- Sport venues have high construction standards and perfect safety performance. First, the main stadium structures designed according to seismic focus class fortification, can withstand the great earthquake. Secondly, sport venues are equipped with emergency generator room, transformer room, EPS power supply equipment, and other facilities, which can guarantee the power supply requirements of refuge in the disaster. Thirdly, the installation of automatic fire alarm smoke control facilities system, sprinkler system and high sensitivity,which can effectively ensure the fire safety evacuation of victims; Fourthly, sports facilities base should have at least one surface or two surfaces of adjacent city road, to provide more favorable conditions for evacuation and rescue
- Part of the Event Management District Housing and security monitoring room are equipped with advanced information transceiver system, which can be used as a disaster emergency command center.

Experience has shown that the investment of construction costs less and the effects is obvious and quick to reform the existing stadium into a disaster prevention refuge, and operational conditions are good and relatively safe. The sport veneu applies to establish command center of disaster rescue, disaster resistance and disaster prevention, the center of information and communication facilities, disaster relief supplies and transit sites, the camps of disaster relief militaries, and ideal offices for various government departments. The proposed stadiums should be designed to have function of disaster prevention at the planning phase to make contributes for urban disaster prevention system.

**The distribution structure of the hierarchical network of sport venues**

Through long-term research, Japanese experts consider that by highly organized and spatial planning, victims will be quickly moved to safey places, and to be stabilized their psychology, which is the significant key to reduce the casualties in disaster prevention planning. Therefore, Japanese disaster prevention system pays special attention to "shelter" plans, whose classification is more detailed, though which, authority institutes could purposefully design refuges and set function allocation.

In our country, the system of stadium in city is generally formed by ‘ small, middle, large scale,’ three dimensions sports venues, which exactly coincided with three levels of refuge,that is, community , district and city sport venues,which was divided by urban administrative divisions[4], shown in Fig.1. Each refuge level has corresponding service radiu standards, and takes on different task in disaster prevention, disaster relief, post disaster reconstruction, and evacuation process, constituting a reasonable and hierarchical network structure. The structure is widely covered and each venue can work independently, but also through the city road connectivity and collaborative operation, which set up urban refuge system in the general. In this system, from the bottom up, the venue size, service radius, the allocation of resources are increasing [5].

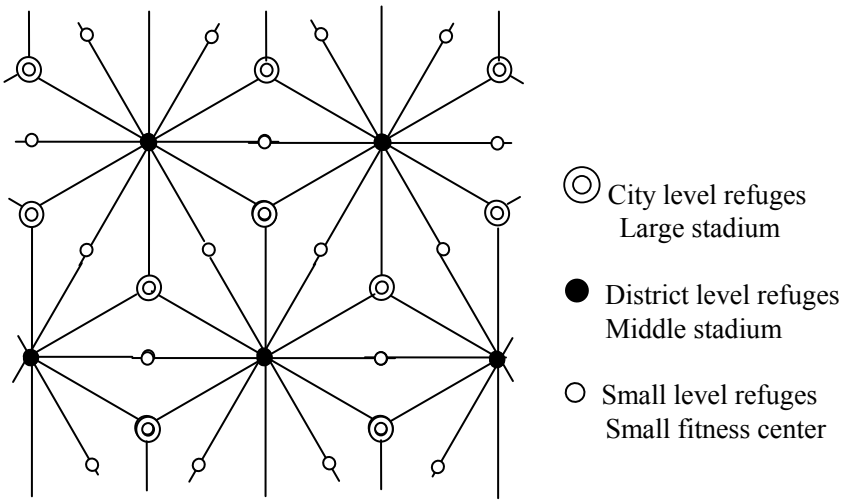

Fig.1 Structure of sport venues [4]

**Examples of sport venues as a disaster prvention reduge**

When "Katrina" hurricane attacked New Orleans City of the United States in 2005, a lot of residents unanimously escaped to the Super Dome Stadium. Mianyang Jiuzhou Stadium which occupied 22 ha. , had accommodated a total of more than 100 thousands people and even maximum capacity of 4.5 million people in a single day in 512 Wenchuan earthquake in 2008. It has been named "the most populous disaster shelter in the world." by overseas media. Not only Jiuzhou Stadium, but also South-River Sports Center in Nanyang city, Deyang Sports Center, even Mianzhu Sports Center not having completed, Dujiangyan Stadium, Beichuan middle school sport veneu all became the best sites for temporary evacuation and disaster reduction shelters for victims. To some extent, this phenomena also reflects that stadiums as a function of disaster prevention is insufficient [5].

**Conclusions**

Sport venue as important urban public construction, its safety and disaster prevention must be concerned about. In addition to meeting essential function, simultaneously the project argumentation and design should be evaluated in urban disaster prevention system. First, Urban Culture Sports Park and Olympic Sport Center, should be incorporate into the urban disaster prevention space system, which will play essential role for urban disaster prevention. Second, the existing sports centers should be transformed with local condition, and combined with demand for urban disaster prevention, to make contributes for the city disaster prevention system planning. Finally, to meet the requirements of urban disaster prevention system, we promote disaster prevention in the overall planning and design phase for future construction of the proposed stadium. Based on these efforts, better requirements of urban disaster prevention and disaster prevention function of stadium can be achieved fundamentally.

**Keywords:** GIS; Visualization; Digital; City; Model.

**Abstract.** As an important living place for human beings, city is regarded as a main place for the birth, spread and development of human civilization. This paper, based on the principle of system development and combining with the need of building "Digital City", makes an overall design of the "Digital City" 3D visualization system. Firstly, a 3D ground objects model, i.e. .x files, is made through inputting the ground objects of the experimental area into 3DSMAX, then, the .x files are converted to .xpc files in order to achieve a better displaying effect in producing a 3D landscape. Secondly, the author makes corresponding pre-processing to the aerial photos, satellite images, topographic data, digital elevation models and a variety of vector geographic data, and then superimposes and loads these data into Terra Builder module of Skyline software, which generates 3D topography landscape, that is, .MPT files and forms the terrain database required in Terra Explorer Pro software. Next, a 3D landscape is preliminarily established by inputting the 3D terrain model and the 3D ground objects model, i.e. .MPT files and .xpl files, in Terra Explorer Pro, and by editing a real and accurate 3D geographic model and a real Digital City 3D landscape model, that is, FLY files, are respectively formed. Finally, on the basis of the 3D landscape model, the system is developed by using Visual Basic + TerraDeveloper and the basic operation of 3D, spatial analysis, visible analysis and other basic functions are preliminarily achieved.

## Introduction

As a part of Digital Earth, Digital City is regarded as the development direction of city information technology, and 3D GIS is a kind of important foundation spatial information of Digital City. The establishment of 3D city can provide people with a variety of city scenes in omni-directional and intuitive ways and build a real and intuitive virtual city environment, which greatly helps the city administrators implement effective measures in making scientific, cultural, and ecological plans[1].

To realize 3D GIS involves many aspects including geography, mapping, computer technology, database technology and others. Currently, there are four major soft-wares used on this issue, namely, Google Earth, the World Word developed by NASA, Geo Fusion's Geo Matrix kit and Skyline [2]. This study takes the example of an experimental area in Tianjin using Skyline software as a platform and combining with 3D model software, and attempts to build and develop a Digital City 3D landscape，finally achieving its basic functions in Digital City.

## System Design

Taking image data, terrain data and 3D architectural model as its cores, this system makes full use of the features and advantages of images and GIS technology, and integrates technologically GIS, RS and virtual simulation technology to build a 3D geographical information platform. The design of this system involves data processing, 3D landscape model establishment, system development and other series of issues. In order to make sure that all jobs are closely related to a database establishment and its application, the building of the system is operated in the following steps:

Firstly, the relative data collection and collation are made, including two-dimensional (2D) data and 3D landscape data. Since the data processing in the primary stage plays an important role in the system operation, it's very crucial to make precise data collection and pre-treatment data.

Secondly, the 3D landscape model is the core of the system, hence, in order to obtain 3D landscape documents and create 3D model quickly, DEM and image data are very vital in running the system. In this step, the DEM and image data are inputted into TerraBuilder to generate the running foundation of the system—3D topography landscape, i.e., .MPT files, then, .MPT files combining with 3D ground objects model are inputted into Terra Explorer Pro and FLY file are produced at last.

Finally, the establishment and application of the system concerning with 3D GIS are carried out and the required functions of the system are basically achieved.

**The Development of 3D Model**

In the geographical landscape, in accordance with the distribution characteristics, the geographic objects can be divided into two categories: terrain objects and ground objects. The former belongs to field-based objects, such as topography, soil type distribution, and etc.; the latter is featured as discrete entity, such as buildings, trees, telephone booths, street lamps, and so on. In city 3D model, different application situations require different ground objects expressions methods and 3D data quality, likewise, data collection and processing methods are also different [3]. In the following section, the study makes some processing of ground objects model and terrain landscape respectively, and the ground objects processing is divided into independent processing and batch processing in order to highlight some important independent objects. Building Digital City 3D landscape scenes is composed of the following four steps:

**2.1 Processing of Independent Ground Objects Model.**

The spatial single model built in 3DS Max has the features of fine structure and clear texture, so this kind of model can be used for some important or symbolic independent objects, and the whole process includes five steps: texture procession[4], importing CAD drawings, building 3D model, mapping design and data export.

(1) Handling texture. In this experiment, images obtained in the experienced field are required to be rotated, stretched, cut, stitched and other processions in Photo Shop to produce a complete texture image of the certain side. Meanwhile, all the texture images colors in the work area must be in balance; textures of independent objects should be processed respectively.

(2) Modifying the CAD drawings. The original data should be converted into DXF format if they are not, and then, inputting CAD drawings in 3DS Max.

(3) Building 3D model. Several methods are mainly used in this process, including stretching, lofting, spinning, Boolean operations and others. To build the 3D model, researchers should firstly take the shape of the model into serious consideration, then, choose the most appropriate modeling method and try to use the method that produces less edge lines, which can help to reduce the amount of data model and increase the operating speed of 3D system.

(4) Mapped mapping of 3D model. By associating the surface of the buildings with their textures, the mappings are just attached to the appropriate position of the 3D model, making sure that different objects should be chosen different mapping projection mode to ensure the realistic sense of 3D model [5].

(5) Exporting 3D model. Finally, the established model is imported into .X format, and buildings models are added to MPT in Terra Explorer Pro module. During this process, Z-axis is not needed to be rotated, and each model is taken as an object to output respectively. Acquiring center coordinates of the building before it is exported, and then, the model files are exported into. X format.

**2.2 Processing of Batch Ground Objects Model**

In 3D scenes, there are many ordinary buildings, such as, a piece of residential or industrial areas, if all of them are used in 3DS MAX model, the cost will be pretty high and the amount of data will also increase, which will affect the system's 3D roaming effect. Skyline is chosen to be a platform to build batch ground objects model, and the building steps are as follows:

(1) Vectorization on buildings after adding 3D images of the experimental area to Arcmap.

(2) Through the investigation in the experimental area, the researchers mark the attribute information of the buildings as well as the number of floors on images; furthermore, gather the texture information to lay the foundation for building model.

(3) Some attribute information is added to Arcmap, including the buildings' codes, floors, height and others, and then, exporting Shp format files and importing them into Skyline.

(4) Adding texture data. After dealt with in Photo Shop, the texture data of different layers are separately put on their folders of each layer, adding texture data according to the height of the floors.

(5) 2D vector data are overlaid in Terra Explorer Pro by connecting spatial databases, labeling and coloring them, also, connecting vector data to Skyline using SED streaming media technology in order to ensure the convenience of updating data later.

**2.3 Processing of 3D Terrain Scenes**

3D geometry spatial data of the terrain objects are the foundation in building 3D geographic model. It can not only add the capability of 3D analysis, but also strengthen the 3D representation of GIS spatial query and analysis, which is convenient for different users to better understand various spatial distribution relationships [6].

Next, a 3D terrain landscape is built using Terra Builder. Terra Builder, as a component of Skyline, is used for terrain visualization application to create a 3D ground model with an accurate geography registration and real sense of scenes. Then, by using Terra Builder, a new experimental area is built and the coordinate system and the ellipsoid information are identified, after that, adding various types of data, images and DEM to the experimental area to generate 3D scenes of the experimental area, that is, MPT format.

**2.4 The Establishment of 3D Landscape**

Skyline is an interactive environment created by the use of aerial imagery, satellite data, digital elevation models and other 2D or 3D information sources . To build a 3D landscape, firstly, the 3D terrain model of "Digital Earth" is imported in Terra Explorer Pro, according to the corresponding requirement, vector data should be overlaid, tagged and colored. Next, 3D ground objects model data are required to import in Terra Explorer Pro, adjusting their location, size and position, and the FLY format project files are finally produced.

## Realization of System Functions

The 3D landscape system can be developed after being established, and this study, taking Terra Developer as its development platform, uses an integrated secondary development model to do the secondary development to 3D landscape.

**3.1 3D Navigation and Information Retrieval Panel**

In the left bottom of the main interface, the system provides switch tabs of both 3D navigation and information retrieval panel, in which data, navigation and query of sceneries, and searching and viewing thematic information can be found.

(1) 3D navigation

Clicking the 3D navigation tab, many functions can be achieved in the panel, such as, 3D landscape navigation, coordinates positions query, 3D ground objects query, browsing helping information and Hawkeye view navigation.

(2) Information retrieval

All the data contained in the item of "digital city 3D visualization system" can be viewed and asked by clicking the Information Retrieval tab.

**3.2 Toolbar**

Toolbar classified gives some common buttons for browse, inquiry, measurement and analysis, also, it provides many functions of 2D and 3D objects, and the following part shows some widely used functions:

(1) Spatial Analysis

As one of the core functions of Digital City system, spatial analysis can provide supporting decisions for city administrators, improving the modernization of city management. Digital City

system based on Skyline can achieve visible analysis, area measurement, space measurement, terrain profile analysis and other 3D spatial analysis functions.

(2) Measurement

User can make vertical, horizontal and area measurement to 3D terrain through measurement tools.

(3) Visible Analysis

Visible analysis is to judge whether the sight between two points has blocks or not, and it can not be used if the two points are blocks.

(4) Query and Position

User can find the required attribute information conveniently if they provide the query conditions, and they can also use coordinate location to find the place where they want.

## Conclusions

This paper takes Digital City as an example and builds Digital City visualization system based on Skyline by establishing model in 3DSMAX and Terra Builder, using Photoshop processing texture, building a database in Arcgis, and the secondary development through Visual Basic + Terra Developer. The feature of this study is to process 3D model in different levels and layers, emphasizing accuracy on some important ground objects and efficiency on batch ground objects. With the further development and deepening of the construction of digital cities, virtual display technology, spatial information visualization technology, GIS technology has developed rapidly. The 3D visualization platform, as one of the key technologies of digital earth, organically combines the virtual display with 3D GIS by using 3D model and visualization technology. The establishment of city virtual 3D visualization can provide a platform for the application of 3D GIS in every walk of life and build various city scenes in a omni-directional and intuitive way, which greatly improves the sharing and using level of city spatial information.

**Keywords:** informatization;GIS;sharing "One-Map"; land and planning management

**Abstract.** Based on the full research on the recent information construction of land and resource department and planning department, and the requirement of the related business management, this article has a detailed illustration of the popular construction ideas, "resources sharing" and "One-Map", along with the construction conception of geographic information system with sharing "One-Map" between land and planning departments.

## Introduction

In recent years, with the construction and application of the GIS platform, planning and land management department has a higher requirement for the information platform on the basis of the original information construction. In terms of domain, the platform needs the smooth interface of the information systems and comprehensive information data sharing, in order to focus on the longitudinal business information together instead of internal management and optimization. In terms of object, the needs transfer from traditional simple data processing to a higher level of information management such as integrated data processing, information extraction and the creation, knowledge management and auxiliary decision-making. In terms of function, the platform's development changes from the traditional standardized to across institutions, cross-industry individuation. At the same time, each information systems has the higher requirements of the personalized needs for different management areas.

At the same time, in the past few years, planning and land departments have been vigorously promoting the construction of "one map". Especially, the Ministry of Land and Resources is launching a national "one map" project construction. Although the "one map" projects between the planning and land apartments are different in content, they both focus on gathering various kinds of data on a unified platform, along with business management synergy. After comparing the contents of the two "one picture", it is not difficult to find much duplication of resources on both platforms. In practical management work, planning and land departments have strong demand in sharing data.
Currently, the geographic information system is used in many aspects of land resources management and planning management, and dozens of working system platforms are set up. However, the information system has not become the core part of planning and land resources management by now, and the management behaviors also have not completely been finished in a unified platform. To some extent, problems exist, such as the basis database not cover enough, poor present situation, data repeating and figures and attributes not corresponding. Data standardization and integrity of management class need to be improved. System construction is isolated and diversification, which is still not fully in accordance with the requirements for full life-cycle management to solve the gap between management departments and steps, achievement of the data connectivity to support all planning departments of land and resources management. The effective support ability of informatization on the resource management has larger development space. Systems available now are mostly isolated, at the same time collaborative work platforms which

have collection of various functions and perfect integration of various aspects of land and planning management business can rarely find.

Based on this background, studying how to promote the level of land and planning management relying information technology has important significance. Not only we can impel a informationization and fine daily land and planning management business, promote the cooperation of business departments, but also improve the decision-making efficiency and quality, make sure to manage and use land fine.

**Daily Land and Planning Management**

**2.1 Land management business**

The major functions of land management department include: to formulate the jurisdiction of the land use planning and land reserve resources development planning; review the scope and quantity of land requisitions; charge implementation of land supervision, investigation and punishment of the illegal cases, as well as land disputes' conciliation; management the land use right transfer, lease, sale, exchange, alteration, donation, inheritance, termination in accordance with the law and deal with relevant formalities; protect cultivated land resources according to the relevant laws and regulations combined with the general and special land use plans, etc.

**2.2 Land planning management**

Urban planning management business mainly includes to organize the formulation of urban planning management, and the implementation management. Planning implementation management comprise planning permission management which including "one note and two card" and supervision after approval.

**Present Informationization Situation of Land and Planning Departments**

**3.1 The "one map" Construction of Land Resources**

"One map" project of land and resources is based on the second national land survey results at the moment of implying the "golden soil project". The project is integrating all the business data of land and resources, trying to establish a comprehensive supervision platform, which contains five application systems of approving, supply, use, management and supervision. Through data concurrent, scraping, updated in real time and establishing data sharing mechanism, we can ensure the present situation and authenticity of "one map", which make sure its vitality.

At present, there are successful cases of "a map" project construction. Tianjin City has done a great job which take the lead to achieve the "one map" management mode through the city, and the efficiency is very obvious. The News of Land and Resources carried a special report on their experience and practice .

**3.2 The "one map" construction of land planning**

"One map" project on land planning earliest originated from the building database after the complete coverage of regulatory detailed planning. Because the regulatory detailed plans are isolated, the edges are hard to be match when plans put in the data warehouse. Since then all the planning unit need to do put edge processing according to neighboring relationship , to ensure data integrity, make its combined complete "regulatory map", and make sure its dynamic updating maintenance. The purpose is to cover the entire city of regulatory detailed planning can complete seamlessly into the database.

In recent years, with the need of resource integration, "one map" on land planning gradually extend from "a graphic map" to "a space map". It means now from the perspective of geographical space, it is a construction of composite all regional planning data collection of information resources based on geographic coordinate system in space unity, so as to realize composite show and comparative analysis function in the information system. From the view of time, it need realize dynamic update, at the same time relying on the powerful function of GIS it can manage data versions, which bringing great convenience for examination and approval of planning business.

**3.3 The foundation geography sharing platform construction**

The real time of the construction into the implementation of basic geographic information sharing platform in our country is not long. In the past there were individual cities to promote the construction, but the effect is not ideal. The main reason is that the application level of construction

is not high. Although some cities have lots of sharing departments, but very few really combine with the business, while most departments only achieve simple browse and query function.

**Analysis of Existing Problems**

**4.1 Independent coordinate systems**

With Yangzhou city as an example. Before 2008, the planning and land departments in Yangzhou were using a same coordinate system which called "54 Beijing coordinate system". Since in 2008 the second of land and resources survey adopted "80 Xian coordinate system", the land resources department built new system based on new data, which leads to the current difficult in interface of land construction coordinates of two departments. In many cities, there are similar problems. On 1st. July, 2008, China started to use the "2000 coordinate system" . The conversion of the data in different coordinate systems in actual work is very difficult. Therefore, in the next period of time, the inconsistent of coordinate systems will be a big problem in data resource sharing.

**4.2 Difficult to share information resources**

Even in Shanghai, land resources and planning departments have merged as Shanghai planning and land resources administration, data resource sharing is also facing many problems on both procedure and system. Especially on the aspects of the integration of historical data has great difficulty. In places there are to separate two independent departments, information resource sharing is much harder.

In communication during the survey, there are some obvious reasons. First of all, each department value own information resources very much. There is factor like department interests, but there are other concerns. Such as planning department would like to share the cadastral data, but the department of land management can not make sure all cadastral data is right. Once the sharing data become basis for other departments to make approvals, governors need to be responsible for bad influence. Second, such as the problems mentioned above like inconsistent coordinate systems and disunity data standard, even if sharing data on one platform, the data is also differ in thousands ways and difficult to correspond.

**4.3 Basic geographic data redundant construction**

During the period of "11th five-year plan", the construction of geographic information system is hot. Not only departments need GIS application very much such as planning and land departments are promoting vigorously, but also be popularizing across the country as an application of digital urban management. For GIS application, every department can not across the construction of basic geographic information data, so we can find redundant construction of the geographic information data in almost every department. The repeated collection and building databases consumes a lot of financial capital. This situation not only caused waste of resources, also influence the practical application effect of systems.

In practical work, planning and land departments both need to refer topographic map, cadastral map and planning data. Therefore they can implement supervision and management through contrasting the real data and planning data. In the existing departments settings, even if the two departments belong to same ministry, the actual planning and land departments' work are separate, the exchange of information still exist certain problems. As a result, it is hard to avoid the basic geographic data collection in order to completely master needed data. Both departments do this work, to a certain extent caused the basic geographic data redundant construction. Even if there can be a merger, it is likely to have built a unified database figure inconsistent or attributes related to one figure. Because each of planning and land departments holds a set of surveying and mapping data, not only there exists data redundant construction, but also they update in different ways.

**Conception of Geographic Information System Construction of Land and Planning Based on Sharing**

**5.1 construction thoughts**

5.1.1 Unified coordinate system and data standards

(1) Unified coordinate system

Although in some cities the functions of planning and land have been merged, but the vast majority of urban planning and land departments are in independent offices. Due to belonging to different ministries, for a long time, planning and land departments exist many differences in informatization standards. In practical work, they are the only two government departments which need docking position relationship. Therefore, uniform spatial reference frame is the premise to realize data sharing, which is also inevitable.

So far, based on the different space reference system, three kinds of coordinate systems are used in our country, namely the 54 Beijing coordinate system, 80 Xi 'an coordinate system and the national 2000 geodetic coordinate system. The state bureau of surveying and mapping has clear requirement to supply the 2000 coordinate system on July 1th, 2008. There is a file which specailly to require the exsit geographic information systems to switch the coordinate system to the 2000 coordinate system in 8 to 10 years. At the national level have realised that a series of problems have been caused without a unified coordinate system.

(2) Unified data standards

In the process of the planning and construction of data layer, it is necessary to formulate uniform database building standards and corresponding data exchange standards. In this way, data can smoothly exchange in related organizations, which avoid hindering data sharing between different organizations and applications due to the difference of data definitions. We should also establish a unified data standard, and formulate corresponding mechanism of the process of data collection to ensure the accuracy and effectiveness of the collected data. Meanwhile, updating in real time and strengthening the quality inspection of the data while data warehousing. To adopt centralized database storage method will make management more convenient.

5.1.2 construction of "one map" Based on the co-construction and sharing

(1) Integration of a set of public fundamental geographic database

Based on To land 1:500 scale topographic map, multi-period aerial image and satellite image in the production of the second survey organized by the land and resources department in 2008, we can establish a GIS database including conventional based geographic data layers, which conclude surveying control points, drainage system, landscape, vegetation and soil property, inhabitants and facilities, geographical names, transportation, pipelines, boundaries and administrative divisions, digital ortho image.

(2) Integration of thematic data of land and planning "one map"

In the daily business work, planning department may want to know about land cadastral distribution and properties and so on, while the land and resources department need to master design conditions such as planning of land use and land indicators when go through land transfers or examination and approval procedures. In this case, the two departments need to integrate their respective business data and the examination and approval data to one map.

**5.2 conception of system architecture supporting distribution**

Considering that in most cities, the planning and land management functions are independent and belong to different departments, the system needs to support sharing of distributed deployment, which means basic geographic database, land management database and planning database may be deployed in different office environments. To achieve the goal of multi-sectoral data sharing would require building a support distributed system architecture.

All kinds of data and information based on the "one map" can be organized and put into database by planning and land departments respectively based on the uniform data standards and technical standards. The databases should be deployed within each data center, and meet the technical requirements for data distribution, resource sharing, maintenance on their own and collaborative management. In this way can prompt the relevant departments of information

management making effective management and information update maintain, maintain efficient collaboration and clear department responsibility at the same time, so as to realize distributed system in a common data support.

Because the business is handled by many departments work together, so the system should run in a network environment. Spatial data, attribute data and document data need be stored on multiple physical distribution devices, forming a physically distributed in each node of the network, while logically exist in a database, as is shown in Fig.1.

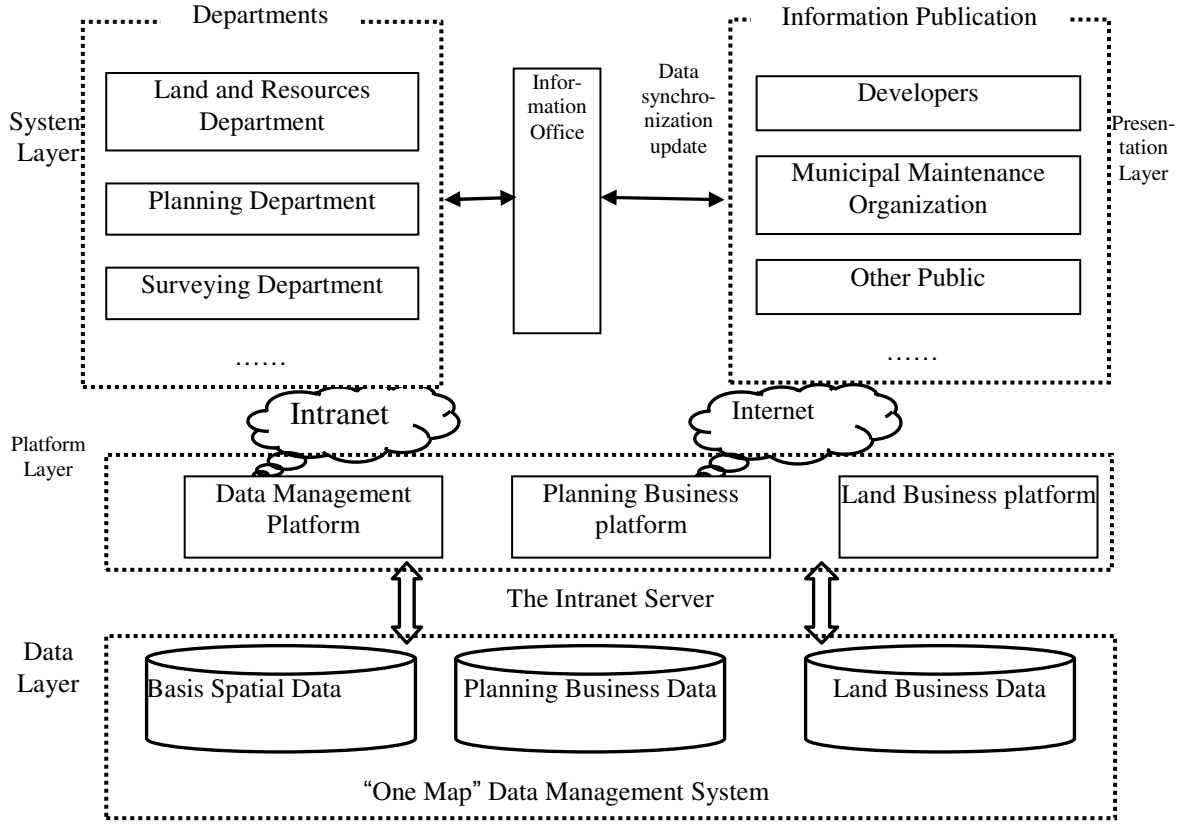

Fig.1. The idea of system structure

Data layer: on the basis of sharing "one map", real-time update the business data. It is responsible for the storage, maintenance and management of the corresponding basic geographic data, planning and land business data and historical archive. All the data should be put in the "one map" management mode in accordance with the unified standards included.

The platform layer: the construction of united application supporting platform, which realize the business system to expand dynamic and sustainable. Unified platform and database will bring great convenience to management. Based on the forward informatization construction and planning, we can modular step by step to achieve full information. Specifically, there are following aspects: unified user management, implement unified identity authentication and single sign-on (SSO); unified workflow to adapt to the changes in the business process; GIS management which provide a unified geographic information services; unified data services to provide the unified basis data services.

System layer: on the basis of the business of real estate resources, set up comprehensive business system and form a multi-level, scalable management technology platform. System function design can be tailored set according to the differences of regions and specific business situation, which realizing step by step. In addition, we need design suitable interface in order to dock the existing OA system.

The presentation layer: with the development of digital and wisdom cities, the concept of mobile office has applied gradually to daily work and life. Information construction in the future will keep pace, fully using the latest scientific and technological achievements, letting the development and construction of information management system to a new level. In addition, there can be related interface make smart phones, tablets and other mobile terminals access to the system conveniently. It will provide quick and convenient access for managers working out to access the system. It also will be easy to access system data and information, which provide statistical analysis on the spot and auxiliary decision-making.

**5.3 establish dynamic updating mechanism of data**

Whether if the "one map" project can be applied normal and sustainable, stable system support and guarantee to update data in time is the key. If the system is not stable, "one map" project cannot run normally. If data condition is poor, the project cannot achieve the desired effect. So there is a strong need to set up a system of data dynamic updating along with effective management mechanism.

In the survey, data update has been a problem in the management. Lots of projects has spend repeated money due to the data can not be updated in time. "One map" project has a great quantity, wide range and huge investment, so we must establish a system including normal operation guarantee mechanism, data update maintenance mechanism and long-term management mechanism.

Update about basic geographic data layer is found going well. Image data update through regular purchase, while terrain data can be synchronous updated due to management function.

Refer to some cities' experience, thematic or management data of land and planning departments can realize dynamic update of figures and attributes through the examination and approval of construction projects and other daily management work, combining with respective administrative functions and meet the business needs at the same time.

## Conclusion

Based on the field research in HongQiao business district management committee in Shanghai and planning and land departments in Yangzhou, and sufficient investigation on the needs of the current government departments, conception of shared "one map" construction is in accordance with the future development direction. For further work, it will help to summarize the needed applications of the land and planning departments more comprehensive and research more deeply about its management system and approval process. the construction of "one map" is more in-depth understanding, make the construction of the "one map" and the system design can combinate business management work better.

As the "Twelfth Five-year" National Informationization Construction Planning has been launching and implementing step by step, the future informationization process of daily work of land and planning is a trend. Continuous development of GIS technology will make better software platform better. Its powerful processing power of figures and attributes is bound to better achieve the construction of information platform. Therefore, it must have a profound impact to the management system of land and planning departments.

**Keywords:** CORS, GIS, Dynamic monitoring, SQL Server.

**Abstract.** CORS is called Continuous Operational Reference System, which comprise a network of Global Positioning System receivers. Traditional sensors were used to determine the working environment parameters and mechanical property parameters of the bridge, and CORS technology was applied to obtain the positions of bridge monitoring points in three axis directions, besides the technology was adapted to combine GIS software with the relational database, in which the function of GIS and SQL Server were to manage the spatial information and the corresponding attribute data. In this paper the technology route was designed in detail to realize the real-time dynamic monitoring and visualization analysis of the deformation of large bridge. This system was developed to evaluate valuable information such as the stability, durability and reliability of the bridge.

## Introduction

Since the emerge of CORS technology in 1990s up to now, many CORS network have been established in big cities, such as Hongkong, Shenzhen, Beijing, Guangdong Province[1]. The main technology of CORS is developed rapidly, and its application is becoming mature. CORS is not only the product of GPS, but also a system combined with internet technology, wireless communication technology, the computer network management and GPS technology.

Health monitoring of large bridges is to determine the features of position change for major feature point in the effect of temperature, wind, load, earthquake and other external factors, and to evaluate the damage, stability and residual life and so on. In the past, due to technical limitations, the major methods of measure the vibration and displacement of structure for huge bridges includes: displacement sensor testing method, accelerometer method, laser interference test and total station measurement [2]. A certain purpose can be achieved although using these methods, some problems still exist, these traditional methods can't meet the needs of continuity, real-time and automatically dynamical observation of bridge monitoring. In recent years, the CORS system are applied in the large-scale cross-sea construction projects, and special CORS have been established for the Hangzhou bay cross-sea bridge, Zhoushan Island mainland Jintang bridge engineering and the Jiaozhou bay bridge [3].

CORS make the continuity, real time and dynamic of monitoring for large bridge become a reality. GIS is a effective tool for collection, storage, management, analysis and display for the data relating to geographic distribution, and it can simultaneous manage the spatial information and attribute data, besides it can establish a dynamic database of monitoring data, and regularly update, backup and recovery the monitoring data. In order to realize the sharing of monitoring data, we used the database management system based on network environment, such as the SQL Server database system. Visualization can clearly reflect the dynamic change situation of the structure. Therefore, the visualization of monitoring data is one of the essential functions of dynamic monitoring system for the bridge health.

## CORS system

CORS is composed of a base station, data processing center, data communication link and the user part. CORS can provide GNSS (Global Navigation Satellite System) data consisting of carrier phase and code range measurements which can provide data for three dimensional position, meteorology, space weather and geophysical applications. Surveyors, GIS users, engineers, scientists can use CORS data to improve the precision of their positions. The data communication between base station and data processing center can use DDN (Digital Data Network) data network or wireless communication method. Bidirectional data communication between station and data processing centers can be realized by GPRS, CDMA [4]. Single reference station system can not solve the problem of the long distance positioning. In order to achieve the goal of the baseline accuracy better than 3 cm for the multi-reference station system, the reference stations should be established densely in a region, and the distance between stations should be less than 30 km. While the CORS technology has a wide precision coverage, and the precision distributes evenly in the covered region. At present, CORS technology have been tested and applied widely both in hardware and software in many countries, such as in Canada, Norway, America, Brazil, South Korea and so on. The CORS system in American has more than 500 reference stations, which is run by NGS (National Geodetic Survey) belonging to Oceanic and Atmospheric Administration. In China, GPS CORS technology has been developed and applied in many projects, according to the actual measurement data, real-time positioning accuracy of CORS can reach ± 3cm in plane and ± 5cm in vertical [4, 5], even up to 1-2cm [6]. The earliest application of the network RTK technology in China is the CORS system in Shenzhen city.

## Method and technology route description

In this paper, we applied the traditional sensors to determine the working environment parameters and the mechanical property parameters, and used CORS techniques to determine the displacements of bridge monitoring point in three axis directions. SQL Server database management system was adopted to manage the bridge monitoring data in the design of the software part, so as to realize the management of the massive data. The monitoring data in some time windows was used to establish the dynamic database, and then to realize the establishment, backup, restore and visit. The visualization technology were applied to describe the key part displacement and the overall displacement of the bridge in real time. The interaction between GIS and other modules was achieved by GIS software, so as to realize the functions of monitoring data input into the database, database backup and restore, database visit through the local area network and visualization of a variety of the access information.

In order to collect on-line information of the bridge, different types of sensors should be mounted on the critical points of the bridge, such as the working environment parameters and mechanical property parameters of the bridge. The displacement of bridge monitoring point in three axis directions should be determined by the CORS technology. GIS and database technology were integrated to transmit the data to the database through the network, the spatial information and the and corresponding relation database were managed by GIS, besides the monitoring data were managed by the relational database. The interfaces were developed, and the reports or charts were also be generated, besides the health condition information of the bridge structure and operational status should be published on online for the user to visit data in real time conveniently.

## Design of database

In order to display the relationship between real-time monitoring data sheets, GPS monitoring point information table and warning information table of the every monitoring point, a primary key between two tables in a database diagram were created. The relationship between real-time monitoring data sheets of the measured point and GPS monitoring point information table was mainly displayed in real time on the displacement of the bridge. During the process of real-time monitoring,

the GPS software could automatically solve the coordinates of GPS monitoring point and these data will be stored in the corresponding MonitorNo table to display the displacement of each point, and the database diagram is established as Fig. 1.

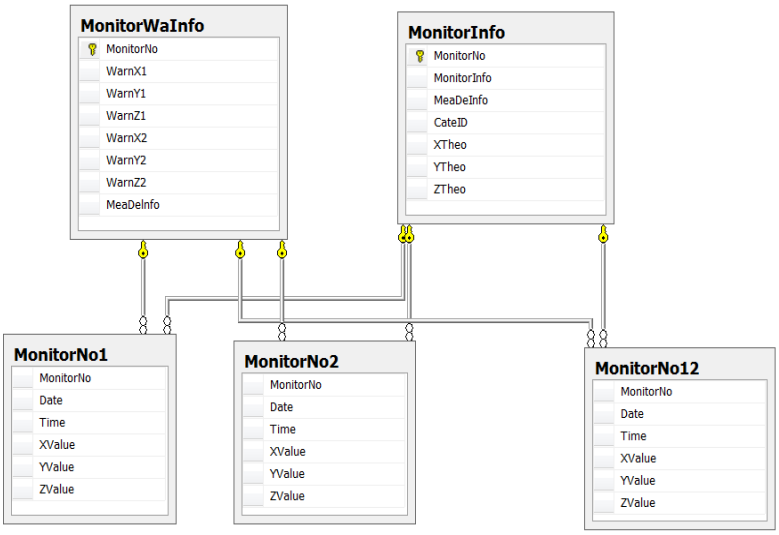

Fig. 1 Database diagram

According to Fig. 1 we were able to make a timely response to the dangerous situations according to the difference between the warning thresholds and displacements of the monitoring point, the number of monitor was set from 1 to 12.

## System function design and realization

Functional design of the system is an important part of system development. This system adopted the modular idea, and the modules were both interactive and independent between each other. The system could be divided into five big modules according to the function: basic operation module, two and three dimensional linkage module, the path planning module, path dynamic demo module and road network extraction module, and the partial functions were listed in Fig. 2, and the interface of realization for these functions was plotted in Fig. 3.

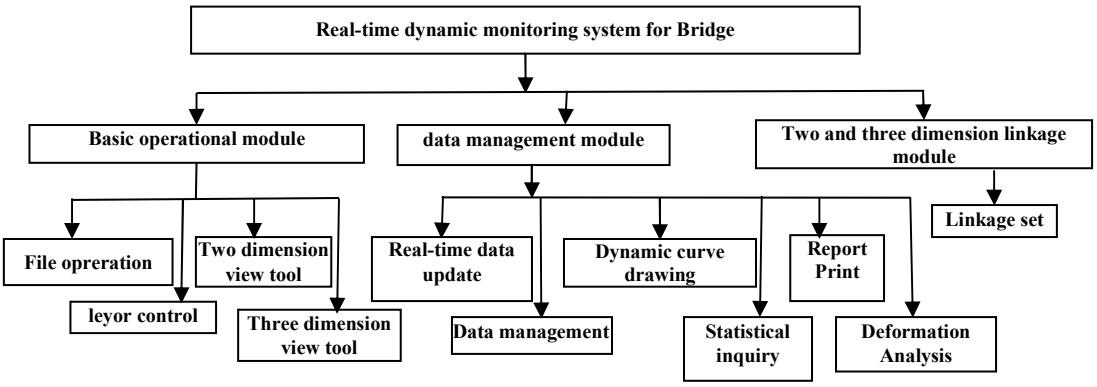

Fig. 2 The function design

In this paper, we developed detail functions for this monitoring system, such as file operation, layer control, two dimension view tool and so on, and Fig. 2 just showed part of functions of this system.

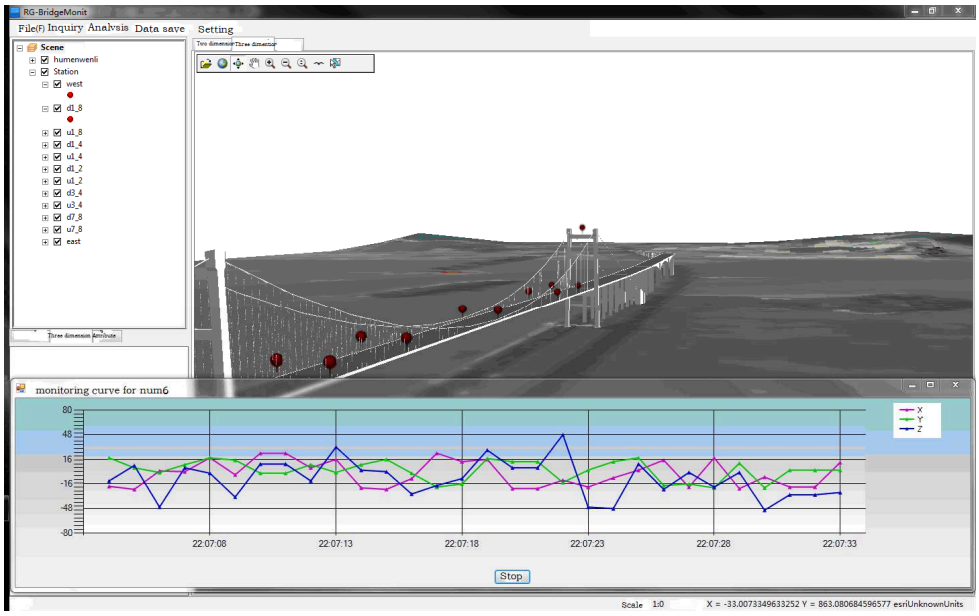

Fig. 3 The interface of visualization of health monitoring system for bridge

Fig.3 showed that according to the displacement of monitoring point this system could draw the curve of displacement of monitoring point 6 as a time series, and the other curves for the other monitoring points can be plotted, at the same time, the three dimension figure of the bridge could be plotted, and the information could be saved according to the table of the interface.

## Conclusions

On the basis of CORS technology and GIS, the health monitoring system for bridge was designed and realized. The application of GIS has enriched the ability of the system, such as storage, management, analysis and visualization for the graphic and attribute data of bridges and sensors. We have applied SQL Server to manage the massive monitoring data, and the developed friendly interface is convenient to inquiry and visit for users. The continuous real-time dynamic monitor and data management for the critical parts of a large bridge could provide valuable messages such as stability, durability and reliability, and the visualization of health monitoring system for bridge was achieved.

**Keywords:**virtual city, Virtual GIS, 3D modeling, AutoCAD VBA

**Abstract.**Aiming at the common problems of virtual city modeling,such as low efficiency and large amount of data, this paper proposes a quick method to build a virtual city.The method realizes data read automatically through AutoCAD VBA programming, generated the VRML code automatically, buildthree-dimensional scene by the VRML code integration and realize the Web publishing of virual city via Web.

## Introduction

At present, people mainly use software such as OpenGL, 3D MAX, VRML to realize the construction of virtual city. However, therearestill many shortcomings in current virtual city development project, such as the relatively large workload, overelaborated program, the low system efficiency and so on. Face with the shortcoming above, this paper proposes a simple and rapid method. The method takes AutoCAD VBA, VRML and database technology as the main means, automatically completes data reading, 3D modeling, texture mapping, Integration and rendering in combination with other modeling software, realizes the basic function of GIS and punishes via the WEB. The specific method is as follows:

## Quick build method of Virtual city

### Data preparation and processing

**Datapreparation**.

The virtual city 3D model needs a lot of data. The data mainly includes the building and affiliated facilities thereof, traffic and affiliated facilities(railway, road, traffic signs, bridge, shelters, toll station andso on), public service(power line, line of communication, Street lamp, mailbox, gas station,bin ,flagpole signs), Landscape and recreation facilities（sculpture, miniature landscape, playground）, the vegetation and green belts(grass, trees, flowers), water (rivers, lakes, reservoirs, etc.).Descriptive Information is encoded according to the classification,and essential attribute is marked as unique identification code. Information database is established with SQL as the platform.

**Dataprocessing.** Because only graphic data can be stored in AutoCAD,the method pays attention to separating graphics data and the graphic datain the data collection. The layer can be divided into: baseboard, building, road, water, vegetation, people, car and so on.Baseboard, building and road are line objects, and their main body is closed polyline, their elevation attribute is their physical

altitude. Vegetation is dot features, its kind can be expressed via color. Some ground objects are not on the map, such as people and cars. They must be drawn on the layer by hand. The AutoCAD sketch map is as below:

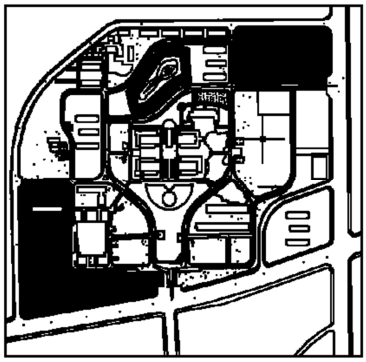

Figure1:Exampleof AutoCAD sketch map.

**Set up texture lab**

**Acquisition and processing of texture data.**There are two main types of texture data acquisition method. The texture with high precision requirements are shot on location, so their volume of data will be large and the texture is hard to disposal.

The texture of the general can be synthesized by computer software (such as 3D MAX) to Reduce the amount of data and increase efficiency. Whereas, for this reason of spatial location, vision angle and meteorological factors, orthogonal projection image cannot be got during the actual acquisition process. So the images should be dealt with. Graphics processing operations mainly includes: distortion correction, removing the mask, image enhancement, and data redundancy reduction.

**Texture encoding and texture information storage.** Processed digital image texture should be code and to realize the automatic modeling. Ground objects can be characterized in the form of geometric shapes in AutoCAD. Because geometry handle is unique in AutoCAD, graphical information, texture information and related graphic data can be linked to each other.

**Automatic 3D modeling**

This paper takes VRML as a modeling tool for the reason of network transmission. However, it will be huge effort to model only depend on VRML.The method links to database via VRML to read the AutoCAD graphic data, automatically complete modeling and automatically generate VRML file. Several kinds of modeling method is introduced as follow:

**Topography modeling method .**The establishment of the real city is based on complex terrain. Topography model is set up in the first place to showcase the virtual city scene. Firstly, write code via VBA, read the corresponding topographic map data and build landscape model. Figure 2 is AutoCAD topographic map, Figure 3 is modeling working sketches.

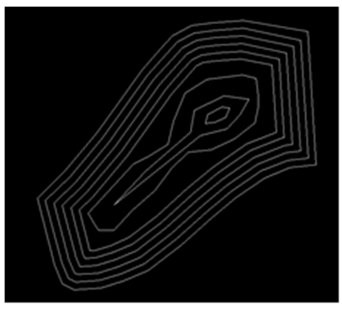

Figure2:Dataof AutoCAD.

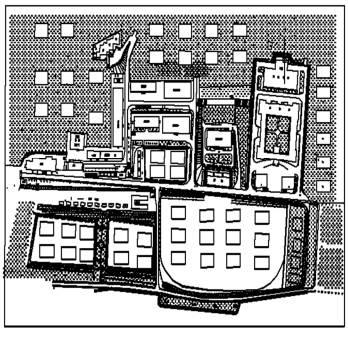
Figure3: Sketch map.

**Ground objects modeling method.** Building is the larger proportion in the urban landscape. Most of the building model are more common. They can be modeled in 3D MAX. The model that built

by 3D MAX is distinct, fine and smooth. However, the method's Achilles heel is that data volume is greatly, roaming is difficult, and the workload is huge. A common building group in the city has a standard geometric features. Read data via automatic programming, batch processing of the model and reduce the workload and the amount of data that scene. The following to a specific example. Figure 4 is AutoCAD topographic map of buildings. Define the building outline as AcadLPolyline object, write code via AutoCAD VBA, stretch processing line, and automatically generate 3D models. Generate models as shown in Figure 5. Connect with the texture library via AutoCAD VBA and map the texture. The scenario building is established by VRML, the part of the code is as follows:

```
Sub GetVrmlMdlFromCAD ()
Dim ExTendV as Double, num As Integer, n As Integer, i As Integer,e As AcadEntity, Pl as AcadLWPolyline, xy () As Double
For Each enIn ThisDrawing.ModelSpace
If e. Object Name = "AcDbPolyline" And e.Layer = "house" Then
Set Pl = e
xy = Pl. Coordinates ()
n = UBound (xy)
num = num + 1
Open "house.wrl" For Output As #1
Print #1, "#VRML V2.0 utf8"
Print #1, "Transform {translation 674.33 0 -311.27"
,Print #1, " coord Coordinate {point [-1.2 0 0.0, 1.2 0 0, 1.2 3
0,-1.2 3 0]"
Print #1, "} coordIndex [0, 1, 2, 3]"
Print #1, " Transform {translation 607.18 0 -311.23 children
USE house1}"
……
Print #1, " Transform {translation 710.63 0 -304.08 children
USE house1}"
End if
Close #1
End Sub
```



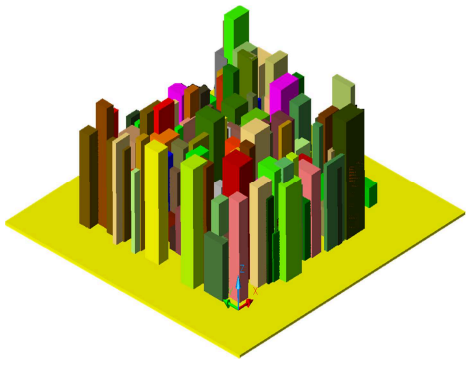


Figure4: Blocks CAD topographic map. Figure5: Diagrammatic figure.

Furthermore, complicated model should be model by 3D MAX.Link models to the corresponding data in the database, and import into 3D MAX to build 3D model. 3 D model will be exported as WRL format, and integrated in VRML.

**Planar feature modeling method.** Models of river network, green belt, grassland in the cityscape can be built via the method of planar feature modeling method. Similar to the geometric entity

modeling method, read the AutoCAD topographic map and conversion to generate planar entities. Due to the reason that precision and texture quality requirement of such a model is not high, map the model by linking to the texture lab.

**The point feature modeling method.** In order to showcase city landscape, improve the fidelity and immersion of the system, trees, pedestrian and vehicle should be added into the model. These features are often occupies little space resources and they can be expressed as dot in the map. Geographic position can be expressed as dot. Due to the shape of the feature is irregular and model data volume is large, transparent texture mapping method is used to build scene. Next, take billboard technology for example to introduce the modeling methods.Data is loaded to determine the object position. Generate planes in the position, and map the planes transparent materials. Models made by the method has small amount of data. Part of the model are as follows:

Figure6: Pedestrian'smodel.

Figure7: Vegetation's model.

Figure8: Vehicle'smodel.

**Automatic 3D modeling.**

The real city scene is very complicated. The paper uses different modeling methods to restore the original landscape realistically.VRML is used as a platform to integrate scene. Models made by AutoCAD can be transformed to VRML code via AutoCAD VBA.Models made by 3D MAX can be generated directly WRL code. Finally the code will be integrated together by link function. The code examples as follows:

Inline {URL "house.wrl"}

The code is adding the file named "house" into the scene. Other integration method of the scene is same to it. The scene after integration is still just structure, cannot be real-time browsing. As the reason of above, the light, sky background, is added into the scene to improve the spectator.

**Basic GIS functions of Virtual city**

**Dynamic interaction function of the 3D scene**

**Manual roaming and automatic roaming function.** Users browse the scene via VRML plug-in to improve immersion and practicability of the system.

According to the different needs, the users can adopt manual roaming and automatic roaming function to browsing scenarios. Users can browse the scene manually via the tools provided by roaming control panel.Following is a manual roaming figure:

Figure9: Virtual roaming.

Besides, users can preset roaming paths, generate show animationtorealize automatic roaming function and roam in the virtual scene along the specified path by setting the speed and height.

**Implementation of viewpoint switching and automatic positioning function.**In the virtual city scene, the method takes hyperlink as main means and combines with the JavaScript program and VRML functions. Part code is as follows:

Function SetVP (cam) {Scene. Engine. Nodes (cam). Fields ("Set bind") = true ;}

<a Href="JavaScript: SetVP ('xiaoqu')">xiaoqu</a>

**The bidirectional query functions**

**Attribute database design.**Only the graphical information of the city can be recorded and displayed in the virtual scene, attribute information of landscape display incomplete. So attribute information database of virtual scene is built to realize the bidirectional query of spatial data and attribute data. One-to-one correspondence is built to provide information services. Users can select query options, such as unit name, corporate, etc., and input the query keywords, like “MA steel Heling”, click on the search.

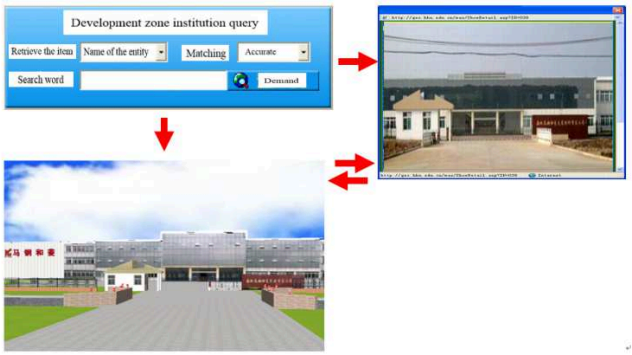

Figure10: Information query.

**Summary**

This scheme takes AutoCAD and AutoCAD VBA as a platform without special software of virtual city, and reduces the operation difficulty. Complete the data read, model and texture map via AutoCAD. In addition, virtual city landscape scene will be released for network by VRML technology. Users complete the data query and browse by VRML plug-in and a WEB browser.

**Keywords:** Three-dimensional (3D) modeling; Visualization; Real estate management

**Abstract.** Real estates are the material basis of the survival and development of a city, and are important parts of urban development. We use 3ds Max as a tool to create 3D models of buildings and Supermap Deskpro.NET as a platform to make an effective combination of 3d models, real estate graphic data and real estate attribute data. Three-dimensional display of surveying and mapping information and three-dimensional visualization management of house property information are realized.

## Introduction

Based on computer graphics, visualization technology and virtual reality technology (VR) etc., 3D visualization technology has been widely used in geographical informatics, ecology, science of surveying and mapping, architecture, medicine and other fields of science, greatly promoted the development of related disciplines with a series of achievement [1].

As the substantial components of digital city geospatial framework construction, real estate surveying and mapping informatization and 3 d visualization lead to spatialized, elaborate, dynamic, visual and actualized real estate information and services, which cover accurately each building, each period of time and each area, so that the property management implements its evolution from extensive management to precise management, from bull management to unified management. This paper starts from the graphic and attribute data of real estate, using 3ds Max to create 3D models of buildings and Supermap Deskpro.NET as an integration platform to realize 3D display of surveying and mapping information and 3D visualization management of house property information.

## Data Preparation

Real estate surveying and mapping information is the main content of the real estate information, it consists of two parts, i.e., real estate surveying and mapping graphic data and attribute data [2]. The former mainly includes building property map and basal relief map, and the latter mainly refers to the attribute information of each building, of each layer and of each household. In order to conform to reality, we also collected the 2D plan of the building, and carried on the field survey, capturing photographs of campus landscape and landmark buildings in Shandong Jianzhu University for textures.

## Establishment of 3D Models

In terms of 3D models of buildings, they are momentous constituents of 3D real estate information management system, which play the decisive role in the quality of the system [3].

**Modification of the Base Ma**p. Import 2D plans of the research area into the CASS software, and remove unnecessary ground objects and landforms, e.g. parterres, street trees, street lamps, etc.

Then modify the 2D plans of buildings the same way, deleting appendages of buildings, remaining brief plans to construct three dimensional models.

**Production of Textures.** To meet the requirements of modeling, photographs need to be refined in PhotoShop software, including adjustment of the shape, restoration of the shadow, etc. After that, we will import the 2D plans of a building, already modified in the procedure above (format: *.dwg), into 3ds Max, then zoom the base maps in the view of Top, Front, Left, Perspective to a suitable size respectively.

**Production of blank models (semifinished product).** In the next, we will use polygon as a major tool to establish the model of each building one by one [4]. As the outline of a building is available through the 2D base map, we can sketch the contour of the building, and then convert it to an editable polygon, on this basis, we extrude the polygon to appropriate height, and that results in a blank model without bottom, which is the so-called semifinished product. And then, detail structures of the building require to be crafted in order to generate a complete 3D model. Over the course, modifiers and tools (like Extrude, Attach, Chamfer, Connect, Cut, Boolean, etc.) are frequently used.

**Texture Mapping.** So far, we have produced textures as well as blank models, what we should do next is just making a combination of the two, i.e., mapping textures for the models. It's not difficult using UVW Mapping modifier to adjust the right picture suitably to a corresponding model. Up to this point, we have finished the whole process of making a lively 3D model for a building.

**Light Configuration.** Proper light illumination results in the optimal effect of material [5]. We use three Target Spot and one Free Spot in the scene, and they are set in different positions. We can adjust the shadow of each spot respectively, so that the scene will looks more alive.

## The Realization of Three-dimensional Visualization Technology

Three-dimensional visualization is a more intuitionistic technique to display 3 d data [6]. As it can show the spatial data more factually, and simulate geographic-information reality more realistically, three-dimensional visualization technology has brought great new technical innovation for GIS.

**Loading of 3D Models.** Taking campus buildings for example, we've created 3D model for each building, and will load them into the 3D scene in the rest. Before that, it is necessary to install the SuperMap plugin for 3ds Max. Merge all of the models together in 3ds Max, use the script tool of the plugin to return the origin of coordinates of each model to its center then bottom.

Now for the most important part, we will take advantage of SuperMap plugin to generate model cache which can be loaded into SuperMap Deskpro.NET later. Click the function button 'To generate cache', enter the corresponding latitude and longitude values in the dialog box and select the file path for texture files, then press the OK button to finish the process.

Import the digital orthophoto map (DOM) and digital elevation model (DEM) into SuperMap Deskpro.NET respectively as image dataset and grid dataset, both of them with the same projected coordinate system. Then load them as well as the model cache into the same new scene to establish a primary3D scene as shown in Fig.1.

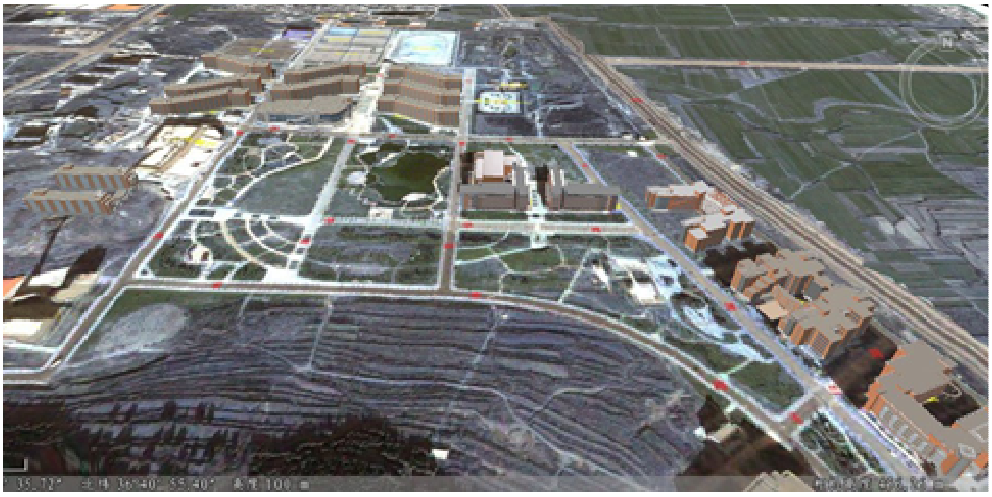

Fig. 1 Display of the primary 3D scene

**Three-dimensional Environment.** In this section we will discuss the embellishment of the 3D environment, including the modeling of vegetation and roads and the setting of flying route.

Modeling of vegetation. The vegetation types in a City are various, and there is no need modeling separately for some kinds of features, e.g., it's feasible to use DOM to express the grassy area of a city or dense forest on a hillside. But in order to keep the sense of reality, it's necessary to model the ornamental plants. It's convenient to realize the visualization of trees in SuperMap Deskpro.NET. Just simply add points that correspond to where the trees lie, then load the point dataset into the existing 3D scene as a layer and change the style of the layer. In more detail, choose a proper 3D tree model in the point database as the layer's style and the points will successfully display as trees in the scene. By the way, you can also produce your own tree model in the editor.

Modeling of roads. In terms of road modeling, it's similar with tree modeling, just create a new line dataset and vectorize along the center of the each road, then put it into the scene and choose a proper 3D line symbol as the layer's style.

Setting of Flying Route. Specifying the route and perform a 3D flying is one of the way to browse the 3D scene [7]. In SuperMap Deskpro.NET , a flying route is specified according to the points on the line. Information of the points stores in a file whose format is *.gml. So pick some points at the desirable places, then set an appropriate height and speed for the route and perform it to check it out. The final result is shown in Fig.2.

Fig. 2 Final result of the 3 d campus

## Conclusions

Three-dimensional visualization of real estate information can effectively implement function as estate information release and display, real estate transaction, real estate planning, residential property management so on and so forth [8]. In our research, 3D models of building were crafted in 3ds Max on the basis of graphic and attribute data of buildings in the campus, and a 3D scene was established realizing the three-dimensional visualization.

Within the scope of super fine little scene production, there is a further dimension we have not delved into: terrain matching. We intend to pursue this line of work in the future to make it perfect.

**Keywords:** Land consolidation potential, Cultivated land, Rural residential land, Geographic information system (GIS)

**Abstract.** Through the analysis of land use actuality, this paper summarizes the characteristics of land use, in virtue of geographic information system(GIS) platform, the database of land consolidation is constructed, combining with different calculation models of cultivated land and rural residential land consolidation potential, the consolidation potentials of cultivated land and rural residential land are calculated, and the thematic maps about land consolidation potential of each village and town in study area are mapped out. The results show that the land consolidation areas are mainly concentrated in the middle of study area.

## Introduction

Land is the important strategic material base and resources for the sustainable development of human economy and society. It's not only the organic component of natural resources, also an essential nonrenewable resource of human production activities. In recent years, with the rapid development of economy, the scope of non-agricultural construction lands is infinitely expanded. Because of the shortage of reserve cultivated land resources and ecological environment constraints, the contradictions are increasingly prominent between cultivated land and construction land [1]. The objective demand of rapid economic development can't achieve dynamic balance of total cultivated land by strictly controlling land supply. So land consolidation becomes an effective way to resolve land tensions at present [2, 3]. Land consolidation potential analysis is preliminary work for land consolidation. That is, under the current economic and technological conditions, analyzing theoretical effective area of increasable cultivated land or farming land by land consolidation [4]. According to land suitability and less reserves, some types of lands such as unused, abandoned and idle lands will not necessarily become cultivated land after they are consolidated. Therefore, cultivated land consolidation and rural residential land consolidation become the main part of land consolidation [5]. This paper takes Mashan County, Guangxi, China as the study area, discussing the land consolidation potential of cultivated land and rural residential land in this region, expecting to provide reference for regional land management planning.

## Calculation model of land consolidation potential

**Calculation model of cultivated land consolidation potential.** The sources of cultivated land consolidation potential include sporadic land and current land feature which is increasable cultivated areas by consolidating cultivated land and uncultivated land such as country roads, irrigation canals, raised path through fields and sporadic land. The calculation method of cultivated land consolidation potential is:

$$S_C = S_x + \sum_{i=1}^{n} (M_i - Y_i) * S_i \quad (1)$$

where, $S_C$ is the cultivated consolidation potential in district, $S_x$ is the area of sporadic land, $n$ is the slope series of cultivated land, $M_i$ is the covering coefficient of linear feature in $i$ slope cultivated land consolidation region, $Y_i$ is the covering coefficient criterion of linear feature in $i$ slope cultivated land consolidation region, $S_i$ is the area of consolidating land.

**Calculation model of rural residential area land consolidation potential.** Rural residential area land consolidation potential is calculated according to villages and towns through questionnaire and other information to statistics resources of rural collective construction land, including population, households, construction land area, homestead area, idle land area, the natural population growth rate and other relevant information. The calculation method of rural residential area land consolidation potential is:

$$S_R = S_0 - B * (Q_0 * (1+r)^t \pm \Delta Q) \quad (2)$$

where, $S_R$ is the rural residential area consolidation potential in district, $S_0$ is the area of current rural construction land, $B$ is the planning land per capita, $Q_0$ is the current rural population, $r$ is the natural population growth rate, $t$ is the planning period, $\triangle Q$ is the mechanical changes in population.

## Land utilization status of land resources in study area

The study area is Mashan County in Nanning City, Guangxi, China, which Contains seven town and four townships. According to the population census data in 2010,the total population is 542700, the birth rate is 26.81‰,the population mortality is 7.08‰,the natural population growth rate is 19.73‰.According to the second national land survey and survey data of land use change in 2010, the structure of land use is shown in figure 1.

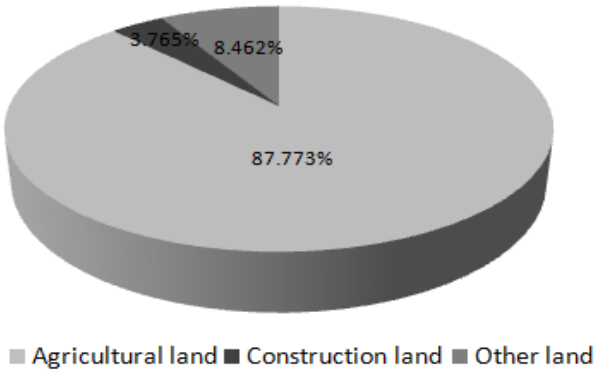

Fig.1 Land use structure

Through the analysis about the present situation of land use, Mashan county land use has some characteristics as follows:① agricultural land is the main land use types of the county, traffic and water conservancy facilities land has small proportion;② agricultural land is mainly farmland and woodland, especially woodland, so the county has high forest coverage rate;③low land reclamation rate and less per-capita cultivated land;④ the quality of cultivated land is not high, and the percentage of paddy fields is low.

**Construction of land consolidation potential database**

Before calculation land consolidation potential, database of land consolidation should be constructed. The databases of land consolidation mainly include databases of cultivated land consolidation and rural residential land which can be constructed by ArcGIS. Taking the cultivated land consolidation as an example, the database structure is shown in table 1.

Table 1 Database structure of cultivated land

| fields | type | width | decimal |
|---|---|---|---|
| township | character | 6 | |
| land class | character | 6 | |
| polygon area | float | 10 | 2 |
| fragmentary land area | float | 10 | 2 |
| consolidation potential | float | 10 | 2 |
| potential absolute coefficient | float | 5 | 2 |
| potential level | integer | 2 | |

**Analysis of cultivated land consolidation potential**

**Present situation investigation of cultivated land consolidation potential.** There are cultivated land areas of 46207.22 hectares in Mashan County. The cultivated land areas, percentages and grades of different gradients are shown in table 2.

Table 2 Classification of cultivated land gradient

| classification | ≤2° | 2～6° | 6～15° | 15～25° | ≥25° |
|---|---|---|---|---|---|
| area[ha] | 14128.98 | 10699.67 | 11870.02 | 2364.78 | 7143.77 |
| percentage[%] | 30.58 | 23.15 | 25.69 | 5.12 | 15.46 |
| level | 1 | 2 | 3 | 4 | 5 |

**Calculation of cultivated land consolidation potential.** In ArcGIS platform, the cultivated land of different gradient, rural roads and ditches are isolated. Combining with specific circumstance of Mashan County, with reference to the cultivated land consolidation standards in Guangxi, the covering coefficient of linear feature in different gradient cultivated land are calculated shown in table 3.

Table 3 The covering coefficient of linear feature in different gradient cultivated land[%]

| gradien level | roads covering coefficient | ditches covering coefficient | ridges covering coefficient | linear feature covering coefficient |
|---|---|---|---|---|
| 1 | 1.8 | 1.2 | 0 | 3.0 |
| 2 | 2.2 | 1.8 | 6.0 | 10.0 |
| 3 | 2.5 | 1.8 | 8 | 12.3 |
| 4 | 2.6 | 1.4 | 15 | 19.0 |
| 5 | 3.1 | 1.6 | 25 | 29.7 |

According to formula (1), the total potential of cultivated land consolidation in Mashan County is 836.00 hectares. The distributions in different township are shown in table 4.

### Analysis of rural residential land consolidation potential

**Present situation investigation of rural residential land consolidation potential.** In Mashan County, there are 5383.46 hectares rural residential area, and 499774 rural populations, land per capita 107.718 square meters. According to the natural population growth rate of Mashan County in recent years, taking 2010 as the base year, there will be 517770 rural population in 2015.

Referring to land use planning and the national economy "twelfth five-year" development planning of Mashan County, the rural residential planning land per capita is determined to be 96 square meters.

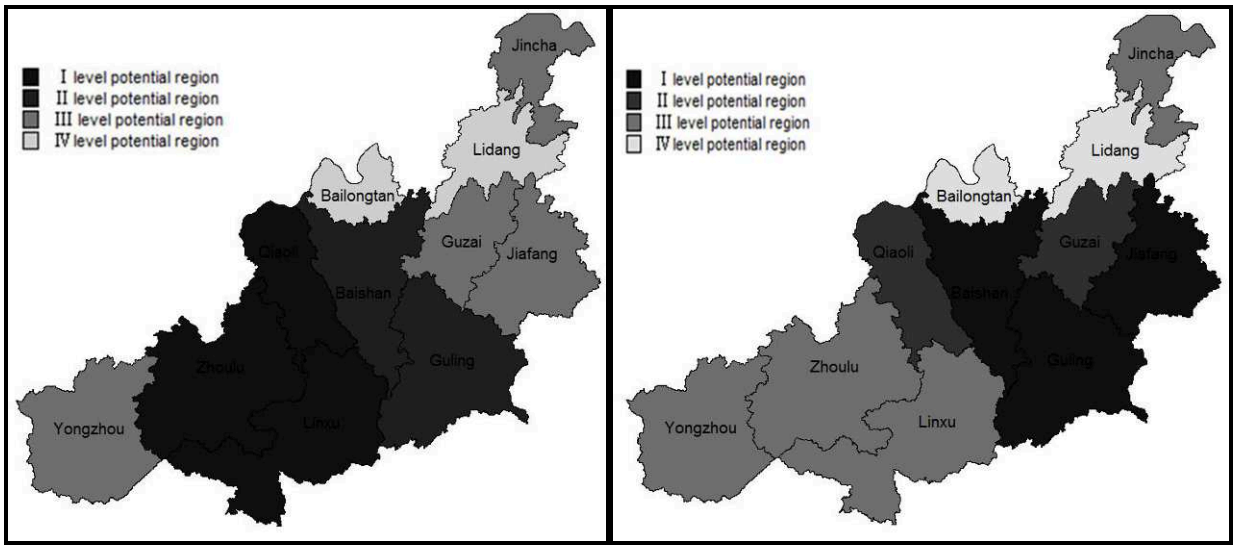
**Calculation of rural residential land consolidation potential.** According to formula (2), the total potential of rural residential land consolidation in Mashan County is 512.38 hectares. The distributions in different township are shown in table 4.

Table 4 The distribution table of cultivated land and rural residential land consolidation potential

| administrative district | cultivated land consolidation potential [ha] | cultivated land consolidation potential absolute coefficient[%] | rural residential land consolidation potential[ha] | rural residential land consolidation potential absolute coefficient[%] |
|---|---|---|---|---|
| Baishan | 75.52 | 9.03 | 82.02 | 16.01 |
| Bailongtan | 24.32 | 2.91 | 4.52 | 0.88 |
| Guling | 86.59 | 10.36 | 82.30 | 16.06 |
| Guzai | 38.63 | 4.62 | 73.11 | 14.27 |
| Jiafang | 64.24 | 7.68 | 78.53 | 15.33 |
| Jincha | 42.52 | 5.09 | 34.58 | 6.75 |
| Lidang | 12.85 | 1.54 | 0.00 | 0.00 |
| Linxu | 165.28 | 19.77 | 45.28 | 8.84 |
| Qiaoli | 125.48 | 15.01 | 65.41 | 12.77 |
| Yongzhou | 65.04 | 7.78 | 26.95 | 5.26 |
| Zhoulu | 135.53 | 16.21 | 19.68 | 3.84 |

### Classification of land consolidation potential

According to the absolute coefficient of cultivated land consolidation potential and rural residential land consolidation potential total land consolidation potential in table 3, taking towns as unit, the land consolidation potential and the absolute coefficient of each town is input into database, with the GIS software platform, the cultivated land consolidation potential and rural residential land consolidation potential are separately divided into four levels, shown in figure 2.



(a) classification of cultivated land consolidation potential

(b) classification of rural residential land consolidation potential

Fig.2 Classification of the land consolidation potential level in Mashan County

## Conclusions

According the absolute coefficient of land consolidation potential, the land consolidation potential of cultivated land and rural residential land in Mashan County can be separately divided into four levels. The results show that the higher land consolidation potential areas are mainly concentrated in the middle of Mashan County, such as Qiaoli village, Guling town, Baishan town; the lowest land consolidation potential areas are Lidang village and Bailongtan town.

**Keywords:** Geographic information system, Maritime work, Spatial information, Feedback.

**Abstract.** Seawall is an important barrier of Zhejiang coastal strip. To effectively manage the information of maritime work in Zhejiang and convert the traditional management into the modern management, the information management system of maritime work based on GIS is developed. Take Kaomen seawall for example, the overall structure of information management system based on GIS is designed, focusing on the data entry, spatial attribute show, spatial attribute query, spatial information statistics and analysis. This design plays a significant role in the flood control and disaster reduction in the future, making the information management of maritime work convenient and practical.

## Introduction

Zhejiang province is near the seashore. Affected by natural conditions, the tide frequently attacks buildings and has a bad impact on local residents' life, therefore, the seawall comes into being[1]. The seawall originated in the mouth of Qiantang river, which was used to prevent the tide entering living quarters and protecting the cultivated land. Today, seawall is still the barrier of the Yangtze river delta. Besides, seawall plays an important role in Zhejiang province economic development which cannot be replaced.

With the development of economy and science, traditional seawall management has been unable to meet the demand of current social development. Based on geographic information system (GIS), the seawall information management can integrate engineering information into electronic map, which can bring convenient information databases and provide a new method for acquising and analysing the seawall information. Take Kaomen seawall for example, information management system based on GIS was designed.

## Introduction of geographic information system

GIS is a kind of important specific spatial information system with various features of information system. With the help of computer hardware and software, combining with geography, GIS is used to collect, store, analyze, manage and deal with a variety of information related to the project[2]. Meanwhile, it is a widely-used technology system. Through the analysis of model and image, the spatial information database is established, which can handle various thematic maps, engineering information, observations and so on[3].

## Information management of maritime work based on GIS

**The overall structure.** Zhejiang kaomen standard seawall is located in Daishan of Zhoushan. It is 3512 meters long. Kaomen seawall forms the closed area with kaomen dam together. And it protects area of 7, 853, 000 square meters and benefits more than twelve thousands people. At the end of July 2007, the government completed the reinforced maintenance engineering of dam.

On the basis of seawall structure model, geological conditions, the settlement of roof and seawall orientation, five section stations are selected, which are 200, 1100, 1800, 2500, 3200. Figure 1 is interface of information management system of Kaomen seawall based on GIS.

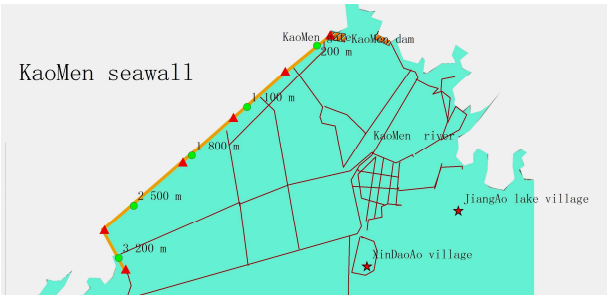

Fig.1 Interface of information management system of Kaomen seawall based on GIS

Information management system of Kaomen seawall sets up a geographical information system by ArcGIS, and then inputs seawall information into the database of geographic information system, making computer graphics and database integrated together. It provides data and mature management mode for seawall management. Afterwards, on the basis of database, data is obtained quickly by attribute query. The information management system achieves high efficiency and practicability. Then the data is processed simply by using the function of the software to realize the visualization of distribution about seawall engineering and data system. It provides technical support for dam safety, and provides theory basis for moistureproof and disaster mitigation. Figure 2 is a simple flowchart of ArcGIS application.

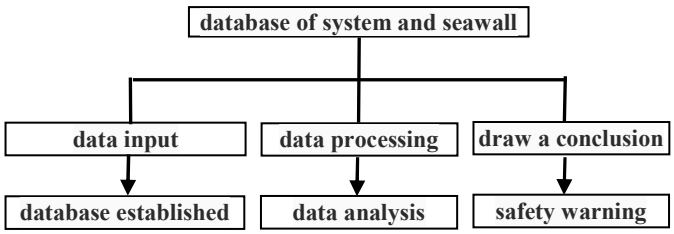

Fig.2 A simple flowchart of ArcGIS application

**Data input.** Engineering data are input into geographic information system of Kaomen seawall. First, information management system establishes seven layers in the same framework, which are "boundaries", "sections", "places", "profile", "inland", "waters" and "buildings". Each layer has a corresponding attribute table. For example, the layer of "sections" has a table of "Attribute of sections". The attribute table adds the required fields and data according to the specific situation. The data of Kaomen seawall is mainly input in sheets of "profile", "table of typical sections" and "table of height and size about cross sections". In addition, the system has many data of five sections, because the comparison is mainly about it. Therefore, two more attribute tables of "Dbase Table" are added, which are "table of typical sections" and "table of height and size about cross sections ".

## The query of attribute

**Attribute table.** In ArcGIS, each spatial data has its corresponding attribute table. The attribute table is one part of the database. It is generally used to check each attribute of geographical elements[4-5]. The attribute table can store much information about elements, and it also can connect with spatial data. The particular elements can be identified in the attribute table. At the same time, the elements of selected on the map are used to update the attributes to reflect changes in the geographical engineering.

Such as geographic information system of kaomen seawall, it adds two attribute tables for each element in the layer of "sections", which are "name" and "profile picture".

**Function of image display.** In ArcGIS, hyperlink is a channel. Users can inquire elements and their attributes in extended table of attribute data. Hyperlink is generally stored in fields. And it can be displayed through clicking on the corresponding elements on the map. Hyperlink is usually used to load images to make the external image showing in ArcMAP. It also provides a great convenience for

query and using. For example, each section has its corresponding images, and they are loaded in the cross section. The image of the cross sections can be displayed by clicking one of them.

**Function of connection and displaying attribute tables.** The function of query is extended by Establishing the connection between two tables. When two attribute tables are checked at the same time, there are two ways to connect two attribute tables, which are "Join" and "Relate". In the first method, a set of data is added to another according to the corresponding field. In the second method, two tables are associated on the logic without changing the appearance. Elements of one attribute table are selected, the corresponding part in another table can be showed at the same time by using the way of "relate". So it is convenient to inquire in different attribute tables. As shown in Figure 3, "Section" and "Table of typical section" are linked through using this function.

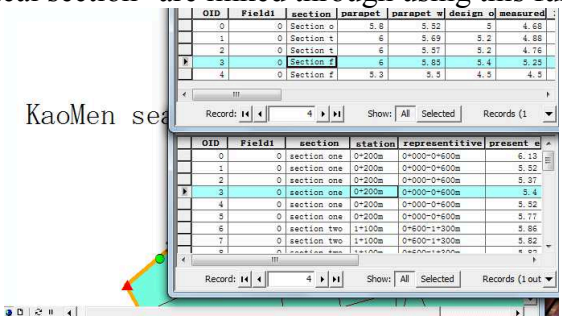

Fig.3 The relationship between two forms

**Information of Kaomen seawall display.** Users can't directly understand some data of the corresponding section through the map document, because the map document only display graphic symbol of sections. To quickly acquire these data, the data can be displayed directly on the diagram. In this way, it is not only easy to see, also to compare, and it can avoid displaying when not needed. It's easy to manage due to the data can be changed along with the change of graphic symbol. So don't worry to zoom in and out of graphic symbol.

Field is one element of a particular attribute, it can be shown on the map, and it will move with geographical elements. It also can zoom in and out with the geographical elements.

### Statistical information of kaomen seawall

The section information mainly deposites in the layer of "profile", "table of typical sections" and "table of height and size about cross section". A rectangular statistical which is used to compare complete elevation with present elevation will be obtained by selecting data related to the elevation into statistical records such as Figure 4.

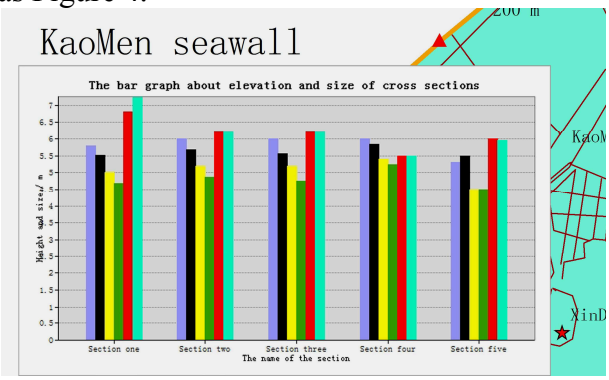

Fig.4 The bar graph about elevation and size of cross sections

Moreover, using ArcGIS, before-after and horizontal comparison of data can proceed at the same time. Various information of each section is recorded in the list of "table of height and size about cross section". Another rectangular statistical diagram of comparison can be gained by the same operation, such as Figure 5. It is apparent that which section has an obvious gap between measured value and designed value from figures. Dangerousness of sections become visual.

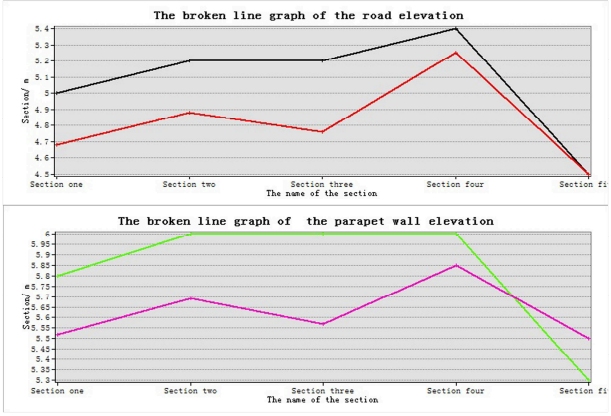

Fig.5 The broken line graph of the section information

## Safety warning of kaomen seawall engineering

Geographic information system is not only used in query and retrieval, but also in comparison and identification of seawall security by processing information. The safety of seawall is a significant item in the seawall management. Five typical cross-sectional elevation of kaomen seawall shows that the size of the constructed road and platform can still meet the designing requirements and the specific requirements. However, every section appears settlement in different degree. After a long time operating, wave facilities are destroyed seriously, and back slope is seriously corroded. But structural integrity is good. There is no phenomenon such as sliding, tilting, and cracking.

## Summary

Information can be inquired and processed conveniently by geographic information system based on ArcGIS. It improves the traditional manual management which was complicated. Attribute tables can be used to complete the query and retrieval quickly by inputting information. Then the safety of the seawall can be monitored through comparing the results in time. And the unknown accident will also be reduced. Geographic information system is used in the seawall engineering to solve some substantive issues. However, more works need to be done to improve the system such as realizing three-dimensional ArcGIS in seawall, which is what we need to study and solve.

# Design and Fabrication of Dynamic Thematic Maps Based on Flash

Yixin Xu [1,a], Junwei Yang [2,b]

[1] Department of Materials and Engineering, Zhejiang University, Zheda Road No. 38, Hangzhou, China, 310027

[2]Henan Province geological environment Investigation Company, Zheng Zhou, China, 450018

[a]1xuyixin@163.com, [b]1827628998@qq.com

**Key words:** Dynamic, Thematic Maps, Flash, Element, Source Material

**Abstract:** This paper exemplified by the dynamic thematic map under different data sources has explained scientifically the dynamic data storage in session objects, thematic map making by aid of the development's function of an object-oriented environment, a real-time map displaying. Experience has proved that the measure in flash platform which editing the geographical map, designing the map elements, doing movie clips, constituting them together,importing sound,etc, is very effective and more flexible.

## Introduction

The traditional statistical thematic maps display geographic spatial distribution attributes, trend information in different ages and variable in a static and digital way. Map users cannot interoperate with the map, read not straightforward. As application popularizes of the computer technology in cartography, the pattern of thematic maps has been gradually converted to dynamic from static [1]. The first act of dynamic thematic maps has been widely recognized across industries and gained rapid application development for its intuitive, easy to read, visible and expressive characteristic. The thematic maps concerning the area, population, GDP throughout all the provinces is designed and fabricated based on Flash platform in this paper, and demonstrate clearly the relation between income growth and increasing environment pollutions.

## Overall Design Ideas

Firstly, collecting information about population, economy, atmospheric condition in recent years, and secondly, make cartographic base by aid of SuperMap software, thirdly, drawing elements in Flash environment, reassemble the elements into the animation, finally, after beautifying the interface , Publishing the results. The flowchart shown in Fig.1.

## Material Preparation

### Collection of Data

Collect the China map in the bmp format, longitude and latitude coordinates of provincial capital city, statistics on area, Population, GDP throughout all the provinces in recent years through various means.

### Make a Cartographic Base

By aid of Supermap software , the China map has imported to data source on bmp format. After a projection setup, finishing a map orientation by executing a image registration command, converting the raster to vector and actualizing a map digitizing by hand, revising the attribute table structure by adding one text field for storing variable name of all provinces ,and four double precision field for the area, population, GDP and atmospheric pollution, tabling the attribute data.

**Production of Dynamic Thematic Maps**

**Production of Elements** [2]

**(1)Production of Push-button Elements**

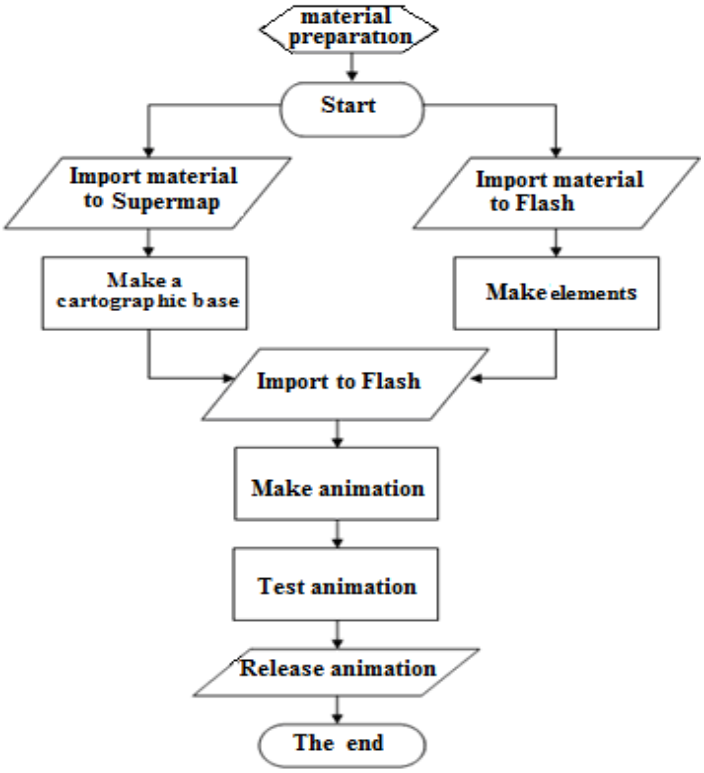

Fig.1 Design Flow

The source materials collected and underlying graph produced has been imported to flash library panel. A new-built element has a timeline containing 4 frames, bouncing, slipping, pressing, clicking respectively, the 3 frames in front displaying three states of the mouse when bouncing, slipping, pressing, the fourth frame defining a living area for the push-button. Three push-buttons for the populations, GDP and air pollution have been made, saved. Returned to the scene 1, the push-button elements have been dragged to the stage, and see the testing effect by clicking self-made push-buttons.

**(2) Production of Movie Clip Elements** [3]

There are two methods of making a movie clip. The one is dragging materials to the stage and right-clicking the material, clicking *Convert to Symbol* on the shortcut menu, selecting *Movie Clip* on the popup windows and naming. The other is making movie clip by inputting command of new-built elements and getting into exclusive scenes.

**(3) Production of Graphic Symbol**

The graphic symbol is the elementary element and the smallest unit, has a timeline. Its playing has highly been affected by the main scene, and therefore the graphics cannot be set up for a ActionScript. The elements have been arranged respectively to the corresponding library folder.

**Scenes Creation and Setup**

First of all, new-building a flash file, setting document attributes, including the speed of frame, stage area, background color, etc. Then creating several layers on the opening scenes, and naming each layer as *Window* for gray background of stage area, *Background* for a copy of the China map, *Contour* for the total outline of animation area, *Push-Button* for the content of push-button, *Headline* for the text of thematic maps, *Playlist* for the listings area, *Areamap* for the movie clip of area graphics.

**Movie Clip Creation of the Thematic Map**

Creating several layers in area graphic 1 of the new-built movie clips, as shown in fig.2. It is worthwhile to note that the element location in movie clip layers must be consistent in the main scene. The playing screen has been placed on the *Background* layer, the china map on the *Base Map* layer, the push-button on the *Push-Button* layer, the playlist button on the *Playlist* layer.

**Animation Production**

In the presentation layer, the key frame has been inserted in certain time interval. The each frame animation has been finished by placing individually each province's area element on the clip stage containing corresponding key frame. The tween animation has been made by clicking the mouse right key, selecting *creating tween animation* on the shortcut menus opened by selecting one of two keys frames in the timeline of the same layer and clicking. As shown Fig.3.

Fig. 2 Movie Clip of the Area Thematic Map

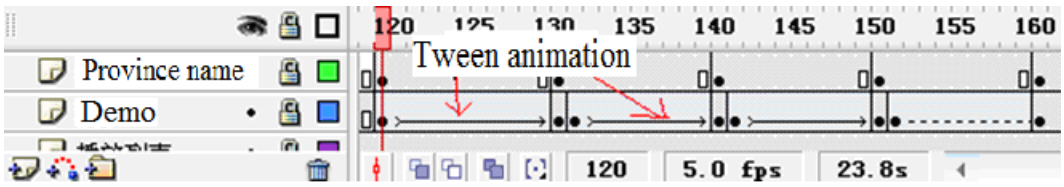

Fig. 3 Tween Animation

**Sound Importing and Editing**

The sound file has been imported to stage by opening dialog box which the needful sound file can be selected, selecting the needful sound file in the pop-up dialog box, clicking *OK* button. After adding the sound file, its attribute has been edited by *Attribute Panel* to a higher degree according with animation demand.

**Controlling Animation Working by ActionScript Language**

Firstly, it need to lock all layers in the main scene and turn on only the *Playlist* layer. Secondly, select the *Area map* button, opening *Action* panel, input script language as below and save.

```
on (release)
{ this.mjt1.play();
  this.tz.play();
  this.zt.play();}
```

Afterwards, turn on the button layer except the other movie clip, select , , , , button one by one, open action panel, respectively input script language as Play, Pause, Stop, Fast Forward, Fast Backward as shown in table 1 and save.

Table 1 Script Code

| Play | Pause | Stop | Fast Forward | Fast Backward |
|---|---|---|---|---|
| on(press) {play();} | On(press) {stop();} | on (press) {gotoAndPlay( );} | on (release) {gotoAndPlay(_currentframe+10);} | on (release) {gotoAndPlay(_currentframe-10);} |

**Releasing of Dynamic Thematic Map** [4]

After the production, the animation can be released in flash format, by clicking File--Releasing Setup to open setting dialogue box in where many items can be set up, for example, the player, loading sequence, ActionScript version, JPEG quality, audio frequency, playback security and the other option [5]. The independent animation software now has finished.

**Questions and Suggestion**

During applying Flash software, there are many problems, for one thing, the similar elements cannot be copied and pasted so that a lot of the repetitive elements production must increase working strength and decrease work efficiency, for another, the animation of flash format can be played only in flash player against the others', the third one is that the bitmap cannot be accurately controlled in locations and sizes when it be imported to the stages [6].

In spite of this, Flash software is still a simple, easy to learn, powerful tool for making animation, the dynamic thematic maps based on flash platform have changed the traditional maps' contents and notation having the characteristics of concise, intuitive, and embodied. Its high qualities not only behave in small memory, but also cannot be changed along with the size's zooming. Its shortcoming will be solved admirably in the near future as updating and improving.

# Development of Topographic Maps Symbols Library

Caimin Sun [1,a], Yixin Xu [2,b]

[1] North China Institute Of Science And Technology, Yanjiao, Beijing East, China,101601

[2] Department of Materials and Engineering, Zhejiang University, Zheda Road No. 38, Hangzhou, China, 310027

[a] Sun888888@ncist.edu.cn, [b]1xuyixin@163.com

**Key words:** Auto LISP, Topographic Maps, Symbols Library, Development

**Abstracts:** Visual LISP language is favored by many people for its simple and practical. Because of most CAD teaching materials centre on introducing concrete languages' use and single symbol making, lack of a comprehensive description of the whole process of developing professional symbols library, it is very difficult for People having mastery of LISP languages to developing professional symbol library by this language. In this article, the authors develop a symbols library for common Topographic Maps and design an environment to transfer and input the symbols with the aid of Visual LISP language, including defining graphic coordinates systems, coordinates transformations, putting library files in order, calling user-defined file etc. This paper provides great help for people who Devote oneself to map symbol library system development.

## Introduction

Autolisp is an important secondary development tool. Differing from other Languages, it is a best Graphics programming language of being encoded in CAD and invoking all internal commands. Even though having many graphic tool commands in CAD, it can't draw sophisticated curve, such as iron chain bridge etc, being deficiency of professional graphic symbols library. It appears particularly important of developing Maps Symbols Library, customizing professional application system, improving mapping efficiency, by the aid of Auto LISP language programming.

## Typical surveying application based on Autolisp

### Execution and Edition of a simple Autolisp program

Example: Drawing a multipoint house[1].

(1) Edit a Autolisp program in a text editor.

(2) Select [save as] submenu from [files] menu, input 'duodianfangwu.lsp' as file name in following dialogue box, press " ok " button.

(3) Loading the 'duodianfangwu.lsp' file. Select 'Tools'→'Autolisp' →'Loading' command, in subsequent dialogue box, selecting 'duodianfangwu.lsp' is ok. A message appears in prompt line: ' loading duodianfangwu.lsp succeed'.

(4) Input 'duodianfangwu' in command line and run it, then a multipoint house displaying on screen as shown in Figure. 1.

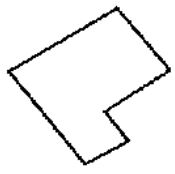

figure.1

## A development process of symbols Library

Here is a detailed Process of developing surveying symbols library by LISP language.

### Defining graphic coordinate system

AutoCAD screen coordinate system differs from surveying coordinate system. Here a surveying coordinate system and proportional scale must be set up. These functions can be achieved by following programs.

1. The program for defining proportional scale and surveying coordinate[2].

```
(DEFUN READ_XYM()
        (setq m (getvar "USERR1")        ;m scale
```

```
                x0 (getvar "USERR2")      ;x0    origin north coordinate
                y0 (getvar "USERR3")      ;y0     origin east coordinate
                hm (getvar "USERR5")      ;hm      elevation scale……
            )
```

This program could share by all graphic programs aimed to get graphic parameters in order to implement coordinate conversion.

2. The program for coordinate conversion[3].

This program is used to change surveying coordinate system (X,Y,Z) into AutoCAD UCS (x,y,z).

```
(defun dtx (hs)    ;Y-x

            (setq hs (- hs y0))
            (setq hs (/ (* hs 1000.0) m))
            (setq hs (+ hs 100))
)
(defun dty(hs)     ;X-y
            (setq hs (- hs x0))
            (setq hs (/ (* hs 1000.0) m))
            (setq hs (+ hs 100))
)
(defun dth(hs)     ;H-z
            (setq hs (/ (* hs 1000.0) hm))
)
```

3. Defining data input mode in surveying coordinate system.

By programming for symbols library, different coordinate data input mode must be considered in order to improve the programs' adaptability, for example, mouse input mode, data files entry mode etc.

(1) The program for input coordinate data from mouse.

```
(defun READS()     ;program name reads.lsp
            (read_xym)     ;
            (setq p (getpoint "\n Input point:"))
)
```

(2) The program for input coordinate data from keyboard.

```
(defun READC()        ;File name;    READC.LSP
          (read_xym)     ;
          (setq p (getpoint "\n Input surveying point(Y,X):"))
        (if p (setq p (list (dtx(car p))))
        (serq p nil)
           )
)
```

(3) The program for read data from files.

```
      (defun PREAD(); File name: READM.lsp
            (read_xym)
            (setq p (getstring    \n point /<point name>:"))
          (if (= strcase p) "P")(setq p (getpoint "\n Mouse position:"))
                (progn
                     (if p (setq p(read p) p (assoc p readh) p (cdr p)))
                     (if p (setq p (list (dtx (car p)) (dty(cadr p))))
                     (setq p nil)
                       )
              (princ)          )
```

**Program for professional symbols library[4].**

There are some tasks must done before programming, such as Analysis each entity symbol features; Define symbol parameters; Encode every graphic element; Design the computing method for coordinate value of positioning base point, in order to improve efficiency of symbol automated drafting. Below is an example for developing a graphic symbols library of an entity similar to iron chain bridge.

1. Example for user-defined file (User.def)

```
1404000                         [symbol code]
1                               [point symbol]
A00                             [layer name:A00]
Land032                         [block name:Land032.dwg]
0                               [no rotate ]
Well symbol                     [symbol name]
3209000                         [symbol code]
2                               [line symbol]
.....          ;END
```

2. Transfer user-defined: rr.lsp

```
(defun C:(/kcode tc code)       ;
                (Chbm)      ;Taking code out
                (user)
 );End
 (defun CHBM()
            (setvar "cmdecho" 0)
            (initget 1 "1")
            (setq code (getreal "\n Input features code (7bites):"))
 )
(defun User(/ f tt name lb kw code1 s n n0 s1)
                    Qq ok code2 lb1 name1 tc1 kw1 code3
 )
  (setq code2(*(fix (/ code 100.0))100.0))
  (setq f (open "user.def" "r"))
  (setq TT (read-line f))
  (while(/ = tt "-End-"))
          (setq code1 (atof tt))
          (setq LB (read-line f) TC(read-line f)
          Name (read-line f) KW(read-line f)
    ) .....
        (princ "\n")
   )
```

3. Build professional symbols library.

Programming graphic subprograms in symbols library such drafting iron chain bridge.

```
;File name:   TSQK.LSP
  (defun H_TSQ(/ pt1 pt ang h width 1 width p1 s1 s2 s3 ang2 ang3 p2 p3 p4 code1 ang1 pt4 pt5
pt6 pt7 pt8 code2 p11 p22 pt2 pt3 os
 )
(setvar "cmdecho" 0)(setq os (getvar "osmode"))
(setq code1 ( + ( * (atof (substr (rtos code 2 0 ) 1 5 ) 100) 3.0)
          code2( - code1 1.0) .....
 )
(command "line" p11 p22 "")
      (setq s3 ( + s3 s0) s2 ( + s2 s1))
 )
```

```
(command "layer" "m" "bound" "s" "bound" "")
(command "elev" "" ( + code1 5.0))
(command "pline" p1 "w" 0 0 p2 p3 p4 "c")
(b_xdata)
(command "layer" "s" "0" "")
(command "elev" "" "0")
(setvar "osmode" os)
(princ "\n symbol finished!")
(princ)
)
```

4. Create folder for symbols library and add search path[5].

Suppose creating folder named Lisp on hard disk. Put created files which including READ_XYM, HXYH.LSP ,READS.LSP ,READC.LSP ,READM.lsp ,User.def ,rr.lsp ,TSQK.LSP into the folder. Select 'tools' → 'option'→ 'file', select 'file search paths' and click 'add' putton, put 'lisp' folder in search path.

5. Transfer symbols library.

```
;Plotting iron chain bridge symbols; File name :TSQ.LSP
 (defun C:TSQ()
            (setq TC "DLSS")          ;Setting layers parameter
            (setq Code 4650000)       ;Setting code parameter
            (setq b_xdata nil)        ;Initializing attribute table
            (SCSFH_JL)                ;Recording  starting point
            (TSQK)                    ;Transferring  symbol library
 )
```

**Realization to symbols library program**

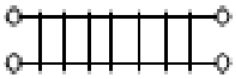

figure. 2

**Load necessary library files.**

First of all, necessary files must be loaded in AutoCAD environment . These files are: *READ_XYM,CHXYH.LSP,READS.LSP,READC.LSP,READM.lsp,User.def,rr.lsp,TSQK.LSP.* Inputting 'load file name' on command line is ok.

**Run program of iron chain bridge named TSQ.**

Input TSQ on command line and 'Enter', then according to prompt message,input proportional scale, coordinate value. After inputting data of three feature points of iron line bridge, finish symbol appears on screen. Shown as Figure. 2.

## Conclusion

Considering experience of developing professional library and purpose by AutoLISP language, this paper introduces detailed producing process and skill of professional library by typical example, help programmers to resolvine difficulties faced.

# Application of Total Station in the Measurement of Transmission Line

Fangru Gui

Sichuan College of Architectural Technology, Deyang, Sichuan, 618000,china

116211747@qq.com

**Keywords:** transmission line , measurement, point guiding alignment, coordinate , total station

**Abstract.** Through analyzing the difficulties in the measurements of Wangling hydropower station's transmission line, this paper proposes an idea that total station is applied to complete line measurement on the basis of the point guiding alignment measuring technique, which aims at providing a reference for other similar projects.

## Introduction

With the development of society, the demands for power resources become more and more, and power grid also develops increasingly faster. The measurement of transmission line is a systematic work in the engineering construction of transmission line, and also a specialized measurement conducted for power engineering construction, therefore, it plays a very important role in the engineering construction of transmission line

## Project Overview

This project is the measuring engineering of 35kV transmission line from Yuexi County 110kV substation to Wangling hydropower station. As its exit number from the 110kV substation is 305 # , this transmission line is called the 305 # power line. This line project is spread along Tiantang Town, Lianyun Village , Zhongguan Village, Xiawuhe , Liufan and Xifo Village of Yuexi County, the overall length of transmission line is 17.5km, and the conductor type is LGJ-185/20. The terrain of the whole line is mainly mountain and steep slope, the way from Huilong Mountain to Wangling hydropower station is spread with high mountains, the terra is advantageous, the region is wooded, resulting in the great difficulties in survey . If the project is put into operation, the western grid structure of Yuexi County would be strengthened and the reliability of power supply in hydroelectric power supplying region would be improved, which is conducive to the development and utilization of water resources in the Dabie Mountains and also further promotes the economic development of mountainous areas .

## Difficulties of the Project

In the measurement of 305 # power line, the measuring instrument used is Nikon 352-O type total station which is qualified with high measuring accuracy and is commonly applied by power supply companies in the counties of Anhui Province. In the mountainous area, the terra is advantageous and the region is wooded, resulting in short range of visibility in the measurement. Therefore, the effectiveness of this measuring instrument is not satisfying, and completing the measurement of the three relatively longer linear segment determined by this line is a major problem

## Implementation of Measurement

To solve the problems in measuring the linear segment of transmission line, a number of new measuring technologies of transmission line engineering are applied in the measurement of 305 # transmission line, and the main technologies are" point guiding alignment measuring technology" and "coordinate back calculation to control direction measuring technology ", which can only be realized

through the field measurement of the total station, the computational analysis of computer software and the computer-aided design. Through the comprehensive application of these two new technologies in the 305 # transmission line, the difficulties in the measurement and orientation caused by the overlength linear segment of transmission lines in mountainous areas are solved. And these two new technologies are also applied in the engineering measurement of 35kV voltage class transmission line in Yuexi County for the first time .

"Guiding point alignment method " is a new measuring and orienting method of transmission line summarized from the actual measuring work of transmission line by Yuexi Power Supply Company, and combined with "coordinate back calculation to control direction method", it can fundamentally solve the difficulties in the measurement and orientation of transmission lines in mountainous areas and is suitable for the orientation measuring engineering of transmission lines in large-scale mountainous area.

In the field measurements, the line route and the basic data of line channels and terrain are preliminarily determined according to topographic map, and total station is applied to measure each linear point, feature point and turning point for obtaining the coordinate and elevation of each point. The coordinate orientation of each point and the relationship between the points would be recorded by the total station. When it comes to the measurement of a turning point, instrument is required to determine the turning direction and turning angle. At this time, terrain condition of mountainous area will affect the measurer 's range of visibility. Meanwhile, the application of the general angle measured by protractor in the topographic map that is 1:1000000 in the field measurements often leads to some unexpected effects, resulting in subsequent rerouting of power lines and the increase in engineering investments. To ensure that the basic directions of field investigation and transmission line determined in accordance with the figure are the same, whether the transmission line can accurately pass the selected feature point of line after turning should be determined.

“Point guiding alignment method " is applied at this time, and instrument is used to measure guiding point from the turning points, to guide the measuring point to the more accurate point ahead. The instrument will record the actual coordinates orientation and elevation of feature points. Then "coordinate back calculation to control direction method" is applied to calculate the coordinate azimuth and horizontal distance between the turning point and the feature point, As shown in Fig.1. And then the turning angle is calculated based on the calculated coordinate azimuth, so as to ensure that direction of transmission line after turning is consistent with the basic direction of transmission line determined by the figure and to reduce the repeated tree felling in the measurement channel of transmission line. The application of this method, whether the line passes complex terrain or even forest, as long as it is measured along this angle, the predetermined direction of line can be guaranteed.

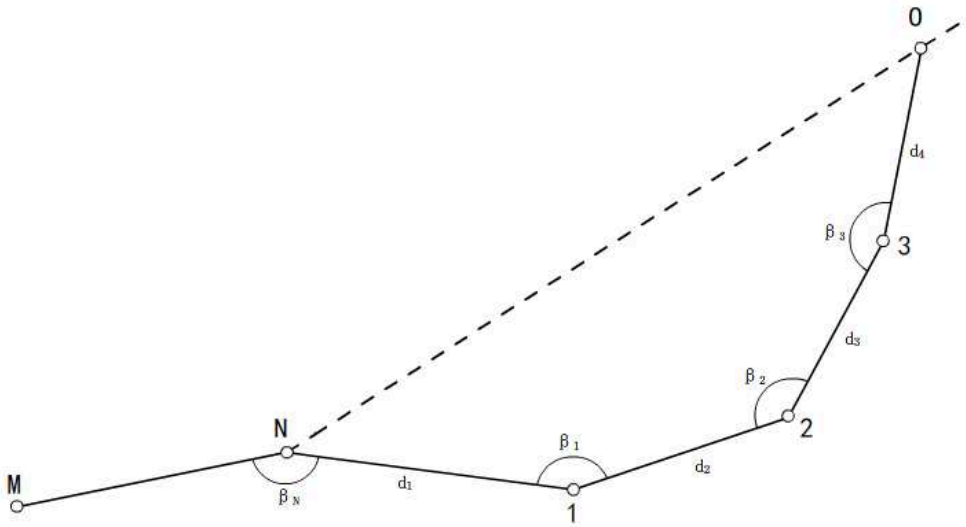

Fig.1 Schematic Diagram of Point Guiding Alignment Method

The specific operational method of "point guiding alignment method " is shown in Figure 1. When measuring transmission line passes through Point M to Point N, the transmission line need to turn left at Point N to Point O according to the design requirements. However, after setting up instrument in the actual place of Point N, it is discovered that the distance between Point N and Point O is long, they are even blocked by mountains, and Point O can not be directly seen from the Point N, so that angle orientation can not be conducted at Point N, and Point O can not continue to be measured.At this moment, the coordinates and azimuth angles of Point M and Point N are determined. If coordinate data of Point O is obtained, the included angle of MN and NO can be calculated according to the coordinates, and then measuring angle can be provided to the instrument installed in Point N for measuring. Therefore , applying "point guiding alignment measuring technique" can measure No.1 Point that is easy to be observed from Point N, and identify the angle βN and horizontal distance d1; measure the No.2 Point, and identify the angle β1 and horizontal distance d2; measure No.3 Point, and identify the angle β2 and horizontal distance d3; and then measure Point O from No.3 Point, and identify the angle β3 and horizontal distance d4. According to the calculation methods of wire measurement, coordinates of Point 1, 2, 3 and O can be determined.

When the coordinates of Point O are determined, the coordinates of Point N and O are calculated according to "coordinate back-calculation to control direction method ". As is shown in Fig.2, the azimuth angle $\alpha_{NO}$ and horizontal distance DNO from Point N to Point O is calculated. Therefore, the ligature of Point N and Point O is determined. The method to calculate the horizontal distance and coordinates azimuth of the two end points of the straight-line NO when the coordinates of Point N and O ($X_N$, $Y_N$) ($X_O$, $Y_O$) are known is called coordinate back-calculation method.

Both methods are used in the extension of the three relatively longer straight lines of 305# transmission line, the surveying effect is perfect, and the accuracy meets the design requirements. The advantages of total station and computer software in the measurements of transmission line are given full play, while the measurement accuracy and efficiency are far superior to the theodolite. In the measurement of transmission line, the actual application of these two measuring technologies of total station is worthy of promotion.

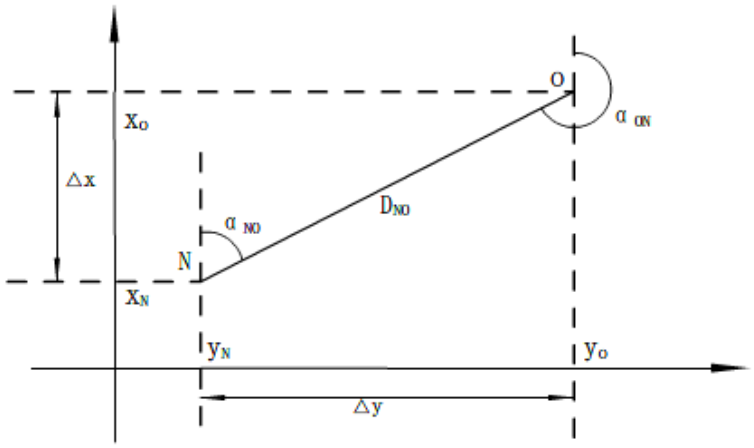

Fig.2 Schematic Diagram of Coordinate back-calculation to Control Direction Method

## Conclusion

In the application of total station, the following problems should be noted. Total Station should not be installed in the place within the range of the electromagnetic field effects, such as in the vicinity of high-voltage object, otherwise it will affect the measurement accuracy. Wireless call should be suspended while measuring; observation station and mirror station should be protected by specially-assigned person after installing the equipment, in case that the equipment would displace or fall. The facing of the lens of total station to the sun and strong light is strongly prohibited, other reflectors located in the measuring line or its extension line ranging should be avoided while measuring, because the total station is very sensitive to light and glare can damage its electronic

measuring system. In the observation, prism surface should be aligned with the ranging lens of total station, and especially when the measuring angle is large, they should be aligned with each other. The instrument has higher measurement accuracy within the range of 30° in elevation to 30° in depression, so the measurement of the elevation and depression that are larger than 30° should be prevented, to avoid the affection of measurement accuracy. The instrument instructions should be strictly observed, the observation should be stopped once abnormal phenomenon arises, and the reasons should be analyzed, to ensure the correctness of measurement results and the safety of instrument.

# Chinese Geodetic Coordinate System 2000 and Its Comparison with WGS84

Houpu LI [1, a], Shaofeng BIAN [1,b] and Zhongmei LI [1,c]

[1] Dept. of Navigation Eng., Naval Univ. of Engineering, Wuhan, 430033, China
[a]lihoupu1985@126.com, [b]sfbian@sina.com, [c]15827116839@163.com

**Keywords:** geodetic datum; geocentric coordinate system; CGCS2000; WGS84

**Abstract:** It is a general trend to adopt the geocentric coordinate system as a geodetic datum for the international measurement community. The definition and realization of Chinese geocentric three-dimensional coordinate system (CGCS2000) which has been employed since July 1st, 2008 were introduced in detail. The defining parameters and derived constants of the reference ellipsoid used were given. The comparison between CGCS2000 and WGS84 was carried out. The differences of geodetic coordinates of a point between the two coordinate systems, normal gravity and vertical gradient of normal gravity on the two ellipsoids caused by the change of the flattening of the ellipsoid were analyzed. The results show that these differences could be neglected in view of present measurement accuracies.

## Introduction

The geodetic coordinate system is not only an important basis of the Earth's spatial framework, but also a three-dimensional reference datum which represents the Earth's spatial physical location. Defining and adopting national geodetic coordinate system scientifically will exert an influence on fields such as aeronautics, astronautics, navigation, positioning, earthquake monitoring, geophysical prospecting, etc[1]. The geodetic coordinate system can be divided into reference-ellipsoid-centric coordinate system and geocentric coordinate system according to the position of its origin relative to the Earth's center of mass. The origin of the reference-ellipsoid-centric coordinate system is offset from the Earth's center of mass by about tens to hundreds of meters, while the origin of the geocentric coordinate system is theoretically coincident with the Earth's center of mass, but inevitably there is some deviation in fact[2].

Beijing coordinate system 1954, Xi'an coordinate system 1980 and modified Beijing coordinate system 1954 have been established by our country since the foundation of the New China. These coordinate systems are non-geocentric, and once played a great role in Chinese economy and defense construction, but they could not meet the necessity of science and technology especially the space technology because the precision of their achievements is relatively low due to technical conditions at that time. In view of the development needs of economy, society, science and technology, the geocentric three-dimensional coordinate system, Chinese Geodetic Coordinate System (CGCS2000), has been formally adopted as Chinese new generation of geodetic datum since July 1, 2008[3,4].

## The Definition of CGCS2000

CGCS2000 is a right-handed, Earth-Centered Earth-fixed (ECEF) orthogonal coordinate system, and its origin and axes are defined as follows:

(1) The origin of CGCS2000 coincides with the Earth's center of mass.

(2) Its Z-axis directs from the origin to the IERS Reference Pole (IRP).

(3) Its X-axis directs from the origin to the intersection of the IERS Reference Meridian (IRM) and the plane through the normal to the Z-axis.

(4) Its Y-axis completes a right-handed, Earth-Centered and Earth-Fixed (ECEF) orthogonal coordinate system.

An equipotential ellipsoid of revolution is taken as the form for the CGCS2000 reference ellipsoid. Its geometric center coincides with the origin of CGCS2000, and axis of revolution coincides with the Z-axis of CGCS2000. Its surface is geometrically the datum plane for surveying calculation, and physically equipotential surface of the Earth's normal gravity. The four defining parameters of the CGCS2000 reference ellipsoid are: semi-major axis, $a = 6378137\text{m}$, flattening, $f = 1/298.257222101$,

Earth's gravitational constant, $GM = 3.986004418 \times 10^{14}\,\mathrm{m^3 s^{-2}}$ , angular velocity of the Earth, $\omega = 7.292115 \times 10^{-5}\,\mathrm{rad\,s^{-1}}$.

According to the above four defining parameters, the more commonly used geometric and physical constants associated with the CGCS2000 ellipsoid derived by [5] are listed in Table 1 and Table 2 respectively.

Table 1 Derived geometric constants for the CGCS2000 ellipsoid

| Constant | Notation | Value | Constant | Notation | Value |
|---|---|---|---|---|---|
| Semi-minor Axis | $b$ | 6356752.31 4140356( m) | Axis Ratio | $b/a$ | 0.9966471893 188177 |

| $m = \omega^2 a^2 b/(GM)$ | $m$ | $3.449786506783957\times10^{-3}$ | Normal Gravity at the Equator | $\gamma_e$ | 9.78032533 6065076(ms$^{-2}$) |

**The Comparison between CGCS2000 and WGS84**

There are many GPS data at present and GPS will still be a main means for obtaining spatial data in future. Since GPS adopts WGS84 coordinate system, it is necessary to compare CGCS2000 with WGS84 in order to guide practical work.

CGCS2000 is consistent with WGS84 in the definitions of the origin, scale, orientation and time evolution of orientation. The reference ellipsoids of the two coordinate systems are also very close to each other. Specifically only the minor difference, $df$, which is equal to $1.64348\times10^{-11}$ exists in the flattening of the four defining parameters.

The geodetic longitude of a point in CGCS2000 is the same as that in WGS84, but the geodetic latitude and height are different. The differences of geodetic latitude and height, designated $dB$ and $dH$ respectively, are shown in Fig. 1 and Fig. 2.

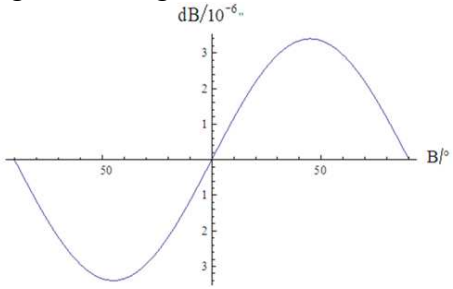

Fig. 1 The difference of geodetic latitude of a point between CGCS2000 and WGS84

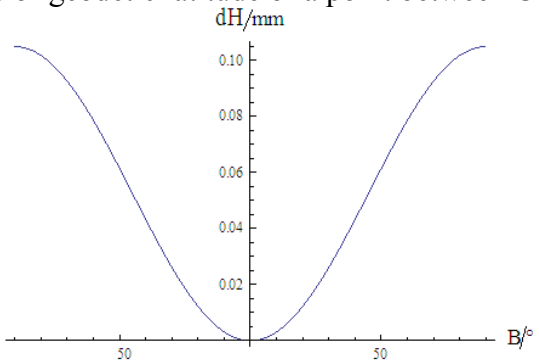

Fig. 2 The difference of geodetic height of a point between CGCS2000 and WGS84

From Fig. 1 and Fig. 2, we could find that the difference of geodetic latitude of a point between CGCS2000 and WGS84 changes by rule of sinusoidal curve with the minimal absolute value being 0 at the equator and poles and the maximal absolute value being about $3.4\times10^{-6}\,''$ which is equal to 0.105 mm after arc second is converted into meter at $45^\circ$N and $45^\circ$S, while the difference of geodetic height changes by rule of inverse cosine cure with the minimal value being 0 at the equator and the maximal value being 0.105 mm at the poles. Generally speaking, the differences of geodetic coordinates between CGCS2000 and WGS84 could be neglected on condition that the present measurement accuracy is at the level of 1 mm. The differences of normal gravity and vertical gradient of normal gravity, designated $d\gamma$ and $dv$, which change with the geodetic latitude on CGCS2000 and WGS84 ellipsoids are shown in Fig. 3 and Fig. 4 respectively.

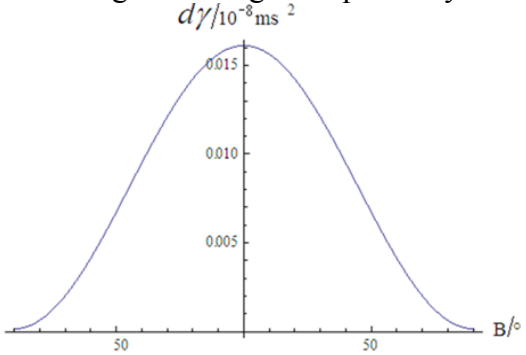

Fig. 3 The difference of normal gravity on CGCS2000 and WGS84 ellipsoids

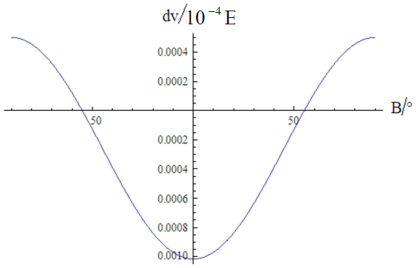

Fig. 4 The difference of vertical gradient of normal gravity on CGCS2000 and WGS84 ellipsoids

From Fig. 3 and Fig. 4, we could find that the normal gravity on CGCS2000 ellipsoid is a little greater than that on WGS84 ellipsoid, with the minimal value of the difference being $0.00016\times10^{-8}\,\mathrm{ms}^{-2}$ at the poles and the maximal value being $0.016\times10^{-8}\,\mathrm{ms}^{-2}$ at the equator, while the maximal absolute value of the difference of vertical gradient of normal gravity is $0.001\times10^{-4}\,\mathrm{E}$ ($1\mathrm{E}=10^{-9}\,\mathrm{s}^{-2}$) at the equator and the minimal absolute value is 0 E at $55^{\circ}\mathrm{N}$ and $55^{\circ}\mathrm{S}$. Generally speaking, these differences could be neglected on condition that the present measurement accuracies of normal gravity and vertical gradient of normal gravity are $10^{-8}\,\mathrm{ms}^{-2}$ and $10^{-4}\,\mathrm{E}$ respectively.

## Conclusions

(1) Geodetic coordinate systems have been established in main developed areas and neighboring countries. The three-dimensional geocentric coordinate system with high precision, CGCS2000, is adopted as Chinese new generation of geodetic datum, which could help us most effectively make use of space technology and derive much benefit from it to great extent.

(2) The maximal differences of geodetic latitude and geodetic height of a point between CGCS2000 and WGS84 are $3.4\times10^{-6}\,''$ and $0.001\times10^{-4}\,\mathrm{E}$ respectively, and the maximal differences of normal gravity and vertical gradient of normal gravity on CGCS2000 and WGS84 ellipsoids are $0.016\times10^{-8}\,\mathrm{ms}^{-2}$ and $0.001\times10^{-4}\,\mathrm{E}$ respectively. The differences of geodetic coordinates of a point between the two coordinate systems, normal gravity and vertical gradient of normal gravity on the two ellipsoids could be neglected in view of present measurement accuracies.

# Discussion on the Measurements in Cantilever Construction with Guyed Hanging Basket

Fangru Gui

Sichuan College of Architectural Technology, Deyang, Sichuan, 618000,china

116211747@qq.com

**Keywords:** girder, construction, elevation , location , hanging basket

**Abstract.** Guyed hanging basket is qualified with reasonable structure , great carrying ability and clear construction process, and also can provide a good operating space for beam segment construction. Applying cantilever pouring construction with guyed hanging basket should be the development direction of the construction of large-span reinforced concrete cable-stayed bridge. By taking the girder construction of the grand bridge over Beijing-Hangzhou Canal as an example, this paper introduces the measurements in cantilever construction with guyed hanging basket, aiming at providing reference for other similar projects.

## Introduction

Cantilever construction with hanging basket is one of the most commonly used construction methods among large-span prestressed concrete cantilever beam, continuous beam and rigid frame bridge in the industry. Hanging basket generally has the following types: beam hanging basket, cable-stayed hanging basket, guyed hanging basket, steel beam type and supporting frame type. And guyed hanging basket mainly consists of load-bearing system, anchorage elevating and shear reisting system, positioning adjustment system , running system and template system. As guyed hanging basket is qualified with simple structure, lightweight design and convenient utilization, it is commonly applied in the cantilever pouring construction of large-span bridge .

## Project Overview

Grand bridge over Beijing-Hangzhou Canal is controlling node project of Jiangliu expressway, bridge type of its main bridge is a cable-stayed bridge of semi-floating system with double pylons and double cable planes , the length of the main bridge is 464m, and auxiliary piers are installed along the side span. The girder which stretches across the Grand Canal is vertical and horizontal two-way prestressed concrete structure. As the river shipping is busy, the security risk of hanging basket construction on the shipping lane is high, especially the security risk when the hanging basket is being lowered or is moving. The girder applies the construction method of front pivot guyed hanging basket which has high requirements for hanging basket system. Front pivot guyed hanging basket pouring cannot convert easily in different working conditions, linear control is used in the girder, elevation control is difficult, and the difficulty of safety control is high.

## Construction Measurement of 0 # Block

Zero block's construction is a key part of hanging basket assembly, which is directly related to the orderly connection of the standard blocks along the girder and the elevation control of the entire deck ( bottom). Zero block often applies brack construction beside the pier, and zero block's brack assembly beside the pier must be guaranteed sufficient strength and rigidity. Before paving baseboard , ballast is required to eliminate non-elastic deformation, observation and recording should be carried out before and after the ballast, and the measured data of elastic deformation can be used as a reference for installing template. Baseboard should be paved after unloading floor, paving elevation is equal to the sum of design elevation, elastic deformation and camber value, and the control points of

construction plane are applied to carry out plane lofting on the beam line and block line. After the baseboard , web and partition rebar have been strapped , relative elevation relationships with baseboard should be maintained to position internal model elevation. After the roof rebar has been strapped, elevation lofting of concrete's top surface should be conducted according to the relative height difference with the baseboard, point density is required to meet the requirements of the construction site , which could be a powerful guarantee for the lateral and longitudinal gradient of beam plane. Settlement observation should be carried out in the pouring process. Observations of completion and transformation are required after the templates are removed.

## Measurements of Hanging Basket Ballast Test

### 3.1 Purposes of Hanging Basket Ballast Test

The test is to examine whether the overall load-carrying ability of hanging basket can meet the requirements of design documents and specifications, to eliminate the inelastic deformation of hanging basket and measure the elastic deformation of hanging basket under the design load for providing data for the linear control of section construction, and also to examine the safety and reliability of hanging basket.

### 3.2 Measurements of Hanging Basket Ballast Test

After the completion of hanging basket assembly , ballast test should be carried out on the assembled hanging basket for effectively eliminating the plastic deformation during hanging basket construction and actually measuring elastic deformation of hanging basket under loaded state. Applying equivalent load to simulate beam weight and conducting hanging basket are the most unfavorable for conducting safety inspection of hanging basket structure with loading in working condition.

## Construction Measurement of the Girder's Standard Segment

### 4.1 Lofting of Plane's Temporary Control Point

According to the control points on the girder, temporary plane control points of controllable blocks without pouring are set out on the poured block. In order to ensure the plane position's controllability of the block to be poured, 8 controllable points are set out on the poured block, and the longitudinal distance between points and block line should be the length in which instrument can be set up ( the best distance between each segment is a constant 0.5m or 1m ) .

### 4.2 Longitudinal Positioning of Hanging Basket

Longitudinal positioning of hanging basket is mainly to facilitate hanging basket's forward moving along a correct direction, so as to prevent the condition that the front-end plug template cannot be set up on the theoretical block line, which would affect the positioning of box beam's internal components. Based on the front-end temporary control lines of poured block, longitudinal positioning of hanging basket applies hammer ruler and plumb bob to conduct distance measurement, and if the measured value is inconsistent with the design value, it would apply jack to adjust the mileage direction of hanging basket to make the difference between the measured values and design value be less than ± 10mm.

### 4.3 Lateral Positioning of Hanging Basket

Lateral positioning of hanging basket is mainly to prevent the abnormal closure of the bridge caused by segment centerline's deviation from the centerline of the entire bridge after pouring. Immediately after initial setting elevation, the lateral deviation adjustment of hanging basket is conducted, theodolite is placed at the front-end bridge axis points of the poured block during adjustment, which is treated as another point of the bridge axis, and then the deviation value between hanging basket midline mark and centerline direction of the girder is measured with directional line method or reverse mirror method. Due to the existence of errors in point location, mirror positioning and so on, the lateral deviation of hanging basket should be controlled within ± 5mm, the central hang

should be locked after adjustment, and the lateral deviation of hanging basket should be measured again after locking, until the error is controlled within the range of ± 5mm .

**4.4 Lofting of Hanging Basket's Front-end Mileage Line**

Lofting of hanging basket's front mileage line is mainly to prevent the problem like beams of varying width after pouring, and this problem would affect the construction of next beam segment.After the lateral positioning of hanging basket( before the rebar is strapped), the total station is set up in the bridge axis point of the temporary control points along the girder, observation station data and back vision azimuth angle are set to conduct operation on the front-end theoretic block line of hanging basket. The lofting point should control the transverse direction of the girder simultaneously, and the density of points should meet the requirements of construction.

**4.5 Examination before Pouring**

The examination contents before pouring concrete include location of cross wall on the top of beam, location and elevation of internal model , location of embedded part, longitudinal position of beam top block line, retest of cableway pipe, web position of box girder's front section, control of beam sideline and so on.

**4.6 Elevation Discharging of Beam Surface before Pouring and Embedding Elevation Measurement Point**

After passing various examinations, the lofting of concrete top elevation can be carried out before pouring. Lofting method is to maintain the relative height between the baseboards of hanging basket, and the density of lofting elevation point should meet the requirements of the construction site, to powerfully guarantee the lateral and vertical gradient of beam surface. In order to facilitate deflection observation, three elevation observation points are required to be embedded in the fracture surface of front-end hanging basket.

**Construction Measurement of Closure Segment**

Before closure , the relative height difference between the beam bottom sections of closure opening's two sides should be measured to find out whether adjustment is needed. After adjustment, changes like girder elevation and temperature field of closure opening's two sides should be observed for 48 hours, and girder vertical displacement measurement, girder centerline measurement, tower deviation measurement and so on are carried out at the same time. According to the change rule of beam temperature and atmospheric temperature, changes of beam elevation in different time and temperatures, relationship between the beam longitudinal expansion volume and temperature and etc., data is collected to identify the most stable period of girder changes, so as to guide the stiff skeleton locking time and pouring time of closure segment. Before the locking of closure segment, the girder elevation and vertical displacement should be measured again, and the data is used as the initial data. After the closure segment is locked, the observation content before locking should be repeated, and the deformation observation should be conducted every 2 hours within 24 hours to test locking effect . In the concrete pouring process, the main work is to conduct tracking measurement on the girder elevation deflection of closure opening's two sides.

**Full-bridge Adjusting Measurement**

An inevitable problem may arise in the construction process, that is, the top or bottom line of girder is not very smooth, and its difference from the design line is always not the same, so that it is necessary to adjust the actual line. After the stretch-draw of girder closure and prestress, full-bridge cable force should be adjusted, the size of adjustment is based on the whole line of girder, and 24-hour observation of deflection on girder and tower deviation measurements should be conducted before the adjustment. Measuring time should be arranged in the constant temperature period of girder, level gauges, as many as possible, should be applied to observe simultaneously, in order to shorten the observation time. In the process of adjusting, tracking measurement on girder deflection and tower

deviation should be conducted until the full-bridge cable force and line meet the requirement. After the adjustment of cable force is completed, full-bridge girder line should be measured once again.

## Conclusion

Measurement control must be strengthened in the construction measurement of the girder, conditions to conduct re-check should be created as much as possible in the measurement process of cantilever construction, to ensure the accuracy of the measuring results. The control on the construction elevation of hanging basket's each block should be strengthened at the same time, to ensure that the final line of girder is smooth. And the measured deflection, elevation and other parameters of girder under various working conditions should be fed back to the designer in advance, so that designers can adjust and control the elevation of pouring block to ensure the successful completion of the girder's construction measurement .

**Keywords:**settlement observation,leveling rod,surveying errors

**Abstract.**Thisdocumentbases on settlement observation of a residential district which is influenced by the subway construction in Shanghai China.Because of the long-term measurement,therewere some equipment boxes installed on the top of the settlement marks.Thus making the leveling rod in an leaning angle to the right or left direction relative to the sight line.In order to know the error of the measurement,wemake analysis of the error.And it also can be a reference for other surveyings when encounter this similar circumstance.

## Introduction

Settlement observation is a fundamental and important part not only in the site construction but also the building's detection and reinforcement.It is significant to reduce the error of the measurement.

The typical factors influence the measurement are:instrumentalerror, malobservation, externalconditions,observationtime,benchmark,settlement marks and observation route[1].In the actual situation,these factors are integrative that some of them can offset each other.And the error will be tiny and satisfy the precision requirement when the measurement is operated according to the regulation.

But there comes endless situations in engineering.Forexample,in order to make a detection and reinforcement to a residential district which is influenced by the subway construction.Some settlement marks were made aroundthe buildings.With the long-term settlement observation,there were some equipment boxes installed on the top of the settlement marks.Thus making the leveling rod in an leaning angle to the right or left direction relative to the sight line(Fig.1).The surveying errors is what we care about most in such circumstance.

## The Error of The Settlement Observation

There will be four cases in Fig.1 to analyze the error.

**Case One.**The level rod was palcedin the same palce in the two successive surveyings(Fig.2).Assuming that the actual settlement is $y$,sight height is $x$,the leaning angel of the leveling rod to the right is α.

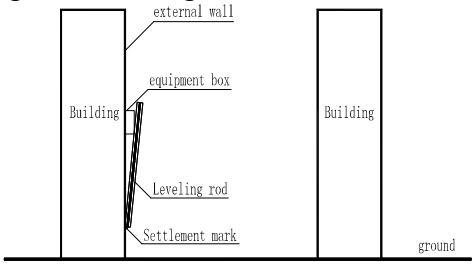

Fig.1 Circumstance of making leveling rod tilt

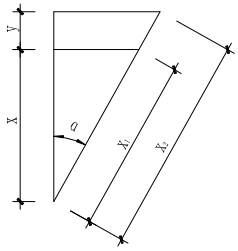

Fig.2 The geometric relationship of the settlement in circumstance 1

The error $\Delta_1$ is(mm):

$$\Delta_1 = x_2 - x_1 - y = \frac{x+y}{\cos\alpha} - \frac{x}{\cos\alpha} - y = \frac{y}{\cos\alpha} - y \tag{1}$$

where,$x_1$ is the first time's reading,$x_2$ is the second time's reading.According to the Eq.1 and in line with the actual,we get some errors in case1 showed in Table 1.

Table.1The measurement error in case 1[mm]

| y (mm) | α | | | |
|---|---|---|---|---|
| | 1° | 3° | 5° | 7° |
| 1 | 0.00 | 0.00 | 0.00 | 0.01 |
| 5 | 0.00 | 0.01 | 0.02 | 0.04 |
| 10 | 0.00 | 0.01 | 0.04 | 0.08 |
| 50 | 0.01 | 0.07 | 0.19 | 0.38 |
| 100 | 0.02 | 0.14 | 0.38 | 0.75 |

Note:The situation we met was that the leaning angle $\alpha$canbe 6°.That is: $\alpha$=tan$^{-1}$(200/1900)= 6°,where 200 is the equipment boxes' thickness is 200 mm,1900 is the vertical length between the benchmark and the equipment box is 1900mm.

We can get the conclution that the error is tiny if the two times' operation are kept on the same.This also verifies the suggestion mentioned in[3].

**Case Two.**The leveling rod was put in the outside and inside in the respective time(Fig.3) and the geometric relationship of the settlement shows in Fig.4.The error $\Delta_2$ is (mm):

$$\Delta_2 = x_2 - x_1 - y = \frac{x+y}{\cos\alpha_2} - \frac{x}{\cos\alpha_1} - y \tag{2}$$

where,$\alpha_1$ is leaning angle of the leveling rod in the first surveying,$\alpha_2$is leaning angle of the leveling rod in the second surveying,the other parameters is the same with the Equ.1.

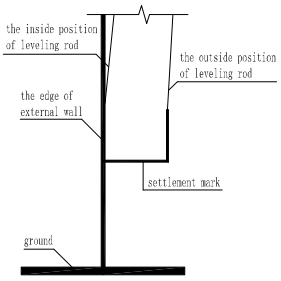

Fig.3 Sketch map of leveling rod's position

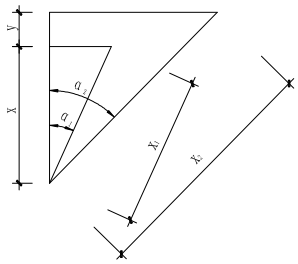

Fig.4 The geometric relationship of the settlement in case 2

According to the Eq.2 and in line with the actual,we get some errors in case 2 showed in Table 2,3.

Table.2 The errors in case 2(1)[mm]

| $x$ (mm) | y (mm) | $\alpha_2$ | $\alpha_1$ | | | |
|---|---|---|---|---|---|---|
| | | | 5.0° | 5.4° | 5.8° | 6° |
| 1500 | 2 | 6° | 2.54 | 1.59 | 0.55 | 0.01 |
| 1540 | | | 2.61 | 1.63 | 0.57 | 0.01 |
| 1580 | | | 2.68 | 1.67 | 0.58 | 0.01 |
| 1500 | 20 | | 2.64 | 1.69 | 0.65 | 0.11 |
| 1540 | | | 2.71 | 1.73 | 0.67 | 0.11 |
| 1580 | | | 2.78 | 1.77 | 0.68 | 0.11 |

Table.3 The errors in case 2(2)[mm]

| $x$ (mm) | $y$ (mm) | $\alpha_2$ | $\alpha_1$ | | | |
|---|---|---|---|---|---|---|
| | | | 1° | 1.4° | 1.8° | 2° |
| 1500 | 2 | 2° | 0.69 | 0.47 | 0.18 | 0.00 |
| 1540 | | | 0.71 | 0.48 | 0.18 | 0.00 |
| 1580 | | | 0.72 | 0.49 | 0.18 | 0.00 |
| 1500 | 20 | | 0.70 | 0.48 | 0.19 | 0.01 |
| 1540 | | | 0.72 | 0.49 | 0.19 | 0.01 |
| 1580 | | | 0.73 | 0.50 | 0.20 | 0.01 |

According to Eq.2 and Table2,3,we can get the conclutions that:

(1)The same D-vlaue in the leaning angle of leveling rod,the more value the benchmark angle the larger the errors.(For example,case A's error is larger than case B's error.where case A is:$x$=1500mm,$y$=2mm,$\alpha_1$=5.4°,$\alpha_2$=6°;case B is :$x$=1500mm,$y$=2mm,$\alpha_1$=1.4°,$\alpha_2$=2° )

(2)The actual settlement $y$'s influence to errors is so tiny that can be ignored.

**Case Three.**Beacause of the bubble on the leveling rod can not reach to the center,the leveling rod may tilt in both right-left and fore-and-aft directions.The geometric relationship of the settlement shows in Fig.5.The error $\Delta_3$ is (mm):

$$\Delta_3 = x_2 - x_1 - y = \frac{x+y}{\cos\alpha_2 \cos\alpha_2'} - \frac{x}{\cos\alpha_1 \cos\alpha_1'} - y \tag{3}$$

where,$\alpha_1$ is the right-left leaning angle of the first time observation, $\alpha_1'$ is the fore-and-aft leaning angle of the first time observation,$\alpha_2$ is the right-left leaning angle of the second time observation, $\alpha_2'$ is the fore-and-aft leaning angle of the second time observation,the other parameters are the same with Eq.2.Thus according to the Eq.3 and in line with the actual,we get some errors in case 3 showed in Table 4.

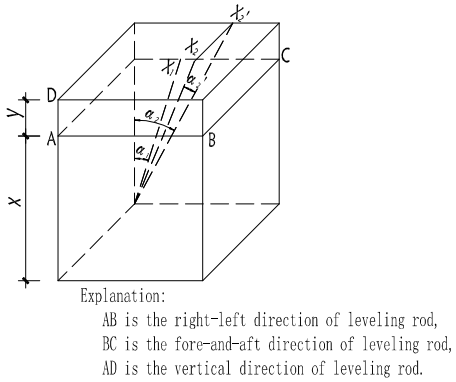

Fig.5 The geometric relationship of the settlement in case 3

Table4The errors in case 3[mm]

| $x$ (mm) | $y$ (mm) | $\alpha_2$ | $\alpha_2'$ | $\alpha_1$ | | | |
|---|---|---|---|---|---|---|---|
| | | | | 5.0° | 5.4° | 5.8° | 6° |
| 1500 | 2 | 6° | 0.0° | 2.54 | 1.59 | 0.55 | 0.01 |
| | | | 0.4° | 2.58 | 1.62 | 0.59 | 0.05 |
| | | | 0.8° | 2.69 | 1.73 | 0.70 | 0.16 |
| | | | 1.2° | 2.87 | 1.92 | 0.89 | 0.34 |
| | | | 1.6° | 3.13 | 2.18 | 1.14 | 0.60 |
| | | | 2° | 3.46 | 2.51 | 1.48 | 0.93 |

(1)We can get the conclution from Eq.3 that leveling rod's right-left leaning and fore-and-aft leaning have the same degree influence on the observation errors.

**Case Four.**The errors caused by reading on the leveling rod(Fig.6).The error $\Delta_4$ is (mm):

$$\Delta_4 = x_2 - x_1 + K\cdot\tan\alpha_2 - y = \frac{x+y}{\cos\alpha_2 \cos\alpha_2'} - \frac{x}{\cos\alpha_1 \cos\alpha_1'} + K\cdot\tan\alpha_2 - y \tag{4}$$

where,$K$ is the length of tick mark on the leveling rod(mm),the other parametes are the same with Eq.3.Thus according to the Eq.4 and in line with the actual,we get some errors in case 4 showed in Table 5.

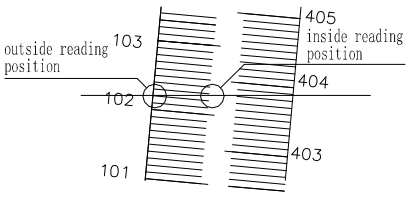

Fig.6 The reading error on the level ruler

Table5 The errors in case 4[mm]

| $x$ (mm) | $y$ (mm) | $K$ (mm) | $\alpha_2$ | $\alpha_2'$ | $\alpha_1$ | | | |
|---|---|---|---|---|---|---|---|---|
| | | | | | 5.0° | 5.4° | 5.8° | 6° |
| 1500 | 2 | 10 | 6° | 0.0° | 3.59 | 2.64 | 1.61 | 1.06 |
| | | | | 0.4° | 3.63 | 2.67 | 1.64 | 1.10 |
| | | | | 0.8° | 3.74 | 2.78 | 1.75 | 1.21 |
| | | | | 1.2° | 3.93 | 2.97 | 1.94 | 1.39 |
| | | | | 1.6° | 4.18 | 3.23 | 2.20 | 1.65 |
| | | | | 2.0° | 4.52 | 3.56 | 2.53 | 1.98 |

**Coarse Judgement of The Observation's Errors**

According to [4],this kind of error belongs to random error(also called accidental error).Its distribution is or approximate normal distribution.And its mathematical expectation is zero.Thus this error Δ's frequency function is :

$$f(\Delta)=\frac{1}{\sqrt{2\pi}\sigma}\exp\left\{-\frac{\Delta^2}{2\sigma^2}\right\} \tag{5}$$

Basing on the above-mentioned result,we can assume that Δ's probability is 95% and 98% respectively in the [-4,4] section.Thus we can get other probability in the different section showed in Table 6.

Table6 The probability distribution ofΔ

| Δ's section | [-4,4] | [-3,3] | [-2,2] | [-1,1] |
|---|---|---|---|---|
| Probability 1 | 95% | 85.8% | 67.3% | 37.6% |
| Probability 2 | 98% | 91.8% | 75.4% | 43.8% |

At the end, we can estimate the error of this settlement observation according to Table 6.

**Conclusions**

According to the analysis mentioned above,we can get the conclutions that:

(1)The error is tiny if the two times' conditions(including instrument, observationmethod,surveying crew ect.) are kept on the same.And we should maintain consistent to reduce the error.

(2) Leveling rod's right-left leaning ang fore-and-aft leaning have the same degree influence on the observation errors.

(3) The actual settlement $y$'s influence to errors is so tiny that can be ignored.

(4) The same D-vlaue in the leaning angle of leveling rod,the more value the benchmark angle the larger the errors.(For example,case A's error is larger than case B's error.where case A is:$x$=1500mm,$y$=2mm,$\alpha_1$=5.4°,$\alpha_2$=6°;case B is :$x$=1500mm,$y$=2mm,$\alpha_1$=1.4°,$\alpha_2$=2° )

**Keywords:** Round hole; stereo vision; edge detection; online measurement

**Abstract.** In precision machining, we often detect the location of some round holes or other geometric parameters. Given the disadvantages of traditional method is contacted, artificial and time-consuming, this paper has proposed a image measurement method based on stereo vision. It uses the method of digital image processing to perform the denoising, binarization, edge detection, and gets centralized location of the orifice image, and analyzes the accuracy of the hole machining and arrangement. Experimental results show that the error of image measurement proposed is less than 0.14mm, which meets the general requirements of the hole measurement in precision and is applicable to online measurement that the accuracy requirement is not high and the task with large amount of object to detect.

## Introduction

The progress of industry proposes higher requirements on the components size measurement accuracy, and also needs to achieve real-time online measurement. The round hole is an important feature in many components, so machining quality of the round hole affects the components normal function. Currently, the method measuring geometric parameters of the round hole is divided into contact measurement and non-contact measurement. The contact measurement tools are caliper, inside micrometer, gauges etc, which are restricted by the size of the hole and the measuring instruments, and sometimes even can not measure the tiny hole and large-size hole. The non-contact measurement methods are universal tool microscope, image measurement, X-rays etc. The disadvantages of universal tool microscope and X-rays are high cost, long cycle and expensive price. Therefore, they are not suitable for the needs of modern industrial development[1-2].

The stereo vision measurement is stable, reliable, non-contact, and rapid speed etc. The extraction algorithm using the accuracy level of pixels and sub-pixel to access the center of the round hole can improve the speed and accuracy of center coordinates detection. The article describes how to use a linear and array type stereo camera and digital image processing technology to detect whether the distance between the hole and the neighboring hole in the industrial components has meet the design standard. Figure 1 is the stereo camera system's sketch map used in this paper.

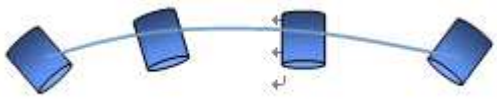

Figure 1 The stereo camera system sketch map

## Multi-camera stereo vision measuring principle

The multi-camera stereo vision measuring principle is getting two or more digital images of the same object in different locations and orientations, after image matching processing by computer and related mathematical calculations, to obtain accurate three-dimensional coordinates of the target point. The schematic diagram is shown in figure 2.

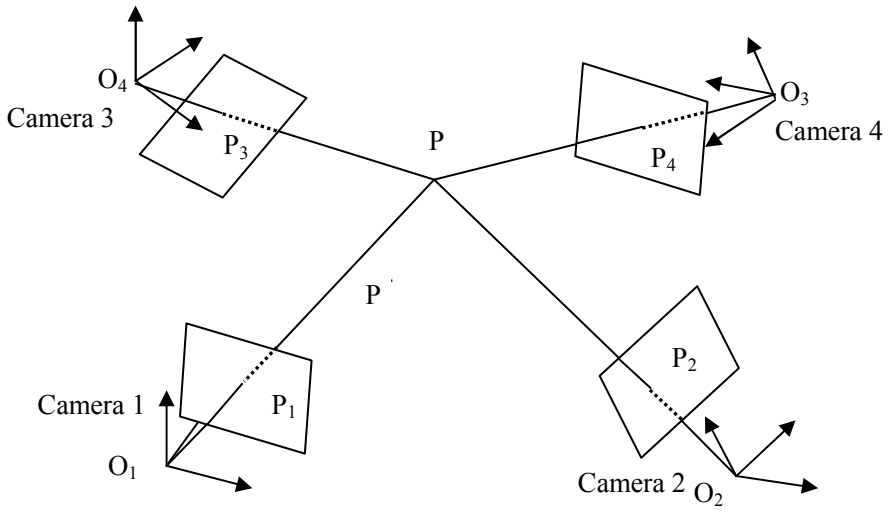

Figure 2 Multi-camera stereo measurement

In photogrammetry, objects imaging model is perspective projection model of a pinhole. Known from Fig.2, for any point P on the surface of the three-dimensional object, if you can see P located $P_1$ in the image from camera 1, but we could not obtain the three-dimensional position of point P. Because for any point P ' in the straight line $P_1O_1$ ($O_1$ is optical center of camera 1 ), the image points are $P_1$. Thus, from the position of point $P_1$, we only know that point in space is located in a position on the straight line P1O1, but do not know the exact location of the point P (namely do not know the deep information). However, if we the observe point P with two cameras: camera 1 and camera 2 simultaneously, the spatial point P is both located on the $P_1O_1$, and on the $P_2O_2$. Point P is the intersection of the straight line $P_1O_1$ and $P_2O_2$. The three-dimensional position of point P is uniquely determined up. These are the basic principles of three-dimensional point reconstruction. Similarly, with camera 3 and camera 4 four camera overall adjustment calculation, we can get a more precise three-dimensional coordinates of point P.

**Corner point extraction edge detection method**

Accurate extraction of corner point position is the premise of high-precision distortion correction. The corner point of image is also known as the turning point, which refers to the points with high curvature in image. It is formed by the larger curvature areas of the target edge, or intersection of two and more edge[3].

Corner point detection method in this paper operates directly on the gray-scale image using sub-pixel corner extraction method of Harris operator. The detection methods can be divided into two steps. The first step is to extract the pixel-level position (x,y) of the corner point based Harris operator. The second step is to do quadratic polynomial interpolation using (x,y) and eight pixels points around. Then we get the sub-pixel position of corner point. The formula of polynomial interpolation is shown as (1)[4].

$$a_0 + a_1x + a_2y + a_3x^2 + a_4xy + a_5y^2 = R(x, y) \quad (1)$$

In the formula, R(x,y) is the reaction function of the corner point. Use 9 pixels to establish overdetermined equation with six coefficients $a_0 \sim a_5$, Then, solve the overdetermined equation using the least squares method.

The sub-pixel position of corner point corresponds maximum of quadratic polynomial, so we calculate the derivation of the quadratic polynomial, as the formula (2), thus, the solution of the binary equations is the sub-pixel position of the corner point[5].

$$\begin{cases} \dfrac{\partial R}{\partial x} = 2a_3 x + a_4 y + a_1 = 0 \\ \dfrac{\partial R}{\partial y} = 2a_5 y + a_4 x + a_2 = 0 \end{cases} \tag{2}$$

**Edge detection**

The detection accuracy of the round edge in the measured hole image directly affects the measurement accuracy. Obtaining the edge of the round hole will be divided into three steps in the paper. The first step is to suppress image noise with the median filtering method. The second step is to extract sub-pixel coordinates of the image edge points based on the principle that least-squares fitting of Gaussian curves. Namely, position the edge roughly with the canny operator. Then, accurately position the edge with fitting a quadratic curve based on least squares fitting method. The third step is to fit the curve equation of the round edges based on least-squares fitting with the edge sub-pixel coordinates. So the radius of the circular edge and exact parameters of the center position can be gained[6-8].

Assuming the center position of the circular edge is $(x_0, y_0, z_0)$, $(x_i, y_i, z_i)$ is the sub-pixel coordinate of edge point, the radius is R. Then, the circle curved equation of edge is the formula (3).

$$(x_i - x_0)^2 + (y_i - y_0)^2 + (z_i - z_0)^2 = R^2 \tag{3}$$

Establish the object equation of the least squares method, as the following formula (4).

$$E = \sum_{i=1}^{n} ((x_i - x_0)^2 + (y_i - y_0)^2 + (z_i - z_0)^2 - R^2)^2 \tag{4}$$

The least squares method here is to find $x_0, y_0, z_0$ and R, and make E is the optimal minimum value. To facilitate solving the equation, order

$$h = x_0^{\,2} + y_0^{\,2} + z_0^{\,2} - R^2 \tag{5}$$

Simplify the formula (5) to equation (6)

$$E = \sum_{i=1}^{n} (x_i^{\,2} - 2x_0 x_i + y_i^{\,2} - 2y_0 y_i + z_i^{\,2} - 2z_0 z_i + h)^2 \tag{6}$$

Using the least squares method, solve the partial derivative of equation (6) and let each partial derivative be 0, as the following equation (7).

$$\begin{cases} \dfrac{\partial E}{\partial x_0} = -4\sum_{i=1}^{n} x_i (x_i^{\,2} + y_i^{\,2} + z_i^{\,2} - 2x_i x_0 - 2y_i y_0 - 2z_i z_0 + h) = 0 \\ \dfrac{\partial E}{\partial y_0} = -4\sum_{i=1}^{n} y_i (x_i^{\,2} + y_i^{\,2} + z_i^{\,2} - 2x_i x_0 - 2y_i y_0 - 2z_i z_0 + h) = 0 \\ \dfrac{\partial E}{\partial z_0} = -4\sum_{i=1}^{n} z_i (x_i^{\,2} + y_i^{\,2} + z_i^{\,2} - 2x_i x_0 - 2y_i y_0 - 2z_i z_0 + h) = 0 \\ \dfrac{\partial E}{\partial h} = 2\sum_{i=1}^{n} (x_i^{\,2} + y_i^{\,2} + z_i^{\,2} - 2x_i x_0 - 2y_i y_0 - 2z_i z_0 + h) = 0 \end{cases} \tag{7}$$

From the formula (7), $x_0$, $y_0, z_0$ can be obtained.

**The identification process of the round hole and the results**

The basic identification process of the round hole image is to obtain the image with multiple orifice firstly, and process the image binarization, then carry on the following operations for the binarization image, corner detection, contour extraction, the geometric center calculation of the hole to obtain the distance between the holes. The processing flow is shown in Figure 3.

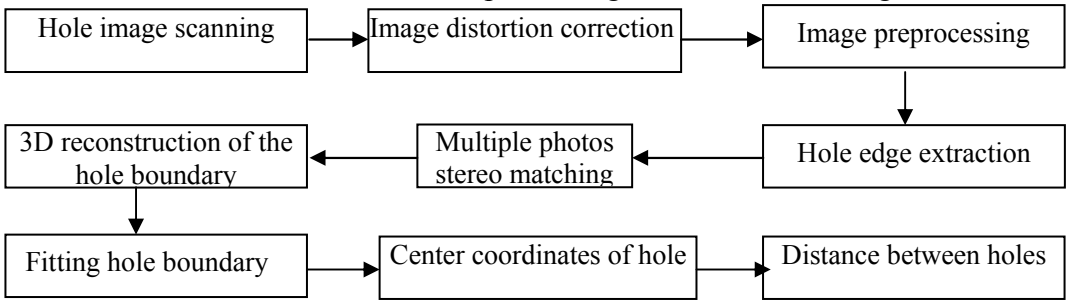

Figure 3 The hole identification processing flow

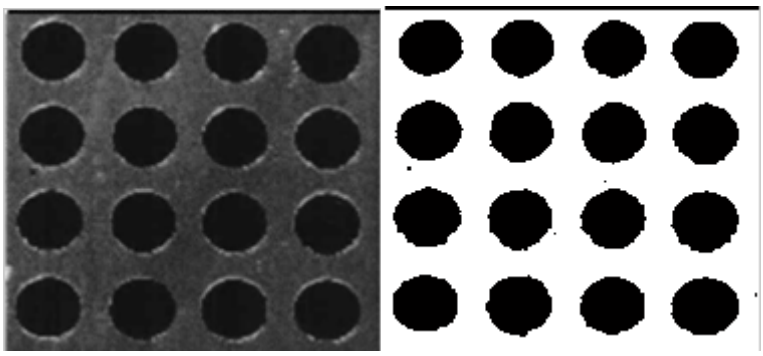
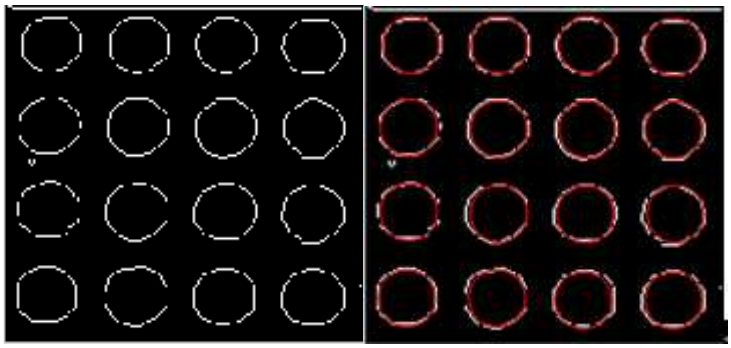
In order to facilitate inspection and comparison, the experiment used an aluminum-alloy plate. There are uniform distribution of the holes drilling by precision drill. Before the experiment, the measured distance between holes as the standard value by micrometer. The original image and the preprocessing results obtained by software processing are shown in figure 4.Edge detection and circle fitting are shown in figure 5.



(a) The original image (b) The preprocessing image

Figure 4 The original image and the preprocessing results



(a) Edge detection results (b) Circle fitting results

Figure 5 Edge detection and circle fitting

By matching multiple images, three-dimensional coordinates of the edge points are obtained. After the hole center location, we can calculate the distance between adjacent holes di (i=1,2,3,4), shown as figure 6. Compared with the standard value of micrometer measurements, we can measure the accuracy of the measurement of stereoscopic images.

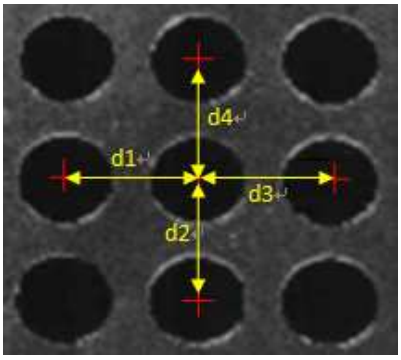


Figure 6 The hole center and center distance

Table 1 Comparison of hole spacing measured results(unit: mm)

| Measurements serial | $d_1$ | $d_2$ | $d_3$ | $d_4$ |
|---|---|---|---|---|
| Hole spacing measured by Micrometer | 13.546 | 13.186 | 13.504 | 13.118 |
| Hole spacing measured in image | 13.463 | 13.287 | 13.644 | 13.053 |
| Differentials | 0.083 | 0.101 | 0.14 | 0.065 |

From Table 1, the measurement error of the hole spacing by stereoscopic measurement is less than 0.14mm, which can be adapted to the measurement tasks of not high precision requirements. Analyzing the reasons, it may be related to the following factors. the internal distortion of camera and the calibration of external parameter exists error; There is noise in the image preprocessing; Edge extraction is inaccurate etc. For high precision measurement tasks, we need further improvement from the above aspects in order to meet the requirements of high-precision measurement.

## Conclusions

Through the introduction of the hole detection theory, the paper processed and analyzed the orifice using noise removal, binarization, edge extraction and other digital processing method, and the the measurement error is less than 0.14mm. This method can be used in rough measurement of the round hole, which is great significance for industrial bulk-production. If we improve it a little, while eliminating the sources of error as far as possible. The high precision measurement of the round hole can be achieved.

**Keywords:** GM (1,1) Model; Settlement; Forecast

**Abstract.** GM (1,1) model was created to forecast the development and change of a high-fill settlement by viewing the high-fill settlement process as a grey system, conducting generation treatment and taking the settlement incremental data sequence as the original data sequence. According to example which demonstrated that the measured settlement at the forecasted model analyzing and monitoring point was practical and relatively accurate.

## Introduction

As the data volume obtained from the observation of a high-fill airport construction process was limited, it was difficult to accurately forecast the actual working conditions of the airport. Although the settlement value had been measured, it was difficult to make a precise description due to the complex relations among these factors. A grey model was created to analyze the development and change of the high-fill settlement by using the grey system theory, viewing the high-fill settlement process as a grey system and conducting generation treatment by taking the settlement incremental data sequence as the original data sequence[1~4].

## Creation of Model [4]

Taking the settlement incremental data $x^{(0)}(k)$ within the same time interval as the original data sequence:

$$x^{(0)}(k) = \left\{x^{(0)}(1), x^{(0)}(2), \mathrm{L}, x^{(0)}(n)\right\} \tag{1}$$

The cumulative settlement volume generation sequence $x^{(1)}(k)$ was obtained by conducting a cumulative generation:

$$x^{(1)}(k) = \left\{x^{(1)}(1), x^{(1)}(2), \mathrm{L}, x^{(1)}(n)\right\} \tag{2}$$

A whitening differential equation of $GM(1,1)$ model of $x^{(1)}(k)$ was created according to the grey theory GM (1,1) model:

$$\frac{dx^{(0)}(k)}{dt} + \alpha x^{(1)}(k) = u \tag{3}$$

By recording the grey parameter column as $\hat{a}$, the least square solution was determined: $\hat{a} = (a \quad u)^T = (B^T B)^{-1} B^T y_n$ , Where:

$$B = \begin{bmatrix} -\frac{1}{2}\left[x^{(1)}(1) + x^{(1)}(2)\right] & 1 \\ -\frac{1}{2}\left[x^{(1)}(2) + x^{(1)}(2)\right] & 1 \\ \mathrm{M} & \mathrm{M} \\ -\frac{1}{2}\left[x^{(1)}(n-1) + x^{(1)}(n-1)\right] & 1 \end{bmatrix} , \quad y_n = \left(x^0(2) \quad x^0(3) \quad \mathrm{K} \quad x^0(n)\right)^T$$

Under the initial value condition $x^{(1)}(1) = x^{(0)}(1)$, the solution of $GM(1,1)$ whitening differential equation (or the time response equation) was solved:

$$\hat{x}^{(1)}(k+1) = \left[ x^{(1)}(1) - \frac{u}{\alpha} \right] e^{-\alpha k} + \frac{u}{\alpha} \tag{4}$$

Then, the reducing value of simulation of the mode was obtained by conducting cumulative generation:

$$\hat{x}^{(0)}(k+1) = \hat{x}^{(1)}(k+1) - \hat{x}^{(1)}(k) \tag{5}$$

When the original data was the measured settlement time sequence, $GM(1,1)$ forecast model was created to conduct fitting to $x^{(1)}$ directly by taking the original data as $x^{(1)}$ and the generated sequence from one cumulative deduction as $x^{(0)}$。

**Model Accuracy Test [4]**

After the establishment of $GM(1,1)$ the forecast model and obtaining the model forecast value (the reducing value), the accuracy of the model, that is, the model fitting degree, must be evaluated in order to evaluate the reliability of the forecast. The common evaluation methods include:

(1) Residual error Test, in which the residual error of the model value and the measured value was tested point by point.

The residual error between the measured value $x^{(0)}(k)$ and the model value $\hat{x}^{(0)}(k)$ and the relative residual error at moment $k$ was recorded to be $q(k)$ and $e(k)$, respectively, $q(k)$ and $e(k)$ were tested point by point, in which:

$$\begin{cases} q(k) = x^{(0)}(k) - \hat{x}^{(0)}(k) \\ e(k) = \dfrac{q(k)}{x^{(0)}(k)} \\ k = 1,2,\mathrm{L},n \end{cases} \tag{6}$$

(2) Test of degree of association, in which the similarity between the model value curve and the modeling sequence curve was tested.

(3) Variance test, in which the statistic property of the residual error distribution was tested, which were jointly descried by the two indexes of the variance specific value $C$ and the small probability of error P. See Table 1.

Table 1 Grey Model Accuracy Class

| Accuracy Class | Relative Residual Error | Variance Ratio C | Small probability Error P |
|---|---|---|---|
| Class One (Good) | 0.01 | <0.35 | >0.95 |
| ClassTwo (Qualified) | 0.05 | <0.45 | >0.80 |
| Class Three (Moderate) | 0.10 | <0.50 | >0.70 |
| Class Four (Disqualified) | 0.20 | ≥0.65 | ≤0.70 |

$x_1$ was recorded to be the variance of $x^{(0)}(k)$, and $\overline{q}$ and $x_2$ the average value and variance of nonzero residual error in $q(k)$ , then:

$$C = \frac{x_2}{x_1}, \quad P = P\left\{ \left| q(k) - \overline{q} \right| < 0.6745 x_1 \right\} \tag{7}$$

For forecast with a good extrapolation, $C$ must be small, a small $C$ indicated a large $x_1$ and a small $x_2$, a small $x_1$ indicated that the observation data discretization was large and the regularity was poor; a small $x_2$ indicated that the residual error discretization was small, so the smaller $C$ was,

the better, which indicated that though the original data regularity was poor, the residual error fluctuation amplitude was small.

When the extrapolation was good, $P$ was large, and a large $P$ indicated that there were more points where the difference between the residual error and the residual average value was smaller than the specified value. Therefore, the smaller $C$ was, the large $P$ was, and the higher its forecasted accuracy was.

**Residual Model Revision**

If $GM(1,1)$ model created in accordance with the original data failed to pass the test, or if its accuracy was not high enough, a residual error model could be considered to be created to revise the original model.

The residual error was as follows:

$$q^{(0)}(k) = x^{(1)}(k) - \hat{x}^{(1)}(k) \qquad k = 1,2,\mathrm{L},n \tag{8}$$

Taking $k = i, i+1, \mathrm{L}, n$, we had residual sequence:

$$q^{(0)} = \left\{ q^{(0)}(i), q^{(0)}(i+1), \mathrm{K}, q^{(0)}(n) \right\} \tag{9}$$

For the sake of convenience of calculation and expression, we rewrote it as:

$$q^{(0)} = \left\{ q^{(0)}(1'), q^{(0)}(2'), \mathrm{K}, q^{(0)}(n') \right\} \quad , \quad n' = n - i \tag{10}$$

Creating a residual error $GM(1,1)$ model to $q^{(0)}$, and adding the $GM(1,1)$ model into the original model, we obtained a revised model as:

$$\hat{x}^{(1)}(k) = (x^{(0)}(1) - \frac{u}{a})e^{-a(k-1)} + \frac{u}{a} + \delta(k-i)(-a')(q^{(0)}(1') - \frac{u'}{a'})e^{-a'(k-i)} \tag{11}$$

Where: $\delta(k-i) = \begin{cases} 1 & k \geq i \\ 0 & k < i \end{cases}$

**Project Example**

The original data after adjustment statistics of a high-fill airport is shown in Table 2.

| 10.11 | -1.38 | -3.06 | -6.79 | -6.25 | -4.01 | -4.69 | -2.91 | -2.54 | -0.96 | -3.50 | -0.64 |

Considering incomplete observation data of the airport, the lack of a long term observation data, and the stable data tendency, a grey $GM(1,1)$ model was used for the modeling and forecast of the vertical displacement of the airport settlement monitoring point XD10.

(1) $GM(1,1)$ modeling

Original sequence: $x^{(0)}(k) = (2.2,1.8,3.1,2.9,3.1,3.7,4.3,3.5)$

One accumulated generating sequence $x^{(1)} = (2.2,4.0,7.1,10.0,13.1,16.8,21.1,24.6)$

The solution of the whitening differential equation (or the time response equation) was:

$$\hat{x}^{(1)}(k+1) = \left[x^{(1)}(1) - \frac{u}{\alpha}\right]e^{-\alpha k} + \frac{u}{\alpha} = 27.019e^{0.0864k} - 24.8194 \tag{12}$$

(2) Accuracy test

Based on the computational simulation value of the whitening response equation, the calculation results and residual error are shown in Table 3.

Table 3 Residual Error Test Calculation Value of XD10 Point

| Sequence | $x^{(0)}(k)$ | $\hat{x}^{(0)}(k)$ | Residual Error $q(k)$ | Relative Residual Error $\varepsilon(k)$ |
|---|---|---|---|---|
| k=2 | 1.8 | 2.4384 | -0.6384 | -0.35467 |
| k=3 | 3.1 | 2.6585 | 0.4415 | 0.142419 |
| k=4 | 2.9 | 2.8985 | 0.0015 | 0.000517 |
| k=5 | 3.1 | 3.1601 | -0.0601 | -0.01939 |
| k=6 | 3.7 | 3.4454 | 0.2546 | 0.068811 |
| k=7 | 4.3 | 3.7564 | 0.5436 | 0.126419 |
| k=8 | 3.5 | 4.0954 | -0.5954 | -0.17011 |

From calculation of Table 3, we had: the average residual error: $\overline{q} = \frac{1}{n-1}\sum_{k=2}^{n}\left|q(k)\right| = 0.1205$, the average accuracy: $P = (1-\overline{q}) \times 100\% = 87.95\% > 80\%$, variance error $C = 0.54$, small error probability $P = 100\%$.

Taking the accuracy represented by the optimal data of each test index as the accuracy of $GM(1,1)$, it showed that the accuracy of the above $GM(1,1)$ model was qualified.

(3) Forecast

Based on the whitening response equation (5) and (12), Plugging $k = 8$ into the above two equations, we got $\hat{x}^{(1)}(9) = 29.1143$, the value was $3.2$, then the forecasted relative residual error of $\hat{x}^{(0)}(9) = 4.5143$ was $\varepsilon(9) = \frac{3.2 - 4.5143}{3.2} \times 100\% = -0.4107\%$.

Taking the accuracy represented by the optimal data of each test index as the accuracy of $GM(1,1)$, it showed that the accuracy of the above $GM(1,1)$ model was qualified.

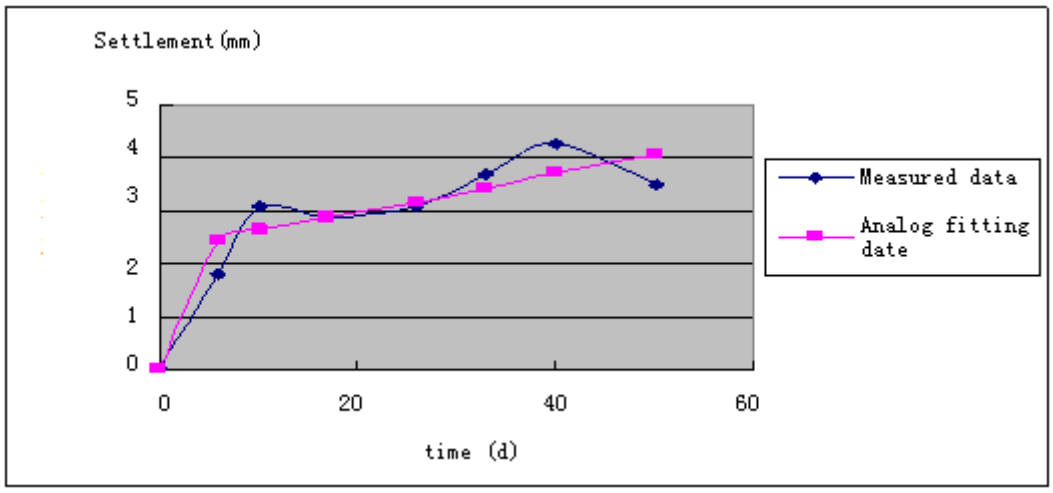

Fig. 1 Comparison Chart of the Fitting Curve of Settlement Monitoring Point XD10 Model and the Measured Curve

From Table 2, Table 3 and Fig. 1, it could be seen that the model accuracy class was good, the accuracy was high, and the model fitting curve agreed very well with the measured settlement curve, indicating that it was practical and accurate to analyze the measured settlement of this observation point by using the grey forecast model.

## Conclusions

The grey model can be used for short term and long term forecasts, which has such merits as less required original information volume, simpler calculation and higher measured accuracy.

(1) Compared with the measured settlement, the accuracy of the high-fill airport settlement forecast by applying the grey forecast model is good.

(2) It is necessary to conduct an accuracy test when carrying out a high-fill airport settlement forecast by using the grey forecast model and the residual error can be revised if the accuracy is not inadequate.

**Keywords:** System parameters. principle of penalized least square, semi-parametric model.

**Abstract.** In this paper, a new solution to the semi-parametric estimation of a mixed model additional system parameters was conducted to derive a calculation method of parameter adjustment at the model regularization matrix, and determine the estimation of parameters and non-parameters as well as the accuracy evaluation formula of the model. The effectiveness of the semi-parametric estimation method was demonstrated through simulation examples, and the semi-parametric model additional system parameters was further extended.

## Introduction

The way to reduce and eliminate the affect of system errors in high accuracy measurement is the main content to improve the adjustment result accuracy. Therefore, it appears to be very important to create a mathematic model that better conforms to the objective reality. The way that is commonly used at present is to regard system errors as model errors of the adjustment model, which are compensated by a function model or random model to reduce and eliminate their impact as a whole so as to ensure a high accuracy of the adjustment result; meanwhile, through estimation of system errors and hypothesis testing, as well as analysis and researches, there have been more understanding to the impact of system errors, followed by adjustment to the model, making it more accurate. This is the superiority of the adjustment processing system error and the intended objective [1]. The concrete methods include the following: parameter adjustment method additional system parameters, additional system power method, additional system parameters and system power method [2], and partial parameter weighting adjustment method [3]. The author puts forward a mixed model semi-parameter method additional the system parameters, and the acquired results are very close to those by the method provided in Reference [3].

## Semi-parameter Model Additional System Parameters

Only a small part of the system parameters in the issue of measurement are random quantities. Some can only be processed as non-random parameters because it is impossible to determine accurately the prior features though they can be regarded as random quantities, and most of the system parameters have random quantities. Additional the prior features of system parameters in the model can eliminate the potential inaccuracy in the model and improve the accuracy of the adjustment results, in fact, this is hard to achieve; therefore, this undoubtedly limits the application scope of the existing model, such as the adjustment model in Reference [1~3]. However, the signal in the semi-parameter model can be random quantities, partial random quantities or non-random quantities, which can be estimated only by the method of parameter estimation, without consideration of the statistical property. Therefore, the author introduced the idea of the semi-parameter model to create a new model, that is, an adjustment model that contains both non-random system parameters and random system parameters, the function model of which is:

$$L = BX + Y + \Delta \tag{1}$$

where $L$ is the observation value, $B$ is coefficient matrix, $X$ is adjustment main parameter vector, $Y$ is a signal, which can be a random quantity, partial random quantity or non-random quantity, $\Delta$ is noise, $\Delta \sim N(0, D_\Delta)$, $D_\Delta = \sigma_0^2 P^{-1}$; as in Reference [3], decomposed as follows: $Y = AS$, $S = \begin{bmatrix} S_1 \\ S_2 \end{bmatrix}$, $S_1$ is a non-random vector additional system parameters, $S_2$ is a random vector additional system parameters, $S_1$ is related to $S_2$ statistics, $Q_{SS} = \begin{pmatrix} Q_{S_1S_1} & Q_{S_1S_2} \\ Q_{S_2S_1} & Q_{S_2S_2} \end{pmatrix}$; $\underset{n\times u}{A} = [A_1 \quad A_2]$, $A_1$ and $A_2$ are the coefficient matrix of $S_1$ and $S_2$, respectively.

Then the formula (1) can be expressed as follows:

$$\underset{n\times 1}{L} = \underset{n\times t}{B}\ \underset{t\times 1}{X} + \underset{n\times u}{A}\ \underset{u\times 1}{S} + \Delta \tag{2}$$

Its corresponding error equation is:

$$V = B\hat{X} + A\hat{S} - L \tag{3}$$

(1) The Estimated Solution of the Semi-parameter Model

We can solve $\underset{n\times u}{A}\ \underset{u\times 1}{S}$ in formula (3) by taking it as a non-parameter component and construct function according to the estimated criterion of penalized least square principle by using the idea of semi-parameter model:

$$\Phi = V^T PV + \alpha \hat{S}^T R\hat{S} + 2K^T (B\hat{X} + A\hat{S} - L - V) \tag{4}$$

Where $R$ is an appropriately given normalized matrix, $\alpha$ is a given smooth factor, and $K$ is Lagrange constant.

Deriving from formula (2), let $\frac{\partial \Phi}{\partial V} = 0, \frac{\partial \Phi}{\partial \hat{S}} = 0, \frac{\partial \Phi}{\partial \hat{X}} = 0$, the following equations are obtained:

$$PV = K \tag{5}$$

$$\alpha R\hat{S} + A^T K = 0 \tag{6}$$

$$B^T K = 0 \tag{7}$$

Uniting formula (3), (5), (6) and (7), the estimated solution of the semi-parameter model is obtained:

$$\begin{cases} \hat{S} = (A^T PA + \alpha R)^{-1} A^T P(L - B\hat{X}) \\ \hat{X} = (B^T P(I - G)B)B^T P(I - G)L \\ G = A(A^T PA + \alpha R)^{-1} A^T P \end{cases} \tag{8}$$

Then the estimated valve of the observation value $L$:

$$\begin{aligned} \hat{L} &= B\hat{X} + A\hat{S} \\ &= B\hat{X} + G(L - B\hat{X}) \\ &= ((I - G)B(B^T P(I - G)B)^{-1} B^T P(I - G) + G)L \\ &\cong U(\alpha)L \end{aligned} \tag{9}$$

Where, $U(\alpha) = (I - G)B(B^T P(I - G)B)^{-1} B^T P(I - G) + G$, $U(\alpha)$ is hat matrix.

The correction value $V$:

$$\begin{aligned} V &= B\hat{X} + A\hat{S} - L \\ &= \hat{L} - L \\ &= (U(\alpha) - I)L \end{aligned} \tag{10}$$

In this way, we can acquire the sole solution of $\hat{X}, \hat{S}$ by selecting appropriate $\alpha, R$ according to the actual condition, and then obtain $\hat{L}, V$ value. When the normalized matrix $R$ is positively defined, we can separate the non-parameter component and parameter component from the observed value to improve the accuracy of the model.

(2) Accuracy Assessment of Semi-parameter Model

Variance matrix of $\hat{X}$:

$$D_{\hat{X}} = G_1 D_{LL} G_1^T = G_1 D_\Delta G_1^T$$
$$G_1 = (B^T P(I-G)B)^{-1} B^T P(I-G) \tag{11}$$

Variance matrix of $\hat{S}$:

$$D_{\hat{S}} = G_2 D_{LL} G_2^T = G_2 D_\Delta G_2^T$$
$$G_2 = (A^T PA + \alpha R)^{-1} A^T P(L - B(B^T P(I-G)B)^{-1} B^T P(I-G)L \tag{12}$$

Variance matrix of $V$:

$$D_V = (U(\alpha)-I)D_{LL}(U(\alpha)-I)^T = (U(\alpha)-I)D_\Delta(U(\alpha)-I)^T \tag{13}$$

Variance matrix of $\hat{\sigma}_0$:

$$\hat{\sigma}_0^2 = \frac{V^T PV}{n - tr(U(\alpha))} \tag{14}$$

Formulas (8) ~ (14) are the adjustment formulas of semi-parameter model additional system parameters.

**Simulation Examples**

Assuming the observation equation is: $\underset{n\times 1}{L} = \underset{n\times t}{B}\ \underset{t\times 1}{X} + \underset{u_1\times 1}{S_1} + \underset{u_2\times 1}{S_2} + \Delta$, in which

$$BX = \begin{pmatrix} 1 & x_1 - \bar{x} & y_1 - \bar{y} \\ 1 & x_2 - \bar{x} & y_2 - \bar{y} \\ \text{L} & \text{L} & \text{L} \\ 1 & x_n - \bar{x} & y_n - \bar{y} \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ a_2 \end{pmatrix} \tag{15}$$

Where $\bar{x}, \bar{y}$ represent the average value of the observation point coordinate, respectively, $\alpha_0$, $\alpha_1$ and $\alpha_2$ are the parameters to be determined in the function, that is, the adjustment main parameter vector $X = \begin{pmatrix} a_0 \\ a_1 \\ a_2 \end{pmatrix}$. $A_1 = A_2 = I$, $P_1^{'}$ and $P_2^{'}$ are non-random system parameters $S_1$, $P_1 \sim P_4$ are random system parameters, the observation value $L$ of the six observation points of $S_2$, $P_1 \sim P_4$, $P_1^{'} \sim P_2^{'}$ and their plane coordinates $x_i, y_i$ are shown in Table 1, and the variance of the observation error (noise) is $D_\Delta = (0.03)^2 I$. Try to calculate the estimated value of $P_1 \sim P_4, P_1^{'} \sim P_2^{'}$.

Table 1: The observation value $L$ of the six observation points $P_1 \sim P_4$, $P_1^{'} \sim P_2^{'}$ and their plane positions.

| Number of the Point | $L[m]$ | $x[m]$ | $y[m]$ |
|---|---|---|---|
| $P_1$ | -0.55 | +6.40 | +4.80 |
| $P_2$ | -0.23 | +4.40 | +4.00 |
| $P_3$ | +0.58 | +1.40 | +1.40 |
| $P_4$ | -1.80 | +6.20 | +1.80 |
| $P_1^{'}$ | | +5.00 | +3.00 |
| $P_2^{'}$ | | +4.60 | +3.00 |

(1) Solution Steps of Semi-parameter Method:

Selection of regular matrix $R$:

$R=(s_{ij})_{n\times n}$, $s_{ij}=\left|t_i-t_j\right|$ is used, where $t$ represents the plane coordinate $(x,y)$, and the distance

$R=\begin{bmatrix}0 & 2.15 & 6.05 & 3.01\\ 2.15 & 0 & 3.97 & 2.84\\ 6.05 & 3.97 & 0 & 4.82\\ 3.01 & 2.84 & 4.82 & 0\end{bmatrix}$ is obtained.

Selection of smooth factor $\alpha$:

By using generalized cross check method $GCV(\alpha)=n^{-1}\sum_{i=1}^{n}(\frac{L_i-\hat{L}_i}{1-n^{-1}tr(U(\alpha))})^2=\min$, $\alpha=0.4$ is found.

Solution of the estimated value:

According to the data given by Table 1, we find from formula (15),

$B=\begin{bmatrix}1 & +1.8 & +1.8\\ 1 & -0.2 & +1.0\\ 1 & -3.2 & -1.6\\ 1 & +1.6 & -1.2\end{bmatrix}$ is found.

From formula (8), we can obtain:

$\hat{X}=(-0.4114,-0.5011,0.3838)^T,\hat{S}_1=(0.0701,0.1346,-0.2923,-0.1219)^T,\hat{S}_2=(-0.1911,-0.2036)^T$

(2) Weighted Adjustment Method of Some Parameters

The idea of solution in Reference [3] is to find the solution by using the weighted adjustment of some parameters, and solve the simulation examples of formula (7) ~ (12) in Reference [3] to obtain the following results (only the calculation results are listed due to space limitation): $\hat{X}=(-0.4109,-0.5013,0.3847)^T,\hat{S}_1=(0.0706,0.1361,-0.2926,-0.1215)^T,\hat{S}_2=(-0.1908,-0.2041)^T$

By comparing the solution results of the two methods, we find that the estimation results of the two methods are very close to each other.

**Semi-parameter Model Extension Additional System Parameters**

Conclusions identical to those in Reference [3] can be drawn by analyzing model (2),

(1) When $S_1=0$, that is, when the model contains only random system parameters, the model becomes a collocation model $\underset{n\times 1}{L}=\underset{n\times t}{B}\underset{t\times 1}{X}+\underset{n\times u_2}{A_2}\underset{u_2\times 1}{S_2}+\Delta$, the solution of which is:

$$\begin{cases}\hat{S}=S_2=(A^TPA+\alpha R)^{-1}A_2P(L-B\hat{X})\\ \hat{X}=(B^TP(I-G)B)B^TP(I-G)L\end{cases}$$

The adjustment principle of collocation model is: $V^TPV+S_2^T\sum_{S_2}^{-1}S_2=\min$. In a semi-parameter model, if the covariance matrix of the signal is known, then a normalized matrix $R=\sum_{S_2}^{-1}$ is selected, at this moment, the adjustment principle of the semi-parameter model is : $V^TPV+\alpha S_2^T\sum_{S_2}^{-1}S_2=\min$, when the smooth factor $\alpha=1$, the semi-parameter model is equivalent to the collocation model, which shows that the semi-parameter model includes the collocation model[6] .

(2) When $S_1 = 0$, $E(S_2) = 0$ and $S_2$ can not be expressed in the function model, the function model becomes: $\underset{n\times 1}{L} = \underset{n\times t}{B}\ \underset{t\times 1}{X} + +\Delta$, and the adjustment principle is $V^T PV = \min$.

(3) When $S_1 \neq 0$, and $S_2$ can not be expressed in the function model, or when $S_2 = 0$, or $A_2 = 0$, the function model becomes: $\underset{n\times 1}{L} = \underset{n\times t}{B}\ \underset{t\times 1}{X} + \underset{n\times u_1}{A_1}\ \underset{u_1\times 1}{S_1} + \Delta$, and the adjustment principle is: $V^T PV + \alpha \hat{S}_1^T R \hat{S}_1 = \min$.

## Conclusions

Semi-parametric estimation of a mixed model additional system parameters is conducted to derive a calculation method of parameter adjustment at the model regularization matrix, and determine the estimation of parameters and non-parameters and the accuracy evaluation formula of the model; the effectiveness of the semi-parametric estimation method is demonstrated through simulation examples; and the semi-parametric model additional system parameters is further extended. It can be explained that the semi-parametric model has the same results in many aspects with the mixed model put forward in reference [3].

# Research on Control Methods of Measuring Super High-rise Buildings

Xuyang Xie

Sichuan College of Architectural Technology, Deyang, Sichuan, 618000,china

10001858@qq.com

**Keywords:** control points, control net, measuring, total station, setting

**Abstract:** This paper took Guangzhou New TV Tower as an example to introduce how to ensure the systematicness and controllability of vertical measurement through the control survey in the process of constructing the high-rise buildings, how to ensure the unity of the each axis system in monomer construction and unity of the whole structure, providing a reference basis for similar projects.

## Project Features

This project is Guangzhou New TV Tower located in the bank of the Pearl River, with a structural height of 610m, and slender tower structures, the structures are prone to shake due to the impact of wind load in the process of construction; The exterior steel frame tube steel column is tilted in three dimensional space, in addition to 3D point positioning, it should still be consider the impact of rotational components; The control requirements of measuring transmission cumulative error is high at the top of the structure and floor structures are irregular, the visibility conditions for measuring are poor.

## Settings of Surveying Control Network

### 2.1 Layout of Plane surveying control network

Combined with the characteristics of the engineering, the three-level control network is set up in the measuring plane control network of the engineering according to the survey grid level and specific application in different parts of this engineering.

#### 2.1.1 First-level GPS Plane Control Network

The first-level control network is set up in the stable and reliable site far away from the construction site, acting as the role of the overall control. The first-level measuring plane control network which is composed of five external locus of control uses the GPS static technology for observation, assisting the high-precision total station for review.

As for the external locus of control, the stable ground or the roof of the building with the age of more than 5 years and height of 50m below is selected for setting observation pillars or stations. Nearby the point location, there is no obstacle above 15° elevation angle, with broad vision; the point location should be far away from the wireless launch station, high-voltage power lines and other interference sources.

As shown in Fig 1, 5 points are laid out in the first-level GPS point. The observation pillar must be built on the control point. The forcible centering device is installed on the top of the pillar, so as to improve the accuracy of plane control, to reduce the error of centration, for the convenience of construction layout. The forcible centering basal disc is laid out on the surface of the pillar, and is connected to the instrument base through a center screw.

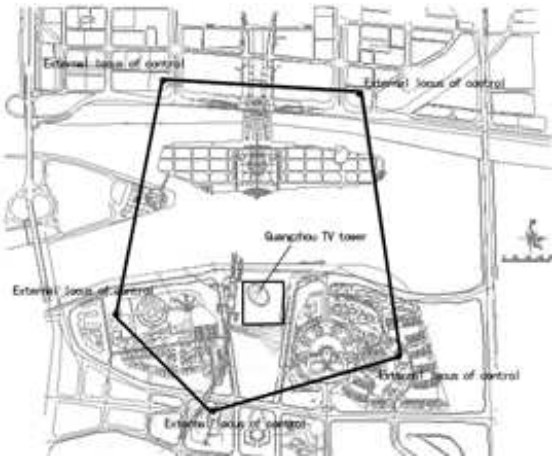

Fig1 Level 1 measuring plane control points arrangement

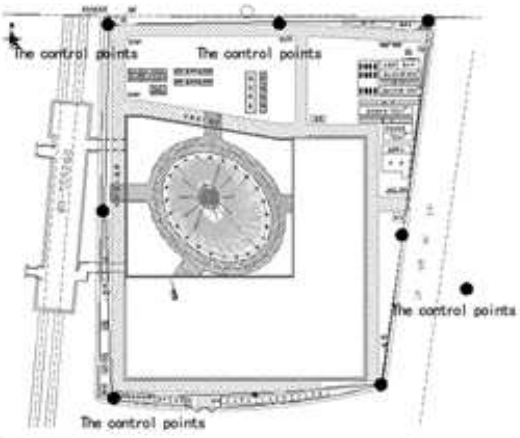

Fig2 Level 2 measuring plane control points arrangement

**2.1.2 Secondary-level Plane Control Network**

The secondary-level control network is used to provide a benchmark for the recovery of the lower-level control network which is likely to be damaged. At the same time, the control point is also directly used in this control network to measure important or critical procedures. Its establishment is based on the first-level control network. The secondary-level control network should be set up around one stable side of the site road of the project, and the convenience of use should be taken in account. The secondary-level network is set as the third-level closed traverse network. The measurement personnel should make an on-the-spot survey before the points are laid out, and data should be rigorously adjusted after field measurement, as shown in Fig.2 Schematic Diagram for Secondary-level Plane Control Network.

**2.1.3 Third-level Control Network**

The third-level control network is laid out on the foundation slab, and is surveyed according to the standard of the first-level square grid. It is primarily used for the measurement of underground structure construction phase, having the nature of short-term use. The use of this control network should be adjusted at any time according to the settlement and deformation in the construction phase. The operating conditions of the engineering are changed greatly, and the third-level control network is laid out within the site and easy to be damaged by the construction. In the process of actual measurement, therefore, besides the real-time adjustment is required in the above cases, the layout position of the network should be adjusted according to the construction situation. The network layout depends on the superior control network. On the ±0.000 floor, the vertical control points of the TV tower and the secondary-level control network are measured simultaneously. As a carrier, the core tube transfers it vertically, with layer-upon-layer closure, As shown in fig 3.

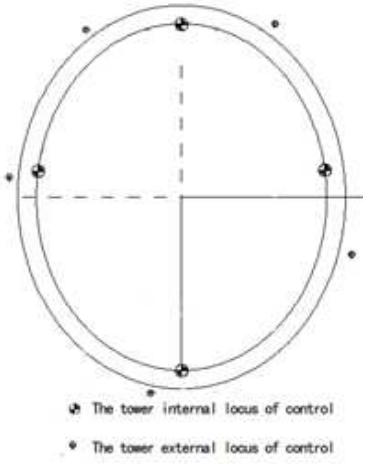

Fig3 Level 3 measuring plane control points arrangement

### 2.2 Layout of Elevation Surveying Control Network

The elevation surveying control network is to provide a stable, unified elevation reference system for long-term construction of the engineering structure. The elevation value is determined by the urban elevation system. In this engineering, the secondary-level elevation control network is set up: the first-level elevation control network is set up in the reliable place outside the construction site. Within the construction site, the secondary-level elevation control network is laid out.

## 3 Construction Measuring Methods

### 3.1 Measuring Methods for Underground Construction Phase

#### 3.1.1 Layout of Plane Control Axis

The down-top construction method is used for basement structure of the TV tower, and the outer control method is used for the plane control. The specific information is as follows:

1) The secondary-level plane control points are used, 2 to 3 temporary transfer stations are set up nearby the foundation pit as a starting point. The temporary transfer stations should be reviewed. If no error, the next step is done;

2) The reviewed temporary transfer stations are used for lofting the construction control axis and for projecting the measurement to the base under-layer.

3) The instrument is moved to Point C on the under-layer for setting a station, and the coordinate method is used for precision review of the interrelationship between control points. Later, the construction control points on the under-layer are used for back vision of each point on the same axis, and a construction chalk line is marked on the under-layer.

#### 3.1.2 Transmission of Elevation Control Points

1) Based on the first-level standard control points, a precise level and the third-class leveling method are adopted, and the elevation is led to the temporary leveling point on the edge of the foundation pit.

2) The elevation for vertical transmission is searched on the edge of the foundation pit. A fixed support is erected, and one end of a steel rule is fixed on the hook of the support, with a heavy hammer for hanging.

3) Two levels are used for the simultaneous measurement up and down. The level above transmits the elevation of the temporary leveling point to the steel rule. The level below transmits the elevation on the steel rule to the construction layer.

### 3.2 Core Tube Control Survey

The core tube of the TV tower is 436.75m in height, and the thickness of its outer wall is changing. The horizontal structure lags behind the construction in the condition of construction. At the same time, controls the vertical deformation of the structure, leading to difficulties in the measurement location.

#### 3.2.1 Measurement of Floor Plane Control Axis

1) A location is calibrated on the internal wall of the core tube (as shown in Fig.3 Internal Locus of Control) to fix the layout of the forced centering platform. The upward projection of integral lifting the steel die is used to fix the layout of the control point receiving platform in place.

2) The total station is set as a station on the monomer control point of the core tube, to measure the center coordinates of the forced platform.

3) The zenith gauge station is set as a station on the force platform, and the plane position of the forced platform center is vertically projected to the control point receiving platform.

4) The above steps are repeated, so that the control points of all forced platform can be vertically projected to the control point receiving platform.

#### 3.2.2 Floor Elevation Control Survey

1) The total station is set as a station on the forced platform, and the sight line of the lens core is adjusted to be vertical.

2) The ranging function is used to lead the ground elevation to the receiving platform.

3) A level is used to transmit the receiving platform elevation to the required position in the construction. It will be put into construction use after reviewed by the supervisor.

### 3.2.3 Floor Control Network Migration

The zenith method used in the measurement of high-rise buildings requires that with the rise of the structure, the benchmark control network on the ±0.000 floor is migrated vertically. The measurement practice of super high-rise buildings, such as Jin Mao Tower and Shimao International Plaza in Shanghai, shows that the building top generates the continuous, slow vertical deformation of the structure in the construction process, and the deformation range increases with the rise of the height. For reasons such as limited instrument resolution capability, the floor control network cannot but be migrated vertically. The migration process will certainly cause the precision losses, thus, the floor control network migration is set up at three times for the engineering. The specific settings are as follows:

1) The total station is set as a station on the monomer control point of the ±0.000 floor, and the control points on the ground are converted to the forced platform, so that each forced platform constitutes the control sub-network of the core tube. The migration mainly refers to the migration of this control network.

2) The layout of the control network migration (conversion) layer is carried out when the core tube is constructed up to 100m, 200m and 300m. Before migration, the control network of the main building should be reviewed to eliminate the displacement of control points caused by structural deformation, etc.

3) The migration of the control network should be carefully operated. After completion of migration, a strict re-survey should be implemented to ensure no error.

## Conclusions

In the construction of this engineering, the role of advanced measuring techniques gives full play in the special-shaped super high-rise buildings construction. In the whole construction process, therefore, the spatial position of the buildings is within a controlled range, to ensure the spatial localization timely, accurate and reasonable, to satisfy the requirements for construction quality and schedule.

**Keywords:** InSAR, MODIS, ASAR, atmospheric correction, surface deformation

**Abstract:** The atmospheric phase delay due to tropospheric water vapor has been one of the major limitations for the application of high precision repeat pass InSAR. In this paper, we present the atmospheric correction methods and key technology for ASAR interferograms with MODIS integrated water vapor data, then, conduct the atmospheric corrections using ASAR interferometric pair over the Taiyuan region as examples. The experimental results show that the MODIS\ASAR atmospheric correction method can greatly improve the quality of interferogram, and the deformation inversion accuracy can be significantly improved, verify the necessity and reliability of MODIS and ASAR data fusion for obtaining information of surface deformation.

## Introduction

Synthetic Aperture Radar Interferometry（InSAR）has been a widely used geodetic technique for measuring the Earth's surface, especially for mapping the Earth's topography and deformations due to its all-weather and day-and-night imaging capability, wide spatial coverage, fine resolution, and high measurement accuracy. However, like other astronomical and space geodetic techniques, InSAR also has its shortcomings. One of the most intractable problems is the effect of the atmosphere, especially the atmospheric water vapor. The radar signal through the atmosphere due to the distribution of temporal changes in the atmosphere, the atmospheric phase delay is unavoidable, thereby affecting the measurement accuracy of the topographic measurement and deformation. Therefore, the effect of atmospheric must be considered when high-precision interferometry.

Massonnet first identified such effects, he first noticed the impact of atmospheric interference fringes in InSAR interferogram in the 1992 Landers earthquake research (Massonnet et al. 1994). Zebker research on SIR-C/X-SAR (Zebker et al. 1997), the results showed that spatial and temporal changes of 20% in the relative humidity of the troposphere could lead up to 10 to 14cm errors in the measured ground deformations and 80 to 290m errors in derived topographic maps for baselines ranging from 100 m to 400m. Since then, some intensive research has been carried out aiming to better understand and mitigate the effects and made a series of achievements. Currently, InSAR atmospheric correction methods can be roughly divided into two categories internationally, the first category is the removal of atmospheric effects based on the data itself features, such as linear correction method (Massonnet et al. 1995), stochastic filtering method (Crosetto et al. 2002), stacking method (Emardson et al. 2003) and timing analysis (Ferretti et al. 2000); the second category based on an external independent data, calculated by modeling the atmospheric effects , such as meteorological information modeling method (Delacourt et al. 1998), numerical weather prediction model method (Foster et al. 2006), GPS measurements (Li et al. 2006) and satellite remote sensing measurements of water vapor (Li et al. 2009,) .The distribution of worldwide vapor can be effectively measured using the existing space-based monitoring systems (such as MODIS, MERIS, FY, etc), so the combined of these satellite remote sensing water vapor data and sparse GPS data is a direction in InSAR atmospheric correction.

The NASA Moderate Resolution Imaging Spectroradiometer(MODIS) is a key instrument on the Terra satellites, and through the descending node equator at around 10:30 am local time, so MODIS images acquired within half an hour of ENVISAT satellites, having a good time consistency. It's

feasible to carry out research on InSAR atmospheric correction methods based on MODIS water vapor data. This paper attempts to correct atmospheric effects in Taiyuan ASAR interferogram using MODIS water vapor data, thereby to evaluate the accuracy and reliability of using MODIS water vapor data to correct InSAR atmospheric effects.

## Integration of ASAR interferometry with MODIS water vapour product

### Overview of the approach

This article will use the MODIS water vapor product MOD05_L2 to correct the atmospheric effects of ASAR interferogram. For the purpose of InSAR atmospheric correction, MODIS precipitable water vapor amount(designated hereafter as MODIS-PWV) needs to be converted into zenith wet delay(ZWD) using the formula (1):

$$ZWD = \left[ 10^{-6} \rho_w \cdot (k' + \frac{k}{T_M}) \cdot R_v \right] \cdot PWV = \Pi \cdot PWV \quad (1)$$

Where $k'$ and $k$ is the refraction constant, $\rho_w$ is the density of liquid water, $T_M$ is the mean temperature of the column containing the water vapour, $R_v$ is a specific atmosphere constant. The conversion factor of $\Pi$ usually varies from 6.0 to 6.5, approximately equal to 6.2.

The spatial resolution and coordinate systems are different between MODIS and ASAR, we need to apply co-registration between ZWD and SAR interferogram firstly. Zenith Path Delay Difference (ZPDDM) can be produced by differencing the ZWD values from two different water vapor fields, and then converted into the phase delay amount in the gaze direction. To achieve the purpose of atmospheric correction, the phase delay amount is subtracted from the calculated difference ASAR. The flow chart of MODIS / ASAR atmospheric correction method is shown in Fig.1.

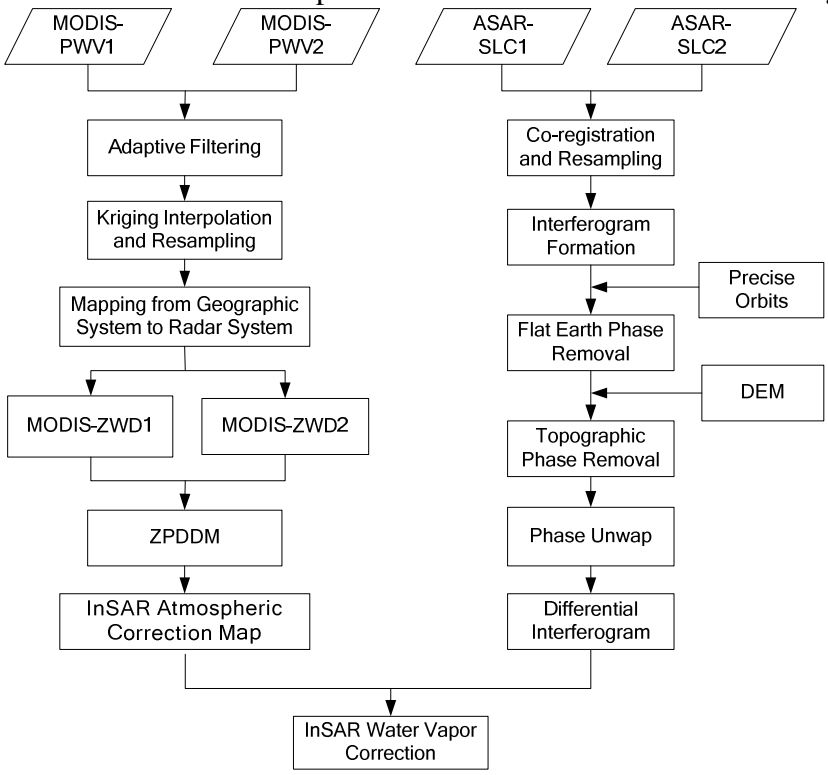

Fig.1 Flowchart of MODIS\ASAR atmospheric correction method

## MODIS water vapor product and process

MODIS water vapor is sensitive to the presence of clouds, when the cloud is present, the calculated value of water vapor is undervalued due to sunlight reflected, so only the water vapor retrievals under cloud-free conditions can be used correct the atmospheric effect, which means the MODIS-PWV

retrieved under cloudy conditions should be corrected first. In order to fill the data vulnerability caused by the presence of cloud, taking into account the large differences between the MODIS water vapor data and ASAR image in resolution, MODIS-PWV need to be interpolated. In this article, we use the Kriging interpolation method.

To properly reduce water vapour effects on interferograms, the step of mapping ZWD from the geographic coordinate system to the radar coordinate system is crucial. Using information from a precise DEM and the satellite orbit, a radar image can be simulated so that its amplitude depends on the local topographic slope and the SAR geometry. As part of this SAR image simulation, a mapping table is generated, mapping each geographic location to the corresponding range-azimuth coordinates. Then the parameters of an affine transformation between the simulated and actual SAR images can be calculated by fitting offsets determined by using a cross-correlation matching algorithm to adjust for any unmodelled geometric parameters. With the simulation mapping table and affine transformation parameters, the ZWD can be mapped from the geographic coordinate system to the SAR coordinate system. This matching method can obtain 1 SAR pixel, 20 m approximately, bearing in mind that the spatial resolution of the ZWD is 1 km, the uncertainty due to matching errors can be neglected.

In order to obtain InSAR atmospheric delay correction phase, ZPDDM need to be converted to phase information, and mapped to the radar line of sight direction(LOS) using the formula (2). The process of InSAR atmospheric correction means removing the calculated atmospheric delay correction phase form ASAR interferometric phase.

$$\Delta\phi_{ifm_atm} = \Delta\phi_{atm1} - \Delta\phi_{atm2} = \frac{4\pi}{\lambda}\frac{ZPDDM}{\cos\theta} \qquad (2)$$

where $\lambda$ is the wavelength of ASAR, and $\theta$ is angle of incidence of radar signal.

## Experimental results

In this paper, ASAR images of July 17, 2005 and August 21, 2005 and the corresponding MODIS water vapor were selected in Taiyuan City. Since the two ASAR image were acquired in 35 days interval, in so short period, there is almost no surface deformation between the two image acquisitions. So the main case of the phase variation may be the tropospheric water vapor. Fig.2 show a comparison between the original interferogram and the interferogram after tropospheric water vapor correction.

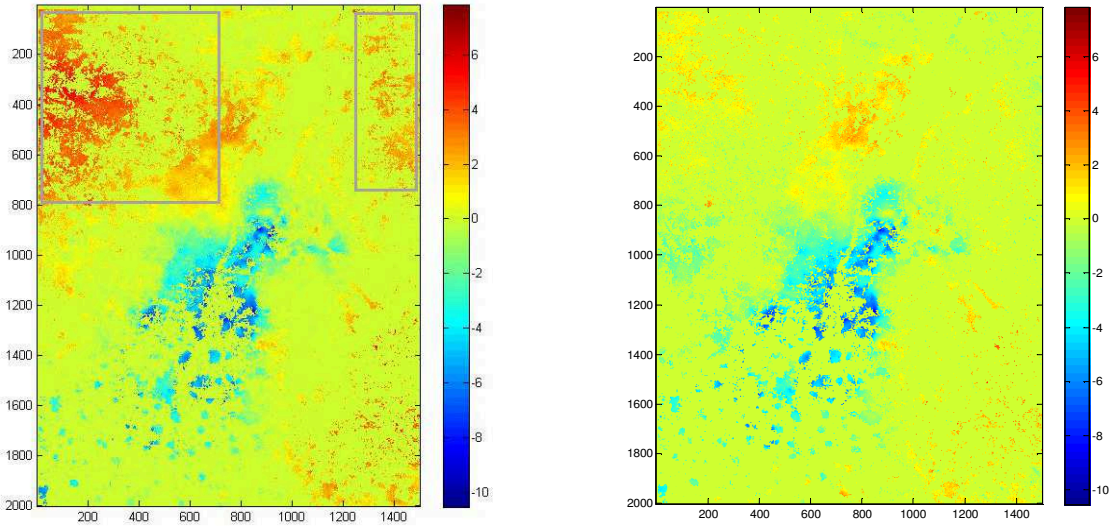

Fig. 2 The interferogram before atmospheric correction (left) and after atmospheric correction (right)

As can be seen from the figure2, the atmospheric effects in original interferogram(block circle) is obvious. After atmospheric correction, the atmospheric effects are significantly reduced. To quantify the effect of correction using a standard deviation of the interference pattern as evaluation criteria, the

standard deviation is 2.88rad before correction, while after correction, the standard deviation reduced to 2.18rad, improving the quality of 24.3% for the interferogram.

Meanwhile, in order to better validate the effect, we made a comparion between the leveling data and InSAR monitoring results before and after atmospheric correction, the result showed that InSAR monitoring results after atmospheric correction were close to the leveling data, and the RMS difference between leveling data and InSAR decreased form 1.40 cm to 1.08 cm, the degree of improvement reached 22.1%, confirming the correction of atmospheric water vapor based on MODIS data validity and reliability.

## Summary

Studying the atmospheric influence on InSAR has become an important field of research. In this paper, MODIS water vapor data was applied to reduce the atmospheric effect on ASAR interferogram. After correction using MODIS water vapor, InSAR deformation measured accuracy has been greatly improved, compared with the same period of leveing data, the RMS differences reduced from 1.40 cm to 1.08 cm, the degree of improvement reached 22.1%. But we should also note that, even after atmospheric correction, InSAR measurements still have a gap comparing with the measured data that may exist many other factors. So in our further study, more operational and accurate technique will be proposed.

**Keywords:** GAT magnetic suspension gyro station, Tunnel, Gyro-orientation, Instrumental constant.

**Abstract.** In this paper, we studied high accuracy azimuth measuring on improving the precision of traverse azimuth from the perspective of transfixion measurement error in a tunnel project. On the basis of a feasible scheme using Gyro Total Station measurement is given. Data processing theory and method are also introduced with a successful tunnel transfixion case. The transfixion results show that the instrument constant measurement precision is 3.7", baseline coordinates azimuth measurement accuracy is 4.8" into tunnel, the final orientation coordinate azimuth value and traverse measurement values differ is 11", to guide the construction of the gyro orientation with survey results achieved tunnel through smoothly.

## Introduction

Since the middle of 20th century, underground engineering survey has been rapid development. It has been widely used in underground military facilities, underground buildings, underground mining, sewers, underground highways, underground railway tunnel and cross-river tunnel[1]. Underground engineering survey played any other technique irreplaceable role, especially in the large tunnel through, underground engineering measurement is correct through a key technology. For a long time, precision traverse have been used in underground engineering of conventional measuring method, with extension of the engineering lead, a variety of error accumulation increases, then will affect the smoothly through underground engineering. Therefore, people often used the method of plus gyro azimuth measuring to determine the correct direction of underground traverse in underground engineering. The method of measuring not only reducing errors on initial direction through but also limits the accumulation of systematic errors. The method also can be on the traverse direction conduct checklist, thereby enhancing and improving the accuracy and reliability of underground traverse[2].

Based on the accuracy of better than ±5" high-precision measuring instruments azimuth orientation-GAT maglev Gyro Station, combined with a passenger line length of 10.8km tunnel directional gyro measurement project, carried out inside the cave, on the outside observer and adjustment, realize the precise localization of underground traverse. In azimuth directional data as an important reference data to guide the construction, the construction of other similar underground engineering measure to carry out has certain reference significance.

## A new type of gyro total station azimuth measurement principle

Unlike traditional gyro theodolite: GAT gyro total station is used for gyro north ontology and total station cooperate together to determine gyro orientation of any survey line. As shown in figure 1: the big circle represents maglev gyroscope horizontal circle, small circle represents the total station horizontal circle, O point is the gyroscope with total station public vertical axis. OT is find north direction of gyro, OM is gyro rotor axis, OL is total station zero horizontal circle direction, OC is total station sighting telescopes line direction of the target.

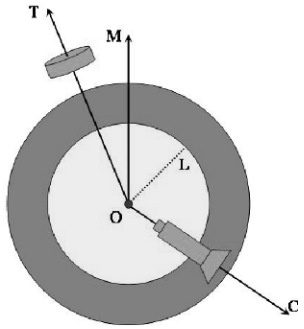

Figure 1 The diagram of GAT gyro total station orientation principle[3, 4]

In azimuth orientation process, the gyro north finder can use at first maglev constitute a pendulum of earth rotation angular velocity gyro sensitive northerly form found north of moment, the moment balance feedback method, the determination of the axis of the gyro angular momentum and astronomical north Angle, and gives the gyro find north direction and the gyro rotor axis Angle (mirror surface normal direction) $\angle TOM$ .

Then, the observer uses the total station observer sighting target direction, according to the direction of the measurement requirements, measure the angle $\angle LOC$ between the goal line and the total station horizontal direction dial zero bits. Thus,

$$\angle TOM + \angle MOL + \angle LOC + \Delta_I = A = \alpha + \gamma \tag{1}$$

In the formula (1), $\Delta_I$ means the instrument constant, $\alpha$ means a known coordinate azimuth survey line, $\gamma$ means convergence of meridian. This can be done by measuring direction of a known survey line and real meridian line direction $\alpha + \gamma$ comparison, to determine

$$\angle MOL + \Delta_I = \alpha + \gamma - \angle TOM - \angle LOC \tag{2}$$

As $\angle MOL + \Delta_I$ be written to $\Delta_I'$. The above measurement process in tunnel hole known online, main purpose is to obtain the instrument constant value. When the hole measurement, also need to measure the gyro find north direction of gyro motor shaft angle $\angle TOM'$; and hole closed line direction and the direction of the total station horizontal dial zero angle $\angle LOC'$ , this hole closed line of gyro directional results can be calculated according to the formula:

$$\alpha' = \angle TOM' + \angle LOC' + \Delta_I' - \gamma \tag{3}$$

## The new gyro total station measurement data processing

The orientation precision of gyro theodolite mainly gyroscopic azimuth error $m_T$ and a directional error $m_\alpha$ in measurement [5]. After the completion of all part of the surveyed area measurement work, first calculated instrument constants $K$ and the accuracy of measurement data according to the hole measurement data. Instrument constants calculated for each observation in the unit to calculate.

Measurements before and after the measurement outside the tunnel measuring the same number of rounds, the rounds are $n$. Let baseline $AB$ measurements outside the tunnel, and known coordinates azimuth is $\alpha_{AB}$ , point $A$ meridian convergence angle is $\gamma_A$ , and each observation angle measurements and gyroscopic measurements respectively are $L_i$ and $T_i$ (i = 1,2, ..., 2 $n$), then

$$K_i = \alpha_{AB} - (L_i + T_i + \gamma_A) \quad (i = 1, 2, \cdots, 2n) \tag{4}$$

Instrument constant $K$ is obtained by calculating the average formula (4). Instrument constant $K$ measuring precision of the calculation method and the azimuth angle and the gyroscope, same as follows

$$\sigma_K = \pm\sqrt{\frac{\sum V_i V_i}{2n-1}} \tag{5}$$

Among them $V_i = K_i - K$ （$i = 1, 2, \cdots, 2n$）。

Instrument constant measurement accuracy checklist meet the conditions, then start all measured baseline coordinates azimuth calculation, calculation formula is as follows:

$$\alpha_i = K + \overline{L_i} + \overline{T_i} + \gamma_i \tag{6}$$

According to the law of error propagation, the coordinate azimuth angle measurement accuracy using the following formula

$$\sigma_{\alpha i} = \pm\sqrt{\sigma_K^2 + \sigma_{\overline{Li}}^2 + \sigma_{\overline{Ti}}^2} \tag{7}$$

Meridian convergence angle according to the meridian convergence angle in geodetic calculation method to calculate, calculated by the geodetic coordinate $(L, B)$ plane meridian convergence angle $\gamma$ formula is:

$$\gamma = \sin B \cdot l + \frac{1}{3}\sin B\cos^2 B \cdot l^3(1 + 3\eta^2 + 2\eta^4) + \frac{1}{15}\sin B\cos^4 B \cdot l^5(2 - t^2) + o(l^5) \tag{8}$$

In Formula (8)： $t = \tan B, \eta = e' \cdot \cos^2 B$ ($e'$ is the second eccentricity)， $B$ is latitude， $l$ is longitude difference。

According to the formula (7), we can also estimate the azimuth angle of each side of the baseline coordinates precision. Assuming total station horizontal angle measured precision is ±2", and precision of gyroscope azimuth measurement is ±5 " in one observation set, all station total station and gyroscope observation three observation set. The constant measurement accuracy of instrument

$$\sigma_K = \pm\sqrt{\frac{5^2 + 2^2}{6}} = \pm 2.2'' \tag{9}$$

Inside the tunnel baseline coordinates azimuth angle measurement accuracy

$$\sigma_{\alpha i} = \pm\sqrt{2.2^2 + \frac{(2^2 + 5^2)}{3}} = \pm 3.8'' \tag{10}$$

## Analysis of azimuth directional and results in underground space

Selection of ground control network Y1→JQ1 two control points make the line of constant instrument calibration, due to limited space, the original observation data is not on this list. According to ground control point coordinate, calculation of line Y1→JQ1 coordinates azimuth and meridian convergence angle measurement site. Can be obtained from the formula $A = \alpha + \gamma$ a ground survey line Y1→JQ1 the true north azimuth

$$A_{Y1 \to JQ1} = 265^\circ 31' 02'' - 0^\circ 03' 47'' = 265^\circ 27' 15''$$

According to $A = T + \Delta$ combination with the ground of the gyro orientation, can be calculated gyro instrument constants, as shown in table 1.

Table 1 Constant of instrument calibration results

| Survey line | Gyro azimuth | True north azimuth | Instrumental constant | V | VV |
|---|---|---|---|---|---|
| Y1→JQ1 | 265°27′22″ | 265°27′15″ | -7″ | -4″ | 16″ |
| | 265°27′19″ | | -4″ | -1″ | 1″ |
| | 265°27′18″ | | -3″ | 0″ | 0″ |
| | 265°27′23″ | | -8″ | -5″ | 25″ |
| | | Average value | -5″ | ∑ | 42″ |
| Error in a measurement instrument constant: $m_\Delta = \pm\sqrt{\frac{[VV]}{n-1}} = \pm\sqrt{\frac{42}{4-1}} = \pm 3.7''$ | | Instrument constant or the most value of error: $M = \frac{m_\Delta}{\sqrt{n}} = \pm 1.8''$ | | | |

Inside traverse side azimuth measurement method and outside constant calibration is same in tunnel, limited space, underground traverse side direction measurement observation data is not in the list. The above calculated instrument constants, cooperate with directional gyro orientation, on the edge of the results, can get underground geographical azimuth, as shown in table 2.

Table 2 The traverse of tunnel hole azimuth measurement results

| Survey line | Gyro calculate azimuth | True north azimuth |
|---|---|---|
| Y11→Y10 | 276°26′55″ | 276°26′51″ |
| Y11→SY14 | 97°33′55″ | 97°33′51″ |
| Y11→Y13 | 96°53′38″ | 96°53′34″ |

According to the traverse point coordinate calculation every directional edge of coordinate azimuth and meridian convergence angle measurement site, as shown in table 3.

Table3 Coordinate azimuth Angle of directional edge

| Instrument station | Convergence of meridians | Sighting point | Gyro calculate azimuth |
|---|---|---|---|
| Y11 | -0°02′54 | Y10 | 276°29′45″ |
| | | SY14 | 97°36′45″ |
| | | Y13 | 96°56′28″ |

## Conclusions

Through the tunnel of underground space azimuth directional can draw the following conclusion:

1) High precision gyro orientation to get the coordinates of the azimuth Angle, compared with the original wire calculate the coordinates of the azimuth is as shown in table 4.

Table 4 Gyro orientation compared with traverse calculated results

| Instrument station | Sighting point | Gyro calculate azimuth | Traverse coordinates azimuth | Difference value |
|---|---|---|---|---|
| Y11 | Y10 | 276°29′45″ | 276°29′37″ | 8″ |
| | SY14 | 97°36′45″ | 97°36′36″ | 9″ |
| | Y13 | 96°56′28″ | 96°56′17″ | 11″ |

2) From the four rounds of the ground constant edge directional gyro measurements assessed in one observation set measurement error is 3.7 ", inside of tunnel the baseline measurement coordinate azimuth measurement accuracy of 4.8", which belongs to high-precision measurement results.

3) For Y11→Y10, Y11→SY14, Y11→Y13 traverse side, it is recommended to make appropriate reference to the outcome of the gyro directional orientation correction.

**Keywords:** Terrestrial 3D laser scanning; earthwork; fine calculation;GPS RTK

**Abstract:** Supported by terrestrial 3D laser scanning technology, by using the GPS RTK technology as the verification. Explored the application of terrestrial 3D laser scanning technology in the calculation of fine earthwork, including the whole process from program design, pre-organization, field measurements applied to the calculation and submit of indoor operation results. In addition, Lanhaiwan project in xi'an of shannxi province was taken as a case to introduce detailed processes of fine earthwork calculation, The results show that the terrestrial 3D laser scanning technology can be well used for accurate measurement of the earthwork.

## Introduction

With the accelerating pace of urbanization, urban construction has become the core of the whole process of urbanization. Earthwork engineering involved in city construction projects, the size of earthwork not only related to the budget of earthwork excavation engineering, but also will affect the investment budget of the whole project. So, accurate calculation if earthwork has important economic significance and practical value on earthwork and the whole investment project.

Traditional earthwork field survey methods most are level measuring method, total station method or GPS RTK method. And traditional methods are measured by selecting feature points of different height, do measure and record to finish the field measurement. inner calculation usually by related software measured the coordinates of discrete points outside the industry as the foundation, in order to achieve the purpose of calculating the amount of earthwork through the establishment of related earthwork calculation model, usually depending on the actual situation and the multi-use method such as one or several sections , grid method , contour method, the average elevation method, region or irregular earthwork balance method of triangulation method .Since the study area to obtain the original data are characterized by discrete point -based , so the final calculation of earthwork accuracy often depends on obtaining accuracy and density characteristics of the study area the original area of the point of the point .Typically , the stacking surface of earth in the study area shape complexity, and actual measurement characteristics of the limited number of discrete points , resulting in the elevation part can not obtain or omitted to save costs and little change in the characteristics of human point, thus resulting in linear interpolation calculation model based earthwork a difference between the results obtained with the actual earthwork .In general, the larger the absolute amount of earthwork difference between the two is greater.Thus, if more accurate access to earthwork within the study area to provide accurate calculation of earthwork has become a key issue under urbanization earthwork calculations are to be solved.

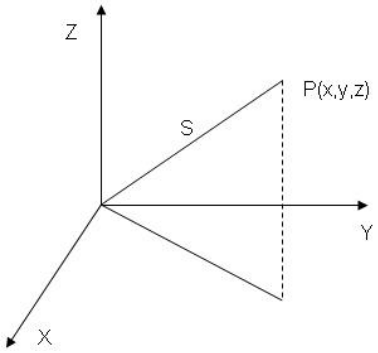
The emergence of terrestrial 3D laser scanning technology to solve these problems has opened up a new way .3D laser scanning technology known as " Virtual replication technology (High definition Survey, HDS)", is one of today's most advanced measurement techniques .This article aims to 3D laser scanning technology as the basis to build massive point cloud data with high accuracy DEM model for the earthwork calculations, supported by means of GPS RTK to verify explore three-dimensional laser scanning technology in earthwork refined calculation of processes, including program design , pre organizations outside the industry Surveying and achievements within the industry consolidation and other related processes , and be verified by actual cases , with

a view to terrestrial 3D laser scanning technology provides a standard reference in the application process paradigm fine calculation of earthwork.

## 3D laser measuring principle and earthwork calculation mode

### 2.1 3D laser measuring principle

The main structure of the 3D laser scanner include: a high-speed precision laser ranging system, a set of guiding the laser reflection and reflector uniform angular velocity scan azimuth deflection controller, the elevation angle of deflection controller, data output processor , part of the instrument also has a built-in digital camera.The basic process is a three-dimensional laser scanner transmits a laser pulse transmitter signal , after the diffuse reflection surface , almost the same along the reverse path back to the receiver , the target can be calculated from the point P to the scanner S, control encoder Simultaneous measurement of each laser pulse observations horizontal scan angle α and vertical scanning angle observations β.Usually the laser scanning instrument defined coordinate system , X -axis in the transverse scan plane , Y -axis in the transverse direction perpendicular to the scanning plane and the X -axis , Z -axis perpendicular to the transverse scan plane and together form a right-handed coordinate system is shown in Figure 1.The coordinates of point P (X, Y, Z) is shown in Figure 2.



$$\begin{cases} X = S\cos\theta\sin\alpha \\ Y = S\cos\theta\cos\alpha \\ Z = S\sin\theta \end{cases}$$

Figure.1. Positioning principle terrestrial laser scanning system Figure.2. The coordinates of any point is calculated

### 2.2 earthwork calculation model

More model earthwork calculations, including section method, grid method , contour method, the average elevation law , regional earthwork balance method and irregular triangulation method. The different methods have advantages and disadvantages and accuracy of different, which many scholars have done research.High resolution mass point cloud data based on 3D laser scanning to obtain the base, moving fitting based on the point by point interpolation, the idea of constructing triangulated irregular network (Triangular Irregular Network, referred to as TIN) model, considering the spatial resolution of DEM is the exact characterization of the study area of surface morphology.Terrain processing module based on ArcGIS, precise calculation and precision evaluation of regional earthwork using high resolution DEM model.

## Application example analysis

### 3.1 The general situation of research area

Study area for a housing construction site in Xi'an city of shaanxi province named Lanhaiwan project, an area of about 6000m$^2$, undulating terrain with slopes, pits and bulldozers and so on.According to owner required within the project area needs to provide accurate earthwork size, in order to provide accurate data for the later earthwork project implementation .Based on this, we use the Leica C10 laser scanner to obtain a three-dimensional precision earthwork project area data. Meanwhile, we used the GPS RTK technology to verify the results.

**3.2 Field reconnaissance**

With terrestrial 3D laser scanner refined estimates of the amount of earthwork .First, according to the actual site conditions, production planning scanned sketches should include: outside the industry operators, scan area and time, station location, the target location.Secondly, in order to avoid duplication of convenient scanning and post- stitching, etc., need science station and two stops to ensure that the target of sigh.Finally set the target position specification, requiring a solid target, while furnishings, in addition to checking not collinear, the target the best set in the two largest public space station at a distance to ensure the accuracy of different splice sites of point cloud data .

**3.3 Establish control network**

Since the scanner is based on data obtained for the center instrument station coordinates heart, in order to make known control point scan data with the Party providing geo-spatial coordinates coincide, it is necessary to establish Surveying Control Network .Surveying method of establishing control network can draw wire control measure ideas.After completion of the control point layout , with 2 " Leica Total Station to get the geographical coordinates of the control point , the project according to the situation of setting three control points , the control point coordinates to obtain the results shown in Table 1 .

**3.4 Surveying course**

The 3D laser scanner mounted on the 1st test site was on the leveling , will be set up in the special target of known control points near the rear-view A as directed .When the directional precision engineering to meet the needs of targeted directly applied to the results of this scanning process.Next, set the resolution and point intervals were scanned , and the exposure setting texture database collected to obtain the target image and the image of the scanning area .The scanning resolution is set to 5cm × 5cm, set to start after the completion of the scanning station , when the scan is complete start scanning the target ( target position coordinates can get by Leica total station measurements Prism ) , scanning is best to follow the target from far and near , or order from near and far at the same time , be sure that the same target at different scanning stations winning consistency of the target number.Otherwise it will cause splicing errors. After scanning every one station can be checked by looking at the function of the station directly scan data results are in line with the accuracy requirements, if it satisfies the requirements, re- moving station .Outside the industry scan task until completed.

At the same time, by using the GPS RTK technology acquisition 0.5m every finite point coordinates of the study area, data collection is completed, the acquired data into CASS9.0, TIN models constructed on the basis of draw contour map survey area, and contour lines based earthwork calculations.

**3.5 Point cloud data processing**

Due to the interference of external factors in the process of field Surveying, the measured point cloud data so that unnecessary noise data, the noise data will reduce the presence of the calculation accuracy of the model .Therefore , the data must be made to eliminate the noise .Common methods include removing the computer automatically removed and set the threshold manually delete two kinds. This project uses manually delete the actual situation the way noise is removed , and can easily achieve the purpose of removing noise , thus ensuring the accuracy of the point cloud data .

Based on this, the use of known control points and the target coordinate point cloud data based on known data splicing control points and check the accuracy of stitching , stitching the project results shown in Figure 3.As can be seen from the stitching error , the maximum error is spliced 0.002m, the smallest error is 0m, thus indicating the measured data processing industry outside the industry to meet the accuracy requirements .After freezing and other operating data , and exported in text format.

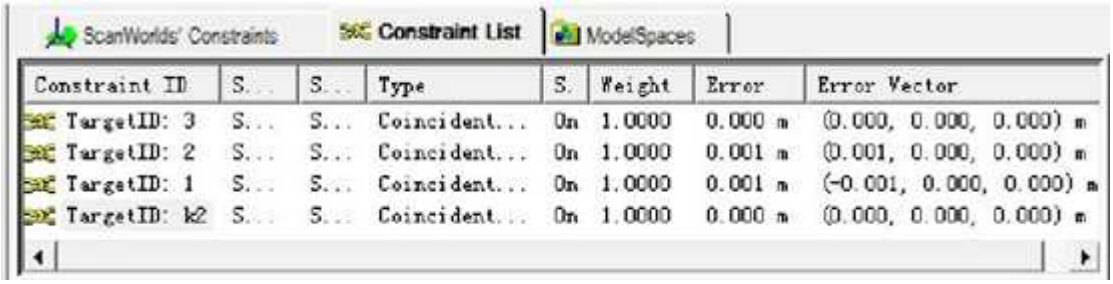


Figure.3. Data based Cyclone splicing error table

### 3.6 Earthwork calculations

The splicing point cloud data. Based on data parsing. Exported to text format. TIN generation model was made in ArcGIS. Open the TIN model in the ArcGIS environment. Analysis of the volume and area of TIN model by the using the 3D surface model. Set the reference elevation of 390.685 meters for the calculation results and output as the text format. The calculation results of the earthwork is the total area is 3224.2m$^2$,the surface soil excavation volume is 9863.6m$^3$,the surface soil fill volume is 12.1m$^3$.

### Result analysis

In this project, the measured point sampling interval is 5cm, and after extracting 20 cm, using the TIN fitting surface three-dimensional model. It can be considered that the model can fully reflect the true sate of surface relief.Therefore,the surface of earthwork calculation based on 3D model can be ignored. At the same time, in order to compare the conventional the GPS technology using by dynamic RTK model to measure the precision of earthwork, outside using zhonghaida V30 GPS RTK method is used to obtain the physiognomy of surveying and mapping. The cumulative gain 1380 detain point data, using CASS 9.0 software calculation function of earthwork, the abnormal point elimination, boundary definition and reference level determination (H=390.685m) and other work, using the same 20cm interval to calculate earthwork grid method based on the calculation results, the total area is 3224.2m$^2$, the surface soil excavation volume is 9880.3m$^3$, the surface soil fill volume is 12.3m$^3$.

Comparative analysis shows that, the latter than the former on the excavation volume more than 16.7m$^3$, fill volume compared with the former more than 0,2m$^3$. Analysis of the causes is that the original morphology fragmentation, 3D laser scanner to complete records this broken form of the landscape, the traditional single point mapping method cannot complete record of the landscape of ups and downs, and only through the measured feature point and feature point encryption method is detailed as the original form of the landscape. Therefore, the traditional single point of surveying and mapping is unable to complete the original form of expression of landforms, the calculation results can only be based on what the measured points and infinite close to the real value, are often short of real value. 3D laser scanning technology, however, it overcomes the defects of this technology, therefore, the used of 3D laser scanning technology to measure the surface condition quantify can reach the point of zero error.

### Conclusions

In this paper, the ground three-dimensional laser scanner LeicaC10 instrument as an example, this paper discusses the three dimensional positioning principle and conditions of pure calculation principle, and mainly discusses the 3D laser scanner is applied to the measuring technology of conditions process and data processing method in the industry, with GPS RTK technique is complementary, compared the results. Analysis found that: (1) through 3D laser scanner to get point cloud data calculated conditions can meet the conditions of high precision calculating the requirements of the project; (2) the traditional single point also has higher measurement precision of surveying and mapping, to meet the demand of the general project, at the same time, in order to

improve the observation accuracy, homework can through the feature points in the process of encryption to improve the calculation precision of the results.

**Keywords:** laser radar technology; point cloud data; steel; deformation monitoring; quality control

**Abstract.** The traditional steel structure deformation monitoring generally uses Total Station and GPS to do monitoring quality control, but there are some disadvantages of these methods. Laser radar technology is a new non-contact measurement technology emerged in recent years. It is ideal for installation and slip construction quality monitoring of large-span steel structure. This paper use laser radar technology to monitor large-span steel structure construction, use laser scanner to scan on steel every period of time and collect 3D point cloud data of the feature points after a period of time. Through the comparative analysis of the data and the chart which reflect the amount of deformation of the feature points, it can accurately obtain the result of structural deformation, oblique direction, and the deviation between the actual coordinates and the design coordinates, which provides the most accurate and direct information for the project. Laser radar technology solves the difficult issues such as workload outside the industry and difficulties in visibility of the traditional measurement methods, greatly improves accuracy and efficiency compared to traditional methods, and achieve a high-precision quality control over the construction.

## Introduction

Over the past decade, with the development of China's economic and continuous progress of science and technology, different patterns of large span steel structure has developed rapidly, which has increasing span and scale and more complex structure in the form, and is widely used in sports stadiums, convention centers, theaters, airport stations and other buildings[1,2]. Because of the main truss span, high precision requirements of fabrication and installation and the distortion produced during the construction process, whether the size of the deformation is reasonable will directly affect the project progress and quality of the construction. So it becomes particularly important to do the high-precision quality monitoring over the whole steel structures [3,4].

Traditional means of steel works deformation monitoring are generally based on a single point acquisition method of three-dimensional coordinates. In recent years, a new type of laser radar technology comes to be widely used. It is very suitable for large-span steel structure construction deformation monitoring [5,6].

This paper uses laser radar technology to monitor large-span steel structure construction process and use three-dimensional model of point cloud data model to get a true visual reproduction of the steel structure. Thus we can accurately get the deformation, oblique direction, as well as the deviation between actual coordinates and design coordinates of the structure observed through the measurement and analysis of the main structure of the model. It provides the most accurate and direct information for the project in progress or to be undertaken to solve such issues like workload

outside, visual difficulties in traditional measurement, and it improves the accuracy and efficiency of the traditional methods and achieve high-precision quality control over the construction process.

**Data Collection**

1) Station. Considering the scanning of opera may be covered in the space, we should change the working position of the instrument to resolve the problem, the so-called "shifting station." we set a total of four sites to get the full data of opera building.

2) Setting common point. We use the reference ball as a common point, altogether five reference balls. Considering that there should be the height difference between the reference balls, we set two reference balls on the ground of the opera house, three reference balls on the second floor.

3) Scanning. After scanning each station we must turn off the scanner, unplug the power cord, and then continue the next stop scanning. We totally collect 4 stops' data from scanning the Opera House on the first phase. After sometime, we complete the second phase of data collection of 4 stops placing the scanner on the first set of base stations.

**Processing point cloud data with Faro software**

**Mass stitch the point data.** We get the scan data every time the 3D laser scanner work, and the data is called a site. Because of the limit of the 3D laser scanning principle, we only get the part of the data when we scan the building. Thus we have to splice the data and make them unified in coordinate system we need if we want a complete building surface point cloud data. The specific approach is as follows.

1) Import the point cloud data into the SCENE software, splice two stations by two stations, and find the reference ball (common point) in the plan view of a station and number the reference ball. For convenience, from number 01, click OK to finish one. Follow the same procedure to the other reference balls with 02, 03……in sequence.

2) As one station is finished, do the same in the next station. Find the same ball and compile the same number. Note: The same ball in each station must be compiled with the same number.

3) After the completion of numbering the reference balls in other stations, select "arrangement" in the workspace to complete the mosaic. Load the rest of the stations in sequence, and complete stitching point cloud data of Opera House .The results is shown in Fig.1:

Fig.1 Original 3D point cloud view

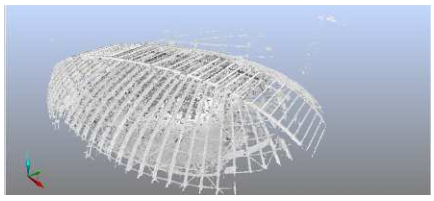

Fig.2 3Dpoint cloud view after denoising

**Denoise the point cloud.** Open 3D view of point cloud data stitched, as indicated in fig.1, we can see many noise points in area of Opera House, which requires denoising. Use polygon selector on the toolbar to select the above noise points and remove them. The effect is shown in Fig.2.

**Export point cloud.** Export point cloud after the above process, and then model and post-process by Cyclone, CAD, 3Dmax. The point cloud data can be changed into XYZ format in the analysis of the data in order to calculate and draw the table.

**Generate 3D model of point cloud data.** There are many ways to reconstruct a 3D model after exporting the point cloud data. The point cloud data derived can be imported into CAD to draw the front view, the left view, the top view, and then put it into 3Dmax to make reconstruction. Here we

use Cyclone software to build the model. Do one scanning of the Opera House and another after sometime. Cut two phases' data of the same part of the Opera House in Faro SCENE software and export it to do 3D modeling analysis.

1) Import coordinates data. Export the required parts of the study point cloud data after finished stitching, and open the Cyclone software to import data coordinates.

2) Fit the model. 3D modeling is to convert the point cloud data to CAD objects. The modeling process in the Cyclone software is using point cloud to do precise calculation and coordinate process. We can choose a clear point cloud to model, for example: select a pipe or point clouds of a sphere surface, then run the command in Cyclone software, and you can automatically fit pipe or a sphere, generate CAD format, and then complete the other operations.

We can find object ball, as well as pipelines in modeling in the third leg of the point cloud.

3) Import to CAD. Draw the building fitted in the CAD and export when finished.

4) Import to 3Dmax to complete modeling. Import the files exported from CAD into 3Dmax to realize 3D modeling of steel structures, as shown inFig.3, Fig.4:

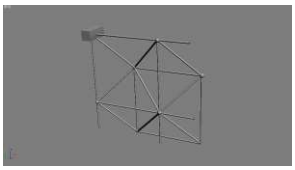

Fig.3 Steel's scan 3D model in first phase

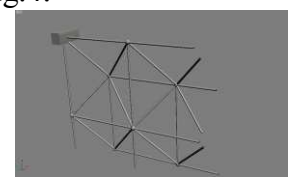

Fig.4 Steel's scan 3D model in second phase

We can see the deformation by two-phase's 3D model, and acquire more intuitive deformation monitoring conditions of the building by comparing the analysis of the two phases' data.

**Analysis of monitoring Data**

1) Select feature points. Before scanning, choose a fixed point in order to compare the characteristics of each of the analysis. The most obvious point in steel is welded ball, so we have a six-point mark on the ball, which can directly reflect changes in the steel structure by comparison.

After making the marks, scan the feature points on the ball in two phases, then do some relevant treatment in Faro software and export the data. In summary, we study monitoring deformation of the steel mainly by analyzing such feature points' data comparatively.

2) Export feature point coordinates. Select 'Export' and 'Export with XYZ format'. So you can see the 3D coordinates of the feature points.

3) Analyze the deformation. The test selects 6 feature points, (X, Y, Z) is the coordinate of the first scan, (X ', Y', Z ') is the coordinate of the second scan. The results are shown in Table 1 and Table 2.

Table 1 X, Y, Z coordinates of six feature points

| coordinate / point number | X | Y | Z | X ' | Y ' | Z ' |
|---|---|---|---|---|---|---|
| 1 | 3.306676 | 22.492647 | 4.077191 | 3.306464 | 22.502067 | 4.065279 |
| 2 | 3.308649 | 22.489273 | 4.068587 | 3.308591 | 22.504867 | 4.074805 |
| 3 | 3.31099 | 22.498175 | 4.086661 | 3.310351 | 22.504558 | 4.071875 |
| 4 | 3.311052 | 22.43841 | 4.071934 | 3.310427 | 22.457629 | 4.080919 |
| 5 | 3.312407 | 22.497925 | 4.089451 | 3.312939 | 22.5041 | 4.095687 |
| 6 | 3.336145 | 22.47812 | 4.123097 | 3.335982 | 22.490137 | 4.138946 |

Table 2 The overall oblique measurement value of feature points

| Point number | Length（mm） | North-South bias（mm） | East-west Bias（mm） | △Z(mm) |
|---|---|---|---|---|
| A-A' | 9.422 | North Bias 9.420 | West Bias 0.212 | -11.912 |
| B-B' | 15.594 | North Bias15.594 | East Bias 0.261 | -6.218 |
| C-C' | 6.415 | North Bias 6.383 | East Bias 0.639 | -14.786 |
| D-D' | 19.229 | North Bias 19.219 | West Bias 0.625 | 8.985 |
| E-E' | 6.198 | North Bias 6.175 | East Bias 0.532 | 6.236 |
| F-F' | 12.018 | North Bias 12.017 | West Bias 0.163 | 15.849 |

By the Table, we can know that: plane displacement, angle offset, and space offset of each point meet the accuracy requirements in the acceptable range in the construction deformation, which also confirms that the application of 3D laser scanning technology in large-span steel structure deformation monitoring is feasible.

## Conclusions

In this paper, laser radar technology is applied to do deformation monitoring of a steel structure. Firstly, we make two scans of the opera (a certain period interval between two scan of before and after). Secondly, model in 3Dmax and extract feature point data in 3D model. Finally, we acquire the amount of deformation through the analysis of comparison with two phases' data. Compared with the construction standards, each offset of steel is within the deformation range of the steel construction requirements.

Practice has proved that using laser radar for steel structure deformation monitoring is feasible and simple, has high precision and fast speed, and greatly reduces the workload of measurements outside the industry. The data observed is more comprehensive, the contrast of 3D model created is very objective, and the analysis of the data by chart is more convincing, which are useful for the Opera steel slip deformation monitoring.

# Discussion on the application of GPS technology in bridge construction plane control net and in survey of bridge axis lofting

Siyi Jiang

Guangxi Polytechnic of Construction, Nanning, Guangxi, China, 530003
1633496530@qq.com

**Key words**: GPS technology; Construction control net; Length of side conversion; Bridge axis lofting

**Abstract**.The article introduces that the GPS technology in the bridge construction survey turns the bridge axis lofting spots and the construction control net into the overall net after completing the plane control net, to centrally gathering information and simultaneously adjustment processing, so as to satisfy the high accuracy request of the bridge axis lofting.

## Introduction

GPS technology are widely applied to various measurement work,because of its high speed,high precision,all-weather,cost saving,a high degree of automation,and not the terrain constraints,etc [1].And with its continuous advancement and improvement, some of the traditional measurements are gradually being replaced by it.

Traditional goniometric net,triangulateration net and trilateration net,demand a good visibility between adjacent control points for the measurement of edge and angle,which bring about a difficulty to the actual setpoint work.So this can demonstrate GPS's superiority.Construction control net call for a high precision to the interior of various control points and a high requirement to the relative accuracy between points.And the interior of GPS observation data meet high precision which is unmatched by conventional measurement methods.Therefore,the use of GPS for surveying control network has very important significance.

Because the processed GPS,s observed data is the corrected results of Gauss projection,for improving the internal precision of control network and facilitating construction use,measurement process and data processing should adopt appropriate technical measures,combined with the characteristics of construction control net and the specific requirements ,to reach the construction control Network requirements.This paper take the GPS construction plane control net and bridge spool thread lofting project about Nanning Huluding Bridge as an example.After the completion of plane control net and bridge axis stakeout work, the bridge axis stakeout points and the control points,in order to satisfy the requirement of the bridge axis lofting precision, have been linked together into a overall net to centrally gathering information and simultaneously adjustment processing.It fully embodies the advantages of GPS technology.

## Technology design

**Overview of the surveyed area.**The GPS measurements is to provide measurement control point for Huluding bridge construction.Huluding Bridge is the main part of nan-ning rapid ring road, baisha road west, east and Zhuxi Avenue extension line, across the Yongjiang river.

The original G1, G2 etc four-level GPS control point is in good condition.So according to the principle in standard that the GPS net can set the overall net in same level [2],a plane control network can be established based on the above starting two points.The new net lay out four four-level GPS plane control points which distribute on the both sides of Yongjiang river and there is a good visibility between the above points.

**Coordinate system design**.The GPS net that used Beijing coordinate system in 1954 lay ou t by four-level net.It don,t be modified by Gauss projection,but in order to in line with the construction projection plane,observation length should projected to the elevation surface he ight of 81.5 m. The datum plane adopt Yellow Sea elevation height datum.

**Layout idea and flow chart.**Adopting four Southern Lingrui S60 static GPS receiver (5mm+1ppm) and it contains a baseline solution and net adjustment software which is used for calculating construction control network.

Then conducting bridge spool thread lofting measurement by the construction control points and linking the bridge axis stakeout points and the control points together into a overall net.Finally using GPS in centrally gathering information and simultaneously adjustment processing, so as to meet the high accuracy request of the bridge spool thread lofting.Layout flow chart as shown in fig.1.

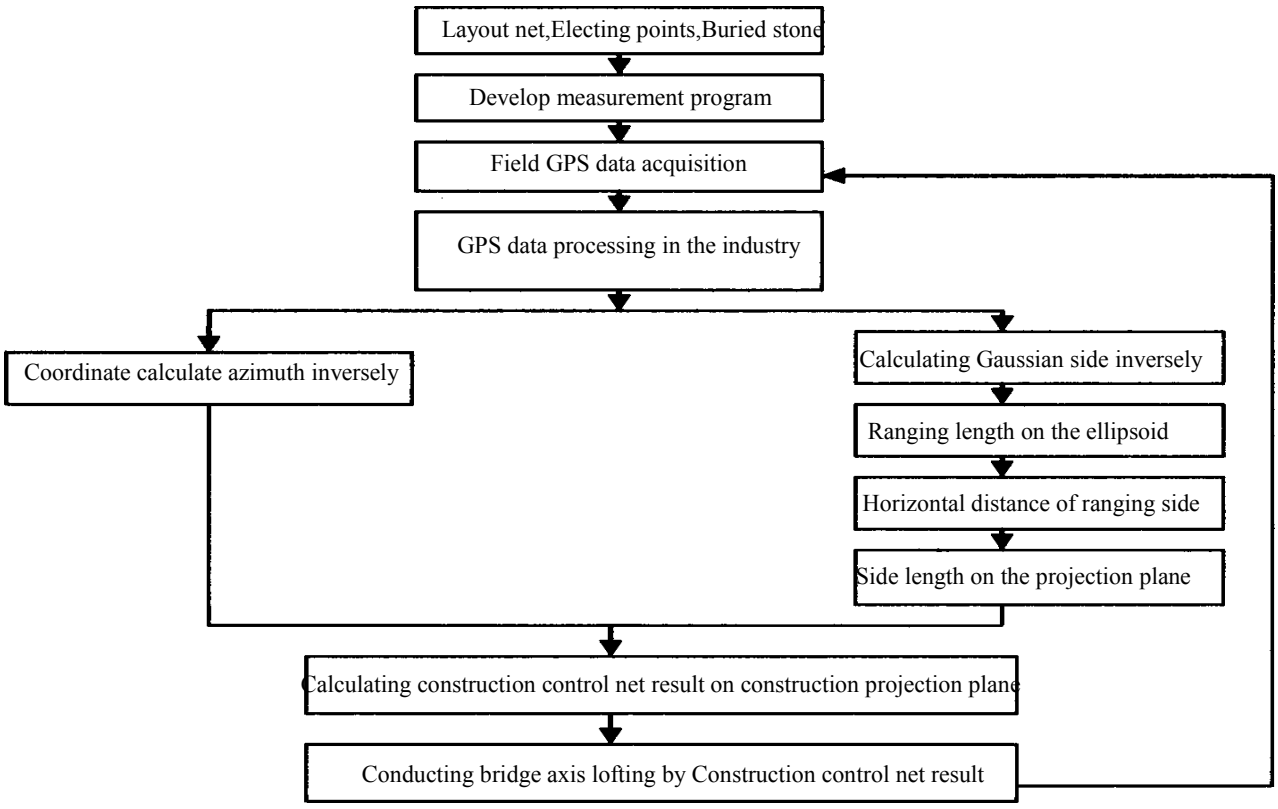

Fig.1 GPS measurement and data processing flow chart

**Math model of side length conversion.**The length that the gauss plane reduction to the ranging side length of reference ellipsoid [3],such as equation 1.

$$D_1 = D_2 / \left[1 + y_m^2 / (2 \times R_m^2) + (\Delta y)^2 / 24 \times R_m^2\right]. \quad (1)$$

where $D_1$ is the reduction ranging side length of reference ellipsoid(unit : m), $D_2$ is the length on the gauss plane(unit : m),$\Delta_y$ is the difference between the two endpoint abscissa of ranging side(unit : m), $y_m$ is the mean between the two endpoint abscissa of ranging side(unit : m),$R_m$ is The average curvature radius of ranging side midpoint on the reference ellipsoid( unit : m).

The ranging side length that reference ellipsoid reduction to the measured horizontal distance,such as equation 2.

$$D = D_1 / \left[1 - (H_m + h_m)/(R_A + H_m + h_m)\right]. \quad (2)$$

Where $h_m$ is The altitude difference that the geoidal surface of measurement area is higher than the reference ellipsoid(unit : m),$H_m$ is the average elevation that the ranging side is higher than the geoidal surface(unit : m),$R_A$ is the bend radius of normal section line to the ranging side(Unit : m),D is the horizontal distance of ranging side length(unit : m).

The ranging side length that the horizontal distance reduction to the average elevation plane of measurement area or any other elevation plane,such as equation 3.

$$D_0 = D\left[1 + (Hp + H_m)/R_A\right]. \quad (3)$$

Where $D_0$ is the ranging side length that reduction to the average elevation plane of measurement area(unit : m),$H_P$ is the average elevation measurement area or any other elevation( unit : m).

**GPS construction control net measurement and precision analysis**

**The construction plane control net figure is shown in Fig.2(a).**

**GPS data processing and precision statistics.Baseline solution.**After completion of field data acquisition, conducting data processing by the baseline solution and net adjustment software that was given by Southern Company. The longest side of the whole net is 1691 meters, the shortest side is 411 meters, with an average side length of 1039 meters.The precision statistics of the synchronized loop Calculated through the net are shown in table 1 and the precision statistics of the asynchronous loop Calculated through the net are shown in table2.The precision statistics of a repeat baseline Calculated through the net are shown in table 3.

Table 1 The precision statistics table of the synchronized loop (Unit: mm)[4]

| NO. | Edge number (n) | Edge length **d** (km) | $W_x$ | $W_{xTolerance}$ $W_{xTolerance} \le d\times 6$ | $W_y$ | $W_{yTolerance}$ $W_{yTolerance} \le d\times 6$ | $W_z$ | $W_{zTolerance}$ $W_{zTolerance} \le d\times 6$ | $W_{Closer}$ | $W_{Closing\ error\ Tolerance}$ $W_{Closing\ error\ Toleranc} \le d\times 10$ |

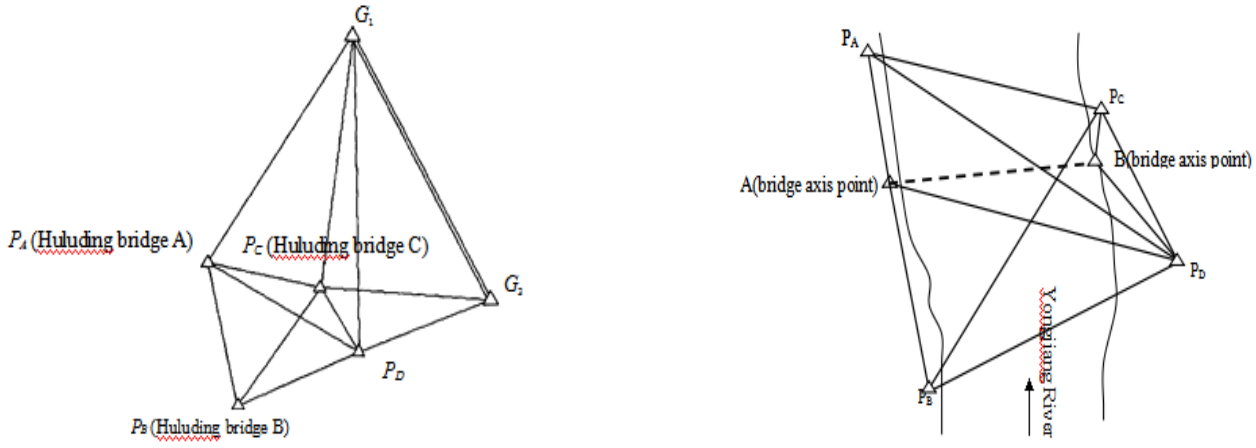
**The bridge axis lofting measurement**

**The bridge axis lofting.**①Get point A and point B on the bridge axis through using total station and utilizing control points in the construction control network.Then build a good mark On-the-spot.

②Use GPS to observe uniformly each control point and A,B points,and then calculating coordinate inspection A',B' of A,B.It should be compare with its theoretical value. If the D-value is greater than the standard requirement, we need to do as follows. With total station at point A, point A ' as station coordinates,and point B ' used fou orientation, rotating equipment and with making the line of sight direction in A' A azimuth, setting point C two meters in that direction.Then calculating distance D between point A and point B. In order to ensure the point A″, measuring the distance D from A' to C through the steel rule and then making a mark in labeled heart. Processing point B in the same way above.

③ Repeat step (2), until the D-value between the Coordinate inspection of point A and point B and its theoretical value meet the standard requirement

**The GPS net diagram of the bridge axis lofting is shown as Fig.2(b)**.



(a) (b)

Fig.2 The construction plane control net diagram(a) and The GPS net diagram of the bridge axis lofting(b)

**The GPS accuracy statistics to detect bridge axis lofting .**Get point A and point B on the bridge axis through construction control points.Then Use GPS for testing,and testing accuracy are shown in table 7

Table 7 Precision statistics table (Units:mm)

| Point name | mean square error of a point | Relative error |
|---|---|---|
| A | 2.236 | 1/203750 |
| B | 2.345 | |

## Conclusions

The control survey conducted with GPS were judged collectively outstanding in quality because of its reasonable net layout and its high accuracy that meet the standard requirements overall.Due to limitations of the terrain, the average side length do not meet the requirements of the four-level GPS net.But after careful measurement, the relative mean square error of each edge side length is very small, only 1/215330 of the largest,fully achieving "urban measurement standard"[5] in the demands of four-level sides.For the requirement of high precision construction control net and the characteristics of shorter edge length,the experience in the practical application is as follows:

① It is reliable for GPS net to replace the classic construction control net.

②The joint measurement method of GPS net and bridge axis lofting point in precision and efficiency are better than the traditional bridge axis lofting method.

③In order to make sure that the observation of long-short baseline edge is not restricted,using dual-frequency GPS receiver to observe.

④On the basis of standard, an appropriate extension of the observation time and an increase of the repeat observations can make the observation results more reliable.

⑤Select a period of satellite observations in good condition to observe, to ensure the reliability of the data.

⑥Observing more than 2 edges length by the high precision Rangefinder for checking.

# Improved BP Neural Network Model Applied in Settlement Analysis

Liangbo Gao[1, a]

[1]University of Science and Technology Liaoning,Anshan,China

[a]gaoliangbo3456@163.com

**Keywords:** the subway; settlement; BP neural network; Analysis and forecasting.

**Abstract.** According to the settlement and deformation of pavement in subway construction, the paper improved on the basis of gray system theory and BP neural network forecasting model. The method is adapted to modified residual prediction model to predict with engineering examples. It provides decision-making basis for construction engineering and monitoring.

## Introduction

The subway construction has a great impact on the road, can also cause a threat to the safety of vehicular traffic. It is particularly important for subsidence monitoring subway along the road, not only can provide useful information for the construction but also for the construction and road transportation to provide security. Therefore, this paper focuses on the analysis of monitoring data and research on settlement prediction model.

## An improved BP network model established

The improved BP neural network modified grey linear regression residual prediction model. The model is the integration of grey linear regression model and improved BP neural network. It uses the residuals of gray linear regression model as the input samples of an improved BP neural network. The network is trained to predict the samples.

The modeling method of the improved BP neural network modified grey linear regression residual prediction model as follows:

1. The original data sequence $\{x^{(0)}(i)\}, i = 1,2,\cdots,n$ , the use of linear regression model was fitted. Simulation and prediction value is obtained, $\hat{x}^{(0)}(i), i = 1,2,\cdots,n$ .It is provided with a residual sequence:

$$e^{(0)}(i) = x^{(0)}(i) - \hat{x}^{(0)}(i), i = 1,2,\cdots,n \tag{1}$$

2. Establish equal dimension and new information model of BP network of a residual sequence $\{e^{(0)}(i)\}$ . Let the number of prediction for K, using the information of $e^{(0)}(i-1), e^{(0)}(i-2),\cdots, e^{(0)}(i-k)$ to predict value of i time. $e^{(0)}(i-1), e^{(0)}(i-2),\cdots, e^{(0)}(i-k)$ as the input of BP network model is trained. The value of $e^{(0)}(i)$ as the target output value for the BP network model. The residuals sequence of BP neural network model by further training, so that different input vectors to obtain a corresponding output value. Then using trained model to simulate and predict the residual sequence.

3. Determine the new prediction values of the residual sequence $\{e^{(0)}(i)\}$ .using BP neural network model to simulate and predict $\{e^{(0)}(i)\}$ and getting new residual sequence $\{\hat{e}^{(0)}(i)\}$ . According to the residual sequence construct a new predictive value $\hat{y}^{(0)}(i)$ :

$$\hat{y}^{(0)}(i) = \hat{x}^{(0)}(i) + \hat{e}^{(0)}(i), i = 1,2,\cdots,n \tag{2}$$

The improved BP network model is an improved model on the basis of BP network model. On the one hand is to improve the standard gradient descent method includes adaptive learning rate, increasing momentum term. On the other hand is the standard of value optimization method includes

the step secant method, quasi Newton method, conjugate gradient method and the Levenberg-Marquardt algorithm.

In view of the small and medium-sized BP neural network is the best use of the Levenberg-Marquardt algorithm, which has faster convergence speed, storage capacity is low.

## Application of improved BP neural network model

This paper chooses a monitoring point for example, the residual sequence: $e^{(0)}$= {0.0127,-0.0114, -0.021,-0.0426, 0.179,-0.1645, 0.044, 0.0064, 0.2779,-0.1949,-0.7554}. Using BP neural network model to simulate and predict $\{e^{(0)}(i)\}$ and getting new residual sequence $\{\hat{e}^{(0)}(i)\}$. According to the residual sequence construct a new predictive value $\hat{y}^{(0)}(i)$.

Residual every 3 value as a cycle, the first three residual values as input samples of improved BP neural network, following period of residual value as the output samples, the formation of 6 training samples and two test samples.

Table 1 Grey neural network sample selection table

| Sample number | | input sample /mm | | | Output sample /mm |
|---|---|---|---|---|---|
| The training sample | 1 | 0.0127 | -0.0114 | -0.0210 | -0.0426 |
| | 2 | -0.0114 | -0.0210 | -0.0426 | 0.1790 |
| | 3 | -0.0210 | -0.0426 | 0.1790 | -0.1645 |
| | 4 | -0.0426 | 0.1790 | -0.1645 | 0.0440 |
| | 5 | 0.1790 | -0.1645 | 0.0440 | 0.0064 |
| | 6 | -0.1645 | 0.0440 | 0.0064 | 0.2779 |
| The test sample | 7 | 0.0440 | 0.0064 | 0.2779 | -0.1949 |
| | 8 | 0.0064 | 0.2779 | -0.1949 | -0.7554 |

Through the test algorithm, Selection of hidden layer neurons as 4 is the best. The formation of the topological structure of BP neural network is 3-4-1. We need to normalize sample data, The transfer function in the input layer is ‘tansig’, The transfer function of hidden layer is ‘logsig’, The transfer function in the output layer is ‘purelin’. The training function of network select Levenberg-Marquardt algorithm—‘trainlm’. Then by using the improved Levenberg-Marquardt algorithm of BP neural network was used to train the neural network. The improved BP network train diagram is shown in fig.1.

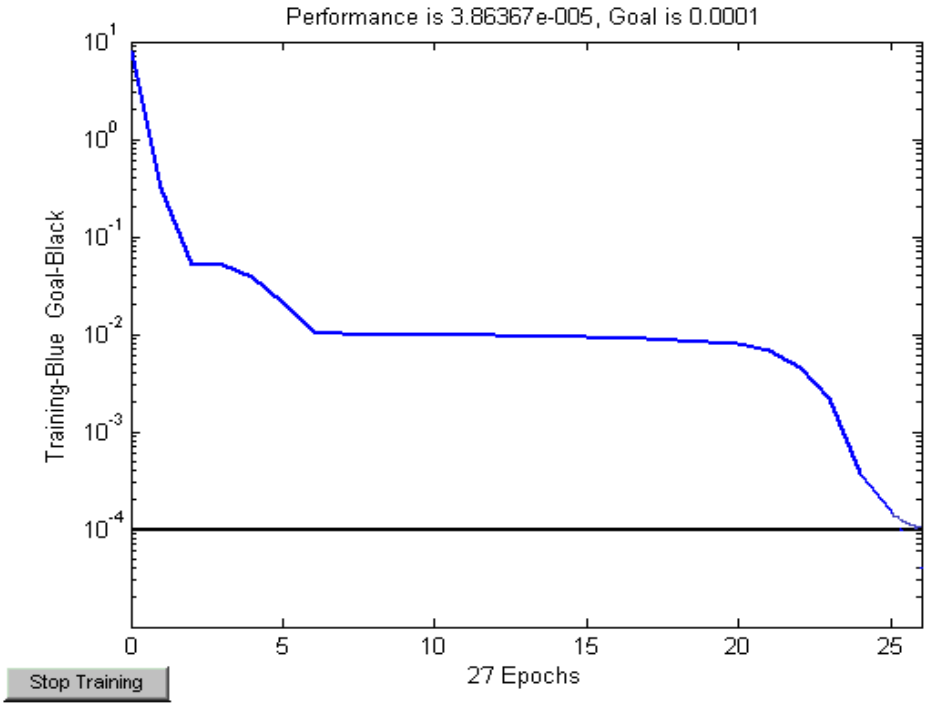

Fig. 1 The improved BP network train diagram

Fig.1 show that in the case of the training function is 'trainlm', to achieve the target error set 0.0001, only need to train 27 iterations. The time compared with BP neural network training is short and less training time.

Table 2 Improved BP neural network modified grey residual prediction results table

| Serial number | original value /mm | Predicted values /mm | Absolute error /mm | Relative error /% |
|---|---|---|---|---|
| 1 | 10.14 | 10.14 | 0 | 0 |
| 2 | 10.44 | 10.44 | 0 | 0 |
| 3 | 10.69 | 10.69 | 0 | 0 |
| 4 | 10.99 | 10.9893 | 0.0007 | 0.006 |
| 5 | 11.61 | 11.6098 | 0.0002 | 0.002 |
| 6 | 11.76 | 11.7607 | -0.0007 | 0.006 |
| 7 | 12.58 | 12.5953 | -0.0153 | 0.121 |
| 8 | 13.3 | 13.299 | 0.001 | 0.008 |
| 9 | 14.51 | 14.5134 | -0.0034 | 0.023 |
| 10 | 15.2 | 15.3724 | -0.1724 | 1.134 |
| 11 | 16.08 | 16.5713 | -0.4913 | 3.055 |

According to table 2 shows the sum of squared residuals of SSE is 0.2713, the average relative error of MRE is 0.5443%, the mean square error of MSE is 0.0339.

The results of simulate and predict models in Table 3.

Table 3 The model prediction and error comparison

| Serial number | actual value | Grey linear regression model | | BP neural network model | | Improved combination model | |
|---|---|---|---|---|---|---|---|
| | | Predicted values/mm | Relative error/% | Predicted values/mm | Relative error/% | Predicted values/mm | Relative error/% |
| 1 | 10.14 | 10.127 | 0.13 | —— | —— | —— | —— |
| 2 | 10.44 | 10.451 | 0.11 | —— | —— | —— | —— |
| 3 | 10.69 | 10.71 | 0.20 | —— | —— | —— | —— |

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 4 | 10.99 | 11.033 | 0.39 | 10.983 | 0.06 | 10.989 | 0.006 |
| 5 | 11.61 | 11.431 | 1.54 | 11.625 | 0.13 | 11.610 | 0.002 |
| 6 | 11.76 | 11.925 | 1.4 | 11.712 | 0.41 | 11.761 | 0.006 |
| 7 | 12.58 | 12.536 | 0.35 | 12.600 | 0.16 | 12.595 | 0.121 |
| 8 | 13.3 | 13.294 | 0.05 | 13.404 | 0.78 | 13.299 | 0.008 |
| 9 | 14.51 | 14.232 | 1.92 | 14.425 | 0.59 | 14.513 | 0.023 |
| 10 | 15.2 | 15.395 | 1.28 | 15.662 | 3.03 | 15.372 | 1.134 |
| 11 | 16.08 | 16.835 | 4.7 | 15.775 | 1.89 | 16.571 | 3.055 |

According to table 3 shows that modified combined model prediction effect is the best. In order to predict the effect of the above models and level of precision, using three error indexes including sum of squares error SSE, mean square error MSE and the average relative error of MRE is analyzed, by comprehensive evaluation of forecasting results.

Table 4 Model prediction error evaluation

| Model evaluation index | SSE | MRE/% | MSE |
|---|---|---|---|
| Grey linear regression model | 0.750 | 1.097 | 0.068 |
| BP neural network model | 0.328 | 0.881 | 0.041 |
| Improved combination model | 0.271 | 0.544 | 0.034 |

According to table 3 shows that forecast effect and the accuracy of combination model is highest.the precision index are better than other models, thus the engineering examples show that there is the best application effect of the improved model.

## Conclusions

1. The improved BP neural network modified grey linear regression residuals model capable of small sample, poor information based on data sample, a strong self-learning and adaptive model.
2. The model is solved stochastic of BP neural network model, prediction precision than GM (1,1) model, grey linear regression model and BP neural network model has greatly improved, forecast effect is improved obviously.
3. The model is feasible and practical in the actual project application.

# Multi-scale Classification Based on Remote Sensing

LI Peng-li[1,a] ,TI Wei-ping[1,b], LI Jia-chun[1,c]

[1] Key Laboratory for Special Area Highway Engineering of Ministry of Education, Chang'an University, Xi'an 710064, China

[a]li.pengli@sohu.com , [b]fz03@chd.edu.cn, [c]fz03@chd.edu.cn

**Key words：** multi-scale classification, segmentation, eCognition approache

**Abstract:**Due to the broadly application of remote sensing imagery, there is an eager need for the classification of objects in the images. The multi-scale classification based on object oriented analysis is not a usual approach for image classification because the users of multi-scale classification do not know how to use the information from multiple scales to do multi-scale classification. Many users rely on some easily accessible tools. nearest neighbour classifier, to do multi-scale classification. The multi-scale classification classifies the images from different scales. The feature values of the object vary from different scales and they may have some trends against scales. These trends may help us to understand multi-scale classification better. This is the scale dependency of features. The difference between multi-scale classification and single-scale classification is not only multiple scales, but also the use of information from different scales. In order to explore the connection between different scales, the research of new features is necessary.

## Introduce:

In current researches, the object in OOA has two meanings. One is the segments in segmentation. Another one is the meaningful composition of pixels in the imagery, e.g. one road or one house in the image. OOA begins with segmentation. Segment means subdivide entire/part of images at a pixel level, and the object is a set of pixels segmented in software (Definiens, 2009)[1]. In OOA, the segmentation is the previous procedure of classification. At first, the image will be segmented by any kinds of algorithms or knowledge-driven threshold. There also a lot of segmentation algorithms. The basic algorithms are edge detection and region extraction. One simple algorithm for edge detection is the local variance. The edge of regions in the image has the relatively bigger heterogeneity in the image, which means it has the relatively bigger local variance. Oppositely, the principle of region extraction is that the pixels in a region are relatively homogeneous. One way to find these regions is that: set a threshold for this homogeneity and merge the neighbor pixels by some searching algorithms. Another way is the transform algorithms, e.g. watershed transform in morphology segmentation (Vincent & Dougherty, 1994)[2]. Just as the name, morphology segmentation assumes the boundaries of regions are similar to the ridgeline of the landform of gray level. The gray level of the regions gradually increases from the center of regions to the boundaries and these centers are the major extrema of the whole image. OOA also have obvious backwards, notwithstanding it is better than pixel-based classification. The segments in segmentation are image objects and the real matters in natural are natural objects, e.g. a highway, a house, etc. But the image objects cannot perfectly match the natural objects due to the accuracy of segmentation and classification (Esch, Thiel, Bock, Roth, & Dech, 2008; Ranasinghe, 2008)[3-5] The image is an IKONOS pan-sharpen imagery of Delhi (see the location in Appendix A. The whole imagery is not

available), and the acquisition date is Jun. 3, 2001. The segmentation is drawn by eCognition software. The whole image is segmented into many objects. During the classification, some of the objects will be classified as object of interest (train station)[6-8].

## Segmentation

### Number of scales

The scales of segmentation depend on the scales of the structure of image objects. Before the segmentation, the number of scales needs to be decided roughly. The complicated structure in the object makes multi-scale classification a necessity. The segmentation should reflect the boundaries of objects and the sub-level of segmentation matches the boundaries of their sub-objects. The number of segmentation scales/levels should not be less than the number of structure scales, there are at least two scales: one scale show the boundaries of road, the second scale reflects the boundaries of lanes with asphalt, mid-barrier in the road, and trees in the road. Sometimes, an extra scale will be used to delete the false positive.

The hierarchy of classification in a planar image is actually a nested system. The object is nested in its super-objects, which means the number of scale is the number of nested layer in hierarchy, e.g. in the image of road, the asphalt pavement, mid-barrier, trees are paralleled object and they are nested in each other, but they are nested in their super-object road.

### The texture of objects

The structure of objects decides which multi-scale feature will be used. The using of multi-scale features will be stated in section 3.1.2: classification. The segmentation should coincide with the texture of objects. For example, in the image of the train station, the segmentation of finer scales should represent the distribution of sub-objects: coaches. The segmentation in sub-level should match the boundaries of elements of texture. The elements of the texture .

These objects match the shape of coach. The group of these objects makes the using of some special features—standard deviation of main direction of sub-objects or the mean of main direction of sub-objects possible.

### The optimal scales

In order to reduce the under/over-segmentation, the choosing of optimal scale is necessary. As stated in section 2.3: optimal scale, there are several methods to select the best segmentation scale. Actually, they all try to distinguish the objects in the whole scene. For single scale classification, the user would like to get a best distinction for all the interesting objects in the image so the ESP tool (Dragut et al., 2010) or plateau objective function (Martha et al., 2011) are good methods; however, for multi-scale classification, the segmentation of a certain object and its sub-objects is extremely important because of the multi-scale features. The user needs an improved strategy for the segmentation the multi-scale analysis.

## Classification

The multi-scale classification is majorly manipulated through multi-scale features. The multi-scale features provide the connection between different scales. They are the major difference between the single-scale classification and multi-scale classification. This section will illustrate the using of multi-scale features. There are five kinds of multi-scale features:

### The first kind of features

One is the “existence of sub-objects” and some geometric features, e.g. “center of the super-object”. “Existence of sub-objects” is used to tell whether an object has a sub-object of a

certain class or not. Similarly, "center of the super-object" tell if an object is the center of its super-object. This kind of features usually was not directly used to classify the object. Usually, the super-object or sub-objects of current objects are classified preliminarily, then current object is classified based on these features.

The Figure1 is the images of farmland and it is a part of image from the Geo-eye 1 pan-sharpen image of Delhi. The bright shining part is water in the wet paddy field. In Figure 1 (a), the parcel of farmland was segmented. And, the shining water is identified in the finer scale segmentation. In single scale, the wet paddy field may be classified by the threshold of brightness or NDVI. Actually, some dry paddy field also has the similar brightness value or NDVI value as the wet field, so they cannot be identified by brightness or NDVI in single scales. In multi-scale classification, the wet field can be identified by its sub-objects—the shining water. And, the brightness of the shining objects is above 131. It is much higher than other objects.

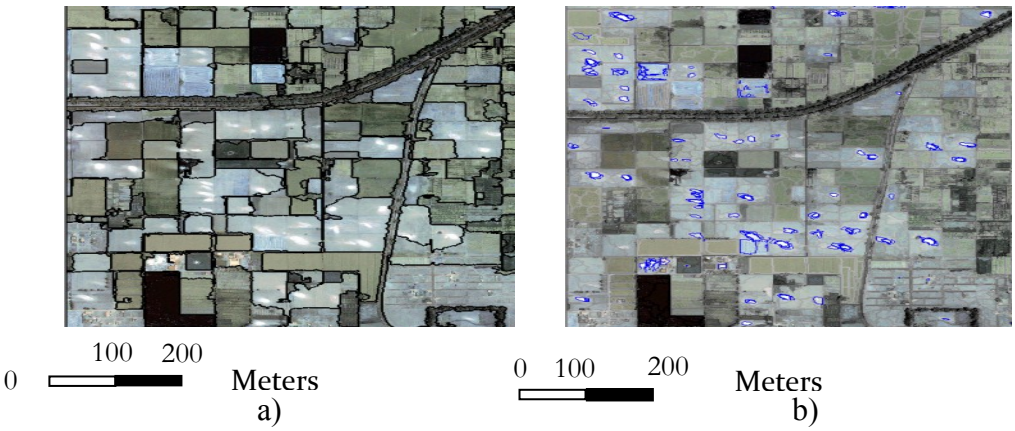

Figure 1: The classification of paddy wet field

When the shinning water is classified, the wet fields can be classified by "existence of sub-objects in shinning water class", i.e. if shining water objects is the sub-objects of one object, then this object will be classified as wet field.

**The second kind of features**

"Existence of super-objects" also describes the hierarchical relation and it is very commonly used in multi-scale classification for large class hierarchy tree. The related strategy of this feature is that: classify the super-objects first, and then classify its sub-objects with this feature to restrict the objects of sub-levels to the region of super-objects.

**The third kind of features**

Another kind of features is the statistical shape features of sub-objects. The shape feature of them are normally used as a replacement of GLCM to describe the texture, e.g. 'mean direction of sub-objects', 'average mean difference to neighbors of sub-objects: asymmetry' etc.

The GLCM is the count of the frequency of neighboring pixel pairs in a moving window. The statistic moment of the GLCM will be recorded in the central pixels of the window. In some OOA software, the GLCM features are not calculated in image objects instead of a moving window. Because the pixels are represented with squares, the direction of 0°, 45°, 90° and 135° is easily calculated.

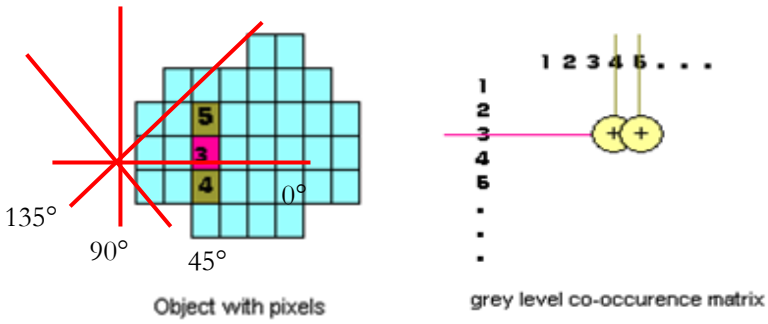

Figure 2: The directionality of GLCM (Definiens, 2009)

The Figure 2 shows the direction of GLCM. The number of the same pair-wise of pixel values will be recorded in the matrix. As a matrix, it has two diagonal: left diagonal and right diagonal. Theoretically, it has 8 directions. Due to calculation method: the pixels with the same value as its left or right neighbour are recorded always in positive value, the number of direction of GLCM is reduced to four. The value relies on the direction of count and the 0°, 45°, 90° and 135° GLCM is very commonly applied) (Definiens, 2009; Roumi, 2009). The usage of the GLCM features depends on their directionality. The GLCM mean and GLCM dissimilarity are the first-order GLCM moment. There are three commonly used second-order GLCM features: GLCM entropy, GLCM contrast. Strictly speaking, the GLCM features do not measure the texture or pattern. They measure the distribution of different sets of neighbouring pixels, the distribution of pair-wise pixels with distance 0 in one object.

Compared to GLCM, the multi-scale features have these advantages:

The GLCM features are only good at measuring the texture in eight directions, but the multi-scale features are not dependent on the direction.

The multi-scale features can identify the type of features more accurately. If an object has linear texture, the mean and standard deviation of main direction of sub-objects or the mean and standard deviation of asymmetry can detect the type of texture. But for GLCM, only the GLCM homogeneous/dissimilarity/contrast can find: in which direction, the object is homogeneous/heterogeneity, which can indirectly indicate the directionality of pattern.

Some multi-scale features can measure the heterogeneity of objects.

**The fourth kind of features**

The fourth kind of features is the statistical spectral features of sub-objects. The statistical spectral features are usually calculated to measure the heterogeneity of objects, e.g. two kinds of vegetation have similar NDVI but the texture is different.

Two examples are below. There are two kind of vegetation in Figure 3. The green object is the vegetation mixed with buildings and the red object is a sparse wood along a highway.

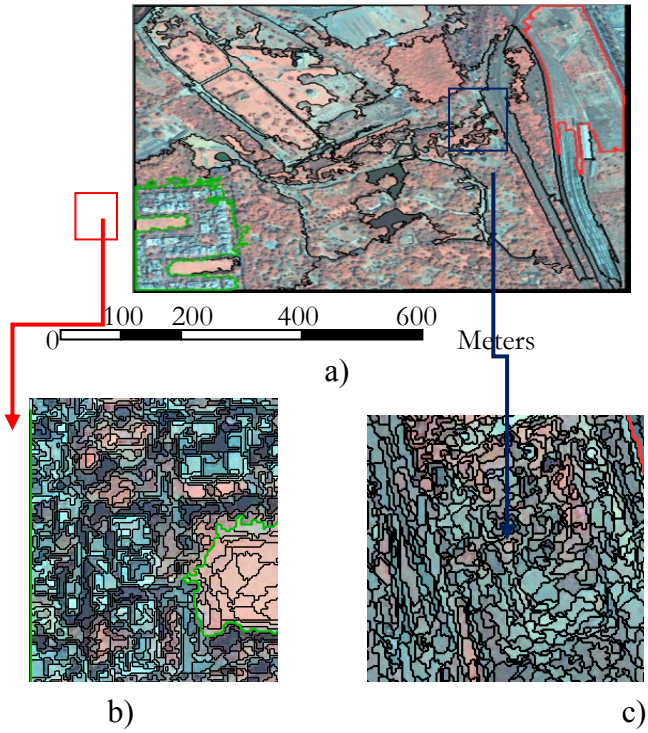

Figure3: Two places (within the red box and the blue box) has nearly same NDVI but the different mean difference of NDVI:

The NDVI of these two objects (within the red box and the blue box in Figure 3 (a)) are 0.098 and 0.091. They are very close. But, when the image is segmented into smaller objects, the mean absolute difference of NDVI has bigger difference between two kinds of vegetation than NDVI. They are 0.079 and 0.064 and the sparse woods have the smaller value. The structure of the two kinds of vegetation is different. In Figure 3 (b), the objects of trees and objects of buildings has big contrast; whereas in the Figure 3 (c), the NDVI of sub-objects of sparse woods change almost gradually.

Actually, NDVI of the red object and the green object are both 0.28. The values of the standard deviation of NDVI of them are 0.62 and 0.39 respectively. The standard deviation is different in these two objects because the red object is not absolutely homogeneous and there are some darker parts in this object.

If possible, the geo-statistic spectral features can be used to detect the texture more precisely.

## The Approaches in eCognition

The features and algorithms in eCognition show some backwards of GUIof eCogntion. Some of the features and algorithms in the software are apparently designed on the basis of feasibility and difficulty of programming instead of the habit of image processing/OOA analyst. There are a great many of featuresin the software. Obviously, not all of them are useful. the class color in the “class hierarchy tree” is a kind of feature, but it is very difficult to think when the user can use it.

The features can be used in multi-scale classification

**Create Customized Features-> Relational Customized Features**

All the multi-scale features can be created in the relational customized features. Some basic statistic parameters of the sub-objects can be calculated. The pattern of image can be measured by these customized features.

**Object Features: Layer Values->To Superobject**

Calculate the basic statistic parameters with the reference of the super-object or compare the statistic parameters with super-object.

**Object Features: Geometry->To Superobject**

Calculate the geometric position of the current objects in the extent of their super-object.

**Object Features: Texture -> Layer Value: Texture Based on Sub-objects**

Measure the texture based on the statistic parameters of spectral values of the sub-objects. It can be customized in relational customized features.-> Shape Texture: Based on Sub-objects

Measure the texture based on the statistic parameters of geometric values of the sub-objects. It can be customized in relational customized features.

The algorithm can be used in multi-scale classification

Multi-resolution Segmentation: this is common segmentation algorithm for multi-scale classification. The FNEA is embedded in it.

Multi-resolution segmentation region growing: just as its name, it can be used after the segmentation of the first scale. The principle is also FNEA.

Convert to Sub-objects: There is no real optimal scale. In some cases, when facing the under segmentation in a small part of the image, we can use it to convert the current object to its smaller sub-objects.

Hierarchical Classification: It is an algorithm similar to decision tree, but it is not real multi-scale classification we want.

## Summery

The major difference between the real multi-scale classification and the single-scale classification is the using of information from multiple scales. This information can be many kinds and they are sorted into five kinds of multi-scale features. They have great potentials to detect the texture. Before the operation of multi-scale classification, the structure of image will be analyzed first, and then the segmentation and classification can be manipulated with multi-scale features. The segmentation also need to match the boundaries of natural objects or texture elements so the multi-scale features can be calculated precisely. These features in eCognition are listed after the conceptualization to help the researcher use eCognition to do multi-scale classification. The algorithm available for multi-scale classification is no more than multi-resolution segmentation. The choosing of parameters is also discussed.

# Research on GPS height partition fitting method

Chang Wang[1, a]

[1] University of Science and Technology Liao Ning School of Civil Engineering, AnShan LiaoNing

[a]wangchang324@163.com

**Keywords**: Partition Fitting;The Quadric Surface Fitting; Mobile Triangle Method

**Abstract.** In Diaobingshan area, Use 76 data points (geodetic height and normal height are known) as experimental data, the quadric surface fitting mean square error as GPS height partition fitting basis in the area. In 76 data points, some data points which GPS height fitting residual value is less than the quadric surface fitting mean square error in a region, other points which GPS height fitting residual value is more than the quadric surface fitting mean square error in a region, in the same time, individual regions(data points is less) use mobile triangle method to establish GPS height the fitting model. The experiment prove that the effect of this kind partition fitting method is better than that of no partition fitting method, has a certain reference value.

## Introduction

With the development of GPS technology, more and more construction units use GPS technology, GPS technology get elevation data belongs to the geodetic height, but use the normal height system as elevation system in China, so geodetic height converting normal height is a urgent problem in the aspect of application of GPS Technology. At present, GPS height fitting method is an effective method. But this method is also influenced by modeling point distribution and areas high low fluctuation, sometimes the effect of the GPS height fitting is not very ideal. This paper mainly studies the GPS height partition fitting method in Diaobingshan area ,uses 76 data points, the quadric surface fitting mean square error as partition basis to establish the fitting model，individual regions use mobile triangle method[1][2].

## GPS Height Fitting Method

1.The Quadric Surface Fitting

the quadric surface polynomial theory formula[3][5]：

$$F(x,y) = a_0 + a_1 x + a_2 y + a_3 xy + a_4 x^2 + a_5 y^2 \tag{1}$$

Among them, $a_i$ as the coefficients which was obtained by least square method.

2.Mobile Triangle Method

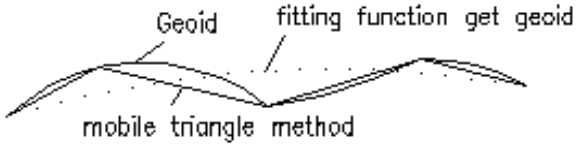

Fig. 1 Different fitting level surface schematic diagram

The basic idea: point A landed in a triangle, elevation abnormal and plane coordinate of the three vertices of the triangle are $(x_1, y_1, \xi_1)$, $(x_2, y_2, \xi_2)$ and $(x_3, y_3, \xi_3)$, determining the plane equation by three points is:

$$\begin{vmatrix} x & y & \xi & 1 \\ x_1 & y_1 & \xi_1 & 1 \\ x_2 & y_2 & \xi_2 & 1 \\ x_3 & y_3 & \xi_3 & 1 \end{vmatrix} = 0 \tag{2}$$

Height anomaly of point A:

$$\xi = \xi_1 - \frac{(x-x_1)(y_{21}\xi_{31} - y_{31}\xi_{21}) + (y-y_1)(\xi_{21}x_{31} - \xi_{31}x_{21})}{x_{21}y_{31} - x_{31}y_{21}} \quad (3)$$

Height of point A:

$$h_p = H_p + \xi_p \quad (4)$$

**Experiment and GPS height fitting model precision analysis**

1.GPS height Fitting model precision analysis in no partition situation

In 76 points, select 42 points as modeling points,34 points as check points, the quadric surface Fitting as GPS height fitting method, we can see modeling points graph and the quadric surface fitting accuracy from figure2 and table1[4],

Table 1 The quadric surface fitting accuracy unit mm

| name | the quadric surface fitting |
|---|---|
| internal accord precision | 12.9 |
| external accord accuracy | 18.2 |

Fig.2 Model points graph (● as modeling points)

From fig.2, table 1, we can see that modeling points should cover the entire region, the quadric surface fitting internal accord accuracy and external accord accuracy are less than 2 cm.

2.GPS height Fitting model precision analysis in partition situation

1）GPS height Fitting Partition method

76 data points as modeling points, get mean square error and the residual value of each point by the quadric surface fitting. in 76 data points, some points which GPS height fitting residual value is less than the quadric surface fitting mean square error in a region, other points which GPS height fitting residual value is more than the quadric surface fitting mean square error in a region. Due to the number of points is less, individual regions use mobile triangle method to establish the fitting model, Fig. 3

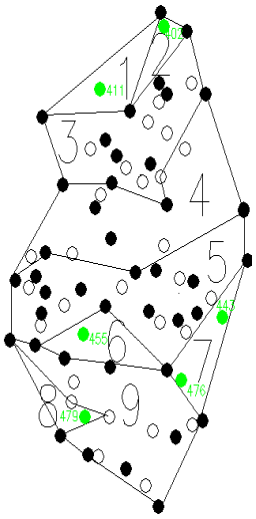

Fig.3 Zoning map

●as modeling point; ○as check points ; ● as mobile triangle method fitting point

From fig.3 ,we can know that the residual value of all points in 3 area, 5 area and 9 area is less than the quadric surface fitting mean square error; the residual value of all points in 4 area is more than the quadric surface fitting mean square error; using mobile triangle method to establish the fitting model in 1 area, 2area , 6area, 7area and 8 area.

2）Partition fitting precision analysis

（1）Use the quadric surface fitting to establish fitting method in 3 area, 4 area, 5 area and 9 area. There are 20 point in 3 area, 12 points as modeling points, 8 points as check points; There are 26 point in 5 area, 18 points as modeling points, 8 points as check points; There are 18 point in 9 area, 10 points as modeling points, 8 points as check points; There are 15 point in 4 area, 10 points as model building points, 5 points as check points.

（2）Use mobile triangle method to establish GPS height fitting method in 1 area, 2area , 6area, 7area and 8 area, from table2, 3 and fig.4～7 can see GPS height fitting result,

Table 2 The quadric surface fitting accuracy in four regions unit :mm

| name | 3region | 5region | 9region | 4region |
|---|---|---|---|---|
| internal accord precision | 11.7 | 8.4 | 8.8 | 17.3 |
| external accord accuracy | 8.6 | 9.3 | 11.0 | 29.8 |

Table 3 Mobile triangle method fitting accuracy unit :mm

| 1 region | check point residual value | 2 region | check point residual value | 6 region | check point residual value |
|---|---|---|---|---|---|
| | δ=46.29 | | δ=1.96 | | δ=31.73 |
| 411 | 46.29 | 402 | 1.96 | 455 | 31.73 |
| 7 region | check point residual value | 8 region | check point residual value | | |
| | δ=17.9 | | δ=33.82 | | |
| 443 | 17 | 479 | 33.82 | | |
| 476 | 18.78 | | | | |

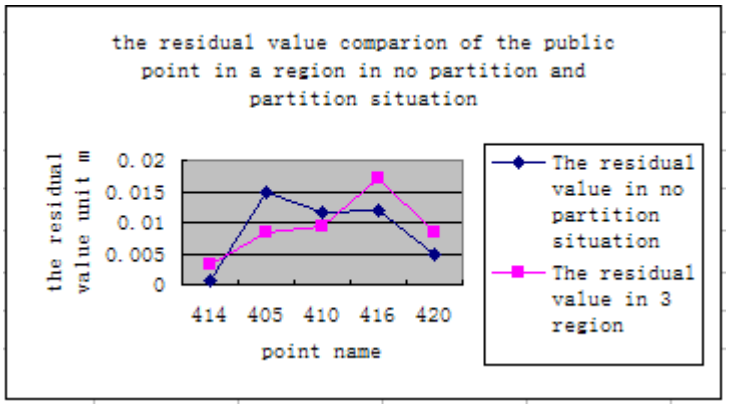

Fig.4 The residual value comparison of the public point in 3 region in no partition and partition situation

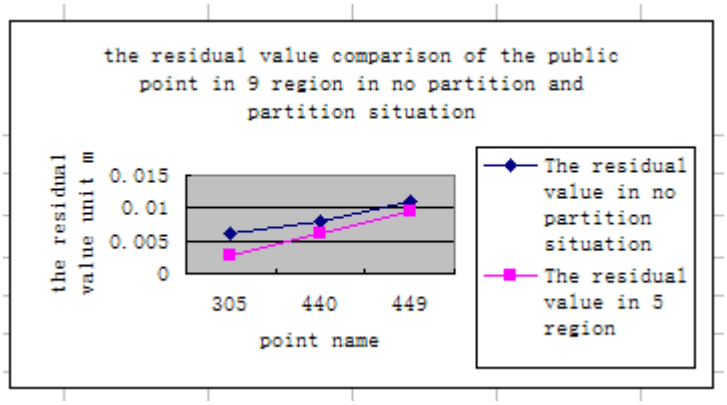

Fig.5 The residual value comparison of the public points in 5 region in no partition and partition situation

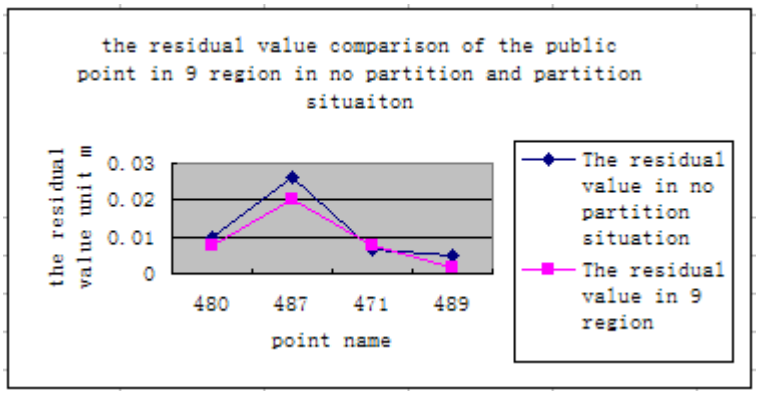

Fig.6 The residual value comparison of the public point in 9 region in no partition and partition situation

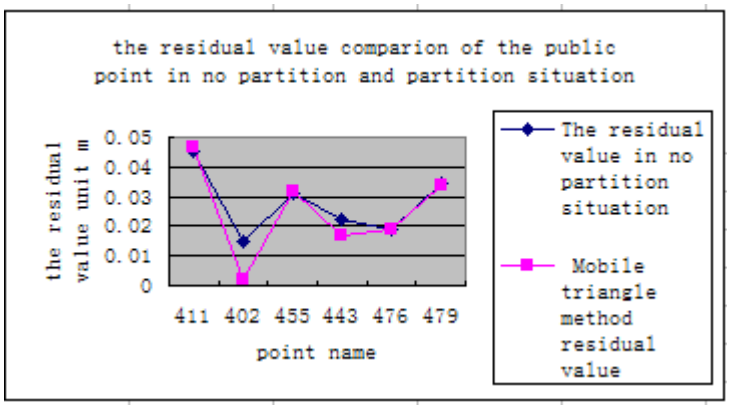

Fig.7 The residual value comparison of the public point in no partition and partition situation

From table 2 ,we can see that internal accord precision and external accord accuracy are higher than that in no partition situation in 3 region, 5 region, 9 region; internal accord precision and external accord accuracy are less than that in no partition situation in 4 region, so 4 region is not suitable for partition fitting.

From fig.5, fig.6 ,we can see that the residual value of public points in partition situation is less than that in no partition situation in 5 region, 9 region.

From fig.7,we can see that the residual value of three points(402, 443, 479) is less than that in no partition situation by mobile triangle method in 2 region, 7 region and 8 region.

**Summary**

1.If the effect of GPS height fitting is better in whole region, use partition fitting to establish fitting model in this region can effectively improves the fitting precision.
2. In Diaobingshan area, use quadric surface fitting mean square error as partition basis, points which fitting residual value is less than the quadric surface fitting mean square error in a region, the effect of GPS height fitting in partition situation in this region is better than that in no partition situation, points which fitting residual value is more than the quadric surface fitting mean square error in a region, the effect of GPS height fitting in no partition situation in this region is better than that in partition situation.
3.there are less data points in some regions, use mobile triangle method to establish GPS height fitting model in these region, can effectively improve the fitting accuracy, and the program design is relatively simple.

# GPS RTK Techniques for Construction Monitoring of Super Deep-water Open-caisson

Hao Yanguang [1, a], Liu Xiangliang [2,b] ,Liu Jianbo [3,c]

（Cccc WuHan Harbour Engineering Design And Research Co.Ltd,wuhan，china,430040）

[a]haoyg1314@163.com, [b]67821205@qq.com

**Keywords:** GPS RTK Techniques, super deep-water open-caisson, Taizhou Yangtze River Bridge, positioning system of anchor piers, real-time monitoring.

**Abstract.** The super open-caisson foundation of Taizhou Yangtze River Bridge was used by positioning system of anchor piers. GPS RTK Techniques was used to real-time monitor the open-caisson and by software compute current geometric posture of open-caisson timely. This could provide guarantee for sinking of caisson, and shorten construction period and save cost.

## Introduction

Taizhou Yangtze River Bridge is located in the middle of the Yangtze River in Jiangsu Province, between Jiangyin Yangtze River Bridge and Runyang Yangtze River Bridge. It connects Taizhou city in the north and Zhenjiang city and Changzhou city in the south. The three-tower suspension bridge consists of 390＋1080＋1080＋390m spans in the main body. The width of main bridge is 33m with designed vehicle speed of 100km/h. The middle tower falls into the gate-type steel structure and the towers in the north and south belong to concrete structure. The distribution of main bridge structures is shown in Fig. 1.

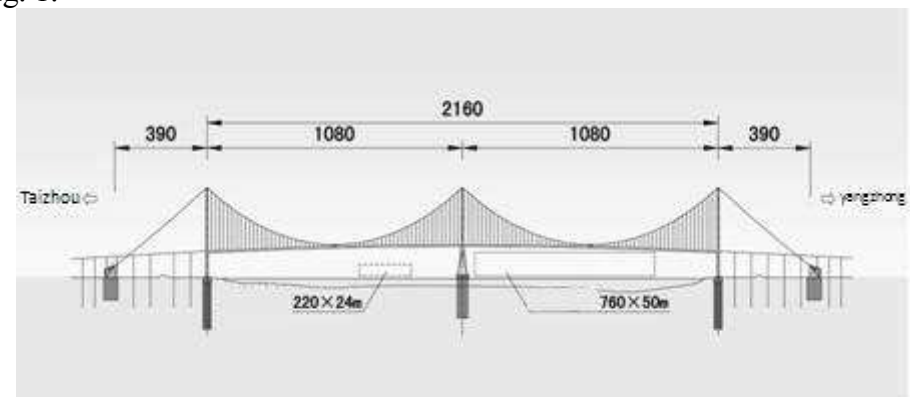

**Fig.1 Distribution of Main Bridge Structures**

The middle tower adopts super deep-water open-caisson foundation and the dimensions of standard caisson section are 44*58m, the radius of transition arc is 8m. The design elevation of caisson cutting-edge is -70m and the bearing layer is fine sand. The total height of caisson is 76m, wherein 38m on the lower part is steel-shell structure, filled with concrete, and 38m on the upper part is concrete structure. The concrete caisson height is completed in three times. The caisson structures and compartment distributions are shown in Fig. 2.

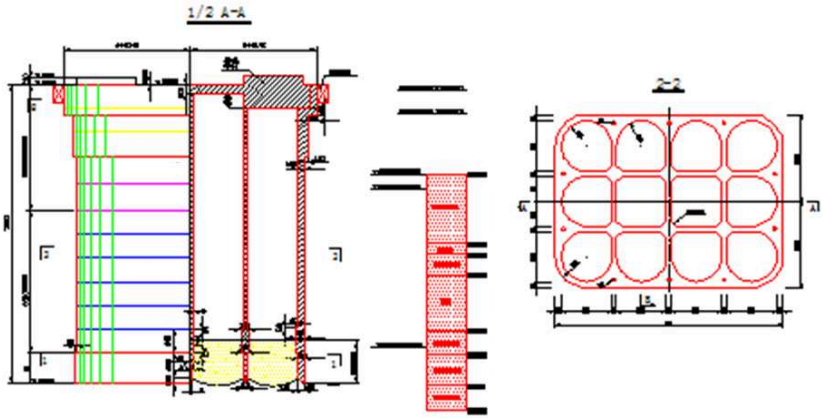

**Fig. 2 Caisson Structures**

## Foundation Construction

The middle tower of Taizhou Yangtze River Bridge is located in deep and rapid current. The riverbed will be greatly affected by rapid current during the process of sinking, which brings big risks to the construction. According to the characteristics of the construction as well as comparison of domestic and foreign data research and scheme selection, the construction of steel caisson will adopt the positioning system of anchor piers in the upstream and downstream.

### 2.1 Positioning System

**1) Design of Positioning System**

The positioning system consists of such equipment as anchor pier, anchor, chain, wire rope and hoist. The plan size of upstream anchor pier is 28*21m, with 20 pieces of φ1200*14mm steel pipe piles as the foundation. The plan size of downstream anchor pier is 25*21m, with 16 pieces of φ1200*14mm steel pipe piles as the foundation. On the platform of every anchor pier distributed with 12 hoists and the wire rope will connect anchor and caisson to the hoist by means of connecting devices. The positioning of steel caisson will be realized by controlling hoist to change the pulling forces, as shown in Fig. 3.

**Fig. 3 Positioning System of Steel Caisson**

**2) Calculation and Analysis of Caisson Resistance**

Positioning of caisson will be affect by external factors such as wind load, current force and wave forces, which will influence the accuracy. According to the hydro geological data and field observation, the external load data will be set as follows:

① wave force: Wave height is 0.5m and period is 3.15s, wave length is 15.5m;

② current force: Current velocity is 1.2m/s, with 10°of southern intersection angle to the upstream and downstream axis at caisson;

③ wind load: Wind speed is 20.8m/s when caisson is positioning and wind speed is 13.8m/s when caisson is implanted; and

④ Other basic data: The high-tide level in construction is +2.50m, riverbed elevation at piers is -15.0m, and the standard section size of caisson is 44.0m*58.0m, with total height 38m.

The unfavorable combination of water resistance, wind resistance and wave forces when caisson is sinking to be implanted will be regarded as the designed load of positioning system in calculation. The caisson assistance will be calculated as in following Table 1:

**Table 1 Calculation of Caisson Resistance Conditions**

| Conditions | | Draft (m) | height above water (m) |
|---|---|---|---|
| Condition 1 | Caisson floated in place | 12.15 | 25.85 |
| Condition 2 | No erosion | 17.5 | 20.5 |
| Condition 3 | 10m of erosion | 27.5 | 10.5 |

Calculations of front and side resistance on caisson in various conditions are shown in Table 2 and Table 3:

**Table 2 Calculation of caisson front resistance (parallel to river)**

| condition | Max Velocity m/s | Draft (m) | Current Force (kN) | Wind Force (kN) | Wave Force (kN) | Joint Force (kN) |
|---|---|---|---|---|---|---|
| Condition 1 | 1.2 | 12.15 | 655.5 | 307.1 | 723.8 | 1686.4 |
| Condition 2 | 1.2 | 17.5 | 944.1 | 243.5 | 906 | 2093.6 |
| Condition 3 | 1.2 | 22.5 | 1483.6 | 55 | 1119.7 | 2658.3 |

**Table 3 Calculation of caisson side resistance (vertical to river)**

| Condition | Max Velocity m/s | Draft (m) | Current Force (kN) | Wind Force (kN) | Wave Force (kN) | Joint Force (kN) |
|---|---|---|---|---|---|---|
| Condition 1 | 1.2 | 12.15 | 335.2 | 451.8 | 582.4 | 1369.4 |
| Condition 2 | 1.2 | 17.5 | 511.6 | 321 | 687.2 | 1519.8 |
| Condition 3 | 1.2 | 27.5 | 803.9 | 72.5 | 849.4 | 1725.8 |

3) Positioning Construction of Caisson

Positioning of steel caisson parallel to river: Steel caisson positioning shall be controlled by 12 sets of hoists and tackles installed on upstream and downstream anchor piers.

Positioning of steel caisson in north-south direction: To lift side anchors at northern and southern side of caisson, and connect the cables on side anchors to the hoist on anchor pier platform through guide device on caisson. Adjust the tensions of each anchor cable to control the plane position.

Positioning of steel caisson consists of preliminary positioning, tilt adjusting and accurate positioning, and the procedures in various construction periods are as follows:

① Preliminary positioning The procedures of preliminary positioning of caisson: Steel caisson floated to pier position; adjust each pull cable in position through anchorage system; adjust the main pull cable on upstream and downstream through hoist system on anchor pier platform and make adjustment to the position parallel to river currency; adjust caisson positions through side anchor cables at northern and southern sides.

② Tilt adjusting The procedures of caisson tilt adjusting: strictly control the pull force of each pull cable when caisson is in position and supervise on drop cables and main cables at upstream, adjust the force on each cable at all time to ensure even stresses on cables. During the process of water

filling, strictly control every compartment and the surveyors conduct overall observations on top elevation differences of caisson. If the differences are too large, adjust drop cable and main cable; when adjust to be horizontal, tighten side anchor cable, drop cable and main cable.

③ Accurate positioning When caisson is filled with water and dropped to the place where there are two meters between cutting edge and riverbed, the accurate positioning of caisson will be conducted. The adjustment method is the same with the preliminary positioning of steel caisson.

### 2.2 Excavation Sinking of Caisson

The caisson sinking at middle tower of Taizhou Bridge will adopt the method of excavation without water drainage, and the overall construction technological process is shown in Fig. 4 as follows:

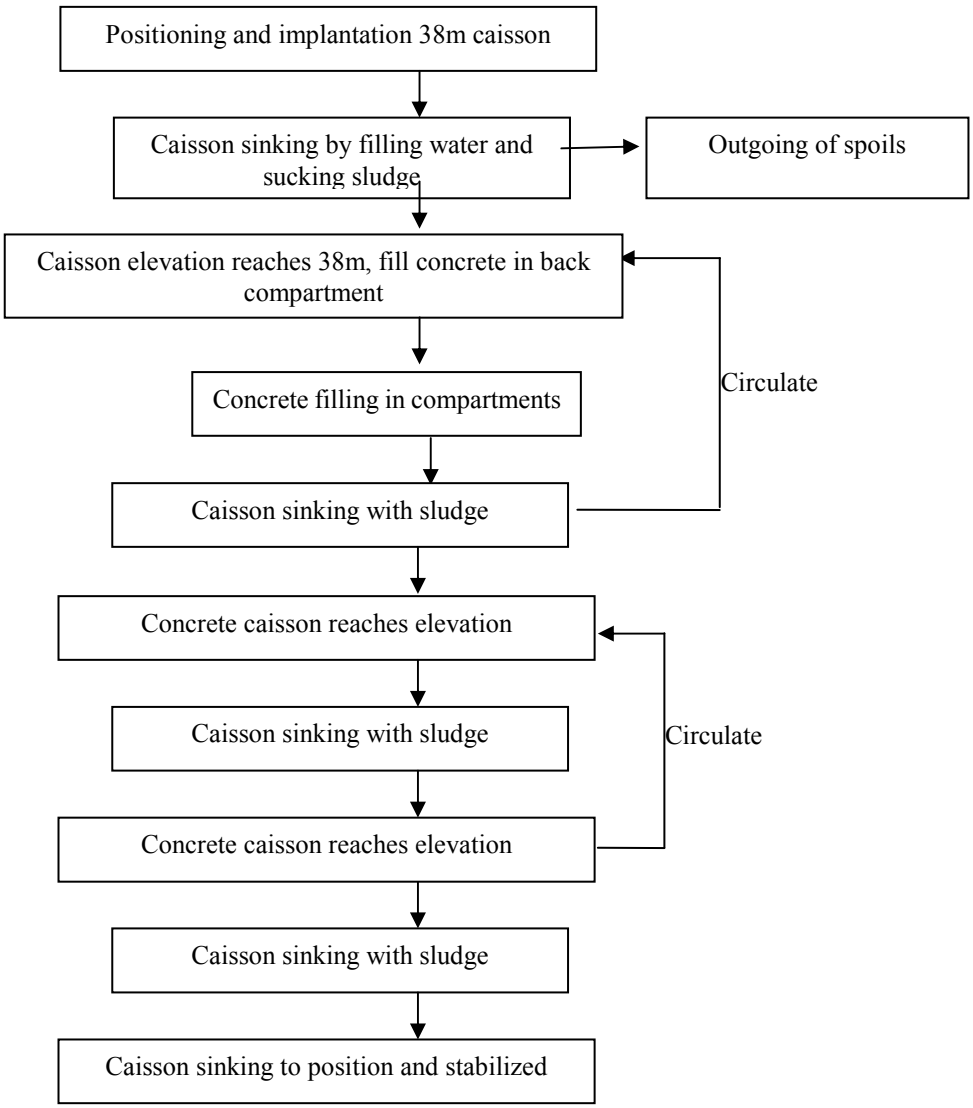

**Fig. 4 Construction Process of Caisson Sinking**

According to on-site geological and environmental conditions, caisson sinking shall adopt the suction method, with diving drill methods as a supplement. On September 2, 2008, the 76m caisson successfully sank to designed elevation.

## Construction Monitoring System of Caisson Positioning

### 3.1 Monitoring System

By means of GPS RTK technology and self-developed software, the monitoring system successfully helped to realize caisson positioning and implantation as well as real-time monitoring

during sinking construction. The monitoring system consists of data acquisition, data processing and data management, and the operating procedures are as follows: GPS device automatically collects data and transmit the real-time data to receiving station through Wireless communication technology. The self-developed software packages will process such data and display the real-time geometric attitudes of caisson such as plane deviation, tilt, subsidence and torsion. GPS measuring instruments and monitoring software interface are shown in Fig. 5 as follows:

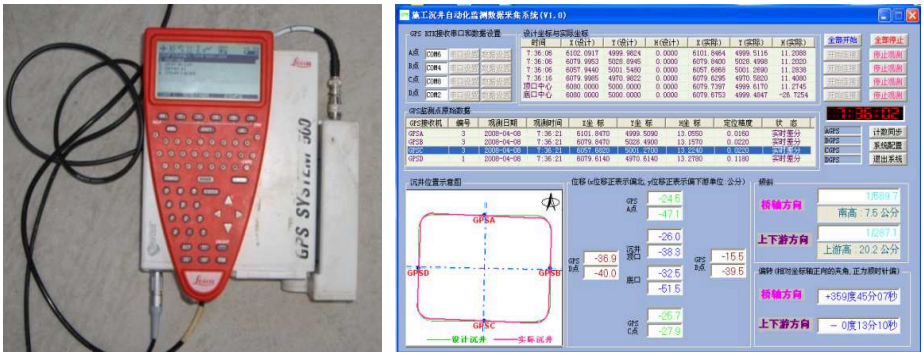

**Fig. 5 Measuring Instrument and Screenshot of Monitoring Software**

### 3.2 Distribution of Measuring Points

In order to accurately display the geometric attitudes of caisson during the process of positioning, implantation and sinking with sludge, measuring points are arranged at the center of all axis on caisson top, which are shown in Fig. 5 as follows.

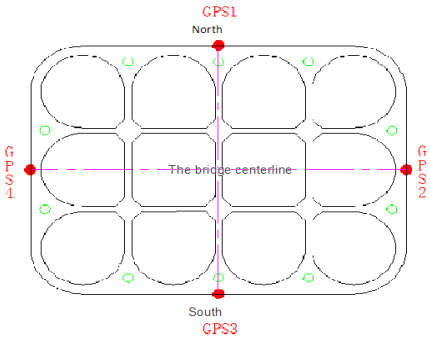

**Fig. 5 Distribution of GPS Measuring Points**

### 3.3 Data Analysis

The foundation construction of middle tower caisson consists of following procedures, such as positioning, implantation, concrete filling in compartment, sinking with sludge and elevation joint of concrete caisson, etc. Wherein, the elevation joint process of concrete caisson is not real-time monitored. In Fig. 6 to Fig. 10, the curve of caisson sinking, the curve of center deflection, the curve of torsion angle and curve of elevation difference in two axis directions.

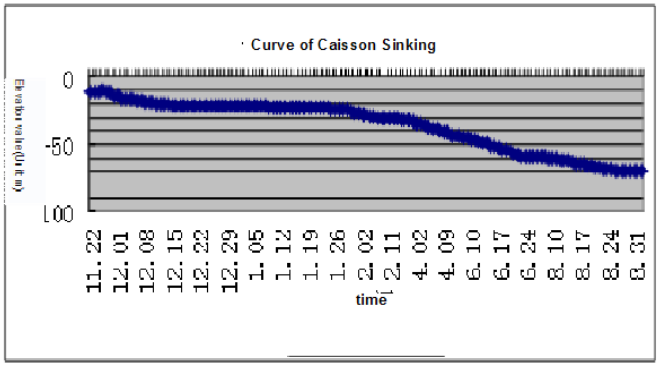

**Fig. 6 Curve of Caisson Sinking (Unit: m)**

According to Fig. 6, in initial period of caisson positioning and implantation, there are elevation fluctuations on cutting edge bottom of caisson, which is due to rise and fall of the river tides. When cutting edge elevation of caisson reaches -21.00m, concrete begins to fill in compartment walls, but sinking with sludge is not started. The curve during such period is nearly horizontal and decreasing a little, that's because the concrete in compartment walls added the self-weight of the whole structure. Meanwhile, we can find that there are several decreasing period in the curve, which means caisson is in the process of sinking with sludge. When caisson cutting edge is approaching design elevation, the sinking speed will be controlled for sake of sinking accuracy, therefore the sinking curve is decreasing quite mildly.

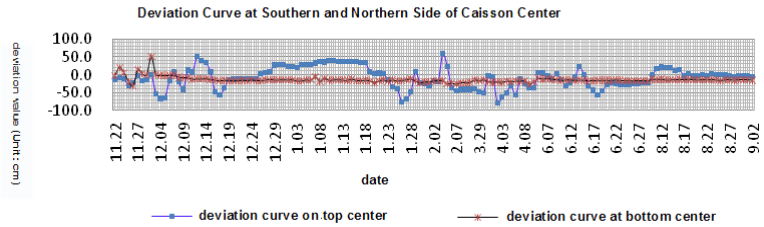

**Fig. 7 Deviation Curve at Southern and Northern Side of Caisson Center (Unit: cm)**

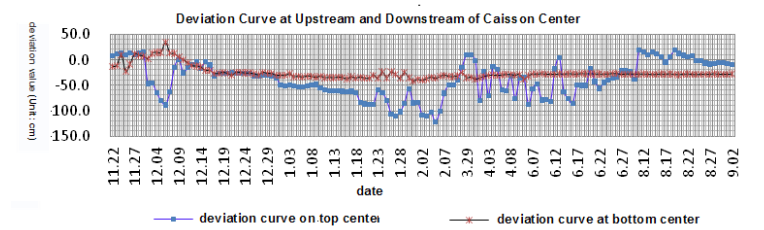

**Fig. 8 Deviation Curve at Upstream and Downstream of Caisson Center (Unit: cm)**

In Fig. 7 and Fig. 8, there are curves of two axis-direction deviations at caisson center, and the north-south deviation will take north as positive, upstream-downstream deviation will take south as positive. The curve with ■ means deviation curve on top center point, which shows big swing amplitude during the process of sinking. But when caisson is sinking to the designed elevation, the swing amplitude is small and deviation value is within 12cm (designed value is 50cm). The curve with ※ means deviation curve at bottom center point. After caisson implantation, especially the compartment concrete has been cast, the deviation is always in a stable condition. We can see that there are certain amounts of reserved deviations at the downstream site of bottom center point of caisson during the initial period of implantation. During the process of sinking, the bottom center point deviated toward upstream gradually, which is due to different side pressures aroused by riverbed elevation difference at upstream and downstream.

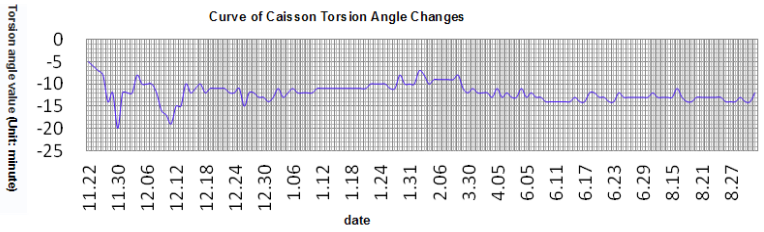

**Fig. 9 Curve of Caisson Torsion Angle Changes (Unit: minute)**

Fig. 9 shows the curve of caisson torsion angle changes, which takes clockwise direction as positive. The caisson torque is always controlled within 20 minutes, which means caisson is under the state of symmetric stress during the process of sinking and elevation joint. When sinking to position, the torque angle of caisson is 12 minutes, which is also in the allowable ranges.

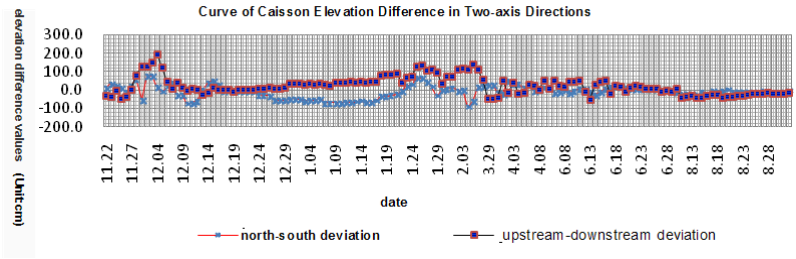

**Fig. 10 Curve of Caisson Elevation Difference in Two-axis Directions (unit: cm)**

Fig. 10 shows the relative elevation difference of caisson in two-axis direction, the north-south deviation will take north as positive and upstream-downstream deviation will take south as positive. In initial period of sinking, the elevation difference in two-axis direction may be large, but the elevation difference values will gradually change mildly after prompt adjustment. According to the Fig, when caisson is sinking to position, the top surface will in the horizontal condition.

In short, when caisson is sinking to position, the maximum deviation of top plane will be 11.4cm, tilt angle will be 1/363 and the torsion angle will be 10.8′, which are all less than the permissible values.

## Conclusion

Monitoring system of GPS positioning successfully completed the whole-process monitoring on middle-tower caisson construction of Taizhou Bridge. During construction, it really realized the automation, information monitoring technology, real-time display of caisson geometric postures, so as to provide technical support to caisson positioning, implantation and sinking with sludge. Meanwhile, because this technology is not influenced by the external environmental factors, it will greatly ensure the construction progress and shorten the construction period, then provide valuable references to similar projects, especially those under harsh environmental conditions.

# Triangle Interpolation on Discrete Point Set

Hongfei Jiang

School of Civil Engineering, Central South University, Changsha China 410075

jhf1967@163.com

**Keywords:** Cone; Interpolation; Discrete points; Mesh; Triangle

**Abstract.** An algorithm for triangle interpolation on discrete points is presented in the paper. It creates a square mesh which covers all the discrete points, then puts the points into the mesh and records the relationship between grids and points. When interpolating elevation of an interpolation point, it can fast find the discrete points which are near the interpolation point and these discrete points can be used to create a special triangle which contains the interpolation point. The elevation of the interpolation point can be obtained from the triangle. The method has the advantage of fast speed, high precision and needing less memory.

## Introduction

Interpolation based on discrete points has a wide variety of applications in GIS and CAD .It not only can create 3D terrain, to calculate ground slope and earthwork, but also is the foundation of realizing 3D visual design in civil engineering.

The key of the algorithm for interpolation is generation of a curved surface which can be used to calculate the value of the interpolation point, in general, the curved surface should not be created based on all discrete points for the number of discrete points is huge, in order to improve the interpolation speed and accuracy it only consists of several points which are near the interpolation point. There are two methods to create curved surface for interpolation. The first method uses a square mesh to administrate discrete points, discrete points can be easily positioned through square mesh; it uses the discrete points which are near the interpolation point to create a curved surface for interpolation, quadric surface or cubic surface is the most popular one for interpolation and it can be created by surfaces fitting method; the principle of this algorithm is simple and the method is easy to realize. The second method must create a triangular mesh based on the discrete points and every triangle can be used for interpolation, it uses the triangle which contains the interpolation point to calculate the value of the interpolation point; the method has higher precision, the shortcomings of the algorithm are that creating triangular mesh need much calculation and saving the triangles need much memory and the speed of searching the triangle which contains the interpolate point is slower.

In reference[4], a method for interpolation based on discrete points is presented, the method can fast find out the discrete points which is correlative to the given point by data blocking technology and block search technology, then interpolating the value of given point by distance weighted interpolating method, the method has a fast speed, but the precision of interpolation is not high because the method can not assure the distribution of discrete points selected by the method to interpolate the value of a given point is even and in some regions there are sudden changes which cannot be well described by discrete points.

In this paper a method for interpolation based on discrete points is presented, the method indexes the discrete points by a square mesh so we can fast find out the discrete points to take part in interpolation as long as we know the grid which the given point locates in when interpolating the

value of the given point, then a interpolating triangle which includes the given point can be created using the discrete points and the value of the given point can be obtained from the triangle.

**Principle of the Algorithm**

When interpolating the value of a given point, we know the value of the given point is mainly decided by the discrete point near the given point, so we hope to create an interpolation triangle to calculate the value of the given point and the triangle contains the given point and the vertices of the triangle are nearest to the given point.

Based on the idea, the algorithm of interpolation in this paper is based on discrete point digital terrain model, so we must build discrete point digital terrain model by general method before interpolation. Through the discrete point digital terrain model we can fast find out the discrete points which are correlative to the given point based on discrete point digital terrain model. To create the triangle, we first select two points which are nearest to the given point; then we select the third point to form a triangle which includes the given point and use the triangle to interpolate the value of the given point.

In order to introduce the algorithm in detail, the definition of cone is given as follows:

if C is a set in $R^n$ and C is not null, $x \in C, \forall p \in R^n \forall$ ,if $x + p \in C$, then $x + tp \in C(t \geq 0)$, set C is called a cone of vertex x. If cone C is convex, set C is called convex cone [5].

A set combined with several vectors $V_0, V_1, ..., V_m$, e.g. $c = \left\{ x \middle| x = x_0 + \sum_{i=0}^{m} r_i V_i, r_i \geq 0 \right\}$ is a convex cone of vertex $x_0$.

Especially, in 2D space, a convex cone making up of vector BA and vector BC is the ∠ABC (the angle is less than π).

In figure 1, the value of O is unknown, in order to calculate the value of O, At first, we can find out point A and point B in discrete points digital terrain model which are the nearest to point O, secondly, find out point P which is near point O and ΔPAB contains O and the shape of ΔPAB is good, finally, we can use ΔPAB to interpolate the value of point O.

In order to get point P, find out the points which is in the convex cone R making up of vector OC(namely -OB) and vector OD(namely -OA) . In following we prove that O is in ΔABP only when P is in convex cone R.

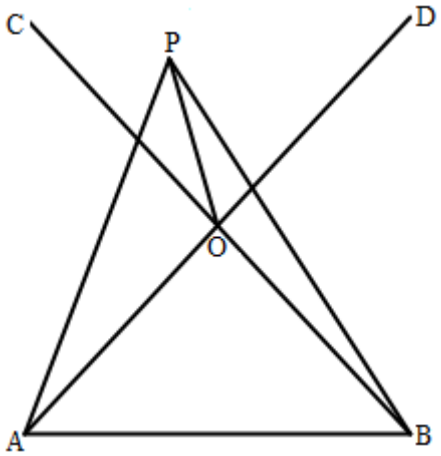

Fig.1 Interpolation triangle formation

Proof:

See figure 1, we can get:

$$OP = r_1 AO + r_2 BO, PB = -OP - BO, PA = -OP - AO \quad (1)$$

Then

$$PO = (r_1 PA + r_2 PB)/(1 + r_1 + r_2) \quad (2)$$

$$PA = PO + OA = (1 + r_1)OA + r_2 OB \quad (3)$$

$$AB = OB - OA \quad (4)$$

Now it is easy to get that:

$$AO = (AP + r_2 AB)/(1 + r_1 + r_2) \tag{5}$$

The following conclusion is available:

(1)When point P is in convex cone R, this means $r_1 \geq 0$ and $r_2 \geq 0$.

$r_1/(1+r_1+r_2) \geq 0$ and $r_2/(1+r_1+r_2) \geq 0$ is true. According to (2) and (5), we know O is not only in the convex cone making up of vector PA and vector PB but also in the convex cone making up of vector AP and vector AB, that means ∆PAB contains point O.

(2)When point P is not in convex cone R, then at least one of r1 and r2 must be less than 0.

$r_1/(1+r_1+r_2)$, $r_2/(1+r_1+r_2)$, $1/(1+r_1+r_2)$ must not be greater than 0 at same time. According to (2) and (5), we know that O is not only in the convex cone making up of vector PA and vector PB but also in the convex cone making up of vector AP and vector AB is impossible, so ∆PAB can not contain point O.

The following theorem can be gotten:

THEOREM: Given three points A,B,O, the sufficient condition of O is in ∆PAB is that P is in the convex cone making up of vector AO and vector BO.

The interpolating triangle can be built according to the following steps:

1.Search for point A and point B which are the nearest to point O to form the first side of interpolating triangle; then create a convex cone R by vector AO and vector BO, the vertex of the convex cone is O;

2.Find point P which is in convex cone R near point O, and ∆PAB is an interpolating triangle, if there are two or more points in convex cone R, several interpolating triangles can be created, the triangle which minimum angle is the greatest is the best for this method can avoid creating long and narrow interpolating triangle, and we certainly can use other law to select the third vertex of interpolating triangle.

It is possible that there are not any discrete points in convex cone R, if this happens, we cannot form an interpolating triangle but it is probable to create an interpolating triangle if we use other two points to form the first side of interpolating triangle, but the new two points should near O as far as possible, so we must consider this circumstances.

**Processing of Terrain Feature Lines**

According to the method presented in this paper, an interpolation triangle must be created for interpolating the height of given point, the shape of the interpolation triangle will greatly influence the precision of interpolation. Because the max-min angle law is used to create interpolation triangle, narrow and long interpolation triangle is effectively restricted. For general terrain, interpolation triangle is close to ground; when interpolation triangle crosses any terrain feature line, it is not close to ground, the precision of interpolation will be reduced. How to deal with this problem? An effective method is to keep interpolation triangle on one side of any terrain feature line; this measure can be taken on a special DTM with terrain feature lines; In this special DTM every grid in square mesh, which administrates discrete points, adds a message to record terrain feature lines which pass through it.

Now we can fast find out the disordered points and terrain feature lines which are near to interpolation point; these disordered points and vertexes of the terrain feature lines can be used to

create a triangle which contains the interpolation point by the method described above; if any side of the triangle do not cross any terrain feature line, the triangle is a interpolation triangle; otherwise, the triangle vertex should not take part in interpolation when the vertex and interpolation point are not on the same side of any terrain feature line and interpolation triangle must be created again until the triangle do not cross any terrain feature line.

## Conclusions

In order to test speed and accuracy of the interpolation method presented in this paper. Firstly, we build a discrete digital terrain model and a triangular grid digital model with the same discrete points, then creating a data elevation model (DEM) with three different interpolation methods. The first method is moving triangle interpolating method; the second method is triangular grid digital terrain model interpolating method; the third method is distance weighted interpolating method. There are 250000 discrete points and 50000 interpolating points, triangular grid digital terrain model interpolating method used 6 min, distance weighted interpolating method used 65s, moving triangle interpolating method used 90s, so moving triangle interpolating method has a fast interpolating speed.

After comparing the value of 1000 points which interpolated by three methods, we find the error of value of 10% points interpolated by distance weighted interpolating method is greater than 1.0 meter, and the max error of value is 5.1 meters; the corresponding values of moving triangle interpolating method are 1.8% and 1.72 meters; the corresponding values of triangular grid digital terrain model interpolating method are 2.3% and 1.80 meters. The contrast between the value of interpolation and practical terrain value is remarkable, the reason is in some areas density of the discrete points is too sparse so sometimes the shape of terrain can not be described with discrete points. Moreover, the test result shows that the precision of moving triangle interpolating method is higher than the precision of triangular grid digital terrain model interpolating method, the reason is the vertices of interpolating triangle creating with moving triangle interpolating method is selected based on interpolating point, the influence of three vertices upon the interpolating point is maximal; but the shape of triangles in triangular grid is considered based on whole triangular grid, so some triangles are not optimal to some interpolating points and the precision of moving triangle interpolating method is higher than the precision of triangular grid digital terrain model interpolating method at some time.

It can be seen that the moving triangle interpolation method based on normal discrete point digital terrain model presented in this paper can replace the interpolation method based on triangular grid digital terrain model. The algorithm can also increase the efficiency.

# Effect of ring support position and geometrical dimension on the free vibration of ring-stiffened cylindrical shells

Xiaowan Liu, Bin Liang

Civil Engineering School, Henan University of Science and Technology, Luoyang, 471023, China

**Key Words:** Ring-stiffened cylindrical shell; Free vibration; Rayleigh-Ritz method.

**Abstract:** Effect of ring support position and geometrical dimension on the free vibration of ring-stiffened cylindrical shells is studied in this paper. The study is carried out by using Sander's shell theory. Based on the Rayleigh-Ritz method, the shell eigenvalue governing equation is derived. The present analysis is validated by comparing results with those in the literature. The vibration characteristics are obtained investigating two different boundary conditions with simply supported-simply supported and clamped-free as the examples.

## Introduction

Ring-stiffened cylindrical shells，relying on its excellent strength , stiffness and buckling behaviors, have received considerable attention in many engineering applications. Studies on the cylindrical shells with intermediate ring support are rare. Among those who has studied vibrational behavior of the isotropic shells include Loy[1], Li gan[2], and composite shells contain Najafizadeh[3]. There are also some good reviews on the coupled vibration of shells with consideration of hydrostatic pressure[4]. Due to the complexity of the ring-stiffened factor and the limitations of analytic method, work on the vibrations of ring-stiffened cylindrical shells has some deficiencies so far.

Based on the Sander's shell theory and Rayleigh-Ritz method, the natural frequency of the cylindrical shell with Clamped-Free and Simply supported ends boundary conditions is obtained. Results are presented on the influence of ring support position and the influence of geometrical dimension.

## Theoretical formulation

Consider a cylindrical shell with internal ring support is shown in Figure 1. $R$ is the radius, $L$ is the length, $h$ donates the thickness and $a$ is the position of the ring support along the axial direction of

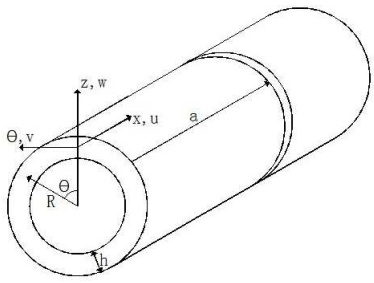

Fig.1 Geometry of ring-stiffened cylindrical shell

the cylindrical shell. The reference surface is taken to be the middle surface of the cylindrical shell where an orthogonal coordinate system $(x,\theta,z)$ is fixed. The $x,\theta$ and z are the axial coordinate, circumferential coordinate and radial coordinate, respectively.

The energy functional $\prod$ is given by the following Lagrangian function.

$$\prod = T_{\max} - U_{\max} \tag{1}$$

where $U_{\max}, T_{\max}$ are the maximum strain energy and kinetic energy.

$$\begin{aligned} U = \frac{1}{2}\int_0^L \int_0^{2\pi} \{ & \frac{E}{1-\mu^2} h[(u_x{}^2 + \frac{1}{R^2}(v_\theta + w)^2 + \frac{h^2}{12} w_{xx}{}^2 + \frac{h^2}{12R^4}(w_{\theta\theta} - v_\theta)^2 + \frac{2\mu}{R} u_x (v_\theta + w) + \\ & \frac{\mu h^2}{6R^2} w_{xx}(w_{\theta\theta} - v_\theta)] + \frac{Eh}{2(1+\mu)}(v_x + \frac{1}{R}u_\theta)^2 + \frac{Eh^3}{6(1+\mu)R^2}(w_{x\theta} + \frac{1}{4R}u_\theta - \frac{3}{4}v_x)^2 \} R dx d\theta \end{aligned} \tag{2}$$

$$T = \frac{1}{2}\int_0^L \int_0^{2\pi} \rho h \left[ u_t{}^2 + v_t{}^2 + w_t{}^2 \right] R dx d\theta \tag{3}$$

Where $E$ is the Young's modulus, $\rho$ is the mass density, $\mu$ is Poisson's ratio, and $u, v, w$ is the deformations in the $x, \theta, z$ directions.

The displacement field can be written in the following form.

$$\begin{cases} u(x,\theta,t) = A\dfrac{\partial \phi(x)}{\partial x}\cos(n\theta)\cos(\omega t) \\ v(x,\theta,t) = B\phi(x)\sin(n\theta)\cos(\omega t) \\ w(x,\theta,t) = C\phi(x)\prod_{i=1}^{N}(x-a_i)^{\xi_i}\cos(n\theta)\cos(\omega t) \end{cases} \tag{4}$$

where $A, B$ and $C$ denote the amplitudes of the vibrations in the $x, \theta$ and z directions, $n$ stands for the number of circumferential waves, $\omega$ is the natural angular frequency of the vibration, $\phi(x)$ is the axial function that satisfies the geometric boundary conditions [1], $a_i$ is the position of the $i$ th ring support and $N$ denotes the number of ring supports, $\xi_i$ is a parameter having a value of 1 when a ring support exists and 0 if there is no ring support.

Minimizing the energy functional with respect to the unknowns $A, B$ and $C$, a set of equations can be expressed as follows.

$$\begin{pmatrix} C_{11} & C_{12} & C_{13} \\ C_{12} & C_{22} & C_{23} \\ C_{13} & C_{23} & C_{33} \end{pmatrix} \begin{bmatrix} A \\ B \\ C \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \tag{5}$$

For a non-trivial solution of Eq.(5), equating the characteristic determinant to zero, a polynomial is obtained as follows.

$$\alpha_0\omega^6 + \alpha_1\omega^4 + \alpha_2\omega^2 + \alpha_3 = 0 \tag{6}$$

The three natural frequencies can be obtained by solving Eq.(6), and the smallest of the three ones is the frequency studied in the present study.

**Results and discussion**

To validate the present analysis, results for simply supported-simply supported and clamped-free cylindrical shells without ring supports are compared with Loy [1], see table 1, 2. The comparison show that the present results agree well with those in the literature.

Tab.1 Comparison of natural frequencies (HZ) for a simply supported cylindrical shell

| n | m | Loy[1] | present | different/% |
|---|---|---|---|---|
| 2 | 1 | 2043.8 | 2043.8 | 0 |
| | 2 | 5635.4 | 5635.4 | 0 |
| | 3 | 8932.5 | 8932.5 | 0 |
| | 4 | 11407.5 | 11407.5 | 0 |
| | 5 | 13253.2 | 13253.2 | 0 |

Tab.2 Comparison of natural frequencies (HZ) for a clamped-free cylindrical shell

| m | n | Loy[1] | present | different/% |
|---|---|---|---|---|
| 1 | 2 | 319.5 | 319.4 | 0.03 |
| | 3 | 769.9 | 769.8 | 0.04 |
| | 4 | 1465.7 | 1465.7 | 0 |
| | 5 | 2366.9 | 2366.9 | 0 |
| | 6 | 3479 | 3479 | 0 |

In this paper, studies are presented the influence of ring support position and geometrical dimension on a ring-stiffened cylindrical shell for simply supported-simply supported (S-S) and clamped-free (C-F) boundary conditions. Frequency parameter $w_f = \omega R\sqrt{(1-\mu^2)\rho/E}$, and Poisson ratio $\mu = 0.3$.

Figure 2 shows the vibration of the frequency parameter $w_f$ with the position of the ring support $a/L$ for S-S, C-F boundary conditions. For the same end conditions, such as S-S, the frequency cure is symmetrical about the center of the shell. Taking account of the frequency increasing with the ring support moving from the end to the center of the shell, the maximum frequency can be achieved with the ring support at the middle of the shell, and there is a significant difference between the maximum and minimum. But, for asymmetric end conditions, such as C-F, the frequency cure is not symmetrical about the center of the shell, and the maximum frequency lies in the range $a/L = 0.7 - 0.9$. Similarly, huge difference appears with the variation about the position of the ring support.

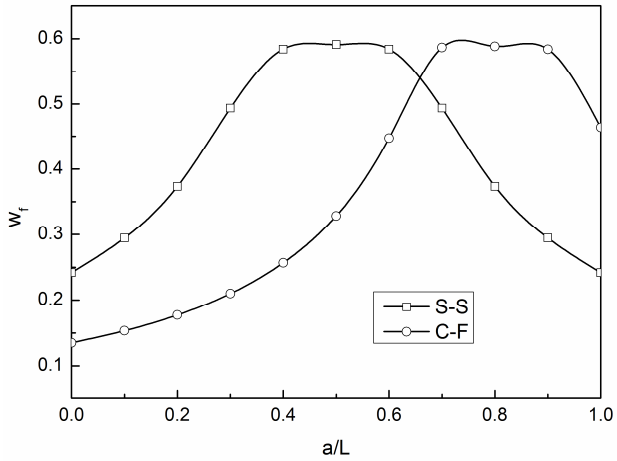

Fig.2 Variation of frequency parameter of cylindrical shells with the position of the ring support a/L

$$(L/R = 20, h/R = 0.01, m = 1, n = 1)$$

Figure 3 and 4 presented the influence of geometrical dimension on the vibration of the shell. Figure 3 shows the vibration of the frequency parameter with the position of the ring support $a/L$ at different $L/R$ ratios for the two boundary conditions. It is apparent that the frequencies are higher at small $L/R$, and the influence of the ring support position on the fundamental frequencies is significant at large $L/R$. Figure 4 shows the vibration of the frequency with the position of the

ring support $a/L$ at different $h/R$ ratios. As can be observed, the frequencies increase with the increasing $h/R$ ratio, and the influence on the fundamental frequencies is significant at small $h/R$ ratios.

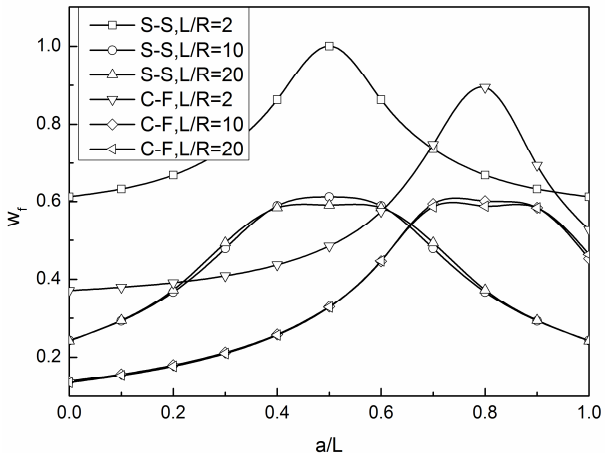

Fig.3 Variation of frequency parameter of cylindrical shells with different $L/R$ ratios ($h/R=0.01, m=1, n=1$)

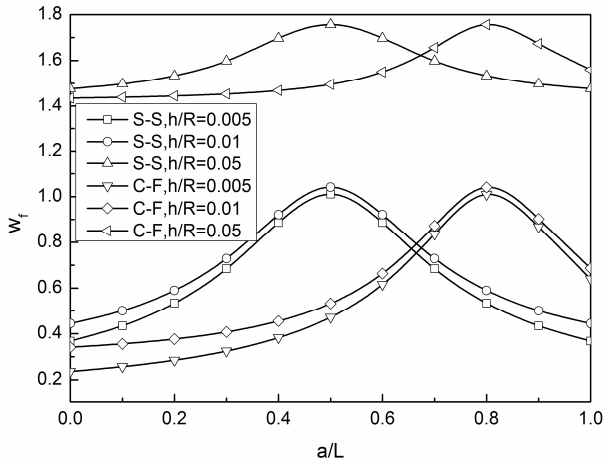

Fig.4 Variation of frequency parameter of cylindrical shells with different $h/R$ ratios ($L/R=20, m=1, n=10$)

## Conclusions

Based on the analysis of the frequency cures with the control factors, the study showed that the position of the ring support has a significant influence on the natural frequency, thus, appropriate ring support position should be taken into consideration in the structure design. The influence of geometric dimensioning on the vibrational behavior mainly presented at small $L/R$ ratio and large $h/R$ ratio.

# Increment-dimensional Precise Integration Method of Oil-water Coupling Flows in a Low Permeability Reservoir with Capillary Pressure

Fuliang Mei[1, a] and Guiling Li [1,b]

[1] Institute of Civil & Engineering, Jiaxing College, Jiaxing ,Zhejiang ,314001,China

[a]Flmei2005@126.com , [b]Lgljx@126.com

**Key words**: low permeability reservoir, startup pressure gradient, capillary force, two-phase flow, increment-dimensional precise integration method (IDPIM), state equation

**Abstract.** The simulation of two-phase oil-water coupling flows in a low permeability reservoir with capillary pressure and start-up pressure gradient was carried out. First of all, the state equations with all the oil pressures at grid nodes were established based on lump-centre finite difference method. Secondly, the recurrence formulae of all the oil pressures and water saturations at grid nodes were built up according to IDPIM and an explicit difference method, respectively. Finally, the simulation of two-phase oil-water coupling flows for a typical five point area water injection as an example was carried out. Simulating results show that capillary pressure has a little effect on moisture rate and oil production, but startup pressure gradients have an outstanding effect on them. Therefore the existence of startup pressure gradients will enhance the difficulty of oil development.

## Introduction

In the procedure of water-injected oil recovery for a low permeability reservoir, the governing equations of two-phase oil-water coupling seepages were always solved by IMPES [1-5], namely, implicitly find oil/water pressures and explicitly find water saturation. Although the implicit method is unconditionally steady, it can inevitably result in numerical instability and decline of accuracy when time step length or grid size is up to a degree. For satisfying requirements of numerical stability and accuracy the time step length or grid size has to be got small enough, but it takes much more CPU to simulate. In more than ten years IDPIM numerical stability and accuracy can be satisfied when time step length is got big enough in the simulation of structural dynamic response and fluid-solid coupling seepages in geotechnical mechanics, but IMPES's numerical stability can not be satisfied at the same time step length as IDPIM [7-8]. In this treatise IDPIM was first introduced into two-phase oil-water coupling flows in a low permeability reservoir with capillary pressure and startup pressure gradients in order to relieve or resolve the numerical instability due to bigger time step length or bigger grid size with IMPES.

## Mathematical Model

It is well-known that water/oil movement does not abide by Darcy flow law in a low permeability reservoir. Here a non-linear flow model with startup pressure gradients is used. Assuming oil, water and rock skeleton are tiny compressible. According to multi-phase fluid flow theory in a pore media, two-phase oil-water coupling seepage equations can be expressed as follows:

$$\nabla\cdot\left(\frac{KK_{rl}}{\mu_l}\nabla P_l\right)+\nabla\left(\frac{KK_{rl}}{\mu_l}G_l\right)+q_{lv}=\phi_i S_l C_{lt}\frac{\partial P_l}{\partial t}+\phi_i\frac{\partial S_l}{\partial t}\qquad (l=o,w) \tag{1}$$

Where $K$ is natural permeability, $K_{rl}$ relative permeability, $G_l$ startup pressure gradient, $\mu_l$ dynamic viscosity, $\phi_i$ initial porosity, $S_l$ saturation, $P_l$ pore pressure, $C_{lt}$ comprehensively compressive coefficient, $t$ time.

Subservience equation can be written as follows:

$$S_{\mathrm{o}}+S_{\mathrm{w}}=1 \tag{2}$$

Capillary force equation may be written as follows:

$$P_c(S_w)=P_o-P_w \tag{3}$$

Where $P_c$ is capillary pressure and it is a function of water saturation ( $S_W$ ).

Choosing oil pressure as unknown function and removing water pressure, a governing seepage equation can be written as follows:

$$\nabla\cdot(\alpha\nabla P_o)+\nabla\beta-\nabla\cdot(\gamma\nabla P_c)+q_{ov}+q_{wv}=\phi_i c_t\frac{\partial P_o}{\partial t} \tag{4}$$

Where $C_{\mathrm{t}}=S_{\mathrm{o}}C_{\mathrm{o}}+S_{\mathrm{w}}C_{\mathrm{w}}+C_{\varphi}$, $\alpha=K\left(\frac{K_{\mathrm{ro}}}{\mu_{\mathrm{o}}}+\frac{K_{\mathrm{rw}}}{\mu_{\mathrm{w}}}\right)$ , $\beta=K\left(\frac{K_{\mathrm{ro}}G_{\mathrm{o}}}{\mu_{\mathrm{o}}}+\frac{K_{\mathrm{rw}}G_{\mathrm{w}}}{\mu_{\mathrm{w}}}\right)$, $\gamma=\frac{KK_{ro}}{\mu_o}$, $C_{\mathrm{t}}$ is the comprehensively compressive coefficient .

**Formulations**

In this section all the formulae were deduced for two-dimension oil water coupling seepages in a low permeability reservoir. Supposing $\Delta x$ and $\Delta y$ be a uniform spacing along x and y–direction respectively, and $\Delta x=\Delta y$ . According to lump-centre finite difference principle and Eq.(4), a finite difference equation at ay grid node $(i,j)$ can be expressed as follows:

$$\begin{aligned}
&\phi_i C_t\Delta x^2\frac{\partial P_{oi,j}}{\partial t}=\alpha_{i,j+\frac{1}{2}}P_{oi,j+1}+\alpha_{i+\frac{1}{2},j}P_{oi+1,j}-(\alpha_{i,j+\frac{1}{2}}+\alpha_{i+\frac{1}{2},j}+\alpha_{i,j-\frac{1}{2}}+\alpha_{i-\frac{1}{2},j})P_{oi,j}\\
&+\alpha_{i,j-\frac{1}{2}}P_{oi,j-1}+\alpha_{i-\frac{1}{2},j}P_{oi-1,j}-\gamma_{i,j+\frac{1}{2}}P_{ci,j+1}-\gamma_{i+\frac{1}{2},j}P_{ci+1,j}+(\gamma_{i,j+\frac{1}{2}}+\gamma_{i+\frac{1}{2},j}+\gamma_{i,j-\frac{1}{2}}+\gamma_{i-\frac{1}{2},j})P_{ci,j}\\
&-\gamma_{i,j-\frac{1}{2}}P_{ci,j-1}-\gamma_{i-\frac{1}{2},j}P_{ci-1,j}+\Delta x\left(\beta_{i+\frac{1}{2},j}-\beta_{i-\frac{1}{2},j}\right)+\Delta x\left(\beta_{i,j+\frac{1}{2}}-\beta_{i,j-\frac{1}{2}}\right)+Q_{OVi,j}+Q_{WVi,j}
\end{aligned} \tag{5}$$

Volumetric water flux per thickness locating at a water-injected well is calculated as follows:

$$Q_{WV1}=\frac{2\pi KK_{\mathrm{rw}}(1-S_{\mathrm{or}})(P_{\mathrm{w}i}-P_{wi,j}-r_{\mathrm{e}}G_{\mathrm{w}})}{\mu_{\mathrm{w}}\ln\frac{r_{\mathrm{e}}}{r_{\mathrm{w}}}} \tag{6}$$

Where $P_{wi}$ is water fluid pressure at a water-injected well, $r_w$ radius of the water-injected well, $r_e = 0.208\sqrt{\Delta x \Delta y}$ equivalent supply radius .

Volumetric water/oil fluxes per thickness locating at a liquid-recovered well are computerized respectively as follows:

$$Q_{\mathrm{WV}\,2} = \frac{2\pi KK_{\mathrm{rw}}\left(P_{wi,j} - P_{\mathrm{wp}} - r_{\mathrm{e}}G_{\mathrm{w}}\right)}{\mu_{\mathrm{w}}\ln\dfrac{r_{\mathrm{e}}}{r_{\mathrm{w}}}} \qquad Q_{\mathrm{OV}\,2} = \frac{2\pi KK_{\mathrm{ro}}\left(P_{oi,j} - P_{\mathrm{op}} - r_{\mathrm{e}}G_{\mathrm{o}}\right)}{\mu_{\mathrm{o}}\ln\dfrac{r_{\mathrm{e}}}{r_{\mathrm{w}}}} \tag{7}$$

Where $P_{wp}$ and $P_{op}$ stand for water and oil pressure at the liquid-recovered well, respectively.

Assembling Eqs.(4-7) together, a group of state equations with all the unknown oil pressures can be expressed as follows:

$$\frac{\partial \mathbf{x}}{\partial t} = \mathbf{H}\mathbf{x} + \mathbf{y} \tag{8}$$

Where $\mathbf{x}$ is a column vector of all the unknown oil pressures, $\mathbf{H}$ coefficient matrix of $\mathbf{x}$, $\mathbf{y}$ column vector of all the non-homogeneous items . Assuming all the unknown oil pressures is N. For sake of avoiding calculating the inverse matrix of $\mathbf{H}$, IDPIM is used. Introducing a new variable $x_{N+1}$ and supposing $x_{N+1}$ is a constant of 1, Eq.(8) can be transformed as follows:

$$\dot{X} = \begin{bmatrix} \dot{\mathbf{x}} \\ \dot{x}_{N+1} \end{bmatrix} = \begin{bmatrix} \mathbf{H} & \mathbf{y} \\ \mathbf{0} & 0 \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ x_{N+1} \end{bmatrix} = \mathbf{W}\mathbf{X} \tag{9}$$

Where $\dot{\mathbf{X}} = \partial \mathbf{X}/\partial t$, $\dot{\mathbf{x}} = \partial \mathbf{x}/\partial t$, $\mathbf{W} = \begin{bmatrix} \mathbf{H} & \mathbf{y} \\ \mathbf{0} & 0 \end{bmatrix}$.

It should be noted that Eq.(9) is a group of nonlinear homogenous state equations in form. Uniformly averaging time domain, say, $t_k = k\Delta t\ (k = 0,1,2,\cdots)$. Where $\Delta t$ is time step length. In interval $[t_k, t_{k+1}]$, Eq.(9) may be rewritten as follows:

$$\dot{\mathbf{X}}(t) = \mathbf{W}(t)\mathbf{X}(t) \tag{10}$$

Where $\mathbf{W}(t)$ may be viewed as a constant matrix in the interval $[t_k, t_{k+1}]$ when the time step length $\Delta t$ is small enough, say, $\mathbf{W}(t)$ can be equal to $\mathbf{W}(k\Delta t)$. Based on matrix theory the solution of Eq.(11) can be written as follows:

$$\mathbf{X}((k+1)\Delta t) = \exp(\Delta t \mathbf{W}(k\Delta t))\mathbf{X}(k\Delta t) = \left[\exp\left(\mathbf{W}(k\Delta t)\cdot \Delta t / m\right)\right]^m \mathbf{X}(k\Delta t) \tag{11}$$

Where the exponent matrix in Eq.(11) can be calculated using a time-precise integration method in literature[9] .

Using Eq.(11) and all the known oil pressures at $t_k$, all the unknown oil pressures can be found at $t_{k+1}$. And then all the unknown water pressures can be computed at $t_{k+1}$ utilizing Eq.(3) and all the known water saturations at $t_k$. Above the calculating procedure is called as IDPIM.

For Eq.(1) using a lump-centre finite difference method in spatial domain and a backward difference method in time domain, respectively, a finite difference equation at a grid node $(i, j)$ can be got as follows:

$$S_{wi,j}^{k+1} = S_{wi,j}^{k} + \frac{\Delta t}{\phi_i \Delta x^2}\left[\alpha^k_{wi,j-\frac{1}{2}} P^{k+1}_{wi,j-1} + \alpha^k_{wi-\frac{1}{2},j} P^{k+1}_{wi-1,j} - \left(\alpha^k_{wi,j-\frac{1}{2}} + \alpha^k_{wi-\frac{1}{2},j} + \alpha^k_{wi,j+\frac{1}{2}} + \alpha^k_{wi+\frac{1}{2},j}\right) P^{k+1}_{wi,j}\right.$$

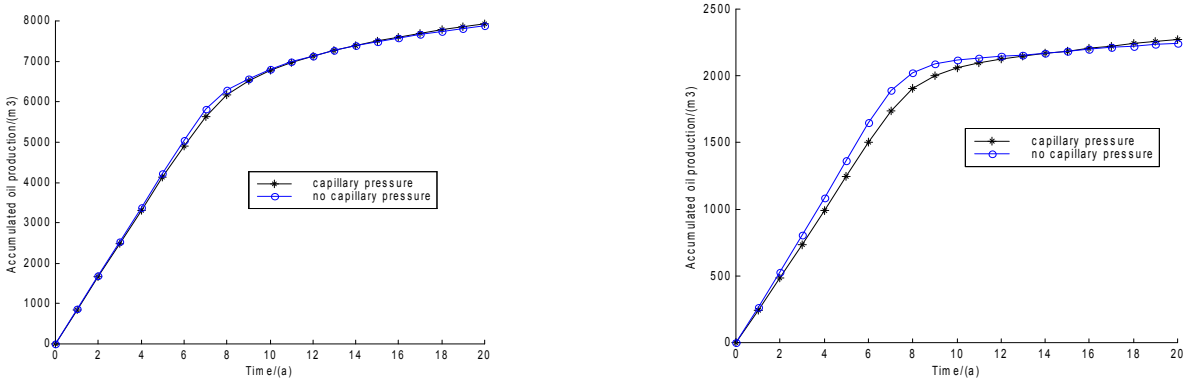
$$\left. + \alpha^k_{wi,j+\frac{1}{2}} P^{k+1}_{wi,j+1} + \alpha^k_{wi+\frac{1}{2},j} P^{k+1}_{wi+1,j} - \Delta x\left(\beta^k_{wi+\frac{1}{2},j} - \beta^k_{wi-\frac{1}{2},j}\right) - \Delta x\left(\beta^k_{wi,j+\frac{1}{2}} - \beta^k_{wi,j-\frac{1}{2}}\right) + Q_{WVi,j}\right]$$

$$- \phi_i C_{wt}\left(P^{k+1}_{wi,j} - P^{k}_{wi,j}\right) \tag{12}$$

**Results and Analysis**

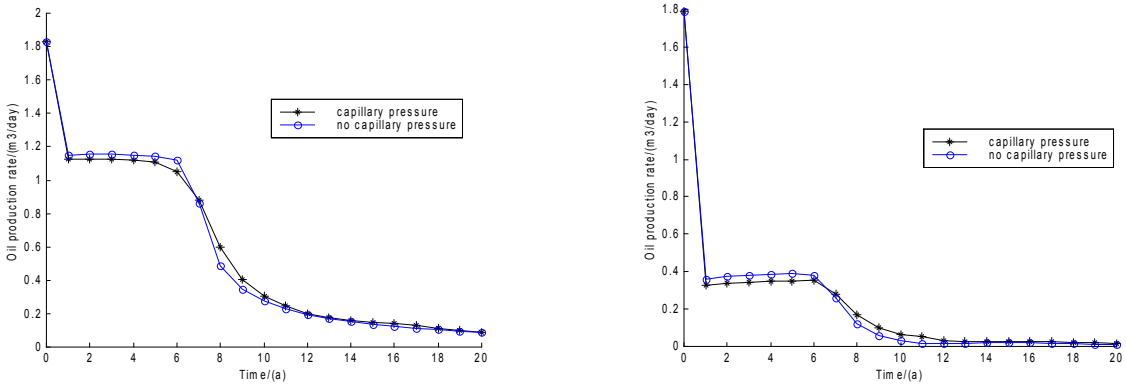
There is a typical five-point injection water reservoir as an example. Its distance is 150m from the water-injected well to the oil-recovered well, and its thickness is 10m. Other parameters are: natural permeability $K$ is $0.01\,\mu m^2$, initial fluid pressure is 12Mpa, $P_{wp}$ is 18Mpa, $P_{wi}$ is 6Mpa, $\mu_o = 1$mPa.s, $\mu_w = 5$mPa.s, $G_o$=0.01Mpa and $G_w$=0.1$G_o$. Relations between capillary pressure and water saturation $(S_w)$ and relative permeability curves with relation to oil/water-phase from literature [10]. For sake of investigating the effects of capillary pressure, start-up pressure gradients on the accumulated oil production quantity, oil production rate and moisture content at the oil-recovered well, the start-up pressure gradient $G_o$ is from 0.0Mpa to 0.04Mpa while $G_w$ is 0.1 times of $G_o$, two case with relation to capillary pressure are utilized as follows: capillary pressure and no capillary pressure , and other parameters are the same as those in previous section. Computational results are shown in Figs.(1-3).

Fig.(1) gives the accumulated oil production with time. The accumulated oil production is proportional to time within initial stage of oil recovery, but it nonlinearly increases with time within later stage of oil recovery. The increase of the accumulated oil production within initial stage of oil recovery is much bigger than that within later stage of oil recovery. The accumulated oil production decreases with the increase of start-up pressure gradients.



(a) $G_o = 0.0MPa, G_w = 0.1G_oMPa$ (b) $G_o = 0.04MPa, G_w = 0.1G_oMPa$

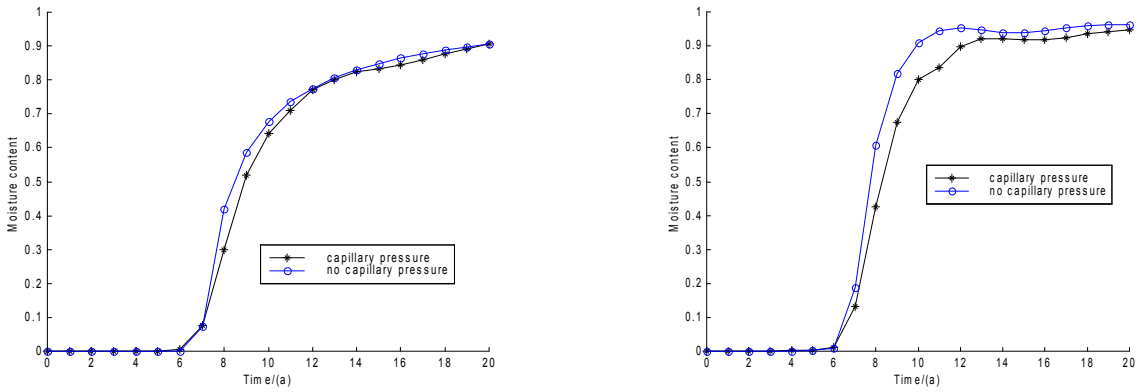
Fig.1 Accumulated oil production versus time



(a) $G_o = 0.0MPa, G_w = 0.1G_oMPa$ (b) $G_o = 0.04MPa, G_w = 0.1G_oMPa$

Fig.2 Oil production rate versus time

Fig.(2) describes the oil production rate varying with time. It can be seen from Fig.(2) that oil production rate changing with time can be divided four stages: first fast decline ( 0-1 year), constant(1-6 years), second fast decline(6-10 years), smooth-steady ( after 10 years). The start-up pressure gradients have an important influence on the oil production rate. The oil production rate decreases with increase of the start-up pressure gradients. The capillary pressure has a little influence on the oil production rate, too. The oil production rate with capillary pressure is smaller than that without capillary pressure within the constant stage of the oil production rate. And then the decline of the oil production rate with capillary pressure is slower than that without capillary pressure within the second fast decline stage of the oil production rate. But the oil production rate with capillary pressure is basically the same as that without capillary pressure within the first fast decline and smooth-steady stages.



(a) $G_o = 0.0MPa, G_w = 0.1G_oMPa$ (b) $G_o = 0.04MPa, G_w = 0.1G_oMPa$

Fig.3 Water saturation at an oil-recovered well versus time

Fig.(3) describes the water saturation at the oil-recovered well varying with time. It goes through three stages: no water-production, fast water-production, slow water-production. The start-up pressure gradients have an important influence on the water saturation after water begins to come out at the oil-recovered well, and the water saturation increases with increase of the start-up pressure gradients. The appearance of water at the oil-recovered well with capillary pressure is earlier than that without capillary pressure.

## Conclusions

There are a few conclusions:(1) IDPIM is a higher property numerical method;(2) In a word, the start-up pressure gradients have a more important influence on oil-recovered parameters such as oil production rate than the capillary pressure;(3) The decline of oil production with capillary pressure is slower than that without capillary pressure around the appearance of water at the oil-recovered well. The anhydrous harvest period with capillary pressure is shorter than that without capillary pressure, and the rise of water production with capillary pressure is slower than that without capillary pressure;(4) The smaller is oil production the bigger are start-up pressure gradients. The rise of water saturation with start-up pressure gradients is faster than that without start-up pressure gradients. Therefore the existence of start-up pressure gradients enhances the difficulty of oil development.

**Keyword:** Vertical vibration; Surface velocity; Liquid bridge, Level set method

**Abstract.** In this paper, the vertical vibration influence on the surface velocity of a 5cSt silicone oil liquid bridge has been investigated numerically. The Navier-Stokes equations coupled with the energy conservation equation are solved on a staggered grid, and the two-phase surface is captured by using the mass conserving level set method. The present results indicate that the axial and radial surface velocities of the liquid bridge are suppressed by the external vertical vibration.

## Introduction

Buoyancy convection becomes relatively weak in the microgravity environment and the convection driven by surface tension rises to dominance. The thermocapillary convection is a typical convection induced by the gradient of surface tension on the gas-liquid surface, which has a strong application background of space material processing. So many researches about this convection have been carried out in recent years. The influence of vibration on the surface flow field of half-floating zone liquid bridge has also been greatly concerned, and this kind of researches may help understand the mechanism of thermocapillary convection.

Kanashima et al.[1] studied the influence of G-jitter on the liquid bridge surface deformation in the thermocapillary convection experiment at the International space station. They discovered that the surface deformation of natural thermocapillary convection can distinguish with surface deformation generated on resonance and non-resonant frequency. Tang and Hu[2] studied influence of high frequency vibration on the critical Ma number and they pointed out that when the frequency of the applied vibration is large enough, the extent of temperature fluctuation disappears. Moreover, the surface of the liquid bridge does not exhibit fluctuation due to the inertia effect. Anilkumar[3] studied the relationship between amplitude, temperature on the liquid bridge surface and additional vertical vibration under normal gravity. They concluded that the velocity of the surface flow increases along as the increasing of the vibration frequency, amplitude and length of floating zone, while the velocity of the surface flow decreases as a decreasing in the viscosity of the liquid bridge. Moreover, they also discussed influence of the vertical vibration on the internal temperature distribution in the liquid bridge.

The present paper studies the vertical vibration influence on the surface velocity of a 5cSt silicone oil liquid bridge. The free surface deformation is captured by introducing the mass conserving level set method[4].

## Physical and Mathematic models

**Physical Model.** The simplified model of the floating-zone method is adopted in the present paper as shown in Fig.1.

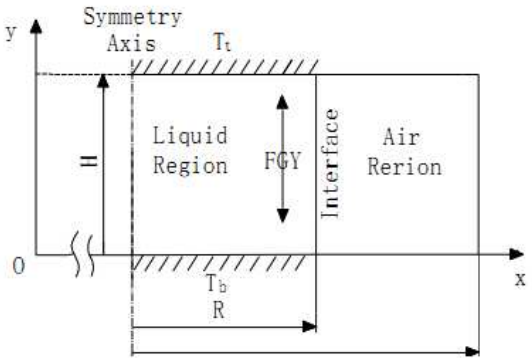

Fig. 1 Schematic of a half-zone liquid bridge model

The height of the liquid bridge is H. $T_t$ is the temperature at the upper disk, and $T_b$ is temperature at the bottom disk. The difference of the upper and the bottom disks is $\Delta T = T_t - T_b$. The radius and height of the liquid bridge are R and H, respectively.

**Controlling Equations.** The basic governing equations of half-floating zone thermocapillary convection include the mass, momentum, and energy conservation equations. Basic non-dimensional governing equations are given as following:

$$\mathbf{u}_t + (\mathbf{u}\cdot\nabla)\mathbf{u} = \mathbf{g}_u + \frac{1}{\rho}\left(-\nabla p + \frac{1}{\mathrm{Re}}\nabla\cdot(2\mu\mathbf{D}) + \left(\frac{1}{\mathrm{We}} - \frac{\mathrm{Ca}}{\mathrm{We}}\Theta\right)\kappa\delta(d)\mathbf{n}\right) + FGY \tag{1}$$

$$\nabla\cdot\mathbf{u} = 0 \tag{2}$$

$$\frac{\partial\Theta}{\partial t} + \nabla\cdot(\mathbf{u}\Theta) = \frac{1}{Ma}\nabla^2\Theta \tag{3}$$

$$\frac{\partial\phi}{\partial t} + \overline{V}\cdot\nabla\phi = 0 \tag{4}$$

where $\mathbf{u} = (u,v)$ is the fluid velocity, $\rho = \rho(\mathbf{x},t)$ is the fluid density, $\mu = \mu(\mathbf{x},t)$ is the fluid viscosity, $\mathbf{D}$ is the viscous stress tensor, $\kappa$ is the curvature of the interface, $d$ is the normal distance to the interface, $\delta$ is the Dirac delta function, $\mathbf{n}$ is the unit normal vector at the interface, $t$ is the dimensionless time, $p$ is the pressure. The surface tension coefficient is considered to be a linearly function of temperature and defined as $\sigma = \sigma_c - \sigma_T(T - T_b)$, where $\sigma_c$ is a reference value of surface tension and $\sigma_T$ is the temperature coefficient of surface tension and we denote $\sigma_T = \partial\sigma/\partial T$, and $T$ is the temperature. $FGY$ is a body force induced by a external acceleration, which is used when a external acceleration is applied, $FGY = g_y\overline{L}/U_\infty^2$, $g_y$ is the external acceleration in Y direction, $g_y = A\omega^2\sin\omega\bar{t}$, $A$ is the vibration amplitude, and $\omega$ is the angular frequency, $\omega = 2\pi f$, and $f$ is the vibration frequency. $\overline{L}$ is characteristic length and we take $\overline{L} = D$, where $D$ is the initial diameter of the droplet. $U_\infty$ is the characteristic velocity and we take $U_\infty = \sqrt{Dg}$ under normal gravity, while $U_\infty = \sigma_T\Delta T/\mu_l$ under microgravity, where $g$ is the gravitational acceleration, $\bar{t}$ is dimensional time, $\bar{t} = t/\overline{L}/U_\infty$.

The key parameters are $\rho_g/\rho_l$ and $\mu_g/\mu_l$, the dimensionless density and viscosity ratio inside the ambient air region, respectively. $\rho_l$ and $\mu_l$ are the dimensional density and viscosity of the liquid bridge, respectively, while $\rho_g$ and $\mu_g$ are the dimensional density and viscosity of the ambient air, respectively. The dimensionless density ($\rho_l/\rho_l$) and viscosity ($\mu_l/\mu_l$) inside the liquid bridge are both equal to 1. $\mathrm{Re} = \rho_l U_\infty\overline{L}/\mu_l$, Reynolds number, $\mathrm{We} = \rho_l U_\infty^2\overline{L}/\sigma$, Weber number, $\mathrm{Pr} = \mu_l/\rho_l a$, Prandtl number, $\mathrm{Ca} = \mu_l U_\infty/\sigma$, Capillary number, $a$ is the thermal diffusivity and $\mathbf{g}_u$ represents a unit gravitational force, $\overline{V} = (u,v)$ is fluid velocity, $\phi$ is the level set function.

### Boundary and Initial conditions

All walls of the computational region are assumed to be adiabatic，and the temperatures at the hot and cold disks of the liquid bridge are maintained at constant temperature $T_t$ and $T_b$, respectively, with a temperature difference of $\Delta T$. Consequently, the following boundaries conditions should be satisfied.

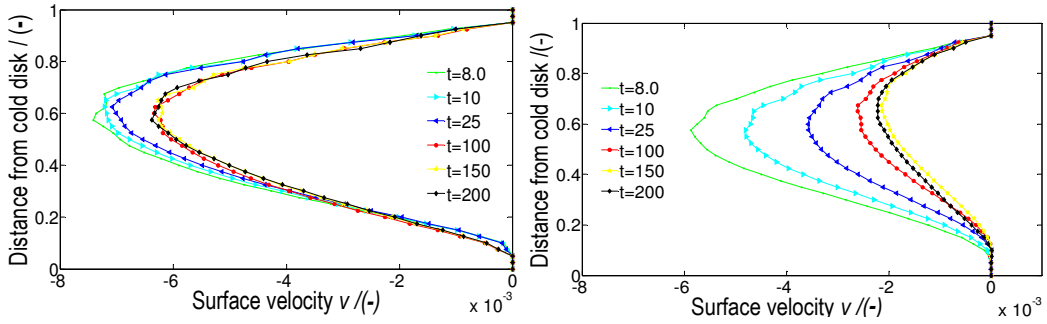
$$\Theta = 0 \quad (z = 0), \Theta = 1.0 \quad (z = 1.0)$$

No-slip boundary condition is adopted on the wall, $\mathbf{u}(t=0) = 0$

Initial conditions is used as follow, $\mathbf{u}(t=0) = 0$

### Results and Discussion

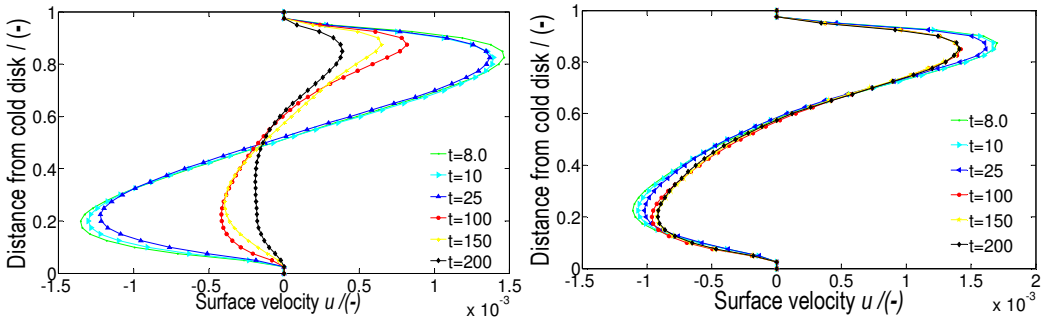
In this paper, we study the vertical vibration influence on the surface velocity of a 5cSt silicone oil liquid bridge under external vertical vibration. The diameter of upper and bottom disks is D=10 mm. The aspect ratio (H/R) is 0.5. We add a 20mg vertical vibration (FGY) to the liquid bridge. The main parameters involved in the calculation include Reynolds number Re=320, Weber number We=3.5, Prandtl number Pr=69, Capillary number Ca=5. The temperature difference between the top and bottom of the disc is $25°C$, density ratio is $\rho_g / \rho_l = 1.350\times10^{-3}$, and viscosity ratio is $\mu_g / \mu_l = 5.528\times10^{-3}$.



(a) 0Hz (b) 5Hz

Fig. 2 Surface axial velocity at different times（Pr=69, Re=320, Ma=22037, FGY=20mg） (a) 0Hz, (b) 5Hz

Figure 2 shows the surface axial velocity distribution of the liquid bridge without or with an external vertical vibration of 5Hz. It can be found that the surface axial velocities are all below zero in Fig.2 (a)-(b), indicating that the surface liquid flows from the upper disk to the cold disk, and the maximum of axial surface velocity is obtained at the distance of 0.6H from the cold disk. In Fig. 2(a), the axial surface velocity decreases from t=8.0 to t=100, and then it becomes stable from t=100 to t=200, which illustrates that the axial surface velocity becomes gradually small and then reaches a steady state. In Fig. 2(b), the axial surface velocity decreases from t=8.0 to t=150, and then it becomes stable from t=150 to t=200, which illustrates that the axial surface velocity becomes gradually small. In addition, the difference between the surface axial velocity at t=8.0 and t=200 in Fig. 2(b) (with external vibration) is greatly larger than that in Fig. 2(a) (without external vibration), indicating that the external vibration suppresses the surface axial velocity.



(a) 0Hz (b) 5Hz

Fig. 3 Surface radial velocity at different times（Pr= 69, Re=320, Ma=22037, FGY=20mg） (a) 0Hz, (b) 5Hz

Figure 3 shows the surface radial velocity distribution of the liquid bridge without or with an external vertical vibration of 5Hz. In Fig. 3(a), the radial surface velocity changes slightly from t=8.0 to t=25, while it decreases greatly from t=25 to t=200, which illustrates that the radial surface velocity becomes gradually small and then reaches a steady state. The positive and negative values of velocities indicate that the direction of the fluid motion. Its value is positive at the positions above 0.5H distance from the cold disk and negative at the positions below 0.5H from the cold disk, which means that the radial velocity of the liquid bridge surface is positive near the upper disk and is negative near the cold disk. The radial velocity of the liquid bridge surface is zero in the middle region. It reflects that the radial velocity distribution of thermocapillary convection in the liquid bridge as well as the trend of the liquid bridge surface deformation. The maximum of the negative velocity appears at 0.2H from the cold disk and the maximum of the positive velocity appears at 0.8H from the cold disk in Fig. 3(a)-(b). As shown in Fig. 3(b), the radial velocity of the liquid bridge changes little from t=8.0 to t=200 under the external vertical vibration of 5Hz. Therefore, the external vibration makes the difference of the radial velocities at different times becoming small.

## Conclusions

In this paper, we studied the 5cSt silicone oil liquid bridge under the vertical direction to study the vertical vibration influence on the surface velocity of the liquid bridge, and the following conclusions are drawn,

1. The axial and radial velocities on the surface of the liquid bridge change a lot at the initial period with the external vertical vibration, while it changes little at the stable period. Moreover, the radial and axial velocities are suppressed by the the external vertical vibration.
2. The maximum of the axial surface velocity of the liquid bridge appears at 0.6H from the cold disk, while the maximum of the radial surface velocity appears at 0.2H and 0.8H from the cold disk, respectively, with and without the external vertical vibration.
3. The external vibration suppresses the surface axial velocity, while the external vibration makes the difference of the radial velocities at different times becoming small.

**Keywords:** constitutive equation of concrete, linear equation, disturbance variable, finite element analysis.

**Abstract.** A linearization method of the uniaxial non-fitting nonlinear stress-strain curve given by the author of the paper is presented. The evolution equation between disturbances variable $D$ and plastic strain $\varepsilon_p$ is derived based on Theory of Duality Disturbance. A simple method for concrete structures preforming elastoplastic analysis is presented (including softening analysis).

## Introduction

Concrete is a kind of multiphase material composed of sand and cement. The mechanical behavior is very complicated due to influences of the water-cement ratio, curing conditions, loading path, ect. Display nonlinear damage, strain softening, the hydrostatic pressure effect [1].

Scholars presented different damage models in accordance with specific constitutive relation of concrete[2-5]. However, most of them are difficult to be used in engineering because of the particularity of its application conditions and the model complexly. It is important to establish the constitutive relation that is of succinct mechanical concepts,can be used to simulate complex mechanical behaviors of concrete structures.

A reduced method of uniaxial non-fitting nonlinear stress-strain curve is given in this paper. The linearization method for concrete structure preforming elastoplastic disturbance simulation is set up based on Theory of Duality Disturbance[6].

## Non-fitting stress - strain equation

Stress-strain relation is the essential constitutive relation of describing concrete mechanical properties. Numerous scholars established the concrete stress-strain equation [7-9]. The first author of the paper established a non-fitting nonlinear stress-strain curve by means of the experimental data of concrete under uniaxial tension-compression, using the informations about the initial elastic modulus $E_0$, peak stress $\sigma_{cb}$, peak strain $\varepsilon_{cb}$, stress inflexion $\sigma_{inf}$ and strain inflexion $\varepsilon_{inf}$, the continuity of curve and the softening inflexion information such as the second derivative is zero, after that established the non-fitting of the nonlinear stress-strain relationship [10]. Uniaxial compression stress-strain curve, Fig.1.

$$\sigma = a\varepsilon(1+b\varepsilon^m) \tag{1}$$

Where, $a = E_0$, $m = \dfrac{E_0 - E_0\varepsilon_{cb} + \sigma_{cb}}{E_0\varepsilon_{cb} - \sigma_{cb}}$, $b = \dfrac{\sigma_{cb} - E_0\varepsilon_{cb}}{E_0\varepsilon_{cb}^{(E_0 - E_0\varepsilon_{cb} + \sigma_{cb})/(E_0\varepsilon_{cb} - \sigma_{cb})}}$. The stress-strain relationship in the stage of softening of uniaxial compression is expressed as

$$\sigma = C/(1 - Ae^{-B\varepsilon}) \tag{2}$$

Where, $C = 3\sigma_{inf}/2$, $B = \ln(3\sigma_{inf}/\sigma_{cb} - 2)/\xi_{inf}$, $A = 1 - 3\sigma_{inf}/2\sigma_{cb}$, $\xi_{inf} = \varepsilon_{inf} - \varepsilon_{cb}$,

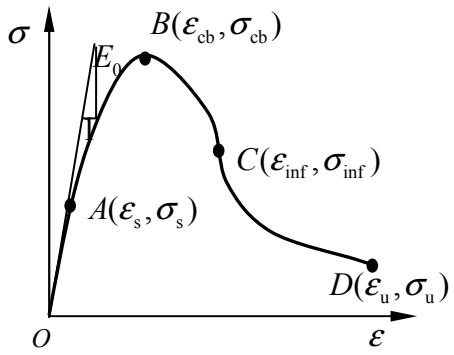

Fig.1 Uniaxial compression

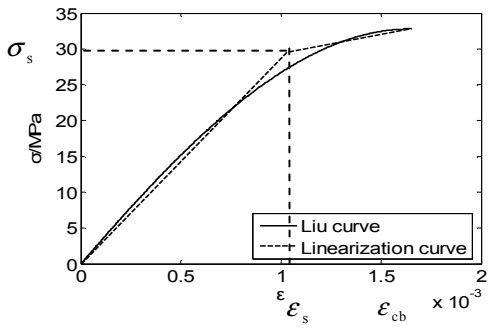

Fig.2 Linearized nonlinear stress-strain equation

**Linearization of the non-fitting stress-strain equation**

The first author of the paper presents a linearization method of nonlinear equation which based on the assumption of strain energy equivalent [11].

According to the assumption of strain energy equivalent, have

$$U_{\text{Non-linear}} = U_{\text{linear}} \tag{3}$$

Where, $U_{\text{Non-linear}}$ is the area of nonlinear reinforcement under the strain of changeover portion; $U_{\text{linear}}$ is the area of the linear under the stress and strain. Using the above condition, the linearize relation is expressed as

$$\begin{cases} \sigma = E_L \varepsilon & (0 \le \varepsilon \le \varepsilon_s) \\ \sigma = \sigma_s + E_1(\varepsilon - \varepsilon_s) & (\varepsilon_s < \varepsilon \le \varepsilon_{cb}) \end{cases} \tag{4}$$

Where, $\varepsilon_s = (a+1)\varepsilon_{cb} - 2W/\sigma_{cb}$, $W = a\left[\varepsilon_{cb}^2/2 + b\varepsilon_{cb}^{m+2}/(m+2)\right]$, $\alpha = (2W/\sigma_{cb} - \varepsilon_{cb})E_0/(\varepsilon_{cb}E_0 - \sigma_{cb})$, $E_L = \alpha\sigma_{cb}/[(a+1)\varepsilon_{cb} - 2W/\sigma_{cb}]$, $E_1 = (\sigma_{cb} - \sigma_s)/(\varepsilon_{cb} - \varepsilon_s)$ .The linearization stress-strain curve in strengthen potion of Kupper test is shown as dotted line in Fig.2.

**The basic equations of the Theory of Duality Disturbance**

The first author of this paper put forword the Theory of Duality Disturbance [6]. The constitutive equation of Theory of Duality Disturbance is expressed as

$$\sigma_{ij}^{o} = (1-D)\sigma_{ij}^{n} + D\sigma_{ij}^{c} \tag{5}$$

Where, $\sigma_{ij}^{o}$ is observed stress; $\sigma_{ij}^{n}$ is the stress at Relatively Non-Disturbed (RND) state; $\sigma_{ij}^{c}$ is the stress at Relatively Complete Disturbed (RCD) state. $D$ is disturbance variable. It is assumed that $D$ is the function of plastic strain trajectory $\xi^{p}$ . i.e.

$$D = D(\xi^{p}) \tag{6}$$

$$\xi^{p} = c\int \mathrm{d}\xi^{p} = c\int \sqrt{\mathrm{d}\varepsilon_{ij}^{p}\mathrm{d}\varepsilon_{ij}^{p}} \tag{7}$$

Where, $\xi^{p}$ shows the accumulation of plastic strain in whole process of deformation(including loading and unloading processes), which is a increasing function. Equation (5) is applied to three-dimensional stress state. In order to make $\xi^{p}$ veduced as uniaxial plastic strain $\varepsilon^{p}$ for uniaxial stress state, the parameter $c = c(\mu)$ is introduced. Where $\mu$ is Poisson's ratio.

For uniaxial observed stress state as shown in Fig. 3 , RND stress-strain curve $\sigma^{n} - \varepsilon^{n}$ and RCD stress-strain curve $\sigma^{c} - \varepsilon^{c}$ are taken as

$$\sigma^{n} = E_0\varepsilon^{n}, \sigma^{c} = 0 \tag{8}$$

From Fig.3, we can see that observed strain $\boldsymbol{\varepsilon}^{o}$, RND strain $\boldsymbol{\varepsilon}^{n}$ and RCD strain $\boldsymbol{\varepsilon}^{c}$ are equal. i.e. $\boldsymbol{\varepsilon}^{o}=\boldsymbol{\varepsilon}^{n}=\boldsymbol{\varepsilon}^{c}=\boldsymbol{\varepsilon}$.This is so called total strain equivalent assumption .

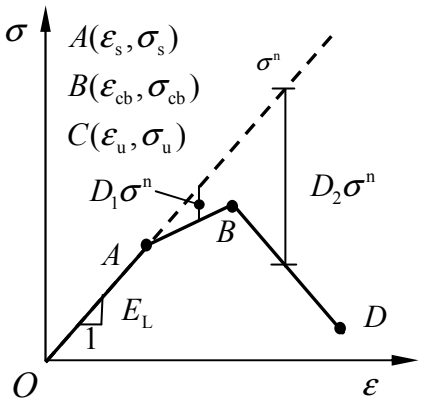

Fig.3 $\sigma^{n}-\varepsilon$ curve and $\sigma^{o}-\varepsilon$

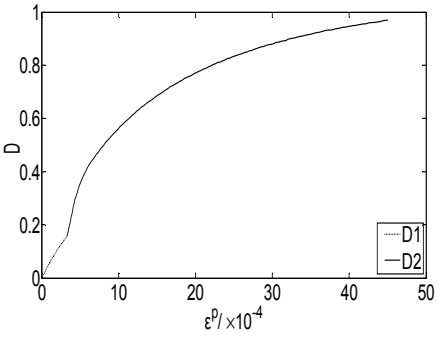

Fig.4 Disturbance *D*-plastic strain $\varepsilon_{p}$ curve of *ABD*

$D=D(\varepsilon_{p})$ curve can be derived by $D=1-\sigma^{o}/\sigma^{n}$. For the linear hardening stage (*OAB*), the observed stress $\sigma^{o}$ is expressed as

$$\sigma^{o}=\sigma_{s}+E_{1}\varepsilon_{p}/(1\text{-}E_{1}/E_{L}) \tag{9}$$

Where, $\varepsilon_{s}\le\varepsilon\le\varepsilon_{cb}$, $\varepsilon_{p}=\varepsilon-\varepsilon_{e}=\varepsilon-\sigma^{o}/E_{L}$.

The relation between disturbance variable $D_{1}$ and plastic strain $\varepsilon_{p}$ can be expressed as

$$D_{1}=1-\frac{\sigma_{s}+E_{1}(\sigma^{o}/E_{L}+\varepsilon_{p}\text{-}\varepsilon_{s})}{\sigma_{s}+E_{1}\varepsilon_{p}} \tag{10}$$

For the softening damage stage (*BD*), the observed stress $\sigma^{o}$ is expressed as

$$\sigma^{o}=k\varepsilon+b=k(\varepsilon_{e}+\varepsilon_{p})+b=k(\sigma^{o}/E+\varepsilon_{p})+b\quad(\varepsilon_{cb}\le\varepsilon\le\varepsilon_{u}) \tag{11}$$

Where, $E=E_{0}[1-\alpha(\varepsilon/\varepsilon_{u})^{n}]$, n=1.5, $\alpha=1-E_{u}/E_{0}$, $\varepsilon_{p}=\varepsilon-\varepsilon_{e}=\varepsilon-\sigma^{o}/E$, $k=(\sigma_{u}-\sigma_{cb})/(\varepsilon_{u}-\varepsilon_{cb})$, $b=\sigma_{cb}-k\varepsilon_{cb}$, $\sigma_{u}$-Ultimate stress, $\varepsilon_{u}$-Ultimate strain.

The relationship between disturbance variable $D_{2}$ and plastic strain $\varepsilon_{p}$ can be expressed as

$$D_{2}=1-[k(\varepsilon_{p}+\sigma^{o}/E)+b]/[E_{L}(\varepsilon_{p}+\sigma^{o}/E)] \tag{12}$$

The relation between disturbance variable $D$ and plastic strain $\varepsilon_{p}$ based on Kupfer text is showed as in Fig. 4. $D_{1}$ and $D_{2}$ correspond to strengthening stage (*AB*) and softening damage stage (*BD*), respectively.

**Verification of the constitutive equation**

Applying the linearization method set up in this paper to predict the compression behavior of the concrete used in Kupfer text. The finite element model is taken as a concrete block of 50mm×150mm×50mm, $E_{0}=26.7$GPa, $\mu=0.2$. The lower end (*xOy* surface) is restrained, i.e, $u_{x}=u_{y}=u_{z}=0$. Uniform lode $q$ is exerted at the upper surface, as showed in Fig.5. In this paper, in order to certify the result of the analysis model, ANSYS code is used to perform linear elastic finite element analysis. Select a RND model $\sigma^{n}=E_{0}\varepsilon$. $q$ is exerted from 10MPa to 150MPa with load step =10MPa.

The stress-strain relation of the node, which is at the *AB* axle and 10mm from *B*, is analyzed. The stress-strain relation in a RND model is shown with solid dots, and the observed stress-strain relation in concrete $\sigma^{o}-\varepsilon$ predicted by the linearization method present in this paper is shown with asterisks, as showed in Fig.6.

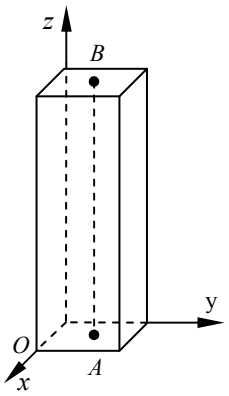

Fig.5 The finite element model

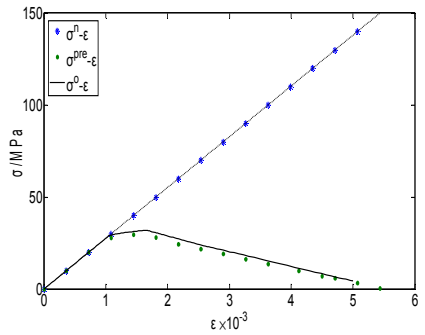

Fig.6 The stress analysis corresponding to $\sigma^{n}-\varepsilon$ curve in pressure

Experimental results show that the simulation results are in agreement with experimental results, which prove the correctness of the linearization model.

## Conclusions

The linearization method of non-fitting nonlinear equation is given based on the assumption of strain energy equivalent. Taking RND model as linear elastic, the evolution equation of disturbance with plastic strainis derived based on Theory of Duality Disturbance. A simple method simulating complex mechanical behavior of concrete structures is presented.

**Keywords:** method of extended domain, numerical methods, boundary problem, structural analysis, mesh functions, approximation of operators, averaging

**Abstract.** The distinctive paper is devoted to general principles of mesh approximation for boundary problems of structural analysis with the use of so-called method of extended domain, proposed by Prof. Alexander B. Zolotov [1-4]. In particular we studied questions dealing with approximation of domain, approximation of functions and approximations of operators. Mesh functions are introduced as well as corresponding mesh operations and various types of implementation. The results are rather efficient algorithms in respect to number of operations, computing time and required memory.

## Approximation of domain.

Let Ω be the domain occupied by considering structure. The given domain Ω is embordered by extended one $\omega$ of arbitrary shape, particularly elementary (for instance, parallelepiped, cylinder and others) [4]. Cross-section of extended domain perpendicular to basic direction is optimally approximated by mesh, topologically equivalent to rectangular (Fig. 1).

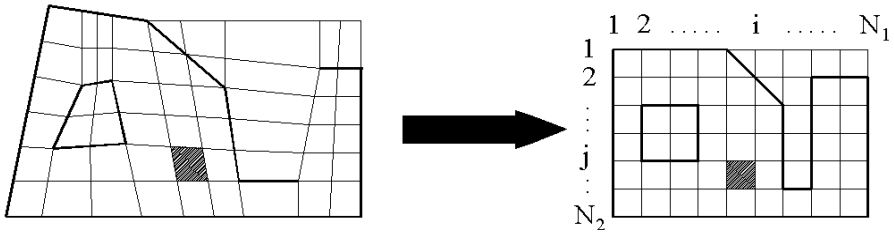

Fig. 1. Sample of approximating mesh.

Concept of topological equivalence in the distinctive case implies that this mesh can be constructed from rectangular one by nondegenerate deformation of its cells without twisting. This type of meshes enables approximations of various structures and buildings on the one hand and allows application of simple regular numeration of nodes on the other hand. This leads to convenient mathematical formulas, effective computational schemes and algorithms, simple data processing and so on. Switch to rectangular mesh can be performed by introduction of corresponding local coordinate system within each cell. General form of equations stays invariable after mesh lining in distinction from matrix elements of original equation set. Direct application of rectangular meshes is especially effective in many instances due to considerable simplification and speed-up of all algorithms. In this connection researcher can use high-density meshes with number of nodes more than ever before and consequently obtain solution with extra accuracy. We should stress the point that inconformity of mesh and contour of structure is allowed [4].

## Approximation of functions.

**2.1. Mesh functions and corresponding operations.** All functions and parameters of boundary problem can be represented with the use of mesh functions. Mesh functions yields dimensions with the same bounds $\varphi(i_1,...,i_N)=\varphi(i)=\overline{\varphi},\ \ i_k=1,...,m_k,\ \ k=1,...,N.$

We will turn down symbol "-" for short in some formulas. Notation $\varphi(i_k \pm 1)$ symbolize increase (decrease) by one of index number $k$: $\varphi(i_k \pm 1) = \varphi(i_1, ..., i_{k-1}, i_k \pm 1, ..., i_{k+1}, ..., i_N)$.
We should also introduce mesh operations in each index line $k = 1, ..., N$:

– "shift": $(C_k^{\pm}\varphi)(i) = \varphi(i_k \pm 1)$; (1)

– "averaging" $(T_k^{\pm}\varphi)(i) = \varphi(i) + \varphi(i_k \pm 1)$; (2)

– "forward difference" $(D_k^{+}\varphi)(i) = \varphi(i_k \pm 1) - \varphi(i)$; (3)

– "backward difference" $(D_k^{-}\varphi)(i) = \varphi(i) - \varphi(i_k - 1)$; (4)

– "identity operator" $(E\varphi)(i) = \varphi(i)$; (5)

– scalar product $(\varphi, \psi) = \sum_{i_1=1}^{m_1} \dots \sum_{i_N=1}^{m_N} \varphi(i_1, ..., i_N)\psi(i_1, ..., i_N)$. (6)

$$T^{\pm} = E + C^{\pm}; \quad D^{+} = C^{+} - E; \quad D^{-} = E - C^{-}; \quad C^{\pm}C^{\mp} = E; \quad C^{\pm}\varphi C^{\mp}u = [C^{\pm}\varphi]u. \tag{7}$$

Let us note that $k$ is arbitrary in (7) and therefore it is turned down. Operations (1)-(5) take into account that $\varphi(i) = 0$ if $i_k < 1$ or $i_k > m_k$, $k = 1, ..., N$. Square brackets in (7) are used for restriction of range of operation. Symbol "+" in the notations of forward operations will be turned down as well. Conjugate operations relative to scalar product are used instead of backward ones. We can also use the following notation: $C = C^{+}$, $T = T^{+}$, $D = D^{+}$. It can be shown in the usual way that $(C^{+}u, v) = (u, C^{-}v)$ and $C^{*} = C^{-}$. In a similar manner $(C^{-})^{*} = C^{+} = C$. Since $E^{*} = E$, it follows that $C^{*} = C^{-}$, $T^{*} = T^{-} = C^{*} + E$, $D^{*} = -D^{-} = C^{*} - E$. Finally note that this operators are commutative in each index line(s) $k$. Let us also remark that mesh operations are vector-mode to the effect that they operate on data bulk. We believe that low-level programming language (for instance Assembler) is especially useful for PC realization. In any case formulation of discrete analogues in mesh terms leads to fastest computing circuits [4].

**2.2. Implementation of mesh functions.** Mesh functions are defined by their nodal values, however original continual boundary problem is defined at all points of the considering domain. Thus we have to implement mesh functions in additional points. This implementation is performed locally at each cell. In most cases we use piece-wise linear (multilinear) approximation within cells and local coordinate systems are introduced in this connection: $x = (x_1, ..., x_N) \Rightarrow (i_1, ..., i_N; t_1, ..., t_N) = (i, t)$. Rectangular meshes with unit array pitch in all directions are considered: $u(x) \Rightarrow u(i, t)$, where $t_k \in [0, 1]$ are local coordinates within mesh elements; $u(i, t)$ is implemented mesh function. For instance, in *N*-dimensional case mesh function is implemented by formulas

$$u(i, t) = \prod_{k=1}^{N} (1 + t_k \Delta_k) u(i), \quad x_k \in [x_k(i), x_k(i_k + 1)], \quad k = 1, ..., N; \tag{8}$$

$$\bar{u}(t) = \Lambda \bar{u}, \quad 0 \le t_k \le 1, \quad \Lambda = \prod_{k=1}^{N} \Lambda_k, \quad \Lambda_k = E + t_k D_k; \quad \partial_k \bar{u}(t) = D_k \tilde{\Lambda}_k \bar{u}, \quad \tilde{\Lambda}_k = \prod_{s \ne k} \Lambda_s, \tag{9}$$

where $\bar{u} = u(i)$ is mesh function; $\bar{u}(t)$ is implemented function, defined in each point of the considering domain; $t = (t_1, ..., t_N)$.
Piece-wise constant implementation of mesh function $\varphi(i)$ within cell elements is wide-spread as well in problems of structural analysis. In particular it can be used for functions corresponding to physical parameters of structures. Here we have $\varphi(i) = 0$ if there is some $i_k = m_k$.

**2.3. Scalar product of implemented functions.** Let us use the following notations for short

$$\sum_{i}^{m-1} = \sum_{i_1=1}^{m_1-1} \dots \sum_{i_N=1}^{m_N-1} \; ; \quad \int_0^1 (\;) dt = \int_0^1 \dots \int_0^1 (\;) dt_1 \dots dt_N \; . \tag{10}$$

Thus, we have

$$(u,v)_x = \sum_{i_1=1}^{m_1-1} \dots \sum_{i_N=1}^{m_N-1} \int_0^1 \dots \int_0^1 u(i,t)v(i,t)dt_1 \dots dt_N = \sum_{i}^{m-1} \theta_\omega(i) \int_0^1 u(i,t)v(i,t)dt = \int_0^1 (\theta_\omega \bar{u}(t), \bar{v}(t))_i dt \; ; \tag{11}$$

$$\theta_\omega(i) = \begin{cases} 1, & i_k < m_k \quad \text{for all} \quad k = 1, ..., N \\ 0, & \text{otherwise i.e. } \exists k : \; i_k = m_k . \end{cases} \tag{12}$$

$\theta_\omega$ is piece-wise constant characteristic function of the mesh, which indicates belonging of the considering mesh element to interior of the extended domain. Symbol $(\;,\;)_i$ denotes scalar product which is taken over $i$ i.e. we have mesh scalar product; $t$ is parameter. The application of formula of implementation yields to the following expressions:

$$(u,v)_x = \int_0^1 (\theta_\omega \Lambda \bar{u}, \Lambda \bar{v})_i dt = \int_0^1 (\Lambda^* \theta_\omega \Lambda \bar{u}, \bar{v})_i dt = (\int_0^1 \Lambda^* \theta_\omega \Lambda dt \cdot \bar{u}, \bar{v})_i \; ; \tag{13}$$

$$(Lu,v)_x = \int_0^1 (L\Lambda \bar{u}, \Lambda \bar{v})_i dt = \int_0^1 (\Lambda^* L \Lambda \bar{u}, \bar{v})_i dt = (\int_0^1 \Lambda^* L \Lambda dt \cdot \bar{u}, \bar{v})_i \; . \tag{14}$$

Let's note, that we normally have situation when functions $u$ or $v$ represent expression $L\varphi$ including characteristic function $\theta$ of the original domain. Support of $\theta_\omega$ contain support of $\theta$ and we can turn down first function. Thus we can get final discrete relations depending on (14), form of $L$ and method of integration with respect to $t$. Hereinafter we will turn down for short indexes $x$ and $i$ indicating space for scalar product.

**2.3. Approximation of operators.** Discrete approximation of original boundary problem presupposes its consideration in the space of implemented mesh functions. Solution of the problem $\boldsymbol{L}u = \boldsymbol{F}$ is considered as a generalized i.e. $(\boldsymbol{L}u, v) = (\boldsymbol{F}, v)$, where $v$ is arbitrary exploratory function. We have to take $u$ and $v$ from mesh functions class in order to obtain approximation of the problem. Elliptic second order differential operator $L$ is the main part of $\boldsymbol{L}$,

$$L = \{L_{pq}\}_{p,q=1,...,M} \; ; \quad L = \{L_{pq}^{st}\}^{s,t=1,...,N} \; ; \quad L_{pq}^{st} = \partial_p^* a_{p,q}^{s,t} \partial_q \; . \tag{15}$$

Hence consideration of $L = \partial_p^* a \partial_q$ or expression $(\partial_p^* a \partial_q u, v) = (a \partial_q u, \partial_p v)$ is of paramount importance. Here $a = \theta a$. Subtracting implemented mesh functions for $u$ and $v$ after taking into account commutativity of $D$ and $\Lambda$ we get

$$(Lu,v) = ((\int_0^1 (D_p^* \tilde{\Lambda}_p^* a D_q \tilde{\Lambda}_q dt)\bar{u}, \bar{v}) \; . \tag{16}$$

We can perform analytical integration with respect to $t$ here. However restriction of the problem to the class of implemented functions in itself leads to errors and therefore analytical integration is

beside the purpose. Approximate integration is recommended here but for all that method of integration should have the order of error equal to corresponding order in mesh approximation. This leads to more simple formulations, fast and effective algorithms. We particularly mentioned method of trapezoids here. Functions $a_{pq}^{st}$ in their turn for many real-world problems can be approximated by functions with constant values in the cell. The results are most compact formulas. They can be obtained in the usual way with the use of (8) and commutativity of all $\Lambda_k$ with each other and other operators. Moreover we take into consideration their sole depending on $t_k$, (10) and commutativity of integrals. Using method of trapezoids we get the auxiliary formulas:

$$\int_0^1 \Lambda_k dt_k \approx 0.5 \cdot T_k; \quad \int_0^1 \Lambda_k^* a \Lambda_k dt_k \approx 0.5 \cdot [T_k^* \alpha]; \quad \int_0^1 \Lambda_k^* dt_k \approx \frac{1}{2} T_k^*; \quad \int_0^1 a dt_k \approx \alpha, \tag{17}$$

where $\alpha$ is the piecewise constant mesh function. The final formulas of discrete approximation of operators can be obtained on the basis of (17) and after numerous transformations have the form:

$$(\partial_p^* a \partial_q u, v) \approx \frac{1}{2^N} (D_p^* T_q^* \left[ \prod_{\substack{k \neq p \\ k \neq q}} T_k^* \alpha \right] T_p D_q \bar{u}, \bar{v}), \quad p \neq q; \quad (\partial_p^* a \partial_p u, v) \approx \frac{1}{2^{N-1}} (D_p^* \left[ \prod_{k \neq p} T_k^* \alpha \right] D_p \bar{u}, \bar{v}). \tag{18}$$

Formulas of approximation of zero order and first order operators are the following

$$(\partial_p^* a u, v) \approx \frac{1}{2^N} (D_p^* \left[ \prod_{k \neq p} T_k^* \alpha \right] T_p \bar{u}, \bar{v}); \quad (a \partial_p u, v) \approx \frac{1}{2^N} (T_q^* \left[ \prod_{k \neq p} T_k^* \alpha \right] D_q \bar{u}, \bar{v}); \tag{19}$$

$$(au, v) \approx \frac{1}{2^N} (\left[ \prod_{k=1}^N T_k^* \alpha \right] \bar{u}, \bar{v}). \tag{20}$$

Consider a general case of elliptic second order self-adjoint differential operator

$$L\bar{u} = \sum_{i=1}^N \sum_{j=1}^N \partial_i^* A_{i,j} \partial_j \bar{u}; \quad A_{i,j} = \begin{bmatrix} a_{i,j}^{1,1} & a_{i,j}^{1,2} & \dots & a_{i,j}^{1,M} \\ a_{i,j}^{2,1} & a_{i,j}^{2,2} & \dots & a_{i,j}^{2,M} \\ \dots & \dots & \dots & \dots \\ a_{i,j}^{M,1} & a_{i,j}^{M,2} & \dots & a_{i,j}^{M,M} \end{bmatrix} = \{a_{ij}^{pq}\}_{p,q=1,\dots,M}; \quad \bar{u} = \begin{bmatrix} u_1 \\ u_2 \\ \dots \\ u_N \end{bmatrix}; \quad A_{i,j} = A_{j,i}^*. \tag{21}$$

Using (18)-(20) we get explicit formula of its discrete approximation:

$$L\bar{u} = \sum_{p=1}^N \left( D_p^* \tilde{A}_{p,p} D_p + \sum_{q \neq p} D_p^* T_q^* \tilde{A}_{p,q} T_p D_q \right) \bar{u}; \quad \tilde{A}_{p,p} = \frac{1}{2^{N-1}} \prod_{k \neq p} T_k^* \bar{A}_{p,p}; \quad \tilde{A}_{p,q} = \frac{1}{2^N} \prod_{k \neq p,q} T_k^* \bar{A}_{p,q}, \tag{22}$$

where $N$ is the number of coordinates; $M$ is function space dimension; $\bar{u}$ is piecewise linear mesh function approximating original function; $\bar{A}_{p,q}$ – piecewise constant mesh approximation of operator coefficients. In arbitrary coordinate system we have

$$\mathsf{A}_{p,q} = J \alpha_{Ep}^* A_{p,q} \alpha_{Eq}; \quad \alpha_E = \alpha \otimes E_M; \quad \alpha_E^* = \alpha^* \otimes E_M; \tag{23}$$

$$\bar{A}_{pq} = \int_0^1 \mathsf{A}_{pq} dt = \int_0^1 \dots \int_0^1 J \alpha_{Ep}^* A_{pq} \alpha_{Eq} dt_1 \dots dt_N. \tag{24}$$

where $\alpha_{Ei}$ is block column of matrix $\alpha_E$ with Jacobian $J$ and Jacobi matrix corresponding to local element transformation of original coordinate system into system where approximating mesh become rectangular with unit array pitch; $E_M$ is identity matrix of the $N$ th order; $\otimes$ is the symbol of direct product. If we choose piecewise constant mesh approximation for $\alpha_{pq}$, $J$ and $\alpha_{pq}$ taking corresponding values in centers of cells, we will have the most simple formula

$$\overline{A}_{p,q} = J\alpha^*_{Ep} A_{p,q} \alpha_{Eq}, \quad t_1 = \ldots = t_N = 0.5. \tag{25}$$

In a special case with rectangular mesh

$$\overline{A}_{p,q}(i) = \frac{1}{h_p(i)h_q(i)} \int_{x_1(i_1)}^{x_1(i_1+1)} \ldots \int_{x_N(i_N)}^{x_N(i_N+1)} A_{p,q} dx_1 \ldots dx_N; \quad \alpha_{p,q} = \begin{cases} 1/h_p, & p = q \\ 0, & p \neq q; \end{cases} \quad J = h_1 \ldots h_N; \tag{26}$$

$$h_p(i) = x_p(i_p + 1) - x_p(i), \quad p = 1, ..., N. \tag{27}$$

Generally $J$ and $\alpha$ depends solely on mesh geometry and normally computed once at the beginning of data processing. In problems with constant $a^{s,t}_{p,q}$ (linear problems with standard parameters) matrices $\widetilde{A}_{p,q}$ computed once too. Piecewise linear approximation leads to effective final formulas of discrete operators. However rapid varying of coefficients within one cell due to heterogeneity of materials, their physical parameters or curvature of cell cause considerable errors. Therefore correct mesh allows strong reducing of errors. The above formulas of discrete approximation for elliptic second order differential operator represent algorithm for computing $Lu$. In other words they may be included into arbitrary step-by-step method. We should stress that operator matrix forming is not required. Upon the whole this is rather efficient method in respect to number of operations, computing time and required memory [4].

**Key words**: Tissue engineering, Porous scaffold, Velocity distribution, Pressure distribution

**Abstract:** Models with main-branch channel, crossing channel and net type channel are established and nutrient liquid with a velocity of 0.01m/s is adopted in the study to investigate the fluid field in the channel by using FEA software FLUENT. The velocity and pressure distribution have been obtained in the investigation. By comparing the results in the three models, pressure and velocity distribution in the second and the third models are relatively uniform and are appropriate for the bionics principles. Studies in this paper will be of benefits for the development of tissue engineering.

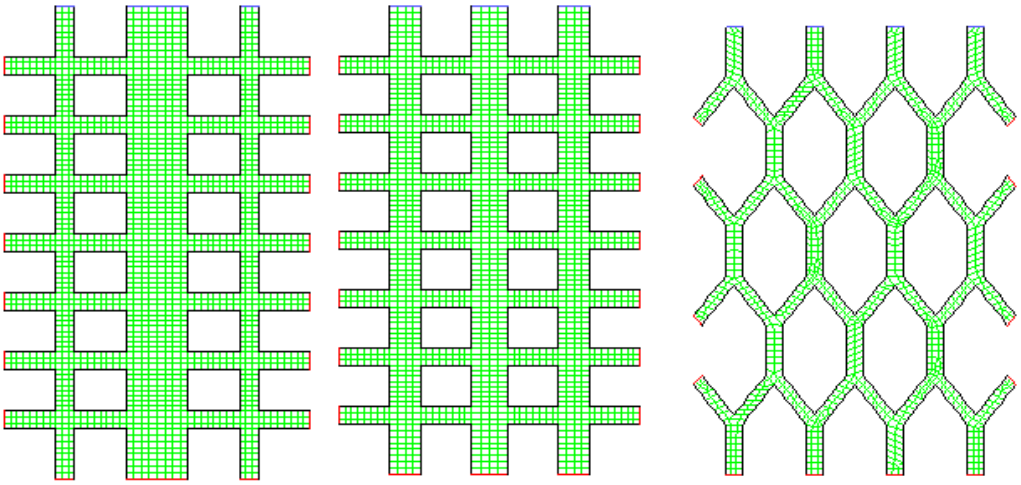
## Introduction

Tissue engineering is a kind of new technology which is also called regenerative medical science, and in this technology bioactive tissues are manufactured outside organisms, and can be used for repairing or replacing organ or tissue for organism [1]. This technology was first declared by the US national science fund committee in 1987, and was developed quickly in the following years. Today, this technology has spread into many science and technology fields such as biology science, material science [2]. This technology has been used in many organs such as bone [3-5].

In this paper, fluid fields in models of porous scaffolds with different internal channels have been studied by using FEA software FLUENT, and the studies in this paper may of a certain sense for the development in tissue engineering.

## Models and the corresponding parameters

As shown in Fig.1, three models are adopted in this study.



Model 1 Model 2 Model 3

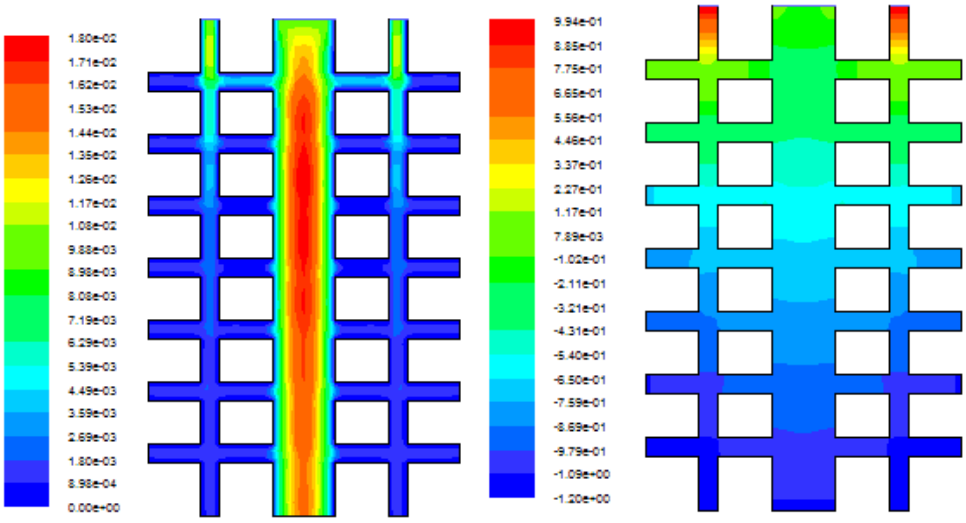
Fig.1 Models

In Fig.1, Model 1 is consist of one main channel and several branch channels and is call a main-branch channel model. Model 2 is consist of several horizontal and vertical channels and is called a crossing channel model. In model 3, channels are arranged in net type and model 3 is called a net type channel model. Nutrient liquid used in this simulation is considered to be of a velocity of

0.01m/s, a density of 1000kg/m$^3$, and a viscosity of 0.0018 Pa·s. The power device in the simulation is set as peristaltic pump. By using FEA software FLUENT, velocity and pressure distribution of the nutrient liquid in the channels have been obtained.

**Simulation results and analysis**

Velocity and pressure distributions for the three models are shown in Fig.2 to Fig. 4. In these figures, the unit of pressure is Pa and the unit of the velocity is m/s.

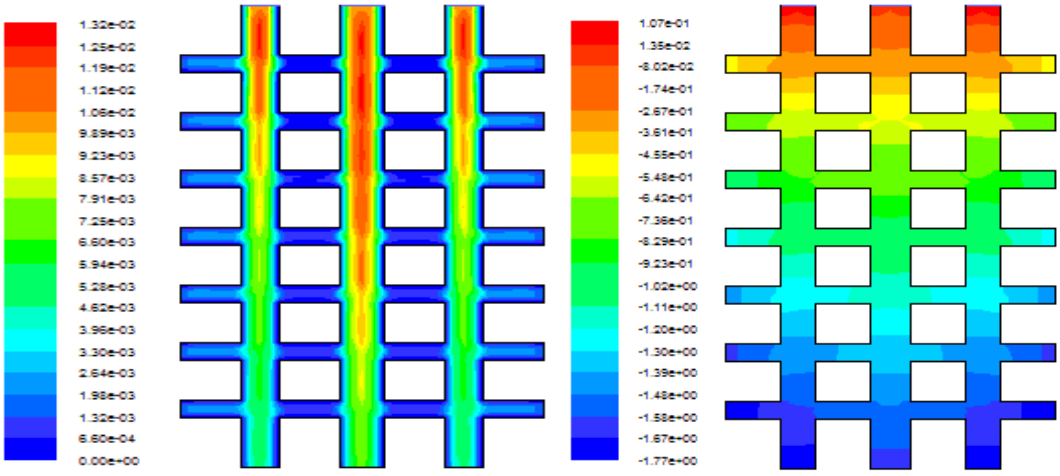


(a) Velocity distribution (b) Pressure distribution

Fig. 2 Velocity and pressure distribution for model 1

As in Fig.2, the velocity does not distribute uniformly and has an obviously difference from the inlet to the outlet. The velocity at the bottom is low. On the same vertical level, the velocity of the main channel varies in great degree and is no uniform. From the inlet to the outlet, the average velocity in the main channel increases first and then decreases while the nutrient liquid processes the main channel. In the branch channels, the velocities distribute uniformly, but the values are generally small i.e. local resistance of a relatively great value exists in these positions. In the flowing process, flow separation appears and a back flows are generated in some areas.

As seen in Fig. 2(b), at the same horizontal line of the inlet, pressures at the left and right sides are higher than that at the center, and it is because they are of the different distance to the inlet point. But at the other horizontal line which is far away from the inlet, pressures in both the main channel and the branch channels are of nearly the same value. A relatively great resistance exists in this model.

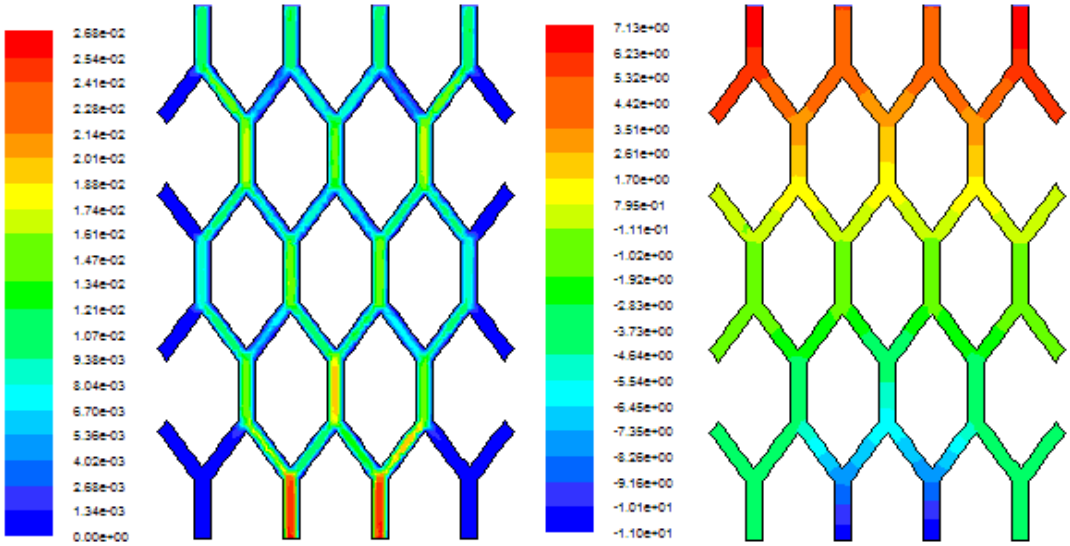


(a)Velocity distribution (b) Pressure distribution

Fig. 3 Velocity and pressure distribution in model 2

In Fig. 3(a), the average velocity values are not obviously different from the model 1, but the distribution of the velocity is a bit more uniform than that in model 1. In the vertical channel on the center, the velocity is great on the inlet, then decreases gradually with the process of the travel, and gets the minimum on the outlet. Other two vertical channels on the left and the right sides are of the same velocity distribution style as the one in the center, and it is suitable for the growth of the cells. In the horizontal channels, velocity does not distributes so uniform, but at the bottom, it gets a bit uniform that other places. On the top and middle parts of the model, velocities in the vertical channels are great, but small in the horizontal channels, and it is not fit for the growth of the cells. In this model, flowing separation and back flow also exist and it is more obvious in the horizontal channels.

Just as the velocity in this model, the pressure is at the top value on the inlet, then gradually decreases in the middle and gets the minimum in the outlet at the bottom of the model. At the same horizontal line, the pressures are almost the same in the middle channel to the channels at the left and the right sides.



(a) Velocity distribution (b) Pressure distribution

Fig. 4 Velocity and pressure distributions in the model 3

In model 3, velocity distributes uniformly in the entire model. From the inlet on the top to the outlet on the bottom, the velocities in the oblique channels are lower than in the vertical channels, and this distribution style is suitable for the flow of the nutrient liquid and the growth of the cells. But at the outlet on the bottom, the velocities distribute not as uniform as others, and velocities in the two outlets in the middle are obviously greater the two on the two sides. Also, velocities in the two oblique channels on the bottom are also small, and this situation is not suitable for the nutrient liquids flowing in the tissues.

In Fig. 4(b), the pressure decreases slowly form the inlet to the outlet, and the pressure gradient on the vertical direction is not as great as the model 1 and model 2. On the horizontal line of the inlet, pressure in the middle channel is almost the same as that in the channel on the two sides. But on the outlet, the pressure in the middle channel is smaller that in the two side.

Generally, velocity in model 3 is uniform and the flow is gentle. The local resistance is small, and the model 3 is fit for the principles of the bionics. Model 3 can provide a fitful environment for the supplies of the nutrient liquids for the tissue and is beneficial for the cell growth. Model 3 is the most suitable model among the three models mentioned in this paper.

## Conclusions

By conducting the numerical simulation for the three models, the internal velocity and the pressure distributions have been obtained, and the main conclusions are as follows.

(1)In model 1, the velocity is greatly different in the main channel from the branch channel, and the velocity does not distribute uniformly. Local resistance is great and flow separation and back flow exist in the bottom of the model.

(2)In model 2, velocity has not changed greatly, and local resistance and flow separation also exist.

(3)In model 3, velocity distributes uniformly and the local flowing resistance is small. So model 3 is a kind of excellent model.

(4)By comparing the three models, fluids flow gently in model 2 and model 3, and the velocity and the pressure distribute uniformly. That is, model 2 and model 3 are more suitable for the tissue engineering.

**Keywords:** Parallel algorithm, preconditioner, subspace iteration, sparse linear system, meso-scale simulation of concrete.

**Abstract.** The general parallel preconditioning subspace iteration software GPPS is developed based on the integration of various preconditioning methods, parallelization techniques, and subspace iterations, to solve general sparse linear systems. The software has several characteristics, including high computational performance, good readability, simple interface, and excellent scalability. In this paper, the functions of the software are outlined, and then it is used to solve the sparse linear systems from meso-scale simulation of concrete specimens. The numerical experiments show that GPPS is clearly superior to the software package AZTEC, which is used in the simulation up to now, and in addition, ICT and the parallelization technique based on factors combination outperform other preconditioning techniques integrated in the software.

## Introduction

Solution of linear systems is one of the core problems in scientific and engineering computing. The so-called Krylov subspace method is the most popular iteration, but the convergence rate depends on the distribution of the spectra of the coefficient matrix. The more concentrated the eigenvalues, the faster convergence it will have. The construction of preconditioners is to make the eigenvalues of the preconditioned matrix more concentrated, so it is very important[1].

The efficiency of preconditioners depends not only on the ability to reduce the distribution area of the eigenvalues, but also on its construction cost and the cost to apply it to vectors. Incomplete factorization preconditioning is very cheap in construction, the application is very economic, and the effectiveness can also be controlled by the number and the position of nonzero fill-ins in the incomplete factors, which makes it to be one of the most effective preconditioning techniques[1]. There are many variants of incomplete factorizations, among which ILU(0)[1], ILUT[1], MRILUT[2], and ICT[3] are the most efficient ones.

Incomplete factorization is very efficient, but it is very difficult to be parallelized. Therefore, many techniques are provided, including multi-coloring[1], non-overlapped domain decomposition[4], pseudo-overlapped incomplete factorization[5], and overlapped domain decomposition[6]. Multi-coloring can increase the degree of parallelization, but will degrade the effectiveness. In pseudo overlapped incomplete factorization, the overall domain is decomposed into multiple non-overlapped sub-domains, but the incomplete factors are corrected with the pseudo overlapped nodes.

In non-overlapped domain decomposition, the off-diagonal fill-ins related to the links between different sub-domains are discarded, and each diagonal block can be incompletely factorized further. This method can be improved by Schur complement, and multicolor resorting can be used to the quotient graph to control the number of fill-ins. Overlapped domain-decomposition is one of the most efficient parallelization method. In this method, the solution related to each sub-domain is approximated directly, and then these local approximations are simply averaged, with certain damping factors during the summation, to derive the global solution, which is in general called

additive Schwarz. To improve the convergence, the local solution corresponding to overlapped nodes can be averaged with weights. Cai and Sarkis provide a simple improvement[7], the restricted additive Schwarz. In this method, the frequency and volume of communication are both halved, and the convergence rate is also often much faster than the additive Schwarz. However, the additive Schwarz and the restricted version are both not tend to the corresponding serial incomplete factorization with the increase of the degree of overlapping. To overcome this shortcoming, there provided a new parallelization method called factors combination[8].

The general parallel preconditioning subspace iteration software GPPS is developed with the currently most efficient incomplete factorizations, incorporated with the widely used non-overlapped and overlapped domain decomposition based parallelization, and several preconditioned Krylov subspace iterations. It can be used to solve not only symmetric positive definite linear systems, but also un-symmetric ones. In this paper, there provide some preliminary results from simulating concrete specimens with meso-scale scheme, to verify the actual performance of the software.

## Outline of GPPS

GPPS is a software package, abbreviated from the first character of four words, i.e. general, parallel, preconditioning, and subspace. It is a general purpose parallel preconditioning subspace package, used to solve general sparse linear systems in parallel. The options that can be selected as preconditioners include none, Jacobi, SSOR, ILU(0), ILU(k), ILUT, MRILUT, ICT and etc. Except none and Jacobi, each preconditioning technique can be parallelized with one of the five methods, i.e., additive Schwarz(AS), restricted additive Schwarz(RAS), additive Schwarz with harmonic extension(ASH), factors combinations (FC), and the block Jacobi analog(BJ). The incorporated subspace iterations include CG, GMRES, BiCGSTAB, CGS, and TFQMR. GPPS is written in Fortran90 and the MPI message passing interface. In parallel computation, the user can specify the partition for the matrix rows and the vectors.

The framework of GPPS can be described as in figure 1, where the linear solver is implemented by invoking the interface to initialize the environment, the interface to invoke preconditioning construction and application, and the interface to invoke subspace iterations. The environment initialization interface is used to input all kinds of parameters for the solver from name-list files, and initialize the distribution of data related to distributed memory parallel computation, then perform some settings and vector structure constructions which will be used during the process of matrix-vector multiplications. The preconditioner interface provides a unified interface to invoke preconditioners, including Jacobi and all other parallelized versions. This interface contains some parameter configurations, memory allocation for both integer and float type data, and actual construction of parallel preconditioners. The subspace iteration interface provides a unified interface to invoke Krylov subspace iterations. Each subspace method needs to set the related initial solution vector, applying matrix vector multiplication and preconditioning process, and invoking basic linear algebraic subroutines and abnormity processing subroutine.

There are two ways to use GPPS. The first is to use the compiled executable program to solve sparse linear systems directly, which requires that the order of the system, the matrix information in CSR format, the right hand side, the number of processed to perform in parallel, and the identification number of each vector component are stored in a input file. The second is to invoke three interfaces provided in the package, that is, the environment initialization interface, the preconditioner construction interface and the subspace iteration unified interface, to solve sparse linear systems. In this situation, the GPPS_mod module should be used in the user program, the sparse matrix should be given in distributed CSR format, and consecutive rows should be distributed to each process. The right hand vector and the solution vector are distributed in the same manner. Before these interfaces are invoked, the parameters locLenN and locBegN in the module GPPS_mod should be given, where locLenN is the number of rows on this process, and locBegN is the global label of the first row on this process. When packages to partition graphs are used, the rows distributed to each process are not

consecutive. At this time, we can reorder the nodes of the graph, to turn it into the consecutive form and invoke the GPPS interfaces.

The function of GPPS is determined by two namelists, preconParameter and solverParameter. The namelist preconParameter contains five parameters, omega, droptol, nr, lfil and idprec, which are used to set various parameters of preconditioners. Different serial preconditioners can be incorporated with each of the provided parallelization schemes, to derive different preconditioning processes. While the namelist solverParameter contains 4 parameters, rstep, maxit, maxeps and imthd, which are used to set the restarted step, the maximum allowed number of iterations, the precision requirement of the current residual vector to the initial residual vector, and the specific type of iterations selected.

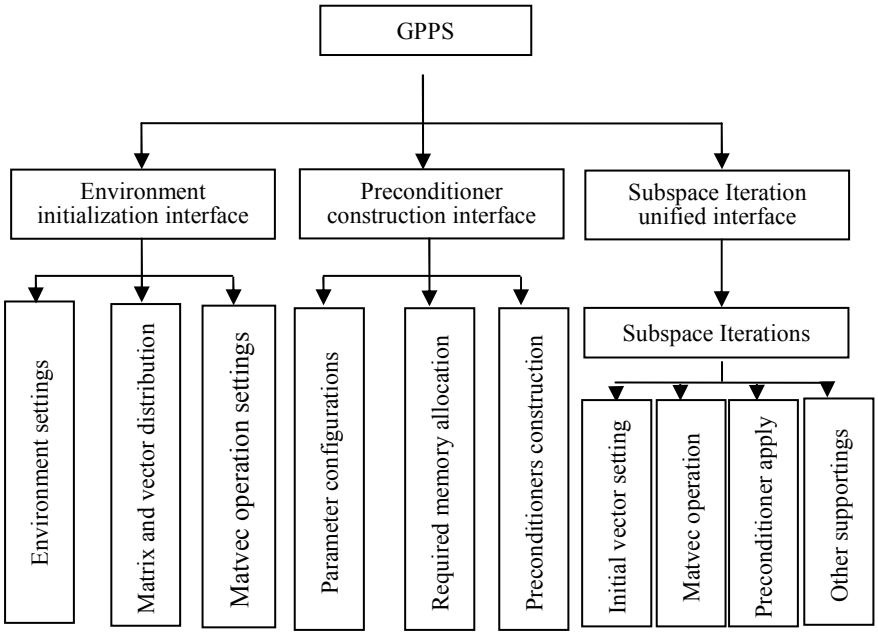

Fig. 1 Framework of GPPS

**Numerical simulation for meso-scale simulation of concrete specimen**

In this section, we will give some of the numerical results with the package GPPS to compute the linear systems from meso-scale simulation of concrete specimen. All the given results are derived on a cluster of Intel(R) Xeon(R) CPU 5150@2.66GHz(cache 4096KB), which are interconnected by infiniband. The operating system is Linux of Red Hat 4.1.2-52. The message passing interface used is mvapich2 and the compiler used is Intel Fortran 11.1.059. For all the linear systems are symmetric positive definite here, only the conjugate gradient(CG) and symmetric preconditioners are tested. The stop criterion is selected as the Euclid norm of the residual vector is reduced by 1E-4. The domain decomposition is based on the software package METIS, and the graph partitioning interface based on bisection is invoked. To use GPPS, all the nodes from partitioning is reordered, such that the nodes belonging to the same partition is labeled consecutively, and the related rows of the coefficient matrix and vector components are distributed to the same process. All the time results are in seconds.

In meso-scale simulation, the specimen can be regarded as a three-phase composite material consisting of aggregate, mortar and interface between them, and it is approximated by the finite element method. We experiment on a cubic concrete specimen of wet-sieved, with size of 550mm x 150mm x 150mm, which is described in [8]. There are 71013 discrete nodes and the number of finite elements is 78800 in all. The two supporting columns lay at $x = -0.15$m and $z = 0$m, and at $x = 0.3$m and $z = 0$m, that is, lay at the bottom and with distances 0.05m from left and right boundaries, respectively. While two loading columns are located at $x = 0$m and $z = 0.15$m, and at $x = 0.15$m and $z = 0.15$m, that is, at the top and with distances 0.2m from left and right boundaries, respectively.

As in [8], we will test GPPS for the linear systems both in static and dynamic loading. In static loading, the loads are increased step by step. The load step is 0.25kN during the numerical simulation. There occur damaged elements at the 59th step, and the specimen is completely cracked at the 94th step. If there are damaged elements at a certain step, several linear systems need to be solved to update the displacements. There are 178 linear systems in all.

In table 1, there list the results of preconditioned conjugate gradient with software package AZTEC and GPPS. For AZTEC, the optimal preconditioning, namely the non-overlapped parallel ILU(0), is used. For GPPS, several symmetric parallel preconditioners is tested, where the relaxation parameter for SSOR is selected as 1.0, the number of non-zeros allowed in each row of ICT factors is 25 and the dropping threshold is selected as 1E-3. In the table, NP denotes the number of processors used. It is clear that the number of iterations from factors combination(FC) parallelization is often less than that from additive Schwarz(AS) or block diagonal approximation(BJ). When factors combination is used, the time required to solve the linear system is also often less than additive Schwarz and block Jacobi. Meanwhile, when parallelization ILU(0) is selected, the number of iteration used with GPPS is often less than AZTEC. But the time elapsed is less than AZTEC only when the number of processors is 64. When parallelized ICT is used as preconditioning process, and the optimal preconditioning is used in AZTEC, GPPS is uniformly better than AZTEC.

Table 1. Average iterations and time[seconds] to solve each linear system during static loading

| | | AZTEC | Parallelized ILU(0) | | | Parallelized ICT(25,1E-3) | | |
|---|---|---|---|---|---|---|---|---|
| | | | AS | FC | BJ | AS | FC | BJ |
| Averag. Iter. | NP=08 | 254.65 | 195.86 | 188.73 | 227.96 | 202.08 | 193.41 | 229.93 |
| | NP=16 | 267.44 | 202.08 | 192.79 | 239.41 | 205.26 | 194.14 | 244.44 |
| | NP=32 | 274.09 | 203.17 | 192.40 | 243.22 | 195.28 | 187.16 | 251.92 |
| | NP=64 | 290.60 | 211.48 | 197.42 | 255.65 | 206.61 | 194.33 | 272.44 |
| Averag. time | NP=08 | 2.5967 | 2.8101 | 2.6475 | 3.0432 | 1.9415 | 1.8019 | 2.0486 |
| | NP=16 | 1.8372 | 2.3411 | 2.1995 | 2.5088 | 1.5961 | 1.4758 | 1.7341 |
| | NP=32 | 1.1718 | 1.5638 | 1.4771 | 1.6256 | 1.0780 | 0.9975 | 1.2117 |
| | NP=64 | 1.1080 | 1.0302 | 0.9669 | 1.0250 | 0.7478 | 0.6990 | 0.8686 |

In dynamic loading, the time step is selected as 0.001 seconds, and the loads is increased linearly with increment of 0.8kN. The sample is completely damaged at the 38th step. Prior to actual test for loading, some eigenvalues should be computed to determine related parameters used in the simulation, which involves the solution of linear systems. Therefore, there are 220 linear systems to be solved in all for the whole simulation process. The average iterations and time elapsed for the solution of each linear system is listed in table 2. From the table, it is clear that though for ILU(0), the time used with factor combination based parallelization is shorter than that with AZTEC when 64 processors used, when preconditioning process other than ICT is used, the time with GPPS used is longer than that with AZTEC. When ICT preconditioning is used, the efficiency of GPPS is better than that of AZTEC in general, especially when factor combination based parallelization technique is incorporated in the iterations, where the iteration time is significantly reduced. Meanwhile, we can see that for GPPS itself, factor combination based parallelization is better than additive Schwarz and block diagonal approximation.

**Summary**

In this paper, the general parallel preconditioning subspace iteration software GPPS is simply described and tested through the solution of linear systems encountered in the meso-scale simulation of concrete sample. The simulation results show that, when the option of ICT preconditioning is used, the performance of GPPS is better than AZTEC incorporated with the best preconditioning option.

Meanwhile, among the preconditioning schemes provided in GPPS, ICT have significant privileges, and the factors combination method outperforms additive Schwarz and block diagonal approximations. At the same time, when ILU(0) used both in AZTEC and GPPS, the time used to solve a linear system in average with GPPS is longer in general than that with AZTEC, which implies that the software package GPPS can be improved further. In future, the parallel implementation of matrix-vector multiplication and the data structures used will be investigated carefully to make it more efficient.

Table 2. Average iterations and time[seconds] to solve each linear system during dynamic loading

**Keywords:** over-thick steel tube, mechanical model, adhesive thin-layer of steel tube/concrete, adhesive shearing stress.

**Abstract.** An axial symmetry elasticity model of the concrete short column which is pushed out from over-thick steel tube is set up, and the equations of displacement method are derived. The experiment of push-out test of the short column was carried out. On the base of the test, the adhesive thin-layer between the concrete and the over-thick steel tube is introduced. The experimental results show that the shearing stress in the adhesive thin-layer is uniform along the height, which is coincide with the results obtained by the axial symmetry elasticity model of the concrete short column set up in this paper. Therefore, the adhesive shearing stress between steel tube and concrete can be precisely measured by the push-out test of the concrete short column and the relation of shearing stress-shearing strain of the adhesive thin-layer can be determined.

## Introduction

Composite structures of concrete-filled steel tube have a number of advantages over conventional steel-reinforced concrete members [1]. It can provide excellent earthquake-resistance properties such as high strength, high ductility and good energy absorption capacity.

The adhesive stresses created between the concrete core and the steel tube is premise guaranteeing the interaction between the concrete core and the outer steel tube. Because of properties difference between steel and concrete, slip on the interface of steel tube/concrete will take place, especially in the case of high-stress level. Unfortunately, the slip is difficult to be effectively measured. How to establish a mechanical model to simulate the slip is noticed [2-6]. Spring-contact model of simulating the slip is studied widely. The fault of the model is that modeling process is complex, and a lot of calculation has to be carried out.

The authors of this paper consider that the interface between concrete and steel tube is essentially adhesive thin-layer. A theoretical elasticity model of the concrete short column which is pushed out from the over-thick steel tube is presented. The test of measuring the adhesive thin-layer is carried out.

## Mechanical model of concrete short column pushed out from over-thick steel tube

**Equations of displacement method.** Considering **t**hat a circular concrete short column constrained with over-thick steel tube is pushed out from over-thick steel tube due to slipping of the interface between the concrete and the over-thick steel tube. The interface is essentially an adhesive thin-layer and subjected mainly to shearing. Under the condition of critical state of the concrete column being pushed out, the ultimate shearing stress in the adhesive thin-layer is far lower than those in the concrete and in the steel tube. The radial constrain normal stress in the steel tube is small. Thus suppose that:(1)Radial stiffness of steel tube is infinite; (2)only axial strain in the concrete column takes place, radial strain is vanish, that is, $\varepsilon_r = 0$ .Mechanical model of the concrete constrained with circular steel tube subjected to axial compression load is shown in Fig.1.

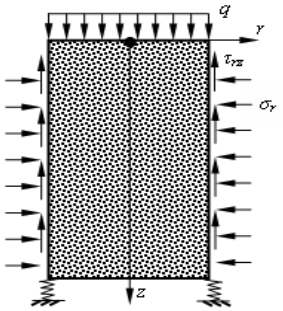

Fig.1 The stress state of the concrete short column

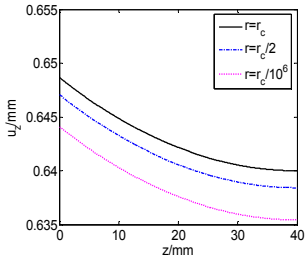

Fig.2 The displacement curves of $u_z$

Basic equations of displacement method for axial-symmetry problems of are expressed as

$$\theta_{,r}/(1-2\mu)+\nabla^2 u_r - u_r/r^2 = 0\ ,\quad \theta_{,z}/(1-2\mu)+\nabla^2 u_z = 0 \tag{1}$$

Whrer, $\theta=\varepsilon_r+\varepsilon_\theta+\varepsilon_z=u_{r,r}+u_r/r+u_{z,z}$ $\varepsilon_r$ , $\varepsilon_\theta$ and $\varepsilon_z$ are radial, loop and axial strain, respectively. $u_r$, $u_\theta$, and $u_z$ are radial, loop and axial displacement, respectively. Right lower subscript "$,x$" expresses derivation to the variable $x$.

For the mechanical model shown in Fig.1, $\varepsilon_\theta = 0$ , $\varepsilon_r = 0$ , and corresponding displacements $u_r$, $u_\theta$ are zeros and volume strain $\theta = u_{z,z}$ . Eq. 1 is reduced as,respectively

$$u_{z,rz}=0 \tag{2}$$

$$\frac{2(1-\mu)}{1-2\mu}u_{z,zz}+u_{z,rr}+\frac{1}{r}u_{z,r}=0 \tag{3}$$

The solution of equations(2)and(3)can be obtained as

$$u_z=\frac{cz^3}{6}+\frac{az^2}{2}+bz+c_1+c_2r^{t_2}+c_3r^{t_3}+\frac{cr^3}{3} \tag{4}$$

$$t_2=\frac{-1+\sqrt{5}}{2}=0.618\ ,t_3=\frac{-1-\sqrt{5}}{2}=-1.618 \tag{5}$$

**Solution of the basic equations**

The stress components $\sigma_r$ , $\sigma_\theta$ and $\sigma_z$ can be expressed as

$$\sigma_r=\sigma_\theta=\frac{\mu_c E_c\varepsilon_z}{(1+\mu_c)(1-2\mu_c)},\quad \sigma_z=\frac{(1-\mu_c)E_c\varepsilon_z}{(1+\mu_c)(1-2\mu_c)},\quad \tau_{zr}=G_c\gamma_{zr}=\frac{E_c u_{z,r}}{2(1-2\mu_c)} \tag{6}$$

Thus, $\varepsilon_z$ and $u_{r,z}$ can be expressed as

$$\varepsilon_z=u_{z,z}=\frac{cz^2}{2}+az+b \tag{7}$$

$$u_{z,r}=c_2t_2r^{t_2-1}+c_3t_3r^{t_3-1}+cr^2 \tag{8}$$

Because $\varepsilon_z$ is independent to hoop coordinate $r$, $\sigma_r$ , $\sigma_\theta$ and $\sigma_z$ are also only related to coordinate $z$. From Eq.7, it can be seen that the shearing stress $\tau_{zr}$ is not relate to $z$ only to $r$. According to equilibrium of the whole concrete column, have

$$\overline{\tau}_{rz}\pi d_c l_c = F=\int_{A_c} q\mathrm{d}A \tag{9}$$

Where $\overline{\tau}_{zr}$ is shearing stress on the column surface of $r$=$r_c$, and $F$ is the resultant of the distributive loads $q$ exerted to the upper surface ($z$=0).

The boundary conditions used to determine the constants in Eq. 4 are Eq.10.

$$\int_{A_c}\sigma_z(0)\mathrm{d}A=-F,\quad \overline{\tau}_{zr}\pi d_c\left(l_c-z\right)=\int_{A_c}\sigma_z(z)\mathrm{d}A\quad(0\le z\le l_c),\quad \int_{A_c}\sigma_z(l_c)\mathrm{d}A=0$$
$$(\tau_{rz})_{r=r_c}=\overline{\tau}_{rz},\quad (u_z)_{z=l_c}=\overline{u}_z,\quad (u_{z,r})_{r=0}=0 \tag{10}$$

Where $\overline{u}_z$ is the vertical displacement $w_3$ of the lower surface of the concrete column measured according to the test (see section 3). The constants $c$ , $a$ , $b$ , $c_1$ , $c_2$ and $c_3$ are determined from boundary conditions (10) as

$$a=\frac{(1+\mu_c)(1-2\mu_c)F}{(1-\mu_c)E_cA_cl_c},\quad b=\frac{-(1+\mu_c)(1-2\mu_c)F}{(1-\mu_c)E_cA_c},\quad c=0, \tag{11}$$
$$c_1=\overline{u}_z+\frac{2(1+\mu_c)(1-2\mu_c)F}{2(1-\mu_c)E_cl_c}\left[\frac{l_c^2}{A_c}-\frac{2(1-\mu_c)}{0.618\pi(1-2\mu_c)}\right],c_2=\frac{Fr_c^{0.382}}{0.618\pi d_cl_cG},\quad c_3=0$$

The average vertical displacement $u_{z,\mathrm{av}}$ at cross-section $z$ is expressed as

$$u_{z,\mathrm{av}}(z)=\frac{1}{A_c}\int_{A_c}u_z\mathrm{d}A=(\frac{az^2}{2}+bz+c_1)+\frac{c_2\pi r_c^{2.618}}{2.618A_c} \tag{12}$$

The displacement curves of $u_z$ is shown in Fig.2.

## Experimental study

**Prepare of specimens and test.** Three series of specimens were designed. The first series has 3 circular concrete columns used to measure the mechanical properties of the concrete. The diameter and length of the specimens were 40mm and 100mm, respectively, so named as c-40-100. The concrete columns were made up plane concrete, course sand (diameter 0.2-1mm) and reduced stone (diameter 3-5mm) through top pouring. The second series has 3 circular steel tubes with diameter of 40mm, thickness of 2mm and length of 300mm, used to measure the mechanical properties of the steel tube, named as s-40-2-300. The third series has 3 thick-walled concrete filled steel tubes. The steel tubes were with diameter of $d_s$=40mm, thickness of $t_s$=6mm and length of $l_s$=100mm, and the concrete column were with diameter of $d_c$=28mm and length of $l_c$=40mm. The series was named as c-s40-6-100-c40. The specimens were made up through pouring the concrete into the steel tubes. Before pouring, the in-surfaces of the steel tubes were degreased with acetone.

The put-out test is shown in Fig.3. The thickness $t_a$ of the adhesive thin thin-layer was approximately determined as 1mm through observation for the debonded interface between concrete and steel tube. Displacement meters Dis.M1, Dis.M2, and Dis.M3 were used to measure the vertical displacement of the upper surface of the concrete, the vertical displacement of the upper surface of the steel tube, and the vertical displacement of the lower surface of the concrete, respectively.

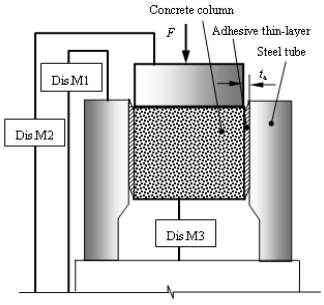

Fig. 3 Test set-up

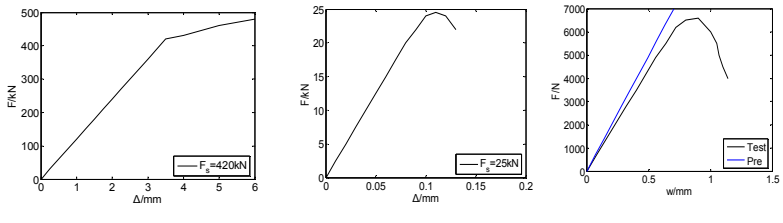

Fig.4 Test curves[(a) steel tube; (b) concrete column; (c) push-out test

## Results

The test results of s-40-6-300 and c-40-10 are shown in Table 1 and Fig.4(a) and (b). The test results of c-s40-6-100-c40 are shown in Table 2 and Fig.4(c). The $w_1$, $w_2$ and $w_3$ in Table 2 are the vertical displacements measured from displacement meter 1, 2 and 3, respectively.

Table 1 Specimens and material properties

| Types of tests | $F_s$ /kN | $F_u$ /kN | $\Delta_s$ /mm | $\sigma_s$ /MPa | $\varepsilon_s$ /$10^{-3}$ | $E$ /GPa |
|---|---|---|---|---|---|---|
| c-40-100 | 22 | 29 | 0.08 | 17.5 | 80.3 | 22 |
| s-40-6-300 | 420 | 560 | 3.3 | 742.7 | 5.3 | 193.1 |

Table 2 Results of c-s40-6-100-c40

| Typical loads/kN | $w_1$/mm | $w_2$/mm | $w_3$/mm |
|---|---|---|---|
| $F_s$= 4 | 0.001 | 0.50 | 0.48 |
| $F_u$= 6.5 | 0.002 | 0.68 | 0.64 |

The comparison between the test result and the predicted result (straight line) from Eq.25 is shown in Fig.4(c). It is shown that predicted result is good agreement with test one. The slip between the concrete short column and over-thick steel tube is expressed by $s$. The curve of $s-z$ is shown in Fig.5. It can be seen from Fig.5 that the slip at the upper surface is almost equal to that at the lower surface, which means that the slip $s$ is almost uniform with $z$.

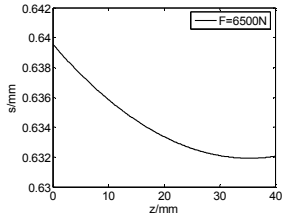

Fig.5 Variation of slip with height

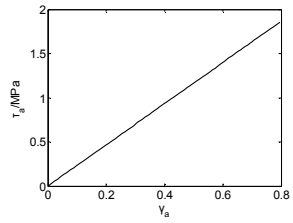

Fig.6 Relation of adhesive shearing stress and shearing strain in adhesive thin layer

The curve of $\tau_a - \gamma_a$ is shown in Fig.6. From Fig.6, it can be seen that the relation between shearing stressing $\tau_a$ and shearing strain $\gamma_a$ in the adhesive thin-layer is linear, i.e., $\tau_a = G_a \gamma_a$. Shearing modulus $G_a$ is 2.3321MPa.

## Conclusions

(1) The shearing stress between the steel tube and concrete is uniform along height for the concrete short column which is pushed out from over-thick steel tube, and the slip between the steel tube and concrete is also approximately uniform along height.

(2) The push-out test shows that the average vertical displacement at the upper surface of the steel tube is proportional to push-force. The average vertical displacement at the upper surface of the concrete column is also proportional to push-force, but very greater than that at the upper surface of the over-thick steel tub. The slip between the steel tube and concrete is approximately uniform along height. The adhesive stress in the adhesive thin-layer can be well determined and shearing modulus of the adhesive thin-layer can be valuated by the push-out test.

# Study on numerical simulation of explosion in soil based on fluid-solid coupling arithmetic

Juan Song[1,a], Shucai Li[1,b]

[1] School of Civil Engineering, Shandong University, Jinan, China

[a]songjuan@sdu.edu.cn, [b] lishucai@sdu.edu.cn

**Keywords:** explosion, soil, shared-node, contact, ALE

**Abstract.** Numerical simulations play a significant role in explosion in a mass of soil due to an underground explosive. Common methods available in hydrocode for fluid-solid coupling process are contact algorithm, Lagrange algorithm, and Arbitrary Lagrange-Euler(ALE) algorithm. A numerical simulation of explosion process with concentrated charge in a mass of soil was carried out by using three methods in this paper. The dynamic response of soil medium, the formation and development law of explosion cavity and the explosion wave propagation law in soil were simulated. Merits and drawbacks of three different methods are analyzed in the aspect of modeling, simulation results and computing cost.

## Introduction

As a matter of fact, the response of surrounding soil media to nearby explosions is complicated by the drastic spatial and time variation of the blast loads. This buried blast usually produces a cavity or a crater and result in the interaction of surrounding soil media and detonation product gas. Furthermore, the propagation of blast-induced stress wave will induce the acceleration of soil particle and soil pressure in the surrounding soil media. It is meaningful to study the interaction between the explosion and soil response because different structures are affected differently, causing deformation due to detonations, which have been widely reported in the literature over the past five decades. Effects of explosions on a soil medium and underground structures can be studied through full-scale model tests, reduced scale/ enhanced acceleration physical tests (as in centrifuge tests), empirical method and numerical modeling. In the recent decades, several experimental and numerical investigations have been carried out to determine the overpressure and crater depth of explosive materials into/on different soil types [1-4]. Accurate prediction of explosion in soil by numerical simulation is needed, due to the fact that the numerical simulations can minimize the number of experimental cases, saving considerable amounts of cost and time. Different types of solvers available in a hydrocode, such as LS-DYNA and AUTODYN, are Lagrange, Euler, Smoothing Particle Hydrodynamics (SPH) and Arbitrary Eulerian-Lagrangian (ALE) [5]. The paper is concentrated on the validation of the methodology that has been implemented in LS-DYNA, to be able to simulate explosive and soil structure interaction problems. Structures with more details and complex geometry will be analyzed next.

## The description of simulation model

**The initial condition.** Only a quarter of the problem domain was simulated, which has the size of 75 cm×75cm×150cm, as shown in Fig 1. There are three materials: explosive, soil, air. Point A was marked in Fig.2 for the convenient reference when presenting the simulation results. The charge with weight 10kg explosive is buried at a depth of 65cm from ground surface along the central axis. The corresponding FEM mesh was illustrated in Fig.2 with a total of 72000 hexahedron elements inclusive of 8 elements for the explosive.

This numerical model has following boundary conditions: Vertical displacements at the bottom are fixed to restrain rigid body movement. Symmetrical boundary is applied to all horizontal displacements along the symmetry plane. The top surface is free surface which can reflect the stress waves. The non-reflecting boundaries are applied to minimize the stress wave reflection at the sides.

**Description of various formulations model.** In this method, there have identical density and the number of nodes in the interface between explosive meshes and structure meshes, which make them shared in nodes. A contact type algorithm is used to handle the coupling between soil and explosive[6]. The difference between shared-node formulation and contact formulation is separate interface for explosive and structure, which can be divided by different mesh size. Namely two kinds of mesh are independent and irrelevant. In this paper, three modes of contact were applied: SURFACE_TO_SURFACE, SLIDING_ONLY, ERODING_SURFACE_TO_SURFACE, respectively[7]. In preprocess phase, the ALE algorithm enable to conduct two spaces which can be intersected and overlapped, one for the explosive and ALE space, and another for structure. An ALE zone is defined for the area around the charge as shown in Fig 3.

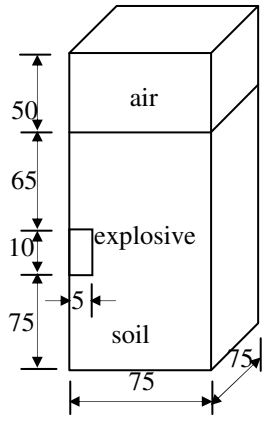

Fig.1 Sketch of model

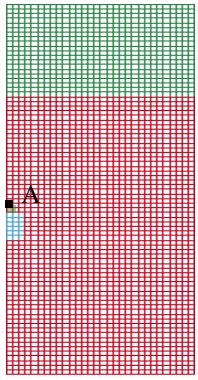

Fig.2 Sketch of mesh

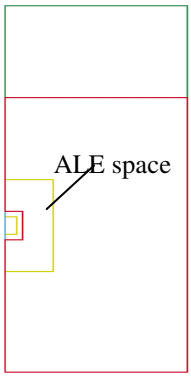

Fig.3 Sketch of ALE formulation

**Constitutive models in computation.** The empirical Jones-Wilkins-Lee (JWL) equation of state is widely used in mine blast calculations (see Table 1), where $A, B, R_1, R_2$ and $\omega$ are material constants, $V$ is the relative volume of detonation product and $E_0$ is the internal energy per initial volume. The model parameters used in simulation are listed in Table 2 for soil, where $\alpha_0$, $\alpha_1$ and $\alpha_2$ are material constants.

Table 1 Explosive Parameters of TNT Dynamite

| Density[ $g \cdot cm^{-3}$ ] | D[ $m \cdot s^{-1}$ ] | $P_{cj}$[GPa] | $A$[GPa] | $B$[GPa] | $R_1$ | $R_2$ | $\omega$ | $E_0$[ $J \cdot m^{-3}$ ] |
|---|---|---|---|---|---|---|---|---|
| 1.6 | 6930 | 18.5 | 371.2 | 3.231 | 4.15 | 0.95 | 0.3 | 7.0e+9 |

Table 2 Soil Parameters for Soil Model

| Density[ $g \cdot cm^{-3}$ ] | Poisson's ratio | $G$[MPa] | $E$[MPa] | $K$[MPa] | $\alpha_0$ [$MPa^2$] | $\alpha_1$ [MPa] | $\alpha_2$ |
|---|---|---|---|---|---|---|---|
| 1.80 | 0.48 | 16.01 | 47.36 | 394.8 | 2.4e-6 | 0.0136 | 0.1232 |

Material Type 9 of LS-DYNA(*MAT_NULL) is used for the air. The standard material constants of air $\gamma = 1.4$, $\rho = 1.2 \times 10^{-3} g \cdot m^{-3}$, $e = 2.5 \times 10^4$ Pa are used, Where $e$ is the internal energy per volume, $\rho$ is the current density of the material, and $\gamma$ is the ratio of specific heat, respectively.

## Comparison and discussion of simulation results

**Computation cost.** A comparative analysis for computational efficiency of various explosion simulation methods has been done when simulation time was set 1500μs as shown in Table.3. It can be seen that the contact algorithm for computing efficiency is the lowest, which can be illustrated by mesh distortion mainly due to the explosive mesh of expansion and caused by calculating step gradually becoming smaller, which resulted in calculation of termination. And sometimes because of the contact calculation does not converge in the calculation process, usually the grid computation

process suddenly was terminated without warning information. The shared-node and ALE algorithm have higher computational efficiency because of the relatively stable step, especially the explosives and the air flowing in the ALE space. So there is no distortion problem of grid and rarely computing termination phenomenon. But the ALE algorithm with higher requirements on memory, is 7-8 times than other algorithms.

Table 3 Comparative result between various methods

| | Shared-node | Eroding | Sliding-only | Surface-to-surface | ALE |
|---|---|---|---|---|---|
| CPU time | 2238 | 6850 | 6372 | 8226 | 2805 |
| memory | 6203180 | 6249329 | 6249473 | 6249329 | 55026614 |
| minimal step | 4.13E-02 | 9.93E-03 | 1.01E-02 | 4.92E-03 | 4.13E-02 |

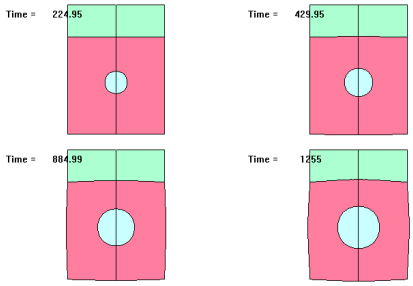

Fig.4 Cavity formed in shared-node method

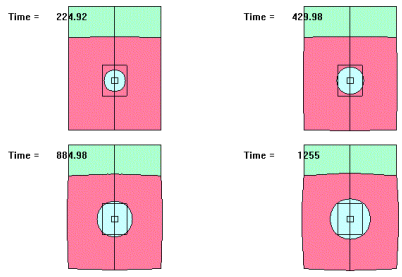

Fig.5 Cavity formed in ALE

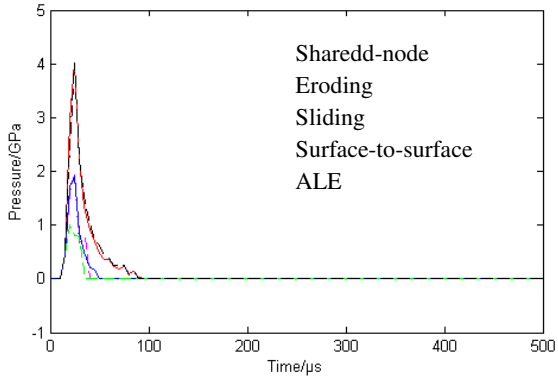

Fig.6 Comparison of blast overpressure

**Simulation process of explosion in soil.** Detonation of explosives generates compressive stress waves in a mass of soil. After detonation, the blast stress waves propagate outwards from the blast hole in all directions. Simultaneously a high velocity shock front departs from the explosive source to the surrounding soil and the particle of soil gain the radial velocity to broaden the blast cavity. With the rapid attenuation of blast energy, over pressures is under the strength limitation of soil. This moment the expand process of cavity reach to the status of termination and the bulge, not the evident crater, is observed in the air. Fig. 4 and Fig.5 shows the shape of the spherical cavity in a mass of soil by using shared-node and ALE at different simulation time, respectively. A very good agreement is observed between the cavity diameter obtained with shared-node method and ALE method. Furthermore, the radius of cavity obtained in two cases is about six times the size of charge, which is in a good agreement with the experimental result of 5~7 times[8]. In the formation of cavity, the contact formulation can be performed up to 600μs in time, after this time, the problem was prevented to run up to physical time. So the simulation result of contact algorithm is not perfect.

**Pressure-time history at reference point.** Fig. 6 shows the comparison of the five pressure time history at point A. It can be seen that all of curves presented a brutal increase of the pressure at

shock arrival time, $t = 24\mu s$, and rapid increment as well as the peak value were captured very well by the numerical simulation. Generally, the numerical simulation of the post-peak dissipation of the stress shows similar trend of the measured curve although with faster dissipation rate. As can be seen, the results of curve shape, magnitude of overpressure and duration time were very similar between the shared-node and ALE, which shows good correlation between the two results. Marked difference is observed in the peak overpressure, where the contact algorithm results exhibit much smaller peak pressure than from other results, as a result of configuration of contact parameters. In practical application, parameters should be adjusted lightly based on experimental result to make identical between simulation and experiment.

## Conclusions

This paper discusses the prediction of blast cavity in a mass of soil due to underground explosion by using different numerical simulation methods. Some meaningful conclusions have been drawn through the following aspects: computational cost and simulation results.

1) As mentioned in the introduction, the Lagrangian formulation is simple in modeling and accurate for material boundary where the mesh is deformed but not highly distorted. Good agreement for the pressure transient in the explosion was obtained using the Lagrangian and ALE method.

2) Unlike the Lagrangian method, the ALE coupling method has no limitation concerning high mesh distortion since the problem is performed using ALE remeshing techniques. This technique can be used for more complex problems where the structure can be defined with all its details. But the limitations of ALE formulation were complicated modeling process and high computational cost.

3) The simulation by using the contact algorithm was terminated due to the configuration of contact parameter or mesh density of slave and master boundary.

# Study on stability of functionally graded cylindrical shells subjected to hydrostatic pressure

Xiaowan Liu, Bin Liang, Rong Li

Civil Engineering School, Henan University of Science and Technology, Luoyang, 471023, China

**Key Words:** critical pressure; functionally graded material; cylindrical shell; hydrostatic pressure

**Abstract:** The stability of submerged functionally graded (FG) cylindrical shell under hydrostatic pressure is examined in this paper. Based on the Flügge's shell theory, the coupled frequency of submerged FG cylindrical shell is obtained, using wave propagation method and Newton method. Then the critical pressure of FG cylindrical shells is given by applying linear fitting method. Results are compared to known solutions, where these solutions exist. The effects of constituent materials, volume fraction, boundary condition and dimensions on the critical pressures of submerged FG cylindrical shell are illustrated by examples.

## Introduction

Studies on coupled vibration of submerged cylindrical shells have received considerable attention, which can be seen in the literature [1-2]. The liquid medium has significant impact on the vibration characteristics of cylindrical shell, especially for the effect of hydrostatic pressure. Because the structure will create instability when the hydrostatic pressure is larger than critical pressure, at this point, it no longer makes sense to do calculate the natural frequency. So the structural analyses need to be carried out in the presence of critical pressure. However, since FG cylindrical shell is a group of innovative material structure, the research on the mechanical behavior of submerged FG cylindrical shell is very limited.

Based on the Flügge shell theory, the coupled frequency of submerged FG cylindrical shell is derived. Then the critical pressure of FG cylindrical shells is given by applying linear fitting method. Results are presented the effect of constituent materials, volume fraction, boundary condition and dimensions on critical pressures of submerged FG cylindrical shell.

## Theoretical formulation

A FG cylindrical shell is considered with radius $R$, length $L$ and thickness $h$, as shown in Fig.1. The reference surface is taken to be the middle surface of the cylindrical shell where an orthogonal coor-

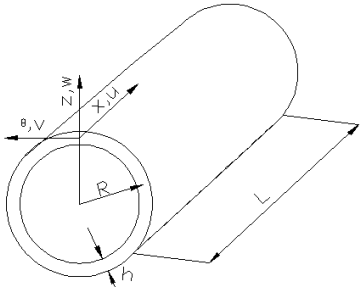

**Fig.1. Geometry of a FG cylindrical shell**

dinate system $(x,\theta,z)$ is fixed. The $x,\theta$ and z are the axial coordinate, circumferential coordinate and radial coordinate, respectively.

When a shell composed with two materials, the material parameters are defined as the Young's modulus $E_1, E_2$, Poisson ratio $\mu_1, \mu_2$ and the mass density $\rho_1, \rho_2$, respectively. So along the thickness of the shell, the Young's modulus $E$, Poisson ratio $\mu$ and the mass density $\rho$ can be expressed as

$$\begin{cases} E = E(z) = (E_1 - E_2)(z/h + 1/2)^N + E_2 \\ \rho = \rho(z) = (\rho_1 - \rho_2)(z/h + 1/2)^N + \rho_2 \\ \mu = \mu(z) = (\mu_1 - \mu_2)(z/h + 1/2)^N + \mu_2 \end{cases} \tag{1}$$

Where $N$ is the power-law exponent $(0 \le N \le \infty)$.

By using Flügge's theory, the equations of motion for a cylindrical shell subjected to hydrostatic pressure are obtained.

$$\begin{cases} \dfrac{2+T}{2}u_{xx} + \dfrac{1-\mu}{2}u_{\theta\theta} + \dfrac{1+\mu}{2}v_{x\theta} + \mu w_x + K\left(\dfrac{1-\mu}{2}u_{\theta\theta} - w_{xxx} + \dfrac{1-\mu}{2}w_{x\theta\theta}\right) + T(u_{\theta\theta} - w_x) = Hu_{tt} \\ \dfrac{1-\mu}{2}v_{xx} + \dfrac{1+\mu}{2}u_{x\theta} + v_{\theta\theta} + w_\theta + K\left(\dfrac{3(1-\mu)}{2}v_{xx} - \dfrac{3-\mu}{2}w_{xx\theta}\right) + \dfrac{T}{2}v_{xx} + T(v_{\theta\theta} - w_\theta) = Hv_{tt} \\ \mu u_x + K\left(\dfrac{1-\mu}{2}u_{x\theta\theta} - u_{xxx} - \dfrac{3-\mu}{2}v_{xx\theta} + w + w_{xxxx} + 2w_{xx\theta\theta} + w_{\theta\theta\theta\theta} + 2w_{\theta\theta}\right) + v_\theta + w - \dfrac{T}{2}w_{xx} \\ \qquad - T(u_x - v_\theta + w_{\theta\theta}) + \dfrac{\rho R^2(1-\mu^2)}{E}w_{tt} = -\dfrac{H}{\rho h}\psi \end{cases} \tag{2}$$

where $T = \dfrac{R}{Eh}(1-\mu^2)P_0$, $K = \dfrac{h^2}{12R^2}$, H= $\dfrac{\rho R^2(1-\mu^2)}{E}$, $P_0$ is the hydrostatic pressure, $\psi$ is the acoustic pressure.

$$\psi = [\omega^2 \rho_f / k_r H_n^{'}(k_r R)] W_m \cos(n\theta) H_n(k_r r) e^{i\omega t - ik_m x} \tag{3}$$

where $H_n()$ is the Hankel function of the second kind, $H_n^{'}()$ denotes differentiation with respect to the argument $k_r R$, $\rho_f$ is the density of the contained fluid in the shell, $k_r$ is radial wave number.

The displacements of the cylindrical shell can be expressed in the form of wave propagation.

$$\begin{cases} u(x,\theta,t) = U_m \cos(n\theta) e^{(i\omega t - ik_m x)} \\ v(x,\theta,t) = V_m \sin(n\theta) e^{(i\omega t - ik_m x)} \\ w(x,\theta,t) = W_m \cos(n\theta) e^{(i\omega t - ik_m x)} \end{cases} \tag{4}$$

where $U_m, V_m, W_m$ are the wave amplitudes in the $x, \theta, z$ directions, $\omega$ is the natural angular frequency.

Substituting Eq.(4) into Eq.(2), which consideration of acoustic pressure on the shell Eq.(3), the equations of motion of coupled system can be obtained. The Newton method is used to acquire the natural frequency of the shell. Because of linear relation between the natural frequency squared and hydrostatic pressure [3], the critical pressure can be derived using linear fitting method.

**Results and discussion**

To validate the present analysis, results for critical pressures for submerged isotropic cylindrical shell are compared with the theoretical formula [4], see table 1. The comparison show that the present results agree well with the traditional method.

**Tab.1 Comparison of critical pressures** ( MPa ) **for a submerged isotropic cylindrical shell**

| h/R | L/R | | | | | |
|---|---|---|---|---|---|---|
| | 2 | | 5 | | 10 | |
| | Present | theoretical values | Present | theoretical values | Present | theoretical values |
| 0.005 | 36.448 | 36.115 | 2.6929 | 2.6586 | 0.2079 | 0.2072 |
| 0.01 | 73.049 | 72.333 | 5.4377 | 5.3692 | 0.461 | 0.4599 |
| 0.02 | 147.1 | 145.48 | 11.287 | 11.154 | 1.2832 | 1.2831 |

As examples, critical pressures with different $h/R$ , $L/R$ , boundary conditions, constituent materials and volume fractions are studied. The functionally graded material has ceramic on its inner surface and metal on its outer surface. The material properties are given in Tab.2.

**Tab.2 Properties of functionally graded materials**

| Properties | outer materials | | inner materials | |
|---|---|---|---|---|
| | Stainless steel | Ti-6Al-4V | $Si_3N_4$ | Zirconia |
| $E$ (N/m²) | $2.07788 \times 10^{11}$ | $1.0570 \times 10^{11}$ | $3.2227 \times 10^{11}$ | $1.68 \times 10^{11}$ |
| $\mu$ | 0.317756 | 0.2981 | 0.24 | 0.3 |
| $\rho$ (kg/m³) | 8166 | 4429 | 2370 | 5700 |

The variations of critical pressures of FG cylindrical shells with various boundary conditions are presented in Fig.1. It is shown that both boundary condition and constituent material have evident influence on critical pressure. The critical pressures for clamped-clamped boundary condition are higher than those for other boundary conditions. There is a significant difference about the pressure values among the selected composite materials, and the combination of stainless steel and $Si_3N_4$ has an advantage over the others.

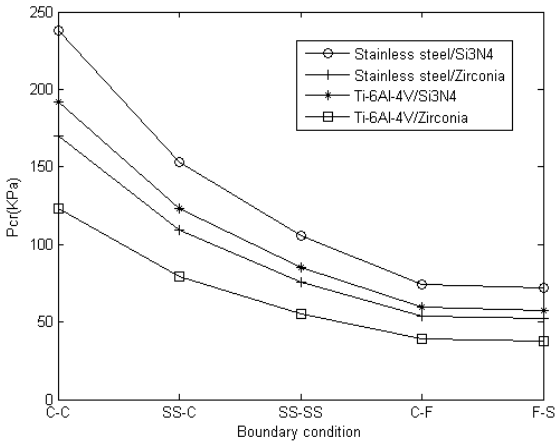

**Fig.1 Variation of critical pressure for a submerged cylindrical shell with various boundary conditions.**

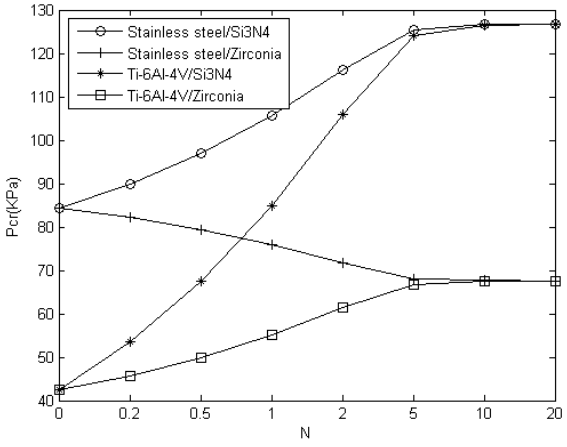

**Fig 2. Variation of critical pressures for a submerged cylindrical shell for some different values of power-law exponent.**

Fig.2 shows the curves of critical pressures of FG cylindrical shells for various values of power-law exponent. It is shown that the effects of power-law exponent on critical pressure are evident. The influences of power-law exponent on critical pressures are mainly reflected in the cases of small power-law exponent. With the increasing of power-law exponent, the functionally graded material is from a pure metal material to a pure ceramic material. This is due to the FG cylindrical shell is reduced to an isotropic cylindrical shell. Since critical pressure is material property dependent, use the FG cylindrical shell which composed of Stain steel and Zirconia as an

example. Because of the critical pressure of pure Stain steel cylindrical shell is larger than pure Zirconia cylindrical shell, the critical pressure decreases with the increasing of power-law exponent.

The critical pressures of simply supported FG cylindrical shells for different $h/R$ are shown in Fig. 3. It is shown that with the increasing of $h/R$, the critical pressure increases rapidly. The influences of constituent material on critical pressure are mainly reflected in the cases of large $h/R$.

For $m=1$ and $n=2$, the curves of critical pressures of simply supported FG cylindrical shells for different $L/R$ are shown in Fig. 4. The critical pressures first increased and then decreased with $L/R$. And the critical pressures for lower $L/R$ ratios are higher than those for higher $L/R$ ratios. The influences of constituent material on critical pressure are mainly reflected in the cases of small $L/R$ ratio. When $L/R$ comes to a certain degree, the effect of dimension on the critical pressure is not significant.

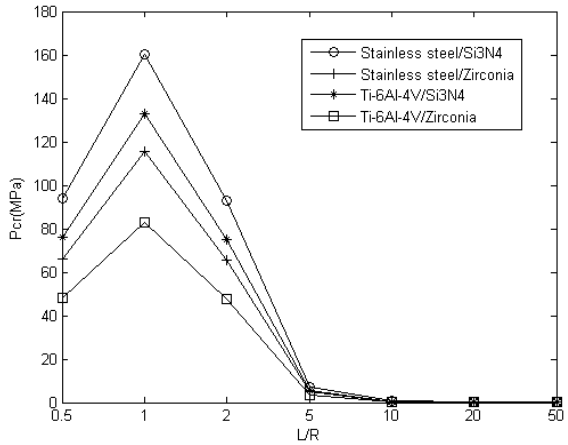

**Fig.3 Variation of critical pressures of submerged cylindrical shell with different $h/R$ ratios.**

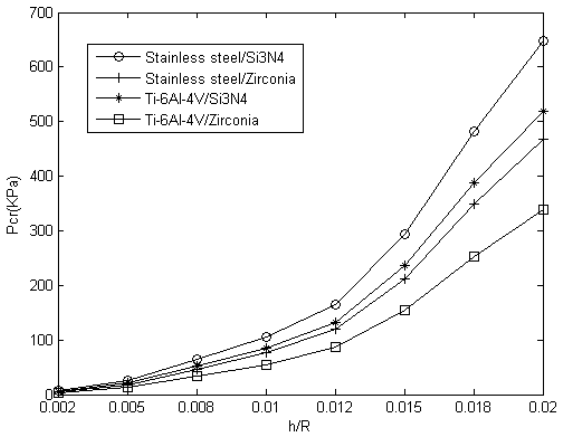

**Fig.4 Variation of critical pressures for a submerged cylindrical shell with different $L/R$ ratios.**

## Conclusions

Based on the analysis of the critical pressures with the control factors, the study showed that the constituent material and boundary conditions have a significant influence on the critical pressure. Critical pressure values of the composite cylindrical shell lie between those of the two kinds of homogenous material structure. The influences of constituent material on critical pressure are mainly reflected in the cases of large $h/R$ and small $L/R$ ratio. The characteristics of critical pressure will certainly provide guidance to the practical use and risk averse.

**Keywords:** wavelet-based methods, boundary problem, local structural analysis, static analysis, Bernoulli beam, discrete wavelet, Haar basis, averaging, reduced wavelet coefficients

**Abstract.** This paper is devoted to correct and efficient method of local static analysis of Bernoulli beam on elastic foundation. First of all, problem discretized by finite difference method, and then transformed to a localized one by using the Haar wavelets. Finally, imposing an optimal reduction in wavelet coefficients, the localized, reduced results can be obtained. It becomes clear after comparison with analytical solutions, that the localization of the problem by multiresolution wavelet approach gives exact solution in desired regions of beam even in high level of reduction in wavelet coefficients. This localization can be applied to any arbitrary region of the beam by choosing optimum reduction matrix and obtaining exact solutions with an acceptable reduced size of the problem.

## Introduction.

Need for providing an accurate and efficient method for the local structural analysis can be determined with the considering of large-scale or complex structures and with the using of personal computers with limited performance. On the other hand, it is practically impossible or very time consuming to obtain the exact (high-accuracy) solution for the entire structure. For instance, we can obtain high-accuracy results with the use of finite-element method (FEM) by choosing smaller element size, leading in its turn to increasing the numbers of finite elements and therefor time of analysis [5]. This is possible as long as the solution is achievable in common personal or even professional computers and in a reasonable time. However, exact solution normally is not required in all regions, and due to structural or loading conditions, the location and approximate dimensions of critical regions of the structure can be determined. The stress-strain state in these regions are important from the standpoint of analysis and design, and may lead to structural failure or cause impairment in structural performance. Thus, using an appropriate method we can achieve sufficient accuracy in these selected regions with a smaller number of unknowns. For covering this goal we can use multilevel analysis of the stress-strain state of the structures. The proposing method allows qualitative and quantitative assessments of the degree of localization of various kinds of phenomena. Wavelet analysis has become one of the most effective and popular contemporary sources for this kind of research in the recent years [1, 2, 3, 4].

## Initial Formulation of the Problem and Transition to Haar Wavelet Basis.

It is commonly known that after discretization of the problem of static beam analysis with the use of finite difference method (FDM) we can obtain the following resultant system of linear algebraic equations

$$A\bar{y} = \bar{f}\,, \tag{1}$$

where $A$ is the coefficient matrix; $\bar{y}$ is the vector of nodal unknowns (displacements); $\bar{f}$ is the right-side vector.

Decomposition of corresponding discrete function with the use of wavelet multiresolution analysis allows obtaining more information about it. We used discrete Haar wavelet (which is one of the simplest and best suited to this purpose) and corresponding direct and inverse algorithms of transformations, proposed by Prof. A.B. Zolotov [5]. We have ($Q_h$ is the transformation matrix; $\bar{v}$ is the vector of Haar wavelet coefficients)

$$\bar{y} = Q_h \bar{v} . \tag{2}$$

Thus, by substitution the equation (2) in equation (1) and then multiplying both sides by $Q_h^T$ (transponsed matrix $Q_h$), the transformation process has been completed:

$$A_v \bar{v} = \bar{f}_v , \quad \text{where} \quad A_v = Q_h^T A Q_h , \quad \bar{f}_v = Q_h^T \bar{f} . \tag{3}$$

**Imposing reduction in wavelet coefficients.**

Localized high-accuracy solution in selected regions and reduced size of the problem

$$A_v^r \bar{v}^r = \bar{f}_v^r \tag{4}$$

can be obtained with the use of appropriate algorithm for the reduction of wavelet coefficients,

$$\bar{v} = R \bar{v}^r , \tag{5}$$

where $R$ is rectangular matrix with a size $n \times n^r$ (so-called reduction matrix, $n^r < n$); $A_v^r$ is the reduced coefficient matrix; $\bar{f}_v^r$ is the reduced right-side vector; $\bar{v}^r$ is the reduced wavelet coefficients after imposing reduction defined by vector $\bar{\chi}$,

$$\bar{v} = [\,(\bar{v}^0)^T \;\; (\bar{v}^1)^T \;\; \ldots \;\; (\bar{v}^M)^T\,]^T , \text{ where } \bar{v}^p = \{v_j^p\}_{j=\overline{1,N_p}}, \; p = \overline{0,M} ; \; N_p = \begin{cases} n/2^{p+1}, & 0 \le p < M \\ 1, & p = M; \end{cases} \tag{6}$$

$$\bar{v}^r = [\,(\bar{v}^{r,0})^T \;\; (\bar{v}^{r,1})^T \;\; \ldots \;\; (\bar{v}^{r,M})^T\,]^T , \quad \text{where} \quad n^r = \sum_{p=0}^{M} \sum_{j=1}^{N_p} \chi_j^p ; \tag{7}$$

$$\bar{\chi} = [(\bar{\chi}^0)^T \;\; (\bar{\chi}^1)^T \;\; \ldots \;\; (\bar{\chi}^M)^T\,]^T , \text{ where } \bar{\chi}^p = \{\chi_j^p\}_{j=\overline{1,N_p}}, \; p = \overline{0,M} ; \; \chi_j^p = \begin{cases} 1, \text{if } v_j^p \text{ is reduced} \\ 0, \text{if } v_j^p \text{ isn't reduced.} \end{cases} \tag{8}$$

$M$ is the maximum order of Haar basis function; $N_p$ is the number of Haar basis of the order $p$; $n = 2^M$; $\bar{v}^{r,p}$ is $n^r$-dimensional vector, obtained by eliminating elements of $v_j^p$ for which $\chi_j^p = 0$.

Let's introduce global indexing system for elements of vector (6) in accordance with formula

$$k \;\Leftrightarrow\; (j,p) , \quad \text{where} \quad k = j + \sum_{q=0}^{p-1} N_q ; \tag{9}$$

$k$ is global index; $j, p$ are initial indexes (multiindex).

We will use the following notations:

$$N_{tot}^{-1} = 0; \quad N_{tot}^{s} = \sum_{q=0}^{s} N_q, \quad s = 1, 2, ..., M. \tag{10}$$

Special algorithm of computing indexes $p$ and $j$ on the base of index $k$ is presented below.
1) Let's assign $s = M$. 2) Compute $N_{tot}^{s}$.
3) Compute $\tau_s$ in accordance with formula (notation $[a]$ means integer part of $a$)

$$\tau_s = [(k-1)/N_{tot}^{s}]. \tag{11}$$

4) If $\tau_s = 1$ then indexes $p$ and $j$ are computed by formulas

$$p = s+1; \quad j = k - N_{tot}^{s}. \tag{12}$$

If $s > 0$ and $\tau_s = 0$ then $s$ must be decremented by one and we shoud go to the second step of the distinctive algorithm. If $s = 0$ and $\tau_s = 0$ then

$$p = 0; \quad j = k. \tag{13}$$

Let's introduce global indexing system for elements of vector (7) in accordance with formula

$$k \;\Leftrightarrow\; (j, p), \quad \text{where} \quad k = \sum_{q=1}^{j} \chi_j^p + \sum_{q=0}^{p-1} N_q^r; \quad N_p^r = \sum_{j=1}^{N_p} \chi_j^p; \tag{14}$$

$k$ is global index; $j, p$ are initial indexes (multiindex).
We will use the following notations:

$$N_{tot,red}^{-1} = 0; \quad N_{tot,red}^{s} = \sum_{q=0}^{s} N_q^r, \quad s = 1, 2, ..., M. \tag{15}$$

Special algorithm of computing indexes $p$ and $j$ on the base of index $k$ is presented below.
1) Let's assign $s = M$. 2) Compute $N_{tot,red}^{s}$. 3) Compute $\tau_s$ in accordance with formula

$$\tau_s = [(k-1)/N_{tot,red}^{s}]. \tag{16}$$

4) If $\tau_s = 1$ then index $p$ and ancillary quantity $t$ are computed by formulas

$$p = s+1; \quad t = k - N_{tot,red}^{s}. \tag{17}$$

Procedure of computing of index $j$ is presented below.
a) Let's assign $m = 1$. b) Compute $r_m$ in accordance with formula

$$r_m = \sum_{i=1}^{m} \chi_i^p. \tag{18}$$

c) If $t = r_m$ then $j = m$. Otherwise $m$ must be incremented by one and we shoud go to step „b“ of the distinctive procedure. If $s > 0$ and $\tau_s = 0$ then $s$ must be decremented by one and we shoud go to the second step of the distinctive algorithm. If $s = 0$ and $\tau_s = 0$ then $p = 0$ and index $j$ can be defined by steps „a“, „b“ and „c“ of the procedure.

Algorithm of computing of reduction matrix is presented below.

1) Let‘s assign initially $R = 0$. 2) Let’s assign $i_1 = n$.

3) In accordance with above-described alogithm we compute indexes $p$ and $j$ of the corresponding element of the vector (6) on the base of index $i_1$.

4) We should consider two possible cases.

4.1) If $\chi_j^p = 1$ then in accordance with above-described alogithm we compute index $i_2$ of the corresponding element of the vector (7) on the base of indexes $p$ and $j$ and then compute element of reduction matrix $R_{i_1,i_2} = 1$, where $i_1$ and $i_2$ are numbers of row and column of reduction matrix.

4.2) If $\chi_j^p = 0$ then we compute the following parameters:

$$m = 1; \quad q = p + 1; \quad t = j; \quad s = [(t+1)/2]. \tag{19}$$

4.2.1) If $\chi_s^q = 1$ then in accordance with above-described alogithm we compute index $i_2$ of the corresponding element of the vector (6) on the base of indexes $q$ and $s$ and then compute element of reduction matrix ($\beta$ is averaging coefficient)

$$R_{i_1,i_2} = \beta^m; \quad \beta = 1/(2\sqrt{2}). \tag{20}$$

4.2.2) If $\chi_s^q = 0$ then $m$ must be incremented by one, $q$ must be incremented by one, we shoud assign $t = s$ and go to formula (19).

**Keywords:** Functionally graded materials, Cylindrical shell, Buckling of bending

**Abstract.** Buckling behavior of functionally graded materials cylindrical shell under pure bending is studied in this paper. The stability equations of functionally graded materials cylindrical shell are derived using the classical plate and shell theory with Kirchhoff hypothesis, importing the bending boundary condition to obtain the critical buckling load. The result shows that the critical moment is linear with the radius, quadratic with the thickness and irrelevant with the length of the cylindrical shell. In addition, the critical moment is decreased by increasing the power law index of the material bulk, trending to a constant finally.

## Introduction

In 1984, the Japanese scientists synthesised the heterogeneous materials-functionally gradient materials(FGMs)which was made of ceramic and metal. FGMs is a new type of micro heterogeneous material whose most remarkable characteristic is that its mechanical properties is very smooth and its physical properties is stable without mutations, thus it is a good way to avoid stress concentration problem. Also, this kind of materials has the outstanding designability characteristic so we can change each component material's volume of space distribution to achieve the goal of optimizing the structure's inner stress distribution. As a kind of high performance refractory materials, FGMs has been applied in various industries, such as the nuclear industry, aerospace, chemical industry, civil, etc.

At present, buckling behavior of functionally graded materials cylindrical shell under pure bending has been studied by many schlars. Feldman and Aboudi have studied the buckling of functionally graded materials plate subjected to uniaxial loading [1]. They used the micro mechanics and structure mechanics method to obtained the critical buckling load. Cheng and Batra used the higher order shear plate theory to study the bucking and vibration of the simply supported functionally graded material plate subjected to axial loading in temperature field [2]. Na and Kim used the finite element model to study thermal buckling of functionally graded material plate in three dimensional temperature field [3]. Shariat and Javaheri discussed the buckling of defective functionally graded material plate under in-plane loading based on the classical plate theory [4]. Woo and Meguid used the higher order shear theory to study the post-buckling of medium thickness shell under thermal-mechanica interaction based on von karman nonlinear theory [5], and they obtained the Fourier series results. Ma Liansheng [6] analysed the buckling of functionally graded materials circular (ring) plate.

This article uses the classical plate and shell theory with Kirchhoff hypothesis to derive the basic equations of functionally graded material cylindrical shell, then obtains the critical moment under pure bending.

## Theory Analysis of Functionally Graded Materials Cylindrical Shell Buckling under Pure Bending

We consider the functionally graded materials cylindrical shell whose radius ,length,thickness are respectively *R, L, h* as is shown in Fig.1. As we use the thin shell theory, the $h/R \leq 0.02$.We suppose that its young's modulus changes as follows:

$$E(z)=E_m+\left(\frac{2z+h}{2h}\right)^N(E_c-E_m) \quad (1)$$

The subscript "m" and "c" represent the metal materials and ceramic materials respectively, and the letter "N" is the power law index of the material bulk.

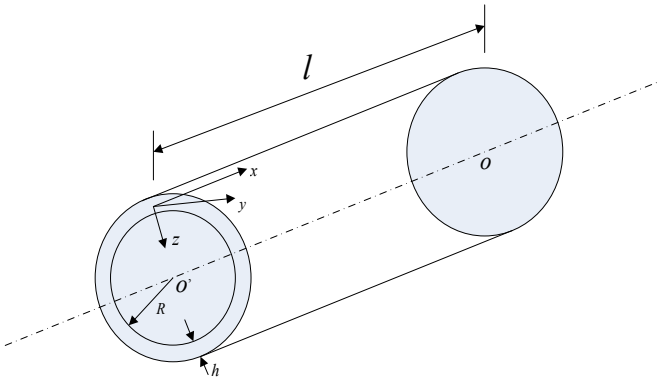

Fig.1 Physical dimension of functionally graded cylindrical shell

Here we set E = E (z), v is a constant.Then the physical equations of functionally graded materials cylindrical shell as follow:

$$\begin{aligned}
N_x &= \int_{-h/2}^{h/2}\sigma_x dz = D_1(\varepsilon_x+\nu\varepsilon_y)+D_2(\chi_x+\nu\chi_y)\\
N_y &= \int_{-h/2}^{h/2}\sigma_y dz = D_1(\varepsilon_y+\nu\varepsilon_x)+D_2(\chi_y+\nu\chi_x)\\
N_{xy} &= N_{yx} = \int_{-h/2}^{h/2}\tau_{xy} dz = \frac{1-\nu}{2}(D_1\gamma_{xy}+2D_2\chi_{xy})\\
M_x &= \int_{-h/2}^{h/2}\sigma_x z dz = D_2(\varepsilon_x+\nu\varepsilon_y)+D_3(\chi_x+\nu\chi_y)\\
M_y &= \int_{-h/2}^{h/2}\sigma_y z dz = D_2(\varepsilon_y+\nu\varepsilon_x)+D_3(\chi_y+\nu\chi_x)\\
M_{xy} &= M_{yx} = \int_{-h/2}^{h/2}\tau_{xy} z dz = \frac{1-\nu}{2}(D_2\gamma_{xy}+2D_3\chi_{xy})
\end{aligned} \quad (2)$$

Among them，

$$D_1=\int_{-h/2}^{h/2}\frac{E(z)}{1-\nu^2}dz, D_2=\int_{-h/2}^{h/2}\frac{E(z)z}{1-\nu^2}dz, D_3=\int_{-h/2}^{h/2}\frac{E(z)z^2}{1-\nu^2}dz \quad (3)$$

Using the classical plate and shell theory, we can obtain the linear buckling equation:

$$D\nabla^8 w+\frac{D_1(1-\nu^2)}{R^2}\frac{\partial^4 w}{\partial x^4}-\left[N_x\nabla^4\left(\frac{\partial^2 w}{\partial x^2}\right)+2N_{xy}\nabla^4\left(\frac{\partial^2 w}{\partial x\partial y}\right)+N_y\nabla^4\left(\frac{\partial^2 w}{\partial y^2}\right)\right]=0 \quad (4)$$

Among them，

$$D=D_3-D_2^2/D_1 \quad (5)$$

Under pure bending M,the compression zone occurs bucking first .At this time,the membrane force as follows:

$$N_x = N_1\cos\frac{y}{R} \quad (6)$$

Among them,

$$N_1=\frac{M}{\pi R^2} \quad (7)$$

For the homogeneous isotropic cylindrical shell, the critical stress under axial compression and the critical stress under pure bending almost have the same value.So here we think that the functionally graded materials cylindrical shell is also in accordance with the law, namely

$$N_{cr-bending} = N_{cr-comp} \tag{8}$$

Now transform the problem into obtaining the critical bucking stress under axial compression of functionally graded materials.So we assume , the axial compression membrane as follows:

$$N_x = N_1, N_y = N_{xy} = 0 \tag{9}$$

Here,the bucking deflection function as follows:

$$w = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} f_{mn} \sin \alpha x \sin \beta y \tag{10}$$

Among them,

$$\alpha = \frac{m\pi}{L}, \beta = \frac{n}{R} \tag{11}$$

Put formula (9) and (10) into the linear buckling control formula(4).

Since $f_{mn} \neq 0$ , $\sin \alpha x \sin \beta y \neq 0$ ,we obtain

$$N_1 = \frac{D}{\alpha^2}\left(\alpha^2 + \beta^2\right)^2 + \frac{D_1\left(1-\nu^2\right)\alpha^2}{R^2\left(\alpha^2+\beta^2\right)^2} \tag{12}$$

So the critical stress of pure bending is

$$M = \pi R^2\left[\frac{D}{\alpha^2}\left(\alpha^2 + \beta^2\right)^2 + \frac{D_1\left(1-\nu^2\right)\alpha^2}{R^2\left(\alpha^2+\beta^2\right)^2}\right] \tag{13}$$

Using the mean inequality,we have

$$M_{cr} = 2\pi R\sqrt{DD_1\left(1-\nu^2\right)} \tag{14}$$

According to formula (1), when the power law index of the material bulk $N = 0$,the FGMs tube degenerates into the pure ceramic isotropic material cylindrical tube. At this time the result of formula (14)has the same value with the isotropic ceramic material pipe.

## The Calculation Results and Analysis

Here we use the functional gradient materials which is made of aluminium and zirconia. Aluminum: *Em=70* GPa, *v=0.3*; Zirconia:*Ec=151*GPa, *v =0.3*.

**Critical Moment Versus Radius**.Now considering the power law index of the material bulk $N = 1$,the thickness *h=0.004 m,* the critical moment along with the change of the radius is shown in Fig.2.The Fig.2 shows that the critical moment is linear with the radius.

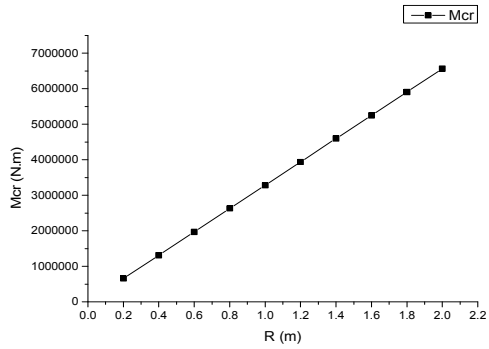

Fig.2 Critical moment versus radius

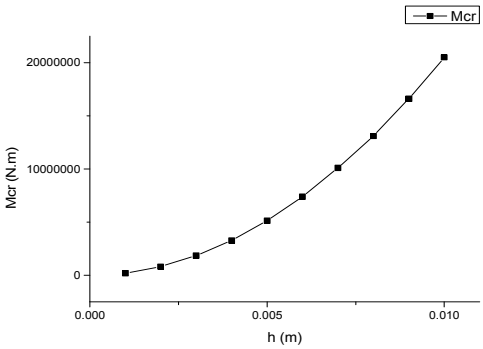

Fig.3 Critical moment versus thickness

**Critical Moment Versus Thickness.**Now we consider the thickness's impact on the critical moment.Here we assume that the power law index of the material bulk *N=1*and other parameters are under certain conditions. In this paper the shell belongs to thick shell, so we assure that R/h>50. From

formula(14) $M_{cr} = 2\pi R\sqrt{DD_1(1-\nu^2)}$ ,and according to formula (3) and (5) ,we have $D_1 \propto h, D \propto h^3$ , namely $M_{cr} \propto h^2$ .As is shown in Fig.3, the critical moment is quadratic with the thickness *h*.

**Critical Moment Versus The Power Law Index of The Material Bulk *N*.** Now we consider the the power law index of the material bulk *N*'s impact on the critical moment.Here we assume *R = 0.2 m, R = 0.6 m, R = 1 m*,and the FGMs tube thickness *h = 0.004 m*.As is shown in Fig.4,the critical moment decreases with the increase of the power law index of the material bulk *N*.When $0 \le N \le 2$,the critical moment decreases quickly with the increase of *N*; When *N>2*, the change become significantly reduced; when *N>5*,the change is no longer apparent. In addition, with the increase of *N*, metal composition is dominant, the critical moment will eventually tend to a constant finally.

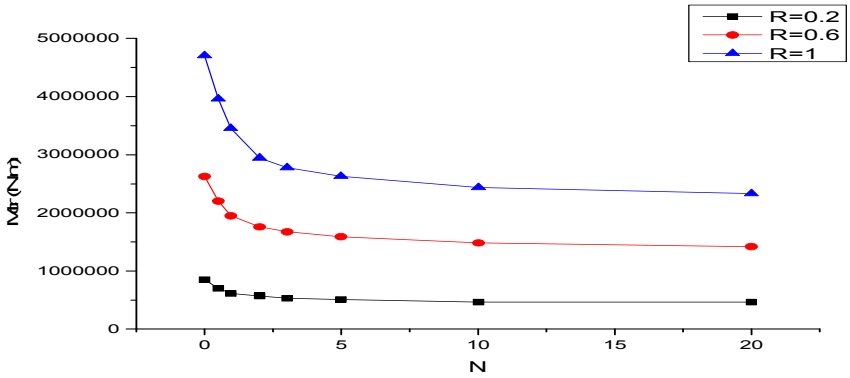

Fig.4 Critical moment versus the power law index of the material bulk *N*

## Summary

This article derives the critical moment expressions of functionally graded materials shell buckling under the pure bending based on the classical plate and shell theory. The result shows that the critical moment is linear with the radius,quadratic with the thickness and irrelevant with the length of the cylindrical shell.In addition,the critical moment is decreased by increasing the power law index of the material bulk *N*. And if *N > 5*, the critical moment changes no longer obvious.At this time,the metal composition is dominant, and the critical moment tends to be the critical moment of the pure metal cylindrical shell along with the increase of *N*.

**Keywords:** contact problem, unilateral constraints, friction, step-by-step analysis, working scheme, discrete model, contact element

**Abstract.** Here computational models of contact of elastic systems with the contact finite elements (CFE) in a 2D or 3D frame-rod systems are reviewed. The solution is based on the method of the step-by-step analysis taking into account the character of loading, the complicated conditions of the contact and other factors consideration of which approaches the calculation circuit of the task to the real operating conditions of any structures or construction

Constructionally nonlinear problems with unilateral constraints and friction with unknown before contact area are frequent while calculation of any structures or construction. For instance, construction and functional joints in the structure can open and close both with frictional sliding and cohesion of conjugated surfaces with different combinations of external loading. The same process can occur at the place of contact of foot construction and its bottom, or in different supporting blocks assuming either detachment or frictional sliding of a construction resting on them. At the same time it is the state of contact area that determine the evaluation of stress strain behavior of structures or construction and their resistibility and working efficiency [1].

Tasks with complicated conditions of contact, the consideration of which is meant to approach the design scheme to the real operating conditions of a construction, are of special interest. It is, for example, solid friction with normal forces of interaction depending on the solution, accounting strain and initial strength of unilateral constraints, sequence of erection and loading, dynamic action of loading and etc. In such cases contact problem becomes more complicated in terms of mathematics and its computational solution becomes more complicated as well. As the consideration of listed factors makes the solution of such tasks depending on character and history of the loading facilities, modeling of contact interaction, and the solution based on the method of the step-by-step analysis respectively, appear appropriate.

While making a solution of unilateral contact problems models of finite elements and algorithm of their numerical implementation are used in this work. So, for unilateral constraints modeling the contact finite elements (CFE), are applied that are be introduced in zones of possible contact of interacting bodies thus discretizing a thin layer (fake or real) between the contacting surfaces. This contact layer combines interacting bodies into a unified system and, due to special properties having given to it and taken into account by numerical computation, can meet the necessary requirements for contact. That sort of approach allows structural nonlinearity of the given system, that is a problem of structural mechanics with unilateral constraints and friction between contacting bodies and brings directly to consideration of the nonlinear discrete contact layer. In our situation contact finite elements in a 2D or 3D frame-rod are suggested for using [2]. The data of CFE interact with common finite elements in a 2D or 3D frame-rod and provide a contact between grid nodes, situated on the boundary surfaces of contacting bodies.

While using the mentioned contact elements there is no necessity for matching of coordinates of conjugated surfaces nodes, i.e. uncorrelated grids can be applied. CFE can be introduced both immediately and consequently, while contacting function between boundary surfaces of bodies, thus performing a registration of contact area state, as well as modeling various contact relations (detachment, bonding, sliding etc.). Moreover, having applied CFE one can consider various characteristics of unilateral connections, such as elastic flexibility, physical nonlinearity, initial strength and etc. Modeling of contact relations is conducted through changing of contact layer physical properties, which are, in their turn, manifested through stiffening characteristics of frame CFE cores.

Let's consider horizontal contact problem for linear elastic body $V^+$ and $V^-$, between boundary surfaces of which ($S_c^+$, $S_c^-$) unilateral constraints and Culon's friction are presented. For modeling of contact in discrete analytical model the suggested core framed contact elements are used (fig. 1).

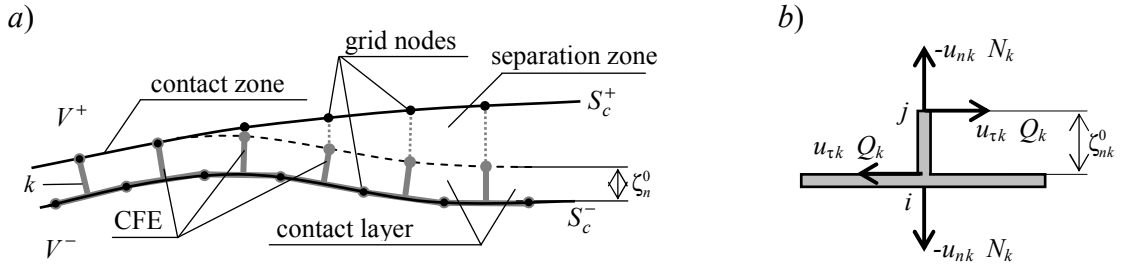

Fig. 1. Contact interaction using by frame CFE

Boundary condition in contact can be manifested through strain and deformation in individual CFE:

$$u_{nk} \le 0;\ \ N_k \le 0;\ \ u_{nk} N_k = 0;\ \ |Q_k| \le |Q_{pk}| = -f_k N_k;\ \ Q_k u_{\tau k} \ge 0;\ \ (Q_k - Q_{pk}) u_{\tau k} = 0,\quad k \in S_c. \quad (1)$$

Where $N_k$, $Q_k$ are contact force in *k*- CFE; $u_{nk}$, $u_{\tau k}$ are mutual displacement of opposed node points on $S_c^+$ and $S_c^-$ ($S_c = S_c^+ \cup S_c^-$) normally and tangentially, $f$ is constant of friction.

For making a solution of unilateral contact problems both methods of nonlinear programming, leading to iterative procedure as the final result, and incremental methods are applied. In the latter case, numerical implementation of boundary conditions (1) is conducted by step-by-step analysis of loading process and conversion of contact in the mentioned core framed model. The moment of state conversion is respectively disconnection, unilateral connection, frictional sliding or locking mating engagement. The step-by-step analysis is the most effective method for contact problems keeping under review, besides, there is a possibility of managing of discrete contact layer in accordance with loading condition, current state of contact area, stress strain behavior level etc.

Static loading is modeling by step-by-step application of the given loading. We assume that between two consecutive events the system deforms in linear fashion - in this case the solution of linearly elastic problem is formed within each step according to the arrangement of common loading. As a result the solution of linearly elastic problem will present a solution of series of linear problems, under the conditions of operating configuration of a construction modification. The procedure of settlements consists of testing and base pitches of loading. Analysis of testing pitches determines the moment of approaching of a recurrent event in contact. The base pitch results in new condition of contact and, in its turn, analysis of operating configuration modification results in designating of a new testing pitch. This allows to refine not only intensity of the current load step but forecast further steps as well, thus building the loading process, optimal in terms of length and complexity [3].

The moments of approaching of a frictional sliding event, detachment or contact for *k*-connection, which before this has been in bonding condition ($k \in S_{1c}$), one-side contact ($k \in S_{2c}$) or detachment, are determined ($k \in S_{3c}$) by the following formulations:

$$\Delta\lambda_k^{s+1} = \Delta\tilde{\lambda}^{s+1}\left(\frac{Q_{pk}^s - Q_k^s}{\Delta\tilde{Q}_k^{s+1} - \Delta\tilde{Q}_{pk}^{s+1}}\right),\ k \in S_{1c};\ \ \Delta\lambda_k^{s+1} = \Delta\tilde{\lambda}^{s+1}\left(\frac{-N_k^s}{\Delta\tilde{N}_k^{s+1}}\right),\ k \in S_{2c};\ \ \Delta\lambda_k^{s+1} = \Delta\tilde{\lambda}^{s+1}\left(\frac{-u_{nk}^s}{\Delta\tilde{u}_{nk}^{s+1}}\right),\ k \in S_{3c}. \quad (2)$$

Conversion from sliding state to bonding state during step (*s*+1) is determined by the conditions: $\left(\Delta\tilde{u}_{\tau k}^{s+1} / \Delta u_{\tau k}^s\right) < 0$, $\Delta u_{\tau k}^s \ne 0$, $k \in S_{2c}$. Where $\Delta\tilde{Q}_k^{s+1}$, $\Delta\tilde{Q}_{pk}^{s+1}$, $\Delta\tilde{N}_k^{s+1}$, $\Delta\tilde{u}_{\tau k}^{s+1}$, $\Delta\tilde{u}_{nk}^{s+1}$ are incrementations of contact forces and reciprocal deflections for *k*-CFE during testing step $\Delta\tilde{\lambda}^{s+1}$.

During dynamic action of loading structural nonlinearity is manifested in operating configuration of a construction modification through time. The moment of contact event modification, i.e. the ap-

proaching of succeeding event, in such case is determined by step-by-step (in time) analysis of core framed contact models with the use of corresponding approximate formulations for transferring, velocities in step $\Delta t$. Furthermore the duration of time step is corrected and subjected to re-computation. As a result the new contact state at this time is settled and, thus the current operating configuration of a construction is modified [4].

Matrix equation of motion is presented here in the form, allowing to lead the solution of constructive nonlinear dynamic contact problems to the solution of succession of linear dynamic problems on the basis of step time analysis of contact condition of the discrete FEM model under consideration:

$$\mathbf{M}\ddot{\mathbf{U}}^{t+\Delta t} + \mathbf{C}\dot{\mathbf{U}}^{t+\Delta t} + \mathbf{K}\Delta\mathbf{U}^{t+\Delta t} = \mathbf{P}^{t+\Delta t} - \mathbf{K}\mathbf{U}^{t}. \tag{3}$$

Besides, the availability of unilateral connection, boundary contact condition, recorded for time $t$, must be performed:

$$u_{nk}^{t} \le 0; \quad N_k^t \le 0; \quad u_{nk}^{t} N_k^t = 0; \quad \left|Q_k^t\right| \le \left|Q_{pk}^t\right|; \quad Q_k^t \dot{u}_{\tau k}^t \ge 0; \quad (Q_k^t - Q_{pk}^t)\dot{u}_{\tau k}^t = 0, \quad k \in S_c. \tag{4}$$

Where $\dot{u}_{\tau k}^t$ is the speed of reciprocal tangent deflections of opposite node points of $k$-CFE in time $t$. Contact states will be determined by the following constraint: when bonding $u_{nk}^t = 0$, $N_k < 0$, $\dot{u}_{\tau k}^t = 0$, $\left|Q_k^t\right| < \left|Q_{pk}^t\right|$; when sliding $u_{nk}^t = 0$, $N_k^t < 0$, $\dot{u}_{\tau k}^t \ne 0$, $\left|Q_k^t\right| = \left|Q_{pk}^t\right|$; when detachment $u_{nk}^t < 0$, $N_k^t = 0$.

Computational solution of dynamic contact problems will present the performing of step-by-step integration in time equation (3) under the conditions in contact in the form of (4). Formulations for the definite time $\widehat{t}_k$ of approaching event – sliding, bonding, detachment or contact correspondingly for $k$-connection will be the following:

$$\begin{aligned}
&\widehat{t}_k = t + \Delta t\left(\frac{Q_{pk}^t - Q_k^t}{(Q_k^{t+\Delta t} - Q_k^t) - (Q_{pk}^{t+\Delta t} - Q_{pk}^t)}\right), \ k \in S_{1c}; \qquad \widehat{t}_k = t + \Delta t\left(\frac{-\dot{u}_{\tau k}^t}{\dot{u}_{\tau k}^{t+\Delta t} - \dot{u}_{\tau k}^t}\right), \ k \in S_{2c}; \\
&\widehat{t}_k = t + \Delta t\left(\frac{-N_k^t}{N_k^{t+\Delta t} - N_k^t}\right), \ k \in S_{1c}, S_{2c}; \qquad\qquad \widehat{t}_k = t + \Delta t\left(\frac{-u_{nk}^t}{u_{nk}^{t+\Delta t} - u_{nk}^t}\right), \ k \in S_{3c}.
\end{aligned} \tag{5}$$

The mentioned CFE models and methods of their calculation can be easily extended to the solution of unilateral constraint problems by taking physical characteristics of contact layer and other complementary factors into account. So, while taking elastic flexibility in unilateral connections into account boundary condition (1) will take the form:

$$\left.\begin{aligned}
&u_{nk} + u_{nk}^{c} \le 0; \ \ N_k \le 0; \ \ (u_{nk} + u_{nk}^{c})N_k = 0; \ \ u_{nk}^{c} = N_k / C_{nk}; \ \ u_{\tau k}^{c} = -Q_k / C_{\tau k} \\
&\left|Q_k\right| \le \left|Q_{pk}\right| = -f_k N_k; \ \ Q_k(u_{\tau k} + u_{\tau k}^{c}) \ge 0; \ \ (Q_k - Q_{pk})(u_{\tau k} + u_{\tau k}^{c}) = 0
\end{aligned}\right\} \ k \in S_c. \tag{6}$$

Where $u_{nk}^{c}$, $u_{\tau k}^{c}$ is longitudinal and transverse strain of $k$-CFE, corresponding to squeezing and shift of contact layer with initial thickness $\zeta_n^0$; $C_{nk} = A_k / \rho_{nk}$, $C_{\tau k} = A_k / \rho_{\tau k}$, $\rho_n = (1 - \mu_c^2)\zeta_n^0 / E_c$, $\rho_\tau = 2(1 + \mu_c)\zeta_n^0 / E_c$ are characteristics of toughness and mechanical compliance of the layer normally and tangentially correspondingly; $A_k$ is a contact area, referring to contact element. Physical nonlinearity of a contact layer can be reduced to internal nonlinearity of frame contact elements, whereas nonlinear properties of as layer will be prescribed with the help of nonlinear properties of CFE.

When taking into account the initial strength of the contact seam disruption and cross section contact conditions will take the following form:

$$\left.\begin{aligned}
&u_{nk} + u_{nk}^{c} \le 0; \quad N_k + \left|Q_k\right| / \alpha_R \le N_{Rk}; \quad (u_{nk} + u_{nk}^{c})(N_k + \left|Q_k\right| / \alpha_R - N_{Rk}) = 0 \\
&\left|Q_k\right| \le Q_{Rk} - \alpha_R N_k; \quad Q_k(u_{\tau k} + u_{\tau k}^{c}) \ge 0; \quad (Q_k - Q_{Rk} + \alpha_R N_k)(u_{\tau k} + u_{\tau k}^{c}) = 0
\end{aligned}\right\} \ k \in S_c. \tag{7}$$

Where $N_{Rk}$, $Q_{Rk}$ are maximum permissible contact tensile and shift forces for *k*-discrete unilateral connection (i.e. *k*- CFE). It should be emphasized that conditions (7) are valid only before until failure of the connections in the contact point, after that conditions (6), describing unilateral connection with friction, will be valid. Thereby, one step-by-step process provide both simultaneous consideration of strength of the contact seam, and exposing or friction of its surfaces in areas where bounding is collapsed.

The mentioned computational models and methods are represented in complex of computational procedures, intended for solving static and dynamic problems of contact interaction. With their assistance computation of a number of structures or construction are performed, taking into account corresponding contact conditions and mode of external actions. Based on the analysis of the obtained results, some proposals concerning structural concepts of structures and loads acting on them have been made [5, 6].

**Keywords:** FEM; BEM; coupling; domain decomposition.

**Abstract.** Conventional and a class of domain decomposition finite element–boundary element coupling (FEM–BEM) methods are reviewed. This is Part I of two papers. In Part II, a review of the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method is presented and optimal dynamic values of the relaxation parameters for the mixed Dirichlet-Neumann FEM-BEM coupling method are, furthermore, derived.

## Introduction

Coupling of the finite element method (FEM) and the boundary element method (BEM) has a rich tradition, see e.g. [1-20] and the references cited therein. This is justified as researchers were motivated to develop coupled methods in order to utilize "appropriate" discretization techniques in different sub-domains of the original problem, a need that arises from the different physics of sub-domains and/or for a better computational efficiency and accuracy.

In the conventional finite element-boundary element coupling (FEM-BEM) formulation, the discretized equations from the BEM and FEM sub-domains are coupled into a unique system of algebraic equations. However, the conventional coupling methods suffer some disadvantages. As an alternative to the conventional coupling of FEM and BEM, a "class" of domain decomposition methods has been developed by many researchers. In these coupling methods there is no need to combine the coefficient matrices of the FEM and the BEM sub-domains, as required in the conventional coupling methods. The domain decomposition coupling methods preserve the nature of both the finite element and boundary element methods. This class of coupling methods can be classified as overlapping and non-overlapping. Overlapping, known also as Schwarz, domain decomposition FEM-BEM coupling methods have been proposed in [1,2]. The domain of the original problem is subdivided into a FEM sub-domain, a BEM sub-domain, such that the two sub-domains partially overlap over a common region. The common region is modelled by both methods. Recently, more elaborate non-overlapping domain decomposition FEM-BEM coupling methods have been developed for a wide range of problems, see e.g. [3-20] and the references cited therein. The non-overlapping coupling methods exhibit advantages compared to the overlapping ones. The systems of equations of the sub-domains are solved independently of each other. The interaction effects are taken into account as boundary conditions, which are imposed on the coupling interfaces. Iterations are performed in order to enforce satisfaction of the coupling conditions. Within the iteration procedure, a relaxation operator is applied to the interface boundary conditions in order to enable and speed up convergence. The non-overlapping domain decomposition coupling methods are easier to implement. However, there are challenging questions concerning the practical applications of such methods and their convergence and optimal convergence conditions.

The main objective of this paper is to present an overview of the FEM-BEM coupling methods. An outline of the paper is as follows. Section 2 briefly reviews the conventional coupling methods. An

overview of several overlapping and non-overlapping domain decomposition FEM-BEM coupling methods is presented in Sections 3 and 4, respectively.

**Conventional FEM-BEM Coupling Methods**

For simplicity, consider the 2-D non-transient, either linear (e.g., potential, elasticity) or nonlinear (e.g., elasto-plasticity), problem of Fig. 1. The original problem is modelled using the BEM and FEM. The corresponding boundary integral equation for the BEM subdomain (linear potential or elasticity problems) can be written in sub-structured form as

$$\begin{bmatrix} \mathbf{H}_{11} & \mathbf{H}_{12} \\ \mathbf{H}_{21} & \mathbf{H}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{u}_B^B \\ \mathbf{u}_B^I \end{bmatrix} = \begin{bmatrix} \mathbf{G}_{11} & \mathbf{G}_{12} \\ \mathbf{G}_{21} & \mathbf{G}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{q}_B^B \\ \mathbf{q}_B^I \end{bmatrix} \text{ on } \Gamma_B, \tag{1}$$

where, $\mathbf{H}$ and $\mathbf{G}$ are influence coefficient matrices. $\mathbf{u}_B^I$ and $\mathbf{u}_B^B$ are the interface and non-interface potentials (displacements) in the BEM sub-domain, respectively. $\mathbf{q}_B^I$ and $\mathbf{q}_B^B$ are the nodal values for interface and non-interface fluxes (tractions), respectively. After solving for the unknowns in Eq. (1), the potentials (displacements) inside the domain can be obtained as

$$\mathbf{u} = \begin{bmatrix} \mathbf{H}_{11}^* & \mathbf{H}_{12}^* \\ \mathbf{H}_{12}^* & \mathbf{H}_{22}^* \end{bmatrix} \begin{bmatrix} \mathbf{u}_B^B \\ \mathbf{u}_B^I \end{bmatrix} + \begin{bmatrix} \mathbf{G}_{11}^* & \mathbf{G}_{12}^* \\ \mathbf{G}_{21}^* & \mathbf{G}_{22}^* \end{bmatrix} \begin{bmatrix} \mathbf{q}_B^B \\ \mathbf{q}_B^I \end{bmatrix}. \tag{2}$$

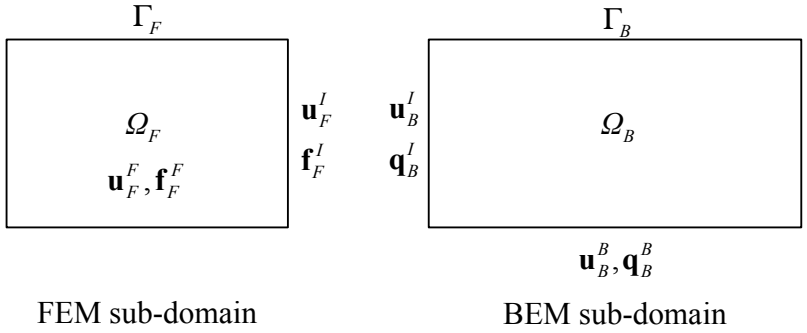

Fig. 1: Domain decomposed into FEM and BEM sub-domains.

For the FEM sub-domain (linear potential or elasticity problems), the assembled element equations in sub-structured form can be written as

$$\begin{bmatrix} \mathbf{K}_{11} & \mathbf{K}_{12} \\ \mathbf{K}_{21} & \mathbf{K}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{u}_F^F \\ \mathbf{u}_F^I \end{bmatrix} = \begin{bmatrix} \mathbf{f}_F^F \\ \mathbf{f}_F^I \end{bmatrix} \text{ in } \Omega_F, \tag{3}$$

where, $\mathbf{K}$ is the stiffness matrix for the system. $\mathbf{u}_F^I$ and $\mathbf{u}_F^F$ are the interface and non-interface potentials (displacements) in the FEM sub-domain, respectively. In the same way, the integrated flux (force) vectors $\mathbf{f}_F^I$ and $\mathbf{f}_F^F$ are defined.

At the interface $\Gamma^I$, the compatibility and equilibrium conditions are $\mathbf{u}_B^I = \mathbf{u}_F^I$ and $\mathbf{f}_F^I + \mathbf{M}\,\mathbf{q}_B^I = 0$, where $\mathbf{M}$ is the converting matrix due to the weighing of the boundary fluxes (tractions) by the interpolation function on the interface.

The standard conventional FEM-BEM coupling methods treat the BEM sub-domain as a large finite element. The potentials (displacements) - fluxes (tractions) equations governing the BEM sub-domain are transformed into FEM-like potentials (displacements) - integrated flux (force)

stiffness equations. In order to combine the FEM and BEM, both sides of Eq. (1) is multiplied by $\mathbf{MG}^{-1}$ which yields

$$\mathbf{M}\begin{bmatrix}\mathbf{G}_{11} & \mathbf{G}_{12}\\ \mathbf{G}_{21} & \mathbf{G}_{22}\end{bmatrix}^{-1}\begin{bmatrix}\mathbf{H}_{11} & \mathbf{H}_{12}\\ \mathbf{H}_{21} & \mathbf{H}_{22}\end{bmatrix}\begin{bmatrix}\mathbf{u}_B^B\\ \mathbf{u}_B^I\end{bmatrix}=\mathbf{M}\begin{bmatrix}\mathbf{q}_B^B\\ \mathbf{q}_B^I\end{bmatrix}. \tag{4}$$

Eq. (4) can be written as

$$\begin{bmatrix}\overline{\mathbf{K}}_{11} & \overline{\mathbf{K}}_{12}\\ \overline{\mathbf{K}}_{21} & \overline{\mathbf{K}}_{22}\end{bmatrix}\begin{bmatrix}\mathbf{u}_B^B\\ \mathbf{u}_B^I\end{bmatrix}=\begin{bmatrix}\mathbf{f}_B^B\\ \mathbf{f}_B^I\end{bmatrix}, \tag{5}$$

which has the same form as that in the finite element method and therefore can be assembled with the FEM matrices to form a global stiffness matrix. The coupled FEM-BEM equations is then formulated as

$$\begin{bmatrix}\mathbf{K}_{11} & \mathbf{K}_{12} & \\ \mathbf{K}_{21} & \mathbf{K}_{22}+\overline{\mathbf{K}}_{22} & \overline{\mathbf{K}}_{21}\\ & \overline{\mathbf{K}}_{12} & \overline{\mathbf{K}}_{11}\end{bmatrix}\begin{bmatrix}\mathbf{u}_F^F\\ \mathbf{u}^I\\ \mathbf{u}_B^B\end{bmatrix}=\begin{bmatrix}\mathbf{f}_F^F\\ \mathbf{f}^I\\ \mathbf{f}_B^B\end{bmatrix}. \tag{6}$$

Some force terms in (2) may be a function of displacement, $u$, or stress may be a nonlinear function of strain, $\varepsilon$, as a result of material non-linearity such as plasticity. In all of these cases, a nonlinear solution procedure is required. Eq. (2) will not be generally satisfied at any stage of computation, and thus the equilibrium equation can be restated in the form of a residual (or out-of-balance) force vector. The FEM equations, in incremental form, are solved at each iteration using a tangent FEM stiffness matrix $\mathbf{K}_T$. The coupled FEM-BEM equations for a typical iteration is then formulated as

$$\begin{bmatrix}\mathbf{K}_{T,11} & \mathbf{K}_{T,12} & \\ \mathbf{K}_{T,21} & \mathbf{K}_{T,22}+\overline{\mathbf{K}}_{22} & \overline{\mathbf{K}}_{21}\\ & \overline{\mathbf{K}}_{12} & \overline{\mathbf{K}}_{11}\end{bmatrix}\begin{bmatrix}\Delta\mathbf{u}_F^F\\ \Delta\mathbf{u}^I\\ \Delta\mathbf{u}_B^B\end{bmatrix}=-\begin{bmatrix}\Delta\boldsymbol{\psi}_F^F\\ \Delta\boldsymbol{\psi}^I\\ \Delta\boldsymbol{\psi}_B^B\end{bmatrix}, \tag{7}$$

where $\boldsymbol{\psi}$ is the residual (or out-of-balance) force vector.

The conventional coupling methods suffer some disadvantages such as:

1- the conventional coupling methods may destroy the desirable features originally existing in the FEM matrices, namely, symmetry, sparsity and bandedness,

2- in dynamic analysis, the conventional coupling methods necessitate an assignment of the same time discretization in both the FEM and BEM sub-domains. In general, based on energy considerations, we are led to incompatible time steps in both FEM and BEM sub-domains,

3- in nonlinear analysis (e.g. elasto-plasticity), with the direct FEM-BEM coupling and at each load increment, solution procedure requires iterations over computation with a combined system of equations,

4- implementation of the direct coupling method needs an integrated FEM-BEM computational environment and results in a highly undesirable requirement of accessing their source codes.

**Overlapping Domain Decomposition Coupling Methods**

The domain of the original problem is subdivided into FEM and BEM sub-domains, such that the two sub-domains partially overlap over a common region that is modeled by both methods (Fig. 2).

References [1,2] treated the coupling of FEM and BEM by a multiplicative Schwarz method, which leads to solving a symmetric positive definite system arising from the FEM discretization and a nonsymmetric system from collocation BEM or a symmetric system from Galerkin BEM. Fast solvers for the FEM and BEM sub-models can be used. The overlapping, however, may create serious complications in the Schwarz method even when the problem is of a simple geometry.

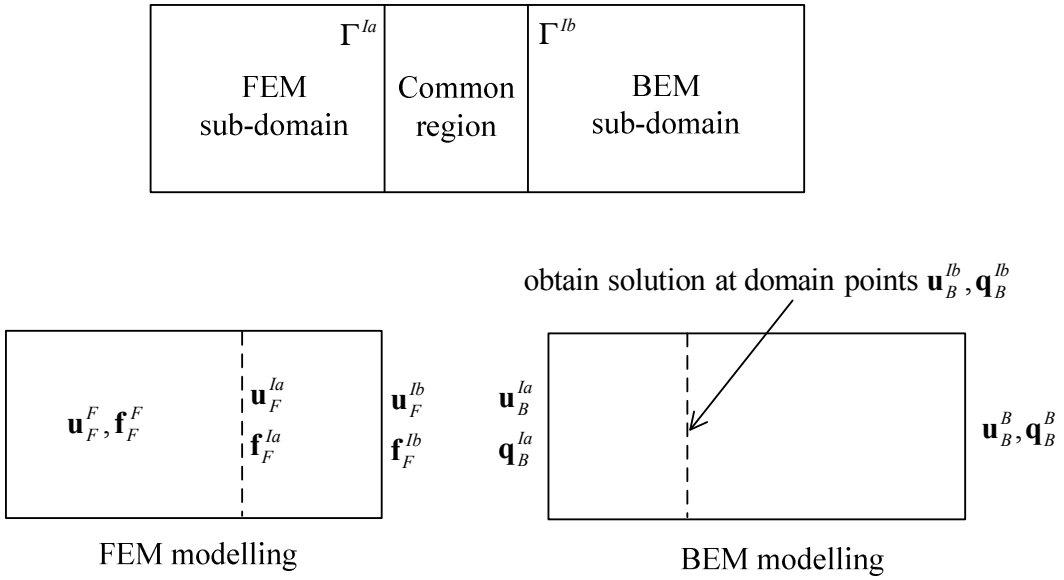

Fig. 2: Overlapping domain decomposition FEM-BEM coupling.

To describe the coupling method [2], let us define $\mathbf{u}_B^{Ia}$, $\mathbf{u}_B^B$ and $\mathbf{u}_B^{Ib}$ as the potentials (displacements) on $\Gamma^{Ia}$ approached from the BEM sub-domain, potentials (displacements) in the BEM sub-domain except at $\mathbf{u}_B^{Ia}$ and potentials (displacements) on $\Gamma^{Ib}$ computed as internal points for the BEM sub-domain, respectively. $\mathbf{u}_F^{Ia}$, $\mathbf{u}_F^F$ and $\mathbf{u}_F^{Ib}$ are the potentials (displacements) on $\Gamma^{Ia}$ approached from the FEM sub-domain, potentials (displacements) except at $\mathbf{u}_F^{Ia}$ and $\mathbf{u}_F^{Ib}$ and potentials (displacements) on $\Gamma^{Ib}$, respectively. Similarly, one can define the BEM fluxes (tractions) by $\mathbf{q}_B^{Ia}$ and $\mathbf{q}_B^B$ and the integrated flux (force) vectors by $\mathbf{f}_F^{Ia}$, $\mathbf{f}_F^F$ and $\mathbf{f}_F^{Ib}$ for the FEM sub-domain. The overlapping domain decomposition method is described as [2]

Set the initial guess $\mathbf{u}_{B,0}^{Ia}$.

Do for $n = 0, 1, 2, ...$

for the BEM sub-domain: solve Eq. (1) for $\mathbf{q}_{B,n}^{Ia}$ and boundary unknowns

for the BEM sub-domain: solve Eq. (2) for $\mathbf{u}_{B,n}^{Ib}$

for the FEM sub-domain: set $\mathbf{u}_{F,n}^{Ib} = \mathbf{u}_{B,n}^{Ib}$

for the FEM sub-domain: solve Eq. (3) for $\mathbf{u}_{F,n}^{Ia}$

apply $\mathbf{u}_{B,n+1}^{Ia} = \mathbf{u}_{F,n}^{Ia}$

**Domain Decomposition (Interface Relaxation) FEM-BEM Coupling Methods**

References [3-8] report a number of FEM-BEM domain decomposition (interface relaxation) FEM-BEM coupling applications in potential flow as well as elastostatics. It did not take long until some researchers started to extend the interface relaxation FEM-BEM coupling algorithms for applications in elasto-plasticity, three-dimensional transient elastodynamics, nonlinear dynamic

analysis, and acoustic-acoustic, elastodynamic-elastodynamic, acoustic-elastonynamic and nonlinear solid-fluid interaction, see e.g. [9-16] and the references cited therein.

Several existing domain decomposition coupling methods (Dirichlet-Neumann, Neumann-Neumann, and geometric construction based) are reviewed in Table 1. For simplicity, the 2-D non-transient (e.g., potential, elasticity) problem of Fig. 1 is considered.

**Summary**

In this paper, conventional and a class of domain decomposition finite element–boundary element coupling (FEM–BEM) are reviewed. Procedures for dynamic calculation of relaxation parameters for the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method and an example application are given in Part II of this paper.

**Keywords:** FEM; BEM; coupling; domain decomposition.

**Abstract.** Part I of this paper presents an overview of the conventional and a class of domain decomposition finite element-boundary element coupling methods. In this part, a review of the mixed Dirichlet-Neumann domain decomposition coupling method, procedures for dynamic calculation of relaxation parameters for the mixed Dirichlet-Neumann FEM-BEM coupling method and an example application are presented.

## Introduction

The main purpose of coupling the finite element method (FEM) and the boundary element method (BEM) is to use the advantages of both methods for solving various problems in applied science and engineering. Each method has areas of applications in which it is superior to the other. The FEM is most suitable for problems where the material is non-homogeneous and/or behaves nonlinearly. The BEM on the other hand, is most suitable when the domain is unbounded and in applications involving a high accuracy of boundary stresses. The theory and algorithms of coupling FEM and BEM (FEM-BEM) reached, by now, a fairly matured state.

In Part I of this paper, an overview of the conventional and a class of domain decomposition finite element-boundary element coupling methods are presented. The main objective of this paper is to derive procedures for dynamic calculation of relaxation parameters for the mixed Dirichlet-Neumann FEM-BEM coupling method. An outline of the paper is as follows. Section 2 reviews the mixed Dirichlet-Neumann FEM-BEM coupling method. Optimal dynamic values of the relaxation parameters are derived in Section 3. Example application is given in Section 4.

## Mixed Dirichlet-Neumann FEM-BEM Coupling [1,2]

In this coupling method, both the Dirichlet and Neumann boundary conditions are assumed on the interface between the sub-domains. For simplicity, consider the 2-D non-transient linear (e.g., potential, elasticity) problem. The original problem is modelled using the BEM and FEM. The corresponding boundary integral equation for the BEM subdomain (linear potential or elasticity problems) can be written in sub-structured form as

$$\begin{bmatrix} \mathbf{H}_{11} & \mathbf{H}_{12} & \mathbf{H}_{13} \\ \mathbf{H}_{21} & \mathbf{H}_{22} & \mathbf{H}_{23} \\ \mathbf{H}_{31} & \mathbf{H}_{32} & \mathbf{H}_{33} \end{bmatrix} \begin{bmatrix} \mathbf{u}_B^B \\ \mathbf{u}_B^{I1} \\ \mathbf{u}_B^{I2} \end{bmatrix} = \begin{bmatrix} \mathbf{G}_{11} & \mathbf{G}_{12} & \mathbf{G}_{13} \\ \mathbf{G}_{21} & \mathbf{G}_{22} & \mathbf{G}_{23} \\ \mathbf{G}_{31} & \mathbf{G}_{32} & \mathbf{G}_{33} \end{bmatrix} \begin{bmatrix} \mathbf{q}_B^B \\ \mathbf{q}_B^{I1} \\ \mathbf{q}_B^{I2} \end{bmatrix} \text{ on } \Gamma_B, \tag{1}$$

where, $\mathbf{u}_B^B$ are the non-interface potentials (displacements) in the BEM sub-domain. $\mathbf{u}_B^{I1}$ and $\mathbf{u}_B^{I2}$ are the interface potentials (displacements), approached from the BEM sub-domain, on $\Gamma^{I1}$ and $\Gamma^{I2}$, respectively. Similarly, one can denote the BEM nodal values for the fluxes (tractions) by $\mathbf{q}_B^B$, $\mathbf{q}_B^{I1}$, and $\mathbf{q}_B^{I2}$.

For the FEM sub-domain (linear potential or elasticity problems), the assembled element equations in sub-structured form can be written as

$$\begin{bmatrix} \mathbf{K}_{11} & \mathbf{K}_{12} & \mathbf{K}_{13} \\ \mathbf{K}_{21} & \mathbf{K}_{22} & \mathbf{K}_{23} \\ \mathbf{K}_{31} & \mathbf{K}_{32} & \mathbf{K}_{33} \end{bmatrix} \begin{bmatrix} \mathbf{u}_F^F \\ \mathbf{u}_{F,n}^{I1} \\ \mathbf{u}_{B,n}^{I2} \end{bmatrix} = \begin{bmatrix} \mathbf{f}_F^F \\ \mathbf{f}_F^{I1} \\ \mathbf{f}_F^{I2} \end{bmatrix} \text{ in } \Omega_F, \tag{2}$$

where, $\mathbf{u}_F^F$, $\mathbf{u}_F^{I1}$ and $\mathbf{u}_F^{I2}$ are non-interface potentials (displacements) in the FEM sub-domain, interface potentials (displacements) on $\Gamma^{I1}$ and $\Gamma^{I2}$ (approached from the FEM sub-domain), respectively. Similarly, one can denote the integrated flux (force) vectors by $\mathbf{f}_F^F$, $\mathbf{f}_F^{I1}$ and $\mathbf{f}_F^{I2}$.

At the interface $\Gamma^I$, the compatibility and equilibrium conditions are $\mathbf{u}_B^{I1} = \mathbf{u}_F^{I1}$, $\mathbf{u}_B^{I2} = \mathbf{u}_F^{I2}$, $\mathbf{f}_F^{I1} + \mathbf{M}_1 \mathbf{q}_B^{I1} = 0$ and $\mathbf{f}_F^{I2} + \mathbf{M}_2 \mathbf{q}_B^{I2} = 0$.

The mixed Dirichlet-Neumann FEM-BEM coupling method may be described as [1,2]

Set initial guess $\mathbf{u}_{B,0}^{I1} = \overline{\mathbf{u}}$ and $\mathbf{q}_{B,0}^{I2} = \overline{\mathbf{q}}$.

For $n = 0, 1, 2, \ldots$, do

for the BEM sub-domain: solve Eq. (1) for $\mathbf{q}_{B,n}^{I1}$ and $\mathbf{u}_{B,n}^{I2}$

set $\mathbf{f}_{F,n}^{I1} + \mathbf{M}_1 \mathbf{q}_{B,n}^{I1} = 0$ and $\mathbf{u}_{F,n}^{I2} = \mathbf{u}_{B,n}^{I2}$

for the FEM sub-domain: solve $\mathbf{f}_{F,n}^{I2} = \mathbf{M}_2 \mathbf{q}_{F,n}^{I2}$ and Eq. (2) for $\mathbf{u}_{F,n}^{I1}$ and $\mathbf{q}_{F,n}^{I2}$

apply $\mathbf{u}_{B,n+1}^{I1} = (1-\alpha)\mathbf{u}_{B,n}^{I1} + \alpha \mathbf{u}_{F,n}^{I1}$ and $\mathbf{q}_{B,n+1}^{I2} = (1-\beta)\mathbf{q}_{B,n}^{I2} - \beta \mathbf{q}_{F,n}^{I2}$

where, $\alpha$ and $\beta$ are relaxation parameters to ensure and/or accelerate convergence.

The mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method is capable of handling problems with any type of boundary conditions imposed on the entire real boundary of the FEM and BEM sub-domains. The convergence conditions for the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method are established in [3]. The convergence depends on the mesh density of the FEM and BEM sub-domains, the specified types of boundary conditions, and the geometrical as well as material properties.

## Dynamic Selection of Relaxation Parameters for the Mixed Dirichlet-Neumann FEM-BEM Coupling Method

The convergence/optimal convergence of the mixed Dirichlet-Neumann FEM-BEM domain decomposition coupling method is ensured by properly set relaxation parameters that can be assigned constant values for all iterations. The optimal and applicable ranges of static relaxation parameters may be obtained by experimenting with different values. Alternatively, prior to coupled FEM-BEM calculations, static values of the relaxation parameters may be obtained [3]. It requires, however, some sort of intricate matrix manipulations. In this Section, we derive optimal dynamic relaxation parameters for the mixed Dirichlet-Neumann FEM-BEM coupling method.

The optimal value of $\alpha$, at successive iterations, can be determined by minimizing the square error functional of the next and current iterations. Substituting

$$\left(\mathbf{u}_B^{I1}\right)_{n+1} = (1-\alpha)\left(\mathbf{u}_B^{I1}\right)_n + \alpha\left(\mathbf{u}_F^{I1}\right)_n \tag{3}$$

into functional

$$g(\alpha) = \left\| \left(\mathbf{u}_B^{I1}\right)_{n+1} - \left(\mathbf{u}_B^{I1}\right)_n \right\|_2^2 \tag{4}$$

results in

$$\begin{aligned} g(\alpha) = \alpha^2 \left\| \left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1} \right\|_2^2 + (1-\alpha)^2 \left\| \left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1} \right\|_2^2 , \\ + 2\alpha(1-\alpha)\left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right).\left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \end{aligned} \tag{5}$$

where $\|\cdot\|_2$ is Euclidean ($l_2$) norm.
Differentiation of (5) with respect to $\alpha$ yields:

$$\begin{aligned} g'(\alpha) = 2\alpha \left\| \left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right) - \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \right\|_2^2 - 2 \left\| \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \right\|_2^2 , \\ + 2\left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right).\left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right) \end{aligned} \tag{6}$$

and $g''(\alpha) = 2\left\| \left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right) - \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \right\|_2^2 > 0$, i.e., Eq (6) corresponds to a minimum. Setting $g'(\alpha) = 0$, we get

$$\alpha_{n+1}\,(\text{optimal}) = \frac{\left\| \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \right\|_2^2 - \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right).\left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right)}{\left\| \left(\left(\mathbf{u}_F^{I1}\right)_n - \left(\mathbf{u}_F^{I1}\right)_{n-1}\right) - \left(\left(\mathbf{u}_B^{I1}\right)_n - \left(\mathbf{u}_B^{I1}\right)_{n-1}\right) \right\|_2^2} . \tag{7}$$

Similarly, optimal value of $\beta$, at successive iterations, can be determined by minimizing the square error functional of the next and current iterations. Substituting

$$\mathbf{q}_{B,\,n+1}^{I2} = (1-\beta)\,\mathbf{q}_{B,\,n}^{I2} - \beta\,\mathbf{q}_{F,\,n}^{I2} \tag{8}$$

into functional

$$g(\beta) = \left\| \left(\mathbf{q}_B^{I2}\right)_{n+1} - \left(\mathbf{q}_B^{I2}\right)_n \right\|_2^2 \tag{9}$$

results in

$$\begin{aligned} g(\beta) = \beta^2 \left\| \left(\mathbf{q}_F^{I2}\right)_n - \left(\mathbf{q}_F^{I2}\right)_{n-1} \right\|_2^2 + (1-\beta)^2 \left\| \left(\mathbf{q}_B^{I2}\right)_n - \left(\mathbf{q}_B^{I2}\right)_{n-1} \right\|_2^2 . \\ - 2\beta(1-\beta)\left(\left(\mathbf{q}_F^{I2}\right)_n - \left(\mathbf{q}_F^{I2}\right)_{n-1}\right).\left(\left(\mathbf{q}_B^{I2}\right)_n - \left(\mathbf{q}_B^{I2}\right)_{n-1}\right) \end{aligned} \tag{10}$$

Differentiation of (10) with respect to $\beta$ yields

$$\begin{aligned} g'(\beta) = 2\beta \left\| \left(\left(\mathbf{q}_F^{I2}\right)_n - \left(\mathbf{q}_F^{I2}\right)_{n-1}\right) + \left(\left(\mathbf{q}_B^{I2}\right)_n - \left(\mathbf{q}_B^{I2}\right)_{n-1}\right) \right\|_2^2 - 2 \left\| \left(\left(\mathbf{q}_B^{I2}\right)_n - \left(\mathbf{q}_B^{I2}\right)_{n-1}\right) \right\|_2^2 , \\ - 2\left(\left(\mathbf{q}_B^{I2}\right)_n - \left(\mathbf{q}_B^{I2}\right)_{n-1}\right).\left(\left(\mathbf{q}_F^{I2}\right)_n - \left(\mathbf{q}_F^{I2}\right)_{n-1}\right) \end{aligned} \tag{11}$$

and $g''(\beta)=2\left\|\left(\left(\mathbf{q}_F^{I2}\right)_n-\left(\mathbf{q}_F^{I2}\right)_{n-1}\right)+\left(\left(\mathbf{q}_B^{I2}\right)_n-\left(\mathbf{q}_B^{I2}\right)_{n-1}\right)\right\|_2^2>0$, i.e., Eq. (11) corresponds to a minimum. Setting $g'(\beta)=0$, we get

$$\beta_{n+1}\,(\text{optimal})=\frac{\left\|\left(\left(\mathbf{q}_B^{I2}\right)_n-\left(\mathbf{q}_B^{I2}\right)_{n-1}\right)\right\|_2^2+\left(\left(\mathbf{q}_B^{I2}\right)_n-\left(\mathbf{q}_B^{I2}\right)_{n-1}\right)\cdot\left(\left(\mathbf{q}_F^{I2}\right)_n-\left(\mathbf{q}_F^{I2}\right)_{n-1}\right)}{\left\|\left(\left(\mathbf{q}_F^{I2}\right)_n-\left(\mathbf{q}_F^{I2}\right)_{n-1}\right)+\left(\left(\mathbf{q}_B^{I2}\right)_n-\left(\mathbf{q}_B^{I2}\right)_{n-1}\right)\right\|_2^2}. \tag{12}$$

Using values of $\alpha$ and $\beta$ obtained by (7) and (12), respectively, with calculations involving simple vector algebra, significantly reduces the required number of iterations.

**Example Application**

Procedures for dynamic calculation of relaxation parameters for the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method are presented in Section 3. In this section, example application is given for elaboration.

Consider the potential flow problem shown in Fig. 1. The two sub-domains $\Omega_B$ and $\Omega_F$ are governed by Laplace equation, i.e., $k_i\nabla^2 u=0$ in $\Omega_i$, $i=1,2$, where $k_i$ is the material property in the sub-domain $\Omega_i$. The domain is decomposed to FEM and BEM sub-domains with $0\le x\le a$. The boundary conditions are $u(0,y)=0$, $u(a,y)=200$, and zero flux ($k_i\nabla u$) elsewhere.

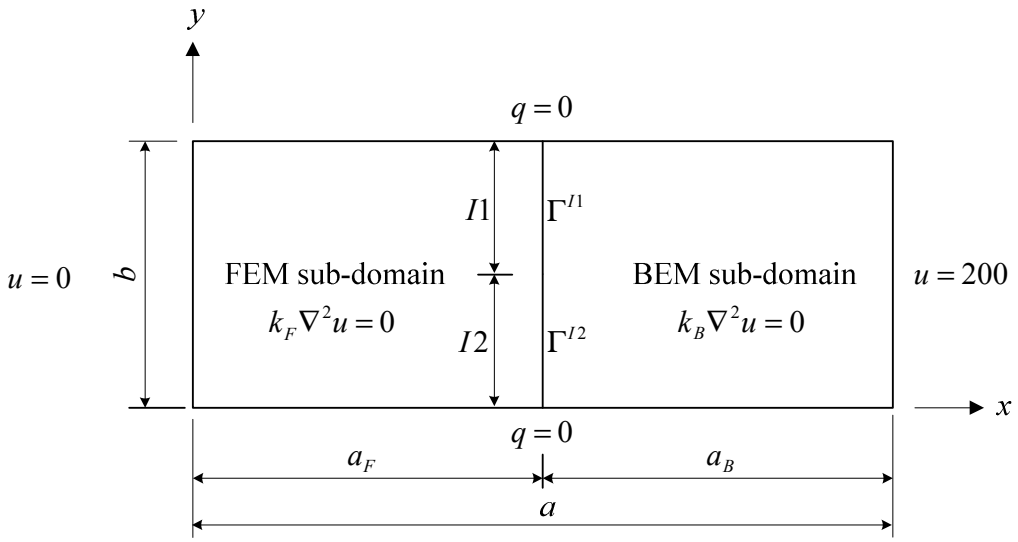

Fig. 1: Potential flow problem.

The problem is solved numerically using the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method for different values of $a_B/a_F$ and $k_B/k_F$. The results are in good agreement with the analytic solutions. Table 1 shows the applicable ranges of the relaxation parameters $\alpha$ and $\beta$ for different combinations of $a_B/a_F$ and $k_B/k_F$. Beyond the values shown in Table 1, the method will not converge. The limit values of the relaxation parameters are in close agreement with the theoretical analysis given in [3]. Table 1 clearly shows that the proper choice of the relaxation parameter is problem dependent. Here comes the contribution of this paper. The dynamic procedures presented in Section 3, significantly reduce the required number of iterations. It is worth emphasizing that the interface update using the dynamically calculated relaxation parameters reduces the required iterations for all values of $a_B/a_F$ and $k_B/k_F$ to less than 3. Furthermore, the dynamic procedures for determining the relaxation parameters eliminate the disadvantage of a user prior definition of the relaxation values.

Table 1: Applicable range of the relaxation parameters [3].

| $a_B/a_F$ | relaxation parameter | $k_B/k_F$ | | | |
|---|---|---|---|---|---|
| | | 0.25 | 0.50 | 1.0 | 2.5 |
| 0.25 | $\beta$ | 0.01-0.99 | 0.01-1.42 | 0.01-1.59 | 0.01-1.81 |
| | $\alpha$ | 0.01-0.99 | 0.01-0.66 | 0.01-0.39 | 0.01-0.18 |
| 1.0 | $\beta$ | 0.01-0.39 | 0.01-0.66 | 0.01-0.99 | 0.01-1.42 |
| | $\alpha$ | 0.01-1.59 | 0.01-1.33 | 0.01-0.99 | 0.01-0.57 |
| 5.0 | $\beta$ | 0.01-0.09 | 0.01-0.18 | 0.01-0.33 | 0.01-0.66 |
| | $\alpha$ | 0.01-1.90 | 0.01-1.81 | 0.01-1.66 | 0.01-1.33 |

**Summary**

In this paper, the mixed Dirichlet-Neumann domain decomposition FEM-BEM coupling method is reviewed. The method is capable of handling problems with any type of boundary conditions imposed on the entire real boundary of the FEM and BEM sub-domains. Procedures are derived for dynamic calculation of relaxation parameters for the mixed Dirichlet-Neumann coupling method. With the dynamic selection of relaxation parameters, the required number of FEM-BEM coupling iterations is significantly reduced. Furthermore, the dynamic procedures presented eliminate the disadvantage of a user prior definition of the relaxation parameters.

# State Space Solution of Response for Piles Subjected to Lateral Loads

Fuliang Mei[1,a], Guiling Li[1,b]

[1] Institute of Civil & Engineering, Jiaxing College, Jiaxing ,Zhejiang ,314001,China

[a]Flmei2005@126.com , [b]Lgljx@126.com

**Keywords**: soil-structure interaction, pile, state space method, foundation reaction method, tri-parameter method

**Abstract:** A state space method has been put forward for finding the deformations and internal forces of piles subjected to lateral loads. First of all, a pile was divided into a number of pile segments, on which the foundation reaction coefficients were viewed as a constant based on the three parameter method. Secondly, state space equations of all the pile segments were established according to Euler-Bernoulli's beam theory and the equilibrium conditions of a pile segment. At last, a state space solution of a pile subjected to lateral loads was obtained using the boundary conditions at the top and bottom end of the pile and the continuous conditions at the interfaces between two adjacent segments. Numerical results show that the state space solution agrees well with the semi-analytical one, and all the computational formula, procedure and programming are very simple.

## Introduction

Not only are upright piles subjected to axial loads such as the gravity of upper structures and piles themselves, but also are they subjected to lateral loads such that waves, wind, earthquake, soil pressures and impact forces between vessels and piles. Now domestic and overseas research institutions and scholars usually study the mechanical characteristics of piles subjected to lateral loads by means of theoretical analysis, numerical simulation and in-situ test methods. Then the theoretical analysis method includes limit foundation reaction force, foundation reaction force and elastic theory methods, of which a linearly elastic foundation reaction force method is one of more popular methods for a several tens of years at home and abroad. The linearly elastic foundation force method can be classified into one, dual and tri-parameter methods according to the foundation reaction parameter amount.

At present there are a few of theoretical methods such that analysis and power series (M.H.Zhao, 1987; Z.Wang, *et al.*, 2005; W.Z.Li, *et al.,*2005),variation (W.D.Guo, *et al.*, 2001;W.Y.Shen, *et al.*, 2004; K.Yang , *et al.* 2006;J.Han , *et al.,*2000) , dimension (H.Matlock, *et al.*,1960), varied stiffness (H.L.Wu,2000) and finite difference method (Z.H.Dai *et al.*,2004). Former three kinds of which were put forward for one parameter method and later three kinds were suggested for a dual parameter method. H.L.Wu [1] has pointed out that both of one and dual parameter methods can not accurately reckon the upper soil reaction force, and thus he has further developed a tri-parameter method which can more precisely reflect the upper soil reaction force. But there is only a semi-analytical method for solving the static response of piles subjected to lateral loads based on the tri-parameter method (L.Zhang , *et al.,*2011).

In this treatise the foundation reaction force coefficients are evaluated according to the mentioned tri-parameter method. First of all, the state space equations for a pile subjected to lateral loads are deduced based on the Euler-Bernoulli's beam theory on Winkler's elastic foundation.

Secondly, for avoiding the difficulty of finding directly above the state space equations, the foundation reaction force coefficient on a tiny segment can be viewed as a constant after a pile can be divided into a number of tiny segments, and the state space equations expressed with the horizontal displacement, rotational angle, shear force and bending moment of all the segments are obtained. Thirdly, the space state equations for all the segments are first solved by matrix theory ,and then the state space solution is obtained by means of prescribed horizontal force, bending moment or horizontal displacement and rotational angle at the top and bottom end of the pile, force equilibrium and continuous and smooth conditions at the interface between two adjacent subsections. At last numerical solution is given and compares with the semi-analytical solution [8].

**Basic equations**

A uniform section pile and a system of coordinate are shown in Fig.1. The length and flexural stiffness are $L$ and $EI$, respectively. A prescribed bending moment and a horizontal force are applied on the top end of the pile by $M_0$ and $Q_0$ respectively. In general the action of surrounding soil on the pile can be simulated by a series of discrete and continuous springs according to the linearly elastic Winkler's foundation beams, and foundation reaction force $p(z,u)$ is

$$p(z,u) = kbu \tag{1}$$

Where b defines the width or diameter of the pile, $u$ the horizontal displacement, $k$ the foundation reaction force coefficient, and z the distance down from the top end of the pile.

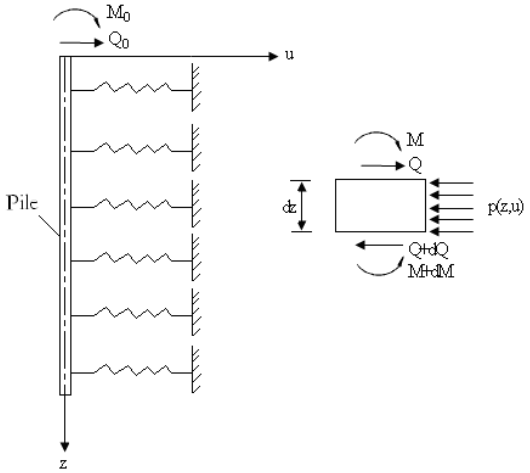

Fig.1 Diagram of a pile and force analysis of a segment

According to the tri-parameter method [1], the foundation reaction force coefficient $k$ is

$$k = m(z_0 + z)^n \tag{2}$$

Where $z_0$ defines an equivalent depth ,namely, deformation resistance capacity of soil body in the vicinity of ground, $m$ and $n$ denote the proportional factor and index of the foundation reaction force size, respectively. The linearly elastic foundation reaction force method can be classified into one ($z_0 = 0$, $n$=constant, $m \neq$ constant), dual ($z_0 = 0$ ,both of $n$ and $m$ are not constant) and tri parameter methods (all of $z_0$ , $n$ and $m$ are not constant) according to the different evaluation

of $z_0$, $m$ and $n$. The one parameter method can further be classified into constant $(n=0)$, $m$ $(n=1)$ and C value methods $(n=0.5)$.

Using the equilibrium conditions for a tiny segment, we can obtain

$$\frac{dQ(z)}{dz} = -p(z) \tag{3}$$

$$\frac{dM(z)}{dz} = Q(z) \tag{4}$$

Where $Q(z)$ and $M(z)$ denote the shear force and bending moment of the pile at z coordinate.

And utilizing Euler-Bernoulli's beam theory, we can acquire

$$\frac{du(z)}{dz} = \varphi(z) \tag{5}$$

$$\frac{d\varphi(z)}{dz} = \frac{M(z)}{EI} \tag{6}$$

Where $\varphi(z)$ denotes the rotational angle of the pile at z coordinate.

Assemble Eqs.(3-6), we can acquire following state space equations in the matrix form

$$\frac{d}{dz}\begin{Bmatrix} u(z) \\ M(z) \\ Q(z) \\ \phi(z) \end{Bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ -k(z)b & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \begin{Bmatrix} u(z) \\ M(z) \\ Q(z) \\ \phi(z) \end{Bmatrix} \tag{7}$$

Eq.(7) is a system of homogeneous state equations with variable coefficients. Its analysis solution is difficult to determine.

**State space solution**

For avoiding the difficulty of finding directly Eq.(7), we evenly divide the pile into $N$ segments where the length of every segment equals to $H/N$ and establish a local coordinate system for a segment $i$ as shown in Fig.2 (b).

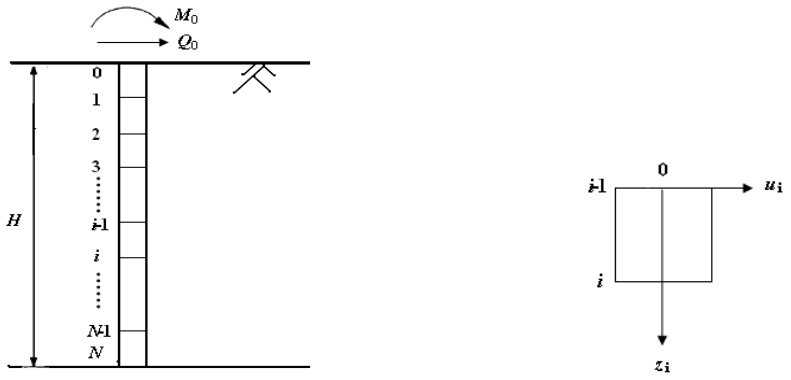

Fig.2 Partition of the pile, number of segment and the local coordinate system of a segment

The foundation reaction force coefficient within the segment can be viewed as a constant when the length of a segment is much smaller. For segment i, $k_i$ can be evaluated by means of Eq.(8)

$$k_i = \frac{m\int_{\frac{(i-1)H}{N}}^{\frac{iH}{N}} (z_0+z)^n\,dz}{H/N} = \frac{Nm\left[\left(z_0+\frac{iH}{N}\right)^{n+1}-\left(z_0+\frac{(i-1)H}{N}\right)^{n+1}\right]}{(n+1)H} \quad (i=1,2,3,\cdots,N) \tag{8}$$

Following Eq.(7), a system of state space equations for segment i is

$$\frac{d}{dz_i}\mathbf{U}_i(z) = \mathbf{G}_i\mathbf{U}_i(z_i) \qquad (i=1,2,3,\cdots,N) \tag{9}$$

Eq.(9) is a system of homogeneous state space equations with constant coefficients, and is very easy to determine. Where $\mathbf{U}_i(z_i)=[u_i(z_i) \quad M_i(z_i) \quad Q_i(z_i) \quad \varphi_i(z_i)]^T$ stands for a state space vector of segment i, $u_i(z_i), \varphi_i(z_i), \quad M_i(z_i)$ and $Q_i(z_i)$ denote the horizontal displacement, rotational angle, bending moment and shear force of segment i, respectively. The transfer matrix $\mathbf{G}_i$ of segment i is

$$\mathbf{G}_i = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ -k_i b & 0 & 0 & 0 \\ 0 & 1/EI & 0 & 0 \end{bmatrix} \tag{10}$$

Based on matrix theory, the solution of Eq.(9) can be expressed as follows

$$\mathbf{U}_i(z_i) = e^{\mathbf{G}_i z_i}\mathbf{U}_i(0) \tag{11}$$

Where $\mathbf{U}_i(0)$ stands for the state space vector at the top end of segment i. When $z_i = H/N$ (at the lower end of segment i), Eq.(11) can be written as follows

$$\mathbf{U}_i(H/N) = \mathbf{\Omega}_i\mathbf{U}_i(0) \tag{12}$$

Where $\mathbf{\Omega}_i = e^{\mathbf{G}_i H/N}$, and $\mathbf{U}_i(H/N)$ denotes the state space vector at the lower end of segment i. Eq.(12) establishes the relation between two state space vectors at the upper and lower ends of segment i.

Smooth and continuous conditions of state space vectors at the interface between two adjacent segments is

$$\mathbf{U}_i(0) = \mathbf{U}_{i-1}(H/N) \qquad (i=2,3,\cdots,N) \tag{13}$$

The state space vector can be written when the top end of the pile is free of constraint.

$$\mathbf{U}_1(0) = [u_1(0) \quad M_0 \quad Q_0 \quad \varphi_1(0)]^T \tag{14}$$

Where $u_1(0)$ and $\varphi_1(0)$ denote the undetermined horizontal displacement and rotational angle at the top end of the pile.

The state space vector can be written when the bottom end of the pile is free of constraint

$$\mathbf{U}_N(H/N) = [u_N(H/N) \quad 0 \quad 0 \quad \varphi_N(H/N)]^T \tag{15}$$

Where $u_N(H/N)$ and $\varphi_N(H/N)$ denote the undetermined horizontal displacement and rotational angle at the top end of the pile.

The state space vector can be written when the bottom end of the pile is fixed

$$\mathbf{U}_N(H/N) = [0 \quad M_N(H/N) \quad Q_N(H/N) \quad 0]^T \tag{16}$$

Where $M_N(H/N)$ and $Q_N(H/N)$ denote the undetermined bending moment and shear force at the bottom end of the pile.

Using Eqs.(12-13), the relation between the two state space vectors at the top and bottom end of the pile can be set up as follows

$$\mathbf{U}_N(H/N) = \mathbf{\Omega}_N \mathbf{\Omega}_{N-1} \cdots \mathbf{\Omega}_1 \mathbf{U}_1(0) \tag{17}$$

The undetermined variables $u_1(0)$ and $\varphi_1(0)$ at the top end of the pile by means of Eq.(17) and the given state space vectors at the top and bottom ends of the pile. And then the state space vectors $\mathbf{U}_i(H/N)(i = 1,2,\cdots N)$ at the bottom end of segment i can be found step by step using Eq.(12). The above solution is called as a state space method.

**Example and analysis**

There is a reinforced concrete pile whose length, width and flexural rigidity are 12m, 1.8m and $8.85\times10^5\, kN.m^4$ respectively. The top and bottom end of the pile are free and fixed, respectively. The horizontal force and bending moment are $30\, kN$ and $135\, kN.m$ at the top end of the pile. Foundation reaction coefficients are that $m = 1.5\times10^4 kN/m^4$, $z_0 = 0m$, $n = 1$.Tab.1 reflects the effect of uniform segments $N$ on the maximum horizontal displacement, maximum bending moment by means of the state space method (SSM). It can be seen from Tab.1 that both of the maximum horizontal displacement and the maximum bending moment do not change after $N$ is equal to or bigger than 30. Thus $N$ equals 30 for following numerical results. Fig.3 describes the curves of the horizontal displacement, rotational angle, bending moment and shear force with the depth of the pile by SSM and semi-analytical method (SAM) [8]. We find that the SSM solution is in line with the SAM one.

Table 1 Relationships among $N$, maximum horizontal displacement $U_{\max}$ and maximum bending moment $M_{\max}$

| $N$ | 10 | 15 | 20 | 25 | 30 | 35 | 40 |
|---|---|---|---|---|---|---|---|
| $U_{\max}(mm)$ | 1.5540 | 1.6143 | 1.6364 | 1.6469 | 1.6526 | 1.6561 | 1.6581 |
| $M_{\max}(kN.m)$ | 156.00 | 159.30 | 159.90 | 161.40 | 161.50 | 161.70 | 162.10 |

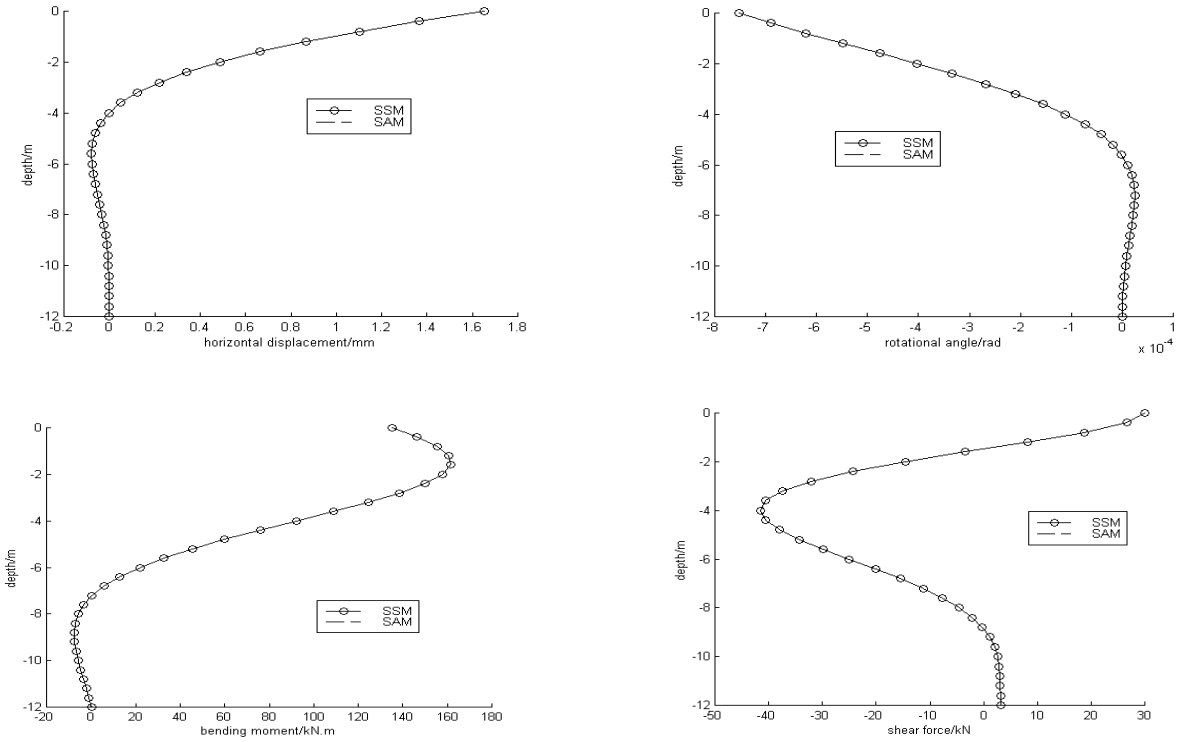

Fig.3 Comparison of SSM solution and SAM one for pile responses

**Conclusions**

In this paper the state space method is developed for the deformations and internal forces of piles subjected to lateral loads. Comparing with SAM solution that method is of faster convergence, easier programming, simpler formula and convenient use.

**Keywords:**downburst; dimensional hillside;computational fluid dynamics;velocity pressure contours;

**Abstract.** Downburst is a strong downdraft thunderstorm in the ground formed after the violent impact and spread along the ground very sudden and destructive winds near the ground short. From an engineering point of view for the structure of wind-resistant design, researching downburst wind field characteristics and ultimately determining a reasonable downburst wind profile is one of the core objectives of the study. Terrain conditions are the major factors of downburst wind field characteristics based on the typical mountain terrain on the wind storm flow condition, this paper established typical 2D slope mountain terrain model, using the method of computational fluid dynamics to calculate the velocity contours and pressure cloud in different locations of the mountain. Finally we get the two-dimensional slope typical mountain terrain wind field distribution.

## Introduction

The effect of Downburst ranges from 2 km to 40 km [1] levelly. Downbursts in small-scale micro downburst occur frequently, and the probability of occurrence of a small-scale micro downburst in thunderstorm reaches up to 60% -70% [2]. Australia's recent analysis of strong wind velocity shows that Downburst belongs strong wind type [3] at a height of 10m. Downburst in the world caused a lot of damage to engineering structures .Melbourne [5] proposed in1972 that downburst should be incorporated into the consideration of the structural design wind load. Terrain condition is a major factor which influences the wind field characteristics of downburst. Under the action of downburst studying the air flow of surrounding two-dimensional slopes and real Mountain is the main purpose for us to seek the wind pressure distribution of the downburst near the ground in two-dimensional slope and real mountain and seek the change rule of the field characteristic before or after the downburst going by the slope. All we have stated above is to establish a theoretical foundation which reflects the wind load of downburst in the characteristics of the mountain terrain. In this paper, we get the features of wind field of special topography by studying a two-dimensional model of a typical hillside, and using CFD numerical simulation.

## Standard Model

In the standard $k-\varepsilon$ model, the turbulent kinetic energy and turbulent energy dissipation rate equations are:

$$\frac{\partial(\rho k)}{\partial t}+\frac{\partial(\rho k u_i)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\left(\mu+\frac{u_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right]+G_k+G_b-\rho\varepsilon-Y_M+S_k \quad (1)$$

$$\frac{\partial(\rho\varepsilon)}{\partial t}+\frac{\partial(\rho\varepsilon u_i)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\left(\mu+\frac{u_t}{\sigma_\varepsilon}\right)\frac{\partial\varepsilon}{\partial x_j}\right]+G_{1\varepsilon}\frac{\varepsilon}{k}(G_k+G_{3_\varepsilon}G_b)-G_{2\varepsilon}\rho\frac{\varepsilon^2}{k}+S_\varepsilon \quad (2)$$

**Dimensional geometric model and parameter settings hillside**

This article gives the initial conditions as blow: jet muzzle velocity Vjet = 29m / s, jet initial diameter Djet = 600m. Geometry reduced scale is 1: 2000, using a reduced scale velocity 1:3 which have been recommended by Mason [7]. Reynolds number is defined as blow, Vjet is the initial velocity jet, Djet is the jet initial diameter, υ is the kinematic viscosity of air, then the corresponding Reynolds number Re = 195000. In this paper, we use 2D as the impact of the jet model. Considering the full development of the turbulence and the impact of the size of the wind field simulation, we use 20 × 10Djet computational domain, the initial injection inlet position is defined as the distance to the ground H / D = 4, the computational domain of geometric proportions with Hangan [6] The computational domain is consistent . Figure 1 is the schematic diagram of the computational domain for anterior hill at 15 °,after we change 15 ° into the 30 °, 45 °, 60 ° respectively , there will be another three computing models. Figure 2 is the schematic diagram of the computational domain for posterior hill at 15 °, after we change 15 °into the 30 °, 45 °, 60 °respectively, there will be another three computing models. Select all axes model as shown in Fig.1 and Fig.2.

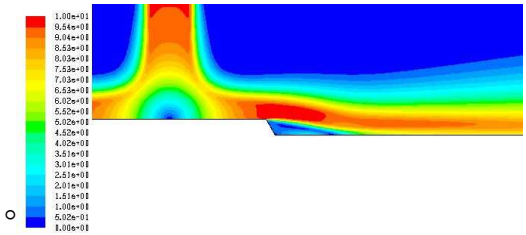
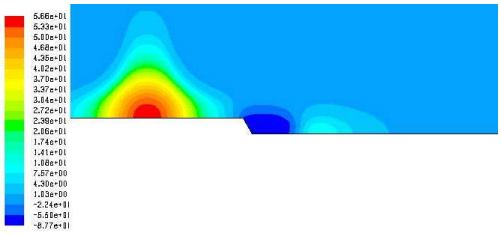
(n) posterior hill partial cloud speed at 45



(o)posterior hill partial cloud speed at 60°



(p)posterior hill partial cloud speed at 60 °

Fig.3 Partial cloud of speed and pressure for each model

From the Fig.3. In the anterior hill ,the maximum speed usually appears near the highest point of slope,.Slope is from 15 degrees to 45 degrees, maximum speed is at the peak of the slope and vertical to the first layer of grid height, Maximum speed is at slope peak for a little right when slope is 60 degrees . When the slope becomes larger, the right side of the slope peak velocity with height changes

more significantly. On the other hand, in the first order type slopes, slope peak nearby appears the negative pressure within a certain range, the slope is greater, the negative pressure range is larger .

From the figure we also know as flow. In the posterior hill , the maximum velocity generally appear in near the highest point slope.Slope is from 15 degrees to 45 degrees, maximum speed is at the peak of the slope and vertical to the first layer of grid height . Maximum speed is at slope peak for a little right when slope is 60 degrees .When the slope becomes large, the speed in the bottom of the slope on the right side changes at smaller range On the other hand, slope peak appears the negative pressure within a certain range, the slope is larger, negative pressure range is bigger, and the negative pressure tends to spread to the slope bottom.

**Key Words:** downburst; CFD; Landform types; roughness; numerical simulation; wind field characteristics.

**Abstract.** Gemorphological type is the important factor influencing the downburst wind profile. In this thesis, firstly we determine four categories of landform types under the criteria of roughness. The CFD pre-processing software GAMBIT was used to build considering the landscape type's downburst CFD computational model. Then, the established CFD computational model was imported to the calculated hydrodynamics software FLUENT to take the numerical simulation of the downburst under different landforms. Finally, in allusion to the numerical simulation result, make the research of the wind characteristics.

## Introduction

Downburst is a strong downdraft thunderstorm in the ground formed after the violent impact and spread along the ground very sudden and destructive winds near the ground a short time, the level of influence in the range of 2 to 40 km [1]. In the world, including Australia, the United States, Japan and other countries and regions, it has been causing extensive damage to engineering structures [2]. Due to the strong destructive they cause, it has become a hot topic in the international architecture and cutting-edge field of wind engineering. The topography is characterized by an important factor downburst wind load impact in the atmospheric boundary layer. The surface roughness of the vertical distribution of wind conditions will have a greater impact near the ground [3]. Surface roughness is an important indicator for the study of landforms characterized downburst impact, it's also an important parameter distribution vertical profiles of wind farm research. The current domestic and international use of CFD simulations considered the influence of surface roughness, but didn't make fine-grained roughness, when doing the wind field experiments, Fine attainment roughness has a greater impact on CFD simulation results, its simulation and study to wind field have an important significance. Therefore, it is necessary to set the fine roughness conditions when simulating the complex terrain wind farm CFD numerical in progress.

## Downburst wind field characteristics

Fujita's definition of downburst is a strong downdraft caused by strong damaging winds near-surface[1]. Chay et al [4] make a further discussion of the general characteristics that downburst of air convection updraft generated, will head a strong buoyancy of warm air to the high altitude location, with highly increasing air cooling and liquefaction, rise process stops. At this point, the air density increases after cold start fast sinking to the ground. When such a strong downdraft impact to spread around the ground, it produced a downburst wind. This wind farm, especially in the impact location near the ground, with the atmospheric boundary layer near the wind has a fundamental difference.

## Turbulence model

Numerical simulation equations in this article is based on continuity equation and Navier - Stokes equations (NS equation), does not consider heat exchange, which shielded the energy equation. Turbulence model uses a standard k-ε turbulence model, which was proposed by the Lauder and Spalding in 1972, k and ε corresponding transport equation is:

$$\frac{\partial(\rho k)}{\partial t}+\frac{\partial(\rho k u_i)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\left(v+\frac{v_T}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right]+G_k+G_b-\rho\varepsilon-Y_M+S_k \quad (1)$$

$$\frac{\partial(\rho\varepsilon)}{\partial t}+\frac{\partial(\rho\varepsilon u_i)}{\partial x_i}=\frac{\partial}{\partial x_j}\left[\left(v+\frac{v_T}{\sigma_g}\right)\frac{\partial\varepsilon}{\partial x_j}\right]+C_{1g}\frac{\varepsilon}{k}\left(G_k+C_{3g}G_b\right)-C_{2g}\rho\frac{\varepsilon^2}{k}+S_g \quad (2)$$

## Numerical simulation and calculation parameters

Since the surface roughness of the main effects of the near-surface winds blow flow field under storm flow, close to the ground using a grid in the form of encryption, mesh size increases up by the next, both rectangular grid rules. Bert Blocken [5] et al concluded that in order to ensure a high degree of accuracy of grid computing, the first floor of the grid should be a minimum height of not less than twice the rough ground. considering the translation of this article has reached the maximum roughness height 0.2m,and reducing the height of the first floor of the grid as possible to improve the quality of the grid, so the height of the first floor of the grid choose 0.4m.Mesh area is shown in Fig. 1 and Fig. 2.

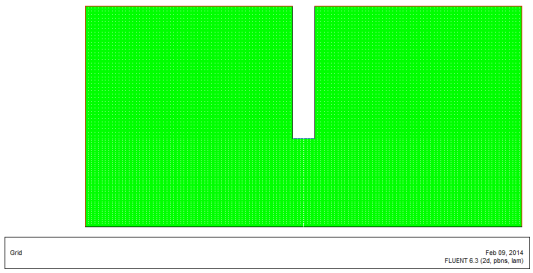

Fig. 1 Overall two-dimensional mesh

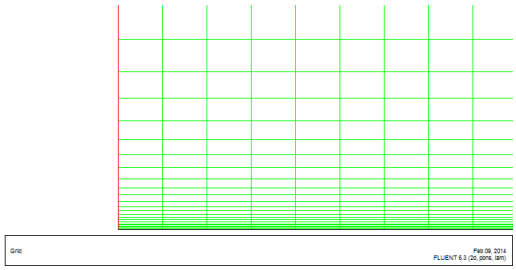

Fig. 2 Mesh encrypted area near the ground

This article is incompressible flow, which can use velocity-inlet boundary. Wherein Velocity Magnitude of 27m / s, Turbulence Specification Method Select Intensity and Hydraulic Diameter, Turbulence Intensity of 1%, Hydraulic Diameter of 900m. Export uses pressure outlet boundary condition. Using Pressure Outlet flow outlet boundary conditions to define the static pressure, when there is a reflux, the boundary conditions used to replace the pressure outlet of the flow boundary conditions often have better convergence results [6]. Gauge Pressure is 0, Backflow Direction Specification Method Select Normal to Boundary. The remaining set is consistent with the speed of the export settings.

## Numerical analysis

Selected as the vertical wind profile from the center line downburst width of 0.5D, 1D, 1.5D, 2D, 2.5D Department, a total of five wind profile, horizontal wind profiles from the ground height of 10m, 50m, 100m, 450m Department, a total of four wind profile. Each vertical wind velocity profile as shown in Fig. 3:

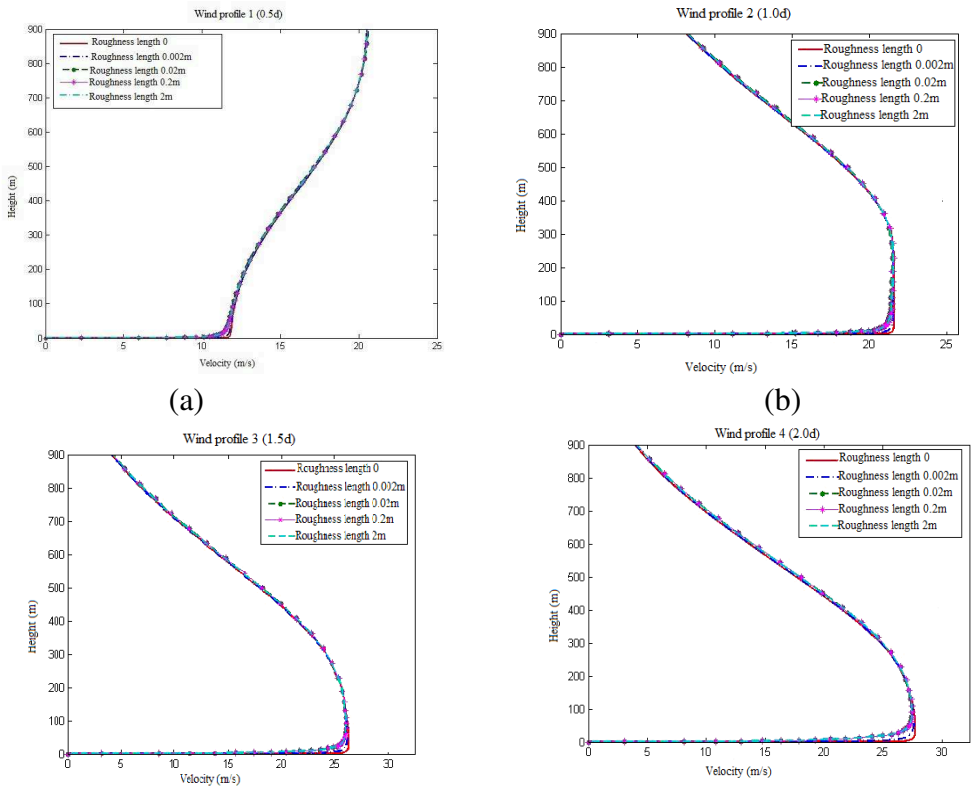

Fig. 3 Each vertical wind velocity profile

Each horizontal wind velocity profile is shown in Fig. 4.

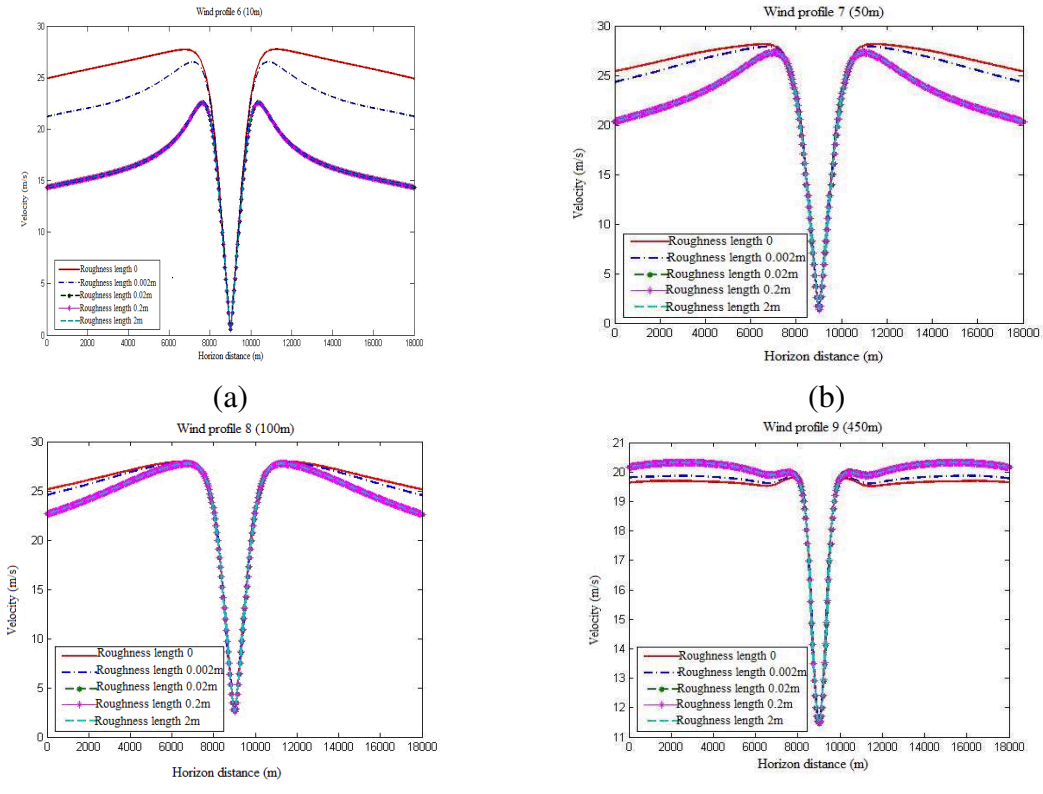

Fig. 4 Each horizontal wind velocity profile

## Conclusions

Based on impinging jet theory, numerical simulation of two-dimensional downburst wind farm built on FLUENT software, by setting different surface roughness conditions, the influence of the roughness conditions downburst wind profile. The study results the following conclusions:

(1) From the vertical wind profile, the effects of roughness on the downburst wind loads are mainly in the area near the ground below 100m , with the increase in the height of the surface roughness of the gradual reduction , when the height of more than 100m altitude , rough a small degree of influence on the wind speed .

(2) From the horizontal wind profile view, away from the center line downburst approximately 1000m ( approximately 1D) within the range of roughness less impact on the wind, when the outside this range, the roughness on the wind speed was become more apparent.

(3) Wind conditions on the effects of surface roughness downburst wind loads , not completely change with changes in the length of the rough , the local table type of class Ⅰ topography ( ie roughness length 0.002m) , the roughness on the wind small, local table type Ⅱ, Ⅲ, Ⅳ class topography ( ie roughness length of 0.02m, 0.2m, 2m), the effects of roughness on the wind speed is no longer with the roughness changes.

**Keywords:** differential equations; column-pile; boundary conditions.

**Abstract.** Based on material mechanics theory that loads-internal force-deformation relationship of rod, this paper establish elastic foundation beam model, and establish loads-internal force-deformation differential equation of piles and columns, and identified boundary conditions according to mechanical analysis of piles and columns, Based on the boundary conditions, deformation coordination and internal force equilibrium conditions, solving differential equations, then obtain column - pile components' internal forces. This method has good mechanical model support, and using mathematical computing software can derive the analytical expressions.

## Introduction

Generally, bridge column - pile foundation shared lateral load[1], Column - pile structure, Elastic foundation beam method usually be used to calculate internal force of pile foundation, in this method ,the soil computing unit between piles structure be treated as a beam on elastic foundation, Displacement of components make the soil compression, soil resistance for components. There are many method to solve elastic foundation beam model, such as semi-analytical methods, finite element method and finite difference method. Internal forces of columns can be solved by cross-sectional method, and using the formula method for solving the deformation. This method is not easy for practice, and the formula derivation process is complex. Many researchers study the solving method of piles with horizontal loads, Guo etc.[2]and Basu etc.[3]use variation method to calculate the internal forces and displacements of piles with horizontal loads. Zhou etc[4]. get elastic modulus of soil with different stress states through analyzing p-y curve. Zhao writ an improved layer- finite calculation program for solve piles with horizontal loads. Poulos assuming soil is elastic continuous medium, considering the pile-pile, pile-soil interaction, using the interaction coefficients method to analysis group pile.

Differential relationship of load-internal force-deformation already established in mechanics of materials, but it only applies to solve the internal forces and deformation of a member. This paper establish differential equations to solve internal force and deformation of column-pile structure.

## Establish differential equation

### 1.1 Differential equation of column

The vertical rod differential equations has been established in material mechanics, the column differential equations is same as it.as follows:

$$\frac{dx_z}{dz} = \theta \tag{1}$$

$$EI\frac{d\theta}{dz} = M \tag{2}$$

$$\frac{dM}{dz} = Q \tag{3}$$

$$\frac{dQ}{dz} = q \tag{4}$$

Where $x_z$ is horizontal displacement perpendicular column axis, $z$ is column length, $\theta$ $\theta$ is rotation angle of axis, $M$ is moment, $Q$ is shear force. Combining Eq.1, Eq.2 Eq.3, Eq.4, to obtain the column differential equations as follows:

$$E \cdot I \cdot \frac{d^4 x_z}{dx^4} = -q(x) \tag{5}$$

### 1.2 Differential equations of pile

According to the above principle, We can draw differential equations of pile, as follows:

$$E \cdot I \cdot \frac{d^4 x_z}{dz^4} + m \cdot z \cdot x_z \cdot b_1 = 0 \tag{6}$$

Where $m$ is coefficient,$b_1$ is width of pile.

Differential equation of column is different with pile's, With the change in the soil, M value also vary, When the size of the column section change, I value changed. E value varies with the material change. Q values vary if there have a force applied to the column, M values vary if there have a moment applied to the column. Therefore, establishing differential equations must based on the actual situation.

## Boundary conditions

### 2.1 Pile bottom boundary conditions

When the external force applied on the structural system, pile bottom line displacements and rotations occur. Using the relationship between the soil resistance and rotation angle of the pile to create a boundary condition, as follows:

$$EI\frac{d^2 x_z}{dz^2} = -\frac{dx_z}{dz} \cdot C_0 \cdot I_0 \tag{7}$$

Where z=h, h is length of pile, $C_0$ is soil factor, $I_0$ moment of inertia.

Shear force of the friction piles bottom is 0, the boundary condition is shown as follows:

$$EI\frac{d^3 x_z}{dz^3} = 0 \tag{8}$$

### 2.2 Column top boundary conditions

When the top of column is free, upper structure applied bending moment C1 and shear force C2 to the top of the column, the boundary condition is shown as follows:

$$\begin{cases} EI\dfrac{d^2x_z}{dz} = C_1 \\ EI\dfrac{d^3x_z}{dz^3} = C_2 \end{cases} \tag{9}$$

When the top of column is elastic embedding, upper structure applied shear force C2 to the top of the column, and rotation angle of column top is 0, the boundary condition is shown as follows:

$$\begin{cases} \dfrac{dx_z}{dz} = 0 \\ EI\dfrac{d^3x_z}{dz^3} = C_2 \end{cases} \tag{10}$$

### Caps border coordination condition

Based on the assumption of rigid cap, the cap only occur rigid translational and rotation, Caps is rigid, so horizontal displacement and rotation angle of each pile is equal, the border coordination condition is shown as follows:

$$\begin{cases} x_{zA} = x_{zB} \\ \dfrac{dx_{zA}}{dz} = \dfrac{dx_{zB}}{dz} \end{cases} \tag{11}$$

Axial displacement of the pile caused by cap rotation and vertical deformation, vertical displacement of the pile which caused by vertical deformation of cap is equal, the vertical displacement causes by rotation angle is equal to product of cap rotation angle and the distance between pile and cap center. Establishing the border coordination condition as follows:

$$u_{zA} - l \cdot \frac{dx_{zA}}{dz} = u_{zB} + l \cdot \frac{dx_{zB}}{dz} \tag{12}$$

### Internal forces balance relationship

Caps and columns - pile internal force analysis diagram shown in Fig. 1, Establishing level, vertical, rotating balance equation as follows:

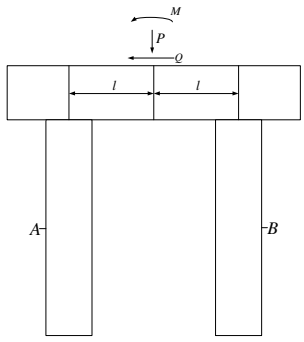

Fig.1 Caps and columns-pile internal force analysis diagram

$$E \cdot I_A \frac{d^3 x_{zA}}{dz} + E \cdot I_B \cdot \frac{d^3 x_{zB}}{dz} = Q \tag{13}$$

$$E \cdot A_A \cdot \frac{du_A}{dz} + E \cdot A_B \cdot \frac{du_B}{dz} = P \tag{14}$$

$$E \cdot A_A \cdot \frac{du_A}{dz} \cdot l + E \cdot A_B \cdot \frac{du_B}{dz} \cdot l + E \cdot I_A \cdot \frac{d^2 x_{zA}}{dz^2} + E \cdot I_B \cdot \frac{d^2 x_{zB}}{dz^2} = M \tag{15}$$

## Conclusion

In this paper, the column-pile components are divided according to the differential equation, establishing a differential equation for each unit, Based on the boundary conditions, deformation coordination and internal force equilibrium conditions, solving differential equations, then obtain column - pile components' internal forces.

Compared with traditional methods, this method has good mechanical model support, and using mathematical computing software can derive the analytical expressions. This method can be used to calculate internal forces of column-pile structure, it's able to simplify the calculation process and improve calculation accuracy.

**Keywords:** duality disturbance, elastoplasticity, relatively non-disturbed material, relatively complete disturbed material.

**Abstract.** The basic thinking, basic assumptions and basic formula system of duality disturbance theory are given in this paper. The theoretical and practical implications of duality disturbance theory are analyzed. The principles of the method of selecting the Stress-Strain relationships of relative non-disturbance material and relative complete disturbance material are given.

## Introduction

Theory of Duality Disturbance (TDD) is a theoretical model of simulating deformable solid bodies mechanical behavior proposed by the author of the paper [1-4]. The basic thinking, basic assumptions and formula system are completely described in this paper. The purpose by doing this is offering help for researchers are interested in TDD in terms of understanding, application developing the TDD.

The traditional deformable solid bodies had elastic, mechanical models of elastoplastic, viscoelasticity and damage models [5-7]. Those models can simulate the mechanical behavior of deformable solid bodies under different research levels, and solve a lot of engineering problems. However, the above models can not predict effectively complexed mechanical behavior material such as strain softening and after-softening-re-hardening materials. TDD can predict and simulate the mechanical behavior of the materials of complexed stress-strain relationship.

## Basic assumptions

Basic assumptions used in TDD are that the mechanical properties of engineering material in service will be changed in comparison to the initial state. The change may be degradation, or hardening. The material changed in properties is called disturbed material. The Ultimate degradation State of the disturbed material is called complete disturbed state. Ideal initial state is considered as complete elastic static, called as ideal non-disturbed state. However, both the ideal non-disturbed state and the complete disturbed state are not exist in nature. Thus the concepts of relative non-disturbed state and relative complete disturbed state are introduced. TDD assumes that the mechanical behavior of disturbed material can be described by relative non-disturbed (RND) material and relative complete disturbed (RCD) material. Disturbed tensor $\boldsymbol{D}$ is considered as a bridge connected RND material and RCD material. Disturbance D expresses a diverge from relative non-disturbed stress $\boldsymbol{\sigma}^{\mathrm{n}}$ to obverse stress $\boldsymbol{\sigma}^{\mathrm{o}}$. The relationship among $\boldsymbol{D}$, $\boldsymbol{\sigma}^{\mathrm{n}}$, $\boldsymbol{\sigma}^{\mathrm{o}}$ and $\boldsymbol{\sigma}^{\mathrm{c}}$ can be expressed as

$$\boldsymbol{\sigma}^{\mathrm{o}}=\left(\boldsymbol{I}-\boldsymbol{D}\right)\cdot\boldsymbol{\sigma}^{\mathrm{n}}+\boldsymbol{D}\cdot\boldsymbol{\sigma}^{\mathrm{c}} \tag{1}$$

The disturbance tension $\boldsymbol{D}$ can be degenerated as a scalar $D$. For uniaxial state, the relation among observed stress $\sigma^{\mathrm{o}}$, RND stress $\sigma^{\mathrm{n}}$, RCD stress $\sigma^{\mathrm{c}}$ and $D$ is expressed as Eq.2 and shown as in Fig.1.

$$D=\frac{\sigma^{\mathrm{n}}-\sigma^{\mathrm{o}}}{\sigma^{\mathrm{n}}-\sigma^{\mathrm{c}}} \tag{2}$$

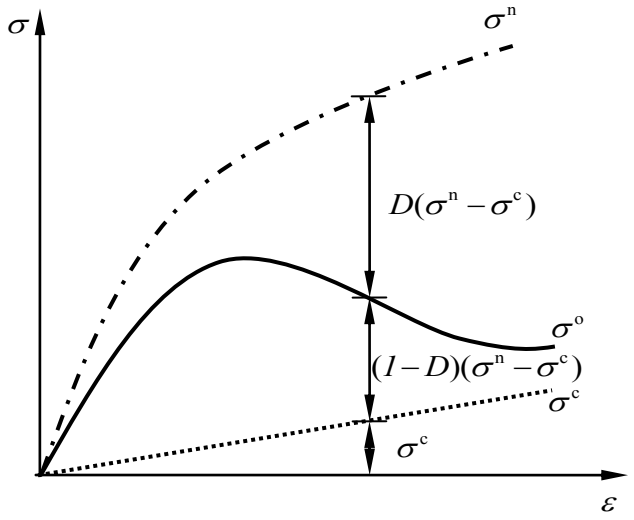

Fig.1 The relation among $D$, $\sigma^{o}$, $\sigma^{n}$ and $\sigma^{c}$

Although $D$ can be defined by Eq.2, Eq.1 is not of general significance due to $\sigma^{o}$ not being a monotropic function in the case of un-loading. Therefore, the key of determing $D$ is finding a monotropic vector $\boldsymbol{\alpha}$ which is related to $\boldsymbol{\sigma}^{o}$, $\boldsymbol{\sigma}^{n}$ and $\boldsymbol{\sigma}^{c}$. The relation between $\boldsymbol{D}$ and $\boldsymbol{\alpha}$ can be expressed as

$$\boldsymbol{D} = \boldsymbol{D}(\boldsymbol{\alpha}) \tag{3}$$

From Fig.1, we can see that the condition of verification of Eq.2 is

$$\boldsymbol{\varepsilon}^{o} = \boldsymbol{\varepsilon}^{n} = \boldsymbol{\varepsilon}^{c} = \boldsymbol{\varepsilon} \tag{4}$$

Eq.4 is called as assumption of total strain equivation. Eq.4 expresses that strain tensions $\boldsymbol{\varepsilon}^{o}$, $\boldsymbol{\varepsilon}^{n}$ and $\boldsymbol{\varepsilon}^{c}$ taken placed in disturbed material, RND material and RCD material, respectively, are equal. Further assume that un-loading elastic strain $\boldsymbol{\varepsilon}^{o}$, $\boldsymbol{\varepsilon}^{n}$ under action of $\boldsymbol{\sigma}^{o}$, $\boldsymbol{\sigma}^{n}$ are also equal, that is

$$\boldsymbol{\varepsilon}_{e}^{o} = \boldsymbol{\varepsilon}_{e}^{n} = \boldsymbol{\varepsilon}_{e}^{c} \tag{5}$$

have,

$$\boldsymbol{\sigma}^{o} = \boldsymbol{C}_{e}^{o}\boldsymbol{\varepsilon}_{e}, \quad \boldsymbol{\sigma}^{n} = \boldsymbol{C}_{e}^{n}\boldsymbol{\varepsilon}_{e}^{n}, \quad \boldsymbol{\sigma}^{c} = \boldsymbol{C}_{o}^{c}\boldsymbol{\varepsilon}_{e}^{c} \tag{6}$$

For the uniaxial stress state, Eq.6 is reduced as

$$\sigma^{o} = E_{e}^{o}\varepsilon_{e}, \ \sigma^{n} = E_{o}^{n}\varepsilon_{e}, \quad \sigma^{c} = E_{o}^{c}\varepsilon \tag{7}$$

**Reduced form of disturbance tension $D$**

For anisotropy disturbance, disturbed variable $\boldsymbol{D}$ should be expressed by two-power tensor, as show in Eq.1 and Eq.3. However, it is very difficult to determine $\boldsymbol{D}$ .For isotropy disturbance, disturbed variable $D$ should be a scalar. If scalar $D$ is used to descript the anisotropy disturbance, then the scalar $D$ reflects an average disturbed level of the anisotropy material. Thus, scalar $D$ is of important engineering significance.

Internal variable $\boldsymbol{\alpha}$ in Eq.3 is key of determining disturbed scalar $D$ . Considering the micromechanisms of disturbance caused in engineering material are commonly fracture of atomic bonds (including molecular bond ) and initiation and development of micro-crack, which gives rise to increasing of plastic strain, taking plastic strain tensor $\boldsymbol{\varepsilon}_{p}^{o}$ as the argument of $D$ is reasonable. Thus, Eq.3 is reduced to

$$D = D(\boldsymbol{\varepsilon}_{p}^{o}) \tag{8}$$

The plastic strain $\boldsymbol{\varepsilon}_{p}^{o}$ of disturbed material is difficult to be determined, since unloading information of the disturbed material is difficult to be known. However, under condition of Eq.4, the

plastic strain $\boldsymbol{\varepsilon}_{\mathrm{p}}^{\mathrm{o}}$ of disturbed material will be equal to that $\boldsymbol{\varepsilon}_{\mathrm{p}}^{\mathrm{n}}$ of RCD material, Eq.8 can be further reduced as

$$D = D(\xi^{\mathrm{p}}) \tag{9}$$

$$\xi^{\mathrm{p}} = c\int \mathrm{d}\xi^{\mathrm{p}} = c\int \sqrt{\mathrm{d}\boldsymbol{\varepsilon}^{\mathrm{p}} : \mathrm{d}\boldsymbol{\varepsilon}^{\mathrm{p}}} \tag{10}$$

Where, $\xi^{\mathrm{p}}$ is called as plastic strain trajectory. $\xi^{\mathrm{p}}$ shows the accumulation of plastic strain in whole process of deformation (including loading and unloading processes), which is a increasing function. Eq.10 is applied to three-dimensional stress state. In order to make $\xi^{\mathrm{p}}$ veduced as uniaxial plastic strain $\varepsilon^{\mathrm{p}}$ for uniaxial stress state, the parameter $c = c(\mu)$ is introduced. Where $\mu$ is Poisson's ratio. The condition of determining disturbed variable $D$ increasing is

$$G = \xi^{\mathrm{p}} - \xi_{\max}^{\mathrm{p}} \geq 0 \tag{11}$$

$\xi_{\max}^{\mathrm{p}}$ in Eq.11 is the maximum plastic strain had taken placed in the deflection history.

The concrete form of Eq.9 can be determined according to the observed stress-strain curve (including unloading information), the stress-strain curve of RND material and the stress-strain curve of RCD material [11-12]. $D$ can be expressed commonly as Webull curve shown as

$$D = D_{\mathrm{u}}(1 - \mathrm{e}^{A(\xi_{\mathrm{p}})^{B}}) \tag{12}$$

Where, $D_{\mathrm{u}}$ is ultimate disturbance value, and $A$, $B$ in Eq.12 are disturbed material constant.

Due to both ideal non-disturbed state and ideal complete disturbed state are untouchable ideal models. Selecting reasonable RND & RCD material models are important. Some possible RND material models are shown in Fig.2.

The RND material model of $\sigma_1^{\mathrm{n}}$, $\sigma_2^{\mathrm{n}}$ and $\sigma_3^{\mathrm{n}}$ is linear, bilinear and elastoplastic strengthen model, respectively. The RCD material model express by $\sigma_1^{\mathrm{c}}$, $\sigma_2^{\mathrm{c}}$ and $\sigma_3^{\mathrm{c}}$ is linear, hydrotatic and void model.

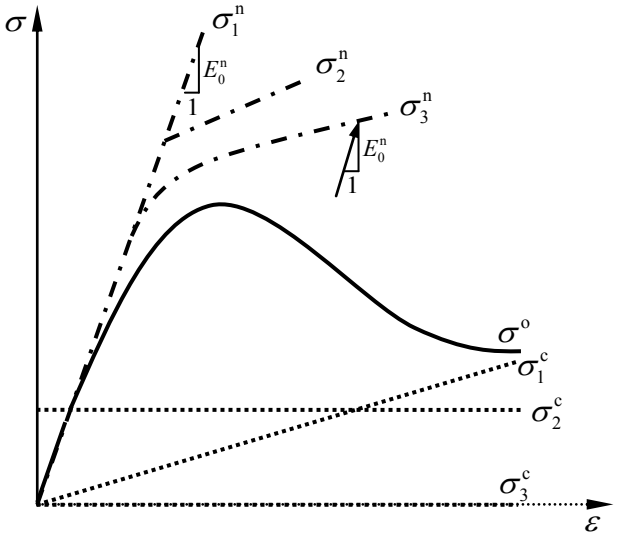

Fig.2 Types of $\sigma - \varepsilon$ curves of RND and RCD material

Although disturbed variable $D$ varies with RND and RCD material models, the varieties of $D$ have little influence for the results of simulating mechanical behavior of disturbed material. This is because that the theory of duality disturbance is self-consistent.

**Applications of TDD**

An important application of TDD is that performing mechanical analysis for softening engineering material based adult elastoplastic finite element method. It was well known that elastoplastic theory is only suitable for strengthen material. It can be used to simulate the mechanical behavior of RND

material model in TDD, such as $\boldsymbol{\sigma}^{n}$, $\boldsymbol{\varepsilon}^{n}$, $\boldsymbol{\varepsilon}_{p}^{n}$ and $\boldsymbol{u}^{n}$. From Eq.2 and Eq.9, stress $\boldsymbol{\sigma}^{o}$ and strain $\boldsymbol{\varepsilon}^{o}$ of disturbed material in uniaxial stress state can be obtained. The solution steps of mechanical behaviors of engineering material based TDD is shown as follows.

1. Set up uniaxial $\sigma^{o}$-$\varepsilon^{o}$ relation (including unloading information);
2. Select RND and RCD material models, set up unit-axial $\sigma^{n}$-$\varepsilon^{n}$, $\sigma^{c}$-$\varepsilon^{c}$ relations;
3. Set up disturbed evolution Eq.9, based Eq.2, Eq.4, Eq.5;
4. Set up the geometry, loading and restrain models of disturbed material;
5. Set up the geometry, loading and restrain models of RND material, which is the same as that of disturbed material;
6. Perform elastoplastic FEA for RND model, obtain $\boldsymbol{\sigma}^{n}$, $\boldsymbol{\varepsilon}^{n}$, $\boldsymbol{u}^{n}$, equivalent stress $\boldsymbol{\sigma}_{eff}^{n}$, equivalent strain $\boldsymbol{\varepsilon}_{eff}^{n}$;
7. Find $\boldsymbol{\sigma}^{o}$, $\boldsymbol{\varepsilon}^{o}$, $\boldsymbol{\varepsilon}_{p}^{o}$, $\boldsymbol{u}^{o}$ from Eq.1, Eq.4 and Eq.5. Find observed external loads exerted on the disturbed material from equivalent cross-section method [8];
8. Further performing strength, stiffness analysis for the disturbed material (member).

## Conclusions

(1) The basic thinking, basic assumptions and basic formula system of TDD are introduced.
(2) The principles of the method of selecting the Stress-Strain relationships of relative non-disturbance material and relative complete disturbance material are given.
(3) The steps performing mechanical analysis for disturbed materials by TDD is given.

**Keywords:** Thermocapillary convection, Low Pr number fluid, Liquid bridge, Uniform magnetic field

**Abstract.** Numerical simulations on thermocapillary convection of low Pr number molten tin under uniform magnetic field have been conducted under microgravity. The Navier-Stokes equations coupled with the energy conservation equation are solved on a staggered grid, and the free surface is captured by using the level set method. The present results show that the transverse uniform magnetic field can restrain the thermocapillary convection, and the fluid velocity at the hot corner fluctuates with a constant frequency at the steady state.

## Introduction

The floating zone method is widely used in the preparation of crystalline material, which avoids contamination of the crucible wall to materials and greatly enhances the purity of the material products. Because natural convection tend to disappear under microgravity, the cross-sectional area and height of the floating zone increase significantly, and the floating zone method can be widely used in growing large single crystals in microgravity. An important topic in the floating zone method is the thermocapillary convection induced by the temperature gradient on the free surface, which may result in the striation on the crystal surface and degrade the quality of the crystals. Therefore, it is important to understand the flow mechanism and control thermocapillary convection. The static magnetic field can suppress effectively thermocapillary convection and decrease the generation of crystal surface streaks, which can improve the quality of the crystal.

In 1996, Chedzey and Hurle investigated the effect of magnetic field on the crystal growth firstly [1]. The main effect of the static magnetic field is to inhibit the melt convection and lower convection velocity of the melt, so the quality of the generating crystal is improved to some extent. Kimura et al. [2] studied the effects of transverse magnetic field on the growth of doped silicon single crystal. The shape of growth interface of crystals tends to be flat in 0.18T magnetic field strength. However, when the magnetic field strength was increased to 0.55T, the growing interface tends to be flat and the layer of interfacial diffusion to be thicker, but there is no inhibition on the growth of impurities stripes. Dold et al. [3] studied the growth of silicon crystals in the axial static magnetic field, and they can get elemental silicon crystal of almost no streaks when the magnetic field strength is higher than 240mT. Pablo and Rivas [4] studied numerically the floating zone melt convection that was in uniform axial magnetic field of moderate-intensity under micro-gravity and analyzed the influence of magnetic field strength and temperature difference on the approximate static area of the center of the floating zone. They got the conclusions that with the increase of the magnetic field strength, the central region was extended and the shape of the central region was more similar to the cylindroid in smaller temperature difference. Although many experiments and numerical calculations have been conducted to study the mechanism of the thermocapillary convection in liquid bridges and verified the effects of static magnetic fields, the most existing studies ignored the effects of free surface deformation of liquid bridges. In this paper, the free surface deformation of liquid bridges and the ambient air will be considered to investigate thermocapillary convection in liquid bridges of low Pr molten metal under the static magnetic fields.

**Physical and Mathematic Models**

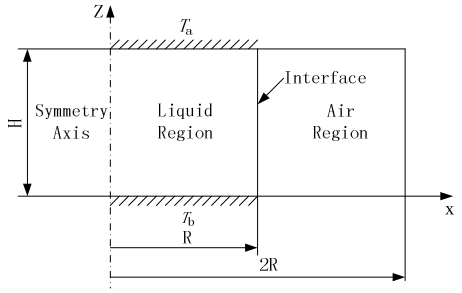

Fig. 1. Schematic of a half-zone liquid bridge model

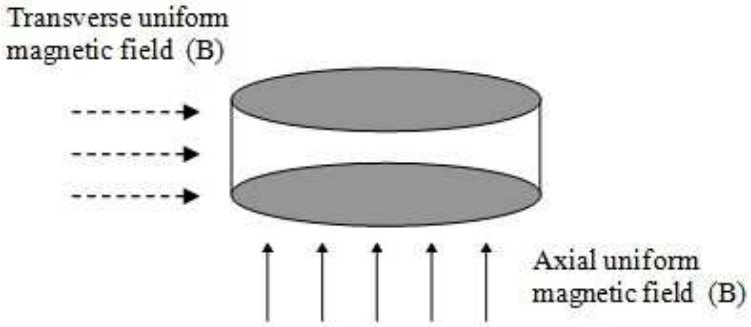

Fig. 2. Schematic of a uniform magnetic field

In our investigation, a liquid bridge with radius R and height H is suspended between two coaxial disks and surrounded by the air in a rectangular container with height H and diameter 4R as shown in Fig.1. The temperature difference between the two disks is $\Delta T=T_t-T_b$, where $T_t$ and $T_b$ are the temperature of the upper and lower rods, respectively.

Figure 2 shows an axial and a transverse uniform magnetic fields. This paper mainly studies the effects of the uniform magnetic field on the thermocapillary convection of the liquid bridge.

Based on the above physical model, we can get the dimensionless equations of the liquid bridge under uniform magnetic fields, which are outlined below.

$$\rho[\vec{u}_t+(\vec{u}\cdot\nabla)\vec{u}]=-\nabla p+\frac{1}{\mathrm{Re}}\nabla\cdot(2\mu D)+\left(\frac{1}{\mathrm{We}}-\frac{\mathrm{Ca}}{\mathrm{We}}\Theta\right)\kappa\delta(d)\vec{n}+\frac{\mathrm{Ha}^2}{\mathrm{Re}}(\vec{U}\times\vec{B}\times\vec{B}) \tag{1}$$

$$\nabla\cdot\vec{u}=0 \tag{2}$$

$$\frac{\partial\Theta}{\partial t}+\nabla\cdot(\vec{u}\cdot\Theta)=\frac{1}{\mathrm{Re}\,\mathrm{Pr}}\nabla^2\Theta \tag{3}$$

$$\frac{\partial\phi}{\partial t}+\vec{u}\cdot\nabla\phi=0 \tag{4}$$

(4)

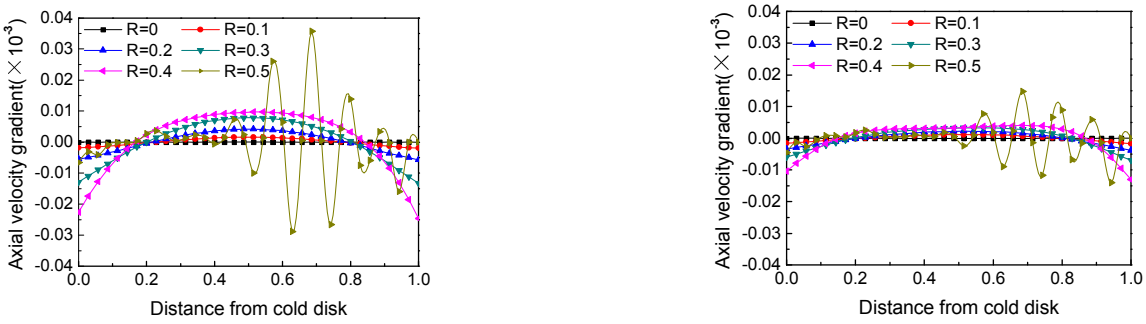
where $\vec{u}=(u,v)$ is the fluid velocity, $\rho=\rho(\vec{x},t)$ is the fluid density, $\mu=\mu(\vec{x},t)$ is the fluid viscosity, D is the viscous stress tensor, $\kappa$ is the curvature of the interface, $d$ is the normal distance to the interface, $\delta$ is the Dirac delta function, $\vec{n}$ is the unit normal vector at the interface, $p$ is the pressure. The surface tension coefficient is considered to be a linearly function of temperature and defined as $\sigma=\sigma_c-\sigma_T(T-T_b)$, where $\sigma_c$ is a reference value of surface tension and $\sigma_T$ is the temperature coefficient of surface tension and we denote $\sigma_T=\partial\sigma/\partial T$, and $T$ is the temperature. $\mathrm{Re}=\rho_l U_\infty \bar{L}/\mu_l$, Reynolds number, $\mathrm{We}=\rho_l U_\infty^2 \bar{L}/\sigma$, Weber number, $\mathrm{Pr}=\mu_l/\rho_l a$, Prandtl number, $Ca=\sigma_T(T_{high}-T_{low})/\sigma_c$, Capillary number, $\mathrm{Ma}=\sigma_T\Delta T\bar{L}/\mu_l a=\mathrm{Re}\,\mathrm{Pr}$, Marangoni number, $\Theta=(T-T_{low})/(T_{high}-T_{low})$, excess temperature, $\mathrm{Ha}=\mathrm{B}_0\bar{L}\sqrt{\beta/\mu_l}$, Hartman number, $a$ is the thermal diffusivity. $U_\infty$ is the characteristic velocity and we take $U_\infty=\sigma_T\Delta T/\mu_l$ under microgravity. $\bar{L}$ is the characteristic length and we take $\bar{L}=2R$. $\phi$ is the level set function.

The Lorentz force generated by the magnetic field is **F** = **J** × **B**, where **J** is the current density vector defined by **J** =$\beta$ ($-\nabla\varphi+$ **U** × **B**), where $\beta$ is the electric conductivity of the liquid, $\varphi$ is the induced electric potential, **U** is the velocity vector. For axial magnetic fields and axisymmetric flows in 2 dimensional cases, no electric potential is induced, hence the Lorentz force reduces to **F** = $\beta$ (**U** × **B**) × **B** [5].

The present mesh adopted is a staggered grid, and the equations of motion are solved by the SIMPLE algorithm. At the same time, the CSF (Continuum Surface Force) model is adopted to calculate the surface tension on the free surface.

## Results and Discussion

The present mathematical and physical models can be applied to numerically simulate the thermocapillary convection in a static magnetic field. The diameter and aspect ratio of the liquid bridge considered are D=5.0mm and H/R=1, respectively. The temperatures of the upper and bottom disks are $T_a$=730K and $T_b$=705K, respectively. The density and viscosity of molten tin are $\rho_g = 6793kg/m^3$ and μ=$1.318\times10^{-3} Pa\cdot S$, respectively, and the density ratio and viscosity ratio of gas phase and liquid phase are $\rho_g / \rho_l = 1.795\times10^{-3}$ and $\mu_g / \mu_l = 1.37\times10^{-2}$, respectively; and Pr=0.09, Re=2000, Ma=20, We=118, Ca=0.005, B=0.01, Ha=3.



(a) B=0.01T (b) B=0.1T

Fig.3. Axial velocity gradient at different radius positions

Figure 3 Shows the distribution of the axial velocity gradient at different radius under transverse uniform magnetic field, where R = 0 represents the center axis of the liquid bridge, R = 0.5 means the free surface of liquid bridge. From the Fig. 3(a) we can see that the distribution of the axial velocity gradient at different radius is different. The velocity gradient at the center area of the liquid bridge (R=0 and R=0.1) is constant almost. The velocity gradient at the interlayer (R=0.2, R=0.3 and R=0.4) increases first and then decreases with the increasing of the distance from the cold disk. At the free surface(R=0.5) the velocity gradient fluctuates slightly at the distance from the cold disk less than 0.4, however, as the distance increases to 0.4 or more, the velocity gradient fluctuates greatly. Comparing Fig. 3(a) (B=0.01T) with Fig. 3(b) (B=0.1T), it also can be found that as the increasing of the transverse uniform magnetic field strength, all the velocity gradients at various radius decrease, indicating that the transverse uniform magnetic field suppresses the thermocapillary convection inside the liquid bridge.

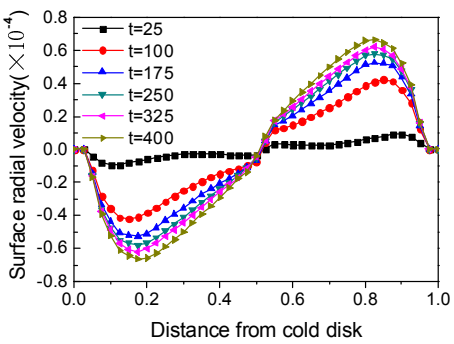


Fig.4 Surface velocity distribution in radial direction

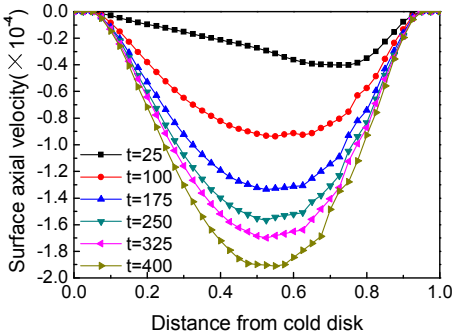

Fig.5 Surface velocity distribution in axial direction

Figure 4 characterizes the surface velocity distribution in radial direction of the liquid bridge at different times under an axial uniform magnetic field. We find that the surface velocity in radial

direction is negative in the positions below the mid-height, and it is positive in the positions above the mid-height. The maximum value of the radial velocity can be obtained at the distances away from the cold disk H=0.2 and H=0.8, respectively. As the development of thermocapillary convection, the value of radial velocity increases, and it reaches steady state until t=400.

Figure 5 characterizes the surface velocity distribution in axial direction of the liquid bridge at different times under an axial uniform magnetic field. We can see that the axial velocity is negative at all times, indicating that the surface flow of liquid bridge flows from the hot disk to the cold disk. Over the time, the maximum value of the axial velocity moves gradually from the hot disk to the midheight of the liquid bridge, and the value also increases. At the distance from cold disk being around 0.7, there are some floating-points, which is due to the effect of hot corner.

The hot corner is a launching point of thermocapillary convection and an important affecting factor to the thermocapillary convection. However, the thermocapillary convection in the hot corners is complex. Figure 6 shows the axial velocity distribution at the hot corner of the liquid bridge in a steady state. It can be observed that the value of the axial velocity at the hot corner is not constant, and the value fluctuates with an amplitude and the frequency is constant approximately. From Fig. 7 we can find that the radial velocity distribution has the same characteristics with that in the axial direction.

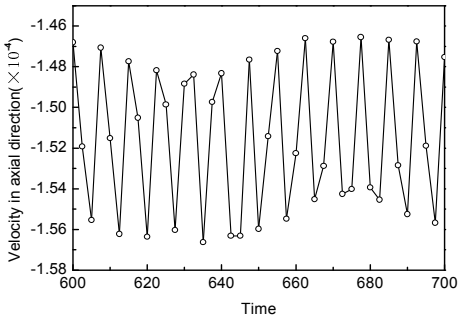

Fig. 6 Axial velocity distribution at hot corner

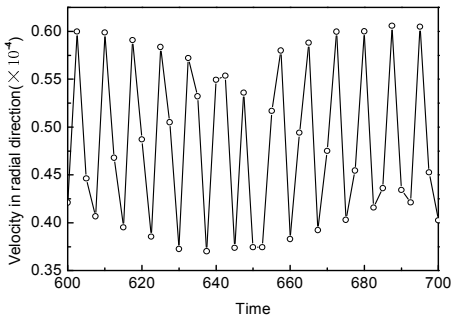

Fig. 7 Radial velocity distribution at hot corner

## Conclusions

This paper takes the molten tin as the object to study thermocapillary convection in the liquid bridge under the uniform magnetic field. It is found that the transverse uniform magnetic field can restrain the thermocapillary convection. Over the time, thermocapillary convection in the liquid bridge becomes gradually a stable state, and the center of thermocapillary convection moves from the hot disk to the mid-height of the liquid bridge. Thermocapillary convection mainly concentrates near the surface of the liquid bridge due to the effect of the axial uniform magnetic field. The velocity at the hot corner fluctuates with a constant frequency at the steady state.

**Keywords:** plane problem, moisture transfer, moisture elasticity, inhomogeneity, forced deformation, thick-walled shell, numerical-analytical calculation method, clay

**Abstract.**The numerical-analytical solution of the non-axisymmetric problem of moisture-elasticity for hollow cylindrical soil massive is provided. We consider the steady-state water transfer. Inhomogeneity of the array due to the dependence of the deformation modulus on the soil moisture. Stress state of the array caused by forced deformations and uneven pressure rebuff of the soil. The method for solving non-axisymmetric problems with radial inhomogeneity in polar coordinates is described. Diagrams on the stress fields in homogeneous and inhomogeneous formulations of the problem are provided. In the paper made a comparative assessment of the impact on the stress state of the power factors and inhomogeneity of the soil

## Introduction

This paper considers the problem of determining the stresses within the soil mass resulting from the process of swelling from moisture penetrating from the ruptured pipe deep into the array.If there is clearancebetween ground and the tube the liquid at first is distributed along the tube and then begins to penetrate into the soil.Thus the problem of moisture conductivity is axisymmetric. At the same time the problem of determining the stress field caused by the swelling of the soil as well as by rebuff of ground will be two-dimensional.Feature of the work is the account of own weight of soil, as well as depending its deformation characteristics on the humidity.

## Problemsetting

Spread of moisture in stationary one-dimensional mode is described byequality:

$$w(\rho) = \frac{w_0 \cdot \ln(\rho/\rho_a) - w_s \cdot \ln(\rho/\rho_b)}{\ln(\rho_b/\rho_a)}. \qquad (1)$$

Here $\rho = r/a$ - the dimensionless radius, $a$ and $b >> a$ - the inner and outer radii of the array (Fig. 1).

For clays relationship between forced deformities of swelling and humidity is practically linear [2] – $\varepsilon_f = \beta(w - w_s)$ and is determined by the swelling coefficient β. The dependence of the modulus of elasticity of moisture $E$ ($w$) described in [1, 2]:

$$E(w) = E_0 \cdot (w/w_s)^{-\gamma}, \qquad (2)$$

where$E_0$ = 19.88 MPa – deformation's modulus of unsaturated clay,$w_s$ = 0.363 – humidity of unsaturated clay,γ = 2.4.

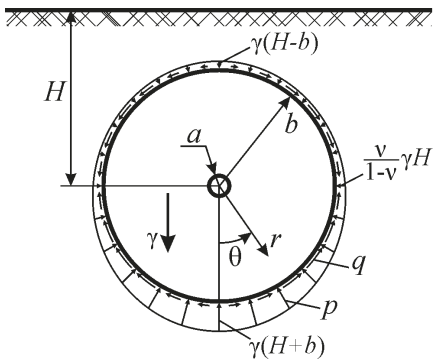

Fig 1. Loading system for solving the problem of stress distribution near an underground cylindrical cavity.

In calculating the stresses we consider a cylindrical hole, located at an average depth (Fig. 1) when $H \cong b$. In this case the normal ($p$) and shear loads ($q$) attached to the outer surface of the cut of the array will not be axisymmetric.The resultant of external pressure balances the weight of the cut volume, i.e. problem should be solved taking into account the volume forces which equal to the specific gravity of the

breed γ [3].Below is the solution for the following geometrical characteristics: $a$ = 0.25 m, $b$ = 2.5 m, $H$ = 5 m. As soil we selected clay which is characterized by the following parameters [1, 4]: $w_s$ = 0.363; $w_0$= 0.2; $\gamma_s$ = 26.95 kN/m3; β = 0.6 - coefficient of linear expansion of moisture; ν = 0.4, the function $E$ ($w$) is described by equation (2).

Boundary conditions on the inner and outer surfaces of the array are of the form:

$$r = a: \quad \sigma_r = 0; \quad \tau_{r\theta} = 0, \tag{3}$$

$$r = b: \quad \begin{cases} \sigma_r = -\dfrac{\gamma \cdot H}{2(1-\nu)} - \dfrac{3-2\nu}{4(1-\nu)} \cdot \gamma \cdot b \cdot \cos\theta - \dfrac{1-2\nu}{2(1-\nu)} \cdot \gamma \cdot H \cdot \cos 2\theta - \dfrac{1-2\nu}{4(1-\nu)} \cdot \gamma \cdot b \cdot \cos 3\theta; \\ \tau_{r\theta} = \dfrac{1-2\nu}{4(1-\nu)} \cdot \gamma \cdot (b \cdot \sin\theta + 2H \cdot \sin 2\theta + b \cdot \sin 3\theta). \end{cases} \tag{4}$$

Bulk forces due to own weight, equal

$$R = \gamma \cdot \cos\theta; \quad \Theta = -\gamma \cdot \sin\theta. \tag{5}$$

We seek a solution of the problem in terms of displacements. Expressions for the stresses in terms of displacements

$$\sigma_r = \lambda \cdot \left( \frac{\partial u}{\partial r} + \frac{u}{r} + \frac{1}{r} \cdot \frac{\partial v}{\partial \theta} \right) + 2\mu \cdot \frac{\partial u}{\partial r} - 3K \cdot \varepsilon_f; \tag{6}$$

$$\sigma_\theta = \lambda \cdot \left( \frac{\partial u}{\partial r} + \frac{u}{r} + \frac{1}{r} \cdot \frac{\partial v}{\partial \theta} \right) + 2\mu \cdot \left( \frac{u}{r} + \frac{1}{r} \cdot \frac{\partial v}{\partial \theta} \right) - 3K \cdot \varepsilon_f; \tag{7}$$

$$\tau_{r\theta} = \mu \cdot \left[ r \cdot \frac{\partial}{\partial r} \left( \frac{v}{r} \right) + \frac{1}{r} \cdot \frac{\partial u}{\partial \theta} \right], \tag{8}$$

where $\lambda = \dfrac{E \cdot \nu}{(1+\nu) \cdot (1-2\nu)}$, $\mu = \dfrac{E}{2(1+\nu)}$, $K = \dfrac{E}{3(1-2\nu)}$ – Lame parameters depending on $r$.

Substituting (6) – (8) in equilibrium equations we get

$$\begin{aligned} &(\lambda + 2\mu) \cdot \left( \frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \cdot \frac{u}{r} - \frac{u}{r^2} \right) + \frac{\mu}{r^2} \cdot \frac{\partial^2 u}{\partial \theta^2} + \frac{\lambda + \mu}{r} \cdot \frac{\partial^2 v}{\partial r \partial \theta} - \frac{\lambda + 3\mu}{r^2} \cdot \frac{\partial v}{\partial \theta} + \frac{\partial(\lambda + 2\mu)}{\partial r} \cdot \frac{\partial u}{\partial r} + \\ &+ \frac{1}{r^2} \cdot \frac{\partial \mu}{\partial \theta} \cdot \left( \frac{\partial u}{\partial \theta} + r \cdot \frac{\partial v}{\partial r} - v \right) + \frac{1}{r} \cdot \frac{\partial \lambda}{\partial r} \cdot \left( u + \frac{\partial v}{\partial \theta} \right) - 3 \frac{\partial}{\partial r} (K \cdot \varepsilon_в) + R = 0; \end{aligned} \tag{9}$$

$$\begin{aligned} &\mu \cdot \left( \frac{\partial^2 v}{\partial r^2} + \frac{1}{r} \cdot \frac{v}{r} - \frac{v}{r^2} \right) + \frac{\lambda + \mu}{r} \cdot \frac{\partial^2 u}{\partial r \partial \theta} + \frac{\lambda + 3\mu}{r^2} \cdot \frac{\partial u}{\partial \theta} + \frac{\lambda + 2\mu}{r^2} \cdot \frac{\partial^2 v}{\partial \theta^2} + \frac{1}{r} \cdot \frac{\partial \mu}{\partial r} \cdot \left( \frac{\partial u}{\partial \theta} + r \cdot \frac{\partial v}{\partial r} - v \right) + \\ &+ \frac{1}{r} \cdot \frac{\partial \lambda}{\partial \theta} \cdot \frac{\partial u}{\partial r} + \frac{1}{r^2} \cdot \frac{\partial(\lambda + 2\mu)}{\partial \theta} \cdot \left( u + \frac{\partial v}{\partial \theta} \right) - 3 \frac{\partial}{\partial \theta} (K \cdot \varepsilon_в) + \Theta = 0. \end{aligned} \tag{10}$$

Solution of equations (9) - (10) will be sought in the form of the following series [5]:

$$\begin{aligned} \begin{pmatrix} u \\ v \end{pmatrix} = &\begin{pmatrix} \varphi_0 \\ \psi_0 \end{pmatrix} + \begin{pmatrix} \varphi_1 \\ \psi_1 \end{pmatrix} \cdot \theta + \begin{pmatrix} \varphi_2 \\ \psi_2 \end{pmatrix} \cdot \theta \cdot \sin\theta + \begin{pmatrix} \varphi_3 \\ \psi_3 \end{pmatrix} \cdot \theta \cdot \cos\theta + \begin{pmatrix} \varphi_4 \\ \psi_4 \end{pmatrix} \cdot \sin\theta + \begin{pmatrix} \varphi_5 \\ \psi_5 \end{pmatrix} \cdot \cos\theta + \\ &+ \sum_{n=2}^{\infty} \left[ \begin{pmatrix} \varphi_{sn} \\ \psi_{sn} \end{pmatrix} \cdot \sin n\theta + \begin{pmatrix} \varphi_{cn} \\ \psi_{cn} \end{pmatrix} \cdot \cos n\theta \right], \end{aligned} \tag{1}$$

were $\varphi_0,...\psi_{cn}$ – functions depending on $r$. Functions $\varepsilon_f(r)$, $R(r)$ and $\Theta(r)$ have a form: $\varepsilon_f = \varepsilon_{f,0}$, $R = R_5 \cdot \cos\theta$, $\Theta = \Theta_4 \cdot \sin\theta$. Given the form of the boundary conditions (3), (4), in (11) we can restrict the terms:

$$u = \varphi_0 + \varphi_5 \cdot \cos\theta + \varphi_{c2} \cdot \cos 2\theta + \varphi_{c3} \cdot \cos 3\theta; \quad v = \psi_4 \cdot \sin\theta + \psi_{s2} \cdot \sin 2\theta + \psi_{s3} \cdot \sin 3\theta \tag{12}$$

Substituting (12) in (9) and (10) we get a system of ordinary differential equations for $\varphi_i$ and $\psi_i$:

$$(\lambda + 2\mu) \cdot \left( \varphi_0'' + \frac{\varphi_0'}{r} - \frac{\varphi_0}{r^2} \right) + (\lambda' + 2\mu') \cdot \varphi_0' + \frac{\lambda'}{r} \cdot \varphi_0 - 3\left(K \cdot \varepsilon_{в,0}\right)' = 0; \tag{2}$$

$$-\frac{\lambda+\mu}{r} \cdot \varphi_5' - \frac{\lambda+3\mu}{r^2} \cdot \varphi_5 + \mu \cdot \left( \psi_4'' + \frac{\psi_4'}{r} - \frac{\psi_4}{r^2} \right) - \frac{\lambda+2\mu}{r^2} \cdot \psi_4 - \frac{\mu'}{r} \cdot (\varphi_5 - r \cdot \psi_4' + \psi_4) + \Theta_4 = 0; \tag{3}$$

$$\begin{gathered} (\lambda + 2\mu) \cdot \left( \varphi_5'' + \frac{\varphi_5'}{r} - \frac{\varphi_5}{r^2} \right) - \frac{\mu}{r^2} \cdot \varphi_5 + \frac{\lambda+\mu}{r} \cdot \psi_4' - \frac{\lambda+3\mu}{r^2} \cdot \psi_4 + \\ + (\lambda' + 2\mu') \cdot \varphi_5' + \frac{\lambda'}{r} \cdot (\varphi_5 + \psi_4) + R_5 = 0; \end{gathered} \tag{4}$$

$$\begin{gathered} -\frac{\lambda+\mu}{r} \cdot 2\varphi_{c2}' - \frac{\lambda+3\mu}{r^2} \cdot 2\varphi_{c2} + \mu \cdot \left( \psi_{s2}'' + \frac{\psi_{s2}'}{r} - \frac{\psi_{s2}}{r^2} \right) - \\ - \frac{\lambda+2\mu}{r^2} \cdot 2^2 \cdot \psi_{s2} - \frac{\mu'}{r} \cdot (2\varphi_{c2} - r \cdot \psi_{s2}' + \psi_{s2}) = 0; \end{gathered} \tag{5}$$

$$\begin{gathered} (\lambda + 2\mu) \cdot \left( \varphi_{c2}'' + \frac{\varphi_{c2}'}{r} - \frac{\varphi_{c2}}{r^2} \right) - \frac{\mu}{r^2} \cdot 2^2 \cdot \varphi_{c2} + \frac{\lambda+\mu}{r} \cdot 2\psi_{s2}' - \\ - \frac{\lambda+3\mu}{r^2} \cdot 2\psi_{s2} + (\lambda' + 2\mu') \cdot \varphi_{c2}' + \frac{\lambda'}{r} \cdot (\varphi_{c2} + 2\psi_{s2}) = 0; \end{gathered} \tag{6}$$

$$\begin{gathered} -\frac{\lambda+\mu}{r} \cdot 3\varphi_{c3}' - \frac{\lambda+3\mu}{r^2} \cdot 3\varphi_{c3} + \mu \cdot \left( \psi_{s3}'' + \frac{\psi_{s3}'}{r} - \frac{\psi_{s3}}{r^2} \right) - \\ - \frac{\lambda+2\mu}{r^2} \cdot 3^2 \cdot \psi_{s3} - \frac{\mu'}{r} \cdot (3\varphi_{c3} - r \cdot \psi_{s3}' + \psi_{s3}) = 0; \end{gathered} \tag{7}$$

$$\begin{gathered} (\lambda + 2\mu) \cdot \left( \varphi_{c3}'' + \frac{\varphi_{c3}'}{r} - \frac{\varphi_{c3}}{r^2} \right) - \frac{\mu}{r^2} \cdot 3^2 \cdot \varphi_{c3} + \frac{\lambda+\mu}{r} \cdot 3\psi_{s3}' - \\ - \frac{\lambda+3\mu}{r^2} \cdot 3\psi_{s3} + (\lambda' + 2\mu') \cdot \varphi_{c3}' + \frac{\lambda'}{r} \cdot (\varphi_{c3} + 2\psi_{s3}) = 0. \end{gathered} \tag{8}$$

Substituting (12) in (6) – (8) we get boundary conditions for $\varphi_i$ and $\psi_i$ included in (13) – (19), that completely determines the boundary value problem.

**Results**

Numerical solution of the system (13) - (19) with boundary conditions has been implemented in the software package Matlab. Fig. 2 and 3 show the distribution of normal stresses along the radius for the typical values of the angle θ. For comparison the results of analytical solutions for the homogeneous material when $E$ = const = $E_{av}$. As averaged modulus $E_{av}$ is selected:

$$E_{av} = \frac{\int_a^b E(w(r))dr}{b-a} = 52{,}27\text{MPa}.$$

To avoid overloading graphs for comparison in Fig. 2, 3, the solution for the homogeneous material is given for only one value of the angle $\theta = \pi / 4$ (dotted lines).

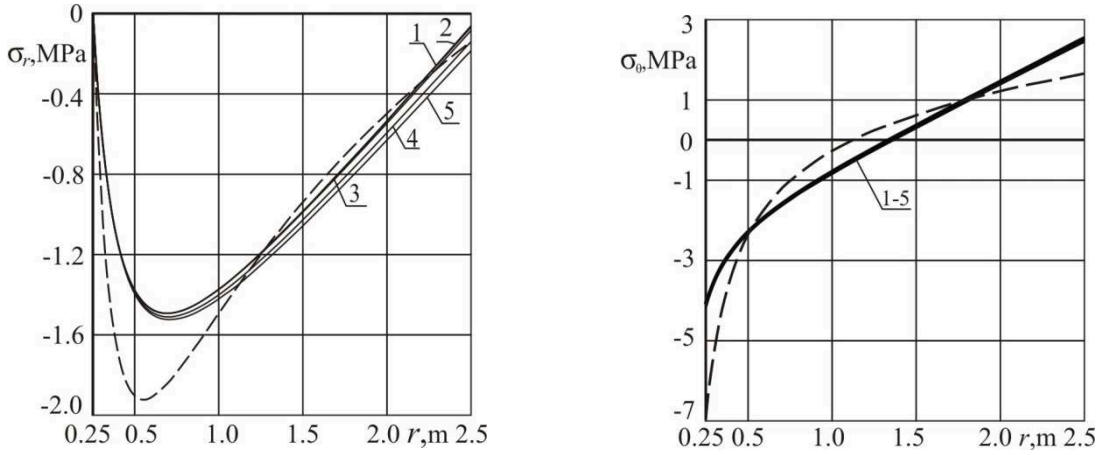

Fig. 2. Diagrams of normal stresses for different values of θ:
1 – θ = π; 2 – θ = 3π/4; 3 – θ = π/2; 4 – θ = π/4; 5 – θ = 0.
—— inhomogeneous material; - - - homogeneousmaterial (θ = π/4).

## Conclusions

Accounting deformation inhomogeneity makes substantial adjustments in the stress state of a cylindrical array with a hole. The most circumferential stressesin the most dangerous stretch zone are 1.5 times higher than the same stresses without regard inhomogeneity.

As can be seen from Fig. 2, the difference between stresses $\sigma_r$ for different values of θ is small, and the curves $\sigma_\theta(r)$ practically coincide.The difference between diagrams 1 - 5 in the figure for $\sigma_r$ is due just to the asymmetry of external pressure.Stresses of its own weight of the array are around 10% of the stresses caused by the swelling soil.Thus it can be concluded that the calculation of the stress state in this problem can be carried out in an axisymmetric formulation [1].

With regard to stresses $\tau_{r\theta}$ (Fig. 3), their values one order less than the values of normal stresses.

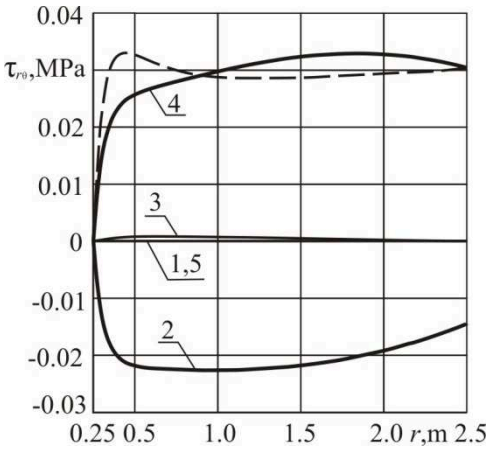

Fig. 3. Diagrams of shear stresses for different values of θ:
1 – θ = π; 2 – θ = 3π/4; 3 – θ = π/2;
4 – θ = π/4; 5 – θ = 0.
—— inhomogeneous material; - - - homogeneousmaterial (θ = π/4).

**Keywords:**hysteretic damping, vibration isolation, micro seismic activity, low-frequency vibration isolation, precision equipment, numerical modelling.

**Abstract.**The article studies the energy method for determining loss factor due to hysteretic damping in systems of vibration and seismic isolation. Typical measure of damping is $\tan\varphi$, where φ is the phase angle between stress and strain sinusoids [1], or damping constant δ ($\delta = \pi \tan\varphi$ [2, 3]). Both of these parameters are acquired through experimental investigations for each type of boundary conditions or element's cross section. Proposed energy method is capable of loss factor ψ determination for different types of beams based on only one experimental investigation. This method is used in the paper to determine the damping ratio of elastic element in vibration isolation system of precision equipment.

## Introduction

Currently, a lot of work is devoted to the protection of high – precision equipment from both ambient vibration, micro seismic and seismic activity [4, 5, 6]. Experiments shows, that damping of structural metals is very low (according to [1]: steel 0,0001; brass $9\times10^{-5}$ and aluminum alloy $<10^{-5}$). Therefore, structural damping is obtained through additional materials with high damping (e.g., rubber pads) or specially designed structures (e.g. viscous dampers). Because vibration isolators of precision equipment have to be effective in the range of 1 – 100 Hz [4, 5], their damping characteristics should possess high values at resonance and low values beyond one. This factor defines the use of dampers with high internal friction, which may in particular be achieved by using compressed beams [1, 2, 8]. One of the vibration isolator types is an isolator, consisting of compressed steel beam that supports the isolated equipment [7, 8]. At the moment, the problem of computing the elastic curve of such isolators is well-studied. However, less attention is given to the problem of calculating the damping characteristics of such isolators. Some authors [1, 7] investigate the influence of internal friction on oscillations of compressed bars, but they measure damping with $\tan\varphi$ parameter. Therefore, they need to perform independent experimental investigations for each type of boundary conditions and cross section type. This paper focuses on the energy model of internal friction, developed in works of Panovko [2]. We investigate the influence of internal damping at low vibrations of compressed beam with variable cross section with initial curvature.

## Proposed energy method

To create a well-posed theory it is important to mention the following experimental fact: energy $\Psi_0$, dissipated per cycle per unit volume of the material depends only on the amplitude value $\varepsilon_0$of deformation. Besides this basic qualitative result, experiments have established for a number of materials particular relationships for uniaxial stress state:

$$\Psi_0 = \Psi_0(\varepsilon_0). \tag{1}$$

Usually, the results of experimental investigations are non-dimensionalized and instead of energy dissipation $\Psi_0$, its ratio to the maximum potential energy of the cycle is used:

$$\psi_0 = \frac{2\Psi_0(\varepsilon_0)}{E\varepsilon_0^2} \tag{2}$$

This ratio, also called the absorption coefficient [2] or loss factor [3], usually depends on the amplitude value of deformation $\varepsilon_0$.

Consider that the vibration mode has the form:

$$X = X(x). \tag{3}$$

We shall normalize it so that the value of X equals unity in a typical section, which deflections are taken as a generalized coordinate. Then the deflection of any section of the beam in the process of oscillations are determined by formula:

$$v(x,t) = X(x)T(t). \tag{4}$$

In Eq. (4)T(t) – is the generalized coordinate, that defines the deflection of the mentioned typical section of the beam. Let the A be the amplitude value of T(t). When the dynamic system is exposed to external excitations, the value of A is constant, but when the system undergo free oscillations, the value of A changes from cycle to cycle. The greatest deviation from the equilibrium position of the system correspond to the deflections:

$$v_{\max} = AX(x). \tag{5}$$

The curvature of the beam in a state of maximum deviation is determined by the approximate expression:

$$\chi = A\frac{d^2X}{dx^2}. \tag{6}$$

Therefore, the amplitude of maximum stress in any point on the beam is determined by:

$$\sigma_0(x,y) = E|\chi y| = EA\left|\frac{d^2X}{dx^2}\right|. \tag{7}$$

As described in [2], further calculations should be based on a specific form of the material dependence – Eq. (1)/ There are various ways of representing these functions, widely discussed in [2, 3]. In our analysis, we will use following simple relation:

$$\Psi_0 = \beta\sigma_0^{n+1}. \tag{8}$$

In Eq. (8)β and n – are the material constants.

Relation (8)can be constructed from the test results, for example from envelope analysis of the beam's free oscillations due to simple constraints, with further approximation of the experimental curve in Curve Fitting Toolbox from MatLab software. According to Eq. (8), Eq. (2) has the form:

$$\psi_0(\sigma_0) = \frac{\Psi_0}{\Pi_0} = 2\beta E\sigma_0^{n+1}. \tag{9}$$

In Eq. (9) $\Pi_0 = \frac{\sigma_0^2}{2E}$ - is specific potential energy in the state of maximum deformation. In order to find all the energy dissipated per cycle, substitute in Eq. (8) the expression σ0, given by Eq. (7) and integrate the result over the entire volume:

$$\Psi = \int_V \Psi_0 dV = \beta(EA)^{n+1} J^* \int_0^l \left|\frac{d^2X}{dx^2}\right|^{n+1} dx. \tag{10}$$

In Eq. (10) $J^* = J(n) = \int_0^l \iint_F |y|^{n+1} dF dx.$ - is a kind of physical – geometric characteristic that depends not only on the shape and cross section size, but also on the beam material.It is important, that the RHS of the equation depends not only on the properties of the material (β and n coefficients), but also on the structure en bloc, besides on the form of the excited vibrations (the latter determines the mode function). In order to get the reduced absorption coefficient, we have to

divide Eq. (10) by potential energy of the beam related to the state of the greatest deviation from the equilibrium position, which has the form:

$$\Pi = \int_V \Pi_0 dV = \frac{EJA^2}{2} \int_0^l \left( \frac{d^2X}{dx^2} \right)^2 dx. \tag{11}$$

After dividing (10) by(11) we will get the reduced absorption coefficient for the whole beam:

$$\psi = 2\beta \frac{J^*}{J} E^n A^{n-1} \frac{\int_0^l \left| \frac{d^2X}{dx^2} \right|^{n+1} dx}{\int_0^l \left( \frac{d^2X}{dx^2} \right)^2 dx}. \tag{12}$$

The absorption coefficient usually depends not only on the material properties, but also on the considered waveform, which defines the form of the derivative $\frac{dX}{dx}$. In addition, it should be noticed, that when n = 1, we obtain a value of the absorption coefficient of the material $\psi = 2\beta E$ .Moreover, Eq. (12) states the fact that the absorption coefficient depends on the amplitude of oscillations.

**Application**

Consider the problem of mass *m* free oscillations on the fixed – fixed compressed beam of variable cross section with initial curvature, which is schematically plotted in Fig. 1.

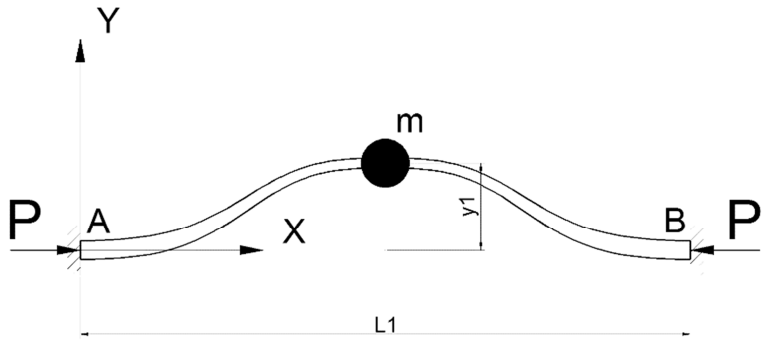

Fig. 1. Scheme of the problem.

Variable beam cross section is described by:

$$EJ(x) = EJ_0 f(x). \tag{13}$$

Consider that the beam's waveform coincides with the curve of static bending subjected to a point force acting in mid span. Since the bending curve in this problem is obtained numerically, it is necessary to represent the Eq. (6) in the finite difference form:

$$A \frac{d^2X}{dx^2} = A \frac{X_{i+1} - 2X_i + X_{i-1}}{h^2}. \tag{14}$$

Then to compute Eq. (12) taking into account Eq. (13) and Eq. (14) we will use formulas for numerical integration like trapezoidal rule or Simpson's rule. Moreover, if the problem involves massive computations, for example,if we need to investigate damping properties for a large number of different beams, parallel integration methods can be applied [9]. In the paper, we consider the following types of variable cross-section, presented in Table 1.

Table 1. Types of variable cross – section.

| №№ | Description | Scheme |
|---|---|---|
| 1 | Linearly varying cross-section |   |
| 2 | Parabolically varying cross - section |   |

The results of calculations are presented on Fig. 2 – 3 for different type of cross section from Table 1. The β and n coefficient were obtained experimentally from beam envelope analysis as stated in [2]. For steel alloy we gathered β = 0,0013, n = 1,3.

a) n = 1 b) n = 1.5

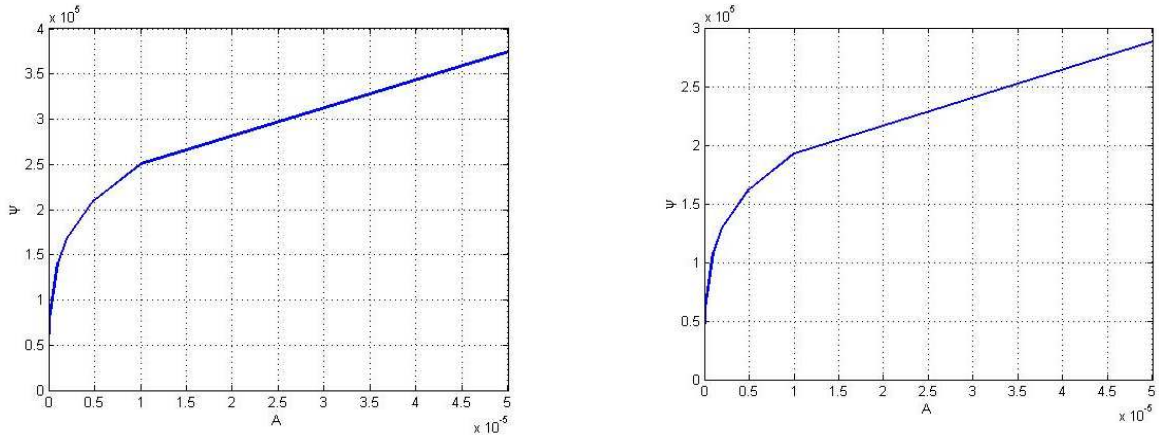

Fig. 2. Curves $\psi - A$ forcrosssectiontype №1.

Cross section type №2 from Table 1 can be made symmetrical or asymmetrical. Cross section type influences both the bending curve and absorption coefficient. Curves $\psi - A$ for symmetrical and asymmetrical cross section of type №2are shown in Fig. 3 in dimensionless form.

a) b)

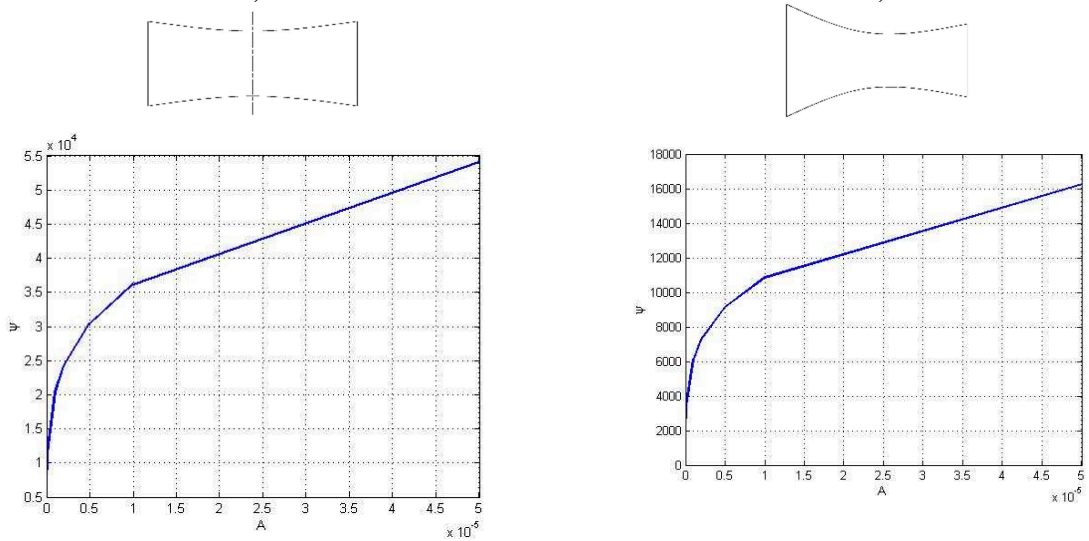

Fig. 3. Curves $\psi - A$ forcrosssectiontype№2.

## Results and discussion

The analysis of calculation results shows that the maximum loss factor has a symmetrical beam with variable cross section of type №2 from Table 1. The lowest loss factor has the beam with asymmetrical cross section of type №2. It can also be noted, that the loss factor is greater in those beams, where the compression zone area is larger. Due to the fact, that asymmetrical cross section beams has smaller compression zone area, compression stresses there are lower, which results in lower potential energy of that part of the beam and lower overall loss factor. That is why it is recommended to use symmetrical cross section beams in applications that require higher internal damping. Although beams with variable asymmetric cross section has lower loss factor, their stiffness characteristics can more convenient in some applications, for example they can possess "soft stiffness", which is favorable for low-frequency vibration isolation purposes. In this case, the process of developing the best isolation system is an optimization problem in which the damping coefficients can be obtainedfrom the calculations presented.

## Conclusion

Energy model for determining the internal friction in the beams takes into account not only the properties of the beam material, but also its boundary conditions and cross section parameters. For this calculation,we do not require numerous experimental studies, which is an advantage of the approach. Thus, the results show that the compressed beam with a variable cross-section have a considerable internal friction, which allows to reduce the amplitude of the resonant oscillation, thereby improving the performance of vibration isolation systems.

**Keywords:** Geological modeling; Hexahedron-dominant mesh generation; Wire frame; Mesh mapping; Block.

**Abstract.** In the field of geotechnical engineering, a numerical simulation model is established by meshing a three-dimensional geological model, which is composed of many seamlessly connected blocks. Each block is enclosed with constrained, triangulated boundary surfaces and called as a constrained block. Due to the complexity of geological structures, a three-dimensional geological model is very complicated in most cases, and will be very difficult to decompose this kind of model into hexahedral mesh by those commonly-used methodologies. Thus, we propose a new mesh generation method which is special for blocks with constrained, triangulated boundary surfaces: hexahedron-dominant mesh generation based on templates (HMGT). In this method, several regular blocks including cuboids, prism, pyramid, tetrahedron, cylinder and their combinations, are decomposed into hexahedron-dominant meshes that serve as mesh templates. Then, a constrained block is abstracted into a simple block, and the simple block is divided into two parts by shrinking: the crust and core. Next, a mesh template of regular blocks or their combinations is selected and mapped to the core of the simple block, and the crust of which is filled with pyramids and tetrahedra in order to obtain the subdivision of the simple block. Finally, the mesh of a simple block is directly mapped to the original constrained block to generate target hexahedron-dominant mesh.

## Introduction

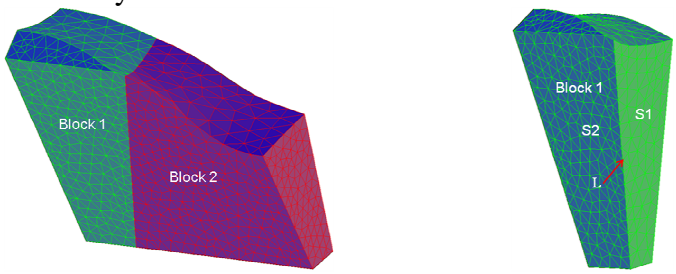
In geotechnical engineering, numerical simulation methods such as finite element methods (FEM) have become indispensable tools. A prerequisite for numerical simulation in geotechnical engineering is the establishment of a computational model representing the geological phenomenon of interest with high mesh quality. Before generating a mesh, it is necessary to establish a realistic geological model using 3D modeling tools. Such geological models consist of a number of closed and connected blocks, and each block is composed of several geological interfaces represented by triangular surfaces. We have proposed a sealed engineering geological modeling method, SEGM [1], to generate the above mentioned geological models. The mesh generation method proposed in this paper is specially designed for this kind of geological model.

At present, the common hexahedral subdivision algorithms include the following: the mapping method, the grid method, tetrahedral decomposition, and the axial surface decomposition method. Cook and Oakes [2] proposed the mapping method. In this method, a mapping function is accepted to transfer a regular mesh unit onto a Euclidean space, and then generate an actual mesh. Price and Armstrong [3,4] divided a meshing area into simple convex areas using central axis planes, and then they decomposed the sub-region into a hexahedral mesh by the mapping method. Chiba, et al. [5,6] developed a semi-automatic all-hexahedral meshing system based on physical recognition and boundary adaptation. Min [7] proposed a hexahedron-dominant mesh method. This method firstly divides a three-dimensional object into a series of convex polyhedrons. For each polyhedron, borders are contracted inward, forming cavities between the old and new borders that are then filled with the four units described above, resulting in the formation of a mesh network.

Building on these advancements, this paper presents a hexahedron-dominant mesh generation method called hexahedron-dominant mesh generation based on templates (HMGT). This method is suitable and valid for generating subdivisions of seamlessly connected blocks with fixed boundaries. The term "hexahedron-dominant" here means that the total space occupied by all hexahedral elements is larger than that by non-hexahedral ones.

## Geometrical Features of Constrained Blocks

In this study, a geological model used in numerical simulation is composed of many blocks, and it is represented using Boundary Representation (B-Rep). Each block is closed by a number of triangular surfaces. The adjacent blocks must meet the conditions of geometrical continuity and topological consistency [1]. A constrained block has the following geometrical features: (1) It is a closed, bounded polyhedron (Fig. 1a); (2) All the boundary surfaces of a constrained block are triangulated (Fig. 1a); (3) Each of its boundary surfaces is continuous and has a closed border loop with no cavity inside the boundary surface. Such a boundary surface is called a simple surface. In Fig. 1b, S1 and S2 are two simple surfaces of Block 2; (4) All interfaces between two connected surfaces of a constrained block are seamless, which means that the two connected surfaces share the same boundary. For example, in Fig. 1b, L is a boundary line shared by S1 and S2; and (5) It is simply connected, with no internal cavity.



**a** **b**

**Fig. 1** (a) Block 1 and Block 2 are two seamlessly connected blocks, and S1 is a boundary surface shared by Block 1 and Block 2; (b) S1 and S2 are two simple surfaces of Block 1, and L is a boundary line shared by S1 and S2

## Methodology

The key procedures of HMGT are as follows. Firstly, some regular blocks, including cuboids, prism, pyramid, tetrahedron, cylinder and their combinations, are divided into hexahedron-dominant meshes that serve as mesh templates. Secondly, a constrained block is abstracted to be a simple block, which is obtained by replacing the simple surfaces of the constrained block with planes. Thirdly, the simple block is divided into two parts: the crust and core. Fourthly, the hexahedral mesh template of a regular block is mapped to the core to obtain mesh of the core. Fifthly, the crust is filled with pyramids and tetrahedrons without any change to the outer surfaces of the block and the core. Lastly, the mesh of a simple block is mapped to the original constrained block to generate subdivision of the constrained block.

## The Hexahedral Mesh Template for Regular Blocks

Although a constrained block can theoretically be any shape, we find that the geological model can be abstracted into several typical regular blocks or their combinations after analyzing a large number of examples. In this paper, cuboid, prism, pyramid, tetrahedron, and cylinder are selected as the typical regular blocks. Since the subdivision method for each regular block is fixed, the mesh quality and the speed of subdivision could be effectively improved. Mesh templates for the cuboid (Fig. 2a), cylinder (Fig. 2b), tetrahedron (Fig. 2c), pyramid (Fig. 2d) and prism (Fig. 2e) are created in this paper.

## Identification and Abstraction of Constrained Blocks

**Shape identification for constrained blocks.** This study presents a method based on geometrical characteristic vertices for shape identification of a constrained block. The method consists of five main steps as follows:

(1) Calculating the average normal for each simple surface of a constrained block

The simple surface of a constrained block is composed of a number of triangles. We can firstly calculate the surface normal of each triangle and then calculate the average normal for a simple surface. The average normal is presented as the direction cosine. In addition, the positive direction of the average normal goes from the inside of a constrained block to the outside. However, if the geometry of a simple surface is very complex, it should be broken down into two or more simple surfaces.

(2) Generating the wire frame for a constrained block

The constrained block in a geological model is enclosed by a number of simple surfaces. Each simple surface is a continuous and connective surface, which is triangulated, and has a closed border loop. The border loops of all simple surfaces form the unedited wire frame for the constrained block.

(3) Editing the wire frame

The wire frame of a constrained block is actually the outline of the block, which is able to demonstrate the block geometry in a simplified way. The wire frame consists of two kinds of simple arcs. One kind of simple arcs includes the geometrical characteristic curves of a block. In the absence of such a simple arc, which is called the geometrical characteristic simple arc, the shape of the block will not be completely. The presence or absence of another kind of simple arc does not affect the shape of the block. This kind of simple arc is called non-characteristic simple arc. The purpose of editing the wire frame is to remove the non-characteristic simple arcs. Because a simple arc is the intersection line of two simple surfaces, removing a simple arc actually merges two connecting simple surfaces together. Obviously, if the average positive normal vectors of two connecting simple surfaces are close, they can be combined into one single simple surface. The process of editing the wire frame is as follows: ① Select each simple arc of the wire frame one by one, and if the angle of the average positive normal between the two simple surfaces sharing this simple arc is less than 30°, remove the arc. ② Remove all simple arcs for which the endpoints belong to only one simple arc.

(4) Determining the geometrical characteristics vertices

There are two types of vertices in the wire frame of a constrained block: characteristic vertices and non-characteristic vertices. Characteristic vertices determine the geometry of a constrained block. If a characteristic vertex is deleted from the wire frame, the geometry of the constrained block will change significantly; if a non-characteristic vertex is deleted from the wire frame, the geometry of the constrained block will not change significantly. Characteristic vertices have the following properties: ① Each characteristic vertex must be an intersection of three or more simple surfaces, meaning that the vertex is shared by three or more simple surfaces; and ② If a node is a characteristic vertex, the angle of the average positive normals between any two connecting simple surfaces sharing the node must be greater than or equal to 30°. After editing the wire frame by removing the non-characteristic simply arcs, the simple surfaces with an angle of average positive

normals less than 30° are merged. We only need to evaluate whether the number of simple surfaces sharing a certain node is greater than or equal to three. Whether or not the node is a characteristic vertex can be determined accordingly.

(5) Determining the geometrical type of a constrained block

Determining the geometrical type of a constrained block involves determining which regular block or block combination is similar to the constrained block. We can determine the geometrical type of a constrained block based on the geometrical characteristic parameters of its wire frame including, the number of characteristic vertices, the number characteristic vertices shared by 3 or 4 simple surfaces, the number of closed loops and the number of simple surfaces. Obviously, the five regular blocks and their combinations can serve as the special constrained blocks. The geometrical characteristic parameters of each type of regular block are listed in Table 1.

**Table 1** The geometrical characteristic parameters of five regular blocks

| Type of regular block | Number of characteristic vertices | Number of characteristic vertices shared by 3 surfaces | Number of characteristic vertices shared by 4 surfaces | Number of closed loops | Number of simple surfaces |
|---|---|---|---|---|---|
| Cuboid | 8 | 8 | 0 | 6 | 6 |
| Prism | 6 | 6 | 0 | 5 | 5 |
| Pyramid | 5 | 4 | 1 | 5 | 5 |
| Petrahedron | 4 | 4 | 0 | 4 | 4 |
| Pylinder | 0 | 0 | 0 | 2 | 3 |

**Abstracting a constrained block.** Abstracting a constrained block involves replacing the triangulated surfaces of the constrained block with planes such that a polyhedron with planar boundaries is formed. Such polyhedron is defined and known as a simple block. When creating a simple block, the geometrical characteristic parameters of the simple block and the constrained block must be the same. The size and shape of the simple block and the constrained block should also match as closely as possible. The specific method for abstracting a constrained block is as follows:

(1) Creating a simple block. ① Select each simple surface on the wire frame of the constrained block one by one, and use the nodes in its closed border loop to fit a plane. ② Compute the intersection of these planes and search a closed loop consisting of the intersecting lines in each plane to form a new wire frame. ③ Calculate the geometrical characteristic parameters for the new wire frame. If the geometrical characteristic parameters for the new wire frame are the same as those for the wire frame of the constrained block, the block surrounded by the new wire frame is a simple block. If not, move and rotate the fitting plane appropriately until a simple block similar to the constrained block is obtained.

(2) Determining the type of simple surface in the constrained block. Each simple surface of the constrained block has a closed boundary loop corresponding to a closed loop in the wire frame of the constrained block. The type of simple surface can be determined according to the number of the characteristic vertices on this closed loop. The types of simple surfaces corresponding to the regular blocks and combination blocks described above include triangle, quadrilateral, pentagon and circle.

(3) Determining the correspondence between the simple surfaces of the constrained block and the boundary planes of the simple block or the corresponding regular block. According to the type of the simple surfaces of the constrained block, its correspondence with the boundary planes of the simple block or regular block can be determined in advance.

(4) Determining the correspondence between the characteristic vertices of the constrained block and those of the simple block or the corresponding regular block. After the preliminary identification of the correspondence between the simple surfaces of the constrained block and the boundary planes of the simple block or regular block, the correspondence between the characteristic

vertices of the constrained block and the vertices of the simple block or corresponding regular block can be established.

### Mesh Mapping Based on the Direct Method

In brief, mesh mapping is the conversion of a surface or block with a certain shape and effective mesh to another surface or block while maintaining the same mesh topology and mesh effectiveness. When the same mesh topology is used for two meshes, it means they have the same number of elements and nodes and the same relationship between the elements and the nodes. They also have the same adjacent relationships among nodes. The spatial coordinates of nodes, however, can be different. In short, everything between two surfaces or blocks is the same only except the coordinates of some of their nodes.

This study applies the direct method to process of mesh mapping for a surface or a block. Proposed by Balendran [15], the direct method is a mesh optimization method for triangular or quadrilateral surfaces. The main idea of this method is to treat the mesh as a deformable object. Maintaining the topological consistency of the mesh, nodes are moved such that each triangle on the mesh remains as close to an equilateral triangle as possible. Similarly, each quadrilateral is kept close to a square, and in this way, mesh optimization is achieved. Because the common types of block mesh elements are hexahedron, pyramid, prism and tetrahedron, these common elements are all surrounded with triangles and/or quadrangles. Therefore, the direct method can also be used for optimization of a block mesh [16]. Because the direct method has been discussed in detail in the literatures [15,16], we will not provide a description here.

### Mesh Generation for a Constrained Block

In this study, the mesh of a constrained block is obtained from mesh mapping with the corresponding simple block. The mesh generation for a constrained block involves two main processes: mesh generation of a simple block and mesh mapping from the simple block to the constrained block.

**Mesh generation of a simple block.** A simple block is formed by the abstraction of a constrained block, which is a transition status in between a constrained block and a regular block. The mesh generation for a simple block is the key step in our proposed algorithm. To show how it is carried out clearly, the mesh generation process of a simple block is introduced with an example. Let B be a constrained block. Using the methods described in Section 5, the corresponding simple block β and regular block b can be obtained.

(1) Division of crust and core in a simple block

If the outer surfaces of a simple block β shrinks inward in parallel, a block with the same shape as β and a smaller block size is obtained, which is called the core. This process divides β into two parts: the crust and the core. The distance between the surfaces of a core and the outer surfaces of β depends on the given mesh size, which is generally the same as that of the element.

(2) Mesh mapping for the core

Core subdivision is to divide the core into a mesh with the same structure as a regular block b, which has the same geometrical characteristic parameters. Using the block mapping method described in Section 6, the mesh of regular block b can be mapped onto the core of a simple block β to get the mesh of the core of β.

(3) Mesh mapping for the surfaces of the simple block

The subdivision of a constrained block is to generate a hexahedron-dominant mesh while the boundary meshes are immutable. Therefore, we must ensure that each mesh on the boundaries of the simple block and its correspondence on the boundaries of the constrained block have an identical structure. The boundary surfaces as well as the characteristic vertices have a one-to-one correspondence between β and B, because the simple block β is the abstraction of the constrained block B. Using the surface mapping subdivision method introduced in the foregoing section, each

boundary surface of B can be mapped onto the corresponding boundary surface of β. In this way, the mesh mapping for the surfaces of a simple block is achieved.

(4) Subdivision for the crust of a simple block

The crust of a simple block is the cavity between the outer surface of the simple block and the outer surface of its core. Because the meshes of the outer surfaces of a simple block are often different from those of the outer surfaces of the core, it is difficult to divide the crust into a hexahedral mesh. Using the filling method, the crust can be divided into a collection of pyramids and tetrahedrons. To introduce easily, the outer surfaces of a simple block and the outer surfaces of its core are respectively called the outer boundary and inner boundary of the crust in the following description.

The filling method is performed as follows: ① Each quadrilateral is selected orderly from the mesh of the inner boundary and treated as the bottom of a pyramid. The coordinates of the centroid of this quadrilateral are calculated. Then, the centroid of the quadrilateral is shifted outward a certain distance along the border of its normal direction to form a vertex. A pyramid is created by connecting the vertex and four vertices of the quadrilateral. After this treatment, the inner boundary is changed from a quadrilateral mesh into a triangular mesh. ② By accepting the algorithm of Constrained Delaunay Triangulation (CDT), the rest part of the crust is subdivided into tetrahedrons.

**Mesh mapping of a simple block onto a constrained block.** After mesh generation of a simple block, the nodes on the outer boundary surfaces of a constrained block are used to replace the corresponding nodes on the boundary surfaces of the simple block. Then, using the direct method, the coordinates of nodes in the simple block are moved to the appropriate positions such that subdivision of the constrained block is achieved.

## An Example of Mesh Generation for a Constrained Block

A constrained block B, of which the simple block is similar to a combination of a cuboid and a prism, is also selected and then meshed (Fig. 3).

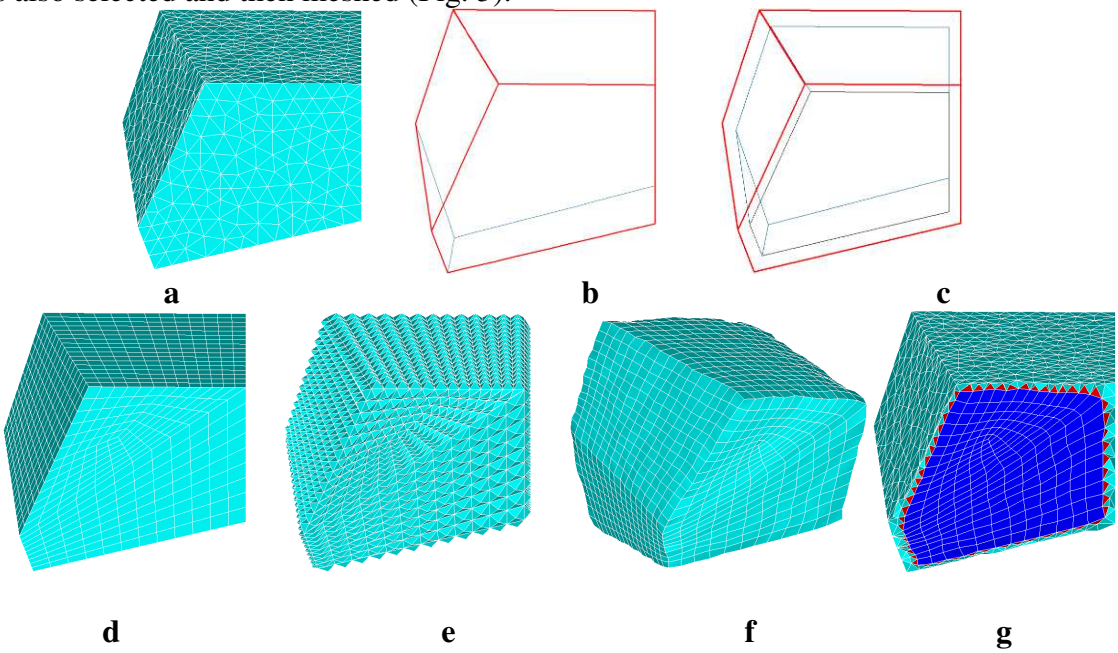

**Fig. 3** (a) A constrained block B; (b) The wire frame of the constrained block; (c) The core and crust of the simple block of B; (d) Hexahedrons of the core of the simple block; (e) Pyramids grown from the boundary surfaces of the core; (f) Hexahedrons in the core of B

## Conclusions

Aiming at the individual constrained block from the three-dimensional geological model, we propose a hexahedron-dominant subdivision method, hexahedron-dominant mesh generation based on templates (HMGT), to decompose the block with constrained triangulated boundary surfaces into hexahedron-dominant meshes. To hold the conditions of geometrical continuity and topological consistency between blocks, the triangular meshes on the border surface of the block are kept in the process of subdivision. The main procedures of HMGT are follows: firstly, a constrained block is abstracted to be a simple block, and the simple block is divided into crust and core by shrinking; secondly, the hexahedral mesh template of a regular block is mapped to the core to obtain its mesh, and the crust is filled with pyramids and tetrahedrons without any change to the outer surfaces of both the block and the core; finally, the mesh of a simple block is mapped to the original constrained block to generate the required subdivision of the constrained block.

**Keywords:** Hydraulics; dam breach; shallow water equations; structured grid; finite volume method

**Abstract.** A high precision structured-based finite volume model for numerical simulation of dam-and dyke-breach flow was proposed. The model regarded the fully two-dimensional shallow water equations as the governing equations, and used the Godunov-type finite volume shock-capturing schemes HLLC to calculate flow flux. Its spatial and temporal accuracy were improved to two order accuracy using the slop limiter and predict-correct method, and the slope source terms and friction source terms were treated with central difference scheme and fully implicit method respectively. And then a robust procedure was adapted in the model to efficiently and accurately simulate the movement of wet and dry boundary and a method of high calculation efficiency was applied in the treatment of complex boundary. A popular example was used to validate the capability of the model. The result shows that the model can capture flow processes over irregular boundary accurately and shows good stability and accuracy.

## Introduction

Frequency of the flood disaster in China have caused tremendous damage to people's lives and property, a combination measures of engineering and non- engineering is used to avoid the risk of flooding and reduce flood losses. As a part of non-engineering, the flow mathematical model is widely applied in the aspects of flood forecasting, dam-and dyke-breach, flood control plan, and river training, etc. [1], which provides a solid foundation for the study on spatial and temporal evolution laws, disaster preparedness and mitigation and risk regulation.

The conventional flow numerical model is suitable for the gradually varied flow, but the good results cannot be achieved when applied in the rapidly varied flow simulation, such as dam- and dyke-breach flood, the mountain flood caused by the strong rainfall, the tidal estuary flow. However, the high performance finite volume computational scheme capturing the shock wave and contact break, along with the two-dimensional shallow water equation, provides the research idea to solve the problem. When using the above method to simulate flow process under the condition of complex topography and boundary, the four aspects as follows merit attention: firstly, the failure to effectively balance the bottom slope and flux will cause false flow velocity [2] ;secondly, it is difficult in the wet-and dry-boundary treatment when rapidly varied flow on the complex terrain[3]; thirdly, complex irregular boundaries treatment will directly affect the numerical reliability, accuracy and computational time[4]; fourthly, complex computational mesh generation is not propitious for the further application in the productive practice.

Some studies or explorations in these aspects are conducted by the scholarships at home and aboard, and good results are acquired [2, 3, 4, 5, 6, 7, 8]. On the basis of relevant research results from scholarship at home and aboard, A high precision structured-based finite volume model for numerical simulation of dam-and dyke-breach flow is proposed, which is built upon the fully two-dimensional shallow water equations and handling efficiently the problems appeared in modeling unsteady and steady flow over topography with wetting and drying and complex boundary.

**Governing Equations**

Under the assumption of the horizontal scale of water in the rivers, lakes, or flood plain being much larger than the vertical scale, hydrostatic pressure distribution, the smaller vertical acceleration, and the neglecting the surface stress term, Coriolis effects term and viscous term, the two-dimensional shallow water equations derived by depth-integrating the three-dimensional Reynolds-averaged Navier-Stokes equations can be expressed as given below.

$$\frac{\partial \zeta}{\partial t}+\frac{\partial (uh)}{\partial x}+\frac{\partial (vh)}{\partial y}=0 \tag{1}$$

$$\frac{\partial (uh)}{\partial t}+\frac{\partial (u^2h)}{\partial x}+\frac{\partial (uvh)}{\partial y}=-\frac{\tau_{bx}}{\rho}-gh\frac{\partial \zeta}{\partial x} \tag{2}$$

$$\frac{\partial (vh)}{\partial t}+\frac{\partial (uvh)}{\partial x}+\frac{\partial (v^2h)}{\partial y}=-\frac{\tau_{by}}{\rho}-gh\frac{\partial \zeta}{\partial y} \tag{3}$$

where, $t$ denotes time, $x$ and $y$ are Cartesian coordinates, $\zeta$ is the free surface elevation above still water depth ($h_s$), $h(=\zeta+h_s)$ is total water depth, $h_s$ is still water depth, $u$ and $v$ are depth-averaged velocity components in the two Cartesian directions; $g$ is the gravitational acceleration, $\rho$ is the density of water, $\tau_{bx}$ and $\tau_b$ are bed friction stresses. To overcome the drawback when water flows over initially dry land, while retaining the mathematical balance the flux gradient and source terms, the free surface gradient term $gh\partial\zeta/\partial x$ and $gh\partial\zeta/\partial y$ in the $x$-and $y$-direction momentum equation can be written as given below[9].

$$gh\frac{\partial \zeta}{\partial x}=\frac{g}{2}\frac{\partial (\eta^2-2z_b\eta)}{\partial x}+g\eta\frac{\partial z_b}{\partial x},\quad gh\frac{\partial \zeta}{\partial y}=\frac{g}{2}\frac{\partial (\eta^2-2z_b\eta)}{\partial y}+g\eta\frac{\partial z_b}{\partial y} \tag{4}$$

where, $\eta$ is surface water level above the datum, $z_b$ is terrain elevation above datum, and water depth is obtained by $h=\eta-z_b$.

Substituting the free surface gradient terms in equation (2) and equation (3) with equation (4), the equation (1), (2), (3) may be written as in the matrix form as given below.

$$\frac{\partial \mathbf{U}}{\partial t}+\frac{\partial \mathbf{F}}{\partial x}+\frac{\partial \mathbf{G}}{\partial y}=\frac{\partial \mathbf{U}}{\partial t}+\nabla\cdot\mathbf{E}=\mathbf{S} \tag{5}$$

where,**U** and **E** are vectors representing conserved variable and the flux of convective flux respectively, **F** and **G** are vectors representing fluxes in $x$- and $y$- direction respectively, **S** is the vector representing source term including bed slope term and friction term.

These vectors are given below.

$$\mathbf{U}=\begin{bmatrix}\eta\\ uh\\ vh\end{bmatrix},\mathbf{F}=\begin{bmatrix}uh\\ u^2h+\frac{1}{2}g\left(\eta^2-2\eta z_b\right)\\ uvh\end{bmatrix},\mathbf{G}=\begin{bmatrix}vh\\ uvh\\ v^2h+\frac{1}{2}g\left(\eta^2-2\eta z_b\right)\end{bmatrix},\mathbf{S}=\begin{bmatrix}0\\ -\frac{\tau_{bx}}{\rho}-g\eta\frac{\partial z}{\partial}\\ -\frac{\tau_{by}}{\rho}-g\eta\frac{\partial z}{\partial}\end{bmatrix} \tag{6}$$

where, $\tau_{bx}$ and $\tau_{by}$ are bed stress terms representing the energy dissipation influence of bed roughness on flow and are calculated empirically from the equations as given below.

$$\tau_{bx}=\rho g n^2 u\sqrt{u^2+v^2}\,/\,h^{1/3},\quad \tau_{by}=\rho g n^2 v\sqrt{u^2+v^2}\,/\,h^{1/3}.$$

The physical significance of other variables is the same as the above relevant content.

**Finite Volume Model**

Governing equations are discretized on the rectangular grid cells, and Fig.1 shows the schematic diagram of a discrete control cell. The adjacent cells of a controlling cell $(i, j)$ is $(i, j\text{-}1)$, $(i\text{+}1, j)$ $(i, j\text{+}1)$, $(i\text{-}1, j)$, and the public boundaries are $(i, j\text{-}1/2)$ $(i\text{+}1/2, j)$ $(i, j\text{+}1/2)$ $(i\text{-}1/2, j)$ respectively. The length of the cells at horizontal axis $x$ is $\Delta x$, while $\Delta y$ at the vertical axis $y$. The model basic variables of $h$ or $z$, $u$, $v$ are stored in the cell center and the terrain elevation is stored in the node of the cell when controlling equations are distributed, so the center elevation is calculated directly from the node elevation interpolation when the model calculates them.

Choosing any of the controlling cell $V_{(i,j)}$, the integral of formula (5) in the controlling cell is:

$$\int_{V_{(i,j)}} \frac{\partial \mathbf{U}}{\partial t} dV + \int_{V_{(i,j)}} \nabla \cdot \mathbf{E} dV = \int_{V_{(i,j)}} \mathbf{S} dV \qquad (7)$$

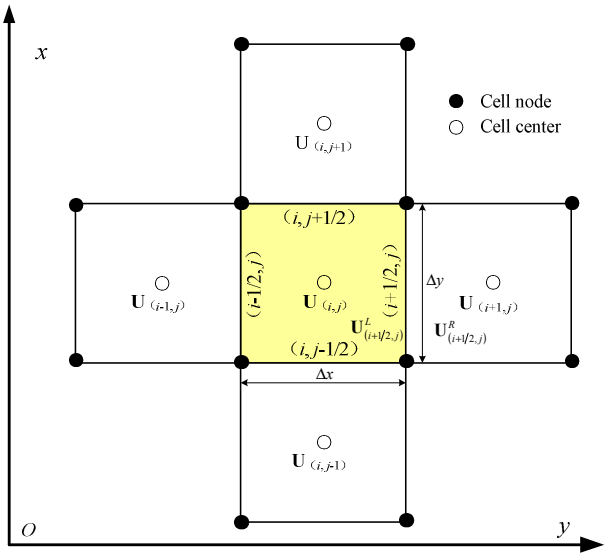

**Fig.1 Schematic diagram of a controlling cell**

Assuming that the average value **U** of the cell is stored in the cell center, converting the second term of area integral in the left of the formula (7) to line integral along the boundary of the controlling cell using the Gauss-Green, then formula (7) can be transformed into the integral equations as given below.

$$\int_{V_{(i,j)}} \frac{\partial \mathbf{U}}{\partial t} dV + \oint_{L_{(i,j)}} \mathbf{E} \cdot \mathbf{n} dL = \int_{V_{(i,j)}} \mathbf{S} dV \qquad (8)$$

where, $L(i,j)$ is the boundary of the grid cell$(i,j)$ , and the formula (8) can be written as follows:

$$\frac{\partial \mathbf{U}}{\partial t} \Delta A_{(i,j)} = -\sum_{k=1}^{4} \mathbf{E}^{k}_{(i,j)} \cdot \mathbf{n}^{k}_{(i,j)} \Delta L^{k}_{(i,j)} + \mathbf{S}_{(i,j)} \Delta A_{(i,j)} \qquad (9)$$

where,$\Delta A(i,j)$ represents the area of the cell$(i,j)$, and $\Delta A(i,j)= \Delta x \Delta y$; $\mathbf{E}^{k}_{(i,j)}$ is the flux of the boundary $k$, $k$=1,2,3,4, corresponding to the lower, right, upper and left boundary; $\mathbf{n}^{k}_{(i,j)}$ is the unit normal vector of boundary $k$; $\Delta L^{k}_{(i,j)}$ is the length of the boundary $k$, and the length of the left and right boundaries is$\Delta y$, while the upper and lower boundary is $\Delta x$. So you can get:

$$\mathbf{U}^{n+1}_{(i,j)} = \mathbf{U}^{n}_{(i,j)} - \frac{\Delta t}{\Delta x}\left(\mathbf{E}_{(i+1/2,j)} - \mathbf{E}_{(i-1/2,j)}\right) - \frac{\Delta t}{\Delta y}\left(\mathbf{E}_{(i,j+1/2)} - \mathbf{E}_{(i,j-1/2)}\right) + \Delta t \mathbf{S}_{i,j} \qquad (10)$$

where, $n$ represents the time, $(i,j)$is the cell index, and $\mathbf{E}_{(i\text{-}1/2,j)}$, $\mathbf{E}_{(i\text{+}1/2,j)}$, $\mathbf{E}_{(i,j\text{+}1/2)}$ and $\mathbf{E}_{(i,j\text{-}1/2)}$ represent the fluxes of the left and right boundaries, and that of the upper and lower boundaries of the cell$(i,j)$ respectively.

**Numerical Flux Calculation**

A Godunov-type scheme solves local Riemann problems at each cell interface to evaluate interface fluxes. The HLLC approximate Riemann solver is chosen to solve these local Riemann problems due to its advantages in offering automatic entropy fix and easy treatment of wetting and drying. Compared with the original HLL approach, the HLLC approximate Riemann solver also presents major benefits in modeling two-dimensional flows, especially when the solute transport is include. Ignoring the middle wave, the two-wave assumption of the HLL Riemann solver is only correct for purely one-dimensional problems an may result in excessive smearing of contact discontinuities for multidimensional simulations. Here, the two-dimensional shallow water equations are considered and hence the HLLC solver should be used [10].

**Time Integral**

MUSCL-Hancock method, where MUSCL stands for Monotone Upwind Schemes for Conservation Laws, is employed to achieve the second-order accuracy in time for the governing equations. It updates flow variables over a time interval via predictor and corrector steps in an explicit scheme.

In the predictor step, the time-marching formula for updating the cell-centered flow variables from formula (10) is：

$$\mathbf{U}_{(i,j)}^{n+1/2}=\mathbf{U}_{(i,j)}^{n}-\frac{\Delta t}{2}\left[\frac{\left(\mathbf{E}_{(i+1/2,j)}^{*}-\mathbf{E}_{(i-1/2,j)}^{*}\right)}{\Delta x}+\frac{\left(\mathbf{E}_{(i,j+1/2)}^{*}-\mathbf{E}_{(i,j-1/2)}^{*}\right)}{\Delta y}-\mathbf{S}_{(i,j)}\right] \tag{11}$$

where, the subscript $(i, j)$ represents cell index, the superscript $n$ denotes the time level，$\Delta t$ represents the time step, $\Delta x$ and $\Delta y$ are the cell sizes in the $x$- and $y$-direction. The bed slope terms are approximated with central differences and interface fluxes are determined at the midpoint of each cell face with linear interpolation.

In the corrector step, the flow variables are calculated over a full time step based on flow data from the predictor step. The explicit updating formula is given below.

$$\mathbf{U}_{(i,j)}^{n+1}=\mathbf{U}_{(i,j)}^{n}-\Delta t\left[\frac{\left(\mathbf{E}_{(i+1/2,j)}^{*n+1/2}-\mathbf{E}_{(i-1/2,j)}^{*n+1/2}\right)}{\Delta x}+\frac{\left(\mathbf{E}_{(i,j+1/2)}^{*n+1/2}-\mathbf{E}_{(i,j-1/2)}^{*n+1/2}\right)}{\Delta y}-\mathbf{S}_{(i,j)}^{n+1/2}\right] \tag{12}$$

Numerical fluxes are calculated using the HLLC approximate Riemann solver, where the face values of the flow variables are again obtained using slope-limited interpolation formula.

**Discretization of Source Terms**

The discretization of the bed slope term and friction term are treated respectively.

The bed slope terms are calculated with the central difference scheme, compatible with the Godunov- type finite volume model, in the $x$- and $y$-direction. And the discretized equations are given below.

$$-g\eta\frac{\partial z_b}{\partial x}=-g\overline{\eta}\left(\frac{z_{bi+1/2,j}-z_{bi-1/2,j}}{\Delta x}\right),\quad -g\eta\frac{\partial z_b}{\partial y}=-g\overline{\eta}\left(\frac{z_{bi,j+1/2}-z_{bi,j-1/2}}{\Delta y}\right) \tag{13}$$

Where $\overline{\eta}=\left(\eta_{i-1/2,j}^{R}+\eta_{i+1/2,j}^{L}\right)/2$， $\overline{\eta}=\left(\eta_{i,j-1/2}^{R}+\eta_{i,j+1/2}^{L}\right)/2$。

The friction source terms are solved by a splitting point-implicit scheme for better stability [11] and it is equivalent to solve the following ordinary differential equations as given below.

$$\frac{d\mathbf{U}}{dt}=\mathbf{S}_f \tag{14}$$

where，$\mathbf{S}_f=[0\ S_{fx}\ S_{fy}]^{\mathrm{T}}$，$S_{fx}=-\tau_{bx}/\rho, S_{fy}=-\tau_{by}/\rho$. The formula (14) is expanded in the Taylor series to obtain the implicit expression as given below.

$$\mathbf{S}_f^{n+1} = \mathbf{S}_f^n + \left(\frac{\partial \mathbf{S}_f}{\partial \mathbf{U}}\right)^n \Delta \mathbf{U} + o\left(\Delta \mathbf{U}^2\right) \quad (15)$$

where, $n$ represents the time level,$\Delta\mathbf{U}=\mathbf{U}^{n+1}-\mathbf{U}^n$, $(\partial\mathbf{S}_f/\partial\mathbf{U})$ is the Jacobian matrix of $\mathbf{S}_f$. The formula (15) can be transformed into the equation as given below.

$$\left[\mathbf{I} - \Delta t\left(\frac{\partial \mathbf{S}_f}{\partial \mathbf{U}}\right)^n\right]\Delta \mathbf{U} = \Delta t \mathbf{S}_f^n \quad (16)$$

where, $\mathbf{I}$ is identity matrix.

## Treatment of Complex Boundary Conditions

Wet and dry boundary treatment is a hot and difficult question in the calculation of extreme flow. The processes of wet and dry on the complex terrain are treated through amending the governing equations, and it can use a method to amend the local bed [9] to avoid the generation of the false flow on the dry bed.

Incorrect treatment of wall boundary will bring a false viscosity in the numerical solution when applied to the curve or irregular boundary and result in numerical oscillations. A simple and practical boundary treatment method proposed in the paper [12] is used to handling this problem.

## Validation Using a Popular Example

The purpose of this example is to test the ability of the model to deal with discontinuity and the ability to adapt to the complex boundary. The calculation area is a flat rectangle channel of 40m long, the width of the entrance on the upper reach of the channel is 30m, while it has a inward contraction of 8.95 degrees on the right bank of the river 10 meters away from the entrance. Hydraulic jumps of a certain angle are formed when the water flows to the contraction of the channel. A boundary of rapid flow is given at the entrance, that is, $u$=8.57m/s, $v$=0m/s, the initial water depth $h$=1m, and then a boundary of a free outflow is given at the outlet. The frictional resistance is not taken into account when calculating.

Analytical solution for the given boundary conditions is that: it generates a steady-state supercritical flow, and the study area is divided into two parts by the hydraulic jump; also there is an angle of 30 degrees between the flow direction and the hydraulic jump, and the water depth of the hydraulic jump is 1.5m.

The model ability of adapt to the complex boundary is shown in Fig.2 without treatment of the boundary when the sharp and steep peaks appear on the water surface near the boundary, causing numerical oscillations, and the flow direction is inconsistent with the boundary direction, incompatible with the real physical phenomena. The model ability of adapt to the complex boundary is shown in Fig.3 after treatment of the boundary. An angle of 30 degrees exists between the flow direction and the hydraulic jump, and the water depth of the hydraulic jump is 1.5m, well capturing the shock wave in 2-3 grid cells, which shows that the model adopted can well adapt to the complex boundary and deal with discontinuous solutions with high accuracy.

**Fig.3 Computational results after boundary treatment**

## Conclusions

A high precision structured-based finite volume model for numerical simulation of dam-and dyke-breach flow was proposed. The model regarded the fully two-dimensional shallow water equations as the governing equations, and used the Godunov-type finite volume shock- capturing schemes HLLC to calculate flow flux. Its spatial and temporal accuracy were improved to two order accuracy using the slop limiter and predict-correct method, and the slope source terms and friction source terms were treated with central difference scheme and fully implicit method respectively. And then a robust procedure was adapted in the model to efficiently and accurately simulate the movement of wet and dry boundary and a method of high calculation efficiency was applied in the treatment of complex boundary. A popular example was used to validate the capability of the model. The result shows that the model can capture flow processes over irregular boundary accurately and shows good stability and accuracy.

**Keywords:**differential-algebraic equations, Newmark methods, subcycling, partitioned methods

**Abstract:** Systems of ODEs arising from transient structural dynamics generally exhibit high-frequency/low-frequency and linear/nonlinear behaviours of subsets of state variables. This paper resorts to the use of different time integrators with different time steps for subsystems, to tailor each method and its time step to the solution behaviour of the corresponding subsystem. Anovel partitioned integration method with the acceleration continuity is proposed whose velocity continuity is also ensured by means of the mass projection strategy. Both its stability and accuracy properties are examined through numerical analysis on Single-DoF split mass system.

## Introduction

Systems of Ordinary Differential Equations (ODEs) arising from transient structural dynamics, like structure-soil interaction problems or structural control problems, very often exhibit high-frequency/low-frequency and linear/nonlinear behaviours of subsets of state variables. In view of those systems, researchers have devoted significant effort to implement partitioned time integration methods to achieve greater computational efficiency. Those with different time steps are also called subcycling[1] or multi-time-step methods[2]. Arnold et al.[3] restricted the communication between subsystems to discrete synchronization points and required interpolation/extrapolation owing to the use of different time steps. They stated that subcycling techniques could suffer from numerical instability that might be further exacerbated by discretization errors introduced by interpolation/extrapolation. To improve stability and/or accuracy, many partitioned integration methods were conceived, including stabilization techniques [4-6].

In transient structural dynamics, partitioned methods mainly relied on Linear Multi-Step methods that were applied to the Euler-Lagrange form of equations of motion[7]. A distinct feature of these algorithms was the use of dual unknowns, i.e. the Lagrange multipliers, in order to enforce the continuity between subsystems. Gravouil and Combescure solved the DAE system of equations with a structural integrator, i.e. the Newmark-$\beta$ scheme[8], thus obtaining a multi-time-step explicit-implicit method [2], hereafter referred to the GC method. In a greater detail, they conceived a method that was endowed with a conservation law and therefore was spectrally stable. However, the accuracy reduced to first order when subcycling was employed.

It was found that the GC method reduced to be first order accuracy due to its velocity continuity and if the acceleration continuity was considered within the framework of the GC method the second order accuracy could be retained. Moreover, the implementation of the acceleration continuity may cause instability and inneglectable displacement drift at the interface. In this respect, a stabilization technique, i.e. the mass projection, is required at the end of each system time step. To

overcome the order reduction without increasing drift and computational cost, a novel method is conceived considering the acceleration continuity and the mass projection. Successively, numerical analyses on single DoF split-mass systems are carried out to investigate its stability and accuracy. Lastly, the insight gained from the analyses of those analyses and the consequent conclusions are confirmed by means of numerical experiments on Single- and Two-DoF split-mass systems.

## Novel partitioned time integration method

For simplicity, consider a system divided into two subdomains *A* and*B*. The basic principles of the novel method can also be illustrated in Fig. 1. Its solution procedure can be detailed as:

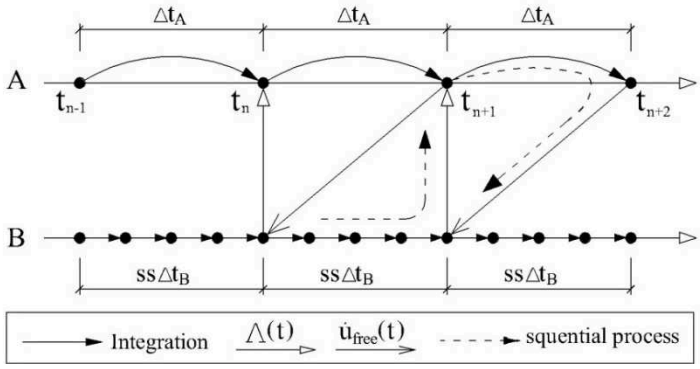

Fig. 1 The solution procedure of the proposed method

1. Solve the free problem in subdomain*A*.

$$\begin{aligned} \tilde{\mathbf{M}}_A \ddot{\mathbf{u}}^A_{n+1,free} &= \mathbf{F}^A_{ext,n+1} - \mathbf{K}_A \tilde{\mathbf{u}}^A_n - \mathbf{C}_A \tilde{\dot{\mathbf{u}}}^A_n \\ \mathbf{u}^A_{n+1,free} &= \tilde{\mathbf{u}}^A_n + \alpha^A_1 \ddot{\mathbf{u}}^A_{n+1,free} \\ \dot{\mathbf{u}}^A_{n+1,free} &= \tilde{\dot{\mathbf{u}}}^A_n + \alpha^A_2 \ddot{\mathbf{u}}^A_{n+1,free} \end{aligned} \tag{1}$$

where

$$\begin{aligned} \tilde{\mathbf{u}}^A_n &= \mathbf{u}^A_n + \Delta t \dot{\mathbf{u}}^A_n + \Delta t^2 \left( \frac{1}{2} - \beta_A \right) \ddot{\mathbf{u}}^A_n \\ \tilde{\dot{\mathbf{u}}}^A_n &= \dot{\mathbf{u}}^A_n + \Delta t \left( 1 - \gamma_A \right) \ddot{\mathbf{u}}^A_n \\ \alpha^A_1 &= \beta_A \Delta t^2 \quad \text{and} \quad \alpha^A_2 = \gamma_A \Delta t. \end{aligned} \tag{2}$$

2. Interpolate the free velocity in subdomain*A*.

$$\dot{\mathbf{u}}^A_{n+j/ss,free} = \left( 1 - \frac{j}{ss} \right) \dot{\mathbf{u}}^A_{n,free} + \frac{j}{ss} \dot{\mathbf{u}}^A_{n+1,free}. \tag{3}$$

3. Solve the free problem in subdomain B.

$$\begin{aligned} \tilde{\mathbf{M}}_B \ddot{\mathbf{u}}^B_{n+j/ss,free} &= \mathbf{F}^B_{ext,n+j/ss} - \mathbf{K}_B \tilde{\mathbf{u}}^B_{n+(j-1)/ss} - \mathbf{C}_B \tilde{\dot{\mathbf{u}}}^B_{n+(j-1)/ss} \\ \mathbf{u}^B_{n+j/ss,free} &= \tilde{\mathbf{u}}^B_{n+(j-1)/ss} + \alpha^B_1 \ddot{\mathbf{u}}^B_{n+j/ss,free} \\ \dot{\mathbf{u}}^B_{n+j/ss,free} &= \tilde{\dot{\mathbf{u}}}^B_{n+(j-1)/ss} + \alpha^B_2 \ddot{\mathbf{u}}^B_{n+j/ss,free} \end{aligned} \tag{4}$$

where

$$\begin{aligned}
\tilde{\mathbf{M}}_B &= \mathbf{M}_B + \alpha_1^B \mathbf{K}_B + \alpha_2^B \mathbf{C}_B \\
\tilde{\mathbf{u}}^B_{n+(j-1)/ss} &= \mathbf{u}^B_{n+(j-1)/ss} + \frac{\Delta t}{ss}\dot{\mathbf{u}}^B_{n+(j-1)/ss} + \left(\frac{\Delta t}{ss}\right)^2\left(\frac{1}{2}-\beta_B\right)\ddot{\mathbf{u}}^B_{n+(j-1)/ss} \\
\tilde{\dot{\mathbf{u}}}^B_{n+(j-1)/ss} &= \dot{\mathbf{u}}^B_{n+(j-1)/ss} + \frac{\Delta t}{ss}(1-\gamma_B)\ddot{\mathbf{u}}^B_{n+(j-1)/ss} \\
\alpha_1^B &= \beta_B\left(\frac{\Delta t}{ss}\right)^2 \quad \text{and} \quad \alpha_2^B = \gamma_B\frac{\Delta t}{ss}.
\end{aligned} \tag{5}$$

4. Calculate the Lagrange multiplier at end of the substep and solve the link problem in Subdomain $B$. The Lagrange multiplier can be obtained with the following equations

$$\Lambda_{n+j/ss} = -\left(\mathbf{H}^*\right)^{-1}\left(\mathbf{G}_A\ddot{\mathbf{u}}^A_{n+j/ss,free} + \mathbf{G}_B\ddot{\mathbf{u}}^B_{n+j/ss,free}\right) \tag{6}$$

where $\mathbf{H}^* = G_A\tilde{\mathbf{M}}_A^{-1}G_A^T + G_B\tilde{\mathbf{M}}_B^{-1}G_B^T$. With the Lagrange multiplier at the end of the substep, we can calculate the link solution.

$$\begin{aligned}
\tilde{\mathbf{M}}^B\ddot{\mathbf{u}}^B_{n+j/ss_{link}} &= \left(\mathbf{G}^B\right)^T\Lambda_{n+j/ss} \\
\mathbf{u}^B_{n+j/ss_{link}} &= \alpha_1^B\ddot{\mathbf{u}}^B_{n+j/ss_{link}} \\
\dot{\mathbf{u}}^B_{n+j/ss_{link}} &= \alpha_2^B\ddot{\mathbf{u}}^B_{n+j/ss_{link}}.
\end{aligned} \tag{7}$$

Finally, the kinematic quantities in subdomain $B$ can be obtained with summing the free solutions and link solutions.

$$\begin{aligned}
\mathbf{u}^B_{n+j/ss} &= \mathbf{u}^B_{n+j/ss,free} + \mathbf{u}^B_{n+j/ss_{link}} \\
\dot{\mathbf{u}}^B_{n+j/ss} &= \dot{\mathbf{u}}^B_{n+j/ss,free} + \dot{\mathbf{u}}^B_{n+j/ss_{link}} \\
\ddot{\mathbf{u}}^B_{n+j/ss} &= \ddot{\mathbf{u}}^B_{n+j/ss,free} + \ddot{\mathbf{u}}^B_{n+j/ss_{link}}.
\end{aligned} \tag{8}$$

5. Solve the link problem in subdomain $A$.

$$\begin{aligned}
\tilde{\mathbf{M}}^A\ddot{\mathbf{u}}^A_{n+1_{link}} &= \left(\mathbf{G}^A\right)^T\Lambda_{n+1} \\
\mathbf{u}^A_{n+1_{link}} &= \alpha_1^A\ddot{\mathbf{u}}^A_{n+1_{link}} \\
\dot{\mathbf{u}}^A_{n+1_{link}} &= \alpha_2^A\ddot{\mathbf{u}}^A_{n+1_{link}}.
\end{aligned} \tag{9}$$

Similarly, the kinematic quantities in subdomain A can be obtained as follows,

$$\begin{aligned}
\mathbf{u}^A_{n+1} &= \mathbf{u}^A_{n+1,free} + \mathbf{u}^A_{n+1_{link}} \\
\dot{\mathbf{u}}^A_{n+1} &= \dot{\mathbf{u}}^A_{n+1,free} + \dot{\mathbf{u}}^A_{n+1_{link}} \\
\ddot{\mathbf{u}}^A_{n+1} &= \ddot{\mathbf{u}}^A_{n+1,free} + \ddot{\mathbf{u}}^A_{n+1_{link}}
\end{aligned} \tag{10}$$

6. Perform the mass projection. The additional Lagrange multiplier can be calculated as

$$\Gamma = -\left(H^*\right)^{-1}\left(G_A\dot{u}^A_{n+1} + G_B\dot{u}^B_{n+1}\right). \tag{11}$$

And then the updated solution of velocity can be obtained as

$$\tilde{\dot{u}}_{n+1}^{A} = \dot{u}_{n+1}^{A} + \left(\tilde{M}_{A}\right)^{-1} G_{A}^{T}\Gamma \quad \text{and} \quad \tilde{\dot{u}}_{n+1}^{B} = \dot{u}_{n+1}^{B} + \left(\tilde{M}_{B}\right)^{-1} G_{B}^{T}\Gamma \tag{12}$$

To continue the computation in the next time step, the following formulations are needed:

$$\dot{u}_{n+1}^{A} = \tilde{\dot{u}}_{n+1}^{A} \text{ and } \dot{u}_{n+1}^{B} = \tilde{\dot{u}}_{n+1}^{B}. \tag{13}$$

This solution procedure does not increase computation cost remarkably, with respect to the original GC method. In the procedure, only the mass projection increases the computation cost and this increment of computation cost is limited for the reason that both Lagrange multipliers requires the same inverse matrix $\mathbf{H}^{*-1}$.

**Numerical performance evaluations of the novel method**

A test problem is considered where a Single-DoF system is split into two subsystems *A*and *B* linked by an interface reaction force $\Lambda$indicated in Figure 2. This test problem were widely used to assess partitioned methods[9, 10]. For simplicity, we choose the following system variables $m=1$ and $k=1$, and $b_1$ defined as

$$b_1 = \frac{m_A}{m_B} = \frac{k_B}{k_A} \tag{14}$$

**Stability analysis**

As mentioned before, the acceleration continuity suffers from stability problem and the mass projection is benefit for its stability. In the sense, the stability of the proposed partitioned method is unknown. In this subsection, the stability analysis is performed by the spectral approach on a Single-DoF split-mass system. In order to highlight the numerical dissipation property of the partitioned method, we consider no physical damping. Moreover, no external force is involved. The application of the methods to this model problem leads to recursive formula of this type, $\mathbf{y}_{n+1} = \mathbf{R}\mathbf{y}_n$. $\mathbf{R}$ defines the amplification matrix. Let $|\lambda_i|$ denote the modulus of an eigenvalues of $\mathbf{R}$. The stability condition requires that $|\lambda_i| \le 1$ and $|\lambda_i| = 1$ with multiplicity 1.

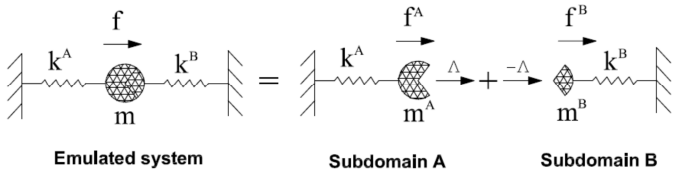

Fig. 2 A Single-DoF emulated system with the relevant split mass

It is noted that the method is not self-starting which requires initialization step. And therefore choosing sufficient state variables for the state vector $\mathbf{y}_n$ is required. It is founded in the solution procedure that the interpolation equation (3) requires the free solution of previous step. Therefore, the state vector $\mathbf{y}_n$ must include the state variables at time $t_{n-1}$. Moreover, the method imposes not only acceleration constraint and velocity constraint at the interface. As a consequence, the state vectors involved in the spectral stability analysis is considered as follows:

$$y_n = \left\{u_{n-1}^{A}, \dot{u}_{n-1}^{A}, \ddot{u}_{n-1}^{A}, u_n^{A}, \dot{u}_n^{A}, \ddot{u}_n^{A}, u_n^{B}\right\} \tag{15}$$

Differently from a direct integration method, $\mathbf{R}$ of a partitioned method does not only depend on system characteristics but also on *ss* and $b_1$ For this reason, two scenarios are intentionally investigated: *ss*=10, $b_1$=1 and *ss*=5, $b_1$=2.

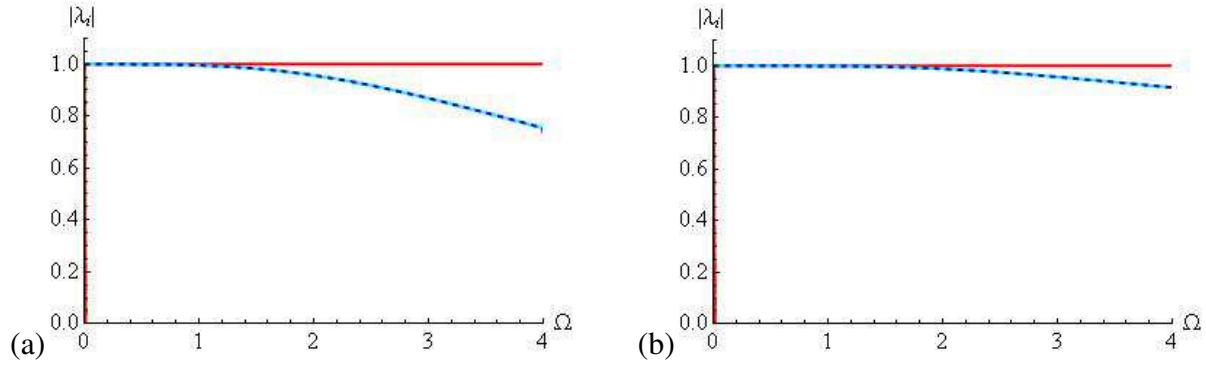

Fig. 3 $|\lambda_i|$ for the partitioned method: (a) $b_1 = 1, ss = 10$ and (b) $b_1 = 2, ss = 5$.

The influences of the acceleration constraint and the mass projection on the stability of the underlying method is analysed in Fig. 3. The number of eigenvalues involved in the recursive formula is 7, which coincides with the size of the state vector $\mathbf{y}_n$. Only two of them are principal eigenvalues which are complex conjugate, whereas the others are spurious which are unitary or zero. This is because both acceleration constraint and velocity constraint at the interface are imposed. Moreover, it can be concluded from the spectral radius plots that the proposed method appears to be stable within all cases considered and slight numerical dissipation is introduced.

**Accuracy analysis**

Numerical study on the single-DoF split mass system is considered. Again, the single-DoF split mass system is assumed be linear and undamped. Its external force is only considered on Subdomain $A$, i.e., $F^A = \sin(2t)$ and its initial displacement and velocity are set to be 0 and 1, respectively. Two cases are considered here: $b_1 = 2, ss = 10$ and $b_1 = 4, ss = 5$. The global errors at $t = 5s$ versus the system time steps $\Delta t_A$ are depicted in Fig 4. The results of the accuracy analysis are in agreement with the fact that the acceleration constraint endows with second order accuracy in displacement, velocity and acceleration responses.

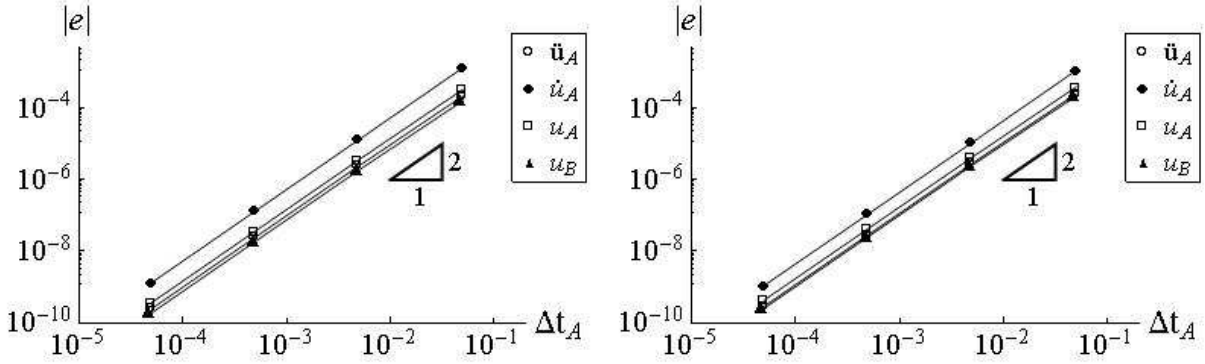

Fig. 4 Global error of the Single-DoF split mass system integrated by the proposed method: (a) $b_1 = 2, ss = 10$ and (b) $b_1 = 4, ss = 5$.

**Representative numerical simulations**

To investigate the merits of the novel method, a series of simulations are conducted on a Single- and Two-DoF system by means of the GC method, and the acceleration-constrained methods without and with the mass projection. The additional mass and spring in the Two-DoF system as shown in Fig 5 are set to be $m_2 = 2$, $k_2 = 3$. In order to examine numerial discrepancies of those methods, a relatively large time step is used, i.e., $\Delta t_A = 0.5s$.

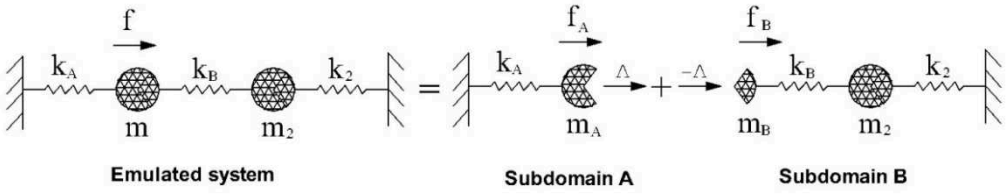

Fig. 5 An emulated Two-DoF system

The numerical solutions in terms of displacement are plotted in Fig 6. It is observed that the original GC method exhibits noticeable oscillation decay and slight period delay. For the method based on the acceleration continuity, less oscillation decay is perceived but slight drift appears at the interface. Obviously, the method with the mass projection entails favourable results: moderate oscillation decay and negligible drift at the interface. Moreover, it is observed in the simulations that the computation time of the novel method only slight overpasses the GC method.

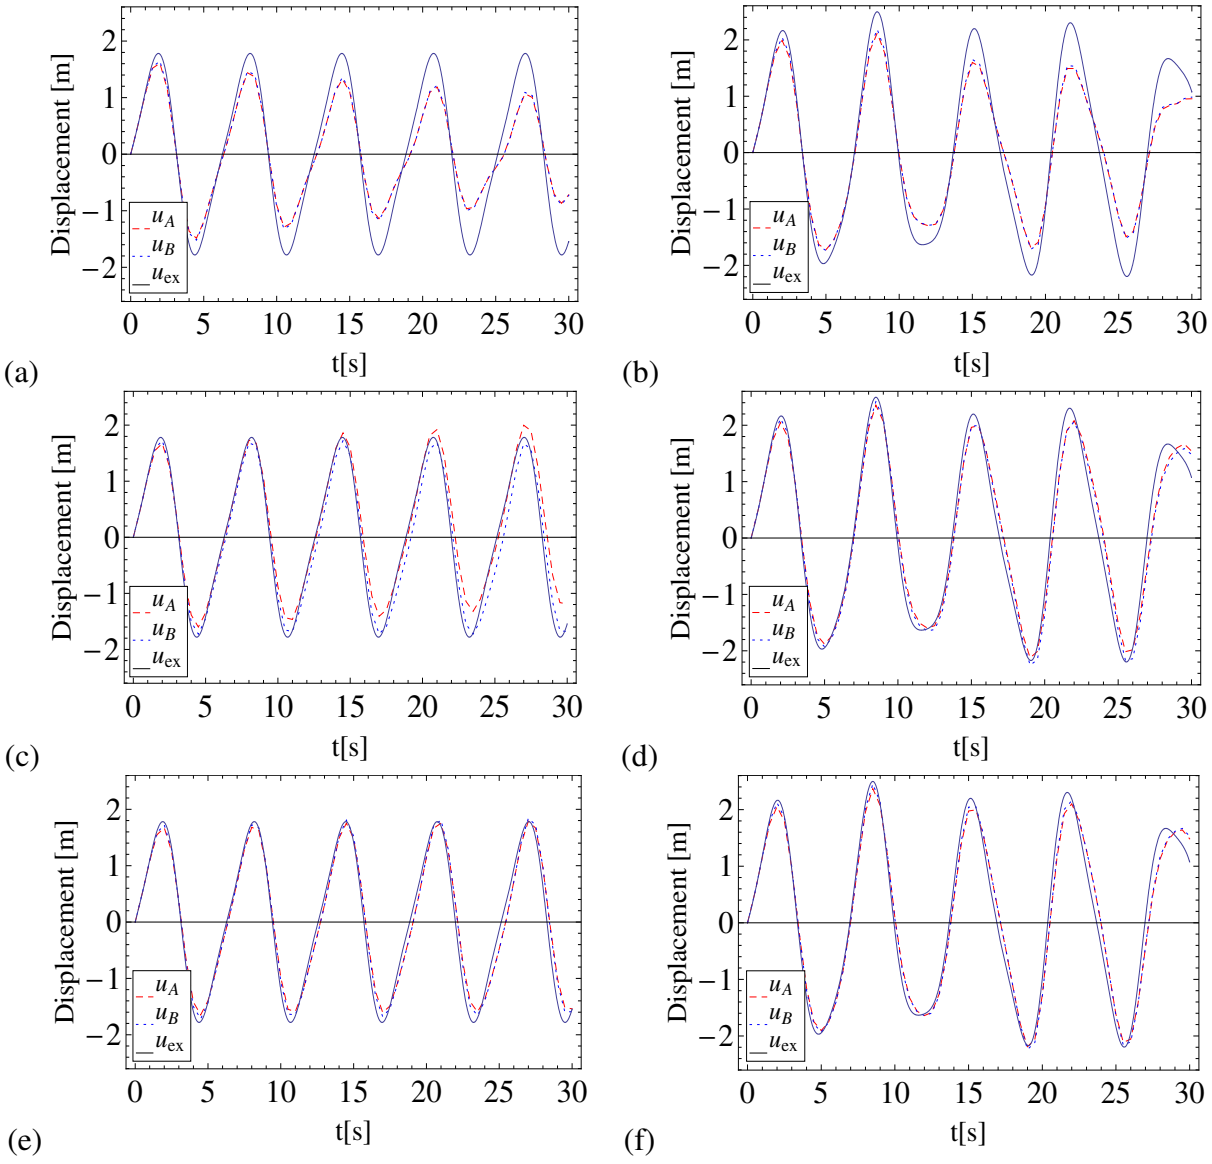

Fig. 6 Numerical simulations of the Single-DoF split mass system with $b_1$=2 (the left figures) and the Two-DoF system with $b_1$=1 (the right figures) integrated by the partitiioned methods with$ss$=10: (a) and (b) the original GC method; (c) and (d) the modified method without projection; (e) and (f) the modified method with projection.

## Conclusions

In this parper, we extend a partitioned integration method with subcycling from the velocity continuity to the acceleration continuity in order to improve its order of accuracy.This extension renders second-order accuracy but induces drift-off effect at the interface. In this respect, the mass projection technique is conceived at the end of each system time step to stabilize the method and to diminish drift-off effect.Furthermore, numerical analyses of the novel method are performed in terms of its stability and accuracy. It is observed that the method allows all the kinematic quantities to be second order accurate without losing stability. Finally, numerical simulations are carried out on Single- and Two-DoF systems with split mass. The simulation results are consistent with the numerical analysis.

**Keywords:** slip line method; bearing capacity of foundation soil; Terzaghi bearing capacity of foundation soil

**Abstract:** Limit bearing capacity of foundation soil was studied in the paper using slip line method. Slip line results are found to be consistent with the results calculated by Terzaghi theoretical formula and Hansen theoretical formula. Then the influence of factors such as cohesion and friction angle is studied under complete smooth or complete tough conditions. The results show that in a certain range, limit bearing capacity of foundation increases with the increase of $C_0$, Φ. Limit bearing capacity of foundation under complete smooth condition is lower than the complete tough one.

## Introduction

The purpose of studying limit bearing capacity is that the pressure on the underside of the building foundation must be limited. The subgrade limit bearing capacity is not allowed to reach the limit bearing capacity. Besides, the subgrade limit bearing capacity has a certain degree of safety to ensure that the foundation will not occur sliding failure. At the same time, to ensure that the structure will not be due to excessive deformation of foundation affects their normal use. Therefore, determining the limit bearing capacity of foundation is an urgent problem to engineering practice to solve.

There are two main methods to determine the limit bearing capacity, the first one is field test methods, such as standard penetration test, static cone penetration test and pressure meter text. After the establishment of a regional relationship, limit bearing capacity of foundation value can be obtained. The other one is theoretical calculation. In 1920, according to the limit equilibrium theory Prandtl derived the formula of limit capacity of strip foundation. When Prandtl derived the formula, he assumed the underside between the foundation and the soil smooth and the soil under foundation without the weight. So the sliding surface obtained is in form of two flat and intermediate transition logarithmic spiral surface. Duo to the assumption made by Prandtl inconsistent with the actual conditions, the result is rough. In 1940s according to the basic theory of Prandtl, Terzaghi proposed limit bearing capacity formula considering the weight of the soil under foundation. In 1950s Meyerhoff proposed limit bearing capacity formula applicable to deep foundation. To be more accurate researching limit bearing capacity of foundation, we use the analysis software Analysis of Bearing Capacity to study it.

## Slip line theory

In calculating the limit bearing capacity of foundation with slip line method, assuming the soil is the ideal rigid-plastic material, obey Mohr-Coulomb criterion or Terzaghi theory. Under load, in certain direction the soil in the plastic zone flowing freely, the deformation of soil large and elastic deformation ignored, the rigid-plastic assumption can deduce more reliable approximate solution. Otherwise, it may lead to large errors. In geotechnical stability problems—the problem of foundation bearing capacity, stress problems of retaining walls and stability problems of slope, the slip line theory has been widely applied.

## Software

ABC (Analysis of Bearing Capacity)is a computer program that uses the method of stress characteristics (also known as the slip line method) to solve the classical geotechnical bearing

capacity problem of a rigid foundation, resting on a cohesive-frictional soil mass, loaded to failure under a central vertical force. Fig.1 shows the terminology used.

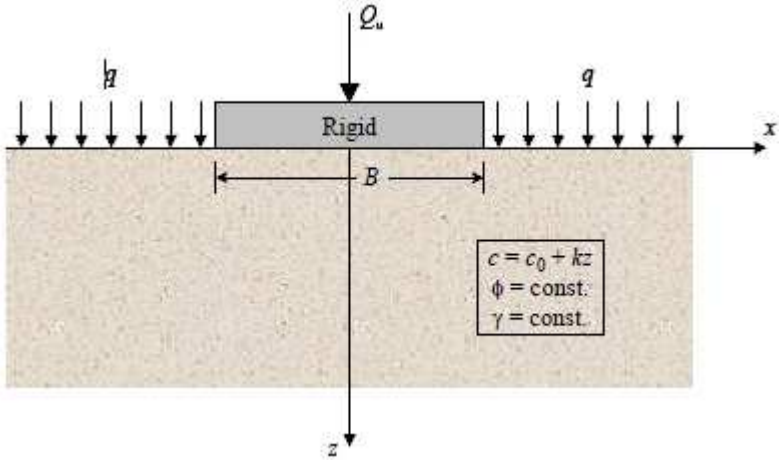

Fig.1 Problem definition

**Basic example**

Foundation soil gravity $\gamma$=17KN/m$^3$, friction angle $\Phi$=18°, cohesion $C_0$=10KPa, foundation width B=2.8m (circular foundation R=2.8m), the foundation depth=2m.At this point the depth is not considered directly. Instead it is replaced by a surcharge pressure of q=$\gamma$ D to simplify the equilibrium. According to the basic example, four foundations with different material strength parameter under smooth or tough conditions are considered in the analysis. The basic information for the model is shown in Table.1 The values and the modes of soil failure are obtained using the ABC softare,shown in Fig.2. Slip line results using the software—ABC are found to be consistent with the results calculated by Terzaghi theoretical formula and Hansen theoretical formula, shown in Fig.3.

Table.1Denote for four computational models

| The type of foundation | Strip and smooth | Strip and tough | Circular and smooth | Circular and tough |

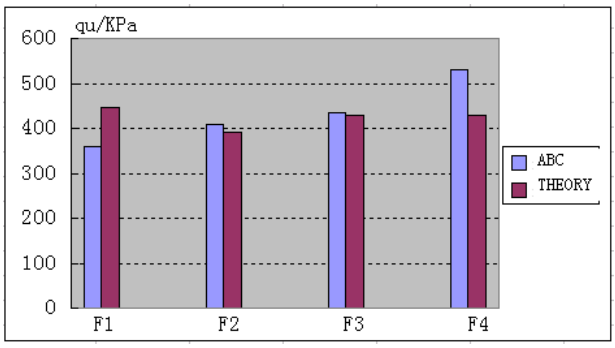

Fig.3Comparison results between ABC and theoretical solution

**Analysis of influence parameter**

In order to analysis the substrate roughness, friction angle and cohesion on the influence of the limit bearing capacity of foundation, three group models are considered as shown in Table.2.

1)F1-1:Strip and Smooth, F2-1:Strip and Tough:$\gamma$=17KN/m$^3$, $C_0$=10KPa, B=2.8m

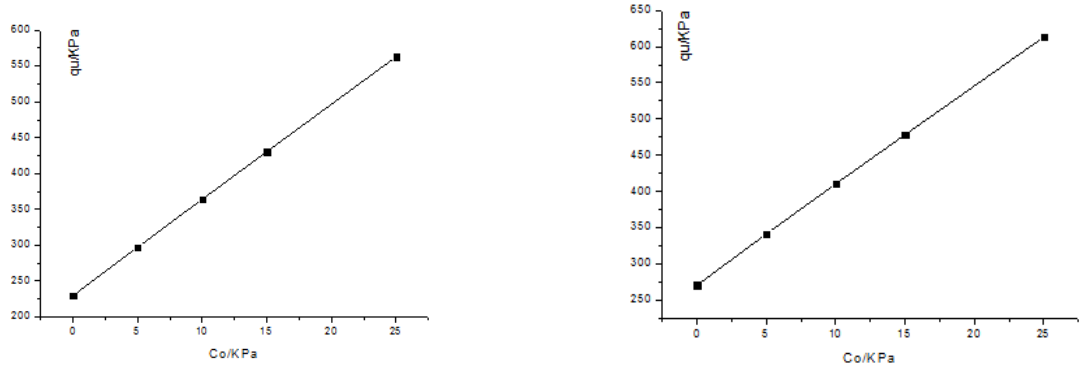
2)F1-2:Strip and Smooth, F2-2:Strip and Tough:$\gamma$=17KN/m$^3$, $\Phi$=18°,B=2.8m

3)F3-1:Circular and Smooth,F4-1:Circular and Tough:$\gamma$=17KN/m$^3$, $C_0$=10KPa,R=2.8m

Table.2Material strength parameters for the model

| F1-1 | F2-1 | F1-2 | F2-2 | F3-1 | F4-1 |
|---|---|---|---|---|---|
| Φ/° | Φ/° | Co/KPa | Co/KPa | Φ/° | Φ/° |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 6 | 6 | 5 | 5 | 6 | 6 |
| 12 | 12 | 10 | 10 | 12 | 12 |
| 18 | 18 | 15 | 15 | 18 | 18 |
| 24 | 24 | 25 | 25 | 24 | 24 |

The bearing capacity for the three group models is performed using ABC software, as shown in Fig. 4. It can be found in a certain range and the other parameters in the same situation, in a certain range, limit bearing capacity of foundation linear increases with the increase of $C_0$.



F1-2 F2-2

Fig.4 Relationship between the limit bearing capacity and cohesion.

It can also be found in a certain range and the other parameters in the same situation, limit bearing capacity of foundation nonlinear increases with the increase of Φ as shown in Fig.5 (a) (b), Fig.6 (a) (b).

At the same time, we can find, limit bearing capacity of foundation under complete smooth condition is lower than the complete tough one in the same parameters shown in Fig.5(c), Fig.6(c).

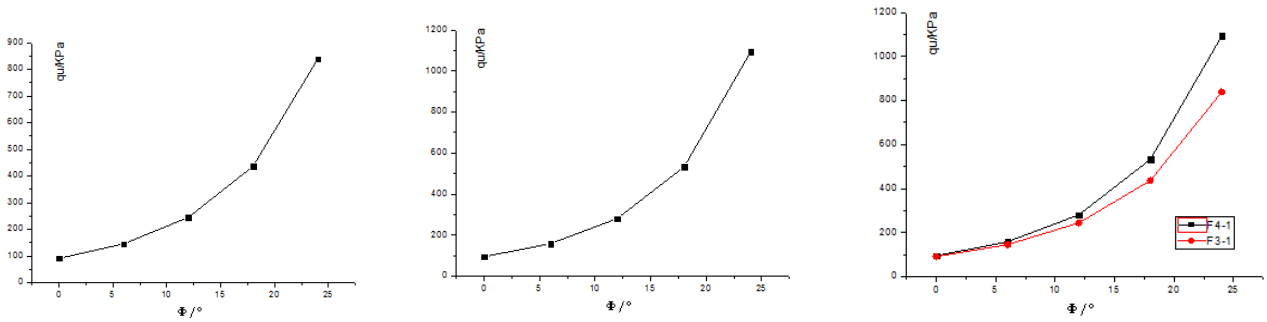
Fig.5 Relationship between the limit bearing capacity and friction angle.



(a) F3-1 (b) F4-1 (c) Comparsion between F3-1 and F4-1

Fig.6 Relationship between the limit bearing capacity and friction angle.

## Conclusions

In the paper , the limit bearing capacity of foundation analysis software ABC was used, the main conclusions are as follows:

1)In an ideal situation, using software Analysis of Bearing Capacity to analysis the limit capacity, the calculation results is high reliable.

2)In a certain range, limit bearing capacity of foundation increases with the increase of $C_0$, Φ.Limit bearing capacity of foundation under complete smooth condition is lower than the complete tough one.

**Keywords:** flow structures; channel bends; the Yangtze River; 3-D numerical simulation.

**Abstract.** The three-dimensional (3-D) flow structures in the Taiziji Waterway of the Lower Yangtze River were simulated by a 3-D numerical model, where the river plan form is a sharp bend and island-braided. The verification results of the 3-D model indicated that the simulated results agree with the measured data. The patterns of 3-D flow structures in this sharp bend with different discharge were analyzed based on the calculated results.The simulated results demostrated that strong 3-D features of flow structures can be found in the sharp bend of Taiziji Waterway, the bottom velocity vectors point to the convex bank while the surface vectors point to the concave bank. The velocity distribution alone the lateral direction in the sharp bend depends mostly on the flow discharge. The discharge ratio of the left branch increases as flow discharge increases.

## Introduction

Meandering river is a common plan form of alluvial channels. This channel pattern is generally composed of straight reaches and river bends. Flow structures in river bends are more complicated than those in straight channels, especially for the sharp bends. Helical flow in river bends is composed of the main flow velocity and the secondary currents, which resulting in bed degradation at concave banks and deposition at convex banks. Thus, the investigation of three-dimensional (3-D) flow structures in natural channel bends is of critical important for the understanding of meander evolution mechanisms.

In the previous studies, flow structures in experimental channel bends with idealized cross-sectional profile were measured. Turbulence intensity distributions in a 90º bend and a 60º bend were studied by Liu (2005) [1]. Flow velocities in a U-shaped bend were measured by H J de Vriend (1979) [2]. Transport and lateral mixing of neutral substance by turbulent flow in a two-connected 90º bend were investigated by Chang (1971) [3]. With the advances of computational technology, flow structures in channel bends were simulated by 2-D numerical models [4, 5]. However, strong 3-D features of flow structures can be found in the sharp bend. More reliable results could be obtained if 3-D model were applied [6]. In this study, the 3-D flow structures in the Taiziji Waterway of the Lower Yangtze River were simulated by a 3-D numerical model, where the river plan form is a sharp bend and island-braided, as shown in Fig.1. The characteristics of flow structures in this sharp bend were analyzed based on the calculated results with different discharge.

## Mathematical Model

The fully 3-D mathematical model used in the present study for the simulation of turbulent flow in a natural river bend was developed by Jia[7,8]. Due to the complexity of the river bends boundary, the Reynolds averaged Navier Stokes equations are solved numerically in a non-orthogonal coordinate system. Turbulence closure is provided by the standard $k-\varepsilon$ turbulence model, which apply a Boussinesq eddy viscosity. The governing equations are solved in a collocated grid system, and the

wall-function is employed to simulate the bed resistance. The finite volume method was applied to discrete the governing equations.

The governing equations for 3-D water flow are described as following:

$$\frac{\partial u_i}{\partial x_i} = 0 \tag{1}$$

$$\frac{\partial u_i}{\partial t} + \frac{\partial (u_i u_j)}{\partial x_j} = -\frac{1}{\rho}\frac{\partial p}{\partial x_i} + \frac{1}{\rho}\frac{\partial \tau_{ij}}{\partial x_j} + F_i \tag{2}$$

where $u_i$ (i=1,2,3) are velocity components; $F_i$ is the gravitational force per unit volume; $\rho$ is the fluid density; and $p$ is the pressure; $\tau_{ij}$ are turbulence stresses ,which can be calculated with the standard $k-\varepsilon$ turbulence model as following:

$$\frac{\partial k}{\partial t} + u\frac{\partial k}{\partial x} + v\frac{\partial k}{\partial y} + w\frac{\partial k}{\partial z} = \frac{\partial}{\partial x}\left[\left(\nu + \frac{\nu_t}{\sigma_k}\right)\frac{\partial k}{\partial x}\right] + \frac{\partial}{\partial y}\left[\left(\nu + \frac{\nu_t}{\sigma_k}\right)\frac{\partial k}{\partial y}\right] + \frac{\partial}{\partial z}\left[\left(\nu + \frac{\nu_t}{\sigma_k}\right)\frac{\partial k}{\partial z}\right] + G - \varepsilon \tag{3}$$

$$\frac{\partial \varepsilon}{\partial t} + u\frac{\partial \varepsilon}{\partial x} + v\frac{\partial \varepsilon}{\partial y} + w\frac{\partial \varepsilon}{\partial z} = \frac{\partial}{\partial x}\left[\left(\nu + \frac{\nu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x}\right] + \frac{\partial}{\partial y}\left[\left(\nu + \frac{\nu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial y}\right] + \frac{\partial}{\partial z}\left[\left(\nu + \frac{\nu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial z}\right] + \frac{C_1\varepsilon}{k}G - C_2\frac{\varepsilon^2}{k} \tag{4}$$

The generation rate of turbulent kinetic energy $G$ is calculated as following:

$$G = \upsilon_t\left\{2\left[\left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial y}\right)^2 + \left(\frac{\partial w}{\partial z}\right)^2\right] + \left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial z} + \frac{\partial w}{\partial y}\right)^2 + \left(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z}\right)^2\right\} \tag{5}$$

The turbulent eddy viscosity can be calculated by the turbulent kinetic energy $k$ and its dissipation rate $\varepsilon$ used the expression of $\nu_t = c_\mu k^2/\varepsilon$.

**Verification of the numerical model**

The Taiziji Waterway is a part of the lower Yangtze River, where the river plan form is a sharp bend and island-braided, as shown in Fig.1. The computatial domain has a total length about 21 km from inlet to outlet. The computational grids are 40~60 meters in length alone the river length direction and 5~10 meters in length alone the river width direction.

Hydrological data measured in November 2011 in this river section are used for model verification, and the corresponding discharge is 29200 $m^3/s$ (close to the annual mean discharge 28700 $m^3/s$). Comparision of water level profiles alone the left and right banks between the calculated results and the measured data are shown in Fig. 2. The difference between the measured data and the simulated results is less than 0.1 m, indicating that the roughness values for this sharp bend applied in the present study are accurate. The Manning's roughness of the study reach changes within the range of 0.018~0.032.

Fig. 3 shows comparisons of depth-averaged velocity distributions at typical cross-sections between the simulated results and the measured data with the discharge of 29200 $m^3/s$ on November

2011. The locations of the cross-sections can be found in Fig.1. It can be seen that the simulated results agree well with the observrd data, and the numerical model can be applied to predict flow patterns in this sharp bend with complex boundary.

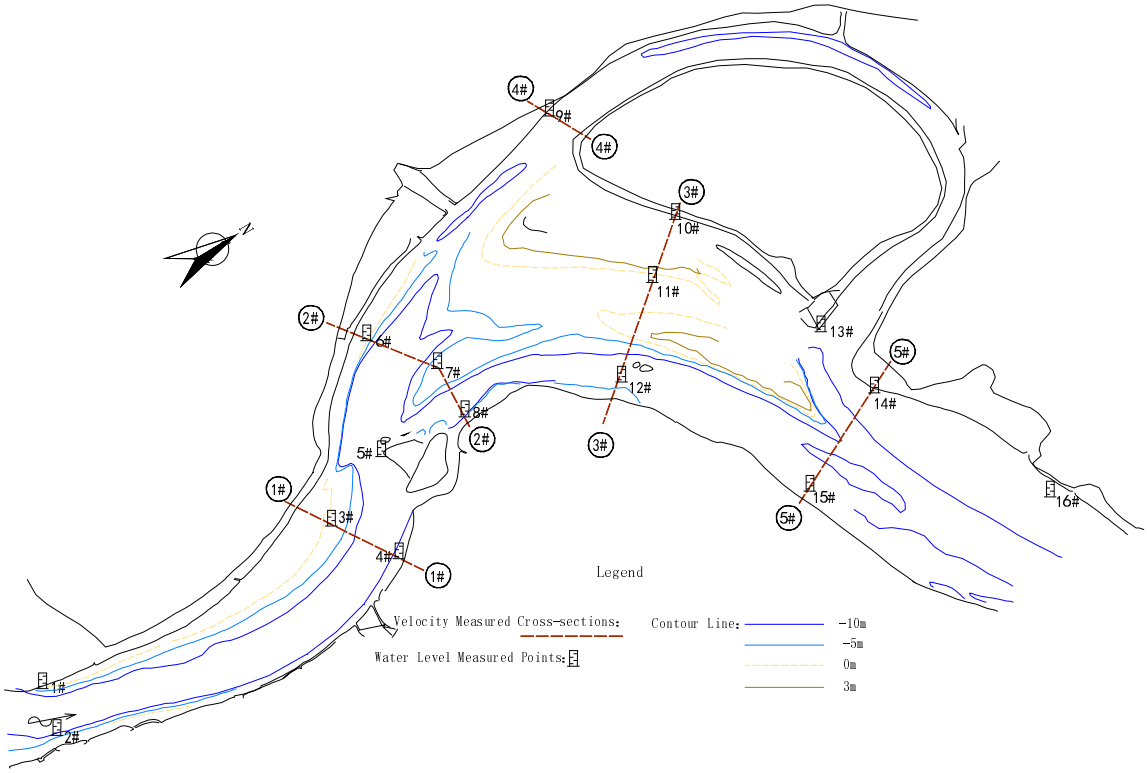

Figure 1. Sketch of the Taiziji Waterway in the Lower Yangtze River

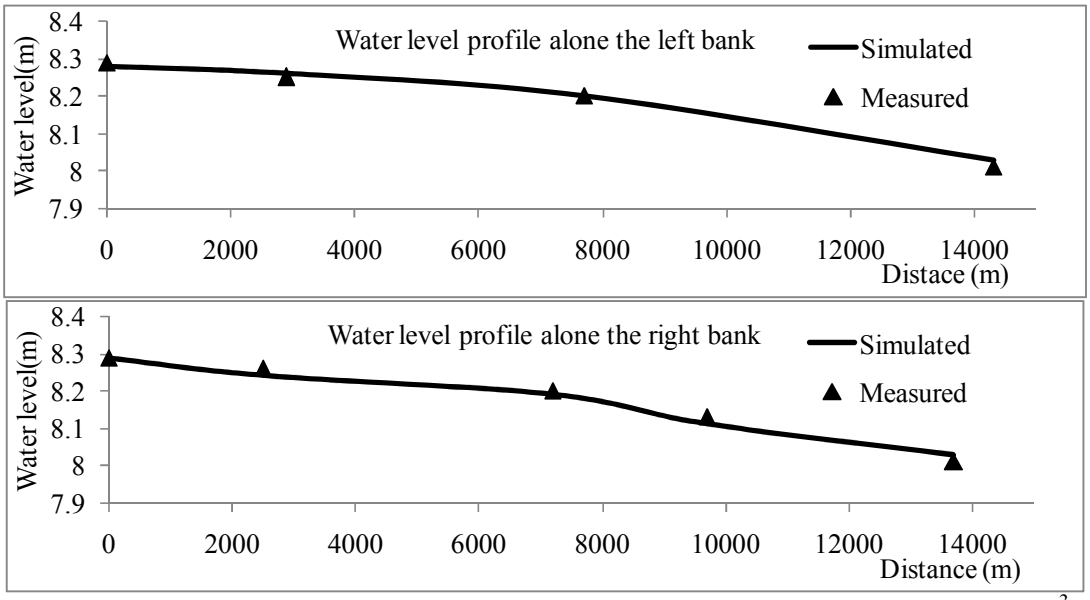

Figure 2. Comparisons of simulated and measured water level profiles (Q=29200 $m^3/s$)

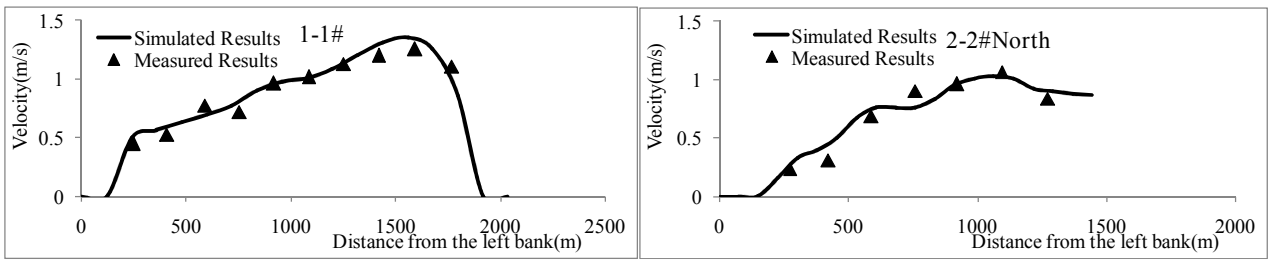

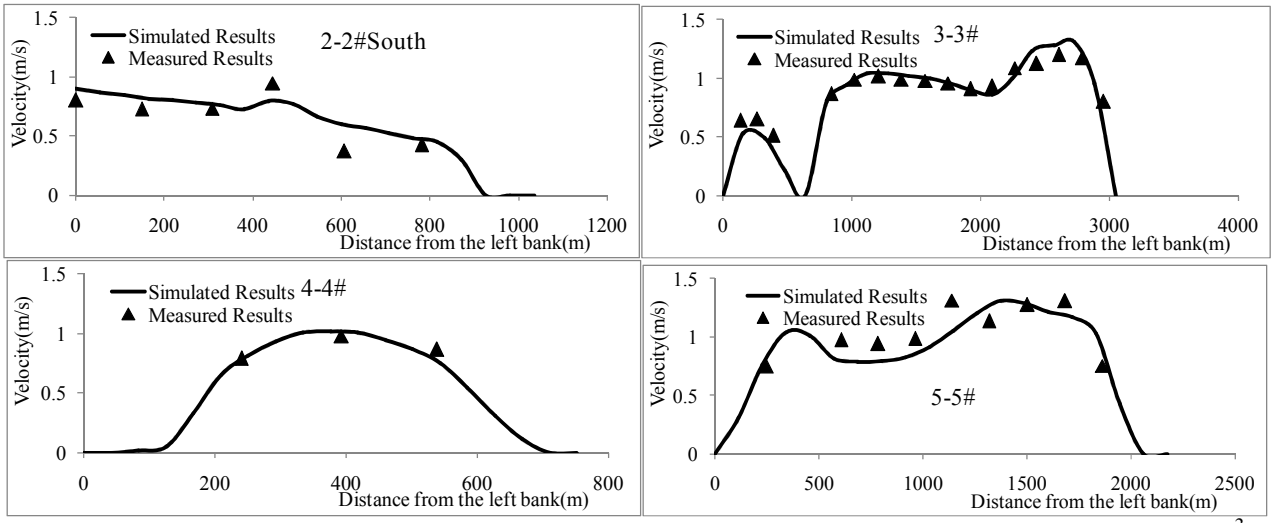

Figure 3. Comparisons of simulated and measured velocity at typical cross-sections (Q=29200 $m^3/s$)

**Three-dimensional Flow Structures**

After the calibration of the 3-D model, the flow patterns in the sharp bend with different discharge are predicted. Figures 4~6 show calculated flow velocities at both the free surface and bottom in the Taiziji Waterway with flow discharge of 11000 $m^3/s$, 29200 $m^3/s$ and 46700 $m^3/s$, respectively. Strong 3-D features can be seen in the bend flows of the Taiziji Waterway, the secondary currents are significant. The bottom velocity vectors point to the convex bank while the surface vectors point to the concave bank (as shown in Figures 4~6, black lines are vectors close to water surface, and red lines are vectors close to bed bottom). In addition, the discharge ratio of the left branch (cross-section No 4-4, the cross-section location is given in Fig.1.) as well as the right branch (cross-section No 3-3, the cross-section location is given in Fig.1.) is calculated based on the simulated values of velocity and water depth. As shown in Table 1, the discharge ratio of the left branch (cross-section No 4-4) increases from 11.80% to 14.10% as flow discharge increases from 11000 to 46700$m^3/s$. Conversely, the discharge ratio of the right branch (cross-section No 3-3) decreases from 88.20% to 85.90% as flow discharge increases. These results imply that the velocity distribution alone the lateral direction in the sharp bend depends mostly on the flow discharge.

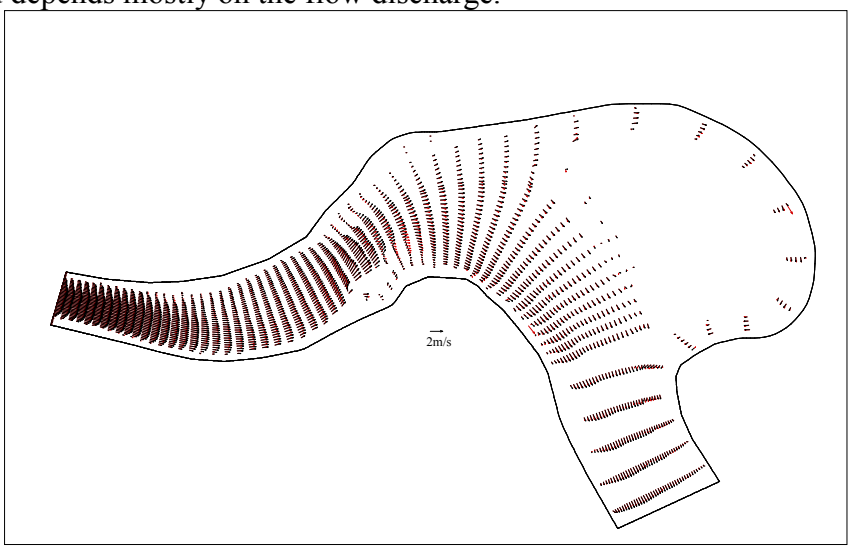

Figure 4. Calculated velocity fields close to bottom and water surface (Q=11000 $m^3/s$)

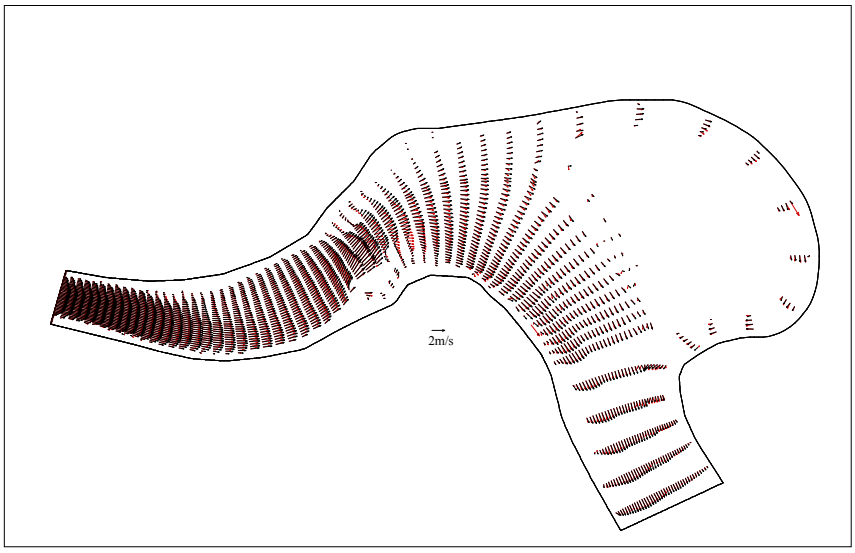

Figure 5. Calculated velocity fields close to bottom and water surface (Q=29200 $m^3/s$)

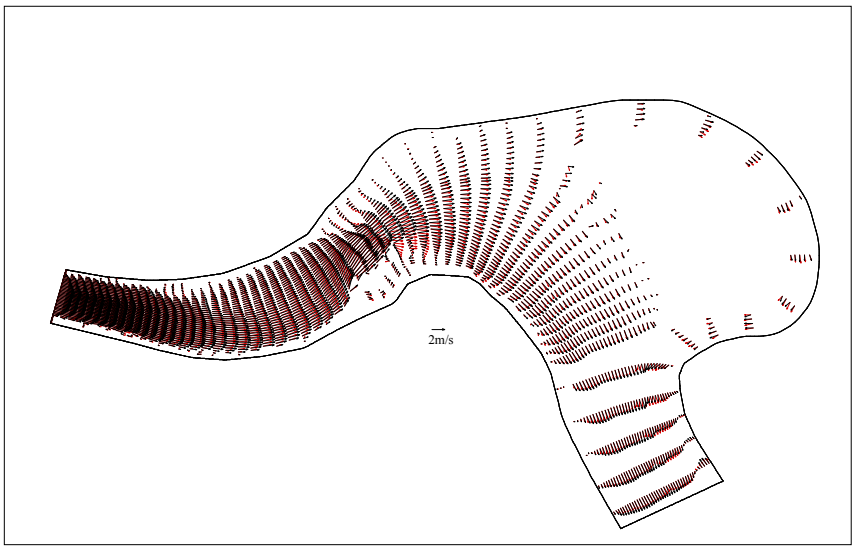

Figure 6. Calculated velocity fields close to bottom and water surface (Q=46700 $m^3/s$)

Table 1. Variation of discharge ratio at Cross-sections No 3-3 and 4-4

| Discharge | 11000$m^{3/}s$ | 29200$m^3/s$ | 46700$m^3/s$ |
|---|---|---|---|
| Left branch Cross-section No 4-4 | 11.80% | 13.00% | 14.10% |
| Right branch Cross-section No 3-3 | 88.20% | 87.00% | 85.90% |

## Conclusions

In the present study, the three-dimensional flow structures in the Taiziji Waterway of the Lower Yangtze River were simulated by a 3-D numerical model, where the river plan form is a sharp bend and island-braided. The characteristics of flow structures in this river bend were analyzed based on the calculated results with different discharge.

The calculated results demostrated that strong 3-D features of flow structures can be found in the sharp bend of Taiziji Waterway, the secondary currents are significant. The bottom velocity vectors point to the convex bank while the surface vectors point to the concave bank. The velocity distribution alone the lateral direction in the sharp bend depends mostly on the flow discharge. The discharge ratio of the left branch (cross-section No 4-4) increases from 11.80% to 14.10% as flow discharge increases from 11000 to 46700$m^3$/s. Conversely, the discharge ratio of the right branch (cross-section No 3-3) decreases from 88.20% to 85.90% as flow discharge increases. It demonstrates that the 3-D model is an effective prediction tool for the investigations of 3-D flow patterns in natural rivers with complex boundary, especially for the channel bends.

# About Verification of Correct Wavelet-Based Approach to Local Static Analysis of Bernoulli Beam

Pavel A. AKIMOV[1, a], Mojtaba ASLAMI[2,b]

[1,2] 26, Yaroslavskoe Sh., Moscow, 129337, Russia, Moscow State University of Civil Engineering

[a] pavel.akimov@gmail.com, [b] aslami.mojtaba@gmail.com

**Keywords:** wavelet-based methods, boundary problem, local structural analysis, static analysis, Bernoulli beam, discrete wavelets, Haar basis, verificarion, analytical solution

**Abstract.** This paper is devoted to verification of correct and efficient wavelet-based method of local static analysis of Bernoulli beam on elastic foundation, proposed by authors [1]. Corresponding results for sample problem have been compared with analytical solutions. Comparison shows that the localization of the problem with reducing its size by proposed method provide high-accuracy results for desired regions of the structure even in high level of reduction in wavelet coefficients. It should be noted that, the wavelet analysis [1, 2, 3, 4, 5] can exactly decompose problem and the sources of the observed error between the analytical solution and numerical result, is based mainly on applied method for solving (in this case, finite difference method), and can be improved.

## Formulation of the Sample Problem.

For the purpose of the paper and comparison with analytical solution [6], the Bernoulli beam on the elastic foundation which is loaded at mid-span with a concentrated force has been considered (Fig. 1).

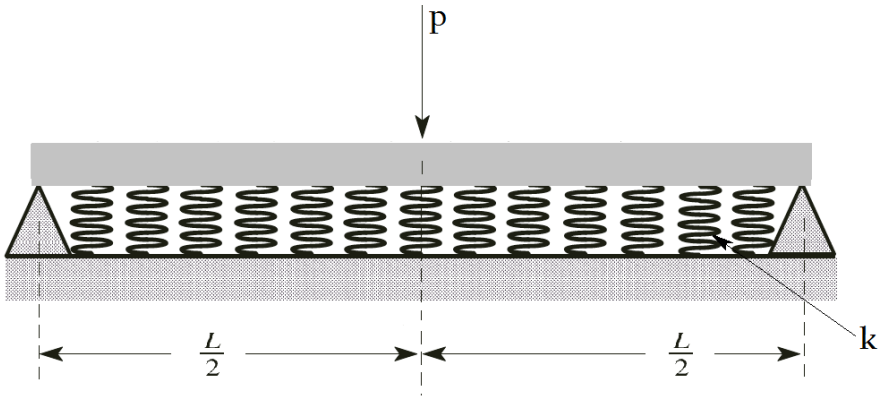

Figure 1. Bernoulli beam on the elastic foundation with concentrated force.

The elastic modelling of the soil bed is considered as one-parameter Winkler model which assumes that the vertical displacement of a point of the elastic foundation is proportional to the pressure at that point. This model can be interpreted as a system of mutually independent vertical springs with stiffness $k$. The General governing equations and boundary conditions for transverse displacement of the beam ( $y$ ) as follows:

$$\begin{cases} y^{(4)}(x) + y(x) = F(x), \quad 0 < x < L \\ y(0) = y(L) = 0 \\ y^{(2)}(0) = y^{(2)}(L) = 0; \end{cases} \qquad 4\alpha^4 = \frac{kb}{EJ}; \quad F(x) = \frac{P}{EJ}\delta\left(x - \frac{L}{2}\right); \tag{1}$$

where $L$ is the length of beam; $b$ is the width of sole of beam; $EJ$ is the bending stiffness of beam; $\delta(x)$ is the Dirac delta function.

**Numerical example and comparison of the solutions.**

Theoretical Foundations of Correct Wavelet-Based Approach to Local Static Analysis of Bernoulli Beam have been presented in [1]. The simple numerical example is under consideration in the distinctive paper (for illustrating the efficiency of this method). We have a Bernoulli beam on the elastic foundation (k=6700 kN/m3) which is loaded at mid-span with a concentrated force of F=1000 kN/m. The beam is 20m long, 0.5m wide and has bending stiffness of EJ = 1125000 kNm2. Solutions of the problem are obtained by using the authoring software software (Fortran programming language). The various input parameters (different numbers of nodes and different order of reduction), corresponding solution and comparison with analytical results are shown at Table 1.

Remark: *Error 1* has been obtained by comparison between analytical and numerical results and *Error 2* by comparison between numerical results with, and without reduction in wavelet coefficients.

According to the applied force, the middle point of the beam has been considered as a local zone for verifying of the proposed method. Then the problem was solved in three cases with various types of reduction in wavelet coefficients. The diagrams of the bending moment and shear force, by comparison with analytical solutions [6] are shown in Figures 2, 3. We can maintain accuracy in the desired region and reduced size of the problem to half. The results converge to analytical solution after increasing numbers of nodes. We can keep this accuracy in the desired region by using the proposed algorithm and also reduce number of unknowns as much as the obtained results are accurate enough. Therefore, reduction performed in the beginning and ending of the beam. Observations showed, that index has been increased by nearing the reduction to the point of loading errors. Results after reduction may be unacceptable in the other zones. The effect of reduction on results, out of the desired region, is proportional to the order of the derivative of transverse deflection ( $y$ ) in the beam.

**Conclusions**

The obtained results show an efficiency of the method and also reducing the size of the problem. By comparing with analytical solution, it is clear that the localization of the problem by multiresolution wavelet, give good results for desired zone even in high level of reduction in wavelet coefficients.

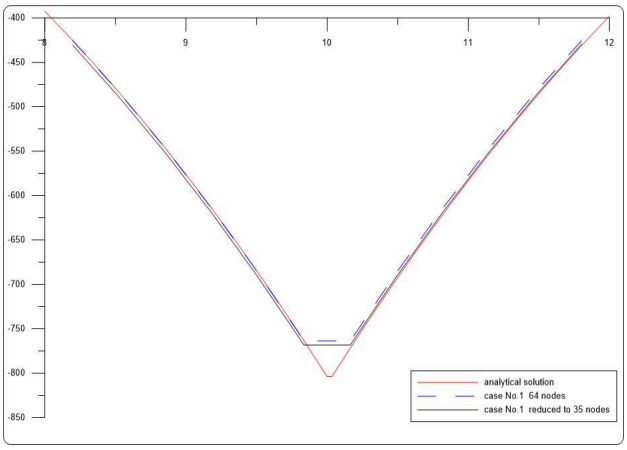

Figure 2a. Bending moment for case No.1 in interval 8-12m.

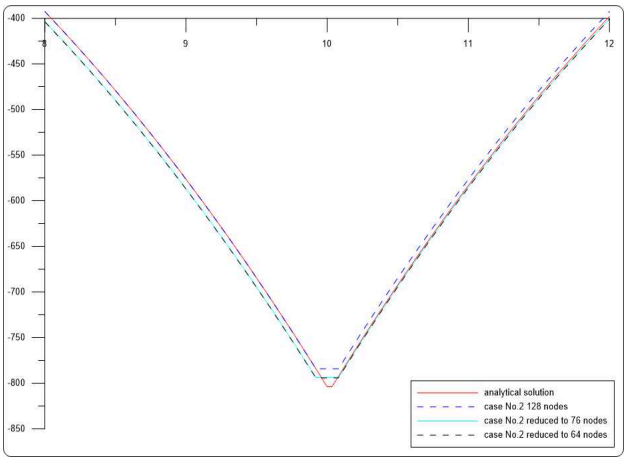

Figure 2b. Bending moment for case No.2 in interval 8-12m.

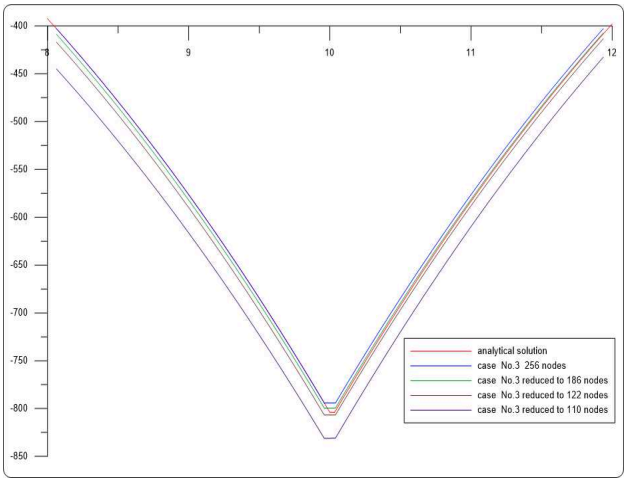

Figure 2c. Bending moment for case No.3 in interval 8-12m.

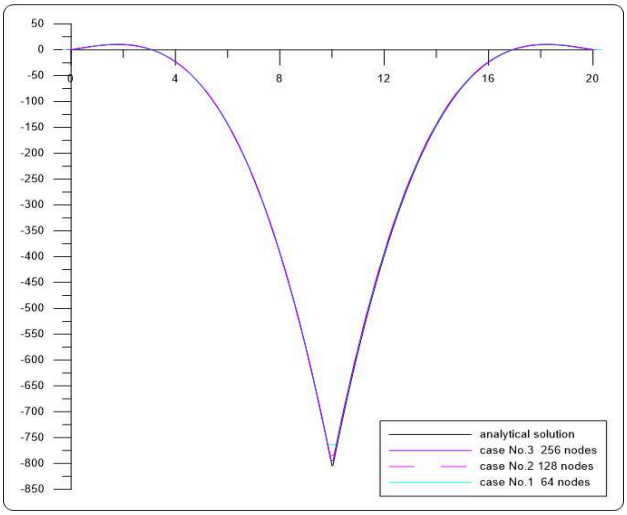

Figure 2d. Bending moment for all cases.

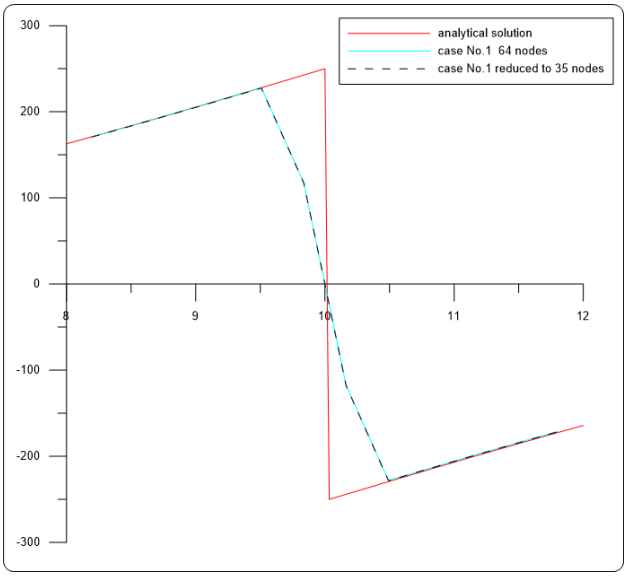

Figure 3a. Shear force for case No.1 in interval 8-12m.

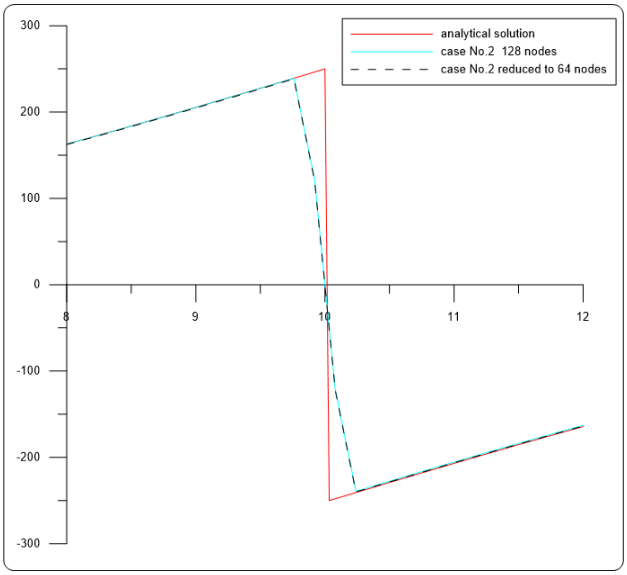

Figure 3b. Shear force for case No.2 in interval 8-12m.

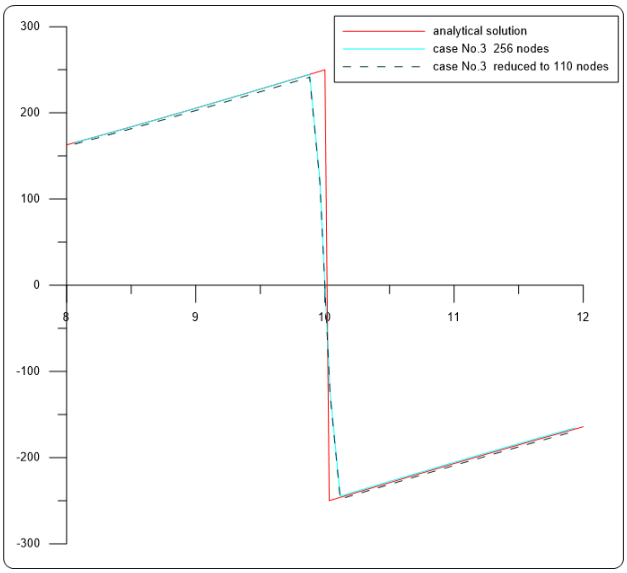

Figure 3c. Shear force for case No.3 in interval 8-12m.

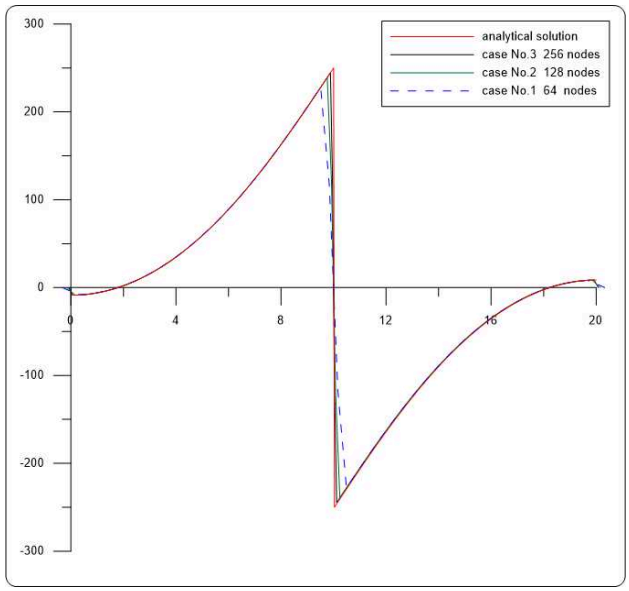

Figure 3d. Shear force for all cases.

This localization can be imposed to any arbitrary point in the beam and, by choosing an optimum reduction matrix, obtain exact solutions with an acceptable reduced size of the problem. Note that, the wavelet analysis can exactly decompose problem and the sources of the observed error between the analytical solution and numerical result, is based on applied method for solving the problem (in this case, finite difference method), and can be improved.

**Keywords:** Mixed Finite Element Method (FEM); geometrical nonlinearity; free oscillations; shells

**Abstract.** Considered small oscillations geometrically nonlinear shallow shell of revolution relative to the initial deformed state. Isotropic material model is considered. Problem is solved by mixed finite element method. Results of solution of test task are represented.

## Introduction

The methodic of determining the frequencies and axisymmetric modes of free oscillation of a shallow shell of revolution freeform with a median surface formed by smooth monotonic curve.

Considered small oscillations geometrically nonlinear shell relative to the initial deformed state. The initial deformed state of shell can be caused by action of static load, for example, dead weight, snow load, etc.

Oscillation equations is linearized in a small deviations of the system relation to the initial equilibrium state. The initial deformed state of shell determined by the solution geometrically nonlinear problem of the deformation of shell under the action initial loads.

Problem is solved by mixed finite element method.

## Solution of the problem

Equations of state of the shell obtained on the basis of the quadratic nonlinear theory of shallow shells [1]. Neglecting the influence of inertial forces in the radial direction and rotation inertia, we have:

$$\frac{1}{Eh}\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\varphi(r,t)}{\partial r}\right)\right)\right)-\frac{1}{r}\frac{\partial}{\partial r}\left(\frac{\partial w(r,t)}{\partial r}\frac{\partial f(r)}{\partial r}\right)+\frac{1}{2r}\frac{\partial}{\partial r}\left(\frac{\partial w(r,t)}{\partial r}\right)^2=0, \tag{1}$$

$$\begin{aligned}&D\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial w(r,t)}{\partial r}\right)\right)\right)+\frac{1}{r}\frac{\partial}{\partial r}\left(\frac{\partial\varphi(r,t)}{\partial r}\frac{\partial f(r)}{\partial r}\right)-\\&-\frac{1}{r}\frac{\partial}{\partial r}\left(\frac{\partial\varphi(r,t)}{\partial r}\frac{\partial w(r,t)}{\partial r}\right)=q-\frac{\gamma h}{g}\frac{\partial^2 w(r,t)}{\partial t^2},\end{aligned} \tag{2}$$

where $\varphi$ - stress function, $w$ – deflection function; $q$ – projection of the distributed loading on the z-axis coordinate; $df(r)$ - generatrix function for shell of revolution, $r$ – radial coordinate, $h$ – thickness of the shell; $E$ - elastic modulus, $D$ - modulus of rigidity of shell, $\nu$ - Poisson ratio; $\gamma$ - volume weight of the material; $g$ - acceleration of gravity; $t$ – time coordinate.

We introduce the dimensionless quantities:

$$r=\frac{h}{\sqrt[4]{\mu}}\rho,\ t=\bar{t}\Big/\sqrt{\frac{gE}{\gamma h^2}},\ \frac{\partial\varphi}{\partial r}=-\frac{Eh^2}{\sqrt[4]{\mu^3}}\overline{\Phi},\ \frac{\partial w}{\partial r}=\frac{1}{\sqrt[4]{\mu}}\overline{\theta},\ \frac{\partial f(\rho)}{\partial\rho}=\frac{h}{\sqrt{\mu}}K,\ \mu=12\left(1-\nu^2\right), \tag{3}$$

and write the function the influence of inertial forces in form:

$$\alpha=\alpha(\rho,t)=\frac{\sqrt{\mu}}{h\rho}\int_{\rho_0}^{\rho}\rho\frac{\partial^2 w(\rho,\bar{t})}{\partial\bar{t}^2}d\rho. \tag{4}$$

where $\bar{t},\rho$ - dimensionless coordinates, $\overline{\Phi}$, $\overline{\theta}$ – dimensionless stress function and the function of the angles of rotation of shell's generating curve.

Integrating over r system of equations (1), (2) once considering (3), (4) we obtain equations:

$$\begin{aligned}
&\rho\frac{\partial}{\partial\rho}\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho\overline{\Phi})\right]-\frac{\overline{\theta}^2}{2}+\overline{\theta}K=A_1,\\
&\rho\frac{\partial}{\partial\rho}\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho\overline{\theta})\right]+\overline{\Phi}\overline{\theta}-\overline{\Phi}K+\alpha\rho=\frac{\sqrt{\mu}}{E}\int_{\rho_0}^{\rho}q\rho d\rho+A_2,\\
&\frac{\partial}{\partial\rho}\left(\frac{1}{\rho}\frac{\partial}{\partial\rho}(\alpha\rho)\right)=\frac{\partial^2\overline{\theta}}{\partial\bar{t}^2}.
\end{aligned} \tag{5}$$

Here, $A_1$ and $A_2$ - the constant of integration. It can be shown that $A_1$=0. If the shell is closed at the top, then $A_2$=0.

The last of the equations (5) is obtained by double differentiation on ρ equation (4) and replacement $\frac{\partial^3 w(\rho,\bar{t})}{\partial\bar{t}^2\partial\rho}=\frac{\partial^2\overline{\theta}}{\partial\bar{t}^2}$ according to (3).

We represent the functions $\overline{\Phi}$ and $\overline{\theta}$ as a sum of components defining the initial state of the shell ($\Phi_0$, $\theta_0$) and components describing deviation of the system in the process of oscillation ($\Phi$, $\theta$):

$$\overline{\Phi}=\Phi_0+\Phi;\ \overline{\theta}=\theta_0+\theta. \tag{6}$$

Equations (5) linearize the small deviations of the system relation to the initial equilibrium state. The system of equations is separated into system, which defines the initial deformed state the shell and the system describing the oscillations of a shell. The first system of equations is similar to the one in [2]. Second, after linearization (including the smallness of $\Phi$ and $\theta$), written as:

$$\begin{aligned}
&\rho\frac{\partial}{\partial\rho}\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho\Phi)\right]+\theta K-\theta_0\theta=0,\\
&\rho\frac{\partial}{\partial\rho}\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho\theta)\right]-\Phi K+\Phi_0\theta+\Phi\theta_0+\alpha\rho=0,\\
&\frac{\partial}{\partial\rho}\left(\frac{1}{\rho}\frac{\partial}{\partial\rho}(\alpha\rho)\right)=\frac{\partial^2\theta}{\partial\bar{t}^2}.
\end{aligned} \tag{7}$$

Boundary conditions on the support contour for elastic-supple fastening are given as:

$$n\Phi-\rho_1\frac{\partial\Phi}{\partial\rho}=0,\ m\theta-\rho_1\frac{\partial\theta}{\partial\rho}=0,\ \alpha=0, \tag{8}$$

where $n$ and $m$ - the elasticity of fastening [2].

Boundary conditions at the top closed shell taken as:

$$\theta=0,\Phi=0,\alpha=0 \tag{9}$$

Creation of a finite element carried by the Galerkin method [3] in the weak form [2].

A finite element equation for the determination of the initial deformed state of the shell is similar, that considered in [2].

Finite element equations for determining the frequency of small free oscillations of shell have the form of a generalized eigenvalue problem:

$$\left[S^*\right]\left\{q^*\right\}=\omega^2[\mathrm{M}]\left\{\mathrm{q}^*\right\}, \tag{10}$$

where $[S^*]=[S_1]+[S_0]$ - state matrix element (stiffness matrix), $[M]$ - mass matrix element, $\left\{q^*\right\}=[\Phi_1,\theta_1,\alpha_1,\Phi_2,\theta_2,\alpha_2]$ - vector of nodal parameters,

$$[M]=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & e_{11} & 0 & 0 & e_{12} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & e_{12} & 0 & 0 & e_{13} & 0 \end{bmatrix}, \tag{11}$$

$$[S_0]=\begin{bmatrix} 0 & \frac{e_5}{20}\theta_1^0+\frac{e_8}{60}\theta_2^0 & 0 & 0 & \frac{e_8}{60}\theta_1^0+\frac{e_7}{60}\theta_2^0 & 0 \\ \frac{-e_5}{20}\theta_1^0+\frac{-e_8}{60}\theta_2^0 & \frac{-e_5}{20}\Phi_1^0+\frac{-e_8}{60}\Phi_2^0 & 0 & \frac{-e_8}{60}\theta_1^0+\frac{-e_7}{60}\theta_2^0 & \frac{-e_8}{60}\Phi_1^0+\frac{-e_7}{60}\Phi_2^0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{e_8}{60}\theta_1^0+\frac{e_7}{60}\theta_2^0 & 0 & 0 & \frac{e_7}{60}\theta_1^0+\frac{e_6}{20}\theta_2^0 & 0 \\ \frac{-e_8}{60}\theta_1^0+\frac{-e_7}{60}\theta_2^0 & \frac{-e_8}{60}\Phi_1^0+\frac{-e_7}{60}\Phi_2^0 & 0 & \frac{-e_7}{60}\theta_1^0+\frac{-e_6}{20}\theta_2^0 & \frac{-e_7}{60}\Phi_1^0+\frac{-e_6}{20}\Phi_2^0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \tag{12}$$

$$[S_1]=\begin{bmatrix} \frac{e_3}{2(\chi-\eta)} & \frac{K}{12}e_1 & 0 & \frac{\chi(\eta+\chi)}{2(\eta-\chi)} & \frac{K}{12}\left(\eta^2-\chi^2\right) & 0 \\ -\frac{K}{12}e_1 & \frac{e_3}{2(\chi-\eta)} & e_9 & \frac{K}{12}\left(\chi^2-\eta^2\right) & \frac{\chi(\eta+\chi)}{2(\eta-\chi)} & e_{10} \\ 0 & 0 & \frac{e_3}{2(\chi-\eta)} & 0 & 0 & \frac{\chi(\eta+\chi)}{2(\eta-\chi)} \\ \frac{\eta(\eta+\chi)}{2(\eta-\chi)} & \frac{K}{12}\left(\eta^2-\chi^2\right) & 0 & \frac{e_4}{2(\chi-\eta)} & -\frac{K}{12}e_2 & 0 \\ \frac{K}{12}\left(\chi^2-\eta^2\right) & \frac{\eta(\eta+\chi)}{2(\eta-\chi)} & e_{10} & \frac{K}{12}e_2 & \frac{e_4}{2(\chi-\eta)} & e_{11} \\ 0 & 0 & \frac{\eta(\eta+\chi)}{2(\eta-\chi)} & 0 & 0 & \frac{e_4}{2(\chi-\eta)} \end{bmatrix}, \tag{13}$$

$$e_9=\frac{\eta^3+2\eta^2\chi+3\eta\chi^2-6\chi^3}{30}, e_{10}=\frac{3\eta^3+\eta^2\chi-\eta\chi^2-3\chi^3}{60}, e_{11}=\frac{6\eta^3-3\eta^2\chi-2\eta\chi^2-\chi^3}{30}, \tag{14}$$

$\eta,\chi$ - dimensionless coordinates of the first and second element nodes, respectively,

Assembling generalized matrices and vectors of the problem is usually carried out for the finite element method.

Account the boundary conditions for the functions $\Phi$ and $\theta$ on the support contour is performed by adding the corresponding diagonal elements of the generalized matrix with values $\eta(1-n)$ (for $\Phi$ function) and $\eta(1-m)$ (for $\theta$ function).

Determining the frequency of free oscillation of a shell is carried out in two stages. First, solve the problem of determining the initial deformed state of the shell [2]. The resulting values are substituted into (10), and then solve the problem of determining the frequency of free oscillation of a shell. Generalized eigenvalue problem (10) has been solved Z-decomposition method.

**Checking the results of calculations**

Table 1 shows the calculation results of minimum frequency value of free oscillations for build-in contour base ( $m=\infty$, $n=-\nu=-0{,}3$ ) shallow spherical shell of revolution under a=0.06 [m]; h=0.001 [m]; $E=1\cdot10^{11}$ [Pa]; $\nu=1/3$; $\rho=10160\,[\text{kg/m}^3]$; q=0. Table 1 also shows the difference in % between the values $\omega_{min}$ obtained by this methodic and the values $\omega_{min}$ obtained by the developed methodic.

Table 1

| Calculation methodic | $\omega_{min}$, [rad/sec] | Value $\omega_{min}$ obtained by the developed methodic [rad/sec] | $\varepsilon$, % |
|---|---|---|---|
| [4] | 11034 | 11680 | 5,7 |
| [5] | 9085 | | 29 |
| COSMOS/M | 10950 | | 6,2 |

As you can see, the frequencies close to those obtained by finite difference method in [4], and the results of calculation using FEM in displacements (COSMOS/M). The difference with the results of [5] explained by the use simplified approach that takes into account only two boundary conditions on a support contour of the three.

**Conclusions**

The developed methodic of determining the free oscillations frequency for shell of revolution, based on the mixed finite element method shows good accuracy and convergence results. The methodic allows to taking into account the effect of the initial deformed state the shell that determined considering the geometric nonlinearity, to evaluate small frequencies of shell's free oscillations.

**Keywords:** underground powerhouse, pumped-storage power station, dynamical analysis, vibration response

**Abstract.** The vibration characteristics and vibration response under different load cases in the underground powerhouse structure of Yixing pumped-storage power station were studied by establishing three-dimensional finite element model. The harmonic and transient analysis methods were proposed to study the vibration response of the powerhouse structure under various generating unit dynamic loads and in transient process. The numerical results were evaluated according to the related rules and regulations. The result shows that the vibration response of the power house structure is in the limit of the rules and regulations and there was little chance of resonance.

## Introduction

Hydropower plant is the supporting structure of the unit. The partial or integral vibration of the hydropower plant may be caused by mechanical force, electromagnetic force or hydraulic exciting force, especially for pumped-storage power station [1-3]. Compared with normal power station, the pumped-storage power station have higher water head, higher speed, bidirectional work and transition process, its vibration problem is more prominent[4-5]. The harmful vibration of supporting structure such as unit foundation may be induced by vibrational excitation [6-7]. In order to analyze the dynamic characteristics of the pumped-storage power station, the three-dimensional numerical simulation for Yixing power station is analyzed as an example and the theoretical basis for structural design and operation is summarized.

## Finite element model

The total installed capacity of Yixing pumped-storage power station in Jiangsu Province is 4× 250MW. The normal rotate speed is 375r/min and the runaway speed is 562r/min. The underground powerhouse cavern group is located to the middle of the water conveyance system and is composed of main and assistant powerhouse, main transformer hole and draft tube. The excavation size of the main and assistant powerhouse is 155.3m×22m×52.4m(length×width×height). The erection bay lies to the left of the cavern group with the length 15m. The main powerhouse is composed of dynamo-layer floor, middle-layer floor, turbine-layer floor and volute-layer floor. The structural joints are set for each unit. The dynamic responses of the underground powerhouse is simulated with the software ANSYS. Solid 45 element is used to simulate the floors, columns and surrounding rock, shell 63 element is used to simulate the turbine. Basic material parameters are shown in Table1. The whole and the profiles of the finite element model are shown in Fig.1 and Fig.2.

Table 1 Basic material parameters

| Material | Elastic modulus/GPa | Poisson ratio | Bulk density/kg.m$^{-3}$ |
|---|---|---|---|
| steel | 210 | 0.300 | 7 850 |
| concrete | 28.0 | 0.167 | 2 500 |
| rock | 3.0 | 0.300 | 2 400 |

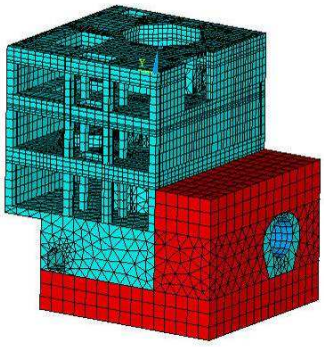

Fig.1 Finite element model of powerhouse

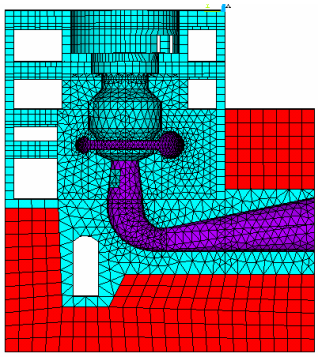

Fig.2 Profiles of the finite element model

**Analysis of vibration characteristics**

The boundary conditions of the side wall upstream and downstream are simplified as the four models below in order to analyze the rock influence on the vibration frequency.

Model 1: The fixed constrains for the boundary nodes.

Model 2: The elastic horizontal constrains for the boundary nodes, the elastic modulus of the surrounding rocks increases to 4GPa.

Model 3: The elastic horizontal constrains for the boundary nodes, the elastic modulus of the surrounding rocks increases to 6GPa.

Model 4: The elastic horizontal constrains for the boundary nodes, the elastic modulus of the surrounding rocks increases to 4GPa, considering the elastic modulus of the cohesive force upstream and downstream as 4GPa.

The natural vibration frequencies calculated for each model are shown in Table 2.

Table 2 Natural vibration frequency of Yixing powerhouse/Hz

| Order | Model 1 | Model 2 | Model 3 | Model 4 |
|---|---|---|---|---|
| 1 | 27.374 | 16.230 | 16.252 | 18.027 |
| 2 | 31.688 | 19.328 | 20.811 | 19.551 |
| 3 | 40.106 | 21.502 | 22.368 | 23.127 |
| 4 | 40.502 | 25.262 | 25.295 | 25.285 |
| 5 | 42.307 | 30.475 | 31.260 | 30.543 |

The result form Table 2 indicates that natural vibration frequencies increases with the enhancement of the boundary conditions. Absolutely model 1 has the highest vibration frequency for its strongest constraints, then the frequency decrease from model 4 to model 3, at last to model 2. In addition, the frequencies of model 2 and model 3 are approximately the same. The frequencies of model 1 and mode 2 are the upper and lower bound of the underground powerhouse structure of Yixing pumped-storage power station. Model 4 is the most close to the real model.

Table 3 Vibration source frequencies of Yixing powerhouse/Hz

| Vibration source | Frequency | Vibration source | Frequency |
|---|---|---|---|
| Normal speed | 6.25 | Low-frequency eddy band | 1.25~2.08 |
| Runaway speed | 9.37 | Number of hydro turbine blade | 56.25 |
| Electromagnetic force | 50.00 | Pressure pulsation after the guide vane | 162.50 |

There are much vibration sources for the water-turbine generator unit such as mechanical force, electromagnetic force and hydraulic force. The frequencies of primary vibration sources are shown in Table 3.According to the design code for hydropower house (SL266-2001), the natural vibration frequency should keep certain distance from the load frequency in order to avoid the resonance effect [8-9]. The results form Table 2 and Table 3 indicate that the above four models are accordance with the criterion, the design scheme is reasonable.

## Analysis of vibration response

Harmonic response analysis is calculated on the assumption that all the load frequency is harmonic. Under normal operation condition the corresponding frequency is normal speed frequency 6.25Hz and under runaway operating status the corresponding frequency is runaway speed frequency 9.37Hz. Both of the two load cases have the same phase position which should be calculated as the worst checking condition.

The load frequency in the transient process is changing with time from 6.25Hz to 9.37Hz. The load amplitude also changes from normal speed to runaway speed. The assumptions are as follows in order to simplify the load curve:

(1) The load frequency is changing linearly from 6.25Hz to 9.37Hz.

$$W(t) = W_{normal} + \frac{W_{runaway} - W_{normal}}{t_{transient}} \tag{1}$$

Where $W$ is the load frequency and $t_{transient}$ is the time needed in transient process. In this project $t_{transient} = 7s$ . Subscript *normal* denotes the load frequency for normal speed and subscript *runaway* denotes the runaway speed, respectively.

(2) The load amplitude is basically in direct proportion to square of rotor speed.

$$P(t) = P_{normal} + (P_{runaway} - P_{normal})(\frac{r - r_{normal}}{r_{runaway} - r_{normal}})^2 \tag{2}$$

Where $P$ is the load amplitude and $r$ is the rotor speed. The subscript *normal* and *runaway* have the same meaning above.

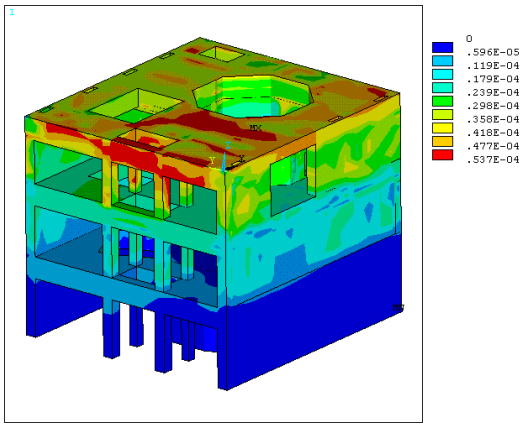

Fig.3(a) Displace envelope diagram-normal

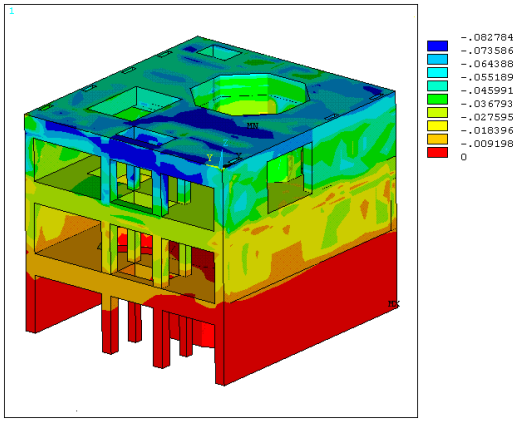

Fig.3(b) Acceleration envelope diagram-normal

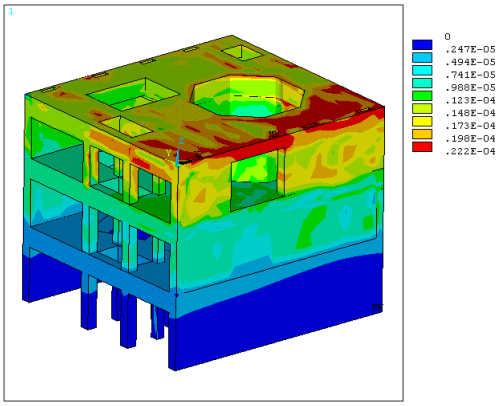

Fig.4(a) Displace envelope diagram-runaway

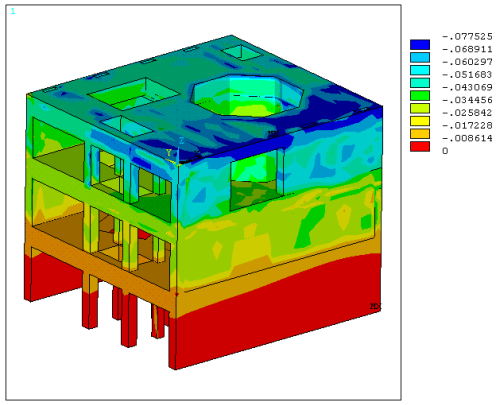

Fig.4(b) Acceleration envelope diagram-runaway

The vibration responses such as displacement and acceleration under different load cases are calculated. Take the horizontal displacement and acceleration as example. Fig.3(a) and Fig.4(a) show the displace envelope diagram under normal load case and runaway load case, respectively.Fig.3(b) and Fig.4(b) show the acceleration envelope diagram under normal load case and runaway load case, respectively.

The results in Fig.3(a) and Fig.4(a) indicate that both the max displacement under two different load cases are less than 0.15mm which satisfy the design requirements. The diagrams also show that the displacement from large to small in turn is dynamo-layer floor, middle-layer floor and turbine-layer floor. The max displacement concentrates around the floor hole. The results in Fig.3(b) and Fig.4(b) indicate that both the max acceleration under two different load cases are less than 85mm/s$^2$ which also satisfy the design requirements. The diagrams also show that the acceleration from large to small in turn is dynamo-layer floor, middle-layer floor and turbine-layer floor. The max acceleration also concentrates around the floor hole. So the floors, beams and columns are the weak parts of the underground powerhouse of pumped-storage power station. The weak parts need more attention at the initial design stage.

## Conclusions

In this paper, dynamical analysis on underground powerhouse of pumped-storage power station is presented. The conclusions are shown as follows:

(1)The vibration problem is more prominent for pumped-storage power station compared with other normal power station, so it is important to control and predict the vibration level at the initial design stage in order to realize the optimization design of vibration resistance.

(2)The vibration characteristic and response of the whole underground powerhouse verify the reasonability of the structural design. The underground powerhouse of Yixing pumped-storage power station satisfies the building vibration control and the human body health standard.

(3)For the lack of special criterion for the underground powerhouse of pumped-storage power station, the corresponding results can be meaningful to the similar project.

**Keywords:**fatigue crack growth test; semi-elliptical surface crack; Stress intensity factor; X80 pipeline steel specimen; relative crack depth; crack aspect ratio

**Abstract.**In this paper, a fatigue test of a X80 pipeline steel specimen with a semi-elliptical defect was performed to study the fatigue propagation stages of the Surface cracks.Based on the obtained test data, a three dimentional finite element procedure was developed for the crack growth estimation of the surface crack in the specimen. In the numerical analysis ofcrack growth, both the crack depth direction and the surface direction were investigated by using two different evolution equations. The stress intensity factors along the crack front were determined by applying the virtual crack closure technique. The predictions of crack growth were compared with the test data.

## Introduction

The emerging carbon capture and storage(CCS) technology has been recognized worldwidely as a promising solution for green-house gas(GHG) emission reduction. Up to now, several demonstration projects have been established in China. Experimentation with enhanced oil recovery(EOR) has been conducted in the Jilin fields and the Shengli fields[1]. The rapid deployment and implementation of CCS in China makes new demands on pipelines, which have been expected to play a significant role in the required transportation infrastructure that links anthropogenic $CO_2$ sources and storage sites[2].For $CO_2$ -transporting pipelines, the traditional crack-arrest design of oil&gas pipelines characterized by Charpy V-notch impact energy of pipeline steels can not be directly introduced herein, i.e.,not only fracture propagation control but fracture initiation control should be considered in the design of $CO_2$ pipelines[3].Therefore, it is significant that the propagation behavior of a very small surface defect in $CO_2$ pipelines are studied before a through-wall defect are formed in the pipe wall.

Given that the assumption that an actual part-through flaw can be replaced by an equivalent elliptical-arc crack has been experimentally verified[4], an experimental and finite element (FE) study was developed in this paper to examine the fatigue crack growth of a X-80 pipeline steel specimen with a semi-elliptical surface crack. In the crack growth analysis, both the crack depth direction and the surface direction were investigated.

## Tension-tension fatigue tests

The fatigue specimen was made of a steel plate which was cut from a segment of a X80 pipeline, as shown in Fig.1. In Fig.1(a), the initial semi-elliptical defect, made by wire electric cutting, was arranged at the central part of the lateral surface of the specimen body, the geometry parameters of which are as follows: $a_0$=0.28mm, $b_0$=0.8mm.The specimen was subjected to axial loading with a constant amplitude, $P_{max}$=170KN and a stress ratio of $R$=0.1.It can be seen from Fig.1(b) that the crack propagation path of the specimen under cyclic axial tention-tention loading remains an elliptical arc plane on the whole. Therefore, the defect configuration can be described by the relative crack depth $\xi = a/t$ in correspondence to the deepest point $A$ on the crack front, and the crack aspect ratio $\alpha = a/b$(seeing Fig.1(d) ). Meanwhile, in order to examine the fatigue propagation stages in the process of crack growth and make a comparison with those by the subsequent numerical simulation, three marks were made through adding different loadings in intervals.Correspondently, three sets of major and minor axis of the semi-elliptical crack were obtained and measured: (1) $a_1$=6.40mm,

$b_1$=7.70mm;(2) $a_2$=7.73mm, $b_2$=10.3mm;(3) $a_3$=9.37mm, $b_3$=12.6mm. The material characteristics of X80 pipeline steel are: $\sigma_y$=560MPa, $E$=206Gpa, $\nu$=0.3.

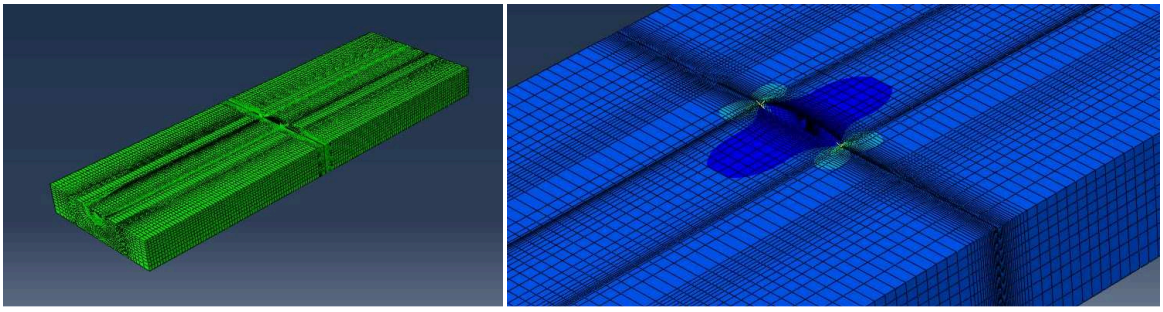
(c) The specimen shape and dimension(units:mm) (d) The geometry parameters of the defect

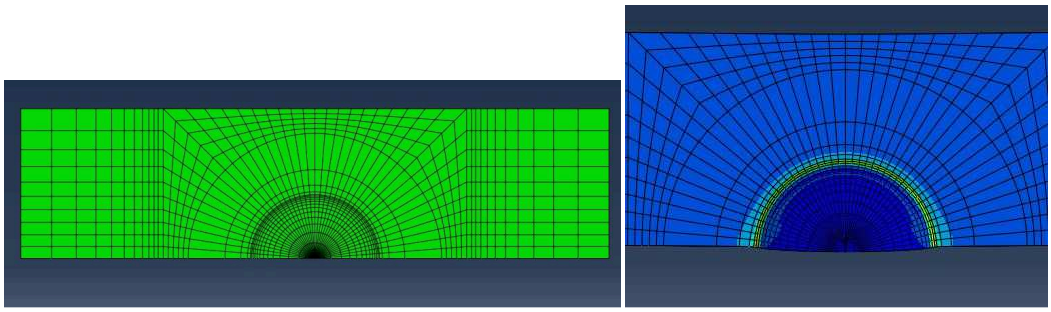
Fig.1 Geometry of the X80 pipeline steel specimen with a semi-elliptical surface crack

## FE modeling of the specimen with an semi-elliptical crack

Since the objective of this paper is to investigate the fatigue behavior of the embeded semi-elliptical surface crack in the specimen, the important aspect is to obtain accurate distributions of stress intensity factor along the crack front. We applied the virtual crack closure technique[5-7] to the FE model of the specimen for calculation of the stress intensity factors. Based on the ABAQUS software platform, we completed the modelling work of a three dimensional (3D) finite plate with a semi-elliptical surface crack, as shown in Fig. 2. For comparison's sake, the initial geometric sizes , material constants , mechanical parameters and loading ways of the FE model were made identical with those of the actual fatigue specimen, including the specimen itself and the crack in it.



(a)View of the FE model (b) Close-up of the semi-elliptical surface crack



(c) Meshing of the crack surface (d) Stress contour of the crack surface

Fig.2 FE model of the plate with a semi-elliptical crack

## Calculation of the fatigue crack growth

The fatigue propagation analysis of a semi-elliptical surface crack problem requires considering two crack growth directions. Actually, Newman and Raju[8]introduced that the aspect ratio change of surface cracks should be calculated by assuming that a semi-elliptical profile is always maintained and it is adequate to use two coupled Paris fatigue laws known as "two-point plus semi-ellipse" method:

$$\frac{da}{dN} = C_A(\Delta K_A)^{m_A} \tag{1}$$

$$\frac{db}{dN} = C_B(\Delta K_B)^{m_B} \tag{2}$$

Where $\Delta K_A$ and $\Delta K_B$ are the ranges of the stress intensity factor at the depth and the surface points of the surface crack; $C_A$, $C_B$, $m_A$ and $m_B$ are material constants.

In this paper, two different cases were considered :(1) Case1: $C_A = C_B, m_A = m_B$; (2) Case2: $C_B = (0.9)^m C_A, m_A = m_B$.

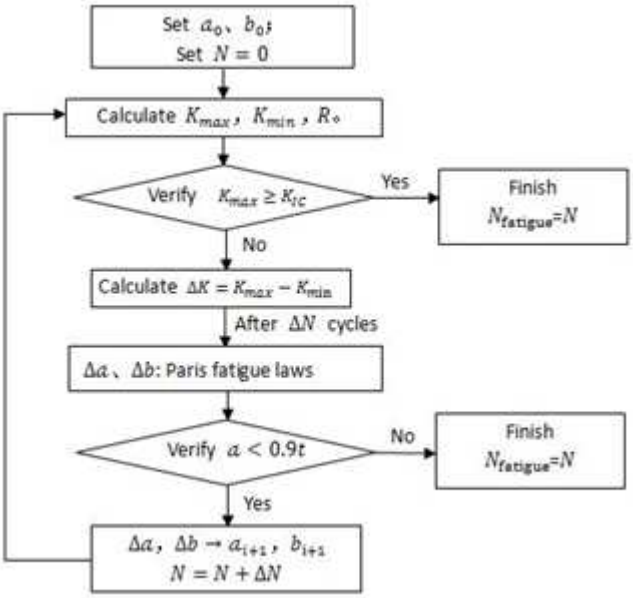


Fig.3 Histogram of crack growth calculating algorithm

## Numerical results

By using the two different evolution equations of the fatigue crack growth along the depth and surface directions, i.e., Case1 and Case2, we calculated two fatigue propagation paths of the semi-elliptical

surface crack through the numerical method, as shown in Fig.3. Although only three marks were made in the fatigue test(Fig.1(b)), which yet could not cover the whole process of crack growth, we still can make a conclusion that the simulated crack growth path by using the "Case1" evolution equation is more in accordance with the actual results of the fatigue test(Fig.4).

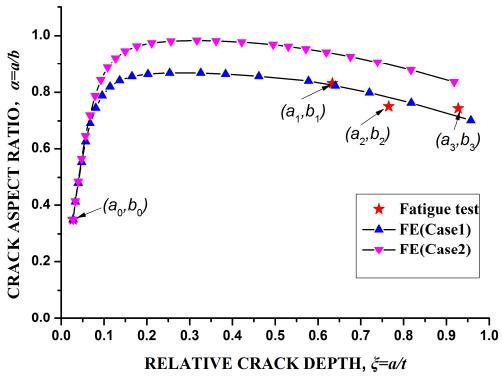

Fig.4 Fatigue propagation paths of the surface crack

## Conclusions

In this paper, we developed an ABAQUS-based three dimensional finite element method to study the fatigue propagation calculation of a semi-elliptical defect in a X80 pipeline steel specimen. the following conclusions could be drawn:

(1) Based on two different evolution equations , a 3D FE procedure is used to analyze the crack growth path of the surface crack. The numerical results show that one of the two simulated paths have a good agreement with the data from the specimen test .
(2) In the process of fatigue crack growth, a large part of crack propagation life is due to the propagation of a very small crack.
(3) The crack aspect ratio of the surface crack tends towards stability when the relative paths of the surface crack reaches around 0.15.

**Keywords:** external wall insulation, phase change material, negative wind pressure, finite element analysis

**Abstract.** With excellent flame retardation and thermal insulation properties, SY self-temperature regulation and phase change energy-saving wall insulation material (the material) is composed of concrete and volcano perlite. At present, applied research of this material is not very thorough，especially under the condition of temperature variation, seasonal wind change in North China. In this paper, finite element analysis of external wall insulation layer of the Experimental Teaching Building in Taiyuan University of Science and Technology under negative wind pressure effect is performed. The negative wind load calculated is applied to the surface of the thermal insulation layer as uniform load, and the results show that the material used in the building which shorter than 80 meters in the Taiyuan area has no shedding or destruction under the negative air pressure. This material is safe and available.

## Introduction

The main composition the material is cement, volcano perlite and fly ash. These elements accounted for 17%, 60% and 7%, respectively. In addition, the material also contains 2% powder, 4-5% fibrous tissue, 8-9% ceramic sintered material, and some cement retarder. Its density is 370~400 kg/m$^2$, close to the lightweight cement's. Some properties of the material are shown in table 1.

Table 1 Properties of SY self-temperature regulation and phase change energy-saving material

| Test items | dry density | Latent heat matter | anti - press strength | Compression shear bond strength | Linear shrinkage | Combustion performance | Wet flow density of steam | Equivalent thermal conductivity |
|---|---|---|---|---|---|---|---|---|
| Units | kg/m$^3$ | kJ | MPa | kPa | % | | g/(m$^2$·h) | W/(m·h) |
| Test results | 360 | 6420 | 0.52 | 116 | 0.29 | Level A | 1.51 | 0.027 |

The weathering test for SY self-temperature regulation and phase change energy-saving material has be done in laboratory. After 80 heat raining cycles and 5 thermal cold cycles in the test, this material does not appear fading, discoloration, cracking, chalking and other damage. The experimental results show that this material has sufficient weatherability. Further, the maximum tensile stress of the material is measured out by drawing experiment. The value of the maximum tensile stress is 0.19MPa.

## Finite element analysis of negative wind stress of SY self-temperature regulation and phase change energy-saving material

The above test can not verify the destruction of the material under temperature stress and negative wind pressure. With the change of day and night or the seasons, the temperature will be significantly different. This phenomenon will cause great temperature stress which may cause the insulating layer falling. Taiyuan city is located in the North Central China. In spring and autumn, this place will have a lot of wind which can produce huge negative wind pressure. The negative wind pressure will produce great suction on the insulating layer and cause the insulating layer shedding or separation.

Therefore, it is necessary to perform a finite element analysis of the insulating material under the negative wind pressure.

**The problem to analysis.** Taking the Experimental Teaching Building in Taiyuan University of Science and Technology (TYUST) as an example, a finite element analysis by ANSYS software on the resistance of SY self-temperature regulation and phase change energy-saving material under negative wind pressure has been performed in this paper.

1. According to "the load code for the design of building structures" (the Code) released in January 10, 2002, the once-in-50-years wind pressure should be taken. The wind pressure changes with height, so two cross sections (at the height of 10 meters and 50 meters) which perpendicular to the direction of building height has be taken in the calculation. Take the wind pressure at same height as uniform load.

2. The construction principle of the material is that mixing the material with water directly, and brushed the mixture to the exterior wall. Then the grid cloth or wire mesh is added into the exterior wall. Finally a layer of anti-crack mortar is brushed outside the insulating layer. When the negative wind pressure occurs, the wind load affects on the anti-crack mortar, and then transferred to the insulating layer. The anti-crack mortar, grid cloth or wire mesh will not affect the value of the wind load. So, the effect of anti-crack mortar, grid cloth and wire mesh can be ignored when the analysis model is constructed. The combination of wall and insulation layer is built directly, in which the thickness of wall and insulation layer is 0.24 meters and 0.04 meters, respectively.

**The basic assumption.** Assuming the stress-strain curve of the material is linear, ultimate strength is 0.52MPa, and its density is 400kg/m$^3$.The properties of and rubber concrete are very similar. In the simulation, the stress-strain curve of rubber concrete can be taken as the material's.

In the analysis, the material is assumed as isotropic elastic body, its elastic modulus is assumed to be 360MPa.

In the research of phase change material, the Poisson ratio is assumed to be 0.3.

**Calculation of Negative Wind Pressure**. According to the Code, the wind pressure calculation must meet certain standards.

The general direction of wind in Taiyuan is northwest according to some data and the long-term living in Taiyuan, and the wind direction is perpendicular to the face of building. According to the Code, when the wind is perpendicular to the surface of a building, the nominal values of wind load should be in accordance with Eq. 1:

$$w_k = \beta_z \mu_s \mu_z w_0 \tag{1}$$

Where, $w_k$ is the nominal value of the wind load. $w_0$ is the reference wind pressure (kN/m$^2$). $\mu_z$ is the exposure factor of wind pressure. $\mu_s$ is the shape factor of wind load. $\beta_z$ is the dynamic response factor of wind load at height z.

Experimental Teaching Building in TYUST is sixteen stories high, which is a high-rise building. Two cross sections (at the height of 10 meters and 50 meters) which perpendicular to the direction of building height has been taken in the analysis. The value of reference wind pressure is 0.3kN/m$^2$ (at the height of 10 meters) and 0.4kN/m$^2$ (at the height of 50 meters) in Taiyuan. Considering the experimental teaching building is a towering structure, the above values of reference wind pressure should be increased to 0.35kN/m$^2$ (at the height of 10 meters) and 0.45kN/m$^2$ (at the height of 50 meters) appropriately.

For the flat or slightly undulating terrain, the exposure factor of wind pressure should be determined by the given table based on the terrain roughness categories. There are a lot of buildings in the place where TYUST is located, so the region should be classified as Class C. The exposure factor of wind pressure is selected as 0.74 (at the height of 10 meters) and 1.25(at the height of 50 meters).

According to the Code, the local shape factor of wind load can be used in the calculation of retaining structure and its connection strength. The structure studied in this paper belongs to building

envelope. Therefore, the calculated shape factor of wind load is -1.0(at the negative pressure zone) and -1.8(at the corner).

For the general cantilever structure, such as high structure frame, tower, chimney, and high-rise buildings whose height is greater than 30m, or whose height to width ratio is greater than 1.5, and the reverse effect could be ignored, only the effect of the first mode is considered. The wind load of the structure could be calculated according to the above formula. Dynamic Response Coefficient of Wind Load at Height z can be calculated as Eq. 2:

$$\beta_z = 1 + \frac{\xi \nu \varphi_z}{\mu_z} \tag{2}$$

Where, $\xi$ is the Fluctuating Amplifying Coefficient. $\nu$ is the Fluctuation Influence Coefficient. $\varphi_z$ is the Coefficient of Vibration Mode. $\mu_z$ is the Exposure Factor of Wind Pressure.

Fluctuation Influence Coefficient can be found in the tables, whose value is 1.39 $kNs^2/m^2$. The Fluctuation Influence Coefficient at the class C region (based on the terrain roughness categories) is 0.64 (at the height of 10 meters) and 0.85(at the height of 50 meters). The Coefficient of Vibration Mode can be determined as 0.17 (at the height of 10 meters) and 0.86(at the height of 50 meters) according to special tables.

Two special interfaces at each height (the height of 10 meters and 50 meters) were calculated. One interface is close to the window, as the window is a symmetric structure, so just 1/4 of the interface has been taken in the calculation. The calculated values of negative wind pressure that close to window are 311Pa (at the height of 10 meters) and 1020Pa (at the height of 50 meters). The other interface is at the corner of wall, its negative wind pressure values are 560Pa (at the height of 10 meters) and 1840Pa (at the height of 50 meters).

**Analysis results**. A comparison has been made between the calculated maximum stress and the limit stress of the material. If the calculated maximum stress is smaller than the limit stress of the material, it means that the insulating layer can resistance the negative wind stress, which also proofed that the material is safe and available.

At the height of 10 meters, the stress of insulating layer close to window as shown in table 2.

Table 2 The value of stress

| principal stress | Maximum[Pa] | Minimum[Pa] | direction of shear stress | Maximum[Pa] | Minimum[Pa] |
|---|---|---|---|---|---|
| X | 352.297 | 0 | XY | 37.4 | -62 |
| Y | 294.702 | -103.434 | YZ | 126.761 | -5.949 |
| Z | 224.341 | -95.5 | XZ | 67.37 | -44 |

From table 2, the maximum principal stress along X direction, its absolute value is 352.297Pa; the maximum shearing stress along YZ direction, its absolute value is 126.761Pa. X direction and XZ direction stress cloud chart as shown in Fig.1.

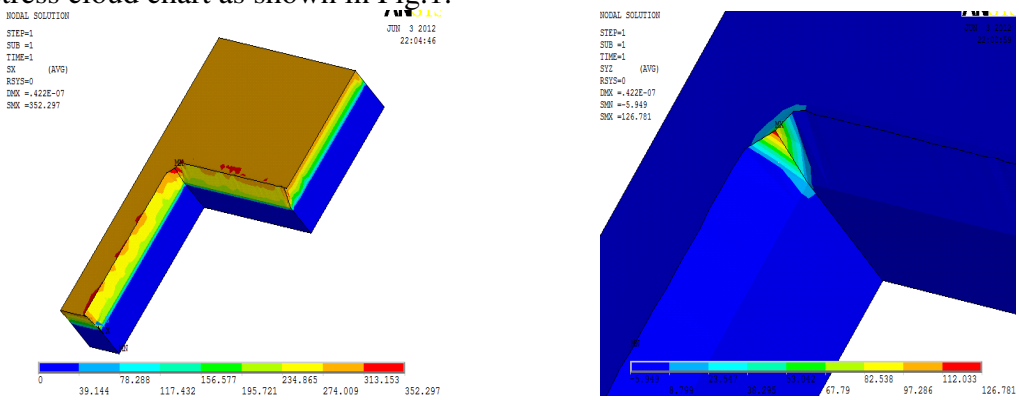

Fig. 1 Stress cloud chart of insulating layer at the height of 10 meters close to window

At the height of 50 meters, the stress of insulating layer close to window as shown in table 3.

Table 3 The value of stress

| principal stress | Maximum[Pa] | Minimum[Pa] | direction of shear stress | Maximum[Pa] | Minimum[Pa] |
|---|---|---|---|---|---|
| X | 1155 | 0 | XY | 122.773 | -205.465 |
| Y | 966.548 | -340.388 | YZ | 415.81 | -19.511 |
| Z | 735.38 | -314.308 | XZ | 220.984 | -146.041 |

From table 3, the maximum principal stress along X direction, its absolute value is 1155Pa; the maximum shearing stress along YZ direction, its absolute value is 415.81Pa.

At the height of 10 meters, the stress of insulating layer at the corner of wall as shown in table 4.

Table 4 The value of stress

| principal stress | Maximum[Pa] | Minimum[Pa] | direction of shear stress | Maximum[Pa] | Minimum[Pa] |
|---|---|---|---|---|---|
| X | 838.439 | -78.569 | XY | 46.169 | -40.26 |
| Y | 417.546 | -121.999 | YZ | 48.195 | -47.818 |
| Z | 735.751 | -157.35 | XZ | 294.866 | -470.164 |

From table 4, the maximum principal stress along X direction, its absolute value is 838.439Pa; the maximum shearing stress along XZ direction, its absolute value is 470.164Pa.

At the height of 50 meters, the stress of insulating layer at the corner of wall as shown in table 5.

Table 5 The value of stress

| principal stress | Maximum[Pa] | Minimum[Pa] | direction of shear stress | Maximum[Pa] | Minimum[Pa] |
|---|---|---|---|---|---|
| X | 2735 | -258.154 | XY | 151.699 | -132.282 |
| Y | 1372 | -400.854 | YZ | 158.354 | -157.116 |
| Z | 2417 | -517.007 | XZ | 968.847 | -1545 |

From table 5, the maximum principal stress along X direction, its absolute value is 2735Pa; the maximum shearing stress along XZ direction, its absolute value is 1545Pa.

## Conclusion

It confirmed that the material is completely suitable for the environmental conditions in Taiyuan. With excellent flame retardation and simple construction techniques, the material is easy to be got, and its performance is too good to its price, which is the development trend of insulating material.

**Keyword:** Tower crane, Finite element model, Working condition, Stability, Strength

**Abstract.** With accelerating urbanization construction, especially with the scale enlargement of high-rise buildings, the crane's hoist boom length and height is increasing.The hoist boom will produce strength and buckling failure easily on the working condition of complex combination, such as gravity, wind load and inertia force.The TC6010 crane was analyzed the mechanics by finite element method. This thesis got its stability and strength data in four kinds of working conditions. It can provide certain reference value for other crane's design and calculation.

## Introduction

With accelerating urbanization construction, especially with the scale enlargement of high-rise buildings, the crane's hoist boom length and height is increasing[1,2]. The hoist boom will produce strength and buckling failure easily on the working condition of complex combination, such as gravity, wind load and inertia force. So not only static analysis was carried out on the tower crane, the dynamic analysis is also very important. This thesis uses the ANSYS finite element method, analyzes its strength and stability and check calculation[3,4]. The calculation results are obtained. In this thesis, the research conclusion can provide a certain reference value for other crane's design and optimization.

## Establish the calculation model

Tower crane structure is complex. There are different forms of the pole in the tower cranes as shown in Fig.1[5,6]. Besides mainly bear axial stress $\sigma_x$ , all kinds of pole also bear the bending stress $\sigma_y$ and $\sigma_z$ along the y direction and z direction, when the tower crane stress under different working conditions. So beam188 were adopted to simulate and the total of more than 3000 nodes.

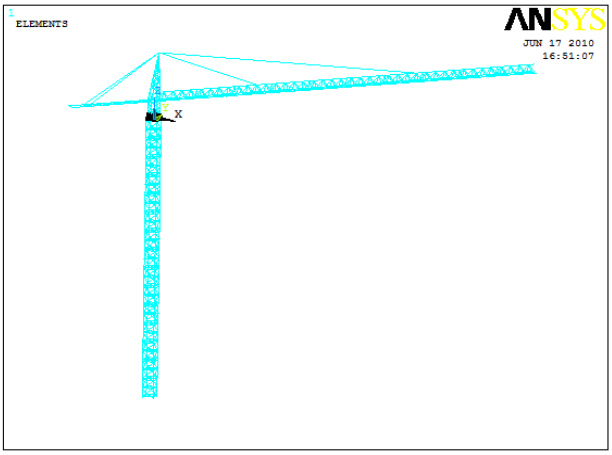

Fig.1 The diagram of tower crane model

The intersection points of web member and chord member are rigid joint. The junction of knuckle arm and knuckle arm, the junction of tie rod and the tower top and the junction of various parts are also processed as rigid joint. The main technical performance parameters: rated load moment for 97t.m, maximum load moment for116t.m, maximum lifting load for 6t, lift height for stationary type 45m , attached type 200m, working range for max=60mand min=2.5m.

Elasticity modulus E=210GPa, Poisson's ratio $\mu$ =0.3, wind load w=620KN/m$^2$, and the density $\rho$ =7800kg/m$^3$, gravitational acceleration is 9.8m/s$^2$.

## Calculation and analysis of stress and deformation under the various working conditions

**Load.**The load that effects on the tower crane include dead weight load $F_g = 43750\times 4\mathrm{N}$, hoisting load $F_g = 627430\mathrm{N}$, inertial load (impact load) $F_c = 2\times F_q$ and wind load $F_w = 4794.03\mathrm{N}$.

**Analysis and calculation of Working condition.** Resistance to overturning stability of tower crane should be checked in accordance with the wording conditions listed as shown in Tab.1[7].

Tab.1 Checking wording conditions

| wording conditions | instructions |
|---|---|
| basic stability | working condition，static state，breezeless |
| dynamic stability | working condition，dynamic state，windiness |
| the storm hitting | off working state |
| sudden unloading | working condition，hopper uninstall |

The design of the concrete foundation used by fixed tower crane should satisfy the resistance to overturning stability condition and strength condition. According to the following formula, the resistance to overturning stability of the concrete foundation can be calculated.

$$e = \frac{M + F_h \times h}{F_v + F_g} \le \frac{b}{3}$$

In the formula, e for eccentric distance; $M$ for bending moment effecting on the foundation; $F_v$ for vertical load effecting on the foundation; $F_h$ for horizontal load effecting on the foundation; $F_g$ for the gravity of the concrete foundation.

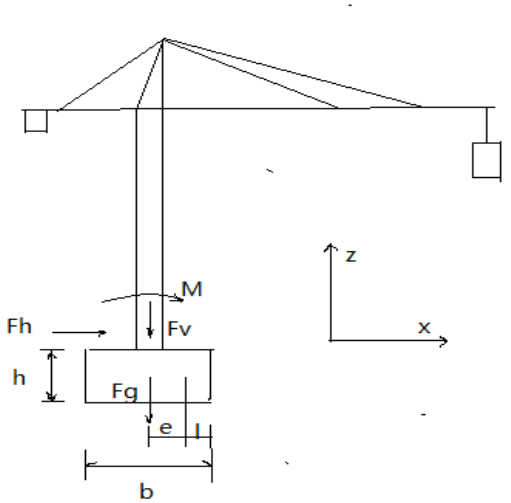

Fig.2 Calculation diagram of resistance to overturning stability

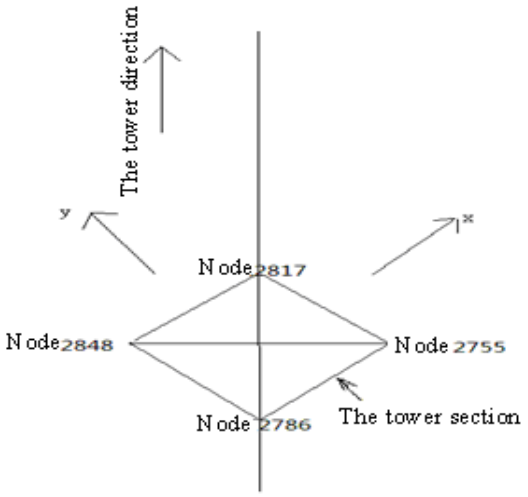

Fig.3 Calculation and introductions

**Calculation the various working conditions.**Considering the length, here will introduce working condition two: including wind load, hoisting load, impact load and dead weight load,as shown in Fig.4,Fig.5 and Tab.2.

| the value of resultant force | 23313. | -22685 | 0.66832E+06 | 11792 | 13863 | -903.19 |

Calculate the resistance to overturning stability according to standard

$$M_{x(z)} = (F_{2786} + F_{2848} - F_{2755} - F_{2817}) \times \frac{1.665}{2} = 1.735 \times 10^6 \,\mathrm{N \cdot m}$$

$$e_y = \frac{M_{x(z)} + M_x - F_y \times h}{F_z + F_g} = 0.8 < 2.3$$

Therefore, the whole tower crane is stable. We can known that the maximum Misses stress appears on the root of the tower and is $\sigma = 117.07\mathrm{MPa} \le [\sigma] = 170\mathrm{MPa}$ by looking up information. The whole crane is satisfied in the strength conditions.

## Conclusion

Looking from the static analysis: the whole tower crane is lower stress levels on the four working conditions concluding basic stability, dynamic stability, the storm hitting and sudden unloading. Only at the bottom of the tower, the Mises equivalent stress of some poles is larger on the various kinds of working conditions. This position is the most dangerous and yields easily. The Mises stress of this position's poles reach to 166.58MPa on the working condition three that is the storm striking working condition and almost reach the allowable stress, so The whole crane is satisfied in the strength conditions.

Looking from the stability: this tower crane is satisfied in whole resistance to overturning stability condition. On the most dangerous working condition three that is the working condition three, the biggest eccentric distance is only 1.08 m which is produced by the tower crane. So the tower crane is stable enough.

After doing finite element analysis to the tower crane TC6010, we can find out the most dangerous section and the most dangerous working condition. It is of great significance in checking poles intensity and check the stability. According to this analysis, it is also easy to find the parts of smaller stress. So we can optimize the design to tower crane and save the cost of tower crane, according to strengthen the poles section of dangerous parts and weaken the poles section of smaller stress. It is helpful to improve the stability and strength.

# Mixed Time Integration Parallel Algorithm for Nonlinear Dynamic Analysis

Chaojiang Fu

College of Civil Engineering, Fujian University of Technology, Fuzhou, 350108, China

email: cjfu@163.com

**Keywords:** Parallel Computing; Mixed Time Integration; Domain Decomposition; Dynamic Analysis

**Abstract.** The mixed time integration parallel algorithm for nonlinear dynamic analysis was presented by synthesising the implicit and explicit time integration techniques. The parallel algorithm employing mixed time integration technique was devised with domain decomposition. Concurrency was introduced into this algorithm by integrating interface nodes with explicit time integration technique and solving local subdomains with implicit algorithm. Numerical example was implemented to validate the performance of the parallel algorithm. Numerical studies indicate that the proposed algorithm is superior in performance to the implicit algorithm.

## Introduction

For large-scale structural dynamic analysis with nonlinearities, the implicit time integration algorithms become highly compute intensive. The equation-solving phase is the most dominating computational phase in these algorithms. With emergence of parallel processing, it provides an effect way for solving this kind of problem[1].

The explicit time integration algorithms like central difference method can easily be moved onto parallel processing machines, as the resulting dynamic equilibrium equations are uncoupled when mass and damping matrices are diagonal. However, explicit algorithms are conditionally stable and cannot be applied efficiently for structural dynamic analysis[2]. On the other hand implicit algorithms are unconditionally stable, but parallel implementation is not so straightforward.

Parallel algorithm research on structure dynamic analysis has been very active. Noor have completed parallel the explicit integration algorithm in the pipeline vector computer[3]. Chiang and Fulton investigated implicit Newmark type methods in shared memory MIMD environment[4]. Noor and Peter derived the finite element discretisation based on a mixed formulation on multiprocessor computers[5]. These studies mainly developed in the vector machine and shared storage MIMD parallel computer. In recent years, parallel computing system based on distributed MIMD network cluster has become one of the mainstream for parallel computer development[6].

In this paper the mixed time integration parallel algorithm for nonlinear dynamic analysis is studied by synthesising the implicit and explicit time integration techniques on workstation cluster. Numerical studies indicate that the proposed algorithm is correct and effective.

## Newmark's Time Stepping Algorithm

The governing equilibrium equation of structural dynamics can be expressed as[7]

$$\boldsymbol{Ma}+\boldsymbol{Cv}+\boldsymbol{Kd}=\boldsymbol{f}(t) \tag{1}$$

where $\boldsymbol{M}$ is the mass matrix, $\boldsymbol{C}$ is the damping matrix and $\boldsymbol{K}$ is the stiffness matrix. $\boldsymbol{a}$, $\boldsymbol{v}$ and $\boldsymbol{d}$ are the acceleration, velocity and displacement vectors, respectively, $\boldsymbol{f}(t)$ is load vector. Solution of this initial value problem requires integration through time. This is achieved numerically by discretising in time the continuous temporal derivatives. The most widely used family of direct time integration methods for solving Eq. (1) is the Newmark family of methods[2]. These methods are based on equilibrium at the ($n$+1)th time step, i.e. at time ($t_{n+1} = t_n + \triangle t$), and is given by

$$\boldsymbol{Ma}_{n+1}+\boldsymbol{Cv}_{n+1}+\boldsymbol{Kd}_{n+1}=\boldsymbol{f}(t)_{n+1} \tag{2}$$

The velocity and displacement vectors are expressed by finite difference approximations

$$\boldsymbol{d}_{n+1} = \boldsymbol{d}_n + \Delta t \boldsymbol{v}_n + 0.5\Delta t^2\{(1-2\beta)\boldsymbol{a}_n + 2\beta \boldsymbol{a}_{n+1}\} \quad (3)$$

$$\boldsymbol{v}_{n+1} = \boldsymbol{v}_n + \Delta t\{(1-\gamma)\boldsymbol{a}_n + \gamma \boldsymbol{a}_{n+1}\} \quad (4)$$

The parameters $\beta$ and $\gamma$ define the Newmark family of algorithms. Solving $\boldsymbol{a}_{n+1}$ and $\boldsymbol{v}_{n+1}$ from Eqs. (3) and (4) and substituting them in Eq. (2), the following system of equations can be obtained, which can be solved for $d_{n+1}$

$$\left(\boldsymbol{K} + \frac{1}{\beta\Delta t^2}\boldsymbol{M} + \frac{\gamma}{\beta\Delta t}\boldsymbol{C}\right)\boldsymbol{d}_{n+1} = \boldsymbol{f}_{n+1} + \boldsymbol{M}\left[\frac{1}{\beta\Delta t^2}\boldsymbol{d}_n + \frac{1}{\beta\Delta t}\boldsymbol{v}_n + (\frac{1}{2\beta}-1)\boldsymbol{a}_n\right] + \boldsymbol{C}\left[\frac{\gamma}{\beta\Delta t}\boldsymbol{d}_n + (\frac{\gamma}{\beta}-1)\boldsymbol{v}_n + \Delta t(\frac{\gamma}{2\beta}-1)\boldsymbol{a}_n\right] \quad (5)$$

**Central Difference Algorithm**

For explicit time integration, central difference algorithm is popularly being used. The difference expressions for $\boldsymbol{v}_n$ and $\boldsymbol{a}_n$ can be written as

$$\boldsymbol{v}_n = (\boldsymbol{d}_{n+1} - \boldsymbol{d}_{n-1})/(2\Delta t) \quad (6)$$

$$\boldsymbol{a}_n = (\boldsymbol{d}_{n+1} - 2\boldsymbol{d}_n + \boldsymbol{d}_{n-1})/(\Delta t^2) \quad (7)$$

Substituting these expressions in the dynamic equilibrium equation, and rearranging terms it can be written as

$$\boldsymbol{d}_{n+1} = (\boldsymbol{M} + \boldsymbol{C}\Delta t/2)^{-1}[\Delta t^2(\boldsymbol{p}_{n-1} - \boldsymbol{f}_{n-1})] + 2\boldsymbol{M}\boldsymbol{d}_n - (\boldsymbol{M} - \boldsymbol{C}\Delta t/2)\boldsymbol{d}_{n-1} \quad (8)$$

where $\boldsymbol{p}$ is the internal force vector. If both $\boldsymbol{M}$ and $\boldsymbol{C}$ are diagonal matrices, the solution for $\boldsymbol{d}_{n+1}$ does not require factorisation. Since the central difference algorithm does not require assembly of global matrices and can be handled at degrees of freedom level, the parallel implementation is pretty straightforward. The interprocessor communication requirement per time step is very small when compared to the implicit algorithms[2].

**Mixed Time Integration Algorithm**

In the mixed time integration algorithms, both implicit and explicit algorithms are employed on implicit and explicit mesh partitions, respectively. In the explicit and implicit mesh partitions, the flexible part of the mesh is integrated explicitly and the stiff part of the mesh is integrated implicitly. In the domain decomposition techniques, the finite element mesh is partitioned into as many numbers of submeshes as the number of processors configured. Each submesh is assigned to an individual processor to solve independently with some cooperation with the neighbouring processors. With this, the global system of equations to be solved in the implicit time integration algorithm are partitioned into smaller subsets and can be solved independently in their assigned processor. The interfaces of all the submeshes are solved employing parallel explicit algorithm.

The nodes in each of the submesh are formed into two distinct groups as interface nodes and interior nodes. Employing the implicit–explicit algorithm, the interface nodes can be integrated explicitly (using parallel explicit algorithm) where the interprocessor requirements are trivial. Once the interface values are known, the interior nodes can be integrated implicitly by constraining interface nodal degrees of freedom with the known values already obtained by using parallel explicit algorithm. It can be observed that submeshes to be integrated with implicit time integration algorithm are totally detached due to the introduction of the explicit integration at the interfaces. With this, the implicit algorithm can be executed on the local submeshes.

**Parallel Implementation of Mixed Time Integration Algorithm**

In the parallel domain decomposition based mixed time integration algorithm, nodes lying along the interface are divided into primary boundary nodes and secondary boundary nodes, with each interface node being a primary boundary node in a submesh and secondary boundary node in all other submeshes sharing that particular node. The nodes which are not interface nodes are called internal nodes. Internal elements are those, which do not have any boundary nodes. The elements, which consist of boundary nodes, are border elements[8].

Once the given finite element mesh is partitioned into required number of submeshes, the primary and secondary boundary nodes of each submesh are identified, the parallel mixed time integration commences first by integrating the identified boundary nodes with explicit time integration technique. This explicit time integration is performed in each processor on their respective primary boundary nodes and the displacements thus computed at these nodes will be communicated to the neighbouring processors. The internal force vector for the elements connected to primary boundary nodes are computed in their respective processors and these partial values are transmitted to their neighbouring counter parts and at the same time receive the corresponding partial internal force vector computed in their neighbouring processors. With this, the time integration of the boundary nodes of the finite element mesh can be accomplished without any load imbalances. The time integration of these interface nodes is continued up to N explicit time steps.

The next step is to compute the dynamic responses in the local submeshes assigned to each processor. This can be accomplished by performing the time integration with Newmark's implicit algorithm on these local submeshes by constraining the boundary nodes with the values obtained from explicit integration. With the proposed implementation, the global solution of equations is no longer needed. The solution of equations is confined only to their assigned submeshes. This results in significant savings in communication time and also computational time, as the bandwidth of the local submesh matrix is considerably smaller than the global matrix.

**Numerical Example**

The numerical example is performed on DELL workstation cluster. It is a cluster with 8 processors arranged in 4 dual-processor nodes with 2.4GHz Intel Xeon chips (512KB cache) and 1.0GB of memory per node. These nodes are connected with a 100.0Mbps Ethernet interconnect. The MPI communication libraries have used to manage the message passing[9].

One quarter of the cylindrical shell is shown in Fig.1. Geometric nonlinearity is considered. The stability and accuracy are examined by the time step size $0.2\times10^{-3}$s. The A nodal displacement time history response computed by the Newmark method and the proposed algorithm are shown in Fig.2. It can be observed that the proposed algorithm yields acceptable results and the solution is in good agreement with the conventional Newmark's solution. This illustrates that the proposed algorithm possess highly the stability and accuracy.

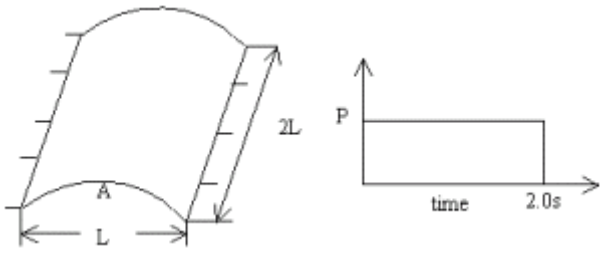

Fig.1 Description of the example

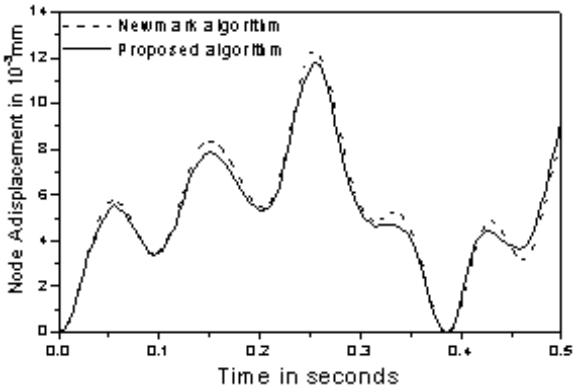

Fig.2 Displacement response of node A

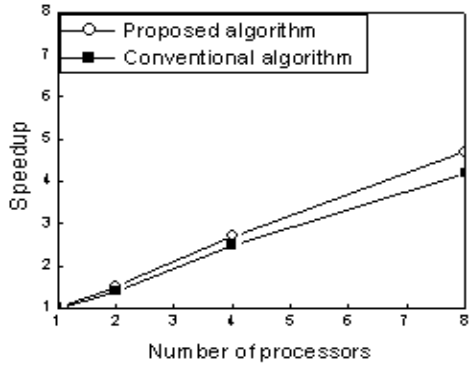

Fig.3 Speedup of algorithm with 4710 dof

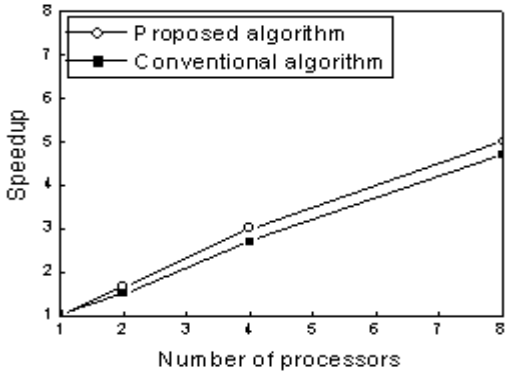

Fig.4 Speedup of algorithm with 17322 dof

To evaluate the performance of the proposed parallel algorithm, the problem size(i.e., degree of freedom) is increased by refining the finite element mesh. The speedups are shown in Fig.3 and Fig.4. It can be observed that the performance of the parallel algorithms improves with increase in the problem size and also the proposed parallel algorithm exhibits superior performance. The proposed parallel algorithm is better than implicit algorithm.

## Conclusions

The parallel mixed time integration algorithm is studied by using synthesis of implicit and explicit time integration technology. The domain decomposition technique is employed in this algorithm. Concurrency is introduced into this algorithm by integrating interface nodes with explicit time integration technique and solving local subdomains with implicit algorithm. Without the need for a parallel solver, the solving equations is significantly reduced. The solving equations is carried out in the local subdomains. Thus half bandwidth of global matrix is significantly reduced. Numerical studies indicate that the proposed algorithm is superior in performance to the implicit algorithm.

# A Comparison Between the Matrix Displacement Method and the Finite Element Method in Solving Frame Structure with SM Solver Software

Lijuan Cheng [a *], Xinchi Yan[b*]

School of Environment & Civil Engineering, Jiangnan University, Wuxi 214122, China

[a]523075436@qq.com, [b]skywalker@jiangnan.edu.cn

**Keywords:** Matrix displacement method, Finite element method, SM Solver.

**Abstract:** Using matrix displacement method and the finite element method to calculate the internal force of the same frame, and then comparing the results. Meanwhile, due to the theory that SM Solver can calculate the exact solution of rigid frame structure forces, we use it to support our experiment. Finally, we succeed in calculating and proving that Matrix displacement method and the finite element method have the same result in solving the rigid frame structure forces.

## Introduction

As we all known, Matrix displacement method is mainly used in the analysis of truss structure and frame structure. Comparing to it, the finite element method has a broader scope. Not only can it be applied to rigid frame and truss, it can also apply to plates, shells, shear walls, bridges and prestressed concrete structures. In addition, you can also analyze the natural frequencies, modal, structural stability and slope stability of structures, etc.

When Matrix displacement method is used for the analysis of the structure of the rod, it can also be called FEM of rod structure which will draw exact conclusions. Well, when the finite element method is used in analyzing the two-dimensional or three-dimensional structure of the physical structure, it will draw approximate conclusions. [1]

Matrix displacement method is the prototype of the finite element method, so structure matrix analysis is sometimes called the finite element method of rod structure.

## Characteristics of matrix displacement method

In the matrix displacement method, the task of element analysis is to establish the element stiffness equation and form element stiffness matrix. The main task of the overall analysis is to turn units into entirety, to form an overall stiffness matrix by the element stiffness matrix according to the stiffness integration rules and to establish the basic equations of the overall structure with displacement method, so we can find answers.

Matrix displacement method in Structural mechanic is expressed by matrix and solved by computers, so it can be used to analyze the complex frame structures. At the same time, these structures are composed by rods whose feature may be analyzed by classical displacement method. [2]

## Characteristics of the finite element method

The key of the finite element method is to split overall structure into several units firstly (Each rod is generally taken to be a unit), which is called discretion, and then turn these units into entirety

according to certain conditions. We transform the calculation of complex structures into simple elements analysis and collection issues in this process. [3]

As we can see, FEM has the similar analysis steps with the matrix displacement method. Its analysis scope is expanded from truss structures to non-stick continuous structures.

**Four distinctive features of plane frame.**

(1) The entire structure consists of several elongate rods and each rod is rigidly connected
(2) The axis of each rod is not on an axis generally.
(3) Each unit of a plane frame is flexural member, which has axial deformation and bending deformation. So not only can it transmits force, but also it can transmit torque.

(4) In terms of each node of frame, we should consider the angular displacement $\theta_i$ of section as well as linear displacement called $u_i$, $v_i$ in both directions. Therefore, each node has three displacement components $u_i$, $v_i$, $\theta_i$, which correspond to three nodal force components $U_i$, $V_i$, $M_i$ differently. [4]

Comparison **between** matrix displacement method and finite element method

According to above-mentioned frame features, analysis in matrix displacement method of such structure can be handled as follows:
(1) Collate raw data and code unit and the frame locally and generally;

(2) Form element stiffness matrix $\bar{k}^e$ in the local coordinate system;
(3) Form element stiffness matrix $k^e$ in the global coordinate system;
(4) Form the overall stiffness matrix *K* with element integration method;

(5) Find unit equivalent nodal loads $\bar{P}^e$ in local coordinate system and convert them into unit equivalent nodal loads $P^e$ in global coordinate system; form equivalent nodal loads $P$ of overall structure by element integration method;
(6) Solve equations $K\Delta = P$ and obtain node displacement $\Delta$;

(7) Find rod end internal forces $\bar{F}^e$ of each rod.[3]

Finite element analysis of such structures can be handled as follows:
(1) Establish mechanical model and make unit number and node number;

(2) Find the element stiffness matrix $\left[\bar{k}\right]^e$ in local coordinate system;

(3) Find the element stiffness matrix $[k]^e$ in whole coordinate system;

(4) Seek overall stiffness matrix $[K]$;

(5) Form load vector;
(6) Introduce support conditions;

(7) Solve equations to seek node displacement;
(8) Seek the rod end internal forces of each unit. [4]

Generally speaking, we should Superimpose on a "Fixed end forces" item when we compute rod end force with Matrix Displacement Method. However, we seek nodal forces by displacement derivation in FEM, which result in a significant decline in the accuracy of stress.

Now we are going to compare the matrix displacement method and the finite element method through a simple frame structure.

**Examples**

Frame as shown in figure 1, assuming these two rods have same rod length and cross-sectional dimension, its section is shown in figure 2,1m length, 0.5m wide, 5m length of rod, $E = 3\times10^7\ KN/m^2$, $I = \frac{1}{24} m^4$. Seeking rod end internal forces of frame.

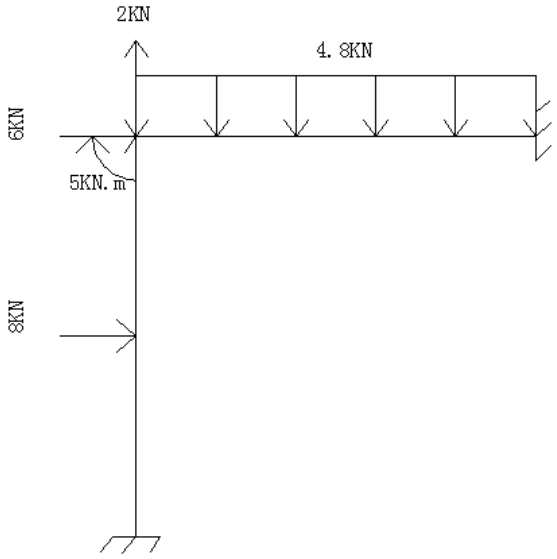

Fig. 1 Frame

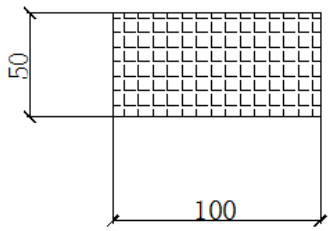

Fig. 2 Rod cross-section

Split the frame structure into the following units ①, ②:

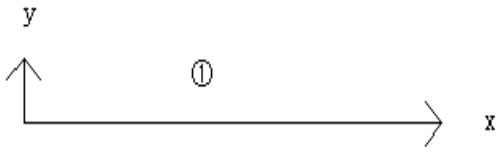

Fig. 3 Unit ①

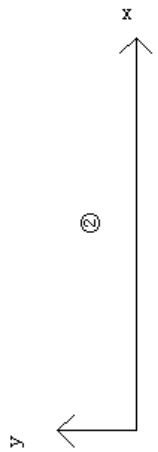

Fig. 4 Unit ②

The results of calculating the internal forces with matrix displacement method and the finite element method as well as auxiliary calculations of SM Solver are shown in Table 1.

Table 1 Comparison of the results

| | | | Matrix Displacement Method | Finite Element Method | SM Solver |
|---|---|---|---|---|---|
| Unit 1 | Rod end 1 | Axial force[N] | 11100.53 | 11100.54 | 11100.5331 |
| | | Shear[N] | 10130.24 | 10130.24 | 10130.2361 |
| | | Moment[N*m] | -4038.46 | 4038.47 | 4038.46153 |
| | Rod end 2 | Axial force[N] | -11100.53 | -11100.54 | -11100.5331 |
| | | Shear[N] | -13869.76 | 13869.78 | 13869.7638 |
| | | Moment[N*m] | -13387.28 | 13387.28 | 13387.2810 |
| Unit 2 | Rod end 1 | Axial force(N) | -13387.28 | 8130.24 | -8130.23610 |
| | | Shear(N) | 2899.47 | 2899.47 | 2899.46686 |
| | | Moment(N*m) | 3535.80 | 3535.80 | 3535.79588 |
| | Rod end 2 | Axial force(N) | -8130.24 | -8130.24 | -8130.23610 |
| | | Shear(N) | 5100.53 | 5100.53 | 5100.53313 |
| | | Moment(N*m) | -9038.46 | -9038.46 | -9038.46153 |

## Conclusion

According to above analysis, solving simple frame is completely equivalent no matter it is Matrix Displacement Method or FEM. The reason is that the rod structural problem, as a kind of simple elasticity problem, can be solved easily. Matrix Displacement Method establishes algebraic equations expressing structural problem characteristic of rod directly by using analytic solutions. FEM, starting from the differential equation, solve the original problem by assuming the demand function. The problem is simple so we assume the unknown displacement function is a linear function, which meets the analytic solutions of the problem. As a result, we will get the same answer. [5]

When we need to solve the exact internal force of plane frame, we can get accurate solutions conveniently with SM Solver software.

**Keywords:**XFEM; Crack Propagation; Tensile and Shear Load

**Abstract:** The extended finite element method (XFEM) is a numerical method for modeling discontinuity such as cracks, holes, inclusions etc within a standard finite element framework. In the XFEM, special functions which can reflect the problem's solution characteristics are added to the finite element approximation using the framework of partition of unity. Compared with the standard finite element method, it obtained more accuracy without remeshing. In this paper, we studied crack propagation behavior under different proportions of tension and shear loads by XFEM.

## Introduction

Northwestern University in the United States in 1999 for the finite element method Belytschko[1] proposed amendments to the finite element method (material weak intermittent problem and geometric strong intermittent problem) intermittent problems - a method for processing extended finite element method (XFEM ). Important improvements in the conventional finite element method based on discontinuous finite element method handle crack interface drawbacks [2].

XFEM is in the framework of the standard finite element method, continuous area using standard finite element method, finite element method displacement approximation functions within a narrow area contains discontinuous boundary correction, and the description of the continuous boundary method. By means of the research questions already known , the increase in displacement approximation functions satisfy the partition of unity under the premise to better reflect the actual discontinuous function of the characteristics of items ( called enrichment function ) , to improve the calculation accuracy .

Since the XFEM retain conventional finite element (CFEM),to solve the conventional finite element required in the difficulties brought about by the stress concentration high density divided unit on the basis of all the advantages. Modeling crack growth without re-meshing, and has been a rapid development[3]. XFEM uses level set method described intermittent interface that allows uninterrupted description is independent of the finite element mesh, avoid remeshing the calculation process. Extended finite element method has been considerable development in just a decade. It has been applied in dynamic fracture, dynamic extension of the shear zone, cohesive fracture polycrystalline interfaces and grain boundaries and dislocations of research fields [4].

## The extendedfinite element based on the partition of unity

The Extended Finite element based of decomposition. The basic idea of unity method is arbitrary function in the solution domain can be expressed as:

$$\psi(x)=\sum_{I} N_I(x)\, q_1 \Phi(x) \tag{1}$$

Where $N_I(x)$ is the standard finite element shape functionsatisfy the partition of unity. $u_I$ is the standard nodal degrees of freedom . The Extenders $\psi(x)$ is used to improve the knowledge field characteristics. $\Phi(x)$ is the expansion of the function .

XFEM add the extender on the basis of the standard field approximation to a more precise description of complex unknown field. Finite element approximation of the unknown field $u^h$ consists of two parts:

$$u^h = \sum_I N_I(x) u_I + \sum_J \psi_J(x) q_J \tag{2}$$

In type 2, solving problems specific need to use a different expansion function. The constructed expansion function, you need to make it having certain characteristics of the unknown field true solution in order to increase the convergence speed. In actual use, often based on the solution space of real solutions to select.

**Level set method**

Level set method is a numerical method for tracking mobile interface proposed by Osher and Sethian. Extended finite element method , using the level set method or the method described in geometric position discontinuities rapid advance its expansion process , so that no continuous surface description is independent of the finite element mesh , which in discontinuous surface extensions can't the complex grid reconstruction [4 ] .

A common level set function constructor signed distance function

$$f(x,t) = \pm \min_{x_\gamma \in \gamma(t)} \left\| x - x_\gamma \right\| \tag{3}$$

It has the physical meaning of the computational domain signed distance function of the arbitrary point is equal to the shortest distance from this point to the discontinuity , and intermittently on both sides of a point having a different symbol .This function can be described through the crack from solving domain interruption. But when a crack in the solution domain is terminated, only one function can't reflect the position of the crack tip , so it needs to define a level set function.

$$g_i = (x - x_i) \cdot \frac{v_i}{\left\| v_i \right\|} \tag{4}$$

Therefore the location of the crack surface can be expressed as the level set function

$$\Gamma_c^0 = \{ x \in \Omega_0 \mid f(x) = 0, g(x,t) > 0 \} \tag{5}$$

**The expansion shape function of discontinuous**

There are two types of typical discontinuous problems in solid mechanics [5]. The first class is weak because the material properties caused by mutations discontinuity problems,The other is inside the object geometry caused by mutations in the strong discontinuous crack problem is that the representatives of such problems.

Those cracks completely through the unit, on both sides of the crack surface displacement the field occurred jump, the expansion of the shape function can take the following forms :

$$\psi_J(x) = N_J(x) H(f(x)) \tag{6}$$

Where $H(x)$ is the Heaviside step function given by

$$H(x)=\begin{cases}1, & x\geq 0\\ -1, & x<0\end{cases} \tag{7}$$

$f(x)$ is a function of the level set.

$$\psi_J(x)=N_J(x)\Phi(x) \tag{8}$$

Where $n^+$ is the discontinuity of the unit normal vector on $\Gamma_0^c$ . For any point $x$ not on the interface r $\Gamma_0^c$ . $f(x)$ is the shortest distance from $x$ to $\Gamma_0^c$.

Nodes around the crack tip, the expansion of the shape function can use the following form:

$$\psi_J(x)=N_J(x)\Phi(x) \tag{9}$$

Where $\Phi(x)$ can be a combination of the following function groups.

$$\Phi(x)=\left[\sqrt{r}\sin\frac{\theta}{2},\sqrt{r}\sin\frac{\theta}{2}\sin\theta,\sqrt{r}\cos\frac{\theta}{2},\sqrt{r}\cos\frac{\theta}{2}\sin\theta\right] \tag{10}$$

Using the two expansion -shaped function, with the displacement of the crack two - dimensional flat field can be expressed as:

$$u^h(x)=\sum_{I\in S}N_I(x)u_I+\sum_{J\in S_h}N_J(x)H(f(x))a_J(t)+\sum_{K\in S_c}N_K(x)\Phi(x)b_K(t) \tag{11}$$

Where $S_h$ is the crack completely cut off unit node, $S_c$ are nodes around the crack tip unit, $a_J$ and $b_k$ is the node additional degree of freedom.

For weak discontinuity can use the following form:

$$u^h(x,t)=\sum_{I\in S}N_I(x)u_I(t)+\sum_{J\in S_{\text{interface}}}N_J(x)\Phi(x)q_J \tag{12}$$

In which the absolute value function

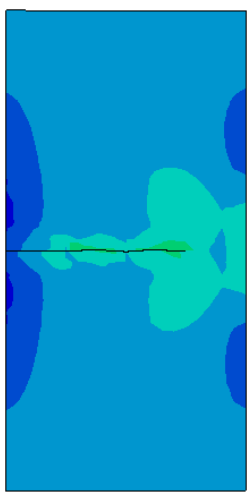
$$\Phi(x)=\sum_I|f(x_I)|N_I(x)-\left|\sum_I f(x_I)N_I(x)\right| \tag{13}$$

**Numerical examples**

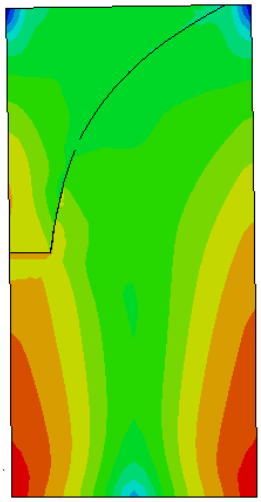
Specimen forms shown in the picture, 60cm*30cm*5cm, and specimens left central with a length of 5cm edge crack. At the bottom of the specimen is fixed, the topfaceloading with displacement.There are 6 kinds of loading, a pure tensile loading, pure shear loading, then keeps the tensile displacement and changing the shear displacement, the tensile displacement and sheardisplacement ratio is 1:1, 1:2.5, 1:5, 1:10. These six kinds of combination of load test of crack propagation is shown in figure 1.

As can be seen, with the increase in tensile and shear displacement ratio, the greater the angle of crack propagation. Crack is not propagation along a straight line extended, but along the arc

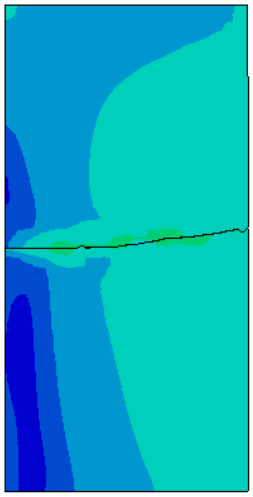
extension. The crack angle becomes smaller with the expansion. This is because at the beginning of the crack starts is dominated by shear. With the crack growth, gradually stretching effect is enhanced and then dominated by stretch.



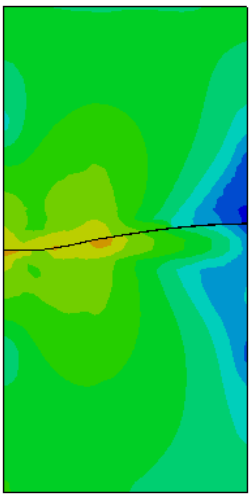
(a) Pure tensile



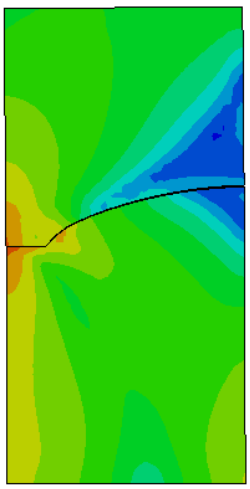
(b) Pure shear



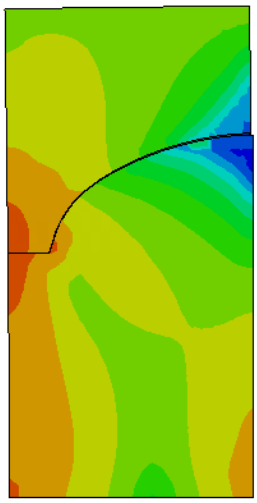
(c) Tensile shear ratio is 1:1



(d) Tensile shear ratio is 1:2.5



(e) Tensile shear ratio is 1:2.5



(f) Tensile shear ratio is 1:2.5

Fig1. The path of crack under different load

## Conclusions

This paper introduces the basic theory of XFEM, and simulatedcrack extension on the different load ratio under tension shear, results show; XFEM can simulate any crack propagation behavior well.Crack propagation path does not depend on the mesh,The crack can be expansion through the mesh. With the increase of the ratio of tension and shear displacement, the angle of crack propagation became smaller. The crack is not a straight line extension, but with the crack growth, the crack angle becomes smaller gradually.

**Keywords**: convection diffusion equation; finite element in fluid mechanics; numerical wave; exponential function based interpolation (EFBI); morphological analysis

**Abstract:** The wave problem of finite element solution of one dimensional stationary convection diffusion equation is analyzed. The reason for wave is the poor continuity of linear Lagrange shape function. By using exponential function based interpolation (EFBI), the results of finite element solution are compared with that of the analytical solution. The results indicate that EFBI is effective to deal with the problem of numerical wave. The shape function of three dimensional EFBI is derived and analyzed. Morphological analysis shows that EFBI has good differentiability and adaptability.

## Introduction

The weak form of Standard Galerkin (SG) finite element format is usually adopted to solve partial differential equations, which relaxes the requirements for the continuity of solution. The finite element method has been proved mathematically to converge to exact solutions when the elements become infinitesimal. However, as it is applied to fluid mechanics analysis, the traditional finite element solution can't satisfy continuity requirements, and can't satisfy the flux conservation conditions[1-2], neither. So there is some error in finite element solution. Since there is no analytical solution to Navier-Stokes equation of fluid mechanics, a lot of research is put on numerical solution. Many researchers study one dimensional stationary convection diffusion equation by simplifying it to constant coefficient differential equation. They compare the solution of finite element method with analytical solution and find finite element numerical wave[3-4]. The famous American mechanics professor Ted Belytschko analyzes the reasons for wave and proposes solutions to improve finite element method. On the basis of the study, Professor Huge puts forward SUPG method. British research team led by professor Zienkiewicz introduces the CBS algorithm , which has been widely used[5-7].

In the paper, the wave problem of finite element solution of one dimensional stationary convection diffusion equation is analyzed. The reason for wave is the poor continuity of linear Lagrange shape function. By using EFBI, the results of finite element solution are compared with that of the analytical solution. The results indicate that EFBI is effective to deal with the problem of numerical wave. EFBI is applied to three-dimensional fluid mechanics. The shape function is derived and analyzed. Morphological analysis shows that it has good differentiability, which can prevent numerical wave in the element, and good adaptability in the process of approximation.

**Finite element solution of one dimensional stationary convection diffusion equation using EFBI**

1.1 Traditional finite element solution

The domain considered is $0 \le x \le L$, with variable $\phi$， the one dimensional stationary convection diffusion equation is

$$u \cdot \frac{\partial \phi}{\partial x} - v \frac{\partial^2 \phi}{\partial x^2} = 0 \tag{1}$$

where $v$ is kinematic viscosity; $u$ is velocity; $\phi$ is independent variable; $x$ is coordinate value, $0 \le x \le L$。

As approximation problem of the initial problem, for the case of constant $u$, the equation above is simplified to constant coefficient differential equation. By introducing boundary conditions ($\phi|_{x=0}=0$, $\phi|_{x=L}$), we can get the analytical solution

$$\phi = \frac{1 - e^{ux/v}}{1 - e^{uL/v}} \tag{2}$$

Eq. (1) can be written as weighted residual form. When Standard Galerkin finite element method is adopted, we can obtain

$$\int_{\Delta x} \boldsymbol{N}^{\mathrm{T}} u \frac{\mathrm{d}\boldsymbol{N}}{\mathrm{d}x} \mathrm{d}x \phi_e - \int_{\Delta x} \boldsymbol{N}^{\mathrm{T}} v \frac{\mathrm{d}^2 \boldsymbol{N}}{\mathrm{d}x^2} \mathrm{d}x \phi_e = 0 \tag{3}$$

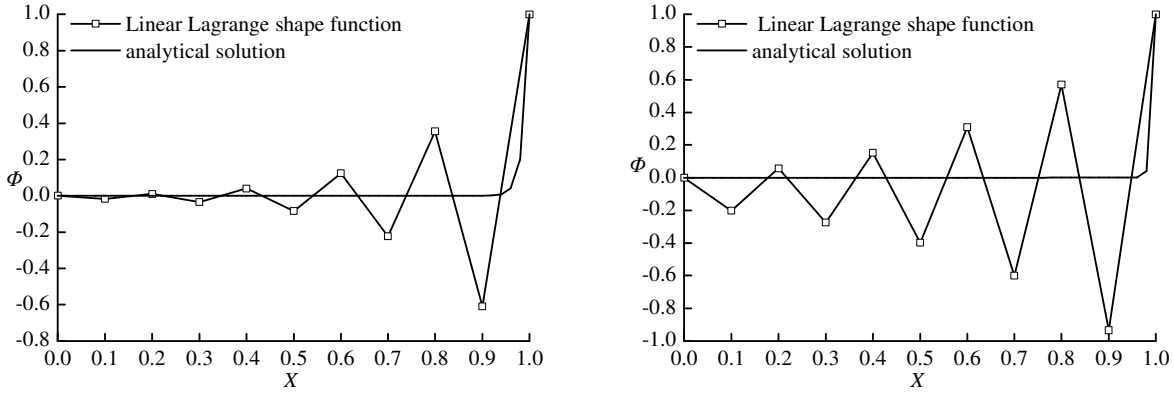
Integrating the second term by parts gives the weak form

$$\int_{\Delta x} \boldsymbol{N}^{\mathrm{T}} u \frac{\mathrm{d}\boldsymbol{N}}{\mathrm{d}x} \mathrm{d}x \phi_e + \int_{\Delta x} v \frac{\mathrm{d}\boldsymbol{N}^{\mathrm{T}}}{\mathrm{d}x} \frac{\mathrm{d}\boldsymbol{N}}{\mathrm{d}x} \mathrm{d}x \phi_e = 0 \tag{4}$$

where $N$ is shape function, $\phi = N\phi_e$, $\phi_e$ is the nodal values of $\phi$. For linear shape function

$$N = \left[ 1 - \frac{x}{\Delta x} \quad \frac{x}{\Delta x} \right] \tag{5}$$

Insertion of Eq. (5) into Eq. (4) gives the finite element solution, in which error is existed. For the case of L=1, J=10, $v$=0.1, $u$ is 8 and 16, the solution shown in Fig. 1 gives the wave situation of finite element solution. The reasons for wave are non-differentiability of linear Lagrange shape function and the discontinuity of first derivative between elements. So choosing the interpolation function with better continuity is effective to deal with the problem of numerical wave[8].



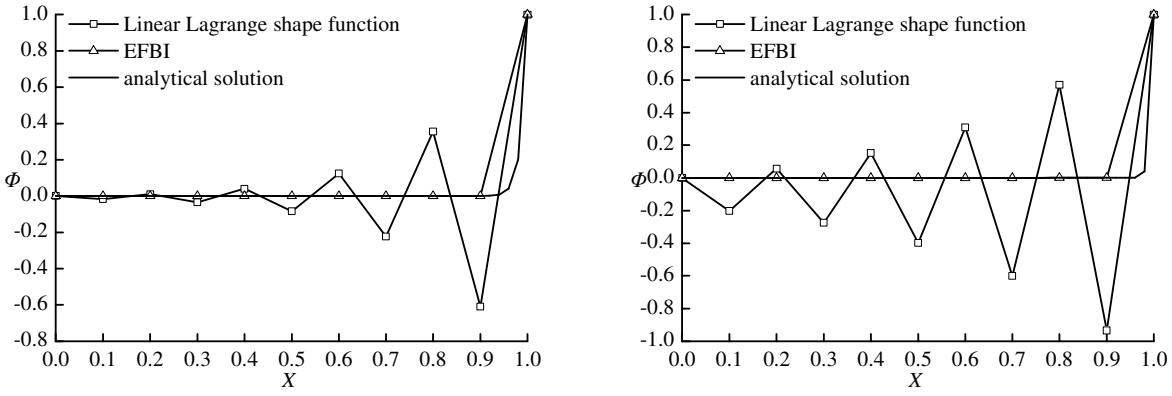
(a) $u$=8 (b) $u$=16

Fig. 1 Traditional finite element solution and analytical solution

1.2 Finite element solution using EFBI

Considering Two-node element, assume that finite element solution is $\phi=c_1+ c_2e^{ax}$, shape function is $N=\left[1-\frac{1-e^{ax}}{1-e^{a\Delta x}} \quad \frac{1-e^{ax}}{1-e^{a\Delta x}}\right]$.The value of $a$ is related to the properties of flow field, with a=$\phi$/$v$ referring to analytical solution.

For the case of L=1, J=10, $v$=0.1, $u$ is 8 and 16, the solution shown in Fig. 2 gives the finite element solution of EFBI and analytical solution.



(a) $u$=8 (b) $u$=16

Fig. 2 Finite element solution using EFBI

As is shown in Fig. 2, compared with traditional finite element solution, EFBI is effective to deal with the problem of numerical wave. Because of its good continuity, which can simulate the distribution of variables within the element accurately, EFBI achieves better numerical solution.

**Three-dimensional fluid mechanics using EFBI**

Compared with that obtained by traditional standard Galerkin (SG) finite element method, the results obtained by EFBI show better accuracy. For the purpose of applying EFBI to three-dimensional fluid mechanics, velocity shape function of tetrahedron element using EFBI is derived. Velocity in the element can be written as[1]

$$U = C_1e^{a_1L_i} + C_2e^{a_2L_j} + C_3e^{a_3L_k} + C_4 \tag{6}$$

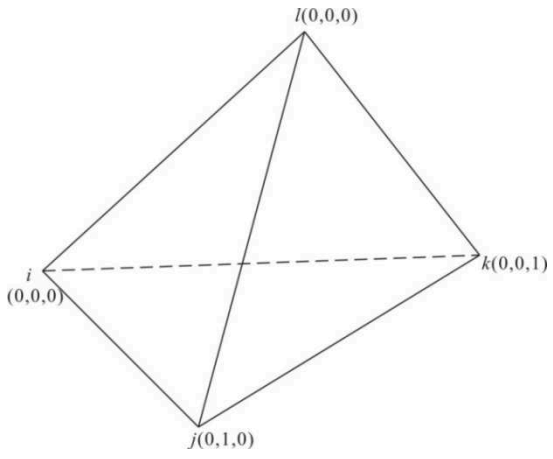


Fig. 3 Tetrahedron element

where

$a_1 = \frac{|v_x|}{v}; a_2 = \frac{|v_y|}{v}; a_3 = \frac{|v_z|}{v}$. $L_i$, $L_j$, $L_k$ are volume coordinates.

For matrix form, the equation above becomes

$$U = LC \tag{7}$$

where

$$L = \begin{bmatrix} e^{a_1 L_i} & e^{a_2 L_j} & e^{a_3 L_k} & 1 \end{bmatrix}, C = \begin{bmatrix} C_1 & C_2 & C_3 & C_4 \end{bmatrix}^T.$$

As is known, the coordinate value of each point is, $i(1,0,0)$, $j(0,1,0)$, $k(0,0,1)$, $l(0,0,0)$.Put them into Eq. (7), we obtain

$$u_e = L_e C \tag{8}$$

where

$$L_e = \begin{bmatrix} e^{a_1} & 1 & 1 & 1 \\ 1 & e^{a_2} & 1 & 1 \\ 1 & 1 & e^{a_3} & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix}$$

From Eq. (8) we have

$$C = L_e^{-1} u_e \tag{9}$$

substituting Eq. (9) into Eq. (7) to obtain

$$U = LC = L \cdot L_e^{-1} u_e = N_u u_i \tag{10}$$

$$\therefore \boldsymbol{N}_u = L \cdot L_e^{-1} = \begin{bmatrix} e^{a_1 L_i} & e^{a_2 L_j} & e^{a_3 L_k} & 1 \end{bmatrix} \begin{bmatrix} e^{a_1} & 1 & 1 & 1 \\ 1 & e^{a_2} & 1 & 1 \\ 1 & 1 & e^{a_3} & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix}^{-1} \tag{11}$$

Thus the shape function

$$\boldsymbol{N}_u = \begin{bmatrix} N_i & N_j & N_k & N_l \end{bmatrix} \tag{12}$$

where

$$N_i = \frac{e^{a_1 L_i} - 1}{e^{a_1} - 1}; \quad N_j = \frac{e^{a_2 L_j} - 1}{e^{a_2} - 1}; \quad N_k = \frac{e^{a_3 L_k} - 1}{e^{a_3} - 1};$$

$$N_l = \left( L_i - \frac{e^{a_1 L_i} - 1}{e^{a_1} - 1} \right) + \left( L_j - \frac{e^{a_2 L_j} - 1}{e^{a_2} - 1} \right) + \left( L_k - \frac{e^{a_3 L_k} - 1}{e^{a_3} - 1} \right) + L_l.$$

Verification shows that the shape function above satisfies the conditions of Kronecker delta and normalization.

**Morphological analysis of EFBI**

The effectiveness and applicability of EFBI has been researched and confirmed in one dimensional convection diffusion equation. The morphology of EFBI will also be analyzed for the purpose of applying it to three dimensional fluid mechanics.

We can find that the shape function of EFBI and linear Lagrange interpolation are rotational symmetry. To be simple, the first terms are taken to analyze.

assuming

$$y_1 = \frac{e^{a_1 L_i} - 1}{e^{a_1} - 1};\ y_2 = L_i;\ y = y_1 - y_2 = \frac{e^{a_1 L_i} - 1}{e^{a_1} - 1} - L_i \tag{13}$$

When $a_1$ approach to infinite decimal $\delta$, $e^{a_1}$ and $e^{a_1 L_i}$ can be Taylor expanded.

$$e^{a_1} = 1 + \delta + \frac{\delta^2}{2!} + \frac{\delta^3}{3!} + \frac{\delta^4}{4!} + \frac{\delta^5}{5!} + \cdots$$

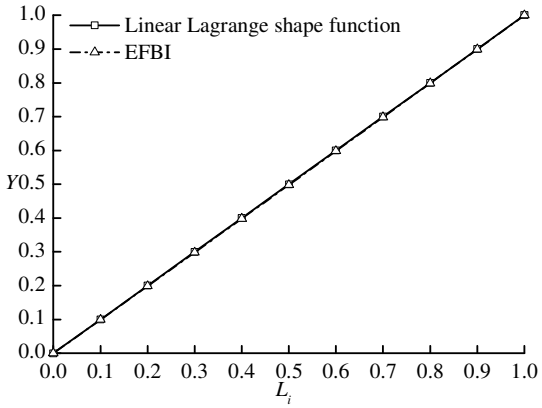
$$e^{a_1 L_i} = 1 + \delta L_i + \frac{(\delta L_i)^2}{2!} + \frac{(\delta L_i)^3}{3!} + \frac{(\delta L_i)^4}{4!} + \frac{(\delta L_i)^5}{5!} + \cdots$$

Take the first six items into Eq. (13) to obtain

$$y = \frac{e^{a_1 L_i} - 1}{e^{a_1} - 1} - L_i = \frac{\delta L_i + \frac{(\delta L_i)^2}{2!} + \frac{(\delta L_i)^3}{3!} + \frac{(\delta L_i)^4}{4!} + \frac{(\delta L_i)^5}{5!}}{\delta + \frac{\delta^2}{2!} + \frac{\delta^3}{3!} + \frac{\delta^4}{4!} + \frac{\delta^5}{5!}} - L_i < \frac{\left(\delta + \frac{\delta^2}{2!} + \frac{\delta^3}{3!} + \frac{\delta^4}{4!} + \frac{\delta^5}{5!}\right) L_i}{\delta + \frac{\delta^2}{2!} + \frac{\delta^3}{3!} + \frac{\delta^4}{4!} + \frac{\delta^5}{5!}} - L_i = 0$$

So the shape function of EFBI is equivalent to linear Lagrange interpolation if $a_1$ is small enough.

For example, in Fig. 4, when the precision $\sigma$= 0.0126($\sigma = \sqrt{\sum_{i=1}^{j} \left( \frac{y_i - y_i'}{y_i} \right)^2}$, where $y_i$ and y' are nodal values of Lagrange interpolation and EFBI), $a$=0.015. In this situation the functions can be seen as equal.



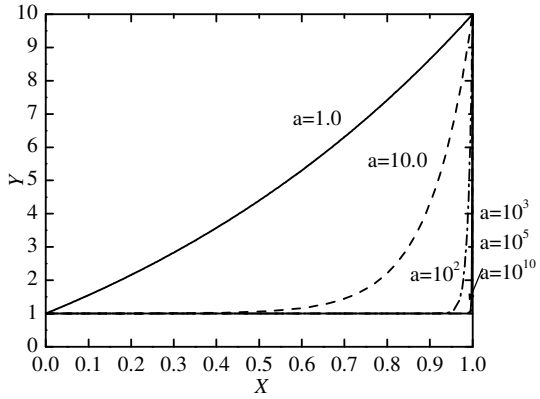


Fig. 4 Linear Lagrange shape function and EFBI when $a$=0.015 Fig. 5 Curve with different $a$

The above analysis clearly demonstrates that EFBI is equivalent to linear Lagrange interpolation if $a_1$, $a_2$ and $a_3$ are less than 0.015.

The value of $a$ in EFBI determines curvature of the curve.when $a$=1.0, $10^2$, $10^3$, $10^5$, $10^{10}$, the curves are shown in Fig. 5.

The solution shown in Fig. 5 tells us that the curve converges when $a$ increases ($a$>1000). The value of $a$ changes with $\phi$, making it adaptable.

The above solution shows that EFBI can approach to linear Lagrange interpolation. They are equivalent when a≤0.015. EFBI has good differentiability, which can prevent numerical wave in the elements. The value of $a$ in EFBI determines curvature of the curve. Choosing a suitable $a$ can improve the accuracy of solution, and it is adaptable in the approaching process. However, the amount of calculation may be increased.

## Conclusions

(1)Finite element method can be used in fluid mechanics. Though there is numerical wave in standard Galerkin (SG) finite element method for one dimensional stationary convection diffusion equation, improving the continuity of the shape function is effective to deal with the problem.

(2)Compared with linear Lagrange interpolation, EFBI has better continuity, which can simulate the distribution of variables within the element accurately. So it can get good solution and is effective to deal with the problem of numerical wave.

(3) The shape function of three dimensional EFBI is derived, but its accuracy needs to be verified by the sample application.

(4) Morphological analysis shows that EFBI has good differentiability, which can prevent numerical wave in the elements. The value of $a$ in EFBI determines curvature of the curve. Choosing a suitable $a$ can improve the accuracy of solution, and it is adaptable in the approaching process.

**Keywords:** Numerical simulation, Reynolds Stress Model(RSM), Atmosphere boundary layer(ABL), Flow around high-rise buildings.

**Abstract.** In this paper, a modified inlet atmosphere boundary layer (ABL) which satisfies the turbulence model equations is applied to computational wind engineering. The new inflow turbulence boundary condition applied to simulating the flow in the cavity is verified that it is more in line with the actual flows, and then it is used to establish the numerical wind tunnel model to simulate the flow around high-rise buildings. The results are in good agreement with the wind tunnel experimental data, which show the modified ABL combined with Reynolds Stress Model (RSM) is able to better simulate the flow around high-rise buildings.

## Introduction

In the numerical simulation of flow around the bluff body in the building wind engineering, the selection of the turbulence model and the boundary conditions of ABL have a significant effect on the computed result. The frequently-used turbulence model have k-ε model, RSM, k-ω model and Large Eddy Simulation (LES) model, etc. Where k-ε model is widely used to calculate the shear flow, interior flow and many other flow phenomena, Richard and Hoxey[1] based on the k-ε model proposes that wind speed and turbulence of the inflow boundary be in accordance with the transport equation for k and ε, but Hargreaves and Wright[2] pointed out there are certain errors in it. Then Yi Yang and Ming Gu[3] proposed a new inflow boundary condition and acquired the mathematical expression of k and ε through the transport equation of k and ε based on the turbulent flow balance and the standard k-ε model, but Ya Zhang and Shuyan Liu[4] pointed out that k-ε model is a simple mode which based on the Boussinesq eddy viscosity hypothesis, which is hard to reflect the anisotropic features on many kinds of flow conditions, and the better method is to directly resolve the transport equations varied on Reynolds Stress, in a word, to adopt the RSM model. Feng Xu and Jinping Ou[5] researched the unsteady flow of the square cylinder using the RSM model and the k-ε model and resulted that the RSM model is better performed in anticipating the boundary layer and the shear flow around the square cylinder. K-ω model can be applied to the wall constraints flow and the free shear flow, but this model mainly focus on low Reynolds number, compressibility and shear flow, and major error will occur for the flow around the bluff body with high Reynolds number. Wei Yang and Yong Quan[6] carried out the numerical simulation and experimental research on the wind load of low-rise buildings based on the k-ω model and found that this model have a huge influence on the results through comparison. The longest calculation time among several turbulence flow models needs higher computers' properties when Large Eddy Simulation

(LES) model is used. Richards and Younis[7] pointed out that different boundary conditions will lead to sizable deviation of the calculation results, especially in the areas of near the wall boundary. On the basis of extensive research, the turbulent kinetic energy 'K', turbulent dissipation rate 'ε' and the inlet velocity 'u' as user defined function (UDF) are added into the inlet boundary, which constitute a new type of ABL to simulate the flow around the three-dimensional high-rise buildings.

**Numerical method and physical models**

The Reynolds stress model is adopted in this paper, which abandoned the Boussinesq eddy viscosity hypothesis, thus directly establishes the differential equation of Reynolds stress and simultaneously solves the Reynolds average equation. The complete Reynolds stress model consists of 12 partial differential equations: three momentum equation, a continuity equation of the mean motion, six Reynolds stress equations, a ε equation and a k equation. The continuity equation and the momentum equation for average motions of turbulent flows are as followed:

$$\frac{\partial u_i}{\partial x_i} = 0 \tag{1}$$

$$\frac{\partial(\rho u_i)}{\partial t} + \frac{\partial}{\partial x_j}(\rho u_i u_j) = -\frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_i}\left(\mu \frac{\partial u_i}{\partial x_j} - \rho \overline{u_i' u_j'}\right) + S_i \tag{2}$$

where $u_i$ is the component of the fluid infinitesimal body in the velocity vector field towards the $i$ direction ($i = 1,2,3$. 1 indicates the flow direction, 2 and 3 indicate direction of perpendicular to the flow direction), $\rho$ is the air density, p is the wind pressure, $S_i$ is the source term of $u_i$, The Reynolds stress transport equation after dimensional analysis is as following:

$$\frac{\partial\left(\rho \overline{u_i' u_j'}\right)}{\partial t} + \frac{\partial\left(\rho u_i \overline{u_i' u_j'}\right)}{\partial x_k} = \frac{\partial}{\partial x_k}\left(\frac{\mu_i}{\sigma_k}\frac{\partial \overline{u_i' u_j'}}{\partial x_k} + \mu \frac{\partial \overline{u_i' u_j'}}{\partial x_k}\right) - \rho\left(\overline{u_i' u_k'}\frac{\partial u_j}{\partial x_k} + \overline{u_j' u_k'}\frac{\partial u_i}{\partial x_k}\right)$$
$$-C_1\rho\frac{\varepsilon}{k}\left(\overline{u_i' u_j'} - \frac{2}{3}k\delta_{ij}\right) - C_2\left(P_{ij} - \frac{1}{3}P_{kk}\delta_{ij}\right) - \frac{2}{3}\rho\varepsilon\delta_{ij} \tag{3}$$

where $C_1 = 1.8$, $C_2 = 0.60$, $P_{ij}$ is the item generated by shear stress, $\delta_{ij}$ is the tensor notation of " Kronecker delta ", under the condition that $i = j$ and $\delta_{ij} = 1$, otherwise $i \neq j$, $\delta_{ij} = 0$. As for RSM, the equation of turbulence kinetic energy k and the dissipation rate $\varepsilon$, satisfy their respective conservation equations, which produces :

$$\frac{\partial(\rho k)}{\partial t} + \frac{\partial(\rho k u_i)}{\partial x_i} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_i}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] + \frac{1}{2}\left(P_{ij} + G_{ij}\right) - \rho\varepsilon \tag{4}$$

$$\frac{\partial(\rho\varepsilon)}{\partial t} + \frac{\partial(\rho\varepsilon u_i)}{\partial x_i} = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_i}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x_j}\right] + C_{1\varepsilon}\frac{1}{2}\left(P_{ij} + C_{3\varepsilon}G_{ij}\right) - C_{2\varepsilon}\rho\frac{\varepsilon^2}{k} \tag{5}$$

where $G_{ij}$ is buoyancy-produced term, $G_{ij} = 0$; $C_{1\varepsilon}$, $C_{2\varepsilon}$, $C_\mu$, $\sigma_k$ and $\sigma_\varepsilon$ are model constants for incompressible fluid, which are usually assigned the values 1.44, 1.92, 0.09, 0.82 and 1.0. The inlet boundary is connected with the UDF compiled in the equations (6) (7) and (8) to form a new type of boundary, which the inlet velocity, turbulent kinetic energy and turbulent dissipation rate are as follows:

Eq. (6) (7) and (8) are quoted from the paper by Wei Yang, Yong Quan [6]. $u_1$ is a function related with the height above ground z, $z_o$ is the roughness length, the related parameters Ks and Cs

$$u_1 = \frac{u_*}{\kappa}\ln\left(\frac{z+z_0}{z_0}\right), u_2 = 0, u_3 = 0 \tag{6}$$

$$K = \frac{u_*^2}{\sqrt{C_\mu}}\sqrt{C_1 \ln\left(\frac{z+z_0}{z_0}\right) + C_2} \tag{7}$$

$$\varepsilon = \frac{u_*^3}{\kappa(z+z_0)}\sqrt{C_1 \ln\left(\frac{z+z_0}{z_0}\right) + C_2} \tag{8}$$

are derived from the paper of Blocken B, Stathopoulos[8]. $u_*$ is the friction velocity; κ is the von Karman constant of 0.42; C1, C2, Cμ are model constant usually assigned with the values -0.17,1.62 and 0.028. Model 1 as follows is to verify the accuracy of the atmospheric boundary layer conditions. In addition, as for the velocity, the turbulent kinetic energy and the turbulent dissipation rate is validated. Model 2 research on the flow around the high-rise buildings based on the conclusions of model 1.

## Numerical examples and analysis

**Model 1.Cavity model** There is no obstacle inside of the model, which primarily verifies the correctness of the UDF compiled above. The size of calculation domain is L×B×H=12m× 1.8m×1.8m, meanwhile, the L, B and H are respectively corresponds to the x, y and z axis. Structured grid is adopted in this model. The height of first mesh layer above the ground is set as 0.01m, and the vertical growing factor of mesh point is 1.06. The mesh size in horizontal and lateral direction is uniform, which is 0.1m. The total grid number is 181440. The RSM model and constant algorithm are adopted calculation. The computational set the SIMPLEC algorithm for pressure-velocity coupling, and the Second Order Upwind are adopted for the turbulent kinetic energy, turbulence dissipation rate, momentum and pressure. The convergence criteria of the scaled residuals for all components and the continuity equation are set as $10^{-6}$. The side faces and upper face of computational domain are set as freeslip. The ground surface is set as Wall. Inlet boundary is set as inlet velocity, which compile with the UDF. Outlet boundary is set as pressure-outlet. The reference mean wind speed $U_H$ is 10m/s at the height of one meter.

The calculation results are shown in Fig.1 and Fig.2, which compared with the SKE2 conclusion in quotation[3], the results of the inlet velocity, the outlet velocity and turbulent dissipation rate are good agreement. It verifies the rationality of the boundary settings and the accuracy of the UDF.

**Model 2.Models for flow around buildings** This model computational domain is the same as that of the model1.But the model 2 has a building inside, which size is L×B×H=0.2m×0.2m×0.8m, and the distance between the building's windward side and the inlet boundary is 1.5m, the distance between the leeside and the outlet boundary is 10.3m, meanwhile, the size from the building sides to the flow field sides is 0.8m respectively, the pttern is shown in Fig.3. Partitioned structured grid is adopted in the model 2 and the grid number is 455600. The computational set the SIMPLEC algorithm for pressure-velocity coupling, and the Second Order Upwind are adopted for the turbulent kinetic energy, turbulent dissipation rate, momentum and pressure. Unsteady algorithm is adopted calculation. The convergence criteria of the scaled residuals for all components and the continuity equation are set as $10^{-6}$. The boundary conditions are the same as that of the model1. In

addition, the wall of the building is regarded as non-sliding wall, among which the $K_s$=0 and $C_s$=0.5.

The across wind force power spectral curve obtained by fast fourier transform is shown in Fig.4, from which we can observe the spectral peak frequency when frequency conversion nB/U is about 0.1. The dimensionless converting frequency nB/U is used as the horizontal axis, n is the frequency (Hz as the unit), U is the gradient wind, and dimensionless power spectrum $nS(n)/\sigma^2$ is set as vertical axis and $\sigma^2$ is the square value of a cross-wind fluctuating wind speed. According to the Fig.4, which compared with the experimental data of the wind tunnel in quotation[9], when $\sqrt{H/BL}=4$, $L/B=1$, the result well matches the data. Hence, the accuracy of the numerical simulation is verified. Besides, acquired from the across wind force power spectral curve, it is equal to the predominant frequency of the vortex shedding, in a word, the Strouhal number. Therefore, the instantaneous development of the vortex can be obtained in one period T, is shown in Fig.5 (a), (b), (c) and (d).

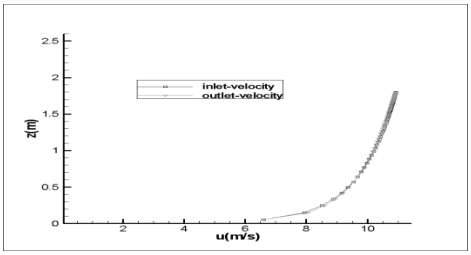

Fig.1 Velocities of inlet and outlet

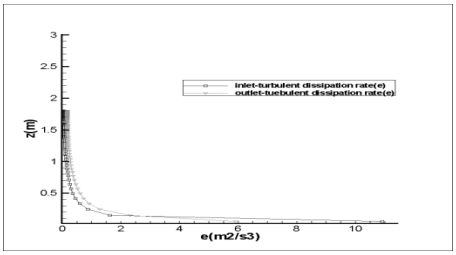

Fig.2 Turbulent dissipation rate of inlet and outlet

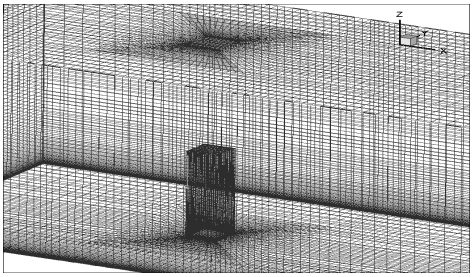

Fig.3 Partial enlarged drawing of building model

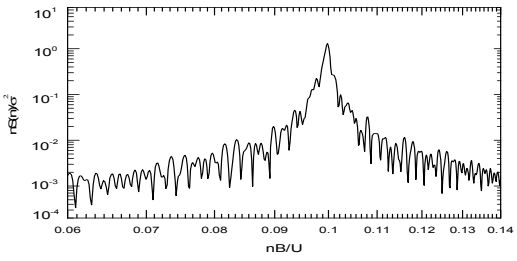

Fig.4 Across-wind force power spectra

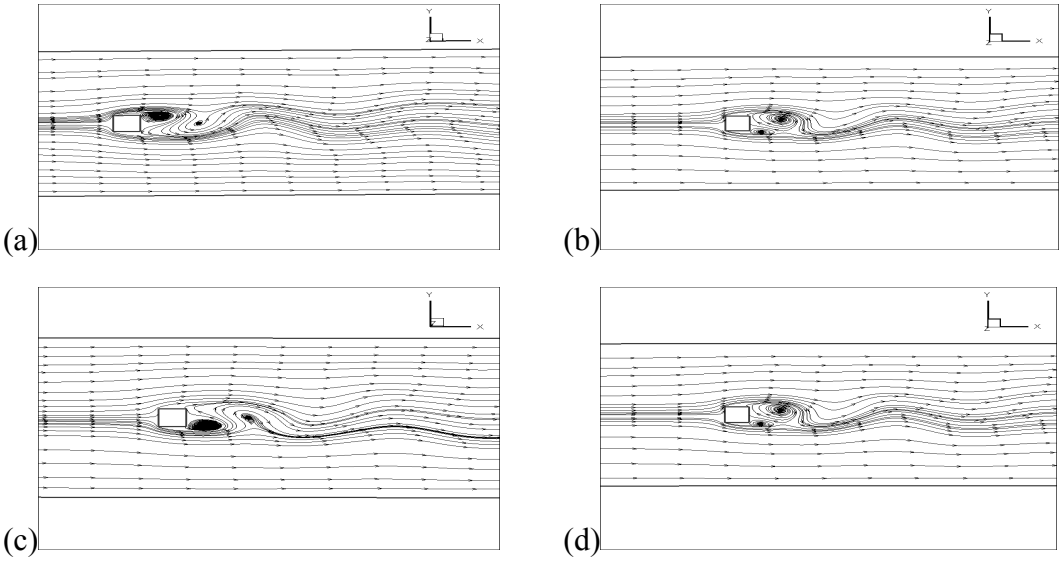

Fig.5 Instantaneous streamlines at z=0.2m (a) t=1/4T, (b) t=2/4T, (c) t=3/4T, (d) t=4/4T.

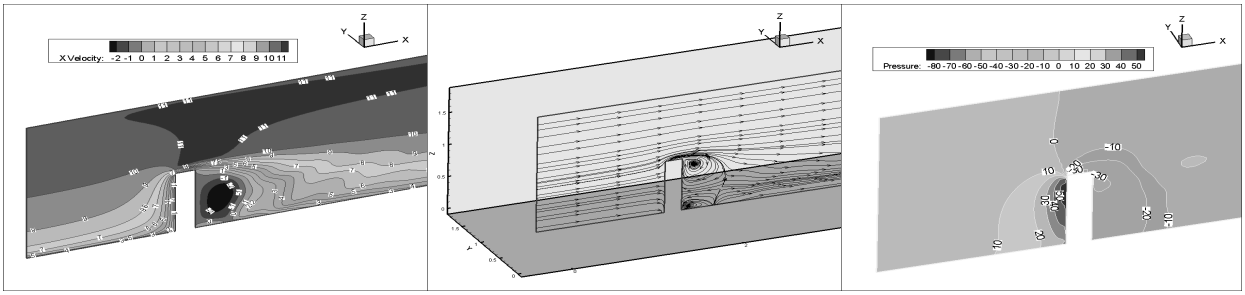
As can be seen from the Fig.6 (a) (b) and (c), along with the flow of the wind, close to the windward side of the building, the wind began to weaken and bypass the building's sides and superstructure, at the moment, the negative wind velocity of the wind speed at the top corners of the building and the formation of large eddy in the leeward side of the building occurs, which generates vortex and results in the occurrence of the negative pressure zone on the back of the building. With the further flow of the wind, the regular off-vortex phenomenon appears in the leeward sides of the building, which verifies that turbulence is relatively active in this region.



(a) (b) (c)

Fig.6 Instantaneous flow pattern at y=0.9m (a) X-velocity (b) Streamline (c) Pressure

## Conclusions

(1) Through the calculation for the cavity model, the validity of the boundary conditions established by the Eq. (6) (7) (8) is verified. Meanwhile, the inlet and outlet boundary speed and the turbulent kinetic energy dissipation rate graph verify the rationality of the Reynolds stress model (RSM) combined with the boundary conditions.

(2) Peak spectral frequency of wind power spectral curve well matches the converting frequency obtained by the wind tunnel experimental of the quotation [9], which is about 0.1, thus verifies the feasibility of the new boundary conditions combined with RSM for flow around the three-dimensional high-rise buildings.

[a]lusgsh@yandex.ru, [b]ag-kolesnikov@mail.ru

**Keywords:** shallow shells, bearing capacities, nonlinearity, critical force, stress.

**Abstract.** Bearing capacities and operating characteristics cover of a building deteriorate since time. Reconstruction of shallow shells cover by increase of their thickness in the center or at the edge. Critical force and stress of shell are considered with the geometric nonlinearity consideration. Vertical static loading and various types of a fixing are investigated. The method allows to describe various forms of shells with defects/

## Introduction

When operating shells coatings possible defects by corrosion, unplanned influences and other's reason. It leads to emergence of inadmissible deflections of a cover, reduction of bearing capacity, change of its form. Recovery of characteristics possibly by changing of the cross-sectional area of a construction along it generating line.

The description of a new form of a middle surface of shallow shells acquired owing to accumulation of defects, it is possible to present by function with the set parameter of a form $\xi_0$ and the set size of raises $f_0^1$ [1] different from initial value at a size of vertical movements received in use (Fig. 1).

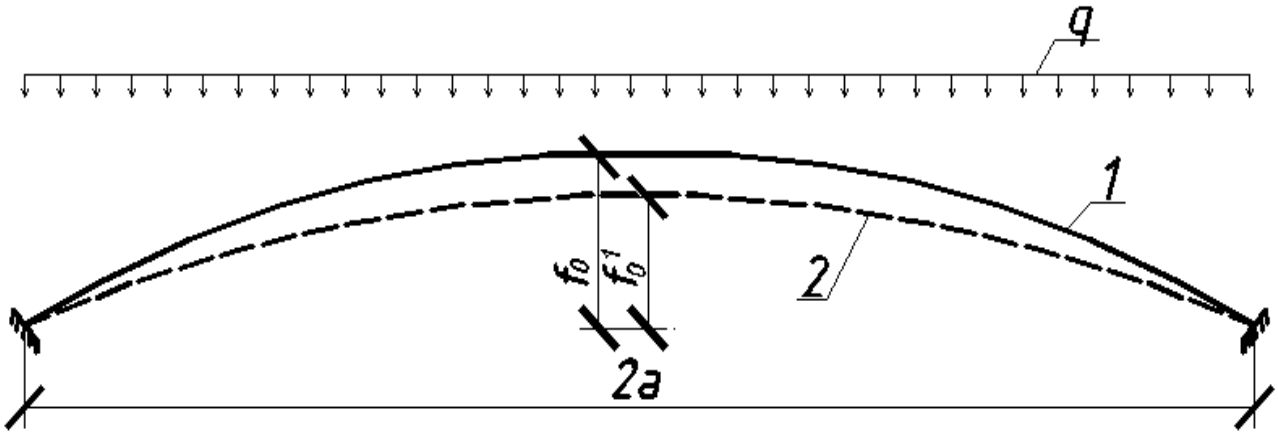

Fig. 1 - Possible changes of a form of a middle surface of shallow shell (a section along an axis x): 1-initial form of shallow shell, 2 – a form of shallow shell owing action uniform the distributed loading and accumulation of defects

## Problem statement

If it is required to restore bearing capacity of shell, it is possible to execute search of a new form of shell, having accepted its thickness of a variable along generating line, but a form of a median surface fixed. Changes for thickness of shells from the center to edge is defined as [2,3]

$$h(x,y) = t\left(1+\kappa\left(\frac{x}{a}\right)^{2\eta}\right)\left(1+\kappa\left(\frac{y}{b}\right)^{2\eta}\right). \quad (1)$$

Where

$t = \frac{h_0}{f}$ - the relative thickness of the shell,

$f$ - rise of arch in the center of the shell,

$a, b$ - dimensions in plan,

$\eta$ - changes in the shape parameter of the shell thickness,

$k$ - parameter responsible for the ratio of the shell thickness at the edge and center (when $k < 0$ the thickness of the shell in the center more than at the edge; when $k > 0$ - shell thickness in the center is smaller than at the edge; when $k = 0$ - shell thickness is constant along middle surface),

$h_0$ - thickness of the shell in the center (Fig. 2).

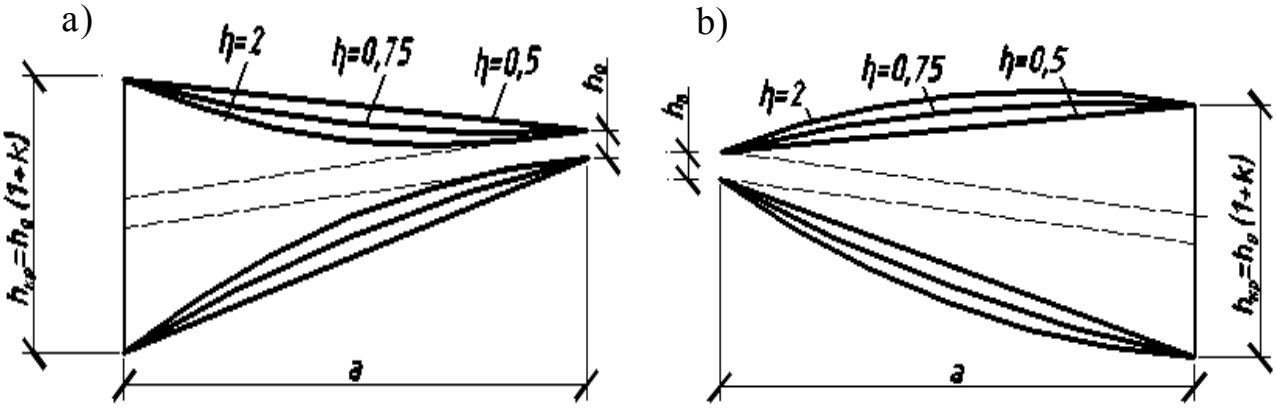

Fig. 2 – Distribution of the shell thickness: a) when k>0; b) when k<0.

The problem of restoration of bearing capacity can be formulated as:

$$\begin{cases} V(k,t,\eta) \to V_{min}, \\ p(k,t,\eta) \geq p_0, \\ \sigma(k,t,\eta) \leq \sigma_0, k \in G, t \in G, \xi \in G, \eta \in G. \end{cases} \quad (2)$$

$$G = \left\{ \begin{array}{l} \eta : 0{,}5 < \eta_y < 2, y = \overline{1,l}; \\ t : 0{,}001 < t_j < 0{,}1, j = \overline{1,m}, k : -1 < k_u < \left(\frac{1}{10}\sqrt{\frac{2a}{h}-1}\right), u = \overline{1,r} \end{array} \right\} \quad (3)$$

It is required to find such distribution of thickness of fixed form shell that the volume of an added material was minimum, when stability and durability conditions performed. Provided mechanical characteristics of a material consider decrease in bearing capacity owing to accumulation of defects.

At change of thickness of shell it is possible to achieve effect of change a form of a median surface of shell (Fig. 3), at the fixed rise of arch.

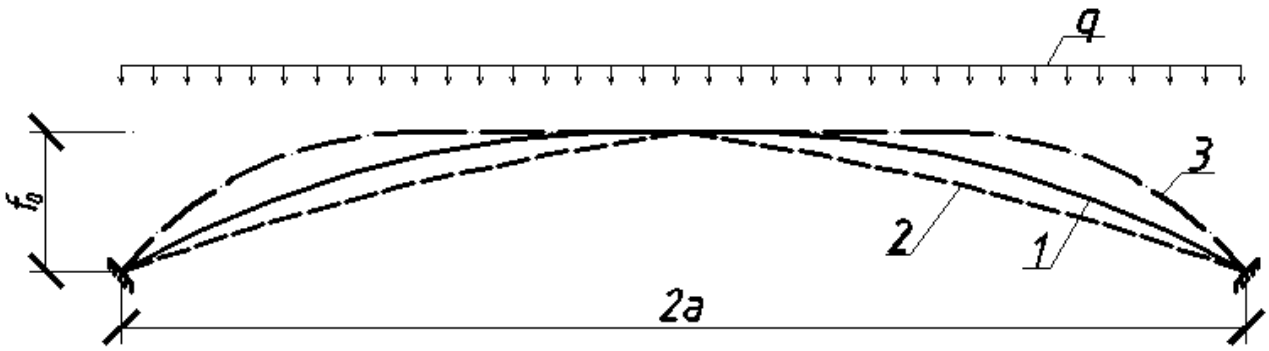

Fig. 3 – Possible changes of a form of shell median surface caused to change of its thickness: 1-initial form of shell, 2 – form of shell median surface (form parameter $\xi < 1{,}0$ ), 3 - form of shell median surface (form parameter $\xi > 1{,}0$ ).

**Solution of a task**

At restoration of bearing capacity it can be increased by increase in cross section (Fig.4).

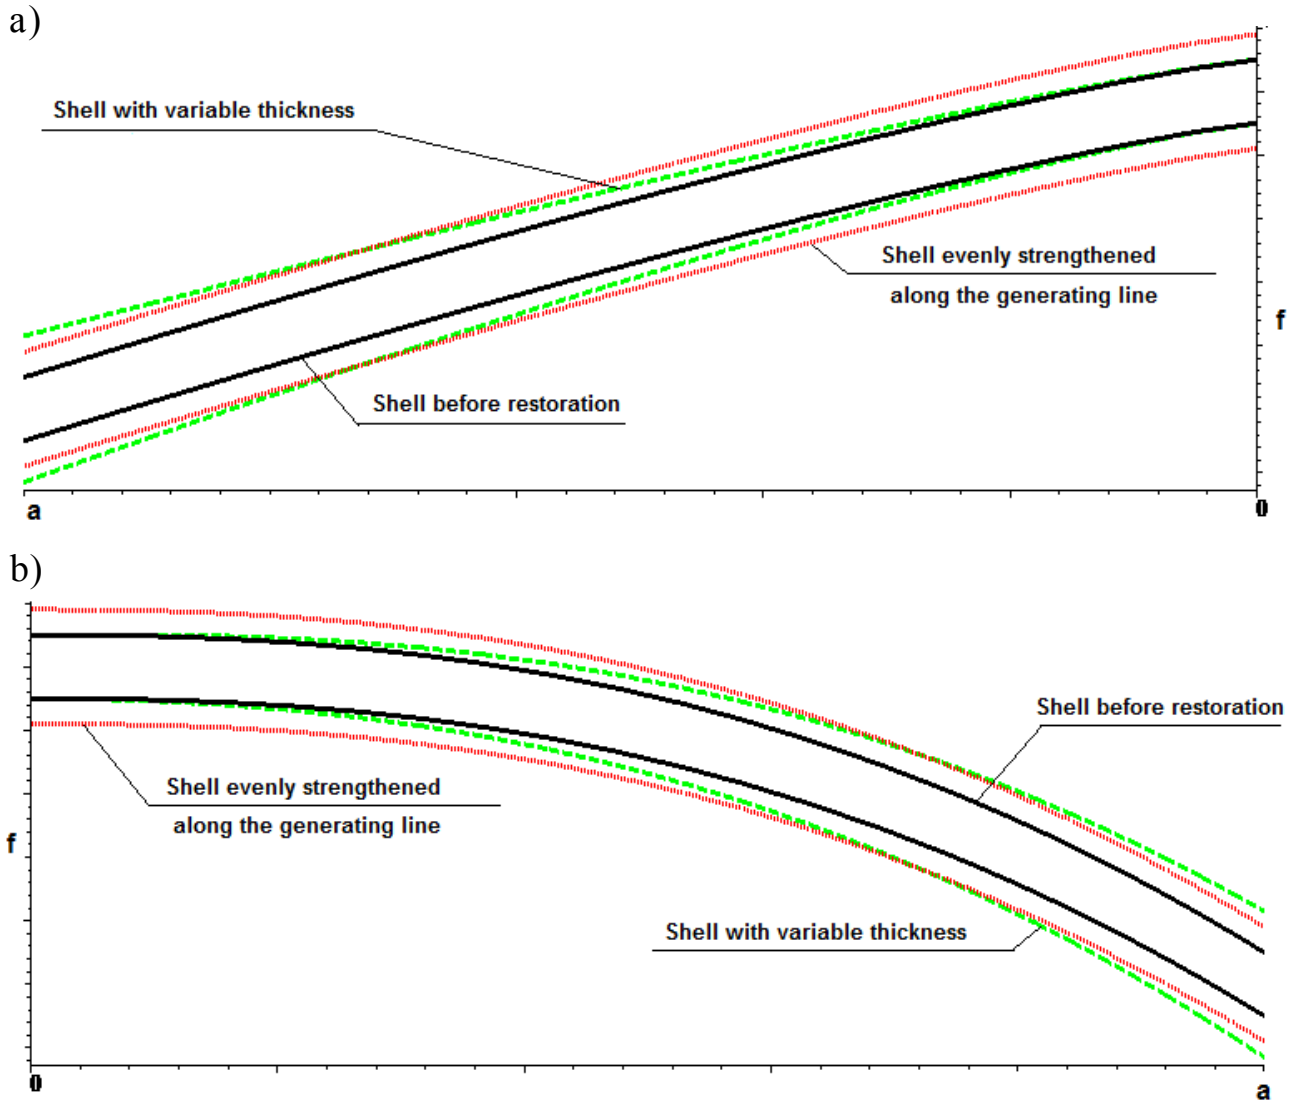

Fig. 4 – Forms of possible distribution of thickness of shell at reconstruction: a) for parameter of a shell's form $\xi < 1{,}0$ , b) for parameter of a shell's form $\xi > 1{,}0$ .

In this case restoration of shell's bearing capacity can be formulated as follows:

$$\begin{cases} V(k,t,\xi,\eta) \to V_{min}, \\ p(k,t,\xi,\eta) \ge p_0, \\ \sigma(k,t,\xi,\eta) \le \sigma_0, k \in G, t \in G, \xi \in G, \eta \in G. \end{cases} \quad (4)$$

$$G = \left\{ \begin{array}{l} \xi : 0{,}75 < \xi_i < 2, i = \overline{1,n}; \eta : 0{,}5 < \eta_y < 2, y = \overline{1,l}; \\ t : 0{,}001 < t_j < 0{,}1, j = \overline{1,m}, k : -1 < k_u < \left( \frac{1}{10} \sqrt{\frac{2a}{h} - 1} \right), u = \overline{1,r} \end{array} \right\}. \quad (5)$$

Algorithms of the solution of tasks are realized in the "Maple" environment. In both options of statement of tasks the decisions, allowing projecting rational strengthening of shells by change of their thickness are received [4,5]. Comparing spherical shells with constant thickness with projects of strengthening, in some cases due to rational distribution of thickness of a cover with defects it is possible to receive economy of a material to 35% at considerable reduction of weight of a design.

The offered technique, allows to put and solve problems of restoration of bearing capacity of shallow geometrically nonlinear shells due to optimum distribution of thickness at:

- restoration of demanded value of stress in a median surface of shell at restriction on value of used material volume;
- restoration of demanded value of critical loading at restriction on value of construction's material volume for any kinds of fixing;
- restoration of demanded value of stress in a median surface of shell at the set size of critical force and restriction on value of volume of used material;
- restoration of demanded value of critical loading at restriction on value of stress in cross sections of shell and construction's material volume for any kinds of fixing.

## Conclusion

The developed optimization algorithm of thickness distribution for restoration of bearing ability of geometrically nonlinear shallow shells can be used at restoration of bearing capacity and operational characteristics of shallow shells of coverings of buildings and constructions.

**Keywords:** Large-span roofs. Vibration under wind actions. Reduced order model

**Abstract.** Reduced order model was for the first time employed for the large-span structure by system identification approach. The structure's modal amplitudes are utilized to construct strain energy function of the system. A high fidelity finite element model is adopted to calculate modes and strain energy information to determine the unknown coefficients in the strain energy function. Wind-induced responses of a large-span structure were computed by the proposed method. The results were compared well with those obtained from the high fidelity finite element model and experiments. It proves that reduced order model is an effective way to compute large-span structure responses under wind actions when taking aero-elastic effects into account.

## Introduction

Wind-induced vibration of large-span structure shows a characteristic of fluid-structure interaction, i.e. aero-elastic effects. The aero-elasticity has a very significant effect on wind-induced vibration of large-span structure, and it is necessary to attach great importance. One of the key problems in numerical simulation is to establish the structural model of large-span structures, which decides complicity of the process and accuracy of the final results. Reduced model is very effective in establishing structural model and in recent years it is widely used in aeroelasticity. Various reduced models have been developed and the most commonly used is normal mode reduced modal methods[1], which have been used in the field of structural dynamics for many years. A lot of work has been done in linear system identification and great progress have been achieved. As far as nonlinear system identification is concerned, though research is being done and some progress has been made, many problems are still need to be solved. In recent work by Epureanu and Dowell, a multivariate, third order polynomial was used as the functional form for a nonlinear structural model [2]. Gabbay and Mehner et al. used polynomial functions whose coefficients were identified using strain energy data to model a microelectromechanical system[3]. Silverder et al. have used a Volterra series approach to identify linear and nonlinear aerodynamic systems[4].

The reduced model for nonlinear large-span structure is constructed by system identification of a high fidelity structural model. The strain energy of the system is written as a polynomial function of the structure's modal amplitudes. And the unknown coefficients of the polynomials are determined by modes and strain energy information calculated from a high fidelity finite element model. Wind-induced responses of a large-span structure are calculated using the proposed method.

## Reduced order aero-elastic equations

The general form of the aero-elastic system can be written in the following manner in terms of modal coordinates [5]

$$\vec{\Phi}^{\mathrm{T}}\vec{\mathrm{M}}\vec{\Phi}_{\ddot{\mathrm{q}}} + \vec{\Phi}^{\mathrm{T}}\vec{\mathrm{C}}\vec{\Phi}_{\dot{\mathrm{q}}} + \vec{\mathrm{F}}^{\mathrm{SE}}(\mathrm{q}) = \vec{\Phi}^{\mathrm{T}}\mathrm{F}^{\mathrm{P}} \tag{1}$$

Where the vector $\bar{\mathrm{u}}$ contains the structural nodal degrees of freedom, the matrix, $\vec{\mathrm{M}}$ is the mass matrix, $\vec{\mathrm{C}}$ is the damping matrix and $\vec{\mathrm{F}}^{\mathrm{P}}$ is the load vector due to the aerodynamic pressure.

The nodal degrees of freedom are expressed as a linear combination of the modes,

$$\vec{u} = \sum_{i=1}^{N_F} q_i(t)\vec{\varphi}_i \tag{2}$$

And the matrix $\vec{\Phi}$ contains the mode shape vectors $\vec{\varphi}_i$. Also, in Eq.(2) $q_i$ is the ith modal degree of freedom and $N_F$ is the total number of structural degrees of freedom. Note that now the force vector due to strain energy, $\widetilde{F}^{SE}$, is a function of the modal amplitudes $q_i$. In practice the summation in Eq.(2)is truncated at N modal degrees of freedom where N is a number much less than $N_F$.

Likewise the aerodynamic equations of motion can now be expressed as

$$\vec{A}_b\vec{\Gamma}_b^{n+1} = \vec{E}\vec{\Phi}\dot{\vec{q}}^{n+1/2} + \vec{E}\vec{d}\vec{\Phi}\vec{q}^{n+1/2} + \vec{\alpha} - \vec{A}_w\vec{I}_w^n \tag{3}$$

Where the matrix $\vec{d}\vec{\Phi}$ is the matrix of x derivations of the modal functions, $\vec{\Gamma}_b$ and $\vec{\Gamma}_w$ are vectors of large-span structure and airflow circulations respectively. The matrices $\vec{A}_b$ and $\vec{A}_w$ are the large-span structure and airflow influence coefficient matrices and the matrix E is the matrix of interpolation coefficients needed to transfer quantities from the finite element mesh to the aerodynamic mesh.

Now a functional form for the strain energy U in terms of the modal coordinates will be defined. Here a multivariate Lagrange polynomial is used. The form of this polynomial can be written as:

$$U = \sum_{i=0}^{M_1}\sum_{j=0}^{M_2}\sum_{k=0}^{M_3}\sum_{l=0}^{M_4}\cdots\sum_{o=0}^{M_N} A_{ijkl\ldots o}q_1^i q_2^j q_3^k \cdots q_N^o = \sum_{i=1}^{N_t} A_i\psi_i(q_1, q_2 \cdots q_N) \tag{4}$$

Where U is the strain energy functional for the system, the coefficients $A_i$ are found using a least squares fit of strain energy data generated using a finite element package and the $\psi_i$ are the Lagrange basis functions. The number of basis functions used, Nt is the product of the values M1,M2,…,MN.

**System identification process**

In order to compute coefficients in Eq.(4), the strain energy U must be computed for various out-of plane spatial distributions $u_Z(x,y)$. The structure is displaced to a static configuration $u_Z^i(x,y)$ determined by the prescribed modal amplitudes $q_j^i$:

$$\vec{u}_Z^i = \sum_{j=1}^{N} q_j^i\varphi_j \tag{5}$$

The strain energy for this ith configuration, Ui, is then computed by solving a nonlinear statics problem. In this paper, this was accomplished by using ANSYS.

Once all of the strain energy values have been calculated using the finite element model, the coefficients in Eq.(4) can be computed using a least square solution of the following set of linear equations:

$$\vec{A}\vec{x} = \vec{b} \tag{6}$$

Where the vector $\vec{b}$ contains the strain energy values for each individual configuration and the vector $\vec{x}$ contains the Nt polynomial coefficients. The marix $\vec{A}$ consists of the basis functions used in the polynomial expansion evaluated for each individual configuration.

**Numerical results**

Using the method developed above, results of wind-induced responses of a flat large-span roof in literature [6]are presented. Its geometry are depicted in Fig.1. Its thickness is 1mm, elastic modulus E=7.1×1010N/m2, its density ρ＝2420kg/ m3, Poisson's ratio γ＝0.31. Wind velocity are range from 8m/s to 12m/s and wind direction angle are from 0°～45° , increasing 15° at a time. The experimental results are also from the literature [6].

The high-fidelity structural finite element model constructed using ANSYS contained 869 thin shell bending elements, with 967 nodes and a total of 5802 degrees of freedom. The structural nonlinearities modeled include large rotation and stress-stiffening. In the reduced model, the values used for the Mi in Eq. (7) are:

$$M_i = 4, i \le 4$$
$$M_i = 2, i \rangle 4 \quad (7)$$

The number of individual values for each mode used for generating strain energy was (from mode 1 to mode 6): 9, 7, 7, 7, 5, 5. In the following results, if it is said four modes have been used to generate the strain energy, then there would be 9×7×7×7×5＝15435 configurations used.

Table1 gives comparison of acceleration mean square deviation for prescribed points on the roof using the first 6 modes, experimental results and ANSYS respectively at a flow velocity of 10m/s.

Tab.1 Comparison of acceleration mean square deviation for prescribed points using different methods（$m/s^2$）

| Wind direction angles \ Prescribed points | | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|---|
| 0° | Experimental | 0.80 | 0.60 | 0.30 | 0.90 | 0.60 |
| | ANSYS | 0.71 | 0.64 | 1.17 | 0.69 | 0.51 |
| | Reduced model | 0.59 | 0.57 | 0.97 | 0.60 | 0.59 |
| 15° | Experimental | 0.80 | 0.60 | 0.30 | 0.90 | 0.60 |
| | ANSYS | 0.94 | 0.65 | 0.97 | 0.76 | 0.76 |
| | Reduced order model | 0.79 | 0.54 | 0.81 | 0.62 | 0.90 |
| 30° | Experimental | 0.80 | 0.70 | 0.30 | 1.10 | 0.60 |
| | ANSYS | 0.65 | 0.51 | 0.87 | 0.83 | 0.66 |
| | Reduced order model | 0.47 | 0.42 | 0.63 | 0.62 | 0.82 |
| 45° | Experimental | 0.80 | 0.70 | 0.30 | 1.10 | 0.60 |
| | ANSYS | 0.74 | 0.57 | 1.24 | 0.85 | 0.54 |
| | Reduced order model | 0.56 | 0.46 | 0.92 | 0.60 | 0.74 |

From the table above, it can be seen that the results obtained using the reduced order model developed in this work tallied well with the results from the experiments and ANSYS. And the results from the reduced order model were more close to those using ANSYS. It illustrates that using reduced order model to construct structural model in simulating its wind-induced vibration of large-span structure is feasible and accurate.

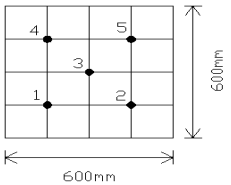

Fig.1Geometry of the flat large-span structure

Fig.2 shows plots of acceleration mean square of prescribed points 1 and 4 using various number of modes at wind azimuth of 0° at various flow velocities. Fig.3shows acceleration mean square of prescribed points 2 and 5 using various number of modes at wind azimuth of 30° at various flow velocities. Fig.4 gives acceleration mean square of prescribed point 3 at wind azimuth of 15° and 45° at various flow velocities.

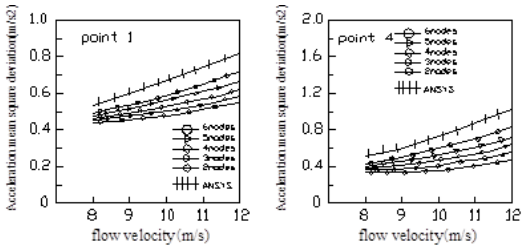

Fig.2 Acceleration mean square deviation of points 1 and 4 at wind azimuth of 0°

As seen from Fig.2 and Fig.3, for wind azimuth of 0° and 30° with various wind velocities, acceleration mean square obtained from reduced order models are compared well with those from ANSYS. With the increase of modes used, the system identification results are approximating to the results from ANSYS. As seen from figure 4, the simulation results are closer to those from ANSYS at wind azimuth 15° than 45°. Thus, more modes are required for more accurate results. In the example, 7 equations are required at most for the structure, 3 order less than using nonlinear finite element models, reducing 2 order the total computer hours, improving the computing efficiency as a result.

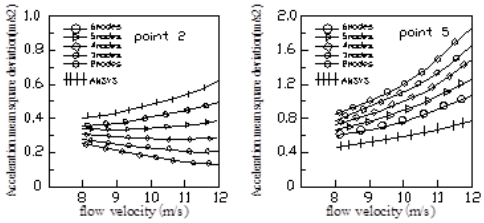

Fig.3 Acceleration mean square deviation of points 2 and 5 at wind azimuth of 30°

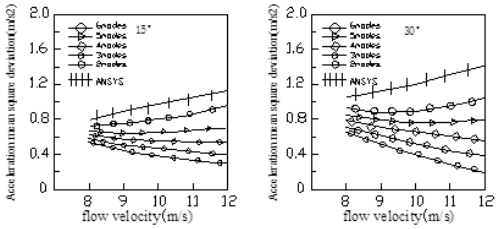

Fig.4 Acceleration mean square deviation of point 3 at wind azimuth of 15° and 45°

## Conclusions

For the first time, the reduced order model was introduced to construct nonlinear structural model in wind-induced vibration of large-span structure. The results of wind-induced vibration of large-span structure obtained using the reduced order model were compared with those from experiments and from ANSYS model. We can reach the following conclusions:

(1)As the numbers of modes used in reduced order model increase, the system identification results would be increasingly accurate. As the wind direction angle increases, numbers of modes need increase to obtain increasingly accurate results.

(2) (1) Structural reduced order model and its system identification is feasible and accurate in wind-induced vibration of large-span structure considering aero-elasticity, with higher efficiency.

**Keywords:** Pseudo-spectral method, domain decomposition method, elastostatic problem, unit decomposition principle

**Abstract.** It presents the coupling of Pseudo-spectral method (PS) and domain decomposition method (DDM) for the elastostatic problem. First, the original problem is decomposed into several sub-problems by DDM. Next combining the advantage of easy programming and high accuracy of Pseudo-spectral method, we can solve these sub-problems in parallel by PS. Finally the global numerical solution is obtained by the partition of unity approximation. Some numerical experiments illustrate the effectiveness and accuracy of our method.

## Introduction

Domain decomposition method (DDM) [1] is one of most effective methods used in large-scale numerical computation. DDM has the advantage that, through decomposition of the area, it can reduce the scale of the problem, and researcher can also use different numerical method according to the characteristics of corresponding problems in different regions, so to achieve a parallel computation of the engineering problems and improve the computation speed.

The pseudo-spectral method is an innovative meshless method with the advantages of simple implementation and high precision, it gradually gains much attention. Based on the research of B.Fornberg and D.Gottlieb et al, Trefethen firstly gave a comprehensive overview of the pseudo-spectral method in the literature [2]. Then, Fasshauer proposed pseudo spectral method based on radial basis function[3], which enhances the applicability of the pseudo-spectral method, and breaks the bottleneck that the method can only applied to solve the problem in regular region.

We propose the coupling of pseudo-spectral method and domain decomposition method, due to the characteristics of each method. This paper is divided into two sections. Section 1 gives the mechanical description of the elastostatic problem, with detailed description of the main coupling idea of the pseudo-spectral method and domain decomposition method (PS-DDM); In Section 2, it presents the numerical examples of the classic cantilever beam, the experimental results show that the coupling method has the advantages of high accuracy and computing speed.

## The coupling of PS and DDM for the Elastostatic Problems

We consider an linear elastostatic problem[4] defined on the region $\Omega \in R^n$ with boundary $\Gamma$, assume that $\Gamma$ is composited by the displacement boundary $\Gamma_D$ and force boundary $\Gamma_t$, $\hat{\mathbf{u}}$ represents a prescribe displacement boundary conditions, $\hat{\mathbf{t}}$ indicates a prescribe traction on the force boundary, $\mathbf{f}$ expresses the density of body force . The elastic body is in the equilibrium state. Three classic equations are: Equilibrium equation $div\ \boldsymbol{\sigma} + \mathbf{f} = \mathbf{0}$, in $\Omega$. Constitutive equation $\boldsymbol{\sigma} = \mathbf{C}\boldsymbol{\varepsilon}$, in $\Omega$. Relationship of strain tensor and displacement tensor: $\boldsymbol{\varepsilon}(\mathbf{u}) = \left(\nabla\mathbf{u} + (\nabla\mathbf{u})^T\right)/2$. Here $\boldsymbol{\sigma} = (\sigma_{ij})_{d\times d}$ is stress tensor, $\boldsymbol{\varepsilon} = (\varepsilon_{ij}(\mathbf{u}))_{d\times d}$ is strain tensor, $\mathbf{C}$ is elasticity tensor. Boundary conditions on displacement boundary $\Gamma_D$ and force boundary $\Gamma_t$ are given as below:

$$\mathbf{u} = \hat{\mathbf{u}}, \quad on\ \Gamma_D, \qquad \boldsymbol{\sigma}\mathbf{v} = \hat{\mathbf{t}}, \quad on\ \Gamma_t.$$

Here $\mathbf{v}$ stands for the unit outward norm vector. We can reorganize the above problem as follows:

$$\begin{cases} \mathbf{Lu}+\mathbf{f}=\mathbf{0} & in\ \Omega, \\ \mathbf{u}=\hat{\mathbf{u}} & on\ \Gamma_D, \\ \mathbf{Tu}=\hat{\mathbf{t}} & on\ \Gamma_t. \end{cases} \tag{1}$$

Where $\mathbf{L},\mathbf{T}$ denote differential operators.

PS method is an efficient method for solving partial differential equations, it has the advantage of easy programming and high accuracy, but is rarely involved in large-scale computation. DDM is one of the most effective methods of large-scale scientific computing. Therefore we hope that the coupling of PS method and DDM can be used to solve the problem (1), that is, region $\Omega$ is divided into several sub-regions $\{\Omega_i\}$, and then PS method is used in parallel to solve the corresponding PDEs defined on these sub-regions. In the following we give the introduction of PS method and the process of the coupling of PS-DDM in detail.

We consider the following PDE problem,

$$\begin{cases} Lu=f & in\ \Omega, \\ Bu=g & on\ \partial\Omega\setminus\Gamma, \\ u=\overline{u} & on\ \Gamma. \end{cases} \tag{2}$$

here $L,B$ denote differential and boundary operators respectively. We use approximate function:

$$u^h(\mathbf{x})=\sum_{j=1}^{N} c_j\Phi_j(\mathbf{x}),\ \mathbf{x}\in\Omega, \tag{3}$$

where $c_j, j=1,\cdots,N$ are unknown coefficients, $\Phi_j, j=1,\cdots,N$, are certain basis functions.

By inserting (3) into the PDE and boundary conditions and forcing these equations to be satisfied at the collocation points $\mathbf{x}_i, i=1,\ldots,N$, we have

$$\mathbf{A}_L\mathbf{c}=\mathbf{f},\ \mathbf{A}_B\mathbf{c}=\mathbf{g},\ \mathbf{A}_D\mathbf{c}=\overline{\mathbf{u}}. \tag{4}$$

Where $\mathbf{A}_L=\left(L\Phi_j(\mathbf{x}_i)\right)_{N_I\times N}, \mathbf{A}_B=\left(B\Phi_j(\mathbf{x}_i)\right)_{N_B\times N}, \mathbf{A}_D=\left(\Phi_j(\mathbf{x}_i)\right)_{N_D\times N}$, $\mathbf{c}=(c_1,\cdots,c_N)^T$ is unknown coefficient vector, $N_I$ denotes the number of nodes in the interior of $\Omega$, $N_B$, $N_D$ respectively denotes the number of nodes on the boundary $\Gamma$ and $\partial\Omega\setminus\Gamma$, here $N=N_I+N_B+N_D$. $\mathbf{f},\mathbf{g}$ and $\overline{\mathbf{u}}$ respectively stands for the vector composed by the values of $f$, $g$ and $\overline{u}$ at the collocation points.

Here $\mathbf{u}=(u_1,\cdots,u_N)^T$ is discrete function vector, from (3) we can obtain $\mathbf{u}=\mathbf{Ac}$, where $\mathbf{A}=\left(\Phi_j(x_i)\right)_{N\times N}$. Assuming that $\mathbf{A}$ is invertible, we can obtain $\mathbf{c}=\mathbf{A}^{-1}\mathbf{u}$. Then the discretized linear systems (4) becomes

$$\begin{pmatrix} \mathbf{A}_L \\ \mathbf{A}_B \\ \mathbf{A}_D \end{pmatrix}\mathbf{A}^{-1}\begin{pmatrix} \mathbf{u}_I \\ \mathbf{u}_B \\ \mathbf{u}_D \end{pmatrix}=\begin{pmatrix} \mathbf{f} \\ \mathbf{g} \\ \overline{\mathbf{u}} \end{pmatrix}. \tag{5}$$

Where $\mathbf{u}_I$ collects the values in the interior of $\Omega$, $\mathbf{u}_B$ and $\mathbf{u}_D$ collect the values on the boundary $\Gamma$ and $\partial\Omega\setminus\Gamma$. Therefore, $\mathbf{u}$ is obtained by solving linear system (5).The Process of the coupling of PS-DDM method is as below:

Step 1: Domain Decomposition and set the initial value

Assuming that $\Omega\subset R^n, n=1,2,3$, we construct two artificial boundarys $\Gamma_1,\Gamma_2$, decomposed $\Omega$ into two sub-regions $\Omega_1,\Omega_2$, and $\Omega_1\cap\Omega_2\neq\phi$. Then we arbitrarily select the initial values $\mathbf{u}_1^0,\mathbf{u}_2^0$ on the artificial boundary, let $k:=0$, $\varepsilon>0$.

Step 2: Obtain $\mathbf{u}_1^n,\mathbf{u}_2^n$ via parallel computing the following systems using PS method in the sub-regions $\Omega_1,\Omega_2$

$$\begin{cases} \mathbf{L}\mathbf{u}_1^n + \mathbf{f} = \mathbf{0} & in\ \ \Omega_1, \\ \mathbf{u}_1^n = \hat{\mathbf{u}} & on\ (\partial\Omega_1 \cap \Gamma_D)\backslash\Gamma_1, \\ \mathbf{T}\mathbf{u}_1^n = \hat{\mathbf{t}} & on\ (\partial\Omega_1 \cap \Gamma_t)\backslash\Gamma_1, \\ \mathbf{u}_1^n = \mathbf{u}_2^{n-1} & on\ \ \Gamma_1. \end{cases} \quad \begin{cases} \mathbf{L}\mathbf{u}_2^n + \mathbf{f} = 0 & in\ \ \Omega_2, \\ \mathbf{u}_2^n = \hat{\mathbf{u}} & on\ (\partial\Omega_2 \cap \Gamma_D)\backslash\Gamma_2, \\ \mathbf{T}\mathbf{u}_2^n = \hat{\mathbf{t}} & on\ (\partial\Omega_2 \cap \Gamma_t)\backslash\Gamma_2, \\ \mathbf{u}_2^n = \mathbf{u}_1^{n-1} & on\ \ \Gamma_2. \end{cases} \tag{6}$$

Step 3: If $\max\left(\left\|\mathbf{u}_1^n - \mathbf{u}_1^{n-1}\right\|, \left\|\mathbf{u}_2^n - \mathbf{u}_2^{n-1}\right\|\right) < \varepsilon$ ,stop iteration, otherwise $k = k+1$, return to Step 2.

Step 4: Using partition of unity approximation to obtain global approximation function [7]

At the end of iteration, two local approximate functions $\mathbf{u}_1^h(\mathbf{x}), \mathbf{u}_2^h(\mathbf{x})$ are finally obtained in the sub-regions $\Omega_1, \Omega_2$. In order to get the global approximate function in the entire region, partition of unity approximation approach is used here. we define compactly supported functions $\omega_i(\mathbf{x})$ in each sub-region, which should satisfy the partition of unity condition, namely $\sum_{i=1}^{2} \omega_i(\mathbf{x}), \mathbf{x} \in \Omega$. Then the global approximation function can be represented as $\mathbf{u}^h(\mathbf{x}) = \sum_{i=1}^{2} \omega_i(\mathbf{x})\mathbf{u}_i(\mathbf{x})$. There are many kinds of compactly supported functions, such as MLS shape functions, finite element shape functions, Shepard function, etc. In this paper, we use $\omega_i(\mathbf{x})$ as below:

$$\omega_i(\mathbf{x}) = \begin{cases} \kappa_i(\mathbf{x}) & \mathbf{x} \in \Omega_1 \cap \Omega_2\ , \\ 1 & \mathbf{x} \in \Omega_i \setminus (\Omega_1 \cap \Omega_2)\ , \\ 0 & \mathbf{x} \in \Omega \setminus \Omega_i\ . \end{cases}$$

where $\kappa_i(\mathbf{x})$ satisfies： $\sum_{i=1}^{2} \kappa_i(\mathbf{x}), \mathbf{x} \in \Omega_1 \cap \Omega_2$.

**Numerical experiments**

We consider the problem of cantilever beam, the left end is fixed, and an external force $P$ is applied at the right end, this will cause beam bent downward and deformed. Here, the beam length $L = 12m$ , The beam width $D = 2m$ , pressure at the end $P = 6N$ , Young's modulus $E = 10^4 Pa$ , Poisson's ratio $\mu = 1/3$ , rotational inertia $I = D^3/12$ . This problem has an analytical solution [4, 5].

(1) Standard RBF-PS method. $11 \times 25$ uniform collocation points are chosen as Fig.1, (including the inner and boundary points). And the basis function is the Gaussian shape function $\Phi(r) = e^{-(\varepsilon r)^2}$ , where $\varepsilon$ is 0.15. Fig.2 shows the curved figures obtained by RBF-PS and analytical solution, it reveals that the solution via RBF-PS method completely coincides with the analytical solution.

The results are sensitive to the choose of parameter, Fig3 ,Fig 4 respectively show parameter - error figure based on Gaussian shape function and MQ shape function( $\Phi(r) = \sqrt{r^2 + c^2}$ ), which intuitively illustrate the impact of the parameter on the result.

(2) RBF-PS and DDM method. Fix a mesh step $h$ , then two sub-regions are $\Omega_1 = [0, L/2 + 2h] \times [-D/2, D/2]$, $\Omega_2 = [L/2 - 2h, L] \times [-D/2, D/2]$. Here we take $h = L/16$, Fig.5 shows the nodes distribution in two sub-regions, as we can see, the middle part is overlapping region.

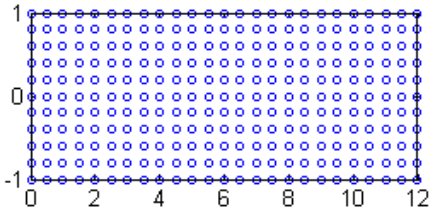

Fig. 1 Node distribution

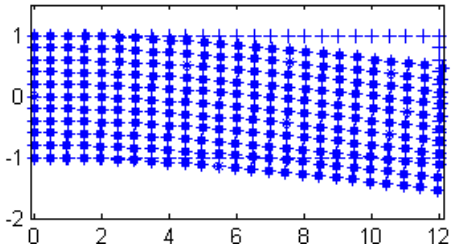

Fig. 2 Curved figures by RBF-PS and analytical solution (' o 'denotes RBF-PS solution, '* ' denotes analytical solution)

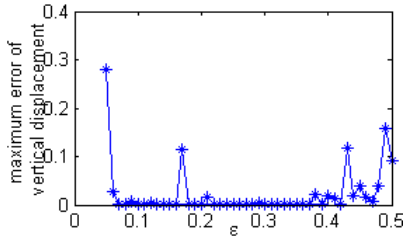

Fig.3 Parameter-maximum error using Gaussian-based PS approach

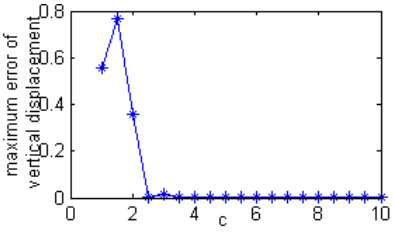

Fig.4 Parameter-maximum error using MQ-based PS approach

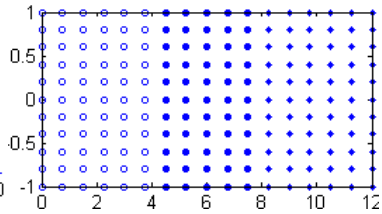

Fig. 5 Nodes distribution

MQ shape function ($c=3.1$) is selected in the two sub-regions, and set $\kappa_i(x)=0.5,\ i=1,2$. When the number of iterations is 129, displacement error has reached $10^{-4}$. As shown in Table1, we can find out that PS-DDM method ($c=3.1$) obtains more precise result than Standard RBF-PS method ($c=3.1$), while it has almost the same accuracy as Standard RBF-PS method under the optimal parameter.

Table 1 Results via coupling method of PS-DDM and Standard RBF-PS method

| | Max displacement error in $\Omega_1$ | Max displacement error in $\Omega_2$ | Max displacement error in $\Omega$ | RMS displacement error in $\Omega$ | Time(s) |
|---|---|---|---|---|---|
| Coupling method | 8.541 (-5) | 2.403 (-3) | 2.403 (-3) | 5.359(-4) | 1.175 |
| Standard RBF-PS (c=3.1) | | | 1.874 (-2) | 8.220 (-3) | 0.338 |
| Standard RBF-PS (c=5 optimal | | | 5.835 (-4) | 3.564 (-4) | 0.515 |

Fig. 6-8 show the results of displacement, normal stress and shear stress. Little difference can be seen from the results via PS-DDM method ($c=3.1$) and RBF-PS method ($c=5.0$). And as the boundary condition in $\Omega_1$ is a Dirichlet-type, while it is a mixed type in $\Omega_2$ (artificial boundary condition is the Dirichlet, the rest boundary condition is Riemann), the graphs reveal that $\Omega_1$ performs a better approximation effect than $\Omega_2$.

# The foundation of Nonlinear finite element model

Bing Wang [1, a], Xiao Liu[1, b], Baidong Zhao [1,c]

[1]School of Architectural and Civil Engineering, Shenyang University, Shenyang, 110044, China

[a]liuxiao19740701@sina.com, [b]489298344@qq.com , [c]283292935@qq.com

**Keywords:** Finite element mode, Constitutive relation, Steel tube filled with steel reinforced concrete column.

**Abstract.** This paper introduces the process of the nonlinear finite element model which is established by using ABAQUS software, and introduces the characteristics of ABAQUS software, meanwhile, lists the constitutive relation of steel pipe, steel and concrete, finally introduces some experimental model.

## The characteristics of ABAQUS

ABAQUS is applicable to all sectors of the large general-purpose finite element analysis software on the most advanced international, can effectively solve the technical problems associated with the calculation, powerful computing performance and extensive analog performance, has the rich of unit base, material model and the analysis process capacity . Both linear elastic analysis of simple problems, or include a variety of different materials, to complex mechanical and thermal loading process, nonlinear combinatorial problem and the change of contact conditions; whether the analysis of static and quasi-static problems, or stable and dynamic problem; whether explicit or implicit solution, ABAQUS is used to calculate the analysis and obtain satisfactory results[1].

## The constitutive relation of steel pipe

For steel commonly used Q235, Q345 and Q390 in the architectural engineering, the relationship of stress-strain is divided into the five stage model :elastic, elastic-plastic, plastic, plastic flow, strengthening and two plastic flow[2] , (see figure 1).

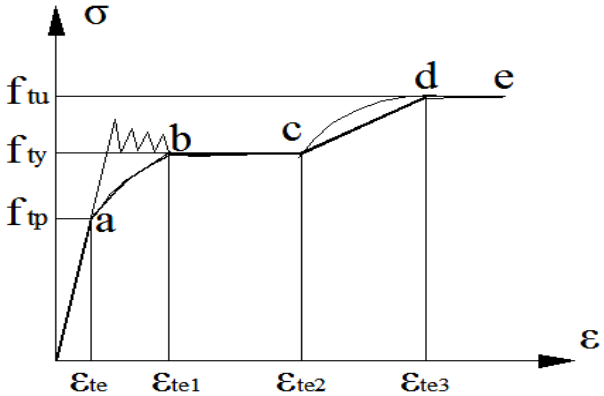

Fig.1 The constitutive relation of steel tube

At the same time, take the following three assumption:

(1)Strengthen stage as a straight line;

(2)Strength reaches the point of D, the steel into the two plastic flow;

(3)Neglecting the radial relative small stress.

According to figure 1 steel stress-strain constitutive relationship can be in accordance with the five stage simplified, the mathematical expressions is:

$$\sigma=\begin{cases} E_t\varepsilon_t & (\varepsilon_t\le\varepsilon_{te}) \\ -A\varepsilon_t^2+B\varepsilon_t+C & (\varepsilon_{te}\le\varepsilon_t\le\varepsilon_{te1}) \\ f_{ty} & (\varepsilon_{te1}\le\varepsilon_t\le\varepsilon_{te2}) \\ f_{ty}\left[1+0.6\dfrac{\varepsilon_t-\varepsilon_{e2}}{\varepsilon_{e3}-\varepsilon_{e2}}\right] & (\varepsilon_{te2}\le\varepsilon_t\le\varepsilon_{te3}) \\ 1.6f_{ty} & (\varepsilon_t>\varepsilon_{te3}) \end{cases}$$

In the formula:

$A=\dfrac{0.2f_{ty}}{(\varepsilon_{te1}-\varepsilon_t)^2}$； $B=2A\varepsilon_{te1}$； $C=0.8f_{ty}+A\varepsilon_{te}^2-B\varepsilon_{te}$； $\varepsilon_{te}=0.8f_{ty}/E_t$； $\varepsilon_{te1}=1.5\varepsilon_{te}$； $\varepsilon_{te2}=10\varepsilon_{te}$ ； $\varepsilon_{te3}=100\varepsilon_{te}$； $E_t$ −The elastic modulus of steel pipe； $f_{ty}$ −The yield strength of pipe； $f_{tu}$ −The ultimate strength of steel pipe.

**The constitutive relation of the core concrete**

The core concrete in steel tube has a lot of core concrete stress - strain relationship model , the Tsinghua University professor Han Linhai proposed the stress - strain model [4]is very widely used, it presents the curve equation of uniform rising section and the descending section of the equation, and use less parameters, many researchers use it.

The test results of axial compression short column of the research group of Wang Lianguang[5], in the steel pipe concrete basis for the stress - strain model[6], considering the influence of steel on the ductility of composite columns, was modified, the specific expression:

$$\sigma_c=f_{cc}(2x-x^2) \qquad (x\le1)$$

$$\sigma_c=\begin{cases} f_{cc}\left[1+q(x^a-1)\right] & (\theta\ge1.12) \\ f_{cc}\left(\dfrac{x}{\beta(x-1)^2+x}\right) & (\theta<1.12) \end{cases} \qquad (x>1)$$

In the formula:

$\sigma_c$ −Concrete compressive strain corresponded by the stress of $\varepsilon_c$; $\varepsilon_c$ −Concrete axial compressive strain; $f_{cc}$ −The compressive strength of concrete confined ;

$x=\dfrac{\varepsilon}{\varepsilon_0}$ ， $\varepsilon_0=\varepsilon_{cc}+[1400+800\left(\dfrac{f_c^{'}}{24}-1\right)](\theta+0.37\rho)^{0.2}$ $(\mu\varepsilon)$ $\varepsilon_{cc}$ −corresponding concrete compressive strain by $f_{cc}$ ； $\varepsilon_{cc}=1300+12.5f_c^{'}$ $(\mu\varepsilon)$ ； $\theta=\dfrac{A_tf_{ty}}{A_cf_{ck}}$ −Confinement index; $\rho=\dfrac{A_sf_{sy}}{A_cf_{ck}}$ −Steel index; $A_t, A_s, A_c$ −the area of Steel pipe, steel and concrete ; $f_{ty}, f_{sy}, f_{ck}$ −the yield strength of pipe, axial compressive strength standard value of concrete;

$\alpha=0.1\theta-0.3\rho$； $\beta=(2.36\times10^{-5})^{[0.25+(\theta-0.5)^7+(\rho-0.2)^5]}f_c^{'2}\times3.51\times10^{-4}$； $q=\dfrac{\theta^{0.545}+\rho^{0.3}}{1+\theta+2\rho}$

**The finite element modeling of steel tube filled with steel reinforced concrete column**

According to the requirement of stress components, steel pipe, steel and core concrete, end plate and the establishment of the corresponding model and assembled in the ABAUQS finite element analysis software.

In the component module, the steel tube is defined as the 3D variability shell, define the core concrete and the built-in steel for 3D deformable solid, definition of end plate for the three-dimensional analytical rigid body, created using the ABAQUS drawing function to finish each part. Because of the specimen is small,select the whole component to calculate.

In the feature modules, based on the determination of each material constitutive relation, respectively, to steel, concrete and beam core material to give the corresponding cross-section and assign sections, of which the core concrete section type end plate and beam for uniform entity , uniform steel casing, casing pipe default reference plane for the neutral surface thickness direction, and in order to meet the accuracy requirements in the thickness direction of the shell using 9 points Simpson integration points.

In the assembly module, create the various components of the entity, types are non independent entities, and the positioning tool to complete the assembly of the whole model of mobile. All member entities and their effect by the completion of the assembly as shown in figure 3.

**Keywords:** Lévy walks; aging phenomena; moving time average; power-law waiting-time distribution

**Abstract.** Lévy walks are a natural model for the description of sub-ballistic, superdiffusive motion. The waiting times and jump lengths of Lévy walks are coupled in the form $\psi(x,t) \propto \frac{1}{2}\delta(|x|-vt)\psi(t)$. The $\delta$-coupling introduces a time cost for each jump in the form of the generalized velocity $v$, such that long jumps get penalized by a higher time cost. In this paper, we firstly investigate the properties of Lévy walks with power-law waiting-time distributions; then discuss its moving time average.

## Introduction

Lévy walks were originally introduced by Klafter and Shlesinger within the framework of the continuous time random walk model[1]. One advantage of Lévy walks is that they allow for a continuous transition from diffusive (Brownian) random walks, through superdiffusion, to ballistic (straight-line) motion. Lévy walk thus provides an important conceptual link between these modes of movement. Another important feature of Lévy walks is that they are scale-free, meaning that they do not have any characteristic spatial scale, and exhibit the same patterns regardless of the range over which they are viewed. In particular, Magziarz et al.[2] showed how to phrase Lévy walks in terms of a dual subordination method based on the Langevin equation. The studies of Viswanathan et al.[3-4] sparked an explosion of interest in Lévy walk and the twin streams of empirical and theoretical research continued in subsequent years.

Aging behavior is found in complex dynamical systems like spin glasses, glasses, and polymers[5]. Aging in diffusion processes yields an interesting insightful perspective on dynamics in disordered medium, and more generally is used as a tool to probe complex systems such as blinking quantum dots, spin glasses, Anderson insulators, and colloidal suspensions.

In this paper, we further analyze the various properties of Lévy walk with power-law waiting-time distribution; and discuss their moving time averages.

## Properties

We are interested in processes evolving in continuous physical time. In Lévy walk, a random walker jumps from one site to another, the waiting times probability density function follows asymptotically a power law $\psi(t) \propto t^{-1-\alpha}$, with $0<\alpha<2$. It takes a flight time proportional to the flight length. Lévy walk is a natural model for the description of super-diffusive motion, in which the waiting times and jump lengths are coupled in the form[6],

$$\psi(x,t) \propto \frac{1}{2}\delta(|x|-vt)\psi(t) \quad (1)$$

The temporal and spatial variables of Lévy walks are strongly correlated, where $\psi(t) \propto t^{-1-\alpha}$ is the so-called waiting time distribution. The spatiotemporal coupling $\delta(|x|-vt)$ ensures the existence of a finite velocity of propagation and existence of the second moment $<x^2(t)>$.

The aging Lévy walk describes the following process: a particle is trapped on the origin for time $t_1$; it then jumps to $r_1$; the particle is then trapped on $r_1$ for time $t_2$; and then it jumps to a new location; the process is then renewed. Thus the aging Lévy walk process is characterized by a set of waiting time $\{r_1,\cdots,r_n,\cdots\}$. The time elapsing between start of observation at $t=0$, and the first jump event is denoted by $t_1$. Here we denote the probability density function of the first waiting time $t_1$ with $\psi(t_1,t_a)$. In aging Lévy walk the random walker during the time interval $\Delta t$ starting not at $t=0$ but at $t=t_a>0$, there $\psi(t_1,t_a)$ depends on age of the process $t_a$. The waiting times $\{t_n\}$ with $n>1$ are independent and identically distributed with a common probability density $\psi(t)$.

In order to address the dependence on the aging time, we have to know how long the walker has to wait from its initiation time until making its first step after the observation started. When the aging time was assumed to be zero, and for this case $\psi(t_1,t_a)=\psi(t)$.

We can get two types of behaviors for $\psi(t_1,t_a)$ .The first is the average waiting time $<t>=\int_0^\infty t\psi(t)dt$ is finite; and then in the long aging time limit one obtains $\lim_{t_a\to\infty}\psi(t_1,t_a)=\dfrac{\int_0^{t_1}\psi(t)dt}{<t>}$. The second case corresponding to a power law waiting time probability density function $\psi(t)\propto t^{-1-\alpha}$, with $0<\alpha<1$. When $t$ is long, the Laplace transform of such a distribution is given by $\psi(s)\sim 1-\beta s^{\alpha}$, where $s$ is small, and $\beta$ is a positive parameter. According to

$$\psi(t_1,t_a)=\int_0^{t_a}k(t')\psi(t_a-t'+t)dt' \quad , \tag{2}$$

where $k(t')=\sum_{n=0}^{\infty}\psi_n(t)$. The Laplace transform of the shifted waiting-time probability density function $\psi(y+t)$ in $y$ reads[7]:

$$\int_0^\infty\psi(y+t)e^{-uy}dy=e^{ut}[\psi(u)-\int_0^t\psi(y)e^{-uy}dy] \tag{3}$$

therefore,

$$\begin{aligned}\psi(t_1,u)&=L\{\psi(t_1,t_a);u\}\\&=\frac{1}{1-\psi}e^{ut}[\psi(u)-\int_0^t\psi(y)e^{-uy}dy]\,.\end{aligned} \tag{4}$$

Then performing the inverse Laplace transform to obtain $\psi(t_1,t_a)$, we rewrite Eq. (4) as

$$\begin{aligned}\psi(t_1,s)&=\frac{1}{1-\psi(s)}e^{st}\int_t^\infty e^{-sy}\psi(y)dy\\&=\frac{\alpha e^{st}}{\Gamma(1-\alpha)}\Gamma(-\alpha,st)\,.\end{aligned} \tag{5}$$

Now, according to the properties of Gamma function, we can take an inverse Laplace transform of Eq. (5) with respect to $s$,

$$\psi(t_1,t_a)=\frac{\sin(\pi\alpha)}{\pi}\cdot\frac{t_a^{\alpha}}{t_1^{\alpha}(t_1+t_a)} \tag{6}$$

For large $t_a$ the forward waiting-time probability density function $\psi(t_1,t_a)$ shows two distinct types of behavior: For $t>t_a$ its decay follows $\psi(t)\propto t^{-1-\alpha}$, which is a pattern of the decay of $\psi(t)$; while for $t<t_a$ the decays as $t^{-\alpha}$, which is quite a slow delay.

**Moving time average**

In order to distinguish between systems with normal and anomalous diffusion, one typically looks at the mean squared displacement (MSD) of particles. Concentrating on the one-dimensional case, the MSD for regular diffusion is given by $< x^2(t) >= 2Kt$, where $K$ is the diffusion coefficient. For anomalous diffusion, the MSD is $< x^2(t) >= \frac{2K_\alpha}{\Gamma(1+\alpha)} t^\alpha$, where $\alpha \neq 1$ and $K_\alpha$ being the anomalous diffusion coefficient. System with $0 < \alpha < 1$ displays subdiffusion, which values of $\alpha > 1$ correspond to superdiffusion[8-9].

We use the Lévy walk to describe the motion of particles. In this model, the MSD at time $t$ defined as the ensemble average over many realizations of the process behaves as $< x^2(t) >_{ens} \propto t^\alpha$, follows a superdiffusive pattern[8-9].

We can analyze the time series $x(t)$ of the particle trajectory and determine the time averaged MSD:

$$< \Delta x^2(t) >_T = \frac{1}{T-t} \int_0^{T-t} (x(t+\tau) - x(\tau))^2 \, d\tau . \tag{7}$$

For normal diffusion, $< \Delta x^2(t) >_{ens} = < \Delta x^2(t) >_T$ provide that $T$ is large enough, which can be referred to as an ergodic property. The behavior of the double (temporal and ensemble) average of the data as given by $<< x^2(t)_T >>_{ens}$.

Note that if the variance (MSD $\sigma^2 = < l^2 >$) of a step displacement in a symmetric random walk exist, the MSD after $n$ steps behave as

$$< x^2(t) >= < l^2 >< n(t) > . \tag{8}$$

For the symmetric aging Lévy walk, we get

$$< x^2(\Delta t) >= < l^2 >< n(\Delta t, t_a) > , \tag{9}$$

where $n(\Delta t, t_a)$ is the number of steps done between $t_a$ and $t_a + \Delta t$.

$$<< \Delta x^2(t) >_T >_{ens} = << \Delta x^2(t) >_{ens} >_T = \frac{1}{T-t} \int_0^{T-t} < (x(t+\tau) - x(\tau))^2 >_{ens} \, d\tau$$

$$= K_\alpha \frac{t}{T^{1-\alpha}} . \tag{10}$$

where $K_\alpha = < l^2 > / \beta$ is the generalized diffusion coefficient. We see that the effective diffusion coefficient depends explicitly on the averaging time $T$. Lévy walks have a mean squared displacement $< x^2(n) > \propto n^r$ with $1 < r < 2$, where $r = 1$ corresponds to normal Brownian diffusion and $r = 2$ is ballistic motion. To calculate the double average

$$< x^2(n) > \propto << (n(t+\Delta t) - n(t))^r >_{ens} >_T . \tag{11}$$

We proceed as follows. For given $t$ the ensemble average corresponds to the average of $< n^r(\Delta t; t_a) >$ of the corresponding power of the number of steps of Lévy walk aged up to the time $t_a$. Let us denote by $t_f$ the forward waiting time for the first step of a Lévy walk aged up to the time $t_a$. The number of steps $n$ entering the average $< n^r(\Delta t; t_a) >_{ens}$ is the number of steps done by Lévy walk during the time $t' = \Delta t - t_f$ between the first step in the interval between $t_a$ and $t_a + \Delta t$.

$$< n^r(\Delta t; t_a) >_{ens} = \int_0^{\Delta t} < n^r(\Delta t - t_f) > \psi_1(t_f; t_a) dt_f . \tag{12}$$

where $\psi_1(t_f; t_a)$ corresponds to $\psi(t_1; t_a)$ is given by Eq.(6), and then

$$< n^r(t) > \approx n^{-\frac{1}{\alpha}-1+r} L_\alpha \left( \frac{t}{\tau n^{\frac{1}{\alpha}}} \right) dn = \left( \frac{t}{\tau} \right)^{\alpha r} \frac{\Gamma(1-r)}{\Gamma(1-\alpha r)} . \tag{13}$$

Since the behavior for $\Delta t << t_a$ will be relevant for what follows, we can use the approximation $\psi_1(t_f;t_a)=\frac{\sin(\pi\alpha)}{\pi}\cdot\frac{t_a^{\alpha-1}}{t_f^{\alpha}}$. Thus

$$< n^r(\Delta t;t_a) >_{ens} \approx const\cdot\frac{t_a^{\alpha-1}}{\tau^{\alpha r}}\Delta t^{1-\alpha(1-r)}, \quad (14)$$

Aging Lévy walk describes a Lévy walk process which begun at time $t_a$. When $t_a$ becomes long we show that a type of an equilibrium process emerges which still depends on time scale $t_a$. Thus generally Lévy walk and aging Lévy walk exhibit different behaviors.

## Summary

As expected from the above theoretical studies of Lévy walks, we further notice that Lévy walks are random processes with an underlying spatiotemporal coupling. This coupling penalizes long jumps, and therefore Lévy walks give a proper stochastic description for a particle's motion with broad jump length distribution. In this work, we study the properties of Lévy walks with the power-law waiting-time distribution; then discuss the moving time average for aging Lévy walks. Lévy walks have a mean squared displacement $< x^2(t) >\sim t^{\alpha}$ with $1<\alpha<2$, where $\alpha=1$ corresponds to normal Brownian diffusion and $\alpha=2$ is ballistic motion.

**Keywords:** SH waves; scattering; circular cylindrical cavity; strip region; dynamic stress concentrations

**Abstract.** The scattering of time harmonic SH waves by arbitrary positions of circular cylindrical cavity is studied in continuous, homogeneous, isotropic, elastic strip region. In this paper, the completely analytical expression of total wave field is explicitly presented and the dynamic stress distribution is symbolically visualized in the strip region. The total wave field is divided into four sub wave fields, incident wave field and scattering wave field by the upper bound, the lower bound and the cylindrical bound, on big arc supposition. Specific wave functions are employed for each wave field expansion in series, such as circular cylindrical functions, respectively. Corresponding infinite linear algebraic equations are constructed by means of solving coefficients of Fourier series expansion on each sub wave field. Coefficients of cylindrical function expansion of each sub wave field are determined by truncated equations, which are reduced number of coefficients on pre-given computational accuracy. Numerical results graphically describe the dynamic stress concentration factor around the circumference of the cavity and the normalized dynamic stress along the cross section directly above the cavity.

## Introduction

The determination of dynamic stress distribution is interesting and exciting problem in the strip region with circular cylindrical cavity, which is disturbed by incident elastic waves. In this paper, the completely analytical expression of this problem has been presented under steady state time harmonic SH waves incident. The dynamic stress distribution is symbolically displayed as the dynamic stress concentration factor around the cylindrical bound of the cavity and the normalized dynamic stress along the cross section directly above the cavity.

Since the theory of elastic waves was constructed by Lamb and Love, the scattering by inclusion or cavity have been widely researched in infinite medium [1]. Y.H. Pao and C.C Mow systematically expounded the diffraction of elastic waves by circular, elliptical, parabolic cylinder and spherical inclusion in infinite medium [2]. D.K. Liu et al originally invented the method of complex functions to dynamic stress analysis [3]. Anti-plane shear motion is the simplest model of elastic waves, SH waves scattering problem has relative mature theories. However, there are many unsolved boundary value problems, only fewer papers were given to the scattering problem by cylindrical cavity in strip region. S. Itou and U. Zakout, N. Akkas obtained some valuable results about transient response of cavity in infinite strip [4, 5]. Recently, Hui Qi et al calculated the scattering of circular inclusion with SH waveguides in infinite strip [6]. Hui Qi and Jie Yang et al researched scattering of SH waves by circular cylindrical inclusion near interface in bi-material half space and some near interfacial problems in half space [7, 8].

In this paper, we divide total wave field into four sub wave fields, incident wave field, scattering wave field by the upper bound, the lower bound and the cylindrical bound on a big arc supposition in the strip region. Four sub wave fields are expressed as specific wave function series expansion, respectively. The boundary value problems have been solved with converted infinite linear algebraic equations by using the effective truncation. Meanwhile we obtained coefficients of wave function expansion on four sub wave fields, separately. The completely analytical expression of total wave field has been presented in the strip region, simultaneously.

## Theoretical background

The simplest model of the scattering problems of elastic waves is SH wave incident, and it only has anti-plane displacement along axis *z* and the displacement is barely a function of *x* and *y*, when the medium impacted by SH waves. The simplest model of the scattering problems of SH waves is time-harmonic steady state SH wave incident, and it has separable variables about time and space.

In this paper, the scattering problem of circular cylindrical cavity in infinite strip region has been investigated with time-harmonic steady state SH wave incident. As Fig.1 shows, one circular cylindrical cavity is located in the homogeneous, isotropic infinite strip region, in which is propagating time-harmonic steady state SH waves.

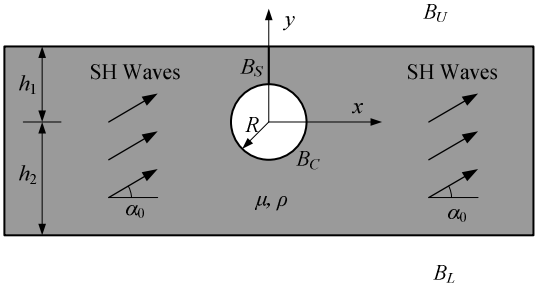

**Fig.1.** The scattering of cylindrical cavity with SH waves in strip region.

The displacement wave function of the total wave field is presented as expression (1) in the strip region. It can be divided into a product of a spatial variable (displacement function) and a time variable (harmonic function which angular frequency is notated as $\omega$). Displacement function $w(x, y)$ is satisfied governing equation (2) in the rectangular coordinate system; $w(r, \theta)$ is satisfied governing equation (3) in the polar coordinate system. Wherein, $k=\omega/c_s$, $c_s^2=\mu/\rho$, $k$ notates the wave number of steady state SH waves, $c_s$ notates phase velocity of shear waves in the strip region.

$$w = w(x, y, t) = w(x, y)e^{-i\omega t} = w(r, \theta, t) = w(r, \theta)e^{-i\omega t} \tag{1}$$

$$\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + k^2 w = 0 \tag{2}$$

$$\frac{\partial^2 w}{\partial r^2} + \frac{1}{r}\frac{\partial w}{\partial r} + \frac{1}{r^2}\frac{\partial^2 w}{\partial \theta^2} + k^2 w = 0 \tag{3}$$

## Wave fields analytical expressions

In this paper, the total wave field is divided as incident wave field and scattering wave field on principle of superposition. We introduce big arc supposition for decomposition of the scattering wave field.

As Fig.2 shows, a straight line is seen as infinite radius arc. In the coordinate (*x, y*), the upper bound of the strip region is treated as infinite radius arc, which convex to the negative direction *y*. In a similar way, the lower bound of the strip region is treated as infinite radius arc, which convex

to the positive direction *y*. Where upon, two bound of the infinite strip region are idealize as a pair of symmetrical infinite radius arcs, so the infinite plane strip is converted to infinite concave strip. This supposition is accurate enough to theoretical researches and engineering applications, if only the radius of the big arc is greater than the length of the infinite strip region by an order of magnitude. Therefore, the total wave field consists of four sub wave fields, incident wave field which is directly disturbed by incident time-harmonic steady state SH waves, and scattering wave fields by the upper bound $B_U$, the lower bound $B_L$, and the circular cylindrical cavity bound $B_C$, respectively. In this paper, $w$ notate the total wave field, $w^{(i)}$ notate the incident wave field, and $w^{(S)}$ notate the resultant scattering wave field, $w^{(U)}$, $w^{(L)}$, $w^{(C)}$ notate scattering wave by $B_U$, $B_L$, and $B_C$, respectively, as expression (4).

$$\begin{aligned} w &= w^{(i)} + w^{(s)} \\ w^{(s)} &= w^{(U)} + w^{(L)} + w^{(C)} \end{aligned} \tag{4}$$

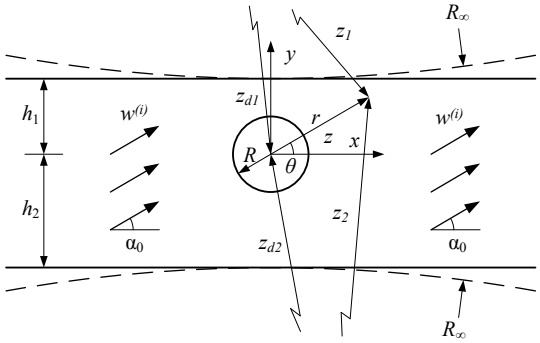

**Fig.2.** The big arc supposition.

On complex function description, the incident wave field $w^{(i)}$ is presented as expression (5), Wherein $w_0$ notate the amplitude of the incident SH waves, and $\alpha_0$ notate the angle of incidence, from direction *x* to incident direction.

$$w^{(i)}(\vec{r},t) = w^{(i)}\left(z,\bar{z}\right)e^{-i\omega t} = w_0 \exp\left[\frac{ik_1}{2}\left(z\cdot e^{-i\alpha_0} + \bar{z}\cdot e^{i\alpha_0}\right)\right]e^{-i\omega t} \tag{5}$$

The scattering wave field consists of three sub wave fields, by the upper bound $B_U$, the lower bound $B_L$, and the circular cylindrical cavity bound $B_C$, which is notated as $w^{(S)}$, $w^{(U)}$, $w^{(L)}$, $w^{(C)}$ in the strip region. On complex function description, $w^{(C)}$ is presented as expression (6), where $A_n$ is undetermined coefficient, which is the coefficient of scattering wave on Fourier-Hankel cylindrical function series expansion by the circular cavity bound $B_C$, $H_n^{(1)}(\cdot)$ is the first kind Hankel function of *n* order. $H_n^{(1)}(\cdot)$ *exp*(-*iωt*), the product of $H_n^{(1)}(\cdot)$ and time harmonic function *exp*(-*iωt*), is represented as circular cylindrical wave which is propagating from origin to infinity, mathematically, it is satisfied Sommerfeld radiation condition.

$$w^{(C)}(\vec{r},t) = w^{(C)}\left(z,\bar{z}\right)e^{-i\omega t} = w_0\sum_{n=-\infty}^{+\infty} A_n H_n^{(1)}\left(k|z|\right)\left(\frac{z}{|z|}\right)^n e^{-i\omega t} \tag{6}$$

On the big arc supposition, we construct two moved right handed circular cylindrical coordinate systems, whose polar point is placed in the center of the upper bound $B_U$ and the lower bound $B_L$, and polar axis is paralleled with positive axis *x*, respectively. Meanwhile, two corresponding complex plane are produced by established polar coordinate systems as expression (7).

$$z_1 = z_{d1} + z = r_1 e^{i\theta_1}, z_2 = z_{d2} + z = r_2 e^{i\theta_2} \tag{7}$$

On complex function description, $w^{(U)}$ is presented as expression (8), where $B_n$ is undetermined coefficient, which is the coefficient of scattering wave on Fourier-Hankel circular cylindrical function series expansion by the upper bound $B_U$. Correspondingly, $w^{(L)}$ is presented as expression (9), where $C_n$ is undetermined coefficient, which is the coefficient of scattering wave on Fourier-Hankel circular cylindrical function series expansion by the lower bound $B_L$.

$$w^{(U)}(\vec{r_1},t)=w^{(U)}\left(z_1,\overline{z_1}\right)e^{-i\omega t}=w_0\sum_{n=-\infty}^{+\infty}B_nH_n^{(1)}\left(k\left|z_1\right|\right)\left(\frac{z_1}{\left|z_1\right|}\right)^n e^{-i\omega t} \tag{8}$$

$$w^{(L)}(\vec{r_2},t)=w^{(L)}\left(z_2,\overline{z_2}\right)e^{-i\omega t}=w_0\sum_{n=-\infty}^{+\infty}C_nH_n^{(1)}\left(k\left|z_2\right|\right)\left(\frac{z_2}{\left|z_2\right|}\right)^n e^{-i\omega t} \tag{9}$$

## Calculations and discussions

In this paper, three boundary conditions have been considered, which comprise three stress free surfaces on the upper bound $B_U$, the lower bound $B_L$, and the circular cylindrical cavity bound $B_C$. It is presented as Eqs. (10).

$$\begin{aligned}&\tau_{yz}=\tau_{yz}^{(i)}+\tau_{yz}^{(C)}+\tau_{yz}^{(U)}+\tau_{yz}^{(L)}=0;\quad y=h_1,-h_2\\&\tau_{rz}=\tau_{rz}^{(i)}+\tau_{rz}^{(C)}+\tau_{rz}^{(U)}+\tau_{rz}^{(L)}=0;\quad r=R\end{aligned} \tag{10}$$

We substitute related stress expressions of Eq. (5),(6),(8),(9) into Eq. (10) in uniform coordinate system on stress transformative relations. Then, we take three infinite dimensions linear algebraic equations about $A_n$, $B_n$ and $C_n$.

We solve boundary value equations (10) with Fourier series expansion method, which transform three infinite dimensional linear algebraic equations about $A_n$, $B_n$ and $C_n$, into three groups of infinite number of infinite dimensional linear algebraic equations, respectively.

Numerical results are explicitly displayed in this section as symbol of the dynamic stress distribution in the strip region.

As Fig.3 shows, the value of the DSCF (Dynamic Stress Concentrations Factor) around the circular cylindrical cavity bound $B_C$ is given with relatively low frequency incident waves ($kR$=0.1), where the center of the circular cylindrical cavity at the different positions in the strip region.

As Fig.4 shows, the value of the DSCF around the circular cylindrical cavity bound $B_C$ is given with relatively high frequency incident waves ($kR$=1), where the center of the circular cylindrical cavity at the different positions in the strip region.

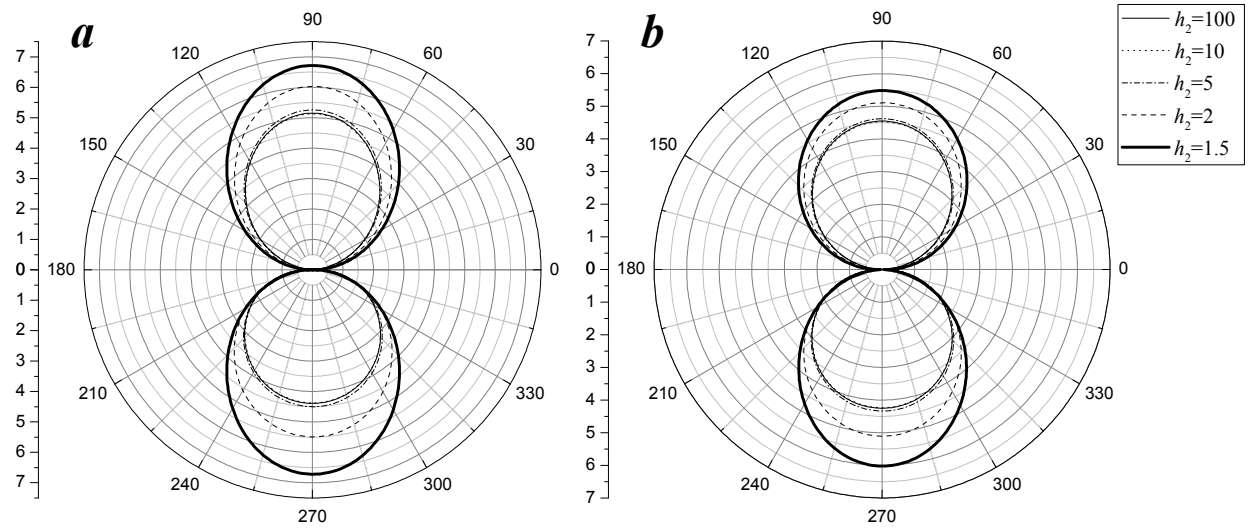

**Fig.3.** Distribution of the DSCF around the cavity with $kR$=0.1, ***a.*** $h_1$=1.5, ***b.*** $h_1$=2.

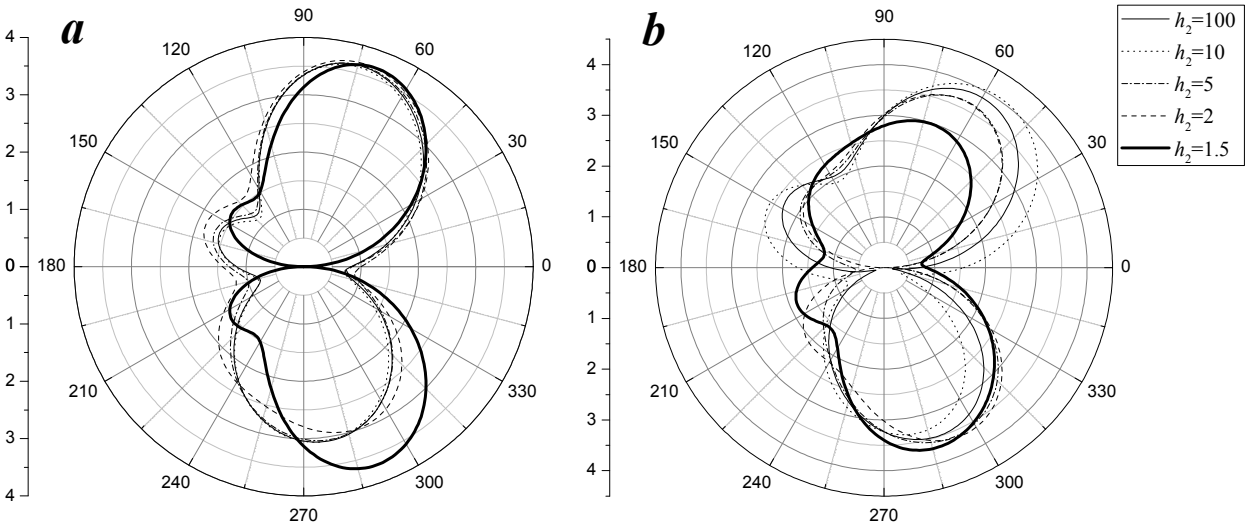

**Fig.4.** Distribution of the DSCF around the cavity with $kR$=1, ***a.*** $h_1$=1.5, ***b.*** $h_1$=2.

## Conclusions

The numerical results definitely depicted the effect of distance between the circular cylindrical cavity and the upper bound and the lower bound, and the effect of different incident angles, with different frequencies. The upper bound and the lower bound have a great influence on the dynamic stress distribution around the circular cylindrical cavity with the relatively high frequency incident waves. Contrarily, the upper bound and the lower bound have a little influence on the dynamic stress distribution around the circular cylindrical cavity with the relative low frequency incident waves, except the cylindrical bound is very close to the bounds of the strip region. However, the maximum dynamic stress around cylindrical cavity with the relatively low frequency incident waves is significantly greater than the relatively high frequency incident waves. Likewise, the dynamic stress distribution with the relatively low frequency incident waves is significantly greater than the relatively high frequency incident waves along the cross section directly above or below the circular cylindrical cavity, especially, in near cylindrical bound, as the distance increased from the cylindrical bound, this effect is decreased rapidly.

**Keywords:** Mast, Wind load, Wind angle, Numerical simulation

**Abstract.** The wind load acted on ship mast at different wind angles of large Reynolds number is numerically simulated in this paper. CFX software was used to analyze the trend of constant and fluctuating forces that the mast surface suffered at different Reynolds numbers.The vortex shedding strength of the wind load around the mast was also analyzed according to the trend of Strouhal number varing with the simulated Reynolds numbers. The results show that the wind angle has an important impact on the lift, drag, and vertical forceof the mast. The vertical force of the inclined side wall on the mast can not be ignored,and the angle of direction wind has great impact on the Strouhal number at different Reynolds numbers.

## Introduction

The load which the mast suffers not only coming from the propeller, host and other sorts of excitation source, but also from the wind when ship navigates in the storm. When the horizontal vortex shedding frequency caused by the air flow through the mast is close to the mast structure frequency, it will lead to the mast's transverse vortex-induced vibration, which sometimes gives rise to the damage of the radar, the weather instrument and communications antenna on the mast. Therefore, CFX software is used in this paper, and the numerical simulation of wind load on ship mast at different wind angles in uniform flow field at high Reynolds number (Re) has a strong engineering practicality.

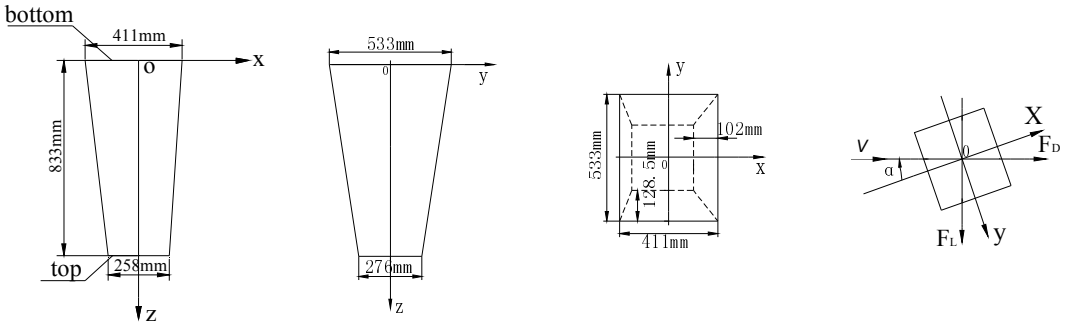
## Calculated condition

The wind load of the mast of this numerical simulation is shown in Table 1.

Table 1 Numerical simulation condition of wind load on the mast

| condition | wind velocity (m/s) | Re ($\times 10^5$) | wind angle α (°) | | | |
|---|---|---|---|---|---|---|
| 1 | 5 | 1.41 | 0 | 15 | 30 | 45 |
| 2 | 10 | 2.82 | 0 | 15 | 30 | 45 |
| 3 | 18 | 5.08 | 0 | 15 | 30 | 45 |
| 4 | 26 | 7.34 | 0 | 15 | 30 | 45 |

The mast model is a cone of columnar structure that is quadrilateral and its surface has inclination. Specific dimensions and the defination of the wind angle are shown in Fig.1.



(a)Front view (b)Side view (c)Top view wind angle

Fig.1 Schematic diagram of mast model and wind angle

The CFX software used in this numerical simulation is to utilize hexahedral grid to discretize the computational domain.The flow field near the mast requires denser grids, while other regions require relatively rare grids.The curvature change of the jointed part of every regional grids should not be too large, otherwise it cannot accurately describe the vortex shedding form when the air flow through the mast[1]. After repeated numerical simulation ,the division of grids that can clearly describe the form of the vortex shedding form is determined as illustrated in Fig. 2.

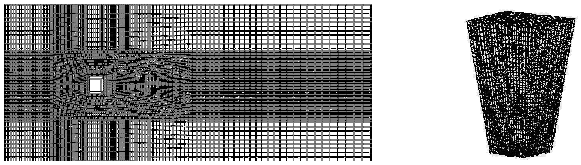


Fig. 2 Division of the grids of the munerical simulation model

The air is selected for the flow field, the surface of inlet is the entrance of wind load, medium turbulence intensity, the the velocity of the flow field of the surface of outlet resumes to the initial wind velocity. The mast is rigid and no-slip and the walls of the flow field is free-slip.

**Lift, drag and vertical force on the mast**

The average lift coefficient $C_l$ and the fluctuating lift coefficient $C_l'$ can be defined as follows.

$$C_l = \frac{\overline{F_l}}{1/2 \cdot \rho V^2 A} \tag{1}$$

$$C_l' = \frac{\sqrt{\sum (F_l - \overline{F_l})^2 / N}}{1/2 \cdot \rho V^2 A} \tag{2}$$

Where, $\overline{F_l}$ and $F_l$ are the average and instantaneous value of the fluid lift that the mast suffers;A is the max projected area where the model is perpendicular to the flow direction when the attack angle is 0º. $V$ , $\rho$ are fluid velocity and density.

The definitions of the average drag coefficient $C_d$ ,the fluctuating drag coefficient $C_d'$, the average vertical force coefficient $C_v$ and the fluctuating vertical force coefficient $C_v'$ are similar to Eq. 1 and Eq. 2.The trend of these coefficients changing with Re are showed in Fig. 3, Fig. 4 and Fig. 5.

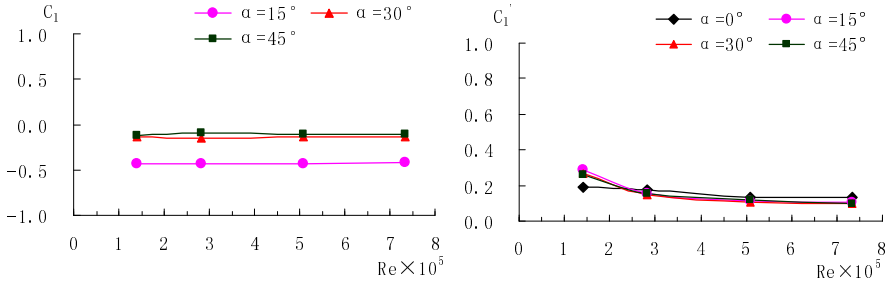

Fig. 3 The trend of $C_l$ and $C_l'$ changing with Re

As is shown in Fig. 3, $C_l$ varies little with Re and is similar to the changes of $C_d$ with Re which can be regarded as constant. The change of $C_l^{'}$ with Re is small when α is 0 and is almost the horizontal line. $C_l^{'}$ decreases with the increasing of Re, and the simulation results when α is 0 are greater than the other wind angles.

We can see in Fig. 4 and Fig. 5, $C_d^{'}$ and $C_v^{'}$ at stable period is about 0.03 while $C_l^{'}$ varies more apparently at different α and is 2 to 3 times bigger than both $C_d^{'}$ and $C_v^{'}$.

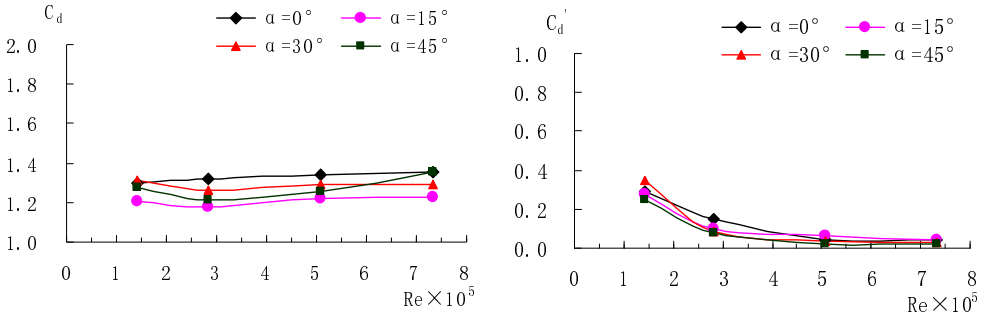

Fig. 4 The trend of $C_d$ and $C_d^{'}$ changing with Re

The mast model is symmetry to the entrance when α is 0, since $C_l$ will be 0[2]. In Fig. 4, $C_d$ varies little with Re and can be regarded as constant. Under the simulation condition, the value of $C_d^{'}$ is relatively small and varies little in the range of wind angle α, and it has smaller influence on $C_d^{'}$ than on $C_d$ .Then wind angle α's influence can thus be ignored in the research of $C_d^{'}$.

The force of superstructure at the bottom of mast will be changed when the vertical force is caused by fluid influence due to the inclination of mast surface.

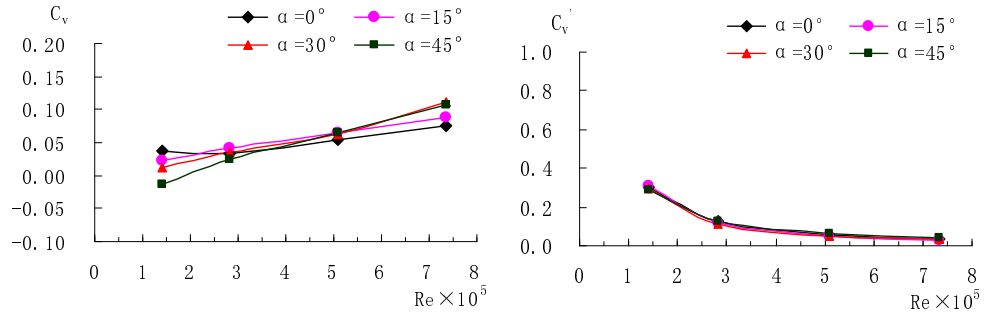

Fig. 5 The trend of $C_v$ and $C_v^{'}$ changing with Re

Fig. 5 shows that $C_v$ increases with Re while $C_v^{'}$ deceases with Re , but both of them share the mild changes. The vertical component will be vertically upward when the force of mast surface is positive while it will be vertically downward when the force is negative. The boundary layer zone will be larger when Re is smaller and the zone of positive pressure will be larger than that of negative pressure, since $C_v$ is smaller or negative. The separation point of boundary layer on mast surface will move forward when Re is higher, since $C_v$ becomes larger and positive .The value of vertical force is related with mast surface gradient and the value will becomes larger if inclination does[3].The vertical force will be very little due to the mast model surface gradient being small.

The natural frequency of mast vibration in flow field will decease or increase due to the changes of vertical force direction when the wind angle α changes , which enlarges bandwidth of natural frequency in the flow field[4]. The mast undertakes lots of electronic equipments on the ship, while the normal operation of electronic equipments entails rigid requirements on virbration, since that enlarging the bandwidth of the natural frequency of mast in flow field is detrimental to the normal operation of electronic equipments.

**Strouhal number**

The definition of Strouhal number is defined as follow:

$$S_{tr} = f_s \times l / V \tag{3}$$

where, $f_s$ is the vortex shedding frequency which is the maximum frequency of amplitude in the fluctuating lift spectral density function $S(f)$, $V$ is the velocity of incoming flow, $l$ is the lenth of the mast.

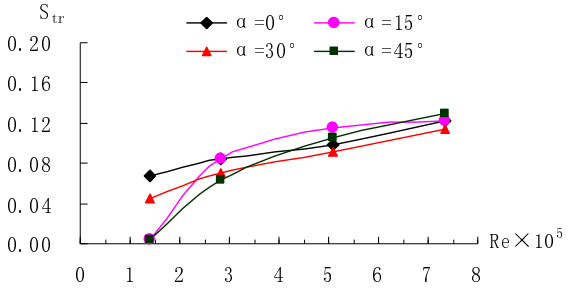

Fig. 6 The trend of $S_{tr}$ changing with Re

As is shown in Fig 6, $S_{tr}$ increases with Re and α. Re has a more sensitive influence on $S_{tr}$ changes when α is 0 and 30 than that of 15 and 45. $S_{tr}$ changes little with α and is around 0.12 when Re is above $5.0\times10^5$.We can see that there is still obvious vortex shedding frequency when air flows around mast model .To circular sectioned cylinder structure $S_{tr}$ is around 0.2 when Re is between $1.0\times10^2$ and $2.0\times10^5$, while the vortex shedding frequency vanishes when Re is not below$1.0\times10^5$[5].Vortex strength of mast model will be bigger than that of cylinder at large Re.

**Conclusions**

(1) $C_d$ and $C_l$ of mast model changes mildly with Re while changes obviously with α, $C_v$ changes obviously with both Re and α.

(2) $C_d^{'}$ and $C_v^{'}$ are both around 0.03 at the stable period while $C_l^{'}$ varies widely at various α and is 2 to 3 times than $C_d^{'}$ and $C_v^{'}$.

(3) $S_{tr}$ is about 0.12 at this numerical simulation Re range. The wind angle α exposes obvious influence on the vortex shedding form ,especially on the region of vortex shedding concentration.

**Keywords:** Short Line Method, Segmental Precast Construction, Construction Control.

**Abstract.** This paper studies the precast and cantilever erection process of pre-stressed concrete continuous beam bridge alignment control in short line method, basis on the construction of a light rail. Various stages of bridge construction performed on simulation analysis and calculated by the finite element software MIDAS, concluded the ultimate internal force and deformation values, and the maximum deformation are within the scope of design elevation deviation 20 mm allowed, as to achieve the target of bridge assembly.

## Introduction

With the continuous development of urban transport, increasing demand for road and bridge construction, bridge construction requires the city to seek a new technique, fast, economical and convenient method of construction. In the city bridge construction, precast segmental box girder construction gradually being adopted. This construction process has little effect on the daily traffic, high level of construction technology, as opposed to the traditional method of bridge construction, which reduces the impact of construction on the surrounding environment.

Long line method is the traditional way of concrete bridge construction, linear control is relatively simple, but the bottom mold to pre-linear aspect cannot be changed, so each must be consistent across the linear, limited to non-horizontal line of the straight bridge, and lower utilization of the bottom die after increasing the number of templates, steel banding spent 45% the total time of segmental precast cycle. The production cycle of short line method is shorter, suitable for straight bridges and all kinds of bridge models, regarding the number of segments more long-span bridges and bridge of a horizontal curve is more suitable. It can be easy to move inside and outside the template, commonly used on the steel mold precast segmental reinforced steel skeleton and then lifted into the pedestal. Short line method will assembling reinforcement the process from order to parallel construction, greatly shorten the segmental precast cycle, production efficiency compared to more than double that of long line method. Short line method of precast precision is higher, computer and professional programs require auxiliary work. In addition, compared with the traditional way of concrete bridge construction, precast segmental construction with short line method, covers an area of less, construction speed is quick, construction control accurate precision, impact of under bridge traffic is small and other advantages, the work can be completed prefabricated in the factory, production molds and production equipment can be reused, therefore, not only to reduce supplies, saving resources and costs, and reduce the impact on the surrounding environment, is advantageous to the concrete quality assurance, thus increasing the service life of the bridge structure, with a significant economic and social benefits.

## Linear control prefabrication and assembly phase

**Technology of prefabricated construction.** Short line method refers to a method of prefabricated sections divided into several sections, within prefabricated pedestal factory fixed template system is presented the matching, segmental precast concrete box girders of flowing water of a kind of construction technology. Prefabricated start from # 1 segment, the first # 1 segment pour between the

fixed end and a movable end die casting mold, this segment is called the initial segment, then the segmental moved forward as the matching section (acts as the activity mode) and second section prefabricated, and so forth, reach the section I segment as the first match of the section I + 1 segment until all segments of precast completed. Before pouring, by adjusting the relative position to match the planar segment and elevation error correction to eliminate the accumulated error, control the geometry of the segment to be cast, so as to achieve the required prefabricated linear.

**The assemble phase linear control process.** If precast segments have sufficient accuracy in the process, at the time of assembly, a section of the segments assembled together to meet the design requirements of linear. Assembly phase linear control theory is assembled by linear analysis, the target coordinates of the beam segment control point coordinates of the user to follow these installation, then these control points were measured to obtain the measured value. Structural analysis based on these measured values to obtain a pre-fight linear displacement values, input linear control program, you can get generated by the pre-fight six linear control point coordinates, then the coordinate values of the coordinate values and comparing the resulting linear design and error analysis, get the beam section adjustment suggestions.

## Engineering project

**The project profile.** This construction began united span arrangement of 13 different concrete link rigid frame composed with span of 20.2m ~ 45.0m, and average of 31.9m. Main beam using a single box single room concrete box girder, beam width is ranging from 9.68 m ~ 11.39 m, standard high beam is 1.8m, in line with a long-span, depth of beam associated to the 11th highest 2.2m. Main beam precast segment method using short line method, lifting the cantilever construction method, the box girder segment is generally 2.5m, weight 31t.

**Finite element simulation of bridge.** Using Midas Civil software to analyze the viaduct construction of the spatial structure with computational analysis as shown in Fig. 1, the model for the x-axis to the bridge longitudinal and transverse axis y, z axis is vertical, the bridge girder using beam element simulation, when moving vehicle loads applied bridge deck surface is set to two-lane, one-way traffic; beam bottom support is divided into two constraints: both ends of the sliding constraints (constraints DX, DZ, RX) and intermediate cross-fixed constraint (constraint DX, DY, DZ, RX).

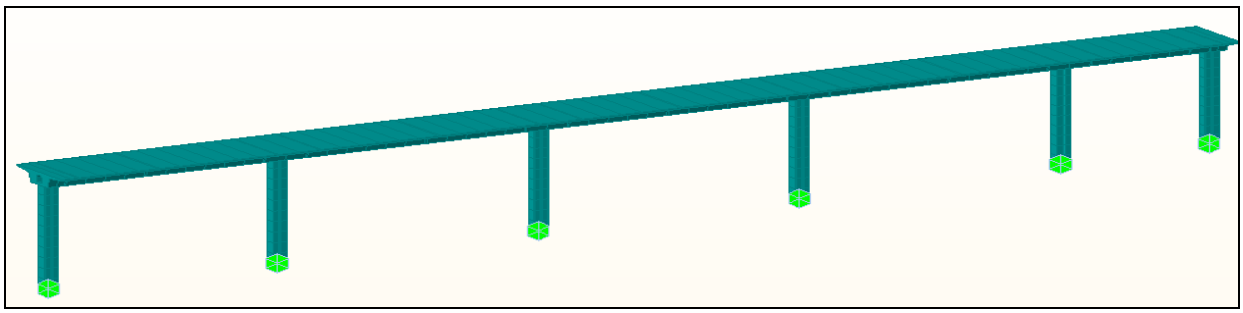

Fig. 1 Calculation model of bridge longitudinal

**Service stage of rebar maximum tensile stress calculation.**

According to specification: service stage of pre-stressed concrete flexural member normal section of pressure stress and the tensile stress of pre-stressed steel, shall meet the following requirements

To steel strand and steel wire of no cracking component $\sigma_{pe} + \sigma_{p} \leq 0.65 f_{pk}$

$\sigma_{pe}$ -Fully prestressed concrete and A kind of prestressed concrete flexural member, effective prestress of prestressed tension zone after deducting all the loss of prestress.

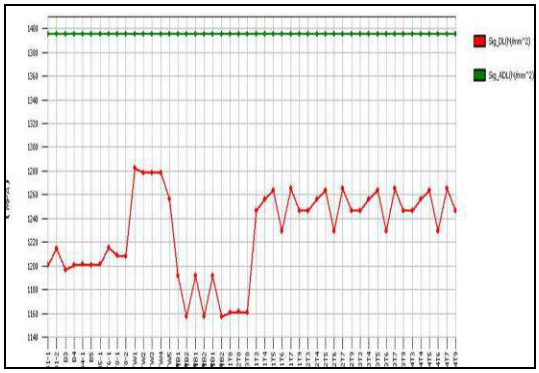

Fig. 2 Calculation of rebar tensile stress (1)

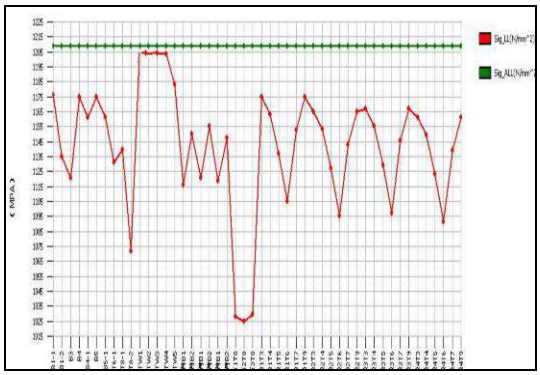

Fig. 3 Calculation of rebar tensile stress (2)

From the above, according to the results of the calculation procedure as shown in Fig. 2 and Fig.3, lasting condition tendons maximum tensile stress 1205MPa <0.65fpk (1209MPa), the construction phase of the largest pre-stressed tension control stress is 1283MPa <0.75fpk (1395MPa) to meet regulatory requirements.

**Transient situation of pre-stressed concrete member normal compressive stress check**

Pre-stressed concrete flexural members, pre-stressed and components under the weight of other construction loads cross section of the edge of the normal stress should meet the following requirements:

Tensile stress

l) When $\sigma_{ct}^{t} \leq 0.70\, f_{tk}^{'}$, pre-stretched areas should configure its reinforcement ratio of not less than 0.2% of the longitudinal reinforcement ;

2) When $\sigma_{ct}^{t}$ =1.15 $f_{tk}^{'}$, the pre-tension areas should configure its reinforcement ratio of not less than 0.4% of the longitudinal reinforcement;

3) When0.70 $f_{tk}^{'} < \sigma_{ct}^{t} <$1.15 $f_{tk}^{'}$, the longitudinal reinforcement ratio pre-tensioners area should be configured according to the straight line drawn above two interpolation. Tensile stress $\sigma_{ct}^{t}$ should not be more than 1.15 $f_{tk}^{'}$ .

pressure stress $\sigma_{cc}^{t} \leq 0.70\, f_{ck}^{'}$

In the formula, $\sigma_{cc}^{t}$, $\sigma_{ct}^{t}$ - when calculated according to a transient situation of preloading conditions , edge of the concrete in pretension area, pressure stress and the tensile stress ;

$f_{ck}^{'}$, $f_{tk}^{'}$ - With the production, transportation, installation of concrete cube in each construction stage compressive of the curvature $f_{tu}^{'}$ of the corresponding axial compressive strength and standard value of tensile strength.

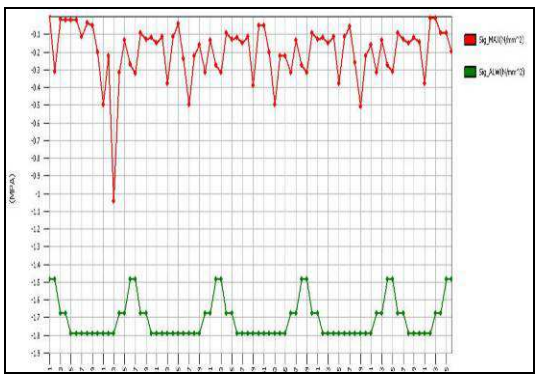

Fig. 4 Calculation of tension stress

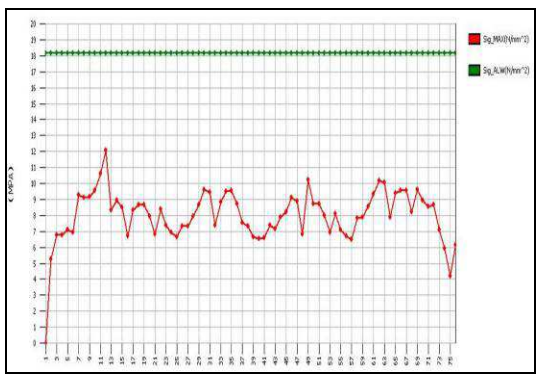

Fig. 5 Calculation of compression stress

As shown in Fig.4 and Fig.5, transient situation pre-stressed concrete members normal direction tensile stress max 1.01MPa <0.70 $f_{tk}^{'}$ (1.28 MPa), the maximum compressive stress 12.1MPa

<0.70 $f_{ck}^{'}$ (15.68 MPa), transient situation pre-stressed concrete members normal direction tensile stress meet the specification requirements.

**Computation of Shear Strength.** Accordance to specification, calculate of carrying capacity ultimate limit state of bridge member, should adopt the following expression: $\gamma_0 S \leq R$

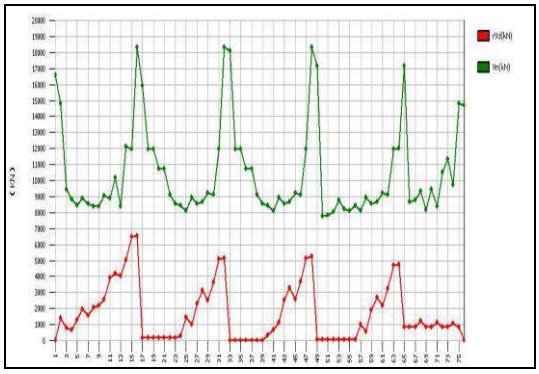

Fig. 6 Computation of Shear Strength

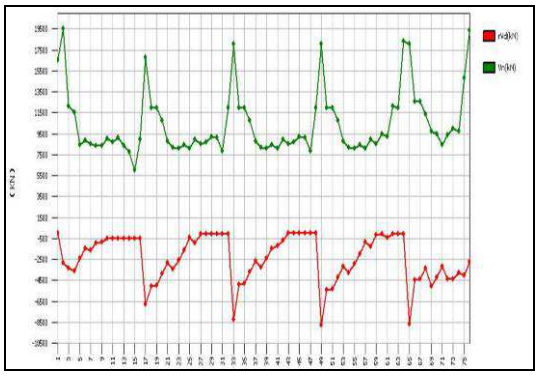

Fig. 7 Computation of Shear Strength

As shown in Fig. 6 and Fig. 7, the safety factor greater than 1, shear strength meet the specification requirements.

**Check and calculation of anti-crack and anti-bending in oblique section.** Pre-stressed concrete flexural member should crack resistance of inclined section calculation according to following provisions. Oblique oblique section of concrete cracking section of the main tensile stress $\sigma_{tp}$ member checking, and shall meet the following requirements: Class A and Class B pre-stressed concrete members, in the role (or load) Short-term effects of group.

Cast in place (including prefabricated assembly) components

$\sigma_{tp} \leq 0.5 f_{tk}$

$\sigma_{tp}$ - principal tensile stress by the action (or load) and short-term effects of a combination

$f_{tk}$ - Standard value of tensile strength of concrete.

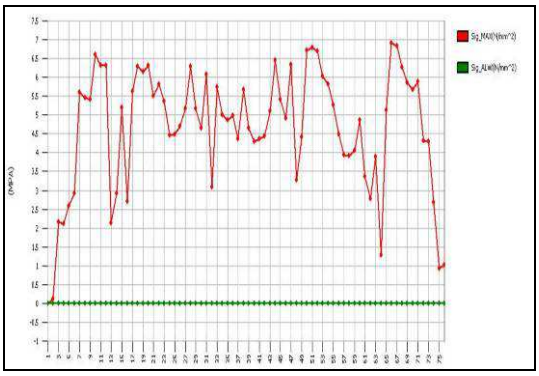

Fig. 8 Calculation of anti-crack

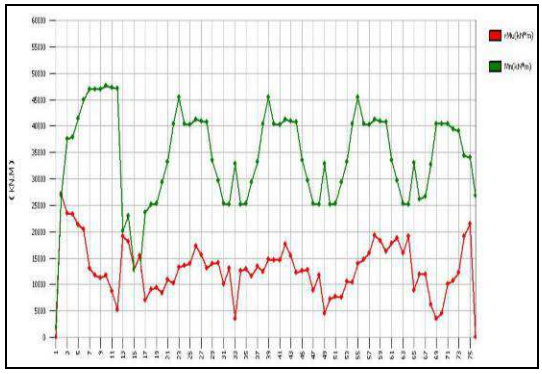

Fig. 9 Calculation of anti-bending

Accordance to specification, calculate of carrying capacity ultimate limit state of bridge member, should adopt the following expression:

$$\gamma_0 S \leq R$$

As shown in Fig. 8 and Fig. 9, there was no tensile stress, oblique section crack is checked and counted meet specifications. Flexural strength of component greater than the factor of safety components, meet regulatory requirements.

**Summary**

Through the modeling analysis and calculation, in view of the bridge process simulation analysis, then get internal force and deformation values of bridges in dead load, settlement of the base, temperature difference, dynamic loads and combined loads. The results show that, The biggest deformation caused by load are in the design elevation level within the scope of allowable deviation of 20 mm. This conclusion also provide a theoretical basis for construction control, Assembly of bridge linear can achieve expected goals, the whole construction process control method and the error processing method has certain feasibility. Precast segmental of short line method is in short construction period, can be large-scale production, standardized production, high quality and efficiency, the continuation of the traffic speed, good stability, less expansion joints in pre-stressed concrete continuous girder bridge, and will be preferred alternative of highway bridge and urban viaduct.

**Keywords:** acoustic cavitation; lattice Boltzmann method; single-component multiphase flow; Keller equation.

**Abstract.** The motion characteristic of cavitation bubble is one of the major factors affecting acoustic cavitation. In this paper, a cavitation model coupled with acoustic pressure is established using lattice Boltzmann pseudopotential model. Aimed at demonstrating the feasibility of applying LB method in acoustic cavitation, the acoustic cavitation simulations are compared with the predictions of Keller equation. The comparison of theoretical prediction and numerical simulation shows that LB method is suitable for acoustic cavitation simulation.

## Introduction

Acoustic cavitation is a series of the kinetic processes of shocking, growing, shrinking and collapsing of tiny gas nucleus in the liquid due to the vibrations of sound waves when pressure level of the sound exceeds the cavitation threshold of the liquid [1]. When the bubble collapses rapidly, the cavitation effect would release huge energy and create special environment that strengthens certain physical and chemical processes. This makes acoustic cavitation widely applied in medical, ultrasonic cleaning, ultrasonic water treatment and many other areas [2-3].

Numerous studies have found that, the motion characteristic of cavitation bubbles is one of the major factors affecting acoustic cavitation [4]. In terms of theory researches, Rayleigh first put forward the dynamic model of single spherical cavitation bubble in infinite incompressible liquid in 1917. Then Plesset et al. modified the Rayleigh equation by considering different factors [5]. By introducing acoustic radiation to Rayleigh-Plesset equation, the earliest acoustic cavitation motion equation was deduced [6]. Since the oversimplified theoretical model (often single and spherical) was incapable of obtaining the analytical solution to the motion rule of cavitation bubbles, numerical methods on cavitation bubble's motion were widely considered. Existing numerical simulation methods of non-spherical cavitation bubble mainly include the volume of fluid (VOF) [7], the finite volume method (FVM) [8], the boundary element method (BEM) [9] and the lattice Boltzmann method (LBM).

The burgeoning lattice Boltzmann method in the recent two decades is a numerical method based on microscopic model and mesoscopic particle dynamics equation [10-11]. In LBM multiphase flows area, the pseudopotential LB model proposed by Shan and Chen (also called Shan-Chen model), which introduced inter-particle potential to describe the interactions among different phases or components, is widely used for its conceptual simplicity and easy implementation [12-13]. Sukop and Or verified the feasibility of LBM on cavitation by simulating the cavitation phenomenon using Shan-Chen model [14]. Zhang et al. studied on the relationship between initial bubble radius and cavitation phenomenon by simulating 3D cavitation phenomenon using Shan-Chen model [15].

Xiao-Peng Chen simulated the cavitating bubble growth with the LBM in both quiescent and shear flows, where the results are compared with the Rayleigh-Plesset equation [16]. Then, Xiao-Peng Chen et al. simulated cavitation bubble of large density ratio by coupling exact difference method (EDM) and Carnahan-Starling real-gas equation of state (EOS) in the Shan-Chen LB model [17]. The known researches have investigated the dynamic characteristics of cavitation bubble and its relationship with several thermodynamic parameters. Some of them have compared experimental results with theoretical ones, and verified the feasibility of the LBM numerical simulation on cavitation. When introducing the influence of acoustic perturbation, the cavitation bubble's motion grows much more complex. Whereas, as far as we are aware that reports about the LBM numerical simulation of cavitation bubble with influence of acoustic pressure have not been published.

In this paper, the acoustic pressure is coupled in the LB Shan-Chen multiphase flow model to set up an acoustic cavitation model. With this model, the expansion, contraction and collapse processes of the cavitation bubble with the acoustic perturbation is simulated. The purpose of this paper is to validate the model by comparing the results with Keller equation to demonstrate the feasibility of using the LBM in simulating acoustic cavitation.

## LBM Model

LBM is a mesoscopic numerical simulation method based on statistical physics and developed from lattice Gas Automata (LGA). The evolution equation with Bhatnagar-Gross-Krook (BGK) collision term can be written as [18]

$$f_a\left(\boldsymbol{x}+\boldsymbol{e}_a\cdot\delta t,\mathrm{t}+\delta t\right)-f_a\left(\boldsymbol{x},\mathrm{t}\right)=-\frac{1}{\tau}\left[f_a\left(\boldsymbol{x},t\right)-f_a^{eq}\left(\boldsymbol{x},t\right)\right],a=0,1,\ldots\ldots\mathrm{b}, \tag{1}$$

where $f_a$ denotes the distribution function along each velocity direction $a$, $f_a^{eq}$ denotes the equilibrium distribution function, $b$ is the number of the neighbors, $\boldsymbol{x}$ is the lattice site coordinates and $\boldsymbol{e}_a$ velocity towards each direction. The function is of single relation time, which is decided by viscosity $\upsilon=(\tau-1/2)c_s^2\delta t$. The motion of particles in LBM is divided into the process of streaming and collision, representing moving from one node to a nearest neighbor node and a relaxation toward a local equilibrium respectively, as the left hand side and the right hand side of equation (1) shows. The discrete velocity in the two-dimensional D2Q9 model is defined as

$$\boldsymbol{e}_a=\begin{cases}(0,0),a=0\\ c\left(\cos\left[(a-1)\frac{\pi}{2}\right],\sin\left[(a-1)\frac{\pi}{2}\right]\right),a=1,2,3,4\\ \sqrt{2}c\left(\cos\left[(2a-1)\frac{\pi}{4}\right],\sin\left[(2a-1)\frac{\pi}{4}\right]\right),a=5,6,7,8\end{cases}, \tag{2}$$

where the lattice speed $\mathrm{c}=\delta x/\delta t$, $\delta x$, $\delta t$ is the lattice unit and time step, respectively.

The equilibrium distribution function satisfying the Maxwell distribution is depicted in D2Q9 model as

$$f_a^{eq}\left(\boldsymbol{x},t\right)=\rho\omega_a[1+3\frac{\boldsymbol{e}_a\cdot\boldsymbol{u}}{c^2}+\frac{9(\boldsymbol{e}_a\cdot\boldsymbol{u})^2}{2c^4}-\frac{3\boldsymbol{u}^2}{2c^2}], \tag{3}$$

where $\boldsymbol{u}$ is the macro-velocity, and the weights $\omega_a$ are set $\omega=4/9$ when $a=0$, $\omega=1/9$ when $a=1,2,3,4$, and $\omega=1/36$ when $a=5,6,7,8$.

In this paper, the widely used Shan-Chen model in LBM multiphase area is applied, which introduced the inter-particle interaction force to simulate the single component multiphase flows.

When the force is large enough, it will lead to phase transition. Consider the nearest-neighbor interactions as

$$\mathrm{F}(\boldsymbol{x},t) = -G\psi(\boldsymbol{x},t)\sum_a \omega_a \psi(\boldsymbol{x}+\boldsymbol{e}_a\delta t,t)\boldsymbol{e}_a, \tag{4}$$

where G denotes the interaction strength whose magnitude controls the interaction potential and sign determines whether it is attractive or repulsive. $\psi$ is the interaction potential with the form $\psi = \psi_0 e^{-\rho_0/\rho}$ , $\psi_0$ and $\rho_0$ are arbitrary constants.

In Shan-Chen model, the interaction force is incorporated into the model by shifting the velocity in the equilibrium distribution function [19], namely,

$$u^{eq} = u(x,t) + \Delta u, \tag{5}$$

$$\Delta u = \frac{\tau \cdot \delta t \cdot F(\boldsymbol{x},\mathrm{t})}{\rho(x,t)}, \tag{6}$$

where the macro-density $\rho$ and macro-velocity $u$ of the fluid are defined as

$$\rho(\boldsymbol{x},t) = \sum_0^8 f_a(\boldsymbol{x},t), \tag{7}$$

$$u(\boldsymbol{x},t) = \frac{\sum_0^8 \boldsymbol{e}_a f_a(\boldsymbol{x},t)}{\rho(\boldsymbol{x},t)}, \tag{8}$$

The Shan-Chen single-component multiphase LBM EOS is of the form

$$p = \rho RT + \frac{GRT}{2}\psi(\rho)^2, \tag{9}$$

where $RT = 1/3$ . For the chosen form $\psi = \psi_0 e^{-\rho_0/\rho}$ , the equation is a nonmonotonic increasing function at certain T, and has the essential feature of the Van der Waals equation that allows liquid-vapor phase coexistence. When the value of G is less than the subcritical interaction strength $G_C$ , phase separation is possible to take place.

## Numerical Simulation

**Determination of thermodynamic parameters.** Cavitation is a transient, multiphase and complex phenomenon with vapor and various gas components inside the cavitation bubble. In this paper, Shan-Chen single-component multiphase (SCMP) model is applied, implying that only saturated vapor inside bubble taken into consideration. To determine the density value of liquid and vapor, the coexisting density of phase segregation result is first presented as the basis of the simulation. Throughout the paper, the lattice unit is adopted for all data if not specially announced, e.g. the unit of length is lattice unit (lu), the unit of time is time step (ts), and the unit of mass is mass unit (mu). The computational domain is set in a 200×200 square gird with periodic boundary conditions applied at four boundaries. The initial density is evenly distributed with slight random perturbations $\delta\rho = \rho_0 \times 1.0(1 - 2\times \mathrm{rand})$ , where rand denotes the random numbers in [0,1]. The equilibrium phase densities are obtained as $\rho_v = 82.0971$ , $\rho_l = 520.4809$ in the equilibrium liquid-vapor system with the parameters $\psi_0 = 4$ , $\rho_0 = 200$ , $G = -120$ and $\tau = 0.8$ , thus the vapor pressure $P_v = 24.9158$ and liquid pressure $P_l = 25.11$ are computed through EOS.

The surface tension can be estimated by simulating a series of drops or bubbles of various initial radii and measuring the pressure difference $\Delta P$ inside and outside the bubble. According to the

Young-Laplace law, pressure difference of stable bubble/droplet is inversely proportional to the radius. As a result, the slope of the plot of curvature $1/\mathrm{R}$ and pressure difference $\Delta\mathrm{P}$ represents the surface tension, the value which is $\sigma = 11.427$ lu mu ts$^{-2}$ as Fig. 1 shows for the parameters used here.

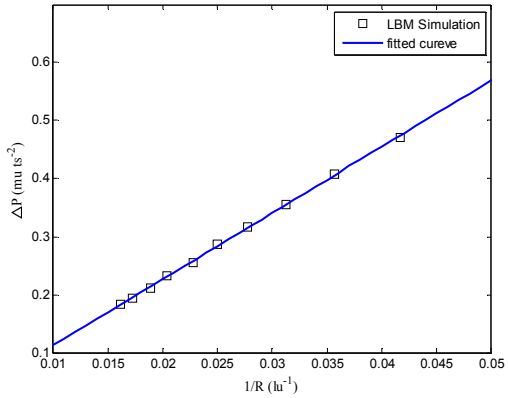

Fig. 1 Pressure difference inside and outside bubble with different curvature

**Establishment of acoustic model.** As a pressure wave [20], acoustic pressure can be introduced into the model by setting the values of distribution function $f_a$ at the inlet boundary to the values of $f_a = f_a^{eq}(\rho_S^A(\mathrm{t}), u_S^A(\mathrm{t}))$. $\rho_S^A(\mathrm{t})$ and $u_S^A(\mathrm{t})$ are the sinusoidal density and velocity perturbations at the inlet, as the equation (10) and (11) shows

$$\rho_S^A(\mathrm{t}) = \rho_S^{(0)} + \delta\rho_s \sin(\omega_s t_s), \tag{10}$$

$$u_S^A(\mathrm{t}) = \delta u_s \sin(\omega_s t_s), \tag{11}$$

where $\rho_S^{(0)}$ is the ambient density, $\omega_s$ is the angular frequency of the sound wave, $\delta\rho_s$ and $\delta u_s$ are the amplitudes of the density and velocity variations respectively with the relationship of $\delta u_s = (\delta\rho_s \cdot c_s / \rho_S^{(0)}, 0)$.

Consider a plane sound wave propagating in an unbound fluid channel along x direction. The domain is set 200 in x-direction and 20 in y-direction, with periodic boundaries on upper-side and down-side boundaries. The sound wave is initialized at the inlet boundary as mentioned above. Full developed boundary is applied on the outlet boundary using the scheme $f_{3,6,7}(N_x, j) = f_{3,6,7}(N_x - 1, j)$, since quantities such as density and velocity can be approximately seen unchanged in mainstream direction in this way, making the instantaneous velocity distribution curve in the centerline of channel maintain relatively stable when the acoustic wave propagates to the boundary. In simulation, the viscosity of fluid is $\upsilon = 0.1$, the density of fluid is set as $\rho_S^{(0)} = 500$ according to the phase segregation result, and amplitudes of density variations is $0.01\rho_S^{(0)}$. As seen, the Mach number here is $\mathrm{Ma} = \dfrac{\delta u_s}{c_s} = \dfrac{\delta\rho_s}{\rho_S^{(0)}} = 0.01 << 1$.

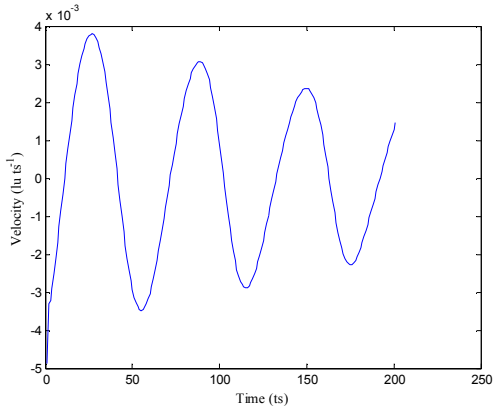

Fig. 2 Instantaneous velocity distribution curve in the centerline of channel(t=10000)

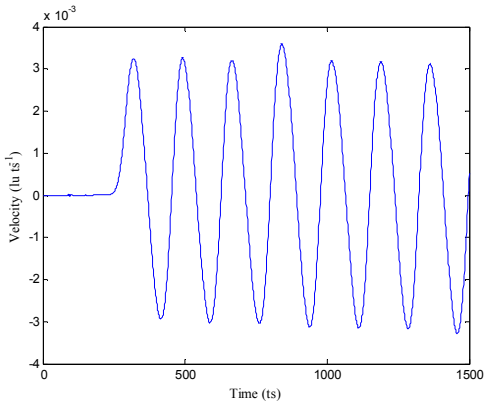

Fig. 3 Velocity evolving curve in (100, 10), t=1500

With the parameters adopted above and wave length $\lambda = 100$, the instantaneous velocity distribution curve in the centerline of channel of stable acoustic field (t=10000) is presented in Fig. 2. The velocity evolving curve in the middle of the domain (100, 10) after propagating in channel for a while (t=1500) is presented in Fig. 3.

**Validation of acoustic cavitation model with Keller equation**. The behavior of a spherical cavitation bubble can be precisely described by Rayleigh-Plesset equation. Taking the acoustic radiation effect caused by the changing bubble into account, Keller deduced the bubble vibration equation of acoustic cavitation on the basis of Rayleigh-Plesset equation, which is called Keller equation [21]. The equation makes following assumptions about the described model: the bubble keeps spherical shape and fixed center in movement; the bubble wall only has radial motion; the influence of gravity is ignored; the gas inside bubble is approximately regarded as ideal. The equation is described as

$$R\ddot{R}+\frac{3}{2}\dot{R}^2=\frac{1}{\rho_L}\left[\left(P_0+\frac{2\sigma}{R_0}-P_v\right)\frac{R_0^{3\kappa}}{\left(R^3-a^3\right)^{\kappa}}-\frac{2\sigma}{R}-\frac{4\mu_L\dot{R}}{R}-P_0+P_v\text{-}P_A\sin wt\right]+$$
$$\frac{R}{\rho_L c}\frac{d}{dt}\left[\left(P_0+\frac{2\sigma}{R_0}-P_v\right)\frac{R_0^{3\kappa}}{\left(R^3-a^3\right)^{\kappa}}\text{-}P_A\sin wt\right], \quad (12)$$

where $R_0$ denotes the initial bubble radii, $R$ the bubble radii at any moment, $\dot{R}$ the change rate of bubble radii, $\ddot{R}$ the rate of bubble's fluctuation speed. In equation (12), $\sigma$ is the surface tension, $\mu_L$ is dynamic viscosity, $P_0$ is ambient pressure, $P_v$ is saturated vapor pressure, $P_A$ is amplitude of acoustic pressure, $\rho_L$ is density of liquid, $c$ is speed of sound in water, $w$ is angular frequency of acoustic wave, $a$ is Van der Waals radius, $\kappa$ is polytropic index.

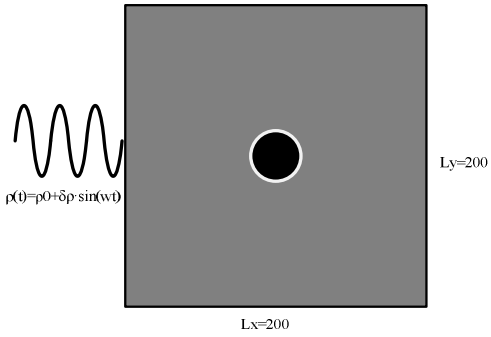

Fig. 4 Physical model of acoustic cavitation (Gray represents liquid phase, black represents vapor phase)

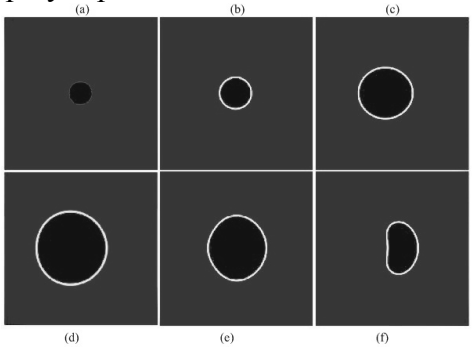

Fig. 5 Growth of acoustic cavitation bubble ((a)~(f) t=0,t=300,t=600,t=900,t=1200,t=1500)

The computational domain of acoustic cavitation simulation is set 200×200. As the physical model show in Fig. 4, the acoustic source is located in x=1, and the cavitation bubble is located in the middle of the flow field (100,100). The initial condition is set as follows, the density inside bubble $\rho_V = 80$, the density outside bubble $\rho_L = 500$, initial radii of bubble $R_{\text{ini}} = 15$. The acoustic pressure is introduced by imposed density and velocity as mentioned above, giving the speed of sound $c_s = 1/\sqrt{3}$ and amplitude of the density variation $\delta\rho_s = 5\%\rho_L = 15$. Nonequilibrium extrapolation scheme is applied on the outlet boundary, and periodic boundaries are applied on the top and bottom. With the acoustic effect, the evolution process of bubble's shape over time within a period is shown in Fig. 5, where the interval of picture (a)~(f) is set t=300. As the figure shows, in the expansion phase, the bubble radius increases gradually remaining spherical; while in the compression phase, the bubble gradually deformed to take on a non-spherical look due to the fact that the side closer to sound source suffers from greater pressure than the other side with the action of acoustic wave.

For the Keller equation, the four step Runge-Kutta algorithm is adopted to solve this second order nonlinear differential equation [22]. Before that, equation (12) should be converted into first order differential equations which substituted by certain initial conditions of lattice unit. Parameters like $\rho_L$, $\sigma$, $\mu_L = \rho_L \upsilon$ is measured from previous simulations, and other parameters in the equation are set as follows. The initial bubble radius $R_0 = 15$, Van der Waals radius $a = R_0 / 8.54$, polytropic index $\kappa = 1.33$. According to the principle that acoustic Reynolds number Re is consistent in lattice unit and physical unit, it is inferred that the sound wave produces approximately 222 times atmosphere pressure if the density perturbation remains 1%. Accordingly, pressure parameters are set $P_0 = 0.0075$, $P_v = 1.74\text{e-}4$, $P_A = 3.5$ respectively.

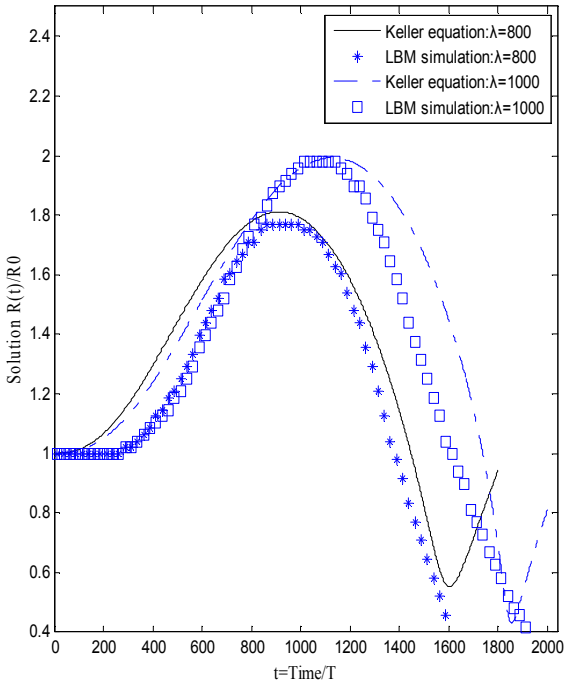

Fig.6 Comparison of simulation of LBM and prediction of Keller equation

Considering two wavelengths of $\lambda = 800$ and $\lambda = 1000$, the bubble radius comparison of numerical simulation results using LB method and prediction results of Keller equation is shown in Fig. 6. Keller equation is based on the assumption of fixed center and spherical shape, while in simulation (as Fig. 5 shows), the cavitation bubble performs certain deformation in acoustic wave and the center moves slightly as well. Therefore, as seen in Fig. 6, there exist slight deviation between

prediction curve and theoretical curve. Meanwhile, the density ratio used in simulation is relatively small against the large density ratio assumption of Keller equation, which is one of the reasons for deviation in the results.

## Conclusion

On the basis of the establishment of acoustic field, the acoustic pressure is coupled in the LB Shan-Chen single-component multiphase pseudo-potential model to build an acoustic cavitation model in this paper. According to the lattice unit conversion results, two wave lengths of $\lambda = 800$, $\lambda = 1000$ are chosen in the model to simulate the acoustic cavitation phenomenon. The comparison of LB simulation with the model and the prediction of Keller equation initially validates the feasibility of applying LB method in acoustic cavitation simulation.

Compared with other numerical simulation methods, LB method takes distinct advantages over simplicity and efficiency. The simulation and validation of acoustic cavitation achieved by LB method in this paper lays a foundation for exploiting the inherent parallelism of LB method to realize the simulation of multi-bubble cavitation in future.

**Keywords:** Similarity Principle. model test. model pile. Static load test.

**Abstract**. Similarity Principle, applied to model test, is an important theoretical basis for simulation of the prototype test. By simulating the prototype test. On the base of model test to make research on this field indirectly. Saving time and energy, the article is based on the similarity principle, and combine with the model pile static pressure test, discuss the application of similarity principle.

## The origin of similarity principle

The similarity theory research is the crystallization of human wisdom. Since ancient times, man has been to explore nature, and through experimental method, people got a lot of important results and conclusions. But many experiments can't be done directly, so it needs to simulate similar conditions to take the model experiments. And people in the exploration of nature gradually formed a special theory: the similarity theory. Similarity theory involves almost all human subjects, it is of great contribution to the research in science.

## The basic theory of similarity

Similar in which each element of the component model must be similar to the prototype of the corresponding elements[1], and it includes geometric and physical elements. The specific performance is: a series of physical elements are similar in a particular field. If there are two physical phenomena of the physical element on the corresponding points and the corresponding moment is proportional to the size and the corresponding vectors are in the same direction, the two physical phenomena are similar. In general, pile of static compressive model test shall meet the following conditions:

## The geometric similarity

In the model test, the structure should satisfy the geometrical similarity between model and prototype, which is between the model and the prototype structure size should be proportional to the corresponding, they have the same similar constant. Now with the subscript m and p respectively stands for model and prototype[2].

Length, Width and Height ratio:

$$\frac{l_m}{l_p}=\frac{b_m}{b_p}=\frac{h_m}{h_p}=C_l \tag{1}$$

Area ratio:

$$\frac{A_m}{A_p}=\frac{b_m h_m}{b_p h_p}=C^2{}_l \tag{2}$$

Modulus of section:

$$\frac{W_m}{W_p}=\frac{\frac{1}{6}b_m h_m^2}{\frac{1}{6}b_p h_p^2}=C_l^3 \tag{3}$$

Moment of inertia:

$$\frac{I_m}{I_p}=\frac{\frac{1}{12}b_m h_m^3}{\frac{1}{12}b_p h_p^3}=C_l^4 \tag{4}$$

The relationship between displacement of pile and the pile top strain:

$$\frac{x_m}{x_p}=\frac{\varepsilon_m l_m}{\varepsilon_p l_p}=C_\varepsilon C_l \tag{5}$$

**The load similarity**

In the vertical bearing capacity of pile model test, the pile top load should in the same direction, probability proportional to size. The pile top load belongs to a concentrated load, the similarity coefficient of concentrated loading: $C_f=\frac{F_m}{F_p}=\frac{A_m\sigma_m}{A_p\sigma_p}=C_l^2 C_\sigma$ (6)

When under horizontal load of pile top , pile bending moment of the similarity coefficient is

$$\frac{\sigma_m W_p}{\sigma_m W_p}=C_\sigma C_l^3 \tag{7}$$

**Physical similarity**

Physical similarity refers to the model and prototype is similar to the relationship between stress and strain, etc. In the static load test of pile includes the following elements:

The vertical stress similarity: $\frac{\sigma_m}{\sigma_p}=\frac{E_{\mathrm{m}}\varepsilon_m}{E_p\varepsilon_p}=C_E C_\varepsilon$ (8)

Shear stress: $\frac{\tau_m}{\tau_p}=\frac{G_m\gamma_m}{G_p\gamma_p}=C_G C_{\mathrm{m}}$ (9)

Poisson's ratio similarity: $\frac{\nu_m}{\nu_p}=C_\nu$ (10)

Constant stiffness similarity: $C_k=\frac{C_p}{C_x}=\frac{C_\sigma C_l^2}{C_l}=C_\sigma C_l$ (11)

$C_\sigma, C_E, C_\varepsilon, C_\tau, C_G, C_\gamma, C$ respectively stand for the similarity constant of the vertical stress, elastic modulus, normal strain and shear stress, shear modulus, shear strain, Poisson's ratio.

**Similarity criterion[3]**

In theory, the vertical and horizontal displacement of the pile and the stress and strain under static load are decided by related differential equations and related theory. When simulate pile static loading, it need to make sure that the model test and prototype test have the same mechanical characteristics and differential equations. Only by doing this can it guarantee model test in the same conditions. In addition, the model test also requires some single-valued condition. The single valued condition must also be similar. The single valued conditions include:

1 The initial conditions: magnitude of force the frequency of force exerting.

2 Geometrical conditions: the size of the Model groove and pile should meet the similarity conditions.

3 maximum conditions: The prototype pile's ultimate bearing capacity and the ultimate displacement.

4 physical conditions: cohesive forces and inner friction angles of soil specific weight of the soil.etc

Therefore, the load-test of the pile must satisfy the vertical load of the pile, the end resistance of the pile, the friction resistance of the pile and the top-displacement of the pile agree with the similarity t heory. When the pile under horizontal load, the top-horizontal displacement of the pile, the bending moment of the pile and the soil pressure besides the pile which changes with the depth also agree wi th the similarity conditions corresponding.

**similarity theorem[4]**

**The first similarity theorem**

For a similar phenomenon, the similarity index is 1. Here said the similarity index refers to the similar phenomenon meet the basic differential equation, and after the convert the number of the coefficient equation is one. Similar to the first theorem is proposed by Baer Tran, put forward the theory to determine the relevant similarity criteria.

For example, in the case of the vertical bearing capacity of pile, the pile reach equilibrium states under the load F, the bearing capacity of pile tip is[5] $F = Q_{\mathrm{uk}} = Q_{\mathrm{sk}} + Q_{pk} = 2\pi r l q_{sk} + \pi r^2 q_{pk}$ (12)

For model pile: $F_m = C_F F_p, r_m = C_r r_p, l_m = C_l l_p, q_{sk_m} = C_{q_{sk}} q_{sk_p}, q_{pk_m} = C_{p_{sk}} q_{pk_p},$ (13)

Take (13) into (12), and according to the first similarity theorem.

$$\frac{C_r C_l C_{q_{sk}}}{C_F} = 1, \frac{C_r^{\,2} C_{q_{pk}}}{C_F} = 1 . \tag{14}$$

$\frac{C_r C_l C_{q_{sk}}}{C_F}, \frac{C_r^{\,2} C_{q_{pk}}}{C_F}$ are the similarity index. The above formula indicates that Similarity coefficient between prototype and the model is not arbitrary, but connect with each other. And in accordance with the relevant conditions, the related parameters can be determined in the model pile.

**The second similarity theorem**

Second Similarity theorem was firstly put forward in 1914 by the British scholar buckingham, when a phenomenon represented by a function of n physical quantities, and the quantities which contains m basic dimension , it can get (n, m) similarity number, the n physical quantities can be expressed as the function relationship on similarity theorem between

$\pi_1\pi_2\pi_3\cdots\cdots\pi_{\text{n-k}}$, according to the second theorem, $f(\pi_1\pi_2\pi_3\cdots\cdots\pi_{n-k})=0$, (15)

When the prototype and the model is similar, if the corresponding points and corresponding time of similarity criterion would remain the same, then the relation of them should be the same, that is

$f(\pi_1\pi_2\pi_3\cdots\cdots\pi_{n-k})_m=0, f(\pi_1\pi_2\pi_3\cdots\cdots\pi_{n-k})_p=0$ (16)

which $\pi_{1m}=\pi_{1p},\pi_{2m}=\pi_{2p},\pi_{3m}=\pi_{3p}.....\pi_{(n-k)m}=\pi_{(n-k)p}$ (17)

For example, the pile foundation in a certain stage of stress can be based on second similarity theory, need not every data of similarity transformation, greatly reducing the amount of calculation.

The second similarity theorem shows that in each other similar phenomena, the similarity criterion can't be derived by the similarity index, the equation describing the relationship between various physical quantities are converted into dimensionless equation form, all the equations are similar criteria.

**Summary:**

The similarity theory is a bridge between model and prototype, combined with the first similarity theory and third similarity theory, according to the known similar conditions, identify other similar parameters. And through the second similarity between model and prototype theory can make the similarity calculation become simplified.

**Keywords:** downburst; wind field characteristics; continuous mountains; CFD numerical simulation;

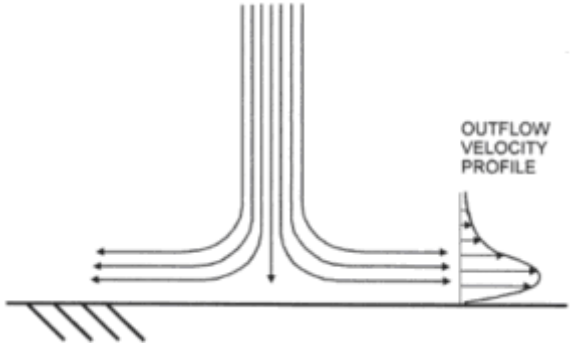
**Abstract.** Downburst is an outburst strong wind on or near the ground, and its wind field characteristics are significantly different from boundary layer winds. Continuous mountains at different distance are one of the main factors for the influence of downburst wind field characteristic. In this thesis, the changes of the wind field characteristics under the influence of continuous mountains at different distance after the downburst happened are studied by CFD numerical simulation. The impact of downburst is analysed and summarized through the charts.

## Introduction

Downburst is an outburst strong wind on or near the ground, and its wind field characteristics are significantly different from boundary layer winds [1]. Microbursts are common phenomenon during thunderstorm weathers, which have been detected on 60% to 70% of the days during thunderstorms[2]. Downburst shave great destructiveness for engineering structures in many countries, including Australia, America, South Africa, Japan and any other countries around the world[3]. In the beginning, the study of downburst was mainly focused on Meteorology and aeronautics. Whitingham [4] found the importance of downburst in the extreme wind in Australia in 1960s,and Melbourne [5] proposed that we should take downburst into wind engineering and structural design consideration. Because of the exchange of heat, terrain-induced and any other reasons, it is common for mountain to have effects on acceleration and changes of direction which are produced by wind flow. So downburst as a strong downdraft which induces an outburst of damaging winds on or near the ground can even do big damage to construction.

## Numerical computational model

*Wind field model.* At present, there are essentially two forms of simplified models for the wind field associated with downburst, namely the "ring vortex" model and the "impinging jet" model [6]. The impinging jet model schematic diagram shows in Fig.1.



Impinging jet model

Fig.1 Impinging jet model models for the wind field

*Governing equations.* Any motions are based on Law of conservation of mass and Law of conservation of energy, and due to the continuous mountains, the two-dimensional wind field of downburst is conducted using the standard k-ε, model. Governing equations of computational simulation studying on two-dimensional continuous mountains at different distance are given by:

$$\frac{\partial p}{\partial t}+\sum_{i=1}^{3}\frac{\partial(\rho u_i)}{\partial x_i}=0 \tag{1}$$

$$\frac{Du_i}{Dt}=f_i-\frac{1}{\rho}\cdot\frac{\partial p}{\partial x_i}-\frac{1}{\rho}\cdot\frac{\partial}{\partial x_i}\left(\frac{2}{3}\mu\frac{\partial u_j}{\partial x_j}\right)+\frac{1}{\rho}\cdot\frac{\partial}{\partial x_i}\left[\mu\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}\right)\right] \tag{2}$$

$$\varepsilon=\frac{\mu}{\rho}\overline{\left(\frac{\partial u_i}{\partial x_k}\right)\left(\frac{\partial u_i}{\partial x_k}\right)} \tag{3}$$

Eq.1 is Law of conservation of mass.Eq.2 is Law of conservation of energy.Eq.3 is standard k-ε model.

**Numerical computational model**

Continuous mountains at different distance adopt cosine equation y=1+ [1+cos (∏r/2$L_1$)] ($L_1$ is the length of half slope showed in Fig.2.).The distance between the mountain which is closed to the center of downburst is 2$D_{jet}$.The initial conditions in this paper are assumed that initial jet diameter $D_{jet}$=1800,Geometric scale 1:3000,initial jet velocity $V_{jet}$=27m/s,Velocity scale based on Mason's [7]study is 1:3. Schematic diagram of computational domain shows in Fig.3.

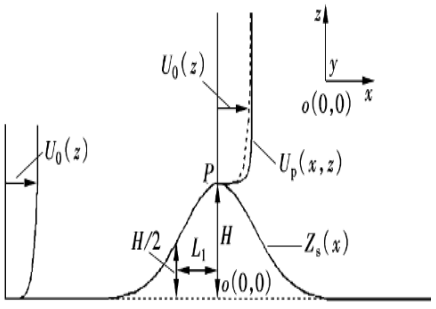


Fig.2 The length of half slope

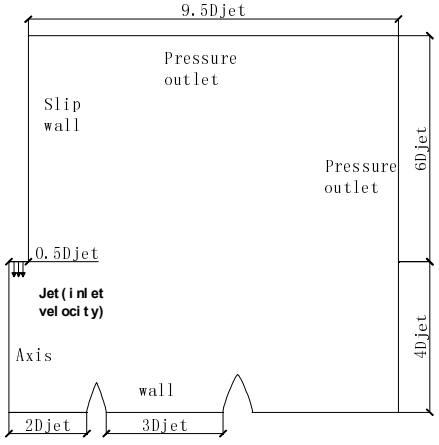

Fig.3 Schematic diagram of computational domain

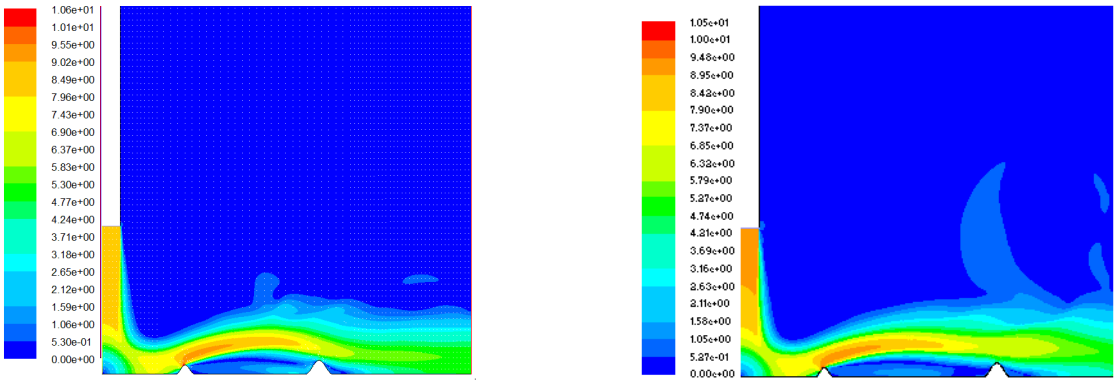
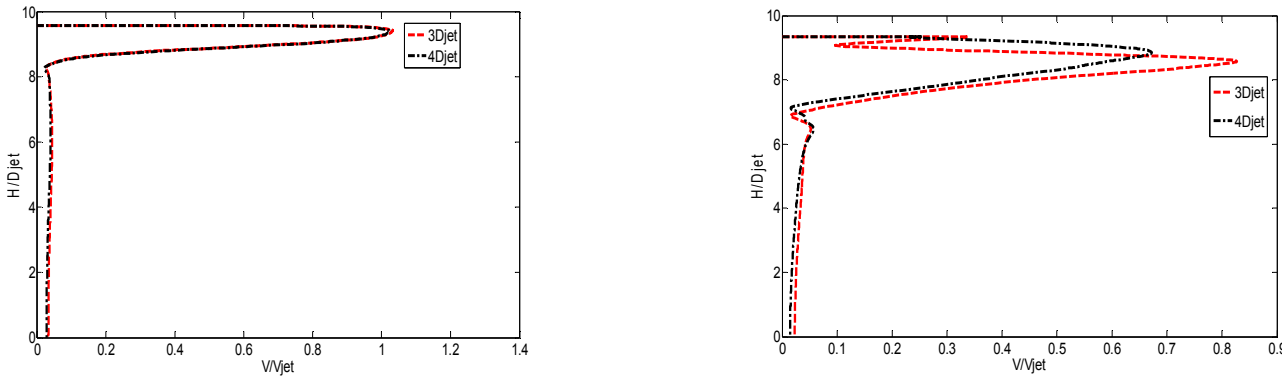
**Results and discussion**

Wind velocity represents the most basic wind field characteristics.Fig.4 depicts wind distribution of wind velocity at different distance between continuous mountains.Fig.5 depicts the wind speed profile.



(a)D=3$D_{jet}$ (b)D=4$D_{jet}$

Fig.4 Wind velocity contours at different distance between continuous mountains



(a) Mountains on the left (b) Mountains on the right

Fig.5 Wind speed profile

As shown in the Fig.4 and Fig.5.There is a velocity distribution of different distance (respectively D=3$D_{jet}$ and D=4$D_{jet}$) between the mountains. We can find the velocity of the top of the first mountain is larger than second's, and the velocity of second mountain of 3$D_{jet}$ is larger than 4$D_{jet}$.Besides,the longer distance between the mountains is, the gentler decrease of velocity is, and the velocity of the district which is between the mountain is essentially the same as the other one.

## Conclusions

The numerical computational simulation method is employed to investigate downburst field characteristics under the influence of two-dimensional continuous mountains at different distance. The two-dimensional wind field of downburst is conducted using the standard k-ε model.The corresponding boundary conditions and boundary treatments make the model more realistic. And CFD method using commercial software FLUENT can effectively simulates the whole process of the downburst field characteristics under the influence of two-dimensional continuous mountains at different distance.

**Keywords:**wind pressure, asymmetric coefficient, transmission line, wind speed, code

**Abstract.** The wind pressure asymmetric coefficient is used to express the variation of wind distribution along the transmission line. In this paper, the value of the wind pressure asymmetric coefficient in some international codes is discussed and compared. It's shown that the coefficient has no relationship with the span length of transmission only in Chinese code.When the span of the checked transmission line is small, the wind pressure calculated based on Chinese code will be smaller than that based on others.

## Introduction

The wind pressure is a random dynamic load, which is not only variable in time but also in space. In usual, the dimension of structure, especially in horizontal direction, is small compared with the turbulence integral length of wind which is used to express the mean dimension of vortex in wind. So, we usually ignore the variation of wind in horizontal direction, which means wind is full-correlation and change synchronously. But, when the structure system is larger than the turbulence integral length of wind, the previous assumption is not suitable. For the transmission line, the distance between two transmission towers is much large than the turbulence integral length of wind, so we must consider the variation of wind along the transmission line [1][2][3].

The wind pressure asymmetric coefficient $\alpha$ is used to express the variation of wind distribution along the transmission line. When we design the transmission line, wind pressure is firstly calculated according to the design wind speed. Then, the wind pressure asymmetriccoefficient is used to discount the wind pressure. But, the value of the coefficient $\alpha$ is related to characteristic of wind flow in nature. At present, we depend on the field measurement to pursue the parameters of wind, which is a big task and many works are carrying out [4][5][6].

In china, the wind pressure asymmetric coefficient $\alpha$ has been provided in codes for twenty years and used to check the stress and wind deflection of wire. But, many accidents occur due to wind deflection of wire beyond the limitation. For example, there are at lest 21 accidents of 500kV transmission line belong to State Grid in summer, 2004, which results a huge damage to power system in China[7][8].

In this paper, the value of the wind pressure asymmetric coefficient $\alpha$ in international codes is discussed and compared in order to provide modifications for the coefficient.

## Specification in Codes

### *China*

Specification of the wind pressure asymmetric coefficient in the Electric Power Industry Standard of China "Code for Design of 110 ~ 500 kV Overhead Transmission Line" (DI/T5092) is shown in Tab. 1.When checking the electrical clearance of tower, if wind speed V ≥120 m/s, $\alpha$ is equal to 0.61[9][10].

**Table 1The wind pressure asymmetric coefficient**

| Span length of transmission line /m | Coefficient |
|---|---|
| ⩽150 | 1.0 |
| 300 | 0.8 |
| 450 | 0.7 |

Notes:

1. Intermediate values can be calculated by the insertion method
2. The coefficient ignores the influence of the wind fluctuation.

### *Japan*

According to the Electrical Association Standardof Japan"Overhead Power Transmission Codes" (JEAC6001), it should multiply by a reduction factor involving the structure scale when calculating the wire wind pressure.The reduction factor $\beta$ can be calculated by the following equation:

$$\beta=0.5+40/S \quad (1)$$

Where,S is the span length and the unit is m.

This provision also states that when the wire windage yaw is calculated using simplified algorithm, if the span length is more than 200 m, $\beta$ will be taken as 0.7. Japanese wire windage yaw was calculated based on the statistically mean wind speed —10 m high above the ground, 10 min and 50 years return period—deriving from the meteorological conditions.

### *Germany*

In the light of Europe Standard "The first part of the high-lifted alternating-current system over 45 kVgeneral conditions and codes" (EN 50341),Germany provides the terms in"The German standard interpretation"(NNA).When designing a new high-lifted alternating-current system,the wind pressure and windage yaw can be calculated according to the following formulation:

$$Q_{WC}=q_c C_{XC} G_{XC} DL \quad (2)$$

Where,$G_{XC}$ is the wire response coefficient, which can be determined by:

$$G_{XC}=\begin{cases}0.75 & L<200m\\ 0.45+60/L & L\geq 200m\end{cases} \quad (3)$$

### *Russia*

According to the provisionof Russian "Electrical installation regulation", thewind pressure can be calculated by the following formulation:

$$P=\alpha K_1 C_X q F \sin^2\psi \quad (4)$$

Where, $\alpha$ is the wind pressure asymmetric coefficient and shown in Table 2; $K_1$ is the span length coefficient:

$$K_1 = \begin{cases} 1.2 & L = 50m \\ 1.0 & L = 100m \\ 1.05 & L = 150m \\ 1.0 & L \geq 200m \end{cases} \quad (5)$$

**Table 2The wind pressure asymmetric coefficient**

| **Wind pressure/（kg·m$^{-2}$）** | 27 | 40 | 55 | 76 |
|---|---|---|---|---|
| **Wind speed /(m·s$^{-1}$)** | 20.8 | 25.3 | 29.7 | 34.9 |
| $\alpha$ | 1.0 | 0.85 | 0.75 | 0.7 |

Considering the cases of wind speed at 29.7 m/s and 25.3 m/s and the provisions of the span length coefficient $K_1$,Table 3 shows the wind pressure asymmetric coefficients changing with the variation of span lengths, and intermediate values are calculated by the insertion method.

**Table 3Thereduction of the wind pressure**

| **Wind speed (m·s$^{-1}$)** | **Span length/m** | | | | |
|---|---|---|---|---|---|
| | 50 | 100 | 150 | 200 | ≥250 |
| 29.7 | 0.81 | 0.743 | 0.709 | 0.692 | 0.675 |
| 25.3 | 1.02 | 0.935 | 0.893 | 0.871 | 0.85 |

**Comparison and analysis**

The values of $\alpha$ based on different international code are compared in Table 4.

**Table 4The comparison of values of $\alpha$**

| **Span length/m** | | | | | | | | | | | | **Codes** |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

| | 0.75 | | | 0.69 | 0.65 | 0.60 | 0.58 | 0.57 | 0.55 | 0.53 | 0.52 | German code |
| 0.81 | 0.74 | 0.71 | 0.69 | | 0.675 | | | | | | | Russian code |

It can be seen that compared with other accessory methods, in the design regulation of China, $\alpha$ is equal to 0.61, which covers a wide range of wind speeds and is suitable to all the span lengths.In the range of small span lengths, $\alpha$ is still 0.61, which is significantly lower than the values of the regulations of other countries. For example, in the case that the span length is less than 363 m, $\alpha$ calculated based on Japanese codes is greater than 0.61 . When the span length is 250 m, $\alpha$ of Japanese, German, and Russian codes is respectively 0.66, 0.69 and 0.675,which are all greater than the value of 0.61. Because the $\alpha$ in Chinese codes has no relationship with the span length, the smaller the span length is, and the greater the wind pressure difference between the windage yaw calculation and load calculation is.It runs contrary to the rules shown in the regulations of all countries' design codes.

## Conclusions

In the paper, specifications in code about wind pressure asymmetric coefficient are investigated. It's shown that the coefficient is 0.61 in Chinese code, and has no relationship with the span length of transmission. But, in other codes, the coefficient depends on the span length, which is more reasonable. When the span is small, the wind pressure based on Chinese code is small, which is dangerous in practice.So, it's necessary to revise the specification in Chinese code.

# Three-Parameter Damage Evolution for Quasi-Brittle Solids

ZHANG Ji

School of Civil Engineering, Tongji University, Shanghai, China

zhang_ji@tongji.edu.cn

**Keywords:** brittle solid; damage evolution; triaxial compression; hydrostatic stress; deviatoric stress

**Abstract.** This paper aims to investigate the performance of a new three-parameter damage mechanics model which describes three basic damage mechanisms of quasi-brittle solids: tension, shear, and hydrostatic compression. The stress is first decomposed into its positive part and negative part, and then the latter is further decomposed into its deviatoric part and hydrostatic part, whereby a three-parameter damage description is formulated. Through matrix representation of the tensor formulation, specific forms of the three-parameter damage theory are illustrated in various stress states. It is found that the proposed framework of three-parameter damage theory can inherit the existing two-parameter models and extend them to a broader scope of application.

## Introduction

One of the complexities of the mechanical behavior of quasi-brittle materials lies in the diversity of damage and failure modes in various stress states. A positive-negative split of the stress advocated by Ladevèze [1] is efficient for the description of different damage mechanisms in tension and compression and has been widely used in subsequent damage models (e.g. that by Voyiadjis et al. [2]). A traditional volumetric-deviatoric split of the strain is featured in many kinds of constitutive models for quasi-brittle materials and has been playing an important role in microplane models since Bažant and Prat [3].

It is the purpose of the present study to combine the benefits from both positive-negative and hydrostatic-deviatoric splits of the stress in a new three-parameter damage model and analyze the qualitative characteristics of its damage evolution in various loading scenarios. It is intended that the successful performance of the existing two-parameter damage models in plane stress problems can be inherited and the inability of them in triaxial compression overcome.

## Tensor Formulation

**Two-Parameter Damage.** In a positive-negative split, the effective stress $\bar{\boldsymbol{\sigma}}$ is decomposed into its positive part $\bar{\boldsymbol{\sigma}}^+$ and negative part $\bar{\boldsymbol{\sigma}}^-$ as

$$\bar{\boldsymbol{\sigma}} = \bar{\boldsymbol{\sigma}}^+ + \bar{\boldsymbol{\sigma}}^-, \tag{1}$$

whose meaning can be clearly expressed with the dyadic forms in the pincipal coordinate system

$$\bar{\boldsymbol{\sigma}} = \sum_i \bar{\sigma}_i \boldsymbol{n}_i \otimes \boldsymbol{n}_i, \quad \bar{\boldsymbol{\sigma}}^+ = \sum_i \langle \bar{\sigma}_i \rangle \boldsymbol{n}_i \otimes \boldsymbol{n}_i, \quad \bar{\boldsymbol{\sigma}}^- = -\sum_i \langle -\bar{\sigma}_i \rangle \boldsymbol{n}_i \otimes \boldsymbol{n}_i, \tag{2}$$

where $\bar{\sigma}_i$ are the principal effective stresses, $\boldsymbol{n}_i$ the corresponding principal direction unit vectors, and the Macaulay brackets $< >$ defined as $< x > = ( | x | + x ) / 2$.

With Eq.(1), a two-parameter damage description can be formulated intuitively as [4]

$$\boldsymbol{\sigma} = (\mathbf{I} - \boldsymbol{D}) : \bar{\boldsymbol{\sigma}} = (1 - d^+)\bar{\boldsymbol{\sigma}}^+ + (1 - d^-)\bar{\boldsymbol{\sigma}}^-, \tag{3}$$

where $\mathbf{I}$ is the fourth-order symmetric identity tensor, $\boldsymbol{D}$ the fourth-order damage tensor, $d^+$ the tensile damage variable, and $d^-$ the compressive damage variable.

**Three-Parameter Damage.** On the basis of Eq.(1), $\bar{\boldsymbol{\sigma}}^-$ is further decomposed into its deviatoric part $\bar{\boldsymbol{\sigma}}_{\mathrm{v}}^-$ and hydrostatic part $\bar{\boldsymbol{\sigma}}_{\mathrm{h}}^-$, forming an overall split of $\bar{\boldsymbol{\sigma}}$

$$\bar{\boldsymbol{\sigma}} = \bar{\boldsymbol{\sigma}}^+ + \bar{\boldsymbol{\sigma}}_{\mathrm{v}}^- + \bar{\boldsymbol{\sigma}}_{\mathrm{h}}^-, \tag{4}$$

where

$$\bar{\boldsymbol{\sigma}}_{\mathrm{v}}^- = \bar{\boldsymbol{\sigma}}^- - \frac{1}{3}\mathrm{tr}\left(\bar{\boldsymbol{\sigma}}^-\right)\mathbf{I}, \quad \bar{\boldsymbol{\sigma}}_{\mathrm{h}}^- = \frac{1}{3}\mathrm{tr}\left(\bar{\boldsymbol{\sigma}}^-\right)\mathbf{I}, \tag{5}$$

in which tr( ) is the trace, and $\mathbf{I}$ the second-order identity tensor (also known as the Euclidean metric).

With Eq.(4), a three-parameter damage description can be formulated intuitively as

$$\boldsymbol{\sigma} = (\mathbf{I} - \boldsymbol{D}) : \bar{\boldsymbol{\sigma}} = \left(1 - d^+\right)\bar{\boldsymbol{\sigma}}^+ + \left(1 - d_{\mathrm{v}}^-\right)\bar{\boldsymbol{\sigma}}_{\mathrm{v}}^- + \left(1 - d_{\mathrm{h}}^-\right)\bar{\boldsymbol{\sigma}}_{\mathrm{h}}^-, \tag{6}$$

where $d_{\mathrm{v}}^-$ is the shear damage variable, and $d_{\mathrm{h}}^-$ the hydrostatic compressive damage variable.

**Matrix Representation**

In order to illustrate the specific forms of the three-parameter damage formulation, in this section the respective stress tensors are represented by their corresponding matrices in the principal coordinate system, from which the evolution modes of the three damage variables can be revealed.

Transposing $\bar{\boldsymbol{\sigma}}$ in Eq.(6) leads to a more straightforward damage expression

$$\bar{\boldsymbol{\sigma}} - \boldsymbol{\sigma} = \boldsymbol{D} : \bar{\boldsymbol{\sigma}} = d^+\bar{\boldsymbol{\sigma}}^+ + d_{\mathrm{v}}^-\bar{\boldsymbol{\sigma}}_{\mathrm{v}}^- + d_{\mathrm{h}}^-\bar{\boldsymbol{\sigma}}_{\mathrm{h}}^-. \tag{7}$$

Matrix representation of Eq.(7) in various typical stress states is listed as follows, where $T_i\left(\bar{T}_i\right)$ and $C_i\left(\bar{C}_i\right)$ are the absolute values of the principal tensile and compressive (effective) stresses $\sigma_i\left(\bar{\sigma}_i\right)$, respectively.

**Uniaxial / Biaxial / Triaxial Tension.**

$$\begin{bmatrix} \bar{T}_1 - T_1 & & \\ & \bar{T}_2 - T_2 & \\ & & \bar{T}_3 - T_3 \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} \bar{T}_1 & & \\ & \bar{T}_2 & \\ & & \bar{T}_3 \end{bmatrix} = d^+ \begin{bmatrix} \bar{T}_1 & & \\ & \bar{T}_2 & \\ & & \bar{T}_3 \end{bmatrix} \tag{8}$$

**Uniaxial Compression.**

$$\begin{bmatrix} 0 & & \\ & 0 & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} 0 & & \\ & 0 & \\ & & -\bar{C}_3 \end{bmatrix}$$
$$= d_{\mathrm{v}}^{-} \begin{bmatrix} \frac{1}{3}\bar{C}_3 & & \\ & \frac{1}{3}\bar{C}_3 & \\ & & -\frac{2}{3}\bar{C}_3 \end{bmatrix} + d_{\mathrm{h}}^{-} \begin{bmatrix} -\frac{1}{3}\bar{C}_3 & & \\ & -\frac{1}{3}\bar{C}_3 & \\ & & -\frac{1}{3}\bar{C}_3 \end{bmatrix} \tag{9}$$

It can be seen from Eq.(9) that $d_{\mathrm{v}}^{-}=d_{\mathrm{h}}^{-}$ since $\bar{\sigma}_1 = \bar{\sigma}_2 = 0$.

**Biaxial Compression.**

$$\begin{bmatrix} 0 & & \\ & -\left(\bar{C}_2 - C_2\right) & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} 0 & & \\ & -\bar{C}_2 & \\ & & -\bar{C}_3 \end{bmatrix}$$
$$= d_{\mathrm{v}}^{-} \begin{bmatrix} \frac{\bar{C}_2 + \bar{C}_3}{3} & & \\ & \frac{-2\bar{C}_2 + \bar{C}_3}{3} & \\ & & \frac{\bar{C}_2 - 2\bar{C}_3}{3} \end{bmatrix} + d_{\mathrm{h}}^{-} \begin{bmatrix} -\frac{\bar{C}_2 + \bar{C}_3}{3} & & \\ & -\frac{\bar{C}_2 + \bar{C}_3}{3} & \\ & & -\frac{\bar{C}_2 + \bar{C}_3}{3} \end{bmatrix} \tag{10}$$

It can be seen from Eq.(10) that $d_{\mathrm{v}}^{-}=d_{\mathrm{h}}^{-}$ since $\bar{\sigma}_1 = 0$.

**Biaxial Tension-Compression.**

$$\begin{bmatrix} \bar{T}_1 - T_1 & & \\ & 0 & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} \bar{T}_1 & & \\ & 0 & \\ & & -\bar{C}_3 \end{bmatrix}$$
$$= d^{+} \begin{bmatrix} \bar{T}_1 & & \\ & 0 & \\ & & 0 \end{bmatrix} + d_{\mathrm{v}}^{-} \begin{bmatrix} \frac{1}{3}\bar{C}_3 & & \\ & \frac{1}{3}\bar{C}_3 & \\ & & -\frac{2}{3}\bar{C}_3 \end{bmatrix} + d_{\mathrm{h}}^{-} \begin{bmatrix} -\frac{1}{3}\bar{C}_3 & & \\ & -\frac{1}{3}\bar{C}_3 & \\ & & -\frac{1}{3}\bar{C}_3 \end{bmatrix} \tag{11}$$

It can be seen from Eq.(11) that $d_{\mathrm{v}}^{-}=d_{\mathrm{h}}^{-}$ since $\bar{\sigma}_2 = 0$.

**Triaxial Tension-Tension-Compression.**

$$\begin{bmatrix} \bar{T}_1 - T_1 & & \\ & \bar{T}_2 - T_2 & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} \bar{T}_1 & & \\ & \bar{T}_2 & \\ & & -\bar{C}_3 \end{bmatrix}$$

$$= d^+ \begin{bmatrix} \bar{T}_1 & & \\ & \bar{T}_2 & \\ & & 0 \end{bmatrix} + d_{\mathrm{v}}^- \begin{bmatrix} \frac{1}{3}\bar{C}_3 & & \\ & \frac{1}{3}\bar{C}_3 & \\ & & -\frac{2}{3}\bar{C}_3 \end{bmatrix} + d_{\mathrm{h}}^- \begin{bmatrix} -\frac{1}{3}\bar{C}_3 & & \\ & -\frac{1}{3}\bar{C}_3 & \\ & & -\frac{1}{3}\bar{C}_3 \end{bmatrix} \tag{12}$$

It can be concluded from Eq.(12) that $d_{\mathrm{v}}^- = d_{\mathrm{h}}^-$ because the damage evolution of principal tensile stresses $(\bar{T}_1, \bar{T}_2)$ should not be subject to that of principal compressive stresses $(-\bar{C}_3)$.

**Triaxial Tension-Compression-Compression.**

$$\begin{bmatrix} \bar{T}_1 - T_1 & & \\ & -\left(\bar{C}_2 - C_2\right) & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} \bar{T}_1 & & \\ & -\bar{C}_2 & \\ & & -\bar{C}_3 \end{bmatrix}$$

$$= d^+ \begin{bmatrix} \bar{T}_1 & & \\ & 0 & \\ & & 0 \end{bmatrix} + d_{\mathrm{v}}^- \begin{bmatrix} \frac{\bar{C}_2 + \bar{C}_3}{3} & & \\ & \frac{-2\bar{C}_2 + \bar{C}_3}{3} & \\ & & \frac{\bar{C}_2 - 2\bar{C}_3}{3} \end{bmatrix} + d_{\mathrm{h}}^- \begin{bmatrix} -\frac{\bar{C}_2 + \bar{C}_3}{3} & & \\ & -\frac{\bar{C}_2 + \bar{C}_3}{3} & \\ & & -\frac{\bar{C}_2 + \bar{C}_3}{3} \end{bmatrix} \tag{13}$$

It can be concluded from Eq.(13) that $d_{\mathrm{v}}^- = d_{\mathrm{h}}^-$ because the damage evolution of principal tensile stresses $(\bar{T}_1)$ should not be subject to that of principal compressive stresses $(-\bar{C}_2, -\bar{C}_3)$.

**Pseudo-Triaxial Compression—Compressive Meridian.** In this case, the lateral compression $C_1 = C_2$ is less than the longitudinal comression $C_3$.

$$\begin{bmatrix} -\left(\bar{C}_1 - C_1\right) & & \\ & -\left(\bar{C}_1 - C_1\right) & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} -\bar{C}_1 & & \\ & -\bar{C}_1 & \\ & & -\bar{C}_3 \end{bmatrix}$$

$$= d_{\mathrm{v}}^- \begin{bmatrix} \frac{-\bar{C}_1 + \bar{C}_3}{3} & & \\ & \frac{-\bar{C}_1 + \bar{C}_3}{3} & \\ & & \frac{2\bar{C}_1 - 2\bar{C}_3}{3} \end{bmatrix} + d_{\mathrm{h}}^- \begin{bmatrix} -\frac{2\bar{C}_1 + \bar{C}_3}{3} & & \\ & -\frac{2\bar{C}_1 + \bar{C}_3}{3} & \\ & & -\frac{2\bar{C}_1 + \bar{C}_3}{3} \end{bmatrix} \tag{14}$$

It can be seen from Eq.(14) that $d_{\mathrm{v}}^{-}$ and $d_{\mathrm{h}}^{-}$ evolve independently of each other.

**Pseudo-Triaxial Compression—Tensile Meridian.** In this case, the lateral compression $C_2 = C_3$ is greater than the longitudinal comression $C_1$.

$$\begin{bmatrix} -\left(\bar{C}_1 - C_1\right) & & \\ & -\left(\bar{C}_3 - C_3\right) & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} -\bar{C}_1 & & \\ & -\bar{C}_3 & \\ & & -\bar{C}_3 \end{bmatrix}$$

$$= d_{\mathrm{v}}^{-} \begin{bmatrix} \dfrac{\bar{C}_1 - \bar{C}_3}{3} & & \\ & \dfrac{\bar{C}_1 - \bar{C}_3}{3} & \\ & & \dfrac{2\bar{C}_3 - 2\bar{C}_1}{3} \end{bmatrix} + d_{\mathrm{h}}^{-} \begin{bmatrix} -\dfrac{\bar{C}_1 + 2\bar{C}_3}{3} & & \\ & -\dfrac{\bar{C}_1 + 2\bar{C}_3}{3} & \\ & & -\dfrac{\bar{C}_1 + 2\bar{C}_3}{3} \end{bmatrix} \tag{15}$$

It can be seen from Eq.(15) that $d_{\mathrm{v}}^{-}$ and $d_{\mathrm{h}}^{-}$ evolve independently of each other.

**True Triaxial Compression.**

$$\begin{bmatrix} -\left(\bar{C}_1 - C_1\right) & & \\ & -\left(\bar{C}_2 - C_2\right) & \\ & & -\left(\bar{C}_3 - C_3\right) \end{bmatrix} = \boldsymbol{D} : \begin{bmatrix} -\bar{C}_1 & & \\ & -\bar{C}_2 & \\ & & -\bar{C}_3 \end{bmatrix}$$

$$= d_{\mathrm{v}}^{-} \begin{bmatrix} \dfrac{-2\bar{C}_1 + \bar{C}_2 + \bar{C}_3}{3} & & \\ & \dfrac{\bar{C}_1 - 2\bar{C}_2 + \bar{C}_3}{3} & \\ & & \dfrac{\bar{C}_1 + \bar{C}_2 - 2\bar{C}_3}{3} \end{bmatrix} + d_{\mathrm{h}}^{-} \begin{bmatrix} -\dfrac{\bar{C}_1 + \bar{C}_2 + \bar{C}_3}{3} & & \\ & -\dfrac{\bar{C}_1 + \bar{C}_2 + \bar{C}_3}{3} & \\ & & -\dfrac{\bar{C}_1 + \bar{C}_2 + \bar{C}_3}{3} \end{bmatrix} \tag{16}$$

It can be seen from Eq.(16) that $d_{\mathrm{v}}^{-}$ and $d_{\mathrm{h}}^{-}$ evolve independently of each other.

**Summary**

Several damage evolution properties can be summarized from the above matrix representation:

1) $d^{+}$ evolves independently of $d_{\mathrm{v}}^{-}$ and $d_{\mathrm{h}}^{-}$.
2) In stress states other than triaxial compression, $d_{\mathrm{v}}^{-} = d_{\mathrm{h}}^{-}$, evolving in synchronization.
3) In triaxial compression, $d_{\mathrm{v}}^{-}$ and $d_{\mathrm{h}}^{-}$ evolve independently of each other.

In the present three-parameter damage model, the positive-negative split of $\bar{\boldsymbol{\sigma}}$ is in the first level, and the volumetric-deviatoric split of $\bar{\boldsymbol{\sigma}}^{-}$ second. The positive-negative split is superordinate to the volumetric-deviatoric split, which leads to property 1. When zero or positive principal stresses are present, the volumetric-deviatoric split is limited to part of the stress components, which leads to property 2. When no zero or positive principal stresses are present, the volumetric-deviatoric split is implemented on all the stress components, which leads to property 3.

It is seen that in stress states other than triaxial compression, the three-parameter damage model reduces to the existing two-parameter one, i.e. $d^- = d_v^- = d_h^-$. So the proposed framework of three-parameter damage description can inherit the successful two-parameter models and extend them to a broader scope of application.

# An Integrated Simulation System for Building Structures

Duan Jin[1,a], Chen Xiao-ming[1], Qi Hu[1], Li Yun-gui[1]

[1]China State Construction Technical Center, Beijing, 101300, PR China

[a] duanjin78@126.com

**Key words**: structural simulation, system integration, FEA, BIM

**Abstract:** In this paper, an integrated simulation system for building structures is presented to satisfy the engineering requirements for high performance simulation.It is a coalition of the traditional design softwares and general finite element analysis (FEA)softwares. This system is developed in the platform ofIntel Fortran, using theprogramming language of Fortran2003/2008.For simplicity, it would be introduced and discussedbriefly in the following article.Andcombining with YJK and ABAQUS,this system is implemented to perform dynamic analysis for a high-rise building.Its capacity and validity would be demonstrated by the numerical results.

## 1. Introduction

With the rapid development of high-rise buildings and long-span structures in the recent years, high performance simulation (HPS) is becoming more and more important, sometimes even crucial, for the structure design and building construction. The traditional design softwares, such as PKPM, ETABS, MIDAS, YJK, and so on, can't match the advanced requirements of HPS. On the other hand, the large scale general finite element analysis (FEA) softwares, such as ABAQUS, ANSYS, ADINA, etc., although have the powerful computational abilities, but can't be applied directly to the architecturalstructure analysis and design, due to the fact that their preprocessors are inconvenient for building modeling and their postprocessors can't present computational results according to the building structure specifications, say, the civil codes and the custom of engineering.

To satisfy the above engineering requirements for HPS, the authors and their co-workers havebeen developingan integrated simulation system for building structures, which is a coalition of some secondary software developments together with the traditional design softwares and general FEA softwares. This simulation system will serve as a sub-system of building information model (BIM) and provide high performance computation, simulation and technical supports for the design and construction of large and complex buildings.

According to the simulation system, there are many important technical indicators needing to be emphasized and enforced, typically the following aspects: (1) data input from the building design softwares, such as PKPM, MIDAS, YJK, etc.; (2) data transformation from the structural model or geometrical model to FEA model; (3) data input to the general FEA softwares, such as ABAQUS, ANSYS, ADINA, etc.; (4) data calculation and sorting-out in statistics according to the building structure specification; (5) a parallel FEA computing kernel developed specially for the building structures, serving as the supplements to the general FEA softwares. All of the above technical indicatorsdeserve seriousand vast consideration,but for simplicity of expression, they are introduced and discussed briefly, say, some details will be omitted in this paper.And finally, to demonstrate the validity of the integrated simulation system, some computational results for the complex building will be presented and discussed.

## 2. Description of the simulation system

The integrated simulation system of building structures would be introduced from two points of view, one the objective of this system and the other its program architecture according to the software development.

### *2.1 Objective of the simulation system*

The ultimateobjective of the simulation system is to provide high performance computation, such as elastic-plastic dynamic analysis, wind-resistant dynamic analysis, etc., for complex building structures, by a simple and even fool mode.That is to say the complicated and redundant computing theories and options are isolated from the user interface. The building structure can be modeled with any popular design software, such as PKPM, MIDAS, YJK, ETABS, etc. And then it can be imported into the simulation system and transformed into FE models automatically, including FE meshing and boundary conditions setting. The general FE software, such as ABAQUS, ANSYS, etc., can be called as a computing kernel to solve the above FE model. And in addition, an independent parallel FEA kernel has been developing, not finished yet, by the authors to act as the supplement of the general business softwares. The calculated results of FEA would be transferred automatically to the postprocessor, which would assessment the structural damage and estimate its security and comfort level according to the theory of mechanics and building structure specifications. And finally, the post-processor would present the calculation reports with WORD and PDF files.The main capabilities and basic flowsof the integrated simulation system are shown in Fig.1.

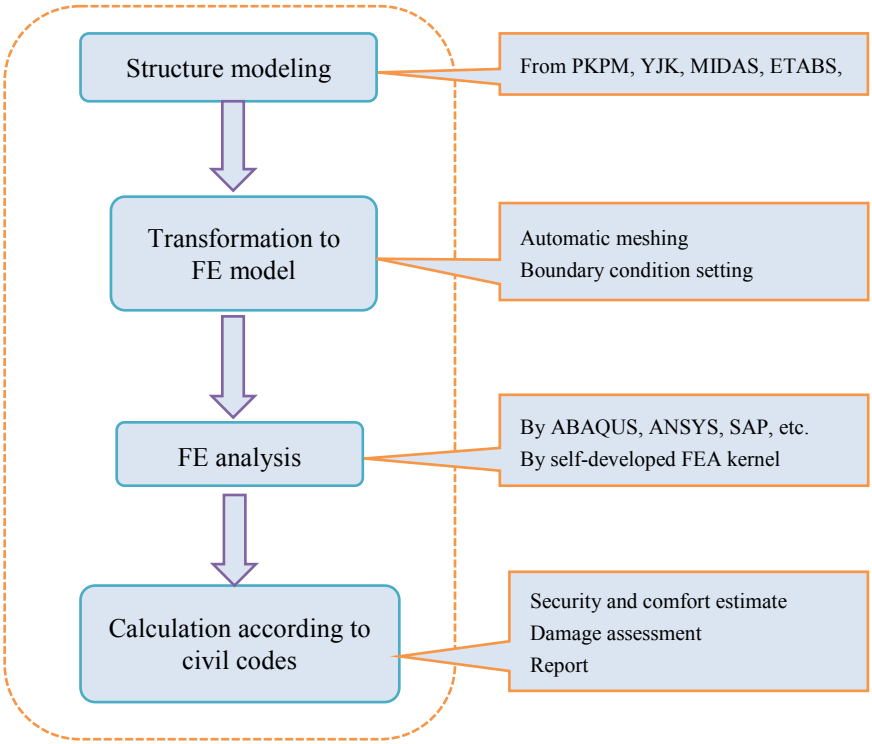

Fig.1 Illustration of the simulation system

### *2.2 Program architecture of the simulation system*

The present simulation system is not a simple binding and piling up of the design softwares and general FE softwares, but a software development with a massive amount of coding, using the

Fortran 2008 language[1,2]. The design softwares, such as PKPM, MIDAS, etc., and general FEA softwares, such as ABAQUS, ANSYS, etc., are integrated into the present software, or system,in the same way as libraries calls in programming. The program architecture of the simulation systemis shown in Fig.2, from which it can be seen that the hard-core of this system is the data processingcenter. This center containsmost of the system codes, including the structural models import, the FE models transformation, i.e., automatic mesh generation[3~5], the programming interface to the general FEA software, and so on. The other codes mainly consist of the auxiliary FEA kernel and the post-processor, which would sort-out in statistics the calculated data results according tostructural engineering and present reports for the engineers. The simulation system presented in this paper istheoretically designed to be strong and open, in other words, any structuraldesign software or FEA software can be added to this system, as long as their data interfaces arenot classified. That's the primary reason why this simulation system can be regarded as a sub-system of building information model (BIM).

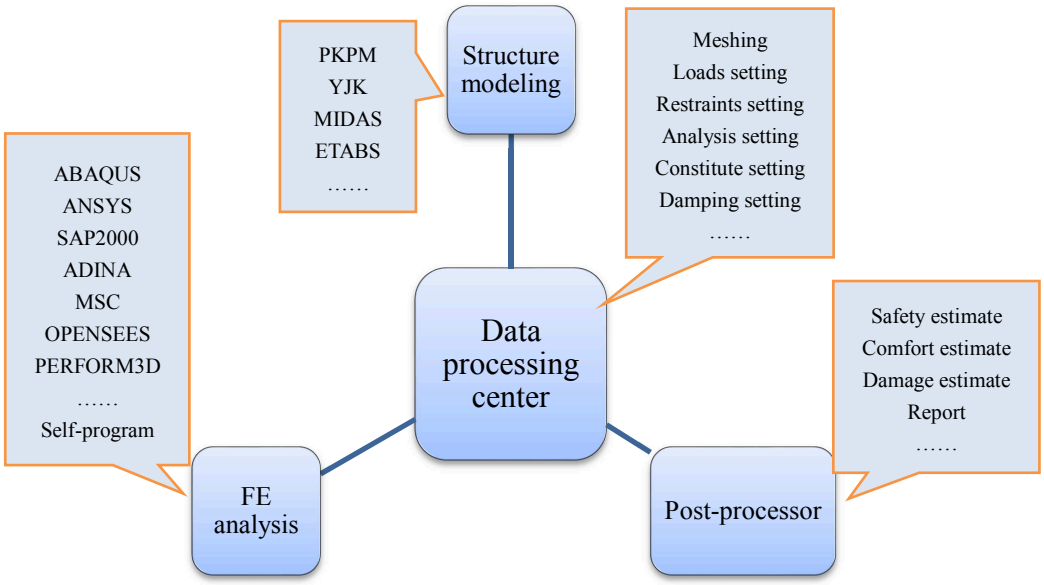

Fig.2 Program architecture of the simulation system

### *2.3 Interface of the simulation system*

The interface of the simulation system is developed by Intel Visual Fortran, shown in Fig.3. It consists of five major parts: (1) data input from the building design softwares, such as YJK, MIDAS, etc.; (2) data transformation from the structural model to FEA model, including transformation options setting and mesh generation, see Ref.[6]; (3) FEA analysis, including constitutive models setting anddata input to the general FEA softwares, such as ABAQUS, and the self-developed computing kernel, seeRef.[7]; (4) data calculation and sorting-out according to the building structure specification; (5) results output and display.

Obviously, the design softwares and FEA softwares have been integrated into a whole. The structure models could be input from the traditional design softwares. The miscellaneous work of mesh generation for the complex buildings has been auto-completed by the system itself. The obscure parameters-setting for nonlinear mechanics analysis has been isolated from the users. The FEA softwares just serve as one of the computing kernels. And finally, the computational results would be recalculated and sorted-out according to the engineering requirements.So using this integrated system, HPS for the complex building are not so profound and complicated as before.

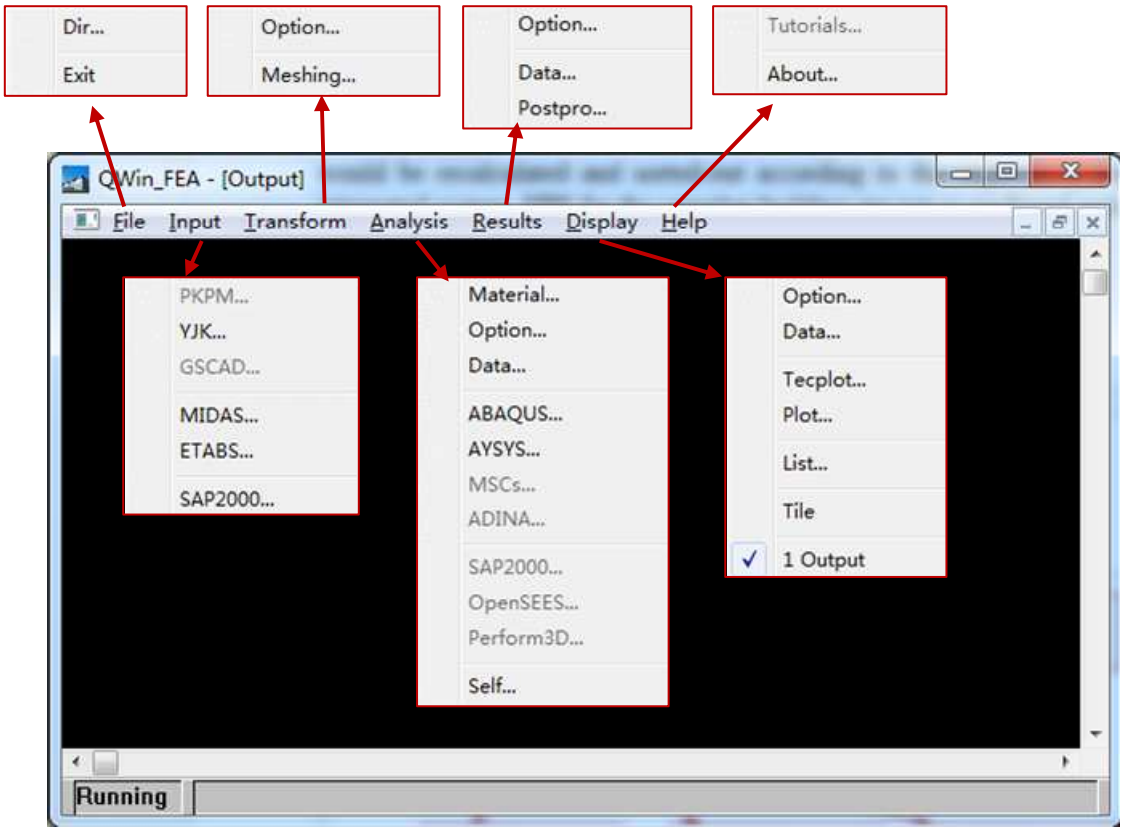

Fig.3 Interface of the simulation system

## 3. Numerical examples

To demonstrate the capacity of the simulation system,a tall-building numerical example would be provided in the following. This building structure is modeled in YJK, meshed by the present system and analyzed by ABAQUS.

### *3.1 Description of the model*

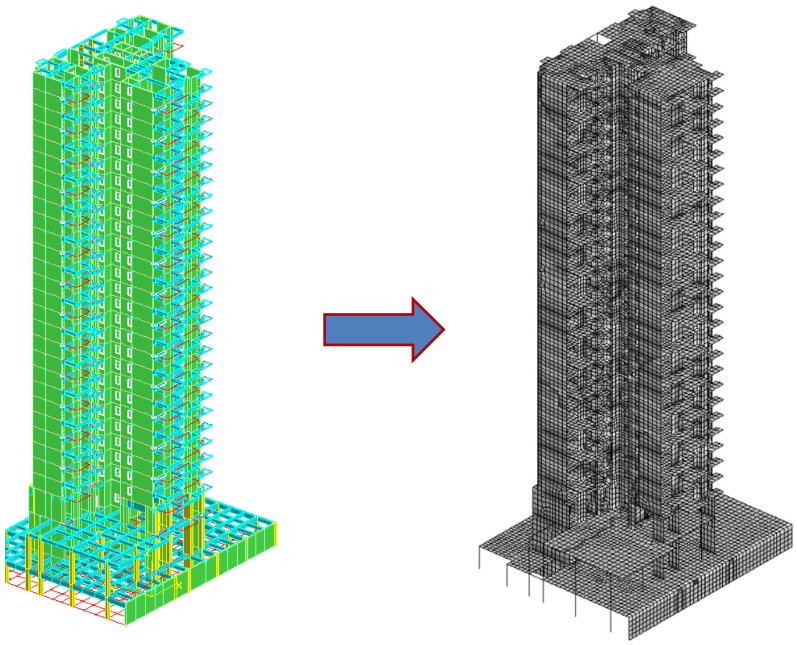

Fig.4 Structural model (YJK) and FE model

The structural model was imported from YJK and transformed into FE model automatically in the system, shown in Fig.4. The most noteworthy feature of this structure is the plane irregularity. Intuitively, the connective bands at the central zone of the floor may be the weak zone of this structure.

In the dynamic analysis, the one-dimensional constitutive model for beams, columns and braces uses that of the code for design of concrete structures (GB-50010-2010) [8], while the two-dimensional constitutive model for walls and slabs adopts the concrete damaged plasticity model of ABAQUS, seeing Abaqus theory manual [9]. The dynamic loads take the seismic wave of America EI Centro (1940.5.18, magnitude is 7, depth is 10 km), whose acceleration history of the first 20 seconds is shown in Fig.5.

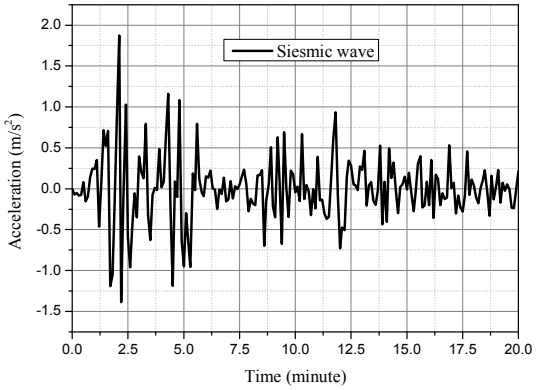

Fig.5Seismic acceleration (America EI Centro)

### *3.2Calculated results*

For simplicity, this paper would only present the response history of the top displacement and base shear, plus the damage assessments of the structure. The other results, especially the statistical results according to the building codes, would be omitted.

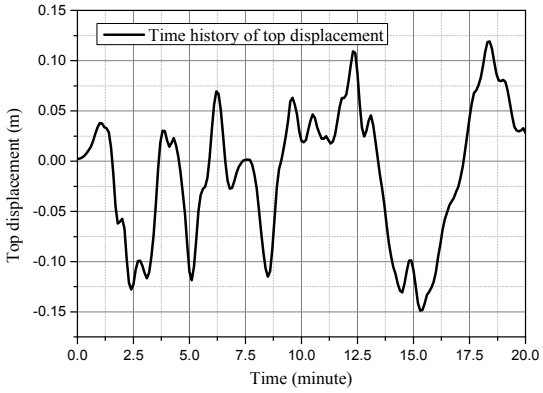

Fig.6 Time history of top displacement

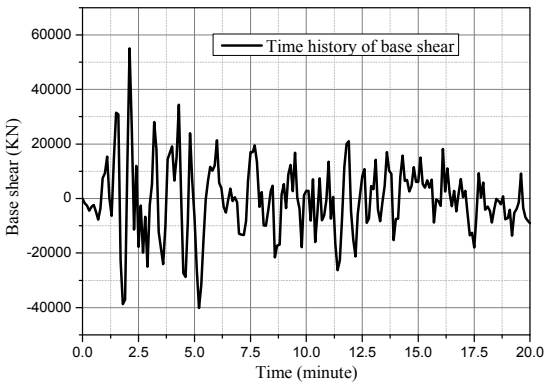

Fig.7 Time history of base shear

The time history of top displacement is shown in Fig.6 and the base shear is shown in Fig.7, from which it can be seen that the history shape of the base shear is very similar to that of seismic acceleration, shown in Fig.5. While if they are normalized and plot in the same graph, seeing Fig.8, the differences become conspicuous. The reasons leading to the differences include the transmission of elastic wave and the others, which are beyond the scope of this paper.

The damage of the structure can be described by the factor of stiffness degradation, which is assumed to be functions of plastic strains and the other field variables. This factor indicates the

degradation of elastic stiffness. Its value belongs to 0~1 interval, in which "0" means no damage has occurred while "1" means the components have been completely damaged. The stiffness degradation of walls, slabs and frames are shown in Fig.9, Fig.10 and Fig.11 respectively, from which it can be observed easily that the damage concentrates at the connective bands at the central zone of the floor, which is identical with the prediction of section 3.1.

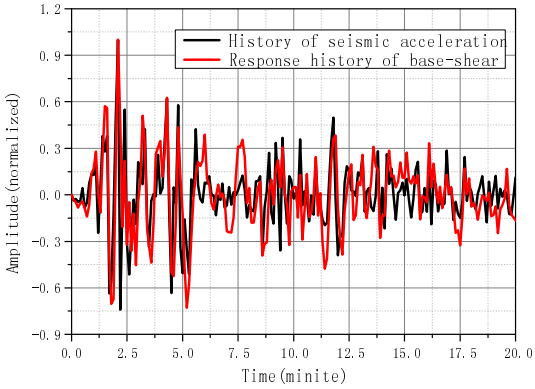

Fig.8Normalization of the seismic input and response

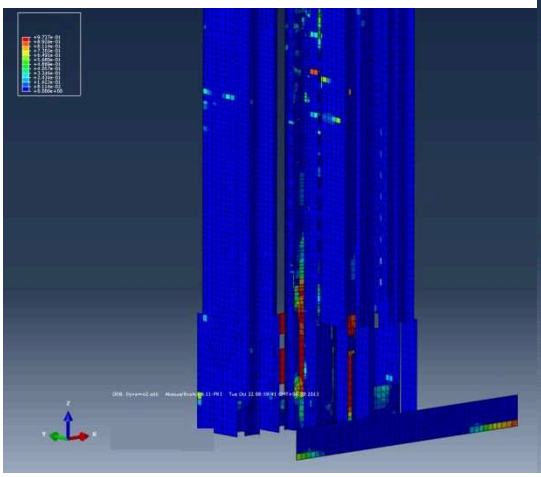

Fig.9The stiffness degradation of walls

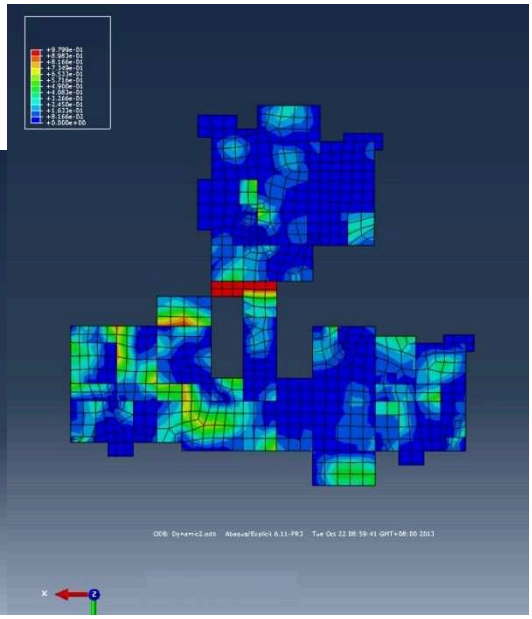

Fig.10 The stiffness degradation of slabs

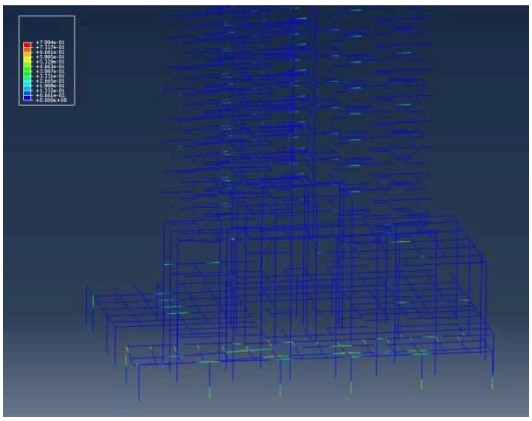

Fig.11The stiffness degradation of frames

## 4. Conclusions

The integrated simulation system of this paper is developed for the high performance computation of building structures, including security assessment and optimization design. And above all, the first purpose is to provide elasto-plastic dynamic analysis for the seismic resistance design of high-rise buildings. To achieve this aim effectively, the popular structural design softwares and the general FEA softwares have been integrated into a whole system by secondary development. Certainly this system has not been completely finished yet, whileitsvalidity for complex building simulation has been demonstrated by the numerical example of sect.3.

# Simulation Analysis of Built Environment Based on Design Builder Software

Lin Zhang

Sichuan College of Architectural Technology, Deyang, Sichuan, 618000,china

7854278 @qq.com

**Keywords:** built environment , building simulation , Design Builder (DB)

**Abstract.** This paper introduces Design Builder (DB) software and analyzes the computational simulation capacity of Design Builder that is used to deal with built environmental issues, in order to help readers to have a more comprehensive understanding of Design Builder's simulation capacity in processing built environment.

## Introduction

Built environment is determined by the outdoor weather conditions, the heating condition of various indoor heat sources, and indoor and outdoor ventilation . As the variation of built environment is a complex process determined by numerous factors, using computer to simulate computing method is required to predict the conditions of built environment, such as indoor temperature and humidity changes over time, HVAV's realtime energy consumption and the energy required by the environment control of building throughout the year. With people's increasingly higher demands for the quality of built environment and increasing emphasis on building energy efficiency , building simulation is increasingly becoming one of the indispensable tools for design , evaluation and analysis.

In the field of building and environmental control, the study on built environment and dynamic simulation of control system had already begun in the mid-1960s. The main research contents in the initial period are the basic theory of heat transfer and calculation method of load. Due to the development of computer technology, in the 1990s , research emphasis of simulation technology was transferred from simulation modeling to simulation software, so that simulation technology could be more widely applied. Today, building simulation technology has been widely applied in built environment related fields , including design , construction, operation, maintenance and management.

## Target of Built Environment Simulation

The built environment can be divided into built light environment , built acoustic environment , built thermal environment and built wind environment .

Built light environment mainly includes sunlight sheltering , indoor lighting and solar radiation. Built acoustic environment mainly includes outdoor noise and indoor sound. Built thermal environment mainly includes indoor temperature condition without air-conditioning and air-conditioning energy consumption in air-conditioned room. And built wind environment mainly includes outdoor wind environment and indoor natural wind .

## Design Builder (DB) Software of Built Environment Simulation

Design Builder is an integrated graphical user interface simulation software developed for dynamic simulation program (Energy Plus) of building energy consumption. It can be applied at any stage of the design process, to optimize the design and evaluation by providing the performance data , and even can be carried out in the initial design stage before the entire design is determined .

Design Builder is applicable to architects, HVAC engineers, energy consultant companies, universities and some research institutions..

### 3.1 Main Purposes

Evaluating the relevant setting items of building envelope from the aspects of overheating, energy consumption and visual effects; optimizing the use of natural light , conducting simulation on lighting control system and calculating the amount of lighting energy savings ; calculating speed, temperature and pressure distribution in the internal and external field of building with CFD module ; visualizing and shading of venue layout ; simulating the natural ventilation of buildings ; HVAC(Heating, Ventilating and Air Conditioning) designing, including the calculation of heating and cooling equipment's capacity.

Design Builder can be easily utilized, so that even a non-professional user can quickly conduct modeling for a complex building . Using data templates , by selecting from the drop-down list, general building structure, activities inside building, HVAC, lighting systems and model can be loaded. The buildings of the same type can be used repeatedly, and also can be added to the template. This function is linked to the database, which can make changes to the building and surrounding area. And in the design and evaluation phase, each building model can be detailedly set.

### 3.2 Main Functions of Design Builder

Design Builder uses OpenGL solid modeler which is easy to operate. Thus , when " block " is configurated in 3D space , by stretching and shearing, building model production can be intuitively carried out . The thickness of building component and the area and volume of room can be controlled visually.

CFD function is combined with simulation model, and CFD boundary conditions can be defined based on the data output by Energyplus.

British EPCS ( Level 3 and 4 ) standard applies the computing method of SBEM.

Natural ventilation simulating.

Natural lighting module：simulation is carried out for lighting control system and the amount of energy savings of lighting is calculated.

Shading can be achieved through blinds, hanging visor , side sun visor, internal shading and curtains' setting.

All the simulation data can be displayed according to one year, one month , one day, one hour , and even more smaller time intervals: building energy consumption , expressed as the consumption of fuel or energy ; indoor temperature ; meteorological data ; heat transfer that gets through walls, roofs , ventilation and other building envelope; heating and cooling loads ; CO2 output .

To determine the capacity of heating or cooling equipment by referring to local meteorological data.

Compact HVAC provides a simple method for detailedly analyzing commonly used heating and cooling systems.

CAD data or scans can be imported, and 3D CAD model can be imported by gbXMl formats.

Parameters analysis panel can be used to adjust the design parameters within its action range, so as to analyze its impact effect.

Rendering image and animation of architectural design can be output, including shading effect.

Design Builder has the latest ASHRAE ( American Society of Heating Refrigerating and Airconditioning Engineer ) world meteorological data and observation location data ( 4429 sets of data) , and can use hourly meteorological files of Energy Plus for free.

## Application of Design Builder (DB) Software in the Built Environment Simulation

### 4.1 Visualization of Design Builder

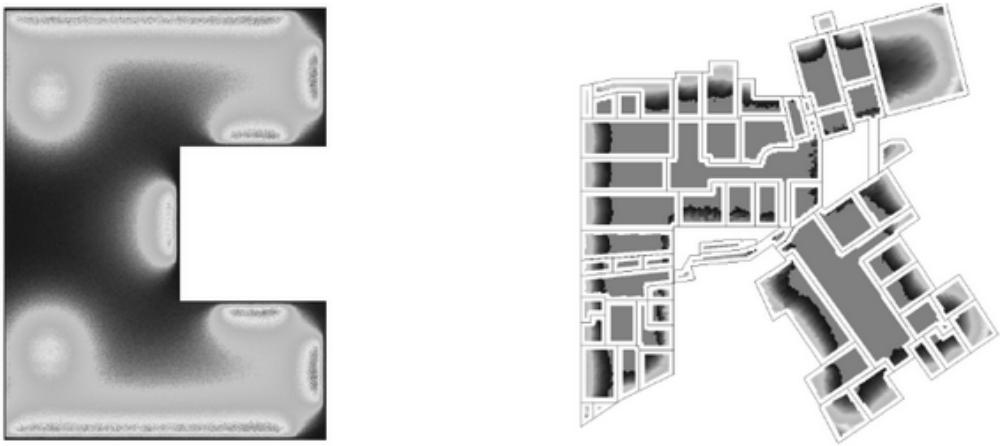
Through the visualization of Design Builder , vivid images of real texture can be obtained with the least amount of effort . At any stage of model making, the rendering image can be obtained by clicking on the label of visualization. Besides, the appearance of the building can be confirmed through amplification and movement, and the interior of the building can be confirmed through browsing function. After the processing of visualization on Design Builder model, 3D model can be output to other softwares and can play a role during the presentation .

### 4.2 HVAC Analysis

Design Builder v3 provides a more powerful and flexible way to access Energy Plus HVAC model, and uses the complete ASHRAE 90.1 baseline HVAC system type to analyze gas load and water route.

### 4.3 Daylighting Analysis

Internationally accepted American Radiance lighting analysis core is applied to map isophotes and calculate the average lighting factor. Through Energyplus daylighting analysis, artificial lighting time can be shortened, to reduce energy consumption and carbon emissions. Radiance rendering is applied to generate realistic lighting analysis chart, and detailed reports can be issued according to LEED EQ8.1 , BREEAM HW1 and Green Star IEQ4 standard .



Contour plot showing daylight availability across a floorplan Daylight distribution within a zone

Fig 1 Daylighting analysis diagram

### 4.4 Design Builder CFD

Integrating the concept of CFD( Computational Fluid Dynamics ) into building model can simulate the air flow and temperature environments inside and outside the building. Specifically, the installation position of air conditioner , the configuration of the shape, window , ventilation, and intake port of building, indoor temperature environment, outdoor air flows and so on can be analyzed .

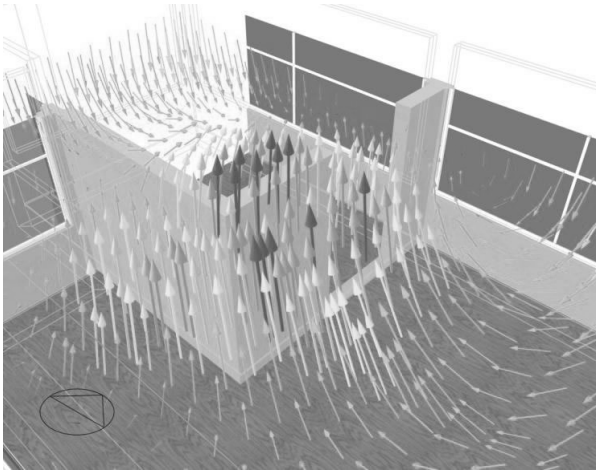


Fig 2 The air flow simulation

## Conclusion

Design Builder building software, through analyzing the basic information of project and the difference of building types , develops different technical route strategies and project location; through providing a rich selection library of products, helps designers effectively analyze the built environment; and through establishing a unified data model, completes the computational analysis of

energy conservation, simulation of building energy conservation, integrated design of solar energy water heater and architecture, and some relevant simulation work, which greatly improves the design efficiency.

**Keywords:** finite element method; SHTB; stress wave problem

**Abstract.** Split Hopkinson Tensile Bar (SHTB) apparatus is widely used in experimentally investigating the mechanical properties of materials. The experimental results are significantly depended on the amplitude, the shape and the wave length of incident wave. However, there's no research on the effect of incident wave especially the influence of parts of the SHTB equipment has been put forward. The mechanism of the overlying and the amplitude of incident wave by FEM has been analyzed, which can give much help for the theory basis of SHTB apparatus design.

## Introduction

Split Hopkinson Tensile Bar (SHTB) apparatus is widely used in experimentally investigating the mechanical properties of materials. Typical experimental device is as Fig.1[1-9] shows.

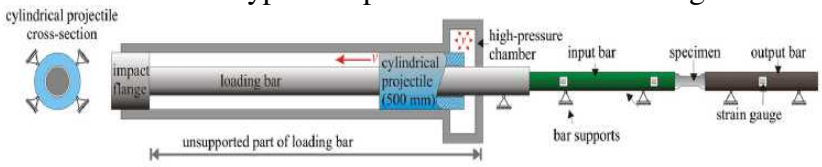

Fig.1 SHTB experimental device

The basic principle is to use a tubular bullet to impact the flange of the incident bar to generate compression waves, which being directly converted to tensile wave by the flange.

currently at home and abroad, the experimental apparatus is used to study the dynamic tensile properties of the material. For tensile wave generation, in particular the size of the components of the experimental apparatus did not see systematic research, and such problems are the key to success SHTB device.

In this paper, dynamic finite element analysis software ANSYS/LS-DYNA is applied to simulate the effects of the size of the components of SHTB experimental apparatus to provide a reference for experimental apparatus improvement.

## Theoretical analysis problem of one-dimensional elastic stress wave overlay

Stress wave propagated in the absence of external force truss is bound to meet the following two conditions at the interface of the variable cross-section rod:

1, Equal internal forces on both sides of the interface, namely Eq.1

$$A_1(\sigma_I + \sigma_R) = A_2\sigma_T \quad (1)$$

2, Particle velocity must be continuous on both sides of the interface, namely

$$v_I - v_R = v_T \quad (2)$$

In which $A_1$ is the cross sectional area of the incident bar, $A_2$ is the cross sectional area of the transmit bar, $\sigma_I$ is incident stress wave, $\sigma_R$ is reflected stress wave, $\sigma_T$ is transmitted stress wave, $v_I$ is incident particle velocity, $v_R$ is reflective particle velocity, $v_T$ is transmission particle velocity.

From Newton's second law formula $Fdt = mdv$ and $m = \rho Adl$, $F = \sigma A$, $C = \frac{dl}{dt}$, we can obtain Eq.3:

$$\sigma = \rho C v \tag{3}$$

In which C is elastic wave velocity of bar, $dl$ is disturbed bar length. Substitute Eq.3 into Eq.2, we can obtain Eq.4:

$$\frac{\sigma_I}{\rho C} - \frac{\sigma_R}{\rho C} = \frac{\sigma_T}{\rho C} \tag{4}$$

For one-dimensional elastic stress wave problem, assuming the bar density and wave velocity are constant, then we can obtain Eq.5:

$$\sigma_I - \sigma_R = \sigma_T \tag{5}$$

Substitute Eq.5 into Eq.1, we can obtain Eq.6 and Eq.7:

$$\sigma_T = \frac{2A_1\sigma_I}{A_1 + A_2} \tag{6}$$

$$\sigma_R = \frac{A_2 - A_1}{A_2 + A_1}\sigma_I \tag{7}$$

When the bullet impact the flange, it generates a reverse tensile wave $\sigma_t^1$ as well as a compress wave $\sigma_c^1$ propagated in the same direction. $\sigma_c^1$ will form reverse tensile wave $\sigma_t^2$ after reflected at the free end of the flange. As Eq.6, Eq.7 shows that the reverse tensile wave $\sigma_t^2$ propagates to the impact surface, part of the wave transmits into the incident bar to form tensile wave $\sigma_t^3$, part is reflected back to flange to form another compress wave $\sigma_c^2$. If the length of the flange is smaller than the length of the stress wave, the transmitted tensile wave $\sigma_t^3$ will overlay with the tensile wave $\sigma_t^1$ at moment of impact, the reflected compress wave $\sigma_c^2$ can be transmitted and reflected again and overlay with previous wave, ultimately form the incident tensile wave for the experiment.

Fourier series by the general cycle shows that any incident wave can be decomposed into a finite number of sine wave form. Assuming the incident wave is expressed as: $A\sin(a\pi t + b)$, cycle is $\frac{2}{a}$, the fourth cycle at the same expression in the form of the incident wave is expressed as: $A\sin[a\pi(t + \frac{1}{2a}) + b]$. Applying the trigonometric function we can transform above formula into $A\cos(a\pi t + b)$. Two incident wave overlay, transform into formula: $A\sin(a\pi t + b) + A\cos(a\pi t + b) = A\sin(a\pi t + c)$, in which $c = \arccos\frac{\cos b - \sin b}{\sqrt{2}}$. Namely two incident waves can be superimposed as one incident and superimposed upon the same cycle, only the different phases. Therefore, the bullet impact the flange while simultaneously generating a compression wave 1 and tensile wave 2, if the head of the tensile wave 3 reflected by compression wave 1 reaches the cross-section, the tensile wave 2 goes through fourth cycle, then they can become a tensile wave. Therefore the length of the impact end of flange is the eighth of the length of stress wave, it will be a similar tensile wave with no overlaid wave.

## Numerical simulation of one-dimensional elastic stress wave overlay

A. Building finite element model

ANSYS/LS-DYNA is universal explicit dynamic finite element analysis software for solving various speed collision problems of nonlinear structures, explosion and other impact dynamic problems. This paper simulates stress pulse propagation process in elastic bar. We use solid 164 solid element to establish a complete finite element model of solid elastic bar. Specific parameters are shown in Table 1. We build the LS-DYNA data model of bar without two-dimensional simplification

and axisymmetric process to ensure accuracy of numerical simulation results. Material is defined as ideal elastic model, material properties are shown in Table 2.

Table 1. Simulate parameter of solid bar (unit mm)

| | Flange length | Bar length | Flange diameter | Diameter of solid bar |
|---|---|---|---|---|
| Solid bar | 500 | 6000 | 100 | 75 |
| | 250 | 6000 | 100 | 75 |
| | 125 | 6000 | 100 | 75 |

Table 2. Material properties

| Material | Modulus of elasticity | Density | Poisson's ratio |
|---|---|---|---|
| Steel | 2.1E11Pa | 7800kg/m3 | 0.3 |

Given the truss shape is regular, we use mapped meshing. Finite element model of the bar system is created in LS-DYNA in fig.4.

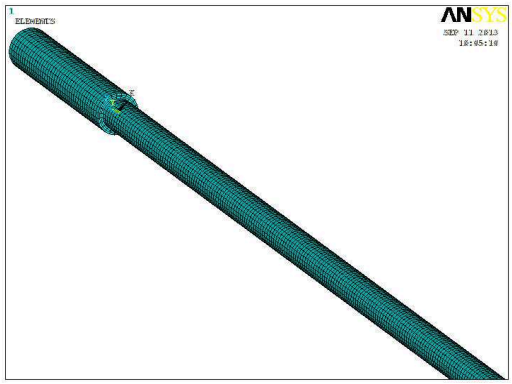

Fig.4 Finite element model of 500mm end of solid bar

Certain pressure load is defined as Table 3. shows on the annular tapered stem unit.

Table 3. Time-press value

| NO | Time/s | Press/MPa |
|---|---|---|
| 1 | 0 | 0 |
| 2 | 2.4E-5 | 55.87 |
| 3 | 1.34E-4 | 55.87 |
| 4 | 1.56E-4 | 0 |
| 5 | 1.7E-4 | 0 |

B. Research on wave overlay problems of different flange length of incident bar

Select a surface measurement point of incident bar to get its Y direction stress time curve, as fig.5 shows.

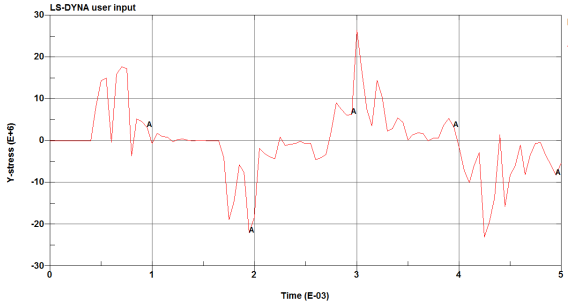

Fig.5 Stress-time curve in solid bar of 500mm end

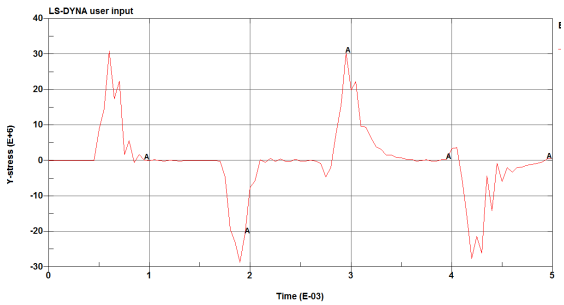

Fig.6 Stress-time curve in solid bar of 250mm end

As the flange length is 250mm, the y direction stress-time curve of the same measurement point is shown in fig.6. As we can see from the figure, a plurality of waves coming sequentially, reflected and transmitted stress wave can't catch up with the front of the wave and the wave hasn't overlay. stress amplitude is relatively small.

As the flange length reducing to 125mm, the y direction stress-time curve is shown in fig.7.

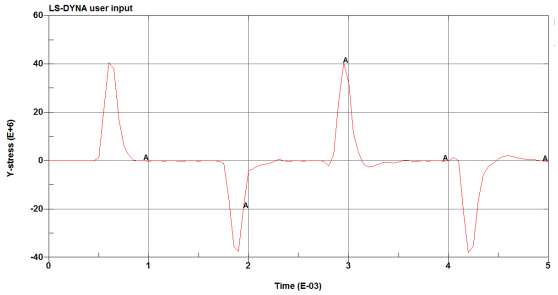

Fig.7 Stress-time curve in solid bar of 125mm end

By simulation we found that when the length of the flange is 125mm, the stress wave superposition is idealized waveform, consistent with the above theoretical derivation. That is, at the measuring point of the incident bar after impacting, when the length of the stress wave propagation in a pulse time is 1000mm, twice the length of the end 500mm, the tensile wave generated by impacting doesn't really overlay with the tensile wave generated by the compression wave reflected at the free surface. When the impact end is 125mm, as it is one-eighth of the stress wave length, they overlay to be a perfect wave.

## Theoretical and numerical simulation of one-dimensional elastic stress wave amplitude value

A. Theoretical analysis of one-dimensional elastic stress wave amplitude value

When the bullet impacts the flange, the compression wave generated at the impact end spreads to the impact end after being reflected at free surface and be reflected and transmitted again, resulting in reflect stress wave and transmit stress wave. This process ends inside repeatedly, if transmit wave reciprocated is too much, it is not conducive to the transmission overlay.

From the Eq.6, Eq.7, we know that stress wave generated by multiple reflection is Eq.8,

$$\sigma_{nR} = \left( \frac{A_2 - A_1}{A_1 + A_2} \right)^n \cdot \sigma_0 \tag{8}$$

The stress wave repeated transmitted is as Eq.9 shows

$$\sigma_{nT} = \frac{2A_1 (A_2 - A_1)^{(n-1)}}{(A_1 + A_2)^n} \sigma_0 \tag{9}$$

Where $\sigma_0$ is the compression stress generated by the bullet impacting the flange, A1, A2 is respectively the flange and the incident bar. Clearly, in order to improve the tensile wave superposition effect, by reducing the number of reflections flange stress waves, reducing the amplitude of the reflected wave to reach.

Form Eq.8, we can know when the cross-sectional area of the flange is close to the incident bar, the generated reflected wave amplitude is smaller and the header wave number of the transmitted wave is also reduced.

B. Numerical simulation of one-dimensional elastic stress amplitude value

192KN impact force is applied to the annular surface of the solid bar. Specific parameters are shown in Table 4, material properties and pressure value are like with above.

Table 4. Different dimension of 500mm end of solid bar

| | Flange length | Bar length | Flange diameter | Diameter of solid bar |
|---|---|---|---|---|
| Solid bar | 500 | 6000 | 100 | 80 |
| | 500 | 6000 | 100 | 50 |
| | 500 | 6000 | 100 | 20 |

Stress-time curve were obtained of the solid bar having different diameters at a measuring point, as fig.8 shown.

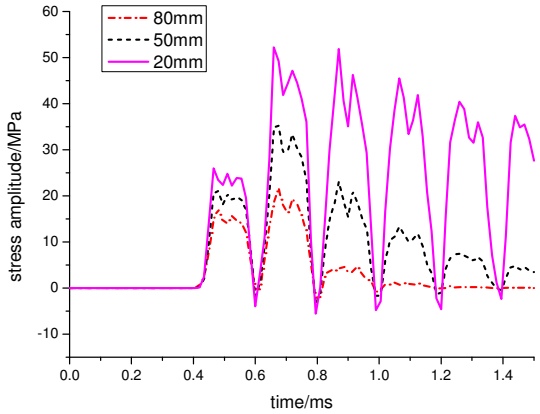

Fig.8 Stress amplitude time curve of 500mm end solid bar with different diameter

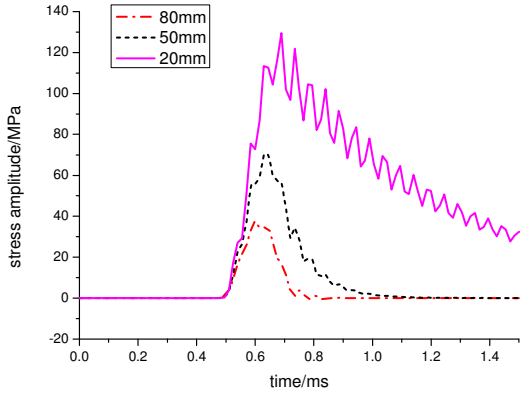

Fig.9 Stress amplitude time curve of 125mm end solid bar with different diameter

When the flange length is 125mm, change the diameter of the incident bar from 80mm, 50mm to 20mm, we get the stress amplitude curve of the same measuring point of the solid bar, as fig.9 shows.

It can be easily seen that, with the decrease of the diameter of the incident bar, although the amplitude of the stress is gradually increased, the number of the transmission waveform is more and is unfavorable for the superposition of the incident wave.

Consistent with the previous derivation, in comparison, the thick solid bar is better than thin solid bar.

## Conclusion

In this paper, we use solid modeling techniques and cell meshing of ANSYS/LS-DYNA to study the effects of the size of the components of SHTB experimental apparatus and find the size and quality of the experimental device is related to the incident wave form.

These results concluded that:

(1) When the flange is one-eighth of the stress wave length, two tensile wave generated around the opposite tensile bar can interfere with each other to become a perfect tensile superimposed wave.

(2) Tensile waveform generated by the superposition of the incident bar that the stress wave of thick bar superimposed effect is the best and the amplitude get the maximum, the thin solid bar superimposed worst.

Through theoretical and modeling studies of the different sizes of the incident bar, the device is expected to optimize SHTB equipment.

# Numerical simulation of SHPB test for concrete under confining pressure

Hua Zhang[1,a] , Aoyu XIE[1,b] , Yuwei Gao[2,c]

[1] College of Civil and Transportation Engineering, Hohai University, Nanjing 210098, China

[2] No.277, Shihua Village 2, Jinshan district, Shanghai, China

[a] zhanghuacd@hotmail.com, [b] xayevan@163com, [c] yuwei-gao@163.com

**Key words:** SHPB, confining pressure, HJC constitutive model, strain-stress curve, strain rate.

**Abstract**: Using the HJC dynamic constitutive model, the Split Hopkinson Pressure Bar (SHPB) impact test with confining pressure for concrete was simulated in the software ANSYS/LS-DYNA. The confining pressure was simulated by applying constant pressure around the specimen. The triangle velocity wave, which has less diffusion, is used as loader in the simulation. The confining pressures used were 0MPa, 2MPa, 4MPa, 8MPa and 16MPa and the stress-strain curves were presented. The influence of confining pressure on the dynamic properties was analyzed by comparing the stress-strain curves of concrete under different stress states. The strain rate decreases sensitively as long as the confining pressure increases. By debugging the impact velocity, the stress-strain curves under the similar strain rate were obtained, which indicate the toughening and reinforcing effect with the increase of confining pressure.

## Introduction

In real-life engineering, many constructions have already been in triaxial stress state before they withstand the dynamic load. A number of studies show that concrete has special mechanical behaviors under confining pressure. But currently, in case of confining pressure, the research about the dynamic mechanical properties of concrete is still not enough, especially under high strain rates. Under high strain rates, the coupling effect of confining pressure and strain rate results in the increase of the peak stress for concrete and its failure mode will change from brittle failure to ductile failure with the increase of confining pressure [1,2].

The Split Hopkinson Pressure Bar (SHPB) experiment with confining pressure is a commonly useful method to investigate the dynamic mechanical behaviors for concrete in triaxial stress state. In the recent decades, the technology of SHPB with confining pressure is developing constantly. In 1972, R. J. Christenson et al. did firstly the SHPB test for the rock under confining pressure [3] and after that, Yu et al. carried on a further research [4]. Candappa et al. made an intensive experiment in order to determine the effect of lateral confinement on the ductility of high strength concrete [5,6]. In 2000, an improved 3-Axis SHPB device was designed by S.Nemat-Nasser and they carried out a research on mortar.

However, the current experimental method has quite a few drawbacks. The numerical simulation can put aside the insufficient such as electromagnetic interference, effects of interfacial friction in the experiment. In this paper, the SHPB test with confining pressure device is simulated by LS-DYNA finite element software using the HJC dynamic constitutive model. The data obtained by numerical simulation are applied in the analysis of dynamic properties for concrete influenced by confining pressure.

## SHPB techniques and data processing

### 2.1. SHPB with active confinement device

The Ø74mm SHPB device with variable cross-section core bars is shown in Fig.1. The length of striker bar, input bar and output bar are, respectively, 400mm, 3200mm, 1600mm and the diameter of the striker bar is 37mm. The input bar is variable cross-section, with the diameter increasing from 37mm to 74mm.

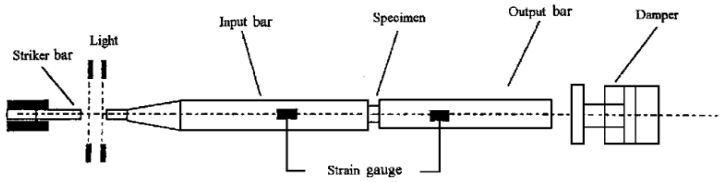

**Fig.1** Schematic illustration of SHPB with variable cross-section

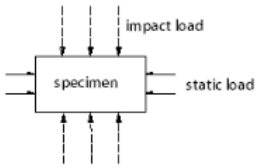

**Fig.2** Schema of SHPB test with confining pressure

Currently, in the commonly used SHPB device, the confinement is obtained by pumping hydraulic oil in the closed oil room as soon as the pressure of the oil room reaches the needed value. The pressure is putted on the specimen by rubber interlayer. The confining pressure value can be adjusted freely in the experiment.

SHPB test with confining pressure is used to investigate dynamic mechanical properties of materials in the triaxial stress state. However, it's hard to get the triaxial stress state because the cylindrical specimen is commonly subjected to impact load in the axial direction and pressure in the radial direction in the test, i.e. two-dimensional load, shown as Fig.2. The load simulates just approximately the triaxial stress state in the real-life engineering project.

### 2.2. Method of data processing

For large diameter SHPB device, the dispersion of waves is wide. We used two waves, the incident wave $\varepsilon_i(t)$ and the transmitted wave $\varepsilon_t(t)$ in the data processing [7]:

$$\varepsilon(t) = \frac{2c_0}{L_0}\int_0^t(\varepsilon_i(t) - \varepsilon_t(t))dt \tag{1}$$

$$\sigma(t) = \frac{A}{A_s} E\ \varepsilon_t(t) \tag{2}$$

where E, $C_0$, A are, respectively, elastic modulus, the propagation velocity of the impact wave in the bars, the cross-sectional area of the bar; $A_s$, $L_0$ the original cross-sectional area, the original length of the concrete specimen, respectively. $\varepsilon_i(t), \varepsilon_t(t)$ the strain signals of incidence, transmitted waves, respectively. Because the numerical simulation experiments can put aside the interference of electrical noise during the experiment, the start location of the incident wave can take the intersection of the incident wave and the baseline [8]. The delay time τ of transmitted wave, relative to the incident wave, is:

$$\tau = \frac{l_1 + l_2}{c_0} + \frac{L_0}{c_1} \tag{3}$$

Where $l_1$, $l_2$ are, respectively, the distance from data collection points of incident wave and transmitted wave to the specimen interface. $c_1$ is the propagation velocity of elastic wave in the concrete specimen.

**Discussion of SHPB numerical simulation methods**

The numerical simulation is carried out by the finite element software ANSYS/LS-DYNA and on the basis of HJC constitutive model. The parameters of HJC model is provided by reference [9], shown as table1.

**Table1.** Parameters of HJC dynamic constitutive model

| $\rho_o$/kg/m$^3$ | $f_c$/Pa | A | B | C | $S_{MAX}$ | G/Pa |
|---|---|---|---|---|---|---|
| 2.4E$^3$ | 48E$^6$ | 0.79 | 1.60 | 0.007 | 7.0 | 14.86E$^9$ |
| $D_1$ | $D_2$ | N | EFMIN | T/Pa | $p_c$/Pa | $\mu_c$ |
| 0.04 | 1.0 | 0.61 | 0.01 | 4E$^6$ | 16.0E$^6$ | 0.001 |
| $P_l$/Pa | $\mu_l$ | $k_1$/Pa | $k_2$/Pa | $k_3$/Pa | E/Pa | |
| 0.8E$^9$ | 0.1 | 85E$^9$ | -171E$^9$ | 208E$^9$ | 35.7E$^9$ | |

The solid 164 unit is used to simulate the pressure bars and the specimen. The linear elastic materials chosen for the input and output bar have the following properties: $\rho_0$=7850 kg/m$^3$, $E_0$=210GPa, $\mu$=0.25. The stress wave is gathered at 1.2m and 0.4m over the end of the strike place. In order to reduce the quantity of calculation，1/4 compressive bar model is constructed, and the constraint is applied on the symmetric boundary.

For the meshing, the input and output bar are divided into 12 parts along the radial direction; the length of axial grid is 10 mm. The concrete specimen is treated with compaction and it is divided into 24 parts radially and 8 parts axially. The total number of units is 56940. The SHPB model with mesh partition is shown in Fig.3.

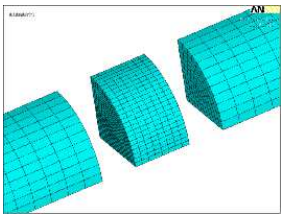

**Fig.3** The SHPB bar model with meshing partition

Considering the wave dispersion of variable cross-section bar and overshoot in the head of stress wave, the triangle velocity wave, which has less dispersion, is used as a loader here. The principles of loading by triangle velocity wave are: the length of the velocity wave is twice the length of the striker bar; the velocity wave that loads directly in the pressure bars interface, whose value is half of the impact velocity [10].

Considering the unit failure of specimen during the course of loading, we will use the corrosion contact ERODING-SURFACE-TO-SURFACE to define the interfaces, which is a kind of interaction between surfaces. The SHPB test with confining pressure can be simulated by applying the constant pressure peripherally the specimen, which will not be influenced by the deformation of

specimen. It is found that the data are stable when rigidity scale factor f takes the default value 0.1. To ensure sufficient damage evolution of materials, the impact velocity is taken as 20m/s and the confining pressure used were 0MPa, 2MPa, 4MPa, 8MPa and 16MPa.

**Material properties analysis of concrete under different confining pressure**

By the numerical simulation, the concrete stress-strain curves under different confining pressure are shown in Fig.4. From Fig.4, it can be seen that the general shapes of the curves are similar. The concrete strength increases as the confining pressure increases and so increase the peak strain, the ultimate strain. That is to say, the ductility and the toughness increase with the increase of confining pressure. The concrete elastic modulus decreases as the confining pressure increases and the triaxial stress makes the concrete deformation become slow. When the confining pressure reaches 16MPa, due to the insufficiency of material damage evolution, it reflects a certain degree of viscoelastic hysteresis.

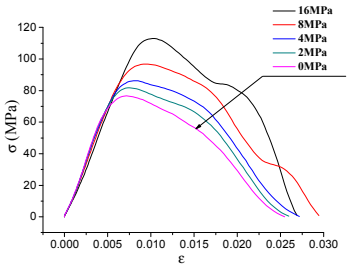

**Fig.4** The concrete stress-strain curves under different confining pressure in the impact velocity of 20m/s

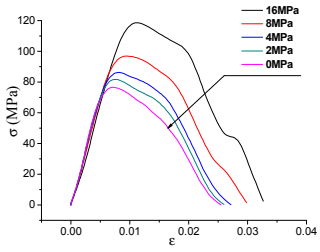

**Fig.5** The concrete stress-strain curves at similar strain rate

The confining pressure restricts the concrete deformation velocity and at the same impact velocity, the average strain rate decreases as the confining pressure increases. To study the confining pressure strengthening effect at the similar strain rate, it is needed to increase the striker bar impact velocity. Here, we debugged only the situation of 8MPa and 16MPa because the strain rates at the confining pressure of 0MPa, 2MPa, 4MPa are very similar. By debugging the impact velocity, it is found that in the event that the confining pressure increases every 4MPa, the impact velocity should be increased about 1m/s. After the debugging, the concrete stress-strain curves at similar strain rate are shown in Fig.5. Fig.5 indicates that at the similar strain rate, the confining pressure improve the strength and the toughness of the concrete. As the confining pressure increases, the damage form changes from the brittle failure in the uniaxial stressed state to the ductile failure in the triaxial stress state.

**Conclusions**

(1) Based on the results of numerical simulations, the finite element software ANSYS/LS-DYNA is an efficient method to analyze the SHPB test with confining pressure. HJC dynamic constitutive model of concrete can be well used to simulate the SHPB test.

(2) According to the obtained concrete stress-strain curves, as the confining pressure increases, so increase the strength, ductility and toughness. The damage form in the material changes with the increase of confining pressure.

(3) The method of numerical simulation of SHPB confining test is given. However, it is also two-dimensional load because in the triaxial stress state, the pressures of bar unit fluctuate and transmitted and reflected waves oscillate. Further experimental and simulation-based researches are necessary to ascertain the response of concrete in triaxial stress state.

**Keywords:** Elasto-plastic time-history analysis, ABAQUS, Super high-rise, Seismic response

**Abstract.** As a general-purpose finite element program, ABAQUS's strong non-linear calculation capacity make it especially suitable for elasto-plastic time-history analysis, in this paper, with a super high-rise project, the experience of elasto-plastic time-history analysis using ABAQUS is described, include the modeling process, material constitutive model, numerical integral method and evaluation of analysis results, some reference will be provided to the other engineering practices.

## Introduction

Compare with the elasto-plastic static analysis method, elasto-plastic time-history analysis method is considered to be a more accurate seismic analysis method, by using the method, engineers can get a more clear understanding of the response of super high-rise buildings under rare earthquake. In recent years, the rapid development of high-rise buildings in China put pressing needs on elasto-plastic time-history analysis method, it has became the key technique in structure seismic reascrh and design.

Currently, ABAQUS is recognized to be the most authoritative software in elasto-plastic time-history analysis, as a general-purpose finite element program, ABAQUS has strong non-linear calculation capacity, which make it suitable for analyze the response of super high-rise buildings under rare earthquake. By sevreal years development, ABAQUS has accumulated much successful experiences in the field of seismic analysis.

In this paper, with a case of engineering practice, the procedures of elasto-plastic time-history analysis using ABAQUS is described to provide reference to the other projects.

## Engineering practice

The engineering practice is a super high-rise office building in Shenyang(shown in Fig.1), the structure is in the form of reinforced concrete frame core tube, the total height of the building is 151.2m, exceeding the limit height (130m) as prescriptive in Technical specification for concrete structures of tall building(JGJ 3-2010) to frame core tube structure in 7 degree seismic intensity. The area of structure is 59,000m$^2$, the shape and dimensions of standard layer are shown in Fig.2 .

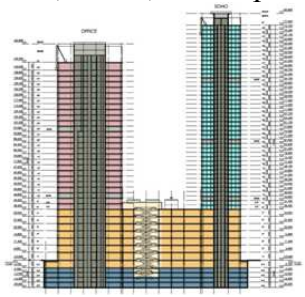

Fig. 1 The office building.

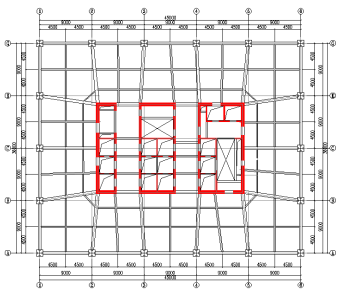

Fig. 2 Standard layer of the building.

## Modeling process

An accurate elastic-plastic model is the foundation of elasto-plastic time-history analysis, since the elasto-plastic model is particularly complex, modeling by ABAQUS/CAE is not feasible. The

modeling process in this paper is establish the elastic analysis model by structural design software YJK, and then transform the elastic model into the ABAQUS elasto-plastic model by using a self-developed interface program, the ABAQUS elasto-plastic model is shown in Fig.3.

In this model, shear walls, coupling beams and slabs are simulated by shell element S4R or S3R, layers of reinforcement in these components are defined by using the Rebar Layer option in ABAQUS. Beams and columns are simulated by beam element B31, layers of reinforcement in Beams and columns are simulated by B31 element with box-section.

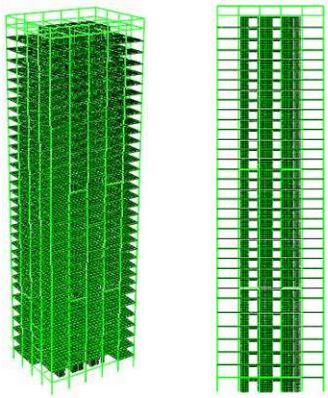

Fig. 3 ABAQUS elasto-plastic model.

**Material constitutive models**

Two kinds of material constitutive model were used in this ABAQUS model, kinematic hardening model was used to simulate the steel constitutive, plastic-damage model was used to simulate the concrete constitutive[1,2], since the plastic-damage model could not be used for B31 element, an ABAQUS user material subroutine of damage constitutive model for concrete under uniaxial stress was developed[3,4], which can be used for B31 element.

**Numerical integration method**

In elasto-plastic time-history analysis, the direct integration method was used to solve the dynamic equations, implicit and explicit are the two main direct integration method. Compare with the implicit method, explicit method neither requires matrix inversion nor the formation of stiffness matrix, thus much shorter time is enough to solve the dynamic equations, moreover explicit method can also avoid divergence problem caused by serious non-linearity in structure as the implicit method encountered, for these two reasons, explicit method is more suitable to solve large-scale computing.

**Model validation**

In order to verify the accuracy of the ABAQUS model, modal analysis was conducted respectively by ABAQUS and SATWE, the comparison of results was given in tab.1, as seen in table, the structural total mass, each order periods and modals calculated by the two softwares are basically the same, thus the ABAQUS model was proved to be correct.

Tab. 1 Comparison of modal analysis

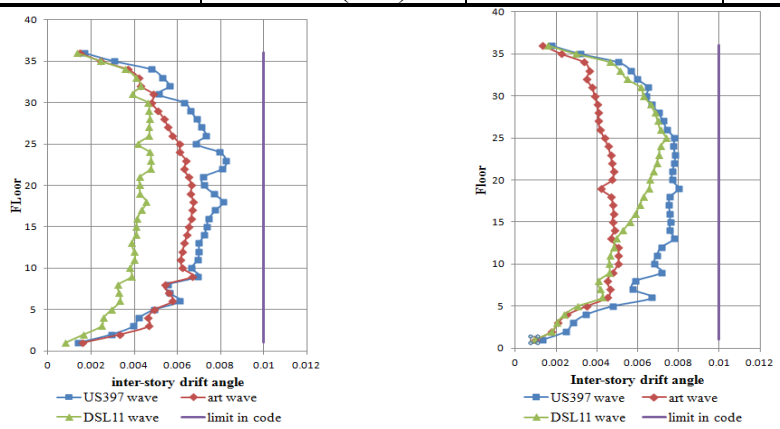
| | | SATWE | ABAQUS | Modal |
|---|---|---|---|---|
| Total mass /ton | | 100363 | 98912 | |
| Period | T1/s | 3.78 | 3.85 | 1st-order translation in X |
| | T2/s | 3.63 | 3.81 | 1st-order translation in Y |
| | T3/s | 2.82 | 2.73 | 1st-order torsion |
| | T4/s | 1.17 | 1.16 | 2nd-order translation in X |
| | T5/s | 0.97 | 0.96 | 2nd-order translation in Y |
| | T6/s | 0.92 | 0.93 | 2nd-order torsion |

**Analysis results**

In order to analyze the seismic response of the structure under rare earthquake, one artificial seismic wave and two natural seismic waves were chosen to input for analysis, according to the analysis results, the maximum vertex displacement and inter-story drift angle of structure under each waves are shown in tab.2, the inter-story drift angle curve are shown in Fig.4, the x direction maximum inter-story drift angle is 1/120, the y direction maximum inter-story drift angle is 1/125, both occurred under the seismic wave of US397, and do not exceed the limit as prescriptive in Code for seismic design of buildings(GB 50011-2010).

Tab. 2 The maximum vertex displacement and inter-story drift angle

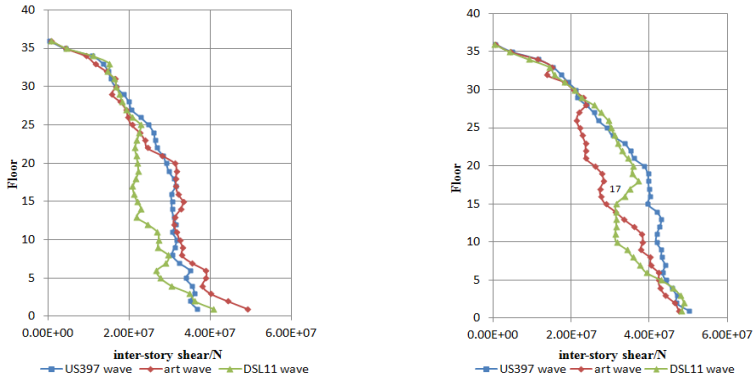
| Waves | X direction | | Y direction | |
|---|---|---|---|---|
| | Maximum vertex displacement /m | Maximum inter story drift angle (Floor) | Maximum vertex displacement /m | Maximum inter story drift angle (Floor) |
| art | 0.75 | 1/149 (18F) | 0.539 | 1/200 (10F) |
| US397 | 0.879 | 1/120 (23F) | 0.903 | 1/125 (19F) |
| DSL11 | 0.482 | 1/213 (22F) | 0.716 | 1/135 (25F) |



a) X-direction b) Y-direction

Fig. 4 Inter-story drift angle curve.

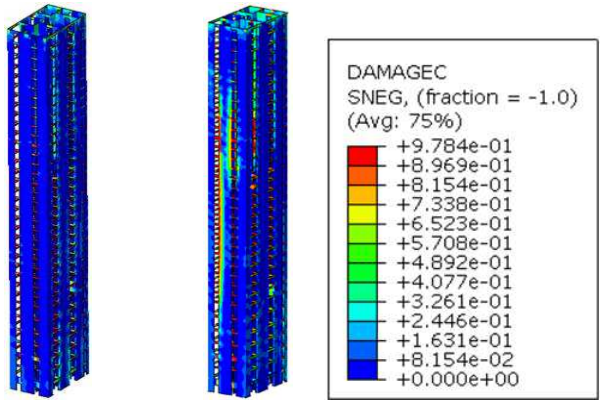
The inter-story shear curve are shown in Fig.5, the shear weight ratio of structure under each waves ranging from 3.8%~5.22%, meeting the requirements of Code for seismic design of buildings(GB 50011-2010).



a) X-direction b) Y-direction

Fig. 5 Inter-story shear curve.

According to the analysis results, The structure was damaged most severely under the seismic wave of US397. The plastic damage nephogram of shear walls under the seismic wave of US397 is shown in Fig.6, except for a few areas, no severe plastic damage appeared in shear walls, the concrete of shear walls was still in elastic state. During the analysis, most of the coupling beams have a serious destruction, and the destruction is acceptable, which can dissipate seismic energy and reduce damage to other members.

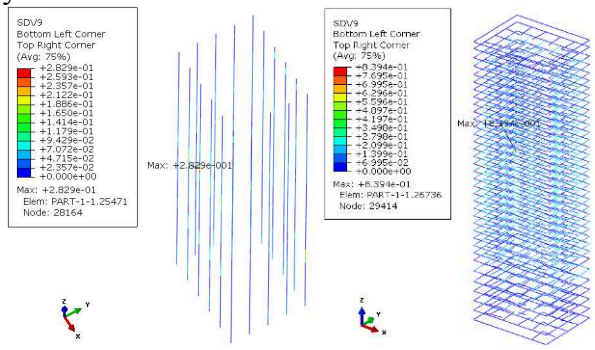


a) X-direction b) Y-direction

Fig. 6 Plastic damage nephogram of shear walls.

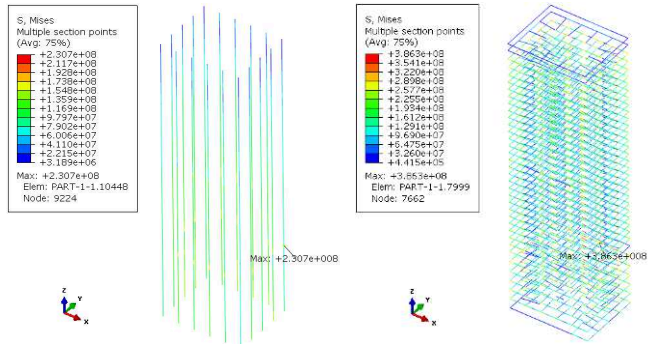
The plastic damage nephograms of columns and beams under the seismic wave of US397 are shown in Fig.7, the maximum plastic damage factor of concrete in columns was about 0.283, the concrete in these sections was just in the peak stress state, and most of the concrete in other sections was still in elastic state. Some beams in core tube suffered serious damage under the seismic wave, the maximum plastic damage factor of concrete in these beams was about 0.839, the plastic hinges were formed in these areas.

The stresses nephograms of reinforcement in columns and beams are shown in Fig.8, the maximum stress of reinforcement in columns was 230.7MPa, the reinforcement was still in elastic state. The maximum stress of reinforcement in beams was 386.3MPa, the reinforcement has already yield.



a) damage in columns b) damage in beams

Fig.7 Plastic damage in columns and beams.



a) reinforcement in columns b) reinforcement in beams

Fig. 8 Stresses of reinforcement in columns and beams.

## Summary

With the progress of computer technology, the elasto-plastic time-history analysis has a rapid development in recent years, as a general-purpose finite element program, ABAQUS has accumulated much successful experiences in this field, its strong non-linear calculation capacity make it especially suitable for analyze the response of super high-rise buildings under rare earthquake, it can help engineers to improve the performance of building in seismic design.

# Calculation on internal force effect of a high-speed highwayprestressed concrete Extra-dosed cable-stayed bridge

XingzhouChen[1, a]

[1]School of Civil Engineering, Southwest Jiaotong University, Chengdu, Sichuan 610031, China
[a]chenxingzhou@live.com

**Keywords:**Prestressed concrete,Extra-dosed cable-stayed bridge,Internal force effect,Dead load, Live load.

**Abstract.**The Extra-dosed cable-stayed bridge is considered as a new popular type of bridge structure in recent 20 years, whose mechanical properties and economic span both lie between continuous beam (or rigid frame ) bridges and cable-stayed bridges.This design is a double-cable-plane (85+150+85)m prestressed concrete Extra-dosed cable-stayed bridge, whose maximum Design speed is 100km/h and its width is 25.50m. The form of the highway is sextuple line which is 10.75m far away,and the cross-sectional slope is 2%.The girder body adopts three cell and single box,the height of beam takes quadratic parabola relation, which is 5m high at the middle support, while at the side support and the midspan is 3m.Vehicle standard load was applied on the bridge.The design uses Midas/Civil to establish the finite element model that is reasonable and simple, analyzing the structure behavior of the girder body under loading, especially the internal forces of bridge structure under dead load, live load and additional force.

## Introduction

Prestressed concrete Extra-dosed cable-stayed bridge's constant load force calculation has a direct relationship with construction methods used. Main girder internal force of dead load consists of the weight internal forces of main girder caused by dead weight and the late girder internal force of dead load caused by secondary dead load (such as pavement, railings, etc.).This design uses midas program to calculate internal force.

## Dead load internal force calculations

**Material Properties.**

(1) C50 grade concrete

Modulus of elasticity: $Ec$＝34500MPa

Axial compressive strength standard limit: $f$ck＝32.4MPa;

Axial tensile strength standard limit: $f$tk＝2.65MPa;

Bulk density:24.1kN/m.

(2)Strand

Modulus of elasticity:$Ep$＝195000MPa;

Axial tensile strength limit:$f$pk＝1860MPa;

Tension control stress: $\sigma con$＝0.6$fpk$＝1116MPa.

(3)Ordinary reinforced

HRB335 steel as main reinforcement($\varphi$12～28)，$f$pk＝335MPa.

**Sectionfeatures.**The whole bridge is divided into three section type, cantilever construction stage unit length beams were 3.5 m, 4.0 m, 5.0 m and 6.0m, middle fold 2.0m long.

**Construction loads.**Construction loads are considered in the process of construction with all kinds of load acting on each beam segment,and they are simplified as a pair of concentrated force acting on anchor point of hanging basket.Concentrated force is calculated from the various stages of hanging basket weight,weight steel mesh,concrete weight and with due consideration on load center of gravity position caused by different beam lengths.The value of the design's construction loads is 750kN.

**Secondary dead load.**The value of the design's secondary dead load is 90.4kN/m.

**Calculation model.**The calculation model for the operational phase is shown Fig.1.

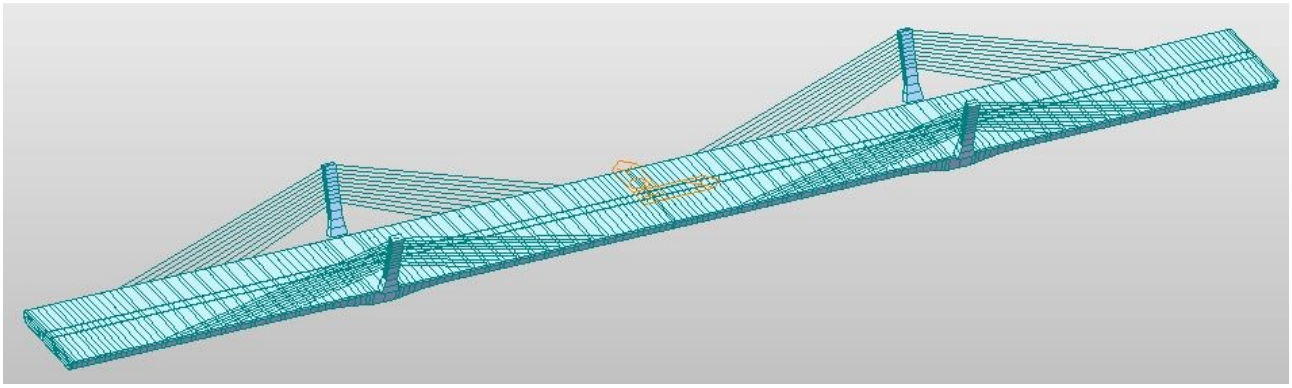

Fig. 1Calculation mode

Dead load calculations.Structure moment is shown in Fig.2, Fig.3 and Fig.4. Structural internal force under dead load is shown in Table 2.

**Live load internal force calculations**

**Calculation Method.**The main beam is statically indeterminate structure, live load internal force still impacts line load method for calculating.We generally use the force influence line of the main beam,then load at the most unfavorable position in the direction of the force influence line in order to seek the maximum live load force of the main beam.For highway bridge,we use concentrated load and equivalent uniform load.

$$S = (1+\mu)(q_k\Omega + P_k y_k) \quad (1)$$

$S$——The unknown section's moment or shear;
$1+\mu$——Impact factor of vehicle standard load;
$q_k$——Uniform load;
$\Omega$——Influence line area of moment or shear;
$P_k$——Concentrated load;
$y_k$——Influence line value of force.

**Live load factor calculations.**The role of live load factor:Program first applied concentrated loadand uniform loadon the main beam,then the obtained result is multiplied by the live load's factor to obtain the final result of loading.

Impact factor calculations:According to general code for design of highway bridges and culverts,we use vehicle vertical static live load multiplied by the power ($1+\mu$) to obtain vehicle vertical load considering the vertical force of vehicle live load.

Under vehicle standard load, $\mu = 0.05$, when $f < 1.5\,Hz$; $\mu = 0.1767\ln f - 0.0157$, when $1.5\text{Hz} \le f \le 14\text{Hz}$; $\mu = 0.45$, when $f > 14$ Hz, $f$ means the structural fundamental frequency, Therefore,$1+\mu$=1.45

**Live load calculation.** Structural internal force under live load is shown in Table 3.Structure moment is shown in Fig.5

. Table 2 Live load calculations

## Conclusions

The design uses Midas software to establish the finite element model,which is widely used in various bridge design.With this design study,we analy the structure behavior of the girder body under loading, especially the internal forces of bridge structure under dead load and live load in order to provide some basis for the later similar bridge design.

# Establishing the digital model of hydraulic system in simulation vibration table

Rui Li[1, a], Xuesen Li[1], Hong Xu[1]

[1] School of Civil Engineering, Xi'an University of Architecture and Technology, Xi'an, Shaanxi,China

[a] liruijsj@xauat.edu.cn

**Key words:** simulation vibration table; hydraulic servo system; actuators; simulation model

**Abstract:** Based on the analysis of the development, defects and motion of present hydraulic system vibrating table, it is divided into several single disciplinary system modes which are organic related in this paper. Establishing unified digital model in integrated simulation environment through analyzing the function of these models, which will guide the design of digital vibration table system.

## Introduction

Simulation vibration table is a kind of test instrument which can reappear and simulate the earthquake effect on specimen, and is one of the most widely used experimental apparatus in structure seismic test [1]. Because of it is a means of simulation which can effectively avoid many defects of using vibration table and maximize the advantages of vibrating table, digital simulation shaking table has been trend in the research of shaking table [2]. What's more, it also can provide incentives for various simulation test [3] - [6], and has significance guidance for the simulation of different dynamic test.

In this paper, hydraulic system of vibration table will be divided into single disciplinary system models which are organic related at first; then, establishing the mathematical model for each of them; finally, estimate the correctness of the simulation model of whole system on account of the system sensitivity analysis of main parameters.

## Modeling

The analysis of the entire hydraulic system is expressed by form of transfer function by mathematical means, which transform the relationship of the demand and actual output of vibrating table into the input and output signal. The whole model is modularized for the convenience of modeling.

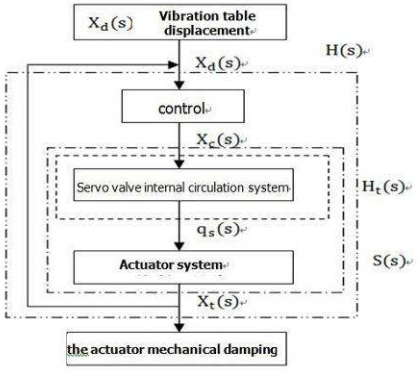

Fig.1 The signal change and the functional scope of Hydraulic system

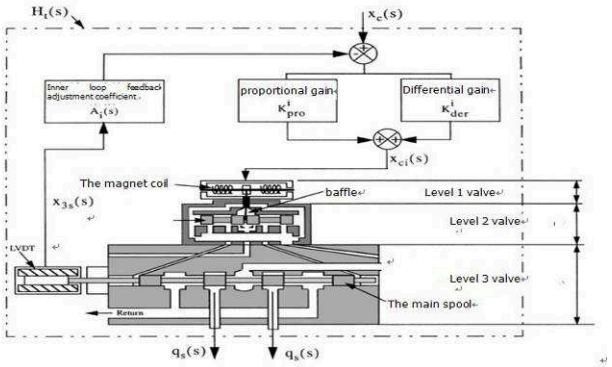

Fig. 2 The third order sketch servo valve's structure and function

Fig.1 shows the shaking table system can be broken down into three transfer function. According to the inclusion relation between them, they are expanded from small to big as following: (1) the servo transfer function $H_t(s)$; (2) the mathematical model of servo - actuator $S(s)$; (3) the servo hydraulic system mathematical model $H(s)$. The establishment of them will be introduced below.

**The third order mathematical model for servo valve**

Because of shaking table always use redundant drive [7] and for large shock tests, and require great actuator and precision, so it often adopt three-stage electro-hydraulic servo valve control system and use symmetrical valve control symmetrical cylinder structure. The three-stage electro-hydraulic servo control system is the first step of the vibration control, known as the inner feedback control loop.

Internal feedback control system is the basic control of the third order servo control system, and is corresponding to the external control, which will also affect the vibration table control system. It is shown in figure 2 that the signal of servo valve command $X_C(s)$ is converted to electrical signals of inner loop $X_c(s)$ by the proportional and differential control, and then join in the work of the third order for servo valve.

According to the working principle of the three-stage electro-hydraulic servo valve aforementioned [8] [9] the linear hypothesis, the three working stages of the whole servo valve is controlled by PID circulation, which suppose that the oil flow velocity from servo valve to the actuator pressure chamber $q_s(s)$ is the output signal, the servo valve command signal $X_C(s)$ is the input signal, and then the transfer function of the servo valve is expressed as the following:

$$H_t(s) = \frac{q_s(s)}{X_C(s)} \tag{2-1}$$

$$= k_{xq} \frac{k_1 k_2 (k_{pro}^i + s k_{der}^i)}{1 + A_i(s) k_1 k_2 (k_{pro}^i + s k_{der}^i)} \tau \tag{2-2}$$

Where $k_{pro}^i$ is the inner loop proportional gain coefficient; $sk_{der}^i$ is the inner loop integral gain coefficient; $A_i(s)$ is the inner loop feedback transfer coefficient.

In addition, in order to reflect the delay phenomenon initiated by the process of signal transmission, such as from external signals to the servo valve and servo valve inside, the delay time $\tau$ is introduced in this paper. It can be understood as that the time which is taken by actuator to overcome the mechanical and hydraulic inertia of the servo valve. Here it is defined as the difference value of time that the time of electrical signal arrive in the first level of servo valve and the time of triple valve response accordingly.

So the original function is turned into the following:

$$X_{3S}(t) = k_1 k_2 X_{ci}(t - \tau) \tag{2-3}$$

And then it is transformed by Laplace:

$$X_{3S}(t) = k_1 k_2 X_{ci}(s) e^{-\tau s} \tag{2-4}$$

It can be cleared up that the transfer function of the servo valve is:

$$\begin{aligned} H_t(s) &= \frac{q_s(s)}{X_C(s)} \\ &= k_{xq} \frac{k_1 k_2 (k_{pro}^i + s k_{der}^i)}{1 + A_i(s) k_1 k_2 (k_{pro}^i + s k_{der}^i) e^{-\tau s}} e^{-\tau s} \end{aligned} \tag{2-5}$$

**The mathematical model of the servo actuator**

Servo and actuator is connected by the oil, the oil in them will keep balance in all time and the amount is a constant. The servo - actuator transfer function S (s) is according to these conditions.

According to the continuity of the oil flow, the flow equation of actuator is obtained:

$$q_s(s) = q_{pm}(s) + q_{le}(s) + q_{comp}(s) \tag{2-6}$$

Where $q_{pm}(s)$ is the variation of volume; $q_{le}(s)$ is the velocity of seepage flow; $q_{comp}(s)$ is the oil amount of compression; and

$$q_{pm}(s) = A \dot{X}_t(t) \tag{2-7}$$

Where $\dot{X}(t)$ is the speed of drive ratio; A is the effective sectional area of actuator piston.

Suppose the relation between the seepage of actuator in seal chamber and the fluid stress in pressure chamber is linear, then:

$$q_{le}(s) = k_{le}^{'} \frac{F_a(t)}{A} = k_{le} F_a(t) \tag{2-8}$$

Where $k_{le}^{'}$ is percolation flow coefficient.

On the basic of the oil amount of compression definition, it can be concluded that compression rate can be defined as a variation of oil volume in pressure chamber:

$$\begin{aligned} q_{comp}(s) &= \frac{d}{dt}[\Delta V(t)] \\ &= \frac{V}{4\beta A} \dot{F_a}(t) \end{aligned} \tag{2-9}$$

Take the above three parts of the oil flow into fluid continuity equation, the oil flow per second in the actuator pressure can be expressed:

$$q_s(s) = q_{pm}(s) + q_{le}(s) + q_{comp}(s) \quad = SA\dot{X_t}(s) + k_{le}F_a(s) + \frac{V}{4\beta A}\dot{F_a}(s) \tag{2-10}$$

Combining with the previous transfer function

$$H_t(s) = \frac{q_s(s)}{X_C(s)} \quad \text{and} \quad S(s) = \frac{X_t(s)}{X_C(s)}$$

It is acquired that the transfer function of servo valve and actuator is:

$$S(s) = \frac{X_t(s)}{X_C(s)} = \frac{H_t(s)}{SAX_t(s) + k_{le}F_a(s) + \frac{V}{4\beta A}F_a(s)} \tag{2-11}$$

**The mathematical model of servo hydraulic system**

To the electrical signals which entrance the servo valve $X_C(s)$, it could be seen as the displacement signals of the actual need movement of actuator. is calculated through the external loop control system of earthquake simulation shaking table of. The $X_C(s)$ is consist of multiple control command in the system, mainly divided into the following several parts:

$$X_C(s) = \varepsilon(t) + X_{ff}(t) + X_{dp}(t) \tag{2-12}$$

For $\varepsilon(t)$ is ratio error value of the flat (that is the ratio error value of the displacement flat needs $X_d(t)$ and the actual output displacement of actuating arm). Due to the external loop control system is feedback control, which is monitored by the error value, so the ratio error value can be a better reflection of the effects of control system for actuators. PID control is used to describe the table error here:

$$\varepsilon(t) = \left[k_{pro} + \frac{1}{s}k_{\text{int}} + sk_{der}\right]\left[x_d(s) - x_t(s)\right] \tag{2-13}$$

$k_{pro}$ is the proportional control gain; $k_{\text{int}}$ is the integral control gain; $k_{der}$ is the differential control gain.

In order to prevent the difference between actual and feedback signal is great in the process of control, giving the value of command a change according to the system performance is frequently. For example: a displacement increment will be given in advance to reflect the feed forward control system's influence on the actuator.

$X_{ff}(t)$ is the proportion of feed forward signal ( the ratio of differential displacement required) :

$$X_{ff}(s) = Sk_{ff}xX_d(s) \tag{2-14}$$

Among them, $k_{ff}$ is the feed forward control gain; $X_{dp}(t)$ is the piston displacement of actuator obtained by different pressure.

$$X_{dp}(s) = k_{dp}\Delta P(s) \tag{2-15}$$

$k_{dp}$ is defined as the pressure change control gain; $\Delta P(s)$ is defined as the change of stress in the pressure cavity.

The driving force of the actuator also can be expressed as following:

$$\Delta P(s) = \frac{F_a(s)}{A} \tag{2 -16}$$

Through mathematical deduction, making the displacement of actuator's actuating arm as output object and the actual displacement of flat needed as the input object, the whole servo hydraulic system transfer function is:

$$H(s) = \frac{x_t(s)}{x_d(s)} = \frac{S(s)\left[(\frac{1}{s})k_{\text{int}} + k_{pro} + S(k_{ff} + k_{der})\right]}{1 + S(s)\left[(\frac{1}{s})k_{\text{int}} + k_{pro}) + Sk_{der}) - \left(\frac{k_{dp}}{A}\right)\left(\frac{F_a(s)}{x_t(s)}\right)\right]} \tag{2-17}$$

**The dynamic model of actuator**

The simulation model of seismic shaking table is often a single-rigid dynamics model, which always ignore the analysis of the stress state of pull rod and hydraulic cylinder under actual working condition. In the process of vibration table movement, as the final output link, the actuator plays an important role on the final results, and the mechanical performances of pull rod and hydraulic cylinder themselves should not be neglected, too. So in this section mathematical model will be established by aiming at actuator, and the process of force in actuator will be simulated.

For the physical model of actuator as figure 3 shows, the quality of is so small compared with the machine body and specimen that its inertia force can be neglected [10]. But the tie rod I slender and long, it is very easy to out of shape in the process of outputting force. So the stiffness and damping of it should not be overlooked. For the hydraulic cylinder, the mass, stiffness and damping of it cannot be ignored because its internal stress is larger, and the walls of the hydraulic cylinder is thicker. Because of the travel of the actuator is shorter and the geometrical non-linearity of the actuator is small, the linear approximation model is used as the mechanical model [11].

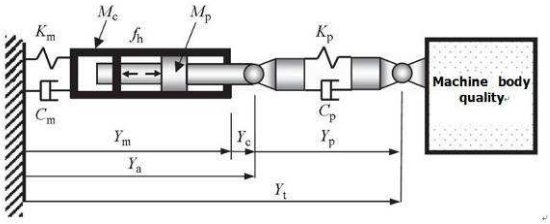

Fig. 3 The schematic structure and symbol of actuator

As shown in figure 3, the actuator drive displacement is written by $Y_t$, and the deformation of the rod length is written by $Y_p$, the actual deformation length of hydraulic cylinder is written by $Y_c$; $Y_a$, $Y_c$, $Y_m$, $Y_p$, $Y_t$, as actual displacement of hydraulic actuator's different parts in the equilibrium states, which is that no force and no displacement output from actuator, the elongation length of them is expressed as $y_a$, $y_c$, $y_m$, $y_p$, $y_t$.

The following hydraulic cylinder and pull rod function is established according to the composition of the final displacement:

$$y_m = -\frac{1}{M_C S^2 + C_m S + k_m} f_h \tag{2-18}$$

$$y_a = \frac{f_h - k_p y_t - C_p \dot{y}_t}{M_p S^2 - C_p S - k_p} \tag{2-19}$$

According to figure 3, and equation (2-18) (2-19) ， the final expression is obtained:

$$y_c = y_a - y_m$$

$$= \frac{f_h - k_p y_t - C_p \dot{y}_t}{M_p S^2 - C_p S - k_p} - \frac{1}{M_C S^2 + C_m S + k_m} f_h \tag{2-20}$$

When $y_c$ is used as actuator actual output values, its physical meaning can be understood as the actual output values that after the actuator drive arm overcomes its own dynamic characteristics.

## Conclusions

As a new method in the research and development of shaking table, the establishing and realizing of the digital model of hydraulic system in simulation vibration table will offer one way for the design of shaking table., The hydraulic system model of multiple subsystems is integrated into a unified digital model in this paper. Set up its system structure and the preliminary simulation of it is established, structure and some key parameters in the system is analyzed and optimized in this paper, which can provide reference for the digital simulation of the vibration table design process, the distribution of precision and error analysis of it.

# Research on SketchUp Application in Graphing of Civil Engineering

Qiang Dong[1, a] Yongshou Yang[1, b]

[1]Shandong Jiaotong University 5001 Haitang Road, Changqing District, Jinan City, Shandong Province, P.R.China, 250357

[a]email:1733834941@qq.com

[b]email:yangyongs616@163.com

**Keywords:** Graphing of Civil Engineering, SketchUp, Modeling, Model Base

**Abstract.** This paper introduces to the application of the software---SketchUp in teaching process, which will make the abstract graph visualize, inspire students' interest and help them to have a better grasp of civil engineering structure. We use SketchUp to create models, assist the teaching of civil engineering Graphing and recognition, improve students' space imagination and cultivate their creativity.

Applied undergraduate education is also called employment education. In order to cultivate advanced applied talents who have sufficient theoretical knowledge and proficient skill, it's necessary to use the personnel evaluation criterion in company to build the evaluation criterion in class teaching, so it's necessary to have the teaching revolution. This article discusses how to use SketchUp (three-dimensional architectural sketch master) of Google company for civil engineering modeling, and the teaching method revolution and methods of projection knowledge in Civil Engineering Graphing and recognition.

## Course Highlights

Civil engineering Graphing and image recognition is the professional basic course for civil engineering major and can cultivate students' ability to map recognition and Graphing. This course is mainly edited by Yong Liu and Qiang Dong, and adopted < Descriptive Geometry and Civil Engineering Graphings> (the second edition) published by National Defence Industry Press. And this book contains three parts: basic knowledge for projection, civil engineering cartography and image recognition. Projection is an abstract part, it demands space imagination ability and operation ability. What's more, this project can overcome some defects in teaching which uses handmade models [1].

## Software Overview

SketchUp is one of the few design tools with design process orientation directly. It helps designers with visual conception in computer. Along with the clearer conception, more and more details, the final model can be passed to other rendering software to do the final render. In this way, designers can decrease mechanical rehandling and control the accuracy of design outcomes.

SketchUp is so simple and easy to learn that college teachers and students can grasp it through short time study. SketchUp is not only limited to sketch design, it also can do accurate Graphing and has convenient push-pull function. Using this software, designers can generate 3D geometry by a graph, instead of complex three-dimensional modeling. It combines the grace of penciling and the natural of Graphing, and it can form, show and edit three-dimensional modeling swiftly. At the same time, it can guide into CAD and image file, guide out two-dimensional image and three-dimensional model, combine AutoCAD, Revit,3DMAX, PIRANESI and some other software, swiftly guide in and out DWG, DXF, JPG, 3DS format file, achieve perfect combination between scheme design and effect picture and construction picture Graphing, provide plug-in with AutoCAD, ARCHICAD and other design tools. In addition, it can smoothly link up with other LightScape, guide the models in

SketchUp into 3ds Max, correct material and model and anew lighting. So it can make construction picture with high quality easily.

## Application in Engineering Graphing

### 3.1 Application in Projection

Line includes projective plane parallel line ( parallels to only one plane and inclines to other two planes, includes horizontal line, flat line and side flat line), projective plane perpendicular line ( perpendicular to one plane, includes plumb line,horizontal--profile line and W-perpendicular line) and normal position line (inclines to three projective planes). Plane includes projective plane parallel surface (parallels to one plane, includes horizontal plane, flat plane and side flat plane), projective plane perpendicular surface (perpendicular to one plane, while inclines to other two planes, includes plumb plane, V-perpendicular plane and W-perpendicular plane) and normal position surface (inclines to three planes). We can build projective line and plane easily and quickly by SketchUp, like Fig.1. It can be showed in the class to increase sensory awareness and cultivate space imagination [2].

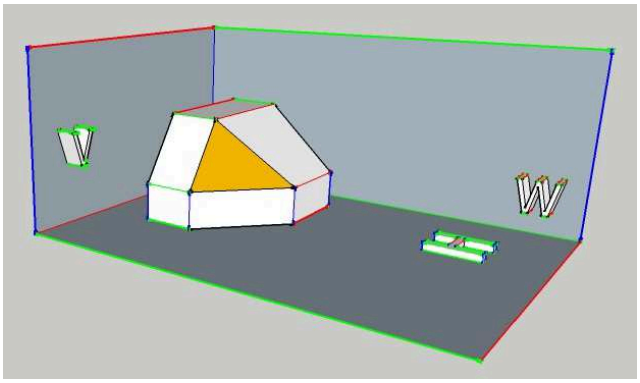

Fig.1 Display of Projective Lines and Planes

### 3.2 Application in Building Configuration

Building three-dimensional model is like Graphing on paper by pencil, SketchUp can automatically recognize these lines and seize them. Its modeling process is forming pictures by lines, then do extrusion forming, which is easy and clear, and this is the most popular method for staircase modeling.

Staircase is the main facility linking the upper and lower space, mainly contains flight, platform and guard rail. Staircase plan mainly shows its location, thickness of wall, flight for each floor, platform, handrail, length and width of staircase, width of each step. When teaching staircase construction, we can guide in CAD graph (Fig.2), then change the plane to three-dimensional shape (Fig.3&Fig.4) by push and pull tool. It is easy to correct and edit, easy to convey the detail of stair construction and makes the class rich and lively.

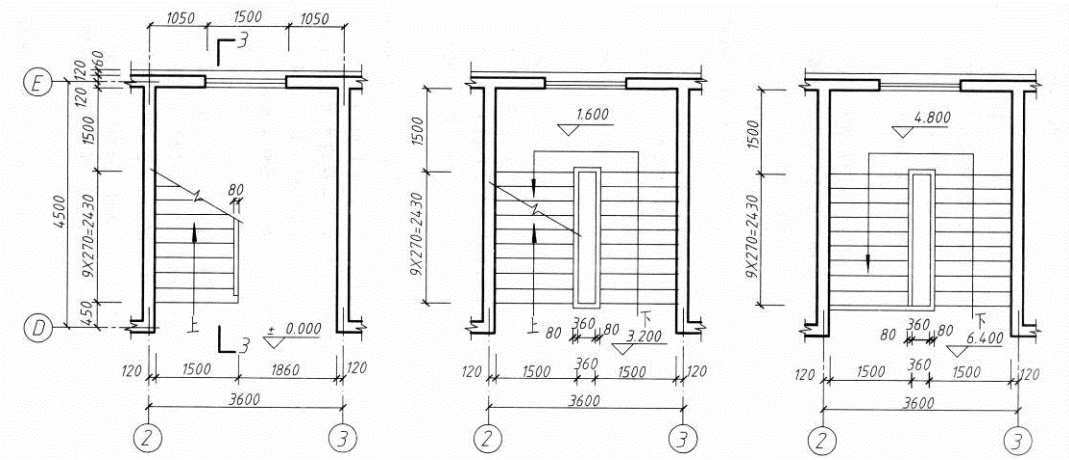

Fig.2 Detail of Staircase

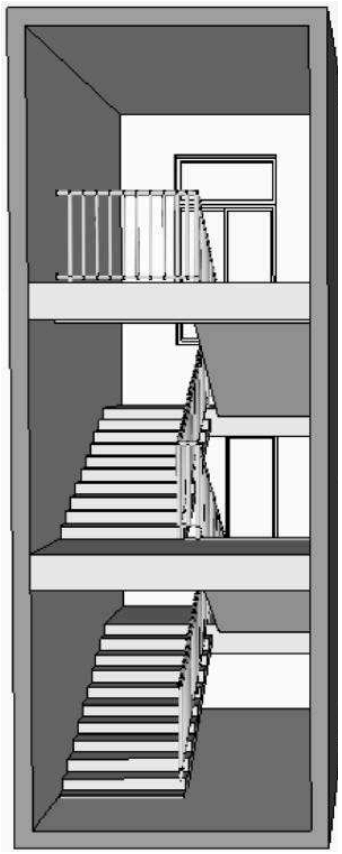

Fig.3 Scenograph of Double Run Stair

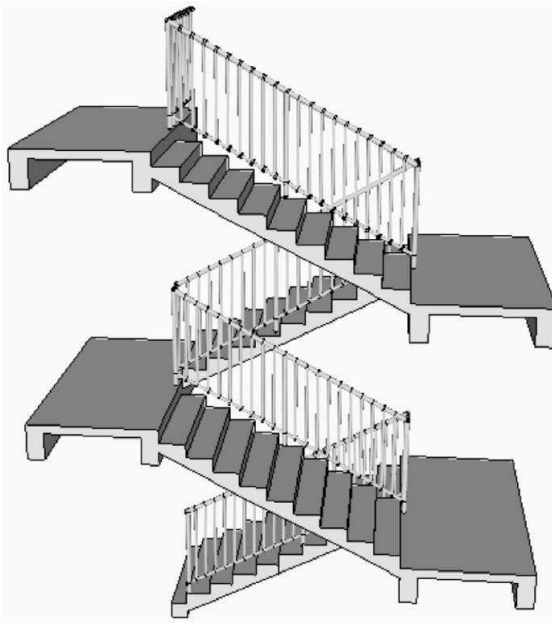

Fig.4 3d Model of Stair Flight and Platform

Application of SketchUp in teaching staircase will not only help students to grasp detail of stair, but also cultivate their space imagination, which lays the foundation for the recognition of the complex modern construction Graphing.

3.3 Structuring Model Base

By the powerful function of SketchUp, we can build various engineering models and form model base, like bridge and culvert model base, like showed in Fig.5-Fig.8. This is helpful to improve recognition ability and cultivate professional skills. With model base, we can calculate construction amount, do feasibility research and three-dimensional simulation.

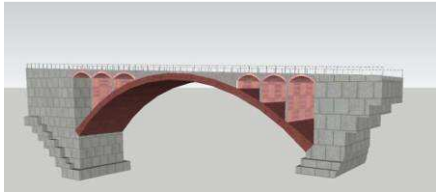

Fig.5 Model Lbase ---Arch bridge

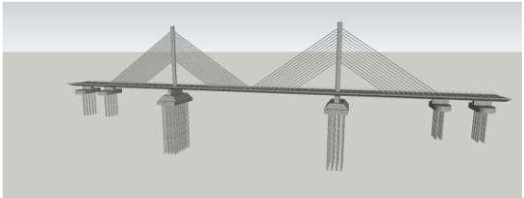

Fig.6 Model Base ---Cable-Stayed Bridge

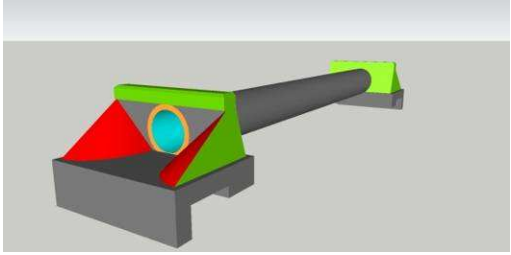

Fig.7 Model Base ---Circular Culvert

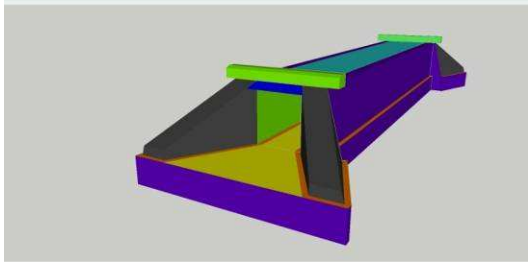

Fig.8 Model Base ---Slab Culvert

3.4 Cultivate Students' Space Imagination

Application of SketchUp cartoon function in class can cultivate students' outsight. As we all known, mental activity of imagination is based on objective things. No observation, no imagination, no creation. In this display teaching, we should attach great importance to students' spatial perception ability. And this needs long-term systematical training.

3.5 Fast Identification for Construction Picture

Modern structure publicizing individuality has unique appearance and complex plane layout. If they only depend on the orthography projective law of point, line, surface and body, it is difficult for students to imagine the space form of structure and grasp the detail. Through the application of SketchUp, students can have a better understanding of design intention and read construction Graphing quickly by simple modeling study and building the complex engineering body.

## Conclusion

SketchUp is an epochal invention, which shows the intuitive design concept "what you see is what you get". Through one term's teaching practice, the author deeply feels that SketchUp has great advantage in engineering cartography, which helps students to grasp basic knowledge and cultivates students' space imagination ability. This lays the root for further study. How to combine projective body with actual complex engineering body together, how to use this software to make reinforcement model for base, beam, board, column and shear wall, and how to do mechanics analysis on models by structure analyze software, remain to be further discussed.

All manuscripts must be in English, also the table and figure texts, otherwise we cannot publish your paper.

Please keep a second copy of your manuscript in your office. When receiving the paper, we assume that the corresponding authors grant us the copyright to use the paper for the book or journal in question. Should authors use tables or figures from other Publications, they must ask the corresponding publishers to grant them the right to publish this material in their paper.

# Analysis of the flow characteristics of multiphase flow fields in the mixing agitator

Xiaobing Wang[1 a]

[1] School Petroleum Engineering of Changzhou University, Changzhou, 213016, China

[a]czdxwxb@163.com

**Keywords:** mixture and agitation; large eddy simulation; Multiphase flow; flow characteristic; numerical analysis

**Abstract.** The numerical simulation for the flow characteristics of multiphase flow fields in the multiple-blade mixing agitator is carried out by means of combining of the large eddy simulation (LES) and multiphase flow model. Then the flow pattern changes and material mixing rule at different speed conditions are analyzed. The result shows that complicated circular flows form among the four groups of blades in the axial cross section. In the mixing process, the upper solid-liquid mixture is transported to the bottom of the agitator under the action of gravity and fluid shear. Finally it mainly distributes at the agitator walls and the inverted cone manifold in the center of the agitating shaft. With the gradually increasing in the agitation rate, there are a large amount of vortex structures near the blade. Then spiral vortex distribution areas are formed.

## Introduction

The agitator is widely used in the architecture, chemical, food and other industries. There is a big difference between geometric shape and impeller type based on different operational goals. Because of the complexity and diversity of the agitator, there are defects of the complex design process, long period and structure without optimization in the semi-empirical design methods used at present. With the development of CFD technology, numerical simulation methods are taken to study the flow characteristics in the mixing process [1-3], which not only save research funding but also get some dates that can't be gotten from the experiment. According to the structural property of the mixing agitator, numerical calculation model is established to calculate the flow structure of multiphase flow fields in different operating conditions and to analyze the inner flow characteristics combined with hydrodynamic mechanism, which provides theoretical basis for further improvement of the mixing agitator.

## The turbulence model

Large eddy simulation control equation is the averaged equation after filtering the N-S equation.

$$\frac{\partial \overline{u_i}}{\partial t}+\frac{\partial}{\partial x_j}\left(\overline{u_i u_j}\right)=-\frac{1}{\rho}\frac{\partial \overline{p}}{\partial x_i}+\nu\frac{\partial^2 \overline{u_i}}{\partial x_j^2}+f_i \tag{1}$$

The micro compressible flow field model is used in the continuity equation.

$$\frac{\partial P}{\partial t}+K\frac{\partial \overline{u_i}}{\partial x_i}=0 \tag{2}$$

In the above equation, horizontal line presents the quantity after filtering. Relation between the filtration rate $\overline{u_i}$ and actual speed $u_i$ in the large eddy model is $u=\overline{u_i}+u_i'$. K is the square of fluid elastic wave velocity. Nonlinear term exits in the momentum equation. $\overline{u_i u_j}=\overline{\overline{u_i}\,\overline{u_j}}+\overline{u_i'\overline{u_j}}+\overline{\overline{u_i}u_i'}+\overline{u_i'u_j'}$. The first item is large scale component and the other three items are small scale components, that is sub-grid reynolds stress. Then it can be expressed as $\overline{u_i u_j}=\overline{\overline{u_i}\,\overline{u_j}}+R_{ij}$.

$R_{ij}$ is the new unknown after filtering, so sub-grid reynolds stress model is established. Then box-filter function is used and the equation (1) can be expressed as follows.

$$\frac{\partial \overline{u}_i}{\partial t}+\frac{\partial}{\partial x_j}\left(\overline{u_i u_j}\right)=-\frac{1}{\rho}\frac{\partial \overline{p}}{\partial x_i}+\nu_t\frac{\partial^2 \overline{u}_i}{\partial x_j^2}-\frac{\partial \tau_{ij}}{\partial x_j}+f_i \tag{3}$$

According to the average concept of the turbulence energy generated and dissipation, Smagorinsky assumes $\nu_t=(C_s\Delta)^2\left(2\overline{S}_{ij}\overline{S}_{ij}\right)^{1/2}$ and $\overline{S}_{ij}=\frac{1}{2}\left[\frac{\partial \overline{u}_i}{\partial x_j}+\frac{\partial \overline{u}_i}{\partial x_i}\right]$. $\Delta$ is filter width, generally it is grid spacing and $\Delta=\left(\Delta_x\Delta_y\Delta_z\right)^{1/3}$. $C_s$ is not only the model coefficient but also empirical constant. When it is taken as 0.1 the result consistent with the experiment can be obtained. So in this paper $C_s$ is 0.1.

Considering the material movement and the effectiveness of evolution law in the agitator, mixture model is taken to calculate the multiphase flow. Mixture model mainly applies to two-phase flow or multi-phase flow. The phases are regarded as unified continuum structures. At the same time the concept of slip velocity is used to allow the phases move at different speeds.

## The calculation model and boundary condition

The middle of the mixing agitator is cylindrical shell, the top is elliptical head, the bottom is conical head and impeller is installed in the center. The above three stage impeller is three-blade rectangular skewed propeller and the lower impeller is two-blade straight propeller. The overall three-dimensional modeling of the agitator flow is established and the calculation model is shown in Figure 1. The flow fluid is discretized by the unstructured meshes. To improve the calculation accuracy, the blades, the interface griddings, as well as the near-wall region are refined. Computing grid is 1,167,268 and mesh of the agitator is shown in Figure 2.

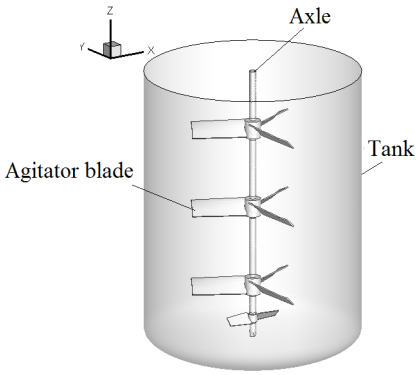

Fig 1 Calculation model and mesh

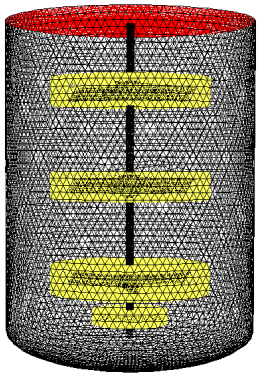

Fig 2 Meshing diagram

A finite volume method is taken to solve the discrete equations, the SIMPLE algorithm is used to couple the pressure and velocity, and Mixture model is applied to simulate the phase separation. The cylinder wall and the blade are set as wall, the type of wall motion is set as moving wall and the starting point of the rotation axis is located in the origin. Moving Reference Frame is taken to simulate fluid motion and the direction of rotation is around the axis direction. In this paper the calculated mediums are water and solid liquid mixtures. For easy figures, the medium is taken as a single component liquid with the higher density and viscosity than water. Rated speeds are 50 r/min, 100 r/min and 200 r/min.

## The calculation results and analysis

Unsteady numerical simulation is used to analyze the distribution law and flow characteristics of the two materials in the mixing agitator. Figure 3 is the volume fraction distribution of the mixture in the

shaft section and the overall barrel at different moments with the rated speed 100 r/min. From Figure 3(b), it can be seen that at the beginning of the mixing, volume fraction of the solid liquid mixtures is small at the bottom center of the agitator and the areas around the agitator bottom, while it is large at the top and the areas near the upper wall. In the mixing process, the force is mainly a combination of gravity and fluid shear owing to the higher density of the solid liquid mixtures. Flow rate near the blade is high and the solid liquid mixtures are gradually transported to the bottom of the agitator under the action of gravity and fluid shear. From Figure 3(d), it can also be obtained that because of the inverted cone manifold near the mixing shaft and the action of the centrifugal force on the mixtures, volume fraction of the solid liquid mixtures is large in the shaft and the area near the cylinder wall.

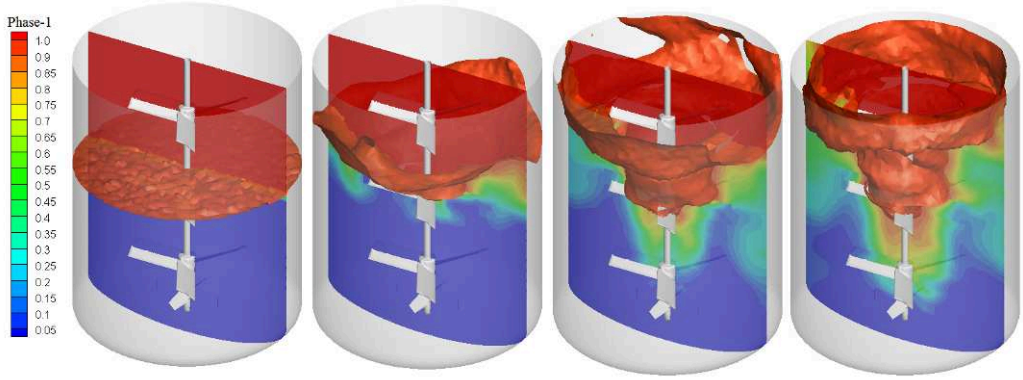

Fig 3 The volume fraction distribution of the mixture at different moments with the rated speed 100 r/min

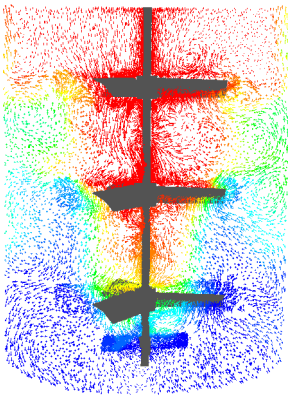

Fig 4 The velocity vector distribution of the axial cross section at X=0m

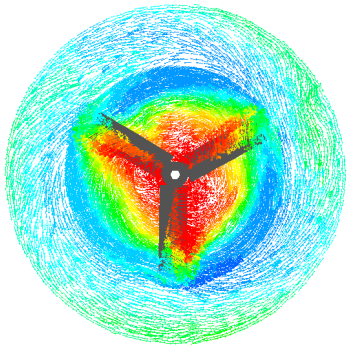

Fig 5 The velocity vector distribution of the radial cross section at Z=2.3m

Figure 4 is the velocity vector distribution of the axial cross section at X=0m. The main loop area is clearly existed among the four blades. At the same time there are two groups of vortex near the third layer of blade tip, which are respectively clockwise vortex and anti-clockwise vortex. Then the mixture is entrained to the second layer of blade rotation area. After analysis of the radial direction vector distribution of the third layer of the blade, it can be seen from Figure 5 that mixture is transported to other area of the agitator by significant speed and high-intensity turbulence near the blade tips.

Coloring the constant vorticity according to Q criterion, the vorticity contours in the agitator flow at different speed conditions are analyzed. The vorticity contour is shown in Figure 6 when Q is 100. A large number of the vortex structures generate near the blade with the increasing agitation rate, and finally they are mainly distributed along the leaf blades. From Figure 6(c), it can be seen that when the speed is 200 r/min, spiral vortex distribution areas are formed near the blade. The radial velocity distributions are shown in Figure 7 at three different speeds. The peak velocity near the hub is in the opposite direction to that near the blade tip. And with the increasing speed, the radial velocity peak difference has become more and more large. Therefore the main loop area is clearly generated between the hub and the blade tip.

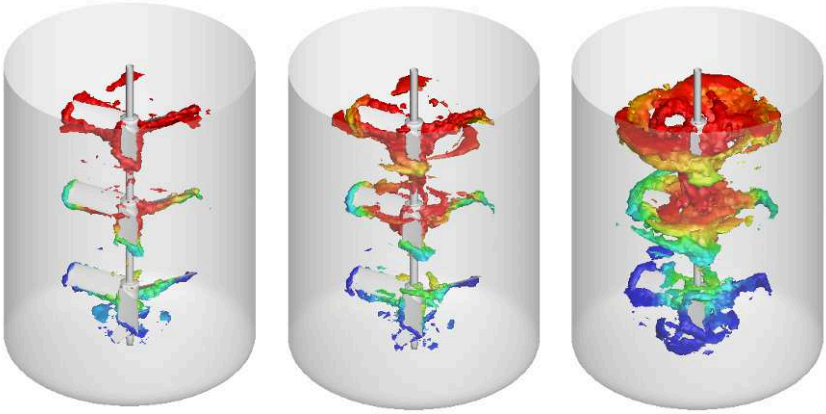

Fig 6 The vorticity contour when Q is 100 and $t$=100s

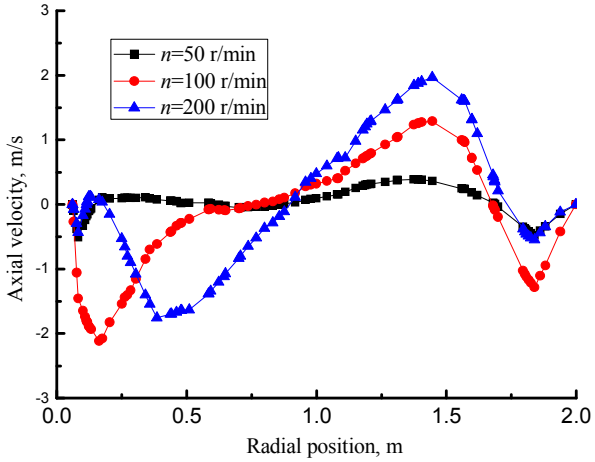

Fig 7 The radial velocity distributions at different speeds

## Conclusions

The flow pattern changes and material mixing rule in the mixing agitator at different speed conditions are analyzed by means of combining of the large eddy simulation (LES) and multiphase flow model. The result shows that complicated circular flows form among the four groups of blades in the axial cross section. In the mixing process, the upper solid-liquid mixture is transported to the bottom of the agitator under the action of gravity and fluid shear. Finally it mainly distributes at the agitator walls and the inverted cone manifold in the center of the agitating shaft. With the gradually increasing in the agitation rate, there are a large amount of vortex structures near the blade. Then spiral vortex distribution areas are formed.

# Building Information Modeling (BIM) and Analysis of More Traditional CAD

Li Jian

Architecture and Civil Engineering School Inner Mongolia University of Science and Technology, Baotou, China

nkdlj@163.com

**Keywords:** BIM, Building Information Modeling, modeling software, traditional CAD

**Abstract.** Building Information Modeling (Building Information Modeling) is the relevant information and data as the basis for building projects model, building model be established to simulate the real information through the building of digital information. It has five characteristics of visualization, coordination, simulation, optimize and can plot and so on. As the construction industry in a brand-new concepts and technologies, BIM has been increasingly used in various construction projects in the country. Building Information Modeling (BIM) provides a platform to complete the continuity and consistency of all information within the whole life cycle of buildings.

## about Building Information Modeling (BIM)

### 1.1 BIM concept and its core modeling software

Building Information Modeling (BIM) is a simulation of a building, which covers the real information about the actual building. BIM is not just software, but an idea - from planning construction projects, design, construction, operation until the removal of the entire life cycle of production and management process to achieve full digitization. Achieve full digitization request, building applications are no longer just using CAD software to complete construction projects or projects so simple, but to use a range of software. BIM software types as shown below as follows:

Core BIM modeling software systems is the carrier for the realization of BIM application platform. The general civil construction using Autodesk Revit, plant design and construction using Bentley series, single professional architectural firms using both can be used. The related software is shown in Fig.1

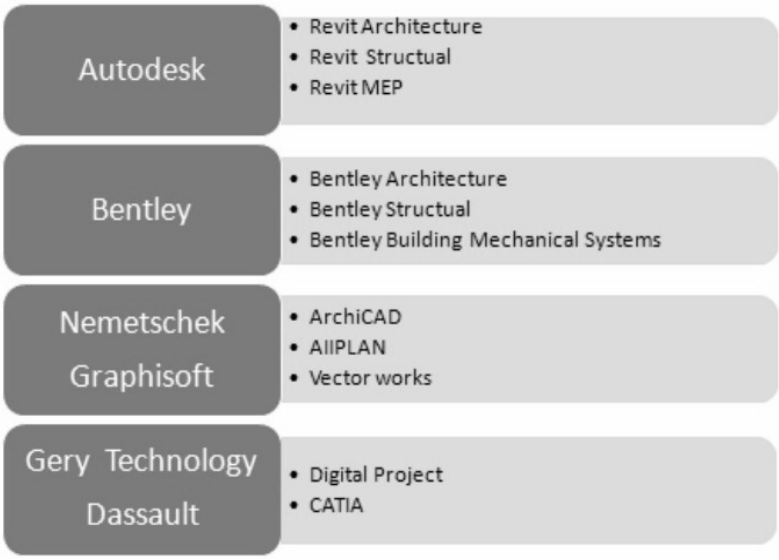

Fig.1. The related software

### 1.2 Application of BIM home and abroad

BIM technology began in the United States. 2009 , Wisconsin requires new intrastate first large-scale public construction projects using BIM technology , while Texas Public Utilities Commission also calls for the design and construction of the project proposes the application of state

government investment BIM technology. In 2010, the government enacted Ohio BIM Protocol. Japan's transport ministry announced the implementation of BIM technology in 2010, has been the rise in the country by the government to vigorously promote. In addition, a number of European government agencies are developing appropriate standards for BIM applications. China's construction industry from the 2003 introduction of BIM technology, and industry associations by the government attaches great importance to the emergence of a variety of domestic and BIM training contest. Shanghai Modern Architectural Design Group, China Construction Design International Ltd. (CCDI) and the U.S. Aedis Architecture and Planning Chinese companies and other companies are beginning to gradually increase the use of BIM technology. However, due to the country's software and hardware environment, BIM technology is still the main stay in the architectural design phase of the major design institutes.

## BIM technology comparisons with conventional CAD

### 2.1 3D/4D (3D+ time) parametric design

Traditional software such as AutoCAD is generally based on two-dimensional graphic design. Build three-dimensional models (AutoCAD comes with three-dimensional modeling software, there are many defects) by Sketch up modeling software, such as when doing renderings, but the two are independent. In the BIM system can be Sketch up, Rhino and From information input into the BIM modeling software core, the core can also be used directly BIM modeling software to build the model (massing studies and architectural design complexity encountered in the early stages When modeling, using Sketch up software is more convenient). This will not affect the use of independent software flexibility while more conducive to the consistency and integrity of project information. Three-dimensional model analysis automation, intelligent provides a platform for the energy building design. BIM's 3D parametric design with specialized three-dimensional design tools, real-time three-dimensional visualization, and more advanced model of collaborative design, create construction details and schedules base map automatically by the model, supporting the analysis and simulation design tools. BIM technology to improve the building design stage information, three-dimensional space also allows designers richer design inspiration. BIM improve the system and shorten the design period, designers no longer have to blindly bury more time for drawing and design innovation. Traditional two-dimensional CAD design construction plans cannot express some complex modeling; BIM through 3D parametric design can be the perfect expression of the designer's creativity. BIM can efficiently solve complex problems spatial arrangement pipeline. All in all, BIM has brought great convenience in the design, construction aspects.

### 2.2 collaborative design and operation

Compared with the traditional CAD technology, BIM ensures the construction operation in various stages of each link in the whole life cycle. It does not only emphasize building projects in planning, design, construction, operation in one aspect, but more emphasis on the process (and the various aspects). Therefore, BIM enables independent operations in each stage while more sophisticated, more prominent BIM technology synergies.

#### 2.2.1 Collaborative Design

(1) With in the same professional collaborative design. Under the conditions of a clear division of labor, with different members of the project design of the project, design and timely content synchronized to the file server, available to other members of the design is used by reference or used a crossover design.

(2) The collaborative design between professionals. BIM platform proposed by various professional requirements, identify problems and timely communication to solve problems.

(3) Coordination between the various systems with each other to avoid the system is affected in space, functionality, usability, ease of management.

(4) Synergies with other software. As described herein, BIM is not software but a series of software. The BIM platform with the core modeling software for the foundation, choice of every aspect of the utility maximum of several software, absorb anything and everything to meet the building life cycle each stage requirements.

By BIM platform, building projects at the design stage to avoid misunderstanding and lack of communication have all kinds of unnecessary error. So the BIM technology can shorten the design cycle, improve the design efficiency and facilitate the design process management.

### 2.2.2 Collaboration

In the design phase, BIM technology to help deal with a variety of design files and office document management, design and planning of any proofreaders flow services, project status query statistics aided design work, and even interactive and collaborative document communication designers, owners, supervision side, the construction side and suppliers between. So, to save a lot of manpower and resources, reduce costs and enhance all aspects of efficiency, thereby increasing business efficiency.

### 2.3 simulation, optimization and plot

BIM in simulation, optimization is the traditional AutoCAD technology not available. AutoCAD technology to do traditional items head only when requested by the owners of green buildings alone will do for a project simulation and optimization. This will extend the operational cycle of the construction project, and the individual is difficult to ensure the accuracy of the simulation. But for 3D visualization model and various boundary conditions of the BIM technology in the simulation and optimization of this block is to make it more simple and. The traditional AutoCAD do projects because of their technical limitations, generally only in accordance with the requirements of relevant standards roughly consider the request parameters such as structure and energy consumption.

In the BIM system, we construct the project is basically the same with the real simulation program solver for buildings with architectural performance analysis, energy analysis , day lighting analysis , sunshine Dan analysis, evacuation analysis, the surrounding buildings and internal flow field analysis , etc. These data will be more accurate to traditional CAD technology, practical. Aspects of the plot, 3D model to ensure the accuracy of the figure drawings. In addition, BIM also offers the possibility for the paperless office.

### 2.4 BIM shortcomings

BIM application has many advantages, but it has not in the domestic promotion, showing it has its own drawbacks. The whole BIM application environment requires high. Throughout the entire project using BIM technology, Aft need to use a variety of software to nearly include all aspects of planning, design, construction, operation four stages. The use of BIM technology for building the project participants is an inherent requirement: the ability to accept, operate and understand this new system. Because of these two points, now the country's BIM mainly stay in the design phase.

In addition, BIM technology is not able to completely fit the actual situation in China now, the lack of comprehensive statistics for the domestic variety of building materials and analysis of the database, the lack of demand for the domestic market and the cost feasible technology system.

## Conclusion

In summary, BIM CAD technology continues the tradition although the specific processes and systems, but in many ways it is more sound and feasible. One day, it will replace the now popular CAD technology.

(1) Visualization model of 3D/4D to ensure the integrity and consistency of project information, help the innovative designer of space design, design and construction problems to solve complex space, complex pipeline. At the same time, 3D technology can shorten the design period, the liberation of the drawing hard on traditional CAD designer. Make BIM truly aided design tools.

(2) In various forms, all kinds of digital content collaboration capabilities to avoid misunderstanding and lack of communication have all kinds of unnecessary errors in the design phase, reducing the consumption of human and material resources. In addition, BIM technology to shorten the design cycle and improve design efficiency and facilitate the management of the entire design process.

(3) The actual digital building model, and a series of precise analysis of the virtual buildings, quantify relevant indicators. According to the simulation to optimize the design reasonable, the actual building is almost perfect in theory.

(4) BIM, there are some drawbacks. Their entire life cycle to achieve architectural hardware requirements are relatively high running BIM is now mainly used for the main reason Institute. BIM in the country as a novelty, the need for a run-in period to allow the construction industry to accept, use it. For the domestic market, BIM lack the necessary database and viable technological system.

## Prospects

Since 2003 the country since the introduction of BIM technology, continue to have the company from a strategic point of view or from starting the actual requirements BIM is applied to actual construction projects. BIM concepts, technologies and related software in the country have been recognized by the building industry. BIM technology because now the Chinese market demand combined with problems in their own small part of the defect, so that by the arrest in China of promotion. However, with respect to BIM used in the construction industry is now mainstream - CAD technology, with more advanced concepts, more intuitive results, better management. In this article, the obvious superiority of BIM technology in the near future, it will replace the current mainstream and become the next generation of mainstream construction industry software architecture.

From CAD to the rapid development of BIM, IT architects create for the complete liberation of the shackles of thinking and expression conditions, new techniques may provide endless architectural creation, a door opened another space in the architect's mind fan windows. Whether you're in the developed or developing city coins, always feel the new building brings an unprecedented strong visual impact, At the same time, from two-dimensional to three-dimensional design, from extensive accurate expression to describe various features of digital simulation models and programs through deduction, control and achieve sustainability while building design products, but also for the design itself sustainability foreshadowed. And all this from a new design concept, design methodologies, design tools and design tools, and a new design pattern thus formed.

The ultimate goal of this new model is BIM. Background as an architect IT managers, when I wrote the above paragraph and character when the mood is excited and spirited, But faced with the reality of the current design , when they had to mind flat, lowered expectations , from CAD to BIM, the future is bound to be bright, but the road is bound to be tortuous.

# From CAD to the rapid development of BIM

Li Jian

Architecture and Civil Engineering School Inner Mongolia University of Science and Technology, Baotou, China

nkdlj@163.com

**Keywords:** BIM, Building Information Modeling, Architectural design, construction industry, informationization

**Abstract.** While architectural design went into the time of BIM, it meant not only the update of tools and methods, but also the update of design procedures and thinking model. In the meantime, while engineering construction went into the time of BIM, it meant not only the update of design delivery methods, but also the update of interactive mode and consequence among the links of entire industry. Therefore, there are so many obstacles to overcome and it depends on the rapid upgrade of information technology application and management standards of the related enterprises as well as the entire industry.

## Introduction

From CAD to the rapid development of BIM, IT architects create for the complete liberation of the shackles of thinking and expression conditions, new techniques may provide endless architectural creation, a door opened another space in the architect's mind fan windows. Whether you're in the developed or developing city coins, always feel the new building brings an unprecedented strong visual impact, At the same time, from two-dimensional to three-dimensional design, from extensive accurate expression to describe various features of digital simulation models and programs through deduction, control and achieve sustainability while building design products, but also for the design itself sustainability foreshadowed. And all this from a new design concept, design methodologies, design tools and design tools, and a new design pattern thus formed.

The ultimate goal of this new model is BIM. Background as an architect IT managers, when I wrote the above paragraph and character when the mood is excited and spirited, But faced with the reality of the current design , when they had to mind flat, lowered expectations , from CAD to BIM, the future is bound to be bright, but the road is bound to be tortuous.

## What BIM applications

The English called BIM Building Information Modeling, Chinese multi translated building information model. But everyone one will find that M is rather Modeling Model; it is referred to, and play a role in the formation process of the model rather than the model itself. So BIM should be accompanied by a building from scratch from birth to death the whole process of digital models of life processes. Discussion of these seemingly little hypocritical, but only make it clear that, in order to truly understand the significance of BIM.

Since it is accompanied by the whole life of the building, then the whole lifetime of BIM which applied?

BIM application project pre- planning stage for the economic, social and environmental benefits of projects to contribute; BIM application design phase for the construction of features, performance, safety, quality and cost control to contribute; construction phase BIM application for the construction of process efficiency, quality and contribute; BIM application for the operation and management of the operational phase of the monitoring architecture to contribute. Contribution BIM application for building the above stage is full of life in terms of revenue they get, not at all stages of their expression.

Very obvious contribution to the design phase of BIM application date, the value will eventually be reflected in the construction and operational phases.

Only from the perspective of the economy and the quality of the contribution the design stage of the building of the whole life is enormous. Although the design of the building itself occupies only 5% of the whole life of the total cost, but decided 70% of its total cost. According to the U.S. BSA (buildings MART alliance) data, the cost of building construction process only 25% of the total cost of the whole life cycle, while the cost of using the operational phase has to account for 75%. According to the U.S. construction-related agency data show that the construction industry practice waste (75%) than manufacturing practices (26%) more than doubled. China's relevant statistics I did not find, but I believe will not be good at this level. This data shows that in the construction industry performance potential is enormous, and the contribution which the design phases will occupy a huge share.

This shows that, aside social and environmental benefits of this concept is not that big, square or building owner will get the most economical in BIM applications, the construction side will reap huge gains in efficiency in BIM applications, and design side before the application of BIM provides benefits both premise and its benefits are designed to enhance the quality of the earnings is not reflected in the economy, at least not therefore significantly improve the design fees in the short term. Meanwhile BIM is unlikely to improve the efficiency of the design phase, but also cannot ignore the design side in which the design itself is more sustainable, such as accumulation and continuous optimization of the basic building blocks of information, data accumulation and analysis of the complete design statistics, these undoubtedly a huge role for the rapid design and submit the results to the design of the control confidence.

**BIM's contributions as well as contributions to the design of BIM**

As discussed previously BIM application in each stage of the whole building life cycle contribution. If we want to compare, there is no doubt in the design phase of the application greatest contribution. BIM application design phase of construction features, improved performance, improved design quality and degree of completion, and for the cost of control, the role of extraordinary.

On the architectural features, BIM capabilities to analyze and optimize the design phase of the program can be integrated urban transport coordination function contradictory impact, environmental impact, such as seeking the most reasonable flow lines, sight and other internal use features allow the design to get rid of dependence on experience get relatively perfect building program through rational analysis and calculation; on building performance, BIM preliminary design stage performance analysis and optimization, you can get a variety of adverse conditions after the safest reasonable tradeoff structure of the program, you can get different internal thermal Under the overall energy, sunshine and lighting features analysis of environmental conditions, in order to identify the most reasonable performance programs; quality in design and finish degrees, professional integrated coordination and conflict checking construction design stage, you can solve almost impossible under the CAD method avoid collisions and other professional errors and omissions touch contradiction pipeline missing issues can help avoid normative specification validation errors, improve the quality of legitimacy; while improving the overall process design stage BIM models, continue to refine engineering report that the project cost has remained under control.

Design from scratch for the construction of full life cycle BIM contribution, from basic to perfect. Thanks to the above contribution BIM design, the design is complete BIM delivery model has almost completed the construction of a virtual equivalent to the state. This is designed to pay for work which of course cannot be mentioned in the same way with the CAD language.

**What BIM tools**

Often hear people ask, BIM is what software? Or, BIM Revit is it? In fact, look at the table in front of BIM applications can know, BIM impossible just software. In the design phase it should at least

include modeling and simulation analysis (including cost management) two categories of software, of course, since it is called Building Information Modeling, BIM modeling is certainly its most important aspects. BIM modeling software also varied, as varied as CAD software. Civil design commonly used modeling software have our very familiar in the era of CAD company Autodesk and Bentley companies , Autodesk 's Revit family of products and Bentley 's GC (General Consultant) series products are still the most widely used . Another GT (Gerry Technology) French Dassoult use Catia software development company DP (Digital Project) series. Different modeling software for different construction projects, GC Series DP Series software and physical modeling of complex building more suitable, of course, capital and technology into applications DP is relatively much higher. In addition, some modeling software such as Sketch up and Rhino is more commonly used design stage modeling software.

Analysis of the model will use a series of simulation analysis simulation software , as usual for the pipeline comprehensive conflict checking software Autodesk Navisworks, Bentley Project wise Navigator and Solibri Model Checker , commonly used in a variety of performance analysis ETABS, Ecotech, IES , etc., is frequently used in the design phase .

**BIM is still a long way road**

As a designer, just to see these tools mentioned earlier, you can learn how different future design and traditionally. Those described earlier application also tells us that we can know in advance exactly how we designed the building will run. All of these, of course we need to do more work in advance. When BIM show a perfect prospect, exciting and inspiring, but when faced with a tight schedule and heavy tasks of the project design fees were not high, if not required or forced, it seems that we have been unable to pursue the beauty of BIM. From the entire construction industry, manufacturing information compared with the relatively low level of applications, this is a special complex industry brings. Although the construction industry is not cutting-edge technology, but it does not need to put so many cutting-edge technology to integrate and industrial chain length, number of participants, BIM to walk every step in this long chain, has experienced numerous participants, their difficult to imagine.

Domestic experts in this transformation from CAD to BIM, the construction side is the biggest beneficiary of the macro, but the technology can be put in enough power is relatively low; designer is the largest contributor to its technical strength and most strong, but the actual benefit the smallest, power can only be living in the middle; while living in the middle of construction technology side, the largest of its actual income, its power is also the largest. Therefore considers the construction side BIM revolution will be the primary ground.

During the construction phase is the construction phase after more biased, the power of BIM applications, is bound to affect its first upstream design stage, therefore, the greatest contribution BIM design side will be dragged into the BIM applications. If you did not become a tool and means BIM design side, the design side facing passive situation. In fact, the domestic situation is not entirely true, arguably those sighted design, and strong technical force and have the industry has taken the lead in the unit responsible BIM way off.

BIAD (Beijing Architectural Design and Research Institute) of BIM road, started in those complex spatial shape description and manipulation needs. Looking at the domestic civil design industry, which is likely to be a general rule. This shows that complex shapes cannot be described by two-dimensional tool design creativity needs, and with the three-dimensional parametric design of interactive, BIM enthusiasm led the design phase, and this power is in front of experts did not notice. Thus embarked on the road to perhaps BIM is Chinese characteristics, but there is that is reasonable, but do not let the minutiae obscures the trunk, a tributary of the collateral as the mainstream.

Although the intersection of BIM has come, but we still have a long road to BIM, we are still far from the ideal of BIM goals. Which requires the popularity and mastery of technology and operations has been very complicated, and change the designer’s thinking and work habits but not an easy task?

From the technical point of view it is especially outside, even completely solve the problem of the design phase; it is only a small part of the completion of the road BIM. First, our CAD foundation is not solid. While we work to complete the design using CAD tools from the beginning has been more than 20 years, but also to a large extent and mode of thinking with print manual era. CAD and document data does not smoothly flow in the various stages of the construction process; the last stage of delivery to the next stage is still mostly hard-copy documents. Leaving aside the electronic document accuracy, reliability and legal validity of the certificate is not to say, even if some of the documents in electronic form, in which the file data standards will also bring trouble confusing the little convenience canceled out. Britain and other countries, if read carefully CAD standards, difficult to find, BIM many of the basic concepts and ideas, has long been lurking in CAD, just waiting for technology to enhance, stimulate and extend it and make it more perfect realization. Secondly into BIM era, the scope and content of the work is more widespread, extending from the enterprise to participate in the entire construction process between the relevant authorities and enterprises, including government, the construction side, the design side, the construction side and suppliers and so on. Collaborative front longer, more complex data flow lines, more unified standards, and these are precisely the construction industry in our short board.

But anyway, BIM is the development direction of the construction industry; this conclusion is the consensus of all parties. And as technology advances and to strengthen the management of this goal will be achieved in the not too distant future. Looking at the domestic construction industry for nearly 30 years history of information technology, it can be said in the 1980s mainly to solve the problem of structural design calculations calculated as the main content of the 1990s basically solved the problem of computer-aided drawing, the early 21st Century Computer and network-assisted solve management problems, then the next 5-10 years, will be based on the industry's BIM-based information integration applications.

# Model reuse technology in building electrical parameters design

Hongke Pu[1, a*], Qingchao Wei[1,b]

[1] School of Civil Engineering, Beijing Jiaotong University, Beijing 100044, China

[a]peakhill@163.com, [b]qcwei@bjtu.edu.cn

**Keywords:** Building electrical design, parameterization, reuse technology, CAD, secondary development.

**Abstract.** Electrical design in a variety of electrical equipment needs to search, copy and modify constantly, so it is inefficient. Parametric design technology is the most common way to achieve rapid design, but less in the electrical design of the specific application. With the electrical equipment model parameterization and the reuse technology model, develop electrical equipment design software based on CAD secondary development. Use of software, design by three levels of reuse technology on the equipment for quick drawing, editing, statistics, to avoid duplication of work more efficiently, to improve design efficiency and reduce human waste.

## Introduction

In electrical design, engineers copy the corresponding equipment drawings from other CAD drawings to the current project, and then layout equipment according to the needs. Each type of equipment having as many as hundreds of equipment is a painful thing for the designers to create the base one. In addition, each device in different places may need to set different parameter information, such as size, power and so on, in order to display the corresponding information of statistics. If according to the traditional way for processing, equipment layout, editing and statistics will spend a lot of time, waste of manpower, and still can't get clear and accurate statistics.

Parametric design technology can realize the rapid drawing design[1]. Using design of mass customization mode, set up the equipment in a large amount of information, including size information. Configuration design as the main means of design, complete product customized design, rapid response to the needs of users. The comprehensive utilization of modular design technology, the configuration design technology and database management technology is used for parameterized system development research. The aim of modular design is to improve the efficiency of product design, shorten product design cycle and reduce production cost. Classify the electrical equipment by the function of different or the same function but different performance module, input the equipment type to the database management according to category, help users quickly find equipment needed.

Design reuse through the reuse of the existing design elements to improve speed and quality of design[2,3], it is widely used in mechanical engineering and software engineering, and other fields, its application in construction engineering fields there are urgent needs and great potential applications. In the electrical design, the basic equipment units in accordance with the requirements of choice, assembled to form a collection of reusable equipment unit can also be designed to be assembled into a standard room in the form of reusable equipment. Based on this theory, this article is to determine the reuse unit, name reuse, and provide a basis for the deployment in order to realize the automatic operation process and achieve rapid equipment drawing[4,5,6].

## Process

Equipment to reuse the basic three levels: reuse unit, reuse collection, reuse of floor (Fig. 1).

- Reuse unit is the most basic equipment parts, separately to editor
- Reuse is set according to a certain region (such as a room), chooses corresponding combination unit assembled, forming regional library equipment
- Reuse is assembled the reuse of composite applications to the whole floor

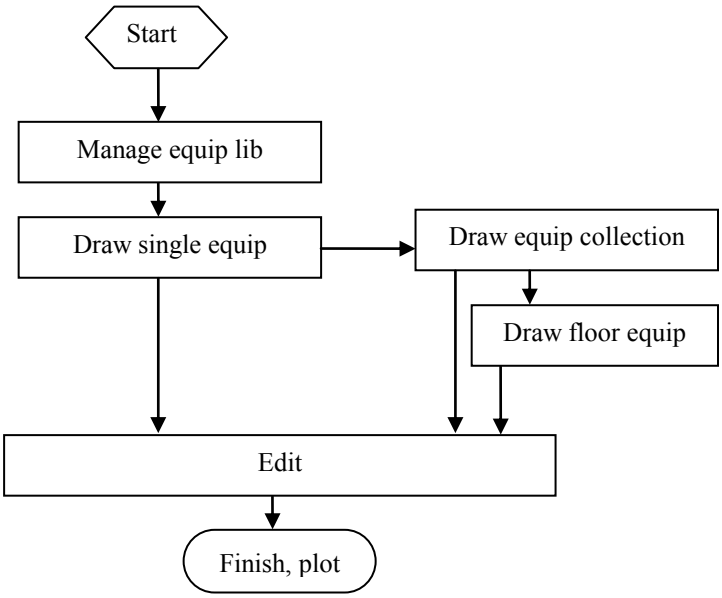

Fig. 1 Design process

The original library needs to input common unit devices by classification. Settings interface, convenient for the user at any time to add new equipment, forming the basic unit library, which is the most basic unit of reuse.

- Analysis of product structure, divided into modules
- According to finalize the design product design units
- Establish parametric model
- Forming block and add to library

The basic unit can be used for electrical equipment layout, fast editing and other functions, but not to play to maximum effect. Multiple devices to select by area layout, are stored in the current database in order to draw quick and batch edit. If the floor number is more, the same or a similar device collection of the region can be used and you can quickly achieve layout floor equipment.

After the device drawing is complete, the device can be unified treatment. According to the device name, device properties, equipment size for device information filtering, select needed device for rapid batch editing process. The select equipment set can also be edited directly in accordance with the device's region, floor.

**Process Model**

Based on AutoCAD secondary development platform and using Visual C++ and ObjectARX SDK development tools to develop functional electrical equipment layout software. Equipment classification and definition of information are stored in the equipment database. Design appropriate tools of device library management (Fig. 2): Equipment classification, equipment input, equipment editor, equipment parameter processing. Each device uses block as the basic unit placed in storage in a single dwg type file, each block having the appropriate device information stored in the block properties in the block mode. When the device is arranged according to the user's choice, export the appropriate equipment from lib to draw the corresponding block and block references to the current drawing, each device has only one block. If there is difference between the current drawing device and the device in the library, you can modify current device before adding to storage, used as a new device. In the drawing, you can set the parameter information for device and describe the device features.

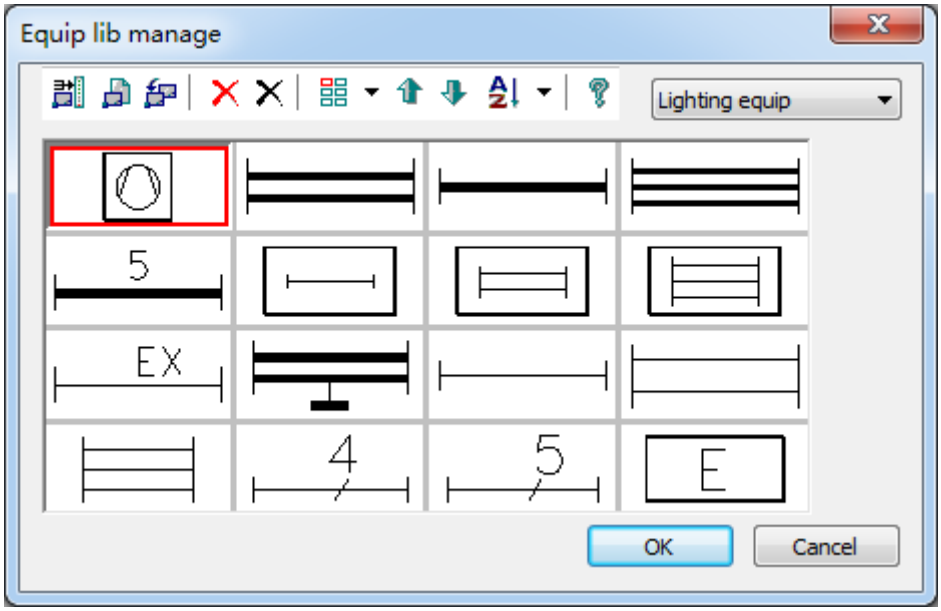

Fig. 2 Lib manage section

Reuse region collection and reuse floor collection are created by the user with the appropriate class name and managed by the user: edit, modify and delete operations. Reuse collection requires the user to select from a collection of drawings to extract information stored in the database, and to get the appropriate base point used for user to insert collection into the drawing. Reuse floors need to select multiple reuse collections from collection lib, and set the location of each set of equipment. Every time draw a lot of equipment rapidly.

With the current tool to draw electrical equipment, you can quickly get statistical information on all devices (Fig. 3): including the number of devices, size, room equipment information, certain floors of the device information, it is convenient for user to quickly understand the final arrangement and construction unit ready to purchase material.

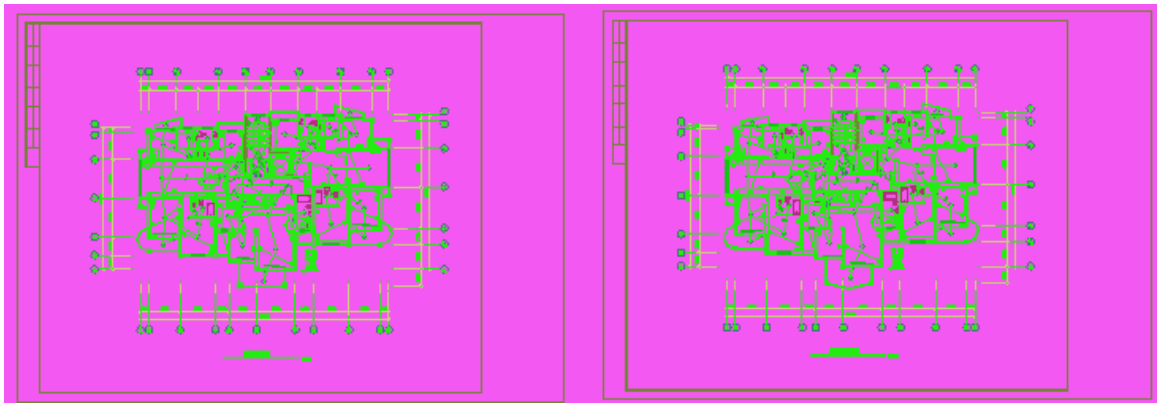

Fig. 3 Equip synchronization draw

## Summary

This article is based on AutoCAD secondary development technique, with the help of a database, develop automated processing software. Fully use parametric model reuse technology in the design, effectively control the reuse scope and the method. Use parameterized module processing electric equipment, realize the different level of reuse of equipment model. The design engineer can carry on the equipment layout, fast and efficient batch edit, thus reducing repetitive work. Allowing designers release from tedious drawing work, apply time to more professional study.

# Normally consolidated Subgrade limit bearing capacity calculation using slip line method

Chen Ming[1, a], *Zhou Taiquan[1,b]

[1]College of Environmental and Civil Engineering, Jiangnan University, Wuxi, Jiangsu 214122, China

[a]my.cm1993@gmail.com,[b]zhoutaiquan@163.com

**Keywords:** slip line method; ultimate bearing capacity of foundation; Terzaghi ultimate bearing capacity of foundation.

**Abstract.** Normally consolidated subgrade limit bearing capacity of foundation soil was studied in the paper using slip line method. Slip line results are found to be consistent with the results calculated by Terzaghi theoretical formula and Hansen theoretical formula. Then the influence of cohesion, friction angle for normally consolidated subgrade is studied under complete smooth or complete tough conditions. The results show that the normally consolidated subgrade limit bearing capacity increases linearly with the increase of k, γ, while it increases nonlinear with the increase of Φ and the increasing growth rate improves with increasing value of Φ.

## Introduction

The purpose of studying limit bearing capacity is that the pressure on the underside of the building foundation must be limited. The subgrade limit bearing capacity is not allowed to reach the limit bearing capacity. Besides, the subgrade limit bearing capacity has a certain degree of safety to ensure that the foundation will not occur sliding failure. At the same time, to ensure that the structure will not be due to excessive deformation of foundation affects their normal use. Therefore, determining the limit bearing capacity of foundation is an urgent problem to engineering practice to solve.

There are two main methods to determine the limit bearing capacity, the first one is field test methods, such as standard penetration test, static cone penetration test and pressure meter text. After the establishment of a regional relationship, limit bearing capacity of foundation value can be obtained. The other one is theoretical calculation. In 1940s according to the basic theory of Prandtl, Terzaghi proposed limit bearing capacity formula considering the weight of the soil under foundation. In 1950s Meyerhoff proposed limit bearing capacity formula applicable to deep foundation. To be more accurate researching limit bearing capacity of foundation, we use the analysis software Analysis of Bearing Capacity to study it.

## Slip line theory

In calculating the limit bearing capacity of foundation with slip line method, assuming the soil is the ideal rigid-plastic material, obey Mohr-Coulomb criterion or Terzaghi theory. Under load, in certain direction the soil in the plastic zone flowing freely, the deformation of soil large and elastic deformation ignored, the rigid-plastic assumption can deduce more reliable approximate solution. Otherwise, it may lead to large errors. In geotechnical stability problems—the problem of foundation bearing capacity, stress problems of retaining walls and stability problems of slope, the slip line theory has been widely applied.

## Software

ABC (Analysis of Bearing Capacity)is a computer program that uses the method of stress characteristics (also known as the slip line method) to solve the classical geotechnical bearing capacity problem of a rigid foundation, resting on a cohesive-frictional soil mass, loaded to failure under a central vertical force. Fig.1 shows the terminology used.

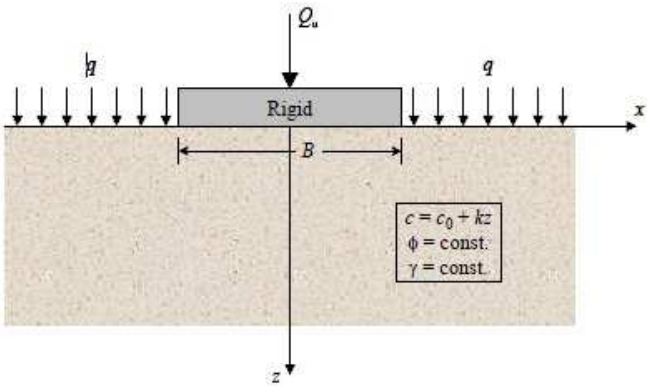

Fig.1 Problem definition

**The Basic Examples**

Severe soil γ =18kN/ $m^3$, friction angle Φ=18°, cohesion coefficient $c_o$ = 10kPa, base width B = 3.0m (round base R = 3.0m), the depth D = 2m. At this depth above the soil as side load to deal with. According to the study, the design of the four foundations, obtained by numerical simulation software, and has been the foundation failure mode, as shown in Fig.2, and the resulting calculation of ultimate bearing capacity $q_u$ calculated values as obtained with Terzaghi, Hansen theoretical formula contrast, the feasibility of the software simulation, as shown in Fig.3.

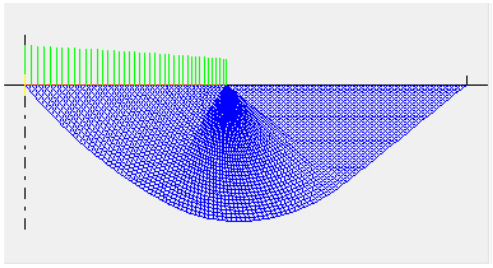

Fig.2.1 Strip and smooth

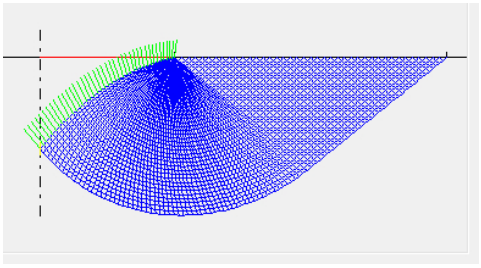

Fig.2.2 Strip and rough

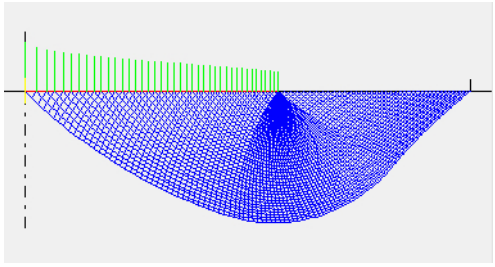

Fig.2.3 Circular and smooth

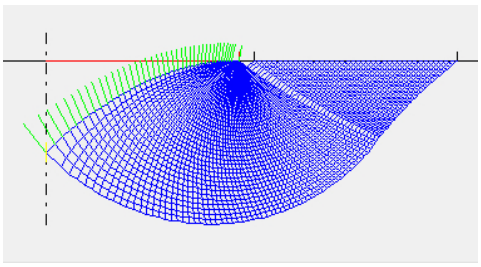

Fig.2.4 Circular and rough

Fig.2 Computational model for 4 subgrade limit bearing capacity groups

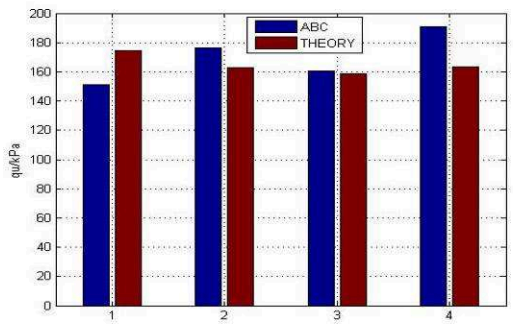

Fig.3 Comparison results between ABC and theoretical solution

**Analysis of influence parameter**

In order to analysis k, γ, Φ parameters on the influence of the limit the bearing capacity of the foundation. Design when $c_0$ = 1.2kPa, Φ = 18°, B = 3.0m, base completely friction strip foundation, depth d = 2m, k = 1,2,3,4 kPa / m, when γ = 18, 19,20 kN/m$^3$. The bearing capacity for the total of 12 sets of models is performed using ABC software, as shown in Fig. 4.

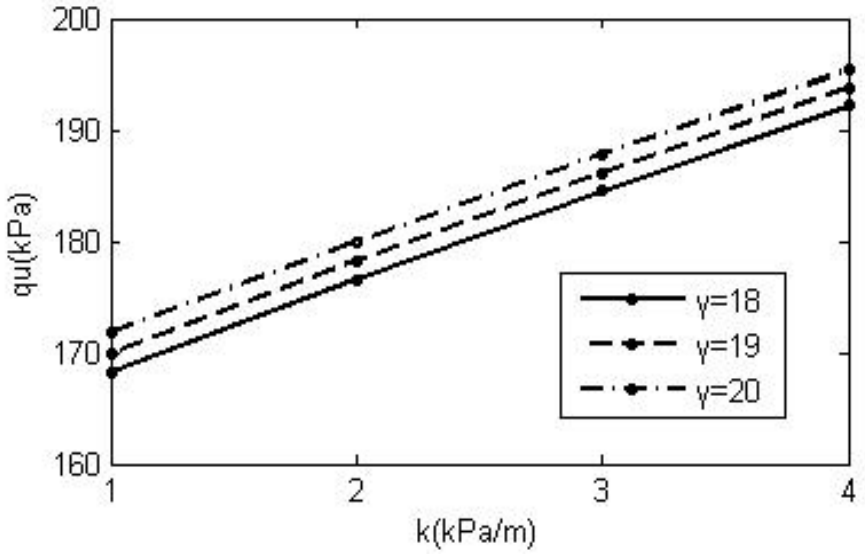

Fig.4 Relationship between the limit bearing capacity and k，γ.

Within a certain range, the other parameters in the same situation, with the increase of γ, the ultimate bearing capacity increase, can be found to improve the bearing capacity of the foundation is approximately linear. Similarly, other parameters in the same situation, with increasing k, the foundation bearing capacity also increased, which also showed a linear rise.

Design When $c_0$ = 1.2kPa, γ = 18kN/m$^3$, B = 2.0m, base completely friction strip foundation, depth d = 2m, respectively, when k is equal to 0,1,2,3,4 kPa / m, Φ = 10,13,16,20 °, the foundation bearing capacity of a total of 20 group model. Solving the size of the foundation bearing capacity, suchTab.1:

Tab.1 Limit bearing capacity of foundation under different k and Φ.

| k\Φ | 10 | 13 | 16 | 20 |
|---|---|---|---|---|
| 0 | 119.725 | 163.741 | 224.992 | 347.561 |
| 1 | 125.121 | 170.702 | 234.041 | 360.599 |
| 2 | 130.218 | 177.381 | 242.807 | 373.336 |
| 3 | 135.073 | 183.824 | 251.334 | 385.811 |
| 4 | 139.728 | 190.068 | 259.653 | 398.056 |

And when k = 1,2,3,4 kPa / m, respectively, and k = 0 comparative analysis made into a line Fig.5:

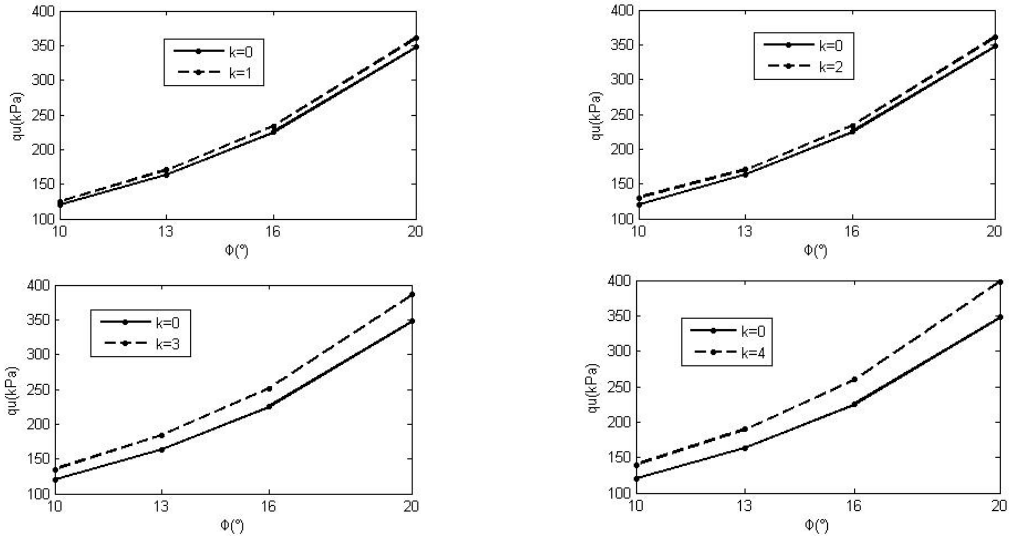

Fig. 5 Relationship between the limit bearing capacity and k and Φ.

Analysis obtained within a certain range, under the same conditions of the other parameters, with increasing k, the limit bearing capacity increases linearly, change contrast foundation bearing capacity Φ = 10,13,16,20 °, the greater the value of Φ , linear foundation bearing capacity increasing faster; while under consistent conditions as other parameters, the foundation bearing capacity values with Φ non-linear increase, and increase more and more, that is, $q_u$-Φ curve slope increases, contrast curve slope k = 0,1,2,3,4 kPa / m when, when Φ is the same, the slope of the curve with a positive correlation between the value of k.

## Conclusion

In the paper, the limit bearing capacity of foundation analysis software ABC was used, the main conclusions are as follows:

1 within a certain range, Analysis of Bearing Capacity Analysis of bearing capacity, the results of the calculation results obtained with Terzaghi, Hansen there are no significant difference between the theoretical formula.

2 Since the limit bearing capacity of the foundation formula Terzaghi theory applies only to the condition k=0, and the actual situation should be considered in the consolidation of the soil, so the method described in this article has some practical significance and innovative;

3 Under certain conditions, limit bearing capacity increases linearly with the increase of k, γ, increases nonlinear with the increase of Φ and increasing growth rate improves with that of Φ.

# Numerical simulation and testing of 45 Architecture steel Welded based on Gaussian heat source

Jianbo Ji[1,a],Jinzhou Zhang[2,b],Lei Zhang[1,c]

[1]Chemical Engineering Institute, Xuzhou College of Industrial Technology, Xuzhou 221140, China

[2]College of Mechanical Engineering, Yangtze University, Jingzhou, Hubei,434023

[a]jijb@mail.xzcit.cn,[b]87221914@qq.com,[c]89202974@qq.com

**Key words:** numerical simulation; weld; stress; strain

**Abstract:** Using sysweld software based on the Gauss heat source, simulated welding process of 45 steel plate, analysed welding temperature field, stress and strain. The maximum stress value appeared at the initial welding position of junction of base metal and weld. As the most dangerous section, the maximum strain value appeared at the end welding position of the junction of base metal and weld. Compressive strain appeared at the central part of weld and the tensile strain appeared at the junction of base material and weld. The deformation was of upward warping, which is helpful to explore the numerical simulation of welding structure.

## Introduction

45 Steel is a type of high-quality carbon structural steel and widely used as building materials. Because of uneven distribution of the heat cycle during welding, it is easy to form larger welding residual stress and lead to adverse effects for the performance of the welded components, such as static load strength, fatigue strength, fracture toughness and so on. Much more high demands is needed to analyze the stress and strain of the welding structure[1][2].

## 1 Numerical simulation of 45 steel welded joints

The materials exit nonlinearity and geometric nonlinearity in the welding stress field. So, taking the complexity of the welding thermal stress and accurate calculation and the function of FEA software into consideration, we took the welding thermal stress field as a problem about material nonlinear transient analysis. Meanwhile, we selected elastic-plastic mechanical model and incremental theory to analyze the problem.

### 1.1 Establishing heat source model

Because the hot spread quickly in metal, highly concentrated heat source was used to transfer much more heat to workpiece in an instant and causes time-variation and unsteady characteristics during welding. we selected realistic model of normal heat considering materials' physical properties changes with temperature[3].

Gauss heat source: Practice has proved that takes heat density as surface heat [4] distribution, positive attitude is more effective during welding. Assuming the distribution of heat is Gaussian normal distribution function, then integrates the equation is:

$$q^* = q^*_{\max} \exp(-kr^2) \tag{1}$$

$$q = \int_F q(r)dF = \int_0^\infty q_{\max} e^{-kr^2} 2\pi r dr \tag{2}$$

$$q = \frac{\pi}{k} q_{\max}, \therefore q^*_{\max} = \frac{k}{\pi} q \tag{3}$$

Where:
q—effective heat power, J/s；
k—heat concentration factor,1/mm2；
r—the distance between a point within the circle heat source and the center.

According to a Gaussian distribution curve, the Heat source in infinite distance was close to zero. Therefore, the role of regional heat source must have a limit. We determined the size of the heating spot and the heat spots takes over more than 95% of heat, namely:

$$q^*_{\min} = 0.05 q^*_{\max} \quad (4)$$

The outer diameter of the heating spot is:

$$d_n = 2\sqrt{3}/\sqrt{k} \quad (5)$$

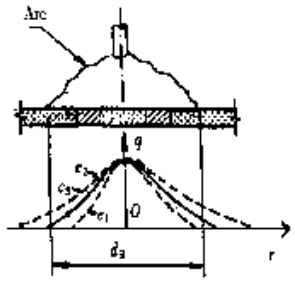

Fig.1 Gauss heat source

**1.2 Establishment of the finite element model**

We use the finite element method to analyze the situation of 45 steel. For the simple shape of the plate member, we can build the model by visual-mesh, and then imported the meshing into the sysweld before meshing it. The Three-dimensional model is shown in Figure 2[5].

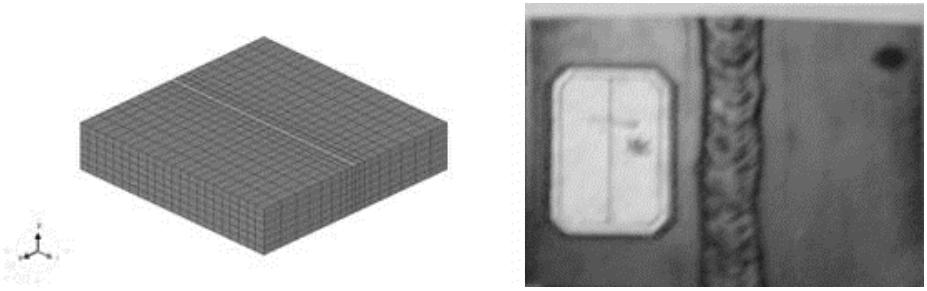

Fig.2 Three-dimensional model and welding sample

**1.3 Mechanical constraints set**

We impose symmetric rigid constraints on both sides of plate.

**1.4 Welding parameters**

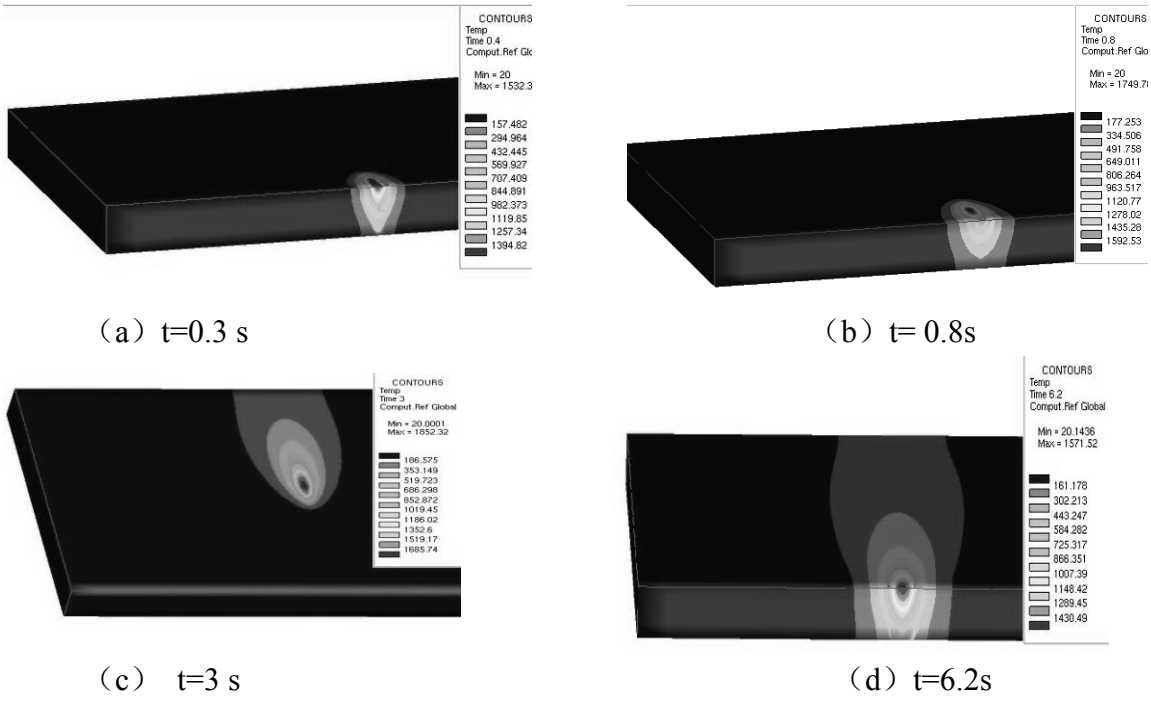
The heat efficiency of TMAW is $\eta = 0.8$, the welding voltage, welding speed and Welding current are U=40v, V=0.8mm/s and I=70A, then starts the welding simulation.

**Numerical simulation results analysis**

**2.1 Welding temperature field analysis**

Arc welding processes require heating from beginning to end, so temperature field has an important influence on welding quality and improving welding productivity.[6]

It can be seen from Figure 3 that the temperature field is symmetric and closer to the heat, the temperature gets higher. It becomes Normal atmospheric temperature at some distance. When welding start 0.3s, the highest temperature only rise to 1394.82 ℃, and at the second of 6.2, the heat has come to the edge of the plate and the maximum temperature is 1430.49 ℃. That is to say, at the beginning and the end of weld, the temperature does not reach the melting point of steel and varies a lot. So we should Increase welding time and slow welding speed here.



（a）t=0.3 s （b）t= 0.8s

（c） t=3 s （d）t=6.2s

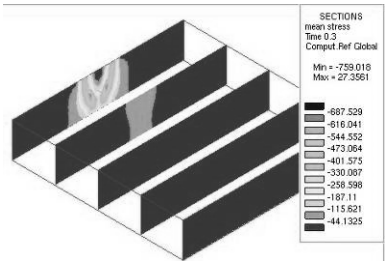
Fig.3 Welding temperature field

**2.2 Welding stress analysis**

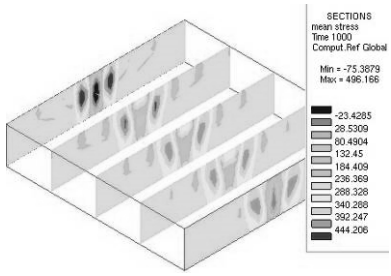
Because we heat part of the weldment while welding, the weld area is heated to a high temperature and so are both sides of the base metal because of welding heat. The farther away from the weld, the temperature gets lower. Therefore, judging from thermal expansion and contraction properties of the metal, different parts of the weldment will get different temperatures, and will lead to different thermal expansion.

It can be seen from Figure 4(a) that at the second of 0.3, the weld area reaches to the highest temperature, and the temperature decreases with distance increases. For the sake of plate is not free to elongate as a whole, all parts of elongation contain each other. Welding heat source heat metal to melt and the weld center gets the highest temperature, so the welding-line area gets the maximum heat expansion. And the welding-line area expansion is limited because of contain around the base metal, so it brings compressive plastic deformation. However, the materials thermal expansion close to molten pool affected by mental around gets deeper than that away from weld seam, which will result in the materials In the weld and around subject to relatively large compressive stress. On the contrary, that away from weld seam gets small compressive stress.

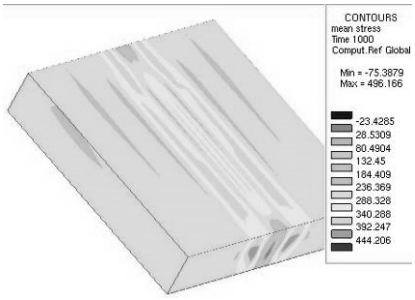
The Figure 4(d) shows transverse magnetic memory testing data in weld central at 1000 seconds. And the points below zero stand a large stress concentration. The bigger slope over zero, the larger is the stress concentration, namely, larger residual stress.



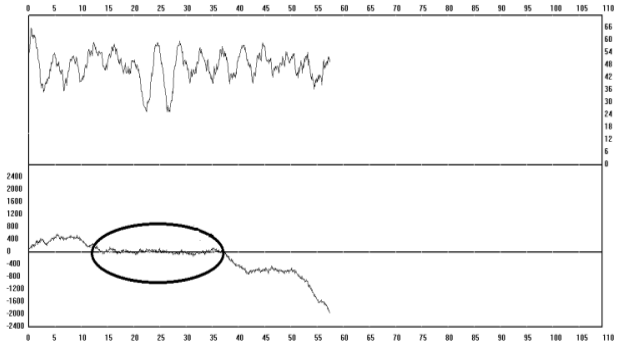
(a) Simulation diagram (t= 0.3s)



(b) Transverse simulation diagram (t= 1000s)



（c）Longitudinal simulation diagram (t=1000s)

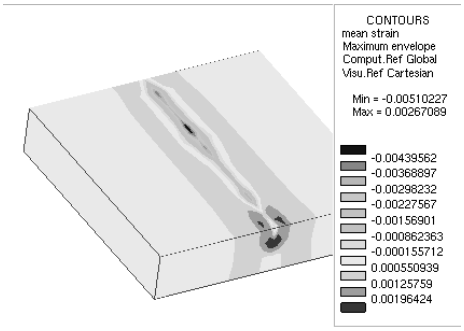


(d) Transverse magnetic memory testing value on Central weld (t= 1000s)

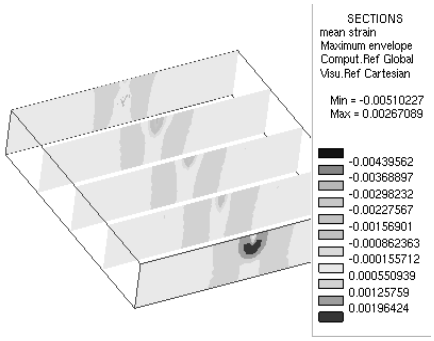
Fig.4 Welding stress

It can be seen from Figure 4(b), (c) and (d)that as the weld-metal zone has generated a compression of plastic deformation after cooling, so the length will shorten. However, both sides of the metal sheet hinder the central weld zone shortened. At the same time, the weld zone support tensile stress and both sides of the metal bear compressive stress and reach equilibrium. Weld and its annex area appears mainly tensile stress and the beginning welding parts bear compressive stress. The maximum tensile stress (about 440MPa) appears at the junction of the base metal and weld, where the dangerous section lies. And so does the welding stress at central longitudinal seam, stabilized. The sheet stress of the upper parts is Significant greater than the half bottom. In cooling process, the weld metal cools and shrinks. Meanwhile, the weld metal shrinkage limited by the surrounding material is greater than that away from it. Therefore, the tensile stress near the weld is bigger than that away from the weld.

**2.3 Welding strain analysis**



(a) Strain simulation diagram



(b)Strain simulation diagram on Weld cross section

Fig.5 Welding strain (t=1000s)

The Figure 5 shows that the welding symmetrically distributed strain after 100 seconds of welding. The seam center appears compressive strain and tensile strain appears at the junction of the base metal and weld. The sheet strain of upper parts is much larger than the half bottom. The strain rises from small to stable with welding, and at the end of welding it increases suddenly. The maximum strain appears at the final position of the base metal and the weld seam junction.

## Conclusions

(1)The result of temperature field simulation indicates that the temperature from positions of welding at the beginning and end varies a lot. We should increase welding time to avoid the lack of penetration and lack of fusion.

(2) The result of stress field modeling indicates that the welding stress main is tensile stress after welding, and maximum stress occurs at the beginning of the welding position. Weld stress between Parent metal and weld remains relatively large, and the sheet stress of the upper parts is larger than the half bottom. What is more, Stress distributes uniform.

(3) The analysis of strain field shows that the seam center bears compressive strain and tensile strain appears at the junction of the base metal and weld. As a result, the plate deformations upwards and the maximum strain appear at the end of welding.

# Research on Tunnel Construction Quality Based on Visualization Management

Qian Li

College of Civil Engineering and Mechanics, Central South University of Forestry and Technology, Changsha 410004, China

semese_li@163.com

**Keywords:** Visualization Management, Tunnel Construction Management, 4D Model

**Abstract.** Through the comprehensive application of modern information technology, network technology and modern construction management 4D theory has carried out the systematic study on the implementation method of the tunnel construction quality information rapid collection, visual management, centralized control and highly sharing. Based on the development of tunnel construction quality information management system, by logging data of design, construction, monitoring, supervision and test during the construction period, digital network management would be achieved in the tunnel construction process. mainly to complete: 1) combined with 3D models and tunnel construction schedule, build a tunnel 4D model; 2) Take additional tunnel construction quality management information for 4D theory to achieve dynamic visualization of construction quality management and query; 3) through practical engineering applications, the system is proved innovation in the tunnel construction quality management.

## Introduction

At the present, tunnel construction management is based on 2D form such as the text, tables and network diagrams. Which is not enough visual image and increases the frequency of communication in the participate parties of construction projects, it is difficult to achieve effective information exchange and share, and reduces the efficiency of construction management [1]. Also, the used software in the project management generally lack tunnel 3D models and cannot achieve a three-dimensional visualization of the building construction management. With the development of computer and network technology, tunnel construction process can be simulated on a computer, using three-dimensional modeling to real-time reflect tunnel construction and completed picture. Meanwhile 4D theory has made considerable progress and applied to the construction in the projects [2, 3]. This article will introduce theory of 4D in construction process and three-dimensional model of the tunnel as the carrier, integrate the tunnel construction progress and management information, achieve efficient management of engineering information and real-time control of the progress of the project, and provide adequate and effective information support for engineering management decisions.

## Development Infrastructure and Major Structure

**Develop infrastructure and hierarchy.** The system developed with *ActionScript* and *Java*-based [4] can be applied on multiple platforms, using *Eclipse* integrated development environment and *B / S* multi-network application for the solution. That makes the system easy to

use and simplify the management and maintenance [5]. Build three-dimensional model of the tunnel use *Flash 3D* modeling techniques. Taking into account the amount of network applications and data is large, so using *SQLServer* 2005 database to process data. System has a certain independence, but also consider and compatible with other management systems [5]. The system runs in the user's browser *Flash Player* plug-in and handles the interaction with the user.

**Design database.** Establish the quality database of construction as shown in Figure 1.

On the basis of the interaction *JDBC* with the database, this system uses *Hibernate* for *JDBC* a lightweight object package [5]. The designer can easily use object-oriented program thinking to manipulate the database.

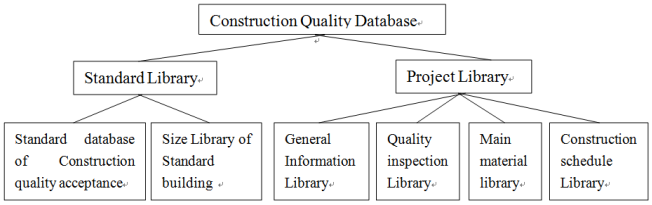

Fig.1 Structure of quality information database

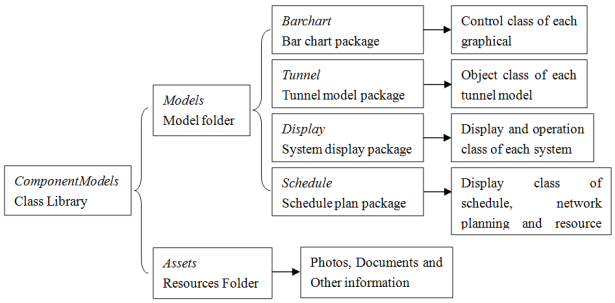

Fig.2 Structure of class library

**Design the system's main class.** *ComponentModels* class Library: Based on object-oriented, this system build a *ComponentModels* class Library as shown in Figure 2.

*QualityManagement* Radical Database: Based on object-oriented, this system builds a *QualityManagement* Radical Database as shown in Table.1.

Table.1 List of member variables and functions of the base class QualityManagement

| *member variables and functions of the base class* | *The main function* |
|---|---|
| isFlowChart | Boolean variables, used to determine whether the flow chart |
| getmapname | Character class variable, used to name for the map |
| pileNo | Integer variables, used to Stake |
| init() | Initialization function |
| InitProjectInfoResult(event:ResultEvent) | Return to the organizational structure of the project xml data, used to treeProject controls |
| OnTunnelComponentClick(event:MouseEvent3D) | Click event handling model components |
| searchComponent(name:String) | Query component, used to Tree node manipulation functions |
| queryFileResult(event:ResultEvent) | For quality check（Including inspection lot, Scene photos, Acceptance forms, etc.） |
| onQuaTextChange(event:ListEvent) | Flowchart and information inquiry |
| GetComponentProperties(event:ResultEvent) | Overloaded in a derived class, used to draw specific model |

Corresponding operation class was established to upload and retrieve flow chart, scene photos and inspection lot in this system. Through local loads and remote upload to collect into the server, simply call these classes can display pictures, documents, etc. on the screen.

### Build a Tunnel 3D Model

To use *Alternativa3D* engine (i.e. *Flash* scripting language *ActionScript*) and *Flash* three-dimensional model draw framework for joint programming and achieve drawing and display of three-dimensional model of tunnel component rendering. And follow the steps to build a three-dimensional model of the tunnel:

**Background mosaic.** In order to the true and image on tunnel model, the first, establishing the corresponding background pattern. Background image mosaic using *Flex* technology embeds a background image into the framework, which generate 3D model on full sense of the scene. This technology allows designers to change the background according to project different images.

**Build model.** To use *Alternativa3D* engine midpoint, line and polygon drawing functions build complex tunnel space model. That means the tunnel model is decomposed into unit structure, then using the appropriate functions draw three-dimensional model of each unit components, and finally combining the parts into a whole three-dimensional model of the tunnel. To enhance the realism of the model are required to model the use of light and texture mapping in the drawing process of the model. On the one hand the use of light functions defined in the view class achieve illumination mapping of suitable project. On the other hand the use of processing three-dimensional model of the surface texture *alternativa.engine3d.materials.SurfaceMaterial* class of each component color fill, or after setting the texture coordinates; define *alternativa.types.Texture* classes on the various components mosaic texture material pictures.

**Show three-dimensional model.** Finally, a series of coordinate transformation complete the transformation from model space to paper space, and display graphics on the screen window. Setting response functions of the mouse actions achieve to using the mouse to drag to change the viewing angle of the model, so that the model were observed from different orientations.

### Implementation of Tunnel Construction and Quality Information Management

**Establish a tunnel construction management 4D model.** Using object-oriented thinking, the system will integrate schedule information, quality information, material information and other information to established dimensional model to form 4D model of the tunnel, to process dynamic simulation of tunnel construction. The tunnel model based on 4D can be inquired by tunnel construction schedule and manage construction information which achieve a three-dimensional visualization of tunnel construction management [5].

**Draw construction schedule.** Construction schedule chart is drawn by the form of dual-period comparison. In accordance with construction organization design determines a reasonable plan-time [5]. With construction total time limit as the timeline length of the construction process and working day as the step, the planned time of each component on the timeline is highlighted. In addition, according to the actual schedule, the actual time of each component is determined. The actual duration compared with the planned duration, is able to directly reflect the relationship of the actual schedule and planned schedule to facilitate the project all parties participating in the construction grasp the actual progress of the project.

**Collect construction quality of the information.** The system includes the information collection module of the construction quality, which includes some multi-source and multi-format data such as

text, data, voice, image and vector files etc. that need to classify and sort and manage. In addition to the above these, but also includes data provided by the supervision unit and the testing units, etc. it need to classify and sort. To respectively demonstrate among the system, that make structured and clear categorized of information management. Tunnel construction management information is entered by three ways: general information input; real-time information input; existing system data input.

**Classify the quality information.** In the 3D state, construction design schedule and quality acceptance criteria of separated parts of a project as the two axes, query and export inspection items and engineering information and quality standards information and raw information and material testing information etc of separated parts of a project.

**Establish a quality evaluation system.** This system will classify examination indexes of the separated parts of the tunnel project; get the weight of each unit's indicator by consulting specialists of the design and construction units; score for each index by the construction process of the quality test results and expert evaluation; finally obtain overall weight of the index and evaluation results. Those ease management personnel to overall grasp the construction quality.

## Conclusions

Above a comprehensive study of the tunnel construction and the development of key technologies of the quality of management information systems based on theory 4D, mainly to complete: 1) combined with 3D models and tunnel construction schedule, build a tunnel 4D model; 2) In the 4D theory, based on the additional tunnel construction quality management information, to achieve dynamic visualization of construction quality management and query; 3) through practical engineering applications, the system is proved innovation in the tunnel construction quality management. On this basis, future research should focus on the perfect of many types and complex tunneling model library, and optimization of construction schedule, resource and cost management library and optimization of construction schedule, resource and cost management of the tunnel.

**Keywords:** basic concept of BIM, granary, characteristics of BIM Technology, analysis on BIM application

**Abstract:** BIM is a kind of multidimensional model information technology based on CAD which has been applied in some large projects at home and abroad. The technology of BIM has the characteristics of 3D visualization, virtual design and collaborative design and so on. In this paper, ideas about applying BIM Technology in granary projects have been put forward from the design stage, project implementation stage and the stage of cost control by taking a big diameter underground silo of reinforced concrete for example, simulating the architecture, structure, process of construction and process of grain flowing of underground silos, then creating the model of architecture, dynamic construction model of 4D. The article provides a new approach of applying BIM technology to granary facilities.

**CLC:** TU9 **WM:** A

## Introduction

With the development of information technology and globalization of internet, digital technology as an important tool, has been developed at very fast speed. Information technology has already brought manufacturing and electronics industry huge and innovative changes, the application of which in construction industry is still at very low level. BIM brings brand-new inspiration for the whole building industry, and it is an information-based technical revolution. BIM shall be promoted in the building industry in China as soon as possible [1].

Grain safety is always the major global strategic issue related to national economic development, social harmony and stability, national security and self-reliance. China's various markets become fully in line with international standards. The grain industry is also faced with severe challenges and good opportunities for development from the production, processing, circulation to consumption. The safety of national grain is mainly measured by the safety coefficient for grain storage. As the key equipment of access in the grain circulation link, granary plays an important role in grain safety, which is related to national security and calls for intensive construction.

This paper proposes to apply BIM to the construction of granary. The roles of BIM in the design stage, project implementation stage and the cost control stage of granary construction are analyzed based on the main technical characteristics of BIM, promoting the construction of grain industry standardization.

**Development of BIM at home and abroad**

BIM, namely Building Information Modeling, is based on all the related information of the construction project to establish the building model. The core of BIM is a database of computer three-dimensional model, including various stages throughout the whole project life cycle, design, construction, operations management and so on. All the information is built in the same database from beginning to end.

The idea of BIM dates back to the 1970s. Auto desk company proposed the word Building Information Modeling（BIM）in 2002, and indicated that BIM is the innovation of architectural design.

The United States National BIM Standard gives the following four levels of interpretation for the meaning of BIM:

a. the digital expression for physical and functional properties of a facility (project).

b. a shared knowledge resource.

c. a process of sharing information about the facility and providing reliable basis for the facility from concept beginning for all decisions in the full lifecycle.

d. At different stages of the project, different stakeholders reflect the collaboration between them through inserting in, extracting, updating and modifying information in BIM [2].

The thought of BIM developed rapidly throughout the world after proposed. In 2009, Wisconsin in the United States became the first state requiring large new public works projects in the state using BIM, and Texas Infrastructure Committee also announced that design and construction projects invested by the state should apply the BIM technology. Ministry of Land, Japan announced the implementation of BIM Technology in 2010. Several government agencies in Europe and South Korea have been dedicated to BIM application standards [3].

Many domestic projects have used the BIM technology after the 2008 Olympic Games under the influence abroad [4]. For example, the Hong Kong subway project, Olympic Sports Center Stadium in Hangzhou and Expo Culture Center in Shanghai all adopted BIM in the design, construction and operation phases. Fig. 1 is the working sketch of Expo Culture Center in Shanghai. BIM was listed as state science and technology support program in the 11th Five-Year Plan in 2011. In the information age, the development and application of BIM have become a trend [5].

Fig. 1 The working sketch of Expo Culture Center in Shanghai

**Main technical characteristics of BIM**

BIM mainly has the following characteristics:

**2.1 Three-dimensional visualization**

For designers, large amount of design work is still based on CAD, using flat, vertical and section 2D drawings to express and show the design results. But the information traditional 2D drawings

conveyed is not intuitive, which is hard for people with little knowledge of architecture and structure to understand. The design software based on BIM popularizes the professional and abstract description of two-dimensional buildings and visualizes three-dimensional buildings. So professional designers, owners and other non-professional technicians can judge whether requirements of the project have been met more clearly and efficiently, thus making decisions more accurately [6]. Fig. 2 is the whole building model of the granary. And Fig. 3 is the whole architectural section of the granary.

Fig. 2 The whole building model of the granary

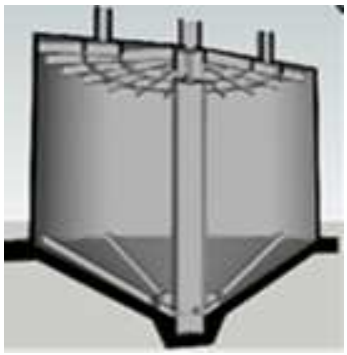

Fig. 3 The whole architectural section of the granary

**2.2 Parametric design**

Parametric design is one of the important ideas of BIM. All the drawings, including 2D and 3D views, reflect the information of the whole project model in design software based on BIM. The component information in BIM is also parameterized, and the designer can modify the components in the model. Parameter changes caused by the moving, deleting and size modifying of the components will be automatically linked to other related components. With the help of these parameterized information, software based on BIM can automatically recognize different components in the model, and get statistics on the number of different components in the model, forming a database to facilitate later modifications. Take the steel as an example, the name, number and size of the required steel can all be generated directly in the BIM model and all the information will always keep consistent with the design [7].

### 2.3 Collaborative design

Current collaborative design is mainly based on CAD, and can not fully achieve the exchange of information between professions. BIM uniformly puts previous scattered and isolated design data and information into the model through a complete 3D model. Various information that different professions need can all be obtained from this model, and data sharing between various professional designs is realized [8].（As shown in Fig. 4）

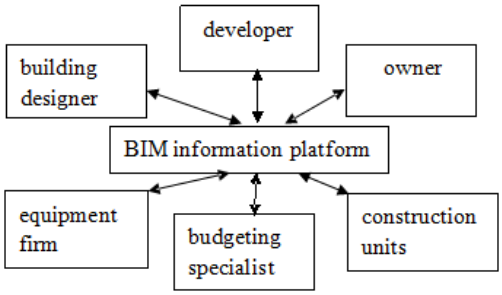

Fig. 4 Various professions sharing BIM information platform

In addition, BIM can not only realize the data connection of different professions, but also check the modified information on project of different professions at any time. This facilitates designers to increase and change the project relevant to their professions timely [9]. Therefore, the concept of using BIM for project collaborative design is realizing different professions draw all dynamic linkage data information for a project model completely utilizing BIM simulation platform.

## The idea of applying BIM in granary projects

### 3.1 Preliminary planning

In the early days of granary construction projects, an argument of stepwise refinement is needed. Collect relevant information and systematically study the overall planning of granary projects according to the rationality of granary medium-term and long-term plans and grain logistics, and make site selection in the preliminary planning stage, preliminarily proposing the development scheme [10].

The main method for preliminary planning based on BIM is: First, create the terrain surface based on exploratory data of the project. Then lead in mass building information of granary projects and geographic data of surrounding environment, intuitively simulating all the information related to the whole granary project. Thereby conveniently design the road, greening, landscape structures and other fields and determine the most reasonable scheme of logistics and transport [11].

### 3.2 The design phase

Designing by BIM is the maturest phase for applying the concept of BIM. Fig.5 lists the application frame in the design phase of BIM. At present the application of BIM is also the most at this stage. The main application value of BIM concept in the design phase is visualization, collaborative design, simulation, optimization and drawing. In traditional design, the designer draws 2D drawings using architectural software like CAD, and it is also the 2D drawings that are finally delivered for audit. However, the traditional 2D drawings are not intuitive, and the information transmission is not clear [12].

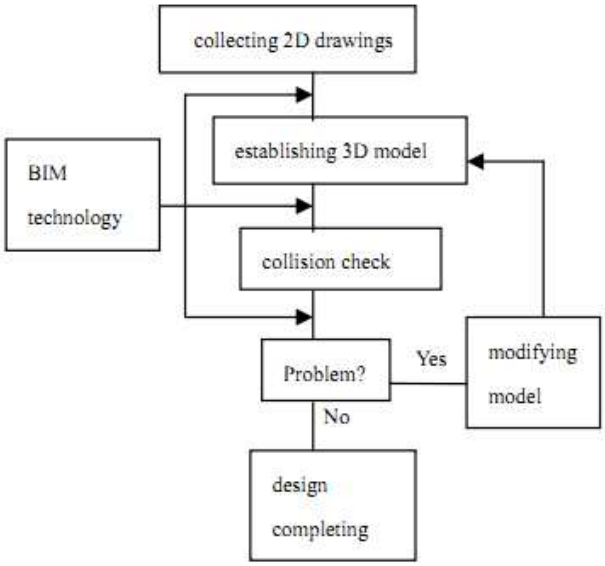

Fig. 5 Application idea in the design phase

Fig.6 and Fig.7 are respectively reinforcement figure of the bottom of an underground granary drawn through CAD and Revit software based on BIM. Comparing Fig.6 and Fig.7, it can be seen obviously that the information conveyed by the software design based on BIM is quite intuitive. And even people with little knowledge of building structure can understand the information contained.

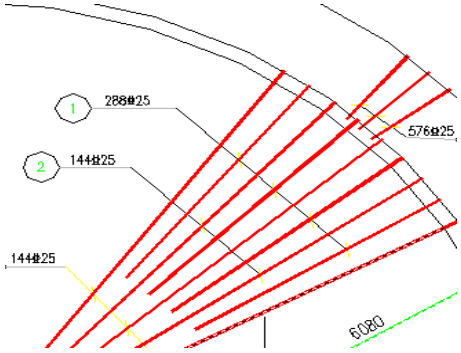

Fig. 6 2D reinforcement figure of the bottom of an underground granary in CAD

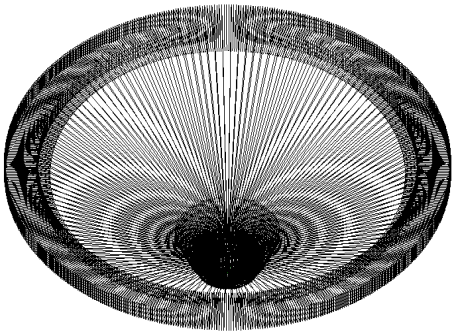

Fig. 7 3D reinforcement figure of the bottom of an underground granary in Revit

In the design phase, a 3D model is created utilizing the modeling software based on the idea of BIM (such as the Revit series software). The 3D model contains all the information of preliminary planning, design, granary construction and structure [13]. The 3D model also provides necessary information for different professions. Different professions can all perform collaborative work on

the 3D model through uniform data format. For example, professions responsible for design and technique can coordinate with each other in the design phase, reducing the possible collision and design changes later.

**3.3 Project implementation stage**

For the construction process, the BIM model established in the design stage and construction planning information, coupled with the construction schedule are simulated through a visualizing process. The feasibility of construction process, schedule and resource allocation is analyzed to constantly improve the construction scheme [14]. Project personnel import construction progress into a 3D model of granary using the software based on BIM technology to simulate the 4D construction process of granary [15]. Fig.8 is the simulation for the construction of granary wall. Fig.9 shows the construction site of granary wall. In this process, the construction personnel can intuitively see the intraday engineering work and schedule from the model through vivid and intuitive process simulation and analyze whether the construction process and the pouring of concrete is reasonable. Once construction problem is found, timely coordination between different professions and modification of construction scheme are required, and simulate again until the optimal construction scheme before construction is obtained so as to ensure the smooth progress of construction and the project quality [16].

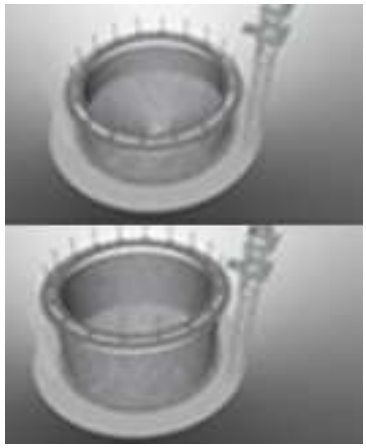

Fig. 8 The simulation for the construction of granary wall

Fig. 9 The construction site of granary wall

### 3.4 The stage of cost control

The 3D building model of granary project is generated using the software based on BIM, and granary schedule is made to form the granary construction schedule. First decompose the granary project objectives with the decomposition model of WBS. Judge and input the expected value of project duration. Create timelines and organize them. Allocate resources to each subproject and specify the relationship and date between these tasks. Then check whether the whole granary bar chart meets the requirements [17]. Finally associate the components of 3D model with schedule table and investment control table, forming the 5D model to intuitively show construction progress.

The "3D + time + cost" multidimensional system is formed after the establishment of relational database on 5D construction resource information model based on BIM, as shown in Fig.10. Let the actual cost data enter into the 5D relational database in time, forming a cost summary statistical table. Build BIM model of the actual cost, adjust and maintain the model on time periodically (month, season) to meet the demands of various cost analysis of the project [18].

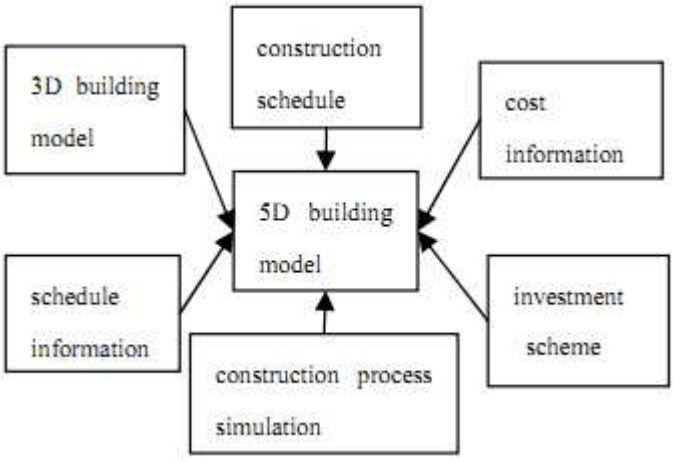

Fig. 10 Multidimensional system flow chart of BIM information

## Conclusion

This paper presents the preliminary idea of applying BIM concept to the granary construction based on the illustration of BIM concept and the developing status of granary. In the preliminary planning stage, prepare feasibility study and make site selection. In the design phase, use the software based on BIM for 3D modeling and conduct detection analysis. In project implementation stage, import construction progress into a 3D model of granary to simulate the 4D construction process of granary. At the stage of cost control, establish the relational database on 5D construction resource information model based on BIM. The application of BIM in granary construction is a long-term process. There are still some problems in unified standard and the software. But BIM has a strong vitality and broad prospect. As BIM is becoming maturer, it will definitely be widely used in granary projects or even the whole construction engineering.

**Funded projects:** Key Projects in the National Science & Technology Pillar Program during the Twelfth Five-year Plan Period (2011BAD03B01); National High Technology Research and Development Program of China (2012AA101608); Henan Higher Education Core of the Youth Instructor Support Program (2010GGJS-083)

# Intelligent and complex monitoring in intelligent buildings

Volkov Andrey, prof., DSc.[1,a], Latyshev Konstantin [2,b],

[1,2] Moscow state university of civil engineering, 129337, Russia, Moscow, Yaroslavskoye shosse, 26

[a]volkov@mgsu.ru, [b] konstantin73@inbox.ru

**Keywords:** complex technics, intelligent building, intelligent monitoring, complex monitoring, building automation systems.

**Abstract.** Conversion of intelligent buildings (IB) is based on a data search, data pattern recognition, data processing and storage of data of projects of intelligent buildings (IB), automated systems (AS) and theirs elements. Author developed a model of a system for data monitoring, allowing for analysis and synthesis of intelligent buildings conversion projects. An intelligent monitoring allows to analyze data both of projects and elements of IB and AS. Complex monitoring allows to synthesize the data used in elements of IB and AS. It is possible to create CAD system and monitoring system for IB and AS conversion using principles described in this article. Vendors of elements for intelligent buildings, vendors of software used in controllers, adapter, etc., can find opportunity to found open community and establish rules for "internet specification" for intelligent elements for AS. Modern state of technology in intelligent search encourages me to say about full-automatic search, assembling and installing of software updates for AS elements of IB. I see that we can use industrial MDM and hypersearch software widely used in big internet vitrines.

Increasing number of buildings obtain automating systems for sustaining proper consumer-valued characteristics. Such buildings become "Intelligent Buildings" (IB). During exploitation, a consequent change of requirements leads to changes in automating systems already created and leads to consequent conversion of IB. At the current state of improvement of internet data searching systems a possibility to delegate functions of technical monitoring and inventory of IB to the IB itself does exist. We suggest that an IB can perform periodic searches in internet for software updates and design changes needed for coming possible IB conversion of it as well. Therefore, it is time to introduce notion "IB Conversion project". An "IB Conversion project" transfers a "conventional IB" to "Converted IB".

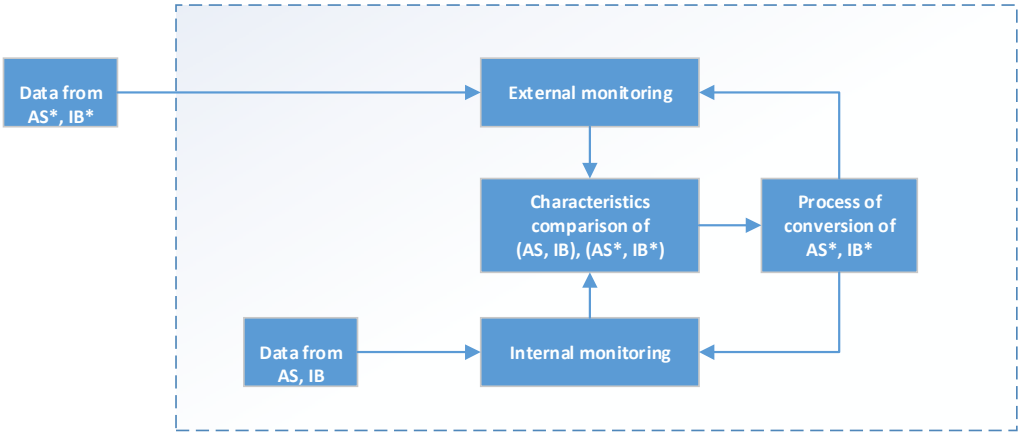

Diagram 1. "Selfconversion of IB"

"Internal monitoring", while providing estimation of running of IB, can be called as "traditional" (conventional). The result of "Internal monitoring" is repair of some out-of-order elements and replacement of some expired elements of (AS, IB).

"External monitoring", while providing estimation of (AS*, IB*), results in "short list" of improvement-promising (AS*, IB*).

Transition from "conventional monitoring" to "Intelligent monitoring" (IM) is necessary in case we need to monitor changes in both internal and external processes. Thus, intelligent monitoring must be multi-criteria and multi-targeted. IM is system union of external monitoring and external one and therefore it provides sufficiently detailed statuses of external environment and inner part of IB to get reliable presentation of IB functioning. In construction industry field (human activity domain) we can define IM as a technology for detecting of system changes of the constructed object to support decision: does an IB meet customer's requirements or does not.

We can regard a system for monitoring of "technology-and-organization safety level of IB functioning" (TOS level of IBF) as example of such IM. The IM functions as follows:

Based on "Consuming resources delivering plan for IB" an average estimation of TOS level can be obtained. This estimation characterizes an organization of IB functioning as whole. Data treatment have be done iteratively to obtain average result of fixed accuracy. This value is input parameter for "IM organization project testing module". TOS level estimation and IM output data are essential for an IB conversion project.

All data obtained in calculations must be stored in a statistics module (statistics warehouse). Data of statistics warehouse (SWH) are used in projects of IB conversion. Gain and treatment of termed data of operative monitoring allows making comparison of measurable indicators, which characterizes functioning of some AS of similar IB in comparable conditions. In frame of schema described we can calculate optimal values of TOS level.

Relations of high-level modules composing Converted IB project creation are drew in the diagram below. Interaction of the modules is transfer of both raw IB monitoring data and accumulated results. To get results that are more accurate we must increase number of data sources for monitoring.

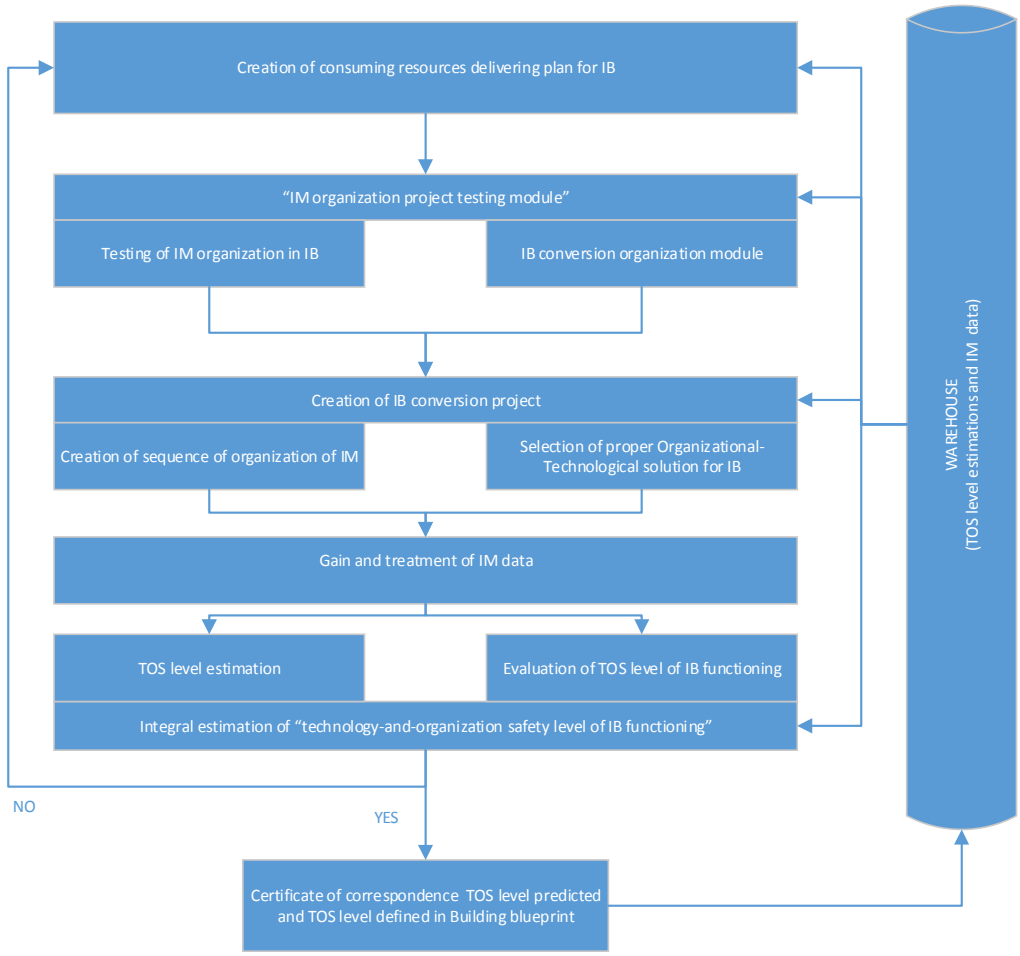

Diagram 2: Monitoring of TOS level of an IB

Multi-criteria data analysis is used to analyze data flow from IM. AS operator can change control parameters of IB. Control parameters of IB can affect control parameters of IM.

Transition from IM to Complex Monitoring (CM), is necessary in case we have “power user-consumer” who exploits and control an upgraded IB. It is clear that modernization of any technical appliance is related to learning of user to use new properties added by modernization. In case of IB which was essentially changed (improved), a consumer not aware of this change, can seriously decrease TOS level of IB functioning. Then an IB and consumer inside it will be in danger. According these reasons, IM must be accomplished by consumer education for he could effectively participate particularly in IM of IB and be engaged in IB modernization in general. “Intellectualization” of Intelligent Building must be complemented by “intellectualization” of a consumer.

According to defined in notion of CM in Constructing, CM is technology of detecting of system changes in process of building improvement towards increasing consumer demands.

According to definition described in this article, CM is complex union of two kinds of monitoring: internal monitoring and external one. CM runs to catch states of both BI and consumer inside it in order to get reliable facts about theirs mutual functioning and select possible IB conversion project.

Conversion of intelligent buildings (IB) is based on a data search, data pattern recognition, data processing and storage of data of projects of intelligent buildings (IB), automated systems (AS) and theirs elements. Specifications of fulfilled projects of IB, statuses of IB and AS before and after successful conversion must constitute a DataBase “IB conversions reference DB”. Another Database “IB conversion elements DB” must contain information about controllers, detectors, etc.

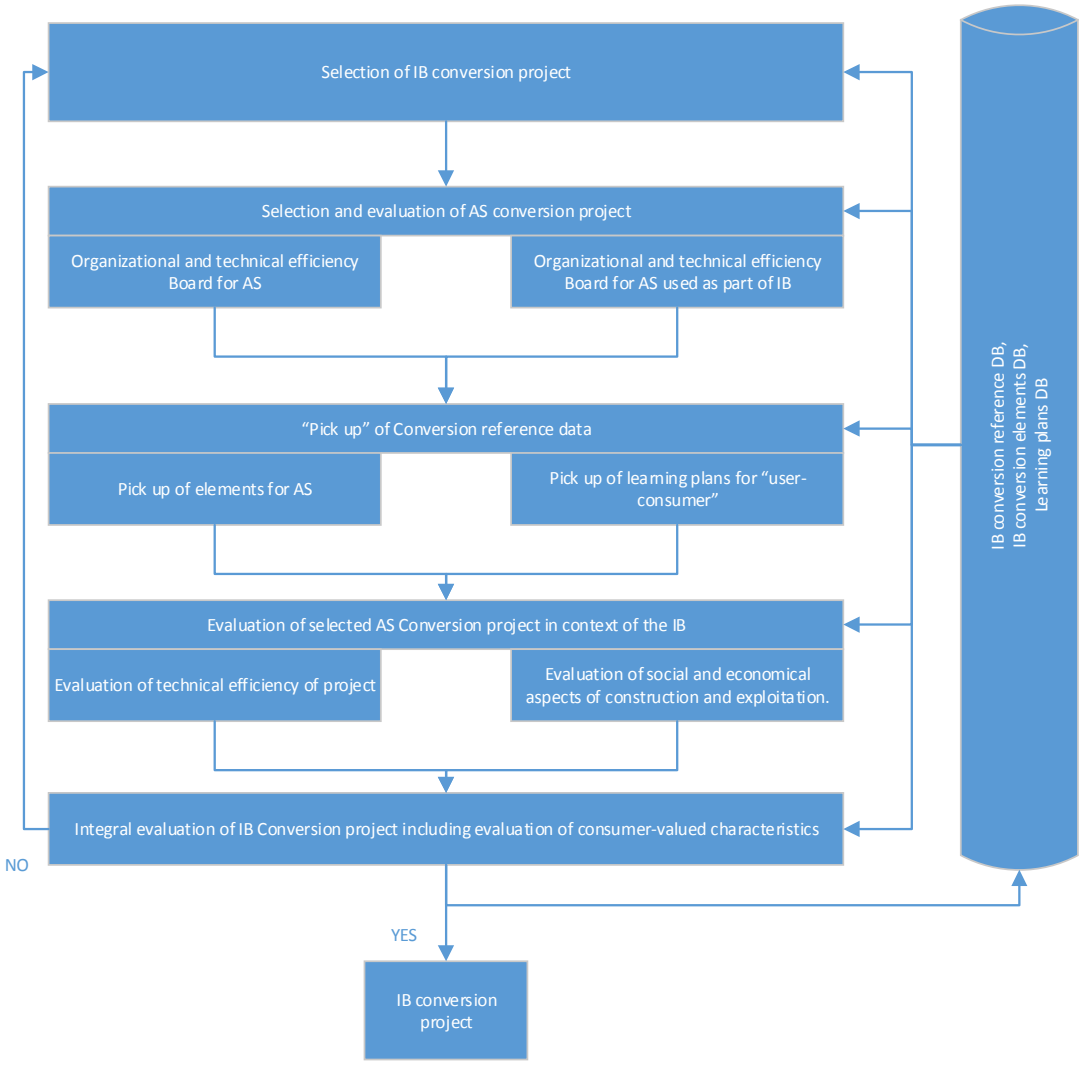

Diagram 3: General IB conversion process.

Next step in general IB conversion process is “pick up” of elements. The main criteria of successful combination is “organizational and technical efficiency”.

Final integral evaluation of IB conversion project must include evaluation of consumer-valued characteristics.

It is possible to create CAD system and monitoring system for IB and AS conversion using principles described in this article. Vendors of elements for intelligent buildings, vendors of software used in controllers, adapter, etc., can find opportunity to found open community and establish rules for “internet specification” for intelligent elements for AS. Modern state of technology in intelligent search encourages me to say about full-automatic search, assembling and installing of software updates for AS elements of IB. We can use industrial MDM and hypersearch software widely used in big internet vitrines.

# Numerical Analysis of Bridge Expansion-Induced Rail Deformation of Ballast Truck

Zhenwei Xiong [1, a], Xinling Liang [1, b], Xianxing Dai [1, c] and Ping Wang [1, d]

[1] Southwest Jiaotong University, Chengdu 610031, China

111 North Second Ring Road, chengdu, china

[a]544470791@qq.com, [b] 993954621@qq.com, [c] 995305844@qq.com, [d]wping@home.swjtu.edu.cn

**Key words:** Ballast truck; Rail deformation; Granular flow; Numerical analysis

**Abstract:** when the ballast track stretch with the bridge, ballast which is near expansion joint will move confusedly. As a result, rail produced vertical deformation. The deformation will affect the running safety and comfortability of train. At present, there are two kinds of treatments which are cover board structure and baffle structure to deal ballast's movement. Aiming at the different modes of stretching when the two kinds of structures and different arrangement condition of bridge plate are applied, the rail-sleeper-ballast discrete element model is developed by the method of two-dimensional granular flow. The relationship between rail deformation and bridge expansion is analyzed on the foundation of the model. Results show as flows: when bridge extends or shortens, rail always produced upwarp deformation. Bridge plate should arrange asymmetrically. Like this, the rail deformation decrease by 40%. And adopting the baffle structure can effectively reduce the influence of bridge expansion in ballast truck.

When ballast track is paved on long-span bridges, in order to prevent the bridge expansion leading ballast to fall from beam end, the measure that beam end are equipped with cover plates is generally made at present. After cover plates are installed, whether the beam ends of long-span bridges are equipped with expansion joint or not, the motion of ballast easily leads to rail deformation. The reasons for this phenomenon are that the changes of temperature lead to the bridge expansion, at that time, the ballast is affected by friction, which makes it moved in the direction of the beam deformation. No matter how the temperature changes, it makes ballast distributed uneven, which will cause all kinds of diseases such as rail vertical irregularity. In order to solve these problems mentioned above, the ballast bed at bridge expansion joint is separated by using the ballast boards on the part of bridges, but the specific effect of this solution lacks theoretical research. Therefore, studying the relation between the bridge expansion and the rail deformation has theoretical and practical value.This paper used PFC2D discrete element software to build particles flow numerical analysis model to study the relation between the bridge expansion and the rail deformation. [1~4]

## The calculation model and basic parameters

### 1.1 Building the model

Building the model of vertical section of the ballast bed under rail, it was divided into four parts. Firstly, Useing wall simulated bridge plate, plate and baffle. Secondly, The disc was used to

simulate ballast articles. Thirdly, that twenty two disk particles with the same size were spliced to simulate the sleepers. The last a series of disk particles were used to simulate the rails. The schematic diagram of model is as follows:

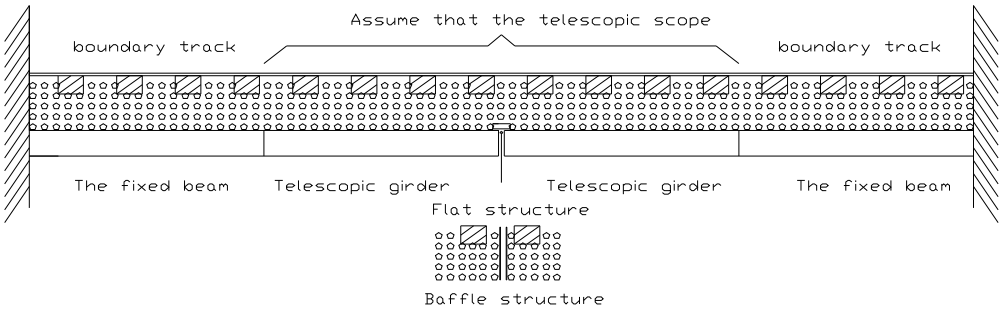

Figure 1.1 Schematic diagram of model

The model was only considered the expansion deformation of the telescopic beam that was 8m from the end of two beams. In conclusion, this paper calculated eight kinds of working conditions in total. For detailed working conditions, see the table below.

Table1.1 Calculation conditions

| Working condition No. | Details |
|---|---|
| 1 | Cover plate structure and beam-slab extend symmetrically |
| 2 | Cover plate structure and beam-slab shrink symmetrically |
| 3 | Cover plate structure and beam-slab extend asymmetrically |
| 4 | Cover plate structure and beam-slab shrink asymmetrically |
| 5 | Baffle structure and beam-slab extend symmetrically |
| 6 | Baffle structure and beam-slab shrink symmetrically |
| 7 | Baffle structure and beam-slab extend asymmetrically |
| 8 | Baffle structure and beam-slab shrink asymmetrically |

**1.2 Parameter selection**

In numerical simulation experiment, the method that the weight of the ballast under the half sleeper and the weight of the half sleeper were integrated into the vertical section under rails was adopted. The thickness of the disk particles is 0.03m in the model. The length of the sleepers is 2.5m. The macroscopic parameters of the rails are showed as follows. The weight of the rails is 60kg/m. The length of the rails is 32.04m, and its sectional area is 77.45cm$^2$. The elasticity modulus of the rails is 2.1e11 Pa, and its shear modulus is 8.1e11Pa. Converting the above parameters to the microscopic parameters of particles is as follows:

（1）The parameter of ballast

The macroscopic density of the particles is 2920kg/m3. Because the ballast under the half sleeper was integrated into the vertical section under rails in the model, the density of the particles needs to be multiplied by an amplification factor. And its value is as below.

$$u = \frac{2.5}{2} \div 0.03 = 41.67 \quad (1)$$

The other parameters can be found by referring to the relevant literature, so the parameter of the ballast particles are as the following table: [7~9]

Table 1.2 Parameters of ballast particles

| Normal stiffness | Shear stiffness | Friction coefficient | Density | Non-stick |
|---|---|---|---|---|
| 1e9N/m | 1e9N/m | 1.0 | 121676.4kg/m$^3$ | / |

（2）The parameter of sleeper

The sleepers are simulated by 22 disk particles whose radii are 0.03m. The density of the concrete is 2500kg/m$^3$. To calculate its integrated density, the density of the sleepers also needs to be multiplied by an amplification factor. The concrete particles are bonded by adopting the method of parallel connection, and for its strength and stiffness, see the table below:

Table 1.3 Parameter of sleeper particle

| Normal stiffness | Shear stiffness | Friction coefficient | Density |
|---|---|---|---|
| 2e9N/m | 2e9N/m | 1.0 | 104175kg/m3 |
| Bonding normal stiffness | Bonding shear stiffness | Bonding normal strength | Bonding shear strength |
| 2e11Pa/m | 2e11Pa/m | 1e20Pa | 1e20Pa |

（3）The parameter of rail

The rails are simulated by 535 disk particles whose radii are 0.03m in the PFC2D model, and the adjacent particles are bonded by adopting the method of parallel connection to bear the effect of shearing force and bending moment. The bonding radii between the particles are 0.03m. When the rails are under stress, in order to ensure that the parallel connection between the particles aren't damaged, the bonding normal strength and the bonding shear strength can be set to a higher value that is 1e20Pa in this paper. There are 16.67 balls within one meter, so the weight of the rails is 3.6kg within the length of the diameter of each ball. The density of the rails can be calculated by the formula below.

$$\rho_g = 3.6 \div (\pi 0.03^2 \times 0.03) = 42454 kg / m^3 \quad (2)$$

When the macroscopic parameters of the model are known, according to the strength equivalent principle, the microcosmic parameters of the particle flow can be confirmed in the PFC2D model. [10] For the final parameters of the rails in the paper, see the table below:

Table 1.4 Parameter of rail particle

| Normal stiffness | Shear stiffness | Friction coefficient | Density |
|---|---|---|---|
| 4.04e11N/m | 4.04e11N/m | 0.15 | 42454kg/m3 |
| Bonding normal stiffness | Bonding shear stiffness | Bonding normal strength | Bonding shear strength |
| 3.5e12Pa/m | 1.35e13Pa/m | 1e20Pa | 1e20Pa |

**The results of the calculation**

According to the above eight kinds of working conditions, the model was calculated in turn to acquire the relation between the movement of the beam-slab and the rail deformation at the center of the beam joint, the relation between the friction force of the beam-slab and its displacement, the relation between the integral rail deformation and the movement of the beam-slab and so on. And then the results were analyzed contrastively.

（1）Using the cover board structure

Working condition 1:

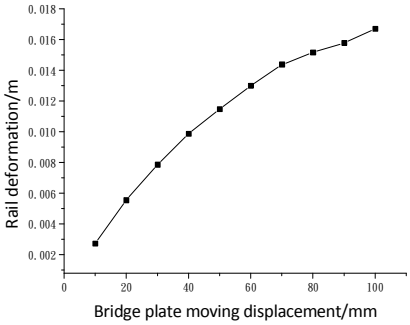

Figure 2.1 The rail deformation1 in the center of beam joints

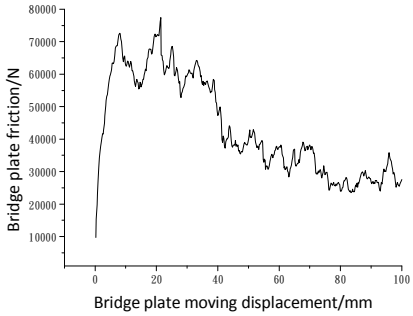

Figure 2.2 The relation 1 between displacement and bridge plate friction

Working condition 2:

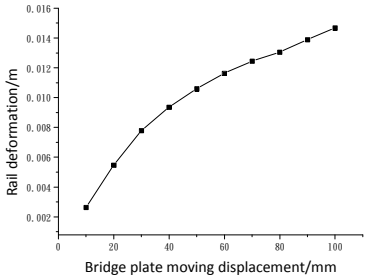

Figure 2.3 The rail deformation 2 in the center of the beam joints

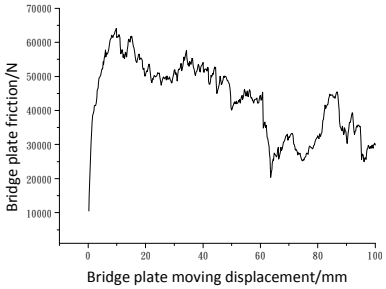

Figure 2.4 The relation 2 between displacement and bridge plate friction

It can be seen that the rail deformation in the center of the beam joints increased gradually with the displacement of the beam-slab by the figure 2.1 and figure 2.3, but the increment decreased gradually, and their corresponding relation was nonlinear relation. The reasons of the rail deformation consisted of two parts. Firstly, the expansion of the bridge plate caused the movement of the ballast, and the ballast rolled to generate dilatancy effect, which caused the rising deformation of the rails within the scope of the whole bridge. The figure 2.2 showed that with the displacement of the beam-slab increasing, the ballast and the beam-slab generated large relative sliding, and the static friction was transformed into the sliding friction or the rolling friction, as generating the shear failure surface, which made the friction decreased gradually. After the movement of the beam-slab reached to 60mm, the friction was stable at 30~40kN, so the increment of the rail deformation decreased. Secondly, when the beam-slab moved because of warming, the ballast at the beam joints was blocked by the ballast on the another beam, and when the beam-slab moved because of cooling, the ballast was blocked by the ballast at the boundary, which leaded the ballast to move up, and increased the deformation of the rails. At the same time, the rail deformation that warming leaded to was slightly greater than the deformation that cooling leaded to by contrasting the figure 2.1 and the figure 2.3.

Working condition 3:

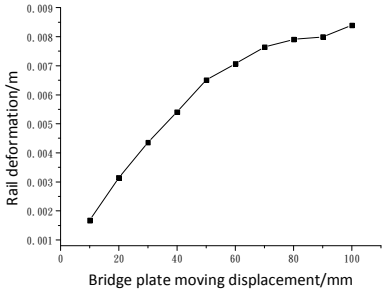

Figure 2.5 The rail deformation 3 in the center of the beam joints

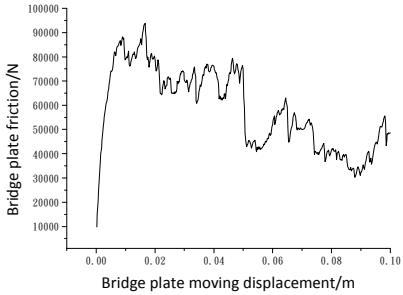

Figure 2.6 The relationship 3 between displacement and bridge plate friction

Working condition 4:

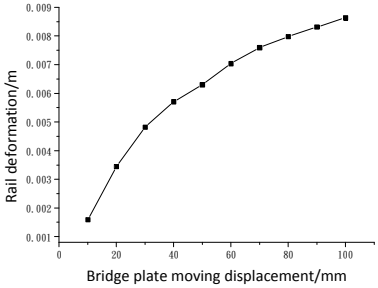

Figure 2.7 The rail deformation 4 in the center of the beam joints

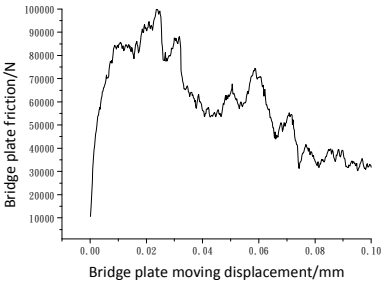

Figure 2.8 The relation 4 between the displacement and bridge plate friction

Analyzing the above four figures knew that the calculation results of the working condition 3 and the working condition 4 were almost the same, and their methods of causing the rail deformation were all due to the movement of the single beam with the fixed ballast blocking. Comparing with the working condition 1 and the working condition 2 knows that the relation between the friction of the beam-slab and the displacement of the beam-slab remained unchanged basically at this moment, and that meant the increasing laws of the rail deformation and the displacement of the beam-slab were the same, but the deformation was about 40% less than theirs. So it should be avoided that two free ends were adjacent, when the bridge was arranged.

（2）Using the baffle structure

The above analysis showed that when the cover board was used, no matter which method of the bridge expansion was used, the rail deformation was great. In order to reduce the influence, the baffle structure was proposed. When the baffle structure was adopted, the calculation results of all kinds of working conditions were as follows.

Working condition 5 and working condition 6:

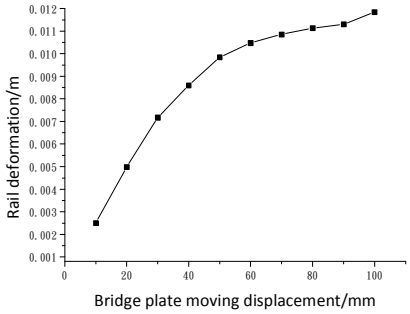

Figure 2.9 The rail deformation 5 in the center of the beam joints

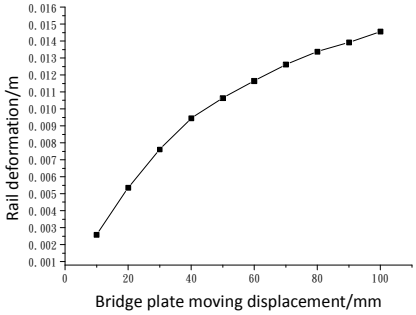

Figure 2.10 The rail deformation 6 in the center of the beam joints

Working condition 7 and working condition 8:

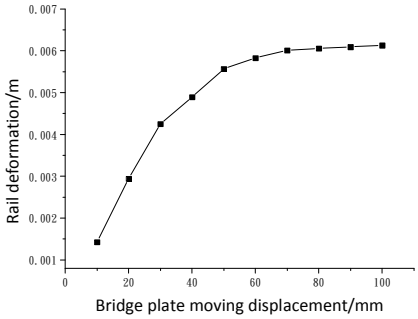

Figure 2.11 The rail deformation 7 in the center of the beam joints

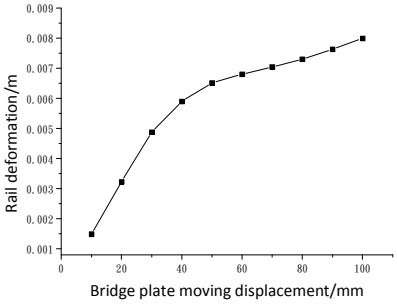

Figure 2.12 The rail deformation 8 in the center of the beam joints

Contrasting the above eight figures knew that when the baffle structure was used at the beam joints, the rail deformation that warming leaded to can be reduced effectively, and the increment of the rail deformation decreased rapidly. When the bridge was extended symmetrically, the increment was stable at 11mm roughly in the end, and when the bridge was extended asymmetrically, the increment was stable at 11mm roughly in the end. However there was little influence on the rail deformation that cooling leaded to. That was because that after the baffle structure was used, as the bridge extended, the front of the ballast at the beam end had little blocking effect, which reduced the rail deformation, and as the bridge shrank, the boundary of the ballast bed still blocked the movement of the ballast, so the rail deformation didn't be decreased.

## Conclusions

（1）No matter whether the bridge extend because of warming or shrank because of cooling, as long as the beam-slab moved, the ballast bed moved under the effect of the friction. The shear dilatancy of the ballast bed occurred at this moment because of the characteristics of the granular mixtures, which made the rails generate the vertical deformation. Because the shear failure surface was generated gradually, the increment of the rail deformation would be smaller and smaller, and if there was no other influence, the value would be stable at 6mm finally.

（2）The bridge should avoid that two adjacent free ends were installed as far as possible, and when the beam joints and beam ends extended and shrank at the same time, the rail deformation would be almost doubled.

（3）When the ballast bed at the expansion joint of the bridge used baffle structure, the effect of blocking in the extension direction of the ballast bed was removed, which made the rail deformation that the extension of the bridge caused decreased greatly, but there was little influence on the rail deformation, as the bridge shrank.

# Real-Time Dynamic Simulation System for Tunnel Construction Based on OpenGL

Qian Li

College of Civil Engineering and Mechanics, Central South University of Forestry and Technology, Changsha 410004, China

semese_li@163.com

**Keywords:** tunnel construction, simulation, real-time system, OpenGL

**Abstract.** Comprehensively using the theories and techniques in connection with the tunnel engineering, geometric modeling, computer graphics, object-oriented method and software engineering, the authors in this paper have made research on the techniques for the three-dimensional solid modeling, tunnel realistic scene graphics rendering and tunnel construction real-time dynamic simulation and on the basis of the research, the authors developed an *openGL*-based real-time dynamic simulation system for tunnel construction. The application of the developed system to a practical tunnel shows that the system has very good vista of application in aspect of the progress control, organization and management of the tunnel construction.

## Introduction

With the development of modern tunnel technology, the complexity of the technical content and construction management of tunnel construction are increasing, tunnel construction project has become a comprehensive, complex production activities. How to make a reasonable construction plans, accurately grasp the construction process, scientific arrange the construction yard, shorten the construction period, reduce costs, improve quality, these have become hot research of tunnel construction management. Meanwhile, *CAD* technology and simulation technology have also been widely used in tunnel engineering.

The currently, simulation of the domestic and international project mainly has focused on two areas: Firstly, the engineering structural design simulation has mainly studied the structure under the load occur deformation, displacement and destruction, which are the main research on abroad. Secondly, in the field of construction engineering, simulating the whole process of the actual construction of the project provide decision making for the construction organization design and project management, which is still in its infancy stage. Systematic studied and applied only in water conservancy and hydropower sector [1, 2, 3], while such study is very rare in the field of railways, highways, municipal, and other high-rise buildings.

## Development tools selection and system Architecture

### System Architecture

Using *Visual C + +* as a language tool and *OpenGL* graphics library to create graphics platform [4,5,6] establish simulation system of real-time dynamic of tunnel construction. The system is mainly to achieve three functions: 1) Building three-dimensional model of the tunnel; 2) Achieving realistic graphics display; 3) Simulating Tunnel construction process.

### Systematic class library structure

On the basis of object-oriented approach design the structure of simulation system of real-time dynamic of the tunnel construction and give definition and implementation of corresponding *Visual C+ +* class. The tunnel as a whole is composed by other simple objects among the tunnel itself， the various components of tunnel hole body, tunnel portal, tunnel subsidiary building and other parts of these components (i.e. lining). These are respectively comprehended as an each object and established

specific object class. Using the inherited and derived idea among object-oriented methods establish a unified base class *CTunnelBase*, in which defined some basic, necessary variables and functions. Some of these functions overloaded in a derived class result in new implementations, such as *OnDraw ( )* function; others will only be used in the implementation of the base class, the derived class because the inheritance relationship with the same implementation, such as *Display ( )* function. Meanwhile, among the base class *CTunnelBase* has defined some related variables of the model such as texture mapping, visibility and time parameters , and are given their settings functions. Member variables and functions of the base class are shown in Table 1.

Table.1 List of member variables and functions of the base class *CTunnelBase*

| *member variables and functions of the base class* | *The main function* |
|---|---|
| BOOL m_bVisible | Boolean variables, used to control the visibility of model |
| CTexture2D* m_pTex | Texture class variables, used to texture mapping of the model |
| CTunnelBase() | The default constructor |
| virtual~CTunnelBase() | The Default destructor |
| BOOL IsVisible() conset | Back visibility model |
| void Set Visible (BOOL bVisible=TRUE) | set visibility model |
| void SetTime(int time=0) | Set the data of the duration |
| int GetTime() const | Back the data of the duration |
| virtual void Display() | Virtual function, used to display the model |
| Virtual void Draw() | Pure virtual function, overloads in a derived class , used to draw the specific model |

Other specific classes of implementation of various components of the tunnel are derived by *CTunnelBase*, these hierarchies of specific class shown in Figure 1.

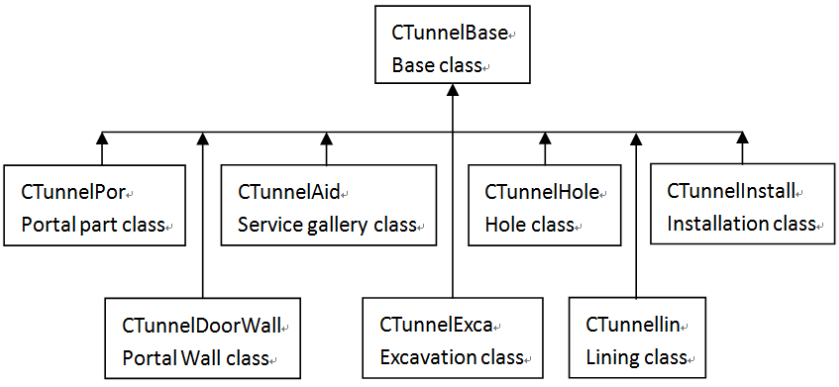

Fig.1 Class hierarchy

**Build three-dimensional model of the tunnel**

*OpenGL* as graphics hardware interface achieve the establishment of three-dimensional model of the tunnel. *OpenGL* is drawing in windows, firstly, it must be rendering graphics scene of *OpenGL*, this system use *wglCreateContext* function to create the rendering scene of *OpenGL* associated with a display device, which is drawing the scene of the model. After the scene is rendered, to use *OpenGL* point, line and polygon draw functions, create complex spatial model. Using the drawing function to generate three-dimensional graphics of each member of the tunnel, then combined into a three-dimensional model of the tunnel overall. In order to achieve realistic graphics rendering must also use lighting and texture mapping in the drawing process of the model. Use of light functions and

texture class *CTexture2D* defined in the view class are realized scene lighting and texture mapping model respectively. Finally, a series of coordinate transformation of the model complete the transformation from model space to paper space, and achieve graphics displayed on the screen window.

## Implementation of Construction Simulation

### Determined Construction period

The system is based on the construction period of all components and considered the construction schedule and flow construction requirements, according to the calculation method of construction organizations to the relevant construction period determine a reasonable period, using irregular flow construction organization get construction period of the whole tunnel. To use the total construction period is obtained by the above steps as the time axis of the simulation process of the system, with 1 day as a simulation step, by time step method to achieve simulation of tunnel construction process. Thus, this system will provide the simulation results of progress status, resource requirements and project completion in any time.

### The realization of animation process

The animation of this system adopts time function of *MFC* to achieve the double buffering technology of *OpenGL*, which can achieve frame memory mapping and exchange both before and after [4,5]. Use *MFC* clock cycle, each cycle add up 1 step to the time axis, and according to the new get time axis length calculated the completed amount of the project, re-instantiated tunnel model object, realized the redrawing of the tunnel model, thus the time axis length can realize smooth animation display of tunnel construction process.

### Interactive and dynamic real-time view

This system gives the model observed the three ways: browsing static and local model, browsing construction status at any time, showing animation throughout the construction process. Through the mouse action response function, the system can use the mouse to drag to achieve angle transformation of the model to observe from different azimuth. Combined with the static browse mode, can achieve all-round browsing tunnel model and each tunnel component.

## Case study

In this paper, to Yangheyan No. 1 tunnel in Jihuai Highway as an example is simulating. Dimension data of the tunnel and construction schedule data input in the system, can be obtained the simulation effect model in each observation mode.

The system is under static observation mode, the project management staff can observe simulation model of various construction process, components and the entire tunnel，which form intuitive understanding to size, location and materials of holes and component of the tunnel and enhance the project management staff to awareness and understanding of the design results on the plane.

Use browsing of construction conditions of simulation system any time, the project management staff can understand in advance project progress at any time, compare with actual project schedule, judge the gap between the actual progress and the plan progress, that is the application of the simulation results, the project management staff achieve the visualization prediction and control of construction process.

Animation can simulate the whole process of project construction, and the production of three-dimensional model of the tunnel changes with time. The animation has different roles in the different stages of the tunnel construction. In the bidding stage, the animation can be used as construction organization design results displayed the owners, which is visual image, and increase the chance of winning. In the construction stage, Demonstration to the related construction personnel deepens their understanding throughout the construction process of the project. In the completion acceptance stage, the animation can clear expression to construction process of the tunnel to

inspection personnel. Through animation, to different people use digital way clear expression of the construction process of the tunnel, overcomes the shortcomings of traditional graphic expression, such as network diagram and Gantt chart, which is not intuitive, difficult to understand.

Compared with the traditional method of network diagram and Gantt chart, three-dimensional model presents project schedule has the characteristics of clear, simple, intuitive and easy to understand. And the application of three-dimensional model, the project management staff can directly obtain the gap between the actual progress and the plan progress, without having to spend a lot of time to study the network chart or bar chart, which is beneficial to improve the efficiency of management of the tunnel construction.

## Summary

This paper comprehensively has studied the key technologies of real-time dynamic simulation of tunnel construction process, established a tunnel model library, developed tunnel modeling and real-time dynamic simulation system, and proved the practicality of the system in tunnel construction management through the practical application. On this basis, future research should focus on the field of building three-dimensional model of the complex tunnel, and simulation optimization of construction schedule, resources and costs.

**Keywords:** three-dimensional reconstruction; epipolar lines constrains; linear searching

**Abstract.** It is important for identifying the correspondences of points in different images. A double epipolar lines approach based on linear searching was proposed to identify the corresponding points in three images. First the component expressions of a given point epipolar equation were derived from the known epipolar model. Then the linear searching method was utilized to solve the problem of no analysis solutions since the numbers of state variables in these expressions were more than those of independent equations. Finally the target was found in looking for the corresponding points. The simulation shows it is effective.

## Introduction

The visual information of intelligent building comes from an abundance of images which are collected by kinds of cameras. Up to now the scenes by these images are all in form of planes. The loss of information cannot be avoided since the real world is three-dimensional. If these planes can be made up to a three-dimensional objection it will approach the real world.

A problem of a three-dimensional objection reconstructing from planes is how to find the corresponding point in different images. Hu presented a matching algorithm for obtaining feature point correspondences across images containing rigid objects undergoing different motions[1]. Papadaki focused on combining photogrammetric and machine vision measurement techniques, through an automated model generation tool based upon dynamic Delaunay triangulation[2]. Jiang put forward a kind of 3D reconstruction method based on affine transformation[3]. Chua attempted to identify (and thereby reject) such mismatched correspondences, within the framework of an affine projection model and the use of three images[4]. The others are in references [5-10]. In this paper an approach of double epipolar lines with linear searching is proposed to meet multiple points matching in different images and has a good result.

## The epipolar lines constraint

**The component expression for a given point.** Suppose the calibration matrix of two cameras is $M_1$ and $M_2$ respective which is in form of

$$M_1 = \begin{bmatrix} m_{111} & m_{112} & m_{113} & m_{114} \\ m_{121} & m_{122} & m_{123} & m_{124} \\ m_{131} & m_{132} & m_{133} & m_{134} \end{bmatrix} = [M_{11} \quad M_{12}] \tag{1}$$

$$M_2 = \begin{bmatrix} m_{211} & m_{212} & m_{213} & m_{214} \\ m_{221} & m_{222} & m_{223} & m_{224} \\ m_{231} & m_{232} & m_{233} & m_{234} \end{bmatrix} = [M_{21} \quad M_{22}] \tag{2}$$

where

$$M_{11}=\begin{bmatrix} m_{111} & m_{112} & m_{113} \\ m_{121} & m_{122} & m_{123} \\ m_{131} & m_{132} & m_{133} \end{bmatrix}, M_{12}=\begin{bmatrix} m_{114} \\ m_{124} \\ m_{134} \end{bmatrix}, M_{21}=\begin{bmatrix} m_{211} & m_{212} & m_{213} \\ m_{221} & m_{222} & m_{223} \\ m_{231} & m_{232} & m_{233} \end{bmatrix}, M_{12}=\begin{bmatrix} m_{214} \\ m_{224} \\ m_{234} \end{bmatrix}$$

So the projection equation of cameras expresses

$$Z_{c1}u_1 = M_1 x_p = (M_{11} \quad M_{12})x_p \tag{3}$$

$$Z_{c2}u_2 = M_2 x_p = (M_{21} \quad M_{22})x_p \tag{4}$$

Where $x_p$ is the homogeneous coordinates of a space point P in the world coordinate system and $x_p = (x_{wp} \quad y_{wp} \quad z_{wp} \quad 1)^T$, in which $x_{wp}, y_{wp}$ and $z_{wp}$ is the x-component, y-component and z-component of $x_p$. $u_1, u_2$ is the homogeneous coordinates of $P_1$ in plane α and $P_2$ in plane β respective. $Z_{c1}$,$Z_{c2}$ is the coordinates of space point P in α-camera coordinate system and in β-camera coordinate system respective.

Definition: An antisymmetric matrix of a three dimensional vector t is defined as in form of

$$[t]_x = \begin{bmatrix} 0 & -t_z & t_y \\ t_x & 0 & -t_x \\ -t_y & t_x & 0 \end{bmatrix} \tag{5}$$

Where $t = (t_x \quad t_y \quad t_z)^T$ and $t_x \quad t_y \quad t_z$ is the x-component, y-component and z-component of t respective.

Let $x_p = (x^T \quad 1)^T$ and $m = M_{22} - M_{21}M_{11}^{-1}M_{12} = [mx1\ mx2\ mx3]^T$, where $x = (x_{wp} \quad y_{wp} \quad z_{wp})^T$, mx1, mx2 and mx3 is the x-component, y-component and z-component of m respective. The epipolar equation (3) and (4) are transformed to equation (6) by eliminating the $Z_{c1}$ and $Z_{c2}$.

$$u_2^T [m]_x M_{21}M_{11}^{-1}u_1 = 0 \tag{6}$$

For a determined $u_1$ let $e = M_{21}M_{11}^{-1}u_1 = [e1 \quad e2 \quad e3]^T$ where e1, e2 and e3 is the x-component, y-component and z-component of e respective. According to the property of antisymmetric matrix there is a component equation for a given point in formula (7) .

$$(mx2 \cdot e3 - mx3 \cdot e2)x + (mx3 \cdot e1 - mx1 \cdot e3)y + (mx1 \cdot e2 - mx2 \cdot e1) \tag{7}$$

**The double epipolar lines approach.** Suppose there are three images denoted as α, β and γ and their calibration matrix is $M_1$, $M_2$ and $M_3$ respective.

Let $m1 = [mx11\ mx12\ mx13]^T = M_{22} - M_{21}M_{11}^{-1}M_{12}, m2 = [mx21\ mx22\ mx23]^T = M_{32} - M_{31}M_{11}^{-1}M_{12}, m3 = [mx31\ mx32\ mx33]^T = M_{32} - M_{31}M_{21}^{-1}M_{22}$.

So the epipolar equations become

$$u_2^T [m1]_x M_{21}M_{11}^{-1}u_1 = 0 \tag{8}$$

$$u_3^T [m2]_x M_{31}M_{11}^{-1}u_1 = 0 \tag{9}$$

$$u_3^T [m3]_x M_{31}M_{21}^{-1}u_2 = 0 \tag{10}$$

Where $u_1$, $u_2$ and $u_3$ is the homogeneous coordinates of $P_1$ in plane α, of $P_2$ in plane β and $P_3$ in plane γ respective and $u_1 = [x_1 \quad y_1 \quad 1]^T, u_2 = [x_2 \quad y_2 \quad 1]^T, u_3 = [x_3 \quad y_3 \quad 1]^T$.

There are six unknown variables in the epipolar equations set (formula (8)-(10)) which has three explicit relations. It is impossible to solve this equation set by analysis. But it is a case in reality that how to find the responding points in the other images while a curtain point in a plane is given. So without lose generality a random point $P_1$ is given in plane α and its responding point $P_2$ in plane β and $P_3$ in plane γ must lie in their epipolar lines.

Let $e1 = M_{21}M_{11}^{-1}u_1 = [e11 \quad e12 \quad e13]^T, e2 = M_{31}M_{11}^{-1}u_1 = [e21 \quad e22 \quad e23]^T, e3 = M_{31}M_{21}^{-1}u_2 = [e31 \quad e32 \quad e33]^T$, so $P_2$ satisfies the epipolar lines of plane β which is in formula (11)

$$(mx12 \cdot e12 - mx13 \cdot e12)x_2 + (mx13 \cdot e11 - mx11 \cdot e13)y_2 + (mx11 \cdot e12 - mx12 \cdot e11) = 0 \quad (11)$$

$P_3$ satisfies the epipolar lines of plane γ which is in formula (12)

$$(mx22 \cdot e22 - mx23 \cdot e22)x_3 + (mx23 \cdot e21 - mx21 \cdot e23)y_3 + (mx21 \cdot e22 - mx22 \cdot e21) = 0 \quad (12)$$

On the other hand both $P_2$ and $P_3$ satisfy formula (10).

The formula (10), (11) and (12) make up the epipolar equations set of a given point which has four variables and three explicit relations. So it also has no analytical solutions. Consider $x_2$ and $y_2$ expresses the same point and has an implicit relation. So do $x_3$ and $y_3$. A searching method is used to find the numerical solution. The problem is transformed to: how to find a point P' in plane γ which satisfies

(1)P" is the crossing point between the epipolar line of P' in plane β and the line determined by formula (11).

(2)The given point $P_1$ is just in the epipolar line of P" in plane α.

So the point P' is the responding point $P_3$ of $P_1$ in plane γ and point P" is the responding point $P_2$ of $P_1$ in plane β.

The epipolar line constraint can reduce the potential responding points of a given point in the other image from two dimensions to one dimension. The searching range of P' in plane γ is narrowed to the epipolar line which is in formula (12).

Object: find P' in the epipolar line of plane γ in order to satisfy $P_1 \epsilon l_1'$, where $P_1$ is the given point in plane α and $l_1'$ is the epipolar line of P" in plane α.

s.t. (1) Epipolar lines constrains. e.g. formula (8), (9) and (10)

(2)Visional windows constrains: e.g. $P'\epsilon\alpha$ in $(x_{\gamma min}, x_{\gamma max})$ and $(y_{\gamma min}, y_{\gamma max})$ and $P''\epsilon\beta$ in $(x_{\beta min}, x_{\beta max})$ and $(y_{\beta min}, y_{\beta max})$ where $x_{\gamma min}, x_{\gamma max}$ is the minimum and the maximum of x coordinate in the visional window of plane γ and $y_{\gamma min}, y_{\gamma max}$ is of y coordinate. $x_{\beta min}, x_{\beta max}$ is the minimum and the maximum of x coordinate in the visional window of plane β and $y_{\beta min}, y_{\beta max}$ is of y coordinate.

**Simulation**

Three cameras are used to take photos for interior scenes from different angles. A point $P_1$ in image α is selected and its responding point $P_2$ in image β and $P_3$ in image γ are determined by the proposed approach and the result is in figure 1 in which the selected point $P_1$ is remarked as notation '*' and the responding points $P_2$ and $P_3$ are remarked as notation 'o'.

Fig.1. The result of a given point $P_1$

The results of $P_1$ at different positions are in table 1 in which the manual data are obtained by data cursor of MATLAB after the responding point is determined by visual method and the automotive

data are obtained by the proposed approach. The absolute errors use Eula distances, e.g. $Err_A = |P_{iA} - P_{iM}|$,(i=1,2,3) and the relative errors use the ratios between the absolute errors and the manual data, e.g. $Err_r = \frac{|P_{iA}-P_{iM}|}{P_{iM}} \times 100\%$.

i

Table 1 The results in different $P_1$

| times | | 1 | 2 | 3 |
|---|---|---|---|---|
| $P_1$ | | 98,148 | 151,308 | 248,206 |
| $P_2$ | Manual data($P_{2M}$) | 100,133.6 | 158,278.1 | 208,353.6 |
| | Automative data($P_{2A}$) | 106,127.78 | 158,282.84 | 215,340.27 |
| | Absolute errors （Err_a） | 0.8568 | 4.129 | 7.7371 |
| | Relative errors（Err_r） | 0.51% | 1.29% | 1.89% |
| $P_3$ | Manual data($P_{2M}$) | 109,137 | 158,282.8 | 219,352.4 |
| | Automation data($P_{2A}$) | 106,121.84 | 158,278.1 | 215,339.53 |
| | Absolute errors （Err_a） | 13.5753 | 4.0948 | 13.0281 |
| | Relative errors（Err_r） | 7.75% | 1.26% | 3.14% |

It is seen from table 1 that the maximum of absolute errors and relative errors happens on $P_3$ and its numbers are 13.5753 and 7.75% while the relative errors of other points are below 5%. It means the proposed approach has high accuracy.

**Keywords:** abaqus embankment, the soft soil foundation, consolidation and settlement

**Abstract** The clay layer finite element analysis model , which is established by using finite element program to simulate the embankment filling , takes the intercoupling between water and clay in drainage consolidation process into full account. The use of the effective stress principle consider the characteristics of clay such as nonlinerity , large deformation and so on ,carry out the plane strain finite element analysis on the clay and solve a series of engineering problems.

## Introduction

The subgrade filling for expressway is a preloading process. Studying and analyzing the development regularity and mechanism of settlement after preloading is of great significance to ensure the expressway security and improve the economic benefit of the expressway.

Some bad engineering geological condition soft clay often occurs in expressway subgrade construction. Because the soft clay has large void ratio, high natural moisture content, low strength, high compressibility, low permeability, long duration of consolidation deformation, etc.. The soft clay roadbed settlement often be calculated by using the method which recommended by the present code of highway soft foundation. The finite element method develops more and more quickly in recent years.

Finite element method can consider the complex boundary conditions, the nonlinear stress-strain relationship of soil, the soil stress history and stress on water and the skeleton of the coupling effect, can consider the interaction of soil and structure, soil anisotropy, also can simulate the scene of loading step by step, can consider the influence which exerted by lateral deformation and the three dimensional seepage on settlement, and can calculate the changes of settlement, horizontal displacement and pore water pressure and effective stress at any time.

This topic research the two kinds of elastic-plastic constitutive model (Mohr - Coulomb model, Cam Clay model), using large-scale finite element software ABAQUS to carry out the numerical simulation of pilot projects, through the contrastive analysis between the measured results and the results of the calculation of two kinds of constitutive model, studies the applicability of the finite element method for soft soil foundation settlement, so as to further guide the practice and guide the construction.

**1.1 Introduction of ABAQUS.** ABAQUS is one of the strongest large general finite element software in the world which contains a wealth of unit model, material model and the analysis process. It can control the very complex problem and simulate highly nonlinear problem. .It has good applicability for the highly nonlinear character of the rock and clay .The excellent analysis and simulation of complex systems reliability of ABAQUS makes the ABAQUS play an important role in a large number of high-tech product research .

**1.2 Cam-clay model.** Cam—Clay model is set up by the British Roscoe and his colleagues at the university of Cambridge .It is a typical clay elastoplastic model, the model adopts the elliptic yield surface and the adaptive flow criterion, and uses the plastomer strain as the hardening parameter .This model is widely accepted and applied in the world.

(1)Yield surface: such as Fig.1 the yield surface function in ABAQUS is slightly different from the expression of soil mechanics by contrast, but the essence is the same. The M in formula is critical state line (CSL), a is an ellipse with CSL line size of the intersection of p.β is the parameters to control the shape of yield surface , in the side of the $t > M_p$ β = 1;In $t < M_p$ side, β cannot equal to 1, affect the yield surface shape.

$$\frac{1}{\beta^2}\left(\frac{p}{a}-1\right)^2+\left(\frac{t}{Ma}\right)^2-1=0$$

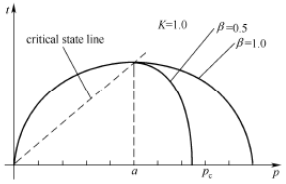

Fig.1 Yield surface

2) The plastic potential surface.Cam Clay model USES the associated flow rule, namely the plastic potential surface is the same as the yield surface

(3) Hardening rule.In ABAQUS, when the β is not equal to 1, $a = p_c / (1 + beta)$, when the β = 1, $a = p_0/2$.

## ABAQUS model

**2.1 Model overview.** Finite element calculation area as shown in figure, along the embankment centerline take 1/2 model as the calculated area, as shown in **Fig. 2**.A 1.8-m-high embankment found on a 4.57-m-thick clay layer, underground water and clay surface are in one place.Below the clay layer bottom is impervious layers, top surface is free to drain.The embankment is constructed in three equal layers, each 0.6 m thick.

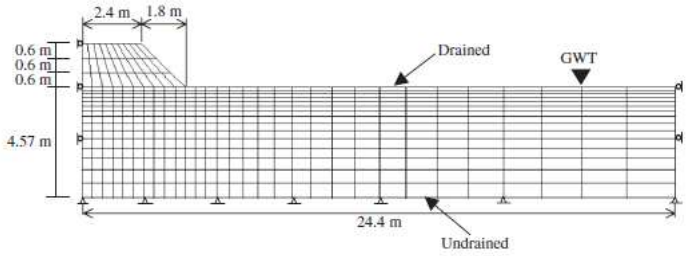

Fig.2 Finite element Discretization of an embankment on a soft foundation

Each embankment layer is constructed in a two-day period, during which consolidation of the clay layer takes place. The total construction time is six days. Assume that the embankment material is linear elastic with ρ = 1923 kg/m3, E = 478 kPa, ν = 0.3, k = 0.1 m/s, and e0 = 1.5. Assume that the clay layer is elastoplastic, obeying the extended Cam clay model (Chapter 2). The Cam clay model parameters for the clay layer are given in Table 1.

Table 1 The Cam clay model parameters for the clay layer

| General | | Plasticity | |
|---|---|---|---|
| ρ (kg/m³) | 1923 | λ | 0.174 |
| $k$ (m/s) | $2.5 \times 10^{-8}$ | Stress ratio, $M$ | 1.5 |
| $\gamma_w$ (kN/m³) | 9.81 | Initial yield surface size = $p_0'/2$ (kPa) | 103 |
| $e_0$ | 0.889 | Wet yield surface size | 1 |
| Elasticity | | Flow stress rate | 1 |
| κ | 0.026 | | |
| $\nu$ | 0.28 | | |

**2.2 The establishment of calculated model.**

1) Definite the model size according to the general situation, establishes the components and use partition function divide the embankment into three layers with the same height. 2) Set up the material and sectional characteristic, set up a Cam - Clay model for clay layer, set up a Mohr - Coulomb model for the embankment layer. 3) Build up member. 4) Define analysis step. Define the type of Geostatic analysis of gravity, this analysis step is used to exert gravity on clay layer .Define three types of soiled analysis step layer1, layer2, layer3, each step time is 2 days, these are used respectively to simulate the load in the process of three layer embankment filling.Define the consolidation step in order to simulate the process of consolidation settlement of clay layer. 5) Define boundary conditions. a. According to survey data, regulate the model with vertical and horizontal seepage , the surface of the foundation is specified for drainage boundary conditions, the bottom of the foundation is specified as undrained boundary. b. Considering the symmetry plane of symmetry subgrade fixed displacement in horizontal direction, it is set to undrained boundary. c. Calculation of right boundary, because the section is far enough away from the roadbed center, it can be set to undrained boundary, and be the fixed horizontal displacement. 6) Define load. 7) Mesh 8) Result

**The analysis of the model calculation results**

**3.1 The analysis of settlement** Figure 3 is the carve of the settlement value in the finite element calculation in the embankment bottom center line changing with time , obviously with the increase of time, settlement increases gradually, and accord well with those of the actual value, the deviation is small.

From the calculated value, the early filling subgrade settlement quantity is big, this because the shape deformation of the saturated soil foundation causes initial sedimentation, and then the settlement stability increases, which reflects the process of the consolidation settlement of foundation. After the stop filling load, along with the soil consolidation gradually completed, the settlement curve changes slow and tends to be stable, this indicates that sedimentation rate became smaller and the subgrade develop in the direction of the stability.

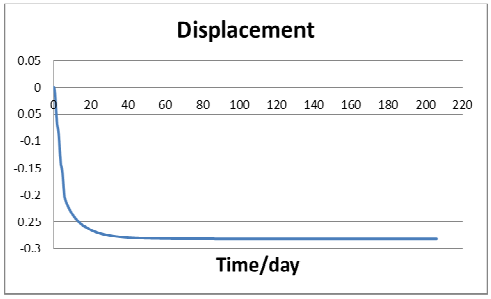

Fig.3 The settlement of embankment

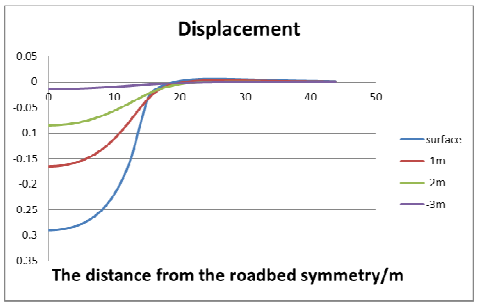

Fig.4 Settlement of different depth

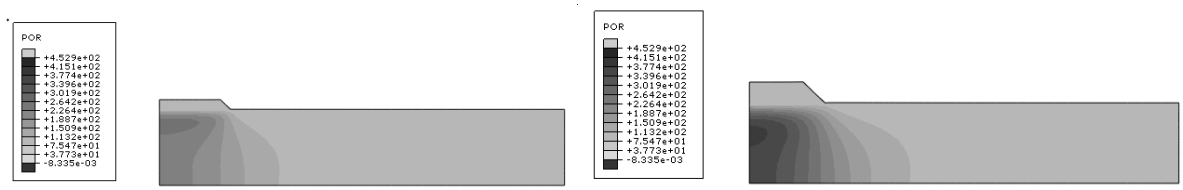
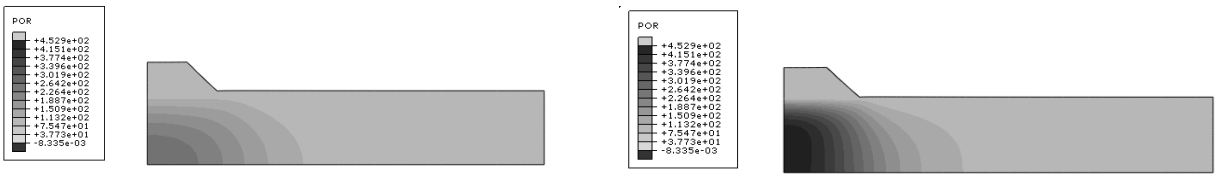
Figure 4 is the different depths of surface settlement curve after the roadbed consolidation settlement. Firstly, the downward settlement of subgrade surface can be seen from the Fig.4 is the largest, but sedimentation increasingly decreases with depth. Secondly, away from the plane of symmetry, the soil has a slightly upward uplift, namely soft soil roadbed settlement within the embankment slope toe is very big, the slope foot outside slightly uplift because of compaction effect.

In the gravity analysis steps , simulate the self-respect through exert physical load on foundation , in analysis steps of layer1 , layer2 and layer3 respectively fill vertical physical load on one, two and three layer , simulate filling process step by step.

**3.2 Analysis of pore pressure.** Fig.5 is the pore pressure of subgrade change over time in 15 days. It can be seen gradually filling 3 layers, pore pressure increasing, after the third layer completed , namely 6 days later, the pore pressure is the maximum in the foundation, especially within the embankment slope toe. But then under the action of vertical force on the load of soil consolidation settlement speeds up, pore water pressure dissipated and the clay tends to be stable.



(A) End of constructionof layer 1 elapsed time, 2 days (B)End of construction of layer 2: elapsed time



(C) End of construction of layer 3: elapsed time, 6 days (D) Elapsed time, 15 days

Fig.5 The change of pore pressure over time

As shown in figure 6, the change carve of super static pore water pressure in the construction of foundation soil reflects the changes of the super static pore water pressure of soil. We can find that pore water pressure increases quickly as a whole is a first and then gradually evaporate, but there are small fluctuations, this is due to the in the interval of two fill time, the pore water pressure drop because of soil consolidation, but the speed of construction is quick, immediately began the next filling, pore pressure rise again. After the full fill construction, subgrade soil under overlying load to consolidation, the pressure drop with the increase of time, until the consolidation becomes stable.

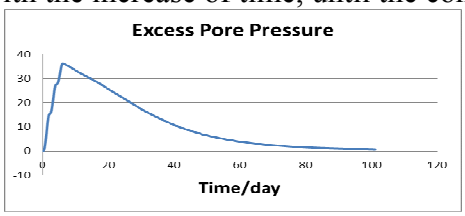


Fig.6 Excess pore water pressure change over time

## Conclusion

(1)Use the finite element program ABAQUS in a successful way, the Mohr - Coulomb model and Cam Clay model are constructed successfully, a numerical simulation is performed for construction of the soft roadbed embankment .Simulate the dynamic subsidence regularity in the process of embankment filling and the settlement size and curve shape, it can guide the construction through calculating feedback.

(2) In the project of embankment fill, there is a great relationship between the super static pore water pressure in soil and the filling rate of construction , the change of pore water pressure in the process of construction is wavy and its change law reflects the process of soft foundation consolidation.

Construction should not be too fast or too quickly in order to prevent the accumulation of excessive pore water pressure which may cause damage in the process of filling subgrade soil.

(3) Clay is a highly nonlinear anisotropic material; we need to carefully and earnestly carry out on-the-spot investigation and measurement, not be superstitious in numerical value and software, reducing the loss of personal property as much as possible

# 3D models as Vista information management governance in the field of development of underground space in cities

V. Belyaev

Moscow State building University RussiaVbelyaev2011@mail.ru

**Keywords:**underground space city, information management, 3D models, 3(D) inventory.

**Abstract.**Consideredespecially the "underground city" in Russia on the example of the three largest cities in approaches to information management governance improvement of spatial development by building 3-d geological and geotechnical models and 3(D) the real estate cadastre.

Due to the fact that underground buildings and facilities (hereinafter CCD) are the objects of capital construction, according to the Russian legislation is regulated within the framework of urban development. The range of these relationships is, in our view, even overly broad to include schema-level interval from the spatial planning of the Russian Federation to the exploitation of a building site. This defines an integrated (sintetičnyj) nature of Russian town-planning and presupposes the existence of effective structures of governance in this area, which for two decades, a return to a market economy has not yet emerged.

"Subterranean town planning" is even more tricky section, because technologically connected not only with traditional land use, but also with the use of underground space (hereinafter-pp). To ensure the effectiveness of the management of this case requires the coordination of a number of federal departments that for Russian conditions it is extremely difficult. For example, for urban planning and design (this is the primary management function) are two different ministries, for land management and cadastre, land use, respectively, two of the Ministry.

Requires the creation of an adequate system of legal, scientific, informational and other types of public administration in this area, which also has not yet been established, for example, legislation in the fields of urban planning and mineral resources requires urgent harmonization, as the most focused solely on mining. However, the special role ofis the information because, as we know, can be thought of as special processing of the information. In urban planning for the information management system of urban development (ISOGD) at municipal level, and it was followed by the Federal spatial planning information system. ISOGD is recreated at the regional level. State Cadastre of real estate is developing in the direction of the technological link to the registry of real property rights. It is planned that all of these systems will be integrated with a single Russian spatial data infrastructure (SDI). However, these systems were essentially a two-dimensional character. At the same time, the PM is, by definition, three-dimensional and the challenges of urban development and protection require the format 3(D). in this connection, in Moscow and some other major cities where the development of PP is the most important issue in pilot mode started work in this direction.

It is essential that in the city of Moscow is tasked to develop integrated automated information system "A geo information space and the works are carried out in the framework of the medium-term public urban programmes" information city "and" town-planning policy. This system within the ideology of SDI is intended, through a common framework to integrate and coordinate the granting of the spatial data contained in information resources of State bodies and organizations of the city of Moscow. Open access to official data already created web application "electronic Atlas. It is also important that the system included data on the territory of the city, presented in three dimensions, covering, including the PM. Tasked with creating a three-dimensional simulation of urban PM and creating three-dimensional digital models of CCD. The main emphasis is on underground engineering communications, and it is only on the territory of the city within the boundaries of the 2011 year.

Meanwhile, in 2012, to Moscow annexed the new territory of almost 1.5 times larger than the old area of the city. In 2014, it should be updated, and as a matter of fact, a new general plan of Moscow. The area of the city was in the engineering-geological terms is well understood, in particular the possibility to build in 2009 year twelve large-scale thematic geological maps. The new territory requires further study, therefore, materials on the master plan for the city to complement the modern 3D modelling estimates. Similar operations recently carried out on European funds, for example, in the Chinese city of Suzhou with the development of a special GIS [1].

Such modelling is proposed as part of the development of GIS "Geology of Moscow», which is to support a specific feature of a 3D model, with level-by-level geological maps in a three-dimensional model rendering fragments of PM [2]. The simulation based on the concept of geological mapping object, which is the subject of a description in the content of the digital model of the geological structure of the territory. With regard to the construction of a 3-d geological model of the PM made the following basic requirements: 1) a description of the geological model elements must correspond to a single stratigraphic scheme; 2) geological boundaries cannot cross, and simulated space must be continuous; 3) build models based on a single, an adapted map database and based on the classification of objects within the model (classifiers, with a list of properties that define the minimal description of objects developed).

Proposed incremental build of several models, based on the fact that specialists in Geotechnics eventually interested in building base of CCD, and watering the soil properties, the presence of dangerous geological processes and phenomena. The geological correlation in the 3D model is solved by applying the method of layer-by-layer geological mapping to a depth of 100 m. in the modeling of geological structure of Stratigraphic sequence and is used in modeling the structure of geological layer sequence indexing locations lithologic strata. Hydrogeological model PP is based on geological 3D model and reflects the spatial location pairs "aquifer SYN.semi-". Engineering geological model PP based on lithological structure that contains data about the properties of rocks and drilling geological processes and phenomena. It is the basis for the creation and implementation of analytical materials and multiple projections (see below).

Digital 3-d geological model of the city and the appropriate software (in this article it is not) allow you to simply and clearly obtain geological information at any point or aspect, by specifying the coordinates. Effective GIS, built on the basis of volume of engineering geological model, should make it possible to assess the risks of interference of the geological environment, built environment, the PLC and the favourableness of the PP for urban design. Methods of evaluating the quality of the test has already been tested in some of the planning works in the central zone of the city of Moscow [2].

At the same time, both for Moscow and other major cities of the country is faced with the task of creating such 3(D)models of both standing and for the entire territory of cities. in tandem with the formation and maintenance of the State Fund for engineering materials and data (GFMiDII) [3] it will give you the opportunity to optimize the many managerial and technical solutions for the development of the territory. that is the direction in the city of St. Petersburg, for example, is devoted to the report of the author of this article, together with e. Lomakin and Alpatov at the international forum «Great Rivers» in May 2014 [4].

Unlike the Moscow program implemented by the Institute of territorial development of three-dimensional models of St. Petersburg until approved. At the same time, in consultation with the Committee for the development of underground space of the National Association of builders has prepared a draft program of work on the creation of different scale models-information base the development of underground space of the BIM technologies. It is extremely important the system approach to the problems of PP on legal, organizational, and information technology (its main provisions discussed below). Emphasis on complexity (both underground and surface objects), as well as on the management aspect of the problem.

The original principle is that planning for the integrated development of PM is only possible after detection of the Geotechnical structure. With detection through the collaboration of full (taking

into account the amount of engineering geological information), multidimensional (3D, 4 d, 5D), multi-scaled (for level of PL for the level region of the city, to the level of a particular object) ongoing integrated geotechnical models (PDGM). BIM models contain descriptions of underground and surface objects (PNS) at all stages of their design, construction and operation.

All construction and calculations are carried out within the framework of specialized technologies. Construction of 3D-PDGM-the under the direction of e. Lomakina information technology maintenance research, design and construction (IT-RPB). Construction of 4 d-PDGM-the software "FEM models» («Georekonstrukcia»), numerically and graphically visualize describing working with geological and PNs. Construction of 5 d-PDGM-in the system and the full multi-dimensional managerial, sociological, and techno-economic models ("system and group projects), vividly describing the interaction of various development projects PP based on subject 4 d-PDGM Description is in terms of operational feasibility assessment of the implications of alternative management and social decision-making.

Using a multidimensional model allows decision-makers to fully document the information and be accompanied by implementation of urban development (GR), planning (PL) and design (ETC). By continually bringing new data that gives the opportunity to create an evolving information environment that enables you to solve problems related to the development and protection of the PP. So on the basis of 3D-PDGM can be the unification of engineering-geological surveys, spatial "coupling" unified information, integration of different scale spatial models. The model 4 d format give Visual spatial images that describe the conditions of alternative design and planning decisions, assessing the completeness and accuracy of the engineering-geological information. This is important not only for the prospector and designer, but for example and for expert. The alkaloids models provide a comprehensive subject, social and technical-economic assessment of the conditions of implementation of specific planning and management decisions on the basis of an analysis of the effectiveness of the terms of use.

Investment attractiveness of the models is the possibility of multiple, multidimensional use. Models are created on the basis of a unified and coherent in the stock information and the results of ongoing surveys (in this respect is crucial, as already indicated, integration with GFMiDII). For unification as well as a system of classifiers in Moscow Engineering-geological conditions of Saint Petersburg. In order to implement the project in the framework of public private partnership filed an application for registration of the specialized private organization as a centre of interaction with the Government of St.-Petersburg, exploration, design, and building community.

One promising application of models would be to create 3(D)the real estate cadastre. Despite this region belongs to the land and property relations, it is closely related to urban development specifically in the context of a single investment and management of the construction cycle and the whole life cycle of the CCD in particular.

When urban development: it's not just about education "flat land", but also on the formation of large immovable objects: hidden underground subsoil areas of EI and State registered in the cadastre and registration of rights deals with the CCD. Meanwhile in Russia, as in other countries the cadastre and registration system is two-dimensional. The problem is the lack of an adequate display underground facilities. For the purposes of the cadastral unit CCD on the land is defined as the set of edges of parts on the surface of the Earth. There are difficulties with the mapping and description of the CCD, in particular non-linear objects. They are often held under several land plots cross each other at different depths. Legal and physical link CCD with an appropriate plot of land is not always obvious, so the principle of accounting and registration of real estate accounting and registration of rights to the land doesn't always work. In market terms, it does not give sufficient guarantees to owners, is less secure, is controversial and the courts (usually the PLC are the most complex, expensive and often dangerous objects with significant service life).

Respond to this call, the national cadastre and registration rights. Where there are intermediate, tradeoffs 2, 5 d inventory (Netherlands, Spain, Canada, Australia, Belarus). However, the main trend is to build three-dimensional inventories that maximally meet the specifics of Government underground construction, allowing the record rights and limitations on CCD [5]. The difficulty is

that the main source of information about the 3D objects are land registration documents, and only through the cadastral map you can view and check vertical borders and giving juridical force 3D parcellam has not yet been achieved. However, in some countries, conducted research in this area, improved legislation and standards.

Objective prerequisites for the transition to the model of the three-dimensional cadastre formed and in the cities of Russia in 2010-2012, the inventory Agency and Rosregister registration of land and cartography of the Netherlands took place on the territory of the city of Nizhny Novgorod, a joint pilot project for the establishment of model 3(D)real estate cadastre, including with respect to several types of CCDS. The Russian Government has set the task of creating, legislative and organizational-technological fix to 2018, the possibility of amending the State real estate cadastre of real estate object information to the description in the 3D space [6].

## Summary

The experience of the three largest Russian cities shows that the use of 3D models is a key area for improving information management governance in the field of development of underground space.

**Keywords***:* CAD, Automations, Building Management Systems, ACS.

**Abstract.**The complexity of modern design objects, especially automatic control systems (ACS), the constant tightening of requirements for projects, the very high price of erroneous design decisions are inconsistent with the traditional tools of technology and design. A way out is to develop and implement a new set of tools - tools of the designer - computer-aided design.

In developing the ACS engineering systems of buildings and structures we should take into account the real (non-idealized) physical characteristics and the nature of its elements, their sources of energy, forms of energy conversion methods and signals inclusions control actions. In the design and manufacturing techniques become essential assembly operation and harmonization of various design and technological forms of individual devices. Designing control systems associated with the development, both the hardware and algorithmic and software that greatly expands the range of issues addressed by designers compared with the recent past. ACS trials are becoming a major design stage as never succeed in developing concepts to take into account all the special design, technological and physical properties of individual devices in ACS.

Complex dynamics control processes ACS associated with number of reasons:

- heterogeneity of devices and components included in the ACS;
- continuous dynamic process of their functioning;
- multicriteriality conditions of use and performance , with many contradictory criteria (accuracy and stability, reliability and weight and size);
- uncertainty of set parameters and disturbing, might be determined by the presence of not only external but also internal "noise" , the time parameters of devices ACS;
- availability of multidimensional control systems.

Unlike engineering systems themselves, which consist of individual devices, ACS is a system of devices working in the mode of control of these systems engineering. At the same time become very important such project procedures as stability analysis, quality and accuracy of the ACS, the synthesis of regulators, the construction of mathematical models of objects and control of individual devices regulators, mathematical modeling, assembly and docking of individual structural units.

ACS design process engineering systems of buildings and structures can be represented as a system design that unites designers, designers tools, measuring instruments, mathematical models, computer, communications with organizations subcontractors, chief designer and experience aimed at issue satisfies the various requirements of technical documentation for production engineering of ACS systems of buildings and structures under given constraints.

The quality of any project ACS engineering systems of buildings and structures can be expressed as:

$$W = F\left[f_1(z), f_2(z), ..., f_n(z)\right],\ z = \{z_i\}, i = \overline{1,n}. \qquad (1)$$

where $z$ - multitude of design decisions taken in the implementation of project procedures $\Pi = \{\Pi_i\}, i = \overline{1,N}$ ; $F$ - functional quality of the project; $f_1, f_2, ..., f_n$ - functions representing the pro-

ject's quality criteria, which take specific numerical values depending on the values of the argument $z$.

Functions $f_1, f_2, ..., f_n$ and functional $F$ will be specific numerical values after substituting for variable specific design solutions $z^*$ (structures by ACS-tion scheme and the composition of its devices, making the electrical and wiring diagrams and constructive process). The physical meaning of the functions $f_1, f_2, ..., f_n$ can be read $f_1$ - labor contribution on the project, $f_2$ - the project time, $f_3$ - difference between the results from the requirements of the terms of reference of the project and so on.

Total cost of project procedures for creating ACS engineering systems of buildings and structures can be represented as:

$$W = F\left(\sum_{i=1}^{n} a_i f_i\right) \tag{2}$$

where $a_1$ - the price of standard-hour of project procedure $\Pi_i$; $f_i$ - planned complexity $\Pi_i$.

When designing the ACS engineering systems of buildings and structures, we should also take into account the various constraints which can be given as:

$$G(g_1, g_2, ..., g_m) \le G_O \tag{3}$$

where $g_1$ - allowable cost of the project, $g_2$ - the resources of project department, $g_3$ - allowed time of the design, quantity and composition of components and so on. Also, in addition to controlled, controllable factors, which include active agents, we should consider uncontrollable factors. To uncontrollable factors may be included various life situations as short supply of components and materials to the object, absenteeism and tardiness of the project staff, fundamentally unexpected results when tested beforehand unknown tactics of customers and designers in coordination of the terms of reference and more. These uncontrollable factors can be expressed in the following set:

$$\delta = \{\delta_k\}, k = \overline{1, M} \tag{4}$$

Accordingly o this, the ACS system design of engineering systems of buildings and structures can be represented by a model:

$$\begin{cases} W = F[f_1(z), f_2(z), ..., f_n(z)], \\ G[g_1(z), g_2(z), ..., g_m(z)] \le G_O, \\ L\{\Pi_i[t, z_{i-1}(t-\tau_1), \delta(t-\tau_2)]\}, i = \overline{1, N}, \end{cases} \tag{5}$$

where $L$ - the choice operator of both the design procedures $\Pi_i$ and their execution sequence (linear sequence, parallel execution, joint implementation, and so on); $\tau_1, \tau_2$ - the inevitable time-lag necessary to obtain information on the previous design decision $z_{i-1}$ and uncertain factors $\delta$ on the processing of information in the design procedure $\Pi_i$ and making design decisions $z_i$.

System of expressions (5) shows mathematically aspiration designed system to increase its performance criterion in the presence of interference and restrictions.

This article was carried out as part of scholarship of the President of the Russian Federation.

**Keywords:** Building Information Modeling; the reinforcement information expressions; three-dimensional design

**Abstract.** BIM (Building Information Modeling) as a new idea and technology, has been attached more and more attention in architecture and BIM is gradually changing the model of traditional 2D products images and decentralized design of construction process. This paper expounds the method of the integration of BIM and the reinforcement information expressions and its obstacles in the process of realization through the introduction of BIT technology.

## Introduction

As the pillar industry of national economy, construction industry has always faced with problems such as low efficiency, severe resource waste, how to conduct energy conservation and emissions reduction. The improvement of the utilization rate of resources has always been a problem urgently to be solved in the construction industry. Research shows that BIM technology can effectively speed up the progress of project schedule by 10% and reduce rework by around 60%.Therefore, the application of BIM technology is the development trend in the field of construction. With the rapid development of our country's economy, all kinds of complex planar structure of the high-rise buildings sprang up, mand the use of the shop drawing has been beyond the traditional reinforcement information expressions, the development of BIM technology in domestic is in full swing.

## Whate is BIM

What is BIM? The American standard (2006) defined it as follows: "A Building Information Model(BIM) is a digital representation of physical and function characteristics of a facility. As such it serves as a characteristics of a facility. As such it serves as a shared knowledge resource for information about a facility forming a reliable basis for decisions during its life-cycle from inception onward. "that is to say, the Building Information Modeling (BIM), is a physical and functional characteristics of the construction of digital expression, for construction in the full life cycle to provide reliable decision and the reliable information resource sharing platform. It is a data model that based on 3D technology and integrated with various kinds of relevant information in construction project, which is a comprehensive expression of the relevant information about the project. The idea was first proposed by the Autodesk company, whose core is the construction entity of virtual simulation and building highly integrated information. So as to realize the industry of information sharing and collaborative work, which greatly improve the work efficiency and work quality, save resources and reduce energy consumption. BIM modeling is based on construction engineering, which can be used for the whole life cycle of construction projects, including design, construction, completion acceptance, sales, fire safety and so on(as shown in figure 1). The use of BIM technology in the whole life cycle of construction projects, its advantage is mainly embodied in the following several parts:

① The architect can use BIM related software such as Revit 3D modeling to express their design ideas, visualize the preliminary design, and benefit to the parties to communicate and work together.

② In deepening the design stage, the use of visualization can detect collisions, find design errors and omissions conveniencely, so that solve problems before construction.

③ In the construction stage, through integratting mass data of the construction, make use of the basis using of BIM technology to realizing calculation, manage, and sharing information.Such as calculation of quantities, steel sample, tall shuttering lookup, material usage analysis, and other functions. It can quickly find and solve the technical problem may arise, so as to shorten the construction period, save material, reduce the project cost.

④ After completion, by using the as-built BIM model, the project owner can make engineering reform, operation and maintenance effectively.It can avoid defects that the traditional paper-based as-built drawings is not easy to save and unviewable.

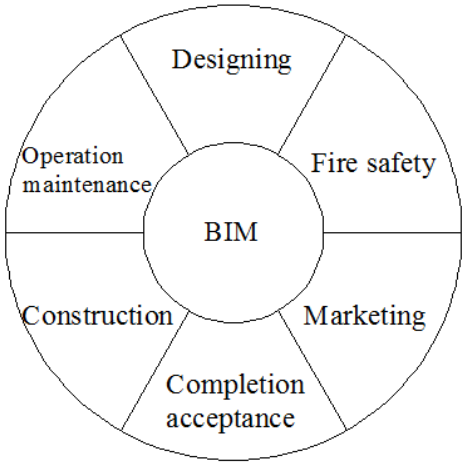

**Fig.1 The application of BIM**.

**The three-dimensional structure design based on BIM**

The three-dimensional model of BIM information not only the geometry information describing building components and status information and its properties, but also includes non-component object state information. All information is closely linked by a certain logic relationship. At various stages of design and even the whole process of project life cycle is around the three-dimensional model of BIM, what's more, it also can constantly modify and join the present stage of information, so that the BIM model can be constantly enriched and perfected.

There is a bidirectional data exchange in BIM model. BIM provides an information sharing and exchanging platform, improving the working efficiency for project participants. For example, when BIM was used to modify the error for three-dimensional design, any operation, together with other relevant information in the process of change can be synchronously processed, which greatly improves the work efficiency, and this is the advantage of three-dimensional BIM design compared with the traditional 2D reinforcement information expressions mapping.

BIM can also be used for simulating the project, making it visualizated. projects will be visualized in the three-dimensional form, such as beam, slab, column and other component connection form of the space. Each structure of the components (reinforcement, space, shape, etc.) can be found in the BIM model by real time, which make it easier for project participants to understand the design intent of the drawings. Construction units can also visually predict construction schedule, safety, and construction plan of the deficiencies, so as to adjust in time. The owner can quickly grasp the latest situations and project information of various project participants through the use of BIM projects.

**The integration of the reinforcement information expressions and BIM**

" the reinforcement information expressions " is the method that make building structure construction drawing expression into a complete set of drawings in the form of graphic design of whole specification, also known as the planar mapping rules of integral representation. It makes the structural working drawing have the standarded plane whole design expression, implementing the national unity of structural working drawing, ensuring the quality of the design and construction.

At present, the reinforcement information expressions still is a common way of construction drawing in building industry of China. Its uniformity and standardization are irreplaceable by other two-dimensional graphics mode. the reinforcement information expressions, with the 2D form, separates graphic symbols of building information with its data, expressing the properties of components succinctly to constitute the structure construction drawing in the form of structure plane as a whole at last. All the information of components are fixed in the whole drawing, making it very difficult to change and update. Lots and lots of work need to be modified one by one by hand, and easily lead to information leakage, error and deviation between the structural drawings. In the design process, the collision check of various professional drawings examination is hard to proceed, thus reducing the efficiency of work. Secondly, the reinforcement information expressions is 2D drawings, which can only presents the surface concrete form of structure layers. When face of complicated structure form, it is not easy to understand and grasp by the parties because its expressing ability is limited,. The Germany pavilion of Shanghai world expo, for example, have complex architectural modeling and spatial relationships, enormous dimension and tight construction schedule. The traditional reinforcement information expressions is obviously unable to meet the requirements. Therefore, the three-dimensional structure drawing of BIM technology is the development trend of current construction drawing.

The traditional reinforcement information expressions goes against the development requirements of BIM, but it is undesirable to completely abandon it accordingly. Thought the reinforcement information expressions is unable to keep up with the development of construction industry era tide, it can not be fully replaced as for all because it is widely recognized by industry as well as unified use according to the development situation of domestic construction industry.

Now many foreign series of BIM software development companies are focusing on "information processing" of the reinforcement information expressions, such as Autodesk Revit software company of American, Bentley MicroStation software company in the United States, Graphsoft ArchiCAD series, etc.

“Autodesk Revit Constructure” is widely used in structure design software of BIM. It is the structural design software based on the three-dimensional model, which can achieve the real time linkage model to modify, provide judge structures connected relations tool, and significantly improve the efficiency of design work. The company of Autodesk has taken the lead in developping the program integrated the reinforcement information expressions and BIM effectively, and includes reinforced symbol of "Chinese localization pack" word stock. The reinforcement information expressions with the fusion of BIM also obtained the further solution. Figure 2 shows the software of Revit Constructure interface after the reinforcement information expressions of flat structure plan (as shown in figure 2) and perspective three-dimensional bar graph (as shown in figure 3).

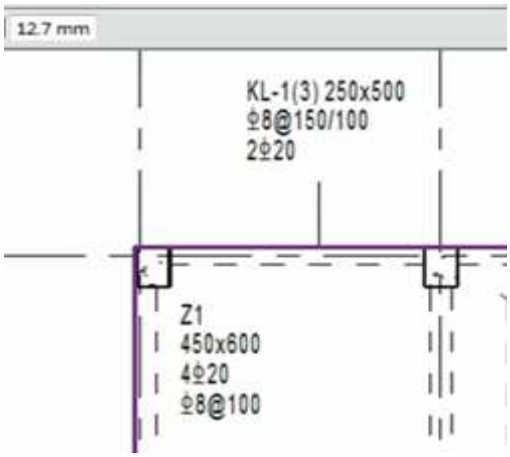

**Fig.2 The reinforcement information reinforced .**

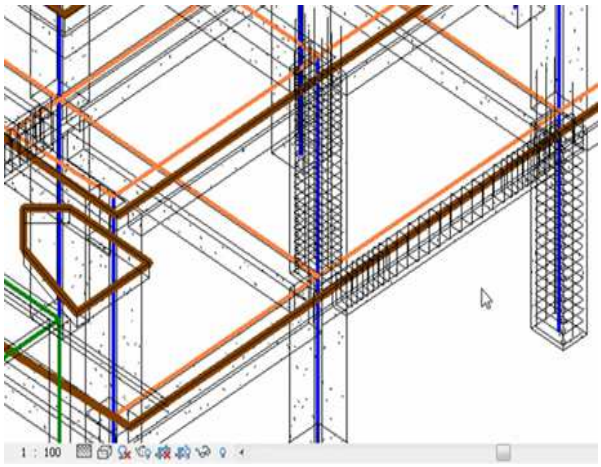

**Fig.3 The three-dimensional viewgraph of expressions expressed by Revit Constructure.**

**Problems of the integration of the reinforcement information expressions and BIM**

At present BIM standard in China is still in the stage of formulation. Compared with foreign architectural industry, China's existing system is not unified and lack of complete BIM standards (CBIMS).To make the reinforcement information expressions perfectly integrate into BIM, improved BIM standards should be developed, making contribute to the traditional reinforcement information expressions to the trend of development to realize the sustainable design.

In the future BIM application practice, more normative regulations should be put forward to divide the responsibility of various project participants. The issues such as design responsibility of each stage, the model information which need to be improved and how much information should have improved are clearly represented. Which kinds of form and the model of the maturity of the interactive data between the parties also need to be clearly defined.

**Conclusion**

The emergence of BIM can be referred to as the second revolution of the construction industry. Because of the unified BIM model, visualization, informatization, collaborative design and construction will be possible. In this new mode, the transition of the traditional reinforcement information expressions to the BIM model is inevitable trend. Therefore, absorbing advantages of the reinforcement information expressions and its information and using computer to digital processing method of standard components will adapt the graphic symbols and data correlation to meet the requirement of BIM viable path. Engineering software developers at home and abroad have tried this method and achieved great effect. But the promotion and application of BIM can not be achieved overnight. The constant improvement of BIM standards in China need to be promoted. At the same time, the joint efforts of the construction industry is also necessary.
