Dental caries ranks as the nation's most widespread public health problem: an estimated 95 percent of the population have decayed, missing, or filled teeth. These dental problems can quickly lead to a multitude of nutrition problems by interfering with a person's ability to chew and eat a wide variety of foods. Where fluoride is lacking, dental decay is common.

Drinking water is usually the best source of fluoride, and 75 percent of the US population served by community water systems receives optimal levels of fluoride (see Figure 13-12).[45] Fluoridation of drinking water (to raise the concentration to 0.7 milligram per liter of water) protects against dental caries and supports oral health.[46] By fluoridating the drinking water, a community offers its residents, particularly the children, a safe, economical, practical, and effective way to defend against dental caries. Most bottled waters lack fluoride.

**Fluoride Toxicity** Too much fluoride can damage the teeth, causing **fluorosis.**[47] For this reason, a UL has been established. In mild cases, the teeth develop small white flecks; in severe cases, the enamel becomes pitted and permanently stained (as shown in Figure 13-13). Fluorosis occurs only during tooth development and cannot be reversed, making its prevention during the first 3 years of life a high priority.[48] To limit fluoride ingestion, take care not to swallow fluoride-containing dental products such as toothpaste and mouthwash and use fluoride supplements only as prescribed by a physician.

**Fluoride Recommendations and Sources** As mentioned earlier, much of the US population has access to water with an optimal fluoride concentration, which typically delivers about 1 milligram per person per day. Fish and most teas contain appreciable amounts of natural fluoride.

### › REVIEW IT

Fluoride makes teeth stronger and more resistant to decay. Fluoridation of public water supplies can significantly reduce the incidence of dental caries, but excess fluoride during tooth development can cause fluorosis—discolored and pitted tooth enamel. The accompanying table provides a summary of fluoride.

**Fluoride**

| AI | Significant Sources |
|---|---|
| Men: 4 mg/day<br>Women: 3 mg/day | Drinking water (if fluoride containing or fluoridated), tea, seafood |
| **UL** | **Deficiency Symptoms** |
| Adults: 10 mg/day | Susceptibility to tooth decay |
| **Chief Functions in the Body** | **Toxicity Symptoms** |
| Strengthens teeth; helps to make teeth resistant to decay | Fluorosis (pitting and discoloration of teeth) |

## Chromium

**Chromium** is an essential mineral that participates in carbohydrate and lipid metabolism. Like iron, chromium assumes different charges. In chromium, the $Cr^{+++}$ ion is the most stable and most commonly found in foods.

**Chromium Roles in the Body** Chromium helps maintain glucose homeostasis by enhancing the activity of the hormone insulin.* When chromium is lacking, a diabetes-like condition may develop, with elevated blood glucose and impaired

*Small organic compounds that enhance insulin's actions are called *glucose tolerance factors (GTF).* Some glucose tolerance factors contain chromium.

**fluorapatite** (floor-APP-uh-tite): the stabilized form of tooth crystal, in which fluoride has replaced the hydroxyl groups of hydroxyapatite.

**fluorosis** (floor-OH-sis): discoloration and pitting of tooth enamel caused by excess fluoride during tooth development.

**chromium** (KRO-mee-um): an essential trace mineral that enhances the activity of insulin.

glucose tolerance, insulin response, and glucagon response. Some research suggests that chromium supplements lower blood glucose or improve insulin responses in type 2 diabetes, but findings have not been consistent.[49]

**Chromium Recommendations and Sources** Chromium is present in a variety of foods. The best sources are unrefined foods, particularly liver, brewer's yeast, and whole grains. The more refined foods people eat, the less chromium they ingest.

**Chromium Supplements** Supplement advertisements have succeeded in convincing consumers that they can lose fat and build muscle by taking chromium picolinate. Whether chromium supplements (either picolinate or plain) reduce body fat or improve muscle strength remains controversial. (Highlight 14 discusses chromium picolinate and other supplements athletes use in the hopes of improving their performance.)

### › REVIEW IT

Chromium enhances insulin's action. A deficiency can impair glucose homeostasis. Chromium is widely available in unrefined foods including brewer's yeast, whole grains, and liver. The accompanying table provides a summary of chromium.

#### Chromium

| AI | Significant Sources |
|---|---|
| Men: 35 µg/day | Meats (especially liver), whole grains, brewer's yeast |
| Women: 25 µg/day | **Deficiency Symptoms** |
| **Chief Functions in the Body** | Diabetes-like condition |
| Enhances insulin action and may improve glucose tolerance | **Toxicity Symptoms** |
| | None reported |

## Molybdenum

**Molybdenum** acts as a working part of several metalloenzymes. Dietary deficiencies of molybdenum are unknown because the amounts needed are minuscule—as little as 0.1 part per million parts of body tissue. Legumes, breads and other grain products, leafy green vegetables, milk, and liver are molybdenum-rich foods. Average daily intakes fall within the suggested range of intakes.

Molybdenum toxicity in people is rare. It has been reported in animal studies, and a UL has been established. Characteristics of molybdenum toxicity include kidney damage and reproductive abnormalities.

**molybdenum** (mo-LIB-duh-num): an essential trace mineral that acts as a cofactor for many enzymes.

### › REVIEW IT

Molybdenum is found in a variety of foods and participates in several metabolic reactions. The accompanying table provides a summary of molybdenum.

#### Molybdenum

| RDA | Significant Sources |
|---|---|
| Adult: 45 µg/day | Legumes, cereals, nuts |
| **UL** | **Deficiency Symptoms** |
| Adults: 2 mg/day | Unknown |
| **Chief Functions in the Body** | **Toxicity Symptoms** |
| Cofactor for several enzymes | None reported; reproductive effects in animals |

## 13.3 Contaminant Minerals

**› LEARN IT** Describe how contaminant minerals disrupt body processes and impair nutrition status.

Chapter 12 and this chapter explain the many ways minerals serve the body—maintaining fluid and electrolyte balance, providing structural support to the bones, transporting oxygen, and assisting enzymes. In contrast to the essential minerals that the body requires, contaminant minerals impair the body's growth, work capacity, and general health. Contaminant minerals include the **heavy metals** lead, mercury, and cadmium, which enter the food supply by way of soil, water, and air pollution. This section focuses on lead poisoning because it is a serious environmental threat to young children and because reducing blood lead levels in children is a goal of the Healthy People initiative. Much of the information on lead applies to the other contaminant minerals as well—they all disrupt body processes and impair nutrition status similarly.

Like other minerals, lead is indestructible; the body cannot change its chemistry. Chemically similar to nutrient minerals such as iron, calcium, and zinc (cations with two positive charges), lead displaces them from some of the metabolic sites they normally occupy so they are then unable to perform their roles. For example, lead competes with iron in heme, but it cannot carry oxygen. Similarly, lead competes with calcium in the brain, but it cannot signal messages from nerve cells. Excess lead in the blood also deranges the structure of red blood cell membranes, making them leaky and fragile. Lead interacts with white blood cells, too, impairing their ability to fight infection, and it binds to antibodies, thwarting their effort to resist disease.

Children with iron deficiency are particularly vulnerable to lead toxicity. Chapter 16 examines the damaging effects of iron deficiency and lead toxicity on a child's growth and development.[50]

**› REVIEW IT** Describe how contaminant minerals disrupt body processes and impair nutrition status.

Lead typifies the ways all heavy metals behave in the body: they interfere with nutrients that are trying to do their jobs. The "good guy" nutrients are shoved aside by the "bad guy" contaminants. Then, when the contaminants cannot perform the roles of the nutrients, health diminishes. To safeguard our health, we must defend ourselves against contamination by eating nutrient-rich foods and preserving a clean environment.

This chapter completes the introductory lessons on the nutrients. Each nutrient from the amino acids to zinc has been described rather thoroughly—its chemistry, roles in the body, sources in the diet, symptoms of deficiency and toxicity, and influences on health and disease. Such a detailed examination is informative, but it can also be misleading. It is important to step back from the detailed study of the individual nutrients to look at them as a whole. After all, people eat foods, not nutrients, and most foods deliver dozens of nutrients. Furthermore, nutrients work cooperatively with one another in the body; their actions are most often *inter*actions. This chapter alone mentioned how iron depends on vitamin C to keep it in its active form and copper to incorporate it into hemoglobin, how zinc is needed to activate and transport vitamin A, and how both iodine and selenium are needed for the synthesis of thyroid hormones. The table on p. 430 provides a summary of the trace minerals for your review. Highlight 13 explores the benefits of phytochemicals.

**heavy metals:** mineral ions such as mercury and lead, so called because they are of relatively high atomic weight. Many heavy metals are poisonous.

## › REVIEW IT The Trace Minerals

| Mineral and Chief Functions | Deficiency Symptoms | Toxicity Symptoms[a] | Significant Sources |
|---|---|---|---|
| **Iron** | | | |
| Part of the protein hemoglobin, which carries oxygen in the blood; part of the protein myoglobin in muscles, which makes oxygen available for muscle contraction; necessary for energy metabolism | Anemia: weakness, fatigue, headaches; impaired work performance; impaired immunity; pale skin, nail beds, mucous membranes, and palm creases; concave nails; inability to regulate body temperature; pica | GI distress; iron overload: infections, fatigue, joint pain, skin pigmentation, organ damage | Red meats, fish, poultry, shellfish, eggs, legumes, dried fruits |
| **Zinc** | | | |
| Part of insulin and many enzymes; involved in making genetic material and proteins, immune reactions, transport of vitamin A, taste perception, wound healing, the making of sperm, and normal fetal development | Growth retardation, delayed sexual maturation, impaired immune function, hair loss, eye and skin lesions, loss of appetite | Loss of appetite, impaired immunity, low HDL, copper and iron deficiencies | Protein-containing foods: red meats, fish, shellfish, poultry, whole grains; fortified cereals |
| **Iodine** | | | |
| A component of the thyroid hormones that help to regulate growth, development, and metabolic rate | Underactive thyroid gland, goiter, mental and physical retardation (cretinism) | Underactive thyroid gland, elevated TSH, goiter | Iodized salt; seafood; plants grown in iodine-rich soil and animals fed those plants |
| **Selenium** | | | |
| Part of an enzyme that defends against oxidation; regulates thyroid hormone | Associated with Keshan disease | Nail and hair brittleness and loss; fatigue, irritability, and nervous system disorders, skin rash, garlic breath odor | Seafoods, organ meats; other meats, whole grains, fruits, and vegetables (depending on soil content) |
| **Copper** | | | |
| Helps form hemoglobin; part of several enzymes | Anemia, bone abnormalities | Liver damage | Seafood, nuts, legumes, whole grains, seeds |
| **Manganese** | | | |
| Cofactor for several enzymes; bone formation | Rare | Nervous symptom disorders | Nuts, whole grains, leafy vegetables, tea |
| **Fluoride** | | | |
| Maintains health of bones and teeth; confers decay resistance on teeth | Susceptibility to tooth decay | Fluorosis (pitting and discoloration) of teeth | Drinking water (if fluoridated), tea, seafood |
| **Chromium** | | | |
| Enhances insulin action, may improve glucose intolerance | Diabetes-like condition | None reported | Meats (liver), whole grains, brewer's yeast |
| **Molybdenum** | | | |
| Cofactor for several enzymes | Unknown | None reported | Legumes, cereals, nuts |

[a]Acute toxicities of many minerals cause abdominal pain, nausea, vomiting, and diarrhea.

# Nutrition Portfolio

Trace minerals from a variety of foods, especially those in the protein foods group, support many of your body's activities. Go to Diet & Wellness Plus and choose one of the days on which you tracked your diet for an entire day. Select the Intake vs. Goals report and then consider the following questions. Remember that scoring 100 percent on this report means you met your goal.

- Your Intake vs. Goals report may only display your intake for two of the trace minerals: iron and zinc. How was your intake for these two trace minerals?

Now look at the Intake Spreadsheet report and consider the following questions:

- How often do you include meats, seafood, poultry, legumes, and enriched or fortified grain products weekly? These foods often contain trace minerals.

# HIGHLIGHT > 13
# Phytochemicals and Functional Foods

© HSNphotography/Shutterstock.com

**› LEARN IT** Define *phytochemicals* and explain how they might defend against chronic diseases.

Chapter 13 completes the introductory lessons on the six classes of nutrients—carbohydrates, lipids, proteins, vitamins, minerals, and water. In addition to these nutrients, foods contain thousands of other compounds, including the **phytochemicals.** Chapter 1 introduces the phytochemicals as compounds found in plant-derived foods that have biological activity in the body. Research on phytochemicals is unfolding daily, adding to our knowledge of their roles in human health, but there are still many questions and only tentative answers. Just a few of the tens of thousands of phytochemicals have been researched at all, and only a sampling are mentioned in this highlight—enough to illustrate their wide variety of food sources and roles in supporting health.

The concept that foods provide health benefits beyond those of the nutrients emerged from numerous epidemiological studies showing the protective effects of plant-based diets on cancer and heart disease. People have been using foods to maintain health and prevent disease for years, but now these foods have been given a name—they are called **functional foods.**[1] (The accompanying glossary defines this and other terms.) As Chapter 1 explains, functional foods include all foods (whole, fortified, enriched, or enhanced foods) that have a potentially beneficial effect on health.[2] Much of this text touts the benefits of nature's functional foods—whole grains rich in dietary fibers, oily fish rich in omega-3 fatty acids, and fresh fruits rich in phytochemicals, for example. This highlight begins with a look at some of these familiar functional foods, the phytochemicals they contain, and their roles in disease prevention. Then the discussion turns to examine the most controversial of functional foods—novel foods to which phytochemicals have been added to promote health. How these foods fit into a healthy diet is still unclear.

## The Phytochemicals

In foods, phytochemicals impart tastes, aromas, colors, and other characteristics. They give hot peppers their burning sensation, garlic its pungent flavor, and tomatoes their red color. In the body, phytochemicals can have profound physiological effects—acting as antioxidants, mimicking hormones, stimulating enzymes, interfering with DNA replication, suppressing inflammation, destroying bacteria, and binding to cell walls. Any of these actions may prevent the development of chronic diseases, depending in part on how genetic factors interact with the phytochemicals. Phytochemicals might also have adverse effects when consumed in excess. Table H13-1 (p. 434) presents the names, possible effects, and food sources of some of the better-known phytochemicals.

### Defending against Cancer

A variety of phytochemicals from a variety of foods appear to protect against DNA damage and defend the body against cancer. A few examples follow.

## GLOSSARY

**carotenoids** (kah-ROT-eh-noyds): pigments commonly found in plants and animals, some of which have vitamin A activity. The carotenoid with the greatest vitamin A activity is beta-carotene.

**flavonoids** (FLAY-von-oyds): yellow pigments in foods; phytochemicals that may exert physiological effects on the body.

**flaxseeds:** the small brown seeds of the flax plant; valued in nutrition as a source of fiber, lignans, and omega-3 fatty acids.

**functional foods:** foods that have a potentially beneficial effect on health when consumed as part of a varied diet on a regular basis at effective levels.

**lignans:** phytochemicals present in flaxseed that are converted to phytosterols by intestinal bacteria and are under study as possible anticancer agents.

**lutein** (LOO-teen): a plant pigment of yellow hue; a phytochemical believed to play roles in eye functioning and health.

**lycopene** (LYE-koh-peen): a pigment responsible for the red color of tomatoes and other red-hued vegetables; a phytochemical that may act as an antioxidant in the body.

**phytochemicals:** nonnutrient compounds found in plants. Some phytochemicals have biological activity in the body.

- **phyto** = plant

**phytoestrogens:** phytochemicals structurally similar to human estrogen that weakly mimic or modulate estrogen's action in the body. Phytoestrogens include the isoflavones *genistein, daidzein,* and *glycitein.*

**plant sterols:** phytochemicals that have structural similarities to cholesterol and lower blood cholesterol by interfering with cholesterol absorption. Plant sterols include *sterol esters* and *stanol esters.*

# HIGHLIGHT > 13

**TABLE H13-1 Phytochemicals—Their Food Sources and Actions**

| Name | Possible Effects | Food Sources |
|---|---|---|
| Alkylresorcinols (phenolic lipids) | May contribute to the protective effect of grains in reducing the risks of diabetes, heart disease, and some cancers. | Whole-grain wheat and rye |
| Allicin (organosulfur compound) | Antimicrobial that may reduce ulcers; may lower blood cholesterol. | Chives, garlic, leeks, onions, scallions |
| Capsaicin | Modulates blood clotting, possibly reducing the risk of fatal clots in heart and artery disease. | Hot peppers |
| Carotenoids (including beta-carotene, lycopene, lutein, zeaxanthin, and hundreds of related compounds) | Act as antioxidants, possibly reducing risks of cancer and other diseases. | Deeply pigmented fruits and vegetables (apricots, broccoli, cantaloupe, carrots, pink grapefruit, pumpkin, spinach, sweet potatoes, tomatoes, red peppers, watermelon) |
| Curcumin (polyphenol) | Acts as an antioxidant and anti-inflammatory agent; may reduce blood clot formation; may inhibit enzymes that activate carcinogens. | Turmeric, a yellow-colored spice common in curry powder |
| Flavonoids (including anthocyanins, flavones, flavonols, isoflavones, catechins, and others) | Act as antioxidants; scavenge carcinogens; bind to nitrates in the stomach, preventing conversion to nitrosamines; inhibit cell proliferation. | Berries, black tea, celery, citrus fruits, green tea, olives, onions, oregano, purple grapes, purple grape juice, soybeans and soy products, vegetables, whole wheat, wine |
| Genistein and daidzein (isoflavonoids) | Phytoestrogens that inhibit cell replication in GI tract; may reduce risk of breast, colon, ovarian, prostate, and other estrogen-sensitive cancers; may reduce cancer cell survival; may reduce risk of osteoporosis. | Soybeans, soy flour, soy milk, tofu, textured vegetable protein, other legume products |
| Indoles (organosulfur compound) | May trigger production of enzymes that block DNA damage from carcinogens; may inhibit estrogen action. | Cruciferous vegetables such as bok choy, broccoli, brussels sprouts, cabbage, cauliflower, collard greens, mustard greens, kale, swiss chard, watercress |
| Isothiocyanates (organosulfur compounds, including sulforaphane) | Act as antioxidants; inhibit enzymes that activate carcinogens; activate enzymes that detoxify carcinogens; may reduce risk of breast cancer, prostate cancer, and colorectal cancer. | Cruciferous vegetables such as bok choy, broccoli, broccoli sprouts, brussels sprouts, cabbage, cauliflower, collard greens, mustard greens, kale, swiss chard, watercress |
| Lignans (polyphenol) | Phytoestrogens that block estrogen activity in cells possibly reducing the risk of cancer of the breast, colon, ovaries, and prostate. | Flaxseed, whole grains |
| Monoterpenes (including limonene) | May trigger enzyme production to detoxify carcinogens; inhibit cancer promotion and cell proliferation. | Citrus fruits, cherries |
| Phenolic acids (including ellagic acid) | May trigger enzyme production to make carcinogens water soluble, facilitating excretion. | Coffee beans, fruits (apples, blueberries, cherries, grapes, oranges, pears, prunes), oats, potatoes, soybeans |
| Phytic acid (phenolic acid) | Binds to minerals, preventing free-radical formation, possibly reducing cancer risk. | Whole grains |
| Resveratrol (flavonoid) | Acts as an antioxidant; may inhibit cancer growth; reduce inflammation, LDL oxidation, and blood clot formation. | Red wine, peanuts, grapes, raspberries |
| Saponins (glucosides) | May interfere with DNA replication, preventing cancer cells from multiplying; stimulate immune response. | Alfalfa sprouts, other sprouts, green vegetables, potatoes, tomatoes |
| Tannins (flavonoid) | Act as antioxidants; may inhibit carcinogen activation and cancer promotion. | Black-eyed peas, grapes, lentils, red and white wine, tea |

© Cengage Learning

Soy may protect against breast and prostate cancers.[3] Soybeans—as well as other legumes, **flaxseeds,** whole grains, fruits, and vegetables—are a rich source of an array of phytochemicals, among them the **phytoestrogens.** Because the chemical structure of phytoestrogens is similar to the hormone estrogen, they can weakly mimic or modulate the effects of estrogen in the body. They also have antioxidant activity that appears to slow the growth of some cancers.

Soy foods appear to be most effective when consumed in moderation early and throughout life.[4] Importantly, soy extracts and phytoestrogen supplements are ill-advised—especially for women with breast cancer and those with high risk factors—as phytoestrogens may promote the growth of estrogen-dependent tumors (such as breast cancer).[5] The American Cancer Society recommends that women with breast cancer should consume only *moderate* amounts of soy as part

of a healthy plant-based diet and should not intentionally ingest high levels of soy or supplements of phytoestrogens.

Limited evidence suggests that tomatoes may offer protection against some cancers.[6] Among the phytochemicals thought to be responsible for this effect is **lycopene,** one of the many **carotenoids.**[7] Lycopene is the pigment that gives apricots, guava, papaya, pink grapefruits, and watermelon their red color—and it is especially abundant in tomatoes. Because food processing and cooking can improve carotenoid absorption, cooked tomato products, such as spaghetti sauce, provide even more lycopene. Lycopene is a powerful antioxidant that seems to inhibit the growth of cancer cells. Importantly, the benefits of lycopene have been seen when people have eaten *foods* containing lycopene; lycopene supplements may interfere with cancer treatments.[8]

Soybeans and tomatoes are only two of the many fruits and vegetables credited with providing anticancer activity. Strong and convincing evidence shows that the risk of many cancers, and perhaps of cancer in general, decreases when diets include an abundance of fruits and vegetables.[9] To that end, current recommendations urge consumers to eat five to nine servings of fruits and vegetables a day.

## Defending against Heart Disease

Diets based primarily on unprocessed foods appear to support heart health better than those founded on highly refined foods—perhaps because of the abundance of nutrients, fiber, or phytochemicals such as the **flavonoids.** Flavonoids, a large group of phytochemicals known for their health-promoting qualities, are found in whole grains, legumes, soy, vegetables, fruits, herbs, spices, teas, chocolate, nuts, olive oil, and red wines.[10] Flavonoids are powerful antioxidants that may help to protect LDL cholesterol against oxidation, minimize inflammation, and reduce blood platelet stickiness, thereby slowing the progression of atherosclerosis and making blood clots less likely. Whereas an abundance of flavonoid-containing *foods* in the diet may lower the risks of chronic diseases, no claims can be made for flavonoids themselves as the protective factor, particularly when they are extracted from foods and sold as supplements. In fact, purified flavonoids may even be harmful.[11]

In addition to flavonoids, fruits and vegetables are rich in carotenoids such as beta-carotene and **lutein.** Studies suggest that a diet rich in carotenoids may lower the risk of heart disease by decreasing inflammation and oxidative stress.[12]

The **plant sterols** of soy and the **lignans** of flaxseed may also protect against heart disease. These cholesterol-like molecules are naturally found in all plants and inhibit cholesterol absorption in the body. As a result, blood cholesterol levels decline.[13] These phytochemicals also seem to protect against heart disease by reducing inflammation and lowering blood pressure.[14]

## Defending against Other Diseases

Most research on phytochemicals has focused on cancer and heart disease, but phytochemicals defend against other diseases as well. The orange-yellow pigment curcumin, commonly found in curry powder, may help reverse insulin resistance, inflammation, and other symptoms associated with obesity.[15] The carotenoids lutein and zeaxanthin may protect the eyes and skin from ultraviolet light damage and the bones from mineral loss.[16]

## The Phytochemicals in Perspective

Because foods deliver thousands of phytochemicals in addition to dozens of nutrients, researchers must be careful in giving credit for particular health benefits to any one compound. Diets rich in whole grains, legumes, vegetables, fruits, and nuts seem to protect against heart disease and cancer, but identifying *the* specific foods or components of foods that are responsible is difficult. Each food possesses a unique array of phytochemicals—citrus fruits provide monoterpenes; grapes, resveratrol; and flaxseed, lignans. (Review Table H13-1, p. 434, for the possible effects and other food sources of these phytochemicals.) Broccoli may contain as many as 10,000 different phytochemicals—each with the potential to influence some action in the body. Beverages such as wine, spices such as oregano, and oils such as olive oil (especially virgin olive oil) contain many phytochemicals that may explain, in part, why people who eat a traditional Mediterranean diet have reduced risks of heart disease and cancer. Phytochemicals might also explain why the DASH diet is so effective in lowering blood pressure and blood lipids. Even identifying all of the phytochemicals and their effects doesn't answer all the questions because the actions of phytochemicals may be complementary or overlapping—which reinforces the principle of variety in diet planning. For an appreciation of the array of phytochemicals offered by a variety of foods, see Figure H13-1 (p. 436).

# Functional Foods

Because foods naturally contain thousands of phytochemicals that are biologically active in the body, virtually all of them have some value in supporting health.[17] In other words, even simple, whole foods, in reality, are functional foods. Cranberries may help prevent urinary tract infections; garlic may lower blood cholesterol; grapes may reduce inflammation; and green tea may protect against nonalcoholic fatty liver disease, just to name a few examples.[18] Functional foods rich in phytochemicals are easy to find in the produce section of grocery stores. Just look for the colorful fruits and vegetables (see Table H13-2, p. 437). But food manufacturers continue to create new functional foods as well.

Many processed foods become functional foods when they are fortified with nutrients or enhanced with phytochemicals or herbs (calcium-fortified orange juice, for example). Less frequently, an entirely new food is created, as in the case of a meat substitute made of mycoprotein—a protein derived from a fungus.* This functional food not only provides dietary fiber, polyunsaturated fats, and high-quality protein, but it also lowers LDL cholesterol, raises HDL cholesterol, improves glucose response, and prolongs satiety after a meal. Such a novel functional food raises the question—is it a food or a drug?

*This mycoprotein product is marketed under the trade name Quorn (pronounced KWORN).

## > FIGURE H13-1 An Array of Phytochemicals in a Variety of Foods and Beverages

Broccoli and broccoli sprouts (and brussels sprouts, bok choy, cabbage, cauliflower, kale, collard greens, swiss chard, turnips, and watercress) contain an abundance of the cancer-fighting phytochemicals sulforaphane and indoles.

The phytochemical resveratrol found in grapes (and nuts) protects against cancer by inhibiting cell growth and against heart disease by limiting clot formation and inflammation.

The flavonoids in cocoa and chocolate defend against oxidation and reduce the tendency of blood to clot.

Spinach (and collard greens, corn, swiss chard, and winter squash) contains the carotenoids lutein and zeaxanthin, which help protect the eyes against macular degeneration.

An apple a day—rich in phenolic acids—may protect against heart disease.

The ellagic acid of strawberries (and blackberries, blueberries, raspberries, and grapes) may inhibit certain types of cancer and decrease cholesterol levels.

Tomatoes (and pink grapefruit, red peppers, and watermelons), with their abundant lycopene, may defend against cancer and heart disease by protecting DNA from oxidative damage.

Quercetins—commonly found in kale (and onions, pears, and grapes)—reduce inflammation from allergies, inhibit tumor growth, and protect the lungs.

The phytoestrogens of soybeans seem to starve cancer cells and inhibit tumor growth; the plant sterols may lower blood cholesterol and protect cardiac arteries.

The monoterpenes of citrus fruits (and cherries) may protect the lungs.

Colorful foods such as apricots (and cantaloupes, carrots, kale, kiwifruit, mangoes, papaya, pumpkins, spinach, sweet potatoes, and winter squash) contain beta-carotene, which may help slow aging, protect against some cancers, improve lung function, and reduce complications of diabetes.

Garlic (and chives, leeks, onions, and scallions), with its abundant organosulfur compounds, may lower blood cholesterol and blood pressure and protect against stomach cancer.

The flavonoids in black tea may protect against heart disease, whereas those in green tea may defend against cancer.

Blueberries (and cherries, plums, and strawberries), a rich source of anthocyanins, may protect against the effects of aging.

Flaxseed, the richest source of lignans, may prevent the spread of cancer.

## Foods as Pharmacy

Hippocrates is credited with saying, "Let food be thy medicine and medicine be thy food." This simple message, uttered thousands of years ago, recognizes how good food supports good health.

Not too long ago, most of us could agree on what was a food and what was a drug. Today, functional foods blur the distinctions. They have characteristics similar to both foods and drugs, but do not fit neatly into either category. Consider margarine, for example.

Eating nonhydrogenated margarine sparingly instead of butter generously may lower blood cholesterol slightly over several months and clearly falls into the food category. Taking a statin drug, on the other hand, lowers blood cholesterol significantly within weeks and clearly falls into the drug category. But margarine enhanced with a plant sterol that lowers blood cholesterol is in a gray area between the two. The margarine looks and tastes like a food, but it acts like a drug.

The use of functional foods as drugs creates a whole new set of diet-planning challenges. Not only must foods provide an adequate intake of all the nutrients to support good health, but they must also deliver druglike ingredients to protect against disease. Like drugs used to treat chronic diseases, functional foods may need to be eaten several times a day for several months or even years to have a beneficial effect. Sporadic users may be disappointed in the results. Margarine enriched with 2 to 3 grams of plant sterols may reduce cholesterol by up to 15 percent, much more than regular margarine does, but not nearly as much as the more than 30 percent reduction seen with cholesterol-lowering drugs. For this reason, functional foods may be

Nature offers a variety of functional foods that provide us with many health benefits.

© Craig M. Moore

Functional foods currently on the market promise to "enhance mood," "promote relaxation and good karma," "increase alertness," and "improve memory," among other claims.

more useful for prevention and mild cases of disease than for intervention and more severe cases. In any case, because prescription medicines are so much more effective and because people respond to plant sterols so differently, consumers should always make treatment decisions in consultation with their health care providers.[19]

Foods and drugs differ dramatically in cost as well. Functional foods such as fruits and vegetables incur no added costs, but foods that have been manufactured with added phytochemicals can be expensive, costing up to six times as much as their conventional counterparts. The price of functional foods typically falls between that of traditional foods and medicines.

## Unanswered Questions

To achieve a desired health effect, which is the better choice: to eat a novel functional food created to affect a specific body function or to adjust the diet? Does it make more sense to use a margarine enhanced with a plant sterol that lowers blood cholesterol or simply to limit the amount of butter eaten?* Is it smarter to eat eggs enriched with omega-3 fatty acids or to restrict egg consumption? Might functional foods offer a sensible solution for improving our nation's health—if done correctly? Perhaps so, but the problem is that the food industry moves faster than either scientists or the Food and Drug Administration. Consumers were able to buy soup with St. John's wort that claimed to enhance mood and fruit juice with echinacea that was supposed to fight colds while scientists were still conducting their studies on these ingredients. Research to determine the safety and effectiveness of these substances is still in progress. Until this work is complete, consumers are on their own in finding answers to the following questions:

- *Does it work?* Research is generally lacking and findings are often inconclusive.
- *How much does it contain?* Food labels are not required to list the quantities of added phytochemicals. Even if they were, consumers have no standard for comparison and cannot deduce whether the amounts listed are a little or a lot. Most importantly, until research is complete, food manufacturers do not know what amounts (if any) are most effective—or most toxic.
- *Is it safe?* Functional foods can act like drugs. They contain ingredients that can alter body functions and cause allergies, drug interactions, drowsiness, and other side effects. Yet, unlike drug labels, food labels do not provide instructions for the dosage, frequency, or duration of treatment.
- *Is it healthy?* Adding phytochemicals to a food does not magically make it a healthy choice. A candy bar fortified with phytochemicals is still made mostly of sugar and fat.

Critics suggest that the designation "functional foods" may be nothing more than a marketing tool. After all, even the most experienced researchers cannot yet identify the perfect combination of nutrients and phytochemicals to support optimal health. Yet manufacturers are freely experimenting with various concoctions as if they possessed that knowledge. Is it okay for them to sprinkle phytochemicals on fried snack foods or caramel candies and label them "functional," thus implying health benefits?

## Future Foods

Nature has elegantly designed foods to provide us with a complex array of dozens of nutrients and thousands of additional compounds that may benefit health—most of which we have yet to identify or understand. Over the years, we have taken those foods, deconstructed them, and then reconstructed them in an effort to "improve" them. With new scientific understandings of how nutrients—and the myriad other compounds in foods—interact with genes, we may someday be able to design *specific* eating patterns to meet the *exact* health needs of *each* individual. Indeed, our knowledge of the human genome and of human nutrition may well merge to allow specific recommendations for individuals based on their predisposition to diet-related diseases.

*Margarine products that lower blood cholesterol contain either sterol esters from vegetable oils, soybeans, and corn or stanol esters from wood pulp.

If the present trend continues, someday physicians may be able to prescribe the perfect foods to enhance your health, and farmers will be able to grow them. As Highlight 19 explains, scientists have already developed gene technology to alter the composition of food crops. They can grow rice enriched with vitamin A and tomatoes containing a hepatitis vaccine, for example. It seems quite likely that foods can be created to meet every possible human need. But then, in a sense, that was largely true 100 years ago when we relied on the bounty of nature.

## CRITICAL THINKING QUESTIONS

A. Which is the better choice—to eat processed foods that have been enhanced with phytochemicals or to eat natural foods that are rich in phytochemicals?

B. Some research suggests that cranberries may help prevent urinary tract infections, but what about cranberry supplements? Limited research suggests that *foods* rich in phytoestrogens may benefit heart, bone, breast, and menopausal health, but *phytoestrogen supplements* or *phytoestrogen-enhanced functional foods* are not recommended, particularly for women at high risk of breast cancer. How can you determine whether a phytochemical and/or functional food offers a safe and sensible solution to improving your health?

# Fitness: Physical Activity, Nutrients, and Body Adaptations

## Nutrition in Your Life

Every day, you choose whether to be physically active or not, and your choices over time can influence how well you feel and how long you live. Today's world makes it easy to be inactive—too easy in fact—but the many health rewards of being physically active make it well worth the effort. You may even discover how much fun it is to be active, and with a little perseverance, you may become physically fit as well. The choice is yours. In the Nutrition Portfolio at the end of this chapter, you can determine whether your physical activities meet current recommendations and whether your daily food, fluid, and carbohydrate intakes are appropriate to support those activities.

Are you physically fit? If so, your joints are flexible, your muscles are strong, and your body is lean with enough, but not too much, fat. You have the endurance to engage in daily physical activities with enough reserve energy to handle added challenges. Carrying heavy suitcases, opening a stuck window, or climbing four flights of stairs, which might strain an unfit person, is easy for you. What's more, you are prepared to meet mental and emotional challenges too. All these characteristics of **fitness** describe the same wonderful condition of a healthy body.

Or perhaps you are **sedentary**. Today's world encourages inactivity, and people who exert minimal physical effort become weak and unhealthy. In fact, a sedentary lifestyle fosters the development of several chronic diseases.[1]

Regardless of your level of fitness, this chapter is written for "you," whoever you are and whatever your goals—whether you want to improve your health, lose weight, hone your athletic skills, or simply adopt an active lifestyle. This chapter begins by discussing fitness and its benefits, and then goes on to explain how the body uses energy nutrients to fuel physical activity. Finally, it describes diets to support fitness.

### LEARNING GPS

**14.1 Fitness 442**

**LEARN IT** Describe the health benefits of being physically fit and explain how to develop the components of fitness.

- Benefits of Fitness 442
- Developing Fitness 443
- The Components of Fitness 445
- Cardiorespiratory Endurance 446
- Muscle Strength and Endurance 447

**14.2 Energy Systems and Fuels to Support Activity 448**

**LEARN IT** Identify the factors that influence fuel use during physical activity and the types of activities that depend more on glucose or fat, respectively.

- The Energy Systems of Physical Activity 448
- Glucose Use during Physical Activity 450
- Fat Use during Physical Activity 452
- Protein Use during Physical Activity—and between Times 453

**14.3 Vitamins and Minerals to Support Activity 455**

**LEARN IT** List which vitamin and mineral supplements, if any, athletes may need and why.

- Dietary Supplements 455
- Nutrients of Concern 456

**14.4 Fluids and Electrolytes to Support Activity 457**

**LEARN IT** Identify the factors that influence an athlete's fluid needs and describe the differences between water and sports drinks.

- Temperature Regulation 457
- Sports Drinks 459
- Poor Beverage Choices: Caffeine and Alcohol 461

**14.5 Diets for Physically Active People 462**

**LEARN IT** Discuss an appropriate daily eating pattern for athletes and list one example of a recommended pregame and recovery meal.

- Choosing a Diet to Support Fitness 462
- Meals before and after Competition 463

**Highlight 14** Supplements as Ergogenic Aids 467

**LEARN IT** Present arguments for and against the use of ergogenic aids.

**fitness:** the characteristics that enable the body to perform physical activity; more broadly, the ability to meet routine physical demands with enough reserve energy to rise to a physical challenge; or the body's ability to withstand stress of all kinds.

**sedentary:** physically inactive (literally, "sitting down a lot").

Physical activity, or lack of it, exerts a significant and pervasive influence on everyone's nutrition and overall health.

# 14.1 Fitness

**› LEARN IT** Describe the health benefits of being physically fit and explain how to develop the components of fitness.

Fitness depends on a certain minimum amount of **physical activity** or **exercise.** Both physical activity and exercise involve body movement, muscle contraction, and enhanced energy expenditure, but "exercise" is often used to describe structured, planned physical activity. This chapter focuses on how the active body uses energy nutrients—whether that body is pedaling a bike across campus or pedaling a stationary bike in a gym. Thus, for our purposes, the terms *physical activity* and *exercise* are used interchangeably.

## Benefits of Fitness

The *Dietary Guidelines for Americans* emphasize the benefits of increasing physical activities and reducing sedentary activities.[2] Extensive evidence confirms that regular physical activity promotes health and reduces the risk of developing a number of diseases.[3] Yet, despite an increasing awareness of the health benefits that physical activity confers, only about 20 percent of adults in the United States meet physical activity guidelines.[4] Like smoking and obesity, physical inactivity is linked to the major degenerative diseases—heart disease, cancer, stroke, diabetes, and hypertension—the primary killers of adults in developed countries.[5]

**> DIETARY GUIDELINES FOR AMERICANS**

Increase physical activity and reduce time spent in sedentary behaviors.

As a person becomes physically fit, the health of the entire body improves. In general, physically fit people enjoy:[6]

- *Restful sleep.* Rest and sleep occur naturally after periods of physical activity.
- *Nutritional health*. Physical activity expends energy and thus allows people to eat more food. If they choose wisely, active people will consume more nutrients and be less likely to develop nutrient deficiencies.
- *Improved body composition*. A balanced program of physical activity limits body fat and increases or maintains lean tissue. Thus physically active people have relatively less body fat than sedentary people at the same body weight.[7]
- *Improved bone density.* Weight-bearing physical activity builds bone strength and protects against osteoporosis.[8]
- *Resistance to colds and other infectious diseases*. Fitness enhances immunity.[9]*
- *Low risks of some cancers*. Lifelong physical activity may help to protect against colon cancer, breast cancer, and some other cancers.[10]
- *Strong circulation and lung function*. Physical activity that challenges the heart and lungs strengthens the circulatory system.
- *Low risk of cardiovascular disease*. Physical activity lowers blood pressure, slows resting pulse rate, and lowers blood cholesterol, thus reducing the risks of heart attacks and strokes.[11] Some research suggests that physical activity may reduce the risk of cardiovascular disease in another way as well—by reducing visceral fat stores.[12]
- *Low risk of type 2 diabetes*. Physical activity normalizes glucose tolerance.[13] Regular physical activity reduces the risk of developing type 2 diabetes and improves glucose control.
- *Reduced risk of gallbladder disease.* Regular physical activity reduces the risk of gallbladder disease—perhaps by facilitating weight control and lowering blood lipid levels.[14]

**physical activity:** bodily movement produced by muscle contractions that substantially increase energy expenditure.

**exercise:** planned, structured, and repetitive body movements that promote or maintain physical fitness.

*Moderate physical activity can stimulate immune function. Intense, vigorous, prolonged activity such as marathon running, however, may compromise immune function.

**TABLE 14-1 Levels of Physical Activity Intensity Compared**

| Level of Intensity | Breathing and/or Heart Rate | Perceived Exertion (on a Scale of 0 to 10) | Talk Test | Energy Expenditure | Walking Pace |
|---|---|---|---|---|---|
| Light | Little to no increase | <5 | Able to sing | <3.5 kcal/min | <3 mph |
| Moderate | Some increase | 5 or 6 | Able to have a conversation | 3.5 to 7 kcal/min | 3 to 4.5 mph |
| Vigorous | Large increase | 7 or 8 | Conversation is difficult or "broken" | >7 kcal/min | >4.5 mph |

SOURCE: Centers for Disease Control and Prevention, www.cdc.gov/physicalactivity/everyone; updated March 30, 2011.

© Cengage Learning

- *Low incidence and severity of anxiety and depression*. Physical activity may improve mood and enhance the quality of life by reducing depression and anxiety.[15]
- *Strong self-image*. The sense of achievement that comes from meeting physical challenges promotes self-confidence.
- *Long life and high quality of life in the later years*. Active people live longer, healthier lives than sedentary people do.[16] Even as little as 15 minutes a day of moderate-intensity activity can add years to a person's life.[17] In addition to extending longevity, physical activity supports independence and mobility in later life by reducing the risk of falls and minimizing the risk of injury should a fall occur.[18]

What does a person have to do to reap the health rewards of physical activity? To gain substantial *health* benefits, most guidelines recommend a minimum amount of time performing **aerobic physical activity.**[19] The minimum amount of time depends on whether the activity is **moderate-intensity physical activity** or **vigorous-intensity physical activity.** Table 14-1 compares intensity levels. Whether moderate or vigorous, a minimum length of 10 minutes for short bouts of aerobic physical activity is recommended.[20] Of course, more time and greater intensity bring even greater health benefits—maintaining a healthy body weight (BMI of 18.5 to 24.9) and further reducing the risk of chronic diseases.

**> DIETARY GUIDELINES FOR AMERICANS**

Choose moderate- or vigorous-intensity physical activities. Slowly build up the amount of physical activity you choose.

In addition to providing health benefits, physical activity helps to develop and maintain *fitness*. Table 14-2 (p. 444) presents the American College of Sports Medicine (ACSM) guidelines for physical activity.[21] Following these guidelines will help adults improve their cardiorespiratory endurance, body composition, strength, and flexibility. At this level of fitness, a person can reap still greater health benefits (substantially lower risk of premature death compared with those who are inactive, improved cardiorespiratory fitness, and improved body composition, for example).[22] Fitness and health both depend on maintaining an active lifestyle every day.

The bottom line is that any physical activity, even moderate activity, *beyond* activities of daily living, provides some health benefits, and these benefits follow a dose-response relationship. In other words, some activity is better than none, and more activity is better still—up to a point. Pursued in excess, intense physical activity, especially when combined with poor eating habits, can undermine health, as Highlight 8, Eating Disorders, explains (pp. 256–263).

## Developing Fitness

A person who practices a physical activity *adapts* by becoming better able to perform that activity after each session. People shape their bodies by what they choose to do (and not do). Muscle cells and tissues respond to a physical activity **overload** by building, within genetic limits, the structures needed to perform it.[23]

Muscles are continually under renovation. Every day, particularly during the fasting periods between meals, a healthy body degrades a small portion of its muscle protein and then rebuilds new muscle with available amino acids during

© Fuse/Jupiterimages

Physical activity helps you look good, feel good, and have fun, and it brings many long-term health benefits as well.

**aerobic physical activity:** activity in which the body's large muscles move in a rhythmic manner for a sustained period of time. Aerobic activity, also called *endurance activity*, improves cardiorespiratory fitness. Brisk walking, running, swimming, and bicycling are examples.

**moderate-intensity physical activity:** physical activity that requires some increase in breathing and/or heart rate and expends 3.5 to 7 kcalories per minute. Walking at a speed of 3 to 4.5 miles per hour (about 15 to 20 minutes to walk 1 mile) is an example.

**vigorous-intensity physical activity:** physical activity that requires a large increase in breathing and/or heart rate and expends more than 7 kcalories per minute. Walking at a very brisk pace (>4.5 miles per hour) or running at a pace of at least 5 miles per hour are examples.

**overload:** an extra physical demand placed on the body; an increase in the frequency, duration, or intensity of an activity. A principle of training that states for a body system to improve, it must be worked at frequencies, durations, or intensities that increase by increments.

**TABLE 14-2 ACSM Guidelines for Physical Fitness**

| | Cardiorespiratory | Strength | Flexibility |
|---|---|---|---|
| |  Steve Cole/Photodisc/Getty Images |  © David Hanover Photography |  © David Hanover Photography |
| **Type of Activity** | Aerobic activity that uses large-muscle groups and can be maintained continuously | Resistance activity that is performed at a controlled speed and through a full range of motion | Stretching activity that uses the major muscle groups |
| **Frequency** | 5 to 7 days per week | 2 to 3 nonconsecutive days per week | 2 to 7 days per week |
| **Intensity** | Moderate (equivalent to walking at a pace of 3 to 4 miles per hour)[a] | Enough to enhance muscle strength and improve body composition | Enough to feel tightness or slight discomfort |
| **Duration** | At least 30 minutes per day | 2 to 4 sets of 8 to 12 repetitions involving each major muscle group | 2 to 4 repetitions of 15 to 30 seconds per muscle group |
| **Examples** | Running, cycling, dancing, swimming, inline skating, rowing, power walking, cross-country skiing, kickboxing, water aerobics, jumping rope; sports activities such as basketball, soccer, racquetball, tennis, volleyball | Pull-ups, push-ups, sit-ups, weightlifting, pilates | Yoga |

© Cengage Learning

[a]For those who prefer vigorous-intensity aerobic activity such as walking at a very brisk pace (>4.5 mph) or running (≥5 mph), a minimum of 20 minutes per day, 3 days per week is recommended.

SOURCE: American College of Sports Medicine position stand: Quantity and quality of exercise for developing and maintaining cardiorespiratory, musculoskeletal, and neuromotor fitness in apparently healthy adults—Guidance for prescribing exercise, *Medicine and Science in Sports and Exercise* 43 (2011): 1334–1359; W. L. Haskell and coauthors, Physical activity and public health: Updated recommendation for adults from the American College of Sports Medicine and the American Heart Association, *Medicine & Science in Sports & Exercise* 39 (2007): 1423–1434.

feeding periods.[24] This balance between protein degradation and synthesis maintains the body's muscle tissue. To *gain* muscle tissue, protein synthesis must be greater than degradation, a condition called **hypertrophy.** When protein degradation is greater than synthesis, the result is **atrophy.** Physical activity tips the balance toward muscle hypertrophy. The opposite is also true: unused muscles diminish in size and weaken over time, tipping the balance toward muscle atrophy.

The muscles adapt and build only the proteins they need to cope with the work performed.[25] Muscles engaged in activities that require strength develop more of the proteins needed for greater muscle mass; body builders have large, well-developed muscles. By comparison, those engaged in endurance activities develop more of the proteins needed to combat muscle fatigue; distance cyclists can pedal for many hours before fatigue sets in.

**Strategies to Build Fitness and Prevent Injuries** A variety of physical activities produces the best overall fitness, and to this end, people need to work different muscle groups from day to day. This strategy provides a day or two of rest for different muscle groups, allowing time to replenish nutrients and to repair any minor damage incurred by the activity.

Other tips for building fitness and minimizing the risk of overuse injuries are:

- Be active all week, not just on the weekends.
- Use proper equipment and wear proper attire.
- Perform exercises using proper form.
- Include **warm-up** and **cool-down** activities in each session. Warming up helps to prepare muscles, ligaments, and tendons for the upcoming activity and mobilizes fuels to support strength and endurance activities. Cooling down reduces muscle cramping and allows the heart rate to slow gradually.
- Train hard enough to challenge your strength or endurance a few times each week rather than every time you work out. Between challenges, do moderate workouts and include at least one day of rest each week.

**hypertrophy** (high-PER-tro-fee): growing larger; with regard to muscles, an increase in size (and strength) in response to use.

**atrophy** (AT-ro-fee): becoming smaller; with regard to muscles, a decrease in size (and strength) because of disuse, undernutrition, or wasting diseases.

**warm-up:** 5 to 10 minutes of light activity, such as easy jogging or cycling, prior to a workout to prepare the body for more vigorous activity.

**cool-down:** 5 to 10 minutes of light activity, such as walking or stretching, following a vigorous workout to gradually return the body's core to near-normal temperature.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Pay attention to body signals. Symptoms such as abnormal heartbeat, dizziness, lightheadedness, cold sweat, confusion, or pain or pressure in the middle of the chest, teeth, jaw, neck, or arm demand immediate medical attention.
- Work out wisely. Do not start with activities so demanding that pain stops you within a day or two. Learn to enjoy small steps toward improvement. Fitness builds slowly.

**Cautions on Starting a Fitness Program** Before beginning a fitness program, make sure it is safe for you to do so. Most apparently healthy people can begin a moderate exercise program such as walking or increasing daily activities without a medical examination, but people with any of the following coronary risk factors may need medical advice:[26]

- Age (men ≥45 yr or women ≥55 yr)
- Family history of heart disease
- Cigarette smoking
- Hypertension
- Serum cholesterol ≥200 mg/dL, LDL ≥130 mg/dL or HDL ≤40 mg/dL, or taking lipid-lowering medication
- Prediabetes or diabetes (fasting plasma glucose ≥100 mg/dL)
- Sedentary lifestyle
- Obesity (BMI ≥30)

Mike Powell/Stockbyte/Getty Images

Choose an active lifestyle. Use the stairs; walk or bike to work, class, or shops; wash and wax the car; mow the grass; rake the leaves; shovel snow; walk the dog; play with children. Be active and have fun.

## The Components of Fitness

To be physically fit, a person must develop enough flexibility, muscle strength and endurance, and cardiorespiratory endurance to meet the everyday demands of life with some to spare, and achieve a healthy body composition. **Flexibility** allows the joints to move freely, reducing the risk of injury. **Cardiorespiratory endurance** supports the ongoing activity of the heart and lungs. **Muscle strength** and **muscle endurance** enable muscles to

**flexibility:** the capacity of the joints to move through a full range of motion; the ability to bend and recover without injury.

**cardiorespiratory endurance:** the ability to perform large-muscle, dynamic exercise of moderate to high intensity for prolonged periods.

**muscle strength:** the ability of muscles to work against resistance.

**muscle endurance:** the ability of a muscle to contract repeatedly without becoming exhausted.

work harder and longer without fatigue. **Body composition** improves as physical activity supports lean body tissues and reduces excess body fat.

Although nutrition influences each component of fitness to some extent, its role in flexibility is not as apparent as for the others. For this reason, cardiorespiratory endurance and muscle strength and endurance are emphasized in the following sections. As the heart and lungs improve their capacity to sustain physical activity and the muscles become stronger and less readily fatigued, body composition improves: body fat decreases and lean body mass increases. Chapter 8 discusses body composition and the health risks of too much body fat.

## Cardiorespiratory Endurance

The length of time a person can remain active with an elevated heart rate—that is, the ability of the heart, lungs, and blood to sustain a given demand—defines a person's cardiorespiratory endurance. Cardiorespiratory endurance training improves a person's ability to sustain vigorous activities such as running, brisk walking, or swimming. Such training enhances the capacity of the heart, lungs, and blood to deliver oxygen to, and remove waste from, the body's cells.[27] Cardiorespiratory endurance training, therefore, is *aerobic,* meaning oxygen requiring. As the cardiorespiratory system gradually adapts to the demands of aerobic activity, the body delivers oxygen more efficiently. In fact, the accepted measure of a person's cardiorespiratory fitness is maximal oxygen uptake **($VO_{2max}$).** The benefits of cardiorespiratory training are not just physical, though, because all of the body's cells, including the brain cells, require oxygen to function. When the cells receive more oxygen more readily, both the body and the mind benefit.

### Cardiorespiratory Conditioning

**Cardiorespiratory conditioning** occurs as aerobic workouts improve heart and lung function. **Cardiac output** increases, thus enhancing oxygen delivery. The heart becomes stronger, and each beat pumps more blood. Because the heart pumps more blood with each beat, fewer beats are necessary, and the resting heart rate slows down. The average resting pulse rate for adults is around 70 beats per minute, but people who achieve cardiorespiratory conditioning may have resting pulse rates of 50 or even lower. The muscles that work the lungs become stronger, too, so breathing becomes more efficient. Circulation through the arteries and veins improves. Blood moves easily, and blood pressure falls.[28] In short, cardiorespiratory conditioning:

- Increases cardiac output and oxygen delivery
- Increases blood volume per heart beat (stroke volume)
- Slows resting pulse rate
- Increases breathing efficiency
- Improves circulation
- Reduces blood pressure

Cardiorespiratory endurance reflects the health of the heart and circulatory system, on which all other body systems depend. To improve your cardiorespiratory endurance, activities must be sustained for 20 minutes or longer and use most of the large-muscle groups of the body (legs, buttocks, and abdomen). The level of training must be intense enough to elevate your heart rate.

A person's own perceived effort is usually a reliable indicator of the intensity of an activity. In general, workouts should be at an intensity that raises your heart rate but still leaves you able to talk comfortably. For those who are more competitive and want to work to their limits on some days, a treadmill test can reveal the maximum heart rate. Workouts are safe at up to 85 percent of that rate. Table 14-2 (p. 444) includes the ACSM guidelines for developing and maintaining cardiorespiratory fitness.

### Muscle Conditioning

One of the benefits of cardiorespiratory training is that fit muscles use oxygen efficiently, reducing the heart's workload. An added bonus is that muscles that use oxygen efficiently can burn fat longer—a plus for body composition and weight control.

**body composition:** the proportions of muscle, bone, fat, and other tissues that make up a person's total body weight.

**$VO_{2max}$:** the maximum rate of oxygen consumption by an individual at sea level.

**cardiorespiratory conditioning:** improvements in heart and lung function and increased blood volume, brought about by aerobic training.

**cardiac output:** the volume of blood discharged by the heart each minute; determined by multiplying the stroke volume by the heart rate. The stroke volume is the amount of oxygenated blood the heart ejects toward the tissues at each beat. Cardiac output (volume/minute) = stroke volume (volume/beat) × heart rate (beats/minute)

The key to regular physical activity is finding an activity you enjoy.

## Muscle Strength and Endurance

**Resistance training** has long been recognized as a means to build and maintain muscle mass, strength, power, and endurance. Additional benefits of resistance training, however, have also emerged. Progressive resistance training helps prevent and manage several chronic diseases, including cardiovascular disease, and enhances psychological well-being.[29] Resistance training can also help to maximize and maintain bone mass.[30] Even in women past menopause (when most women are losing bone), resistance training can improve bone density, especially in combination with adequate dietary calcium and vitamin D intake.[31]

By promoting strong muscles in the back and abdomen, resistance training can improve posture and reduce the risk of back injury. Resistance training can also help prevent the decline in physical mobility that often accompanies aging.[32] Older adults, even those in their 80s, who participate in resistance training programs not only gain muscle strength but also improve their muscle endurance, which enables them to walk longer before exhaustion. Leg strength and walking endurance are powerful indicators of an older adult's physical abilities.

Resistance training builds muscle strength, **muscle power,** and muscle endurance. To emphasize muscle strength, combine high resistance (heavy weight) with a low number of repetitions (8 to 12).[33] To emphasize muscle power, combine moderate resistance (light to medium weight) with high velocity (as fast as safely possible). To emphasize muscle endurance, combine less resistance (lighter weight) with more repetitions (15 to 20). Resistance training enhances performance in other sports too. Swimmers can develop a more efficient stroke and tennis players a more powerful serve when they train with weights, for example.

### A Balanced Fitness Program

The intensity and type of physical activities that are best for one person may not be good for another. A person who has been sedentary will initially perform at a dramatically different level of intensity than a fit person.

The type of physical activity that is best for you depends, too, on what you want to achieve and what you enjoy doing. Some people love walking, whereas others prefer to dance or ride a bike. Those who want to be stronger and firmer, lift weights. Keep in mind that muscle is more metabolically active than body fat, so the more muscle you have, the more energy you'll expend.

In a balanced fitness program, aerobic activity improves cardiorespiratory fitness, stretching enhances flexibility, and resistance training develops muscle strength, muscle power, and muscle endurance. Table 14-3 provides an example of a balanced fitness program.

**TABLE 14-3 A Sample Balanced Fitness Program**

**Monday, Tuesday, Wednesday, Thursday, Friday:**

- 5 minutes of warm-up activity
- 30–60 minutes of aerobic activity
- 10 minutes of cool-down activity and stretching

**Tuesday, Thursday, Saturday:**

- 5 minutes of warm-up activity
- 30 minutes of resistance training
- 10 minutes of cool-down activity and stretching

**Saturday and/or Sunday:**

- Sports, walking, hiking, biking, or swimming

© Cengage Learning

**resistance training:** the use of free weights or weight machines to provide resistance for developing muscle strength, power, and endurance; also called *weight training*. A person's own body weight may also be used to provide resistance such as when a person does push-ups, pull-ups, or abdominal crunches.

**muscle power:** the product of force generation (strength) and movement velocity (speed); the speed at which a given amount of exertion is completed.

› **REVIEW IT** Describe the health benefits of being physically fit and explain how to develop the components of fitness.

Physical activity brings good health and long life. To develop fitness—whose components are flexibility, cardiorespiratory endurance, muscle strength and endurance, and body composition—a person must condition the body, through training, to adapt to the activity performed.

## 14.2 Energy Systems and Fuels to Support Activity

› **LEARN IT** Identify the factors that influence fuel use during physical activity and the types of activities that depend more on glucose or fat, respectively.

Nutrition and physical activity go hand in hand. Activity demands carbohydrate and fat as fuel, protein to build and maintain lean tissues, vitamins and minerals to support both energy metabolism and tissue building, and water to help distribute the fuels and to dissipate the resulting heat and wastes. This section describes how nutrition supports a person who decides to get up and go.

### The Energy Systems of Physical Activity

As Chapter 7 describes, the high-energy compound ATP provides the energy that powers all the activities of living cells. ATP is present in small amounts in all body tissues all the time, and it can deliver energy instantly. Muscle cells may need additional ATP to power their many activities. When an ATP molecule is split in the muscle cells, the energy released contracts muscles and generates heat. Thus physical exertion consumes ATP. Three major energy systems enable muscle cells to regenerate ATP during different types of physical activity:

- the phosphagen system (also called the creatine phosphate system)
- the lactic acid system (anaerobic glycolysis)
- the aerobic system (aerobic glycolysis, fatty acid oxidation, and TCA cycle)

All three energy systems function at all times, but depending on the intensity of the activity and the conditioning of the athlete, one system will predominate at any given time. The following sections describe each of these systems.

#### The Phosphagen System

Immediately after the onset of a demand, before muscle ATP pools dwindle, a muscle enzyme begins to break down another high-energy compound that is stored in the muscle, **creatine phosphate (CP).** CP is made from creatine, a compound commonly found in muscles, with a phosphate group attached. CP can split anaerobically (not requiring oxygen) to release phosphate, which can be used to replenish ATP. Supplies of CP in a muscle last for only about 10 seconds, producing enough quick energy, without oxygen, for a 100-meter dash.

When activity ceases and the muscles are resting, ATP gives up one of its phosphate groups to creatine. Thus CP is produced during rest by reversing the process that occurs during muscular activity. (Highlight 14 includes creatine supplements in its discussion of substances commonly used in the pursuit of fitness.)

**creatine phosphate (CP):** a high-energy compound in muscle cells that acts as a reservoir of energy that can maintain a steady supply of ATP. CP provides the energy for short bursts of activity; also called *phosphocreatine*.

- During rest: ATP + creatine → CP
- During activity: CP → ATP + creatine

#### The Lactic Acid System

After the first 10 seconds or so of intense activity, energy from the phosphagen system diminishes, so muscle cells call upon the lactic acid system to produce more ATP. As Chapter 7 describes, the lactic acid system involves the anaerobic breakdown of glucose to pyruvate (and then of pyruvate to lactate). The primary source of glucose is muscle glycogen. This system can generate a small amount of ATP quickly for high-intensity activity lasting up to 3 minutes. A later section describes the consequences of lactate accumulation.

#### The Aerobic System

To meet the more prolonged demands of sustained activity, the muscles rely on the aerobic system to provide ATP for muscle contraction. As Chapter 7 describes, carbohydrate, fat, and some amino acids are continuously oxidized to ensure an uninterrupted supply of ATP.

Pete Saloutos/UpperCut Images/Alamy

Sustained muscular efforts as in a long-distance rowing event or a cross-country run involve *aerobic* work.

© Comstock/JupiterImages

Split-second surges of power as in the heave of a barbell or jump of a basketball player involve *anaerobic* work.

During rest, the body derives more than half of its ATP from the oxidation of fatty acids, most of the rest from the complete oxidation of glucose, and a small percentage from the oxidation of amino acids. During physical activity, the body adjusts its mixture of fuels. Muscles always use a mixture of fuels—never just one. How much of which fuel the muscles use during physical activity depends on an interplay among the fuels available from the diet, the intensity and duration of the activity, and the degree to which the body is conditioned to perform that activity. The next sections explain these relationships by examining each of the energy-yielding nutrients individually, but keep in mind that although one fuel may predominate at a given time, the other two will still be involved. Table 14-4 shows how fuel use changes according to the intensity and duration of the activity.

**Anaerobic versus Aerobic** Oxygen—or its lack—is central to the energy systems just described. The phosphagen and lactic acid systems are anaerobic—meaning without oxygen. As its name suggests, the aerobic system uses oxygen. As you read the following pages, notice how the fuel mixture shifts depending on whether the activity is anaerobic or aerobic.

Anaerobic activities are associated with strength, agility, and split-second surges of power. The jump of a slam dunk, the power of a tennis serve, and the heave of a

**TABLE 14-4 Primary Fuels Used for Activities of Different Intensities and Durations**

| Activity Intensity | Activity Duration | Energy System | Preferred Fuel Source | Oxygen Needed? | Activity Example |
|---|---|---|---|---|---|
| Extreme | 5 to 10 sec | Phosphagen system | ATP-CP (immediate availability) | No | 100-meter sprint, shot put, golf or baseball bat swing, tennis or volleyball serve |
| Very high | 20 sec to 2 min | Lactic acid system | ATP from carbohydrate (anaerobic glycolysis) | No | 400-meter run, 100-meter swim, gymnastic routines |
| High | 2 min to 20 min | Aerobic system | ATP from carbohydrate (glycolysis and TCA cycle) | Yes | Cycling, swimming, running |
| Moderate | > 20 min | Aerobic system | ATP from fat (fatty acid-oxidation and TCA cycle) | Yes | Hiking |

NOTE: All energy systems function at all times, but depending on the intensity of the activity and the conditioning of the athlete, one system will predominate at any given time.

bench press all involve anaerobic work. Such high-intensity, short-duration activities depend mostly on glucose as the chief energy fuel in the lactic acid system.

Endurance activities of low to moderate intensity and long duration depend more on fat to provide energy through the aerobic system. The ability to continue swimming to the shore, to keep on hiking to the top of the mountain, or to continue pedaling all the way home reflects aerobic capacity. As mentioned earlier, aerobic capacity is also crucial to maintaining a healthy heart and circulatory system. Because various physical activities use different energy systems and quantities of nutrients to various degrees, a person's food choices can greatly influence performance.

## Glucose Use during Physical Activity

Glucose, stored in the liver and muscles as glycogen, is vital to physical activity. During exertion, the liver breaks down its glycogen and releases the glucose into the bloodstream. The muscles use this glucose as well as their own private glycogen stores to fuel their work. Glycogen supplies can easily support everyday activities but are limited to less than 2000 kcalories of energy, enough for about 20 miles of running. The more athletes can fill muscle glycogen stores, the longer the glycogen will last during physical activity, which in turn influences performance. When glycogen is depleted, the muscles become fatigued.

### Diet Affects Glycogen Storage and Use

How much carbohydrate a person eats influences how much glycogen is stored. A classic study compared fuel use during activity among three groups of runners on different diets.[34] For several days before testing, one group consumed a normal mixed diet, a second group consumed a high-carbohydrate diet, and the third group consumed a no-carbohydrate diet (fat and protein diet). As Figure 14-1 shows, the high-carbohydrate diet allowed the runners to keep going longer before exhaustion. This study and many others that followed have confirmed that high-carbohydrate diets enhance endurance by ensuring ample glycogen stores. Thus, to fill glycogen stores, eat plenty of carbohydrate-rich foods.

### Intensity of Activity Affects Glycogen Use

How long an exercising person's glycogen will last depends not only on diet, but also on the intensity of the activity. Moderate activities such as jogging use glycogen slowly. The lungs and circulatory system have no trouble keeping up with the muscles' need for oxygen. The individual breathes easily, and the heart beats steadily—the activity is aerobic. The muscles derive their energy from both glucose and fatty acids. By depending partly on fatty acids, moderate aerobic activity conserves glycogen.

Intense activities—the kind that make it difficult "to catch your breath," such as a quarter-mile race—use glycogen quickly. In such activities, the muscles rely on the lactic acid system to break down glucose to pyruvate anaerobically, producing ATP quickly.

**> FIGURE 14-1 The Effect of Diet on Physical Endurance**

A high-carbohydrate diet can increase an athlete's endurance. In this study, the fat and protein diet provided 94 percent of kcalories from fat and 6 percent from protein; the normal mixed diet provided 55 percent of kcalories from carbohydrate; and the high-carbohydrate diet provided 83 percent of kcalories from carbohydrate.

### Lactate

When the rate of glycolysis exceeds the capacity of the mitochondria to accept hydrogens with their electrons for the electron transport chain, the accumulating pyruvate molecules are converted to lactate. Lactate is the product of anaerobic glycolysis. At low intensities, lactate is readily cleared from the blood, but at higher intensities, lactate accumulates. When the rate of lactate production exceeds the rate of clearance, intense activity can be maintained for only 1 to 3 minutes (as in a 400- to 800-meter race or a boxing match). Lactate has long been blamed for muscle fatigue, but research disputes this idea. Working muscles may produce lactate and experience fatigue, but the lactate does not cause the fatigue.[35]

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Lactate quickly leaves the muscles and travels in the blood to the liver. There, liver enzymes convert the lactate back into glucose. Glucose can then return to the muscles to fuel additional activity. (The recycling process that regenerates glucose from lactate is known as the *Cori cycle,* as shown in Figure 7-7 on p. 209.)

**Duration of Activity Affects Glycogen Use** Glycogen use depends not only on the intensity of an activity, but also on its duration. Initially, a person uses mostly glycogen for fuel. As the muscles devour their own glycogen, they become ravenous for more glucose. Glucagon signals the liver to empty out its glycogen stores to provide the muscles with more glucose.

A person who continues exercising moderately (mostly aerobically) begins to use less and less glucose and more and more fat for fuel (review Table 14-4 on p. 449). Still, glucose use continues, and if the activity lasts long enough and is intense enough, blood glucose declines and muscle and liver glycogen stores become depleted. Physical activity can continue for a short time thereafter only because glucagon signals the liver to produce, from lactate and certain amino acids, the minimum amount of glucose needed to briefly forestall total depletion.

David Leahy/The Image Bank/Getty Images

Moderate- to high-intensity aerobic exercises that can be sustained for only a short time (less than 20 minutes) use some fat, but more glucose for fuel.

**Glucose Depletion** Gluconeogenesis could support an activity of low intensity, such as walking, but cannot support continued strenuous activity. After a couple of hours of strenuous activity, glucose stores are depleted. When depletion occurs, it brings nervous system function to a near halt, making continued exertion at the same intensity almost impossible. Marathon runners refer to this point of glucose exhaustion as "hitting the wall."

To avoid such debilitation, endurance athletes try to maintain their blood glucose for as long as they can. The following guidelines will help endurance athletes maximize glucose supply:

- Eat a high-carbohydrate diet (approximately 8 grams of carbohydrate per kilogram of body weight or about 70 percent of energy intake) regularly.*
- Consume glucose (usually in sports drinks) periodically during activities that last for 1 hour or more.
- Eat carbohydrate-rich foods (approximately 60 grams of carbohydrate) immediately following activity; for example, a 16-ounce sports drink and a small bagel, 16 ounces of milk and four oatmeal cookies, or 8 ounces of pineapple juice and a granola bar.

Another strategy, **carbohydrate loading,** involves training the muscles to store as much glycogen as they can, while supplying the dietary glucose to enable them to do so. This strategy benefits endurance athletes who exercise at high intensity for longer than 90 minutes and who cannot meet their carbohydrate needs during competition. Although carbohydrate-loading can increase an individual's glycogen stores, performance may or may not improve. Those who exercise for shorter times or at a slower pace are better served by a regular high-carbohydrate diet. The last section of this chapter, "Diets for Physically Active People," discusses how to design a high-carbohydrate diet for performance.

**Glucose during Activity** Muscles can obtain the glucose they need not only from glycogen stores, but also from foods and beverages consumed during activity. Consuming carbohydrate is especially useful during exhausting endurance activities (lasting more than 1 hour) and during games such as soccer or hockey, which last for hours and demand repeated bursts of intense activity.[36]

*Percentage of energy intake is meaningful only when total energy intake is known. Consider that at high energy intakes (say, 5000 kcalories/day), even a moderate-carbohydrate diet (50 percent of energy intake) supplies 625 grams of carbohydrate—enough for a 165-pound (75 kilogram) athlete in heavy training. By comparison, at a moderate energy intake (2000 kcalories/day), a high-carbohydrate intake (70 percent of energy intake) supplies 350 grams—plenty of carbohydrate for most people, but not enough for athletes in heavy training.

**carbohydrate loading:** a regimen of moderate exercise followed by the consumption of a high-carbohydrate diet that enables muscles to store glycogen beyond their normal capacities; also called *glycogen loading* or *glycogen super compensation.*

Endurance athletes often run short of glucose by the end of competitive events. To ensure optimal carbohydrate intake, sports nutrition experts recommend 30 to 60 grams of carbohydrate per hour during prolonged events.[37] Carbohydrate-based sports drinks offer a convenient way to meet this recommendation and also help replace water and electrolyte losses, as a later section explains. Thus, to ensure optimal hydration and carbohydrate intake, endurance athletes are advised to drink one-half to one liter of a 4 to 8 percent carbohydrate-based sports drink per hour, in small, frequent doses during activity.[38] During the last stages of an endurance competition, when glycogen is running low, glucose consumed during the event can slowly make its way from the digestive tract to the muscles and augment the body's supply of glucose enough to forestall exhaustion.

Some researchers have questioned whether adding protein to carbohydrate-containing sports beverages would offer a performance advantage to endurance athletes.[39] Evidence so far suggests that when carbohydrate intake is optimal, protein provides no additional performance benefit.

**Glucose after Activity** Muscles depleted of glycogen have greater insulin sensitivity, which enhances glucose uptake and promotes glycogen synthesis. Thus, eating high-carbohydrate foods *after* physical activity also enlarges glycogen stores. To accelerate the rate of glycogen storage, train normally; then, within 2 hours after physical activity, consume a high-carbohydrate meal, such as a glass of orange juice and some graham crackers, toast, or cereal.[40] After 2 hours, the rate of glycogen storage declines by almost half. This strategy is particularly important to athletes who train hard more than once a day.

Chapter 4 introduces the glycemic response and discusses the possible health benefits of eating a *low*-glycemic diet. Such a diet may also benefit endurance performance. Some research indicates that foods with a low glycemic response enhance fatty acid availability and use during subsequent activity, thereby reducing reliance on the muscles' own lipid and glycogen stores.[41] More research is needed to confirm these findings.

**Training Affects Glycogen Use** Training, too, affects how much glycogen muscles will store. Muscle cells that repeatedly deplete their glycogen through hard work adapt to store greater amounts of glycogen to support that work.

Conditioned muscles also rely less on glycogen and more on fat for energy, so glycogen breakdown and glucose use occur more slowly in trained than in untrained individuals at a given work intensity. A person attempting an activity for the first time uses much more glucose than an athlete who is trained to perform the same activity. Oxygen delivery to the muscles by the heart and lungs plays a role, but equally importantly, trained muscles are better equipped to use the oxygen because their cells contain more mitochondria, the structures within a cell responsible for producing ATP (see Figure 7-14 on p. 213). Untrained muscles depend more heavily on anaerobic glucose breakdown, even when physical activity is just moderate.

Ryan McVay/Jupiter Images

Abundant energy from the breakdown of fat comes from aerobic metabolism.

## Fat Use during Physical Activity

Sports nutrition experts recommend that athletes consume 20 to 35 percent of their energy from fat to meet nutrient and energy needs—the same recommendation as for others.[42] Athletes who restrict fat below 20 percent of total energy intake may fail to consume adequate energy and nutrients. Recommendations to include vegetable oils, nuts, olives, fatty fish, and other sources of health-promoting fats in the diet apply to athletes as well as to everyone else.

Diets high in saturated fat carry risks of heart disease. Physical activity offers some protection against cardiovascular disease, but athletes may still suffer heart attacks and strokes. Limiting saturated fat intake to less than 10 percent of total energy intake is another way athletes can protect themselves from heart disease.

In contrast to *dietary* fat, *body* fat stores are extremely important during physical activity, as long as the activity is not too intense. Unlike glycogen stores, the body's fat stores can usually provide more than 70,000 kcalories and fuel hours of activity without running out.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The fat used in physical activity is liberated as fatty acids from the internal fat stores and from the fat under the skin. Areas that have the most fat to spare donate the greatest amounts to the blood (although they may not be the areas that appear fattiest). Thus "spot reducing" doesn't work because muscles do not "own" the fat that surrounds them. Fat cells release fatty acids into the blood, not into the underlying muscles. Then the blood gives to each muscle the amount of fat that it needs. Proof of this is found in a tennis player's arms—the skinfold measures of fat are the same in both arms, even though the muscles of one arm work much harder and may be larger than those of the other. A balanced fitness program that includes strength training will tighten muscles underneath the fat, improving the overall appearance. Keep in mind that some body fat is essential to good health. (Chapter 8 discusses the health risks of too little body fat.)

**Duration of Activity Affects Fat Use** Early in an activity, as the muscles draw on fatty acids, blood levels fall. If the activity continues for more than a few minutes, the hormone epinephrine signals the fat cells to begin breaking down their stored triglycerides and liberating fatty acids into the blood. As physical activity continues, the blood fatty acid concentration surpasses the normal resting concentration. Thereafter, sustained, moderate activity uses body fat stores as its major fuel.

**Intensity of Activity Affects Fat Use** The intensity of physical activity also affects fat use. As the intensity of activity increases, fat makes less and less of a contribution to the fuel mixture. Remember that fat can be broken down for energy only by aerobic metabolism. For fat to fuel activity, then, oxygen must be abundantly available. If a person is breathing easily during activity, the muscles are getting all the oxygen they need and are able to use more fat in the fuel mixture.

**Training Affects Fat Use** Training—repeated aerobic activity—produces the adaptations that permit the body to draw more heavily on fat for fuel. Training stimulates the muscle cells to manufacture more and larger mitochondria, the "powerhouse" structures of the cells that produce ATP for energy. Another adaptation: the heart and lungs become stronger and better able to deliver oxygen to muscles at high activity intensities. Still another: hormones in the body of a trained person slow glucose release from the liver and speed up the use of fat instead. These adaptations reward not only trained athletes but all active people; a person who trains in aerobic activities such as distance running or cycling becomes well suited to the activity.

Erik Isakson/Jupiter images

Low- to moderate-intensity aerobic exercises that can be sustained for a long time (more than 20 minutes) use some glucose, but more fat, for fuel.

## Protein Use during Physical Activity—and between Times

Table 14-4 on p. 449 summarizes the fuel uses discussed so far, but does not include the third energy-yielding nutrient, protein, because protein is not a major fuel for physical activity. Nevertheless, physically active people use protein just as other people do—to build muscle and other lean tissues and, to some extent, to fuel activity. The body does, however, handle protein differently during activity than during rest.

**Protein Used in Muscle Building** Synthesis of body proteins is suppressed during activity. In the hours of recovery following activity, though, protein synthesis accelerates beyond normal resting levels. As noted earlier, eating high-carbohydrate foods immediately after exercise accelerates muscle glycogen storage. Similarly, research shows that eating high-quality protein, either by itself or together with carbohydrate, enhances muscle protein synthesis.[43] With food intake, of course, insulin is secreted. Insulin not only stimulates muscle protein synthesis, but also greatly inhibits muscle protein breakdown.[44] Remember that the body adapts and builds the molecules, cells, and tissues it needs for the next period of activity. Whenever the body remodels a part of itself, it tears down old structures to make way for new ones. Repeated activity, with just a slight overload, triggers the protein-dismantling and protein-synthesizing equipment of each muscle cell to make needed changes—that is, to adapt.

The physical work of each muscle cell acts as a signal to its DNA and RNA to begin producing the kinds of proteins that will best support that work. Take running, for example. In the first difficult sessions, the body is not yet equipped

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

to perform aerobic work easily, but with each session, the cells' genetic material gets the message that an overhaul is needed. In the hours that follow the session, the genes send molecular messages to the protein-building equipment that tell it what old structures to break down and what new structures to build. Within the limits of its genetic potential, the body responds. Running (or any aerobic activity) stimulates synthesis of mitochondria to facilitate efficient aerobic metabolism. Over time, the body adapts and running becomes easier.

The body of a weightlifter responds to training as well, but the response differs from that of aerobic training. Weightlifting stimulates synthesis of muscle fiber protein to enhance muscle mass and strength—with little change in mitochondria. An athlete may add between ¼ ounce and 1 ounce (between 7 and 28 grams) of protein to muscle mass each day during active muscle-building phases of training.

**Protein Used as Fuel** Not only do athletes retain more protein in their muscles, but they also use more protein as fuel. Muscles speed up their use of amino acids for energy during physical activity, just as they speed up their use of fat and carbohydrate. Still, protein contributes only about 10 percent of the total fuel used, both during activity and during rest. The most active people of all—endurance athletes—use large amounts of all energy fuels, including protein, during performance, but they also eat more food and therefore usually consume enough protein.

**Diet Affects Protein Use during Activity** Diet influences how much protein is used during physical activity. People who consume diets adequate in energy and rich in *carbohydrate* use less protein than those who eat protein- and fat-rich diets. Recall that carbohydrates spare proteins from being broken down to make glucose when needed. Because physical activity requires glucose, a diet lacking in carbohydrate necessitates the conversion of amino acids to glucose. The same is true for a diet high in fat because fatty acids can never provide glucose. In short, to conserve protein, eat a diet adequate in energy and rich in carbohydrate.

**Intensity and Duration of Activity Affect Protein Use during Activity** The intensity and duration of activity also modifies protein use. Endurance athletes who train for more than an hour a day, engaging in aerobic activity of moderate intensity and long duration, may deplete their glycogen stores by the end of their workouts and become somewhat more dependent on body protein for energy.

In contrast, anaerobic strength training does not use more protein for energy, but it does demand more protein to build muscle. Thus the protein needs of both endurance and strength athletes are slightly higher than those of sedentary people, but certainly not as high as the protein intakes many athletes consume.

**Protein Recommendations for Active People** As mentioned, all active people, and especially athletes in training, probably need more protein than sedentary people do. Endurance athletes, such as long-distance runners and cyclists, use more protein for fuel than strength or power athletes do, and they retain some, especially in the muscles used for their sport. Strength athletes, such as weightlifters, and power athletes, such as football players, use less protein for fuel, but they still use some and retain much more. Therefore, *all* athletes in training should attend to protein needs, but they should first meet their energy needs with adequate carbohydrate intakes. Without adequate carbohydrate intake, athletes will burn off as fuel the very protein they wish to retain in muscle.

How much protein, then, should an active person consume? The DRI Committee does not recommend greater than normal protein intakes for athletes, but other authorities do.[45] Recommendations specify different protein intakes for athletes pursuing different activities (see Table 14-5).[46] Even the highest protein recommendations can be met without protein supplements, or even excessive servings of meat. Chapter 6 reviews the potential dangers of using protein and amino acid supplements (see pp. 190–191).

**› REVIEW IT** Identify the factors that influence fuel use during physical activity and the types of activities that depend more on glucose or fat, respectively.

The mixture of fuels the muscles use during physical activity depends on diet, the intensity and duration of the activity, and training. During intense activity, the fuel mix contains mostly glucose, whereas during less intense, moderate activity, fat makes a greater contribution. With endurance training, muscle cells adapt to store more glycogen and to rely less on glucose and more on fat for energy. Athletes in training may need more protein than sedentary people do, but they typically eat more food as well and therefore obtain enough protein without supplements.

## 14.3 Vitamins and Minerals to Support Activity

**› LEARN IT** List which vitamin and mineral supplements, if any, athletes may need and why.

Many of the vitamins and minerals assist in releasing energy from fuels and in transporting oxygen. This knowledge has led many people to believe, mistakenly, that vitamin and mineral *supplements* offer physically active people both health benefits and athletic advantages. (Review Highlight 10 for a discussion of vitamin and mineral supplements, and see Highlight 14, which explores supplements and other products people use in the hope of enhancing athletic performance.)

### Dietary Supplements

Nutrient supplements do not enhance the performance of well-nourished people. Deficiencies of vitamins and minerals, however, do impede performance. Regular, strenuous, physical activity increases the demand for energy, and athletes and active people tend to eat more food. If they select nutrient-dense foods to meet those increased energy needs, they will, in most cases, also meet their vitamin and mineral needs. Remember, however, that nutrient recommendations are based on the needs of healthy people in different life stages and do not reflect the potentially greater needs that some athletes may incur.

As Highlight 8 mentions, some athletes who struggle to meet low body-weight requirements may eat so little food that they fail to obtain all the nutrients they need.[47] The practice of "making weight" is opposed by many health and fitness organizations, but for athletes who choose this course of action, a single daily multivitamin-mineral supplement that provides no more than the DRI recommendations for nutrients may be beneficial. In addition, some athletes simply do not eat enough food to maintain a healthy body weight during times of intense training or competition. For these athletes as well, a daily multivitamin-mineral supplement can be helpful.

© IM_photo/Shutterstock.com

For perfect functioning, every nutrient is needed.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Some athletes believe that taking vitamin or mineral supplements directly before competition will enhance performance. These beliefs are contrary to scientific reality. Most vitamins and minerals function as small parts of larger working units. After absorption into the blood, these nutrients travel to the cells for assembly with their appropriate other parts before they can do their work. This takes time—hours or days. Vitamins or minerals taken right before an event are useless for improving performance, even if the person is actually suffering deficiencies of them.

## Nutrients of Concern

In general, then, active people who eat well-balanced meals do not need vitamin or mineral supplements. Two nutrients, vitamin E and iron, do merit special mention here, however, each for a different reason. Vitamin E is discussed because so many athletes take vitamin E supplements. Iron is discussed because some athletes may be unaware that they need iron supplements.

### Vitamin E

During prolonged, high-intensity physical activity, the muscles' consumption of oxygen increases tenfold or more, which increases the production of free radicals in the body.[48] As Highlight 11 explains, vitamin E is a potent antioxidant that vigorously defends cell membranes against the oxidative damage of free radicals.

Does vitamin E supplementation protect against exercise-induced oxidative stress? Some studies find that it does; others show no effect, and still others report enhanced oxidative stress.[49] Recent research may offer some insight into these inconsistencies. Although free radicals are usually damaging, during repeated episodes of endurance activities, they may actually be beneficial. Free radicals activate powerful antioxidant enzymes, which may enhance the athlete's tolerance to oxidative stresses.[50] Researchers speculate that antioxidant supplements such as vitamin E interfere with this protective adaptation. This may explain why, in some studies, athletes taking vitamin E show signs of increased oxidative stress. Clearly, more research is needed on supplements, but in the meantime, active people can benefit by using vitamin E–rich vegetable oils and eating generous servings of antioxidant-rich fruits and vegetables regularly. Beta-carotene and vitamin C in fruits and vegetables, as well as many of the phytochemicals in these foods, are also potent antioxidants.

### Iron Deficiency

Physically active young women, especially those who engage in endurance activities such as distance running, are prone to iron deficiency.[51] Habitually low intakes of iron-rich foods, high iron losses through menstruation, and the high demands of muscles for the iron-containing electron carriers of the mitochondria and the muscle protein myoglobin can contribute to iron deficiency in physically active young women. In addition, endurance activities temporarily increase the release of hepcidin, which limits iron absorption (see Chapter 13).[52]

Adolescent female athletes who eat vegetarian diets may be particularly vulnerable to iron deficiency. As Chapter 13 explains, the bioavailability of iron is often poor in vegetarian diets.[53] To protect against iron deficiency, vegetarian athletes need to select good dietary sources of iron (fortified cereals, legumes, nuts, and seeds) and include vitamin C–rich foods with each meal. So long as vegetarian athletes, like all athletes, consume enough nutrient-dense foods, they can perform as well as anyone.

### Iron-Deficiency Anemia

Iron-deficiency anemia impairs physical performance because iron is an essential component of hemoglobin. Without adequate iron, hemoglobin in red blood cells cannot deliver oxygen to the cells for energy metabolism. Without adequate oxygen, an active person cannot perform aerobic activities and tires easily. Iron deficiency without clinical signs of anemia may also impair physical performance.[54]

### Sports Anemia

Early in training, athletes may develop low blood hemoglobin for a while. This condition, sometimes called **sports anemia,** is not a true iron-deficiency condition. Strenuous aerobic activity promotes destruction of the more fragile, older red blood cells, and the resulting cleanup work reduces the blood's iron content temporarily. Strenuous activity also expands the blood's plasma volume, thereby reducing the red blood cell count per unit of blood. This low hematocrit looks like iron-deficiency anemia, but it is not the same.

**sports anemia:** a transient condition of low hemoglobin in the blood, associated with the early stages of sports training or other strenuous activity.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

In sports anemia, the red blood cells do not diminish in size or number as in anemia, so the oxygen-carrying capacity is not hindered. Most researchers view sports anemia as an *adaptive,* temporary response to endurance training. Iron-deficiency anemia requires iron supplementation, but sports anemia does not.

**Iron Recommendations for Athletes** The best strategy for maintaining adequate iron nutrition depends on the individual. Menstruating women may border on iron deficiency even without the iron losses incurred by physical activity. Active teens of both genders have high iron needs because they are growing. Especially for women and teens, then, prescribed supplements may be needed to correct iron deficiencies. Physicians use the results of blood tests to determine whether such supplementation is needed. (Review Chapter 13 for many more details about iron, and see Appendix E for a description of the tests used in assessing anemia.)

**› REVIEW IT** List which vitamin and mineral supplements, if any, athletes may need and why.

With the possible exception of iron, well-nourished active people and athletes do not need nutrient supplements. Women and teens may need to pay special attention to their iron needs.

## 14.4 Fluids and Electrolytes to Support Activity

**› LEARN IT** Identify the factors that influence an athlete's fluid needs and describe the differences between water and sports drinks.

The need for water far surpasses the need for any other nutrient. The body relies on watery fluids as the medium for all of its life-supporting activities, and if it loses too much water, its well-being will be compromised.

Obviously, the body loses water via sweat. Breathing uses water, too, exhaled as vapor. During physical activity, water losses from both routes are significant, and dehydration becomes a threat. Dehydration's first symptom is fatigue: a water loss of greater than 2 percent of body weight can reduce a person's capacity to do muscular work.[55] With a water loss of about 7 percent, a person is likely to collapse. For perspective, a water loss of 2 percent in a person weighing 150 pounds is equal to 3 pounds; a water loss of 7 percent is equal to 10.5 pounds.

**Temperature Regulation** As Chapter 7 discusses, working muscles produce heat as a by-product of energy metabolism. During intense activity, muscle heat production can be 15 to 20 times greater than at rest. The body cools itself by sweating. Each liter of sweat dissipates almost 600 kcalories of heat, preventing a rise in body temperature of almost 10 degrees on the Celsius scale.* The body routes its blood supply through the capillaries just under the skin, and the skin secretes sweat to evaporate and cool the skin and the underlying blood. The blood then flows back to cool the deeper body chambers.

**Hyperthermia** In hot, humid weather, sweat doesn't evaporate well because the surrounding air is already laden with water. In **hyperthermia,** body heat builds up and triggers maximum sweating, but without sweat evaporation, little cooling takes place. In such conditions, active people must take precautions to prevent **heat stroke.** To reduce the risk of heat stroke, drink enough fluid before and during the activity, rest in the shade when tired, and wear lightweight clothing that allows sweat to evaporate. (Hence the danger of rubber or heavy suits that supposedly promote weight loss during physical activity—they promote profuse sweating, prevent sweat evaporation, and invite heat stroke.) If you ever experience any of the symptoms of heat stroke listed in Table 14-6 (p. 458) stop your activity, ask for help, and cool down as quickly as possible. Heat stroke can be fatal, people often die of it, and these symptoms demand attention.

**Hypothermia** In cold weather, **hypothermia,** or low body temperature, can be as serious as heat stroke is in hot weather. Inexperienced, slow runners participating in long races on cold or wet, chilly days are especially vulnerable to

*10 degrees on the Celcius scale is about 18 degrees on the Fahrenheit scale.

Edward Frazer/Solus/Corbis

To prevent dehydration and the fatigue that accompanies it, drink liquids before, during, and after physical activity.

**hyperthermia:** an above-normal body temperature.

**heat stroke:** a dangerous accumulation of body heat with accompanying loss of body fluid.

**hypothermia:** a below-normal body temperature.

hypothermia. Slow runners who produce little heat can become too cold if clothing is inadequate. Early symptoms of hypothermia include feeling cold, shivering, apathy, and social withdrawal.[56] As body temperature continues to fall, shivering may stop, and disorientation, slurred speech, and change in behavior or appearance set in (see Table 14-6). People with these symptoms soon become helpless to protect themselves from further body heat losses. Even in cold weather, however, the active body still sweats and still needs fluids. The fluids should be warm or at room temperature to help protect against hypothermia.

**Fluid Replacement via Hydration** Endurance athletes can easily lose 1.5 liters or more of fluid during *each hour* of activity. Table 14-7 presents a suggested schedule of hydration for physical activity. To prepare for fluid losses, a person must hydrate before activity; to replace fluid losses, the person must rehydrate during and after activity. Even then, in hot weather, the GI tract may not be able to absorb enough water fast enough to keep up with sweat losses, and some degree of dehydration may be inevitable. Athletes who know their body's **hourly sweat rate** can strive to replace the total amount of fluid lost during activity to prevent dehydration.

Athletes who are preparing for competition are often advised to drink extra fluids in the *days* immediately before the event, especially if they are still training. The extra water is not stored in the body, but drinking extra water ensures maximum hydration at the start of the event. Full hydration is imperative for every athlete both in training and in competition. The athlete who arrives at an event even slightly dehydrated begins with a disadvantage.

**TABLE 14-7 Suggested Hydration Schedule for Physical Activity**

| Timing | Recommended Intakes (based on body weight) | Males | Females |
|---|---|---|---|
| ≥4 hours before activity | 1 oz/10 lb | 16 oz | 12 oz |
| 2 hours before activity, if heavy sweating is expected | Add 0.6 oz/10 lb | +9 oz | +7 oz |
| Every 15 min during activity | Drink enough to minimize loss of body weight, but don't drink too much | 8 oz | 4 oz |
| After activity | ≥2 cups for each pound of body weight lost[a] | | |

© Cengage Learning

NOTE: Intakes are based on a 70-kilogram (154-pound) man and a 55-kilogram (121-pound) woman.

[a]Drinking 2 cups of fluid every 20 to 30 minutes after exercise until the total amount required is consumed is more effective for rehydration than drinking the needed amount all at once. Rapid fluid replacement after exercise stimulates urine production and results in less body water retention.

SOURCE: C. A. Rosenbloom and E. J. Coleman, eds., *Sports Nutrition: A Practice Manual for Professionals* (Chicago: Academy of Nutrition and Dietetics, 2012), p. 115; Position of the American Dietetic Association, Dietitians of Canada, and the American College of Sports Medicine: Nutrition and athletic performance, *Journal of the American Dietetic Association* 109 (2009): 509–527; American College of Sports Medicine, Position stand; Exercise and fluid replacement, *Medicine and Science in Sports and Exercise* 39 (2007): 377–390.

**hourly sweat rate:** the amount of weight lost plus fluid consumed during exercise per hour. One pound equals roughly 2 cups (500 milliliters) of fluid.

What is the best fluid for an exercising body? For noncompetitive, everyday active people, plain, cool water is recommended, especially in warm weather, for two reasons: (1) water rapidly leaves the digestive tract to enter the tissues where it is needed, and (2) it cools the body from the inside out. For endurance athletes, carbohydrate-containing beverages may be appropriate. Fluid ingestion during the event has the dual purposes of replenishing water lost through sweating and providing a source of carbohydrate to supplement the body's limited glycogen stores. Many carbohydrate-containing sports drinks are marketed for active people; a later section compares them with water.

© Chuck Wagner/Shutterstock.com

Water is the best fluid for most physically active people, but some consumers prefer the flavors of sports drinks.

**Electrolyte Losses and Replacement** When a person sweats, small amounts of electrolytes—the electrically charged minerals sodium, potassium, chloride, and magnesium—are lost from the body along with water. Losses are greatest in beginners; training improves electrolyte retention.

To replenish lost electrolytes, a person ordinarily needs only to eat a regular diet that meets energy and nutrient needs. In events lasting more than 1 hour, sports drinks may be needed to replace fluids and electrolytes. Salt tablets can worsen dehydration and impair performance; they increase potassium losses, irritate the stomach, and cause vomiting. Endurance athletes considering the use of salt tablets to replace sodium are advised to consult with a health care professional before doing so.

**Hyponatremia** When athletes compete in endurance sports lasting longer than 3 hours, replenishing electrolytes is crucial. If athletes sweat profusely over a long period of time and do not replace lost sodium, a dangerous condition known as **hyponatremia** may result. Research shows that some athletes who sweat profusely may also lose more sodium in their sweat than others—and are prone to debilitating heat cramps.[57] These athletes lose twice as much sodium in sweat as athletes who don't cramp. Depending on individual variation, exercise intensity, and changes in ambient temperature and humidity, sweat rates for these athletes can exceed 2 liters per hour.

Hyponatremia may also occur when endurance athletes drink such large amounts of water over the course of a long event that they overhydrate, diluting the body's fluids to such an extent that the sodium concentration becomes extremely low. During long competitions, when athletes lose sodium through heavy sweating *and* consume excessive amounts of liquids, especially water, hyponatremia becomes likely.

Some athletes may still be vulnerable to hyponatremia even when they consume sports drinks during an event. Sports drinks do contain sodium, but as a later section points out, the sodium content of sports drinks is low and, in some cases, too low to replace sweat losses. Still, sports drinks do offer more sodium than plain water.

To prevent hyponatremia, athletes need to replace sodium during prolonged events. Sports drinks, salty pretzels, and other sodium sources can provide sodium during long competitions. Some athletes may need beverages with higher sodium concentrations than commercial sports drinks. In the days before the event, especially an event in the heat, athletes should not restrict salt in their diets. The symptoms of hyponatremia are similar to, but not the same as, those of dehydration (see Table 14-8).

**TABLE 14-8 Symptoms of Hyponatremia**

- Bloating, puffiness from water retention (shoes tight, rings tight)
- Confusion
- Seizure
- Severe headache
- Vomiting

© 2016 Cengage Learning

**hyponatremia** (HIGH-poe-na-TREE-mee-ah): a decreased concentration of sodium in the blood.

- **hypo** = below
- **natrium** = sodium (Na)
- **emia** = blood

## Sports Drinks

Hydration is critical to optimal performance. As stated earlier, water best meets the fluid needs of most people, yet manufacturers market many good-tasting sports drinks that deliver both fluid and carbohydrate for active people. The term *sports drink* generally refers to beverages that contain carbohydrates and electrolytes in specific concentrations, and they are the focus of this discussion.

## >How To

### Calculate the Carbohydrate Concentration of Sports Drinks

Sports drinks with a carbohydrate concentration of 6 to 8 percent best support athletes participating in events lasting 1 hour or longer. To calculate the carbohydrate concentration of a sports drink, divide the grams of carbohydrates per serving by the serving size (in milliliters) and multiply by 100.

Consider a sports drink that contains 22 grams of carbohydrates per serving and lists the serving size as 360 milliliters (12 ounces):

$$\frac{22 \text{ grams carbohydrate}}{360 \text{ milliliters}} = 0.06$$

$$0.06 \times 100 = 6\% \text{ carbohydrates}$$

› **TRY IT** Calculate the carbohydrate concentration of a sports drink that contains 14 grams of carbohydrate per serving (240 milliliters).

Many sports drinks compete for their share of the multi-billion-dollar market. What do sports drinks have to offer?

**Fluid** Sports drinks offer fluids to help offset the loss of fluids during physical activity, but plain water can do this too. Alternatively, diluted fruit juices or flavored water can be used if preferred to plain water.

**Glucose** Sports drinks offer simple sugars or **glucose polymers** that help maintain hydration and blood glucose and enhance performance as effectively as, or in some circumstances, even better than, water. Such measures are especially beneficial for strenuous endurance activities lasting longer than 1 hour, during intense activities, or during prolonged competitive games that demand repeated intermittent activity.[58] Sports drinks may also be used for events lasting less than 1 hour, although plain water is appropriate as well.

Fluid transport to the tissues from beverages containing up to 8 percent glucose is rapid. Most sports drinks contain about 7 percent carbohydrate (about half the sugar of ordinary soft drinks, or about 5 teaspoons in each 12 ounces). Less than 6 percent carbohydrate may not enhance performance, and more than 8 percent may cause abdominal cramps, nausea, and diarrhea. The accompanying "How To" feature describes how to calculate the carbohydrate concentration of sports drinks.

Although glucose can enhance endurance and performance in strenuous competitive events, for the moderate exerciser, it can be counterproductive if weight loss is the goal. Glucose is sugar, and like candy, it provides only empty kcalories—no vitamins or minerals. Most sports drinks provide between 50 and 100 kcalories per 8-ounce cup.

**Sodium and Other Electrolytes** Sports drinks offer sodium and other electrolytes to help replace those lost during physical activity. Sodium in sports drinks also helps to increase the rate of fluid absorption from the GI tract and maintain plasma volume during activity and recovery. Most physically active people do not need to replace the minerals lost in sweat immediately; a meal eaten within hours of competition replaces these minerals soon enough. Most sports drinks are relatively low in sodium, however, so those who choose to use these beverages run little risk of excessive intake.

**Good Taste** Manufacturers reason that if a drink tastes good, people will drink more, thereby ensuring adequate hydration. For athletes who prefer the flavors of sports drinks over water, it may be worth paying for good taste to replace lost fluids.

For athletes who exercise for 1 hour or more, sports drinks provide an advantage over water. Sports drinks may also be beneficial for athletes who:

- Exercise on an empty stomach
- Don't eat enough carbohydrate

**glucose polymers:** compounds that supply glucose, not as single molecules, but linked in chains somewhat like starch. The objective is to attract less water from the body into the digestive tract (osmotic attraction depends on the number, not the size, of particles).

- Want to load carbohydrates
- Want to gain weight
- Train at altitude or in extreme weather
- Had diarrhea (or vomiting) recently
- Refuse to drink adequate amounts of water

For most physically active people, though, water is the best fluid to replenish the body's lost fluids. The most important thing to do is drink—even if you don't feel thirsty.

**Enhanced Water** Another beverage often marketed to athletes and active people is **enhanced water.** Enhanced waters are lightly flavored waters with added sugars, vitamins, minerals, and in some cases, protein. They are neither natural nor healthy, as marketing ads claim. In fact, most enhanced waters contain small amounts of only a few minerals, some of the B vitamins, and sometimes vitamin C or vitamin E. In the context of daily needs, the vitamins and minerals in these drinks do not add up to much. For example, it takes a quart of most of these beverages to provide only 10 percent of the RDA for iron or calcium. Quite simply, enhanced waters are not a substitute for eating nutrient-rich fruits and vegetables. Enhanced waters may not be harmful (except maybe to the wallet), but most people do not need them. Plain water can meet fluid needs. If the flavor of enhanced waters encourages greater fluid intake, then they may offer some advantage. Serious endurance athletes need the carbohydrate-electrolyte sports drinks discussed earlier.

## Poor Beverage Choices: Caffeine and Alcohol

Athletes, like others, sometimes drink beverages that contain caffeine or alcohol. Each of these substances can influence physical performance.

**Caffeine** Caffeine is a stimulant, and athletes sometimes use it to enhance performance, as Highlight 14 explains. Carbonated soft drinks, with or without caffeine, may not be a wise choice for athletes: bubbles make a person feel full quickly and so limit fluid intake. Some of the increasingly popular beverages, called energy drinks, contain amounts of caffeine equivalent to a cup or two of coffee. When used in excess or in combination with stimulants or other unregulated substances, energy drinks can hinder performance and are potentially dangerous.[59] Another reason energy drinks should not be used for fluid replacement during athletic events is that the carbohydrate concentrations are too high for optimal fluid absorption. The caffeine contents of selected energy drinks are listed in the table at the beginning of Appendix H.

**Alcohol** Some athletes mistakenly believe that they can replace fluids and load up on carbohydrates by drinking beer. Beer is not carbohydrate-rich. A 12-ounce beer provides 13 grams of carbohydrate—one-third the amount of carbohydrate in a glass of orange juice the same size. In addition to carbohydrate, beer also contains alcohol, of course. Energy from alcohol breakdown generates heat, but it does not fuel muscle work because alcohol is metabolized in the liver.

Beer is not rich in vitamins or minerals. Beer contains traces of some B vitamins, but it cannot compete with food sources. As for minerals, beer contains a few minerals, but to replace the minerals lost in sweat, athletes need good sources such as fruit juices or sports drinks.

Alcohol's diuretic effect impairs the body's fluid balance, making dehydration likely. After physical activity, a person needs to replace fluids, not lose them by drinking beer. Alcohol also impairs the body's ability to regulate its temperature, increasing the likelihood of hypothermia or heat stroke.

It is difficult to overstate alcohol's detrimental effects on physical activity. Alcohol alters perceptions; slows reaction time; reduces strength, power, and endurance; and hinders accuracy, balance, eye-hand coordination, and coordination in general—all opposing optimal athletic performance. In addition, it deprives people of their judgment, thereby compromising safety in sports. Many sports-related fatalities and injuries involve alcohol or other drugs.

**enhanced water:** water that is fortified with ingredients such as vitamins, minerals, protein, oxygen, or herbs. Enhanced water is marketed as *vitamin water, sports water, oxygenated water,* and *protein water.*

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Clearly, alcohol impairs performance. For those who do drink, do not drink alcohol before exercising and drink plenty of water after exercising before drinking alcohol.

› **REVIEW IT** Identify the factors that influence an athlete's fluid needs and describe the differences between water and sports drinks.

Active people need to drink plenty of water; endurance athletes need to drink both water and carbohydrate-containing beverages, especially during training and competition. During events lasting longer than 3 hours, athletes need to pay special attention to replace sodium losses to prevent hyponatremia.

## 14.5 Diets for Physically Active People

› **LEARN IT** Discuss an appropriate daily eating pattern for athletes and list one example of a recommended pregame and recovery meal.

No one diet best supports physical performance. Active people who choose foods within the framework of the diet-planning principles presented in Chapter 2 can design many excellent diets.

### Choosing a Diet to Support Fitness

Above all, keep in mind that water is depleted more rapidly than any other nutrient. A diet to support fitness must provide water, energy, and all the other nutrients.[60]

**Water** Even casual exercisers must attend conscientiously to their fluid needs. Physical activity blunts the thirst mechanism, especially in cold weather. During activity, thirst signals come too late, so don't wait to feel thirsty before drinking. To find out how much water is needed to replenish activity losses, weigh yourself before and after the activity—the difference is almost all water. One pound equals roughly 2 cups (500 milliliters) of fluid.

**Nutrient Density** A healthful diet is based on nutrient-dense foods—foods that supply adequate vitamins and minerals for the energy they provide. Active people need to eat both for nutrient adequacy and for energy—and energy needs can be extremely high. For example, during training, meals for some Olympic athletes provide as much as 12,000 kcalories a day. Still, a nutrient-rich diet remains central for adequacy's sake. Though vital, energy alone is not enough to support performance. Table 14-9 offers convenient, nutrient-dense snack ideas for athletes and active people.[61]

**Carbohydrate** A diet that is high in carbohydrate (60 to 70 percent of total kcalories), moderate in fat (20 to 35 percent), and adequate in protein (10 to 20 percent) ensures full glycogen and other nutrient stores. On two occasions, however, the active person's regular high-carbohydrate, fiber-rich diet may require temporary adjustment. Both of these exceptions involve training for competition rather than

**TABLE 14-9 Nutrient-Dense Snacks for Athletes and Active People**

| One ounce of almonds provides protein, fiber, calcium, vitamin E, and healthy unsaturated fats. Similar choices include other nuts or trail mix consisting of dried fruit, nuts, and seeds. | Low-fat Greek yogurt contains more protein per serving than regular yogurt, but a little less calcium. A small amount of fresh fruit adds fiber and vitamins. A similar choice is low-fat cheese paired with fresh fruit. | Low-fat milk or chocolate milk together with fig bars or oatmeal-raisin cookies offer protein and fiber. A similar choice is whole-grain cereal with low-fat milk. | Popcorn offers fiber and a fruit smoothie quenches thirst and provides valuable vitamins. A similar choice is pretzels and fruit juice. |

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

for fitness in general. One special occasion is the pregame meal, when fiber-rich, bulky foods are best avoided. The pregame meal is discussed in a later section.

The other occasion is during intensive training, when energy needs may be so high as to outstrip the person's capacity to eat enough food to meet them. In this case, the athlete can add concentrated carbohydrate foods, such as dried fruits, sweet potatoes, and nectars, and even high-fat foods, such as avocados and nuts. Some athletes use commercial high-carbohydrate liquid supplements to obtain the carbohydrate and energy needed for intense training and top performance. These supplements do not *replace* regular food; they are meant to be used in *addition* to it. Unlike the sports drinks discussed earlier, these high-carbohydrate supplement beverages are too concentrated in carbohydrate to be used for fluid replacement.

**Protein** In addition to carbohydrate and some fat (and the energy they provide), physically active people need protein. Meats and milk products are rich protein sources, but recommending that active people emphasize these foods is narrow advice. As mentioned repeatedly, active people need diets rich in carbohydrate, and of course, meats have none to offer. Legumes, whole grains, and vegetables provide some protein with abundant carbohydrate.

## Meals before and after Competition

No single food improves speed, strength, or skill in competitive events, although some *kinds* of foods do support performance better than others, as already explained. Still, a competitor may eat a particular food before or after an event for psychological reasons. One eats a steak the night before wrestling. Another eats a spoonful of honey within 5 minutes of diving. So long as these practices remain harmless, they should be respected.

© Polara Studios Inc.

A variety of foods is the best source of nutrients for athletes.

**Pregame Meals** Science indicates that the pregame meal or snack should include plenty of fluids and be light and easy to digest. It should provide between 300 and 800 kcalories, primarily from carbohydrate-rich foods that are familiar and well tolerated by the athlete. The meal should end 3 to 4 hours before competition to allow time for the stomach to empty before exertion.

Breads, potatoes, pasta, and fruit juices—that is, carbohydrate-rich foods low in fat and fiber—form the basis of the best pregame meal (see Figure 14-2 on p. 464 for some examples). Bulky, fiber-rich foods such as raw vegetables or high-bran cereals, although usually desirable, are best avoided just before competition. Fiber in the digestive tract attracts water and can cause stomach discomfort during performance. Liquid meals are easy to digest, and many such meals are commercially available. Alternatively, athletes can mix fat-free milk or fruit juices, frozen fruits, and flavorings in a blender. For example, mixing fat-free milk or apple juice with a frozen banana and cinnamon or vanilla makes a tasty, high-carbohydrate, liquid pregame meal.

**Recovery Meals** Athletes who perform intense practice sessions several times a day or compete for hours on consecutive days need to quickly replenish glycogen to be ready for the next activity. As mentioned earlier, eating high-carbohydrate foods *after* physical activity enhances glycogen storage. Because people are usually not hungry immediately following physical activity, carbohydrate-containing beverages such as sports drinks or fruit juices may be preferred. If an active person does feel hungry after an event, then foods high in carbohydrate, moderate in protein, and low in fat and fiber are the ones to choose—similar to those recommended prior to competition.

**› REVIEW IT** Discuss an appropriate daily eating pattern for athletes and list one example of a recommended pregame and recovery meal.

The person who wants to excel physically will apply accurate nutrition knowledge along with dedication to rigorous training. A diet that provides ample fluid and includes a variety of nutrient-dense foods in quantities to meet energy needs will enhance not only athletic performance, but overall health as well. Carbohydrate-rich foods that are light and easy to digest are recommended for both the pregame and recovery meal.

**> FIGURE 14-2 Examples of High-Carbohydrate Pregame Meals**

Pregame meals should be eaten 3 to 4 hours before the event and provide 300 to 800 kcalories, primarily from carbohydrate-rich foods. Each of these sample meals provides at least 65 percent of total kcalories from carbohydrate.

***300-kcalorie meal***
1 large apple
4 saltine crackers
1½ tbs reduced-fat peanut butter

***500-kcalorie meal***
1 large whole-wheat bagel
2 tbs jelly
1½ c low-fat milk

***750-kcalorie meal***
1 large baked potato
2 tsp margarine
1 c steamed broccoli
1 c mixed carrots and green peas
5 vanilla wafers
1½ c apple or pineapple juice

© Matthew Farruggio (all)

Training and genetics being equal, who will win a competition? The athlete who habitually consumes inadequate amounts of needed nutrients will lag behind the competitor who arrives at the event with a long history of full nutrient stores and well-met metabolic needs. Some athletes learn that nutrition can support physical performance and turn to pills and powders instead of foods. In case you need further convincing that a healthful diet surpasses such potions, the following highlight addresses this issue.

## Nutrition Portfolio

The foods and beverages you eat and drink provide fuel and other nutrients to support your physical activity. Go to Diet & Wellness Plus and choose one of the days on which you tracked your diet and activity for an entire day. Select the Activities Spreadsheet report to help you answer the following.

- Describe your daily physical activities and how they compare with recommendations to be physically active for at least 30 minutes, and preferably 60 minutes, a day on most or all days of the week.

Now click on the Intake vs. Goals report and consider the following:

- Estimate your daily fluid intake, making note of whether you drink fluids, especially water, before, during, and after physical activity.
- Evaluate the carbohydrate contents of your diet and consider whether it would meet the needs of a physically active person.

DIET & WELLNESS PLUS

To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com**.

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

## Supplements as Ergogenic Aids

© stefanolunardi/Shutterstock.com

**› LEARN IT** Present arguments for and against the use of ergogenic aids.

Athletes gravitate to promises that they can enhance their performance by taking pills, powders, or potions. Unfortunately, they often hear such promises from their coaches and peers, who advise them to use dietary supplements, take drugs, or follow procedures that claim to deliver results with little effort.[1] When such performance-enhancing aids are harmless, they are only a waste of money; when they impair performance or harm health, they waste athletic potential and cost lives. This highlight looks at scientific evidence for and against dietary supplements and hormonal preparations available to athletes.

Many substances or treatments claim to be *ergogenic*, meaning work enhancing. In connection with athletic performance, **ergogenic aids** are substances or treatments that purportedly improve athletic performance above and beyond what is possible through training. For practical purposes, most ergogenic aids can be categorized as follows:[2]

- Those that perform as claimed
- Those that may perform as claimed but for which there is insufficient evidence at this time
- Those that do not perform as claimed
- Those that are dangerous, banned, or illegal, and therefore should not be used

The accompanying glossary defines several of the commonly used ergogenic aids discussed in this highlight.

For the vast majority of ergogenic aids, research findings do not support the claims made.[3] Athletes who hear that a product is ergogenic should ask who is making the claim and who will profit from the sale. Chapter 6 includes a discussion on protein powders and amino acid supplements (pp. 190–191).

Athletes who supplement their diets with products promoted to improve athletic performance should be aware that some supplements are contaminated with illegal substances such as steroids or stimulants that are not listed on the label.[4] Supplements contaminated with illegal substances pose health risks to those who use them as well as the risk of positive drug testing for athletes subject to such tests.

## GLOSSARY

**anabolic steroids:** drugs related to the male sex hormone, testosterone, that stimulate the development of lean body mass.

- **anabolic** = promoting growth
- **sterols** = compounds chemically related to cholesterol

**androstenedione:** *See DHEA.*

**beta-alanine:** a nonessential amino acid that is the rate-limiting precursor for the synthesis of the dipeptide carnosine. Carnosine acts primarily as a buffer in skeletal muscle. Beta-alanine supplements raise carnosine concentrations, which enhance the muscles' buffering capacity.

**beta-hydroxymethylbutyrate (HMB):** a metabolite of the amino acid leucine promoted to increase muscle mass and strength.

**caffeine:** a natural stimulant found in many common foods and beverages, including coffee, tea, and chocolate; may enhance endurance by stimulating fatty acid release. High doses cause headaches, trembling, rapid heart rate, and other undesirable side effects.

**carnitine:** a nonessential nonprotein amino acid made in the body from lysine that helps transport fatty acids across the mitochondrial membrane. As a supplement, carnitine supposedly "burns" fat and spares glycogen during endurance events, but in reality it does neither.

**chromium picolinate** (CROW-mee-um pick-oh-LYN-ate): a trace mineral supplement; falsely promoted as building muscle, enhancing energy, and burning fat. *Picolinate* is a derivative of the amino acid tryptophan that seems to enhance chromium absorption.

**convenient dietary supplements:** liquid meal replacers, energy drinks, energy bars, and energy gels that athletes and active people use to replenish energy and nutrients when time is limited.

**creatine** (KREE-ah-tin): a nitrogen-containing compound that combines with phosphate to form the high-energy compound creatine phosphate (or phosphocreatine) in muscles.

**DHEA (dehydroepiandrosterone) and androstenedione:** hormones made in the adrenal glands that serve as precursors to the male sex hormone, testosterone; falsely promoted as burning fat, building muscle, and slowing aging.

**ergogenic** (ER-go-JEN-ick) **aids:** substances or techniques used in an attempt to enhance physical performance.

- **ergo** = work
- **genic** = gives rise to

**hGH (human growth hormone):** a hormone produced by the brain's pituitary gland that regulates normal growth and development; also called *somatotropin.*

**ribose:** a naturally occurring 5-carbon sugar needed for the synthesis of ATP.

**sodium bicarbonate (baking soda):** a white crystalline powder that is used to buffer acid that accumulates in the muscles and blood during high-intensity exercise.

## Dietary Supplements that Perform as Claimed

Among the extensive array of dietary supplements and other ergogenic aids that athletes use, a few seem to live up to the claims made for them, based on research so far. Convenient dietary supplements, caffeine, creatine, sodium bicarbonate, and beta-alanine are the examples discussed here.

### Convenient Dietary Supplements

Ready-to-drink supplements such as liquid meal replacers and energy drinks, energy bars, and energy gels are **convenient dietary supplements** for athletes and active people, especially when time is limited. Many such products appeal to athletes by claiming to provide "complete" nutrition. These supplements usually taste good and provide extra carbohydrate and food energy, but they fall short of providing "complete" nutrition. They can be useful as a pregame meal or a between-meal snack, but they should not replace regular meals.

Liquid meal replacers may help a nervous athlete who cannot tolerate solid food on the day of an event. A liquid meal 2 to 3 hours before competition can supply some of the fluid and carbohydrate needed in a pregame meal, but a shake of fat-free milk or juice (such as apple or papaya) and frozen fat-free yogurt or frozen fruit (such as strawberries or bananas) can do the same thing less expensively.

### Caffeine

Some research supports the use of **caffeine** to enhance endurance and, to some extent, to enhance short-term, high-intensity exercise performance.[5] Caffeine may stimulate fatty acid release during endurance activity, but in contrast to what was previously thought, caffeine does not slow muscle glycogen use.[6] Light activity before a workout also stimulates fat release, and unlike caffeine, also warms the muscles and connective tissues, making them flexible and resistant to injury.

Caffeine is a stimulant that elicits a number of physiological and psychological effects in the body. Caffeine may enhance alertness and reduce the perception of fatigue.[7] The possible benefits of caffeine use must be weighed against its adverse effects—stomach upset, nervousness, irritability, headaches, and diarrhea. Caffeine-containing beverages should be used in moderation, if at all, and *in addition* to other fluids, not as a substitute for them.

Caffeine is a *restricted* substance by the National Collegiate Athletic Association, which allows urine concentrations of 15 milligrams per liter or less (equivalent to about 5 cups of coffee consumed within a few hours before testing). Urine tests that detect more caffeine than this disqualify athletes from competition. (The table at the start of Appendix H provides a list of common caffeine-containing items and the doses they deliver.)

### Creatine

Interest in—and use of—**creatine** supplements to enhance performance during intense activity has grown dramatically in the last few years. Power athletes such as weightlifters use creatine supplements to enhance stores of the high-energy compound creatine phosphate (CP) in muscles. Theoretically, the more creatine phosphate in muscles, the higher the intensity at which an athlete can train. High-intensity training stimulates the muscles to adapt, which in turn, improves performance.

Research suggests that creatine supplementation does enhance performance of short-term, repetitive, high-intensity activity such as weightlifting or sprinting.[8] Creatine may improve performance by increasing muscle strength and size, cell hydration, or glycogen loading capacity. In contrast, creatine supplementation has not been shown to benefit endurance activity.

The question of whether short-term use (up to a year) of creatine supplements (up to 5 grams per day) is safe continues to be studied, but so far, the supplements are considered safe for healthy adults.[9] More research is needed, however, to confirm the safety of larger doses and long-term use. Creatine supplementation may pose risks to athletes with kidney disease or other conditions.[10] One side effect of creatine supplementation that no one disputes is weight gain. For some athletes, weight gain, especially muscle gain, is beneficial, but for others, it is not.

Some medical and fitness experts voice concern that, like many performance enhancement supplements before it, creatine is being taken in huge doses (up to 30 *grams* per day) before evidence of its value has been ascertained. Even people who eat red meat, which is a creatine-rich food, do not consume nearly the amount supplements provide. (Creatine content varies, but on average, pork, chicken, and beef provide 65 to 180 *milligrams* per ounce.) Despite the uncertainties, creatine supplements are not illegal in international competition. The American Academy of Pediatrics strongly discourages the use of creatine supplements, as well as the use of any performance-enhancing substance in adolescents younger than 18 years old.

### Sodium Bicarbonate

During short-term, high-intensity activity, acid and carbon dioxide accumulate in the blood and muscles. **Sodium bicarbonate** (0.3 gram per kilogram of body weight) ingested prior to high-intensity sports performance buffers the acid and neutralizes the carbon dioxide, thereby maintaining muscle pH levels closer to normal and enhancing exercise capacity.[11] Sodium bicarbonate supplementation may cause unpleasant side effects such as diarrhea in some athletes.

### Beta-Alanine

**Beta-alanine** is a nonessential amino acid that has recently received much attention from exercise researchers.[12] Beta-alanine is the rate-limiting precursor for the synthesis of the dipeptide carnosine. Carnosine occurs in high concentrations in skeletal muscle and is one of the primary buffering substances available in muscles. Supplementation with beta-alanine has been shown to raise the concentration of muscle carnosine, which enhances the muscles' buffering

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

capacity.[13] This enhanced buffering is especially beneficial to high-intensity exercise performance such as sprinting. The only known adverse side effect of beta-alanine supplementation is a "pins and needles" sensation that occurs with high (more than 800 milligrams) single doses. Additional research is needed to confirm the safety of beta-alanine supplementation.[14]

# Dietary Supplements that May Perform as Claimed

For some dietary supplements, it is just too early to tell whether they deliver on the promises made for them because research thus far is inconclusive. Examples of supplements that may perform as claimed, but for which there is insufficient evidence of efficacy, include beta-hydroxymethylbutyrate and ribose.

## Beta-hydroxymethylbutyrate

**Beta-hydroxymethylbutyrate (HMB)** is a metabolite of the amino acid leucine. Supplementing the diet with HMB during training has been shown to increase muscle mass and strength, especially among untrained individuals.[15] Additional research is needed, however, to determine whether HMB supplementation in trained athletes enhances training adaptations.

## Ribose

Manufacturers of ribose supplements claim that **ribose** increases ATP and improves performance. Ribose, a naturally occurring sugar, does help resynthesize muscle ATP. Based on research thus far, however, ribose supplements do not improve athletic performance.[16]

# Dietary Supplements that Do Not Perform as Claimed

Most of the dietary supplements promoted as ergogenic aids fall into the category of "those that do not perform as claimed." Carnitine and chromium picolinate are two examples of ineffective supplements discussed here, but others include bee pollen, boron, coenzyme Q, ginseng, pyruvate, and vanadium.[17]

## Carnitine

In the body, **carnitine** facilitates the transfer of fatty acids across the mitochondrial membrane. Supplement manufacturers suggest that with more carnitine available, fat oxidation will be enhanced, but this does not seem to be the case. Carnitine supplements neither raise muscle carnitine concentrations nor enhance exercise performance. Milk and meat products are good sources of carnitine, and supplements are not needed.

## Chromium Picolinate

Chapter 13 introduces chromium as an essential trace mineral involved in carbohydrate and lipid metabolism. Claims that **chromium picolinate,** which is more easily absorbed than chromium alone, builds muscle, enhances energy, and burns fat derive from one or two early studies reporting that men who strength-trained while taking chromium picolinate supplements increased lean body mass and reduced body fat. Most subsequent studies, however, show no effects of chromium picolinate on strength, lean body mass, or body fat. Chromium-rich foods include whole grains, liver, and nuts.

# Dangerous, Banned, or Illegal Supplements

The dietary supplements discussed thus far may or may not help athletic performance, but in the doses commonly taken, they seem to cause little harm. The remaining discussion features hormonal preparations that are clearly damaging: anabolic steroids, DHEA (dehydroepiandrosterone), androstenedione, and hGH (human growth hormone). All of these ergogenic aids are dangerous to use and are banned by most professional sports leagues and the World Anti-Doping Agency (WADA) established by the International Olympic Committee. The American Academy of Pediatrics and the American College of Sports Medicine also condemn athletes' use of these substances.

## Anabolic Steroids

Among the most dangerous and illegal ergogenic practices is the taking of **anabolic steroids.** These drugs are derived from the male sex hormone testosterone, which promotes the development of male characteristics and lean body mass. Athletes who take steroids do so to stimulate muscle bulking.

The known toxic side effects of steroids include, but are not limited to, extreme aggression and hostility, heart disease, and liver damage. Taking these drugs is a form of cheating. Other athletes are put in the difficult position of either conceding an unfair advantage to competitors who use steroids or taking steroids and accepting the risk of harmful side effects. Athletes, especially young athletes, should not be forced to make such a choice.

The price for the potential competitive edge that steroids confer is high—sometimes it is life itself. Steroids are not simple pills that build bigger muscles. They are complex chemicals to which the body reacts in many ways, particularly when bodybuilders and other athletes take large amounts. The safest, most effective way to build muscle has always been through hard training and a sound diet, and—despite popular misconceptions—it still is.

Some manufacturers peddle specific herbs as legal substitutes for steroid drugs. They falsely claim that these herbs contain hormones, enhance the body's hormonal activity, or both. In some cases, an herb may contain plant sterols, such as gamma-oryzanol, but these

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

compounds are poorly absorbed. Even if absorption occurs, the body cannot convert herbal compounds to anabolic steroids. None of these products has any proven anabolic steroid activity, none enhances muscle strength, and some contain natural toxins. In short, "natural" does not mean "harmless."

## DHEA and Androstenedione

Some athletes use **DHEA** and **androstenedione** as alternatives to anabolic steroids. DHEA (dehydroepiandrosterone) and androstenedione are hormones made in the adrenal glands that serve as precursors to the male hormone testosterone. Advertisements claim the hormones "burn fat," "build muscle," and "slow aging," but evidence to support such claims is lacking.

Short-term side effects of DHEA and androstenedione may include oily skin, acne, body hair growth, liver enlargement, testicular shrinkage, and aggressive behavior. Long-term effects such as serious liver damage may take years to become evident. The potential for harm from DHEA and androstenedione supplements is great, and athletes, as well as others, should avoid them.

## Human Growth Hormone

A wide range of athletes, including weightlifters, baseball players, cyclists, and track and field participants use **hGH (human growth hormone)** to build lean tissue and improve athletic performance. The athletes use hGH, believing the injectable hormone will provide the benefits of anabolic steroids without the dangerous side effects.

Taken in large quantities, hGH causes the disease acromegaly, in which the body becomes huge and the organs and bones overenlarge. Other effects include diabetes, thyroid disorder, heart disease, menstrual irregularities, diminished sexual desire, and shortened life span.

Sometimes it is difficult to distinguish valid claims from bogus ones. Fitness magazines and Internet websites are particularly troublesome because many of them present both valid and invalid nutrition information along with slick advertisements for nutrition products. Advertisements often feature colorful anatomical figures, graphs, and tables that appear scientific. Some ads even include references, citing or linking to such credible sources as the *American Journal of Clinical Nutrition* and the *Journal of the American Medical Association*. These ads create the illusion of endorsement and credibility to gain readers' trust. Keep in mind, however, that the ads are created not to teach, but to sell. A careful reading of the cited research might reveal that the ads have presented the research findings out of context. For example, an ad might use a research article to conclude that its human growth hormone supplement "increases lean body mass and bone mineral," when in fact, the researchers would conclude that "its general use now or in the immediate future is not justified." Scientific facts are often exaggerated and twisted to promote sales. Highlight 1 describes ways to recognize misinformation and quackery.

The search for a single food, nutrient, drug, or technique that will safely and effectively enhance athletic performance will no doubt continue as long as people strive to achieve excellence in sports. When athletic performance does improve after use of an ergogenic aid, the improvement can often be attributed to the placebo effect, which is strongly at work in athletes. Even if a reliable source reports a performance boost from a newly tried product, give the effect time to fade away. Chances are excellent that it simply reflects the power of the mind over the body.

The overwhelming majority of performance-enhancing aids sold for athletes are frauds. Wishful thinking will not substitute for talent, hard training, adequate diet, and mental preparedness in competition. But don't discount the power of mind over body for a minute—it is formidable, and sports psychologists dedicate their work to harnessing it. You can use it by imagining yourself a winner and visualizing yourself excelling in your sport. You don't have to buy magic to obtain a winning edge; you already possess it—your physically fit mind and body.

# CRITICAL THINKING QUESTIONS

A. What are the moral implications of using ergogenic aids?
B. Because of serious doping violations, Lance Armstrong was stripped of his seven Tour de France titles and banned from cycling for life. For him, these actions are "equivalent to a death sentence." What is your opinion of Armstrong's doping violations and the imposed consequences? If you were a member of the International Cycling Union, how would you propose determining which, if any, substances to allow and/or ban?

# Life Cycle Nutrition: Pregnancy and Lactation

## Nutrition in Your Life

Food choices have consequences. Sometimes they are immediate, such as when you get heartburn after eating a pepperoni pizza. Other times they sneak up on you, such as when you gain weight after repeatedly overindulging in hot fudge sundaes. Quite often, they are temporary and easily resolved, such as when hunger pangs strike after you skip lunch. During pregnancy, however, the consequences of a woman's food choices are dramatic. They affect not only her health, but also the growth and development of another human being—and not just for today, but for years to come. Making smart food choices is a huge responsibility, but fortunately, it's fairly simple. In the Nutrition Portfolio at the end of this chapter, you can determine how well your current diet might support the needs of a pregnant woman.

Each person enters this world with a unique genetic map that determines the primary ways that person's physical and mental characteristics will develop throughout life. Some of those characteristics cannot be changed, but others can be influenced within genetically defined limits. One of several ways to ensure the optimal growth, maintenance, and health of the body is through proper nutrition. Ideally, a person's diet supplies sufficient amounts of all the nutrients to meet the needs incurred by the physiological demands of pregnancy, lactation, growth, and aging.

All people—pregnant and lactating women, infants, children, adolescents, and adults—need the same nutrients, but the amounts they need vary depending on their stage of life. This chapter focuses on nutrition in preparation for, and support of, pregnancy and lactation. The next two chapters address the needs of infants, children, adolescents, and older adults.

### LEARNING GPS

**15.1 Nutrition prior to Pregnancy 474**
**LEARN IT** List the ways men and women can prepare for a healthy pregnancy.

**15.2 Growth and Development during Pregnancy 475**
**LEARN IT** Describe fetal development from conception to birth and explain how maternal malnutrition can affect critical periods.
- Placental Development 475
- Fetal Growth and Development 475
- Critical Periods 476

**15.3 Maternal Weight 480**
**LEARN IT** Explain how both underweight and overweight can interfere with a healthy pregnancy and how weight gain and physical activity can support maternal health and infant growth.
- Weight prior to Conception 480
- Weight Gain during Pregnancy 480
- Exercise during Pregnancy 482

**15.4 Nutrition during Pregnancy 483**
**LEARN IT** Summarize the nutrient needs of women during pregnancy.
- Energy and Nutrient Needs during Pregnancy 484
- Vegetarian Diets during Pregnancy and Lactation 487
- Common Nutrition-Related Concerns of Pregnancy 487

**15.5 High-Risk Pregnancies 488**
**LEARN IT** Identify factors predicting low-risk and high-risk pregnancies and describe ways to manage them.
- The Infant's Birthweight 489
- Malnutrition and Pregnancy 489
- Food Assistance Programs 490
- Maternal Health 490
- The Mother's Age 492

Young adults can prepare for a healthy pregnancy by taking care of themselves today.

# 15.1 Nutrition prior to Pregnancy

**› LEARN IT** List the ways men and women can prepare for a healthy pregnancy.

Both a man's and a woman's nutrition may affect **fertility** and possibly the genetic contributions they make to their children, but it is the woman's nutrition that has the most direct influence on the developing fetus.[1] Her body provides the environment for the growth and development of a new human being. Prior to pregnancy, however, both men and women have a unique opportunity to prepare physically, mentally, and emotionally for the many changes to come.[2] In preparation for a healthy pregnancy, they can establish the following habits:

- *Achieve and maintain a healthy body weight.* Both underweight and overweight are associated with infertility. Overweight and obese men have low sperm counts and hormonal changes that reduce fertility.[3] Excess body fat in women disrupts menstrual regularity and ovarian hormone production.[4] Should a pregnancy occur, mothers, both underweight and overweight, and their newborns, face increased risks of complications.
- *Choose an adequate and balanced diet.* Malnutrition reduces fertility and impairs the early development of an infant should a woman become pregnant. In contrast, a healthy diet that includes a full array of vitamins and minerals can favorably influence fertility.[5] Men with diets rich in antioxidant nutrients and low in saturated fats have higher sperm numbers and motility.[6]
- *Be physically active.* A woman who wants to be physically active *when* she is pregnant needs to become physically active *beforehand*.
- *Receive regular medical care.* Regular health-care visits help ensure a healthy start to pregnancy.
- *Manage chronic conditions.* Conditions such as diabetes, hypertension, HIV/AIDS, phenylketonuria (PKU), and sexually transmitted diseases can adversely affect a pregnancy and need close medical attention to help ensure a healthy outcome.
- *Avoid harmful influences.* Both maternal and paternal ingestion of, or exposure to, harmful substances (such as cigarettes, alcohol, drugs, or environmental contaminants) can cause miscarriage or abnormalities, alter genes or their expression, and may interfere with fertility.[7]

Young adults who nourish and protect their bodies do so not only for their own sakes, but also for future generations.

**> DIETARY GUIDELINES FOR AMERICANS**

Women who are capable of becoming pregnant should:

- Achieve and maintain a healthy weight before becoming pregnant.
- Choose foods that supply heme iron, which is more readily absorbed by the body, additional iron sources, and enhancers of iron absorption such as vitamin C–rich foods.
- Consume 400 micrograms per day of synthetic folate from fortified foods and/or supplements in addition to folate from a varied diet.

**› REVIEW IT** List the ways men and women can prepare for a healthy pregnancy.

Prior to pregnancy, the health and behaviors of both men and women can influence fertility and fetal development. In preparation, they can achieve and maintain a healthy body weight, choose an adequate and balanced diet, be physically active, receive regular medical care, manage chronic diseases, and avoid harmful influences.

**fertility:** the capacity of a woman to produce a normal ovum periodically and of a man to produce normal sperm; the ability to reproduce.

# 15.2 Growth and Development during Pregnancy

**› LEARN IT** Describe fetal development from conception to birth and explain how maternal malnutrition can affect critical periods.

A whole new life begins at **conception.** Organ systems develop rapidly, and nutrition plays many supportive roles. This section describes placental development and fetal growth, paying close attention to times of intense developmental activity.

## Placental Development

In the early days of pregnancy, a spongy structure known as the **placenta** develops in the **uterus.** Two associated structures also form (see Figure 15-1). One is the **amniotic sac,** a fluid-filled balloonlike structure that houses the developing fetus. The other is the **umbilical cord,** a ropelike structure containing fetal blood vessels that extends through the fetus's "belly button" (the umbilicus) to the placenta. These three structures play crucial roles during pregnancy, and then are expelled from the uterus during childbirth.

The placenta develops as an interweaving of fetal and maternal blood vessels embedded in the uterine wall. The maternal blood transfers oxygen and nutrients to the fetus's blood and picks up fetal waste products. By exchanging oxygen, nutrients, and waste products, the placenta performs the respiratory, absorptive, and excretory functions that the fetus's lungs, digestive system, and kidneys will provide after birth.

The placenta is a versatile, metabolically active organ. Like all body tissues, the placenta uses energy and nutrients to support its work. It produces an array of hormones that maintain pregnancy and prepare the mother's breasts for lactation (making milk). A healthy placenta is essential for the developing fetus to attain its full potential.[8]

## Fetal Growth and Development

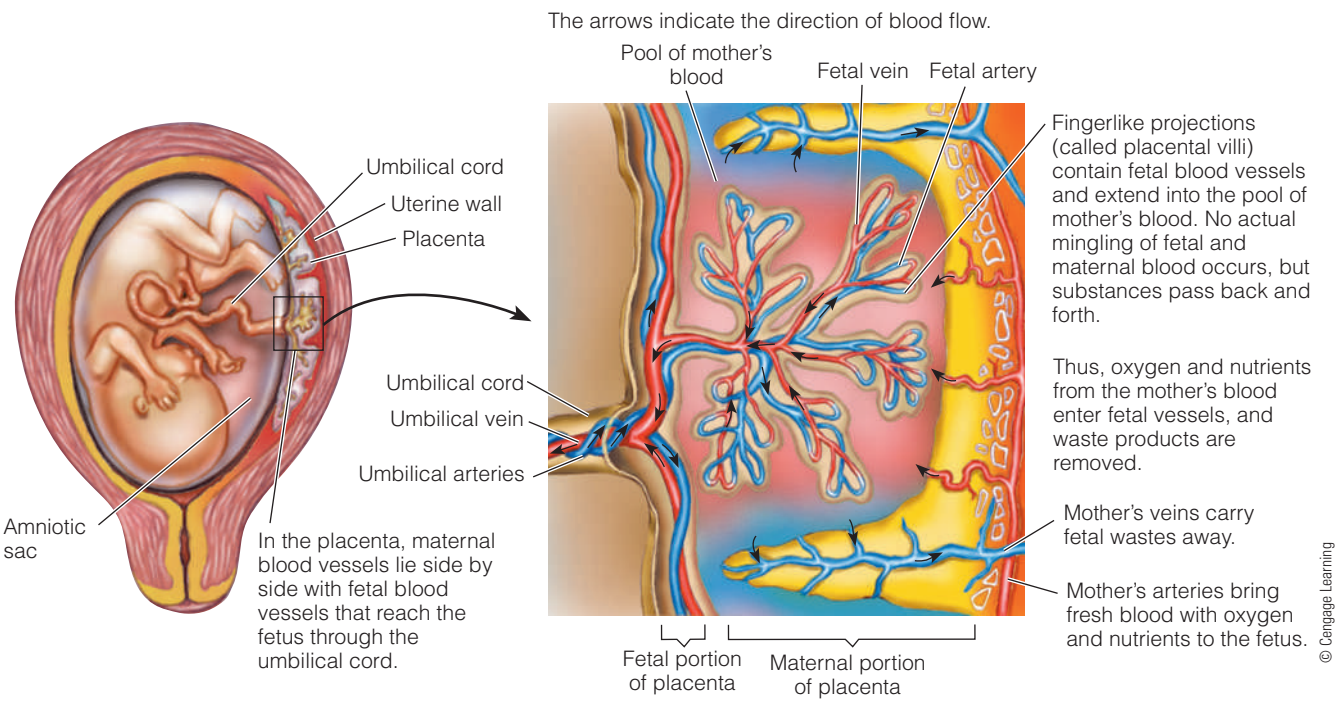
Fetal development begins with the fertilization of an **ovum** by a **sperm.** Three stages follow: the zygote, the embryo, and the fetus (see Figure 15-2, p. 476).

**conception:** the union of the male sperm and the female ovum; fertilization.

**placenta** (plah-SEN-tuh): the organ that develops inside the uterus early in pregnancy, through which the fetus receives nutrients and oxygen and returns carbon dioxide and other waste products to be excreted.

**uterus** (YOU-ter-us): the muscular organ within which the infant develops before birth.

**amniotic** (am-nee-OTT-ic) **sac:** the "bag of waters" in the uterus, in which the fetus floats.



**umbilical** (um-BILL-ih-cul) **cord:** the ropelike structure through which the fetus's veins and arteries reach the placenta; the route of nourishment and oxygen to the fetus and the route of waste disposal from the fetus. The scar in the middle of the abdomen that marks the former attachment of the umbilical cord is the *umbilicus* (um-BILL-ih-cus), commonly known as the "belly button."

**ovum** (OH-vum): the female reproductive cell, capable of developing into a new organism upon fertilization; commonly referred to as an egg.

**sperm:** the male reproductive cell, capable of fertilizing an ovum.

**> FIGURE 15-1 The Placenta and Associated Structures**

To understand how placental villi absorb nutrients without maternal and fetal blood interacting directly, think of how the intestinal villi work. The GI side of the intestinal villi is bathed in a nutrient-rich fluid (chyme). The intestinal villi absorb the nutrient molecules and release them into the body via capillaries. Similarly, the maternal side of the placental villi is bathed in nutrient-rich maternal blood. The placental villi absorb the nutrient molecules and release them to the fetus via fetal capillaries.

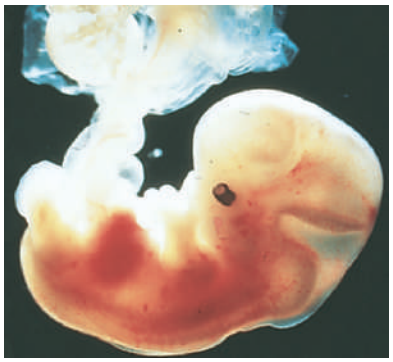
> **FIGURE 15-2 Stages of Embryonic and Fetal Development**



Petit Format/Nestle/Science Source (photos 1, 2, 3)

1 A newly fertilized ovum is called a **zygote** and is about the size of the period at the end of this sentence. Less than 1 week after fertilization, these cells have rapidly divided multiple times to become a blastocyst ready for implantation.

3 A **fetus** after 11 weeks of development is just over an inch long. Notice the umbilical cord and blood vessels connecting the fetus with the placenta.

2 After implantation, the placenta develops and begins to provide nourishment to the developing embryo. An **embryo** 5 weeks after fertilization is about ½ inch long.

© Cindy Vannelli

4 A **newborn infant** after 9 months of development measures close to 20 inches in length. From 8 weeks to term, this infant grew 20 times longer and 50 times heavier.

**The Zygote** The newly fertilized ovum is called a **zygote.** It begins as a single cell and rapidly divides to become a **blastocyst.** During that first week, the blastocyst floats down into the uterus, where it will embed itself in the inner uterine wall—a process known as **implantation.** Cell division continues at an amazing rate as each set of cells divides into many other cells.

**The Embryo** At first, the number of cells in the **embryo** doubles approximately every 24 hours; later the rate slows, and only one doubling occurs during the final 10 weeks of pregnancy. At 8 weeks, the 1¼-inch embryo has a complete central nervous system, a beating heart, a digestive system, well-defined fingers and toes, and the beginnings of facial features.

**The Fetus** The **fetus** continues to grow during the next 7 months. Each organ grows to maturity according to its own schedule, with greater intensity at some times than at others. As Figure 15-2 shows, fetal growth is phenomenal: weight increases from less than an ounce to about 7½ pounds (3500 grams). Most successful pregnancies are **full term**—defined as births occurring at 39 through 40 weeks—and produce a healthy infant weighing 6½ to 8 pounds.[9]

## Critical Periods

Times of intense development and rapid cell division are called **critical periods**—critical in the sense that those cellular activities can occur only at those times. If cell division and number are limited during a critical period, full recovery is not possible (see Figure 15-3). Damage during these critical times of pregnancy has permanent consequences for the life and health of the fetus.[10]

The development of each organ and tissue is most vulnerable to adverse influences (such as nutrient deficiencies or toxins) during its own critical period (see Figure 15-4). The neural tube, for example, is the structure that eventually becomes the brain and the spinal cord, and its critical period of development is from 17 to 30 days of **gestation.** Consequently, neural tube development is most vulnerable to nutrient deficiencies, nutrient excesses, or toxins during this critical time—when most women do not yet even realize they are pregnant. Any abnormal development of the neural tube or its failure to close completely can cause a major defect in the central nervous system.

**zygote** (ZY-goat): the initial product of the union of ovum and sperm; a fertilized ovum.

**blastocyst** (BLASS-toe-sist): the developmental stage of the zygote when it is about 5 days old and ready for implantation.

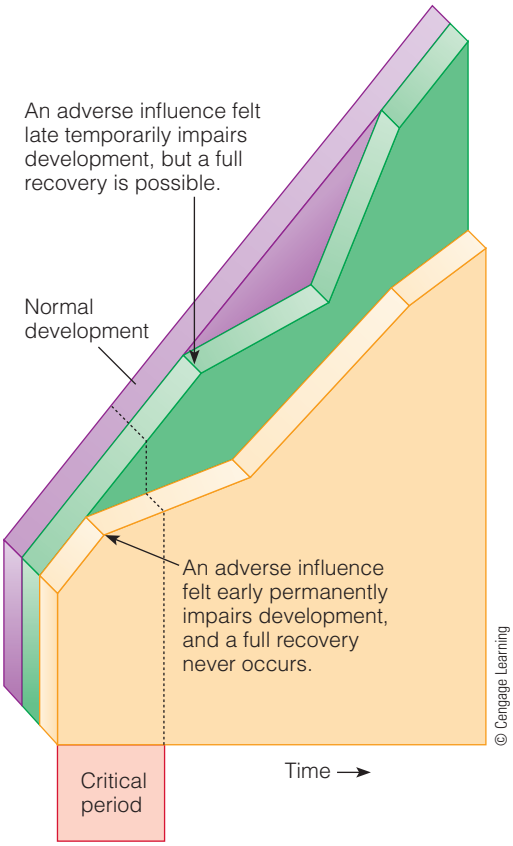
**implantation** (IM-plan-TAY-shun): the embedding of the blastocyst in the inner lining of the uterus.

**embryo** (EM-bree-oh): the developing infant from 2 to 8 weeks after conception.

**fetus** (FEET-us): the developing infant from 8 weeks after conception until term.

**full term:** births occurring at 39 through 40 weeks of gestation.

**critical periods:** finite periods during development in which certain events occur that will have irreversible effects on later developmental stages; usually a period of rapid cell division.



**gestation** (jes-TAY-shun): the period from conception to birth. For human beings, the average length of a healthy gestation is 40 weeks. Pregnancy is often divided into 3-month periods, called *trimesters.*

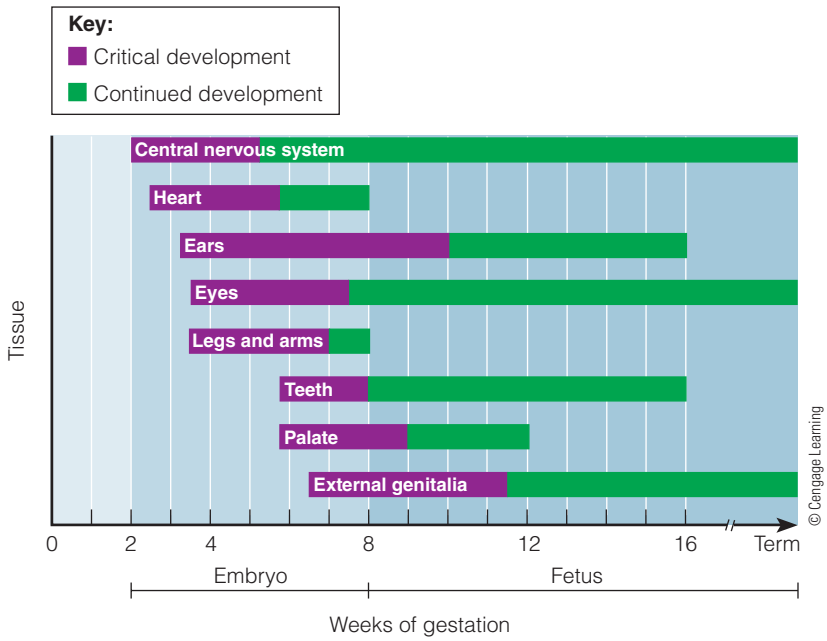


### > FIGURE 15-3 The Concept of Critical Periods in Fetal Development

Critical periods occur early in fetal development. An adverse influence felt early in pregnancy can have a much more severe and prolonged impact than one felt later on.

### > FIGURE 15-4 Critical Periods of Development

During embryonic development (from 2 to 8 weeks), many of the tissues are in their critical periods (purple area of the bars); events occur that will have irreversible effects on the development of those tissues. In the later stages of development (green area of the bars), the tissues continue to grow and change, but the events are less critical in that they are relatively minor or reversible.

SOURCE: Adapted from *Before We Are Born: Essentials of Embryology and Birth Defects* by K. L. Moore and T.V.N. Persaud (W. B. Saunders, 2003).

**Neural Tube Defects** Each year in the United States, approximately 3000 pregnancies are affected by a **neural tube defect**—a malformation of the brain, spinal cord, or both during embryonic development.* The two most common types of neural tube defects are anencephaly (no brain) and spina bifida (split brain). In **anencephaly,** the upper end of the neural tube fails to close. Consequently, the brain is either missing or fails to develop. Pregnancies affected by anencephaly often end in miscarriage; infants born with anencephaly die shortly after birth.

**Spina bifida** is characterized by incomplete closure of the spinal cord and its bony encasement (see Figure 15-5, p. 478). The meninges membranes covering the spinal cord often protrude as a sac, which may rupture and lead to meningitis, a life-threatening infection. Spina bifida is accompanied by varying degrees of paralysis, depending on the extent of the spinal cord damage. Mild cases may not even be noticed, but severe cases lead to death. Common problems include clubfoot, dislocated hip, kidney disorders, curvature of the spine, muscle weakness, mental impairments, and motor and sensory losses.

The cause of neural tube defects is unknown, but researchers are examining several gene-gene, gene-nutrient, and gene-environment interactions. A pregnancy affected by a neural tube defect can occur in any woman, but these factors make it more likely:[11]

- A personal or family history of a neural tube defect
- Maternal diabetes or gestational diabetes
- Maternal Hispanic ethnicity

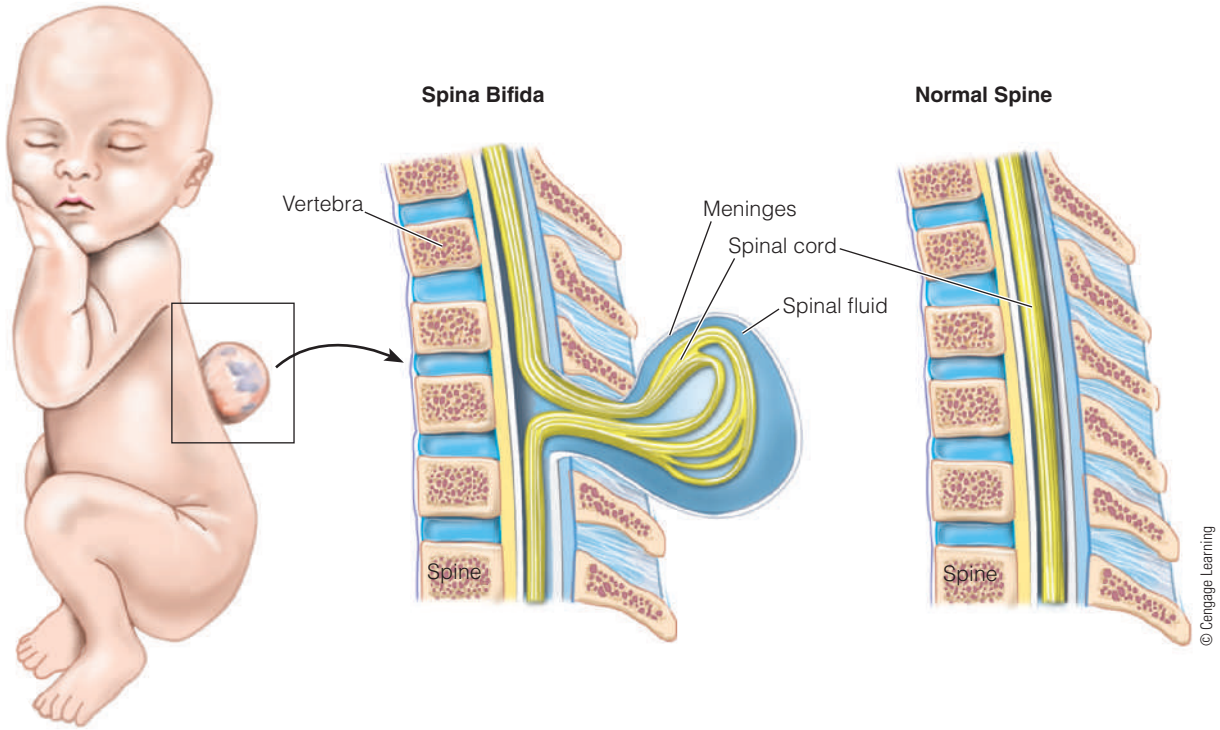
*Worldwide, some 300,000 pregnancies are affected by neural tube defects each year.

**neural tube defect:** malformations of the brain, spinal cord, or both during embryonic development that often results in lifelong disability or death.

**anencephaly** (AN-en-SEF-a-lee): an uncommon and always fatal type of neural tube defect, characterized by the absence of a brain.

- **an** = not (without)
- **encephalus** = brain

**spina** (SPY-nah) **bifida** (BIFF-ih-dah): one of the most common types of neural tube defects, characterized by the incomplete closure of the spinal cord and its bony encasement.



- **spina** = spine
- **bifida** = split

> **FIGURE 15-5 Spina Bifida**

Spina bifida, a common neural tube defect, occurs when the vertebrae of the spine fail to close around the spinal cord, leaving it unprotected. The B vitamin folate—consumed prior to and during pregnancy—helps prevent spina bifida and other neural tube defects.

- Maternal use of certain antiseizure medications
- Inadequate folate
- Maternal obesity

Not all cases of neural tube defects can be prevented, but folate supplementation greatly reduces the incidence and severity.[12]

**Folate Supplementation** Chapter 10 describes how folate supplements taken 1 month before conception and continued throughout the first trimester can help support a healthy pregnancy, prevent neural tube defects, and reduce the severity of defects that do occur. For this reason, all women of childbearing age who are capable of becoming pregnant should consume 400 micrograms (0.4 milligrams) of folate daily. A woman who has previously had an infant with a neural tube defect may be advised by her physician to take folate supplements in doses ten times larger—4 milligrams daily. Because high doses of folate can mask the symptoms of pernicious anemia associated with a vitamin $B_{12}$ deficiency, quantities of 1 milligram or more require a prescription. Most over-the-counter multivitamin-mineral supplements contain 400 micrograms of folate; prenatal supplements usually contain 800 micrograms.

Because half of the pregnancies each year are unplanned and because neural tube defects occur early in development before most women realize they are pregnant, grain products in the United States are fortified with folate to help ensure an adequate intake. Labels on fortified products may claim that an "adequate intake of folate has been shown to reduce the risk of neural tube defects." Fortification has improved folate status in women of childbearing age and lowered the number of neural tube defects that occur each year, as shown in Figure 10-11 (p. 318).

**> DIETARY GUIDELINES FOR AMERICANS**

Women who are pregnant are advised to consume 600 micrograms of dietary folate equivalents from all sources.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Fetal Programming** Clearly, substances such as nutrients influence the growth and development of an infant, but recent genetic research is beginning to explain how they might influence the infant's development of obesity and diseases in *adulthood*. This process is commonly known as **fetal programming,** although "developmental origins of disease" may more appropriately describe the ever-changing interactions involved in disease development.[13] In the case of pregnancy, the mother's nutrition can change gene expression in the fetus.[14] Such epigenetic changes during pregnancy can affect the infant's development of obesity and related adult diseases.[15] Some research suggests that these epigenetic changes during pregnancy may even influence succeeding generations. (See Highlight 6 for further discussion of epigenetics.)

**Chronic Diseases** Much research suggests that dietary influences at critical times during fetal development program the infant's future development, metabolism, and health.[16] Maternal diet during pregnancy may alter the infant's bodily functions by permanently changing an organ's structure and resulting secretions, altering gene expression through epigenetics, or influencing the regulation of cellular aging.[17] For example, undernutrition may limit liver growth and program lipid metabolism in such a way that the infant will develop risk factors for cardiovascular disease as an adult.[18] Similarly, overnutrition and maternal obesity may program the fetus to develop chronic diseases later in life.[19] On a positive note, a maternal diet rich in nutrients such as folate can have epigenetic effects that protect the developing fetus against some cancers into adulthood.[20] (See Highlight 6 for a detailed discussion of epigenetics and folate's role in methylation reactions.)

Malnutrition during the critical period of pancreatic cell growth provides an example of how type 2 diabetes may develop in adulthood. The pancreatic cells responsible for producing insulin (the beta cells) normally increase more than 130-fold between 12 weeks of gestation and 5 months after birth. Nutrition is a primary determinant of beta cell growth, and infants who have suffered prenatal malnutrition have significantly fewer beta cells than well-nourished infants. They are also more likely to be low-birthweight infants—and low birthweight correlates with insulin resistance later in life.[21] One hypothesis suggests that diabetes may develop from the interaction of inadequate nutrition early in life (low birthweight) with abundant nutrition later in life (overweight adult): the small mass of beta cells developed in times of undernutrition during fetal development may be insufficient in times of overnutrition during adulthood when the body needs more insulin.

Hypertension may develop from a similar scenario of inadequate growth during placental and gestational development followed by accelerated growth during early childhood: the small mass of kidney cells developed during malnutrition may be insufficient to handle the excessive demands of later life. As adults, low-birthweight infants may be particularly sensitive to the blood-pressure raising effects of salt.[22]

**› REVIEW IT** Describe fetal development from conception to birth and explain how maternal malnutrition can affect critical periods.

Maternal nutrition before and during pregnancy affects both the mother's health and the infant's growth. As the infant develops through its three stages—the zygote, embryo, and fetus—its organs and tissues grow, each on its own schedule. Times of intense development are critical periods that depend on nutrients to proceed smoothly. Without folate, for example, the neural tube fails to develop completely during the first month of pregnancy, prompting recommendations that all women of childbearing age take folate daily.

Because critical periods occur throughout pregnancy, a woman should continuously take good care of her health. That care should include achieving and maintaining a healthy body weight prior to pregnancy and gaining sufficient weight during pregnancy to support a healthy infant.

**fetal programming:** the influence of substances during fetal growth on the development of diseases in later life.

Fetal growth and maternal health depend on a sufficient weight gain during pregnancy.

# 15.3 Maternal Weight

› **LEARN IT** Explain how both underweight and overweight can interfere with a healthy pregnancy and how weight gain and physical activity can support maternal health and infant growth.

Birthweight is the most reliable indicator of an infant's health. As a later section of this chapter explains, compared with a normal-weight infant, an underweight infant is more likely to have physical and mental abnormalities, suffer illnesses, and die. In general, higher birthweights present fewer risks for infants. Two characteristics of the mother's weight influence an infant's birthweight: her weight *prior* to conception and her weight gain *during* pregnancy.

## Weight prior to Conception

A woman's weight prior to conception influences fetal growth. Even with the same weight gain during pregnancy, underweight women tend to have smaller babies than heavier women. Ideally, before a woman becomes pregnant, she will have established diet and activity habits to support an adequate, and not excessive, weight gain during pregnancy.[23]

### Underweight

An underweight woman (BMI <18.5) has a high risk of having a low-birthweight infant, especially if she is malnourished or unable to gain sufficient weight during pregnancy. In addition, the rates of **preterm** births and infant deaths are higher for underweight women. An underweight woman improves her chances of having a healthy infant by gaining sufficient weight prior to conception or by gaining extra pounds during pregnancy. To gain weight and ensure nutrient adequacy, an underweight woman can follow the dietary recommendations for pregnant women (described on pp. 484–487).

### Overweight and Obesity

An estimated one-third of all pregnant women in the United States are obese (BMI ≥30), which can create problems related to pregnancy, infancy, and childbirth.[24] Obese women have an especially high risk of medical complications such as gestational hypertension, gestational diabetes, and postpartum infections. Compared with other women, obese women are also more likely to have other complications of labor and delivery. Complications in women after gastric bypass surgery are lower than in obese women, but their infants are more likely to be small, perhaps because of limited nutrient absorption; careful monitoring during pregnancy is advised.[25]

Infants of obese women are more likely to be large for gestational age, weighing more than 9 pounds.[26] Problems associated with **macrosomia** include increases in the likelihood of a difficult labor and delivery, birth trauma, and **cesarean delivery,** which presents a high risk in obese women.[27] Consequently, these infants have a greater risk of poor health and death than infants of normal weight.

Of greater concern than infant birthweight is the poor development of infants born to obese mothers.[28] Obesity may double the risk for neural tube defects. Folate's role has been examined, but a more likely explanation seems to be poor glycemic control. Undiagnosed diabetes might also explain why obese women have a greater risk of giving birth to infants with heart defects and other abnormalities.

Even moderate overweight increases the risks for some complications, such as gestational hypertension, gestational diabetes, preterm births, and cesarean deliveries; risks tend to increase as BMI increases.[29] Health-care providers have traditionally advised against weight-loss dieting during pregnancy. Limited research, however, suggests that following a well-balanced, kcalorie-restricted diet and regular exercise program can support a healthy pregnancy with little or no weight gain. Ideally, overweight and obese women will achieve a healthier body weight before becoming pregnant and avoid excessive weight gain during pregnancy.[30]

## Weight Gain during Pregnancy

Fetal growth and maternal health depend on a sufficient weight gain during pregnancy. Maternal weight gain during pregnancy correlates closely with infant birthweight, which is a strong predictor of the health and subsequent development of the infant.[31]

**preterm (premature):** births occurring before 37 weeks of gestation; births occurring at 37 to 38 weeks of gestation are designated *early term.*

**macrosomia** (mak-roh-SO-me-ah): abnormally large body size. In the case of infants, a birthweight at the 90th percentile or higher for gestational age (roughly 9 lb—or 4000 g—or more); macrosomia results from prepregnancy obesity, excessive weight gain during pregnancy, or uncontrolled gestational diabetes.

- **macro** = large
- **soma** = body

**cesarean** (si-ZAIR-ee-un) **delivery:** a surgically assisted birth involving removal of the fetus by an incision into the uterus, usually by way of the abdominal wall.

**TABLE 15-1 Recommended Weight Gains Based on Prepregnancy Weight**

| | Recommended Weight Gain | |
|---|---|---|
| **Prepregnancy Weight** | **For single birth** | **For twin birth** |
| Underweight (BMI <18.5) | 28 to 40 lb (12.5 to 18.0 kg) | Insufficient data to make recommendation |
| Healthy weight (BMI 18.5 to 24.9) | 25 to 35 lb (11.5 to 16.0 kg) | 37 to 54 lb (17.0 to 25.0 kg) |
| Overweight (BMI 25.0 to 29.9) | 15 to 25 lb (7.0 to 11.5 kg) | 31 to 50 lb (14.0 to 23.0 kg) |
| Obese (BMI ≥30) | 11 to 20 lb (5.0 to 9.0 kg) | 25 to 42 lb (11.0 to 19.0 kg) |

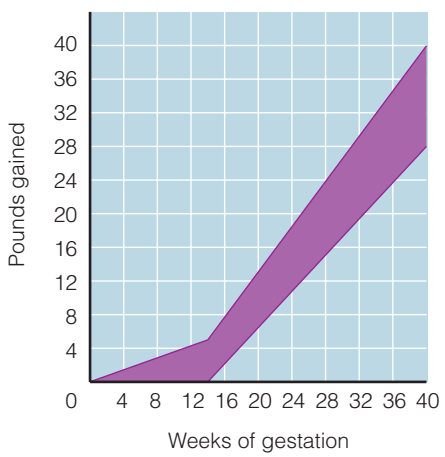
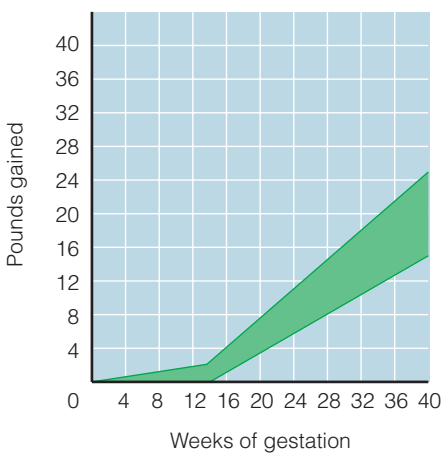
### > DIETARY GUIDELINES FOR AMERICANS

Maintain appropriate kcalorie balance during pregnancy. Pregnant women are encouraged to gain weight within the gestational weight gain guidelines (see Table 15-1).



**Recommended Weight Gains** Table 15-1 presents recommended weight gains for various prepregnancy weights. The recommended gain for a woman who begins pregnancy at a healthy weight and is carrying a single fetus is 25 to 35 pounds. An underweight woman needs to gain between 28 and 40 pounds; and an overweight woman, between 15 and 25 pounds. About one-third of US women gain weight within these recommended ranges; about half gain more than recommended.[32] Appropriate weight gains reduce complications, help women limit weight retention and gains after pregnancy, and help their infants prevent obesity during childhood.[33] To limit excessive weight gains, pregnant women can select foods with a high nutrient density (nutrient per kcalorie) but a low energy density (kcalorie per gram). Physical activity also plays a key role in preventing excessive weight gains during pregnancy and minimizing weight retention after the birth.[34]

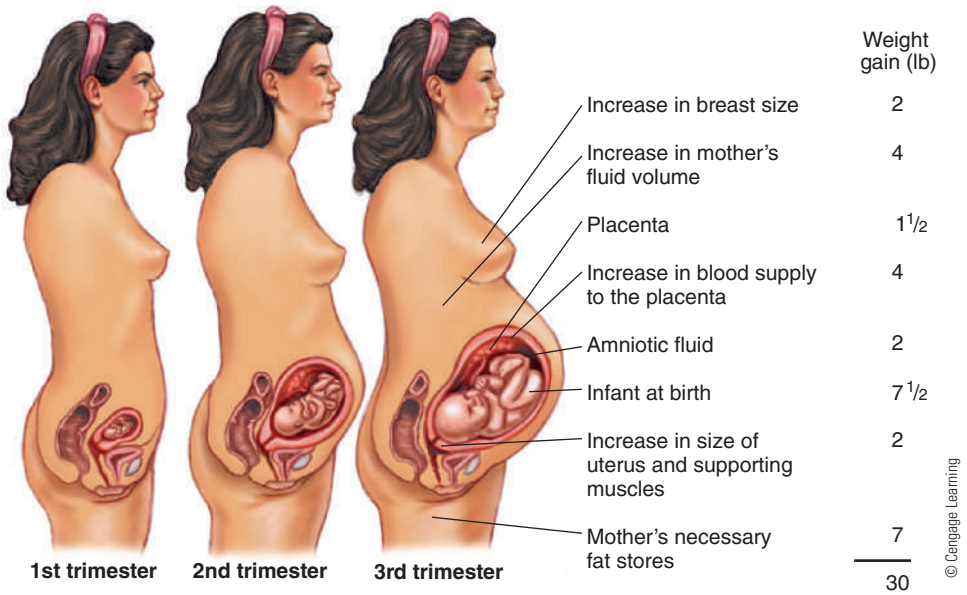
**Weight-Gain Patterns** For the normal-weight woman, weight gain ideally follows a pattern of 3½ pounds during the first trimester and 1 pound per week thereafter. Health-care professionals monitor weight gain using a prenatal weight-gain grid (see Figure 15-6). Identifying inadequate or excessive weight gains by the second trimester allows sufficient time for adjustments in diet and activity.[35]



**> FIGURE 15-6 Recommended Prenatal Weight Gain Based on Prepregnancy Weight**

**Normal-weight women** should gain about 3½ pounds in the first trimester and just under 1 pound/week thereafter, achieving a total gain of 25 to 35 pounds by term.

**Underweight women** should gain about 5 pounds in the first trimester and just over 1 pound/week thereafter, achieving a total gain of 28 to 40 pounds by term.



**Overweight women** should gain about 2 pounds in the first trimester and ⅔ pound/week thereafter, achieving a total gain of 15 to 25 pounds.

> FIGURE 15-7 Components of Weight Gain during Pregnancy

**Components of Weight Gain** Women often express concern about the weight gain that accompanies a healthy pregnancy. They may find comfort by remembering that most of the gain supports the growth and development of the placenta, uterus, blood, and breasts, the increase in blood supply and fluid volume, as well as a healthy 7½-pound infant. A small amount goes into maternal fat stores, and even that fat has a special purpose—to provide energy for growth, labor, and lactation. Figure 15-7 shows the components of a healthy 30-pound weight gain.

**Weight Loss after Pregnancy** The pregnant woman loses some weight at delivery. In the following weeks, she loses more as her blood volume returns to normal and she sheds accumulated fluids. Quite likely, her goal is to return to her prepregnancy weight, but that may depend in part on whether she stayed within the pregnancy weight gain recommendations. In general, the more weight a woman gains beyond the needs of pregnancy, the more she retains and the more likely she will continue to gain over the next several years.[36] Even with an average weight gain during pregnancy, most women tend to retain a couple of pounds with each pregnancy.[37] When those couple of pounds become several more, complications such as diabetes and hypertension in future pregnancies as well as chronic diseases in later life become more likely—even for women who are not overweight. Those who are successful in losing their pregnancy weight are more likely to limit weight gains through middle adulthood.[38] Eating breakfast regularly supports postpartum weight loss.[39] A combination of diet and exercise is most effective in supporting weight loss as well as improving maternal cardiovascular fitness.[40]

## Exercise during Pregnancy

An active, physically fit woman experiencing a normal pregnancy can continue to exercise throughout pregnancy, adjusting the duration, intensity, and type of activity as the pregnancy progresses. Inactive women and those experiencing pregnancy complications should discuss physical activity options with their health-care provider. With approval, inactive women can safely begin walking three to four times per week, gradually increasing from 25 to 40 minutes per session.[41]

Physical activity during pregnancy offers many benefits.[42] Staying active can improve cardiovascular fitness, limit excessive weight gain, prevent or manage gestational diabetes and gestational hypertension, and reduce stress.[43] Women who exercise during pregnancy report fewer discomforts throughout their pregnancies. Regular exercise develops the strength and endurance a woman needs to carry the extra weight through pregnancy and to labor through an intense

> **FIGURE 15-8** Exercise Guidelines during Pregnancy

**DO**

Do begin to exercise gradually.

Do exercise regularly (most, if not all, days of the week).

Do warm up with 5 to 10 minutes of light activity.

Do 30 minutes or more of moderate physical activity.

Do cool down with 5 to 10 minutes of slow activity and gentle stretching.

Do drink water before, after, and during exercise.

Do eat enough to support the needs of pregnancy plus exercise.

Do rest adequately.

Tracy Frankel/The Image Bank/Getty Images

Pregnant women can enjoy the benefits of exercise.

**DON'T**

Don't exercise vigorously after long periods of inactivity.

Don't exercise in hot, humid weather.

Don't exercise when sick with fever.

Don't exercise while lying on your back after the 1st trimester of pregnancy or stand motionless for prolonged periods.

Don't exercise if you experience any pain, discomfort, or fatigue.

Don't participate in activities that may harm the abdomen or involve jerky, bouncy movements.

Don't scuba dive.

© Cengage Learning

delivery. It also maintains the habits that help a woman lose excess weight and get back into shape after the birth.

A pregnant woman should participate in low-impact activities and avoid sports in which she might fall or be hit by other people or objects. For example, playing singles tennis with one person on each side of the net is safer than a fast-moving game of racquetball in which the two competitors can collide. Swimming and water aerobics are particularly beneficial because they allow the body to remain cool and move freely with the water's support, thus reducing back pain. Figure 15-8 provides some guidelines for exercise during pregnancy. Several of the guidelines are aimed at preventing excessively high internal body temperature and dehydration, both of which can harm fetal development. To this end, pregnant women should also stay out of saunas, steam rooms, and hot tubs or hot whirlpool baths.

**› REVIEW IT** Explain how both underweight and overweight can interfere with a healthy pregnancy and how weight gain and physical activity can support maternal health and infant growth.

A healthy pregnancy depends on a sufficient weight gain. Women who begin their pregnancies at a healthy weight need to gain about 30 pounds, which covers the growth and development of the placenta, uterus, blood, breasts, and infant. By remaining active throughout pregnancy, a woman can develop the strength she needs to carry the extra weight and maintain habits that will help her lose weight after the birth.

## 15.4 Nutrition during Pregnancy

**› LEARN IT** Summarize the nutrient needs of women during pregnancy.

A woman's body changes dramatically during pregnancy. Her uterus and its supporting muscles increase in size and strength; her blood volume increases by half to carry the additional nutrients and other materials; her joints become more flexible in preparation for childbirth; her feet swell in response to high concentrations of the hormone estrogen, which promotes water retention and helps to ready the uterus for delivery; and her breasts enlarge in preparation for lactation. The hormones that mediate all these changes may influence her mood. She can best prepare to handle these changes given a nutritious diet, regular physical activity, plenty of rest, and caring companions. This section highlights the role of nutrition.

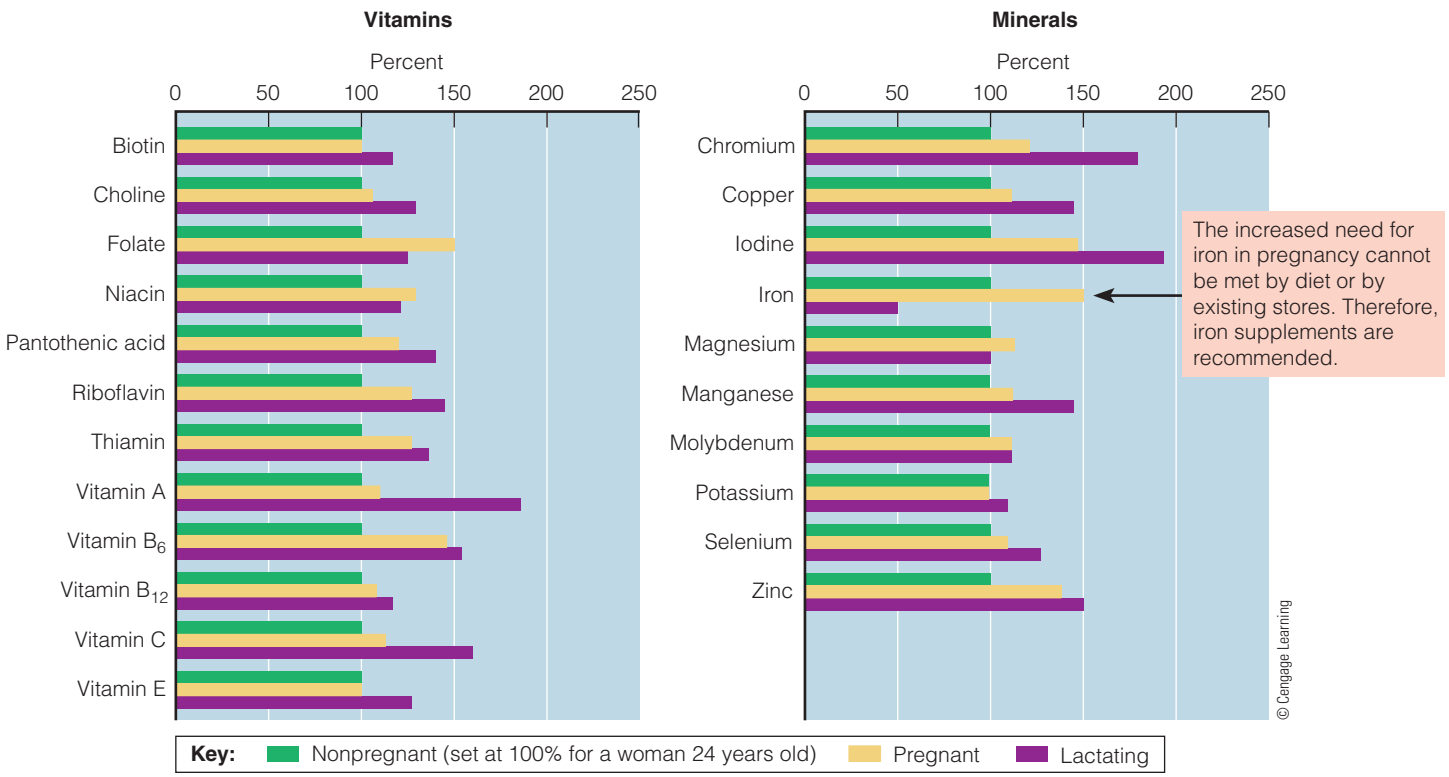
A pregnant woman's food choices support both her health and her infant's growth and development.

In general, the following guidelines will allow most women to enjoy a healthy pregnancy:

- Strive for good nutrition and health prior to pregnancy and get prenatal care during pregnancy.
- Gain a healthy amount of weight.
- Eat a balanced diet, safely prepared, and engage in physical activity regularly.
- Take prenatal vitamin and mineral supplements as prescribed.
- Refrain from cigarettes, alcohol, and drugs (including herbal remedies, unless prescribed by a physician).

An adequate diet may also help a woman manage the challenges and possible depression that can arise *after* the infant arrives. Details follow.

## Energy and Nutrient Needs during Pregnancy



From conception to birth, all parts of the infant—bones, muscles, blood cells, skin, and all other tissues—are made from nutrients in the foods the mother eats. For most women, nutrient needs during pregnancy and lactation are higher than at any other time (see Figure 15-9). Yet intakes do not consistently meet recommendations for energy and key nutrients.[44] To meet the high nutrient demands of pregnancy, a woman will need to make careful food choices, but her body will also help by maximizing absorption and minimizing losses. The Dietary Reference Intakes (DRI) table on the inside front cover provides separate listings for women during pregnancy and lactation, reflecting their heightened nutrient needs.

### Energy

The enhanced work of pregnancy raises the woman's basal metabolic rate dramatically and demands extra energy. After the first trimester, energy needs of pregnant women are greater than those of nonpregnant women—an additional 340 kcalories per day during the second trimester and an extra 450 kcalories per day during the third trimester. A woman can easily get these added kcalories with nutrient-dense selections from the five food groups. See Table 2-3 (p. 43) for

**> FIGURE 15-9 Comparison of Nutrient Recommendations for Nonpregnant, Pregnant, and Lactating Women**

For actual values, turn to the table on the inside front cover. For vitamins and minerals not shown here, the values do not change for pregnant and lactating women.

> **FIGURE 15-10 Daily Food Choices for Pregnant and Lactating Women**

| Food Group | Amount | SAMPLE MENU |
|---|---|---|
| Fruits | 2 c | ***Breakfast*** |
| | | 1 whole-wheat English muffin |
| | | 2 tbs peanut butter |
| Vegetables | 2½–3 c | 1 c low-fat vanilla yogurt |
| | | ½ c fresh strawberries |
| | | 1 c orange juice |
| Grains | 6–8 oz | ***Midmorning snack*** |
| | | ½ c cranberry juice |
| | | 1 oz pretzels |
| Protein foods | 5½–6½ oz | ***Lunch*** |
| | | Sandwich (tuna salad on whole-wheat bread) |
| | | ½ carrot (sticks) |
| Milk | 3 c | 1 c low-fat milk |
| | | ***Dinner*** |
| | | Chicken cacciatore |
| | | 3 oz chicken |
| | | ½ c stewed tomatoes |
| | | 1 c rice |
| | | ½ c summer squash |
| | | 1½ c salad (spinach, mushrooms, carrots) |
| | | 1 tbs salad dressing |
| | | 1 slice Italian bread |
| | | 2 tsp soft margarine |
| | | 1 c low-fat milk |

© Cengage Learning

NOTE: The range of recommended amounts reflects the differences of the first trimester versus the second and third trimesters. This sample meal plan provides about 2500 kcalories (55% from carbohydrate, 20% from protein, and 25% from fat) and meets most of the vitamin and mineral needs of pregnant and lactating women.

suggested dietary patterns for several kcalorie levels. A sample menu for pregnant and lactating women is presented in Figure 15-10.

For a 2000-kcalorie daily intake, these added kcalories represent about 15 to 20 percent more food energy than before pregnancy. The increase in nutrient needs is often greater than this, so nutrient-dense foods should be chosen to supply the extra kcalories: foods such as whole-grain breads and cereals, legumes, dark green vegetables, citrus fruits, low-fat milk and milk products, and lean meats, fish, poultry, and eggs.

**Carbohydrate** Ample carbohydrate (ideally, 175 grams or more per day and certainly no less than 135 grams) is necessary to fuel the fetal brain. Sufficient carbohydrate also ensures that the protein needed for growth will not be broken down and used to make glucose.

**Protein** The protein RDA for pregnancy is an additional 25 grams per day higher than for nonpregnant women. Pregnant women can easily meet their protein needs by selecting meats, milk products, and protein-containing plant foods such as legumes, whole grains, nuts, and seeds. Because use of high-protein supplements during pregnancy may be harmful to the infant's development, it is discouraged unless medically prescribed and carefully monitored to treat fetal growth problems.[45]

**Essential Fatty Acids** The high nutrient requirements of pregnancy leave little room in the diet for excess fat, but the essential long-chain polyunsaturated fatty acids are particularly important to the growth and development of the fetus.[46] The brain is largely made of lipid material, and it depends heavily on the long-chain omega-3 and omega-6 fatty acids for its growth, function, and structure.[47] (See Table 5-4 on p. 153 for a list of good food sources of the omega fatty acids.)

**Nutrients for Blood Production and Cell Growth** New cells are laid down at a tremendous pace as the fetus grows and develops. At the same time, the mother's red blood cell mass expands. All nutrients are important in these processes, but for folate, vitamin $B_{12}$, iron, and zinc, the needs are especially great because of their key roles in the synthesis of DNA and new cells.

The requirement for folate increases dramatically during pregnancy (from 400 micrograms to 600 micrograms daily). It is best to obtain sufficient folate from a combination of supplements, fortified foods, and a diet that includes fruits, juices, green vegetables, and whole grains. The "How To" feature in Chapter 10 on p. 317 describes how folate from each of these sources contributes to a day's intake.

The pregnant woman also has a slightly greater need for the B vitamin that activates the folate enzyme—vitamin $B_{12}$. Generally, even modest amounts of meat,

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

fish, eggs, or milk products together with body stores easily meet the need for vitamin $B_{12}$. Vegans who exclude all foods of animal origin, however, need daily supplements of vitamin $B_{12}$ or vitamin $B_{12}$–fortified foods to prevent the neurological complications of a deficiency.

Pregnant women need iron to support their increased blood volume and to provide for placental and fetal needs.[48] The developing fetus draws on maternal iron stores to create sufficient stores of its own to last through the first 4 to 6 months after birth. Ideally, a woman enters pregnancy with adequate iron stores and maintains sufficient iron nutrition throughout the pregnancy.[49] The transfer of significant amounts of iron to the fetus is regulated by the placenta, which gives the iron needs of the fetus priority over those of the mother.[50] Women with inadequate iron stores are left with too little iron to meet their own health needs. In addition, blood losses are inevitable at birth and can further drain the mother's iron supply.

During pregnancy, the body makes several adaptations to help meet the exceptionally high need for iron. Menstruation, the major route of iron loss in women, ceases, and iron absorption improves thanks to an increase in transferrin, the body's iron-absorbing and iron-carrying protein. Without sufficient intake, though, iron stores quickly dwindle. Women with iron-deficiency anemia are likely to give birth to low-birthweight infants.[51]

Few women enter pregnancy with adequate iron stores, so a daily iron supplement is recommended early in pregnancy, if not before.[52] To enhance iron absorption, the supplement should be taken between meals or at bedtime and with liquids other than milk, coffee, or tea, which inhibit iron absorption. Drinking orange juice does not enhance iron absorption from supplements as it does from foods; vitamin C enhances iron absorption by converting iron from ferric to ferrous, but supplemental iron is already in the ferrous form. Vitamin C is helpful, however, in preventing the premature rupture of amniotic membranes.

**> DIETARY GUIDELINES FOR AMERICANS**

Women who are pregnant should take an iron supplement as recommended by an obstetrician or other health-care provider.

Zinc is required for DNA and RNA synthesis and thus for protein synthesis and cell development. Typical zinc intakes for pregnant women are lower than recommendations, but fortunately, zinc absorption increases when intakes are low.

**Nutrients for Bone Development** Vitamin D and the bone-building minerals calcium, phosphorus, magnesium, and fluoride are in great demand during pregnancy. All are needed to produce healthy fetal bones and teeth.[53]

Vitamin D plays a central role in calcium absorption and utilization. Consequently, severe maternal vitamin D deficiency interferes with normal calcium metabolism, resulting in rickets in the infant and osteomalacia in the mother.[54] Regular exposure to sunlight and consumption of vitamin D–fortified milk are usually sufficient to provide the recommended amount of vitamin D during pregnancy, which is the same as for nonpregnant women.[55] Pregnant women who do not receive sufficient dietary vitamin D or enough exposure to sunlight may need a supplement.

Calcium absorption and retention increases dramatically in pregnancy, helping the mother to meet the calcium needs of pregnancy. During the last trimester, as the fetal bones begin to calcify, up to 350 milligrams a day are transferred to the fetus. If the diet is inadequate in calcium, the mother's bones give up their calcium to meet fetal needs and become less dense.[56] Recommendations to ensure an adequate calcium intake during pregnancy help to conserve maternal bones while meeting fetal needs.

Calcium intakes for pregnant women typically fall below recommendations. Because bones are still actively depositing minerals until about age 30, adequate calcium is especially important for young women. Pregnant women younger than age 25 who receive less than 600 milligrams of dietary calcium daily need to increase their intake of milk, cheese, yogurt, and other calcium-rich foods. The USDA Food Patterns suggest consuming 3 cups per day of fat-free or low-fat

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

milk or the equivalent in milk products. Alternatively, and less preferably, they may need a daily supplement of 600 milligrams of calcium, taken with meals.

**Other Nutrients** The nutrients mentioned here are those most intensely involved in blood production, cell growth, and bone development. Of course, other vitamins and minerals are also needed during pregnancy to support the growth and health of both fetus and mother.[57] Even with adequate nutrition, repeated pregnancies within a short time span can deplete nutrient reserves. Short intervals between pregnancies compromise the growth of the fetus and health of the mother.[58] The optimal interval between pregnancies is 18 to 23 months.

**Nutrient Supplements** A healthy pregnancy and optimal infant development depend on the mother's diet. Pregnant women who make wise food choices can meet most of their nutrient needs, with the possible exception of iron. Even so, physicians routinely recommend daily multivitamin-mineral supplements for pregnant women. Prenatal supplements typically contain greater amounts of folate, iron, and calcium than regular multivitamin-mineral supplements. These supplements are particularly beneficial for women who do not eat adequately and for those in high-risk groups: women carrying multiple fetuses, cigarette smokers, and alcohol and drug abusers. The use of prenatal supplements may help reduce the risks of preterm delivery, low infant birthweights, and birth defects.[59] Prenatal supplement use seems to support the infant's physical growth and cognitive development for the first couple of years as well.[60]

## Vegetarian Diets during Pregnancy and Lactation

In general, a well-planned vegetarian diet can support a healthy pregnancy and successful lactation if it provides adequate energy and contains a wide variety of legumes, whole grains, nuts, seeds, fruits, and vegetables.[61] Many vegetarian women are well nourished, with nutrient intakes from diet alone exceeding the RDA for most vitamins and minerals except iron, which is low for most women. In contrast, vegan women who restrict themselves to an exclusively plant-based diet generally have low energy intakes and are underweight. For pregnant women, this can be a problem. Women with low prepregnancy weights and insufficient weight gains during pregnancy jeopardize a healthy pregnancy.

Vegan diets may require supplementation with vitamin $B_{12}$, calcium, and vitamin D, or the addition of foods fortified with these nutrients. Infants may suffer spinal cord damage and develop severe psychomotor retardation due to a lack of vitamin $B_{12}$ in the mother's diet during pregnancy. Breastfed infants of vegan mothers have been reported to develop vitamin $B_{12}$ deficiency and severe movement disorders. Giving infants vitamin $B_{12}$ supplements corrects the blood and neurological symptoms of the deficiency, as well as the structural abnormalities, but cognitive and language development delays may persist. A pregnant woman needs a regular source of vitamin $B_{12}$–fortified foods or a supplement that provides 2.6 micrograms daily.

## Common Nutrition-Related Concerns of Pregnancy

Nausea, constipation, heartburn, and food sensitivities are common nutrition-related concerns during pregnancy. A few simple strategies can help alleviate maternal discomforts (see Table 15-2).

**TABLE 15-2 Strategies to Alleviate Maternal Discomforts**

| To Alleviate the Nausea of Pregnancy | To Prevent or Alleviate Constipation | To Prevent or Relieve Heartburn |
|---|---|---|
| • On waking, arise slowly.<br>• Eat dry toast or crackers.<br>• Chew gum or suck hard candies.<br>• Eat small, frequent meals.<br>• Avoid foods with offensive odors.<br>• When nauseated, drink carbonated beverages instead of citrus juice, water, milk, coffee, or tea. | • Eat foods high in fiber (fruits, vegetables, and whole grains).<br>• Exercise regularly.<br>• Drink at least eight glasses of liquids a day.<br>• Respond promptly to the urge to defecate.<br>• Use laxatives only as prescribed by a physician; do not use mineral oil, because it interferes with absorption of fat-soluble vitamins. | • Relax and eat slowly.<br>• Chew food thoroughly.<br>• Eat small, frequent meals.<br>• Drink liquids between meals.<br>• Avoid spicy or greasy foods.<br>• Sit up while eating; elevate the head while sleeping.<br>• Wait 3 hours after eating before lying down.<br>• Wait 2 hours after eating before exercising. |

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Nausea and Vomiting** Not all women have queasy stomachs in the early months of pregnancy, but many do. The nausea of "morning sickness" may actually occur anytime and ranges from mild queasiness to debilitating nausea and vomiting. Severe and continued vomiting may require hospitalization if it results in acidosis, dehydration, or excessive weight loss. The hormonal changes of early pregnancy seem to be responsible for a woman's sensitivities to the appearance, texture, or smell of foods. The problem typically peaks at 9 weeks of gestation and resolves within a month or two.[62] Traditional strategies for quelling nausea are listed in Table 15-2 (p. 487), but there is little evidence to support such advice.[63] Many women benefit most from simply resting when nauseous and eating the foods they want when they feel like eating. They may also find comfort in a clean, quiet, and temperate environment.

**Constipation and Hemorrhoids** As the hormones of pregnancy alter muscle tone and the growing fetus crowds intestinal organs, an expectant mother may experience constipation. She may also develop hemorrhoids (swollen veins of the rectum). Hemorrhoids can be painful, and straining during bowel movements may cause bleeding. She can gain relief by following the strategies listed in Table 15-2.

**Heartburn** Heartburn is another common complaint during pregnancy. The hormones of pregnancy relax the digestive muscles, and the growing fetus puts increasing pressure on the mother's stomach. This combination causes gastroesophageal reflux, the painful sensation a person feels behind the breastbone when stomach acid splashes back up into the lower esophagus (see Highlight 3). Tips to help relieve heartburn are included in Table 15-2.

**Food Cravings and Aversions** Some women develop cravings for, or aversions to, particular foods and beverages during pregnancy. **Food cravings** and **food aversions** are fairly common, but they do not seem to reflect real physiological needs. In other words, a woman who craves pickles does not necessarily need salt. Similarly, cravings for ice cream are common in pregnancy but do not signify a calcium deficiency. Cravings and aversions that arise during pregnancy are most likely due to hormone-induced changes in sensitivity to taste and smell.

**Nonfood Cravings** Some pregnant women develop cravings for nonfood items such as freezer frost, laundry starch, clay, soil, or ice—a practice known as **pica.**[64] Pica is a cultural phenomenon that reflects a society's folklore; it is especially common among African American women. Pica is often associated with iron-deficiency anemia, but whether iron deficiency leads to pica or pica leads to iron deficiency is unclear. Eating clay or soil may interfere with iron absorption and displace iron-rich foods from the diet.

**› REVIEW IT** Summarize the nutrient needs of women during pregnancy.

Energy and nutrient needs are high during pregnancy. A balanced diet that includes an extra serving from each of the five food groups can usually meet these needs, with the possible exception of iron and folate (supplements are recommended). The nausea, constipation, and heartburn that sometimes accompany pregnancy can usually be alleviated with a few simple strategies. Food cravings do not typically reflect physiological needs.

**food cravings:** strong desires to eat particular foods.

**food aversions**: strong desires to avoid particular foods.

**pica** (PIE-ka): a craving for and consumption of nonfood substances. Pica is known as *geophagia* (gee-oh-FAY-gee-uh) when referring to eating clay, baby powder, chalk, ash, ceramics, paper, paint chips, or charcoal; *pagophagia* (pag-oh-FAY-gee-uh) when referring to eating large quantities of ice; and *amylophagia* (AM-ee-low-FAY-gee-ah) when referring to eating uncooked starch (flour, laundry starch, or raw rice).

**high-risk pregnancy:** a pregnancy characterized by risk factors that make it likely the birth will be surrounded by problems such as premature delivery, difficult birth, restricted growth, birth defects, and early infant death.

**low-risk pregnancy:** a pregnancy characterized by factors that make it likely the birth will be normal and the infant healthy.

## 15.5 High-Risk Pregnancies

**› LEARN IT** Identify factors predicting low-risk and high-risk pregnancies and describe ways to manage them.

Some pregnancies jeopardize the life and health of the mother and infant. Table 15-3 identifies several risk factors for a **high-risk pregnancy.** A woman with none of these risk factors is said to have a **low-risk pregnancy.** The more factors that apply, the higher the risk. All pregnant women, especially those in high-risk categories, need prenatal medical care, including the following nutrition advice:

- Eat well-balanced meals.
- Gain enough weight to support fetal growth.

**TABLE 15-3 High-Risk Pregnancy Factors**

| Factor | Condition that Raises Risk |
|---|---|
| Maternal weight | |
| • Prior to pregnancy | Prepregnancy BMI either <18.5 or ≥25 |
| • During pregnancy | Insufficient or excessive pregnancy weight gain (see Table 15-1, p. 481) |
| Maternal nutrition | Nutrient deficiencies or toxicities; eating disorders |
| Socioeconomic status | Poverty, lack of family support, low level of education, limited food availability |
| Lifestyle habits | Smoking, alcohol or other drug use |
| Age | Teens, especially 15 years or younger; women 35 years or older |
| Previous pregnancies | |
| • Number | Many previous pregnancies (3 or more to mothers younger than age 20; 4 or more to mothers age 20 or older) |
| • Interval | Short or long intervals between pregnancies (<18 months or >59 months) |
| • Outcomes | Previous history of problems |
| • Multiple births | Twins or triplets |
| • Birthweight | Low- or high-birthweight infants |
| Maternal health | |
| • High blood pressure | Development of gestational hypertension |
| • Diabetes | Development of gestational diabetes |
| • Chronic diseases | Diabetes; heart, respiratory, and kidney disease; certain genetic disorders; special diets and medications |

- Take prenatal supplements as prescribed.
- Stop drinking alcohol.

**The Infant's Birthweight** A high-risk pregnancy is likely to produce an infant with **low birthweight (LBW).** Low-birthweight infants, defined as infants who weigh 5½ pounds or less, are classified according to their gestational age. Preterm infants are born before they are fully developed; they are often underweight and have trouble breathing because their lungs are immature. Preterm infants may be small, but if their size and weight are appropriate for their gestational age, they can catch up in growth given adequate nutrition support. In contrast, small-for-gestational-age infants have suffered growth failure in the uterus and do not catch up as well. For the most part, survival improves with increased gestational age and birthweight.

Low-birthweight infants are more likely to experience complications during delivery than normal-weight babies. They also have a statistically greater chance of having physical and mental birth defects, becoming ill, and dying early in life. Of infants who die before their first birthdays, about two-thirds were low-birthweight newborns. Very-low-birthweight infants (3½ pounds or less) struggle not only for their immediate physical health and survival, but for their future cognitive development and abilities as well.

A strong association is seen between socioeconomic disadvantage and low birthweight. Low socioeconomic status impairs fetal development by causing stress and by limiting access to medical care and nutritious foods. Low socioeconomic status often accompanies teen pregnancies, smoking, and alcohol and drug abuse—all predictors of low birthweight.

© Photodisc/Jupiterimages

Low-birthweight babies need special care and nourishment.

**Malnutrition and Pregnancy** Good nutrition clearly supports a healthy pregnancy. In contrast, malnutrition interferes with the ability to conceive, the likelihood of implantation, and the subsequent development of a fetus should conception and implantation occur.

**Malnutrition and Fertility** The nutrition habits and lifestyle choices people make can influence the course of a pregnancy they are not even planning at the time. Inadequate nutrition and food deprivation can reduce fertility because women

**low birthweight (LBW):** a birthweight of 5½ pounds (2500 grams) or less; indicates probable poor health in the newborn and poor nutrition status in the mother during pregnancy, before pregnancy, or both. Optimal birthweight for a full-term baby is about 6½ to 8 pounds.

United States Department of Agriculture

The nutrition education and nutritious foods WIC provides to infants, children to age 5, and pregnant and breastfeeding women improves health and saves lives.

may develop amenorrhea—the temporary or permanent absence of menstrual periods.* Men who are poorly nourished may be unable to produce viable sperm. Furthermore, both men and women lose sexual interest during times of starvation. Starvation arises predictably during famines, wars, and droughts, but it can also occur amid peace and plenty. Many young women who diet excessively are starving and suffering from malnutrition (see Highlight 8).

**Malnutrition and Early Pregnancy** If a poorly nourished woman does become pregnant, she faces the challenge of supporting both the growth of a baby and her own health with inadequate nutrient stores. Inadequate nutrition prior to and around conception prevents the placenta from developing fully. A poorly developed placenta cannot deliver optimal nourishment to the fetus, and the infant will be born small and possibly with physical and cognitive abnormalities. If this small infant is a female, she may develop poorly and have an elevated risk of developing a chronic condition that could impair her ability to give birth to a healthy infant. Thus a woman's poor nutrition status can adversely affect not only her children but also her *grandchildren*.

**Malnutrition and Fetal Development** Without adequate nutrition during pregnancy, fetal growth and infant health are compromised.[65] In general, consequences of inadequate nutrition during pregnancy include fetal growth restriction, congenital malformations (birth defects), spontaneous abortion and stillbirth, preterm birth, and low infant birthweight. Nutrient deficiencies, coupled with low birthweight, are responsible for more than half of all deaths of children younger than 4 years of age worldwide.

## Food Assistance Programs

Women in high-risk pregnancies can find assistance from the WIC program—a high-quality, cost-effective health-care and nutrition services program for women, infants, and children in the United States. Formally known as the Special Supplemental Nutrition Program for Women, Infants, and Children, WIC provides nutrition education and nutritious foods to infants, children to age 5, and pregnant and breastfeeding women who qualify financially and have a high risk of medical or nutritional problems. The program is both remedial and preventive: services include health-care referrals, nutrition education, and food packages or vouchers for specific foods. These foods supply nutrients known to be lacking in the diets of the target population—most notably, protein, calcium, iron, vitamin A, and vitamin C. WIC-sponsored foods include tuna, tofu, fruits, vegetables, eggs, milk, iron-fortified cereal, whole-grain breads, vitamin C–rich juices, cheeses, legumes, peanut butter, and iron-fortified infant formula and cereal.

More than 9 million people—most of them young children—receive WIC benefits each month. Prenatal WIC participation can effectively reduce iron deficiency, infant mortality, low birthweight, and maternal and newborn medical costs. In 2012, Congress appropriated more than $6.6 billion for WIC. For every dollar spent on WIC, an estimated $3 in medical costs are saved in the first 2 months after birth. Table 15-4 presents some of the many benefits of WIC.

**TABLE 15-4 Benefits of WIC**

- Earlier prenatal care
- Better diet during pregnancy
- Better weight gain during pregnancy
- Longer duration of pregnancy
- Fewer fetal and infant deaths
- Fewer low-birthweight infants
- Better growth in infants and children
- Less iron-deficiency anemia in children
- Better diet for children
- Better medical care for children
- Better preparation for school
- Improved intellectual development

© 2016 Cengage Learning

## Maternal Health

Medical disorders can threaten the life and health of both mother and fetus. If diagnosed and treated early, many diseases can be managed to ensure a healthy outcome—another strong argument for early prenatal care. Furthermore, the changes in pregnancy can reveal disease risks, making screening important and early intervention possible.

**Preexisting Diabetes** The risks of diabetes depend on how well it is managed before and during pregnancy. Without proper management of maternal diabetes, women face high infertility rates, and those who do conceive may experience episodes of severe hypoglycemia or hyperglycemia, preterm labor, and pregnancy-related hypertension. Infants may be large, suffer physical and mental

*Amenorrhea is normal before puberty, after menopause, during pregnancy, and during lactation; otherwise it is abnormal.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

abnormalities, and experience other complications such as severe hypoglycemia or respiratory distress, both of which can be fatal. Signs of fetal health problems are apparent even when maternal glucose is above normal but still below the diagnosis of diabetes. To minimize complications, a woman needs to achieve glucose control before conception and continued glucose control throughout pregnancy.[66]

**Gestational Diabetes** An estimated 2 to 10 percent of pregnancies in the United States are complicated by a condition known as **gestational diabetes.**[67] Gestational diabetes usually develops during the second half of pregnancy, with subsequent return to normal after childbirth. Some women with gestational diabetes, however, develop diabetes (usually type 2) after pregnancy, especially if they are overweight. For this reason, health-care professionals strongly advise against excessive weight gain during—and after—pregnancy. Weight gains after pregnancy increase the risk of gestational diabetes in the next pregnancy.[68]

The most common consequences of gestational diabetes are complications during labor and delivery and a high infant birthweight. Birth defects associated with gestational diabetes include heart damage, limb deformities, and neural tube defects. To ensure that the problems of gestational diabetes are dealt with promptly, physicians screen for the risk factors listed in Table 15-5 and test high-risk women for glucose intolerance immediately and average-risk women between 24 and 28 weeks gestation.[69]

Dietary recommendations should meet the needs of pregnancy and control maternal blood glucose.[70] Diet and moderate exercise may control gestational diabetes, but if blood glucose fails to normalize, insulin or other drugs may be required. Importantly, treatment reduces preeclampsia, birth complications, large newborns, and infant deaths.[71]

**Chronic Hypertension** Hypertension complicates pregnancy and affects its outcome in different ways, depending on when the hypertension first develops and on how severe it becomes.[72] In addition to the threats hypertension always carries (such as heart attack and stroke), high blood pressure increases the risks of fetal growth restriction, preterm birth, and separation of the placenta from the wall of the uterus before the birth, resulting in stillbirth.[73] To minimize complications, blood pressure needs to be under control before a woman with hypertension becomes pregnant.

**Gestational Hypertension** Women with chronic hypertension have a greater likelihood of developing **gestational hypertension**—high blood pressure during the second half of pregnancy.* For some women with gestational hypertension, the rise in blood pressure is mild and does not affect the pregnancy adversely. Blood pressure usually returns to normal during the first few weeks after childbirth. For others, gestational hypertension increases the risks of subsequent hypertension and type 2 diabetes. Gestational hypertension is also an early sign of the most serious maternal complication of pregnancy—preeclampsia.

**Preeclampsia** **Preeclampsia** is a condition characterized not only by gestational hypertension but also by protein in the urine. Table 15-6 presents the signs and symptoms of preeclampsia. The cause of preeclampsia remains unclear, but it usually occurs with first pregnancies and most often after 20 weeks of gestation. Obesity may increase the risk.[74] Symptoms typically regress within 2 days of delivery. Both men and women who were born of pregnancies complicated by preeclampsia are more likely to have a child born of a pregnancy complicated by preeclampsia, suggesting a genetic predisposition. They also tend to have a higher BMI and increased blood pressure during childhood and adolescence, indicating a greater risk for heart disease.[75] Black women have a much greater risk of preeclampsia than white women.

Preeclampsia affects almost all of the mother's organs—the circulatory system, liver, kidneys, and brain. Blood flow through the vessels that supply oxygen and nutrients to the placenta diminishes. For this reason, preeclampsia often restricts fetal growth. It also seems to increase the risk of epilepsy for the infant. In some cases, the placenta separates from the uterus, resulting in preterm birth or stillbirth.

*Blood pressure of 140/90 millimeters of mercury or greater during the second half of pregnancy in a woman who has not previously exhibited hypertension indicates high blood pressure.

**TABLE 15-5 Risk Factors for Gestational Diabetes**

- Age 25 or older
- BMI ≥25 or excessive weight gain
- Complications in previous pregnancies, including gestational diabetes or high-birthweight infant (>9 lb)
- Prediabetes or symptoms of diabetes
- Family history of type 2 diabetes

Pregnancy during the teen years has major health, emotional, social, and financial consequences for young mothers and their children.

Preeclampsia can progress rapidly to **eclampsia**—a condition characterized by seizures and coma. Maternal death during pregnancy and childbirth is rare in developed countries, but when it does occur, eclampsia is a common cause.[76] The rate of death for black women with eclampsia is more than four times the rate for white women.

Preeclampsia demands prompt medical attention. Treatment focuses on controlling blood pressure and preventing seizures. If preeclampsia develops early and is severe, induced labor or cesarean delivery may be necessary, regardless of gestational age. The infant will be preterm, with all of the associated problems, including poor lung development and special care needs. Several dietary factors have been studied, but none have proved beneficial in preventing preeclampsia.

## The Mother's Age

Maternal age also influences the course of a pregnancy. Compared with women of the physically ideal childbearing age of 20 to 25, both younger and older women face more complications of pregnancy.

### Pregnancy in Adolescents

Almost 40 percent of adolescents are sexually active before age 19.[77] More than 350,000 adolescent girls give birth each year in the United States; almost 20 percent of them already have at least one child.[78] Nourishing a growing fetus adds to a teenage girl's nutrition burden, especially if her growth is still incomplete. Simply being young and physically immature increases the risks of pregnancy complications. Pregnant teens are less likely to receive early prenatal care and are more likely to smoke during pregnancy—two factors that predict low birthweight and infant death.

The typical energy-dense, but nutrient-poor diet of pregnant adolescents increases the risk of low-birthweight infants. Common complications among adolescent mothers include iron-deficiency anemia (which may reflect poor diet and inadequate prenatal care) and prolonged labor (which reflects the mother's physical immaturity). On a positive note, maternal death is lowest for mothers younger than age 20.

The rates of stillbirths, preterm births, and low-birthweight infants are high for teenagers—both for teen moms and for teen dads. Many of these infants suffer physical problems, require intensive care, and die within the first year. The care of teen mothers and their infants costs our society billions of dollars annually. Because teenagers have few financial resources, they cannot pay these costs. Furthermore, their low economic status contributes significantly to the complications surrounding their pregnancies. At a time when prenatal care is most important, it is less accessible. And the pattern of teenage pregnancies continues from generation to generation, with daughters of teenage mothers more likely to become teenage mothers themselves. Clearly, teenage pregnancy is a major public health problem.

To support the needs of both mother and fetus, young teenagers (13 to 16 years old) are encouraged to strive for the highest weight gains recommended for pregnancy. For a teen who enters pregnancy at a healthy body weight, a weight gain of approximately 35 pounds is recommended; this amount minimizes the risk of delivering a low-birthweight infant. Pregnant and lactating teenagers can use the food patterns presented in Table 2-3 (p. 43), making sure to select a high enough kcalorie level to support adequate weight gain.

Without the appropriate economic, social, and physical support, a young mother will not be able to care for herself during her pregnancy and for her child after the birth. To improve her chances for a successful pregnancy and a healthy infant, she must seek prenatal care. WIC provides health-care referrals and helps pregnant teenagers obtain adequate food for themselves and their infants. (WIC is introduced on p. 490.)

### Pregnancy in Older Women

In the past several decades, many women have delayed childbearing while they pursue education and careers. As a result, the number of first births to women 35 and older has increased dramatically. Most of these women, even those older than age 50, have healthy pregnancies.

**eclampsia** (eh-KLAMP-see-ah): a condition characterized by extremely high blood pressure, elevated protein in the urine, seizures, and possibly coma.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The few complications associated with later childbearing often reflect chronic conditions such as hypertension and diabetes, which can complicate an otherwise healthy pregnancy. These complications may result in a cesarean delivery, which is twice as common in women older than 35 as among younger women. For all these reasons, maternal death rates are higher in women older than 35 than in younger women.

The babies of older mothers face problems of their own, including higher rates of preterm births and low birthweight. Their rates of birth defects are also high. Because 1 out of 50 pregnancies in older women produces an infant with genetic abnormalities, obstetricians routinely screen women older than 35. For a 40-year-old mother, the risk of having a child with **Down syndrome,** for example, is about 1 in 100 compared with 1 in 300 for a 35-year-old and 1 in 10,000 for a 20-year-old. In addition, fetal death is twice as high for women 35 years and older than for younger women. Why this is so remains unclear. One possibility is that the uterine blood vessels of older women may not fully adapt to the increased demands of pregnancy.

**Practices Incompatible with Pregnancy** Besides malnutrition, a variety of lifestyle factors can have adverse effects on pregnancy, and some may be **teratogenic,** causing abnormal fetal development and birth defects. By practicing healthy behaviors, people who are planning to have children can reduce the risks.

**Alcohol** One out of 13 pregnant women drinks alcohol at some time during her pregnancy; 1 out of 75 reports binge drinking.[79] Alcohol consumption during pregnancy can cause the irreversible mental and physical retardation of the fetus known as fetal alcohol syndrome (FAS). Of the leading causes of mental retardation, FAS is the only one that is totally *preventable.* To that end, the surgeon general urges all pregnant women to refrain from drinking alcohol. Fetal alcohol syndrome is the topic of Highlight 15, which includes mention of how alcohol consumption by men may also affect fertility and fetal development. In addition to fetal alcohol syndrome, maternal alcohol use has been associated with SIDS and leukemia.[80]

> **DIETARY GUIDELINES FOR AMERICANS**
Women who are pregnant should not drink alcohol.

**Medicinal Drugs** Drugs other than alcohol can also cause complications during pregnancy, problems in labor, and serious birth defects. For these reasons, pregnant women should not take any medicines without consulting their physicians, who must weigh the benefits against the risks.

**Herbal Supplements** Similarly, pregnant women should seek a physician's advice before using herbal supplements. Women sometimes seek herbal preparations during their pregnancies to quell nausea, induce labor, aid digestion, promote water loss, support restful sleep, and fight depression. As Highlight 18 explains, some herbs may be safe, but others may be harmful.

**Illicit Drugs** The recommendation to avoid drugs during pregnancy also includes illicit drugs, of course. Unfortunately, use of illicit drugs, such as cocaine, methamphetamine, and marijuana, is common among some pregnant women.[81]

Drugs of abuse, such as cocaine, easily cross the placenta and impair fetal growth and development. Furthermore, they are responsible for preterm births, low-birthweight infants, **perinatal** deaths, and sudden infant deaths. If these newborns survive, central nervous system damage is evident: their cries, sleep, and behaviors early in life are abnormal, and their cognitive development later in life is impaired.[82] They may be hypersensitive or underaroused; many suffer the symptoms of withdrawal. Their growth and development throughout childhood and adolescence continues to be delayed.[83]

**Smoking and Chewing Tobacco** Unfortunately, an estimated 12 percent of pregnant women in the United States smoke.[84] Smoking cigarettes and chewing tobacco at any time exert harmful effects, and pregnancy dramatically magnifies the hazards of these practices. Smoking restricts the blood supply to the growing fetus

**Down syndrome:** a genetic abnormality that causes mental retardation, short stature, and flattened facial features.

**teratogenic** (ter-AT-oh-jen-ik): causing abnormal fetal development and birth defects.

**perinatal:** referring to the time between the twenty-eighth week of gestation and 1 month after birth.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

and thus limits oxygen and nutrient delivery and waste removal. A mother who smokes is more likely to have a complicated birth and a low-birthweight infant. Indeed, of all preventable causes of low birthweight in the United States, smoking is at the top of the list. Although most infants born to cigarette smokers are low birthweight, some are not, suggesting that the effect of smoking on birthweight also depends, in part, on genes involved in the metabolism of smoking toxins.

In addition to contributing to low birthweight, smoking interferes with heart and lung growth and arterial structure and function; consequently, it increases the risks of heart defects, poor lung function, respiratory infections, and childhood asthma.[85] It can also cause death in an otherwise healthy fetus or newborn. A positive relationship exists between **sudden infant death syndrome (SIDS)** and both cigarette smoking during pregnancy and postnatal exposure to passive smoke. Smoking during pregnancy may reduce brain size and impair the intellectual and behavioral development of the child later in life. Table 15-7 lists complications of smoking during pregnancy.

**TABLE 15-7 Complications Associated with Smoking during Pregnancy**

- Fetal growth restriction
- Preterm birth
- Low birthweight
- Premature separation of the placenta
- Miscarriage
- Stillbirth
- Sudden infant death syndrome (SIDS)
- Congenital malformations

© 2016 Cengage Learning

Alternatives to smoking—such as using snuff or chewing tobacco—are not safe during pregnancy.[86] The safety and effectiveness of nicotine-replacement patches has not been determined, and therefore this therapy cannot be recommended at this time.[87] Any woman who uses nicotine in any form and is considering pregnancy or who is already pregnant needs to quit. Avoiding secondhand smoke is also advised. Pregnant women exposed to secondhand smoke during pregnancy are more likely to experience complications such as stillbirth and the birth of an infant with congenital malformations.[88]

**Environmental Contaminants** Proving that environmental contaminants cause reproductive damage is difficult, but evidence in wildlife is established and seems likely for human beings. Infants and young children of pregnant women exposed to environmental contaminants such as lead show signs of delayed mental and psychomotor development. During pregnancy, lead readily crosses into the placenta, inflicting severe damage on the developing fetal nervous system. In addition, infants exposed to even low levels of lead during gestation weigh less at birth and consequently struggle to survive. For these reasons, it is particularly important that pregnant women receive foods and beverages grown and prepared in environments free of contamination.

Mercury is another contaminant of concern. As Chapter 5 mentions, fatty fish are a good source of omega-3 fatty acids, but some fish contain large amounts of the pollutant mercury, which can impair fetal growth and harm the developing brain and nervous system. Because the benefits of seafood consumption seem to outweigh the risks, pregnant (and lactating) women need reliable information on which fish are safe to eat.[89] In general, they need to do the following:

- Avoid shark, swordfish, king mackerel, and tilefish (also called golden snapper or golden bass).
- Limit average weekly consumption to 12 ounces (cooked or canned) of seafood *or* to 6 ounces (cooked or canned) of white (albacore) tuna.

Ideally, pregnant (and lactating) women will select fish that are both high in omega-3 fatty acids and low in mercury.[90] Supplements of fish oil are not recommended because they may contain concentrated toxins and because their effects on pregnancy remain unknown.

**> DIETARY GUIDELINES FOR AMERICANS**

Women who are pregnant or breastfeeding should consume 8 to 12 ounces of seafood per week from a variety of seafood types. Fish relatively high in omega-3 fatty acids and low in mercury include anchovies, bonito, eel, herring, mackerel, pollock, salmon, sardines, smelt, tilapia, and trout. Because of the high methyl mercury content of some types of fish, pregnant or breastfeeding women should avoid tilefish, shark, swordfish, and king mackerel and should limit white (albacore) tuna to 6 ounces per week.

**sudden infant death syndrome (SIDS):** the unexpected and unexplained death of an apparently well infant; the most common cause of death of infants between the second week and the end of the first year of life; also called *crib death*.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Foodborne Illness** As Chapter 19 explains, foodborne illnesses arise when people eat foods that contain infectious microbes or microbes that produce toxins. At best, the vomiting and diarrhea associated with these illnesses can leave a pregnant woman exhausted and dehydrated; at worst, foodborne illnesses can cause meningitis, pneumonia, or even fetal death. Pregnant women are about 20 times more likely than other healthy adults to get the foodborne illness **listeriosis.** Table 15-8 presents tips to prevent listeriosis; Chapter 19 includes precautions to minimize the risks of other common foodborne illnesses.

### > DIETARY GUIDELINES FOR AMERICANS

Women who are pregnant should:

- Eat foods containing seafood, meat, poultry, or eggs only if cooked to recommended safe minimum internal temperatures.
- Take special precautions not to consume unpasteurized juice or milk products.
- Reheat deli and luncheon meats and hot dogs to steaming hot and not eat raw sprouts.

**Vitamin-Mineral Megadoses** Pregnant women who are trying to eat well may mistakenly assume that more is better when it comes to multivitamin-mineral supplements. This is simply not true; many vitamins and minerals are toxic when taken in excess. Excessive vitamin A is particularly infamous for its role in fetal malformations.[91] Intakes before the seventh week appear to be the most damaging. (Review Figure 15-4 on p. 477 to see how many tissues are in their critical periods prior to the seventh week.) For this reason, vitamin A supplements are not given during pregnancy unless there is specific evidence of deficiency, which is rare. A pregnant woman can obtain all the vitamin A and most of the other vitamins and minerals she needs by making wise food choices. She should take supplements only on the advice of a registered dietitian nutritionist or physician.

**Caffeine** Caffeine crosses the placenta, and the developing fetus has a limited ability to metabolize it. Research studies have not proved that caffeine (even in high doses) causes birth defects or preterm births in human infants (as it does in animals), but limited evidence suggests that heavy use increases the risk of hypertension, miscarriage, and stillbirth.[92] (In these studies, heavy caffeine use is defined as the equivalent of more than 3 cups of coffee a day.) Depending on the quantities consumed and the mother's metabolism, caffeine may also interfere with fetal growth.[93] Lower doses of caffeine—say, at levels equivalent to 3 cups of coffee or less—appear to be compatible with healthy pregnancies.[94] All things considered, it may be most sensible to limit caffeine consumption to the equivalent of a cup or two of coffee a day. (The caffeine contents of selected beverages, foods, and drugs are listed at the beginning of Appendix H.)

**Restrictive Dieting** Restrictive dieting, even for short periods, can be hazardous during pregnancy. Low-carbohydrate diets or fasts that cause ketosis deprive the fetal brain of needed glucose and may impair cognitive development. Such diets are also likely to lack other nutrients vital to fetal growth. Regardless of prepregnancy weight, pregnant women need an adequate diet to support healthy fetal development.

**Sugar Substitutes** Artificial sweeteners have been approved by the FDA and are generally considered safe to use during pregnancy.[95] Recent studies, however, have reported an association between a high intake of artificially sweetened soft drinks and an increased risk of preterm births.[96] Pregnant women might be wise to use sweeteners in moderation, if at all, and within an otherwise nutritious and well-balanced diet. Women with the inherited disease phenylketonuria (PKU) should not use the artificial sweetener aspartame. Aspartame contains the amino acid phenylalanine, and people with PKU are unable to dispose of any excess phenylalanine. The accumulation of phenylalanine and its by-products is toxic to the developing nervous system, causing irreversible brain damage.

**TABLE 15-8 Tips to Prevent Listeriosis**

- Use only pasteurized juices and dairy products; do not eat soft cheeses such as feta, brie, Camembert, Panela, "queso blanco," "queso fresco," and blue-veined cheeses such as Roquefort; do not drink raw (unpasteurized) milk or eat foods that contain it.
- Thoroughly cook meat, poultry, eggs, and seafood.
- Do not eat hot dogs or luncheon meats unless heated until steaming hot.
- Wash all fruits and vegetables.
- Do not eat refrigerated pâtés or meat spreads.
- Do not eat refrigerated smoked seafood such as salmon or trout, or any fish labeled "nova," "lox," or "kippered," unless prepared in a cooked dish.

© 2016 Cengage Learning

© nata-lunata/Shutterstock.com

Prenatal dietary supplements may be beneficial, but megadoses can be toxic.

**listeriosis** (lis-TEAR-ee-OH-sis): an infection caused by eating food contaminated with the bacterium *Listeria monocytogenes*, which can be killed by pasteurization and cooking but can survive at refrigerated temperatures; certain ready-to-eat foods, such as hot dogs and deli meats, may become contaminated after cooking or processing, but before packaging.

**› REVIEW IT** Identify factors predicting low-risk and high-risk pregnancies and describe ways to manage them.

High-risk pregnancies, especially for teenagers, threaten the life and health of both mother and infant. Proper nutrition and abstinence from smoking, alcohol, and other drugs improve the outcome. In addition, prenatal care includes monitoring pregnant women for gestational diabetes, gestational hypertension, and preeclampsia.

# 15.6 Nutrition during Lactation

**› LEARN IT** Summarize the nutrient needs of women during lactation.

Childbirth marks the end of pregnancy and the beginning of a new set of parental responsibilities—including feeding the newborn. Before the end of her pregnancy, a woman needs to consider whether to feed her infant breast milk, infant formula, or both. These options are the only recommended foods for an infant during the first 4 to 6 months of life. The current rate of breastfeeding met the Healthy People goal of 75 percent at birth, but it falls short of goals at 3 months, 6 months, and 1 year.[97] This section focuses on how the mother's nutrition supports the making of breast milk, and the next chapter describes how the infant benefits from drinking breast milk.

In many countries around the world, a woman breastfeeds her newborn without considering the alternatives or making a conscious decision. In other parts of the world, a woman feeds her newborn formula simply because she knows so little about breastfeeding. She may have misconceptions or feel uncomfortable about a process she has never seen or experienced. Breastfeeding offers many health benefits to both mother and infant, and every pregnant woman should seriously consider it (see Table 15-9).[98] Even so, women's choices are often influenced by factors other than health and science—factors such as culture, politics, religion, and marketing. In any case, keep in mind that mothers may have valid reasons for not breastfeeding and that formula-fed infants grow and develop into healthy children.

**lactation:** production and secretion of breast milk for the purpose of nourishing an infant.

**mammary glands:** glands of the female breast that secrete milk.

**prolactin** (pro-LAK-tin): a hormone secreted from the anterior pituitary gland that acts on the mammary glands to promote the production of milk. The release of prolactin is mediated by *prolactin-inhibiting hormone (PIH).*

- **pro** = promote
- **lacto** = milk

**oxytocin** (OCK-see-TOH-sin): a hormone that stimulates the mammary glands to eject milk during lactation and the uterus to contract during childbirth.

**let-down reflex:** the reflex that forces milk to the front of the breast when the infant begins to nurse.

**TABLE 15-9 Benefits of Breastfeeding**

**For Infants**

- Provides the appropriate composition and balance of nutrients with high bioavailability
- Provides hormones that promote physiological development
- Improves cognitive development
- Protects against a variety of infections and illnesses, including diarrhea, ear infections, and pneumonia
- May protect against some chronic diseases—such as diabetes (both types), obesity, atherosclerosis, asthma, some cancers, and hypertension—later in life
- Protects against food allergies
- Reduces the risk of SIDS
- Supports healthy weight

**For Mothers**

- Contracts the uterus
- Delays the return of regular ovulation, thus lengthening birth intervals (this is not, however, a dependable method of contraception)
- Conserves iron stores (by prolonging amenorrhea)
- May protect against breast and ovarian cancer and reduce the risk of diabetes (type 2)
- Increases energy expenditure, which may contribute to weight loss

**Other**

- Cost and time savings from not needing medical treatment for childhood illnesses or leaving work to care for sick infants
- Cost and time savings from not needing to purchase and prepare formula (even after adjusting for added foods in the diet of a lactating mother)[a]
- Environmental savings to society from not needing to manufacture, package, and ship formula and dispose of the packaging
- Convenience of not having to shop for and prepare formula

[a]Estimated savings of $1200–$1500 in the first year.

## Lactation: A Physiological Process

**Lactation** naturally follows pregnancy, as the mother's body continues to nourish the infant. The **mammary glands** secrete milk for this purpose. The mammary glands develop during puberty but remain fairly inactive until pregnancy. During pregnancy, hormones promote the growth and branching of a duct system in the breasts and the development of the milk-producing cells.

The hormones **prolactin** and **oxytocin** finely coordinate lactation. The infant's demand for milk stimulates the release of these hormones, which signal the mammary glands to supply milk. Prolactin is responsible for milk production. As long as the infant is nursing, prolactin concentrations remain high, and milk production continues.

The hormone oxytocin causes the mammary glands to eject milk into the ducts, a response known as the **let-down reflex.** The mother feels this reflex as a contraction of the breast, followed by the flow of milk and the release of pressure. By relaxing and eating well, the nursing mother promotes easy let-down of milk and greatly enhances her chances of successful lactation.

## Breastfeeding: A Learned Behavior

Lactation is an automatic physiological process that virtually all mothers are capable of doing. Breastfeeding, on the other hand, is a learned behavior that not all mothers decide to do. Of women who do breastfeed, those who receive early and repeated information and support breastfeed their infants longer than others. Mothers who are confident and committed are most successful in breastfeeding, especially when challenged by obstacles such as a lack of support from friends and family. Health-care professionals play an important role in providing encouragement and accurate information on breastfeeding. Especially helpful are **certified lactation consultants,** who specialize in helping new mothers establish a healthy breastfeeding relationship with their newborn. These consultants are often registered nurses with specialized training in breast and infant anatomy and physiology. Women who have been successful breastfeeding can offer advice and dispel misperceptions about lifestyle issues. Table 15-10 lists tips to promote successful breastfeeding among new mothers.

The mother's partner also plays an important role in encouraging breastfeeding. When partners support the decision, mothers are more likely to start and continue breastfeeding. Clearly, educating those closest to the mother could change attitudes and promote breastfeeding.

Most healthy women who want to breastfeed can do so with a little preparation. Physical obstacles to breastfeeding are rare, although most nursing mothers quit within a few months because of perceived difficulties. Obese mothers seem to have a particularly difficult time because of both biological and sociocultural factors.[99] Successful breastfeeding requires adequate nutrition and rest. This, plus the support of all who care, will help to enhance the well-being of mother and infant.

A woman who decides to breastfeed provides her infant with a full array of nutrients and protective factors to support optimal health and development.

## Maternal Energy and Nutrient Needs during Lactation

Ideally, the mother who chooses to breastfeed her infant will continue to eat nutrient-dense foods throughout lactation. An adequate diet is needed to support the stamina, patience, and self-confidence that nursing an infant demands.

### Energy Intake and Exercise

A nursing mother produces about 25 ounces of milk per day, with considerable variation from woman to woman and in the same woman from time to time, depending primarily on the infant's demand for milk. To produce an adequate supply of milk, a woman needs extra energy—almost 500 kcalories a day above her regular need during the first 6 months of lactation. To meet this energy need, she can eat an extra 330 kcalories of food each day during the first 6 months and an extra 400 kcalories each day during the second 6 months and the fat reserves she accumulated during pregnancy can provide the rest. Most women need at least 1800 kcalories a day to receive all the nutrients required for successful lactation. Severe energy restriction may hinder milk production.

After the birth of the infant, many women actively try to lose the extra weight and body fat they accumulated during pregnancy. How much weight a woman retains after pregnancy depends on her gestational weight gain and the duration and intensity of breastfeeding.[100] Many women who follow recommendations for gestational weight gain and breastfeeding can readily return to prepregnancy weight by 6 months. Neither the quality nor the quantity of breast milk is adversely affected by moderate weight loss, and infants grow normally.

**TABLE 15-10 Tips for Successful Breastfeeding**

- Learn about the benefits of breastfeeding
- Initiate breastfeeding within 1 hour after birth
- Ask a health-care professional to explain how to breastfeed and how to maintain lactation
- Give newborn infants no food or drink other than breast milk, unless medically indicated
- Breastfeed on demand
- Give no artificial nipples or pacifiers to breastfeeding infants[a]
- Find breastfeeding support groups, books, or websites to help troubleshoot breastfeeding problems

[a]Compared with nonusers, infants who use pacifiers breastfeed less frequently and stop breastfeeding at a younger age.

A jog through the park provides an opportunity for physical activity and fresh air.

Women often exercise to lose weight and improve fitness, and this is compatible with breastfeeding and infant growth.[101] Because intense physical activity can raise the lactate concentration of breast milk and influence the milk's taste, some infants may prefer milk produced prior to exercise. In these cases, mothers can either breastfeed before exercise or express their milk before exercise for use afterward.

**> DIETARY GUIDELINES FOR AMERICANS**

Maintain appropriate kcalorie balance during breastfeeding.

**Energy Nutrients** Recommendations for protein and fatty acids remain about the same during lactation as during pregnancy, but they increase for carbohydrates. Nursing mothers need additional carbohydrate to replace the glucose used to make the lactose in breast milk. The fiber recommendation is 1 gram higher simply because it is based on kcalorie intake, which increases during lactation.

**Vitamins and Minerals** A question often raised is whether a mother's milk may lack a nutrient if she fails to get enough in her diet. The answer differs from one nutrient to the next, but in general, nutrient inadequacies reduce the *quantity*, not the *quality*, of breast milk. Women can produce milk with adequate protein, carbohydrate, fat, and most minerals, even when their own supplies are limited. For these nutrients and for the vitamin folate as well, milk quality is maintained at the expense of maternal stores. This is most evident in the case of calcium: dietary calcium has no effect on the calcium concentration of breast milk, but maternal bones lose some density during lactation if calcium intakes are inadequate. Exercise may help protect against bone loss during lactation. The nutrients in breast milk that are most likely to decline in response to prolonged inadequate intakes are the vitamins—especially vitamins $B_6$, $B_{12}$, A, and D. Review Figure 15-9 (p. 484) to compare a lactating woman's nutrient needs with those of pregnant and nonpregnant women.

**Water** Despite misconceptions, a mother who drinks more fluid does not produce more breast milk. To protect herself from dehydration, however, a lactating woman needs to drink plenty of fluids. The recommendation for *total* water (including drinking water, other beverages, and foods) during lactation is 3.8 liters per day. Because foods provide about 20 percent of total water intake, beverages—including drinking water—should provide about 3.1 liters per day (roughly 13 cups). A sensible guideline is to drink a glass of milk, juice, or water at each meal and each time the infant nurses.

**Nutrient Supplements** Most lactating women can obtain all the nutrients they need from a well-balanced diet without taking multivitamin-mineral supplements. Nevertheless, some may need iron supplements, not to enhance the iron in breast milk, but to refill depleted iron stores. The mother's iron stores dwindle during pregnancy as she supplies the developing fetus with enough iron to last through the first 4 to 6 months of the infant's life. In addition, childbirth may have caused blood losses. Thus a woman may need iron supplements during lactation even though, until menstruation resumes, her iron requirement is about half that of other nonpregnant women her age.

**Food Assistance Programs** In general, women most likely to participate in the food assistance program WIC—those who are poor and have little education—are less likely to breastfeed.[102] Furthermore, WIC provides infant formula at no cost. Because WIC recognizes the many benefits of breastfeeding, efforts are made to overcome this dilemma.[103] In addition to nutrition education and encouragement, breastfeeding mothers receive the following WIC incentives:

- Higher priority in certification into WIC
- Greater quantity and variety of foods
- Longer eligibility to participate in WIC

Nutritious foods support successful lactation.

**Particular Foods** Foods with strong or spicy flavors (such as garlic) may alter the flavor of breast milk. A sudden change in the taste of the milk may annoy some infants. Familiar flavors may enhance enjoyment. Flavors in breast milk from the mother's diet can influence the infant's later food preferences.[104]

Current evidence does not support a major role for maternal dietary restrictions during lactation to prevent or delay the onset of food allergy in infants. Infants who develop symptoms of food allergy, however, may be more comfortable if the mother's diet excludes the most common offenders—cow's milk, eggs, fish, peanuts, and tree nuts. Generally, infants with a strong family history of food allergies benefit from breastfeeding.

A nursing mother can usually eat whatever nutritious foods she chooses. If she suspects a particular food is causing the infant discomfort, her physician may recommend a dietary challenge: eliminate the food from the diet to see if the infant's reactions subside, then return the food to the diet and again monitor the infant's reactions. If a food must be eliminated for an extended time, appropriate substitutions must be made to ensure nutrient adequacy.

## Maternal Health

If a woman has an ordinary cold, she can continue nursing without worry. If susceptible, the infant will catch it from her anyway. Thanks to the immunological protection of breast milk, the baby may be less susceptible than a formula-fed baby would be. With appropriate treatment, a woman who has an infectious disease such as tuberculosis or hepatitis can breastfeed; transmission is rare. Women with HIV (human immunodeficiency virus) infections, however, should consider other options.

**HIV Infection and AIDS** Mothers with HIV infections can transmit the virus (which causes AIDS) to their infants through breast milk, especially during the early months of breastfeeding. In developed countries such as the United States, where safe alternatives are available, HIV-positive women should *not* breastfeed their infants. In developing countries, where the feeding of inappropriate or contaminated formulas causes more than 1 million infant deaths each year, breastfeeding can be critical to infant survival. Thus, in making the decision of whether to breastfeed, HIV-infected women in developing countries must weigh the potential risks and benefits. The World Health Organization (WHO) recommends exclusive breastfeeding for infants of HIV-infected women for the first six months of life unless formula feeding is acceptable, feasible, affordable, sustainable, and safe before that time. Alternatively, HIV-exposed infants may be protected by receiving antiretroviral treatment while being breastfed.

**Diabetes** Women with diabetes (type 1) may need careful monitoring and counseling to ensure successful lactation. These women need to adjust their energy intakes and insulin doses to meet the heightened needs of lactation. Maintaining good glucose control helps to initiate lactation and support milk production.

**Postpartum Amenorrhea** Women who breastfeed experience prolonged **postpartum amenorrhea.** Absent menstrual periods, however, do not protect a woman from pregnancy. To prevent pregnancy, a couple must use some form of contraception. Breastfeeding women who use oral contraceptives should use progestin-only agents for at least the first 6 months. Estrogen-containing oral contraceptives reduce the volume and the protein content of breast milk.

**Breast Health** Some women fear that breastfeeding will cause their breasts to sag. The breasts do swell and become heavy and large immediately after the birth, but even

**postpartum amenorrhea** (ay-MEN-oh-REE-ah): the normal temporary absence of menstrual periods immediately following childbirth.

when they produce enough milk to nourish a thriving infant, they eventually shrink back to their prepregnancy size. Given proper support, diet, and exercise, breasts often return to their former shape and size when lactation ends. Breasts change their shape as the body ages, but breastfeeding does not accelerate this process.

Whether the physical and hormonal events of pregnancy and lactation protect women from later breast cancer is an area of active research. Some research suggests a protective effect between breastfeeding and breast cancer.[105]

## Practices Incompatible with Lactation

Some substances impair milk production or enter breast milk and interfere with infant development. This section discusses practices that a breastfeeding mother should avoid.

### Alcohol

Alcohol easily enters breast milk, and its concentration peaks within an hour after ingestion. Infants drink less breast milk when their mothers have consumed even small amounts of alcohol (equivalent to a can of beer). Three possible reasons, acting separately or together, may explain why. For one, the alcohol may have altered the flavor of the breast milk and thereby the infants' acceptance of it. For another, because infants metabolize alcohol inefficiently, even low doses may be potent enough to suppress their feeding and cause sleepiness. Third, the alcohol may have interfered with lactation by inhibiting the hormone oxytocin.

In the past, alcohol has been recommended to mothers to facilitate lactation despite a lack of scientific evidence that it does so. The research summarized here suggests that alcohol actually hinders breastfeeding. An occasional alcoholic beverage may be within safe limits, but breastfeeding should be delayed for at least 2 hours afterward.

### Medicinal Drugs

Most medicines are compatible with breastfeeding, but some are contraindicated, either because they suppress lactation or because they are secreted into breast milk and can harm the infant.[106] As a precaution, a nursing mother should consult with her physician prior to taking any drug, including herbal supplements.

### Illicit Drugs

Illicit drugs, of course, are harmful to the physical and emotional health of both the mother and the nursing infant. Breast milk can deliver such high doses of illicit drugs as to cause irritability, tremors, hallucinations, and even death in infants. Women whose infants have overdosed on illicit drugs contained in breast milk have been convicted of murder. Women who use methadone to control withdrawal symptoms for opiate addiction can safely breastfeed their infants.

### Smoking

Many women who quit smoking during pregnancy relapse after delivery. Smoking following childbirth may help them with weight loss at that time, but it harms the infant as well as the mother.[107] Because cigarette smoking lowers the concentrations of lipids and proteins and reduces milk volume, the breast milk of smokers may not meet their infants' energy needs.[108] The milk they do produce contains nicotine, which alters its smell and flavor. Furthermore, smoking increases the risk for SIDS.[109] Breastfeeding helps to protect against SIDS, but infant exposure to passive smoke negates this protective effect.[110]

### Environmental Contaminants

Chapter 19 discusses environmental contaminants in the food supply. Some of these environmental contaminants, such as DDT, PCBs, and dioxin, can find their way into breast milk. Inuit mothers living in Arctic Québec who eat seal and beluga whale blubber have high concentrations of DDT and PCBs in their breast milk, but the impact on infant development is unclear. Preliminary studies indicate that the children of these Inuit mothers are developing normally. Researchers speculate that the abundant omega-3 fatty acids of the Inuit diet may protect against damage to the central nervous system. Breast milk tainted with dioxin interferes with tooth development during early infancy, producing soft, mottled teeth that are vulnerable to dental caries. To limit mercury intake, lactating women should heed the fish restrictions for pregnant women that were mentioned previously (see p. 494).

**Caffeine** Caffeine enters breast milk and may make an infant irritable and wakeful. As during pregnancy, caffeine consumption should be moderate—the equivalent of 1 to 2 cups of coffee a day. Larger doses of caffeine may interfere with the bioavailability of iron from breast milk and impair the infant's iron status.

**› REVIEW IT** Summarize the nutrient needs of women during lactation.

The lactating woman needs extra fluid and enough energy and nutrients to produce about 25 ounces of milk a day. Breastfeeding is contraindicated for those with HIV/AIDS. Alcohol, other drugs, smoking, and contaminants may reduce milk production or enter breast milk and impair infant development.

This chapter has focused on the nutrition needs of the mother during pregnancy and lactation. The next chapter explores the dietary needs of infants, children, and adolescents.

## Nutrition Portfolio

The choices a woman makes in preparation for, and in support of, pregnancy and lactation can influence both her health and her infant's development—today and for decades to come. Go to Diet & Wellness Plus and choose one of the days on which you tracked your diet and activity for an entire day. Select the Intake vs. Goals report to help you answer the following questions:

- For women of childbearing age, determine whether you consume at least 400 micrograms of dietary folate equivalents daily.
- For women who are pregnant, evaluate whether you are meeting your nutrition needs and gaining the amount of weight recommended.
- For women who are about to give birth, carefully consider all the advantages of breastfeeding your infant and obtain the needed advice to support you.

DIET & WELLNESS PLUS To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com.**

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

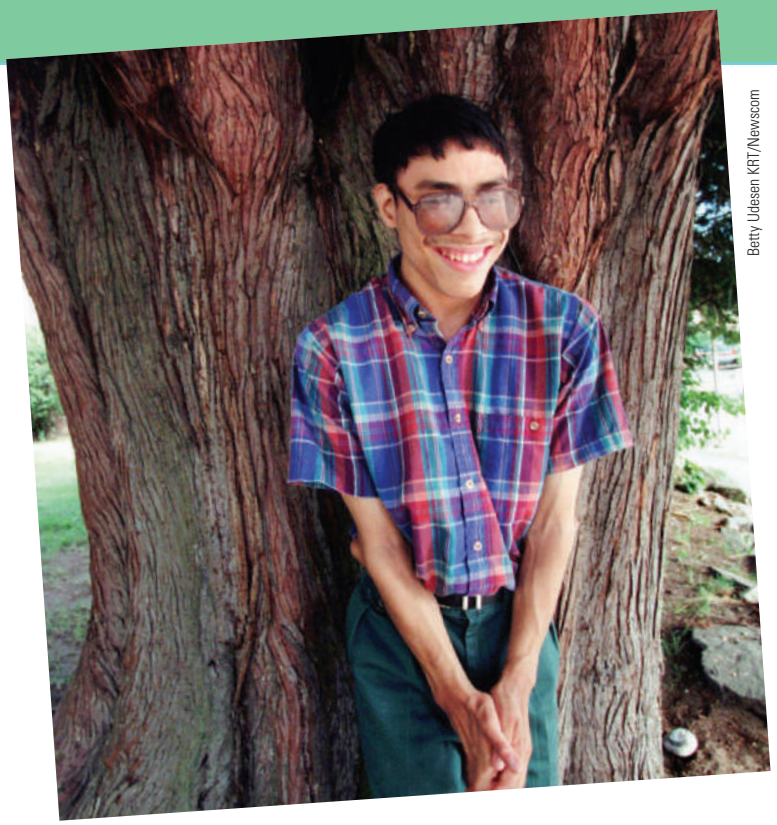
## Fetal Alcohol Syndrome



**› LEARN IT** Explain how drinking alcohol endangers the fetus and how women can prevent fetal alcohol syndrome.

As Chapter 15 mentions, drinking alcohol during pregnancy endangers the fetus.[1] Alcohol crosses the placenta freely and deprives the developing fetus of both nutrients and oxygen. The damaging effects of alcohol on the developing fetus cover a range of abnormalities referred to as **fetal alcohol spectrum disorder** (see the accompanying glossary).[2] Those at the most severe end of the spectrum are described as having **fetal alcohol syndrome (FAS),** a cluster of physical, mental, and neurobehavioral symptoms that includes:[3]

- Prenatal and postnatal growth restriction
- Abnormalities of the brain and central nervous system, with consequent impairment in cognition and behavior
- Physical abnormalities of the face and skull that alter normal patterns of symmetry (see Figure H15-1, p. 506)[4]
- Increased frequency of major birth defects such as cleft palate, heart defects, and defects in ears, eyes, genitals, and urinary system

Those with more severe physical abnormalities have more cognitive limitations. Tragically, the damage evident at birth persists: children with FAS never fully recover.

Each year, an estimated 6000 infants are born in the United States with FAS because their mothers drank too much alcohol during pregnancy.[5] In addition, at least three times as many infants have had enough **prenatal alcohol exposure** to result in some symptoms of fetal alcohol spectrum disorder. The cluster of *mental* problems associated with prenatal alcohol exposure is known as **alcohol-related neurodevelopmental disorder (ARND),** and the *physical* malformations are referred to as **alcohol-related birth defects (ARBD).** Some children with ARBD and ARND have no outward signs; others may be short or have only minor facial abnormalities. Diagnosis is often overlooked until after 1 year of age.[6] Children commonly go undiagnosed even when they develop learning difficulties in the early school years. Mood disorders and problem behaviors, such as aggression, are common. These children typically need support and guidance to function and participate in daily activities.

Betty Udesen KRT/Newscom

The surgeon general states that pregnant women should abstain from alcohol. Abstinence from alcohol is the best policy for pregnant women both because alcohol consumption during pregnancy has such severe consequences and because FAS can only be prevented—it cannot be treated. Further, because the most severe damage occurs around the time of conception—*before a woman may even realize that she is pregnant*—the warning to abstain includes women who may become pregnant.

**> DIETARY GUIDELINES FOR AMERICANS**
Women who are pregnant should not drink alcohol.

## Drinking during Pregnancy

As mentioned in Chapter 15, 1 out of 13 pregnant women drinks alcohol at some time during her pregnancy; 1 out of 75 admits to binge drinking.[7] When a woman drinks during pregnancy, she causes damage in two ways: directly, by intoxication, and indirectly, by malnutrition.

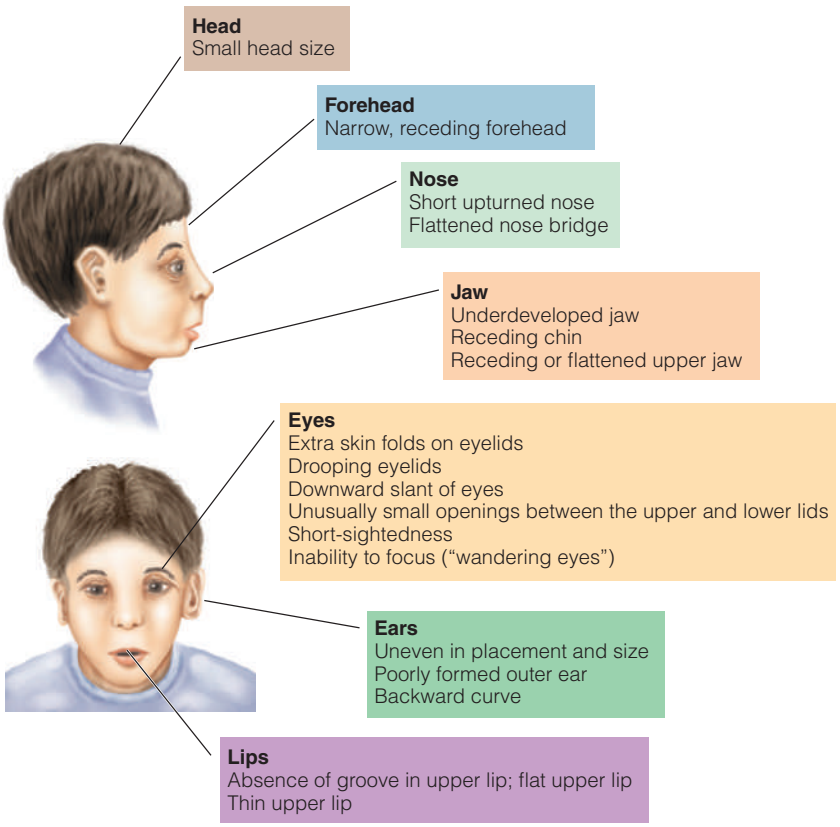
## GLOSSARY

**alcohol-related birth defects (ARBD):** malformations in the skeletal and organ systems (heart, kidneys, eyes, ears) associated with prenatal alcohol exposure.

**alcohol-related neurodevelopmental disorder (ARND):** abnormalities in the central nervous system and cognitive development associated with prenatal alcohol exposure.

**fetal alcohol spectrum disorder:** a range of physical, behavioral, and cognitive abnormalities caused by prenatal alcohol exposure.

**fetal alcohol syndrome (FAS):** a cluster of physical, behavioral, and cognitive abnormalities associated with prenatal alcohol exposure, including facial malformations, growth retardation, and central nervous disorders.



**prenatal alcohol exposure:** subjecting a fetus to a pattern of excessive alcohol intake characterized by substantial regular use or heavy episodic drinking.

Note: See Highlight 7 for other alcohol-related terms and information.

> FIGURE H15-1 Typical Facial Characteristics of FAS

© Cengage Learning

Stuart Wong Krt/Newscom

As can be seen from this 25-year-old woman with FAS, the characteristic facial features may diminish with time, but physical impairments continue, resulting in short height.

Prior to the complete formation of the placenta (approximately 12 weeks), alcohol diffuses directly into the tissues of the developing embryo, causing incredible damage. (Review Figure 15-4 on p. 477 and note that the critical periods for most tissues occur during this time of embryonic development.) Alcohol interferes with the orderly development of tissues during their critical periods, reducing the number of cells and damaging those that are produced. The damage of alcohol toxicity during brain development is apparent in its reduced size and impaired function.

When alcohol crosses the placenta, fetal blood alcohol rises until it reaches equilibrium with maternal blood alcohol. The mother may not even appear drunk, but the fetus may be poisoned. The fetus's body is small, its detoxification system is immature, and alcohol remains in fetal blood long after it has been cleared from maternal blood.

A pregnant woman harms her unborn child not only by consuming alcohol but also by not consuming food. This combination enhances the likelihood of malnutrition and a poorly developed infant. It is important to realize, however, that malnutrition is not the cause of FAS. It is true that mothers of FAS children often have unbalanced diets and nutrient deficiencies. It is also true that nutrient deficiencies may exacerbate the clinical signs seen in these children, but it is the *alcohol* that causes the damage. An adequate diet alone will not prevent FAS if alcohol use continues.

## How Much Is Too Much?

A pregnant woman need not have an alcohol-abuse problem to give birth to a baby with FAS. She need only drink in excess of her liver's capacity to detoxify alcohol. The damaging effects on the developing fetus are dose dependent, becoming greater as the dose increases.[8] Even one drink a day threatens neurological development and behaviors. Four drinks a day dramatically increase the risk of having an infant with physical malformations.

In addition to total alcohol intake, drinking patterns play an important role. Most FAS studies report their findings in terms of average intake per day, but people often drink more heavily on some days than on others. For example, a woman who drinks an *average* of 1 ounce of alcohol (2 drinks) a day may not drink at all during the week, but then have 10 drinks on Saturday night, exposing the fetus to extremely toxic quantities of alcohol. Whether various drinking patterns incur damage depends on the frequency of consumption, the quantity consumed, and the stage of fetal development at the time of each drinking episode.

An occasional drink may be innocuous, but researchers are unable to say how much alcohol is safe to consume during pregnancy. For this reason, health-care professionals urge women to stop drinking alcohol as soon as they realize they are pregnant, or better, as soon as they *plan* to become pregnant. Why take any risk? The only sure way to protect an infant from alcohol damage is for the mother to abstain.

Bill Roth/MCT/Newscom

Children born with FAS must live with the long-term consequences of alcohol damage. This 20-year-old man was born 3 months preterm with a 0.237 blood alcohol level, which took his 2-pound body 4 days to clear from his system.

© Matt Faruggio Photography

All containers of beer, wine, and liquor warn women not to drink alcoholic beverages during pregnancy because of the risk of birth defects.

## When Is the Damage Done?

The type of abnormality observed in an FAS infant depends on the developmental events occurring at the times of alcohol exposure. During the first trimester, developing organs such as the brain, heart, and kidneys may be malformed. During the second trimester, the risk of spontaneous abortion increases. During the third trimester, body and brain growth may be retarded. Quite simply, the risk begins with any use.[9]

The father's alcohol ingestion may also affect fertility and fetal development. Animal studies have found smaller litter sizes, lower birthweights, reduced survival rates, and impaired learning ability in the offspring of males consuming alcohol prior to conception. An association between paternal alcohol intake 1 month prior to conception and low infant birthweight has been reported in human beings. Alcohol use creates epigenetic changes in sperm DNA that may alter gene expression and result in features of fetal alcohol spectrum disorders.

In view of the damage caused by FAS, prevention efforts focus on educating women not to drink during pregnancy. Public service announcements and alcohol beverage warning labels help to raise awareness. Everyone should hear the message loud and clear: don't drink alcohol during pregnancy.

## CRITICAL THINKING QUESTIONS

A. What are the moral implications of using alcohol during pregnancy?
B. Clearly, drinking alcohol during pregnancy endangers the developing fetus, yet controversy surrounds the questions as to how much alcohol causes damage and when the damage is done. What difficulties might researchers encounter in trying to determine the exact amount of alcohol and the timing during pregnancy that might be reasonably safe for fetal development?

# Life Cycle Nutrition: Infancy, Childhood, and Adolescence

## Nutrition in Your Life

Much of this book has focused on you—your food choices and how they might affect your health. This chapter shifts the focus from you the recipient to you the caregiver. One day (if not already), children may depend on you to feed them well and teach them wisely. The responsibility of nourishing children can seem overwhelming at times, but the job is fairly simple. Offer children a variety of nutritious foods to support their growth and teach them how to make healthy food and activity choices. Presenting foods in a relaxed and supportive environment nourishes both physical and emotional well-being. In the Nutrition Portfolio at the end of this chapter, you can plan a day's menu for a child 4 to 8 years of age and determine whether it meets nutrient requirements to support healthy growth but not so much as to promote obesity.

Nutrient needs change throughout the growing years and vary from individual to individual. The first year of life (infancy) is a time of phenomenal growth and development. The infant's high nutrient needs and developing maturity determine which foods are most appropriate to meet the needs for each stage of the first year. After the first year, a child continues to grow and change, but more slowly. Still, the cumulative effects over the next decade are remarkable. Then as the child enters the teen years, the pace toward adulthood accelerates dramatically. The physical changes of adolescents make their nutrient needs high, and their emotional, intellectual, and social changes make meeting those needs a challenge. Sound nutrition throughout infancy, childhood, and adolescence promotes normal growth and development, facilitates academic and physical performance, and may help prevent the development of obesity, diabetes, heart disease, some cancers, and other chronic diseases in adulthood. This chapter examines the special nutrient needs of infants, children, and adolescents.

## LEARNING GPS

**16.1 Nutrition during Infancy 510**

**LEARN IT** List some of the components of breast milk and describe the appropriate foods for infants during the first year of life.

- Energy and Nutrient Needs 510
- Breast Milk 512
- Infant Formula 515
- Special Needs of Preterm Infants 516
- Introducing Cow's Milk 516
- Introducing Solid Foods 517
- Mealtimes with Toddlers 520

**16.2 Nutrition during Childhood 520**

**LEARN IT** Explain how children's appetites and nutrient needs reflect their stage of growth and why iron deficiency and obesity are often concerns during childhood.

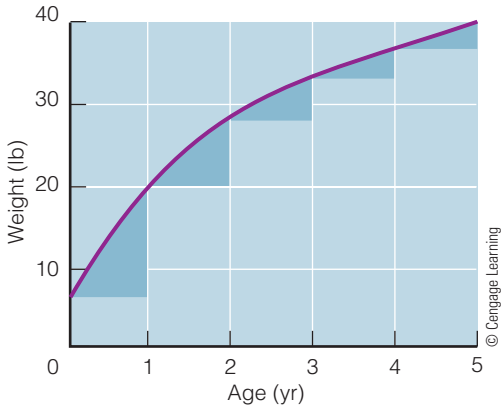
- Energy and Nutrient Needs 520
- Hunger and Malnutrition in Children 523
- The Malnutrition-Lead Connection 524
- Hyperactivity and "Hyper" Behavior 526
- Food Allergy and Intolerance 527
- Childhood Obesity 528
- Mealtimes at Home 534
- Nutrition at School 536

**16.3 Nutrition during Adolescence 539**

**LEARN IT** Describe some of the challenges in meeting the nutrient needs of adolescents.

- Growth and Development 539
- Energy and Nutrient Needs 539
- Food Choices and Health Habits 541

**Highlight 16** Childhood Obesity and the Early Development of Chronic Diseases 548



**LEARN IT** Describe the lifestyle factors that can help prevent childhood obesity and the development of type 2 diabetes and heart disease.

After 6 months, energy saved by slower growth is spent in increased activity.

# 16.1 Nutrition during Infancy

**› LEARN IT** List some of the components of breast milk and describe the appropriate foods for infants during the first year of life.

Initially, the infant drinks only breast milk or formula but later begins to eat some foods, as appropriate. Common sense in the selection of infant foods—along with a nurturing, relaxed environment—supports an infant's health and well-being.

## Energy and Nutrient Needs

An infant grows fast during the first year, as Figure 16-1 shows. Growth directly reflects nutrient intake and is an important factor in assessing the nutrition status of infants and children. Health-care professionals measure the height and weight of an infant or child at intervals and compare the measurements with standard growth charts for gender and age and with previous measures of that infant or child (see the accompanying "How To" feature).

### Energy Intake and Activity

A healthy infant's birthweight doubles by about 5 months of age and triples by 1 year, typically reaching 20 to 25 pounds. The infant's length changes more slowly than weight, increasing about 10 inches from birth to 1 year. By the end of the first year, infant growth slows considerably; during the second year, an infant typically gains less than 10 pounds and grows about 5 inches in length. At the age of 2, healthy children have attained approximately half of their adult height.

Not only do infants grow rapidly, but their energy requirement is remarkably high—about twice that of an adult, based on body weight. A newborn baby requires about 450 kcalories per day, whereas most adults require about 2000 kcalories per day. In terms of body weight, the difference is remarkable. Infants require about 100 kcalories per kilogram of body weight per day, whereas most adults need fewer than 40 (see Table 16-1). If an infant's energy needs were applied to an adult, a 170-pound adult would require more than 7000 kcalories a day. After 6 months, the infant's energy needs decline as the growth rate slows, but some of the energy saved by slower growth is spent in increased activity.

### Energy Nutrients

Recommendations for the energy nutrients—carbohydrate, fat, and protein—during the first 6 months of life are based on the average intakes of healthy, full-term infants fed breast milk.[1] During the second 6 months of life, recommendations reflect typical intakes from solid foods as well as breast milk.

As Chapter 4 discusses, carbohydrates provide energy to all the cells of the body, but those in the brain depend primarily on glucose to fuel activities. Relative to the size of the body, the size of an infant's brain is greater than that of an adult's. An infant's brain weight is about 12 percent of its body weight, whereas an adult's brain weight is about 2 percent. Thus, an infant's brain uses *relatively* more glucose—about 60 percent of the day's total energy intake.

Fat provides most of the energy in breast milk and standard infant formula. Its high energy density supports the rapid growth of early infancy. Fat also provides the essential fatty acids needed for normal growth and development. As Chapter 5 mentions, DHA (docosahexaenoic acid) is the most abundant fatty acid in the brain and is also present in the retina of the eye, contributing to neural and visual development. DHA accumulation in the brain is greatest during fetal development and early infancy.[2]

No single nutrient is more essential to growth than protein; it is the basic building material of the body's tissues. All of the body's cells and most of its fluids contain protein. Consequently, inadequate protein intake has widespread effects, limiting brain function, weakening immune defenses, and disrupting digestion and absorption. The term *failure to thrive* is used to describe the many problems associated with infants and children suffering from protein deficiency. Excess dietary protein can cause problems, too, especially in a small infant. Too much protein stresses the liver and kidneys, which have to metabolize and excrete the excess nitrogen. Signs of protein overload include acidosis, dehydration, diarrhea, elevated blood ammonia, elevated blood urea, and fever. Such

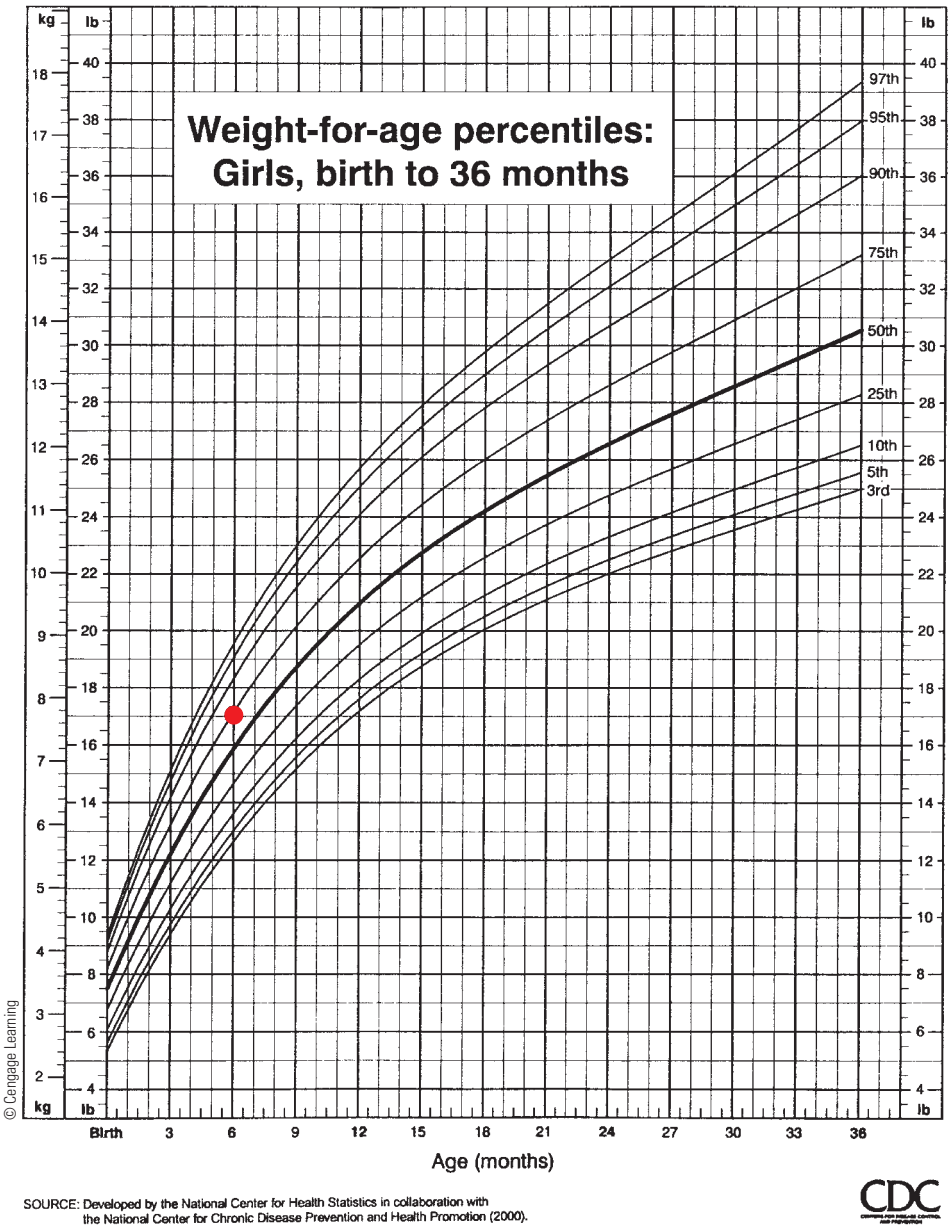
## >How To



### Plot Measures on a Growth Chart

You can assess the growth of infants and children by plotting their measurements on a percentile graph. Percentile graphs divide the measures of a population into 100 equal divisions so that half of the population falls at or above the 50th percentile and half falls below. Using percentiles allows for comparisons among people of the same age and gender.

To plot measures on a growth chart, follow these steps:

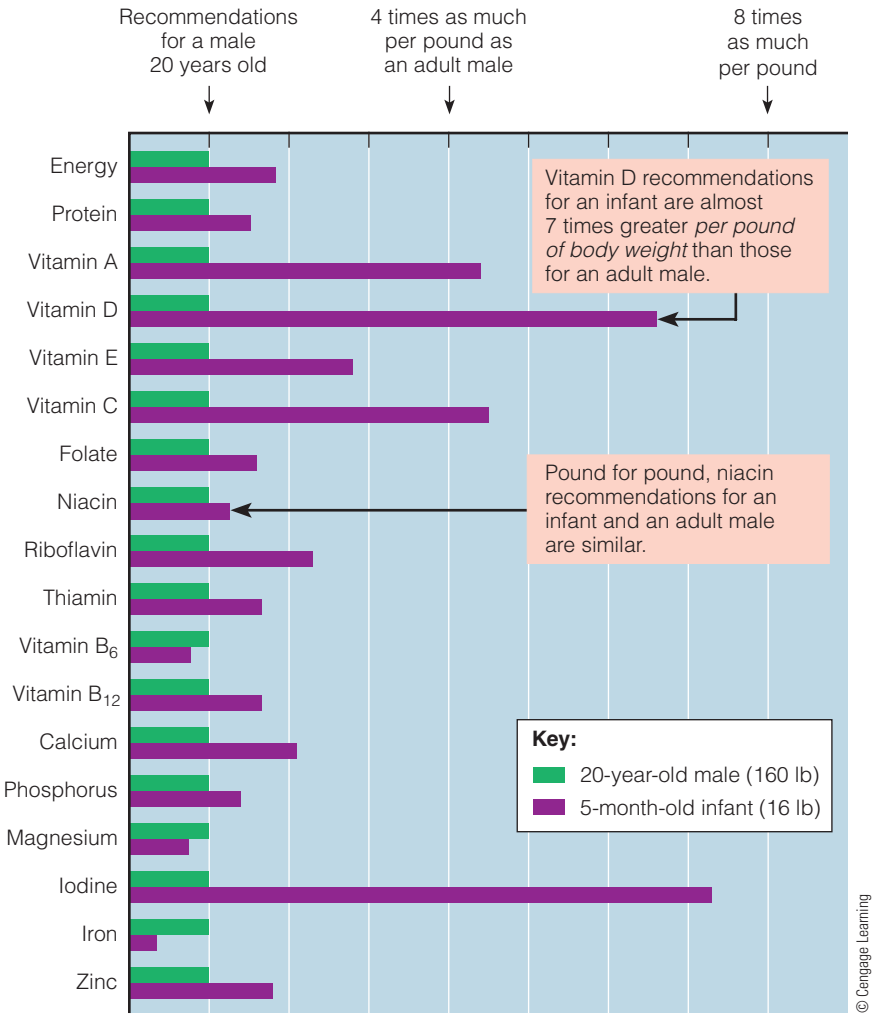
- Select the appropriate chart based on age and gender. For this example, use the accompanying chart, which gives percentiles for weight for girls from birth to 36 months. (Appendix E provides other growth charts for both boys and girls of various ages.)
- Locate the infant's age along the horizontal axis at the bottom of the chart (in this example, 6 months).
- Locate the infant's weight in pounds or kilograms along the vertical axis of the chart (in this example, 17 pounds or 7.7 kilograms).
- Mark the chart where the age and weight lines intersect (shown here with a red dot), and follow the curved line to find the percentile.

This 6-month-old infant is at the 75th percentile. Her pediatrician will weigh her again over the next few months and expect the growth curve to follow the same percentile throughout the first year. In general, dramatic changes or measures much above the 80th percentile or much below the 10th percentile may be cause for concern.

› **TRY IT** Determine the percentile for a 12-month-old girl who weighs 21 pounds.

problems are not common, but they have been observed in infants fed inappropriate foods, such as fat-free milk or concentrated formula.

**Vitamins and Minerals** An infant's needs for most nutrients, in proportion to body weight, are more than double those of an adult. Figure 16-2 (p. 512) illustrates this by comparing a 5-month-old infant's needs per unit of body weight with those of an adult man. Some of the differences are extraordinary. Infant recommendations are based on the average amount of nutrients consumed by thriving infants breastfed by well-nourished mothers.



**Water** One of the most essential nutrients for infants, as for everyone, is water. The younger the infant, the greater the percentage of body weight is water. During

**> FIGURE 16-2 Recommended Intakes of an Infant and an Adult Compared on the Basis of Body Weight**

Because infants are small, they need smaller total amounts of the nutrients than adults do, but when comparisons are based on body weight, infants need more than twice as much of many nutrients. Infants use large amounts of energy and nutrients, in proportion to their body size, to keep all their metabolic processes going.

© Cengage Learning

early infancy, breast milk or infant formula normally provides enough water to replace fluid losses in a healthy infant. If the environmental temperature is extremely high, however, infants need supplemental water.[3] Because much of the fluid in an infant's body is located *outside* the cells—between the cells and within the blood vessels—rapid fluid losses and the resulting dehydration can be life-threatening. Conditions that cause rapid fluid loss, such as diarrhea or vomiting, require prompt treatment with an electrolyte solution designed for infants.

## Breast Milk

In the United States, the two dietary practices that have the most significant effect on an infant's nutrition are the milk the infant receives and the age at which solid foods are introduced. A later section discusses the introduction of solid foods, but as to the milk, the American Academy of Pediatrics strongly recommends breastfeeding for healthy full-term infants, except where specific contraindications exist. The Academy of Nutrition and Dietetics also advocates breastfeeding for the nutritional health of the infant as well as for the many other benefits it provides both infant and mother (review Table 15-9 on p. 496).[4]

Breast milk excels as a source of nutrients for infants. Its unique nutrient composition and protective factors promote optimal infant health and development throughout the first year of life. Ideally, infants will receive exclusive breastfeeding for 6 months, and breastfeeding with complementary foods for at least 12 months.[5] Experts add, though, that iron-fortified formula, which imitates the nutrient composition of breast milk, is an acceptable alternative. After all, the primary goal is to provide the infant nourishment in a relaxed and loving environment. Chapter 15 discusses maternal nutrition to support successful breastfeeding.

### Frequency and Duration of Breastfeeding

Breast milk is more easily and completely digested than formula, so breastfed infants usually need to eat more frequently than formula-fed infants do. During the first few weeks, approximately 8 to 12 feedings a day, on demand, as soon as the infant shows early signs of hunger such as increased alertness, activity, or suckling motions. Such a schedule promotes optimal milk production and infant growth. Crying is a late indicator of hunger. An infant who nurses every 2 to 3 hours and sleeps contentedly between feedings is adequately nourished. As the infant gets older, stomach capacity enlarges and the mother's milk production increases, allowing for longer intervals between feedings.

Even though the infant obtains about half the milk from the breast during the first 2 to 3 minutes of suckling, the infant should be encouraged to breastfeed on the first breast for as long as he or she is actively suckling, before being offered the second breast. The next feeding begins on the breast offered last. The infant's suckling, as well as the complete removal of milk from the breast, stimulates milk production.

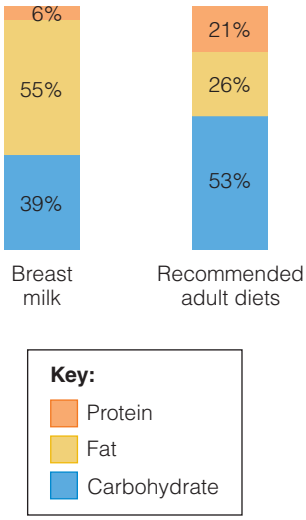
**Energy Nutrients** The energy-nutrient composition of breast milk differs dramatically from that recommended for adult diets (see Figure 16-3). Yet for infants, breast milk is nature's most nearly perfect food, providing the clear lesson that people at different stages of life have different nutrient needs.

The main carbohydrate in breast milk (and standard infant formula) is the disaccharide lactose. In addition to being easily digested, lactose enhances calcium absorption. The carbohydrate component of breast milk also contains abundant oligosaccharides, which are present only in trace amounts in cow's milk and infant formula made from cow's milk.[6] Breast milk oligosaccharides help protect the infant from infection by preventing the binding of pathogens to the infant's intestinal cells.[7]

The amount of protein in breast milk is less than in cow's milk, but this quantity is actually beneficial because it places less stress on the infant's immature kidneys to excrete urea, the major end product of protein metabolism. Much of the protein in breast milk is **alpha-lactalbumin,** which is efficiently digested and absorbed.

As for the lipids, breast milk contains a generous proportion of the essential fatty acids linoleic acid and linolenic acid, as well as their longer-chain derivatives arachidonic acid and DHA. DHA accumulation in the brain is higher in breastfed infants than in formula-fed infants.[8] Research has focused on the mental and visual development of breastfed infants and infants fed standard formula with and without DHA added.[9] Results of studies for visual acuity are mixed, perhaps because of factors such as the amount of DHA provided, the source of the DHA, and the sensitivity of different measures for visual acuity.[10] Some evidence from studies examining the effects of DHA status during fetal and infant development on cognitive function suggests that DHA supplementation can make a positive difference.[11] Adding DHA to standard infant formulas has no adverse effects; most standard formulas are currently fortified with both DHA and arachidonic acid.

**Vitamins** With the exception of vitamin D, the vitamins in breast milk are ample to support infant growth. The vitamin D in breast milk is low, however, and vitamin D deficiency impairs bone mineralization.[12] Vitamin D deficiency is most likely in infants who are not exposed to sunlight daily, have darkly pigmented skin, and receive breast milk without vitamin D supplementation. Reports of infants in the United States developing the vitamin D–deficiency disease rickets and recommendations to keep infants younger than 6 months of age out of direct sunlight prompted revisions in vitamin D guidelines. The American Academy of Pediatrics currently recommends a vitamin D supplement for all infants who are breastfed exclusively and for all infants who do not receive at least 1 liter (1000 milliliters, roughly 1 quart or 32 ounces) of vitamin D–fortified formula daily.[13]



**Minerals** The calcium content of breast milk is ideal for infant bone growth, and the calcium is well absorbed. Breast milk contains relatively small amounts of iron, but the iron has a high bioavailability. Zinc also has a high bioavailability, thanks to the presence of a zinc-binding protein. Breast milk is low in sodium, another benefit for the infant's immature kidneys. Fluoride promotes the development of strong teeth, but breast milk is not a good source.

**Supplements** Many pediatricians routinely prescribe liquid supplements containing vitamin D, iron, and fluoride as outlined in Table 16-2. In addition, infants receive a single dose of vitamin K at birth to protect them from bleeding to death. (See Chapter 11 for a description of vitamin K's role in blood clotting.)

**Immunological Protection** In addition to its nutritional benefits, breast milk offers immunological protection. Not only is breast milk sterile, but it also actively fights disease and protects infants from illnesses.[14] Such protection is most valuable

**> FIGURE 16-3 Percentages of Energy-Yielding Nutrients in Breast Milk and in Recommended Adult Diets**

The proportions of energy-yielding nutrients in human breast milk differ from those recommended for adults.

© Cengage Learning

NOTE: The values listed for adults represent approximate midpoints of the acceptable ranges for protein (10 to 35 percent), fat (20 to 35 percent), and carbohydrate (45 to 65 percent).

**alpha-lactalbumin** (lact-AL-byoo-min): a major protein in human breast milk, as opposed to *casein* (CAY-seen), a major protein in cow's milk.

**TABLE 16-2 Supplements for Full-Term Infants**

| | Vitamin D[a] | Iron[b] | Fluoride[c] |
|---|---|---|---|
| **Breastfed infants** | | | |
| Birth to 6 months of age | ✓ | | |
| 6 months to 1 year | ✓ | ✓ | ✓ |
| **Formula-fed infants** | | | |
| Birth to 6 months of age | | | |
| 6 months to 1 year | | ✓ | ✓ |

[a]Vitamin D supplements are recommended for all infants who are exclusively breastfed and for any infants who do not receive at least 1 liter (1000 milliliters, roughly 1 quart or 32 ounces) of vitamin D–fortified formula per day.

[b]All infants 6 months of age need additional iron, preferably in the form of iron-fortified infant cereal and/or infant meats. Formula-fed infants need iron-fortified infant formula.

[c]At 6 months of age, breastfed infants and formula-fed infants who receive ready-to-use formulas (these are prepared with water low in fluoride) or formula mixed with water that contains little or no fluoride (less than 0.3 ppm) need supplements.

**TABLE 16-3 Protective Factors in Breast Milk**

| Factor(s) | Action(s) |
|---|---|
| Antibodies | Offer protection in the upper respiratory tract and gastrointestinal tract by inhibiting pathogen attachment to the mucosa and protecting against invasive infections; may stimulate the infant's immune system |
| Bifidus factors | Favor the growth of the "friendly" bacterium *Lactobacillus bifidus* in the infant's digestive tract so that other, harmful bacteria cannot become established |
| Growth factors: | |
| Epidermal growth factor | Regulates cell growth, proliferation, and differentiation |
| Transforming growth factor-beta (TGF-β) | Inhibits inflammatory bowel diseases; supports a healthy epithelial barrier |
| Lactadherin | Inhibits pathogen attachment to the intestinal mucosa |
| Lactoferrin | Prevents bacteria from getting the iron needed to grow; helps absorb iron into the infant's bloodstream; kills some bacteria directly; inhibits viral activity |
| Lysozyme | Kills bacteria by assisting lactoferrin |
| Oligosaccharides | Help to establish and maintain growth of desired bacteria in gastrointestinal tract; inhibit pathogen attachment to the intestinal mucosa |

The infant thrives on infant formula offered with affection.

during the first year, when the infant's immune system is not fully prepared to mount a response against infections.

During the first 2 to 3 days after delivery, the breasts produce **colostrum,** a premilk substance containing mostly serum with antibodies and white blood cells. Colostrum (like breast milk) helps protect the newborn from infections against which the mother has developed immunity. The maternal antibodies in the breast milk inactivate disease-causing bacteria within the infant's digestive tract before they can start infections.[15] This explains, in part, why breastfed infants have fewer intestinal infections than formula-fed infants. In addition to antibodies, colostrum and breast milk provide other powerful agents that help to fight against bacterial and viral infection (see Table 16-3).

**Allergy and Disease Protection** In addition to protection against infections, breast milk may offer protection against the development of allergies.[16] Compared with formula-fed infants, breastfed infants have a lower incidence of allergic reactions, such as recurrent wheezing and skin rashes. This protection is especially noticeable among infants with a family history of allergies.[17] Breastfeeding may also reduce the risk of sudden infant death syndrome (SIDS).[18] The protective effect against SIDS is stronger when infants are exclusively breastfed, but breastfeeding to any extent for any duration offers some protection. Similarly, breast milk may offer protection against the development of cardiovascular disease in adulthood, but additional research, using consistent and precise definitions of breastfeeding, is needed to confirm this effect.[19]

**Other Potential Benefits** Breastfeeding may offer some protection against excessive weight gain later, although findings are inconsistent.[20] For example, some research suggests that the longer the duration of breastfeeding, the lower the risk of overweight in childhood, while other research conflicts with such findings.[21] Researchers note that many other factors—socioeconomic status, other infant and child feeding practices, and especially the mother's weight—strongly predict a child's body weight.[22]

Many studies suggest a beneficial effect of breastfeeding on intelligence, but when subjected to strict standards of methodology (for example, large sample size and appropriate intelligence testing), the evidence is less than convincing.[23] Nevertheless, the possibility that breastfeeding may positively affect later intelligence is intriguing. It may be that some specific component of breast milk, such as DHA, stimulates brain development or that certain factors associated with the feeding process itself promote intellect.[24] Most likely, a combination of factors is involved. More large, well-controlled studies are needed to confirm the effects, if any, of breastfeeding on brain development and intelligence.

**Breast Milk Banks** Similar to blood banks that collect blood from individuals to give to others in need, **breast milk banks** receive milk from lactating women who have an abundant supply to give to infants whose own mothers' milk is unavailable or insufficient.[25] The women who donate breast milk are carefully screened to exclude those who smoke cigarettes, use illicit drugs, take medications (including high doses of dietary supplements), drink more than two alcoholic beverages a day, or have communicable diseases. The breast milk from several donors is pooled to ensure an even distribution of all components, pasteurized to destroy bacteria,

**colostrum** (ko-LAHS-trum): a milklike secretion from the breast, present during the first few days after delivery before milk appears; rich in protective factors.

**breast milk bank:** a service that collects, screens, processes, and distributes donated human milk.

checked for contamination, and frozen before being shipped overnight to hospitals, where it is dispensed by physician prescription. In the absence of a mother's own breast milk, donor milk may be the life-saving solution for fragile infants, most notably those with very low birthweight or unusual medical conditions.

## Infant Formula

A woman who breastfeeds for a year can **wean** her infant to cow's milk, bypassing the need for infant formula. A woman who decides to feed her infant formula from birth, to wean to formula after less than a year of breastfeeding, or to substitute formula for breastfeeding on occasion must select an appropriate infant formula and learn to prepare it. Cow's milk is inappropriate during the first year of life.

### Infant Formula Composition

Formula manufacturers attempt to copy the nutrient composition of breast milk as closely as possible. Figure 16-4 illustrates the energy-nutrient balance of breast milk, infant formula, and cow's milk. All formula-fed infants should be given iron-fortified infant formulas.[26] The increasing use of iron-fortified formulas over the past few decades is responsible for the decline in iron-deficiency anemia among infants in the United States.

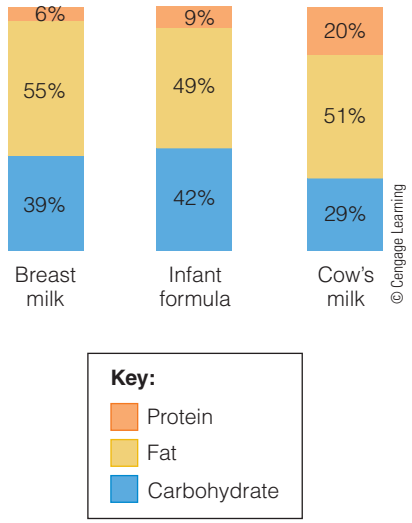
### Risks of Formula Feeding

Infant formulas contain no protective antibodies for infants, but in general, vaccinations, purified water, and clean environments in developed countries help protect infants from infections. Formulas can be prepared safely by following the rules of proper food handling and by using water that is free of contamination. Of particular concern is lead-contaminated water, a major source of lead poisoning in infants. Because the first water drawn from the tap each day is highest in lead, a person living in a house with old, lead-soldered plumbing should let the water run a few minutes before drinking or using it to prepare formula or food.

Water supplies contain variable concentrations of minerals, including fluoride. As mentioned in Chapter 13, optimal levels of fluoride protect against dental caries, but too much fluoride during tooth development can cause defects in the teeth known as fluorosis. Inadequate fluoride after 6 months of age may also be a concern. Thus, health experts urge caregivers to have their well water analyzed for mineral contents and to check with the local health department to determine the fluoride content of the community water supply. Caregivers should reconstitute powdered or concentrated liquid formulas with optimally fluoridated water (0.7 to 1.2 parts per million).[27] If fluoride levels are excessive, ready-to-feed formulas or formulas prepared with fluoride-free or low-fluoride water can be used. Such waters are labeled "purified," "demineralized," "deionized," or "distilled." If fluoride levels are inadequate, formulas may need to be prepared with fluoridated bottled water once the infant is 6 months of age.

In developing countries and in poor areas of the United States, formula may be unavailable, prepared with contaminated water, or overdiluted in an attempt to save money. Contaminated formulas may cause infections, leading to diarrhea, dehydration, and malabsorption. Without sterilization and refrigeration, formula is an ideal breeding ground for bacteria. Whenever such risks are present, breastfeeding can be a life-saving option: breast milk is sterile, and its antibodies enhance an infant's resistance to infections.

### Infant Formula Standards



National and international standards have been set for the nutrient contents of infant formulas. In the United States, the standard developed by the American Academy of Pediatrics reflects "human milk taken from well-nourished mothers during the first or second month of lactation, when the infant's growth rate is high." The Food and Drug Administration (FDA) mandates the safety and nutritional quality of infant formulas. Formulas meeting these standards have similar nutrient compositions. Small differences among formulas are sometimes confusing, but they are usually unimportant.

### Special Formulas

Standard formulas are inappropriate for some infants. Special formulas have been designed to meet the dietary needs of infants with specific conditions such as prematurity or inherited diseases. Most infants allergic to milk protein can drink formulas based on soy protein.[28] Soy formulas also

**> FIGURE 16-4 Percentages of Energy-Yielding Nutrients in Breast Milk, Infant Formula, and Cow's Milk**

The average proportions of energy-yielding nutrients in human breast milk and formula differ slightly. In contrast, cow's milk provides too much protein and too little carbohydrate.

**wean:** to gradually replace breast milk with infant formula or other foods appropriate to an infant's diet.

use cornstarch and sucrose instead of lactose and so are recommended for infants with lactose intolerance as well. They are also useful as an alternative to milk-based formulas for vegan families. Despite these limited uses, soy formulas account for about 15 percent of the infant formulas sold today. Although soy formulas support the normal growth and development of infants, for infants who don't need them, they offer no advantage over milk formulas.

Some infants who are allergic to cow's milk protein may also be allergic to soy protein.[29] For these infants, special formulas based on hydrolyzed protein are available. The protein in these formulas is a mixture of free amino acids, dipeptides, tripeptides, and short-chain peptides that do not elicit an allergic reaction in most infants.

**Inappropriate Formulas** Caregivers must use only products designed for infants; soy *beverages,* for example, are nutritionally incomplete and inappropriate for infants. Goat's milk is also inappropriate for infants in part because of its low folate content.[30] An infant receiving goat's milk is likely to develop "goat's milk anemia," an anemia characteristic of folate deficiency.

**Nursing Bottle Tooth Decay** An infant cannot be allowed to sleep with a bottle because of the potential damage to developing teeth. Salivary flow, which normally cleanses the mouth, diminishes as the infant falls asleep. Prolonged sucking on a bottle of formula, milk, or juice bathes the upper teeth in a carbohydrate-rich fluid that nourishes decay-producing bacteria. (The tongue covers and protects most of the lower teeth, but they, too, may be affected.) The result is extensive and rapid tooth decay (see Figure 16-5). To prevent **nursing bottle tooth decay,** no infant should be put to bed with a bottle of nourishing fluid.

## Special Needs of Preterm Infants

An estimated one out of eight pregnancies in the United States results in a preterm birth.[31] The terms *preterm* and *premature* imply incomplete fetal development, or immaturity, of many body systems. As might be expected, preterm birth is a leading cause of infant deaths. Preterm infants face physical independence from their mothers before some of their organs and body tissues are ready. The rate of weight gain in the fetus is greater during the last trimester of gestation than at any other time. Therefore, a preterm infant is most often a low-birthweight infant as well. A premature birth deprives the infant of the nutritional support of the placenta during a time of maximal growth.

The last trimester of gestation is also a time of building nutrient stores. Being born with limited nutrient stores intensifies the already precarious situation for the infant. The physical and metabolic immaturity of preterm infants further compromises their nutrition status. Nutrient absorption, especially of fat and calcium, from an immature GI tract is limited. Consequently, preterm, low-birthweight infants are candidates for nutrient imbalances. Deficiencies of the fat-soluble vitamins, calcium, iron, and zinc are common.

Preterm breast milk is well suited to meet a preterm infant's needs. During early lactation, preterm breast milk contains higher concentrations of protein and is lower in volume than term breast milk. The low milk volume is advantageous because preterm infants consume small quantities of milk per feeding, and the higher protein concentration allows for better growth. In many instances, supplements of nutrients specifically designed for preterm infants are added to the mother's expressed breast milk and fed to the infant from a bottle. When fortified with a preterm supplement, preterm breast milk supports growth at a rate that approximates the growth rate that would have occurred within the uterus.[32]

## Introducing Cow's Milk

The age at which cow's milk should be introduced to the infant's diet has long been a source of controversy. The American Academy of Pediatrics advises that cow's milk is not appropriate during the first year.[33] For some infants, particularly those younger than 6 months of age, cow's milk may cause intestinal bleeding, which can lead to iron deficiency.[34] Cow's milk is also a poor source of iron. Consequently, it both causes iron loss and fails to replace iron. Furthermore,

**nursing bottle tooth decay:** extensive tooth decay due to prolonged tooth contact with formula, milk, fruit juice, or other carbohydrate-rich liquid offered to an infant in a bottle.

the bioavailability of iron from infant cereal and other foods is reduced when cow's milk replaces breast milk or iron-fortified formula during the first year. Compared with breast milk or iron-fortified formula, cow's milk is higher in calcium and lower in vitamin C, characteristics that further reduce iron absorption. In addition, the higher protein concentration of cow's milk can stress the infant's kidneys. In short, infants need breast milk or iron-fortified infant formula, *not* cow's milk.

**> DIETARY GUIDELINES FOR AMERICANS**

Children 2 to 3 years of age should consume 2 cups of milk or milk products per day, and children 4 to 8 years of age should consume 2½ cups per day.

Ideally, by 1 year, the infant is obtaining at least two thirds of the total daily food energy from a balanced mixture of cereals, vegetables, fruits, and other foods. At this time, reduced-fat or low-fat cow's milk is an acceptable and recommended beverage to accompany a diet that supplies 30 percent of kcalories from fat.[35] After the age of 2, a transition to fat-free milk can take place, but care should be taken to avoid excessive restriction of dietary fat.

Until recently, the American Academy of Pediatrics recommended the use of whole cow's milk for children between the ages of 1 and 2 years. That guideline was dropped in light of accumulating evidence that atherosclerosis begins in childhood and that risk factors (such as the saturated fat of whole milk) should be limited as early as possible. Among the new guidelines is the recommendation that children 1 to 2 years of age consume reduced-fat (2 percent fat) or low-fat (1 percent fat) milk and that children 2 years of age and older consume fat-free milk to limit saturated fat in the diet.

## Introducing Solid Foods

The high nutrient needs of infancy are met first by breast milk or formula only and then by the limited addition of selected foods over time. Infants gradually develop the ability to chew, swallow, and digest the wide variety of foods available to adults. The caregiver's selection of appropriate foods at the appropriate stages of development is prerequisite to the infant's optimal growth and health.

### When to Begin

In addition to breast milk or formula, an infant can begin eating solid foods between 4 and 6 months.[36] The American Academy of Pediatrics supports exclusive breastfeeding for 6 months but recognizes that infants are often developmentally ready to accept complementary foods between 4 and 6 months of age. The main purpose of introducing solid foods is to provide needed nutrients that are no longer supplied adequately by breast milk or formula alone.[37] The foods chosen must be those that the infant is developmentally capable of handling both physically and metabolically. As digestive secretions gradually increase throughout the first year of life, the digestion of solid foods becomes more efficient. The exact timing depends on the individual infant's needs and developmental readiness (see Table 16-4, p. 518), which vary from infant to infant because of differences in growth rates, activities, and environmental conditions. In addition to the infant's nutrient needs and physical readiness to handle different forms of foods, the need to detect and control allergic reactions should also be considered when introducing solid foods.

### Food Allergies

To prevent allergy and to facilitate its prompt identification should it occur, experts recommend introducing single-ingredient foods, one at a time, in small portions, and waiting 3 to 5 days before introducing the next new food.[38] For example, rice cereal is usually the first cereal introduced because it is the least allergenic. When it is clear that rice cereal is not causing an allergy, another grain, perhaps barley or oat is introduced. Wheat cereal is offered last because it is the most common offender. If a cereal causes an allergic reaction such as a skin rash, digestive upset, or respiratory discomfort, it should be discontinued before introducing the next food. A later section in this chapter offers more information about food allergies.

**TABLE 16-4 Infant Development and Recommended Foods**

Because each stage of development builds on the previous stage, the foods from an earlier stage continue to be included in all later stages.

| Age (mo) | Feeding Skill | Appropriate Foods Added to the Diet |
|---|---|---|
| 0–4 | Turns head toward any object that brushes cheek.<br>Initially swallows using back of tongue; gradually begins to swallow using front of tongue as well.<br>Strong reflex to push food out (extrusion) during first 2 to 3 months. | Feed breast milk or infant formula. |
| 4–6 | Extrusion reflex diminishes, and the ability to swallow nonliquid foods develops.<br>Indicates desire for food by opening mouth and leaning forward.<br>Indicates satiety or disinterest by turning away and leaning back.<br>Sits erect with support at 6 months.<br>Begins chewing action.<br>Brings hand to mouth.<br>Grasps objects with palm of hand. | Begin iron-fortified cereal mixed with breast milk, formula, or water.<br>Begin pureed meats, legumes, vegetables, and fruits. |
| 6–8 | Able to self-feed finger foods.<br>Develops pincer (finger to thumb) grasp.<br>Begins to drink from cup. | Begin textured vegetables and fruits.<br>Begin unsweetened, diluted fruit juices from cup. |
| 8–10 | Begins to hold own bottle.<br>Reaches for and grabs food and spoon.<br>Sits unsupported. | Begin breads and cereals from table.<br>Begin yogurt.<br>Begin pieces of soft, cooked vegetables and fruit from table.<br>Gradually begin finely cut meats, fish, casseroles, cheese, eggs, and mashed legumes. |
| 10–12 | Begins to master spoon, but still spills some. | Add variety.<br>Gradually increase portion sizes.[a] |

[a]Portion sizes for infants and young children are smaller than those for an adult. For example, a grain serving might be ½ slice of bread instead of 1 slice, or ¼ cup rice instead of ½ cup.

Foods such as iron-fortified cereals and formulas, mashed legumes, and strained meats provide iron.

**Choice of Infant Foods** Infant foods should be selected to provide variety, balance, and moderation. Commercial baby foods offer a wide variety of palatable, nutritious foods in a safe and convenient form. Parents or caregivers should not feed directly from the jar; instead, spoon the needed portion into a dish and feed from there, leaving the leftovers in the jar uncontaminated by a used spoon. Homemade infant foods can be as nutritious as commercially prepared ones, so long as the cook minimizes nutrient losses during preparation. Ingredients for homemade foods should be fresh, whole foods without added salt, sugar, or seasonings. Pureed food can be frozen in ice cube trays, providing convenient-size blocks of food that can be thawed, warmed, and fed to the infant. To guard against foodborne illnesses, hands and equipment must be kept clean.

**Foods to Provide Iron** Rapid growth demands iron. At about 4 to 6 months of age, the infant begins to need more iron than body stores plus breast milk or iron-fortified formula can provide. In addition to breast milk or iron-fortified formula, infants can receive iron from iron-fortified cereals and, once they readily accept solid foods, from meats or legumes. Iron-fortified cereals contribute a significant amount of iron to an infant's diet, but the iron's bioavailability is poor.[39] Caregivers can enhance iron absorption from iron-fortified cereals by serving vitamin C–rich foods with meals.

**Foods to Provide Vitamin C** The best sources of vitamin C are fruits and vegetables (see pp. 330–332 in Chapter 10). It has been suggested that infants who are introduced to fruits before vegetables may develop a preference for sweets and find the vegetables less palatable, but there is no evidence to support offering these foods in a particular order.[40]

Fruit juice is a good source of vitamin C, but excessive juice intake can lead to diarrhea in infants and young children.[41] Furthermore, too much fruit juice contributes excessive kcalories and displaces other nutrient-rich foods. The American Academy of Pediatrics recommends limiting juice consumption for infants and children (2 to 10 years of age) to 4 ounces per day.[42] Fruit juices should be diluted and served in a cup, not a bottle, once the infant is 6 months of age or older.

> **DIETARY GUIDELINES FOR AMERICANS**

Monitor intake of 100 percent fruit juice for children, especially those who are overweight or obese.

**Foods to Omit** Concentrated sweets, including baby food "desserts," have no place in an infant's diet. They convey no nutrients to support growth, and the extra food energy can promote obesity. Products containing sugar alcohols such as sorbitol should also be limited because they may cause diarrhea. Canned vegetables are also inappropriate for infants because they often contain too much sodium. Honey and corn syrup should never be fed to infants because of the risk of **botulism.*** Infants and young children are vulnerable to foodborne illnesses, and the *Dietary Guidelines for Americans* address this risk.

> **DIETARY GUIDELINES FOR AMERICANS**

Infants and young children should not eat or drink unpasteurized milk, milk products, or juices; raw or undercooked eggs, meat, poultry, fish, or shellfish; or raw sprouts.

Infants and even young children cannot safely chew and swallow any of the foods listed in Table 16-5; they can easily choke on these foods, a risk not worth taking. Nonfood items may present even greater choking hazards to infants and young children. Parents and caregivers must pay careful attention to eliminate choking hazards in children's environments.

**Vegetarian Diets during Infancy** The newborn infant is a lacto-vegetarian. As long as the infant has access to sufficient quantities of either iron-fortified infant formula or breast milk (plus a vitamin D supplement) from a mother who eats an adequate diet, the infant will thrive during the early months. "Health-food beverages," such as rice milk, are inappropriate choices because they lack the protein, vitamins, and minerals infants and toddlers need; in fact, their use can lead to nutrient deficiencies.

Infants older than about 6 months of age present a greater challenge in terms of meeting nutrient needs by way of vegetarian and, especially, vegan diets. Continued breastfeeding or formula feeding is recommended, but supplementary feedings are necessary to ensure adequate energy and iron intakes. Infants and young children in vegetarian families should be given iron-fortified infant cereals well into the second year. Mashed or pureed legumes, tofu, and cooked eggs can be added to their diets in place of meats.[43]

Infants who receive a well-balanced vegetarian diet that includes milk products and a variety of other foods can easily meet their nutritional requirements for growth. This is not always true for vegan infants; the growth of vegan infants slows significantly when weaning from breast milk to solid foods. Deficiencies of protein, vitamin D, vitamin $B_{12}$, iron, and calcium have been reported in infants fed vegan diets. Vegan diets that are high in fiber, other complex carbohydrates, and water will fill infants' stomachs before meeting energy needs. This problem can be partially alleviated by providing more energy-dense foods, such as mashed legumes, tofu, and avocado. Using soy formulas (or milk) fortified with calcium, vitamin $B_{12}$, and vitamin D and including vitamin C–containing foods at meals to enhance iron absorption will help prevent some nutrient deficiencies in vegan diets. Parents or caregivers who choose to feed their infants vegan diets should consult with their pediatrician and a registered dietitian nutritionist frequently to ensure a nutritionally adequate diet that will support growth.

**Foods at 1 Year** At 1 year of age, reduced-fat or low-fat cow's milk can become a primary source of most of the nutrients an infant needs; 2 to 3 cups a day meets those needs sufficiently. Ingesting more milk than this can displace iron-rich foods, which can lead to **milk anemia.** If powdered milk is used, it should contain some fat.

*In infants, but not in older individuals, ingestion of *Clostridium botulinum* spores can cause illness when the spores germinate in the intestine and produce a toxin, which is absorbed. Symptoms include poor feeding, constipation, loss of tension in the arteries and muscles, weakness, and respiratory compromise. Infant botulism has been implicated in 5 percent of cases of sudden infant death syndrome (SIDS).

**TABLE 16-5 Examples of Common Choking Items**

| Foods | |
|---|---|
| • Gum | • Raw carrots |
| • Hard or gel-type candies | • Raw celery |
| • Hot dog slices | • Sausage sticks or slices |
| • Large raw apple slices | • Whole beans |
| • Marshmallows | • Whole cherries |
| • Nuts | • Whole grapes |
| • Peanut butter | |
| • Popcorn | |
| **Nonfood items** | |
| • Balloons | • Small balls and marbles |
| • Coins | • Other items of similar size |
| • Pen tops | |

Let toddlers explore and enjoy their food.

Other foods—meats, other protein foods, iron-fortified cereals, enriched or whole-grain breads, fruits, and vegetables—should be supplied in variety and in amounts sufficient to round out total energy needs. Ideally, a 1-year-old will sit at the table, eat many of the same foods everyone else eats, and drink liquids from a cup, not a bottle. Figure 16-6 shows a meal plan that meets a 1-year-old's requirements.

**Mealtimes with Toddlers** The nurturing of a young child involves more than nutrition. Those who care for young children are responsible not only for providing nutritious foods, milk, and water, but also a safe, loving, secure environment in which the children may grow and develop. In light of toddlers' developmental and nutrient needs and their often contrary and willful behavior, a few feeding guidelines may be helpful:

- *Discourage unacceptable behavior, such as standing at the table or throwing food.* Be consistent and firm, not punitive. For example, instead of saying "You make me mad when you don't sit down," say "The fruit salad tastes good; please sit down and eat some with me." The child will soon learn to sit and eat.
- *Let toddlers explore and enjoy food, even if this means eating with fingers for a while.* Learning to use a spoon will come in time. Children who are allowed to touch, mash, and smell their food while exploring it are more likely to accept it.
- *Don't force food on children.* Rejecting new foods is normal, and acceptance is more likely as children become familiar with new foods through repeated opportunities to taste them. Instead of saying "You cannot go outside to play until you taste your carrots," say "You can try the carrots again another time."
- *Provide nutritious foods and let children choose which ones, and how much, they will eat.* Gradually, they will acquire a taste for different foods.
- *Limit sweets.* Infants and young children have little room for empty-kcalorie foods in their daily energy allowance. Do not use sweets as a reward for eating meals.
- *Don't turn the dining table into a battleground.* Make mealtimes enjoyable. Teach healthy food choices and eating habits in a pleasant environment. Mealtimes are not the time to fight, argue, or scold.

**› REVIEW IT** List some of the components of breast milk and describe the appropriate foods for infants during the first year of life.

The primary food for infants during the first 12 months is either breast milk or iron-fortified formula. In addition to nutrients, breast milk also offers immunological protection. At about 4 to 6 months of age, infants should gradually begin eating solid foods. By 1 year, they are drinking from a cup and eating many of the same foods as the rest of the family.

## 16.2 Nutrition during Childhood

**› LEARN IT** Explain how children's appetites and nutrient needs reflect their stage of growth and why iron deficiency and obesity are often concerns during childhood.

Each year from age 1 to adolescence, a child typically grows taller by 2 to 3 inches and heavier by 5 to 6 pounds. Growth charts provide valuable clues to a child's health. Weight gains out of proportion to height gains may reflect overeating and inactivity, whereas measures significantly less than the standard suggest inadequate nutrition.

Increases in height and weight are only two of the many changes growing children experience (see Figure 16-7). At age 1, children can stand alone and are beginning to toddle; by 2, they can walk and are learning to run; and by 3, they can jump and climb with confidence. Bones and muscles increase in mass and density to make these accomplishments possible. Thereafter, lengthening of the long bones and increases in musculature proceed unevenly and more slowly until adolescence.

**Energy and Nutrient Needs** Children's appetites begin to diminish around 1 year, consistent with the slowing growth. Thereafter, children spontaneously vary their food intakes to coincide with their growth patterns; they demand more food

during periods of rapid growth than during slow growth. Sometimes they seem insatiable, and other times they seem to live on air and water.

Children's energy intakes also vary widely from meal to meal. Even so, their total daily intakes remain remarkably constant. If children eat less at one meal, they typically eat more at the next, and vice versa. Overweight children do not always adjust their energy intakes appropriately, however, and may eat in response to external cues such as television commercials, disregarding hunger and satiety signals.[44]

**Energy Intake and Activity** As mentioned, children's energy needs vary widely, depending on their growth and physical activity. A 1-year-old child needs about 800 kcalories a day; an active 6-year-old child needs twice as many kcalories a day. By age 10, an active child needs about 2000 kcalories a day. Total energy needs increase slightly with age, but energy needs per kilogram of body weight actually decline gradually.

> **FIGURE 16-7 Body Shape of 1-Year-Old and 2-Year-Old Compared**

The body shape of a 1-year-old (left) changes dramatically by age 2 (right). The 2-year-old has lost much of the baby fat; the muscles (especially in the back, buttocks, and legs) have firmed and strengthened; and the leg bones have lengthened.

© Anthony M. Vannelli (all)

Physically active children of any age need more energy because they expend more, and inactive children can become obese even when they eat less food than the average. Unfortunately, our nation's children are becoming less and less active; child care programs and schools would serve our children well by offering more activities to promote physical fitness.[45] Children who learn to enjoy physical play and exercise, both at home and at school, are best prepared to maintain active lifestyles as adults.

> **DIETARY GUIDELINES FOR AMERICANS**

Children should do 60 minutes or more of physical activity daily. Children are encouraged to spend no more than 1 to 2 hours each day watching television, playing electronic games, or using the computer (other than for homework).

Some children, notably those adhering to a vegan diet, may have difficulty meeting their energy needs. Grains, vegetables, and fruits provide plenty of fiber, adding bulk, but may provide too little energy to support growth. Soy products, other legumes, and nut or seed butters offer more concentrated sources of energy to support optimal growth and development.[46]

**Carbohydrate and Fiber** Carbohydrate recommendations are based on the brain's glucose needs. After 1 year of age, the brain's use of glucose remains fairly constant and is within the adult range. Carbohydrate recommendations for children older than 1 year are therefore the same as for adults (see inside front cover).

Fiber recommendations derive from adult intakes shown to reduce the risk of heart disease and are based on energy intakes. Consequently, fiber recommendations for younger children with low energy intakes are less than those for older ones with high energy intakes (see inside front cover).

> **DIETARY GUIDELINES FOR AMERICANS**

Children and adolescents should consume whole-grain products often, and at least half of the grains should be whole grains.

**Fat and Fatty Acids** No RDA for total fat has been established, but the DRI Committee recommends a fat intake of 30 to 40 percent of energy for children 1 to 3 years of age and 25 to 35 percent for children 4 to 18 years of age. As long as children's energy intakes are adequate, however, fat intakes less than 30 percent of total energy do not impair growth.[47] Children who eat low-fat diets, however, tend to have low intakes of some vitamins and minerals. Recommended intakes of the essential fatty acids are based on average intakes (see inside front cover).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**> DIETARY GUIDELINES FOR AMERICANS**

Keep total fat intake between 30 to 40 percent of kcalories for children 1 to 3 years of age and between 25 and 35 percent of kcalories for children and adolescents 4 to 18 years of age, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils.

**Protein** Like energy needs, total protein needs increase slightly with age, but when the child's body weight is considered, the protein requirement actually declines slightly (see inside front cover). Protein recommendations must consider the requirements for maintaining nitrogen balance, the quality of protein consumed, and the added needs of growth.

**Vitamins and Minerals** The vitamin and mineral needs of children increase with age (see inside front cover). A balanced diet of nutritious foods can meet children's needs for these nutrients, with the notable exception of iron, and possibly vitamin D. Iron-deficiency anemia is a major problem worldwide and is prevalent among US children, especially toddlers 1 to 3 years of age.[48] During the second year of life, toddlers progress from a diet of iron-rich infant foods such as breast milk, iron-fortified formula, and iron-fortified infant cereal to a diet of adult foods and iron-poor cow's milk. In addition, their appetites often fluctuate—some become finicky about the foods they eat, and others prefer milk and juice to solid foods. These situations can interfere with children eating iron-rich foods at a critical time for brain growth and development.

To prevent iron deficiency, children's foods must deliver 7 to 10 milligrams of iron per day. To achieve this goal, snacks and meals should include iron-rich foods, and milk intake should be reasonable so that it will not displace lean meats, fish, poultry, eggs, legumes, and whole-grain or enriched products. (Chapter 13 describes iron-rich foods and ways to maximize iron absorption.)

The DRI committee recently revised their recommendations for vitamin D intakes for healthy Americans.[49] Children typically obtain most of their vitamin D from fortified milk (2.5 micrograms per 1 cup serving) and dry cereals (1 microgram per ½ cup serving). Children who do not meet their RDA from these sources should receive a vitamin D supplement.[50] Remember that sunlight is also a source of vitamin D, especially in tropical climates and warm seasons.

**Supplements** With the exception of specific recommendations for fluoride, iron, and vitamin D during infancy and childhood, the American Academy of Pediatrics and other professional groups agree that well-nourished children do not need vitamin and mineral supplements. Despite this, many children and adolescents take supplements.[51] Researchers are still studying the safety of supplement use by children. The Federal Trade Commission has warned parents about giving supplements advertised to prevent or cure childhood illnesses such as colds, ear infections, or asthma. Dietary supplements on the market today include many herbal products that have not been tested for safety and effectiveness in children.

**Planning Children's Meals** To provide all the needed nutrients, children's meals should include a variety of foods from each food group—in amounts suited to their appetites and needs. Table 16-6 provides USDA Food Patterns for several kcalorie levels. Estimated daily kcalorie needs for active and sedentary children of various ages are shown in Table 16-7. MyPlate online resources for preschoolers (2 to 5 years) translate the eating patterns into messages that can help parents ensure that the foods they provide meet their child's needs. For older children (6 to 11 years), the site provides an interactive

**TABLE 16-6 USDA Food Patterns: Recommended Daily Amounts from Each Food Group (1000 to 1800 kCalories)**

| Food Group | 1000 kcal | 1200 kcal | 1400 kcal | 1600 kcal | 1800 kcal |
|---|---|---|---|---|---|
| Fruits | 1 c | 1 c | 1½ c | 1½ c | 1½ c |
| Vegetables | 1 c | 1½ c | 1½ c | 2 c | 2½ c |
| Grains | 3 oz | 4 oz | 5 oz | 5 oz | 6 oz |
| Protein foods | 2 oz | 3 oz | 4 oz | 5 oz | 5 oz |
| Milk | 2 c | 2½ c | 2½ c | 3 c | 3 c |

"Blast Off" nutrition teaching game and other resources for teachers, parents, and children themselves (Figure 16-8). These guidelines and resources also stress the importance of balancing kcalorie intake with kcalorie expenditure through adequate physical activity to promote growth without increasing the risks of developing obesity. Childhood obesity is the topic of a later section in this chapter.

Children whose diets follow the patterns presented in Table 16-6 can meet their nutrient needs fully, but few children eat according to these recommendations.[52] One analysis of the quality of children's diets found that most (up to 88 percent) children between 2 and 9 years of age have diets that need substantial improvement.[53] A comprehensive survey, called the Feeding Infants and Toddlers Study (FITS), assessed the food and nutrient intakes of more than 3000 infants and toddlers.[54] The survey found that fruit and vegetable intakes of infants and toddlers are limited, and in fact, about 25 percent of infants and toddlers older than 9 months did not eat a single serving of fruits or vegetables in a day.[55] Not only are nutritious fruits and vegetables lacking, but more than 80 percent of young preschoolers (2 to 3 years of age) consumed nutrient-poor, energy-dense beverages, desserts, and snack foods each day. The most popular vegetable among this age group is french fries. Parents and caregivers of infants and toddlers thus need to offer a much greater variety of nutrient-dense vegetables and fruits at meals and snacks to help ensure adequate nutrition. Among other nutrition concerns for US children are inadequate intakes of vitamin E, potassium, and fiber, and excessive intakes of sodium.[56]

**TABLE 16-7 Estimated Daily Energy Needs for Children**

| Children | Sedentary[a] | Active[b] |
|---|---|---|
| 2 to 3 yr | 1000 kcal/day | 1400 kcal/day |
| **Females** | | |
| 4 to 8 yr | 1200 kcal/day | 1800 kcal/day |
| 9 to 13 yr | 1400 kcal/day | 2200 kcal/day |
| **Males** | | |
| 4 to 8 yr | 1200 kcal/day | 2000 kcal/day |
| 9 to 13 yr | 1600 kcal/day | 2600 kcal/day |

[a] *Sedentary* describes a lifestyle that includes only the activities typical of day-to-day life.

[b] *Active* describes a lifestyle that includes at least 60 minutes per day of moderate physical activity (equivalent to walking more than 3 miles per day at 3 to 4 miles per hour) in addition to the activities of day-to-day life.

## Hunger and Malnutrition in Children

Most children in the United States have access to regular meals, but hunger and malnutrition are not uncommon, especially among children in very low-income families. More than 16 million US children are hungry at least some of the time and are living in poverty.[57] Chapter 20 examines the causes and consequences of hunger in the United States and around the world.

### Hunger and Behavior

Both short-term and long-term hunger exert negative effects on behavior and health. Short-term hunger, such as when a child misses a meal, impairs the child's ability to pay attention and be productive. Hungry

Healthy, well-nourished children are alert in the classroom and energetic at play.

children are irritable, apathetic, and uninterested in their environment. Long-term hunger impairs growth and immune defenses. Food assistance programs such as the WIC program (discussed in Chapter 15) and the School Breakfast and National School Lunch Programs (discussed later in this chapter) are designed to protect against hunger and improve children's health.[58]

Children who eat no breakfast are more likely to be overweight, perform poorly in tasks requiring concentration, have shorter attention spans, and achieve lower test scores than their well-fed peers.[59] A nutritious breakfast is a central feature of a diet that meets the needs of children and supports their healthy growth and development.[60] Children who skip breakfast typically do not make up the deficits at later meals—they simply have lower intakes of energy, vitamins, and minerals than those who eat breakfast. Poorly nourished children are particularly vulnerable. Common sense dictates that it is unreasonable to expect anyone to learn and perform without fuel. For the child who hasn't had breakfast, the morning's lessons may be lost altogether. Even if a child has eaten breakfast, discomfort from hunger may become distracting by late morning. Teachers aware of the late-morning slump in their classrooms wisely request that midmorning snacks be provided; snacks improve classroom performance all the way to lunchtime.[61]

**> DIETARY GUIDELINES FOR AMERICANS**

Eat a nutrient-dense breakfast. Not eating breakfast has been associated with excess body weight, especially among children and adolescents.

**Iron Deficiency and Behavior** Iron deficiency has well-known and widespread effects on children's behavior and intellectual performance.[62] In addition to carrying oxygen in the blood, iron transports oxygen within cells, which use it during energy metabolism. Iron is also used to make neurotransmitters—most notably, those that regulate the ability to pay attention, which is crucial to learning. Consequently, iron deficiency not only causes an energy crisis, but also directly impairs attention span and learning ability.

Iron deficiency is often diagnosed by a quick, easy, inexpensive hemoglobin or hematocrit test that detects a deficit of iron in the *blood*. A child's *brain*, however, is sensitive to low iron concentrations long before the blood effects appear. Iron deficiency lowers the motivation to persist in intellectually challenging tasks and impairs overall intellectual performance. Anemic children perform poorly on tests and are disruptive in the classroom; iron supplementation improves learning and memory. When combined with other nutrient deficiencies, iron-deficiency anemia has synergistic effects that are especially detrimental to learning. Furthermore, children who had iron-deficiency anemia *as infants* continue to perform poorly as they grow older, even if their iron status improves.[63] The long-term damaging effects on mental development make prevention and treatment of iron deficiency during infancy and early childhood a high priority.

**Other Nutrient Deficiencies and Behavior** A child with any of several nutrient deficiencies may be irritable, aggressive, and disagreeable, or sad and withdrawn. Such a child may be labeled "hyperactive," "depressed," or "unlikable," when in fact these traits may be due to simple, even marginal, malnutrition. Parents and medical practitioners often overlook the possibility that malnutrition may account for abnormalities of appearance and behavior. Any departure from normal healthy appearance and behavior is a sign of possible poor nutrition (see Table 16-8). In any such case, inspection of the child's diet by a registered dietitian nutritionist or other qualified health-care professional is in order. Any suspicion of dietary inadequacies, no matter what other causes may be implicated, should prompt steps to correct those inadequacies immediately.

## The Malnutrition-Lead Connection

Children who are malnourished are vulnerable to lead poisoning. They absorb more lead if their stomachs are empty;

**TABLE 16-8 Physical Signs of Malnutrition in Children**

| | Well-Nourished | Malnourished | Possible Nutrient Deficiencies |
|---|---|---|---|
| **Hair** | Shiny, firm in the scalp | Dull, brittle, dry, loose; falls out | Protein |
| **Eyes** | Bright, clear pink membranes; adjust easily to light | Pale membranes; spots; redness; adjust slowly to darkness | Vitamin A, the B vitamins, zinc, and iron |
| **Teeth and gums** | No pain or caries, gums firm, teeth bright | Missing, discolored, decayed teeth; gums bleed easily and are swollen and spongy | Minerals and vitamin C |
| **Face** | Clear complexion without dryness or scaliness | Off-color, scaly, flaky, cracked skin | Protein, vitamin A, and iron |
| **Glands** | No lumps | Swollen at front of neck, cheeks | Protein and iodine |
| **Tongue** | Red, bumpy, rough | Sore, smooth, purplish, swollen | B vitamins |
| **Skin** | Smooth, firm, good color | Dry, rough, spotty; "sandpaper" feel or sores; lack of fat under skin | Protein, essential fatty acids, vitamin A, B vitamins, and vitamin C |
| **Nails** | Firm, pink | Spoon-shaped, brittle, ridged | Iron |
| **Internal systems** | Regular heart rhythm, heart rate, and blood pressure; no impairment of digestive function, reflexes, or mental status | Abnormal heart rate, heart rhythm, or blood pressure; enlarged liver, spleen; abnormal digestion; burning, tingling of hands, feet; loss of balance, coordination; mental confusion, irritability, fatigue | Protein and minerals |
| **Muscles and bones** | Muscle tone; posture, long bone development appropriate for age | "Wasted" appearance of muscles; swollen bumps on skull or ends of bones; small bumps on ribs; bowed legs or knock-knees | Protein, minerals, and vitamin D |

© Cengage Learning

if they have low intakes of calcium, zinc, vitamin C, or vitamin D; and, of greatest concern because it is so common, if they have an iron deficiency. Iron deficiency weakens the body's defenses against lead absorption, and lead poisoning can cause iron deficiency.[64] Common to both iron deficiency and lead poisoning are a low socioeconomic background and a lack of immunizations against infectious diseases. Another common factor is pica—a craving for nonfood items. Many children with lead poisoning eat dirt or chips of old paint, two common sources of lead.

The anemia brought on by lead poisoning may be mistaken for a simple iron deficiency and therefore may be incorrectly treated. Like iron deficiency, mild lead toxicity has nonspecific symptoms, including diarrhea, irritability, and fatigue. Adding iron to the diet does not reverse the symptoms; exposure to lead must stop and treatment for lead poisoning must begin. With further exposure, the symptoms become more pronounced, and children develop learning disabilities and behavioral problems. Still more severe lead toxicity can cause irreversible nerve damage, paralysis, mental retardation, and death.

Approximately half a million children between the ages of 1 and 5 in the United States have blood lead concentrations above 5 micrograms per deciliter, the level at which the Centers for Disease Control and Prevention recommend public health actions be initiated.[65] Lead toxicity in young children comes from their own behaviors and activities—putting their hands in their mouths, playing in dirt and dust, and chewing on nonfood items. Unfortunately, the body readily absorbs lead during times of rapid growth and hoards it possessively thereafter. Lead is not easily excreted and accumulates mainly in the bones, but also in the brain, teeth, and kidneys. Tragically, a child's neuromuscular system is also maturing during these first few years of life. No wonder children with elevated lead levels experience impairment of balance, motor development, and the relaying of nerve messages to and from the brain. Deficits in intellectual development are only partially reversed when blood lead levels decline.

Federal laws mandating reductions in leaded gasoline, lead-based solder, and other products over the past four decades have helped to reduce the amounts of lead in food and in the environment in the United States. As a consequence, the prevalence of lead toxicity in children has declined dramatically for most of the United States, but lead exposure is still a threat in certain communities. The "How To" feature on p. 526 presents strategies for defending children against lead toxicity.

## >How To

### Protect against Lead Toxicity

Strategies to protect children from lead poisoning:

- Ask a pediatrician whether your child should be tested for lead poisoning.
- Prevent small children from putting dirty or old painted objects in their mouths, and make sure children wash their hands before eating. Similarly, keep small children from eating any nonfood items. Lead poisoning has been reported in young children who have eaten crayons or pool cue chalk.
- Wash floors, window sills, and other surfaces regularly. Use a mop or sponge with warm water and a general all-purpose cleaner.
- Wash children's bottles, pacifiers, and toys often.
- Feed children balanced, timely, meals with ample iron and calcium.
- Be aware that other countries do not have the same regulations protecting consumers against lead. Children have been poisoned by eating crayons made in China and drinking fruit juice canned in Mexico.
- Do not use lead-contaminated water to make infant formula.
- Have the water in your home tested by a competent laboratory.
- Use only cold water for drinking, cooking, and making formula (cold water absorbs less lead).
- When water has been standing in pipes for more than two hours, flush the coldwater pipes by running water through them for 30 seconds before using it for drinking, cooking, or mixing formulas.

By taking these steps, parents can protect their children from this preventable danger.

› **TRY IT** Visit the lead section of the website for the Environmental Protection Agency (www.epa.gov/lead) and identify the most common sources of lead poisoning.

## Hyperactivity and "Hyper" Behavior

All children are naturally active, and many of them become overly active on occasion—for example, in anticipation of a birthday party. Such behavior is markedly different from true **hyperactivity.**

**hyperactivity:** inattentive and impulsive behavior that is more frequent and severe than is typical of others a similar age; professionally called *attention-deficit/hyperactivity disorder (ADHD).*

### Hyperactivity

Hyperactive children have trouble sleeping, cannot sit still for more than a few minutes at a time, act impulsively, and have difficulty paying attention. These behaviors interfere with social development and academic progress. The cause of hyperactivity remains unknown, but it affects about 11 percent of young school-age children.[66] To resolve the problems surrounding hyperactivity, physicians often recommend specific behavioral strategies, special educational programs, and psychological counseling. If these interventions are ineffective, they may prescribe medication.[67]

Research on hyperactivity has focused on several nutritional factors as possible causes or treatments.[68] Parents often blame sugar. They mistakenly believe that simply eliminating candy and other sweet treats will solve the problem. This dietary change will not solve the problem, however, and studies have consistently found no convincing evidence that sugar causes hyperactivity or worsens behavior. Such speculation has been based on personal stories. No scientific evidence supports a relationship between sugar and hyperactivity or other misbehaviors.

Food additives have also been blamed for hyperactivity and other behavior problems in children, but scientific evidence to substantiate the connection has been elusive.[69] Limited research suggests that food additives such as artificial colors or sodium benzoate preservative (or both) may exacerbate hyperactive symptoms such as inattention and impulsivity in some children.[70] Additional studies are needed to confirm the findings and to determine which additives might be responsible for specific negative behaviors. A Food and Drug Administration (FDA) review determined that evidence linking color additives to hyperactivity is lacking.[71] The FDA did not rule out the possibility that some food additives, including food colorings, may aggravate hyperactivity and other behavioral problems in some susceptible children.

### Misbehaving

Even a child who is not truly hyperactive can be difficult to manage at times. Michael may act unruly out of a desire for attention, Jessica may be cranky because of a lack of sleep, Christopher may react violently after watching too much television, and Ashley may be unable to sit still in class because of a lack of exercise. All of these children may benefit from more consistent care—regular hours of sleep, regular mealtimes, and regular outdoor activity.

## Food Allergy and Intolerance

**Food allergy** is frequently blamed for physical and behavioral abnormalities in children, but only 4 to 8 percent of children younger than 4 years of age are diagnosed with true food allergies.[72] Food allergies diminish with age, until in adulthood they affect less than 4 percent of the population. The prevalence of food allergy, especially peanut allergy, is on the rise, however.[73] Reasons for an increase in peanut allergy are not yet clear, but possible contributing factors include genetics, food preparation methods (roasting peanuts at very high temperatures makes them more allergenic), and exposure to medicinal skin creams containing peanut oil.

A true food allergy occurs when fractions of a food protein or other large molecule are absorbed into the blood and elicit an immunologic response. (Recall that proteins are normally dismantled in the digestive tract to amino acids that are absorbed without such a reaction.) The body's immune system reacts to these large food molecules as it does to other antigens—by producing antibodies, histamines, and other defensive agents.

### Detecting Food Allergy

Allergies may have one or two components. They always involve antibodies, but they may or may not involve symptoms.* Therefore, allergies cannot be diagnosed from symptoms alone. The National Institute of Allergy and Infectious Diseases (NIAID) has developed clinical guidelines for the diagnosis and management of food allergy.[74] Even symptoms exactly like those of an allergy may not be caused by an allergy. The NIAID recommends that food allergy should be considered when an individual experiences symptoms such as skin rash, respiratory difficulties, vomiting, diarrhea, or anaphylactic shock (described later) within minutes to hours of eating food, especially in young children.

Diagnosis of food allergy requires medical testing and food challenges. Once a food allergy has been diagnosed, the required treatment is strict elimination of the offending food. Children with allergies, like all children, need all their nutrients, so it is important to include other foods that offer the same nutrients as the omitted foods.[75] Nutritional counseling and growth monitoring are recommended for all children with food allergies.[76]

Allergic reactions to food may be immediate or delayed. In either case, the antigen interacts immediately with the immune system, but the timing of symptoms varies from minutes to 24 hours after consumption of the antigen. Identifying the food that causes an immediate allergic reaction is fairly easy because the symptoms appear shortly after the food is eaten. Identifying the food that causes a delayed reaction is more difficult because the symptoms may not appear until much later. By this time, many other foods may have been eaten, complicating the picture.

### Anaphylactic Shock

The life-threatening food allergy reaction of **anaphylactic shock** is most often caused by peanuts, tree nuts, milk, eggs, wheat, soy, fish, or shellfish. Among these foods, eggs, milk, soy, and peanuts most often cause problems in children.[77] Children are more likely to outgrow allergies to eggs, milk, and soy than allergies to peanuts. Peanuts cause more life-threatening reactions than do all other food allergies combined. Research is currently under way to help people with peanut allergies tolerate small doses, thus saving lives and minimizing reactions.[78] Families of children with a life-threatening food allergy and the school personnel who supervise those children must guard them against any exposure to the allergen. The child must learn to identify which foods pose a problem and then learn and use refusal skills for all foods that may contain the allergen.

Parents of children with allergies can pack safe lunches and snacks and ask school officials to strictly enforce a "no swapping" policy in the lunchroom. The child and caregivers must be able to recognize symptoms of impending anaphylactic shock:

- Tingling sensation in mouth
- Swelling of the tongue and throat
- Irritated, reddened eyes

*A person who produces antibodies *without* having any symptoms has an *asymptomatic allergy;* a person who produces antibodies *and* has symptoms has a *symptomatic allergy.*

© Polara Studios, Inc.

These normally wholesome foods—peanuts, tree nuts, milk, eggs, wheat, soy, fish, and shellfish—may cause life-threatening symptoms in people with allergies.

**food allergy:** an adverse reaction to food that involves an immune response; also called *food-hypersensitivity reaction.*

**anaphylactic** (ana-fill-LAC-tic) **shock:** a life-threatening, whole-body allergic reaction to an offending substance.

- Difficulty breathing, asthma
- Hives, swelling, rashes
- Vomiting, abdominal cramps, diarrhea
- Drop in blood pressure
- Loss of consciousness

Any person with food allergies severe enough to cause anaphylactic shock should wear a medical alert bracelet or necklace. Finally, the responsible child and the school staff should be prepared with injections of epinephrine, which prevents anaphylactic shock after exposure to the allergen.* Many preventable deaths occur each year when people with food allergies accidentally ingest the allergen but have no epinephrine available.

**Food Labeling** Food labels must list the presence of common allergens in plain language, using the names of the eight most common allergy-causing foods. For example, a food containing "textured vegetable protein" must say "soy" on its label. Similarly, "casein" must be identified as "milk," and so forth. Food producers must also prevent cross-contamination during production and clearly label foods in which it is likely to occur. For example, equipment used for making peanut butter cookies must be scrupulously clean before being used to make oatmeal cookies; even then, the oatmeal cookie label warns consumers that this product "may contain peanuts" or "was made in a facility that uses peanuts."

Technology may soon offer new solutions. New drugs are being developed that may interfere with the immune response that causes allergic reactions. Also, through genetic engineering, scientists may one day create allergen-free peanuts, soybeans, and other foods to make them safer.

**Food Intolerances** Not all **adverse reactions** to foods are food allergies, although even physicians may describe them as such. Signs of adverse reactions to foods include stomachaches, headaches, rapid pulse rate, nausea, wheezing, hives, bronchial irritation, coughs, and other such discomforts. Among the causes may be reactions to chemicals in foods, such as the flavor enhancer monosodium glutamate (MSG), the natural laxative in prunes, or the mineral sulfur; digestive diseases, obstructions, or injuries; enzyme deficiencies, such as lactose intolerance; and even psychological aversions. These reactions involve symptoms but no antibody production. Therefore, they are **food intolerances,** not allergies.

Pesticides on produce may also cause adverse reactions. Pesticides that were applied in the fields may linger on foods. Health risks from pesticide exposure may be low for healthy adults, but children are vulnerable. Therefore, government agencies have set a **tolerance level** for each pesticide by first identifying foods that children commonly eat in large amounts and then considering the effects of pesticide exposure during each stage of development. Chapter 19 revisits the issues surrounding the use of pesticides on food crops.

Hunger, lead poisoning, hyperactivity, and allergic reactions can all adversely affect a child's nutrition status and health. Fortunately, each of these problems has solutions. They may not be easy solutions, but programs are in place and improvements are evident. As for the most pervasive health problem for children in the United States today—obesity—health experts and researchers understand much about the causes of, the consequences of, and even the solutions, but putting this knowledge into action that meets with success is an ongoing challenge.

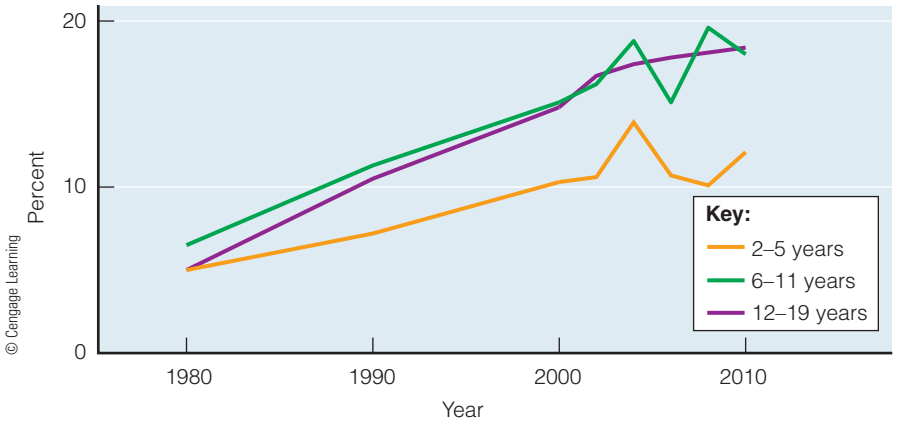
## Childhood Obesity

The number of overweight children has increased dramatically over the past four decades (see Figure 16-9).[79] Like their parents, children in the United States are becoming fatter. An estimated 32 percent of US children and adolescents 2 to 19 years of age are overweight and 17 percent are obese.[80] Based on

**adverse reactions:** unusual responses to food (including intolerances and allergies).

**food intolerances:** adverse reactions to foods that do not involve the immune system.

**tolerance level:** the maximum amount of residue permitted in a food when a pesticide is used according to the label directions.



*Epinephrine is a hormone of the adrenal gland that modulates the stress response; formerly called *adrenaline.* When administered by injection, epinephrine counteracts anaphylactic shock by opening the airways and maintaining heartbeat and blood pressure.

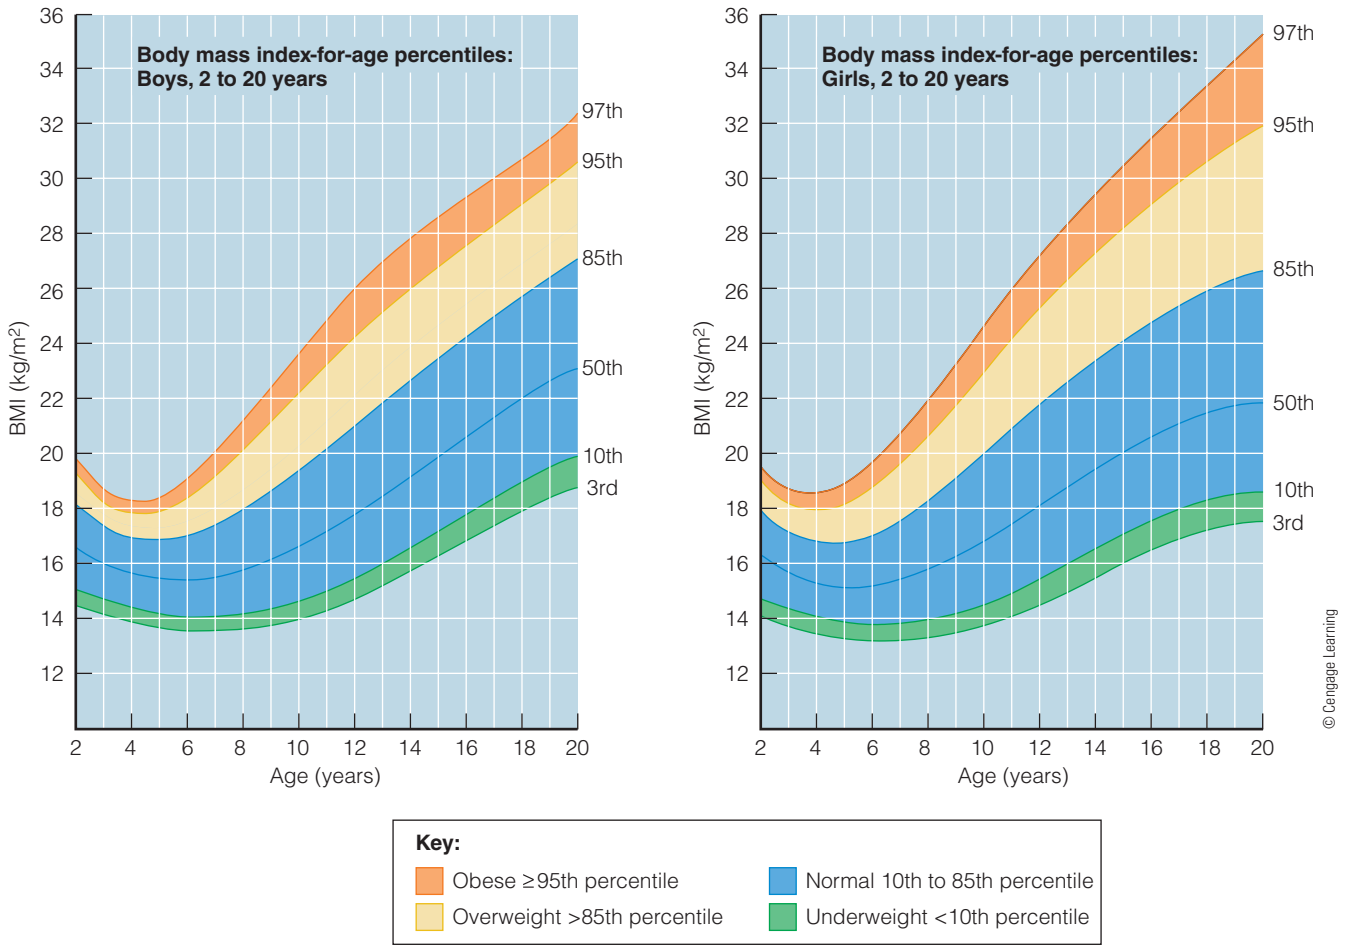
data from the BMI-for-age growth charts, children and adolescents are categorized as *overweight* above the 85th percentile and as *obese* at the 95th percentile and above.[81] There are exceptions to the use of the 85th and 95th percentile cutoff points. For older adolescents, a BMI at the 95th percentile is higher than a BMI of 30, the adult obesity cutoff point. Therefore, obesity is defined as a BMI at the 95th percentile or a BMI of 30 or greater, whichever is lower. For children younger than 2 years of age, BMI values are not available. For this age group, weight-for-height values above the 95th percentile are classified as overweight. Figure 16-10 presents the BMI for children and adolescents, indicating cutoff points for obesity and overweight.



> **FIGURE 16-9 Trends in Childhood Obesity**

The Expert Committee of the American Medical Association recommends a third cutoff point (99th percentile) to define severe obesity in childhood. Unfortunately, severe obesity in children is becoming more prevalent. Many of these children have multiple risk factors for cardiovascular disease and a high risk of severe obesity in adulthood.[82] The special risks and treatment needs of severely obese children need to be recognized.

The problem of obesity in children is especially troubling because overweight children have the potential of becoming obese adults with all the social, economic, and medical ramifications that often accompany obesity. They have additional problems,

too, arising from differences in their growth, physical health, and psychological development. In trying to explain the rise in childhood obesity, researchers point to both genetic and environmental factors.

**Genetic and Environmental Factors** Parental obesity predicts an early increase in a young child's BMI, and it more than doubles the chances that a young child will become an obese adult.[83] Children with neither parent obese have a less than 10 percent chance of becoming obese in adulthood, whereas overweight teens with at least one obese parent have a greater than 80 percent chance of being obese adults. The chances of an obese child becoming an obese adult grow greater as the child grows older.[84] The link between parental and child obesity reflects both genetic and environmental factors (as described in Chapter 9).

Diet and physical inactivity are the two strongest environmental factors explaining why children are heavier today than they were 40 or so years ago. In that time, the prevalence of childhood obesity throughout the United States more than doubled for young children and more than tripled for children 6 to 11 years of age and adolescents. As a society, our eating and activity patterns changed considerably. In many families, both parents work outside the home and work longer hours; more emphasis is placed on convenience foods and foods eaten away from home; meal choices at school are more diverse and often less nutritious; sedentary activities such as watching television and playing video or computer games occupy much of children's free time; and opportunities for physical activity and outdoor play both during and after school have declined.[85] All of these factors—and many others—influence children's eating and activity patterns.

Children learn food behaviors from their families, and research confirms the significant roles parents play in teaching their children about healthy food choices, providing nutrient-dense foods, and serving as role models.[86] When parents eat fruits and vegetables frequently, their children do too.[87] The more fruits and vegetables children eat, the more vitamins, minerals, and fiber, and the less saturated fat, in their diets.[88]

In children 2 to 18 years of age, about 40 percent of total energy intake comes from solid fats and added sugars—in other words—empty kcalories.[89] About half of these empty kcalories are contributed by six specific foods: soda, fruit drinks, dairy desserts (ice cream, frozen yogurt, sorbet, sherbet, pudding, and custard), grain desserts (cakes, cookies, pies, cobblers, donuts, and granola bars), pizza, and whole milk. Not surprisingly, when researchers ask "Are today's children eating more kcalories than those of 40 years ago?" the answer is, "Yes."

As Highlight 4 discusses, as the prevalence of obesity among both children and adults has surged over the past four decades, so has the consumption of added sugars and, especially, high-fructose corn syrup—the easily consumed, energy-dense liquid sugar added to soft drinks.[90] Each 12-ounce can of soft drink provides the equivalent of about 10 teaspoons of sugar and 150 kcalories. More than half of school-age children consume at least one soft drink each day at school; adolescent males consume the most—two or more cans daily. Research shows that soft drink consumption is associated with increased energy intake and body weight.[91]

No doubt, the tremendous increase in soft drink consumption plays a role, but much of the obesity epidemic can be explained by lack of physical activity. Children have become more sedentary, and sedentary children are more often overweight.[92] Television watching may contribute most to physical inactivity. Children 8 to 18 years of age spend an average of 4.5 hours per day watching television.[93] Longer television time is linked with overweight in children.[94] Television fosters overweight and obesity because it:

- Requires no energy beyond basal metabolism
- Replaces vigorous activities
- Encourages snacking
- Promotes a sedentary lifestyle

A child who spends more than an hour or two each day in front of a television, computer monitor, or other media can become overweight even while eating

fewer kcalories than a more active child. Too much screen time and not enough activity time also contributes to a child's psychological distress.

Children who have television sets in their bedrooms spend more time watching TV, less time being physically active, and are more likely to be overweight than children who do not have televisions in their rooms.[95] Watching television influences food intake as well as physical activity.[96] Children who watch a great deal of television are most likely to be overweight and least likely to eat family meals or fruits and vegetables.[97] They often snack on the nutrient-poor, energy-dense foods that are advertised.[98]

The average child sees approximately 12 television food ads each day—most peddling foods high in sugar, saturated fat, and salt such as sugar-coated breakfast cereals, candy bars, chips, fast foods, and carbonated beverages.[99] More than half of all food advertisements are aimed specifically at children and market their products as fun and exciting , oftentimes using sports heroes. Not surprisingly, the more time children spend watching television, the more they request these advertised foods and beverages—and they get their requests about half of the time. The most popular foods and beverages are marketed to children and adolescents on the Internet as well, using "advergaming" (advertised product as part of a game), cartoon characters or "spokes-characters," and designated children's areas.[100] Food marketing to children, including TV ads and Internet ads, as well as marketing to children in their local communities by way of store giveaways, restaurant promotions, school activities, and sporting events has a profound effect on children's nutrition and health.[101] Despite initiatives by the food industry to answer public health concerns about child-targeted advertising, much remains to be done to reduce the marketing of unhealthy foods to children.

Photodisc/Getty Images

Excessive television watching promotes physical inactivity and poor snacking habits.

The physically inactive time spent watching television is second only to time spent sleeping. Children also spend more time playing computer and video games. In most cases, these activities use no more energy than resting, displace participation in more vigorous activities, and foster snacking on high-fat foods.[102] Compared to sedentary screen-time activities, playing active video games does expend a little more energy, but not enough to count toward the daily 60 minutes of moderate-to-vigorous physical activity recommended for children.[103] Simply reducing the amount of time spent watching television (and playing sedentary video games) can improve a child's BMI. The American Academy of Pediatrics recommends no television viewing before 2 years of age and thereafter limiting television and video time to 2 hours per day as a strategy to help prevent childhood obesity.[104]

**Growth** Overweight children develop a characteristic set of physical traits. They typically begin puberty earlier and so grow taller than their peers at first, but then they stop growing at a shorter height. They develop greater bone and muscle mass in response to the demand of having to carry more weight—both fat and lean weight. Consequently, they appear "stocky" even when they lose their excess fat.

**Physical Health** Like overweight adults, overweight and obese children display a blood lipid profile indicating that atherosclerosis is beginning to develop—high levels of total cholesterol, triglycerides, and LDL cholesterol. Overweight and obese children also tend to have high blood pressure; in fact, obesity is a leading cause of pediatric hypertension.[105] Their risks for developing type 2 diabetes and respiratory diseases (such as asthma) are also exceptionally high.[106] These relationships between childhood obesity and chronic diseases are discussed fully in Highlight 16.

**Psychological Development** In addition to the physical consequences, childhood obesity brings a host of emotional and social problems.[107] Because people frequently judge others on appearance more than on character, overweight and obese children are often victims of prejudice and bullying. Many suffer discrimination by adults and rejection by their peers. They may have poor self-images, a sense of failure, and a passive approach to life. Television shows, which are a major influence in children's lives, often portray the fat person as the bumbling misfit. Overweight children may come to accept this negative stereotype in themselves and in others,

**TABLE 16-9 Recommended Eating and Physical Activity Behaviors to Prevent Obesity**

The Expert Committee of the American Medical Association recommends the following healthy habits for children 2 to 18 years of age to help prevent childhood obesity:

- Limit consumption of sugar-sweetened beverages, such as soft drinks and fruit-flavored punches.
- Eat the recommended amounts of fruits and vegetables every day (2 to 4.5 cups per day based on age).
- Learn to eat age-appropriate portions of foods.
- Eat foods low in energy density such as those high in fiber and/or water and modest in fat.
- Eat a nutritious breakfast every day.
- Eat a diet rich in calcium.
- Eat a diet balanced in recommended proportions for carbohydrate, fat, and protein.
- Eat a diet high in fiber.
- Eat together as a family as often as possible.
- Limit the frequency of restaurant meals.
- Limit television watching or other screen time to no more than 2 hours per day and do not have televisions or computers in bedrooms.
- Engage in at least 60 minutes of moderate to vigorous physical activity every day.

SOURCE: S. E. Barlow, Expert Committee recommendations regarding the prevention, assessment, and treatment of child and adolescent overweight and obesity: Summary report, *Pediatrics* 120 (2007): S164–S192.

© Cengage Learning

which can lead to additional emotional and social problems. Researchers investigating children's reactions to various body types find that both normal-weight and underweight children respond unfavorably to overweight bodies.

**Prevention and Treatment of Obesity** Medical science has worked wonders in preventing or curing many of even the most serious childhood diseases, but obesity remains a challenge. Once excess fat has been stored, it is difficult to lose. In light of all this, parents are encouraged to make major efforts to prevent childhood obesity, starting at birth, or to begin treatment early—before adolescence. The Expert Committee of the American Medical Association recommends specific eating and physical activity behaviors to prevent obesity, for all children (see Table 16-9).

The main goal of obesity treatment is to improve long-term physical health through permanent changes in lifestyle habits. The most successful approach integrates diet, physical activity, psychological support, and behavioral changes.[108] As a first step, the Expert Committee recommends that overweight and obese children and their families adopt the same healthy eating and activity behaviors presented in Table 16-9 for obesity prevention. The goal for overweight and obese children is to improve BMI. If the child's BMI does not improve after several months, the Expert Committee recommends increasing the intensity of the treatment. The level of intensity depends on treatment response, age, degree of obesity, health risks, and the family's readiness to change.[109] Advanced treatment involves close follow-up monitoring by a health-care provider and greater support and structure for the child.

**Diet** The initial goal for overweight children is to reduce the rate of weight gain; that is, to maintain weight as the child grows taller. Continued growth will then accomplish the desired change in BMI. Weight loss is usually not recommended because diet restriction can interfere with growth and development. Intervention for some overweight children with accompanying medical conditions may warrant weight loss, but this treatment requires an individualized approach based on the degree of overweight and severity of the medical conditions.[110] Dietary strategies begin with those listed in Table 16-9 and progress to more structured family meal plans when necessary. For example, the child or the parent may be instructed to keep detailed records of dietary intake and physical activity.

**> DIETARY GUIDELINES FOR AMERICANS**

Children are encouraged to maintain kcalorie balance to support normal growth and development without promoting excess weight gain. Children who are overweight or obese should change their eating and physical activity behaviors so that their BMI-for-age percentile does not increase over time.

**Physical Activity** The many benefits of physical activity are well known but often are not enough to motivate overweight people, especially children. Yet regular vigorous activity can improve a child's weight, body composition, and physical fitness.[111] Ideally, parents will limit sedentary activities and encourage at least 1 hour of daily physical activity to promote strong skeletal, muscular, and cardiovascular development and instill in their children the desire to be physically active throughout life. Opportunities to be physically active can include team, individual, and recreational activities (see Table 16-10). Most importantly, parents need to set a good example. Physical activity is a natural and lifelong

behavior of healthy living. It can be as simple as riding a bike, playing tag, jumping rope, or doing chores. The American Academy of Pediatrics supports the efforts of schools to include more physical activity in the curriculum and encourages parents to support their children's participation.

### > PHYSICAL ACTIVITY GUIDELINES FOR AMERICANS

- Children and adolescents should do 60 minutes (1 hour) or more of physical activity daily.
- *Aerobic.* Most of the 60 or more minutes a day should be either moderate- or vigorous-intensity aerobic physical activity and should include vigorous-intensity physical activity at least 3 days a week.
- *Muscle-strengthening.* As part of their 60 or more minutes of daily physical activity, children and adolescents should include muscle-strengthening physical activity on at least 3 days of the week.
- *Bone-strengthening.* As part of their 60 or more minutes of daily physical activity, children and adolescents should include bone-strengthening physical activity on at least 3 days of the week.

**Psychological Support** Weight-loss programs that involve parents and other caregivers in treatment report greater success than those without parental involvement. Because obesity in parents and their children tends to be positively correlated, both benefit when parents participate in a weight-loss program. Parental attitudes about food greatly influence children's eating behavior, so it is important that the influence be positive. Otherwise, eating problems may become exacerbated.

**Behavioral Changes** In contrast to traditional weight-loss programs that focus on *what* to eat, behavioral programs focus on *how* to eat. These techniques involve learning new habits that lead a child to make healthy choices.

© oliveromg/Shutterstock.com

Physical activity is fun—play games in the park, build a sandcastle or a snowman, row a boat, toss a Frisbee, run with the dog, or plant a garden.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Drugs** The use of weight-loss drugs to treat obesity in children merits special concern because the long-term effects of these drugs on growth and development have not been studied. The drugs may be used in addition to structured lifestyle changes for carefully selected children or adolescents who are at high risk for severe obesity in adulthood. Orlistat (see Chapter 9) is the only prescription weight-loss medication that has been approved for use in adolescents 12 years of age and older.[112] Alli, the over-the-counter version of orlistat, should not be given to anyone younger than age 18.

**Surgery** The use of surgery to treat severe obesity in adults (see Chapter 9) has created interest in its use for adolescents. Limited research shows that after surgery extremely obese adolescents lose significant weight and experience improvements in type 2 diabetes and cardiovascular risk factors.[113] The selection criteria for surgery to treat obesity in adolescents are based on recommendations of a panel of pediatricians and surgeons and include the following:

- Physically mature
- BMI ≥40 or BMI >35 with significant weight-related health problems
- Failure in a formal, 6-month weight-loss program
- Capable of adhering to the long-term lifestyle changes required after surgery

Obesity is prevalent in our society. Because treatment of obesity is frequently unsuccessful, it is most important to prevent its onset. Above all, be sensible in teaching children how to maintain appropriate body weight. Children can easily get the impression that their worth is tied to their body weight. Parents and the media are most influential in shaping self-concept, weight concerns, and dieting practices.[114] Some parents fail to realize that society's ideal of slimness can be perilously close to starvation and that a child encouraged to "diet" cannot obtain the energy and nutrients required for normal growth and development. Weight loss in obese children can be managed without compromising growth, but it should be overseen by a health-care professional.

## Mealtimes at Home

Traditionally, parents served as **gatekeepers,** determining what foods and activities were available in their children's lives. Then the children made their own selections. Gatekeepers who wanted to promote nutritious choices and healthful habits provided access to nutrient-dense foods and opportunities for active play at home.

In today's consumer-oriented society, children have greater influence over family decisions concerning food—the fast-food restaurant the family chooses when eating out, the snacks the family eats at home, and the specific brands the family purchases at the grocery store. Parental guidance in food choices is still necessary, but teaching children consumer skills to help them make informed choices is equally important.

**Honoring Children's Preferences** Researchers attempting to explain children's food preferences encounter contradictions. Children say they like colorful foods, yet they most often reject green and yellow vegetables in favor of brown peanut butter and white potatoes, apple wedges, and bread. They seem to like raw vegetables better than cooked ones, so it is wise to offer vegetables that are raw or slightly undercooked, served separately, and easy to eat. Foods should be warm, not hot, because a child's mouth is much more sensitive than an adult's. The flavor should be mild because a child has more taste buds, and smooth foods such as mashed potatoes or split-pea soup should contain no lumps (a child wonders, with some disgust, what the lumps might be).

Make mealtimes fun for children. Young children like to eat at little tables and to be served small portions of food. They like sandwiches cut in different geometric shapes and common foods called silly names. They also like to eat with other children, and they tend to eat more when in the company of their friends. Children are also more likely to give up their prejudices against foods when they see their peers eating them.[115]

©Istockphoto.com/monkeybusinessimages

Eating is more fun for children when friends are there.

**gatekeepers:** with respect to nutrition, key people who control other people's access to foods and thereby exert profound impacts on their nutrition. Examples are the spouse who buys and cooks the food, the parent who feeds the children, and the caregiver in a day-care center.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Learning through Participation** Allowing children to help plan and prepare the family's meals provides enjoyable learning experiences and encourages children to eat the foods they have prepared. Vegetables are attractive, especially when fresh, and provide opportunities for children to learn about color, seeds, growing vegetables, and shapes and textures—all of which are fascinating to young children. Measuring, stirring, washing, and arranging foods are skills that even a young child can practice with enjoyment and pride (see Table 16-11).

**Avoiding Power Struggles** Problems over food often arise during the second or third year, when children begin asserting their independence. For example, very young children may suddenly refuse foods they once liked, but as they get a little older, these same children will begin to request favorite foods and make simple choices when given the opportunity. Many food choice problems stem from the conflict between children's developmental stages and capabilities and parents who, in attempting to do what they think is best for their children, try to control every aspect of eating. Such conflicts can disrupt children's abilities to regulate their own food intakes and to determine their own likes and dislikes. For example, many people share the misconception that children must be persuaded or coerced to try new foods. In fact, the opposite is true. When children are forced to try new foods, even by way of rewards, they are less likely to try those foods again than are children who are left to decide for themselves. Similarly, when children are restricted from eating their favorite foods, they are more likely to want those foods. Wise parents provide healthful foods and allow their child to determine *how much* and even *whether* to eat.

When introducing new foods, offer them one at a time and only in small amounts such as a small bite at first. The more often a food is presented to a young child, the more likely the child will accept that food.[116] Offer the new food at the beginning of the meal, when the child is hungry, and allow the child to make the decision to accept or reject it. Never make an issue of food acceptance. Table 16-12 (p. 536) offers tips for feeding picky eaters.

**Choking Prevention** Parents must always be alert to the dangers of choking. A choking child is silent, so an adult should be present whenever a child is eating. Make sure the child sits when eating; choking is more likely when a child is running or falling. See Table 16-5 on p. 519 for foods and nonfood items most likely to cause choking.

**Playing First** Children may be more relaxed and attentive during meals if outdoor play or other fun activities are scheduled before, rather than immediately after, mealtimes. Otherwise children "hurry up and eat" so that they can go play.

**Snacking** Parents may find that when their children snack, they aren't hungry at mealtimes. Instead of teaching children *not* to snack, parents are wise to teach them *how* to snack. Provide snacks that are as nutritious as the foods served at mealtime. Snacks can even be mealtime foods served individually over time, instead of all at once on one plate. When providing snacks to children, think of the five food groups and offer such snacks as pieces of cheese, tangerine slices, and egg salad on whole-wheat crackers (see Table 16-13, p. 537). Replacing nutrient-poor, high-kcalorie snacks such as potato chips with nutrient-rich, low-kcalorie snacks such as vegetables not only reduces children's energy intakes, but improves their nutrient intakes as well.[117] Snacks that are easy to prepare should be readily available to children, especially if they arrive home from school before their parents.

To ensure that children have healthy appetites and plenty of room for nutritious foods when they are hungry, parents and teachers must limit access to candy, soft drinks, and other concentrated sweets. Limiting access includes limiting the amount of pocket money children have to buy such foods themselves. If these foods are permitted in large quantities, the only possible outcomes are nutrient deficiencies, obesity, or both. The preference for sweets is innate; most children do not naturally select nutritious foods on the basis of taste. When children are allowed to create meals freely from a variety of foods, they typically select

**TABLE 16-11 Food Skills of Preschool Children**

Age 2 years, when large muscles develop:

- Uses a spoon
- Helps feed self
- Lifts and drinks from a cup
- Helps scrub fruits and vegetables, tear lettuce or greens, snap green beans, or dip foods
- Wipes table
- Places items in recycle bin or trash

Age 3 years, when medium hand muscles develop:

- Spears food with a fork
- Feeds self independently
- Adds ingredients to pancake batters, cookie recipes, salads or other mixed dishes
- Helps wrap, pour, mix, shake, stir, or spread foods
- Helps crack nuts with supervision
- Follows simple instructions

Age 4 years, when small finger muscles develop:

- Uses all utensils and napkin
- Helps roll, juice, or mash foods
- Helps measure dry ingredients
- Cracks egg shells
- Helps make sandwiches and toss salads
- Peels foods such as hard-boiled eggs and bananas
- Learns table manners

Age 5 years, when fine coordination of fingers and hands develops:

- Measures liquids
- Helps grind, grate, and cut (soft foods with dull knife)
- Uses hand mixer with supervision

© 2016 Cengage Learning

NOTE: These ages are approximate. Healthy children develop at their own pace.

**TABLE 16-12 Tips for Feeding Picky Eaters**

**Get Them Involved**

- Encourage children to help with meal planning.
- Take children grocery shopping.
- Ask children to help with cooking.
- Help children garden and harvest foods they will eat.

**Be Creative**

- Try serving vegetables as finger foods with dips or spreads.
- Use cookie cutters to cut breads, fruits, and vegetables into fun shapes.
- Put healthy snacks in ice cube trays or muffin pans where children can easily reach them and graze as they play.
- Serve traditional meals out of order (for example, breakfast for dinner).
- Use healthy foods such as vegetables and whole grains in craft projects to help kids become familiar with them and encourage their interest in and enthusiasm for these foods.

**Enhance Favorite Recipes**

- Include sliced or shredded vegetables in sauces, casseroles, pancakes, and muffins.
- Serve fruit over cereal, yogurt, or ice cream.
- Bake brownies with black beans or cookies with lentils as an ingredient.

**Model and Share**

- Be a role model to children by eating healthy foods alongside them and offer to share your healthy snack with them.
- Make healthy options readily available and don't give up on repeatedly offering foods in which your child might not seem interested.
- Encourage your child to taste at least one bite of each food served at a meal.

**Respect and Relax**

- Remember that it is not uncommon for children to eat sporadically. They have smaller stomachs, and therefore are likely to feel full faster and become hungry again not long after a snack or meal.
- Focus on your child's overall weekly intake of foods and nutrients rather than daily consumptions.
- Discuss concerns with your child's doctor. It might be helpful to maintain a 3-day food record to review at the next appointment.

SOURCE: Adapted from Mayo Clinic Staff, Children's nutrition: 10 tips for picky eaters, 2011, www.mayoclinic.com/health/childrens-health/HQ01107.

foods that provide a lot of sugar. When their parents are watching, or even when they only think their parents are watching, children improve their selections.

Sweets need not be banned altogether. Children who are exceptionally active can enjoy high-kcalorie foods such as ice cream or pudding from the milk group or pancakes from the bread group. Sedentary children need to become more active so they can also enjoy some of these foods without unhealthy weight gain.

**Preventing Dental Caries** Children frequently snack on sticky, sugary foods that stay on the teeth and provide an ideal environment for the growth of bacteria that cause dental caries. Teach children to brush and floss after meals, to brush or rinse after eating snacks, to avoid sticky foods, and to select crisp or fibrous foods frequently.

**Serving as Role Models** In an effort to practice these many tips, parents may overlook perhaps the single most important influence on their children's food habits—themselves. Parents who don't eat carrots shouldn't be surprised when their children refuse to eat carrots. Likewise, parents who comment negatively on the smell of brussels sprouts may not be able to persuade children to try them. Children learn much through imitation. It is not surprising that children prefer the foods other family members enjoy and dislike foods that are never offered to them. Parents, older siblings, and other caregivers set an irresistible example by sitting with younger children, eating the same foods, and having pleasant conversations during mealtimes.

While serving and enjoying food, caregivers can promote both physical and emotional growth at every stage of a child's life. They can help their children develop both a positive self-concept and a positive attitude toward food. With good beginnings, children will grow without the conflicts and confusions about food that can lead to nutrition and health problems.

## Nutrition at School

While parents are doing what they can to establish good eating habits in their children at home, others are preparing and serving foods to their children at day-care centers and schools. In addition, children begin to learn about food and nutrition in the classroom. Meeting the nutrition and education needs of children is critical to supporting their healthy growth and development.[118]

The Academy of Nutrition and Dietetics has set nutrition standards for child-care programs. Among them, meal plans should:

- Be nutritionally adequate and consistent with the *Dietary Guidelines for Americans*.
- Emphasize fresh fruit, fresh and frozen vegetables, whole grains, and low-fat milk and milk products.
- Limit foods and beverages high in energy, added sugars, solid fats, and sodium, and low in vitamins and minerals.
- Provide foods and beverages in quantities and meal patterns appropriate to ensure optimal growth and development.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Involve parents in planning.
- Provide furniture and eating utensils that are age appropriate and developmentally suitable to encourage children to accept and enjoy mealtime.

In addition, child-care providers can encourage active play for children by creating opportunities for children to engage in both structured and unstructured activity throughout the day.

**Meals at School** The US government assists schools financially so that every student can receive nutritious meals at school. Both the School Breakfast Program and the National School Lunch Program provide meals free or at reduced cost to children from low-income families. In addition, schools can obtain food commodities. Nationally, the US Department of Agriculture (USDA) administers the programs; on the state level, state departments of education operate them. The educational rewards of school meal programs are great. Several studies have reported that children who participate in school food programs perform better in the classroom.[119] Unfortunately, many school districts are finding it more and more difficult to operate the programs because the cost to produce lunches and breakfasts exceeds the reimbursement rate. Furthermore, the number of children qualifying for free and reduced-price school meals continues to rise.[120]

**TABLE 16-13 Healthful Snack Ideas—Think Food Groups, Alone and in Combination**

Selecting two or more foods from different food groups adds variety and nutrient balance to snacks. The combinations are endless, so be creative. Whenever possible, choose whole grains, low-fat or reduced-fat milk products, and lean meats.

**Grains**

Grain products are filling snacks, especially when combined with other foods:

- Cereal with fruit and milk
- Crackers and cheese
- Whole-grain toast with peanut butter
- Popcorn with grated cheese
- Oatmeal raisin cookies with milk

**Vegetables**

Cut-up, fresh, raw vegetables make great snacks alone or in combination with foods from other food groups:

- Celery with peanut butter
- Broccoli, cauliflower, and carrot sticks with a flavored cottage cheese dip

**Fruits**

Fruits are delicious snacks and can be eaten alone—fresh, dried, or juiced—or combined with other foods:

- Apples and cheese
- Bananas and peanut butter
- Peaches with yogurt
- Raisins mixed with sunflower seeds or nuts

**Protein Foods**

Seafood, meat, poultry, eggs, legumes, nuts, seeds, and soy products add protein to snacks:

- Refried beans with nachos and cheese
- Tuna on crackers
- Luncheon meat on whole-grain bread

**Milk and Milk Products**

Milk can be used as a beverage with any snack, and many other milk products, such as yogurt and cheese, can be eaten alone or with other foods as listed above.

© Cengage Learning

More than 31 million children receive lunches through the National School Lunch Program—more than half of them free or at a reduced price.[121] School lunches offer a variety of food choices and help children meet at least one third of their recommended intakes for energy, protein, vitamin A, vitamin C, iron, and calcium. Table 16-14 (p. 538) shows school lunch patterns for children of different ages and specifies the numbers of servings of milk, protein-rich foods (meat, poultry, fish, cheese, eggs, legumes, or peanut butter), vegetables, fruits, and whole grains. In an effort to help reduce disease risk, all government-funded meals served at schools must follow the *Dietary Guidelines for Americans*.

The USDA Food and Nutrition Service recently updated the meal patterns and nutrition standards for school meals.[122] Changes to meals include greater availability of fruits, vegetables, whole grains, and fat-free and low-fat milk; decreased levels of sodium, saturated fat, and *trans* fat; and guidelines for meeting nutrient needs within specified kcalorie ranges based on age/grade groups for school children.

Parents often rely on school lunches to meet a significant part of their children's nutrient needs on school days. Indeed, students who regularly eat school lunches have higher intakes of many nutrients and fiber than students who do not. Children don't always like what they are served, however, and school lunch programs must strike a balance between what children want to eat and what will nourish them and guard their health.

The School Breakfast Program is available in more than 80 percent of the nation's schools that offer school lunch, and close to 12 million children participate in

it.[123] At a minimum, the school breakfast must contain:

- One serving of fluid milk (either unflavored low-fat or flavored or unflavored fat-free)
- One serving of fruit or vegetable (no more than half of the servings may be 100% full-strength juice)
- One to two servings of whole grains; or one serving of whole grains and one serving of meat or meat alternatives

Unfortunately, for many children who need it, the School Breakfast Program is either unavailable or the children do not participate in it.[124] The majority of children who eat school breakfasts are from low-income families. As research results continue to emphasize the positive impact breakfast has on school performance and health, vigorous campaigns to expand and improve school breakfast programs are under way.[125]

Another federal program, the Child and Adult Care Food Program (CACFP), operates similarly and provides funds to organized child-care programs. All eligible children, centers, and family day-care homes may participate. Sponsors are reimbursed for most meal costs and may also receive USDA commodity foods.

**Competing Influences at School** Serving healthful lunches is only half the battle; students need to eat them too. Short lunch periods and long waiting lines prevent some students from eating a school lunch and leave others with too little time to finish their meals.[126] Nutrition efforts at schools are also undermined when students can buy what the USDA labels "competitive" or "nonreimbursable" foods—meals from fast-food restaurants or a la carte foods such as pizza or snack foods and carbonated beverages from snack bars, school stores, and vending machines.[127] When students have access to competitive foods, participation in the school lunch program decreases, nutrient intake from lunch declines, and more food is discarded.[128]

Increasingly, school-based nutrition issues are being addressed by legislation. Some states restrict the sale of competitive foods and have higher rates of participation in school meal programs than the national average. Federal legislation mandates that all school districts that participate in the USDA's National School Lunch Program develop and implement a local wellness policy.[129] By law, wellness policies must:

- Set goals for nutrition education, physical activity, and other school-based activities.
- Establish nutrition guidelines for all foods available on school campuses during the school day.
- Develop a plan to measure policy implementation.

School districts across the nation have made progress toward meeting these goals, but implementation is inconsistent, and because wellness policies are established locally, a great deal of variety exists among them.[130] Some are well defined and detailed, while others are vague and less detailed.[131] To enhance local wellness policies, standards for competitive foods and beverages served in schools define limits for fat, saturated fat, kcalories, sugar, and sodium.

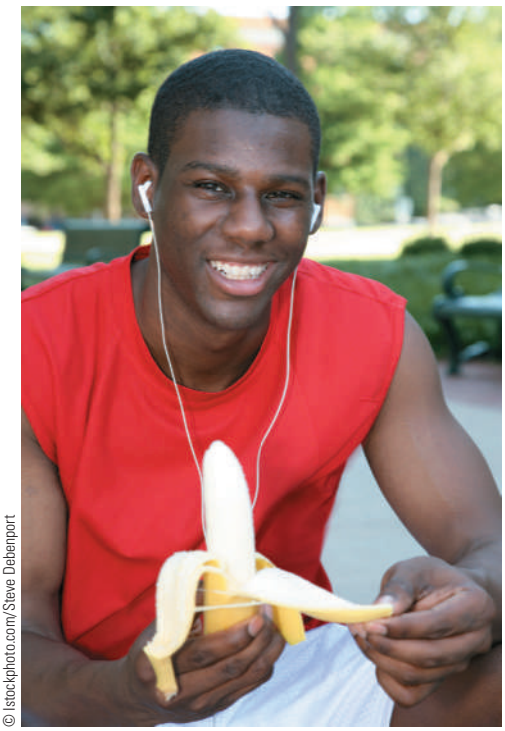
Establishing and implementing these nutrition standards for competitive foods and beverages help to ensure that all foods served in schools are consistent and comply with the *Dietary Guidelines for Americans.*



› **REVIEW IT** Explain how children's appetites and nutrient needs reflect their stage of growth and why iron deficiency and obesity are often concerns during childhood.

Children's appetites and nutrient needs reflect their stage of growth. Those who are chronically hungry and malnourished suffer growth retardation; when hunger is temporary and nutrient deficiencies are mild, the problems are usually more subtle—such as poor academic performance. Iron deficiency is widespread and has many physical and behavioral consequences. Hyperactivity is not caused by poor nutrition; misbehavior may be due to lack of sleep, too little physical activity, or too much television, among other factors. Childhood obesity has become a major health problem. Adults at home and at school need to provide children with nutrient-dense foods and teach them how to make healthful diet and activity choices

# 16.3 Nutrition during Adolescence

› **LEARN IT** Describe some of the challenges in meeting the nutrient needs of adolescents.

Teenagers make many more choices for themselves than they did as children. They are not fed, they eat; they are not sent out to play, they choose to go. At the same time, social pressures thrust choices at them, such as whether to drink alcoholic beverages and whether to develop their bodies to meet extreme ideals of slimness or athletic prowess. Their interest in nutrition—both valid information and misinformation—derives from personal, immediate experiences. They are concerned with how diet can improve their lives now—they engage in fad dieting in order to fit into a new bathing suit, avoid greasy foods in an effort to clear acne, or eat a plate of spaghetti to prepare for a big sporting event. In presenting information on the nutrition and health of adolescents, this section includes many topics of interest to teens.

© Istockphoto.com/Steve Debenport

Nutritious snacks contribute valuable nutrients and energy to an active teen's diet.

## Growth and Development

With the onset of **adolescence,** the steady growth of childhood speeds up abruptly and dramatically, and the growth patterns of females and males become distinct. Hormones direct the intensity of the adolescent growth spurt, profoundly affecting every organ of the body, including the brain. After 2 to 3 years of intense growth and a few more at a slower pace, physically mature adults emerge.

In general, the adolescent growth spurt begins at age 10 to 11 for females and at 12 to 13 for males. It lasts about 2½ years. Before **puberty,** male and female body compositions differ only slightly, but during the adolescent spurt, differences between the genders become apparent in the skeletal system, lean body mass, and fat stores. In females, fat assumes a larger percentage of total body weight, and in males, the lean body mass—principally muscle and bone—increases much more than in females (review Figure 1-1 on p. 7). During adolescence, males grow an average of 8 inches taller, and females, 6 inches taller. Males gain approximately 45 pounds, and females, about 35 pounds.

## Energy and Nutrient Needs

Energy and nutrient needs are greater during adolescence than at any other time of life, except pregnancy and lactation. In general, nutrient needs rise throughout childhood, peak in adolescence, and then level off or even diminish as the teen becomes an adult.

### Energy Intake and Activity

The energy needs of adolescents vary greatly, depending on the current rate of growth, gender, body composition, and physical activity.[132] Boys' energy needs may be especially high; they typically grow faster than girls and, as mentioned, develop a greater proportion of lean body mass. An exceptionally active boy of 15 may need 3500 kcalories or more a day just

**adolescence:** the period from the beginning of puberty until maturity.

**puberty:** the period in life in which a person becomes physically capable of reproduction.

to maintain his weight. Girls start growing earlier than boys and attain shorter heights and lower weights, so their energy needs peak sooner and decline earlier than those of their male peers. A sedentary girl of 15 whose growth is nearly at a standstill may need fewer than 1800 kcalories a day if she is to avoid excessive weight gain. Thus adolescent girls need to pay special attention to being physically active and selecting foods of high nutrient density so as to meet their nutrient needs without exceeding their energy needs.

The problems of obesity become ever more apparent in adolescence, especially for African American females and Hispanic teens of both genders. Without intervention, overweight adolescents face numerous physical and emotional consequences. The consequences of obesity are so dramatic and our society's attitude toward thin people is so positive that even teens of normal or below-normal weight may perceive a need to lose weight. When taken to extremes, restrictive diets bring dramatic physical consequences of their own, as Highlight 8 explains.

### > DIETARY GUIDELINES FOR AMERICANS

- Adolescents are encouraged to maintain kcalorie balance to support normal growth and development without promoting excess weight gain. Adolescents who are overweight or obese should change their eating and physical activity behaviors so that their BMI-for-age percentile does not increase over time.
- Adolescents should do 60 minutes or more of physical activity daily. Adolescents are encouraged to spend no more than 1 to 2 hours each day watching television, playing electronic games, or using the computer (other than for homework).

**Vitamins** The RDA (or AI) for most vitamins increases during the adolescent years (see the inside front cover). Several of the vitamin recommendations for adolescents are similar to those for adults, including the recently revised recommendations for vitamin D.[133] Vitamin D is essential for bone growth and development. Recent studies of vitamin D status in adolescents show that many adolescents are vitamin D deficient; blacks, females, and overweight adolescents are most at risk.[134] Adolescents who do not receive enough vitamin D from fortified foods such as milk and cereals, or from sun exposure each day, may need a vitamin D supplement.[135]

**Iron** The need for iron increases during adolescence for both females and males, but for different reasons. Iron needs increase for females as they start to lose blood through menstruation and for males as their lean body mass develops. Hence the RDA increases at age 14 for both males and females. For females, the RDA remains high into late adulthood. For males, the RDA returns to preadolescent values in early adulthood.

In addition, iron needs increase when the adolescent growth spurt begins, whether that occurs before or after age 14. Therefore, boys in a growth spurt need an additional 2.9 milligrams of iron per day above the RDA for their age; girls need an additional 1.1 milligrams per day.

Furthermore, iron recommendations for girls before age 14 do not reflect the iron losses of menstruation. The average age of menarche (first menstruation) in the United States is 12.5 years. Therefore, for girls younger than the age of 14 who have started to menstruate, an additional 2.5 milligrams of iron per day is recommended. Thus the RDA for iron depends not only on age and gender but also on whether the individual is in a growth spurt or has begun to menstruate, as listed in Table 16-15.

Iron intakes often fail to keep pace with increasing needs, especially for females, who typically consume fewer iron-rich foods such as meat and fewer total kcalories than males. Not surprisingly, iron deficiency is most prevalent among adolescent girls. Iron-deficient children and teens score lower on standardized tests than those who are not iron deficient.

**TABLE 16-15 Iron Recommendations for Adolescents**

| Males | Females |
|---|---|
| 9–13 yr: 8 mg/day | 9–13 yr: 8 mg/day |
| 9–13 yr in growth spurt: 10.9 mg/day | 9–13 yr in menarche: 10.5 mg/day |
| | 9–13 yr in menarche and growth spurt: 11.6 mg/day |
| 14–18 yr: 11 mg/day | 14–18 yr: 15 mg/day |
| 14–18 yr in growth spurt: 13.9 mg/day | 14–18 yr in growth spurt: 16.1 mg/day |

> **DIETARY GUIDELINES FOR AMERICANS**

Adolescent girls should choose foods that supply heme iron, which is more readily absorbed by the body, additional iron sources, and enhancers of iron absorption such as vitamin C–rich foods.

**Calcium** Adolescence is a crucial time for bone development, and the requirement for calcium reaches its peak during these years.[136] Unfortunately, many adolescents, especially females, have calcium intakes below recommendations.[137] Low calcium intakes during times of active growth, especially if paired with physical inactivity, can compromise the development of peak bone mass, which is considered the best protection against adolescent fractures and adult osteoporosis. Increasing milk and milk products in the diet to meet calcium recommendations greatly increases bone density.[138] Once again, however, teenage girls are most vulnerable because their milk—and therefore their calcium—intakes begin to decline at the time when their calcium needs are greatest.[139] Furthermore, women have much greater bone losses than men in later life. In addition to dietary calcium, physical activity causes bones to grow stronger. Because some high schools do not require students to participate in physical education classes, however, many adolescents are not as physically active as healthy bones demand.

©Dotshock/Shutterstock

Bones grow stronger with physical activity.

> **DIETARY GUIDELINES FOR AMERICANS**

Children 9 years of age and older should consume 3 cups per day of fat-free or low-fat milk or equivalent milk products.

## Food Choices and Health Habits

Teenagers like the freedom to come and go as they choose. They eat what they want if it is convenient and if they have the time. With a multitude of after school, social, and job activities, they almost inevitably fall into irregular eating habits. At any given time on any given day, a teenager may be skipping a meal, eating a snack, preparing a meal, or consuming food prepared by a parent or restaurant.[140] Adolescents who frequently eat meals with their families, however, eat more fruits, vegetables, grains, and calcium-rich foods, and drink fewer soft drinks, than those who seldom eat with their families.[141] Some research shows that the more often teenagers eat dinner with their families, the less likely they are to smoke, drink, or use drugs; other research supports these findings only in teenage girls.[142] Many adolescents also begin to skip breakfast on a regular basis, missing out on important nutrients that are not made up at later meals during the day. Compared with those who skip breakfast, teenagers who do eat breakfast have higher intakes of vitamin A, vitamin C, and riboflavin, as well as calcium, iron, and zinc.[143] Teenagers who eat breakfast are therefore more likely to meet their nutrient recommendations.

Breakfast skipping may also lead to weight gain in adolescents. Eating breakfast each day, especially a breakfast rich in fiber and protein, improves satiety and reduces hunger and the desire to eat throughout the day.[144] As adolescents make the transition to adulthood, not only do they skip breakfast more often, but they also eat fast food more often. Both skipping breakfast and eating fast foods lead to weight gain.[145]

Ideally, parents continue to play the role of gatekeepers, providing nutritious, easy-to-grab foods in the refrigerator (meats for sandwiches; low-fat cheeses; fresh, raw vegetables and fruits; fruit juices; and milk) and more in the cabinets (whole-grain breads and crackers, peanut butter, nuts, popcorn, and cereal). In many households today, adults work outside the home and teenagers help with some of the gatekeepers' tasks, such as shopping for groceries or choosing fast or prepared foods.

**Snacks** Snacks typically provide at least 25 percent of the average teenager's daily food energy intake. If chosen carefully, snacks can contribute some needed

nutrients (see Table 16-13 on p. 537). A survey of more than 5000 adolescents, found that those who ate snacks more often were less likely to be overweight or obese compared with those who ate snacks less often.[146]

**Beverages** Most frequently, adolescents drink soft drinks instead of fruit juice or milk with lunch, supper, and snacks. About the only time they select fruit juices is at breakfast. When teens drink milk, they are more likely to consume it with a meal (especially breakfast) than as a snack. Because of their greater food intakes, boys are more likely than girls to drink enough milk to meet their calcium needs.[147]

Soft drinks, when chosen as the primary beverage, may affect bone density, partly because they displace milk from the diet. Over the past three decades, teens (especially girls) have been drinking more soft drinks and less milk. Adolescents who drink soft drinks regularly have a higher energy intake and a lower calcium intake than those who do not.[148]

Soft drinks containing caffeine present another problem if caffeine intake becomes excessive. Many adolescents consume energy drinks on a regular basis and these beverages contain much more caffeine than soft drinks.[149]* Caffeine seems to be relatively harmless when used in *moderate* doses (less than 100 milligrams per day, roughly the equivalent of fewer than three 12-ounce cola beverages a day). In greater amounts, however, caffeine can cause symptoms associated with anxiety, such as sweating, tenseness, and inability to concentrate. Teens with certain diseases such as diabetes, heart abnormalities, and mood disorders and those taking certain medications may encounter more severe consequences such as seizures, heart failure, and death.

**> DIETARY GUIDELINES FOR AMERICANS**

Reduce intake of sugar-sweetened beverages. Children and adolescents who consume more sugar-sweetened beverages have higher body weight compared to those who drink less.

**Eating Away from Home** Adolescents eat about one-third of their meals away from home, and their nutritional welfare is enhanced or hindered by the choices they make.[150] A lunch consisting of a hamburger, a chocolate shake, and french fries supplies substantial quantities of many nutrients at a kcalorie cost of about 800, an energy intake some adolescents can afford. When they eat this sort of lunch, teens can adjust their breakfast and dinner choices to include fruits and vegetables for vitamin A, vitamin C, folate, and fiber and lean meats and legumes for iron and zinc. (See Appendix H for the nutrient contents of fast foods.) Fortunately, many fast-food restaurants are offering more nutritious choices than the standard hamburger meal.

**Peer Influence** Physical maturity and growing independence present adolescents with new choices. The consequences of those choices will influence their health and nutrition status both today and throughout life. Many of the food and health choices adolescents make reflect the opinions and actions of their peers. When others perceive milk as "babyish," a teen may choose soft drinks instead; when others skip lunch and hang out in the parking lot, a teen may join in for the camaraderie, regardless of hunger. Some teenagers begin using drugs, alcohol, and tobacco; others wisely refrain. Adults can set up the environment so that nutritious foods are available and can stand by with reliable information and advice about health and nutrition, but the rest is up to the adolescents. Ultimately, they make the choices. (Highlight 8 examines the influence of social pressures on the development of eating disorders.)

© Monkeybusiness Images/ Dreamstime.com

Because their lunches rarely include fruits, vegetables, or milk, many teens fail to get all the vitamins and minerals they need each day.

*Caffeine-containing soft drinks typically deliver about 30 mg of caffeine per 12-ounce can; energy drinks typically deliver about 100 mg of caffeine for equivalent amounts. A pharmacologically active dose of caffeine is defined as 200 mg. Appendix H starts with a table listing the caffeine contents of selected foods, beverages, and drugs.

**› REVIEW IT** Describe some of the challenges in meeting the nutrient needs of adolescents.

Nutrient needs rise dramatically as children enter the rapid growth phase of adolescence. Teenagers' busy lifestyles add to the challenge of meeting their nutrient needs, especially for iron and calcium.

The nutrition and lifestyle choices people make as children and adolescents have long-term, as well as immediate, effects on their health. Highlight 16 describes how sound choices and good habits during childhood and adolescence can help prevent chronic diseases later in life.

## Nutrition Portfolio

Encouraging children to eat nutritious foods today helps them learn how to make healthy food choices tomorrow.

- If there are children in your life, think about the food they eat and consider whether they receive enough food for healthy growth, but not so much as to lead to obesity.
- Describe the advantages of physical activity to children's health and well-being.
- Plan a day's menu for a child 4 to 8 years of age, making sure to include foods that provide enough calcium and iron.
- Now, go to Diet & Wellness Plus and create a profile for a child 4 to 8 years of age. Enter the day's menu you suggested in the previous exercise and see if you met the basic requirements for that child.

DIET & WELLNESS PLUS To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com**.

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

## Childhood Obesity and the Early Development of Chronic Diseases

© Zhudifeng/Dreamstime.com

**› LEARN IT** Describe the lifestyle factors that can help prevent childhood obesity and the development of type 2 diabetes and heart disease.

When people think about the health problems of children and adolescents, they typically think of ear infections, colds, and acne—not heart disease, diabetes, or hypertension. Today, however, unprecedented numbers of US children are being diagnosed with obesity and serious "adult diseases," such as **type 2 diabetes,** that accompany overweight.[1] When type 2 diabetes develops before the age of 20, the incidence of diabetic kidney disease and death in middle age increases dramatically, largely because of the long duration of the disease. For children born in the United States in the year 2000, the risk of developing type 2 diabetes sometime in their lives is estimated to be 30 percent for boys and 40 percent for girls. US children are not alone—rapidly rising rates of obesity threaten the health of an alarming number of children around the globe.[2] Without immediate intervention, millions of children are destined to develop type 2 diabetes and hypertension in childhood followed by **cardiovascular disease (CVD)** in early adulthood.[3] (See the accompanying glossary for this and related terms.)

This highlight focuses on efforts to prevent childhood obesity and the development of heart disease and type 2 diabetes, but the benefits extend to other obesity-related diseases as well. The years of childhood (ages 2 to 18) are emphasized here because the earlier in life health-promoting habits become established, the better they will stick. Chapter 18 fills in the rest of the story of nutrition's role in reducing chronic disease risk.

Invariably, questions arise as to what extent genetics is involved in disease development. For heart disease and type 2 diabetes, genetics does not appear to play a *determining* role; that is, a person is not simply destined at birth to develop these diseases. Instead, genetics appears to play a *permissive* role—the potential is inherited and will develop if given a push by poor health choices such as excessive weight gain, poor diet, sedentary lifestyle, and cigarette smoking.[4]

Many experts agree that preventing or treating obesity in childhood will reduce the rate of chronic diseases in adulthood. Without intervention, most obese children become obese adolescents who become obese adults, and being obese exacerbates every chronic disease that adults face.[5] Fatty liver, a condition that correlates directly with BMI, was not even recognized in pediatric research until recently. Today, fatty liver disease has a high prevalence in obese children.[6]

## Early Development of Type 2 Diabetes

In recent years, type 2 diabetes, a chronic disease closely linked with obesity, has been on the rise among children and adolescents as the prevalence of obesity in US youth has increased.[7] Obesity is the most important risk factor for type 2 diabetes; it is most likely to occur in those who are obese and sedentary and have a family history of

## GLOSSARY

**atherosclerosis** (ATH-er-OH-scler-OH-sis): a type of artery disease characterized by plaques (accumulations of lipid-containing material) on the inner walls of the arteries (see Chapter 18).

- **athero** = porridge or soft
- **scleros** = hard
- **osis** = condition

**cardiovascular disease (CVD):** diseases of the heart and blood vessels throughout the body. Atherosclerosis is the main cause of CVD. When the arteries that carry blood to the heart muscle become blocked, the heart suffers damage known as *coronary heart disease (CHD).*

- **cardio** = heart
- **vascular** = blood vessels

**fatty streaks:** accumulations of cholesterol and other lipids along the walls of the arteries.

**plaque** (PLACK): an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue that develops in the artery walls in atherosclerosis. Plaque associated with atherosclerosis is known as *atheromatous* (ATH-er-OH-ma-tus) *plaque.*

**type 2 diabetes:** the more common type of diabetes in which the cells fail to respond to insulin. Type 2 diabetes usually accompanies obesity and results from insulin resistance coupled with insufficient insulin secretion.

diabetes. Diagnoses typically are made during puberty, but as younger children become more obese and less active, the trend is shifting to younger ages.

In type 2 diabetes, the cells become insulin-resistant—that is, the cells become less sensitive to insulin, reducing the amount of glucose entering the cells from the blood. The combination of obesity and insulin resistance produces a cluster of symptoms, including high blood cholesterol and high blood pressure, which, in turn, promotes the development of atherosclerosis and the early development of heart disease.[8] Other common problems evident by early adulthood include kidney disease, blindness, and miscarriages. The complications of diabetes, especially when encountered at a young age, can shorten life expectancy.

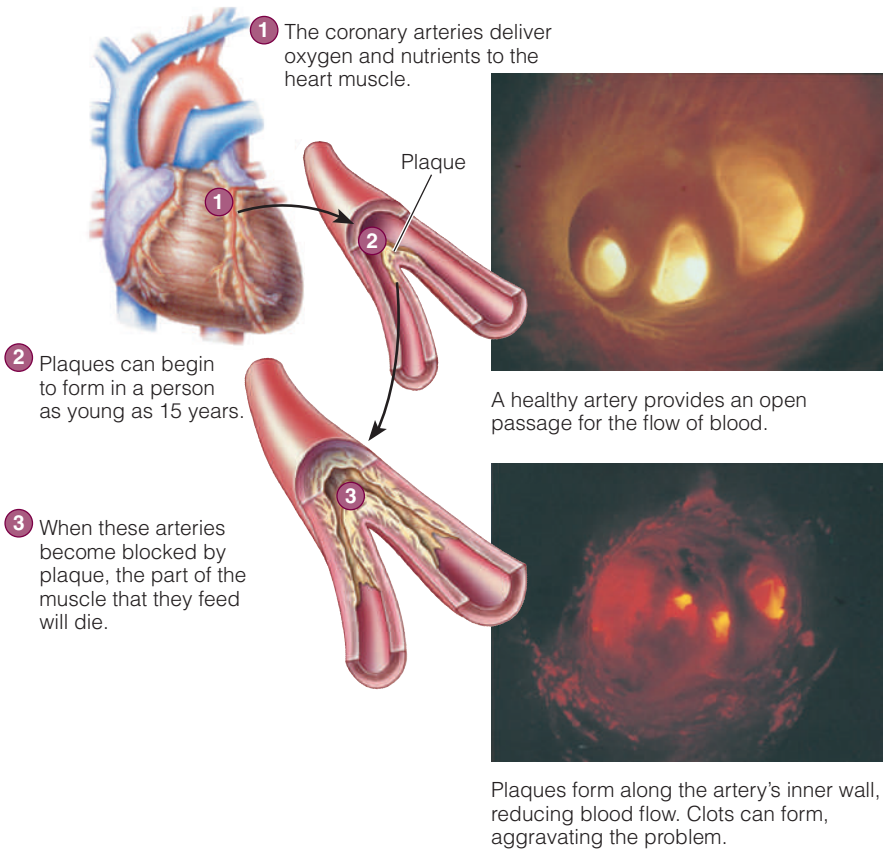
Prevention and treatment of type 2 diabetes depend on weight management, which can be particularly difficult in a child's world of food advertising, video games, and pocket money for candy bars. The activity and dietary suggestions to help defend against heart disease later in this highlight apply to type 2 diabetes as well.

# Early Development of Heart Disease

Most people consider heart disease to be an adult disease because its incidence rises with advancing age, and symptoms rarely appear before age 30. The disease process actually begins much earlier.

## Atherosclerosis

Most cardiovascular disease involves **atherosclerosis**. Atherosclerosis develops when regions of an artery's walls become progressively thickened with **plaque**—an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue. If it progresses, atherosclerosis may eventually block the flow of blood to the heart and cause a heart attack or cut off blood flow to the brain and cause a stroke. Infants are born with healthy, smooth, clear arteries, but within the first decade of life, **fatty streaks** may begin to appear (see Figure H16-1). During adolescence, these fatty streaks may begin to accumulate fibrous connective tissue. By early adulthood, the fibrous plaques may begin to calcify and become raised lesions, especially in boys and young men. As the lesions grow more numerous and enlarge, the heart disease rate begins to rise, most dramatically at about age 45 in men and 55 in women. From this point on, arterial damage and blockage progress rapidly, and heart attacks and strokes threaten life. In short, the consequences of atherosclerosis, which become apparent only in adulthood, have their beginnings in the first decades of life.[9]



Atherosclerosis is not inevitable; people can grow old with relatively clear arteries. Early lesions may either progress or regress, depending on several factors, many of which reflect lifestyle behaviors. Smoking, for example, is strongly associated with the prevalence of fatty streaks and raised lesions, even in young adults.

## Blood Cholesterol

As blood cholesterol rises, atherosclerosis worsens. Cholesterol values at birth are similar in all populations; differences emerge in early childhood. Standard values for cholesterol in children and adolescents (ages 2 to 18 years) are listed in Table H16-1 on p. 550. Cholesterol concentrations change with age in children and adolescents, however, and are especially variable during puberty.[10] Thus, use of a single cut-off point for all pediatric age groups has limitations.

In general, blood cholesterol tends to rise as dietary saturated fat intakes increase. Blood cholesterol also correlates with childhood obesity, especially abdominal obesity; LDL cholesterol rises and HDL declines. These relationships are apparent throughout childhood, and their magnitude increases with age.

**TABLE H16-1 Cholesterol Values for Children and Adolescents**

| Disease Risk | Total Cholesterol (mg/dL) | LDL Cholesterol (mg/dL) |
|---|---|---|
| Acceptable | <170 | <110 |
| Borderline | 170–199 | 110–129 |
| High | ≥200 | ≥130 |

NOTE: Adult values appear in Chapter 18.

© Cengage Learning

Children who are both overweight or obese and have high blood cholesterol are likely to have parents who develop heart disease early. For this reason, selective screening is recommended for children and adolescents of any age who are overweight or obese; those whose parents (or grandparents) have premature heart disease (≤55 years of age for men and ≤65 years of age for women); those whose parents have elevated blood cholesterol; those who have other risk factors for heart disease such as hypertension, cigarette smoking, or diabetes; and those whose family history is unavailable. Because blood cholesterol in children is a good predictor of adult values, some experts recommend universal screening for all children aged 9 to 11.[11]

Early—but not advanced—atherosclerotic lesions are reversible, making screening and education a high priority. Both those with family histories of heart disease and those with multiple risk factors need intervention. Children with the highest risks of developing heart disease are sedentary and obese, with high blood pressure and high blood cholesterol.[12] In contrast, children with the lowest risks of heart disease are physically active and of normal weight, with low blood pressure and favorable lipid profiles. Routine pediatric care should identify these known risk factors and provide intervention when needed.

## Blood Pressure

Pediatricians routinely monitor blood pressure in children and adolescents. High blood pressure may signal an underlying disease or the early onset of hypertension. Childhood hypertension, left untreated, can accelerate the development of atherosclerosis.

Like atherosclerosis and high blood cholesterol, hypertension may develop in the first decades of life, especially among obese children, and worsen with time. Children can control their hypertension by participating in regular aerobic activity and by losing weight or maintaining their weight as they grow taller. Restricting dietary sodium also causes an immediate drop in most children's and adolescents' blood pressure.[13]

# Physical Activity

Research has also confirmed an association between blood lipids and physical activity in children, similar to that seen in adults. Physically active children have a better lipid profile and lower blood pressure than physically inactive children, and these positive findings often persist into adulthood.[14] The *Physical Activity Guidelines for Americans* recommendations for children and adolescents are listed in Table 16-10 on p. 533.

Just as blood cholesterol and obesity track over the years, so does a child's level of physical activity. Those who are inactive now are likely to still be inactive years later. Similarly, those who are physically active now tend to remain so. Compared with inactive teens, those who are physically active weigh less, smoke less, eat a diet lower in saturated fats, and have better blood lipid profiles. Both obesity and blood cholesterol correlate with the inactive pastime of watching television. The message is clear: physical activity offers numerous health benefits, and children who are active today are most likely to be active for years to come.

# Dietary Recommendations for Children

Regardless of family history, experts agree that all children older than age 2 should eat a variety of foods and maintain desirable weight (see Table H16-2). For heart health, children (2 to 18 years of age) should receive at least 25 percent and no more than 30 percent of total energy from fat, less than 10 percent from saturated fat, and less than 300 milligrams of cholesterol per day.[15]

## Moderation, Not Deprivation

Healthy children older than age 2 can begin the transition to eating according to recommendations by selecting more fruits and vegetables and fewer foods high in saturated fat. Healthy meals can occasionally include moderate amounts of a child's favorite food, such as ice cream, even if it is high in saturated fat. A steady diet from the children's menus in some restaurants—which feature chicken nuggets, hot dogs, and french fries—easily exceeds a prudent intake of saturated fat, *trans* fat, and kcalories, however, and invites both nutrient shortages and weight gains.[16] Fortunately, most restaurant chains are changing children's menus to include steamed vegetables, fruit cups, and broiled or grilled chicken—additions welcomed by busy parents who often dine out or purchase take-out foods.

Other fatty foods, such as nuts, vegetable oils, and some varieties of fish such as tuna or salmon, contribute essential fatty acids. Low-fat milk and milk products also deserve special attention in a child's diet for the needed calcium and other nutrients they supply.

Parents and caregivers play a key role in helping children establish healthy eating habits. Balanced meals need to provide lean meat, poultry, fish, and legumes; fruits and vegetables; whole grains; and low-fat milk products. Such meals can provide enough energy and nutrients to support growth and maintain blood cholesterol within a healthy range.

**TABLE H16-2 American Heart Association Dietary Guidelines and Strategies for Children**

- Balance dietary kcalories with physical activity to maintain normal growth.
- Every day, engage in 60 minutes of moderate to vigorous play or physical activity.
- Eat vegetables and fruits daily. Serve fresh, frozen, or canned vegetables and fruits at every meal; limit those with added fats, salt, and sugar.
- Limit juice intake (4 ounces per day for children 2 to 10 years of age, 4 to 6 ounces for children 11 to 18 years of age).
- Use vegetable oils (canola, soybean, olive, safflower, or other unsaturated oils) and soft margarines low in saturated fat and *trans*-fatty acids instead of butter or most other animal fats in the diet.
- Choose whole-grain breads and cereals rather than refined products; read labels and make sure that "whole grain" is the first ingredient.
- Limit or avoid the intake of sugar-sweetened beverages; encourage water.
- Consume low-fat and non-fat milk and milk products daily.
- Include two servings of fish per week, especially fatty fish such as broiled or baked salmon.
- Choose legumes and tofu in place of meat for some meals.
- Choose only lean cuts of meat and reduced-fat meat products; remove the skin from poultry.
- Use less salt, including salt from processed foods. Breads, breakfast cereals, and soups may be high in salt and/or sugar, so read food labels and choose high-fiber, low-salt, low-sugar alternatives.
- Limit the intake of high-kcalorie add-ons such as gravy, Alfredo sauce, cream sauce, cheese sauce, and hollandaise sauce.
- Serve age-appropriate portion sizes on appropriately sized plates and bowls.

NOTE: These guidelines are for children 2 years of age and older.

Cigarette smoking is the number one preventable cause of deaths.

Pediatricians warn parents to avoid extremes. Although intentions may be good, excessive food restriction may create nutrient deficiencies and impair growth. Furthermore, parental control over eating may instigate battles and foster attitudes about foods that can lead to inappropriate eating behaviors.

## Diet First, Drugs Later

Experts agree that children with high blood cholesterol should first be treated with diet. If high blood cholesterol persists despite dietary intervention in children 10 years of age and older, then drugs may be necessary to lower blood cholesterol. Drugs can effectively lower blood cholesterol without interfering with adolescent growth or development.

## Smoking

Even though the focus of this text is nutrition, another risk factor for heart disease that starts in childhood and carries over into adulthood must also be addressed—cigarette smoking. Each day nearly 4000 young people between the ages of 12 and 17 light up for the first time, and an estimated 1000 become daily cigarette smokers.[17] Among high school students, one in seven smokes regularly.[18] Approximately 90 percent of all adult smokers began smoking before the age of 18.

Of those teenagers who continue smoking, half will eventually die of smoking-related causes. Efforts to teach children about the dangers of smoking need to be aggressive. Children are not likely to consider the long-term health consequences of tobacco use. They are more likely to be struck by the immediate health consequences, such as shortness of breath when playing sports, or social consequences, such as having bad breath. Whatever the context, the

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

message to all children and teens should be clear: don't start smoking. If you've already started, quit.

In conclusion, *adult* heart disease is a major *pediatric* problem. Without intervention, some 60 million children are destined to suffer its consequences within the next 30 years. Optimal prevention efforts focus on children, especially on those who are obese. Just as young children receive vaccinations against infectious diseases, they need screening for, and education about, chronic diseases. Many health education programs have been implemented in schools around the country. These programs are most effective when they include education in the classroom, heart-healthy meals in the lunch room, fitness activities on the playground, and parental involvement at home.[19]

## CRITICAL THINKING QUESTIONS

A. How does childhood obesity influence a person's health and a country's health care system?
B. Child abuse is defined as either action or neglect that damages a child or puts the child at risk of injury. If found guilty of child abuse, parents can lose their parental rights and face criminal charges. Recently, the mother of a 14-year-old was arrested and charged with criminal neglect because her son weighed more than 500 pounds. Is severe childhood obesity a life-threatening form of abuse that justifies removing a child from his or her parents?

# Life Cycle Nutrition: Adulthood and the Later Years

## Nutrition in Your Life

Take a moment to envision yourself at age 60, 75, or even 90. Are you physically fit and healthy? Can you see yourself walking on the beach with friends or tossing a ball with children? Are you able to climb stairs and carry your own groceries? Importantly, are you enjoying life? If you're lucky, you will enjoy old age in good health. Making nutritious foods and physical activities a priority in your life can help bring rewards of continued health and enjoyment throughout life. In the Nutrition Portfolio at the end of this chapter, you can examine the nutritional health and concerns of an older adult.

Much of this text has focused on nutrition to support health, and Chapter 18 features prevention of chronic diseases such as cancer and heart disease. This chapter focuses on aging and the nutrition needs of older adults. As you will see, the same diet and behaviors that reduce disease risks also slow aging.

Our society uses the arbitrary age of 65 years to define the transition point between middle age and old age, but growing "old" happens day by day, with changes occurring gradually over time. Since 1950 the population of those older than 65 has almost tripled. Remarkably, the fastest-growing age group has been people older than 85 years; since 1950 their numbers have increased sevenfold. The number of people in the United States age 100 or older doubled in the last decade. Similar trends are occurring in populations worldwide. Interestingly, there are places around the world where people live long and, importantly, healthy and active lives even after the age of 100 years. These places have been called *Blue Zones,* and include Sardinia, Italy; Okinawa, Japan; Loma Linda, California; Nicoya, Costa Rica; and Ikaria Island, Greece. The "secrets" of these peoples' **longevity** are presented on p. 557.

**longevity:** long duration of life.

# 17.1 Nutrition and Longevity

› **LEARN IT** Describe the role nutrition plays in longevity.

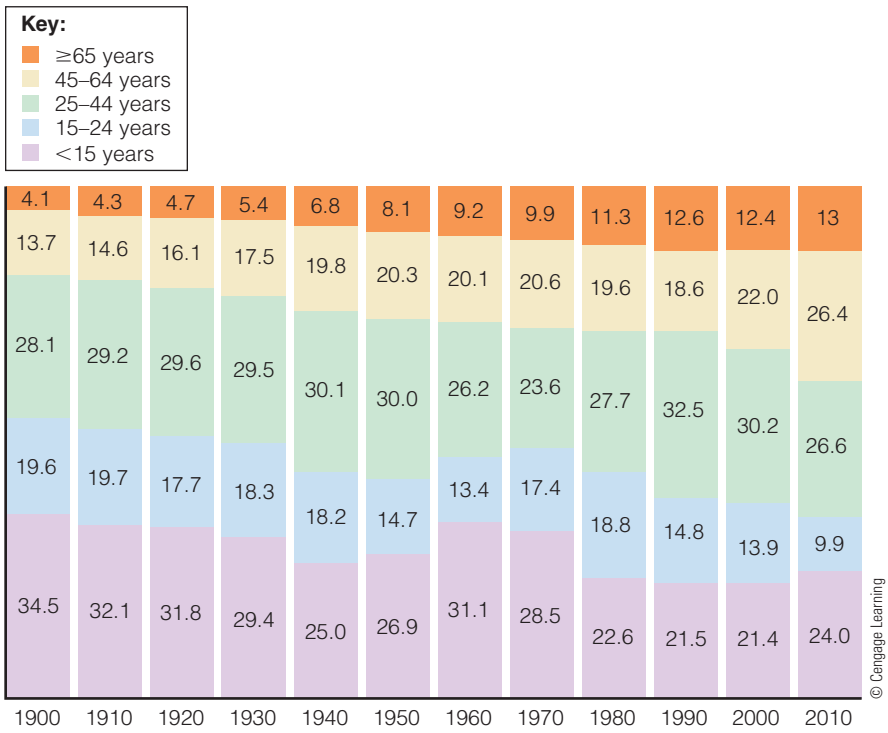

Figure 17-1 shows how the US population is growing older. The majority is now middle-aged, and the ratio of old people to young is increasing. In 1900, only 1 out of 25 people was 65 or older. In 2000, 1 out of 8 had reached age 65. Projections for 2030 are 1 out of 5. **Life expectancy** in the United States is 79 years: 81 years for white women and 78 years for black women, 77 years for white men and 72 years for black men.[1] All of these record highs are much higher than the average life expectancy of 47 years in 1900. Women who live to 75 can expect to survive an additional 13 years, on average; men, an additional 11 years.[2] Advances in medical science—antibiotics and other treatments—are largely responsible for almost doubling the life expectancy in the 20th century. Improved nutrition and an abundant food supply have also contributed to lengthening life expectancy. Ironically, an abundant food supply has also jeopardized the chances of lengthening life expectancy as obesity rates increase.

The **life span** has not lengthened as dramatically; human longevity appears to have an upper limit. The maximum potential human life span is currently about 130 years. The verifiably oldest person died in 1997 at age 122. With recent advances in medical technology and genetic knowledge, researchers may one day be able to extend the life span even further by slowing, or perhaps preventing, aging and its accompanying diseases.

Research in the field of aging is active—and difficult. Researchers are challenged by the diversity of older adults. When older adults experience health problems, it is hard to know whether to attribute these problems to genetics, aging, or environmental factors such as nutrition. The idea that nutrition can influence the

> **FIGURE 17-1** **The Aging of the US Population**

In general, the percentage of older people in the population has increased over the decades whereas the percentage of younger people has decreased.

aging process is particularly appealing because people can control and change their eating habits. The questions being asked include:

- To what extent is aging inevitable, and can it be slowed through changes in lifestyle and environment?
- What role does nutrition play in the aging process, and what role can it play in slowing aging?

With respect to the first question, it seems that aging is an inevitable, natural process, programmed into the genes at conception. People can, however, slow the process within genetic limits by adopting healthy lifestyle habits such as eating nutritious foods and engaging in physical activities. In fact, a person's life expectancy depends on both individual health-related behaviors and genes.[3]

With respect to the second question, good nutrition helps to maintain a healthy body and can therefore ease the aging process in many significant ways. Clearly, nutrition can improve the **quality of life** in the later years.

## Observation of Older Adults

The strategies adults use to meet two goals that motivate them to make changes—promoting health and slowing aging—are actually very much the same. What to eat, how physically active to be, and other lifestyle choices greatly influence both physical health and the aging process.

### Healthy Habits

A person's **physiological age** reflects his or her health status and may or may not reflect the person's **chronological age.** Quite simply, some people seem younger, and others older, than their years. Some behaviors seem to have the greatest influence on people's health and therefore on their physiological age:[4]

- Following a healthy plant-based eating pattern, such as the Mediterranean diet (rich in fruits, vegetables, whole grains, poultry, fish, and low fat milk products)[5]
- Engaging in moderate physical activity daily
- Not smoking
- Not using alcohol, or using it in moderation
- Maintaining a healthy body weight
- Sleeping regularly and adequately
- Having a sense of purpose
- Relieving stress (through meditation, prayer, naps, or other calming activity)
- Belonging to a community of loving family and friends (home, church, or other social networks)

Over the years, the effects of these lifestyle choices accumulate—that is, people who follow most of these practices live longer and have a better quality of life as they age.[6] They are in better health, even when older in chronological age, than people who do not adopt these behaviors. Even though people cannot change their birth dates, they may be able to add years to, and enhance the quality of, their lives. Physical activity seems to be most influential in preventing or slowing the many changes that define a stereotypical "old" person. After all, many of the physical limitations that accompany aging occur because people become inactive, not because they become older.

### Physical Activity

The many remarkable benefits of regular physical activity outlined in Chapter 14 are not limited to the young. Compared with those who are inactive, older adults who are active weigh less; have greater flexibility, more endurance, better balance, and better health; and they live longer. Perhaps most importantly, they enjoy better overall health.[7] They reap additional benefits from various activities as well: aerobic activities improve cardiorespiratory endurance, blood pressure, and blood lipid concentrations; moderate-endurance activities improve the quality of sleep; and strength training improves posture and mobility. In

**quality of life:** a person's perceived physical and mental well-being.

**physiological age:** a person's age as estimated from her or his body's health and probable life expectancy.

**chronological age:** a person's age in years from his or her date of birth.

fact, regular physical activity is the most powerful predictor of a person's mobility in the later years. Mobility, in turn, is closely associated with longevity.[8] Physical activity also increases blood flow to the brain, thereby preserving mental ability, alleviating depression, supporting independence, and improving quality of life.[9]

Muscle mass and muscle strength tend to decline with aging, making older people vulnerable to falls and immobility. Falls are a major cause of fear, injury, disability, and even death among older adults. Many lose their independence as a result of falls. Regular physical activity tones, firms, and strengthens muscles, helping to improve balance, restore confidence, reduce the risk of falling, and lessen the risk of injury should a fall occur.

Even without a fall, older adults may become so weak that they can no longer perform life's daily tasks, such as climbing stairs, carrying packages, and opening jars. Resistance training helps older adults to maintain independence by improving mobility and muscle strength to perform these tasks.[10] Even in frail, elderly people older than 85 years of age, strength training not only improves balance, muscle strength, and mobility, but it also increases energy expenditure and energy intake, thereby enhancing nutrient intakes. This finding highlights another reason to be physically active: a person expending energy can afford to eat more food and thus receives more nutrients. People who are committed to an ongoing fitness program can benefit from higher energy and nutrient intakes and still maintain healthy body weights.

© Purestock/Jupiterimages

Regular physical activity promotes a healthy, independent lifestyle.

Ideally, physical activity should be part of each day's schedule and should be intense enough to prevent muscle atrophy and to speed the heartbeat and respiration rate. Although aging reduces both speed and endurance to some degree, older adults can still train and achieve exceptional performances. Some older adults may enjoy pumping iron and running marathons, but such activities are not essential to good health. Daily activities can be as simple as growing gardens and doing household chores.

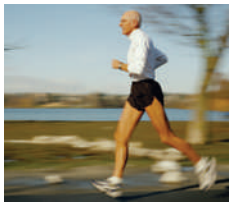
Healthy older adults who have not been active can ease into a suitable routine, becoming as physically active as their abilities allow. They can start by walking short distances until they are walking at least 10 minutes continuously, and then gradually increase their distance to a 30- to 60-minute workout at least 5 days a week. Table 17-1 provides exercise goals and guidelines for older adults. Relatively few older adults meet these goals. People with medical conditions should check with a physician before beginning an exercise routine, as should sedentary men older than 40 and sedentary women older than 50 who want to participate in a vigorous program.

**> DIETARY GUIDELINES FOR AMERICANS**

Older adults should be as physically active as their abilities and conditions will allow.

## Manipulation of Diet

In their efforts to understand longevity, researchers have not only observed people, but they have also manipulated influencing factors, such as diet, in animals. This research has given rise to some interesting and suggestive findings.



### Energy Restriction in Animals

Decades of research has revealed that animals live longer and have fewer age-related diseases when their energy intakes are restricted.[11] These life-prolonging benefits become evident when the diet provides enough food to prevent malnutrition and an energy intake of about 70 percent of normal; benefits decline as the age of starting the energy restriction is delayed. Exactly how energy restriction prolongs life remains unexplained, although gene activity appears to play a key role. The genetic activity of old mice differs from that

[a]On a 10-point scale, where sitting = 0 and maximum effort = 10, moderate intensity = 5 to 6 and vigorous intensity = 7 to 8.
NOTE: Activity recommendations are in addition to routine activities of daily living (such as getting dressed, cooking, grocery shopping) and moderate activities lasting less than 10 minutes.
SOURCE: Centers for Disease Control and Prevention, Division of Nutrition Physical Activity and Obesity, National Center for Chronic Disease prevention and Health Promotion, 2011, www.cdc.gov/physicalactivity/everyone/guidelines/olderadults.html; C. E. Garber and coauthors, Quantity and quality of exercise for developing and maintaining cardiorespiratory, musculoskeletal, and neuromotor fitness in apparently healthy adults: Guidance for prescribing exercise, *Medicine & Science in Sports & Exercise* 43 (2011): 1334–1359.

of young mice, with some genes becoming more active with age and others less active. With an energy-restricted diet, many of the genetic activities of older mice revert to those of younger mice. These "slow-aging" genetic changes are apparent in as little as 1 month on an energy-restricted, but still nutritionally adequate, diet.

The consequences of energy restriction in animals include a delay in the onset, or prevention, of chronic diseases such as cancer and atherosclerosis and age-related conditions such as neuron degeneration; prolonged growth and development; and improved blood glucose, insulin sensitivity, and blood lipids. In addition, energy metabolism slows and body temperature drops—indications of a reduced rate of oxygen consumption. As Highlight 11 explains, the use of oxygen during energy metabolism produces free radicals, which have been implicated in the aging process. Restricting energy intake in animals not only produces fewer free radicals, but also increases antioxidant activity and enhances DNA repair. Reducing oxidative stress may at least partially explain how restricting energy intake lengthens life expectancy.

Interestingly, longevity appears to depend on restricting energy intake and not on energy balance or body composition.[12] Genetically obese rats live longer when given a restricted diet even though their body fat is similar to that of other rats allowed to eat freely.

**Energy Restriction in Human Beings** Research on a variety of species—including mice, rats, monkeys, spiders, and fish—confirms the relationship between energy restriction and longevity.[13] Applying the results of animal studies to human beings is problematic, however, and conducting studies on human beings raises numerous questions—beginning with how to define *energy restriction*.[14] Does it mean eating less or just weighing less? Is it less than you want or less than the

average? Does eating less have to result in weight loss? Does it matter whether weight loss results from more exercise or from less food? Or whether weight loss is intentional or unintentional? Answers await additional research.

Extreme starvation to extend life, like any extreme, is rarely, if ever, worth the price. Hunger is persistent when energy is restricted by 30 percent. Furthermore, using animal data to extrapolate to humans, researchers estimate that it would take 30 years of such energy-restricted dieting to increase life expectancy by less than 3 years.

Moderation, on the other hand, may be valuable. Many of the physiological responses to energy restriction seen in animals also occur in people whose intakes are *moderately* restricted.[15] When people cut back on their usual energy intake by 10 to 20 percent, body weight, body fat, inflammatory proteins, growth factors, and blood pressure drop, and blood lipids and insulin response improve—favorable changes for preventing chronic diseases such as some cancers, type 2 diabetes, hypertension, and heart disease.[16] (For perspective, a person with a usual energy intake of 2000 kcalories might cut back to 1600 to 1800 kcalories.) Some research suggests that fasting on alternative days may provide similar benefits.[17]

The reduction in oxidative damage that occurs with energy restriction in animals also occurs in people whose diets include antioxidant nutrients and phytochemicals. Diets, such as the Mediterranean diet, which include an abundance of fruits, vegetables, olive oil, and moderate amounts of red wine—with their array of phytochemicals that have antioxidant activity—support good health and long life.[18] Clearly, nutritional adequacy is essential to living a long and healthy life.

**› REVIEW IT** Describe the role nutrition plays in longevity.

Life expectancy in the United States increased dramatically in the 20th century. Factors that enhance longevity include well-balanced meals, regular physical activity, abstinence from smoking, limited or no alcohol use, healthy body weight, adequate sleep, and strong social relationships. Energy restriction in animals seems to lengthen their lives. Whether such dietary intervention in human beings is beneficial remains unknown. At the very least, nutrition—especially when combined with regular physical activity—can influence aging and longevity in human beings by supporting good health and preventing disease.

## 17.2 The Aging Process

**› LEARN IT** Summarize how nutrition interacts with the physical, psychological, economic, and social changes involved in aging.

As people get older, each person becomes less and less like anyone else. The older people are, the more time has elapsed for such factors as nutrition, genetics, physical activity, and everyday **stress** to influence physical and psychological aging.

Stress contributes to a variety of age-related conditions. Both physical **stressors** (such as alcohol abuse, other drug abuse, smoking, pain, and illness) and psychological stressors (such as exams, divorce, moving, and the death of a loved one) elicit the body's **stress response.** The body responds to such stressors with an elaborate series of physiological steps, as the nervous and hormonal systems bring about defensive readiness in every body part. These effects favor physical action—the classic fight-or-flight response. Prolonged or severe stress can drain the body of its reserves and leave it weakened, aged, and vulnerable to illness, especially if physical action is not taken. As people age, they lose their ability to adapt to both external and internal disturbances. When disease strikes, the reduced ability to adapt makes the aging individual more vulnerable to death than a younger person. Strategies to preserve health forestall disease, disability, and death.

**stress:** any threat to a person's well-being; a demand placed on the body to adapt.

**stressors:** environmental elements, physical or psychological, that cause stress.

**stress response:** the body's response to stress, mediated by both nerves and hormones.

Because the stress response is mediated by hormones, it differs between men and women. The fight-or-flight response may be more typical of men than of women. Women's reactions to stress more typically follow a pattern of "tend-and-befriend." Women *tend* by nurturing and protecting themselves, their children,

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

and other loved ones. These actions promote safety and reduce stress. Women *befriend* by creating and maintaining a social group that can help in the process.

Highlight 11 describes the oxidative stresses and cellular damage that occur when free radicals exceed the body's ability to defend itself. Increased free-radical activity and decreased antioxidant protection are common features of aging—and foods rich in antioxidants may help slow the aging process and improve cognition.[19] Such findings seem to suggest that the fountain of youth may actually be a cornucopia of fruits and vegetables rich in antioxidants. (Return to Highlight 11 for more details on the antioxidant action of fruits and vegetables in defending against oxidative stress.)

## Physiological Changes

As aging progresses, inevitable changes in each of the body's organ systems contribute to the body's declining function. These physiological changes influence nutrition status, just as growth and development do in the earlier stages of the life cycle.[20]

### Body Weight

An estimated 35 percent of older adults in the United States are now considered obese. Chapter 8 presents the many health problems that accompany obesity and the BMI guidelines for a healthy body weight (18.5 to 24.9). These guidelines apply to all adults, regardless of age, but they may be too restrictive for older adults. The importance of body weight in defending against chronic diseases differs for older adults.[21] Being *moderately overweight* may not be harmful. For adults older than 65, the lowest mortality correlates with a higher BMI (23.5 to 27.5).[22] Older adults who are *obese*, however, may still face serious medical complications, at least until age 85.[23]

For some older adults, a low body weight may be more detrimental than a high one. Low body weight often reflects malnutrition and the trauma associated with a fall. Many older adults experience unintentional weight loss, in large part because of inadequate food intake. Without adequate body fat and nutrient reserves, an underweight person may be unprepared to fight against diseases. For underweight people, even a slight weight loss (5 percent) increases the likelihood of disease and premature death, making every meal a life-saving event. Drinking liquid nutritional supplements and snacking between meals can help older adults obtain needed nutrients and energy.

**> DIETARY GUIDELINES FOR AMERICANS**

Maintain appropriate kcalorie balance during older age. Adults aged 65 and older who are overweight are encouraged to not gain additional weight.

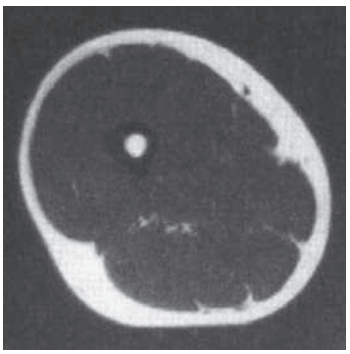
### Body Composition

In general, older people tend to lose bone and muscle and gain body fat. Many of these changes occur because some hormones that regulate appetite and metabolism become less active with age, whereas others become more active.

Loss of muscle, known as **sarcopenia,** can be significant in the later years, and its consequences can be quite dramatic (see Figure 17-2 on p. 562).[24] As muscles diminish and weaken, people lose the ability to move and maintain balance—making falls likely. The limitations that accompany the loss of muscle mass and strength play a key role in the diminishing health that often accompanies aging. Optimal nutrition with sufficient protein at each meal along with regular strength-building physical activity can help maintain muscle mass and strength and minimize the changes in body composition associated with aging.[25] Omega-3 fatty acids may also stimulate muscle protein synthesis in older adults and help prevent sarcopenia.[26]

**sarcopenia** (SAR-koh-PEE-nee-ah): loss of skeletal muscle mass, strength, and quality.
- **sarco** = flesh
- **penia** = loss or lack

### Immunity and Inflammation



As people age, the immune system loses function. As they become ill, the immune system becomes overstimulated. The combination of an inefficient and overactive response in aging—known as "inflammaging"—results in a chronic inflammation that accompanies frailty, illness, and death.

Most diseases common in older adults—such as atherosclerosis, Alzheimer's disease, obesity, and rheumatoid arthritis—are different in obvious ways, but they all reflect an underlying inflammatory process. Because of this association with diseases, inflammation is often perceived as a harmful process, yet it is critical in supporting health as the immune system destroys invading organisms and repairs damaged tissues. Thus inflammation presents a challenge to identify factors that will both protect the beneficial effects and limit the harmful consequences.

In addition to aging and diseases, the immune system is compromised by nutrient deficiencies. Thus the combination of age, illness, and poor nutrition makes older people particularly vulnerable to infectious diseases. Adding insult to injury, antibiotics often are not effective against infections in people with compromised immune systems. Consequently, infectious diseases are a major cause of death in older adults. Older adults may improve their immune system responses with diets rich in fruits and vegetables and regular physical activity.[27]

**GI Tract** In the GI tract, numerous changes take place, contributing to poor appetite, early satiety, and malnutrition.[28] The intestinal wall loses strength and elasticity with age, and GI hormone secretions change. All of these actions slow motility. Constipation is much more common in the elderly than in the young. Changes in GI hormone secretions also diminish appetite, leading to decreased energy intake and unintentional weight loss.

Atrophic gastritis, a condition that affects almost one-third of those older than 60, is characterized by an inflamed stomach, bacterial overgrowth, and a lack of hydrochloric acid and intrinsic factor. All of these factors can impair the digestion and absorption of nutrients, most notably, vitamin $B_{12}$, but also biotin, folate, calcium, iron, and zinc.

Difficulty swallowing, medically known as **dysphagia,** occurs in all age groups, but especially in the elderly. Being unable to swallow a mouthful of food can be scary, painful, and dangerous. Even swallowing liquids can be a problem for some people. Consequently, the person may eat less food and drink fewer beverages, resulting in weight loss, malnutrition, and dehydration. Dietary intervention for dysphagia is highly individualized based on the person's abilities and tolerances. The diet typically provides moist, soft-textured, tender-cooked, or pureed foods and thickened liquids.

**Tooth Loss** Regular dental care over a lifetime protects against tooth loss and gum disease, which are common in old age. These conditions make chewing difficult or painful. Dentures, even when they fit properly, are less effective than natural teeth, and inefficient chewing can cause choking. Chewing crushes foods into smaller pieces in preparation for digestion. Inefficient chewing leaves larger pieces of food moving from the stomach into the small intestine, thus limiting enzyme accessibility. Simple changes in food texture might improve chewing efficiency and benefit digestion. For example, research suggests that, for older adults, chopped beef is more rapidly digested and absorbed than beef steak, resulting in increased amino acid availability.[29]

People with tooth loss, gum disease, and ill-fitting dentures tend to limit their food selections to soft foods.* If foods such as corn on the cob and apples are replaced by creamed corn and applesauce, then nutrition status may not be greatly affected. However, when food groups are eliminated and variety is limited, poor nutrition follows. People without teeth typically eat fewer fruits and vegetables and have less variety in their diets. Consequently, they have low intakes of fiber and vitamins, which exacerbates their dental and overall health problems.

**dysphagia** (dis-FAY-jah): difficulty swallowing.

*The medical term for lack of teeth is *edentulous* (ee-DENT-you-lus).

The following conditions help to determine whether a visit to the dentist is needed:

- Dry mouth
- Eating difficulty
- No dental care within 2 years
- Tooth or mouth pain
- Altered food selections
- Lesions, sores, or lumps in mouth

**Sensory Losses and Other Physical Problems** Sensory losses and other physical problems can also interfere with an older person's ability to obtain adequate nourishment. Failing eyesight, for example, can make driving to the grocery store impossible and shopping for food a frustrating experience. It may become so difficult to read food labels and count money that the person doesn't buy needed foods. Carrying bags of groceries may be an unmanageable task. Similarly, a person with limited mobility may find cooking and cleaning up too hard to do. Not too surprisingly, the prevalence of undernutrition is high among those who are home-bound.

Sensory losses can also interfere with a person's ability or willingness to eat. Taste and smell sensitivities tend to diminish with age and may make eating less enjoyable. If a person eats less, then weight loss and nutrient deficiencies may follow. Loss of vision and hearing may contribute to social isolation, and eating alone may lead to poor intake.

## Other Changes

In addition to the physiological changes that accompany aging, adults change in many other ways that influence their nutrition status.[30] Psychological, economic, and social factors play major roles in a person's ability and willingness to eat.

**Psychological Changes** Late-life depression is associated with an increased risk of mortality.[31] Although not an inevitable component of aging, depression is common among older adults, especially among those in poor health and those living in long-term nursing homes.[32] Relatively few receive adequate treatment from either antidepressant medication or mental health counseling.[33]

Depressed people, even those without physical disabilities, lose their ability to perform simple physical tasks. They frequently lose their appetite and the motivation to cook or even to eat. An overwhelming sense of grief and sadness at the death of a spouse, friend, or family member may leave a person, especially an elderly person, feeling powerless to overcome depression. When a person is suffering the heartache and loneliness of bereavement, cooking meals may not seem worthwhile. The support and companionship of family and friends, especially at mealtimes, can help overcome depression and enhance appetite.

Several nutrient interventions to relieve depression have been studied, but evidence of effectiveness is inconclusive. A balanced, healthy diet may be the best nutritional approach to reducing symptoms of depression and improving quality of life.[34]

**Economic Changes** Overall, older adults today have higher incomes than their cohorts of previous generations. Still, 9 percent of the people older than age 65 live in poverty.[35] Factors such as living arrangements and income make significant differences in the food choices, eating habits, and nutrition status of older adults, especially those older

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

than age 80. People of low socioeconomic means are likely to have inadequate food and nutrient intakes. Only about one-third of eligible seniors participate in the Supplemental Nutrition Assistance Program (SNAP).

**Social Changes** Malnutrition is most likely to occur among those living alone, especially men; those with the least education; those living in federally funded housing (an indicator of low income); and those who have recently experienced a change in lifestyle. Adults who live alone do not necessarily make poor food choices, but they often consume too little food. Loneliness is directly related to nutritional inadequacies, especially of energy intake. Feeling lonely is also associated with a decline in activities of daily living and mobility as well as an increased risk of death.[36]

**› REVIEW IT** Summarize how nutrition interacts with the physical, psychological, economic, and social changes involved in aging.

Many changes that accompany aging can impair nutrition status. Among physiological changes, hormone activity alters body composition, immune system changes raise the risk of infections, atrophic gastritis interferes with digestion and absorption, and tooth loss limits food choices. Psychological changes such as depression, economic changes such as loss of income, and social changes such as loneliness contribute to poor food intake.

## 17.3 Energy and Nutrient Needs of Older Adults

**› LEARN IT** Explain why the needs for some nutrients increase or decrease during aging.

Knowledge about the nutrient needs and nutrition status of older adults has grown considerably in recent years. The Dietary Reference Intakes (DRI) cluster people older than 50 into two age categories—one group of 51 to 70 years and one of 71 and older.

Setting standards for older people is difficult because individual differences become more pronounced as people grow older. People start out with different genetic predispositions and ways of handling nutrients, and the effects of these differences become magnified with years of unique dietary habits. For example, one person may tend to omit fruits and vegetables from his diet, and by the time he is old, he may have a set of nutrition problems associated with a lack of fiber and antioxidants. Another person may have omitted milk and milk products all her life—her nutrition problems may be related to a lack of calcium. Also, as people age, they suffer different chronic diseases and take various medicines—both of which will affect nutrient needs. For all of these reasons, researchers have difficulty even defining *healthy aging,* a prerequisite to developing recommendations to meet the "needs of practically all healthy persons." The following discussion gives special attention to the nutrients of greatest concern.

© Fancy/Alamy

To ensure adequate hydration, keep a glass of water next to you at home, drink from water fountains whenever you walk by, and put a bottle of water in your car.

**Water** Despite real fluid needs, many older people do not seem to feel thirsty or notice mouth dryness. Many nursing home employees say it is hard to persuade their elderly clients to drink enough water and fruit juices. Older adults may find it difficult and bothersome to get a drink or to get to a bathroom. Those who have lost bladder control may be afraid to drink too much water.

Dehydration is a risk for older adults. Total body water decreases as people age, so even mild stresses such as fever or hot weather can precipitate rapid dehydration in older adults. Dehydrated older adults seem to be more susceptible to urinary tract infections, pneumonia, **pressure ulcers,** and confusion and disorientation. To prevent dehydration, older adults need to drink *at least* six glasses of water or other beverages every day. Emphasizing foods with high-water content, such as melons and soups, can also be helpful.

**pressure ulcers:** damage to the skin and underlying tissues as a result of compression and poor circulation; commonly seen in people who are bedridden or chair-bound.

## Energy and Energy Nutrients

On average, energy needs decline an estimated 5 percent per decade. One reason is that people usually reduce their physical activity as they age, although they need not do so. Another reason is that basal metabolic rate declines 1 to 2 percent per decade in part because lean body mass and thyroid hormones diminish.

The lower energy expenditure of older adults means that they need to eat less food to maintain their weight. Accordingly, the estimated energy requirements for adults decrease steadily after age 19.

Older adults need fewer kcalories as they age, but their nutrient needs remain high. For this reason, it is most important that they select mostly nutrient-dense foods. There is little leeway for added sugars, solid fats, or alcohol; such nutrient-poor selections can easily lead to weight gain and malnutrition. The USDA Food Patterns (Table 2-3 on p. 43) offer a dietary framework for adults of all ages.

© Corbis Super RF/Alamy

Growing old can be enjoyable for people who take care of their health and live each day fully.

### Protein

Because energy needs decrease, protein must be obtained from low-kcalorie sources of high-quality protein, such as lean meats, poultry, fish, and eggs; fat-free and low-fat milk products; and legumes. Protein is especially important for the elderly to support a healthy immune system, prevent muscle wasting, and optimize bone mass. Maintaining muscles helps to support protein metabolism and immune function.

Underweight or undernourished older adults need protein- and energy-dense snacks such as hard-boiled eggs, tuna salad, peanut butter on wheat toast, and hearty soups. Drinking liquid nutritional supplements between meals can also boost energy and nutrient intakes. Importantly, the diet should provide enjoyment as well as nutrients.[37]

### Carbohydrate and Fiber

As always, abundant carbohydrate is needed to protect protein from being used as an energy source. Carbohydrate-rich foods such as legumes, vegetables, whole grains, and fruits are also rich in fiber and essential vitamins and minerals. Average fiber intakes among older adults are lower than current recommendations (14 grams per 1000 kcalories). Eating high-fiber foods and drinking water can alleviate constipation—a condition common among older adults, especially nursing home residents. (Physical inactivity and medications also contribute to the high incidence of constipation.)

### Fat

As is true for people of all ages, fat intake needs to be moderate in the diets of most older adults—enough to enhance flavors and provide valuable nutrients, but not so much as to raise the risks of atherosclerosis and other degenerative diseases. This recommendation should not be taken too far; limiting fat too severely may lead to nutrient deficiencies and weight loss—two problems that carry greater health risks in the elderly than being overweight.

## Vitamins and Minerals

Most people can achieve adequate vitamin and mineral intakes simply by including foods from all food groups in their diets, but older adults often omit fruits and vegetables. Similarly, few older adults consume the recommended amounts of milk or milk products.

### Vitamin $B_{12}$

An estimated 10 to 30 percent of adults older than 50 have **atrophic gastritis;** as Chapter 10 explains, people with atrophic gastritis are particularly vulnerable to vitamin $B_{12}$ deficiency. The bacterial overgrowth that accompanies this condition uses up the vitamin, and without hydrochloric acid and intrinsic factor, digestion and absorption of vitamin $B_{12}$ are inefficient. Given the poor cognition, anemia, and devastating neurological effects associated with a vitamin $B_{12}$ deficiency, an adequate intake is imperative. The RDA for older adults is the same as for younger adults, but with the added suggestion to obtain most of a day's intake from vitamin $B_{12}$–fortified foods and supplements. The bioavailability of vitamin $B_{12}$ from these sources is better than from foods.

**atrophic** (a-TRO-fik) **gastritis** (gas-TRY-tis): chronic inflammation of the stomach accompanied by a diminished size and functioning of the mucous membranes and glands. This condition is also characterized by inadequate hydrochloric acid and intrinsic factor—two substances needed for vitamin $B_{12}$ absorption.

Taking time to nourish your body well is a gift you give yourself.

> **DIETARY GUIDELINES FOR AMERICANS**
Individuals aged 50 years and older should consume foods fortified with vitamin $B_{12}$, such as fortified cereals, or take dietary supplements.

**Vitamin D** Vitamin D deficiency is a problem for many older adults. Vitamin D–fortified milk is the most reliable source of vitamin D, but many older adults drink little or no milk. Further compromising the vitamin D status of many older people, especially those in nursing homes, is their limited exposure to sunlight. Finally, aging reduces the skin's capacity to make vitamin D and the kidneys' ability to convert it to its active form. Not only are older adults not getting enough vitamin D, but they may actually need more to improve both muscle and bone strength. To prevent bone loss and to maintain vitamin D status, especially in those who engage in minimal outdoor activity, adults 51 to 70 years old need 15 micrograms daily, and those 71 and older need 20 micrograms. Supplements may be needed to achieve adequate levels of vitamin D.[38]

> **DIETARY GUIDELINES FOR AMERICANS**
Choose fortified foods and dietary supplements to provide more vitamin D, a nutrient of concern.

**Folate** As is true of vitamin $B_{12}$, folate intakes of older adults typically fall short of recommendations. The elderly are also more likely to have medical conditions or to take medications that can compromise folate status (see Highlight 17).

**Calcium** Both Chapter 12 and Highlight 12 emphasize the importance of abundant dietary calcium throughout life, especially for women after menopause, to protect against osteoporosis. The DRI Committee recommends 1200 milligrams of calcium daily for women older than 50 and men older than 70, but the calcium intakes of older people in the United States are well below recommendations. Some older adults avoid milk and milk products because they dislike these foods or associate them with stomach discomfort. Simple solutions include using calcium-fortified juices, adding powdered milk to recipes, and taking supplements. Chapter 12 offers many other strategies for including nonmilk sources of calcium for those who do not drink milk.

**Iron** The iron needs of men remain unchanged throughout adulthood. For women, iron needs decrease substantially at menopause when blood loss through menstruation ceases. Consequently, iron-deficiency anemia is less common in older adults than in younger people. In fact, elevated iron stores are more likely than deficiency in older people, especially for those who take iron supplements, eat red meat regularly, and include vitamin C–rich fruits in their daily diet.

Nevertheless, iron deficiency may develop in older adults, especially when their food energy intakes are low. Aside from diet, two other factors may lead to iron deficiency in older people: chronic blood loss from diseases and medicines and poor iron absorption due to reduced stomach acid secretion and antacid use. Iron deficiency impairs immunity and leaves older adults vulnerable to infectious diseases. Anyone concerned with older people's nutrition should keep these possibilities in mind.

**Zinc** Zinc intake is commonly low in older people. Zinc deficiency can depress the appetite and blunt the sense of taste, thereby reducing food intake and worsening zinc status. Many medications that older adults commonly use can impair zinc absorption or enhance its excretion and thus lead to deficiency. Low zinc status impairs immune function and increases the risk of pneumonia and death.[39]

## Dietary Supplements

People judge for themselves how to manage their nutrition, and more than half of older adults turn to dietary supplements.[40] When

**TABLE 17-2 Nutrient Concerns of Aging**

| Nutrient | Effect of Aging | Comments |
|---|---|---|
| Water | Lack of thirst and decreased total body water make dehydration likely. | Mild dehydration is a common cause of confusion. Difficulty obtaining water or getting to the bathroom may compound the problem. |
| Energy | Need decreases as muscle mass decreases (sarcopenia). | Physical activity moderates the decline. |
| Fiber | Likelihood of constipation increases with low intakes and changes in the GI tract. | Inadequate water intakes and lack of physical activity, along with some medications, compound the problem. |
| Protein | Needs may stay the same or increase slightly. | Low-fat, high-fiber legumes and grains meet both protein and other nutrient needs. |
| Vitamin $B_{12}$ | Atrophic gastritis is common. | Deficiency causes neurological damages; supplements may be needed. |
| Vitamin D | Increased likelihood of inadequate intake; skin synthesis declines. | Daily sunlight exposure in moderation or supplements may be beneficial. |
| Calcium | Intakes may be low; osteoporosis is common. | Stomach discomfort commonly limits milk intake; calcium substitutes or supplements may be needed. |
| Iron | In women, status improves after menopause; deficiencies are linked to chronic blood losses and low stomach acid output. | Adequate stomach acid is required for absorption; antacid or other medicine use may aggravate iron deficiency; vitamin C and meat increase absorption. |
| Zinc | Intakes are often inadequate and absorption may be poor, but needs may also increase. | Medications interfere with absorption; deficiency may depress appetite and sense of taste. |

© Cengage Learning

recommended by a physician or registered dietitian nutritionist, vitamin D and calcium supplements for osteoporosis or vitamin $B_{12}$ for pernicious anemia may be beneficial. Many health-care professionals recommend a daily multivitamin-mineral supplement that provides 100 percent or less of the Daily Value for the listed nutrients. They reason that such a supplement is more likely to be beneficial than to cause harm. Supplement use may help older adults obtain enough of some nutrients, but it may also lead to excessive intakes of others.[41]

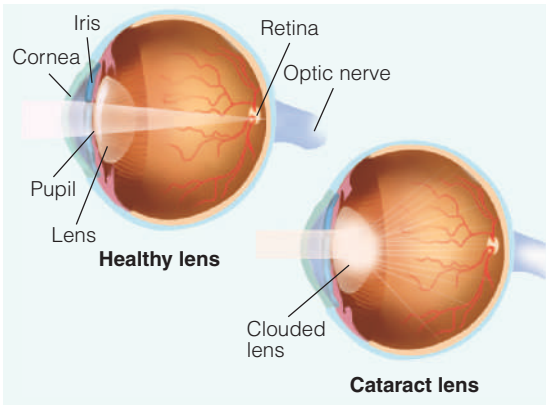
People with small energy allowances would do well to become more active so they can afford to eat more food. Food is the best source of nutrients for everybody. Supplements are just that—supplements to foods, not substitutes for them. For anyone who is motivated to obtain the best possible health, it is never too late to learn to eat well, drink water, exercise regularly, and adopt other lifestyle habits such as quitting smoking and moderating alcohol use.

**› REVIEW IT** Explain why the needs for some nutrients increase or decrease during aging.

Table 17-2 provides a summary of the nutrient concerns of aging. Although some nutrients need special attention in the diet, supplements are not routinely recommended. The ever-growing number of older people creates an urgent need to learn more about how their nutrient requirements differ from those of others and how such knowledge can enhance their health.

## 17.4 Nutrition-Related Concerns of Older Adults

**› LEARN IT** Identify how nutrition might contribute to, or prevent, the development of age-related problems associated with vision, arthritis, the brain, and alcohol use.



Nutrition may play a greater role than has been realized in preventing many changes once thought to be inevitable consequences of growing older. The following discussions of vision, arthritis, the aging brain, and alcohol use show how nutrition interacts with these conditions.

**Vision** One key aspect of healthy aging is maintaining good vision. Age-related eye diseases that impair vision, such as cataracts and macular degeneration, correlate with poor survival that cannot be explained by other risk factors.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

> FIGURE 17-3 Healthy Lens and Cataract Lens Compared

© 2016 Cengage Learning

The healthy lens (on the left) focuses light, producing clear, sharp images on the retina. A lens affected by cataracts (on the right) scatters the light, resulting in blurred vision.

© Panu Ruangjan/Shutterstock.com

Vision through a healthy lens (on the left) is crisp and clear, whereas vision through cataracts (on the right) is cloudy.

**Cataracts** **Cataracts** are age-related cloudy areas in the lenses of the eyes that impair vision (see Figure 17-3). If not surgically removed, they ultimately lead to blindness. Cataracts may develop as a result of ultraviolet light exposure, oxidative stress, injury, viral infections, toxic substances, and genetic disorders. Most cataracts, however, are vaguely called senile cataracts—meaning "caused by aging." In the United States, more than half of all adults 65 and older have a cataract.

Oxidative stress appears to play a significant role in the development of cataracts, but supplements of the antioxidant nutrients (vitamin C, vitamin E, and carotenoids) do not seem to prevent or slow the progression.[42] By comparison, a healthy diet that includes plenty of fruits and vegetables rich in these antioxidant nutrients does seem to slow the progression or reduce the risk of developing cataracts.[43] A word of caution: vitamin C supplements in high doses (1000 milligrams) and long duration (several years) may *increase* the risk of cataracts.[44]

One other diet-related factor may play a role in the development of cataracts—obesity. Obesity appears to be associated with cataracts, but its role has not been identified. Risk factors that typically accompany obesity, such as inactivity, diabetes, or hypertension, do not explain the association.

**Macular Degeneration** The leading cause of visual loss among older people is age-related **macular degeneration,** a deterioration of the macular region of the retina. As with cataracts, risk factors for age-related macular degeneration include oxidative stress from sunlight. Preventive factors may include supplements of the omega-3 fatty acids, some B vitamins (folate, vitamin $B_6$, and vitamin $B_{12}$), antioxidants (vitamin C, vitamin E, and beta-carotene), zinc, and the carotenoids lutein and zeaxanthin.[45]

## Arthritis

More than 50 million people in the United States have some form of **arthritis.**[46] As the population ages, it is expected that the prevalence will increase to 70 million by 2030. Arthritis pain and fear of further damage limit physical activity.

**Osteoarthritis** The most common type of arthritis that disables older people is **osteoarthritis,** a painful deterioration of the cartilage in the joints. During movement, the ends of bones are normally protected from wear by cartilage and by small sacs of fluid that act as a lubricant. With age, cartilage begins to deteriorate, and the joints may become malformed and painful to move.

Obesity is common among adults with arthritis.[47] Weight loss may relieve some of the pain for overweight persons with osteoarthritis, partly because the joints affected are often weight-bearing joints that are stressed and irritated by having to carry excess pounds. Interestingly, though, weight loss often relieves

**cataracts** (KAT-ah-rakts): clouding of the eye lenses that impairs vision and can lead to blindness.

**macular** (MACK-you-lar) **degeneration:** deterioration of the macular area of the eye that can lead to loss of central vision and eventual blindness. The *macula* is a small, oval, yellowish region in the center of the retina that provides the sharp, straight-ahead vision so critical to reading and driving.

**arthritis:** inflammation of a joint, usually accompanied by pain, swelling, and structural changes.

**osteoarthritis:** a painful, degenerative disease of the joints that occurs when the cartilage in a joint deteriorates; joint structure is damaged, with loss of function; also called *degenerative arthritis.*

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

much of the pain of arthritis in the hands as well, even though they are not weight-bearing joints. Importantly, walking and other weight-bearing exercises do not worsen arthritis. In fact, low-impact aerobic activity and resistance strength training offer improvements in physical performance and pain relief, especially when accompanied by even modest weight loss.[48]

**Rheumatoid Arthritis** Another type of arthritis known as **rheumatoid arthritis** has possible links to diet through the immune system. In rheumatoid arthritis, the immune system mistakenly destroys bone and cartilage as if they were made of foreign tissue.[49]

The omega-3 fatty acids commonly found in fatty fish reduce joint tenderness and improve mobility in some people with rheumatoid arthritis. The same diet recommended for heart health—a Mediterranean-type diet low in saturated fat from meats and milk products and high in vegetables, olive oil, and omega-3 fats from fish—helps prevent or reduce the inflammation in the joints that makes arthritis so painful.

Another possible link between nutrition and rheumatoid arthritis involves the oxidative damage to the membranes within joints that causes inflammation and swelling. The antioxidant vitamins C and E and the carotenoids defend against oxidation, and increased intakes of these nutrients may help prevent or relieve the pain of rheumatoid arthritis.

**Gout** Another form of arthritis, which most commonly affects men, is **gout,** a condition characterized by deposits of uric acid crystals in the joints. Uric acid derives from the breakdown of **purines,** primarily from those made by the body but also from those found in foods. Recommendations to lower uric acid levels and the risk of gout include limiting alcohol and excessive amounts of meat, seafood, and sugar-sweetened beverages.[50] For most people, however, such strategies are insufficient, and drugs are needed to control symptoms.[51]

**Treatment** Treatment for arthritis—dietary or otherwise—may help relieve discomfort and improve mobility, but it does not cure the condition. Traditional medical intervention for arthritis includes medication and surgery. Alternative therapies to treat arthritis abound, but none have proved safe and effective in scientific studies. Popular supplements—glucosamine, chondroitin, or a combination—may relieve pain and improve mobility as well as over-the-counter pain relievers, but mixed reports from studies emphasize the need for additional research.[52]

## The Aging Brain

Dementia affects an estimated 15 percent of adults older than 70 years of age in the United States and represents a financial burden of between $157 billion and $215 billion.[53] The brain, like all of the body's organs, ages in response to both genetic and environmental factors—such as physical activities, intellectual challenges, social interactions, and nutritious diets—that enhance or diminish its amazing capacities.[54] One of the challenges researchers face when studying the human brain is to distinguish among normal age-related physiological changes, changes caused by diseases, and changes that result from cumulative, environmental factors such as diet.

The brain normally changes in some characteristic ways as it ages. For one thing, its blood supply decreases. For another, the number of **neurons,** the brain cells that specialize in transmitting information, diminishes as people age. When the number of neurons in one part of the cerebral cortex diminishes, hearing and speech are affected. Losses of neurons in other parts of the cortex can impair memory and cognitive function. When the number of neurons in the cerebellum diminishes, balance and posture are affected. Losses of neurons in other parts of the brain affect still other functions. Some of the cognitive loss and forgetfulness generally attributed to aging may be due in part to environmental, and therefore controllable, factors—including nutrient deficiencies.

**Nutrient Deficiencies and Brain Function** Nutrients influence the development and activities of the brain. The ability of neurons to synthesize specific neurotransmitters depends in part on the availability of precursor nutrients that are

© rj lerich/Shutterstock.com

Both foods and mental challenges nourish the brain.

**rheumatoid** (ROO-ma-toyd) **arthritis:** a disease of the immune system involving painful inflammation of the joints and related structures.

**gout** (GOWT): a common form of arthritis characterized by deposits of uric acid crystals in the joints.

**purines:** compounds of nitrogen-containing bases such as adenine, guanine, and caffeine. Purines that originate from the body are *endogenous* and those that derive from foods are *exogenous.*

**neurons:** nerve cells; the structural and functional units of the nervous system. Neurons initiate and conduct nerve impulse transmissions.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

obtained from the diet. The neurotransmitter serotonin, for example, derives from the amino acid tryptophan. To function properly, the enzymes involved in neurotransmitter synthesis require vitamins such as vitamin C and pantothenic acid. The B vitamins folate, vitamin $B_6$, and vitamin $B_{12}$ slow brain atrophy and improve cognition and memory.[55] The essential fatty acid DHA counteracts the cognitive decline commonly seen in elderly adults.[56] Thus nutrient deficiencies may contribute to the loss of memory and cognition that some older adults experience. Such losses may be preventable or at least diminished or delayed through diet and exercise. Healthy eating patterns, such as the Mediterranean diet, seem to slow cognitive decline and lower the risk of dementia.[57]

In some instances, the degree of cognitive loss is extensive. Some **senile dementia** may be attributable to a specific disorder such as a brain tumor or Alzheimer's disease.

**senile dementia:** the loss of brain function beyond the normal loss of physical adeptness and memory that occurs with aging.

**Alzheimer's** (AHLZ-high-merz) **disease:** a degenerative disease of the brain involving memory loss and major structural changes in neuron networks; also known as *senile dementia of the Alzheimer's type (SDAT), primary degenerative dementia of senile onset,* or *chronic brain syndrome.*

**senile plaques:** clumps of the protein fragment beta-amyloid on the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

**neurofibrillary tangles:** snarls of the threadlike strands that extend from the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

**Alzheimer's Disease** Much attention has focused on the *abnormal* deterioration of the brain called **Alzheimer's disease,** which affects one out of eight US adults older than age 65 and almost half of adults aged 85 and older.[58] Nerve cells in the brain die, and communication between the cells breaks down. Diagnosis of Alzheimer's disease depends on its characteristic symptoms: the victim gradually loses memory and reasoning, the ability to communicate, physical capabilities, and eventually life itself.[59] Table 17-3 compares the signs of Alzheimer's disease with typical age-related changes.

The primary risk factor for Alzheimer's disease is age, but the exact cause remains uknown.[60] Clearly, genetic factors are involved. Free radicals and oxidative stress also seem to be involved. Nerve cells in the brains of people with Alzheimer's disease show evidence of free-radical attack—damage to DNA, cell membranes, and proteins. They also show evidence of the minerals that trigger free-radical attacks—iron, copper, zinc, and aluminum. Increasing evidence also suggests that obesity in middle age is associated with cognitive decline and dementia in general, and with Alzheimer's disease in particular.[61]

**TABLE 17-3 Signs of Alzheimer's and Typical Age-Related Changes Compared**

| Signs of Alzheimer's | Typical Age-Related Changes |
|---|---|
| Memory loss that disrupts daily life such as asking for the same information repeatedly or asking others to handle tasks of daily living | Forgetting a name or missing an appointment |
| Challenges in planning or solving problems such as following a recipe or paying monthly bills | Missing a monthly payment or making an error when balancing the checkbook |
| Difficulty completing familiar tasks at home such as using the microwave, at work such as preparing a report, or at leisure such as playing a game | Needing help recording a television program |
| Confusion with time or place including current season and location | Not knowing today's date |
| Trouble understanding visual images and spatial relationships such as judging distances and recognizing self in a mirror | Experiencing visual changes due to cataracts |
| New problems with words in speaking or writing such as knowing the name of a common object | Being unable to find the right word to use |
| Misplacing things and losing the ability to retrace steps such as putting the milk in the closet and having no idea when or where the milk was last seen | Misplacing a pair of glasses or the car keys |
| Decreased or poor judgment such as giving large sums of money to strangers | Making a bad decision on occasion |
| Withdrawal from work projects or social activities | Feeling too tired to participate in work, family, or social activities |
| Changes in mood and personality such as confusion, suspicion, depression, and anxiety especially when in unfamiliar places or with unfamiliar people | Becoming irritable when routines are disrupted |

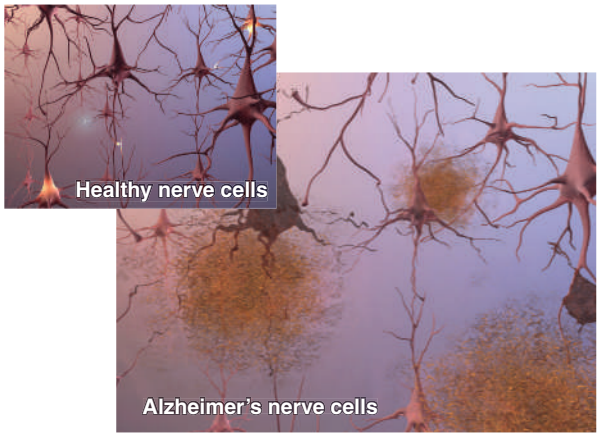
© Cengage Learning



In Alzheimer's disease, the brain develops **senile plaques** and **neurofibrillary tangles** (see Figure 17-4).[62] Senile plaques are clumps of a protein fragment called beta-amyloid, whereas neurofibrillary tangles are snarls of the fibers that extend from the nerve cells. Biochemical markers of beta-amyloid deposits and impaired brain metabolism are apparent decades before the onset of symptoms.[63] Oxidative stress seems to be a contributing factor, but antioxidant supplements do not seem to be effective in preventing the progression of the disease.[64] The accumulation of beta-amyloid seems to be a problem of impaired clearance more than excessive production.[65] Much treatment research focuses on lowering beta-amyloid levels.[66] Interestingly, the fat cell hormone leptin that decreases appetite and increases energy expenditure, also promotes beta-amyloid clearance in animals and lowers the risk of Alzheimer's disease.

Late in the course of the disease there is a decline in the activity of the enzyme that assists in the production of the neurotransmitter acetylcholine from choline and acetyl CoA. Acetylcholine is essential to memory, but supplements of choline (or of lecithin, which contains choline) have

Plaques—clumps of beta-amyloid protein pieces—block cell-to-cell synapse signals. Tangles—twisted strands of protein—destroy the cell transport system. As plaques and tangles block essential nutrients from reaching the nerve cells, they eventually die.

As nerve cells die, the brain shrinks and loses its ability to think, plan, remember, and form new memories. The fluid-filled spaces within the brain grow larger.

no effect on memory or on the progression of the disease. Drugs that inhibit the breakdown of acetylcholine, on the other hand, have proved beneficial.

Research suggests that cardiovascular disease risk factors such as high blood pressure, diabetes, obesity, smoking, and physical inactivity may be related to the development of dementia and Alzheimer's disease.[67] Heart healthy diets that include the omega-3 fatty acid DHA and vitamin E may benefit brain health as well, although supplements may not be beneficial in treating Alzheimer's, given that they are often initiated "too late" in the disease process.[68] Similarly, physical activity supports heart health and slows cognitive decline.[69] Just as saturated fatty acids contribute to heart disease, they also worsen cognition and memory and contribute to Alzheimer's disease.[70]

Treatment for Alzheimer's disease includes providing care to clients and support to their families. Drugs may be used to improve or at least to slow the loss of short-term memory and cognition, but they do not cure the disease. Other drugs may be used to control depression, anxiety, and behavior problems.

Maintaining appropriate body weight may be the most important nutrition concern for the person with Alzheimer's disease. Depression and forgetfulness can lead to changes in eating behaviors and poor food intake. Perhaps the best that a caregiver can do nutritionally for a person with Alzheimer's disease is to supervise food planning and mealtimes. Providing well-liked and well-balanced meals and snacks in a cheerful atmosphere encourages food consumption. To minimize confusion, offer a few ready-to-eat foods, in bite-size pieces, with seasonings and sauces. To avoid mealtime disruptions, control distractions such as music, television, children, and the telephone. One study reported that simply having an aquarium in the dining area increased food intake and helped to maintain body weight, perhaps because it provided a naturally attractive and calming environment.[71]

**Alcohol** Highlight 7 presented information on alcohol metabolism and some of the health consequences of excessive use. Among the consequences of chronic alcohol use are impaired memory and cognition, which can complicate the diagnosis and treatment of age-related dementia.[72]

A variety of tools can be used to diagnose alcohol abuse, but simply asking a question or two can identify hazardous drinking behaviors and potential problems in the elderly.[73] "In the past year, how often did you drink four (for women, and five for men) or more drinks? What is the maximum number of drinks you

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

consumed on any given day?" Such questions help to identify regular heavy use of alcohol and binge drinking.

Although the age group with the most binge drinkers is adults younger than 35, the age group that binge drinks most often is adults 65 and older.[74] Excessive alcohol use among elderly adults is associated with other risk factors as well, including illicit drug use, tobacco use, and misuse of prescription medications—all factors exacerbating overall health, independence, and health-care costs. Fortunately, alcohol-dependent elderly adults seeking treatment seem to experience less intense alcohol cravings during withdrawal therapy than younger adults.[75]

**› REVIEW IT** Identify how nutrition might contribute to, or prevent, the development of age-related problems associated with vision, arthritis, the brain, and alcohol use.

Senile dementia and other losses of brain function, including the impaired memory and cognition of alcohol use, afflict millions of older adults, and others face loss of vision due to cataracts or macular degeneration or cope with the pain of arthritis. As the number of people older than age 65 continues to grow, the need for solutions to these problems becomes urgent. Some problems may be inevitable, but others are, preventable, and good nutrition may play a key role.

## 17.5 Food Choices and Eating Habits of Older Adults

**› LEARN IT** Instruct an adult on how to shop for groceries and prepare healthy meals for one person on a tight budget.

Older people are an incredibly diverse group, and for the most part, they are independent, socially sophisticated, mentally lucid, fully participating members of society who report themselves to be happy and healthy. In fact, the quality of life among the elderly has improved, and their chronic disabilities have declined dramatically in recent years. By practicing stress-management skills, maintaining physical fitness, participating in activities of interest, and cultivating spiritual health, as well as obtaining adequate nourishment, people can support a high quality of life into old age (see Table 17-4 for some strategies).

Compared with other age groups, older people spend more money per person on foods to eat at home and less money on foods away from home. Manufacturers would be wise to cater to the preferences of older adults by providing good-tasting, nutritious foods in easy-to-open, single-serving packages with labels that are easy to read. Such services enable older adults to maintain their independence

**TABLE 17-4 Strategies for Growing Old Healthfully**

- Choose nutrient-dense foods.
- Be physically active. Walk, run, dance, swim, bike, or row for aerobic activity. Lift weights, do calisthenics, or pursue some other activity to tone, firm, and strengthen muscles. Practice balancing on one foot or doing simple movements with your eyes closed. Modify activities to suit changing abilities and preferences.
- Maintain appropriate body weight.
- Reduce stress—cultivate self-esteem, maintain a positive attitude, manage time wisely, know your limits, practice assertiveness, release tension, and take action.
- For women, discuss with a physician the risks and benefits of estrogen replacement therapy.
- For people who smoke, discuss with a physician strategies and programs to help you quit.
- Expect to enjoy sex, and learn new ways of enhancing it.
- Use alcohol only moderately, if at all; use drugs only as prescribed.
- Take care to prevent accidents.
- Expect good vision and hearing throughout life; obtain glasses and hearing aids if necessary.
- Take care of your teeth; obtain dentures if necessary.
- Be alert to confusion as a disease symptom, and seek diagnosis.
- Take medications as prescribed; see a physician before self-prescribing medicines or herbal remedies and a registered dietitian nutritionist before self-prescribing supplements.
- Control depression through activities and friendships; seek professional help if necessary.
- Drink six to eight glasses of water every day.
- Practice mental skills. Keep on solving math problems and crossword puzzles, playing cards or other games, reading, writing, imagining, and creating.
- Make financial plans early to ensure security.
- Accept change. Work at recovering from losses; make new friends.
- Cultivate spiritual health. Cherish personal values. Make life meaningful.
- Go outside for sunshine and fresh air as often as possible.
- Be socially active—play bridge, join an exercise or dance group, take a class, teach a class, eat with friends, volunteer time to help others.
- Stay interested in life—pursue a hobby, spend time with grandchildren, take a trip, read, grow a garden, or go to the movies.
- Enjoy life.

and to feel a sense of control and involvement in their own lives. Another way older adults can take care of themselves is by remaining or becoming physically active. As mentioned earlier, physical activity helps preserve one's ability to perform daily tasks and so promotes independence.

Familiarity, taste, and health beliefs are most influential on older people's food choices. Eating foods that are familiar, especially ethnic foods that recall family meals and pleasant times, can be comforting. Older adults are less likely to diet to lose weight than younger people are, but they are more likely to diet in pursuit of medical goals such as controlling blood glucose and cholesterol.

**Malnutrition** As mentioned, most older adults are adequately nourished, but an estimated one out of six is malnourished. Chronic illnesses, medications, depression, and social isolation can all contribute to malnutrition. Malnutrition limits a person's ability to function and diminishes quality of life by:[76]

- Impairing muscle function
- Decreasing bone mass
- Limiting immune defenses
- Reducing cognitive abilities
- Delaying wound healing
- Slowing recovery from surgery
- Increasing hospitalizations

Healthy snacks or liquid nutrition supplements between meals enhance energy and nutrient intakes, which improves body weight and body composition as well as physical and cognitive functioning.[77]

The Nutrition Screening Initiative is part of a national effort to identify and treat nutrition problems in older adults; it uses a screening checklist to *determine* the risk of malnutrition (see Table 17-5). Providing access to safe, adequate food and nutrition programs and services can help ensure healthful aging.[78]

**Food Assistance Programs** An integral component of the Older Americans Act (OAA) is the OAA Nutrition Program. Its services are designed to improve older people's nutrition status and enable them to avoid medical problems, continue living in communities of their own choice, and stay out of institutions. Its specific goals are to provide low-cost, nutritious meals; opportunities for social interaction; homemaker education and shopping assistance; counseling and referral to social services; and transportation. The program's mission has always been to provide "more than a meal."

The OAA Nutrition Program provides for **congregate meals** at group settings such as community centers. Administrators try to select sites for congregate meals

**TABLE 17-5 Risk Factors for Malnutrition in Older Adults**

| | These questions help *determine* the risk of malnutrition in older adults: |
|---|---|
| **D**isease | • Do you have an illness or condition that changes the types or amounts of foods you eat? |
| **E**ating poorly | • Do you eat fewer than two meals a day? Do you eat fruits, vegetables, and milk products daily? |
| **T**ooth loss or mouth pain | • Is it difficult or painful to eat? |
| **E**conomic hardship | • Do you have enough money to buy the food you need? |
| **R**educed social contact | • Do you eat alone most of the time? |
| **M**ultiple medications | • Do you take three or more different prescribed or over-the-counter medications daily? |
| **I**nvoluntary weight loss or gain | • Have you lost or gained 10 pounds or more in the last 6 months? |
| **N**eeds assistance | • Are you physically able to shop, cook, and feed yourself? |
| **E**lderly person | • Are you older than 80? |

Social interactions at a congregate meal site can be as nourishing as the foods served.

where as many eligible people as possible can participate. Volunteers may also deliver meals to those who are home-bound either permanently or temporarily; these home-delivered meals are known as **Meals on Wheels.** Home-delivered meals help older adults live independently in the community.[79] Although the home-delivery program ensures nutrition, its recipients miss out on the social benefits of the congregate meals. Therefore, every effort is made to persuade older people to come to the shared meals, if they can. All persons aged 60 years and older and their spouses are eligible to receive meals from these programs, regardless of their income. Priority is given to those who are economically and socially needy. An estimated 3 million of our nation's older adults benefit from these meals.

These programs provide at least one meal a day that meets one-third of the RDA for this age group, and they operate five or more days a week. Many programs voluntarily offer additional services designed to appeal to older adults: provisions for special diets (to meet medical needs or religious preferences), food pantries, ethnic meals, and delivery of meals to the homeless. Adding breakfast to the service increases energy and nutrient intakes, which helps to relieve hunger and depression.

Older adults can also take advantage of the Senior Farmers Market Nutrition Program, which provides low-income older adults with coupons that can be exchanged for fresh fruits, vegetables, and herbs at community-supported farmers' markets and roadside stands. This program increases fresh fruit and vegetable consumption, provides nutrition information, and even reaches the home-bound elderly, a group of people who normally do not have access to farmers' markets.

Older adults can learn about the available programs in their communities by contacting the Eldercare section of the Department of Health and Human Services.* In addition, the local senior center and hospital can usually direct people to programs that provide nutrition and other health-related services.

In addition to programs designed specifically for older adults, the Supplemental Nutrition Assistance Program (SNAP) offers services to eligible people of all ages. As mentioned earlier, though, the participation rate for eligible seniors is only about 30 percent.

## Meals for Singles

Many older adults live alone, and singles of all ages face challenges in purchasing, storing, and preparing food. Large packages of meat and vegetables are often intended for families of four or more, and even a head of lettuce can spoil before one person can use it all. Many singles live in small dwellings and have little storage space for foods. A limited income presents additional obstacles. This section offers suggestions that can help to solve some of the problems singles face, beginning with a special note about the dangers of foodborne illnesses.

### Foodborne Illnesses

The risk of older adults getting a foodborne illness is greater than for other adults. The consequences of an upset stomach, diarrhea, fever, vomiting, abdominal cramps, and dehydration are oftentimes more severe, sometimes leading to paralysis, meningitis, or even death. For these reasons, older adults need to carefully follow the food safety suggestions presented in Chapter 19.

**> DIETARY GUIDELINES FOR AMERICANS**

- Older adults should not eat or drink unpasteurized milk, milk products, or juices; raw or undercooked eggs, meat, poultry, fish, or shellfish; or raw sprouts.
- Older adults should eat deli meats and frankfurters only if they have been reheated to steaming hot.

**Meals on Wheels:** a nutrition program that delivers food for the elderly to their homes.

**Spend Wisely** People who have the means to shop and cook for themselves can cut their food bills simply by being wise shoppers. Large supermarkets are usually less expensive than convenience stores. Shopping when not hungry and having a grocery list helps reduce impulse buying, and specials and coupons can save money when the items featured are those that the shopper needs and uses.

Buying the right amount so as not to waste any food is a challenge for people eating alone. They can buy fresh milk in the size best suited for personal needs. Boxes of milk that have been exposed to temperatures above those of pasteurization just long enough to sterilize the milk—a process called *ultrahigh temperature (UHT)*—are available and can be stored unopened on a shelf for as long as 3 months without refrigeration.

Foods in bulk are usually less expensive than packaged items. Staples such as rice, pastas, oatmeal, dry powdered milk, and dried legumes can be purchased in bulk and stored for months at room temperature.

A person who has ample freezer space can buy large packages of meat or whole chickens when they are on sale. Then the meat or chicken can be portioned and immediately wrapped into individual servings for the freezer. All the individual servings can be put in a bag marked appropriately with the contents and the date.

Frozen vegetables are more economical in large bags than in small boxes. After the amount needed is taken out, the bag can be closed tightly with a twist tie or rubber band. If the package is returned quickly to the freezer each time, the vegetables will stay fresh for a long time.

Finally, breads and cereals usually must be purchased in larger quantities. Again the amount needed for a few days can be taken out and the rest stored in the freezer. Consider buying day-old bread and baked goods for added savings.

Grocers will break open a package of wrapped meat and rewrap the portion needed. Similarly, eggs can be purchased by the half-dozen. Eggs do keep for long periods, though, if stored properly in the refrigerator.

Fresh fruits and vegetables generally cost less when they are in season. A person can buy individual pieces of fresh fruit at various stages of ripeness: a ripe one to eat right away, a semiripe one to eat soon after, and a green one to ripen on the windowsill. If vegetables are packaged in large quantities, the grocer can divide the package so that a smaller amount can be purchased. Small cans of fruits and vegetables, even though they are more expensive per unit, are a reasonable alternative, considering that it is expensive to buy a regular-size can and let the unused portion spoil.

**Be Creative** Creative chefs think of various ways to use foods when only large amounts are available. For example, a head of cauliflower can be divided into thirds. Then one-third is cooked and eaten hot. Another third is put into a vinegar and oil marinade for use in a salad. And the last third can be used in a casserole or stew.

A variety of vegetables and meats can be enjoyed stir-fried; inexpensive vegetables such as cabbage, celery, and onion are delicious when sautéed in a little oil with herbs or lemon added. Interesting frozen vegetable mixtures are available in larger grocery stores. Cooked, leftover vegetables can be dropped in at the last minute. A bonus of a stir-fried meal is that there is only one pan to wash. Similarly, a microwave oven allows a chef to use fewer pots and pans. Meals and leftovers can also be frozen or refrigerated in microwavable containers to reheat as needed.

Many frozen dinners offer nutritious options. Adding a fresh salad, a whole-wheat roll, and a glass of milk can make a nutritionally balanced meal.

Finally, single people might want to invite someone to share meals with them whenever there is enough food. It's likely that the person will return the invitation, and both parties will get to enjoy companionship and a meal prepared by others.

Invite guests to share a meal.

**› REVIEW IT** Instruct an adult on how to shop for groceries and prepare healthy meals for one person on a tight budget.

Older people can benefit from both the nutrients provided and the social interaction available at congregate meals. Other government programs deliver meals to those who are home-bound. With creativity and careful shopping, those living alone can prepare nutritious, inexpensive meals.

Healthy meal patterns throughout adulthood support good health and long life. Physical activity, mental challenges, stress management, and social activities can also help people grow old comfortably. The next chapter describes how similar lifestyle choices help prevent chronic diseases as well.

## Nutrition Portfolio

By eating a balanced diet, maintaining a healthy body weight, and engaging in a variety of physical, social, and mental activities, you can enjoy good health in later life. Visit older adults in your community and do the following:

- Consider whether they have the financial means, physical ability, and social support they need to eat adequately.
- Note whether they have experienced an unintentional loss of weight recently.
- Discuss how they occupy their time physically, socially, and mentally.
- Offer to analyze the diet of an older adult who you care about using Diet & Wellness Plus. Have the person write down 1, 2, or even 3 days of their food and beverage intake, and then enter it into the program and print out a 3-day average report of the results. It will be fun and educational to go over it together. Remind the person that you are not a doctor and that this is a learning tool for an introductory nutrition course.

DIET & WELLNESS PLUS

To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com.**

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

## Nutrient-Drug Interactions

David Woods/Flirt/Corbis

**› LEARN IT** Explain why certain nutrients and medications interact.

As people age, their likelihood of taking medicines increases. People older than the age of 65 take about 35 percent of all the over-the-counter drugs and 40 percent of the prescription drugs sold in the United States. They receive an average of 14 to 18 prescriptions a year and may take as many as 6 drugs at a time.[1] Older adults taking five or more medications have high risks of frailty, disability, falls, and mortality.[2] They take a variety of non-vitamin-mineral supplements, such as glucosamine, as well.

Most often, older adults take multiple drugs and supplements for heart disease, but also to treat arthritis, respiratory problems, and gastrointestinal disorders. They often go to different doctors for each condition and receive different prescriptions from each. Furthermore, physiologic changes associated with aging may alter drug metabolism and excretion, which may in turn, diminish drug effectiveness or create potential toxicities. For all these reasons, physicians need to "start low and go slow" when prescribing for older adults.

An estimated 35 percent of all reported adverse drug reactions involve older adults. To avoid harmful drug interactions, consumers need to inform all of their physicians and pharmacists of all the medicines being taken. These medicines enable people of all ages to enjoy better health, but they also bring side effects and risks.

This highlight focuses on some of the nutrition-related consequences of medical drugs, both prescription drugs and over-the-counter drugs. Highlight 7 describes the relationships between nutrition and the drug alcohol, and Highlight 18 presents information on herbal supplements and other alternative therapies.

## The Actions of Drugs

Most people think of drugs either as medicines that help them recover from illnesses or as illegal substances that lead to bodily harm and addiction. Actually, both uses of the term *drug* are correct because any substance that modifies one or more of the body's functions is, technically, a drug. Even medical drugs have both desirable and undesirable consequences within the body.

Consider aspirin. One action of aspirin is to limit the production of certain prostaglandins (biologically active compounds derived from the omega-3 fatty acid EPA). Some prostaglandins help to produce fevers, some sensitize pain receptors, some cause contractions of the uterus, some stimulate digestive tract motility, some control nerve impulses, some regulate blood pressure, some promote blood clotting, and some cause inflammation. By interfering with prostaglandin actions, aspirin reduces fever and inflammation, relieves pain, and slows blood clotting, among other actions.

A person cannot use aspirin to produce one of its effects without producing all of its other effects. Someone who is prone to strokes and heart attacks might take aspirin to prevent blood clotting, but it will also ease that person's sense of pain. Another person who takes aspirin only for pain will also experience slow blood clotting. The anticlotting effect might be dangerous if it causes abnormal bleeding. A single two-tablet dose of aspirin doubles the bleeding time of wounds, an effect that lasts from 4 to 7 hours. For this reason, physicians instruct clients to refrain from taking aspirin before surgery.

## The Interactions between Drugs and Nutrients

Hundreds of drugs and nutrients interact, and these interactions can lead to nutrient imbalances or interfere with drug effectiveness. Adverse nutrient-drug interactions are most likely if drugs are taken over long periods, if several drugs are taken, or if nutrition status is poor or deteriorating. Understandably, then, elderly people with chronic diseases are most vulnerable.

Nutrients and medications may interact in many ways:[3]

- Drugs can alter food intake and the absorption, metabolism, and excretion of nutrients.
- Foods and nutrients can alter the absorption, metabolism, and excretion of drugs.
- Combinations can be toxic.

The following paragraphs describe these interactions, and Table H17-1 (p. 580) summarizes this information and provides specific examples.[4]

### Drugs Alter Food Intake

Some medications can make eating difficult or unpleasant. They may suppress appetite, alter taste sensations, induce nausea or vomiting, cause mouth dryness, or create inflammation or lesions in the mouth, stomach, or intestinal lining. Side effects, such as abdominal discomfort, constipation, and diarrhea may worsen when food is eaten. Medications that cause drowsiness may make a person too tired to eat. All

**TABLE H17-1 Examples of Diet-Drug Interactions**

| |
|---|
| **Drugs May Alter Food Intake by** |
| • Altering the appetite (Amphetamines suppress appetite; corticosteroids increase appetite.) |
| • Interfering with taste or smell (Amphetamines change taste perceptions.) |
| • Inducing nausea or vomiting (Digitalis may do both.) |
| • Interfering with oral function (Some antidepressants may cause dry mouth.) |
| • Causing sores or inflammation in the mouth (Methotrexate may cause painful mouth ulcers.) |
| **Drugs May Alter Nutrient Absorption by** |
| • Changing the acidity of the digestive tract (Antacids may interfere with iron and folate absorption.) |
| • Damaging mucosal cells (Cancer chemotherapy may damage mucosal cells.) |
| • Binding to nutrients (Bile acid binders bind to fat-soluble vitamins.) |
| **Foods and Nutrients May Alter Drug Absorption by** |
| • Stimulating secretion of gastric acid (The antifungal agent ketoconazole is absorbed better with meals due to increased acid secretion.) |
| • Altering rate of gastric emptying (Intestinal absorption of drugs may be delayed when they are taken with food.) |
| • Binding to drugs (Calcium binds to tetracycline, reducing both drug and calcium absorption.) |
| • Competing for absorption sites in the small intestine (Dietary amino acids interfere with levodopa absorption.) |
| **Drugs and Nutrients May Interact and Alter Metabolism by** |
| • Acting as structural analogs (Warfarin and vitamin K are structural analogs.) |
| • Using similar enzyme systems (Phenobarbital induces liver enzymes that increase metabolism of folate, vitamin D, and vitamin K.) |
| • Competing for transport on serum proteins (Fatty acids and drugs may compete for the same sites on the serum protein albumin.) |
| **Drugs May Alter Nutrient Excretion by** |
| • Altering nutrient reabsorption in the kidneys (Some diuretics increase the excretion of sodium and potassium.) |
| • Causing diarrhea or vomiting (Diarrhea and vomiting may cause electrolyte losses.) |
| **Foods May Alter Medication Excretion by** |
| • Inducing activities of liver enzymes that metabolize drugs, increasing drug excretion (Components of charcoal-broiled meats increase metabolism of warfarin, theophylline, and acetominophen.) |
| **Diet and Drug Interactions May Cause Toxicity** |
| • Increasing side effects of the drug (Caffeine in beverages can increase adverse effects of stimulants.) |
| • Increasing drug action to excessive levels (Grapefruit components inhibit the enzymes that degrade certain drugs, increasing drug concentrations in the body.) |

© Cengage Learning

of these complications limit food intake and can lead to weight loss and malnutrition if not resolved.

Some medications stimulate appetite and cause weight gain. Unintentional weight gain may result from the use of some antipsychotics, antidepressants, and corticosteroids (for example, prednisone).[5] People using these drugs do not feel satiated and sometimes gain 40 to 60 pounds in just a few months. For many adults, fear of weight gain is a common reason for avoiding treatment. For patients with diseases that cause wasting, such as cancer or AIDS, weight gain may be desirable. They may be prescribed appetite enhancers, such as megestrol acetate (Megace), a progesterone analog, or dronabinol (Marinol), which is derived from the active ingredient in marijuana.

## Drugs Alter Nutrient Absorption

Nutrient malabsorption is most likely to occur with medications that upset GI function or damage the intestinal mucosa. Antineoplastic and antiretroviral drugs are especially detrimental, although nonsteroidal anti-inflammatory drugs (NSAIDs) and some antibiotics can have similar, though milder, effects.

Some medications bind to nutrients in the GI tract, preventing their absorption. For example, bile acid binders (such as cholestyramine, or Questran), which are used to reduce cholesterol levels, also bind to the fat-soluble vitamins A, D, E, and K. Some antibiotics, notably tetracycline and ciprofloxacin (Cipro), bind to the calcium in foods and supplements, reducing the absorption of both the drug and the calcium. Other minerals, such as iron, magnesium, and zinc, may also bind to antibiotics. For this reason, pharmacists advise consumers to use dairy products and all mineral supplements at least 2 hours apart from these medications.

Medications that reduce stomach acidity may interfere with the absorption of vitamin $B_{12}$, folate, and iron. Examples include antacids, which neutralize stomach acid by acting as weak bases, and antiulcer drugs (such as proton pump inhibitors and H2 blockers), which interfere with acid secretion.

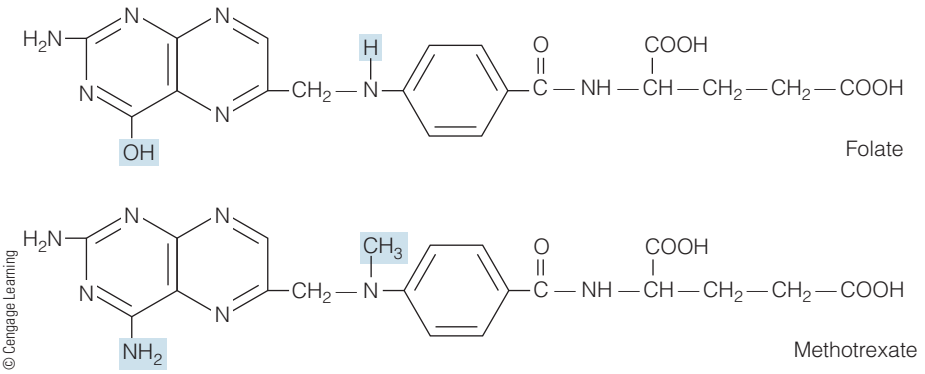
Several drugs impede nutrient absorption by interfering with the intestinal metabolism or transport into mucosal cells. For example, the antibiotics trimethoprim (Proloprim) and pyrimethamine (Daraprim) compete with folate for absorption into intestinal cells. The anti-inflammatory medication colchicine, a treatment for gout, inhibits vitamin $B_{12}$ absorption.

## Diets Alter Drug Absorption

Major influences on drug absorption include the stomach-emptying rate, level of acidity in the stomach, and direct interactions with dietary components. The drug's formulation may also influence its absorption, and pharmacists often provide instructions advising whether food should be eaten or avoided when using a medication.

Drugs reach the small intestine more quickly when the stomach is empty. Therefore, taking a medication with meals may delay its absorption, even though the total amount absorbed may not be lower. As an example, aspirin works faster when taken on an empty stomach, but taking it with food is often encouraged to reduce stomach irritation. Slow stomach emptying can sometimes enhance drug absorption because the drug's absorption sites in the small intestine are less likely to become saturated. A slow drug absorption rate due to slow stomach emptying can be a problem if high drug concentrations are needed for effectiveness, as when a hypnotic is given to induce sleep.

Some drugs are better absorbed in an acidic environment, whereas others are better absorbed in alkaline conditions. For example, reduced stomach acidity (due to disorders or antacid medications) may



Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

reduce the absorption of ketoconazole (Nizoral, an antifungal medication) and atazanavir (an antiretroviral medication), but increase the absorption of digoxin (Lanoxin, which treats heart failure) and alendronate (Fosamax, which treats osteoporosis). Some drugs can be damaged by acid and are available in coated forms that resist the action of the stomach's acidity.

Both nutrients and nonnutrients may bind to drugs and inhibit their absorption. For example, high-fiber meals may decrease the absorption of some tricyclic antidepressants. Conversely, the absorption of many lipophilic drugs is improved when the drugs are taken with a fat-contaning meal.[6] As mentioned earlier, minerals may bind to some antibiotics, reducing absorption of both the minerals and the drugs.

**> FIGURE H17-1 Folate and Methotrexate**

By competing for the enzyme that activates folate, methotrexate prevents cancer cells from obtaining the folate they need to multiply. This interference with folate metabolism creates a secondary deficiency of folate that deprives normal cells of the folate they need as well. Notice the similarities in their chemical structures.

© Cengage Learning

## Drugs Alter Nutrient Metabolism

Drugs and nutrients share similar enzyme systems in the small intestine and the liver. Consequently, some drugs may enhance or inhibit the activities of enzymes that are needed for nutrient metabolism. For example, the anticonvulsants phenobarbital and phenytoin increase levels of the liver enzymes that metabolize folate, vitamin D, and vitamin K; therefore, persons using these drugs may require supplements of these vitamins.

The drug methotrexate, used to treat cancer and some inflammatory conditions, acts by interfering with folate metabolism and thus depriving rapidly dividing cancer cells of the folate they need to multiply. Methotrexate resembles folate in structure (see Figure H17-1) and competes with folate for the enzyme that converts folate to its active form. The adverse effects of using methotrexate therefore include symptoms of folate deficiency. These adverse effects can be reduced by using a pre-activated form of folate (called leucovorin), which is often prescribed along with methotrexate to ensure that the body's rapidly dividing cells (such as cells of the digestive tract, skin cells, and red blood cells) receive adequate folate. Isoniazid, an antibacterial agent used to treat and prevent tuberculosis, inhibits the conversion of vitamin $B_6$ to its coenzyme form (pyridoxal phosphate), which is involved in neurotransmitter synthesis. To prevent the resulting peripheral neuropathy, supplements of vitamin $B_6$ are routinely given during the course of isoniazid treatment.[7]

## Diet Alters Drug Metabolism

Some foods affect the activities of enzymes that metabolize drugs or may counteract the drugs' effects in other ways. For example, compounds in grapefruit and grapefruit juice interfere with enzymes that metabolize a number of drugs. As a result of reduced enzyme action, blood concentrations of the drugs increase, leading to stronger physiological effects. The effect of the grapefruit juice lasts for a substantial period, possibly as long as several days after the juice is consumed; thus, the interaction cannot be avoided by simply separating grapefruit juice consumption from drug usage.[8] Table H17-2 provides examples of drugs that interact with grapefruit juice, as well as some drugs that are not affected.

**TABLE H17-2 Grapefruit Juice–Drug Interactions—Selected Examples**

| Drug Category | Drugs Affected by Grapefruit Juice | Drugs Unaffected by Grapefruit Juice |
|---|---|---|
| **Anticoagulants** | — | Acenocoumarol<br>Warfarin |
| **Anti-diabetic drugs** | Repaglinide<br>Saxagliptin | Glyburide<br>Metformin |
| **Anti-infective drugs** | Erythromycin<br>Saquinavir | Clarithromycin<br>Indinivir |
| **Cardiovascular drugs** | Amiodarone<br>Felodipine<br>Nicardipine | Amlodipine<br>Digoxin<br>Diltiazem |
| **Central nervous system drugs** | Buspirone<br>Carbamazepine<br>Diazepam | Haloperidol<br>Lorazapam<br>Risperidone |
| **Cholesterol-lowering drugs** | Atorvastatin<br>Lovastatin<br>Simvastatin | Fluvastatin<br>Pravastatin<br>Rosuvastatin |
| **Immunosuppressants** | Cyclosporine<br>Tacrolimus | Prednisone |

© Cengage Learning

A number of dietary factors affect the activity of the anticoagulant drug warfarin (Coumadin). One important interaction is with vitamin K, which is structurally similar to warfarin. Warfarin acts by blocking the enzyme that activates vitamin K, thereby preventing the synthesis of blood-clotting factors. The amount of warfarin prescribed is dependent, in part, on how much vitamin K is in the diet. If vitamin K consumption from foods or supplements changes substantially, it can alter the effect of the drug. Individuals using warfarin are advised to consume similar amounts of vitamin K daily to keep warfarin activity stable. The dietary sources highest in vitamin K are dark-green, leafy vegetables.

## Drugs Alter Nutrient Excretion

Drugs that increase urine production may reduce nutrient reabsorption in the kidneys, resulting in greater urinary losses of the nutrients. For example, some diuretics accelerate the losses of calcium, potassium, magnesium, and thiamin; thus, dietary supplements may be needed to avoid deficiency. Risk of mineral depletion is highest if multiple drugs with the same effect are used, if kidney function is impaired, or if medications are used for a long time. Note that some diuretics may cause certain minerals to be retained, rather than excreted.

Corticosteroids, which are used as anti-inflammatory agents and immunosuppressants, promote sodium and water retention and increase urinary potassium excretion.[9] Long-term use of corticosteroids can have multiple adverse effects, which include muscle wasting, bone loss, weight gain, and hyperglycemia, with eventual development of osteoporosis and diabetes.

## Diets Alter Drug Excretion

Inadequate excretion of medications can cause toxicity, whereas excessive losses may reduce the amount available for therapeutic effect. Some food components influence drug excretion by altering the amount of drug reabsorbed by the kidneys. For example, the amount of lithium (a mood stabilizer) reabsorbed by the kidneys correlates with the amount of sodium reabsorbed. Consequently, both dehydration and sodium depletion, which increase sodium reabsorption, may result in lithium retention. Similarly, a person with a high sodium intake will excrete more sodium in the urine, and therefore more lithium. Individuals using lithium are advised to maintain a consistent sodium intake from day to day in order to maintain stable blood concentrations of lithium.

Urine acidity can also affect drug excretion due to the effects of pH on a compound's chemical structure. The medication quinidine, used to treat arrhythmias, is excreted more readily in acidic urine. Foods or drugs that cause urine to become more alkaline may reduce quinidine excretion and raise its blood levels.

## Diet-Drug Toxicities

Some interactions between foods and drugs can cause toxicity or exacerbate a drug's side effects. The combination of tyramine, a compound in some foods, and monoamine oxidase (MAO) inhibitors, which treat depression and Parkinson's disease, can be fatal. MAO inhibitors block an enzyme that normally inactivates tyramine, as well as the hormones epinephrine and norepinephrine. When people who take MAO inhibitors consume excessive tyramine, the increased tyramine in the blood can cause a sudden release of accumulated norepinephrine. This surge in norepinephrine results in severe headaches, rapid heartbeat, and a dangerous increase in blood pressure. For this reason, people taking MAO inhibitors are advised to restrict their intakes of foods rich in tyramine (see Table H17-3). Tyramine occurs naturally in foods and is also formed when bacteria degrade the protein in foods. Thus, the tyramine content of a food usually increases when a food ages or spoils. Individuals at risk of tyramine toxicity are advised to buy mainly fresh foods and consume them promptly.

**TABLE H17-3 Examples of Foods with a High Tyramine Content**

- Aged cheeses (cheddar, Gruyère)
- Aged or cured meats (sausage, salami)
- Beer
- Fermented vegetables (sauerkraut, kimchi)
- Fish or shrimp sauce
- Prepared soy foods (miso, tempeh, tofu)
- Soy sauce
- Yeast extract (Marmite, Vegemite)

NOTE: The tyramine content of foods depends on storage conditions and processing; thus the amounts in similar products can vary substantially.

# The Inactive Ingredients in Drugs

Besides the active ingredients, medicines may contain other substances such as sugar, sorbitol, lactose, and sodium. For most people who use medicines on occasion and in small amounts, such ingredients pose no problem. When medicines are taken regularly or in large doses, however, people on special diets may need to be aware of these additional ingredients and their effects.

## Sugar, Sorbitol, and Lactose

Many liquid preparations contain sugar or sorbitol to make them taste better. For people who must regulate their intakes of carbohydrates, such as people with diabetes, the amount of sugar in these medicines may need to be considered. Large doses of liquids containing sorbitol may cause diarrhea. The lactose added as filler to some medications may cause problems for people who are lactose intolerant.

## Sodium

Antibiotics and antacids often contain sodium. People who take Alka Seltzer, for example, may not realize that a single two-tablet dose may exceed their recommended sodium intake for a whole day. In addition, antacids neutralize stomach acid, and many nutrients depend on acid for their digestion. Taking any antacid regularly will reduce the absorption of many nutrients.

Nutrient interactions and risks are not unique to prescription drugs. People who buy over-the-counter drugs also need to protect themselves. The increasing availability of over-the-counter drugs allows people to treat themselves for many ailments from arthritis to yeast infections. Consumers need to ask their physicians about potential interactions and check with their pharmacists for instructions on taking drugs with foods. If problems arise, they should seek professional care without delay.

## CRITICAL THINKING QUESTIONS

A. What could be done to minimize the risks associated with nutrient-drug interactions?

B. Drug packaging commonly includes an oversized sheet of paper with small writing that includes a description of the many possible side effects, including possible nutrient-drug interactions. Unfortunately, few people take the time to carefully read and follow these instructions. How might you improve patient education and compliance with these instructions?

# Diet and Health

## Nutrition in Your Life

No doubt, you're familiar with the recommendations. Eat more veggies. Eat more fiber. Eat more fish. Put down the saltshaker. Limit saturated fats. Be active. Don't smoke. And don't drink too much alcohol. What's the deal? If you follow this advice, will it really make a difference in how well or how long you live? In a word, yes. You can bet your life on it. If you could grow old in good health without having a heart attack or stroke, or getting diabetes, hypertension, or cancer, wouldn't you be willing to do just about anything—including improving your diet and activity habits? Of course, you would. And you can start today. In the Nutrition Portfolio at the end of this chapter, you can determine your risk factors for chronic diseases and learn how to minimize those risks.

Much of this text has described how good nutrition supports good health. This chapter examines some of the relationships between nutrition and disease—exploring how poor nutrition may promote the progression of diseases and how good nutrition may guard against the development of diseases. The bulk of this chapter focuses on the chronic diseases that pose the greatest threat to the lives of most people in developed countries, but it begins with a description of the immune system and its inflammatory response. As you will see, inflammation underlies the development of many chronic diseases. Chronic diseases develop over a lifetime as a result of metabolic abnormalities induced by such factors as genetics, age, gender, and lifestyle. As you have learned, diet is among the many lifestyle factors that influence the development of chronic diseases.[1]

In their efforts to prevent and treat chronic diseases, many people in the United States turn to complementary and alternative medicine—which includes products such as herbs and practices such as acupuncture. Because complementary and alternative approaches range from useful folk medicine to dangerous frauds, consumers need to become informed about the products and practices they are considering and discuss their decisions with their health care providers. Highlight 18 explores the usefulness and safety of complementary and alternative medicine and its role in improving health care.

### LEARNING GPS

**18.1 Nutrition and Infectious Diseases 586**
**LEARN IT** Identify factors that protect people from the spread of infectious diseases and describe the role of nutrition in immunity.
- The Immune System 586
- Nutrition and Immunity 587
- HIV and AIDS 588
- Inflammation and Chronic Diseases 588

**18.2 Nutrition and Chronic Diseases 589**
**LEARN IT** List the leading nutrition-related causes of death in the United States.

**18.3 Cardiovascular Disease 590**
**LEARN IT** Describe how atherosclerosis develops and strategies to lower blood cholesterol levels.
- How Atherosclerosis Develops 590
- Risk Factors for Coronary Heart Disease 592
- Recommendations for Reducing Cardiovasular Disease Risk 595

**18.4 Hypertension 598**
**LEARN IT** Present strategies to lower blood pressure.
- How Hypertension Develops 598
- Risk Factors for Hypertension 598
- Treatment of Hypertension 598

**18.5 Diabetes Mellitus 600**
**LEARN IT** Compare the dietary strategies to manage type 1 diabetes with those to prevent and treat type 2 diabetes.
- How Diabetes Develops 601
- Complications of Diabetes 602
- Recommendations for Diabetes 604

**18.6 Cancer 605**
**LEARN IT** Differentiate among cancer initiators, promoters, and antipromoters and describe how nutrients or foods might play a role in each category.
- How Cancer Develops 606
- Recommendations for Reducing Cancer Risks 609

**18.7 Recommendations for Chronic Diseases 610**
**LEARN IT** Summarize dietary recommendations to prevent chronic diseases.

**Highlight 18** Complementary and Alternative Medicine 617
**LEARN IT** Present arguments for and against the use of complementary and alternative medicine.

# 18.1 Nutrition and Infectious Diseases

**› LEARN IT** Identify factors that protect people from the spread of infectious diseases and describe the role of nutrition in immunity.

**Infectious diseases** such as smallpox once claimed the lives of many children and limited the average life expectancy of adults. Thanks to medical science's ability to identify disease-causing microorganisms and develop preventive strategies, most people now live well into their later years, and the average life expectancy far exceeds that of our ancestors. In developed nations, purification of water and safe handling of foods help prevent the spread of infection. Antibiotics and immunizations provide additional protection for individuals.[2]

Despite these advances, some infectious diseases still endanger many lives today. Disease strains such as tuberculosis and some foodborne infections, for example, have become resistant to antibiotics, while other diseases such as measles and pertussis, despite vaccine availability, have resurged periodically.[3] Public health strategies help the entire country defend against the spread of infection, and each individual's immune system provides a personal line of defense. A strong immune system depends on adequate nutrition. Poor nutrition weakens the immune system, which increases susceptibility to infections.[4]

## The Immune System

The **immune system** defends the body so diligently that people do not even notice the thousands of enemy attacks mounted against them every day (the accompanying glossary defines immune system terms). If the immune system fails, though, the body suddenly becomes vulnerable to every wayward disease-causing agent that comes its way. Infectious disease invariably follows.

The body's first lines of defense—the skin, mucous membranes, and GI tract—normally deter foreign substances. If these barriers fail, then the organs (spleen, lymph nodes, and thymus) and cells of the immune system race into action. Foreign substances that gain entry into the body and elicit such a response—the **immune response**—are called **antigens.** Examples include bacteria, viruses, toxins, and food proteins that cause allergies.

Of the 100 trillion cells that make up the human body, one in every hundred is a white blood cell. Two types of white blood cells, the phagocytes and lymphocytes, defend the body against infectious diseases.

### Phagocytes: Neutrophils and Macrophages

**Phagocytes,** the scavengers of the immune system, are the first to arrive at the scene if an invader, such as a microorganism, gains entry. Upon recognizing the foreign invader, the phagocyte engulfs and digests it, if possible, in a process called **phagocytosis.** Two types of immune system cells ingest and destroy foreign antigens by phagocytosis: **neutrophils** and **macrophages.** Neutrophils are the most common type of white blood cell and are responsible for much of the body's protection against

**infectious diseases:** diseases caused by bacteria, viruses, parasites, or other microorganisms that can be transmitted from one person to another through air, water, or food; by contact; or through vector organisms such as mosquitoes.

## GLOSSARY OF IMMUNE SYSTEM TERMS

**antibodies:** large proteins of the blood and body fluids, produced by the immune system in response to the invasion of the body by foreign molecules (usually proteins called *antigens*). Antibodies combine with and inactivate the foreign invaders, thus protecting the body.

**antigens:** substances that elicit the formation of antibodies or an inflammation reaction from the immune system. A bacterium, a virus, a toxin, and a protein in food that causes allergy are all examples of antigens.

**B-cells:** lymphocytes that produce antibodies. *B* stands for *bone marrow,* where the B-cells develop and mature.

**cytokines** (SIGH-toe-kines): special proteins that direct immune and inflammatory responses.

**immune response:** the body's reaction to foreign antigens, which neutralizes or eliminates them, thus preventing damage.

**immune system:** the body's natural defense against foreign materials that have penetrated the skin or mucous membranes.

**immunoglobulins** (IM-you-noh-GLOB-you-linz): proteins capable of acting as antibodies.

**lymphocytes** (LIM-foh-sites): white blood cells that participate in acquired immunity; B-cells and T-cells.

**macrophages** (MAK-roe-fay-jez): large phagocytic cells that serve as scavengers of the blood, clearing it of old or abnormal cells, cellular debris, and antigens.

**neutrophils** (NEW-tro-fills): the most common type of white blood cell. Neutrophils destroy antigens by phagocytosis.

**phagocytes** (FAG-oh-sites): white blood cells (neutrophils and macrophages) that have the ability to ingest and destroy foreign substances.

- **phagein** = to eat

**phagocytosis** (FAG-oh-sigh-TOH-sis): the process by which phagocytes engulf and destroy foreign materials.

**T-cells:** lymphocytes that attack antigens. *T* stands for the *thymus gland,* where the T-cells mature.

infection. Macrophages move and kill bacteria more slowly than neutrophils, but they are larger and can engulf larger targets, including the body's dead and damaged cells. Phagocytes also secrete special proteins called **cytokines** that activate the metabolic and immune responses to infection.

**Lymphocytes: B-cells** There are two distinct types of **lymphocytes:** B-cells and T-cells. **B-cells** respond to infection by rapidly dividing and producing large proteins known as **antibodies.** Antibodies travel in the bloodstream to the site of infection. There they stick to the surfaces of antigens and kill or otherwise inactivate them, making them easy for phagocytes to ingest.

The antibodies are members of a class of proteins known as **immunoglobulins**—literally, large globular proteins that provide immunity.Antibodies react selectively to a specific foreign organism, and the B-cells retain a memory of how to make them. Consequently, the immune system can respond with greater speed the next time it encounters the same foreign organism. By doing so, B-cells play a major role in resistance to infection.

**Lymphocytes: T-cells** The **T-cells** travel directly to the invasion site to battle the invaders. T-cells recognize the antigens displayed on the surfaces of phagocyte cells and multiply in response. Then they release powerful cytokines to destroy all the foreign particles that have this antigen on their surfaces. As the T-cells begin to win the battle against infection, they release signals to slow down the immune response.

Unlike the phagocytes, which are capable of inactivating many different types of invaders, T-cells are highly specific. Each T-cell can attack only one type of antigen. This specificity is remarkable, for nature creates millions of antigens. After destroying a particular antigen, some T-cells retain the necessary information to serve as memory cells so that the immune system can rapidly produce the same type of T-cells again if the identical infection recurs.

T-cells actively defend the body against fungi, viruses, parasites, and a few types of bacteria; they can also destroy cancer cells. In organ transplant patients, T-cells participate in the rejection of newly transplanted tissues, which is why physicians prescribe immunosuppressive drugs following such surgery.

Each of the immune system cells plays a key role in fighting infectious disease. The differentiation and multiplication of these cells depends on a full array of nutrients.

## Nutrition and Immunity

The immune system is sensitive to subtle changes in nutrition status. Malnutrition—whether undernutrition or overnutrition—compromises both immune system tissues and immune responses.[5] From day to day, the immune system requires adequate amounts of protein, fat, carbohydrate, vitamins, and minerals to maintain its tissues and mount a response. Immune cells in tissues, lymph, and blood constantly survey their surroundings to detect foreign invaders and destroy those invaders before any symptoms of illness set in. If some of these foreign invaders escape destruction, then the immune system initiates a response. The immune response demands greater amounts of nutrients for the synthesis of antibodies and cytokines, for cell multiplication, for free radical generation, and for the active process of ending the response.[6] Exactly which nutrients are needed in greater quantities, and how much, is not yet fully known, but Table 18-1 (p. 588) lists several nutrients known to play key roles in immunity.

Impaired immunity opens the way for infectious diseases, which typically raise nutrient needs and reduce food intake. Consequently, nutrition status suffers further. Thus disease and malnutrition create a **synergistic** downward spiral that must be broken for recovery to occur.

Quite simply, optimal immunity depends on optimal nutrition—enough, but not too much, of each of the nutrients. People with weakened immune systems, such as the elderly, benefit from a nutritious diet and supplements of selected nutrients.

**synergistic** (SIN-er-JIS-tick): multiple factors operating together in such a way that their combined effects are greater than the sum of their individual effects.

**TABLE 18-1 Selected Nutrients in Immune Function**

The immune system requires all nutrients for optimal functioning. The nutrients listed here have well-known, specific roles in immunity.

| Nutrient | Key Role(s) in Immune Function |
|---|---|
| Protein | Maintains healthy skin and other epithelial tissues (barriers to infection); participates in the synthesis and function of the organs and cells of the immune system and antibody production |
| Omega-3 fatty acids | Help to resolve inflammation when it is no longer needed for the immune response through production of lipid mediators known as resolvins and protectins, which also play a role in enhancing host defense |
| Vitamin A | Maintains healthy skin and other epithelial tissues (barriers to infection); participates in the cell replication and specialization that supports immune-cell and antibody production and the anti-inflammatory response |
| Vitamin D | Regulates immune cell (T-cell) responses; participates in antibody production |
| Vitamins C and E | Protect against oxidative damage |
| Vitamin $B_6$ | Helps maintain an effective immune response; participates in antibody production |
| Vitamin $B_{12}$ and folate | Assist in cell replication and specialization that support immune cell and antibody production |
| Selenium | Protects against oxidative damage |
| Zinc | Helps maintain an effective immune response; participates in antibody production |

© 2016 Cengage Learning

## HIV and AIDS

Perhaps the most well-known infectious disease today is **AIDS (acquired immune deficiency syndrome).** AIDS develops from infection by **HIV (human immunodeficiency virus),** which is transmitted by direct contact with contaminated body fluids, including semen, vaginal secretions, and blood (but not saliva), or by passage of the infection from a mother to her infant during pregnancy, birth, or breastfeeding. HIV attacks the immune system and disables the body's defenses against other diseases. Then these diseases, which would produce only mild, if any, illness in people with healthy immune systems, destroy health and life.

Even though remarkable progress has been made in understanding and treating HIV infection, the disease still has no cure. Without a cure, the best course is prevention. Unlike the chronic diseases featured in the remainder of this chapter, AIDS prevention does not in any way depend on good nutrition. Although good nutrition cannot prevent or cure AIDS, an adequate diet may improve responses to drugs, shorten hospital stays, promote independence, and improve the quality of life.[7] In addition, because common food bacteria can easily overwhelm a compromised immune system, attention to food safety is critical. (Chapter 19 provides food safety strategies.)

## Inflammation and Chronic Diseases

The immune system's response to infection or injury results in inflammation. The blood supply to the infected area increases and the blood vessels become permeable, which allows the white blood cells to rush to the site. As phagocytes engulf the offending microbes, they release oxidative molecules, such as hydrogen peroxide, that kill the microbes. In this acute phase, inflammation fights off the infection or injury, removes damaged tissue, heals wounds, and promotes recovery from external stressors.[8] In this way, acute inflammation and oxidative stress are beneficial.

When the inflammatory process persists, however, chronic inflammation is harmful. Cells of chronically inflamed tissues produce cytokines, oxidative molecules, blood clotting factors, and other bioactive chemicals that sustain the inflammatory response.[9] Chronic inflammation is apparent in obesity, and helps to explain why obesity underlies so many of the chronic diseases discussed in the remainder of this chapter.

**› REVIEW IT** Identify factors that protect people from the spread of infectious diseases and describe the role of nutrition in immunity.

Public health measures such as purification of water and safe handling of food help prevent the spread of infection in developed nations, and immunizations and antibiotics protect individuals. Nevertheless, some infectious diseases still endanger people today. Nutrition cannot prevent or cure infectious diseases, but adequate intakes of all the nutrients can help support the immune system as the body defends against disease-causing agents. If the immune system is impaired because of malnutrition or diseases such as AIDS, a person becomes vulnerable to infectious disease. Inflammation underlies obesity and many chronic diseases.

**AIDS (acquired immune deficiency syndrome):** the late stage of HIV infection, in which severe complications of opportunistic infections and cancers develop.

**HIV (human immunodeficiency virus):** the virus that destroys lymphocytes and impairs immunity, eventually causing AIDS.

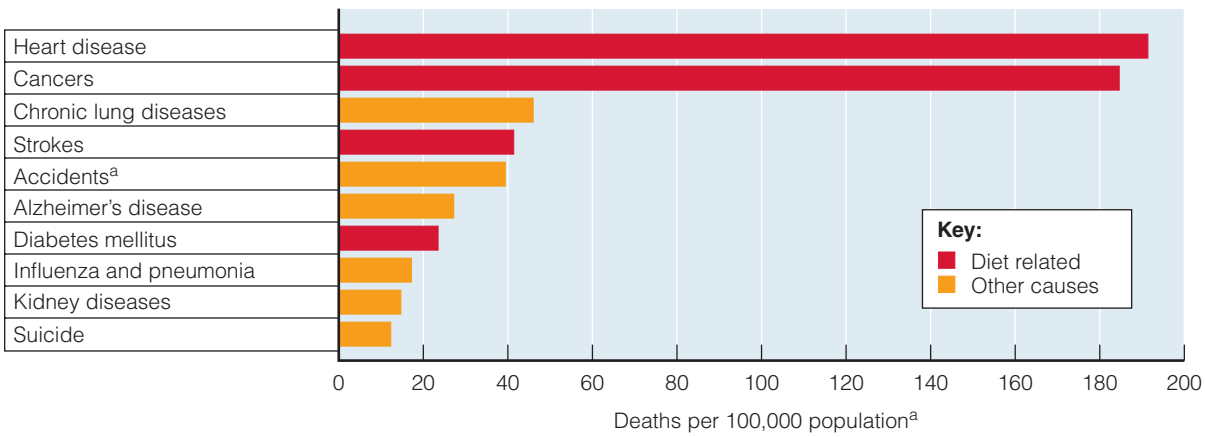
## 18.2 Nutrition and Chronic Diseases

**› LEARN IT** List the leading nutrition-related causes of death in the United States.

Figure 18-1 shows the 10 leading causes of death in the United States.[10] Many of these deaths reflect chronic diseases that developed in response to lifestyle factors such as diet, physical inactivity, overweight, tobacco use, and alcohol and drug abuse. Note that four of these causes of death, including the top two, have some relationship with diet. Taken together, these four conditions account for 60 percent of the nation's more than 2 million deaths each year. Worldwide, statistics are similar, with developing nations sharing many of the same chronic diseases as developed nations.[11]

© 2001 PhotoDisc, Inc.



Vegetables rich in fiber, phytochemicals, and the antioxidant nutrients (beta-carotene, vitamin C, and vitamin E) help to protect against chronic diseases.

This chapter explains how the major chronic diseases develop and summarizes their most important links with nutrition. Earlier chapters that describe the connections between individual nutrients and diseases may have left the mistaken impression of "one disease–one nutrient" relationships. Indeed, valid links do exist between saturated fat and heart disease, calcium and osteoporosis, and antioxidant nutrients and cancer, but focusing only on these links oversimplifies the story. In reality, each nutrient may have connections with several diseases because its role in the body is not specific to a disease but to a body function. Furthermore, each of the chronic diseases develops in response to multiple risk factors, including many nondietary factors such as genetics, physical inactivity, and smoking. This chapter presents an integrated and balanced approach to disease prevention, paying careful attention to all of the factors involved. Table 18-2 (p. 590) presents some of the relationships between risk factors and chronic diseases. Figure 18-2 (p. 590) shows how many of the diseases themselves are risk factors for other chronic diseases. Notice that obesity is a gateway disease that contributes to several other diseases.

All of the diseases listed in Table 18-2 have a genetic component. A family history of a certain disease is a powerful indicator of a person's tendency to contract that disease. Still, lifestyle factors are often pivotal in determining whether that tendency will be expressed.[12] Genetics and lifestyle often work synergistically; for instance, cigarette smoking is especially likely to bring on heart disease in people who

**> FIGURE 18-1 The 10 Leading Causes of Death in the United States**

Many deaths have multiple causes, but diet influences the development of several chronic diseases—notably, heart disease, some cancers, stroke, and diabetes.

NOTE: Rates are age adjusted to allow relative comparisons of mortality among groups and over time.
[a]Motor vehicle and other accidents are the leading cause of death among people aged 15–24, followed by homicide, suicide, cancer, and heart disease. Alcohol contributes to about half of all accident fatalities.

**> FIGURE 18-2 Interrelationships among Chronic Diseases**

Notice that many chronic diseases are themselves risk factors for other chronic diseases and that all of them are linked to obesity. The risk factors highlighted in blue define the metabolic syndrome.

© Cengage Learning

are genetically predisposed to develop it. Not smoking would benefit everyone's health, of course, regardless of genetic predisposition, but some recommendations to prevent chronic diseases best meet an individual's needs when family history is considered. For example, women with a family history of breast cancer might reduce their risks if they abstain from alcohol, whereas those with a family history of heart disease might benefit from one or two glasses of wine a week.

**› REVIEW IT** List the leading nutrition-related causes of death in the United States.

Heart disease and cancers are the two leading causes of death in the United States, and strokes and diabetes also rank among the top 10. All four of these chronic diseases have significant links with nutrition. Other lifestyle risk factors and genetics are also important.

## 18.3 Cardiovascular Disease

**› LEARN IT** Describe how atherosclerosis develops and strategies to lower blood cholesterol levels.

The major causes of death around the world today are diseases of the heart and blood vessels, collectively known as **cardiovascular disease (CVD).** (The accompanying glossary defines this and other heart disease terms.) In the United States, cardiovascular disease claims the lives of more than 800,000 people each year.[13]

**Coronary heart disease (CHD)** is the most common form of cardiovascular disease and is usually caused by **atherosclerosis** in the **coronary arteries** that supply blood to the heart muscle. Atherosclerosis is the accumulation of lipids and other materials in the arteries.

### How Atherosclerosis Develops

As Highlight 16 points out, no one is free of the fatty streaks that may one day become the **plaques** of atherosclerosis.*

*Plaque associated with atherosclerosis is known as *atheromatous* (ATH-er-OH-ma-tus) *plaque.*

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

For most adults, the question is not whether you have plaques, but how advanced they are and what you can do to slow or reverse their progression.

Atherosclerosis or "hardening of the arteries" usually begins with the accumulation of soft fatty streaks along the inner arterial walls, especially at branch points (review Figure H16-1 on p. 549). These fatty streaks gradually enlarge and harden as they fill with cholesterol, other lipids, and calcium, and they become encased in fibrous connective tissue, forming plaques. Plaques stiffen the arteries and narrow the passages through them. Most people have well-developed plaques by the age of 30. As Chapter 5 points out, a diet high in saturated and *trans* fats contributes to the development of plaques and the progression of atherosclerosis.[14] But atherosclerosis is much more than the simple accumulation of lipids within the artery wall—it is a complex inflammatory response to tissue damage. Indeed, extensive evidence confirms that inflammation is centrally involved in all stages of atherosclerosis.[15]

**Inflammation** The cells lining the blood vessels may incur damage from high LDL cholesterol, hypertension, toxins from cigarette smoking, obesity, elevated homocysteine, or some viral and bacterial infections.[16] Such damage increases the permeability of the blood vessel walls and elicits an inflammatory response. The immune system sends in macrophages (the large, phagocytic cells of the immune system mentioned earlier), and the smooth muscle cells of the artery wall try to repair the damage. Particles of LDL cholesterol become trapped in the blood vessel walls. Free radicals produced during inflammatory responses oxidize the LDL cholesterol, and the macrophages engulf it. The macrophages swell with large quantities of oxidized LDL cholesterol and eventually become the cells of plaque. Arterial damage and the inflammatory response also favor the formation of blood clots and allow minerals to harden plaque and form the fibrous connective tissue that encapsulates it.

The inflammatory response of atherosclerosis weakens the walls of the arteries and may cause an **aneurysm**—the abnormal bulging of a blood vessel wall. Aneurysms can rupture and lead to massive bleeding and death, particularly when a large blood vessel such as the aorta is affected. The central role of the inflammatory response in atherosclerosis has led researchers to look for signs or markers of inflammation in the blood vessel walls. One of these markers is a protein known as **C-reactive protein (CRP).** High levels of CRP have proved to more accurately predict future heart attack than high LDL cholesterol, which has a strong relationship with atherosclerosis, as a later section explains.[17] Another important inflammatory marker, **lipoprotein-associated phospholipase A(2)** or

**C-reactive protein (CRP):** a protein released during the acute phase of infection or inflammation that enhances immunity by promoting phagocytosis and activating platelets. Its presence may be used to assess a person's risk of an impending heart attack or stroke.

**lipoprotein-associated phospholipase A(2)** or **(Lp-PLA(2):** a lipoprotein-bound enzyme that generates potent proinflammatory and proatherogenic products such as oxidized free fatty acids and lysophosphatidylcholine. LpPLA(2) is a specific marker of plaque inflammation.

## GLOSSARY OF HEART DISEASE TERMS

**aneurysm** (AN-you-rizm): an abnormal enlargement or bulging of a blood vessel (usually an artery) caused by damage to or weakness in the blood vessel wall.

**angina** (an-JYE-nah or AN-ji-nah): a painful feeling of tightness or pressure in and around the heart, often radiating to the back, neck, and arms; caused by a lack of oxygen to an area of heart muscle.

**atherosclerosis** (ATH-er-oh-scler-OH-sis): a type of artery disease characterized by plaques along the inner walls of the arteries.

**cardiovascular disease (CVD):** diseases of the heart and blood vessels throughout the body.

**CHD risk equivalents:** disorders that raise the risk of heart attacks, strokes, and other complications associated with cardiovascular disease to the same degree as existing CHD. These disorders include symptomatic carotid artery disease, peripheral arterial disease, abdominal aortic aneurysm, and diabetes mellitus.

**coronary arteries:** blood vessels that supply blood to the heart.

**coronary heart disease (CHD):** the damage that occurs when the blood vessels carrying blood to the heart (the *coronary arteries*) become narrow and occluded.

**embolism** (EM-boh-lizm): the obstruction of a blood vessel by an *embolus* (EM-boh-luss), or traveling clot, causing sudden tissue death.

- **embol** = to insert, plug

**heart attack:** sudden tissue death caused by blockages of vessels that feed the heart muscle; also called *myocardial* (my-oh-KAR-dee-al) *infarction* (in-FARK-shun) or *cardiac arrest*.

- **myo** = muscle
- **cardial** = heart
- **infarct** = tissue death

**hypertension:** consistently higher-than-normal blood pressure. Hypertension that develops without an identifiable cause is known as *essential* or *primary hypertension*; hypertension that is caused by a specific disorder such as kidney disease is known as *secondary hypertension*.

**plaques** (PLACKS): the accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue that develops in the artery walls in atherosclerosis.

**prehypertension:** slightly higher than normal blood pressure, but not as high as hypertension (see Table 18-4, p. 593).

**stroke:** an event in which the blood flow to a part of the brain is cut off; also called *cerebrovascular accident (CVA)*.

- **cerebro** = brain
- **vascular** = blood vessels

**thrombosis** (throm-BOH-sis): the formation of a *thrombus* (THROM-bus), or a blood clot, that may obstruct a blood vessel, causing gradual tissue death.

- **thrombo** = clot

**transient ischemic attack (TIA):** a temporary reduction in blood flow to the brain, which causes temporary symptoms that vary depending on the part of the brain affected. Common symptoms include light-headedness, visual disturbances, paralysis, staggering, numbness, and inability to swallow.

**Lp-PLA(2),** appears to be a highly specific marker for plaque inflammation and the formation of plaques that are most susceptible to rupture.[18]

**Plaques** Once plaque has formed, a sudden spasm or surge in blood pressure in an artery can tear away part of its fibrous coat, causing it to rupture. Some plaques are more unstable than others and are therefore more vulnerable to rupture.[19]* Such plaques have a thin fibrous cap, a large lipid core, and an abundance of macrophages—characteristics that undermine plaque stability. Researchers now know that the *composition* of plaques—rather than the *size* of plaques—is a key predictor of plaque rupture and subsequent clot formation. When plaques rupture, the immune system responds to the damage as it would to other tissue injuries.

**Blood Clots** Blood clots form when **platelets** and other factors cover an injured or damaged area. Abnormal blood clotting can trigger life-threatening events. For example, a blood clot may gradually grow large enough to restrict or close off a blood vessel **(thrombosis).** A *coronary thrombosis* blocks blood flow through an artery that feeds the heart muscle. A *cerebral thrombosis* blocks blood flow through an artery that feeds the brain. A clot may also break free from an artery wall and travel through the circulatory system until it lodges in a small artery and suddenly shuts off blood flow to the tissues **(embolism).**

The action of platelets is under the control of certain eicosanoids, known as prostaglandins and thromboxanes, which are made from the 20-carbon omega-6 and omega-3 fatty acids (introduced in Chapter 5). Each eicosanoid plays a specific role in helping to regulate many of the body's activities, including the regulation of blood pressure, blood clot formation, blood vessel contractions, immune response, and nerve impulse transmissions. Sometimes their actions oppose each other.[20] For example, one eicosanoid prevents clot formation, and another promotes it. Similarly, one dilates the blood vessels, and another constricts them. When omega-3 fatty acids are abundant in the diet, they make more of the kinds of eicosanoids that favor heart health.[21] (Table 5-4 on p. 153 includes good sources of omega-3 fatty acids.)

**Blood Pressure** The stress of blood flow along artery walls can cause physical damage to arteries.[22] High blood pressure intensifies the stress of blood flow on arterial tissue, provoking a low-grade inflammatory state that may stimulate plaque formation and progression.[23]

**The Result: Heart Attacks and Strokes** When atherosclerosis in the coronary arteries becomes severe enough to restrict blood flow and deprive the heart muscle of oxygen, CHD develops. The person with CHD often experiences pain and pressure in the area around the heart **(angina).** A **heart attack** occurs when blood flow to the heart is cut off and that area of the heart muscle dies. Restricted blood flow to the brain causes a **transient ischemic attack (TIA)** or **stroke.** Coronary heart disease and strokes are the first and fourth leading causes of death, respectively, for adults in the United States.

## Risk Factors for Coronary Heart Disease

Although atherosclerosis can develop in any blood vessel, the coronary arteries are most often affected, leading to CHD. Table 18-3 lists the major risk factors for CHD. Notice that some risk factors, such as diet and physical activity, are *modifiable,* meaning that they can be changed; others, such as age, gender, and family history are not modifiable. The criteria for defining blood lipids, blood pressure, and obesity in relation to CHD risk are shown in Table 18-4; Table H16-1 on p. 550 presents cholesterol standards for children and adolescents.

By age 20, half of the adults in the United States have at least one major risk factor for CHD, and many have more than one.[24] Public health officials in the

**TABLE 18-3 Risk Factors for CHD**

**Major Risk Factors for CHD (not modifiable)**

- Increasing age
- Male gender
- Family history of premature heart disease

**Major Risk Factors for CHD (modifiable)**

- High blood LDL cholesterol
- Low blood HDL cholesterol
- High blood triglyceride (VLDL) levels
- High blood pressure (hypertension)
- Diabetes
- Obesity (especially abdominal obesity)
- Physical inactivity
- Cigarette smoking
- An "atherogenic" diet (high in saturated fats and low in vegetables, fruits, and whole grains)

NOTE: Risk factors highlighted in yellow have relationships with diet.

**TABLE 18-4 Standards for CHD Risk Factors**

| Risk Factors | Desirable | Borderline | High Risk |
|---|---|---|---|
| Total blood cholesterol (mg/dL) | <200 | 200–239 | ≥240 |
| LDL cholesterol (mg/dL) | <100[a] | 130–159 | 160–189[b] |
| HDL cholesterol (mg/dL) | ≥60 | 59–40 | <40 |
| Triglycerides, fasting (mg/dL) | <150 | 150–199 | 200–499[c] |
| Body mass index (BMI)[d] | 18.5–24.9 | 25–29.9 | ≥30 |
| Blood pressure (systolic and/or diastolic pressure)[e] | <120/<80 | 120–139/80–89[f] | ≥140/≥90[g] |

© Cengage Learning

[a]100–129 mg/dL LDL indicates a near or above optimal level.
[b]≥190 mg/dL LDL indicates a very high risk.
[c]≥500 md/dL triglycerides indicates a very high risk.
[d]Body mass index (BMI) is defined in Chapter 8; BMI standards are found on the inside back cover.
[e]Blood pressure is measured in millimeters of mercury (mm Hg). Blood pressure is measured both when the heart muscle contracts (systolic blood pressure) and when it relaxes (diastolic blood pressure).
[f]These values indicate prehypertension.
[g]These values indicate stage one hypertension; ≥160/≥100 indicates stage two hypertension. Physicians use these classifications to determine medical treatment.

United States recommend screening to identify risk factors in individuals and offer preventive advice for the population.[25] Regular screening and early detection have proved successful: since 1960, both blood cholesterol levels and deaths from cardiovascular disease among US adults have shown a continuous and substantial downward trend.[26] These trends also reflect behavior changes in individuals. As adults grow older, many of them stop smoking, limit alcohol consumption, and become mindful that their food choices can improve their cardiovascular health.

**Age, Gender, and Family History** A review of Table 18-3 shows that three of the major risk factors for CHD cannot be modified by diet or otherwise: age, gender, and family history. As men and women grow older, the risk of CHD rises. The increasing risk of CHD with advancing age reflects the steady progression of atherosclerosis.[27] On average, older people have more atherosclerosis than younger people do.

In men, aging becomes a significant risk factor at age 45 and older. CHD occurs about 10 to 15 years later in women than in men. Women younger than 45 tend to have lower LDL cholesterol than men of the same age, but women's blood cholesterol typically begins to rise between ages 45 and 55. Thus aging becomes a significant risk factor for women who are 55 and older. The gender difference has been attributed to a protective effect of estrogen in women. After menopause, women's risks increase, in part, because low estrogen levels have unfavorable effects on lipoprotein levels and arterial function.[28] As in men, however, heart disease rates increase linearly with age. The speed at which atherosclerosis progresses, however, depends more on the presence or absence of risk factors such as hypertension, high blood cholesterol, diabetes, and smoking than on age alone.[29] Ultimately, CHD kills as many women as men—and kills more women in the United States than any other disease.

Nonetheless, at every age, men have a greater risk of CHD than women do. The reasons for this gender difference are not completely understood, but they can be partly explained by the earlier onset of risk factors such as elevated LDL cholesterol and blood pressure in men. Levels of the amino acid homocysteine, which damages artery walls and increases oxidative stress, rise with age and are generally higher in men. Researchers have not determined whether the damage is caused by homocysteine itself or by an associated factor.[30]

A history of early CHD in immediate family members is an independent risk factor even when other risk factors are considered. The more family members affected and the earlier the age of onset, the greater the risk.[31]

**High LDL and Low HDL Cholesterol** In population studies, the relationship between total blood cholesterol and atherosclerosis is strong—and most of the total

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

cholesterol is made up of LDL cholesterol. The higher the LDL cholesterol, the greater the risk of CHD. In contrast, the lower the LDL cholesterol and blood pressure, the slower the progression of atherosclerosis.[32]

The LDL are clearly the most **atherogenic** lipoproteins. As Chapter 5 explains, HDL also carry cholesterol, but HDL are helpfully returning the cholesterol from the cells to the liver, where it will be used to make bile and excreted in the GI tract. Because HDL remove cholesterol from circulation and contain proteins that inhibit inflammation, LDL oxidation, and plaque accumulation, *low* HDL levels can contribute to the development of atherosclerosis as well.[33] Having adequate levels of HDL is beneficial, but high levels of HDL do not necessarily confer additional benefit.[34]

Any LDL cholesterol that remains in the blood after the body's cells take up the amount they need becomes vulnerable to oxidation. High blood levels of LDL cholesterol, especially oxidized LDL, trigger a series of events that promote plaque formation and contribute to plaque instability.[35] Oxidized LDL cholesterol stimulates production of atherogenic signaling molecules. These signaling molecules attract immune cells and allow them to adhere to, and penetrate, the innermost layer of the arterial wall. Within the arterial wall, these immune cells become macrophages that form the lipid-rich foam cells characteristic of fatty streaks. Macrophages within the arterial wall perpetuate chronic inflammation by releasing inflammatory cytokines that contribute to plaque rupture.[36] When plaques rupture, a heart attack or stroke may occur. In the early stages of atherosclerosis, the goal of treatment is to slow plaque development. In the later stages, the goal of treatment is to stabilize plaques.

LDL vary in size and density, and these LDL subtypes have differing effects on heart disease risk. The smallest, most dense LDL can slip into the artery walls easily and are therefore more atherogenic than the larger, less dense LDL.[37]

**High Blood Triglycerides** High blood triglycerides (found in VLDL) also promote atherosclerosis, either by influencing the production of other atherogenic lipoproteins or by causing molecular changes in endothelial cells and macrophages that promote inflammation and plaque development.[38] About one-third of adults in the United States have high blood triglyceride levels. High blood triglyceride levels are associated with a sedentary lifestyle, overweight and obesity (especially abdominal obesity), and type 2 diabetes.

**High Blood Pressure (Hypertension)** Atherosclerosis is frequently accompanied by chronic high blood pressure (**hypertension**). The higher blood pressure is above normal, the greater the risk of heart disease. However, even values only slightly higher than desirable—classified as **prehypertension** in Table 18-4—increase the risk of heart attack and stroke.[39] This relationship between hypertension and heart disease risk holds true for men and women, young and old. High blood pressure injures the artery walls and accelerates plaque formation, thus initiating or worsening the progression of atherosclerosis. Then the plaques and reduced blood flow raise blood pressure further, and hypertension and atherosclerosis become mutually aggravating conditions.

**Diabetes** Diabetes is a major independent risk factor for cardiovascular disease and substantially increases the risk of death from CHD.[40] In diabetes, blood vessels often become blocked and circulation diminishes. Atherosclerosis progresses rapidly. For many people with diabetes, the risk of heart attack is similar to that for people with CHD. In fact, physicians describe diabetes and other disorders that have risks similar to CHD as **CHD risk equivalents.** Treatment to lower LDL cholesterol in diabetes follows the same recommendations as in CHD.

**Obesity and Physical Inactivity** Obesity, especially abdominal obesity, and physical inactivity significantly increase risk factors for CHD, contributing to high

**atherogenic:** able to initiate or promote atherosclerosis.

LDL cholesterol, low HDL cholesterol, high triglycerides, hypertension, and diabetes.[41] Conversely, weight loss and physical activity protect against CHD by lowering LDL, raising HDL, lowering triglycerides, improving insulin sensitivity, and lowering blood pressure.[42]

**Cigarette Smoking** Cigarette smoking is a powerful risk factor for CHD and other forms of cardiovascular disease.[43] The risk increases the more a person smokes and is the same for men and women. Smoking damages the heart directly by increasing blood pressure and the heart's workload. It deprives the heart of oxygen and damages platelets, making blood clot formation likely. Toxins in cigarette smoke damage blood vessels, setting the stage for atherosclerosis. When people quit smoking, their risk of CHD begins to decline within a few months.

**Atherogenic Diet** Diet also influences the risk of CHD. An "atherogenic" diet—high in saturated fats, *trans* fats, and cholesterol and low in vegetables, fruits, and whole grains—elevates LDL cholesterol. Conversely, eating patterns rich in fruits, vegetables, and whole grains seem to lower the risk of CHD even more than might be expected based on risk factors such as LDL cholesterol alone.[44] A number of beneficial factors share the credit, including vitamins, minerals, fibers, phytochemicals, and omega-3 fatty acids. Research shows that a diet rich in raw vegetables and fruits may protect against CHD even in people who are genetically susceptible to the disease.[45] Dietary and other lifestyle strategies to reduce the risk of CHD are presented in a later section.

**Metabolic Syndrome** As Table 18-3 (p. 592) shows, most of the modifiable risk factors for CHD are directly related to diet. Several of these diet-related risk factors—low HDL, high blood triglycrides, high blood pressure, elevated fasting blood glucose, and abdominal obesity—comprise a cluster of health risks known as **metabolic syndrome.** As Figure 18-2 (p. 590) shows, the risks that define metabolic syndrome underlie several chronic diseases and increase the risks of CHD and type 2 diabetes.[46] Abdominal obesity and **insulin resistance** are both considered primary factors contributing to the metabolic syndrome.[47] Metabolic syndrome, like the chronic diseases associated with it, also includes markers of inflammation and thrombosis.[48] Overeating and physical inactivity play major roles in the development of metabolic syndrome. The prevalence of metabolic syndrome among US adults is high, and treatment to reduce these risk factors for heart disease and diabetes should begin early and focus on changes in lifestyle.

## Recommendations for Reducing Cardiovascular Disease Risk

Recommendations to reduce cardiovascular disease (CVD) risk, including CHD, comprise both screening and intervention. The American Heart Association, together with the American College of Cardiology, developed guidelines for the assessment of CVD risk, the treatment of elevated blood cholesterol, and the management of lifestyle factors that reduce risk.[49]

**Screening for Cardiovascular Disease Risk** The American Heart Association has developed an online calculator and downloadable spreadsheet to estimate risk for CVD.* The risk factors included in the assessment are age, sex, race, total cholesterol, HDL cholesterol, blood pressure, blood pressure medication use, diabetes, and smoking. Once risks have been assessed, the guidelines define when physicians should prescribe the use of cholesterol-lowering medications (statins),

**metabolic syndrome:** a combination of risk factors—elevated fasting blood glucose, hypertension, abnormal blood lipids, and abdominal obesity—that greatly increase a person's risk of developing coronary heart disease; also called *Syndrome X, insulin resistance syndrome,* or *dysmetabolic syndrome.*

**insulin resistance:** the condition in which a normal amount of insulin produces a subnormal effect in muscle, adipose, and liver cells, resulting in an elevated fasting glucose; a metabolic consequence of obesity that precedes type 2 diabetes.

*To calculate your risk for CVD, visit http://my.americanheart.org/cvriskcalculator and http://www.cardiosource.org/science-and-quality/practice-guidelines-and-quality-standards/2013-prevention-guideline-tools.aspx.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**TABLE 18-5 Recommendations and Strategies for Reducing CVD Risk**

| Recommendation | Strategy |
|---|---|
| **Dietary patterns:** Choose a dietary pattern that emphasizes vegetables, fruits, and whole grains; includes low-fat dairy products, poultry, fish, legumes, nontropical vegetable oils, and nuts; and limits intake of sweets, sugar-sweetened beverages, and red meats. | Adopt a heart-healthy eating pattern such as DASH, the USDA Food Pattern, Mediterranean diet, or other well-planned plant-based dietary pattern. |
| **Energy:** Balance energy intake and physical activity to prevent weight gain and to achieve or maintain a healthy body weight. | Engage in at least 30 minutes of moderate-intensity endurance activity or 15 minutes of vigorous-intensity endurance activity on most days of the week. |
| **Saturated fat, *trans* fat, and cholesterol:** Limit saturated fat to less than 10 percent of total kcalories, *trans* fat to less than 1 percent of total kcalories, and cholesterol to less than 300 milligrams a day. For those who have been advised to lower LDL cholesterol or those who have diabetes, limit saturated fat to 5 to 6 percent of total kcalories and cholesterol to less than 200 milligrams a day. | Replace solid fats (saturated and *trans* fats) with food or oils containing unsaturated fatty acids such as omega-3 fatty fish, avocado, nuts, olive oil, canola oil, safflower oil, corn oil, and soybean oil. |
| **Sodium:** Limit sodium intake to 1500 milligrams per day. | Choose and prepare foods with little or no salt. |
| **Alcohol:** If alcohol is consumed, practice moderation. | Limit alcohol intake to no more than one drink daily for women and two drinks daily for men. |
| **Tobacco:** Avoid exposure to any form of tobacco or tobacco smoke. | Do not smoke or use tobacco in any form and avoid exposure to second-hand smoke. |

Dennis Welsh/UpperCut Images/Alamy

Regular aerobic exercise can help to defend against heart disease by strengthening the heart muscle, promoting weight loss, and improving blood lipids and blood pressure.

with cautions to use clinical judgments with each individual.[50] Thus, health care providers are encouraged to discuss options with their patients and to consider personal preferences, possible harms, costs, and inconveniences of taking medications. In this way, the assessment guidelines focus on patient-centered care. In addition to medications, treatment plans include major lifestyle changes in diet, physical activity, and smoking cessation.

**Lifestyle Interventions** To reduce the risk of CVD, people are encouraged to increase physical activity, lose weight (if necessary), implement dietary changes, and reduce exposure to tobacco smoke either by quitting smoking or by avoiding secondhand smoke. Altering one's lifestyle is challenging, and instruction and guidance are critical for success. Health professionals can explain the reasons for change, set obtainable goals, and offer practical suggestions. If lifestyle changes fail to lower LDL or blood pressure to acceptable levels, then medications are prescribed. Table 18-5 summarizes strategies to reduce the risk of heart disease.[51] The "How To" feature on p. 597 offers suggestions for implementing a heart-healthy diet.

**> DIETARY GUIDELINES FOR AMERICANS**

Consume less than 300 milligrams per day of dietary cholesterol. Individuals at high risk of cardiovascular disease should consume less than 200 milligrams of cholesterol daily.

**› REVIEW IT** Describe how atherosclerosis develops and strategies to lower blood cholesterol levels.

Atherosclerosis is characterized by plaque build-up in artery walls. Plaques rupturing or blood clotting can cause heart attacks and strokes. Dietary recommendations to lower the risks of cardiovascular disease are summarized in Table 18-5. Quitting smoking and engaging in regular physical activity also improve heart health.

## >How To

# Implement a Heart-Healthy Diet

Following a heart-healthy diet can require major changes in dietary choices. It helps to make a few changes at a time and to focus on positive choices (what to eat) first, rather than negative ones (what not to eat).

### Grains

- Choose whole-grain breads and cereals that list "whole wheat" as the first ingredient on labels and provide at least 1.1 grams of dietary fiber per 10 grams of carbohydrate.
- Limit foods that list any *trans* fat in the Nutrition Facts panel or "hydrogenated oil" in the ingredients list.
- Limit products that contain tropical oils (coconut, palm, and palm kernel oil), which are high in saturated fat.

### Fruits and Vegetables

- Consume fruits and vegetables frequently. Keep the refrigerator stocked with a variety of colorful fruits and vegetables (carrots, grapes, blueberries, melon).
- Incorporate at least one or two servings of fruits and vegetables into each meal.
- Choose canned products carefully. Canned vegetables (especially tomato-based products) may be high in sodium. Canned fruits may be high in added sugars.
- Limit high-sodium foods such as pickles, olives, sauerkraut, and kimchee.
- Limit french fries from fast-food restaurants, which are often loaded with *trans* fats.

### Lunch and Dinner Entrées

- Limit meat, fish, and poultry servings to 5 ounces per day.
- Include at least two 3-ounce servings of fish rich in omega-3 fatty acids (salmon, mackerel, herring, trout) each week.
- Select lean cuts of beef, such as sirloin tip, round steak, and arm roast, and lean cuts of pork, such as center-cut ham, loin chops, and tenderloin. Trim visible fat before cooking.
- Select extra-lean ground meat and drain well after cooking. Use lean ground turkey, without skin added, in place of ground beef.
- Limit cholesterol-rich organ meats (liver, brain, sweetbreads).
- Limit egg yolks to no more than three per week; replace whole eggs in recipes with egg whites or commercial egg substitutes.
- Include more vegetarian entrées or legume dishes to reduce meat intake and boost vegetable, soluble fiber, and soy protein intakes.
- Restrict these high-sodium foods:
  - Cured or smoked meats such as beef jerky, bologna, corned or chipped beef, frankfurters, ham, luncheon meats, salt pork, and sausage
  - Salty or smoked fish, such as anchovies, caviar, salted or dried cod, herring, sardines, and smoked salmon
  - Packaged, canned, or frozen soups, sauces, and entrées

### Milk Products

- To obtain two to three servings of milk daily, include a portion of fat-free or low-fat milk, yogurt, or cottage cheese in each meal.
- Use yogurt or fat-free sour cream to make dips or salad dressings. Substitute evaporated fat-free milk for heavy cream.
- Limit foods high in saturated fat or sodium, such as cheese, processed cheeses, ice cream, and other milk-based desserts.

### Fats and Oils

- Add nuts (not salted) and avocados to meals to increase monounsaturated fat intakes and make meals more appetizing.
- Include unsaturated vegetable oils such as canola, corn, olive, peanut, saflower, sesame, soybean, and sunflower oils, in salad dressings and recipes.
- Use margarines with added plant sterols or stanols regularly.
- Select soft margarines in tubs or liquid form; limit stick margarines and solid vegetable shortenings.

### Spices and Seasonings

- Use salt only at the end of cooking, and you will need to add much less. Use salt substitutes at the table.
- Spices and herbs improve the flavor of foods without adding sodium. Try using more garlic, ginger, basil, curry or chili powder, cumin, pepper, lemon, mint, oregano, rosemary, and thyme.
- Check the sodium content on labels. Flavorings and sauces that are usually high in sodium include bouillon cubes, soy sauce, steak and barbecue sauces, relishes, mustard, and catsup.

### Snacks and Desserts

- Select low-sodium and low-saturated fat choices such as unsalted pretzels, nuts, popcorn, chips, and crackers.
- Choose canned or dried fruits and some raw vegetables to boost fruit and vegetable intake.
- Enjoy angel food cake, which is made without egg yolks and added fat.
- Select low-fat frozen desserts such as sherbet, sorbet, fruit bars, and some low-fat ice creams.

**› TRY IT** Plan heart-healthy meals for a day and analyze them using your personal profile. Discuss whether these meals meet the strategies listed in Table 18-5 (p. 596) and how to improve any shortcomings.

# 18.4 Hypertension

**› LEARN IT** Present strategies to lower blood pressure.

Anyone concerned about atherosclerosis and the risk it presents must also be concerned about hypertension. Together, the two are a life-threatening combination. The higher the blood pressure is above normal, the greater the risk. Low blood pressure is generally a sign of long life expectancy and low heart disease risk.[52]

Hypertension affects about one out of three adults in the United States.[53] It contributes to an estimated 1 million heart attacks and almost 800,000 strokes each year. People usually do not feel the physical effects of high blood pressure, but it can impair life's quality and end life prematurely.

## How Hypertension Develops

The underlying causes of most cases of hypertension are not fully understood, but much is known about the physiological factors that affect blood pressure. Blood pressure arises from contractions in the heart muscle that pump blood away from the heart (**cardiac output**) and the resistance blood encounters in the arterioles (**peripheral resistance**). When either cardiac output or peripheral resistance increases, blood pressure rises. Cardiac output is raised when heart rate or blood volume increases; peripheral resistance is affected mostly by the diameters of the arterioles. Blood pressure is therefore influenced by the nervous system, which regulates heart muscle contractions and the arteriole's diameters, and hormonal signals, which may cause fluid retention or blood vessel constriction. The kidneys play a key role in regulating blood pressure by controlling the secretion of the hormones involved in vasoconstriction and retention of sodium and water (review Figure 12-3 on p. 376).

## Risk Factors for Hypertension

Several major risk factors predicting the development of hypertension have been identified, including:

- *Aging.* Hypertension risk increases with age. An estimated two-thirds of persons 65 and older have hypertension.[54] Individuals who have normal blood pressure at age 55 still have a 90 percent risk of developing high blood pressure during their lifetimes.
- *Genetics.* Hypertension risk is similar among family members. It is also more prevalent and severe in certain ethnic groups: for African Americans in the United States, the prevalence of high blood pressure is among the highest in the world.[55] Compared with others, African Americans typically develop high blood pressure earlier in life, and their average blood pressure is much higher.
- *Obesity.* Most people with hypertension—an estimated 70 percent—are overweight or obese.[56] Obesity is recognized as a major cause of high blood pressure, and the combination of obesity and hypertension greatly increases the risk for CVD. Obesity raises blood pressure by altering kidney function, increasing blood volume, and promoting blood vessel damage through insulin resistance.[57]
- *Salt intake.* Excess intake of salt plays a major role in hypertension.[58] Reducing salt intake lowers blood pressure in people with or without hypertension, and also diminishes the age-related rise in blood pressure.
- *Alcohol.* Alcohol consumption, especially if consumed regularly in amounts greater than two drinks per day, is strongly associated with hypertension.[59] Alcohol is also associated with strokes independently of hypertension and its use may interfere with medications.

## Treatment of Hypertension

The single most effective step people can take against hypertension is to find out whether they have it. At checkup time, a health-care professional can provide an accurate resting blood pressure reading. Under normal conditions, blood pressure fluctuates continuously in response to a variety of factors, including stress, and such actions as talking or shifting position. Some people react emotionally to the procedure, which raises the blood

**cardiac output:** the volume of blood discharged by the heart each minute; determined by multiplying the stroke volume by the heart rate. The stroke volume is the amount of oxygenated blood the heart ejects toward the tissues at each beat. Cardiac output (volume/minute) = stroke volume (volume/beat) × heart rate (beats/minute).

**peripheral resistance:** the resistance to pumped blood in the small arterial branches (arterioles) that carry blood to the tissues.

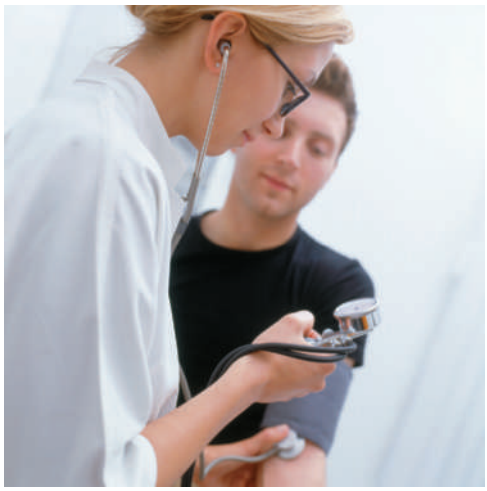
pressure reading. For these reasons, if the resting blood pressure is above normal, the reading should be repeated before confirming the diagnosis of hypertension (see Table 18-4 on p. 593 for blood pressure standards). Thereafter, blood pressure should be checked regularly. Both lifestyle modifications and medications are used to treat hypertension. Recently, new guidelines for initiating medication in the treatment of hypertension in adults have been issued.[60] Table 18-6 describes the lifestyle changes that reduce blood pressure and the expected reduction in systolic blood pressure for each change.

**Weight Control** Efforts to lower blood pressure focus on weight control. Weight loss alone is one of the most effective nondrug treatments for hypertension.[61] Those who are using drugs to control their blood pressure can often reduce or discontinue the drugs when they lose weight. Even a modest weight loss of 5 to 10 percent of body weight can lower blood pressure significantly.



**The DASH Eating Pattern** Results of the Dietary Approaches to Stop Hypertension (DASH) trials show that an eating pattern rich in fruits, vegetables, low-fat milk products, whole grains, and nuts, and low in total fat and saturated fat can significantly lower blood pressure. In addition to lowering blood pressure, DASH lowers total cholesterol and LDL cholesterol, and reduces inflammation.[62] Compared to the typical American diet, DASH provides more fiber, potassium, magnesium, and calcium and less red meat, sweets, and sugar-containing beverages. Table 18-7 (p. 600) shows how DASH compares to the USDA Food Pattern (introduced in Chapter 2). Both eating patterns meet the goals specified in the *Dietary Guidelines for Americans*.[63]

**> DIETARY GUIDELINES FOR AMERICANS**

African Americans and individuals with hypertension should increase their intakes of potassium.

**Salt/Sodium Intake** Strong evidence supports the important role restricting sodium and/or salt plays in preventing and reducing hypertension. Lowering

Kraus/F1online digitale Bildagentur GmbH/Alamy

To guard against hypertension, have your blood pressure checked regularly.

**TABLE 18-6 Lifestyle Modifications to Reduce Blood Pressure**

| Modification | Recommendation | Expected Reduction in Systolic Blood Pressure |
|---|---|---|
| Weight reduction | Maintain healthy body weight (BMI 18.5–24.9). | 10 mm Hg/10 kg lost |
| DASH pattern | Adopt a diet rich in fruits, vegetables, and low-fat milk products to reduce saturated fat intake. | 5–6 mm Hg |
| Sodium restriction | Reduce dietary sodium intake to less than 2300 mg sodium (less than 6 g salt) per day, and further reduce intake to 1500 mg among persons who are 51 and older and those of any age who are African American or have hypertension, diabetes, or chronic kidney disease. | 2–7 mm Hg |
| Physical activity | Perform aerobic physical activity for at least 40 minutes per day, most days of the week. | 2–5 mm Hg |
| Moderate alcohol consumption | Men: Limit to two drinks per day.<br>Women and lighter-weight men: Limit to one drink per day. | 2–4 mm Hg |

sodium intake reduces blood pressure regardless of gender or race, presence or absence of hypertension, or whether people follow the DASH eating pattern or a typical American diet. The combination of DASH with a limited intake of sodium, however, improves blood pressure better than either strategy alone.[64] Furthermore, the lower the sodium intake, the greater the drop in blood pressure. (See the "How To" feature in Chapter 12 on p. 384 for suggestions to limit sodium intake.) Research shows that salt restriction provides additional protection against heart disease, beyond lowering blood pressure.[65]

**> DIETARY GUIDELINES FOR AMERICANS**

Reduce daily sodium intake to less than 2300 milligrams and further reduce intake to 1500 milligrams among persons who are 51 and older and those of any age who are African American or have hypertension, diabetes, or chronic kidney disease.

© stocker1970/Shutterstock.com

Increasing potassium in the diet helps to lower blood pressure and defend against losses caused by some hypertension medicines. The richest sources of potassium are fresh fruits and vegetables of all kinds.

**Physical Activity** The higher the blood pressure and the less active a person is to begin with, the greater the effect physical activity has in reducing blood pressure. Physical activity helps with weight control, of course, but moderate aerobic activity, such as 30 to 60 minutes of brisk walking most days, also helps to lower blood pressure directly.[66] Those who engage in regular aerobic activity may be able to control mild hypertension without medication.

**Medications** When diet and physical activity fail to reduce blood pressure, diuretics and antihypertensive drugs may be prescribed. Diuretics lower blood pressure by increasing fluid loss and lowering blood volume.

Some diuretics can lead to a potassium deficiency. People taking these diuretics need to include rich food sources of potassium or supplements daily and watch for signs of potassium imbalances such as weakness (particularly of the legs), unexplained numbness or tingling sensation, cramps, irregular heartbeats, and excessive thirst and urination. Blood potassium should be monitored regularly. Although some diuretics can lead to a potassium deficiency, others spare potassium. A combination of these two types of diuretics may be prescribed to prevent potassium deficiency.

Most people with hypertension use two or more medications to meet their blood pressure goals. Using a combination of drugs with different modes of action can reduce the doses needed and minimize side effects.

**› REVIEW IT** Present strategies to lower blood pressure.

The most effective dietary strategy for preventing hypertension is weight control. Also beneficial are diets rich in fruits, vegetables, nuts, and low-fat milk products and low in fat, saturated fat, and sodium.

## 18.5 Diabetes Mellitus

**› LEARN IT** Compare the dietary strategies to manage type 1 diabetes with those to prevent and treat type 2 diabetes.

The incidence of diabetes among children and adults has risen dramatically in recent years (see Figure 18-3). An estimated 21 million people in the United States have been diagnosed with diabetes.[67] As many as 86 million adults have **prediabetes**—their blood glucose is elevated but not to such an extent as to be classified as diabetes.[68] People with prediabetes have a high risk of developing diabetes. The glossary on p. 602 defines diabetes terms.

Diabetes ranks seventh among the leading causes of death (review Figure 18-1 on p. 589). In addition, diabetes underlies, or contributes to, several other major diseases, including heart disease, stroke, hypertension, blindness, and kidney failure. Cardiovascular disease is the leading cause of diabetes-related deaths.[69]

## How Diabetes Develops

**Diabetes mellitus** includes several metabolic disorders characterized by high blood glucose concentrations and disturbed insulin metabolism. People with diabetes may have insufficient insulin, ineffective insulin, or a combination of the two. The result is **hyperglycemia,** a marked elevation in blood glucose that can ultimately damage blood vessels, nerves, and tissues.

To appreciate the problems presented by an absolute or relative lack of insulin, consider insulin's normal action. After a meal, insulin signals the body's cells to receive the energy nutrients from the blood—amino acids, glucose, and fatty acids. Insulin helps to maintain blood glucose within normal limits and stimulates protein synthesis, glycogen synthesis in liver and muscle, and fat synthesis. Without insulin, glucose regulation falters, and metabolism of the energy-yielding nutrients changes.

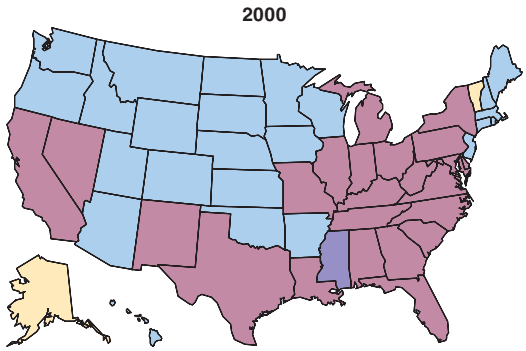
### Diagnosis of Diabetes

Diabetes can be diagnosed by one of several tests, including a **fasting plasma glucose** or a nonfasting **A1C**.[70] A fasting plasma glucose test measures plasma glucose after a person has fasted for at least 8 hours to determine whether current glucose levels are within the normal range (see Table 18-8 on p. 602). The A1C test measures the percentage of a person's hemoglobin that has glucose attached to it. The higher the percentage, the higher a person's blood glucose levels have been over time. Because red blood cells typically live for about 3 months, the A1C test provides a long-term evaluation of glucose control. Table 18-8 includes A1C values.

### Types of Diabetes Mellitus

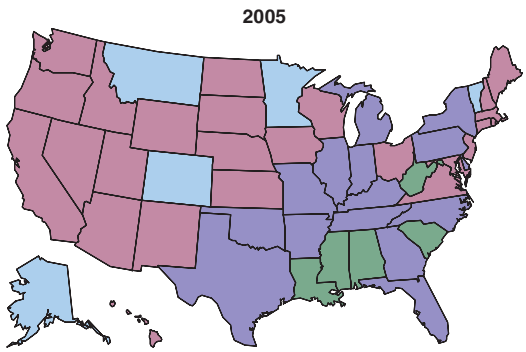
Table 18-9 (p. 602) shows the distinguishing features of the two main forms of diabetes, type 1 diabetes and type 2 diabetes. As the following pages explain, the development of type 1 and type 2 diabetes differs, but some of their complications are similar.

### Type 1 Diabetes



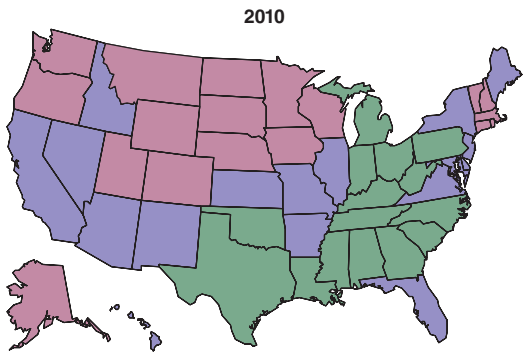
In **type 1 diabetes,** the less common type of diabetes (about 5 to 10 percent of all diagnosed cases), the pancreas loses its ability to synthesize the hormone insulin. Type 1 diabetes is an **autoimmune disorder.** In most cases, the individual inherits a defect in which immune cells mistakenly attack and destroy the insulin-producing beta cells of the pancreas. The rate of beta cell destruction in type 1 diabetes varies. In some people (mainly infants and children), destruction is rapid; in others (mainly adults), it is slow. Type 1 diabetes commonly occurs in childhood and adolescence, but it can occur at any age, even late in life.

Without insulin, the body's energy metabolism changes, with such severe consequences as to threaten survival. The cells must have insulin to take up the needed fuels from the blood. People with type 1 diabetes must receive insulin either by injection or external pumps; insulin cannot be taken orally because it is a protein, and the enzymes of the GI tract would digest it.



### Type 2 Diabetes

**Type 2 diabetes** is the most prevalent form of diabetes, accounting for 90 to 95 percent of cases.[71] The primary defect in type 2 diabetes is insulin resistance, a reduced sensitivity to insulin. Consequently, muscle and adipose cells cannot remove glucose from the blood, and liver cells continue to make glucose. To compensate, the pancreas secretes larger amounts of insulin, and plasma insulin concentrations can rise to abnormally high levels (hyperinsulinemia). Over time, the pancreas becomes less able to compensate for the cells' reduced sensitivity to insulin, and hyperglycemia worsens. The high demand for insulin can eventually exhaust the beta cells of the pancreas and lead to impaired insulin secretion



**> FIGURE 18-3 Prevalence of Diabetes among Adults in the United States**

| <4.5% | 4.5%–5.9% | 6.0%–7.4% | 7.5%–8.9% | ≥9.0% |
|---|---|---|---|---|
| 2 states | 24 states | 23 states | 1 state | 0 states |

| <4.5% | 4.5%–5.9% | 6.0%–7.4% | 7.5%–8.9% | ≥9.0% |
|---|---|---|---|---|
| 0 states | 5 states | 25 states | 15 states | 5 states |

| <4.5% | 4.5%–5.9% | 6.0%–7.4% | 7.5%–8.9% | ≥9.0% |
|---|---|---|---|---|
| 0 states | 0 states | 18 states | 17 states | 15 states |

**hyperglycemia:** elevated blood glucose concentrations.

**fasting plasma glucose:** a test that measures plasma glucose after a person has fasted (no food or kcaloric beverages) for at least 8 hours.

**A1C:** a test that measures the percentage of hemoglobin that has glucose attached, which helps to diagnose diabetes and evaluate long-term glycemic control.

**autoimmune disorder:** a condition in which the body develops antibodies to its own proteins and then proceeds to destroy cells containing these proteins. In type 1 diabetes, the body develops antibodies to its insulin and destroys the pancreatic cells that produce the insulin, creating an insulin deficiency.

**TABLE 18-9 Features of Type 1 and Type 2 Diabetes**

| | Type 1 | Type 2 |
|---|---|---|
| Prevalence in diabetic population | 5–10% of cases | 90–95% of cases |
| Age of onset | <30 years | >40 years[a] |
| Associated conditions | Autoimmune diseases, viral infections, inherited factors | Obesity, aging, inherited factors |
| Major defect | Destruction of pancreatic beta cells; insulin deficiency | Insulin resistance; insulin deficiency (relative to needs) |
| Insulin secretion | Little or none | Varies; may be normal, increased, or decreased |
| Requirement for insulin therapy | Always | Sometimes |
| Older names | Juvenile-onset diabetes<br>Insulin-dependent diabetes mellitus (IDDM) | Adult-onset diabetes<br>Noninsulin-dependent diabetes mellitus (NIDDM) |

[a]Incidence of type 2 diabetes is increasing in children and adolescence; in more than 90 percent of these cases, it is associated with overweight or obesity and a family history of type 2 diabetes.

© Cengage Learning

and reduced plasma insulin concentrations. Type 2 diabetes is therefore associated both with insulin resistance and with relative insulin deficiency; that is, the amount of insulin is insufficient to compensate for its diminished action in cells.

Although the actual causes of type 2 diabetes are unknown, the risk is substantially increased by obesity (especially abdominal obesity), poor dietary habits, smoking, excessive alcohol consumption, aging, and physical inactivity. When people take action to control their lifestyle choices, prevention of type 2 diabetes is not only possible, but likely.[72]

Most people with type 2 diabetes are obese, and obesity itself can directly cause some degree of insulin resistance.[73] As discussed in Highlight 16, obesity has led to a dramatic rise in the incidence of type 2 diabetes among children and adolescents during the past two decades.[74] Inherited factors also strongly influence risk, and type 2 diabetes is more common in certain ethnic populations, including Native Americans, Hispanic Americans, Mexican Americans, African Americans, Asian Americans, and Pacific Islanders.

Inflammation contributes to insulin resistance, and its many links with obesity, metabolic syndrome, and CVD make inflammation central to the development of diabetes as well.[75] Chronic inflammation correlates with increases in blood glucose and decreases in insulin effectiveness.

## Complications of Diabetes

In both types of diabetes, glucose fails to gain entry into the cells and consequently accumulates in the blood. These two problems lead to both acute and chronic complications. Figure 18-4 summarizes the metabolic changes and acute complications that can arise in uncontrolled diabetes. Notice that when some glucose enters the cells, as in type 2 diabetes, many of the symptoms of type 1 diabetes do not occur.

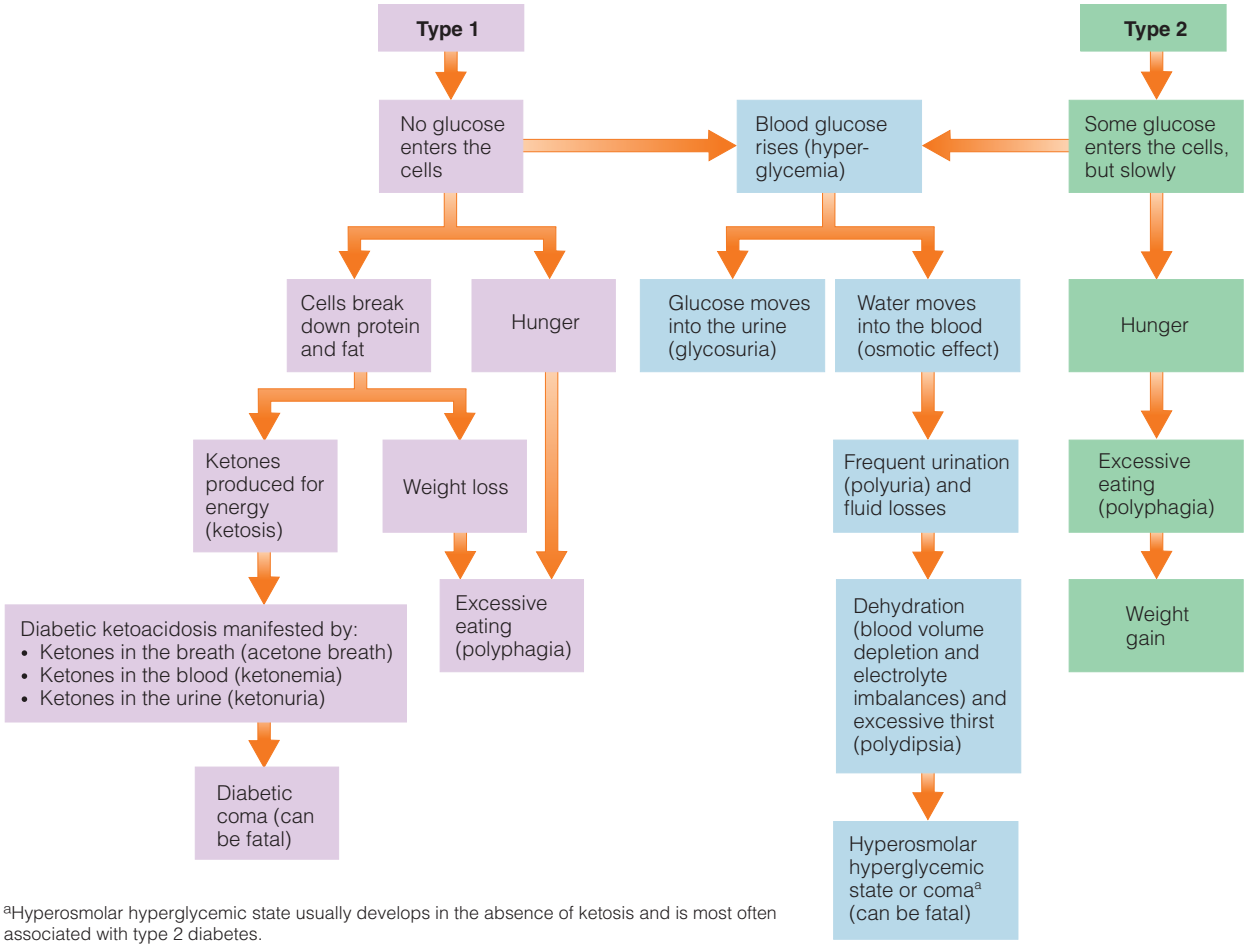
Over the long term, the person with diabetes suffers not only from the acute complications shown in Figure 18-4, but also from its chronic effects. Chronically elevated blood glucose alters glucose metabolism in virtually every cell of the body.

## GLOSSARY OF DIABETES TERMS

**diabetes** (DYE-uh-BEE-teez): metabolic disorder characterized by elevated blood glucose resulting from insufficient insulin, ineffective insulin, or both; the complete medical term is *diabetes mellitus* (meh-LIE-tus).

- **mellitus** = honey-sweet (sugar in urine)

**prediabetes:** condition in which blood glucose levels are higher than normal but below the diagnosis of diabetes; formerly called *impaired glucose tolerance*. Prediabetes is considered a major risk factor for future diabetes and cardiovascular diseases.



**type 1 diabetes:** the less common type of diabetes in which the pancreas produces little or no insulin. Type 1 diabetes usually results from autoimmune destruction of pancreatic beta cells.

**type 2 diabetes:** the more common type of diabetes in which the cells fail to respond to insulin. Type 2 diabetes usually accompanies obesity and results from insulin resistance coupled with insufficient insulin secretion.

## > FIGURE 18-4 Metabolic Consequences of Untreated Diabetes

The metabolic consequences of type 1 diabetes differ from those of type 2. In type 1, no insulin is available to allow any glucose to enter the cells. When glucose cannot enter the cells, a cascade of metabolic changes quickly follows. In type 2 diabetes, some glucose enters the cells. Because the cells are not "starved" for glucose, the body does not shift into the metabolism of fasting (losing weight and producing ketones).

[a]Hyperosmolar hyperglycemic state usually develops in the absence of ketosis and is most often associated with type 2 diabetes.

Some cells begin to convert excess glucose to sugar alcohols, for example, causing toxicity and cell distention—distended cells in the lenses of the eyes, for example, cause blurry vision. Some cells produce glycoproteins by attaching excess glucose to an amino acid in a protein; the altered proteins cannot function normally, which leads to a host of other problems. (Attachment of glucose to the hemoglobin protein is the basis of the A1C test for diabetes diagnosis mentioned earlier.) The structures of the blood vessels and nerves become damaged, leading to loss of circulation and nerve function. Poor circulation coupled with glucose-rich blood and urine readily lead to infections. People with diabetes must pay special attention to hygiene and keep alert for early signs of infection. Early, aggressive treatment to control blood glucose significantly reduces the risk of long-term diabetes-related complications.

**Diseases of the Large Blood Vessels** As mentioned, atherosclerosis tends to develop early, progress rapidly, and be more severe in people with diabetes. The interrelationships among insulin resistance, obesity, hypertension, and atherosclerosis help explain why about 75 percent of people with diabetes die as a consequence of cardiovascular diseases, especially heart attacks. Intensive diabetes treatment that keeps blood glucose levels tightly controlled can reduce the risk of cardiovascular disease among some people with diabetes.[76]* Although intensive therapy is associated

*Intensive treatment may be inappropriate for some individuals with diabetes; examples include individuals with limited life expectancy or a history of hypoglycemia and middle-aged and older adults with previous heart disease or multiple heart disease risk factors.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

with some risks, including an increased risk of abnormally low blood glucose (hypoglycemia), benefits usually outweigh these disadvantages.

**Diseases of the Small Blood Vessels** For people with diabetes, disorders of the small blood vessels (capillaries)—called **microangiopathies**—may also develop and lead to loss of kidney function and retinal degeneration with accompanying loss of vision. Diabetes is the leading cause of both kidney failure and blindness in adults in the United States.[77]

**Diseases of the Nerves** Nerve tissues may also deteriorate with diabetes, expressed at first as a painful prickling sensation, often in the arms and legs. Later, the person may lose sensation in the hands and feet. Injuries to these areas may go unnoticed, and infections can progress rapidly. With loss of both circulation and nerve function, undetected injury and infection may lead to death of tissue (gangrene), necessitating amputation of the limbs (most often the legs or feet). People with diabetes are advised to take conscientious care of their feet and visit a podiatrist regularly.

## Recommendations for Diabetes

Diet is an important component of diabetes treatment. The American Diabetes Association recognizes that a variety of eating patterns—for example, DASH, the Mediterranean diet, and a plant-based diet—are all acceptable for the management of diabetes and can be designed based on personal preferences and metabolic goals.[78] Similarly, the percentage of kcalories from carbohydrate, protein, and fat is flexible and based on an individual's current eating patterns, metabolic goals, and personal preferences. Diabetes is best managed with the help of a registered dietitian nutritionist, who can provide education and support.

**Carbohydrate Intake** To maintain near-normal blood glucose levels, the diet is designed to deliver the same amount of carbohydrate each day, spaced evenly throughout the day. Several approaches can be used to plan such diets, but many people with diabetes learn to count carbohydrates using the exchange system that is presented in Appendix G.

Providing a consistent carbohydrate intake spaced throughout the day helps to maintain appropriate blood glucose levels and maximize the effectiveness of drug therapy. Eating too much carbohydrate at one time can raise blood glucose too high, stressing the already-compromised insulin-producing cells. Eating too little carbohydrate can lead to hypoglycemia. As is true for the general US population, carbohydrate intake from vegetables, fruits, whole grains, legumes, and low-fat or nonfat dairy products is recommended over intake from other carbohydrate sources, especially those that have added fats, sugars, or sodium.[79]

**Carbohydrate Sources** Different carbohydrate-containing foods have varying effects on blood glucose levels; for example, consuming a portion of white rice may cause blood glucose to rise higher and quicker than would a similar portion of barley. As Chapter 4 describes, this *glycemic effect* of foods is influenced by a food's fiber content, the preparation method, the other foods included in a meal, and individual tolerances. For individuals with diabetes, using the glycemic index may provide some additional benefit for achieving glucose control as compared with that obtained by considering only the amount of carbohydrate consumed. In addition, high-fiber, minimally processed foods—which typically have more moderate effects on blood glucose than do highly processed, starchy foods—are among foods frequently recommended for people with diabetes.

Sugar recommendations for people with diabetes are similar to those for the general population, which suggests limiting foods and beverages with added sugars. Of course, sugars and sugary foods must be counted as part of the daily carbohydrate allowance.

**Dietary Fat** People with diabetes are advised to follow the *Dietary Guidelines for Americans* regarding saturated fat, dietary cholesterol, and *trans* fat intake.[80] These recommendations include reducing saturated fat intake to less than 10 percent of kcalories, limiting daily cholesterol intake to less than 300 milligrams, and limiting *trans* fat as much as possible. As is true for the general population, foods rich

**microangiopathies:** disorders of the small blood vessels.
- **micro** = small
- **angeion** = vessel
- **pathos** = disease

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

in omega-3 fatty acids are recommended for those with diabetes because such foods have beneficial effects on lipoproteins and the prevention of heart disease.

**Protein** An ideal protein intake to control blood glucose or to improve CVD risk factors in diabetes has not been determined.[81] Protein intake goals should therefore be individualized. Because dietary protein increases the insulin response, but does not increase blood glucose concentrations, carbohydrates rich in protein should not be used to treat or prevent hypoglycemia.

**Alcohol** Adults with diabetes can drink alcohol in moderation. Guidelines are similar to those for the general population, which advise a daily limit of one drink for women and two drinks for men.

**Recommendations for Type 1 Diabetes** Normally, the body secretes a constant baseline amount of insulin at all times and secretes more as blood glucose rises following meals. People with type 1 diabetes, however, produce little or no insulin. They must learn to adjust the amount and schedule of their insulin doses to accommodate meals, physical activity, and health status. To maintain blood glucose within a fairly normal range requires a lifelong commitment to a carefully coordinated program of diet, physical activity, and insulin.

Nutrition therapy for type 1 diabetes focuses on maintaining optimal nutrition status, controlling blood glucose, achieving a desirable blood lipid profile, controlling blood pressure, and preventing and treating the complications of diabetes. In addition to meeting basic nutrient requirements, the diet must provide a fairly consistent carbohydrate intake from day to day and at each meal and snack to help minimize fluctuations in blood glucose. Further alterations in diet may be necessary for a person with chronic complications such as cardiovascular or kidney disease.

Participation in all levels of physical activity is possible for people with type 1 diabetes who have good blood glucose control and no complications, but they should check with their physician first. One potential problem is hypoglycemia, which can occur during, immediately after, or many hours after physical activity. To avoid hypoglycemia, the person must monitor blood glucose before and after activity to identify when adjustments in insulin or food intake are needed. Carbohydrate-rich foods should be readily available during and after activity to prevent hypoglycemia.

**Recommendations for Type 2 Diabetes** In overweight people with type 2 diabetes, even moderate weight loss (5 to 10 percent of body weight) can help improve insulin resistance, blood lipids, and blood pressure. Together with diet, a regular routine of moderate physical activity not only supports weight loss, but also improves blood glucose control, blood lipid profiles, and blood pressure. Thus the benefits of regular, long-term physical activity for the treatment and prevention of type 2 diabetes are substantial.[82]

**› REVIEW IT** Compare the dietary strategies to manage type 1 diabetes with those to prevent and treat type 2 diabetes.

Diabetes is characterized by high blood glucose and insufficient insulin, ineffective insulin, or a combination of the two. People with type 1 diabetes coordinate diet, insulin, and physical activity to help control their blood glucose. Those with type 2 diabetes benefit most from a diet and physical activity program that controls glucose fluctuations and promotes weight loss.

© Gregg Matthews/The New York Times/Redux

Phil Southerland has raced his bicycle across America and checks his blood glucose regularly. With appropriate diet, regular physical activity, frequent glucose checks, and treatment as needed, people with diabetes can achieve their dreams (www.teamtype1.org).

## 18.6 Cancer

**› LEARN IT** Differentiate among cancer initiators, promoters, and antipromoters and describe how nutrients or foods might play a role in each category.

Cancer, the growth of **malignant** tissue, ranks just below cardiovascular disease as a cause of death in the United States. (See the glossary, p. 606, of cancer terms.) As with cardiovascular disease, the prognosis for cancer today is far brighter than in the past. Identification of risk factors, new detection techniques, and innovative therapies offer hope and encouragement.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## GLOSSARY OF CANCER TERMS

**antipromoters:** factors that oppose the development of cancer.

**cancers:** malignant growths or tumors that result from abnormal and uncontrolled cell division.

**carcinogenesis** (CAR-sin-oh-JEN-eh-sis): the process of cancer development.

**carcinogen** (CAR-sin-oh-jen or car-SIN-oh-jen): a substance that can cause cancer; the adjective is *carcinogenic*.

- **carcin** = cancer
- **gen** = gives rise to

**initiators:** factors that cause mutations that give rise to cancer, such as radiation and carcinogens.

**malignant** (ma-LIG-nant): describes a cancerous cell or tumor, which can injure healthy tissue and spread cancer to other regions of the body.

**metastasize** (me-TAS-tah-size): the spread of cancer from one part of the body to another.

**promoters:** factors that favor the development of cancers once they have begun.

**tumor:** an abnormal tissue mass with no physiological function; also called a *neoplasm* (NEE-oh-plazm).

Cancers are classified by the tissues or cells from which they develop:

*Adenomas* (ADD-eh-NOH-mahz) arise from glandular tissues.

*Carcinomas* (KAR-see-NOH-mahz) arise from epithelial tissues.

*Gliomas* (gly-OH-mahz) arise from glial cells of the central nervous system.

*Leukemias* (loo-KEE-mee-ahz) arise from white blood cell precursors.

*Lymphomas* (lim-FOH-mahz) arise from lymph tissue.

*Melanomas* (MEL-ah-NOH-mahz) arise from pigmented skin cells.

*Sarcomas* (sar-KOH-mahz) arise from connective tissues, such as muscle or bone.

Cancer is not a single disorder. There are many **cancers;** that is, many different kinds of malignant growths. They have different characteristics, occur in different locations in the body, take different courses, and require different treatments.

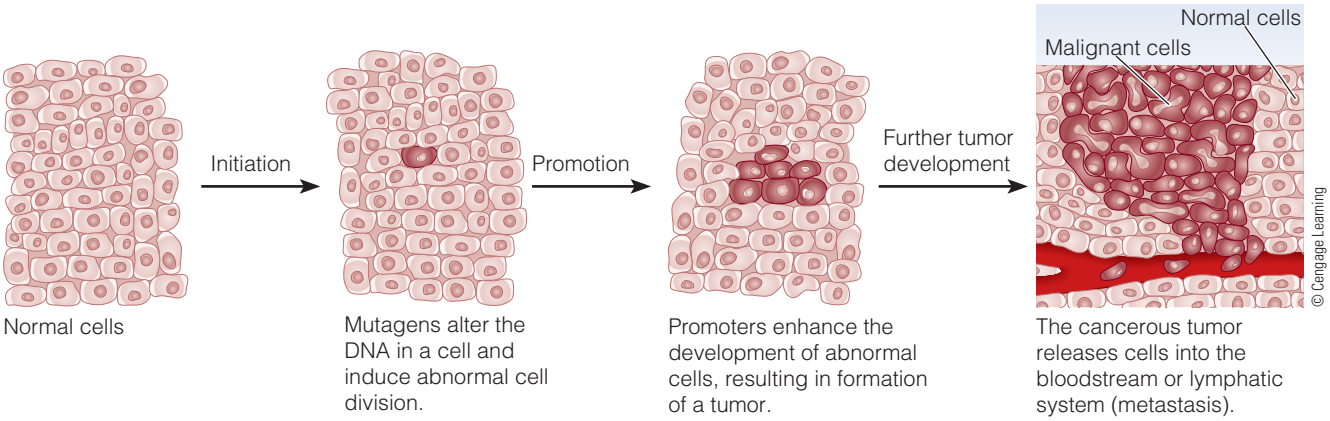
**How Cancer Develops** The development of cancer, called **carcinogenesis,** begins as a single cell that loses control of its normal growth and replication processes. A cancer arises from mutations in the genes that control cell division in a single cell. These mutations may promote cellular replication, interfere with growth restraint, or prevent cellular death.[83] The affected cell thereby loses its built-in capacity for halting cell division, and it produces daughter cells with the same genetic defects. As the abnormal mass of cells, called a **tumor,** grows, a network of blood vessels develops to supply the tumor with the nutrients it needs to support its growth.* The tumor can disrupt the functioning of the normal tissue around it, and some tumor cells may **metastasize** to other regions of the body. Figure 18-5 illustrates cancer development. In leukemia (cancer affecting the white blood cells) the cells do not form a tumor, but rather accumulate in blood and other tissues.

The reasons cancers develop are numerous and varied. Vulnerability to cancer is sometimes inherited, such as when a person is born with a genetic defect that alters DNA structure, function, or repair. A few cancers are linked with microbial infections.[84]** Certain metabolic processes may initiate carcinogenesis, as when phagocytes of the immune system produce oxidants that cause DNA damage or when chronic inflammation enhances the rate of cell division and the risk of a damaging mutation. More often, cancers are caused by interactions between a person's genes and the environment. Exposure to a cancer-causing substance, or **carcinogen,** may either induce genetic mutations that lead to cancer or promote proliferation of cancerous cells.

**Environmental Factors** Among environmental factors, exposure to radiation and sun, water and air pollution, and smoking are known to cause cancer. Lack of physical activity may also play a role in the development of some cancers.[85] Men and women whose lifestyles include regular, vigorous physical activity have the lowest risk of colon cancer, for example.[86] Physical activity may also protect against breast cancer by reducing body weight and by other mechanisms, such as changes in hormone levels and immune functions not related to body weight.[87]

Obesity itself is clearly a risk factor for certain cancers (such as colon, breast in postmenopausal women, endometrial, pancreas, kidney, and esophageal) and possibly for other types (such as gallbladder) as well.[88] Because different cancers have various causes, obesity's influence on cancer development depends on the site as well as other factors such as hormonal interactions. In the case of breast

AP images/Michael Dwyer



People with cancer take comfort from the support of others and from the knowledge that medical science is waging an unrelenting battle in their defense.

*An abnormal mass of cells that is noncancerous is called a *benign* tumor.
**Examples include viral hepatitis and liver cancer, human papillomavirus and cervical cancer, and *Helicobacter pylori* bacterium (the ulcer bacterium) and stomach cancer.

> **FIGURE 18-5 Cancer Development**

cancer in postmenopausal women, for example, the hormone estrogen is implicated. Obese postmenopausal women have much higher levels of estrogen than lean women do because fat tissue produces estrogen. Researchers believe that the extended exposure to estrogen in obese women is linked to the increased risk of breast cancer after menopause.[89] The relationships between excessive body weight and certain cancers provide yet another reason to adopt a lifestyle that embraces physical activity and good nutrition.

As Table 18-10 shows, specific dietary constituents are associated with an increased risk of certain cancers. Some dietary factors may initiate cancer development (**initiators**), others may promote cancer development once it has started (**promoters**), and still others may protect against the development of cancer (**antipromoters**).

**TABLE 18-10 Factors Associated with Cancer at Specific Sites**

| Cancer Sites | Risk Factors | Protective Factors |
|---|---|---|
| Breast (postmenopause) | Alcoholic drinks, body fatness, adult attained height,[a] abdominal fatness, adult weight gain | Lactation, physical activity |
| Breast (premenopause) | Alcoholic drinks, adult attained height,[a] greater birth weight | Lactation, body fatness |
| Colon and rectum | Red meat, processed meat, alcoholic drinks, body fatness, abdominal fatness, adult attained height[a] | Physical activity, foods containing dietary fiber, garlic, milk, calcium |
| Endometrium | Body fatness, abdominal fatness | Physical activity |
| Esophagus | Alcoholic drinks, body fatness, maté[b] | Nonstarchy vegetables, fruits, foods containing beta-carotene, foods containing vitamin C |
| Gallbladder | Body fatness | |
| Kidney | Body fatness | |
| Liver | Aflatoxins,[c] alcoholic drinks | |
| Lung | Arsenic in drinking water, beta-carotene supplements[d] | Fruits, foods containing carotenoids |
| Mouth, pharynx, and larynx | Alcoholic drinks | Nonstarchy vegetables, fruits, foods containing carotenoids |
| Nasopharynx | Cantonese-style salted fish | |
| Ovary | Adult attained height[a] | |
| Pancreas | Body fatness, abdominal fatness, adult attained height[a] | Foods containing folate |
| Prostate | Diets high in calcium | Foods containing lycopene, foods containing selenium, selenium[e] |
| Skin | Arsenic in drinking water | |
| Stomach | Salt, salty and salted foods | Nonstarchy vegetables, allium vegetables,[f] fruits |

[a]Adult attained height is unlikely to directly modify the risk of cancer. It is a marker for genetic, environmental, hormonal, and also nutritional factors affecting growth during the period from preconception to completion of linear growth.
[b]As drunk traditionally in parts of South America, scalding hot through a metal straw. Any increased risk of cancer is judged to be caused by epithelial damage resulting from the heat, and not by the herb itself.
[c]Aflatoxins are toxins produced by molds or fungi. The main foods that may be contaminated are all types of grains (wheat, rye, rice, corn, barley, oats) and legumes, notably peanuts.
[d]The evidence is derived from studies using high-dose supplements (20 mg/day for beta-carotene; 25,000 IU/day for retinol) in smokers.
[e]The evidence is derived from studies using supplements at a dose of 200 µg/day. Selenium is toxic at higher doses.
[f]This includes vegetables such as garlic, onions, leeks, and shallots.
NOTE: Strength of evidence for all these factors is either "convincing" or "probable."

**Dietary Factors—Cancer Initiators** Some experts estimate that diet may be linked to as many as one-third of all cancer cases.[90] Consequently, many people think that certain foods are carcinogenic, especially those that contain additives or pesticides. As Chapter 19 explains, our food supply is one of the safest in the world. Additives that have been approved for use in foods are not carcinogens. Some pesticides are carcinogenic at high doses, but not at the concentrations commonly found on fruits and vegetables. The benefits of eating fruits and vegetables are far greater than the current risks.

Cancers of the head and neck correlate strongly with the combination of alcohol and tobacco use and with low intakes of fruits and vegetables. Alcohol intake alone is associated with cancers of the mouth, throat, and breast, and alcoholism often damages the liver and precedes the development of liver cancer.[91] These findings illustrate clearly why any potential benefit of moderate alcohol consumption on cardiovascular disease must be weighed against the potential dangers.

Cooking meats at high temperatures (frying, broiling) causes amino acids and creatine in the meats to react together and form carcinogens.* Grilling meat, fish, or other foods over a direct flame causes fat and added oils to splash on the fire, creating carcinogens that vaporize onto the food.** Eating grilled food introduces these carcinogens to the digestive system, where they may damage the stomach and intestinal lining. Once these compounds are absorbed into the blood, however, they are detoxified by the liver. To minimize carcinogen formation when grilling, line the grill with foil or wrap the food in foil, take care not to burn foods, and marinate meats beforehand.

Evidence from population studies spanning the globe for more than 30 years strongly suggests that diets high in red meat and processed meat (meat preserved by smoking, curing, or salting, or by the addition of preservatives) are a cause of colon cancer.[92] Based on such evidence, replacing most servings of red meat with poultry, fish, or legumes and choosing only occasional servings of grilled, fried, blackened, or smoked foods is in the best interest of health.

Another reason to moderate consumption of fried foods such as french fries and potato chips is the presence of acrylamide, a potential carcinogen. Acrylamide is produced when certain starches such as potatoes are fried or baked at high temperatures. In the body, some acrylamide is metabolized to a substance that may mutate or damage genetic materal. As such, acrylamide is classified as "reasonably anticipated to be a human carcinogen."[93] Chapter 19 also discusses acrylamide in foods.

**Dietary Factors—Cancer Promoters** Unlike carcinogens, which initiate cancers, some dietary components promote cancers. That is, once the initiating step has taken place, these components may accelerate cancer development.

Although studies of animals suggest that high-fat diets may promote cancer, studies of human beings have not proved that the effects of fat are independent of the effects of energy intake and physical inactivity. Overall, the evidence associating fats and oils with cancer risk is limited.[94]

The type of fat in the diet, however, may influence cancer promotion or prevention. Studies of colon cancer implicate animal fats but not vegetable fat, and although a number of studies suggest that omega-3 fatty acids from fish may protect against some cancers, other studies do not support such findings.[95] Researchers note that factors such as total fat intake, the ratio of dietary omega-3 fatty acids to omega-6 fatty acids, an individual's genetic risk of cancer, body fatness, and gender, as well as the specific cancer studied, may all influence the relationship between omega-3 fatty acids and cancer. Such findings underscore the importance of consulting with a health care provider before taking fish oil or other supplements to prevent disease.

**Dietary Factors—Antipromoters** Some foods may contain antipromoters—dietary compounds that defend against cancer. Table 18-10 (p. 607) includes these protective dietary factors. Research on dietary patterns of populations has led to recommendations aimed at reducing cancer risks.

*These carcinogens are *heterocyclic amines*.
**These carcinogens are *polycyclic aromatic hydrocarbons*.

## Recommendations for Reducing Cancer Risks

A diet rich in fruits and vegetables may provide protection against the development of some cancers.[96] Fruits and vegetables contain both nutrients and phytochemicals with antioxidant activity, and antioxidants may prevent or reduce the oxidative reactions in cells that damage DNA. Phytochemicals may also enhance immune functions that protect against cancer development and promote enzyme reactions that inactivate carcinogens. The nutrients and phytochemicals in fruits and vegetables may also reduce the risk of some cancers by way of epigenetic actions such as DNA methylation and gene silencing.[97] For example, the **cruciferous vegetables**—cabbage, cauliflower, broccoli, and brussels sprouts—contain a variety of phytochemicals that defend against certain cancers. Further knowledge and understanding of the roles and interactions among environmental, genetic, and epigenetic factors will help to explain cancer development, predict a person's susceptibility, and provide specific treatment recommendations.

Fruits and vegetables, as well as legumes and whole grains, are rich in fiber. As Chapter 4 explains, fiber may protect against cancer by binding, diluting, and rapidly removing potential carcinogens from the GI tract. High-fiber and whole-grain foods also help a person to maintain a healthy body weight—another preventive measure against cancer. Physical activity also helps maintain a healthy body weight and reduce the risk of some cancers. Table 18-11 summarizes dietary and lifestyle recommendations for reducing cancer risk.

**› REVIEW IT** Differentiate among cancer initiators, promoters, and antipromoters and describe how nutrients or foods might play a role in each category.

Some dietary factors, such as alcohol and heavily smoked foods, may initiate cancer development; others, such as animal fats, may promote cancer once it has gotten started; and still others, such as fiber, antioxidant nutrients, and phytochemicals, may act as antipromoters that protect against the development of cancer. By eating many fruits, vegetables, legumes, and whole grains and reducing saturated fat intake, people obtain the best possible nutrition at the lowest possible risk. Minimizing weight gain through regular physical activity and a healthy diet is also beneficial.

© Polara Studios, Inc.

Cruciferous vegetables, such as cauliflower, broccoli, and brussels sprouts, contain nutrients and phytochemicals that may inhibit cancer development.

**cruciferous vegetables:** vegetables of the cabbage family, including cauliflower, broccoli, and brussels sprouts.

**TABLE 18-11 Recommendations and Strategies for Reducing Cancer Risk**

| Recommendation | Strategy |
|---|---|
| **Body fatness:** Achieve and maintain a healthy body weight throughout life. | Follow the USDA food pattern for your appropriate energy level. |
| | Engage in regular physical activity. |
| | Limit consumption of energy-dense foods and avoid beverages with added sugars. |
| | Consume "fast foods" sparingly, if at all. |
| **Physical activity:** Adopt a physically active lifestyle. | Engage in at least 150 minutes of moderate-intensity physical activity or 75 minutes of vigorous-intensity activity or an equivalent combination throughout the week. |
| | Limit sedentary behaviors such as sitting, lying down, watching television, or other forms of screen-based recreation. |
| **Plant foods:** Consume a healthy diet with an emphasis on plant foods. | Eat at least the daily amounts of vegetables and fruits recommended by the USDA food patterns. |
| | Choose whole grains instead of refined grain products. |
| | Limit intake of red meat. |
| | Limit refined starchy foods. |
| **Alcoholic drinks:** If you drink alcoholic beverages, limit consumption. | Drink no more than two drinks a day for men and one drink a day for women. |
| **Preservation, processing, preparation:** Limit consumption of salt-cured foods and processed meats. | Avoid salt-preserved, salted, or salty foods. |
| | Limit consumption of processed foods with added salt to ensure an intake of less than 6 grams of salt (2.4 grams of sodium) a day. |
| | Avoid processed meats. |
| **Dietary supplements:** Aim to meet nutritional needs through diet. | Dietary supplements are not recommended for cancer prevention. |

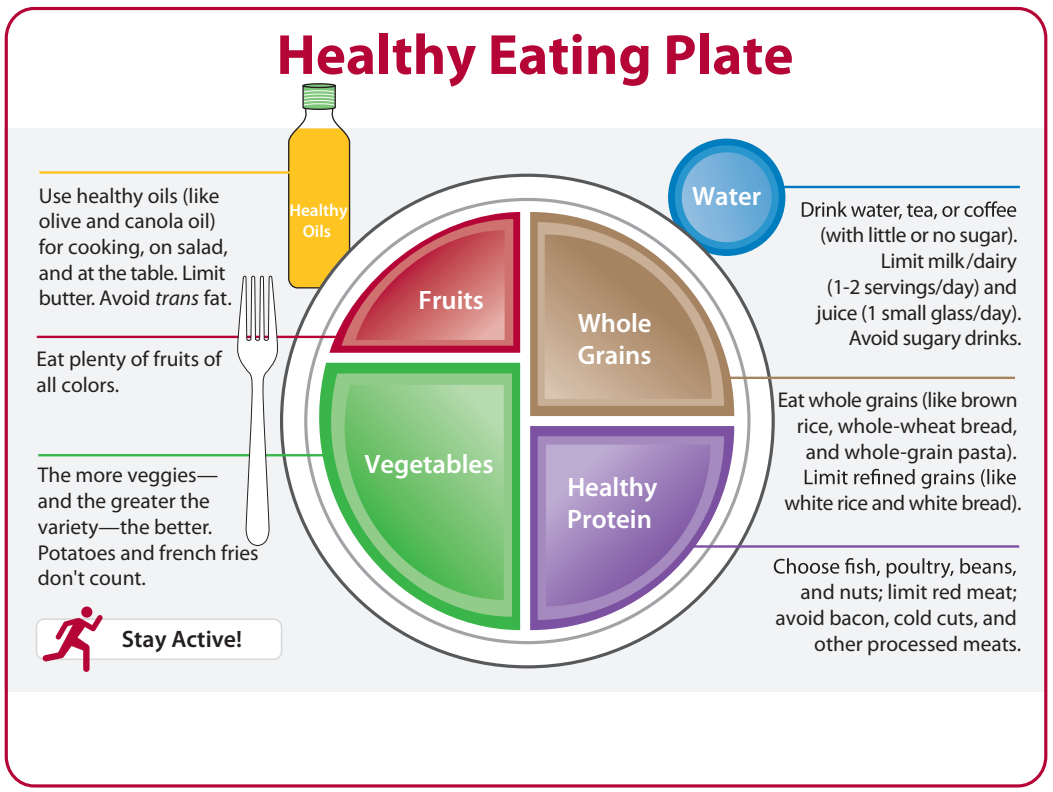
# 18.7 Recommendations for Chronic Diseases

**› LEARN IT** Summarize dietary recommendations to prevent chronic diseases.

This chapter's discussion of chronic diseases described cardiovascular diseases, hypertension, diabetes, and cancer—four different conditions with distinct sets of causes. Yet dietary excesses, particularly excess food energy and saturated fat intakes, increase the likelihood of all of them.[98] Similarly, all are responsive to diet, and in most cases, the beneficial foods are similar.

Not all diet recommendations apply equally to all of the diseases or to all people with a particular disease, but fortunately for the consumer, dietary recommendations do not contradict one another. In fact, they support one another. Most people can gain some disease-prevention benefits by making dietary changes. To that end, the recommendations presented earlier for reducing the risks of heart disease (Table 18-5, p. 596), hypertension (Table 18-6, p. 599), and cancer (Table 18-11, p. 609) describe the kinds of foods people should include or limit. Table 18-12 compares the *Dietary Guidelines for Americans* with all these recommendations for chronic diseases. (A summary of the *Diet, Nutrition, and Prevention of Chronic Diseases* report from the World Health Organization is presented in Appendix I.)

Several recommendations are aimed at weight control. Obesity is common in the United States, and it is linked with most of the chronic diseases that threaten life (review Figure 18-2 on p. 590).[99] The problems of obesity multiply when medical conditions develop. For example, obese people readily develop diabetes, which is often accompanied by high blood pressure and high blood cholesterol.



Ryan McVay/Photodisc/Getty Images

Physical activity and a moderate weight loss of even 10 to 20 pounds can help improve blood glucose, blood lipids, and blood pressure.

> FIGURE 18-6 The Healthy Eating Plate—An Alternative to USDA MyPlate

© Cengage Learning

Such a combination of problems may require only one treatment: adopting a healthful diet and regular exercise program.

> DIETARY GUIDELINES FOR AMERICANS

Increase physical activity and reduce time spent in sedentary behaviors.

The USDA Food Patterns and MyPlate offer guidance on selecting a healthy diet, but as Chapter 2 discusses, critics have noted several shortcomings. An alternative plate was created by the nutrition faculty from the Harvard School of Public Health.[100] The *Healthy Eating Plate* (Figure 18-6) is based on their critical review of links between diet and health.[101]

**Recommendations for the Population** Recommendations to prevent chronic diseases take a population approach and urge all people to make dietary changes believed to forestall or prevent diseases. Such a strategy is similar to national efforts to vaccinate to prevent measles, fluoridate water to prevent dental caries, and fortify grains with folate to prevent neural tube defects.

**Recommendations for Individuals** Unlike nutrient-deficiency diseases, which develop when nutrients are lacking and disappear when the nutrients are provided, chronic diseases are neither caused nor prevented by diet alone. Many people have followed dietary advice and developed heart disease or cancer anyway; others have ignored all advice and lived long and healthy lives. For many people, though, diet does influence the time of onset and course of some chronic diseases.

To determine whether dietary recommendations are important to you personally, look at your family history to see which diseases are common to your relatives. In addition, examine your personal history, taking note of your body weight, blood pressure, blood lipid profile, and lifestyle habits such as smoking and physical activity.

**› REVIEW IT** Summarize dietary recommendations to prevent chronic diseases.

Clearly, optimal nutrition plays a key role in keeping people healthy and reducing the risk of chronic diseases. To have the greatest impact possible, dietary recommendations are aimed at the entire population, not just at the individuals who might benefit most. Recommendations focus on weight control and urge people to limit saturated and *trans* fat; increase fiber-rich fruits, vegetables, legumes, and whole grains; and balance food intake with physical activity.

Not all diseases can be prevented through good nutrition, but many can. This chapter has presented the eating and activity patterns that can help people reduce the risk of chronic diseases and promote overall health. In addition to promoting health and preventing chronic diseases, a healthy eating pattern should also prevent foodborne illnesses, as described in the next chapter.

## Nutrition Portfolio

Identifying your risk factors is the first step in taking action to defend yourself against heart attack, stroke, hypertension, diabetes, and cancer.

- Review your personal and family history of heart disease, hypertension, diabetes, and cancer.

Go to Diet & Wellness Plus and choose one of the days on which you tracked your diet and activity for an entire day. Select the Energy Balance report to help you answer the following questions:

- In this report, did you expend more energy (kcalories) than you consumed or vice versa? Consider whether you are sedentary or overweight and how you might become more physically active and achieve a healthy body weight. If you smoke cigarettes, develop a reasonable plan for quitting.
- Learn whether you have high blood cholesterol or high blood pressure.

Go to Diet & Wellness Plus and choose the Intake vs. Goals report to help you answer the following questions:

- In this report many dietary factors related to heart disease are assessed: sodium intake, fat intake, cholesterol intake, vitamin and mineral intake, and more. Describe how your Intake vs. Goals report relates to your risk factors. Is your diet helping to protect you or could it be putting you at higher risk?

Finally, go to Diet & Wellness Plus and choose the Fat Breakdown report.

- We know from Chapter 5 that some types of fats appear to be protective against heart disease (monounsaturated and polyunsaturated) and some appear to put us more at risk (saturated fats and cholesterol). How was your intake for each type of fat?

DIET & WELLNESS PLUS

To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com**.

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

# Complementary and Alternative Medicine

John Block/The Image Bank/Getty Images

**› LEARN IT** Present arguments for and against the use of complementary and alternative medicine.

If you suffered from migraine headaches or severe joint pain, where would you turn for relief? Would you visit a physician? Or are you more likely to go to an herbalist or an acupuncturist? Most physicians diagnose and treat medical conditions in ways that are accepted by the established medical community; herbalists and acupuncturists, among others, offer alternatives to standard medical practice. Instead of taking two aspirin, for example, you might be advised to chew two fresh leaves of the herb feverfew or to swallow a tincture of white willow bark. Or you might receive a massage and several acupuncture needles.

**Complementary and alternative medicine (CAM)** has become increasingly popular in recent decades (see the accompanying glossary for this and related terms).[1] People use these therapies for a variety of reasons. Some want to take more responsibility for both maintaining their own health and finding cures for their own diseases, especially when traditional medical therapies prove ineffective. Others have become distrustful of, and feel overwhelmed by, the high-tech diagnostic tests and costly treatments that **conventional medicine** offers. This highlight explores alternative therapies in search of their possible benefits and with an awareness of their potential harms.

## Defining Complementary and Alternative Medicine

By definition, complementary and alternative medicine is not conventional medicine because there is insufficient scientific evidence that it is safe and effective. It includes a variety of approaches, philosophies, and treatments, some of which are defined in the glossary of alternative therapies on p. 618. When these therapies are used instead of conventional medicine, they are called *alternative;* when used together with conventional medicine, they are called *complementary.* **Integrative medicine** combines conventional medicine and CAM treatments for which there is some high-quality scientific evidence of safety and effectiveness.[2]

A growing number of health-care professionals are learning about alternative therapies; more than half of US medical schools now offer elective courses in alternative medicine, and even more include discussions of these therapies in their required courses. More than ever before, health-care professionals are incorporating some of the beneficial alternative therapies into their practices, thus the gap between conventional medicine and CAM is narrowing.[3]

For some alternative therapies, preliminary and limited scientific evidence suggests some effectiveness; but for most, well-designed scientific studies have yet to determine safety and effectiveness. If proved safe and effective, an alternative therapy may be adopted by conventional medicine. Cancer radiation therapy, for example, was once considered an unconventional therapy, but it proved its clinical value and became part of accepted medical practice. In some cases, a therapy that is accepted by conventional medicine for a specific ailment is used for a different purpose in an alternative therapy. For example, chelation therapy, the preferred medical treatment for lead poisoning, is a common alternative therapy for cardiovascular disease.[4]

## Sound Research, Loud Controversy

Much information on alternative therapies comes from folklore, tradition, and testimonial accounts. Relatively few clinical trials have been conducted. Consequently, scientific evidence proving the safety and effectiveness of many alternative therapies is lacking. Some say that alternative

## GLOSSARY

**complementary and alternative medicine (CAM):** diverse medical and health-care systems, practices, and products that are not currently considered part of conventional medicine; also called *adjunctive, unconventional,* or *unorthodox therapies.*

**conventional medicine:** diagnosis and treatment of diseases as practiced by medical doctors (M.D.), doctors of osteopathy (D.O.), and allied health professionals such as physical therapists and registered nurses; also called *allopathy, Western, mainstream, orthodox,* or *regular medicine;* and *biomedicine.*

**integrative medicine:** care that combines conventional and complementary therapies for which there is some high-quality scientific evidence of safety and effectiveness. Integrative medicine emphasizes the importance of the relationship between the practitioner and the patient and focuses on wellness, healing, and the whole person.

therapies simply do not work; others suggest that these therapies have not been given a fair trial. In an effort to "explore complementary and alternative healing practices through vigorous science," the National Center for Complementary and Alternative Medicine supports clinical trials of these therapies. Articles reporting the results of these clinical trials are available at their website **(nccam.nih.gov/research).**

Sound research would answer two important questions. First, does the treatment offer better results than either doing nothing or giving a placebo? Second, do the benefits clearly outweigh the risks? Each of these points is worthy of elaboration.

## Placebo Effect

Stories abound that credit alternative therapies with miraculous cures. Without scientific research to determine effectiveness, however, one is left to wonder whether it is the therapies or the placebo effect that produces the cure. Recall from Chapter 1 that giving a placebo often brings about a healing effect in people who believe they are receiving the treatment.[5] Conventional medicine tends to neglect this powerful remedy, whereas many alternative therapies embrace it.[6]

## Risks versus Benefits

Ideally, a therapy provides benefits with little or no risk. Figure H18-1 presents several examples of herbal remedies that appear to be generally safe and possibly effective in treating various conditions.[7] Such findings, if replicated, hold promise that these alternative therapies may one day be integrated into conventional medicine.

Some alternative therapies are innocuous, providing little or no benefit for little or no risk. Sipping a cup of warm tea with a pleasant aroma, for example, won't cure heart disease, but it may improve one's mood and help relieve tension. Given no physical hazard and little financial risk, such therapies are acceptable.

In contrast, other products and procedures are downright dangerous, posing great risks while providing no benefits. One example is the folk practice of geophagia (eating earth or clay), which can cause GI impaction and impair iron absorption. Another is the taking of laetrile to treat cancer, which can cause cyanide poisoning. Clearly, such therapies are too harmful to be used.

Perhaps most controversial are alternative therapies that may provide benefits, but also carry significant, unknown, or debatable risks. Smoking marijuana is an example of such an alternative therapy.[8] The compounds in marijuana seem to provide relief from symptoms such as nausea, vomiting, and pain that commonly accompany cancer, AIDS, and other diseases, but marijuana use also poses risks that some people consider acceptable whereas others deem them intolerable. Figure H18-2 summarizes the relationships between risks and benefits.

## GLOSSARY OF ALTERNATIVE THERAPIES

**acupuncture** (AK-you-PUNK-cher): a technique that involves piercing the skin with long thin needles at specific anatomical points to relieve pain or illness. Acupuncture sometimes uses heat, pressure, friction, suction, or electromagnetic energy to stimulate the points.

**aroma therapy:** a technique that uses oil extracts from plants and flowers (usually applied by massage or baths) to enhance physical, psychological, and spiritual health.

**ayurveda** (AH-your-VAY-dah): a traditional Hindu system of improving health by using herbs, diet, meditation, massage, and yoga to stimulate the body, mind, and spirit to prevent and treat disease.

**bioelectromagnetic medical applications:** the use of electrical energy, magnetic energy, or both to stimulate bone repair, wound healing, and tissue regeneration.

**biofeedback:** the use of special devices to convey information about heart rate, blood pressure, skin temperature, muscle relaxation, and the like to enable a person to learn how to consciously control these medically important functions.

**biofield therapeutics:** a manual healing method that directs a healing force from an outside source (commonly God or another supernatural being) through the practitioner and into the client's body; commonly known as "laying on of hands."

**cartilage therapy:** the use of cleaned and powdered connective tissue, such as collagen, to improve health.

**chelation** (kee-LAY-shun) **therapy:** the use of ethylene diamine tetraacetic acid (EDTA) to bind with metallic ions, thus healing the body by removing toxic metals.

**chiropractic** (KYE-roh-PRAK-tik): a manual healing method of manipulating the spine to restore health.

**faith healing:** healing by invoking divine intervention without the use of medical, surgical, or other traditional therapy.

**herbal** (ERB-al) **medicine:** the use of plants to treat disease or improve health; also known as *botanical medicine* or *phytotherapy*.

**homeopathy** (hoh-me-OP-ah-thee): a practice based on the theory that "like cures like," that is, that substances that cause symptoms in healthy people can cure those symptoms when given in very dilute amounts.

- **homeo** = like
- **pathos** = suffering

**hydrotherapy:** the use of water (in whirlpools, as douches, or packed as ice, for example) to promote relaxation and healing.

**hypnotherapy:** a technique that uses hypnosis and the power of suggestion to improve health behaviors, relieve pain, and heal.

**imagery:** a technique that guides clients to achieve a desired physical, emotional, or spiritual state by visualizing themselves in that state.

**iridology:** the study of changes in the iris of the eye and their relationships to disease.

**macrobiotic diet:** a philosophical eating pattern based on mostly plant foods such as whole grains, legumes, and vegetables, with small amounts of fish, fruits, nuts, and seeds.

- **macro** = large, great
- **biotic** = life

**massage therapy:** a healing method in which the therapist manually kneads muscles to reduce tension, increase blood circulation, improve joint mobility, and promote healing of injuries.

**meditation:** a self-directed technique of relaxing the body and calming the mind.

**naturopathic** (nay-chur-oh-PATH-ick) **medicine:** a system that taps the natural healing forces within the body by integrating several practices, including traditional medicine, herbal medicine, clinical nutrition, homeopathy, acupuncture, East Asian medicine, hydrotherapy, and manipulative therapy.

**orthomolecular medicine:** the use of large doses of vitamins to treat chronic disease.

**ozone therapy:** the use of ozone gas to enhance the body's immune system.

**qi gong** (chée GUNG): a Chinese system that combines movement, meditation, and breathing techniques to enhance the flow of *qi* (vital energy) in the body.

# Nutrition-Related Alternative Therapies

Most alternative therapies fall outside the field of nutrition, but nutrition itself can be an alternative therapy. Furthermore, many alternative therapies prescribe specific dietary regimens even though most practitioners are not registered dietitian nutritionists (see Highlight 1). Nutrition-related alternative therapies include the use of foods, vitamin and mineral supplements, and herbs to prevent and treat illnesses.

## Foods

The many dietary recommendations presented throughout this text are based on scientific evidence and do *not* fall into the alternative therapies category; strategies that are still experimental, however, do. For example, alternative therapists may recommend macrobiotic diets to help prevent chronic diseases, whereas most registered dietitian nutritionists would advise people to eat a balanced diet that includes servings from each of the five food groups. Similarly, enough scientific evidence is available to recommend including soy foods in the diet to protect against heart disease—but not to determine whether the phytoestrogens of soy supplements are safe or beneficial in managing the symptoms of menopause.[9]

Highlight 13 explores the potential health benefits of soy and many other functional foods and concludes that no one food is magical. As part of a balanced diet, these foods can support good health and protect against disease. Importantly, the benefits derive from a variety of *foods*. More research is needed to determine the safety and effectiveness of taking supplements of the nutrients and phytochemicals found in these foods.

## Vitamin and Mineral Supplements

Like foods, vitamin and mineral supplements may fall into either the conventional or the alternative realm of medicine. For example, conventional advice recommends consuming 400 micrograms of folate to prevent neural tube defects, but not the taking of 1000 milligrams of vitamin C to prevent the common cold. Highlight 10 examines the appropriate use of supplements and potential dangers of excessive intakes.

As research on nutrition and chronic diseases has revealed many of the roles played by the vitamins and minerals in supporting health, conventional medicine has warmed up to the possibility that vitamin and mineral supplements might be an appropriate preventive therapy.[10] Some vitamin and mineral supplements appear to be in transition from alternative medicine to conventional medicine; that is, they have begun to prove their safety and effectiveness. Herbal remedies, however, still remain clearly in the realm of complementary and alternative medicine.

## Herbal Remedies

From earliest times, people have used myriad herbs and other plants to cure aches and ills with varying degrees of success (review Figure H18-1). In fact, today's pharmaceutical industry originated from the use of plant-derived products for human health.[11] Upon scientific study, dozens of these folk remedies reveal their secrets. For example, myrrh, a plant resin used as a painkiller in ancient times, does indeed have an analgesic effect. The herb valerian, which has long been used as a tranquilizer, contains oils that have a sedative effect. Senna leaves, brewed as a laxative tea, produce compounds that act as a potent cathartic drug. Green tea, brewed from the dried leaves of *Camellia sinensis,* contains phytochemicals that induce cancer cells to self-destruct. Naturally occurring salicylates provide the same protective effects as low doses of aspirin. Salicylates are found in spices such as curry, paprika, and thyme; fruits; vegetables; teas; and candies flavored with wintergreen (methylsalicylate).

Beneficial compounds from wild species contribute to about half of our modern medicines. By analyzing these compounds, pharmaceutical labs can synthesize pure forms of the drugs. Unlike herbs and wild species, which vary from batch to batch, synthesized

medicines deliver exact dosages. By synthesizing drugs, we are also able to conserve endangered species. Consider that it took all of the bark from one 40-foot-tall, 100-year-old Pacific yew tree to produce one 300 milligram dose of the anticancer drug paclitaxel (Taxol), until scientists learned how to synthesize it. Many yet undiscovered cures may be forever lost as wild species are destroyed, long before their secrets are revealed to medicine.

## Herbal Precautions

Plants are "natural," but that does not mean all plants are beneficial or even safe.[12] Nothing could be more natural—and deadly—than the poisonous herb hemlock. Several herbal remedies have toxic effects. The popular Chinese herbal potion jin bu huan, which is used as a pain and insomnia remedy, has been linked with several cases of acute hepatitis. Germanium, a nonessential mineral commonly found in many herbal products, has been associated with chronic kidney failure. Paraguay tea produces symptoms of agitation, confusion, flushed skin, and fever. Kombucha tea, commonly used in the hopes of preventing cancer, relieving arthritis, curing insomnia, and stimulating hair regrowth, can cause severe metabolic acidosis. Table H18-1 (p. 622) provides an overview of selected herbs.[13]

Although some people use herbs to treat or prevent disease, herbs are not regulated as drugs; they are considered dietary supplements. The Food and Drug Administration (FDA) does not evaluate dietary supplements for safety or effectiveness, nor does it monitor their contents. Under the Dietary Supplement Health and Education Act, rather than the herb manufacturers having to prove the safety of their products, the FDA has the burden of proving that a product is not safe. Consequently, consumers may lack information about or find discrepancies regarding:

- *True identification of herbs.* Most mint teas are safe, for instance, but some varieties contain the highly toxic pennyroyal oil. Mistakenly used to soothe a colicky baby, mint tea laden with pennyroyal has been blamed for the liver and neurological injuries of at least two infants, one of whom died.
- *Purity of herbal preparations.* A young child diagnosed with lead poisoning had been given an herbal vitamin that contained large quantities of lead and mercury for 4 years. Twelve cases of lead poisoning among adults using ayurvedic remedies were reported to the Centers for Disease Control and Prevention in recent years. In New York, investigators found six cases of lead poisoning in pregnant women who had taken ayurvedic medications made in India.[14] Some of the medications also contained mercury or arsenic.
- *Appropriate uses and contraindications of herbs.* Herbal remedies alone may be appropriate for minor ailments—a cup of chamomile tea to ease gastric discomfort or the gel of an aloe vera plant to soothe a sunburn, for example—but not for major health problems such as cancer or AIDS.
- *Effectiveness of herbs.* Herbal remedies may claim to work wonders without having to prove effectiveness. Research studies often report conflicting findings, with some suggesting a benefit and others indicating no effectiveness.
- *Variability of herbs.* Not all species are created equal. The various species of coneflower provide an example. *Echinacea purpurea,* for example, may help in the early treatment of colds, but *Echinacea augustifolia* may not. Similarly, not all parts of a plant provide the same compounds. Leaves, roots, and oils contain different compounds and extracts, and the temperatures used during manufacturing may affect their potency. Consumers are not always aware of such differences, and manufacturers do not always make such distinctions when preparing and labeling supplements.
- *Accuracy of labels.* Supplements may contain none of an herb or mixed species, and labels are often inaccurate. More often than not, supplements do not contain the species or the quantities of active ingredients stated on their labels.[15] In several cases, supplements do not even contain herbs, but drugs that are known to interact with prescription medicines and lower blood pressure to dangerous levels. Such discrepancies in the contents of supplements can be dangerous to the consumer, interfere with scientific research, and make it difficult to interpret the findings. Consumers may want to shop for supplements bearing a logo from either US Pharmacopeia or Consumer Lab indicating that the contents have been analyzed and found to contain the ingredients and quantities listed on the label.
- *Safe dosages of herbs.* Herbs may contain active ingredients—compounds that affect the body. Each of these active ingredients has a different potency, time of onset, duration of activity, and consequent effects, making the plant itself too unpredictable to be useful. Foxglove leaves, for example, contain dozens of compounds that have an effect on the heart; digoxin, a drug derived from foxglove, offers a standard dosage that allows for a more predictable cardiac response. Even when herbs are manufactured into capsules or liquids, their concentrations of active ingredients differ dramatically from batch to batch and from the quantities stated on the labels.
- *Interactions of herbs with medicines and other herbs.* Like drugs, herbs may interfere with, or potentiate, the effects of other herbs and drugs (see Table H18-2, p. 623).[16] A person taking both cardiac medication and the herb foxglove may be headed for disaster from the combined effect on the heart. Similarly, taking St. John's wort with medicines used to treat heart disease, depression, seizures, and certain cancers might diminish or exaggerate the intended effects.[17] Because *Ginkgo biloba* impairs blood clotting, it can cause bleeding problems for people taking aspirin or other blood-thinning medicines regularly.[18]
- *Adverse reactions and toxicity levels of herbs.* Herbs may produce undesirable reactions. The herbal root kava, commonly used to treat anxiety and insomnia, can cause liver abnormalities and may have such a sedating effect as to impair driving. Chinese herbal treatments containing *Aristolochia fangchi* are known to cause kidney damage and cancers.[19] Table H18-1 (p. 622) includes risks associated with commonly used herbs. To ensure the safety and standardization of herbal remedies, Congress may need to establish new regulations.

# HIGHLIGHT > 18

**TABLE H18-1 Overview of Selected Herbs**

| Common and Scientific Names | Claims | Research Findings | Risks[a] |
|---|---|---|---|
| Aloe (gel)<br>*Aloe vera* | Promote wound healing | May help heal minor burns and abrasions; may cause infections in severe wounds | Generally considered safe |
| Black cohosh (stems and roots)<br>*Actaea racemosa, Cimifuga racemosa* | Ease menopause symptoms | Conflicting evidence | May cause headaches, stomach discomfort, liver damage |
| Chamomile (flowers)<br>*Matricaria recutita, Chamomilla recutita* | Relieve indigestion | Little evidence available | Generally considered safe |
| Chaparral (leaves and twigs)<br>*Larrea tridentata* | Slow aging, "cleanse" blood, heal wounds, cure cancer, treat acne | No evidence available | Acute, toxic hepatitis; liver damage |
| Cinnamon (bark)<br>*Cinnamomum zeylanicum, C. cassia* | Relieve indigestion, lower blood glucose and blood lipids | May lower blood glucose in type 2 diabetes | May have a blood-thinning effect; not safe for pregnant women or those taking diabetes medication |
| Comfrey (leafy plant)<br>*Symphytum officinale, S. asperum, S. x uplandicum* | Soothe nerves | No evidence available | Liver damage |
| Echinacea (roots)<br>*Enchinacea angustifolia, E. pallida, E. purpurea* | Alleviate symptoms of colds, flus, and infections; promote wound healing; boost immunity | Ineffective in preventing colds or other infections | Generally considered safe; may cause headache, dizziness, nausea |
| Ephedra (stems)<br>*Ephedra sinica* | Promote weight loss | Little evidence available; FDA has banned the sale of ephedra-containing products | Rapid heart rate, tremors, seizures, insomnia, headaches, hypertension |
| Feverfew (leaves)<br>*Tanacetum parthenium* | Prevent migraine headaches | May prevent migraine headaches | Generally considered safe; may cause mouth irritation, swelling, ulcers, and GI distress |
| Garlic (bulbs)<br>*Allium sativum* | Lower blood lipids and blood pressure | May lower blood cholesterol slightly; conflicting evidence on blood pressure | Generally considered safe; may cause garlic breath, body odor, gas, and GI distress; inhibits blood clotting |
| Ginger (roots)<br>*Zingiber officinale* | Prevent motion sickness, nausea | May relieve pregnancy-induced nausea; conflicting evidence on nausea caused by motion, chemotherapy, or surgery | Generally considered safe |
| Ginkgo (tree leaves)<br>*Ginkgo biloba* | Improve memory, relieve vertigo | Little evidence available | Generally considered safe; may cause headache, GI distress, dizziness; may inhibit blood clotting |
| Ginseng (roots)<br>*Panax ginseng* (Asian), *P. quinquefolius* (American) | Boost immunity, increase endurance | Little evidence available | Generally considered safe; may cause insomnia, headaches, and high blood pressure |
| Goldenseal (roots)<br>*Hydrastis canadensis* | Relieve indigestion, treat urinary infections | Little evidence available | Generally considered safe; not safe for people with hypertension or heart disease |
| Kava (roots)<br>*Piper methysticum* | Relieves anxiety, promotes relaxation | Little evidence available | Liver failure |
| Saw palmetto (ripe fruits)<br>*Serenoa repens* | Relieve symptoms of enlarged prostate; diuretic; enhance sexual vigor | Little evidence available | Generally considered safe; may cause nausea, vomiting, diarrhea |
| St. John's wort (leaves and tops)<br>*Hypericum perforatum* | Relieve depression and anxiety | May relieve mild depression | Generally considered safe; may cause fatigue, increased sensitivity to sunlight, and GI distress |
| Turmeric (roots)<br>*Curcuma longa* | Reduces inflammation; relieves heartburn; prevents or treats cancer | No evidence available | Generally considered safe; may cause indigestion; not safe for people with gallbladder disease |
| Valerian (roots)<br>*Valeriana officinalis* | Calm nerves, improve sleep | Little evidence available | Long-term use associated with liver damage |
| Yohimbe (tree bark)<br>*Pausinystalia yohimbe* | Enhance "male performance" | No evidence available | Kidney failure, seizures |

[a]Allergies are always a possible risk; see Table H18-2 (p. 623) for drug interactions. Pregnant women should not use herbal supplements.

**TABLE H18-2 Herb and Drug Interactions**

| Herb | Drug | Interaction |
|---|---|---|
| American ginseng | Estrogens, corticosteroids | Enhances hormonal response |
| American ginseng | Breast cancer therapeutic agent | Synergistically inhibits cancer cell growth |
| American ginseng, karela | Blood glucose regulators | Affect blood glucose levels |
| Echinacea (possible immunostimulant) | Cyclosporine and corticosteroids (immunosuppressants) | May reduce drug effectiveness |
| Evening primrose oil, borage | Anticonvulsants | Lower seizure threshold |
| Feverfew | Aspirin, ibuprofen, and other nonsteroidal anti-inflammatory drugs | Negates the effect of the herb in treating migraine headaches |
| Feverfew, garlic, ginkgo, ginger, and Asian ginseng | Warfarin, coumarin (anticlotting drugs, "blood thinners") | Prolong bleeding time; increase likelihood of hemorrhage |
| Garlic | Protease inhibitor (HIV drug) | May reduce drug effectiveness |
| Kava, valerian | Anesthetics | May enhance drug action |
| Kelp (iodine source) | Synthroid or other thyroid hormone replacers | Interferes with drug action |
| Kyushin, licorice, plantain, uzara root, hawthorn, Asian ginseng | Digoxin (cardiac antiarrhythmic drug derived from the herb foxglove) | Interfere with drug action and monitoring |
| St. John's wort, saw palmetto, black tea | Iron supplements | Tannins in herbs inhibit iron absorption |
| St. John's wort | Protease inhibitors (HIV drugs), warfarin (anticlotting drug), digoxin (cardiac antiarrhythmic drug), oral contraceptives, tamoxifen (breast cancer drug) | May enhance or reduce drug effectiveness |
| Valerian | Barbiturates | Causes excessive sedation |

© Cengage Learning

Because herbal medicines are sold as dietary supplements, their labels cannot claim to cure a disease, but they can make various other claims. Not surprisingly, when a label claims that an herbal product may strengthen immunity, improve memory, support eyesight, or maintain heart health, consumers believe that taking the product will provide those benefits. Beware. Manufacturers need not prove effectiveness; they need only state on the product label that this claim "Has not been evaluated by the FDA." Consumers who decide to use herbs need to become informed of the possible risks.

## Internet Precautions

As Highlight 1 points out, just because something appears on the Internet, "it ain't necessarily so." Keep in mind that the thousands of websites touting the benefits of herbal medicines and other dietary supplements are marketing their products. Most product advertisements claim to prevent or treat specific diseases, but few include the FDA disclaimer statement. Many of the websites promote products by quoting researchers or physicians. Such quotations lend an air of authority to advertisements, but be aware that these sources may not even exist—and if they do, their comments may have been taken out of context. When asked, these experts may not agree at all with the claims attributed to them by the manufacturer.

Other deceits and dangers lurk in cyberspace as well. Potentially toxic substances, illegal and unavailable in many countries, are now easy to obtain via the Internet. Electronic access to products such as absinthe and oil of wormwood could be deadly. When the FDA discovers websites selling unapproved drugs, such as laetrile, it can order the business to shut down. But consumers need to remain vigilant because other similar businesses pop up quickly.

## The Consumer's Perspective

Some health-care professionals may dismiss alternative therapies as ineffective and perhaps even dangerous, but many consumers think otherwise. About 4 out of 10 adults have used at least one alternative therapy for a variety of medical symptoms ranging from back pain and anxiety to heart disease and cancer. Interestingly, those who seek alternative therapies seem to do so not so much because they are dissatisfied with conventional medicine as because they find these alternatives more in line with their beliefs about health and life.

Most often, people use alternative therapies in addition to, rather than in place of, conventional therapies. Few consult an alternative therapist without also seeing a physician. In fact, most people seek alternative therapies for nonserious medical conditions or for health promotion. They simply want to feel better and access is easy. Sometimes their symptoms are chronic and subjective, such as pain and fatigue, and difficult to treat. In these cases, the chances of finding relief are often as good with a placebo, standard medical intervention, or even nonintervention.

# HIGHLIGHT > 18

Consumers spend billions of dollars on alternative health services and related products such as herbs, crystals, and aromas. As Highlight 1 points out, selecting a reliable practitioner depends on finding out about training, qualifications, and licenses. (To review how a person can identify health fraud and quackery, turn to p. 31. For a list of credible sources of nutrition information, see p. 33.)

In addition, consumers should inform their physicians about the use of any alternative therapies so that a comprehensive treatment plan can be developed and potential problems can be averted. Remember to include supplements, teas, and garden plants. Sometimes herbal products may need to be discontinued, especially before surgery when interactions with anesthesia or normal blood clotting can be life-threatening.

Alternative therapies come in a variety of shapes and sizes. Both their benefits and their risks may be small, none, or great. Wise consumers and health-care professionals accept the beneficial, or even neutral, practices with an open mind and reject those practices known to cause harm. Making healthful choices requires understanding all the choices.

## CRITICAL THINKING QUESTIONS

A. How would you judge the accuracy or validity of complementary and alternative medicine practices?

B. A friend of yours was recently diagnosed with cancer. His physician discussed surgery, radiation, and possibly chemotherapy as recommended treatment options. His sister suggested that in *addition* to the physician's treatment, your friend might also benefit from a few acupuncture sessions and yoga classes. His roommate disagreed, suggesting that *instead* of following the physician's recommendations, your friend should start taking high doses of dietary supplements and doing colonic enemas daily. At this point, your friend is confused. What advice might you offer to help him make an informed decision?

# Consumer Concerns about Foods and Water

## Nutrition in Your Life

Do you know what causes food poisoning and how to protect yourself against it? Were you alarmed to learn that french fries contain acrylamide or that fish contain mercury? Are you concerned about the pesticides that might linger on fruits and vegetables—or the hormones and antibiotics that remain in beef and chicken? Do you wonder whether foods contain enough nutrients—or too many additives? Making informed choices and practicing a few food safety tips will allow you to enjoy a variety of foods while limiting your risks of experiencing food-related illnesses. In the Nutrition Portfolio at the end of this chapter, you can review your food-handling practices.

Take a moment to consider the task of supplying food to more than 300 million people in the United States (and millions more in all corners of the world). To feed this nation, farmers grow and harvest crops; dairy producers supply milk products; ranchers raise livestock; shippers deliver foods to manufacturers by land, sea, and air; manufacturers prepare, process, preserve, and package products for refrigerated food cases and grocery-store shelves; and grocers store the food and supply it to consumers. After much time, much labor, and extensive transport, an abundant supply of a large variety of safe foods finally reaches consumers at reasonable market prices.

The **FDA** is a large federal agency with a multitude of global responsibilities.[1] Its primary mission is to protect consumers from unsafe foods and drugs, which it does by using a network of people and sophisticated equipment.[2] More than 2000 FDA inspectors process more than 24 million shipments from more than 300,000 manufacturers representing more than 150 countries. (The glossary on p. 628 identifies the various food regulatory agencies by their abbreviations.)

Markus Moellenberg/zefa/Corbis

With the benefits of a safe and abundant food supply comes the responsibility to select, prepare, and store foods safely.

# 19.1 Food Safety and Foodborne Illnesses

**› LEARN IT** Describe how foodborne illnesses can be prevented.

Government agencies focus on the potential **hazard** of foods, which differs from the **toxicity** of a substance—a distinction worth understanding. Anything can be toxic. Toxicity simply means that a substance *can* cause harm *if* enough is consumed. We consume many substances that are toxic, without **risk,** because the amounts are so small. The term *hazard,* on the other hand, is more relevant to our daily lives because it refers to the harm that is *likely* under real-life conditions. Consumers rely on government monitoring agencies to set **safety** standards and can learn to protect themselves from food-related illnesses by taking a few preventive measures.

This chapter focuses on the actions of individuals to promote food safety. It addresses the following food safety concerns:

- Foodborne illnesses
- Nutritional adequacy of foods
- Environmental contaminants
- Naturally occurring toxicants
- Pesticides
- Food additives
- Water safety

The chapter begins with the FDA's highest priority—the serious and prevalent threat of foodborne illnesses. The highlight that follows looks at genetically engineered foods.

**Foodborne illness** is the leading food safety concern because **outbreaks** of food poisoning far outnumber episodes of any other kind of food contamination. The **CDC** estimates 48 million cases of foodborne illnesses occur each year in the United States.[3] More than 100,000 people become so sick as to need hospitalization. For some 3000 people each year, the symptoms are so severe as to cause death. The following symptoms demand medical attention:

- Bloody diarrhea or diarrhea lasting more than 3 days
- Difficulty breathing or swallowing
- Double vision
- Fever lasting more than 24 hours
- Headache, muscle stiffness, and fever
- Numbness, muscle weakness, and tingling sensations in the skin
- Rapid heart rate, fainting, and dizziness

Most vulnerable are pregnant women; very young, very old, sick, or malnourished people; and those with a weakened immune system (as in AIDS).[4] By taking the proper precautions, people can minimize their chances of contracting foodborne illnesses.

**hazard:** a source of danger; used to refer to circumstances in which harm is possible under normal conditions of use.

**toxicity:** the ability of a substance to harm living organisms. All substances are toxic if high enough concentrations are used.

**risk:** a measure of the probability and severity of harm.

**safety:** the condition of being free from harm or danger.

**foodborne illness:** an illness transmitted to human beings through food and water, caused by either an infectious agent (foodborne infection) or a poisonous substance (food intoxication); commonly known as *food poisoning.*

**outbreaks:** two or more cases of a similar illness resulting from the ingestion of a common food.

## GLOSSARY OF FOOD REGULATORY AGENCIES

**CDC (Centers for Disease Control and Prevention):** a branch of the Department of Health and Human Services that is responsible for, among other things, monitoring foodborne diseases.
**www.cdc.gov**

**EPA (Environmental Protection Agency):** a federal agency that is responsible for, among other things, regulating pesticides and establishing water quality standards.
**www.epa.gov**

**FAO (Food and Agriculture Organization):** an international agency (part of the United Nations) that has adopted standards to regulate pesticide use among other responsibilities.
**www.fao.org**

**FDA (Food and Drug Administration):** the federal agency responsible for ensuring the safety and wholesomeness of all dietary supplements and foods processed and sold in interstate commerce except meat, poultry, and eggs (which are under the jurisdiction of the USDA); inspecting food plants and imported foods; and setting standards for food composition and product labeling.
**www.fda.gov**

**USDA (US Department of Agriculture)**: the federal agency responsible for enforcing standards for the wholesomeness and quality of meat, poultry, and eggs produced in the United States; conducting nutrition research; and educating the public about nutrition.
**www.usda.gov**

**WHO (World Health Organization):** an international agency concerned with promoting health and eradicating disease.
**www.who.int**

## Foodborne Infections and Food Intoxications

Foodborne illness can be caused by either an infection or an intoxication. Table 19-1 summarizes the foodborne illnesses responsible for 90 percent of illnesses, hospitalizations, and deaths, along with their food sources, general symptoms, and prevention methods.

### Foodborne Infections

Foodborne infections are caused by eating foods contaminated by infectious microbes. Among foodborne infections, norovirus and *Salmonella* are the leading causes of hospitalizations and deaths.[5] **Pathogens** commonly enter the GI tract in contaminated foods such as undercooked poultry and unpasteurized milk. Symptoms generally include abdominal cramps, fever, vomiting, and diarrhea.

### Food Intoxications

Food intoxications are caused by eating foods containing natural toxins or, more likely, microbes that produce toxins. The most common food toxin is produced by *Staphylococcus aureus;* it affects more than

Science Source

An infection with *Salmonella* bacteria typically causes diarrhea, fever, and abdominal cramps.

**pathogens** (PATH-oh-jenz): microorganisms capable of producing disease.

**TABLE 19-1 Foodborne Illnesses**

| Common Organism Name | Most Frequent Food Sources | Onset and General Symptoms | Prevention Methods[a] |
|---|---|---|---|
| **Foodborne Infections** | | | |
| ***Campylobacter*** (KAM-pee-loh-BAK-ter) bacterium | Raw and undercooked poultry, unpasturized milk, contaminated water | Onset: 2 to 5 days. Diarrhea, vomiting, abdominal cramps, fever; sometimes bloody stools; lasts 2 to 10 days. | Cook foods thoroughly; use pasteurized milk; use sanitary food-handling methods. |
| ***E.coli:*** (**O157:H7**) bacterium | Undercooked ground beef, unpasteurized milk and juices, raw cookie dough, raw fruits and vegetables, contaminated water, and person-to-person contact | Onset: 1 to 8 days. Severe bloody diarrhea, abdominal cramps, vomiting; lasts 5 to 10 days. | Cook ground beef thoroughly; use pasteurized milk; use sanitary food-handling methods; use treated, boiled, or bottled water. |
| **Norovirus** | Person-to-person contact; raw foods, salads, sandwiches | Onset: 1 to 2 days. Vomiting; lasts 1 to 2 days. | Use sanitary food-handling methods. |
| ***Listeria*** (lis-TER-ee-AH) bacterium | Unpasteurized milk; fresh soft cheeses; luncheon meats, hot dogs | Onset: 1 to 21 days. Fever, muscle aches; nausea, vomiting, blood poisoning, complications in pregnancy, and meningitis (stiff neck, severe headache, and fever). | Use sanitary food-handling methods; cook foods thoroughly; use pasteurized milk. |
| ***Clostridium*** (klo-STRID-ee-um) ***perfringens*** (per-FRINGE-enz) bacterium | Meats and meat products stored at between 120°F and 130°F | Onset: 8 to 16 hours. Abdominal pain, diarrhea, nausea; lasts 1 to 2 days. | Use sanitary food-handling methods; use pasteurized milk; cook foods thoroughly; refrigerate foods promptly and properly. |
| ***Salmonella*** (sal-moh-NEL-ah) bacteria (>2300 types) | Raw or undercooked eggs, meats, poultry, raw milk and other dairy products, shrimp, frog legs, yeast, coconut, pasta, and chocolate | Onset: 1 to 3 days. Fever, vomiting, abdominal cramps, diarrhea; lasts 4 to 7 days; can be fatal. | Use sanitary food-handling methods; use pasteurized milk; cook foods thoroughly; refrigerate foods promptly and properly. |
| **Food Intoxications** | | | |
| **Botulism** (BOT-chew-lizm) Botulinum toxin produced by *Clostridium botulinum* bacterium, which grows without oxygen, in low-acid foods, and at temperatures between 40°F and 120°F; the ***botulinum*** (BOT-chew-line-um) ***toxin*** responsible for botulism is called ***botulin*** (BOT-chew-lin). | Anaerobic environment of low acidity (canned corn, peppers, green beans, soups, beets, asparagus, mushrooms, ripe olives, spinach, tuna, chicken, chicken liver, liver pâté, luncheon meats, ham, sausage, stuffed eggplant, lobster, and smoked and salted fish) | Onset: 4 to 36 hours. Nervous system symptoms, including double vision, inability to swallow, speech difficulty, and progressive paralysis of the respiratory system; often fatal; leaves prolonged symptoms in survivors. | Use proper canning methods for low-acid foods; refrigerate homemade garlic and herb oils; avoid commercially prepared foods with leaky seals or with bent, bulging, or broken cans.<br>Do not give infants honey because it may contain spores of *Clostridium botulinum,* which is a common source of infection for infants. |
| **Staphylococcal** (STAF-il-oh-KOK-al) **food poisoning** Staphylococcal toxin (produced by *Staphylococcus aureus* bacterium) | Toxin produced in improperly refrigerated meats; egg, tuna, potato, and macaroni salads; cream-filled pastries | Onset: 1 to 6 hours. Diarrhea, nausea, vomiting, abdominal cramps, fever; lasts 1 to 2 days. | Use sanitary food-handling methods; cook food thoroughly; refrigerate foods promptly and properly; use proper home-canning methods. |
| ***Toxoplasma*** (TOK-so-PLAZ-ma) parasite | Raw or undercooked meat; unwashed fruits and vegetables; contaminated water | Onset: 7 to 21 days. Swollen glands, fever, headache, muscle pain, stiff neck. | Use sanitary food-handling methods; cook foods thoroughly. |

NOTE: Travelers' diarrhea is most commonly caused by *E. coli, Campylobacter jejuni, Shigella,* and *Salmonella.*

[a]The "How To" on pp. 632–633 provides more details on the proper handling, cooking, and refrigeration of foods.

To prevent food intoxication from homemade flavored oils, wash and dry the herbs before adding them to the oil and keep the oil refrigerated.

1 million people each year. Less common, but more infamous, is *Clostridium botulinum*, an organism that produces a deadly toxin in anaerobic conditions such as improperly canned (especially home-canned) foods and improperly stored foods (such as homemade herb-flavored oils or commercially made, chilled foods stored at room temperature). The botulinum toxin paralyzes muscles, making it difficult to see, speak, swallow, and breathe. Because death can occur within 24 hours of onset, botulism demands immediate medical attention. Even then, survivors may suffer the effects for months or years.

Other microbial toxins—called aflatoxins—are not common in the United States, but threaten the health of more than half the world's population.[6] Aflatoxins contaminate corn, grains, and nuts in tropical countries where foods are stored in warm, humid conditions that promote fungal growth. Strategies to reduce exposure in vulnerable populations need to become a worldwide priority.

## Food Safety in the Marketplace

Transmission of foodborne illness has changed as our food supply and lifestyles have changed.[7] In the past, foodborne illness was caused by one person's error in a small setting, such as improperly refrigerated egg salad at a family picnic, and affected only a few victims. Today, we eat more foods that have been prepared and packaged by others. Consequently, when a food manufacturer or cruise ship chef makes an error, foodborne illness can quickly affect many people. An estimated 80 percent of reported foodborne illnesses are caused by errors in a commercial setting, such as the improper **pasteurization** of milk at a large dairy.

In 2010, a *Salmonella* outbreak led to the recall of 500 million eggs from two farms. In 2011, a cantaloupe farm had to recall more than 300,000 cases of fruit when *Listeria* poisoning killed 29 people and made 139 others sick. In 2013, *Cyclospora* from salads and fresh cilantro from Mexico infected more than 600 people in 25 states. In 2014, 1.8 million pounds of ground beef contaminated with *E. Coli* was recalled. These incidents and others focus the national spotlight on two important safety issues: disease-causing organisms are commonly found in foods, and safe food-handling practices can minimize harm from most of these foodborne pathogens.

### Industry Controls

All food producers use a **Hazard Analysis Critical Control Point (HACCP)** plan to help prevent foodborne illnesses at their source. Each slaughterhouse, packer, distributor, and transporter of susceptible foods must identify "critical control points" that pose a risk of contamination and then devise and implement verifiable ways to eliminate or minimize the risk. The HACCP system has proved a remarkable success for domestic products, but such programs do not apply to imported foods.

An estimated 10 to 15 percent of all food consumed in the United States is imported from more than 230 countries each year. Many countries cooperate with the FDA and have adopted many of the safe food-handling practices used in the United States, but some imported foods come from countries with little or no regulatory oversight. To help consumers distinguish between imported and domestic foods, certain foods—including fish, shellfish, meats, fruits, vegetables, and some nuts—must display the country of origin on the label, specifying where they were produced.

### Consumer Awareness

Canned and packaged foods sold in grocery stores are easily controlled, but rare accidents do happen. Batch numbering makes it possible to recall contaminated foods through public announcements via the Internet, newspapers, television, and radio. In the grocery store, consumers can buy items before the "sell by" date and inspect the safety seals and wrappers of packages. A broken seal, bulging can lid, or mangled package fails to protect the consumer against microbes, insects, spoilage, or even vandalism.

State and local health regulations provide guidelines on the cleanliness of facilities and the safe preparation of foods for restaurants, cafeterias, and

**pasteurization:** heat processing of food that inactivates some, but not all, microorganisms in the food; not a sterilization process. Bacteria that cause spoilage are still present.

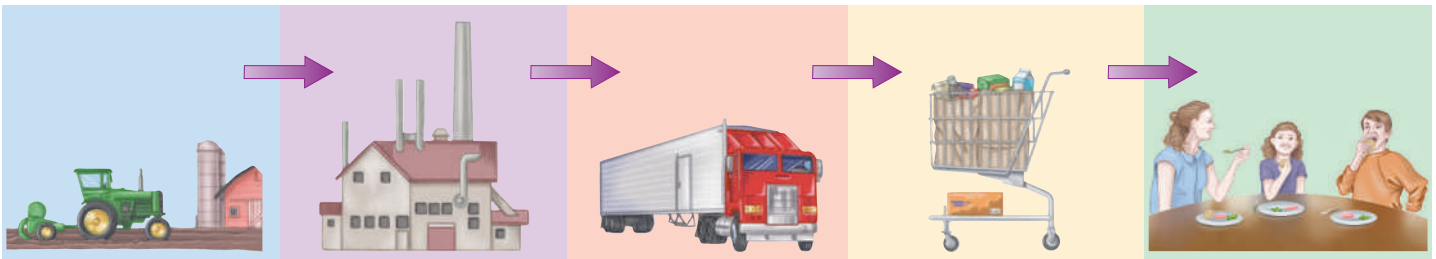
**Hazard Analysis Critical Control Points (HACCP):** a systematic plan to identify and correct potential microbial hazards in the manufacturing, distribution, and commercial use of food products; commonly referred to as "HASS-ip."

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

fast-food establishments. Even so, consumers can also take the following actions to help prevent foodborne illnesses when dining out:

- Wash hands with hot, soapy water before meals.
- Expect clean tabletops, dinnerware, utensils, and food preparation areas.
- Expect cooked foods to be served piping hot and salads to be fresh and cold.
- Refrigerate take-home items within 2 hours and use leftovers within 3 to 4 days.

Improper handling of foods can occur anywhere along the line from commercial farms and manufacturers to supermarkets and restaurants to private homes. Maintaining a safe food supply requires everyone's efforts (see Figure 19-1).



## Food Safety in the Kitchen

Whether microbes multiply and cause illness depends, in part, on a few key food-handling behaviors in the kitchen—whether the kitchen is in your home, a school cafeteria, a gourmet restaurant, or a commercial canning facility. Figure 19-2 (p. 632) summarizes the four simple things that can help most to prevent foodborne illness:

- *Clean.* Keep a clean, safe kitchen by washing hands and surfaces often. Wash countertops, cutting boards, sponges, and utensils in hot, soapy water before and after each step of food preparation. To reduce bacterial contamination on hands, wash hands with soap and warm water; if soap and water are not available, use an alcohol-based sanitizing gel.[8]
- *Separate.* Avoid foodborne infections by keeping raw eggs, meat, poultry, and seafood separate from other foods. Wash all utensils and surfaces (such as cutting boards or platters) that have been in contact with these foods with hot, soapy water before using them again. Bacteria inevitably left on the surfaces from the raw meat can recontaminate the cooked meat or other foods—a problem known as **cross-contamination.** Washing raw eggs, meat, and poultry is not recommended because the extra handling increases the risk of cross-contamination.
- *Cook.* Keep hot foods hot by cooking to proper temperatures. Foods need to cook long enough to reach internal temperatures that will kill microbes and maintain adequate temperatures to prevent bacterial growth until the foods are served.

**cross-contamination:** the contamination of food by bacteria that occurs when the food comes into contact with surfaces previously touched by raw meat, poultry, or seafood.

> FIGURE 19-1 **Food Safety from Farm to Table**

**FARM**
Workers must use safe methods of growing, harvesting, sorting, packing, and storing food to minimize contamination hazards.

**PROCESSING**
Processors must follow FDA guidelines concerning contamination, cleanliness, and education and training of workers and must monitor for safety at critical control points.

**TRANSPORTATION**
Containers and vehicles transporting food must be clean. Cold food must be kept cold at all times.

**RETAIL**
Employees in grocery stores and restaurants must follow the FDA's Food Code on how to prevent foodborne illnesses. Establishments must pass local health inspections and train staff in sanitation.

**TABLE**
Consumers must learn and use sound principles of food safety as taught in this chapter. Be mindful that foodborne illness is a real possibility, and take steps to prevent it.

## >How To

### Prevent Foodborne Illnesses

Most foodborne illnesses can be prevented by following four simple rules: clean, separate, cook, and chill.

#### Clean

- Wash fruits and vegetables in a clean sink with a scrub brush and warm water; store washed and unwashed produce separately.
- Use hot, soapy water to wash hands, utensils, dishes, nonporous cutting boards, and countertops before handling food and between tasks when working with different foods. Use a bleach solution on cutting boards (one capful per gallon of water).
- Cover cuts with clean bandages before food preparation; dirty bandages carry harmful microorganisms.
- Mix foods with utensils, not hands; keep hands and utensils away from mouth, nose, and hair.
- Anyone may be a carrier of bacteria and should avoid coughing or sneezing over food. A person with a skin infection or infectious disease should not prepare food.
- Clean sponges every day by microwaving wet sponges at full power for one minute or running them through the dishwasher. Wash dish cloths and dish towels regularly and use fresh, clean ones every day.
- Clean up food spills and crumb-filled crevices.

#### Separate

- Wash all surfaces that have been in contact with raw meats, poultry, eggs, fish, and shellfish before reusing.
- Serve cooked foods on a clean plate with a clean utensil. Separate raw foods from those that have been cooked.
- Don't use marinade that was in contact with raw meat for basting or sauces.

#### Cook

- When cooking meats or poultry, use a thermometer to test the internal temperature. Insert the thermometer between the thigh and the body of a turkey or into the thickest part of other meats, making sure the tip of the thermometer is not in contact with bone or the pan. Cook to the temperature indicated for that particular meat (see Figure 19-4 on p. 634); cook hamburgers to at least medium well done. If you have safety questions, call the USDA Meat and Poultry Hotline: (800) 535-4555.
- Cook stuffing separately, or stuff poultry just prior to cooking.
- Do not cook large cuts of meat or turkey in a microwave oven; it leaves some parts undercooked while overcooking others.
- Cook eggs before eating them (soft-boiled for at least 3½ minutes; scrambled until set, not runny; fried for at least 3 minutes on one side and 1 minute on the other).
- Cook seafood thoroughly. If you have safety questions about seafood, call the FDA hotline: (800) FDA-4010.
- When serving foods, maintain temperatures at 140°F or higher.
- Heat leftovers thoroughly to at least 165°F. Do not reheat leftovers in crock pots, slow cookers, or chafing dishes.
- Bring sauces, soups, and gravies to a boil.

#### Chill

- When running errands, stop at the grocery store last. When you get home, refrigerate the perishable groceries (such as meats and dairy products) immediately. Do not leave perishables in the car any longer than it takes for ice cream to melt.
- Put packages of raw meat, fish, or poultry on a plate before refrigerating to prevent juices from dripping on food stored below.
- Buy only foods that are solidly frozen in store freezers.
- Keep cold foods at 40°F or less; keep frozen foods at 0°F or less (keep a thermometer in the refrigerator).
- Marinate meats in the refrigerator, not on the counter.
- Look for "Keep Refrigerated" or "Refrigerate After Opening" on food labels.

(*Continued*)

**> FIGURE 19-2 Fight Bac!**

The FightBac! website (www.fightbac.org) describes four ways to keep food safe.

From The Partnership for Food Safety Education (PFSE), www.fightbac.org.

- *Chill.* Keep cold foods cold by refrigerating promptly. Go directly home upon leaving the grocery store and immediately place foods in the refrigerator or freezer. After a meal, refrigerate any leftovers immediately.

Unfortunately, consumers commonly fail to follow these simple food-handling recommendations.[9] See the accompanying "How To" feature for additional food safety tips.

**Safe Handling of Meats and Poultry** Figure 19-3 (p. 634) presents label instructions for the safe handling of meat and poultry and two types of USDA seals. Meats and poultry contain bacteria and provide a moist, nutrient-rich environment that favors microbial growth. Ground meat is especially susceptible because it receives more handling than other kinds of meat and has more surface area exposed to bacterial contamination. Consumers cannot detect the harmful bacteria in or on meat. For safety's sake, cook meat thoroughly, using a thermometer to test the internal temperature (see Figure 19-4 on p. 634).

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).

- Refrigerate leftovers promptly; use shallow containers to cool foods faster; use leftovers within 3 to 4 days.
- Thaw meats or poultry in the refrigerator, not at room temperature. If you must hasten thawing, use cool water (changed every 30 minutes) or a microwave oven.
- Freeze meat, fish, or poultry immediately if not planning to use within a few days.

### In General

- Do not reuse disposable containers; use nondisposable containers or recycle instead.
- Do not taste food that is suspect. "If in doubt, throw it out."
- Throw out foods with danger-signaling odors. Be aware, though, that most food-poisoning bacteria are odorless, colorless, and tasteless.
- Do not buy or use items that have broken seals or mangled packaging; such containers cannot protect against microbes, insects, spoilage, or even vandalism. Check safety seals, buttons, and expiration dates.
- Follow label instructions for storing and preparing packaged and frozen foods; throw out foods that have been thawed or refrozen.
- Discard foods that are discolored, moldy, or decayed or that have been contaminated by insects or rodents.

### For Specific Food Items

- *Canned goods.* Carefully discard food from cans that leak or bulge so that other people and animals will not accidentally ingest it; before canning, seek professional advice from the USDA Extension Service (find information and local offices at the USDA website).
- *Milk and cheeses.* Use only pasteurized milk and milk products. Aged cheeses, such as cheddar and Swiss, do well for an hour or two without refrigeration, but they should be refrigerated or stored in an ice chest for longer periods.
- *Eggs.* Use clean eggs with intact shells. Do not eat eggs, even pasteurized eggs, raw; raw eggs are commonly found in Caesar salad dressing, eggnog, cookie dough, hollandaise sauce, and key lime pie. Cook eggs until whites are firmly set and yolks begin to thicken.
- *Honey.* Honey may contain dormant bacterial spores, which can awaken in the human body to produce botulism. In adults, this poses little hazard, but infants younger than 1 year of age should never be fed honey. Honey can accumulate enough toxin to kill an infant; it has been implicated in several cases of sudden infant death. (Honey can also be contaminated with environmental pollutants picked up by the bees.)
- *Mayonnaise.* Commercial mayonnaise may actually help a food to resist spoilage because of the acid content. Still, keep it refrigerated after opening.
- *Mixed salads.* Mixed salads of chopped ingredients spoil easily because they have extensive surface area for bacteria to invade, and they have been in contact with cutting boards, hands, and kitchen utensils that easily transmit bacteria to food (regardless of their mayonnaise content). Chill them well before, during, and after serving.
- *Picnic foods.* Choose foods that last without refrigeration, such as fresh fruits and vegetables, breads and crackers, and canned spreads and cheeses that can be opened and used immediately. Pack foods cold, layer ice between foods, and keep foods out of water.
- *Seafood.* Buy only fresh seafood that has been properly refrigerated or iced. Cooked seafood should be stored separately from raw seafood to avoid cross-contamination.

NOTE: Learn more about food safety at www.HomeFoodSafety.org or by downloading *Is My Food Safe?*, a free phone app sponsored by the Academy of Nutrition and Dietetics.

**› TRY IT** After cutting the fat from a pork loin, you rinse the wooden cutting board under warm water before using it to chop vegetables. Discuss whether this precaution is adequate to protect against cross-contamination.

Unrelated to safe handling practices, **bovine spongiform encephalopathy (BSE)** is a slowly progressive, fatal disease that affects the central nervous system of cattle and wild game such as deer and elk.[10] A similar disease develops in people who have eaten contaminated beef from infected cows (milk products appear to be safe).* The USDA has taken numerous steps to prevent the transmission of BSE in cattle, and consequently, the risks from US cattle are extremely low.

**Safe Handling of Seafood** Most seafood available in the United States is safe, but eating it undercooked or raw can cause severe illnesses—hepatitis, worms, parasites, viral intestinal disorders, and other diseases.** Rumor has it that freezing fish will make it safe to eat raw, but this is only partly true. Commercial freezing kills mature parasitic worms, but only cooking can

© Istockphoto.com/jo unruh

Wash your hands with warm water and soap for at least 20 seconds before preparing or eating food to reduce the chance of microbial contamination.

**bovine spongiform encephalopathy** (BOH-vine SPON-jih-form in-SEF-eh-LOP-eh-thee) or **BSE:** an often fatal illness of cattle and wild game that affects the nervous system and is transmitted to people by eating infected meats; commonly called *mad cow disease*.

*The human form of BSE is called *variant Creutzfeldt-Jakob Disease (vCJD)*.
**Diseases caused by toxins from the sea include ciguatera poisoning, scombroid poisoning, and paralytic and neurotoxic shellfish poisoning.

## > FIGURE 19-3 Meat and Poultry Safety, Grading, and Inspection Seals

James Leynse/Corbis News/Corbis

Neither inspection nor grading guarantees that the product will not cause foodborne illnesses, but consumers can help to prevent foodborne illnesses by following the safe handling instructions.

© Cengage Learning

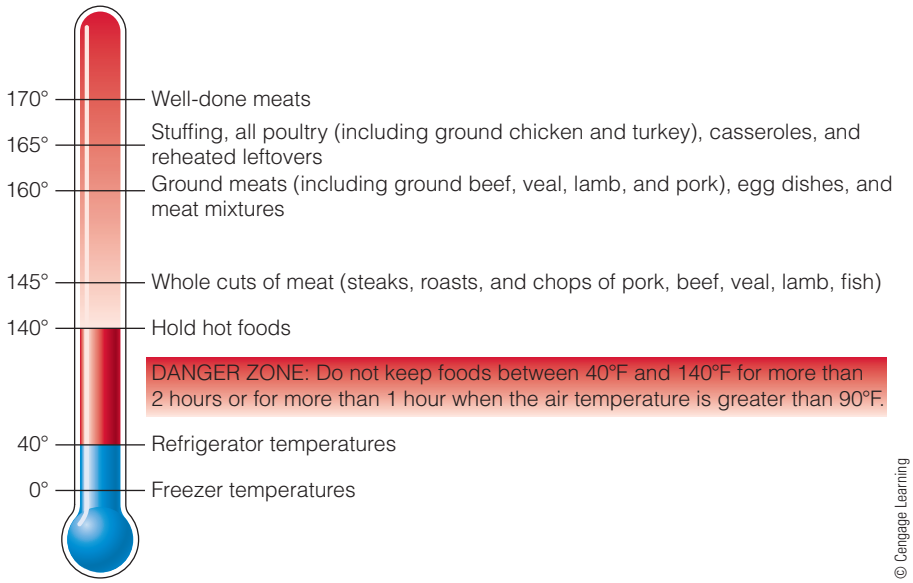
The mandatory "Inspected and Passed by the USDA" seal ensures that meat and poultry products are safe, wholesome, and correctly labeled. Inspection does not guarantee that the meat is free of potentially harmful bacteria.

© Cengage Learning

The voluntary "Graded by USDA" seal indicates that the product has been graded for tenderness, juiciness, and flavor. Beef is graded Prime (abundant marbling of the meat muscle), Choice (less marbling), or Select (lean). Similarly, poultry is graded A, B, or C.

© Cengage Learning

The USDA requires that safe handling instructions appear on all packages of meat and poultry.



© Charles Stirling/Alamy

Cook hamburgers to 160°F; color alone cannot determine doneness. Some burgers will turn brown before reaching 160°F, whereas others may retain some pink color, even when cooked to 175°F.

## > FIGURE 19-4 Recommended Safe Temperatures (Fahrenheit)

Bacteria multiply rapidly at temperatures between 40°F and 140°F. Cook foods to the minimum internal temperatures shown on this thermometer and hold them at 140°F or higher. Place the thermometer in the thickest part of the meat; for whole cuts of meat, allow the meat to rest for 3 minutes before carving or consuming.

© Cengage Learning

NOTE: To reduce the risk of foodborne illnesses, the *Dietary Guidelines for Americans* suggest that consumers heed this temperature danger zone. Professionals in the food industry must adhere to more specific guidelines as published in the FDA Food Code, available at www.fda.gov/FoodCode.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

kill all worm eggs and other microorganisms that can cause illness. For safety's sake, all seafood should be cooked until it is opaque.

As for **sushi,** even a master chef cannot detect harmful microbes that may occur in even the best-quality, freshest fish. The marketing term *sushi grade* implies wholesomeness, but is not legally defined and does not guarantee quality, purity, or freshness. Sushi can be safe to eat when chefs combine cooked seafood and other ingredients into these delicacies.

Eating raw oysters can be dangerous for anyone, but people with liver disease and weakened immune systems are most vulnerable. At least 10 species of bacteria found in raw oysters can cause serious illness and even death. Raw oysters may also carry the hepatitis A virus, which can cause liver disease. Some hot sauces can kill many of these bacteria, but not the virus; alcohol inactivates some bacteria, but not enough to guarantee protection (or to recommend drinking alcohol). Pasteurization of raw oysters—holding them at a specified temperature for a specified time—holds promise for killing bacteria without cooking the oyster or altering its texture or flavor.

© Marcelo_Krelling/Shutterstock.com

Eating raw seafood is a risky proposition.

As population density increases along the shores of seafood-harvesting waters, pollution inevitably invades the sea life there. Preventing seafood-borne illness is in large part a task of controlling water pollution. To help ensure a safe seafood market, the FDA requires processors to adopt food safety practices based on the HACCP system mentioned earlier.

Chemical pollution and microbial contamination lurk not only in the water, but also in the boats and warehouses where seafood is cleaned, prepared, and refrigerated. Because seafood is one of the most perishable foods, time and temperature are critical to its freshness, flavor, and safety. To keep seafood as fresh as possible, people in the industry must "keep it cold, keep it clean, and keep it moving." Wise consumers eat it cooked.

**Other Precautions and Procedures** Fresh food generally smells fresh. Not all types of food poisoning are detectable by odor, but some bacterial wastes produce "off" odors—and food with an abnormal odor is spoiled. Throw it out or, if it was recently purchased, return it to the grocery store. Do not taste it. Table 19-2 lists safe refrigerator storage times for selected foods.

Local health departments and the USDA and FDA websites can provide additional information about food safety. If precautions fail and a mild foodborne illness develops, drink clear liquids to replace fluids lost through vomiting and diarrhea. If serious foodborne illness is suspected, first call a physician. Then wrap the remainder of the suspected food and label the container so that the food cannot be mistakenly eaten, place it in the refrigerator, and hold it for possible inspection by health authorities.

### > DIETARY GUIDELINES FOR AMERICANS

Follow food safety recommendations when preparing and eating foods to reduce the risk of foodborne illnesses. To avoid microbial foodborne illness:

- Clean hands, food contact surfaces, and fruits and vegetables.
- Separate raw, cooked, and ready-to-eat foods while shopping, preparing, or storing foods.
- Cook foods to a safe temperature to kill microorganisms.
- Chill (refrigerate) perishable foods promptly and defrost foods properly.
- Do *not* wash or rinse meat or poultry.
- Avoid raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, unpasteurized juices, and raw sprouts.

**TABLE 19-2 Safe Refrigerator Storage Times (≤40°F)**

| | |
|---|---|
| **1 to 2 Days** | Raw ground meats, breakfast or other raw sausages, raw fish or poultry; gravies |
| **3 to 5 Days** | Raw steaks, roasts, or chops; cooked meats, poultry, vegetables, and mixed dishes; lunchmeats (packages opened); mayonnaise salads (chicken, egg, pasta, tuna); fresh vegetables (spinach, green beans, tomatoes) |
| **1 Week** | Hard-cooked eggs, bacon or hot dogs (opened packages); smoked sausages or seafood; milk, cottage cheese |
| **1 to 2 Weeks** | Yogurt; carrots, celery, lettuce |
| **2 to 4 Weeks** | Fresh eggs (in shells); lunchmeats, bacon, or hot dogs (packages unopened); dry sausages (pepperoni, hard salami); most aged and processed cheeses (Swiss, brick) |
| **2 Months** | Mayonnaise (opened jar); most dry cheeses (Parmesan, Romano) |

## Food Safety while Traveling

People who travel to other countries have a 50–50 chance of contracting a foodborne illness, commonly described as **travelers' diarrhea.** Like many other foodborne illnesses, travelers' diarrhea is a sometimes serious, always annoying bacterial infection of the digestive tract. The risk is high because, for one thing, some countries' cleanliness standards for food and water are lower than those in the United States. For another, every region's microbes are different, and although people are immune to the microbes in their own neighborhoods, they have had no chance to develop immunity to the pathogens in places they are visiting for the first time. In addition to the food safety tips outlined on pp. 632–633, precautions while traveling include:

- Wash hands frequently with soap and hot water, especially before handling food or eating. Use sanitizing gel or hand wipes regularly.
- Eat only well-cooked and hot or canned foods. Eat raw fruits or vegetables only if washed in purified water and peeled with clean hands.
- Use purified, bottled water for drinking, making ice cubes, and brushing teeth. Alternatively, use disinfecting tablets or boil water.
- Refuse dairy products that have not been pasteurized and refrigerated properly.
- Travel with antidiarrheal medication in case efforts to avoid illness fail.

To sum up these recommendations, "Boil it, cook it, peel it, or forget it."

## Advances in Food Safety

Advances in technology have dramatically improved the quality and safety of foods available on the market. From pasteurization in the early 1900s to irradiation in the early 2000s, these advances offer numerous benefits, but they also raise consumer concerns.*

### Irradiation

The use of low-dose **irradiation** protects consumers from foodborne illnesses by:

- Controlling mold in grains
- Sterilizing spices and teas for storage at room temperature
- Controlling insects and extending shelf life in fresh fruits and vegetables (inhibits the growth of sprouts on potatoes and onions and delays ripening in some fruits such as strawberries and mangoes)
- Destroying harmful bacteria in fresh and frozen beef, poultry, lamb, and pork

Some foods, however, are not candidates for irradiation. For example, when irradiated, high-fat meats develop off-odors, egg whites turn milky, grapefruits become mushy, and milk products change flavor. Incidentally, the milk in those boxes kept at room temperature on grocery-store shelves is *not* irradiated; it is sterilized with an **ultrahigh temperature (UHT) treatment.**

The use of food irradiation has been extensively evaluated over the past 50 years; approved for use in more than 40 countries; and supported by numerous health agencies, including the **FAO, WHO,** and the American Medical Association. Irradiation does not make foods radioactive, nor does it noticeably change the taste, texture, or appearance of approved foods. Vitamin loss is minimal and comparable to amounts lost in other food-processing methods such as canning. Because irradiation kills bacteria without the use of heat, it is sometimes called "cold pasteurization."

### Consumer Concerns about Irradiation

Many consumers associate the term *radiation* with cancer, birth defects, and mutations, and consequently have strong negative emotions about using irradiation on foods. Some may mistakenly fear that irradiated food has been contaminated by radioactive particles, such as occurs in

**travelers' diarrhea:** nausea, vomiting, and diarrhea caused by consuming food or water contaminated by any of several organisms, most commonly, *E. coli, Shigella, Campylobacter jejuni,* and *Salmonella.*

**irradiation:** sterilizing a food by exposure to energy waves, similar to ultraviolet light and microwaves; sometimes called *ionizing radiation.*

**ultrahigh temperature (UHT) treatment:** sterilizing a food by brief exposure to temperatures above those normally used.

*During the past century, pasteurization of milk helped to control typhoid fever, tuberculosis, scarlet fever, diphtheria, and other infectious diseases.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the aftermath of a nuclear accident. Some balk at the idea of irradiating, and thus sterilizing, contaminated foods and prefer instead the elimination of unsanitary slaughtering and food preparation conditions. Food producers, on the other hand, are eager to use irradiation, but they hesitate to do so until consumers are ready to accept it and willing to pay for it. Once consumers understand the benefits of irradiation, about half are willing to use irradiated foods, but most are not willing to pay more.

**Regulation of Irradiation** The FDA has established regulations governing the specific uses of irradiation and allowed doses. Each food that has been treated with irradiation must say so on its label (see Figure 19-5). Labels can be misleading, however. Products that use irradiated foods as ingredients are not required to say so on the label. Furthermore, consumers may interpret the *absence* of the irradiation symbol to mean that the food was produced without any kind of treatment. This is not true; it is just that the FDA does not require label statements for other treatments used for the same purpose, such as postharvest fumigation with pesticides.

**Other Pasteurizing Systems** Other technologies using high-intensity pulsed light or electron beams have also been approved by the FDA. Like irradiation, these technologies kill microorganisms and extend the shelf life of foods without diminishing their nutrient content.

**› REVIEW IT** Describe how foodborne illnesses can be prevented.

Millions of people suffer mild to life-threatening symptoms caused by foodborne illnesses (review Table 19-1, p. 629). As the "How To" feature on pp. 632–633 describes, most of these illnesses can be prevented by storing and cooking foods at their proper temperatures and by preparing them in sanitary conditions. Irradiation of certain foods protects consumers from foodborne illnesses, but it also raises some concerns.

## 19.2 Nutritional Adequacy of Foods and Diets

**› LEARN IT** Explain how to minimize nutrient losses in the kitchen.

In years past, when most foods were whole and farm fresh, the task of meeting nutrient needs primarily involved balancing servings from the various food groups. Today, however, foods have changed. Advances in food production over the past century have set the stage for the widespread dissemination of ultra-processed products—new creations that have little to do with natural foods and contain highly processed ingredients. Many of these "new" foods appeal to consumers' demands for convenience and flavor, but do not necessarily deliver a balanced assortment of needed nutrients. In fact, most lack fiber, vitamins, minerals, and phytochemicals, but deliver excessive amounts of sugar, salt, and *trans* and saturated fats—the perfect combination of dietary factors to promote obesity and chronic diseases.[11] Advertisers spend much effort and money encouraging consumers to buy their products quickly, frequently, and abundantly, not on promoting healthy eating habits—unless that would increase sales too. For health's sake, consumers will want to buy fewer processed foods, prepare more meals at home using whole fresh foods, and dine at restaurants that prepare meals from scratch.

**Obtaining Nutrient Information** To help consumers find their way among the abundance of available foods, the FDA has developed extensive nutrition labeling regulations, as Chapter 2 describes. In addition, the USDA's *Dietary Guidelines for Americans* help consumers combine foods into healthful eating patterns, and MyPlate helps them to put those guidelines into practice (see Chapter 2).

**Minimizing Nutrient Losses** In addition to selecting nutritious foods and preparing them safely, consumers can improve their nutrition health by learning to store and cook foods in ways that minimize nutrient losses. Water-soluble

**> FIGURE 19-5 Irradiation symbol**

This international symbol, called the radura, identifies retail foods that have been irradiated. The phrases "Treated by irradiation" or "Treated with radiation" must accompany the symbol. The irradiation label is not required on commercially prepared foods that contain irradiated ingredients, such as spices. Foods approved for irradiation include eggs; fresh fruit (strawberries, citrus, papaya); oysters, clams, mussels, scallops, crabs, lobsters, shrimp; raw beef, lamb, poultry, pork; spices, tea; vegetables (iceberg lettuce, fresh spinach, potatoes, tomatoes, onions); wheat.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

vitamins are the most vulnerable of the nutrients, but both vitamins and minerals can be lost when they dissolve in water that is then discarded.

Fruits and vegetables contain enzymes that both synthesize and degrade vitamins. After a fruit or vegetable has been picked, vitamin synthesis stops, but degradation continues. To slow the degradation of vitamins, most fruits and vegetables should be kept refrigerated until used. Because many vitamins are easily destroyed by oxygen, fruits and vegetables that have been cut and juice that has been opened should be stored in airtight containers and refrigerated. (Degradative enzymes are most active at warmer temperatures.)

Water-soluble vitamins readily dissolve in water. To prevent losses during washing, rinse fruits and vegetables before cutting. To minimize losses during cooking, steam, griddle, or microwave vegetables; pressure cooking and boiling cause the greatest nutrient losses. Alternatively, use the cooking water when preparing meals such as casseroles and soups.

Finally, keep in mind that most vitamin losses are not catastrophic and that a law of diminishing returns operates. Do not fret over small losses or waste time that may be valuable in improving your health in other ways. Be assured that if you start with plenty of fruits and vegetables and are reasonably careful in their storage and preparation, you will receive a sufficient supply of all the nutrients they provide.

**› REVIEW IT** Explain how to minimize nutrient losses in the kitchen.

In the marketplace, food labels, the *Dietary Guidelines for Americans*, and MyPlate all help consumers learn about nutrition and how to plan healthy diets. At home, consumers can minimize nutrient losses from fruits and vegetables by refrigerating them, washing them before cutting them, storing them in airtight containers, and cooking them for short times in minimal water.

## 19.3 Environmental Contaminants

**› LEARN IT** Explain how environmental contaminants get into foods and how people can protect themselves against contamination.

Concern about environmental contamination of foods is growing as the world becomes more populated and more industrialized. Industrial processes pollute the air, water, and soil. Plants absorb the **contaminants,** and people consume the plants (grains, vegetables, legumes, and fruits) or the meat and milk products from livestock that have eaten the plants. Similarly, polluted water contaminates the fish and other seafood that people eat. Environmental contaminants in air, water, and foods find their way into our bodies and have the potential to cause numerous health problems.

### Harmfulness of Environmental Contaminants

The potential harmfulness of a contaminant depends in part on its **persistence**—the extent to which it lingers in the environment or in the body. Some contaminants in the environment are short-lived because microorganisms or agents such as sunlight or oxygen can break them down. Some contaminants in the body may linger for only a short time because the body rapidly excretes them or metabolizes them to harmless compounds. These contaminants present little cause for concern. Some contaminants, however, resist breakdown and can accumulate. Each level of the **food chain,** then, has a greater concentration than the one below **(bioaccumulation).** Figure 19-6 shows how bioaccumulation leads to high concentrations of toxins in animals and in people at the top of the food chain.

Contaminants enter the environment in various ways. Accidental spills are rare but can have devastating effects. More commonly, small amounts are released over long periods. The following paragraphs describe how contaminants can enter the food supply.

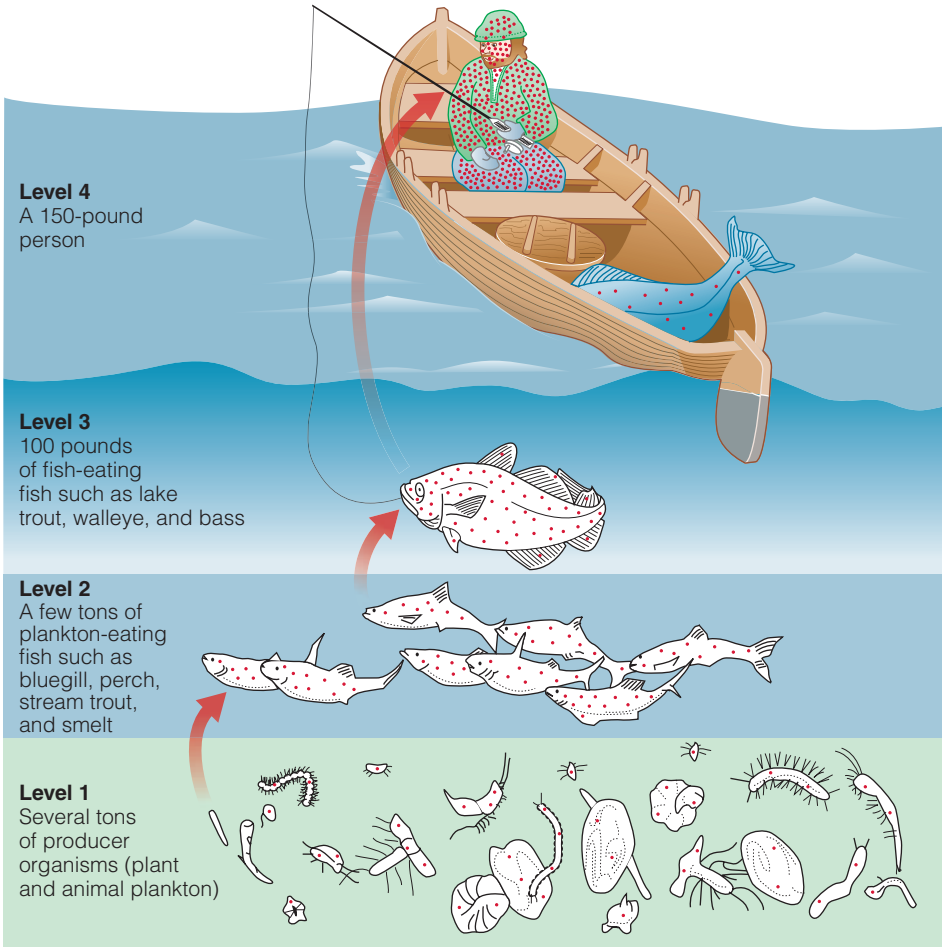
**contaminants:** substances that make a food impure and unsuitable for ingestion.

**persistence:** stubborn or enduring continuance; with respect to food contaminants, the quality of persisting, rather than breaking down, in the bodies of animals and human beings.

**food chain:** the sequence in which living things depend on other living things for food.

**bioaccumulation:** the accumulation of contaminants in the flesh of animals high on the food chain.

#### Methylmercury



A classic example of acute contamination occurred in 1953 when a number of people in Minamata, Japan, became ill with a disease no one had seen before. By 1960, 121 cases had been reported, including 23 in infants. Mortality

> **FIGURE 19-6 Bioaccumulation of Toxins in the Food Chain**

This example features fish as the food for human consumption, but bioaccumulation of toxins occurs on land as well when cows, pigs, and chickens eat or drink contaminated foods or water.

© Cengage Learning

was high; 46 died, and the survivors suffered blindness, deafness, lack of coordination, and intellectual deterioration. The cause was ultimately revealed to be methylmercury contamination of fish from the bay where these people lived. The infants who contracted the disease had not eaten any fish, but their mothers had, and even though the mothers exhibited no symptoms during their pregnancies, the poison affected their unborn babies. Manufacturing plants in the region were discharging mercury-containing waste into the waters of the bay, the mercury was turning into methylmercury, and the fish in the bay were accumulating this poison in their bodies. Some of the affected families had been eating fish from the bay every day.

**PBB and PCB** In 1973, half a ton of **PBB (polybrominated biphenyls)**, toxic **organic halogens**, were accidentally mixed into some livestock feed that was distributed throughout the state of Michigan. The PBB found its way into millions of animals and then into the people who ate the meat. The seriousness of the accident came to light when dairy farmers reported that their cows were going dry, aborting their calves, and developing abnormal growths on their hooves. Although more than 30,000 cattle, sheep, and swine and more than a million chickens were destroyed, an estimated 97 percent of Michigan's residents had been exposed to PBB. Some of the exposed farm residents suffered nervous system aberrations and liver disorders.

A similar accident occurred in 1979 when **PCB (polychlorinated biphenyls)** contaminated rice oil in Taiwan. Women who had eaten the tainted rice oil gave birth to children with developmental problems. Decades later, young men who were exposed to PCB during gestation had reduced fertility. The interactive

**PBB (polybrominated biphenyl)** and **PCB (polychlorinated biphenyl):** toxic organic halogens used in pesticides, paints, and flame retardants.

**organic halogens:** an organic compound containing one or more atoms of a halogen—fluorine, chlorine, iodine, or bromine.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

effects of PCB and mercury—two environmental contaminants found in fish—are especially damaging to brain functions such as balance and coordination.

**Arsenic** The FDA routinely tests apple juice and other fruit juices, looking for harmful substances, and has found that the vast majority of apple juice tested contains trace amounts of arsenic.[12] Arsenic—whether naturally occurring or a result of industrial contamination—is found in the water, air, and soil. Arsenic-based pesticides were commonly used in the United States until 1970, and so low levels of arsenic can be detected in agricultural fields. For this reason, even organic juices may contain arsenic. After assessing the quantities of arsenic in apple juice and the quantities of apple juice children commonly consume, the FDA is confident about the overall safety of apple juice. The FDA will take action when arsenic in apple juice is detected at 10 parts per billion, or greater. (For perspective, 1 part per billion is equivalent to about 1 second in 32 years or 1 cent in $10 million.)

© Matt Farruggio

Because albacore ("white") tuna has more mercury than canned light tuna, consumers should limit their intake to no more than 6 ounces of albacore tuna per week.

## Guidelines for Consumers

How much of a threat do environmental contaminants pose to the food supply? For the most part, the hazards appear to be small. The FDA regulates the presence of contaminants in foods and requires foods with unsafe amounts to be removed from the market. Similarly, health agencies may issue advisories informing consumers about the potential dangers of eating contaminated foods.

Most recently, mercury poisoning has aroused concerns—even at levels one-tenth of those in the Minamata catastrophe. Fish and other seafood are the main sources of dietary mercury. Virtually all fish have at least trace amounts of mercury (median, 0.17 parts per million). (For perspective, 1 part per million is equivalent to about 1 minute in 2 years or 1 cent in $10,000.) Mercury, PCB, chlordane, dioxins, and DDT are the toxins most responsible for fish contamination, but mercury leads the list by threefold. Chronic mercury exposure increases blood levels over time.

Review Figure 19-6 (p. 639) and notice how toxins such as mercury become more concentrated in animals and in people high in the food chain. Because of bioaccumulation, large game fish at the top of the aquatic food chain (such as tilefish, swordfish, king mackerel, and shark) generally have the highest concentrations of mercury (10 times the average). Consumers who enjoy eating these fish should select the smaller, younger ones (within legal limits). Also because of bioaccumulation, the concentrations in fish may be a million times higher than the concentrations in the water itself.

The **EPA** regulates commercial fishing to help ensure that fish destined for consumption in the United States meet safety standards for mercury and other contaminants. Farm-raised fish usually have lower concentrations of mercury than fish caught in the wild. Consequently, most consumers in the United States are not in danger of receiving harmful levels of mercury from fish.

The potential harm from contaminants must be balanced against the potential benefits from nutrients.[13] Pregnant and lactating women and young children are most vulnerable because mercury toxicity damages the developing brain. Yet they are also likely to benefit from consuming seafood rich in omega-3 fatty acids. To receive the benefits and minimize the risks, the FDA advises that pregnant and lactating women and young children can safely consume up to 12 ounces of a variety of seafood per week. Commonly eaten choices that are relatively low in mercury include shrimp, canned light tuna, salmon, pollock, and catfish. In addition, albacore ("white") tuna should be limited to 6 ounces per week and large predatory fish (tilefish, swordfish, king mackerel, and shark) should be avoided altogether. Although limiting seafood during pregnancy is advisable, such a strategy may have a relatively small effect on prenatal blood mercury levels.[14]

What about the noncommercial fish a person catches from a local lake, river, or ocean? After all, it's almost impossible to tell whether water is contaminated without sophisticated equipment. Each state monitors its waters and issues advisories to inform the public if chemical contaminants have been found in the local fish. To find out whether a fish advisory has been posted in your region, call the local or state environmental health department.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

All things considered, fish continue to support a healthy diet, providing valuable protein, omega-3 fatty acids, and minerals. For most adults, the benefits of protecting against heart disease outweigh the risks of consuming seafood regularly.[15] Ideally, consumers would select fish with high levels of omega-3 fatty acids and low levels of mercury, such as anchovies, herring, lake trout, mackerel, pollock, salmon, sardines, smelt, and tilapia.[16] In addition, they should select a variety of seafood to reduce the risk of exposure to contaminants from a single source.

**› REVIEW IT** Explain how environmental contaminants get into foods and how people can protect themselves against contamination.

Foods may become contaminated as pollutants enter the air, land, and sea. So far, the hazards appear relatively small. In all cases, two principles apply. First, remain alert to the possibility of contamination of foods and keep an ear open for public health announcements and advice. Second, eat a variety of foods. Varying food choices is an effective defensive strategy against the accumulation of toxins in the body. Each food eaten dilutes contaminants that may be present in other components of the diet.

## 19.4 Natural Toxicants in Foods

**› LEARN IT** Identify natural toxicants and determine whether they are hazardous.

Consumers concerned about food contamination may think that they can eliminate all poisons from their diets by eating only "natural" foods. On the contrary, nature has provided plants with an abundant array of toxicants. A few examples will show how even "natural" foods may contain potentially harmful substances. They also show that although the *potential* for harm exists, *actual* harm rarely occurs.

Poisonous mushrooms are a familiar example of plants that can be harmful when eaten. Few people know, though, that other commonly eaten foods contain substances that can cause illnesses. Cabbage, bok choy, turnips, mustard greens, kale, brussels sprouts, cauliflower, broccoli, kohlrabi, and radishes contain small quantities of goitrogens—compounds that can enlarge the thyroid gland. Eating exceptionally large amounts of goitrogen-containing vegetables can aggravate a preexisting thyroid problem, but it usually does not initiate one. Problems may develop when exceptionally large amounts (2 to 3 pounds a day) of these vegetables are eaten raw; cooking deactivates the enzyme that normally inhibits the uptake of iodine in the thyroid.[17]

Lima beans and fruit seeds such as apricot pits contain cyanogens—inactive compounds that produce the deadly poison cyanide upon activation by a specific plant enzyme. For this reason, many countries restrict commercially grown lima beans to those varieties with the lowest cyanogen contents. As for fruit seeds, they are seldom deliberately eaten. An occasional swallowed seed or two presents no danger, but a couple of dozen seeds can be fatal to a small child. Perhaps the most infamous cyanogen in seeds is laetrile—a compound erroneously represented as a cancer cure. True, laetrile kills cancer, but only at doses that kill the person too. The combination of cyanide poisoning and lack of medical attention is life-threatening.

The humble potato contains many natural poisons, including **solanine,** a powerful narcotic-like substance. Most of a potato's solanine is found in the sprouts and in the green layer that develops just beneath the skin. Solanine poisoning is extremely rare, however, because the small amounts of solanine (8 milligrams per 100 grams of potato) normally found in potatoes are harmless—even when the potato skin is eaten. Solanine can be toxic, however, and presents a hazard when consumed in large quantities (20 to 25 milligrams per 100 grams of potato). Cooking does not destroy solanine, but it can be removed by peeling the potato. Symptoms of solanine poisoning include gastrointestinal disturbances and neurological disorders.

**solanine** (SOH-lah-neen): a poisonous narcotic-like substance present in potato skins and sprouts.

**› REVIEW IT** Identify natural toxicants and determine whether they are hazardous.

Natural toxicants include the goitrogens in cabbage, cyanogens in lima beans, and solanine in potatoes. These examples of naturally occurring toxicants illustrate two familiar principles. First, any substance can be toxic when consumed in excess. Second, poisons are poisons, whether made by people or by nature. Remember, it is not the source of a chemical that makes it hazardous, but its chemical structure and the quantity consumed.

## 19.5 Pesticides

**› LEARN IT** Debate the risks and benefits of using pesticides.

The use of **pesticides** in agriculture is controversial. They help to ensure the survival of crops, but they leave **residues** in the environment and on some of the foods we eat. Balancing the benefits of pesticides to agriculture and food production against the risks to the environment and human health is an ongoing challenge.[18]

### Hazards and Regulation of Pesticides

Ideally, a pesticide destroys the pest and quickly degenerates to nontoxic products without accumulating in the food chain. Then, by the time consumers eat the food, no harmful residues remain. Unfortunately, no such perfect pesticide exists. As new pesticides are developed, government agencies assess their risks and benefits and vigilantly monitor their use.

**pesticides:** chemicals used to control insects, weeds, fungi, and other pests on plants, vegetables, fruits, and animals. Used broadly, the term includes herbicides (to kill weeds), insecticides (to kill insects), and fungicides (to kill fungi).

**residues:** whatever remains. In the case of pesticides, those amounts that remain on or in foods when people buy and use them.

**tolerance level:** the maximum amount of a residue permitted in a food when a pesticide is used according to label directions.

**Hazards of Pesticides** Pesticides applied in the field may linger on foods. Health risks from pesticide exposure are probably small for healthy adults, but children, the elderly, and people with weakened immune systems may be vulnerable to some types of pesticide poisoning. Studies report associations between pesticides and childhood cancers, decreased cognitive function, and behavioral problems.[19] To protect infants and children, government agencies set a **tolerance level** for each pesticide by first identifying foods that children commonly eat in large amounts and then considering the effects of pesticide exposure during each developmental stage. Research shows that estimates of dietary pesticide intakes in children are similar to actual measured intakes.[20]

Michael Blann/Photodisc/Getty Images

As many as 400 varieties of fruits and vegetables are imported from other countries.

**Regulation of Pesticides** Consumers depend on the EPA and the FDA to keep pesticide use within safe limits. These agencies evaluate the risks and benefits of a pesticide's use by asking such questions as: How dangerous is it? How much residue is left on the crop? How much harm does the pesticide do to the environment? How necessary is it? What are the alternatives to its use?

If the pesticide is approved, the EPA establishes a tolerance level for its presence in foods, well below the level at which it could cause any conceivable harm. Tolerance regulations also state the specific crops to which each pesticide can be applied. If a pesticide is misused, growers risk fines, lawsuits, and destruction of their crops.

Once tolerances are set, the FDA enforces them by monitoring foods and livestock feeds for the presence of pesticides. Over the past several decades of testing, the FDA has seldom found residues above tolerance levels, so it appears that pesticides are generally used according to regulations. Minimal pesticide use means lower costs for growers. In addition to costs, many farmers are also concerned about the environment, the quality of their farmland, and a safe food supply. Where violations are found, they are usually due to unusual weather conditions, use of unapproved pesticides, or misuse—for example, application of a particular pesticide to a crop for which it has not been approved.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**Pesticides from Other Countries** A substantial and increasing amount of the fruits and vegetables consumed in the United States are imported from other countries. These countries have their own pesticide regulations—some more, and others less, stringent than those in the United States. To export into the United States, countries are required to comply with US pesticide tolerance limits, but FDA testing of imported produce is fairly limited.[21] Consequently, the extent to which US consumers are exposed to elevated levels of pesticide residues from imported foods compared with domestic crops is relatively unknown.

## Monitoring Pesticides

The FDA collects and analyzes samples of both domestic and imported foods. If the agency finds samples in violation of regulations, it can seize the products or order them destroyed. Individual states also scan for pesticides (as well as for industrial chemicals) and provide information to the FDA.

**Food in the Fields** In addition to its ongoing surveillance, the FDA conducts focused sampling to determine the presence of particular pesticides in specific crops. For example, the agency might search for aldicarb in potatoes, captan in cherries, and diaminozide (the chemical name for Alar) in apples, among others.

**Food on the Plate** In addition to monitoring crops in the field for pesticides, the FDA also monitors people's actual intakes. The agency conducts the Total Diet Study (sometimes called the "Market Basket Survey") to estimate the dietary intakes of pesticide residues by eight age and gender groups from infants to senior citizens. Four times a year, FDA surveyors buy almost 300 foods from US grocery stores, each time in several cities. They prepare the foods table ready and then analyze them not only for pesticides, but also for essential minerals, industrial chemicals, **heavy metals**, and radioactive materials. In all, the survey reports on more than 6000 samples a year, including samples imported from 100 countries. Most heavily sampled are fresh vegetables, fruits, and dairy products.

The Total Diet Study provides a direct estimate of the amounts of pesticide residues that remain in foods as they are usually eaten—after they have been washed, peeled, and cooked. Analyses reveal that almost all samples fall well below the amounts considered acceptable. The amount considered acceptable is "the daily intake of a chemical, which, if ingested over a lifetime, appears to be without appreciable risk." *Without appreciable risk* means "practical certainty that injury will not result even after a lifetime of exposure." All in all, these findings confirm the safety of the US food supply.

## Consumer Concerns

Despite these reassuring reports, consumers still worry that food monitoring may not be adequate. For one thing, manufacturers develop new pesticides all the time. For another, as described earlier, other countries use different pesticides and follow less stringent guidelines. For still another, although US regulations may protect crops adequately, they may not necessarily protect the environment or the people who work in the fields. Concerns over poisoning of soil, waterways, wildlife, and workers may well be valid. In addition to harming workers, occupational exposure to pesticides is associated with brain tumors in their children.[22]

The FDA does not sample *all* food shipments or test for *all* pesticides in each sample. In fact, the FDA inspects only about 1 percent of the food that enters the United States. The FDA is a *monitoring* agency, and as such, it cannot, nor can it be expected to, guarantee 100 percent safety in the food supply. Instead, it sets standards so that substances do not become a hazard, checks enough samples to adequately assess average food safety, and acts promptly when problems or suspicions arise.

**Minimizing Risks** Whether consumers ingest pesticide residues depends on a number of factors. How much of a given food does the consumer eat? What pesticide was used on it? How much was used? How long ago was the food last sprayed? Did environmental conditions promote pest growth or pesticide breakdown? How well was the produce washed? Was it peeled or cooked? With so

© Istockphoto.com/Rich Legg

Washing fresh fruits and vegetables removes most, if not all, of the pesticide residues that might have been present.

**heavy metals:** mineral ions such as mercury or lead, so called because of their relatively high atomic weight; many heavy metals are poisonous.

**TABLE 19-3 Tips to Minimize Pesticide Residues and Bacteria Contamination**

| When Shopping for Foods |
|---|
| • Select fruits and vegetables that do not have holes.<br>• Select a variety of foods to minimize exposure to any one pesticide.<br>• Consider buying certified organic foods when shopping for produce most likely to be contaminated (see Table 19-4). |
| **When Preparing Foods** |
| • Wash your hands for 20 seconds with warm water and soap before and after preparing foods.<br>• Trim the fat from meat, and remove the skin from poultry and fish; discard fats and oils in broths and pan drippings (pesticide residues concentrate in the animal's fat).<br>• Wash fresh produce in warm running water, gently rub soft produce or use a scrub brush on firm produce, and rinse thoroughly.<br>• Use a knife to peel an orange and grapefruit; do not bite into the peel.<br>• Discard the outer leaves of leafy vegetables such as cabbage and lettuce.<br>• Cut away damaged or bruised areas.<br>• Wash fruits and vegetables before peeling to avoid transferring dirt and bacteria from the knife onto the produce. Peel waxed fruits and vegetables; waxes don't wash off and can seal in pesticide residues.<br>• Peel vegetables such as carrots and fruits such as apples when possible (peeling removes dirt, bacteria, and pesticides that remain in or on the peel, but also removes fibers, vitamins, and minerals). |

© Cengage Learning

many factors, consumers cannot know for sure whether pesticide residues remain on foods, but they can minimize their risks by following the guidelines offered in Table 19-3; washing, peeling, and cooking fruits and vegetables reduces pesticide residue levels.[23] The food supply is protected well enough that consumers who take these precautions can feel secure that the foods they eat are safe.

**Alternatives to Pesticides** The use of pesticides has helped to generate higher crop yields that feed the world and protect against diseases transmitted by insects. Still, many consumers are leery. To feed a nation while using fewer pesticides requires creative farming methods. Highlight 19 describes how scientists can genetically alter plants to enhance their production of natural pesticides, and Chapter 20 presents alternative, or sustainable, agriculture methods. These methods include such practices as rotating crops, releasing organisms into fields to destroy pests, and planting nonfood crops nearby to kill pests or attract them away from the food crops. For example, releasing sterile male fruit flies into orchards helps to curb the population growth of these pests; some flowers, such as marigolds, release natural insecticides and are often planted near crops such as tomatoes. Such alternative farming methods are more labor-intensive and may produce smaller yields than conventional methods, at least initially. Over time, though, by eliminating expensive pesticides, fertilizers, and fuels, these alternatives may actually cut costs more than they cut yields.

**Organically Grown Crops** Alternative methods are especially useful for farmers who want to produce and market **organic** crops that are grown and processed according to USDA regulations defining the use of synthetic fertilizers, herbicides, insecticides, fungicides, preservatives, and other chemical ingredients. Similarly, meat, poultry, eggs, and dairy products may be called organic if the livestock has been raised according to USDA regulations defining the grazing conditions and the use of organic feed, hormones, and antibiotics. In addition, producers may *not* claim products are organic if they have been irradiated, genetically engineered, or grown with fertilizer made from sewer sludge. Figure 19-7 shows examples of food labels for products using organic ingredients.

**organic:** in agriculture, crops grown and processed according to USDA regulations defining the use of fertilizers, herbicides, insecticides, fungicides, preservatives, and other chemical ingredients.

Neil Holmes/Holmes Garden Photos/Alamy

People can grow organic crops when their gardens or farms are relatively small.

Most organic foods are marked as such, but consumers can also determine whether fruits and vegetables are organic by reading the product code on produce stickers. Codes for conventionally grown produce are four digits. Regular bananas, for example, have the code 4011. Codes for organic produce are five digits and begin with 9. (Thus the product code for organic bananas is 94011.) Codes for genetically modified produce are also five digits and begin with 8. (Genetically modified bananas are given the product code 84011.)

Consumers spend more than $25 billion a year on organic foods. Reasons for buying organic include avoiding pesticides, benefiting the environment, protecting animals, improving worker safety, and obtaining safer and more nutritious foods.

## > FIGURE 19-7 Food Labels for Organic Products

Source: United States Department of Agriculture

Organic foods that have met USDA standards may use this seal on their labels.

Foods made with 100 percent organic ingredients may claim "100% organic" and use the seal.

Foods made with at least 95 percent organic ingredients may claim "organic" and use the seal.

Foods made with at least 70 percent organic ingredients may list up to three of those ingredients on the front panel.

Foods made with less than 70 percent organic ingredients may list them on the side panel, but cannot make any claims on the front.

Eating organic foods does reduce exposure to pesticide residues.[24] In as little as five days, eating organic foods can reduce urinary pesticide metabolites to nondetectable levels; this relatively simple and quick way to reduce pesticide exposure may be especially valuable to children.[25] Each year, an environmental advocacy group publishes a list of the most popular fruits and vegetables that are most and least likely to have pesticide residues (see Table 19-4).[26] The suggestion is that because pesticide residues in conventionally grown foods are higher than in organic foods, consumers may want to pay attention to these lists when considering whether to make organic purchases. Some research contradicts such advice and indicates that the pesticide residues on even the most contaminated fruits and vegetables pose negligible risks and that using organic products does not reduce risks.[27] Whether buying conventionally grown or organically grown produce, consumers benefit most from eating at least five servings of fruits and vegetables daily.

Are organic foods nutritionally superior to conventional foods? For the most part, nutrient differences are relatively small and within the range that normally occurs in crops. Some research suggests that organic crops may have a longer shelf life and better flavor, perhaps due to differences in soil type, soil nutrients, or environmental conditions.[28] Limited research suggests that foods produced organically have increased amounts of some phytochemicals.[29] Researchers disagree about whether eating organic foods offers any real health benefits.[30]

Interestingly, organic has intense meanings for many consumers. In one study, participants tasting foods, such as two yogurts, rated the one labeled "organic" as more nutritious, lower in fat, and worth more money and the one labeled "regular" as more flavorful—even though both yogurts were organic and identical (only their labels differed).[31]

**› REVIEW IT** Debate the risks and benefits of using pesticides.

Pesticides can safely improve crop yields when used according to regulations, but they can also be hazardous when used inappropriately. The FDA tests both domestic and imported foods for pesticide residues in the fields and in market basket surveys of foods prepared table ready. Consumers can minimize their ingestion of pesticide residues on foods by following the suggestions in Table 19-3. Alternative farming methods may allow farmers to grow crops with few or no pesticides.

© Polara Studios, Inc.

Many consumers are willing to pay a little more for organic produce.

### TABLE 19-4 Most and Least Pesticide-Contaminated Fruits and Vegetables

| Most Contaminated | Least Contaminated |
|---|---|
| Apples | Corn |
| Strawberries | Onions |
| Grapes | Pineapples |
| Celery | Avocados |
| Peaches | Cabbage |
| Spinach | Peas |
| Bell peppers | Papayas |
| Nectarines (imported) | Mangoes |
| Cucumbers | Asparagus |
| Potatoes | Eggplant |
| Cherry tomatoes | Kiwi |
| Hot peppers | Grapefruit |
| Blueberries | Cantaloupe |
| Lettuce | Sweet potatoes |
| Snap peas (imported) | Mushrooms |

NOTE: These fruits and vegetables are ranked in order of their pesticide load.

# 19.6 Food Additives

› **LEARN IT** List common food additives, their purposes, and examples.

**Additives** confer many benefits on foods. Some reduce the risk of foodborne illness (for example, nitrites used in curing meat prevent poisoning from the botulinum toxin). Others enhance nutrient quality (as in vitamin D–fortified milk). Most additives are **preservatives** that help prevent spoilage during the time it takes to deliver foods long distances to grocery stores and then to kitchens. Some additives simply make foods look and taste good.

© Polara Studios, Inc.

Without additives, bread would quickly get moldy, and salad dressing would go rancid.

Intentional additives are put into foods on purpose, whereas indirect additives may get in unintentionally before or during processing. This discussion begins with the regulations that govern additives, then presents intentional additives class by class, and finally says a word about indirect additives.

## Regulations Governing Additives

The FDA's regulation of additives focuses primarily on safety.[32] To receive permission to use a new additive in food products, a manufacturer must satisfy the FDA that the additive is:

- Effective (it does what it is supposed to do)
- Detectable and measurable in the final food product
- Safe (when fed in large doses to animals under strictly controlled conditions, it causes no cancer, birth defects, or other injury)

On approving an additive's use, the FDA writes a regulation stating in what amounts and in what foods the additive may be used. No additive receives permanent approval, and all must undergo periodic review.

### The GRAS List

Many familiar substances are exempted from complying with the FDA's approval process because they are **generally recognized as safe (GRAS),** based either on their extensive, long-term use in foods or on current scientific evidence. Several hundred substances are on the GRAS list, including such items as salt, sugar, caffeine, and many spices. Whenever substantial scientific evidence or public outcry has questioned the safety of any substance on the GRAS list, it has been reevaluated. If a legitimate question has been raised about a substance, it has been removed or reclassified. Meanwhile, the entire GRAS list is subjected to ongoing review.

### The Delaney Clause

One risk that the US law on additives refuses to tolerate at any level is the risk of cancer. To remain on the GRAS list, an additive must not have been found to be a **carcinogen** in any test on animals or human beings. The **Delaney Clause** (the part of the law that states this criterion) is uncompromising in addressing carcinogens in foods and drugs; in fact, it has been under fire for many years for being too strict and inflexible.

The Delaney Clause is best understood as a product of a different historical era. It was adopted decades ago, at a time when scientists knew less about the relationships between carcinogens and cancer development. At that time, most substances were detectable in foods only in relatively large amounts, such as parts per thousand. Today, scientific understanding of cancer has progressed, and technology has advanced so that carcinogens in foods can be detected even when they are present only in parts per billion or even per trillion. (For perspective, one part per trillion is equivalent to about 1 inch in 16 million miles; or 1 second in 32,000 years.) Earlier, "zero risk" may have seemed attainable, but today we know it is not: all substances, no matter how pure, can be shown to be contaminated at some level with one carcinogen or another. For these reasons, the FDA prefers to deem additives (and pesticides and other contaminants) safe if lifetime use presents no more than a one-in-a-million risk of cancer to human beings. Thus, instead of the "zero-risk" policy of the Delaney Clause, the FDA uses a "negligible-risk" standard, sometimes referred to as the ***de minimis* rule.**

### Margin of Safety

Whatever risk level is permitted, actual risks must be determined by research. To determine risks posed by an additive, researchers feed test

**additives:** substances not normally consumed as foods but added to food either intentionally or by accident.

**preservatives:** antimicrobial agents, antioxidants, and other additives that retard spoilage or maintain desired qualities, such as softness in baked goods.

**generally recognized as safe (GRAS):** food additives that have long been in use and are believed to be safe. First established by the FDA in 1958, the GRAS list is subject to revision as new facts become known.

**carcinogen:** a substance that can cause cancer; the adjective is *carcinogenic*.

**Delaney Clause:** a 1958 amendment to the Food, Drugs, and Cosmetic Act of 1938, named after Congressman James Delaney of New York that states that no substance known to cause cancer in animals or human beings at any dose level shall be added to foods.

***de minimis* rule:** a guideline that defines risk as a cancer rate of less than one cancer per million people exposed to a contaminant over a 70-year lifetime.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

animals the additive at several concentrations throughout their lives. The additive is then permitted in foods in amounts 100 times *below* the lowest level that is found to cause any harmful effect—that is, at a 1/100 **margin of safety.** In many foods, *naturally* occurring substances occur with narrower margins of safety. Even nutrients pose risks at dose levels above those recommended and normally consumed: for older adults, the RDA for vitamin D is only 1/5 of the Upper Level.

**Risks versus Benefits** Of course, additives would not be added to foods if they only presented risks. In general, additives are used in foods when they offer benefits that outweigh the risks or make the risks worth taking. No amount of risk may be worth taking in the case of color additives that only enhance appearance but do not improve health or safety. In contrast, the FDA finds it worth taking the small risks associated with the use of nitrites on meat products, for example, because nitrites inhibit the formation of the deadly botulinum toxin. The choice involves a compromise between the risks of using additives and the risks of doing without them.

It is the manufacturers' responsibility to use only the amounts of additives that are necessary to achieve the needed effect, and no more. The FDA also requires that additives *not* be used:

- To disguise faulty or inferior products
- To deceive the consumer
- If use would significantly destroy nutrients
- If effects can be achieved by economical, sound manufacturing processes instead

## Intentional Food Additives

**Intentional food additives** are added to foods to give them some desirable characteristic: resistance to spoilage, color, flavor, texture, stability, or nutritional value. Some food additives derive from natural sources (for example, beets may provide food coloring); others are not found in nature, but can be synthesized as artificial ingredients. In addition, some natural ingredients can also be synthesized as artificial ingredients (for example, vitamin C may be derived from an orange or manufactured in a laboratory). All additives—whether natural or artificial—are subject to the same FDA safety standards. This section describes additives people most often ask about.

Foods can go bad in many ways. One way is by becoming contaminated with microbes that cause foodborne illnesses, a hazard that justifies the use of antimicrobial agents.

**Antimicrobials** The most widely used antimicrobial agents are ordinary salt and sugar. Salt has been used throughout history to preserve meat and fish; sugar serves the same purpose in canned and frozen fruits and in jams and jellies. Both exert their protective effect primarily by capturing water and making it unavailable to microbes.

Other antimicrobial agents, the **nitrites,** are added to foods for three main purposes: to preserve color, especially the pink color of hot dogs and other cured meats; to enhance flavor by inhibiting rancidity, especially in cured meats and poultry; and to protect against bacterial growth. In amounts smaller than those needed to confer color, nitrites prevent the growth of the bacteria that produce the deadly botulinum toxin.

Nitrites clearly prevent food spoilage and bacterial contamination, but their use has been controversial. During the curing process and in the human body, nitrites can be converted to **nitrosamines.** Some nitrosamines are known to cause cancer in animals, but evidence is lacking in humans.[33] In fact, limited evidence suggests that nitrites may actually be beneficial to human health.[34] The USDA and FDA regulate and monitor the use of nitrites in foods and beverages.

Another food additive used in ready-to-eat meat and poultry products—such as sausages, hot dogs, and bologna—is a mixture of viruses known as **bacteriophages.** Bacteriophages destroy the bacterium *Listeria monocytogenes,* thus protecting consumers from the potentially life-threatening foodborne illness listeriosis. These additives are included in the ingredients list on food labels as a "bacteriophage preparation."

© Polara Studios, Inc.

Both salt and sugar act as preservatives by extracting water from food; microbes cannot grow without water.

**margin of safety:** when speaking of food additives, a zone between the concentration normally used and that at which a hazard exists. For common table salt, for example, the margin of safety is 1/5 (five times the amount normally used would be hazardous).

**intentional food additives:** additives intentionally added to foods, such as nutrients, colors, and preservatives.

**nitrites** (NYE-trites): salts added to food to prevent botulism. One example is sodium nitrite, which is used to preserve meats.

**nitrosamines** (nye-TROHS-uh-meens): derivatives of nitrites that may be formed in the stomach when nitrites combine with amines. Nitrosamines are carcinogenic in animals.

**bacteriophages** (bak-TIR-ee-oh-fayjz): viruses that infect bacteria.

- **bacterio** = bacteria
- **phage** = eat

© iStockphoto.com/Saturated

Color additives not only make foods attractive, but they identify flavors as well. Everyone agrees that yellow jellybeans should taste lemony and black ones should taste like licorice.

**Antioxidants** Another way food can go bad is by exposure to oxygen (oxidation). Often, these changes involve no hazard to health, but they damage the food's appearance, flavor, and nutritional quality. Oxidation is easy to detect when sliced apples or potatoes turn brown or when oil goes rancid. Antioxidants prevent these reactions. Among the antioxidants approved for use in foods are vitamin C (ascorbate) and vitamin E (tocopherol).

Another group of antioxidants, the **sulfites,** cost less than the vitamins. Sulfites prevent oxidation in many processed foods and alcoholic beverages (especially wine). Because some people experience adverse reactions, the FDA prohibits sulfite use on foods intended to be consumed raw, with the exception of grapes, and requires foods and drugs that contain sulfite additives to declare it on their labels. For most people, sulfites pose no hazard in the amounts used in products, but there is one more consideration—sulfites destroy the B vitamin thiamin. For this reason, the FDA prohibits their use in foods that are important sources of the vitamin, such as enriched grain products.

Two other antioxidants in wide use are **BHA** and **BHT,** which prevent rancidity in baked goods and snack foods. Several tests have shown that animals fed large amounts of BHT develop *less* cancer when exposed to carcinogens and live *longer* than controls. Apparently, BHT protects against cancer through its antioxidant effect, which is similar to that of the antioxidant nutrients. The amount of BHT ingested daily from the US diet, however, contributes little to the body's antioxidant defense system. A caution: at intakes higher than those that protect against cancer, BHT *causes* cancer. Vitamins E and C remain the most important dietary antioxidants to strengthen defenses against cancer. (See Highlight 11 for a full discussion.)

**Colors** Only a few artificial colors remain on the FDA's list of additives approved for use in foods—a highly select group that has survived considerable testing. Colors derived from the natural pigments of plants must meet standards of purity and safety, just as artificial colors do. Examples of natural pigments commonly used by the food industry are the caramel that tints cola beverages and baked goods and the carotenoids that color margarine, cheeses, and pastas. Carotenoids are also added to the feed for farm-raised salmon, which deepens the pink flesh color.

**Flavors** Myriad natural flavors, artificial flavors, and flavor enhancers are among the most often used food additives. Many foods taste delicious because manufacturers have added the natural flavors of spices, herbs, essential oils, fruits, and fruit juices. Some spices, notably those used in Mediterranean cooking, provide antioxidant protection as well as flavors. Often, natural flavors are used in combination with artificial flavors.

One of the best-known flavor enhancers is **monosodium glutamate,** or **MSG**—a sodium salt of the amino acid glutamic acid. MSG is used widely in a number of foods, especially Asian foods, canned vegetables, soups, and processed meats. Besides enhancing the well-known sweet, salty, bitter, and sour tastes, MSG itself may possess a unique flavor. Adverse reactions to MSG—known as the **MSG symptom complex**—may occur in people with asthma and in sensitive individuals who consume large amounts of MSG, especially on an empty stomach. Otherwise, MSG is considered safe for adults. It is not allowed in foods designed for infants, however. Food labels require ingredient lists to itemize all additives, including MSG.

**Sugar Alternatives** The sugar alternatives, introduced in Chapter 4, are among the most widely used artificial flavor additives. Table 4-8 (p. 119) provides a summary of alternative sweeteners. This section presents safety issues surrounding a few of the most controversial ones.

Questions about the safety of the artificial sweetener saccharin surfaced in 1977, when experiments suggested that large doses of saccharin (equivalent to hundreds of cans of diet soda daily for a lifetime) increased the risk of bladder cancer in rats. As a result, the FDA proposed banning saccharin. Public outcry in favor of saccharin was so loud, however, that Congress imposed a moratorium on the ban while additional safety studies were conducted. Products containing

**sulfites:** salts containing sulfur that are added to foods to prevent spoilage.

**BHA** and **BHT:** preservatives commonly used to slow the development of off-flavors, odors, and color changes caused by oxidation. BHA is butylated hydroxyanisole, and BHT is butylated hydroxytoluene.

**monosodium glutamate (MSG):** a sodium salt of the amino acid glutamic acid commonly used as a flavor enhancer. The FDA classifies MSG as a "generally recognized as safe" ingredient.

**MSG symptom complex:** an acute, temporary intolerance reaction that may occur after the ingestion of the additive MSG (monosodium glutamate). Symptoms include burning sensations, chest and facial flushing and pain, and throbbing headaches.

saccharin were required to carry a warning label until 2001, when studies concluded that saccharin did not cause cancer in humans. Common sense dictates that consuming large amounts of any substance is probably not wise, but at current, moderate intake levels, saccharin appears to be safe for most people.

Aspartame—a simple chemical compound made of two amino acids (phenylalanine and aspartic acid) and a methyl group ($CH_3$)—must bear a warning label for people with the inherited disease phenylketonuria (PKU). People with PKU are unable to dispose of any excess phenylalanine. The accumulation of phenylalanine and its by-products is toxic to the developing nervous system, causing irreversible brain damage. The little extra phenylalanine from aspartame poses only a small risk, even in heavy aspartame users, but people with PKU need to get all their required phenylalanine from protein- and nutrient-rich foods instead of from an artificial sweetener.

During metabolism in the body, the methyl group of aspartame temporarily becomes methyl alcohol (methanol)—a potentially toxic compound. This breakdown also occurs in aspartame-sweetened beverages when they are stored at warm temperatures over time. The amount of methanol produced may be safe to consume, but a person may not want to, considering that the beverage has lost its sweetness. In the body, enzymes convert methanol to formaldehyde, another toxic compound. Finally, formaldehyde is broken down to carbon dioxide. Before aspartame could be approved, the quantities of these products generated during metabolism had to be determined, and they were found to fall below the threshold at which they would cause harm. In fact, ounce for ounce, tomato juice yields six times as much methanol as a diet soda.

The amount of artificial sweetener considered safe is called the **Acceptable Daily Intake (ADI)** and represents the amount of consumption that, if maintained every day throughout a person's life, would still be considered safe by a wide margin. It usually reflects an amount 100 times less than the level at which no observed effects occur in animal research studies. The ADI for aspartame, for example, is 50 milligrams per kilogram of body weight. For a 150-pound adult, the ADI is equivalent to 97 packets of Equal or 20 cans of soft drinks sweetened only with aspartame every day for a lifetime. Most people who use aspartame consume less than 5 milligrams per kilogram of body weight per day. Table 4-8 (p. 119) includes the ADI for approved sweeteners.

**Texture and Stability** Some additives help to maintain a desirable consistency in foods. Emulsifiers keep mayonnaise stable, control crystallization in syrups, disperse spices in salad dressings, and allow powdered coffee creamer to dissolve easily. Gums are added to thicken foods and help form gels. Yeast may be added to provide leavening, and bicarbonates and acids may be used to control acidity.

**Nutrients** As mentioned earlier, nutrients are sometimes added as antioxidants (vitamins C and E) or for color (beta-carotene and other carotenoids). In addition, manufacturers sometimes add nutrients to fortify or maintain the nutritional quality of foods. Included among nutrient additives are the five nutrients added to grains (thiamin, riboflavin, niacin, folate, and iron), the iodine added to salt, the vitamins A and D added to milk, and the nutrients added to fortified breakfast cereals. Appropriate uses of nutrient additives are to:

- Correct dietary deficiencies known to result in diseases
- Restore nutrients to levels found in the food before storage, handling, and processing
- Balance the vitamin, mineral, and protein contents of a food in proportion to the energy content
- Correct nutritional inferiority in a food that replaces a more nutritious traditional food

A nutrient-poor food with nutrients added may appear to be nutrient-rich, but it is rich only in those nutrients chosen for addition. Table 19-5 (p. 650) summarizes intentional food additives.

**Acceptable Daily Intake (ADI):** the estimated amount of a sweetener that individuals can safely consume each day over the course of a lifetime without adverse effect.

**TABLE 19-5 Intentional Food Additives**

| Food Additive | Purpose | Common Examples |
|---|---|---|
| Antimicrobials | Prevent food spoilage from microorganisms | Salt, sugar, nitrites and nitrates (such as sodium nitrate), bacteriophages |
| Antioxidants | Prevent oxidative changes in color, flavor, or texture and delay rancidity and other damage to foods caused by oxygen | Vitamin C (erythorbic acid, sodium ascorbate), vitamin E (tocopherol), sulfites (sulfur dioxide, sodium sulfite, sodium bisulfite, potassium bisulfite, sodium metabisulfite, potassium metabisulfite), BHA and BHT |
| Colors | Enhance appearance | Artificial: indigotine, erythrosine, tartrazine<br>Natural: annatto (yellow), caramel (yellowish brown), carotenoids (yellowish orange), dehydrated beets (reddish brown), grape skins (red, green) |
| Flavors | Enhance taste | Salt, sugar, spices, artificial sweeteners, MSG |
| Emulsifiers and gums | Thicken, stabilize, or otherwise improve consistency and texture | Emulsifiers: lecithin, alginates, mono- and diglycerides<br>Gums: agar, alginates, carrageenan, guar, locust bean, psyllium, pectin, xanthan gum, gum arabic, cellulose derivatives |
| Nutrients (vitamins and minerals) | Improve the nutritive value by replacing vitamins and minerals lost in processing (enrichment) or adding vitamins or minerals that may be lacking in the diet (fortification) | Thiamin, niacin, riboflavin, folate, iron (in grain products); iodine (in salt); vitamins A and D (in milk); vitamin C and calcium (in fruit drinks); vitamin $B_{12}$ (in vegetarian foods) |

## Indirect Food Additives

**Indirect** or **incidental additives** find their way into foods during harvesting, production, processing, storage, or packaging. Incidental additives may include tiny bits of plastic, glass, paper, tin, and other substances from packages as well as chemicals from processing, such as the solvent used to decaffeinate coffee. The following paragraphs discuss six different types of indirect additives that sometimes make headline news.

**Acrylamide** Raw potatoes don't have it, but french fries do—acrylamide, a compound that forms when carbohydrate-rich foods containing sugars and the amino acid asparagine are cooked at high temperatures. Apparently, acrylamide has been in foods ever since we started baking, frying, and roasting, but only recently has its presence been analyzed. At high doses, acrylamide causes cancer in animals and nerve damage in people. As such, scientists classify it as both a carcinogen and a **genotoxicant.** Quantities commonly found in foods such as french fries, potato chips, breakfast cereals, and cookies, however, appear to be well below the amounts that cause such damage. The FDA is investigating how acrylamide is formed in foods, how its formation can be limited, and whether its presence is harmful.

**Food Packaging** The FDA ensures the safety of food packaging and assesses whether packaging materials might migrate into foods. These materials include coatings on can interiors, plastics, papers, and sealants.

Some microwave products are sold in "active packaging" that helps to cook the food; for example, pizzas are often heated on a metalized film laminated to paperboard. This film absorbs the microwave energy in the oven and reaches temperatures as high as 500°F. At such temperatures, packaging components migrate into the food. For this reason, manufacturers must perform specific tests to determine whether materials are migrating into foods. If they are, their safety must be confirmed by strict procedures similar to those governing intentional additives.

Most microwave products are sold in "passive packaging" that is transparent to microwaves and simply holds the food as it cooks. These containers don't get much hotter than the foods, but materials still migrate at high temperatures. Consumers should not reuse these containers in the microwave oven. Instead they should use only glass or ceramic containers labeled as microwave safe; tiny air bubbles in some glass may expand when microwaved, causing the glass to break and glazes on some ceramics to leach, contaminating the food. In the United States, these ceramic containers cannot be sold without a permanent marking stating "Not for food use." Similarly, use only plastic wraps labeled as microwave-safe. Avoid using disposable styrofoam or plastic containers such as those used for carryout or margarine.

Similarly, a chemical known as bisphenol A (BPA) can leach from hard-plastic bottles and coatings of some food cans into food and beverages. The FDA has some concern about the potential health effects of BPA and is taking steps to

**indirect** or **incidental additives:** substances that can get into food as a result of contact during growing, processing, packaging, storing, cooking, or some other stage before the foods are consumed; sometimes called *accidental additives.*

**genotoxicant:** a substance that mutates or damages genetic material.

reduce exposure in the food supply, including banning its use in baby bottles and sippy cups.[35] Consumers who want to limit their exposure to BPA should know that plastic containers marked with recycle codes 3 or 7 may be made with BPA. In addition, consumers should not expose plastic containers made with BPA to heat, including hot liquids, microwaves, or dishwashers.

To limit contamination and waste from packaging, some manufacturers are creating food wrappers and containers that are edible and soluble. For example, coatings similar to those used to cover pills might encase powdered cocoa; when dropped into hot water, the casing dissolves.

**Dioxins** Coffee filters, milk cartons, paper plates, and frozen food packages, if made from bleached paper, can contaminate foods with small quantities of **dioxins**—compounds formed during chlorine treatment of wood pulp during paper manufacture. Dioxin contamination of foods from such products appears only in trace quantities—in the parts-per-trillion range (recall, for perspective, that one part per trillion is equal to 1 second in 32,000 years). Such levels appear to present no health risks to people, but scientists recognize that dioxins are extremely toxic and are likely to cause cancer in humans. Accordingly, the paper industry has reduced its use of chlorine to cut dioxin exposure. In the meantime, the FDA has concluded that drinking milk from bleached-paper cartons presents no health hazard. Contrary to e-mail warnings, plastics do not yield dioxins when broken down, and dioxins are not released from plastic wrap when microwaved. Human exposure to dioxins comes primarily from foods such as beef, milk products, pork, fish, and shellfish.

**Decaffeinated Coffee** Many consumers have tried to eliminate caffeine from their diets by selecting decaffeinated coffee. To remove caffeine from coffee beans, manufacturers often use methylene chloride in a process that leaves traces of the chemical in the final product. The FDA estimates that the average cup of coffee decaffeinated this way contains about 0.1 part per million of methylene chloride, which seems to pose no significant threat. A person drinking decaffeinated coffee containing 100 times as much methylene chloride every day for a lifetime has a one-in-a-million chance of developing cancer from it. People are exposed to much more methylene chloride from other sources such as hair sprays and paint-stripping solutions. Still, some consumers prefer either to return to caffeine or to select coffee decaffeinated in another way, perhaps by steam. Unfortunately, manufacturers are not required to state on their labels the type of decaffeination process used in their products. Many labels provide consumer-information telephone numbers for those who have such questions.

**Hormones** Hormones are a unique type of incidental additive in that their use is intentional, but their presence in the final food product is not. The FDA has approved about a dozen hormones for use in food-producing animals, and the USDA has established limits for residues allowed in meat products.

Some ranchers in the United States treat cattle with **bovine growth hormone (BGH).** All cows make BGH naturally, but when given higher doses, animals produce leaner meats, and dairy cows produce more milk. Scientists can genetically alter bacteria to produce BGH, which allows laboratories to harvest huge quantities of the hormone and sell it to farmers as a drug.

Indeed, traces of BGH do remain in the meat and milk of both hormone-treated and untreated cows. BGH residues have not been tested for safety in human beings because residues of the natural hormone have always been present in milk and meat, and the amount found in treated cows is within the range that can occur naturally. Furthermore, BGH, being a peptide hormone, is denatured by the heat used in processing milk and cooking meat, and it is also digested by enzymes in the GI tract. The FDA has determined that BGH absorption does not occur in humans and that BGH is biologically inactive in humans even if injected. According to the National Institutes of Health, "As currently used in the United States, meat and milk from [hormone] treated cows are as safe as those from untreated cows." Whether hormones that have passed through the animals into feces and then contaminated the soil and water interfere with plants or animals in the environment remains controversial.

**dioxins** (dye-OCK-sins): a class of chemical pollutants created as by-products of chemical manufacturing, incineration, chlorine bleaching of paper pulp, and other industrial processes. Dioxins persist in the environment and accumulate in the food chain.

**bovine growth hormone (BGH)**: a hormone produced naturally in the pituitary gland of a cow that promotes growth and milk production; now produced for agricultural use by bacteria.

- **bovine** = of cattle

**Antibiotics** Like hormones, antibiotics are also intentionally given to livestock, and residues may remain in the meats and milks. Consequently, people consuming these foods receive tiny doses of antibiotics regularly, and those with sensitivity to antibiotics may suffer allergic reactions. To minimize drug residues in foods, the FDA requires a specified time between the time of medication and the time of slaughter to allow for drug metabolism and excretion.

Of greater concern to the public's health is the widespread use of antibiotics in food animal production and the consequent development of antibiotic resistance.[36] Physicians and veterinarians use an estimated 5 million pounds of antibiotics to treat infections in people and animals, but farmers add five times as much to livestock feed to enhance growth. Not surprisingly, meat from these animals contains resistant bacteria. Such indiscriminate use of antibiotics can be catastrophic to the treatment of disease in human beings. Antibiotics are less effective in treating people who are infected with resistant bacteria. The FDA continues to monitor the use of antibiotics in the food industry with the goal of ensuring that antibiotics remain effective in treating human disease. Antibiotic resistance is immediately and significantly reduced when conventional farms remove antibiotics in their transition to becoming organic farms.[37]

**› REVIEW IT** List common food additives, their purposes, and examples.

On the whole, the benefits of food additives seem to justify the risks associated with their use. The FDA regulates the use of the intentional additives (summarized in Table 19-5, p. 650). Incidental additives sometimes get into foods during processing, but rarely present a hazard, although some processes such as treating livestock with hormones and antibiotics raise consumer concerns.

## 19.7 Consumer Concerns about Water

**› LEARN IT** Discuss consumer concerns about water.

Foods are not alone in transmitting diseases; water is guilty too.[38] In fact, *Cryptosporidium* and *Cyclospora*, commonly found in fresh fruits and vegetables, and *Vibrio vulnificus*, found in raw oysters, are commonly transmitted through contaminated water. In addition to microorganisms, water may contain many of the same impurities that foods do: environmental contaminants, pesticides, and additives such as chlorine used to kill pathogenic microorganisms and fluoride used to protect against dental caries. A glass of "water" is more than just $H_2O$. This discussion examines the sources of drinking water, harmful contaminants, and ways to ensure water safety.

### Sources of Drinking Water

Water that is suitable for drinking is called **potable.** Only 1 percent of all the earth's water is potable. Drinking water comes from two sources—surface water and groundwater. In the United States, each source supplies water for about half of the population.

Most major cities obtain their drinking water from surface water—the water in lakes, rivers, and reservoirs. Surface water is readily contaminated because it is directly exposed to acid rain, runoff from highways and urban areas, pesticide runoff from agricultural areas, and industrial wastes that are dumped directly into it. Surface water contamination is reversible, however, because fresh rain constantly replaces the water. It is also cleansed to some degree by aeration, sunlight, and plants and microorganisms that live in it.

Groundwater is the water in underground aquifers—rock formations that are saturated with and yield usable water. People who live in rural areas rely mostly on groundwater pumped up from private wells. Groundwater is contaminated more slowly than surface water, but also more permanently. Contaminants deposited on the ground migrate slowly through the soil before reaching groundwater. Once there, the contaminants break down less rapidly than in surface water because of the lack of aeration, sunlight, and aerobic microorganisms. The slow replacement of groundwater also helps contaminants remain for a long time. Groundwater is especially susceptible to contamination from hazardous waste sites, dumps and landfills,

**potable** (POH-tah-bul): suitable for drinking.

underground tanks storing gasoline and other chemicals, and improperly discarded household chemicals and solvents.

**Water Systems and Regulations** Public water systems treat water to remove contaminants that have been detected above acceptable levels. During treatment, a disinfectant (usually, chlorine) is added to kill bacteria. The addition of chlorine to public water is an important public health measure that appears to offer great benefits and small risks. On the one hand, chlorinated water has eliminated such waterborne diseases as typhoid fever, which once ravaged communities, killing thousands of people. On the other hand, it has been associated with an increase in bladder cancer and dioxin contamination of the environment. The EPA is responsible for ensuring that public water systems meet minimum standards for protecting public health.*

Even safe water may have characteristics that some consumers find unpleasant. Most of these problems reflect the mineral content of the water. For example, manganese and copper give water a metallic taste, and sulfur produces a "rotten egg" odor. Iron leaves a rusty brown stain on plumbing fixtures and laundry. Calcium and magnesium (commonly found in "hard water") build up in coffeemakers and hot water heaters. Similarly, soap is not easily rinsed away in hard water, leaving bathtubs and laundry looking dingy. For these and other reasons, some consumers have adopted alternatives to the public water system.

Joe Cornish/Dorling Kindersley/Getty Images

Clean rivers represent irreplaceable water resources.

**Home Water Treatments** To ease concerns about the quality of drinking water, some people purchase home water-treatment systems. Because the EPA does not certify or endorse these water-treatment systems, consumers must shop carefully. Manufacturers offer a variety of units for removing contaminants from drinking water. None of them removes all contaminants, and each has its own advantages and disadvantages. Choosing the right treatment unit depends on the kinds of contaminants in the water. For example, activated carbon filters are particularly effective in removing chlorine, heavy metals such as mercury, and organic contaminants from sediment. Reverse osmosis forces pressurized water through a membrane, flushing out minerals such as sodium and some microorganisms such as *Giardia*. Ozonation uses ozone gas to disinfect water. And distillation systems, which boil water and condense the steam to water, kill microorganisms but leave behind minerals such as lead. Therefore, before purchasing a home water-treatment unit, a consumer must first determine the quality of the water. In some cases, a state or county health department will test water samples or can refer the consumer to a certified laboratory. Consumers need to be aware that unscrupulous vendors may use scare tactics during home inspections to prompt sales.

**Bottled Water** Despite the higher cost, many people turn to bottled water as an alternative to tap water. Almost 10 billion gallons of bottled water are sold in the United States annually—an average of more than 30 gallons per person.[39] The FDA regulates bottled drinking water and has established quality and safety standards compatible with those set by the EPA for public water systems. In addition, all bottled waters must be processed, packaged, and labeled in accordance with FDA regulations. Water quality may vary among brands because of variations in the source water used and company practices, but bottled water is neither safer nor healthier than tap water.

As Chapter 14 discusses, some bottled waters are marketed as "enhanced water"—water that has been enhanced with sweeteners, juices, coloring, flavors, vitamins, minerals, protein, or extra oxygen. Consumers perceive these bottled waters as healthful and sales have skyrocketed.

Labels on bottled water must identify the water's source. Approximately 75 percent of bottled waters derive from protected groundwater (from springs

Realizing that fossil fuels and many gallons of water are used to create and transport plastic water bottles, concerned consumers use refillable bottles to save money and the environment.

or wells)—the same as tap water. This water is usually treated before being bottled. For example, it may be disinfected with ozone gas rather than chlorine. Ozone kills microorganisms, then disintegrates spontaneously into water and oxygen, leaving behind no toxic by-products. Other bottled waters may be treated by filtration to remove pathogens and other particles. Bottled waters may also be treated by reverse osmosis or ion exchange to remove minerals. Alternatively, the water may be distilled into a vapor and then condensed again into water, thus removing any dissolved solids. These processes allow the bottle to be labeled "purified water." Most bottled waters do not contain fluoride; consequently, they do not provide the tooth protection of fluoridated water from community public water systems.

Despite government regulations, some contamination has been detected in some bottled waters.[40] Although the amounts of most contaminants found in bottled waters are probably insignificant, consumers should be aware that bottled water is not necessarily purer than the water from their taps. In fact, some bottled waters come from the same municipal water sources as that for consumers' home taps. As a safeguard, the FDA recommends that bottled water be handled like other foods and be refrigerated after opening.

Protection of drinking water is a subject of ongoing concern and controversy. It may soon become a source of conflict between the world's nations as the population continues to grow and the renewable water supply remains constant. Estimates are that within the next 50 years, half of the world's people will not have enough clean water to meet their needs. To avert this potential calamity, we must take active steps to conserve water, clean polluted water, desalinate seawater, and curb population growth.

**› REVIEW IT** Discuss consumer concerns about water.

Like foods, water may contain infectious microorganisms, environmental contaminants, pesticide residues, and additives. The EPA monitors the safety of the public water system, but many consumers choose home water-treatment systems or bottled water instead of tap water.

As this chapter said at the start, supplying food safely to hundreds of millions of people is an incredible challenge—one that is met, for the most part, with incredible efficiency. The following chapter describes a contrasting situation—that of the food supply not reaching the people.

## Nutrition Portfolio

Practicing food safety allows you to eat a variety of foods, with little risk of foodborne illnesses.

- Review your food-handling practices and describe how effectively you wash your hands, utensils, and kitchen surfaces when preparing foods.
- Describe the steps you take to separate raw and cooked foods while storing and preparing them.
- Describe how you can ensure that you cook foods to a safe temperature and refrigerate perishable foods promptly.

Go to Diet & Wellness Plus and choose one of the days on which you tracked your diet and activity for an entire day. Select the Intake Spreadsheet report to help you answer the following questions:

- Imagine for a moment that you got a foodborne illness on this particular day. Which food would you most suspect to have contained the illness-causing organism or toxin? Why would you suspect that food more than the other foods you ate that day?

DIET & WELLNESS PLUS To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com**.

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

## Food Biotechnology

© Tony Freeman/Photo Edit

**› LEARN IT** Debate the pros and cons surrounding genetically engineered foods.

Advances in food **biotechnology** promise just about everything from the frivolous (a tear-free onion) to the profound (a hunger-free world). Already biotechnology has produced leaner meats, longer shelf lives, better nutrient composition, and greater crop yields grown with fewer pesticides. Overall, biotechnology offers numerous opportunities to overcome food shortages, improve the environment, and eliminate disease. But it also raises concerns about possible risks to the environment and human health. Critics assert that biotechnology will exacerbate world hunger, destroy the environment, and endanger health. This highlight presents some of the many issues surrounding genetically engineered foods, and the accompanying glossary defines key terms.

## The Promises of Genetic Engineering

For centuries, farmers have been selectively breeding plants and animals to shape the characteristics of their crops and livestock. They have created prettier flowers, hardier vegetables, and leaner animals. Consider the success of selectively breeding corn. Early farmers in Mexico began with a wild, native plant called teosinte (tay-oh-SEEN-tay) that bears only five or six kernels on each small spike. Many years of patient selective breeding have produced large ears filled with hundreds of plump kernels aligned in perfect formation, row after row.

Such genetic improvements, together with the use of irrigation, fertilizers, and pesticides, were responsible for more than half of the increases in US crop yields in the 20th century. Farmers still use selective breeding, but now, in the 21st century, advances in **genetic engineering** have brought rapid and dramatic changes to agriculture and food production.

Although selective breeding works, it is slow and imprecise because it involves mixing thousands of genes from two plants and hoping for the best. With genetic engineering, scientists can improve crops (or livestock) by introducing a copy of the specific gene needed to produce the desired trait. Figure H19-1 illustrates the difference. Once introduced, the selected gene acts like any other gene—it provides instructions for making a protein. The protein then determines a characteristic in the genetically modified plant or animal. In short, the process is now faster and more refined. Farmers no longer need to wait patiently for breeding to yield improved crops and animals, nor must they even respect natural lines of reproduction among species. Laboratory scientists can copy genes from one organism and insert them into almost any other organism—plant, animal, or microbe. Their work is changing not only the way farmers plant, fertilize, and harvest their crops, but also the ways the food industry processes food and consumers receive nutrients, phytochemicals, and drugs.

This wild predecessor of corn, with its sparse five or six kernels, bears little resemblance to today's large, full, sweet ears.

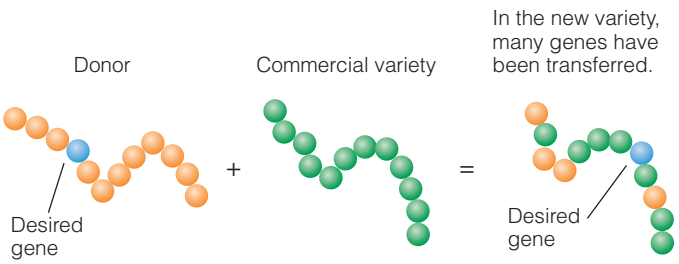
## GLOSSARY

**biotechnology:** the use of biological systems or organisms to create or modify products. Examples include the use of bacteria to make yogurt, yeast to make beer, and cross-breeding to enhance crop production.

**clone:** a genetic copy of an organism created without sexual reproduction; similar to identical twins, but born at different times.

**genetic engineering:** the use of biotechnology to modify the genetic material of living cells so that they will produce new substances or perform new functions. Foods produced via this technology are called *genetically modified (GM)* or *genetically engineered (GE) foods.*

**plant-pesticides:** pesticides made by the plants themselves.



**rennin:** an enzyme that coagulates milk; found in the gastric juice of cows, but not human beings.

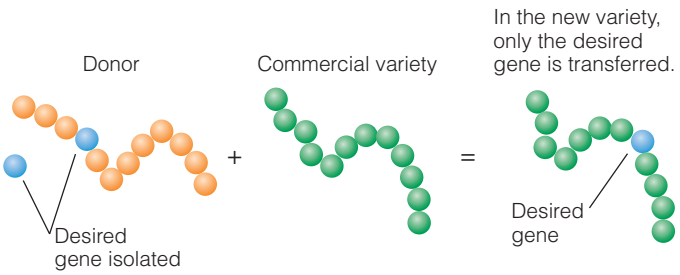
**> FIGURE H19-1 Selective Breeding and Genetic Engineering Compared**



**Traditional Selective Breeding**

Traditional selective breeding combines many genes from two varieties of the same species to produce one with the desired characteristics.

**Genetic Engineering**

Through genetic engineering, a single gene is (or several are) transferred from the same or different species to produce one with the desired characteristics.

Genetically modified cauliflower is orange, reflecting a change in a single gene that increases its production of beta-carotene 100-fold.

## Extended Shelf Life

Among the first products of genetic engineering to hit the market were tomatoes that stay firm and ripe longer than regular tomatoes that are typically harvested green and ripened in the stores. These genetically modified tomatoes promise less waste and higher profits. Normally, tomatoes produce an enzyme (remember that enzymes are proteins) that softens them after they have been picked. Scientists can now introduce into a tomato plant a gene that is a mirror image of the one that codes for the "softening" enzyme. This gene blocks synthesis of the softening enzyme. Without this enzyme, the genetically altered tomato softens more slowly than a regular tomato, allowing growers to harvest it at its most flavorful and nutritious vine-ripe stage.

## Improved Nutrient Composition

Genetic engineering can also improve the nutrient composition of foods.[1] Instead of manufacturers adding nutrients to foods during processing, plants can be genetically altered to do the fortification work—a strategy called *biofortification.* Biofortification of staple crops with key vitamins and minerals can effectively combat the nutrient deficiency diseases that claim so many lives worldwide. Genetically modifying cassava, one of the world's major staple crops, can improve its protein and iron content.[2] Soybeans may be implanted with a gene that upgrades soy protein to a quality approaching that of milk. Corn has been modified to contain twice the amount of lysine and tryptophan, its two limiting amino acids.[3] Soybean and canola plants can be genetically modified to alter the composition of their oils, making them richer in the heart-healthy monounsaturated fatty acids. "Golden rice," which has received genes from a daffodil and a bacterium that enable it to make beta-carotene, offers promise in treating vitamin A deficiency worldwide.[4] (Chapter 11 describes how vitamin A deficiency contributes to the deaths of 2 million children and the blindness of a half million each year.) Of course, increasing nutrients in crops may have unintended consequences as well. For example, when broccoli is manipulated to increase its selenium content, production of the cancer-fighting phytochemical sulforaphane declines.

In addition to enhancing the nutrient composition, genetically modified crops can also produce more of the phytochemicals that help maintain health and reduce the risks of chronic diseases (see Highlight 13). They can also be coaxed to produce less phytate, which allows more zinc to be absorbed. The possibilities seem endless.

## Efficient Food Processing

Genetic engineering also helps to process foods more efficiently, which saves money. For example, the protein **rennin**, which is used to coagulate milk in the production of cheese, has traditionally been harvested from the stomachs of calves, a costly process. Now scientists can insert a copy of the rennin gene into bacteria and then use bacterial cultures to mass-produce rennin—saving time, money, space, and animals.

Genetic engineering can also help to bypass costly food-processing steps. At present, people who are lactose intolerant can buy milk that has been processed to include the lactase enzyme. Wouldn't it

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

be more convenient, and less expensive, if scientists could genetically modify cows to make lactose-free milk directly? They've done it. Decaffeinated coffee beans are another real possibility.

Genetic research today has progressed well beyond tweaking a gene here and there to produce a desired trait. Scientists can now **clone** animals. By cloning animals, scientists have the ability to produce both needed food and pharmaceutical products. The FDA has declared that food from cloned livestock is safe to eat, but the USDA has asked farmers to keep cloned animals off the market. Because cloning an animal costs tens of thousands of dollars, it would be incredibly unprofitable to slaughter it for meat. For this reason, cloned animals are used primarily for breeding and their natural-born offspring are used primarily for food. Because the FDA does not distinguish between foods from cloned animals or their offspring and foods from conventional animals, food labels are not required to provide this information.

## Efficient Drug Delivery

Using cloned animals and other organisms in the development of pharmaceuticals is whimsically called "biopharming." For example, a goat that has been genetically modified to produce a malaria vaccine in its milk could provide both nourishment and immunization to a whole village of people now left unprotected because they lack food and medical help. Similarly, researchers have figured out how to induce hens to produce eggs with a drug to treat multiple sclerosis. Bananas and potatoes have been designed to make hepatitis vaccines, and tobacco leaves to make AIDS drugs. Researchers can also harvest vaccines by genetically altering hydroponically grown tomato plants to secrete a protein through their root systems into the water. Using foods to deliver drugs is only a small part of the promise and potential that biotechnology offers the field of medicine.

## Genetically Assisted Agriculture

Genetic engineering has helped farmers to increase yields, extend growing seasons, and grow crops that resist herbicides. More than 90 percent of the soybean crops in the United States have been genetically engineered to withstand a potent herbicide. As a result, farmers can spray whole fields with this herbicide and kill the weeds without harming the soybeans.

Similarly, farmers can grow crops that produce their own pesticides—substances known as **plant-pesticides.** Corn, broccoli, and potatoes have received a gene from a bacterium that produces a protein that is toxic to leaf-chewing caterpillars (but not to humans). Yellow squash has been given two genes that confer resistance to the most common viral diseases. Potatoes can now produce a beetle-killing toxin in their leaves. These crops and many others like them are currently being grown or tested in fields around the United States. Growing crops that make their own pesticides allows farmers to save time, increase yields, and use fewer, or less harmful, pesticides. Genetically modified crops have decreased the environmental impact associated with pesticide use.

## Other Possibilities

Many other biotechnology possibilities are envisioned for the near future. Shrimp may be empowered to fight diseases with genetic ammunition borrowed from sea urchins. Milk may be produced without its major allergen.[5] Plants may be given special molecules to help them grow in polluted soil. With these and other advances, farmers may reliably produce bumper crops of food every year on far fewer acres of land, with less loss of water and topsoil, and far less use of toxic pesticides and herbicides. Supporters of biotechnology predict that these efforts will enhance food production and help meet the challenge of feeding an ever-increasing world population. They contend that genetically modified crops have the potential to eliminate hunger and starvation. Others suggest that the problems of world hunger are more complex than biotechnology alone can resolve and that the potential risks of genetic engineering may outweigh the potential benefits.

The projects mentioned in this highlight are already in progress. Close on their heels are many more ingenious ideas. What if salt tolerance could be transplanted from a coastal marsh plant into crop plants? Could crops then be irrigated with seawater, thus conserving dwindling freshwater supplies? Or could crops be genetically designed to use less water? Would the world food supply increase if rice farmers could grow plants that were immune to disease? What if consumers could dictate which traits scientists insert into food plants? Would they choose to add phytochemicals to fight cancer or reduce the risk of heart disease? These and other possibilities seem unlimited, and though they may sound incredible, many such products have already been developed and are awaiting approval from the FDA, EPA, and USDA.

# The Potential Problems and Concerns

Consumers accept or reject foods and technology depending on their perceptions of the associated benefits and risks.[6] For the most part, when something is perceived as being beneficial, it is also perceived as having low risk. Perceptions of risk and rejection increase when conditions are unfamiliar, uncertain, unknown, or uncontrollable or consequences are severe, whereas perceptions of benefits and acceptance increase when conditions are traditional, well known, and familiar. In the case of genetically modified foods, many consumers are understandably suspicious of an unfamiliar and complicated processing technique; they haven't accepted that the benefits might outweigh the risks.

Although many scientists hail biotechnology with confidence, others have reservations. Most consumers know little about biotechnology or the extent to which their foods contain genetically modified foods. Some consumers have concerns about what they call "Frankenfoods." Those who oppose biotechnology fear for the safety of a world where genetic tampering produces effects that are not yet fully understood. They suspect that the food industry may be driven by potential profits, without ethical considerations or laws to harness the effects. They point out that even the scientists who developed the techniques cannot predict the ultimate outcomes of their discoveries. These consumers don't want to eat a scientific experiment or interfere with natural systems. Genetic decisions, they say, are best left to the powers of nature.

Many consumers believe that genetically modified foods should be labeled as such.

If science and the marketplace are allowed to drive biotechnology without restraint, critics fear that the following problems may result:

- *Disruption of natural ecosystems.* New, genetically unique organisms that have no natural place in the food chain or evolutionary biological systems could escape into the environment and reproduce.
- *Introduction of diseases.* Newly created viruses may mutate to cause deadly diseases that may attack plants, animals, or human beings. Genetically modified bacteria may develop resistance to antibiotics, making the drugs useless in fighting infections.
- *Introduction of allergens and toxins.* Genetically modified crops may contain new substances that have consequences, such as causing allergies.
- *Creation of biological weapons.* Fatal bacterial and viral diseases may be developed for use as weapons.
- *Ethical dilemmas.* Critics pose the question "How many human genes does an organism have to contain before it is considered human? For instance, how many human genes would a green pepper have to contain before one would have qualms about eating it?"

Proponents of biotechnology respond that evidence to date does not justify these concerns. Opponents counter that the lack of evidence showing harm does not provide evidence showing safety. These opposing views illustrate the tension between the forward thrust of science and the hesitation of consumers. Some would argue for more research on the safety of genetically modified food, while others assert that more research is a waste of resources and that it is time to embrace biotechnology with enthusiasm.[7] In addition to evaluating the potential risks and benefits, genetically modified crops need international oversight. Table H19-1 (p. 660) summarizes the issues.

From another perspective, some argue that the concerns expressed by those protesting genetically engineered foods reflect prejudices acquired in an elitist world of fertile land and abundant food. Those living in poverty-stricken areas of the world do not have the luxury of determining how to grow crops and process foods. They cannot afford the delays created when protesters destroy test crops and disrupt scientific meetings. They need solutions now. People are starving, and genetic engineering holds great promise for increasing crop yields and providing those people with food.[8]

The work of Nobel Peace Prize Laureate Dr. Norman Borlaug and his team over the past four decades attests to the benefits of using technology to defend against hunger. By developing grains that resist pests and diseases, they have been able to increase yields and provide real solutions to global hunger problems. When Mexico used Borlaug's special breed of dwarf wheat, yields increased threefold compared with traditional varieties. India increased wheat production tenfold and became self-sufficient in its grain production. Pakistan increased its wheat production fivefold and sub-Saharan Africa more than tripled crop yields by changing farming practices. The combination of improved conventional systems and biotechnology produces more food to meet the nutritional needs of more people.[9]

At a minimum, critics of biotechnology have made a strong case for rigorous safety testing and labeling of new products. They contend, for example, that when a new gene has been introduced into a food, tests should ensure that other, unwanted genes have not accompanied it. If a disease-producing microorganism has donated genetic material, scientists must prove that no dangerous characteristic from the microorganism has also entered the food. If the inserted genetic material comes from a source to which some people develop allergies, such as nuts, then the new product should be labeled to alert them. Furthermore, if the newly altered genetic material creates proteins that have never before been encountered by the human body, their effects should be rigorously studied to ensure that people can eat them safely.

## FDA Regulations

The FDA has taken the position that foods produced through biotechnology and cloning are not substantially different from others and require no special testing, regulations, or labeling. After all, most foods available today have already been genetically altered by years of selective breeding. The new vegetable broccoflower, a product of sophisticated cross-breeding of broccoli with cauliflower, met no testing or approval barriers on its way to the dinner plate. When the vegetable became available on the market, scientists studied its nutrient contents, but they did not question its safety.

In most cases, the new genetically modified food differs from the old conventional one only by a gene or two. The rennin produced by bacteria is structurally and functionally the same as the rennin produced by calves, for example. For that reason, the FDA considers it and other genetically engineered foods "generally recognized as safe (GRAS)."

A product such as the tomato described earlier need not be tested because its new gene *prevents* synthesis of a protein and adds nothing but a tiny fragment of genetic material. Nor does this tomato require special labeling because it is not significantly different from the many other varieties of tomatoes on the market. On the other hand, any substance introduced into a food (such as a hormone or protein) by way of bioengineering must meet the same safety standards applied to all additives. A tomato plant with a gene that, for example, produces a pesticide cannot be marketed until tests prove it safe for consumption.

# HIGHLIGHT > 19

**TABLE H19-1 Food Biotechnology: Point, Counterpoint**

| Arguments in Opposition to Genetic Engineering | Arguments in Support of Genetic Engineering |
|---|---|
| 1. **Ethical and moral issues.** It's immoral to "play God" by mixing genes from organisms unable to do so naturally. Religious and vegetarian groups object to genes from prohibited species occurring in their allowable foods. | 1. **Ethical and moral issues.** Scientists throughout history have been persecuted and even put to death by fearful people who accuse them of playing God. Yet, today many of the world's citizens enjoy a long and healthy life of comfort and convenience because of once-feared scientific advances put to practical use. |
| 2. **Imperfect technology.** The technology is young and imperfect—genes rarely function in just one way, their placement is imprecise ("shotgun"), and all of their potential effects are impossible to predict. Toxins are as likely to be produced as the desired trait. More than 95 percent of DNA is called "junk" because scientists have not yet determined its function. | 2. **Advanced technology.** Recombinant DNA technology is precise and reliable. Many of the most exciting recent advances in medicine, agriculture, and technology were made possible by the application of this technology. |
| 3. **Environmental concerns.** Environmental side effects are unknown. The power of a genetically modified organism to change the world's environments is unknown until such changes actually occur—then the "genie is out of the bottle." Once out, insects, birds, and the wind distribute genetically altered seed and pollen to points unknown. | 3. **Environmental protection.** Genetic engineering may be the only hope of saving rain forest and other habitats from destruction. Through genetic engineering, farmers can make use of previously unproductive lands such as salt-rich soils and arid areas. |
| 4. **"Genetic pollution."** Other kinds of pollution can often be cleaned up with money, time, and effort. Once genes are spliced into living things, those genes forever bear the imprint of human tampering. | 4. **Genetic improvements.** Genetic side effects are more likely to benefit the environment than to harm it. |
| 5. **Crop vulnerability.** Pests and diseases can quickly adapt to overtake genetically identical plants or animals around the world. Diversity is key to defense. | 5. **Improved crop resistance.** Pests and diseases can be specifically fought on a case-by-case basis. Biotechnology is the key to defense. |
| 6. **Loss of gene pool.** Loss of genetic diversity threatens to deplete valuable gene banks from which scientists can develop new agricultural crops. | 6. **Gene pool preserved.** Thanks to advances in genetics, laboratories around the world are able to stockpile the genetic material of millions of species that, without such advances, would have been lost forever. |
| 7. **Profit motive.** Genetic engineering will profit industry more than the world's poor and hungry. | 7. **Everyone profits.** Industries benefit from genetic engineering, and a thriving food industry benefits the nation and its people, as witnessed by countries lacking such industries. Genetic engineering promises to provide adequate nutritious food for millions who lack such food today. Developed nations gain cheaper, more attractive, more delicious foods with greater variety and availability year round. |
| 8. **Unproven safety for people.** Human safety testing of genetically altered products is generally lacking. The population is an unwitting experimental group in a nationwide laboratory study for the benefit of industry. | 8. **Safe for people.** Human safety testing of genetically altered products is unneeded because the products are essentially the same as the original foodstuffs. |
| 9. **Increased allergens.** Allergens can be unwittingly transferred into foods. | 9. **Control of allergens.** A few allergens can be transferred into foods, but these are known. Also, foods likely to contain them are clearly labeled to warn consumers. Some foods are being designed to eliminate the allergen. |
| 10. **Decreased nutrients.** A fresh-looking tomato or other produce held for several weeks may have lost substantial nutrients. | 10. **Increased nutrients.** Genetic modifications can easily enhance the nutrients in foods. |
| 11. **No product tracking.** Without labeling, the food industry cannot track problems to the source. | 11. **Excellent product tracking.** The identity and location of genetically altered foodstuffs are known, and they can be tracked should problems arise. |
| 12. **Overuse of herbicides.** Farmers, knowing that their crops resist herbicide effects, will use them liberally. | 12. **Conservative use of herbicides.** Farmers will not waste expensive herbicides in second or third applications when the prescribed amount gets the job done the first time. |
| 13. **Increased consumption of pesticides.** When a pesticide is produced by the flesh of produce, consumers cannot wash it off the skin of the produce with running water as they can with ordinary sprays. | 13. **Reduced pesticides on foods.** Pesticides produced by plants in tiny amounts known to be safe for consumption are more predictable than applications by agricultural workers who make mistakes. Because other genetic manipulations will eliminate the need for postharvest spraying, fewer pesticides will reach the dinner table. |
| 14. **Lack of oversight.** Government oversight is run by industry people for the benefit of industry—no one is watching out for the consumer. | 14. **Sufficient regulation and rapid response.** Government agencies are efficient in identifying and correcting problems as they occur in the industry. |

The FDA assures consumers that all bioengineered foods on the market today are as safe as their traditional counterparts.

Foods produced through biotechnology that are substantially different from others must be labeled to identify that difference. For example, if the nutrient composition of the new product differs from its traditional counterpart, as in the soybean and canola oils mentioned earlier, then labeling is required. Similarly, if an allergy-causing protein has been introduced to a nonallergenic food, then labeling must warn consumers.

Most consumers want all genetically altered products clearly labeled. Consumer advocacy groups claim that by not requiring such labeling, the FDA forces millions of consumers to be guinea pigs, unwittingly testing genetically engineered foods. Additionally, they say, people who have religious objections to consuming foods to which genes of prohibited organisms have been added have no way of identifying those foods. For example, someone keeping a kosher kitchen may unknowingly use a food containing genes from a pig. Currently, labeling is voluntary. Manufacturers may state that a product has been "genetically engineered." Those who do would be wise to explain its purpose and benefit. When consumers recognize a personal health benefit, most tend to accept genetically engineered foods.

Speaking in defense of the FDA's position are the FDA itself, recognized as the nation's leading expert and advocate for food safety, and the Academy of Nutrition and Dietetics, which represents current scientific thinking in nutrition.[10] Many other scientific organizations agree, contending that biotechnology can deliver an improved food supply if we give it a fair chance to do so.

Will these new technologies provide foods to meet the needs of the future? Some would say yes. Biotechnology holds a world of promise, and with proper safeguards and controls, it may yield products that meet the needs of consumers almost perfectly.

## CRITICAL THINKING QUESTIONS

A. How might people from different countries view the risks and benefits of biotechnology?

B. Controversy surrounds the safety and use of food biotechnology. Genetically modified foods raise concerns about long-term health and environmental consequences. Even though most scientists agree that these foods are safe and perhaps even beneficial to consumers, many consumers still express uncertainty. What is your position on food biotechnology and genetically modified foods? What could be done to minimize any associated risks and alleviate fears?

# Hunger and the Global Environment

## Nutrition in Your Life

Imagine living with hunger from the moment you wake up until the time you thankfully fall asleep—and all through your dreams as well. Meal after meal, day after day, you have little or no food to eat. You need food, but you have no money. Would you beg on the street corner or go "dumpster diving" at a fast-food restaurant? And then where would you find your next meal? How will you ever get enough to eat as long as you live in poverty? Resolving the hunger problem—whether in your community or on the other side of the world—depends on alleviating poverty and using resources wisely. In the Nutrition Portfolio at the end of this chapter, you can consider ways to get involved in hunger relief.

Worldwide, one person in every eight experiences hunger—not the healthy appetite triggered by anticipation of a meal, but the painful sensation caused by a lack of food.[1] In this chapter, **hunger** takes on the greater meaning—hunger that develops from prolonged, recurrent, and involuntary lack of food and results in illness, weakness, or pain that exceeds the usual uneasy sensation. Such hunger deprives a person of the physical and mental energy needed to enjoy a full life and often leads to severe malnutrition and death. Millions of people die of hunger-related causes every year—one child every 10 seconds.

The enormity of the world hunger problem is reflected not only by huge numbers, but also by major challenges. As people populate and pollute the earth, resources become depleted, making food less available. Hunger and poverty, population growth, and environmental degradation are linked together; thus they tend to worsen one another. Because their causes overlap, so do their solutions. Eliminating hunger requires a balance among the distribution of food, the numbers of people, and the care of the environment.

Feeding the hungry—in the United States.

# 20.1 Hunger in the United States

› **LEARN IT** Identify some reasons why hunger is present in a country as wealthy as the United States.

Ideally, all people at all times would have access to enough food to support an active, healthy life. In other words, they would experience **food security.** Unfortunately, an estimated 49 million people in the United States, including almost 16 million children, live in poverty and cannot afford to buy enough food to maintain good health.[2] Said another way, one out of seven households experiences hunger or the threat of hunger. Given the agricultural bounty and enormous wealth in this country, do these numbers surprise you? The limited or uncertain availability of nutritionally adequate and safe foods is known as **food insecurity** and is a major social problem in our nation today. Inadequate diets lead to poor health in adults and impaired physical, psychological, and cognitive development in children.

Table 20-1 presents the questions used in national surveys to identify food insecurity in the United States, and Figure 20-1 shows the most recent findings. Responses to these questions provide crude, but necessary, data to estimate the degree of hunger in this country. Specific questions and measures focus on food insecurity in children. Even short-term food insecurity in a household can interfere with a young child's development.

**food security:** access to enough food to sustain a healthy and active life. Food security categories include:

- *High food security:* no indications of food-access problems or limitations
- *Marginal food security:* one or two indications of food-access problems but with little or no change in food intake

**food insecurity:** limited or uncertain access to foods of sufficient quality or quantity to sustain a healthy and active life. Food insecurity categories include:

- *Low food security:* reduced quality of life with little or no indication of reduced food intake; formerly known as *food insecurity without hunger*
- *Very low food security:* multiple indications of disrupted eating patterns and reduced food intake; formerly known as *food insecurity with hunger*

**food insufficiency:** an inadequate amount of food due to a lack of resources.

## Defining Hunger in the United States

At its most extreme, people experience hunger because they have absolutely no food. More often, they have too little food (**food insufficiency**) and try to stretch their limited resources by eating small meals or skipping meals—often for days at a time. Sometimes hungry people obtain enough food to satisfy their hunger, perhaps by seeking food assistance or finding food through socially unacceptable ways—begging from strangers, stealing from markets, or scavenging through garbage cans, for example. Sometimes obtaining food raises concerns for food safety—for example, when rot, slime, mold, or insects have damaged foods or when people eat others' outdated leftovers or meat from roadkill.

**TABLE 20-1 Questions to Identify Food Insecurity in a US Household**

To determine the extent of food insecurity in a household, surveys ask questions about behaviors and conditions known to characterize households having difficulty meeting basic food needs during the past 12 months. Most often, adults tend to protect their children from hunger. In the most severe cases, children also suffer from hunger and eat less.

1. Did you worry whether food would run out before you got money to buy more?
2. Did you find that the food you bought just didn't last and you didn't have money to buy more?
3. Were you unable to afford to eat balanced meals?
4. Did you or other adults in your household ever cut the size of your meals or skip meals because there wasn't enough food?
5. Did this happen in 3 or more months during the previous year?
6. Did you ever eat less than you felt you should because there wasn't enough money for food?
7. Were you ever hungry but didn't eat because you couldn't afford enough food?
8. Did you lose weight because you didn't have enough money to buy food?
9. Did you or other adults in your household ever not eat for a whole day because you were running out of money to buy food?
10. Did this happen in 3 or more months during the previous year?
11. Did you rely on only a few kinds of low-cost food to feed your children because you were running out of money to buy food?
12. Were you unable to feed your children a balanced meal because you couldn't afford it?
13. Were your children not eating enough because you just couldn't afford enough food?
14. Did you ever cut the size of your children's meals because there wasn't enough money for food?
15. Were your children ever hungry but you just couldn't afford more food?
16. Did your children ever skip a meal because there wasn't enough money for food?
17. Did this happen in 3 or more months during the previous year?
18. Did your children ever not eat for a whole day because there wasn't enough money for food?

The more positive responses, the greater the food insecurity. Households with children answer all of the questions and are categorized as follows:

| | |
|---|---|
| ≤2 positive responses | = food secure |
| 3–7 positive responses | = low food security |
| ≥8 positive responses | = very low food security |

Households without children answer the first 10 questions and are categorized as follows:

| | |
|---|---|
| ≤2 positive responses | = food secure |
| 3–5 positive responses | = low food security |
| ≥6 positive responses | = very low food security |

Figure 20-1 shows the results of the 2012 surveys.

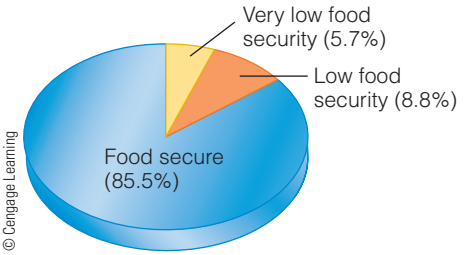
**Food Poverty** Hunger has many causes, but in developed countries, the primary cause is **food poverty.** People are hungry not because there is no food nearby to purchase, but because they lack money. The rate and severity of US poverty has increased over the past decade. An estimated 15 percent of the people in the United States lives in poverty.[3] Even those above the poverty line (about $11,500 per year for an individual) may not have food security. Physical and mental illnesses and disabilities, unemployment, low-paying jobs, unexpected or ongoing medical expenses, and high living expenses threaten financial stability. When money is tight, people must choose between food and life's other necessities—utilities, housing, and medical care. Food costs are more variable and flexible; people can purchase fewer groceries to lower the monthly food bill, but they usually can't pay only a portion of the bills for electricity, rent, or medication. Other problems further contribute to food poverty, such as abuse of alcohol and other drugs; lack of awareness of available food assistance programs; and the reluctance of people, particularly the elderly, to accept what they perceive as "welfare" or "charity."



In the United States, poverty and hunger reach across various segments of society, touching some more than others—notably, single parents living in households with their children, Hispanics and African Americans, and those living in the inner cities. People living in poverty are simply unable to buy sufficient amounts of nourishing foods, even if they are wise shoppers. Consequently, their diets tend to be inadequate. For many of the children in these families, school lunch (and breakfast, where available) may be the only nourishment for the day. Otherwise they go hungry, waiting for an adult to find money for food. Not surprisingly, these children are more likely to have health problems and iron-deficiency anemia than those who eat regularly. They also tend to perform poorly in school and in social situations. For adults, the risk of developing chronic diseases increases.[4] For pregnant women, the risk of developing gestational diabetes more than doubles.[5]

**Obesity Paradox** Ironically, hunger and obesity often exist side by side—sometimes within the same household or even the same person.[6] That hunger reflects an inadequate food intake and obesity implies an excessive intake seems paradoxical, but research studies have confirmed the association.[7] The highest rates of obesity occur among those living in the greatest poverty—the same people who live with food insecurity.[8]

Unfortunately, many healthful food choices, such as fruits and vegetables, are not readily available in low-income or rural neighborhoods.Instead of supermarkets, these neighborhoods typically have corner stores that stock canned foods, sodas, and chips, but not fresh produce.[9] Neighborhoods and communities characterized by limited access to nutritious and affordable foods are known as **food deserts.** Food deserts are more prevalent in low-income and African American communities. With limited access to grocery stores carrying varieties of fruits and vegetables, residents in these neighborhoods fall short of meeting dietary guidelines.[10] Furthermore, fruits and vegetables tend to cost more than the energy-dense foods that foster weight gain.[11] Foods such as doughnuts, pizzas, and hamburgers provide the most energy and satiety for the least cost. Quite simply, poor-quality diets deliver more kcalories, but fewer nutrients, for less money; high-quality diets deliver fewer kcalories, but more nutrients, for more money.[12] The challenge, of course, is finding the foods that deliver the most nutrients for the least cost.[13] Lowering the price of fruits and vegetables is one easy and effective way to improve diet quality.[14]

Economic uncertainty and stress greatly influence the prevalence of obesity.[15] People who are unsure about their next meal may overeat when food or money are available. Interestingly, food insecure people who do *not* participate in food assistance programs have a *greater* risk of obesity than those who do participate—illustrating that providing food actually helps to prevent obesity.[16] Figure 20-2 shows how poverty and food insecurity can lead to both malnutrition and obesity.

The fight against hunger depends on the helping hands of caring volunteers.

## Relieving Hunger in the United States

The Academy of Nutrition and Dietetics calls for aggressive action to bring an end to domestic food insecurity and hunger and to achieve food and nutrition security for everybody living in the United States.[17] Many federal and local programs aim to prevent or relieve malnutrition and hunger in the United States.

### Federal Food Assistance Programs

Adequate nutrition and food security are essential to supporting good health and achieving the public health goals of the United States. To that end, an extensive network of federal assistance programs provides life-sustaining food to millions of US citizens daily. An estimated one out of every five Americans receives some kind of food assistance at a total cost of more than $105 billion per year. Even so, the programs are not fully successful in preventing hunger, but they do seem to improve the nutrient intakes of those who participate. Programs described in earlier chapters include the WIC program for low-income pregnant women, breastfeeding mothers, and their young children (Chapter 15); the school lunch, breakfast, and child-care food programs for children (Chapter 16); and the food assistance programs for older adults such as congregate meals and Meals on Wheels (Chapter 17).

The Supplemental Nutrition Assistance Program (SNAP), administered by the US Department of Agriculture (USDA), is the largest of the federal food assistance programs, both in amount of money spent and in number of people served. Participation in SNAP significantly decreases food insecurity.[18] It provides assistance to more than 45 million people at a cost of $75 billion per year; about half of the recipients are children. The USDA issues debit cards through state agencies to households—people who buy and prepare food together. The amount a household receives depends on its size, resources, and income. The average monthly benefit is about $135 per person. Recipients may use the cards to purchase food and food-bearing plants and seeds, but not to buy tobacco, cleaning items, alcohol, or other nonfood items. Controversy surrounds the question of whether SNAP participants should be allowed to purchase soft drinks and other nonnutritious foods and beverages.[19] Some argue that government programs should not support poor-quality foods that promote obesity and other diseases; others argue that government programs should not tell consumers what they cannot eat and drink and to do so is discriminatory and unfair. This lack of quality control on food purchases may not only promote obesity and disease, but it may also exacerbate hunger; consider that, given the same number of kcalories, a child will become hungrier sooner after drinking a 20-ounce soft drink than after eating a large apple with a heaping spoonful of peanut butter.[20] In general, SNAP participants have low-quality diets and poor health.[21] Providing sufficient benefits and aligning SNAP policy with the *Dietary Guidelines for Americans* would help to improve the nutritional quality of diets and health of participants.[22] The accompanying "How To" feature offers healthy shopping tips for those on a limited budget.

Food assistance programs improve nutrient intakes significantly, but hunger continues to plague the United States. Homeless people in the United States are eligible, but relatively few receive food assistance. For some, reading, understanding, and completing the application can be difficult. For others, having to verify identity and homelessness can be frustrating. For many, accepting hunger is simply easier than meeting these challenges.

### National Food Recovery Programs

Efforts to resolve the problem of hunger in the United States do not depend solely on federal assistance programs. National **food recovery** programs have made a dramatic difference. The largest program, Feeding America, coordinates the efforts of 200 **food banks** across the country that feed an estimated 25 million people a year.

Each year, an estimated one-third of the world's food supply is wasted along the way from farm to final consumption. Consumers in wealthy nations such as the United States waste an estimated 200 to 250 pounds of food per person

**food recovery:** collecting wholesome food for distribution to low-income people who are hungry. Four common methods of food recovery include:

- *Field gleaning:* collecting crops from fields that either have already been harvested or are not profitable to harvest
- *Perishable food rescue or salvage:* collecting perishable produce from wholesalers and markets
- *Prepared food rescue:* collecting prepared foods from commercial kitchens
- *Nonperishable food collection:* collecting processed foods from wholesalers and markets

**food banks:** facilities that collect and distribute food donations to authorized organizations feeding the hungry.

## >How To

### Stretch Food Dollars and Reduce Waste

Chapter 2 introduced the principles for planning a healthy diet. Meeting that goal on a limited budget adds to the challenge. To save money and spend wisely, plan and shop for healthy meals with the following tips in mind.

#### Plan Ahead

- Plan menus and make a grocery list before going to the store to avoid expensive "impulse" items.
- Center meals on whole grains, legumes, and vegetables.
- Use small quantities of meat, poultry, fish, or eggs.
- Use cooked cereals such as oatmeal instead of ready-to-eat breakfast cereals.
- Cook large quantities when time and money allow; freeze portions for convenient meals another time.
- Check for sales and use coupons for products you need; plan meals to take advantage of sale items.

#### Shop Smart

- Do not shop when hungry.
- Look for bargains on day-old bread and other bakery products.
- Select whole foods instead of convenience foods (potatoes instead of instant mashed potatoes, for example).
- Try store brands.
- Buy fresh produce that is in season; buy canned or frozen items at other times.
- Buy large bags of frozen items or dry goods; when cooking, take out the amount needed and store the remainder.
- Buy fat-free dry milk; mix and refrigerate quantities needed for a day or two. Buy fresh milk by the gallon or half-gallon if you can use it before it spoils.
- Buy less expensive cuts of meat, such as beef chuck and pork shoulder roasts; cover during cooking and cook with liquid long enough to make meat tender.
- Buy whole chickens instead of pieces; ask the butcher to show you how to cut them up.
- Compare the unit price (cost per ounce, for example) of similar foods so that you can select the least expensive brand or size.
- Buy nonfood items such as toilet paper and laundry detergent at discount stores instead of grocery stores.

#### Reduce Waste

- Be creative with the foods you have available. Consumers can search websites for recipes using ingredients they have on hand.
- Use leftovers to save time and money as well as to reduce waste.
- Store foods properly and use older foods first.
- Use every little bit. The ends of a loaf of bread can become croutons, excess rice can become the start of a casserole, leftover fruit can be a yogurt topping, and vegetable trimmings can form a base for soups, sauces, and stocks.
- Buy only the amount of fresh foods that you will eat before it spoils.
- Compost fruit and vegetable scraps to use in the garden or other outdoor plants.

For daily menus and recipes to help you eat better on a budget, visit the Healthy Eating on a Budget section of the MyPlate website: **www.choosemyplate.gov/budget.**

**› TRY IT** Review the sample meals at the Healthy Eating on a Budget section of the MyPlate website (www.choosemyplate.gov/budget) and select a day's meals to analyze using your personal profile in a diet analysis program.

per year.[23] (By comparison, consumers in the develping regions of Southern Asia, Sub-Saharan Africa, and Eastern Asia throw away only 10 to 25 pounds per person per year.) Food recovery programs collect and distribute good food that would otherwise go to waste. Volunteers might pick corn left in an already harvested field, a grocer might deliver ripe bananas to a local food bank, and a caterer might take leftover chicken salad to a community shelter, for example. All of these efforts help to feed the hungry in the United States.

**Community Efforts** Food recovery programs depend on volunteers. Concerned citizens work through local agencies and churches to feed the hungry. Community-based food pantries provide groceries, and soup kitchens serve prepared meals. A combination of various strategies helps to build food security in a community.

**› REVIEW IT** Identify some reasons why hunger is present in a country as wealthy as the United States.

Food insecurity and hunger are widespread in the United States among those living in poverty. Ironically, hunger and poverty coexist with obesity. Government assistance programs help to relieve poverty and hunger. Food recovery programs and other community efforts also provide some relief.

International efforts cannot fully relieve the hunger and poverty in Somalia and other parts of the world.

# 20.2 World Hunger

› **LEARN IT** Identify some reasons why hunger is present in the developing countries of the world.

As distressing as hunger is in the United States, the prevalence is far greater and the consequences more severe in developing countries, where an estimated 827 million people do not have enough to eat. Although hunger in developing countries has diverse causes, once again, the primary cause is poverty, and the poverty is far more extreme than in the United States. Most people cannot grasp the severity of poverty in the developing world. Of the world's 7 billion people, 25 percent have no land and no possessions *at all.* They are the "poorest poor." They survive on little more than $1 a day each, and they lack safe housing, clean water, and health care. They cannot read or write. The average US housecat receives twice as much protein every day as one of these people, and the cost of keeping a pet cat is greater than such a person's annual income.

The "poorest poor" are usually female. Many societies around the world undervalue females, providing girls with poorer diets, less education, and fewer opportunities than boys. Malnourished girls become malnourished mothers who give birth to low-birthweight infants—and the cycle of hunger, malnutrition, and poverty continues. The consequences of stunted growth in early childhood are evident throughout life.[24]

Not only does poverty cause hunger, but tragically, hunger worsens poverty by robbing a person of the good health and the physical and mental energy needed to be active and productive. Hungry people simply cannot work hard enough to get themselves out of poverty. Providing nourishment is a necessary investment in the well-being of both individuals and nations.[25] Economists calculate that cutting world hunger and malnutrition in half by 2015 would generate a value of more than $120 billion in longer, healthier, and more productive lives.

## Food Shortages

World hunger brings to mind victims of **famine,** a severe food shortage in an area that causes widespread starvation and death. In recent years, the natural causes of famine—drought, flood, and pests—have become less important than the political and economic crises created by people.[26] Figure 20-3 shows the hunger hotspots in the world.

### Political Turbulence

A sudden increase in food prices, a drop in workers' wages, or a change in government policy can quickly leave millions hungry. An estimated 30 million people died during the Chinese famine of 1959 through 1961, the worst famine of the 20th century. The main cause was government policies associated with the Great Leap Forward, a government initiative that was intended to transform China's economy. However, the poorly planned communal farm system and the widespread waste of resources devastated the Chinese agricultural system.

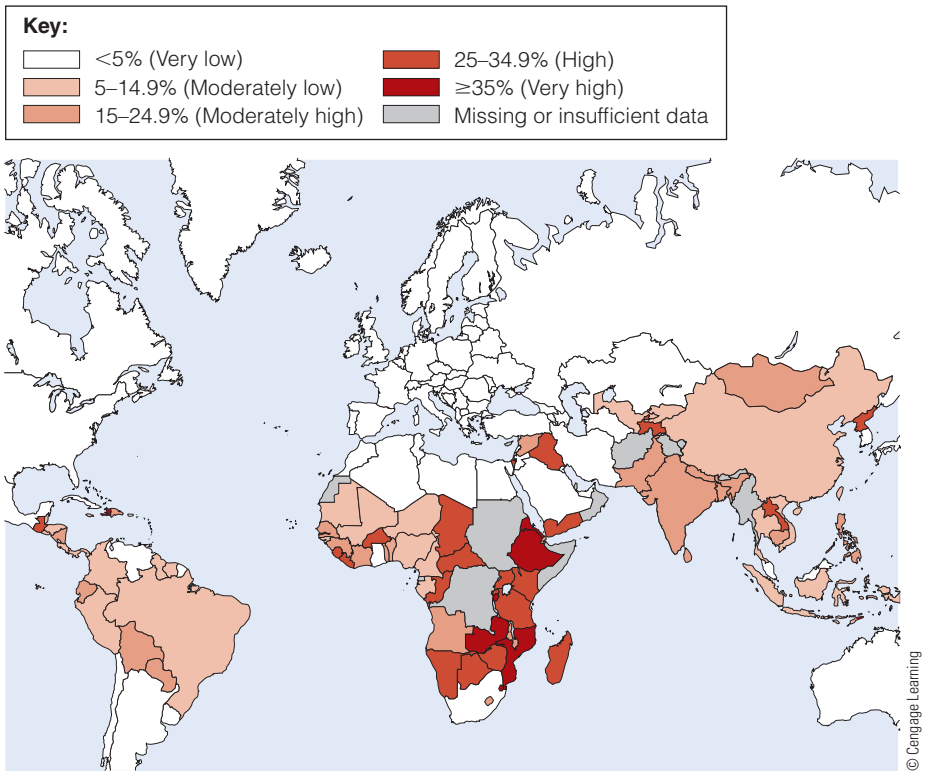
The famine Somalia is currently experiencing has left an estimated 12 million people starving and more than 30,000 children younger than the age of 5 dead. Drought has clearly contributed to the crisis, but war and political factors are the primary causes of this famine.[27] Without an effective government for the past decade, Somalia is plagued by political unrest and terrorist activities.

### Armed Conflicts

Armed conflict is a major cause of famine worldwide. In times of war, farmers become warriors, their agricultural fields become battlegrounds, the citizens go hungry, and the warring factions often block famine relief. The world continues to struggle to find a middle ground between respecting the sovereignty of nations and insisting that all nations allow humanitarian assistance to reach the people. Supplementary food programs provide temporary relief to the people in war-torn countries.

### Natural Disasters

Natural disasters and other poor weather conditions create food shortages. In 2011, an earthquake and flooding in Japan dramatically reduced food supplies. During such natural disasters, emergency food relief



**famine:** widespread and extreme scarcity of food in an area that causes starvation and death in a large portion of the population.

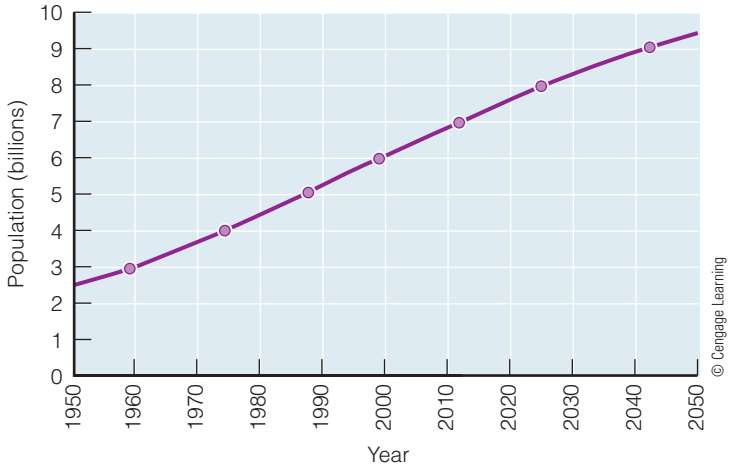
from countries around the world provides a safety net for countries in need. International food relief programs also provide ongoing food assistance to countries such as South Sudan that are chronically short of food because of ongoing drought and poverty.

© Kai-Otto Melau / Alamy

Feeding the hungry—in Kenya.

**Poverty and Overpopulation** Future demands for food require multiple solutions, including controlling overpopulation. The world's population continues to grow, as Figure 20-4 (p. 670) shows. Ever-increasing numbers threaten earth's capacity to provide safe water and adequate food for its inhabitants.* Contaminated water and food shortages are responsible for much of the world's disease and death.

The sheer magnitude of the world's annual population increase of an estimated 80 million people is difficult to comprehend. Every minute, the world's population increases by another 152 people. In 6 months, the world adds the equivalent of another California.



As the world's population continues to grow, much of the increase is occurring in developing countries where hunger and malnutrition are already widespread. More people sharing the little food available can only worsen the problem. Stabilizing the population is essential if food production is ever going to keep up with demands. Without population stabilization, the world can neither support the lives of people nor halt environmental degradation. Before the population problem can be resolved, it may be necessary to remedy the poverty problem. In countries around the world, economic growth has been accompanied by slowed population growth.

*The maximum number of people earth can support over time is its *human carrying capacity*.

**> FIGURE 20-4 World Population**

SOURCE: US Census Bureau, International Data Base, updated June 2011.

Population growth is a central factor contributing to poverty and hunger. The reverse is also true: poverty and hunger contribute to population growth.

**Population Growth Leads to Hunger and Poverty** The first of these cause-and-effect relationships is easy to understand. As a population grows larger, more mouths must be fed, and poverty and hunger worsen.

Population growth also contributes to hunger indirectly by using agricultural land for cities and industry. Remaining lands are insufficient to produce enough food to support the people. The world's poorest people live in the world's most damaged and inhospitable environments.

**Hunger and Poverty Lead to Population Growth** How does poverty lead to overpopulation? Poverty and its consequences—inadequate food and shelter—leave women vulnerable to physical abuse, forced marriages, and prostitution. Furthermore, impoverished women lack access to reproductive health care and family planning counseling. Also, in some regions of the world, families depend on children to farm the land, haul water, and care for adults in their old age. For these families, children are an economic asset. Poverty claims many young children, who are among the most likely to die from malnutrition and disease. If a family faces ongoing poverty, the parents often choose to have many children to ensure that some will survive to adulthood. People are willing to risk having fewer children only if they are sure that their children will survive to adulthood and that the family can develop other economic assets (such as skills, businesses, and land).

Families in developing countries depend on their children to help provide for daily needs.

Sean Sprague/Alamy

**Breaking the Cycle** Relieving poverty and hunger may be a necessary first step in curbing population growth. When people attain better access to health care, education, and family planning, the death rate falls. Then, as the standard of living continues to improve, the birth rate falls. Thus improvements in living standards help stabilize the population.

The link between improved economic status and slowed population growth has been demonstrated in several countries. Central to achieving this success is sustainable development that includes not only economic growth, but a sharing of resources among all groups. Where this has happened, population growth has slowed the most: in parts of Sri Lanka, Taiwan, Malaysia, and Costa Rica, for example. Where economic growth has occurred but only the rich have grown richer, population growth has remained high. Examples include Brazil, the Philippines, and Thailand, where large families continue to be a major economic asset for the poor.

As a society gains economic footing, education also becomes a higher priority. A society that educates its children, both males and females, experiences a drop in birth rates. Education, particularly for girls and women, brings improvements in family life, including improved nutrition, better sanitation, effective birth control, and elevated social and economic status. With improved conditions, more infants live to adulthood, making smaller families feasible.

**› REVIEW IT** Identify some reasons why hunger is present in the developing countries of the world.

Natural causes such as drought, flood, and pests and political causes such as armed conflicts and government policies all contribute to the extreme hunger and poverty seen in the developing countries. In addition, overpopulation means more mouths to feed, which worsens the problems of poverty and hunger. Poverty and hunger, in turn, encourage parents to have more children to help support the family. Breaking this cycle requires improving the economic status of the people and providing them with health care, education, and family planning.

# 20.3 Malnutrition

**› LEARN IT** Describe the consequences of nutrient and energy inadequacies.

Persistent hunger inevitably leads to malnutrition. Although malnutrition touches many adult lives, it most often strikes early in childhood and results in specific nutrient deficiencies or overall growth failure. Providing optimal nutrition during the critical time of gestation and the first 2 years of life—commonly called the first 1000 days—best supports an infant's growth and development, but dietary interventions whenever possible throughout childhood and adolescence, is also helpful.[28]

## Nutrient Deficiencies

A child suffering from a nutrient deficiency may continue to grow, but without adequate nourishment, body functions begin to fail and signs of deficiency diseases become apparent. Problems resulting from nutrient deficiencies include birth defects, learning disabilities, mental retardation, impaired immunity, blindness, incapacity to work, and premature deaths. Nutrients most likely to be deficient are iron, iodine, vitamin A, and zinc.* The prevalence and consequences of these nutrient deficiencies stagger the mind. More than 25 percent of the world's population has iron-deficiency anemia, a leading cause of maternal deaths, preterm births, low birthweights, infections, and premature deaths.[29] Iodine deficiency affects one out of seven, resulting in stillbirths and irreversible mental retardation (cretinism) in 40 million newborns every year. More than 100 million children (younger than age 5) suffer from symptoms of vitamin A deficiency—blindness, growth retardation, and poor resistance to common childhood infections such as measles. An estimated 20 percent of the world's population risk zinc deficiency, which contributes to growth failure, diarrhea, and pneumonia. (The deficiency symptoms of these nutrients and those of the other vitamins and minerals are presented in Chapters 10 through 13.)

The consequences of nutrient deficiencies are felt not only by individuals, but also by entire nations. When people suffer from mental retardation, blindness, infections, and other consequences of malnutrition, the economy of their country declines as productivity decreases and health-care costs increase. The dramatic signs of malnutrition are most evident at each end of the life span in a nation's high infant mortality rate and short life expectancy.

## Growth Failure

In addition to specific nutrient deficiencies, inadequate food intake leads to poor growth in children. Nearly one in four children in the developing world is severely underweight by the age of 5. These underweight children are malnourished and readily develop the diseases of poverty: parasitic and infectious diseases that cause diarrhea (dysentery and cholera), acute respiratory illnesses (pneumonia and whooping cough), measles, and malaria.[30] The synergistic combination of infectious disease and malnutrition dramatically increases the likelihood of early death. Compared with adequately nourished children, the risk of death is 2.5 times greater for children with mild malnutrition, 4.6 times greater for children with moderate malnutrition, and 8.4 times greater for children with severe malnutrition. Each year, 7.6 million children younger than the age of 5 die; as many as 5 children *every minute* die as a result of hunger and malnutrition.[31] Most of them do not starve to death—they die from the diarrhea and dehydration that accompany infections.

Poor growth due to malnutrition is easy to overlook because a small child may look quite normal, but it is the most common sign of malnutrition. Growth may be impaired in two ways. Children who are suffering from **acute malnutrition** (recent severe food deprivation) may be underweight for their height (described as *wasting*). By comparison, children who have experienced **chronic malnutrition** (long-term food deprivation) are short for their age (described as *stunting*). An estimated

© Eddie Gerald / Alamy

Donated food may temporarily ease hunger for some, but it is usually insufficient to prevent nutrient deficiencies or support growth.

**acute malnutrition:** malnutrition caused by recent severe food restriction; characterized in children by underweight for height (*wasting*).

**chronic malnutrition:** malnutrition caused by long-term food deprivation; characterized in children by short height for age (*stunting*).

*Nutrients associated with deficiencies that have characteristic clinical symptoms are sometimes referred to as Type I nutrients. Examples include iron (anemia), vitamin C (scurvy), and iodine (cretinism).

The edema characteristic of kwashiorkor is apparent in this child's swollen belly. Malnourished children commonly have an enlarged abdomen from parasites as well.

**kwashiorkor** (kwash-ee-OR-core or kwash-ee-or-CORE): severe malnutrition characterized by failure to grow and develop, edema, changes in the pigmentation of hair and skin, fatty liver, anemia, and apathy.

**marasmus** (ma-RAZ-mus): severe malnutrition characterized by poor growth, dramatic weight loss, loss of body fat and muscle, and apathy.

25 percent of the world's children younger than the age of 5 are stunted and about 10 percent are wasted.[32] Children with both stunting and wasting have an exceptionally high risk of mortality.[33] Table 20-2 compares key features of acute malnutrition with those of chronic malnutrition.

Acute malnutrition presents itself in two clinical forms: marasmus and kwashiorkor. Historically, **kwashiorkor** was attributed to protein deficiency and **marasmus** was attributed to energy deficiency. Together, they were named *protein-energy malnutrition*. Traditional thinking about protein-energy malnutrition was challenged by findings that the diets of children with marasmus or kwashiorkor do not differ. Furthermore, treatment based on the concepts of protein-energy malnutrition failed to restore physiological homeostasis or healthy body composition.[34] Most cases are a mix of the two diseases.[35] Interestingly, children who develop kwashiorkor weigh almost ¾ pound more at birth than those who develop marasmus, suggesting a role for prenatal factors.[36]

Current understanding of kwashiorkor and marasmus recognizes that the primary cause of malnutrition is a deficiency of *many* nutrients, including amino acids, potassium, magnesium, zinc, and phosphorus.* Such poor-quality diets result in loss of appetite, diminished growth, and inability to resist infection or respond to environmental stresses. The following paragraphs present descriptions of the kwashiorkor and marasmus.

**Kwashiorkor** *Kwashiorkor* is a Ghanaian word that refers to the birth position of a child and is used to describe the illness a child develops when the next child is born. When a mother who has been nursing her first child bears a second child, she weans the first child and puts the second one on the breast. The first child, suddenly switched from nutrient-dense, protein-rich breast milk to a starchy, nutrient-poor cereal, soon begins to sicken and die. The child appears withdrawn or irritable and obviously ill. Loss of appetite interferes with any attempts to provide nourishment.

In kwashiorkor, some muscle wasting may occur, but it may not be apparent because the child's face, limbs, and abdomen become swollen with edema—a distinguishing feature of kwashiorkor. Fluid balance shifts in response to decreased concentrations of the blood protein albumin. A fatty liver develops because of a lack of the protein carriers to transport lipids out of the liver. The fatty liver lacks enzymes to clear metabolic toxins from the body, so their harmful effects are prolonged. Inflammation in response to these toxins and to infections further contributes to the edema that accompanies kwashiorkor. Without sufficient tyrosine to make melanin, hair loses its color, and inadequate protein synthesis leaves the skin patchy and scaly, often with sores that fail to heal. The lack of proteins to carry or store iron leaves iron free. Free iron is common in kwashiorkor and may contribute to edema by increasing the secretion of ADH—the antidiuretic hormone responsible for water retention. In addition, iron may contribute to illness and death by promoting bacterial growth and free-radical damage. (Free-radical damage is discussed fully in Highlight 11.)

**Marasmus** Appropriately named from the Greek word meaning "dying away," marasmus occurs most commonly in children in all the overpopulated and impoverished areas of the world. Children living in poverty simply do not have enough to eat. They subsist on diluted cereal drinks that supply scant energy and protein of low quality; such food can barely sustain life, much less support growth. The loose skin on the buttocks and thighs sags down and looks as if the child is wearing baggy pants. Sadly, children with marasmus are often described as just "skin and bones."

*Nutrients associated with deficiencies that impair growth, but have no characteristic clinical symptoms, are sometimes referred to as Type II nutrients. Examples include essential amino acids, potassium, sodium, magnesium, zinc, and phosphorus.

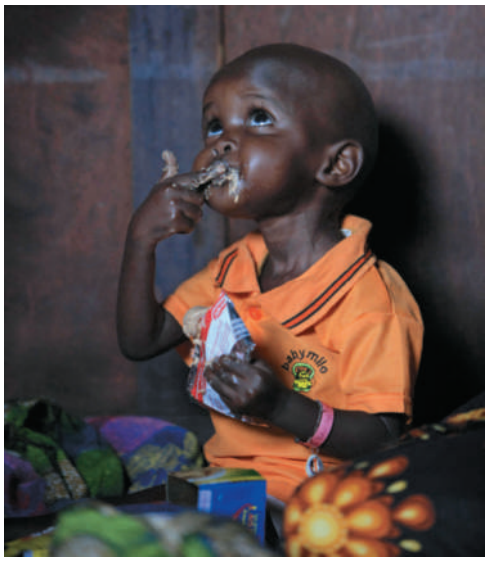
Because the brain normally grows to almost its full adult size within the first 2 years of life, marasmus impairs brain development and learning ability. Reduced synthesis of key hormones slows metabolism and lowers body temperature. There is little or no fat under the skin to insulate against cold. Hospital workers find that children with marasmus need to be clothed, covered, and kept warm. Because these children often suffer delays in their mental and behavioral development, they also need loving care, a stimulating environment, and parental attention.

The starving child faces this threat to life by engaging in as little activity as possible—not even crying for food. The body musters all its forces to meet the crisis, so it cuts down on any expenditure of energy not needed for the functioning of the heart, lungs, and brain. Growth ceases; the child is no larger at age 4 than at age 2. Enzymes are in short supply, and the GI tract lining deteriorates. Consequently, what little food is eaten can't be digested and absorbed.

AP Images/Farah Abdi Warsameh



The severe wasting characteristic of marasmus is apparent in this child's "matchstick" arms.

**Rehabilitation** Ideally, optimal breastfeeding and improved complementary feedings would prevent malnutrition and save the lives of children. When mild to moderate malnutrition did occur, it might be quickly remedied with supplemental foods in the community. Severe acute malnutrition, on the other hand, requires hospitalization, which demands intensive nursing care, a therapeutic diet, and medication.[37]

Because the causes of malnutrition extend beyond insufficient food to include an individual's genetics, environmental stresses, and gastrointestinal bacteria, treatment must be individualized. Providing foods fortified with multiple vitamins and minerals protects against some deficiency diseases; whether it improves illnesses, growth, or cognition is less clear.[38] To support physical growth, mental development, metabolic balance, and recovery from illnesses, malnourished children need specially formulated diets. They also need antibiotics to alter the GI bacteria, improve recovery rates, and decrease mortality; the GI bacteria of children with kwashiorkor impair energy metabolism and contribute to weight loss.[39]

To ensure rapid weight gain and correct nutrient deficiencies, children suffering from uncomplicated, but severe acute malnutrition may be given ready-to-use therapeutic food (RUTF)—a paste made of local commodities such as peanut butter and powdered milk and fortified with vitamins and minerals.[40] Because it does not need to be mixed with water, the risk of bacterial contamination is greatly minimized. Another benefit is that it can be stored for 3 to 4 months without refrigeration. Whether these therapeutic foods should be used for the *prevention* of childhood malnutrition is currently being considered.[41]

In addition to nutrition intervention, children suffering from diarrhea commonly need rehydration. In severe cases, diarrhea will have incurred dramatic fluid and mineral losses that need to be replaced immediately to help raise the blood pressure and strengthen the heartbeat. Health-care workers around the world save millions of lives each year by effectively reversing dehydration and correcting the diarrhea with **oral rehydration therapy (ORT).** ORT is a simple, inexpensive, and effective treatment that consists of giving a sugar and salt solution orally. In addition to ORT, adequate sanitation and clean water are essential to prevent death from diarrheal disease.

© ERIC DESSONS/JDD/SIPA/Newscom

Ready-to-use therapeutic food (RUTF)—made of peanut butter and powdered milk fortified with vitamins and minerals—nourishes hundreds of thousands of malnourished children each year.

**› REVIEW IT** Describe the consequences of nutrient and energy inadequacies.

Hunger leads to malnutrition, which appears most evident in nutrient deficiencies and growth failure. Children suffering from acute malnutrition (recent severe food deprivation) may be underweight for their height, while those experiencing chronic malnutrition (long-term food deprivation) are short for their age. Problems resulting from nutrient deficiencies include preterm births and low birth weights (iron), stillbirths and cretinism (iodine), blindness (vitamin A), and growth failure (zinc). Treatment should be individualized to ensure rapid weight gain and correct nutrient deficiencies.

**oral rehydration therapy (ORT):** the administration of a simple solution of sugar, salt, and water, taken by mouth, to treat dehydration caused by diarrhea. A simple ORT recipe:

- ½ L boiling water
- 4 tsp sugar
- ½ tsp salt

# 20.4 The Global Environment

**› LEARN IT** Explain why relieving environmental problems will also help to alleviate hunger and poverty.

The world currently produces enough food to feed all of its people, and the problem of hunger today remains a problem of unequal distribution of land to grow crops or income to purchase foods. If present trends continue, however, the time is fast approaching when there will be an absolute deficit of food. This conclusion seems inescapable. The world's increasing population threatens the world's capacity to produce adequate food.

In recent years, even as crop yields set new record highs, more people needed more food and reserves dwindled. Food prices skyrocketed as the costs of energy and fertilizer increased dramatically. Hunger worsened as the world experienced its worst **food crisis** in a generation.[42] Efforts to identify some of the causes of, and possible solutions for, hunger have focused on the environment.

## Hunger and Environment Connections

Hunger interacts with the environment in two major ways:

- Food production to feed billions of people around the world damages the environment.
- A damaged environment cannot support food production to feed billions of people around the world.

Without concerted efforts to improve food production in ways that will protect the environment, the vicious cycle of hunger and environmental degradation will continue, and poverty and population growth will escalate.

### Planting Crops

Producing food costs the earth dearly. To grow food, we clear land—prairie, wetland, and forest—replacing native ecosystems with crops. The soil loses nutrients as each crop is harvested, so fertilizer is applied. Some nitrogen in the fertilizer is released as a gas that contributes to greenhouse gas emissions. With rain or irrigation, fertilizer runs off into the waterways and stimulates algae growth. As the algae dies and decomposes, it depletes oxygen, forming **dead zones** and killing marine life. Some plowed soil erodes into the waterways and interferes with the growth of aquatic plants and animals.

AP Images/Imaginechina/Zhang jun jx

Without water, croplands become deserts.

To protect crops against weeds and pests, farmers apply herbicides and pesticides, which also kill native plants, native insects, and animals that eat those plants and insects. Ironically, with continued widespread use of pesticides and herbicides, pests and weeds become more resistant. Consequently, farmers must use more pesticides and herbicides. These chemicals pose hazards for farm workers who handle them, and the residues can create health problems for consumers as well (as Chapter 19 discusses).

Finally, when fields are irrigated, the water evaporates, but the salts do not. As salts accumulate on the soil surface, plant growth fails. Irrigation can also deplete the water supply over time as much of the water taken from surface waters or from underground evaporates or runs off. Excessive irrigation can dry up rivers and lakes and lower the water table of entire regions. A vicious cycle develops. The drier the region becomes, the more farmers must irrigate, and the more they irrigate, the drier the region becomes.

### Raising Livestock

Raising livestock also takes an enormous toll on land and energy resources.[43] Like plant crops, herds of livestock occupy land that once maintained itself in a natural state. The land suffers losses of native plants and animals, soil erosion, water depletion, and desert formation. Animals raised in large concentrated areas such as cattle feedlots or hog farms create environmental problems when huge masses of animal wastes are produced. In an effort to prevent contamination of local soils and water supplies, the US Environmental Protection Agency offers incentives to livestock farmers who clean up their wastes and allow inspections. In addition to manure, animals produce large quantities of methane—a greenhouse gas that may contribute to climate change.

**food crisis:** a sharp rise in the rates of hunger and malnutrition, usually set off by a shock to either the supply of, or demand for, food and a sudden spike in food prices.

**dead zones:** oxygen-depleted areas of bodies of water in which marine life cannot survive; often caused by algae overgrowth that occurs when agricultural fertilizers and wastes enter the waterways.

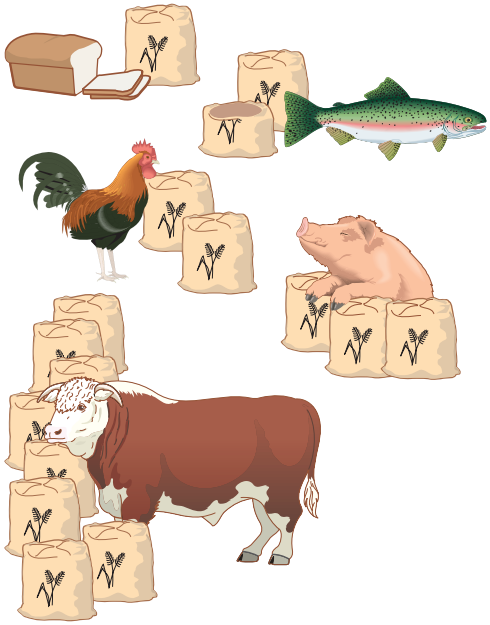
In addition to the waste problems, animals in feedlots must be fed and grain is grown for them on other land. That grain may require fertilizers, herbicides, pesticides, and irrigation, too. In the United States, more cropland is used to produce grains for livestock than to produce grains for people. Figure 20-5 compares the grain required to produce various foods.

**Fishing** Fishing also incurs environmental costs. On the sea, we harvest fish, often with little thought to the dwindling supplies or the environmental damage incurred. Excessive fishing—catching fish at a faster rate than they can reproduce—diminishes the availability of seafood for people to eat, upsets the balance of marine life, and reduces water quality. Some fishing methods, such as nets and filament line, kill nonfood species and deplete large populations of aquatic animals such as dolphins. Some fishing methods damage the ocean floor. Table H20-1 (p. 685) in the highlight that follows this chapter presents lists of seafood sorted from an environmental perspective.

Catching wild fish cannot keep pace with consumer consumption. The shortfall has spurred the rapid growth of **aquaculture,** which now provides roughly half of the world's food fish and shellfish.[44] It continues to grow more rapidly than any other kind of food animal production.

Some aquaculture "farms" consist of vast net cages that enclose fish in ocean water or freshwater lakes, where natural water flow refreshes the cages. Other types of farms house fish in artificial ponds of various shapes positioned inland close to natural water or farther inland. On the coast, natural water is diverted through the ponds, bringing fresh water in and carrying out wastes. Farther inland, pond water is continuously filtered and cleansed, recycling through the ponds. All farmed fish must be fed, and fish chow consists of grains and fish harvested from wild species, diminishing their stocks for human consumption. Adequate environmental safeguards are a must to prevent environmental degradation from aquaculture. Aquaculture can be sustainable, however, with the appropriate technologies and practices.

Fishing is also energy-intensive, requiring fuel for boats, refrigeration, processing, packing, and transport. Water pollution incurs health risks when people eat contaminated fish. Bioaccumulation of toxins in fish may rule out fish consumption altogether in some areas (review Figure 19-6, p. 639).



**Energy Overuse** The entire food industry, whether based on growing crops, raising livestock, or fishing, requires energy, which primarily entails burning **fossil fuels.** Massive fossil fuel use threatens the environment by causing air and water pollution, changing climate patterns, depleting the ozone layer, and more. In the United States, the food industry consumes about 20 percent of all the energy the nation uses. Most of this energy is used to run farm machinery and to produce fertilizers and pesticides. Energy is also used to process, package, transport, refrigerate, store, and prepare foods. Suggested changes that might reduce fossil fuel energy include:

- Using small machinery and less fuel
- Replacing fertilizer with cover crops and manure
- Tilling to reduce soil erosion
- Reducing consumption of meat and dairy products (to levels of nutrient adequacy without excess)
- Limiting transportation distances
- Combining efficient practices with renewable systems (such as biomass and photovoltaic cells)

**Water Misuse** Food production also uses an enormous amount of water. It takes an estimated 1.5 million gallons of water to produce the food for one US consumer for 1 year. Consider that it takes 10 gallons of water to produce 1 slice of bread, 100 gallons to produce 1 pound of corn, and 10,000 gallons to produce 1 pound of hamburger meat. According to the Environmental Protection Agency,

**> FIGURE 20-5 Pounds of Grain Needed to Produce 1 Pound of Bread and 1 Pound of Animal Weight Gain**

To gain 1 pound, animals raised for food have to eat many more pounds of grain than it takes to make a pound of bread.

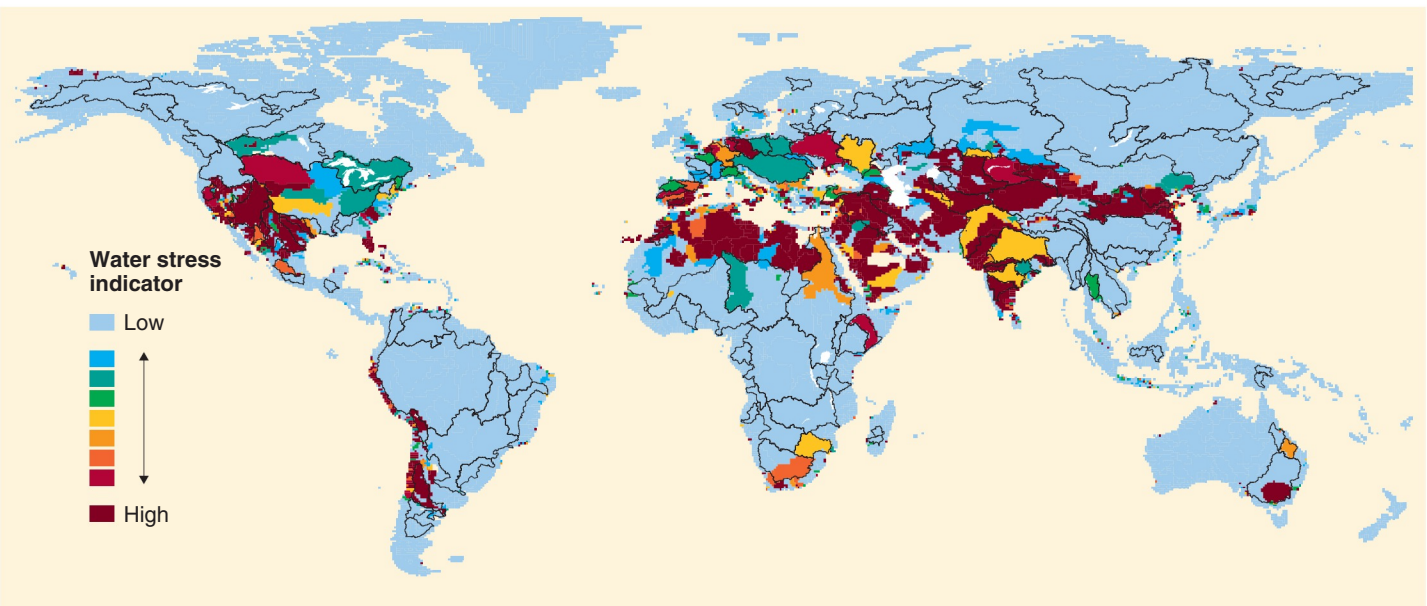
current farming practices are responsible for an estimated 70 percent of the pollution in US rivers and streams. Growing crops adds sediment, nutrients, and pesticides to the water. Irrigating crops depletes groundwater supplies, causing the land to become desert, which ironically can lead to flooding.

As human populations grow, so does the demand for clean potable water. In areas of high **water stress,** natural and manmade influences converge to limit access to safe drinking water (see Figure 20-6). Poor water management causes many of the world's water problems. Each day, people dump 2 million tons of waste into the world's rivers, lakes, and streams. More than 4000 children die each day because of unclean water and poor sanitation. By 2025, if present patterns continue, two of every three persons on earth will live in water-stressed regions of the world.[45]

**Biodiversity** Biodiversity is declining.[46] By the year 2050, some 40,000 plant species may become extinct. Agricultural practices and the increasing uniformity of global food habits have contributed to the loss of species. Wheat, rice, soybeans, and maize provide 75 percent of the food energy around the world.[47] Only two dozen other crops provide the remainder. As people everywhere eat the same limited array of foods, demand for a local regions' native, genetically diverse plants is no longer financially worth preserving. Yet, in the future, as the climate and environment change, those very plants may be needed for food. A wild species of corn that grows in a dry climate, for example, might contain the genetic information necessary to help make domestic corn resistant to drought.

**Food Waste** Food waste has a major environmental impact—both by squandering resources and by contributing to greenhouse gases. More than 1 billion tons of food is wasted each year.[48] As a consequence, the many resources used in the production of these foods are also wasted. Each year, food waste accounts for more than 25 percent of the water used and about 300 million barrels of oil. In addition, the methane and carbon dioxide from decomposing food contributes to greenhouse gases and climate change.



In short, food production takes a tremendous toll on the environment. And environmental problems are reducing the world's ability to feed its people and keep them healthy. For the most part, our food production systems are not **sustainable.**

**water stress:** intense demands on water resources by human activities such as municipal water supplies, industries, power plants, and agriculture.

**sustainable:** able to continue indefinitely; using resources at such a rate that the earth can keep on replacing them and producing pollutants at a rate with which the environment and human cleanup efforts can keep pace, so that no net accumulation of pollution occurs.

> **FIGURE 20-6 Water-Stress Hot Spots**

"Water stress" reflects the amount of pressure placed on water resources by users such as municipal water systems, industries, power plants, and agricultural users. As human population increases in an area, water stress worsens.

**Sustainable Solutions** Can advances in agriculture compensate for the increases in population growth and the losses caused by environmental degradation? Historically, agricultural yields improved with advances in irrigation systems, fertilizers, and genetic strains. Today, however, the contributions these measures can make are reaching their limits, in part because they have also created environmental problems.

Adding more irrigation would not increase crop yields because almost all the land that can benefit from irrigation is already receiving it. In fact, rising concentrations of salt in the soil—a by-product of irrigation—are *lowering* yields on many of the world's irrigated croplands.

Nor can fertilizer use significantly enhance agricultural production. Much of the fertilizing that can be done is being done—and with great effect; fertilizers support some 40 percent of the world's total crop yields. Using more fertilizer, however, would not increase yields further and would add to the pollution of nearby waterways.

As for the development of high-yielding strains of crops, recent advances have been dramatic, but even they may be inadequate to meet increasing needs. Furthermore, the raw materials necessary for developing new crops have become less available as genetic variation for many plant species is lost. Of the 5000 food plants grown throughout the world a few centuries ago, only 150 are cultivated in commercial agriculture today. Most of the world's population relies on only five cereals, three legumes, and three root crops to meet their energy needs. Even among these, valuable strains are vanishing.

Janine Wiedel Photolibrary / Alamy

Each person's choice to get involved and be heard can help lead to needed change.

**Sustainable Agriculture** For each environmental problem, agricultural solutions are being considered. Many farmers are implementing **sustainable agriculture** practices that can be adapted to meet the particular needs of a local area. The crop yields from farms that employ these practices often compare favorably with those from farms using less sustainable methods. Table 20-3 (p. 678) contrasts low-input, sustainable agriculture methods with high-input, unsustainable methods. Many sustainable practices are not really new, incidentally; they would be familiar to our great-grandparents. Farmers today are rediscovering the benefits of traditional techniques as they adapt and experiment with them in search of sustainable methods.

**Sustainable Development** Both developed and developing nations can work to resolve the world's hunger, poverty, and environmental problems in their own ways. The poor, developing nations need to provide contraceptive technology and family planning information to their citizens, develop better programs to assist the poor, and slow and reverse the destruction of environmental resources. The rich, developed nations need to stem their wasteful and polluting uses of resources and energy, which are contributing to global environmental degradation. They also must become willing to ease the debt burden that many poor nations face. Relieving poverty will help relieve environmental degradation and hunger.

To rephrase a well-known adage: If you give a man a fish, he will eat for a day. If you teach him to fish and enable him to buy and maintain his own gear and bait, he will eat for a lifetime and help to feed others. Unlike food giveaways and money doles, which are only stopgap measures, social programs that permanently improve the lives of the poor can permanently solve the hunger problem.

**Sustainable Actions** Dietitians and foodservice managers have a special role to play, and their efforts can make an impressive difference. Their professional organization, the Academy of Nutrition and Dietetics, urges members to conserve resources and minimize waste in both their professional and their personal lives. In addition, members can educate themselves and others on hunger, its consequences, and programs to fight it; conduct research on the effectiveness and

**sustainable agriculture:** ability to produce food indefinitely, with little or no harm to the environment.

**TABLE 20-3 Agricultural Methods Compared**

| Environmental Issues | Unsustainable Methods | Sustainable Methods |
|---|---|---|
| Soil | Growing the same crop repeatedly on the same land takes nutrients out of the soil, making fertilizer use necessary; favors soil erosion; and invites weeds and pests to become established, making pesticide use necessary. | Rotating crops increases nitrogen in the soil so there is less need to use fertilizers. |
| | | Using appropriate plowing methods reduces soil erosion and problems caused by weeds and pests. |
| | Plowing the same way everywhere, allows water runoff and erosion. | Using cover crops, crop rotation, no-till planting, contour planting, ridge till, mulch, terraces, and grass strips conserves both soil and water. |
| Fertilizer | Using fertilizers pollutes ground and surface water and increases costs. | Reducing the use of fertilizers and using livestock manure more effectively lowers costs. |
| | | Planting cover crops, such as legumes, after harvest restores nutrients and reduces erosion. |
| | | Composting all plant residues not harvested into the soil improves its nutrient content and water-holding capacity. |
| Livestock | Feeding livestock in feedlots concentrates manure that pollutes water and releases methane, a global warming gas. | Feeding livestock or buffalo on the open range allows their manure to fertilize the ground. |
| | Injecting animals with antibiotics prevents diseases. | Collecting feedlot animals' manure enables it to be used as fertilizer or treated before it is released. |
| | | Maintaining animals' health can prevent disease. |
| Herbicide/ pesticide | Spraying herbicides and pesticides over large areas wipes out weeds, pests, and other plants and insects. | Using crop rotations, cover crops, and mechanical cultivation can control weeds. |
| | | Using resistant crops and rotating crops foils pests that lay their eggs in the soil where last year's crop was grown. |
| | | Using biological controls such as predators can destroy pests. |
| Water | Irrigating on a large scale depletes water supplies and concentrates salts in the soil. | Irrigating only during dry spells and applying only spot irrigation conserves water. |
| Energy | Using only fossil fuels depletes resources. | Using renewable energy technologies such as hydroelectric, biomass, photovoltaics, wind power, solar thermal, geothermal, biogas, and methanol conserves resources. |
| | | Using machinery scaled to the job at hand, and operating it at efficient speeds conserves energy. |
| | | Combining operations such as harrowing, planting, and fertilizing in the same operation conserves energy. |

"We do not inherit the earth from our ancestors, we borrow it from our children." —ascribed to Chief Seattle, a 19th-century Native American leader

benefits of programs; and serve as advocates on the local, state, and national levels to help end hunger in the United States. Globally, these professionals support programs that combat malnutrition, provide food security, promote **sustainable foods,** respect local cultures, protect the environment, and sustain the economy.[49]

Indeed, every segment of our society can join in the fight against hunger, poverty, and environmental degradation. The federal government, the states, local communities, big business and small companies, educators, and all individuals have many opportunities to resolve these problems.

Resolving the hunger problem may seem at first beyond the influence of an individual. Can one person's choice to reduce food waste or to recycle a bottle or to volunteer at a food recovery program make a difference? In truth, such choices produce several benefits. For one, a person's action may influence many other people over time. For another, a repeated action becomes a habit, with compounded benefits. For still another, making choices with an awareness of the consequences improves behaviors and gives a person a sense of personal control, hope, and effectiveness. The daily actions of many concerned people can help solve the problems of hunger in their own communities or on the other side of the world. As Margaret Mead said, "Never doubt that a small group of thoughtful, committed people can change the world. Indeed, it is the only thing that ever has."

Individuals can assist the global community in solving its poverty and hunger problems by joining and working for hunger-relief organizations (see Table 20-4). They can also support the needed changes in economic policies that influence food availability and price volatility both at home and in developing countries.[50]

**sustainable foods:** foods produced by farmers and ranchers who care for the health of their animals and the land; sourced locally and seasonally; cooked from scratch to minimize processed ingredients; and beneficial for the environment, the growers, and the consumers.

© Cengage Learning

Most importantly, all individuals can try to make lifestyle choices that consider the environmental consequences. Many small decisions each day have major consequences for the environment. Highlight 20 describes how consumers can conserve resources and minimize waste when making food-related choices.

The personal rewards of making environmentally friendly food choices are many, from saving money to the satisfaction of knowing that you are treading lightly on the earth. But do they really help? They do, if enough people join in. Because we number more than 7 billion, individual actions can add up to exert an immense impact.

"Be part of the solution, not part of the problem" another adage says. In other words, don't waste time or energy moaning and groaning about how bad things are. Do something to improve them. They are our problems; human beings created them, and human beings must solve them.

**› REVIEW IT** Explain why relieving environmental problems will also help to alleviate hunger and poverty.

Environmental degradation reduces our ability to produce enough food to feed the world's people. The rapid increase in the world's population exacerbates the situation. The global environment, which supports all life, is deteriorating, largely because of our irresponsible use of resources and energy. Governments, businesses, and all individuals have many opportunities to make environmentally conscious choices, which may help solve the hunger problem, improve quality of life, and generate jobs. Personal choices, made by many people, can have a great impact.

## Nutrition Portfolio

Your choice to get involved in the fight against hunger—whether in your community or across the globe—can make a big difference in the health and survival of others.

- Find out about the hunger-relief programs in your area.
- Write to your legislators and voice your opinions on issues such as food assistance programs, environmental degradation, and international debt relief.
- Read the highlight (pp. 682–687) and consider which environmentally friendly behaviors you are willing to adopt when making food-related choices.

DIET & WELLNESS PLUS To complete this exercise, go to your Diet & Wellness Plus at **www.cengagebrain.com.**

**› STUDY IT** To review the key points of this chapter and take a practice quiz, go to the study cards at the end of the book.

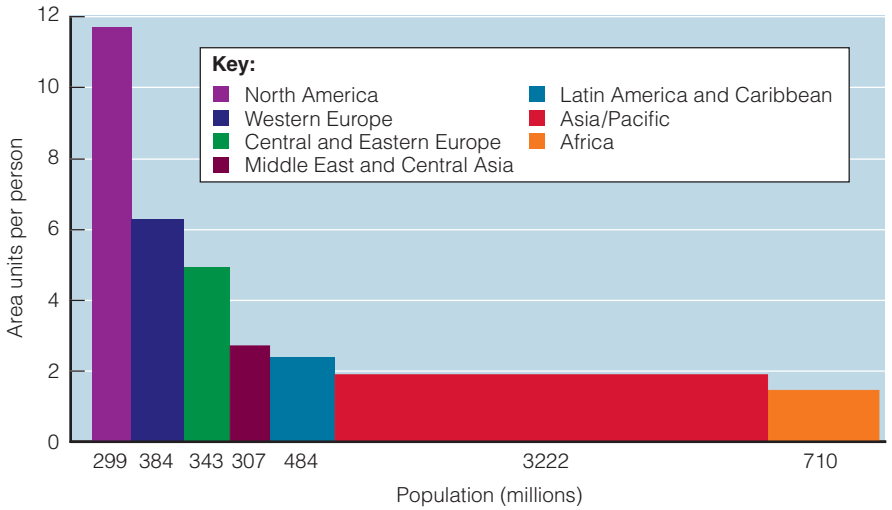
# HIGHLIGHT > 20
# Environmentally Friendly Food Choices

Randy Faris/Bridge/Corbis

**› LEARN IT** Discuss ways consumers can conserve resources when making food-related choices.

Chapter 20 concludes its examination of US and world hunger by focusing on the environment. It explains how producing enough food to feed billions of people around the world damages the environment—and how a damaged environment cannot adequately feed billions of people around the world. Efforts to resolve hunger and protect the environment demand improvements in our ways of producing, processing, packaging, transporting, storing, and preparing foods. Because sustainable food strategies have social, economic, and environmental impacts, their success depends on pleasing the people, providing reasonably priced products, and protecting the planet. Consumers' preferences for sustainable practices seems to be a growing trend.[1]

The United Nations describes a nation's impact on the environment as its "ecological footprint"—a measure of the resources used to support a nation's consumption of food, materials, and energy. This measure takes into account the two most challenging aspects of sustainability—per capita resource consumption and population growth. As Figure H20-1 shows, the people of North America are the world's greatest consumers on a per capita basis. Some have estimated that it would take four more planet earths to accommodate every person in the world using resources at the level currently used in the United States. This highlight explores ways that consumers can conserve resources when making food-related choices. Such conscientious food choices can reduce pollution production and resource use. The accompanying "How To" feature asks questions to determine your "food footprint"—a measure of the environmental impacts of food production, stated in terms of land usage.



## Choice: Animal or Vegetable?

Some foods require more water, more fertilizer, more pesticides, and more energy for their production than others. One way to reduce these costs of food production is for consumers to eat low on the food chain. For the most part, that means eating more foods derived from plants and fewer foods derived from animals. Compared with vegetarian diets, meat-based diets use 2.9 times more water, 2.5 times more energy, 13 times more fertilizer, and 1.4 times more pesticides.

Consider that relatively little energy is needed to produce grains: it takes less than 1 kcalorie of fuel to produce each kcalorie of grain, whereas most animal-derived foods require from 10 to 90 kcalories of fuel per kcalorie of edible food; kcalories to produce fruits and vegetables are generally greater than grains, but less than animal-derived foods. In general, meat-based diets require much more energy, as well as more land and water, than do plant-based diets. An exception is livestock raised on the open range; these animals require about as much energy as most plant foods. Because we raise so much more grain-fed, than range-fed, livestock, however, the average energy requirement for meat production is high. Figure H20-2 (p. 684) shows how much less fuel vegetarian diets require than meat-based diets and shows that vegan diets require the least fuel of all.

**> FIGURE H20-1 Ecological Footprints**

The width of a bar represents the region's population, and the height represents per capita consumption (in terms of area of productive land or sea required to produce the natural resources consumed). Thus the footprint of the bar represents the region's total consumption. For example, Asia's population is more than 10 times as great as North America's, but because its consumption is only one-sixth as large, their footprints are similar in size.

## >How To

### Determine Your Food Footprint

What's your food footprint? Answer the following questions, add up your score, and use the key below to determine how many acres are used to support your food habits.

1. How often do you eat meat?
   a. I'm vegan. (I eat no animal products.)
   b. I'm a vegetarian. (I don't eat any meat.)
   c. I eat meat 1 to 4 days a week.
   d. I eat meat every day.

2. If you eat meat, which type of meat do you eat most often?
   a. I told you already, I don't eat meat!
   b. Turkey or chicken
   c. Lamb or pork
   d. Beef

3. How often do you eat fast food?
   a. I never eat fast food.
   b. Sometimes; 2–3 times a month.
   c. I eat fast food a lot. But I would rather eat healthy!
   d. I love fast food. I would eat it everyday if I could (and sometimes I do).

4. How often do you buy food from local farmers' markets?
   a. I go to the farmers' market every week.
   b. I go to the farmers' market sometimes; maybe once a month.
   c. I don't know of any farmers' markets but I am interested in going!
   d. Never; I am not really interested in starting.

5. How much of your own food do you grow?
   a. I grow lots of my own food! I have a garden or a farm.
   b. I grow some food. I have a few plants in my yard or window garden.
   c. I don't have a garden but I would like to grow some food.
   d. I have never grown any food; I'm not that interested.

6. Do you try to eat food that is in season?
   a. Yes, I only eat food that is in season.
   b. Sometimes if I remember.
   c. I don't know what food is in season when, but I would like to learn.
   d. No, I eat what I want when I want.

7. How often do you eat home-cooked food?
   a. I eat home-cooked food almost every night.
   b. I eat home-cooked food 3-5 times a week.
   c. I eat out a lot, but I would eat more home-cooked food if I knew how.
   d. I never eat home-cooked food.

8. Do you try to buy fruit and vegetables that were grown locally or in your state?
   a. I always check to see where my food is grown. If it isn't grown locally, I don't buy it.
   b. I try to buy locally grown fruits and vegetables usually but not always.
   c. I never thought about where my food was grown. I will try to eat more local food.
   d. I don't care where my food comes from.

1 point for every **a** answer
2 points for every **b** answer
3 points for every **c** answer
5 points for every **d** answer

**Your Score**

**8–14** Congratulations, you have awesome eating habits! Your next challenge: work to make sure ALL people have access to healthy, affordable food.

**15–24** Not too bad. Seems like you have some good eating habits and aspire to have even better ones. 10–24 acres are used to support your food habits. Unfortunately we would still need at least one more planet to support your consumption.

**25–33** Yikes, big foot! It seems some of your habits are damaging to the environment. 24–40 acres are used to support your food habits. We would need 3–4 more planets to sustain your lifestyle into the future.

› **TRY IT** Review the questions with high scores and list steps you can take to reduce your food footprint.

# HIGHLIGHT > 20

**> FIGURE H20-2 Amounts of Fuel Required to Feed People Eating at Different Points on the Food Chain**

Three people who eat differently are compared here. Each has the same energy intake: 3300 kcalories a day. The fossil fuel amounts necessary to produce these different diets are calculated based on US conditions.

© Cengage Learning

To support our meat intake, we maintain several billion livestock, about four times our own weight in animals. Livestock consume 10 times as much grain each day as we do. We could use much of that grain to make grain products for ourselves and for others around the world. Making this shift could free up enough grain to feed 400 million people while using less fuel, water, and land.

Part of the solution to the livestock problem may be to cease feeding grain to animals and return to grazing them on the open range, which can be a sustainable practice. Ranchers have to manage the grazing carefully to hold the cattle's numbers to what the land can support without environmental degradation. To accomplish this, the economic benefits of traditional livestock and feed-growing operations would have to end. If producers were to pay the true costs of the environmental damage incurred by irrigation water, fertilizers, pesticides, and fuels, the price of meats might double or triple. According to classic economic theory, people would then buy less meat (reducing demand), and producers would respond by producing less meat (reducing supply). Meat production would then fall to a sustainable level.

Completely eliminating meat from the diet is not necessary to design a sustainable diet that meets dietary requirements and lowers greenhouse gas emissions.[2] Consumers can choose smaller portions of meat or select range-fed beef or buffalo. Livestock on the range eat grass, which people cannot eat. "Rangeburger" buffalo also offers nutrient advantages over grain-fed beef because it is lower in fat and because the fat has more polyunsaturated fatty acids, including the omega-3 fatty acids.

Some consumers are opting for vegetarian, and even vegan, diets—at least occasionally. Choosing fish instead of meat may be a practical alternative if seafood is selected with an awareness of the environmental consequences. Table H20-1 presents seafood options grouped according to their impact on the environment.

## Choice: Global or Local?

Plant-based diets have an environmental advantage over meat-based diets, but some would argue that they don't go far enough. A more ecologically responsible diet is also based on locally grown products. On average, an item of food is transported 1500 miles before it is eaten— even when the crops are grown and the final destination are both in the United States. That our foods now travel more than we do has several costly ramifications:

- *Energetically costly.* Foods must be refrigerated and transported thousands of miles to provide a full array of all produce all year round.
- *Socially unjust.* Farmers in impoverished countries, where the people are malnourished, are paid meager wages to grow food for wealthy nations.
- *Economically unwise.* It supports agribusinesses that buy land and labor cheaply in foreign countries instead of supporting local farmers raising crops in our communities.
- *Biologically risky.* Highly perishable foods are shipped from countries with unsafe drinking water and sanitation practices.

Yellow Dog Productions/Iconica/Getty Images

Locally grown foods offer benefits to both the local economy and the global environment.

**TABLE H20-1 Environmental Impact of Commonly Eaten Seafood Choices**

| Seafood | Best Choices | Good Alternatives | Avoid |
|---|---|---|---|
| Catfish | US farmed | — | — |
| Clams | Worldwide farmed, US Pacific hand harvested, US Atlantic rake/shovel-caught | US Atlantic dredge-caught | — |
| Cod | US Pacific longline, jig, and trap-caught | US Pacific trawl-caught | US Atlantic wild-caught |
| Crab, blue | US Atlantic trotline-caught | US trap-caught | — |
| Crab, Dungeness | US Pacific trap-caught | Alaska trap-caught | — |
| Crab, Jonah | — | US Atlantic wild-caught | — |
| Crab, king | — | US trap-caught | Imported trap-caught |
| Crab, kona | Australia wild-caught | Hawaii wild-caught | — |
| Crab, snow | US trap-caught | Canada trap-caught | — |
| Crab, stone | US Atlantic and Gulf of Mexico trap-caught | — | — |
| Flounder | — | US Pacific wild-caught | — |
| Halibut | US Pacific wild-caught or handline-caught | US farmed, US Pacific bottom trawl and set netgill-caught | US Atlantic bottom trawl-caught |
| Plaice | — | US Pacific wild-caught, US Atlantic bottom trawl-caught | — |
| Pollock | — | Alaska wild caught | — |
| Salmon | US farmed, Alaska drift gillnet, purse seine, and troll-caught | US Pacific drift gillnet, purse seine, and troll-caught | Worldwide farmed |
| Scallops, bay | Worldwide farmed | US Pacific diver-caught | — |
| Scallops, sea | US Pacific diver-caught | US Atlantic wild-caught | — |
| Shrimp | US farmed, Alaska wild-caught | US Gulf of Mexico and South Atlantic wild-caught | Imported farmed, US Gulf of Mexico trawl-caught and wild-caught |
| Tilapia | US farmed | Imported farmed | — |
| Tuna, albacore[a] | US Pacific troll/pole-caught | Hawaii longline, South Atlantic troll/pole-caught | Worldwide (except Hawaii) longline, North Atlantic wild-caught |
| Tuna, bigeye | US Atlantic troll/pole-caught | Worldwide troll/pole-caught, US Atlantic longline | Worldwide except US Atlantic longline |
| Tuna, bluefin | — | — | Worldwide wild-caught and ranched |
| Tuna, skipjack[a] | Worldwide troll/pole-caught | US Atlantic and Hawaii longline | Imported longline, worldwide purse seine-caught |
| Tuna, yellowfin[a] | US Atlantic and Pacific troll/pole-caught | Worldwide troll/pole, US Atlantic and Hawaii longline | Worldwide purse seine-caught |

[a]Canned tuna is predominantly sold as either "chunk white" (albacore) or "chunk light" (yellowfin and skipjack tuna).

For all these reasons, consumers may want to support the global environment by buying locally.

Buying locally offers other benefits as well. Families buying home-grown produce tend to eat a greater quantity and selection of fruits and vegetables.

Adopting a local diet presents a bit of a challenge at first, especially when local fruits and vegetables are "out of season." But a nutritionally balanced diet of delicious foods is quite possible with a little creative planning.

## Defining *Local*

Consumers shopping for "locally grown" produce are often trying to find fresh foods that will both help support small farms and protect the environment. Grocers tapping into this "local" marketing concept have seen significant increases in sales. But what exactly does *local* mean? How far is "locally grown" from the farm to the market? Given that *local* is not defined by the FDA, consumers and grocers do not always share the same understanding of the term. Some would say *local* means reasonably nearby—say, within 10 to 50 miles, or up to 100 miles. Others say it means within a day's drive, or within the state or a geographic region. Without agreement, consumers are left to identify which goods meet their limited definition, and grocers are free to market their goods with a broad definition.

Consumers who think of *local* as "fresh from a small farm" may be surprised to learn that is not always the case. "Local" may be a corporate-managed 1000-acre tomato farm or a family-run 3-acre blueberry farm. Because large retail stores need large volumes, they tend to deal with a few large producers. Shipments typically go through a distribution center, which can delay deliveries for several hours or even days. In contrast, small producers tend to sell to farmers' markets and small stores. Deliveries often arrive within hours of harvest.

## Eco-Friendly Miles

Consumers who support the concept of purchasing local foods may believe that the fewer miles a food travels, the better for the environment—but this is not always the case. The type of transportation also contributes to environmental costs. In general, transporting by ship is cleaner than by airplane; by train is cleaner than by truck. It may be obvious that the eco-friendly choice for a person living in San Francisco is a California wine, but what about a person living in Atlanta? Is it "greener" to buy wine trucked across the country from California or shipped across the ocean from France?

## Eco-Friendly Products and Packaging

Some consumers are attracted to products and packaging that claim to be "eco-friendly," expecting far-reaching environmental benefits, even though such claims may be unsubstantiated. The Federal Trade

## >How To

### Make Environmentally Friendly Food-Related Choices

Food production taxes environmental resources and causes pollution. Consumers can make environmentally friendly choices at every step from food shopping to cooking and use of kitchen appliances to serving, cleanup, and waste disposal.

#### Food Shopping

Transportation

- Whenever possible, walk or ride a bicycle; use carpools and mass transit.
- Shop only once a week, share trips, or take turns shopping with others.
- When buying a car, choose an energy-efficient one.

Food Choices

- Choose foods low on the food chain; that is, eat more plants and fewer animals that eat plants (this suggestion also complements the *Dietary Guidelines for Americans* for eating for good health).
- Eat small portions of meat; select range-fed beef, buffalo, and poultry.
- Shop at farmers' markets and roadside stands for local foods; they require less transportation, packaging, and refrigeration.
- Limit use of imported canned beef products such as stews, chili, and corned beef that frequently come from cleared rain forest land.
- Choose seafood that has been farmed or fished in environmentally responsible ways (see Table H20-1, p. 685).
- Choose chickens from local farms.
- Plan wisely and buy smart to reduce the amount of food wasted.
- Donate excess food to food banks or shelters.
- Give food scraps to farmers for animal feed.

Food Packages

- Whenever possible, select foods with no packages; next best are minimal, reusable, or recyclable ones.
- Buy juices and sodas in large glass or recyclable plastic bottles (not small individual cans or cartons); grains, legumes, and nuts in bulk (not separate little packages); and eggs in pressed fiber cartons (not foam, unless it is recycled locally).
- Carry reusable string or cloth shopping bags; alternatively, reuse plastic bags.

#### Gardening

- Grow some of your own food, even if it is only herbs planted in pots on your kitchen windowsill.
- Compost all vegetable scraps, fruit peelings, and leftover plant foods.

#### Cooking Food

- Cook foods quickly in a stir-fry, pressure cooker, or microwave oven.
- When using the oven, bake a lot of food at one time and keep the door closed tightly.
- Use nondisposable utensils, dishes, and pans.
- Use pumps instead of spray products.
- Prepare smaller recipes to minimize waste.
- Eat leftovers.

#### Kitchen Appliances

- Use fewer small electrical appliances; open cans, mix batters, sharpen knives, and chop vegetables by hand.
- When buying a large appliance, choose an energy-efficient one.
- Consider solar power to meet home electrical needs.
- Set the water heater at <130°F (54°C), no hotter; put it on a timer; wrap it and the hot-water pipes in insulation; install water-saving faucets.
- Set the refrigerator at 37°F to 40°F and the freezer to 0°F.
- Keep all appliances clean and in good repair.

#### Food Serving, Dish Washing, and Waste Disposal

- Use "real" plates, cups, and glasses instead of disposable ones.
- Use cloth towels and napkins, reusable storage containers with lids, reusable pans, and dishcloths instead of paper towels, plastic wrap, plastic storage bags, aluminum foil, and sponges.
- Run the dishwasher only when it is full.
- Recycle all paper, glass, plastic, and aluminum.

These suggested lifestyle changes can easily be extended from food to other areas.

Commission, which is responsible for enforcing truth-in-advertising laws, has recently created "green guidelines." To claim that packaging is "biodegradable," it must completely break down and return to nature within one year. Claims of "being green" cannot be used if the environmental costs of creating and delivering the product exceed the benefits of using it. For example, it is deceptive to claim a product is eco-friendly when the environmental damage of long-distance shipping outweighs the benefits of using recycled packaging.

## Other Food-Related Choices

Eating more foods derived from plants and produced locally are two major trends that can influence the food industry. Consumers can also make dozens of other smaller decisions every day to help conserve resources and protect the environment. The accompanying "How To" feature lists some of the ways consumers can "tread lightly on the earth" through their daily food choices.

Chapter 20 and this highlight have presented many problems and have suggested that, although many of the problems are global in scope, the solutions depend on the actions of individual people at the local level. On learning of this, concerned people may take a perfectionist attitude, believing that they should be doing more than they realistically can, and so feel defeated. Keep in mind that striving for perfection even while falling short is progress. A positive attitude can bring about improvement, and sometimes improvement is enough. Celebrate the changes that are possible today by making them a permanent part of your life; do the same with changes that become possible tomorrow and every day thereafter. The results may surprise you.

## CRITICAL THINKING QUESTIONS

A. What do choices about food shopping, cooking, storage, and disposal say about a person's values?
B. At first glance, labeling appears to be a helpful way for consumers to make informed choices about the products they are buying. But given the lack of consensus on criteria to qualify as "green," manufacturers have taken advantage of this marketing scheme and slapped "eco-labels" on a variety of products with little, or no, thought given to the environment. If you served on a labeling-regulation committee, what criteria would you propose in determining which, if any, food products and packages could claim to be environmentally friendly? How important is it for consumers to adopt environmentally friendly food behaviors?

# Appendix A Cells, Hormones, and Nerves

APPENDIX A

CONTENTS

Cells
Hormones
Nerves
Putting It Together

This appendix offers an understanding of how the body coordinates its activities. It presents a brief summary of the structure and function of the body's basic working unit (the cell) and of the body's two major regulatory systems (the hormonal system and the nervous system).

## Cells

The body's organs are made up of millions of cells and of materials produced by them. Each **cell** is specialized to perform its organ's functions, but all cells have common structures (see the accompanying glossary and Figure A-l). Every cell is contained within a **cell membrane.** The cell membrane assists in moving materials into and out of the cell, and some of its special proteins act as "pumps" (described in Chapter 6). Some features of cell membranes, such as microvilli (described in Chapter 3), permit cells to interact with other cells and with their environments in highly specific ways.

Inside the membrane lies the **cytoplasm,** which is filled with **cytosol,** a jelly-like fluid. The cytoplasm contains much more than just cytosol, though. It is a highly organized system of fibers, tubes, membranes, particles, and subcellular **organelles** as complex as a city. These parts intercommunicate, manufacture and exchange materials, package and prepare materials for export, and maintain and repair themselves.

Within each cell is another membrane-enclosed body, the **nucleus.** Inside the nucleus are the **chromosomes,** which contain the genetic material, DNA. The DNA encodes all the instructions for carrying out the cell's activities. The role of DNA in coding for the synthesis of cell proteins is summarized in Figure 6-7 on p. 178. Chapter 6 also describes the variety of proteins produced by cells and some of the ways they perform the body's work.

Among the organelles within a cell are ribosomes, mitochondria, and lysosomes. Figure 6-7 briefly refers to the **ribosomes;** they assemble amino acids into proteins, following directions conveyed to them by RNA.

### GLOSSARY OF CELL STRUCTURES

**cell:** the basic structural unit of all living things.

**cell membrane:** the thin layer of tissue that surrounds the cell and encloses its contents, made primarily of lipid and protein.

**chromosomes:** structures within the nucleus of a cell made of DNA and associated proteins. Human beings have 46 chromosomes in 23 pairs. Each chromosome has many genes.

**cytoplasm** (SIGH-toh-plazm): the cell contents, except for the nucleus.

**cytosol:** the fluid of cytoplasm that contains water, ions, nutrients, and enzymes.

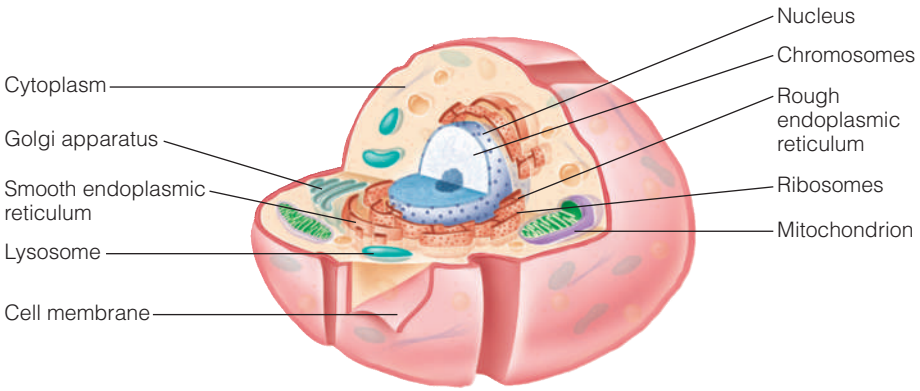
**endoplasmic reticulum** (en-doh-PLAZ-mic reh-TIC-you-lum): a complex network of intracellular membranes. The *rough endoplasmic reticulum* is dotted with ribosomes, where protein synthesis takes place. The *smooth endoplasmic reticulum* bears no ribosomes.

**Golgi** (GOAL-gee) **apparatus:** a set of membranes within the cell where secretory materials are packaged for export.

**lysosomes** (LYE-so-zomes): cellular organelles; membrane-enclosed sacs of degradative enzymes.

**mitochondria** (my-toh-KON-dree-uh): the cellular organelles responsible for producing ATP aerobically; made of membranes with enzymes mounted on them. (The singular is *mitochondrion.*)

**nucleus:** a major membrane-enclosed body within cells, which contains the cell's genetic material (DNA) embedded in chromosomes.



**organelles:** subcellular structures such as ribosomes, mitochondria, and lysosomes.

**ribosomes** (RYE-boh-zomes): protein-making organelles in cells that are composed of RNA and protein.

## > FIGURE A-I The Structure of a Typical Cell

The cell shown might be one in a gland (such as the pancreas) that produces secretory products (enzymes) for export (to the intestine). The rough endoplasmic reticulum with its ribosomes produces the enzymes; the smooth reticulum conducts them to the Golgi region; the Golgi membranes merge with the cell membrane, where the enzymes can be released into the extracellular fluid.

The **mitochondria** are made of intricately folded membranes that bear thousands of highly organized sets of enzymes on their inner and outer surfaces. Mitochondria are crucial to energy metabolism (described in Chapter 7) and muscles conditioned to work aerobically are packed with them. Their presence is implied whenever the TCA cycle and electron transport chain are mentioned because the mitochondria house the needed enzymes.*

The **lysosomes** are membrane-enclosed sacs of degradative enzymes. When a cell needs to self-destruct or to digest materials in its surroundings, its lysosomes release their enzymes. Lysosomes are active when tissue repair or remodeling is taking place—for example, in cleaning up infections, healing wounds, shaping embryonic organs, and remodeling bones.

In addition to these and other cellular organelles, the cell's cytoplasm contains a highly organized system of membranes, the **endoplasmic reticulum.** The ribosomes, mentioned earlier, may either float freely in the cytoplasm or be mounted on the endoplasmic reticulum. A surface dotted with ribosomes looks speckled under the microscope and is called "rough" endoplasmic reticulum; such a surface without ribosomes is called "smooth." Some intracellular membranes are organized into tubules that collect cellular materials, merge with the cell membrane, and discharge their contents to the outside of the cell; these membrane systems are named the **Golgi apparatus,** after the scientist who first described them. The rough and smooth endoplasmic reticula and the Golgi apparatus are continuous with one another, so secretions produced deep in the interior of the cell can be efficiently transported and released to the outside. These and other cell structures enable cells to perform a multitude of specialized functions.

The actions of cells are coordinated by both hormones and nerves. Among the types of cellular organelles are receptors for the hormones delivering instructions that originate elsewhere in the body. Some hormones penetrate the cell and its nucleus and attach to receptors on chromosomes, where they activate certain genes to initiate, stop, speed up, or slow down synthesis of certain proteins as needed. Other hormones attach to receptors on the cell surface and transmit their messages from there. The hormones are described in the next section; the nerves, in the one following.

*For the reactions of glycolysis, the TCA cycle, and the electron transport chain, see Chapter 7 and Appendix C. The reactions of glycolysis take place in the cytoplasm; the conversion of pyruvate to acetyl CoA takes place in the mitochondria, as do the TCA cycle and electron transport chain reactions. The mitochondria then release carbon dioxide, water, and ATP as their end products.

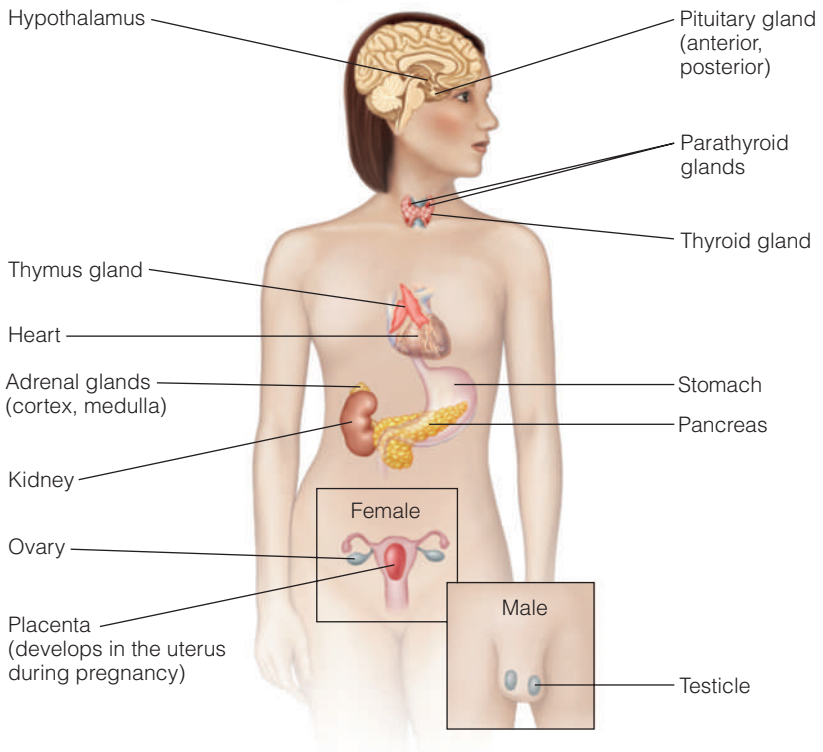
# Hormones

**Hormones** are chemical messengers secreted by a variety of glands in response to altered conditions in the body. Each hormone travels in the blood to all parts of the body, but only its specific target cells possess receptors to accept it. Only then can the hormone elicit a response to restore homeostasis.

The hormones, the glands they originate in, their target cells, and their effects are described in Table A-1. Figure A-2 identifies the glands that produce the hormones.



A hormone typically has one or more signals that turn it on and another (or others) that turns it off. Hormones are often turned off by their own effects; they are said to be regulated by *negative feedback* (see Figure 3-12 on p. 86). Consider, for example, the hormone prolactin, which promotes milk production. High prolactin levels ensure that milk is made; they also trigger the release of prolactin-inhibiting hormone (PIH), which ensures that prolactin levels don't get too high. But when the infant is suckling—and creating a demand for milk—PIH is not allowed to work (suckling turns off PIH). The consequence is that prolactin remains high, and milk production continues. Demand from the infant thus directly adjusts the supply of milk. The need is met through the interaction of the nerves and hormones.

Every body part is affected by hormones. Each different hormone has unique effects, and hormones that oppose each other are produced in carefully regulated amounts, so each can respond to the exact degree that is appropriate to the condition.

As Table A-1 summarizes, hormones have an enormous impact on body processes. The body's other overall regulating agency is the nervous system.

**> FIGURE A-2 The Endocrine System**

These organs and glands release hormones that regulate body processes. An *endocrine gland* secretes its product directly into *(endo)* the blood; for example, the pancreas cells that secrete insulin into the blood. An *exocrine gland* secretes its product(s) out *(exo)* to an epithelial surface either directly or through a duct; the sweat glands of the skin and the pancreas cells that secrete digestive enzymes into the gastrointestinal tract are both examples. The pancreas is therefore both an endocrine and an exocrine gland.

**hormones:** chemical messengers. Hormones are secreted by a variety of endocrine glands in response to altered conditions in the body. Each hormone travels to one or more specific target tissues or organs, where it elicits a specific response to maintain homeostasis. The study of hormones and their actions is called *endocrinology*.

**TABLE A-1 Summary of Major Hormones**

| Gland | Hormone | Target Cells | Action |
|---|---|---|---|
| Anterior pituitary | Adrenocorticotropin (ACTH) | Adrenal cortex | Stimulates secretion of glucocorticoids and androgens |
| Adrenal cortex | Aldosterone | Kidneys | Stimulates sodium reabsorption, thereby regulating acid-base balance, blood volume, and blood pressure |
| Posterior pituitary | Antidiuretic hormone (ADH); also called vasopressin | Arteries | Causes vasoconstriction |
| | | Kidneys | Promotes water retention |
| Thyroid gland | Calcitonin | Bones | Lowers blood calcium by moving calcium from the bloodstream into the bones whenever blood calcium rises above normal |
| | | Kidneys | Increases excretion of calcium and phosphorus |
| Duodenum | Cholecystokinin | Gallbladder | Releases bile into the intestine |
| | | Pancreas | Releases pancreatic juices into the intestine |
| Hypothalamus | Corticotropin-releasing hormone (CRH) | Anterior pituitary | Controls release of adrenocorticotropin (ACTH) |
| Kidneys | Erythropoietin | Bone marrow | Stimulates red blood cell production |
| Ovaries | Estrogens | Female sexual tissues | Promotes growth, development, and health of all tissues involved in female sexuality |
| Anterior pituitary | Follicle-stimulating hormone (FSH) | Ovaries (female) | Stimulates follicular development and ovulation |
| | | Testicles (male) | Stimulates sperm production |
| Stomach, duodenum | Gastrin | Stomach | Stimulates gastric acid secretion; slows motility |
| Hypothalamus | Growth hormone releasing hormone (GHRH) and growth hormone inhibiting hormone (GHIH or somatostatin) | Anterior pituitary | Controls release of growth hormone (GH) |
| Pancreas (alpha cells) | Glucagon | Liver | Promotes the breakdown of glycogen to glucose |
| | | Most cells | Increases use of fat and amino acids for energy |
| Adrenal cortex | Glucocorticoids | Most cells | Protects against stress; raises blood glucose |
| Hypothalamus | Gonadotropin-releasing hormone (GnRH) | Anterior pituitary | Controls release of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) |
| Anterior pituitary | Growth hormone (GH); also called somatotropin | All tissues | Stimulates growth; regulates metabolism |
| Pancreas (beta cells) | Insulin | Most cells | Stimulates nutrient uptake into cells |
| Anterior pituitary | Luteinizing hormone (LH) | Ovaries (female) | Stimulates follicular development and ovulation |
| | | Testicles (male) | Stimulates testosterone production |
| Adrenal medulla | Norepinephrine and epinephrine; formerly called noradrenalin and adrenalin, respectively | Many cells | Facilitates the body's readiness for fight or flight: maintains blood pressure, increases cardiac output, constricts blood vessels, keeps airways open, raises blood glucose levels |
| Posterior pituitary | Oxytocin | Uterus (female in late pregnancy) | Induces muscle contractions during childbirth |
| | | Mammary glands (female in lactation) | Causes milk ejection during lactation |
| Parathyroid gland | Parathyroid hormone (PTH); also called parathormone | Bones | Releases stored calcium into the blood |
| | | Kidneys | Slows calcium excretion |
| | | Intestines | Increases calcium absorption |
| Corpus luteum, placenta | Progesterone | Uterus | Facilitates implantation at the start of pregnancy |
| | | Mammary glands | Stimulates mammary gland development for lactation |
| Anterior pituitary | Prolactin | Mammary glands (female in lactation) | Stimulates milk production |
| Hypothalamus | Prolactin-inhibiting hormone (PIH) | Anterior pituitary | Controls release of prolactin |
| Duodenum | Secretin | Pancreas | Stimulates bicarbonate secretion into the intestine; slows stomach motility |
| Testicles | Testosterone | Male sexual tissues | Promotes growth, development, and health of all tissues involved in male sexuality |
| Anterior pituitary | Thyroid-stimulating hormone (TSH) | Thyroid gland | Stimulates synthesis and release of thyroid hormones (thyroxine and triiodothyronine) |
| Thyroid gland | Thyroxine | Many cells | Regulates metabolic rate, growth, and heat production |
| Hypothalamus | TSH-releasing hormone (TRH) | Anterior pituitary | Controls release of thyroid-stimulating hormone (TSH) |
| Skin | Vitamin D | Intestines | Increases calcium absorption |

# Nerves

The nervous system has a central control system that can evaluate information about conditions within and outside the body, and an expansive communication system that receives information and sends instructions. The control system is the brain and spinal cord, called the **central nervous system;** and the communication system between the center and the parts is the **peripheral nervous system.** The smooth functioning that results from the systems' adjustments to changing conditions is homeostasis.

The nervous system is best understood as two systems that use the same or similar pathways to receive and transmit their messages. The **somatic nervous system** controls the voluntary muscles; the **autonomic nervous system** controls the involuntary, internal muscles and organs.

When scientists were first studying the autonomic nervous system, they noticed that when something hurt one organ of the body, some of the other organs reacted as if in sympathy for the afflicted one. They therefore named the nerve network they were studying the **sympathetic nervous system.** The term is still used today to refer to the branch of the autonomic nervous system that responds to stressful conditions. The other branch that supports normal conditions is called the **parasympathetic nervous system.** (Think of the sympathetic branch as the emergency responder when homeostasis needs prompt restoring and the parasympathetic branch as the steady commander during normal times.) Both systems transmit their messages through the brain and spinal cord. Nerves of the two branches travel side by side along the same pathways to transmit their messages, but they oppose each other's actions (see Figure A-3).

An example will show how the sympathetic and parasympathetic nervous systems work to maintain homeostasis. When you go outside in cold weather, your skin's temperature receptors send "cold" messages to the spinal cord and brain. Your conscious mind may intervene at this point to tell you to zip your jacket, but let's say you have no jacket. Your sympathetic nervous system reacts to the external stressor, the cold. It signals your skin-surface capillaries to shut down so that your blood will circulate deeper in your tissues, where it will conserve heat. Your sympathetic nervous system also signals involuntary contractions of the small muscles just under the skin surface. The product of these muscle contractions is heat, and the visible result is goose bumps. If these measures do not raise your body temperature enough, then the sympathetic nerves signal your large muscle groups to shiver; the contractions of these large muscles produce still more heat. All of this activity helps to maintain your homeostasis (with respect to temperature) under conditions of external extremes (cold) that would throw it off balance. The cold was a stressor; the body's response was resistance.

Now let's say you come in and sit by a fire and drink hot cocoa. You are warm and no longer need all that sympathetic activity. At this point, your parasympathetic nerves take over; they signal your skin-surface capillaries to dilate again, your goose bumps to subside, and your muscles to relax. Your body is back to normal. This is recovery.

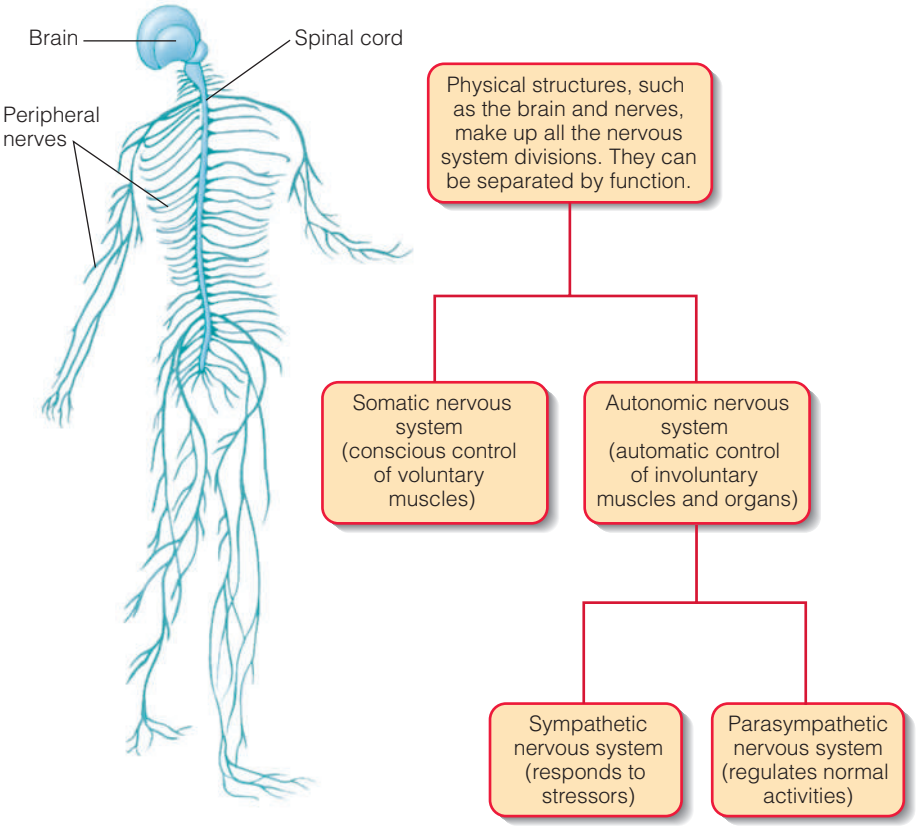
## GLOSSARY OF NERVOUS SYSTEM

**autonomic nervous system:** the division of the nervous system that controls the body's automatic responses. Its two branches are the *sympathetic* branch, which helps the body respond to stressors from the outside environment, and the *parasympathetic* branch, which regulates normal body activities between stressful times.

**central nervous system:** the central part of the nervous system; the brain and spinal cord.

**parasympathetic nervous system:** the part of the autonomic nervous system that dominates during nonstressful conditions and includes such effects as normal heart rate, pupil dilation, and peristalsis.

**peripheral** (puh-RIFF-er-ul) **nervous system:** the peripheral (outermost) part of the nervous system; the vast complex of wiring that extends from the central nervous system to the body's outermost areas. It contains both *somatic* and *autonomic* components.



**somatic** (so-MAT-ick) **nervous system:** the division of the nervous system that controls the voluntary muscles, as distinguished from the autonomic nervous system, which controls involuntary functions.

**sympathetic nervous system:** the part of the autonomic nervous system that dominates during stressful conditions and includes such effects as increased heart rate, dilated pupils, slowed peristalsis, and secretion of epinephrine and norepinephrine.

> **FIGURE A-3 The Organization of the Nervous System**

The brain and spinal cord evaluate information about conditions within and outside the body, and the peripheral nerves receive information and send instructions.

## Putting It Together

The hormonal and nervous systems coordinate body functions by transmitting and receiving messages. The point-to-point messages of the nervous system travel through the spinal cord and brain, whereas the messages of the hormonal system are sent through the bloodstream, and any organ with the appropriate receptors can pick them up. Nerve impulses travel faster than hormonal messages do—although both are remarkably swift. Whereas your brain's command to wiggle your toes reaches the toes within a fraction of a second and stops as quickly, a gland's message to alter a body condition may take several seconds or minutes to get started and may fade away equally slowly.

Together, the two systems possess every characteristic a superb communication network needs: varied speeds of transmission, along with private communication lines or public broadcasting systems, depending on the needs of the moment. The hormonal system, together with the nervous system, integrates the whole body's functioning so that all parts act smoothly together.

# Appendix B Basic Chemistry Concepts

CONTENTS

The Properties of Atoms
Chemical Bonding
Formation of Ions
Water, Acids, and Bases
Chemical Reactions
Formation of Free Radicals

APPENDIX B

This appendix provides the background in basic chemistry needed to understand the nutrition concepts presented in this book. Chemistry is the branch of natural science that deals with the composition and properties of substances, how substances interact, and the **energy** associated with these interactions. The accompanying glossary defines related terms.

## The Properties of Atoms

Every substance has physical and chemical properties that distinguish it from all other substances and thus give it a unique identity. The physical properties include such characteristics as color, taste, texture, and odor, as well as the temperatures at which a substance changes its state (from a solid to a liquid or from a liquid to a gas) and the weight of a unit volume (its density). The chemical properties of a substance have to do with how it reacts with other substances or responds to a change in its environment.

A physical change does not change a substance's chemical composition. The three physical states—ice, water, and steam—all consist of two hydrogen atoms and one oxygen atom bound together. In contrast, a chemical change occurs when an electric current passes through water. The water disappears, and two different substances are formed: hydrogen gas, which is flammable, and oxygen gas, which supports life.

### Substances: Elements and Compounds

The smallest part of a substance that can exist separately without losing its physical and chemical properties is a **molecule**. If a molecule is composed of **atoms** that are alike, the substance is an **element** (for example, $O_2$). If a molecule is composed of two or more different kinds of atoms, the substance is a **compound** (for example, $H_2O$).

More than 100 elements are known, and these are listed in Table B-1 (p. B-1). A familiar example of an element is hydrogen, whose molecules are composed only of hydrogen atoms linked together in pairs ($H_2$). On the other hand, more than a million compounds are known. An example of a compound is the sugar glucose. Each of its molecules is composed of 6 carbon, 6 oxygen, and 12 hydrogen atoms linked together in a specific arrangement (as described in Chapter 4).

### The Nature of Atoms

Atoms themselves are made of smaller particles. Within an atom's nucleus are protons (positively charged particles), and surrounding the nucleus are an equal number of electrons (negatively charged particles). The number of protons in the nucleus of an atom determines the atomic number. The positive charge on a proton is equal to the negative charge on an electron, so the charges cancel each other out and leave the atom neutral to its surroundings.

The nucleus may also include neutrons, subatomic particles that have no charge. Protons and neutrons are of equal mass, and together they give an atom its atomic mass. Electrons bond atoms together to make molecules, and they are involved in chemical reactions.

## GLOSSARY

**anions** (AN-eye-uns)**:** negatively changed ions.

**atoms:** the smallest components of an element that have all of the properties of the element.

**cations** (CAT-eye-uns)**:** positively changed ions.

**compound:** a substance composed of two or more different atoms—for example, water ($H_2O$).

**covalent bonds:** strong chemical bonds formed between atoms by sharing electrons.

**element:** a substance composed of atoms that are alike—for example, iron (Fe).

**energy:** the capacity to do work. The energy in food is chemical energy. The body can convert this chemical energy to mechanical, electrical, or heat energy.

**ions** (EYE-uns)**:** atoms or molecules that have gained or lost one or more electrons and therefore have electrical charges. Examples include the positively charged sodium ion ($Na^+$) and the negatively charged chloride ion ($Cl^-$).

**molecule:** two or more atoms of the same or different elements joined by chemical bonds. Examples are molecules of the element oxygen, composed of two oxygen atoms ($O_2$), and molecules of the compound water, composed of two hydrogen atoms and one oxygen atom ($H_2O$).

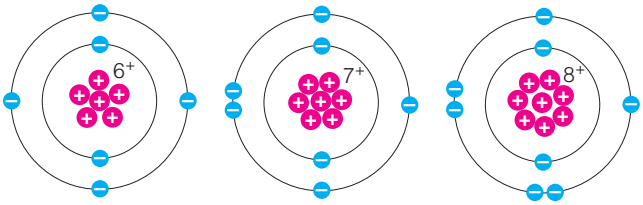
Key
- Elements found in energy-yielding nutrients, vitamins, and water
- Major minerals
- Trace minerals

Each element has a characteristic number of protons in its atom's nucleus. For example, the hydrogen atom (the simplest of all) possesses a single proton, with a single electron associated with it:

Hydrogen atom (H), atomic number 1

Just as hydrogen always has one proton, helium always has two, lithium three, and so on. The atomic number of each element is the number of protons in the nucleus of that atom, and this never changes in a chemical reaction; it gives the atom its identity. The atomic numbers for the known elements are listed in Table B-1.



In addition to hydrogen, the atoms most common in living things are carbon (C), nitrogen (N), and oxygen (O), whose atomic numbers are 6, 7, and 8, respectively. Their structures

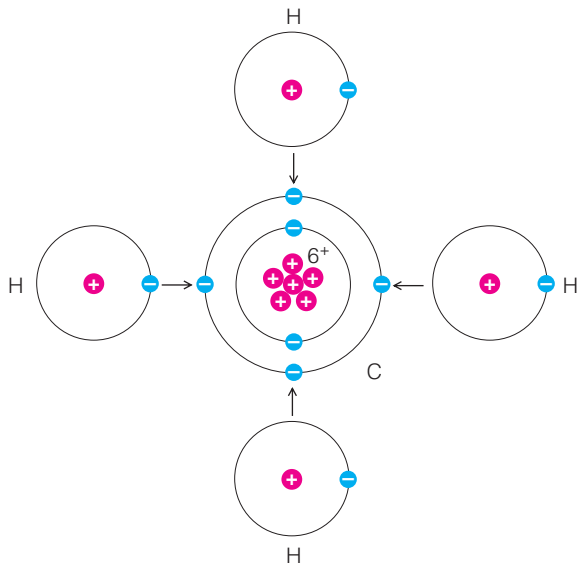
are more complicated than that of hydrogen, but each of them possesses the same number of electrons as there are protons in the nucleus. These electrons are found in orbits, or shells (shown below).

Carbon atom (C), atomic number 6 | Nitrogen atom (N), atomic number 7 | Oxygen atom (O), atomic number 8

In these and all diagrams of atoms that follow, only the protons and electrons are shown. The neutrons, which contribute only to atomic weight, not to charge, are omitted.

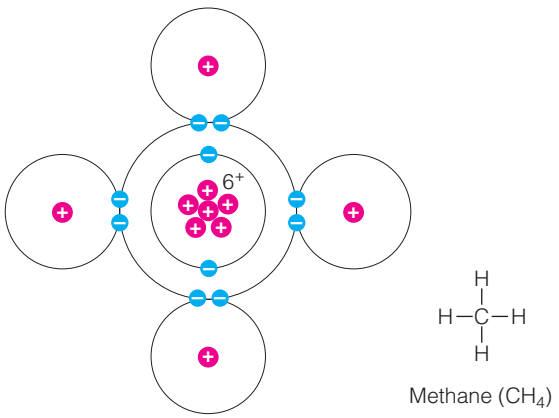
The most important structural feature of an atom for determining its chemical behavior is the number of electrons in its outermost shell. The first, or innermost, shell is full when it is occupied by two electrons; so an atom with two or more electrons has a filled first shell. When the first shell is full, electrons begin to fill the second shell.

The second shell is completely full when it has eight electrons. A substance that has a full outer shell tends not to enter into chemical reactions. Atomic number 10, neon, is a chemically inert substance because its outer shell is complete. Fluorine, atomic number 9, has a great tendency to attract an electron from other substances to complete its outer shell, and thus it is highly reactive. Carbon has a half-full outer shell, which helps explain its great versatility; it can combine with many other elements in a variety of ways to form a large number of compounds.



Atoms seek to reach a state of maximum stability or of lowest energy in the same way that a ball will roll down a hill until it reaches the lowest place. An atom achieves a state of maximum stability:

- By gaining or losing electrons to either fill or empty its outer shell.
- By sharing its electrons with other atoms and thereby completing its outer shell.

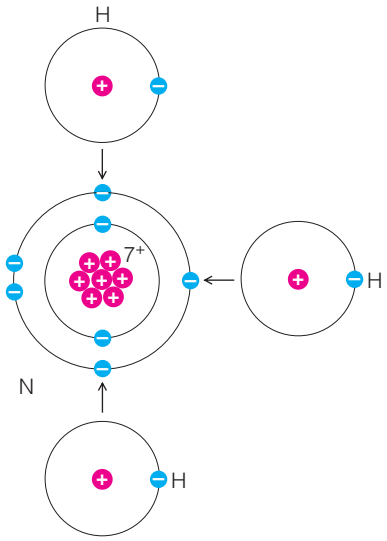


The number of electrons determines how the atom will chemically react with other atoms.

## Chemical Bonding

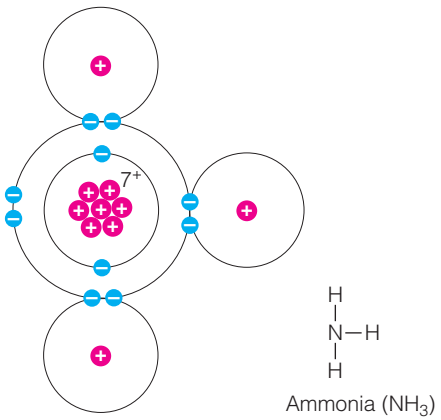
Atoms often complete their outer shells by sharing electrons with other atoms. In order to complete its outer shell, a carbon atom requires four electrons. A hydrogen atom requires one. Thus, when a carbon atom shares electrons with four hydrogen atoms, each completes its outer shell (as shown in the next drawing). Electron sharing binds the atoms together and satisfies the conditions of maximum stability for the molecule. The outer shell of each atom is complete because hydrogen effectively has the required 2 electrons in its first (outer) shell, and carbon has 8 electrons in its second (outer) shell; and the molecule is electrically neutral, with a total of 10 protons and 10 electrons.

When a carbon atom shares electrons with four hydrogen atoms, a methane molecule is made.



The chemical formula for methane is $CH_4$. Note that by sharing electrons, every atom achieves a filled outer shell.

Bonds that involve the sharing of electrons, like the bonds in methane between the one carbon and the four hydrogens, are the most stable kind of association that atoms can form with one another. These bonds are called **covalent bonds,** and the resulting combination of atoms is called a molecule. A single pair of shared electrons forms a single bond. A simplified way to represent a single bond is with a single line.



Similarly, one nitrogen atom and three hydrogen atoms can share electrons to form one molecule of ammonia ($NH_3$):

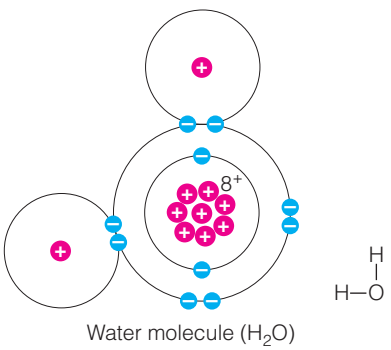
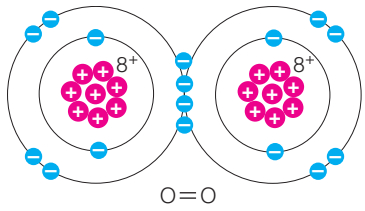
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



When a nitrogen atom shares electrons with three hydrogen atoms, an ammonia molecule is made.



The chemical formula for ammonia is $NH_3$. Count the electrons in each atom's outer shell to confirm that it is filled.

One oxygen atom may be bonded to two hydrogen atoms to form one molecule of water ($H_2O$):

When two oxygen atoms form a molecule of oxygen, they must share two pairs of electrons. This double bond may be represented as two lines:

Small atoms form the tightest, most stable bonds. H, O, N, and C are the smallest atoms capable of forming one, two, three, and four electron-pair bonds, respectively. This is the basis for the statement in Chapter 4 that in drawings of compounds containing these atoms, hydrogen must always have one, oxygen two, nitrogen three, and carbon four bonds radiating to other atoms:

The stability of the associations between these small atoms (hydrogen, carbon, nitrogen, and oxygen) and the versatility with which they can combine make them very common in living things. Interestingly all cells—whether they come from animals, plants, or bacteria—contain the same elements in very nearly the same proportions. The elements commonly found in living things are shown in Table B-2.

**TABLE B-2 Elemental Composition of the Human Body**

| Element | Chemical Symbol | By Weight (%) |
|---|---|---|
| Oxygen | O | 65.0 |
| Carbon | C | 18.0 |
| Hydrogen | H | 10.0 |
| Nitrogen | N | 3.0 |
| Calcium | Ca | 1.5 |
| Phosphorus | P | 1.0 |
| Potassium | K | 0.4 |
| Sulfur | S | 0.3 |
| Sodium | Na | 0.2 |
| Chloride | Cl | 0.1 |
| Magnesium | Mg | 0.1 |
| Total | | 99.6[a] |

[a]The remaining 0.4 percent by weight is contributed by the trace elements: chromium (Cr), copper (Cu), zinc (Zn), selenium (Se), molybdenum (Mo), fluorine (F), iodine (I), manganese (Mn), and iron (Fe). Cells may also contain variable traces of some of the following: boron (B), cobalt (Co), Lithium (Li), strontium (Sr), aluminum (AL), silicon (Si), Lead (Pb), vanadium (V), arsenic (As), bromine (Br), and others.

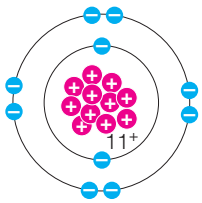
# Formation of Ions

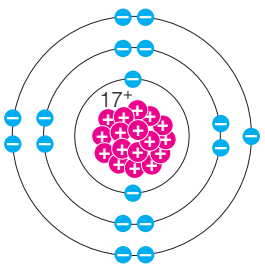


An atom such as sodium (Na, atomic number 11) cannot easily fill its outer shell by sharing. Sodium possesses a filled first shell of two electrons and a filled second shell of eight; there is only one electron in its outermost shell:

Sodium atom (Na)
11 + charges
11 – charges

0 net charge with one reactive electron in the outer shell

Loss of 1 electron

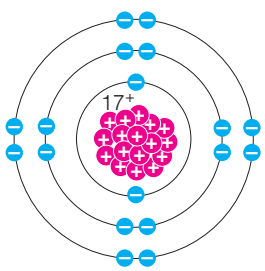


Sodium ion ($Na^+$)
11 + charges
10 – charges

1 + net charge and a filled outer shell

If sodium loses this electron, it satisfies one condition for stability: a filled outer shell (now its second shell counts as the outer shell). However, it is not electrically neutral. It has 11 protons (positive) and only 10 electrons (negative). It therefore has a net positive charge. An atom or molecule that has lost or gained one or more electrons and so is electrically charged is called an **ion**.

An atom such as chlorine (Cl, atomic number 17), with seven electrons in its outermost shell, can share electrons to fill its outer shell, or it can gain one electron to complete its outer shell and thus give it a negative charge:

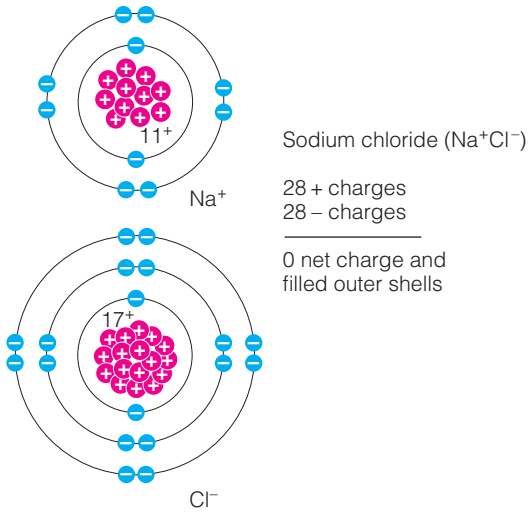


Chlorine atom (Cl)

17 + charges
17 – charges

0 net charge but lacks one electron to fill outer shell

Gain of 1 electron



Chloride ion ($Cl^-$)

17 + charges
18 – charges

1 – net charge and a filled outer shell

Positively charged ions, such as a sodium ion ($Na^+$), are called **cations**; negatively charged ions, such as a chloride ion ($Cl^-$), are called **anions**. Cations and anions attract one another to form salts:

Sodium chloride ($Na^+Cl^-$)

28 + charges
28 – charges

0 net charge and filled outer shells

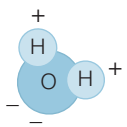
With all its electrons, sodium is a shiny, highly reactive metal; chlorine is the poisonous greenish yellow gas that was used in World War I. But after sodium and chlorine have shared electrons, they become stable and are familiar to you as table salt, or sodium chloride ($Na^+Cl^-$). The dramatic difference illustrates how profoundly the electron arrangement can influence the nature of a substance. The wide distribution of salt in nature attests to the stability of the union between the ions. Each meets the other's needs (a good marriage).

When dry, salt exists as crystals; its ions are stacked very regularly into a lattice, with positive and negative ions alternating in a three-dimensional checkerboard structure. In water, however, the salt quickly dissolves, and its ions separate from one another, forming an electrolyte solution in which they move about freely. Covalently bonded molecules rarely dissociate like this in a water solution. The most common exception is when they behave like acids and release $H^+$ ions, as discussed in the next section.

An ion can also be a group of atoms bound together in such a way that the group has a net charge and enters into reactions as a single unit. Many such groups are active in the fluids of the body. The bicarbonate ion is composed of five atoms—one H, one C, and three Os—and has a net charge of −1 ($HCO_3^-$). Another example is the phosphate ion with one H, one P, and four O, that has a net charge of −2 ($HPO_4^{-2}$).

Whereas many elements have only one configuration in the outer shell and thus only one way to bond with other elements, some elements have the possibility of varied configurations. Iron is such an element. Under some conditions iron loses two electrons, and under other circumstances it loses three. If iron loses two electrons, it then has a net charge of +2 and is called ferrous iron ($Fe^{++}$). If it loses three electrons, it becomes the +3 ion called ferric iron ($Fe^{+++}$).

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

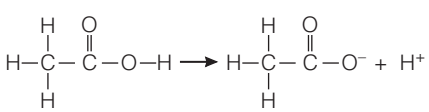


| Ferrous iron ($Fe^{++}$) | Ferric iron ($Fe^{+++}$) |
|---|---|
| (lost 2 outer-shell electrons) | (lost 3 outer-shell electrons) |
| 26 + charges | 26 + charges |
| 24 − charges | 23 − charges |
| 2 + net charge | 3 + net charge |

Remember that a positive charge on an ion means that negative charges—electrons—have been lost and not that positive charges have been added to the nucleus.

# Water, Acids, and Bases

**Water** The water molecule is electrically neutral, having equal numbers of protons and electrons. When a hydrogen atom shares its electron with oxygen, however, that electron will spend most of its time closer to the positively charged oxygen nucleus. This leaves the positive proton (nucleus of the hydrogen atom) exposed on the outer part of the water molecule. We know, too, that the two hydrogens both bond toward the same side of the oxygen. These two facts explain why water molecules are polar: they have regions that are more positively and more negatively charged.



Polar molecules like water are attracted to one another by the forces between the positive areas of one and the negative areas of another. These attractive forces, sometimes known as polar bonds or hydrogen bonds, occur among many molecules and also within different parts of the same molecule. Although very weak in comparison with covalent bonds, polar bonds may occur in such abundance that they become exceedingly important in determining the structure of large molecules such as proteins and DNA.

This diagram of a polar water molecule shows the negative area near the O and the positive area near the H atoms.

Water molecules have a slight tendency to ionize, separating into positive ($H^+$) and negative ($OH^-$) ions. In pure water, a small but constant number of these ions is present, and the number of positive ions exactly equals the number of negative ions.

**Acids** An acid is a substance that releases $H^+$ ions (protons) in a water solution. Hydrochloric acid ($HCl^-$) is such a substance because it dissociates in a water solution into $H^+$ and $Cl^-$ ions. Acetic acid is also an acid because it dissociates in water to acetate ions and free $H^+$:

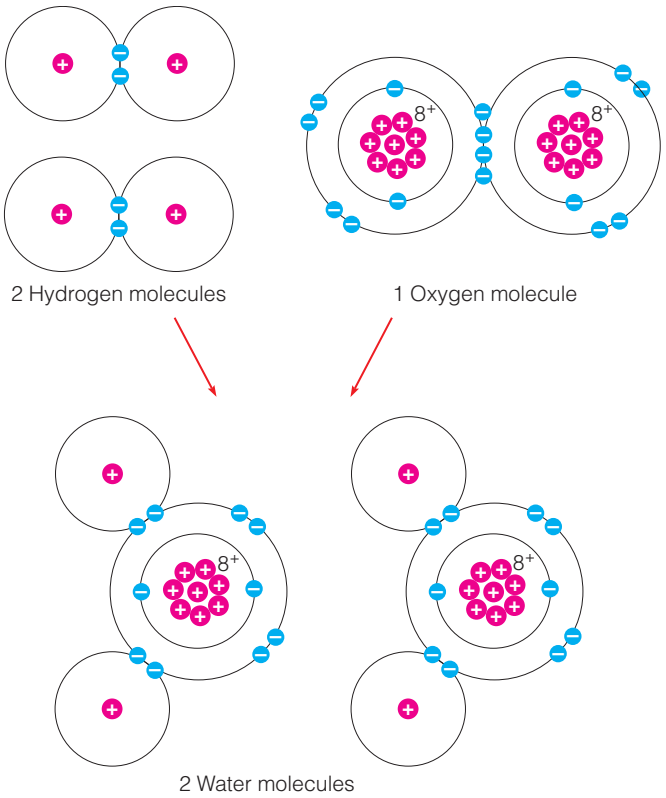
Acetic acid dissociates into an acetate ion and a hydrogen ion.

The more $H^+$ ions released, the stronger the acid. Chemists define degrees of acidity by means of the pH scale, which runs from 0 to 14. The pH expresses the concentration of $H^+$ ions: a pH of 1 is extremely acidic, 7 is neutral, and 13 is very basic. There is a tenfold difference in the concentration of $H^+$ ions between points on this scale. A solution with pH 3, for example, has 10 times as many $H^+$ ions as a solution with pH 4. Figure 3-6 on p. 77 presents the pH of common substances.

**Bases** A base is a substance that can combine with $H^+$ ions, thus reducing the acidity of a solution. The compound ammonia is such a substance. The ammonia molecule has two electrons that are not shared with any other atom; a hydrogen ion ($H^+$) is a proton without an outer shell of electrons. The proton readily combines with the ammonia molecule to form an ion; thus a free $H^+$ is withdrawn from the solution and no longer contributes to its acidity. Many nitrogen-containing compounds are important bases in living systems. Acids and bases neutralize each other to produce substances that are neither acid nor base.

# Chemical Reactions

A chemical reaction results in the breakdown or formation of substances. Almost all such reactions involve a change in the bonding of atoms. Old bonds are broken, and new ones are formed. The nuclei of atoms are never involved in chemical reactions—only the outer-shell electrons participate. At the end of a chemical reaction, the number of atoms of each type is always the same as at the beginning. For example, two hydrogen molecules ($2H_2$) can react with one oxygen molecule ($O_2$) to form two water molecules ($2H_2O$). In this reaction two substances (hydrogen and oxygen) disappear, and a new one (water) is formed, but at the end of the reaction there are still four H atoms and two O atoms, just as there were at the beginning. Because the atoms are now linked in a different way, their characteristics and properties have changed.



In many instances chemical reactions involve the exchange of electrons or protons between molecules. In such reactions the molecule that gains one or more electrons (or loses one or more protons) is said to be reduced; the molecule that loses electrons (or gains protons) is oxidized. A hydrogen ion is equivalent to a proton.

Oxidation and reduction reactions take place simultaneously because an electron or proton that is lost by one molecule is accepted by another. The addition of an atom of oxygen is also oxidation because oxygen (with six electrons in the outer shell) accepts two electrons in becoming bonded. Oxidation occurs, then, with the loss of electrons, the gain of protons, or the addition of oxygen (with six electrons); reduction occurs with the opposite—a gain of electrons, a loss of protons, or a loss of oxygen. The addition of hydrogen atoms to oxygen to form water can thus be described as the reduction of oxygen *or* the oxidation of hydrogen.

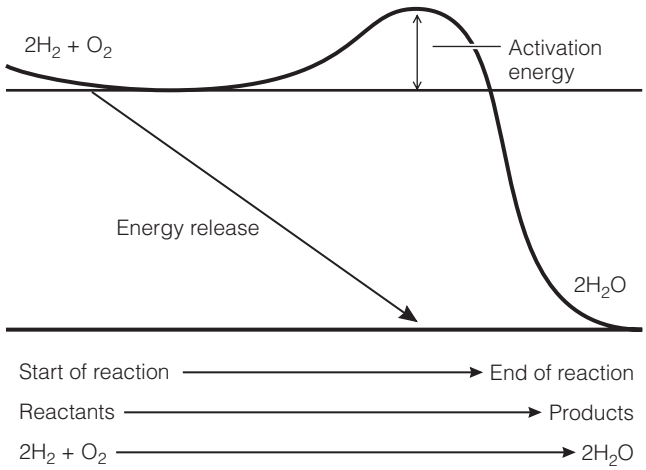
Structures:

Formulas:



$$2H_2 + O_2 \longrightarrow 2H_2O$$

Hydrogen and oxygen react to form water.

Reactions in which the end products contain more energy than the reacting compounds started with are called endergonic, or "uphill," reactions and do not occur until an energy source is provided. An example of such an energy source is the sunlight used in photosynthesis reactions that combine carbon dioxide and water (low-energy compounds) to form glucose (a higher-energy compound). Conversely, the oxidation of glucose to carbon dioxide and water is an exergonic, or "downhill," reaction because the end products have less energy than the starting product. Oftentimes, but not always, reduction reactions are endergonic, resulting in an increase in the energy of the end products. Oxidation reactions often, but not always, are exergonic.

Chemical reactions tend to occur spontaneously if the end products are in a lower energy state and therefore are more stable than the reacting compounds. These reactions often give off energy in the form of heat as they occur. The generation of heat by wood burning in a fireplace and the maintenance of warmth in the human body both depend on energy-yielding chemical reactions. These downhill reactions occur easily although they may require some activation energy to get them started, just as a ball requires a push to start rolling.

Energy change as reaction occurs

## Formation of Free Radicals

Normally, when a chemical reaction takes place, bonds break and re-form to create new, stable compounds. Occasionally, bonds break in such a way as to create a free radical—a molecule with one or more unpaired electrons. When they do, free radicals are formed. Free radicals are highly unstable and quickly react with other compounds, forming more free radicals in a chain reaction. A cascade may ensue in which many highly reactive radicals are generated, resulting in damage that contributes to the development of many chronic diseases (see Highlight 11 for more details). Free radicals are of special interest in nutrition because the antioxidant properties of vitamins C and E as well as those of beta-carotene and the mineral selenium protect against the destructive effects of these free radicals.

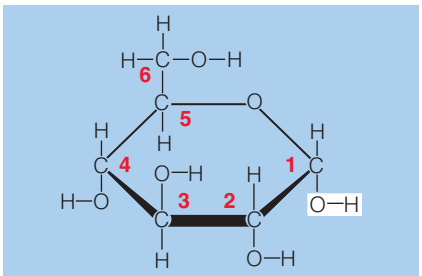
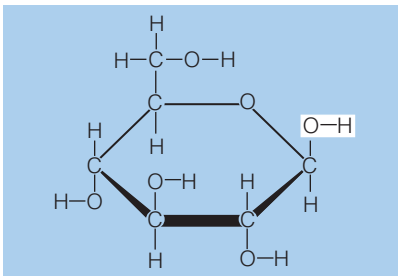
# Appendix C Biochemical Structures and Pathways

This appendix describes the biochemical structures and pathways most important to the study of nutrition. It begins by presenting diagrams of nutrients commonly found in the human diet. Following the diagrams of nutrients are sections on the major metabolic pathways mentioned in Chapter 7—glycolysis, fatty acid oxidation, amino acid degradation, the TCA cycle, and the electron transport chain—and a description of how alcohol interferes with these pathways. Discussions of the urea cycle and the formation of ketone bodies complete the appendix.

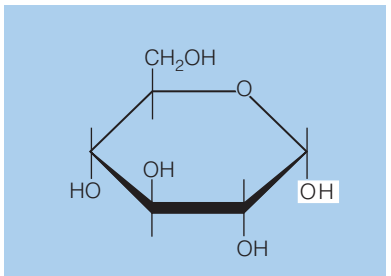


CONTENTS

Carbohydrates
Lipids
Protein: Amino Acids
Vitamins and Coenzymes
Glycolysis
Fatty Acid Oxidation
Amino Acid Degradation
The TCA Cycle
The Electron Transport Chain
Alcohol's Interference with Energy Metabolism
The Urea Cycle
Formation of Ketone Bodies

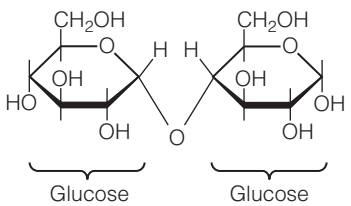


## Carbohydrates

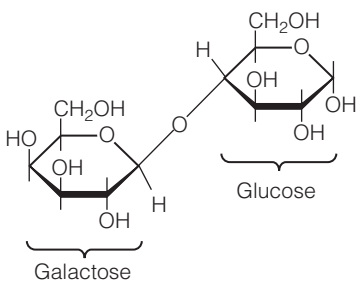


### Monosaccharides

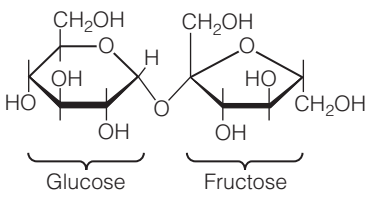
**Glucose (alpha form).** The ring would be at right angles to the plane of the paper. The bonds directed upward are above the plane; those directed downward are below the plane. This molecule is considered an alpha form because the OH on carbon 1 points downward.



**Glucose (beta form).** The OH on carbon 1 points upward.
**Fructose, galactose:** see Chapter 4.



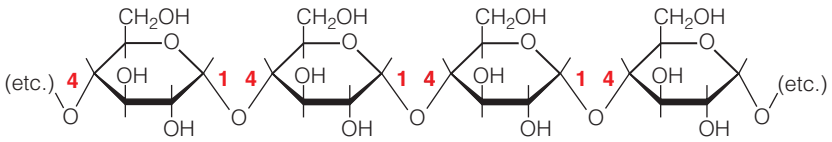
**Glucose (alpha form) shorthand notation.** This notation, in which the carbons in the ring and single hydrogens have been eliminated, will be used throughout this appendix.



### Disaccharides

**Maltose.**

**Lactose (alpha form).**



**Sucrose.**

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

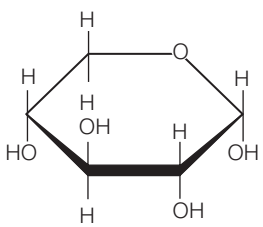
## Polysaccharides: Starches

As described in Chapter 4, starch, glycogen, and cellulose are all long chains of glucose molecules covalently linked together. (Appendix B discusses covalent bonding.)

Amylose (unbranched starch)

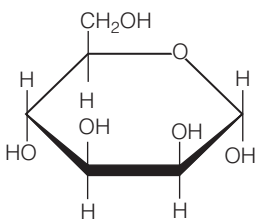
Amylopectin (branched starch)

**Starch.** Two kinds of covalent bonds link the glucose molecules in starch, giving rise to two kinds of chains. Amylose is composed of straight chains, with carbon 1 of one glucose linked to carbon 4 of the next ($\alpha$-1,4 linkage). Amylopectin is made up of straight chains like amylose, but has occasional branches where the carbon 6 of a glucose is also linked to the carbon 1 of another glucose ($\alpha$-1,6 linkage).



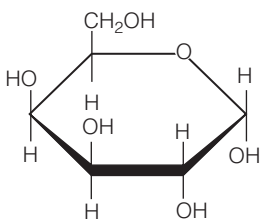
**Glycogen.** The structure of glycogen is like amylopectin but with many more branches.

**Cellulose.** Like starch and glycogen, cellulose is also made of chains of glucose units, but there is an important difference: in cellulose, the OH on carbon 1 is in the beta position (see p. C-1). When carbon 1 of one glucose is linked to carbon 4 of the next, it forms a $\beta$-1,4 linkage, which cannot be broken by digestive enzymes in the human GI tract.



## Polysaccharides: Fibers

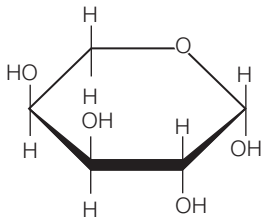
Fibers, such as hemicelluloses, consist of long chains of various monosaccharides.



Monosaccharides common in the backbone chain of hemicelluloses:*

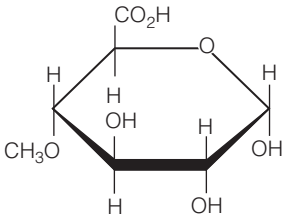
Xylose

Mannose

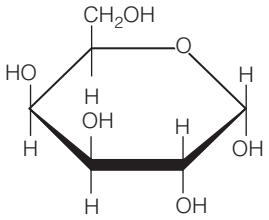


Galactose

*These structures are shown in the alpha form with the H on the carbon pointing upward and the OH pointing downward, but they may also appear in the beta form with the H pointing downward and the OH upward.



Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



Monosaccharides common in the side chains of hemicelluloses:

Arabinose

Glucuronic acid

Galactose

**Hemicelluloses.** The most common hemicelluloses are composed of a backbone chain of xylose, mannose, and galactose, with branching side chains of arabinose, glucuronic acid, and galactose.

# Lipids

**TABLE C-1 Saturated Fatty Acids Found in Natural Fats**

| Saturated Fatty Acids | Chemical Formulas | Number of Carbons | Major Food Sources |
|---|---|---|---|
| Butyric | $C_3H_7COOH$ | 4 | Butterfat |
| Caproic | $C_5H_{11}COOH$ | 6 | Butterfat |
| Caprylic | $C_7H_{15}COOH$ | 8 | Coconut oil |
| Capric | $C_9H_{19}COOH$ | 10 | Palm oil |
| Lauric | $C_{11}H_{23}COOH$ | 12 | Coconut oil, palm oil |
| Myristic | $C_{13}H_{27}COOH$ | 14 | Coconut oil, palm oil |
| Palmitic | $C_{15}H_{31}COOH$ | 16 | Palm oil |
| Stearic | $C_{17}H_{35}COOH$ | 18 | Most animal fats |
| Arachidic | $C_{19}H_{39}COOH$ | 20 | Peanut oil |
| Behenic | $C_{21}H_{43}COOH$ | 22 | Seeds |
| Lignoceric | $C_{23}H_{47}COOH$ | 24 | Peanut oil |

NOTE: The most common fatty acids are myristic, palmitic, and stearic.

**TABLE C-2 Unsaturated Fatty Acids Found in Natural Fats**

| Unsaturated Fatty Acids | Chemical Formulas | Number of Carbons | Number of Double Bonds | Standard Notation[a] | Omega Notation[b] | Major Food Sources |
|---|---|---|---|---|---|---|
| Palmitoleic | $C_{15}H_{29}COOH$ | 16 | 1 | 16:1;9 | 16:1ω7 | Seafood, beef |
| Oleic | $C_{17}H_{33}COOH$ | 18 | 1 | 18:1;9 | 18:1ω9 | Olive oil, canola oil |
| Linoleic | $C_{17}H_{31}COOH$ | 18 | 2 | 18:2;9,12 | 18:2ω6 | Sunflower oil, safflower oil |
| Linolenic | $C_{17}H_{29}COOH$ | 18 | 3 | 18:3;9,12,15 | 18:3ω3 | Soybean oil, canola oil |
| Arachidonic | $C_{19}H_{31}COOH$ | 20 | 4 | 20:4;5,8,11,14 | 20:4ω6 | Eggs, most animal fats |
| Eicosapentaenoic | $C_{19}H_{29}COOH$ | 20 | 5 | 20:5;5,8,11,14,17 | 20:5ω3 | Seafood |
| Docosahexaenoic | $C_{21}H_{31}COOH$ | 20 | 6 | 22:6;4,7,10,13,16,19 | 22:6ω3 | Seafood |

NOTE: A fatty acid has two ends; designated the methyl ($CH_3$) end and the carboxyl, or acid (COOH), end.

[a]Standard chemistry notation begins counting carbons at the acid end. The number of carbons the fatty acid contains comes first, followed by a colon and another number that indicates the number of double bonds; next comes a semicolon followed by a number or numbers indicating the positions of the double bonds. Thus the notation for linoleic acid, an 18-carbon fatty acid with two double bonds between carbons 9 and 10 and between carbons 12 and 13, is 18:2;9,12.

[b]Because fatty acid chains are lengthened by adding carbons at the acid end of the chain, chemists use the omega system of notation to ease the task of identifying them. The omega system begins counting carbons at the methyl end. The number of carbons the fatty acid contains comes first, followed by a colon and the number of double bonds; next come the omega symbol (ω) and a number indicating the position of the double bond nearest the methyl end. Thus linoleic acid with its first double bond at the sixth carbon from the methyl end would be noted 18:2ω6 in the omega system.

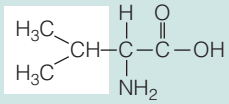
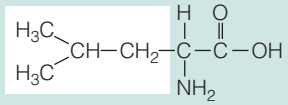
# Protein: Amino Acids

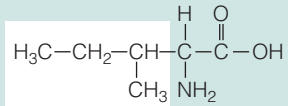
The common amino acids may be classified into the seven groups listed below based on their structural similarities. Amino acids marked with an asterisk (*) are essential.



1. Amino acids with aliphatic side chains, which consist of hydrogen and carbon atoms (hydrocarbons):

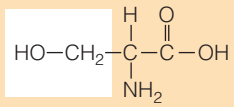


**Glycine (Gly)**

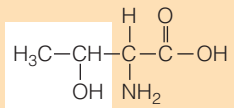


**Alanine (Ala)**

**Valine* (Val)**

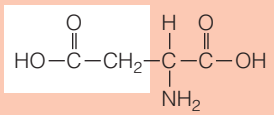


**Leucine* (Leu)**

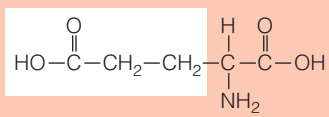


**Isoleucine* (Ile)**

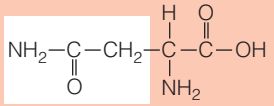
2. Amino acids with hydroxyl (OH) side chains:



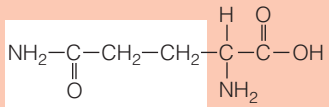
**Serine (Ser)**



**Threonine* (Thr)**

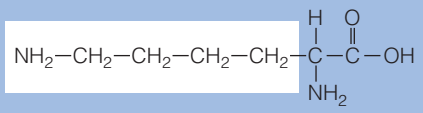


3. Amino acids with side chains containing acidic groups or their amides, which contain the group $NH_2$:

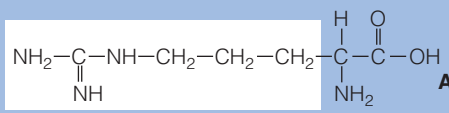


**Aspartic acid (Asp)**

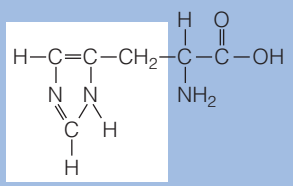
**Glutamic acid (Glu)**



**Asparagine (Asn)**

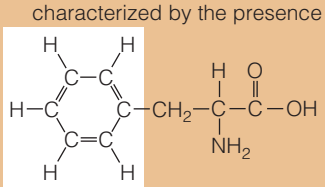


**Glutamine (Gln)**

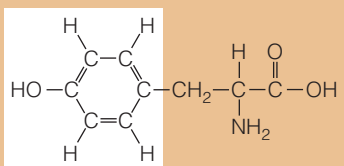


4. Amino acids with basic side chains:

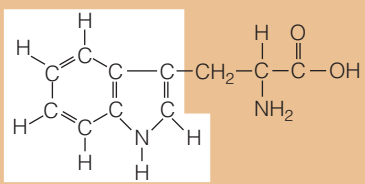
**Lysine* (Lys)**



**Arginine (Arg)**

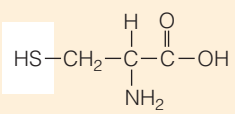


**Histidine* (His)**

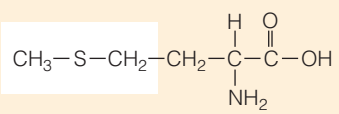


5. Amino acids with aromatic side chains, which are characterized by the presence of at least one ring structure:

**Phenylalanine* (Phe)**

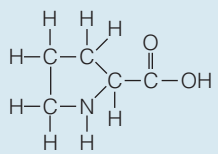


**Tyrosine (Tyr)**



**Tryptophan* (Trp)**

6. Amino acids with side chains containing sulfur atoms:

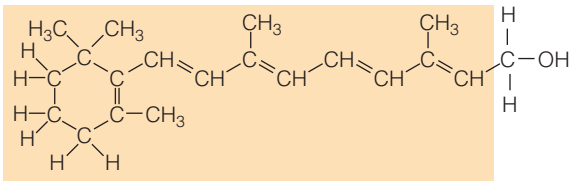


**Cysteine (Cys)**

**Methionine* (Met)**

7. Imino acid:

**Proline (Pro)**



Proline has the same chemical structure as the other amino acids, but its amino group has given up a hydrogen to form a ring.

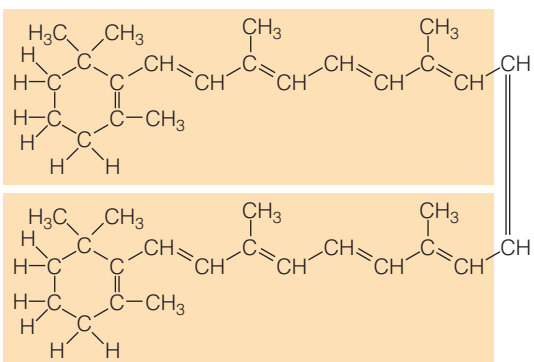
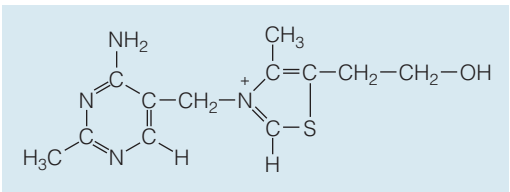
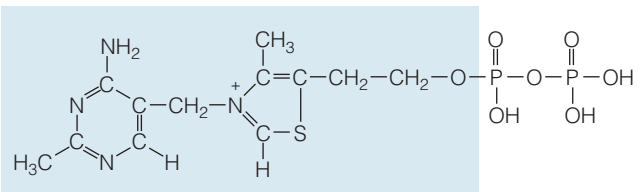
# Vitamins and Coenzymes



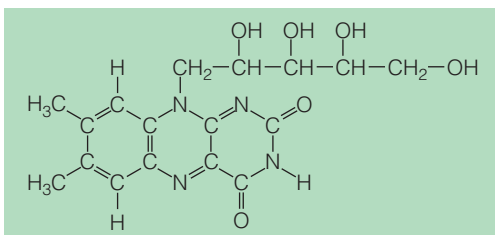
**Vitamin A: retinol.** Retinol is the alcohol form of vitamin A.



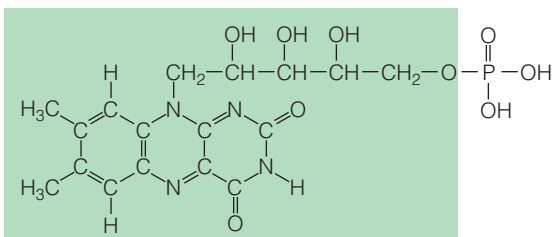
**Vitamin A: retinal.** Retinal is the aldehyde form of vitamin A.



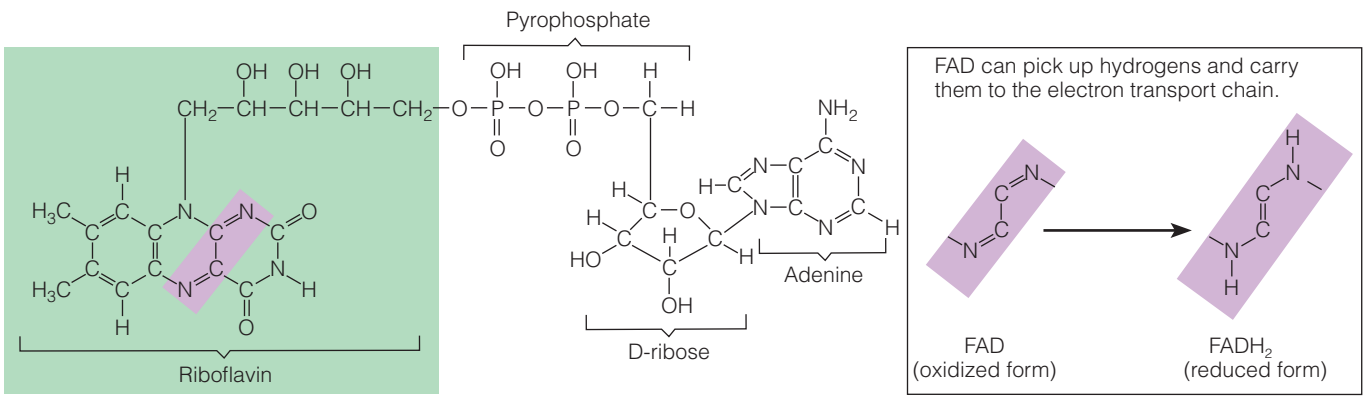
**Vitamin A: retinoic acid.** Retinoic acid is the acid form of vitamin A.



**Vitamin A precursor: beta-carotene.** Beta-carotene is the carotenoid with the most vitamin A activity.



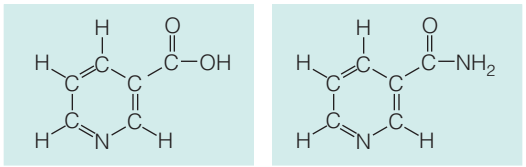
**Thiamin.** Thiamin is part of the coenzyme thiamin pyrophosphate (TPP).



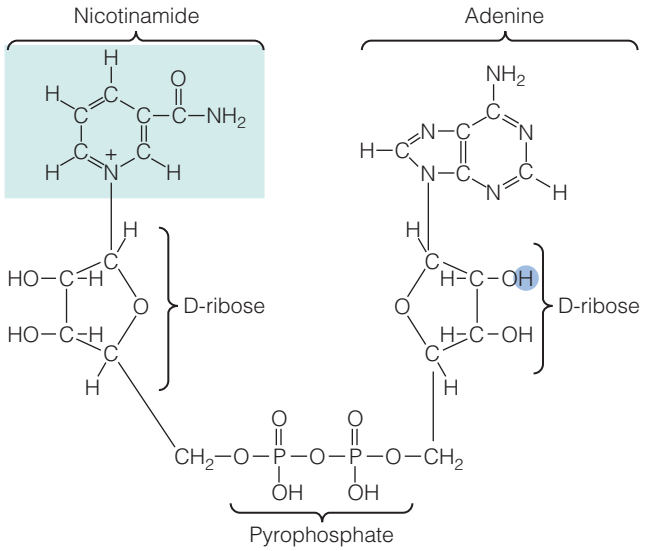
**Thiamin pyrophosphate (TPP).** TPP is a coenzyme that includes the thiamin molecule as part of its structure.

**Riboflavin.** Riboflavin is a part of two coenzymes—flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD).

**Flavin mononucleotide (FMN).** FMN is a coenzyme that includes the riboflavin molecule as part of its structure.



**Flavin adenine dinucleotide (FAD).** FAD is a coenzyme that includes the riboflavin molecule as part of its structure.



APPENDIX C

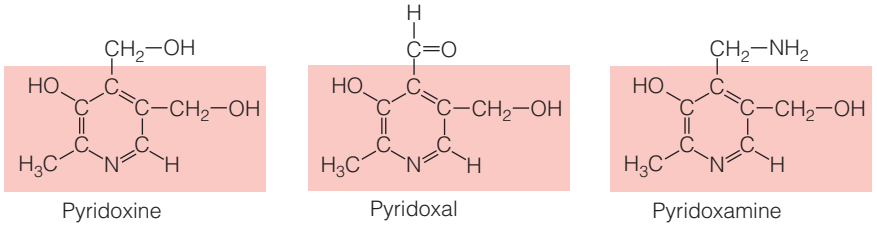
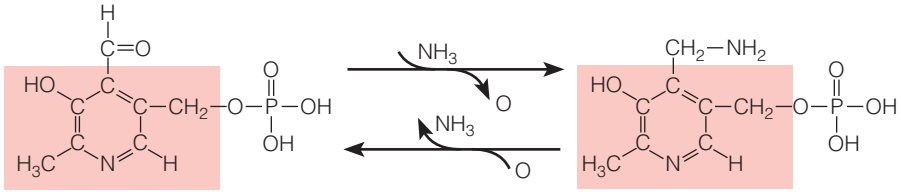
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



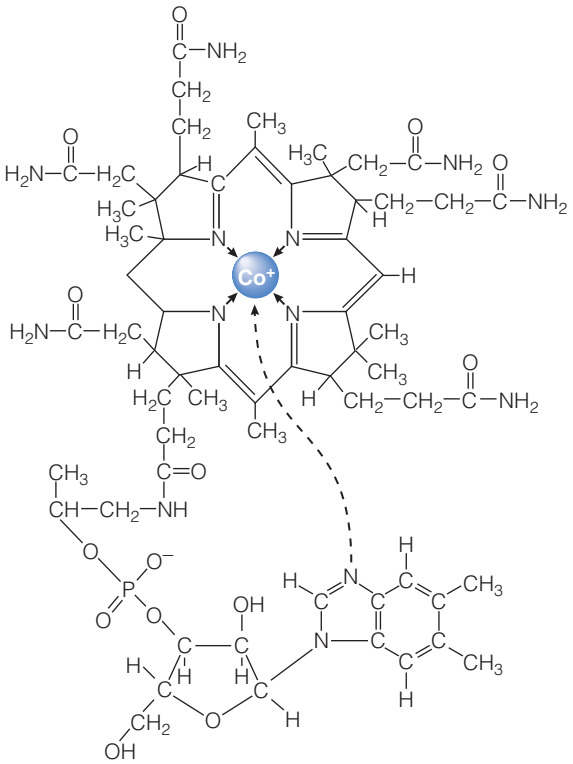
**Niacin (nicotinic acid and nicotinamide).** Niacin is a part of two coenzymes—nicotinamide adenine dinucleotide ($NAD^+$) and nicotinamide adenine dinucleotide phosphate ($NADP^+$).

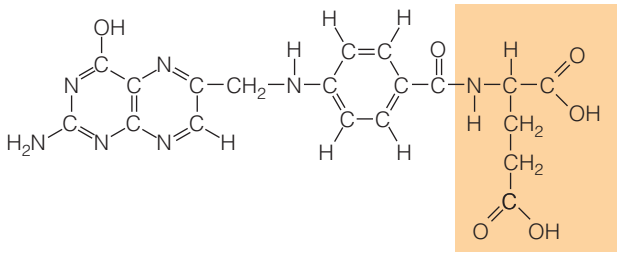
**Nicotinamide adenine dinucleotide ($NAD^+$).** NAD is a coenzyme that includes niacin as part of its structure. NADP has the same structure as NAD but with a phosphate group attached to the O instead of the H.

**Reduced $NAD^+$ (NADH).** When $NAD^+$ is reduced by the addition of $H^+$ and two electrons, it becomes the coenzyme NADH. (The dots on the H entering this reaction represent electrons—see Appendix B.)

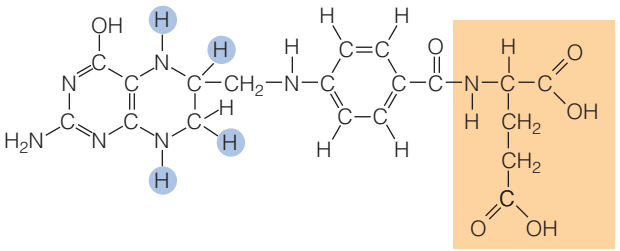


**Vitamin $B_6$.** Vitamin $B_6$ is a general name for three compounds—pyridoxine, pyridoxal, and pyridoxamine, which become a part of two coenzymes—pyridoxal phosphate and pyridoxamine phosphate.

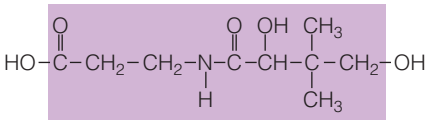




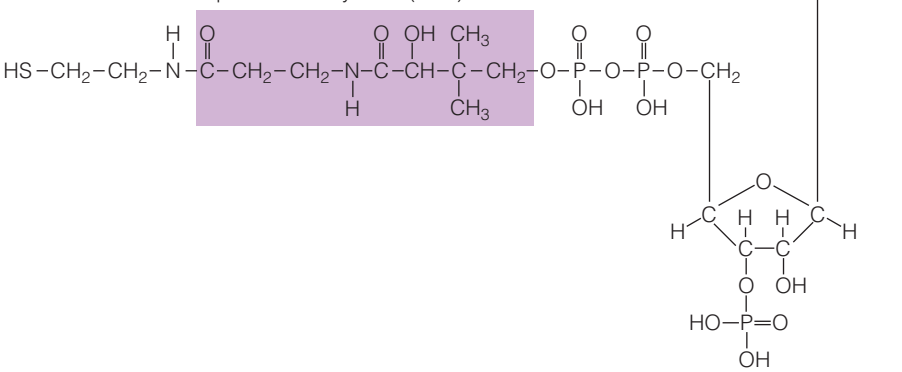
Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



**Pyridoxal phosphate (PLP) and pyridoxamine phosphate.** These coenzymes include vitamin $B_6$ as part of their structures.



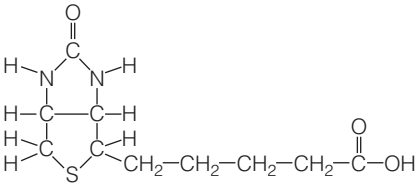
**Vitamin $B_{12}$ (cyanocobalamin).** The arrows in this diagram indicate that the spare electron pairs on the nitrogens attract them to the cobalt.



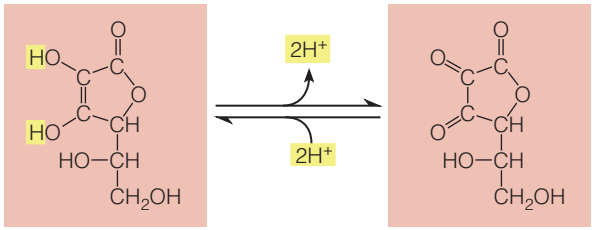
**Folate (folacin or folic acid).** Folate consists of a double ring combined with a single ring and at least one glutamate (a nonessential amino acid highlighted in color). Folate is a part of the coenzyme tetrahydrofolate (THF).

**Tetrahydrofolate (THF).** THF is the active coenzyme form of folate and has four added hydrogens. An intermediate form, dihydrofolate, has two added hydrogens.

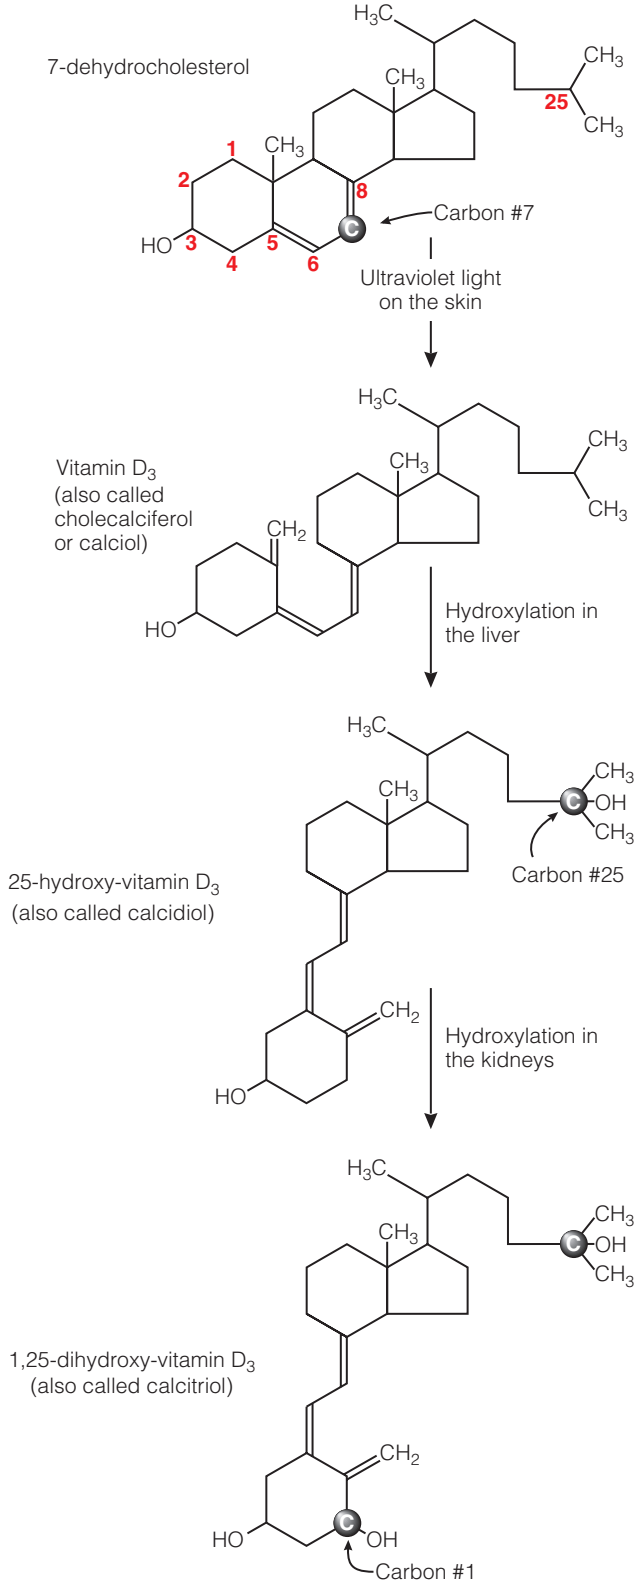
**Pantothenic acid.** Pantothenic acid is part of coenzyme A (CoA).



**Coenzyme A (CoA).** Coenzyme A is a coenzyme that includes pantothenic acid as part of its structure.



Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

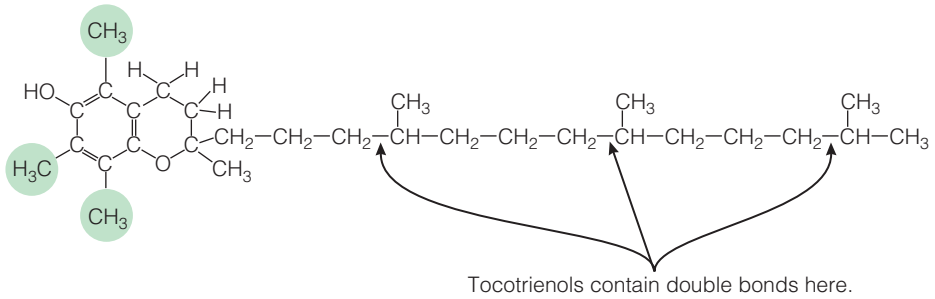


**Biotin.**

Ascorbic acid
(reduced form)

Dehydroascorbic acid
(oxidized form)

**Vitamin C.** Two hydrogen atoms with their electrons are lost when ascorbic acid is oxidized and gained when it is reduced again.



**Vitamin D.** The synthesis of active vitamin D begins with 7-dehydrocholesterol, a precursor made in the liver from cholesterol. (The carbon atoms at which changes occur are numbered.)

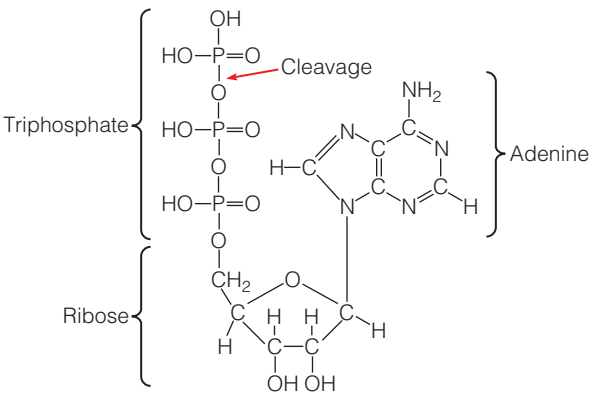
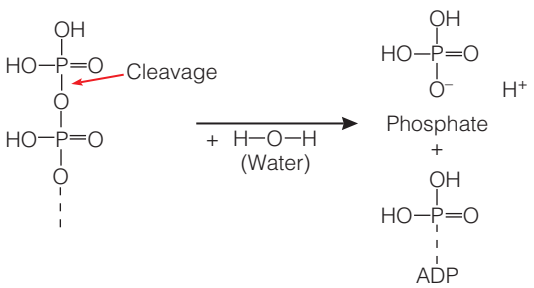
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



**Vitamin E (alpha-tocopherol).** Vitamin E consists of two subgroups—the tocopherols and the tocotrienols. All are made up of a complex ring structure with a long saturated (in tocopherols) or unsaturated (in tocotrienols) side chain. The number and positions of methyl groups ($CH_3$) distinguish the members within each subgroup.



**Vitamin K (phylloquinone).** Naturally occurring compounds with vitamin K activity include phylloquinones (from plants) and menaquinones (from bacteria). The chemical structure of menaquinones differs only slightly from that of phylloquinones.

**Vitamin K (menadione).** Menadione is a synthetic compound that has the same activity as natural vitamin K.

**Adenosine triphosphate (ATP).** The high-energy compound ATP releases energy when one or two phosphate groups split off. The cleavage point marks the bond that is broken when ATP splits to become ADP + P.

**Adenosine diphosphate (ADP).**

# Glycolysis

Figure C-1 depicts glycolysis. The following text describes key steps as numbered on the figure.

**> FIGURE C-1 Glycolysis**

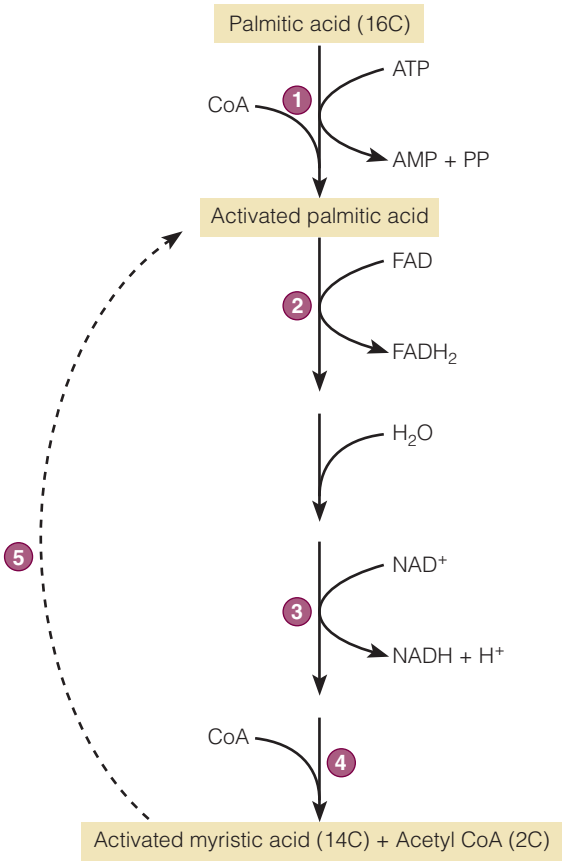
Notice that galactose and fructose enter at different places but continue on the same pathway.

1. A phosphate is attached to glucose at the carbon that chemists call number 6 (review the first diagram of glucose on p. C-1 to see how chemists number the carbons in a glucose molecule). The product is called, logically enough, glucose-6-phosphate. One ATP molecule is used to accomplish this.
2. Glucose-6-phosphate is rearranged by an enzyme.
3. A phosphate is added in another reaction that uses another molecule of ATP. The resulting product is fructose-1,6-diphosphate. At this point the 6-carbon sugar has a phosphate group on its first and sixth carbons and is ready to break apart.
4. When fructose-1,6-diphosphate breaks in half, the two 3-carbon compounds are not identical. Each has a phosphate group attached, but only glyceraldehyde-3-phosphate converts directly to pyruvate. The other compound, however, converts easily to glyceraldehyde-3-phosphate.
5. In the next step, $NAD^+$ is reduced to NADH + $H^+$.
6. In two of the following steps ATP is regenerated.

Remember that in effect two molecules of glyceraldehyde-3-phosphate are produced from glucose; therefore, four ATP molecules are generated from each glucose molecule. Two ATP were needed to get the sequence started, so the net gain at this point is two ATP and two molecules of NADH + $H^+$. As you will see later, each NADH + $H^+$ moves to the electron transport chain to unload its hydrogens, producing more ATP.

# Fatty Acid Oxidation

Figure C-2 presents fatty acid oxidation. The sequence is as follows.



1. The fatty acid is activated by combining with coenzyme A (CoA). In this reaction, ATP loses two phosphorus atoms and becomes AMP (adenosine monophosphate)—the equivalent of a loss of two ATP.
2. In the next reaction, two H with their electrons are removed and transferred to FAD, forming $FADH_2$.
3. In a later reaction, two H are removed and go to $NAD^+$ (forming NADH + $H^+$).
4. The fatty acid is cleaved at the "beta" carbon, the second carbon from the carboxyl (COOH) end. This break results in a fatty acid that is two carbons shorter than the previous one and a 2-carbon molecule of

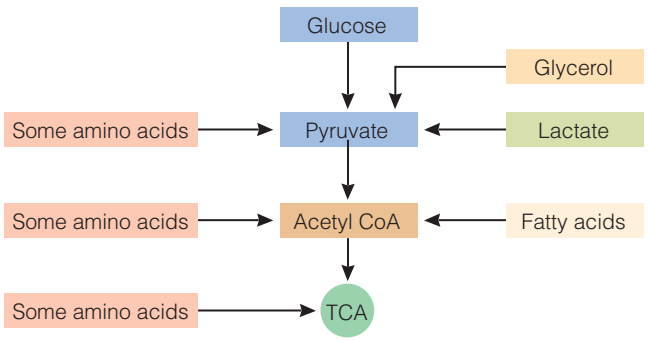
> FIGURE C-2 **Fatty Acid Oxidation**

acetyl CoA. At the same time, another CoA is attached to the fatty acid, thus activating it for its turn through the series of reactions.

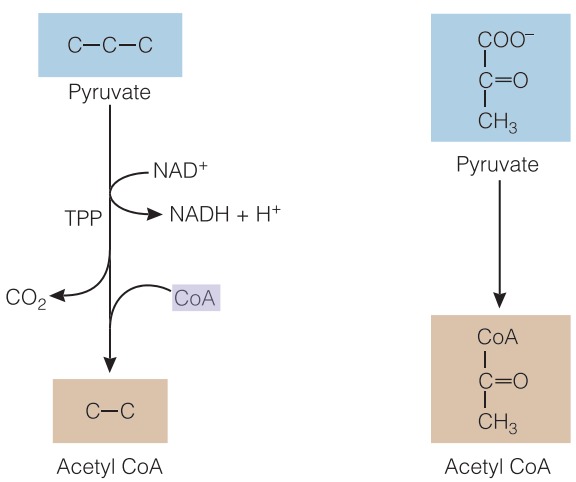
5. The sequence is repeated with each cycle producing an acetyl CoA and a shorter fatty acid until only a 2-carbon fatty acid remains—acetyl CoA.



In the example shown in Figure C-2, palmitic acid (a 16-carbon fatty acid) will go through this series of reactions seven times, using the equivalent of two ATP for the initial activation and generating seven $FADH_2$, seven NADH + $H^+$, and eight acetyl CoA. As you will see later, each of the seven $FADH_2$ will enter the electron transport chain, yielding two ATP (for a total of 14). Similarly, each NADH + $H^+$ will enter the electron transport chain, yielding three ATP (for a total of 21). Thus the oxidation of a 16-carbon fatty acid uses 2 ATP and generates 35 ATP. When the eight acetyl CoA enter the TCA cycle, even more ATP will be generated, as a later section describes.

## Amino Acid Degradation

The first step in amino acid degradation is the removal of the nitrogen-containing amino group through either deamination (Figure 6-11 on p. 183) or transamination (Figure 6-12 on p. 183) reactions. Then the remaining carbon skeletons may enter the metabolic pathways at different places, as shown in Figure C-3 (p. C-12).



## The TCA Cycle

The tricarboxylic acid, or TCA, cycle is the set of reactions that break down acetyl CoA to carbon dioxide and hydrogen atoms. Pyruvate derived from glycolysis does not enter the TCA cycle directly; instead pyruvate enters the mitochondrion, loses a carbon group, and bonds with a molecule of CoA to become acetyl CoA. The TCA cycle uses any substance that can be converted to acetyl CoA directly or indirectly through pyruvate.

Any substance that can be converted to acetyl CoA directly, or indirectly through pyruvate, may enter the TCA cycle.

The pathway from pyruvate to acetyl CoA is complex. We have included only those steps that will help you understand the transfer of energy from the nutrients. Pyruvate loses a carbon to carbon dioxide and is attached to a molecule of CoA. In the process, $NAD^+$ picks up two hydrogens with their associated electrons, becoming NADH + $H^+$.

**The step from pyruvate to acetyl CoA.** (TPP and NAD are coenzymes containing the B vitamins thiamin and niacin, respectively.)

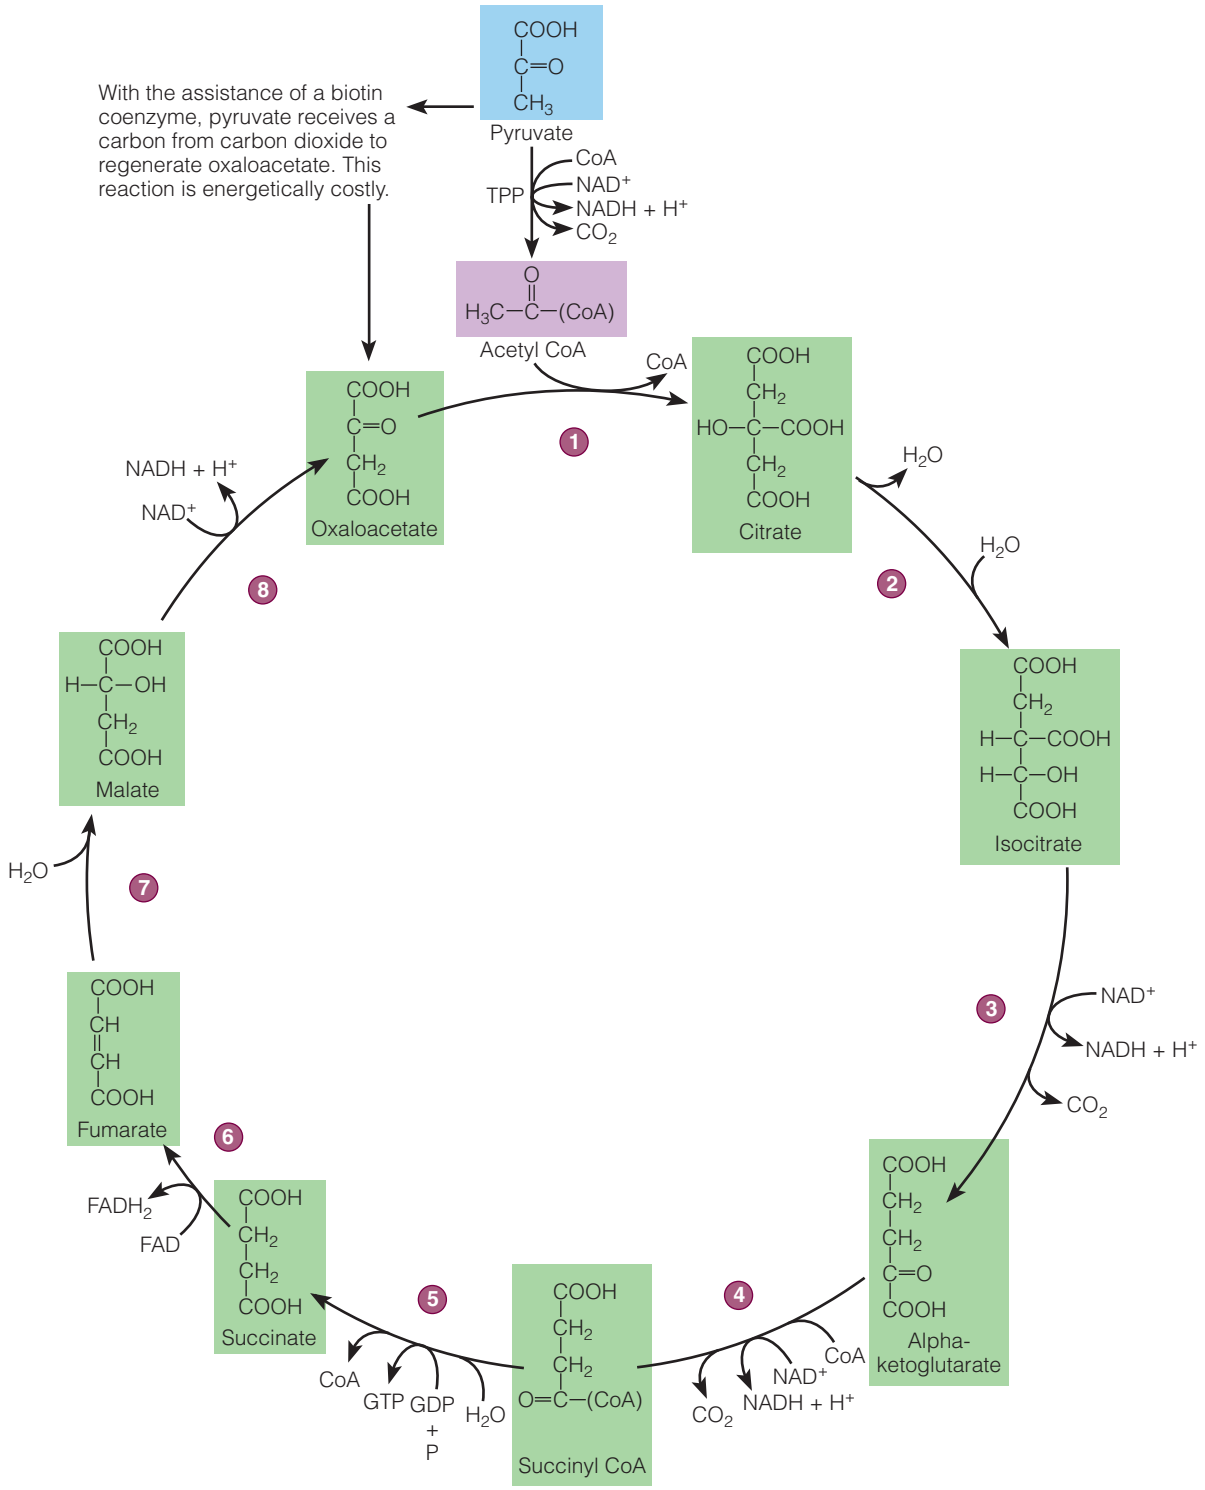
> **FIGURE C-3 Amino Acids Enter the Metabolic Pathways**

After losing their amino groups, carbon skeletons can be converted to one of seven molecules that can enter the TCA cycle (presented in Figure C-4).



Let's follow the steps of the TCA cycle (see the corresponding numbers in Figure C-4 on the next page).

1. The 2-carbon acetyl CoA combines with a 4-carbon compound, oxaloacetate. The CoA comes off, and the product is a 6-carbon compound, citrate.
2. The atoms of citrate are rearranged to form isocitrate.
3. Now two H (with their two electrons) are removed from the isocitrate. $NAD^+$ accepts the hydrogens with their electrons and becomes NADH + $H^+$. (Remember this NADH + $H^+$, but let's follow the carbons first.) A carbon is combined with two oxygens, forming carbon dioxide (which diffuses away into the blood and is exhaled). What is left is the 5-carbon compound alpha-ketoglutarate.
4. Now two compounds interact with alpha-ketoglutarate—a molecule of CoA and a molecule of $NAD^+$. In this complex reaction, a carbon and two oxygens are removed (forming carbon dioxide); two hydrogens are removed and go to $NAD^+$ (forming NADH + $H^+$); and the remaining 4-carbon compound is attached to the CoA, forming succinyl CoA. (Remember this NADH + $H^+$ also. You will see later what happens to it.)
5. Now two molecules react with succinyl CoA—a molecule called GDP and one of phosphate (P). The CoA comes off, the GDP and P combine to form the high-energy compound GTP (similar to ATP), and succinate remains. (Remember this GTP.)
6. In the next reaction, two H with their electrons are removed from succinate and are transferred to a molecule of FAD (a coenzyme like $NAD^+$) to form $FADH_2$. The product that remains is fumarate. (Remember this $FADH_2$.)
7. Next a molecule of water is added to fumarate, forming malate.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

> **FIGURE C-4 The TCA Cycle**

8. A molecule of $NAD^+$ accepts two H with their associated electrons and forms NADH + $H^+$. The product that remains is the 4-carbon compound oxaloacetate. (Remember this NADH + $H^+$.)

The cycle is complete and we are back where we started. The oxaloacetate can combine with another molecule of acetyl CoA (step 1), and the cycle can begin again.

So far, we have seen two carbons brought in with acetyl CoA and two carbons ending up in carbon dioxide. But where are the energy and the ATP that were promised?

A review of the eight steps of the TCA cycle shows that the compounds NADH + $H^+$ (three molecules), $FADH_2$, and GTP captured energy along the way. To see how this energy ends up in ATP, we must follow the electrons further—into the electron transport chain.

# The Electron Transport Chain

The six reactions described here are a highly simplified overview of the electron transport chain, which is shown below the TCA cycle in Figure C-5. Since oxygen is required for these reactions, and ADP and P are combined to form ATP in several of them (ADP is phosphorylated), the reactions of the electron transport chain are also called *oxidative phosphorylation*.

An important concept to remember at this point is that an electron is not a fixed amount of energy. The electrons that bond the H to $NAD^+$ in NADH have a relatively large amount of energy. In the series of reactions that follow, they release this energy in small amounts, until at the end they are attached (with H) to oxygen (O) to make water ($H_2O$). In some of the steps, the energy they release is captured into ATP in coupled reactions.

> **FIGURE C-5 The Electron Transport Chain**

1. In the first step of the electron transport chain, NADH transfers its high-energy electrons to a molecule called a flavoprotein, leaving $NAD^+$ and reduced flavoprotein. A little energy is released as heat in this reaction.
2. The flavoprotein passes on the electrons to a molecule called coenzyme Q. Again a little energy is released as heat, but ADP and P bond together and form ATP, storing much of the energy. This is a coupled reaction: ADP + P → ATP.
3. Coenzyme Q passes the electrons to cytochrome *b*. Again the electrons release energy.
4. Cytochrome *b* passes the electrons to cytochrome *c* in a coupled reaction in which ATP is formed: ADP + P → ATP.
5. Cytochrome *c* passes the electrons to cytochrome *a*.
6. Cytochrome *a* passes them (with their H) to an atom of oxygen (O), forming water ($H_2O$). This is a coupled reaction in which ATP is formed: ADP + P → ATP.

At the end of the chain, the low-energy electrons are passed to oxygen, which combines with the free $H^+$ ions to form water. As Figure C-5 shows, each time the three NADH are oxidized (losing their electrons), the energy released is captured in three ATP molecules. This completes the story of the electrons from NADH.

As for $FADH_2$, its electrons enter the electron transport chain at coenzyme Q. From coenzyme Q to water, ATP is generated in two steps. Therefore, $FADH_2$ coming out of the TCA cycle yields two ATP molecules.

One other compound of the TCA cycle—GTP—does not enter the electron transport chain but gives its energy directly to ADP in a simple phosphorylation reaction. This reaction yields one ATP.

It is now possible to draw up a balance sheet of glucose metabolism (see Table C-3). Glycolysis has yielded 4 NADH + $H^+$ and 4 ATP molecules and has spent 2 ATP. The 2 acetyl CoA going through the TCA cycle have yielded 6 NADH + $H^+$, 2 $FADH_2$, and 2 GTP molecules. After the NADH + $H^+$ and $FADH_2$ have gone through the electron transport chain, there are 28 ATP. Added to these are the 4 ATP from glycolysis and the 2 ATP from GTP, making the total 34 ATP generated from one molecule of glucose. After the expense of 2 ATP is subtracted, there is a net gain of 32 ATP.*

A similar balance sheet from the complete breakdown of one 16-carbon fatty acid would show a net gain of 129 ATP.

*The total may sometimes be 30 ATP. The NADH + $H^+$ generated in the cytoplasm during glycolysis pass their electrons on to shuttle molecules, which move them into the mitochondria. One shuttle, malate, contributes its electrons to the electron transport chain before the first site of ATP synthesis, yielding 5 ATP. Another, glycerol phosphate, adds its electrons into the chain beyond that first site, yielding 3 ATP. Thus sometimes 5, and sometimes 3, ATP result from the NADH + $H^+$ that arise from glycolysis. The amount depends on the cell.

**TABLE C-3 Balance Sheet for Glucose Metabolism**

| | | ATP |
|---|---|---|
| Glycolysis: | 4 ATP − 2 ATP | 2 |
| 1 glucose to 2 pyruvate | 2 NADH + $H^+$ | 3–5[a] |
| 2 pyruvate to 2 acetyl CoA | 2 NADH + $H^+$ | 5 |
| TCA cycle and electron transport chain: | | |
| 2 isocitrate | 2 NADH + $H^+$ | 5 |
| 2 alpha-ketoglutarate | 2 NADH + $H^+$ | 5 |
| 2 succinyl CoA | 2 GTP | 2 |
| 2 succinate | 2 $FADH_2$ | 3 |
| 2 malate | 2 NADH + $H^+$ | 5 |
| Total ATP collected from one molecule glucose: | | 30–32 |

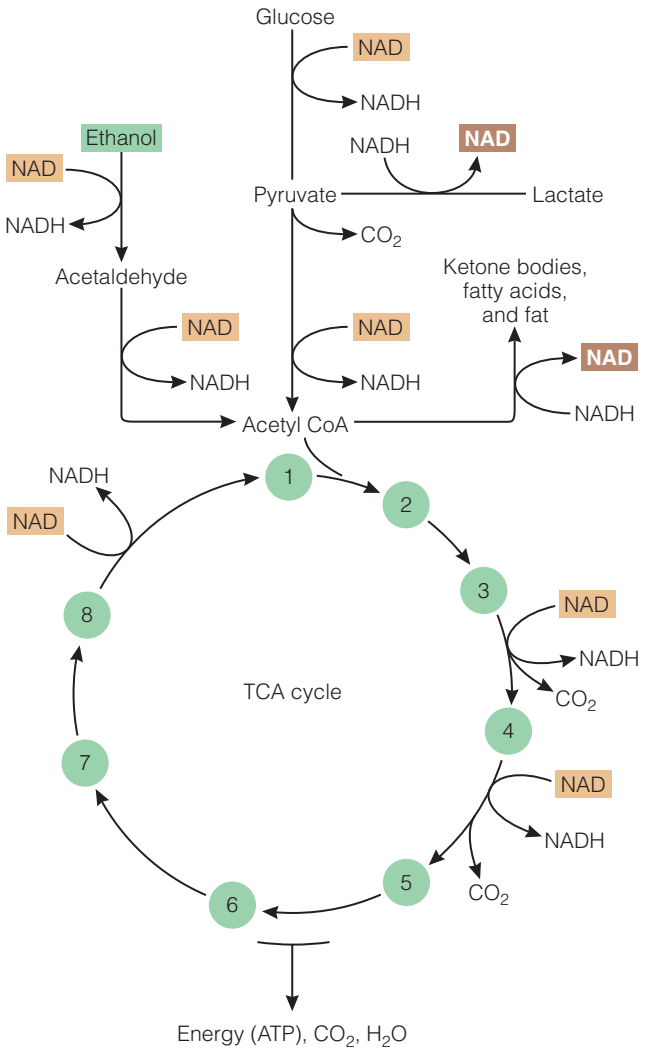
[a]Each NADH + $H^+$ from glycolysis can yield 1.5 or 2.5 ATP. See the accompanying text.

As mentioned earlier, 35 ATP were generated from the 7 $FADH_2$ and 7 NADH + $H^+$ produced during fatty acid oxidation. The 8 acetyl CoA produced will each generate 12 ATP as they go through the TCA cycle and the electron transport chain, for a total of 96 more ATP. After subtracting the 2 ATP needed to activate the fatty acid initially, the net yield from one 16-carbon fatty acid: 35 + 96 − 2 = 129 ATP.

These calculations help explain why fat yields more energy (measured as kcalories) per gram than carbohydrate or protein. The more hydrogen atoms a fuel contains, the more ATP will be generated during oxidation. The 16-carbon fatty acid molecule, with its 32 hydrogen atoms, generates 129 ATP, whereas glucose, with its 12 hydrogen atoms, yields only 32 ATP.

The TCA cycle and the electron transport chain are the body's major means of capturing the energy from nutrients in ATP molecules. Other means, such as anaerobic glycolysis, contribute energy quickly, but the aerobic processes are the most efficient.

## Alcohol's Interference with Energy Metabolism



Highlight 7 provides an overview of how alcohol interferes with energy metabolism. With an understanding of the TCA cycle, a few more details may be appreciated. During alcohol metabolism, the enzyme alcohol dehydrogenase oxidizes alcohol to acetaldehyde while it simultaneously reduces a molecule of $NAD^+$ to NADH + $H^+$. The related enzyme acetaldehyde dehydrogenase reduces another $NAD^+$ to NADH + $H^+$ while it oxidizes acetaldehyde to acetyl CoA, the compound that enters the TCA cycle to generate energy. Thus, whenever alcohol is being metabolized in the body, $NAD^+$ diminishes, and NADH + $H^+$ accumulates, thus altering the body's "redox state." $NAD^+$ can oxidize, and NADH + $H^+$ can reduce, many other compounds as well. During alcohol metabolism, however, $NAD^+$ becomes unavailable for the multitude of reactions for which it is required.

As the previous sections just explained, for glucose to be completely metabolized, the TCA cycle must be operating, and $NAD^+$ must be present. If these conditions are not met (and when alcohol is present, they may not be), the pathway will be blocked, and traffic will back up—or an alternate route will be taken. Think about this as you follow the pathway shown in Figure C-6.

In each step of alcohol metabolism in which $NAD^+$ is converted to NADH + $H^+$, hydrogen ions accumulate, resulting in a dangerous shift of the acid-base balance toward acid (Chapter 12 explains acid-base balance). The accumulation of NADH + $H^+$ slows TCA cycle activity, so pyruvate and acetyl CoA build up. This condition favors the conversion of

**> FIGURE C-6 Ethanol Enters the Metabolic Pathways**

This is a simplified version of the glucose-to-energy pathway showing the entry of ethanol. The coenzyme NAD (which is the active form of the B vitamin niacin) is the only one shown here; however, many others are involved.

APPENDIX C

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

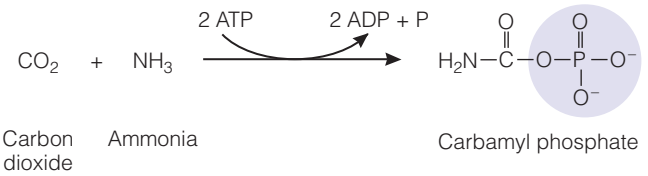
pyruvate to lactate, which serves as a temporary storage place for hydrogens from NADH + $H^+$. The conversion of pyruvate to lactate restores some $NAD^+$, but a lactate buildup has serious consequences of its own. It adds to the body's acid burden and interferes with the excretion of uric acid, causing goutlike symptoms. Molecules of acetyl CoA become building blocks for fatty acids or ketone bodies. The making of ketone bodies consumes acetyl CoA and generates $NAD^+$; but some ketone bodies are acids, so they push the acid-base balance further toward acid.

Thus alcohol cascades through the metabolic pathways, wreaking havoc along the way. These consequences have physical effects, as Highlight 7 describes.

## The Urea Cycle

Chapter 6 sums up the process by which waste nitrogen is eliminated from the body by stating that ammonia molecules combine with carbon dioxide to produce urea. This is true, but it is not the whole story. Urea is produced in a multistep process within the cells of the liver.

Ammonia, freed from an amino acid or other compound during metabolism anywhere in the body, arrives at the liver by way of the bloodstream and is taken into a liver cell. There, it is first combined with carbon dioxide and a phosphate group from ATP to form carbamyl phosphate:



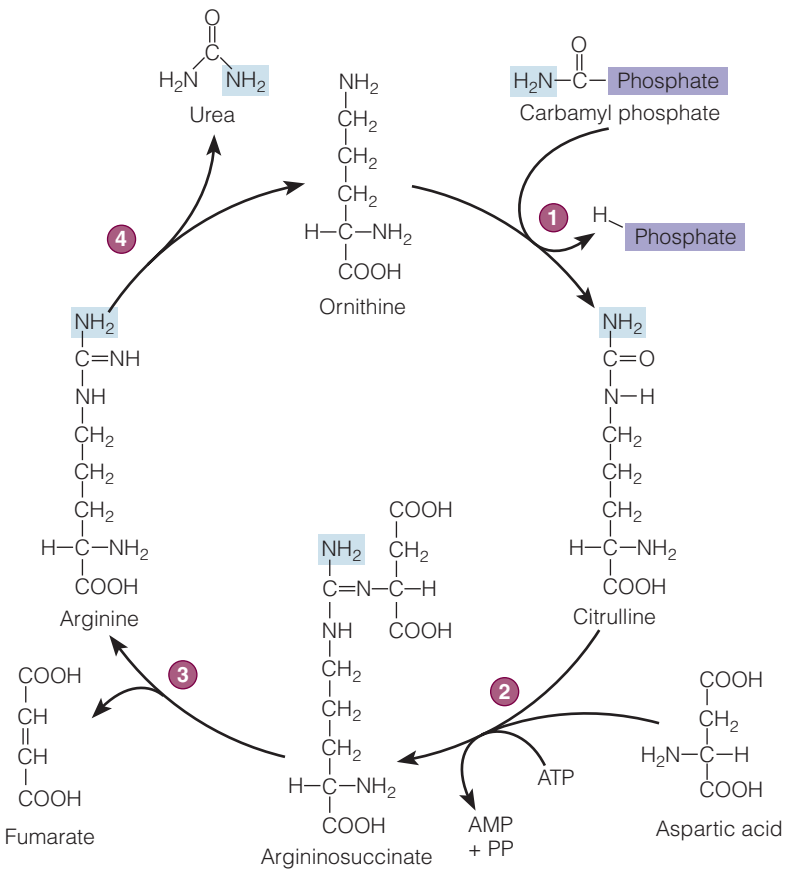


Figure C-7 shows the cycle of four reactions that follow.

1. Carbamyl phosphate combines with the amino acid ornithine, losing its phosphate group. The compound formed is citrulline.
2. Citrulline combines with the amino acid aspartic acid, to form argininosuccinate. The reaction requires energy from ATP. (In this reaction, ATP loses two phosphorus atoms, and becomes adenosine monophosphate, AMP.)
3. Argininosuccinate is split, forming another acid, fuma-rate, and the amino acid arginine.
4. Arginine loses its terminal carbon with two attached amino groups and picks up an oxygen from water. The

> FIGURE C-7 **The Urea Cycle**

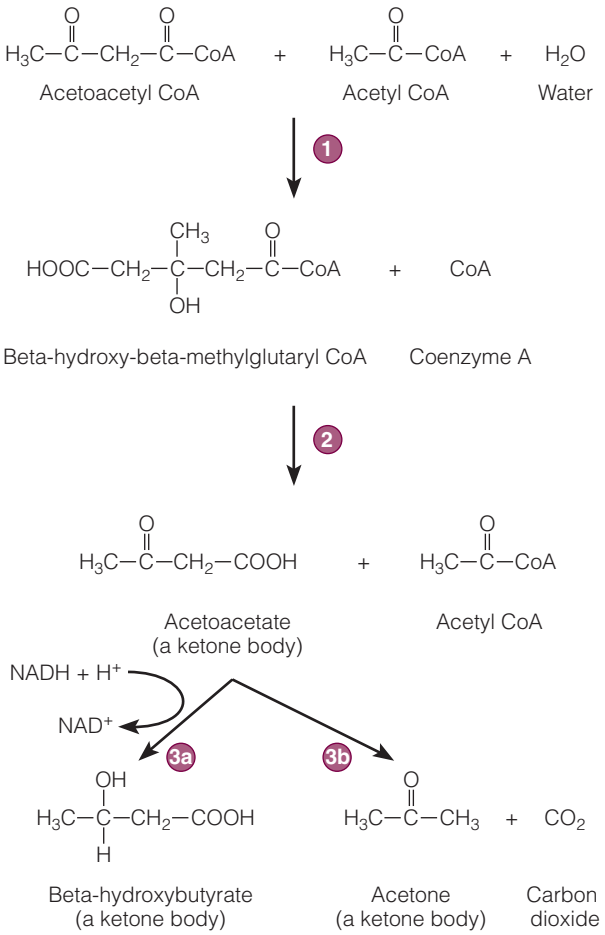
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

end product is urea, which the kidneys excrete in the urine. The compound that remains is ornithine, identical to the ornithine with which this series of reactions began, ready to react with another molecule of carbamyl phosphate and turn the cycle again.



## Formation of Ketone Bodies

Normally, fatty acid oxidation proceeds all the way to carbon dioxide and water. In ketosis, however, an intermediate is formed from the condensation of two molecules of acetyl CoA: acetoacetyl CoA. Figure C-8 shows the formation of ketone bodies from that intermediate.

1. Acetoacetyl CoA condenses with acetyl CoA to form a 6-carbon intermediate, beta-hydroxy-beta-methylglutaryl CoA.
2. This intermediate is cleaved to acetyl CoA and acetoacetate.
3. Acetoactate can be metabolized either to beta-hydroxybutyrate acid (step 3a) or to acetone (3b).

Acetoacetate, beta-hydroxybutyrate, and acetone are the ketone bodies of ketosis. Two are real ketones (they have a C=O group between two carbons); the other is an alcohol that has been produced during ketone formation—hence the term *ketone bodies*, rather than ketones, to describe the three of them. There are many other ketones in nature; these three are characteristic of ketosis in the body.

> **FIGURE C-8** The Formation of Ketone Bodies

APPENDIX C

# Appendix D Measures of Protein Quality

CONTENTS

Amino Acid Score
PDCAAS
DIAAS
Biological Value
Net Protein Utilizatin
Protein Efficiency Ratio

In a world where food is scarce and many people's diets contain marginal or inadequate amounts of protein, it is important to know which foods contain the highest-quality protein. Chapter 6 describes protein quality, and this appendix presents different measures researchers use to assess the quality of a food protein. Measures of protein quality aim to determine how well a food protein supports the body's normal metabolism and growth. The accompanying glossary defines related terms.

## Amino Acid Score

The **amino acid score** predicts protein quality based on the pattern of essential amino acids. It compares the essential amino acid composition of a food protein with that of a reference protein (egg). The score of each amino acid in the food protein is described as a percentage of the amino acid in the reference protein. The amino acid with the lowest percentage score is the most limiting amino acid. For example, results might find that compared with the reference amino acids, leucine gets a 93, lysine gets an 80, and all the other essential amino acids get higher scores. Lysine is the limiting amino acid (the one that falls shortest compared with egg). If the protein's limiting amino acid is 80 percent of the amount found in the reference protein, it receives an amino acid score of 80. The advantages of amino acid scoring are that it is simple and inexpensive, it easily identifies the limiting amino acid, and it can be used to score mixtures of different proportions of multiple proteins mathematically without having to create a mixture to test. Its chief weakness is that it fails to estimate the digestibility of a protein, which may strongly affect the protein's quality.

## PDCAAS

The **protein digestibility-corrected amino acid score,** or **PDCAAS,** is a widely used measurement of protein quality.[1] The PDCAAS compares the amino acid composition of a food protein with human amino acid requirements and corrects for digestibility. First the protein's essential amino acid composition is

APPENDIX D

## GLOSSARY

**amino acid score:** a measure of protein quality assessed by comparing a protein's amino acid pattern with that of a reference protein; also called the *chemical score*.

**biological value (BV):** a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen absorbed.

**DIAAS (digestible indispensable amino acid score):** a measure of protein quality similar to PDCAAS, except it determines protein digestibility at the end of the small intestine, which more accurately reflects the extent of amino acid absorption.

**net protein utilization (NPU):** a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen eaten.

**PDCAAS (protein digestibility-corrected amino acid score):** a measure of protein quality assessed by comparing the amino acid score of a food protein with the amino acid requirements of preschool-age children and then correcting for the true digestibility of the protein.

**protein efficiency ratio (PER):** a measure of protein quality assessed by determining how well a given protein supports weight gain in growing rats; used to establish the protein quality for infant formulas and baby foods.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

determined, and then it is compared against the amino acid requirements of preschool-aged children.[2] This comparison reveals the most limiting amino acid—the one that falls shortest compared with the reference. If a food protein's limiting amino acid is 70 percent of the amount found in the reference protein, it receives a score of 70. The amino acid score is multiplied by the food's protein digestibility percentage to determine the PDCAAS. The accompanying "How To" provides an example of how to calculate the PDCAAS, and Table D-1 lists the PDCAAS values of selected foods.

**TABLE D-1 PDCAAS Values of Selected Foods**

| | |
|---|---|
| Casein (milk protein) | 1.00 |
| Egg white | 1.00 |
| Soybean (isolate) | .99 |
| Beef | .92 |
| Pea flour | .69 |
| Kidney beans (canned) | .68 |
| Chickpeas (canned) | .66 |
| Pinto beans (canned) | .66 |
| Rolled oats | .57 |
| Lentils (canned) | .52 |
| Peanut meal | .52 |
| Whole wheat | .40 |

NOTE: 1.0 is the maximum PDCAAS a food protein can receive.

## DIAAS

Recently, the Food and Agriculture Organization of the United Nations recommended that a new method, known as Digestible Indispensable Amino Acid Score (DIAAS), should replace PDCAAS as the preferred method to determine protein quality.[3] The DIAAS overcomes some of the weaknesses of the current PDCAAS method. Whereas PDCAAS estimates protein digestibility over the entire intestine and uses a single digestibility score, the DIAAS determines amino acid digestibility at the end of the small intestine, which more accurately reflects the extent of amino acids absorption, and considers the digestibility of individual amino acids, as opposed to the protein as a whole.

## >How To

### Measure Protein Quality Using PDCAAS

To calculate the PDCAAS (protein digestibility-corrected amino acid score), researchers first determine the amino acid profile of the test protein (in this example, pinto beans). The second column of the table below presents the essential amino acid profile for pinto beans. The third column presents the amino acid reference pattern.

To determine how well the food protein meets human needs, researchers calculate the ratio by dividing the second column by the third column (for example, 30 ÷ 18 = 1.67). The amino acid with the lowest percentage is the most limiting amino acid—in this case, methionine. Its percentage is the amino acid score for the protein—in this case, 0.84.

The amino acid score alone, however, does not account for digestibility. Protein digestibility, as determined by animal studies, yields a value of 79 percent for pinto beans. Together, the amino acid score and the digestibility value determine the PDCAAS:

$$\text{PDCAAS} = \text{protein digestibility} \times \text{amino acid score}$$

$$\text{PDCAAS for pinto beans} = 0.79 \times 0.84 = 0.66$$

Thus the PDCAAS for pinto beans is 0.66 as Table D-1 shows.

| Essential Amino Acids | Amino Acid Profile of Pinto Beans (mg/g protein) | Amino Acid Reference Pattern (mg/g protein) | Amino Acid Score |
|---|---|---|---|
| Histidine | 30.0 | 18 | 1.67 |
| Isoleucine | 42.5 | 25 | 1.70 |
| Leucine | 80.4 | 55 | 1.46 |
| Lysine | 69.0 | 51 | 1.35 |
| Methionine (+ cystine) | 21.1 | 25 | 0.84 |
| Phenylalanine (+ tyrosine) | 90.5 | 47 | 1.93 |
| Threonine | 43.7 | 27 | 1.62 |
| Tryptophan | 8.8 | 7 | 1.26 |
| Valine | 50.1 | 32 | 1.57 |

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## Biological Value

The **biological value (BV)** of a food protein measures its efficiency in supporting the body's growth and maintenance. In a test of biological value, two nitrogen balance studies are done. In the first, no protein is fed, and nitrogen (N) excretions in the urine and feces are measured. It is assumed that under these conditions, N lost in the urine is the amount the body loses each day, regardless of food protein; this endogenous N is "urinary N on a zero-protein diet." The N lost in the feces is the amount the body loses each day, regardless of food protein; this metabolic N is "fecal N on a zero-protein diet."

In the second study, a diet containing the test protein in an amount equal to the requirement is fed. Intakes and losses are measured; then the BV is derived using this formula:

$$\text{BV} = \frac{\text{N retained}}{\text{N absorbed}} \times 100$$

The more nitrogen retained, the higher the protein quality. (Recall that when an essential amino acid is missing, protein synthesis stops, and the remaining amino acids are deaminated and the nitrogen excreted.)

Egg protein has a BV of 100, indicating that 100 percent of the nitrogen absorbed is retained. Supplied in adequate quantity, a protein with a BV of 70 or greater can support human growth as long as energy intake is adequate. Table D-2 presents the BV for selected foods.

**TABLE D-2 Biological Values (BV) of Selected Foods**

| | |
|---|---|
| Egg | 100 |
| Milk | 93 |
| Beef | 75 |
| Fish | 75 |
| Corn | 72 |

NOTE: 100 is the maximum BV a food protein can receive.

## Net Protein Utilization

Like BV, **net protein utilization (NPU)** measures how efficiently a protein is used by the body and involves two balance studies. The difference is that NPU measures retention of food nitrogen consumed rather than food nitrogen absorbed (as in BV). The formula for NPU is:

$$\text{NPU} = \frac{\text{N retained}}{\text{N intake}} \times 100$$

The numerator is the same as for BV, but the denominator represents food N intake only—not N absorbed.

## Protein Efficiency Ratio

The **protein efficiency ratio (PER)** measures the weight gain of a growing animal and compares it to the animal's protein intake. To determine the PER of a food protein, young, growing animals are given a standard diet containing about 10 percent (by weight) of the test protein. After a specified period of time, weight gain is measured and compared to the amount of test protein consumed. The PER is expressed as:

$$\text{PER} = \frac{\text{weight gain (g)}}{\text{protein intake (g)}}$$

Table D-3 presents PER values for selected foods.

**TABLE D-3 Protein Efficiency Ratio (PER) Values of Selected Proteins**

| | |
|---|---|
| Casein (milk) | 2.8 |
| Soy | 2.4 |
| Glutein (wheat) | 0.4 |

# Appendix E Nutrition Assessment

Nutrition assessment evaluates a person's health from a nutrition perspective. Many factors influence or reflect nutrition status. Consequently, the assessor, usually a registered dietitian assisted by other qualified health-care professionals, gathers information from many sources, including:

- Historical information.
- Anthropometric measurements.
- Physical examinations.
- Biochemical analyses (laboratory tests).

Each of these methods involves collecting data in a variety of ways and interpreting each finding in relation to the others to create a total picture.

The accurate gathering of this information and its careful interpretation are the basis for a meaningful evaluation. The more information gathered about a person, the more accurate the assessment will be. Gathering information is a time-consuming process, however, and time is often a rare commodity in the health care setting. Nutrition care is only one part of total care. It may not be practical or essential to collect detailed information on each person.

A strategic compromise is to screen patients by collecting preliminary data. Data such as height-weight and hematocrit are easy to obtain and can alert health-care workers to potential problems. **Nutrition screening** identifies patients who will require additional nutrition assessment. This appendix provides a sample of the procedures, standards, and charts commonly used in nutrition assessment.

Biochemical Analyses
Cautions about Nutrition Assessment

## Historical Information

Clues about a person's nutrition status and nutrient requirements become evident with a careful review of a person's historical information (see Table E-1). A thorough history identifies risk factors associated with poor nutrition status (see Table E-2) and reveals personal preferences that need consideration when developing a nutrition care plan. Historical information is obtained from the medical record and interviews with the patient or caregiver.

**TABLE E-1 Historical Information Used in Nutrition Assessments**

| Type of History | What It Identifies |
|---|---|
| Medical history | Current and previous mental and physical health problems and surgeries, chronic disease risks, and family medical history that affect nutrient needs, nutrition status, or the need for intervention to prevent or alleviate health problems |
| Personal and social history | Personal, cultural, financial, and environmental influences on food intake, nutrient needs, and diet therapy options |
| Medication and supplement history | Medications (prescription and over-the-counter), illicit drugs, dietary supplements, and alternative therapies that affect nutrition status |
| Food and nutrition history | Nutrient intake excesses or deficiencies and reasons for imbalances |

**nutrition screening:** the use of preliminary nutrition assessment techniques to identify people who are malnourished or are at risk for malnutrition.

**TABLE E-2 Risk Factors for Malnutrition**

**Medical History**

- Acquired immune deficiency syndrome (AIDS)
- Alcoholism
- Anorexia (lack of appetite)
- Anorexia nervosa
- Bulimia nervosa
- Burns (extensive or severe)
- Cancer
- Celiac disease
- Chewing or swallowing difficulties (including poorly fitted dentures, dental caries, missing teeth, and mouth ulcers)
- Chronic obstructive pulmonary disease
- Circulatory problems
- Constipation
- Crohn's disease
- Cystic fibrosis
- Decubitus ulcers (pressure sores)
- Dementia
- Depleted blood proteins
- Depression
- Diabetes mellitus
- Diarrhea, prolonged or severe
- Drug addiction
- Dysphagia
- Failure to thrive
- Feeding disabilities
- Fever
- GI tract disorders or surgery
- Heart disease
- HIV infection
- Hormonal imbalance
- Hyperlipidemia
- Hypertension
- Infections
- Inflammatory bowel diseases
- Kidney disease
- Liver disease
- Lung disease
- Malabsorption
- Mental illness
- Mental retardation
- Multiple pregnancies
- Nausea
- Neurologic disorders
- Organ failure
- Overweight
- Pancreatic insufficiency
- Paralysis
- Physical disability
- Pneumonia
- Pregnancy
- Radiation therapy
- Surgery (recent or major)
- Tobacco use
- Trauma
- Ulcerative colitis
- Ulcers
- Underweight
- Vomiting (prolonged or severe)

**Personal and Social History**

- Access to groceries
- Activities
- Age
- Cognitive abilities
- Economic status
- Education
- Employment
- Ethnic/cultural identity
- Home and family situation
- Kitchen facilities
- Religious beliefs

**Medication and Supplement History**

- Dietary and herbal supplements
- Illicit drug use
- Over-the-counter drugs
- Prescription medicines

**Food and Nutrition History**

- Deficient or excessive food intakes
- Food allergies or intolerances
- Food insecurity
- Frequently eating out
- Intravenous fluids (other than total parenteral nutrition) for 7 or more days
- Monotonous diet (lacking variety)
- Nutrition knowledge
- Poor appetite
- Restricted or fad diets
- Unbalanced diet (omitting any food group)
- Weight gains or losses (recent)

An adept history taker uses the interview both to gather facts and to establish a rapport with the patient. This section briefly reviews the major areas of nutrition concern in a person's history.

## Medical History

The assessor can obtain a **medical history** from records completed by the attending physician, nurse, or other health-care professional. In addition, conversations with the patient can uncover valuable information previously overlooked because no one thought to ask or because the patient was not thinking clearly when asked.

An accurate, complete medical history includes the family medical history as well and can reveal conditions that increase a patient's risk for malnutrition (review Table E-2). Diseases and their therapies can have either immediate or long-term effects on nutrition status by interfering with ingestion, digestion, absorption, metabolism, or excretion of nutrients.

## Personal and Social History

A **personal and social history** reveals factors that influence food choices and a person's ability to manage health

**medical history:** an account of a patient's current and past health status and disease risks.

**personal and social history:** a record of a person's social and economic background, including such factors as education, income, and ethnic identity.

and nutrition problems. The ethnic background and religious beliefs of both the patient and the other members of the household influence food choices. Financial concerns influence access to healthy food choices. In general, the quality of the diet declines as income falls. At some point, the ability to purchase the foods required to meet nutrient needs is lost; an inadequate income puts an adequate diet out of reach. Agencies use poverty indexes to identify people at risk for poor nutrition and to qualify people for government food assistance programs.

Low income affects not only the power to purchase foods but also the ability to shop for, store, and cook them; some individuals depend on others to procure and prepare meals. A skilled assessor will note whether a person has transportation to a grocery store that sells a sufficient variety of low-cost foods, and whether the person has access to a refrigerator and stove.

## Medication and Supplement History

The many interactions of foods and drugs require that healthcare professionals take a **medication and supplement history** and pay special attention to any patient who takes drugs routinely. If a person is taking any drug, the assessor records the name of the drug; the dose, frequency, and duration of intake; the reason for taking the drug; and signs of any adverse effects.

The interactions of drugs and nutrients may take many forms:

- Drugs can alter food intake and the absorption, metabolism, and excretion of nutrients.
- Foods and nutrients can alter the absorption, metabolism, and excretion of drugs.

Highlight 17 discusses nutrient-drug interactions in more detail, and Table H17-1 (p. 580) summarizes the mechanisms by which these interactions occur and provides specific examples.

## Food and Nutrition History

A **food and nutrition history** (often called a *diet history*) provides a record of a person's eating habits and food intake and can help identify possible nutrient imbalances. Food choices are an important part of lifestyle. The assessor who asks nonjudgmental questions about eating habits and food intake encourages trust and enhances the likelihood of obtaining accurate information.

Besides identifying possible nutrient imbalances, food and nutrition histories provide valuable clues about how a person will accept diet changes should they be necessary. Information about what and how a person eats provides the background for realistic and attainable nutrition goals. The following section describes the most common methods of gathering food intake information.

## Food Intake Data

Assessors evaluate food intake using various tools such as the 24-hour recall, the food record, the food frequency questionnaire, and direct observation. Food models or photos and measuring devices can help patients identify the types of foods and quantities consumed. The assessor also needs to know how the foods are prepared and when they are eaten. In addition to asking about foods, assessors will ask about beverage consumption, including beverages containing alcohol or caffeine.

### 24-Hour Dietary Recall

The **24-hour dietary recall** provides data for one day only and is commonly used in nutrition surveys to obtain estimates of the typical food intakes for a population. The assessor asks an individual to recount all the foods and beverages consumed in the past 24 hours or for the previous day. The interview includes questions about the times of meals and snacks, amounts consumed, and methods of food preparation.

**medication and supplement history:** a record of all the drugs, over-the-counter and prescribed, as well as dietary and herbal supplements that a person takes routinely.

**food and nutrition history:** a record of eating behaviors and the foods a person eats.

**24-hour dietary recall:** a record of foods eaten by a person for one 24-hour period.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The multiple-pass method is the most effective approach for obtaining an accurate list of foods consumed. In this procedure, the interview includes four or five separate passes through the 24-hour period of interest. In the first pass, the person provides a "quick list" of foods consumed without being prompted by the interviewer. The second pass helps the person remember foods that are often forgotten, such as beverages, bread, additions to foods (such as butter on toast), savory snacks, and sweets. Third and fourth passes elicit additional details about the foods consumed, such as the amounts eaten, preparation methods, and places where foods were obtained or consumed. A final pass provides an opportunity to recall foods and to probe for additional details. The entire multiple-pass interview can be conducted in about 30 to 45 minutes.

An advantage of the 24-hour recall is that it is relatively easy to obtain. It does not, however, provide enough information to allow accurate generalizations about an individual's usual food intake. The previous day's intake may not be typical, for example, or the person may be unable to report portion sizes accurately or may conceal or forget information about foods eaten. This limitation is partially overcome when 24-hour dietary recalls are collected on several nonconsecutive days.

**Food Record** Another tool for history taking is the **food record,** in which the person records food and beverages consumed, including the quantity and method of preparation. Chapter 9 (Figure 9-8, p. 286) provides an example. A food record can help both the assessor and the patient to determine factors associated with eating that may affect dietary balance and adequacy.

Food records work especially well with cooperative people but require considerable time and effort on their part. A prime advantage is that the record keeper assumes an active role and may for the first time become aware of personal food habits and assume responsibility for them. It also provides the assessor with an accurate picture of the person's lifestyle and factors that affect food intake. For these reasons, a food record can be particularly useful in outpatient counseling for such nutrition problems as overweight, underweight, or food allergy. The major disadvantages stem from poor compliance in recording the data and conscious or unconscious changes in eating habits that may occur while the person is keeping the record.

**Food Frequency Questionnaire** An assessor uses a **food frequency questionnaire** to survey the foods and beverages regularly consumed during a specific time period. Some questionnaires are qualitative only: food lists contain common foods, organized by food group, with check boxes to indicate frequency of consumption. Other types of questionnaires can collect semiquantitative information by including portion sizes as well. This information helps pinpoint foods and food groups, and therefore nutrients, that may be excessive or deficient in the diet. That a person ate no vegetables yesterday may not seem particularly significant, but never eating vegetables is a warning of possible nutrient deficiencies. When used with the usual intake or 24-hour recall approach, the food frequency questionnaire enables the assessor to double-check the accuracy of the information obtained.

**Direct Observation** In facilities that serve meals, food intakes can be directly observed and analyzed. This method can also reveal a person's food preferences, changes in appetite, and any problems with a prescribed diet. Health practitioners use direct observation to estimate a patient's intake of food energy (and often, protein) during a single day or on several consecutive days. To estimate food and nutrient intakes, the clinician records the dietary items that a patient is given at meals and subtracts the amounts remaining after meals are completed; this procedure allows an estimate of the amounts of foods and beverages actually consumed. Although a useful means of discerning patients' intakes, direct observation requires regular and careful documentation and can be labor-intensive and costly.

**Analysis of Food Intake Data** After collecting food intake data, the assessor estimates nutrient intakes, either informally by using food guides or formally by

**food record:** an extensive, accurate log of all foods eaten over a period of several days or weeks. A food record that includes associated information such as when, where, and with whom each food is eaten is sometimes called a *food diary.*

**food frequency questionnaire:** a checklist of foods on which a person can record the frequency with which he or she eats each food.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

using diet analysis programs. The assessor compares intakes with standards, usually nutrient recommendations or dietary guidelines, to determine how closely the person's diet meets the standards. Are the types and amounts of proteins, carbohydrates (including fiber), and fats (including cholesterol) appropriate? Are all food groups included in appropriate amounts? Is caffeine or alcohol consumption excessive? Are intakes of any vitamins or minerals (including sodium and iron) excessive or deficient? An informal evaluation is possible only if the assessor has enough prior experience with formal calculations to "see" nutrient amounts in reported food intakes without calculations. Even then, such an informal analysis is best followed by a spot check for key nutrients by actual calculation.

Formal calculations can be performed either manually (by looking up each food in a table of food composition, recording its nutrients, and adding them up) or by using a diet analysis program. The assessor then compares the intakes with standards such as the RDA.

**Limitations of Food Intake Analysis** Diet histories can be most informative, but the skillful assessor also keeps their limitations in mind. For example, a diet analysis program tends to imply greater accuracy than is possible to obtain from data as uncertain as the starting information. Nutrient contents of foods listed in tables of food composition or stored in computer databases are averages and, for some nutrients, incomplete. In addition, the available data on nutrient contents of foods do not reflect the amounts of nutrients a person actually absorbs. Iron is a case in point: its availability from a given meal may vary depending on the person's iron status; the relative amounts of heme iron, nonheme iron, vitamin C, meat, fish, and poultry eaten at the meal; and the presence of inhibitors of iron absorption such as tea, coffee, and nuts. (Chapter 13 describes the many factors that influence iron absorption from a meal.)

Furthermore, reported portion sizes may not be correct. The person who reports eating "a serving" of greens may not distinguish between ¼ cup and 2 cups; only individuals who have practice measuring food quantities can accurately report serving sizes. Children tend to remember the serving sizes of foods they like as being larger than serving sizes of foods they dislike.

An estimate of nutrient intakes from a food and nutrition history, combined with other sources of information, allows the assessor to confirm or eliminate the possibility of suspected nutrition problems. The assessor must constantly remember that nutrient intakes in adequate amounts do not guarantee adequate nutrient status for an individual. Likewise, insufficient intakes do not always indicate deficiencies, but instead alert the assessor to possible problems. Each person digests, absorbs, metabolizes, and excretes nutrients in a unique way; individual needs vary. Intakes of nutrients identified by diet histories are only pieces of a puzzle that must be put together with other indicators of nutrition status in order to extract meaning.

# Anthropometric Measurements

**Anthropometrics** are physical measurements that reflect body composition and development (see Table E-3). They serve three main purposes: first, to evaluate the progress of growth in pregnant women, infants, children, and adolescents; second, to detect undernutrition and overnutrition in all age groups; and third, to measure changes in body composition over time.

Health-care professionals compare anthropometric measurements taken on an individual with population standards specific for gender and age or with previous measures of the individual. Measurements taken periodically and compared with previous measurements reveal changes in an individual's status.

Mastering the techniques for taking anthropometric measurements requires proper instruction and practice to ensure reliability. Once the correct techniques are learned, taking measurements is easy and requires minimal equipment.

**anthropometrics** (AN-throw-poe-MET-ricks)**:** measurements of the physical characteristics of the body, such as height and weight.
- **anthropos** = human
- **metric** = measuring

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**> FIGURE E-1 Length Measurement of an Infant**

An infant is measured lying down on a measuring board with a fixed headboard and a movable footboard. Note that two people are needed to measure the infant's length.

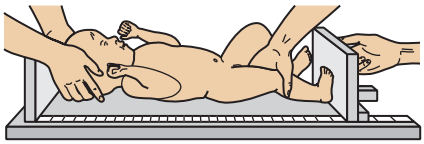

**TABLE E-3 Anthropometric Measurements Used in Nutrition Assessments**

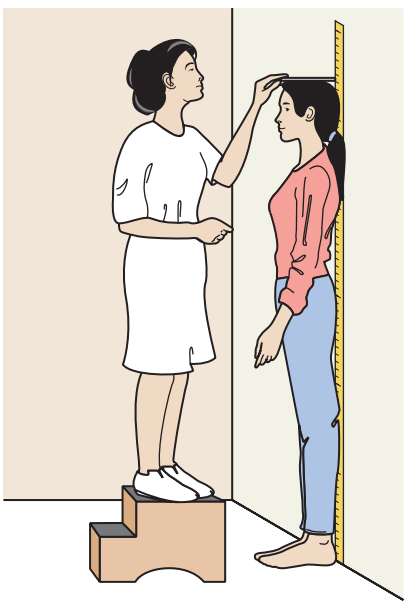
| Type of Measurement | What It Reflects |
|---|---|
| Abdominal girth measurement | Abdominal fluid retention and abdominal organ size |
| Height-weight | Overnutrition and undernutrition; growth in children |
| Head circumference | Brain growth and development in infants and children under age 2 |
| Skinfold | Subcutaneous and total body fat |
| Waist circumference | Body fat distribution |

© Cengage Learning

Height and weight are well-recognized anthropometrics; other anthropometrics include skinfold measurements and various measures of lean tissue. Other measures are useful in specific situations. For example, a head circumference measurement may help to assess brain development in an infant, and an abdominal girth measurement supplies information about abdominal fluid retention in individuals with liver disease.

## Measures of Growth and Development



Height and weight are among the most common and useful anthropometric measurements. Length measurements for infants and children up to age 3 and height measurements for children over 3 are particularly valuable in assessing growth and therefore nutrition status. For adults, height measurements alone are not critical, but help to estimate healthy weight and to interpret other assessment data. Once adult height has been reached, changes in body weight provide useful information in assessing overnutrition and undernutrition.

### Height

For infants and children younger than 3, health-care professionals may use special equipment to measure length. The assessor lays the barefoot infant on a measuring board that has a fixed headboard and movable footboard attached at right angles to the surface (see Figure E-1). Often two people are needed to obtain an accurate measurement: one to gently hold the infant's head against the headboard, and the other to straighten the infant's legs and move the footboard to the bottom of the infant's feet.

**> FIGURE E-2 Height Measurement of an Older Child or Adult**

Height is measured most accurately when the person stands against a flat wall to which a measuring tape has been affixed.

The procedure for measuring a child who can stand erect and cooperate is the same as for an adult. The best way to measure standing height is with the person's back against a flat wall to which a nonstretchable measuring tape or stick has been fixed (see Figure E-2). The person stands erect, without shoes, with heels together. The person's line of sight should be horizontal, with the heels, buttocks, shoulders, and head touching the wall. The assessor places a ruler or other inflexible object on top of the head at a right angle to the wall; carefully checks the height measurement; and records it immediately in either inches or centimeters so that the correct measurement will not be forgotten.

The measuring rod of a scale is commonly used, but is less accurate because it bends easily. The assessor follows the same general procedure, asking the person to face away from the scale and to take extra care to stand erect.

Unfortunately, many health-care professionals merely ask patients how tall they are rather than measuring their height. Self-reported height is often inaccurate and should be used only as a last resort when measurement is impractical (in the case of an uncooperative patient, an emergency admission, or the like).

### Weight

Valid weight measurements require scales that have been carefully maintained, calibrated, and checked for accuracy at regular intervals. Beam balance and electronic scales are the most accurate. To measure infants' weight, assessors use special scales that allow infants to lie or sit (see Figure E-3). Weighing infants naked, without diapers, is standard procedure. Children who can stand are weighed in the same way as adults (see Figure E-4). To make repeated measures useful, standardized conditions are necessary. Each weighing should take

place at the same time of day (preferably before breakfast), in the same amount of clothing (without shoes), after the person has voided, and on the same scale. Special scales and hospital beds with built-in scales are available for weighing people who are bedridden. Bathroom scales are inaccurate and inappropriate in a professional setting. As with all measurements, the assessor records the observed weight immediately in either pounds or kilograms.

**Head Circumference** Assessors may also measure head circumference to confirm that infant growth is proceeding normally or to help detect malnutrition and evaluate the extent of its impact on brain size. To measure head circumference, the assessor places a nonstretchable tape so that it encircles the largest part of the infant's or child's head: just above the eyebrow ridges, just above the point where the ears attach, and around the occipital prominence at the back of the head. To ensure accurate recording, the assessor immediately notes the measure in either inches or centimeters.

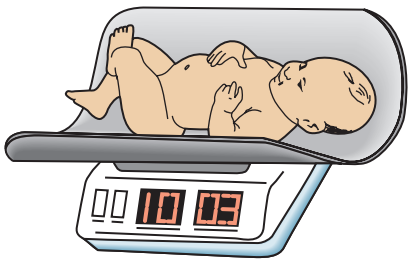
**Analysis of Measures in Infants and Children** Growth retardation is a sign of poor nutrition status. Obesity is also a sign that dietary intervention may be needed.

Health professionals generally evaluate physical development by monitoring the growth rate of a child and comparing this rate with standard charts. Standard charts compare weight to age, height to age, and weight to height; ideally, height and weight are in roughly the same percentile. Although individual growth patterns may vary, a child's growth curve will generally stay at about the same percentile throughout childhood. In children whose growth has been retarded, nutrition rehabilitation will ideally induce height and weight to increase to higher percentiles. In overweight children, the goal is for weight to remain stable as height increases, until weight becomes appropriate for height.

To evaluate growth in infants, an assessor uses charts such as those in Figures E-5 (A and B) through E-10 (A and B). The assessor follows these steps to plot a weight measurement on a percentile graph:

- Select the appropriate chart based on age and gender.
- Locate the child's age along the horizontal axis on the bottom of the chart.
- Locate the child's weight in pounds or kilograms along the vertical axis.
- Mark the chart where the age and weight lines intersect, and read off the percentile.

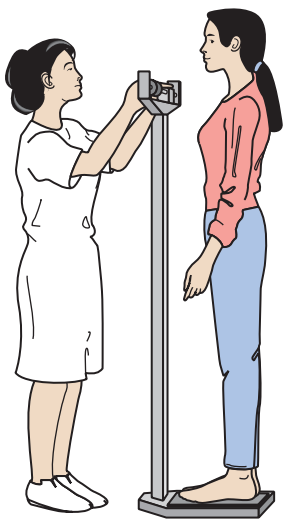
To assess length, height, or head circumference, the assessor follows the same procedure, using the appropriate chart. (When length is measured, use the chart for birth to 36 months; when height is measured, use the chart for 2 to 20 years.) Head circumference percentile should be similar to the child's height and weight percentiles. With height, weight, and head circumference measures plotted on growth percentile charts, a skilled clinician can begin to interpret the data.



Percentile charts divide the measures of a population into 100 equal divisions. Thus half of the population falls above the 50th percentile, and half falls below. The use of percentile measures allows for comparisons among people of the same age and gender. For example, a 6-month-old female infant whose weight is at the 75 percentile weighs more than 75 percent of the female infants her age.

Head circumference is generally measured in children under 2 years of age. Because the brain grows rapidly before birth and during early infancy, extreme and chronic malnutrition during these times can impair brain development, curtailing the number of brain cells and the size of head circumference. Nonnutritional factors, such as certain disorders and genetic variation, can also influence head circumference.

**Analysis of Measures in Adults** For adults, health-care professionals typically compare weights with weight-for-height standards. One such standard is the body mass index (BMI), described in Chapter 8, which is useful for estimating the risk to health associated with overnutrition. The inside back cover shows BMI for various heights and weights.



**> FIGURE E-3 Weight Measurement of an Infant**

Infants sit or lie down on scales that are designed to hold them while they are being weighed.

**> FIGURE E-4 Weight Measurement of an Older Child or Adult**

Whenever possible, children and adults are measured on beam balance or electronic scales to ensure accuracy.

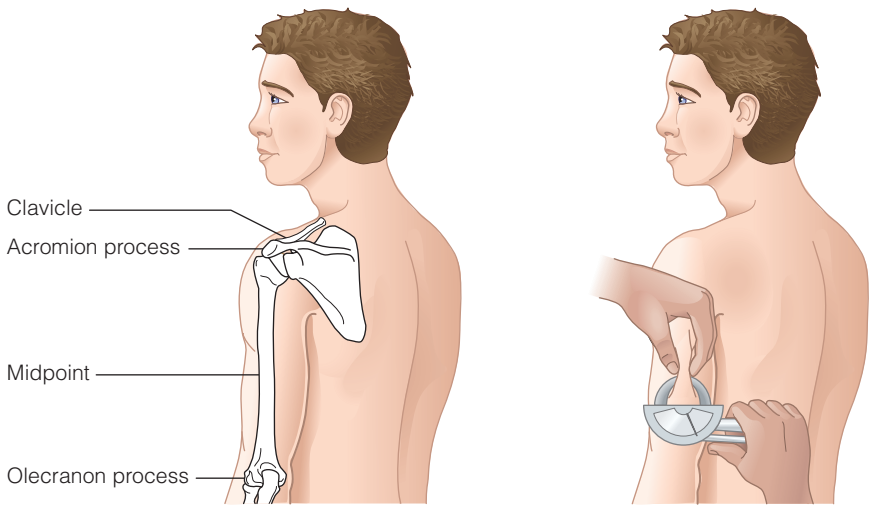
## Measures of Body Fat and Lean Tissue



Significant weight changes in both children and adults can reflect overnutrition and undernutrition. To estimate the degree to which fat stores or lean tissues are affected by overnutrition or malnutrition, several anthropometric measurements are useful (review Table E-3 on p. E-6).

### Skinfold Measures

Skinfold measures provide a good estimate of total body fat and a fair assessment of the fat's location. Approximately half the fat in the body lies directly beneath the skin, and the thickness of this subcutaneous fat reflects total body fat. In some parts of the body, such as the back and the back of the arm over the triceps muscle, this fat is loosely attached; a person can pull it up between the thumb and forefinger to obtain a measure of skinfold thickness. (Other common sites for skinfold measures include the biceps, subscapular area below the shoulder blade, suprailiac area above the hip bone, abdomen, and upper thigh.) To measure skinfold, a skilled assessor follows a standard procedure using reliable calipers (illustrated in Figure E-11) and then compares the measurement with standards.

Skinfold measurements correlate directly with the risk of heart disease. They assess central obesity and its associated risks better than do weight measures alone. If a person gains body fat, the skinfold increases proportionately; if the person loses fat, it decreases. Measurements taken from central-body sites (around the abdomen) better reflect changes in fatness than those taken from upper sites (arm and back). A major limitation of the skinfold test is that fat may be thicker under the skin in one area than in another. A pinch at the side of the waistline may not yield the same measurement as a pinch on the back of the arm. This limitation can be overcome by taking skinfold measurements at several

> **FIGURE E-11** How to Measure the Triceps Skinfold

A. Find the midpoint of the arm:
   1. Ask the subject to bend his or her arm at the elbow and lay the hand across the stomach. (If he or she is right-handed, measure the left arm, and vice versa.)
   2. Feel the shoulder to locate the acromion process. It helps to slide your fingers along the clavicle to find the acromion process. The olecranon process is the tip of the elbow.
   3. Place a measuring tape from the acromion process to the tip of the elbow. Divide this measurement by 2, and mark the midpoint of the arm with a pen.

B. Measure the skinfold:
   1. Ask the subject to let his or her arm hang loosely to the side.
   2. Grasp a fold of skin and subcutaneous fat between the thumb and forefinger slightly above the midpoint mark. Gently pull the skin away from the underlying muscle. (This step takes a lot of practice. To be sure you don't have muscle as well as fat, ask the subject to contract and relax the muscle. You should be able to feel if you are pinching muscle.)
   3. Place the calipers over the skinfold at the midpoint mark, and read the measurement to the nearest 1.0 millimeter in two to three seconds. (If using plastic calipers, align pressure lines, and read the measurement to the nearest 1.0 millimeter in two to three seconds.)
   4. Repeat steps 2 and 3 twice more. Add the three readings, and then divide by 3 to find the average.

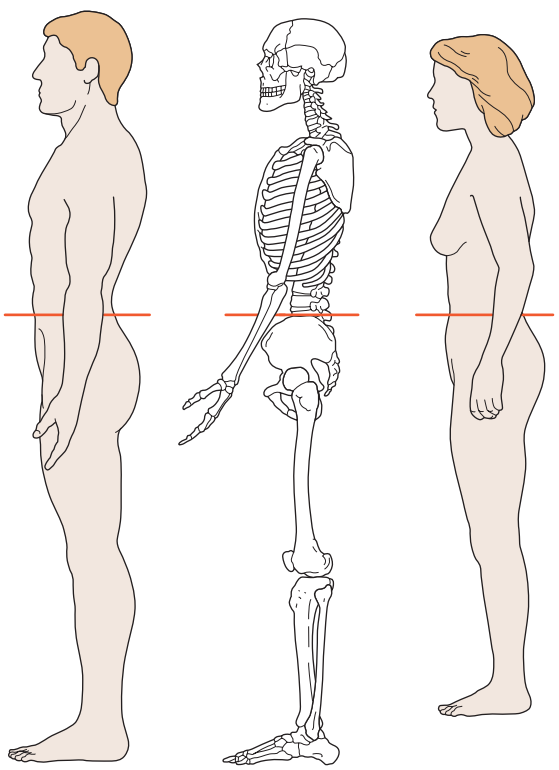
(often three) different places on the body (including upper-, central-, and lower-body sites) and comparing each measurement with standards for that site. Multiple measures are not always practical in clinical settings, however, and most often, the triceps skinfold measurement alone is used because it is easily accessible. Skinfold measures are not useful in assessing changes in body fat over time.



**Waist Circumference** Chapter 8 describes how fat distribution correlates with health risks and mentioned that the waist circumference is a valuable indicator of fat distribution. To measure waist circumference, the assessor places a non-stretchable tape around the person's body, crossing just above the upper hip bones and making sure that the tape remains on a level horizontal plane on all sides (see Figure E-12). The tape is tightened slightly, but without compressing the skin.

**Waist-to-Hip Ratio** Alternatively, some clinicians measure both the waist and the hips. To calculate the waist-to-hip ratio, divide the waistline measurement by the hip measurement. For example, a woman with a 28-inch waist and 38-inch hips would have a ratio of 28 ÷ 38 = 0.74. Like the waist circumference, the waist-to-hip ratio also assesses abdominal obesity, but provides no more information than using the waist circumference alone. In general, women with a waist-to-hip ratio of 0.80 or greater and men with a waist-to-hip ratio of 0.90 or greater have a high risk of health problems.

**Hydrodensitometry** To estimate body density using hydrodensitometry, the person is weighed twice—first on land and then again when submerged under water. Underwater weighing usually generates a good estimate of body fat and is useful in research, although the technique has drawbacks: it requires bulky, expensive, and

**> FIGURE E-12 How to Measure Waist Circumference**

Place the measuring tape around the waist just above the bony crest of the hip. The tape runs parallel to the floor and is snug (but does not compress the skin). The measurement is taken at the end of normal expiration.

**TABLE E-4 Methods of Estimating Body Fat and Its Distribution**

| Method | Cost | Ease of Use | Accuracy | Measures Fat Distribution |
|---|---|---|---|---|
| Height and weight | Low | Easy | High | No |
| Skinfolds | Low | Easy | Low | Yes |
| Circumferences | Low | Easy | Moderate | Yes |
| Ultrasound | Moderate | Moderate | Moderate | Yes |
| Hydrodensitometry | Low | Moderate | High | No |
| Heavy water tritiated | Moderate | Moderate | High | No |
| Deuterium oxide, or heavy oxygen | High | Moderate | High | No |
| Potassium isotope ($^{40}K$) | Very high | Difficult | High | No |
| Total body electrical conductivity (TOBEC) | High | Moderate | High | No |
| Bioelectric impedance (BIA) | Moderate | Easy | High | No |
| Dual-energy X-ray absorptiometry (DEXA) | High | Easy | High | No |
| Computed tomography (CT) | Very high | Difficult | High | Yes |
| Magnetic resonance imaging (MRI) | Very high | Difficult | High | Yes |

SOURCE: Adapted from G. A. Bray, a handout presented at the North American Association for the Study of Obesity and Emory University School of Medicine Conference on Obesity. Update: Pathophysiology, Clinical Consequences, and Therapeutic Options, Atlanta, Georgia, August 31–September 2, 1992.

nonportable equipment. Furthermore, submerging some people (especially those who are very young, very old, ill, or fearful) under water is not always practical.

**Bioelectric Impedance** To measure body fat using the bioelectric impedance technique, a very-low-intensity electrical current is briefly sent through the body by way of electrodes placed on the wrist and ankle. As is true of other anthropometric techniques, bioelectrical impedance requires standardized procedures and calibrated instruments to provide reliable results. Recent food intake and hydration status, for example, influence results. Bioelectrical impedance is most accurate for people within a normal fat range; it tends to overestimate fat in lean people and underestimate fat in obese people.

Chapter 8 (Figure 8-10, p. 251) illustrates several anthropometric measures of body fat and lean tissue. Clinicians use other methods to estimate body fat and its distribution as well. Each has its advantages and disadvantages as Table E-4 summarizes.

# Physical Examinations

An assessor can use a physical examination to search for signs of nutrient deficiency or toxicity. Like the other assessment methods, such an examination requires knowledge and skill. Many physical signs are nonspecific; they can reflect any of several nutrient deficiencies as well as conditions not related to nutrition (see Table E-5). For example, cracked lips may be caused by sunburn, windburn, dehydration, or any of several B vitamin deficiencies, to name just a few possible causes. For this reason, physical findings are most valuable in revealing problems for other assessment techniques to confirm or for confirming other assessment measures.

With this limitation understood, physical symptoms can be most informative about nutrition health. Many tissues and organs can reflect signs of malnutrition. The signs appear most rapidly in parts of the body where cell replacement occurs at a high rate, such as in the hair, skin, and digestive tract (including the mouth and tongue). The summary tables in Chapters 10, 11, 12, and 13 list additional physical signs of vitamin and mineral malnutrition.

**TABLE E-5 Physical Findings Used in Nutrition Assessments**

| Body System | Signs of Good Health | Signs of Malnutrition | Other Possible Causes |
|---|---|---|---|
| Hair | Shiny, firm in the scalp | Dull, brittle, dry, loose; falls out (severe acute malnutrition); corkscrew hair (vitamin C) | Excessive hair bleaching; hair loss from aging, chemotherapy, or radiation therapy |
| Eyes | Bright, clear, pink, moist membranes; adjust easily to light | Pale membranes (iron); spots, dryness, night blindness (vitamin A); redness at corners of eyes (B vitamins) | Anemia unrelated to nutrition; eye disorders; allergies; aging |
| Mouth | No sores, swelling, or bleeding; red tongue; normal sense of taste; no caries; ability to chew and swallow; smooth lips | Bleeding gums (vitamin C); smooth or magenta tongue (B vitamins); poor taste sensation (zinc); dry, cracked, or sores in the corners of the lips (B vitamins) | Sunburn, windburn, excessive salivation from ill-fitting dentures or various disorders, medications, periodontal diseases, poor dental hygiene |
| Skin | Smooth, firm, good color | Poor wound healing (severe acute malnutrition, vitamin C, zinc); dry, rough, lack of fat under skin (essential fatty acids, vitamin A, B vitamins); bruising or bleeding under skin (vitamin C and vitamin K); pale (iron) | Poor skin hygiene, diabetes mellitus, aging, medications |
| Nails | Firm, pink, smooth | Spoon-shaped, brittle, pale (iron); rigid (protein malnutrition) | |

# Biochemical Analyses

All of the approaches to nutrition assessment discussed so far are external approaches. Biochemical analyses or laboratory tests help to determine what is happening to the body internally. Common tests are based on analysis of blood and urine samples, which contain nutrients, enzymes, and metabolites that reflect nutrition status. Other tests, such as blood glucose, help pinpoint disease-related problems with nutrition implications. Tests that define fluid and electrolyte balance, acid-base balance, and organ function also have nutrition implications. Table E-6 lists biochemical tests most useful for assessing vitamin and mineral status.

The interpretation of biochemical data requires skill. Long metabolic sequences lead to the production of the end-products and metabolites seen in blood and urine. No single test can reveal nutrition status because many factors influence test results. The low blood concentration of a nutrient may reflect a primary deficiency of that nutrient, but it may also be secondary to the deficiency of one or several other nutrients or to a disease. Taken together with other assessment data, however, laboratory test results help to create a picture that becomes clear with careful interpretation. They are especially useful in helping to detect subclinical malnutrition by uncovering early signs of malnutrition before the clinical signs of a classic deficiency disease appear.

Laboratory tests used to assess vitamin and mineral status (review Table E-6) are particularly useful when combined with diet histories and physical findings. Vitamin and mineral levels present in the blood and urine sometimes reflect recent rather than long-term intakes. This makes detecting subclinical deficiencies difficult. Furthermore, many nutrients interact; therefore, the amounts of other nutrients in the body can affect a lab value for a particular nutrient. It is also important to remember that nonnutrient conditions such as diseases influence biochemical measures.

It is beyond the scope of this text to describe all lab tests and their relations to nutrition status. Instead, the emphasis is on lab tests used to detect protein malnutrition and nutritional anemias.

**Protein Malnutrition** No single biochemical analysis can adequately evaluate protein malnutrition. This discussion focuses on the measures commonly used today—transthyretin, retinol-binding protein, serum transferrin, and IGF-1 (insulin-like growth factor 1). Table E-7 provides standards for these indicators.

**TABLE E-6 Biochemical Tests Useful for Assessing Vitamin and Mineral Status**

| Nutrient | Assessment Tests |
|---|---|
| **Vitamins** | |
| Vitamin A | Serum retinol, retinol-binding protein |
| Thiamin[a] | Erythrocyte (red blood cell) transketolase activity, erythrocyte thiamin pyrophosphate |
| Riboflavin[a] | Erythrocyte glutathione reductase activity |
| Vitamin $B_6$[a] | Urinary xanthurenic acid excretion after tryptophan load test, erythrocyte transaminase activity, plasma pyridoxal 5′-phosphate (PLP) |
| Niacin | Plasma or urinary metabolites NMN (N-methyl nicotinamide) or 2-pyridone, or preferably both expressed as a ratio |
| Folate[b] | Serum folate, erythrocyte folate (reflects liver stores) |
| Vitamin $B_{12}$[b] | Serum vitamin $B_{12}$, serum and urinary methylmalonic acid, Schilling test |
| Biotin | Urinary biotin, urinary 3-hydroxyisovaleric acid |
| Vitamin C | Plasma vitamin C[c], leukocyte vitamin C |
| Vitamin D | Serum vitamin D |
| Vitamin E | Serum $\alpha$-tocopherol, erythrocyte hemolysis |
| Vitamin K | Serum vitamin K, plasma prothrombin; blood-clotting time (prothrombin time) is not an adequate indicator |
| **Minerals** | |
| Phosphorus | Serum phosphate |
| Sodium | Serum sodium |
| Chloride | Serum chloride |
| Potassium | Serum potassium |
| Magnesium | Serum magnesium, urinary magnesium |
| Iron | Hemoglobin, hematocrit, serum ferritin, total iron-binding capacity (TIBC), erythrocyte protoporphyrin, serum iron, transferrin saturation |
| Iodine | Serum thyroxine or thyroid-stimulating hormone (TSH), urinary iodine |
| Zinc | Plasma zinc, hair zinc |
| Copper | Erythrocyte superoxide dismutase, serum copper, serum ceruloplasmin |
| Selenium | Erythrocyte selenium, glutathione peroxidase activity |

[a]Urinary measurements for these vitamins are common, but may be of limited use. Urinary measurements reflect recent dietary intakes and may not provide reliable information concerning the severity of a deficiency.
[b]Folate assessments should always be conducted in conjunction with vitamin $B_{12}$ assessments (and vice versa) to help distinguish the cause of common deficiency symptoms.
[c]Vitamin C shifts between the plasma and the white blood cells known as leukocytes; thus a plasma determination may not accurately reflect the body's pool. A measurement of leukocyte vitamin C can provide information about the body's stores of vitamin C. A combination of both tests may be more reliable than either one alone.
SOURCE: Adapted from H. E. Sauberlich, *Laboratory Tests for the Assessment of Nutritional Status* (Boca Raton, FIA.: CRC Press, 1999).

Although serum albumin is easily and routinely measured, it lacks the sensitivity to assess protein malnutrition because of its long turnover rate.*

**Transthyretin and Retinol-Binding Protein** Transthyretin and retinol-binding protein occur as a complex in the plasma.** They have a rapid turnover and thus respond quickly to dietary protein inadequacy and therapy.*** Conditions other than malnutrition that lower transthyretin include metabolic stress, hemodialysis, and hypothyroidism; those that raise transthyretin include kidney disease and corticosteroid use. Conditions other than protein malnutrition that lower retinol-binding protein include vitamin A deficiency, metabolic stress, hyperthyroidism, liver disease, and cystic fibrosis; kidney disease raises retinol-binding protein levels.

**TABLE E-7 Normal Values for Serum Proteins**

| Test | Normal Values |
|---|---|
| Albumin (g/dL) | 3.5–5.0 |
| Transferrin (mg/dL) | 200–400 |
| Transthyretin (mg/dL) | 16–40 |
| Retinol-binding protein (mg/dL) | 3–7 |
| IGF-1 (μg/L) | 300 |

NOTE: Levels less than normal suggest compromised protein status.

*The half-life of albumin is 14 to 20 days, an indication of a slow degradation rate.
**Transthyretin is also known as *prealbumin* or *thyroxine-binding prealbumin*.
***The half-lives of transthyretin and retinol-binding protein are 2 days and 12 hours, respectively.

**Serum Transferrin** Serum transferrin transports iron; consequently, its concentrations reflect both protein and iron status. Using transferrin as an indicator of protein status is complicated when an iron deficiency is present. Transferrin rises as iron deficiency grows worse and falls as iron status improves. Markedly reduced transferrin levels indicate severe protein malnutrition; in mild-to-moderate protein malnutrition, transferrin levels may vary, limiting their usefulness. Conditions other than protein malnutrition that lower transferrin include liver disease, kidney disease, and metabolic stress; those that raise transferrin include pregnancy, iron deficiency, hepatitis, blood loss, and oral contraceptive use. Although transferrin breaks down in the body more quickly than albumin, it is still relatively slow to respond to changes in protein intake and is not a sensitive indicator of the response to therapy.*

**IGF-1 (Insulin-like Growth Factor 1)** IGF-1 (insulin-like growth factor 1) declines in protein malnutrition. IGF-1 has a relatively short half-life and responds specifically to dietary protein rather than energy.** For these reasons, it is a sensitive indicator of protein status and response to therapy. Conditions that decrease IGF-1 include anorexia nervosa, inflammatory bowel disease, celiac disease, HIV infection, and fasting.

## Nutritional Anemias

Anemia, a symptom of a wide variety of nutrition- and nonnutrition-related disorders, is characterized by a reduced number of red blood cells. Iron, folate, and vitamin $B_{12}$ deficiencies caused by inadequate intake, poor absorption, or abnormal metabolism of these nutrients are the most common nutritional anemias. The remainder of this appendix describes laboratory tests that distinguish among the various nutrition-related anemias. Some nonnutrition-related causes of anemia include massive blood loss, infections, hereditary blood disorders such as sickle-cell anemia, and chronic liver or kidney disease.

## Assessment of Iron-Deficiency Anemia

Iron deficiency, a common mineral deficiency, develops in stages. First, iron stores diminish, then transport iron decreases, and finally hemoglobin production falls. Chapter 13 describes iron deficiency in detail. This section describes tests used to uncover iron deficiency as it progresses. Table E-8 (p. E-20) provides values used for assessing iron status. Although other tests are more specific in detecting early deficiencies, hemoglobin and hematocrit are the most commonly available tests.

**Hemoglobin** Iron forms an integral part of the hemoglobin molecule that transports oxygen to the cells. In iron deficiency, the body cannot synthesize hemoglobin. Low hemoglobin values signal depleted iron stores. Table E-8 provides normal hemoglobin values. Hemoglobin's usefulness in evaluating iron status is limited, however, because hemoglobin concentrations drop fairly late in the development of iron deficiency, and other nutrient deficiencies and medical conditions can also alter hemoglobin concentrations.

**Hematocrit** Hematocrit is commonly used to diagnose iron-deficiency anemia, even though it is an inconclusive measure of iron status. The hematocrit is the percentage of red blood cells in the total blood volume. Table E-8 on p. E-20 includes normal values for hematocrit. Low values indicate microcytic (abnormally small-celled), hypochromic (abnormally lacking in color) red blood cells.

Low hemoglobin and hematocrit values alert the assessor to the possibility of iron deficiency. However, many nutrients and other conditions can affect hemoglobin and hematocrit. The following tests of iron status help pinpoint true iron deficiency.

**Serum Ferritin** In the first stage of iron deficiency, iron stores diminish. Measures of serum ferritin provide an estimate of iron stores. Serum ferritin is

*The half-life of transferrin is 8 to 10 days.
**The half-life of IGF-1 is 12 to 15 hours.

**TABLE E-8 Normal Values for Iron**

| Test | Normal Values |
|---|---|
| Hemoglobin (g/dL) | 12–16 (female) |
| | 13–17 (male) |
| Hematocrit (%) | 35–45 (female) |
| | 39–49 (male) |
| Serum ferritin (ng/mL) | 30–300 |
| Total iron-binding capacity (μg/dL) | 250–450 |
| Serum iron (mg/dL) | 50–180 |
| Mean corpuscualr volume (fL) | 80–100 |
| Transferrin (mg/dL) | 200–360 |
| Transferrin saturation (%) | 20–50 |
| Erythrocyte protoporphyrin (μg/dL RBC) | <70 |

not a reliable indicator of iron deficiency, however, because its concentrations are increased by infection, inflammation, alcohol consumption, and liver disease.

The second stage of iron deficiency is characterized by a decrease in transport iron. This is revealed by an increase in the iron-binding capacity of the protein transferrin and a decrease in serum iron. These changes are reflected by the transferrin saturation, which is calculated from the ratio of the other two values as described in the following paragraphs.

**Total Iron-Binding Capacity (TIBC)** Iron travels through the blood bound to the protein transferrin. TIBC is a measure of the total amount of iron that transferrin can carry. Lab technicians measure iron-binding capacity directly. Table E-8 includes the normal values for TIBC.

**Serum Iron** Lab technicians can also measure serum iron directly. Elevated values indicate iron overload; reduced values indicate iron deficiency. Table E-8 shows the normal values for serum iron.

**Transferrin Saturation** The percentage of transferrin that is saturated with iron is an indirect measure that is derived from the serum iron and total iron-binding capacity measures as follows:

$$\%\ \text{Transferrin} = \frac{\text{serum iron}}{\text{total iron-binding capacity}} \times 100$$

Table E-8 shows normal values for transferrin saturation. During iron deficiency, transferrin saturation decreases. The transferrin saturation value is a useful indicator of iron status because it includes information about both the iron and transferrin content of the blood.

The third stage of iron deficiency occurs when the supply of transport iron diminishes to the point that it limits hemoglobin production. It is characterized by increases in erythrocyte protoporphyrin, a decrease in mean corpuscular volume, and decreased hemoglobin and hematocrit.

**Erythrocyte Protoporphyrin** The iron-containing portion of the hemoglobin molecule is heme. Heme is a combination of iron and protoporphyrin. Protoporphyrin accumulates in the blood when iron supplies are inadequate for the formation of heme. Protoporphyrin may also increase when hemoglobin synthesis is impaired for other reasons, such as lead poisoning or inflammation. Lab

technicians can measure erythrocyte protoporphyrin directly in a blood sample. The normal values of erythrocyte protoporphyrin are shown in Table E-8.

**Mean Corpuscular Volume (MCV)** The hematocrit value divided by the red blood cell count provides a measure of the average size of a red blood cell, referred to as the mean corpuscular volume (MCV). Such a measure helps to classify the type of nutrient anemia. In iron deficiency, the red blood cells are smaller than average.

## Assessment of Folate and Vitamin $B_{12}$ Anemias

Folate deficiency and vitamin $B_{12}$ deficiency present a similar clinical picture—an anemia characterized by abnormally large red blood cell precursors (megaloblasts) in the bone marrow and abnormally large, mature red blood cells (macrocytic cells) in the blood. Distinguishing between these two deficiencies is essential because their treatments differ. Giving folate to a person with vitamin $B_{12}$ deficiency improves many of the lab test results indicative of vitamin $B_{12}$ deficiency, but this is a dangerous error because vitamin $B_{12}$ deficiency causes nerve damage that folate cannot correct. Thus inappropriate folate administration masks vitamin $B_{12}$–deficiency anemia, and nerve damage worsens. For this reason, it is critical to determine whether the anemia results from a folate deficiency or from a vitamin $B_{12}$ deficiency. The following biochemical assessment measures help to make this distinction.

**Mean Corpuscular Volume (MCV)** As previously mentioned, the MCV is a measure of red blood cell size. In folate and vitamin $B_{12}$ deficiencies, the red blood cells are larger than average (macrocytic). Additional tests must be performed to differentiate folate deficiency from vitamin $B_{12}$ deficiency. Macrocytic cells may also result from a high alcohol intake, liver disease, and various medications.

**Serum Folate and Vitamin $B_{12}$ Levels** Analyses of serum folate and vitamin $B_{12}$ levels are usually among the first tests conducted to determine the cause of macrocytic red blood cells. Low serum levels of either nutrient is consistent with a deficiency, whereas adequate levels can help rule out deficiency. Folate levels are not a specific measure of folate status, however; they increase with folate consumption and decrease with alcohol consumption, pregnancy, or use of anticonvulsant medications. Folate depletion is characterized by a fall in the folate concentrations of red blood cells (erythrocytes). As erythrocyte folate levels diminish, folate-deficiency anemia develops. Because low erythrocyte folate concentrations also occur with vitamin $B_{12}$ deficiency, serum vitamin $B_{12}$ concentrations must also be measured. Table E-9 shows standards for folate and vitamin $B_{12}$ assessment.

**Methylmalonic Acid and Homocysteine Levels** To determine whether a nutrient is deficient, measures are taken of substances that accumulate when the functions of the nutrient are impaired. For example, the amino acid homocysteine

**TABLE E-9 Normal Values for Folate and Vitamin $B_{12}$**

| Test | Normal Values |
|---|---|
| Serum folate (ng/mL)[a] | 3–16 |
| Serum homocysteine (μmol/L) | 5–14 |
| Erythrocyte folate (ng/mL)[a] | 140–628 |
| Serum vitamin $B_{12}$ (pg/mL) | 200–835 |
| Serum methylmalonic acid (nmol/L) | 70–270 |

NOTE: A nanogram (ng) is one-billionth of a gram; a picogram (pg) is one-trillionth of a gram.
[a]To convert folate values (ng/mL) to international standard units (nmol/L), multiply by 2.266.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

usually increase in both folate and vitamin $B_{12}$ deficiencies because both nutrients are needed for its metabolism. Methylmalonic acid is a breakdown product of several amino acids and requires vitamin $B_{12}$ for its metabolism; its concentrations are elevated in vitamin $B_{12}$ deficiency, but not in folate deficiency. Thus this measure is useful in distinguishing between the two.

**Schilling Test** Vitamin $B_{12}$ deficiency usually arises from malabsorption, not from poor intake. To determine whether malabsorption is the cause, a small oral dose of radioactive vitamin $B_{12}$ is given, and urinary excretion is measured. This test is rarely performed, but it measures vitamin $B_{12}$ absorption and is called a Schilling test.

**Antibodies to Intrinsic Factor** Serum antibodies for intrinsic factor can help confirm a diagnosis of pernicious anemia, an autoimmune disease characterized by destruction of the cells that produce intrinsic factor. Intrinsic factor is a protein required for vitamin $B_{12}$ absorption, as Chapter 10 explains.

## Cautions about Nutrition Assessment

The tests outlined here yield information that becomes meaningful only when conducted and interpreted by a skilled clinician. Potential sources of error may be introduced at any step, from the collection of samples and data to their reporting and analyses. Equipment must be regularly calibrated to ensure accuracy of measurements. In addition, the assessor must keep in mind that each assessment method and measure is useful to confirm or eliminate the possibility of suspected nutrition problems. For example, the assessor must constantly remember that a sufficient intake of a nutrient does not guarantee adequate nutrient status for an individual. Conversely, the apparent inadequate intake of a nutrient does not, by itself, establish that a deficiency exists.

# Appendix F Estimated Energy Needs

Chapter 8 described how to calculate estimated energy requirements (EER) by using an equation that accounts for gender, age, weight, height, and physical activity level. This appendix presents tables that provide a shortcut to estimating daily energy requirements, as developed by the *Dietary Guidelines for Americans*, and based on the EER equations of the Dietary Reference Intakes.

Table F-1 describes three activity levels: sedentary, moderately active, and active. Table F-2 presents estimated daily energy needs by age, gender, and these three levels of physical activity. Keep in mind that these values are estimates that have been rounded to the nearest 200 kcalories; an individual's energy needs may be higher or lower than these average estimates. EER equations for this table use reference heights and weights. For children and adolescents, reference heights and weights vary. For adults, the reference man is 5 feet 10 inches tall and weighs 154 pounds and the reference woman is 5 feet 4 inches tall and weighs 126 pounds. Estimates for women do not include women who are pregnant or breastfeeding.

**TABLE F-1 Sedentary, Moderately Active, and Active People**

| | |
|---|---|
| Sedentary | A lifestyle that includes only the light physical activity associated with typical day-to-day life. |
| Moderately active | A lifestyle that includes physical activity equivalent to walking about 1.5 to 3 miles per day at 3 to 4 miles per hour in addition to the light physical activity associated with typical day-to-day life. |
| Active | A lifestyle that includes physical activity equivalent to walking more than 3 miles per day at 3 to 4 miles per hour in addition to the light physical activity associated with typical day-to-day life. |

# Appendix G Exchange Lists for Diabetes

Chapter 2 introduces the exchange system, and this appendix provides details from the *2008 Choose Your Foods: Exchange Lists for Diabetes*. Exchange lists can help people with diabetes to manage their blood glucose levels by controlling the amount and kinds of carbohydrates they consume. These lists can also help in planning diets for weight management by controlling kcalorie and fat intake.*

CONTENTS

The Exchange System
Serving Sizes
The Foods on the Lists
Controlling Energy, Fat, and Sodium
Planning a Healthy Diet

## The Exchange System

The exchange system sorts foods into groups by their proportions of carbohydrate, fat, and protein (Table G-1). These groups may be organized into several exchange lists of foods (Tables G-2 through G-12 on pp. G-3–G-16). For example, the carbohydrate group includes these exchange lists:

- Starch
- Fruits
- Milk (fat-free, reduced-fat, and whole)
- Sweets, Desserts, and Other Carbohydrates
- Nonstarchy Vegetables

**TABLE G-1 The Food Lists**

| Lists | Typical Item/Portion Size | Carbohydrate (g) | Protein (g) | Fat (g) | Energy[a] (kcal) |
|---|---|---|---|---|---|
| **Carbohydrates** | | | | | |
| Starch[b] | 1 slice bread | 15 | 0–3 | 0–1 | 80 |
| Fruits | 1 small apple | 15 | — | — | 60 |
| Milk | | | | | |
| Fat-free, low-fat, 1% | 1 c fat-free milk | 12 | 8 | 0–3 | 100 |
| Reduced-fat, 2% | 1 c reduced-fat milk | 12 | 8 | 5 | 120 |
| Whole | 1 c whole milk | 12 | 8 | 8 | 160 |
| Sweets, desserts, and other carbohydrates[c] | 2 small cookies | 15 | varies | varies | varies |
| Nonstarchy vegetables | ½ c cooked carrots | 5 | 2 | — | 25 |
| **Meat and Meat Substitutes** | | | | | |
| Lean | 1 oz chicken (no skin) | — | 7 | 0–3 | 45 |
| Medium-fat | 1 oz ground beef | — | 7 | 4–7 | 75 |
| High-fat | 1 oz pork sausage | — | 7 | 8+ | 100 |
| Plant-based proteins | ½ c tofu | varies | 7 | varies | varies |
| **Fats** | 1 tsp butter | — | — | 5 | 45 |
| **Alcohol** | 12 oz beer | varies | — | — | 100 |

[a]The energy value for each exchange list represents an approximate average for the group and does not reflect the precise number of grams of carbohydrate, protein, and fat. For example, a slice of bread contains 15 grams of carbohydrate (60 kcalories), 3 grams protein (12 kcalories), and a little fat—rounded to 80 kcalories for ease in calculating. A ½ cup of vegetables (not including starchy vegetables) contains 5 grams carbohydrate (20 kcalories) and 2 grams protein (8 more), which has been rounded down to 25 kcalories.
[b]The Starch list includes cereals, grains, breads, crackers, snacks, starchy vegetables (such as corn, peas, and potatoes), and legumes (dried beans, peas, and lentils).
[c]The Sweets, Desserts, and Other Carbohydrates list includes foods that contain added sugars and fats such as sodas, candy, cakes, cookies, doughnuts, ice cream, pudding, syrup, and frozen yogurt.

*The Exchange Lists are the basis of a meal planning system designed by a committee of the American Diabetes Association and The Academy of Nutrition and Dietetics. While designed primarily for people with diabetes and others who must follow special diets, the Exchange Lists are based on principles of good nutrition that apply to everyone. © 2008 by the American Diabetes Association and The American Dietetic Association.

Then any food on a list can be "exchanged" for any other on that same list. Another group for alcohol has been included as a reminder that these beverages often deliver substantial carbohydrate and kcalories, and therefore warrant their own list.

## Serving Sizes

The serving sizes have been carefully adjusted and defined so that a serving of any food on a given list provides roughly the same amount of carbohydrate, fat, and protein, and, therefore, total energy. Any food on a list can thus be exchanged, or traded, for any other food on the same list without significantly affecting the diet's energy-nutrient balance or total kcalories. For example, a person may select 17 small grapes or ½ large grapefruit as one fruit exchange, and either choice would provide roughly 15 grams of carbohydrate and 60 kcalories. A whole grapefruit, however, would count as 2 fruit exchanges.

To apply the system successfully, users must become familiar with the specified serving sizes. A convenient way to remember the serving sizes and energy values is to keep in mind a typical item from each list (review Table G-1).

## The Foods on the Lists

Foods do not always appear on the exchange list where you might first expect to find them. They are grouped according to their energy-nutrient contents rather than by their source (such as milks), their outward appearance, or their vitamin and mineral contents. For example, cheeses are grouped with meats (not milk) because, like meats, cheeses contribute energy from protein and fat but provide negligible carbohydrate.

For similar reasons, starchy vegetables such as corn, green peas, and potatoes are found on the Starch list with breads and cereals, not with the vegetables. Likewise, bacon is grouped with the fats and oils, not with the meats.

Diet planners learn to view mixtures of foods, such as casseroles and soups, as combinations of foods from different exchange lists. They also learn to interpret food labels with the exchange system in mind.

## Controlling Energy, Fat, and Sodium

The exchange lists help people control their energy intakes by paying close attention to serving sizes. People wanting to lose weight can limit foods from the Sweets, Desserts, and Other Carbohydrates and Fats lists, and they might choose to avoid the Alcohol list altogether. The Free Foods list provide low-kcalorie choices.

By assigning items like bacon to the Fats list, the exchange lists alert consumers to foods that are unexpectedly high in fat. Even the Starch list specifies which grain products contain added fat (such as biscuits, cornbread, and waffles) by marking them with a symbol to indicate added fat (the symbols are explained in the table keys). In addition, the exchange lists encourage users to think of fat-free milk as milk and of whole milk as milk with added fat, and to think of lean meats as meats and of medium-fat and high-fat meats as meats with added fat. To that end, foods on the milk and meat lists are separated into categories based on their fat contents (review Table G-1). The Milk list is subdivided for fat-free, reduced fat, and whole; the meat list is subdivided for lean, medium fat, and high fat. The meat list also includes plant-based proteins, which tend to be rich in fiber. Notice that many of these foods (p. G-11) bear the symbol for "high fiber."

People wanting to control the sodium in their diets can begin by eliminating any foods bearing the "high sodium" symbol. In most cases, the symbol identifies foods that, in one serving, provide 480 milligrams or more of sodium. Foods

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

on the Combination Foods or Fast Foods lists that bear the symbol provide more than 600 milligrams of sodium. Other foods may also contribute substantially to sodium (consult Chapter 12 for details).

# Planning a Healthy Diet

To obtain a daily variety of foods that provide healthful amounts of carbohydrate, protein, and fat, as well as vitamins, minerals, and fiber, the meal plan for adults and teenagers should include at least:

- Two to three servings of nonstarchy vegetables
- Two servings of fruits
- Six servings of grains (at least three of whole grains), beans, and starchy vegetables
- Two servings of low-fat or fat-free milk
- About 6 ounces of meat or meat substitutes
- *Small* amounts of fat and sugar

The actual amounts are determined by age, gender, activity levels, and other factors that influence energy needs.

## TABLE G-2 Starch

The Starch list includes bread, cereals and grains, starchy vegetables, crackers and snacks, and legumes (dried beans, peas, and lentils).
1 starch choice = 15 grams carbohydrate, 0–3 grams protein, 0–1 grams fat, and 80 kcalories.

NOTE: In general, one starch exchange is ½ cup cooked cereal, grain, or starchy vegetable; ⅓ cup cooked rice or pasta; 1 ounce of bread product; ¾ ounce to 1 ounce of most snack foods.

| Bread | |
|---|---|
| **Food** | **Serving Size** |
| Bagel, large (about 4 oz) | ¼ (1 oz) |
| ▽ Biscuit, 2½ inches across | 1 |
| Bread | |
| ☺ reduced-kcalorie | 2 slices (1½ oz) |
| white, whole-grain, pumpernickel, rye, unfrosted raisin | 1 slice (1 oz) |
| Chapatti, small, 6 inches across | 1 |
| ▽ Cornbread, 1¾ inch cube | 1 (1½ oz) |
| English muffin | ½ |
| Hot dog bun or hamburger bun | ½ (1 oz) |
| Naan, 8 inches by 2 inches | ¼ |
| Pancake, 4 inches across, ¼ inch thick | 1 |
| Pita, 6 inches across | ½ |
| Roll, plain, small | 1 (1 oz) |
| ▽ Stuffing, bread | ⅓ cup |
| ▽ Taco shell, 5 inches across | 2 |
| Tortilla, corn, 6 inches across | 1 |
| Tortilla, flour, 6 inches across | 1 |
| Tortilla, flour, 10 inches across | ⅓ |
| ▽ Waffle, 4-inch square or 4 inches across | 1 |

| Cereals and Grains | |
|---|---|
| **Food** | **Serving Size** |
| Barley, cooked | ⅓ cup |
| Bran, dry | |
| ☺ oat | ¼ cup |
| ☺ wheat | ½ cup |
| ☺ Bulgur (cooked) | ½ cup |
| Cereals | |
| ☺ bran | ½ cup |
| cooked (oats, oatmeal) | ½ cup |
| puffed | 1½ cups |
| shredded wheat, plain | ½ cup |
| sugar-coated | ½ cup |
| unsweetened, ready-to-eat | ¾ cup |
| Couscous | ⅓ cup |
| Granola | |
| low-fat | ¼ cup |
| ▽ regular | ¼ cup |
| Grits, cooked | ½ cup |
| Kasha | ½ cup |
| Millet, cooked | ⅓ cup |

KEY

☺ = More than 3 grams of dietary fiber per serving.

▽ = Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)

▯ = 480 milligrams or more of sodium per serving.

## TABLE G-2 Starch (*continued*)

| Cereals and Grains—continued | |
|---|---|
| **Food** | **Serving Size** |
| Muesli | ¼ cup |
| Pasta, cooked | ⅓ cup |
| Polenta, cooked | ⅓ cup |
| Quinoa, cooked | ⅓ cup |
| Rice, white or brown, cooked | ⅓ cup |
| Tabbouleh (tabouli), prepared | ½ cup |
| Wheat germ, dry | 3 Tbsp |
| Wild rice, cooked | ½ cup |

| Starchy Vegetables | |
|---|---|
| **Food** | **Serving Size** |
| Cassava | ⅓ cup |
| Corn | ½ cup |
| on cob, large | ½ cob (5 oz) |
| Hominy, canned | ¾ cup |
| Mixed vegetables with corn, peas, or pasta | 1 cup |
| Parsnips | ½ cup |
| Peas, green | ½ cup |
| Plantain, ripe | ⅓ cup |
| Potato | |
| baked with skin | ¼ large (3 oz) |
| boiled, all kinds | ½ cup or ½ medium (3 oz) |
| mashed, with milk and fat | ½ cup |
| french fried (oven-baked)[a] | 1 cup (2 oz) |
| Pumpkin, canned, no sugar added | 1 cup |
| Spaghetti/pasta sauce | ½ cup |
| Squash, winter (acorn, butternut) | 1 cup |
| Succotash | ½ cup |
| Yam, sweet potato, plain | ½ cup |

| Crackers and Snacks[b] | |
|---|---|
| **Food** | **Serving Size** |
| Animal crackers | 8 |
| Crackers | |
| round-butter type | 6 |
| saltine-type | 6 |
| sandwich-style, cheese or peanut butter filling | 3 |
| whole-wheat regular | 2–5 (¾ oz) |
| whole-wheat lower fat or crispbreads | 2–5 (¾ oz) |
| Graham cracker, 2½-inch square | 3 |
| Matzoh | ¾ oz |
| Melba toast, about 2-inch by 4-inch piece | 4 |
| Oyster crackers | 20 |
| Popcorn | 3 cups |
| with butter | 3 cups |
| no fat added | 3 cups |
| lower fat | 3 cups |
| Pretzels | ¾ oz |
| Rice cakes, 4 inches across | 2 |
| Snack chips | |
| fat-free or baked (tortilla, potato), baked pita chips | 15–20 (¾ oz) |
| regular (tortilla, potato) | 9–13 (¾ oz) |

| Beans, Peas, and Lentils[c] | |
|---|---|
| The choices on this list count as 1 starch + 1 lean meat. | |
| **Food** | **Serving Size** |
| Baked beans | ⅓ cup |
| Beans, cooked (black, garbanzo, kidney, lima, navy, pinto, white) | ½ cup |
| Lentils, cooked (brown, green, yellow) | ½ cup |
| Peas, cooked (black-eyed, split) | ½ cup |
| Refried beans, canned | ½ cup |

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)

= 480 milligrams or more of sodium per serving.

[a]Restaurant-style french fries are on the Fast Foods list.
[b]For other snacks, see the Sweets, Desserts, and Other Carbohydrates list. For a quick estimate of serving size, an open handful is equal to about 1 cup or 1 to 2 ounces of snack food.
[c]Beans, peas, and lentils are also found on the Meat and Meat Substitutes list.

## TABLE G-3 Fruits

### Fruit[a]

The Fruits list includes fresh, frozen, canned, and dried fruits and fruit juices. 1 fruit choice = 15 grams carbohydrate, 0 grams protein, 0 grams fat, and 60 kcalories.

NOTE: In general, one fruit exchange is ½ cup canned or fresh fruit or unsweetened fruit juice; 1 small fresh fruit (4 ounces); 2 tablespoons dried fruit.

| Food | Serving Size |
|---|---|
| Apple, unpeeled, small | 1 (4 oz) |
| Apples, dried | 4 rings |
| Applesauce, unsweetened | ½ cup |
| Apricots | |
| canned | ½ cup |
| dried | 8 halves |
| fresh | 4 whole (5½ oz) |
| Banana, extra small | 1 (4 oz) |
| Blackberries | ¾ cup |
| Blueberries | ¾ cup |
| Cantaloupe, small | ⅓ melon or 1 cup cubed (11 oz) |
| Cherries | |
| sweet, canned | ½ cup |
| sweet fresh | 12 (3 oz) |
| Dates | 3 |
| Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins) | 2 Tbsp |
| Figs | |
| dried | 1½ |
| fresh | 1½ large or 2 medium (3½ oz) |
| Fruit cocktail | ½ cup |
| Grapefruit | |
| large | ½ (11 oz) |
| sections, canned | ¾ cup |
| Grapes, small | 17 (3 oz) |
| Honeydew melon | 1 slice or 1 cup cubed (10 oz) |
| Kiwi | 1 (3½ oz) |
| Mandarin oranges, canned | ¾ cup |
| Mango, small | ½ (5½ oz) or ½ cup |
| Nectarine, small | 1 (5 oz) |
| Orange, small | 1 (6½ oz) |
| Papaya | ½ or 1 cup cubed (8 oz) |
| Peaches | |
| canned | ½ cup |
| fresh, medium | 1 (6 oz) |
| Pears | |
| canned | ½ cup |
| fresh, large | ½ (4 oz) |
| Pineapple | |
| canned | ½ cup |
| fresh | ¾ cup |
| Plums | |
| canned | ½ cup |
| dried (prunes) | 3 |
| small | 2 (5 oz) |
| Raspberries | 1 cup |
| Strawberries | 1¼ cup whole berries |
| Tangerines, small | 2 (8 oz) |
| Watermelon | 1 slice or 1¼ cups cubes (13½ oz) |

### Fruit Juice

| Food | Serving Size |
|---|---|
| Apple juice/cider | ½ cup |
| Fruit juice blends, 100% juice | ⅓ cup |
| Grape juice | ⅓ cup |
| Grapefruit juice | ½ cup |
| Orange juice | ½ cup |
| Pineapple juice | ½ cup |
| Prune juice | ⅓ cup |

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)

= 480 milligrams or more of sodium per serving.

[a]The weight listed includes skin, core, seeds, and rind.

## TABLE G-4 Milk

The Milk list groups milks and yogurts based on the amount of fat they have (fat-free/low fat, reduced fat, and whole). Cheeses are found on the Meat and Meat Substitutes list and cream and other dairy fats are found on the Fats list.

NOTE: In general, one milk choice is 1 cup (8 fluid ounces or ½ pint) milk or yogurt.

| Milk and Yogurts | |
|---|---|
| **Food** | **Serving Size** |
| **Fat-free or low-fat (1%)** | |
| 1 fat-free/low-fat milk choice = 12 g carbohydrate, 8 g protein, 0–3 g fat, and 100 kcal. | |
| Milk, buttermilk, acidophilus milk, Lactaid | 1 cup |
| Evaporated milk | ½ cup |
| Yogurt, plain or flavored with an artificial sweetener | ⅔ cup (6 oz) |
| **Reduced-fat (2%)** | |
| 1 reduced-fat milk choice = 12 g carbohydrate, 8 g protein, 5 g fat, and 120 kcal. | |
| Milk, acidophilus milk, kefir, Lactaid | 1 cup |
| Yogurt, plain | ⅔ cup (6 oz) |
| **Whole** | |
| 1 whole milk choice = 12 g carbohydrate, 8 g protein, 8 g fat, and 160 kcal. | |
| Milk, buttermilk, goat's milk | 1 cup |
| Evaporated milk | ½ cup |
| Yogurt, plain | 8 oz |

| Dairy-Like Foods | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Chocolate milk | | |
| fat-free | 1 cup | 1 fat-free milk + 1 carbohydrate |
| whole | 1 cup | 1 whole milk + 1 carbohydrate |
| Eggnog, whole milk | ½ cup | 1 carbohydrate + 2 fats |
| Rice drink | | |
| flavored, low fat | 1 cup | 2 carbohydrates |
| plain, fat-free | 1 cup | 1 carbohydrate |
| Smoothies, flavored, regular | 10 oz | 1 fat-free milk + 2½ carbohydrates |
| Soy milk | | |
| light | 1 cup | 1 carbohydrate + ½ fat |
| regular, plain | 1 cup | 1 carbohydrate + 1 fat |
| Yogurt | | |
| and juice blends | 1 cup | 1 fat-free milk + 1 carbohydrate |
| low carbohydrate (less than 6 grams carbohydrate per choice) | ⅔ cup (6 oz) | ½ fat-free milk |
| with fruit, low-fat | ⅔ cup (6 oz) | 1 fat-free milk + 1 carbohydrate |

## TABLE G-5 Sweets, Desserts, and Other Carbohydrates

1 other carbohydrate choice = 15 grams carbohydrate, variable grams protein, variable grams fat, and variable kcalories.

NOTE: In general, one choice from this list can substitute for foods on the Starch, Fruits, or Milk lists.

| Beverages, Soda, and Energy/Sports Drinks | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Cranberry juice cocktail | ½ cup | 1 carbohydrate |
| Energy drink | 1 can (8.3 oz) | 2 carbohydrates |
| Fruit drink or lemonade | 1 cup (8 oz) | 2 carbohydrates |

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## TABLE G-5 Sweets, Desserts, and Other Carbohydrates (*continued*)

**Beverages, Soda, and Energy/Sports Drinks—continued**

| Food | Serving Size | Count as |
|---|---|---|
| Hot chocolate | | |
| regular | 1 envelope added to 8 oz water | 1 carbohydrate + 1 fat |
| sugar-free or light | 1 envelope added to 8 oz water | 1 carbohydrate |
| Soft drink (soda), regular | 1 can (12 oz) | 2½ carbohydrates |
| Sports drink | 1 cup (8 oz) | 1 carbohydrate |

**Brownies, Cake, Cookies, Gelatin, Pie, and Pudding**

| Food | Serving Size | Count as |
|---|---|---|
| Brownie, small, unfrosted | 1¼-inch square, ⅞ inch high (about 1 oz) | 1 carbohydrate + 1 fat |
| Cake | | |
| angel food, unfrosted | ½ of cake (about 2 oz) | 2 carbohydrates |
| frosted | 2-inch square (about 2 oz) | 2 carbohydrates + 1 fat |
| unfrosted | 2-inch square (about 2 oz) | 1 carbohydrate + 1 fat |
| Cookies | | |
| chocolate chip | 2 cookies (2¼ inches across) | 1 carbohydrate + 2 fats |
| gingersnap | 3 cookies | 1 carbohydrate |
| sandwich, with crème filling | 2 small (about ⅔ oz) | 1 carbohydrate + 1 fat |
| sugar-free | 3 small or 1 large (¾-1 oz) | 1 carbohydrate + 1–2 fats |
| vanilla wafer | 5 cookies | 1 carbohydrate + 1 fat |
| Cupcake, frosted | 1 small (about 1¾ oz) | 2 carbohydrates + 1–1½ fats |
| Fruit cobbler | ½ cup (3½ oz) | 3 carbohydrates + 1 fat |
| Gelatin, regular | ½ cup | 1 carbohydrate |
| Pie | | |
| commercially prepared fruit, 2 crusts | ⅛ of 8-inch pie | 3 carbohydrates + 2 fats |
| pumpkin or custard | ⅛ of 8-inch pie | 1½ carbohydrates + 1½ fats |
| Pudding | | |
| regular (made with reduced-fat milk) | ½ cup | 2 carbohydrates |
| sugar-free or sugar- and fat-free (made with fat-free milk) | ½ cup | 1 carbohydrate |

**Candy, Spreads, Sweets, Sweeteners, Syrups, and Toppings**

| Food | Serving Size | Count as |
|---|---|---|
| Candy bar, chocolate/peanut | 2 "fun size" bars (1 oz) | 1½ carbohydrates + 1½ fats |
| Candy, hard | 3 pieces | 1 carbohydrate |
| Chocolate "kisses" | 5 pieces | 1 carbohydrate + 1 fat |
| Coffee creamer | | |
| dry, flavored | 4 tsp | ½ carbohydrate + ½ fat |
| liquid, flavored | 2 Tbsp | 1 carbohydrate |
| Fruit snacks, chewy (pureed fruit concentrate) | 1 roll (¾ oz) | 1 carbohydrate |
| Fruit spreads, 100% fruit | 1½ Tbsp | 1 carbohydrate |
| Honey | 1 Tbsp | 1 carbohydrate |
| Jam or jelly, regular | 1 Tbsp | 1 carbohydrate |
| Sugar | 1 Tbsp | 1 carbohydrate |
| Syrup | | |
| chocolate | 2 Tbsp | 2 carbohydrates |
| light (pancake type) | 2 Tbsp | 1 carbohydrate |
| regular (pancake type) | 1 Tbsp | 1 carbohydrate |

(*continued*)

## TABLE G-5 Sweets, Desserts, and Other Carbohydrates (*continued*)

### Condiments and Sauces[a]

| Food | Serving Size | Count as |
|---|---|---|
| Barbeque sauce | 3 Tbsp | 1 carbohydrate |
| Cranberry sauce, jellied | ¼ cup | 1½ carbohydrates |
| Gravy, canned or bottled | ½ cup | ½ carbohydrate + ½ fat |
| Salad dressing, fat-free, low-fat, cream-based | 3 Tbsp | 1 carbohydrate |
| Sweet and sour sauce | 3 Tbsp | 1 carbohydrate |

### Doughnuts, Muffins, Pastries, and Sweet Breads

| Food | Serving Size | Count as |
|---|---|---|
| Banana nut bread | 1-inch slice (1 oz) | 2 carbohydrates + 1 fat |
| Doughnut | | |
| cake, plain | 1 medium (1½ oz) | 1½ carbohydrates + 2 fats |
| yeast type, glazed | 3¾ inches across (2 oz) | 2 carbohydrates + 2 fats |
| Muffin (4 oz) | ¼ muffin (1 oz) | 1 carbohydrate + ½ fat |
| Sweet roll or Danish | 1 (2½ oz) | 2½ carbohydrates + 2 fats |

### Frozen Bars, Frozen Desserts, Frozen Yogurt, and Ice Cream

| Food | Serving Size | Count as |
|---|---|---|
| Frozen pops | 1 | ½ carbohydrate |
| Fruit juice bars, frozen, 100% juice | 1 bar (3 oz) | 1 carbohydrate |
| Ice cream | | |
| fat-free | ½ cup | 1½ carbohydrates |
| light | ½ cup | 1 carbohydrate + 1 fat |
| no sugar added | ½ cup | 1 carbohydrate + 1 fat |
| regular | ½ cup | 1 carbohydrate + 2 fats |
| Sherbet, sorbet | ½ cup | 2 carbohydrates |
| Yogurt, frozen | | |
| fat-free | ⅓ cup | 1 carbohydrate |
| regular | ½ cup | 1 carbohydrate + 0–1 fat |

### Granola Bars, Meal Replacement Bars/Shakes, and Trail Mix

| Food | Serving Size | Count as |
|---|---|---|
| Granola or snack bar, regular or low-fat | 1 bar (1 oz) | 1½ carbohydrates |
| Meal replacement bar | 1 bar (1⅓ oz) | 1½ carbohydrates + 0–1 fat |
| Meal replacement bar | 1 bar (2 oz) | 2 carbohydrates + 1 fat |
| Meal replacement shake, reduced kcalorie | 1 can (10–11 oz) | 1½ carbohydrates + 0–1 fat |
| Trail mix | | |
| candy/nut-based | 1 oz | 1 carbohydrate + 2 fats |
| dried fruit-based | 1 oz | 1 carbohydrate + 1 fat |

**KEY**

= 480 milligrams or more of sodium per serving.

[a]You can also check the Fats list and Free Foods list for other condiments.

## TABLE G-6 Nonstarchy Vegetables

The Nonstarchy Vegetables list includes vegetables that have few grams of carbohydrates or kcalories; starchy vegetables are found on the Starch list. 1 nonstarchy vegetable choice = 5 grams carbohydrate, 2 grams protein, 0 grams fat, and 25 kcalories.

NOTE: In general, one nonstarchy vegetable choice is ½ cup cooked vegetables or vegetable juice or 1 cup raw vegetables. Count 3 cups of raw vegetables or 1½ cups of cooked vegetables as one carbohydrate choice.

| Nonstarchy Vegetables[a] | |
|---|---|
| Amaranth or Chinese spinach | Kohlrabi |
| Artichoke | Leeks |
| Artichoke hearts | Mixed vegetables (without corn, peas, or pasta) |
| Asparagus | Mung bean sprouts |
| Baby corn | Mushrooms, all kinds, fresh |
| Bamboo shoots | Okra |
| Beans (green, wax, Italian) | Onions |
| Bean sprouts | Oriental radish or daikon |
| Beets | Pea pods |
| Borscht | Peppers (all varieties) |
| Broccoli | Radishes |
| Brussels sprouts | Rutabaga |
| Cabbage (green, bok choy, Chinese) | Sauerkraut |
| Carrots | Soybean sprouts |
| Cauliflower | Spinach |
| Celery | Squash (summer, crookneck, zucchini) |
| Chayote | Sugar pea snaps |
| Coleslaw, packaged, no dressing | Swiss chard |
| Cucumber | Tomato |
| Eggplant | Tomatoes, canned |
| Gourds (bitter, bottle, luffa, bitter melon) | Tomato sauce |
| Green onions or scallions | Tomato/vegetable juice |
| Greens (collard, kale, mustard, turnip) | Turnips |
| Hearts of palm | Water chestnuts |
| Jicama | Yard-long beans |

**KEY**

= More than 3 grams of dietary fiber per serving.

= 480 milligrams or more of sodium per serving.

[a]Salad greens (like chicory, endive, escarole, lettuce, romaine, spinach, arugula, radicchio, watercress) are on the Free Foods list.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## TABLE G-7 Meat and Meat Substitutes

The Meat and Meat Substitutes list groups foods based on the amount of fat they have (lean meat, medium-fat meat, high-fat meat, and plant-based proteins).

### Lean Meats and Meat Substitutes

1 lean meat choice = 0 grams carbohydrate, 7 grams protein, 0–3 grams fat, and 45 kcalories.

| Food | Amount |
|---|---|
| Beef: Select or Choice grades trimmed of fat: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin | 1 oz |
| Beef jerky | 1 oz |
| Cheeses with 3 grams of fat or less per oz | 1 oz |
| Cottage cheese | ¼ cup |
| Egg substitutes, plain | ¼ cup |
| Egg whites | 2 |
| Fish, fresh or frozen, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna | 1 oz |
| Fish, smoked: herring or salmon (lox) | 1 oz |
| Game: buffalo, ostrich, rabbit, venison | 1 oz |
| Hot dog with 3 grams of fat or less per oz (8 dogs per 14 oz package) *Note: May be high in carbohydrate.* | 1 |
| Lamb: chop, leg, or roast | 1 oz |
| Organ meats: heart, kidney, liver *Note: May be high in cholesterol.* | 1 oz |
| Oysters, fresh or frozen | 6 medium |
| Pork, lean | |
| Canadian bacon | 1 oz |
| rib or loin chop/roast, ham, tenderloin | 1 oz |
| Poultry, without skin: Cornish hen, chicken, domestic duck or goose (well-drained of fat), turkey | 1 oz |
| Processed sandwich meats with 3 grams of fat or less per oz: chipped beef, deli thin-sliced meats, turkey ham, turkey kielbasa, turkey pastrami | 1 oz |
| Salmon, canned | 1 oz |
| Sardines, canned | 2 medium |
| Sausage with 3 grams of fat or less per oz | 1 oz |
| Shellfish: clams, crab, imitation shellfish, lobster, scallops, shrimp | 1 oz |
| Tuna, canned in water or oil, drained | 1 oz |
| Veal, lean chop, roast | 1 oz |

### Medium-Fat Meat and Meat Substitutes

1 medium-fat meat choice = 0 grams carbohydrate, 7 grams protein, 4–7 grams fat, and 75 kcalories.

| Food | Amount |
|---|---|
| Beef: corned beef, ground beef, meatloaf, Prime grades trimmed of fat (prime rib), short ribs, tongue | 1 oz |
| Cheeses with 4–7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string | 1 oz |
| Egg *Note: High in cholesterol, so limit to 3 per week.* | 1 |
| Fish, any fried product | 1 oz |
| Lamb: ground, rib roast | 1 oz |
| Pork: cutlet, shoulder roast | 1 oz |
| Poultry: chicken with skin; dove, pheasant, wild duck, or goose; fried chicken; ground turkey | 1 oz |
| Ricotta cheese | 2 oz or ¼ cup |
| Sausage with 4–7 grams of fat per oz | 1 oz |
| Veal, cutlet (no breading) | 1 oz |

### High-Fat Meat and Meat Substitutes

1 high-fat meat choice = 0 grams carbohydrate, 7 grams protein, 8+ grams fat, and 100 kcalories. These foods are high in saturated fat, cholesterol, and kcalories and may raise blood cholesterol levels if eaten on a regular basis. Try to eat 3 or fewer servings from this group per week.

| Food | Amount |
|---|---|
| Bacon | |
| pork | 2 slices (16 slices per lb or 1 oz each, before cooking) |
| turkey | 3 slices (½ oz each before cooking) |
| Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso, and Swiss | 1 oz |
| Hot dog: beef, pork, or combination (10 per lb-sized package) | 1 |
| Hot dog: turkey or chicken (10 per lb-sized package) | 1 |
| Pork: ground, sausage, spareribs | 1 oz |
| Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami | 1 oz |
| Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer | 1 oz |

(*continued*)

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)

= 480 milligrams or more of sodium per serving.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## TABLE G-7 Meat and Meat Substitutes (*continued*)

**Plant-Based Proteins**[a]

1 plant-based protein choice = variable grams carbohydrate, 7 grams protein, variable grams fat, and variable kcalories.
Because carbohydrate content varies among plant-based proteins, you should read the food label.

| Food | Serving Size | Count as |
|---|---|---|
| "Bacon" strips, soy-based | 3 strips | 1 medium-fat meat |
| Baked beans | ⅓ cup | 1 starch + 1 lean meat |
| Beans, cooked: black, garbanzo, kidney, lima, navy, pinto, white[a] | ½ cup | 1 starch + 1 lean meat |
| "Beef" or "sausage" crumbles, soy-based | 2 oz | ½ carbohydrate + 1 lean meat |
| "Chicken" nuggets, soy-based | 2 nuggets (1½ oz) | ½ carbohydrate + 1 medium-fat meat |
| Edamame | ½ cup | ½ carbohydrate + 1 lean meat |
| Falafel (spiced chickpea and wheat patties) | 3 patties (about 2 inches across) | 1 carbohydrate + 1 high-fat meat |
| Hot dog, soy-based | 1 (1½ oz) | ½ carbohydrate + 1 lean meat |
| Hummus | ⅓ cup | 1 carbohydrate + 1 high-fat meat |
| Lentils, brown, green, or yellow | ½ cup | 1 carbohydrate + 1 lean meat |
| Meatless burger, soy-based | 3 oz | ½ carbohydrate + 2 lean meats |
| Meatless burger, vegetable- and starch-based | 1 patty (about 2½ oz) | 1 carbohydrate + 2 lean meats |
| Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter | 1 Tbsp | 1 high-fat meat |
| Peas, cooked: black-eyed and split peas | ½ cup | 1 starch + 1 lean meat |
| Refried beans, canned | ½ cup | 1 starch + 1 lean meat |
| "Sausage" patties, soy-based | 1 (1½ oz) | 1 medium-fat meat |
| Soy nuts, unsalted | ¾ oz | ½ carbohydrate + 1 medium-fat meat |
| Tempeh | ¼ cup | 1 medium-fat meat |
| Tofu | 4 oz (½ cup) | 1 medium-fat meat |
| Tofu, light | 4 oz (½ cup) | 1 lean meat |

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat. (Add an additional fat choice to this food.)

= 480 milligrams or more of sodium per serving (based on the sodium content of a typical 3-oz serving of meat, unless 1 or 2 oz is the normal serving size).

[a]Beans, peas, and lentils are also found on the Starch list; nut butters in smaller amounts are found in the Fats list.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

## TABLE G-8 Fats

Fats and oils have mixtures of unsaturated (polyunsaturated and monounsaturated) and saturated fats. Foods on the Fats list are grouped together based on the major type of fat they contain. 1 fat choice = 0 grams carbohydrate, 0 grams protein, 5 grams fat, and 45 kcalories.

NOTE: In general, one fat exchange is 1 teaspoon of regular margarine, vegetable oil, or butter; 1 tablespoon of regular salad dressing.
When used in large amounts, bacon and peanut butter are counted as high-fat meat choices (see Meat and Meat Substitutes list). Fat-free salad dressings are found on the Sweets, Desserts, and Other Carbohydrates list. Fat-free products such as margarines, salad dressings, mayonnaise, sour cream, and cream cheese are found on the Free Foods list.

### Monounsaturated Fats

| Food | Serving Size |
|---|---|
| Avocado, medium | 2 Tbsp (1 oz) |
| Nut butters (trans fat-free): almond butter, cashew butter, peanut butter (smooth or crunchy) | 1½ tsp |
| Nuts | |
| almonds | 6 nuts |
| Brazil | 2 nuts |
| cashews | 6 nuts |
| filberts (hazelnuts) | 5 nuts |
| macadamia | 3 nuts |
| mixed (50% peanuts) | 6 nuts |
| peanuts | 10 nuts |
| pecans | 4 halves |
| pistachios | 16 nuts |
| Oil: canola, olive, peanut | 1 tsp |
| Olives | |
| black (ripe) | 8 large |
| green, stuffed | 10 large |

### Polyunsaturated Fats

| Food | Serving Size |
|---|---|
| Margarine: lower-fat spread (30%–50% vegetable oil, *trans* fat-free) | 1 Tbsp |
| Margarine: stick, tub (*trans* fat-free) or squeeze (*trans* fat-free) | 1 tsp |
| Mayonnaise | |
| reduced-fat | 1 Tbsp |
| regular | 1 tsp |
| Mayonnaise-style salad dressing | |
| reduced-fat | 1 Tbsp |
| regular | 2 tsp |
| Nuts | |
| Pignolia (pine nuts) | 1 Tbsp |
| walnuts, English | 4 halves |
| Oil: corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower | 1 tsp |
| Oil: made from soybean and canola oil—Enova | 1 tsp |
| Plant stanol esters | |
| light | 1 Tbsp |
| regular | 2 tsp |

### Polyunsaturated Fats—continued

| Food | Serving Size |
|---|---|
| Salad dressing | |
| reduced-fat<br>*Note: May be high in carbohydrate.* | 2 Tbsp |
| regular | 1 Tbsp |
| Seeds | |
| flaxseed, whole | 1 Tbsp |
| pumpkin, sunflower | 1 Tbsp |
| sesame seeds | 1 Tbsp |
| Tahini or sesame paste | 2 tsp |

### Saturated Fats

| Food | Serving Size |
|---|---|
| Bacon, cooked, regular or turkey | 1 slice |
| Butter | |
| reduced-fat | 1 Tbsp |
| stick | 1 tsp |
| whipped | 2 tsp |
| Butter blends made with oil | |
| reduced-fat or light | 1 Tbsp |
| regular | 1½ tsp |
| Chitterlings, boiled | 2 Tbsp (½ oz) |
| Coconut, sweetened, shredded | 2 Tbsp |
| Coconut milk | |
| light | ⅓ cup |
| regular | 1½ Tbsp |
| Cream | |
| half and half | 2 Tbsp |
| heavy | 1 Tbsp |
| light | 1½ Tbsp |
| whipped | 2 Tbsp |
| whipped, pressurized | ¼ cup |
| Cream cheese | |
| reduced-fat | 1½ Tbsp (¾ oz) |
| regular | 1 Tbsp (½ oz) |
| Lard | 1 tsp |
| Oil: coconut, palm, palm kernel | 1 tsp |
| Salt pork | ¼ oz |
| Shortening, solid | 1 tsp |
| Sour cream | |
| reduced-fat or light | 3 Tbsp |
| regular | 2 Tbsp |

**KEY**

= 480 milligrams or more of sodium per serving.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).

## TABLE G-9 Free Foods

A "free" food is any food or drink choice that has less than 20 kcalories and 5 grams or less of carbohydrate per serving.

- Most foods on this list should be limited to 3 servings (as listed here) per day. Spread out the servings throughout the day. If you eat all 3 servings at once, it could raise your blood glucose level.
- Food and drink choices listed here without a serving size can be eaten whenever you like.

### Low Carbohydrate Foods

| Food | Serving Size |
|---|---|
| Cabbage, raw | ½ cup |
| Candy, hard (regular or sugar-free) | 1 piece |
| Carrots, cauliflower, or green beans, cooked | ¼ cup |
| Cranberries, sweetened with sugar substitute | ½ cup |
| Cucumber, sliced | ½ cup |
| Gelatin | |
| dessert, sugar-free | |
| unflavored | |
| Gum | |
| Jam or jelly, light or no sugar added | 2 tsp |
| Rhubarb, sweetened with sugar substitute | ½ cup |
| Salad greens | |
| Sugar substitutes (artificial sweeteners) | |
| Syrup, sugar-free | 2 Tbsp |

### Modified Fat Foods with Carbohydrate

| Food | Serving Size |
|---|---|
| Cream cheese, fat-free | 1 Tbsp (½ oz) |
| Creamers | |
| nondairy, liquid | 1 Tbsp |
| nondairy, powdered | 2 tsp |
| Margarine spread | |
| fat-free | 1 Tbsp |
| reduced-fat | 1 tsp |
| Mayonnaise | |
| fat-free | 1 Tbsp |
| reduced-fat | 1 tsp |
| Mayonnaise-style salad dressing | |
| fat-free | 1 Tbsp |
| reduced-fat | 1 tsp |
| Salad dressing | |
| fat-free or low-fat | 1 Tbsp |
| fat-free, Italian | 2 Tbsp |
| Sour cream, fat-free or reduced-fat | 1 Tbsp |
| Whipped topping | |
| light or fat-free | 2 Tbsp |
| regular | 1 Tbsp |

### Condiments

| Food | Serving Size |
|---|---|
| Barbecue sauce | 2 tsp |
| Catsup (ketchup) | 1 Tbsp |
| Honey mustard | 1 Tbsp |

**KEY**

🧂 = 480 milligrams or more of sodium per serving.

### Condiments—continued

| Food | Serving Size |
|---|---|
| Horseradish | |
| Lemon juice | |
| Miso | 1½ tsp |
| Mustard | |
| Parmesan cheese, freshly grated | 1 Tbsp |
| Pickle relish | 1 Tbsp |
| Pickles | |
| 🧂 dill | 1½ medium |
| sweet, bread and butter | 2 slices |
| sweet, gherkin | ¾ oz |
| Salsa | ¼ cup |
| 🧂 Soy sauce, light or regular | 1 Tbsp |
| Sweet and sour sauce | 2 tsp |
| Sweet chili sauce | 2 tsp |
| Taco sauce | 1 Tbsp |
| Vinegar | |
| Yogurt, any type | 2 Tbsp |

### Drinks/Mixes

Any food on the list—without a serving size listed—can be consumed in any moderate amount.

- 🧂 Bouillon, broth, consommé
- Bouillon or broth, low-sodium
- Carbonated or mineral water
- Club soda
- Cocoa powder, unsweetened (1 Tbsp)
- Coffee, unsweetened or with sugar substitute
- Diet soft drinks, sugar-free
- Drink mixes, sugar-free
- Tea, unsweetened or with sugar substitute
- Tonic water, diet
- Water
- Water, flavored, carbohydrate free

### Seasonings

Any food on this list can be consumed in any moderate amount.

- Flavoring extracts (for example, vanilla, almond, peppermint)
- Garlic
- Herbs, fresh or dried
- Nonstick cooking spray
- Pimento
- Spices
- Hot pepper sauce
- Wine, used in cooking
- Worcestershire sauce

## TABLE G-10 Combination Foods

Many foods are eaten in various combinations, such as casseroles. Because "combination" foods do not fit into any one choice list, this list of choices provides some typical combination foods.

| Entrees | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Casserole type (tuna noodle, lasagna, spaghetti with meatballs, chili with beans, macaroni and cheese) | 1 cup (8 oz) | 2 carbohydrates + 2 medium-fat meats |
| Stews (beef/other meats and vegetables) | 1 cup (8 oz) | 1 carbohydrate + 1 medium-fat meat + 0–3 fats |
| Tuna salad or chicken salad | ½ cup (3½ oz) | ½ carbohydrate + 2 lean meats + 1 fat |
| **Frozen Meals/Entrees** | | |
| **Food** | **Serving Size** | **Count as** |
| Burrito (beef and bean) | 1 (5 oz) | 3 carbohydrates + 1 lean meat + 2 fats |
| Dinner-type meal | generally 14–17 oz | 3 carbohydrates + 3 medium-fat meats + 3 fats |
| Entrée or meal with less than 340 kcalories | about 8–11 oz | 2–3 carbohydrates + 1–2 lean meats |
| Pizza | | |
| cheese/vegetarian, thin crust | ¼ of a 12 inch (4½–5 oz) | 2 carbohydrates + 2 medium-fat meats |
| meat topping, thin crust | ¼ of a 12 inch (5 oz) | 2 carbohydrates + 2 medium-fat meats + 1½ fats |
| Pocket sandwich | 1 (4½ oz) | 3 carbohydrates + 1 lean meat + 1–2 fats |
| Pot pie | 1 (7 oz) | 2½ carbohydrates + 1 medium-fat meat + 3 fats |
| **Salads (Deli-Style)** | | |
| **Food** | **Serving Size** | **Count as** |
| Coleslaw | ½ cup | 1 carbohydrate + 1½ fats |
| Macaroni/pasta salad | ½ cup | 2 carbohydrates + 3 fats |
| Potato salad | ½ cup | 1½–2 carbohydrates + 1–2 fats |
| **Soups** | | |
| **Food** | **Serving Size** | **Count as** |
| Bean, lentil, or split pea | 1 cup | 1 carbohydrate + 1 lean meat |
| Chowder (made with milk) | 1 cup (8 oz) | 1 carbohydrate + 1 lean meat + 1½ fats |
| Cream (made with water) | 1 cup (8 oz) | 1 carbohydrate + 1 fat |
| Instant | 6 oz prepared | 1 carbohydrate |
| with beans or lentils | 8 oz prepared | 2½ carbohydrates + 1 lean meat |
| Miso soup | 1 cup | ½ carbohydrate + 1 fat |
| Oriental noodle | 1 cup | 2 carbohydrates + 2 fats |
| Rice (congee) | 1 cup | 1 carbohydrate |
| Tomato (made with water) | 1 cup (8 oz) | 1 carbohydrate |
| Vegetable beef, chicken noodle, or other broth-type | 1 cup (8 oz) | 1 carbohydrate |

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat.

= 600 milligrams or more of sodium per serving (for combination food main dishes/meals).

## TABLE G-11 Fast Foods

The choices on the Fast Foods list are not specific fast-food meals or items, but are estimates based on popular foods. Ask the restaurant or check its website for nutrition information about your favorite fast foods.

| Breakfast Sandwiches | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Egg, cheese, meat, English muffin | 1 sandwich | 2 carbohydrates + 2 medium-fat meats |
| Sausage biscuit sandwich | 1 sandwich | 2 carbohydrates + 2 high-fat meats + 3½ fats |

| Main Dishes/Entrees | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Burrito (beef and beans) | 1 (about 8 oz) | 3 carbohydrates + 3 medium-fat meats + 3 fats |
| Chicken breast, breaded and fried | 1 (about 5 oz) | 1 carbohydrate + 4 medium-fat meats |
| Chicken drumstick, breaded and fried | 1 (about 2 oz) | 2 medium-fat meats |
| Chicken nuggets | 6 (about 3½ oz) | 1 carbohydrate + 2 medium-fat meats + 1 fat |
| Chicken thigh, breaded and fried | 1 (about 4 oz) | ½ carbohydrate + 3 medium-fat meats + 1½ fats |
| Chicken wings, hot | 6 (5 oz) | 5 medium-fat meats + 1½ fats |

| Oriental | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Beef/chicken/shrimp with vegetables in sauce | 1 cup (about 5 oz) | 1 carbohydrate + 1 lean meat + 1 fat |
| Egg roll, meat | 1 (about 3 oz) | 1 carbohydrate + 1 lean meat + 1 fat |
| Fried rice, meatless | ½ cup | 1½ carbohydrates + 1½ fats |
| Meat and sweet sauce (orange chicken) | 1 cup | 3 carbohydrates + 3 medium-fat meats + 2 fats |
| Noodles and vegetables in sauce (chow mein, lo mein) | 1 cup | 2 carbohydrates + 1 fat |

| Pizza | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Pizza | | |
| cheese, pepperoni, regular crust | ⅛ of a 14 inch (about 4 oz) | 2½ carbohydrates + 1 medium-fat meat + 1½ fats |
| cheese/vegetarian, thin crust | ¼ of a 12 inch (about 6 oz) | 2½ carbohydrates + 2 medium-fat meats + 1½ fats |

| Sandwiches | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Chicken sandwich, grilled | 1 | 3 carbohydrates + 4 lean meats |
| Chicken sandwich, crispy | 1 | 3½ carbohydrates + 3 medium-fat meats + 1 fat |
| Fish sandwich with tartar sauce | 1 | 2½ carbohydrates + 2 medium-fat meats + 2 fats |
| Hamburger | | |
| large with cheese | 1 | 2½ carbohydrates + 4 medium-fat meats + 1 fat |
| regular | 1 | 2 carbohydrates + 1 medium-fat meat + 1 fat |
| Hot dog with bun | 1 | 1 carbohydrate + 1 high-fat meat + 1 fat |
| Submarine sandwich | | |
| less than 6 grams fat | 6-inch sub | 3 carbohydrates + 2 lean meats |
| regular | 6-inch sub | 3½ carbohydrates + 2 medium-fat meats + 1 fat |
| Taco, hard or soft shell (meat and cheese) | 1 small | 1 carbohydrate + 1 medium-fat meat + 1½ fats |

(*continued*)

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat.

= 600 milligrams or more of sodium per serving (for fast-food main dishes/meals).

## TABLE G-11 Fast Foods (*continued*)

| Salads | | |
|---|---|---|
| **Food** | **Serving Size** | **Count as** |
| Salad, main dish (grilled chicken type, no dressing or croutons) | | 1 carbohydrate + 4 lean meats |
| Salad, side, no dressing or cheese | Small (about 5 oz) | 1 vegetable |
| **Sides/Appetizers** | | |
| **Food** | **Serving Size** | **Count as** |
| French fries, restaurant style | small | 3 carbohydrates + 3 fats |
| | medium | 4 carbohydrates + 4 fats |
| | large | 5 carbohydrates + 6 fats |
| Nachos with cheese | small (about 4½ oz) | 2½ carbohydrates + 4 fats |
| Onion rings | 1 serving (about 3 oz) | 2½ carbohydrates + 3 fats |
| **Desserts** | | |
| **Food** | **Serving Size** | **Count as** |
| Milkshake, any flavor | 12 oz | 6 carbohydrates + 2 fats |
| Soft-serve ice cream cone | 1 small | 2½ carbohydrates + 1 fat |

**KEY**

= More than 3 grams of dietary fiber per serving.

= Extra fat, or prepared with added fat.

= 600 milligrams or more of sodium per serving (for fast-food main dishes/meals).

## TABLE G-12 Alcohol

1 alcohol equivalent = variable grams carbohydrate, 0 grams protein, 0 grams fat, and 100 kcalories.

NOTE: In general, one alcohol choice (½ ounce absolute alcohol) has about 100 kcalories. For those who choose to drink alcohol, guidelines suggest limiting alcohol intake to 1 drink or less per day for women, and 2 drinks or less per day for men. To reduce your risk of low blood glucose (hypoglycemia), especially if you take insulin or a diabetes pill that increases insulin, always drink alcohol with food. While alcohol, by itself, does not directly affect blood glucose, be aware of the carbohydrate (for example, in mixed drinks, beer, and wine) that may raise your blood glucose.

| Alcoholic Beverage | Serving Size | Count as |
|---|---|---|
| Beer | | |
| light (4.2%) | 12 fl oz | 1 alcohol equivalent + ½ carbohydrate |
| regular (4.9%) | 12 fl oz | 1 alcohol equivalent + 1 carbohydrate |
| Distilled spirits: vodka, rum, gin, whiskey, 80 or 86 proof | 1½ fl oz | 1 alcohol equivalent |
| Liqueur, coffee (53 proof) | 1 fl oz | 1 alcohol equivalent + 1 carbohydrate |
| Sake | 1 fl oz | ½ alcohol equivalent |
| Wine | | |
| dessert (sherry) | 3½ fl oz | 1 alcohol equivalent + 1 carbohydrate |
| dry, red or white (10%) | 5 fl oz | 1 alcohol equivalent |

# Appendix H Table of Food Composition

This edition of the table of food composition includes a wide variety of foods. It is updated with each edition to reflect current nutrient data for foods, to remove outdated foods, and to add foods that are new to the marketplace.* The nutrient database for this appendix is compiled from a variety of sources, including the USDA Nutrient Database and manufacturers' data. The USDA database provides data for a wider variety of foods and nutrients than other sources. Because laboratory analysis for each nutrient can be quite costly, manufacturers tend to provide data only for those nutrients mandated on food labels. Consequently, data for their foods are often incomplete; any missing information on this table is designated as a dash. Keep in mind that a dash means only that the information is unknown and should not be interpreted as a zero. A zero means that the nutrient is not present in the food.

Whenever using nutrient data, remember that many factors influence the nutrient contents of foods. These factors include the mineral content of the soil, the diet fed to the animal or the fertilizer used on the plant, the season of harvest, the method of processing, the length and method of storage, the method of cooking, the method of analysis, and the moisture content of the sample analyzed. With so many influencing factors, users should view nutrient data as a close approximation of the actual amount.

Diet & Wellness Plus, the dietary analysis software that accompanies this text, contains a database of 55,000 foods. The following comments will help in using that program and this appendix.

- ***Fats*** Total fats, as well as the breakdown of total fats to saturated, monounsaturated, and polyunsaturated are listed in the table. The fatty acids seldom add up to the total in part due to rounding but also because values may include some non-fatty acids, such as glycerol, phosphate, or sterols. *Trans*-fatty acids are not listed separately in this edition because newer hydrogenated fats generally add less than 0.5 grams *trans* fat to a serving of food, an amount often reported as 0.
- ***Vitamin A, Vitamin E, and Folate*** In keeping with the RDA for vitamin A, this appendix presents data for vitamin A in micrograms (µg) RAE. Similarly because the RDA for vitamin E is based only on the alpha-tocopherol form of vitamin E, this appendix reports vitamin E data in milligrams alpha-tocopherol, listed on the table as Vit E (mg α). Folate values are listed in µg DFE, a measure that adjusts for lower bioavailability of naturally occurring folate from foods compared to that from fortified foods or supplements.
- ***Bioavailability*** Keep in mind that the availability of nutrients from foods depends not only on the quantity provided by a food, but also on the amount absorbed and used by the body—the bioavailability. Chapters 10–13 provide conversion factors and additional details.

*This food composition table has been prepared by Cengage Learning. The nutritional data are supplied by Axxya Systems.

- ***Using the Table*** The foods and beverages in this table are organized into several categories, which are listed at the head of each right-hand page. Page numbers are provided, and each group is color-coded to make it easier to find individual foods.
- ***Caffeine Sources*** Caffeine occurs in several plants, including the familiar coffee bean, the tea leaf, and the cocoa bean from which chocolate is made. Most human societies use caffeine regularly, most often in beverages, for its stimulant effect and flavor. Caffeine contents of beverages vary depending on the plants they are made from, the climates and soils where the plants are grown, the grind or cut size, the method and duration of brewing, and the amounts served. The accompanying table shows that, in general, a cup of coffee contains the most caffeine; a cup of tea, less than half as much; and cocoa or chocolate, less still. As for cola beverages, they are made from kola nuts, which contain caffeine, but most of their caffeine is added, using the purified compound obtained from decaffeinated coffee beans. The FDA lists caffeine as a multipurpose GRAS (generally recognized as safe) substance that may be added to foods and beverages. Drug manufacturers also use caffeine in many products.

**TABLE Caffeine Content of Selected Beverages, Foods, and Medications**

| Beverages and Foods | Serving Size | Average (mg) |
|---|---|---|
| **Coffee** | | |
| Brewed | 8 oz | 95 |
| Decaffeinated | 8 oz | 2 |
| Expresso | 1 oz | 64 |
| Instant | 8 oz | 64 |
| **Tea** | | |
| Brewed, green | 8 oz | 30 |
| Brewed, herbal | 8 oz | 0 |
| Brewed, leaf or bag | 8 oz | 47 |
| Instant | 8 oz | 26 |
| Lipton, Nestea, bottled iced tea | 12 oz | 10 |
| Snapple iced tea (all flavors) | 16 oz | 42 |

| Beverages and Foods | Serving Size | Average (mg) |
|---|---|---|
| **Soft Drinks** | | |
| A&W Creme Soda | 12 oz | 29 |
| Barq's Root Beer | 12 oz | 18 |
| Colas, Dr. Pepper, Mr. Pibb, Sunkist Orange | 12 oz | 30–40 |
| A&W Root Beer, club soda, Fresca, ginger ale, 7-Up, Sierra Mist, Sprite, Squirt, tonic water, caffeine-free soft drinks | 12 oz | 0 |
| Mello Yello, Mountain Dew | 12 oz | 45–55 |

## TABLE Caffeine Content of Selected Beverages, Foods, and Medications (*continued*)

| Beverages and Foods | Serving Size | Average (mg) |
|---|---|---|
| **Energy Drinks** | | |
| Amp | 16 oz | 145 |
| Full Throttle | 16 oz | 200 |
| Monster | 16 oz | 160 |
| NOS | 16 oz | 160 |
| Red Bull | 8.3 oz | 75 |
| Rockstar | 16 oz | 160 |
| Xyience Xenergy | 16 oz | 185 |
| **Other Beverages** | | |
| Chocolate milk or hot cocoa | 8 oz | 5 |
| Coffee liqueur | 1 oz | 50 |
| Starbucks Frappuccino Mocha | 9.5 oz | 72 |
| Starbucks Frappuccino Vanilla | 9.5 oz | 64 |
| Yoohoo chocolate drink | 9 oz | 3 |
| **Candies** | | |
| Baker's chocolate | 1 oz | 26 |
| Dark chocolate covered coffee beans | 1 oz | 235 |
| Dark chocolate | 1 oz | 20 |
| Gum, caffeinated | 1 piece | 95 |
| Java pops | 1 pop | 60 |
| Milk chocolate | 1 oz | 6 |
| Milk chocolate covered coffee beans | 1 oz | 224 |
| White chocolate | 1 oz | 0 |
| **Foods** | | |
| Frozen yogurt, Ben & Jerry's coffee fudge | 1 cup | 85 |
| Frozen yogurt, Häagen-Dazs coffee | 1 cup | 40 |
| Frozen yogurt, chocolate | 1 cup | 5 |
| Ice cream, Starbucks coffee | 1 cup | 50 |
| Ice cream, Starbucks Frappuccino bar | 1 bar | 15 |
| Puddings, chocolate | 1 cup | 5 |
| Yogurt, Dannon coffee flavored | 1 cup | 45 |
| **Drugs[a]** | **Serving Size** | **Average (mg)** |
| **Cold Remedies** | | |
| Coryban-D, Dristan | 1 tablet | 30 |
| **Diuretics** | | |
| Aqua-Ban | 1 tablet | 100 |
| Pre-Mens Forte | 1 tablet | 100 |
| **Pain Relievers** | | |
| Anacin, BC Fast Pain Reliever | 1 tablet | 32 |
| Excedrin, Midol, Midol Max Strength | 1 tablet | 65 |
| **Stimulants** | | |
| Awake, NoDoz | 1 tablet | 100 |
| Awake Maximum Strength, Caffedrine, NoDoz Maximum Strength, Stay Awake, Vivarin | 1 tablet | 200 |
| **Weight-Control Aids** | | |
| Dexatrim | 1 tablet | 200 |

[a]A pharmacologically active dose of caffiene is defined as 200 milligrams.

NOTE: The FDA suggests a maximum of 65 milligrams per 12-ounce cola beverage but does not regulate the caffeine contents of other beverages. Because products change, contact the manufacturer for an update on products you use regularly.

## TABLE H-1 Table of Food Composition (*continued*)

(Computer code is for Cengage Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <0.1, 0.01)

| DA+ Code | Food Description | Quantity | Measure | Wt (g) | $H_2O$ (g) | Ener (kcal) | Prot (g) | Carb (g) | Fiber (g) | Fat (g) | Fat Breakdown (g) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | Sat | Mono | Poly |
| **Cereal, Flour, Grain, Pasta, Noodles, Popcorn—*continued*** | | | | | | | | | | | | | |
| | **Popcorn** | | | | | | | | | | | | |
| 476 | Air popped | 1 | cup(s) | 8 | 0.3 | 31 | 1.0 | 6.2 | 1.2 | 0.4 | 0 | 0.1 | 0.2 |
| 4619 | Caramel | 1 | cup(s) | 35 | 1.0 | 152 | 1.3 | 27.8 | 1.8 | 4.5 | 1.3 | 1.0 | 1.6 |
| 4620 | Cheese flavored | 1 | cup(s) | 35 | 0.9 | 185 | 3.3 | 18.2 | 3.5 | 11.7 | 2.3 | 3.4 | 5.4 |
| 477 | Popped in oil | 1 | cup(s) | 11 | 0.1 | 64 | 0.8 | 5.0 | 0.9 | 4.8 | 0.8 | 1.1 | 2.6 |
| **Fruit and Fruit Juices** | | | | | | | | | | | | | |
| | **Apples** | | | | | | | | | | | | |
| 226 | Applesauce, sweetened, canned | ½ | cup(s) | 123 | 100.8 | 84 | 0.2 | 21.5 | 1.5 | 0.2 | 0 | 0 | 0.1 |
| 227 | Applesauce, unsweetened, canned | ½ | cup(s) | 122 | 107.6 | 51 | 0.2 | 13.7 | 1.3 | 0.1 | 0 | 0 | 0 |
| 38492 | Crabapples | 1 | item(s) | 35 | 27.6 | 27 | 0.1 | 7.0 | 0.9 | 0.1 | 0 | 0 | 0 |
| 948 | Dried, sulfured | ¼ | cup(s) | 22 | 6.8 | 52 | 0.2 | 14.2 | 1.9 | 0.1 | 0 | 0 | 0 |
| 952 | Juice, prepared from frozen concentrate | ½ | cup(s) | 120 | 105.0 | 56 | 0.2 | 13.8 | 0.1 | 0.1 | 0 | 0 | 0 |
| 225 | Juice, unsweetened, canned | ½ | cup(s) | 124 | 109.4 | 57 | 0.1 | 14.0 | 0.2 | 0.2 | 0 | 0 | 0 |
| 223 | Raw medium, with peel | 1 | item(s) | 182 | 155.7 | 95 | 0.5 | 25.1 | 4.4 | 0.3 | 0.1 | 0 | 0.1 |
| 224 | Slices | ½ | cup(s) | 55 | 46.6 | 28 | 0.1 | 7.5 | 1.3 | 0.1 | 0 | 0 | 0 |
| 946 | Slices without skin, boiled | ½ | cup(s) | 86 | 73.1 | 45 | 0.2 | 11.7 | 2.1 | 0.3 | 0 | 0 | 0.1 |
| | **Apricot** | | | | | | | | | | | | |
| 228 | Fresh without pits | 4 | item(s) | 140 | 120.9 | 67 | 2.0 | 15.6 | 2.8 | 0.5 | 0 | 0.2 | 0.1 |
| 229 | Halves with skin, canned in heavy syrup | ½ | cup(s) | 129 | 100.1 | 107 | 0.7 | 27.7 | 2.1 | 0.1 | 0 | 0 | 0 |
| 230 | Halves, dried, sulfured | ¼ | cup(s) | 33 | 10.1 | 79 | 1.1 | 20.6 | 2.4 | 0.2 | 0 | 0 | 0 |
| | **Avocado** | | | | | | | | | | | | |
| 233 | California, whole, without skin or pit | ½ | cup(s) | 115 | 83.2 | 192 | 2.3 | 9.9 | 7.8 | 17.7 | 2.4 | 11.3 | 2.1 |
| 234 | Florida, whole, without skin or pit | ½ | cup(s) | 115 | 90.6 | 138 | 2.6 | 9.0 | 6.4 | 11.6 | 2.3 | 6.3 | 1.9 |
| 2998 | Pureed | ½ | cup(s) | 115 | 84.2 | 184 | 2.3 | 9.8 | 7.7 | 16.9 | 2.4 | 11.3 | 2.1 |
| | **Banana** | | | | | | | | | | | | |
| 4580 | Dried chips | ¼ | cup(s) | 18 | 0.8 | 93 | 0.4 | 10.5 | 1.4 | 6.0 | 5.2 | 0.4 | 0.1 |
| 235 | Fresh whole, without peel | 1 | item(s) | 118 | 88.4 | 105 | 1.3 | 27.0 | 3.1 | 0.4 | 0.1 | 0 | 0.1 |
| | **Blackberries** | | | | | | | | | | | | |
| 958 | Frozen, unsweetened | ½ | cup(s) | 76 | 62.1 | 48 | 0.9 | 11.8 | 3.8 | 0.3 | 0 | 0 | 0.2 |
| 237 | Raw | ½ | cup(s) | 72 | 63.5 | 31 | 1.0 | 6.9 | 3.8 | 0.4 | 0 | 0 | 0.2 |
| | **Blueberries** | | | | | | | | | | | | |
| 959 | Canned in heavy syrup | ½ | cup(s) | 128 | 98.3 | 113 | 0.8 | 28.2 | 2.0 | 0.4 | 0 | 0.1 | 0.2 |
| 960 | Frozen, unsweetened | ½ | cup(s) | 78 | 67.1 | 40 | 0.3 | 9.4 | 2.1 | 0.5 | 0 | 0.1 | 0.2 |
| 238 | Raw | ½ | cup(s) | 74 | 62.3 | 42 | 0.5 | 10.7 | 1.8 | 0.2 | 0 | 0 | 0.1 |
| | **Boysenberries** | | | | | | | | | | | | |
| 961 | Canned in heavy syrup | ½ | cup(s) | 128 | 97.6 | 113 | 1.3 | 28.6 | 3.3 | 0.2 | 0 | 0 | 0.1 |
| 962 | Frozen, unsweetened | ½ | cup(s) | 66 | 56.7 | 33 | 0.7 | 8.0 | 3.5 | 0.2 | 0 | 0 | 0.1 |
| 35576 | Breadfruit | 1 | item(s) | 384 | 271.3 | 396 | 4.1 | 104.1 | 18.8 | 0.9 | 0.2 | 0.1 | 0.3 |

## TABLE H-1 Table of Food Composition (*continued*)

(Computer code is for Cengage Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <0.1, 0.01)

| DA+ Code | Food Description | Quantity | Measure | Wt (g) | $H_2O$ (g) | Ener (kcal) | Prot (g) | Carb (g) | Fiber (g) | Fat (g) | Fat Breakdown (g) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | Sat | Mono | Poly |
| **Fruit and Fruit Juices—*continued*** | | | | | | | | | | | | | |
| | **Fruit cocktail & salad** | | | | | | | | | | | | |
| 245 | Fruit cocktail, canned in heavy syrup | ½ | cup(s) | 124 | 99.7 | 91 | 0.5 | 23.4 | 1.2 | 0.1 | 0 | 0 | 0 |
| 978 | Fruit cocktail, canned in juice | ½ | cup(s) | 119 | 103.6 | 55 | 0.5 | 14.1 | 1.2 | 0 | 0 | 0 | 0 |
| 977 | Fruit cocktail, canned in water | ½ | cup(s) | 119 | 107.6 | 38 | 0.5 | 10.1 | 1.2 | 0.1 | 0 | 0 | 0 |
| 979 | Fruit salad, canned in water | ½ | cup(s) | 123 | 112.1 | 37 | 0.4 | 9.6 | 1.2 | 0.1 | 0 | 0 | 0 |
| | **Gooseberries** | | | | | | | | | | | | |
| 982 | Canned in light syrup | ½ | cup(s) | 126 | 100.9 | 92 | 0.8 | 23.6 | 3.0 | 0.3 | 0 | 0 | 0.1 |
| 981 | Raw | ½ | cup(s) | 75 | 65.9 | 33 | 0.7 | 7.6 | 3.2 | 0.4 | 0 | 0 | 0.2 |
| | **Grapefruit** | | | | | | | | | | | | |
| 251 | Juice, pink, sweetened, canned | ½ | cup(s) | 125 | 109.1 | 57 | 0.7 | 13.9 | 0.1 | 0.1 | 0 | 0 | 0 |
| 249 | Juice, white | ½ | cup(s) | 124 | 111.2 | 48 | 0.6 | 11.4 | 0.1 | 0.1 | 0 | 0 | 0 |
| 3022 | Pink or red, raw | ½ | cup(s) | 114 | 100.8 | 48 | 0.9 | 12.2 | 1.8 | 0.2 | 0 | 0 | 0 |
| 247 | Raw, white | ½ | cup(s) | 115 | 104.1 | 38 | 0.8 | 9.7 | 1.3 | 0.1 | 0 | 0 | 0 |
| 248 | Sections, canned in light syrup | ½ | cup(s) | 127 | 106.2 | 76 | 0.7 | 19.6 | 0.5 | 0.1 | 0 | 0 | 0 |
| 983 | Sections, canned in water | ½ | cup(s) | 122 | 109.6 | 44 | 0.7 | 11.2 | 0.5 | 0.1 | 0 | 0 | 0 |
| | **Grapes** | | | | | | | | | | | | |
| 255 | American, slip skin | ½ | cup(s) | 46 | 37.4 | 31 | 0.3 | 7.9 | 0.4 | 0.2 | 0.1 | 0 | 0 |
| 256 | European, red or green, adherent skin | ½ | cup(s) | 76 | 60.8 | 52 | 0.5 | 13.7 | 0.7 | 0.1 | 0 | 0 | 0 |
| 3159 | Juice drink, canned | ½ | cup(s) | 125 | 106.6 | 71 | 0 | 18.2 | 0.1 | 0 | 0 | 0 | 0 |
| 259 | Juice, sweetened, with added vitamin C, prepared from frozen concentrate | ½ | cup(s) | 125 | 108.6 | 64 | 0.2 | 15.9 | 0.1 | 0.1 | 0 | 0 | 0 |
| 3060 | Raisins, seeded, packed | ¼ | cup(s) | 41 | 6.8 | 122 | 1.0 | 32.4 | 2.8 | 0.2 | 0.1 | 0 | 0.1 |
| 987 | **Guava, raw** | 1 | item(s) | 55 | 44.4 | 37 | 1.4 | 7.9 | 3.0 | 0.5 | 0.1 | 0 | 0.2 |
| 35593 | **Guava, strawberry** | 1 | item(s) | 6 | 4.8 | 4 | 0 | 1.0 | 0.3 | 0 | 0 | 0 | 0 |
| 3027 | **Jackfruit** | ½ | cup(s) | 83 | 60.6 | 78 | 1.4 | 19.2 | 1.2 | 0.5 | 0.2 | 0.1 | 0.1 |
| 990 | **Kiwi fruit or Chinese gooseberries** | 1 | item(s) | 76 | 63.1 | 46 | 0.9 | 11.1 | 2.3 | 0.4 | 0 | 0 | 0.2 |
| | **Lemon** | | | | | | | | | | | | |
| 262 | Juice | 1 | tablespoon(s) | 15 | 14.1 | 3 | 0.1 | 1.1 | 0 | 0 | 0 | 0 | 0 |
| 993 | Peel | 1 | teaspoon(s) | 2 | 1.6 | 1 | 0 | 0.3 | 0.2 | 0 | 0 | 0 | 0 |
| 992 | Raw | 1 | item(s) | 108 | 94.4 | 22 | 1.3 | 11.6 | 5.1 | 0.3 | 0 | 0 | 0.1 |
| | **Lime** | | | | | | | | | | | | |
| 269 | Juice | 1 | tablespoon(s) | 15 | 14.0 | 4 | 0.1 | 1.3 | 0.1 | 0 | 0 | 0 | 0 |
| 994 | Raw | 1 | item(s) | 67 | 59.1 | 20 | 0.5 | 7.1 | 1.9 | 0.1 | 0 | 0 | 0 |
| 995 | **Loganberries, frozen** | ½ | cup(s) | 74 | 62.2 | 40 | 1.1 | 9.6 | 3.9 | 0.2 | 0 | 0 | 0.1 |
| | **Mandarin orange** | | | | | | | | | | | | |
| 1038 | Canned in juice | ½ | cup(s) | 125 | 111.4 | 46 | 0.8 | 11.9 | 0.9 | 0 | 0 | 0 | 0 |
| 1039 | Canned in light syrup | ½ | cup(s) | 126 | 104.7 | 77 | 0.6 | 20.4 | 0.9 | 0.1 | 0 | 0 | 0 |
| 999 | **Mango** | ½ | cup(s) | 83 | 68.9 | 49 | 0.7 | 12.4 | 1.3 | 0.3 | 0.1 | 0.1 | 0.1 |
| 1005 | **Nectarine, raw, sliced** | ½ | cup(s) | 69 | 60.4 | 30 | 0.7 | 7.3 | 1.2 | 0.2 | 0 | 0.1 | 0.1 |
| | **Melons** | | | | | | | | | | | | |
| 271 | Cantaloupe | ½ | cup(s) | 80 | 72.1 | 27 | 0.7 | 6.5 | 0.7 | 0.2 | 0 | 0 | 0.1 |
| 1000 | Casaba melon | ½ | cup(s) | 85 | 78.1 | 24 | 0.9 | 5.6 | 0.8 | 0.1 | 0 | 0 | 0 |
| 272 | Honeydew | ½ | cup(s) | 89 | 79.5 | 32 | 0.5 | 8.0 | 0.7 | 0.1 | 0 | 0 | 0.1 |
| 318 | Watermelon | ½ | cup(s) | 76 | 69.5 | 23 | 0.5 | 5.7 | 0.3 | 0.1 | 0 | 0 | 0 |
| | **Orange** | | | | | | | | | | | | |
| 14412 | Juice with calcium and vitamin D | ½ | cup(s) | 120 | 105.5 | 55 | 1.0 | 13.0 | 0 | 0 | 0 | 0 | 0 |
| 29630 | Juice, fresh squeezed | ½ | cup(s) | 124 | 109.5 | 56 | 0.9 | 12.9 | 0.2 | 0.2 | 0 | 0 | 0 |
| 14411 | Juice, not from concentrate | ½ | cup(s) | 120 | 105.5 | 55 | 1.0 | 13.0 | 0 | 0 | 0 | 0 | 0 |
| 278 | Juice, unsweetened, prepared from frozen concentrate | ½ | cup(s) | 125 | 109.7 | 56 | 0.8 | 13.4 | 0.2 | 0.1 | 0 | 0 | 0 |
| 3040 | Peel | 1 | teaspoon(s) | 2 | 1.5 | 2 | 0 | 0.5 | 0.2 | 0 | 0 | 0 | 0 |
| 273 | Raw | 1 | item(s) | 131 | 113.6 | 62 | 1.2 | 15.4 | 3.1 | 0.2 | 0 | 0 | 0 |
| 274 | Sections | ½ | cup(s) | 90 | 78.1 | 42 | 0.8 | 10.6 | 2.2 | 0.1 | 0 | 0 | 0 |
| | **Papaya** | | | | | | | | | | | | |
| 16830 | Dried, strips | 2 | item(s) | 46 | 9.6 | 131 | 1.4 | 33.0 | 5.2 | 0.8 | 0.2 | 0.2 | 0.2 |
| 282 | Raw | ½ | cup(s) | 70 | 61.6 | 30 | 0.3 | 7.6 | 1.2 | 0.2 | 0.1 | 0.1 | 0 |

## TABLE H-1 Table of Food Composition (*continued*)

(Computer code is for Cengage Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <0.1, 0.01)

| DA+ Code | Food Description | Quantity | Measure | Wt (g) | $H_2O$ (g) | Ener (kcal) | Prot (g) | Carb (g) | Fiber (g) | Fat (g) | Fat Breakdown (g) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | Sat | Mono | Poly |
| **Vegetables, Legumes—*continued*** | | | | | | | | | | | | | |
| | **Collard greens** | | | | | | | | | | | | |
| 610 | Boiled, drained | ½ | cup(s) | 95 | 85.7 | 31 | 2.6 | 5.4 | 3.8 | 0.7 | 0 | 0 | 0.2 |
| 611 | Frozen, chopped, boiled, drained | ½ | cup(s) | 85 | 75.2 | 31 | 2.5 | 6.0 | 2.4 | 0.3 | 0.1 | 0 | 0.2 |
| | **Corn** | | | | | | | | | | | | |
| 29614 | Yellow corn, fresh, cooked | 1 | item(s) | 100 | 73.0 | 95 | 3.4 | 20.9 | 2.4 | 1.5 | 0.2 | 0.4 | 0.6 |
| 615 | Yellow creamed sweet corn, canned | ½ | cup(s) | 128 | 100.8 | 92 | 2.2 | 23.2 | 1.5 | 0.5 | 0.1 | 0.2 | 0.3 |
| 612 | Yellow sweet corn, boiled, drained | ½ | cup(s) | 82 | 60.2 | 79 | 2.8 | 17.2 | 2.0 | 1.2 | 0.2 | 0.3 | 0.5 |
| 614 | Yellow sweet corn, frozen, boiled, drained | ½ | cup(s) | 82 | 63.2 | 66 | 2.1 | 15.8 | 2.0 | 0.5 | 0.1 | 0.2 | 0.3 |
| | **Cucumber** | | | | | | | | | | | | |
| 703 | Pickled, dill | ¼ | cup(s) | 39 | 36.6 | 5 | 0.2 | 1.0 | 0.4 | 0.1 | 0 | 0 | 0 |
| 2755 | Pickled, dill, low sodium | ¼ | cup(s) | 39 | 35.5 | 7 | 0.2 | 1.6 | 0.5 | 0.1 | 0 | 0 | 0 |
| 618 | Raw | ¼ | item(s) | 75 | 71.7 | 11 | 0.5 | 2.7 | 0.4 | 0.1 | 0 | 0 | 0 |
| | **Dandelion greens** | | | | | | | | | | | | |
| 620 | Chopped, boiled, drained | ½ | cup(s) | 53 | 47.1 | 17 | 1.0 | 3.4 | 1.5 | 0.3 | 0.1 | 0 | 0.1 |
| 2734 | Raw | 1 | cup(s) | 55 | 47.1 | 25 | 1.5 | 5.1 | 1.9 | 0.4 | 0.1 | 0 | 0.2 |
| 1066 | **Eggplant, boiled, drained** | ½ | cup(s) | 50 | 44.4 | 17 | 0.4 | 4.3 | 1.2 | 0.1 | 0 | 0 | 0 |
| 621 | **Endive or escarole, chopped, raw** | 1 | cup(s) | 50 | 46.9 | 9 | 0.6 | 1.7 | 1.6 | 0.1 | 0 | 0 | 0 |
| 8784 | **Jicama or yambean** | ½ | cup(s) | 67 | 60.1 | 25 | 0.5 | 5.9 | 3.3 | 0.1 | 0 | 0 | 0.0 |
| | **Kale** | | | | | | | | | | | | |
| 623 | Frozen, chopped, boiled, drained | ½ | cup(s) | 65 | 58.8 | 20 | 1.8 | 3.4 | 1.3 | 0.3 | 0 | 0 | 0.2 |
| 29313 | Raw | 1 | cup(s) | 67 | 56.3 | 33 | 2.9 | 5.9 | 1.3 | 0.6 | 0.1 | 0 | 0.2 |
| | **Kohlrabi** | | | | | | | | | | | | |
| 1072 | Boiled, drained | ½ | cup(s) | 83 | 74.5 | 24 | 1.5 | 5.5 | 0.9 | 0.1 | 0 | 0 | 0 |
| 1071 | Raw | 1 | cup(s) | 135 | 122.8 | 36 | 2.3 | 8.4 | 4.9 | 0.1 | 0 | 0 | 0.1 |
| | **Leeks** | | | | | | | | | | | | |
| 1074 | Boiled, drained | ½ | cup(s) | 52 | 47.2 | 16 | 0.4 | 4.0 | 0.5 | 0.1 | 0 | 0 | 0.1 |
| 1073 | Raw | 1 | cup(s) | 89 | 73.9 | 54 | 1.3 | 12.6 | 1.6 | 0.3 | 0 | 0 | 0.1 |
| | **Lentils** | | | | | | | | | | | | |
| 522 | Boiled | ¼ | cup(s) | 50 | 34.5 | 57 | 4.5 | 10.0 | 3.9 | 0.2 | 0 | 0 | 0.1 |
| 1075 | Sprouted | 1 | cup(s) | 77 | 51.9 | 82 | 6.9 | 17.0 | — | 0.4 | 0 | 0.1 | 0.2 |
| | **Lettuce** | | | | | | | | | | | | |
| 625 | Butterhead leaves | 11 | piece(s) | 83 | 78.9 | 11 | 1.1 | 1.8 | 0.9 | 0.2 | 0 | 0 | 0.1 |
| 624 | Butterhead, Boston or Bibb | 1 | cup(s) | 55 | 52.6 | 7 | 0.7 | 1.2 | 0.6 | 0.1 | 0 | 0 | 0.1 |
| 626 | Iceberg | 1 | cup(s) | 72 | 68.9 | 10 | 0.6 | 2.1 | 0.9 | 0.1 | 0 | 0 | 0.1 |
| 628 | Iceberg, chopped | 1 | cup(s) | 55 | 52.6 | 8 | 0.5 | 1.6 | 0.7 | 0.1 | 0 | 0 | 0 |
| 629 | Looseleaf | 1 | cup(s) | 36 | 34.2 | 5 | 0.5 | 1.0 | 0.5 | 0.1 | 0 | 0 | 0 |
| 1665 | Romaine, shredded | 1 | cup(s) | 47 | 44.5 | 8 | 0.6 | 1.5 | 1.0 | 0.1 | 0 | 0 | 0.1 |
| | **Mushrooms** | | | | | | | | | | | | |
| 15585 | Crimini (about 6) | 3 | ounce(s) | 85 | — | 28 | 3.7 | 2.8 | 1.9 | 0 | 0 | 0 | 0 |
| 8700 | Enoki | 30 | item(s) | 90 | 79.5 | 33 | 2.4 | 7.0 | 2.4 | 0.3 | 0 | 0 | 0.1 |
| 1079 | Mushrooms, boiled, drained | ½ | cup(s) | 78 | 71.0 | 22 | 1.7 | 4.1 | 1.7 | 0.4 | 0 | 0 | 0.1 |
| 1080 | Mushrooms, canned, drained | ½ | cup(s) | 78 | 71.0 | 20 | 1.5 | 4.0 | 1.9 | 0.2 | 0 | 0 | 0.1 |
| 630 | Mushrooms, raw | ½ | cup(s) | 48 | 44.4 | 11 | 1.5 | 1.6 | 0.5 | 0.2 | 0 | 0 | 0.1 |
| 35465 | Portabella, raw | 1 | item(s) | 84 | 78.0 | 18 | 1.8 | 3.3 | 1.1 | 0.3 | 0.1 | 0 | 0.1 |
| 2743 | Shiitake, cooked | ½ | cup(s) | 73 | 60.5 | 41 | 1.1 | 10.4 | 1.5 | 0.2 | 0 | 0.1 | 0 |
| | **Mustard greens** | | | | | | | | | | | | |
| 2744 | Frozen, boiled, drained | ½ | cup(s) | 75 | 70.3 | 14 | 1.7 | 2.3 | 2.1 | 0.2 | 0 | 0.1 | 0 |
| 29319 | Raw | 1 | cup(s) | 56 | 50.8 | 15 | 1.6 | 2.6 | 1.8 | 0.2 | 0 | 0.1 | 0 |
| | **Okra** | | | | | | | | | | | | |
| 16866 | Batter coated, fried | 11 | piece(s) | 83 | 50.3 | 159 | 4.0 | 20.1 | 2.3 | 7.1 | 1.4 | 2.8 | 2.4 |
| 32742 | Frozen, boiled, drained, no salt added | ½ | cup(s) | 92 | 83.8 | 27 | 1.5 | 5.9 | 1.9 | 0.2 | 0.1 | 0 | 0.1 |
| 632 | Sliced, boiled, drained | ½ | cup(s) | 80 | 74.1 | 18 | 1.5 | 3.6 | 2.0 | 0.2 | 0 | 0 | 0 |
| | **Onions** | | | | | | | | | | | | |
| 635 | Chopped, boiled, drained | ½ | cup(s) | 105 | 92.3 | 46 | 1.4 | 10.7 | 1.5 | 0.2 | 0 | 0 | 0.1 |
| 2748 | Frozen, boiled, drained | ½ | cup(s) | 106 | 97.8 | 30 | 0.8 | 7.0 | 1.9 | 0.1 | 0 | 0 | 0 |
| 1081 | Onion rings, breaded and pan fried, frozen, heated | 10 | piece(s) | 71 | 20.2 | 289 | 3.8 | 27.1 | 0.9 | 19.0 | 6.1 | 7.7 | 3.6 |

## TABLE H-1 Table of Food Composition (*continued*)

(Computer code is for Cengage Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <0.1, 0.01)

| DA+ Code | Food Description | Quantity | Measure | Wt (g) | $H_2O$ (g) | Ener (kcal) | Prot (g) | Carb (g) | Fiber (g) | Fat (g) | Fat Breakdown (g) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | Sat | Mono | Poly |
| **Vegetables, Legumes—*continued*** | | | | | | | | | | | | | |
| 16860 | **Palm hearts, cooked** | ½ | cup(s) | 73 | 50.7 | 84 | 2.0 | 18.7 | 1.1 | 0.1 | 0 | 0 | 0.1 |
| 637 | **Parsley, chopped** | 1 | tablespoon(s) | 4 | 3.3 | 1 | 0.1 | 0.2 | 0.1 | 0 | 0 | 0 | 0 |
| 638 | **Parsnips, sliced, boiled, drained** | ½ | cup(s) | 78 | 62.6 | 55 | 1.0 | 13.3 | 2.8 | 0.2 | 0 | 0.1 | 0 |
| | **Peas** | | | | | | | | | | | | |
| 639 | Green peas, canned, drained | ½ | cup(s) | 88 | 72.0 | 60 | 3.9 | 9.9 | 4.3 | 0.7 | 0.1 | 0.1 | 0.3 |
| 641 | Green peas, frozen, boiled, drained | ½ | cup(s) | 80 | 63.6 | 62 | 4.1 | 11.4 | 4.4 | 0.2 | 0 | 0 | 0.1 |
| 35694 | Pea pods, boiled with salt, drained | ½ | cup(s) | 80 | 71.1 | 32 | 2.6 | 5.2 | 2.2 | 0.2 | 0 | 0 | 0.1 |
| 1082 | Peas and carrots, canned with liquid | ½ | cup(s) | 128 | 112.4 | 48 | 2.8 | 10.8 | 2.5 | 0.3 | 0.1 | 0 | 0.2 |
| 1083 | Peas and carrots, frozen, boiled, drained | ½ | cup(s) | 80 | 68.6 | 38 | 2.5 | 8.1 | 2.5 | 0.3 | 0.1 | 0 | 0.2 |
| 2750 | Snow or sugar peas, frozen, boiled, drained | ½ | cup(s) | 80 | 69.3 | 42 | 2.8 | 7.2 | 2.5 | 0.3 | 0.1 | 0 | 0.1 |
| 640 | Snow or sugar peas, raw | ½ | cup(s) | 32 | 28.0 | 13 | 0.9 | 2.4 | 0.8 | 0.1 | 0 | 0 | 0 |
| 29324 | Split peas, sprouted | ½ | cup(s) | 60 | 37.4 | 74 | 5.3 | 16.3 | — | 0.4 | 0.1 | 0 | 0.2 |
| | **Peppers** | | | | | | | | | | | | |
| 644 | Green bell or sweet, boiled, drained | ½ | cup(s) | 68 | 62.5 | 19 | 0.6 | 4.6 | 0.8 | 0.1 | 0 | 0 | 0.1 |
| 643 | Green bell or sweet, raw | ½ | cup(s) | 75 | 69.9 | 15 | 0.6 | 3.5 | 1.3 | 0.1 | 0 | 0 | 0 |
| 1664 | Green hot chili | 1 | item(s) | 45 | 39.5 | 18 | 0.9 | 4.3 | 0.7 | 0.1 | 0 | 0 | 0 |
| 1663 | Green hot chili, canned with liquid | ½ | cup(s) | 68 | 62.9 | 14 | 0.6 | 3.5 | 0.9 | 0.1 | 0 | 0 | 0 |
| 1086 | Jalapeno, canned with liquid | ½ | cup(s) | 68 | 60.4 | 18 | 0.6 | 3.2 | 1.8 | 0.6 | 0.1 | 0 | 0.3 |
| 8703 | Yellow bell or sweet | 1 | item(s) | 186 | 171.2 | 50 | 1.9 | 11.8 | 1.7 | 0.4 | 0.1 | 0 | 0.2 |
| 1087 | **Poi** | ½ | cup(s) | 120 | 86.0 | 134 | 0.5 | 32.7 | 0.5 | 0.2 | 0 | 0 | 0.1 |
| | **Potatoes** | | | | | | | | | | | | |
| 1090 | Au gratin mix, prepared with water, whole milk and butter | ½ | cup(s) | 122 | 96.3 | 113 | 2.8 | 15.7 | 1.1 | 5.0 | 3.2 | 1.4 | 0.2 |
| 1089 | Au gratin, prepared with butter | ½ | cup(s) | 123 | 90.7 | 162 | 6.2 | 13.8 | 2.2 | 9.3 | 5.8 | 2.6 | 0.3 |

## TABLE H-1 Table of Food Composition (*continued*)

(Computer code is for Cengage Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <0.1, 0.01)

| DA+ Code | Food Description | Quantity | Measure | Wt (g) | $H_2O$ (g) | Ener (kcal) | Prot (g) | Carb (g) | Fiber (g) | Fat (g) | Fat Breakdown (g) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | Sat | Mono | Poly |
| **Vegetables, Legumes—*continued*** | | | | | | | | | | | | | |
| 3952 | Red, diced | ½ | cup(s) | 90 | 85.1 | 16 | 0.8 | 3.5 | 1.1 | 0.2 | 0 | 0 | 0.1 |
| 1120 | Red, stewed, canned | ½ | cup(s) | 128 | 116.7 | 33 | 1.2 | 7.9 | 1.3 | 0.2 | 0 | 0 | 0.1 |
| 1125 | Sauce, canned | ¼ | cup(s) | 61 | 55.6 | 15 | 0.8 | 3.3 | 0.9 | 0.1 | 0 | 0 | 0 |
| 8778 | Sun dried | ½ | cup(s) | 27 | 3.9 | 70 | 3.8 | 15.1 | 3.3 | 0.8 | 0.1 | 0.1 | 0.3 |
| 8783 | Sun dried in oil, drained | ¼ | cup(s) | 28 | 14.8 | 59 | 1.4 | 6.4 | 1.6 | 3.9 | 0.5 | 2.4 | 0.6 |
| | **Turnips** | | | | | | | | | | | | |
| 678 | Turnip greens, chopped, boiled, drained | ½ | cup(s) | 72 | 67.1 | 14 | 0.8 | 3.1 | 2.5 | 0.2 | 0 | 0 | 0.1 |
| 679 | Turnip greens, frozen, chopped, boiled, drained | ½ | cup(s) | 82 | 74.1 | 24 | 2.7 | 4.1 | 2.8 | 0.3 | 0.1 | 0 | 0.1 |
| 677 | Turnips, cubed, boiled, drained | ½ | cup(s) | 78 | 73.0 | 17 | 0.6 | 3.9 | 1.6 | 0.1 | 0 | 0 | 0 |
| | **Vegetables, mixed** | | | | | | | | | | | | |
| 1132 | Mixed vegetables, canned, drained | ½ | cup(s) | 82 | 70.9 | 40 | 2.1 | 7.5 | 2.4 | 0.2 | 0 | 0 | 0.1 |
| 680 | Mixed vegetables, frozen, boiled, drained | ½ | cup(s) | 91 | 75.7 | 59 | 2.6 | 11.9 | 4.0 | 0.1 | 0 | 0 | 0.1 |
| 7489 | V8 100% vegetable juice | ½ | cup(s) | 122 | 114.1 | 25 | 1.0 | 5.0 | 1.0 | 0 | 0 | 0 | 0 |
| 7490 | V8 low-sodium vegetable juice | ½ | cup(s) | 122 | 114.1 | 25 | 1.0 | 5.0 | 1.0 | 0 | 0 | 0 | 0 |
| 7491 | V8 Spicy Hot vegetable juice | ½ | cup(s) | 122 | 114.2 | 25 | 1.0 | 5.0 | 1.0 | 0 | 0 | 0 | 0 |
| | **Water chestnuts** | | | | | | | | | | | | |
| 31073 | Sliced, drained | ½ | cup(s) | 75 | — | 20 | 0 | 5.0 | 1.0 | 0 | 0 | 0 | 0 |
| 31087 | Whole | ½ | cup(s) | 75 | — | 20 | 0 | 5.0 | 1.0 | 0 | 0 | 0 | 0 |
| 1135 | Watercress | 1 | cup(s) | 34 | 32.3 | 4 | 0.8 | 0.4 | 0.2 | 0 | 0 | 0 | 0 |
| **Nuts, Seeds, and Products** | | | | | | | | | | | | | |
| | **Almonds** | | | | | | | | | | | | |
| 32940 | Almond butter with salt added | 1 | tablespoon(s) | 16 | 0.3 | 98 | 3.4 | 3.0 | 1.6 | 8.9 | 1.0 | 5.2 | 2.2 |
| 1137 | Almond butter, no salt added | 1 | tablespoon(s) | 16 | 0.3 | 98 | 3.4 | 3.0 | 1.6 | 8.9 | 0.7 | 5.2 | 2.2 |
| 32886 | Blanched | ¼ | cup(s) | 36 | 1.6 | 214 | 7.8 | 6.8 | 3.6 | 19.0 | 1.4 | 12.1 | 4.5 |
| 32887 | Dry roasted, no salt added | ¼ | cup(s) | 35 | 0.9 | 205 | 7.3 | 7.3 | 3.8 | 18.0 | 1.4 | 11.2 | 4.5 |
| 29724 | Dry roasted, salted | ¼ | cup(s) | 35 | 0.9 | 205 | 7.3 | 7.3 | 3.8 | 18.0 | 1.4 | 11.2 | 4.5 |
| 29725 | Oil roasted, salted | ¼ | cup(s) | 39 | 1.1 | 238 | 8.3 | 6.9 | 4.1 | 21.7 | 1.7 | 13.7 | 5.3 |
| 508 | Slivered | ¼ | cup(s) | 27 | 1.3 | 155 | 5.7 | 5.9 | 3.3 | 13.3 | 1.0 | 8.3 | 3.3 |
| 1138 | **Beechnuts, dried** | ¼ | cup(s) | 57 | 3.8 | 328 | 3.5 | 19.1 | 5.3 | 28.5 | 3.3 | 12.5 | 11.5 |
| 517 | **Brazil nuts, dried, unblanched** | ¼ | cup(s) | 33 | 1.2 | 218 | 4.8 | 4.1 | 2.5 | 22.1 | 5.0 | 8.2 | 6.8 |
| 1166 | **Breadfruit seeds, roasted** | ¼ | cup(s) | 57 | 28.3 | 118 | 3.5 | 22.9 | 3.4 | 1.5 | 0.4 | 0.2 | 0.8 |
| 1139 | **Butternuts, dried** | ¼ | cup(s) | 30 | 1.0 | 184 | 7.5 | 3.6 | 1.4 | 17.1 | 0.4 | 3.1 | 12.8 |
| | **Cashews** | | | | | | | | | | | | |
| 32931 | Cashew butter with salt added | 1 | tablespoon(s) | 16 | 0.5 | 94 | 2.8 | 4.4 | 0.3 | 7.9 | 1.6 | 4.7 | 1.3 |

# Appendix I WHO Nutrition Recommendations

The World Health Organization (WHO) has assessed the relationships between diet and the development of chronic diseases. This appendix presents its nutrition recommendations for adults:

- Energy: sufficient to support growth, physical activity, and a healthy body weight (BMI between 18.5 and 24.9) and to avoid weight gain greater than 11 pounds (5 kilograms) during adult life
- Total fat: 15 to 30 percent of total energy
- Saturated fatty acids: <10 percent of total energy
- Polyunsaturated fatty acids: 6 to 10 percent of total energy
- Omega-6 polyunsaturated fatty acids: 5 to 8 percent of total energy
- Omega-3 polyunsaturated fatty acids: 1 to 2 percent of total energy
- *Trans*-fatty acids: <1 percent of total energy
- Total carbohydrate: 55 to 75 percent of total energy
- Sugars: <10 percent of total energy, preferably <5 percent of total energy
- Protein: 10 to 15 percent of total energy
- Cholesterol: <300 mg per day
- Salt (sodium): <5 g salt per day (<2 g sodium per day), appropriately iodized
- Potassium: ≥3510 mg per day
- Fruits and vegetables: ≥400 g per day (about 1 pound)
- Total dietary fiber: >25 g per day from foods
- Physical activity: one hour of moderate-intensity activity, such as walking, on most days of the week

# Appendix J Healthy People 2020

Table 1-4 (p. 25) lists the objectives from the Nutrition and Weight Status section of the Healthy People 2020 initiative. Table J-1 presents additional nutrition-related objectives from other topic areas.

**TABLE J-1 Nutrition-Related Objectives from Other Topic Areas**

**Access to Health Services**

- Increase the proportion of persons who receive appropriate evidence-based clinical preventive services.

**Adolescent Health**

- Increase the proportion of schools with a school breakfast program.

**Arthritis, Osteoporosis, and Chronic Back Conditions**

- Reduce hip fractures among older adults.
- Reduce the proportion of adults with osteoporosis.

**Cancer**

- Reduce the cancer death rate.
- Increase the mental and physical health-related quality of life of cancer survivors.

**Diabetes**

- Reduce the annual number of new cases of diagnosed diabetes in the population.
- Reduce the death rate among the population with diabetes.
- Reduce the diabetes death rate.
- Improve glycemic control among the population with diagnosed diabetes.
- Improve lipid control among persons with diagnosed diabetes.
- Increase the proportion of the population with diagnosed diabetes whose blood pressure is under control.
- Increase the proportion of persons with diagnosed diabetes who receive formal diabetes education.
- Increase prevention behaviors in persons at high risk for diabetes with prediabetes.

**Early and Middle Childhood**

- Increase the proportion of elementary, middle, and senior high schools that require school health education.

**Educational and Community-Based Programs**

- Increase the proportion of preschool Early Head Start and Head Start programs that provide health education to prevent health problems in the following areas: unintentional injury; violence; tobacco use and addiction; alcohol and drug use, unhealthy dietary patterns; and inadequate physical activity, dental health, and safety.
- Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS), and STD (sexually transmitted diseases) infection; unhealthy dietary patterns; and inadequate physical activity.
- Increase the proportion of college and university students who receive information from their institution on each of the priority health risk behavior areas (all priority areas; unintentional injury; violence; suicide; tobacco use and addiction; alcohol and other drug use; unintended pregnancy, human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS), and STD (sexually transmitted diseases) infection,; unhealthy dietary patterns; and inadequate physical activity).
- Increase the proportion of worksites that offer an employee health promotion program to their employees.
- Increase the number of community-based organizations (including local health departments, tribal health services, nongovernmental organizations, and state agencies) providing population-based primary prevention services.

**Environmental Health**

- Reduce blood lead levels in children.
- Reduce the number of US homes that are found to have lead-based paint or related hazards.

**TABLE J-1 Nutrition-Related Objectives from Other Topic Areas (*continued*)**

### Food Safety

- Reduce infections caused by key pathogens transmitted commonly through food.
- Reduce the number of outbreak-associated infections due to Shiga toxin-producing *Escherichia coli* O157:H7, or *Campylobacter, Listeria*, or *Salmonella* species associated with food commodity groups.
- Reduce severe allergic reactions to food among adults with a food allergy diagnosis.
- Increase the proportion of consumers who follow key food safety practices.
- Improve food safety practices associated with foodborne illness in foodservice and retail establishments.

### Heart Disease and Stroke

- Increase overall cardiovascular health in the US population.
- Reduce coronary heart disease deaths.
- Reduce stroke deaths.
- Reduce the proportion of persons in the population with hypertension.
- Reduce the proportion of adults with high total blood cholesterol levels.
- Reduce the mean total blood cholesterol levels among adults.
- Increase the proportion of adults with prehypertension who meet the recommended guidelines.
- Increase the proportion of adults with hypertension who meet the recommended guidelines.
- Increase the proportion of adults with elevated LDL cholesterol who have been advised by a health-care provider regarding cholesterol-lowering management including lifestyle changes and, if indicated, medication.
- Increase the proportion of adults with elevated LDL-cholesterol who adhere to the prescribed LDL cholesterol–lowering management lifestyle changes and, if indicated, medication.

### Maternal, Infant, and Child Health

- Reduce low birth weight (LBW) and very low birth weight (VLBW).
- Reduce preterm births.
- Increase the proportion of pregnant women who receive early and adequate prenatal care.
- Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies.
- Increase the proportion of women of childbearing potential with intake of at least 400 micrograms of folic acid from fortified foods or dietary supplements.
- Reduce the proportion of women of childbearing potential who have low red blood cell folate concentrations.
- Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors.
- Increase the proportion of infants who are breastfed.
- Increase the proportion of employers that have worksite lactation support programs.
- Reduce the proportion of breastfed newborns who receive formula supplementation within the first 2 days of life.
- Reduce the occurrence of fetal alcohol syndrome (FAS).
- Reduce occurrence of neural tube defects.

### Mental Health and Mental Disorders

- Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight.

### Older Adults

- Increase the proportion of the health-care workforce (including dietitians) with geriatric certification.

### Oral Health

- Increase the proportion of the US population served by community water systems with optimally fluoridated water.

### Physical Activity

- Reduce the proportion of adults who engage in no leisure-time physical activity.
- Increase the proportion of adolescents and adults who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.
- Increase the proportion of the nation's public and private schools that require daily physical education for all students.
- Increase the proportion of adolescents who participate in daily school physical education.
- Increase regularly scheduled elementary school recess in the United States.
- Increase the proportion of children and adolescents who do not exceed recommended limits for screen time.

# Appendix K Aids to Calculation

Many mathematical problems have been worked out in the "How To" features of the text. This appendix offers additional help and examples.

## Conversions

A conversion factor is a fraction that converts a measurement expressed in one unit to another unit—for example, from pounds to kilograms or from feet to meters. To create a conversion factor, an equality (such as 1 kilogram = 2.2 pounds) is expressed as a fraction:

$$\frac{1\text{ kg}}{2.2\text{ lb}} \text{ and } \frac{2.2\text{ lb}}{1\text{ kg}}$$

To convert the units of a measurement, use the fraction with the desired unit in the numerator.

**Example 1** Convert a weight of 130 pounds to kilograms.
Multiply 130 pounds by the conversion factor that includes both pounds and kilograms, with the desired unit (kilograms) in the numerator:

$$130\text{ lb} \times \frac{1\text{ kg}}{2.2\text{ lb}} = \frac{130\text{ kg}}{2.2} = 59\text{ kg}$$

Alternatively, to convert a measurement from one unit of measure to another, multiply the given measurement by the appropriate equivalent found on the next page of weights and measures.

**Example 2** Convert 64 fluid ounces to liters.
Locate the equivalent measure from the volume section on the next page (1 ounce = 0.03 liter) and multiply the number of ounces by 0.03:

$$64\text{ oz} \times 0.03\text{ oz/L} = 1.9\text{ L}$$

## Percentages

A percentage is a fraction whose denominator is 100. For example:

$$50\% = \frac{50}{100}$$

Like other fractions, percentages are used to express a portion of a quantity. Fractions whose denominators are numbers other than 100 can be converted to percentages by first dividing the numerator by the denominator and then multiplying the result by 100.

**Example 3** Express 5/8 as a percent.

$$\frac{5}{8} = 5 \div 8 = 0.625$$

$$0.625 \times 100 = 62.5\%$$

The following examples show how to calculate specific percentages.

**Example 4** Suppose your energy intake for the day is 2000 kcalories (kcal) and your recommended energy intake is 2400 kcalories. What percent of the recommended energy intake did you consume?

Divide your intake by the recommended intake.
2000 kcal (intake) ÷ 2400 kcal (recommended) = 0.83
Multiply by 100 to express the decimal as a percent.
0.83 × 100 = 83%

**Example 5** Suppose a man's intake of vitamin C is 120 milligrams and his RDA is 90 milligrams. What percent of the RDA for vitamin C did he consume?

Divide the intake by the recommended intake.
120 mg (intake) ÷ 90 mg (RDA) = 1.33
Multiply by 100 to express the decimal as a percent.
1.33 × 100 = 133%

**Example 6** Dietary recommendations suggest that carbohydrates provide 45 to 65 percent of the day's energy intake. If your energy intake is 2000 kcalories, how much carbohydrate should you eat?

Because this question has a range of acceptable answers, work the problem twice. First, use 45% to find the least amount you should eat.

Divide 45 by 100 to convert to a decimal.
45 ÷ 100 = 0.45
Multiply kcalories by 0.45.
2000 kcal × 0.45 = 900 kcal
Divide kcalories by 4 to convert carbohydrate kcal to grams.
900 kcal ÷ 4 kcal/g = 225 g

Now repeat the process using 65% to find the maximum number of grams of carbohydrates you should eat.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Divide 65 by 100 to convert it to a decimal.
65 ÷ 100 = 0.65
Multiply kcalories by 0.65.
2000 kcal × 0.65 = 1300 kcal
Divide kcalories by 4 to convert carbohydrate kcal to grams.
1300 kcal ÷ 4 kcal/g = 325 g

If you plan for between 45% and 65% of your 2000-kcalorie intake to be from carbohydrates, you should eat between 225 grams and 325 grams of carbohydrates.

# Weights and Measures

## Length

1 centimeter (cm) = 0.39 inches (in)
1 foot (ft) = 30 centimeters (cm)
1 inch (in) = 2.54 centimeters (cm)
1 meter (m) = 39.37 inches (in)

## Weight

1 gram (g) = 0.001 kilograms (kg)
= 1000 milligrams (mg)
= 0.035 ounces (oz)
1 kilogram (kg) = 1000 grams (g)
= 2.2 pounds (lb)
1 microgram (µg) = 0.001 milligrams (mg)
1 milligram (mg) = 0.001 grams (g)
= 1000 micrograms (µg)
1 ounce (oz) = 28 grams (g)
= 0.03 kilograms (kg)
= 1/16 or 0.0625 pound (lb)
1 pound (lb) = 454 grams (g)
= 0.45 kilograms (kg)
= 16 ounces (oz)

## Volume

1 cup = 16 tablespoons (tbs or T)
= 0.25 liters (L)
= 236 milliliters (mL, commonly rounded to 250 mL)
= 8 ounces (oz)
1 liter (L) = 33.8 fluid ounces (fl oz)
= 0.26 gallons (gal)
= 2.1 pints (pt)
= 1.06 quarts (qt)
= 1000 milliliters (mL)
1 milliliter (mL) = 0.001 liters (L)
= 0.03 fluid ounces (fl oz)
= 1/5 teaspoon (tsp)
1 ounce (oz) = 0.03 liters (L)
= 30 milliliters (mL)
= 2 tablespoons (tbs)
1 pint (pt) = 2 cups (c)
= 0.47 liters (L)
= 16 ounces (oz)
= 0.5 quarts (qt)
1 quart (qt) = 4 cups (c)
= 0.95 liters (L)
= 32 ounces (oz)
= 1/4 or 0.25 gallon (gal)
= 2 pints (pt)
1 tablespoon (tbs or T) = 3 teaspoons (tsp)
= 15 milliliters (mL)
1 teaspoon (tsp) = 5 milliliters (mL)
1 gallon (gal) = 16 cups (c)
= 3.8 liters (L)
= 128 ounces (oz)
= 8 pints (pt)
= 4 quarts (qt)
1 cup (c) = 8 ounces (oz)
= 16 tablespoons (tbs)
= 250 milliliters (mL)

## Energy

1 megajoule (MJ) = 240 kcalories (kcal)
1 kilojoule (kJ) = 0.24 kcalories (kcal)
1 kcalorie (kcal) = 4.2 kilojoule (kJ)
1 g alcohol = 7 kcal = 29 kJ
1 g carbohydrate = 4 kcal = 17 kJ
1 g fat = 9 kcal = 37 kJ
1 g protein = 4 kcal = 17 kJ

## Temperature

To change from Fahrenheit (°F) to Celsius (°C), subtract 32 from the Fahrenheit measure and then multiply that result by 0.56.

To change from Celsius (°C) to Fahrenheit (°F), multiply the Celsius measure by 1.8 and add 32 to that result.

A comparison of some useful temperatures is given below.

| | Celsius | Fahrenheit |
|---|---|---|
| Boiling point | 100°C | 212°F |
| Body temperature | 37°C | 98.6°F |
| Freezing point | 0°C | 32°F |

# Glossary

Many medical terms have their origins in Latin or Greek. By learning a few common derivations, you can glean the meaning of words you have never heard of before. For example, once you know that "hyper" means above normal, "glyc" means glucose, and "emia" means blood, you can easily determine that "hyperglycemia" means high blood glucose. The derivations below will help you to learn many terms presented in this glossary.

## General

**a-** or **an-** = not, without
**ana-** = (build) up
**ant-** or **anti-** = against
**ante-** or **pre-** = before
**bi-** or **di-** = two, twice
**bio-** or **-biotic** = life
**bovine** = of cattle
**calor** = heat
**cata-** or **kata-** = (break) down
**chele** = claw
**chroma** = color
**co-** = with, together
**dys-** or **mal-** = bad, difficult, painful
**endo-** = inner, within, inside
**epi-** = upon (over)
**erythro-** = red
**exo-** = outside of, without
**extra-** = outside of, beyond, in addition
**gen** or **genesis** = producing, arising, making
**homeo-** = like, similar, the same, constant unchanging state
**hyper-** = over, above, excessive
**hypo-** = below, under, beneath, too little
**in-** = not
**inter-** = between, in the midst
**intra-** = within
**lac-** or **lacto-** = milk
**-lysis** = breaking, breakdown
**macro-** = large, great
**malacia** = softening
**metallo-** = metal
**micro-** = small
**mono-** = one, single
**neo-** = new, recent
**oligo-** = few, small
**-osis** or **-asis** = condition
**para-** = near
**peri-** = around, about
**phag-** or **phago-** = eat
**-philia, -phil, -philic** = love
**-phobia** = fear
**phyto-** = plant
**poly-** = many, much
**pro-** = for, in front of
**re-** = back, again
**semi-** = half
**-stat** or **-stasis-** = stationary, staying
**sub-** = beneath
**tri-** = three
**xero-** = dry

## Body

**angi-** or **vaso-** = vessel
**arterio-** = artery
**cardi-, cardiac, cardio-,** or **cardial** = heart
**cerebro** = brain
**cyst** = closed sac
**-cyte** or **–cytic** = cell
**encephalic** = brain
**entero-** or **enteric** = intestine
**fibro-** = fibrous tissue
**gastro-** = stomach
**globin** = globular protein
**hema-, hemo-,** or **-emia** = blood
**hepatic** = liver
**myo-** = muscle
**nephr-** or **renal** = kidney
**neuro-** = nerve
**osteo-** = bone
**pulmo-** = lung
**sarco-** = flesh
**soma** = body
**ure-** or **-uria** = urine
**vascular** = blood vessels
**vena** = vein

## Chemistry

**-al** = aldehyde
**amino-** or **amine** = containing nitrogen
**-ase** = enzyme
**-ate** = salt
**carbo-** = carbon (C)
**glyc-, glyco-, gluc-,** or **gluco-** = sweet (glucose)
**glyceride** = of glycerol
**hydro-** or **hydrate** = water
**lipo-** = lipid
**-ol** = alcohol
**-ose** = carbohydrate
**peptide** = referring to amino acids
**saccha-** or **sucro-** = sugar

## Disease

**athero-** = porridge, fatty plaque
**carcin-** = cancer
**-itis** = infection, inflammation
**-osis** or **-asis** = condition
**thrombo** = clot

**24-hour dietary recall:** a record of foods eaten by a person for one 24-hour period.

## A

**A1C:** a test that measures the percentage of hemoglobin that has glucose attached, which helps to diagnose diabetes and evaluate long-term glycemic control.

**absorption:** the uptake of nutrients by the cells of the small intestine for transport into either the blood or the lymph.

**Academy of Nutrition and Dietetics:** the professional organization of dietitians in the United States; formerly the American Dietetic Association.

**Acceptable Daily Intake (ADI):** the estimated amount of a sweetener that individuals can safely consume each day over the course of a lifetime without adverse effect.

**Acceptable Macronutrient Distribution Ranges (AMDR):** ranges of intakes for the energy nutrients that provide adequate energy and nutrients and reduce the risk of chronic diseases.

**accredited:** approved; in the case of medical centers or universities, certified by an agency recognized by the US Department of Education.

**acetaldehyde** (ass-et-AL-duh-hide)**:** an intermediate in alcohol metabolism.

**acetyl CoA** (ASS-eh-teel or ah-SEET-il, coh-AY)**:** a 2-carbon compound (acetate, or acetic acid) to which a molecule of CoA is attached.

**acid controllers:** medications used to prevent or relieve indigestion by suppressing production of acid in the stomach; also called *H2 blockers*.

**acid-base balance:** the equilibrium in the body between acid and base concentrations.

**acidosis** (assi-DOE-sis)**:** higher-than-normal acidity in the blood and body fluids.

**acids:** compounds that release hydrogen ions in a solution.

**acne:** a chronic inflammation of the skin's follicles and oil-producing glands, which leads to an accumulation of oils inside the ducts that surround hairs; usually associated with the maturation of young adults.

**acupuncture** (AK-you-PUNK-cher)**:** a technique that involves piercing the skin with long thin needles at specific anatomical points to relieve pain or illness. Acupuncture sometimes uses heat, pressure, friction, suction, or electromagnetic energy to stimulate the points.

**acute malnutrition:** malnutrition caused by recent severe food restriction; characterized in children by underweight for height (*wasting*).

**adaptive thermogenesis:** adjustments in energy expenditure related to changes in environment such as extreme cold and to physiological events such as overfeeding, trauma, and changes in hormone status.

**added sugars:** sugars and other kcaloric sweeteners that are added to foods during processing, preparation, or at the table. Added sugars do not include the naturally occurring sugars found in fruits and milk products.

**additives:** substances not normally consumed as foods but added to food either intentionally or by accident.

**adequacy (dietary):** providing all the essential nutrients, fiber, and energy in amounts sufficient to maintain health.

**Adequate Intake (AI):** the average daily amount of a nutrient that appears sufficient to maintain a specified criterion; a value used as a guide for nutrient intake when an RDA cannot be determined.

**adipokines** (ADD-ih-poe-kines)**:** proteins synthesized and secreted by adipose cells.

**adiponectin:** a protein produced by adipose cells that inhibits inflammation and protects against insulin resistance, type 2 diabetes, and cardiovascular disease.

**adipose** (ADD-ih-poce) **tissue:** the body's fat tissue; consists of masses of triglyceride-storing cells.

**adolescence:** the period from the beginning of puberty until maturity.

**adrenal glands:** glands adjacent to, and just above, each kidney.

**adverse reactions:** unusual responses to food (including intolerances and allergies).

**aerobic** (air-ROE-bic)**:** requiring oxygen.

**aerobic physical activity:** activity in which the body's large muscles move in a rhythmic manner for a sustained period of time. Aerobic activity, also called *endurance activity,* improves cardiorespiratory fitness. Brisk walking, running, swimming, and bicycling are examples.

**AIDS (acquired immune deficiency syndrome):** the late stage of HIV infection, in which severe complications of opportunistic infections and cancers develop.

**alcohol:** a class of organic compounds containing hydroxyl (OH) groups.

**alcohol abuse:** a pattern of drinking that includes failure to fulfill work, school, or home responsibilities; drinking in situations that are physically dangerous (as in driving while intoxicated); recurring alcohol-related legal problems (as in aggravated assault charges); or continued drinking despite ongoing social problems that are caused by or worsened by alcohol.

**alcohol dehydrogenase** (dee-high-DROJ-eh-nayz)**:** an enzyme active in the stomach and the liver that converts ethanol to acetaldehyde.

**alcoholism:** a pattern of drinking that includes a strong craving for alcohol, a loss of control and an inability to stop drinking once begun, withdrawal symptoms (nausea, sweating, shakiness, and anxiety) after heavy drinking, and the need for increasing amounts of alcohol to feel "high."

**alcohol-related birth defects (ARBD):** malformations in the skeletal and organ systems (heart, kidneys, eyes, ears) associated with prenatal alcohol exposure.

**alcohol-related neurodevelopmental disorder (ARND):** abnormalities in the central nervous system and cognitive development associated with prenatal alcohol exposure.

**aldosterone** (al-DOS-ter-own)**:** a hormone secreted by the adrenal glands that regulates blood pressure by increasing the reabsorption of sodium by the kidneys. Aldosterone also regulates chloride and potassium concentrations.

**alkalosis** (alka-LOE-sis)**:** higher-than-normal alkalinity (base) in the blood and body fluids.

**alpha cells:** cells of the pancreas that secrete glucagon in response to low blood glucose concentration.

**alpha-lactalbumin** (lact-AL-byoo-min)**:** a major protein in human breast milk, as opposed to *casein* (CAY-seen), a major protein in cow's milk.

**alpha-tocopherol:** the active vitamin E compound.

**Alzheimer's** (AHLZ-high-merz) **disease:** a degenerative disease of the brain involving memory loss and major structural changes in neuron networks; also known as *senile dementia of the Alzheimer's type (SDAT), primary degenerative dementia of senile onset,* or *chronic brain syndrome*.

**amenorrhea** (ay-MEN-oh-REE-ah)**:** the absence of or cessation of menstruation. *Primary amenorrhea* is menarche delayed beyond 16 years of age. *Secondary amenorrhea* is the absence of three to six consecutive menstrual cycles.

**amino** (a-MEEN-oh) **acids:** building blocks of proteins. Each contains an amino group, an acid group, a hydrogen atom, and a distinctive side group, all attached to a central carbon atom.

**amino acid pool:** the supply of amino acids derived from either food proteins or body proteins that collect in the cells and circulating blood and stand ready to be incorporated in proteins and other compounds or used for energy.

**amino acid score:** a measure of protein quality assessed by comparing a protein's amino acid pattern with that of a reference protein; also called the *chemical score*.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**ammonia:** a compound with the chemical formula $NH_3$, produced during the deamination of amino acids.

**amniotic** (am-nee-OTT-ic) **sac:** the "bag of waters" in the uterus, in which the fetus floats.

**amylase** (AM-ih-lace)**:** an enzyme that hydrolyzes amylose (a form of starch). Amylase is a *carbohydrase,* an enzyme that breaks down carbohydrates.

**anabolic steroids:** drugs related to the male sex hormone, testosterone, that stimulate the development of lean body mass.

**anabolism** (an-AB-o-lism)**:** reactions in which small molecules are put together to build larger ones. Anabolic reactions require energy.

**anaerobic** (AN-air-ROE-bic)**:** not requiring oxygen.

**anaphylactic** (ana-fill-LAC-tic) **shock:** a life-threatening, whole-body allergic reaction to an offending substance.

**androstenedione:** hormones made in the adrenal glands that serve as precursors to the male sex hormone, testosterone; falsely promoted as burning fat, building muscle, and slowing aging.

**anecdote:** a personal account of an experience or event; not reliable scientific information.

**anemia** (ah-NEE-me-ah)**:** literally, "too little blood." Anemia is any condition in which too few red blood cells are present, or the red blood cells are immature (and therefore large) or too small or contain too little hemoglobin to carry the normal amount of oxygen to the tissues. Anemia is not a disease itself but can be a symptom of many different disease conditions, including many nutrient deficiencies, bleeding, excessive red blood cell destruction, and defective red blood cell formation.

**anencephaly** (AN-en-SEF-a-lee)**:** an uncommon and always fatal type of neural tube defect, characterized by the absence of a brain.

**aneurysm** (AN-you-rizm)**:** an abnormal enlargement or bulging of a blood vessel (usually an artery) caused by damage to or weakness in the blood vessel wall.

**angina** (an-JYE-nah or AN-ji-nah)**:** a painful feeling of tightness or pressure in and around the heart, often radiating to the back, neck, and arms; caused by a lack of oxygen to an area of heart muscle.

**angiotensin I** (AN-gee-oh-TEN-sin)**:** an inactive precursor that is converted by an enzyme to yield active angiotensin II.

**angiotensin II:** a hormone involved in blood pressure regulation.

**angiotensinogen:** a precursor protein that is hydrolyzed to angiotensin I by renin.

**anions** (AN-eye-uns)**:** negatively charged ions.

**anorexia** (an-oh-RECK-see-ah) **nervosa:** an eating disorder characterized by a refusal to maintain a minimally normal body weight and a distortion in perception of body shape and weight.

**antacids:** medications used to relieve indigestion by neutralizing acid in the stomach.

**antagonist:** a competing factor that counteracts the action of another factor. When a drug displaces a vitamin from its site of action, the drug renders the vitamin ineffective and thus acts as a vitamin antagonist.

**anthropometric** (AN-throw-poe-MET-rick)**:** relating to measurement of the physical characteristics of the body, such as height and weight.

**antibodies:** large proteins of the blood and body fluids, produced by the immune system in response to the invasion of the body by foreign molecules (usually proteins called *antigens*). Antibodies combine with and inactivate the foreign invaders, thus protecting the body.

**antidiuretic hormone (ADH):** a hormone produced by the pituitary gland in response to dehydration (or a high sodium concentration in the blood) that stimulates the kidneys to reabsorb more water and therefore to excrete less. In addition to its antidiuretic effect, ADH elevates blood pressure and so is also called *vasopressin* (VAS-oh-PRES-in).

**antigens:** substances that elicit the formation of antibodies or an inflammation reaction from the immune system. A bacterium, a virus, a toxin, and a protein in food that causes allergy are all examples of antigens.

**antioxidants:** in the body, substances that significantly decrease the adverse effects of free radicals on normal physiological functions.

**antioxidants:** as a food additive, preservatives that delay or prevent rancidity of fats in foods and other damage to food caused by oxygen.

**antipromoters:** factors that oppose the development of cancer.

**antiscorbutic** (AN-tee-skor-BUE-tik) **factor:** the original name for vitamin C.

**anus** (AY-nus)**:** the terminal outlet of the GI tract.

**aorta** (ay-OR-tuh)**:** the large, primary artery that conducts blood from the heart to the body's smaller arteries.

**apoptosis:** cell death.

**appendix:** a narrow blind sac extending from the beginning of the colon that contains bacteria and lymph cells.

**appetite:** the integrated response to the sight, smell, thought, or taste of food that initiates or delays eating.

**aquaculture:** the practice of fish farming.

**arachidonic** (a-RACK-ih-DON-ic) **acid:** an omega-6 polyunsaturated fatty acid with 20 carbons and four double bonds; present in small amounts in meat and other animal products and synthesized in the body from linoleic acid.

**ariboflavinosis** (ay-RYE-boh-FLAY-vin-oh-sis)**:** riboflavin deficiency.

**aroma therapy:** a technique that uses oil extracts from plants and flowers (usually applied by massage or baths) to enhance physical, psychological, and spiritual health.

**arteries:** vessels that carry blood from the heart to the tissues.

**artesian water:** water drawn from a well that taps a confined aquifer in which the water is under pressure.

**arthritis:** inflammation of a joint, usually accompanied by pain, swelling, and structural changes.

**artificial fats:** zero-energy fat replacers that are chemically synthesized to mimic the sensory and cooking qualities of naturally occurring fats but are totally or partially resistant to digestion.

**artificial sweeteners:** sugar substitutes that provide negligible, if any, energy; sometimes called *nonnutritive sweeteners.*

**ascorbic acid:** one of the two active forms of vitamin C. Many people refer to vitamin C by this name.

**-ase** (ACE)**:** a suffix denoting an enzyme. The root of the word often identifies the compounds the enzyme works on. Examples include: *carbohydrase* (KAR-boe-HIGH-drase), an enzyme that hydrolyzes carbohydrates; *lipase* (LYE-pase), an enzyme that hydrolyzes lipids (fats); and *protease* (PRO-tee-ase), an enzyme that hydrolyzes proteins.

**atherogenic:** able to initiate or promote atherosclerosis.

**atherosclerosis** (ATH-er-oh-scler-OH-sis)**:** a type of artery disease characterized by plaques (accumulations of lipid-containing material) on the inner walls of the arteries.

**atoms:** the smallest components of an element that have all of the properties of the element.

**ATP,** or **adenosine** (ah-DEN-oh-seen) **triphosphate** (try-FOS-fate)**:** a common high-energy compound composed of a purine (adenine), a sugar (ribose), and three phosphate groups. ATP = A–P~P~P, with each ~ denoting a "high-energy" bond.

**atrophic** (a-TRO-fik) **gastritis** (gas-TRY-tis)**:** chronic inflammation of the stomach accompanied by a diminished size and functioning of the mucous membranes and glands. This condition is also characterized by inadequate hydrochloric acid and intrinsic factor—two substances needed for vitamin $B_{12}$ absorption.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**atrophy** (AT-ro-fee)**:** becoming smaller; with regard to muscles, a decrease in size (and strength) because of disuse, undernutrition, or wasting diseases.

**autoimmune disorder:** a condition in which the body develops antibodies to its own proteins and then proceeds to destroy cells containing these proteins. In type 1 diabetes, the body develops antibodies to its insulin and destroys the pancreatic cells that produce the insulin, creating an insulin deficiency.

**autonomic nervous system:** the division of the nervous system that controls the body's automatic responses. Its two branches are the *sympathetic* branch, which helps the body respond to stressors from the outside environment, and the *parasympathetic* branch, which regulates normal body activities between stressful times.

**avidin** (AV-eh-din)**:** the protein in egg whites that binds biotin.

**ayurveda** (AH-your-VAY-dah)**:** a traditional Hindu system of improving health by using herbs, diet, meditation, massage, and yoga to stimulate the body, mind, and spirit to prevent and treat disease.

## B

**bacteriophages** (bak-TIR-ee-oh-fayjz)**:** viruses that infect bacteria.

**balance (dietary):** providing foods in proportion to one another and in proportion to the body's needs.

**bariatric:** pertaining to the field of medicine that specializes in treating obesity.

**basal metabolic rate (BMR):** the rate of energy use for metabolism under specified conditions: after a 12-hour fast and restful sleep, without any physical activity or emotional excitement, and in a comfortable setting. It is usually expressed as kcalories per kilogram body weight per hour.

**basal metabolism:** the energy needed to maintain life when a body is at complete digestive, physical, and emotional rest.

**bases:** compounds that accept hydrogen ions in a solution.

**B-cells:** lymphocytes that produce antibodies. *B* stands for *bone marrow,* where the B-cells develop and mature.

**beer:** an alcoholic beverage traditionally brewed by fermenting malted barley and adding hops for flavor.

**behavior modification:** the changing of behavior by the manipulation of antecedents (cues or environmental factors that trigger behavior), the behavior itself, and consequences (the penalties or rewards attached to the behavior).

**belching:** the release of air or gas from the stomach through the mouth.

**benign:** an abnormal mass of cells that is noncancerous.

**beriberi:** the thiamin-deficiency disease characterized by muscle weakness, edema, or both.

**beta-carotene** (BAY-tah KARE-oh-teen)**:** one of the carotenoids; an orange pigment and vitamin A precursor found in plants.

**beta cells:** cells in the pancreas that secrete insulin in response to elevated blood glucose concentration.

**beta-alanine:** a nonessential amino acid that is the rate-limiting precursor for the synthesis of the dipeptide carnosine. Carnosine acts primarily as a buffer in skeletal muscle. Beta-alanine supplements raise carnosine concentrations, which enhance the muscles' buffering capacity.

**beta-hydroxymethylbutryate (HMB):** a metabolite of the amino acid leucine promoted to increase muscle mass and strength.

**BHA** and **BHT:** preservatives commonly used to slow the development of off-flavors, odors, and color changes caused by oxidation; BHA is butylated hydroxyanisole and BHT is butylated hydroxytoluene.

**bicarbonate:** an alkaline compound with the formula $HCO_3$ that is secreted from the pancreas as part of the pancreatic juice. Bicarbonate is also produced in all cell fluids from the dissociation of carbonic acid to help maintain the body's acid-base balance.

**bile:** an emulsifier that prepares fats and oils for digestion; an exocrine secretion made by the liver, stored in the gallbladder, and released into the small intestine when needed.

**binders:** chemical compounds in foods that combine with nutrients (especially minerals) to form complexes the body cannot absorb. Examples include *phytates* (FYE-tates) and *oxalates* (OCK-sa-lates).

**binge drinking:** pattern of drinking that raises blood alcohol concentration to 0.08 percent or higher; usually corresponds to four or more drinks for women and five or more drinks for men on a single occasion, generally within a couple of hours.

**binge-eating disorder:** an eating disorder characterized by recurring episodes of eating a significant amount of food in a short period of time with marked feelings of lack of control.

**bioaccumulation:** the accumulation of contaminants in the flesh of animals high on the food chain.

**bioavailability:** the rate at and the extent to which a nutrient is absorbed and used.

**bioelectromagnetic medical applications:** the use of electrical energy, magnetic energy, or both to stimulate bone repair, wound healing, and tissue regeneration.

**biofeedback:** the use of special devices to convey information about heart rate, blood pressure, skin temperature, muscle relaxation, and the like to enable a person to learn how to consciously control these medically important functions.

**biofield therapeutics:** a manual healing method that directs a healing force from an outside source (commonly God or another supernatural being) through the practitioner and into the client's body; commonly known as "laying on of hands."

**biological value (BV):** a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen absorbed.

**biotechnology:** the use of biological systems or organisms to create or modify products. Examples include the use of bacteria to make yogurt, yeast to make beer, and cross-breeding to enhance crop production.

**biotin** (BY-oh-tin)**:** a B vitamin that functions as a coenzyme in metabolism.

**blastocyst** (BLASS-toe-sist)**:** the developmental stage of the zygote when it is about 5 days old and ready for implantation.

**blind experiment:** an experiment in which the subjects do not know whether they are members of the experimental group or the control group.

**bloating:** uncomfortable abdominal fullness or distention.

**blood lipid profile:** results of blood tests that reveal a person's total cholesterol, triglycerides, and various lipoproteins.

**body composition:** the proportions of muscle, bone, fat, and other tissue that make up a person's total body weight.

**body mass index (BMI):** a measure of a person's weight relative to height; determined by dividing the weight (in kilograms) by the square of the height (in meters).

**bolus** (BOH-lus)**:** a portion; with respect to food, the amount swallowed at one time.

**bomb calorimeter** (KAL-oh-RIM-eh-ter)**:** an instrument that measures the heat energy released when foods are burned, thus providing an estimate of the potential energy (kcalories) of the foods.

**bone density:** a measure of bone strength. When minerals fill the bone matrix (making it dense), they give it strength.

**bone meal:** crushed or ground bone preparations intended to supply calcium to the diet. Calcium from bone is not well absorbed and is often contaminated with toxic minerals such as arsenic, mercury, lead, and cadmium.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**bottled water:** drinking water sold in bottles.

**botulism** (BOT-chew-lism)**:** an often fatal foodborne illness caused by the ingestion of foods containing a toxin produced by bacteria that grow without oxygen.

**bovine growth hormone (BGH):** a hormone produced naturally in the pituitary gland of a cow that promotes growth and milk production; now produced for agricultural use by bacteria.

**bovine spongiform encephalopathy** (BOH-vine SPON-jih-form in-SEF-eh-LOP-eh-thee) or **BSE:** an often fatal illness of cattle and wild game that affects the nervous system and is transmitted to people by eating infected meats; commonly called *mad cow disease*.

**bran:** the protective coating around the kernel of grain, rich in nutrients and fiber.

**branched-chain amino acids:** the essential amino acids leucine, isoleucine, and valine, which are present in large amounts in skeletal muscle tissue; falsely promoted as fuel for exercising muscles.

**breast milk bank:** a service that collects, screens, processes, and distributes donated human milk.

**brite adipocytes:** white fat cells with brown fat cell characteristics; also called *beige adipocytes*.

**brown adipose tissue:** masses of specialized fat cells packed with pigmented mitochondria that produce heat instead of ATP.

**brown sugar:** refined white sugar crystals to which manufacturers have added molasses syrup with natural flavor and color; 91 to 96 percent pure sucrose.

**buffers:** compounds that keep a solution's pH constant when acids or bases are added.

**bulimia** (byoo-LEEM-ee-ah) **nervosa:** an eating disorder characterized by repeated episodes of binge eating usually followed by self-induced vomiting, misuse of laxatives or diuretics, fasting, or excessive exercise.

## C

**caffeine:** a natural stimulant found in many common foods and beverages, including coffee, tea, and chocolate; may enhance endurance by stimulating fatty acid release. High doses cause headaches, trembling, rapid heart rate, and other undesirable side effects.

**calbindin:** a calcium-binding transport protein that requires vitamin D for its synthesis.

**calcidiol:** vitamin D found in the blood that is made from the hydroxylation of calciol in the liver; also called *25-hydroxyvitamin D*.

**calciferol** (kal-SIF-er-ol)**:** vitamin D.

**calciol:** vitamin D derived from animals in the diet or made in the skin from 7-dehydrocholesterol, a precursor of cholesterol, with the help of sunlight; also called *cholecalciferol* or *vitamin* $D_3$.

**calcitonin** (KAL-seh-TOE-nin)**:** a hormone secreted by the thyroid gland that regulates blood calcium by lowering it when levels rise too high.

**calcitriol:** vitamin D that is made from the hydroxylation of calcidiol in the kidneys; the biologically active hormone; also called *1,25-dihydroxyvitamin D* or *active vitamin D*.

**calcium:** the most abundant mineral in the body; found primarily in the body's bones and teeth.

**calcium-binding protein:** a protein in the intestinal cells, made with the help of vitamin D, that facilitates calcium absorption.

**calcium rigor:** hardness or stiffness of the muscles caused by high blood calcium concentrations.

**calcium tetany** (TET-ah-nee)**:** intermittent spasm of the extremities due to nervous and muscular excitability caused by low blood calcium concentrations.

**calmodulin** (cal-MOD-you-lin)**:** a calcium-binding protein that regulates such cell activities as muscle contractions.

**calories:** a measure of *heat* energy. Energy provided by foods and beverages is measured in *kilocalories* (1000 calories equal 1 kilocalorie), abbreviated *kcalories* or *kcal*. One kcalorie is the amount of heat necessary to raise the temperature of 1 kilogram (kg) of water 1°C. The scientific use of the term *kcalorie* is the same as the popular use of the term *calorie*.

**cancers:** malignant growths or tumors that result from abnormal and uncontrolled cell division.

**capillaries** (CAP-ill-aries)**:** small vessels that branch from an artery. Capillaries connect arteries to veins. Exchange of oxygen, nutrients, and waste materials takes place across capillary walls.

**carbohydrase** (KAR-boe-HIGH-drase)**:** an enzyme that hydrolyzes carbohydrates.

**carbohydrate loading:** a regimen of moderate exercise followed by the consumption of a high-carbohydrate diet that enables muscles to store glycogen beyond their normal capacities; also called *glycogen loading* or *glycogen super compensation*.

**carbohydrates:** compounds composed of carbon, oxygen, and hydrogen arranged as monosaccharides or multiples of monosaccharides. Most, but not all, carbohydrates have a ratio of one carbon molecule to one water molecule: $(CH_2O)_n$.

**carbonated water:** water that contains carbon dioxide gas, either naturally occurring or added, that causes bubbles to form in it; also called *bubbling* or *sparkling water*. The FDA defines seltzer, soda, and tonic waters as soft drinks; they are not regulated as water.

**carbonic acid:** a compound with the formula $H_2CO_3$ that results from the combination of carbon dioxide ($CO_2$) and water ($H_2O$); of particular importance in maintaining the body's acid-base balance.

**carcinogenesis** (CAR-sin-oh-JEN-eh-sis)**:** the process of cancer development.

**carcinogen** (CAR-sin-oh-jen or car-SIN-oh-jen)**:** a substance that can cause cancer; the adjective is *carcinogenic*.

**cardiac output:** the volume of blood discharged by the heart each minute; determined by multiplying the stroke volume by the heart rate. The stroke volume is the amount of oxygenated blood the heart ejects toward the tissues at each beat. Cardiac output (volume/minute) = stroke volume (volume/beat) × heart rate (beats/minute).

**cardiorespiratory conditioning:** improvements in heart and lung function and increased blood volume, brought about by aerobic training.

**cardiorespiratory endurance:** the ability to perform large-muscle, dynamic exercise of moderate to high intensity for prolonged periods.

**cardiovascular disease (CVD):** diseases of the heart and blood vessels throughout the body. Atherosclerosis is the main cause of CVD. When the arteries that carry blood to the heart muscle become blocked, the heart suffers damage known as *coronary heart disease (CHD)*.

**carnitine** (CAR-neh-teen)**:** a nonessential, nonprotein amino acid made in the body from lysine that helps transport fatty acids across the mitochondrial membrane. As a supplement, carnitine supposedly "burns" fat and spares glycogen during endurance events, but in reality it does neither.

**carotenoids** (kah-ROT-eh-noyds)**:** pigments commonly found in plants and animals, some of which have vitamin A activity. The carotenoid with the greatest vitamin A activity is beta-carotene.

**cartilage therapy:** the use of cleaned and powdered connective tissue, such as collagen, to improve health.

**catabolism** (ca-TAB-o-lism)**:** reactions in which large molecules are broken down to smaller ones. Catabolic reactions release energy.

**catalyst** (CAT-uh-list)**:** a compound that facilitates chemical reactions without itself being changed in the process.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**cataracts** (KAT-ah-rakts)**:** clouding of the eye lenses that impairs vision and can lead to blindness.

**cathartic** (ka-THAR-tik)**:** a strong laxative.

**cations** (CAT-eye-uns)**:** positively charged ions.

**CDC (Centers for Disease Control and Prevention):** a branch of the Department of Health and Human Services that is responsible for, among other things, monitoring foodborne diseases.

**celiac disease:** an intestinal disorder in which the inability to absorb the protein portion of gluten results in an immune response that damages intestinal cells; also called *celiac sprue* or *gluten-sensitive enteropathy.*

**cell:** the basic structural unit of all living things.

**cell differentiation** (DIF-er-EN-she-AY-shun)**:** the process by which immature cells develop specific functions different from those of the original that are characteristic of their mature cell type.

**cell membrane:** the thin layer of tissue that surrounds the cell and encloses its contents, made primarily of lipid and protein.

**central nervous system:** the central part of the nervous system; the brain and spinal cord.

**central obesity:** excess fat around the trunk of the body; also called *abdominal fat* or *upper-body fat.*

**cerebral thrombosis:** a clot that blocks blood flow through an artery that feeds the brain.

**certified lactation consultants:** health-care providers who specialize in helping new mothers establish a healthy breastfeeding relationship with their newborn. These consultants are often registered nurses with specialized training in breast and infant anatomy and physiology.

**certified nutritionist** or **certified nutritional consultant** or **certified nutrition therapist:** a person who has been granted a document declaring his or her authority as a nutrition professional.

**cesarean** (si-ZAIR-ee-un) **delivery:** a surgically assisted birth involving removal of the fetus by an incision into the uterus, usually by way of the abdominal wall.

**chaff:** the outer inedible part of a grain; also called the *husk.*

**CHD risk equivalents:** disorders that raise the risk of heart attacks, strokes, and other complications associated with cardiovascular disease to the same degree as existing CHD. These disorders include symptomatic carotid artery disease, peripheral arterial disease, abdominal aortic aneurysm, and diabetes mellitus.

**cheilosis** (kye-LOH-sis or kee-LOH-sis)**:** a condition of reddened lips with cracks at the corners of the mouth.

**chelate** (KEY-late)**:** a substance that can grasp the positive ions of a mineral.

**chelation** (kee-LAY-shun) **therapy:** the use of ethylene diamine tetraacetic acid (EDTA) to bind with metallic ions, thus healing the body by removing toxic metals.

**chiropractic** (KYE-roh-PRAK-tik)**:** a manual healing method of manipulating the spine to restore health.

**chloride** (KLO-ride)**:** the major anion in the extracellular fluids of the body. Chloride is the ionic form of chlorine, $Cl^-$.

**chlorophyll** (KLO-row-fil)**:** the green pigment of plants, which absorbs light and transfers the energy to other molecules, thereby initiating photosynthesis.

**cholecalciferol** (KO-lee-kal-SIF-er-ol)**:** vitamin D derived from animals in the diet and made in the skin from 7-dehydrocholesterol, a precursor of cholesterol, with the help of sunlight; also called *vitamin* $D_3$.

**cholecystokinin** (COAL-ee-SIS-toe-KINE-in), or **CCK:** a hormone produced by cells of the intestinal wall. Target organ: the gallbladder. Response: release of bile and slowing of GI motility.

**cholesterol** (koh-LESS-ter-ol)**:** one of the sterols containing a four-ring carbon structure with a carbon side chain.

**cholesterol-free:** less than 2 milligrams of cholesterol per serving and 2 grams or less of saturated fat and *trans* fat combined per serving.

**choline** (KOH-leen)**:** a nitrogen-containing compound found in foods and made in the body from the amino acid methionine. Choline is part of the phospholipid lecithin and the neurotransmitter acetylcholine.

**chromium:** an essential trace mineral that enhances the activity of insulin.

**chromium picolinate** (CROW-mee-um pick-oh-LYN-ate)**:** a trace mineral supplement; falsely promoted as building muscle, enhancing energy, and burning fat. *Picolinate* is a derivative of the amino acid tryptophan, which seems to enhance chromium absorption.

**chromosomes:** structures within the nucleus of a cell made of DNA and associated proteins. Human beings have 46 chromosomes in 23 pairs. Each chromosome has many genes.

**chronic diseases:** diseases characterized by slow progression and long duration. Examples include heart disease, diabetes, and some cancers.

**chronic malnutrition:** malnutrition caused by long-term food deprivation; characterized in children by short height for age (*stunting*).

**chronological age:** a person's age in years from his or her date of birth.

**chylomicrons** (kye-lo-MY-cronz)**:** the class of lipoproteins that transport lipids from the intestinal cells to the rest of the body.

**chyme** (KIME)**:** the semiliquid mass of partly digested food expelled by the stomach into the duodenum.

**cirrhosis** (seer-OH-sis)**:** advanced liver disease in which liver cells turn orange, die, and harden, permanently losing their function; often associated with alcoholism.

***cis*:** on the near side of; refers to a chemical configuration in which the hydrogen atoms are located on the same side of a double bond.

**citric acid cycle:** a series of metabolic reactions that break down molecules of acetyl CoA to carbon dioxide and hydrogen atoms; also called the *TCA cycle, tricarboxylic acid cycle,* or the *Krebs cycle.*

**clinically severe obesity:** a BMI of 40 or greater or a BMI of 35 or greater with additional medical problems. A less preferred term used to describe the same condition is *morbid obesity.*

**clone:** a genetic copy of an organism created without sexual reproduction; similar to identical twins, but born at different times.

**CoA** (coh-AY): coenzyme A; the coenzyme derived from the B vitamin pantothenic acid and central to energy metabolism.

**coenzymes:** complex organic molecules that work with enzymes to facilitate the enzymes' activity. Many coenzymes have B vitamins as part of their structures.

**cofactor:** a small, inorganic or organic substance that facilitates the action of an enzyme.

**colitis** (ko-LYE-tis)**:** inflammation of the colon.

**collagen** (KOL-ah-jen)**:** the structural protein from which connective tissues such as scars, tendons, ligaments, and the foundations of bones and teeth are made.

**colonic irrigation:** the popular, but potentially harmful practice of "washing" the large intestine with a powerful enema machine; also called *colonic hydrotherapy.*

**colostrum** (ko-LAHS-trum)**:** a milklike secretion from the breast, present during the first few days after delivery before milk appears; rich in protective factors.

**complementary and alternative medicine** (CAM)**:** diverse medical and health-care systems, practices, and products that are not currently considered part of conventional medicine; also called *adjunctive, unconventional,* or *unorthodox therapies.*

**complementary proteins:** two or more dietary proteins whose amino acid assortments complement each other in such a way that the essential amino acids limited in one are supplied by the other.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**complex carbohydrates:** polysaccharides (starches and fibers).

**compound:** a substance composed of two or more different atoms—for example, water ($H_2O$).

**conception:** the union of the male sperm and the female ovum; fertilization.

**condensation:** a chemical reaction in which water is released as two molecules combine to form one larger product.

**conditionally essential amino acid:** an amino acid that is normally nonessential, but must be supplied by the diet in special circumstances when the need for it exceeds the body's ability to make it.

**conditionally essential nutrient:** a nutrient that is normally nonessential, but must be supplied by the diet in special circumstances when the need for it exceeds the body's ability to make it.

**confectioners' sugar:** finely powdered sucrose, 99.9 percent pure.

**congregate meals:** nutrition programs that provide food for the elderly in conveniently located settings such as community centers.

**conjugated linoleic acids:** several fatty acids that have the same chemical formula as linoleic acid (18 carbons, two double bonds) but with different configurations (the double bonds occur on adjacent carbons).

**constipation:** the condition of having infrequent or difficult bowel movements.

**contaminants:** substances that make a food impure and unsuitable for ingestion.

**contamination iron:** iron found in foods as the result of contamination by inorganic iron salts from iron cookware, iron-containing soils, and the like.

**control group:** a group of individuals similar in all possible respects to the experimental group except for the treatment. Ideally, the control group receives a placebo while the experimental group receives a real treatment.

**convenient dietary supplements:** liquid mean replacers, energy drinks, energy bars, and energy gels that athletes and active people use to replenish energy and nutrients when time is limited.

**conventional medicine:** diagnosis and treatment of diseases as practiced by medical doctors (M.D.), doctors of osteopathy (D.O.), and allied health professionals such as physical therapists and registered nurses; also called *allopathy; Western, mainstream, orthodox,* or *regular medicine;* and *biomedicine.*

**cool-down:** 5 to 10 minutes of light activity, such as walking or stretching, following a vigorous workout to gradually return the body's core to near-normal temperature.

**copper:** an essential trace mineral that is part of many enzymes.

**Cori cycle:** the pathway in which glucose is metabolized to lactate (by anaerobic glycolysis) in the muscle, lactate is converted back to glucose in the liver, then glucose is returned to the muscle; named after the scientist who elucidated this pathway.

**corn sweeteners:** corn syrup and sugars derived from corn.

**corn syrup:** a syrup made from cornstarch that has been treated with acid, high temperatures, and enzymes to produce glucose, maltose, and dextrins. It may be dried and used as *corn syrup solids*. See also *high-fructose corn syrup (HFCS).*

**cornea** (KOR-nee-uh)**:** the transparent membrane covering the outside of the eye.

**coronary arteries:** blood vessels that supply blood to the heart.

**coronary heart disease (CHD):** the damage that occurs when the blood vessels carrying blood to the heart (the *coronary arteries*) become narrow and occluded.

**coronary thrombosis:** a clot that blocks blood flow through an artery that feeds the heart muscle.

**correlation** (CORE-ee-LAY-shun)**:** the simultaneous increase, decrease, or change in two variables. If A increases as B increases, or if A decreases as B decreases, the correlation is *positive*. (This does not mean that A causes B or vice versa.) If A increases as B decreases, or if A decreases as B increases, the correlation is *negative*. (This does not mean that A prevents B or vice versa.) Some third factor may account for both A and B.

**cortical bone:** the very dense bone tissue that forms the outer shell surrounding trabecular bone and comprises the shaft of a long bone.

**coupled reactions:** pairs of chemical reactions in which some of the energy released from the breakdown of one compound is used to create a bond in the formation of another compound.

**covalent bonds:** strong chemical bonds formed between atoms by sharing electrons.

**covert** (KOH-vert): hidden, as if under covers.

**C-reactive protein (CRP):** a protein released during the acute phase of infection or inflammation that enhances immunity by promoting phagocytosis and activating platelets. Its presence may be used to assess a person's risk of an impending heart attack or stroke.

**creatine** (KREE-ah-tin)**:** a nitrogen-containing compound that combines with phosphate to form the high-energy compound creatine phosphate (or phosphocreatine) in muscles.

**creatine phosphate (CP):** a high-energy compound in muscle cells that acts as a reservoir of energy that can maintain a steady supply of ATP. CP provides the energy for short bursts of activity; also called *phosphocreatine.*

**cretinism** (CREE-tin-ism)**:** a congenital disease characterized by mental and physical retardation and commonly caused by maternal iodine deficiency during pregnancy.

**critical periods:** finite periods during development in which certain events occur that will have irreversible effects on later developmental stages; usually a period of rapid cell division.

**cross-contamination:** the contamination of food by bacteria that occurs when the food comes into contact with surfaces previously touched by raw meat, poultry, or seafood.

**cruciferous vegetables:** vegetables of the cabbage family, including cauliflower, broccoli, and brussels sprouts.

**crypts** (KRIPTS)**:** tubular glands that lie between the intestinal villi and secrete intestinal juices into the small intestine.

**cultural competence:** having an awareness and acceptance of cultures and the ability to interact effectively with people of diverse cultures.

**cytokines** (SIGH-toe-kines)**:** special proteins that direct immune and inflammatory responses.

**cytoplasm** (SIGH-toh-plazm)**:** the cell contents, except for the nucleus.

**cytosol:** the fluid of cytoplasm that contains water, ions, nutrients, and enzymes.

## D

**Daily Values (DV):** reference values developed by the FDA specifically for use on food labels.

**dead zones:** oxygen-depleted areas of bodies of water in which marine life cannot survive; often caused by algae overgrowth that occurs when agricultural fertilizers and wastes enter the waterways.

**deamination** (dee-AM-ih-NAY-shun)**:** removal of the amino ($NH_2$) group from a compound such as an amino acid.

**defecate** (DEF-uh-cate)**:** to move the bowels and eliminate waste.

**deficient:** inadequate; a nutrient amount that fails to meet the body's needs and eventually results in deficiency symptoms.

**dehydration:** the condition in which body water output exceeds water input. Symptoms include thirst, dry skin and mucous membranes, rapid heartbeat, low blood pressure, and weakness.

**Delaney Clause:** a 1958 amendment to the Food, Drugs, and Cosmetic Act of 1938, named after Congressman James Delaney of New York

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

that states that no substance that is known to cause cancer in animals or human beings at any dose level shall be added to foods.

***de minimis* rule:** a guideline that defines risk as a cancer rate of less than one cancer per million people exposed to a contaminant over a 70-year lifetime.

**denaturation** (dee-NAY-chur-AY-shun)**:** the change in a protein's shape and consequent loss of its function brought about by heat, agitation, acid, base, alcohol, heavy metals, or other agents.

**dental caries:** decay of teeth.

**dental plaque:** a gummy mass of bacteria that grows on teeth and can lead to dental caries and gum disease.

**dextrose:** the name food manufacturers use for the sugar that is chemically the same as glucose; *anhydrous dextrose* is similar, differing primarily in the temperature of crystallization.

**DHEA** (dehydroepiandrosterone) and **androstenedione:** hormones made in the adrenal glands that serve as precursors to the male sex hormone, testosterone; falsely promoted as burning fat, building muscle, and slowing aging.

**DHF (dihydrofolate):** a coenzyme form of folate.

**DIAAS (digestible indispensable amino acid score):** a measure of protein quality similar to PDCAAS, except it determines protein digestibility at the end of the small intestine, which more accurately reflects the extent of amino acid absorption.

**diabetes** (DYE-uh-BEE-teez)**:** metabolic disorders characterized by elevated blood glucose resulting from insufficient insulin, ineffective insulin, or both; the complete medical term is *diabetes mellitus* (meh-LIE-tus).

**diarrhea:** the frequent passage of watery bowel movements.

**diet:** the foods and beverages a person eats and drinks.

**diet history:** a record of eating behaviors and the foods a person eats.

**dietary fibers:** in plant foods, the *nonstarch polysaccharides* that are not digested by human digestive enzymes, although some are digested by GI tract bacteria.

**dietary folate equivalents (DFE):** the amount of folate available to the body from naturally occurring sources, fortified foods, and supplements, accounting for differences in the bioavailability from each source. DFE = µg food folate + (1.7 × µg synthetic folate).

**Dietary Reference Intakes (DRI):** a set of nutrient intake values for healthy people in the United States and Canada. These values are used for planning and assessing diets and include: Estimated Average Requirements (EAR), Recommended Dietary Allowances (RDA), Adequate Intakes (AI), and Tolerable Upper Intake Levels (UL).

**dietary supplement:** any pill, capsule, tablet, liquid, or powder that contains vitamins, minerals, herbs, or amino acids intended to increase dietary intake of these substances.

**dietetic technician:** a person who has completed a minimum of an associate's degree from an accredited university or college and an approved dietetic technician program that includes a supervised practice experience. See also *dietetic technician, registered (DTR)*.

**dietetic technician, registered (DTR):** a dietetic technician who has passed a national examination and maintains registration through continuing professional education.

**dietitian:** a person trained in nutrition, food science, and diet planning. See also *registered dietitian nutritionist*.

**digestion:** the process by which food is broken down into absorbable units.

**digestive enzymes:** proteins found in digestive juices that act on food substances, causing them to break down into simpler compounds.

**digestive system:** all the organs and glands associated with the ingestion and digestion of food.

**dioxins** (dye-OCK-sins)**:** a class of chemical pollutants created as by-products of chemical manufacturing, incineration, chlorine bleaching of paper pulp, and other industrial processes. Dioxins persist in the environment and accumulate in the food chain.

**dipeptide** (dye-PEP-tide)**:** two amino acids bonded together.

**diploma mills:** entities without valid accreditation that provide worthless degrees.

**direct calorimetry:** a means of estimating energy expenditure by measuring the amount of heat released.

**disaccharides** (dye-SACK-uh-rides)**:** pairs of monosaccharides linked together.

**discretionary kcalories:** the kcalories remaining in a person's energy allowance after consuming enough nutrient-dense foods to meet all nutrient needs for a day.

**disordered eating:** eating behaviors that are neither normal nor healthy, including restrained eating, fasting, binge eating, and purging.

**dispensable amino acids:** nonessential amino acids.

**dissociates** (dis-SO-see-aites)**:** physically separates.

**distilled water:** water that has been vaporized and recondensed, leaving it free of dissolved minerals.

**diverticula** (dye-ver-TIC-you-la)**:** sacs or pouches that develop in the weakened areas of the intestinal wall (like bulges in an inner tube where the tire wall is weak).

**diverticulitis** (DYE-ver-tic-you-LYE-tis)**:** infected or inflamed diverticula.

**diverticulosis** (DYE-ver-tic-you-LOH-sis)**:** the condition of having diverticula.

**DNA (deoxyribonucleic acid):** the double helix molecules of which genes are made.

**docosahexaenoic** (DOE-cossa-HEXA-ee-NO-ick) **acid (DHA):** an omega-3 polyunsaturated fatty acid with 22 carbons and six double bonds; present in fatty fish and synthesized in limited amounts in the body from linolenic acid.

**dolomite:** a compound of minerals (calcium magnesium carbonate) found in limestone and marble. Dolomite is powdered and is sold as a calcium-magnesium supplement. However, it may be contaminated with toxic minerals, is not well absorbed, and interferes with absorption of other essential minerals.

**double-blind experiment:** an experiment in which neither the subjects nor the researchers know which subjects are members of the experimental group and which are serving as control subjects, until after the experiment is over.

**Down syndrome:** a genetic abnormality that causes mental retardation, short stature, and flattened facial features.

**drink:** a dose of any alcoholic beverage that delivers ½ ounce of pure ethanol: 5 ounces of wine, 10 ounces of wine cooler, 12 ounces of beer, or 1½ ounces of liquor (80 proof whiskey, scotch, rum, or vodka).

**drug:** a substance that can modify one or more of the body's functions.

**drug history:** a record of all the drugs, over-the-counter and prescribed, that a person takes routinely.

**DTR:** see *dietetic technician, registered*.

**duodenum** (doo-oh-DEEN-um or doo-ODD-num)**:** the top portion of the small intestine (about "12 fingers' breadth" long in ancient terminology).

**dysphagia** (dis-FAY-jah)**:** difficulty swallowing.

## E

**eating disorders:** disturbances in eating behavior that jeopardize a person's physical or psychological health.

**eating pattern:** customary intake of foods and beverages over time.

**eclampsia** (eh-KLAMP-see-ah)**:** a condition characterized by extremely high blood pressure, elevated protein in the urine, seizures, and possibly coma.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**edema** (eh-DEEM-uh)**:** the swelling of body tissue caused by excessive amounts of fluid in the interstitial spaces; seen in protein deficiency (among other conditions).

**edentulous** (ee-DENT-you-lus)**:** lack of teeth.

**eicosanoids** (eye-COSS-uh-noyds)**:** derivatives of 20-carbon fatty acids; biologically active compounds that help to regulate blood pressure, blood clotting, and other body functions. They include *prostaglandins* (PROS-tah-GLAND-ins), *thromboxanes* (throm-BOX-ains), and *leukotrienes* (LOO-ko-TRY-eens).

**eicosapentaenoic** (EYE-cossa-PENTA-ee-NO-ick) **acid** (EPA)**:** an omega-3 polyunsaturated fatty acid with 20 carbons and five double bonds; present in fatty fish and synthesized in limited amounts in the body from linolenic acid.

**electrolyte solutions:** solutions that can conduct electricity.

**electrolytes:** salts that dissolve in water and dissociate into charged particles called ions.

**electron transport chain:** the final pathway in energy metabolism that transports electrons from hydrogen to oxygen and captures the energy released in the bonds of ATP; also called the *respiratory chain*.

**element:** a substance composed of atoms that are alike—for example, iron (Fe).

**embolism** (EM-boh-lizm)**:** the obstruction of a blood vessel by an *embolus* (EM-boh-luss), or traveling clot, causing sudden tissue death.

**embryo** (EM-bree-oh)**:** the developing infant from 2 to 8 weeks after conception.

**emetic** (em-ETT-ic)**:** an agent that causes vomiting.

**empty-kcalorie foods:** a popular term used to denote foods that contribute energy but lack protein, vitamins, and minerals.

**emulsifier** (ee-MUL-sih-fire)**:** a substance with both water-soluble and fat-soluble portions that promotes the mixing of oils and fats in a watery solution.

**endogenous** (en-DODGE-eh-nus)**:** from within the body.

**endoplasmic reticulum** (en-doh-PLAZ-mic reh-TIC-you-lum)**:** a complex network of intracellular membranes. The *rough endoplasmic reticulum* is dotted with ribosomes, where protein synthesis takes place. The *smooth endoplasmic reticulum* bears no ribosomes.

**endosperm:** the inner edible part of a kernel of grain, rich in starch and proteins.

**enema:** solution inserted into the rectum and colon to stimulate a bowel movement and empty the lower large intestine.

**energy:** the capacity to do work. The energy in food is chemical energy. The body can convert this chemical energy to mechanical, electrical, or heat energy.

**energy balance:** the energy (kcalories) consumed from foods and beverages compared with the energy expended through metabolic processes and physical activities.

**energy density:** a measure of the energy a food provides relative to the weight of the food (kcalories per gram).

**energy-yielding nutrients:** the nutrients that break down to yield energy the body can use (carbohydrate, fat, and protein).

**enhanced water:** water that is fortified with ingredients such as vitamins, minerals, protein, oxygen, or herbs. Enhanced water is marketed as *vitamin water, sports water, oxygenated water,* and *protein water.*

**enriched:** the addition to a food of specific nutrients to replace losses that occur during processing so that the food will meet a specified standard.

**enteropancreatic** (EN-ter-oh-PAN-kree-AT-ik) **circulation:** the circulatory route from the pancreas to the intestine and back to the pancreas.

**enzymes:** proteins that facilitate chemical reactions without being changed in the process; protein catalysts.

**EPA (Environmental Protection Agency):** a federal agency that is responsible for, among other things, regulating pesticides and establishing water quality standards.

**epidemic** (ep-ih-DEM-ick)**:** the appearance of a disease (usually infectious) or condition that attacks many people at the same time in the same region.

**epigenetics:** the study of heritable changes in gene function that occur without a change in the DNA sequence.

**epiglottis** (epp-ih-GLOTT-iss)**:** cartilage in the throat that guards the entrance to the trachea and prevents fluid or food from entering it when a person swallows.

**epinephrine** (EP-ih-NEFF-rin)**:** a hormone of the adrenal gland that modulates the stress response; formerly called *adrenaline.* When administered by injection, epinephrine counteracts anaphylactic shock by opening the airways and maintaining heartbeat and blood pressure.

**epithelial** (ep-i-THEE-lee-ul) **cells:** cells on the surface of the skin and mucous membranes.

**epithelial tissue:** the layer of the body that serves as a selective barrier between the body's interior and the environment. Examples are the cornea of the eyes, the skin, the respiratory lining of the lungs, and the lining of the digestive tract.

**ergocalciferol** (ER-go-kal-SIF-er-ol)**:** vitamin D derived from plants in the diet; also called *vitamin* $D_2$.

**ergogenic** (ER-go-JEN-ick) **aids:** substances or techniques used in an attempt to enhance physical performance.

**erythrocyte** (eh-RITH-ro-cite) **hemolysis** (he-MOLL-uh-sis)**:** the breaking open of red blood cells (erythrocytes); a symptom of vitamin E–deficiency disease in human beings.

**erythrocyte protoporphyrin** (PRO-toe-PORE-fe-rin)**:** a precursor to hemoglobin.

**erythropoietin** (eh-RITH-ro-POY-eh-tin)**:** a hormone that stimulates red blood cell production.

**esophageal** (ee-SOFF-ah-GEE-al) **sphincter:** a sphincter muscle at the upper or lower end of the esophagus. The *lower esophageal sphincter* is also called the *cardiac sphincter* because of its proximity to the heart.

**esophagus** (ee-SOFF-ah-gus)**:** the food pipe; the conduit from the mouth to the stomach.

**essential amino acids:** amino acids that the body requires but cannot make, and so must be obtained from the diet; also called *indispensable amino acids*.

**essential fatty acids:** fatty acids that the body requires but cannot make, and so must be obtained from the diet; both linoleic acid and linolenic acid are essential fatty acids.

**essential nutrients:** nutrients a person must obtain from food because the body cannot make them for itself in sufficient quantity to meet physiological needs; also called *indispensable nutrients.* About 40 nutrients are currently known to be essential for human beings.

**Estimated Average Requirement (EAR):** the average daily amount of a nutrient that will maintain a specific biochemical or physiological function in half the healthy people of a given age and gender group.

**Estimated Energy Requirement (EER):** the average dietary energy intake that maintains energy balance and good health in a person of a given age, gender, weight, height, and level of physical activity.

**estrogens:** hormones responsible for the menstrual cycle and other female characteristics.

**ethanol:** a particular type of alcohol found in beer, wine, and liquor; also called *ethyl alcohol.*

**ethnic foods:** foods associated with particular cultural groups.

**excessive drinking:** heavy drinking, binge drinking, or both.

**exchange lists:** diet-planning tools that organize foods by their proportions of carbohydrate, fat, and protein. Foods on any single list can be used interchangeably.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**exercise:** planned, structured, and repetitive body movements that promote or maintain physical fitness.

**exogenous** (eks-ODGE-eh-nus)**:** from outside the body.

**experimental group:** a group of individuals similar in all possible respects to the control group except for the treatment. The experimental group receives the real treatment.

**extra lean:** less than 5 grams of fat, 2 grams of saturated fat and *trans* fat combined, and 95 milligrams of cholesterol per serving and per 100 grams of meat, poultry, and seafood.

**extracellular fluid:** fluid outside the cells. Extracellular fluid includes two main components—the interstitial fluid between cells and the intravascular fluid inside blood vessels. Extracellular fluid accounts for approximately one-third of the body's water.

## F

**FAD (flavin adenine dinucleotide):** a coenzyme form of riboflavin.

**fad diets:** popular eating plans that promise quick weight loss. Most fad diets severely limit certain foods or overemphasize others (for example, never eat potatoes or pasta, or eat cabbage soup daily).

**faith healing:** healing by invoking divine intervention without the use of medical, surgical, or other traditional therapy.

**false negative:** a test result indicating that a condition is not present (negative) when in fact it is present (therefore false).

**false positive:** a test result indicating that a condition is present (positive) when in fact it is not (therefore false).

**famine:** widespread and extreme scarcity of food in an area that causes starvation and death in a large portion of the population.

**FAO (Food and Agriculture Organization):** an international agency (part of the United Nations) that has adopted standards to regulate pesticide use among other responsibilities.

**fasting plasma glucose:** a test that measures plasma glucose after a person has fasted (no food or kcaloric beverages) for at least 8 hours.

**fat replacers:** ingredients that replace some or all of the functions of fat and may or may not provide energy.

**fat-free:** less than 0.5 gram of fat per serving (and no added fat or oil); synonyms include *zero-fat*, *no fat*, and *nonfat*.

**fats:** lipids that are solid at room temperature (77°F, or 25°C).

**fatty acid oxidation:** the metabolic breakdown of fatty acids to acetyl CoA; also called *beta oxidation*.

**fatty acids:** organic compounds composed of a carbon chain with hydrogens attached and an acid group (COOH) at one end and a methyl group ($CH_3$) at the other end.

**fatty liver:** an early stage of liver deterioration seen in several diseases, including obesity and alcoholic liver disease. Fatty liver is characterized by an accumulation of fat in the liver cells.

**fatty streaks:** accumulations of cholesterol and other lipids along the walls of the arteries.

**FDA (Food and Drug Administration):** the federal agency responsible for ensuring the safety and wholesomeness of all dietary supplements and foods processed and sold in interstate commerce except meat, poultry, and eggs (which are under the jurisdiction of the USDA); inspecting food plants and imported foods; and setting standards for food composition and product labeling.

**female athlete triad:** a potentially fatal combination of three medical problems—disordered eating, amenorrhea, and osteoporosis.

**fermentable:** the extent to which bacteria in the GI tract can break down fibers to fragments that the body can use.

**ferritin** (FAIR-ih-tin)**:** the iron storage protein.

**fertility:** the capacity of a woman to produce a normal ovum periodically and of a man to produce normal sperm; the ability to reproduce.

**fetal alcohol spectrum disorder:** a range of physical, behavioral, and cognitive abnormalities caused by prenatal alcohol exposure.

**fetal alcohol syndrome (FAS):** a cluster of physical, behavioral, and cognitive abnormalities associated with prenatal alcohol exposure, including facial malformations, growth retardation, and central nervous disorders.

**fetal programming:** the influence of substances during fetal growth on the development of diseases in later life.

**fetus** (FEET-us)**:** the developing infant from 8 weeks after conception until term.

**fibrocystic** (FYE-bro-SIS-tik) **breast disease:** a harmless condition in which the breasts develop lumps, sometimes associated with caffeine consumption. In some, it responds to abstinence from caffeine; in others, it can be treated with vitamin E.

**fibrosis** (fye-BROH-sis)**:** an intermediate stage of liver deterioration seen in several diseases, including viral hepatitis and alcoholic liver disease. In fibrosis, the liver cells lose their function and assume the characteristics of connective tissue cells (fibers).

**filtered water:** water treated by filtration, usually through *activated carbon filters* that reduce the lead in tap water, or by *reverse osmosis* units that force pressurized water across a membrane removing lead, arsenic, and some microorganisms from tap water.

**fitness:** the characteristics that enable the body to perform physical activity; more broadly, the ability to meet routine physical demands with enough reserve energy to rise to a physical challenge; or the body's ability to withstand stress of all kinds.

**flatulence:** passage of excessive amounts of intestinal gas.

**flavonoids** (FLAY-von-oyds)**:** yellow pigments in foods; phytochemicals that may exert physiological effects on the body.

**flaxseeds:** the small brown seeds of the flax plant; valued in nutrition as a source of fiber, lignans, and omega-3 fatty acids.

**flexibility:** the capacity of the joints to move through a full range of motion; the ability to bend and recover without injury.

**fluid balance:** maintenance of the proper types and amounts of fluid in each compartment of the body fluids.

**fluorapatite** (floor-APP-uh-tite)**:** the stabilized form of tooth crystal, in which fluoride has replaced the hydroxyl groups of hydroxyapatite.

**fluoride:** an essential trace mineral that makes teeth stronger and more resistant to decay.

**fluorosis** (floor-OH-sis)**:** discoloration and pitting of tooth enamel caused by excess fluoride during tooth development.

**FMN (flavin mononucleotide):** a coenzyme form of riboflavin.

**folate** (FOLE-ate)**:** a B vitamin; also known as folic acid, folacin, or pteroylglutamic (tare-o-EEL-glue-TAM-ick) acid (PGA). The coenzyme forms are *DHF* (*dihydrofolate*) and *THF* (*tetrahydrofolate*).

**follicle-stimulating hormone (FSH):** a hormone that stimulates maturation of the ovarian follicles in females and the production of sperm in males. (The ovarian follicles are part of the female reproductive system where the eggs are produced.) The release of FSH is mediated by *follicle-stimulating hormone releasing hormone (FSH–RH)*.

**food allergy:** an adverse reaction to food that involves an immune response; also called *food-hypersensitivity reaction*.

**food and nutrition history:** a record of eating behaviors and the foods a person eats.

**food aversions:** strong desires to avoid particular foods.

**food banks:** facilities that collect and distribute food donations to authorized organizations feeding the hungry.

**food chain:** the sequence in which living things depend on other living things for food.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**food cravings:** strong desires to eat particular foods.

**food crisis:** a sharp rise in the rates of hunger and malnutrition, usually set off by a shock to either the supply of, or demand for, food and a sudden spike in food prices.

**food deserts:** neighborhoods and communities characterized by limited access to nutritious and affordable foods.

**food frequency questionnaire:** a checklist of foods on which a person can record the frequency with which he or she eats each food.

**food group plans:** diet-planning tools that sort foods into groups based on nutrient content and then specify that people should eat certain amounts of foods from each group.

**food insecurity:** limited or uncertain access to foods of sufficient quality or quantity to sustain a healthy and active life.

**food insufficiency:** an inadequate amount of food due to a lack of resources.

**food intolerances:** adverse reactions to foods that do not involve the immune system.

**food poverty:** hunger resulting from inadequate access to available food for various reasons, including inadequate resources, political obstacles, social disruptions, poor weather conditions, and lack of transportation.

**food record:** an extensive, accurate log of all foods eaten over a period of several days or weeks. A food record that includes associated information such as when, where, and with whom each food is eaten is sometimes called a *food diary*.

**food recovery:** collecting wholesome food for distribution to low-income people who are hungry.

**food security:** access to enough food to sustain a healthy and active life.

**food substitutes:** foods that are designed to replace other foods.

**foodborne illness:** an illness transmitted to human beings through food and water, caused by either an infectious agent (foodborne infection) or a poisonous substance (food intoxication); commonly known as *food poisoning*.

**foods:** products derived from plants or animals that can be taken into the body to yield energy and nutrients for the maintenance of life and the growth and repair of tissues.

**fortified:** the addition to a food of nutrients that were either not originally present or present in insignificant amounts. Fortification can be used to correct or prevent a widespread nutrient deficiency or to balance the total nutrient profile of a food.

**fossil fuels:** coal, oil, and natural gas.

**fraudulent:** the promotion, for financial gain, of devices, treatments, services, plans, or products (including diets and supplements) that alter or claim to alter a human condition without proof of safety or effectiveness.

**free:** "nutritionally trivial" and unlikely to have a physiological consequence; synonyms include *without, no,* and *zero*. A food that does not contain a nutrient naturally may make such a claim, but only as it applies to all similar foods (for example, "applesauce, a fat-free food").

**free radical:** an unstable molecule with one or more unpaired electrons.

**fructose** (FRUK-tose or FROOK-tose)**:** a monosaccharide; sometimes known as *fruit sugar* or *levulose*. Fructose is found abundantly in fruits, honey, and saps.

**fuel:** compounds that cells can use for energy. The major fuels include glucose, fatty acids, and amino acids; other fuels include ketone bodies, lactate, glycerol, and alcohol.

**full term:** births occurring at 39 through 40 weeks of gestation.

**functional foods:** foods that have a potentially beneficial effect on health when consumed as part of a varied diet on a regular basis at effective levels.

## G

**g:** grams; a unit of weight equivalent to about 0.03 ounces.

**galactose** (ga-LAK-tose)**:** a monosaccharide; part of the disaccharide lactose.

**gallbladder:** the organ that stores and concentrates bile. When it receives the signal that fat is present in the duodenum, the gallbladder contracts and squirts bile through the bile duct into the duodenum.

**gastric glands:** exocrine glands in the stomach wall that secrete gastric juice into the stomach.

**gastric juice:** the digestive secretion of the gastric glands of the stomach.

**gastrin:** a hormone secreted by cells in the stomach wall. Target organ: the glands of the stomach. Response: secretion of gastric acid.

**gastroesophageal reflux:** the backflow of stomach acid into the esophagus, causing damage to the cells of the esophagus and the sensation of heartburn; commonly known as *heartburn* or *acid indigestion*.

**gastroesophageal reflux disease (GERD):** a condition characterized by symptoms of reflux occurring two or more times a week.

**gastrointestinal (GI) tract:** the digestive tract. The principal organs are the stomach and intestines.

**gatekeepers:** with respect to nutrition, key people who control other people's access to foods and thereby exert profound impacts on their nutrition. Examples are the spouse who buys and cooks the food, the parent who feeds the children, and the caregiver in a day-care center.

**gene expression:** the process by which a cell converts the genetic code into RNA and protein.

**gene pool:** all the genetic information of a population at a given time.

**generally recognized as safe (GRAS):** food additives that have long been in use and are believed to be safe. First established by the FDA in 1958, the GRAS list is subject to revision as new facts become known.

**genes:** sections of chromosomes that contain the instructions needed to make one or more proteins.

**genetic engineering:** the use of biotechnology to modify the genetic material of living cells so that they will produce new substances or perform new functions. Foods produced via this technology are called *genetically modified (GM)* or *genetically engineered (GE) foods*.

**genetics:** the study of genes and inheritance.

**genome** (GEE-nome)**:** the complete set of genetic material (DNA) in an organism or a cell. The study of genomes is called *genomics*.

**genomics:** the study of all the genes in an organism and their interactions with environmental factors.

**genotoxicant:** a substance that mutates or damages genetic material.

**geophagia:** the specific craving for nonfood items such as clay, baby powder, chalk, ash, ceramics, paper, paint chips, charcoal, or dirt.

**germ:** the seed that grows into a mature plant, especially rich in vitamins and minerals.

**gestation** (jes-TAY-shun)**:** the period from conception to birth. For human beings, the average length of a healthy gestation is 40 weeks. Pregnancy is often divided into 3-month periods, called *trimesters*.

**gestational diabetes:** glucose intolerance with onset or first recognition during pregnancy.

**gestational hypertension:** high blood pressure that develops in the second half of pregnancy and resolves after childbirth, usually without affecting the outcome of the pregnancy.

**ghrelin** (GRELL-in)**:** a protein produced by the stomach cells that enhances appetite and decreases energy expenditure.

**glands:** cells or groups of cells that secrete materials for special uses in the body. Glands may be *exocrine* (EKS-oh-crin) *glands,* secreting their materials "out" (into the digestive tract or onto the surface of the skin), or *endocrine* (EN-doe-crin) *glands,* secreting their materials "in" (into the blood).

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**glossitis** (gloss-EYE-tis)**:** an inflammation of the tongue.

**glucagon** (GLOO-ka-gon)**:** a hormone secreted by special cells in the pancreas in response to low blood glucose concentration. Glucagon elicits release of glucose from liver glycogen stores.

**glucocorticoids:** hormones from the adrenal cortex that affect the body's management of glucose.

**glucogenic amino acids:** amino acids that can make glucose via either pyruvate or TCA cycle intermediates.

**gluconeogenesis** (gloo-ko-nee-oh-JEN-ih-sis)**:** the making of glucose from a noncarbohydrate source such as amino acids or glycerol.

**glucose** (GLOO-kose)**:** a monosaccharide; sometimes known as *blood sugar* in the body or *dextrose* in foods.

**glucose polymers:** compounds that supply glucose, not as single molecules, but linked in chains somewhat like starch. The objective is to attract less water from the body into the digestive tract (osmotic attraction depends on the number, not the size, of particles).

**glucose tolerance factors (GTF):** small organic compounds that enhance insulin's actions.

**gluten-free:** a food that contains less that 20 parts per million of gluten from any source; synonyms include *no gluten*, *free of gluten*, or *without gluten*.

**glycemic** (gly-SEEM-ic) **index:** a method of classifying foods according to their potential for raising blood glucose.

**glycemic response:** the extent to which a food raises the blood glucose concentration and elicits an insulin response.

**glycerol** (GLISS-er-ol)**:** an alcohol composed of a three-carbon chain, which can serve as the backbone for a triglyceride.

**glycobiology:** the study of sugars and their derivatives.

**glycogen** (GLY-ko-jen)**:** an animal polysaccharide composed of glucose; a storage form of glucose manufactured and stored in the liver and muscles. Glycogen is not a significant food source of carbohydrate and is not counted as a dietary carbohydrate in foods.

**glycolipids:** sugars attached to lipids in a cell's membrane.

**glycolysis** (gly-COLL-ih-sis)**:** the metabolic breakdown of glucose to pyruvate. Glycolysis does not require oxygen (anaerobic).

**glycoproteins:** sugars attached to a protein.

**goblet cells:** cells of the GI tract (and lungs) that secrete mucus.

**goiter** (GOY-ter)**:** an enlargement of the thyroid gland due to an iodine deficiency, malfunction of the gland, or overconsumption of a goitrogen. Goiter caused by iodine deficiency is sometimes called *simple goiter*.

**goitrogen** (GOY-troh-jen)**:** a substance that enlarges the thyroid gland and causes *toxic goiter*. Goitrogens occur naturally in such foods as cabbage, kale, brussels sprouts, cauliflower, broccoli, and kohlrabi.

**Golgi** (GOAL-gee) **apparatus:** a set of membranes within the cell where secretory materials are packaged for export.

**good source of:** the product provides between 10 and 19 percent of the Daily Value for a given nutrient per serving.

**gout** (GOWT)**:** a common form of arthritis characterized by deposits of uric acid crystals in the joints.

**growth hormone** (GH)**:** a hormone secreted by the pituitary that regulates the cell division and protein synthesis needed for normal growth; also called *somatotropin*. The release of GH is mediated by *GH-releasing hormone (GHRH)* and *GH-inhibiting hormone*.

## H

**hard water:** water with a high calcium and magnesium content.

**hazard:** a source of danger; used to refer to circumstances in which harm is possible under normal conditions of use.

**Hazard Analysis Critical Control Points (HACCP):** a systematic plan to identify and correct potential microbial hazards in the manufacturing, distribution, and commercial use of food products; commonly referred to as "HASS-ip."

**HDL (high-density lipoprotein):** the type of lipoprotein that transports cholesterol back to the liver from the cells; composed primarily of protein.

**health claims:** statements that characterize the relationship between a nutrient or other substance in a food and a disease or health-related condition.

**health history:** an account of a client's current and past health status and disease risks.

**healthy:** on food labels, a food that is low in fat, saturated fat, cholesterol, and sodium and that contains at least 10 percent of the Daily Values for vitamin D, potassium, iron, calcium, protein, or fiber.

**Healthy Eating Index:** a measure that assesses how well a diet meets the recommendations of the *Dietary Guidelines for Americans*.

**Healthy People:** a national public health initiative under the jurisdiction of the US Department of Health and Human Services (DHHS) that identifies the most significant preventable threats to health and focuses efforts toward eliminating them.

**heart attack:** sudden tissue death caused by blockages of vessels that feed the heart muscle; also called *myocardial* (my-oh-KAR-dee-al) *infarction* (in-FARK-shun) or *cardiac arrest*.

**heartburn:** a burning sensation in the chest area caused by backflow of stomach acid into the esophagus; medically known as *gastroesophageal reflux*.

**heat stroke:** a dangerous accumulation of body heat with accompanying loss of body fluid.

**heavy drinking:** more than three drinks on any day for women and more than four drinks on any day for men.

**heavy metals:** mineral ions such as mercury and lead, so called because of their relatively high atomic weight; many heavy metals are poisonous.

**Heimlich** (HIME-lick) **maneuver (abdominal thrusts):** a technique for dislodging an object from the trachea of a choking person; named for the physician who developed it.

**hematocrit** (hee-MAT-oh-krit)**:** the percentage of total blood volume that consists of red blood cells.

**heme** (HEEM) **iron:** the iron in foods that is bound to the hemoglobin and myoglobin proteins; found only in meat, fish, and poultry.

**hemochromatosis** (HE-moh-KRO-ma-toe-sis)**:** a genetically determined failure to prevent absorption of unneeded dietary iron that is characterized by iron overload and tissue damage.

**hemoglobin** (HE-moh-GLO-bin)**:** the globular protein of the red blood cells that transports oxygen from the lungs to tissues throughout the body; hemoglobin accounts for 80 percent of the body's iron.

**hemolytic** (HE-moh-LIT-ick) **anemia:** the condition of having too few red blood cells as a result of erythrocyte hemolysis.

**hemophilia** (HE-moh-FEEL-ee-ah)**:** a hereditary disease in which the blood is unable to clot because it lacks the ability to synthesize certain clotting factors.

**hemorrhagic** (hem-oh-RAJ-ik) **disease:** a disease characterized by excessive bleeding.

**hemorrhoids** (HEM-oh-royds)**:** painful swelling of the veins surrounding the rectum.

**hemosiderin** (heem-oh-SID-er-in)**:** an iron-storage protein primarily made in times of iron overload.

**hepatic portal vein:** the vein that collects blood from the GI tract and conducts it to the liver.

**hepatic vein:** the vein that collects blood from the liver and returns it to the heart.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**hepcidin:** a hormone produced by the liver that regulates iron balance.

**herbal** (ERB-al) **medicine:** the use of plants to treat disease or improve health; also known as *botanical medicine* or *phytotherapy.*

**hGH (human growth hormone):** a hormone produced by the brain's pituitary gland that regulates normal growth and development; also called *somatotropin.*

**high:** on food labels, 20 percent or more of the Daily Value for a given nutrient per serving; synonyms include *rich in* or *excellent source.*

**high fiber:** 5 grams or more of fiber per serving. A high-fiber claim made on a food that contains more than 3 grams of fat per serving and per 100 grams of food must also declare total fat.

**high food security:** no indications of food-access problems or limitations.

**high potency:** 100% or more of the Daily Value for the nutrient in a single supplement and for at least two-thirds of the nutrients in a multinutrient supplement.

**high-fructose corn syrup (HFCS):** a syrup made from cornstarch that has been treated with an enzyme that converts some of the glucose to the sweeter fructose; made especially for use in processed foods and beverages, where it is the predominant sweetener. With a chemical structure similar to sucrose, HFCS has a fructose content of 42 or 55 percent, with glucose making up the remainder.

**high-quality proteins:** dietary proteins containing all the essential amino acids in relatively the same amounts that human beings require. They may also contain nonessential amino acids.

**high-risk pregnancy:** a pregnancy characterized by indicators that make it likely the birth will be surrounded by problems such as premature delivery, difficult birth, restricted growth, birth defects, and early infant death.

**histamine** (HISS-tah-mean or HISS-tah-men)**:** a substance produced by cells of the immune system as part of a local immune reaction to an antigen.

**HIV (human immunodeficiency virus):** the virus that destroys lymphocytes and impairs immunity, eventually causing AIDS.

**HMB (beta-hydroxybetamethylbutyrate):** a metabolite of the branched-chain amino acid leucine promoted to increase muscle mass and strength.

**homeopathy** (hoh-me-OP-ah-thee)**:** a practice based on the theory that "like cures like," that is, that substances that cause symptoms in healthy people can cure those symptoms when given in very dilute amounts.

**homeostasis** (HOME-ee-oh-STAY-sis)**:** the maintenance of constant internal conditions (such as blood chemistry, temperature, and blood pressure) by the body's control systems. A homeostatic system is constantly reacting to external forces to maintain limits set by the body's needs.

**honey:** sugar (mostly sucrose) formed from nectar gathered by bees. Composition and flavor vary, but honey always contains a mixture of sucrose, fructose, and glucose.

**hormones:** chemical messengers. Hormones are secreted by a variety of glands in response to altered conditions in the body. Each hormone travels to one or more specific target tissues or organs, where it elicits a specific response to maintain homeostasis. The study of hormones and their actions is called *endocrinology.*

**hormone-sensitive lipase:** an enzyme inside adipose cells that responds to the body's need for fuel by hydrolyzing triglycerides so that their parts (glycerol and fatty acids) enter the general circulation and thus become available to other cells for fuel. The signals to which this enzyme responds include epinephrine and glucagon, which oppose insulin.

**hourly sweat rate:** the amount of weight lost plus fluid consumed during exercise per hour. One pound equals roughly 2 cups (500 milliliters) of fluid.

**human carrying capacity:** the maximum number of people the earth can support over time.

**human genome** (GEE-nome)**:** the complete set of genetic material (DNA) in a human being.

**human microbiome:** the collection of microbes found in or on the human body.

**hunger:** the painful sensation caused by a lack of food that initiates food-seeking behavior; a consequence of food insecurity that, because of prolonged, involuntary lack of food, results in discomfort, illness, weakness, or pain that goes beyond the usual uneasy sensation.

**husk:** the outer inedible part of a grain; also called the *chaff.*

**hydrochloric acid:** an acid composed of hydrogen and chloride atoms (HCl) that is normally produced by the gastric glands.

**hydrogenation** (HIGH-dro-jen-AY-shun or high-DROJ-eh-NAY-shun)**:** a chemical process by which hydrogens are added to monounsaturated or polyunsaturated fatty acids to reduce the number of double bonds, making the fats more saturated (solid) and more resistant to oxidation (protecting against rancidity). Hydrogenation produces *trans*-fatty acids.

**hydrolysis** (high-DROL-ih-sis)**:** a chemical reaction in which one molecule is split into two molecules, with hydrogen (H) added to one and a hydroxyl group (OH) added to the other (from water, $H_2O$). The noun is *hydrolysis;* the verb is *hydrolyze.*

**hydrophilic** (high-dro-FIL-ick)**:** a term referring to water-loving, or water-soluble, substances.

**hydrophobic** (high-dro-FOE-bick)**:** a term referring to water-fearing, or non-water-soluble, substances; also known as *lipophilic* (fat loving).

**hydrotherapy:** the use of water (in whirlpools, as douches, or packed as ice, for example) to promote relaxation and healing.

**hydroxyapatite** (high-drox-ee-APP-ah-tite)**:** crystals made of calcium and phosphorus.

**hyperactivity:** inattentive and impulsive behavior that is more frequent and severe than is typical of others a similar age; professionally called *attention-deficit/hyperactivity disorder (ADHD).*

**hypercalcemia:** high blood calcium that may develop from a variety of disorders, including vitamin D toxicity. It does *not* develop from a high calcium intake.

**hyperglycemia:** elevated blood glucose concentrations.

**hyperplastic obesity:** obesity due to an increase in the *number* of fat cells.

**hypertension:** consistently higher-than-normal blood pressure. Hypertension that develops without an identifiable cause is known as *essential* or *primary hypertension;* hypertension that is caused by a specific disorder such as kidney disease is known as *secondary hypertension.*

**hyperthermia:** an above-normal body temperature.

**hypertrophic obesity:** obesity due to an increase in the *size* of fat cells.

**hypertrophy** (high-PER-tro-fee)**:** growing larger; with regard to muscles, an increase in size (and strength) in response to use.

**hypnotherapy:** a technique that uses hypnosis and the power of suggestion to improve health behaviors, relieve pain, and heal.

**hypoglycemia** (HIGH-po-gly-SEE-me-ah)**:** an abnormally low blood glucose concentration.

**hyponatremia** (HIGH-poe-na-TREE-mee-ah)**:** a decreased concentration of sodium in the blood.

**hypothalamus** (high-po-THAL-ah-mus)**:** a brain center that controls activities such as maintenance of water balance, regulation of body temperature, and control of appetite.

**hypothermia:** a below-normal body temperature.

**hypothesis** (hi-POTH-eh-sis)**:** an unproven statement that tentatively explains the relationships between two or more variables.

**hypothyroidism:** underactivity of the thyroid gland that may be caused by iodine deficiency or any number of other causes.

## I

**ileocecal** (ill-ee-oh-SEEK-ul) **valve:** the sphincter separating the small and large intestines.

**ileum** (ILL-ee-um)**:** the last segment of the small intestine.

**imagery:** a technique that guides clients to achieve a desired physical, emotional, or spiritual state by visualizing themselves in that state.

**imitation foods:** foods that substitute for and resemble another food, but are nutritionally inferior to it with respect to vitamin, mineral, or protein content. If the substitute is not inferior to the food it resembles and if its name provides an accurate description of the product, it need not be labeled "imitation."

**immune response:** the body's reaction to foreign antigens, which neutralizes or eliminates them, thus preventing damage.

**immune system:** the body's natural defense against foreign materials that have penetrated the skin or mucous membranes.

**immunity:** the body's ability to defend itself against diseases.

**immunoglobulins** (IM-you-noh-GLOB-you-linz)**:** proteins capable of acting as antibodies.

**implantation** (IM-plan-TAY-shun)**:** the embedding of the blastocyst in the inner lining of the uterus.

**indigestion:** incomplete or uncomfortable digestion, usually accompanied by pain, nausea, vomiting, heartburn, intestinal gas, or belching.

**indirect calorimetry:** a means of estimating energy expenditure by measuring the amount of oxygen consumed.

**indirect** or **incidental additives:** substances that can get into food as a result of contact during growing, processing, packaging, storing, cooking, or some other stage before the foods are consumed; sometimes called *accidental additives*.

**indispensable amino acids:** essential amino acids.

**indispensable nutrients:** nutrients a person must obtain from food because the body cannot synthesize them in amounts sufficient to meet physiological needs; also called *essential nutrients*.

**infectious diseases:** diseases caused by bacteria, viruses, parasites, or other microorganisms that can be transmitted from one person to another through air, water, or food; by contact; or through vector organisms such as mosquitoes.

**inflammation:** an immunological response to cellular injury characterized by an increase in white blood cells.

**initiators:** factors that cause mutations that give rise to cancer, such as radiation and carcinogens.

**inorganic:** not containing carbon or pertaining to living organisms. The two classes of nutrients that are inorganic are minerals and water.

**inositol** (in-OSS-ih-tall)**:** a nonessential nutrient that can be made in the body from glucose. Inositol is a part of cell membrane structures.

**insoluble fibers:** nonstarch polysaccharides that do not dissolve in water. Examples include the tough, fibrous structures found in the strings of celery and the skins of corn kernels.

**insulin** (IN-suh-lin)**:** a hormone secreted by special cells in the pancreas in response to (among other things) elevated blood glucose concentration. Insulin controls the transport of glucose from the bloodstream into the muscle and fat cells.

**insulin resistance:** the condition in which a normal amount of insulin produces a subnormal effect in muscle, adipose, and liver cells, resulting in an elevated fasting glucose; a metabolic consequence of obesity that precedes type 2 diabetes.

**integrative medicine:** care that combines conventional and complementary therapies for which there is some high-quality scientific evidence of safety and effectiveness. Integrative medicine emphasizes the importance of the relationship between the practitioner and the patient and focuses on wellness, healing, and the whole person.

**intentional food additives:** additives intentionally added to foods, such as nutrients, colors, and preservatives.

**intermittent claudication** (klaw-dih-KAY-shun)**:** severe calf pain caused by inadequate blood supply. It occurs when walking and subsides during rest.

**Internet (the Net):** a worldwide network of millions of computers linked together to share information.

**interstitial** (IN-ter-STISH-al) **fluid:** fluid between the cells (intercellular), usually high in sodium and chloride. Interstitial fluid is a large component of extracellular fluid.

**intestinal ischemia** (is-KEY-me-ah)**:** a diminished blood flow to the intestines that is characterized by abdominal pain, forceful bowel movements, and blood in the stool.

**intra-abdominal fat:** fat stored within the abdominal cavity in association with the internal abdominal organs, as opposed to the fat stored directly under the skin (subcutaneous fat); also called *visceral fat*.

**intracellular fluid:** fluid within the cells, usually high in potassium and phosphate. Intracellular fluid accounts for approximately two-thirds of the body's water.

**intravascular fluid:** fluid within blood vessels.

**intrinsic factor:** a glycoprotein (a protein with short polysaccharide chains attached) secreted by the stomach cells that binds with vitamin $B_{12}$ in the small intestine to aid in the absorption of vitamin $B_{12}$.

**invert sugar:** a mixture of glucose and fructose formed by the hydrolysis of sucrose in a chemical process; sold only in liquid form and sweeter than sucrose. Invert sugar is used as a food additive to help preserve freshness and prevent shrinkage.

**iodide:** the ion form of iodine.

**iodine:** an essential trace mineral that is needed for the synthesis of thyroid hormones.

**ions** (EYE-uns): atoms or molecules that have gained or lost electrons and therefore have electrical charges. Examples include the positively charged sodium ion ($Na^+$) and the negatively charged chloride ion ($Cl^-$).

**iridology:** the study of changes in the iris of the eye and their relationships to disease.

**iron:** an essential trace mineral that is needed for the transport of oxygen and the metabolism of energy nutrients.

**iron deficiency:** the state of having depleted iron stores.

**iron-deficiency anemia:** severe depletion of iron stores that results in low hemoglobin and small, pale red blood cells. Iron-deficiency anemia is a *microcytic* (my-cro-SIT-ic) *hypochromic* (high-po-KROME-ic) *anemia*.

**iron overload:** toxicity from excess iron.

**irradiation:** sterilizing a food by exposure to energy waves, similar to ultraviolet light and microwaves; sometimes called *ionizing radiation*.

**irritable bowel syndrome:** an intestinal disorder of unknown cause. Symptoms include abdominal discomfort and cramping, diarrhea, constipation, or alternating diarrhea and constipation.

**IU:** international units; an old measure of vitamin activity determined by biological methods (as opposed to new measures that are determined by direct chemical analyses). Many fortified foods and supplements use IU on their labels.

## J

**jejunum** (je-JOON-um)**:** the first two-fifths of the small intestine beyond the duodenum.

**joule:** a measure of *work* energy; the amount of energy expended when 1 kilogram is moved 1 meter by a force of 1 newton.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).

## K

**kcal:** abbreviation of kcalories; a unit by which energy is measured.

**kcalorie:** a unit by which energy is measured. One kcalorie is the amount of heat necessary to raise the temperature of 1 kilogram (kg) of water 1°C. The scientific use of the term *kcalorie* is the same as the popular use of the term *calorie*.

**kcalorie (energy) control:** management of food energy intake.

**kcalorie-free:** fewer than 5 kcalories per serving.

**kefir** (keh-FUR)**:** a fermented milk created by adding *Lactobacillus acidophilus* and other bacteria that break down lactose to glucose and galactose, producing a sweet, lactose-free product.

**keratin** (KARE-uh-tin)**:** a water-insoluble protein; the normal protein of hair and nails.

**keratinization:** accumulation of keratin in a tissue; a sign of vitamin A deficiency.

**keratomalacia** (KARE-ah-toe-ma-LAY-shuh)**:** softening of the cornea that leads to irreversible blindness; a sign of severe vitamin A deficiency.

**Keshan** (KESH-an or ka-SHAWN) **disease:** the heart disease associated with selenium deficiency; named for one of the provinces of China where it was first studied. Keshan disease is characterized by heart enlargement and insufficiency; fibrous tissue replaces the muscle tissue that normally composes the middle layer of the walls of the heart.

**keto** (KEY-toe) **acid:** an organic acid that contains a carbonyl group (C=O).

**ketogenic amino acids:** amino acids that are degraded to acetyl CoA.

**ketone** (KEE-tone) **bodies:** acidic compounds produced by the liver during the incomplete breakdown of fat when carbohydrate is not available.

**ketosis** (kee-TOE-sis)**:** an undesirably high concentration of ketone bodies in the blood and urine.

**Krebs cycle:** named after the scientist who elucidated this biochemistry, a series of metabolic reactions that break down molecules of acetyl CoA to carbon dioxide and hydrogen atoms; also called the *citric acid cycle* or the *TCA cycle*.

**kwashiorkor** (kwash-ee-OR-core or kwash-ee-or-CORE)**:** severe malnutrition characterized by failure to grow and develop, edema, changes in the pigmentation of hair and skin, fatty liver, anemia, and apathy.

## L

**lactase:** an enzyme that hydrolyzes lactose.

**lactase deficiency:** a lack of the enzyme required to digest the disaccharide lactose into its component monosaccharides (glucose and galactose).

**lactate:** a 3-carbon compound produced from pyruvate during anaerobic metabolism.

**lactation:** production and secretion of breast milk for the purpose of nourishing an infant.

**lacteals** (LACK-tee-als)**:** the lymphatic vessels of the intestine that take up nutrients and pass them to the lymph circulation.

**lacto-ovo-vegetarian diet:** an eating pattern that includes milk, milk products, and eggs, but excludes meat, poultry, and seafood from the diet.

**lactose** (LAK-tose)**:** a disaccharide composed of glucose and galactose; commonly known as *milk sugar*.

**lactose intolerance:** a condition that results from the inability to digest the milk sugar lactose; characterized by bloating, gas, abdominal discomfort, and diarrhea. Lactose intolerance differs from milk allergy, which is caused by an immune reaction to the protein in milk.

**lactovegetarian diet:** an eating pattern that includes milk and milk products, but excludes meat, poultry, seafood, and eggs from the diet.

**large intestine or colon** (COAL-un)**:** the lower portion of intestine that completes the digestive process. Its segments are the *ascending colon*, the *transverse colon*, the *descending colon*, and the *sigmoid colon*.

**larynx** (LAIR-inks)**:** the entryway to the trachea that contains the vocal cords; also called the *voice box*.

**laxatives:** substances that loosen the bowels and thereby prevent or treat constipation.

**LDL (low-density lipoprotein):** the type of lipoprotein derived from very-low-density lipoproteins (VLDL) as triglycerides are removed and broken down; composed primarily of cholesterol.

**lean:** less than 10 grams of fat, 4.5 grams of saturated fat and *trans* fat combined, and 95 milligrams of cholesterol per serving and per 100 grams of meat, poultry, and seafood. For mixed dishes such as burritos and sandwiches, less than 8 grams of fat, 3.5 grams of saturated fat, and 80 milligrams of cholesterol per reference amount customarily consumed.

**lean body mass:** the body minus its fat.

**lecithin** (LESS-uh-thin)**:** one of the phospholipids. Both nature and the food industry use lecithin as an emulsifier to combine water-soluble and fat-soluble ingredients that do not ordinarily mix, such as water and oil.

**legumes** (lay-GYOOMS or LEG-yooms)**:** plants of the bean and pea family, with seeds that are rich in protein compared with other plant-derived foods.

**leptin:** a protein produced by fat cells under direction of the *ob* gene that decreases appetite and increases energy expenditure.

**less:** on food labels, at least 25 percent less of a given nutrient or kcalories than the comparison food; synonyms include *fewer* and *reduced*.

**less cholesterol:** 25 percent or less cholesterol than the comparison food (reflecting a reduction of at least 20 milligrams per serving), and 2 grams or less of saturated fat and *trans* fat combined per serving.

**less fat:** 25 percent or less fat than the comparison food.

**less saturated fat:** 25 percent or less saturated fat and *trans* fat combined than the comparison food.

**let-down reflex:** the reflex that forces milk to the front of the breast when the infant begins to nurse.

**levulose:** an older name for fructose.

**license to practice:** permission under state or federal law, granted on meeting specified criteria, to use a certain title (such as dietitian) and offer certain services. *Licensed dietitians* may use the initials *LD* after their names.

**life expectancy:** the average number of years lived by people in a given society.

**life span:** the maximum number of years of life attainable by a member of a species.

**light** or **lite:** one-third fewer kcalories than the comparison food; 50 percent or less of the fat or sodium than the comparison food; any use of the term other than as defined must specify what it is referring to (for example, "light in color" or "light in texture").

**lignans:** phytochemicals present in flaxseed that are converted to phytosterols by intestinal bacteria and are under study as possible anticancer agents.

**limiting amino acid:** the essential amino acid found in the shortest supply relative to the amounts needed for protein synthesis in the body. Four amino acids are most likely to be limiting: lysine, methionine, threonine, and tryptophan.

**lingual:** pertaining to the tongue.

**linoleic** (lin-oh-LAY-ick) **acid:** an essential fatty acid with 18 carbons and two double bonds.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**linolenic** (lin-oh-LEN-ick) **acid:** an essential fatty acid with 18 carbons and three double bonds.

**lipases** (LYE-pasez)**:** enzymes that hydrolyze lipids (fats). *Lingual lipase* is a fat-digesting enzyme secreted from the salivary gland at the base of the tongue; *gastric lipase* is a fat-digesting enzyme secreted from the cells of the stomach.

**lipids:** a family of compounds that includes triglycerides, phospholipids, and sterols. Lipids are characterized by their insolubility in water. (Lipids also include the fat-soluble vitamins.)

**lipoprotein-associated phospholipase A(2)** or **Lp-PLA(2):** a lipoprotein-bound enzyme that generates potent proinflammatory and proatherogenic products such as oxidized free fatty acids and lysophosphatidylcholine. Lp-PLA(2) is a specific marker of plaque inflammation.

**lipoprotein lipase (LPL):** an enzyme that hydrolyzes triglycerides passing by in the bloodstream and directs their parts into the cells, where they can be metabolized for energy or reassembled for storage.

**lipoproteins** (LIP-oh-PRO-teenz)**:** clusters of lipids associated with proteins that serve as transport vehicles for lipids in the lymph and blood.

**lipotoxicity:** the adverse effects of fat in nonadipose tissues.

**liquor** or **distilled spirits:** an alcoholic beverage traditionally made by fermenting and distilling a carbohydrate source such as molasses, potatoes, rye, beets, barley, or corn.

**Listeriosis** (lis-TEAR-ee-OH-sis)**:** an infection caused by eating food contaminated with the bacterium *Listeria monocytogenes*, which can be killed by pasteurization and cooking but can survive at refrigerated temperatures; certain ready-to-eat foods, such as hot dogs and deli meats, may become contaminated after cooking or processing, but before packaging.

**liver:** the organ that manufactures bile, among many other functions.

**longevity:** long duration of life.

**low:** on food labels, an amount that would allow frequent consumption of a food without exceeding the Daily Value for the nutrient. A food that is naturally low in a nutrient may make such a claim, but only as it applies to all similar foods (for example, "fresh cauliflower, a low-sodium food"); synonyms include *little, few,* and *low source of.*

**low birthweight (LBW):** a birthweight of 5½ pounds (2500 grams) or less; indicates probable poor health in the newborn and poor nutrition status in the mother during pregnancy, before pregnancy, or both. Optimal birthweight for a full-term baby is 6½ to 8 pounds.

**low cholesterol:** 20 milligrams or less of cholesterol per serving and 2 grams or less of saturated fat and *trans* fat combined per serving.

**low fat:** 3 grams or less of fat per serving.

**low food security:** reduced quality of life with little or no indication of reduced food intake; formerly known as *food insecurity without hunger.*

**low kcalorie:** 40 kcalories or less per serving.

**low saturated fat:** 1 gram or less of saturated fat and less than 0.5 gram of *trans* fat per serving.

**low sodium:** 140 milligrams or less per serving.

**low-risk pregnancy:** a pregnancy characterized by factors that make it likely the birth will be normal and the infant healthy.

**lumen** (LOO-men)**:** the space within a vessel such as the intestine.

**lutein** (LOO-teen)**:** a plant pigment of yellow hue; a phytochemical believed to play roles in eye functioning and health.

**luteinizing** (LOO-tee-in-EYE-zing) **hormone (LH):** a hormone that stimulates ovulation and the development of the corpus luteum (the small tissue that develops from a ruptured ovarian follicle and secretes hormones); so called because the follicle turns yellow as it matures. In men, LH stimulates testosterone secretion. The release of LH is mediated by *luteinizing hormone–releasing hormone (LH–RH).*

**lycopene** (LYE-koh-peen)**:** a pigment responsible for the red color of tomatoes and other red-hued vegetables; a phytochemical that may act as an antioxidant in the body.

**lymph** (LIMF)**:** a clear yellowish fluid that is similar to blood except that it contains no red blood cells or platelets. Lymph from the GI tract transports fat and fat-soluble vitamins to the bloodstream via lymphatic vessels.

**lymphatic** (lim-FAT-ic) **system:** a loosely organized system of vessels and ducts that convey fluids toward the heart. The GI part of the lymphatic system carries the products of fat digestion into the bloodstream.

**lymphocytes** (LIM-foh-sites)**:** white blood cells that participate in acquired immunity; B cells and T cells.

**lysosomes** (LYE-so-zomes)**:** cellular organelles; membrane-enclosed sacs of degradative enzymes.

## M

**macrobiotic diet:** a philosophical eating pattern based on mostly plant foods such as whole grains, legumes, and vegetables, with small amounts of fish, fruits, nuts, and seeds.

**macrocytic:** abnormally large blood cells.

**macronutrients:** carbohydrate, fat, and protein; the nutrients the body requires in relatively large amounts (many grams daily).

**macrophages** (MAK-roe-fay-jez)**:** large phagocytic cells that serve as scavengers of the blood, clearing it of old or abnormal cells, cellular debris, and antigens.

**macrosomia** (mak-roh-SO-me-ah)**:** abnormally large body size. In the case of infants, a birthweight at the 90th percentile or higher for gestational age (roughly 9 lb—or 4000 g—or more); macrosomia results from prepregnancy obesity, excessive weight gain during pregnancy, or uncontrolled gestational diabetes.

**macular** (MACK-you-lar) **degeneration:** deterioration of the macular area of the eye that can lead to loss of central vision and eventual blindness. The *macula* is a small, oval, yellowish region in the center of the retina that provides the sharp, straight-ahead vision so critical to reading and driving.

**magnesium:** a cation within the body's cells, active in many enzyme systems.

**major minerals:** essential mineral nutrients the human body requires in relatively large amounts (greater than 100 milligrams per day); sometimes called *macrominerals.*

**malignant** (ma-LIG-nant)**:** describes a cancerous cell or tumor, which can injure healthy tissue and spread cancer to other regions of the body.

**malnutrition:** any condition caused by excess or deficient food energy or nutrient intake or by an imbalance of nutrients.

**malt syrup:** a sweetener made from sprouted barley and containing mostly maltose.

**maltase:** an enzyme that hydrolyzes maltose.

**maltose** (MAWL-tose)**:** a disaccharide composed of two glucose units; sometimes known as *malt sugar.*

**mammary glands:** glands of the female breast that secrete milk.

**manganese:** an essential trace mineral that acts as a cofactor for many enzymes.

**maple sugar:** a sugar (mostly sucrose) purified from the concentrated sap of the sugar maple tree.

**marasmus** (ma-RAZ-mus)**:** severe malnutrition characterized by poor growth, dramatic weight loss, loss of body fat and muscle, and apathy.

**margin of safety:** when speaking of food additives, a zone between the concentration normally used and that at which a hazard exists. For

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

common table salt, for example, the margin of safety is 1/5 (five times the amount normally used would be hazardous).

**marginal food security:** one or two indications of food-access problems but with little or no change in food intake.

**massage therapy:** a healing method in which the therapist manually kneads muscles to reduce tension, increase blood circulation, improve joint mobility, and promote healing of injuries.

**mastication:** the process of chewing.

**matrix** (MAY-tricks)**:** the basic substance that gives form to a developing structure; in the body, the formative cells from which teeth and bones grow.

**matter:** anything that takes up space and has mass.

**Meals on Wheels:** a nutrition program that delivers food for the elderly to their homes.

**meat replacements:** products formulated to look and taste like meat, fish, or poultry; usually made of textured vegetable protein.

**medical history:** an account of a patient's current and past health status and disease risks.

**medication and supplement history:** a record of all the drugs, over-the-counter and prescribed, as well as dietary and herbal supplements that a person takes routinely.

**meditation:** a self-directed technique of relaxing the body and calming the mind.

**megaloblastic:** abnormally large blood cells.

**menadione** (men-uh-DYE-own)**:** the synthetic form of vitamin K.

**menaquinone** (men-ah-KWYN-own)**:** the bacteria-produced form of vitamin K; also called *vitamin* $K_2$.

**Menkes disease:** a genetic disorder of copper transport that creates a copper deficiency and results in mental retardation, poor muscle tone, seizures, brittle kinky hair, and failure to thrive.

**MEOS** or **microsomal** (my-krow-SO-mal) **ethanol oxidizing system:** a system of enzymes in the liver that oxidize not only alcohol but also several classes of drugs.

**metabolic syndrome:** a combination of risk factors—elevated fasting blood glucose, hypertension, abnormal blood lipids, and abdominal obesity—that greatly increase a person's risk of developing coronary heart disease; also called *Syndrome X, insulin resistance syndrome,* or *dysmetabolic syndrome.*

**metabolic water:** water generated during metabolism.

**metabolism:** the sum total of all the chemical reactions that go on in living cells. *Energy metabolism* includes all the reactions by which the body obtains and expends the energy from food.

**metalloenzymes** (meh-TAL-oh-EN-zimes)**:** enzymes that contain one or more minerals as part of their structures.

**metallothionein** (meh-TAL-oh-THIGH-oh-neen)**:** a sulfur-rich protein that avidly binds with and transports metals such as zinc.

**metastasize** (me-TAS-tah-size)**:** the spread of cancer from one part of the body to another.

**methylation:** the addition of a methyl group ($CH_3$).

**MFP factor:** a peptide released during the digestion of meat, fish, and poultry that enhances nonheme iron absorption.

**mg:** milligrams; one-thousandth of a gram.

**mg NE:** milligrams of niacin equivalents; a measure of niacin activity.

**micelles** (MY-cells)**:** tiny spherical complexes of emulsified fat that arise during digestion; most contain bile salts and the products of lipid digestion, including fatty acids, monoglycerides, and cholesterol.

**microangiopathies:** disorders of the small blood vessels.

**microarray technology:** research tools that analyze the expression of thousands of genes simultaneously and search for particular gene changes associated with a disease. DNA microarrays are also called *DNA chips.*

**microbes** (MY-krobes)**:** microscopically small organisms including bacteria, viruses, fungi, and protozoa; also called *microorganisms.*

**microcytic** (my-cro-SIT-ic) **hypochromic** (high-po-KROME-ic) **anemia:** small, pale red blood cells that develop in iron-deficiency anemia.

**microgram (μg):** one millionth of a gram.

**microgram DFE (μg DFE):** micrograms dietary folate equivalents; a measure of folate activity.

**microgram RAE (μg RAE):** micrograms retinol activity equivalents; a measure of vitamin A activity.

**micronutrients:** vitamins and minerals; the nutrients the body requires in relatively small amounts (milligrams or micrograms daily).

**microvilli** (MY-cro-VILL-ee or MY-cro-VILL-eye)**:** tiny, hairlike projections on each cell of every villus that can trap nutrient particles and transport them into the cells; singular *microvillus.*

**milk anemia:** iron-deficiency anemia that develops when an excessive milk intake displaces iron-rich foods from the diet.

**milliequivalents per liter (mEq/L):** the concentration of electrolytes in a volume of solution. Milliequivalents reveal characteristics about the solution that are not evident when the concentration is expressed in terms of weight.

**mineral oil:** a purified liquid derived from petroleum and used to treat constipation.

**mineral water:** water from a spring or well that naturally contains at least 250 parts per million (ppm) of minerals. Minerals give water a distinctive flavor. Many mineral waters are high in sodium.

**mineralization:** the process in which calcium, phosphorus, and other minerals crystallize on the collagen matrix of a growing bone, hardening the bone.

**minerals:** inorganic elements. Some minerals are essential nutrients required in small amounts by the body for health.

**misinformation:** false or misleading information.

**mitochondria** (my-toh-KON-dree-uh)**:** the cellular organelles responsible for producing ATP aerobically; made of membranes with enzymes mounted on them. (The singular is *mitochondrion.*)

**mmol:** millimoles; one thousandth of a mole, the molecular weight of a substance. To convert mmol to mg, multiply by the atomic weight of the substance.

**moderate-intensity physical activity:** physical activity that requires some increase in breathing and/or heart rate and expends 3.5 to 7 kcalories per minute. Walking at a speed of 3 to 4.5 miles per hour (about 15 to 20 minutes to walk 1 mile) is an example.

**moderation (alcohol):** up to one drink per day for women and up to two drinks per day for men.

**moderation (dietary):** providing enough but not too much of a substance.

**molasses:** the thick brown syrup produced during sugar refining. Molasses retains residual sugar and other by-products and a few minerals; blackstrap molasses contains significant amounts of calcium and iron.

**molecule:** two or more atoms of the same or different elements joined by chemical bonds. Examples are molecules of the element oxygen, composed of two oxygen atoms ($O_2$), and molecules of the compound water, composed of two hydrogen atoms and one oxygen atom ($H_2O$).

**molybdenum** (mo-LIB-duh-num)**:** an essential trace mineral that acts as a cofactor for many enzymes.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**monoglycerides:** molecules of glycerol with one fatty acid attached. A molecule of glycerol with two fatty acids attached is a *diglyceride*.

**monosaccharides** (mon-oh-SACK-uh-rides)**:** carbohydrates of the general formula $C_nH_{2n}O_n$ that typically form a single ring. The monosaccharides important in nutrition are *hexoses*, sugars with six atoms of carbon and the formula $C_6H_{12}O_6$.

**monosodium glutamate (MSG):** a sodium salt of the amino acid glutamic acid commonly used as a flavor enhancer. The FDA classifies MSG as a "generally recognized as safe" ingredient.

**monounsaturated fatty acid:** a fatty acid that lacks two hydrogen atoms and has one double bond between carbons; abbreviated *MUFA*. Examples include palmitoleic acid and oleic acid. A *monounsaturated fat* is composed of triglycerides in which most of the fatty acids are monounsaturated.

**more:** on food labels, at least 10 percent more of the Daily Value for a given nutrient than the comparison food; synonyms include *added* and *extra*.

**motility** (moh-TIL-ih-tee)**:** the spontaneous movement of the GI tract muscles.

**mouth:** the oral cavity containing the tongue and teeth.

**MSG symptom complex:** an acute, temporary intolerance reaction that may occur after the ingestion of the additive MSG (monosodium glutamate). Symptoms include burning sensations, chest and facial flushing and pain, and throbbing headaches.

**mucous** (MYOO-kus) **membranes:** the membranes, composed of mucus-secreting cells, that line the surfaces of body tissues.

**mucus** (MYOO-kus)**:** a slippery substance secreted by cells of the GI lining (and other body linings) that protects the cells from exposure to digestive juices (and other destructive agents). The lining of the GI tract with its coat of mucus is a *mucous membrane*. (The noun is *mucus;* the adjective is *mucous*.)

**muscle dysmorphia** (dis-MORE-fee-ah)**:** a psychiatric disorder characterized by a preoccupation with building body mass.

**muscle endurance:** the ability of a muscle to contract repeatedly without becoming exhausted.

**muscle power:** the product of force generation (strength) and movement velocity (speed); the speed at which a given amount of exertion is completed.

**muscle strength:** the ability of muscles to work against resistance.

**mutations:** permanent changes in the DNA that can be inherited.

**myoglobin:** the oxygen-holding protein of the muscle cells.

## N

**NAD (nicotinamide adenine dinucleotide):** the main coenzyme form of the vitamin niacin. Its reduced form is NADH.

**NADP (the phosphate form of NAD):** a coenzyme form of niacin.

**nanoceuticals:** substances with extremely small particles that have been manufactured by nanotechnology.

**nanotechnology:** a manufacturing technology that manipulates atoms to change the structure of matter.

**narcotic** (nar-KOT-ic)**:** a drug that dulls the senses, induces sleep, and becomes addictive with prolonged use.

**natural water:** water obtained from a spring or well that is certified to be safe and sanitary. The mineral content may not be changed, but the water may be treated in other ways such as with ozone or by filtration.

**naturopathic** (nay-chur-oh-PATH-ick) **medicine:** a system that taps the natural healing forces within the body by integrating several practices, including traditional medicine, herbal medicine, clinical nutrition, homeopathy, acupuncture, East Asian medicine, hydrotherapy, and manipulative therapy.

**nectar:** a sugary fluid secreted by plants to encourage pollination by insects.

**neotame** (NEE-oh-tame)**:** an artificial sweetener composed of two amino acids (phenylalanine and aspartic acid); approved for use in the United States.

**net protein utilization (NPU):** a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen eaten.

**neural tube:** the embryonic tissue that forms the brain and spinal cord.

**neural tube defects:** malformations of the brain, spinal cord, or both during embryonic development that often result in lifelong disability or death. The two main types of neural tube defects are *spina bifida* (literally "split spine") and *anencephaly* ("no brain").

**neurofibrillary tangles:** snarls of the threadlike strands that extend from the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

**neurons:** nerve cells; the structural and functional units of the nervous system. Neurons initiate and conduct nerve impulse transmissions.

**neuropeptide Y:** a chemical produced in the brain that stimulates appetite, diminishes energy expenditure, and increases fat storage.

**neurotransmitters:** chemicals that are released at the end of a nerve cell when a nerve impulse arrives there. They diffuse across the gap to the next cell and alter the membrane of that second cell to either inhibit or excite it.

**neutrophils** (NEW-tro-fills)**:** the most common of white blood cell. Neutrophils destroy antigens by phagocytosis.

**niacin** (NIGH-a-sin)**:** a B vitamin. The coenzyme forms are *NAD (nicotinamide adenine dinucleotide)* and *NADP (the phosphate form of NAD)*. Niacin can be eaten preformed or made in the body from its precursor, tryptophan, an essential amino acid.

**niacin equivalents (NE):** the amount of niacin present in food, including the niacin that can theoretically be made from its precursor, tryptophan, present in the food. 1 NE = 1 mg niacin or 60 mg tryptophan.

**niacin flush:** a temporary burning, tingling, and itching sensation that occurs when a person takes a large dose of nicotinic acid; often accompanied by a headache and reddened face, arms, and chest.

**night blindness:** slow recovery of vision after flashes of bright light at night or an inability to see in dim light; an early symptom of vitamin A deficiency.

**nitrites** (NYE-trites)**:** salts added to food to prevent botulism. One example is sodium nitrite, which is used to preserve meats.

**nitrogen balance:** the amount of nitrogen consumed (N in) as compared with the amount of nitrogen excreted (N out) in a given period of time.

**nitrosamines** (nye-TROHS-uh-meens)**:** derivatives of nitrites that may be formed in the stomach when nitrites combine with amines. Nitrosamines are carcinogenic in animals.

**nonessential amino acids:** amino acids that the body can make; also called *dispensable amino acids*.

**nonexercise activity thermogenesis (NEAT):** energy expended in everyday spontaneous activities.

**nonheme iron:** the iron in foods that is not bound to proteins; found in both plant-derived and animal-derived foods.

**nonnutritive sweeteners:** sweeteners that yield no energy (or insignificant energy in the case of aspartame).

**nucleotide bases:** the nitrogen-containing building blocks of DNA and RNA—cytosine (C), thymine (T), uracil (U), guanine (G), and adenine (A). In DNA, the base pairs are A–T and C–G and in RNA, the base pairs are A–U and C–G.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**nucleotides:** the subunits of DNA and RNA molecules, composed of a phosphate group, a 5-carbon sugar (deoxyribose for DNA and ribose for RNA), and a nitrogen-containing base.

**nucleus:** a major membrane-enclosed body within cells, which contains the cell's genetic material (DNA), embedded in chromosomes.

**nursing bottle tooth decay:** extensive tooth decay due to prolonged tooth contact with formula, milk, fruit juice, or other carbohydrate-rich liquid offered to an infant in a bottle.

**nutrient claims:** statements that characterize the quantity of a nutrient in a food.

**nutrient density:** a measure of the nutrients a food provides relative to the energy it provides. The more nutrients and the fewer kcalories, the higher the nutrient density.

**nutrient profiling:** ranking foods based on their nutrient composition.

**nutrients:** chemical substances obtained from food and used in the body to provide energy, structural materials, and regulating agents to support growth, maintenance, and repair of the body's tissues. Nutrients may also reduce the risks of some diseases.

**nutrigenetics:** the science of how genes affect the activities of nutrients.

**nutrigenomics:** the science of how nutrients affect the activities of genes.

**nutrition:** the science of the nutrients in foods and of their actions within the body. A broader definition includes the study of human behaviors related to food and eating.

**nutrition assessment:** a comprehensive analysis of a person's nutrition status that uses health, socioeconomic, drug, and diet histories; anthropometric measurements; physical examinations; and laboratory tests.

**nutrition screening:** the use of preliminary nutrition assessment techniques to identify people who are malnourished or are at risk for malnutrition.

**nutritional genomics:** the science of how nutrients affect the activities of genes (*nutrigenomics*) and how genes affect the activities of nutrients (*nutrigenetics*).

**nutritionist:** a person who specializes in the study of nutrition. Note that this definition does not specify qualifications and may apply not only to registered dietitian nutritionists but also to self-described experts whose training is questionable. Most states have licensing laws that define the scope of practice for those calling themselves nutritionists.

**nutritive sweeteners:** sweeteners that yield energy, including both sugars and sugar alcohols.

## O

**obese:** too much body fat with adverse health effects; BMI 30 or more.

**obesogenic** (oh-BES-oh-JEN-ick) **environment:** all the factors surrounding a person that promote weight gain, such as increased food intake, especially of unhealthy choices, and decreased physical activity.

**obligatory** (ah-BLIG-ah-TORE-ee) **water excretion:** the minimum amount of water the body has to excrete each day to dispose of its wastes—about 500 milliliters (about 2 cups, or 1 pint).

**oils:** lipids that are liquid at room temperature (77°F, or 25°C).

**olestra:** a synthetic fat made from sucrose and fatty acids that provides 0 kcalories per gram; also known as *sucrose polyester.*

**oligopeptide** (OL-ee-go-PEP-tide)**:** string of four to nine amino acids.

**omega:** the last letter of the Greek alphabet (ω), used by chemists to refer to the position of the closest double bond to the methyl ($CH_3$) end of a fatty acid.

**omega-3 fatty acid:** a polyunsaturated fatty acid in which the closest double bond to the methyl ($CH_3$) end of the carbon chain is three carbons away.

**omega-6 fatty acid:** a polyunsaturated fatty acid in which the closest double bond to the methyl ($CH_3$) end of the carbon chain is six carbons away.

**omnivorous:** an eating pattern that includes foods derived from both animals and plants.

**opsin** (OP-sin): the protein portion of visual pigment molecules.

**oral rehydration therapy (ORT):** the administration of a simple solution of sugar, salt, and water, taken by mouth, to treat dehydration caused by diarrhea.

**organelles:** subcellular structures such as ribosomes, mitochondria, and lysosomes.

**organic:** in agriculture, crops grown and processed according to USDA regulations defining the use of fertilizers, herbicides, insecticides, fungicides, preservatives, and other chemical ingredients.

**organic:** in chemistry, substances or molecules containing carbon-carbon bonds or carbon-hydrogen bonds that are characteristic of living organisms. The four classes of nutrients that are organic are carbohydrates, lipids (fats), proteins, and vitamins.

**organic:** on food labels, that at least 95 percent of the product's ingredients have been grown and processed according to USDA regulations defining the use of fertilizers, herbicides, insecticides, fungicides, preservatives, and other chemical ingredients.

**organic halogens:** an organic compound containing one or more atoms of a halogen—fluorine, chlorine, iodine, or bromine.

**orthomolecular medicine:** the use of large doses of vitamins to treat chronic disease.

**osmosis:** the movement of water across a membrane *toward* the side where the solutes are more concentrated.

**osmotic pressure:** the amount of pressure needed to prevent the movement of water across a membrane.

**osteoarthritis:** a painful, degenerative disease of the joints that occurs when the cartilage in a joint deteriorates; joint structure is damaged, with loss of function; also called *degenerative arthritis.*

**osteoblasts:** cells that build bone during growth.

**osteocalcin** (os-teo-KAL-sen)**:** a calcium-binding protein in bones, essential for normal mineralization.

**osteoclasts:** cells that destroy bone during growth.

**osteomalacia** (OS-tee-oh-ma-LAY-shuh)**:** a bone disease characterized by softening of the bones. Symptoms include bending of the spine and bowing of the legs. The disease occurs most often in adult women.

**osteoporosis** (OS-tee-oh-pore-OH-sis)**:** a disease in which the bones become porous and fragile due to a loss of minerals; also called *adult bone loss.*

**outbreaks:** two or more cases of a similar illness resulting from the ingestion of a common food.

**overload:** an extra physical demand placed on the body; an increase in the frequency, duration, or intensity of an activity. A principle of training that states for a body system to improve, it must be worked at frequencies, durations, or intensities that increase by increments.

**overnutrition:** excess energy or nutrients.

**overt** (oh-VERT)**:** out in the open and easy to observe.

**overweight:** body weight greater than the weight range that is considered healthy; BMI 25 to 29.9.

**ovum** (OH-vum)**:** the female reproductive cell, capable of developing into a new organism upon fertilization; commonly referred to as an egg.

**oxaloacetate** (OKS-ah-low-AS-eh-tate)**:** a carbohydrate intermediate of the TCA cycle.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**oxidants** (OKS-ih-dants)**:** compounds (such as oxygen itself) that oxidize other compounds. Compounds that prevent oxidation are called *antioxidants*, whereas those that promote it are called *prooxidants*.

**oxidation** (OKS-ee-DAY-shun)**:** the process of a substance combining with oxygen; oxidation reactions involve the loss of electrons.

**oxidative stress:** a condition in which the production of oxidants and free radicals exceeds the body's ability to handle them and prevent damage.

**oxytocin** (OCK-see-TOH-sin)**:** a hormone that stimulates the mammary glands to eject milk during lactation and the uterus to contract during childbirth.

**oyster shell:** a product made from the powdered shells of oysters that is sold as a calcium supplement, but it is not well absorbed by the digestive system.

**ozone therapy:** the use of ozone gas to enhance the body's immune system.

## P

**pancreas:** a gland that secretes digestive enzymes and juices into the duodenum. (The pancreas also secretes hormones into the blood that help to maintain glucose homeostasis.)

**pancreatic** (pank-ree-AT-ic) **juice:** the exocrine secretion of the pancreas that contains enzymes for the digestion of carbohydrate, fat, and protein as well as bicarbonate, a neutralizing agent. The juice flows from the pancreas into the small intestine through the pancreatic duct. (The pancreas also has an endocrine function, the secretion of insulin and other hormones.)

**pantothenic** (PAN-toe-THEN-ick) **acid:** a B vitamin. The principal active form is part of coenzyme A, called "CoA" throughout Chapter 7.

**parasympathetic nervous system:** the part of the autonomic nervous system that dominates during nonstressful conditions and includes such effects as normal heart rate, pupil dilation, and peristalsis.

**parathyroid hormone:** a hormone from the parathyroid glands that regulates blood calcium by raising it when levels fall too low; also known as *parathormone* (PAIR-ah-THOR-moan).

**pasteurization:** heat processing of food that inactivates some, but not all, microorganisms in the food; not a sterilization process. Bacteria that cause spoilage are still present.

**pathogens** (PATH-oh-jenz)**:** microorganisms capable of producing disease.

**PBB (polybrominated biphenyl)** and **PCB (polychlorinated biphenyl):** toxic organic halogens used in pesticides, paints, and flame retardants.

**PDCAAS (protein digestibility–corrected amino acid score):** a measure of protein quality assessed by comparing the amino acid score of a food protein with the amino acid requirements of preschool-age children and then correcting for the true digestibility of the protein.

**peak bone mass:** the highest attainable bone density for an individual, developed during the first three decades of life.

**peer review:** a process in which a panel of scientists rigorously evaluates a research study to ensure that the scientific method was followed.

**pellagra** (pell-AY-gra)**:** the niacin-deficiency disease, characterized by diarrhea, dermatitis, dementia, and eventually death.

**pepsin:** a gastric enzyme that hydrolyzes protein. Pepsin is secreted in an inactive form, *pepsinogen*, which is activated by hydrochloric acid in the stomach.

**pepsinogen:** an inactive compound that is activated by hydrochloric acid in the stomach to form pepsin.

**peptic ulcer:** a lesion in the mucous membrane of either the stomach (a *gastric ulcer*) or the duodenum (a *duodenal ulcer*).

**peptidase:** a digestive enzyme that hydrolyzes peptide bonds. *Tripeptidases* cleave tripeptides; *dipeptidases* cleave dipeptides.

**peptide bond:** a bond that connects the acid end of one amino acid with the amino end of another, forming a link in a protein chain.

**percent Daily Value (%DV):** the percentage of a Daily Value recommendation found in a specified serving of food for key nutrients based on a 2000-kcalorie diet.

**percent fat-free:** may be used only if the product meets the definition of *low fat* or *fat-free* and must reflect the amount of fat in 100 grams (for example, a food that contains 2.5 grams of fat per 50 grams can claim to be "95 percent fat-free").

**perinatal:** referring to the time between the twenty-eighth week of gestation and 1 month after birth.

**peripheral** (puh-RIFF-er-ul) **nervous system:** the peripheral (outermost) part of the nervous system; the vast complex of wiring that extends from the central nervous system to the body's outermost areas. It contains both *somatic* and *autonomic* components.

**peripheral resistance:** the resistance to pumped blood in the small arterial branches (arterioles) that carry blood to the tissues.

**peristalsis** (per-ih-STALL-sis)**:** wavelike muscular contractions of the GI tract that push its contents along.

**pernicious** (per-NISH-us) **anemia:** a blood disorder that reflects a vitamin $B_{12}$ deficiency caused by lack of intrinsic factor and characterized by abnormally large and immature red blood cells. Other symptoms include muscle weakness and irreversible neurological damage.

**persistence:** stubborn or enduring continuance; with respect to food contaminants, the quality of persisting, rather than breaking down, in the bodies of animals and human beings.

**personal and social history:** a record of a person's economic and social background, including such factors as education, income, and ethnic identity.

**pesticides:** chemicals used to control insects, weeds, fungi, and other pests on plants, vegetables, fruits, and animals. Used broadly, the term includes herbicides (to kill weeds), insecticides (to kill insects), and fungicides (to kill fungi).

**pH:** the unit of measure expressing a substance's acidity or alkalinity. The lower the pH, the higher the $H^+$ ion concentration and the stronger the acid. A pH above 7 is alkaline, or base (a solution in which $OH^-$ ions predominate).

**phagocytes** (FAG-oh-sites)**:** white blood cells (neutrophils and macrophages) that have the ability to ingest and destroy foreign substances.

**phagocytosis** (FAG-oh-sigh-TOH-sis)**:** the process by which phagocytes engulf and destroy foreign materials.

**pharmacological effect:** the body's response to a large dose of a nutrient (levels commonly available only from supplements) that overwhelms some body system and acts like a drug.

**pharynx** (FAIR-inks)**:** the passageway leading from the nose and mouth to the larynx and esophagus, respectively.

**phenylketonuria** (FEN-il-KEY-toe-NEW-ree-ah) or **PKU:** an inherited disorder characterized by failure to metabolize the amino acid phenylalanine to tyrosine.

**phlebotomy:** the withdrawal of blood from the body.

**phosphocreatine (PC):** a high-energy compound in muscle cells that acts as a reservoir of energy that can maintain a steady supply of ATP and provides the energy for short bursts of activity; also called *creatine phosphate (CP)*.

**phospholipid** (FOS-foe-LIP-id)**:** a compound similar to a triglyceride but having a phosphate group (a phosphorus-containing salt) and choline (or another nitrogen-containing compound) in place of one of the fatty acids.

**phosphorus:** a major mineral found mostly in the body's bones and teeth.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**photosynthesis:** the process by which green plants use the sun's energy to make carbohydrates from carbon dioxide and water.

**phylloquinone** (FILL-oh-KWYN-own)**:** the plant form of vitamin K; also called *vitamin* $K_1$.

**physical activity:** bodily movement produced by muscle contractions that substantially increase energy expenditure.

**physiological age:** a person's age as estimated from her or his body's health and probable life expectancy.

**physiological effect:** the body's response to a normal dose of a nutrient (levels commonly found in foods) that provides a normal blood concentration.

**physiological fuel value:** the number of kcalories that the body derives from a food, in contrast to the number of kcalories determined by calorimetry.

**phytic** (FYE-tick) **acid:** a nonnutrient component of plant seeds; also called *phytate* (FYE-tate). Phytic acid occurs in the husks of grains, legumes, and seeds and is capable of binding minerals such as zinc, iron, calcium, magnesium, and copper in insoluble complexes in the intestine, which the body excretes unused.

**phytochemicals** (FIE-toe-KEM-ih-cals)**:** nonnutrient compounds found in plants. Some phytochemicals have biological activity in the body.

**phytoestrogens:** phytochemicals structurally similar to human estrogen that weakly mimic or modulate estrogen's action in the body. Phytoestrogens include the isoflavones *genistein*, *daidzein,* and *glycitein*.

**pica** (PIE-ka)**:** a craving for and consumption of nonfood substances. Pica is known as *geophagia* (gee-oh-FAY-gee-uh) when referring to eating clay, baby powder, chalk, ash, ceramics, paper, paint chips, or charcoal; *pagophagia* (pag-oh-FAY-gee-uh) when referring to eating large quantities of ice; and *amylophagia* (AM-ee-low-FAY-gee-ah) when referring to eating uncooked starch (flour, laundry starch, or raw rice).

**pigment:** a molecule capable of absorbing certain wavelengths of light so that it reflects only those that we perceive as a certain color.

**placebo** (pla-SEE-bo)**:** an inert, harmless medication given to provide comfort and hope; a sham treatment used in controlled research studies.

**placebo effect:** a change that occurs in response to expectations about the effectiveness of a treatment that actually has no pharmaceutical effects.

**placenta** (plah-SEN-tuh)**:** the organ that develops inside the uterus early in pregnancy, through which the fetus receives nutrients and oxygen and returns carbon dioxide and other waste products to be excreted.

**plant-based diets:** an eating pattern that derives most of its protein from plant products (although some animal products may be included).

**plant-pesticides:** pesticides made by the plants themselves.

**plant sterols:** phytochemicals that have structural similarities to cholesterol and lower blood cholesterol by interfering with cholesterol absorption. Plant sterols include *sterol esters* and *stanol esters.*

**plaque** (PLACK)**:** an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue that develops in the artery walls in atherosclerosis. Plaque associated with atherosclerosis is known as *atheromatous* (ATH-er-OH-ma-tus) *plaque.*

**platelets:** tiny, disc-shaped bodies in the blood, important in blood clot formation.

**PLP (pyridoxal phosphate):** the primary active coenzyme form of vitamin $B_6$.

**point of unsaturation:** the double bond of a fatty acid, where hydrogen atoms can easily be added to the structure.

**polar:** characteristic of a neutral molecule, such as water, that has opposite charges spatially separated within the molecule.

**polypeptide:** many (10 or more) amino acids bonded together.

**polysaccharides:** compounds composed of many monosaccharides linked together. An intermediate string of 3 to 10 monosaccharides is an *oligosaccharide.*

**polyunsaturated fatty acid:** a fatty acid that lacks four or more hydrogen atoms and has two or more double bonds between carbons; abbreviated *PUFA*. Examples include linoleic acid (two double bonds) and linolenic acid (three double bonds). A *polyunsaturated fat* is composed of triglycerides in which most of the fatty acids are polyunsaturated.

**portion sizes:** the quantity of a food served or eaten at one meal or snack; *not* a standard amount.

**postpartum amenorrhea** (ay-MEN-oh-REE-ah)**:** the normal temporary absence of menstrual periods immediately following childbirth.

**potable** (POT-ah-bul)**:** suitable for drinking.

**potassium:** the principal cation within the body's cells; critical to the maintenance of fluid balance, nerve impulse transmissions, and muscle contractions.

**powdered bone:** crushed or ground bone preparations intended to supply calcium to the diet. Calcium from bone is not well absorbed and is often contaminated with toxic minerals such as arsenic, mercury, lead, and cadmium.

**prebiotics:** food components (such as fibers) that are not digested by the human body but are used as food by the GI bacteria to promote their growth and activity.

**precursors:** substances that precede others; with regard to vitamins, compounds that can be converted into active vitamins; also known as *provitamins.*

**prediabetes:** condition in which blood glucose levels are higher than normal, but below the diagnosis of diabetes; formerly called *impaired glucose tolerance.* Prediabetes is considered a major risk factor for future diabetes and cardiovascular diseases.

**preeclampsia** (PRE-ee-KLAMP-see-ah)**:** a condition characterized by high blood pressure and some protein in the urine.

**preformed vitamin A:** dietary vitamin A in its active form.

**prehypertension:** slightly higher-than-normal blood pressure, but not as high as hypertension.

**prenatal alcohol exposure:** subjecting a fetus to a pattern of excessive alcohol intake characterized by substantial regular use or heavy episodic drinking.

**preservatives:** antimicrobial agents, antioxidants, and other additives that retard spoilage or maintain desired qualities, such as softness in baked goods.

**pressure ulcers:** damage to the skin and underlying tissues as a result of compression and poor circulation; commonly seen in people who are bedridden or chair-bound.

**preterm (premature):** births occurring before 37 weeks of gestation; births occurring at 37 to 38 weeks of gestation are designated *early term.*

**primary deficiency:** a nutrient deficiency caused by inadequate dietary intake of a nutrient.

**probiotics:** living microorganisms found in foods and dietary supplements that, when consumed in sufficient quantities, are beneficial to health.

**processed foods:** foods that have been treated to change their physical, chemical, microbiological, or sensory properties.

**proenzyme:** the inactive form of an enzyme; also called a *zymogen.*

**progesterone:** the hormone of gestation (pregnancy).

**prolactin** (pro-LAK-tin)**:** a hormone secreted from the anterior pituitary gland that acts on the mammary glands to promote the production of milk. The release of prolactin is mediated by *prolactin-inhibiting hormone (PIH).*

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**promoters:** factors that favor the development of cancers once they have begun.

**proof:** a way of stating the percentage of alcohol in distilled liquor. Liquor that is 100 proof is 50 percent alcohol; 90 proof is 45 percent, and so forth.

**prooxidants:** substances that significantly induce oxidative stress.

**proteases** (PRO-tee-aces)**:** enzymes that hydrolyze proteins.

**protein digestibility:** a measure of the amount of amino acids absorbed from a given protein intake.

**protein efficiency ratio (PER):** a measure of protein quality assessed by determining how well a given protein supports weight gain in growing rats; used to establish the protein quality for infant formulas and baby foods.

**protein turnover:** the degradation and synthesis of protein.

**protein-sparing action:** the action of carbohydrate (and fat) in providing energy that allows protein to be used for other purposes.

**proteins:** compounds composed of carbon, hydrogen, oxygen, and nitrogen atoms, arranged into amino acids linked in a chain. Some amino acids also contain sulfur atoms.

**proteome:** all proteins in a cell. The study of all proteins produced by a species is called *proteomics*.

**puberty:** the period in life in which a person becomes physically capable of reproduction.

**public health dietitians:** dietitians who specialize in providing nutrition services through organized community efforts.

**public water:** water from a municipal or county water system that has been treated and disinfected.

**purified water:** water that has been treated by distillation or other physical or chemical processes that remove dissolved solids. Because purified water contains no minerals or contaminants, it is useful for medical and research purposes.

**purines:** compounds of nitrogen-containing bases such as adenine, guanine, and caffeine. Purines that originate from the body are *endogenous* and those that derive from foods are *exogenous*.

**pyloric** (pie-LORE-ic) **sphincter:** the circular muscle that separates the stomach from the small intestine and regulates the flow of partially digested food into the small intestine; also called *pylorus* or *pyloric valve*.

**pyruvate** (PIE-roo-vate)**:** a 3-carbon compound that plays a key role in energy metabolism.

## Q

**qi gong** (chée GUNG)**:** a Chinese system that combines movement, meditation, and breathing techniques to enhance the flow of *qi* (vital energy) in the body.

**quality of life:** a person's perceived physical and mental well-being.

## R

**rachitic** (ra-KIT-ik) **rosary:** the poorly formed rib attachments that may develop in a vitamin D deficiency; literally, "the rosary of rickets."

**radura:** an international symbol used to identify retail foods that have been irradiated.

**randomization** (RAN-dom-ih-ZAY-shun)**:** a process of choosing the members of the experimental and control groups without bias.

**raw sugar:** the first crop of crystals harvested during sugar processing. Raw sugar cannot be sold in the United States because it contains too much filth (dirt, insect fragments, and the like). Sugar sold as "raw sugar" domestically has actually gone through more than half of the refining steps.

**RDN:** see *registered dietitian nutritionist*.

**Recommended Dietary Allowance (RDA):** the average daily amount of a nutrient considered adequate to meet the known nutrient needs of practically all healthy people; a goal for dietary intake by individuals.

**rectum:** the muscular terminal part of the intestine, extending from the sigmoid colon to the anus.

**reduced kcalorie:** at least 25 percent fewer kcalories per serving than the comparison food.

**reference protein:** a standard against which to measure the quality of other proteins.

**refined:** the process by which the coarse parts of a food are removed. When wheat is refined into flour, the bran, germ, and husk are removed, leaving only the endosperm.

**refined flour:** finely ground endosperm that is usually enriched with nutrients and bleached for whiteness; sometimes called *white flour*.

**reflux:** a backward flow.

**registered dietitian (RD):** an alternative term for an RDN.

**registered dietitian nutritionist (RDN):** a person who has completed a minimum of a bachelor's degree from an accredited university or college, has completed approved course work and a supervised practice program, has passed a national examination, and maintains registration through continuing professional education; also called *registered dietitian (RD)*.

**registration:** listing; with respect to health professionals, listing with a professional organization that requires specific course work, experience, and passing of an examination.

**relaxin:** the hormone of late pregnancy.

**remodeling:** the dismantling and re-formation of a structure.

**renin** (REN-in)**:** an enzyme from the kidneys that hydrolyzes the protein angiotensinogen to angiotensin I, which results in the kidneys reabsorbing sodium.

**rennin:** an enzyme that coagulates milk; found in the gastric juice of cows, but not human beings.

**replication** (REP-lih-KAY-shun)**:** repeating an experiment and getting the same results.

**requirement:** the lowest continuing intake of a nutrient that will maintain a specified criterion of adequacy.

**residues:** whatever remains. In the case of pesticides, those amounts that remain on or in foods when people buy and use them.

**resistance training:** the use of free weights or weight machines to provide resistance for developing muscle strength, power, and endurance; also called *weight training*. A person's own body weight may also be used to provide resistance such as when a person does push-ups, pull-ups, or abdominal crunches.

**resistant starches:** starches that escape digestion and absorption in the small intestine of healthy people.

**resistin** (ree-ZIS-tin)**:** a protein produced by adipose cells that promotes inflammation and causes insulin resistance.

**respiratory chain:** the final pathway in energy metabolism that transports electrons from hydrogen to oxygen and captures the energy released in the bonds of ATP; also called the *electron transport chain*.

**resting metabolic rate (RMR):** similar to the basal metabolic rate (BMR), a measure of the energy use of a person at rest in a comfortable setting, but with less stringent criteria for recent food intake and physical activity. Consequently, the RMR is slightly higher than the BMR.

**retina** (RET-in-uh)**:** the innermost membrane of the eye, composed of several layers, including one that contains the rods and cones.

**retinal** (RET-ih-nal)**:** the aldehyde form of vitamin A.

**retinoic** (RET-ih-NO-ick) **acid:** the acid form of vitamin A.

**retinoids** (RET-ih-noyds)**:** chemically related compounds with biological activity similar to that of retinol; metabolites of retinol.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**retinol** (RET-ih-nol)**:** the alcohol form of vitamin A.

**retinol activity equivalents (RAE):** a measure of vitamin A activity; the amount of retinol that the body will derive from a food containing preformed retinol or its precursor, beta-carotene.

**retinol-binding protein (RBP):** the specific protein responsible for transporting retinol.

**rheumatoid** (ROO-ma-toyd) **arthritis:** a disease of the immune system involving painful inflammation of the joints and related structures.

**rhodopsin** (ro-DOP-sin)**:** a light-sensitive pigment of the retina that contains the retinal form of vitamin A and the protein opsin.

**riboflavin** (RYE-boh-flay-vin)**:** a B vitamin. The coenzyme forms are *FMN (flavin mononucleotide)* and *FAD (flavin adenine dinucleotide)*.

**ribose:** a naturally occurring 5-carbon sugar needed for the synthesis of ATP.

**ribosomes** (RYE-boh-zomes)**:** protein-making organelles in cells that are composed of RNA and protein.

**rickets:** the vitamin D–deficiency disease in children characterized by inadequate mineralization of bone (manifested in bowed legs or knock-knees, outward-bowed chest, and "beads" on ribs). A rare type of rickets, not caused by vitamin D deficiency, is known as *vitamin D–refractory rickets*.

**risk:** a measure of the probability and severity of harm.

**risk factor:** a condition or behavior associated with an elevated frequency of a disease but not proved to be causal. Leading risk factors for chronic diseases include obesity, cigarette smoking, high blood pressure, high blood cholesterol, physical inactivity, and a diet high in saturated fats and low in vegetables, fruits, and whole grains.

**RNA (ribonucleic acid):** a compound similar to DNA, but RNA is a single strand with a ribose sugar instead of a deoxyribose sugar and uracil instead of thymine as one of its bases.

## S

**safety:** the condition of being free from harm or danger.

**saliva:** the secretion of the salivary glands. Its principal enzyme begins carbohydrate digestion.

**salivary glands:** exocrine glands that secrete saliva into the mouth.

**salt:** a compound composed of a positive ion other than $H^+$ and a negative ion other than $OH^-$. An example is sodium chloride ($Na^+Cl^-$).

**sarcopenia** (SAR-koh-PEE-nee-ah)**:** loss of skeletal muscle mass, strength, and quality.

**satiating:** having the power to suppress hunger and inhibit eating.

**satiation** (say-she-AY-shun)**:** the feeling of satisfaction and fullness that occurs during a meal and halts eating. Satiation determines how much food is consumed during a meal.

**satiety** (sah-TIE-eh-tee)**:** the feeling of fullness and satisfaction that occurs after a meal and inhibits eating until the next meal. Satiety determines how much time passes between meals.

**saturated fat-free:** less than 0.5 gram of saturated fat and 0.5 gram of *trans* fat per serving.

**saturated fatty acid:** a fatty acid carrying the maximum possible number of hydrogen atoms—for example, stearic acid. A *saturated fat* is composed of triglycerides in which most of the fatty acids are saturated.

**scurvy:** the vitamin C–deficiency disease.

**secondary deficiency:** a nutrient deficiency caused by something other than an inadequate intake such as a disease condition or drug interaction that reduces absorption, accelerates use, hastens excretion, or destroys the nutrient.

**secretin** (see-CREET-in)**:** a hormone produced by cells in the duodenum wall. Target organ: the pancreas. Response: secretion of bicarbonate-rich pancreatic juice.

**sedentary:** physically inactive (literally, "sitting down a lot").

**segmentation** (SEG-men-TAY-shun)**:** a periodic squeezing or partitioning of the intestine at intervals along its length by its circular muscles.

**selenium** (se-LEEN-ee-um)**:** an essential trace mineral that is part of an antioxidant enzyme.

**senile dementia:** the loss of brain function beyond the normal loss of physical adeptness and memory that occurs with aging.

**senile plaques:** clumps of the protein fragment beta-amyloid on the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

**serotonin** (SER-oh-TONE-in)**:** a neurotransmitter important in sleep regulation, appetite control, and sensory perception, among other roles. Serotonin is synthesized in the body from the amino acid tryptophan with the help of vitamin $B_6$.

**serving sizes:** the standardized quantity of a food; such information allows comparisons when reading food labels and consistency when following the *Dietary Guidelines*.

**set point:** the point at which controls are set (for example, on a thermostat). The set-point theory that relates to body weight proposes that the body tends to maintain a certain weight by means of its own internal controls.

**sickle-cell anemia:** a hereditary form of anemia characterized by abnormal sickle- or crescent-shaped red blood cells. Sickled cells interfere with oxygen transport and blood flow. Symptoms are precipitated by dehydration and insufficient oxygen (as may occur at high altitudes) and include hemolytic anemia (red blood cells burst), fever, and severe pain in the joints and abdomen.

**simple carbohydrates:** monosaccharides and disaccharides (the sugars).

**small for gestational age (SGA):** term describing an infant whose birthweight is low compared with the number of weeks in utero, often reflecting growth failure.

**small intestine:** a 10-foot length of small-diameter intestine that is the major site of digestion of food and absorption of nutrients. Its segments are the *duodenum*, *jejunum*, and *ileum*.

**sodium:** the principal cation in the extracellular fluids of the body; critical to the maintenance of fluid balance, nerve impulse transmissions, and muscle contractions.

**sodium bicarbonate (baking soda):** a white crystalline powder that is used to buffer acid that accumulates in the muscles and blood during high-intensity exercise.

**sodium-free** and **salt-free:** less than 5 milligrams of sodium per serving.

**soft water:** water with a high sodium or potassium content.

**solanine** (SOH-lah-neen)**:** a poisonous narcotic-like substance present in potato skins and sprouts.

**solid fats:** fats that are not usually liquid at room temperature; commonly found in most foods derived from animals and vegetable oils that have been hydrogenated. Solid fats typically contain more saturated and *trans* fats than most oils.

**soluble fibers:** nonstarch polysaccharides that dissolve in water to form a gel. An example is pectin from fruit, which is used to thicken jellies.

**solutes** (SOLL-yutes)**:** the substances that are dissolved in a solution. The number of molecules in a given volume of fluid is the *solute concentration*.

**somatic** (so-MAT-ick) **nervous system:** the division of the nervous system that controls the voluntary muscles, as distinguished from the autonomic nervous system, which controls involuntary functions.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**somatostatin (GHIH):** a hormone that inhibits the release of growth hormone; the opposite of *somatotropin (GH)*.

**sperm:** the male reproductive cell, capable of fertilizing an ovum.

**sphincter** (SFINK-ter)**:** a circular muscle surrounding, and able to close, a body opening. Sphincters are found at specific points along the GI tract and regulate the flow of food particles.

**spina** (SPY-nah) **bifida** (BIFF-ih-dah)**:** one of the most common types of neural tube defects, characterized by the incomplete closure of the spinal cord and its bony encasement.

**sports anemia:** a transient condition of low hemoglobin in the blood, associated with the early stages of sports training or other strenuous activity.

**spring water:** water originating from an underground spring or well. It may be bubbly (carbonated), or "flat" or "still," meaning not carbonated. Brand names such as "Spring Pure" do not necessarily mean that the water comes from a spring.

**starches:** plant polysaccharides composed of many glucose molecules.

**sterile:** free of microorganisms, such as bacteria.

**sterols** (STARE-ols or STEER-ols)**:** compounds containing a four-ring carbon structure with any of a variety of side chains attached.

**stomach:** a muscular, elastic, saclike portion of the digestive tract that grinds and churns swallowed food, mixing it with acid and enzymes to form chyme.

**stools:** waste matter discharged from the colon; also called *feces* (FEE-seez).

**stress:** any threat to a person's well-being; a demand placed on the body to adapt.

**stress fractures:** bone damage or breaks caused by stress on bone surfaces during exercise.

**stress response:** the body's response to stress, mediated by both nerves and hormones.

**stressors:** environmental elements, physical or psychological, that cause stress.

**stroke:** an event in which the blood flow to a part of the brain is cut off; also called *cerebrovascular accident (CVA)*.

**structure-function claims:** statements that characterize the relationship between a nutrient or other substance in a food and its role in the body.

**subclavian** (sub-KLAY-vee-an) **vein:** the vein that provides passageway from the lymphatic system to the vascular system.

**subclinical deficiency:** a deficiency in the early stages, before the outward signs have appeared.

**subcutaneous fat:** fat stored directly under the skin.

**subjects:** the people or animals participating in a research project.

**successful weight-loss maintenance:** achieving a weight loss of at least 5 to 10 percent of initial body weight and maintaining the loss for at least 1 year.

**sucrase:** an enzyme that hydrolyzes sucrose.

**sucrose** (SUE-krose)**:** a disaccharide composed of glucose and fructose; commonly known as *table sugar, beet sugar,* or *cane sugar.* Sucrose also occurs in many fruits and some vegetables and grains.

**sudden infant death syndrome (SIDS):** the unexpected and unexplained death of an apparently well infant; the most common cause of death of infants between the second week and the end of the first year of life; also called *crib death*.

**sugar alcohols:** sugarlike compounds that can be derived from fruits or commercially produced from dextrose; also called *polyols*. Examples include *erythritol, isomalt, lactitol, maltitol, mannitol, sorbitol,* and *xylitol.*

**sugar-free:** less than 0.5 gram of sugar per serving.

**sugars:** simple carbohydrates composed of monosaccharides, disaccharides, or both.

**sulfate:** a salt produced from the oxidation of sulfur.

**sulfites:** salts containing sulfur that are added to foods to prevent spoilage.

**sulfur:** a mineral present in the body as part of some proteins.

**sushi:** vinegar-flavored rice and seafood, typically wrapped in seaweed and stuffed with colorful vegetables. Some sushi is stuffed with raw fish; other varieties contain cooked seafood.

**sustainable:** able to continue indefinitely; using resources at such a rate that the earth can keep on replacing them and producing pollutants at a rate with which the environment and human cleanup efforts can keep pace, so that no net accumulation of pollution occurs.

**sustainable agriculture:** ability to produce food indefinitely, with little or no harm to the environment.

**sympathetic nervous system:** the part of the autonomic nervous system that dominates during stressful conditions and includes such effects as increased heart rate, dilated pupils, slowed peristalsis, and secretion of epinephrine and norepinephrine.

**symptomatic allergy:** an immune response that produces antibodies and symptoms.

**synergistic** (SIN-er-JIS-tick)**:** multiple factors operating together in such a way that their combined effects are greater than the sum of their individual effects.

## T

**tagatose** (TAG-ah-tose)**:** poorly absorbed monosaccharide similar in structure to fructose; naturally occurring or derived from lactose.

**TCA cycle** or **tricarboxylic** (try-car-box-ILL-ick) **acid cycle:** a series of metabolic reactions that break down molecules of acetyl CoA to carbon dioxide and hydrogen atoms; also called the *citric acid cycle* or the *Krebs cycle* after the biochemist who elucidated its reactions.

**T-cells:** lymphocytes that attack antigens. *T* stands for the *thymus gland,* where the T-cells mature.

**tempeh** (TEM-pay)**:** a fermented soybean food, rich in protein and fiber.

**teratogen** (ter-AT-oh-jen)**:** a substance that causes abnormal fetal development and birth defects.

**teratogenic** (ter-AT-oh-jen-ik)**:** causing abnormal fetal development and birth defects.

**testosterone:** a steroid hormone from the testicles, or testes. The steroids are chemically related to, and some are derived from, the lipid cholesterol.

**textured vegetable protein:** processed soybean protein used in vegetarian products such as soy burgers.

**theory:** a tentative explanation that integrates many and diverse findings to further the understanding of a defined topic.

**thermic effect of food (TEF):** an estimation of the energy required to process food (digest, absorb, transport, metabolize, and store ingested nutrients); also called the *specific dynamic effect (SDE)* of food or the *specific dynamic activity (SDA)* of food. The sum of the TEF and any increase in the metabolic rate due to overeating is known as *diet-induced thermogenesis (DIT)*.

**thermogenesis:** the generation of heat; used in physiology and nutrition studies as an index of how much energy the body is expending.

**THF (tetrahydrofolate):** a coenzyme form of folate.

**thiamin** (THIGH-ah-min)**:** a B vitamin. The coenzyme form is *TPP (thiamin pyrophosphate)*.

**thirst:** a conscious desire to drink.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**thoracic** (thor-ASS-ic) **duct:** the main lymphatic vessel that collects lymph and drains into the left subclavian vein.

**thrombosis** (throm-BOH-sis)**:** the formation of a *thrombus* (THROM-bus), or a blood clot, that may obstruct a blood vessel, causing gradual tissue death.

**thyroid-stimulating hormone (TSH):** a hormone secreted by the pituitary that stimulates the thyroid gland to secrete its hormones—thyroxine and triiodothyronine. The release of TSH is mediated by *TSH-releasing hormone (TRH)*.

**thyrotropin:** another name for thyroid-stimulating hormone (TSH).

**tocopherols** (tuh-KOFF-uh-rawls)**:** members of the vitamin E family having the chemical structure of a complex ring structure with a long saturated side chain.

**tocotrienols** (TOE-koh-try-EE-nawls): members of the vitamin E family having the chemical structure of a complex ring structure with a long unsaturated side chain.

**tofu** (TOE-foo)**:** a curd made from soybeans, rich in protein and often fortified with calcium; used in many Asian and vegetarian dishes in place of meat.

**Tolerable Upper Intake Level (UL):** the maximum daily amount of a nutrient that appears safe for most healthy people and beyond which there is an increased risk of adverse health effects.

**tolerance level:** the maximum amount of residue permitted in a food when a pesticide is used according to the label directions.

**toxicity:** the ability of a substance to harm living organisms. All substances are toxic if high enough concentrations are used.

**TPP (thiamin pyrophosphate):** the coenzyme form of thiamin.

**trabecular** (tra-BECK-you-lar) **bone:** the lacy inner structure of calcium crystals that supports the bone's structure and provides a calcium storage bank.

**trace minerals:** essential mineral nutrients the human body requires in relatively small amounts (less than 100 milligrams per day); sometimes called *microminerals*.

**trachea** (TRAKE-ee-uh)**:** the air passageway from the larynx to the lungs; also called the *windpipe*.

***trans*:** on the other side of; refers to a chemical configuration in which the hydrogen atoms are located on opposite sides of a double bond.

***trans* fat-free:** less than 0.5 gram of *trans* fat and less than 0.5 gram of saturated fat per serving.

**transamination** (TRANS-am-ih-NAY-shun)**:** the transfer of an amino group from one amino acid to a keto acid, producing a new nonessential amino acid and a new keto acid.

**transcription:** the process of messenger RNA being made from a template of DNA.

**transcription factors:** proteins that bind to specific sites in DNA and alter gene expression.

***trans*-fatty acids:** fatty acids with hydrogens on opposite sides of the double bond.

**transferrin** (trans-FAIR-in)**:** the iron transport protein.

**transient ischemic** (is-KEY-mik) **attack (TIA):** a temporary reduction in blood flow to the brain, which causes temporary symptoms that vary depending on the part of the brain affected. Common symptoms include light-headedness, visual disturbances, paralysis, staggering, numbness, and inability to swallow.

**translation:** the process of messenger RNA directing the sequence of amino acids and synthesis of proteins.

**travelers' diarrhea:** nausea, vomiting, and diarrhea caused by consuming food or water contaminated by any of several organisms, most commonly, *E. coli*, *Shigella*, *Campylobacter jejuni*, and *Salmonella*.

**triglycerides** (try-GLISS-er-rides)**:** the chief form of fat in the diet and the major storage form of fat in the body; composed of a molecule of glycerol with three fatty acids attached; also called *triacylglycerols* (try-ay-seel-GLISS-er-ols).

**tripeptide:** three amino acids bonded together.

**tumor:** an abnormal tissue mass with no physiological function; also called a *neoplasm* (NEE-oh-plazm).

**turbinado** (ter-bih-NOD-oh) **sugar:** sugar produced using the same refining process as white sugar, but without the bleaching and anticaking treatment. Traces of molasses give turbinado its sandy color.

**type 1 diabetes:** the less common type of diabetes in which the pancreas produces little to no insulin. Type 1 diabetes usually results from autoimmune destruction of pancreatic beta cells.

**type 2 diabetes:** the more common type of diabetes in which the cells fail to respond to insulin. Type 2 diabetes usually accompanies obesity and results from insulin resistance coupled with insufficient insulin secretion.

## U

**ulcer:** a lesion of the skin or mucous membranes characterized by inflammation and damaged tissues. See also *peptic ulcer*.

**ultrahigh temperature (UHT) treatment:** sterilizing a food by brief exposure to temperatures above those normally used.

**umbilical** (um-BILL-ih-cul) **cord:** the ropelike structure through which the fetus's veins and arteries reach the placenta; the route of nourishment and oxygen to the fetus and the route of waste disposal from the fetus. The scar in the middle of the abdomen that marks the former attachment of the umbilical cord is the *umbilicus* (um-BILL-ih-cus), commonly known as the "belly button."

**uncoupled reactions:** chemical reactions in which energy is released as heat.

**undernutrition:** deficient energy or nutrients.

**underweight:** body weight lower than the weight range that is considered healthy; BMI less than 18.5.

**unsaturated fatty acid:** a fatty acid that lacks hydrogen atoms and has at least one double bond between carbons (includes monounsaturated and polyunsaturated fatty acids). An *unsaturated fat* is composed of triglycerides in which most of the fatty acids are unsaturated.

**urea** (you-REE-uh)**:** the principal nitrogen-excretion product of protein metabolism. Two ammonia fragments are combined with carbon dioxide to form urea.

**USDA (US Department of Agriculture):** the federal agency responsible for enforcing standards for the wholesomeness and quality of meat, poultry, and eggs produced in the United States; conducting nutrition research; and educating the public about nutrition.

**uterus** (YOU-ter-us)**:** the muscular organ within which the infant develops before birth.

## V

**validity** (va-LID-ih-tee)**:** having the quality of being founded on fact or evidence.

**variables:** factors that change. A variable may depend on another variable (for example, a child's height depends on his age), or it may be independent (for example, a child's height does not depend on the color of her eyes). Sometimes both variables correlate with a third variable (a child's height and eye color both depend on genetics).

**variety (dietary):** eating a wide selection of foods within and among the major food groups.

**vasoconstrictor** (VAS-oh-kon-STRIK-tor)**:** a substance that constricts or narrows the blood vessels.

**vasopressin** (VAS-oh-PRES-in)**:** another name for antidiuretic hormone, so called because it elevates blood pressure.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

**vegan** (VEE-gan) **diet:** an eating pattern that excludes all animal-derived foods (including meat, poultry, fish, eggs, and dairy products) from the diet; also called *pure vegetarian*, *strict vegetarian*, or *total vegetarian*.

**vegetarian diet:** a general term used to describe an eating pattern that excludes meat, poultry, fish, or other animal-derived foods from the diet.

**veins** (VANES)**:** vessels that carry blood to the heart.

**very low food security:** multiple indications of disrupted eating patterns and reduced food intake; formerly known as *food insecurity with hunger.*

**very low sodium:** 35 milligrams or less per serving.

**vigorous-intensity physical activity:** physical activity that requires a large increase in breathing and/or heart rate and expends more than 7 kcalories per minute. Walking at a very brisk pace (>4.5 miles per hour) or running at a pace of at least 5 miles per hour are examples.

**villi** (VILL-ee or VILL-eye)**:** fingerlike projections from the folds of the small intestine; singular *villus.*

**visceral fat:** fat stored within the abdominal cavity in association with the internal abdominal organs; also called *intra-abdominal fat*.

**viscous:** a gel-like consistency.

**vitamin A:** all naturally occurring compounds with the biological activity of *retinol,* the alcohol form of vitamin A.

**vitamin A activity:** a term referring to both the active forms of vitamin A and the precursor forms in foods without distinguishing between them.

**vitamin $B_6$:** a family of compounds—pyridoxal, pyridoxine, and pyridoxamine. The primary active coenzyme form is *PLP* (*pyridoxal phosphate*).

**vitamin $B_{12}$:** a B vitamin characterized by the presence of cobalt. The active forms of coenzyme $B_{12}$ are *methylcobalamin* and *deoxyadenosylcobalamin*.

**vitamin $D_2$:** vitamin D derived from plants in the diet; also called *ergocalciferol* (ER-go-kal-SIF-er-ol).

**vitamin $D_3$:** vitamin D derived from animals in the diet or made in the skin from 7-dehydrocholesterol, a precursor of cholesterol, with the help of sunlight; also called *cholecalciferol* (KO-lee-kal-SIF-er-ol) or *calciol.* After hydroxylation in the liver, calciol becomes *calcidiol* and after hydroxylation in the kidneys, calcidiol becomes *calcitriol.*

**vitamins:** organic, essential nutrients required in small amounts by the body for health. Vitamins regulate body processes that support growth and maintain life.

**VLDL** (very-low-density lipoprotein)**:** the type of lipoprotein made primarily by liver cells to transport lipids to various tissues in the body; composed primarily of triglycerides.

**$VO_{2max}$:** the maximum rate of oxygen consumption by an individual at sea level.

**vomiting:** expulsion of the contents of the stomach up through the esophagus to the mouth.

**vulnerable plaque:** plaque that is susceptible to rupture because it has only a thin fibrous barrier between its lipid-rich core and the artery lining.

## W

**waist circumference:** an anthropometric measurement used to assess a person's abdominal fat.

**warm-up:** 5 to 10 minutes of light activity, such as easy jogging or cycling, prior to a workout to prepare the body for more vigorous activity.

**water balance:** the balance between water intake and output (losses).

**water intoxication:** the rare condition in which body water contents are too high in all body fluid compartments.

**water stress:** intense demands on water resources by human activities such as municipal water supplies, industries, power plants, and agriculture.

**wean:** to gradually replace breast milk with infant formula or other foods appropriate to an infant's diet.

**websites:** Internet resources composed of text and graphic files, each with a unique URL (Uniform Resource Locator) that names the site (for example, www.usda.gov).

**weight management:** maintaining body weight in a healthy range by preventing gradual weight gains over time and losing weight if overweight, and by preventing weight losses and gaining weight if underweight.

**well water:** water drawn from ground water by tapping into an aquifer.

**Wernicke-Korsakoff** (VER-nee-key KORE-sah-kof) **syndrome:** a neurological disorder typically associated with chronic alcoholism and caused by a deficiency of the B vitamin thiamin; also called *alcohol-related dementia.*

**wheat flour:** any flour made from the endosperm of the wheat kernel.

**whey protein:** a by-product of cheese production; falsely promoted as increasing muscle mass. Whey is the watery part of milk that separates from the curds.

**white sugar:** granulated sucrose or "table sugar," produced by dissolving, concentrating, and recrystallizing raw sugar.

**WHO (World Health Organization):** an international agency concerned with promoting health and eradicating disease.

**whole grain:** a grain that maintains the same relative proportions of starchy endosperm, germ, and bran as the original (all but the husk); not refined.

**whole-wheat flour:** any flour made from the entire wheat kernel.

**Wilson's disease:** a genetic disorder of copper metabolism that creates a copper toxicity and results in neurologic symptoms such as tremors, impaired speech, inappropriate behaviors, and personality changes.

**wine:** an alcoholic beverage traditionally made by fermenting a sugar source such as grape juice.

**without appreciable risk:** practical certainty that injury will not result even after a lifetime of exposure.

## X

**xanthophylls** (ZAN-tho-fills)**:** pigments found in plants responsible for the color changes seen in autumn leaves.

**xerophthalmia** (zer-off-THAL-mee-uh)**:** progressive blindness caused by inadequate mucus production due to severe vitamin A deficiency.

**xerosis** (zee-ROW-sis)**:** abnormal drying of the skin and mucous membranes; a sign of vitamin A deficiency.

## Y

**yields:** production per acre.

**yogurt:** milk product that results from the fermentation of lactic acid in milk by *Lactobacillus bulgaricus* and *Streptococcus thermophilus.*

## Z

**zinc:** an essential trace mineral that is part of many enzymes and a constituent of insulin.

**zygote** (ZY-goat)**:** the initial product of the union of ovum and sperm; a fertilized ovum.

**zymogen** (ZYE-mo-jen)**:** the inactive precursor of an enzyme; sometimes called a *proenzyme.*

STUDY IT

# 1 An Overview of Nutrition

Review the key points of this chapter below, learn the definitions of bold terms, and then take the practice quiz on the back of this card.

## 1.1 Food Choices

- People select **foods** based on such factors as taste and convenience, but **diets** based on **nutrition** knowledge may better support good health.
- Individual foods are neither "good" nor "bad"; daily food choices made over a lifetime may improve health or contribute to **chronic diseases.**

## 1.2 The Nutrients

- Foods provide **nutrients**—substances that provide **energy,** structural materials, and regulating agents to support the growth, maintenance, and repair of the body's tissues. **Essential nutrients** *must* be obtained from foods.
- The six classes of nutrients include carbohydrates, lipids (fats), proteins, **vitamins, minerals,** and water. Carbohydrates, lipids, proteins, and vitamins are **organic,** meaning they contain carbon; minerals and water are **inorganic,** meaning they do not contain carbon.
- Energy is measured in **kcalories**—a measure of heat energy. One kcalorie is the amount of heat necessary to raise the temperature of 1 kg water 1°C.
- The **energy-yielding nutrients** are carbohydrate (4 kcal/g), fat (9 kcal/g), and protein (4 kcal/g). Alcohol provides 7 kcal/g, but it is not considered a nutrient.
- Vitamins, minerals, and water do not provide energy; instead, they facilitate a variety of activities in the body.

## 1.3 The Science of Nutrition

- The science of nutrition is the study of nutrients and other substances in foods and the body's handling of them.
- Researchers follow the scientific method (review Figure 1-3, p. 13). They randomly assign **control** and **experimental groups,** use large sample sizes, provide **placebos,** and are **blind** to treatments. Their findings are reviewed and **replicated** by other scientists before being accepted as **valid.**
- **Correlations** indicate an association between **variables,** not a cause.

## 1.4 Dietary Reference Intakes

- **Dietary Reference Intakes (DRI)** are a set of nutrient intake values used to plan and evaluate diets for healthy people.
- **Estimated Average Requirement (EAR)** defines the amount of a nutrient that supports a specific function in the body for half of the population. **Recommended Dietary Allowance (RDA)** is based on the EAR and establishes a goal for dietary intake that will meet the needs of almost all healthy people. **Adequate Intake (AI)** serves a similar purpose when an RDA cannot be determined.
- **Estimated Energy Requirement (EER)** defines the average amount of energy intake needed to maintain energy balance, and **Acceptable Macronutrient Distribution Ranges (AMDR)** define the proportions contributed by carbohydrate, fat, and protein to a healthy diet. Carbohydrates should consist of 45 to 65 percent of kcalories, fat 20 to 35 percent, and protein 10 to 35 percent.
- **Tolerable Upper Intake Level (UL)** establishes the highest amount that appears safe for regular consumption.

## 1.5 Nutrition Assessment

- **Malnutrition** develops when people get too little **(undernutrition),** too much **(overnutrition),** or an imbalance of energy or nutrients.
- Four **nutrition assessment** methods include historical information on diet and health, **anthropometric** measurements, physical examinations, and laboratory tests. Together, these methods reveal the stages of a nutrient deficiency (review Figure 1-7, p. 24).
- A **primary deficiency** is caused by an inadequate intake of a nutrient; a **secondary deficiency** is caused by a condition that reduces absorption, accelerates use, increases excretion, or destroys the nutrient.

## 1.6 Diet and Health

- **Risk factors** such as obesity and cigarette smoking increase the likelihood of disease development (review Table 1-6).
- Some risk factors, such as genetics, are important but cannot be changed. Recommendations focus on changeable, personal life choices such as diet and activity habits.
- Diet has no influence on some diseases but is linked closely to others (review Table 1-5).

**TABLE 1-5 Leading Causes of Death in the United States**

| | Percentage of Total Deaths |
|---|---|
| 1. **Heart disease** | 23.7 |
| 2. **Cancers** | 22.9 |
| 3. Chronic lung diseases | 5.7 |
| 4. **Strokes** | 5.1 |
| 5. Accidents | 4.9 |
| 6. Alzheimer's disease | 3.4 |
| 7. **Diabetes mellitus** | 2.9 |
| 8. Pneumonia and influenza | 2.1 |
| 9. Kidney disease | 1.8 |
| 10. Suicide | 1.5 |

NOTE: The diseases highlighted in bold have relationships with diet.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 1.1 Food Choices (pp. 4–6)

**LEARN IT** Describe how various factors influence personal food choices.

1. When people eat the foods typical of their families or geographic region, their choices are influenced by:
   a. habit.
   b. nutrition.
   c. personal preference.
   d. heritage or tradition.

## 1.2 The Nutrients (pp. 6–12)

**LEARN IT** Name the six major classes of nutrients and identify which are organic and which yield energy.

2. What is the difference between organic and inorganic?
3. How much energy do carbohydrates, fats, and proteins yield per gram? How is energy measured?
4. Describe how alcohol resembles nutrients. Why is alcohol not considered a nutrient?
5. The nutrient found most abundantly in both the human body and most foods is:
   a. fat.
   b. water.
   c. minerals.
   d. proteins.
6. The inorganic nutrients are:
   a. proteins and fats.
   b. vitamins and minerals.
   c. minerals and water.
   d. vitamins and proteins.
7. The energy-yielding nutrients are:
   a. fats, minerals, and water.
   b. minerals, proteins, and vitamins.
   c. carbohydrates, fats, and vitamins.
   d. carbohydrates, fats, and proteins.

## 1.3 The Science of Nutrition (pp. 12–18)

**LEARN IT** Explain the scientific method and how scientists use various types of research studies and methods to acquire nutrition information.

8. What is the science of nutrition?
9. Explain how variables might be correlational but not causal.
10. Studies of populations that reveal correlations between dietary habits and disease incidence are:
    a. clinical trials.
    b. laboratory studies.
    c. case-control studies.
    d. epidemiological studies.
11. An experiment in which neither the researchers nor the subjects know who is receiving the treatment is known as:
    a. double blind.
    b. double control.
    c. blind variable.
    d. placebo control.

## 1.4 Dietary Reference Intakes (pp. 18–22)

**LEARN IT** Define the four categories of the DRI and explain their purposes.

12. What judgment factors are involved in setting the energy and nutrient recommendations?
13. An RDA represents the:
    a. highest amount of a nutrient that appears safe for most healthy people.
    b. lowest amount of a nutrient that will maintain a specified criterion of adequacy.
    c. average amount of a nutrient considered adequate to meet the known nutrient needs of practically all healthy people.
    d. average amount of a nutrient that will maintain a specific biochemical or physiological function in half the people.

## 1.5 Nutrition Assessment (pp. 22–26)

**LEARN IT** Explain how the four assessment methods are used to detect energy and nutrient deficiencies and excesses.

14. What methods are used in nutrition surveys? What kinds of information can these surveys provide?
15. Historical information, physical examinations, laboratory tests, and anthropometric measurements are:
    a. techniques used in diet planning.
    b. steps used in the scientific method.
    c. approaches used in disease prevention.
    d. methods used in a nutrition assessment.
16. A deficiency caused by an inadequate dietary intake is called a(n):
    a. overt deficiency.
    b. covert deficiency.
    c. primary deficiency.
    d. secondary deficiency.

## 1.6 Diet and Health (pp. 26–28)

**LEARN IT** Identify several risk factors and explain their relationships to chronic diseases.

17. Behaviors such as smoking, dietary habits, physical activity, and alcohol consumption that influence the development of disease are known as:
    a. risk factors.
    b. chronic causes.
    c. preventive agents.
    d. disease descriptors.

## HIGHLIGHT 1 Nutrition Information and Misinformation (pp. 30–35)

**LEARN IT** Recognize misinformation and describe how to identify reliable nutrition information.

18. Nutrition misinformation is often based on:
    a. clinical trials.
    b. anecdotal evidence.
    c. double blind studies.
    d. epidemiological research.

**Multiple Choice Answers**

1. d 5. b 6. c 7. d 10. d 11. a 13. c 15. d 16. c 17. a 18. b

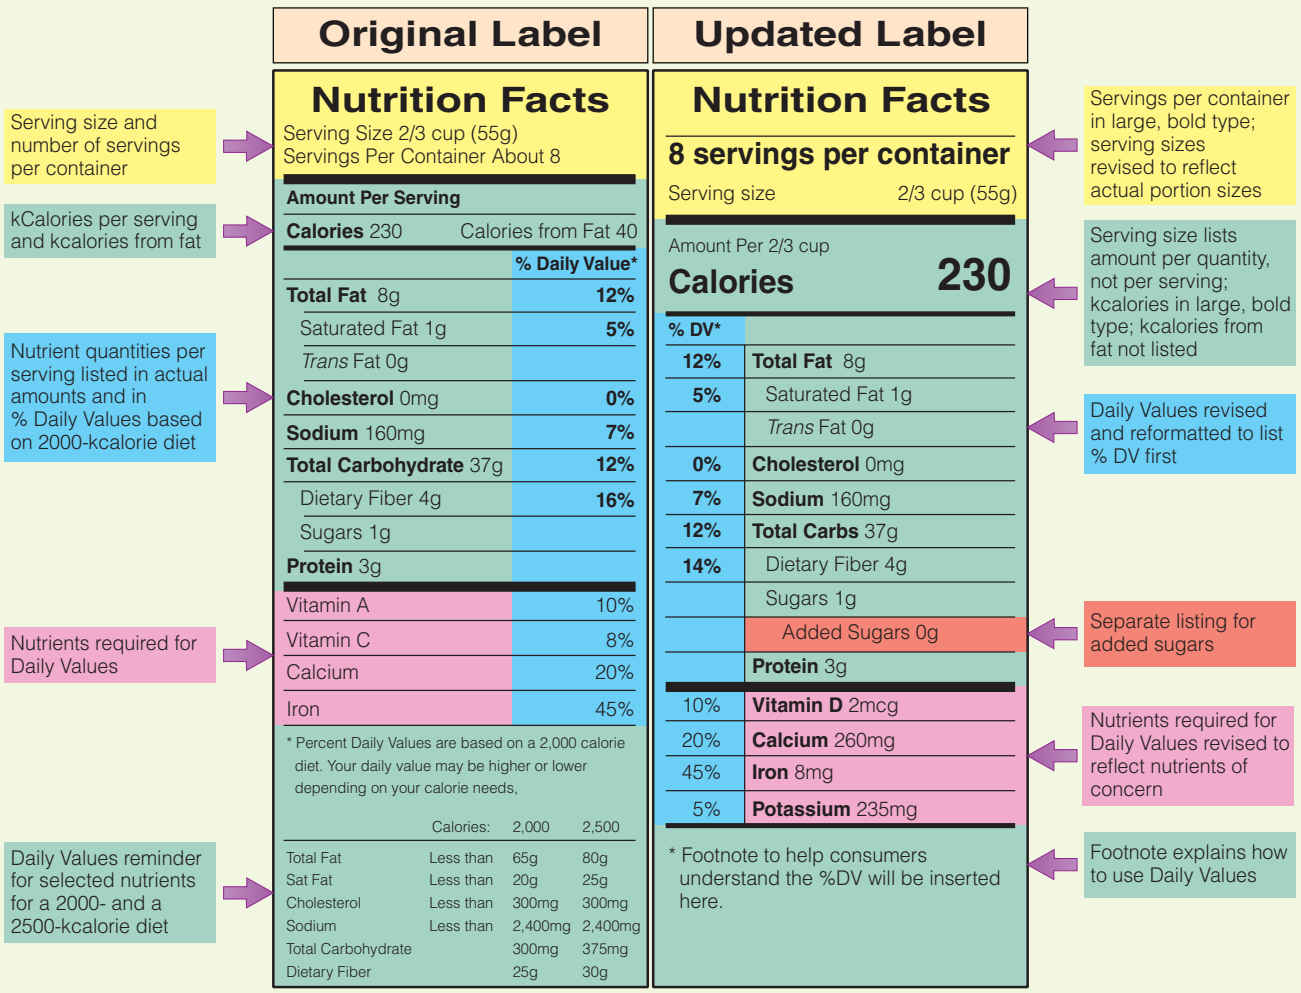
STUDY IT

# 2 Planning a Healthy Diet

Review the key points of this chapter below, learn the definitions of bold terms, and then take the practice quiz on the back of this card.

## 2.1 Principles and Guidelines

- A well-planned **eating pattern** delivers *adequate* nutrients, a *balanced* array of nutrients, and an appropriate amount of *energy* (*kcalories*). It is based on ***nutrient-dense*** foods, ***moderate*** in substances that can be detrimental to health, and *varied* in its selections.
- The *Dietary Guidelines for Americans* offer practical advice on how to eat for good health (review Table 2-1, p. 41).



## 2.2 Diet-Planning Guides

- The USDA Food Patterns help consumers select the types and amounts of foods to provide **adequacy, balance,** and **variety** in the diet. It makes it easier to plan a diet that includes a balance of grains, vegetables, fruits, protein foods, and milk products. In making any food choice, remember to view the food in the context of the total diet.
- The combination of many different foods provides the array of nutrients that are essential to a healthy diet (review Figure 2-2, pp. 44–45).
- MyPlate reminds consumers to make healthy choices from the five **food groups** (review Figure 2-4, p. 48).

## 2.3 Food Labels

- Food labels list ingredients in descending order of predominance by weight, nutrition facts based on standard **serving sizes,** and **Daily Values** based on a 2000-kcalorie diet (review Figure 2-9).
- **Nutrient claims** reflect the quantity of a nutrient (high or low), **health claims** reflect relationships between a nutrient and a disease (potassium reduces risk of hypertension), and **structure-function claims** reflect relationships between a nutrient and its function in the body (calcium builds bones).

> **FIGURE 2-9** Example of a Food Label

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 2.1 Principles and Guidelines (pp. 38–42)

**LEARN IT** Explain how each of the diet-planning principles can be used to plan a healthy diet.

1. What recommendations appear in the *Dietary Guidelines for Americans*?
2. The diet-planning principle that provides all the essential nutrients in sufficient amounts to support health is:
   a. balance.
   b. variety.
   c. adequacy.
   d. moderation.
3. A person who chooses a chicken leg that provides 0.5 milligram of iron and 95 kcalories instead of 2 tablespoons of peanut butter that also provides 0.5 milligram of iron but 188 kcalories is using the principle of nutrient:
   a. control.
   b. density.
   c. adequacy.
   d. moderation.
4. Which of the following is consistent with the *Dietary Guidelines for Americans*?
   a. Choose a diet restricted in fat and cholesterol.
   b. Balance the food you eat with physical activity.
   c. Choose a diet with plenty of milk products and meats.
   d. Eat an abundance of foods to ensure nutrient adequacy.

## 2.2 Diet-Planning Guides (pp. 42–56)

**LEARN IT** Use the USDA Food Patterns to develop a meal plan within a specified energy allowance.

5. Review the *Dietary Guidelines*. What types of grocery selections would you make to achieve those recommendations?
6. According to the USDA Food Patterns, cheese is grouped as a:
   a. meat.
   b. protein food.
   c. milk product.
   d. miscellaneous fat.
7. Foods within a given food group of the USDA Food Patterns are similar in their contents of:
   a. energy.
   b. proteins and fibers.
   c. vitamins and minerals.
   d. carbohydrates and fats.
8. In the exchange system, each portion of food on any given list provides about the same amount of:
   a. energy.
   b. satiety.
   c. vitamins.
   d. minerals.
9. Enriched grain products are fortified with:
   a. fiber, folate, iron, niacin, and zinc.
   b. thiamin, iron, calcium, zinc, and sodium.
   c. iron, thiamin, riboflavin, niacin, and folate.
   d. folate, magnesium, vitamin $B_6$, zinc, and fiber.

## 2.3 Food Labels (pp. 56–63)

**LEARN IT** Compare the information on food labels to make selections that meet specific dietary and health goals.

10. What information can you expect to find on a food label? How can this information help you choose between two similar products?
11. What are the Daily Values? How can they help you meet health recommendations?
12. Describe the differences between nutrient claims, health claims, and structure-function claims.
13. Food labels list ingredients in:
   a. alphabetical order.
   b. ascending order of predominance by weight.
   c. descending order of predominance by weight.
   d. manufacturer's order of preference.
14. "Milk builds strong bones" is an example of a:
   a. health claim.
   b. nutrition fact.
   c. nutrient content claim.
   d. structure-function claim.
15. Daily Values on food labels are based on a:
   a. 1500-kcalorie diet.
   b. 2000-kcalorie diet.
   c. 2500-kcalorie diet.
   d. 3000-kcalorie diet.

## HIGHLIGHT 2 Vegetarian Diets (pp. 64–69)

**LEARN IT** Develop a well-balanced vegetarian meal plan.

16. Which of the following nutrients is most likely to be lacking in a vegan diet?
   a. fiber
   b. folate
   c. vitamin C
   d. vitamin $B_{12}$

**Multiple Choice Answers**

2. c 3. b 4. b 6. c 7. c 8. a 9. c 13. c 14. d 15. b 16. d

STUDY IT

# 3 Digestion, Absorption, and Transport

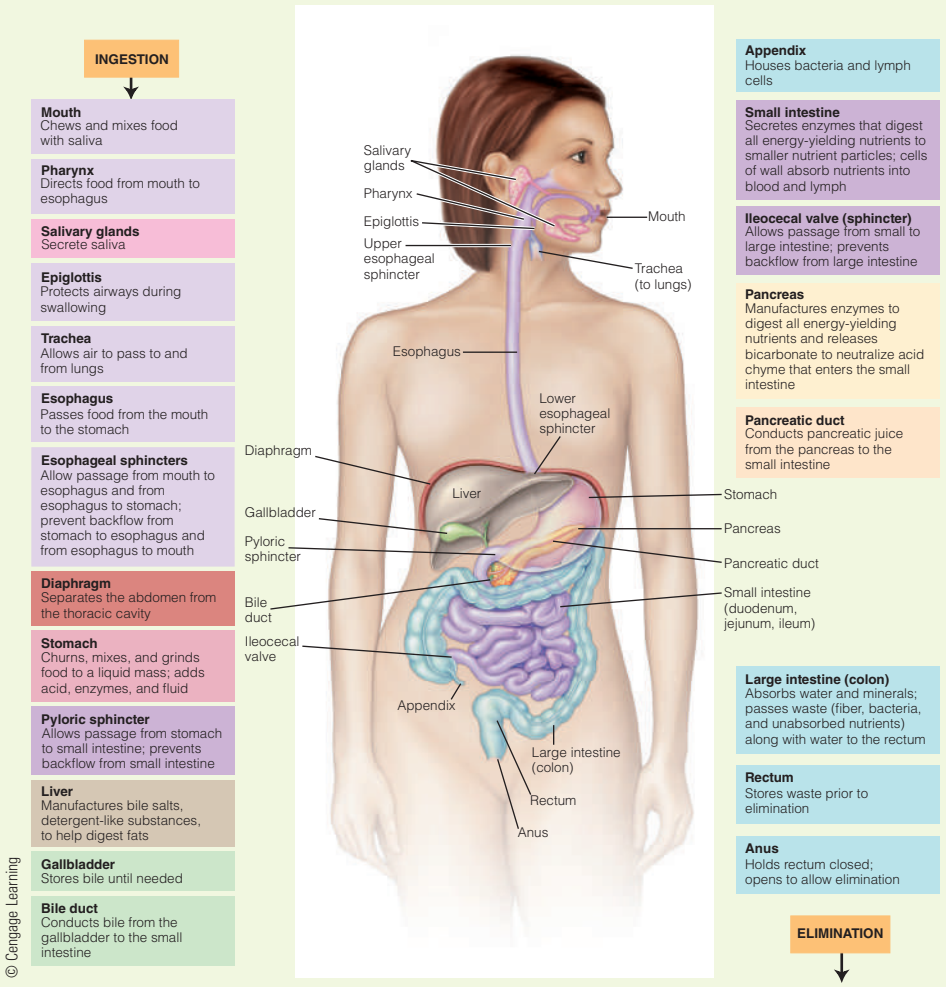
Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 3.1 Digestion

- **Digestion** breaks down foods into nutrients. **Absorption** brings the nutrients into the cells of the **small intestine** for transport to the body's cells.
- Food enters the **mouth** and travels along the **gastrointestinal tract**—down the **esophagus** and through the upper and lower esophageal **sphincters** to the **stomach,** then through the **pyloric sphincter** to the small intestine, on through the **ileocecal valve** to the **large intestine,** past the **appendix** to the **rectum,** ending at the **anus** (review Figure 3-1).
- The wavelike contractions of **peristalsis** and the periodic squeezing of **segmentation** keep things moving at a reasonable pace. Along the way, secretions from the **salivary glands,** stomach, **pancreas, liver** (via the **gallbladder**), and small intestine deliver fluids and **digestive enzymes** (review Table 3-1).

## 3.2 Absorption

- The many folds and **villi** of the small intestine increase its surface area, making nutrient absorption efficient.
- Nutrients pass through the cells of the intestinal villi and enter either the blood (if they are water soluble or small fat fragments) or the **lymph** (if they are fat soluble).



## 3.3 The Circulatory Systems

- Nutrients leaving the **digestive system** via the blood are routed directly to the liver before being transported to the body's cells.
- Nutrients leaving via the lymphatic system bypass the liver at first, but eventually enter the vascular system via the **thoracic duct,** which opens into the **subclavian vein.**

## 3.4 The Health and Regulation of the GI Tract

- A diverse and abundant population of **microbes** supports GI health.
- The regulation of GI processes depends on the coordinated efforts of the hormonal system and the nervous system.
- Together, digestion and absorption break down foods into nutrients for the body's use.
- To function optimally, a healthy GI tract needs a balanced diet, adequate rest, and regular physical activity.

**> FIGURE 3-1 The Gastrointestinal Tract**

© Cengage Learning

**TABLE 3-1 Summary of Digestive Secretions and Their Major Actions**

| Organ or Gland | Target Organ | Secretion | Action |
|---|---|---|---|
| Salivary glands | Mouth | Saliva | Fluid eases swallowing; salivary enzyme breaks down some **carbohydrate.*** |
| Gastric glands | Stomach | Gastric juice | Fluid mixes with bolus; hydrochloric acid uncoils **proteins;** enzymes break down proteins; mucus protects stomach cells.* |
| Pancreas | Small intestine | Pancreatic juice | Bicarbonate neutralizes acidic gastric juices; pancreatic enzymes break down **carbohydrates, fats,** and **proteins.** |
| Liver | Gallbladder | Bile | Bile is stored until needed. |
| Gallbladder | Small intestine | Bile | Bile emulsifies **fat** so that enzymes can have access to break it down. |
| Intestinal glands | Small intestine | Intestinal juice | Intestinal enzymes break down **carbohydrate, fat,** and **protein** fragments; mucus protects the intestinal wall. |

*Saliva and gastric juice also contain lipases, but most fat breakdown occurs in the small intestine.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 3.1 Digestion (pp. 72–78)

**LEARN IT** Explain how foods move through the digestive system, describing the actions of the organs, muscles, and digestive secretions along the way.

1. Describe the challenges associated with digesting food and the solutions offered by the human body.
2. Name five organs that secrete digestive juices. How do the juices and enzymes facilitate digestion?
3. The semiliquid, partially digested food that travels through the intestinal tract is called:
   a. bile.
   b. lymph.
   c. chyme.
   d. secretin.
4. The muscular contractions that move food through the GI tract are called:
   a. hydrolysis.
   b. sphincters.
   c. peristalsis.
   d. bowel movements.
5. The main function of bile is to:
   a. emulsify fats.
   b. catalyze hydrolysis.
   c. slow protein digestion.
   d. neutralize stomach acidity.
6. The pancreas neutralizes stomach acid in the small intestine by secreting:
   a. bile.
   b. mucus.
   c. enzymes.
   d. bicarbonate.
7. Which nutrient passes through the GI tract mostly undigested and unabsorbed?
   a. fat
   b. fiber
   c. protein
   d. carbohydrate

## 3.2 Absorption (pp. 78–82)

**LEARN IT** Describe the anatomical details of the intestinal cells that facilitate nutrient absorption.

8. The fingerlike projections on the small intestine that dramatically increase its surface area are called:
   a. villi.
   b. crypts.
   c. goblet cells.
   d. chylomicrons.
9. Absorption occurs primarily in the:
   a. mouth.
   b. stomach.
   c. small intestine.
   d. large intestine.

## 3.3 The Circulatory Systems (pp. 82–84)

**LEARN IT** Explain how nutrients are routed in the circulatory systems from the GI tract into the body and identify which nutrients enter the blood directly and which must first enter the lymph.

10. All blood leaving the GI tract travels first to the:
    a. heart.
    b. liver.
    c. kidneys.
    d. pancreas.
11. Which nutrients leave the GI tract by way of the lymphatic system?
    a. water and minerals
    b. proteins and minerals
    c. all vitamins and minerals
    d. fats and fat-soluble vitamins

## 3.4 The Health and Regulation of the GI Tract (pp. 85–89)

**LEARN IT** Describe how bacteria, hormones, and nerves influence the health and activities of the GI tract.

12. How does the composition of the diet influence the functioning of the GI tract?
13. What steps can you take to help your GI tract function at its best?
14. Digestion and absorption are coordinated by the:
    a. pancreas and kidneys.
    b. liver and gallbladder.
    c. hormonal system and the nervous system.
    d. vascular system and the lymphatic system.
15. Gastrin, secretin, and cholecystokinin are examples of:
    a. crypts.
    b. enzymes.
    c. hormones.
    d. goblet cells.

## HIGHLIGHT 3 Common Digestive Problems (pp. 90–96)

**LEARN IT** Outline strategies to prevent or alleviate common GI problems.

16. Which of the following is most likely to aggravate heartburn?
    a. eat small meals
    b. drink liquids between meals
    c. eat slowly and chew thoroughly
    d. lie down to rest immediately after eating

**Multiple Choice Answers**

3. c 4. c 5. a 6. d 7. b 8. a 9. c 10. b 11. d 14. c 15. c 16. d

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

STUDY IT

# 4 The Carbohydrates: Sugars, Starches, and Fibers

Review the key points of this chapter below, learn the definitions of bold terms, and then take the practice quiz on the back of this card.

## 4.1 The Chemist's View of Carbohydrates

- **Carbohydrates** include **monosaccharides, disaccharides,** and **polysaccharides** (review Table 4-1).
- Carbohydrates are made of carbon (C), oxygen (O), and hydrogen (H); each atom forms a specified number of chemical bonds: carbon forms four, oxygen forms two, and hydrogen forms one (review Figure 4-1, p. 100).
- Monosaccharides (**glucose, fructose,** and **galactose**) all have the same chemical formula ($C_6H_{12}O_6$), but their structures differ. Disaccharides (**maltose, sucrose,** and **lactose**) each contain a glucose paired with one of the three monosaccharides.
- A **condensation** reaction can bond two monosaccharides together to form a disaccharide and water (review Figure 4-4, p. 102). A **hydrolysis** reaction can use water to split a disaccharide into its two monosaccharides (review Figure 4-5, p. 102).
- Chains of monosaccharides are called **polysaccharides** and include **glycogen, starches,** and **dietary fibers.** Both glycogen and starch are storage forms of glucose—glycogen in the body, and starch in plants—and both yield energy.
- Dietary fibers contain glucose (and other monosaccharides), but their bonds cannot be broken by human digestive enzymes; they yield little, if any, energy.
- **Soluble fibers** dissolve in water to form gels and are easily digested by bacteria in the colon. **Insoluble fibers** do not dissolve in water or form gels and are less readily fermented.

**TABLE 4-1 The Carbohydrate Family**

| | |
|---|---|
| **Monosaccharides** | |
| Glucose | |
| Fructose | |
| Galactose | |
| **Disaccharides** | |
| Maltose (glucose + glucose) | |
| Sucrose (glucose + fructose) | |
| Lactose (glucose + galactose) | |
| **Polysaccharides** | |
| Glycogen[a] | |
| Starches (amylose and amylopectin) | |
| Fibers (soluble and insoluble) | |

[a]Glycogen is a polysaccharide, but not a common dietary source of carbohydrate.

© Cengage Learning

## 4.2 Digestion and Absorption of Carbohydrates

- The body digests starches into the disaccharide maltose. Maltose and the other disaccharides (lactose and sucrose) from foods are broken down into monosaccharides, which are absorbed (review Figure 4-9, p. 107).
- Fibers help to regulate the passage of food through the GI tract and slow the absorption of glucose.
- **Lactose intolerance** occurs when there is insufficient lactase to digest the disaccharide lactose found in milk and milk products. Symptoms include GI distress.

## 4.3 Glucose in the Body

- Dietary carbohydrates provide glucose that can be used by the cells for energy, stored by the liver and muscles as glycogen, or converted into fat if intakes exceed needs.
- All of the body's cells depend on glucose; those of the central nervous system are especially dependent on it.
- Without glucose, the body is forced to break down its protein tissues to make glucose **(gluconeogenesis)** and to alter energy metabolism to make **ketone bodies** from fats.
- Blood glucose regulation depends on two pancreatic hormones: **insulin** to move glucose from the blood into the cells when levels are high and **glucagon** to free glucose from glycogen stores and release it into the blood when levels are low (review Figure 4-10, p. 111).

## 4.4 Health Effects and Recommended Intakes of Sugars

- Excessive intakes of **sugars** may increase the risk of dental caries, displace needed nutrients and fiber, and contribute to obesity when energy intake exceeds needs.
- Concentrated sweets are relatively low in nutrients, high in kcalories, and may need to be limited; sugars that occur naturally in fruits, vegetables, and milk are acceptable.
- To control weight gain, blood glucose, and dental caries, consumers may use alternative sweeteners (**artificial sweeteners,** herbal products, and **sugar alcohols**) to limit kcalories and minimize sugar intake (review Table 4-8, p. 119).

## 4.5 Health Effects and Recommended Intakes of Starch and Fibers

- Adequate intake of fiber fosters weight management, lowers blood cholesterol, and may help prevent colon cancer, diabetes, hemorrhoids, appendicitis, and diverticulosis.
- Excessive intake of fiber displaces energy- and nutrient-dense foods, causes intestinal discomfort and distention, and may interfere with mineral absorption.
- Because starches and fibers help control body weight and prevent heart disease, cancer, diabetes, and GI disorders, the *Dietary Guidelines* suggest plenty of whole grains, vegetables, legumes, and fruits—enough to provide 45 to 65 percent of the daily energy intake from carbohydrate.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 4.1 The Chemist's View of Carbohydrates

(pp. 100–105)

**LEARN IT** Identify the monosaccharides, disaccharides, and polysaccharides common in nutrition by their chemical structures and major food sources.

1. What happens in a condensation reaction? In a hydrolysis reaction?
2. How are starch and glycogen similar, and how do they differ? How do the fibers differ from the other polysaccharides?
3. Disaccharides include:
   a. starch, glycogen, and fiber.
   b. amylose, pectin, and dextrose.
   c. sucrose, maltose, and lactose.
   d. glucose, galactose, and fructose.
4. The making of a disaccharide from two monosaccharides is an example of:
   a. digestion.
   b. hydrolysis.
   c. condensation.
   d. gluconeogenesis.
5. The significant difference between starch and cellulose is that:
   a. starch is a polysaccharide, but cellulose is not.
   b. animals can store glucose as starch, but not as cellulose.
   c. hormones can make glucose from cellulose, but not from starch.
   d. digestive enzymes can break the bonds in starch, but not in cellulose.

## 4.2 Digestion and Absorption of Carbohydrates (pp. 105–108)

**LEARN IT** Summarize carbohydrate digestion and absorption.

6. What role does fiber play in digestion and absorption?
7. Describe lactose intolerance and its symptoms.
8. The ultimate goal of carbohydrate digestion and absorption is to yield:
   a. fibers.
   b. glucose.
   c. enzymes.
   d. amylase.
9. The enzyme that breaks a disaccharide into glucose and galactose is:
   a. amylase.
   b. maltase.
   c. sucrase.
   d. lactase.

## 4.3 Glucose in the Body (pp. 108–113)

**LEARN IT** Explain how the body maintains its blood glucose concentration and what happens when blood glucose rises too high or falls too low.

10. What are the possible fates of glucose in the body? What is the protein-sparing action of carbohydrate?
11. The storage form of glucose in the body is:
    a. insulin.
    b. maltose.
    c. glucagon.
    d. glycogen.
12. With insufficient glucose in metabolism, fat fragments combine to form:
    a. dextrins.
    b. mucilages.
    c. phytic acids.
    d. ketone bodies.
13. What does the pancreas secrete when blood glucose rises? When blood glucose falls?
    a. insulin; glucagon
    b. glucagon; insulin
    c. insulin; glycogen
    d. glycogen; epinephrine

## 4.4 Health Effects and Recommended Intakes of Sugars (pp. 113–120)

**LEARN IT** Describe how added sugars can contribute to health problems.

14. What are the dietary recommendations regarding concentrated sugar intakes?
15. Describe the risks and benefits of using alternative sweeteners.

## 4.5 Health Effects and Recommended Intakes of Starch and Fibers (pp. 120–127)

**LEARN IT** Identify the health benefits of, and recommendations for, starches and fibers.

16. What foods provide starches and fibers?
17. Carbohydrates are found in virtually all foods except:
    a. milks.
    b. meats.
    c. breads.
    d. fruits.
18. What percentage of the daily energy intake should come from carbohydrates?
    a. 15 to 20
    b. 25 to 30
    c. 45 to 50
    d. 45 to 65

## HIGHLIGHT 4 Carbs, kCalories, and Controversies (pp. 128–131)

**LEARN IT** Summarize the key scientific evidence behind some of the current controversies surrounding carbohydrates and their kcalories.

19. Which of the following is true?
    a. High-fructose corn syrup is chemically similar to sucrose.
    b. Diets with a high glycemic index are most effective in fostering weight loss.
    c. Energy intake from carbohydrates has remained stable over the past 40 years.
    d. Some people have a physiological addiction to sugar that makes it impossible for them to moderate use.

**Multiple Choice Answers**

3. c 4. c 5. d 8. b 9. d 11. d 12. d 13. a 17. b 18. d 19. a

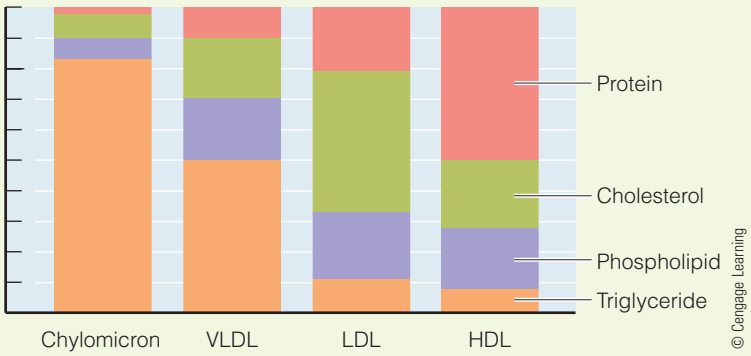
STUDY IT

# 5 The Lipids: Triglycerides, Phospholipids, and Sterols

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 5.1 The Chemist's View of Fatty Acids and Triglycerides



- The predominant **lipids** both in foods and in the body are **triglycerides: glycerol** with three **fatty acids** attached by way of condensation reactions (review Figure 5-3, p. 137). Other lipids include phospholipids and sterols (review Table 5-2).
- Fatty acids vary in the length of their carbon chains, their degrees of unsaturation, and the location of their double bond(s). **Saturated fatty acids** are fully loaded with hydrogens; **unsaturated (monounsaturated** or **polyunsaturated)** fatty acids are missing hydrogens and have double bonds.
- **Hydrogenation** protects against oxidation (thereby promoting shelf-life) and alters the texture of foods by making liquid vegetable **oils** more solid. This process makes polyunsaturated **fats** more saturated and creates ***trans*-fatty acids.**

## 5.2 The Chemist's View of Phospholipids and Sterols

- The chemical structure of **phospholipids,** including **lecithin,** allows them to be soluble in both water and fat. In the body, phospholipids are part of cell membranes; in foods, phospholipids act as emulsifiers to mix fats with water.
- **Sterols** have a multiple-ring structure that differs from the structure of other lipids. In the body, sterols include **cholesterol,** bile, vitamin D, and some hormones. Animal-derived foods contain cholesterol.

## 5.3 Digestion, Absorption, and Transport of Lipids

- **Bile emulsifies** fats, making them accessible to the **lipases** that dismantle triglycerides to **monoglycerides** and fatty acids for absorption (review Figure 5-12, p. 143).
- Four types of **lipoproteins** carry triglycerides, phospholipids, and cholesterol throughout the body: **chylomicrons** are the largest and contain mostly dietary triglycerides, **VLDL** are smaller and are about half triglycerides, **LDL** are smaller still and contain mostly cholesterol, and **HDL** are the densest and are rich in protein (review Figure 5-16, p. 146).

© Cengage Learning

**TABLE 5-2 The Lipid Family**

| |
|---|
| **Triglycerides** |
| ■ 1 Glycerol (per triglyceride) and |
| ■ 3 Fatty acids (per triglyceride); depending on the number of double bonds, fatty acids may be: |
| • *Saturated* (no double bonds) |
| • *Monounsaturated* (one double bond) |
| • *Polyunsaturated* (more than one double bond); depending on the location of the double bonds, polyunsaturated fatty acids may be: |
| ◆ *Omega-3* (double bond closest to methyl end is 3 carbons away) |
| ◆ *Omega-6* (double bond closest to methyl end is 6 carbons away) |
| **Phospholipids** (such as lecithin) |
| **Sterols** (such as cholesterol) |

© Cengage Learning

## 5.4 Lipids in the Body

- In the body, triglycerides provide energy, insulate against temperature extremes, protect against shock, and help the body use carbohydrate and protein efficiently.
- **Linoleic acid** (18 carbons, omega-6) and **linolenic acid** (18 carbons, omega-3) are **essential fatty acids,** serving as structural parts of cell membranes and as precursors to the longer fatty acids that can make **eicosanoids.**
- The body stores fat if given excesses, and uses body fat for energy when needed. (The liver can also convert excess carbohydrate and protein into fat.) Fat breakdown requires carbohydrate for maximum efficiency; without carbohydrate, fatty acids break down to **ketone bodies.**

## 5.5 Health Effects and Recommended Intakes of Saturated Fats, *Trans* Fats, and Cholesterol

- Some fat in the diet is necessary, but too much fat provides energy (kcalories) without nutrients, which leads to obesity and nutrient inadequacies.
- Too much saturated fat, *trans* fat, and cholesterol increases the risk of heart disease and possibly cancer.
- Recommendations advise that a diet be moderate in total fat and low in saturated fat, *trans* fat, and cholesterol.

## 5.6 Health Effects and Recommended Intakes of Monounsaturated and Polyunsaturated Fats

- Some fat in the diet has health benefits, especially the monounsaturated and polyunsaturated fats that protect against heart disease and possibly cancer.
- The *Dietary Guidelines* recommend replacing saturated fats with monounsaturated and polyunsaturated fats, particularly **omega-3** fatty acids from foods such as fatty fish, not from supplements.
- Many selection and preparation strategies can help bring these goals within reach, and food labels help to identify foods consistent with these guidelines.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 5.1 The Chemist's View of Fatty Acids and Triglycerides (pp. 134–140)

**LEARN IT** Recognize the chemistry of fatty acids and triglycerides and differences between saturated and unsaturated fats.

1. Name three classes of lipids found in the body and in foods. What are some of their functions in the body? What features do fats bring to foods?
2. What features distinguish fatty acids from each other?
3. What does the term *omega* mean with respect to fatty acids? Describe the roles of the omega fatty acids in disease prevention.
4. Describe the structure of a triglyceride.
5. What does hydrogenation do to fats? What are *trans*-fatty acids, and how do they influence heart disease?
6. Saturated fatty acids:
   a. are always 18 carbons long.
   b. have at least one double bond.
   c. are fully loaded with hydrogens.
   d. are always liquid at room temperature.
7. A triglyceride consists of:
   a. three glycerols attached to a lipid.
   b. three fatty acids attached to a glucose.
   c. three fatty acids attached to a glycerol.
   d. three phospholipids attached to a cholesterol.
8. The difference between *cis*- and *trans*-fatty acids is:
   a. the number of double bonds.
   b. the length of their carbon chains.
   c. the location of the first double bond.
   d. the configuration around the double bond.

## 5.2 The Chemist's View of Phospholipids and Sterols (pp. 140–141)

**LEARN IT** Describe the chemistry, food sources, and roles of phospholipids and sterols.

9. Which of the following is *not* true? Lecithin is:
   a. an emulsifier.
   b. a phospholipid.
   c. an essential nutrient.
   d. a constituent of cell membranes.

## 5.3 Digestion, Absorption, and Transport of Lipids (pp. 142–147)

**LEARN IT** Summarize fat digestion, absorption, and transport.

10. What do lipoproteins do? What are the differences among the chylomicrons, VLDL, LDL, and HDL?
11. Chylomicrons are produced in the:
    a. liver.
    b. pancreas.
    c. gallbladder.
    d. small intestine.
12. Transport vehicles for lipids are called:
    a. micelles.
    b. lipoproteins.
    c. blood vessels.
    d. monoglycerides.

## 5.4 Lipids in the Body (pp. 148–150)

**LEARN IT** Outline the major roles of fats in the body, including a discussion of essential fatty acids and the omega fatty acids.

13. Which of the following is *not* true? Fats:
    a. contain glucose.
    b. provide energy.
    c. protect against organ shock.
    d. carry vitamins A, D, E, and K.
14. The essential fatty acids include:
    a. stearic acid and oleic acid.
    b. oleic acid and linoleic acid.
    c. palmitic acid and linolenic acid.
    d. linoleic acid and linolenic acid.

## 5.5 Health Effects and Recommended Intakes of Saturated Fats, *Trans* Fats, and Cholesterol (pp. 150–152)

**LEARN IT** Explain the relationships among saturated fats, *trans* fat, and cholesterol and chronic diseases, noting recommendations.

15. How does excessive fat intake influence health? What factors influence LDL, HDL, and total blood cholesterol?
16. What are the dietary recommendations regarding saturated fat and cholesterol intake? List ways to reduce intake.
17. The lipoprotein most associated with a high risk of heart disease is:
    a. CHD.
    b. HDL.
    c. LDL.
    d. LPL.

## 5.6 Health Effects and Recommended Intakes of Monounsaturated and Polyunsaturated Fats (pp. 153–162)

**LEARN IT** Explain the relationships between monounsaturated and polyunsaturated fats and health, noting recommendations.

18. What is the Daily Value for fat (for a 2000-kcalorie diet)?
19. A person consuming 2200 kcalories a day who wants to meet health recommendations should limit daily fat intake to:
    a. 20 to 35 grams.
    b. 50 to 85 grams.
    c. 75 to 100 grams.
    d. 90 to 130 grams.

## HIGHLIGHT 5 High-Fat Foods–Friend or Foe? (pp. 164–169)

**LEARN IT** Identify which fats support health and which impair it.

20. List foods that are high in saturated fats and foods that are high in unsaturated fats that could easily be used to replace them.

**Multiple Choice Answers**

6. c 7. c 8. d 9. c 11. d 12. b 13. a 14. d 17. c 19. b

STUDY IT

# 6 Protein: Amino Acids

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 6.1 The Chemist's View of Proteins

- **Proteins** are more chemically complex than carbohydrates or lipids; they are made of 20 different **amino acids,** 9 of which the body cannot make. These 9 are the **essential amino acids**—histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine.
- Each amino acid contains an amino group, an acid group, a hydrogen atom, and a distinctive side group, all attached to a central carbon atom.
- Cells link amino acids together by a **peptide bond** in a series of condensation reactions to create proteins (review Figure 6-3, p. 173). The distinctive sequence of amino acids in each protein determines its unique shape and function.

## 6.2 Digestion and Absorption of Proteins

- The stomach's hydrochloric acid first denatures dietary proteins, then **enzymes** cleave them into smaller polypeptides and some amino acids.
- Pancreatic and intestinal enzymes split **polypeptides** further, to **oligo-, tri-,** and **dipeptides,** and then split most of these to single amino acids that can be absorbed into the intestinal cells (review Figure 6-6, p. 176).

## 6.3 Proteins in the Body

- Cells synthesize proteins according to the **genetic** information provided by the **DNA** in the nucleus of each cell (review Figure 6-7, p. 178). This information dictates the sequence in which amino acids are linked together to form a given protein. Sequencing errors occasionally occur, sometimes with significant consequences.
- A sampling of protein functions are summarized in Table 6-3.
- Proteins are constantly being synthesized and broken down as needed, a process known as **protein turnover.**
- The body's assimilation of amino acids into proteins and its release of amino acids via protein degradation and excretion can be tracked by measuring **nitrogen balance,** which should be positive during growth and steady in adulthood. An energy deficit or an inadequate protein intake may force the body to break down lean body tissue and use amino acids as fuel, creating a negative nitrogen balance.
- Protein eaten in excess of need is degraded and stored as body fat.

## 6.4 Protein in Foods

- **High-quality proteins** deliver all of the essential amino acids in adequate amounts, which ensures protein synthesis. Mixtures of foods containing **complementary proteins** can each supply the amino acids missing in the other.
- In addition to its amino acid content, the quality of a protein is measured by its **digestibility** and its ability to support growth.

## 6.5 Health Effects and Recommended Intakes of Protein

- Protein deficiency impairs the body's ability to grow and function optimally.
- Excess protein offers no advantage and may incur health problems as well.
- The optimal diet is adequate in energy from carbohydrate and fat and delivers 0.8 grams of protein per kilogram of healthy body weight each day.
- Healthy people do not need protein or amino acid supplements.

**TABLE 6-3 Protein Functions in the Body**

| | |
|---|---|
| **Structural materials** | Proteins form integral parts of most body tissues and provide strength and shape to skin, tendons, membranes, muscles, organs, and bones. |
| **Enzymes** | Proteins facilitate chemical reactions. |
| **Hormones** | Proteins regulate body processes. (Some, but not all, hormones are proteins.) |
| **Fluid balance** | Proteins help to maintain the volume and composition of body fluids. |
| **Acid-base balance** | Proteins help to maintain the acid-base balance of body fluids by acting as **buffers.** |
| **Transportation** | Proteins transport substances, such as lipids, vitamins, minerals, and oxygen, around the body. |
| **Antibodies** | Proteins inactivate foreign invaders, thus protecting the body against diseases. |
| **Energy and glucose** | Proteins provide some fuel, and glucose if needed, for the body's energy needs. |
| **Other** | The protein fibrin creates blood clots; the protein **collagen** forms scars; the protein opsin participates in vision. |

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 6.1 The Chemist's View of Proteins

(pp. 172–175)

**LEARN IT** Recognize the chemical structures of amino acids and proteins.

1. Explain how the sequence of amino acids affects protein shape and function.
2. What are essential amino acids?
3. Which part of its chemical structure differentiates one amino acid from another?
   a. its side group
   b. its acid group
   c. its amino group
   d. its double bonds
4. Isoleucine, leucine, and lysine are:
   a. proteases.
   b. polypeptides.
   c. essential amino acids.
   d. complementary proteins.

## 6.2 Digestion and Absorption of Proteins (pp. 175–176)

**LEARN IT** Summarize protein digestion and absorption.

5. In the stomach, hydrochloric acid:
   a. denatures proteins and activates pepsin.
   b. hydrolyzes proteins and denatures pepsin.
   c. emulsifies proteins and releases peptidase.
   d. condenses proteins and facilitates digestion.

## 6.3 Proteins in the Body (pp. 177–184)

**LEARN IT** Describe how the body makes proteins and uses them to perform various roles.

6. What are enzymes? What roles do they play in chemical reactions? Describe the differences between enzymes and hormones.
7. How does the body use amino acids? What is deamination? Define *nitrogen balance*. What conditions are associated with zero, positive, and negative balance?
8. Proteins that maintain the acid-base balance of the blood and body fluids by accepting and releasing hydrogen ions are:
   a. buffers.
   b. enzymes.
   c. hormones.
   d. antigens.
9. If an essential amino acid that is needed to make a protein is unavailable, the cells must:
   a. deaminate another amino acid.
   b. substitute a similar amino acid.
   c. break down proteins to obtain it.
   d. synthesize the amino acid from glucose and nitrogen.
10. Protein turnover describes the amount of protein:
    a. found in foods and the body.
    b. absorbed from the diet.
    c. synthesized and degraded.
    d. used to make glucose.

## 6.4 Protein in Foods (pp. 185–186)

**LEARN IT** Explain the differences between high-quality and low-quality proteins, including notable food sources of each.

11. How can vegetarians meet their protein needs without eating meat?
12. Which of the following foods provides the highest quality protein?
    a. egg
    b. corn
    c. gelatin
    d. whole grains

## 6.5 Health Effects and Recommended Intakes of Protein (pp. 186–191)

**LEARN IT** Identify the health benefits of, and recommendations for, protein.

13. How might protein excess, or the type of protein eaten, influence health?
14. What factors are considered in establishing recommended protein intakes?
15. What are the benefits and risks of taking protein and amino acid supplements?
16. The protein RDA for a healthy adult who weighs 180 pounds is:
    a. 50 milligrams/day.
    b. 65 grams/day.
    c. 180 grams/day.
    d. 2000 milligrams/day.
17. Which of these foods has the least protein per ½ cup?
    a. rice
    b. broccoli
    c. pinto beans
    d. orange juice

## HIGHLIGHT 6 Nutritional Genomics (pp. 194–199)

**LEARN IT** Explain how nutrients influence gene activity (nutrigenomics) and how genes influence the activities of nutrients (nutrigenetics).

18. The area of study that examines how environmental factors influence gene expression without changing the DNA is known as:
    a. epigenetics.
    b. chromosomal biology.
    c. methylation translation.
    d. microarray technologies.

**Multiple Choice Answers**

3. a 4. c 5. a 8. a 9. c 10. c 12. a 16. b 17. d 18. a

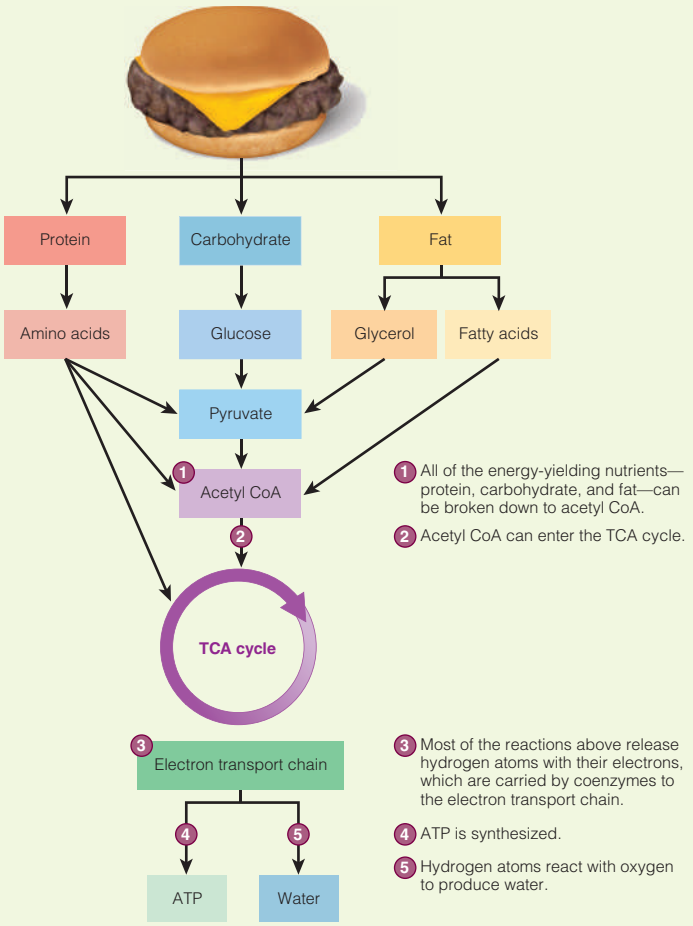
STUDY IT

# 7 Energy Metabolism

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 7.1 Chemical Reactions in the Body

- During digestion, the energy-yielding nutrients—carbohydrates, lipids, and proteins—are broken down to glucose (and other monosaccharides), glycerol, fatty acids, and amino acids. These compounds may enter metabolic pathways to yield energy (review Figure 7-5).
- **Enzymes** with their **coenzymes** help cells use nutrients to build compounds **(anabolism)** or break them down to release energy **(catabolism)**—review Figure 7-2, p. 203.
- **ATP**—a high-energy compound—captures the energy released during catabolism (review Figure 7-4, p. 204).



## 7.2 Breaking Down Nutrients for Energy

- Glucose breakdown begins with **glycolysis,** a pathway that produces **pyruvate** (review Figure 7-6, p. 208).
- Pyruvate may be converted to **lactate anaerobically** (without oxygen) or to **acetyl CoA aerobically** (with oxygen).
- Pyruvate can make glucose; acetyl CoA cannot make glucose (review Figure 7-9, p. 210).
- The glycerol part of a triglyceride can make either pyruvate (and then glucose) or acetyl CoA. The fatty acids of a triglyceride *cannot* make glucose; they can provide abundant acetyl CoA (review Figure 7-11, p. 211).
- Some amino acids can be used to make glucose; others can be used either to provide energy or to make fat. Before an amino acid enters these metabolic pathways, its nitrogen-containing amino group must be removed through deamination.
- The digestion of carbohydrate yields glucose (and other monosaccharides); some glucose is stored as glycogen, and some is broken down to pyruvate and acetyl CoA.
- The digestion of fat yields glycerol and fatty acids; some are reassembled and stored as body fat, and others are broken down to acetyl CoA.
- The digestion of protein yields amino acids; most amino acids are used to build body protein or other nitrogen-containing compounds, some are broken down to acetyl CoA, and others enter the **TCA cycle** directly.
- Acetyl CoA may enter the TCA cycle to release energy (review Figure 7-15, p. 214) or combine with other molecules of acetyl CoA to make body fat.

## 7.3 Feasting and Fasting

- If energy intake exceeds energy needs, the result will be weight gain—regardless of whether the excess is from protein, carbohydrate, or fat (review Table 7-2). The body is most efficient at storing excess energy from dietary fat.
- When fasting, the body adapts to conserve energy and minimize losses by increasing fat breakdown to **fuel** most cells, using glycerol and amino acids to make glucose for the brain and red blood cells, producing **ketone bodies** for the brain, suppressing appetite, and slowing **metabolism.**

**> FIGURE 7-5 Simplified Overview of Energy-Yielding Pathways**

© Cengage Learning

**TABLE 7-2 Review of Energy-Yielding Nutrient End Points**

| Nutrient | Yields energy? | Yields glucose? | Yields amino acids and body proteins? | Yields fat stores? |
|---|---|---|---|---|
| Carbohydrates (glucose) | Yes | Yes | Yes—when nitrogen is available, can yield *nonessential* amino acids | Yes |
| Lipids (fatty acids) | Yes | No | No | Yes |
| Lipids (glycerol) | Yes | Yes—when carbohydrate is unavailable | Yes—when nitrogen is available, can yield *nonessential* amino acids | Yes |
| Proteins (amino acids) | Yes | Yes—when carbohydrate is unavailable | Yes | Yes |

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 7.1 Chemical Reactions in the Body

(pp. 202–205)

**LEARN IT** Identify the nutrients involved in energy metabolism and the high-energy compound that captures the energy released during their breakdown.

1. Define *metabolism*, *anabolism*, and *catabolism*; give an example of each.
2. What are coenzymes, and what service do they provide in metabolism?
3. Hydrolysis is an example of a(n):
   a. coupled reaction.
   b. anabolic reaction.
   c. catabolic reaction.
   d. synthesis reaction.
4. During metabolism, released energy is captured and transferred by:
   a. enzymes.
   b. pyruvate.
   c. acetyl CoA.
   d. adenosine triphosphate.

## 7.2 Breaking Down Nutrients for Energy

(pp. 205–215)

**LEARN IT** Summarize the main steps in the energy metabolism of glucose, glycerol, fatty acids, and amino acids.

5. Name the four basic units, derived from foods, that are used by the body in energy metabolism. How many carbons are in the "backbones" of each?
6. Define *aerobic* and *anaerobic*. How does insufficient oxygen influence metabolism?
7. How does the body dispose of excess nitrogen?
8. The body derives most of its energy from:
   a. proteins and fats.
   b. vitamins and minerals.
   c. glucose and fatty acids.
   d. glycerol and amino acids.
9. Glycolysis:
   a. requires oxygen.
   b. generates abundant energy.
   c. converts glucose to pyruvate.
   d. produces ammonia as a by-product.
10. The pathway from pyruvate to acetyl CoA:
    a. produces lactate.
    b. is known as gluconeogenesis.
    c. is metabolically irreversible.
    d. requires more energy than it produces.
11. For complete oxidation, acetyl CoA enters:
    a. glycolysis.
    b. the TCA cycle.
    c. the Cori cycle.
    d. the electron transport chain.
12. Deamination of an amino acid produces:
    a. vitamin $B_6$ and energy.
    b. pyruvate and acetyl CoA.
    c. ammonia and a keto acid.
    d. carbon dioxide and water.
13. Before entering the TCA cycle, each of the energy-yielding nutrients is broken down to:
    a. ammonia.
    b. pyruvate.
    c. electrons.
    d. acetyl CoA.

## 7.3 Feasting and Fasting (pp. 216–221)

**LEARN IT** Explain how an excess of any of the three energy-yielding nutrients contributes to body fat and how an inadequate intake of any of them shifts metabolism.

14. What adaptations does the body make during a fast? What are ketone bodies? Define *ketosis*.
15. Distinguish between a loss of *fat* and a loss of *weight,* and describe how each might happen.
16. The body stores energy for future use in:
    a. proteins.
    b. acetyl CoA.
    c. triglycerides.
    d. ketone bodies.
17. During a fast, when glycogen stores have been depleted, the body begins to synthesize glucose from:
    a. acetyl CoA.
    b. amino acids.
    c. fatty acids.
    d. ketone bodies.
18. During a fast, the body produces ketone bodies by:
    a. hydrolyzing glycogen.
    b. condensing acetyl CoA.
    c. transaminating keto acids.
    d. converting ammonia to urea.

## HIGHLIGHT 7 Alcohol in the Body (pp. 222–233)

**LEARN IT** Describe how alcohol disrupts metabolism and impairs health.

19. Alcohol metabolism occurs primarily in the:
    a. liver.
    b. brain.
    c. kidneys.
    d. muscles.

**Multiple Choice Answers**

3. c 4. d 8. c 9. c 10. c 11. b 12. c 13. d 16. c 17. b 18. b 19. a

STUDY IT

# 8 Energy Balance and Body Composition

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

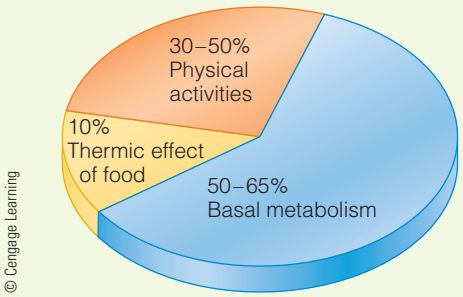
## 8.1 Energy Balance

- When energy consumed equals energy expended, a person is in **energy balance** and body weight is stable.
- If more energy is taken in than is expended, a person gains weight. If more energy is expended than is taken in, a person loses weight.

## 8.2 Energy In: The kCalories Foods Provide

- Scientists use a **bomb calorimeter** to estimate the potential energy of foods by measuring the heat energy released when foods are burned.
- **Hunger** and **appetite** initiate eating, whereas **satiation** and **satiety** stop and delay eating, respectively (review Figure 8-2, p. 238). Each responds to messages from the nervous and hormonal systems. Superimposed on these signals are complex factors involving emotions, habits, and other aspects of human behavior.

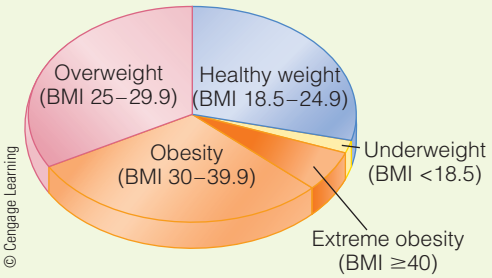
## 8.3 Energy Out: The kCalories the Body Expends



- A person in energy balance takes in energy from food and expends much of it on **basal metabolism,** some of it on physical activities, and a little on the **thermic effect of food** (review Figure 8-4).
- Energy requirements vary from person to person based on such factors as gender, age, weight, and height as well as the intensity and duration of physical activity.

## 8.4 Body Weight and Body Composition

- Body weight standards are based on a person's weight in relation to height, called the **body mass index (BMI),** and reflect disease risks, not **body composition.** BMI does not identify body fat or its distribution, and it may misclassify muscular people as overweight.
- $\text{BMI} = \frac{\text{weight (kg)}}{\text{height (m)}^2}$ or $\frac{\text{weight (lb)}}{\text{height (in)}^2} \times 703.$



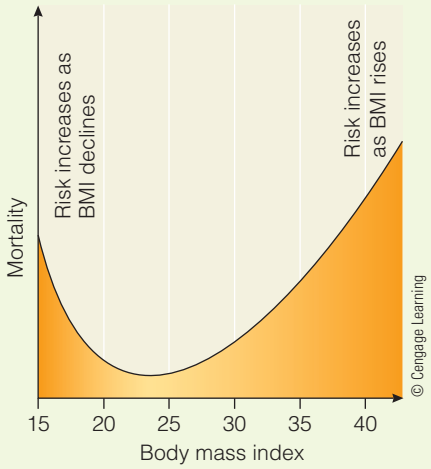
**> FIGURE 8-4 Components of Energy Expenditure**

The amount of energy expended in voluntary physical activities has the greatest variability, depending on a person's activity patterns. For a sedentary person, physical activities may account for less than half as much energy as basal metabolism, whereas an extremely active person may expend as much on activity as for basal metabolism.

The amount of energy expended in a day differs for each individual, but in general, basal metabolism is the largest component of energy expenditure and thermic effect of food is the smallest.

**> FIGURE 8-7 Distribution of Body Weights in US Adults**

**Underweight: BMI <18.5**
**Healthy: BMI 18.5 to 24.9**
**Overweight: BMI 25 to 29.9**
**Obese: BMI ≥30**



- Two-thirds of US adults have a BMI greater than 25 (review Figure 8-7).
- The ideal amount of body fat varies from person to person, but excess body fat poses health risks.
- **Central obesity**—excess abdominal fat distributed around the trunk of the body— is more common in men and presents greater health risks than excess fat distributed on the lower body, which is more common in women (review Figure 8-8 and Figure 8-9, p. 250).
- Women with a **waist circumference** greater than 35 inches and men with a waist circumference greater than 40 inches have a high risk of central obesity–related health problems.

## 8.5 Health Risks Associated with Body Weight and Body Fat

- The healthiest weight for an individual depends on personal factors such as body fat distribution, family health history, and current health status. At the extremes, both overweight and underweight impose health risks (review Figure 8-11).

**> FIGURE 8-11 BMI and Mortality**

This J-shaped curve describes the relationship between body mass index (BMI) and mortality and shows that both underweight and overweight present risks of a premature death.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 8.1 Energy Balance (p. 236)

**LEARN IT** Describe energy balance and the consequences of not being in balance.

1. A person who consistently consumes 1700 kcalories a day and expends 2200 kcalories a day for a month would be expected to:
   a. lose ½ to 1 pound.
   b. gain ½ to 1 pound.
   c. lose 4 to 5 pounds.
   d. gain 4 to 5 pounds.

## 8.2 Energy In: The kCalories Foods Provide

(pp. 236–240)

**LEARN IT** Discuss some of the physical, emotional, and environmental influences on food intake.

2. A bomb calorimeter measures:
   a. physiological fuel.
   b. energy available from foods.
   c. kcalories a person derives from foods.
   d. heat a person releases in basal metabolism.

3. The psychological desire to eat that accompanies the sight, smell, or thought of food is known as:
   a. hunger.
   b. satiety.
   c. appetite.
   d. palatability.

4. A person watching television after dinner reaches for a snack during a commercial in response to:
   a. external cues.
   b. hunger signals.
   c. stress arousal.
   d. satiety factors.

## 8.3 Energy Out: The kCalories the Body Expends (pp. 240–244)

**LEARN IT** List the components of energy expenditure and factors that might influence each.

5. The largest component of energy expenditure is:
   a. basal metabolism.
   b. physical activity.
   c. indirect calorimetry.
   d. thermic effect of food.

6. A major factor influencing BMR is:
   a. hunger.
   b. food intake.
   c. body composition.
   d. physical activity.

7. The thermic effect of an 800-kcalorie meal is about:
   a. 8 kcalories.
   b. 80 kcalories.
   c. 160 kcalories.
   d. 200 kcalories.

## 8.4 Body Weight and Body Composition

(pp. 245–251)

**LEARN IT** Distinguish between body weight and body composition, including methods to assess each.

8. What problems are involved in defining "ideal" body weight?

9. What is central obesity, and what is its relationship to disease?

10. For health's sake, a person with a BMI of 21 might want to:
    a. lose weight.
    b. maintain weight.
    c. gain weight.

11. Which of the following reflects height and weight?
    a. body mass index
    b. central obesity
    c. waist circumference
    d. body composition

## 8.5 Health Risks Associated with Body Weight and Body Fat (pp. 251–254)

**LEARN IT** Identify relationships between body weight and chronic diseases.

12. Which of the following increases disease risks?
    a. BMI 19–21
    b. BMI 22–25
    c. lower-body fat
    d. central obesity

## HIGHLIGHT 8 Eating Disorders (pp. 256–263)

**LEARN IT** Compare the diagnoses, characteristics, and treatments of the different eating disorders.

13. Which of the following is *not* commonly seen in RED-S
    a. amenorrhea
    b. osteoporosis
    c. disordered eating
    d. muscle dysmorphia

**Multiple Choice Answers**

# STUDY IT 9 Weight Management: Overweight, Obesity, and Underweight

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 9.1 Overweight and Obesity

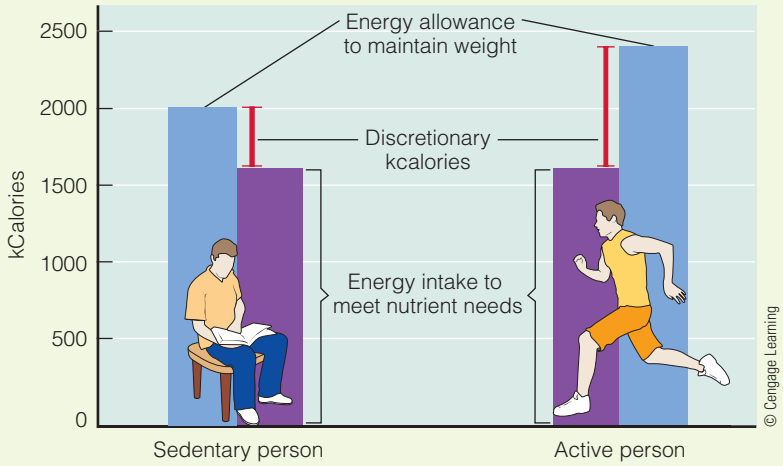
- Fat cells develop by increasing in number and size (review Figure 9-2, p. 267).
- Preventing weight gain depends on limiting the number of fat cells; weight loss depends on decreasing the size of fat cells.
- **Lipoprotein lipase (LPL)** removes triglycerides from the blood for storage in both adipose tissue and muscle cells. LPL activity is influenced by weight and gender.
- With weight gains or losses, the body adjusts in an attempt to return to its previous weight (**set point** theory).

## 9.2 Causes of Overweight and Obesity

- Obesity has multiple causes and different combinations of causes in different people.
- Some environmental causes, such as overeating and physical inactivity, may be within a person's control, and some, such as genetics, may be beyond it.
- Proteins such as **ghrelin** and **leptin** regulate food intake and energy homeostasis. Ghrelin enhances appetite and decreases energy expenditure, whereas leptin suppresses appetite and increases energy expenditure.

## 9.3 Problems of Overweight and Obesity

- Whether a person should lose weight depends on factors such as the extent of overweight, age, health risks, and genetics.
- Not all obesity will cause disease or shorten life expectancy. Just as there are unhealthy, normal-weight people, there are healthy, overweight people.
- Some people risk more in the process of losing weight than in remaining overweight.
- **Fad diets** and weight-loss supplements can be as physically and psychologically damaging as excess body weight.



## 9.4 Aggressive Treatments for Obesity

- Obese people with high risks of medical problems may need aggressive treatment, including drugs or surgery.
- Others may benefit most from improving eating and physical activity habits.

## 9.5 Weight-Loss Strategies

- A person who adopts a lifelong "eating plan for good health" rather than a "diet for weight loss" will be more likely to keep the lost weight off.
- Table 9-3 (p. 281) provides several tips for successful **weight management.**

> FIGURE 9-7 **Influence of Physical Activity on Discretionary kCalories**

- Physical activity can increase energy expenditure (review Figure 9-7), improve body composition, help control appetite, reduce stress and stress eating, and enhance physical and psychological well-being.
- A surefire remedy for obesity has yet to be found; a combination of approaches is most effective.
- Weight loss depends on adjusting diet and physical activity so that more energy is expended than is taken in.
- For weight loss, energy intake should be reduced by 500 to 750 kcalories per day, depending on starting body weight and usual food intake.
- Safe rate for weight loss is ½ to 2 pounds per week or 5 to 10 percent body weight within 6 months.
- **Behavior modification** and cognitive restructuring retrain habits to support a healthy eating and activity plan.
- Treatment requires time, individualization, and sometimes the assistance of a registered dietitian nutritionist or support group.
- Preventing weight gains and **successful weight-loss maintenance** require vigilant attention to diet and physical activity; taking care of oneself is a lifelong responsibility.

## 9.6 Underweight

- Both the incidence of **underweight** and the health problems associated with it are less prevalent than overweight and its associated problems.
- To gain weight, a person must train physically and increase energy intake by selecting energy-dense foods, eating regular meals, taking larger portions, and consuming extra snacks and beverages.
- Table 9-5 (p. 291) includes a summary of weight-gain strategies.

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 9.1 Overweight and Obesity (pp. 266–268)

**LEARN IT** Describe how body fat develops and why it can be difficult to maintain weight gains and losses.

1. With weight loss, fat cells:
   a. decrease in size only.
   b. decrease in number only.
   c. decrease in both number and size.
   d. decrease in number, but increase in size.
2. Describe the role of lipoprotein lipase (LPL).

## 9.2 Causes of Overweight and Obesity

(pp. 268–272)

**LEARN IT** Review some of the causes of obesity.

3. Obesity is caused by:
   a. overeating.
   b. inactivity.
   c. defective genes.
   d. multiple factors.
4. The protein produced by the fat cells under the direction of the *ob* gene is called:
   a. leptin.
   b. serotonin.
   c. sibutramine.
   d. phentermine.

## 9.3 Problems of Overweight and Obesity

(pp. 272–274)

**LEARN IT** Discuss the physical, social, and psychological consequences of overweight and obesity.

5. Which of the following is *not* used to evaluate the risks to health from obesity?
   a. body mass index
   b. blood leptin levels
   c. waist circumference
   d. disease risk profiles

## 9.4 Aggressive Treatments for Obesity

(pp. 274–276)

**LEARN IT** Explain the risks and benefits, if any, of aggressive ways to treat obesity.

6. Gastric bypass surgery:
   a. is the best noninvasive treatment for obesity.
   b. limits food intake by reducing the capacity of the stomach.
   c. allows a person to eat unlimited amounts of food without weight gain.
   d. suppresses hunger by increasing production of gastrointestinal hormones.

## 9.5 Weight-Loss Strategies (pp. 276–289)

**LEARN IT** Outline reasonable strategies for achieving and maintaining a healthy body weight.

7. What are the benefits of increased physical activity in a weight-loss program?
8. Describe the behavioral strategies for changing an individual's dietary habits. What role does personal attitude play?
9. A realistic goal for weight loss is to reduce body weight:
   a. down to the weight a person was at age 25.
   b. down to the ideal weight in the weight-for-height tables.
   c. by 10 percent over 6 months.
   d. by 15 percent over 3 months.
10. A nutritionally sound weight-loss diet might restrict daily energy intake to create a:
    a. 1000-kcalorie-per-month deficit.
    b. 500-kcalorie-per-month deficit.
    c. 500-kcalorie-per-day deficit.
    d. 3500-kcalorie-per-day deficit.
11. Successful weight loss depends on:
    a. avoiding fats and limiting water.
    b. taking supplements and drinking water.
    c. increasing proteins and restricting carbohydrates.
    d. reducing energy intake and increasing physical activity.
12. Physical activity does *not* help a person to:
    a. lose weight.
    b. retain muscle.
    c. maintain weight loss.
    d. lose fat in trouble spots.
13. Which strategy would *not* help an overweight person to lose weight?
    a. Exercise.
    b. Eat slowly.
    c. Limit high-fat foods.
    d. Eat energy-dense foods regularly.

## 9.6 Underweight (pp. 289–291)

**LEARN IT** Summarize strategies for gaining weight.

14. Which strategy would *not* help an underweight person to gain weight?
    a. Exercise.
    b. Drink plenty of water.
    c. Eat snacks between meals.
    d. Eat large portions of foods.

## HIGHLIGHT 9 The Latest and Greatest Weight-Loss Diet–Again (pp. 296–299)

**LEARN IT** Contrast the differences between popular fad diets and weight-loss diets based on sound nutrition.

15. A real benefit typical of many fad diets is:
    a. ketosis.
    b. a diet plan.
    c. changes in metabolism.
    d. quick and permanent weight loss.

**Multiple Choice Answers**

1. a 2. d 3. d 4. a 5. b 6. b 7. c 8. c 9. c 10. c 11. d 12. d 13. d 14. b 15. b

STUDY IT

# 10 The Water-Soluble Vitamins: B Vitamins and Vitamin C

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 10.1 The Vitamins—An Overview

- The **vitamins** are organic, essential nutrients needed in tiny amounts in the diet both to prevent deficiency diseases and to support optimal health. The body handles the vitamins differently depending on whether they are water- or fat-soluble (review Table 10-2).
- The water-soluble vitamins are the B vitamins and vitamin C; the fat-soluble vitamins are vitamins A, D, E, and K. The B vitamins include thiamin, niacin, riboflavin, vitamin $B_6$, folate, vitamin $B_{12}$, pantothenic acid, and biotin.

## 10.2 The B Vitamins

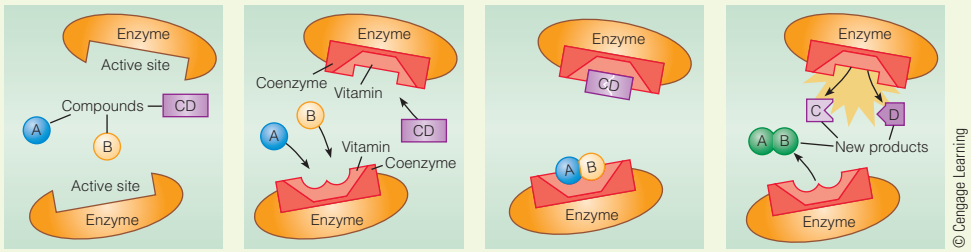
- The B vitamins serve as **coenzymes**—small organic molecules closely associated with enzymes that facilitate the work of cells (review Figure 10-2).
- **Thiamin** is part of the coenzyme TPP, which assists in energy metabolism. Deficiency can result in **beriberi.** Thiamin occurs in small quantities in many nutritious foods; pork is an exceptionally good source.
- **Riboflavin** is part of the coenzymes FMN and FAD that accept and donate hydrogens during energy metabolism. Milk and milk products are good sources.
- **Niacin** is part of the coenzymes NAD and NADP that participate in many metabolic reactions. The deficiency disease, **pellagra,** causes diarrhea, dermatitis, dementia, and eventually death ("the 4 Ds"). Toxicity produces **"niacin flush"**—a tingling, painful sensation. The amino acid tryptophan can be converted to niacin in the body: 60 mg tryptophan = 1 **NE (niacin equivalent)**. Good sources of niacin are protein-rich foods.
- **Biotin** plays a critical role in energy metabolism, replenishing oxaloacetate in the TCA cycle. Biotin is widespread in foods; deficiencies and toxicities are rare.
- **Pantothenic acid** is part of coenzyme A that forms acetyl CoA in many metabolic pathways. Pantothenic acid is widespread in foods; deficiencies and toxicities are rare.
- **Vitamin $B_6$** occurs as pyridoxal, pyridoxine, and pyridoxamine; all can become part of the coenzyme PLP, which is active in amino acid metabolism. Deficiency causes convulsions; toxicity causes nerve damage.
- **Folate** is part of the coenzyme THF that activates vitamin $B_{12}$, synthesizes DNA, and regenerates the amino acid methionine from homocysteine. Folate helps prevent **neural tube defects.** Excessive folate can mask the **anemia** of a vitamin $B_{12}$ deficiency, but it will not prevent the associated nerve damage. Folate is abundant in legumes, fruits, and vegetables.

**TABLE 10-2 Water-Soluble and Fat-Soluble Vitamins Compared**

| | Water-Soluble Vitamins: B Vitamins and Vitamin C | Fat-Soluble Vitamins: Vitamins A, D, E, and K |
|---|---|---|
| **Absorption** | Directly into the blood | First into the lymph, then the blood |
| **Transport** | Travel freely | Many require transport proteins |
| **Storage** | Circulate freely in water-filled parts of the body | Stored in the cells associated with fat |
| **Excretion** | Kidneys detect and remove excess in urine | Less readily excreted; tend to remain in fat-storage sites |
| **Toxicity** | Possible to reach toxic levels when consumed from supplements | Likely to reach toxic levels when consumed from supplements |
| **Requirements** | Needed in frequent doses (perhaps 1 to 3 days) | Needed in periodic doses (perhaps weeks or even months) |

NOTE: Exceptions occur, but these differences between the water-soluble and fat-solule vitamins are valid generalizations.

© Cengage Learning



- **Vitamin $B_{12}$** activates folate, synthesizes DNA, regenerates methionine from homocysteine, and maintains the sheath that protects nerve fibers. Deficiencies typically occur when either hydrochloric acid or **intrinsic factor** is lacking. Vitamin $B_{12}$ is found primarily in foods derived from animals.
- Many substances (including **inositol and carnitine**) that people claim as B vitamins are not. Fortunately, a variety of foods from each food group provides an adequate supply of all B vitamins.

## 10.3 Vitamin C

- Vitamin C acts as an **antioxidant**—a substance that decreases the adverse effects of **free radicals** in the body.
- Vitamin C works as a **cofactor** in the synthesis of **collagen,** neurotransmitters (serotonin and norepinephrine), hormones (thyroxine), and other compounds.
- Vitamin C deficiency causes **scurvy.**

**> FIGURE 10-2 Coenzyme Action**

Some vitamins form part of the coenzymes that enable enzymes either to synthesize compounds (as illustrated by the lower enzymes in this figure) or to dismantle compounds (as illustrated by the upper enzymes).

Without coenzymes, compounds A, B, and CD don't respond to their enzymes.

With the coenzymes in place, compounds are attracted to their sites on the enzymes . . .

. . . and the reactions proceed instantaneously. The coenzymes often donate or accept electrons, atoms, or groups of atoms.

The reactions are completed with either the formation of a new product, AB, or the breaking apart of a compound into two new products, C and D, and the release of energy.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 10.1 The Vitamins—An Overview

(pp. 302–304)

**LEARN IT** Describe how vitamins differ from the energy nutrients and how fat-soluble vitamins differ from water-soluble vitamins.

1. Vitamins:
   a. are inorganic compounds.
   b. yield energy when broken down.
   c. are soluble in either water or fat.
   d. perform best when linked in long chains.
2. The rate at and the extent to which a vitamin is absorbed and used in the body is known as its:
   a. bioavailability.
   b. intrinsic factor.
   c. physiological effect.
   d. pharmacological effect.

## 10.2 The B Vitamins (pp. 304–327)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for each of the B vitamins (thiamin, riboflavin, niacin, biotin, pantothenic acid, vitamin $B_6$, folate, and vitamin $B_{12}$).

3. Which B vitamins are involved in energy metabolism? Protein metabolism? Cell division?
4. What is the relationship of tryptophan to niacin?
5. Describe the relationship between folate and vitamin $B_{12}$.
6. What risks are associated with high doses of niacin? Vitamin $B_6$? Vitamin C?
7. Many of the B vitamins serve as:
   a. coenzymes.
   b. antagonists.
   c. antioxidants.
   d. serotonin precursors.
8. With respect to thiamin, which of the following is the most nutrient dense?
   a. 1 slice whole-wheat bread (69 kcalories and 0.1 milligram thiamin)
   b. 1 cup yogurt (144 kcalories and 0.1 milligram thiamin)
   c. 1 cup snow peas (69 kcalories and 0.22 milligram thiamin)
   d. 1 chicken breast (141 kcalories and 0.06 milligram thiamin)
9. The body can make niacin from:
   a. tyrosine.
   b. serotonin.
   c. carnitine.
   d. tryptophan.
10. The vitamin that protects against neural tube defects is:
    a. niacin.
    b. folate.
    c. riboflavin.
    d. vitamin $B_{12}$.
11. A lack of intrinsic factor may lead to:
    a. beriberi.
    b. pellagra.
    c. pernicious anemia.
    d. atrophic gastritis.
12. Which of the following is a B vitamin?
    a. inositol
    b. carnitine
    c. vitamin $B_{15}$
    d. pantothenic acid

## 10.3 Vitamin C (pp. 327–333)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for vitamin C.

13. Vitamin C serves as a(n):
    a. coenzyme.
    b. antagonist.
    c. antioxidant.
    d. intrinsic factor.
14. The requirement for vitamin C is highest for:
    a. smokers.
    b. athletes.
    c. alcoholics.
    d. the elderly.

See p. 332–333 for a summary of the water-soluble vitamins.

## HIGHLIGHT Vitamin and Mineral Supplements (pp. 335–341)

**LEARN IT** Present arguments for and against the use of dietary supplements.

15. The best vitamin and mineral supplements:
    a. are high-potency.
    b. are nanoceuticals.
    c. are made from organic vegetables.
    d. provide 50 to 150 percent of the Daily Value.

**Multiple Choice Answers**

1. c 2. a 7. a 8. c 9. d 10. b 11. c 12. d 13. c 14. a 15. d

STUDY IT

# 11 The Fat-Soluble Vitamins: A, D, E, and K

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

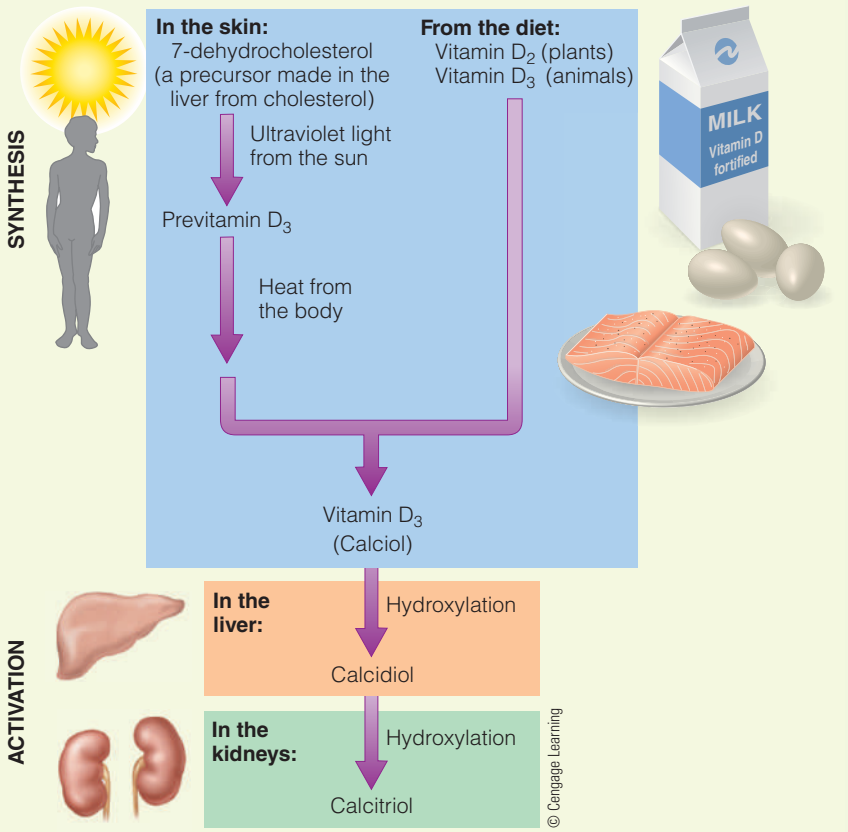
## 11.1 Vitamin A and Beta-Carotene

- **Vitamin A** is found in the body in three forms: **retinol, retinal,** and **retinoic acid.** Together, they are essential to vision, healthy epithelial tissues, and growth.
- Vitamin A deficiency is a major health problem worldwide, leading to infections, blindness, and **keratinization.**
- Toxicity can also cause problems and is most often associated with supplement abuse.
- Animal-derived foods such as liver and whole or fortified milk provide **retinoids,** whereas brightly colored plant-derived foods such as spinach, carrots, and pumpkins provide **beta-carotene** and other **carotenoids.**
- In addition to serving as a precursor for vitamin A, beta-carotene may act as an antioxidant in the body.

## 11.2 Vitamin D

- **Vitamin D** can be synthesized in the body with the help of sunlight (see Figure 11-8) or obtained from fortified milk.
- Vitamin D sends signals to three primary target sites: the GI tract to absorb more calcium and phosphorus, the bones to release more, and the kidneys to retain more. These actions maintain blood calcium concentrations and support bone formation.
- A vitamin D deficiency causes **rickets** in childhood and **osteomalacia** in later life.

## 11.3 Vitamin E



- Vitamin E **(alpha-tocopherol)** acts as an antioxidant, defending lipids and other components of the cells against oxidative damage.
- Deficiencies are rare, but they do occur in premature infants, the primary symptom being **erythrocyte hemolysis** (red blood cell breakage).
- Vitamin E is found predominantly in vegetable oils and appears to be one of the least toxic of the fat-soluble vitamins.

## 11.4 Vitamin K

- Vitamin K helps with blood clotting (review Figure 11-11, p. 359), and its deficiency causes **hemorrhagic disease** (uncontrolled bleeding).
- Bacteria in the GI tract can make vitamin K; people typically receive about half of their requirements from bacterial synthesis and half from foods such as green vegetables and vegetable oils.
- Because people depend on bacterial synthesis for vitamin K, deficiency is most likely in newborn infants and in people taking antibiotics.

**> FIGURE 11-8 Vitamin D Synthesis and Activation**

The final activation step in the kidneys is tightly regulated by hormones.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 11.1 Vitamin A and Beta-Carotene

(pp. 344–351)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for vitamin A.

1. What are vitamin precursors? Name the precursors of vitamin A, and tell in what classes of foods they are found. Give examples of foods with high vitamin A activity.

2. The form of vitamin A active in vision is:
   a. retinal.
   b. retinol.
   c. rhodopsin.
   d. retinoic acid.

3. Vitamin A–deficiency symptoms include:
   a. rickets and osteomalacia.
   b. hemorrhaging and jaundice.
   c. night blindness and keratomalacia.
   d. fibrocystic breast disease and erythrocyte hemolysis.

4. Good sources of vitamin A include:
   a. oatmeal, pinto beans, and ham.
   b. apricots, turnip greens, and liver.
   c. whole-wheat bread, green peas, and tuna.
   d. corn, grapefruit juice, and sunflower seeds.

## 11.2 Vitamin D (pp. 351–356)

**LEARN IT** Identify the main roles, deficiency symptoms, and sources for vitamin D.

5. How is vitamin D unique among the vitamins?

6. To keep minerals available in the blood, vitamin D targets:
   a. the skin, the muscles, and the bones.
   b. the kidneys, the liver, and the bones.
   c. the intestines, the kidneys, and the bones.
   d. the intestines, the pancreas, and the liver.

7. Vitamin D can be synthesized from a precursor that the body makes from:
   a. bilirubin.
   b. tocopherol.
   c. cholesterol.
   d. beta-carotene.

## 11.3 Vitamin E (pp. 357–358)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for vitamin E.

8. Vitamin E's most notable role is to:
   a. protect lipids against oxidation.
   b. activate blood-clotting proteins.
   c. support protein and DNA synthesis.
   d. enhance calcium deposits in the bones.

9. The classic sign of vitamin E deficiency is:
   a. rickets.
   b. xeropthalmia.
   c. muscular dystrophy.
   d. erythrocyte hemolysis.

## 11.4 Vitamin K (pp. 358–361)

**LEARN IT** Identify the main roles, deficiency symptoms, and sources for vitamin K.

10. What conditions may lead to vitamin K deficiency?

11. Without vitamin K:
    a. muscles atrophy.
    b. bones become soft.
    c. skin rashes develop.
    d. blood fails to clot.

12. A significant amount of vitamin K comes from:
    a. vegetable oils.
    b. sunlight exposure.
    c. bacterial synthesis.
    d. fortified grain products.

See p. 361 for a summary of the fat-soluble vitamins.

## HIGHLIGHT 11 Antioxidant Nutrients in Disease Prevention (pp. 364–368)

**LEARN IT** Describe how antioxidants defend against free radicals that contribute to diseases.

13. Free radicals:
    a. are highly reactive.
    b. defend against cancer.
    c. act as antioxidants in the body.
    d. are found abundantly in fruits and vegetables.

**Multiple Choice Answers**

2. a 3. c 4. b 6. c 7. c 8. a 9. d 11. d 12. c 13. a

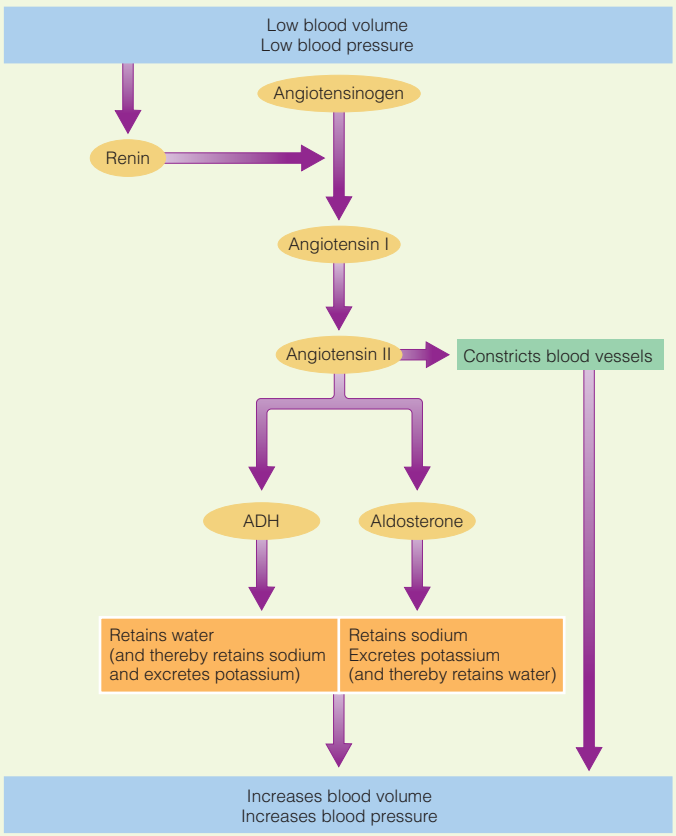
STUDY IT

# 12 Water and the Major Minerals



Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 12.1 Water and the Body Fluids

- Water makes up about 60 percent of an adult's body weight.
- Water assists with the transport of nutrients and waste products throughout the body, participates in chemical reactions, acts as a solvent, serves as a shock absorber, and regulates body temperature.
- To maintain **water balance,** intake from liquids, foods, and metabolism must equal losses from the kidneys, skin, lungs, and GI tract (review Table 12-3, p. 373).
- Whenever the body experiences low blood volume, low blood pressure, or highly concentrated body fluids, the actions of **ADH, renin, angiotensin,** and **aldosterone** restore homeostasis (review Figure 12-3).
- **Electrolytes** (charged minerals) in the fluids help distribute the fluids inside and outside the cells, thus ensuring the appropriate water balance and acid-base balance to support all life processes.
- Excessive losses of fluids and electrolytes upset these balances, and the kidneys play a key role in restoring homeostasis.

**> FIGURE 12-3 How the Body Regulates Blood Volume and Blood Pressure**

The renin-angiotensin-aldosterone system helps regulate blood volume and therefore blood pressure.

© Cengage Learning

## 12.2 The Minerals—An Overview

- The **major minerals** are needed in the diet and found in the body in larger quantities than the **trace minerals** (review Figure 12-9, p. 381).
- Minerals are inorganic elements that retain their chemical identities; receive special handling and regulation in the body; and may bind with other substances or interact with other minerals, thus limiting their absorption.
- The major minerals, especially sodium, chloride, and potassium, influence the body's fluid balance; whenever an **anion** moves, a **cation** moves—always maintaining homeostasis.
- Sodium, chloride, potassium, calcium, and magnesium are key members of the team of nutrients that direct nerve impulse transmission and muscle contraction. They are also the primary nutrients involved in regulating blood pressure.
- Phosphorus and magnesium participate in many reactions involving glucose, fatty acids, amino acids, and the vitamins. Calcium, phosphorus, and magnesium combine to form the structure of the bones and teeth. Each major mineral also plays other specific roles in the body.

## 12.3 The Major Minerals

- **Sodium** is the main cation outside cells and one of the primary electrolytes responsible for maintaining fluid balance. Dietary deficiency is rare; excesses seem to aggravate hypertension, and so health professionals advise a diet moderate in **salt** and sodium.
- **Chloride** is the major anion outside cells, and it associates closely with sodium. In addition to its role in fluid balance, chloride is part of the stomach's hydrochloric acid.
- **Potassium** is the primary cation inside cells and plays an important role in maintaining fluid balance. Fresh foods, notably fruits and vegetables, are its best sources.
- **Calcium** is found primarily in the bones, where it provides a rigid structure and a reservoir of calcium for the blood. Blood calcium participates in muscle contraction, blood clotting, and nerve impulses, and it is closely regulated by a system of hormones and vitamin D (review Figure 12-12, p. 389). Milk and milk products are good sources of calcium, but certain vegetables and tofu also provide calcium. Even when calcium intake is inadequate, blood calcium remains normal, but at the expense of bone loss, which can lead to **osteoporosis.**
- **Phosphorus** accompanies calcium both in the crystals of bone and in many foods such as milk. Phosphorus is also important in energy metabolism, as part of phospholipids, and as part of the genetic materials DNA and RNA.
- **Magnesium** supports bone **mineralization** and participates in numerous enzyme systems and in heart function. It is found abundantly in legumes and dark green, leafy vegetables and, in some areas, in water.
- **Sulfate** is found in all protein-containing foods. Its primary role in amino acids is to stabilize proteins by forming disulfide bridges.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 12.1 Water and the Body Fluids (pp. 372–381)

**LEARN IT** Explain how the body regulates fluid balance.

1. List the roles of water in the body.
2. List the sources of water intake and routes of water excretion.
3. What is ADH? Where does it exert its action? What is aldosterone? How does it work?
4. How does the body use electrolytes to regulate fluid balance?
5. The body generates water during the:
   a. buffering of acids.
   b. dismantling of bone.
   c. metabolism of minerals.
   d. oxidation of energy nutrients through the electron transport chain.
6. Regulation of fluid and electrolyte balance and acid-base balance depends primarily on the:
   a. kidneys.
   b. intestines.
   c. sweat glands.
   d. specialized tear ducts.

## 12.2 The Minerals—An Overview (pp. 381–382)

**LEARN IT** List some of the ways minerals differ from vitamins and other nutrients.

7. What do the terms major and trace mean when describing the minerals in the body?
8. Describe some characteristics of minerals that distinguish them from vitamins.
9. The distinction between the major and trace minerals reflects the:
   a. ability of their ions to form salts.
   b. amounts of their contents in the body.
   c. importance of their functions in the body.
   d. capacity to retain their identity after absorption.

## 12.3 The Major Minerals (pp. 382–398)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for each of the major minerals (sodium, chloride, potassium, calcium, phosphorus, magnesium, and sulfate).

10. What is the major function of sodium in the body? Describe how the kidneys regulate blood sodium. Is a dietary deficiency of sodium likely? Why or why not?
11. List calcium's roles in the body. How does the body keep blood calcium constant regardless of intake?
12. Name significant food sources of calcium. What are the consequences of inadequate intakes?
13. List the roles of phosphorus in the body. Discuss the relationships between calcium and phosphorus. Is a dietary deficiency of phosphorus likely? Why or why not?
14. State the major functions of chloride, potassium, magnesium, and sulfur in the body. Are deficiencies of these nutrients likely to occur in your own diet? Why or why not?
15. The principal cation in extracellular fluids is:
    a. sodium.
    b. chloride.
    c. potassium.
    d. phosphorus.
16. The role of chloride in the stomach is to help:
    a. support nerve impulses.
    b. convey hormonal messages.
    c. maintain a strong acidity.
    d. assist in muscular contractions.
17. Which would provide the most potassium?
    a. bologna
    b. potatoes
    c. pickles
    d. whole-wheat bread
18. Calcium homeostasis depends on:
    a. vitamin K, aldosterone, and renin.
    b. vitamin K, parathyroid hormone, and renin.
    c. vitamin D, aldosterone, and calcitonin.
    d. vitamin D, calcitonin, and parathyroid hormone.
19. Calcium absorption is hindered by:
    a. lactose.
    b. oxalates.
    c. vitamin D.
    d. stomach acid.
20. Phosphorus assists in many activities in the body, but not:
    a. energy metabolism.
    b. the clotting of blood.
    c. the transport of lipids.
    d. bone and teeth formation.
21. Most of the body's magnesium can be found in the:
    a. bones.
    b. nerves.
    c. muscles.
    d. extracellular fluids.

See p. 397 for a summary of the major minerals.

## HIGHLIGHT 12 Osteoporosis and Calcium

(pp. 400–405)

**LEARN IT** Describe factors that contribute to the development of osteoporosis and strategies to prevent it.

22. Which of the following is not a risk factor for osteoporosis?
    a. overweight
    b. cigarette smoking
    c. sedentary lifestyle
    d. inadequate dietary calcium and vitamin D

**Multiple Choice Answers**

5. d 6. a 9. b 15. a 16. c 17. b 18. d 19. b 20. b 21. a 22. a

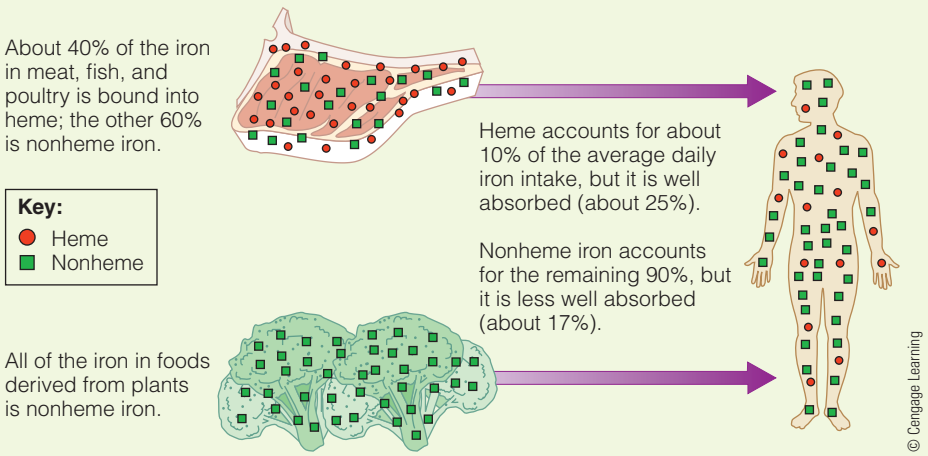
STUDY IT

# 13 The Trace Minerals

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 13.1 The Trace Minerals—An Overview

- The body needs tiny amounts of the **trace minerals.**
- The trace minerals can be toxic at levels not far above estimated requirements—a consideration for supplement users (review Figure 13-1, p. 408).
- Like the other nutrients, the trace minerals are best obtained by eating a variety of foods.



## 13.2 The Trace Minerals

- **Iron** is found in **hemoglobin** and **myoglobin** where it carries oxygen for energy metabolism; iron also acts as a **cofactor** for some enzymes. **Iron deficiency** is most common among infants and young children, teenagers, women of childbearing age, and pregnant women. Symptoms include fatigue and anemia. **Iron overload** is most common in men. **Heme iron,** which is found only in meat, fish, and poultry, is better absorbed than **nonheme iron,** which occurs in most foods (review Figure 13-4). Nonheme iron absorption is improved by eating iron-containing foods with foods containing the **MFP factor** and vitamin C; absorption is limited by phytates and oxalates.
- Zinc-requiring enzymes participate in reactions affecting growth, vitamin A activity, and pancreatic digestive enzyme synthesis. Both dietary **zinc** and zinc-rich pancreatic secretions (via **enteropancreatic circulation**) are available for absorption. Absorption is monitored by a special binding protein (**metallothionein**) in the small intestine. Protein-rich foods derived from animals are the best sources of bioavailable zinc. Fiber and phytates in cereals bind zinc, limiting absorption. Symptoms of deficiency include growth retardation and sexual immaturity.
- Iodide, the **iodine** ion, is an essential component of the thyroid hormone. A deficiency can lead to **goiter** (enlargement of the thyroid gland) and can impair fetal development, causing **cretinism.** Iodization of salt has largely eliminated iodine deficiency in the United States.
- **Selenium** is an antioxidant nutrient that works closely with the glutathione peroxidase enzyme and vitamin E. Selenium is found with protein in foods. Deficiencies are associated with a predisposition to a type of heart abnormality known as **Keshan disease.**
- **Copper** is a component of several enzymes, all of which are involved with oxygen or oxidation. Some act as antioxidants; others are essential to iron metabolism. Legumes, whole grains, and shellfish are good sources of copper.
- Manganese-dependent enzymes are involved in bone formation and various metabolic processes. Because **manganese** is widespread in plant foods, deficiencies are rare, although regular use of calcium and iron supplements may limit manganese absorption.
- **Fluoride** makes teeth more resistant to decay. Fluoridation of public water reduces the incidence of dental caries; excess fluoride during tooth development can discolor and pit tooth enamel **(fluorosis).**
- **Chromium** enhances insulin's action. Deficiency can result in a diabetes-like condition. Chromium is widely available in unrefined foods including brewer's yeast, whole grains, and liver.
- **Molybdenum** is a part of many **metalloenzymes.** Deficiencies are unknown and toxicity is rare. It is found in a variety of foods.

## 13.3 Contaminant Minerals

- Contaminant minerals include the **heavy metals** lead, mercury, and cadmium that enter the food supply by way of soil, water, and air pollution.
- Lead typifies the ways all heavy metals behave in the body: they interfere with nutrients that are trying to do their jobs. The "good guy" nutrients are shoved aside by the "bad guy" contaminants. Then, when the contaminants cannot perform the role of the nutrients, health diminishes.
- To safeguard our health, we must defend ourselves against contamination by eating nutrient-rich foods and preserving a clean environment.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 13.1 The Trace Minerals—An Overview

(pp. 408–409)

**LEARN IT** Summarize key factors unique to the trace minerals.

1. Discuss the importance of balanced and varied diets in obtaining the essential minerals and avoiding toxicities.
2. Describe some of the ways trace minerals interact with one another and with other nutrients.

## 13.2 The Trace Minerals (pp. 410–428)

**LEARN IT** Identify the main roles, deficiency symptoms, and food sources for each of the essential trace minerals (iron, zinc, iodine, selenium, copper, manganese, fluoride, chromium, and molybdenum).

3. Distinguish between heme and nonheme iron. Discuss the factors that enhance iron absorption.
4. Iron absorption is impaired by:
   a. heme.
   b. phytates.
   c. vitamin C.
   d. MFP factor.
5. Which of these people is *least* likely to develop an iron deficiency?
   a. 3-year-old boy
   b. 52-year-old man
   c. 17-year-old girl
   d. 24-year-old woman
6. Which of the following would *not* describe the blood cells of a severe iron deficiency?
   a. anemic
   b. microcytic
   c. pernicious
   d. hypochromic
7. Which provides the most absorbable iron?
   a. 1 apple
   b. 1 cup milk
   c. 3 ounces steak
   d. ½ cup spinach
8. What causes iron overload? What are its symptoms?
9. Describe the similarities and differences in the absorption and regulation of iron and zinc.
10. Discuss possible reasons for a low intake of zinc. What factors affect the bioavailability of zinc?
11. The intestinal protein that helps to regulate zinc absorption is:
    a. albumin.
    b. ferritin.
    c. hemosiderin.
    d. metallothionein.
12. A classic sign of zinc deficiency is:
    a. anemia.
    b. goiter.
    c. mottled teeth.
    d. growth retardation.
13. What public health measure has been used in preventing simple goiter?
14. Cretinism is caused by a deficiency of:
    a. iron.
    b. zinc.
    c. iodine.
    d. selenium.
15. The mineral best known for its role as an antioxidant is:
    a. copper.
    b. selenium.
    c. manganese.
    d. molybdenum.
16. What measure has been recommended for protection against tooth decay?
17. Fluorosis occurs when fluoride:
    a. is excessive.
    b. is inadequate.
    c. binds with phosphorus.
    d. interacts with calcium.
18. Which mineral enhances insulin activity?
    a. zinc
    b. iodine
    c. chromium
    d. manganese

See p. 430 for a summary of the trace minerals.

## 13.3 Contaminant Minerals (p. 429)

**LEARN IT** Describe how contaminant minerals disrupt body processes and impair nutrition status.

19. Which of the following does lead *not* compete with?
    a. iron
    b. zinc
    c. fluoride
    d. calcium

## HIGHLIGHT 13 Phytochemicals and Functional Foods (pp. 433–439)

**LEARN IT** Define *phytochemicals* and explain how they might defend against chronic diseases.

20. Examples of phytochemicals include:
    a. LDL and DNA.
    b. lycopene and lutein.
    c. soybeans and flaxseeds.
    d. carcinogens and goitrogens.

**Multiple Choice Answers**

4. b 5. b 6. c 7. c 11. d 12. d 14. c 15. b 17. a 18. c 19. c 20. b

STUDY IT

# 14 Fitness: Physical Activity, Nutrients, and Body Adaptations

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 14.1 Fitness

- **Physical activity** promotes good health and reduces the risk of developing a number of diseases.
- The components of **fitness** are **flexibility, muscle strength, muscle endurance,** and **cardiorespiratory endurance.**
- Participating in cardiorespiratory, strength, and flexibility activities improves fitness and benefits health (review Table 14-2, p. 444).

## 14.2 Energy Systems and Fuels to Support Activity

- The high-energy compound ATP provides the energy that powers all the activities of living cells.
- Physical activity uses ATP.
- Three major energy systems enable muscle cells to replenish ATP during activity: the phosphagen system, the lactic acid system, and the aerobic system.
- The phosphagen system relies on the breakdown of another high-energy compound **CP,** to replenish ATP. CP can split anaerobically to release phosphate and restore ATP.

  During rest: ATP + creatine → CP

  During activity: CP → ATP + creatine
- The lactic acid system involves the incomplete oxidation of glucose anaerobically to lactate.
- The aerobic system generates ATP from the oxidation of carbohydrate, fat, and some amino acids.
- Fuel mixture during physical activity depends on diet, the intensity and duration of activity, and training (review Table 14-4).
- During intense activity, the fuel mix is mostly glucose; during less intense activity, fat makes a greater contribution.
- With endurance training, muscle cells adapt to store more glycogen and to rely less on glucose and more on fat for energy.
- Active athletes may need more protein than **sedentary** people do; they typically eat more food and therefore obtain enough protein without supplements (review Table 14-5, p. 455).

## 14.3 Vitamins and Minerals to Support Activity

- With the possible exception of iron for women, well-nourished active people and athletes do not need dietary supplements.

## 14.4 Fluids and Electrolytes to Support Activity

- **Heat stroke** and **hypothermia** can be fatal (review Table 14-6, p. 458).
- Active people need to drink plenty of water (review Table 14-7, p. 458).
- Endurance athletes need to drink both water and carbohydrate-containing beverages, especially during training and competition.
- During events lasting longer than 3 hours, athletes may need to replace sodium losses to prevent **hyponatremia.**

## 14.5 Diets for Physically Active People

- To enhance athletic performance and overall health, a diet should provide ample fluid and a variety of nutrient-dense foods in quantities to meet energy needs.
- Carbohydrate-rich foods that are light and easy to digest are best for pregame and recovery meals.

**TABLE 14-4 Primary Fuels Used for Activities of Different Intensities and Durations**

| Activity Intensity | Activity Duration | Energy System | Preferred Fuel Source | Oxygen Needed? | Activity Example |
|---|---|---|---|---|---|
| Extreme | 5 to 10 sec | Phosphagen system | ATP-CP (immediate availability) | No | 100-meter sprint, shot put, golf or baseball bat swing, tennis or volleyball serve |
| Very high | 20 sec to 2 min | Lactic acid system | ATP from carbohydrate (anaerobic glycolysis) | No | 400-meter run, 100-meter swim, gymnastic routines |
| High | 2 min to 20 min | Aerobic system | ATP from carbohydrate (glycolysis and TCA cycle) | Yes | Cycling, swimming, running |
| Moderate | > 20 min | Aerobic system | ATP from fat (fatty acid-oxidation and TCA cycle) | Yes | Hiking |

NOTE: All energy systems function at all times, but depending on the intensity of the activity and the conditioning of the athlete, one system will predominate at any given time.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 14.1 Fitness (pp. 442–448)

**LEARN IT** Describe the health benefits of being physically fit and explain how to develop the components of fitness.

1. Explain physical activity overload.
2. Define *cardiorespiratory conditioning* and list some of its benefits.
3. Physical inactivity is linked to all of the following diseases except:
   a. cancer.
   b. diabetes.
   c. emphysema.
   d. hypertension.
4. Physical activity overload can be applied by performing:
   a. an activity less often.
   b. an activity with more intensity.
   c. an activity in a different setting.
   d. a different activity each day of the week.

## 14.2 Energy Systems and Fuels to Support Activity (pp. 448–455)

**LEARN IT** Identify the factors that influence fuel use during physical activity and the types of activities that depend more on glucose or fat, respectively.

5. What types of activity are anaerobic? Which are aerobic? Describe the relationships among energy expenditure, type of activity, and oxygen use.
6. The process that regenerates glucose from lactate is known as the:
   a. Cori cycle.
   b. ATP-CP cycle.
   c. adaptation cycle.
   d. cardiac output cycle.
7. "Hitting the wall" is a term runners sometimes use to describe:
   a. dehydration.
   b. competition.
   c. indigestion.
   d. glucose depletion.
8. The technique endurance athletes use to maximize glycogen stores is called:
   a. aerobic training.
   b. muscle conditioning.
   c. carbohydrate loading.
   d. progressive overloading.
9. Conditioned muscles rely less on _____ and more on _____ for energy.
   a. protein; fat
   b. fat; protein
   c. glycogen; fat
   d. fat; glycogen

## 14.3 Vitamins and Minerals to Support Activity (pp. 455–457)

**LEARN IT** List which vitamins and mineral supplements, if any, athletes may need and why.

10. Why are some athletes likely to develop iron-deficiency anemia? Compare iron-deficiency anemia and sports anemia, explaining the differences.
11. Vitamin or mineral supplements taken just before an event are useless for improving performance because the:
    a. athlete sweats the nutrients out during the event.
    b. stomach can't digest supplements during physical activity.
    c. nutrients are diluted by all the fluids the athlete drinks.
    d. body needs hours or days for the nutrients to do their work.
12. Physically active young women, especially those who are endurance athletes, are prone to:
    a. energy excess.
    b. iron deficiency.
    c. protein overload.
    d. vitamin A toxicity.

## 14.4 Fluids and Electrolytes to Support Activity (pp. 457–462)

**LEARN IT** Identify the factors that influence an athlete's fluid needs and describe the differences between water and sports drinks.

13. Discuss the importance of hydration during training, and list recommendations to maintain fluid balance.
14. The body's need for _____ far surpasses its need for any other nutrient.
    a. water
    b. protein
    c. vitamins
    d. carbohydrate

## 14.5 Diets for Physically Active People (pp. 462–464)

**LEARN IT** Discuss an appropriate daily eating pattern for athletes and list one example of a recommended pregame and recovery meal.

15. A recommended pregame meal includes plenty of fluids and provides between:
    a. 300 and 800 kcalories, mostly from fat-rich foods.
    b. 50 and 100 kcalories, mostly from fiber-rich foods.
    c. 1000 and 2000 kcalories, mostly from protein-rich foods.
    d. 300 and 800 kcalories, mostly from carbohydrate-rich foods.

## HIGHLIGHT 14 Supplements as Ergogenic Aids (pp. 467–471)

**LEARN IT** Present arguments for and against the use of ergogenic aids.

16. Discuss two ergogenic aids that seem to perform as claimed and two that are dangerous, banned, or illegal.

**Multiple Choice Answers**

3. c 4. b 6. a 7. d 8. c 9. c 11. d 12. b 14. a 15. d

STUDY IT

# 15 Life Cycle Nutrition: Pregnancy and Lactation

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 15.1 Nutrition prior to Pregnancy

- Prior to pregnancy, the health and behaviors of both men and women can influence **fertility** and fetal development. In preparation, they can achieve and maintain a healthy body weight, choose an adequate and balanced diet, be physically active, receive regular medical care, manage chronic conditions, and avoid harmful influences.

## 15.2 Growth and Development during Pregnancy

- The infant develops through three stages—the **zygote, embryo,** and **fetus** (review Figure 15-2, p. 476). Each organ and tissue grows on its own schedule (review Figure 15-4, p. 477).
- Times of intense development are **critical periods** that depend on nutrients (review Figure 15-3, p. 477).
- Without folate, the neural tube fails to develop completely during the first month of pregnancy; all women of childbearing age should take folate daily. Common **neural tube defects** include **anencephaly** and **spina bifida.**

## 15.3 Maternal Weight

- A healthy pregnancy depends on a sufficient weight gain.
- Women who begin their pregnancies at a healthy weight need to gain about 30 pounds to cover the growth and development of the **placenta, uterus,** blood, breasts, and infant (review Figure 15-7, p. 482).
- Physical activity throughout pregnancy can help a woman develop the strength she needs to carry the extra weight and maintain habits that will help her lose it after the birth.

## 15.4 Nutrition during Pregnancy

- Energy and nutrient needs are high during pregnancy; the diet should include an extra serving from each of the five food groups.
- Supplements of iron and folate are recommended.
- Nausea, constipation, and heartburn commonly accompany pregnancy and can usually be alleviated with a few simple strategies (review Table 15-2, p. 487). **Food cravings** do not typically reflect physiological needs.

## 15.5 High-Risk Pregnancies

- High-risk pregnancies (review Table 15-3) threaten the life and health of both mother and infant and are likely to produce an infant with a low birth weight.
- Proper nutrition and abstinence from smoking, alcohol, and other drugs improve the outcome as can prenatal care to monitor for **gestational diabetes** and **preeclampsia.**

## 15.6 Nutrition during Lactation

- During **lactation,** women need extra fluid and enough energy and nutrients to produce about 25 ounces of milk a day.
- Breastfeeding is contraindicated for those with HIV/AIDS.
- Alcohol, other drugs, smoking, and contaminants may reduce milk production or enter breast milk and impair infant development.

**TABLE 15-3 High-Risk Pregnancy Factors**

| Factor | Condition that Raises Risk |
|---|---|
| Maternal weight | |
| • Prior to pregnancy | Prepregnancy BMI either <18.5 or ≥25 |
| • During pregnancy | Insufficient or excessive pregnancy weight gain (see Table 15-1, p. 481) |
| Maternal nutrition | Nutrient deficiencies or toxicities; eating disorders |
| Socioeconomic status | Poverty, lack of family support, low level of education, limited food available |
| Lifestyle habits | Smoking, alcohol or other drug use |
| Age | Teens, especially 15 years or younger; women 35 years or older |
| Previous pregnancies | |
| • Number | Many previous pregnancies (3 or more to mothers younger than age 20; 4 or more to mothers age 20 or older) |
| • Interval | Short or long intervals between pregnancies (<18 months or >59 months) |
| • Outcomes | Previous history of problems |
| • Multiple births | Twins or triplets |
| • Birthweight | Low- or high-birthweight infants |
| Maternal health | |
| • High blood pressure | Development of gestational hypertension |
| • Diabetes | Development of gestational diabetes |
| • Chronic diseases | Diabetes; heart, respiratory, and kidney disease; certain genetic disorders; special diets and medications |

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 15.1 Nutrition prior to Pregnancy (p. 474)

**LEARN IT** List the ways men and women can prepare for a healthy pregnancy.

1. The health and behaviors of men and women prior to pregnancy can influence all of the following except:
   a. fertility.
   b. infant's gender.
   c. placenta development.
   d. infant's mental development.

## 15.2 Growth and Development during Pregnancy (pp. 475–479)

**LEARN IT** Describe fetal development from conception to birth and explain how maternal malnutrition can affect critical periods.

2. Describe the placenta and its function.
3. Explain why women of childbearing age need folate in their diets. How much is recommended, and how can women ensure that these needs are met?
4. The spongy structure that delivers nutrients to the fetus and returns waste products to the mother is called the:
   a. embryo.
   b. uterus.
   c. placenta.
   d. amniotic sac.

## 15.3 Maternal Weight (pp. 480–483)

**LEARN IT** Explain how both underweight and overweight can interfere with a healthy pregnancy and how weight gain and physical activity can support maternal health and infant growth.

5. Which of these strategies is *not* a healthy option for an overweight woman?
   a. Limit weight gain during pregnancy.
   b. Postpone weight loss until after pregnancy.
   c. Follow a weight-loss diet during pregnancy.
   d. Try to achieve a healthy weight before becoming pregnant.
6. A reasonable weight gain during pregnancy for a normal-weight woman is about:
   a. 10 pounds.
   b. 20 pounds.
   c. 30 pounds.
   d. 40 pounds.

## 15.4 Nutrition during Pregnancy (pp. 483–488)

**LEARN IT** Summarize the nutrient needs of women during pregnancy.

7. Which nutrients are needed in the greatest amounts during pregnancy? Why are they so important? Describe wise food choices for the pregnant woman.

## 15.5 High-Risk Pregnancies (pp. 488–496)

**LEARN IT** Identify factors predicting low-risk and high-risk pregnancies and describe ways to manage them.

8. What is the significance of infant birthweight in terms of the child's future health?
9. Describe some of the special problems of the pregnant adolescent. Which nutrients are needed in increased amounts?
10. What practices should be avoided during pregnancy? Why?
11. To help prevent neural tube defects, grain products are now fortified with:
    a. iron.
    b. folate.
    c. protein.
    d. vitamin C.
12. Pregnant women should *not* take supplements of:
    a. iron.
    b. folate.
    c. vitamin A.
    d. vitamin C.
13. The combination of high blood pressure, protein in the urine, and edema signals:
    a. jaundice.
    b. preeclampsia.
    c. gestational diabetes.
    d. gestational hypertension.

## 15.6 Nutrition during Lactation (pp. 496–501)

**LEARN IT** Summarize the nutrient needs of women during lactation.

14. To facilitate lactation, a mother needs:
    a. about 5000 kcalories a day.
    b. adequate nutrition and rest.
    c. vitamin and mineral supplements.
    d. a glass of wine or beer before each feeding.
15. A breastfeeding woman should drink plenty of water to:
    a. produce more milk.
    b. suppress lactation.
    c. prevent dehydration.
    d. dilute nutrient concentration.
16. A woman may need iron supplements during lactation:
    a. to enhance the iron in her breast milk.
    b. to provide iron for the infant's growth.
    c. to replace the iron in her body's stores.
    d. to support the increase in her blood volume.

## HIGHLIGHT 15 Fetal Alcohol Syndrome (pp. 505–507)

**LEARN IT** Explain how drinking alcohol endangers the fetus and how women can prevent fetal alcohol syndrome.

17. Public health recommendations for alcohol consumption during pregnancy advise:
    a. abstinence from alcohol.
    b. beer or wine, but not liquor.
    c. alcohol in moderation (one drink a day).
    d. abstinence in the first trimester, moderation in the second trimester, and no restrictions in the third trimester.

**Multiple Choice Answers**

1. b 4. c 5. c 6. c 11. b 12. c 13. b 14. b 15. c 16. c 17. a

STUDY IT

# 16 Life Cycle Nutrition: Infancy, Childhood, and Adolescence

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 16.1 Nutrition during Infancy

- The primary food for infants during the first 12 months is either breast milk or iron-fortified formula. Cow's milk is not appropriate until after age 1.
- Breast milk offers both nutrients and immunological protection.
- Breast milk provides many factors that protect infants from illnesses and support better nutrition (review Table 16-3, p. 514).
- At 4 to 6 months of age, infants should gradually begin eating solid foods, including iron-fortified cereals and vitamin-C rich fruits and vegetables.
- By 1 year, infants are drinking from a cup and eating a variety of foods.
- Infants may benefit from supplements containing vitamin D, iron, and fluoride (review Table 16-2, p. 513).

## 16.2 Nutrition during Childhood

- Children's appetites and nutrient needs reflect their stage of growth.
- Children who are chronically hungry and malnourished suffer growth retardation; temporary hunger and mild nutrient deficiencies produce more subtle problems—such as poor academic performance.
- Iron deficiency is widespread and has many physical and behavioral consequences.
- **Hyperactivity** is not caused by poor nutrition; misbehavior may be due to lack of sleep, too little physical activity, or too much television, among other factors.
- Some children have **food allergies**—**adverse reactions** that involve an immune response—most often caused by peanuts, tree nuts, milk, eggs, wheat, soybeans, fish, or shellfish.
- Childhood obesity is a major health problem (review Figure 16-9, p. 529).
- Children need to eat nutrient-dense foods and learn how to make healthful diet and activity choices.

## 16.3 Nutrition during Adolescence

- The need for iron increases during **adolescence** for both males and females; blood losses incurred through menstruation increase iron needs for females further (review Table 16-15, p. 540).
- Sufficient calcium intake during adolescence supports optimal bone growth and density.
- The adolescent growth spurt increases the need for energy and nutrients.
- Adolescents who drink soft drinks regularly have a higher energy intake and a lower calcium intake; they are also more likely to be overweight.

**TABLE 16-9 Recommended Eating and Physical Activity Behaviors to Prevent Obesity**

The Expert Committee of the American Medical Association recommends the following healthy habits for children 2 to 18 years of age to help prevent childhood obesity:

- Limit consumption of sugar-sweetened beverages, such as soft drinks and fruit-flavored punches.
- Eat the recommended amounts of fruits and vegetables every day (2 to 4.5 cups per day based on age).
- Learn to eat age-appropriate portions of foods.
- Eat foods low in energy density such as those high in fiber and/or water and modest in fat.
- Eat a nutritious breakfast every day.
- Eat a diet rich in calcium.
- Eat a diet balanced in recommended proportions for carbohydrate, fat, and protein.
- Eat a diet high in fiber.
- Eat together as a family as often as possible.
- Limit the frequency of restaurant meals.
- Limit television watching or other screen time to no more than 2 hours per day and do not have televisions or computers in bedrooms.
- Engage in at least 60 minutes of moderate to vigorous physical activity every day.

SOURCE: S. E. Barlow, Expert Committee recommendations regarding the prevention, assessment, and treatment of child and adolescent overweight and obesity: Summary report, *Pediatrics* 120 (2007): S164–S192.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 16.1 Nutrition during Infancy (pp. 510–520)

**LEARN IT** List some of the components of breast milk and describe the appropriate foods for infants during the first year of life.

1. What are the appropriate uses of formula feeding? What criteria would you use in selecting an infant formula?
2. Why are solid foods not recommended for an infant during the first few months of life? When is an infant ready to start eating solid food?
3. Identify foods that are inappropriate for infants and explain why they are inappropriate.
4. A reasonable weight for a healthy 5-month-old infant who weighed 8 pounds at birth might be:
   a. 12 pounds.
   b. 16 pounds.
   c. 20 pounds.
   d. 24 pounds.
5. Dehydration can develop quickly in infants because:
   a. much of their body water is extracellular.
   b. they lose a lot of water through urination and tears.
   c. only a small percentage of their body weight is water.
   d. they drink lots of breast milk or formula, but little water.
6. An infant should begin eating solid foods between:
   a. 2 and 4 weeks.
   b. 1 and 3 months.
   c. 4 and 6 months.
   d. 8 and 10 months.

## 16.2 Nutrition during Childhood (pp. 520–539)

**LEARN IT** Explain how children's appetites and nutrient needs reflect their stage of growth and why iron deficiency and obesity are often concerns during childhood.

7. What nutrition problems are most common in children? What strategies can help prevent these problems?
8. Describe the relationships between nutrition and behavior. How does television influence nutrition?
9. Describe a true food allergy. Which foods most often cause allergic reactions? How do food allergies influence nutrition status?
10. Describe the problems associated with childhood obesity and the strategies for prevention and treatment.
11. List strategies for introducing nutritious foods to children.
12. What impact do school meal programs have on the nutrition status of children?
13. Among US children, the most prevalent nutrient deficiency is of:
   a. iron.
   b. folate.
   c. protein.
   d. vitamin D.
14. A true food allergy always:
   a. elicits an immune response.
   b. causes an immediate reaction.
   c. creates an aversion to the offending food.
   d. involves symptoms such as headaches or hives.
15. Which of the following strategies is *not* effective?
   a. Play first, eat later.
   b. Provide small portions.
   c. Encourage children to help prepare meals.
   d. Use dessert as a reward for eating vegetables.

## 16.3 Nutrition during Adolescence (pp. 539–543)

**LEARN IT** Discuss some of the challenges in meeting the nutrient needs of adolescents.

16. Describe the changes in nutrient needs from childhood to adolescence. Why is an adolescent girl more likely to develop an iron deficiency than an adolescent boy?
17. How do adolescents' eating habits influence their nutrient intakes?
18. To help teenagers consume a balanced diet, parents can:
   a. monitor the teens' food intake.
   b. give up—parents can't influence teenagers.
   c. keep the pantry and refrigerator well stocked.
   d. forbid snacking and insist on regular, well-balanced meals.
19. During adolescence, energy and nutrient needs:
   a. reach a peak.
   b. fall dramatically.
   c. rise, but do not peak until adulthood.
   d. fluctuate so much that generalizations can't be made.
20. The nutrients most likely to fall short in the adolescent diet are:
   a. sodium and fat.
   b. folate and zinc.
   c. iron and calcium.
   d. protein and vitamin A.
21. To balance the day's intake, an adolescent who eats a hamburger, fries, and cola at lunch might benefit most from a dinner of:
   a. fried chicken, rice, and banana.
   b. ribeye steak, baked potato, and iced tea.
   c. pork chop, mashed potatoes, and apple juice.
   d. spaghetti with meat sauce, broccoli, and milk.

## HIGHLIGHT 16 Childhood Obesity and the Early Development of Chronic Diseases (pp. 548–553)

**LEARN IT** Describe the lifestyle factors that can help prevent childhood obesity and the development of type 2 diabetes and heart disease.

22. Describe the dietary strategies to help prevent the early development of chronic diseases.

**Multiple Choice Answers**

4. b 5. a 6. c 13. a 14. a 15. d 18. c 19. a 20. c 21. d

STUDY IT

# 17 Life Cycle Nutrition: Adulthood and the Later Years

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 17.1 Nutrition and Longevity

- **Life expectancy** in the United States increased dramatically in the 20th century.
- Factors that enhance **longevity** include limited or no alcohol use, regular balanced meals, weight control, abstinence from smoking, regular physical activity, and adequate sleep.
- Energy restriction in animals seems to lengthen their lives; whether such dietary intervention in human beings is beneficial remains unknown.
- Nutrition—especially when combined with regular physical activity—can influence aging and longevity by supporting good health and preventing disease.

## 17.2 The Aging Process

- Changes that accompany aging can impair nutrition status. Among physiological changes, hormone activity alters body composition, immune system changes raise the risk of infections, **atrophic gastritis** interferes with digestion and absorption, and tooth loss limits food choices.
- Psychological changes such as depression, economic changes such as loss of income, and social changes such as loneliness contribute to poor food intake.

## 17.3 Energy and Nutrient Needs of Older Adults

- Some nutrients need special attention in the diet, but supplements are not routinely recommended.
- Table 17-5 helps determine the risk of malnutrition in older adults.

## 17.4 Nutrition-Related Concerns of Older Adults

- **Senile dementia** and cognitive losses afflict many older adults; some face loss of vision due to **cataracts** or **macular degeneration** or cope with the pain of **arthritis.**

**TABLE 17-5 Risk Factors for Malnutrition in Older Adults**

| | These questions help *determine* the risk of malnutrition in older adults: |
|---|---|
| **D**isease | • Do you have an illness or condition that changes the types or amounts of foods you eat? |
| **E**ating poorly | • Do you eat fewer than two meals a day? Do you eat fruits, vegetables, and milk products daily? |
| **T**ooth loss or mouth pain | • Is it difficult or painful to eat? |
| **E**conomic hardship | • Do you have enough money to buy the food you need? |
| **R**educed social contact | • Do you eat alone most of the time? |
| **M**ultiple medications | • Do you take three or more different prescribed or over-the-counter medications daily? |
| **I**nvoluntary weight loss or gain | • Have you lost or gained 10 pounds or more in the last 6 months? |
| **N**eeds assistance | • Are you physically able to shop, cook, and feed yourself? |
| **E**lderly person | • Are you older than 80? |

© Cengage Learning

- Table 17-2 provides a summary of the nutrient concerns of aging.
- Some problems may be inevitable, but others are preventable and good nutrition may play a key role.

## 17.5 Food Choices and Eating Habits of Older Adults

- **Congregate meals** provide older adults with both nutrients and social interactions; those who are homebound receive delivered meals **(Meals on Wheels).**
- Adults living alone can prepare nutritious, inexpensive meals with a little creativity and careful shopping.

**TABLE 17-2 Nutrient Concerns of Aging**

| Nutrient | Effect of Aging | Comments |
|---|---|---|
| Water | Lack of thirst and decreased total body water make dehydration likely. | Mild dehydration is a common cause of confusion. Difficulty obtaining water or getting to the bathroom may compound the problem. |
| Energy | Need decreases as muscle mass decreases **(sarcopenia).** | Physical activity moderates the decline. |
| Fiber | Likelihood of constipation increases with low intakes and changes in the GI tract. | Inadequate water intakes and lack of physical activity, along with some medications, compound the problem. |
| Protein | Needs may stay the same or increase slightly. | Low-fat, high-fiber legumes and grains meet both protein and other nutrient needs. |
| Vitamin $B_{12}$ | Atrophic gastritis is common. | Deficiency causes neurological damages; supplements may be needed. |
| Vitamin D | Increased likelihood of inadequate intake; skin synthesis declines. | Daily sunlight exposure in moderation or supplements may be beneficial. |
| Calcium | Intakes may be low; osteoporosis is common. | Stomach discomfort commonly limits milk intake; calcium substitutes or supplements may be needed. |
| Iron | In women, status improves after menopause; deficiencies are linked to chronic blood losses and low stomach acid output. | Adequate stomach acid is required for absorption; antacid or other medicine use may aggravate iron deficiency; vitamin C and meat increase absorption. |
| Zinc | Intakes are often inadequate and absorption may be poor, but needs may also increase. | Medications interfere with absorption; deficiency may depress appetite and sense of taste. |

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 17.1 Nutrition and Longevity (pp. 556–560)

**LEARN IT** Describe the role nutrition plays in longevity.

1. Life expectancy in the United States is about:
   a. 48 to 60 years.
   b. 58 to 70 years.
   c. 68 to 80 years.
   d. 78 to 90 years.

2. The human life span is about:
   a. 85 years.
   b. 100 years.
   c. 115 years.
   d. 130 years.

3. A 72-year-old person whose physical health is similar to that of people 10 years younger has a(n):
   a. chronological age of 62.
   b. physiological age of 72.
   c. physiological age of 62.
   d. absolute age of minus 10.

4. Rats live longest when given diets that:
   a. eliminate all fat.
   b. provide lots of protein.
   c. allow them to eat freely.
   d. restrict their energy intakes.

## 17.2 The Aging Process (pp. 560–564)

**LEARN IT** Summarize how nutrition interacts with the physical, psychological, economic, and social changes involved in aging.

5. Which characteristic is *not* commonly associated with atrophic gastritis?
   a. inflamed stomach
   b. vitamin $B_{12}$ toxicity
   c. bacterial overgrowth
   d. lack of intrinsic factor

## 17.3 Energy and Nutrient Needs of Older Adults (pp. 564–567)

**LEARN IT** Explain why the needs for some nutrients increase or decrease during aging.

6. Why does the risk of dehydration increase as people age?

7. Why do energy needs usually decline with advancing age?

8. Identify some factors that complicate the task of setting nutrient standards for older adults.

9. On average, adult energy needs:
   a. decline 5 percent per year.
   b. decline 5 percent per decade.
   c. remain stable throughout life.
   d. rise gradually throughout life.

## 17.4 Nutrition-Related Concerns of Older Adults (pp. 567–572)

**LEARN IT** Identify how nutrition might contribute to, or prevent, the development of age-related problems associated with vision, arthritis, the brain, and alcohol use.

10. Which nutrients seem to protect against cataract development?
    a. minerals
    b. lecithins
    c. antioxidants
    d. amino acids

11. The best dietary advice for a person with osteoarthritis might be to:
    a. avoid milk products.
    b. take fish oil supplements.
    c. take vitamin E supplements.
    d. lose weight, if overweight.

## 17.5 Food Choices and Eating Habits of Older Adults (pp. 572–576)

**LEARN IT** Instruct an adult on how to shop for groceries and prepare healthy meals for one person on a tight budget.

12. What characteristics contribute to malnutrition in older people?

13. Congregate meal programs are preferable to Meals on Wheels because they provide:
    a. nutritious meals.
    b. referral services.
    c. social interactions.
    d. financial assistance.

14. The OAA Nutrition Program is available to:
    a. all people 65 years and older.
    b. all people 60 years and older.
    c. homebound people only, 60 years and older.
    d. low-income people only, 60 years and older.

## HIGHLIGHT 17 Nutrient-Drug Interactions (pp. 579–583)

**LEARN IT** Explain why certain nutrients and medications interact.

15. Why are elderly people with chronic diseases most vulnerable to interactions that can create nutrient imbalances or interfere with drug effectiveness?

**Multiple Choice Answers**

1. c 2. d 3. c 4. d 5. b 9. b 10. c 11. d 13. c 14. b

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

STUDY IT

# 18 Diet and Health

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

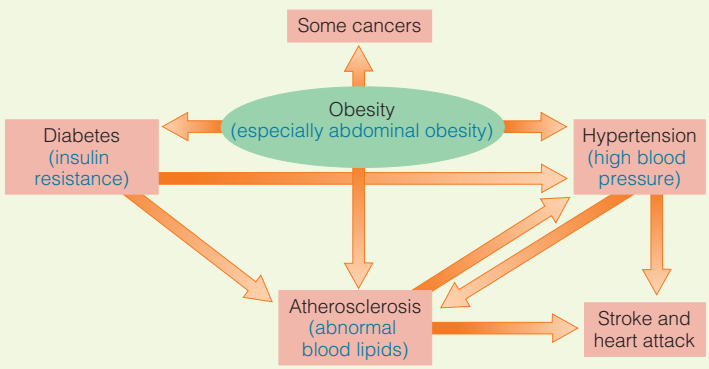
## 18.1 Nutrition and Infectious Diseases

- Public health measures such as purification of water and safe handling of food help prevent the spread of infection in populations; immunizations and antibiotics protect individuals.
- Nutrition cannot prevent or cure **infectious diseases,** but adequate intakes of all the nutrients can help support the immune system as the body defends against disease-causing agents.
- If the immune system is impaired because of malnutrition or diseases such as **AIDS,** a person becomes vulnerable to infectious disease.
- Inflammation underlies many chronic diseases.

## 18.2 Nutrition and Chronic Diseases

- Heart disease, cancers, and strokes are the three leading causes of death in the United States, and diabetes also ranks among the top 10.
- These four chronic diseases have significant links with nutrition and with one another (review Figure 18-2); other lifestyle risk factors and genetics also play a role.

## 18.3 Cardiovascular Disease



- **Atherosclerosis** is characterized by a build-up of plaque in an artery wall.
- Rupture of **plaque** or abnormal blood clotting can cause heart attacks and strokes.
- Dietary recommendations to lower the risks of **cardiovascular disease** are summarized in Table 18-5 (p. 596); quitting smoking and engaging in regular physical activity also improve heart health.

## 18.4 Hypertension

- The most effective dietary strategy for preventing **hypertension** is weight control.
- The **DASH eating pattern** is rich in fruits, vegetables, nuts, and low-fat milk products and low in fat, saturated fat, and sodium (review Table 18-7, p. 600).

**> FIGURE 18-2 Interrelationships among Chronic Diseases**

Notice that many chronic diseases are themselves risk factors for other chronic diseases and that all of them are linked to obesity. The risk factors highlighted in blue define the **metabolic syndrome.**

© Cengage Learning

**TABLE 18-12 Dietary Guidelines and Recommendations for Chronic Diseases Compared**

| Dietary Guidelines | Heart Disease | Hypertension | Diabetes | Cancer |
|---|---|---|---|---|
| Prevent and/or reduce overweight and obesity. | ✓ | ✓ | ✓ | ✓ |
| Increase physical activity and reduce time spent in sedentary behaviors. | ✓ | ✓ | ✓ | ✓ |
| Keep total fat 20 to 35 percent of kcalories. | ✓ | | | |
| Consume less than 10 percent of kcalories from saturated fatty acids and keep *trans*-fatty acid consumption as low as possible. | ✓ | | ✓ | ✓ |
| Increase vegetable and fruit intake. Consume at least half of all grains as whole grains. | ✓ | ✓ | ✓ | ✓ |
| Reduce the intake of kcalories from added sugars. | ✓ | | ✓ | |
| Reduce daily sodium intake to less than 2300 milligrams.[a] | ✓ | ✓ | ✓ | ✓ |
| If alcohol is consumed, it should be consumed in moderation. | ✓ | ✓ | ✓ | ✓ |

[a]Further reduce daily sodium intake to 1500 milligrams among persons who are 51 and older and those of any age who are African American or have hypertension, diabetes, or chronic kidney disease.

© Cengage Learning

## 18.5 Diabetes Mellitus

- **Diabetes** is characterized by high blood glucose and either insufficient insulin, ineffective insulin, or a combination of the two.
- People with **type 1 diabetes** coordinate diet, insulin, and physical activity to help control their blood glucose.
- People with **type 2 diabetes** benefit most from a diet and physical activity program that controls glucose fluctuations and promotes weight loss.

## 18.6 Cancer

- Some dietary factors, such as alcohol and heavily smoked foods, may **initiate cancer** development; others, such as animal fats, may **promote** cancer once it develops; and still others, such as fiber, antioxidant nutrients, and phytochemicals, may serve as **antipromoters** that protect against cancer development.
- To obtain the best possible nutrition at the lowest possible cancer risk, eat many fruits, vegetables, legumes, and whole grains and little saturated fat; minimize weight gain through regular physical activity and a healthy diet (review Table 18-11, p. 609).

## 18.7 Recommendations for Chronic Diseases

- Optimal nutrition keeps people healthy and reduces the risk of chronic diseases.
- Dietary recommendations are aimed at populations and focus on controlling weight; limiting saturated and *trans* fat; increasing fiber-rich fruits, vegetables, and whole grains; and balancing food intake with physical activity (review Table 18-12).

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).
Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 18.1 Nutrition and Infectious Diseases

(pp. 586–588)

**LEARN IT** Identify factors that protect people from the spread of infectious diseases and describe the role of nutrition in immunity.

1. The immune cells of the body do *not* include:
   a. B-cells.
   b. T-cells.
   c. antigens.
   d. phagocytes.

2. Which of the following produce antibodies?
   a. phagocytes
   b. T-cells
   c. antigens
   d. B-cells

## 18.2 Nutrition and Chronic Diseases

(pp. 589–590)

**LEARN IT** List the leading nutrition-related causes of death in the United States.

3. The leading cause of death in the United States is:
   a. AIDS.
   b. cancer.
   c. diabetes.
   d. heart disease.

## 18.3 Cardiovascular Disease (pp. 590–597)

**LEARN IT** Describe how atherosclerosis develops and strategies to lower blood cholesterol levels.

4. Plaques in the arteries contribute to the development of:
   a. cancer.
   b. diabetes.
   c. atherosclerosis.
   d. infectious diseases.

5. Which blood lipid correlates directly with heart disease?
   a. HDL
   b. LDL
   c. VLDL
   d. triglycerides

6. Weight loss and physical activity may protect against heart disease by:
   a. raising LDL and insulin levels.
   b. raising HDL and lowering blood pressure.
   c. lowering LDL and increasing clot formation.
   d. improving insulin sensitivity and raising blood pressure.

## 18.4 Hypertension (pp. 598–600)

**LEARN IT** Present strategies to lower blood pressure.

7. What is the most effective strategy for most people to lower their blood pressure?
   a. lose weight
   b. restrict salt
   c. monitor glucose
   d. supplement protein

## 18.5 Diabetes Mellitus (pp. 600–605)

**LEARN IT** Compare the dietary strategies to manage type 1 diabetes with those to prevent and treat type 2 diabetes.

8. Describe the differences between type 1 diabetes and type 2 diabetes.

9. All of the following factors increase the risk of type 2 diabetes *except:*
   a. aging.
   b. inactivity.
   c. obesity.
   d. smoking.

10. The most important dietary strategy in diabetes is to:
    a. provide for a consistent carbohydrate intake.
    b. restrict fat to 30 percent of daily kcalories.
    c. limit carbohydrate intake to 300 milligrams a day.
    d. take multiple vitamin and mineral supplements daily.

## 18.6 Cancer (pp. 605–609)

**LEARN IT** Differentiate among cancer initiators, promoters, and antipromoters and describe how nutrients or foods might play a role in each category.

11. Describe the characteristics of a diet that might offer the best protection against the onset of cancer.

12. Which of the following help(s) to protect against cancer?
    a. alcohol
    b. pickled foods
    c. phytochemicals
    d. omega-6 fatty acids

## 18.7 Recommendations for Chronic Diseases (pp. 610–612)

**LEARN IT** Summarize dietary recommendations to prevent chronic diseases.

13. Describe the dietary choices that best protect against the development of most chronic diseases.

## HIGHLIGHT 18 Complementary and Alternative Medicine (pp. 617–625)

**LEARN IT** Present arguments for and against the use of complementary and alternative medicine.

14. Which of the following is generally considered safe?
    a. chaparral to cleanse blood
    b. aloe to promote wound healing
    c. ephedra to promote weight loss
    d. yohimbe to enhance male sexual performance

**Multiple Choice Answers**

1. c 2. d 3. d 4. c 5. b 6. b 7. a 9. d 10. a 12. c 14. b

Copyright 2016 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s).

# STUDY IT 19 Consumer Concerns about Foods and Water

Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 19.1 Food Safety and Foodborne Illnesses

- Maintaining a safe food supply requires everyone's efforts (review Figure 19-1, p. 631).
- Millions of people suffer mild to life-threatening symptoms caused by **foodborne illnesses** (review Table 19-1, p. 629).
- The "How To" (pp. 632–633) describes how these illnesses can be prevented by storing and cooking foods at their proper temperatures and by preparing them in sanitary conditions.
- **Irradiation** of certain foods protects consumers from foodborne illness, but also raises some concerns.

## 19.2 Nutritional Adequacy of Foods and Diets

- In the marketplace, food labels, the *Dietary Guidelines for Americans,* and MyPlate all help consumers learn about nutrition and how to plan healthy diets.
- At home, consumers can minimize nutrient losses from fruits and vegetables by refrigerating them, washing them before cutting them, storing them in airtight containers, and cooking them for short times in minimal water.

## 19.3 Environmental Contaminants

- Environmental contamination of foods is a concern, but so far, the **hazards** appear relatively small.
- Remain alert to the possibility of contamination, and keep an ear open for public health announcements and advice.
- Eat a variety of foods to protect against the accumulation of toxins in the body. Each food eaten dilutes **contaminants** that may be present in other components of the diet.

## 19.4 Natural Toxicants in Foods

- Natural toxicants include the goitrogens in cabbage, cyanogens in lima beans, and **solanine** in potatoes.
- Any substance can be **toxic** when consumed in excess.
- Poisons are poisons, whether made by people or by nature. The source of a chemical does not make it hazardous; its chemical structure and the quantity consumed do.

## 19.5 Pesticides

- **Pesticides** can safely improve crop yields when used according to regulations, but they can also be hazardous when used inappropriately.
- The FDA tests both domestic and imported foods for pesticide **residues** in the fields and in market basket surveys of foods prepared table ready.
- Consumers can minimize their ingestion of pesticide residues on foods by following the suggestions in Table 19-3 (p. 644).
- Alternative farming methods may allow farmers to grow crops with few or no pesticides.

## 19.6 Food Additives

- The benefits of food **additives** seem to justify the **risks** associated with their use.
- The FDA regulates the use of these **intentional additives:** antimicrobial agents (such as **nitrites**) to prevent microbial spoilage; antioxidants (such as vitamins C and E, **sulfites,** and **BHA** and **BHT**) to prevent oxidative changes; colors (such as tartrazine) and flavor enhancers (such as **MSG**) to appeal to senses; and nutrients (such as iodine in salt) to enrich or fortify foods (see Table 19-5).
- **Incidental additives** sometimes get into foods during processing, but rarely present a hazard; some processes such as treating livestock with hormones and antibiotics raise consumer concerns.

## 19.7 Consumer Concerns about Water

- Like foods, water may contain infectious microorganisms, environmental contaminants, pesticide residues, and additives.
- The EPA monitors the **safety** of the public water system, but many consumers choose home water treatment systems or bottled water instead of tap.

**TABLE 19-5 Intentional Food Additives**

| Food Additive | Purpose | Common Examples |
|---|---|---|
| Antimicrobials | Prevent food spoilage from microorganisms | Salt, sugar, nitrites and nitrates (such as sodium nitrate), bacteriophages |
| Antioxidants | Prevent oxidative changes in color, flavor, or texture and delay rancidity and other damage to foods caused by oxygen | Vitamin C (erythorbic acid, sodium ascorbate), vitamin E (tocopherol), sulfites (sulfur dioxide, sodium sulfite, sodium bisulfite, potassium bisulfite, sodium metabisulfite, potassium metabisulfite), BHA and BHT |
| Colors | Enhance appearance | Artificial: indigotine, erythrosine, tartrazine<br>Natural: annatto (yellow), caramel (yellowish brown), carotenoids (yellowish orange), dehydrated beets (reddish brown), grape skins (red, green) |
| Flavors | Enhance taste | Salt, sugar, spices, artificial sweeteners, MSG |
| Emulsifiers and gums | Thicken, stabilize, or otherwise improve consistency and texture | Emulsifiers: lecithin, alginates, mono- and diglycerides<br>Gums: agar, alginates, carrageenan, guar, locust bean, psyllium, pectin, xanthan gum, gum arabic, cellulose derivatives |
| Nutrients (vitamins and minerals) | Improve the nutritive value by replacing vitamins and minerals lost in processing (enrichment) or adding vitamins or minerals that may be lacking in the diet (fortification) | Thiamin, niacin, riboflavin, folate, iron (in grain products); iodine (in salt); vitamins A and D (in milk); vitamin C and calcium (in fruit drinks); vitamin $B_{12}$ (in vegetarian foods) |

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 19.1 Food Safety and Foodborne Illnesses (pp. 628–637)

**LEARN IT** Describe how foodborne illnesses can be prevented.

1. Distinguish between the two types of foodborne illnesses and provide an example of each.
2. What special precautions apply to meats? To seafood?
3. Eating a contaminated food such as undercooked poultry or unpasteurized milk might cause a:
   a. food allergy.
   b. food infection.
   c. food intoxication.
   d. botulinum reaction.
4. The temperature danger zone for foods ranges from:
   a. –20°F to 120°F.
   b. 0°F to 100°F.
   c. 20°F to 120°F.
   d. 40°F to 140°F.
5. Examples of foods that frequently cause foodborne illness are:
   a. canned foods.
   b. steaming-hot foods.
   c. fresh fruits and vegetables.
   d. raw milk, seafood, meat, and eggs.
6. Irradiation can help improve our food supply by:
   a. cooking foods quickly.
   b. killing microorganisms.
   c. minimizing the use of preservatives.
   d. improving the nutrient content of foods.

## 19.2 Nutritional Adequacy of Foods and Diets (pp. 637–638)

**LEARN IT** Explain how to minimize nutrient losses in the kitchen.

7. Describe which nutrients are most vulnerable to destruction.

## 19.3 Environmental Contaminants (pp. 638–641)

**LEARN IT** Explain how environmental contaminants get into foods and how people can protect themselves against contamination.

8. How does bioaccumulation of toxins occur and how does that influence the safety of foods?

## 19.4 Natural Toxicants in Foods (pp. 641–642)

**LEARN IT** Identify natural toxicants and determine whether they are hazardous.

9. Solanine is an example of a(n):
   a. heavy metal.
   b. artificial color.
   c. natural toxicant.
   d. animal hormone.

## 19.5 Pesticides (pp. 642–645)

**LEARN IT** Debate the risks and benefits of using pesticides.

10. How do pesticides become a hazard to the food supply, and how are they monitored? In what ways can people reduce the concentrations of pesticides in and on foods that they prepare?

## 19.6 Food Additives (pp. 646–652)

**LEARN IT** List common food additives, their purposes, and examples.

11. What is the difference between a GRAS substance and a regulated food additive? Give examples of each.
12. The standard that deems additives safe if lifetime use presents no more than a one-in-a-million risk of cancer is known as the:
    a. Delaney Clause.
    b. zero-risk policy.
    c. GRAS list of standards.
    d. *de minimis* rule.
13. Common antimicrobial additives include:
    a. salt and nitrites.
    b. carrageenan and MSG.
    c. dioxins and sulfites.
    d. vitamin C and vitamin E.
14. Common antioxidants include:
    a. BHA and BHT.
    b. tartrazine and MSG.
    c. sugar and vitamin E.
    d. nitrosamines and salt.
15. Incidental additives that may enter foods during processing include:
    a. dioxins and BGH.
    b. dioxins and folate.
    c. beta-carotene and agar.
    d. nitrites and irradiation.

## 19.7 Consumer Concerns about Water (pp. 652–654)

**LEARN IT** Discuss consumer concerns about water.

16. Chlorine is added to water to:
    a. protect against dental caries.
    b. destroy harmful minerals such as lead and mercury.
    c. kill pathogenic microorganisms.
    d. remove the sulfur that produces a "rotten egg" odor.

## HIGHLIGHT 19 Food Biotechnology (pp. 656–661)

**LEARN IT** Debate the pros and cons surrounding genetically engineered foods.

17. Describe genetic engineering and how it is similar to, and how it differs from, the way farmers have been breeding their crops for centuries.

**Multiple Choice Answers**
3. b 4. d 5. d 6. b 9. c 12. d 13. a 14. a 15. a 16. c

STUDY IT

# 20 Hunger and the Global Environment

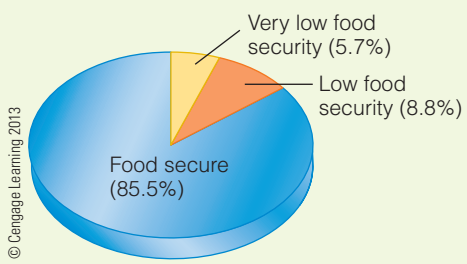
Review the key points of this chapter below, learn the definitions of the bold terms, and then take the practice quiz on the back of this card.

## 20.1 Hunger in the United States

- **Food insecurity** and **hunger** are widespread in the United States among those living in poverty (review Figure 20-1).
- Ironically, hunger and malnutrition can occur among obese people (review Figure 20-2).
- Government assistance programs help to relieve poverty and hunger; **food recovery** programs and other community efforts are equally important.

## 20.2 World Hunger

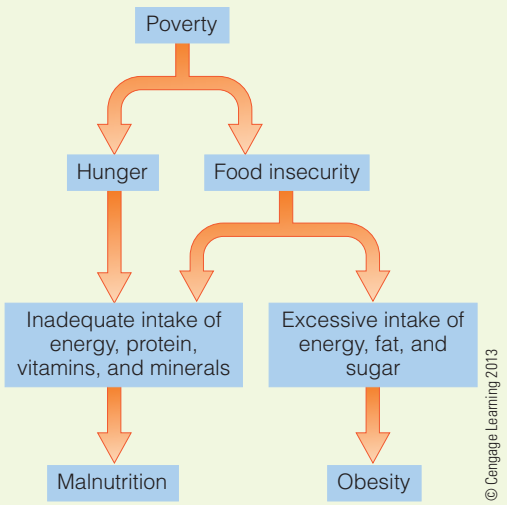
- Natural causes such as drought, flood, and pests and political causes such as armed conflicts and government policies all contribute to the extreme hunger and poverty seen in developing countries.
- More people means more mouths to feed, which worsens the problems of poverty and hunger.
- Poverty and hunger encourage parents to have more children; breaking this cycle requires improving the economic status of the people and providing them with health care, education, and family planning.
- Hunger leads to **acute malnutrition** and **chronic malnutrition,** which appear most evident in nutrient deficiencies and growth failure.



## 20.3 Malnutrition

- Inadequate food intake in children leads to poor growth and nutrient deficiencies.
- Children suffering from acute malnutrition (recent severe food deprivation) may be underweight for their height, whereas those experiencing chronic malnutrition (long-term food deprivation) are short for their age.
- Problems resulting from nutrient deficiencies include preterm births and low birth weights (iron), stillbirths and cretinism (iodine), blindness (vitamin A), and growth failure (zinc).
- Treatment for malnutrition should be individualized to ensure rapid weight gain and to correct nutrient deficiencies.

## 20.4 The Global Environment



- The global environment is deteriorating, largely because of our irresponsible use of resources and energy.
- Environmental degradation reduces our ability to produce enough food to feed the world's people.
- The rapid increase in the world's population exacerbates the situation.
- Governments, businesses, and all individuals can make environmentally conscious choices to help solve the hunger problem, improve the quality of life, and generate jobs.
- Personal choices, made by many people, can have a great impact.

# TEST IT

Take the quiz below to test your mastery of the key chapter concepts.

## 20.1 Hunger in the United States

(pp. 664–667)

**LEARN IT** Identify some reasons why hunger is present in a country as wealthy as the United States.

1. Food insecurity refers to the:
   a. uncertainty of foods' safety.
   b. fear of eating too much food.
   c. limited availability of foods.
   d. reliability of food production.

2. The most common cause of hunger in the United States is:
   a. poverty.
   b. alcohol abuse.
   c. mental illness.
   d. lack of education.

3. SNAP debit cards cannot be used to purchase:
   a. tomato plants.
   b. birthday cakes.
   c. cola beverages.
   d. laundry detergent.

4. Which action is not typical of a food recovery program?
   a. gathering potatoes from a harvested field
   b. collecting overripe tomatoes from a wholesaler
   c. offering SNAP debit cards to low-income people
   d. delivering restaurant leftovers to a community shelter

## 20.2 World Hunger (pp. 668–670)

**LEARN IT** Identify some reasons why hunger is present in the developing countries of the world.

5. The primary cause of the worst famine in the 20th century was:
   a. armed conflicts.
   b. natural disasters.
   c. food contaminations.
   d. government policies.

6. Which of the following is most critical in providing food to all the world's people?
   a. decreasing air pollution
   b. increasing water supplies
   c. decreasing population growth
   d. increasing agricultural land

## 20.3 Malnutrition (pp. 671–673)

**LEARN IT** Describe the consequences of nutrient and energy inadequacies.

7. The most likely cause of death in malnourished children is:
   a. growth failure.
   b. diarrheal disease.
   c. simple starvation.
   d. vitamin A deficiency.

## 20.4 The Global Environment (pp. 674–680)

**LEARN IT** Explain why relieving environmental problems will also help to alleviate hunger and poverty.

8. Discuss the different paths by which rich and poor countries can attack the problems of world hunger and the environment.

## HIGHLIGHT 20 Environmentally Friendly Food Choices (pp. 682–687)

**LEARN IT** Discuss ways consumers can conserve resources when making food-related choices.

9. The most ecologically sound diet is:
   a. animal based and locally produced.
   b. animal based and globally produced.
   c. vegetable based and locally produced.
   d. vegetable based and globally produced.

**Multiple Choice Answers**

1. c 2. a 3. d 4. c 5. d 6. c 7. b 9. c

# Daily Values (DV) for Food Labels

The Daily Values (DV) are standards developed by the Food and Drug Administration (FDA) for use on food labels. The values are based on 2000 kcalories a day for adults and children aged 4 years and older. Chapter 2 provides more details.

| Nutrient | Amount |
|---|---|
| **Vitamins** | |
| Biotin | 30 µg |
| Choline | 550 mg |
| Folate | 400 µg DFE |
| Niacin | 16 mg NE |
| Pantothenic acid | 5 mg |
| Riboflavin | 1.3 mg |
| Thiamin | 1.2 mg |
| Vitamin A | 900 µg RAE |
| Vitamin $B_6$ | 1.7 mg |
| Vitamin $B_{12}$ | 2.4 µg |
| Vitamin C | 90 mg |
| Vitamin D | 20 µg |
| Vitamin E (α-tocopherol) | 15 mg |
| Vitamin K | 120 µg |
| **Minerals** | |
| Calcium | 1300 mg |
| Chloride | 2300 mg |
| Chromium | 35 µg |
| Copper | 0.9 mg |
| Iodine | 150 µg |
| Iron | 18 mg |
| Magnesium | 420 mg |
| Manganese | 2.3 mg |
| Molybdenum | 45 µg |
| Phosphorus | 1250 mg |
| Potassium | 4700 mg |
| Selenium | 55 µg |
| Sodium | 2300 mg |
| Zinc | 11 mg |

| Food Component | Amount | Calculation Factors |
|---|---|---|
| Fat | 65 g | 30% of kcalories |
| Saturated fat | 20 g | 10% of kcalories |
| Cholesterol | 300 mg | Same regardless of kcalories |
| Carbohydrate (total) | 300 g | 60% of kcalories |
| Fiber | 28 g | 14 g per 1000 kcalories |
| Protein | 50 g | 10% of kcalories |

## GLOSSARY OF NUTRIENT MEASURES

**kcal:** kcalories; a unit by which energy is measured (Chapter 1 provides more details).

**g:** grams; a unit of weight equivalent to about 0.03 ounces.

**mg:** milligrams; one-thousandth of a gram.

**µg:** micrograms; one-millionth of a gram.

**IU:** international units; an old measure of vitamin activity determined by biological methods (as opposed to new measures that are determined by direct chemical analyses).For those still using IU, the following factors can be used for conversions.

- For vitamin A, 1 IU = 0.3 µg retinol
- For vitamin D, 1 IU = 0.02 µg cholecalciferol
- For vitamin E, 1 IU = 0.67 mg α-tocopherol

**mg NE:** milligrams niacin equivalents; a measure of niacin activity (Chapter 10 provides more details).

- 1 NE = 1 mg niacin
  = 60 mg tryptophan (an amino acid)

**µg DFE:** micrograms dietary folate equivalents; a measure of folate activity (Chapter 10 provides more details).

- 1 µg DFE = 1 µg food folate
  = 0.6 µg folic acid from fortified food or as a supplement taken with food

**µg RAE:** micrograms retinol activity equivalents; a measure of vitamin A activity (Chapter 11 provides more details).

- 1 µg RAE = 1 µg retinol
  = 12 µg β-carotene
  = 24 µg other vitamin A carotenoids

**mmol:** millimoles; one-thousanth of a mole, the molecular weight of a substance. To convert mmol to mg, multiply by the atomic weight of the substance.

- For sodium, mmol × 23 = mg Na
- For chloride, mmol × 35.5 = mg Cl
- For sodium chloride, mmol × 58.5 = mg NaCl

# Body Mass Index (BMI)

Find your height along the left-hand column and look across the row until you find the number that is closest to your weight. The number at the top of that column identifies your BMI. Chapter 8 describes how BMI correlates with disease risks and defines obesity, and Chapter 16 presents BMI for children and adolescents. The area shaded in blue represents healthy weight ranges.

| | Underweight | Healthy Weight | | | | | | Overweight | | | | | Obese | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | (<18.5) | (18.5–24.9) | | | | | | (25–29.9) | | | | | (≥30) | | | | | | | | | | |
| | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40 |
| ***Height*** | ***Body weight (pounds)*** | | | | | | | | | | | | | | | | | | | | | | |
| 4′10″ | 86 | 91 | 96 | 100 | 105 | 110 | 115 | 119 | 124 | 129 | 134 | 138 | 143 | 148 | 153 | 158 | 162 | 167 | 172 | 177 | 181 | 186 | 191 |
| 4′11″ | 89 | 94 | 99 | 104 | 109 | 114 | 119 | 124 | 128 | 133 | 138 | 143 | 148 | 153 | 158 | 163 | 168 | 173 | 178 | 183 | 188 | 193 | 198 |
| 5′0″ | 92 | 97 | 102 | 107 | 112 | 118 | 123 | 128 | 133 | 138 | 143 | 148 | 153 | 158 | 163 | 168 | 174 | 179 | 184 | 189 | 194 | 199 | 204 |
| 5′1″ | 95 | 100 | 106 | 111 | 116 | 122 | 127 | 132 | 137 | 143 | 148 | 153 | 158 | 164 | 169 | 174 | 180 | 185 | 190 | 195 | 201 | 206 | 211 |
| 5′2″ | 98 | 104 | 109 | 115 | 120 | 126 | 131 | 136 | 142 | 147 | 153 | 158 | 164 | 169 | 175 | 180 | 186 | 191 | 196 | 202 | 207 | 213 | 218 |
| 5′3″ | 102 | 107 | 113 | 118 | 124 | 130 | 135 | 141 | 146 | 152 | 158 | 163 | 169 | 175 | 180 | 186 | 191 | 197 | 203 | 208 | 214 | 220 | 225 |
| 5′4″ | 105 | 110 | 116 | 122 | 128 | 134 | 140 | 145 | 151 | 157 | 163 | 169 | 174 | 180 | 186 | 192 | 197 | 204 | 209 | 215 | 221 | 227 | 232 |
| 5′5″ | 108 | 114 | 120 | 126 | 132 | 138 | 144 | 150 | 156 | 162 | 168 | 174 | 180 | 186 | 192 | 198 | 204 | 210 | 216 | 222 | 228 | 234 | 240 |
| 5′6″ | 112 | 118 | 124 | 130 | 136 | 142 | 148 | 155 | 161 | 167 | 173 | 179 | 186 | 192 | 198 | 204 | 210 | 216 | 223 | 229 | 235 | 241 | 247 |
| 5′7″ | 115 | 121 | 127 | 134 | 140 | 146 | 153 | 159 | 166 | 172 | 178 | 185 | 191 | 198 | 204 | 211 | 217 | 223 | 230 | 236 | 242 | 249 | 255 |
| 5′8″ | 118 | 125 | 131 | 138 | 144 | 151 | 158 | 164 | 171 | 177 | 184 | 190 | 197 | 203 | 210 | 216 | 223 | 230 | 236 | 243 | 249 | 256 | 262 |
| 5′9″ | 122 | 128 | 135 | 142 | 149 | 155 | 162 | 169 | 176 | 182 | 189 | 196 | 203 | 209 | 216 | 223 | 230 | 236 | 243 | 250 | 257 | 263 | 270 |
| 5′10″ | 126 | 132 | 139 | 146 | 153 | 160 | 167 | 174 | 181 | 188 | 195 | 202 | 209 | 216 | 222 | 229 | 236 | 243 | 250 | 257 | 264 | 271 | 278 |
| 5′11″ | 129 | 136 | 143 | 150 | 157 | 165 | 172 | 179 | 186 | 193 | 200 | 208 | 215 | 222 | 229 | 236 | 243 | 250 | 257 | 265 | 272 | 279 | 286 |
| 6′0″ | 132 | 140 | 147 | 154 | 162 | 169 | 177 | 184 | 191 | 199 | 206 | 213 | 221 | 228 | 235 | 242 | 250 | 258 | 265 | 272 | 279 | 287 | 294 |
| 6′1″ | 136 | 144 | 151 | 159 | 166 | 174 | 182 | 189 | 197 | 204 | 212 | 219 | 227 | 235 | 242 | 250 | 257 | 265 | 272 | 280 | 288 | 295 | 302 |
| 6′2″ | 141 | 148 | 155 | 163 | 171 | 179 | 186 | 194 | 202 | 210 | 218 | 225 | 233 | 241 | 249 | 256 | 264 | 272 | 280 | 287 | 295 | 303 | 311 |
| 6′3″ | 144 | 152 | 160 | 168 | 176 | 184 | 192 | 200 | 208 | 216 | 224 | 232 | 240 | 248 | 256 | 264 | 272 | 279 | 287 | 295 | 303 | 311 | 319 |
| 6′4″ | 148 | 156 | 164 | 172 | 180 | 189 | 197 | 205 | 213 | 221 | 230 | 238 | 246 | 254 | 263 | 271 | 279 | 287 | 295 | 304 | 312 | 320 | 328 |
