.

The similarity in $VI$ analysis under two member removal scenarios includes that the local mechanism is formed in 2nd floor side point in both load set.

The total number of scenarios with $VI$>0 under two member removal is respectively 43 and 39. Among 29 scenarios, vulnerability index $VI$ in LS1 is less than that in LS2, while among10 scenarios $VI_1$>$VI_2$.

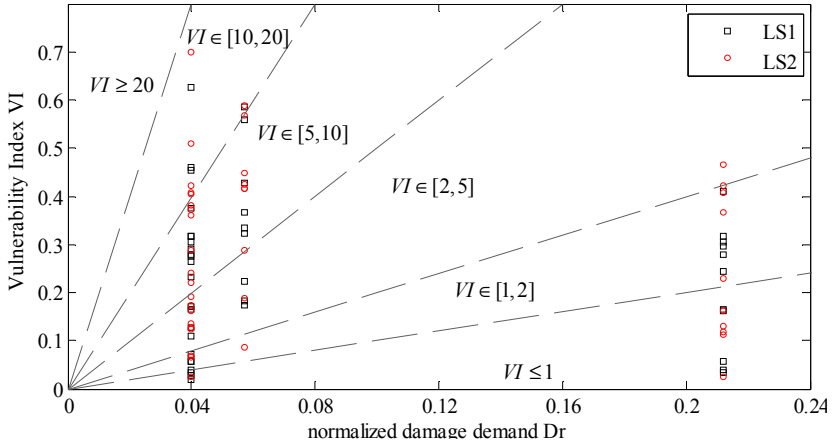

Fig. 12 The risk level map under damaged scenarios of one and two member removal

The risk level map under damaged scenarios is illustrated in Fig. 12, which showed that: 1) when $VI \in [10,20]$, the maximum *VI* in LS1 is larger than that in LS2, 2) the number of damage scenarios in each risk division is similar, 3) with the same normalized damage demand, the scenarios with the maximum and minimum *VI* are both under the load set LS2.

Under two different load set, member importance factor ranks differently. Importance factor of 1st floor middle column in LS1 is 5.1 times of that in LS2, but the general principle is similar that the column is much important than beam and brace. Among two-member removal scenarios, the maximum difference in *VI* under two load sets is 5.7 times; the most vulnerable scenarios is the failure of member (1+15), and the total number of scenarios in each risk division is similar.

According to the previous analysis, the load set in the structure has great influence on the member importance factor and vulnerability index of damage scenarios. So it is essential to consider accurately the load distribution in order to reach correct conclusion about vulnerability assessment.

## Conclusion

The method of structural vulnerability assessment presented in this paper is closely in accordance with the definition based on two aspects, strain energy of structure and damage demand of members.

1. The search process of hazard scenarios was carried out by an example of truss structure, and the results of analyses were including important factor of members, hazard scenarios with the minimum number of killed members, and local damage occurred in advance.

2. The influence of loading on member importance factor and vulnerability index is discussed and it shows that though with the agreement of general trend, the rank of importance factor or VI under a specified scenario varies greatly. So it is essential to consider accurately the load distribution in order to reach correct conclusion about vulnerability assessment.

3. The analyses could be utilized as the proof of measurement to enhance structural capacity of the truss to bear the extreme event. It also could be extended to the frame or more complex system since the assessment process is similar, but some aspects like the selection of parameter to stand for structural performance, the measurement of structural failure, and the simulation of member failure need to re-consider.

**Keywords:** reservoir; Hongyanzi landslide; multi-parameter monitoring; ground water; deformation prediction

**Abstract:** Hydropower reservoirs change the local geo-environment greatly and often induce reservoir bank landslides. Hongyanzi landslide is a large rejuvenated ancient landslide in Pubugou Hydropower Station reservoir area in western China Sichuan Province. To study the deformation of the Hongyanzi landslide, we arranged multi-parameter monitoring using GPS, fixed borehole tilt-meter, osmometer, and crack-meter and collected continuous data of displacement and ground water table. The monitoring data, together with the reservoir water level data, show that the landslide deforms obviously during reservoir water level is falling, while it deforms little in the other period. Comprehensive analysis of the deformation and reservoir water level implies that the seepage force caused by water level difference between the inner and outer slope may be the key factor. Through regression analysis, the authors established a forecast model for landslide deformation based on ground water table and reservoir water level; thus concluded that reducing the falling velocity of reservoir water level may slow the landslide deformation down.

## Introduction

A large amount of hydropower stations were built in recent years in China, and many of them have a large reservoir to preserve water energy. During the running of hydropower plants, reservoir water level will change periodically. The cycling change of reservoir water level induces many reservoir bank landslides. According to the study, more than 90% of reservoir bank landslides are closely related to the fluctuation of reservoir water level[1]. About 40-49 % of reservoir-induced landslides occur in the rising period of reservoir water table, while 30-60 % of them occur in the dropping period. Large reservoir bank landslides often take place when the water level drops rapidly[2-5].

More than 75% of reservoir bank landslides are rejuvenated ancient landslides[6]. The reservoir bank landslides are very harmful, due to release of a large amount of rock and soil into the reservoir, reducing the reservoir capacity, and they can even produce huge water wave when sliding with high speed.

Hongyanzi landslide is a typical reservoir-related landslide in Hanyuan County, Sichuan Province. To investigate the deformation and the main impact factors of the landslide, a multi-parameter monitoring network was installed in the sliding body; detailed data of surface movement, deep movement, and ground water level were measured.

## General settings

Hongyanzi landslide is located in the right bank of Dadu River, a secondary tributary of the Yangtze River. The landslide is about 23km away from the Pubugou Dam (Fig.1).

The slope of Hongyanzi landslide area is 20-30° in average with a steep head scarp about 40-50°. The general shape of Hongyanzi landslide is irregular half-round. The sliding direction is about 340° (Fig.2). The altitude of Hongyanzi landslide ranges from 954 meter above sea level (masl) to 810 masl, the length is 600m, and the width is 580m. The thickness of the landslide is about 20-50m, thicker in the front part and thinner in the rear part. The volume of the landslide is about $7.5\times10^6 m^3$. The sliding surface is relatively flat in the front and steep in the rear (Fig.3). The left and right boundaries can be identified easily in the field because of the distortions up to 1.7m vertically of the Lake Road.

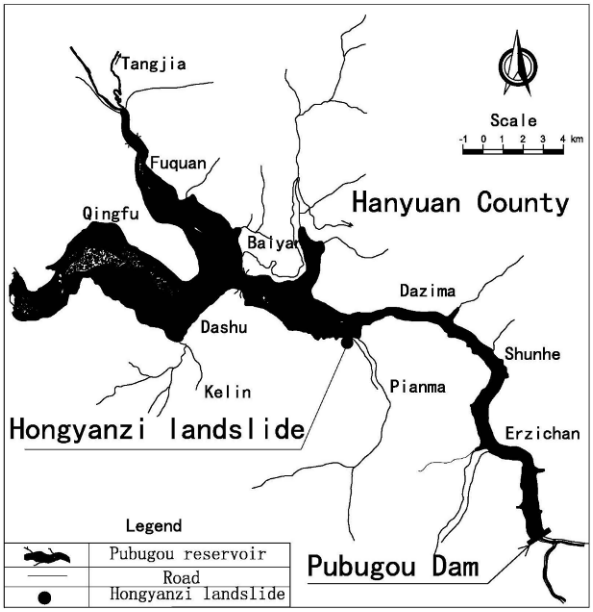

Fig.1 Location of Hongyanzi landslide

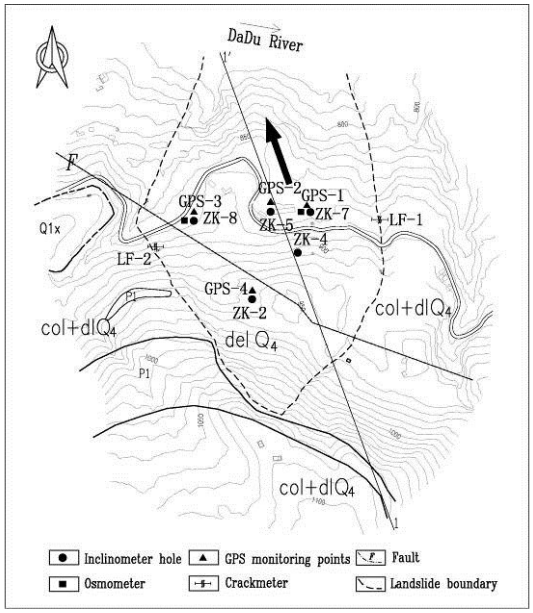

Fig.2 Setting of monitoring apparatus

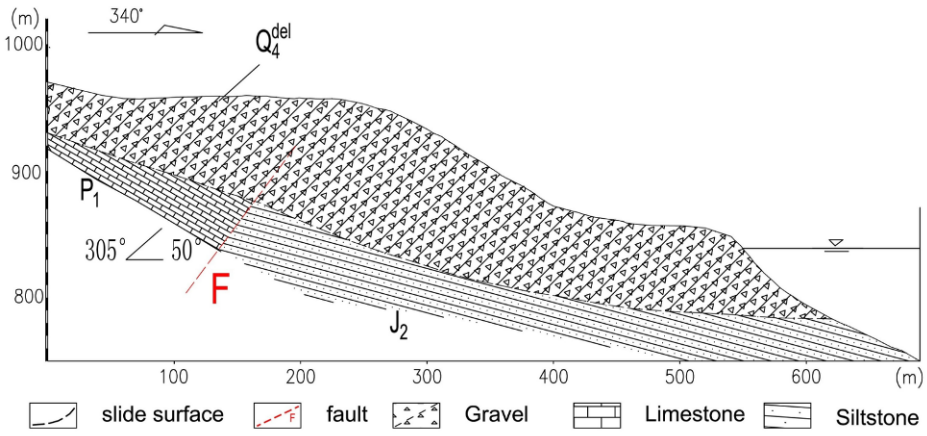

Fig.3 Geologic profile of Hongyanzi landslide

According to the investigation, Hongyanzi landslide is an ancient landslide. The sliding body consists of Quaternary gravel, silty clay, and many boulders with diameter of 1-3m in the body. The gravel and boulders are mostly fractured limestone, with a compact structure. The stratum of sliding bed is Jurassic reddish sandstone in the footwall of Hanyuan-Zhaojue fault, and Permian limestone in hanging wall of the fault[7,8].

The hydrogeological condition of the Hongyanzi landslide area is relatively simple. The ground water is mainly phreatic water, and the main recharge is from precipitation. The topography is very steep, facing the Dadu River in the north, and gullies in the east and west, which is convenient for the ground water to discharge. So the ground water table is very low. The water level of hydropower reservoir varies from 790 to 850masl; the largest landslide submerged height is about 55m. The fluctuations of reservoir water level have a great impact on the groundwater table.

Hongyanzi landslide was in an overall stable state before the Pubugou reservoir was built. When the water filled the reservoir, landslide deformation started. The reservoir began to store water and the power plant started operation in November 2010. Hongyanzi landslide deformed significantly in February 2011; the displacement was up to 1-2m. Significant deformation occurred again in 2012 when the reservoir water level dropped. The maximum displacement exceeded 2m during March-May 2013. But in the rising periods of the reservoir water level, the deformation slowed down, and the landslide came into a relatively stable state again.

## Multi-parameter monitoring

A multi-parameter monitoring system was installed in Hongyanzi landslide at the end of 2012, in order to study the deforming characteristics and influencing factors. The apparatuses include 5 GPS receivers (4 as the measurements and 1 for reference), fixed tiltmeters (three boreholes in the

mid-front: ZK5, ZK7 and ZK8), and osmometers (also in ZK5, ZK7 and ZK8), crack displacement meters (near the left and right boundaries), and a rain gauge. Manual measurement using a tiltmeter at ZK2 and ZK4 is also arranged. The setting map is shown in Fig.2.

The measurement started since the end of 2012. In this paper, datasets of different monitoring apparatuses were chosen, to study the principles of the deformation of the Hongyanzi landslide.

**Rainfall.** The rainfall of the landslide area is up to 250mm from January to June. There is barely effective rain before the middle of March. Two precipitation events over 50mm occurred in March 26 to April 12 and 19-26 June, respectively. The maximum daily rainfall, up to 40.8mm, appeared on June 30. The second largest daily rainfall is 23.1mm, took place on May 24. For both rainfall processes, no significant deformation of the landslide was monitored.

**Ground water table.** An osmometer was installed at ZK5, near GPS-2; it measured the groundwater table. Because of the borehole depth, we got ground water table data above 825 masl (Fig. 4). There is a positive correlation between groundwater table of ZK5 and the reservoir water level. From October 2012 to April 2013, the reservoir water level kept dropping, the ground water table of ZK5 was also descending. The descending speed of groundwater table of ZK5 was almost equal to that of reservoir water level before February 2013. After that, the dropping of reservoir water level accelerated, the difference between groundwater and reservoir water increased. From May 2013, the reservoir began refilling and the groundwater table of ZK5 also rose slowly.

**Surface displacement.** Four sets of GPS were installed on the landslide. GPS data and reservoir water level are shown in Fig.5. The total displacement from January to June is up to 1800mm. The value from GPS-1(right front) is the largest, then GPS-4(middle rear), GPS-2(middle front), the value from GPS-3(middle left) is the smallest. The data from GPS-1, GPS-2, and GPS-3 show the same change pattern, with a moving direction of NNW22-24°. Date from GPS-4 show a vertical-dominate displacement, probably induced by the local relief near the measuring site.

A positive correlation between the surface displacement and reservoir water level is observed here again. Before February 2013, the reservoir water level dropped slowly and steady, the surface displacement was very small. During March to April, with the reservoir water dropping speed rising, surface displacement accelerated, with a daily increase up to 60mm. From May on, with the reservoir began refilling, the surface displacements slowed down.

**Other data.** The data acquired from tiltmeters at ZK2, ZK4 and ZK7 and crack displacement meters near left and right boundaries also show a spontaneous change pattern with the reservoir water level, i.e., relatively stable before February, accelerating during March-April, and slowed down again in May-June (Fig.6 and Fig.7).

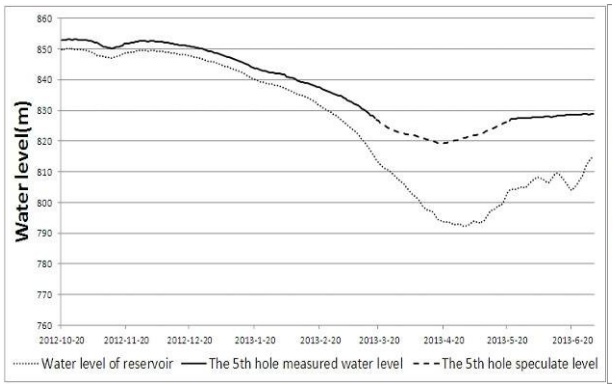

Fig.4 Reservoir water level and ground water table at ZK5

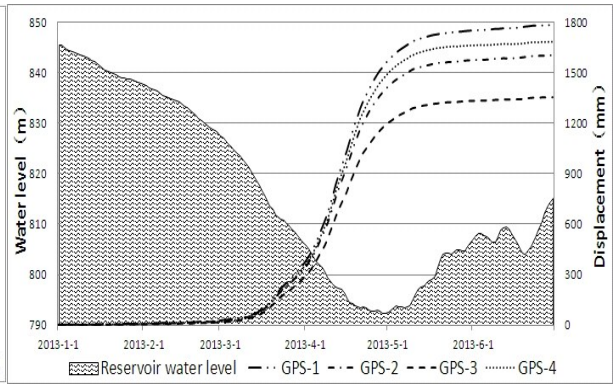

Fig.5 Reservoir water level and GPS Displacement

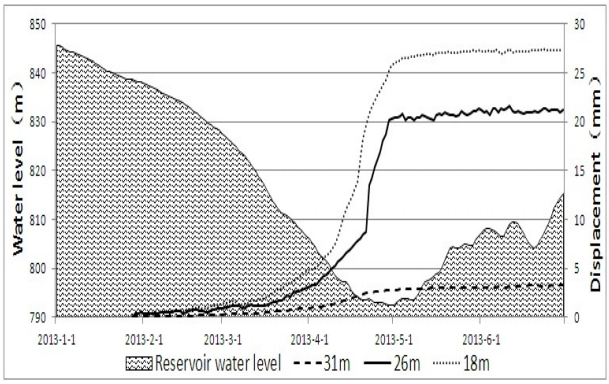

Fig.6 Reservoir water level and deep displacement of ZK7

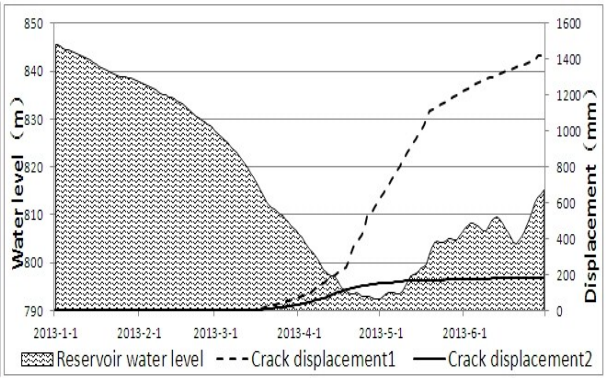

Fig.7 Reservoir water level and crack displacement

The epicenter of the April 20, 2013 Lushan MS7.0 earthquake was about 100km from Hongyanzi landslide. The seismic intensity in the landslide area was about VI degree, the maximum seismic acceleration nearby was about 0.4g[9,10]. GPS and deep tiltmeter measurements did not show significant deformation during the earthquake. The crack displacement meters showed a little bit quicker movement of 50mm in the right boundary and 10mm in the left boundary which may be resulted in the local relief response to the earthquake.

**Deformation forecasting of Hongyanzi landslide**

The monitoring data show that the landslide deformation starts significantly when the reservoir water level dropping speed reaches a certain value. The mechanisms behind this may be as the following. When the reservoir water level drops, the ground water in the landslide drops as well. However, because of the limited permeability of landslide mass, the groundwater table cannot drop as fast as that of the reservoir water level does. So the difference between reservoir water level and ground water table increases and the seepage pressure in the landslide body also increases, it seems

to be this increased seepage pressure that reduces the stability coefficient, and the landslide starts to deform. This phenomenon is distinct especially when the permeability of rock mass is low（11-14).

The surface deformation and the difference between the reservoir water level and the ground water table of ZK5 is plotted in Fig.8. When the difference is less than 7m, the deformation is very small. The deformation accelerates with the difference growth. The changes can be fitted with equation 1 and the fitting coefficient ($R^2$) is 0.91.

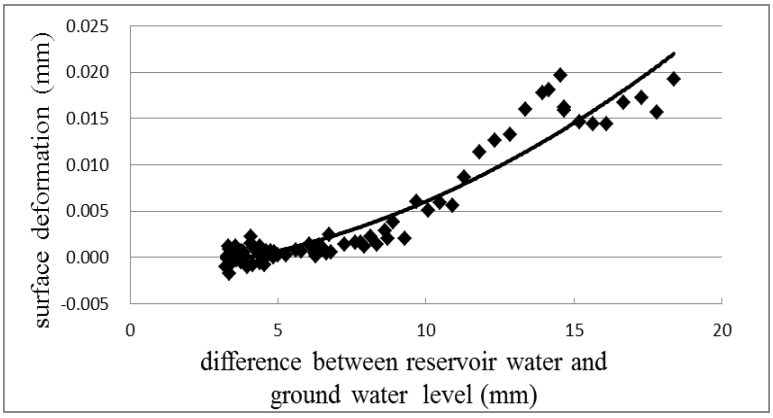

Fig.8 Relationship between surface deformation and the difference between reservoir water level and ground water table of ZK5

The regression equition in Fig.8 is:

$$D_n = 6\times10^{-5}\times(B_n-A_n)^2+0.0001\times(B_n-A_n)-0.0015 \quad (1)$$

where $D_n$ is the deformation value of day n, $B_n$ is the ground water table of ZK5 of day n and $A_n$ is the reservoir water level of day n.

The difference between reservoir water level and ground water table can be derived through the following linear fitting (data are shown in Fig.4):

$$B_n - A_n = 1.019\times(B_{n-1}-A_{n-1}) + 0.448\times (A_{n-1}-A_n) – 0.154 \quad (2)$$

From (1) and (2), we got:

$$D_n = 6\times10^{-5}\times(1.019\times (B_{n-1}-A_{n-1}) + 0.448\times(A_{n-1}-A_n) - 0.154)^2 + 0.0001\times(1.019\times(B_{n-1}-A_{n-1}) + 0.448\times(A_{n-1}-A_n)-0.154) - 0.0015 \quad (3)$$

Thus, we can get the pricipited deformation value in one day ahead.

We can also tell that, in order to lower the expected deformation value, we can reduce the speed of the reservior water level dropping ($A_{n-1}$-$A_n$ in equation 3).

## Conclusions

Through this study, we can draw the following conclusions:

(1) Hongyanzi landslide deforms significantly when the reservoir water level drops fast and the maximum deformation is up to 1800mm. The influences from rainfall and Lushan Earthquake are relatively small.

(2) Seepage pressure due to the difference between reservoir water level and ground water table plays a key role in landslide deformation.

(3) We put forward a formula to predict the landslide deformation on day in advance, using quadratic fitting.

(4) The landslide deformation can be relieved to a certain degree by lowering down the dropping speed of reservoir water level.

**Keywords:** single-layer cable, mechanical performance, glass breakage, critical temperature, fire-resisting design

**Abstract:** High-strength prestressed cables were main bearing parts in single-layer cable mesh point-supported glass curtain wall structures, and it was always unable to take effective fire prevention measures on steel cables due to small sections. That the elastic modulus and yield strength of prestressed cables decreased sharply under fire conditions would threaten safety performance of the whole structure seriously. When glass breakage is considered and not considered, nonlinear finite element complete-process analysis for the single-layer cable mesh point-supported glass curtain wall structure was conducted. Influences of various factors on structure mechanical performance were studied under fire conditions. Through the calculation analysis of different joint constraint models, the ultimate temperature table suitable for different sizes and cable spacing of glass curtain walls was obtained under uniform heating conditions, and proposals for fire-resisting design were given.

## Introduction

The single-layer cable mesh point-supported glass curtain wall structure (Gu, Hao, and Luo, 2011) provides spacious internal space, and it can be constructed easily and conveniently. As a kind of new large space building structure, it represents the developing trend of large-dimensional curtain wall structures.

The single-layer cable mesh point-supported glass curtain wall structure adopts the prestressed cable system to provide the initial stiffness. Not only the performance of steel cables (Perrin, Gaillet, and Tessier, 2010) and glass (Samuel, et al, 2007; Kai, 2009; Popea and Bailey, 2007), but also the synergistic effect (Wang, 2008; Gao, and Hu, 2011) between steel cables and glass under different joint constraint models should be considered when making the design of the structure. The elastic modulus and yield strength of high-strength prestressed cables decreases significantly (Bai, et al, 2010), and glass breaks at a different degree under fire conditions. Both lead to mechanical performance of the whole structures changing distinctly. Mechanical performance of the single-layer cable mesh point-supported glass curtain wall structure under fire conditions was studied when glass breakage is considered and not considered in this paper.

## Finite element analysis of the glass curtain wall structure

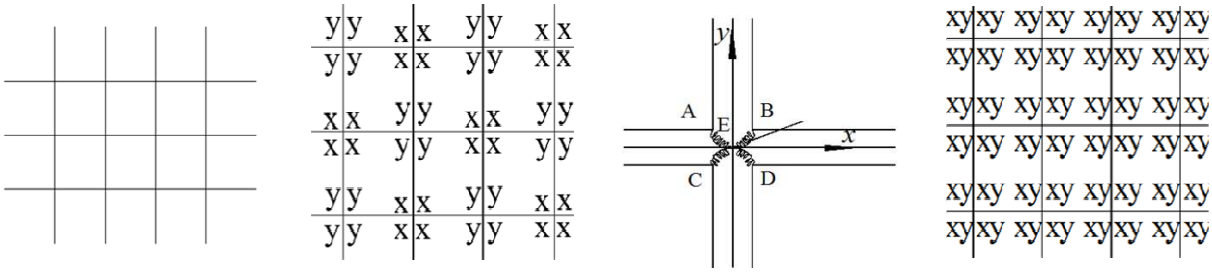
### Numerical calculation model

The diameter of steel cables simulated by LINK10 takes 16mm in calculation models. The glass panel is simulated by SHELL181, and the tension-compression spring by COMBIN14. The deadweight of curtain wall connectors and glass take 0.2kN/m2 and 0.26kN/m2 respectively. Horizontal load takes 1.0kN/m2.

Two kinds of temperature rising models are calculated depending on different fire locations. All steel cables are regarded to be uniformly heated up to 600℃ when the fire is far away from the glass curtain wall. When the fire is close to the glass curtain wall, the steel cables close to the fire are considered to be heated to 600℃ quickly, and others to 100℃.

Three kinds of joint constraint models (Wang, et al, 2007; Yin and Zhang, 2004) are calculated in this paper, including cross coupling (CPM1), tension-compression spring (CPM2) and fully coupled model (CPM3). CPM0 is the joint constraint model without considering the effect of glass panels, as

shown in figure 1. According to the development situation of the glass curtain wall in recent years, five kinds of glass curtain walls are chosen in this paper, numbering A, B, C, D, E, as shown in table 1.



(a) CPM0 (b) CPM1 (c) CPM2 (d) CPM3

Figure1 Joint constraint models between glass and supported system

Table1 Sizes of the curtain wall

| Number | A | B | C | D | E |
|---|---|---|---|---|---|
| Cable space (m) | 1 | 1.5 | 2 | 1 | 2.5 |
| The curtain wall area ($m^2$) | 15×15 | 15×15 | 20×20 | 10×10 | 20×20 |

**Failure criterion**

The single-layer cable mesh point-supported glass curtain wall structure is regarded as destruction under the following cases. 1) Global displacement of the curtain wall is greater than 1/50 of the span (Jussi, 1999; Rice and Hugh, 1995), 2) The temperature of glass is greater than 450℃,3) The cable stress is greater than 844MPa.

**Mechanical performance of the glass curtain wall under fire conditions without considering glass breakage**

**The influence of joint constraint on the glass curtain wall global displacement**

The initial stress of horizontal and vertical cables takes the same value, 90.6kN, in calculation models. The displacement variation of different joint constraint models under fire conditions is shown in figure 2.

According to figure 2, when the overall sizes of glass curtain walls are the same, glass curtain wall displacements decrease with decreasing of cable spacing. And glass curtain wall displacements decrease with the overall sizes decreasing when the cable spacing is kept the same. The steel cable displacements under the non-uniform heating conditions are greater than that under the uniform heating conditions. The reason is that the cable stiffness decreases uniformly under the uniform heating conditions, and the global stiffness is smaller than that under the non-uniform heating conditions.

Under conditions of the same temperature and section area, the stronger the joint constraint is, the smaller the curtain wall displacement is. The case of that glass curtain wall displacements without considering the glass rigid effect are smaller than that with considering the glass rigid effect occurs at the low temperature range. The reason is that concentrated loads are applied at the cable nodes when without considering the glass rigid effect, and uniform loads are applied on the glass panels when considering the glass rigid effect.

**The critical temperature value of the curtain wall without considering the glass breakage effect**

L/50 is used as the ultimate displacement of the single-layer cable mesh point-supporting glass curtain wall structure under fire conditions (L is the span of the curtain wall). The ultimate temperature of glass is 450℃, and the glass curtain wall is considered to have been broken when the glass temperature is greater than 450℃. The critical temperature takes the smaller value between 450℃ and the temperature value corresponding to the displacement of L/50, as shown in table 2.

| E | — | — | — | 432 | 450 | 450 |

**Mechanical performance of glass curtain wall structures under fire conditions with considering glass breakage**

The glass panels participate in structural bearing, and have a certain influence on the structure rigid. Under fire conditions, that a part of glass in curtain walls breaks will lead to the variation of global and localized rigid of the structure. So the study of mechanical performance on single-layer cable mesh point-supported glass curtain walls after glass breaks still has a great significance. Two kinds of joint constraint models, CPM1and CPM2, are calculated in this paper.

**Cable mesh force analysis after glass breaks**

The largest cable forces when the effect of glass breakage is considered are shown in table 3-6.

The calculation results show that the largest cable force under non-uniform heating conditions is greater than that under uniform heating conditions. But, the cable force variance is smaller than that of the latter after glass breaks. For the CPM1 joint constraint model, the largest cable forces after glass broke increase 33.33% uniformly than that before glass breaks under uniform heating conditions. However, under non-uniform heating conditions, this value is just 4.75%. The reason is that a small rigid area has been existed in the cable mesh before glass breaks under non-uniform heating conditions, so glass breakage can't lead to the largest cable forces changing significantly.

Table 3 CPM1: the largest cable force under uniform heating conditions (kN)

| State of the glass | A | B | C | D | E |

**Displacement analysis of the single-layer cable mesh point-supported glass curtain structure after glass breaks**

The displacements of glass curtain walls are calculated by ANSYS, and the calculation results are shown in table 7-10.

The data in table 7-10 show that glass breakage has little effect on displacements of glass curtain walls under uniform heating conditions. For the CPM1 joint constraint model, the curtain wall displacements will decrease at an instant with glass breaking under non-uniform heating conditions. The largest reduction rate reaches 21.6%, while the displacements keep mostly unchangeable under the condition of the CPM2 joint constraint model. The reason is that mechanical performance of the structure changes because of glass breakage. There are only steel cables participating in structural bearing after glass breaks, and the global displacements tend to increase. At the same time, glass

breakage leads to the external load, especially the wind load, decreasing, and the global displacements tend to decrease.

Table 7 CPM1: curtain wall displacements under uniform heating conditions (mm)

| State of the glass | A | B | C | D | E |

**Influence of factors on curtain wall mechanical performance under fire conditions**

Glass size has a great influence on global rigid of glass curtain wall structures. When the global size of the glass curtain wall is determined, the glass size is larger, the number of steel cables is smaller, and the global displacement of the structure is larger. And the security of the glass curtain wall structure will decrease. Under the non-uniform heating conditions, the global displacement of the B glass curtain wall structure is 38% larger than that of the A glass curtain wall before glass breaks, and this value is 41% after glass broke.

The larger the joint constraint rigid is, the smaller the global displacement of glass curtain wall structure is. Under uniform heating conditions, the uniform global displacements of five kinds of glass curtain walls with CMP2 joint constraint model (k=105 N/m) is 48% greater than that of glass curtain walls with CMP2 joint constraint model (k=107 N/m). And this value is 34% under non-uniform heating conditions. However, when the joint constraint rigidity is too high, the glass panel deformation will be restricted remarkably under fire conditions, and the deformation of glass panels and the cable net will be very different. Glass panels will lead to structural displacement increasing and cause unfavorable effect. Therefore, the joint constraint rigidity should not be designed too stiffed in order to insure fire-resisting performance.

Glass panels have a certain contribution on the structure stiffness. The glass breakage will lead to mechanical performance of the whole structure changing distinctly during fire heating process. Therefore, the finite element analysis when glass breakage is considered can simulate the real situation.

**Conclusion**

1) When the joint constraint rigidity is high, it will always lead to fragmentation of glass panels and large structural displacement with the rise of temperature. The joint constraint rigidity should not be designed too stiffed in order to insure the fire-resisting performance.

2) The largest cable force under non-uniform heating conditions is larger than that under uniform heating conditions, which leads to single-layer cable mesh point-supported glass curtain walls breaking more easily.

3) The structure global displacements continue to decrease with the temperature rise. Through the calculation analysis of different joint constraint models, the ultimate temperature table suitable for

different sizes and cable spacing of glass curtain walls was obtained under uniform heating conditions, as shown in table 2.

**Keywords:** 3S, geological disaster, 3D model, ArcGIS.

**Abstract:** This paper absorbs much successful experience from geological disasters database system designed and built at home and abroad, based on remote sensing (RS), geographic information systems (GIS) and GPS technology, adopt AHP, fuzzy comprehensive evaluation model and method of establishing three-dimensional model of geological disasters in high-risk areas, the paper constructs geological disasters database system in Liaoning Province, this database system can manage and monitor geological disasters and provide strong support analysing geological disasters for Liaoning province areas.

## Introduction

Geological environment is very complex and natural variation is intense in Liaoning province so it is one of provinces which is easily suffering from geological disasters in China. Geological disaster features have many types, extensive distribution and great harmfulness. Geological disaster types are mainly ground fissure, land subsidence, landslide, debris flow, etc. At present, there are 6448 checked hidden trouble areas of geological disaster in the whole province while there are 1685 land subsidence areas, 535 landslide areas, 1759 debris flow areas, 1497 land collapse areas, 157 ground crack areas and 1742 unstable slopes.

Geological disaster causes harm to people's lives as well as property and influences urban planning layout in Liaoning province, efficient utilization of land and rational exploitation of underground space so it has become a non-negligible factor to restrict economic and social sustainable development in Liaoning province. In order to actively and effectively develop geological disaster prevention work, take feasible prevention measures, avoid and reduce losses which are caused by geological diaster to people's life and property, it is necessary to apply advanced technology to set up a comprehensive functional geological diaster database system and realize science, information, standardization and visualization of geological disaster prevention management.

In recent decades, 3S technologies (geological information system(GIS), global positioning system (GPS), Remote sensing (RS)) are extensively applied in geological diaster investigation and prevention field, which achieves better effect.He Zhengwei [1],etc, apply remote sense and GIS technology to study comprehensive broadcast on landslide stage, landslide region danger evaluation method and establish geological disaster determination supporting geographical information system in Tianshan highway.Tang Chuan[2], etc, applies p5 remote sensing data after Wenchuan earthquake, aerial remote sensing data after earthquake and SPOT5 after Septermber 24th storm to carry out remote sensing investigation and analysis on source area features of Beichuan debris flow and perform dynamic monitoring on three classical areas(Tang jiashan-Beichuan, Jiaba, Leiguzhen) in high seismic intensity area in WenChuan.In Oct,19th 2011, 3S-based technology three gorges reservoir area 1:10000 disaster geological map compilation and database construction program accomplishes acceptance. 1:10000 disaster geological maps are completed and database construction is completed according to technology requirement. All data are put in base and they can complete seamless integration with geological disaster prewarning commanding system.

In this paper, remote sensing image processing platform in American Exelis Visual Information Solutions company is applied to process multi-temporal and high accuracy remote sensing image.

This paper uses GPS R4 receiver which adopts point-to-net to perform accuracy monitoring in geological disaster areas in American Trimble company and utilize commercial GIS software platform Arcgis10.0 in ERSI company to establish multi-source fusion geological disaster database system which takes visual studio 2010 as the developed environment.

## System Design

1.Data Preparation

Geological disaster data in Liaoning province mainly contain 1:500000 geological disaster distribution map (whose format is *.jpg) in Liaoning province in 2008, remote sensing image data and monitoring point data of GPS sampling. Geological disaster distribution map in Liaoning province performs division rendering on geological disaster types and development in Liaoning province and it marks the suffered geological disaster position and types in detail.From this map, Liaoning province belongs to frequent occurrence area including collapse, landslide and debris flow. Remote sensing data are mainly recent 3-year-landsat satellite data in eastern region of Liaoning province and QuickBird satellite data in some high risk regions. Remote sensing data process is divided into two aspects: at one aspect, envi4.8 is applied to interpret remote sensing data. At the other aspect, remote sensing data after explanation is introduced into ArcMap to edit, process and update image data and attribute data in database system. In order to accurately construct 3 dimensional model, GPS receiver is applied to net-arrangement monitor monitoring points which are designed in high risk area .

2. Systematic Overall Framework

According to practical requirements, geological disaster database system in Liaoning province is divided into four layers: users' interface layer, functional module layer, technological supply layer and data layer (refer with: Fig. 1).User interface layer is the layer that system directly faces users. Through various functions which are provided by interface, users can operate in visualization to check geological disaster situation in various regions of Liaoning province, query, analyze and perform statistics on geological disasters.Function module layer is various functions of system realization which contains data management, map operation, query analysis, geological disaster evaluation, 3 dimensional display, etc. Technology support layer is technological means which is used during systematic development (i.e. database access technology), advanced programming language (VS2010) and assistant software. Geological disaster information has features of multi-sources, non-determinacy, random abruptness, etc. It is essential for geological diaster database system to establish a database which can fuse multi-source data and database is the basis for system to develop and operate.

3 .Main Function Modules

This system applies 3S technology, adopts multi-source data fusion method and solves difficulties including huge data quantity of geological disaster and strong timeliness as well as spatiality of data. The system also performs mutual query, spatial analysis and statistical analysis on geological disaster data and studies spatial distribution, change tendency and inducing factors. This is the main function for system realization.On the other hand, attribute data based on database in system utilizes hierarchy method to determine various index weight.it adopts fuzzy comprehensive evaluation model to combine GIS technology to establish geological disaster risk evaluation model and to perform hazard analysis as well as evaluation on geological disaster in Liaoning province. It uses combined generating three dimension image model of DEM which is generated by high-definition two-dimension remote sensing image (QuickBird) and GIS platform. It carries out multi-view angle and multi-scale dynamic monitoring on geological disaster in high risk area. These are assistant functions of system realization.

In order to effectively realize system functions, this system mainly designs data management, query analysis, map operation, risk evaluation and three dimension image for users.

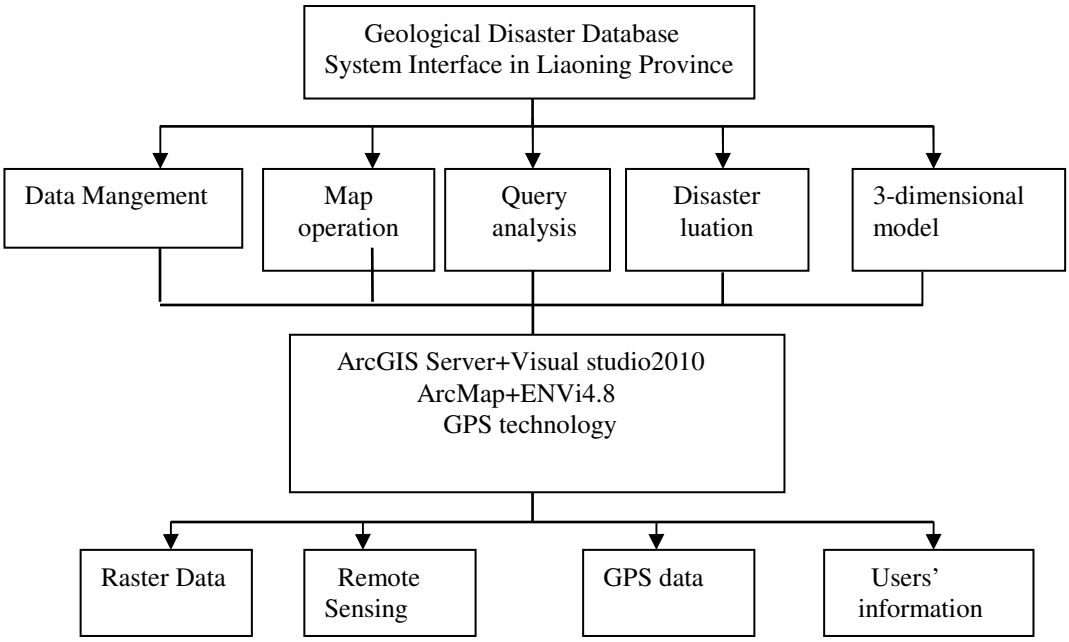

Fig.1 Overall Framework Figure in System

**Systematic Key Technology**

1. 3S-based Technology Integration

3S refers to remote system, global positioning system and geographic information system. 3S integrated technology refers that RS, GPS and GIS are integrated a united organism and it is a very effective space information technology.

Geological disaster information has multi-sources, timeliness, spatiality and random abruptness. In addition, geological disaster needs huge data quantity, these factors become a bottleneck which restricts development and application of geological disaster database system.

In order to solve this problem, this system applies 3S technology to design and research of geological disaster database system in Liaoning province. 3S integration will promote GIS to obtain the ability of accurate acquisition and rapid positioning on current remote sensing information. It can realize rapid updating of database. Under support of analyzing decision model, GIS can rapidly complete multiple dimensions and multiple elements compound analysis .GPS can rapidly and accurately realize precise positioning of disaster area, border characteristic point positioning and observing subsidence observation point. It imports results into space database to provide accurate point-source information for space information analysis of geological diaster. With 3S integration technology, this system can utilize large-area synchronized observation as well as interpretation of remote sensing data, GPS high accuracy and observation and real-time observation and apply functions of GIS platform intelligent analysis, 3 dimension modeling, decision support, etc to construct 3S-based technology geological disaster database system in Liaoning province.

2. ArcEngine Technology

ArcGIS Engine is the new product of ESRI based on ArcGIS9 version. It is a set of complete embedded GIS component library and tool library. It uses GIS application program which is developed by ArcGIS Engine. Meanwhile, it can be operated without ArcGIS Desktop. Using ArcGIS Engine development kit can realize browsing map, query analysis, layer rendering, map layer displaying thematic map, dynamic drawing real-time data, etc.

This system adopts ArcEngine+Vb.net redevelopment method, that is, .net language as programming development language of ArcEngine. At first, through ArcMap to edit, processing multi-source data to generate map, the developed system of ArcEngine+Vb.net is applied to perform query analysis on the generated map data to produce various thematic map and finally constructs model to perform risk evaluation.

## System Realization

1. System Development Environment and Equipment

System adopts object-oriented interface design and uses ArcGIS10.0 series software as development platform. In Vs2010 environment, target-oriented Visual Basic.NET language is applied to develop and system makes use of ArcSDe spatial database engine to store and manage space map data and two dimensions and three dimension map data are made through desk software such as ArcMap and ArcGlobe.

2. Main Interface of System Realization

In order that users can rapidly master geologic disaster database system in Liaoning province, system adopts simple and intuitive interface style. Under condition that interface elements are consistent, according to principle of prominent key-point and clear level, approximate Windows application programming interface is designed.System interface contains 12 forms which are main interface, overlay analysis, SQL query, map layout, etc. Main interface in system is constituted by data display, layers showing and geological disaster introduction, etc.

3. Space Analysis Module

Space analysis is an important part in geographical information system and is also one of important indexes in geographical information system function. The basic purpose of space analysis lies in to obtain new information through deep processing or analyzing space data and applies powerful data management and space analysis function of GIS technology to provide strong technological support for evaluating, predicting and prewarning of geological disaster. Through analyzing geological condition and its relevant environmental background condition, distribution principle of geological disaster is performed comprehensive research and provide direct data support for regional geological disaster easy-occurrence and risk area.

4. Map Operation Module

Map operation in this system contains map element edit and attribute data edit. Besides adding and deleting map element, map element edit also contains space calculation between map elements. Attribute data edit contains attribute table maintenance and attribute value maintenance. In addition, it also has map output function. Map element edit function makes system to perform data maintenance in time and provides powerful support for systematic query analysis, three dimension dynamic display, etc.

## Summary

Geological disaster occurrence has seriously influenced economic and social development in Liaoning province for many years. In particular, recently, with people's lives improvement, social economy rapidly develops, resource exploitation and consumption largely intensifies geological disaster occurrence. Constructing an effective geological disaster database, updating geological disaster data in time and establishing effective geological disaster management as well as analysis model can reduce losses of humans' lives and properties which are caused by geological diaster.

This system applies ArcGis series software as the developed platform. Under Visual Studio program environment, target-oriented Visual basic.net programming language is applied to develop 3S integration technology-based geological disaster database system in Liaoning Province. This system has functions including query analysis, risk evaluation and thematic analysis and three dimension modeling to realize geological disaster management and evaluation in Liaoning Province.

Although system can successfully realize corresponding functions of geological disaster database design, since system development manipulating time is short and it also has some problems which are needing to be improved. Dynamic three dimensional modeling process in high risk area needs to consume a lot of memory and too huge data quantity cause system to slowly operate.

Since Liaoning province area is very large, geological disaster in many areas cannot be updated in time and collecting quantity of GPS data point is still not enough.

**Keywords:** water quality monitoring, fuzzy clustering, FCM, PSO-FCM.

**Abstract.** Due to the complicated coal mine flooding water quality monitoring data, in order to extract the effective data from vast amounts of data， this article used the fuzzy clustering to analyze the monitoring data processing. This study makes a brief analysis of monitoring data structure， then analyzes the shortcomings of fuzzy C mean clustering algorithm（FCM），which also proposes fuzzy C-means algorithm based on particle swarm optimization (PSO-FCM). Finally samples of the underground water data are used to carry out the instance simulation. The experiment results showed that in dealing with data samples. The algorithm had some advantages and it was worthy of research.

## Introduction

Coal is the main energy sources, coal mine production safety influence the coal industry sustainable development and national energy security which also influence more than 500 million lives and safety and health of miners.

Therefore this paper proposes a clustering analysis will be applied to real-time monitoring of coal mine flooding water system. The system includes a data acquisition, wireless transmission, monitoring and analysis system with integrated real-time display. Because of many kinds of water monitoring data, within a certain period of time the amount of data will be accumulated to a certain extent. It is difficulty to collect early effective warning informations in the vast data. In this paper, a method for using the PSO-FCM to analyze the amount of mine flooding water data can save time and improve efficiency.

## The analysis of coal mine water quality data

Underground water quality monitoring mainly are about the major ion concentration of water, temperature, PH value monitoring. Because of the complexity of coal mine geological environment, water quality data obtained by many, it is unable to determine whether the mine will produce water inrush based on particular ion data. It is necessary to cluster analysis of water quality data. Cluster analysis of water quality data can be available for the qualitative analysis of water quality. Classification algorithms can classify if the ion concentration in the water is within safe value. The clustering algorithm is capable of clustering monitoring data of the underground water quality, the clustering results determine whether the occurrence of future mine water inrush[1].

From the entire real-time monitoring system, including data acquisition modules, wireless communication module and data analysis module, the overall structure is shown in Fig. 1.

Data acquisition device collect the mine flooding water data through sensor, which contains the water temperature, PH value, the ion concentration and the location of measurement data. Wireless transmission will sent the collection data to a remote data monitoring center via GPRS transmission

mode. The data will be received by the monitoring center for data pre-processing and cluster analysis, determine the rationality of data expert systems, and the results is output via graphics and multimedia output.

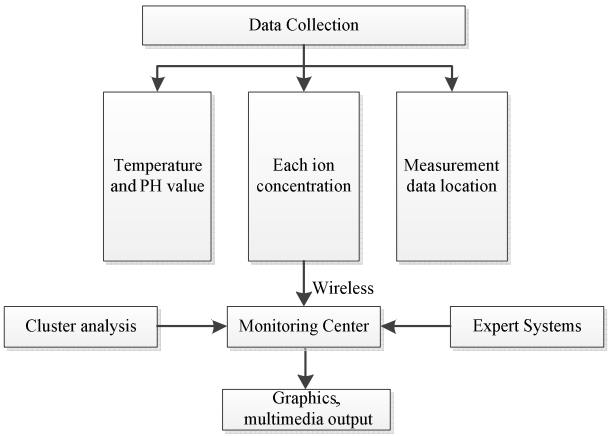

Fig. 1 The structure diagram of underground water quality monitoring data

**FCM algorithm**

Let monitoring samples collection $X=\{x_1, x_{2,\ldots,}x_n\} \in R^s$is a limited sample set in n modes of pattern space, $x_k=\{x_{k1},x_{k2},\ldots,x_{ks}\}^T \in R^s$is a set of data samples,$x_{kj}$ is the monitoring value of the j indicators for the sample $x_k$.

$u_{ik}=u_{xi}(x_{ik})$ ($u_{ik} \in [0,1]$) shows the affiliations about sample $x_k$ and subset $\{x_i\}$. Plurality of subsets of the membership function can be denoted by: $U=[u_{ik}]_{c\times n}$。

Clustering prototype model $P=\{p_1,p_2,\ldots,p_c\}$ ,$p_i$ (i=1,2,…,c) on behalf of the class i for class center .

The calculating process of FCM algorithm is to ensure a minimum objective function $J_m$, then solve the partition matrix U and cluster prototype P.Expression is calculated:

$$J_m(U,P) = \sum_{k=1}^{n}\sum_{i=1}^{c} u_{ik}^m\, d(x_k,p_i). \quad (1)$$

Among $\sum_{i=1}^{c} u_{ik} = 1, u_{ik} \in [0,1], \forall k: d(x_k,p_i) = \|x_k,p_i\|$ ,m is the weighting function, $d(x_k,p_i)$ represent the degree of difference between $x_k$ and $p_i$ , the distance measured between the two vectors.

The formula of iteration rule is as follows:

$$p_i = \frac{\sum_{k=1}^{n} u_{ik}^m x_k}{\sum_{k=1}^{n} u_{ik}^m}, (i = 1,2,\cdots,c). \quad (2)$$

FCM process is as follows:

① Given the number of categories of clustering c, set the iteration stop threshold ε, initialize the cluster prototype model $P^{(0)}$. Set iteration counter b = 0;

② Using formula (2) updates the partition matrix $U^{(b)}$;

③ For $\forall i,k$ ,if $\exists\, d_{ik}^{(b)} > 0$， then： $u_{ik}^{(b)} = \dfrac{1}{\left(\sum_{j=1}^{c} \dfrac{d_{ik}^{(b)}}{d_{jk}^{(b)}}\right)^{\frac{2}{m-1}}}$. (3)

Using equation (3) updates the clustering prototype of pattern matrix $P^{(b+1)}$;

④ If $\left\|p^{(b)} - p^{(b+1)}\right\| < \varepsilon$, then the algorithm stops and divided matrix U and cluster prototype P will be output.Otherwise let b = b +1, go to step two. ‖■‖is a suitable matrix norm[2].

Since the FCM algorithm is find by gradient descent method, so when the number of samples in the larger cluster of cases, algorithm exist locally optimal problems. In addition, initial value impact the convergence speed of FCM. This article uses the advantages of PSO algorithm about global optimization and fast convergence, combining with FCM algorithm presents a new fuzzy clustering algorithm. Using PSO algorithm instead of the iterative process of FCM achieves fuzzy clustering.

## Improved particle swarm optimization algorithm based on FCM

The direction of particle motion not only affected by formerly experience, but also affected by its companion experience. If remember the position of the i particle of the j is $x_i(j)$. The optimal solution search by itself and the whole Particle swarm are $q_i(j)$ and $q_g(j)$.The movement velocity vector for it is $v_i(j)$, then the j +1 generation of the i particle will move:

$$v_i(j+1) = \omega\emptyset_1 v_i(j) + \beta_1\emptyset_2\big(q_i(j) - x_i(j)\big) + \beta_2\emptyset_3\left(q_g(j) - x_i(j)\right). \quad (4)$$

$$x_i(j+1) = x_i(j) + v_i(j+1). \quad (5)$$

$\omega$, $\beta_1$, $\beta_2 \in [0,1]$ are adjustable parameters, $\Phi_1$, $\Phi_2$, $\Phi_3 \in [0,1]$ are random numbers.

For the evaluation of each particle, we define the following fitness function:

$$f(a_i) = \frac{1}{J(\mu,P)+1}. \quad (6)$$

If the clustering effect is better, then J (μ, P) is smaller, individual fitness $f(a_i)$ is higher.

PSO encoded $p_i$. For any particle can be encoded $A_i$ as follows:

$$a_i = \left(p_{i1}, p_{i2}, \cdots, p_{ij}, \cdots, p_{ic}\right). \quad (7)$$

$p_{ij}$ is the i cluster approach in the j cluster center[3].

Each class of n dimensional cluster centers uses real-coded and ultimately P represents the optimal solution. The process of PSO-FCM algorithm can be described as:

① A fuzzy index m was given. The number of categories of clustering c is given. The particle colony scale N is given. Individual cluster centers c samples are randomly selected. In order to compose of an individual we do N times to produce N × c sample points. The random rate of $v_i$ for each individual is update.

② According to the fitness function f(x) and the fitness value of each individual fit calculate $q_i(j)$ and $q_g(j)$. According to the formula (4) the speed of each individual new $v_i$ can be calculated. By formula (5) we a new generation $x_i(j+1)$is obtained.

③ If the abort condition $\left\|p^{(b)} - p^{(b+1)}\right\| < \varepsilon$ is satisfied, the algorithm terminates.

## The simulation

In this paper, the monitoring of a total of nine factors namely are water temperature, PH value, , $C_a^{2+}, M_g^{2+}, K^+, N_a^+, HCO_3^-, Cl^-, SO_4^{2-}$ and other factors. These elements are obtained by sensors, data collected by sensors are passed to the monitoring center via a wireless network. The experimental simulation data are shown in Table 1.

Table1 Monitoring data from underground water quality

| | PH | T/℃ | $\rho(C_a^{2+})$ | $\rho(M_g^{2+})$ | $\rho(K^+)$、$\rho(N_a^+)$ | $\rho(HCO_3^-)$ | $\rho(Cl^-)$ | $\rho(SO_4^{2-})$ |
|---|---|---|---|---|---|---|---|---|
| | 7.36 | 20.98 | 167.46 | 52.38 | 994.27 | 198.29 | 1074.95 | 900.17 |
| | 7.60 | 21.59 | 167.33 | 52.33 | 994.21 | 198.33 | 1074.78 | 900.11 |
| Top | 7.76 | 22.12 | 167.20 | 52.20 | 994.12 | 198.22 | 1075.03 | 900.32 |
| Sand | 7.81 | 22.32 | 166.50 | 51.65 | 994.37 | 198.48 | 1075.22 | 900.61 |
| Layer | 7.42 | 21.23 | 166.97 | 51.97 | 994.23 | 198.39 | 1074.92 | 900.01 |
| | 7.13 | 21.79 | 167.32 | 52.46 | 994.02 | 198.31 | 1074.90 | 799.96 |
| | ... | ... | ... | ... | ... | ... | ... | ... |

To succeed warning before flooding occurs, the data recorded in Table1 are need to use, randomly selected 100 samples from the database as a source of clustering. Software VB6.0 are used to

simulation and use MFC to achieve clustering results, programming and run the program FCM.exe. Enter nine monitoring factors of values in the clustering parameters, set the appropriate parameters, the number of classes c is set to 10, the population size N is 20, weight index m is set to 2, iterative threshold is set to 0.01, and then click on the "clustering" button display the results shown in Fig.2.

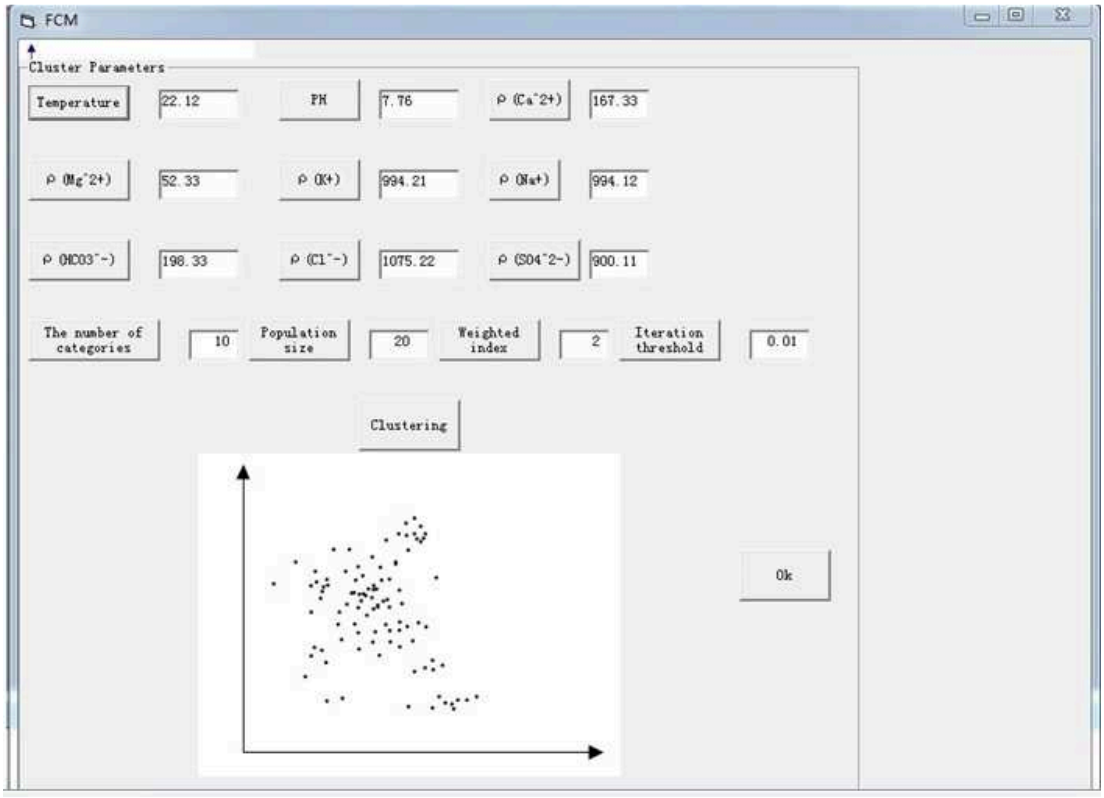

Fig. 2 Simulation results

## Conclusions

From the simulation results In coordinate system the horizontal axis represents the probability of flooding occurs. Cluster analysis is concentrated in a position not far from the origin. Water quality data are in the normal range. In this paper, PSO-FCM algorithm are used to clustering analysis for monitoring data from underground water quality, and achieve early warning case underground flooding disasters occur[4] .First traditional FCM algorithm processes are described, analyzed the shortcomings of the algorithm, so that PSO-FCM algorithm is proposed. Experimental verification, when dealing with incomplete data samples huge cluster, the algorithm has excellent properties, so it is suitable for clustering analysis monitoring data from underground water quality.

**Keywords:** Bridge, Fire hazard, Fire scenario, Research needs, Collapse

**Abstract.** In recent years, numerous bridges have been damaged seriously even destroyed by fire hazards in China. Fires in bridges can result in significant losses of life and property, as well as traffic jam. Therefore, fire hazard in bridges is becoming a growing concern in the whole life cycle of design, construction, use and maintenance. There are few literatures on bridge fire incidents and research data in developed countries. In this paper, several typical bridge hazards in China shall be introduced firstly. Some research progress on bridge fire in China is described secondly. Critical research needs and are pointed lastly. The authors hope this paper may be a useful reference for people who hope to learn about the situation and research progress of bridge fires in China.

## Introduction

Recently, numerous bridges have been damaged seriously even destroyed by fires hazards in China (vide Table 1). Although numerous research projects on building fire have been conducted all over the world, much of the data on fire resistance from building elements and cannot directly be used for bridge members. In recent decades, there has been a move toward performance-based design, adoption of which implies a shift away from dependence on empirical and experience-based conventions and toward a rational design and assessment process more firmly rooted in the realistic prediction of structural response under realistic loading, fire, and failure conditions. For predicting realistic performance under performance-based codes, fire hazard in bridges should be an important design consideration.

**Table 1 Major bridge fire incidents in China in recent years**

| No. | Bridge and location | Date | Cause of fire | Damage description |
|---|---|---|---|---|
| 1 | Zhuoshui Covered Bridge cross Qian River, Chongqing | November 28, 2013 | Unknown reasons. | The wooden bridge was destroyed completely. |
| 2 | Guangzhou-Shenzhen Highway bridge near Xiagang | June 29, 2012 | A gasoline tanker was crashed by a heavy truck and ignited the wood beneath the bridge. | Column piers and beam were damaged seriously. 20 people died. |
| 3 | Caogou Bridge of G210 highway in Yulin | August 2, 2011 | Tanker truck exploded. | Eight prestressed box girders were damaged. |
| 4 | Yuqing Bridge, Wuyishan | May 28, 2011 | Children played fire and ignited the wood bridge. | The wooden bridge was destroyed completely. |
| 5 | G15/G324 interchange in Guokeng town | June 26, 2010 | Gasoline tanker truck overturned. | Beam, concrete girders, and underside of the deck were damaged seriously. |
| 6 | Hedong cable-stayed bridge in Guangzhou | December 26, 2008 | Landscape lamps burned. | More than 10 cables were damaged. |

## Typical Bridge Fire Incidents in China

**Historical wood bridges.** China is a country with a long history and large number wood bridges were constructed and some of them are used up to now. Wood can burn in fires, so it is important to

prevent fire initiation and growth in bridges. Otherwise, wood bridges may be destroyed in fires. Yuqing Bridge was a wood bridge erected in 1889, located at Wuyishan, Zhejiang province, China. On May 28, 2011, Yuqing Bridge was destroyed by fire which resulted from playing with fire of two girls (vide Fig.2). Zhuoshui Covered Bridge, crossing Apeng River, Chongqing, was built in 1591 and is recognized as the longest covered bridge in Asia(vide Fig.3). On November 28, 2013, the 303-metre wooden bridge was destroyed after a fire because it was constructed entirely of wood without any nails (vide Fig.4).

Fig.1 Yuqing Bridge

Fig.2 Yuqing Bridge in fire

Fig.3 Zhuoshui Covered Bridge, crossing Apeng River, Chongqing

(a)

(b)

Fig.4 Zhuoshui Covered Bridge during fire

**Concrete girder bridges.** Reinforced concrete is commonly used as a primary material in bridge girders, bridge piers, roadway slabs. The mechanical properties of concrete, such as initial stiffness, are not immune to degradation when subjected to elevated temperatures. On the evening 21:30 of August 2nd 2011, a tanker truck carrying 24 tons of gasoline crashed with a truck carrying coal on the Caogou Bridge of G210 in Yulin, Shanxi Province, China. The tanker truck exploded and total 9 trucks caught fires (vide Fig.5). Eight damaged prestressed box girders of the bridge were changed (vide Fig.6) according to the on-site inspection, and the bridge opened to public after closed 56 days.

Fig.5 Caogou Bridge fire

Fig.6 Install a new box girder

On the morning 4:35 of June 26th 2010, a tanker truck carrying 21 tons of gasoline overturned and burst into flames (vide Fig.7) on the G15/G324 interchange in Guokeng town, Fujian Province, China. The tanker truck fire damaged the bridge seriously because the concrete cover of some main girders spalled (vide Fig.8) and steel reinforcements exposed to fire directly and some fell down to ground, as a result, the bridge was demolished.

Fig.7 Guokeng highway bridge during fire

Fig.8 Guokeng highway bridge after fire

On the morning 4:30 of June 29, 2012, a tank truck carrying 40 tons of solvent oil impacted by a lorry full of concrete poles on the Guangzhou-Shenzhen Highway bridge near Xiagang, and the oil leaked out and ignited the large amount of wood beneath the bridge (vide Fig.9), 20 people lost their life. The column piers and beam were damaged seriously (vide Fig.10).

Fig.9 Bridge in fire

Fig.10 Bridge after fire

**Cable-stayed bridges.** It is necessary to consider the impact of fire on a major cable-stayed bridge because that collapse or closure of the bridge may lead to unacceptable commercial consequences. Hedong cable-stayed bridge (vide Fig.11), in Guangzhou, China, crosses Pearl River with the main span of 360m. On the evening 19:10 of December 26, 2008, fire occurred round more than 10 cables at the level of more than 100m above the bridge. The fire last 4 hours, and total 144 cables were checked after the fire. Xupu Bridge is a cable-stayed bridge span Huangpu River in Shanghai, China. Since its completion, Xupu Bridge has seen occasional fires in 2008 and 2011. On May 3, 2011, the bridge caught fire due to a chemical tank truck carrying xylene burst into flames (vide Fig.12). The bridge was immediately closed to traffic.

## Review of Research Progress in China

**Numerical simulation.** The thermal and structural behavior of a steel girder of highway bridge overpass in the East Bay's MacArthur Maze in Oakland collapsed on April 29, 2007 was studied by using general purpose finite element analysis software ABAQUS and ANSYS[1,2](vide Fig.13). It is difficult to conduct full-scale test study of fire effect on overall behavior of cable-stayed bridges. Numerical simulation is a useful way. Potential fire scenarios relevant for a cable-stayed bridge crossing the Yangtze River are analyzed by Liu and Ning[2]. The temperature distribution in key elements and the global structural behavior of the bridge under tanker truck fires is calculated by using general purpose finite element analysis software ANSYS(vide Fig.14).

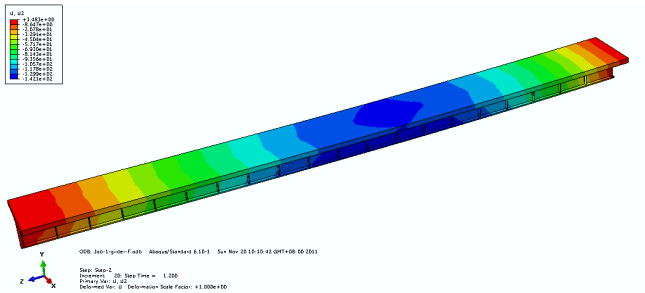

Fig.13 Vertical displacement of girder in fire[1]

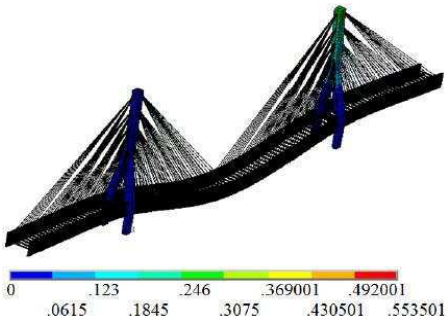

Fig.14 Vertical displacement in fire[2]

**Test study.** Identification of failure modes and validation of advanced numerical models requires well controlled full-scale experiments. Some experimental program was performed to analyze the effects of fire on bridges. Recently, a new facility in Shenyang Jianzhu University (SJZU), Liaoning Province of China, was established for structural fire research (vide Fig.15).

## Research Needs in China

**Test study on fire scenarios.** The selection of suitable fire scenarios for bridge fire resistance design is very important. Therefore, special experimental studies on temperature-time curves of tanker truck fires, which are commonly the cause of bridge fires, are urgent to be conducted.

**Fire prevention and protection technology.** If fire prevention and protection technologies were used in some collapsed wood and steel bridges, the collapse could have been prevented. There is a need to develop performance based design guidelines and standards for fire protection design of steel bridges.

**Rapid girder replacement technology for concrete bridge.** Concrete girder bridges have been widely used in highway bridges, which are critical components of the nation's transportation network. Some research projects are needed to identify strategies and technologies to restore the use of a damaged bridge quickly. In addition, how to estimate the remaining fatigue life of bridges exposed fire is a key issue to study.

**International cooperation.** China is a developing country**,** it is essential to cooperate with experts of developed country for Chinese researchers. The cooperation includes sharing fire test data, co-designing large scale bridges for fire safety such as Tianxingzhou cable-stayed bridge cross Yangtze River in Wuhan[3].

## Conclusions

Conclusions derived from the work include the following:

(1)Fire hazards have occurred in bridges frequently in China, and some fires have led to partial or complete collapse of bridges. Critical bridges, say large span cable-stayed bridges, should be designed to have satisfactory fire resistance and to endure severe fire hazard without major damage or collapse.

(2)Extensive researches including large scale fire test of bridges are urgently needed, which is the base for us to put forward detailed guides, codes, and standards for fire safety design of bridges.

## Acknowledgments

This work is supported by the Scientific Research Foundation for the Returned Overseas Chinese Scholars, State Education Ministry of P.R. China.

# Risk Assessment of Debris Flow Based on Multi-Objective Fuzzy Pattern Recognition Method in Mountain Highway Construction

Yue Wang

Inner Mongolia Kaitong Construction Co., Ltd, Erdos Street, Huhehaote, 010010, China

ktwy6789@sina.com

**Keywords:** debris flow, multi-objective fuzzy pattern recognition, evaluation index, grade of risk

**Abstract:** It is inevitable that road routes cross the valley landforms in the construction of mountain road, and the debris flow risk assessment is one of the important basis works of engineering geological investigation. This paper presents the evaluation indexes and the classification standards of the danger evaluation based on the surveying data of road and analysis of the developing characteristic, formation conditions and influent factors of the debris flow in mountain highway construction area, Zhangjiakou city. With the multi-objective fuzzy pattern recognition method, the evaluation model is also established. With this model, the 15 debris flow valleys in the construction area are evaluated. The result is consistent with the field surveying result, which proves that the model represented by this paper is feasible and effective, and the results can reflect the actual situation. Thus, the multi-objective fuzzy pattern recognition method can be one of the methods to evaluate the danger grade of the debris flow.

## Introduction

Debris flow is a common unexpected geological disaster in mountainous areas. It happens suddenly, lasts shortly, destroys strongly and endangers greatly. The danger evaluation of debris flow is focus on its possibility of happening, which is mainly in the debris flow research. Danger evaluation is important for the economic development layout in mountainous area, the forecasting of debris flow and the disaster controlling of debris flow. Danger evaluation is an extremely complex job. After the research of many scholars, some evaluation methods have been mastered, such as the empirical formula law, multivariate statistics method and fuzzy evaluation method [1]. Each method has advantages and disadvantages. At present, there isn't a widely accepted method for the evaluation.

Based on the surveying data in mountain highway construction area, Zhangjiakou city, this paper applied the multi-objective fuzzy pattern recognition method to establish a model for calculating the debris flow danger grade. With this model, the 15 debris flow valleys in the construction area are evaluated. The result is consistent with the field surveying result, which proves that this model is feasible and effective.

## Selection and classification of danger evaluation index of debris flow

According to current situation and studying level of the debris flow in Beijing mountain area, the danger is divided to 5 grades, which is no danger (I), low danger (II), medium danger (III), less high danger (IV) and high danger (V). Thus, the danger grades of debris flow are made up of the field V = { I , II , III , IV , V }.

Based on the previous research, we find that whether the debris flow can occur and the possibility of this occurring depend on three basic conditions[2], which are the rich solid masses, precipitous landform and concentrated water replenishment. These conditions are controlled by geology, geomorphic, climate, plant cover and human activities. Based on the research of the development characteristic, formation condition and activity regular of the debris flow in Huairou County, this

paper chose basin area ($F_1$), relative differential height of basin ($F_2$), gradient of valley ($F_3$), degree of slope ($F_4$), percentage of the plant coverage ($F_5$), quantity of the loose fill ($F_6$), frequency of joint fissure ($F_7$), average rain in flood season ($F_8$), the most daily rain in flood season ($F_9$) and the most hour rain in flood season ($F_{10}$) to be the evaluation indexes. The division standards of each index are shown in Table 1. Thus, the evaluation indexes are made up of the field $F = \{F_1, F_2,\ldots, F_{10}\}$.

Table 1. Evaluating index and classification

| index | | Danger grades | | | | |
|---|---|---|---|---|---|---|
| | | Ⅰ | Ⅱ | Ⅲ | Ⅳ | Ⅴ |
| landform | basin area（$km^2$）$F_1$ | >10 | 10~5 | 5~1 | 1~0.5 | <0.5 |
| | relative differential height of basin（m）$F_2$ | <200 | 200~300 | 300~400 | 400~500 | >500 |
| | gradient of valley（‰）$F_3$ | <50 | 50~100 | 100~150 | 150~200 | >200 |
| | degree of slope（°）$F_4$ | <15 | 15~25 | 25~35 | 35~45 | >45 |
| | percentage of the plant coverage（%）$F_5$ | >80 | 60~80 | 40~60 | 40~20 | <20 |
| geology | quantity of the loose fill（$10^4m^3$）$F_6$ | <0.1 | 0.1~1 | 1~3 | 3~5 | >5 |
| | frequency of joint fissure（peice/$m^2$）$F_7$ | <5 | 5~10 | 10~15 | 15~20 | >20 |
| Water source | average rain in flood season（mm）$F_8$ | <350 | 350~400 | 400~450 | 450~500 | >500 |
| | the most daily rain in flood season（mm）$F_9$ | <100 | 100~200 | 200~300 | 300~400 | >400 |
| | the most hour rain in flood season（mm）$F_{10}$ | <30 | 30~60 | 60~90 | 90~120 | >120 |

**Multi-objective fuzzy pattern recognition model for danger evaluation**

According to fuzzy pattern recognition theory, danger evaluation problem is defined as limited region *U*. The n coming valleys are the element in the region. Each element can be described by m factors. The relation of above definition is expressed as:

$$U = \begin{bmatrix} u_{11} & u_{12} & \ldots & u_{1m} \\ u_{21} & u_{22} & \ldots & u_{2m} \\ \ldots & \ldots & u_{ij} & \ldots \\ u_{n1} & u_{n2} & \ldots & u_{nm} \end{bmatrix} \tag{1}$$

$u_{ij}$ is the value of the $j$ th index in $i$ th debris flow valley ( $i$ =1,2…, $n$; $j$ = 1,2,…$m$).

The grading is defined as evaluation field V and divided to $c$ grades, which is represented as:

$$V = \begin{bmatrix} a_{11} & a_{12} & \ldots & a_{1m} \\ a_{21} & a_{22} & \ldots & a_{2m} \\ \ldots & \ldots & a_{ij} & \ldots \\ a_{c1} & a_{c2} & \ldots & a_{cm} \end{bmatrix} \tag{2}$$

$a_{ij}$ is the value of the $j$ th index in $i$ th grade ( $i$ =1,2…, $c$; $j$ = 1,2,…$m$).

**Determination of the membership grade.** The membership grade is divided to increasing type and decreasing type based on the increasing and decreasing of the index value.

The increasing type is that when the index value is bigger, whose membership grade $\gamma_{ij}$ is getting bigger. The relation is represented as

$$\gamma_{ij} = (u_{ij} - a_{i\min}) / (a_{i\max} - a_{i\min}) \tag{3}$$

The decreasing type is that when the index value is bigger, whose membership grade $\gamma_{ij}$ is getting smaller. The relation is represented as

$$\gamma_{ij} = (a_{i\max} - u_{ij}) / (a_{i\max} - a_{i\min}) \tag{4}$$

The value $a_{i\max}$ and $a_{i\min}$ are the maximum and minimum value of the *j* th index in matrix V.

The value $\gamma_{ij}$ is the relative membership grade of the *j* th index in *i* th debris flow valley ( $i$ =1,2…, $n$; $j$ = 1,2,…$m$). Thus, the relative membership grade matrix $R$ can be obtained. In this matrix, there are *n* debris flow valleys with *m* indexes.

$$R = \begin{bmatrix} \gamma_{11} & \gamma_{12} & \cdots & \gamma_{1m} \\ \gamma_{21} & \gamma_{22} & \cdots & \gamma_{2m} \\ \cdots & \cdots & \gamma_{ij} & \cdots \\ \gamma_{n1} & \gamma_{n2} & \cdots & \gamma_{nm} \end{bmatrix} \tag{5}$$

Based on the above analysis, we can find that there is an optimum grade, each of whose relative membership grade value is 1; there is a worst grade, each of whose relative membership grade value is 0.

**Determination of weight.** Value $\omega$ is presented to reflect the weight of each evaluation index to the result. The weight vector is $\omega = (\omega_1, \omega_2, ..., \omega_m)$. The sum of the value $\omega$ is 1.

$$\sum_{i=1}^{m} \omega_i = 1 \tag{6}$$

Debris flow is the synthetically result of various factors. However, their influence and position are different. To reflect this difference objectively, the weight of each index is determined by step analysis method and the expert marking method.

$$\omega = \{0.062, 0.105, 0.098, 0.096, 0.034, 0.207, 0.095, 0.102, 0.100, 0.101\} \tag{7}$$

**Establishing the model.** There are various kinds of multi-objective fuzzy pattern recognition operators. Among these operators, the weighted average operator can not lose the information. Thus, the model with the least sum of the distance based on the generalized weight is chosen [3].

The value $u_i$ expresses the relative excellent membership grade of *i* th sample, and the value $(1-u_i)$ expresses the relative bad membership of *i* th sample. In fuzzy field theory, membership grade can be used as weight [4]. Equation (8) and (9) can used to calculate the distance from the sample to the excellent and bad grades.

The distance from sample to excellent grade can be expressed as

$$D_{ig} = u_i p \sqrt{\sum_{j=1}^{m} [w_j (1-\gamma_{ij})]^p} \tag{8}$$

The distance from sample to bad grade can be expressed as

$$D_{ib} = (1-u_i) p \sqrt{\sum_{j=1}^{m} [w_j (\gamma_{ij}-0)]^p} \tag{9}$$

In equation (8) and (9), $P$ is a distance modulus. When $P$ =1, it is the Haiming distance; when $P$=2, it is the Euclidean distance.

To find the solution of value $u_i$, an optimize criterion is built as follows: Sum of the excellent distance square and the bad distance square is minimal [5], which is expressed as

$$\min F(u_i) = D_{ig}^2 + D_{ib}^2 = u_i^2 \left\{ \sum_{j=1}^{m} [w_j (1-\gamma_{ij})]^p \right\}^{2/p} + (1-u_i)^2 \left\{ \sum_{j=1}^{m} [w_j (\gamma_{ij}-0)]^p \right\}^{2/p} \tag{10}$$

To differentiate the equation (10) and make the value $u_i$ to be zero, the solution is as

$$u_i = \frac{1}{1+\left[\frac{\sum_{j=1}^{m}(w_j \mid \gamma_{ij}-1\mid)^p}{\sum_{j=1}^{m}(w_j * \gamma_{ij})^p}\right]^{2/p}} \tag{11}$$

Equation (11) is the model with the least sum of the distance based on the generalized weight.

According to the current situation and studying level of this area, the danger grade can be decided by the logics method with four values and five grades. The calculated result can be intercepted and formatted as a table of the fuzzy danger grade. With the value $u_i$, the danger grade of the debris flow can be looked up from table 2.

Table 2 Danger grading characteristic of the debris flow

| grades | Danger grades | Fuzzy field | Characteristic description |
|---|---|---|---|
| Ⅴ | High danger | $u$>0.65 | Each index is the most dangerous |
| Ⅳ | Less high danger | 0.5<$u$<0.65 | Each index is dangerous, has great threaten |
| Ⅲ | Medium danger | 0.35<$u$<0.5 | Few indexes are dangerous, can breakout a disaster |
| Ⅱ | Low danger | 0.2<$u$<0.35 | Very few indexes are dangerous, may have a disaster |
| Ⅰ | No danger | $u$<0.2 | No danger |

**Example analysis**

According to the surveying data of the debris flow in mountain highway construction area, Zhangjiakou city, the danger division is made for 15 typical valleys. The measured values of each valley are shown in Table 3.

Table 3 Measured values of the valley debris flow

| No. | Valley name | $F_1$ | $F_2$ | $F_3$ | $F_4$ | $F_5$ | $F_6$ | $F_7$ | $F_8$ | $F_9$ | $F_{10}$ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | Nanling valley | 5.25 | 225 | 111 | 27.8 | 85 | 2.1 | 5.3 | 412.5 | 115 | 38 |
| 2 | Beidadi valley | 5.14 | 375 | 105 | 37.5 | 80 | 5.04 | 5.4 | 412.5 | 115 | 37 |
| 3 | Xiaodong valley | 5.37 | 367 | 67 | 17.4 | 60 | 4 | 5.4 | 415 | 115 | 38 |
| 4 | Mingzi valley | 5.05 | 301 | 120 | 20 | 80 | 4.14 | 5.4 | 412.5 | 114 | 38 |
| 5 | Dongyu valley | 5.98 | 354 | 115 | 16.5 | 85 | 2.76 | 11 | 412.5 | 105 | 36.5 |
| 6 | Detian valley | 5.77 | 344 | 60 | 28 | 80 | 2.9 | 5.9 | 420 | 102 | 36 |
| 7 | Longquanyu valley | 3.42 | 512 | 121 | 17.5 | 75 | 5.3 | 12.1 | 412.5 | 102 | 36 |
| 8 | Qian'anling valley | 5.07 | 478 | 57 | 16.8 | 80 | 3.87 | 6.5 | 412.5 | 100 | 35 |
| 9 | Xishandong valley | 2.54 | 380 | 137 | 21 | 85 | 2.5 | 12.8 | 413.5 | 102 | 37 |
| 10 | Xinshanxi valley | 5.19 | 450 | 129 | 36 | 80 | 5.1 | 3 | 412.5 | 102 | 36.5 |
| 11 | Sancha valley | 6.04 | 365 | 78 | 20 | 70 | 5.2 | 13.1 | 412.5 | 103 | 37 |
| 12 | Yingbei valley | 5.13 | 324 | 100 | 17.5 | 80 | 4.1 | 2 | 415.5 | 103 | 37 |
| 13 | Dong'anzi valley | 3.12 | 345 | 147 | 17.5 | 85 | 5.13 | 6.3 | 412.5 | 101 | 36 |
| 14 | Yangshu valley | 5.41 | 305 | 109 | 17.5 | 85 | 5.19 | 2 | 412.5 | 81 | 32 |
| 15 | Shuiquanyu valley | 5.04 | 984 | 65.6 | 38.99 | 85 | 5.4 | 11.2 | 412.5 | 119 | 41 |

The danger value of each sample can be calculated by equation (10). In the calculation, the value $n$ is 15, $m$ is 10, $P$ is 2, $c$ is 5. The results are shown in table 4. From the values in table 4, we can find that the calculation results are almost the same as the measured results, which proves that the multi-objective fuzzy pattern recognition method is feasible in the danger evaluation of debris flow.

Table 4 Danger evaluation results of the debris flow valley

| No. | Valley name | Danger value | grade | Measured results |
|---|---|---|---|---|
| 1 | Nanling valley | 0.178 | Ⅰ | Ⅰ |
| 2 | Beidadi valley | 0.595 | Ⅳ | Ⅳ |
| 3 | Xiaodong valley | 0.405 | Ⅲ | Ⅲ |
| 4 | Mingzi valley | 0.432 | Ⅲ | Ⅲ |
| 5 | Dongyu valley | 0.294 | Ⅱ | Ⅱ |
| 6 | Detian valley | 0.283 | Ⅱ | Ⅱ |
| 7 | Longquanyu valley | 0.629 | Ⅳ | Ⅲ |
| 8 | Qian'anling valley | 0.427 | Ⅲ | Ⅲ |
| 9 | Xishandong valley | 0.349 | Ⅲ | Ⅲ |
| 10 | Xinshanxi valley | 0.587 | Ⅳ | Ⅳ |
| 11 | Sancha valley | 0.560 | Ⅳ | Ⅳ |
| 12 | Yingbei valley | 0.410 | Ⅲ | Ⅲ |
| 13 | Dong'anzi valley | 0.548 | Ⅳ | Ⅳ |
| 14 | Yangshu valley | 0.489 | Ⅲ | Ⅲ |
| 15 | Shuiquanyu valley | 0.658 | Ⅴ | Ⅳ |

## Conclusions

The risk Degree of debris flow is closely related with the factors such as topography, geology, rainfall, vegetation, rainfall, etc. During these factors, some is difficult to choose and to decide the number. The multi-objective fuzzy pattern recognition method can obtain all of the influent factors and have advantages in the multi-objective synthesis judgment problem of debris flow. From the risk evaluation of debris flow valleys in mountain highway construction area, Zhangjiakou city, the model represented by this paper is proved to be feasible and effective, and the results can reflect the actual situation. Thus, the multi-objective fuzzy pattern recognition method can be one of the methods to evaluate the danger grade of the debris flow.

The risk evaluation of debris flow is an extensively involved and synthesis problem. The research of multi-objective fuzzy pattern recognition method in this field is not many. In this paper, the application of this method is superficial discussed. Further, the choosing of the evaluation index and membership grade function establishing need more research.

**Key words:** Fire, safety, risk management.

**Abstract**. Tourist hotels are part of service industry, thus fire safety issues are particularly important. Due to the complexity of the hotel's construction, most of the tourists are not familiar with the environment.In case of fire it would be hard for them to evacuate the building. Therefore, this study collects and organizes documents, regulations and cases. By applying risk management this study summarizes the key items of the fire safety risk assessment application are: Whether fire evacuation facilities have been blocked and major risk items must be examined daily.

## Preface

The patterns of area usageintourist hotels are complex, most of the tourists are not familiar with the living environment. Hotels' managers' attitude toward fire safety, maintenance of fire evacuation facilities and adaptation to fire are all important factors of fire safety. It is hard for people to evacuate from a fire, thus fire safety depends on managers'self-reinforcingof fire safety. The study's intentions are to find out hotels' damage caused by fire and provide quantization of fire safety risk identification and analysis methods, as to be standers and operation examples of each tourist hotels' fire safety risk assessment.

Examples of fire safety assessment techniques are ISO/PD 16732[1], BSI 7994-7[2], NFPA 551[3] and etc. In addition, there arefire safety assessment guidesin SFPE [4-6]. On the aspect of regulations, there are many references of fire risk and construction risk in ICC and ICC Performance Code for Buildings and Facilities [7,8]. NFPA 5000[9] and NFPA 101[10] have reveal the importance of reorganization of the smallest risk and reliability factors.

This study has collected domestic tourist hotels-related public places' fire safety assessment documents. Through brain storming, deeply interview with experts, cases analyzing and etc. And then comprehensively summarize factors of fire management's risk assessment.

## Impact factors of tourist hotel's fire safety.

Contents of expert's questionnaire are made of secondary information collection, brainstorming, interview with experts, domestic construction and fire-related regulation, conflagration cases, then sum up the impact factors of tourist hotels' fire risk identification. This study concludes the aspects of fire risk identification, among them there are 108 impact factors. As shownin Table1.

**Questionnaire results and analysis.**

**Questionnaire.**Applying qualitative risk analysis, this study use Likert scale to estimate the three aspects of 108 factors' risk occurring rate and severe degree. 8 tourist hotels, 6 international hotels and 2 normal tourist hotels in Taichung are targets of the questionnaire. International hotels are as followed:Howard Hotel, Windsor Hotel, Hotel National, Splendor Hotel, Evergreen Laurel Hotel and Plaza International Hotel. Normal hotels are Taichung Harbor Hotel and Dragon Valley Hotel. The questionnairesare also finished by firefighting-related people, insurance companies employees total of 31 experts questionnaires were handed out and finished

**Results and discussion.**This study statistic analyzed the results of the questionnaire, calculated the average and by the product of the probability of the risk occurring and severe degree, this study calculated the RPN value and risk order. This study applied Plato 80-20 law to find out top 20% items. There are 22 major impact factors. Major impacts are as shown in table 2, C stands for severe degree, P stands for rate of occurring and R stands for risk priority number (RPN).

Table 2.Top 20% of tourist's hotels fire risk analysis major items.

| Order | Risk impact factors | C | P | R=C*P |
|---|---|---|---|---|
| 1 | 2.1.12 Whether hotels' evacuation passages(corridors, stairs and safety stairs) are blocked or not? | 3.61 | 3.16 | 11.42 |
| 2 | 1.1.1Is there any prevention of electronic fire measure in hotel? | 3.13 | 2.84 | 8.88 |
| 3 | 2.1.14 Whether the evacuation roof top has blocked the way of evacuation? | 3.10 | 2.81 | 8.69 |
| 4 | 1.2.4 Whether it is forbidden to smoke in some special area(such as places stocked with many inflammables)? | 2.71 | 2.55 | 6.91 |

| | | | | |
|---|---|---|---|---|
| 5 | 2.2.4 Whether there is a fire proof Rolling Door to protect the evacuation facilities? Or facilities that can protect evacuation facilities from early stage of fire, smoke and heat? | 2.65 | 2.58 | 6.83 |
| 6 | 3.1.1 Is there a firefighting administrator? | 2.61 | 2.55 | 6.66 |
| 7 | 3.1.3 Whether firefighting management missions have been firmly executed.? | 2.61 | 2.55 | 6.66 |
| 8 | 1.8.1 Whether exterior contractor fully comprehends the fire safety regulations? | 2.61 | 2.52 | 6.57 |
| 9 | 3.1.12 Whether there is a good contact with fire station? | 2.55 | 2.55 | 6.49 |
| 10 | 1.4.1 Is there any management measures for portable heat facilities? | 2.58 | 2.52 | 6.49 |
| 11 | 1.3.1Prevention of arson? | 2.65 | 2.45 | 6.48 |
| 12 | 2.1.4Whether it is easy to open the safety doors? | 2.58 | 2.45 | 6.33 |
| 13 | 3.1.2Designation of experts for assist of fire prevention and protection measures? | 2.58 | 2.45 | 6.33 |
| 14 | 2.1.1Facilities that can help people successfully evacuate in the case of fire? | 2.52 | 2.48 | 6.25 |
| 15 | 2.1.5 Whether exists are open toward to the right evacuation way? | 2.58 | 2.42 | 6.24 |
| 16 | 2.7.3 Installation of CO2 fire extinguishers in power room and boiler room? | 2.55 | 2.42 | 6.17 |
| 17 | 2.1.2Whether evacuation routes conform to regulations? | 2.48 | 2.45 | 6.09 |
| 18 | 1.1.5 Is there a person in charge of management of extension cords and transforms usage? | 2.42 | 2.52 | 6.09 |
| 19 | 2.1.3 Whether there are enough exits? | 2.55 | 2.39 | 6.08 |
| 20 | 1.5.1 Is there any fire safety protection to prevent cooking fire? | 2.48 | 2.42 | 6.01 |
| 21 | 1.1.2 Whether fixed electronic facilities are examined and test regularly? | 2.55 | 2.35 | 6.00 |
| 22 | 1.5.3 Installation of oil fire extinguishers in kitchen? | 2.55 | 2.35 | 6.00 |

The questionnaire separates into tourist hotel managers, insurance companies' employees and firefighting facilities managers, firefighting technician sections. The case that the result has the highest overall score, Such case as firefighting related person believes that electrician would ignore the indoors decoration's regulations in order to save money, and thus buried the risk of electric fire.

From this study's questionnaire analysis, could found out that in the keys of fire prevention measures, fire evacuation facilities to impact factors, whether it is easy to open evacuation door has the highest value of RPN impact factors. This shows that it is the first priority that tourist hotel fire risk analyses have to cope with. It is also the most important factor of fire safety.

**Fire safety managementstrategy.** This study has put 22 major risk items into a daily examination management table and 86 of subordinate risk items into seasonal examination management table, by these two tables we can efficiently lower the risk of fire.

## Conclusion

1. According to questionnaire analysis, whether fire evacuation facilities have been blocked has the highest RPN value, it is also the first implementation priority of tourist's hotel fire risk management assessment. It can effectively prevent the failure of evacuation.
2. Implementation of daily risk items check up can improve the tourist's hotel safety and it can also simplify the examination procedures.
3. From the aspect of fire risk management assessment, major risk items assessment can reduce the risk of fire, simplify examination procedures. It is worth it to promote the rules of fire risk management assessment.

**Keywords:** Mountainous freeways; Geometric factor; Crash occurrence; Vertical alignment; Horizontal alignment; Cross section

**Abstract.** Mountainous freeway goes through complex geographic and geological regions and causes safety problem. Making clear of the inner relationship of the crash occurrence and the geometric factors is the most fundamental prerequisite to solve the problem. This paper reveals the contributing geometric factors through analyzing the crash data from Changjin Freeway, a typical mountainous freeway located in Jiangxi Province, China. Based on crash records and designed alignment data, contributing geometric factors are generally classified into three categories: vertical alignment, horizontal alignment, and cross section. And then detailed effects of geometric variables are separately discussed and quantified through the relation with crash rate (CR).

## Introduction

China has a tremendous area of territory, which more than 70% was covered by mountain and hilly terrain, especially in South China. In the past 20 years, China has made great achievements in freeway construction, resulting in reaching 96,200 kilometers up to 2012. And a large portion of it goes through mountainous regions. However, due to the mountainous landscape, the mountainous freeway's safety condition is serious. Over the past years, with the enormous losses to society resulting from crashes and fatalities on mountainous highways, numerous researches have continually sought a variety of quantitative ways to gain a better understanding of factors and causes that affect the occurrence likelihood of crashes so as to provide decision-making support for policies and countermeasures for reducing the crashes and facilities [1-5].

This study focused on exploring the affecting mechanism of variable alignment on crashes using a statistical analysis method. Changjin Freeway is used as a case to conduct this study based on total 1023 crash records and detailed geometric information. For a precise analysis, the count of the number of crashes is viewed as a function of various geometric contributing factors (e.g. radius of curvature and gradient). Several statistical models such as a linear-regression model are used [6].

## Date description

Changjin Freeway (K905+000~K982+600) is a section of Hukun Freeway in Jiangxi. The crash data was provided by the Department of Transport of Jiangxi Province. It collected 1,023 crash records from 2006 to 2012, including 182 common accidents and 841 simple accidents, respectively. It should be pointed out that common accidents mean those which cause serious injuries or casualties or more than 5,000 CHY losses, while the simple accidents representing the opposite cases. In this study, average crash rate (*CR*) of segment *i* can be then considered as the average count of crashes (*ACC*) per 100 million entering vehicles (100MEV), obtained as:

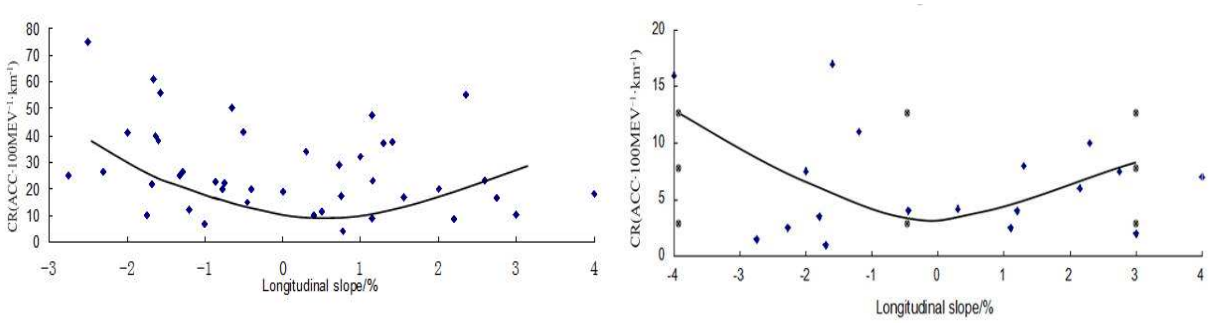
$$CR_i = \frac{ACC_i}{365AADT_i \cdot L_i} \times 10^8 \quad (1)$$

where, $ACC_i$ = crash count of segment $i$; $AADT_i$ = average daily volume of segment $i$, pcu/day; $L_i$ = length of segment $_i$, km.

**Typical geometric factors analysis and comment**

The contributing factors are classified into three components consisting of: vertical alignment includes: (1) grade; (2) radius of curve; horizontal alignment includes (3) maximum curvature; (4) angle of deflection; and cross sections.

**Vertical alignment.** In the past years, many accidents, especially truck involved cases, have frequently occurred at segments with big grades. When a vehicle brakes at down grade, it always takes longer distance than that of up grade at the same speed. Thus, it is difficult for driver to keep safe distance with the front vehicle when a emergency brake occurred. At long-down grade sections, the situation seems much more serious, especially for trucks due to that the brake function will decrease when the brake block get hotter. Generally, locations at down grade witnesses more crash occurrences. Figure 1 presents a comparison of CR values at locations of up and down grades.



a. simple accidents b. common accidents

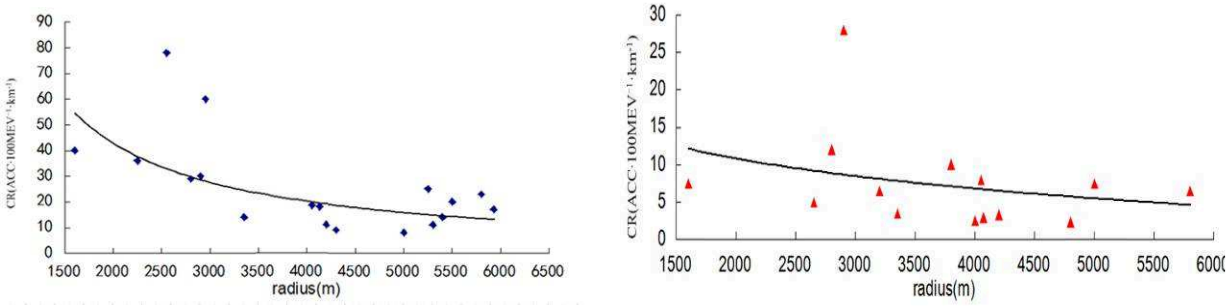
Fig.1 Comparison of crash rates at locations of down and up-grades of Changjin Freeway

Reconsidering the above listed Fig. 1, it is clear that both types of *CR* values come to a great increase with an increase grade. That's mainly due to less effective brake system performance and driver's incorrect operation under stress.

The vertical curve can be categorized into crest and concave. It's the necessary part to join two sections with different grades. However, it brings down the driver' sight distance and cause potential risk, particularly over crests. The radius of vertical curve determines the effect of transition between two different segments. The bigger, driver's sight distance gets better; the smaller, the worse. It should be pointed out that at the same vertical radius, crest curve generally witness bigger *CR* values than that of concave curve. By crash records of Changjin Freeway, 88 crashes occurred at crest sections while 53 at concave.

**Horizontal alignment.** Safety performance has a close relation with the maximum value of horizontal curvature in mountainous freeway. Fig. 2 shows the relation between CR with the radius of horizontal curve of Changjin Freeway.

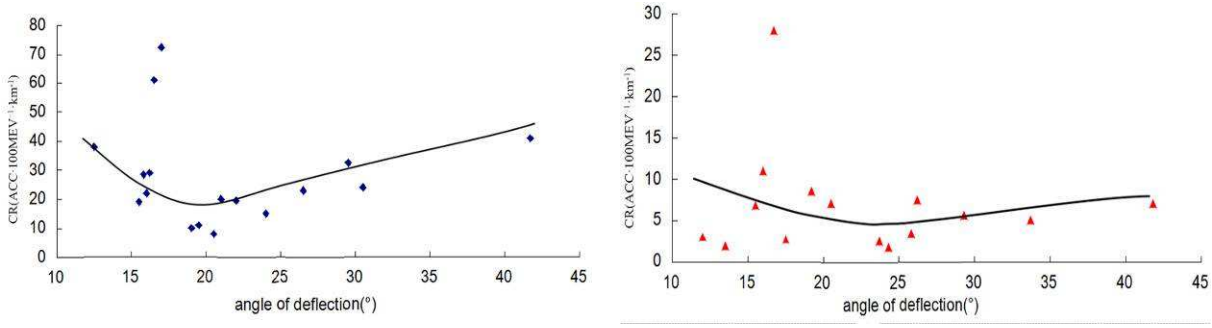
Through the Fig. 2, we could find that CR values decline with the increase of the radius. It should also be pointed out that driving on curves with different radius behaves more dangerous than that with same or similar radius. Particularly, it is much more dangerous when a small radius curve is inserted into long and straight line. That is partly due to the driver's unconsciousness of speed on the latter and may cause overturn or run off road crashes on the curve.



a. simple accidents b. common accidents

Fig.2 Crash rates related to radius of horizontal curve

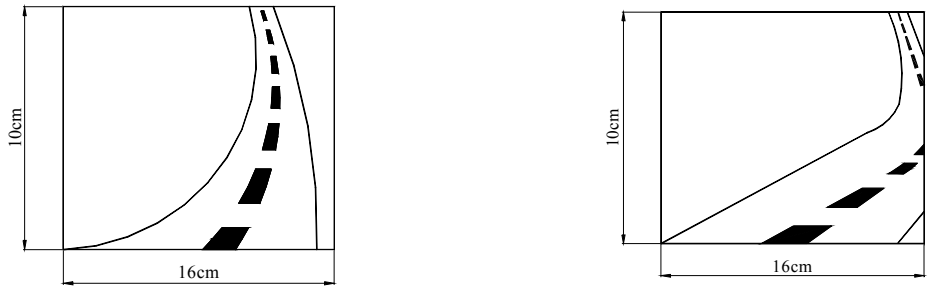
Angle of deflection has a direct influence on the driving safety. In the geometric database of Changjin Freeway, the maximum and minimum angles of deflection are 41°26′40″ and 12°12′14.4″, respectively. Crash rates vary with the angle of deflection, as shown in Fig. 3.



a. simple accidents b. common accidents

Fig.3 Crash rates with angle of deflection of Changjin Freeway

Reconsidering these two figures, we see the lower CR values, when the angle of deflection varies over 17°-25° for Changjin Freeway. This is because drivers could have a better view sight, when the angle of deflection locate within this scope. Otherwise, part of curve are beyond driver's sight and discontinuous pavement view is more prone to crashes, as shown in Fig. 4.



a. when the angle of deflection is 20° b. when the angle of deflection is more than 30°

Fig.4 Schematic design of angle of deflection for roadway safety

**Cross section.** Run off crashes, rear end crashes are the most common type of crash on mountainous freeway. And cross section is closely connected with these crashes. The width of roadway is important to driving safety, which consist of travel line, hardship and grass verge. Generally speaking, driving in wider sections is safer than that in narrow ones. Particularly, the width of hardship is also important, for it can provide a "buffer region" for drivers when emergency cases occur. Additionally, turnover is another common type of crashes with a higher crash rate,

which is mainly caused by high sub-grade design of roadway. Thus, it is better not to use high sub-grade and otherwise, enough traffic claim signs and other kind of safety facilities must be equipped together. Another factor that is worth investigating is the roadway number of lanes.

## Conclusion

Aiming at identifying contributory geometric factors which contributing to higher crash rate and sever injuries or deaths in mountainous area, a series of statistics investigation research has been performed. The considered or discussed geometric factors that affect or relate to safety and operational quality of mountainous freeway include: vertical alignment, horizontal alignment and cross section. By this research, we made a deeper understanding of the mechanism of crash occurrence and its relation with different roadway alignment. Surely, crashes may be affected by many factors (human, environment, vehicle, roadway etc.). Therefore, we should still make more quantitative researches to overcome this difficult issue.

**Keywords:** construction enterprise; safety Investment; safety economic

**Abstract:** Too many construction accidents have happened, which mainly caused because of the lack of safety investment. Analyzing the inner reason of the lack of investment in the construction of our country, looking for measures on guaranteeing that safety fund can be well applied on, increasing safety investment are preconditions to assure producing safety.

## Introduction

Therefore, how to improve the level of safety management in construction enterprises has becoming the main problems and attract the attention from the government, business and academia. Safety investment should be injected in the production of construction enterprise. It is a kind of economic behavior to improve the system's safety, prevent different kinds of accidents and to ensure production management runs smoothly[1]. It is generally held views that in safety activities need more safety investment, such as professional staff, safety devices, safety education and training costs, individual labor protection and health care costs. However, in a long time, illegal behavior of safety investment is an objective phenomenon[2]. The safety production and debates isn't received adequate attention, especially in stated-owned construction enterprises, small and medium enterprises and individual enterprises[3]. As a result, analyzing the inner reason of non-rational behaviors in safety investment and put forward the useful coal-mining safety solutions.

## The basic utility model

The investment behavior of the safety construction enterprise is not only affected by its internal factor, but also by the external environment, namely, the influence of social environments. There are two constraint conditions about the construction enterprise manager: regulation constrains and quality constrains[4]. Only by these two constrains can be realized the social income maximization. In order to prevent the irregularities on safety investment, the visible hand—the national safety regulations and the invisible hand --- quality of construction enterprise must be observed. From these two ways, we can discuss the irregularities and put forth the long-term and effective inspiriting mechanism.

When the construction enterprise make a decision on safety investment (it can be called '$\tau$'), they must make clear about the expected effectiveness which is come from the cognition and evaluation. On the rational assumption, the effectiveness has totally cognition and evaluation. But on the non-rational assumption, just because of the little knowledge about the effectiveness, the cognition and evaluation are limited. Based on this, we are concluded the safety investment function like this:

$$U(T) = \sigma \int_0^i u(t)dt + \int_i^m u(t)dt + \lambda \int_m^T u(t)dt \quad (1)$$

U(T) is the safety investment that the construction enterprise to continue the effect of T time ,which will bring the timeline effect. Assuming that the utility function U(T) is the continuous distribution function, its density function u(t) is continuously differentiable from the interval t [0， T].

Among them, in the interval （i，m）, the effect of the safety investment is recognized in the reason vision. Safety investment has a big effect for construction enterprise. For the effect in the interval of （0，i）to （m，T）can not be known. Irrational factors- σ, λ are existed separately.

In general state, the value of σ, λ is among (0,1). In this state, the utility function of the construction enterprise is u(T). The Utility function u(T) above the rational state is $\int_0^T u(t)dt$ . When λ, σ equals to one, it states that the safety investment of the construction enterprise is totally rational before $\tau$ or after $\tau$ . At present, the expected utility function is $\int_0^T u(t)dt$ . Therefore, in common state, the construction enterprise is irrational, and its expected utility function does not equal to the totally rational expected utility function.

**External inspiriting of national regulation**

The importance of safety regulations are determined by how to make it comprehensive and how to make the operation mechanism runs smoothly. The regulations laid down by the state will be helpful to prevent the irregularities on safety investment and purse it can make full use of its external inspiriting function to encourage the behavior on the right safety investment[5]. Through the enforcement regulations will be decrease the damage which is caused by irregularities investment behavior, and make effort the damage turn into the internal costs, namely the inside spillover accident[6]. If the illegal safety investment will be caused the risk of construction's business and make it difficult for the further development. The safety regulations, on one hand, it limited the occurrence and expand it's the illegal safety investment. On the other hand, it increases the market invisible value and lays a foundation for a good reputation. If the external constrains go smoothly and it may shaped into a behavior which would be expel the safety investment from passive adaptation to active consciousness. And finally, the concept will lead to active choice in the construction enterprises.

Based on the safety regulation, we will analyse the changes in the investment's security of the cognitive and the expected utility. After introduce the safety rules, the construction enterprise will have a certain understanding on the legal and illegal behavior.

Safety regulation factor is expressed by y, irrational factor δ and λ are functions of regulatory factors of y. $\sigma(y)$ and $\lambda(y)$ are equation which can be continuously differentiable. Among them, $y \in [0,+\infty)$, $d^2\delta / d^2 y < 0$， $d^2\lambda / d^2 y < 0$. Therefore, the expected utility function of the safety investment of the construction enterprise is as follows:

$$U_a(T) = \sigma(y)\int_0^i u(t)dt + \int_i^m u(t)dt + \lambda(y)\int_m^T u(t)dt \tag{2}$$

While considering to the non-perfection of making the safety regulatory rules and the limit of the safety monitoring behavior, which the violations of the construction enterprise under safety rules can not be totally prevented. That is to say, when $d\sigma / dy = 0$, $\bar{y}$ should be existed. Derivative

$$\sigma'(y) = 0， \quad 1 > \sigma\left(\bar{y}\right) \geq \sigma\left(y \neq \bar{y}\right) \tag{3}$$

In the same way , when $d\lambda / dy = 0$, at least a $y^*$ should be existed. That means derivative $\sigma'(y) = 0$, and also $1 > \lambda(y^*) \geq \lambda(y \neq y^*)$,

So, $\max \sigma(y) = \sigma\left(\bar{y}\right) < 1$， $\max \lambda(y) = \lambda(y^*) < 1$， $\sigma(0) \neq 0$， $\lambda(0) \neq 0$， (4)

$$\max U_a(T) = \max[\sigma(y)\int_0^i u(t)dt + \int_i^m u(t)dt + \lambda(y)\int_m^T u(t)dt]$$

$$= \sigma(\bar{y})\int_0^i u(t)dt + \int_i^m u(t)dt + \lambda(\bar{y})\int_m^T u(t)dt < \int_0^T u(t)dt$$

From the analysis above, if regulatory rules are needed to regulate the safety investment of construction enterprise, the value of expected utility of construction enterprise is less than the expected utility under rational condition. Therefore, only to adopt the regulatory rules to normalize the safety investment behavior can not achieve the biggest effect of it. Pareto opitimal goal is unable to achieve.

**The internal excitation mechanism**

In a certain degree, safety regulations can weaken the choices of the unlawful behavior, but it can't eliminate the foundation radically. If we can't take some effective measures to put an end on it, which will be cause more negative effects to society[7]. For the sake of the right investment behavior in construction enterprises, we should combine safety regulations with the internal quality. Both of this can prepare for bigger tasks and increase the control of the investment. All in all, we must obey by the regulations and also should take the quality of our own construction enterprises into deeply consideration.

It is important to introduce the quality factor to change the original model. The quality is a conception. The quality of construction enterprises can be identified as moral quality and septennial quality. It aims at to improve the quality. From safety investment, the moral quality is the rational support of safety investment. It will have two results: development and unbalanced development. The higher moral quality, the weaker costing is. On the contrary, the costing still increases, the internal control will affect moral quality.

At first, intellectual qualities x are added in irregular state. Among them, the higher intellectual and the control of construction enterprises are included.. Here we consider these intellectual qualities as independent variable. When these elements play a key role, the function can be nearly one. Here we give a function form which add the intellectual quality to safety investment function:

$$U_b(t)=\sigma(x,y)\int_0^i u(t)dt+\int_i^m u(t)dt+\lambda(x,y)\int_m^T u(t)dt \tag{5}$$

The formal function λ（y）, σ（y）now turns into intellectual element x and safety regulatory element y, that isλ(x，y)，σ(x，y). Among them, assuming, $x\in[0,+\infty)$， $\partial\lambda/\partial x>0$， $\partial\sigma/\partial x>0$ ， $\sigma(0,y)\neq 0$， $\sigma(0,y)\neq 0$，

$$\partial^2\lambda/\partial^2 x<0,\ \partial^2\sigma/\partial^2 x<0,\ \partial^2\lambda/\partial x\partial y=\partial^2\lambda/\partial y\partial x \tag{6}$$

$$\lim_{\substack{x\to+\infty\\ y\to\bar{y}}}\lambda(x,y)=1,\ \lim_{\substack{x\to+\infty\\ y\to\bar{y}}}\sigma(x,y)=1$$

Therefore, when $x\to+\infty$,

$$\max_{x,y}U_b(T)=\lim_{\substack{x\to+\infty\\ y\to\bar{y}}}[\sigma(x,y)\int_0^i u(t)dt+\int_i^m u(t)dt+\lambda(x,y)\int_m^T u(t)dt]$$

$$=\int_0^i u(t)dt+\int_i^m u(t)dt+\int_m^T u(t)dt \tag{7}$$

$$=\int_0^T u(t)dt$$

From the above we can seen that safety investment's irrational coefficient will be tend to 1 when it shows more rational and understanding attitudes toward the investment behaviors. The quality of sapiential will make better understanding on the safety investment. Only by this way, the rational investment will play an important role and make more profits to eh construction enterprises. The rational investment will promote the understanding, the quality of sapiential and beneficial to the initiative about their safety investment. The factor of initiative is the necessary condition for the rational development of construction enterprise.

The function is different between moral quality and sapiential quality. Moral quality gives expression on the spirit of humanity, impartial, generous and public welfare. It will produce altruism

and bring about more profitable effects. From that point of safety investment, "People First" is the important management philosophy. If we want to realize that we should build scientific development perspective, put people's life and property at first and make safety and prevention first.

Z can be used for intellectual morality, $\varepsilon(z)$ stands that the effect which can be produced in safety investment of construction under the control of intellectual morality. These morality elements can be added to the safety investment expected utility function as follows:

$$U_c(T)=\sigma(x,y)\int_0^i u(t)dt+\int_i^m u(t)dt+\lambda(x,y)\int_m^T u(t)dt+\varepsilon(z) \tag{8}$$

Among them, $\varepsilon(z)>0$ is under the morality of construction enterprise because of paying attention to the outer effect which can be produced from safety investment. In it, $\varepsilon(z)/dz>0$, $\varepsilon^2(z)/d^2z<0$ .Therefore, the constraint of safety investment behavior will be an effect of construction enterprise $\varepsilon(z)$, and $\varepsilon(z)>0$. At this time, if construction enterprise is under outer control of safety ruls and the constraint of their own morality of construction. The utility function of construction enterprise will be :

$$U_c(T)=U_b(T)+\varepsilon(z)>U_b(T) \tag{9}$$

But in fact, the safety investment behavior of the construction enterprise is hard to do all things well, for example, if the construction enterprise lack the intellectual morality, the utility function of the safety investment of construction will be :

$$U_d(T)=\sigma(y)\int_0^i u(t)dt+\int_i^m u(t)dt+\lambda(y)\int_m^T u(t)dt+\varepsilon(z) \tag{10}$$

This utility function will be smaller to rules and the expected utility function of moral qualities;

$$U_d(T)=U_a(T)+\varepsilon(z)<U_b(T) \tag{11}$$

Safety regulations and the internal quality is the necessary condition during the development of rational safety investment, both safety regulations and septennial quality is vital element to the operation for its safety investment, the moral quality is complementary factor and will have affect on the long-term development. In conclusion, the construction enterprises must change their concept thoroughly and the behavior must translate the principle of harm others into the conception of "Double Win".

## Conclusions

All in all, the external control of safety investment and the internal quality of construction enterprises would not decrease the illegal behavior. Draw on advantages and disadvantages are the immanent conception on construction enterprises. This would be give rise to more opportunism. In this background, the construction enterprise emphasize its internal quality and external control may be too weakness that would be cause resistant to the safety investment. Only combine the internal quality with external control, it can build rational atmosphere in safety investment. Finally, the aim to decrease or reduction the illegal behavior for safety investment can be reached.

**Keywords:** prevention refuge, sport venues, evacuation, safety, earthquake

**Abstract.** Through the survey of the current situation of sport venues as disaster refuge at home and abroad, the advantages of sport venue were widely dissussed from open space outside the sports venues, characteristic of main stadium and information transceiver system. The distribution structure of the hierarchical network of sport venues was analysised. Finally, some examples of sport venues as disasger refuge were proposed. It will be new development trend of stadium and sport venue in the future.

## Introduction

All previous significant disaster demonstrates that, when disaster takes place, a large number of people will evacuate to the same or multiple directions. At that time people want to know where to escape, where is the safety place and how to arrive at refuges [1]? Therefore, reasonably constructing prevention refuges can greatly minimize life and property losses and lower secondary disasters when disaster approaches, which is an important subject in various fields. Sport veneus has good disaster prevention capability and can become temporary or fixing asylums, disaster prevention control centers and medium-term or long-term shelters, etc, so, studying sport veneu as a disaster prevention refuge has an extremely important practical significance [2].

## The present situation of sport venues as a disaster prevention refuge at abroad and home

**At abroad.** In Japan, earthquake frequently occurs, so Japanese have extensive experiences in asylum evacuation sites and resettlement victims from ancient times. On early the Edo Period，when earthquake or fire disaster took place, local government immediately built "Protection Shelter" to rescue victims and provide relevant assistances [1]. Now, refuges in Japan include parks, green places, schools, sport veneus, and other public halls. Among which, sport veneus are playing a significant role. In modern Japanese Kanto earthquake and Kobe earthquake, sport veneus sheltered more than 200,000 refugees and were equipped with enough supplies for victims [3].

**At home.**In recent years, the Chinese Government attaches great importance to succor, recovery and reconstruction effort from disasters, and has promulgated a series of related regulations. The regulation of / Planning and Management Requirements of Urban Seismic and Disaster Prevention / was officially executed on November 1, 2003. Article 9 of the regulation stipulates planning of urban seismic and disaster prevention should include earthquake prevention passages, evacuation sites (such as green places, squares) in the city and district, setting evacuation centers and measures of refugee evacuation.

Currently, many cities have proposed comments and suggestions about planning and construction of disaster prevention refuges. On October 1, 2003, in Beijing City， Beijing Yuan Dadu City Wall Relics Park was completed and opened, which is the first systematic planning emergency shelter in China. The park has 11 functions with emergency escape.

**Advantage of sport venue as a disaster prevention reduge**

Sport veneu has such a great deal of open and public space that it becomes an indispensable earthquake disaster prevention site. The planning land areas of sport venue are generally in a few hectares or more, easily to meet the areas requirements of temporary refuges and center refuges. The overall layout, facilities configuration, traffic organization of sport veneu are carefully designed, scope of services including peripheral dozens of hundreds of kilometers. Once a great disaster happening, even warning level high, a large number of victims, the duration of disaster long, sport venues can become the ideal places for victims and concentrated zones against disaster.

- There is a large open space outside the sports venues, where can be used as emergency shelters lands and a helicopter parking apron.
