- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–178

Patient Population Studied

Eligibility criteria included histologic diagnosis of stage IIIB (with pleural effusion) or stage IV NSCLC (based on the sixth TNM staging system), presence of activating EGFR mutations (exon 19 deletion or L858R mutation in exon 21), and no history of chemotherapy for metastatic disease (neoadjuvant or adjuvant chemotherapy was allowed if it ended ≥6 months before study entry). Patients with asymptomatic, stable brain metastases were eligible to participate

Baseline Demographic and Clinical Characteristics of the Intention-to-Treat Population Randomized to Erlotinib (n = 86)

Sex, female	58 (67%)
Age, Years

Brain Metastasis	
Yes	9 (10%)
No	77 (90%)
Type of *EGFR* Mutation	
Deletion of exon 19	57 (66%)
L858R mutation in exon 21	29 (34%)

*Four undifferentiated carcinomas, 1 pleomorphic carcinoma, and 1 adenosquamous carcinoma

Treatment Monitoring

1. *Weekly, then monthly, then every 3 months:* History and physical exam, pulse O_2
2. *Weekly, then monthly, then every 3 months:* Serum creatinine
   - Especially in patient at risk of dehydration
3. *Weekly, then monthly, then every 3 months:* LFTs
   - More frequent monitoring in patients with biliary obstruction or hepatic impairment

Dose Adjustments

Adapted in part from: Tarceva (erlotinib) tablets, for oral use; 05/2013 product label. Genentech USA, Inc., 1 DNA Way, South San Francisco, CA

Acute onset of new or progressive pulmonary symptoms, such as dyspnea, cough or fever	Interrupt treatment with erlotinib pending diagnostic evaluation
Interstitial lung disease (ILD)	Discontinue erlotinib and institute appropriate treatment as necessary
Hepatic failure or gastrointestinal perforation	Discontinue erlotinib
Dehydration, severe bullous, blistering or exfoliative skin conditions, or acute worsening ocular disorders	Interrupt or discontinue erlotinib
G1/2 diarrhea	Interrupt erlotinib temporarily and institute loperamide therapy. Resume erlotinib at same dose or with a dose reduction in 50-mg increments
G3/4 diarrhea	Interrupt erlotinib temporarily and institute loperamide therapy. Resume erlotinib with a dose reduction in 50-mg increments
G3/4 diarrhea despite loperamide	Discontinue erlotinib
G1/2 skin reaction	Interrupt erlotinib temporarily and institute symptomatic therapy. Resume erlotinib at same dose or with a dose reduction in 50-mg increments
G3/4 skin reaction	Interrupt erlotinib temporarily and institute symptomatic therapy. Resume erlotinib with a dose reduction in 50-mg increments
Total bilirubin >3 × ULN and/or transaminases >5 × ULN in the setting of normal pretreatment values	Interrupt or discontinue erlotinib

Notes: In patients who are taking erlotinib with a strong CYP3A4 inhibitor such as, but not limited to, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, troleandomycin (TAO), voriconazole, or grapefruit products, a dose reduction should be considered if severe adverse reactions occur. Similarly, in patients who are taking erlotinib with an inhibitor of both CYP3A4 and CYP1A2 like ciprofloxacin, a dose reduction of erlotinib should be considered if severe adverse reactions occur.

Toxicity

Common Adverse Events in the Safety Population*

	Erlotinib (n = 84)			Standard Chemotherapy (n = 82)			P Value for G3/4

Toxicity (*continued*)

Safety Data

	Erlotinib (n = 84)	Standard Chemotherapy (n = 82)
Any adverse event (all grades)	82 (98%)	81 (99%)
Treatment-related adverse event (all grades)	78 (93%)	78 (95%)
Grade 3 or 4 adverse event	38 (45%)	55 (67%)
Dose reduction because of adverse event	18 (21%)	23 (28%)
Dose reduction because of drug-related adverse event	18 (21%)	21 (26%)
Discontinuation because of an adverse event	11 (13%)	19 (23%)
Discontinuation because of drug-related adverse event	5 (6%)	16 (20%)
Any severe adverse event	27 (32%)	25 (30%)
Treatment-related severe adverse event	5 (6%)	16 (20%)
Treatment-related death†	1 (1%)	2 (2%)
Interstitial lung disease-like events	1 (1%)	1 (1%)

*The safety analysis included all patients who were randomly allocated to treatment groups and received at least 1 dose of study drug
†One patient in the erlotinib group experienced hepatotoxicity, 2 patients in the chemotherapy group had cerebrovascular accidents (1 after a grade 5 infection)

NSCLC REGIMEN
PATIENTS WITH TUMORS HARBORING EGFR MUTATIONS

AFATINIB

Yang JC et al. Lancet Oncol 2012;13:539–548
Katakami N et al. J Clin Oncol 2013;31:3335–3341
Wu YL et al. Lancet Oncol 2014;15:213–222

Note: In the US afatinib is approved for first-line treatment of patients with metastatic non-small cell lung cancer (NSCLC) whose tumors have epidermal growth factor receptor (EGFR) exon 19 deletions or exon 21 (L858R) substitution mutations as detected by an FDA-approved test

Afatinib 40 mg orally, once daily

Notes:
- Instruct patient to take afatinib >1 hour before and >2 hours after a meal
- For patients who require therapy with a P-glycoprotein (Pgp) inhibitor, reduce the afatinib daily dose by 10 mg if not tolerated
- For patients who require chronic therapy with a Pgp inducer, increase afatinib daily dose by 10 mg as tolerated
- Increase dose to 50 mg per day if no rash, diarrhea, mucositis, or any other treatment-related adverse event >G1 in the first 21 days of treatment. In the study by Wu et al 38 of 239 (15.9%) patients had dose escalated

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

***Persistent diarrhea*:**

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

***Antibiotic therapy during latent or delayed onset diarrhea*:**

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–178

Treatment Modifications

Adverse Event	Dose Modification
Any NCI CTCAE* toxicity ≥G3	Withhold afatinib. Resume treatment when the adverse reaction fully resolves, returns to baseline, or improves to G ≤1. Reinstitute afatinib at a dose that is 10 mg per day less than the dose at which the adverse reaction occurred
G ≥2 diarrhea persisting for ≥2 consecutive days while taking anti-diarrheal medication	
G ≥2 cutaneous reactions lasting ≥7 days or intolerable	
G ≥2 renal dysfunction	
Life-threatening bullous, blistering, or exfoliative skin lesions	Discontinue afatinib
Confirmed interstitial lung disease (ILD)	
Severe drug-induced hepatic impairment	
Persistent ulcerative keratitis	
Symptomatic left ventricular dysfunction	
Severe or intolerable adverse reaction occurring at a dose of 20 mg per day	

*National Cancer Institute Common Terminology Criteria for Adverse Events, v 3.0
Note: In study by Wu et al 122 of 182 (67.0%) patients were still receiving the starting dose of afatinib 40 mg at the end of treatment; while 67 of 239 (28.0%) had their dose reduced to 30 mg, and ten (4.2%) had further reductions to 20 mg

Patient Population Studied

Randomized, open-label, phase 3 trial at 36 centers in China, Thailand, and South Korea. Eligible patients had pathologically confirmed and previously untreated stage IIIB (with pleural effusion) or IV lung adenocarcinoma according to American Joint Committee on Cancer criteria and ECOG PS of 0 or 1. Tumor tissue had to be EGFR mutation-positive at the screening stage. Twenty-nine mutations, including common ones (Leu858Arg, exon 19 deletions) were detected.

Efficacy

Afatinib group (N = 242)

Best overall tumor response [data are n (%)]	Independent Review	Investigator Review
Disease control	224 (92.6%)	225 (93.0%)
Objective response	162 (66.9%)	180 (74.4%)
Complete response	3 (1.2%)	0 (0%)
Partial response	159 (65.7%)	180 (74.4%)
Stable disease	52 (21.5%)	45 (18.6%)
Progressive disease	9 (3.7%)	10 (4.1%)
Not evaluable*	9 (3.7%)	7 (2.9%)

Progression-free survival, response duration and overall survival in months [95%CI]		
Median duration of treatment	398 days	
Median progression-free survival	11.0 [9.7–13.7)]	13.7 [11.5–13.9]
Median progression-free survival exon 19 deletions and Leu858Arg	11.0 [9.7–13.7]	13.8 [12.5–14.4]
Median duration of response	9.7 [8.3–12.5]	—
Median duration disease control	11.1 [9.7–13.8]	—
Median overall survival	22.1 [20.0–not estim]	—

*Withdrew with insufficient data for RECIST assessment after baseline. For the independent/investigator review reasons for withdrawal were: withdrawal of consent (1/1), adverse event (4/3), non-compliance with protocol (3/3), and classed as progressive disease but insufficient imaging for central review (1/0)

Therapy Monitoring

1. Before each 28-day cycle: CBC with differential, LFTs, BUN, and creatinine
2. Response evaluation: Every 2 cycles. Continue treatment until disease progression or unacceptable toxicity

Toxicity

Most Common Treatment-related Adverse Events (N = 239)*

	All Grades	Grade 1–2	Grade 3	Grade 4
Total	**236 (98.7%)**	**150 (62.8%)**	**82 (34.3%)**	**3 (1.3%)**

Diarrhea	211 (88.3%)	198 (82.8%)	13 (5.4%)	0 (0%)
Rash or acne*	193 (80.8%)	158 (66.1%)	34 (14.2%)	1 (0.4%)
Stomatitis or mucositis*	124 (51.9%)	111 (46.4%)	13 (5.4%)	0 (0.0%)
Paronychia	78 (32.6%)	78 (32.6%)	0 (0%)	0 (0%)
Epistaxis	30 (12.6%)	29 (12.1%)	1 (0.4%)	0 (0%)
Pruritus	26 (10.9%)	25 (10.5%)	1 (0.4%)	0 (0%)
Decreased appetite	24 (10.0%)	21 (8.8%)	3 (1.3%)	0 (0%)
Fatigue*	24 (10.0%)	23 (9.6%)	1 (0.4%)	0 (0%)
Vomiting	23 (9.6%)	21 (8.8%)	2 (0.8%)	0 (0%)
Nausea	18 (7.5%)	18 (7.5%)	0 (0%)	0 (0%)
Constipation	4 (1.7%)	4 (1.7%)	0 (0%)	0 (0%)
Laboratory or hematological adverse events as reported by investigator not based on laboratory data				
↑Alanine aminotransferase	48 (20.1%)	44 (18.4%)	4 (1.7%)	0 (0%)
↑Aspartate aminotransferase	36 (15.1%)	35 (14.6%)	1 (0.4%)	0 (0%)
Anemia	13 (5.4%)	12 (5.0%)	1 (0.4%)	0 (0%)
Neutropenia	5 (2.1%)	4 (1.7%)	1 (0.4%)	0 (0%)
Thrombocytopenia	2 (0.8%)	1 (0.4%)	1 (0.4%)	0 (0%)

*Data are n (%). Events are included if reported for more than 10% of patients at G1–2 or more than 1% of patients for G3–5 in any treatment group. In addition, one sudden death (G5) occurred that was considered related to treatment

REGIMEN

PEMETREXED

Hanna N et al. J Clin Oncol 2004;22:1589–1597

Folic acid 350–1000 mcg per day; administer orally beginning 1–2 weeks before the first dose of pemetrexed and continuing until 3 weeks after the last dose of pemetrexed
Cyanocobalamin (vitamin B_{12}) 1000 mcg; administer intramuscularly every 9 weeks, beginning 1–2 weeks before the first dose of pemetrexed
Dexamethasone 4 mg/dose; administer orally twice daily for 3 consecutive days (6 doses), starting the day before pemetrexed administration to decrease the risk and severity of severe skin rash associated with pemetrexed (total dose/cycle = 24 mg)
Pemetrexed 500 mg/m²; administer intravenously in 100 mL 0.9% sodium chloride injection over 10 minutes on day 1, every 21 days (total dosage/cycle = 500 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential: **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 283 patients with stages III–IV NSCLC

Efficacy (N = 265)

Overall response rate	9.1%
1-year overall survival	29.7%
Median survival time	8.3 months
Median progression-free survival	2.9 months
Median time to progression	3.4 months
Median duration of response	4.6 months

Toxicity (N = 265)*

	% Any G	% G3/4
Hematologic		
Neutropenia	Not given	5.3
Febrile neutropenia	Not given	1.9

Edema	4.5	0

*NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Treatment Modifications

Adverse Event	Dose Modification
G3 hematologic toxicities	Hold therapy until toxicity returns to baseline, then reduce pemetrexed dosage by 25%
G4 hematologic toxicities (thrombocytopenia)	Hold therapy until toxicity returns to baseline, then reduce pemetrexed dosage by 50%
Increased serum creatinine to 1.6–2 mg/dL (141–177 µmol/L)	Reduce pemetrexed dosage by 25%
Serum creatinine increased to ≤2 mg/dL (≤177 µmol/L)	Hold pemetrexed until serum creatinine <1.5 mg/dL (<133 µmol/L), then resume with pemetrexed dosage reduced by 25%
G ≥2 diarrhea	Hold pemetrexed until toxicity resolves to G <2, then resume with pemetrexed dosage reduced by 25%
G3/4 mucositis	Reduce pemetrexed dosage by 50%
Increased liver transaminases	Hold therapy until toxicity resolves, then resume with pemetrexed dosage reduced by 25%
Other G ≥3 nonhematologic toxicities (except nausea, vomiting, elevated transaminases, and alopecia)	Delay treatment until toxicity resolves to baseline, then resume with pemetrexed dosage reduced by 25% from previous dose level

Note: If a patient requires 3 dose reductions, discontinue pemetrexed

Therapy Monitoring

1. *Before each 21-day cycle:* CBC with differential, LFTs, BUN, and creatinine
2. *Weekly:* CBC with differential
3. *Response evaluation every 2 cycles:* Continue treatment until disease progression or unacceptable toxicity
4. *Every 2–3 months:* Consider plasma homocysteine levels. (High homocysteine concentrations are a sensitive indicator of folate deficiency and may predict pemetrexed toxicity)

Notes

In the study reported by Hanna et al. (J Clin Oncol 2004;22:1589–1597), 288 patients were treated with docetaxel 75 mg/m^2 by intravenous infusion every 21 days. Treatment with docetaxel resulted in clinically equivalent efficacy outcomes, but had significantly greater side effects compared with pemetrexed

REGIMEN

PACLITAXEL + CARBOPLATIN + BEVACIZUMAB

Johnson DH et al. J Clin Oncol 2004;22:2184–2191
Sandler AB et al. N Engl J Med 2006;355:2542–2550

Premedication (primary prophylaxis against hypersensitivity reactions from paclitaxel):
Dexamethasone 20 mg/dose for 2 doses; administer orally the evening before and the morning of chemotherapy prior to paclitaxel, *plus:*
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel, *and:*
Ranitidine 50 mg or **cimetidine** 300 mg; administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes, 30 minutes before paclitaxel
Paclitaxel 200 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 3 weeks (total dosage/cycle = 200 mg/m^2)

Carboplatin (calculated dose) AUC = 6 mg/mL • min; administer intravenously diluted in D5W or 0.9% NS to a concentration as low as 0.5 mg/mL over 15–30 minutes on day 1, 60 minutes after completing paclitaxel, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL • min) (see equation below)

Bevacizumab 15 mg/kg; administer intravenously in 100 mL 0.9% NS every 3 weeks on day 1, (total dosage/cycle = 15 mg/kg)

Note: Administration duration for the initial bevacizumab dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes and, finally, to a minimum duration of 30 minutes

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential: **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Additional Supportive Care
Dexamethasone 8 mg/dose orally every 12 hours for 6 doses after chemotherapy if G ≥2 arthralgias/myalgias occur
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

Note: Carboplatin dose is based on Calvert's formula to achieve a target area under the plasma concentration versus time curve (AUC) (AUC units = mg/mL • min)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia	Reduce carboplatin dosage to AUC = 5 if previous cycle dose was AUC = 6; or to AUC = 4 if previous cycle dose was AUC = 5
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia after 2 carboplatin dose reductions (AUC in previous cycle = 4)	Reduce paclitaxel dosage to 200 mg/m^2, and decrease carboplatin dosage to AUC = 3
Day 1 ANC <1500/mm^3 orplatelet <100,000/mm3	Delay chemotherapy until ANC >1500/mm^3 and platelet >100,000/mm^3, for maximum delay of 2 weeks
Delay of >2 weeks in reaching ANC >1500/mm^3 and platelet >100,000/mm3	Discontinue therapy
G2 neurotoxicity	Reduce paclitaxel dosage to 200 mg/m^2
G3 neurotoxicity	Reduce paclitaxel dosage to 175 mg/m^2
G2 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 200 mg/m^2
G3 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 175 mg/m^2
G ≥2 AST or ≥G3 bilirubin	Hold paclitaxel
Moderate hypersensitivity	Patient may be retreated
Severe hypersensitivity	Discontinue therapy
Chest pain or arrhythmia during chemotherapy	Immediately stop chemotherapy and evaluate the patient
Symptomatic arrhythmias, or ≥2-degree AV block, or an ischemic event	Discontinue therapy

Patient Population Studied

A study of 855 patients with advanced, previously untreated stage IIIB (pleural or pericardial effusion only) NSCLC (nonsquamous histologies). A randomized comparison with paclitaxel + carboplatin. ECOG PS 0 (40%) or 1 (60%). INR <1.5 and PTT no greater than upper limit normal. No history of thrombotic or hemorrhagic disorders. No gross hemoptysis defined as one-half teaspoon or more of bright red blood per day. Brain metastases were not allowed; 43% were age ≥65 years, and 28% had ≥5% weight loss

Efficacy (N = 357)

Overall response	27.2%
Complete response	1.4%
Partial response	25.8%
6-month progression-free survival	55%
12-month progression-free survival	14.6%
Median survival	12.5 months
1-year survival	51.9%
2-year survival	22.1%

Toxicity (N = 420)

Hematologic	
Toxicity	**% G4**
Neutropenia	24*
Fever + neutropenia	3.3*
Thrombocytopenia	1.4
Anemia	0
Nonhematologic	
	% ≥G3
Hemorrhage	4.5*
Hemoptysis	1.9*
CNS	1*
Gastrointestinal	1.2
Other	1
Hypertension	6*
Venous thrombosis	3.8
Arterial thrombosis	1.9
Treatment-Related Deaths	
Hemoptysis	5 (1.2%)
Gastrointestinal bleeding	2 (0.5%)
Fever + neutropenia	1 (0.25%)

*These values were statistically worse than those with paclitaxel + carboplatin alone

Therapy Monitoring

1. *Every week:* CBC with differential and platelet count
2. *Response evaluation:* Every 2–3 cycles

Notes

1. Compared with paclitaxel + carboplatin, overall survival advantage is confined to men; not seen in women ($P = 0.8$), despite statistically significant advantage for progression-free survival and response rate in women
2. Bevacizumab is associated with a small increase in serious bleeding, including hemoptysis. In a phase II trial, apparent risk factors for life-threatening hemorrhages included baseline hemoptysis brain metastases, anticoagulant therapy, and squamous histology (Johnson DH et al. J Clin Oncol 2004;22:2184–2191)
3. This therapy is the ECOG reference standard for first-line treatment of advanced NSCLC and is recommended by NCCN. Confirmatory trials have yet to be performed
4. Only patients with nonsquamous histologies were included in this study

Small Cell Lung Cancer (SCLC)

Work-up

General work-up

1. History and physical examination
2. Complete blood count, liver and renal function tests, LDH, and serum electrolytes with special attention to serum sodium
3. Chest x-ray
4. CT scan of chest and upper abdomen including adrenals
5. Brain MRI (or CT scan)
6. Bone scan
7. FDG-PET scan (optional)

Individualized work-up

1. Bone marrow biopsy in selected patients
2. Pulmonary function tests and cardiac function assessment if thoracic radiation therapy is going to be performed
3. If a patient presents with pleural effusion, a diagnostic thoracocentesis is recommended. Consider thoracoscopy if thoracocentesis is inconclusive
4. Plain-film x-rays of bone scan abnormalities

Staging

Limited disease	Disease confined to ipsilateral hemithorax within a single radiation port
Extensive disease	Disease beyond ipsilateral hemithorax or obvious metastatic disease

Østerlind K et al. Cancer Treat Rep 1983;67:3–9

Five-Year Survival for Each Stage

Limited Disease	
Median survival	14–20 months
2-year survival	40%
Extensive Disease	
Median survival	8–12 months
2-year survival	5%

More information at http://www.seer.cancer.gov

Expert Opinion

Treatment of limited disease

1. Etoposide + cisplatin combination for 4–6 cycles is the regimen of choice to combine with concurrent chest radiation therapy
2. Chest radiation therapy increases local control and survival. Several studies suggest starting chest radiotherapy early
3. Prophylactic cranial irradiation is indicated in patients with complete remission; it reduces the risk of cerebral metastases and improves survival

Treatment of extensive disease

1. Etoposide + platinum or cyclophosphamide + doxorubicin regimens for 4–6 cycles
2. Prophylactic cranial irradiation should be considered in patients with response after chemotherapy

Second-line chemotherapy for both limited and extensive disease

1. Patients who relapse after a response to first-line chemotherapy should be considered for second-line chemotherapy with topotecan

REGIMEN

ETOPOSIDE + CISPLATIN WITH CONCURRENT THORACIC RADIATION THERAPY

Turrisi AT et al. N Engl J Med 1999;340:265–271

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2–4 hours
Cisplatin 60 mg/m²; administer intravenously in 50–150 mL 0.9% NS over 60 minutes, on day 1, every 3 weeks for 4 cycles (total dosage/cycle = 60 mg/m²)
Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Etoposide 120 mg/m² per dose; administer intravenously, diluted in 0.9% NS or 5% dextrose injection to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes, for 3 consecutive days, on days 1, 2, and 3, every 3 weeks for 4 cycles (total dosage/cycle = 360 mg/m²)
Thoracic RT begins concurrently with the first cycle of chemotherapy to a total dose of 45 Gy delivered as:

1. Once daily in 1.8-Gy fractions for 25 treatments over 5 weeks, *or*
2. Twice daily in 1.5-Gy fractions for 30 treatments over 3 weeks

Prophylactic cranial RT is offered to patients who achieve a CR after completing systemic chemotherapy

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is HIGH. Potential for delayed symptoms
Emetogenic potential on days 2 and 3 is LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 417 patients with previously untreated limited SCLC. A randomized comparison between twice-daily and once-daily thoracic radiation therapy, both combined with etoposide and cisplatin given at fixed dosages

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, LFTs, BUN, creatinine, and serum electrolytes
2. *Response evaluation:* Evaluate therapy at the end of treatment

Efficacy (N = 206/211)

	RT Fractionation	
	Once Daily (N = 206)	Twice Daily (N = 211)
Complete response	49%	56%
Partial response	38%	31%
Local failure	52%	36%
Median survival	19 months	23 months
2-year survival	41%	47%
5-year survival	16%	26%

Treatment Modifications

Adverse Event	Dose Modification
G4 toxicities, febrile neutropenia, documented infection, or thrombocytopenia with bleeding during cycles 3 and 4	Reduce etoposide dosage by 25%
Serum creatinine = 1.6–2.5 mg/dL (141–221 μmol/L) during cycles 3 and 4	Reduce cisplatin dosage by 25%
Platelets ≤50,000/mm³	Interrupt radiation therapy
G2 weight loss (≥4.5 kg or ≥10 pounds)	
Hospitalization for febrile neutropenia or sepsis	
Difficulty swallowing	Do not interrupt radiation therapy*
Fever with low ANC	

*In general, interruptions of thoracic radiation therapy are discouraged
Note: DO NOT modify chemotherapy during the first 2 cycles

Toxicity (N = 206/211)

Toxicity	% G3	% G4	% G5
Once-Daily RT (N = 206)			
Overall toxicity	23	63	2
Esophagitis	11	5	0
Granulocytopenia	15	60	0
Thrombocytopenia	16	8	0
Anemia	23	3	0
Infection	6	1	1
Vomiting	8	2	0
Pulmonary effects	3	0.5	0.5
Weight loss	3	0	0
Twice-Daily RT (N = 211)			
Overall toxicity	25	62	3
Esophagitis	27	5	0
Granulocytopenia	21	59	0
Thrombocytopenia	13	8	0
Anemia	23	5	0
Infection	6	2	1
Vomiting	8	1	0
Pulmonary effects	4	1	1
Weight loss	2	0	0

REGIMEN

TOPOTECAN

von Pawel J et al. J Clin Oncol 1999;17:658–667

Topotecan HCl 1.5 mg/m² per day; administer intravenously in 50–250 mL 0.9% sodium chloride injection or 5% dextrose injection over 30 minutes, for 5 consecutive days, on days 1 through 5, every 21 days (total dosage/cycle = 7.5 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–5 is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue filgrastim until ANC >10,000/mm³ on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 107 patients with SCLC and disease progression at least 60 days after having completed first-line chemotherapy. A randomized comparison with combination chemotherapy, including cyclophosphamide, doxorubicin, and vincristine

Efficacy (N = 107)

Intention-to-treat response rate	24.3%*
Median survival	25 weeks
6-month survival	46.7%
1-year survival	14.2%

*Partial responses

Toxicity (N = 107)*

	% G3/4
Neutropenia	88
Thrombocytopenia	58
Anemia	42
Nausea	3.7
Fatigue	4.7
Vomiting	1.9
Stomatitis	1.9
Fever†	1.9
Diarrhea	0.9

Worsening LVEF: 2 of 26 patients (7.7%)

*NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
†Excludes patients with febrile neutropenia

Treatment Modifications

Adverse Event	Dose Modification
Day 1 ANC <1000/mm³, platelets <100,000/mm³	Delay treatment until ANC >1000/mm³, platelets >100,000/mm³
Toxicity G <2 during the previous cycle	Increase topotecan dosage to a maximum daily dose of 2 mg/m² during repeated cycles (ie, first cycle escalated to 1.75 mg/m² · d for 5 days; second cycle escalated to 2 mg/m² · d for 5 days)
G4 neutropenia with fever or infection, or of duration ≥7 days	Decrease daily topotecan dosage from the previous cycle by 0.25 mg/m²*
G3 neutropenia during the preceding cycle persisting after day 21	
G4 thrombocytopenia	
G3/4 nonhematologic toxicity, excluding grade 3 nausea	Decrease daily topotecan dosage from the previous cycle by 0.25 mg/m² or discontinue treatment*
Treatment delay >2 weeks	Discontinue treatment

*The minimum permissible daily topotecan dosage is 1 mg/m² per day for 5 days

Therapy Monitoring

1. *Before day 1 chemotherapy:* CBC with differential, LFTs, serum BUN, and creatinine and electrolytes
2. *Weekly:* CBC with differential
3. *Day 15:* LFTs, serum BUN, and creatinine
4. *Before starting and after completing treatment:* ECG and multiple-gated acquisition or echocardiogram assessment of left ventricular ejection fraction (LVEF)
5. *Response evaluation:* Every 2–3 cycles

Notes

Patients with objective responses continue treatment until disease progression or unacceptable toxicity, or for 6 additional cycles after maximal response

23. Lymphoma, Hodgkin

Michael Fuchs, MD, Dennis A. Eichenauer, MD, and Volker Diehl, MD

Epidemiology

Incidence: 9,190 (male: 5,070; female: 4,120. Estimated new cases for 2014 in the United States) 3.2 per 100,000 males; 2.4 per 100,000 females
Deaths: Estimated 1,180 in 2014 (male: 670; female: 510)
Median age: 38 years
Male to female ratio: 1.2:1

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Since 1944, several classifications have been proposed for Hodgkin lymphoma (HL). Currently, the World Health Organization (WHO) Classification of Hematologic Malignancies is used:

1. Lymphocyte predominant, nodular (NLPHL) (5%)
2. Classic
   a. Lymphocyte-rich (LRCHL) (5%)
   b. Nodular sclerosis (NSHL) (60–80%)
   c. Mixed cellularity (MCHL) (15–30%)
   d. Lymphocyte depleted (LDHL) (1%)
   e. Unclassifiable (<1%)

Jaffe ES, Harris NL, Stein H, Vardiman JW, eds. World Health Organization Classification of Tumours. Pathology and Genetics of Tumours of Haematopoietic and Lymphoid Tissues. Lyon, France: IARC Press, 2001

Work-up

1. History and physical exam
2. Laboratory tests: CBC with differential, ESR, electrolytes, albumin, liver function tests, mineral panel, LDH
3. HIV and hepatitis B and C serologies as clinically indicated
4. Chest x-ray (PA and lateral)
5. CT scan of chest, abdomen, and pelvis (and neck in selected cases)
6. Positron emission tomography (PET) scan if clinically indicated (equivocal CT)
7. Bone marrow aspirate and biopsy
8. Pulmonary function tests
9. Echocardiogram or MUGA scan to determine cardiac ejection fraction
10. Excisional lymph node biopsy to completely assess lymph node architecture is required at initial diagnosis. Fine-needle aspiration biopsy alone is not desirable for the initial diagnosis of lymphoma
11. Fertility counseling, if appropriate

Five-Year Survival Rate

NLPHL	90% (10 years)
Classic HL	70–80%

Jaffe ES, Harris NL, Stein H, Vardiman JW, eds. World Health Organization Classification of Tumours. Pathology and Genetics of Tumours of Haematopoietic and Lymphoid Tissues. Lyon, France: IARC Press, 2001

Staging

Ann Arbor Staging Classification for Hodgkin and Non-Hodgkin Lymphomas

Stage	Description
I	Involvement of a single lymph node region (I) or involvement of a single extralymphatic organ or site (IE)
II	Involvement of 2 or more lymph node regions or lymphatic structures on the same side of the diaphragm alone (II) or with involvement of limited, contiguous extralymphatic organ or tissue (IIE)
III	Involvement of lymph node regions on both sides of the diaphragm (III), which may include the spleen (IIIS), or limited, contiguous extralymphatic organ or site (IIIE), or both (IIIES)
IV	Diffuse or disseminated foci of involvement of one or more extralymphatic organs or tissues with or without associated lymphatic involvement

Abbreviations

A	Asymptomatic
B	Unexplained persistent or recurrent fever with temperature higher than 38°C (100.4°F) or recurrent drenching night sweats within 1 month or unexplained loss of >10% body weight within 6 months
E	Limited direct extension into extralymphatic organ from adjacent lymph node

Carbone PP et al. Cancer Res 1971;31:1860–1861

(*continued*)

Staging (*continued*)

Criteria that predict an unfavorable prognosis in ***limited-stage HL*** differ among study groups Patients with one or more of these factors are considered to have an unfavorable prognosis

Factor	EORTC	GHSG	NCIC	Stanford
Age (years)	≥50	—	≥40	—
Histology	—	—	MC/LD	—
ESR/B-symptoms	≥30 mm with any B ≥50 mm without B	≥30 mm with any B ≥50 mm without B	≥50 mm or any B	Any B
Mediastinal mass	MTR ≥0.35	MMR >0.33	10 cm or MMR >0.33	MMR >0.33
Number of nodal sites	≥4	≥3	≥4	—
E-lesions	—	Present	—	—

EORTC, European Organization for Research and Treatment of Cancer; GHSG, German Hodgkin *Lymphoma* Study Group; NCIC, National *Cancer* Institute of *Canada*

For patients with ***advanced stage HL*** the German Hodgkin *Lymphoma* Study Group (*GHSG*) has developed the following prognostic score model:

Number of Factors	Percent of the Population	Estimated Freedom from Disease Progression at 5 Years
0	7%	84%
1	22%	77%
2	29%	67%
3	23%	60%
4	12%	51%
5+	7%	42%

Factors: Stage IV; male sex; age >45 years; hemoglobin <10.5 g/dL; WBC ≥15,000/mm³; lymphocytes <8% or <600/mm³; albumin <4 g/dL

Hasenclever D, Diehl V. N Engl J Med 1998;339: 1506–1514

Expert Opinion

The treatment of adult patients with HL should be stage adapted with respect to age and additional factors such as comorbidities

1. Patients with early favorable stage HL

- Combined modality treatment with a chemotherapy regimen such as ABVD followed by involved-field radiotherapy (IF-RT) is considered the treatment of choice[*,†] with a 5-year event-free survival rate (EFS) of 98% (data from the H8F trial of the EORTC)

2. Patients with stage IA nodular lymphocyte predominant Hodgkin Lymphoma (NLPHL)

- Local radiotherapy is widely accepted as the standard treatment due to the excellent prognosis of this subgroup of patients[‡]

3. Patients with early unfavorable (intermediate) stage HL

- Combined modality treatment, for example, 4–6 cycles of ABVD followed by IF-RT[§]
- Despite excellent initial remission rates, approximately 15% of patients relapse within 5 years. Thus, an intensification of chemotherapy might improve results. Several ongoing studies are addressing this issue

4. Patients with advanced stage HL

- *Low-risk patients:* IPS <3 risk factors → FDG-PET might help to identify patients for whom 6–8 cycles of ABVD ± IF-RT is sufficient to achieve a cure
- *High-risk patients:* IPS >3 risk factors → intensive chemotherapy such as dose-escalated BEACOPP is be the treatment of choice.[¶] For patients with advanced HL, eight cycles of BEACOPPescalated are no longer standard of care. The final analysis of the GHSG HD15 trial has shown that six cycles of BEACOPPescalated followed by localized RT of PET-positive residual lymphoma larger than 2.5 cm represent the optimal treatment for these patients
- The impact of radiotherapy after effective chemotherapy if a CR is achieved is doubtful. Therefore radiotherapy should be restricted to patients in whom FDG-PET scan demonstrates positive lesions after the end of chemotherapy

(*continued*)

Expert Opinion (*continued*)

5. The following protocols may be considered in the management of patients with Hodgkin lymphoma:

First-line protocols for newly diagnosed Hodgkin lymphoma

1. ABVD
2. Stanford V
3. BEACOPP

Salvage/induction protocols

4. DHAP
5. ICE
6. IGEV
7. GVD
8. Dexa-BEAM
9. IVE

High-dose/conditioning protocols

10. BEAM
11. CBV

Palliative protocols (regimens/drugs)

12. Brentuximab vedotin
13. Gemcitabine
14. Vinorelbine
15. Bendamustine

*Several studies have demonstrated FDG-PET to be a good prognostic predictor when performed after the first or second cycle of chemotherapy. However, because almost all studies were retrospective analyses, it is necessary to prove the value of FDG-PET for tailoring therapy within a large prospective trial. Trials addressing this issue are ongoing

†Patients older than 60 years of age should not receive dose-escalated BEACOPP because of an increased rate of toxicity. These patients should be treated with 6–8 cycles of ABVD followed by radiotherapy in case of residual lymphomas

‡HL patients who relapse or do not respond to primary treatment require an adequate salvage therapy. For most of them, high-dose chemotherapy (HDCT) followed by autologous stem cell transplantation (ASCT) is the treatment of choice. The best regimen for reinduction therapy has not yet been defined

§Patients with contraindications to undergo ASCT or with multiple relapses should either receive a classical palliative treatment with drugs such as gemcitabine or vinorelbine, or be enrolled in clinical trials evaluating novel approaches

ᶜASCT still has to be regarded as an experimental approach as it is associated with high relapse and mortality rates. It should only be considered for patients younger than 30 years of age who are in a good general condition

Bonadonna G, Bonfante V, Viviani S, Di Russo A, Villani F, Valagussa P. ABVD plus subtotal nodal versus involved-field radiotherapy in early-stage Hodgkin's disease: long-term results. J Clin Oncol 2004;22:2835–2841

Noordijk EM, Carde P, Dupouy N et al. Combined-modality therapy for clinical stage I or II Hodgkin's lymphoma: long-term results of the European Organisation for Research and Treatment of Cancer H7 randomized controlled trials. J Clin Oncol 2006;24:3128–3135

REGIMEN FOR NEWLY DIAGNOSED HODGKIN LYMPHOMA

DOXORUBICIN (Adriamycin), BLEOMYCIN, VINBLASTINE, DACARBAZINE (ABVD)

Bonadonna G et al. Cancer 1975;36:252–259
Canellos GP et al. New Engl J Med 1992;327:1478–1484
Duggan DB et al. J Clin Oncol 2003;21:607–614
Hoskins PJ et al. J Clin Oncol 2009;27:5390–5396

Doxorubicin 25 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 2 doses on days 1 and 15, every 28 days (total dosage/cycle = 50 mg/m²)
Bleomycin 10 units/m² per dose; administer intravenously by slow injection over 10 minutes for 2 doses on days 1 and 15, every 28 days (total dosage/cycle = 20 units/m²)
Vinblastine 6 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 2 doses on days 1 and 15, every 28 days (total dosage/cycle = 12 mg/m²)
Dacarbazine 150 mg/m² per dose; administer intravenously in 100–250 mL 0.9% sodium chloride injection or 5% dextrose injection over 15–30 minutes for 5 consecutive days on days 1–5, every 28 days (total dosage/cycle = 750 mg/m²)

Note: There is evidence that ABVD can be given without any dose modification on time irrespective of the peripheral blood count (Evens AM et al. Br J Haematol 2007;137:545–552)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Days 1–5 is ***HIGH***
Emetogenic potential on Day 15 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection
- Begin use 24–72 h after myelosuppressive chemotherapy is completed
- G-CSF use with bleomycin-containing regimens for Hodgkin's disease has been associated with an increased rate of pulmonary toxicity

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)

See Chapter 47 for more information

Patient Population Studied

Hoskins PJ et al. J Clin Oncol 2009;27:5390–5396

Multicenter, prospective, randomized controlled trial compared the efficacy and toxicity of 2 chemotherapy regimens, ABVD and Stanford V, in advanced Hodgkin lymphoma

Baseline Demographic and Clinical Characteristics

Characteristic	Treatment Arm: ABVD (n = 261) Number (%)	Treatment Arm: Stanford V (n = 259) Number (%)	Total (N = 520) Number (%)
Age, median (range)	35 years (18–60)	34 years (18–67)	35 years (18–67)
Male sex	154 (59%)	154 (59%)	308 (59%)
Stage			
I to II	119 (46%)	134 (52%)	253 (49%)
III	81 (31%)	72 (28%)	153 (29%)
IV	61 (23%)	53 (20%)	114 (22%)
"B" symptoms present	184 (73%)	185 (75%)	369 (74%)

(continued)

Treatment Modifications

Adverse Event*	Dose Modification
WBC 3,999–3,000/mm³ or platelet count 129,000–100,000/mm³	Reduce doxorubicin and vinblastine dosages by 50%
WBC 2,999–2,000/mm³ or platelet count 99,000–80,000/mm³	Reduce dacarbazine dosage by 50%. Reduce doxorubicin and vinblastine dosages by 75%
WBC 1,999–1,500/mm³ or platelet count 79,000–50,000/mm³	Reduce dacarbazine dosage by 75%. Hold doxorubicin and vinblastine
WBC <1,500/mm³ or platelet count <50,000/mm³	Hold doxorubicin, vinblastine, and dacarbazine
Clinical or radiologic evidence of pulmonary fibrosis or DLCO <50% pretreatment value	Discontinue bleomycin
Moderate-to-severe renal function impairment (creatinine clearance <50 mL/min [<0.83 mL/s])	Discontinue bleomycin until creatinine clearance improves to ≥50 mL/min

*Refers to values on days 1 or 15

Therapy Monitoring

1. *Semiweekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam, chest x-ray
3. *After second and each subsequent cycle:* DLCO
4. *Response evaluation:* CT of chest, abdomen, and pelvis every 2 cycles starting after cycle 4. FDG-PET scan at conclusion of therapy to document extent of remission. Bone marrow biopsy (if disease existed before therapy) performed 1 month after completing the sixth cycle

Patient Population Studied (*continued*)

Hematologic†	15 (5%)

*G ≥2 dyspnea, partial pressure of oxygen/carbon dioxide, diffusing capacity for carbon monoxide, fibrosis, acute respiratory distress syndrome, noninfectious pneumonitis, cardiac function, or arrhythmia, all of which would result in dose modification or elimination of doxorubicin or bleomycin
†Maximum toxicity G ≥3, severe, life-threatening, or fatal
Note: there were 9 deaths during initial therapy

Duggan DB et al. J Clin Oncol 2003;21:607–614

REGIMEN FOR NEWLY DIAGNOSED HODGKIN LYMPHOMA

STANFORD V

Bartlett NL et al. J Clin Oncol 1995;13:1080–1088

Doxorubicin 25 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 2 doses on days 1 and 15, every 28 days, for 3 cycles (total dosage/cycle = 50 mg/m²)
Vinblastine 6 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 2 doses on days 1 and 15, every 28 days, for 3 cycles (total dosage/cycle = 12 mg/m²)

Note: For patients ≥50 years of age, during the third cycle, decrease vinblastine dosage to 4 mg/m² per dose for 2 doses on days 1 and 15 (total dose during the third cycle = 8 mg/m²)

Mechlorethamine 6 mg/m²; administer by intravenous injection over 1–2 minutes on day 1, every 28 days for 3 cycles (total dosage/cycle = 6 mg/m²)
Vincristine 1.4 mg/m² per dose; administer (maximum single dose = 2 mg) by intravenous injection over 1–2 minutes for 2 doses on days 8 and 22, every 28 days, for 3 cycles (total dosage/cycle = 2.8 mg/m²; maximum dose/cycle = 4 mg)

Note: For patients ≥50 years of age, during the third cycle, decrease vincristine dosage to 1 mg/m² per dose (maximum single dose = 2 mg) for 2 doses on days 8 and 22 (total dosage during the third cycle = 2 mg/m²; maximum dose during the third cycle = 4 mg)

Bleomycin 5 units/m² per dose; administer by slow intravenous injection over 10 minutes for 2 doses on days 8 and 22, every 28 days, for 3 cycles (total dosage/cycle = 10 units/m²)
Etoposide 60 mg/m² per day; administer intravenously, diluted in 0.9% sodium chloride injection or 5% dextrose injection to a concentration within the range 0.2–0.4 mg/mL over 1 hour for 2 doses on days 15 and 16, every 28 days, for 3 cycles (total dosage/cycle = 120 mg/m²)
Prednisone 40 mg/m² per dose; administer orally every other day (days 1, 3, 5, and so on) for 14 doses, every 28 days

Note: Prednisone dosage is tapered by 10 mg/dose every other day starting on day 14 of the third cycle (total dosage/28-day cycle = 560 mg/m² until tapering begins)

Consolidative irradiation, starting 2 weeks after the completion of chemotherapy. Administer 36 Gy to sites of initial tumor bulk defined as disease ≥5 cm in horizontal diameter. The treatment port for patients with bulky mediastinal HL is referred to as a modified mantle and is restricted to the mediastinum and bilateral hilar and supraclavicular regions. Extension of HL to contiguous extralymphatic sites, usually associated with bulky disease is also included in the port. Limit doses to the lung and pleura to 16.5 Gy delivered in 0.75- to 0.9-Gy fractions; pericardial and subcarinal blocks should be placed at 15 Gy and 30 Gy, respectively

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Day 1 is ***HIGH***
Emetogenic potential on Days 8 and 22 is ***MINIMAL***
Emetogenic potential on Day 15 is ***MODERATE***
Emetogenic potential on Day 16 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection
- Begin use 24–72 h after myelosuppressive chemotherapy is completed
- G-CSF use with bleomycin-containing regimens for Hodgkin's disease has been associated with an increased rate of pulmonary toxicity

See Chapter 43 for more information

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC <1000/mm³	Reduce doxorubicin, vinblastine, mechlorethamine, and etoposide dosages by 35%
ANC <500/mm³	Delay treatment 1 week then reduce doxorubicin, vinblastine, mechlorethamine, and etoposide dosages by 35%
Dose reduction or dose delay	Administer filgrastim 5 mcg/kg · day subcutaneously on days 3–13 and 16–26
Clinical or radiologic evidence of pulmonary fibrosis or DLCO <50% pretreatment value	Discontinue bleomycin
Moderate-to-severe renal function impairment (creatinine clearance <50 mL/min [<0.83 mL/s])	Discontinue bleomycin until creatinine clearance improves to ≥50 mL/min (≥0.83 mL/s)

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

Note: Although the primary report recommended daily ketoconazole, imidazole and triazole antifungals are highly potent cytochrome P450 (CYP3A subfamily) inhibitors that may interfere with drug metabolism. It may be prudent to withhold these drugs the day before, the day of, and the day after doxorubicin, vinblastine, vincristine, and etoposide are administered

See Chapter 47 for more information

Steroid-associated gastritis

Add a **proton pump inhibitor** concurrent with steroid use to prevent gastritis and duodenitis

Patient Population Studied

Patients between 15 and 60 years of age with either advanced-stage (III or IV) HL or stage II with bulky mediastinal involvement were treated with 3 cycles of chemotherapy followed by consolidative radiation to sites of initial bulky (>5 cm) disease

Toxicity (N = 60)

Toxicities Requiring Hospitalization	
Fever/neutropenia	17%
Obstipation/ileus	11%
DVT	3%
Pneumonitis	2%
Palpitations	2%
Phlebitis	2%

Overall Toxicities	% Any Grade	% G3/4
Neutropenia	82	45
Anemia	60	34
Nausea/vomiting	52	9
Sensory neuropathy	71	11
Motor neuropathy	34	8
Autonomic neuropathy	46	12
Phlebitis	38	
Myalgias/arthralgias	24	
Aseptic necrosis femoral head	2	

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before every cycle:* CBC with differential, alkaline phosphatase and LDH, chest x-ray; DLCO after second and each subsequent cycle
3. *Response evaluation after completion of therapy:* CT of chest, abdomen, and pelvis after 2 cycles of chemotherapy and before the start of radiation therapy or after 3 cycles of chemotherapy. FDG-PET scan at conclusion of therapy to document extent of remission. Bone marrow biopsy (if disease existed before therapy) performed 1 month after completing therapy

Efficacy (N = 65)

Stage at Diagnosis	Status at 3 Years: Failure-Free Survival
II (n = 21)	100
III (n = 20)	92
IV (n = 24)	76
Progression while on therapy	0

Four of 28 patients had positive gallium scans with mediastinal uptake. None had relapsed 6–42 months after consolidative mediastinal RT

Failure-free survival (FFS) time was calculated from the initial date of treatment until disease progression, relapse, death from any cause, or last follow-up evaluation

The 3 year overall survival and FFS were 96% and 87% respectively

The 3 year FFS for stage III to IV patients combined was 82%

Note

Stanford V is widely used, but requires radiation therapy in all patients with attendant late complications

REGIMEN FOR NEWLY DIAGNOSED HODGKIN LYMPHOMA

BLEOMYCIN, ETOPOSIDE, DOXORUBICIN (Adriamycin), CYCLOPHOSPHAMIDE, VINCRISTINE (Oncovin), PROCARBAZINE, PREDNISONE (BEACOPP)

Diehl V et al. J Clin Oncol 1998;16:3810–3821. Erratum in: N Engl J Med 2005;353:744
Diehl V et al. N Engl J Med 2003;348:2386–2395

BEACOPP

Doxorubicin 25 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 21 days (total dosage/cycle = 25 mg/m^2)
Cyclophosphamide 650 mg/m^2; administer intravenously in 25–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 10–30 minutes on day 1, every 21 days (total dosage/cycle = 650 mg/m^2)
Etoposide 100 mg/m^2 per day; administer intravenously, diluted in 0.9% NS or D5W to a concentration within the range 0.2–0.4 mg/mL over 1 hour for 3 consecutive days, on days 1, 2, and 3, every 21 days (total dosage/cycle = 300 mg/m^2)
Procarbazine 100 mg/m^2 per day; administer orally for 7 consecutive days on days 1–7, every 21 days (total dosage/cycle = 700 mg/m^2)
Prednisone 40 mg/m^2 per day; administer orally for 14 consecutive days on days 1–14, every 21 days (total dosage/cycle = 560 mg/m^2)
Bleomycin 10 units/m^2; administer by slow intravenous injection over 10 minutes on day 8, every 21 days (total dosage/cycle = 10 units/m^2)
Vincristine 1.4 mg/m^2 (maximum single dose = 2 mg); administer by intravenous injection over 1–3 minutes on day 8, every 21 days (total dosage/cycle = 1.4 mg/m^2; maximum dose/cycle = 2 mg)

Dose-Escalated BEACOPP

Doxorubicin 35 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 21 days (total dosage/cycle = 35 mg/m^2)
Cyclophosphamide 1250 mg/m^2; administer intravenously in 100–1000 mL 0.9% NS or D5W over 10–30 minutes on day 1, every 21 days (total dosage/cycle = 1250 mg/m^2)
Etoposide 200 mg/m^2 per day; administer intravenously, diluted in 0.9% NS or D5W to a concentration within the range 0.2–0.4 mg/mL, over 1 hour for 3 consecutive days, on days 1, 2, and 3, every 21 days (total dosage/cycle = 600 mg/m^2)
Procarbazine 100 mg/m^2 per day; administer orally for 7 consecutive days on days 1–7, every 21 days (total dosage/cycle = 700 mg/m^2)
Prednisone 40 mg/m^2 per day; administer orally for 14 consecutive days on days 1–14, every 21 days (total dosage/cycle = 560 mg/m^2)
Bleomycin 10 units/m^2; administer by slow intravenous injection over 10 minutes on day 8, every 21 days (total dosage/cycle = 10 units/m^2)
Vincristine 1.4 mg/m^2 (maximum single dose = 2 mg); administer by intravenous injection over 1–3 minutes on day 8, every 21 days (total dosage/cycle = 1.4 mg/m^2; maximum dose/cycle = 2 mg)

Special instructions:
Procarbazine is a weak monoamine oxidase inhibitor. Concurrent use of sympathomimetic or tricyclic antidepressant drugs and ingestion of tyramine-rich foods may produce severe hypertensive episodes in a patient receiving procarbazine

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
BEACOPP and Dose-Escalated BEACOPP	
WBC <2500/mm^3 or platelet count <80,000/mm^3	Delay cycle until WBC >2500/mm^3 and platelet count >80,000/mm^3; if delayed >2 weeks, reduce dosage of doxorubicin, cyclophosphamide, etoposide, and procarbazine by 25%
Clinical or radiologic evidence of pulmonary fibrosis or DLCO <50% pretreatment value	Discontinue bleomycin
Moderate to severe impairment renal function (creatinine clearance <50 mL/min [<0.83 mL/s])	Discontinue bleomycin until creatinine clearance improves to ≥50 mL/min (≥0.83 mL/s)
Dose-Escalated BEACOPP	
Any G4 toxicity or a 2-week postponement in start of next cycle per above guidelines	Stepwise reduction of cyclophosphamide and etoposide dosages by 25% of the difference between the escalated dosage and standard BEACOPP; immediate reduction to standard BEACOPP dosages if G4 toxicity occurs in 2 successive cycles

(*continued*)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Day 1 is ***HIGH***
Emetogenic potential on Days 2–7 is ***MODERATE***
Emetogenic potential on Day 8 is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 300 mcg/day (patients with body weight <75 kg) or 480 mcg/day (body weight ≥75 kg) by subcutaneous injection starting on day 8 and continuing until WBC ≥1000/mm^3 on 3 consecutive days

- G-CSF use with bleomycin-containing regimens for Hodgkin's disease has been associated with an increased rate of pulmonary toxicity

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Steroid-associated gastritis

Add a **proton pump inhibitor** concurrent with steroid use to prevent gastritis and duodenitis

Patient Population Studied

Phase III multicenter trial of 935 patients with advanced stage HL, ages 16–65 years. Patients were randomized to receive 8 cycles of BEACOPP or dose-escalated BEACOPP. An additional 260 patients were randomized to standard treatment with COPP/ABVD. This arm was prematurely closed because of the superiority of the BEACOPP arms in terms of FFTF. Radiation therapy was planned to sites of initial bulky disease (>5 cm)

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* PE, CBC with differential, BUN, creatinine, LFTs, and LDH
3. *After the second and each subsequent cycle:* DLCO
4. *Response evaluation after completion of therapy:* CT of chest, abdomen, and pelvis every 2 cycles starting after cycle 4. FDG-PET scan at conclusion of therapy to document extent of remission. Bone marrow biopsy (if disease existed before therapy) performed 1 month after completing the sixth cycle

Efficacy (N = 323)

	BEACOPP	Dose-Escalated BEACOPP
Complete remission	88%	96%
Early progression	8%	2%
FFTF at 5 years	76%	87%
OS at 5 years	88%	91%

Notes

1. Approximately 70% of all patients received radiation therapy after chemotherapy had been completed. However, subsequent studies have demonstrated that the percentage of patients that require radiation can be decreased. The latest interim analysis from the HD15 trial showed that only 12% of patients require additional radiotherapy. RT can be restricted to patients who continue to have areas that are positive by PET scan after the completion of chemotherapy (Kobe C et al. Blood 2008;112:3989–3994)
2. Patients older than 60 years of age should not receive dose-escalated BEACOPP because of an increased rate of toxicity

Toxicity (N = 1140; 854 Cycles)

	% G3/4	
Toxicity	BEACOPP	Dose-Escalated BEACOPP
Leukopenia	73%	98%
Thrombocytopenia	9%	70%
Anemia	17%	66%
Infection	16%	22%
Nausea	12%	20%
Mucositis	2%	8%
Respiratory tract effects	5%	4%

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

DEXAMETHASONE + CYTARABINE (Ara-C) + CISPLATIN (DHAP)

Josting A et al. Ann Oncol 2002;13:1628–1635

Hydration: Administer 0.9% sodium chloride injection (0.9% NS); administer by continuous intravenous infusion at 200–250 mL/h starting 6 hours before cisplatin. Monitor and replace magnesium and other electrolytes as needed

Dexamethasone 40 mg/day; administer intravenously in 10–100 mL 0.9% NS or 5% dextrose injection (D5W) over 15–30 minutes for 4 consecutive days on days 1–4, every 14 days (total dose/cycle = 160 mg)

Cisplatin 100 mg/m^2; administer by continuous intravenous infusion over 24 hours in 100–1000 mL 0.9% NS on day 1, every 14 days (total dosage/cycle = 100 mg/m^2)

Cytarabine 2000 mg/m^2 per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 3 hours every 12 hours for 2 doses on day 2, every 14 days (total dosage/cycle = 4000 mg/m^2)

Supportive Care

Glucocorticoid eye drops; for example, **dexamethasone sodium phosphate** 0.1% ophthalmic drops; administer 2 drops by instillation into both eyes every 6 hours starting just before cytarabine administration begins, and continuing for 2 days after the last dose of cytarabine

- Steroid eye drops are given to prevent and mitigate conjunctivitis associated with cytarabine excretion in tears

Antiemetic prophylaxis

Emetogenic potential on day 1 is ***HIGH***

Emetogenic potential on day 2 is ***MODERATE–HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection starting 24 hours after the last dose of cytarabine, and continuing until WBC ≥2500/mm^3 for 3 consecutive days

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

	Complete Response	Partial Response	Treatment Failure
All patients	21%	67%	12%
Late relapse	26%	65%	9%
Early relapse	17%	76%	7%
Multiple relapse	23%	69%	8%
Progressive disease	12%	53%	35%

Note: Using the chi-square test for independence, remission status (relapsed HL vs. progressive HL) and stage at relapse (stages I/II vs. stages III/IV) were significant factors for response to DHAP

Treatment Modifications

Adverse Event	Dose Modification
ANC <2500/mm^3 or platelets <80,000/mm^3	Delay start of cycle 2 until ANC >2500/mm^3 and platelets >80,000/mm^3

Otherwise, no treatment modifications specified as part of this tumor-reducing program before autologous stem cell transplantation

Patient Population Studied

Phase II multicenter trial, 102 patients with refractory or relapsed HL; age range: 21–64 years. Eleven patients had received COPP/ABVD, ABVD, BEACOPP, or similar regimens as frontline chemotherapy

Definitions	
Primary progressive or refractory	Disease progression during first-line chemotherapy, or only transient response (CR or PR lasting ≤90 days) after induction treatment
Progressive disease	(a) ≥5% increase from nadir in the sum of the products of the greatest perpendicular diameters of any previously identified abnormal lymph node for partial responders or nonresponders; (b) appearance of any new lesion during or ≤90 days after the end of therapy
Relapsed HD	Complete disappearance of all detectable clinical and radiographic evidence of disease and disappearance of all disease-related symptoms if present before therapy for ≥3 months
Early relapse	CR lasting ≥3 months to 12 months
CR in late relapses	CR must last ≥12 months

Toxicity

Toxicity	Number of Courses = 201	
	WHO G3	WHO G4
Leukocytopenia*	50 (25%)	86 (43%)
Thrombocytopenia†	42 (21%)	97 (48%)‡
Anemia§	33 (16%)	1 (0.5%)
Mucositis	0 (0)	0 (0)
Infection‹	2 (1%)	0 (0)
Nausea/vomiting	49 (24%)	3 (2%)
Renal	0 (0)	0 (0)
Neurotoxicity	1 (0.5%)	0 (0)
Ototoxicity	2 (1%)	0 (0)

*Duration of WHO grade 3 leukocytopenia: median 1.1 days (range: 0–6 days)
†Mean number of platelet transfusions: 0.4 (range: 0–4) transfusions
‡Duration of WHO grade 4 thrombocytopenia: median 1.4 days (range: 0–11 days)
§Mean number of red blood cell units transfused: 0.5 (range: 0–4) units
‹Days with fever ≥38°C (≥100.4°F): 0.3 days (range: 0–8 days); neither severe infections nor treatment-related deaths occurred

Therapy Monitoring

1. *Semiweekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam
3. *Response evaluation:* CT of all initially involved sites. Bone marrow biopsy if BM-involvement before start of therapy

Notes

1. Stem cell mobilization for autologous stem cell transplantation was performed after the first and, if necessary, the second cycle
2. High-dose chemotherapy and autologous stem cell transplantation was performed after 2 cycles, if patients achieved at least partial remission

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

IFOSFAMIDE + CARBOPLATIN + ETOPOSIDE (ICE)

Moskowitz CH et al. Blood 2001;97:616–623

Etoposide 100 mg/m² per day; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration within the range of 0.2–0.4 mg/mL, over 60 minutes for 3 consecutive days, on days 1–3, every 2 weeks (total dosage/cycle = 300 mg/m²)
Carboplatin (calculated dose) AUC = 5 mg/mL • min* (maximum absolute dose/cycle = 800 mg); administer intravenously in 100–500 mL 5% dextrose injection (D5W) or 0.9% NS over 15–30 minutes on day 2, every 2 weeks (total dosage/cycle calculated to produce an AUC = 5 mg/mL • min; maximum absolute dose/cycle = 800 mg)
Ifosfamide 5000 mg/m²; administer intravenously in 0.9% NS or D5W to a concentration within the range of 0.6–20 mg/mL, prepared as an admixture (in the same container) with **mesna** 5000 mg/m²; administer by continuous intravenous infusion over 24 hours on day 2, every 2 weeks (total dosage/cycle for ifosfamide = 5000 mg/m² and for mesna = 5000 mg/m²)

*Carboplatin dose is based on Calvert et al's formula to achieve a target area under the plasma concentration versus time curve (AUC) (AUC units = mg/mL • min)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. The FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on days 1 and 3 is ***LOW***
Emetogenic potential on day 2 is ***MODERATE–HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection on days 5–12 (except during peripheral blood progenitor cells mobilization)

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC <1000/mm³ or platelet count <50,000/mm³	Delay next cycle until ANC ≥1000/mm³ and platelet count ≥50,000/mm³

Patient Population Studied

Phase II single-center trial of 65 patients with relapsed or primary refractory HL after chemotherapy/combined modality therapy; age range: 12–59 years

Efficacy

	Percent of Patients Receiving ICE	Event-Free at a Median Follow-up of 43 Months
Complete response	26	82%*
Partial response	58	59%*
Minor response	3	
Progressive disease	12	Median survival = 5 months

*$P = 0.10$

(*continued*)

Accelerated fractionation involved field radiotherapy (IFRT):
- Of the 57 patients with chemosensitive disease, 41 received IFRT
- Administered to patients who had nodal sites of disease that measured ≥5 cm prior to the start of ICE chemotherapy or who had residual disease after receiving ICE chemotherapy
- IFRT started within 2 weeks after successful collection of stem cells
- IFRT dose was 18,000–36,000 cGy administered in ten to twenty 180-cGy fractions twice daily (minimal 7-hour interval between fractions) within a period of 5–10 days

Notes:
- Patients who underwent prior radiotherapy to a dose above standard tolerance for a specific site had reduced-dose IFRT or no radiotherapy

Toxicity

Toxicity	Number of Patients
Gram-negative sepsis and neutropenia	1
Pneumonitis and death from aspiration pneumonia and acute respiratory distress syndrome*,†	1
Marantic endocarditis with cerebral emboli and subsequent multisystem organ failure*,†	1
Upper airway bleeding from a tracheal tear that resolved spontaneously†	1
ICE administration delayed beyond planned 14-day interval	40 (62%)
Scheduling difficulty	21 (32%)
Thrombocytopenia	17 (26%)
Infection	2 (3%)
Median Dose Intensities	
Ifosfamide	2187 mg/m² per week (87.5%)
Carboplatin	AUC 2.187 mg/mL • min per week (87.5%)
Etoposide	43.5 mg/m² per week (87.5%)

*No evidence of HL at time of death
†Toxicity not thought to be caused by chemotherapy

Therapy Monitoring

1. *Semi-weekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam
3. *Response evaluation:* CT of all initially involved sites. Bone marrow biopsy if BM involvement before start of therapy

Notes

1. Stem cell mobilization for autologous stem cell transplantation was performed after the second cycle of ICE using filgrastim (10 mcg/kg per day) beginning on day 5, and continuing until the completion of leukapheresis. Leukapheresis was initiated when the white blood cell count was greater than 5000/mm³
2. Patients who achieved CR, PR, or a minor response received high-dose chemotherapy and autologous stem cell transplantation

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

IFOSFAMIDE + GEMCITABINE, + VINORELBINE (IGEV)

Santoro A et al. Haematologica 2007;92:35–41

Hyperhydration during ifosfamide:
Administer 2000 mL 0.9% sodium chloride injection (0.9% NS) per day by intravenous infusion concurrently with ifosfamide administration, for 4 consecutive days, on days 1–4, every 3 weeks

- If feasible, continue maintenance intravenous hydration during intervals between ifosfamide administration. Encourage oral fluid ingestion. Monitor daily weight, or if implemented in an inpatient setting, monitor fluid input and output. Replace electrolytes as medically appropriate

Ifosfamide 2000 mg/m^2 per day; administer intravenously, diluted in 0.9% NS or 5% dextrose injection (D5W) to a concentration within the range of 0.6–20 mg/mL, over 2 hours for 4 consecutive days, on days 1–4, every 3 weeks (total dosage/cycle = 8000 mg/m^2)
Mesna 2600 mg/m^2 per day; administer intravenously for 4 consecutive days, on days 1–4, every 3 weeks (total dosage/cycle = 10,400 mg/m^2)

- Mesna utilization strategies, include:

1. Mesna 2600 mg/m^2 per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or D5W over 12 hours starting simultaneously with ifosfamide
2. Mesna 650 mg/m^2 per dose; administer intravenously in 25–100 mL 0.9% NS or D5W over 15–30 minutes every 3 hours for 4 doses each day. The first dose is given when ifosfamide commences (ie, hours 0, 3, 6, and 9)
3. Mesna 650 mg/m^2; administer intravenously in 25–100 mL 0.9% NS or D5W over 15–30 minutes coincident with the start of ifosfamide administration (hour 0), then mesna 800 mg orally every 3–4 hours for an additional 3 doses (every 3 hours: at hours 3, 6, and 9; every 4 hours: at hours 4, 8, and 12; the regimen results in a different total mesna dose/cycle)

Gemcitabine 800 mg/m^2 per dose; administer intravenously, diluted in 0.9% NS to a concentration as low as 0.1 mg/mL over 30 minutes, for 2 doses on days 1 and 4, every 3 weeks (total dosage/cycle = 1600 mg/m^2), *followed by:*
Vinorelbine 20 mg/m^2; administer intravenously, diluted in 0.9% NS or D5W to a concentration between 1.5 and 3 mg/mL, over 6–10 minutes, on day 1, every 3 weeks (total dosage/cycle = 20 mg/m^2)
Prednisolone 100 mg/day; administer orally, or by intravenous injection or intravenous infusion over 10–30 minutes for 4 consecutive days, on days 1–4, every 3 weeks (total dose/cycle = 400 mg)

- Alternatively, give **prednisone** orally at the same dose and administration schedule, and for the same duration

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–4 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection on days 7–12, or until apheresis in the course of mobilization commences

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Treatment Modifications

None specified as part of this regimen often used as a preparative regimen

Patient Population Studied

Phase II multicenter trial; 91 patients with refractory or relapsed HL; age range: 17–59 years. Nodular sclerosis was the most frequent histologic subtype (74.7%). A high percentage of patients had B symptoms (59.3%), extranodal involvement (47.2%), more than 3 involved sites (45.1%), and/or bulky disease (45.1%)

Efficacy

Response	Proportion
CR	54%
PR	27%
PD	10%

Response Rate According to Disease Status

	CR	PR	IF
Refractory	33.3%	27.8%	38.9%
Relapse	67.3%	27.3%	5.4%

Response Rate According to Prior RT

Prior radiotherapy	60%	30.9%	9.1%
No prior radiotherapy	44.4%	22.2%	33.3%

CR, Complete response; PR, partial response; IF, induction failure

Notes:
- Stem cell mobilization was performed at various time points (66% after cycle 3)
- High-dose chemotherapy and autologous stem cell transplantation was performed after 4 IGEV cycles
- Overall, 64 of 74 (86%) patients in complete or partial remission after IGEV proceeded to single (29 cases) or tandem (35 cases) high-dose chemotherapy with PBSC support

Toxicity

Delayed cycles		4.2%
Cycles with dose reductions		8.6%
Cycles with infection		3.5%
Toxicity	**G3**	**G4**
Hematologic Toxicity		
Neutropenia	22.7%	5.7%
Thrombocytopenia	15.3%	4.8%
Anemia	16.6%	1.6%
Nonhematologic Toxicity		
Mucositis	1.9%	0.3%
Nausea	3.2%	0
Cystitis	0.3%	0

Therapy Monitoring

1. *Semi-weekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam
3. *Response evaluation:* CT of all initially involved sites. Bone marrow biopsy if BM involvement before start of therapy

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

GEMCITABINE + VINORELBINE, + DOXORUBICIN, LIPOSOMAL (GVD)

Bartlett NL et al. Ann Oncol 2007;18:1071–1079

Hypersensitivity prophylaxis:
Patients who experienced an acute infusion-related reaction to doxorubicin HCl liposome injection (liposomal doxorubicin), defined as flushing, shortness of breath, facial swelling, chills, back pain, or tightness in the chest or throat, should receive 30–60 minutes before all subsequent liposomal doxorubicin doses:

- **Diphenhydramine** 50 mg; administer by intravenous injection
- **Ranitidine** 150 mg (or another histamine subtype H_2 receptor antagonist); administer orally, or 50 mg by intravenous infusion
- **Hydrocortisone** 100 mg; administer by intravenous injection or intravenous infusion

For patients who had NOT received an autologous hematopoietic stem cell transplantation (ASCT):
Vinorelbine 20 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration between 1.5 and 3 mg/mL, over 6–10 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 40 mg/m²), *followed by:*
Gemcitabine 1000 mg/m² per dose; administer intravenously, diluted in 0.9% NS to a concentration as low as 0.1 mg/mL over 30 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 2000 mg/m²), *followed by:*
Doxorubicin HCl liposome injection 15 mg/m² per dose; administer intravenously in 250 mL D5W over 60 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 30 mg/m²)

For patients who previously received an ASCT:
Vinorelbine 15 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration between 1.5 and 3 mg/mL, over 6–10 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 30 mg/m²), *followed by:*
Gemcitabine 800 mg/m² per dose; administer intravenously, diluted in 0.9% NS to a concentration as low as 0.1 mg/mL, over 30 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 1600 mg/m²), *followed by:*
Doxorubicin HCl liposome injection 10 mg/m² per dose; administer intravenously in 250 mL D5W over 60 minutes, for 2 doses on days 1 and 8, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 20 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on Days 1 and 8 is MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated. Administer in case of febrile neutropenia after dose reduction
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Toxicity	Dose Modification
Episode of febrile neutropenia	Reduce each chemotherapy dose as follows during subsequent cycles: gemcitabine 800 mg/m², vinorelbine, 15 mg/m²; liposomal doxorubicin 10 mg/m²
Febrile neutropenia despite dose reduction	Reduce doses of gemcitabine and vinorelbine an additional 25% or add hematopoietic growth factor support
Febrile neutropenia despite a second dose reduction or after the addition of growth factor support	Discontinue chemotherapy
Platelet nadir <20,000/mm³	Reduce gemcitabine and vinorelbine doses by 25% during subsequent cycles
Day 1 ANC <1200/mm³ or platelet count <100,000/mm³	Delay start of next cycle until ANC ≥1200/mm³ and platelet count ≥100,000/mm³
Day 8 ANC 500–1199/mm³ or platelet count 75,000–99,000/mm³	Reduce day 8 gemcitabine and vinorelbine doses by 25%
Day 8 ANC <500/mm³ or platelet count <75,000/mm³	Delay day 8 therapy until ANC ≥500/mm³ and platelet count ≥75,000/mm³, then administer day 8 gemcitabine and vinorelbine doses at doses decreased by 25%
Left ventricular ejection fraction <45%	Seek an alternative therapy that does not include liposomal doxorubicin

Patient Population Studied

Phases I/II multicenter trial of 91 patients with refractory or relapsed HL, ages 19–83 years. Both transplant-naïve and patients who had undergone ASCT were enrolled. Patients had not been previously treated with gemcitabine, vinorelbine, or liposomal doxorubicin. This therapy was not considered for patients *in lieu* of SCT

Of 91 patients, 40 had previously undergone ASCT and relapsed. Among transplant-naïve patients (n = 51), 79% had received 1 prior regimen, 17% 2 prior regimens, and 4% 3 or more prior regimens. Seventy percent of previously transplanted patients received 3 or more prior regimens. Most patients had chemosensitive disease, among whom 84% (61/73 with available data) had responded to their most recent treatment, including 89% of patients in whom the prior transplant had failed. Eighty-seven percent of patients (67/77 with available data) had previously received ABVD

Efficacy

	No Prior ASCT	Prior ASCT
Complete response	20	18
Partial response	45	59
Stable disease	31	13
Progressive disease	2	0
Indeterminate	2	10

Toxicity

Grade 3–4 Toxic Effects at Maximum Tolerated Dose

	Transplant-Naïve (N = 43)		Prior Transplant (N = 37)	
Toxicity	G3	G4	G3	G4
Blood and Bone Marrow				
ANC	28%	35%	27%	24%
Leucocytes	28%	5%	13%	3%
Hemoglobin	14%	2%	16%	0
Platelets	12%	2%	40%	3%
Constitutional Symptoms				
Fatigue	5%	0	11%	0
Gastrointestinal				
Anorexia	5%	0	0	0
Nausea/vomiting	2%	0	3%	0
Stomatitis/pharyngitis	21%	2%	0	0
Infection and Febrile Neutropenia				
Infection without neutropenia	5%	0	3%	0
Febrile neutropenia	7%	0	8%	3%
Infection (documented clinically)	5%	0	5%	0
Infection with unknown ANC	0	0	3%	0
Pulmonary				
Dyspnea	7%	2%	11%	0
Summary				
Maximum toxicity	44%	40%	54%	27%

Note: Of patients with prior autologous stem cell transplantation, 1 of 37 died

Therapy Monitoring

1. *Semiweekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam
3. *Response evaluation:* Every 2 cycles, CT of all initially involved sites. Bone marrow biopsy if BM involvement before start of therapy

Notes

1. Patients with prior stem cell transplantation received reduced doses of chemotherapy from the outset (**gemcitabine** 800 mg/m^2 per dose; **vinorelbine** 15 mg/m^2 per dose; and **liposomal doxorubicin** 10 mg/m^2 per dose)
2. Of transplant-naïve patients, 80% received high-dose chemotherapy and autologous stem cell transplantation after completion of GVD
3. EFS rate for patients with additional ASCT after GVD is 53%, compared to 50% for patients who did not have a transplant

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

DEXAMETHASONE, CARMUSTINE (BCNU), ETOPOSIDE, CYTARABINE (Ara-C), MELPHALAN (Alkeran) (Dexa-BEAM)

Pfreundschuh MG. J Clin Oncol 1994;12:580–586

Dexamethasone 8 mg; administer orally every 8 hours for 10 consecutive days (30 doses) on days 1–10, every 28 days (total dose/cycle = 240 mg)
Carmustine 60 mg/m²; administer intravenously in 100–250 mL 5% dextrose injection (D5W) over at least 60 minutes on day 2, every 28 days (total dosage/cycle = 60 mg/m²)
Melphalan 20 mg/m²; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration ≤0.45 mg/mL, over 15–20 minutes on day 3, every 28 days (total dosage/cycle = 20 mg/m²)
Etoposide 75 mg/m² per day; administer intravenously, diluted in 0.9% NS or D5W to a concentration within the range 0.2–0.4 mg/mL, over 1 hour for 4 doses on days 4–7, every 28 days (total dosage/cycle = 300 mg/m²)
Cytarabine 100 mg/m² per dose; administer intravenously in 25–500 mL 0.9% NS or D5W over 2 hours every 12 hours for 8 doses on days 4–7, every 28 days (total dosage/cycle = 800 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on Day 2 is ***HIGH***
Emetogenic potential on Day 3 is ***MODERATE***
Emetogenic potential on Days 4–7 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, or
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for one dose
• Begin use 24–72 h after myelosuppressive chemotherapy is completed
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
• Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
• Antifungal—consider use during neutropenia and for anticipated mucositis
• Antiviral—antiherpes antivirals (eg, acyclovir)
See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** concurrent with steroid use to prevent gastritis and duodenitis

Patient Population Studied

A study of 55 patients with HL who had received prior therapy with COPP + ABVD or COPP + ABVD + IMEP. Forty-two patients had received radiation as well; 28 patients were at first relapse, 22 were on second salvage, and 5 patients had previously received 3 chemotherapy regimens

Efficacy (N = 54)

Response to Prior Therapy	% Complete Response	% Partial Response
Complete response; relapse >12 months (n = 12)	58	25
Complete response; relapse <12 months (n = 15)	27	33
Progressive disease (n = 27)	22	30
Total (N = 54)	31.5	29.6

Treatment Modifications

Adverse Event	Dose Modification
WBC <4000/mm³ or platelet count <125,000/mm³	Delay start of therapy 1 week, or reduce dosages of carmustine, melphalan, etoposide, and cytarabine by 20%

Toxicity (N = 54)*

Toxicity	% Patients/ Cycles
G3/4 granulocytopenia	92
G3/4 thrombocytopenia	87
Mucositis	21
G3/4 infection	10†
Nausea/vomiting	10
Cardiotoxicity	1.9
Psychosis	1.9
Death‡	7.5

*WHO Criteria
†Ten percent of cycles
‡Gram-negative sepsis during neutropenia

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* History and physical exam, CBC with differential, chest x-ray
3. *Response evaluation:* Clinical examination, CT of chest, abdomen, and pelvis. FDG-PET scan at conclusion of therapy to document extent of remission. Bone marrow biopsy (if disease existed before therapy) performed 1 cycle after clinical complete response

SALVAGE/INDUCTION REGIMEN HODGKIN LYMPHOMA

HIGH-DOSE IFOSFAMIDE, ETOPOSIDE AND EPIRUBICIN (IVE)

Proctor SJ et al. Ann Oncol 2003;14:i47–i50

Anticonvulsant prophylaxis:
Phenytoin 300 mg/day; administer orally for 6 consecutive days, from day −1 (1 day before chemotherapy begins) through day 5, every 21 days (total dose/cycle = 1800 mg)
Epirubicin 50 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days, for a maximum of 3 cycles (total dosage/cycle = 50 mg/m²)
Etoposide 200 mg/m² per day; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration within the range of 0.2–0.4 mg/mL, over 60 minutes for 3 consecutive days, days 1–3, every 21 days, for a maximum of 3 cycles (total dosage/cycle = 600 mg/m²)
Ifosfamide 3000 mg/m² per day; administer intravenously, diluted in 0.9% NS or 5% dextrose injection (D5W) to a concentration within the range 0.6 to 20 mg/mL, over 22 hours on 3 consecutive days, days 1–3, every 21 days for a maximum of 3 cycles (total dosage/cycle = 9000 mg/m²)
Mesna 1800 mg/m²; administer intravenously in 10–50 mL 0.9% NS or D5W over 15 minutes on day 1 just before starting ifosfamide administration, every 21 days, then:
Mesna 3000 mg/m² per day; administer intravenously, diluted in 25–1000 mL 0.9% NS or D5W over 22 hours, for 3 consecutive days, days 1–3, every 21 days, for a maximum of 3 cycles (total dosage/cycle = 9000 mg/m²), *followed on day 3 by*
Mesna 1636 mg/m²; administer intravenously in 50–1000 mL 0.9% NS or D5W over 12 hours on day 3, after ifosfamide administration is completed, every 21 days (total mesna dosage/cycle = 12,436 mg/m²)

- Mesna administered by prolonged infusion over 22 hours at the same time as ifosfamide may be prepared conveniently as an admixture (in the same container) with ifosfamide
- Proctor et al. did not identify the amount of mesna they gave after ifosfamide administration was completed. The amount of mesna identified for administration on day 3 after ifosfamide administration is completed is calculated from the amount of mesna given within a 12-hour interval during continuous ifosfamide administration over 22 hours

Note: Hematopoietic growth factor support is not routinely given as primary prophylaxis

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH***
Emetogenic potential on days 2 and 3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Patient Population Studied

Phase II multicenter trial, 51 patients with refractory or relapsed HL, ages 16–53 years. The majority of patients were treated following a first relapse. Disease histologies included lymphocyte predominant ($n = 4$), mixed cellularity ($n = 8$), and nodular sclerosing subtypes ($n = 39$)

Treatment Modifications

None specified as part of this regimen. Often used as a preparative regimen for hematopoietic stem cell transplantation

Efficacy

Response	Percent of Patients
Complete response	61
Partial response	22
SD or progression	16

Overall Survival According to Response to Prior Therapy

<PR to primary therapy	8 months
PR to primary therapy	24 months
CR to primary therapy; first relapse	Not reached
CR to primary therapy; second relapse	46 months
CR to primary therapy; second relapse	18 months

Toxicity

Toxicity	Frequency
G4 hematologic toxicity	100% of patients
G3 infections	10% of all courses
Neurotoxicity	2% of patients
Treatment-related deaths	0

Therapy Monitoring

1. *Semi-weekly and before each cycle:* CBC with differential
2. *Before each cycle:* Physical exam
3. *Response evaluation after 3 cycles:* CT scan, and bone marrow biopsy if BM-involvement before start of therapy

Notes

Often used as a preparative regimen; 61% of the patients proceeded to high-dose chemotherapy and autologous stem cell transplantation

HIGH DOSE/CONDITIONING REGIMEN (PRETRANSPLANTATION)

CARMUSTINE (BCNU) + ETOPOSIDE + CYTARABINE (Ara-C) + MELPHALAN (BEAM)

Schmitz N et al. Lancet 2002;359:2065–2071

Carmustine 300 mg/m²; administer intravenously in 100–500 mL 5% dextrose injection (D5W) over at least 60 minutes on day −7 (total dosage = 300 mg/m²)
Etoposide 150 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration within the range of 0.2–0.4 mg/mL, over 60 minutes every 12 hours for 4 consecutive days (8 doses) on days −7 to −4 (total dosage = 1200 mg/m²)
Cytarabine 200 mg/m² per dose; administer intravenously in 25–1000 mL 0.9% NS or D5W over 30 minutes every 12 hours for 4 consecutive days (8 doses) on days −7 to −4 (total dosage = 1600 mg/m²)
Melphalan 140 mg/m²; administer intravenously, diluted in 0.9% NS to a concentration ≤0.45 mg/mL, over 15–20 minutes on day −3 (total dosage = 140 mg/m²)

Note: Hematopoietic stem cell transplantation (**HSCT**) occurs on **day 0**. See notes at end of this regimen

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day −7 is ***HIGH***
Emetogenic potential on days −6, −5, and −4 is ***LOW***
Emetogenic potential on day −3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 10 mcg/kg per day by subcutaneous injection, *or*
Sargramostim (GM-CSF) 250 mcg/m² per day by subcutaneous injection
- Begin use on day 0 (after cryopreserved hematopoietic progenitor cells are administered, and continue until leukocyte counts recover)

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Treatment Modifications

None specified as part of this preparative regimen

Patient Population Studied

Phase III multicenter trial in patients with relapsed Hodgkin disease. Comparison of high-dose chemotherapy followed by transplantation of autologous hemopoietic stem cells (BEAM-HSCT) with conventional aggressive chemotherapy without stem cell transplantation (Dexa-BEAM). Included 61 patients with chemosensitive relapse after treatment for advanced stage HL; age range: 21–57 years; treated with BEAM

Toxicity (N = 51)

Toxicity	% WHO G3/4

Multiple relapses (N = 11)	34	70

FFTF, Freedom from treatment failure; OS, overall survival

Therapy Monitoring

Intensive in-hospital monitoring

Notes

1. Preparative regimen for HSCT
2. Patients assigned BEAM-HSCT underwent high-dose chemotherapy (2 cycles of Dexa-BEAM) followed by transplantation of either autologous bone marrow or peripheral-blood-progenitor cells
3. **BEAM** was started 4 weeks after white blood cell count returned to normal after 2 cycles of Dexa-BEAM
4. Cryopreserved bone-marrow or peripheral-blood progenitor cells were infused on day 0 followed by granulocyte-colony-stimulating factor until leucocyte recovery
5. Bone-marrow or progenitor cells were harvested after the first or second course of Dexa-BEAM. Only patients who had complete or partial remission after 2 courses of Dexa-BEAM continued treatment. These patients were considered "chemosensitive"
6. Involved-field radiotherapy was recommended for all patients with residual lesions judged to represent active Hodgkin disease

HIGH DOSE/CONDITIONING REGIMEN (PRETRANSPLANTATION)

CYCLOPHOSPHAMIDE, CARMUSTINE (BCNU), ETOPOSIDE (VP-16) (CBV)

Jagannath S et al. J Clin Oncol 1989;7:179–185

Note: Treatment days are enumerated with respect to autologous hematopoietic stem cell transplantation (HSCT), in which the autologous graft is readministered on day zero
Carmustine 300 mg/m²; administer intravenously in 100–500 mL 5% dextrose injection (D5W) over at least 60 minutes on day −6 (total dosage = 300 mg/m²)
Cyclophosphamide 1500 mg/m² per day; administer intravenously in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or D5W over 30–60 minutes for 4 consecutive days on days −6, −5, −4, and −3 (total dosage = 6000 mg/m²)
Etoposide 125 mg/m² per dose; administer intravenously, diluted in 0.9% NS to a concentration within the range 0.2–0.4 mg/mL, over 1 hour every 12 hours for 6 doses on days −6, −5, and −4 (total dosage = 750 mg/m²)
Autologous BMT/HSCT is administered on day zero

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Days −6, −5, −4, and −3 is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, or
Sargramostim (GM-CSF) 250 mcg/m² per day, by subcutaneous injection
• Begin use 24–72 h after myelosuppressive chemotherapy is completed (or transplant day 0)
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
• Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
• Antifungal—recommended
• Antiviral—Ganciclovir 5 mg/kg; administer intravenously every 12 hours for 10 consecutive days (adjust dose for renal insufficiency) on days 1–10 after transplantation
See Chapters 47 and 50 for more information

Patient Population Studied

A study of 61 patients with relapsed HL. Median age 28 years (range: 15–56 years). Median time from diagnosis to BMT 35 months (range: 6–11 months). Marrow stored an average of 1 month (range: 1–113 weeks) before transplantation. Zubrod performance status: 0 (n = 35), 1 (n = 18), 2 (n = 6), and 3 (n = 2). Disease staging: stage I (n = 5), stage II (n = 11), stage III (n = 6), and stage IV (n = 37), with 2 patients intensified in third complete response. Twenty-one patients had nodal disease only; 38 also had extranodal disease, including lung (n = 23), pleura (n = 7), bone (n = 5), and liver (n = 3)

Efficacy (N = 59)

	%	Median Survival
Complete response	46	>30 months
Partial response*	31	15 months
No response	23	2.7 months
All patients		30 months

*Six of 18 patients with partial response achieved complete response after radiation therapy to local sites

Treatment Modifications

None specified as part of this preparative regimen

Toxicity (N = 61)

	% of Patients
Nausea/vomiting	89
Severe mucositis	27
Hematuria	13.1
Seizures	3.3
Congestive heart failure	1.6
Febrile neutropenia	>90
Death*	6.6
Median time to ANC >500/mm³	22 days
Median time to platelets >50,000/mm³	26 days

*Candidemia in 2 patients; pulmonary fibrosis in 2 patients; all had received a cumulative etoposide dosage of 900 mg/m²

Therapy Monitoring

Intensive in-hospital monitoring. See Chapter 50, *Complications and Follow-up After Hematopoietic Stem Cell Transplantation*, for additional information

PALLIATIVE REGIMEN RELAPSED OR REFRACTORY HODGKIN LYMPHOMA

BRENTUXIMAB VEDOTIN

Younes A et al. J Clin Oncol 2012;30:2183–2189

Brentuximab vedotin 1.8 mg/kg (maximum dose = 180 mg); administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a concentration with the range 0.4–1.8 mg/mL (minimum volume, 100 mL) over 30 minutes on day 1, every 3 weeks for up to 16 doses (total dosage/cycle = 1.8 mg/kg; maximum dose/cycle = 180 mg)

Notes:

- The dose for patients whose body weight is >100 kg should be calculated based on a weight of 100 kg (maximum single dose = 180 mg)
- The recommended starting dose in patients with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s]) is 1.2 mg/kg intravenously over 30 minutes every 3 weeks
- The recommended starting dose in patients with hepatic impairment is 1.2 mg/kg intravenously over 30 minutes every 3 weeks
- Do not administer brentuximab vedotin as an intravenous injection or more rapidly than over 30 minutes

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm^3 on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Treatment Modification

Adverse Event	Dose Modification
New or worsening G2/3 peripheral neuropathy	Hold brentuximab vedotin until neuropathy improves to G <1 or baseline, and then, restart at 1.2 mg/kg
G4 peripheral neuropathy	Discontinue brentuximab vedotin
G3/4 neutropenia	Hold brentuximab vedotin until neutropenia improves to G ≤2 or baseline. Consider filgrastim support
Recurrent G4 neutropenia despite the use of filgrastim (or another G-CSF)	Discontinue brentuximab vedotin or hold until neutropenia resolves, and then, restart at 1.2 mg/kg

Patient Population Studied

Patients with relapsed or refractory HL after high-dose chemotherapy and auto-SCT with histologically documented CD30-positive Hodgkin Reed-Sternberg cells. Patients could not have previously received allogeneic stem-cell transplantation (SCT)

Demographics and Baseline Clinical Characteristics

Demographic or Clinical Characteristic	Patients	
	Number	Percent
Age, median (range)	31 years (15–77 years)

PALLIATIVE REGIMEN HODGKIN LYMPHOMA

GEMCITABINE

Venkatesh H et al. Clin Lymphoma 2004;5:110–115

Gemcitabine 1000 mg/m^2 per dose; administer intravenously, diluted with 0.9% sodium chloride injection to a concentration as low as 0.1 mg/mL, over 30 minutes for 2 doses on days 1 and 8, every 3 weeks (total dosage/cycle = 2000 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Day 1 is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (N = 27)

Complete response	0%
Partial response	22%
Median duration of partial response	5.1 months (range: 2.3–19.3 months)

Toxicity (N = 27)

Toxicity	% G3	% G4
Hematologic (1000 mg/m^2; N = 19)

Treatment Modifications

Adverse Event	Dose Modification
WBC <3500/mm^3, ANC <1500/mm^3, or platelet count <100,000/mm^3	Delay treatment until WBC >3500/mm^3, ANC >1500/mm^3, and platelet count >100,000/mm^3

Patient Population Studied

A study of 29 patients with relapsed HL. All patients had received at least 2 (range: 2–7) prior regimens for HL; 62% experienced a relapse after autologous BMT. Performance status among patients Eastern Cooperative Oncology Group (ECOG) was 0 (41.4%), 1 (48.3%), and 2 (10.3%)

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 2–3 cycles:* History and physical exam, chest x-ray
3. *Response evaluation:* Every 3 cycles, CT of chest, abdomen, and pelvis. FDG-PET scan at conclusion of therapy to document extent of remission

Notes

Gemcitabine has been increasingly used for the treatment of refractory or relapsed HL, either alone or in combination with other drugs such as cisplatin or dexamethasone. Gemcitabine doses usually range between 1000 and 1250 mg/m^2 given weekly 2 or 3 times per 21- or 28-day cycle

PALLIATIVE REGIMEN HODGKIN LYMPHOMA

VINORELBINE

Devizzi L et al. Ann Oncol 1994;5:817–820

Vinorelbine 30 mg/m^2 per dose; administer intravenously, diluted in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a solution with a concentration within the range 1.5–3 mg/mL, over 6–10 minutes every week for 4 consecutive weeks (total dosage/cycle = 120 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Day 1 is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 24 patients who had received at least 2 (range: 2–7) prior regimens for HL, consisting of MOPP and ABVD given sequentially or in alternation, followed by various salvage regimens, including autologous BMT in 4 cases. All patients had been previously treated with at least 2 vinca alkaloids. Fifteen patients had undergone extensive radiation therapy

Efficacy (N = 22)

*NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Treatment Modifications

Adverse Event	Dose Modification
WBC <3500/mm^3, ANC <1500/mm^3, or platelet count <100,000/mm^3	Delay treatment until WBC >3500/mm^3, ANC >1500/mm^3, and platelet count >100,000/mm^3

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 4 weeks:* Physical exam, chest x-ray
3. *Response evaluation:* Every 4–8 courses, CT of chest, abdomen, and pelvis. FDG-PET scan at conclusion of therapy to document extent of remission. Bone marrow biopsy (if disease existed before therapy) performed 1 cycle after clinical complete response

PALLIATIVE REGIMEN RELAPSED OR REFRACTORY HODGKIN LYMPHOMA

BENDAMUSTINE HCl

Moskowitz AJ et al. J Clin Oncol 2012;31:456–460

Bendamustine HCl 120 mg/m² per dose; administer intravenously in a volume of 0.9% sodium chloride injection sufficient to produce a concentration with the range 0.2–0.6 mg/mL over 60 minutes, on 2 consecutive days, days 1 and 2, every 28 days for a total of 6 cycles (total dosage/cycle = 240 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

Note: Growth factor support with pegfilgrastim or filgrastim was administered with each cycle of treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Patient Population Studied

Patients with biopsy-confirmed relapsed/refractory classical Hodgkin lymphoma (HL) were eligible. Failure of ASCT or ineligibility for ASCT was required. Previous alloSCT was allowed if relapse was >6 months after transplantation

Patient Demographic and Clinical Characteristics (N = 36)

Treatment Modification

Adverse Event	Treatment Modification
ANC <1000/mm³ and/or platelet count <75,000/mm³ on day 1 of a cycle	Hold bendamustine until ANC ≥1000/mm³ and platelet count ≥75,000/mm³. If start is delayed by >5 days, reduce the bendamustine dosage to 90–100 mg/m²
ANC <1,000/mm³ and/or platelet count <75,000/mm³ on day 1 of a cycle after bendamustine 90–100 mg/m² in previous cycle	Hold bendamustine until ANC ≥1000/mm³ and platelet count ≥75,000/mm³. If start is delayed by >5 days reduce the bendamustine dose to 60–70 mg/m²
ANC <1000/mm³ and/or platelet count <75,000/mm³ on day 1 of a cycle that does not resolve within 21 days	Discontinue bendamustine
Clinically significant G ≥2 nonhematologic toxicity	Hold bendamustine until nonhematologic toxicity has recovered to G ≤1. If toxicity was G ≥3 reduce the bendamustine dose to 90–100 mg/m² in subsequent cycles
Clinically significant G ≥2 nonhematologic toxicity after bendamustine 90–100 mg/m² in previous cycle	Hold bendamustine until nonhematologic toxicity has recovered to G ≤1. If toxicity was G ≥3, reduce the bendamustine dose to 60–70 mg/m² in subsequent cycles

Treatment Monitoring

1. *Baseline assessment:* Computed tomography of the chest, abdomen, and pelvis, [^{18}F] fluorodeoxyglucose–positron emission tomography (FDG-PET) scan, and bone marrow biopsy within 28 days before beginning treatment
2. *Twice weekly and before each cycle:* CBC with differential
3. *Before each cycle:* Physical exam, chest x-ray
4. *Response evaluation:* CT of chest, abdomen, and pelvis every 2 cycles starting after cycle 4. FDG-PET scan at conclusion of therapy to document extent of remission
5. Bone marrow biopsy to document response (if disease existed before therapy)

24. Lymphoma, Non-Hodgkin

Carla Casulo, MD, Julia Schaefer-Cutillo, MD, Jonathan W. Friedberg, MD, MMSc and Richard Fisher, MD

Epidemiology

Incidence: 70,800 (male: 38,270; female: 32,530. Estimated new cases for 2014 in the United States)
23.9 per 100,000 male, 16.4 per 100,000 female
Deaths: Estimated 18,990 in 2014
(male: 10,470; female: 8,520)
Median age: 66 years
Male to female ratio: 1.5 to 1.6 for all lymphoid neoplasms

Work-up

1. Immunophenotyping
2. Cytogenetics for CLL/SLL and Burkitt lymphoma
3. PET scan
   Aggressive histology
   - PET scan recommended before and after treatment, mid cycle only appropriate in clinical trial setting
   - Also indicated for relapsed indolent disease when suspect aggressive transformation

Seam P et al. Blood 2007;110:3507–3516

CNS lymphomas (non–HIV-related; additional staging work-up recommended)
1. Slit-lamp exam by ophthalmologist
2. HIV testing
3. Lumbar puncture
4. Brain and spine MRI
5. Testicular exam in men

Staging

Ann Arbor Staging Classification for Hodgkin and Non-Hodgkin Lymphomas

Stage	Description
I	Involvement of a single lymph node region (I) or involvement of a single extralymphatic organ or site (IE)
II	Involvement of ≥2 lymph node regions or lymphatic structures on the same side of the diaphragm alone (II) or with involvement of limited, contiguous extralymphatic organ or tissue (IIE)
III	Involvement of lymph node regions on both sides of the diaphragm (III), which may include the spleen (IIIS) or limited, contiguous extralymphatic organ or site (IIIE) or both (IIIES)
IV	Diffuse or disseminated foci of involvement of one or more extralymphatic organs or tissues, with or without associated lymphatic involvement

(continued)

Pathology (WHO 2008) (*continued*)

- Lymphoplasmacytic lymphoma/Waldenström's macroglobulinemia
- Heavy-chain disease
- Plasma cell myeloma
- Solitary plasmacytoma of bone
- Extraosseous plasmacytoma
- Extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT) type
- Nodal marginal zone lymphoma
- Follicular lymphoma
- Primary cutaneous follicular lymphoma
- Mantle cell lymphoma
- Diffuse large B-cell lymphoma, NOS
  - T-cell/histiocyte-rich large B-cell lymphoma
  - EBV+ DLBCL of the elderly
  - Diffuse large B-cell lymphoma associated with chronic inflammation
  - Lymphomatoid granulomatosis
- Primary CNS type
- Primary leg skin type
- Primary mediastinal large B-cell lymphoma
- Intravascular large B-cell lymphoma
- ALK+ large B-cell lymphoma
- Plasmablastic lymphoma
- Large B-cell lymphoma associated with HHV8+ Castleman disease
- Primary effusion lymphoma
- Burkitt lymphoma
- B-cell lymphoma, unclassifiable, Burkitt-like
- B-cell lymphoma, unclassifiable, Hodgkin lymphoma-like

Mature T-Cell and NK-Cell Neoplasms

- T-cell prolymphocytic leukemia
- T-cell large granular lymphocytic leukemia
- Chronic lymphoproliferative disorder of NK-cells
- Aggressive NK-cell leukemia
- Systemic EBV+ T-cell lymphoproliferative disorder of childhood
- Hydroa vacciniforme-like lymphoma
- Adult T-cell lymphoma/leukemia
- Extranodal T-cell/NK-cell lymphoma, nasal type
- Enteropathy-associated T-cell lymphoma
- Hepatosplenic T-cell lymphoma
- Subcutaneous panniculitis-like T-cell lymphoma
- Mycosis fungoides
- Sézary syndrome
- Primary cutaneous CD30+ T-cell lymphoproliferative disorder
- Primary cutaneous gamma-delta T-cell lymphoma
- Peripheral T-cell lymphoma, NOS
- Angioimmunoblastic T-cell lymphoma
- Anaplastic large cell lymphoma, ALK+ type
- Anaplastic large cell lymphoma, ALK− type

Swerdlow SH, Campo E, Harris NL, Jaffe ES, Pileri SA, Stein H, Thiele J, Vardiman JW, eds. World Health Organization Classification of Tumours of Haematopoietic and Lymphoid Tissues. Lyon, France: IARC Press, 2008

Staging (*continued*)

Stage	Description
	Abbreviations
A	Asymptomatic
B	Unexplained persistent or recurrent fever with temperature higher than 38°C (100.4°F), or recurrent drenching night sweats within 1 month, or unexplained loss of >10% body weight within 6 months
E	Limited direct extension into extralymphatic organ from adjacent lymph node
X	Bulky disease (mediastinal tumor width > one-third of the transthoracic diameter at T5/6, or a tumor diameter >10 cm)

Moormeier JA et al. Semin Oncol 1990;17:43–50

5-Year Survival Rate

NHL Subtype	5-Year Survival Rates
Diffuse large B-cell lymphoma	Varies according to IPI and treatment
Follicular lymphoma	Varies according to FLIPI
Mantle cell lymphoma	≃30%

IPI, International Prognostic Index; FLIPI, Follicular Lymphoma International Prognostic Index

Fisher RI et al. Blood 1995;85:1075–1082

Expert Opinion

The choice of therapy requires consideration of many factors, including age, comorbid pathologies, and future therapies (eg, stem cell transplantation). Therefore, treatment selection should be individualized

Diffuse Large B-cell Lymphoma

First-line therapy

- Rituximab-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone)
- Dose-adjusted EPOCH-R (etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin, rituximab)
- R-CHOP-14

For elderly (over 80):

- RminiCHOP (cyclophosphamide, doxorubicin, vincristine, prednisone)
- R-CEOP (cyclophosphamide, etoposide, vincristine, prednisone)

(*continued*)

Expert Opinion (*continued*)

Second-line therapy
- RICE (rituximab, ifosfamide, carboplatin, etoposide)
- ESHAP (etoposide, methylprednisolone, cytarabine, cisplatin)
- Dose-adjusted EPOCH + rituximab
- DHAP (dexamethasone/high dose cytarabine/cisplatin)
- GDP (gemcitabine/dexamethasone/cisplatin)
- Autologous or allogeneic (experimental) hematopoietic progenitor cell transplantation for sensitive diseases
- Clinical trials, if available

Follicular Lymphoma

First-line therapy
- CVP (cyclophosphamide, vincristine, prednisone) ± rituximab
- Rituximab + CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone)
- Fludarabine ± rituximab
- Bendamustine + rituximab
- FND (fludarabine, mitoxantrone, dexamethasone) ± rituximab
- Alkylating agents (eg, chlorambucil or cyclophosphamide) ± prednisone ± rituximab
- Rituximab (selected circumstances)
- Maintenance/extended schedule rituximab

Second-line therapy
- Rituximab
- Treatments listed under *First-line therapy*
- Radioimmunotherapy
- Allogeneic hematopoietic progenitor cell transplantation (experimental)
- Clinical trials, if available

Small Lymphocytic Lymphoma

First-line therapy
- Fludarabine ± rituximab
- FC ± rituximab
- Alkylating agents (eg, chlorambucil or cyclophosphamide) ± prednisone ± rituximab
- CVP ± rituximab
- FCR (fludarabine, cyclophosphamide, and rituximab)
- Bendamustine + rituximab

Second-line therapy
- PC (pentostatin, cyclophosphamide) ± rituximab
- Treatments listed under *First-line therapy*
- Allogeneic hematopoietic progenitor cell transplantation (experimental)
- Ibrutinib

(*continued*)

Prognostic Indices

International Prognostic Index (IPI)

A predictive model for aggressive non-Hodgkin's lymphoma. The International Non-Hodgkin's Lymphoma Prognostic Factors Project. N Engl J Med 1993;329:987–994

The **International Prognostic Index (IPI)** is a clinical tool to aid in predicting the prognosis of patients with aggressive non-Hodgkin lymphoma. First developed in 1993, it replaced the Ann Arbor stage as a prognosis tool. The original report was a retrospective analysis performed on 2031 patients with aggressive non-Hodgkin lymphoma treated between 1982 and 1987. Patients of all ages were included; all had been treated with doxorubicin-based regimens, most commonly CHOP (Shipp et al. A predictive model for aggressive non-Hodgkin's lymphoma. The International Non-Hodgkin's Lymphoma Prognostic Factors Project. N Engl J Med 1993;329:987–994). Five patient characteristics emerged as significant. Although the IPI has been shown to be a useful clinical tool, it should be kept in mind that the studies on which it was based did not include rituximab. How this omission may impact the IPI in the era of rituximab and newer agents targeting CD20 is uncertain

One point is assigned for each of the following risk factors:
- Age greater than 60 years
- Stage III or IV disease
- Elevated serum LDH
- ECOG/Zubrod performance status of 2, 3, or 4
- More than 1 extranodal site

The sum of the points allotted correlates with the following risk groups:

Points	Risk Category	5-Year Survival
0–1 points	Low risk	73%
2 points	Low-intermediate risk	51%
3 points	High-intermediate risk	43%
4–5 points	High risk	26%

Age-Adjusted IPI

A simplified index can be used when comparing patients within an age group (ie 60 or younger, or over 60) and includes only 3 of the above risk factors

One point is assigned for each of the following risk factors:
- Stage III or IV disease
- Elevated serum LDH
- ECOG/Zubrod performance status of 2, 3, or 4

The sum of the points allotted correlates with the following risk groups:

Points	Risk Category	5-Year Survival
0 point	Low risk	83%
1 point	Low-intermediate risk	69%
2 points	High-intermediate risk	46%
3 points	High risk	32%

(*continued*)

Expert Opinion (*continued*)

Mantle Cell Lymphoma

First-line therapy

- Rituximab + CHOP
- Hyper-CVAD (cyclophosphamide, vincristine, doxorubicin, and dexamethasone, alternating with high-dose methotrexate and cytarabine) + rituximab
- Bendamustine + rituximab
- Consolidation with autologous stem cell transplant

Second-line therapy

- Treatments listed under *First-line therapy*
- FC (fludarabine + cyclophosphamide) ± rituximab
- PCR (pentostatin, cyclophosphamide, rituximab)
- Bortezomib
- Lenalidomide
- Ibrutinib
- Older patients – R-FC or R-CHOP
- Autologous or allogeneic hematopoietic progenitor cell transplantation (experimental)
- Lenalidomide
- Ibrutinib

T-Cell Lymphomas

First-line therapy

- CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone))
- CHEOP (cyclophosphamide, doxorubicin, etoposide, vincristine, prednisone)

Second-line therapy

- Romidepsin
- Pralatrexate

Burkitt's Lymphoma

- EPOCH-R
- Cyclophosphamide, vincristine (oncovin), doxorubicin, methotrexate (CODOX-M) + Ifosfamide, etoposide (VP-16), and cytarabine (ARA-C) (I-VAC)
- NHL-BFM 86 (Berlin-Frankfurt-Münster 86)
- Rituximab + hyperfractionated cyclophosphamide, vincristine, doxorubicin (adriamycin), and dexamethasone (R-hyper-CVAD)
- Methotrexate, cytarabine (ARA-C), cyclophosphamide, vincristine (oncovin), prednisone, and bleomycin (MACOP-B)

Prognostic Indices (*continued*)

Follicular Lymphoma International Prognostic Index (FLIPI)

Solal-Céligny et al. Blood 2004;104:1258–1265

Developed for the most common low-grade lymphoma, follicular lymphoma, following the success of the IPI. Five prognostic factors emerged

One point is assigned for each of the following adverse prognostic factors:

- Age greater than 60 years
- Stage III or IV disease
- Greater than 4 lymph node groups involved
- Serum hemoglobin less than 12 g/dL
- Elevated serum LDH

The sum of the points allotted correlates with the following risk groups:

Points	Risk Category	5-Year Survival	10-Year Survival
0–1 points	Low risk	91%	71%
2 points	Intermediate risk	78%	51%
3–5 points	High risk	53%	36%

Mantle Cell Lymphoma International Prognostic Index (MIPI)

Hoster et al. Blood 2008;111:558–565

A similar effort has led to a prognostic index predictive of outcome in advanced mantle cell lymphoma. Four prognostic factors emerged

The point values are assigned as follows:

0 point	• Age less than 50 years • ECOG performance status of 0–1 • LDH less than 0.67 of the upper limit of normal • WBC of less than 6700 cells/mcl
1 point	• Age 50–59 • LDH 0.67–0.99 of the upper limit of normal • WBC 6700 to 9999 cells/mcl
2 points	• Age 60–69 • ECOG performance status of 2–4 • LDH 1–1.49 times the upper limit of normal • WBC 10,000–14,000 cells/mcl
3 points	• Age 70 or greater • LDH 1.5 times the upper limit of normal or greater • WBC of 15,000 cells/mcl or greater

The sum of the allotted points correlates with the following risk groups:

Points	Risk Category	Median Survival
0–3 points	Low risk	Not yet reached
4–5 points	Intermediate risk	51 months
6–11 points	High risk	29 months

REGIMEN

CYCLOPHOSPHAMIDE, DOXORUBICIN (HYDROXYLDAUNORUBICIN), VINCRISTINE (ONCOVIN), PREDNISONE (CHOP) + RITUXIMAB

Coiffier B et al. N Engl J Med 2002;346:235–242

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab
Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, on day 1, every 21 days (total dosage/cycle = 375 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration after adverse events abate

Intravenous hydration before and after cyclophosphamide administration:
500–1000 mL 0.9% NS

Cyclophosphamide 750 mg/m^2; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes, given on day 1, every 3 weeks (total dosage/cycle = 750 mg/m^2)
Doxorubicin 50 mg/m^2; administer by intravenous injection over 3–5 minutes, given on day 1, every 3 weeks (total dosage/cycle = 50 mg/m^2)
Vincristine 1.4 mg/m^2 (maximum dose = 2 mg); administer by intravenous injection over 1–2 minutes, given on day 1, every 3 weeks (total dosage/cycle = 1.4 mg/m^2; maximum dose/cycle = 2 mg)
Prednisone 40 mg/m^2 per day; administer orally for 5 consecutive days, days 1–5 every 3 weeks (total dosage/cycle = 200 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATELY HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Treatment Modifications

Adverse Event	Dose Modification
G4 ANC or febrile neutropenia after any cycle of chemotherapy	Filgrastim prophylaxis after chemotherapy during subsequent cycles*
G4 ANC during a cycle in which filgrastim was administered	Reduce cyclophosphamide and doxorubicin dosages 50% during subsequent cycles
G3/4 thrombocytopenia	
ANC <1500/mm^3 or platelet count <100,000/mm^3 on first day of a repeated cycle	Delay cycle for up to 2 weeks. Stop treatment if recovery has not occurred after a 2-week delay

*Filgrastim 5 mcg/kg per day; administer subcutaneously, starting on day 2 and continuing beyond ANC nadir until ANC exceeds 5000/mm^3 on 1 reading

Rituximab Infusion-Related Toxicities

Onset of infusion-related events (fevers, chills, rigors edema, congestion of the head and neck mucosa, hypotension):
1. Interrupt rituximab infusion
2. For fever, chills: Give additional dose of acetaminophen 650 mg orally and diphenhydramine 25–50 mg by intravenous injection
3. For rigors: Give meperidine 12.5–25 mg by intravenous injection ± promethazine 12.5–25 mg by intravenous infusion in at least 10 mL 0.9% NS or D5W over 5–15 minutes. If after 15–20 minutes the response to a single dose is considered inadequate, the dose may be repeated
4. After symptoms resolve, resume rituximab infusion at 50 mg/hour and increase by 50 mg/hour every 30 minutes, as tolerated, up to a maximum rate of 200 mg/hour

Dyspnea or wheezing, without allergic findings (urticaria, or tongue or laryngeal edema):
1. Interrupt rituximab infusion immediately
2. Give hydrocortisone 100 mg by intravenous injection (or glucocorticoid equivalent)
3. Give a histamine H_2-antagonist (ranitidine 150 mg, cimetidine 300 mg, or famotidine 20 mg) by intravenous injection
4. After symptoms resolve, resume rituximab infusion at 25 mg/hour with close monitoring. Do not increase rate

Note: Medications for the treatment of hypersensitivity reactions should be available for immediate use in the event of a reaction during administration (eg, intravenous fluids, epinephrine, antihistamines, glucocorticoids, and O_2)

Patient Population Studied

Previously untreated patients with diffuse large B-cell lymphoma 60–80 years of age were randomly assigned to receive 8 cycles of CHOP every 3 weeks (197 patients) or 8 cycles of CHOP plus rituximab given on the first day of each cycle (202 patients). Patients who were serologically positive for HIV and patients with active hepatitis B infection were excluded

Efficacy

	CHOP	RCHOP	
CR and CRu	63%	75%	$p = 0.005$
PR and SD	6%	8%	
PD during treatment	22%	9.5%	
Death during treatment	6%	6%	
Median OS	3.1 years	Not reached	
5-Year PFS	30%	54%	
5-Year PFS in low aaIPI* risk	34%	69%	$p = 0.00013$
5-Year PFS in high aaIPI* risk	29%	47%	$p = 0.00078$
5-Year DFS	45%	66%	
5-Year OS	45%	58%	
5-Year OS in low aaIPI* risk	62%	80%	$p = 0.023$
5-Year OS in high aaIPI* risk	39%	48%	$p = 0.062$

*Age-adjusted International Prognostic Index

Feugier P et al. J Clin Oncol 2005;23:4117–4126

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* LFTs, serum BUN, creatinine, PE

REGIMEN

DOSE-ADJUSTED ETOPOSIDE, PREDNISONE, VINCRISTINE (ONCOVIN), CYCLOPHOSPHAMIDE, AND DOXORUBICIN (HYDROXYLDAUNORUBICIN) WITH RITUXIMAB (DA-EPOCH WITH RITUXIMAB)

Wilson et al. Haematologica 2012;97(5):758–765

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab
Rituximab 375 mg/m²; administer intravenously diluted to a concentration of 1–4 mg/mL in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) on day 1, every 21 days (total dosage/cycle = 375 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration after adverse events abate

Etoposide 50 mg/m² per day; administer by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, every 21 days (total dosage/cycle = 200 mg/m²)
Doxorubicin 10 mg/m² per day; administer by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, every 21 days (total dosage/cycle = 40 mg/m²)
Vincristine 0.4 mg/m² per day; administer by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, every 21 days (total dosage/cycle = 1.6 mg/m²)

Intravenous hydration before and after cyclophosphamide administration:

Cyclophosphamide Dosage	Volume of 0.9% NS Before and After Dosage
≤900 mg/m²	500 mL
1080–1555 mg/m²	1000 mL
≥1866 mg/m²	1250 mL

Cyclophosphamide 750 mg/m²; administer intravenously in 100 mL 0.9% NS or D5W over 15–30 minutes, given on day 5 after completing etoposide + doxorubicin + vincristine infusion, every 21 days (total dosage/cycle = 750 mg/m²)
Prednisone 60 mg/m² twice daily; administer orally for 5 consecutive days on days 1–5, every 21 days (total dosage/cycle = 600 mg/m²)
Filgrastim 5 mcg/kg per day; administer subcutaneously, starting on day 6 and continuing until ANC >5000/mm³

Notes:
- See instructions below for preparing a 3-in-1 admixture with etoposide, doxorubicin, and vincristine
- Etoposide + doxorubicin + vincristine admixtures are administered with an ambulatory (portable) infusion pump through a central venous access device
- Repeated cycles begin on day 22 if the ANC is ≥1000/mm³ and the platelet count is ≥100,000/mm³

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–4 is ***LOW***
Emetogenic potential on day 5 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

(*continued*)

Treatment Modifications

Events*	Dose Modification†
Previous cycle ANC nadir count ≥500/mm³	Increase etoposide, doxorubicin, and cyclophosphamide dosages by 20% greater than the dosages given during the previous cycle
Previous cycle ANC nadir <500/mm³ on 1 or 2 measurements	Give the same dosages as last cycle
Previous cycle ANC nadir <500/mm³ on at least 3 measurements	Reduce etoposide, doxorubicin, and cyclophosphamide dosages by 20% less than the dosages given during the previous cycle
Previous cycle platelet nadir <25,000/mm³ on 1 measurement	
Total bilirubin >4.0 mg/dL (>68.4 µmol/L)	Hold vincristine‡
Total bilirubin >3.0 mg/dL, but <4.0 mg/dL (>51.3 µmol/L but (<68.4 µmol/L)	Reduce vincristine dosage by 75%‡
Total bilirubin >1.5 mg/dL but <3.0 mg/dL (>25.6 µmol/L but <51.3 µmol/L)	Reduce vincristine dosage by 50%‡
G2 neuropathy	Reduce vincristine dosage by 25%‡
G3 neuropathy	Reduce vincristine dosage by 50%‡

*ANC and platelet nadir measurements are based on *twice-weekly* CBC with differential only
†Dosage adjustments *greater than the starting dose level* apply to etoposide, doxorubicin, and cyclophosphamide only. Dose adjustments *less than the starting dose level* apply to cyclophosphamide only
‡Vincristine dosage is increased to 100% if neuropathy resolves to G ≤1 or total bilirubin to <1.5 mg/dL (<25.6 µmol/L)

(*continued*)

(continued)

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, starting on day 4, and continue use until the ANC >5000/mm^3

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Give **stool softeners** and/or laxatives during and after infusional vincristine administration

Instructions for Preparing a 3-in-1 Admixture with Etoposide, Doxorubicin, and Vincristine

Dilute the 3 drugs in 0.9% NS as follows:

Total Dose of Etoposide	Volume of 0.9% NS
≤62 mg	250 mL
62.1–125 mg	500 mL
>125 mg	1000 mL

Etoposide (base) + doxorubicin + vincristine 3-in-1 admixtures:

Etoposide 50 mg/m^2, doxorubicin hydrochloride 10 mg/m^2, and vincristine sulfate 0.4 mg/m^2 admixtures diluted in 0.9% NS to produce a final etoposide concentration <250 mcg/mL in polyolefin-lined infusion bags were stable and compatible for 72 hours at 23°–25°C (73.4°–77°F), and at 31°–33°C (87.8°–91.4°F) when protected from exposure to light

Wolfe JL et al. Am J Health Syst Pharm 1999;56:985–989

Etoposide (PHOSphate) + doxorubicin + vincristine 3-in-1 admixtures:

Etoposide PHOSphate, doxorubicin hydrochloride, and vincristine sulfate admixtures diluted in 0.9% NS to produce a final etoposide concentration <250 mcg/mL in polyolefin-lined infusion bags were stable and compatible for up to 124 hours at 2°–6°C (35.6°–42.8°F) and 35°–40°C (95°–104°F) in the dark and in regular fluorescent light. In admixtures stored at 35°–40°C (95°–104°F) and exposed to light, the initial drug concentrations decreased slightly, but remained within acceptable concentrations

Yuan P et al. Am J Health Syst Pharm 2001;58:594–598

The 3-in-1 admixtures described above do not prevent microbial growth after exposure to bacterial and fungal contamination. With respect to product sterility, expiration dating should be determined by the aseptic techniques used in preparation and local and national guidelines

Efficacy*

CR/Cru	94%
CR/CRu; high-risk IPI (3–5 IPI factors)	82%
PFS	79% at 5 years
OS	80% at 5 years

*Five-year follow up of 72 patients with untreated de novo DLBCL who were at least 18 years of age and at stage II or higher. Radiation consolidation was not permitted

Wilson WH et al. J Clin Oncol 2008;26:2717–2724

Patient Population Studied

A study of 69 patients with newly diagnosed diffuse large B-cell lymphoma. All patients were serologically negative for HIV

Therapy Monitoring

1. *Twice weekly:* CBC with differential
2. *At the beginning of every cycle:* CBC with differential and LFTs

Treatment Modifications (*continued*)

Rituximab Infusion-Related Toxicities

Onset of infusion-related events (fevers, chills, rigors edema, congestion of the head and neck mucosa, hypotension):

1. Interrupt rituximab infusion
2. For fever, chills: Give additional dose of acetaminophen 650 mg orally and diphenhydramine 25–50 mg by intravenous injection
3. For rigors: Give meperidine 12.5–25 mg by intravenous injection ± promethazine 12.5–25 mg by intravenous infusion in at least 10 mL 0.9% NS or D5W over 5–15 minutes. If after 15–20 minutes the response to a single dose is considered inadequate, the dose may be repeated
4. After symptoms resolve, resume rituximab infusion at 50 mg/hour and increase by 50 mg/hour every 30 minutes, as tolerated, up to a maximum rate of 200 mg/hour

Dyspnea or wheezing, without allergic findings (urticaria, or tongue or laryngeal edema):

1. Interrupt rituximab infusion immediately
2. Give hydrocortisone 100 mg by intravenous injection (or glucocorticoid equivalent)
3. Give a histamine H_2-antagonist (ranitidine 150 mg, cimetidine 300 mg, or famotidine 20 mg) by intravenous injection
4. After symptoms resolve, resume rituximab infusion at 25 mg/hour with close monitoring. Do not increase rate

Note: Medications for the treatment of hypersensitivity reactions should be available for immediate use in the event of a reaction during administration (eg, intravenous fluids, epinephrine, antihistamines, glucocorticoids, and O_2)

Toxicity* 72 Patients/414 Cycles

ANC nadir ≥100/mm^3, ≤499/mm^3	38% of cycles
ANC <100/mm^3	24% of cycles
Platelet count <25,000/mm^3	9% of cycles
Hospitalization for fever with neutropenia	19% of cycles
G 3 gastrointestinal toxicities	5% of cycles
G 3 neurologic toxicities	5% of cycles
Deaths†	4.2% (3/72)

*Five-year follow up of 72 patients with untreated de novo DLBCL who were at least 18 years of age and at stage II or higher. Radiation consolidation was not permitted

†*Aspergillus fumigatus* infection; subdural hematoma after anticoagulation for a pulmonary embolus; and presumed sepsis

Wilson WH et al. J Clin Oncol 2008;26:2717–2724

REGIMEN

CYCLOPHOSPHAMIDE, DOXORUBICIN (HYDROXYDAUNORUBICIN), VINCRISTINE (ONCOVIN), PREDNISONE (CHOP) + RITUXIMAB EVERY 14 DAYS (R-CHOP-14)

Pfreundschuh M et al. Lancet Oncol 2008;9:105–116

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab
Rituximab 375 mg/m^2; administer by intravenous infusion in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, once every 2 weeks (total dosage: 2250 mg/m^2 for 6 cycles; 3000 mg/m^2 for 8 cycles)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Hydration: 500–1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously before and after cyclophosphamide administration
- May be administered concurrently or after completing rituximab

Cyclophosphamide 750 mg/m^2; administer intravenously in 25–250 mL 0.9% NS or 5% dextrose injection, over 10–30 minutes on day 1, every 14 days (total dosage/cycle = 750 mg/m^2)
Doxorubicin 50 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 14 days (total dosage/cycle = 50 mg/m^2)
Vincristine 2 mg; administer by intravenous injection over 1–2 minutes on day 1, every 14 days (total dosage/cycle = 2 mg)
Prednisone 100 mg/day; administer orally for 5 consecutive days, days 1–5, every 14 days (total dose/cycle = 500 mg)

Notes on administration of drug regimen:
- ***R-CHOP is repeated every 2 weeks for 6 or 8 cycles after WBC count >2500/mm^3 and platelet count >80,000/mm^3 are achieved***
- Patients with poor performance status are given ***Prephase Treatment*** before starting R-CHOP-14

  Vincristine 1 mg; administer by intravenous injection over 1–2 minutes, *plus*
  Prednisone 100 mg/day; administer orally for 7 days before starting R-CHOP-14

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, starting on day 4
- Obtain a CBC before starting filgrastim therapy, and monitor twice weekly during filgrastim use until the ANC has reached 10,000/mm^3 following the expected chemotherapy-induced neutrophil nadir

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Day 15 WBC count <2500/mm^3 or platelet count <80,000/mm^3	Hold start of next chemotherapy cycle until WBC count >2500/mm^3 and platelet count >80,000/mm^3

Patient Population Studied

A study of 1222 elderly patients (61–80 years of age) who had not received any prior therapy were randomly assigned to 6 or 8 cycles of CHOP-14 with or without rituximab. Median age was 68 years, approximately 50% had advanced stage disease, and 38% were classified as bulky. Excluded patients with HIV or other major comorbidities, WBC <2500/mm^3, platelet count <100,000/mm^3. Radiotherapy was planned to sites of initial bulky disease with or without extranodal involvement. The primary endpoint was event-free survival; secondary end points were response, progression during treatment, progression-free survival, overall survival, and frequency of toxic effects. Analyses were done by intention to treat

Therapy Monitoring

Prior to each cycle
1. CBC with differential
2. Serum chemistry with LFTs

(*continued*)

Steroid-associated gastritis
Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Note: Patients with initial bulky disease (defined as lymphoma masses or conglomerates with a diameter ≥7.5 cm) or extranodal involvement received radiotherapy (36 Gy) to these areas irrespective of the result of chemotherapy. However, the role of additional radiotherapy to treat bulky disease and sites of extranodal involvement in patients assigned to radiotherapy (54% of patients) is unclear and was not studied in this trial. Comparison to 150 elderly patients with a very similar risk profile treated with 6 cycles of R-CHOP-14 without radiotherapy in a subsequent phase II study suggests the effect of radiotherapy in these patients is marginal, if existing at all

Efficacy

	6 × CHOP-14 (n = 307)	8 × CHOP-14 (n = 305)	6 × R-CHOP-14 (n = 306)	8 × R-CHOP-14 (n = 304)

REGIMEN

Elderly Patients (Age >80 Years)

R-miniCHOP (RITUXIMAB + CYCLOPHOSPHAMIDE + DOXORUBICIN + VINCRISTINE [ONCOVIN] + PREDNISONE)

Peyrade F et al. Lancet Oncol 2011;12:460–468

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration of 1–4 mg/mL on day 1 every 3 weeks for a total of 6 cycles (total dosage/cycle = 375 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Hydration: 500–1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously before and after cyclophosphamide administration
- May be administered concurrently with rituximab or after completing administration

Cyclophosphamide 400 mg/m^2; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes on day 1 every 3 weeks for a total of 6 cycles (total dosage/cycle = 400 mg/m^2)
Doxorubicin 25 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1 every 3 weeks for a total of 6 cycles (total dosage/cycle = 25 mg/m^2)
Vincristine 1 mg; administer by intravenous injection over 1–2 minutes on day 1 every 3 weeks for a total of 6 cycles (total dose/cycle = 1 mg)
Prednisone 40 mg/m^2 per dose; administer orally for 5 consecutive days on days 1–5 every 3 weeks for a total of 6 cycles (total dosage/cycle = 200 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is HIGH. Potential for delayed emetic symptoms
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

(continued)

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Steroid-associated gastritis

Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Decreased bowel motility prophylaxis

Give **stool softeners** in a scheduled regimen, and **saline, osmotic, and lubricant laxatives**, as needed to prevent constipation associated with vincristine use. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed cause defecation

Treatment Modifications

Adverse Event	Treatment Modifications
Severe neutropenia (G3 lasting ≥7 days or G4) or fever + neutropenia	Do not adjust dosages. Administer filgrastim during subsequent cycles from days 6–13 (8 doses) or until ANC is ≥1000/mm^3
Any hematologic toxicity	Do not adjust dosages
On day 1 of a cycle, ANC <1000/mm^3 or platelet count <100,000/mm^3	Delay start of cycle until ANC ≥1000/mm^3 and platelet count ≥100,000/mm^3 with a maximum of 28 days between two consecutive cycles
ANC <1000/mm^3 or platelet count <100,000/mm^3 1 week (day 28) after day 1 of a cycle despite withholding chemotherapy	Discontinue therapy
G2 neurologic vincristine-related toxicity including sensory or motor polyneuritis, constipation, or visual or auditory changes	Discontinue vincristine

Treatment Monitoring

1. *Within 1 month before the first treatment cycle:* full history, physical examination, instrumental activities of daily living (IADL) scale, thoracic and abdominal computerized scans, electrocardiogram, and assessment of resting left ventricular ejection fraction by echocardiography or an isotopic method
2. *Laboratory assessments within 1 week before first chemotherapy:* lactate dehydrogenase, β_2-microglobulin, serum creatinine, serum transaminases, bilirubin, alkaline phosphatase, and C-reactive protein concentrations
3. *Tumor response assessment:* after 3 cycles and at the end of treatment
4. *Follow-up:* every 3 months for the first 2 years after treatment and every 6 months thereafter

Efficacy

Response at End of Treatment (N = 149)

	Number of Patients (%)
Complete response	59 (40%)
Unconfirmed complete response	34 (23%)
Partial response	16 (11%)
Stable disease	2 (1%)
Progression during treatment	8 (5%)
Death	27 (18%)
Not assessed	3 (2%)

Prognostic Factors for Overall Survival: Univariate Analyses

	2-Year Overall Survival	Hazard Ratio (95% CI)	Log-Rank *p* Value
Performance status ≥2	40.4% vs. 68.4%	2.9 (1.8–4.9)	<0.0001
Ann Arbor stages III–IV	55.9% vs. 68.5%	1.6 (0.8–2.9)	0.17
LDH concentration >618 U/L	54.4% vs. 67.6%	1.6 (0.9–2.9)	0.12
Age-adjusted IPI 2–3	50.4% vs. 74.7%	2.6 (1.4–4.9)	0.0024
Number of extranodal sites >1	45.1% vs. 67%	2.1 (1.3–3.6)	0.0033
Serum albumin ≤3.5 g/dL	40.5% vs. 80.4%	3.6 (1.9–6.6)	<0.0001
β_2-Microglobulin ≥3 mg/L	59.6% vs. 58%	1.1 (0.6–2.2)	0.69
Tumor mass >10 cm	30.3% vs. 65.1%	2.2 (1.2–3.8)	0.0071
IADL score <4	52.7% vs. 65.6%	1.8 (1.0–3.1)	0.0394

CI, confidence interval; IADL, instrumental activities of daily living; IPI, International Prognostic Index; LDH, lactate dehydrogenase
Note: IADL consisted of a simple questionnaire that included the following items: ability to use a telephone, shopping, medication use, and ability to handle finance. The sum score of all 4 items was calculated and patients were classified as being without limitation in the event of a full sum score (4) and with limitation in the event of a sum score less than 4

Prognostic Factors for Overall Survival: Multivariate Analyses

	Hazard Ratio (95% CI)	*p* Value
Age-adjusted IPI 2–3	1.4 (0.6–3.5)	0.46
Number of extranodal sites >1	1.2 (0.6–2.4)	0.59
Serum albumin ≤3.5 g/dL	3.2 (1.4–7.1)	0.0053

REGIMEN

Elderly Patients (Age >80 Years)

Mini-CEOP (CYCLOPHOSPHAMIDE + EPIRUBICIN + VINBLASTINE + PREDNISONE)

Merli et al. Leuk Lymphoma 2007;48:367–373

Hydration: 500–1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously before and after cyclophosphamide administration
Cyclophosphamide 750 mg/m²; administer intravenously in 25–250 mL 0.9% NS or 5% dextrose injection over 10–30 minutes on day 1 every 3 or 4 weeks, according to hematologic toxicity (total dosage/cycle = 750 mg/m²)
Epirubicin 50 mg/m²; administer by intravenous injection over 3–5 minutes on day 1 every 3 or 4 weeks, according to hematologic toxicity (total dosage/cycle = 50 mg/m²)
Vinblastine 5 mg/m²; administer by intravenous injection over 1–2 minutes on day 1 every 3 or 4 weeks, according to hematologic toxicity (total dosage/cycle = 5 mg/m²)
Prednisone 50 mg/m² per dose; administer orally for 5 consecutive days on days 1–5 every 3 or 4 weeks, according to hematologic toxicity (total dosage/cycle = 250 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is HIGH. Potential for delayed emetic symptoms
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Treatment Modifications

Adverse Event	Treatment Modifications
ANC ≥1000/mm³	Administer full doses of epirubicin and cyclophosphamide
ANC 500–999/mm³	Administer 2/3 doses of epirubicin and cyclophosphamide
Anemia or thrombocytopenia	No reduction in treatment intensity
On day 1 of a cycle, ANC <500/mm³	Delay start of cycle until ANC ≥1000/mm³ with a maximum of 28 days between two consecutive cycles.
ANC <500/mm³ 1 week (day 35) after day 1 of a cycle despite withholding chemotherapy	Discontinue therapy
G2 neurologic vinblastine-related toxicity including sensory or motor polyneuritis, constipation, or visual or auditory changes	Discontinue vinblastine

Toxicity

Adverse Event	Percentage of Patients (Number)
Treatment program stopped for toxicity	2% (2)
Toxic deaths	7% (9)
Grades 3/4 neutropenia	27%
Cardiac events	6%
Nausea and vomiting	5%
Severe infections	10%
Neurologic problems	4%

†Among eligible patients

REGIMEN

RITUXIMAB, IFOSFAMIDE, CARBOPLATIN, AND ETOPOSIDE (RICE)

Kewalramani T et al. Blood 2004;103:3684–3688

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

Induction phase:
Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, 48 hours before initiation of the first cycle, then every 2 weeks on day 1 of each cycle (total dosage/3 cycles = 1500 mg/m^2)

Notes on rituximab administration:
- An initiating dose was given 48 hours before the first cycle of RICE. Subsequently, rituximab was given on the first day of each cycle of RICE
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Note: ICE chemotherapy is administered on an inpatient basis beginning on day 3 of each cycle Cycles are administered at 2-week intervals such that the second and third cycles of RICE would begin on day 15 of the previous cycle

Etoposide 100 mg/m^2 per day; administer intravenously diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL, over 1 hour for 3 consecutive days, days 3–5, every 2 weeks (total dosage/cycle = 300 mg/m^2)
Carboplatin (calculated dose) AUC = 5 mg/mL · min* (maximum absolute dose/cycle = 800 mg); administer intravenously in 100–500 mL D5W or 0.9% NS over 15–30 minutes on day 4, every 2 weeks (total dosage/cycle calculated to produce an AUC = 5 mg/mL · min; maximum absolute dose/cycle = 800 mg)
Ifosfamide 5000 mg/m^2 with **mesna** 5000 mg/m^2; administer by continuous intravenous infusion diluted in 0.9% NS or D5W to an ifosfamide concentration within the range of 0.6–20 mg/mL over 24 hours on day 4, every 2 weeks (total ifosfamide and mesna dosages/cycle = 5000 mg/m^2)
- Ifosfamide and mesna may be combined in a single container, or may be administered separately

*Carboplatin dose is based on a formula developed by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC; AUC units = mg/mL · min)

$$\text{Total Carboplatin Dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 \pm \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

(*continued*)

Patient Population Studied

A study comparing 37 patients 18–72 years of age who had diffuse large B-cell lymphoma (DLBCL), according to the World Health Organization classification, that relapsed after, or was refractory to, a single standard anthracycline-based regimen, to historical control treated with ICE alone

Treatment Modifications

Adverse Event	Dose Modification
ANC <1000/mm^3 and platelet count <50,000/mm^3	Delay start of treatment until ANC is >1000/mm^3 and platelet count is >50,000/mm^3

Toxicity

G3/4 Toxicity	No. of Events
Neutropenia and fever	8
Infection	4
Cardiac ischemia	2
Venous thromboembolism	2
Hemorrhagic cystitis	2
Nausea/vomiting	2
Syncope	1
G3/4 neutropenia resulting in treatment delay	11
G3/4 thrombocytopenia resulting in treatment delay	14
G3/4 neutropenia and thrombocytopenia resulting in treatment delay	11

(*continued*)

Note: A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. The FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1, 3, and 5 is ***LOW***

Emetogenic potential on day 4 is ***MODERATE–HIGH. Potential for delayed symptoms***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection for 8 consecutive days, on days 5–12

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

Response Rates to RICE Compared with ICE Historical Controls

	Overall Response Rate (%)			Complete Response Rate (%)		
Patient Subgroup	R-ICE	ICE*	*p*-Value	R-ICE	ICE*	*p*-Value
All patients	78	71	0.53	53	27	0.01
Relapsed	96	79	0.07	65	34	0.01
Refractory	46	63	0.36	31	19	0.46
sAAIPI L/LI	79	86	0.47	53	39	0.42
sAAIPI H/HI	76	61	0.28	53	19	0.01

sAAIP, Second-line age-adjusted international prognostic index; L, low risk; LI, low–intermediate risk; HI, high–intermediate risk; H, high risk

*ICE historical control

Therapy Monitoring

Before each cycle: CBC with differential, serum BUN, and creatinine

Notes

1. Used for cytoreduction and stem cell mobilization in transplant-eligible patients. There were no dose reductions. Of 381 cycles, 66 were delayed because of hematologic toxicity
2. Four patients developed confusion that resolved without intervention. These patients were not retreated

REGIMEN

ETOPOSIDE, METHYLPREDNISOLONE (SOLU-MEDROL), CYTARABINE (ARA-C), CISPLATIN (ESHAP)

Sweetenham JW, Johnson PWM. [Comment] J Clin Oncol 1994;12:2766
Velasquez WS et al. J Clin Oncol 1994;12:1169–1176

Hydration:
≥1000 mL 0.9% sodium chloride injection (0.9% NS) + 25–50 g mannitol daily; administer intravenously, continuously throughout chemotherapy administration or longer if medically appropriate, every 21–28 days, for 6–8 cycles. Monitor and replace magnesium/electrolytes as needed
Cisplatin 25 mg/m² per day; administer by continuous intravenous infusion in 100 mL to >1000 mL 0.9% NS over 24 hours for 4 consecutive days on days 1–4, every 21–28 days, for 6–8 cycles (total dosage/cycle = 100 mg/m²)
Etoposide 40 mg/m² per day; administer intravenously, diluted in 0.9% NS to a concentration within the range 0.2–0.4 mg/mL over 1 hour for 4 consecutive days on days 1–4, every 21–28 days, for 6–8 cycles (total dosage/cycle = 160 mg/m²)
Methylprednisolone 250–500 mg per day; administer intravenously in 25–500 mL 0.9% NS over 15 minutes for 5 consecutive days on days 1–5, every 21–28 days, for 6–8 cycles (total dose/cycle = 1250–2500 mg)
Cytarabine 2000 mg/m²; administer intravenously in 25–1000 mL 0.9% NS or 5% dextrose injection over 2 hours on day 5, every 21–28 days, for 6–8 cycles (total dosage/cycle = 2000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–4 is ***HIGH***
Emetogenic potential on day 5 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
• Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
• Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
• Antifungal—consider use during neutropenia and for anticipated mucositis
• Antiviral—antiherpes antivirals (eg, acyclovir)
See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during methylprednisolone use to prevent gastritis and duodenitis

Patient Population Studied

A study of 122 patients with relapsed or refractory NHL

Efficacy (N = 122)

Complete response	37%
Partial response	27%
Overall response rate	64%

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, serum electrolytes, BUN, creatinine, and LFTs
2. *Daily on days of drug administration:* Serum electrolytes, magnesium, calcium, and phosphorus. Cardiac, pulmonary, and renal status should be carefully monitored during administration of fluids
3. *Weekly:* CBC with differential

Treatment Modifications

Adverse Event*	Dose Modification
Previous cycle ANC nadir ≤200/mm³	Reduce etoposide dosage by 20% and reduce cytarabine dosage by 50% during subsequent cycles
Previous cycle platelet count nadir ≤20,000/mm³	
Documented sepsis during previous cycles	
Nonhematologic adverse events G3/4 in previous cycles	
Serum creatinine 1.5–2.0 mg/dL (133–177 µmol/L) immediately prior to a cycle	Reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 µmol/L) immediately prior to a cycle	Reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL (>265 µmol/L) immediately before a cycle	Hold cisplatin

*For neutropenia consider Filgrastim 5 mcg/kg per day subcutaneously, starting on day 6 and continuing beyond ANC nadir until ANC exceeds 5000/mm³ on 1 reading

Toxicity (N = 122)

Median ANC nadir	500/mm³
Median platelet nadir	70,000/mm³
G1/2 nausea/vomiting	49%
G3 nausea/vomiting	6%
>2-Fold increase in creatinine from baseline measurement	
Reversible	18%
Permanent	4%
Fever and neutropenia	30%
Treatment-related death	5%

REGIMEN

DEXAMETHASONE, CYTARABINE (HIGH-DOSE ARA-C), AND CISPLATIN (DHAP)

Gisselbrecht C et al. J Clin Oncol 2010;28:4184–4190

Hydration:
0.9% sodium chloride injection (0.9% NS) + at a rate of 250 mL/hour for 36 hours; administer intravenously beginning at least 6 hours before starting cisplatin administration, every 3–4 weeks, for 6–10 cycles. Monitor and replace magnesium/electrolytes as needed
Cisplatin 100 mg/m^2; administer by continuous intravenous infusion over 24 hours in a volume equivalent to the dose, or diluted in 100 mL to ≥1000 mL 0.9% NS. Begin administration on day 1 after completing 6 hours of hydration, every 3–4 weeks, for 6–10 cycles (total dosage/cycle = 100 mg/m^2)
Cytarabine
Patients ≤ 70 years: **Cytarabine** 2000 mg/m^2 per dose; administer intravenously over 3 hours in 50–500 mL 0.9% NS or 5% dextrose injection (D5W) every 12 hours for 2 doses, starting after the completion of cisplatin administration on day 2, every 3–4 weeks, for 6–10 cycles (total dosage/cycle = 4000 mg/m^2)
Patients > 70 years: **Cytarabine** 1000 mg/m^2 per dose; administer intravenously over 3 hours in 50–500 mL 0.9% NS or D5W every 12 hours for 2 doses, starting after the completion of cisplatin administration on day 2, every 3–4 weeks, for 6–10 cycles (total dosage/cycle = 2000 mg/m^2)
Dexamethasone 40 mg/day; administer orally or intravenously in 10–100 mL 0.9% NS or D5W over 10–30 minutes for 4 consecutive days on days 1–4, every 3–4 weeks, for 6–10 cycles (total dosage/cycle = 160 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on day 2 is ***MODERATE–HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

Patient Population Studied

A study of 90 patients with recurrent or refractory NHL

Efficacy (N = 90)

Complete response	31%
Partial response	24%
Overall response rate	55%
2-Year survival	25%

Treatment Modifications

Adverse Event*	Dose Modification
ANC <200/mm^3 during any cycle	Reduce cytarabine dosage to 1000 mg/m^2 per dose; maintain cisplatin dosage at 100 mg/m^2
Platelet count <20,000/mm^3 during any cycle	
Sepsis associated with neutropenia during any cycle	Reduce cytarabine dosage to 500 mg/m^2 per dose; maintain cisplatin dosage at 100 mg/m^2
Serum creatinine increase to 1.5–2.0 mg/mL (133–177 µmol/L)	Reduce cisplatin dosage to 75 mg/m^2
Serum creatinine increase to 2.1–3.0 mg/mL (186–265 µmol/L)	Reduce cisplatin dosage to 50 mg/m^2

*For neutropenia consider Filgrastim 5 mcg/kg per day subcutaneously, starting on day 6 and continuing beyond ANC nadir until ANC exceeds 5000/mm^3 on 1 reading

Toxicity (N = 90)

	% of Patients
ANC nadir $<300/mm^3$	53
Platelet count nadir $<20{,}000/mm^3$	39
Gastrointestinal (severe)	20
Acute cerebellar syndrome	1
Acute tumor lysis syndrome	6
Early deaths	
Because of tumor lysis syndrome	3
Because of sepsis	2
Because of thromboembolism	1
Because of subdural hemorrhage	1
Reversible ↑ serum creatinine to >2 × baseline	16
Permanent ↑ serum creatinine to >2 × baseline	4
Chronic polyneuritis	4
Tinnitus	4
Severe hearing loss	3
Respiratory failure	6
Hospitalization for IV antibiotics	48
Documented sepsis	31
Death from complications of sepsis	11

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, serum electrolytes, BUN, creatinine, LFTs
2. *Daily on days of drug administration:* Serum electrolytes. Cardiac, pulmonary, and renal status are carefully monitored during administration of fluids
3. *Weekly:* CBC with differential

REGIMEN

GEMCITABINE + DEXAMETHASONE + CISPLATIN (GDP)

Crump et al. Cancer 2004;101:1835–1842
Crump et al. Clin Lymphoma 2005;6:56–60

Gemcitabine 1000 mg/m² per dose; administer intravenously in 0.9% sodium chloride injection (0.9% NS) to a concentration within the range 0.1–38 mg/mL over 30 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 2000 mg/m²)
Dexamethasone 40 mg/dose; administer orally in 2 or more divided doses for 4 consecutive days, on days 1–4, every 21 days (total dose/cycle = 160 mg)
Hydration before cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 1 hour before commencing cisplatin administration
(Optional) **Mannitol** 12.5–50 g; administer by intravenous injection or intravenous infusion over 5–60 minutes either before or concurrent with cisplatin administration
- Mannitol may be given to patients who have received adequate hydration. Continued hydration is essential to ensure diuresis
- Mannitol may be prepared as an admixture (in the same container) with cisplatin

Cisplatin 75 mg/m²; administer intravenously in 50–500 mL 0.9% NS over 60 minutes on day 1 every 21 days (total dosage/cycle = 75 mg/m²)
Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours on day 1. Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Notes:
- The initial dexamethasone dose may be administered intravenously before chemotherapy commences as part of antiemetic primary prophylaxis

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Emetogenic potential on day 8 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(continued)

Treatment Modifications

ANC <1000/mm³ or platelet count <100,000/mm³ on day 1 of a cycle	Delay start of next treatment cycle by 1 week or until ANC ≥1000/mm³ and platelet count ≥100,000/mm³
Day 8 ANC <500/mm³ or platelet count <50,000/mm³	Omit day 8 gemcitabine dose, or delay treatment 1 week and administer gemcitabine only if ANC ≥500/mm³ and platelet count ≥50,000/mm³
Day 8 ANC <500/mm³ with platelet count >50,000/mm³	Administer full dose of gemcitabine and begin therapy with filgrastim, or administer gemcitabine with a dose reduction of 25%
Day 8 platelet count 50,000–99,000/mm³ with ANC >500/mm³	Reduce day 8 gemcitabine dose by 25%
One dose delay or dosage attenuation for neutropenia	Administer filgrastim with subsequent treatment cycles to maintain dose intensity
One episode of febrile neutropenia	Administer filgrastim with subsequent treatment cycles

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial brand, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy (N = 51)

All Patients	
CR after 2 cycles of GDP	8 (16%)
PR after 2 cycles of GDP	17 (33%)
ORR after 2 cycles of GDP	25 (49%, 95% CI = 37–63%)
CR after completing all cycles of GDP	11 (22%)
PR after completing all cycles of GDP	16 (31%)
ORR after completing all cycles of GDP	27 (53%, 95% CI = 40–67%)
Patients >65 Years of Age not Usually Considered for High-dose Chemotherapy + ASCT	
Median time to progression	3.1 months (95% CI = 2.3–9.2)
Median overall survival	8.9 months (95% CI = 5.2–18.5)

CI, confidence interval; CR, complete response; GDP, gemcitabine + dexamethasone + cisplatin; ORR, overall response rate (CR + PR); PR, partial response

Patient Population Studied

Patients with diffuse large B-cell, large-cell immunoblastic, anaplastic large-cell (B-cell or null-cell type), primary mediastinal large B-cell, or T-cell–rich B-cell lymphoma with disease recurrence after or refractory to 1 previous anthracycline-containing chemotherapy regimen. Patients with a diagnosis of transformed or composite lymphoma were excluded

Treatment Monitoring

1. Before treatment
   - History and physical examination
   - CBC with differential, serum creatinine, AST, ALT, alkaline phosphatase, and serum bilirubin
2. During treatment
   - History and physical examination before each cycle
   - CBC with differential, serum creatinine, AST, ALT, alkaline phosphatase, and serum bilirubin on day 1 of each treatment cycle
   - CBC with differential on day 8
3. Reassessment of efficacy: CT scan or sonographic examination after 2 and 4 cycles and at the end of treatment

REGIMEN

CYCLOPHOSPHAMIDE, VINCRISTINE, AND PREDNISONE (CVP)

Bagley CM Jr et al. Ann Intern Med 1972;76:227–234
Flinn IW et al. Ann Oncol 2000;11:691–695

Cyclophosphamide 400 mg/m² per day; administer orally for 5 consecutive days on days 1–5, every 3 weeks, for at least 4 cycles, +2 additional cycles after complete response (total dosage/cycle = 2000 mg/m²)

or

Cyclophosphamide 1000 mg/m²; administer intravenously, as either undiluted cyclophosphamide (20 mg/mL) or diluted in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), over 15–60 minutes, given on day 1, every 3 weeks, for at least 4 cycles, +2 additional cycles after complete response (total dosage/cycle = 1000 mg/m²)
Vincristine 1.4 mg/m²; administer by intravenous injection over 1–2 minutes, given on day 1, every 3 weeks, for at least 4 cycles, +2 additional cycles after complete response (total dosage/cycle = 1.4 mg/m²)
Prednisone 100 mg/m² per day; administer orally for 5 consecutive days on days 1–5, every 3 weeks, for at least 4 cycles, +2 additional cycles after complete response (total dosage/cycle = 500 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–5 is ***MODERATE–HIGH****. Potential for delayed emetic symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Decreased bowel motility prophylaxis
Give **stool softeners** in a scheduled regimen, and **saline, osmotic, and lubricant laxatives,** as needed to prevent constipation for as long as vincristine use continues. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed to produce defecation

Treatment Modifications

At the start of a treatment cycle:

		% of Planned Dosages		
ANC	Platelet Count	C	V	P
>4000/mm³	≥100,000/mm³	100	100	100
3–4000/mm³	50–100,000/mm³	75	100	100
2–3000/mm³	50–100,000/mm³	50	100	100
1–2000/mm³	<50,000/mm³	25	50	100
0–1000/mm³	<50,000/mm³	0	0	0

C, cyclophosphamide; V, vincristine; P, prednisone
Note: Repeated cycles may be delayed for up to 1 week for incomplete hematologic recovery (ie, day 1 ANC must be >1000/mm³ from prior treatment)

Toxicity (N = 35)

Severe infections	14%
Mild cystitis without bleeding	8.6%

Hematologic Nadirs During 6 Consecutive Cycles

Cycle	WBC Count	Platelet Count
1	2400/mm³	220,000/mm³
2	2300/mm³	204,000/mm³
3	3100/mm³	192,000/mm³
4	2000/mm³	200,000/mm³
5	3200/mm³	224,000/mm³
6	2800/mm³	213,000/mm³

Therapy Monitoring

1. *Prior to each cycle:* PE, CBC, differential, LFTs, serum BUN, and creatinine
2. *Weekly:* CBC with differential and LFTs

Patient Population Studied

A study of 35 patients with advanced NHL, among whom 32 previously had not received antineoplastic therapy

Efficacy (N = 35)

Complete response	57%
Partial response	34%
Overall response rate	91%

REGIMEN

RITUXIMAB + CYCLOPHOSPHAMIDE, VINCRISTINE, AND PREDNISONE (R-CVP)

Marcus R et al. Blood 2005;105:1417–1423

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously 30–60 minutes before starting rituximab

Rituximab 375 mg/m²; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 375 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Cyclophosphamide 750 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W, over 10–30 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 750 mg/m²)
Vincristine 1.4 mg/m² (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes, on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 1.4 mg/m², maximum dose/cycle = 2 mg)
Prednisone 40 mg/m² per day; administer orally for 5 consecutive days, days 1–5, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 200 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

Adverse Event	CVP	R-CVP
At least 1 adverse event	95%	97%
Life-threatening events	—	3.1%
Adverse event within 24 hours after an infusion	51%	71%
G 3/4, rituximab infusion-related reaction	N/A	9%
G 3/4 neutropenia	14%	24%
Overall infection rate or incidence of neutropenia and sepsis	No difference	

Patient Population Studied

A study of 321 patients age 18 years or older with advanced stage untreated CD20+ follicular lymphoma who were randomized to RCVP or CVP for 8 cycles. All patients had stage III or IV disease, an Eastern Clinical Oncology Group (ECOG) performance status of 0–2, and a need for therapy in the opinion of the participating clinician. Median age was 52–53 years. Majority were grade 1 or 2 follicular lymphoma

Treatment Modification

ANC	Adverse Event: Platelet Count	Dose Modification: Percent of Planned Dosages C	V	P
>4000/mm³	≥100,000/mm³	100%	100%	100%
3000–4000/mm³	50,000–100,000/mm³	75%	100%	100%
2000–3000/mm³	50,000–100,000/mm³	50%	100%	100%
1000–2000/mm³	<50,000/mm³	25%	50%	100%
0–1000/mm³	<50,000/mm³	0	0	0
G2 neurotoxicity		Reduce vincristine dosage 50%		
G3/4 neurotoxicity		Discontinue vincristine		
Rituximab-induced infusion reaction		Interrupt therapy; resume rituximab and CVP once symptoms resolve		

C, cyclophosphamide; V, vincristine; P, prednisone
Note: Repeated cycles may be delayed for up to 1 week for incomplete hematologic recovery (ie, day 1 ANC must be >1000/mm³ from prior treatment)

Efficacy (Median Follow-up: 30 Months)

	CVP (N = 159)	R-CVP (N = 162)
Tumor Response*		
Complete response	8%	30%
Complete response, unconfirmed	3%	11%
Partial response	47%	40%
CR + CRu + PR	57%	81%
Stable disease	21%	7%
Progressive disease	20%	11%
Could not be assessed	3%	1%
Median time to progression*	15 months	32 months
Median time to treatment failure*	7 months	27 months
Median duration of response*	14 months	35 months
Median disease-free survival†	21 months	Not reached
Median time to new antilymphoma treatment or death	14 months	Not reached
KM estimates for overall survival at 30 months‡	85%	89%

CVP, Cyclophosphamide, vincristine, and prednisone; CR, complete response; CRu, complete response, unconfirmed; PR, partial response
*$P < 0.001$
†$P = 0.0009$
‡Not significant

Therapy Monitoring

1. *Prior to each cycle:* PE, CBC with differential, LFTs, serum BUN, and creatinine
2. *Weekly:* CBC with differential and LFTs

REGIMEN

FLUDARABINE

Solal-Céligny P et al. J Clin Oncol 1996;14:514–519

Prophylaxis against tumor lysis:
See also Chapter 39

Allopurinol 300 mg per day; administer orally for 9 consecutive days, beginning the day before fludarabine treatment starts. Repeat a course of prophylaxis during at least the first 2 treatment cycles and for additional cycles if judged clinically appropriate
Fludarabine 25 mg/m² per day; administer intravenously in 100–125 mL 0.9% sodium chloride injection or 5% dextrose injection over 30 minutes for 5 consecutive days on days 1–5, every 4 weeks, for up to 9 cycles (total dosage/cycle = 125 mg/m²)
Note: The maximum planned treatment duration is 9 cycles. Treatment is discontinued in the event of disease progression or after 6 cycles for patients who achieve a CR after 3 cycles and for those whose disease does not respond during the first 6 cycles

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–5 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 54 untreated patients with advanced follicular lymphoma. All patients were serologically negative for HIV

Efficacy (N = 49)

Overall response	65%
Complete response	37%
Partial response	28%

Toxicity* (N = 53 Patients; 336 Cycles)

Toxicity	% of Patients	% of Cycles
G ≥3 neutropenia	41	14.4
G ≥3 thrombocytopenia	5.7	1.2
	% of Patients	
G1 Infections	15	
G2 infections	9	
G ≥3 infections	0	
Neurologic toxicity	3.8	
Interstitial pneumonitis	1.9	
Hepatitis	1.9	

*WHO Criteria

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ or platelet count <100,000/mm³	Delay treatment until ANC is ≥500/mm³ and platelet count ≥100,000/mm³, then resume treatment but reduce fludarabine dosage to 20 mg/m² per day for 5 days
Treatment delay >2 weeks	Discontinue fludarabine treatment

Therapy Monitoring

Before each cycle: CBC with differential, LFTs, serum BUN, and creatinine

REGIMEN

FLUDARABINE + RITUXIMAB

Czuczman MS et al. J Clin Oncol 2005;23:694–704

Cycle 1 (duration 35 days)
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m² per dose; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration of 1–4 mg/mL for 2 doses on days 1 and 5 (total dosage/cycle = 750 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Fludarabine 25 mg/m² per dose; administer intravenously in 100–125 mL 0.9% NS or D5W over 30 minutes for 5 consecutive days, on days 8–12 during a 35-day cycle (total dosage/cycle = 125 mg/m²)

Note: Fludarabine administration commences 72 hours after the second dose of rituximab given during cycle 1

Cycles 2, 4, and 6
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m²; administer intravenously in 0.9% NS or D5W diluted to a concentration of 1–4 mg/mL, 3 days before commencing retreatment with fludarabine (total dosage/cycle = 375 mg/m²)

Cycles 2–6 (five 28-day cycles)
Fludarabine 25 mg/m² per dose; administer intravenously in 100–125 mL 0.9% NS or D5W over 30 minutes for 5 consecutive days, on days 1–5, every 28 days for 5 cycles (total dosage/cycle = 125 mg/m²)

Note: During cycles 2, 4, and 6, fludarabine administration begins 72 hours after rituximab doses are administered

Cycle 7 (after completing six 28-day cycles with fludarabine)
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m² per dose; administer intravenously diluted to a concentration of 1–4 mg/mL with 0.9% NS or D5W diluted to a concentration of 1–4 mg/mL for 2 doses on days 1 and 5 (total dosage/cycle = 750 mg/m²)

Supportive Care
Treatment support included transfusion of blood and blood products, antibiotics, antiemetics, and colony-stimulating factors (filgrastim or granulocyte macrophage colony-stimulating factor)

Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modifications
G3/4 neutropenia, G3/4 thrombocytopenia, or G3/4 anemia	Observe without treatment until these hematologic parameters recover to within 20% of the baseline value. Thereafter, if toxicity = G3, administer 75% of the original fludarabine dosage for subsequent cycles. If toxicity = G4, administer 50% of the original fludarabine dosage for subsequent cycles. If G ≥3 persists ≥3 consecutive weeks, discontinue therapy
Nonhematologic toxicities, including nausea, vomiting, fatigue, diarrhea, and drug-related fever or chills	Administer symptomatic treatment but do not reduce dosages
G ≥2 nonhematologic toxicities other than nausea, vomiting, fatigue, diarrhea, and drug-related fever or chills attributed to fludarabine	Hold fludarabine therapy until toxicity G <2, then reduce the fludarabine dosage by 50% in subsequent cycles. If after 3 weeks toxicity has not resolved to G ≤1, discontinue treatment
G2 irreversible nonhematologic toxicity and G3/4 nonhematologic toxicities	Evaluate to determine appropriateness of continuing the fludarabine therapy
Infection in the absence of G3/4 neutropenia	Observe without further CLL treatment until the infection resolves, but do not alter chemotherapy dosages
Major infection	Reduce fludarabine dosage to 20 mg/m² · d × 5 days. If further dose reduction is needed, reduce the fludarabine dosage to 15 mg/m² · d × 5 days. Rituximab dosage is not reduced

(continued)

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)
- *Note:* Antiviral prophylaxis was prescribed to patients for 6 to 12 months after completion of therapy because of the relatively high incidence of herpes infections (6 of 40 patients; 15%) believed to be secondary to T-cell depletion from fludarabine. No patient receiving acyclovir prophylaxis developed herpes infection

See Chapter 47 for more information

Infusion reactions associated with rituximab
Fevers, chills, and rigors
1. Interrupt rituximab administration for severe symptoms and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)
1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/hs with close monitoring. Do not increase the administration rate

Patient Population Studied

Baseline Clinical Characteristics	Number of Patients (%)
Age, median (range)	53 years (40–77)
Sex, female-to-male ratio	20 (50%)/ 20 (50%)

2	4 (10%)	3 (30%)	1 (3%)
3/4	4 (10%)	1 (10%)	3 (10%)

CR, complete response; CRu, unconfirmed complete response; G-CSF, granulocyte colony-stimulating factor; PR, partial response; PRu, unconfirmed partial response
*"Unexpected" hematologic toxicities in the first 10 patients (subgroup 1), prompted treatment modifications instituted by protocol amendment. The subsequent 30 patients were designated subgroup 2. However, hematologic toxicities were very similar between both groups
†Overall, G3/4 neutropenia was transient and reversible in subgroup 2. Whereas 70% in subgroup 1 required G-CSF support, only 24% in subgroup 2 received G-CSF support including 2/7 who received G-CSF transiently only after completion of all scheduled study drugs. In subgroup 2 patients, transient therapy delay was required in 9 patients: starting with the third cycle of therapy in 4 patients, the fourth cycle in 2 patients, the fifth cycle in 1 patient, and the sixth cycle in 2 patients. Excluding a single patient removed from study at mid-therapy secondary to prolonged cytopenia in subgroup 2, 3 patients required a 40% fludarabine dose reduction: 1 patient starting at cycle 4 and 2 patients with cycle 6 only

(*continued*)

Toxicity (*continued*)

Association of Clinical Characteristics to Grade 3 or 4 Neutropenia (Subgroup 2 Patients) in Univariate Analysis

Variable	Odds Ratio (95% CI)	*P* Value
International Prognostic Index (IPI) score, ≥2 vs. ≤1	22.40 (2.19–2,228.70)	0.009
Marrow involvement, positive vs. negative	0.19 (0.02–1.84)	0.15

(N = 40 + Infectious Complications, Hospitalizations, and Nonhematologic Toxicities*)

Staphylococcal or culture-negative Mediport infections	3 (7.5%)
Fever + neutropenia requiring hospitalization	4 (10%)
Primary or secondary herpes simplex/zoster skin infections†	6 (15%)
Recurrent urinary tract infection	1 (2.5%)
Rituximab infusional toxicities	"Usual"
Intermittent G1/2 fludarabine-associated nausea/vomiting and liver function test abnormalities‡	1 (2.5%)
Interstitial pneumonitis believed secondary to fludarabine§	1 (2.5%)

*There were no differences in infectious complications noted between patients in subgroup 1 vs. subgroup 2

†Acyclovir prophylaxis was subsequently prescribed to all treated patients for 6–12 months after completion of therapy because of the relatively high incidence of herpes infections (6 of 40 patients; 15%) believed to be secondary to T-cell depletion from fludarabine. No patient receiving acyclovir prophylaxis developed herpes infection

‡Resolved after completion of therapy

§One case was seen in a single patient in subgroup 1 that necessitated taking the patient off of study after fludarabine cycle 5. This patient's symptoms resolved quickly with initiation of corticosteroids

Treatment Monitoring

1. *Pretreatment/screening period:* medical history and baseline laboratory and imaging studies, serum pregnancy test, bilateral bone marrow aspirates and core biopsies for assessment of the extent of disease
2. *Evaluations performed during and after treatment:* physical examination, CBC counts, serum chemistry, imaging studies for disease assessment

REGIMEN

Indolent (Follicular) Lymphoma
Small Lymphocytic Lymphoma
Mantle Cell Lymphoma

BENDAMUSTINE + RITUXIMAB

Rummel MJ et al. Lancet 2013;381:1203–1210

Bendamustine HCl 90 mg/m^2 per dose; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) sufficient to produce a concentration with the range 0.2–0.7 mg/mL over 30–60 minutes, on 2 consecutive days, days 1 and 2, every 4 weeks for up to 6 cycles (total dosage/cycle = 180 mg/m^2)

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m^2; administer intravenously in 0.9% NS or 5% dextrose injection diluted to a concentration of 1–4 mg/mL on day 1, every 4 weeks for up to 6 cycles (total dosage/cycle = 375 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate
- The regimen did not include maintenance or consolidation treatment with rituximab

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab
Fevers, chills, and rigors
1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)
1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/hs with close monitoring. Do not increase the administration rate

Treatment Modifications

Adverse Effect	Treatment Modifications
WBC <2000/mm³, ANC <1000/mm³, or platelet count <100,000/mm³ at time of cycle start	Delay start of next treatment cycle for 1 week or until WBC ≥2000/mm³ (or ANC ≥1000/mm³) and platelet count ≥100,000/mm³. If restarting treatment is delayed by >5 days, reduce the bendamustine dosage to 70–80 mg/m² per day ×2 days
ANC <1000/mm³ and/or platelet count <75,000/mm³ on day 1 of a cycle with bendamustine dosage during the previous cycle = 70–80 mg/m²	Hold bendamustine until ANC ≥1000/mm³ and platelet count ≥75,00/mm³. If restarting treatment is delayed by >5 days, reduce the bendamustine dosage to 60–70 mg/m² per day ×2 days
ANC <1000/mm³ and/or platelet count <75,000/mm³ on day 1 of a cycle that does not resolve within 21 days	Discontinue bendamustine
WBC <1000/mm³ or platelet count <50,000/mm³ on 2 consecutive days between cycles	Reduce the bendamustine dosage to 70 mg/m² per day ×2 days during subsequent cycles
Clinically significant G ≥2 nonhematologic toxicity	Hold bendamustine until nonhematologic toxicity has recovered to G ≤1. If toxicity was G ≥3, reduce the bendamustine dosage to 70–80 mg/m² per day ×2 days during subsequent cycles
Clinically significant G ≥2 nonhematologic toxicity with bendamustine dosage during the previous cycle = 70–80 mg/m²	Hold bendamustine until nonhematologic toxicity has recovered to G ≤1. If toxicity was G ≥3, reduce the bendamustine dosage to 60–70 mg/m² per day ×2 days during subsequent cycles

Patient Population Studied

Patients with a histologically confirmed mantle cell or indolent non-Hodgkin lymphoma, including CD20-positive subtypes: grades 1/2 follicular, lymphoplasmacytic (Waldenström's macroglobulinemia), small lymphocytic, and marginal-zone lymphoma. All had previously untreated stages III/IV disease, and patients with indolent lymphoma subtypes had at least 1 of the following criteria: impaired hemopoiesis (Hgb <10 g/dL, ANC <1500/mm³, or platelet count <100,000/mm³); presence of B symptoms; large tumor burden (3 areas >5 cm or 1 area >7.5 cm); bulky disease with impingement on internal organs; progressive disease, defined as a more than 50% increase of tumor mass within 6 months; or a hyperviscosity syndrome. Patients younger than 65 years with mantle cell lymphoma were referred to clinical trials incorporating autologous stem cell transplantation

Patient Characteristics (N = 261 + 253 = 514)

Open-label, Multicenter, Randomized, Phase 3, Noninferiority Trial Comparing Bendamustine Plus Rituximab (B-R) versus Chop Plus Rituximab (Chop-R) as First-line Treatment for Patients with Indolent and Mantle Cell Lymphomas

Skin (erythema)	42 (16%)	23 (9%)	0.024
Skin (allergic reaction)	40 (15%)	15 (6%)	0.0006
Infectious episodes	96 (37%)	127 (50%)	0.0025
Sepsis	1 (<1%)	8 (3%)	0.019

CHOP + R, cyclophosphamide + doxorubicin + vincristine + prednisone + rituximab (R-CHOP); R, rituximab
*Includes only patients who received 3 or more cycles

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistry; serum immunoelectrophoresis; measurement of immunoglobulin concentrations; CT scan of the chest, abdomen, and pelvis; sonography of the abdomen; and bone marrow aspiration and biopsy as indicated. If clinically relevant, endoscopy of the gastrointestinal tract is done
2. *Weekly:* CBC with differential once weekly
3. *Assessment of efficacy:* CT scan or sonographic examination after cycles 3 and 6, or at the end of treatment

REGIMEN

FLUDARABINE, MITOXANTRONE (NOVANTRONE), AND DEXAMETHASONE (FN-D)

McLaughlin P et al. J Clin Oncol 1996;14:1262–1268

Fludarabine 25 mg/m² per day; administer intravenously in 100–125 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes for 3 consecutive days on days 1–3, every 4 weeks, for up to 8 cycles (total dosage/cycle = 75 mg/m²)
Mitoxantrone 10 mg/m²; administer intravenously in 50–150 mL 0.9% NS or D5W over 5–30 minutes, given on day 1, every 4 weeks, for up to 8 cycles (total dosage/cycle = 10 mg/m²)
Dexamethasone 20 mg/day; administer orally or by intravenous infusion in 10–100 mL 0.9% NS or D5W over 10–30 minutes for 5 consecutive days on days 1–5, every 4 weeks, for up to 8 cycles (total dose/cycle = 100 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on days 2–5 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis
Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Patient Population Studied

A study of 224 patients (median age: 58 years) with >10 million CD5+/19+/23+ cells. Patients with serum creatinine >2 mg/dL (176.8 µmol/L) or total bilirubin >2 mg/dL (34.2 µmol/L) were excluded

Efficacy

	FC	FCR
Complete response	35%	70%*
Nodular partial response	29%	10%
Overall response rate	88%	95%
Flow-negative complete response	12%	66%

FC, Fludarabine and cyclophosphamide; FCR, fludarabine, cyclophosphamide, and rituximab
*p <0.05

Toxicity (N = 51 Patients; 182 Cycles)

Adverse Event	% of Cycles
ANC <500/mm³	20
Platelet count <100,000/mm³	31
Platelet count <50,000/mm³	8
Infectious complications	12

Toxicity	% of Patients
Nausea	20
Vomiting	6
Stomatitis	12
Neurologic toxicities	8
Congestive heart failure	4
Diarrhea	4

Treatment Modifications

Adverse Event	Dose Modification
Sepsis during any cycle	Reduce fludarabine and mitoxantrone dosages by 20% during subsequent cycles
ANC <100/mm³ or platelet count <20,000/mm³ during any cycle	

Therapy Monitoring

1. *On days of drug administration:* CBC with differential, LFTs, serum BUN, and creatinine
2. *Cardiac status:* Monitor every 2–3 cycles with a cardiac scan or echo cardiogram

Notes

In monitoring cardiac status and deciding whether to continue mitoxantrone, the authors used the following approach: Monitoring of cardiac status was performed after every 2–3 courses with cardiac scan or echocardiogram. For patients who had received prior anthracyclines, a potential cumulative cardiotoxic dose was estimated by assuming that a full cardiotoxic dose of mitoxantrone was 160 mg/m², and that of doxorubicin, by bolus, was 450 mg/m². (For doxorubicin by continuous infusion, the thresholds used were 675 mg/m² for 48-hour infusion and 800 mg/m² for 96-hour infusion.) The following calculation was used: if the total doses of mitoxantrone and doxorubicin per square meter are "m" and "d" respectively, then m/160 + d/450 must be less than 1. If this potential cardiotoxic threshold was exceeded, or if cardiac symptoms occurred, discontinuation of mitoxantrone was advised

REGIMEN

RITUXIMAB

Davis TA et al. J Clin Oncol 1999;17:1851–1857

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously 30–60 minutes before starting rituximab
Rituximab 375 mg/m^2; administer intravenously diluted to a concentration of 1–4 mg/mL in 0.9% sodium chloride injection or 5% dextrose injection, weekly, for 4 consecutive weeks (days 1, 8, 15, and 22) (total dosage/course = 1500 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration after adverse events abate

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 31 patients who had either low-grade or follicular B-cell NHL with either relapsed disease or primary therapy failure and progressive disease that required further treatment. Additional requirements included a demonstrable monoclonal CD20-positive B-cell population in a pathologic lymph node or bone marrow specimen and a WHO PS of 0, 1, or 2. Concurrent steroid use was not permitted

Efficacy (N = 28)

Complete response	4%
Partial response	39%
Overall response rate	43%

Toxicity*

	% of Patients
Transient fever	61
Leukopenia	23
Nausea	19
Dizziness	19
Throat irritation	19
G1/2 chills	36
G3/4 chills	3
G3/4 pulmonary disorders	6
G3/4 infusion-related hypotension	3

*NCI Adult Toxicity Criteria (February 1988 guidelines)

Treatment Modifications

Treatment prerequisites: Within 2 weeks before starting rituximab, study patients were required to have a hemoglobin ≥8.0 g/dL, ANC ≥1500/mm^3, platelet count ≥75,000/mm^3, serum creatinine concentration ≤2 mg/dL (≤177 µmol/L), total bilirubin level ≤2 mg/dL (≤34.2 µmol/L), and alkaline phosphatase and AST ≤2 times the upper limit of normal

Rituximab Infusion-Related Toxicities

Onset of infusion-related events (fevers, chills, rigors edema, congestion of the head and neck mucosa, hypotension):
1. Interrupt rituximab infusion
2. For fever, chills: Give additional dose of acetaminophen 650 mg orally and diphenhydramine 25–50 mg by intravenous injection
3. For rigors: Give meperidine 12.5–25 mg by intravenous injection ± promethazine 12.5–25 mg by intravenous infusion in at least 10 mL 0.9% NS or D5W over 5–15 minutes. If after 15–20 minutes the response to a single dose is considered inadequate, the dose may be repeated
4. After symptoms resolve, resume rituximab infusion at 50 mg/hour and increase by 50 mg/hour every 30 minutes, as tolerated, up to a maximum rate of 200 mg/hour

Dyspnea or wheezing, without allergic findings (urticaria, or tongue or laryngeal edema):
1. Interrupt rituximab infusion immediately
2. Give hydrocortisone 100 mg by intravenous injection (or glucocorticoid equivalent)
3. Give a histamine H_2-antagonist (ranitidine 150 mg, cimetidine 300 mg, or famotidine 20 mg) by intravenous injection
4. After symptoms resolve, resume rituximab infusion at 25 mg/hour with close monitoring. Do not increase rate

Note: Medications for the treatment of hypersensitivity reactions should be available for immediate use in the event of a reaction during administration (eg, intravenous fluids, epinephrine, antihistamines, glucocorticoids, and O_2)

Therapy Monitoring

Weekly: CBC with differential, LFTs, serum BUN, and creatinine

REGIMEN

EXTENDED-SCHEDULE RITUXIMAB

Ghielmini M et al. Blood 2004;103:4416–4423

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

Induction phase:
Rituximab 375 mg/m²; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, once per week for 4 consecutive weeks (total dosage: 1500 mg/m²), *followed by:*

Extended schedule phase:
Rituximab 375 mg/m²; administer intravenously in 0.9% NS or D5W, diluted to a concentration of 1–4 mg/mL, at week 12 (8 weeks after the last *induction phase* dose), and again at months 5, 7, and 9, for a total of 4 doses (total dosage during maintenance phase = 1500 mg/m²; total dosage during induction phase plus extended schedule phase = 3000 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 202 newly diagnosed (32%) or relapsed/refractory follicular lymphoma patients. Biopsy-proven CD20+ follicular lymphoma, grade I (34%), II (45%), or III (12%) according to the REAL classification. ECOG performance status 0 (73%), 1 (21%), or 2 (6%), and a cardiac ejection fraction (EF) of at least 50% as determined by echocardiography. Median age was 57 years

Therapy Monitoring

Before each rituximab administration: CBC before each rituximab and at months 2 and 12

REGIMEN

MAINTENANCE RITUXIMAB

Salles G et al. Lancet 2011;377:42–51

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

Induction phase:
Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, once per week, for 4 weeks (total dosage/4-week course = 1500 mg/m^2), *followed by:*

Maintenance phase:
Rituximab 375 mg/m^2; administer intravenously in 0.9% NS or D5W, diluted to a concentration of 1–4 mg/mL, once per week for 4 weeks, administered at 6-month intervals times 4 cycles (total dosage = 1500 mg/m^2 every 6 months; potential total dosage during maintenance phase [4 cycles] = 6000 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MINIMAL
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

	Retreatment Group (No Maintenance)	Maintenance Group	*p* Value

Response to subsequent treatment			
CR	4	27	0.007
ORR	35	52	—
Median PFS	7.4 months	31.3 months	0.007
Median duration rituximab benefit	27.4 months	31.3 months	0.94
3-year survival	68%	72%	NS

Patient Population Studied

A study of 114 patients who had received previous chemotherapy (previous rituximab not allowed) for indolent non-Hodgkin lymphoma (follicular and small lymphocytic), who were treated with a standard 4-week course of rituximab. Patients with objective response or stable disease were randomly assigned to receive either maintenance rituximab therapy (standard 4-week courses administered at 6-month intervals) or rituximab retreatment at the time of lymphoma progression. The duration of rituximab benefit was measured from the date of first rituximab treatment until the date other treatment was required

Toxicities

	Retreatment Group (No Maintenance; N = 46)	Maintenance Group (N = 44)
G3 infusion reactions	0%	4.5%
G3 hematologic toxicity	2.2%	2.3%
G3 nonhematologic toxicity	2.2%	2.3%

Therapy Monitoring

Every 3 months: CBC with differential and serum chemistries

REGIMEN

FLUDARABINE + CYCLOPHOSPHAMIDE + RITUXIMAB (FCR)

Keating MJ et al. J Clin Oncol 2005;23:4079–4088

Prophylaxis against tumor lysis syndrome (cycle 1):
Allopurinol 300 mg/day; administer orally or intravenously, for 7 consecutive days, days 1–7

Premedication for rituximab (all cycles):
Acetaminophen 650 mg; administer orally, *plus*
Diphenhydramine 25 mg; administer intravenously, 30–60 minutes before starting rituximab

Cycle 1	Cycles 2–6
Rituximab 375 mg/m²; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration within the range of 1–4 mg/mL, on day 1, every 28 days (total dosage/cycle = 375 mg/m²)	**Rituximab** 500 mg/m²; administer intravenously in 0.9% NS or D5W, diluted to a concentration within the range of 1–4 mg/mL, on day 1, every 28 days (total dosage/cycle = 500 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour

Cycle 1	Cycles 2–6
Cyclophosphamide 250 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes, daily for 3 consecutive days, days 2–4, every 28 days (total dosage/cycle = 750 mg/m²)	**Cyclophosphamide** 250 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes, daily for 3 consecutive days, days 1–3, every 28 days (total dosage/cycle = 750 mg/m²)
Fludarabine 25 mg/m² per day; administer intravenously in 100–125 mL 0.9% NS or D5W over 20–30 minutes, daily for 3 consecutive days, days 2–4, every 28 days (total dosage/cycle = 75 mg/m²)	**Fludarabine** 25 mg/m² per day; administer intravenously in 100–125 mL 0.9% NS or D5W over 20–30 minutes, daily for 3 consecutive days, days 1–3, every 28 days (total dosage/cycle = 75 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on cycle 1, day 1 is ***LOW***
Emetogenic potential on cycle 1, days 2–4 is ***MODERATE***
Emetogenic potential on cycle 2 and subsequent cycles, days 1–3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Major	2.6%	
Minor	10%	

Efficacy (N = 224)

Complete response:	70%
Nodular partial remission:	10%
Partial response:	15%
No response:	5%

Treatment Modifications

ANC ≤1000/mm³ or platelet ≤80,000/mm³ after the first treatment cycle	Treatment postponed until ANC >1000/mm³ and platelets >80,000/mm³. If delay >1 week, restart treatment with reduction of the cyclophosphamide dosage to 200 mg/m² and fludarabine dosage to 20 mg/m². If further dose reduction is needed, reduce the cyclophosphamide dosage to 150 mg/m² and fludarabine dosage to 15 mg/m². The rituximab dose is not reduced
Major infection	Reduce cyclophosphamide dosage to 200 mg/m² and fludarabine dosage to 20 mg/m². If further dose reduction is needed, reduce the cyclophosphamide dosage to 150 mg/m² and fludarabine dosage to 15 mg/m². The rituximab dose is not reduced

Rituximab Infusion-Related Toxicities

Onset of infusion-related events (fevers, chills, rigors edema, congestion of the head and neck mucosa, hypotension):

1. Interrupt rituximab infusion
2. For fever, chills: Give additional dose of acetaminophen 650 mg orally and diphenhydramine 50 mg by intravenous injection
3. For rigors: Give meperidine 12.5–25 mg by intravenous injection ± promethazine 12.5–25 mg by intravenous infusion in at least 10 mL 0.9% NS or D5W over 5–15 minutes. If after 15–20 minutes the response to a single dose is considered inadequate, the dose may be repeated
4. After symptoms resolve, resume rituximab infusion at 50 mg/hour and increase by 50 mg/hour every 30 minutes, as tolerated, up to a maximum rate of 200 mg/hour

Dyspnea or wheezing, without allergic findings (urticaria, or tongue or laryngeal edema):

1. Interrupt rituximab infusion immediately
2. Give hydrocortisone 100 mg by intravenous injection (or glucocorticoid equivalent)
3. Give a histamine H_2-antagonist (ranitidine 150 mg, cimetidine 300 mg, or famotidine 20 mg) by intravenous injection
4. After symptoms resolve, resume rituximab infusion at 25 mg/hour with close monitoring. Do not increase rate

Patient Population Studied

A study of 224 patients (median age: 58 years) with CLL (Rai stages I–II, 67%; Rai stages III–IV, 33%)

Therapy Monitoring

1. *Prior to each cycle:* CBC with differential, serum electrolytes, BUN, creatinine, and LFTs
2. *Response evaluation:* Every 2–3 cycles

Notes

Keating MJ et al. [abstract 2118] Blood 2005;106:599a; reported at the 2005 American Society of Hematology meeting. Three hundred previously untreated patients with CLL who received FCR had 83% 4-year survival, and 77% (CR + PR) had a 4-year remission duration. Autoimmune hemolytic anemia or red cell aplasia occurred in 25 and 6 cases, respectively. Three cases of acute myelogenous leukemia and 3 additional cases of myelodysplastic syndrome occurred

REGIMEN

^{131}I TOSITUMOMAB

Kaminski MS et al. J Clin Oncol 2001;19:3918–3928

Note: The treatment regimen consists of 2 products: tositumomab, a murine IgG_{2a} lambda monoclonal antibody that reacts specifically with the CD20 antigen, and ^{131}I-tositumomab, a radioiodinated derivative of tositumomab that has been covalently linked to iodine-131 (^{131}I)

Treatment requirements:

- *Within 2 weeks of therapy:* Bone marrow ≤25% involvement with lymphoma
- *Within 4 weeks of therapy:* ANC >1500/mm^3 and platelet count >100,000/mm^3
- Adequate liver and renal function

Premedication:

Saturated solution of potassium iodide (SSKI); administer 4 drops orally, 3 times daily, starting 24 hours prior to dosimetric dose and continuing for 14 days post therapy to prevent uptake of ^{131}I by the thyroid

Note: Patients should not receive the dosimetric dose of iodine ^{131}I-tositumomab unless they have received at least 3 doses of SSKI, 3 doses of Lugol solution, or 1 dose of potassium iodide 130 mg at least 24 hours prior to the dosimetric dose

Acetaminophen 650 mg; administer orally prior to dosimetric and therapeutic doses

Diphenhydramine 50 mg; administer orally prior to dosimetric and therapeutic doses

The administration of iodine ^{131}I-tositumomab follows a procedure in which a dosimetric dose precedes a subsequent therapeutic dose

	Dosimetric Step
Day 0	(Unlabeled) Tositumomab 450 mg; administer intravenously in 50 mL 0.9% sodium chloride injection (0.9% NS) over 60 minutes • Decrease the rate of infusion by 50% for mild-to-moderate infusional toxicity; interrupt administration for severe infusional toxicity • After complete resolution of severe infusional toxicity, administration may resume at a rate of infusion decreased by 50%
	Iodine ^{131}I-tositumomab (containing 5.0 mCi iodine ^{131}I + 35 mg tositumomab); administer intravenously in 30 mL 0.9% NS over 20 minutes • Decrease the rate of infusion by 50% for mild-to-moderate infusional toxicity; interrupt administration for severe infusional toxicity • After complete resolution of severe infusional toxicity, administration may resume at a rate of infusion decreased by 50%
Day 0; day 2, 3, or 4; and day 6 or 7	Measure whole-body gamma dosimetry and evaluate biodistribution using a gamma camera. Use the measurements to determine the patient-specific activity (in mCi) of radiolabeled tositumomab required to deliver a maximum tolerated therapeutic dose of 75 cGy total-body dose based on standard internal radiation dosimetry methods
Day 6 or 7	Calculate patient-specific activity of iodine ^{131}I-tositumomab to deliver 75 cGy total body dose (in mCi)

(*continued*)

Treatment Modifications

Platelet count between <150,000/mm^3	Attenuate therapeutic iodine ^{131}I dose to 65 Gy total-body dose
Obese patients (patients weighing more than 137% of their lean body weight)	Adjust dose in the dosimetry calculations based on 137% of their lean body weight

Patient Population Studied

Sixty patients with chemotherapy-refractory low-grade or transformed low-grade CD20+ B-cell non-Hodgkin lymphomas who had been treated with at least 2 protocol-specified qualifying chemotherapy regimens and had not responded or progressed within 6 months after their last qualifying chemotherapy lymphoma. Median age was 60 years; 98% had stage 3 or 4 disease. Patients who had >25% involvement of bone marrow, CNS lymphoma, HIV, or those with human antimouse antibodies (HAMA) were excluded

Efficacy

	^{131}I Tositumomab	Last Chemotherapy Received
CR	20%	2%
CR + PR	65%	28%
Median duration of response	6.5 months	3.4 months

(*continued*)

Therapeutic Step	
Days 7–14	(Unlabeled) Tositumomab 450 mg; administer intravenously in 50 mL 0.9% NS over 60 minutes • Decrease the rate of infusion by 50% for mild-to-moderate infusional toxicity; interrupt administration for severe infusional toxicity • After complete resolution of severe infusional toxicity, administration may resume at a rate of infusion decreased by 50%
	The activity of iodine ^{131}I calculated to deliver 75 cGy total-body irradiation (in mCi) conjugated with 35 mg tositumomab; administer intravenously in 30 mL 0.9% NS over 20 minutes • Decrease the rate of infusion by 50% for mild-to-moderate infusional toxicity; interrupt administration for severe infusional toxicity • After complete resolution of severe infusional toxicity, administration may resume at a rate of infusion decreased by 50%

Safety note

Radiation safety = minimal risk, but check with local and institutional policies regarding radiation safety

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Anemia	—	0%	—
MDS in expanded access studies	3%		

*One patient hospitalized for fever and neutropenia; time to count nadir is 4–7 weeks with recovery after 2–3 weeks

Therapy Monitoring

1. Baseline liver and renal function tests
2. Baseline TSH, then annual TSH
3. CBC 2 days prior to therapeutic dose, and weekly until at least week 10. Continue if cytopenias are prolonged. Patients with more severe cytopenias need more frequent monitoring. Monitoring should be more frequent in patients who develop moderate or severe cytopenia, or as clinically indicated
4. Vital signs and signs and symptoms of infusion-related or allergic reactions should be monitored during each of the infusions
5. *Note:* Patients who had prior exposure to murine proteins should be screened for HAMA prior to treatment as they may be at increased risk for hypersensitivity

REGIMEN

YTTRIUM ^{90}Y IBRITUMOMAB TIUXETAN (ZEVALIN) + RITUXIMAB

Witzig TE et al. J Clin Oncol 2002;20:2453–2463

Note: Zevalin is a radionuclide tagged immunoconjugate resulting from a stable covalent bond between the monoclonal antibody, ibritumomab, the murine IgG_1 kappa monoclonal anti-CD20 parent of the chimeric antibody rituximab, and the linker-chelator tiuxetan, which provides a high affinity, conformationally restricted chelation site for indium-111 (^{111}In) or yttrium-90 (^{90}Y)

Premedication for all rituximab doses:
Acetaminophen 650 mg; administer orally prior to dosimetric and therapeutic doses
Diphenhydramine 50 mg; administer orally prior to dosimetric and therapeutic doses

Day 1	Administer **rituximab** 250 mg/m^2; administer intravenously *Notes on rituximab administration:* • Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. If administration on day 1 was well tolerated, start subsequent treatments at 100 mg/hour and increase in increments of 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour • Immediately stop rituximab administration for serious infusion reactions and discontinue the ibritumomab tiuxetan regimen • Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate • Temporarily slow or interrupt rituximab administration for less-severe infusion reactions. If symptoms improve, continue administration at 50% the previous rate • For signs or symptoms of extravasation, immediately stop rituximab administration and restart in another limb
	Within 4 hours after completing rituximab infusion, administer **indium ^{111}In ibritumomab tiuxetan** (containing 5.0 mCi [185 MBq] ^{111}In + up to 1.6 mg ibritumomab tiuxetan) by intravenous injection over 10 minutes • Use a 0.22-µm, low-protein-binding, inline filter between the syringe containing indium ^{111}In ibritumomab tiuxetan and the port into which it is injected • After injection, flush the line through which indium ^{111}In ibritumomab tiuxetan was given with at least 10 mL 0.9% NS
Days 2–7	Wiseman GA et al. Crit Rev Oncol Hematol 2001;39:181–194 Assess for biodistribution (see below). Proceed only if biodistribution is normal. Dosimetry using indium ^{111}In ibritumomab tiuxetan should be conducted for all patients who are receive treatment with yttrium ^{90}Y ibritumomab. Eligibility for treatment with yttrium ^{90}Y ibritumomab tiuxetan is based on MIRDOSE3-estimated radiation-absorbed doses to normal organs and red marrow. Yttrium ^{90}Y ibritumomab tiuxetan should not be administered if the predicted delivered dose of radiation is more than 20 Gy to any nontumor organ or more than 3 Gy to the bone marrow

(*continued*)

Patient Population Studied

Phase 3 randomized trial comparing traditional weekly rituximab for 4 doses versus rituximab plus a single dose of ^{90}Y ibritumomab tiuxetan. One hundred forty-three patients with histologically confirmed, relapsed or refractory low-grade or follicular or transformed NHL requiring treatment as determined by an increase in overall tumor size, the presence of B symptoms, and/or the presence of masses that were causing ongoing clinical symptomatology. Prior therapy had to be completed at least 3 weeks prior to receiving ^{90}Y ibritumomab tiuxetan. Median age 59 years; 65% had stage 3 or 4 disease. Also required: hemoglobin ≥8 g/dL, absolute neutrophil count ≥1500 cells/mm^3, platelet count ≥150,000 cells/mm^3, total bilirubin <2.0 mg/dL (34.2 µmol/L), alkaline phosphatase and AST (aspartate aminotransferase) <4 times the upper limit of normal range, and serum creatinine level less than 2.0 mg/dL (176.8 µmol/L). Patients were excluded if their bone marrow biopsy or aspirate demonstrated ≥25% involvement with NHL, if their peripheral blood lymphocyte count was ≥5000 cells/mm^3, if they had prior external beam radiation therapy to more than 25% of their bone marrow, or if they had a history of human antimurine antibodies (HAMA) or human antichimeric antibodies (HACA). Patients with CNS NHL, chronic lymphocytic leukemia, mantle-cell lymphoma, human immunodeficiency virus, prior radioimmunotherapy, hematopoietic growth factors within 2 weeks before treatment, or prior autologous or allogeneic stem cell transplant were not eligible

(*continued*)

Day 8	Administer **rituximab** 250 mg/m² by intravenous infusion as described above for day 1
	Within 4 hours after completing rituximab infusion, administer **yttrium ^{90}Y ibritumomab tiuxetan** by intravenous injection over 10 minutes

Platelet Count	Yttrium ^{90}Y Ibritumomab Tiuxetan Dose (per kg actual body weight)*
≥150,000/mm³	0.4 mCi (14.8 MBq)
100,000–149,000/mm³	0.3 mCi (11.1 MBq)

*DO NOT administer ^{90}Y doses >32 mCi (>1184 MBq) regardless of a patient's body weight

- Use a 0.22-µm, low-protein-binding, inline filter between the syringe containing yttrium ^{90}Y ibritumomab tiuxetan and the port into which it is injected
- After injection, flush the line through which yttrium ^{90}Y ibritumomab tiuxetan was given with at least 10 mL 0.9% NS

Safety note:
Radiation safety = minimal risk, but check with local and institutional policies regarding radiation safety

Expected biodistribution
- Activity in the blood pool areas (heart, abdomen, neck, and extremities) may be faintly visible
- Moderately high to high uptake in normal liver and spleen
- Moderately low or very-low uptake in normal kidneys, urinary bladder, and normal (uninvolved) bowel
- Nonfixed areas within the bowel lumen that change position with time; delayed imaging as described above may be necessary to confirm gastrointestinal clearance
- Focal fixed areas of uptake in the bowel wall (localization to lymphoid aggregates in bowel wall)

Tumor uptake may be visualized however tumor visualization on the ^{111}In scan is not required for treatment with yttrium ^{90}Y ibritumomab tiuxetan

Altered biodistribution
The criteria for altered biodistribution are met if any of the following is detected on visual inspection of the required gamma images:
- Intense localization of radiotracer in the liver and spleen and bone marrow indicative of reticuloendothelial system uptake
- Increased uptake in normal organs (not involved by tumor) such as:
  - Diffuse uptake in normal lung more intense than the liver
  - Kidneys have greater intensity than the liver on the posterior view
  - Fixed areas (unchanged with time) of uptake in the normal bowel greater than uptake in the liver
  - In less than 0.5% of patients receiving indium ^{111}In ibritumomab tiuxetan, prominent bone marrow uptake was observed, characterized by clear visualization of the long bones and ribs

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Therapy Monitoring

1. Baseline liver and renal function tests
2. Baseline TSH, then annual TSH
3. CBC 2 days prior to therapeutic dose and weekly until at least week 10. Continue if cytopenias are prolonged. Patients with more severe cytopenias need more frequent monitoring. Monitoring should be more frequent in patients who develop moderate or severe cytopenia, or as clinically indicated
4. Vital signs and signs and symptoms of infusion-related or allergic reactions should be monitored during each of the infusions
5. *Note:* Patients who have had prior exposure to murine proteins should be screened for HAMA prior to treatment as they may be at increased risk for hypersensitivity

REGIMEN

FLUDARABINE + RITUXIMAB

Byrd J C et al. Blood 2003;101:6–14
Byrd JC et al. Blood 2005;105:49–53

Induction (Concurrent) Regimen
Cycles 1–6
Fludarabine 25 mg/m² per dose; administer intravenously in 100–125 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 20–30 minutes for 5 consecutive days, on days 1–5, every 28 days for 6 cycles (total dosage/cycle = 125 mg/m²)
Cycle 1
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m² per dose; administer intravenously in 0.9% NS or D5W diluted to a concentration of 1–4 mg/mL for 2 doses on days 1 and 4 (total dosage/cycle = 750 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- The investigators altered the dosage-schedule for rituximab for the last 7 patients who received study treatment based on their observation that stepped-up dosing improved patients' tolerability for rituximab
- For those patients, rituximab was given as follows:

Cycle and Day of Treatment	Rituximab Dosage	Rituximab Rate
Cycle 1, Day 1	Rituximab 50 mg/m²	Dose given over 4 hours without rate escalation
Cycle 1, Day 3	Rituximab 325 mg/m²	1. Initial rate = 50 mg/h 2. If administration was tolerated during the first 30 min, the rate was escalated every 30 min as tolerated to a maximum rate of 400 mg/h
Cycle 1, Day 5	Rituximab 375 mg/m²	1. Initial rate = 100 mg/h for 15 min 2. If administration was tolerated during the first 15 min, the remainder of the dose was administered over 45 min to complete administration over a 1-hour period
Cycles 2–6, Day 1	Rituximab 375 mg/m²	

- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Cycles 2–6
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m²; administer intravenously in 0.9% NS or D5W diluted to a concentration of 1–4 mg/mL on day 1, every 28 days for 5 cycles (total dosage/cycle = 375 mg/m²)

Consolidation Regimen
Patients were observed for 2 months after completing 6 cycles of fludarabine + rituximab. Those judged to have achieved stable disease or a better response were treated with 4 additional weekly doses of rituximab, *thus:*
Rituximab 375 mg/m² per dose; administer intravenously in 0.9% NS or D5W diluted to a concentration of 1–4 mg/mL once weekly for 4 weeks (total dosage/4-week course = 1500 mg/m²)

Supportive Care
The investigators administered **allopurinol** 300 mg orally, once daily for 14 consecutive days, days 1–14 during cycle 1 only
Note: Persons who express a variant human leukocyte antigen allele, HLA-B*58:01, are at increased risk for severe cutaneous adverse reactions from allopurinol (Hershfield MS et al. Clin Pharmacol Ther 2013;93:153–158, Zineh I et al. Pharmacogenomics 2011;12:1741–1749)

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

(*continued*)

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Treatment Modifications

Adverse Event	Treatment Modifications
G3/4 neutropenia, G3/4 thrombocytopenia, or G3/4 anemia	Observe without treatment until these hematologic parameters recover to within 20% of the baseline value. Thereafter, if toxicity = G3, administer 75% of the original fludarabine dosage during subsequent cycles. If toxicity = G4, administer 50% of the original fludarabine dosage during subsequent cycles
Nonhematologic toxicities, including nausea, vomiting, fatigue, diarrhea, and drug-related fever or chills	Administer symptomatic treatment but do not reduce chemotherapy dosages
G ≥2 nonhematologic toxicities other than nausea, vomiting, fatigue, diarrhea, and drug-related fever or chills attributed to fludarabine	Hold fludarabine therapy until toxicity G <2, then reduce the fludarabine dosage by 50% in subsequent cycles
G2 irreversible nonhematologic toxicity and G3/4 nonhematologic toxicities	Evaluate to determine appropriateness of continuing fludarabine therapy
Infection in the absence of G3/4 neutropenia	Observe without further CLL treatment until the infection resolves, but do not modify chemotherapy dosages
Major infection	Reduce fludarabine dosage to 20 mg/m². If further dose reduction is needed, reduce the fludarabine dosage to 15 mg/m². Rituximab dosage is not reduced

Notes:
Grade hematologic toxicity according to the modified NCI criteria for CLL (Cheson BD et al. Blood 1996;87:4990–4997)
Grade nonhematologic toxicity according to National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 4.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm (accessed December 7, 2013)

Patient Population Studied

CALGB 9712, a randomized phase II trial open to accrual from 1997–1999, examined administration of rituximab either concurrently (n = 51) or sequentially (n = 53) with fludarabine therapy. At a median follow-up of 43 months among patients followed for progression, the PFS and overall survival (OS) of the concurrent and sequential arms were found to be similar. On the basis of this finding, all 104 patients enrolled on this trial were combined into 1 comparison group for the analyses reported here. CALGB 9011, open to accrual from 1990–1994, randomly assigned patients to either fludarabine, chlorambucil, or the combination. The fludarabine-only arm of that trial, with a sample size of 178, was used as the comparison group

Demographic and Clinical Characteristics of Patients According to Treatment

Characteristics	Fludarabine + Rituximab (CALGB 9712)	Fludarabine Alone (CALGB 9011)	*P* Value
No. of patients	104	178	
Median age, years (range)	63 (38–88)	64 (37–87)	0.75
Patients, ages <50 years	14%	14%	0.93
Patients, ages ≥70 years	23%	25%	0.88
Rai stage I	2%	2%	
Rai stage II	57%	55%	
Rai stage III	14%	41%	<0.0001
Rai stage IV	26%	2%	
Enlarged liver	15%	20%	0.43
Enlarged spleen	61%	68%	0.19
Median WBC, $\times 10^9$/L (range)	83 (9–436)	77 (9–709)	0.39
Median Hgb, g/dL (range)	12.3 (1.3–16.1)	12.0 (4.6–16.6)	0.26
Median platelets, $\times 10^9$/L (range)	158 (33–316)	155 (12–451)	0.57
Median, LDH, IU (range)	212 (92–950)	198 (39–1389)	0.20

Efficacy

Treatment Outcome

Response Evaluation	Percent (95% CI)
Induction CR	33 (20–46)
Induction CR + PR	90 (82–98)
Consolidation PR to CR[6–150*]	10 (2–18)
Overall CR	47 (33–61)
Overall PR + CR	90 (82–98)

CR, complete response; PR, partial response
*Includes patients with PR after induction except for those with residual cytopenias

(*continued*)

Efficacy (continued)

Retrospective comparative analysis of CALGB 9712 and CALGB 9011

	CALGB 9712 (Fludarabine + Rituximab)	CALGB 9011 Fludarabine alone	*P* Value
Complete response*	38%	20%	$P = 0.002$
Overall response*	84%	63%	$P = 0.0003$
PFS	Patients who received fludarabine + rituximab had significantly improved PFS as compared patients who received fludarabine alone		$P < 0.0001$
2-Year PFS probability†	0.67 (CI, 0.58–0.76)	0.45 (CI, 0.37–0.52)	—
	Patients who received fludarabine + rituximab had significantly improved OS as compared patients who received fludarabine alone		$P = 0.003$
2-Year OS probability‡	0.93 (CI, 0.88–0.98)	0.81 (CI, 0.75–0.87)	—

*Multivariate analyses of the effect of treatment assignment on response, controlling for sex, age, WBC, LDH, and stage, showed that the treatment effect remained essentially unchanged after controlling for these covariates

†The treatment effect was unchanged in a multivariate analysis controlling for age, WBC, LDH, stage, and splenomegaly. Fludarabine-alone treatment assignment ($P < 0.0001$), high WBC ($P = 0.0003$), and high LDH ($P = 0.01$) were significantly associated with early progression

‡The treatment effect was unchanged in a multivariate analysis controlling for age, WBC, LDH, stage, and splenomegaly. Fludarabine-alone treatment assignment ($P = 0.0006$), high WBC ($P = 0.009$), older age ($P = 0.001$), and high LDH ($P = 0.02$) were significantly associated with shortened survival

Hazard Ratios from Multivariate Analysis of Overall Survival*

Clinical Predictor (Hazard Ratio Comparison)	Hazard Ratio (95% CI)	*P* Value
Treatment, CALGB 9712 vs. CALGB 9011†	2.59 (1.50–4.46)	0.0006
WBC, 75th vs. 25th percentile	1.23 (1.05–1.44)	0.009
Age, 75th vs. 25th percentile	1.59 (1.18–1.93)	0.001
LDH, 75th vs. 25th percentile	1.18 (1.03–1.36)	0.02
Sex, male vs. female	1.25 (0.86–1.81)	0.24
Rai stage, high vs. intermediate	1.22 (0.88–1.69)	0.23
Splenomegaly, present vs. absent	1.20 (0.84–1.71)	0.33

*These comparative data are retrospective and could be confounded by differences in supportive care or dissimilar enrollment of genetic subsets on each trial

†CALGB 9712 = Fludarabine + Rituximab; CALGB 9011 = Fludarabine alone

Toxicity

Fludarabine + Rituximab: Maximum Toxicity During Induction

	Toxicity Grade

Treatment Monitoring

1. *Before each cycle:* CBC with manual differential
2. *After 6 cycles of fludarabine + rituximab:* clinical restaging (physical examination with lymph node, liver, and spleen measurement; and CBC with differential)
3. *Two months after completion of the initial 6 cycles of fludarabine + rituximab:* clinical restaging (physical examination, CBC with manual differential) and bone marrow aspirate and biopsy to determine response to induction therapy
4. *After completion of weekly rituximab ×4:* clinical staging (physical examination with lymph node, liver, and spleen measurement; and CBC with differential)
5. *Two months after completion of weekly rituximab ×4:* complete restaging (physical examination with lymph node, liver, and spleen measurement; and CBC with differential) and bone marrow aspirate and biopsy to determine overall response according to the NCI 1996 CLL criteria (Cheson BD et al. Blood 1996;87:4990–4997)

REGIMEN

FLUDARABINE + CYCLOPHOSPHAMIDE + RITUXIMAB

Hallek M et al. Lancet 2010;376:1164–1174

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration of 1–4 mg/mL, every 4 weeks for 6 cycles

	Cycle 1	Cycles 2–6
Dosage	375 mg/m²	500 mg/m²
Treatment day	0 (zero; the day before commencing treatment with fludarabine and cyclophosphamide	Day 1
Total dosage per cycle	375 mg/m²	500 mg/m²

Notes on rituximab administration:
Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
Fludarabine 25 mg/m² per day; administer intravenously in 100–125 mL 0.9% NS or D5W over 20–30 minutes for 3 consecutive days, on days 1–3, every 28 days for 6 cycles (total dosage/cycle = 75 mg/m²)
Cyclophosphamide 250 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes for 3 consecutive days, on days 1–3, every 28 days for 6 cycles (total dosage/cycle = 750 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab
Fevers, chills, and rigors
1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

(*continued*)

(*continued*)

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/hs with close monitoring. Do not increase the administration rate

Patient Population Studied

Randomized phase II trial investigating whether the addition of rituximab to first-line chemotherapy with fludarabine and cyclophosphamide would improve the outcome of patients with chronic lymphocytic leukemia/small lymphocytic lymphoma

Patients' Demographics and Baseline Characteristics

CI, confidence interval; G-CSF, granulocyte colony-stimulating factor (filgrastim); IGHV, immunoglobulin heavy-chain variable gene region
*Data are number (%), unless otherwise indicated
†FC = chemotherapy (fludarabine + cyclophosphamide)
‡FCR = chemoimmunotherapy (fludarabine + cyclophosphamide + rituximab)
Notes:

- Filgrastim was administered in 86 treatment cycles, for a median of 7 days in the FC group and 6 days in the FCR group. It was given more frequently in the FCR group (n = 75 vs. n = 11). In 40 treatment cycles, filgrastim was given as prophylaxis without any sign of neutropenia; in 46 cycles, it was administered to treat an adverse event (neutropenia or leukocytopenia)
- Ten (3%) deaths were related to treatment in the FC group, and 8 (2%) in the FCR group. Of these, 6 FC-treated patients and 5 FCR-treated patients died from infections (septicemia [n = 6], pneumonia [n = 3], hepatitis B [n = 1], and cryptosporidium gastroenteritis [n = 1]). In 7 patients (3 in the FC group and 4 in the FCR group), death occurred before the third treatment course (fatal septicemia [n = 6], sudden cardiac death [n = 1])

REGIMEN

CYCLOPHOSPHAMIDE + PENTOSTATIN + RITUXIMAB

Lamanna N et al. J Clin Oncol 2006;24:1575–1581

Cycle 1 (clinicians' discretion during subsequent cycles)
Premedication: prophylaxis against hyperuricemia with **allopurinol** 300 mg/day for 5–7 days, starting the day before chemotherapy commences
- Persons who express a variant human leukocyte antigen allele, HLA-B*58:01, are at increased risk for severe cutaneous adverse reactions from allopurinol (Hershfield MS et al. Clin PharmacolTher 2013;93:153–158; Zineh I et al. Pharmacogenomics 2011;12:1741–1749)

Cycles 1–6
Hydration on day 1: Administer intravenously at least 1500 mL 5% dextrose injection (D5W), 0.45% sodium chloride injection, or 0.9% sodium chloride injection (0.9% NS) on day 1 before starting chemotherapy
Cyclophosphamide 600 mg/m^2; administer intravenously in 50–250 mL 0.9% NS or 5% dextrose injection (D5W) over 15–60 minutes on day 1 every 3 weeks for 6 cycles (total dosage/cycle = 600 mg/m^2)
Pentostatin 4 mg/m^2; administer intravenously in 25–50 mL D5W or 0.9% NS over 20–30 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 4 mg/m^2)
Filgrastim; administer by subcutaneous injection, daily, starting on cycle day 3 and continue until a patient achieves a single postnadir ANC >5000/mm^3 *or* an ANC >1500/mm^3 on 2 consecutive days
- Filgrastim doses are based on a patient's body weight as follows:

Body Weight	Filgrastim Dose
≤70 kg	300 mcg/day
>70 kg	480 mcg/day

Cycles 2–6
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m^2; administer intravenously in D5W or 0.9% NS diluted to a concentration within the range of 1–4 mg/mL on day 1 after cyclophosphamide and pentostatin administration were completed, every 3 weeks for 5 cycles (total dosage/cycle = 375 mg/m^2)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Rituximab was not given during cycle 1. The investigators explained that infusion reactions to rituximab tend to be more severe in patients with hyperleukocytosis, which in a prior study had been shown to be alleviated by treatment with pentostatin and cyclophosphamide; therefore, rituximab was withheld until the second treatment cycle

Notes: Chemotherapy was administered in the following sequence: cyclophosphamide, then pentostatin, then rituximab
After 3 cycles, patients who did not achieve ≥PR were considered to have experienced treatment failure and were removed from study. Responding patients continued on treatment for a total of 6 cycles

Supportive Care
Antiemetic prophylaxis
Emetogenic potential with or without rituximab is ***MODERATE***
See Chapter 39 for antiemetic recommendations

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Serum creatinine ≥2.0 mg/dL (≥177 μmol/L) or more than 20% higher than the baseline value measured at the start of treatment	Withhold pentostatin until serum creatinine <2.0 mg/dL (<177 μmol/L) or <120% the baseline measured at the start of treatment, or the creatinine clearance ≥50 mL/min (≥0.83 mL/s)
Severe rash	Withhold pentostatin therapy until rash resolves
Patients showing evidence of nervous system toxicity	Withhold therapy until toxicity resolves to baseline or consider discontinuing treatment with pentostatin
ANC ≤1000/mm^3 or platelet count ≤80,000/mm^3 after the first treatment cycle	Postponed treatment until ANC >1000/mm^3 and platelet count is >80,000/mm^3. If delay is >1 week, restart treatment cyclophosphamide dosage decreased to 500 mg/m^2. If further dosage reduction is needed, reduce the cyclophosphamide dosage to 400 mg/m^2. Pentostatin and rituximab dosages are not reduced
Major infection	Reduce cyclophosphamide dosage to 500 mg/m^2. If further dosage reduction is needed, reduce the cyclophosphamide dosage to 400 mg/m^2. Pentostatin and rituximab dosages are not reduced

Note: Reductions in pentostatin dosages are not recommended during treatment in patients with anemia and thrombocytopenia if patients can be otherwise supported hematologically. Pentostatin should be temporarily withheld if the absolute neutrophil count during treatment decreases to <200 cells/mm^3 in a patient whose initial ANC was >500 cells/mm^3. Pentostatin use may resume when ANC returns to pretreatment levels

(*continued*)

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose

- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Patient Population Studied

Characteristic (N = 46)	Number (Percent)
Age, median (range)	62 years (30–80 years)
Sex, male-to-female ratio	30 (65%)/ 16 (35%)
Patient diagnosis	
SLL*	9 (20%)
Waldenström's macroglobulinemia	1 (2%)
Follicular lymphoma	4 (9%)
CLL intermediate risk	7 (15%)
CLL high risk	25 (54%)
Blood	
WBC, median (range)	49 cells/mm^3 (2.6–256.9)
Hemoglobin, median (range)	10.8 g/dL (6.5–15.8)
PLT, median (range)	96 cells/mm^3 (34–380)
CLL patients (N = 32)	
Anemia (hemoglobin <11 g/dL)	16 (50%)
Thrombocytopenia (<100,000 cells/mm^3)	17 (53%)
β_2-microglobulin, mg/L median (range)	3.8 (0.8–12.1)
Patients with β_2-microglobulin >4	12 (38%)
CD38 expression >20%	28 (87%)

CLL, chronic lymphocytic leukemia; PLT, platelets; SLL, small lymphocytic lymphoma
*SLL, histologically (and immunophenotypically); most had the "CLL type" of SLL but did not meet the NCI Working Group definition of CLL because of the degree of blood and BM involvement

(*continued*)

Efficacy

Response	Number (%)
CLL Patients (N = 32)	
Total responses	24 (75%)
Complete responses	8 (25%)
Nodular responses	1 (3%)
Partial responses	15 (47%)
Median duration of response	25 months
Median time to treatment failure	40 months
Median time to treatment failure for patients with CR/NR	Not reached
Median time to treatment failure for patients with PR	17 months
Median overall survival	44 months
Median overall survival (patients with CR/NR)	Not reached
Median overall survival at 36 months (patients with CR/NR)	100%
Median overall survival (patients with PR/No Response)	32 months
Median overall survival at 36 months (patients with PR/No Response)	28%
Non-CLL Patients (N = 14)	
Total responses	7 (50%)
Complete responses	1 (7%)
Partial responses	6 (43%)

CLL, chronic lymphocytic leukemia

Toxicity

G3/4 neutropenia	53%
G3/4 anemia	9%
G3/4 thrombocytopenia	16%
G3/4 infections (including fever of unknown origin) in CLL patients	9/32 (28%)*
G3 nausea	1/32 (3%)
Asymptomatic tumor lysis in CLL	56%†
Number of CLL patients who did not receive the planned number of cycles	9/32 (28%)‡

*Eight of these patients had pneumonia. There was 1 death from progressive pneumonia
†The fraction may underestimate the true risk of tumor lysis syndrome because all patients received hydration and allopurinol before initiating therapy. Rapid cytoreduction was manifested as a prompt decline in the number of circulating lymphocytes, with a median reduction of 78% seen following the first cycle of chemotherapy
‡Therapy stopped in 5 because of infections and in 4 other patients for a variety of comorbid conditions (lung cancer, amegakaryocytic thrombocytopenia, chylous pleural effusion, and an acute confusional state of undetermined etiology)

Patient Population Studied (*continued*)

Prior Therapy	Number of Patients (%)
CLL Patients (N = 32)	
Number prior regimens, median (range)	2 (1–7)
Prior fludarabine	25 (78%)
Refractory	8 (25%)
Prior alkylating agent	25 (78%)
Refractory	7 (22%)
Prior rituximab therapy	7 (22%)
Refractory	4 (13%)
Non-CLL Patients (N = 14)	
Number prior regimens, median (range)	2 (1–6)
Prior fludarabine	6
Refractory	1
Prior alkylating agents	13
Refractory	4
Prior rituximab	9
Refractory	5

CLL, chronic lymphocytic leukemia

Treatment Monitoring

1. *Baseline and response assessment (performed pretreatment, then after 3 and 6 cycles of therapy):* complete physical examination, CBC with differential, BM aspirate, and biopsy. Peripheral blood and/or BM samples analyzed by flow cytometry for CD5/CD19 (or CD5/CD20) dual staining and kappa/lambda clonal excess. Trisomy 12 also tested at the time of response assessment in patients shown to have trisomy 12. Patients who had abnormal computed tomography imaging pretreatment had repeat computed tomography imaging for response assessment
2. *Before each dose and at other appropriate intervals during therapy:* serum creatinine
3. *After completion of therapy:* follow patients at 2- to 3-month intervals for at least 1 year

REGIMEN

Small Lymphocytic Lymphoma
Mantle Cell Lymphoma

IBRUTINIB

Byrd JC et al. N Engl J Med 2013;369:32–42
Wang ML et al. N Engl J Med 2013;369:507–516

Ibrutinib 420–560 mg/day; administer orally, continually (total dose/week = 2940--3920 mg)
• Administration with food increases ibrutinib exposure approximately 2-fold compared with administration after overnight fasting (IMBRUVICA [ibrutinib] capsules, for oral use; November 2013 product label. Janssen Biotech, Inc. Horsham, PA-C, USA)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
• Antibacterial—not indicated
• Antifungal—not indicated
• Antiviral—not indicated unless patient previously had an episode of HSV
See Chapter 47 for more information

Diarrhea management
Loperamide 4 mg orally, initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
• Continue for at least 12 hours after diarrhea resolves
• Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
• Rehydrate orally with fluids and electrolytes during a diarrheal episode
• If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
• Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
• Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
• Encourage patients to maintain intake of nonalcoholic fluids
• Evaluate patients for oral pain and provide analgesic medications
• Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
• *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea
Patients with intact oral mucosa:
• Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
• Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
• Patients may use saline or commercial brand, nonalcoholic rinses
  ▪ Do not use mouthwashes that contain alcohols
If mucositis or stomatitis is present:
• Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
• Rinse mouth several times a day to remove debris
  ▪ Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  ▪ Do not use mouthwashes that contain alcohols

(*continued*)

(continued)

- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

Byrd JC et al. N Engl J Med 2013;369:32–42

Patients with a diagnosis of relapsed or refractory CLL or small lymphocytic lymphoma, defined according to the International Workshop on Chronic Lymphocytic Leukemia and World Health Organization classifications. Those enrolled were deemed to be in need of treatment. The first and second cohorts were required to have received ≥2 previous therapies, including a purine analog. A third cohort included patients with high-risk disease that did not respond to a chemoimmunotherapy regimen or whose disease progressed within 24 months after completion of the regimen

Patient Characteristics (N = 85)

Age—median (range)	66 (37–82)
≥70 years	30 (35%)
Sex—male-to-female ratio	65 (76%)/20 (24%)
Diagnosis	
Chronic lymphocytic leukemia	82 (96%)
Small lymphocytic lymphoma	3 (4%)
Time since last systemic anticancer therapy—median (range)	3 months (1–98)
Rai stage at treatment initiation*—[Data missing = 1 (1%)]	
0, I, or II	29 (34%)
III or IV	55 (65%)
Number of previous therapies—median (range)	4 (1–12)
Previous therapy	
Nucleoside analog	81 (95%)
Rituximab	83 (98%)
Alkylator	76 (89%)
Alemtuzumab	18 (21%)
Bendamustine	33 (39%)
Ofatumumab	22 (26%)
Bulky nodes—[Data missing = 3 (4%)]	
≥5 cm in diameter	44 (52%)
≥10 cm in diameter 13 (15)	
Unmutated immunoglobulin variable-region heavy-chain gene	
Patients with data that could be evaluated	69 (81%)
Data missing	4 (5%)
Interphase cytogenetic abnormality—no. (%)	
17p13.1 deletion	28 (33%)
11q22.3 deletion	31 (36%)
β_2-Microglobulin level >3 mg/L [Data missing = 5 (6%)]	39 (46%)
Disease resistant to purine analogue†	41 (48%)

*Rai stage 0 = low-risk, stages I/II = intermediate-risk, and stages III/IV = high-risk
†Defined as treatment failure (stable disease or progressive disease) or disease progression within 12 months after receipt of a regimen containing a purine analogue

(continued)

Patient Population Studied (*continued*)

Wang ML et al. N Engl J Med 2013;369:507–516

Patients with a confirmed diagnosis of mantle cell lymphoma with cyclin D_1 overexpression or translocation breakpoints at t(11;14) and measurable disease (lymph-node diameter ≥2 cm). All had received at least 1 but no more than 5 previous lines of treatment, with no partial or better response to the most recent treatment

Patient Characteristics (N = 111)*

Age—median (range)	68 years (40–84 years)
Sex—male-to-female ratio	85 (77%)/26 (23%)
ECOG performance status	
0 or 1	99 (89%)
2	11 (10%)
>2	1 (1%)
Number of prior regimens—median (range)	3 (1–5)
≥3	61 (55%)
Previous therapy	
Hyper-CVAD†	33 (30%)
Stem cell transplantation	12 (11%)
Lenalidomide	27 (24%)
Rituximab or rituximab-containing regimen	99 (89%)
Simplified MIPI‡	
Low risk	15 (14%)
Intermediate risk	42 (38%)
High risk	54 (49%)
Bulky mass§	9 (8%)
At least 1 node ≥5 cm	43 (39%)
Refractory disease¶	50 (45%)
Advanced disease**	80 (72%)

*Four patients enrolled but did not receive ibrutinib (investigator's decision)
†Hyperfractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone
‡The simplified Mantle-Cell Lymphoma International Prognostic Index (MIPI) score was derived with the use of the 4 prognostic factors of age, ECOG score, lactate dehydrogenase level, and white-cell count at baseline, and its range depends on the range of these characteristics. The index classifies patients as having low-risk (0–3), intermediate-risk (4 or 5), or high-risk (6–11) disease
§Bulky mass = tumor with a diameter ≥10 cm
¶Refractory disease = lack of at least a partial response to the last therapy before study
**Advanced disease = involvement of bone marrow, extranodal sites, or both
Note: Percentages may not add up to 100% because of rounding

Efficacy (N = 85)

*Data = adverse events reported during treatment in the 111 patients included in the study. Listed events occurred in at least 15% of patients on or before the data-cutoff date. For 4 events (1 event each of diarrhea, depression, asthenia, and hypersomnia), the grade was not available; these 4 events are included as G3
†One grade 5 event

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistry; serum immunoelectrophoresis; measurement of immunoglobulin concentrations; CT scan of the chest, abdomen, and pelvis; and bone marrow aspiration and biopsy as indicated. If clinically relevant, endoscopy of the gastrointestinal tract is done
2. *Weekly:* CBC with differential and platelet count once weekly
3. *Assessment of efficacy:* CT scan or sonographic examination at 2- or 3-cycle intervals after and at the end of treatment in MCL. Cycles 2, 5, 8, 12, 15, and 24 in SLL

REGIMEN

RITUXIMAB WITH HYPERFRACTIONATED CYCLOPHOSPHAMIDE + VINCRISTINE + DOXORUBICIN + DEXAMETHASONE (R-HYPER-CVAD) ALTERNATING WITH RITUXIMAB WITH METHOTREXATE + CYTARABINE (R-MC)

Romaguera JE et al. J Clin Oncol 2005;23:7013–7023
Wang M et al. Cancer 2008;113:2734–2741

If indicated: Prophylaxis against tumor lysis syndrome during the first cycle:
Hydration with 2500–3000 mL/day, as tolerated; administer intravenously at 100–125 mL/hour
Notes:
- Sodium bicarbonate is added to parenteral hydration solutions in the presence of plasma uric acid >9 mg/dL to maintain urine pH >7.0, but pH <8. The choice of hydration fluid and amount of sodium bicarbonate added to the fluid should NOT EXCEED the sodium concentration present in 0.9% sodium chloride injection (154 mEq/L); for example:
  - 5% Dextrose/0.45% sodium chloride injection with sodium bicarbonate 50–75 mEq/1000 mL, *or*
  - 5% Dextrose/0.2% sodium chloride injection with sodium bicarbonate 100–125 mEq/1000 mL, *or*
  - 5% Dextrose injection with sodium bicarbonate 125–150 mEq/1000 mL
- Potassium is NOT added to parenteral hydration solutions during the first few days of induction therapy unless serum potassium decreases to <3.0 mEq/dL
- Furosemide 20–40 mg; administer intravenously every 12–24 hours to maintain fluid balance
- Diuresis is maintained for at least the first 72 hours after starting chemotherapy in the absence of metabolic aberrations, or after metabolic complications normalize
- **Allopurinol** 300 mg/day; administer orally for 7 consecutive days on days 1–7 (longer treatment may be needed)
  - Persons who express a variant human leukocyte antigen allele, HLA-B*58:01, are at increased risk for severe cutaneous adverse reactions from allopurinol (Hershfield MS et al. Clin Pharmacol Ther 2013;93:153–158; Zineh I et al. Pharmacogenomics 2011;12:1741–1749)

R-Hyper-CVAD (odd-numbered cycles; ie, 1, 3, 5, ±7)
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously 30–60 minutes before starting rituximab
Rituximab 375 mg/m² per dose; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration within the range of 1–4 mg/mL on day 1, for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total dosage/cycle = 375 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes, as tolerated, to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes, as tolerated, to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate
- *Patients with evidence of peripheral blood involvement (as determined by flow cytometric analysis at the time of initial presentation) may have their first dose of rituximab delayed or omitted when they are believed to be at risk for tumor lysis syndrome or cytokine-release syndrome*

Cyclophosphamide 300 mg/m² per dose; administer intravenously in 500 mL 0.9% NS over 3 hours, every 12 hours for 6 doses, on days 2, 3, and 4, for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total dosage/cycle = 1800 mg/m²)
Mesna 600 mg/m² per day; administer by continuous intravenous infusion over 24 hours in 1000–2000 mL 0.9% NS on days 2, 3, and 4, starting 1 hour before cyclophosphamide and continuing until 12 hours after the last dose of cyclophosphamide, for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total duration of mesna administration per cycle is approximately 76 hours; total dosage/cycle is approximately 1900 mg/m²)
Vincristine 1.4 mg/m² per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes for 2 doses, 12 hours after the last dose of cyclophosphamide on day 5 and on day 12, for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total dosage/cycle = 2.8 mg/m²; maximum total dose/cycle = 4 mg)
Doxorubicin 16.6 mg/m² per day; administer by continuous intravenous infusion over 24 hours in 25–250 mL 0.9% NS or D5W for 3 consecutive days starting 12 hours after the last dose of cyclophosphamide, on days 5, 6, and 7, for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total dosage/cycle ~50 mg/m²)
Dexamethasone 40 mg/day; administer orally or intravenously in 25–150 mL 0.9% NS or D5W over 15–30 minutes for 8 doses, on days 2–5 and days 12–15 for 3–4 cycles, cycles 1, 3, 5 (±7). Cycle duration is 21 days (total dosage/cycle = 320 mg)

R-MC (even-numbered cycles; ie, 2, 4, 6, ±8)
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

(*continued*)

(*continued*)

Rituximab 375 mg/m² per dose; administer intravenously in 0.9% NS or D5W diluted to a concentration within the range of 1–4 mg/mL on day 1 for 3–4 cycles, cycles 2, 4, 6 (±8). Cycle duration is 21 days (total dosage/cycle = 375 mg/m²)

Notes on rituximab administration:

- Infuse initially at 100 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 100 mg/h every 30 minutes, as tolerated, to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes, as tolerated, to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Hydration with 2500–3000 mL/day, as tolerated; administer intravenously at 100–125 mL/hour

Notes:

- Sodium bicarbonate is added to parenteral hydration solutions in the presence of plasma uric acid >9 mg/dL to maintain urine pH ≥7.0, but pH <8. The choice of hydration fluid and amount of sodium bicarbonate added to the fluid should NOT EXCEED the sodium concentration present in 0.9% sodium chloride injection (154 mEq/L); for example:
  - 5% Dextrose/0.45% sodium chloride injection with sodium bicarbonate 50–75 mEq/1000 mL, *or*
  - 5% Dextrose/0.2% sodium chloride injection with sodium bicarbonate 100–125 mEq/1000 mL, *or*
  - 5% dextrose injection with sodium bicarbonate 125–150 mEq/1000 mL

Methotrexate 200 mg/m²; administer intravenously in 250 mL to >1000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 2 hours, *followed by:*

Methotrexate 800 mg/m²; administer intravenously in 250 mL to >1000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 22 hours, on day 2, for 3–4 cycles, cycles 2, 4, 6 (±8). Cycle duration is 21 days (total dosage/cycle [not including intrathecal methotrexate] = 1000 mg/m²)

Notes on methotrexate administration:

- Patients with an initial serum creatinine level >1.5 mg/dL (>133 μmol/L), reduce the dose of methotrexate by 50%
- Patients with evidence of third spacing of fluids, remove the fluid as completely as possible or, if this is not possible, repeat rituximab plus hyper-CVAD until third spacing of fluid is resolved

Cytarabine 3000 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS or D5W over 2 hours, every 12 hours, for 4 doses, on days 3 and 4, for 3–4 cycles, cycles 2, 4, 6 (±8). Cycle duration is 21 days (total dosage/cycle [not including intrathecal cytarabine] = 12,000 mg/m²)

Notes on cytarabine administration:

- Reduce the cytarabine dose to 1000 mg/m² in patients whose age is ≥60 years and in those with a serum creatinine level >1.5 mg/dL (>133 μmol/L)
- Administer a **1% ophthalmic solution of**, at a rate of 2 drops in each eye 4 times daily, beginning on day 3 at the start of cytarabine infusion and continue for 7 days to prevent chemical conjunctivitis

Leucovorin calcium 50 mg; administer intravenously in 10–100 mL 0.9% NS or D5W over 10–20 minutes, on day 3, 36 hours after methotrexate administration began (12 hours after completing methotrexate), followed 6 hours later by:

Leucovorin calcium 15 mg; administer orally *or* intravenously in 10–100 mL 0.9% NS or D5W over 10–20 minutes, every 6 hours, for 8 doses or until blood methotrexate concentrations is <0.1 μmol/L

If methotrexate elimination is delayed or attenuated, both the dose and administration schedule for leucovorin calcium are escalated, thus:

leucovorin calcium 100 mg/dose intravenously every 3 hours, if serum methotrexate concentrations are:

Time After Methotrexate Administration Began	Serum Methotrexate Concentration
24 hours	>20 μmol/L (>20 × 10^{26} mol/L)
48 hours	>1 μmol/L (>1 × 10^{26} mol/L)
72 hours	>0.1 μmol/L (>1 × 10^{27} mol/L)

If methotrexate elimination is delayed, measure serum methotrexate concentrations at daily intervals and continue leucovorin administration until serum methotrexate concentration is ≤0.05 μmol/L (≤5 × 10^{28} mol/L) or undetectable

Treatment Duration:

- Patients who achieved a CR after the first 2 cycles (1 cycle with rituximab plus hyper-CVAD and 1 cycle with rituximab plus methotrexate and cytarabine) received 4 more cycles, for a total of 6 cycles
- Patients who achieved a partial response (PR) after 2 cycles and a complete remission after 6 cycles received 2 more cycles, for a total of 8 cycles
- Patients with evidence of disease after 6 cycles did not receive further therapy
- Patients whose disease was responding could be referred at any time during treatment for consolidation with stem cell transplantation

Supportive Care

Antiemetic prophylaxis for R-Hyper-CVAD *(cycles 1, 3, 5, ± 7)*

Emetogenic potential on day 1 is ***MINIMAL***

Emetogenic potential on days 2, 3, and 4 is ***MODERATE***

(*continued*)

(*continued*)

Emetogenic potential on days 5, 6, and 7 is ***LOW–MODERATE***
Emetogenic potential on day 12 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Antiemetic prophylaxis for R-MC *(cycles 2, 4, 6, ± 8)*
Emetogenic potential on day 1 is ***MINIMAL***
Emetogenic potential on day 2 is ***MODERATE***
Emetogenic potential on days 3 and 4 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis *(all cycles)*
Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection for 10 days
- Begin use from 24–36 hours after myelosuppressive chemotherapy is completed
- Discontinue daily filgrastim use at least 24 hours before restarting myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:

R-Hyper-CVAD (cycles 1, 3, 5, ±7)		
Antibacterial prophylaxis	**Ciprofloxacin** 500 mg orally, twice daily (or an alternative fluoroquinolone at an equivalent dose and schedule)	Days 8–17 (10 days)
	Cotrimoxazole (160 mg trimethoprim + 800 mg sulfamethoxazole), orally	One dose, 3 days per week, continually throughout all cycles
Antifungal prophylaxis	**Fluconazole** 100 mg/day, orally	Days 8–17 (10 days)
Antiviral prophylaxis	**Valacyclovir** 500 mg/day, orally (or acyclovir or famciclovir at an equivalent dose and schedule)	Days 8–17 (10 days)
R-MC (cycles 2, 4, 6, ±8)		
Antibacterial prophylaxis	**Ciprofloxacin** 500 mg, orally, twice daily (or an alternative fluoroquinolone at an equivalent dose and schedule)	Days 5–14 (10 days)
	Cotrimoxazole (160 mg trimethoprim + 800 mg sulfamethoxazole), orally	One dose, 3 days per week, continually throughout all cycles
Antifungal prophylaxis	**Fluconazole** 100 mg/day, orally	Days 5–14 (10 days)
Antiviral prophylaxis	**Valacyclovir** 500 mg/day, orally (or acyclovir or famciclovir at an equivalent dose and schedule)	Days 5–14 (10 days)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Decreased bowel motility prophylaxis
Give **stool softeners** in a scheduled regimen, and **saline, osmotic, and lubricant laxatives**, as needed to prevent constipation for as long as vincristine use continues. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed to produce defecation

Patient Population Studied

Prior Therapies and Responses to Prior Therapies in 29 Patients with Relapsed or Refractory Mantle Cell Lymphoma

Wang M et al. Cancer 2008;113:2734–2741

Prior Therapies

Therapy	Number of Patients
Median prior no. of regimens (range)	1 (1–5)
Doxorubicin-containing regimens	21
Fludarabine-containing regimens	5
Rituximab-containing regimens	18
Radiotherapy (excluding TBI)	9
Zevalin or Bexxar	2
Rituximab plus hyper-CVAD alternating with rituximab plus methotrexate-cytarabine	4
Autologous stem cell transplantation or TBI	5

Responses to Prior Therapies

	Number of Patients (%)
CR	10 (35)
PR	7 (24)
Less than PR	12 (41)

Bexxar, tositumomab and iodine (^{131}I) tositumomab; TBI indicates total body irradiation; Zevalin, ibritumomab tiuxetan

Patient Characteristics (N = 97)

Romaguera JE et al. J Clin Oncol 2005;23:7013–7023

Characteristic	Number of patients		
	All Ages	≤65 Years	>65 Years
Number of patients	97	65	32
Age, median (range)	61 years (41–80 years)

Large spleen	40	40	41
International Prognostic Index >2	57	34	91

*Fourteen patients had no lymph node to biopsy

Treatment Modifications

Adverse Event	Treatment Modifications
Platelet count 75,000–100,000/mm^3, or an ANC 750–1000/mm^3 on day 21 of a treatment cycle	Delay start of next cycle until platelets >100,000/mm^3 and ANC >1000/mm^3, reevaluating hematologic values every 3 days. Then resume therapy without a decrease in drug dosages
Platelet count was <75,000/mm^3 or ANC was <750/mm^3 on day 21 of a treatment cycle	Delay start of next cycle until platelet count >100,000/mm^3 and ANC >1000/mm^3 reevaluating hematologic values every 3 days. Then resume therapy with a decrease in the dose of cyclophosphamide and doxorubicin (cycles 1, 3, 5, ±7) or methotrexate and cytarabine (cycles 2, 4, 6, ± 8) by 25–50%
Patient age ≥60 years	Reduce cytarabine dosage to 1000 mg/m^2 per dose
Blood methotrexate concentration >20 μmol/L at the start of cytarabine treatment	Reduce cytarabine dosage to 2000 mg/m^2 per dose and reduce methotrexate dosage by 50% in subsequent cycles
Serum creatinine >2 mg/dL (>177 μmol/L)	
Serum creatinine >3 mg/dL (>265 μmol/L)	Reduce methotrexate dosage by 75%
Delayed methotrexate excretion or nephrotoxicity attributable to previous methotrexate treatment	Reduce methotrexate dosage by 50–75% (commensurate with the severity of nephrotoxicity)
Total bilirubin >2 g/dL (>34.2 μmol/L)	Reduce vincristine dose to 1 mg/dose
Total bilirubin 2–3 g/dL (34.2–51.3 μmol/L)	Reduce doxorubicin dosage by 25%
Total bilirubin 3–4 g/dL (51.3–68.4 μmol/L)	Reduce doxorubicin dosage by 50%

(continued)

Efficacy

Response Rates Among 29 Patients with Relapsed or Refractory Mantle Cell Lymphoma

Wang M et al. Cancer 2008;113:2734–2741

Response	Number (%)
Complete response/unconfirmed complete response	13 (45)
Partial response	14 (48)
Complete response/unconfirmed complete response + Partial response	27 (93)
No benefit	2 (7)

Failure-free and Overall Survival

Median failure-free survival (FFS)*	11 months
Median overall survival (OS)	19 months

**Note:* No pretreatment variable (number of prior chemotherapy regimens, response to the previous regimen, pretreatment serum levels of β_2-microglobulin or LDH, and age) was associated with better FFS

Romaguera JE et al. J Clin Oncol 2005;23:7013–7023

CR/CRu Rates After 6 Courses

Variable	CR/CRu Response Rate (%) [95% CI (%)]			$\chi^2 P$
Overall	**87 [79 to 93]**			
High serum β_2M: No vs. Yes	98 [88 to 100]	vs.	79 [66 to 89]	0.01

β_2M, β_2-microglobulin; BM, bone marrow; CR, complete response; CRu, complete response unconfirmed; FFS, failure-free survival; LDH, lactate dehydrogenase; IPI, International Prognostic Index; OS, overall survival

Treatment Modifications (*continued*)

Adverse Event	Treatment Modifications
Total bilirubin >4 g/dL (>68.4 μmol/L)	Reduce doxorubicin dosage by 75%
Disease involving the stomach or small bowel	Eliminate doxorubicin during the first hyper-CVAD cycle
If cytarabine is eliminated because of adverse effects	Omit the high-dose methotrexate + cytarabine regimen, replacing it with repeated cycles of hyper-CVAD
Peripheral neuropathy	Discontinue vincristine
Proximal myopathy	Discontinue dexamethasone
Cerebellar neurotoxicity	Reduce cytarabine dosage or omit cytarabine during subsequent treatments
G3 mucositis	Reduce methotrexate dosage

Cycles with Dose Reductions According to Age and Regimen

Romaguera JE et al. J Clin Oncol 2005;23:7013–7023

Age/ Regimen	Number of Patients	Number of Cycles	Reduced Cycles		*P* Value
			Number	%	
Patient age					
All ages	97	602	142	24

Stomatitis	5	6	0	0
Constipation	4	11	0	0
Vomiting	4	10	0	0

Hematologic Toxic Effects After 602 Courses

Romaguera JE et al. J Clin Oncol 2005; 23:7013–7023

Course Number	Neutropenia (%)		Thrombocytopenia (%)	
	G3	G4	G3	G4
1	10	51	12.5	2
2	7	64	9	28
3	7	28	23	14
4	5	64	9	42
5	7	31	17	12
6	3	68	5	46
7	14	37	15	17
8	4	55	7	50

Nonhematologic Toxic Effects After 602 Cycles

G3/4 Toxic Effect	Number of Events (%)
Neutropenic fever*	80 (13)
R-hyper-CVAD	20†
R-MC	60†
Infection*	35 (6)
Bacteremia	20 (3)
Pneumonia	6 (1)
Other	9 (1.5)
Fatigue	18 (3)
Stomatitis	6 (1)
Bleeding	3 (0.5)
Pancreatitis	1 (0.1)
Kidney failure	1 (0.1)
CNS	1 (0.1)

R-hyper-CVAD, rituximab plus fractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone; R-MC, rituximab plus methotrexate and cytarabine
*No difference for patients ≤65 years vs. patients >65 years
†$P = 0.00001$
Note: Lethal acute toxicity occurred in five patients: sepsis in 3 patients (*Staphylococcus aureus*, *Escherichia coli*, *Proteus mirabilis*); pulmonary hemorrhage in 1 patient; unknown cause in 1 patient

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, LFTs, serum BUN, creatinine, and urinalysis
2. *Daily during treatment:* serum electrolytes, glucose, BUN, creatinine, total bilirubin, LFTs, LDH, uric acid, albumin, alkaline phosphatase, and CBC with differential
3. *Daily following high-dose systemic methotrexate administration:* methotrexate levels
4. *Response assessment every 2 cycles:* CT of the chest, abdomen, and pelvis; gallium scan or PET, and bilateral bone marrow biopsy with unilateral aspiration

   Note: To confirm CR, esophagogastroduodenoscopy and colonoscopy were performed, with biopsies performed randomly
5. *Response assessment upon completion of therapy:* CT of the chest, abdomen, and pelvis every 3 months during the first year, every 4 months during the second year, every 6 months during the third and fourth years, and yearly thereafter

REGIMEN

BORTEZOMIB

Fisher RI et al. J Clin Oncol 2006;24:4867–4874
Goy A et al. Ann Oncol 2009;20:520–525

Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 21 days for up to 17 cycles or four cycles beyond initial reporting of CR/CRu (total dosage/cycle = 5.2 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Baseline Patient and Disease Characteristics

(N = 155, unless otherwise noted)

Characteristic	Patients Number (%)
Sex, Male	125 (81)
Race/ethnicity	
White	142 (92)
Black	6 (4)
Hispanic	4 (3)
Asian or Pacific Islander	3 (2)
Age, median (range)	65 years (42–89 y)
KPS, <90%	44/153 (29)
IPI, ≥3	65/147 (44)
LDH > ULN	54/149 (36)

(continued)

Dose Modifications

Bortezomib Dose Levels

Starting dose	1.3 mg/m² per dose on days 1, 4, 8, and 11
Level −1	1 mg/m² per dose on days 1, 4, 8, and 11
Level −2	0.7 mg/m² per dose on days 1, 4, 8, and 11
Level −3	1.3 mg/m² per dose on days 1 and 8

Adverse Event	Treatment Modifications
G3 thrombocytopenia (platelet count <50,000/mm³)	Reduce bortezomib dosage by 1 dose level
G ≥3 neutropenia with fever, or G4 neutropenia lasting longer than 7 days,	Hold treatment until toxicity resolves to G ≤1, then resume with bortezomib at 1 dose level lower
G3 nonhematologic toxicity or G4 hematologic toxicity	
Second occurrence of G3 nonhematologic toxicity or G4 hematologic toxicity	

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy

Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage 1 dose level
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate reducing bortezomib dosage 1 dose level
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

Efficacy

Median Efficacy Values in Months (95% confidence interval)

	All Patients (N = 155)	CR/Cru + PR (N = 45)*	CR/Cru (N = 11)*	PR (N = 34)*	SD (N = 52)*	PD (N = 34)*

REGIMEN

LENALIDOMIDE

Goy A et al. J Clin Oncol 2013;31:3688–3695

Lenalidomide; administer orally for 21 consecutive days on days 1–21, every 28 days

Note: The investigators based lenalidomide dose on a patient's renal function, thus:

	Lenalidomide Doses	
Creatinine Clearance	**Daily Dose**	**Total Weekly Dose**
≥60 mL/min (≥1 mL/s)	25 mg/day	175 mg
≥30 to <60 mL/min (≥0.5 to <1 mL/s)	10 mg/day	70 mg

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with risk factors related to treatment

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013 (Accessed October 8, 2013, at www.nccn.org)

Individual Risk Factors	
• Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia	For patients at low thromboembolic risk with ≤1 Individual risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual risk factors present: • **LMWH,* equivalent to enoxaparin sodium 40** mg/day *or* **dalteparin sodium** 5000 IU/day, subcutaneously, *or* • **Warfarin,** targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-factor Xa concentrations

Lenalidomide Dose Levels

Starting dose	25 mg/day
Level −1	20 mg/day
Level −2	15 mg/day
Level −3	10 mg/day
Level −4	5 mg/day
Level −5	Discontinue

Adverse Event (AE)	Treatment Modifications
G ≥2 allergic reaction or hypersensitivity	Hold lenalidomide dosing for up to 21 days to allow toxicity to resolve, then restart at the same dose or reduce the lenalidomide dosage by 1 dose level
>3× upper limit of normal AST, ALT, or bilirubin	
G ≥1 tumor lysis syndrome	
G ≥3 neutropenia for ≥7 days or associated with fever (≥38.5°C [≥101.3°F])	
Platelets <50,000/mm^3	
Constipation	
Venous thrombosis/embolism	
New peripheral neuropathy	
Lenalidomide-related nonhematologic AE	
Tumor flare reaction	
G3/4 neutropenia	Hold lenalidomide dosing for up to 21 days to allow toxicity to resolve to G ≤2, then restart at the same dose or reduce the lenalidomide daily dose by 1 dose level
Febrile neutropenia (ANC <1000/mm^3 with fever ≥38°C [≥101.3°F])	
Desquamating (blistering) rash (or G4 non-desquamating rash	
Any AE G ≥3 excluding nausea, vomiting, diarrhea, or lenalidomide-induced maculopapular rash	
G ≥3 nausea, vomiting, or diarrhea despite maximal therapy	
G4 fatigue lasting >7 days	

Patient Population Studied

Characteristic	Number of Patients	Percent
Age—median (range)	67 years (43–83 years)	
≥65 years	85	63
Male	108	81
Stage III to IV	124	93

Positive bone marrow involvement†	55	41
High tumor burden‡	77	57
Bulky disease§	44	33
Number of prior treatment regimens—median (range)	4 (2–10)	
Number of prior systemic therapies: 2/3/≥4	29/34/71	22/25/53
Prior bortezomib: Received/Refractory	134/81	100/60
Refractory to last therapy	74	55
Prior high-dose or dose-intensive therapy¶	44	33
Prior ABMT or ASCT	39	29
Time from prior systemic therapy—median (range)	3.1 months (0.3–37.7 months)	
<6 months/≥6 months	96/38	72/28

ABMT, autologous bone marrow transplantation; ASCT, autologous stem cell transplantation; ECOG PS, Eastern Cooperative Oncology Group performance status; MCL, mantle cell lymphoma; MIPI, MCL International Prognostic Index

*Moderate renal insufficiency was defined as creatinine clearance (CrCl) ≥30 to <60 mL/min; severe renal insufficiency defined as CrCl <30 mL/min

†Bone marrow involvement was not required per protocol; prior data for bone marrow biopsy and aspirate were collected in 115 evaluable patients

‡Defined as at least 1 lesion ≥5 cm in diameter, or ≥3 lesions that were ≥3 cm in diameter by central radiology review

§Defined as at least 1 lesion ≥7 cm in diameter by central radiology review

¶Includes stem cell transplantation, hyper-CVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, dexamethasone), or R-hyper-CVAD (rituximab plus hyper-CVAD)

Efficacy

*One G5 event per AE
† Two G5 events

Treatment Monitoring

1. CBC with differential day 1
2. CT scans every 2 cycles
3. Confirmatory bone marrow aspirate and unilateral biopsy for patients achieving CR (by CT)

REGIMEN

(Older Patients)

RITUXIMAB + FLUDARABINE + CYCLOPHOSPHAMIDE (R-FC) *OR* RITUXIMAB + CYCLOPHOSPHAMIDE + DOXORUBICIN + VINCRISTINE + PREDNISONE (R-CHOP)

Kluin-Nelemans HC et al. N Engl J Med 2012;367:520–531

Notes:
- Induction therapy consisted of either R-FC or R-CHOP open-label chemoimmunotherapy
- Rituximab was added to the chemotherapy when the count of circulating lymphoma cells was $<10 \times 10^9$/L ($<10{,}000/mm^3$)

R-FC Regimen:
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m² (maximum single dose, 750 mg); administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration of 1–4 mg/mL on day 1, every 28 days for 6 cycles (total dosage/cycle = 375 mg/m²; maximum dose/cycle = 750 mg)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Fludarabine 30 mg/m²; administer intravenously in 100–125 mL 0.9% NS or D5W over 30 minutes for 3 consecutive days, days 1–3, every 28 days for 6 cycles (total dosage/cycle = 90 mg/m²)
Cyclophosphamide 250 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 30 minutes for 3 consecutive days, days 1–3, every 28 days for 6 cycles (total dosage/cycle = 750 mg/m²)

R-CHOP Regimen:
Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m² (maximum single dose, 750 mg); administer intravenously on day 1, every 21 days for 8 cycles (total dosage/cycle = 375 mg/m²; maximum dose/cycle = 750 mg)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Cyclophosphamide 750 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 30 minutes on day 1, every 21 days for 8 cycles (total dosage/cycle = 750 mg/m²)
Doxorubicin 50 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 8 cycles (total dosage/cycle = 50 mg/m²)
Vincristine 1.4 mg/m² (maximum single dose, 2 mg); administer by intravenous injection over 1–2 minutes on day 1, every 21 days, for 8 cycles (total dosage/cycle = 1.4 mg/m²; maximum dose/cycle = 2 mg)
Prednisone 100 mg; administer orally for 5 consecutive days, on days 1–5, every 21 days, for 8 cycles (total dose/cycle = 500 mg)

Supportive Care
Antiemetic prophylaxis: R-FC regimen
*Emetogenic potential is **MODERATE** on days 1–3*
Antiemetic prophylaxis: R-CHOP regimen
*Emetogenic potential is **HIGH**. Potential for delayed emetic symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours

(*continued*)

(*continued*)

- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Steroid-associated gastritis

Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Decreased bowel motility prophylaxis

Give **stool softeners** in a scheduled regimen, and **saline, osmotic, and lubricant laxatives**, as needed to prevent constipation for as long as vincristine use continues. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed to produce defecation

Treatment Modification

Adverse Event	Treatment Modifications
G2 neuropathy	Reduce the dose of vincristine by 25%
G3 neuropathy	Reduce the dose of vincristine by 50%
G4 neuropathy	Discontinue vincristine
WBC <4000/mm^3 or platelet count <100,000/mm^3 on day 1 of a cycle	Delay start of next cycle by 1 week. Then, if WBC >4000/mm^3 and platelet count >100,000/mm^3, resume therapy
Persistent cytopenias with WBC 2000–3000/mm^3 and platelet count >100,000/mm^3 after a 1-week treatment delay	Start the next cycle but reduce fludarabine, cyclophosphamide, and doxorubicin dosages by 75%
Persistent cytopenias WBC 1000–2000/mm^3 and platelet count 50,000–100,000/mm^3 after a 1-week treatment delay	Resume next cycle but reduce the doses of fludarabine, cyclophosphamide, and doxorubicin dosages by 50%
Persistent cytopenias with WBC <1000/mm^3 and platelet count <50,000/mm^3 after a 1-week treatment delay	Discontinue therapy
WBC nadir <1000/mm^3 and/or platelet nadir <50,000/mm^3	Decrease fludarabine, cyclophosphamide, and/or doxorubicin dosages by 25%

Baseline Characteristics

Characteristic	Total (N = 485)	R-FC (N = 246)	R-CHOP (N = 239)
Age—median (range)	70 years (60–87 years)	70 years (60–83 years)	70 years (61–87 years)
Male sex—no. (%)	340 (70)	178 (72)	162 (68)
Ann Arbor stage—no. (%)			
II	30 (6)	18 (7)	12 (5)
III	55 (11)	30 (12)	25 (10)
IV	400 (82)	198 (80)	202 (85)
Systemic symptom—no. (%)*	182 (38)	93 (38)	89 (37)
ECOG performance status of 2—no. (%)†	39 (8)	21 (9)	18 (8)
Bone-marrow involvement—no. (%)	364 (75)	182 (74)	182 (76)
LDH elevation—no. (%)	206 (42)	104 (42)	102 (43)
Median ratio of LDH activity to ULN	0.94	0.93	0.95
Median leukocyte count—$\times 10^{-9}$/L	7.8	7.7	7.9
MIPI‡			
Median score	6.20	6.20	6.18
Low risk—no. (%)	42 (9)	24 (10)	18 (8)
Intermediate risk—no. (%)	201 (41)	98 (40)	103 (43)
High risk—no. (%)	242 (50)	124 (50)	118 (49)

LDH denotes lactate dehydrogenase; R-CHOP rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone; R-FC rituximab, fludarabine, and cyclophosphamide; ULN upper limit of the normal range

*Systemic symptoms were defined as B symptoms in the Ann Arbor classification

†Scores on the Eastern Cooperative Oncology Group (ECOG) performance status range from 0 to 5, with 0 indicating asymptomatic, 1 symptomatic but ambulatory, and 2 symptomatic and in bed less than half the day; 5 indicates death

‡The Mantle-Cell Lymphoma International Prognostic Index (MIPI) score is calculated from the individual patient characteristics of age, ECOG performance status, LDH, and leukocyte count, and its range depends on the range of these characteristics. Scores range from 0 to 11, with higher scores indicating higher-risk disease. The index classifies patients as having low-, intermediate-, or high-risk disease

Toxicity*

G3/4	4	6
Infection		
G1/2	18	31
G3/4	17	14‡
Myalgia or arthralgia		
G1/2	9	12
G3/4	0	3†
Febrile neutropenia¶	11	17

*Adverse events were graded according to the National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm (accessed December 7, 2013). The maximal grade is the highest grade of adverse event that a patient had during the treatment period; patients were included only in the percentage for the highest grade of event they had. The following events were associated with no significant difference between the 2 induction regimens or between the 2 maintenance regimens and were grades 3 or 4 in none to 8% of patients: elevated creatinine, elevated aminotransferases, vomiting, diarrhea, mucositis, decreased cardiac function, decreased pulmonary function, depression, allergy, weight loss, and bleeding

†P <0.05 for adverse events of maximal grade 0 versus G1/2 versus G3/4 for R-FC versus R-CHOP

‡P <0.01 for adverse events of maximal grade 0 versus G1/2 versus G3/4 for R-FC versus R-CHOP

§P <0.001 for adverse events of maximal grade 0 versus G1/2 versus G3/4 for R-FC versus R-CHOP

¶This adverse event was graded only within the G3 and G4 categories

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistries; CT scan of the chest, abdomen, and pelvis; and bone marrow aspiration and biopsy as indicated. If clinically relevant, endoscopy of the gastrointestinal tract is done
2. *Weekly:* CBC with differential and platelet count once weekly
3. *Assessment of efficacy:* CT scan or sonographic examination at 2- or 3-cycle intervals after and at the end of treatment in MCL

REGIMEN

CYCLOPHOSPHAMIDE + DOXORUBICIN + VINCRISTINE + ETOPOSIDE + PREDNISOLONE (CHOEP)

Pfreundschuh M et al. Ann Oncol 2008;19:545–552
Schmitz et al. Blood 2010;116:3418–3425

Hydration with 500–1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously before starting cyclophosphamide administration and 500–1000 mL 0.9% NS after completing cyclophosphamide
Cyclophosphamide 750 mg/m^2; administer intravenously in 25–250 mL 0.9% NS or 5% dextrose injection (D5W) over 30 minutes on day 1, every 21 days (total dosage/cycle = 750 mg/m^2)
Doxorubicin 50 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 21 days (total dosage/cycle = 50 mg/m^2)
Vincristine 2 mg; administer by intravenous injection over 1–2 minutes on day 1, every 21 days (total dose/cycle = 2 mg)
Etoposide 100 mg/m^2 per day; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.2–0.4 mg/mL over 60 minutes for 3 consecutive days, on days 1–3, every 21 days (total dosage/cycle = 300 mg/m^2)
Prednisolone *or* **prednisone** 100 mg/day; administer orally for 5 consecutive days, on days 1–5, every 21 days (total dose/cycle = 500 mg)
Notes:

- Prednisolone and prednisone may be used interchangeably at the same dose and administration schedule
- In the study reported by Pfreundschuh et al., patients were to receive radiotherapy (36 Gy) to sites of primary bulky and extranodal disease, and 85% of patients received radiotherapy according to protocol

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days 2 and 3 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Patient Population Studied

A total of 343 patients with mature nodal or extranodal T-cell or NK-cell lymphoma who were enrolled on several protocols of the German High-Grade Non-Hodgkin Lymphoma Study Group between October 1993 and May 2007. Of 343 patients, 320 could be assigned to 1 of the following subtypes:

Anaplastic large cell lymphoma kinase-positive, ALK-positive (ALCL, ALK-positive)	78 (24.4%)
Anaplastic large cell lymphoma kinase-positive, ALK-negative (ALCL, ALK-negative)	113 (35.3%)
Peripheral T-cell lymphoma unspecified (PTCLU)	70 (21.9%)
Angioimmunoblastic T-cell lymphoma (AITL)	28 (8.8%)
NK/T-cell lymphoma	19 (5.9%)
Lymphoblastic lymphoma	7 (2.2%)
Enteropathy-type T-cell lymphoma	2 (0.6%)
Hepatosplenic gamma/delta (γ/δ) T-cell lymphoma	2 (0.6%)
Subcutaneous panniculitis-like T-cell lymphoma	1 (0.3%)

- All patients were treated on either phase II or phase III trials. The phase II studies were dose-finding studies using escalating doses of cyclophosphamide, doxorubicin, and etoposide compared with standard CHOP plus etoposide protocols. The phase III trials compared the standard CHOP regimen to 6 or 8 courses of CHOP given every 2 weeks (CHOP-14) or to CHOP plus etoposide (CHOEP-14 or -21), or compared CHOEP to a dose-escalated (Hi-CHOEP), or a mega-dose (Mega CHOEP) variant, the latter regimen necessitated repeated transplantation of hematopoietic stem cells
- Radiotherapy to sites of bulky disease (>7.5 cm) and to extranodal disease was part of all protocols except for the Mega CHOEP phase II trial where radiotherapy was optional
- Extranodal disease was common in all subtypes (41–56%)
- Highly significant ($P < 0.001$) differences were seen for involvement of soft tissues (21% in ALK-positive ALCL, 8% in ALK-negative ALCL, 0–1% in other subtypes) and bone marrow (none in ALK-positive ALCL, 4% in ALK-negative ALCL, 11% in PTCLU, 27% in AITL, and 13% in other subtypes) when the 4 major subgroups were compared

Treatment Modification

Adverse Event	Treatment Modifications
G4 ANC or febrile neutropenia after any cycle	Administer filgrastim during subsequent cycles
G4 neutropenia during a cycle in which filgrastim was administered	Cyclophosphamide, doxorubicin, and etoposide dosages are reduced by 25–50% during subsequent cycles
G3/4 thrombocytopenia	Cyclophosphamide, doxorubicin, and etoposide dosages are reduced by 25–50% during subsequent cycles
ANC <1500/mm^3 or platelets <100,000/mm^3 on day 1 of a scheduled cycle	The cycle is delayed for up to 2 weeks. Treatment is stopped if recovery has not occurred after a 2-week delay

Efficacy (N = 289)

(Median Follow-up of 43.8 Months for the Whole Group)

	ALK-positive ALCL (N = 78)	ALK-negative ALCL (N = 113)	PTCLU (N = 70)	AITL (N = 28)	NK/T (N = 19)
3-Year EFS % (95% CI)	75.8% (65.8%–85.8%)	45.7% (36.3%–55.1%)	41.1% (29.5%–52.7%)	50.0% (31.6%–68.4%)	36.1% (14.1%–58.1%)
3-Year OS % (95% CI)	89.8% (82.5%–97.1%)	62.1% (52.9%–71.3%)	53.9% (41.7%– 66.1%)	67.5% (50.1%–84.9%)	46.3% (23.4%–69.2%)

Younger Patients (<60 years) with Normal LDH NHLB1 Trial*

	CHOP (N = 41)	CHOEP (N = 42)	
3-Year EFS % (95% CI)	75.4% (62.1%–88.7%)	51.0% (35.7%–66.3%)	$P = 0.003$
3-Year OS % (95% CI)	—	—	$P = 0.176$

Younger Patients (<60 years) with Normal LDH NHLB1 Trial + Hi-CHOEP Phase II/II Trials*

	CHOP (N = 41)	CHOEP (N = 103)	
3-Year EFS % (95% CI)	51.0% (35.7%–66.3%)	70.5% (61.3%–79.7%)	$P = 0.004$
3-Year OS % (95% CI)	75.2% (61.9%–88.5%)	81.3% (73.5%–89.1%)	$P = 0.285$

ALK-positive ALCL

	CHOP (N = 12)	CHOEP (N = 34)	
3-Year EFS	57.1% (28.5%–85.7%)	91.2% (81.6%–100.0%)	$P = 0.012$

AITL, angioimmunoblastic T-cell lymphoma; ALK-negative ALCL, anaplastic large cell lymphoma kinase ALK-negative; ALK-positive, ALCL, anaplastic large cell lymphoma kinase ALK-positive; CI, confidence interval; EFS, event-free survival; NK/T, NK-/T-cell lymphoma; PTCLU, peripheral T-cell lymphoma, unspecified; OS, overall survival
*In patients >60 years of age, 6 courses of CHOP administered every 3 weeks remains the standard therapy

Toxicity

(N = 194)

Pfreundschuh M et al. Ann Oncol 2008;19:545–552

Leukocytopenia	87.2%
Thrombocytopenia	9.6%
Anemia	11.8%
Infection	10.8%
Polyneuropathy	3.3%
Mucositis	2.7%
Cardiac toxicity	0.5%
Renal toxicity	0
Lung toxicity	0
Nausea or vomiting	4.8%
Alopecia	69.8%
Therapeutic Interventions	
Red blood cell transfusions (per patient/per cycle)	11.2/4.1
Platelet transfusion (per patient/per cycle)	2.1/0.4
Intravenous antibiotics (per patient/per cycle)	32.6/8.7

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistries; CT scan of the chest, abdomen, and pelvis and bone marrow aspiration and biopsy as indicated
2. *Before each cycle:* CBC with differential and platelet count
3. *Assessment of efficacy:* Radiographic examination at 2- or 3-cycle intervals and at the end of treatment

REGIMEN

ROMIDEPSIN

Coiffier B et al. J Clin Oncol 2012;30:631–636

Romidepsin 14 mg/m² per dose; administer intravenously in 500 mL 0.9% sodium chloride injection over 4 hours for 3 doses, on days 1, 8, and 15, every 28 days for up to 6 cycles (total dosage/cycle = 43.2 mg/m²)

Notes:

- Check serum magnesium and serum potassium before each dose to ensure serum magnesium ≥1.5 mg/dL and serum potassium ≥4 mEq/L. Supplement potassium and magnesium in all patients BEFORE administering romidepsin if laboratory results do not meet these criteria
- In the study, patients with stable disease (SD), partial response (PR), or CR/CRu could continue to receive romidepsin until they demonstrated disease progression (PD) or met another criterion for withdrawal

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **LOW–MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Decreased bowel motility prophylaxis

Give a bowel regimen to prevent constipation based initially on **stool softeners,** and **saline, osmotic, and lubricant laxatives,** as needed to prevent constipation for as long as romidepsin use continues. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed to produce defecation

Treatment Modifications

Adverse Event	Treatment Modifications
G2/3 nonhematologic toxicities except alopecia	Withhold treatment with romidepsin until toxicity returns to G ≤1 or baseline. Resume romidepsin therapy at 14 mg/m² per dose
Recurrent G3 nonhematologic toxicities	Withhold treatment with romidepsin until toxicity returns to G ≤1 or baseline. Resume romidepsin therapy at 10 mg/m² per dose. Do not attempt to escalate the dose
G4 nonhematologic toxicity	Withhold treatment with romidepsin until toxicity returns to G ≤1 or baseline. Resume romidepsin therapy at 10 mg/m² per dose. Do not attempt to escalate the dose
Recurrent G3/4 nonhematologic toxicities after romidepsin 10 mg/m²	Discontinue romidepsin
G3/4 neutropenia or thrombocytopenia	Withhold treatment with romidepsin until the specific cytopenia recovers to ANC ≥1500/mm³ and/or platelet count ≥75,000/mm³ or baseline. Resume romidepsin therapy at 14 mg/m per dose²
Grade 4 febrile (≥38.5°C [101.3°F]) neutropenia	Withhold treatment with romidepsin until the specific cytopenia recovers to G ≤1 or baseline. Resume romidepsin therapy at 10 mg/m² per dose. Do not attempt to escalate the dose
Thrombocytopenia requiring platelet transfusion	

Note: In patients with congenital long QT syndrome, patients with a history of significant cardiovascular disease, and patients taking antiarrhythmic medicines or medicinal products that lead to significant QT prolongation, appropriate cardiovascular monitoring precautions should be considered, such as the monitoring of electrolytes and ECGs at baseline and periodically during treatment

Patient Population Studied

A prospective, single-arm, phase II trial that enrolled patients with PTCL. Patients had relapsed or had disease refractory to one or more systemic therapies. Concomitant use of any other anticancer therapy, drugs that could significantly prolong the QTc interval, moderate-to significant inhibitors of CYP3A4, or therapeutic warfarin were prohibited. Patients were excluded if they had nontransformed mycosis fungoides or Sézary syndrome, or any known significant cardiac abnormalities (eg, congenital long QT syndrome, QTc interval >480 msec, myocardial infarction within previous 6 months, other significant ECG abnormalities, symptomatic coronary artery disease, congestive heart failure, hypertrophic cardiomyopathy or restrictive cardiomyopathy, uncontrolled hypertension, cardiac arrhythmia requiring antiarrhythmic medications, known history of sustained ventricular tachycardia, ventricular fibrillation, torsades de pointes, or cardiac arrest)

Demographic Characteristics at Study Baseline (Histologically Confirmed Population, N = 130)

	Number (%)
Age, years—median (range)	61 (20–83)
Sex–male-to-female ratio	88 (68%)/42 (32%)
White race/ethnicity	116 (89%)
ECOG performance status*	
0	46 (35)
1	66 (51)
2	17 (13)
International Prognostic Index <2/≥2	31 (24%)/99 (76%)
Time since diagnosis, years—median (range)	1.3 (0.2–17.0)
PTCL subtype based on central diagnosis†	
PTCL NOS	69 (53%)
Angioimmunoblastic T-cell lymphoma	27 (21%)
ALK-1–negative ALCL	21 (16%)
Enteropathy-type T-cell lymphoma	6 (5%)
Subcutaneous panniculitis-like T-cell lymphoma	3 (2%)
ALK-1–positive ALCL‡	1 (1%)
Cutaneous gamma/delta T-cell lymphoma	1 (1%)
Extranodal NK/T-cell lymphoma, nasal type	1 (1%)
Transformed mycosis fungoides	1 (1%)
Type of prior systemic therapy	
Chemotherapy	129 (99%)
Monoclonal antibody therapy	20 (15%)
Other type of immunotherapy	14 (11%)
Number of prior systemic therapies—median (range)	2 (1–8)
1	38 (29%)
2	44 (34%)
3	19 (15%)
4	15 (12%)
>4	14 (11%)
Received prior autologous stem cell transplantation	21 (16%)
Refractory to most recent therapy	49 (38%)

ALCL, anaplastic large-cell lymphoma; ALK-1, anaplastic lymphoma kinase-1; NK, natural killer; NOS, not otherwise specified; PTCL, peripheral T-cell lymphoma
*One patient had missing ECOG performance status at baseline
†Also eligible but not enrolled: hepatosplenic TCL
‡Eligible because disease progressed after prior autologous bone marrow transplant

Efficacy (N = 130)

Response Rates*

Best Response Category	
Objective disease response	
(CR/CRu + PR)	38 (29%)
CR/CRu	21 (16%)
CR	19 (15%)
CRu	2 (2%)
PR	17 (13%)
SD	22 (17%)
PD or N/E†	70 (54%)
Time to response, months	
All responders (CR/CRu + PR)—median (range)	1.8 (1.0–4.3)
CR/Cru—median (range)	2.4 (1.6–9.6)
Duration of response in months	
All responders (CR/CRu + PR)—median (range)	11.6 (0.5‡–34.0)‡
CR/Cru—median (range)	N/E (1.2–34.0)‡

CR, complete response; CRu, unconfirmed complete response; N/E, not evaluable; PD, progressive disease; PR, partial response; SD, stable disease
*Based on Investigator Assessment. Comparable to Independent Review Committee
†Insufficient efficacy data to determine response because of early termination (ie, includes patients determined to have PD by investigators prior to first postbaseline assessment and therefore assessed as N/E according to the IRC)
‡Denotes a censored value

CR/CRu Rate and ORR Based on Overall IRC Assessment in Patient Subgroups (Histopathologically confirmed population; N = 130)

Subgroup	Total Number of Patients	CR/CRu Rate	*P* Value	ORR	*P* Value

Stomatitis	13 (10%)	0	9 (7%)	0
Tachycardia	13 (10%)	0	6 (5%)	0

SOC, system organ class (according to Medical Dictionary for Regulatory Activities)
*None of the individual preferred term events in the infections SOC were reported with an incidence ≥10%

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistries; CT scan of the chest, abdomen, and pelvis and bone marrow aspiration and biopsy as indicated
2. *Before each romidepsin dose:* CBC with differential and platelet count; serum electrolytes, including potassium and magnesium
3. *Assessment of efficacy:* radiographic examination at 2- or 3-cycle intervals and at the end of treatment

REGIMEN

PRALATREXATE

O'Connor OA et al. J Clin Oncol 2011;29:1182–1189

Vitamin supplementation to ameliorate mucositis associated with pralatrexate use:

Cyanocobalamin (vitamin B_{12}) 1 mg; administer by intramuscular injection within 2 weeks before the first dose of pralatrexate repeated every 8–10 weeks after previously administered doses

Folic acid 1–1.25 mg/day; administer orally, continually, starting at least 10 days before the first dose of pralatrexate, and continuing for 30 days after the last dose of pralatrexate

Notes:

- Increased methylmalonic acid (>200 nmol/L [>0.2 μmol/L]) or homocysteine (>10 μmol/L) at screening required initiating vitamin supplementation ≥10 days before the first dose of pralatrexate
- Vitamin B_{12} injections may be given on the same day as pralatrexate administration

Pralatrexate 30 mg/m² per dose; administer by intravenous injection over 3–5 minutes once weekly for 6 consecutive weeks followed by 1 week without treatment, every 7 weeks (total dosage/7-week cycle = 180 mg/m²)

Note: Continue treatment until progressive disease (PD) or unacceptable toxicity occurs or at patient/physician discretion

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial brand, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

Patients with PTCL according to the Revised European American Lymphoma WHO disease classification were eligible for study (Harris NL, Jaffe ES, Diebold J et al: Lymphoma classification-from controversy to consensus: The R.E.A.L. and WHO Classification of lymphoid neoplasms. Ann Oncol 2000;11[Suppl 1]:S3--S10). Patients were required to have documented disease progression after ≥1 prior treatment

Additional exclusion criteria included: prior allogeneic stem cell transplant (SCT); relapse <75 days after ASCT

Baseline Characteristics of Patients (N = 111)

Sex, male-to-female ratio	76 (68%)/35 (32%)
Ethnicity	
White	80 (72%)
African American	14 (13%)
Asian	6 (5%)
Hispanic	9 (8%)
Other/Unknown	1 (1%)/1 (1%)
Age, years—mean (range)	55.7 (21–85)
≥65 y	40 (36%)
Number of prior therapies for PTCL—median (range)	3 (1–13)
Number of prior systemic therapies for PTCL—median (range)	3 (1–12)
Type of prior therapy for PTCL	
Local therapy	
Radiation therapy	25 (23%)
Photopheresis	10 (9%)
Topical nitrogen mustard	4 (4%)
Systemic therapy	
CHOP	78 (70%)
Platinum-containing multiagent chemotherapy	45 (41%)
Non–platinum-containing multiagent chemotherapy	43 (39%)
Single-agent chemotherapy	36 (32%)
Autologous stem cell transplant	18 (16%)
Bexarotene	15 (14%)
Other	13 (12%)
Corticosteroids alone	8 (7%)
Hyper-CVAD	8 (7%)
Denileukin diftitox	7 (6%)
Systemic investigational agents	7 (6%)
Histopathology per central review	
PTCL unspecified	59 (53%)
Anaplastic large cell lymphoma, primary systemic type*	17 (15%)
Angioimmunoblastic T-cell lymphoma	13 (12%)
Transformed mycosis fungoides	12 (11%)
Blastic NK lymphoma (skin, lymph node, or visceral involved)	4 (4%)
Other	2 (2%)
T/NK-cell lymphoma nasal	2 (2%)
Extranodal peripheral T/NK-cell lymphoma unspecified	1 (<1%)
Adult T-cell leukemia/lymphoma (HTLV-1+)	1 (<1%)

CHOP, cyclophosphamide, doxorubicin, vincristine, and prednisone; HTLV, human T-lymphotropic virus; ALK, anaplastic lymphoma kinase; Hyper-CVAD, hyperfractionated cyclophosphamide with vincristine, doxorubicin, and corticosteroids; NK, natural killer; PTCL, peripheral T-cell lymphoma

*Eleven ALK-negative, 4 ALK-positive, 2 did not have ALK status determined

Note: Patients treated with corticosteroids alone received other systemic therapies

Dose Modification

Adverse Event	Treatment Modifications
G2 mucositis	Withhold pralatrexate therapy or omit dose. When toxicity recovers to G ≤1, resume pralatrexate therapy at previous dose
Recurrent G2 mucositis G3 mucositis	Withhold pralatrexate therapy or omit dose. When toxicity recovers to G ≤1, resume pralatrexate therapy at 20 mg/m² per week. Do not attempt to escalate dose
G4 mucositis	Discontinue pralatrexate therapy
G3 nonhematologic toxicity	Withhold pralatrexate therapy or omit dose. When toxicity recovers to G ≤1, resume pralatrexate therapy at 20 mg/m² per week. Do not attempt to escalate dose
G4 nonhematologic toxicity	Discontinue pralatrexate therapy
Platelet count <50,000/mm³ for 1 week	Withhold pralatrexate therapy or omit dose. When platelet count >50,000/mm³, resume pralatrexate therapy at previous dose
Platelet count <50,000/mm³ for 2 weeks	Withhold pralatrexate therapy or omit dose. When platelet count >50,000/mm³, resume pralatrexate therapy at 20 mg/m² per week. Do not attempt to escalate dose
Platelet count <50,000/mm³ for ≥3 weeks	Discontinue pralatrexate therapy
ANC 500–1000/mm³ without fever for 1 week	Withhold pralatrexate therapy or omit dose. When ANC >1000/mm³, resume pralatrexate therapy at previous dose

(*continued*)

*Twenty-three percent (n = 26) withdrew from treatment because of AEs, most frequently for mucositis (6%) or thrombocytopenia (5%)
†Included a grouping of similar preferred terms
‡Platelet count <10,000/mm³ was seen in 5 patients
Note: Patients could have >1 adverse event

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistries, as well as methylmalonic acid and homocysteine levels; CT scan of the chest, abdomen, and pelvis and bone marrow aspiration and biopsy as indicated
2. *Before each pralatrexate dose:* CBC with differential and platelet count
3. *Assessment of efficacy:* radiographic examination at 2- or 3-cycle intervals and at the end of treatment

REGIMEN

DOSE-ADJUSTED ETOPOSIDE + PREDNISONE + VINCRISTINE + CYCLOPHOSPHAMIDE + DOXORUBICIN + RITUXIMAB (DA-EPOCH-R)

Dunleavy K et al. New Engl J Med 2013;369:1915–1925

Prophylaxis against hyperuricemia during cycle 1: **Allopurinol** 600 mg; administer orally for 1 dose 24 hours before administering antineoplastic treatment, *and then:*
Allopurinol 300 mg/day; administer orally for 6 consecutive days, on days 2–7
Notes:
- Monitor chemistries (uric acid, potassium, phosphorus, calcium) for tumor lysis
- The initial 600-mg dose may be replaced by a 300-mg dose in patients who are already receiving allopurinol
- Additional measures, such as hospitalization with aggressive intravenous hydration, were used at investigators' discretion
- Persons who express a variant human leukocyte antigen allele, HLA-B*58:01, are at increased risk for severe cutaneous adverse reactions from allopurinol (Hershfield MS et al. Clin PharmacolTher 2013;93:153–158; Zineh I et al. Pharmacogenomics 2011;12:1741–1749)
  - Consider alternative prophylaxis (rasburicase) in patients at high risk for hyperuricemia, and for treatment

Prednisone 60 mg/m²; administer orally, twice daily for 5 consecutive days, on days 1–5 (10 doses), every 21 days, for 6–8 cycles (total dosage/cycle = 600 mg/m²)
- The first prednisone dose should be given at least 1 hour before rituximab administration begins
- Patients who were unable to ingest oral medications may receive a parenterally administered steroid at a glucocorticoid equivalent dosage for the same number of doses on the same administration schedule (eg, methylprednisolone 48 mg/m² per dose)

Premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally *plus* **diphenhydramine** 25–50 mg; administer orally or intravenously 30–60 minutes before each dose of rituximab
Rituximab 375 mg/m²; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration within the range of 1–4 mg/mL, on day 1, every 21 days, for 6–8 cycles (total dosage/cycle = 375 mg/m²)

Notes on rituximab administration:
- Infuse initially at 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h. Subsequently, if previous administration was well tolerated, start at 100 mg/h and increase by 100 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- Interrupt rituximab administration for fever chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Etoposide + doxorubicin + vincristine "3-in-1" admixture (preparation instructions appear below*)
Etoposide; administer by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days, for 6–8 cycles (see the table below for daily dosage and total dosage/cycle†)
Doxorubicin; administer by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days, for 6–8 cycles (see the table below for daily dosage and total dosage/cycle†)
Vincristine; administer by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days, for 6–8 cycles (total dosage/cycle = 1.6 mg/m²)

Hydration before and after cyclophosphamide administration: Give 0.9% NS (volumes specified below) at 300–500 mL/h

EPOCH Dose Level	Total Volume of Hydration Fluid‡
1 and 2	1000 mL
3, 4, and 5	2000 mL
≥6	2500 mL

Cyclophosphamide 750 mg/m²; administer intravenously in 100–150 mL 0.9% NS or D5W over 30 minutes on day 5 (after completing infusional etoposide + doxorubicin + vincristine), every 21 days for 6–8 cycles (see the table below for dosage specifications†)
Filgrastim 480 mcg/day; administer by subcutaneous injection, daily for 10 consecutive days, on days 6–15, *or* until postnadir ANC is >5000/mm³

*Etoposide + doxorubicin + vincristine "3-in-1" admixtures—preparation, storage, and stability
- To prepare a "3-in-1" admixture with etoposide + doxorubicin + vincristine, dilute all 3 drug products in 0.9% sodium chloride injection (0.9% NS) as follows:

Total Dose of Etoposide	0.9% NS Volume to Use
≤130 mg	500 mL
>130 mg	1000 mL

(*continued*)

(*continued*)

- Admixture with etoposide (base):
  - Etoposide 50 mg/m², doxorubicin hydrochloride 10 mg/m², and vincristine sulfate 0.4 mg/m² admixtures diluted in 0.9% NS to produce an etoposide concentration <250 mcg/mL, in polyolefin-lined infusion bags are stable and compatible for 72 hours at 23°–25°C (73.4°–77°F), and at 31°–33°C (87.8°–91.4°F) when protected from exposure to light (Wolfe JL et al. Am J Health Syst Pharm 1999;56:985–989)
- Admixture with etoposide PHOSphate:
  - Etoposide PHOSphate, doxorubicin hydrochloride, and vincristine sulfate admixtures diluted in 0.9% NS to produce an etoposide concentration <250 mcg/mL, in polyolefin-lined infusion bags are stable and compatible for up to 124 hours at 2°–6°C (35.6°–42.8°F) and 35°–40°C (95°–104°F) in the dark and in regular fluorescent light. In admixtures stored at 35°–40°C (95°–104°F) and exposed to light, the initial drug concentrations decreased slightly, but remained within acceptable concentrations (Yuan P et al. Am J Health Syst Pharm 2001;58:594–598)
- The "3-in-1" admixtures described above will not prevent microbial growth after exposure to bacterial and fungal contamination. With respect to product sterility, expiration dating should be determined by the aseptic techniques used in preparation and local and national guidelines

†EPOCH Dosage Levels:

- At dosage levels 1 through 6, adjustments apply *only* to etoposide, doxorubicin, and cyclophosphamide
- At dosage levels −1 or −2, adjustments apply *only* to cyclophosphamide (20% dosage reductions for each dosage decrement)

	Dosage Levels							
	−2	−1	1	2	3	4	5	6
Drugs	**Daily Dosages (mg/m² · day)**							
Doxorubicin	10	10	10	12	14.4	17.3	20.7	24.8
Etoposide	50	50	50	60	72	86.4	103.7	124.4
Cyclophosphamide	480	600	750	900	1080	1296	1555	1866

	Total Dosage per Cycle (mg/m² · 96 hours)							
Doxorubicin	40	40	40	48	57.6	69.2	82.8	99.2
Etoposide	200	200	200	240	288	345.6	414.8	497.6
Cyclophosphamide	480	600	750	900	1080	1296	1555	1866

†Give half the total volume of fluid is before starting cyclophosphamide administration and give half the total volume after completing cyclophosphamide

Notes:

- Patients received 2 cycles after complete remission was established, for a total of 6–8 cycles
- HIV-positive patients did not receive antiretroviral therapy during chemotherapy
- DA-EPOCH-R was pharmacodynamically dose-adjusted on the basis of the ANC nadir
- Patients without evidence of cerebrospinal fluid (CSF) involvement received prophylactic intrathecal methotrexate 12 mg via lumbar puncture. Intrathecal treatment was administered on days 1 and 5, every 3 weeks (8 doses), during cycles 3, 4, 5, and 6 (total dose/cycle = 24 mg)
- Patients with evidence of CSF involvement received intrathecal treatment with methotrexate 12 mg via lumbar puncture *or* methotrexate 6 mg via an Ommaya reservoir, twice weekly until 2 weeks after CSF samples are cytologically negative for lymphoma *or* for a minimum duration of 4 weeks, then once weekly for 6 weeks, and then once monthly for 6 months

Antiemetic prophylaxis

Emetogenic potential on Days 1–4 is ***LOW***
Emetogenic potential on Day 5 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) use is integral within the R-EPOCH regimen described above

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

(*continued*)

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/h

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/h with close monitoring. Do not increase the administration rate

Steroid-associated gastritis

Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Decreased bowel motility prophylaxis

Give **stool softeners** in a scheduled regimen, and **saline, osmotic, and lubricant laxatives**, as needed to prevent constipation for as long as vincristine use continues. If needed, circumspectly add **stimulant (irritant) laxatives** in the least amounts and for the briefest durations needed to produce defecation

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial brand, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Events*	Treatment Modifications†
Creatinine clearance <50 mL/min (<0.83 mL/s)	At any dosage level, decrease etoposide dosage by 50%. If creatinine clearance recovers to >50 mL/min (>0.83 mL/s), etoposide should be given at 100% of planned dosage level
Previous cycle ANC nadir count ≥500/mm³	Increase etoposide, doxorubicin, and cyclophosphamide dosages by 20% greater than the dosages given during the previous cycle (increase by 1 dosage level)
Previous cycle ANC nadir count <500/mm³ on 1 or 2 measurements	Give the same dosages as last cycle
Previous cycle ANC nadir count <500/mm³ on at least 3 measurements	Reduce etoposide, doxorubicin, and cyclophosphamide dosages by 20% less than the dosages given during the previous cycle (decrease by 1 dosage level)
Previous cycle platelet nadir count <25,000/mm³ on 1 measurement	Continue treatment, but withhold vincristine‡
Total bilirubin >4.0 mg/dL (>68.4 μmol/L)	Reduce vincristine dosage by 75%‡
Total bilirubin >1.5 mg/dL but <3 mg/dL (>25.7 μmol/L but <51.3 μmol/L)	Reduce vincristine dosage by 50%‡
G2 neuropathy	Reduce vincristine dosage by 25%‡
G3 neuropathy	Reduce vincristine dosage by 50%‡

*ANC and platelet values based on twice weekly CBC with differential
†Dosage adjustment *greater than the starting dose levels* applies only to etoposide, doxorubicin, and cyclophosphamide. Dosage adjustment *less than the starting dose levels* applies only to cyclophosphamide
‡Vincristine dosage is increased to 100% if neuropathy resolves to G ≤1 or serum total bilirubin is <1.5 mg/dL (<25.7 μmol/L)

Characteristics of the Patients

Characteristic	All Patients (N = 30)	DA-EPOCH-R (N = 19)	SC-EPOCH-RR (N = 11)

EBER in situ hybridization	6/21 (29)	4/14 (29)	2/7 (29)

DA-EPOCH-R, dose-adjusted infusional therapy with etoposide, doxorubicin, vincristine, with cyclophosphamide, prednisone, and rituximab; ECOG-PS, Eastern Cooperative Oncology Group performance status; EBER, Epstein-Barr virus-encoded RNA; SC-EPOCH-RR short-course infusional therapy with etoposide, doxorubicin, and vincristine, with cyclophosphamide, prednisone, and 2 doses of rituximab; ULN upper limit of the normal range

*Patients may have had more than 1 extranodal site

†Lymphomes malins B (LMB) risk groups are defined as follows:

- Group A includes patients with low-risk disease (resected stage I or abdominal stage II cancer)
- Group B includes those with intermediate-risk disease (patients not in group A or C)
- Group C includes those with high-risk disease (central nervous system involvement, at least 25% blasts in bone marrow, or both characteristics)

(Société Française d'Oncologie Pédiatrique lymphomes malins B (LMB) prognostic categories [Patte C et al. Blood 2007;109:2773–2780])

‡Patients with the immunodeficiency-associated variant may have had HIV infection, the autoimmune lymphoproliferative syndrome, or a deficiency of dedicator of cytokinesis 8

§*P* value = 0.03

‖*P* value = 0.04; *P* value = 0.03

**P* value <0.001; all other *P* values >0.06

Efficacy

Clinical Outcome	Immunodeficiency-associated Burkitt Lymphoma	DA-EPOCH-R (N = 19)	SC-EPOCH-RR (N = 11)
Median duration of follow-up	—	86 months	73 months
Rate of freedom from progression	92%	100% (95% CI, 72–100)	95% (95% CI, 75–99)
Overall survival	92%	90% (95% CI, 60–98)	100% (95% CI, 82–100)

CI, confidence interval; DA-EPOCH-R, dose-adjusted infusional therapy with etoposide, doxorubicin, vincristine, with cyclophosphamide, prednisone, and rituximab; SC-EPOCH-RR short-course infusional therapy with etoposide, doxorubicin, and vincristine with cyclophosphamide, prednisone, and 2 doses of rituximab

None of the patients in either group had a recurrence of disease or died from Burkitt lymphoma. However, 1 patient with primary immunodeficiency-associated Burkitt lymphoma did not have a pathologic complete response and received localized radiotherapy. Acute myeloid leukemia developed in 1 HIV-positive patient 2.5 years after the completion of SC-EPOCH-RR, and the patient died 4 months later

Toxicity

Adverse Events

Event	All Cycles (N = 155)	DA-EPOCH-R Cycles (N = 116)	SC-EPOCH-RR Cycles (N = 39)

Motor impairment	2/30 (7)	2/19 (11)	0/11

NA, not applicable; TLS, Tumor lysis syndrome
*All the gastrointestinal events were G3
†All the sensory-impairment events were G3, and all the motor-impairment events were G2

Treatment Monitoring

1. *Twice weekly:* CBC with differential
2. *At the beginning of every cycle:* CBC with differential and LFTs

REGIMEN

CYCLOPHOSPHAMIDE, VINCRISTINE (ONCOVIN), DOXORUBICIN, METHOTREXATE (CODOX-M) + IFOSFAMIDE, ETOPOSIDE (VP-16), AND CYTARABINE (ARA-C) (I-VAC)

Magrath I et al. J Clin Oncol 1996;14:925–934

Patients are stratified into high-risk and low-risk groups according to extent of disease and LDH at presentation

Findings at Presentation	Treatment Regimen
Low Risk	
A single extraabdominal mass or completely resected abdominal disease, *and* serum LDH <350 units/L or a concentration within institutional normal range	3 Cycles A → A → A
High Risk	
All other patients	4 Cycles A → B → A → B

High- and Low-Risk Patients

Preparation for definitive therapy:

Allopurinol; administer orally or intravenously

- *Initial dosage:* **Allopurinol** 3.3 mg/kg per dose, 3 times daily (daily dosage = 10 mg/kg)
- *Three days after induction treatment commences:* Allopurinol dosage may be decreased to 1.7 mg/kg per dose, 3 times daily (daily dosage = 5 mg/kg)
- *Two weeks after beginning induction treatment:* Allopurinol may be discontinued

Hydration with allopurinol:

3000–4500 mL/m² per day, as tolerated; administer intravenously with a solution containing at least 75 mEq sodium/1000 mL

- **Sodium bicarbonate** is added to parenteral hydration solutions in the presence of plasma uric acid ≥9 mg/dL to maintain urine pH ≥7.0

Notes:

- Discontinue urinary alkalinization after serum uric acid decreases to <8 mg/dL and before starting chemotherapy
- **Potassium** is not added to parenteral hydration solutions during the first few days of induction therapy unless serum potassium decreases to <3.0 mEq/dL
- **Furosemide** 20–40 mg; administer orally or intravenously, is used to ensure that fluid output is consistent with intake
- Diuresis is maintained for at least the first 72 hours after starting chemotherapy in the absence of metabolic aberrations or after metabolic complications have normalized

High-Risk Patients

4 Cycles A → B → A → B

Regimen A: CODOX-M

Cyclophosphamide 800 mg/m²; administer intravenously in 50–100 mL 0.9% sodium chloride (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes, given on day 1, *followed by*:

Cyclophosphamide 200 mg/m² per day; administer intravenously in 50–100 mL 0.9% NS D5W over 15 minutes for 4 consecutive days, on days 2–5 (total dosage/cycle = 1600 mg/m²)

Doxorubicin 40 mg/m²; administer by intravenous injection over 3–5 minutes, given on day 1 (total dosage/cycle = 40 mg/m²)

Vincristine 1.5 mg/m² per dose (maximum single dose is 2.5 mg); administer by intravenous injection over 1–2 minutes, as follows:

- During cycle 1, for 2 doses, on days 1 and 8 (total dosage/cycle = 3 mg/m²; maximum dose/cycle = 5 mg)
- During cycle 3, for 3 doses, on days 1, 8, and 15 (total dosage/cycle = 4.5 mg/m²; maximum dose/cycle = 7.5 mg)

Hydration with methotrexate:

3000 mL/m² per day with a solution containing at least 75 mEq sodium/1000 mL; administer intravenously during methotrexate administration (day 10) and for at least 24 hours afterward. **Sodium bicarbonate** 50–100 mEq/1000 mL is added to the parenteral solution to maintain urine pH ≥7.0

Methotrexate 1200 mg/m²; administer intravenously in 25–250 mL dextrose or saline fluids ± 50–100 mEq sodium bicarbonate over 1 hour on day 10, *followed immediately by*:

Methotrexate 240 mg/m² per hour; administer by continuous intravenous infusion in 250–6000 mL dextrose or saline fluids ± sodium bicarbonate 50–100 mEq/1000 mL over 23 hours on day 10 (total dosage/cycle [not including intrathecal methotrexate] = 6720 mg/m²)

Notes:

- For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration
- Methotrexate administration is discontinued after a total duration of 24 hours without regard for any portion not administered

(*continued*)

(continued)

Calcium leucovorin 192 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 1 hour at 36 hours after methotrexate administration began, *followed 6 hours later by:*
Calcium leucovorin 12 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15 minutes every 6 hours until serum methotrexate concentration is <0.05 µmol/L
Note:
- Calcium leucovorin may be administered orally after completing 1 day of parenteral administration if patients are compliant, not vomiting, and without other potentially mitigating complications

Regimen B: IVAC
Ifosfamide 1500 mg/m² + **mesna** 360 mg/m² per day; administer intravenously in 100–250 mL 0.9% NS or D5W over 1 hour, for 5 consecutive days, on days 1–5 (total ifosfamide dosage/cycle = 7500 mg/m²)
Mesna 360 mg/m² per dose; administer intravenously in 25–150 mL 0.9% NS or D5W over 15 minutes every 3 hours, for 6 doses, starting 3 hours after each ifosfamide + mesna administration is completed (total mesna dosage/day [7 doses/24 hours] = 2520 mg/m²; total mesna dosage/cycle = 12,600 mg/m²)
Etoposide 60 mg/m² per day; administer intravenously in 150 mL 0.9% NS or D5W over 1 hour for 5 consecutive days, on days 1–5 (total dosage/cycle = 300 mg/m²)
Cytarabine 2000 mg/m² per dose; administer intravenously in 150 mL D5W over 3 hours every 12 hours, for 4 doses, on days 1 and 2 (total dosage/cycle = 8000 mg/m²)

Supportive Care
Antiemetic prophylaxis for Regimen A, CODOX-M
Emetogenic potential on days 1 and 10 is ***HIGH***
Emetogenic potential on days 2–5 is ***MODERATE***
Emetogenic potential on days 8 and 15 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Antiemetic prophylaxis for Regimen B, IVAC
Emetogenic potential on days 1–5 is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis after CODOX-M and IVAC
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, starting on day 13 and continuing until the next treatment cycle (ie, when ANC recovers to ≥1000/mm³)
See Chapter 43 for more information

Antimicrobial prophylaxis after CODOX-M and IVAC
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis
Give **stool softeners** and/or laxatives during and after vincristine administration

Intrathecal Medications for Prophylaxis of High-Risk Patients and Treatment of Patients with CNS Disease

Dose in Milligrams Adjusted to Patient's Age in Years (y)			Days of Administration			
			Prophylaxis		Treatment	
≥3 y	2 y	1 y	A	B	A	B
Cytarabine by Lumbar Puncture						
70	50	35	1, 3	—	1, 3, 5	7, 9
Cytarabine by Intraventricular Route						
15	12	9	1, 3	—	1, 3, 5	7, 9
Methotrexate by Lumbar Puncture*						
12	10	8	15	5	15, 17	5
Methotrexate by Intraventricular Route*						
2	1.5	1	15	5	15, 17	5

A, CODOX-M Cycles 1 and 3; B, IVAC cycles 2 and 4
*Calcium leucovorin 12 mg/m² orally for 1 dose at 24 hours after each intrathecal dose of methotrexate

Low-Risk Patients

3 Cycles: A → A → A

Modified regimen A: (modified) CODOX-M

Cyclophosphamide 800 mg/m²; administer intravenously in 50–100 mL 0.9% NS or D5W over 30 minutes, given on day 1, *followed by:*
Cyclophosphamide 200 mg/m² per day; administer intravenously in 50–100 mL 0.9% NS D5W over 15 minutes, for 4 consecutive days, on days 2–5 (total dosage/cycle = 1600 mg/m²)
Doxorubicin 40 mg/m²; administer by intravenous injection over 3–5 minutes, given on day 1 (total dosage/cycle = 40 mg/m²)
Vincristine 1.5 mg/m² per dose (maximum single dose is 2.5 mg); administer by intravenous injection over 1–2 minutes, for 2 doses, on days 1 and 8 (total dosage/cycle = 3 mg/m²; maximum dose/cycle = 5 mg)

Hydration with methotrexate:
3000 mL/m² per day with a solution containing at least 75 mEq sodium/1000 mL; administer intravenously during methotrexate administration (day 10) and for at least 24 hours afterward. **Sodium bicarbonate** 50–100 mEq/1000 mL is added to the parenteral solution to maintain urine pH ≥7.0
Methotrexate 1200 mg/m²; administer intravenously in 25–250 mL dextrose or saline fluids ± 50–100 mEq sodium bicarbonate over 1 hour on day 10, *followed immediately by:*
Methotrexate 240 mg/m² per hour; administer by continuous intravenous infusion in 250–6000 mL dextrose or saline fluids ± sodium bicarbonate 50–100 mEq/1000 mL, over 23 hours on day 10 (total dosage/cycle [not including intrathecal methotrexate] = 6720 mg/m²)
Notes:
- For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration
- Methotrexate administration is discontinued after a total duration of 24 hours without regard for any portion not administered

Calcium leucovorin 192 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 1 hour at 36 hours after methotrexate administration began, *followed 6 hours later by:*
Calcium leucovorin 12 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15 minutes every 6 hours until serum methotrexate concentration is <0.05 µmol/L
Note:
- Calcium leucovorin may be administered orally after completing 1 day of parenteral administration if patients are compliant, are not vomiting, and have no other potentially mitigating complications

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on days 1 and 10 is ***HIGH***
Emetogenic potential on days 2–5 is ***MODERATE***
Emetogenic potential on days 8 and 15 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with
Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, starting on day 13 and continuing until the next treatment cycle (ie, when ANC recovers to ≥1000/mm³)
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis
Give **stool softeners** and/or laxatives during and after vincristine administration

CNS Prophylaxis*

Cytarabine on Day 1/Methotrexate on Day 3

Patient's Age	Cytarabine	Methotrexate
1 year	35 mg	8 mg
2 years	50 mg	10 mg
≥3 years	70 mg	12 mg

*Administer intrathecally by lumbar puncture

Toxicity (N = 41)

	Regimen	Patient's Age (Years)	% of Cycles G3	% of Cycles G4
Neutropenia	A	<18	0	97.6
		≥18	2.2	97.8
	B	<18	0	100
		≥18	0	100
Leukopenia	A	<18	0	97.6
		≥18	4.4	95.6
	B	<18	0	100
		≥18	0	100
Thrombocytopenia	A	<18	17.1	53.7
		≥18	9.3	39.5
	B	<18	14.3	82.9
		≥18	3.7	96.3
Liver function abnormalities	A	<18	24.4	2.4
		≥18	24.4	2.4
	B	<18	5.9	0
		≥18	0	0
Stomatitis	A	<18	26.8	41.5
		≥18	28.9	20
	B	<18	5.7	2.9
		≥18	3.4	0
Documented infection	A	All ages	46.6	
	B		54.5	
Fever of unknown origin	A + B	<18	46.3	
		≥18	32.4	
Septicemia	A + B	<18	22.5	
		≥18	21.6	

Neurologic Adverse Events (N = 41 Patients)

Toxicity	% of Patients
Painful disabling neuropathy	26.8
Marked motor/severe sensory neuropathy	19.5
Severe motor weakness	7.3
Mild-moderate neuropathy	29.3

A, CODOX-M; B, IVAC

Magrath I et al. J Clin Oncol 1996;14:925–934
Weintraub M et al. J Clin Oncol 1996;14:935–940

Efficacy

Complete response	95%
Partial response	5%
Event-free survival	92% at 2 years

Patient Population Studied

A study of 41 previously untreated patients with small noncleaved (Burkitt or Burkitt-like) lymphoma. Thirty-four patients (15 adults + 19 children) were considered to be at high risk by the criteria stated above. Seven patients (5 adults + 2 children) were considered low risk

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, LFTs, serum BUN, creatinine, creatinine clearance, urinalysis
2. *During the first 3–5 days of induction therapy:*
   - *Every 4–6 hours:* Serum creatinine and electrolytes, calcium, and phosphorus
   - *Daily until normal levels are achieved:* LDH
   - *On days of chemotherapy:* CBC with differential, serum creatinine, electrolytes, calcium, and phosphorus
3. *Weekly during the intervals between treatments:* CBC with differential, serum creatinine and electrolytes, calcium, and phosphorus
4. *After high-dose systemic methotrexate administration:* Daily methotrexate levels

Treatment Modifications

Treatment prerequisites:

- Cycles 2, 3, and 4 are started, when possible, on the day that the ANC recovers to ≥1000/mm^3 after prior treatment
- A platelet count ≥50,000/mm^3 without platelet transfusion support is required before starting repeated cycles. If a patient's ANC recovers to ≥1000/mm^3, but the platelet count has not recovered to ≥50,000/mm^3 without platelet transfusion, the patient should continue to receive daily filgrastim until the platelet count recovers to ≥50,000/mm^3
- For CODOX-M, methotrexate is given without regard for blood counts
- Intravenously administered methotrexate is given only if creatinine clearance is >50 mL/min (>0.83 mL/s)

Adverse Event	Dose Modification
Motor weakness or unremitting obstipation	Continue treatment, but hold vincristine. When symptoms resolve, reintroduce vincristine at 50% dosage during subsequent treatments
Severe sensory symptoms	Reduce vincristine dosage by 50% during subsequent treatment
Serum sodium <130 mmol/L	Hold cyclophosphamide. Resume cyclophosphamide after serum sodium recovers to ≥130 mmol/L and change hydration fluid and diluent fluids to 0.9% NS
Hemorrhagic cystitis	Hold cyclophosphamide
Total bilirubin >2.5 mg/dL (42.8 μmol/L)	Reduce doxorubicin dosage by 50%
Total bilirubin >3.0 mg/dL (51.3 μmol/L)	Hold doxorubicin
Cerebellar toxicity	Hold cytarabine
Acute renal failure	Hold ifosfamide

NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

REGIMEN

NHL-BFM 86 (BERLIN-FRANKFURT-MÜNSTER 86)

Reiter A et al. J Clin Oncol 1995;13:359–372

Group B Regimen: Treatment was stratified by stage into 3 arms of different intensity. All patients received a cytoreductive prephase followed by 2 alternating courses of chemotherapy as follows:

B-SRG: Stage I and Completely Resected Stage II	
3 cycles	A → B → A
B-RG: Stage II Nonresected and Stage III	
6 cycles	A → B → A → B → A → B
B-IV/ALL: Stage IV and B-ALL	
6 cycles	AA → BB → AA → BB → AA → BB

Prophylaxis against tumor lysis syndrome during the first cycle:
Hydration with 2400–3000 mL/day, as tolerated, 5% dextrose/0.45% sodium chloride injection (D5W/0.45% NS) with sodium bicarbonate injection 100 mEq/1000 mL; administer intravenously at 100–125 mL/hour (2400–3000 mL/day)

Notes:

- **Sodium bicarbonate** is added to parenteral hydration solutions in the presence of plasma uric acid ≥9 mg/dL to maintain urine pH ≥7.0
- **Potassium** is not added to parenteral hydration solutions during the first few days of induction therapy unless serum potassium decreases to <3.0 mEq/L
- **Furosemide** 20–40 mg; administer intravenously every 12–24 hours to maintain fluid balance

Note: Diuresis is maintained for at least the first 72 hours after starting chemotherapy in the absence of metabolic aberrations or after metabolic complications normalize

Allopurinol; administer orally or intravenously

- *Initial dosage:* **Allopurinol** 3.3 mg/kg per dose 3 times daily (daily dosage = 10 mg/kg)
- *Three days after induction treatment commences:* Allopurinol dosage may be decreased to 1.7 mg/kg per dose 3 times daily (daily dosage = 5 mg/kg)
- *Two weeks after beginning induction treatment:* Allopurinol may be discontinued

Cytoreductive prephase:
Prednisone 30 mg/m² per day; administer orally for 5 consecutive days on days 1–5 (total dosage = 150 mg/m²)
Cyclophosphamide 200 mg/m² per day; administer intravenously in 50–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–60 minutes for 5 consecutive days on days 1–5 (total dosage = 1000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–5 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Additional prophylaxis
Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Course A:
Dexamethasone 10 mg/m² per day; administer orally for 5 consecutive days on days 1–5 (total dosage/course = 50 mg/m²)
Ifosfamide 800 mg/m² per day; administer intravenously in 100–250 mL 0.9% NS or D5W over 1 hour for 5 consecutive days on days 1–5 (total dosage/course = 4000 mg/m²)
Methotrexate 50 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 30 minutes, given on day 1, *followed immediately by*:
Methotrexate 450 mg/m²; administer by continuous intravenous infusion in 250 mL to ≥1000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 23.5 hours on day 1 (total dosage/course [not including intrathecal methotrexate] = 500 mg/m²)
Methotrexate 12 mg*; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course [not including systemic methotrexate] = 12 mg)

(*continued*)

(*continued*)

Cytarabine 30 mg*; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course [not including systemic cytarabine] = 30 mg)
Prednisolone 10 mg; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course = 10 mg)
Leucovorin calcium 15 mg/m² per dose; administer intravenously in 10–250 mL 0.9% NS or D5W over 15–30 minutes for 3 doses at hours 48, 51, and 54 after systemic methotrexate began (total dosage/course = 45 mg/m²)
Cytarabine 150 mg/m² per dose; administer intravenously in 25–500 mL 0.9% NS or D5W over 1 hour every 12 hours, for 4 doses, on days 4 and 5 (total dosage/course [not including intrathecal cytarabine] = 600 mg/m²)
Teniposide 100 mg/m² per day; administer intravenously, diluted in 0.9% NS or D5W to a concentration of 0.1, 0.2, or 0.4 mg/mL, over 1 hour, for 2 consecutive days, on days 4 and 5 (total dosage/course = 200 mg/m²)

Course B:
Dexamethasone 10 mg/m² per day; administer orally for 5 consecutive days on days 1–5 (total dosage/course = 50 mg/m²)
Cyclophosphamide 200 mg/m² per day; administer intravenously in 50–1000 mL 0.9% NS or D5W over 1 hour for 5 consecutive days on days 1–5 (total dosage/course = 1000 mg/m²)
Methotrexate 50 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 30 minutes, given on day 1, *followed immediately by*:
Methotrexate 450 mg/m²; administer by continuous intravenous infusion in 250 mL to ≥1000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 23.5 hours on day 1 (total dosage/course [not including intrathecal methotrexate] = 500 mg/m²)
Methotrexate 12 mg*; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course [not including systemic methotrexate] = 12 mg)
Cytarabine 30 mg*; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course = 30 mg)
Prednisolone 10 mg; administer intrathecally on day 1, 2 hours after systemic methotrexate began (total dose/course = 10 mg)
Leucovorin calcium 15 mg/m² per dose; administer intravenously in 10–250 mL 0.9% NS or D5W over 15–30 minutes for 3 doses at hours 48, 51, and 54 after systemic methotrexate began (total dosage/course = 45 mg/m²)
Doxorubicin 25 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 1 hour, for 2 consecutive days, on days 4 and 5 (total dosage/course = 50 mg/m²)

Course AA:
Dexamethasone 10 mg/m² per day; administer orally for 5 consecutive days on days 1–5 (total dosage/course = 50 mg/m²)
Ifosfamide 800 mg/m² per day; administer intravenously in 100–250 mL 0.9% NS or D5W over 1 hour, for 5 consecutive days on days 1–5 (total dosage/course = 4000 mg/m²)
Vincristine 1.5 mg/m² (maximum: 2 mg/dose); administer by intravenous injection over 1–2 minutes, given on day 1 (total dosage/course = 1.5 mg/m²; maximum 2 mg/dose)
Methotrexate 500 mg/m²; administer intravenously in 50–250 mL 0.9% NS or D5W over 30 minutes, given on day 1, *followed immediately by*:
Methotrexate 4500 mg/m²; administer by continuous intravenous infusion in 250 mL to ≥1000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/course [not including intrathecal methotrexate] = 5000 mg/m²)
Methotrexate 6 mg/dose*; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1 and then again on day 5 (total dose/course [not including systemic methotrexate] = 12 mg)
Cytarabine 15 mg/dose*; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1, and then again on day 5 (total dose/course [not including systemic cytarabine] = 30 mg)
Prednisolone 5 mg/dose; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1, and then again on day 5 (total dose/course = 10 mg)
Leucovorin calcium 15 mg/m² per dose; administer by intravenous infusion in 10–250 mL 0.9% NS or D5W over 15–30 minutes every 6 hours for 6 doses, starting 36 hours after systemic methotrexate began (total dosage/course = 90 mg/m²)
Cytarabine 150 mg/m² per dose; administer intravenously in 25–500 mL 0.9% NS or D5W over 1 hour every 12 hours, for 4 doses, on days 4 and 5 (total dosage/course [not including intrathecal cytarabine] = 600 mg/m²)
Teniposide 100 mg/m² per day; administer intravenously, diluted in 0.9% NS or D5W to a concentration of 0.1, 0.2, or 0.4 mg/mL, over 1 hour, for 2 consecutive days on days 4 and 5 (total dosage/course = 200 mg/m²)

Course BB:
Dexamethasone 10 mg/m² per day; administer orally for 5 consecutive days on days 1–5 (total dosage/course = 50 mg/m²)
Cyclophosphamide 200 mg/m² per day; administer intravenously in 50–1000 mL 0.9% NS or D5W over 1 hour, for 5 consecutive days, on days 1–5 (total dosage/course = 1000 mg/m²)
Vincristine 1.5 mg/m² (maximum 2 mg/dose); administer by intravenous injection over 1–2 minutes, given on day 1 (total dosage/course = 1.5 mg/m²; maximum 2 mg/dose)
Methotrexate 500 mg/m²; administer intravenously in 50–250 mL 0.9% NS or D5W over 30 minutes, given on day 1, *followed immediately by*:
Methotrexate 4500 mg/m²; administer by continuous intravenous infusion in 250 mL to ≥1000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/course [not including intrathecal methotrexate] = 5000 mg/m²)
Methotrexate 6 mg/dose*; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1, and then again on day 5 (total dose/course [not including systemic methotrexate] = 12 mg)
Cytarabine 15 mg/dose*; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1, and then again on day 5 (total dose/course = 30 mg)
Prednisolone 5 mg/dose; administer intrathecally for 2 doses on days 1 and 5, 2 hours after systemic methotrexate began on day 1, and then again on day 5 (total dose/course = 10 mg)

(*continued*)

(continued)

Leucovorin calcium 15 mg/m² per dose; administer intravenously in 10–250 mL 0.9% NS or D5W over 15–30 minutes every 6 hours for 6 doses, starting 36 hours after systemic methotrexate began (total dosage/course = 90 mg/m²)
Doxorubicin 25 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 1 hour, for 2 consecutive days, on days 4 and 5 (total dosage/course = 50 mg/m²)

*Doses are adjusted for patients <3 years of age. See following table

CNS Prophylaxis (Intrathecal)

A and B: Cytarabine/Methotrexate on Day 1
(AA and BB: Cytarabine/Methotrexate on Days 1–5)

Patient's Age	Cytarabine (Dose/Day)	Methotrexate (Dose/Day)
1 year	18 mg (9 + 9)	8 mg (4 + 4)
2 years	24 mg (12 + 12)	10 mg (5 + 5)
≥3 years	30 mg (15 + 15)	12 mg (6 + 6)

Supportive Care
Antiemetic prophylaxis, courses A, B, AA, and BB
Emetogenic potential on days 1, 4, and 5 is ***HIGH***
Emetogenic potential on days 2 and 3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis
Give **stool softeners** and/or laxatives during and after vincristine administration

Therapy Monitoring

1. *After the first 2 treatment courses, and then before each subsequent treatment course:* Evaluation of tumor response
2. *Daily methotrexate levels:* Following high-dose systemic methotrexate administration
3. In patients with proven bone marrow or CNS involvement, bone marrow biopsies and CSF sampling, respectively, were repeated only until there was no more evidence of disease

Notes

1. Second-look surgery was projected for patients who had residual tumors by physical examination or imaging modalities after completing 2 treatment courses
2. Most patients were treated before the widespread use of filgrastim

Patient Population Studied

A study of 319 pediatric patients (ages ≤18 years), among whom 111 patients had a diagnosis of Burkitt lymphoma. Group B included Burkitt-type lymphomas, B-ALL, and most large cell lymphomas, including Ki-1 anaplastic large-cell lymphoma

Efficacy

For 152 patients with Burkitt lymphoma or B-ALL, the probability of event-free survival at 7 years was 79% ± 3%

Treatment Group	Probability of Event-Free Survival at 7 Years
SRG (N = 42)	98 ± 2%
RG (N = 117)	79 ± 4%
IV/B-ALL (N = 66)	75 ± 5%

Treatment Modifications

Treatment prerequisites
1. *Conditions for starting treatment courses 2, 3, and 4:* Platelet count >50,000/mm³; WBC count >1000/mm³; ANC >200/mm³
2. *Conditions for starting treatment courses 5 and 6:* WBC count >2000/mm³; ANC >500/mm³
3. Minimally, a 2-week interval must elapse between the first days of 2 courses in succession

Treatment notes
1. All treatments were completed within 2–3 months for the B-SRG arm, and within 4–5 months for the B-RG and B-IV/B-ALL arms
2. Cranial irradiation was optional for patients with overt CNS disease
3. Patients without CNS disease did not receive cranial radiation
4. Males with testicular involvement were to receive radiation to the testes
5. Local radiation therapy was limited to patients with residual unresectable active disease

Toxicity

Not described

REGIMEN

RITUXIMAB + HYPERFRACTIONATED CYCLOPHOSPHAMIDE, VINCRISTINE, DOXORUBICIN (ADRIAMYCIN), AND DEXAMETHASONE (R-HYPER-CVAD)

Thomas DA et al. J Clin Oncol 1999;17:2461–2470
Thomas DA et al. Cancer 2006;106:1569–1580

Prophylaxis against tumor lysis syndrome during the first cycle:
Hydration with 2500–3000 mL/day, as tolerated; administer intravenously at 100–125 mL/hour (2500–3000 mL/day)

Notes:

- **Sodium bicarbonate** is added to parenteral hydration solutions in the presence of plasma uric acid ≥9 mg/dL to maintain urine pH ≥7.0, but pH <8. The choice of hydration fluid and amount of sodium bicarbonate added to the fluid should NOT EXCEED the sodium concentration present in 0.9% sodium chloride injection (154 mEq/L); for example:
  - 5% Dextrose/0.45% sodium chloride injection, USP, with sodium bicarbonate 50–75 mEq/1000 mL *or*
  - 5% Dextrose/0.2% sodium chloride injection, USP, with sodium bicarbonate 100–125 mEq/1000 mL *or*
  - 5% dextrose injection, USP, with sodium bicarbonate 125–150 mEq/1000 mL
- **Potassium** is NOT added to parenteral hydration solutions during the first few days of induction therapy unless serum potassium decreases to <3.0 mEq/dL

Furosemide 20–40 mg; administer intravenously every 12–24 hours to maintain fluid balance
Note: Diuresis is maintained for at least the first 72 hours after starting chemotherapy in the absence of metabolic aberrations, or after metabolic complications normalize
Allopurinol 300 mg/day; administer orally for 7 consecutive days, on days 1–7 (longer treatment may be needed)

Hyper-CVAD (cycles 1 and 3), premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

Rituximab 375 mg/m² per dose; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration of 1–4 mg/mL, for 2 doses during cycles 1 and 3, on days 1 and 11 of hyper-CVAD (total dosage/cycle = 750 mg/m²)

Notes on rituximab administration:

- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Hyper-CVAD (cycles 1, 3, 5, and 7)
Cyclophosphamide 300 mg/m² per dose; administer intravenously over 2 hours in 500 mL 0.9% sodium chloride injection (0.9% NS) every 12 hours for 6 doses (days 1, 2, and 3), for 4 cycles, cycles 1, 3, 5, and 7 (total dosage/cycle = 1800 mg/m²)
Mesna 600 mg/m² per day; administer by continuous intravenous infusion over 24 hours in 1000–2000 mL 0.9% NS, starting 1 hour before cyclophosphamide and continuing until 12 hours after the last dose of cyclophosphamide (total duration approximately 76 hours/cycle), for 4 cycles, cycles 1, 3, 5, and 7 (total dosage/cycle = 1900 mg/m²)
Vincristine 2 mg/dose; administer by intravenous injection over 1–2 minutes for 2 doses, on days 4 and 11 (total dose/cycle = 4 mg)
Doxorubicin 50 mg/m²; administer intravenously via central venous access in 25–250 mL 0.9% NS or 5% dextrose injection (D5W) over 2 hours on day 4 (total dosage/cycle = 50 mg/m²)

(*continued*)

Treatment Modifications

Treatment prerequisites

- Second and subsequent cycles are implemented when WBC count ≥3000/mm³ and platelet count ≥60,000/mm³ at least 24 hours after a filgrastim dose was administered
- Subsequent cycles may be repeated at intervals less than every 21 days, but not more frequently than 14 days after the previous cycle

Adverse Event	Dose Modification
On day 21 of a treatment cycle, if WBC count ≥3000/mm³, but platelet count <60,000/mm³	Reevaluate hematologic laboratories every 3 days until platelet count ≥60,000/mm³
On day 21 of a treatment cycle, if WBC count ≥30,000/mm³, but platelet count <60,000/mm³	Hold filgrastim and reevaluate hematologic laboratories every 3 days until platelet count ≥60,000/mm³
Patient age ≥60 years	Reduce cytarabine dosage to 1000 mg/m² per dose
Blood methotrexate concentration >20 µmol/L at the start of treatment	Reduce cytarabine dosage to 2000 mg/m² per dose and reduce methotrexate dosage by 50%
Serum creatinine >2 mg/dL (>177 µmol/L)	
Serum creatinine >3 mg/dL (>265 µmol/L)	Reduce methotrexate dosage by 75%
Delayed methotrexate excretion or nephrotoxicity attributable to previous methotrexate treatment	Reduce methotrexate dosage by 50–75% (commensurate with the severity of nephrotoxicity)
Total bilirubin >2 g/dL (34.2 µmol/L)	Reduce vincristine dose to 1 mg
Total bilirubin 2–3g/dL (34.2–51.3 µmol/L)	Reduce doxorubicin dosage by 25%
Total bilirubin 3–4g/dL (51.3–68.4 µmol/L)	Reduce doxorubicin dosage by 50%
Total bilirubin >4g/dL (68.4 µmol/L)	Reduce doxorubicin dosage by 75%

(*continued*)

(continued)

Dexamethasone 40 mg/day; administer orally or by intravenous infusion in 25–150 mL 0.9% NS or D5W over 15–30 minutes for 8 doses, on days 1–4 and days 11–14 (total dosage/cycle = 320 mg)

High-dose methotrexate and cytarabine (cycles 2 and 4), premedication for rituximab:
Acetaminophen 650–1000 mg; administer orally, *plus*
Diphenhydramine 25–50 mg; administer orally or intravenously, 30–60 minutes before starting rituximab

Rituximab 375 mg/m² per dose; administer intravenously in 0.9% NS or D5W, diluted to a concentration of 1–4 mg/mL, for 2 doses during cycles 2 and 4, on days 2 and 8 of high-dose methotrexate and cytarabine (total dosage/cycle = 750 mg/m²)

Notes on rituximab administration:

- Infuse initially at 100 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour. Subsequently if previous administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes, as tolerated, to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

High-dose methotrexate and cytarabine (cycles 2, 4, 6, and 8)
Hydration with 2500–3000 mL/day, as tolerated; administer intravenously at 100–125 mL/hour (2500–3000 mL/day)

Notes

- **Sodium bicarbonate** is added to parenteral hydration solutions in the presence of plasma uric acid ≥9 mg/dL to maintain urine pH ≥7.0, but pH <8. The choice of hydration fluid and amount of sodium bicarbonate added to the fluid should NOT EXCEED the sodium concentration present in 0.9% sodium chloride injection (154 mEq/L); for example:
  - 5% Dextrose/0.45% sodium chloride injection, USP, with sodium bicarbonate 50–75 mEq/1000 mL *or*
  - 5% Dextrose/0.2% sodium chloride injection, USP, with sodium bicarbonate 100–125 mEq/1000 mL *or*
  - 5% dextrose injection, USP, with sodium bicarbonate 125–150 mEq/1000 mL

Methotrexate 1000 mg/m²; administer by continuous intravenous infusion in 250 mL to ≥1000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 24 hours on day 1 (total dosage/cycle [not including intrathecal methotrexate] = 1000 mg/m²)
Cytarabine 3000 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS or D5W over 2 hours, every 12 hours, for 4 doses, on days 2 and 3 (total dosage/cycle [not including intrathecal cytarabine] = 12,000 mg/m²)
Calcium leucovorin 50 mg; administer intravenously in 10–100 mL 0.9% NS or D5W over 10–20 minutes for 1 dose, 12 hours after methotrexate administration is completed (36 hours after starting methotrexate), *followed 6 hours later by:*
Calcium leucovorin 15 mg; administer intravenously in 10–100 mL 0.9% NS or D5W over 10–20 minutes, every 6 hours, for 8 doses or until blood methotrexate concentrations is <0.1 µmol/L

- Calcium leucovorin doses are escalated to 50–100/dose intravenously every 4–6 hours if serum methotrexate concentrations are:
  - >20 µmol/L at the end of methotrexate administration (hour 24)
  - >1 µmol/L at 24 hours after the end of methotrexate administration (hour 48), *or*
  - >0.1 µmol/L at 48 hours after the end of methotrexate administration (hour 72)

CNS prophylaxis (all patients)
Methotrexate; administer intrathecally on day 2 for 8 cycles (8 doses): 12 mg/dose via lumbar puncture or 6 mg/dose via intraventricular route (eg, Ommaya reservoir; total dose throughout 8 cycles [not including systemic methotrexate] = 96 mg via lumbar puncture or 48 mg intraventricularly)

(continued)

Treatment Modifications *(continued)*

Adverse Event	Dose Modification
Disease involving the stomach or small bowel	Eliminate doxorubicin during the first hyper-CVAD cycle
If high-dose cytarabine is eliminated because of adverse effects	Omit the high-dose methotrexate + cytarabine regimen, replacing it with repeated cycles of hyper-CVAD
Peripheral neuropathy	Discontinue vincristine
Proximal myopathy	Discontinue dexamethasone
Cerebellar neurotoxicity	Reduce cytarabine dosage or omit cytarabine during subsequent treatments
Tumor lysis syndrome during induction with renal failure requiring hemodialysis	Reduce methotrexate dosage
G3 mucositis	

Patient Population Studied

A study of 26 consecutive adult patients with newly diagnosed, untreated Burkitt-type acute lymphoblastic leukemia (23 patients with FAB L3 subtype; 3 patients classified L1 or L2)

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, LFTs, serum BUN, creatinine, and urinalysis
2. *Daily during treatment:* Serum electrolytes, glucose, BUN, creatinine, total bilirubin, LFTs, LDH, uric acid, albumin, alkaline phosphatase, and CBC with differential
3. *Daily following high-dose systemic methotrexate administration:* Methotrexate levels

(*continued*)

Cytarabine 100 mg; administer intrathecally via lumbar puncture or intraventricular routes, on day 7 for 8 cycles (total of dose 8 doses throughout 8 cycles [not including systemic cytarabine] = 800 mg)

CNS treatment

Methotrexate 12 mg/dose; administer intrathecally via lumbar puncture or 6 mg/dose via intraventricular route twice weekly until CSF cell count normalizes and cytology becomes negative for malignant disease, then administer intrathecally during subsequent cycles on day 2 per the regimen for CNS prophylaxis

Cytarabine 100 mg; administer intrathecally via lumbar puncture or intraventricular route, twice weekly until CSF cell count normalizes and cytology becomes negative for malignant disease, then administer intrathecally during subsequent cycles on day 7 per the regimen for CNS prophylaxis

Supportive Care

Antiemetic prophylaxis with Hyper-CVAD (cycles 1, 3, 5, and 7)
Emetogenic potential on days 1–4 is ***MODERATE***

Antiemetic prophylaxis with high-dose methotrexate and cytarabine (cycles 2, 4, 6, and 8)
Emetogenic potential on days 1, 2, and 3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with hyper-CVAD (cycles 1, 3, 5, and 7) and with high-dose methotrexate and cytarabine (cycles 2, 4, 6, and 8):

Filgrastim (G-CSF) 10 mcg/kg per day; administer by subcutaneous injection starting 24 hours after the last dose of chemotherapy; and continuing until postnadir WBC count ≥3000/mm^3
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis
Give **stool softeners** and/or laxatives during and after vincristine administration

Efficacy

Sequential comparison of hyper-CVAD plus rituximab versus hyper-CVAD alone

Parameter	Hyper-CVAD Plus Rituximab (N = 31)	Hyper-CVAD Alone (N = 48)	*p* Value
Percent CR	86%	85%	
Median follow-up	22 months	74 months	
Induction deaths	0%	13%	0.04
Percent relapse	7%	30%	0.008
Percent 3-year survival	89%	53%	<0.01
Percent 3-year EFS	80%	52%	0.02
Percent 3-year DFS	88%	60%	0.03
Percent 3-year CRD	91%	66%	0.024

EFS, Event-free survival; DFS, disease-free survival; CRD, complete response duration

Toxicity*

Toxicities in Patients with CR (N = 21)	Age <60 Years (N = 13)	Age ≥60 Years (N = 8)
G3/4 neurotoxicity	15%	29%
Tumor lysis in first cycle	8%	25%
Creatinine increased more than 2-fold after methotrexate	23%	12%
Infection with cycle 2	54%	38%

Infectious Complications During First Cycle (N = 37)	
Febrile neutropenia	86%
Fever of unknown origin	38%
Pneumonia	32%
Sepsis	11%
Bacterial meningitis	3%
Herpes simplex virus infections	3%

Infectious Complications in Cycles After First (N = 152)	
Febrile neutropenia during high-dose methotrexate/cytarabine	47–55%
Febrile neutropenia during hyper-CVAD	30–39%
Herpes simplex virus infections	8%

Events Concurrent with Thrombocytopenia (N = 152)	
Hemorrhage with thrombocytopenia (all)	12%
Severe epistaxis	4%
Retinal	2%
Gastrointestinal	2%
CNS	2%
Pulmonary	1%
Antecubital hematoma	1%

Other Toxicities	
Deaths during induction	19%
Cerebellar neurotoxicity	3.8%

*NCI CTC

REGIMEN

METHOTREXATE, CYTARABINE (ARA-C), CYCLOPHOSPHAMIDE, VINCRISTINE (ONCOVIN), PREDNISONE, AND BLEOMYCIN (MACOP-B)

Klimo P, Connors JM. Ann Intern Med 1985;102:596–602

Odd-Numbered Weeks: 1, 3, 5, 7, 9, and 11

Doxorubicin 50 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 6 doses on day 1 during weeks 1, 3, 5, 7, 9, and 11 (total dosage/12-week course = 300 mg/m²)

Oral hydration before and after cyclophosphamide administration:
32–64 oz/day on the day cyclophosphamide is administered and for at least 1 day afterward

or

Intravenous hydration before and after cyclophosphamide administration:
500–1000 mL 0.9% sodium chloride injection (0.9% NS)
Cyclophosphamide 350 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or 5% dextrose injection (D5W) over 10–30 minutes for 6 doses on day 1 during weeks 1, 3, 5, 7, 9, and 11 (total dosage/12-week course = 2100 mg/m²)

Even-Numbered Weeks: 2, 4, 6, 8, 10, and 12

Oral hydration with methotrexate:
100–128 oz/day

or

Intravenous hydration with methotrexate:
100–150 mL/hour 0.9% NS, D5W or 5% dextrose/0.45% sodium chloride (D5W/0.95% NS) injection, before, during, and after intravenous methotrexate administration
Sodium bicarbonate 500–2000 mg (sufficient to increase urine pH to 7.0); administer orally every 6 hours for 48–60 hours, starting 8–12 hours before starting methotrexate administration

Notes:
- Sodium bicarbonate may be administered parenterally to patients who require intravenous hydration (50–100 mEq sodium bicarbonate/1000 mL of parenteral fluid)
- In patients with measurable serum or plasma methotrexate concentrations ≥48 hours after methotrexate administration is completed, continue sodium bicarbonate administration and vigorous oral or parenteral hydration until methotrexate is no longer detectable

Methotrexate 100 mg/m² per dose; administer intravenously in 10–50 mL 0.9% NS or D5W over 5–15 minutes or by intravenous injection over 0.5–2 minutes, on day 1, *followed by*
Methotrexate 300 mg/m² per dose; administer intravenously in 50–1000 mL 0.9% NS or D5W over 4 hours for 3 doses on day 1 during weeks 2, 6, and 10 (total intravenously administered dosage/12-week course = 1300 mg/m²)
Leucovorin rescue:
Leucovorin calcium 15 mg/dose; administer orally every 6 hours for 6 doses, starting 28 hours after starting methotrexate during weeks 2, 6, and 10 (total dose during each week intravenous methotrexate is given = 90 mg)

Note: For patients with mucositis that precedes methotrexate administration and for those who develop mucositis during methotrexate or leucovorin administration, increase the total number of leucovorin doses from 6–12 doses

Vincristine 1.4 mg/m² per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes for 6 doses on day 1 during weeks 2, 4, 6, 8, 10, and 12 (total dosage/12-week course = 8.4 mg/m²; maximum dose/12-week course = 12 mg)
Bleomycin 10 units/m² per dose; administer by slow intravenous injection over 10 minutes for 3 doses on day 1 during weeks 4, 8, and 12 (total dosage/12-week course = 30 units/m²)
Prednisone 75 mg/day; administer orally for 69 consecutive days, then taper the daily dose during the last 15 days of treatment (days 70–84)

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC ≥1000/mm³ on a day of treatment	Administer 100% of planned chemotherapy doses
ANC 100–999/mm³ on a day of treatment	Administer 65% of planned chemotherapy doses
ANC <100/mm³ on a day of treatment	Delay treatment for 1 week
Thrombocytopenia (any severity)	Do not modify treatment, but give platelet transfusions for platelet count <10,000/mm³
Creatinine clearance <60 mL/min (<1 mL/s)	Give bleomycin 10 units/m² instead of methotrexate on weeks 2, 6, and 10*

*If low creatinine clearance is a result of lymphoma and improves during treatment, reintroduce methotrexate

Patient Population Studied

A study of 61 patients with advanced newly diagnosed diffuse large B-cell lymphoma

Efficacy (N = 61)

Complete response	84%
Partial response	16%

(continued)

CNS prophylaxis:
For all patients with lymphoma involving bone marrow, starting after documented remission in bone marrow
Methotrexate 12 mg; administer intrathecally via lumbar puncture twice weekly for 6 doses (total dose/week = 24 mg)
Cytarabine 30 mg/m^2; administer intrathecally via lumbar puncture twice weekly for 6 doses (total dose/week = 60 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Odd-numbered weeks (1, 3, 5, 7, 9, and 11)
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Even-numbered weeks (2, 6, and 10)
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 1 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Oral care
- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:
- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Toxicity (N = 61)

	% G1/2	% G3/4
Mucositis	56	26
Neurologic	92	8
Cutaneous	39	3
Hematologic		
Granulocytopenia (<500/mm^3)		21

Severe		3

Therapy Monitoring

1. *Weekly:* CBC with differential, LFTs, serum BUN, and creatinine
2. *Daily following systemic methotrexate administration:* Methotrexate levels

REGIMEN

THE BONN PROTOCOL

Pels H et al. J Clin Oncol 2003;21:4489–4495

Sequence of cycles (periods of drug administration are separated by a 2-week interval)

A1 → B1 → C1 → A2 → B2 → C2

D1–5 D22–26 D43–49 D64–68 D85–89 D106–112

Cycle A:

Hydration with 5% dextrose/0.45% sodium chloride injection (D5W/0.45% NS) with sodium bicarbonate injection 100 mEq/1000 mL; administer intravenously at 100–125 mL/hour (2400–3000 mL/day). Monitor fluid status carefully

Patients ≤64 years:

Methotrexate loading dose 500 mg/m²; administer intravenously in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes, given on day 1, *followed immediately by:*

Methotrexate continuous infusion 4500 mg/m²; administer by continuous intravenous infusion in 250–3000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/cycle [not including intrathecal methotrexate] = 5000 mg/m²)

Patients >64 years:

Methotrexate loading dose 500 mg/m²; administer intravenously in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes, given on day 1, *followed immediately by:*

Methotrexate continuous infusion 2500 mg/m²; administer by continuous intravenous infusion in 250–3000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/cycle [not including intrathecal methotrexate] = 3000 mg/m²)

All patients:

Leucovorin calcium 30 mg/m²; administer intravenously in 5–50 mL D5W or 0.9% NS over 10–30 minutes

Leucovorin Administration Schedule

Normal Methotrexate Clearance Anticipated	Delayed Methotrexate Clearance
At 10, 18, 24, 30, and 42 hours after methotrexate administration concludes	Every 4 hours until serum methotrexate is <0.2 µmol/L

Vincristine 2 mg; administer by intravenous injection over 1–2 minutes, given on day 1 (total dose/cycle = 2 mg)

Ifosfamide 800 mg/m² per day; administer intravenously in 100–250 mL 0.9% NS or D5W over 1 hour, for 4 consecutive days, on days 2–5 (total dosage/cycle = 3200 mg/m²)

Mesna 800 mg/m² per day; administer by continuous intravenous infusion in 250–1000 mL 0.9% NS or D5W over 24 hours, for 4 consecutive days, on days 2–5 (total dosage/cycle = 3200 mg/m²)

Dexamethasone 10 mg/m² per day; administer orally for 4 consecutive days on days 2–5, *only during the A2 cycle* (total dosage/cycle = 40 mg/m²)

Prednisolone 25 mg per day; administer intrathecally for 3 consecutive days on days 1–4 (total dose/cycle = 10 mg)

Methotrexate 3 mg per day; administer intrathecally for 3 consecutive days on days 1–4 (total dose/cycle [not including systemic methotrexate] = 12 mg)

Cytarabine 30 mg; administer intrathecally on day = (total dose/cycle = 30 mg)

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
Creatinine clearance (Clcr) <100 mL/min	Decrease methotrexate dosage by a percentage equivalent to the percentage decrease from creatinine clearance of 100 mL/min (eg, for Clcr = 90 mL/min, decrease methotrexate dosage by 10%)
G ≥3 peripheral neuropathy	Omit vincristine and vindesine from subsequent cycles. Can reinstitute at reduced dosage (50%) if neuropathy improves to G ≤2

Patient Population Studied

A study of 65 consecutive patients with newly diagnosed primary central nervous system lymphoma. Radiation therapy was deferred

Efficacy (N = 61)

Complete response	61%
Partial response	10%
Progressive disease	20%
Not evaluated	9%
Estimated time to treatment failure*	21 months
Estimated median overall survival*	50 months
Estimated 2-year survival	69% (57–80%)
Estimated 5-year survival	43% (26–60%)

*Kaplan-Meser estimate

(*continued*)

Cycle B:

Hydration with D5W/0.45% NS with sodium bicarbonate injection 100 mEq/1000 mL; administer intravenously at 100–125 mL/hour (2400–3000 mL/day). Monitor fluid status carefully

Patient ≤64 years:

Methotrexate loading dose 500 mg/m²; administer intravenously in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes, given on day 1, *followed immediately by:*

Methotrexate continuous infusion 4500 mg/m²; administer by continuous intravenous infusion in 250–3000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/cycle [not including intrathecal methotrexate] = 5000 mg/m²)

Patient >64 years:

Methotrexate loading dose 500 mg/m²; administer intravenously in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes, given on day 1, *followed immediately by:*

Methotrexate continuous infusion 2500 mg/m²; administer by continuous intravenous infusion in 250–3000 mL 0.9% NS or D5W over 23.5 hours on day 1 (total dosage/cycle [not including intrathecal methotrexate] = 3000 mg/m²)

All patients:

Leucovorin calcium 30 mg/m²; administer intravenously in 5–50 mL D5W or 0.9% NS over 10–30 minutes

Leucovorin Administration Schedule

Normal Methotrexate Clearance Anticipated	Delayed Methotrexate Clearance
At 10, 18, 24, 30, and 42 hours after methotrexate administration concludes	Every 4 hours until serum methotrexate is <0.2 µmol/L

Vincristine 2 mg; administer by intravenous injection over 1–2 minutes, given on day 1 (total dose/cycle = 2 mg)

Cyclophosphamide 200 mg/m² per day; administer intravenously in 25–1000 mL 0.9% NS over 1 hour for 4 consecutive days on days 2–5 (total dosage/cycle = 800 mg/m²)

Mesna 200 mg/m² per day; administer by continuous intravenous infusion in 250–1000 mL 0.9% NS or D5W over 24 hours, for 4 consecutive days, on days 2–5 (total dosage/cycle = 800 mg/m²)

Dexamethasone 10 mg/m² per day; administer orally, for 4 consecutive days, on days 2–5, *only during the B2 cycle* (total dosage/cycle = 40 mg/m²)

Prednisolone 2.5 mg per day; administer intrathecally, for 3 consecutive days, on days 1–4 (total dose/cycle = 10 mg)

Methotrexate 3 mg per day; administer intrathecally, for 3 consecutive days, on days 1–4 (total dose/cycle [not including systemic methotrexate] = 12 mg)

Cytarabine 30 mg; administer intrathecally on day 5 (total dose/cycle = 30 mg)

Cycle C:

Cytarabine 3000 mg/m² per day; administer intravenously in 50–500 mL 0.9% NS or D5W over 3 hours for 2 doses on days 1 and 2 (total dosage/cycle [not including intrathecal cytarabine] = 6000 mg/m²)

Vindesine* 5 mg; administer by intravenous injection over 1–2 minutes, given on day 1 (total dose/cycle = 5 mg)

Dexamethasone 10 mg/m² per day; administer orally for 5 consecutive days on days 3–7 (total dosage/cycle = 50 mg/m²)

Prednisolone 2.5 mg per day; administer intrathecally for 4 consecutive days on days 3–6 (total dose/cycle = 10 mg)

Methotrexate 3 mg per day; administer intrathecally for 4 consecutive days on days 3–6 (total dose/cycle = 12 mg)

Cytarabine 30 mg; administer intrathecally on day 7 (total dose/cycle [not including systemic cytarabine] = 30 mg)

*Although vindesine had once received FDA approval for commercial use, it is not currently marketed in the United States

Transient encephalopathy†	9
Clinical peripheral neuropathy	2
White matter changes on MRI	35‡

*WHO Toxicity Scale
†With methotrexate and ifosfamide
‡Twenty of 57 patients

Therapy Monitoring

1. *Daily on days of chemotherapy:* CBC with differential, serum electrolytes, BUN, creatinine, and LFTs
2. *Weekly:* CBC with differential, serum electrolytes, BUN, creatinine, and LFTs
3. *Following methotrexate administration:* Daily methotrexate levels

(*continued*)

Supportive Care

Antiemetic prophylaxis during A and B cycles

Emetogenic potential on day 1 is ***HIGH***

Emetogenic potential on days 2–5 is ***MODERATE***

Antiemetic prophylaxis during C cycles

Emetogenic potential on days 1 and 2 is ***HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

Give **stool softeners** and/or laxatives during and after vincristine administration

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

REGIMEN

NEW APPROACHES TO BRAIN TUMOR THERAPY (NABTT) CNS CONSORTIUM 96-07

Batchelor T et al. J Clin Oncol 2003;21:1044–1049
Herrlinger U et al. Ann Neurol 2002;51:247–252

Hydration with each cycle:
5% Dextrose/0.45% sodium chloride injection with sodium bicarbonate 50–75 mEq/1000 mL, *or* 5% Dextrose/0.2% sodium chloride injection with sodium bicarbonate 100–125 mEq/1000 mL; administer intravenously at a rate sufficient to produce a urine output >100 mL/hour and urine pH ≥7.0. Continue until serum methotrexate concentration is <0.1 μmol/L. Begin methotrexate administration after urine output >100 mL/hour and urine pH ≥7.0 for ≥4 hours

Induction
Methotrexate 8000 mg/m²; administer by continuous intravenous infusion in 100 mL to ≥1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 4 hours, every 14 days until complete response or a maximum of 8 cycles (total dosage/cycle = 8000 mg/m²)
Calcium leucovorin 25 mg; administer intravenously in 25–250 mL 0.9% NS or D5W over 5–30 minutes every 6 hours, starting 24 hours after methotrexate began, continuing until serum methotrexate <0.10 μmol/L

Consolidation (after CR):
Methotrexate 8000 mg/m²; administer by continuous intravenous infusion in 100 mL to ≥1000 mL 0.9% NS or D5W over 4 hours, every 14 days, for 2 cycles (total dosage/cycle = 8000 mg/m²), *then:*
Calcium leucovorin 25 mg; administer intravenously in 25–250 mL 0.9% NS or D5W over 5–30 minutes every 6 hours, starting 24 hours after methotrexate began, continuing until serum methotrexate <0.10 μmol/L

Maintenance:
Methotrexate 8000 mg/m²; administer by continuous intravenous infusion in 100 mL to ≥1000 mL 0.9% NS or D5W over 4 hours, every 28 days, for 11 cycles (total dosage/cycle = 8000 mg/m²)
Calcium leucovorin 25 mg; administer intravenously in 25–250 mL 0.9% NS or D5W over 5–30 minutes every 6 hours, starting 24 hours after methotrexate begun, continuing until serum methotrexate <0.10 μmol/L

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

1. After 287 cycles of high-dose methotrexate, 12 patients experienced 18 episodes of G3/4 adverse events (unspecified)
2. Mini-Mental State Evaluation score declined from 29 at baseline to 27 at follow-up in 1 of 19 patients

Therapy Monitoring

1. *Daily during hospital admission for high-dose methotrexate:* Serum BUN, creatinine, WBC, hemoglobin, platelet count, and methotrexate level
2. *Before each repeated cycle:* 24-hour urine collection for creatinine clearance, CBC with differential, ophthalmologic examination, and CSF cytopathology if it was originally positive before repeated cycles

Treatment Modification

Adverse Event	Dose Modification
Creatinine clearance (Clcr) <100 mL/min (<1.66 mL/s)	Decrease methotrexate dosage by a percentage equivalent to the percentage decrease from creatinine clearance of 100 mL/min (eg, for Clcr = 90 mL/min, decrease methotrexate dosage by 10%)

Patient Population Studied

A study of 25 patients with primary CNS lymphoma, among whom 5 patients had evidence of ocular lymphoma

Efficacy (N = 23)

Radiographic complete response	52%
Radiographic partial response	22%
Disease progression during treatment	22%
Among 5 Patients with Ocular Involvement	
Radiographic complete response in brain	80%
Radiographic partial response in brain	20%
Resolution of ocular signs	80%

REGIMEN

MEMORIAL SLOAN-KETTERING REGIMEN (RTOG 93-10)

DeAngelis LM et al. J Clin Oncol 2002;20:4643–4648

Induction (pre-irradiation) chemotherapy
Methotrexate 2500–3500 mg/m² per dose; administer intravenously in 250 mL to ≥1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) (or saline and dextrose combinations) over 2–3 hours, every second week, for 5 doses on day 1 during weeks 1, 3, 5, 7, and 9 (total dosage/10-week course [not including intrathecal methotrexate] = 12,500–17,500 mg/m²)

Hydration after methotrexate:
D5W, 5% dextrose/0.2% sodium chloride injection (D5W/0.2% NS), or 5% dextrose/0.45% sodium chloride injection (D5W/0.45% NS), with sodium bicarbonate injection 50–125 mEq/1000 mL; administer intravenously at 1500–1800 mL/m² for 24 hours, then 1000 mL/m² per day for the next 48 hours

Vincristine 1.4 mg/m² per dose (maximum single dose = 2.8 mg); administer by intravenous injection over 1–2 minutes every second week for 5 doses on day 1 during weeks 1, 3, 5, 7, and 9 (total dosage/10-week course = 7 mg/m²; maximum dose/10-week course = 14 mg)
Procarbazine 100 mg/m² per day; administer orally for 7 consecutive days every 28 days for 3 cycles on days 1–7 during weeks 1, 5, and 9 (total dosage/cycle = 700 mg/m²; total dosage/10 week course = 2100 mg/m²)
Methotrexate 12 mg/dose; administer intrathecally via intraventricular catheter or reservoir (eg, Ommaya) every second week for 5 doses, weeks 2, 4, 6, 8, and 10 (total dosage/10-week course [not including systemic methotrexate] = 60 mg)
Leucovorin calcium 10 mg/dose; administer orally every 6 hours for 8 doses, starting the evening after each intrathecal methotrexate administration
Dexamethasone; administer orally every day on a deescalating dose sequence during weeks 1–6, as follows:

Dexamethasone Dose*

Week	Daily	Total per week
1	16 mg	112 mg
2	12 mg	84 mg
3	8 mg	56 mg
4	6 mg	42 mg
5	4 mg	28 mg
6	2 mg	14 mg

*Dexamethasone dose can be adjusted based on a patient's neurologic condition; can discontinue after week 6

Supportive Care
Antiemetic prophylaxis during induction chemotherapy (weeks 1, 5, and 9)
Emetogenic potential on day 1 is HIGH
Emetogenic potential on days 2–7 is MODERATE

Antiemetic prophylaxis during induction chemotherapy (weeks 3 and 7)
Emetogenic potential on day 1 is MODERATE

Antiemetic prophylaxis during postirradiation chemotherapy (weeks 16 and 19)
Emetogenic potential on days 1 and 2 is MODERATE
See Chapter 39 for antiemetic recommendations

(continued)

Treatment Modifications

None described

Patient Population Studied

A study of 102 patients with primary CNS lymphoma

(*continued*)

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated during induction (preradiation) chemotherapy

Primary prophylaxis is indicated after postirradiation chemotherapy (weeks 16 and 19) with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis
Give **stool softeners** and/or laxatives during and after vincristine administration

Whole-brain radiation therapy

Consider delaying RT in patients >60 years of age because of concern for delayed neurotoxicity
1.8 Gy/fraction per day for 5 days/week for 5 weeks, weeks 11–15 (ie, "standard radiation therapy"; total dose/course = 45 Gy)

Notes:

- For ocular lymphoma, both eyes are included in the irradiated field at 1.8 Gy/fraction to a total dose of 36 Gy in 20 fractions
- Dose rate is modified for patients who achieve a CR at the end of the initial 10 weeks of chemotherapy to 1.2 Gy/fraction, 2 fractions/day separated by ≥6 hours, for 15 days (total dose/course = 36 Gy)

Postirradiation chemotherapy

Cytarabine 3000 mg/m² per day by intravenous infusion in 50–500 mL 0.9% NS over 3 hours for 2 consecutive days, weeks 16 and 19 (total dosage/course = 6000 mg/m²)

Efficacy (N = 50*)

Response after pre-irradiation chemotherapy	
Complete response	58%
Partial response	36%

*Patients in whom tumors had not been completely resected prior to study treatment

Toxicity*

Adverse Event	All Ages	Age <60 Years	Age ≥60 Years
Induction Therapy (N = 98 Patients)			
Any G3/4 adverse event	53%	46%	63%
G3/4 myelosuppression	28%	—	—
G3/4 nephrotoxicity	3%	—	—
G3/4 acute CNS symptoms	9%	—	—
Radiation Therapy (N = 82 Patients)			
Any G3/4/5 adverse event	73%	—	—
G3/4 myelosuppression†	46%	—	—
Severe delayed neurologic toxicities‡	15%	—	—
Leukoencephalopathy	16%	14%	19%
Death as a result of neurologic toxicity	10%	6%	16%
Patients with a CR After Chemotherapy and Standard Radiation Therapy (N = 27)			
G3 neurotoxicity	3.7%	—	—
Patients with a CR After Chemotherapy and Hyperfractionated Radiation Therapy (N = 13)			
G4/5 neurotoxicity	23%	—	—

*NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
†The final chemotherapy cycle may have contributed to this toxicity
‡Median time of onset = 504 days (range: 80–1540 days) after start of cranial irradiation

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, LFTs, BUN, and creatinine
2. *Daily during hospital admission for high-dose methotrexate:* Serum BUN, creatinine, WBC count, hemoglobin, platelet count, and methotrexate level
3. *Before each repeated cycle:* 24-hour urine collection for creatinine clearance, CBC with differential, ophthalmologic examination, and CSF cytopathology if it was originally positive before repeated cycles

25. Melanoma

Ahmad A. Tarhini, MD, PhD, Amanda L. Gillespie-Twardy, MD, and John M. Kirkwood, MD

Epidemiology

Incidence: 76,100 (male: 43,890; female: 32,210. Estimated new cases for 2014 in the United States)
21.1 per 100,000 male and female per year (27.4 per 100,000 male 16.7 per 100,000 female)
Deaths: Estimated 9,710 in 2014 (male: 6,470; female: 3,240)
Median age: 61 years
Male to female ratio: 1.5:1

Stage at Presentation
Stage 0: 49.3%
Stage I: 36.3%
Stage II: 7.3%
Stage III: 3.7%
Stage IV: 3.4%

Koh HK. N Engl J Med 1991;325:171–182

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

Stage IB Stage II	Chest x-ray (optional), LDH Further imaging as clinically indicated for stage IIB, IIC patients (CT scan ± PET/MRI)
Stage IIIA	Chest x-ray, LDH. Further imaging if clinically indicated (CT scan ± PET, and/or MRI)
Stage IIIB Stage IIIC	FNA preferred, if feasible, otherwise lymph node biopsy Chest x-ray, LDH, pelvic CT and if inguinofemoral nodes positive Further imaging if clinically indicated (CT scan ± PET, or MRI)
Stage IV	FNA preferred, if feasible, otherwise lymph node biopsy Chest x-ray and/or chest CT, LDH; consider abdomen/pelvic CT, head MRI and/or PET Further imaging if clinically indicated

Notes:
1. Consider sentinel lymph node biopsy (SLNB) for stage IA with adverse features (positive deep margins, lymphovascular invasion, mitotic rate ≥1 mm²)
2. Encourage SLNB for stage IB and II
3. Discuss the impact of SLNB as an important staging tool and that the impact on survival is still unclear

Five-Year Relative Survival

Stage I: 91–99%
Stage II: 56–77%
Stage III: 27–59%*
Stage IV: 18%

*Rates are not available for stage IIIA patients (with microscopic lymph node involvement) because patients have at most 4 years of follow-up

Gimotty PA et al. A population-based validation of the American Joint Committee on Cancer melanoma staging system. J Clin Oncol 2005;23:8065–8075
NCI, Surveillance, Epidemiology and End Results (SEER) Program

Pathology

Melanoma types

1. Superficial spreading melanoma	60–70%
2. Nodular melanoma	15–30%
3. Lentigo maligna melanoma	5%
4. Acral lentiginous melanoma	2–8%

	T1–4a	N2a	M0
IIIB	T1–4b	N1a	M0
	T1–4b	N2a	M0
	T1–4a	N1b	M0
	T1–4a	N2b	M0
	T1–4a	N2c	M0
IIIC	T1–4b	N1b	M0
	T1–4b	N2b	M0
	T1–4b	N2c	M0
	Any T	N3	M0
IV	Any T	Any N	M1

Note: Pathologic staging includes microstaging of the primary melanoma and pathologic information about the regional lymph nodes after partial (ie, sentinel node biopsy) or complete lymphadenectomy. Pathologic stage 0 or stage IA patients are the exception; they do not require pathologic evaluation of their lymph nodes

Expert Opinion

Tumor Thickness	Recommended Margins*
In situ	0.5 cm
≤1.0 mm	1.0 cm
1.01–2.0 mm	1–2 cm
2.01–4.0 mm	2.0 cm
>4.0 mm	2.0 cm

*The recommended surgical margin in the treatment of melanoma depends on the tumor thickness

- **Prognosis according to stage:**
  - *Stage I:* Excellent prognosis with surgical treatment alone and a cure rate of more than 85%
  - *Stages IIA and IIB:* The 3–5-year postsurgical relapse rate in patients with stages IIA and IIB is 20--30% and 40–55%, respectively
  - *Stage III:* Patients with regional lymph node involvement have a 5-year relapse rate of 60–80%
  - *Stage IV:* Continues to be associated with a dismal prognosis with a median survival of 6–9 months
- Diagnosis and initial surgical management:
  - For patients with a suspicious pigmented lesion, an **excisional biopsy** is preferred
  - When an excisional biopsy is thought inappropriate because of location (eg, face, ear, palm, sole, digit, subungual), a full-thickness **incisional biopsy** or a punch biopsy rather than a shave is acceptable
  - Patients with initial presentation of melanoma T1–4 should be treated by wide excision of the primary. Definitive surgery should include **wide excision of the primary and lymphadenectomy**. For subungual melanoma, a distal interphalangeal amputation with histologically negative margins constitutes an adequate **wide excision**
  - Consider **sentinel lymph node biopsy (SLNB)** for stage IA with adverse features (positive deep margins, lymphovascular invasion, mitotic rate ≥1/mm^2). Encourage SLNB for stage IB and II. SLNB is an important staging tool, but its effect on survival is still unclear
- **Adjuvant therapy**
  - For the adjuvant treatment of malignant melanoma, the current U.S. Food and Drug Administration (FDA) approved regimens are high-dose interferon alfa-2b (HDI), which was approved in 1995, and pegylated interferon alfa-2b, which was recently approved for the treatment of stage III disease based on the EORTC 18991 study
  - HDI is the only form of adjuvant therapy that has ever shown a consistent, significant, and durable relapse-free survival benefit in multicenter randomized controlled trials from U.S. Cooperative Groups. Estimated relapse frequency reductions of 24–38% and mortality reductions of 22–32% based on the hazard ratios for patients treated with interferon alfa versus observation, or the GMK vaccine have been demonstrated
  - Based on the EORTC 18991 study, pegylated interferon alfa-2b has recurrence-free survival benefits that seem to be confined to the subpopulation of patients with microscopic nodal disease, and therefore, it can be offered to patients who cannot undertake high-dose interferon alfa-2b treatment
- **Metastatic melanoma**
  - For metastatic melanoma, survival is estimated at less than 2% at 5 or more years. However, major improvements in patient survival have been demonstrated with recently approved agents (ipilimumab, vemurafenib) and with several agents that are still in development (dabrafenib, PD1/PDL1 inhibitors)
  - Single-agent **dacarbazine** is the only *cytotoxic* chemotherapy agent approved by the FDA for metastatic melanoma. Response rates range from 20% in early trials to 6.7% in one of the largest recent phase III trials. Median response durations range from 4–6 months. Higher response rates have been achieved with strategies involving combination chemotherapy and autologous bone marrow transplant, but with higher toxicities and no benefit in terms of relapse or survival

Bedikian AY et al. J Clin Oncol 2006;24:4738–4745
Chapman PB et al. J Clin Oncol 1999;17:2745–2751
Kirkwood JM. Cancer Principles and Practice of Oncology, 1993, pp 1–16

- **Temozolomide (TMZ)** is transformed *in vivo* to monomethyltriazenoimidazole carboxamide (MTIC), the same active metabolite derived from hepatic metabolism of dacarbazine. Temozolomide crosses the blood–brain barrier and does not require metabolic activation; it undergoes spontaneous chemical degradation to MTIC at physiologic pH. A large randomized trial compared temozolomide with dacarbazine in patients with melanoma after the first presentation of metastatic disease. The median overall survival was 7.7 months with temozolomide and 6.4 months with dacarbazine (HR = 1.18; p = 0.2). The 6-month overall survival rate for temozolomide compared to dacarbazine was 61% versus 51%, respectively (HR = 1.36; p = 0.063). The difference between the treatment groups for overall survival did not reach statistical

(continued)

Expert Opinion (*continued*)

significance (p = 0.20), the 95% confidence interval for the HR (0.92–1.52) indicated temozolomide was at least equivalent to dacarbazine. Continuous prolonged daily administration of temozolomide has been found to more effectively deplete the activity of the DNA repair enzyme O_6-methylguanine-DNA-methyltransferase (MGMT) (73% after 21 days, with low levels persisting up to day 28). In phase I studies of daily temozolomide use, including a trial in which the drug was administered for 21 days during a 28-day cycle, temozolomide 75 mg/m² per day resulted in a 2.1-fold greater exposure to drug per 28-day period than a 5-day schedule. A recent Phase III trial described temozolomide use on an extended schedule (150 mg/m² per day orally on days 1–7, repeated every 14 days). There was no significant difference in overall survival (HR = 0.99, median 9.13 months [temozolomide] vs. 9.36 months [dacarbazine]), progression-free survival (HR = 0.92, median 2.30 months [temozolomide] vs. 2.17 months [dacarbazine]),or overall response rates (CR/PR) (14% temozolomide vs. 10 % dacarbazine)

- **High-dose aldesleukin** (high-dose IL-2, HD IL-2) is approved by the U.S. Food and Drug Administration for metastatic melanoma based on a retrospective analysis of 8 phase II trials that demonstrated an objective response rate of 16% with durable responses in approximately 4% of patients. However, the major toxicities associated with this regimen, including a capillary leak syndrome leading to hypotension, renal insufficiency, and hypoxia, has precluded its widespread application. The use of high-dose aldesleukin is currently limited to specialized programs with experienced personnel, and it is generally offered to patients with good performance and excellent organ function

  Atkins MB et al. J Clin Oncol 1999;17:2105–2116

- Promising results from a single-arm study of **paclitaxel and carboplatin plus sorafenib (PC + SOR)** in advanced melanoma has led to further investigation in a randomized phase III trial as second-line treatment. The addition of SOR to PC did not improve PFS or ORR, but overall, PC showed an improvement in the disease control rate (DCR) compared to historical data (DCR 62%; ORR 11%; SD 51%)
- Agarwala SS et al. J Clin Oncol 2007;25(June 20 Suppl) [abstract 8510]
- In 2011, the FDA approved ipilimumab for late-stage (metastatic) melanoma. Ipilimumab (Yervoy; Bristol-Myers Squibb Company, Princeton, NJ) is a monoclonal antibody to cytotoxic T-lymphocyte antigen-4 (CTLA4), which is also known as CD152 (cluster of differentiation 152). *CTLA4, a member of the immunoglobulin superfamily, is expressed on the surface of T cells and transmits an inhibitory signal.* CTLA4 is similar to ***CD28***, a ***costimulatory protein*** that is also present on the surface of T-cells. Both CTLA4 and CD28 bind to CD80 (B7–1) and CD86 (B7–2) on antigen-presenting cells (APCs). Response to an antigen begins when an APC loads a peptide on its major histocompatibility complex (MHC) antigen and presents this to a resting T cell through its T-cell receptor (TCR). The outcome depends in part on the interaction of CD80 and CD86 on the APC with CTLA4 and CD28 on the T-cell surface. An interaction with CTLA4 transmits an inhibitory signal to T cells, whereas CD28 transmits a stimulatory signal. By targeting CTLA4, ipilimumab reduces inhibitory signals and may augment the immune response. Ipilimumab's safety and effectiveness were established in a single international study of 676 patients. All patients in the study had stopped responding to other FDA approved or commonly used treatments for melanoma. Because of the unusual and severe side effects associated with ipilimumab, it was approved with a Risk Evaluation and Mitigation Strategy to inform healthcare professionals about these serious risks. A medication guide is also provided to patients to inform them about potential side effects

  Hodi FS et al. N Engl J Med 2010;363:711–723

- In 2011, the FDA also approved vemurafenib for the treatment of late-stage (metastatic) or unresectable melanoma with the BRAF V600E mutation. Vemurafenib is a potent inhibitor of oncogenic BRAF kinase activity. In the BRIM-3 study, vemurafenib produced improved rates of overall and progression-free survival in patients with previously untreated melanoma with the BRAF V600E mutation. Vemurafenib resulted in a 63% relative reduction in the risk of death and a 74% relative reduction in the risk of either death or disease progression when compared to dacarbazine

  Chapman PB et al. N Engl J Med 2011;364:2507–2516

- In 2013 the FDA approved the MEK inhibitor trametinib in combination with the BRAF inhibitor dabrafenib to treat patients with advanced melanoma that is unresectable or metastatic. The FDA had approved both drugs as single agents to treat patients with unresectable or metastatic melanoma. They were approved as a combination therapy for patients with melanoma whose tumors express BRAF V600E and V600K. Trametinib in combination with dabrafenib was the first drug approved for combination treatment of melanoma. The safety and effectiveness of the combination were demonstrated in a clinical trial of 162 participants with unresectable or metastatic melanoma with the BRAF V600E or V600K mutation, most of whom had not received prior therapy. Participants received either the combination or dabrafenib as a single agent. Results showed that 76% of participants treated with the combination had an OR that lasted 10.5 months. In contrast, 54% of participants treated with dabrafenib as a single agent experienced an OR that lasted 5.6 months. One of the serious side effects of dabrafenib—the development of a new squamous cell carcinoma of the skin—was reduced with the combination, consistent with the biology of the effects of these two drugs on the targeted molecular pathway. The incidence of squamous cell carcinoma of the skin in this trial was 7% with the combination compared to 19% with single agent dabrafenib. The FDA approved the combination under the agency's accelerated approval program.

Expert Opinion (*continued*)

- The programmed death-1 (PD-1) receptor is a T-cell co-inhibitory molecule that binds to PD-1 and PD-2 ligands (PD-L1 and PD-L2) on antigen-presenting cells and suppresses T-cell activation. These ligands are aberrantly expressed in several tumors, including melanoma. Inhibiting the interaction between PD-1 and PD-L1 has been shown to enhance T-cell responses in vitro and mediates preclinical anti-tumor activity. As a result, the anti-PD-1 monoclonal antibody BMS-936558 (also known as MDX-1106 and ONO-4538) and the anti-PD-L1 monoclonal antibody BMS-936559 were developed. In a phase I dose-escalation study, the anti-PD-1 antibody BMS-936558 was administered to 104 patients with advanced melanoma. Twenty-six objective responses were observed in 94 evaluable patients (28%) at doses ranging from 0.1 to 10 mg/kg. At a dose of 3 mg/kg, the response rate was 41% (in 7 of 17 patients). The response was also durable; in 13 of the 26 patients with an objective response, the response lasted for 1 year or more. Stable disease lasting at least 24 weeks was seen in 6 patients (6%). PFS at 24 weeks was 41%. The most common treatment-related adverse events were fatigue, rash, diarrhea, pruritis, decreased appetite, and nausea. Grade 3 or 4 treatment-related adverse events were seen in 14%, and there were 3 drug-related deaths (1%) due to pneumonitis. In a separate phase I study, the anti-PD-L1 antibody BMS-936559 was tested in 55 patients with advanced melanoma. Nine out of 52 patients with melanoma (17%) had an objective response at escalating dose ranges (1 to 10 mg/kg), with 3 patients achieving a complete response. All 9 patients started treatment at least 1 year before the data analysis, and of these patients, 5 had an objective response lasting for at least 1 year. In addition, 14 of 52 patients (27%) had stable disease lasting at least 24 weeks. PFS at 24 weeks was 42%. The most common treatment-related adverse events were fatigue, infusion reactions, diarrhea, arthralgia, rash, nausea, pruritis, and headache. Grade 3 or 4 treatment-related adverse events were seen in 9%

REGIMEN

INTERFERON ALFA-2B

Kirkwood JM et al. J Clin Oncol 1996;14:7–17 [Trial E1684]

Interferon alfa-2b 20 million units/m² per dose; administer intravenously over 20 minutes in 0.9% sodium chloride injection (0.9% NS), sufficient to produce a solution with an interferon concentration ≥10 million units/100 mL, 5 consecutive days/week for 4 weeks (total dosage/week = 100 million units/m²), *then:*
Interferon alfa-2b 10 million units/m² per dose; administer subcutaneously 3 days/week for 48 weeks (total dosage/week = 30 million units/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

ECOG 1684 was a study of 143 patients with deep primary (T4) or regionally metastatic (N1) cutaneous melanoma who had no evidence of distant metastatic disease or significant medical or psychiatric comorbidity and who had not previously received systemic adjuvant therapy

Efficacy (N = 143)

Median relapse-free survival	1.72 years
Overall median survival	3.8 years
5-Year relapse-free survival rate	37%

Treatment Modifications

Adverse Event	Dose Modification
First occurrence of a DLT*	Hold dose until resolution, then reduce interferon alfa dosage by 33%
Second occurrence of a DLT*	Hold dose until resolution, then decrease interferon alfa dosage by 66%
Third occurrence of a DLT*	Discontinue interferon alfa therapy

*Definitions of dose-limiting toxicities (DLTs): hematologic DLT, granulocyte count <500/mm³; hepatic DLT, SGPT (ALT) or SGOT (AST) >5 times ULN (upper limit of normal)

Notes:
1. Dose reductions or delays are usually required at least once for 50% of patients during the IV treatment phase and for 48% during the subcutaneous treatment phase
2. Of patients with appropriate dose reductions, 74–90% continue treatment on protocol for 1 year or until relapse
3. Dose delays and reductions as a result of adverse events occur in 28–44% of patients during the induction phase and in 36–52% of patients during the maintenance phase
4. A response to other adverse events is determined largely by the patient and treating physician. Side effects are rarely life-threatening and should not lead to discontinuation if appropriate and proactive supportive care is provided

Kirkwood JM et al. J Clin Oncol 2002;20:3703–3718

Three U.S. national cooperative group studies have evaluated the benefit of HDI as an adjuvant for high-risk melanoma. All demonstrate significant and durable reduction in the frequency of relapse, while the first and third trials demonstrated significant improvement in the fraction of patients surviving compared to observation (E1684) or to GMK that was a promising vaccine in 1994. E1684 showed a median relapse-free survival (RFS) of 1.72 years for HDI versus 0.98 year with observation (P1 = 0.0023), and a median OS of 3.82 versus 2.78 years (P1 = 0.0237), respectively. E1694 was closed early, based on analysis demonstrating significantly increased mortality and relapse risk for patients who did not receive HDI. E1690 was inconsistent in that mortality benefit did not track with RFS benefit as it did in the E1684 and E1694 trials, but was unique in that it began before FDA approval of HDI, but was completed after FDA approval of HDI for treatment of high-risk melanoma. Not surprisingly, patients who were assigned observation in this trial, where no nodal staging by either elective or sentinel lymph node surgery was required, were associated with systematic crossover from observation to posttrial treatment at nodal relapse with HDI. This may explain why this trial showed RFS, but not OS differences that were observed in the prior and subsequent U.S. Cooperative Group trials. The analysis of each of the foregoing studies has been updated to April 2001, representing a median follow-up of 12.6 years for E1684, where significant clinical benefit of HDI versus observation is evident with respect to RFS (HR = 1.38; P2 = 0.02). Improvement of OS with HDI over observation remains, with diminished magnitude, at this most recent update (HR = 1.22; P2 = 0.18). The changes observed with late reanalysis of this study do not detract from the meaning of the mature observation published at a median follow-up of 6.9 years—considerably longer than many other trial reports. It raises interesting questions regarding competing causes of mortality, because the differences in RFS for the HDI group remain stable out to more than 15 years—and may be a result of deaths from vascular or other events, among the treatment cohort now well into the eighth decade of life (median age now >70 years). In E1694, at a median follow-up of 2.1 years, HDI continued to demonstrate superiority to the GMK in terms of both RFS (HR = 1.33; P2 = 0.006) and OS (HR = 1.32; P2 = 0.04).

Toxicity (N = 143)

	% G1/2	% G3/4
Constitutional*	50	48
Myelosuppression	66	24
Neutropenia		26
Neurologic	55	28
Depression		10
Hepatotoxicity	48	14

*Fever, chills, fatigue, malaise, diaphoresis

Notes:

1. Other adverse effects of IFN alfa-2b: anorexia, weight loss, alopecia, transient mild rash-like erythema, exacerbation of psoriasis, erythema or induration at the site of injection, impaired cognitive function, alternating episodes of manic depression
2. Rare adverse effects of IFN alfa-2b: rhabdomyolysis, delirium, cutaneous necrosis at the site of injection
3. Thyroid dysfunction (hypothyroidism or hyperthyroidism) occurs in 8–20% of patients

Kirkwood JM et al. J Clin Oncol 1996;14:7–17
Kirkwood JM et al. J Clin Oncol 2002;20:3703–3718

Therapy Monitoring

1. *WBC, LFTs, electrolytes, and mineral panel:* Weekly during induction, monthly during maintenance therapy for at least 3 months, then no less frequently than every 3 months in patients who are stable with no new complaints
2. *Other standard tests (eg, serum electrolytes, thyroid-stimulating hormone [TSH] creatine kinase [CK] levels):* Recommended at baseline and at least every 3 months during treatment

Note

Developed as an adjuvant regimen

REGIMEN

PEGYLATED INTERFERON ALFA-2B

Eggermont AMM et al. J Clin Oncol 2012;30:3810–3818
Eggermont AMM et al. Lancet 2008;372:117–126

Premedication:
Acetaminophen 650–1000 mg; administer orally 30 minutes before the first dose and as needed prior to subsequent doses of peginterferon alfa-2b
Peginterferon alfa-2b 6 mcg/kg per dose; administer subcutaneously, once weekly for 8 consecutive weeks (induction phase; total dosage/week = 6 mcg/kg), *and then:*
Peginterferon alfa-2b 3 mcg/kg per dose; administer subcutaneously, once weekly for 5 years (maintenance phase; total dosage/week = 3 mcg/kg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Absolute neutrophil count (ANC) <500/mm^3, platelet count <50,000/mm^3, ECOG PS ≥2, or nonhematologic toxicity G ≥3	Hold dose until ANC ≥500/mm^3, platelet count ≥50,000/mm^3, ECOG PS 0-1, and nonhematologic toxicity G ≤1. Then, resume at a reduced dose (see below)
Persistent or worsening severe neuropsychiatric disorders, G4 nonhematologic toxicity, inability to tolerate a dose of 1 mcg/kg per week, or new or worsening retinopathy	Permanently discontinue treatment

ECOG PS, Eastern Cooperative Oncology Group Performance Status

Starting Dose	Dose Modification
6 mcg/kg per week	**For doses 1 to 8** First modification: 3 mcg/kg per week Second modification: 2 mcg/kg per week Third modification: 1 mcg/kg per week Permanently discontinue peginterferon if patient is unable to tolerate 1 mcg/kg per week
3 mcg/kg per week	**For doses 9 to 260** First modification: 2 mcg/kg per week Second modification: 1 mcg/kg per week Permanently discontinue peginterferon if patient is unable to tolerate 1 mcg/kg per week

NR, Not reported

Therapy Monitoring

Every 3 months for 3 years and then every 6 months for 2 years: CBC with differential, LFTs, basic metabolic panel, LDH, physical examination, chest x-ray, and CT scans

REGIMEN

DACARBAZINE (DTIC)

Middleton MR et al. J Clin Oncol 2000;18:158–166

Dacarbazine 250 mg/m² (initial dosage) per day; administer intravenously in 50–250 mL of either 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over 30 minutes for 5 consecutive days on days 1–5, every 21 days (total dosage/cycle = 1250 mg/m²)

Alternative regimen:

Eggermont AMM, Kirkwood JM. Eur J Cancer 2004;40:1825–1836

Dacarbazine 1000 mg/m²; administer intravenously in 50–250 mL D5W or 0.9% NS over 30 minutes on day 1, every 28 days, for 2 cycles (total dosage/cycle = 1000 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days of chemotherapy is HIGH

Potential for delayed symptoms

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 136 patients with histologically confirmed incurable or unresectable advanced metastatic melanoma. Patients with nonmeasurable disease, ocular melanoma, or CNS metastases were excluded

Efficacy (N = 136)

Complete response	2.9%
Partial response	10.3%
Stable disease	17.7%
Progressive disease	69.1%
Median overall survival	6.4 months

Toxicity (N = 136)

Treatment Modifications

Retreatment allowed if ANC ≥1500/mm³ and platelet count ≥100,000/mm³

Adverse Event	Dose Modification
Retreatment delayed by ≥2 weeks	Reduce dacarbazine dosage by 25%
G3/4 nonhematologic toxicity	Reduce dacarbazine dosage by 50%
>2 Dosage reductions	Discontinue therapy

Therapy Monitoring

1. *Before each cycle:* CBC with differential, LFTs, mineral panel, and electrolytes
2. *Response evaluation every 2 cycles:* PE, chest x-ray, and CT scans

REGIMEN

TEMOZOLOMIDE

Middleton MR et al. J Clin Oncol 2000;18:158–166

Temozolomide 200 mg/m² per day; administer orally for 5 consecutive days on days 1–5, every 28 days (total dosage/cycle = 1000 mg/m²)

Alternative regimens:

Brock CS et al. Cancer Res 1998;58:4363–4367

Temozolomide 75 mg/m² per day; administer orally for 21 consecutive days, every 28 days, for 2 cycles, followed by reevaluation of index measurable disease (total dosage/week = 525 mg/m²; total dosage/28-day cycle = 1575 mg/m²)

Patel PM et al. EORTC 18032 [poster]. In: 33rd Annual ESMO Congress. Stockholm, Sweden; 2008

Temozolomide 150 mg/m² per day; administer orally for 7 consecutive days, on days 1–7, every 14 days ("7 days on/7 days off"; total dosage/14-day cycle = 1050 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

ADVANCED DISEASE REGIMEN

CARBOPLATIN + PACLITAXEL

Hauschild A et al. J Clin Oncol 2009;27:2823–2830

Premedications:

Dexamethasone 20 mg per dose; administered orally or intravenously for 2 doses: the first dose between 12 and 14 hours before starting paclitaxel, and a second dose 6–7 hours before starting paclitaxel

Diphenhydramine 50 mg; administer intravenously per push 30 minutes before starting paclitaxel

Ranitidine 50 mg; administer intravenously in 25–100 mL of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes, 30–60 minutes before starting paclitaxel

Cycles 1 through 4

Paclitaxel 225 mg/m^2; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration between 0.3 and 1.2 mg/mL, over 3 hours before carboplatin on day 1, every 21 days cycle (total dosage/cycle = 225 mg/m^2)

Carboplatin AUC = 6 mg/mL • min*; administer intravenously, diluted in 0.9% NS or D5W to a concentration >0.5 mg/mL, over 30 minutes on day 1 every 21 days (total dose/cycle calculated to produce an AUC = 6 mg/mL • min*)

Cycles 5 through 10

Paclitaxel 175 mg/m^2; administer intravenously, diluted in 0.9% NS or D5W to a concentration between 0.3 and 1.2 mg/mL, over 3 hours on day 1, every 21 days (total dosage/cycle = 175 mg/m^2)

Carboplatin AUC = 5 mg/mL • min*; administer intravenously, diluted in 0.9% NS or D5W to a concentration >0.5 mg/mL, over 30 minutes on day 1, every 21 days (total dose/cycle calculated to produce an AUC = 5 mg/mL • min*)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Note: A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. The FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Notes:

1. If paclitaxel is discontinued because of hypersensitivity, carboplatin may be continued
2. If carboplatin is discontinued because of hypersensitivity, tinnitus, or hearing loss, paclitaxel may be continued
3. After 4 cycles of chemotherapy, the dose of both chemotherapy agents will be reduced to carboplatin AUC of = 5 mg/mL • min and paclitaxel 175 mg/m^2. Patients who had a dose reduction during the first 4 chemotherapy cycles will continue at reduced doses. There is no additional dose reduction at cycle 5; a second dose reduction would be triggered by an occurrence of toxicity
4. In the absence of unacceptable toxicity, patients may continue to receive chemotherapy until disease progression. After completing 10 cycles of chemotherapy, carboplatin and paclitaxel may be discontinued at the discretion of a treating physician

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **HIGH** with potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

• Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

See Chapter 47 for more information

Dose Modifications

Adverse Event	Dose Modification
If carboplatin target dose is an AUC = 6 mg/mL · min and paclitaxel dose is 225 mg/m² and one of the following occurs: • G4 neutropenia (ANC <500/mm³) lasting >7 days • G4 neutropenia (ANC <500/mm³) with fever (≥38°C [≥100.5°F]) • G4 thrombocytopenia (<25,000/mm³) • Lack of ANC or platelet count recovery to pretreatment levels by day 28 of each cycle • Any G3/4 nonhematologic toxicity (including neuropathy) attributed to carboplatin or paclitaxel, with the exception of G4 hypersensitivity reactions	Reduce carboplatin dose to AUC = 5 mg/mL · min and paclitaxel dose to 175 mg/m² on the same administration schedule *Note:* This dose reduction is permanent. Do not increase doses during subsequent cycles
If carboplatin target dose is an AUC = 5 mg/mL · min and paclitaxel dose is 175 mg/m² and one of the following occurs: • G4 neutropenia (ANC <500/mm³) lasting >7 days • G4 neutropenia (ANC <500/mm³) with fever (≥38°C [≥100.5°F]) • G4 thrombocytopenia (<25,000/mm³) • Lack of ANC or platelet count recovery to pretreatment levels by day 28 of each cycle • Any G3/4 nonhematologic toxicity (including neuropathy) attributed to carboplatin or paclitaxel, with the exception of G4 hypersensitivity reaction	Reduce carboplatin dose to AUC = 4 mg/mL · min and paclitaxel dose to 125 mg/m² on the same administration schedule *Note:* This dose reduction is permanent. Do not increase doses during subsequent cycles *Note:* If any of the criteria for dose reduction are met after this second dose reduction, discontinue carboplatin and paclitaxel
G4 hypersensitivity reactions to either paclitaxel or carboplatin	Discontinue the agent responsible for the hypersensitivity reaction *Note:* Continue the remaining chemotherapy agent at the same dose and administration schedule, in the absence of the discontinued agent

Toxicity (N = 134)

Therapy Monitoring

1. *Before each cycle:* CBC with differential, serum sodium, potassium, BUN, creatinine, glucose, SGOT (AST), SGPT (ALT), total bilirubin, alkaline phosphatase, LDH, albumin, amylase, lipase
2. *Response evaluation:* Every 2 cycles

ADVANCED/UNRESECTABLE MELANOMA REGIMEN

IPILIMUMAB

Hodi FS et al. N Engl J Med 2010;363:711–723

Ipilimumab 3 mg; administer intravenously, diluted in 0.9% sodium chloride injection or 5% dextrose injection to a concentration between 1 and 2 mg/mL, over 90 minutes, once every 3 weeks, for a total of 4 doses (total dosage/3-week cycle = 3 mg/kg)

Note: Adverse events associated with the administration of ipilimumab consist primarily of reactions that are immune in nature. Almost all immune-related adverse events can be managed with supportive care or corticosteroids. Corticosteroids do not appear to adversely affect patients who had an immune-related adverse event or alter objective antitumor responses. Glucocorticoids do not appear to alter the activity of activated CD8 + cells, and, therefore, may explain this unique characteristic of CTLA4 inhibition. Rash and colitis are reported most often during early use, whereas hypophysitis is reported with later doses. Ipilimumab immune-related adverse events are dose-dependent in incidence, and occurred more frequently after 10-mg/kg doses than with lower dosages

Patient Population Studied

Patients with a diagnosis of unresectable stage III or IV melanoma who had previously received therapy, including one or more of the following: dacarbazine, temozolomide, fotemustine, carboplatin, or aldesleukin. Other inclusion criteria were: Eastern Cooperative Oncology Group performance status of 0 or 1, and positive status for HLA-A*0201. Exclusion criteria included long-term use of systemic corticosteroids

Dose Modifications

Adverse Event	Dose Modification
Note: Among almost 3000 patients treated with ipilimumab, approximately 60% reported an adverse immune-related event; however, only 15% reported a serious adverse immune-related event	
Dermatologic Immune-Related Adverse Event	
Transient G1/2 skin rash	Continue therapy and treat symptoms with antihistamines or similar
G1/2 skin rash persisting >1–2 weeks	Administer topical or systemic corticosteroids
G3/4 skin rash	Administer intravenous corticosteroids until control is achieved
Stevens-Johnson syndrome, toxic epidermal necrolysis, or rash complicated by full-thickness dermal ulceration; or necrotic, bullous, or hemorrhagic manifestations; or erythema Multiforme	Permanently discontinue ipilimumab. Administer systemic glucocorticoid at a dose equivalent to 1–2 mg/kg per day of prednisone. When dermatitis is controlled, corticosteroid dose tapering toward discontinuation should occur over a period of at least 1 month
Nondermatologic Immune-Related Adverse Events	
Nondermatologic G1 toxicities	Continue therapy and treat symptoms
G2 enterocolitis	Withhold scheduled ipilimumab doses; administer antidiarrheal treatment and, if symptoms persist for >1 week, initiate systemic glucocorticoid at a dose equivalent to 0.5 mg/kg per day prednisone. If toxicities resolve to G ≤1, and if patient is receiving >7.5 mg prednisone per day or another glucocorticoid at an equivalent daily dose, resume ipilimumab at a dose of 3 mg/kg every 3 weeks until all 4 planned ipilimumab doses are administered, or 16 weeks after the first dose was given have elapsed, whichever occurs earlier. If toxicity does not improve to G ≤1, discontinue treatment permanently
G2 hepatotoxicity: aspartate aminotransferase (AST) or alanine aminotransferase (ALT) >3–5 times the ULN, or total bilirubin >1.5–3 times the ULN, or alkaline phosphatase >2.5–5 times the ULN	Withhold scheduled ipilimumab doses until toxicity improves to G ≤1. If toxicities resolve to G ≤1, and if patient is receiving >7.5 mg prednisone per day or another glucocorticoid at an equivalent daily dose, resume ipilimumab at a dose of 3 mg/kg every 3 weeks until all 4 planned ipilimumab doses are administered, or 16 weeks after the first dose was given have elapsed, whichever occurs earlier. If toxicity does not improve to G ≤1, discontinue treatment permanently
G2 neuropathy (not interfering with daily activities)	
G2 immune-mediated adverse reaction other than enterocolitis or symptomatic endocrinopathy	

(*continued*)

Dose Modifications (*continued*)

Adverse Event	Dose Modification
G2 immune-mediated endocrinopathies	Withhold scheduled dose of ipilimumab until toxicity improves to G ≤1. If toxicities resolve to G ≤1, and if patient is receiving less than 7.5 mg prednisone or equivalent per day, resume ipilimumab at a dose of 3 mg/kg every 3 weeks until administration of all 4 planned doses or 16 weeks from first dose have elapsed, whichever occurs earlier. If toxicity does not improve to G ≤1, discontinue treatment permanently. **Initiate appropriate hormone replacement therapy**
G2 immune-mediated ocular disease	Withhold scheduled dose of ipilimumab. If toxicities resolve to G ≤1, and if patient is receiving less than 7.5 mg prednisone or equivalent per day, resume ipilimumab at a dose of 3 mg/kg every 3 weeks until administration of all 4 planned doses or 16 weeks from first dose have elapsed, whichever occurs earlier. If toxicity does not improve to G≤1, discontinue treatment permanently. **Administer corticosteroid eye drops to patients who develop uveitis, iritis, or episcleritis**
Persistent G2 immune-mediated adverse reaction, or symptomatic endocrinopathy, or inability to reduce corticosteroid dose to 7.5 mg prednisone per day, or another glucocorticoid at an equivalent daily dose	Permanently discontinue ipilimumab
Failure to complete full treatment course within 16 weeks after administration of first dose of ipilimumab	
G3/4 immune-mediated colitis with abdominal pain, fever, ileus, or peritoneal signs; increase in stool frequency (≥7 over baseline); or stool incontinence, need for intravenous hydration for >24 hours, gastrointestinal hemorrhage, or gastrointestinal perforation	Permanently discontinue ipilimumab and initiate systemic corticosteroids at a dose of 1–2 mg/kg of prednisone per day or another glucocorticoid at an equivalent daily dose. Upon improvement to G ≤1, initiate corticosteroid taper and continue to taper over at least 1 month. In clinical trials, rapid corticosteroid tapering resulted in recurrence or worsening symptoms of enterocolitis in some patients
G3/4 hepatotoxicity: aspartate aminotransferase (AST) or alanine aminotransferase (ALT) >5 times the ULN, or total bilirubin >3 times the ULN, or alkaline phosphatase >5 times the ULN	Permanently discontinue ipilimumab and administer systemic corticosteroids at a dose of 1–2 mg/kg of prednisone per day or another glucocorticoid at an equivalent daily dose. When liver function tests show sustained improvement or return to baseline, initiate corticosteroid tapering and continue to taper over 1 month. During clinical development, **mycophenolate** treatment was administered to patients who had persistent severe hepatitis despite high-dose corticosteroids
G3/4 motor or sensory neuropathy (interfering with daily activities), Guillain-Barré syndrome, or myasthenia gravis	Permanently discontinue ipilimumab. Institute medical intervention as appropriate for management of severe neuropathy. Consider initiation of systemic corticosteroids at a dose of 1–2 mg/kg of prednisone per day or another glucocorticoid at an equivalent daily dose for severe neuropathies
G3/4 immune-mediated endocrinopathy	Permanently discontinue ipilimumab. Initiate systemic corticosteroids at a dose of 1–2 mg/kg of prednisone per day or another glucocorticoid at an equivalent daily dose, and **initiate appropriate hormone replacement therapy**
G3/4 immune-mediated ocular disease or disease that is unresponsive to topical immunosuppressive therapy (conjunctivitis, blepharitis, episcleritis, scleritis)	Permanently discontinue ipilimumab
G3/4 immune-mediated reactions involving any organ system (eg, nephritis, pneumonitis, pancreatitis, noninfectious myocarditis, angiopathy, temporal arteritis, vasculitis, polymyalgia rheumatica, leukocytoclastic vasculitis, or arthritis)	

ULN, Upper limit of normal

Efficacy (N = 137)

Median overall survival	10.1 months (95% CI, 8.0–13.8)
Rate of overall survival at 12 months	45.6%
Rate of overall survival at 18 months	33.2%
Rate of overall survival at 24 months	23.5%
Objective response*,†	10.9%
Complete response†	1.5%
Partial response†	9.5%
Stable disease†	17.5%
Reinduction (n = 8)	
Complete response	12.5% (1/8)
Partial response	25% (2/8)
Stable disease	37.5% (3/8)

*Responses to ipilimumab continued to improve beyond week 24: 2 patients with SD improved to a PR, and 3 patients with a PR improved to a CR. Among 31 patients given reinduction therapy with ipilimumab, 21 patients achieved a CR, PR, or SD
†Duration of response: 60.0% maintained an objective response for at least 2 years (26.5–44 months, ongoing)

Injection-site reactions	17%
Vitiligo	12.8%
Proctocolitis with rectal pain	4.3%
Endocrine immune-related adverse event*	8.5%

*Required hormone-replacement therapy

Therapy Monitoring

1. Monitor liver function tests (LFTs), thyroid function tests (TFTs) and clinical chemistries at the start of treatment, before each dose, and as clinically indicated based on symptoms
2. Monitor patients for signs and symptoms of enterocolitis (diarrhea, abdominal pain, mucus or blood in stool, with or without fever) and bowel perforation
3. Monitor patients for signs and symptoms of dermatitis
4. Monitor for symptoms of motor or sensory neuropathy
5. Monitor patients for clinical signs and symptoms of hypophysitis, adrenal insufficiency, and hyper- or hypothyroidism. Patients may present with fatigue, headache, mental status changes, abdominal pain, unusual bowel habits, and hypotension, or nonspecific symptoms that may resemble other causes such as brain metastasis or underlying disease
6. Imaging studies (enlargement of the pituitary gland) may be considered in the diagnosis of hypophysitis
7. Endoscopy may be considered for persistent or severe gastrointestinal symptoms

Toxicity (N = 131) (*continued*)

Toxicity—General Notes:

1. All immune-related events occurred during the induction and reinduction periods
2. Median time to the resolution of immune-related adverse events of G2–4 was 4.9 weeks (95% CI, 3.1–6.4)
3. After administration of corticosteroids, median time to resolution of diarrhea G ≥2 was 2.3 weeks for 14 of 15 patients
4. In addition to corticosteroids, 4 patients received infliximab (antitumor necrosis factor-α antibody) for diarrhea G ≥3 or colitis
5. Ongoing events in 94 persons who survived ≥2 years included rash, pruritus, diarrhea, anorexia, and fatigue, generally G1/2 (5–15% of patients) and G3 leukocytosis (1 patient)
6. There were 14 deaths related to the study drugs (2.1%), of which 7 were associated with immune-related adverse events

Toxicity—Specific Notes:

Skin:

1. Rash is the most common immune related toxicity associated with ipilimumab (incidence ≈20%)
2. Median time to onset of moderate, severe, or life-threatening immune-mediated dermatitis was 3.1 weeks (range: days to 17.3 weeks after initiation)

Gastrointestinal:

1. Most common serious adverse event affects the lower gastrointestinal tract and manifests as diarrhea and/or intestinal bleeding
2. Serious lower intestinal toxicity was reported in ≈13% of patients treated at 10 mg ipilimumab/kg of body weight
3. *Onset of diarrhea occurred within first 12 weeks after starting treatment, and was generally reversible*

Hepatic:

1. Immune-related hepatotoxicity consists of elevated LFTs and immune hepatitis
2. Patients with right upper quadrant pain, nausea, or vomiting should have LFTs evaluated immediately, although hepatotoxicity can occur in the absence of symptoms
3. In patients with hepatotoxicity, rule out infectious or malignant causes and increase frequency of LFT monitoring until resolution

Endocrine:

1. Most patients with hypophysitis/hypopituitarism present with headache; however, visual disturbances, fatigue, confusion, and impotency are common symptoms
2. Median time to onset of moderate-to-severe immune-mediated endocrinopathy was 11 weeks (range: days to 19.3 weeks after initiation)
3. Of 21 patients with moderate to life-threatening endocrinopathy, 17 required long-term hormone replacement therapy, most commonly adrenal (n = 10) and thyroid (n = 13) replacement

Neurologic:

1. Myasthenia gravis and cases of Guillain-Barré syndrome have been reported in association with ipilimumab use
2. Monitor for symptoms of motor and sensory neuropathy

ADVANCED/UNRESECTABLE MELANOMA REGIMEN

VEMURAFENIB

Chapman PB et al. N Engl J Med 2011;364:2507–2516

Vemurafenib 960 mg/dose; administer orally, twice daily without regard to food, continually (total dose/week = 13,440 mg)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

Adverse Event	Dose Modification
G1 or G2 (tolerable)	None; maintain dose at 960 mg twice daily
G2 (intolerable) or G3	Hold dose until G ≤1, then resume vemurafenib at 720 mg twice daily. If the adverse event recurs, hold dose until G ≤1, then further reduce the vemurafenib dose to 480 mg twice daily. If the adverse event occurs a third time, permanently discontinue vemurafenib
G4	Discontinue permanently or hold dose until G ≤1 and then resume vemurafenib at 480 mg twice daily. If the adverse event recurs, discontinue permanently
Cutaneous squamous cell carcinoma	None; maintain dose at 960 mg twice daily; resect lesion

Patient Population Studied

The study evaluated 337 patients with unresectable, previously untreated stage IIIC or stage IV melanoma that tested positive for the BRAFV600E mutation. Patients were excluded if they had a history of cancer within the past 5 years (except basal or squamous cell carcinoma of the skin or carcinoma of the cervix), metastases to the central nervous system (unless such metastases were definitively treated more than 3 months previously with no progression and no requirement for continued glucocorticoid therapy), or if they were on any other concomitant anticancer therapy

Therapy Monitoring

1. *At baseline:* Contrast CT or MRI of the brain, chest, abdomen, pelvis, and other anatomical regions as clinically indicated; physical and dermatologic examination; electrocardiography; CBC with differential; LFTs; basic metabolic panel; and LDH
2. *Every 3 weeks:* Physical examination, CBC with differential, LFTs, basic metabolic panel, and LDH
3. *Every 6 weeks:* Electrocardiography
4. Tumor assessments are performed at baseline, at weeks 6 and 12, and every 9 weeks thereafter

Therapy Modifications

Dose Levels	Vemurafenib Dose
Initial dose	960 mg twice daily
First dose reduction	720 mg twice daily
Second dose reduction	480 mg twice daily

Efficacy

Overall Survival (N = 336)	
Hazard ratio	0.37

ADVANCED/UNRESECTABLE MELANOMA REGIMEN

DABRAFENIB + TRAMETINIB

Flaherty et al. N Engl J Med 2012;367:1694–1703

Dabrafenib 150 mg; administer orally twice daily at least 1 hour before or 2 hours after a meal
Trametinib 2 mg; administer orally once daily at least 1 hour before or 2 hours after a meal

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with histologically confirmed metastatic melanoma with either BRAF V600E or BRAF V600K mutations were eligible for inclusion. Eligible patients had measurable disease, an ECOG PS of 0 or 1. Patients with treated brain metastases and at least a 3-month history of stable disease were allowed to enroll. Patients were randomly assigned to receive 150 mg of dabrafenib twice daily plus once-daily trametinib at a dose of either 1 mg (combination 150/1) or 2 mg (combination 150/2) or 150 mg of dabrafenib monotherapy twice daily. There were no significant differences among groups except that patients in the combination 150/2 group were older than those in the monotherapy group ($P = 0.04$).

Dabrafenib and Trametinib Dose Modifications

Dabrafenib Dose Levels

Dose Reductions	Dose and Schedule
First dose reduction	100 mg dabrafenib orally twice daily
Second dose reduction	75 mg dabrafenib orally twice daily
Third dose reduction	50 mg dabrafenib orally twice daily
If unable to tolerate 50 mg twice daily	Discontinue dabrafenib

Dabrafenib Dose Modification

Target Organ	Adverse Reactions*	Dose Modification
Febrile drug reaction	Fever of 101.3°F to 104°F	Withhold dabrafenib until AE resolves then resume dabrafenib at same dose or at a reduced dose
	• Fever higher than 104°F • Fever complicated by rigors, hypotension, dehydration or renal failure	• Permanently discontinue dabrafenib or • Withhold dabrafenib until AE resolves then resume dabrafenib at same dose or at a reduced dose
Other	• Intolerable G2 AE • Any G3 AE	Withhold dabrafenib until AE resolves to ≤G1 then resume dabrafenib at a reduced dose
	First occurrence of any G4 AE	Either: • Permanently discontinue dabrafenib or • Withhold dabrafenib until AE resolves to ≤G1 then resume dabrafenib at a reduced dose
	Recurrent G4 AE Intolerable G2 or any G3/4 AE on dabrafenib 50 mg twice daily	Permanently discontinue dabrafenib

(*continued*)

Dabrafenib and Trametinib Dose Modifications (*continued*)

Trametinib Dose Modification

Target Organ	Adverse Reactions*	Dose Modification
Cutaneous	G2 rash	Reduce dose of trametinib by 0.5 mg or discontinue trametinib in patients taking trametinib 1 mg daily
	Intolerable G2 rash that does not improve within 3 weeks following dose reduction G3/4 rash	Withhold trametinib for up to 3 weeks. If improved resume trametinib at a lower dose (reduced by 0.5 mg)
	Intolerable G2 or G3/4 rash that does not improve within 3 weeks despite interruption of trametinib dosing	Permanently discontinue trametinib
Cardiac	Asymptomatic, absolute decrease in LVEF of 10% or greater from baseline and is below institutional lower limits of normal (LLN) from pretreatment value	Withhold trametinib for up to 4 weeks
	Asymptomatic, absolute decrease in LVEF of ≥10% from baseline and is <LLN that improves to normal LVEF value within 4 weeks following interruption of trametinib	If improved within 4 weeks, resume trametinib at a lower dose (reduced by 0.5 mg) or discontinue trametinib in patients taking trametinib 1 mg daily
	• Symptomatic congestive heart failure • ≤Absolute decrease in LVEF of ≥20% from baseline that is <LLN • Absolute decrease in LVEF of ≥10% from baseline and is <LLN that does not improve to normal LVEF value within 4 weeks following interruption of trametinib	Permanently discontinue trametinib
Ocular	G2/3 retinal pigment epithelial detachments (RPED)	Withhold trametinib for up to 3 weeks
	G2/3 RPED that improves to Grade 0–1 within 3 weeks	If improved within 3 weeks, resume trametinib at a lower dose (reduced by 0.5 mg)
	• Retinal vein occlusion • G2/3 RPED that does not improve to at least G1 within 3 weeks	Permanently discontinue trametinib
Pulmonary	Interstitial lung disease/pneumonitis	Permanently discontinue trametinib
Other	G3 AE	Withhold trametinib for up to 3 weeks
	If G3 AE improves to G0/1 following interruption of trametinib within 3 weeks	Reduce dose of trametinib by 0.5 mg or discontinue trametinib in patients taking trametinib 1 mg daily
	• G4 AE • G3 AE that does not improve to G0/1 within 3 weeks	Permanently discontinue trametinib

AE, adverse event; RPED, retinal pigment epithelial detachments
*National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) version 4.0

*Adverse events reported in ≥20% of patients in any group, regardless of whether a causal relationship was likely. In addition to these events, there was one death from sepsis in 150/1 combination group and three deaths in the 150/2 combination group (two from brain hemorrhage and one from pulmonary embolism). None were considered related to study drug. Neutropenia (G3/4) occurred in 11% of patients in the 150/2 combination group, with one case of febrile neutropenia. Acneiform dermatitis occurred in 11% of patients in the 150/1 combination group, 16% in the combination group, and 4% in the 150/2 monotherapy group, with no G3/4 events reported

†One patient who was assigned to the monotherapy group received combination 150/2 and so was included in the combination 150/2 safety analyses

‡For these categories, no G4 events were reported

§Keratoacanthoma was classified as cutaneous squamous-cell carcinoma

Treatment Monitoring

1. At baseline: Contrast CT or MRI of the brain, chest, abdomen, pelvis, and other anatomical regions as clinically indicated; physical and dermatologic examination; electrocardiography; CBC with differential; LFTs; basic metabolic panel; and LDH
2. Every 3 weeks: Physical examination, CBC with differential, LFTs, basic metabolic panel, and LDH
3. Tumor assessments are performed at baseline, at weeks 6 and 12, and every 9 weeks thereafter

26. Mesothelioma

Verna Vanderpuye, MD, Anish Thomas, MD, and Nicholas J. Vogelzang, MD

Pleural Mesothelioma

Epidemiology

Incidence: 3000 new cases per year
Median age: 60 years
Male to female ratio: 3:1

Peto J et al. Lancet 1995;345:535–539
Vogelzang NJ et al. Cancer 1984;53:377–383

Pathology

H & E staining
1. Epithelioid: 60% of cases = tubopapillary, granular, solid (occasional 5-year survival)
2. Sarcomatoid/mixed: 40% of cases (0% 5-year survival)

Immunohistochemical staining: Keratin positive, CEA negative, Leu M negative, calretinin positive
Cytogenetics: Deletion of short arm of chromosome 1 and 3 and long arm of chromosome 22

Chaihinan AP et al. In: Holland JC, Frei E, eds. Cancer Medicine. 5th ed. Hamilton, ON: BC Decker; 2000: 1293–1312
Corson JM. Semin Thorac Cardiovasc Surg 1997;9:347–355

Staging

No defined universal staging system

Rusch VW. Chest 1995;108:1122–1128

Additional information
1. *Thoracic lymph node involvement:* 20% at presentation/70% at autopsy
2. *Hematogenous metastases:* Liver, lung, and bone: usually late in disease course

Curran D et al. J Clin Oncol 1998;16:145–152
Herndon JE et al. Chest 1998;113:723–731
Symanowski JT et al. Proc Am Soc Clin Oncol 2003;22:647 [Abstract 2602]

Work-up

1. *Chest x-ray:* Initial tool in diagnosing pleural plaques and effusion
2. *CT scan or MRI:* CT scan or MRI can be used to assess extent of disease. Calcifications are not generally visible on CT scan. Furthermore, the CT scan is less sensitive than the MRI in depicting diaphragmatic, pericardial, and chest wall involvement
3. *PET scan:* Has shown benefit in assessing lymph node involvement but is useful in only 50–70% of cases
4. *Thoracentesis:* Used when there is a pleural effusion (30% diagnostic yield)
5. *CT-guided biopsy:* Depends on CT findings. If tumor is thick and easily biopsied, do a CT-directed biopsy
6. *Video-assisted thoracopic (VAT) surgery:* Do if on CT scan disease is thin or minimal or in a difficult location and thoracentesis is negative (90% diagnostic yield)

Steele JPC. Semin Oncol 2002;29:36–40

Survival

Overall survival: 6–18 months

Expert Opinion

Surgical management

Data regarding the choice of surgical procedure are derived mostly from observational studies involving selected patient populations treated with a variety of surgical techniques and adjuvant chemotherapies

- Pleurectomy and decortication (lung sparing surgery): Indicated for minimal bulky disease associated with massive or recurrent pleural effusions
- Extrapleural pneumonectomy (en bloc resection of ipsilateral lung, pleura [parietal and visceral], pericardium, and hemidiaphragm): Indicated for highly selected patients with early stage epithelioid type disease with extensive involvement of the diaphragm and visceral pleural surfaces, no nodal metastases, good performance status, and no comorbidities

Radiation therapy

Because of the large volume of lung in the radiation field, delivery of tumoricidal doses of radiation is difficult without causing serious toxicities. Hence, radiation is not usually recommended as single-modality treatment. It is, however, recommended for palliating pain and to prevent or treating chest wall masses that are the result of seeding from sites of invasive procedures, such as prior thoracocentesis or thorascopic surgery. It is also used as part of a combined modality approach in patients with surgically resectable disease

Chemotherapy

Chemotherapy is indicated in patients with malignant pleural mesothelioma whose disease is either unresectable or who are not otherwise candidates for curative surgery. Pemetrexed in combination with cisplatin is the standard first-line chemotherapy with vitamin B_{12} and folic acid given prophylactically to mitigate leukopenia and gastrointestinal adverse effects associated with pemetrexed

Yanagawa J, Rusch V. Thorac Surg Clin 2013;23:73–78

REGIMEN

PEMETREXED + CISPLATIN

Vogelzang NJ et al. J Clin Oncol 2003;21:2636–2644

Folic acid 350–1000 mcg daily; administer orally, beginning 1–3 weeks before chemotherapy and continuing throughout treatment with pemetrexed + cisplatin, *and*
Cyanocobalamin (vitamin B_{12}) 1000 mcg; administer intramuscularly every 9 weeks, beginning 1–3 weeks before chemotherapy and continuing throughout treatment with pemetrexed + cisplatin
Dexamethasone 4 mg; administer intravenously or orally twice daily for 3 consecutive days, starting the day before pemetrexed administration to decrease the risk of severe skin rash associated with pemetrexed (total dose/cycle = 24 mg)
Hydration: 0.9% Sodium chloride injection (0.9% NS), ≥1000 mL before and after cisplatin; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral nonalcoholic fluid intake. Monitor and replace magnesium/electrolytes as needed
Pemetrexed 500 mg/m²; administer intravenously in 100 mL 0.9% NS over 10 minutes, given before cisplatin on day 1, every 21 days (total dosage/cycle = 500 mg/m²)
Cisplatin 75 mg/m²; administer intravenously in 1000 mL 0.9% NS over 2 hours on day 1, beginning 30 minutes after pemetrexed has been administered, every 21 days (total dosage/cycle = 75 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Additional supportive care
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

Patient Population Studied

A study of 456 patients with advanced measurable pleural mesothelioma

Efficacy

Response rate	40–45%
Median time to progression	5–6 months
1-Year survival	50%
Median survival	12–13 months

Therapy Monitoring

1. *Before initial and repeated treatments:* H&P, CBC with differential, calculated creatinine clearance, serum electrolytes glucose, calcium, LFTs, and vitamin metabolites
2. *Treatment evaluation:* Every 2 cycles

Toxicity (N = 168 Fully Supplemented with Vitamins)

	% CTC G3/4
Hematologic	
Hemoglobin	4.2
Leukocytes	14.9
Neutrophils	23.2
Platelets	5.4
Febrile neutropenia	0.6
Nonhematologic	
Nausea	11.9
Fatigue	10.1
Vomiting	10.7
Diarrhea	3.6
Dehydration	4.2
Stomatitis	3
Anorexia	1.2
Rash	0.6

Three deaths thought possibly related to pemetrexed + cisplatin occurred before folic acid and vitamin B_{12} supplementation was added; none occurred thereafter

Treatment Modifications

Delay cycle until ANC is >1500/mm³ and platelet >100,000/mm³

Adverse Event	Dose Modification
G3 hematologic toxicities	Hold therapy until returns to baseline. Then decrease both drug dosages by 25%
G4 hematologic toxicities (thrombocytopenia)	Hold therapy until returns to baseline. Then decrease both drug dosages by 50%
Serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Decrease cisplatin dosage by 25%
Serum creatinine ≥2 mg/dL (≥177 µmol/L)	Hold therapy until serum creatinine <2 mg/dL (<177 µmol/L), then decrease cisplatin dosage by 25%
G ≥2 diarrhea	Hold chemotherapy until toxicity resolves to grade <2, then decrease both drug dosages by 25%
G3/4 mucositis	Decrease pemetrexed dosage 50%
Increased liver transaminases	Hold therapy until toxicity resolves, then decrease pemetrexed dosage by 25%
Other G ≥3 nonhematologic toxicities (except N/V, elevated transaminases and alopecia)	Delay treatment until toxicity resolves to baseline, then, decrease both drug dosages by 25% from previous dose levels

Delays of ≤42 days are permitted for recovery from pemetrexed- and cisplatin-related toxicities
Patients requiring 3 dose reductions: discontinue therapy

Notes

1. G2 neutropenia and anemia secondary to pemetrexed are brief and not cumulative
2. Anemia is cumulative with cisplatin. Consider using erythropoietin therapy if anemia G >1 occurs
3. Folate deficiency is best measured with homocysteine levels
4. Vitamin B_{12} deficiency can be tested most readily with methylmalonic acid (MMA) levels

(*continued*)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is at least ***MODERATE****. Potential for delayed emetic symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial brand, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm^3 or platelet count <100,000/mm^3	Delay start of cycle up to 42 days until ANC ≥1500/mm^3 and platelet count ≥100,000/mm^3
ANC nadir <500/mm^3 *and* platelets ≥50,000/mm^3	Administer 75% of the previous pemetrexed dose, *or* carboplatin AUC = 4 mg/mL per min
Platelet nadir count <50,000/mm^3 *and* any ANC	Administer 50% of the previous pemetrexed dose, *or* carboplatin AUC = 3 mg/mL per min
Recurrence of G3/4 thrombocytopenia or neutropenia after 2 dose reductions	Discontinue therapy
G3/4 nonhematologic toxicities	Delay treatment until there is resolution to G ≤1 then proceed with pemetrexed reduced to 75% of the previous dose and carboplatin at AUC = 4 mg/mL per min
Creatinine clearance* <45 mL/min (<0.75 mL/s)	Delay the next cycle until creatinine clearance ≥45 mL/min (≥0.75 mL/s)

*Calculated by the Cockcroft and Gault formula before each dose

Efficacy (N = 102)

Response Rate*,†	
Objective response rate	18.6% (95% CI, 11.6–27.5%)
Complete response	1.96% (2 patients) (10+ and 11 months)
Partial response	16.66% (17 patients)
Stable disease	47% (95% CI, 37.1–57.2%) (48 patients)
Progressive disease	34.3% (35 patients)
Response According to Histology	
Epithelial MPM	15/80 (18.8%)
Mixed histotype MPM	4/8 (50%)
Sarcomatoid MPM	0/7
Effect on ECOG Performance Status‡	
Patients with OR/baseline PS (N = 19)	0 (3)/1 (16)
Patients with OR/posttreatment PS	0 (10)/1 (9)
Patients with SD/baseline PS (N = 48)	0 (21)/1 (25)/2 (2)
Patients with SD/posttreatment PS	0 (23)/1 (22)/2 (3)
Median Follow-Up Time of 14.2 Months (95% CI, 12.2–15 Months) 26 without any Evidence of Disease Progression	
Median TTP§	6.5 months
Median OS‹	12.7 months
6-month survival estimates	70.0% (95% CI, 60.0–78.0%)
1-year survival estimates	51.6% (95% CI, 40.7–61.5%)

*Best tumor response was assessed according to an intent-to-treat analysis
†Response to treatment showed a trend that correlated with OS in univariate analysis (P = 0.069) and reached statistical significance in the multivariate model (P = 0.024). When SD patients were grouped with responders, the correlation with OS was much more significant (P <0.001)
‡Sixty-nine patients (68%) were symptomatic at the time of study enrollment. ECOG PS improved or was stable in the majority of patients who achieved response or SD
§TTP was significantly related to good PS (P = 0.047) and epithelial histology (P = 0.02) in both univariate and multivariate analyses
‹Patients' PS was the only factor significantly related to OS in univariate and multivariate analyses (P = 0.04)

Patient Population Studied

Patients with histologically proven malignant pleural mesothelioma who were not candidates for curative surgery. Eligibility criteria included ages >18 years, Eastern Cooperative Oncology Group (ECOG) performance status (PS) ≤2, and an estimated life expectancy of ≥12 weeks. Creatinine clearance ≥45 mL/min. Patients were excluded if they were unable to discontinue administration of aspirin and/or other nonsteroidal antiinflammatory agents for 2 days before (5 days for long-acting agents), the day of, and 2 days after the dose of pemetrexed

Patient Characteristics

Characteristic	Number of Patients (N = 102)	Percent
Sex

*G3/4 thrombocytopenia occurred after the second cycle in 7/10 (70%) patients
†G3/4 anemia occurred after the second cycle in 15 (88%) of 17 patients
‡Febrile neutropenia was reported in 2 patients
§Other toxicities reported as rare events included G4 rhabdomyolysis (1 patient), G2 hepatotoxicity (1 patient), G2 arthralgia-myalgia (2 patients), G2 genitourinary mucositis (2 patients), and G1 skin rash (2 patients)

Therapy Monitoring

1. *Before initial and repeated treatments:* H&P, CBC with differential, calculated or measured creatinine clearance, serum electrolytes, glucose, calcium, LFTs, and vitamin metabolites
2. *Treatment evaluation:* Every 2 cycles

REGIMEN

GEMCITABINE + CISPLATIN

Byrne MJ et al. J Clin Oncol 1999;17:25–30
van Haarst JW et al. Br J Cancer 2002;86(3):342–345

Hydration: 0.9% Sodium chloride injection (0.9% NS) ≥1000 mL before and after cisplatin; administer intravenously over a minimum of 2–4 hours. Monitor and replace magnesium/electrolytes as needed
Cisplatin 100 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 60 minutes, given before gemcitabine on day 1, every 28 days for 6 cycles (total dosage/cycle = 100 mg/m²), *plus*
Gemcitabine 1000 mg/m² per dose; administer intravenously in 50–250 mL 0.9% NS over 30 minutes, given on days 1, 8, and 15, every 28 days for 6 cycles (total dosage/cycle = 3000 mg/m²)

or

Cisplatin 80 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 60 minutes, on day 1, every 3 weeks for a maximum of 6 cycles (total dosage/cycle = 80 mg/m²), *plus*
Gemcitabine 1250 mg/m² per dose; administer intravenously in 50–250 mL 0.9% NS over 30 minutes, on days 1 and 8, every 3 weeks for a maximum of 6 cycles (total dosage/cycle = 2500 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is HIGH. Potential for delayed symptoms
Emetogenic potential with gemcitabine alone is LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 21 patients with advanced measurable pleural mesothelioma (Byrne MJ et al.)
A study of 25 patients with advanced measurable pleural mesothelioma (van Haarst JW et al.)

Therapy Monitoring

1. *Before chemotherapy on cycle days 1, 8, and 15:* CBC with differential, serum electrolytes, creatinine, bilirubin, ALT, and alkaline phosphatase
2. *Treatment evaluation:* Every 2 cycles

Byrne MJ et al. J Clin Oncol 1999;17:25–30

Efficacy (N = 46)

Response rate	18–47%
Duration of response	5–7 months
Estimated median survival	9.5–12 months
Estimated 1-year survival	41%

Nine of 10 responding patients achieved substantial or complete symptomatic improvement. Symptoms decreased significantly in 3 additional patients who achieved disease stabilization

From Byrne MJ et al. J Clin Oncol 1999;17:25–30
van Haarst JW et al. Br J Cancer 2002;86(3):342–345

Treatment Modifications

Serum creatinine >1.4 mg/dL (>124 µmol/L), but <1.7 mg/dL (<150 µmol/L)	Decrease cisplatin by 50% and gemcitabine by 25%
Serum creatinine >1.7 mg/dL (>150 µmol/L)	Withhold cisplatin and gemcitabine until serum creatinine <1.7 mg/dL (<150 µmol/L), then administer 50% of the previous cisplatin dosage and 75% of the previous gemcitabine dosage
WBC <3000/mm³ or platelet <100,000/mm³ on days 1 and 8 or days 1, 8, and 15 when gemcitabine treatment is planned	Decrease gemcitabine by 25%
WBC <2000/mm³ or platelet <75,000/mm³ when gemcitabine treatment is planned for day 8 or days 8 and 15	Omit gemcitabine

Byrne MJ et al. J Clin Oncol 1999;17:25–30

Toxicity (N = 21)

	Worst Toxicity Grade (%)				
	0	1	2	3	4
Hematologic					
Leukopenia	29	10	24	38	0
Thrombocytopenia*	24	14	29	14	19
Anemia	14	29	57	0	0
Nonhematologic					
Nausea/vomiting†	0	14	52	33	0
Stomatitis	62	38	0	0	0
Alopecia	71	24	5	0	0
Hearing loss	57	33	5	5	0
Neurologic	90	10	0	0	0

*Thrombocytopenia on days 8 and 15 was the major cause of dose modification
†One-third of patients had ≥1 episodes of severe nausea and vomiting, and symptoms were worse >24 hours after treatment

From Byrne MJ et al. J Clin Oncol 1999;17:25–30

Peritoneal Mesothelioma

Epidemiology

Incidence: 10% of all mesothelioma (200–400 new cases per year)
Median age: 53 years
Male to female ratio: 1:1

Survival

Median survival: 1 year

Expert Opinion

1. No standard treatment
2. Resectable disease
   a. *In women:* Treatment is the same as for ovarian cancer because these tumors behave and respond similarly to cytoreduction followed by cisplatin-based chemotherapy. Intraperitoneal (IP) chemotherapy has shown superiority over intravenous chemotherapy for advanced ovarian cancer
   b. *In men:* Treatment is the same as for pleural mesothelioma, or if disease is not related to asbestos exposure, it can be treated with IP chemotherapy
3. Locally advanced or recurrent disease: Give systemic chemotherapy as for pleural mesothelioma

Alberts DS et al. [Editorial]. J Clin Oncol 2002;20:3944–3949
Eltabbakh GH et al. J Surg Oncol 1999;70:6–12
Markman M, Kelsen D. J Cancer Res Clin Oncol 1992;118:547–550
Markman M et al. J Clin Oncol 2001;19:1001–1007

REGIMEN

INTRAPERITONEAL (IP) CISPLATIN + PACLITAXEL

Rothenberg ML et al. J Clin Oncol 2003;21:1313–1319

Dexamethasone 20 mg/dose; administer orally for 2 doses, 12 hours and 6 hours before paclitaxel on days 1 and 8, *plus*
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel on days 1 and 8, *plus*
Ranitidine 50 mg or **cimetidine** 300 mg; administer intravenously in 25–100 mL of a compatible solution; for example, 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes beginning 30–60 minutes before paclitaxel on days 1 and 8
Paclitaxel 135 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 24 hours on day 1, every 21 days for 6 cycles (total paclitaxel dosage/cycle given intravenously = 135 mg/m²)
Cisplatin 100 mg/m²; administer intraperitoneally in 2000 mL 0.9% NS warmed to body temperature on day 2, every 21 days for 6 cycles (total dosage/cycle = 100 mg/m²)
Paclitaxel 60 mg/m²; administer intraperitoneally in 2000 mL 0.9% NS, warmed to body temperature on day 8, every 21 days for 6 cycles (total paclitaxel dosage/cycle from IP route = 60 mg/m²)
Additional information: Drug distribution is facilitated by sequentially placing patients R side down, L side down, in Trendelenburg and in reverse Trendelenburg position for 15 minutes each after drugs are instilled IP. Cisplatin- and paclitaxel-containing fluids are not drained after instillation

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1 and 8 is ***LOW***
Emetogenic potential on day 2 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity (N = 68)

	% G3	% G4
Hematologic		
Neutropenia	21	59
Anemia	15	4
Thrombocytopenia	9	0
Infection with neutropenia	12	0
Nonhematologic		
Nausea	50	0

Catheter-related infection	10	0
	% G1	% G2
Alopecia	10	66

96% of patients experienced ≥1 G3/4 toxicity

Therapy Monitoring

1. *Before each treatment cycle:* PE, CBC with differential, serum creatinine, and serum bilirubin
2. *Weekly:* CBC, serum electrolytes, serum creatinine, calcium, magnesium, and LFTs

Patient Population Studied

A study of 68 patients with FIGO stage III epithelial ovarian cancer (tumor extending outside the pelvis and/or positive retroperitoneal or inguinal lymph nodes) with residual peritoneal disease ≤1 cm in largest dimension after surgical staging by GOG standards

Efficacy (N = 68)

Median disease-free survival	33 months
Median survival	51 months
2-Year survival rate	91%

Treatment Modifications

ANC ≥3000/mm³ and platelet ≥100,000/mm³ required to start cycle. Delay therapy up to 2 weeks to allow hematologic recovery

Adverse Event	Dose Modification
Hematologic toxicity	No dose modifications. Day 8 paclitaxel given without regard for CBC
G >2 peripheral neuropathy	Delay therapy until toxicity grade ≤2, then decrease all drug dosages by 20%
G2 abdominal pain	Decrease IP drug dosages by 20%
G3/4 abdominal pain	Decrease IP drug dosages by 40%
CrCl <50 mL/min	Hold cisplatin until CrCl >50 mL/min (>0.83 mL/s), then decrease cisplatin dosage to 75 mg/m² during all subsequent cycles
Peritoneal catheter dysfunction or inability to administer therapy IP	Modify regimen schedule and route of administration for all remaining cycles: Paclitaxel 135 mg/m² intravenously over 24 hours on day 1, every 21 days; cisplatin 100 mg/m² intravenously over 60 minutes on day 2, every 21 days

27. Multiple Myeloma

Aldo Roccaro, MD, PhD, Giada Bianchi, MD, Irene M. Ghobrial, MD, and Kenneth C. Anderson, MD

Epidemiology

Incidence: 24,050 (male: 13,500; female: 10,550.
Estimated new cases for 2014 in the United States)
7.5 per 100,000 males, 4.8 per 100,000 females
Deaths: Estimated 11,090 in 2014 (male: 6,110; female: 4,980)
Median age: 69 years
Male to female ratio: 1.4:1

Durie-Salmon Stage at presentation
Stage I 6%
Stage II 21%
Stage III 73%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Monoclonal gammopathy of uncertain significance (MGUS)
- Stable serum M-protein level <3 g/dL and bone marrow clonal plasma cells <10%
- Urine Bence Jones protein absent or minimal
- No related organ/tissue impairment (ROTI)*
- No evidence of other B-lymphoproliferative disorders
- Progression to multiple myeloma (MM) in ~1% per year (median 10 years)

Smoldering (asymptomatic) myeloma
- M-protein in serum ≥30 g/L and/or bone marrow clonal plasma cells ≥10%
- No ROTI or symptoms

Active (symptomatic) myeloma†
- Requires one or more of the following (CRAB criteria):
- Calcium elevation (>11.5 mg/dL [>2.88 mmol/L])
- Renal insufficiency (creatinine >2 mg/dL [>177 μmol/L])
- Anemia (hemoglobin <10 g/dL or 2 g less than normal)
- Bone disease (lytic or osteopenic)

Extramedullary plasmacytoma
- Extramedullary tumor of clonal plasma cells
- Normal bone marrow
- Normal skeletal survey
- M-protein absent or disappears from blood/urine after excision or irradiation of solitary lesion
- Absence of ROTI*
- Progression to MM in ~15%

Solitary plasmacytoma of bone
- Three to 5% of plasma cell dyscrasias
- Isolated bone tumor consisting of monoclonal plasma cells
- Normal bone marrow
- M-protein absent or disappears from blood/urine after excision or irradiation of solitary lesion
- Absence of other myeloma ROTI*
- Multiple or recurrent in up to 5% of patients
- Progression to MM in ~50%

(*continued*)

Work-up

All patients
1. H&P
2. CBC with differential; serum electrolytes, BUN, creatinine, calcium and albumin, LDH
3. Quantitative immunoglobulins, serum protein electrophoresis, and immunofixation
4. Twenty-four–hour urine protein electrophoresis, immunofixation, and Bence Jones quantitation
5. Serum free light-chain assay
6. Skeletal survey
7. Unilateral bone marrow aspirate and biopsy with flow and immunohistochemistry
8. Bone marrow cytogenetics and interphase FISH
9. Albumin and β_2-microglobulin (see staging system)

Selected patients
1. MRI of the spine (evaluate for solitary plasmacytoma of bone or suspected cord compression)
2. FDG-PET/CT scan in selected patients to evaluate for increased uptake
3. Tissue biopsy (evaluate for solitary plasmacytoma)
4. Serum viscosity (if M-protein level is markedly elevated or symptoms of hyperviscosity are present)
5. *Additional tests (prognostic markers):* plasma cell labeling index, C-reactive protein, and LDH

Pathology (*continued*)

Plasma cell leukemia

- Five percent of newly presenting MM patients
- Peripheral blood absolute plasma cell count ≥2000/mm^3
- More than 20% plasma cells in differential count of peripheral blood leukocytes

*ROTI: myeloma-related organ/tissue impairment:
1. Hypercalcemia
2. Renal insufficiency
3. Recurrent bacterial infections (>2 episodes in 12 months)
4. Bone lesions (lytic or osteoporotic with compression fractures)
5. Symptomatic hyperviscosity
6. Amyloidosis
7. Anemia

†Other examples of active disease include:
- Repeated infections
- Secondary amyloidosis
- Hyperviscosity
- Hypogammaglobulinemia

The International Myeloma Working Group. Br J Haematol 2003;121:749–757

Staging

Durie-Salmon Staging System

	Stage I	Stage II*	Stage III†
Myeloma cell mass	Low	Intermediate	High
Hemoglobin	>10 g/dL	8.5–10 g/dL	<8.5 g/dL
Serum calcium	≤12 mg/dL (≤3 mmol/L)	Fitting neither stage I nor stage II	>12 mg/dL (>3 mmol/L)
Skeletal survey	Normal‡		Advanced lytic bone lesions
Serum M-protein levels: IgG	<5 g/dL	5–7 g/dL	>7 g/dL
Serum M-protein levels: IgA	<3 g/dL	3–5 g/dL	>5 g/dL
24-hour urinary light chain excretion	<4 g/24 hours	4–12 g/24 hours	>12 g/24 hours

*Not meeting criteria for either stage I or stage III
†Need to meet 1 or more of the criteria listed
‡Or solitary plasmacytoma
Note: Subclassification: For each stage, "A" denotes serum creatinine <2 mg/dL (<177 μmol/L) and "B" denotes serum creatinine ≥2 mg/dL (≥177 μmol/L)

International Staging System

	Stage I	Stage II		Stage III
Serum β_2-microglobulin	<3.5 mg/L	<3.5 mg/L	3.5 to <5.5 mg/mL	≥5.5 mg/L
Serum albumin	≥3.5 g/dL (≥35 g/L)	<3.5 g/dL	—	—

Greipp PR et al. J Clin Oncol 2005;23:3412–3420

Response Criteria

International Myeloma Working Group Uniform Response Criteria

CR and Other Response Categories

CR = Complete Response

- Negative immunofixation on the serum and urine
- Disappearance of any soft tissue plasmacytomas
- ≤5% plasma cells in bone marrow

sCR = Stringent Complete Response

CR as described above, PLUS:
- Normal free light chain (FLC) ratio AND
- Absence of clonal cells in bone marrow by immunohistochemistry or immunofluorescence

VGPR = Very Good Partial Response

- Serum and urine M-protein detectable by immunofluorescence but not on electrophoresis OR
- ≥90% reduction in serum M-protein + urine M-protein level <100 mg/24 hours

PR = Partial Response

- ≥50% reduction of serum M-protein + reduction in 24-hour urinary M-protein by ≥90% or to <200 mg/24 hours

If the serum and urine M-protein are unmeasurable:
- A ≥50% decrease in the difference between involved and uninvolved FLC levels is required in place of the M-protein criteria

If serum and urine M-protein are unmeasurable, and serum FLC assay is also unmeasurable:
- ≥50% reduction in plasma cells is required in place of M-protein, provided baseline bone marrow plasma cell percentage was ≥30%

Note: In addition to the above listed criteria, if present at baseline, a ≥50% reduction in the size of soft-tissue plasmacytomas is also required

SD = Stable Disease*

- Not meeting criteria for CR, VGPR, PR, or progressive disease

*Not recommended for use as an indicator of response; stability of disease is best described by providing the time-to-progression estimates

Median Survival

Treatments for myeloma have expanded in the last decade. A recent study[1] examined the survival trends over time of 2 groups of patients seen at Mayo Clinic, one from time of diagnosis and the other from the time of relapse:

- Among 387 patients who relapsed after stem cell transplantation, a clear improvement was seen in overall survival from the time of relapse. Patients whose disease relapsed after the year 2000 had a median overall survival of 23.9 months versus 11.8 months (P <0.001) for those who relapsed prior to this date. This improvement was independent of other prognostic factors
- Patients treated with 1 or more of the newer drugs (thalidomide, lenalidomide, bortezomib) had longer survival from relapse (30.9 vs. 14.8 months; P <0.001)
- In a larger group of 2981 patients with newly diagnosed myeloma, those diagnosed during the last decade had a 50% improvement in overall survival (44.8 vs. 29.9 months; P <0.001)

A second study[2,3] estimated trends in age-specific 5- and 10-year relative survival of patients with multiple myeloma (MM) in the United States from 1990–1992 to 2002–2004 from the 1973–2004 database of the Surveillance, Epidemiology, and End Results (SEER) Program. Techniques of period analysis were used to show most recent developments:

Five- and 10-Year Estimates of Relative Survival of Patients with MM by Age Group and Calendar Period

	1990–1992		2002–2004			
	PE*	SE*	PE	SE	Increase†	P‡
5-Year Relative Survival						
All ages	28.8	0.9	34.7	0.9	5.9	<0.001
Younger than 50 years	44.8	3.5	56.7	3.0	11.9	0.001
50 to 59 years	38.8	2.5	48.2	2.1	9.4	0.001
60 to 69 years	30.6	1.8	36.3	1.8	5.7	0.09
70 to 79 years	27.1	1.7	28.7	1.6	1.6	0.21
80 years and older	13.8	2.0	15.2	1.9	1.4	0.96

(*continued*)

International Myeloma Working Group Uniform Response Criteria

Disease Progression and Relapse

Progressive Disease*

Any one or more of the following:

- Increase of ≥25% from baseline in serum M-component (absolute increase must be ≥0.5 g/dL)
- Increase of ≥25% from baseline in urine M-component (absolute increase must be ≥200 mg/24 hours)
- Increase of ≥25% from baseline in the difference between involved and uninvolved FLC levels—only in patients without measurable serum and urine M-protein levels (absolute increase must be ≥10 mg/dL)
- Increase of ≥25% from baseline in bone marrow plasma cell percentage (absolute percentage must be ≥10%)
- Definite development of new bone lesions or soft-tissue plasmacytomas or definite increase in the size of existing bone lesions or soft-tissue plasmacytomas
- Development of hypercalcemia (corrected serum calcium >11.5 mg/dL or >2.88 mmol/L) that can be attributed solely to the plasma cell proliferative disorder

Clinical Relapse

One or more of the following:

- Development of new soft-tissue plasmacytomas or bone lesions
- Definite increase in the size of existing plasmacytomas or bone lesions. A definite increase is defined as a 50% (and at least 1 cm) increase as measured serially by the sum of the products of the cross-diameters of the measurable lesion
- Hypercalcemia >11.5 mg/dL (>2.88 mmol/L)
- Decrease in hemoglobin of ≥2 g/dL
- Rise in serum creatinine by ≥2 mg/dL (≥177 μmol/L)

Relapse from CR†

One or more of the following:

- Reappearance of serum or urine M-protein by immunofixation or electrophoresis
- Development of ≥5% plasma cells in the bone marrow
- Appearance of any other sign of progression (ie, new plasmacytoma, lytic bone lesion, or hypercalcemia)

*Used for calculation of time to progression and progression-free survival outcomes for all patients, including those in CR (includes primary progressive and disease progression on or off therapy)
†Used only if the outcome studied is disease-free survival (DFS)

2. Brenner H et al. Recent major improvement in long-term survival of younger patients with multiple myeloma. Blood 2008;111:2521–2526
3. Ghobrial IM, Anderson KC. The road to cure in multiple myeloma. Blood 2008;111:2503

A recent update (Pulte et al. Leuk Lymphoma 2013 Sep 3. [Epub ahead of print]) continues to demonstrate increased survival for patients with myeloma, but with a disparity in survival between non-Hispanic whites and minorities that has been persistent or slightly increasing over time, especially for younger patients. The reasons for these differences cannot be definitively ascertained from the SEER database, the source of the data since it lacks important information concerning several critical factors including cytogenetics, staging of myeloma, chemotherapeutic regimens employed and insurance data.

Expert Opinion

1. *Treatment by stage:*

Asymptomatic MGUS, smoldering MM, and Stage I MM

These patients do not need primary therapy and should be ***monitored without therapy*** unless they have evidence of disease progression. Clinical trials are being conducted in these stages. Follow-up every 3 to 6 months is recommended. Progression of the disease to stage II or higher, is defined by:

- 25% increase in the monoclonal component (serum or urine)
- >25% increase in plasma cells bone marrow infiltration
- Increased size of bone lesions or development of new lytic lesions
- Hypercalcemia
- Increased plasmacytoma tumor volume

Symptomatic patients (Stages II and III MM)

These patients should be ***treated with combination therapy followed by consideration for stem cell transplantation*** if eligible. Determine whether a patient is a candidate for high-dose therapy with autologous peripheral blood stem cell (PBSC) transplantation before initiating chemotherapy. Avoid alkylating agents in such patients before autologous PBSCs are collected, because exposure to alkylating agents may prevent the collection of an adequate number of PBSCs for autologous transplantation

   - Monoclonal protein present in the serum and/or urine*
   - Myeloma-related organ dysfunction (≥1)†

   [C] Calcium elevation in the blood (serum calcium >10.5 mg/dL [>2.63 mmol/L] or greater than the upper limit of normal range)
   [R] Renal insufficiency (serum creatinine >2 mg/dL [>177 μmol/L])
   [A] Anemia (hemoglobin <10 g/dL or 2 g less than the lower limit of normal range)
   [B] Lytic bone lesions or osteoporosis‡

*If no monoclonal protein is detected (nonsecretory disease), then >30% monoclonal bone marrow plasma cells and/or a biopsy-proven plasmacytoma required
†A variety of other types of end-organ dysfunctions can occasionally occur and lead to a need for therapy. Such dysfunction is sufficient to support classification of myeloma if proven to be myeloma related
‡If a solitary (biopsy-proven) plasmacytoma or osteoporosis alone (without fractures) is the sole defining criteria, then >30% plasma cells are required in the bone marrow

Note: THESE CRITERIA IDENTIFY STAGE IB and STAGES II and III A/B MYELOMA BY DURIE/SALMON STAGE. Stage IA becomes smoldering or indolent myeloma

3. *Solitary plasmacytoma:*
   - Primary radiation therapy (≥45 Gy) to the involved fields represents the initial treatment for patients diagnosed with osseous plasmacytoma
   - Same approach and/or surgery represent the initial treatment for patients with extraosseous plasmacytomas
   - Follow-up for either solitary or extraosseous plasmacytomas includes blood and urine tests every 4 weeks to monitor response to radiation treatment
   - If a complete disappearance of the monoclonal component is demonstrated, blood and urine tests will be performed every 3–6 months
   - If the monoclonal component persists, follow-up should continue every 4 weeks
   - If a progression in the disease is documented, a reevaluation for recurrent extraosseous plasmacytomas and/or myeloma should be considered

(*continued*)

Expert Opinion (*continued*)

4. Treatment with a bisphosphonate is recommended to reduce skeletal complications for all myeloma patients with skeletal lesions. Alternatives that have demonstrated efficacy in this setting include:
   - Pamidronate, *or*
   - Zoledronic acid, *or*
   - Clodronate

   Notes:
   - Because renal toxicity can result from bisphosphonate therapy, renal function should be monitored closely. Bisphosphonate doses may need to be modified or discontinued in renally impaired individuals
   - Myeloma patients with bone lesions should receive treatment with a bisphosphonate. Whether to administer bisphosphonates to myeloma patients without evidence of bone disease is unclear. Some research has shown bisphosphonates may have a clinical benefit even in patients without bone disease. Recommendations on how often bisphosphonates should be administered will likely evolve over time. Current recommendations are to administer standard doses of bisphosphonates every 3–4 weeks. The duration for which repeated doses should be administered is also unclear. Currently, there are no data from randomized studies to guide bisphosphonate use for more than 2 years. The risks and benefits of continuing bisphosphonate treatment after 2 years must be considered in each patient. To prevent osteonecrosis of the jaw, patients treated with bisphosphonates should maintain good dental hygiene and should stop bisphosphonate treatment for 90 days before and after invasive dental procedures. Caregivers must ensure that myeloma patients get enough vitamin D and calcium. This is a concern because 60% of myeloma patients are vitamin D and calcium deficient. U.S. Food and Drug Administration product labeling for both zoledronic acid and pamidronate disodium recommend vitamin D and calcium supplementation in conjunction with bisphosphonate treatment, but calcium supplementation should be used cautiously for patients with kidney problems
5. Anemia is present in most patients with multiple myeloma. Reversible causes of anemia should be evaluated and treated. Patients with symptomatic anemia may benefit from therapy with recombinant erythropoietin (see Chapter 43)
6. Waldenström macroglobulinemia presents with lymphoplasmacytic bone marrow infiltration and IgM paraproteinemia. Therapy usually consists of rituximab along with an alkylating agent such as cyclophosphamide, or bortezomib or nucleoside analogs such as fludarabine. Other management considerations focus on complications caused by macroglobulinemia, such as hyperviscosity, cryoglobulinemia, and hemolytic anemia
7. Primary amyloidosis is characterized by organ dysfunction resulting from monoclonal light-chain production and tissue deposition. Carefully selected patients may benefit from high-dose melphalan with autologous PBSC support, which can result in hematologic remission, regression of light-chain deposition, and improvement in organ function. Other options include the use of bortezomib- or lenalidomide-based regimens
8. The optimal prophylaxis strategy for thromboembolic complications of IMiD therapy (thalidomide and lenalidomide) is not clear. Therapy with low-molecular-weight heparins or full-dose warfarin anticoagulation are standard treatments for DVT and pulmonary embolism in the general population. However, in patients with multiple myeloma, data exist supporting the protective effect of aspirin against VTE, despite its mechanism of arterial anticoagulation. Until more is known about the nature and mechanism of thromboembolism induced by the IMiDs, it is difficult to say which agent is most appropriate. At this time, any of the agents may be considered reasonable; however, all patients receiving combination therapy with lenalidomide or thalidomide should have some form of thromboembolic prophylaxis incorporated into therapy

Palumbo A et al. Enoxaparin or aspirin for the prevention of recurrent thromboembolism in newly diagnosed myeloma patients treated with melphalan and prednisone plus thalidomide or lenalidomide. J Thromb Haemost 2006;4:1842–1845
Palumbo A et al. Prevention of thalidomide- and lenalidomide-associated thrombosis in myeloma. Leukemia 2008;22:414–423

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)
LENALIDOMIDE + LOW-DOSE DEXAMETHASONE

Rajkumar SV et al. Lancet Oncol 2010;11:29–37

Lenalidomide 25 mg/day; administer orally, continually, for 21 consecutive days on days 1–21, every 28 days (total dose/cycle = 525 mg)
Dexamethasone 40 mg/dose; administer orally for 4 doses on days 1, 8, 15, and 22, every 28 days (total dose/cycle = 160 mg)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Platelet count <30,000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. Resume lenalidomide at 15 mg/day after platelet count is ≥30,000/mm^3
For each subsequent platelet count <30,000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. After platelet count recovers to ≥30,000/mm^3, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
ANC <1000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. Resume lenalidomide at 15 mg/day after ANC ≥1000/mm^3
For each subsequent ANC <1000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. After ANC recovers to ≥1000/mm^3, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
Febrile neutropenia	Interrupt lenalidomide treatment, follow closely, and resume lenalidomide at 15 mg/day after fever abates
G3/4 nonhematologic toxicity	Interrupt lenalidomide treatment, follow clinically. After toxicity abates to G ≤2, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Adverse Event	Treatment Modification
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce dexamethasone dose to 20 mg per day
Lenalidomide starting dose adjustment for Renal Impairment in Multiple Myeloma (Days 1–21 of Each 28-day Cycle)	
Moderate renal impairment CrCl 30–60 mL/min (0.5–1 mL/s)	10 mg lenalidomide every 24 hours
Severe renal impairment CrCl <30 mL/min (<0.5 mL/s), not requiring dialysis	15 mg lenalidomide every 48 hours
End-stage renal disease CrCl <30 mL/min (<0.5 mL/s), requiring dialysis	5 mg/day. On dialysis days, administer a daily dose following dialysis

CrCl, Creatinine clearance

Patient Population Studied

Randomized phase III trial of 445 patients with newly diagnosed multiple myeloma. Patients were eligible if they had previously untreated symptomatic multiple myeloma, bone marrow plasmacytosis (≥10% plasma cells or sheets of plasma cells), or a biopsy-proven plasmacytoma, and measurable disease defined as serum monoclonal protein >10 g/L or urine monoclonal protein ≥0.2 g/day or more. Study eligibility also required hemoglobin >7 g/dL, platelet count ≥75,000/mm³, ANC ≥1000/mm³, and an acceptable serum creatinine. Patients were excluded if they had G ≥2 peripheral neuropathy, active infection, current or prior deep vein thrombosis, or Eastern Cooperative Oncology Group performance status = 3/4

Efficacy (N = 208)

Best overall Response to Therapy	Percent of Patients
Overall response rate (partial response or better)	70%
Complete plus very good partial response	40%
Complete response	4%
Immunofixation-negative complete response	10%
Very good partial response	26%
Partial response	30%
Minimal response	13%
No response/stable disease	8%
Progressive disease	2%
Unevaluable	7%

1-year overall survival*	96% (95% CI, 94–99)
2-year overall survival*	87% (95% CI, 81–93)
1-year overall survival, ages <65 years old	98% (95% CI, 92–99)
1-year overall survival, ages ≥65 years old	94% (95% CI, 89–99)
Median time to partial response or better	1 month†
Median response duration	24.1 months (95% CI, 21.5–28.1)
Median progression-free survival	25.3 months (22.3–not reached)

*Overall survival was not a protocol-specified end point in this study. However, the study was stopped on recommendations of the independent data monitoring committee at a median follow-up of 12.5 months (95% CI, 11.5–14.6), because overall survival was significantly higher with low-dose dexamethasone than with high-dose dexamethasone ($p = 0.0002$). All patients in the high-dose group were instructed to crossover to receive low-dose dexamethasone

†Among patients who responded

Toxicity

G ≥3 Toxicities (N = 220)	
Toxicity	Percent of patients
Hematologic	
Hemoglobin	7%
Platelets	5%
Neutrophils	20%
Nonhematologic	
Deep vein thrombosis or pulmonary embolism	12%
Infection or pneumonia	9%
Hyperglycemia	6%
Cardiac ischemia	<1%
Atrial fibrillation or flutter	<1%
Fatigue	9%
Neuropathy	2%
Nonneuropathic weakness	4%
Summary	
Any G ≥3 toxicity in first 4 months	35%
Any G ≥3 nonhematologic toxicity at any time during therapy	48%
Any G ≥4 nonhematologic toxicity at any time during therapy	14%
Early mortality (first 4 months)	<1%
Reason for Discontinuation (N = 222)	
Treatment completed per protocol	25%
Disease progression	17%
Adverse events or complications	23%
Death on study	3%
Patient withdrawal or refusal	5%
Alternative therapy	17%
Other complicating disease	1%
Other	8%

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) BORTEZOMIB + DEXAMETHASONE

Harousseau J-L et al. J Clin Oncol 2010;28:4621–4629

Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 3 weeks for 4 cycles (total dosage/cycle = 5.2 mg/m²)
Dexamethasone 40 mg/dose; administer orally, as follows:

- *Cycles 1 and 2:* For 4 consecutive days on days 1–4, and for 4 consecutive days on days 9–12, every 3 weeks for 2 cycles (total dose/cycle = 320 mg)
- *Cycles 3 and 4:* For 4 consecutive days on days 1–4, every 3 weeks for 2 cycles (total dose/cycle = 160 mg)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use

- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Febrile neutropenia	Withhold therapy until fever abates, then resume therapy at the same dosages and schedules
G4 hematologic toxicity	Withhold therapy until counts recover to ANC >750/mm³ and platelets >50,000/mm³, then resume therapy
G3/4 nonhematologic toxicity	Interrupt therapy, follow clinically and resume therapy when toxicity G ≤2
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability and insomnia, oral candidiasis	Reduce dexamethasone dose to 20 mg per dose

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function, but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate at a dosage of 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Patient Population Studied

Phase III study of 482 patients with multiple myeloma who were ≤65 years of age and eligible for autologous stem cell transplantation. All patients had untreated symptomatic MM with measurable paraprotein in serum (>10 g/L) or urine (>0.2 g/24 hours). Key eligibility criteria, included Eastern Cooperative Oncology Group PS ≤2, adequate renal function (no end-stage renal failure requiring dialysis), and hematologic (platelets ≥50,000/mm³, neutrophils ≥750/mm³), and hepatic (bilirubin ≤3 times the upper limit of normal range [ULN] and AST and ALT ≤4 times ULN) indices. Patients with confirmed diagnosis of amyloidosis and G ≥2 peripheral neuropathy were excluded

Efficacy

Response to Induction Therapy Overall and According to Baseline Disease Stage and Prognostic Factors	
Evaluable Population (N = 223)	
ORR (at least PR)	78.5%
At least VGPR	37.7%

G2 Peripheral neuropathy†	15.5%
G3 Peripheral neuropathy†	7.1%

*No antiviral prophylaxis for *Herpes zoster* was specified in the protocol

†Medical Dictionary for Regulatory Activities (MedDRA) Preferred Terms used by investigators that were considered related to neurologic toxicity included accommodation disorder, anosmia, areflexia, difficulty in walking, dysesthesia, fall, formication, hypoesthesia, hyporeflexia, muscle spasms, pain in limb, paraparesis, paresthesia, peripheral motor neuropathy, peripheral neuropathy, sensory loss, vertigo, and vision blurred

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN
NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)
BORTEZOMIB + LENALIDOMIDE + DEXAMETHASONE

Richardson PG et al. Blood 2010;116:679–686

All Cycles:
Bortezomib 1–1.3 mg/m^2 per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 3 weeks for 8 cycles (total dosage/cycle for 1 mg/m^2 per dose = 4 mg/m^2; total dosage/cycle for 1.3 mg/m^2 per dose = 5.2 mg/m^2)
Lenalidomide 15–25 mg per day; administer orally for 14 consecutive days on days 1–14, every 3 weeks for 8 cycles (total dose/cycle for 15 mg/day = 210 mg; total dose/cycle for 25 mg/day = 350 mg)
Cycles 1–4:
Dexamethasone 40 mg per dose; administer orally for 8 doses on days 1, 2, 4, 5, 8, 9, 11, and 12, every 3 weeks for 4 cycles (total dose/cycle = 320 mg), *then*
Cycles 5–8:
Dexamethasone 20 mg per dose; administer orally for 8 doses on days 1, 2, 4, 5, 8, 9, 11, and 12, every 3 weeks for 4 cycles (total dose/cycle = 160 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Decreased bowel motility prophylaxis
Give a bowel regimen to prevent constipation based initially on **stool softeners**

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Platelet count <30,000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. Resume lenalidomide at 15 mg/day after platelet count is ≥30,000/mm^3
For each subsequent platelet count <30,000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. After platelet count recovers to ≥30,000/mm^3, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
ANC <1000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. Resume lenalidomide at 15 mg/day after ANC ≥1000/mm^3
For each subsequent ANC <1000/mm^3	Interrupt lenalidomide treatment, follow CBC weekly. After ANC recovers to ≥1000/mm^3, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
Febrile neutropenia	Interrupt lenalidomide treatment, follow closely, and resume lenalidomide at 15 mg/day after fever abates
G3/4 non-hematologic toxicity	Interrupt lenalidomide treatment and follow clinically. After toxicity abates to G ≤2, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce dexamethasone dose to 20 mg per day

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

• **Pamidronate sodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*

• **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modifications of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate at a dosage of 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

Lenalidomide Starting Dose Adjustment for Renal Impairment in Multiple Myeloma (Days 1–21 of Each 28-Day Cycle)

Moderate renal impairment CrCl 30–60 mL/min (0.5–1 mL/s)	10 mg lenalidomide every 24 hours
Severe renal impairment CrCl <30 mL/min (<0.5 mL/s), not requiring dialysis	15 mg lenalidomide every 48 hours
End-stage renal disease CrCl <30 mL/min (<0.5 mL/s), requiring dialysis	Lenalidomide 5 mg/day. On dialysis days, administer a daily dose following dialysis

CrCl, Creatinine clearance

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Efficacy

Best Response to Treatment for Treated and Phase II Populations

*Including 34 (52%) = G1 and 18 (27%) = G2

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)
BORTEZOMIB + THALIDOMIDE + DEXAMETHASONE

Cavo M et al. Lancet 2010;376:2075–2085

Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 21 days for 3 cycles (total dosage/cycle = 5.2 mg/m²)
Thalidomide 200 mg/day; administer orally, continually, for 21 consecutive days on days 1–21, every 21 days for 3 cycles (total dose/cycle = 4200 mg)
Dexamethasone 40 mg per dose; administer orally for 8 doses on days 1, 2, 4, 5, 8, 9, 11, and 12, every 21 days for 3 cycles (total dose/cycle = 320 mg)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use

- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurological adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Bortezomib Dosage Levels	
Dose Level 1	1.3 mg/m²
Dose Level −1	1 mg/m²
Dose Level −2	0.7 mg/m²
Thalidomide Dose Levels	
Dose Level 1	200 mg daily
Dose Level −1	100 mg daily
Dose Level −2	50 mg daily
Adverse Event	**Treatment Modification**
Febrile neutropenia	Withhold therapy until fever abates then resume therapy
G4 hematologic toxicity	Withhold therapy until ANC >750/mm³ and platelets >50,000/mm³, then resume therapy at a dose decreased by 1 dose level
G3/4 nonhematologic toxicity	Interrupt therapy, follow clinically. After toxicity abates to G ≤2, resume therapy at a dose decreased by 1 dose level
G ≥3 thalidomide neuropathy	Interrupt therapy and follow clinically. After toxicity abates to G ≤2, resume therapy at a dose decreased by 1 dose level
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce dexamethasone dose to 20 mg per dose

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies • Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired r enal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Treatment Modifications (*continued*)

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function, but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate at a dosage of 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3 113–3120

Patient Population Studied

A phase III study of 480 patients, ages 18 to 65 years, with previously untreated, symptomatic newly diagnosed multiple myeloma who were eligible for stem cell transplantation

Eligible subjects demonstrated a Karnofsky performance status ≥60%, adequate hematologic function (ANC ≥1000/mm³ and platelet count ≥70,000/mm³), and serum creatinine ≤2 mg/dL (≤177 μmol/L). Patients with peripheral neuropathy G ≥2, a history of venous thromboembolism, or a previous diagnosis of thrombophilic alterations, were ineligible

Efficacy

Response to Different Treatment Phases and Best Response	
N = 236	% (95% CI)
After Induction Therapy	
Complete response	19% (13.7–23.6)
Complete or near complete response	31% (25–36.8)
Very good partial response or better	62% (55.7–68.1)
Partial response or better	93% (90–96.4)
Minimal response or stable disease	7% (3.6–10)
Progressive disease	5% (2.3–7.8)
After First Autologous Stem Cell Transplantation	
Complete response	38% (31.5–43.9)
Complete or near complete response	52% (45.7–58.5)
Very good partial response or better	79% (73.6–84)
Partial response or better	93% (90–96.4)
Minimal response or stable disease	6% (3.2–9.5)
Progressive disease	<1% (0–1.3)
After Second Autologous Stem Cell Transplantation	
Complete response	42% (35.2–47.8)
Complete or near complete response	55% (48.7–61.4)
Very good partial response or better	82% (76.9–86.7)
Partial response or better	93% (90–96.4)
Minimal response or stable disease	6% (2.9–8.9)
Progressive disease	8% (4.9–11.9)
After Consolidation Therapy	
Complete response	49% (42.8–55.5)
Complete or near complete response	62% (56.1–68.5)
Very good partial response or better	85% (80.6–89.7)
Partial response or better	92% (89–95.8)
Minimal response or stable disease	5% (2.3–7.9)
Progressive disease	9% (5.2–12.4)
Best Response to Overall Treatment Protocol	
Complete response	58% (51.3–63.9)
Complete or near complete response	71% (65.4–77)
Very good partial response or better	89% (85–93)
Partial response or better	96% (93.7–98.6)
Minimal response, stable disease, or progressive disease	4% (1.4–6.3)

Toxicity

Serious and G3/4 Adverse Events Reported in ≥2% of Patients During Induction Therapy	
Any serious adverse event	13%
Any grade 3 or 4 adverse event	56%
Any grade 3 or 4 nonhematologic adverse event	51%
Skin rash	10%
Peripheral neuropathy	10%
Deep vein thrombosis	3%
Constipation	4%
Infections excluding herpes zoster	3%
Gastrointestinal events (excluding constipation)	2%
Cardiac toxicity	2%
Liver toxicity	2%
Discontinuation during or after induction therapy	6%
Toxic effects	4%
Disease progression	0
Other reasons	1%
Early death	<1%

Nonhematologic Adverse Events of Any Grade Reported in at Least 10% of Patients During Induction Therapy (N = 236)		
	% G1–4	% G3/4
Constipation	42	4
Neuropathy	34	10
Skin rash	28	10
Fever	12	1
Infections	10	3
Edema	11	1
Gastrointestinal events (excluding constipation)	19	2

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) BORTEZOMIB + DOXORUBICIN + DEXAMETHASONE

Sonneveld P et al. J Clin Oncol 2012;30:2946–2955

Induction:

Bortezomib 1.3 mg/m² per dose intravenously over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 28 days for 3 cycles (total dosage/cycle = 5.2 mg/m²)
Doxorubicin 9 mg/m² per day by slow intravenous injection over 3–5 minutes for 4 consecutive days on days 1–4, every 28 days for 3 cycles (total dosage/cycle = 36 mg/m²)
Dexamethasone 40 mg/dose orally for 12 doses on days 1–4, days 9–12, and days 17–20 for 3 cycles (total dose/cycle = 480 mg)

Notes:

- Stem cell collection was performed 4–6 weeks after induction
- High-dose melphalan (HDM) 200 mg/m², and autologous stem cell transplantation (ASCT) were administered
- Starting 4 weeks after HDM, patients received maintenance with bortezomib 1.3 mg/m² intravenously every 2 weeks for 2 years
- Patients with an HLA-identical sibling could proceed to nonmyeloablative allogeneic stem cell transplantation (alloSCT) after HDM
- Maintenance therapy was not given after alloSCT

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with doxorubicin is **LOW***
*Emetogenic potential on days with bortezomib ± dexamethasone is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir) throughout bortezomib induction

See Chapter 47 for more information

Steroid-associated gastritis

Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
G3 nonhematologic toxicity or G4 hematologic toxicity	Hold treatment until toxicity resolves to G ≤ 1, then resume with bortezomib 1 mg/m² per dose and/or 25% reduction in doxorubicin dosage
G3 nonhematologic toxicity or G4 hematologic toxicity in a patient receiving bortezomib 1 mg/m²	Hold treatment until toxicity resolves to G ≤ 1, then resume with bortezomib 0.7 mg/m² per dose and/or 25% reduction in doxorubicin dosage
Severe manifestations of hypercorticism, including severe hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce daily dexamethasone dose by 20% for G3 toxicity, and by 40% for G4 or recurrent G3 toxicity

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate with bortezomib 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWH s should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Patient Population Studied

Patients 18–65 years of age with newly diagnosed MM (Durie-Salmon stages II to III) WHO performance status 0 to 2, or WHO 3 when caused by MM. Exclusion criteria were systemic amyloid light chain amyloidosis, nonsecretory MM, neuropathy G ≥2, serum bilirubin ≥1.8 mg/dL (≥30 µmol/L) or aminotransferases ≥2.5 times the upper limit of normal range. Prior corticosteroids were allowed for a maximum of 5 days. Patients with renal impairment were not excluded. Local radiotherapy for painful MM lesions was allowed

Patient Characteristic (N = 413)	No (%)

AE, adverse event (including infection); N/A, not applicable; SAE, serious adverse event

Therapy Monitoring

1. Blood counts and physical examinations on day 1 of each cycle
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle as indicated and at the end of treatment

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) CYCLOPHOSPHAMIDE + BORTEZOMIB + DEXAMETHASONE (CyBorD)

Reeder CB et al. Leukemia 2009;23:1337–1341

Bortezomib 1.3 mg/m² per dose intravenously over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 28 days, for 4 cycles (total dosage/cycle = 5.2 mg/m²)
Cyclophosphamide 300 mg/m² per dose orally for 4 doses on days 1, 8, 15, and 22, every 28 days, for 4 cycles (total dosage/cycle = 1200 mg/m²)
Dexamethasone 40 mg/dose orally for 12 doses on days 1–4, days 9–12, and days 17–20 for 3 cycles (total dose/cycle = 480 mg)

Notes:
- Dose escalation was not allowed
- At the end of 4 cycles patients proceeded to stem cell mobilization and harvest

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on days with cyclophosphamide is ***MODERATE–HIGH***
Emetogenic potential on days with bortezomib ± dexamethasone is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir) throughout bortezomib induction

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

(*continued*)

Treatment Modifications

Note: Dose reduction was allowed after the first cycle, but cyclophosphamide and bortezomib can be held during cycle 1 for neutropenia or thrombocytopenia G ≥3

Cyclophosphamide Dose Levels	
Starting dose	300 mg/m² per dose on days 1, 8, 15, and 22
Level –1	300 mg/m² per dose on days 1, 8, and 15
Level –2	300 mg/m² per dose on days 1 and 8
Level –3	300 mg/m² on day 1
Adverse Event	**Treatment Modification**
G3 hematologic toxicity	Reduce cyclophosphamide 1 dose level
G1/2 cystitis	Reduce cyclophosphamide 1 dose level
G3/4 cystitis	Discontinue cyclophosphamide

Bortezomib Dose Levels	
Starting dose	1.3 mg/m² per dose on days 1, 4, 8, and 11
Level –1	1 mg/m² per dose on days 1, 4, 8, and 11
Level –2	0.7 mg/m² per dose on days 1, 4, 8, and 11
Level –3	1.3 mg/m² per dose on days 1 and 8
Adverse Event	**Treatment Modification**
G3 thrombocytopenia (platelet count <50,000/mm³)	Reduce bortezomib dosage by 1 dose level

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWH s should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage 1 dose level
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate reducing bortezomib dosage 1 dose level
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

Dexamethasone Dose Levels

Starting dose	40 mg per dose on days 1–4, 9–12, and 17–20
Level –1	20 mg per dose on days 1–4, 9–12, and 17–20
Level –2	20 mg per dose on days 1–4
Level –3	10 mg per dose on days 1–4

Adverse Event	Treatment Modification
G2 muscle weakness, G3 gastrointestinal tract, hyperglycemia, confusion or mood alteration	Reduce dexamethasone dose by 1 dose level

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Efficacy

Responses	By ITT (N = 33)	By ITT if Completed 4 Cycles (N = 28)	After SCT (N = 23)
ORR (≥PR)	29 (88%)	27 (96%)	23 (100%)
≥VGPR	20 (61%)*	20 (71%)	17 (74%)
PR	9 (27%)	7 (25%)	6 (26%)

ITT, intention to treat; ORR, overall response (partial response or better); PR, partial response; SCT, stem cell transplantation; ≥VGPR, very good partial response or better
*One in CR, 12 in nCR, and 7 in VGPR

Risk Category as Assessed by Bone Marrow Plasma Cell Fish Analysis and ISS Stage, and Corresponding Response After 4 Cycles

Risk Category	Frequency	ORR	≥VGPR
Deletion 13	50% (16/32)	94% (15/16)	63% (10/16)
Deletion 17	13% (4/31)	75% (3/4)	50% (2/4)
t(4;14)	18% (6/33)	83% (5/6)	50% (3/6)
Hyperdiploid	21% (7/33)	100% (7/7)	71% (5/7)
ISS stage 3	30% (10/33)	80% (8/10)	60% (6/10)

FISH, fluorescent in situ hybridization; ISS, international staging system; ORR, overall response; VGPR, very good partial response

Therapy Monitoring

1. Blood counts and physical examinations on day 1 of each cycle
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle as indicated and at the end of treatment

Patient Population Studied

Newly diagnosed, symptomatic MM of Durie–Salmon stage II or III, Eastern Cooperative Oncology Group performance status ≤2, creatinine ≤3.5 mg/dL (≤309 μmol/L), absolute neutrophil count ≥1000/mm^3, platelets ≥100,000/mm^3

Patient Characteristics	
Mean age	60 (38–75) years
Gender: M/F	52%/48%
International Staging System, stages I/II/III,	33/36/30%
Durie–Salmon stage II or III; symptomatic disease	100%
del13 in 16/32	16/32 (50%)
del17*	4/31 (13%)
t(4;14)*	6/33 (18%)
Favorable hyperdiploid karyotype	7/33 (21%)

*Genetic high-risk categories

Toxicity

Adverse Events	G3/4*
Anemia	12%
Neutropenia	13%
Thrombocytopenia	25%
Hyperglycemia	13%
Diarrhea	6%
Hypokalemia	9%
Neuropathy	7%
Thrombosis	7%

*National Cancer Institute Common Terminology Criteria for Adverse Events (version 3.0) severity grades

REGIMEN
NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)
CARFILZOMIB + LENALIDOMIDE + DEXAMETHASONE (CRd)

Jakubowlak AJ et al. Blood 2012;120:1801–1809

Hydration with carfilzomib: During cycle 1, days 1 and 2, administer intravenously 250–500 mL 0.9% NS before each carfilzomib dose, *and* an additional 250–500 mL of fluid after carfilzomib. During repeated treatments, continue intravenous hydration as needed. Encourage oral hydration

Carfilzomib 36 mg/m² per dose intravenously in 50-mL 5% dextrose injection over 30 minutes

- *Cycles 1–8:* for 6 doses, on days 1, 2, 8, 9, 15, and 16, every 28 days (total dosage/cycle = 216 mg/m²)
- *Cycle 9 and subsequent cycles:* for 4 doses, on days 1, 2, 15, and 16, every 28 days (total dosage/cycle = 144 mg/m²)

Lenalidomide 25 mg/day orally, continually for 21 consecutive days on days 1–21, every 28 days (total dose/cycle = 525 mg)

Dexamethasone administer orally or intravenously for 4 doses on days 1, 8, 15, and 22, every 28 days

- *Cycles 1–4:* 40 mg/dose (total dose/cycle = 160 mg)
- Cycle 5 and subsequent cycles: 20 mg/dose (total dose/cycle = 80 mg)

Notes:

- After cycle 4, transplantation-eligible candidates underwent stem cell collection (SCC) then continued CRd with the option of transplantation
- Thirty-five patients underwent SCC, 7 proceeded to transplantation, and the remainder resumed CRd
- After 8 cycles, patients received maintenance CRd. Per initial design, CRd maintenance was planned for an indefinite period of time, but because progression events were limited and no maintenance treatments were discontinued because of toxicity, the study was amended to 24 total cycles of CRd. After completion of 24 cycles, single-agent lenalidomide off protocol was recommended

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days with lenalidomide ± carfilzomib is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Steroid-associated gastritis

Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

(*continued*)

(continued)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

• **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*

• **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

(continued)

(continued)

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Lenalidomide Starting Dose Adjustment for Renal Impairment in Multiple Myeloma (Days 1–21 of Each 28-Day Cycle)*

Moderate renal impairment: CrCl 30–60 mL/min (0.5–1 mL/s)	Lenalidomide 10 mg q24h
Severe renal impairment: CrCl <30 mL/min (<30 mL/s), not requiring dialysis	Lenalidomide 15 mg q48h
End-stage renal disease: requiring dialysis	Lenalidomide 5 mg/day. On dialysis days, administer the daily dose following dialysis

CrCl, creatinine clearance
*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Treatment Modifications

Carfilzomib Dose Levels	
Starting dose	36 mg/m² per dose
Level –1	27 mg/m² per dose
Level –2	20 mg/m² per dose
Level –3	15 mg/m² per dose
Level –4	11 mg/m² per dose
Level –5	Discontinue
Adverse Event	**Treatment Modification**
Hematologic Toxicity	
G3/4 neutropenia	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dosage, or reduce the carfilzomib dosage by 1 dose level. If counts recover to G2 neutropenia or G3 thrombocytopenia, reduce carfilzomib dosage by 1 dose level. If tolerated, the reduced dose may be escalated to the previous dose level
Febrile neutropenia (ANC <1000/mm³ with fever ≥38°C)	
G4 thrombocytopenia	
G3/4 thrombocytopenia associated with bleeding	
Nonhematologic Toxicity	
G3/4 cardiac toxicity New onset or worsening: • Congestive heart failure • Decreased left ventricular function • Myocardial ischemia	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dosage or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level
Pulmonary hypertension	
G3/4 pulmonary complications	
G3/4 elevation of transaminases, bilirubin, or other liver abnormalities	

(continued)

Treatment Modifications (continued)

Nonhematologic Toxicity	
Serum creatinine ≥2× baseline	If attributable to carfilzomib, hold carfilzomib doses for up to 21 days to resolve toxicity to G1 or to baseline and then restart at the same dosage, or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level
G2 neuropathy with pain	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dose, or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level
G3/4 peripheral neuropathy	
Other G3/4 nonhematologic toxicities	If attributable to carfilzomib, hold carfilzomib doses for up to 21 days to resolve toxicity to G1 or to baseline and then restart at the same dosage or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level
Lenalidomide Dose Levels	
Starting dose	25 mg/day
Level –1	20 mg/day
Level –2	15 mg/day
Level –3	10 mg/day
Level –4	5 mg/day
Level –5	Discontinue
Adverse Event	**Treatment Modification**
G3/4 neutropenia	Hold lenalidomide dosing for up to 21 days to resolve toxicity and then restart at the same dosage or reduce the lenalidomide dosage by 1 dose level
Febrile neutropenia (ANC <1000/mm^3 with fever ≥38°C)	
G3/4 nonhematologic toxicity	Hold lenalidomide dosing for up to 21 days to resolve toxicity to G ≤2 and then restart at the same dosage or reduce the lenalidomide dosage by 1 dose level
• Any adverse event G ≥3 (excluding nausea, vomiting, diarrhea, lenalidomide-induced maculopapular rash or dexamethasone-induced hyperglycemia) • G ≥3 nausea, vomiting, or diarrhea despite maximal therapy • G4 fatigue lasting >7 days	Hold carfilzomib and lenalidomide dosing for up to 21 days to resolve toxicity to G ≤2 and then, depending on presumed attribution of toxicity, restart at the same dosage or reduce the carfilzomib dosage and/or lenalidomide daily dose by 1 dose level
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, or oral candidiasis	Hold dexamethasone dosing for up to 21 days to resolve toxicity and then restart at the same dose, or reduce dexamethasone doses by 50%

Patient Population Studied

Enrolled both transplantation-eligible and -ineligible patients with newly diagnosed, symptomatic MM. Patients were required to have an Eastern Cooperative Oncology Group performance status of 0–2. Patients were ineligible if they had G3/4 neuropathy, and an estimated creatinine clearance <50 mL/min (<0.83 mL/s) or serum creatinine ≥2 g/dL (>177 µmol/L)

Unfavorable (*n* = 17)†	16 (94)	13 (76)	11 (65)	9 (53)

ISS, International Staging System; nCR, near-complete response; PR, partial response; sCR, stringent complete response; VGPR, very good partial response
*Assessed by Modified International Myeloma Working Group (IMWG) Uniform Criteria with the addition of nCR
†Any of del 13 by metaphase or hypodiploidy or t(4;14) or t(14;16) or del 17p considered as unfavorable; all others considered normal/favorable

Toxicity

Treatment-Emergent Adverse Events During Induction (Cycles 1–8; N = 53)

	Any Grade, *n* (%)	G3/4, *n* (%)
Nonhematologic		
Hyperglycemia	38 (72)	12 (23)
Edema	25 (47)	2 (4)
Hypophosphatemia	24 (45)	13 (25)
Fatigue	20 (38)	1 (2)
Muscle cramping	17 (32)	0
Rash	15 (28)	4 (8)
Elevated liver function test	15 (28)	4 (8)
Diarrhea	14 (26)	0
Infection*	12 (23)	2 (4)
Phlebitis	12 (23)	0
Peripheral neuropathy	12 (23)†	0
Dyspnea	8 (15)	2 (4)
Deep vein thrombosis	6 (11)	2 (4)
Pulmonary embolism	3 (6)	3 (6)
Nausea	7 (13)	0
Renal	5 (9)	1 (2)
Constipation	5 (9)	0
Mood alterations	5 (9)	1 (2)
Hematologic		
Thrombocytopenia	36 (68)	9 (17)
Anemia	32 (60)	11 (21)
Neutropenia	16 (30)	9 (17)

*Grade 3/4 events were pneumonia, and grade 1/2 events were upper respiratory infections
†Three (6%) grade 2, remaining grade 1

Therapy Monitoring

1. Blood counts and physical examinations on day 1 of each cycle
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle as indicated and at the end of treatment

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (TRANSPLANTATION CANDIDATES)

INDUCTION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) THALIDOMIDE + DEXAMETHASONE

Rajkumar SV et al. J Clin Oncol 2006;24:431–436

Four-week cycles:
Thalidomide 200 mg/day; administer orally, continually, for 4 weeks (total dose/4-week cycle = 5600 mg)
Dexamethasone 40 mg/dose; administer orally for three 4-day periods on days 1 to 4, 9 to 12, and 17 to 20, every 4 weeks (total dose/4-week cycle = 480 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MINIMAL - LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including: agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Thromboprophylaxis
Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

(*continued*)

Treatment Modifications

Thalidomide Dose Levels	
Dose Level 1	200 mg daily
Dose Level −1	100 mg daily
Dose Level −2	50 mg daily
Adverse Event	**Treatment Modification**
Febrile neutropenia	Withhold therapy until fever abates, then resume therapy
G4 hematologic toxicity	Withhold therapy until ANC >750/mm^3 and platelets >50,000/mm^3, then resume therapy with thalidomide dose decreased by 1 dose level
G3/4 nonhematologic toxicity G ≥3 thalidomide neuropathy	Interrupt therapy and follow clinically. After toxicity abates to G ≤2, resume therapy with thalidomide dose decreased by 1 dose level
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce dexamethasone dose to 20 mg per dose

Efficacy

Best response within 4 cycles of therapy	63%
Complete response within 4 cycles of therapy	4%
Disease progression within 4 cycles of therapy	2%
Stem cell harvest efficiency	90%

(continued)

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin,** targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin,** targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Patient Population Studied

Phase III trial of 207 patients with newly diagnosed, previously untreated, measurable myeloma. Patients were eligible to enter onto the study if they had previously untreated symptomatic multiple myeloma, bone marrow plasmacytosis (≥10% plasma cells or sheets of plasma cells), or a biopsy-proven plasmacytoma, and measurable disease defined as serum monoclonal protein >1 g/dL and/or urine monoclonal protein ≥200 mg/24 hours. Study eligibility criteria also included hemoglobin >7 g/dL, platelet count >50,000 cells/mm^3, absolute neutrophil count >1000 cells/mm^3, creatinine <3 mg/dL (<265 µmol/L), bilirubin ≤1.5 mg/dL (≤26 µmol/L), and ALT and AST ≤2.5-times the upper limit of normal. No prior systemic therapy was permitted with the exception of bisphosphonates

Toxicity (N = 102)

Grade 3/4 neutropenia	9%
Deep venous thrombosis (G ≥3)	17%
Skin rash (G ≥3)	4%
Sinus bradycardia (G ≥3)	1%
Peripheral neuropathy (G ≥3)	7%
Toxicity of any type (G ≥4)	34%

Treatment-related deaths	5%
G ≥3 Thrombosis/embolism	20%
G ≥3 Hyperglycemia	15%
G ≥3 Fatigue	15%
G ≥3 Dyspnea	11%
G ≥3 Hypocalcemia	8%
G ≥3 Confusion	8%
G ≥3 Constipation	8%
G ≥3 Neuropathy-motor	7%
G ≥3 Muscle weakness	6%
G ≥3 Edema	6%
G ≥3 Pneumonitis/pulmonary infiltrates	5%
G ≥3 Hyponatremia	4%
G ≥3 Hypotension	4%
G ≥3 Dehydration	4%
G ≥3 Neuropathy-sensory	4%
G ≥3 Rash/desquamation	4%
G ≥3 Nausea	4%
G ≥3 Hypoxia	3%
G ≥3 Depressed level of consciousness	3%
G ≥3 Anorexia	3%
G ≥3 Seizure	3%

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA (ELDERLY AND THOSE *NOT* TRANSPLANTATION CANDIDATES)

MELPHALAN + PREDNISONE + THALIDOMIDE (MPT)

Palumbo A et al. Lancet 2006;367:825–831
Palumbo A et al. Blood 2008;112:3107–3114

Induction:
Melphalan 4 mg/m^2 per day; administer orally for 7 consecutive days on days 1–7, every 4 weeks, for 6 cycles (total dosage/cycle = 28 mg/m^2)
Prednisone 40 mg/m^2 per day; administer orally for 7 consecutive days on days 1–7, every 4 weeks, for 6 cycles (total dosage/cycle = 280 mg/m^2)
Thalidomide 100 mg/day; administer orally for 28 consecutive day on days 1–28, every 4 weeks for 6 cycles (total dose/cycle = 2800 mg)

Maintenance:
Thalidomide 100 mg/day; administer orally, continually, until confirmation of relapsed or refractory disease (total dose/week = 700 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Melphalan Dosage Levels	
Dosage Level 1	4 mg/m^2
Dosage Level −1	3 mg/m^2
Dosage Level −2	2 mg/m^2
Adverse Event	**Treatment Modification**
Febrile neutropenia	Withhold therapy until fever abates, then resume therapy
G4 hematologic toxicity	Withhold therapy until ANC >750/mm^3 and platelets>50,000/mm^3, then resume therapy with the melphalan dose decreased by 1 dose level
G3/4 nonhematologic toxicity	Interrupt therapy and follow clinically. After toxicity abates to G ≤2, resume therapy with thalidomide dose decreased by 1 dose level
G ≥3 thalidomide neuropathy	
If ANC nadir is ≤1000/mm^3 or platelets nadir is ≤50,000/mm^3	Continue treatment, but reduce melphalan dosage by 1 level
G2 nonhematologic toxicity	Reduce thalidomide dose by 50% to 50 mg/day
G ≥3 nonhematologic toxicity	Discontinue thalidomide
G3 toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce daily prednisone dosage by 20%
G4 or recurrent G3 toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, and oral candidiasis	Reduce daily prednisone dosage by 40%

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate sodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Patient Population Studied

A multicenter randomized trial of 331 previously untreated patients with Durie and Salmon stage II or III multiple myeloma who were older than 65 years (or younger but unable to undergo transplantation), and had measurable disease. Exclusion criteria included any G2 peripheral neuropathy. Abnormal cardiac function, chronic respiratory disease, and abnormal liver or renal function were not criteria for exclusion

Efficacy (N = 129)

Complete or partial response	76%
Complete response	15.5%
Partial response	60.4%
Near-complete response	12.4%
90% to 99% myeloma protein reduction	8.5%
50% to 89% myeloma protein reduction	39.5%
Minimal response	5.4%
No response	5.4%
Progressive disease	7.8%
Responses not available	5.4%
Progression free survival*	21.8 months
Median overall survival†	45 months

*After a median follow-up of 38.1 months.
The magnitude of PFS benefit was consistent irrespective of age, serum concentrations of β_2-microglobulin, or high International Staging System
†The median OS of 45 months for melphalan + prednisone (MP) + thalidomide (T) compared to a median OS of 47.6 months for MP was not statistically significant ($P = 0.79$). New agents in the management of relapsed disease could explain this finding

Toxicity (N = 129)

Adverse Event	G3/4 Adverse Events Percent of Patients
≥1 Event	48%
Hematologic	22%
Neutropenia	16%
Anemia	3%
Thrombocytopenia	3%
Thrombosis/embolism	12%
Deep venous thrombosis	9%
Pulmonary embolism	2%
Neurologic	10%
Peripheral neuropathy	8%
Somnolence or fatigue	3%
Infection	10%
Pneumonia	5%
Fever of unknown origin	2%
Herpes zoster	1%
Upper respiratory	2%
Cardiac	7%
Arrhythmia	2%
Myocardial infarction/ angina	2%
Cardiac failure	3%
Hypertension	1%
Gastrointestinal	6%
Constipation	6%
Mucositis	0
Dermatologic	3%
Rash	2%
Toxic epidermal necrolysis	1%
Renal	1%
Creatinine increase	1%
Edema	1%
Bleeding	0

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN
NEWLY DIAGNOSED MULTIPLE MYELOMA (*NOT* TRANSPLANTATION CANDIDATES)

BORTEZOMIB + MELPHALAN + PREDNISONE

San Miguel JF et al. N Engl J Med 2008;359:906–917

All Cycles:
Melphalan 9 mg/m² per day; administer orally for 4 consecutive days on days 1–4, every 6 weeks, for 9 cycles (total dosage/cycle = 36 mg/m²)
Prednisone 60 mg/m² per day; administer orally for 4 consecutive days on days 1–4, every 6 weeks, for 9 cycles (total dosage/cycle = 240 mg/m²), *plus*
Cycles 1–4:
Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 8 doses, on days 1, 4, 8, 11, 22, 25, 29, and 32, every 6 weeks, for 4 cycles (total dosage/cycle = 10.4 mg/m²)

Cycles 5–9:
Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 8, 22, and 29, every 6 weeks, for 5 cycles (total dosage/cycle = 5.2 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Decreased bowel motility prophylaxis
Give a bowel regimen to prevent constipation based initially on **stool softeners**

(*continued*)

Treatment Modifications

Bortezomib Dosage Levels (per dose)	
Dosage Level 1	1.3 mg/m²
Dosage Level −1	1 mg/m²
Dosage Level −2	0.7 mg/m²

Melphalan Dose Levels (per day)	
Dosage Level 1	9 mg/m²
Dosage Level −1	6.75 mg/m²
Dosage Level −2	4.5 mg/m²

Adverse Event	Treatment Modification
Febrile neutropenia	Withhold therapy until fever abates then resume therapy
G4 hematologic toxicity	Withhold therapy until ANC >750/mm³ and platelets >50,000/mm³, then resume therapy with bortezomib and melphalan dosages decreased by 1 dose level
G3/4 nonhematologic toxicity	Withhold therapy. After toxicity abates to G ≤2, resume therapy with bortezomib and melphalan dosages decreased by 1 dose level
G≥3 thalidomide neuropathy	Continue treatment, but reduce thalidomide dose by 1 dose level
If ANC nadir is ≤1000/mm³ or platelets nadir is ≤50,000/mm³	Continue treatment, but reduce bortezomib and melphalan dosages by 1 level
G3 toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce daily prednisone dosage by 20%
G4 or recurrent G3 toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce daily prednisone dosage by 40%

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

• **Pamidronate sodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*

• **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain, or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain, or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate at a dosage of 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Patient Population Studied

A randomized, open-label, phase III trial of 682 patients with newly diagnosed, untreated, symptomatic, measurable myeloma who, because of age (≥65 years), were not candidates for high-dose therapy plus stem cell transplantation

Efficacy (N = 337)*

European Group for Blood and Marrow Transplantation (EBMT) Criteria	
Complete or partial response	71%
Complete response	30%
Partial response	40%
Minimal response	9%
Stable disease	18%
Progressive disease	1%
Time to Event	
Median time to response†	
First response (months)	1.4
Complete response	4.2
Median duration of response†	
Complete or partial response	19.9
Complete response	24
Time to subsequent myeloma therapy‡	Not reached
Treatment-free interval‡	Not reached
International Uniform Response Criteria§	
Complete, very good partial, or partial response	74%
Complete response	33%
Very good partial response	8%
Partial response	33%
Stable disease	23%
Progressive disease	1%

*Seven patients could not be evaluated for a response. Among patients evaluated, responses were not determined for 4. Percentages may not total 100 because of rounding
†Data determined by computer algorithm, applying EBMT criteria
‡Data based on 344 patients
§Of 79 patients considered to have stable disease on the basis of International Uniform Response Criteria who could be evaluated, 4 patients (1%) had negative results on immunofixation (complete response) and 19 (6%) had a reduction of at least 50% in M-protein (partial response). These patients were not recorded as having a complete or partial response because confirmatory results were missing. If these patients are included, the response rate is 81% and the complete-response rate is 34%. Patients could not be assessed for the category of stringent complete response because immunohistochemical, immunofluorescence, and free light-chain assays were not performed. International Uniform Response Criteria do not require changes in M-protein be confirmed a minimum of 6 weeks after the initial assessment

Toxicity (N = 340)*

	G1/2	G3	G4
Any Event	18	53	28
Hematologic Events†			
Thrombocytopenia	15	20	17

Back pain	14	3	<1
Dyspnea	11	3	1
Hypokalemia	6	6	1
Arthralgia	10	1	0
Deep venous thrombosis	1	1	0

*Listed adverse events were reported in ≥15% of patients, and G3 or G4 events were reported in ≥5% of patients. Patients may have more than 1 adverse event. Included are all patients who received at least 1 dose of a study drug
†Rates of red cell transfusions were 26%; erythropoiesis-stimulating agents for treatment-related anemia were used in 30% of patients

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

REGIMEN

NEWLY DIAGNOSED MULTIPLE MYELOMA *NOT* TRANSPLANTATION CANDIDATES

MELPHALAN + PREDNISONE + LENALIDOMIDE

Palumbo A et al. J Clin Oncol 2007;25:4459–4465

Induction:
Melphalan 0.18 mg/kg per day; administer orally for 4 consecutive days on days 1–4, every 4 weeks, for 9 cycles (total dosage/cycle = 0.72 mg/kg)
Prednisone 2 mg/kg per day; administer orally for 4 consecutive days on days 1–4, every 4 weeks, for 9 cycles (total dosage/cycle = 8 mg/kg)
Lenalidomide 10 mg per day; administer orally for 21 consecutive days on days 1–21, every 4 weeks, for 9 cycles (total dose/cycle = 210 mg)
Maintenance:
Lenalidomide 10 mg/day; administer orally for 21 consecutive days on days 1–21, every 4 weeks until signs of relapse or disease progression (total dose/cycle = 210 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MINIMAL–LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurological adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Decreased bowel motility prophylaxis
Give a bowel regimen to prevent constipation based initially on **stool softeners**

(*continued*)

Treatment Modifications

Lenalidomide Dose Levels	
Dose Level 1	10 mg/day
Dose Level −1	5 mg/day
Melphalan Dose Levels	
Dosage Level 1	0.18 mg/kg
Dosage Level −1	0.135 mg/kg
Adverse Event	**Treatment Modification**
Febrile neutropenia	Withhold therapy until fever abates, then resume therapy
G4 neutropenia for ≥7 days despite filgrastim administration, any other G4 hematologic toxicities, or any G ≥3 nonhematologic toxicities	Withhold therapy until toxicities resolve to G ≤2 then resume therapy with a subsequent dose/dosage reduction in lenalidomide and melphalan at the start of the following cycle
G ≥3 neuropathy	Interrupt therapy and follow clinically. After toxicity abates to G ≤2, resume lenalidomide with a dose decreased by 1 dose level
G3/4 non-hematologic toxicity	Interrupt lenalidomide treatment and follow clinically. Resume lenalidomide at 5 mg/day after toxicity abates to G ≤2
ANC <1000/mm^3, platelet count <50,000/mm^3, or nonhematologic adverse events G ≥2	Withhold therapy as long as 2 weeks until ANC ≥1000/mm^3, platelet count is ≥50,000/mm^3, and nonhematologic toxicities are G ≤1, then resume therapy. A delay of 2 weeks is allowed without any dose modification. A new cycle delay beyond a maximum of 2 weeks requires a dose/dosage reduction in lenalidomide and melphalan by 1 dose level
Toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including: hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce prednisone dose to 20 mg/day

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate sodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Lenalidomide Starting Dose Adjustment for Renal Impairment in Multiple Myeloma (Days 1–21 of Each 28-Day Cycle)*

Moderate renal impairment CrCl 30–60 mL/min (0.5–1 mL/s)	10 mg lenalidomide every 24 hours
Severe renal impairment CrCl <30 mL/min, not requiring dialysis	15 mg lenalidomide every 48 hours
End-stage renal disease CrCl <30 mL/min, requiring dialysis	Lenalidomide 5 mg/day. On dialysis days, administer a daily dose following dialysis

CrCl, Creatinine clearance

*Richardson PG et al. J Clin Oncol 2006;24:3 113–3120

Patient Population Studied

Phase I/II trial of 54 patients ages ≥65 years or younger if ineligible for high-dose therapy for newly diagnosed multiple myeloma. Karnofsky performance status ≥60%; platelet count ≥75,000/mm³; absolute neutrophil count ≥1500/mm³; corrected serum calcium ≤3.5 mmol/L (≤14 mg/dL)

Therapy Monitoring

1. *Before each cycle:* CBC with differential and blood chemistries (including BUN, creatinine, and calcium)
2. *Every 6 weeks to 3 months:* Measure serum and urine M-protein

Efficacy

	Dose Levels Evaluated			
	1	2	3 (MTD)	4
Lenalidomide (mg)	5	5	10	10
Melphalan (mg/kg)	0.18	0.25	0.18	0.25
Number of patients	6	6	21	20
Complete or partial response	66.7	83.3	81	85
CR, immunofixation negative	—	—	23.8	10

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA

BORTEZOMIB ± DEXAMETHASONE

Richardson PG et al. N Engl J Med 2003;348:2609–2617

Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 21 days (total dosage/cycle = 5.2 mg/m²)

In patients with disease progression after 2 cycles, or stable disease after 4 cycles, add:
Dexamethasone 20 mg per dose; administer orally for 8 doses on days 1, 2, 4, 5, 8, 9, 11, and 12, every 21 days (total dose/cycle = 160 mg)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use

- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurological adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Decreased bowel motility prophylaxis
Give a bowel regimen to prevent constipation based initially on **stool softeners**

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
G3 nonhematologic toxicity or G4 hematologic toxicity	Hold treatment until toxicity resolves to G ≤1, then resume with bortezomib 1 mg/m²
G3 nonhematologic toxicity or G4 hematologic toxicity in a patient receiving bortezomib 1 mg/m²	Hold treatment until toxicity resolves to G ≤1, then resume with bortezomib 0.7 mg/m²
Severe manifestations of hypercorticism, including severe hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce daily dexamethasone dosage by 20% for G3 toxicity, and by 40% for G4 or recurrent G3 toxicity

Patient Population Studied

Study of 202 patients with relapsed multiple myeloma, refractory to the therapy subjects had most recently received. A multicenter, open-label, nonrandomized, phase II trial

Efficacy (N = 193)

European Group for Blood and Marrow Transplantation Criteria	
Complete response	10%
Partial response	18%
Minimal response	7%
No change	24%
Progressive disease	41%
Median time to first response	1.3 months
Median response duration*	12 months

*In the 67 patients with a complete, partial, or minimal response to bortezomib alone

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Toxicity (N = 202)

NCI Common Toxicity Criteria, version 2.0

Toxicity	Percentage of Patients: Bortezomib-Related	Percentage of Patients: G3/4
Nonhematologic Toxicity		
Nausea	55	6
Diarrhea	44	8
Fatigue	41	12
Peripheral neuropathy	31	12
Vomiting	27	9
Anorexia	25	2
Fever	22	4
Headache	19	3
Constipation	16	2
Rash	15	<1
Limb pain	13	7
Dizziness, not vertigo	12	1
Weakness	11	6
Dehydration	10	7
Hematologic Toxicity		
Thrombocytopenia	40	31
Anemia	21	8
Neutropenia	19	14

Note: Ten deaths occurred within 20 days after the last bortezomib dose. Most deaths were attributed to progressive disease; 2 deaths were possibly related to treatment

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 2 cycles:* Serum BUN, creatinine, and LFTs. Serum and urine M-protein

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA

LENALIDOMIDE + DEXAMETHASONE

Weber DM et al. N Engl J Med 2007;357:2133–2142
Dimopoulos M et al. N Engl J Med 2007;357:2123–2132

Lenalidomide 25 mg per day; administer orally for 21 consecutive days on days 1–21, every 28 days (total dose/cycle = 525 mg)
Cycles 1–4:
Dexamethasone 40 mg per dose; administer orally for 12 doses on days 1–4, 9–12, and 17–20, every 28 days for 4 cycles (total dose/cycle = 480 mg)
Cycle 5 and subsequently:
Dexamethasone 40 mg per dose; administer orally for 4 doses on days 1–4, every 28 days, until the occurrence of disease progression or unacceptable toxic effects (total dose/cycle = 160 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use
- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

Treatment Modifications

Lenalidomide Dose Levels	
Dose Level 1	25 mg
Dose Level −1	15 mg
Dose Level −2	10 mg
Dose Level −3	5 mg
Dexamethasone Dose Levels	
Dose Level 1	40 mg/dose for 12 doses on days 1 to 4, 9 to 12, and 17 to 20
Dose Level −1	40 mg daily for 4 days every 2 weeks (days 1–4 and 15–18)
Dose Level −2	40 mg daily for 4 days every 4 weeks (days 1–4)
Dose Level −3	20 mg daily for 4 days every 4 weeks (days 1–4)
Adverse Event	**Treatment Modification**
G3/4 neutropenia	Interrupt lenalidomide treatment and follow clinically. After ANC recovers to ≥1000/mm^3, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
Febrile neutropenia	Interrupt lenalidomide treatment and follow closely. After fever abates, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
G3/4 nonhematologic toxicity	Interrupt lenalidomide treatment and follow clinically. After toxicity abates to G ≤2, resume lenalidomide at a dose decreased from the previous dose by 5 mg/day, but the daily dose should not be less than 5 mg/day
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, or oral candidiasis	Reduce dexamethasone dose to the next lowest dose level

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3

Treatment Modifications (*continued*)

Lenalidomide Starting Dose Adjustment for Renal Impairment in Multiple Myeloma (Days 1–21 of Each 28-Day Cycle)*

Moderate renal impairment CrCl 30–60 mL/min (0.5–1 mL/s)	10 mg lenalidomide every 24 hours
Severe renal impairment CrCl <30 mL/min, not requiring dialysis	15 mg lenalidomide every 48 hours
End-stage renal disease CrCl <30 mL/min, requiring dialysis	Lenalidomide 5 mg/day. On dialysis days, administer a daily dose following dialysis

CrCl, Creatinine clearance

*Richardson PG et al. J Clin Oncol 2006;24:3 113–3120

Patient Population Studied

Two multicenter, randomized, phase III studies that enrolled patients with progressive multiple myeloma not resistant to dexamethasone who had received at least 1 previous treatment. Patients were considered to have disease that was resistant to dexamethasone if they had had progression during previous therapy containing high-dose dexamethasone (total monthly dose >200 mg). Measurable disease was defined as a serum monoclonal protein (M-protein) level of ≥0.5 g/dL or a urinary Bence Jones protein level ≥0.2 g/day. Additional eligibility criteria included an Eastern Cooperative Oncology Group performance status ≤2

European Study
(Dimopoulos M et al. N Engl J Med 2007;357: 2123–2132)

(351 patients: N = 176 lenalidomide group; N = 175 placebo group)

North America Study

Therapy Monitoring

1. Blood counts and physical examinations
   - Cycle 1: days 1, 8, and 15
   - Cycles 2 and 3: days 1 and 15
   - Cycle 4, and subsequently: day 1
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle and at the end of treatment
3. Serum electrolytes and creatinine before beginning each treatment cycle

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA (PRIOR BORTEZOMIB AND BORTEZOMIB NAÏVE)

CARFILZOMIB

Vij R et al. Blood 2012;119:5661–5670 (Bortezomib-naïve)
Vij R et al. Br J Haematol 2012;158:739–748 (Prior bortezomib)

Hydration with carfilzomib: During cycle 1, days 1 and 2, administer intravenously 250–500 mL 0.9% NS before each carfilzomib dose, *and* an additional 250–500 mL of fluid intravenously after carfilzomib. During repeated treatments, continue intravenous hydration as needed. Encourage oral hydration

Carfilzomib 36 mg/m² per dose intravenously in 50-mL 5% dextrose injection over 30 minutes for 6 doses, on days 1, 2, 8, 9, 15, and 16, every 28 days for a maximum of 12 cycles (total dosage/cycle = 216 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3

(*continued*)

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation
See Chapter 43 for more information

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Patient Population Studied (*continued*)

Prior Therapies	Bortezomib-Naïve* (N = 129) *n* (%)	Prior Bortezomib† (N = 35) *n* (%)
Median number of prior regimens (range)	2 (1–4)	3.0 (1–13)

Refractory to last therapy, *n* (%)		22 (62.9)

*Includes 2 patient cohorts: (a) cohort 1 (n = 59) was treated with 20 mg/m² carfilzomib; (b) cohort 2 (n = 70) was treated with 20/27 mg/m² carfilzomib
†Patients treated with 20 mg/m² carfilzomib
‡Bortezomib exposure not considered therapeutic
§20/35 (57.1%) had bortezomib in last regimen

Treatment Modifications

Carfilzomib Dose Levels	
Starting dose	36 mg/m² per dose
Level –1	27 mg/m² per dose
Level –2	20 mg/m² per dose
Level –3	15 mg/m² per dose
Level –4	11 mg/m² per dose
Level –5	Discontinue
Adverse Event	**Treatment Modification**
Hematologic Toxicity	
G3/4 neutropenia	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dosage, or reduce the carfilzomib dosage by 1 dose level. If counts recover to G2 neutropenia or G3 thrombocytopenia, reduce carfilzomib dosage by 1 dose level. If tolerated, the reduced dose may be escalated to the previous dose level
Febrile neutropenia (ANC $<1.0 \times 10^9$/L with fever ≥38°C)	
G4 thrombocytopenia	
G3/4 thrombocytopenia associated with bleeding	
Nonhematologic Toxicity	
G3/4 cardiac toxicity New onset or worsening of: • Congestive heart failure • Decreased left ventricular function • Myocardial ischemia	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dosage or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level
Pulmonary hypertension	
G3/4 pulmonary complications	
G3/4 elevation of transaminases, bilirubin or other liver abnormalities	
Serum creatinine equal to or greater than 2× baseline	Hold carfilzomib dosing for up to 21 days to resolve toxicity to G1 or to baseline and then restart at the same dosage, or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dose may be escalated to the previous dose level
G2 neuropathy with pain	Hold carfilzomib dosing for up to 21 days to resolve toxicity and then restart at the same dose or reduce the carfilzomib dose by 1 level. If tolerated, the reduced dosage, or reduce the carfilzomib dosage by 1 dose may be escalated to the previous dose level
G3/4 peripheral neuropathy	
Other G3/4 nonhematologic toxicities	Hold carfilzomib dosing for up to 21 days to resolve toxicity to G1 or to baseline and then restart at the same dosage, or reduce the carfilzomib dosage by 1 dose level. If tolerated, the reduced dosage may be escalated to the previous dose level

RELAPSED/REFRACTORY MULTIPLE MYELOMA

POMALIDOMIDE + DEXAMETHASONE

Leleu X et al. Blood 2013;121:1968–1975
Lacy MQ et al. Leukemia 2010;24:1934–1939

Pomalidomide 4 mg/day orally, continually, for 21 consecutive days, on days 1–21, every 28 days (total dose/cycle = 84 mg)
Dexamethasone 40 mg/dose; orally for 4 doses on days 1, 8, 15, and 22, every 28 days (total dose/cycle = 160 mg)

or

Pomalidomide 2 mg/day; orally, continually, for 28 consecutive days, on days 1–28, every 28 days (total dose/cycle = 56 mg)
Dexamethasone 40 mg daily orally on days 1, 8, 15, and 22, every 28 days (total dose/cycle = 160 mg)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3

(*continued*)

Treatment Modifications

Pomalidomide Dose Levels	
Starting dose	4 mg/day
Level –1	3 mg/day
Level –2	2 mg/day
Level –3	1 mg/day
Level –4	Discontinue

Dexamethasone Dose Levels	
Starting dose	40 mg/dose
Level –1	20 mg/dose
Level –2	12 mg/dose
Level –3	8 mg/dose
Level –4	4 mg/dose
Level –5	Discontinue

Adverse Event	Treatment Modification
ANC <500/mm³	Interrupt pomalidomide treatment, and follow CBC weekly. When ANC ≥500/mm³ and platelet count 50,000/mm³, resume pomalidomide 1 dose level lower
Febrile neutropenia (fever ≥38.5°C + ANC <1000/mm³)	
Platelets <25,000/mm³	
Nonhematologic G3/4 toxicity	Interrupt pomalidomide treatment, and follow weekly or more frequently. Restart treatment 1 dose level lower than the previous dose when toxicity has resolved G ≤2
G4 rash, neuropathy, hypersensitivity, or G ≥3 bradycardia or cardiac arrhythmia	Permanently discontinue pomalidomide
G3/4 adverse events occurring on or after day 15 during a single cycle	Withhold pomalidomide for the remainder of the cycle and reduce by 1 dose level beginning with the next cycle
Toxicities ascribed to dexamethasone such as severe manifestations of hypercorticism, including hyperglycemia, irritability, insomnia, or oral candidiasis	Hold dexamethasone dosing for up to 21 days to resolve toxicity and then restart at the same dose or reduce the dexamethasone dose by 50%

(*continued*)

Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease
*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Therapy Monitoring

1. Blood counts and physical examinations on day 1 of each cycle
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle as indicated and at the end of treatment

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA

POMALIDOMIDE + CYCLOPHOSPHAMIDE + PREDNISONE

Larocca A et al. Blood 2013;122:2799–2806

Induction:

Cyclophosphamide 50 mg/dose orally, every other day (eg, days 1, 3, 5…, etc. *or* days 2, 4, 6…, etc.) continually, for 14 doses every 28 days (total dose/cycle = 700 mg)
Prednisone 50 mg/dose orally, every other day (eg, days 1, 3, 5…, etc. *or* days 2, 4, 6…, etc.) continually, for 14 doses every 28 days (total dose/cycle = 700 mg)

plus

Pomalidomide 2–3 mg/day orally, continually, for 28 consecutive days, on days 1–28, every 28 days (total dose/cycle = 56–84 mg), *or*
Pomalidomide 4 mg/day orally, continually, for 21 consecutive days, on days 1–21, every 28 days (total dose/cycle = 84 mg)

Maintenance:

Pomalidomide 1 mg/day orally, continually, until disease relapse or progression (total dose/week = 7 mg)
Prednisone 25 mg/dose orally, every other day (eg, days 1, 3, 5…, etc. *or* days 2, 4, 6…, etc.) continually, until disease relapse or progression

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Pomalidomide Dose Levels	
Starting dose	2.5 mg/day
Level –1	2 mg/day
Level –2	1.5 mg/day
Level –3	1 mg/day
Level –4	0.5 mg/day
Level –5	Discontinue

Prednisone Dose Levels	
Starting dose	50 mg/dose
Level –1	25 mg/dose
Level –2	20 mg/dose
Level –3	10 mg/dose
Level –4	5 mg/dose
Level –5	Discontinue

Adverse Event	Treatment Modification
ANC <500/mm³	Interrupt pomalidomide and cyclophosphamide treatment, and follow CBC weekly. When ANC ≥500/mm³ and platelet count ≥50,000/mm³, resumepomalidomide 1 dose level lower and cyclophosphamide at a dose of 25 mg every other day
Febrile neutropenia (fever ≥38.5°C + ANC <1000/mm³)	
Platelets <25,000/mm³	
Nonhematologic G3/4 toxicity	Interrupt pomalidomide treatment, and follow weekly or more frequently. Restart treatment 1 dose level lower than the previous dose when toxicity has resolved G ≤2
ANC <1000/mm³, platelet count <50,000/mm³, hemoglobin <8 g/dL, and/or nonhematologic adverse events G ≥3	Delay the start of a new cycle. If delayed by ≥2 weeks, reduce the dose of pomalidomide by 1 dose level

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications (*continued*)

Adverse Event	Treatment Modification
G4 rash, neuropathy or hypersensitivity, or G ≥3 bradycardia or cardiac arrhythmia	Permanently discontinue pomalidomide
G3/4 adverse events occurring on or after day 15 during a single cycle	Withhold pomalidomide for the remainder of the cycle, and reduce pomalidomide dose by 1 dose level beginning with the next cycle
Toxicities ascribed to prednisone such as severe manifestations of hypercorticism, including: hyperglycemia, irritability, insomnia, or oral candidiasis	Hold prednisone doses for up to 21 days to resolve toxicity and then restart at the same dose level or reduce the prednisone dose by 50%

Efficacy

Patient Population Studied

Patients with MM who had received 1–3 prior lines of therapy and whose disease had relapsed after lenalidomide or was refractory. Relapse was defined as reoccurrence of disease requiring the initiation of a salvage therapy. Refractory disease was defined as relapse while on salvage therapy or progression within 60 days after the most recent therapy. Patients were required to have Karnofsky performance status ≥60%, platelet count ≥50,000/mm^3, neutrophil count ≥1000/mm^3, corrected serum calcium ≤3.5 mmol/L (≤14 mg/dL), and serum creatinine ≤2 mg/dL (≤177 μmol/L)

Baseline Patients Characteristics (N = 66)

Median age, years (range)	69 (41–84)

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA

LIPOSOMAL DOXORUBICIN + BORTEZOMIB

Orlowski RZ et al. J Clin Oncol 2007;25:3892–3901

Bortezomib 1.3 mg/m² per dose; administer by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 3 weeks (total dosage/cycle = 5.2 mg/m²)
Doxorubicin HCl Liposome Injection ([pegylated] liposomal doxorubicin) 30 mg/m²; administer intravenously in 250 mL (doses ≤90 mg)
or 500 mL (doses >90 mg) 5% dextrose injection over 60 minutes after bortezomib on day 4, every 3 weeks (total dosage/cycle = 30 mg/m²)
Notes:

1. Liposomal doxorubicin doses >60 mg are administered at an initial rate of 1 mg/min to minimize the risk of infusion reactions. If no infusion-related adverse reactions are observed within 15 minutes after starting administration, the infusion rate may be increased to complete administration over 1 hour
2. Treatment on study continued until disease progression, unacceptable treatment-related toxicities, or for 8 cycles. Patients still responding after 8 cycles were permitted to continue, provided treatment was well tolerated

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with bortezomib alone is **MINIMAL–LOW***
*Emetogenic potential on days with liposomal doxorubicin is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use

- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVC or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVC, central venous catheter; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring anti-Factor Xa concentrations

Hand-foot reaction (palmar-plantar erythrodysesthesia)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patients who have developed G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE

(*continued*)

Toxicity (N = 318) (*continued*)

Efficacy (N = 324)

Total response (CR + PR)	44%
CR	4%
PR	40%
nCR	9%
CR + VGPR	27%

Median time to first response	43 days
Median number of cycles administered	5 cycles
Median treatment duration	105 days
Median duration of response	10.2 months
Median time to progression	9.3 months
Median progression-free survival	9 months
Median duration of overall survival	311 days
15-month survival rate	76%

CR, complete response; nCR, near-complete response; PR, partial response; VGPR, very good partial response

(continued)

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine H_2-receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Patient Population Studied

A randomized phase III study of 646 patients with relapsed refractory multiple myeloma. Eligible subjects had an Eastern Cooperative Oncology Group performance status ≤1, must have experienced disease progression after a response to 1 or more lines of therapy or were refractory to initial treatment, but were bortezomib naïve. Subjects were excluded if their disease progressed while receiving anthracycline-containing therapy, and if they had already received >240 mg/m² doxorubicin, clinically significant cardiac disease, a left ventricular ejection fraction less than institutional normal limits, or peripheral neuropathy G ≥2

Therapy Monitoring

1. Blood counts with differential leukocyte count and physical examinations on day 1 of each cycle
2. Serum and urinary protein electrophoresis studies on day 1 of each cycle and at the end of treatment

Treatment Modifications

Bortezomib Dosage Levels

Dosage Level 1	1.3 mg/m²
Dosage Level −1	1 mg/m²
Dosage Level −2	0.7 mg/m²

Modification Guidelines for Hematologic Toxicity on Day 1 of Planned Therapy

Toxicity	Treatment Modification
ANC 1000–1500/mm³ or platelets 75,000–100,000/mm³	Resume treatment with no dosage reduction
ANC 500–999/mm³ or platelets 50,000–75,000/mm³	Hold treatment until toxicity resolves to G ≤1 or 75% of the counts measured at the start of the previous cycle, then resume without dosage reduction
ANC <500/mm³ or platelets <25,000/mm³	First episode: Hold treatment until toxicity resolves to G ≤1, then resume with a 25% dosage reduction of both liposomal doxorubicin and bortezomib or continue full dose with hematopoietic growth factor support (filgrastim, sargramostim) Reduce dose by 25% if neutropenia occurs despite growth factor use
Febrile neutropenia	Withhold therapy until fever abates then resume therapy

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage to 1 mg/m² per dose
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate at a dosage of 0.7 mg/m² per dose once weekly
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Liposomal Doxorubicin

Treatment Modification Guidelines for Cardiac Toxicity

Toxicity	Treatment Modification
LVEF decreases by ≥15% from baseline, or to <45%	Discontinue liposomal doxorubicin

LVEF, left ventricular ejection fraction

(continued)

Treatment Modifications (*continued*)

Treatment Modification Guidelines for Palmar-Plantar Erythrodysesthesia (PPE, Hand-Foot Syndrome)

Grade of Toxicity	Liposomal Doxorubicin Dosing Interval		
	4 Weeks	5 Weeks	6 Weeks
G1: Mild erythema, swelling, or desquamation not interfering with daily activities	Resume unless patient has previous G3/4 skin toxicity. If so, delay an additional week	Resume unless patient has previous G3/4 skin toxicity. If so, delay an additional week	Resume liposomal doxorubicin at a 25% dose reduction; return to a 4-week dosing interval or discontinue therapy
G2: Erythema, desquamation, or swelling interfering with, but not precluding, normal physical activities; small blisters or ulcerations <2 cm in diameter	Delay treatment 1 week	Delay treatment 1 week	Resume liposomal doxorubicin at a 25% dose reduction; return to 4-week dosing interval or discontinue therapy
G3: Blistering, ulceration, or swelling interfering with walking or normal daily activities; cannot wear regular clothing	Delay treatment 1 week	Delay treatment 1 week	Discontinue therapy
G4: Diffuse or local process causing infectious complications, or a bedridden state, or hospitalization	Delay treatment 1 week	Delay treatment 1 week	Discontinue therapy

REGIMEN
RELAPSED/REFRACTORY MULTIPLE MYELOMA

CONDITIONING REGIMEN BEFORE AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

HIGH-DOSE MELPHALAN

Moreau P et al. Blood 2002;99:731–735

Conditioning for autologous PBSC transplant:
Melphalan 200 mg/m^2; administer intravenously, diluted in sufficient 0.9% sodium chloride injection (0.9% NS) to produce a concentration ≤0.45 mg/mL over 30 minutes, 2 days before PBSC reinfusion (on day −2) (total dosage = 200 mg/m^2). PBSC reinfusion on day 0 (zero), *or*
Melphalan 100 mg/m^2 per day; administer intravenously, diluted in sufficient 0.9% NS to produce a concentration ≤0.45 mg/mL over 30 minutes, for 2 consecutive days, starting 3 days before PBSC reinfusion (on days −3 and −2) (total dosage = 200 mg/m^2). PBSC reinfusion on day 0 (zero)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH** on days melphalan is administered. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Filgrastim (G-CSF), 5–10 mcg/kg per day; administer by subcutaneous injection starting on day +7 after PBSC reinfusion, and continue until granulocyte counts recover, *or*
Sargramostim (GM-CSF) 5–10 mcg/kg per day; administer by subcutaneous injection starting on day +7 after PBSC reinfusion, and continue until granulocyte counts recover

Antimicrobial prophylaxis
Antibacterial prophylaxis (*P. jirovecii* pneumonia prophylaxis):
Trimethoprim + Sulfamethoxazole (**TMP + SMZ**) 160 mg/800 mg; administer orally, daily, continually for 3 months, *or*
TMP + SMZ 80 mg/400 mg; administer orally daily, continually for 3 months, *or*
TMP + SMZ 160 mg/800 mg; administer orally 3 days per week, continually for 3 months
Antifungal prophylaxis
Fluconazole 200–400 mg/day; administer orally or intravenously daily for 30 days after PBSC reinfusion or until neutrophil engraftment occurs (ANC >500/mm^3)
Antiviral prophylaxis for HSV-seropositive recipients to prevent reactivation of HSV during the early posttransplant period
Acyclovir 200 mg; administer orally every 8 hours for 30 days, *or*
Acyclovir 250 mg/m^2 per dose; administer intravenously every 12 hours for 30 days, *or*
Valacyclovir 500 mg; administer orally daily for 30 days

Note: Routine acyclovir prophylaxis for >30 days after HSCT is not recommended

Caution: Acyclovir and famciclovir accumulate in patients with impaired renal function and may exacerbate renal dysfunction (valacyclovir is a *prodrug* for acyclovir). Monitor kidney function serially during acyclovir, valacyclovir, and famciclovir use

- Acyclovir and famciclovir elimination is inversely related to renal function
- Acyclovir, famciclovir, and valacyclovir utilization is modified in renally impaired individuals (consult product labeling or Summary of Product Characteristics for guidance about dose/dosage and administration frequency modifications, and, when relevant, recommendations for drug dilution, administration rate, concurrent fluid administration, and fluid supplementation as a function of urine output)
- Impaired acyclovir elimination is associated with neurologic adverse effects, including agitation, ataxia, coma, confusion, dizziness, dysarthria, encephalopathy, hallucinations, paresthesia, seizure, somnolence, and tremors

See Chapter 47 for more information

(*continued*)

Patient Population Studied

A study of 142 patients ≤65 years of age with symptomatic multiple myeloma responding to primary chemotherapy with VAD

Exclusions:
1. Stable stage 1 MM deemed not to require therapy (Durie-Salmon classification)
2. Previous cytotoxic chemotherapy other than VAD in preparation for transplantation*
3. Previous radiation therapy
4. Severe abnormalities of cardiac, pulmonary, and hepatic function (not characterized)
5. Serum creatinine concentration >5.7 mg/dL (>504 μmol/L)

*VAD was chosen as the regimen because of its "speedy tumor cell reduction without induction of hematopoietic stem cell compromise"

Efficacy (N = 142)

Response to HDT	
Complete response	35%
Very good partial response*	20%
Partial response	39%
Stable or progressive disease	6%
Toxic death	0
Median event-free survival	20.5 months

*Ninety percent decrease in serum paraprotein level

(continued)

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine H_2-receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Notes:

This conditioning regimen was part of a more comprehensive therapy for multiple myeloma that included the following:

1. Before PBSC harvest, patients received 3 cycles of vincristine + doxorubicin + dexamethasone (VAD)
2. In the absence of tumor progression (>25% increase in tumor mass), and if cardiopulmonary, hepatic, and renal function (serum creatinine <1.7 mg/dL [<150 µmol/L]) remained adequate after a third course of VAD, peripheral blood stem cells (PBSCs) were collected
3. After PBSC collection, patients received a fourth course of VAD

(continued)

Adverse Events (N = 142)

Event	Duration in Days Median (Range)
Hematopoietic growth factor	7 (0–23)
Neutropenia	8 (4–34)
Thrombocytopenia	7 (0–30)
Intravenous antibiotics	8 (0–30)
Length of hospital stay	19 (11–47)
Supportive Measure	**Number Median (Range)**
Platelet transfusions	1 (0–18)
RBC transfusions	2 (0–9)
G3/4 Toxicity	**WHO Criteria**
Cardiac	0.7%
Mucositis	30%
Pulmonary	1.4%
Renal	2.1%
Liver	0.7%
Toxic death	0

Therapy Monitoring

CBC with differential, daily to every third day as hematological recovery occurs

(*continued*)

Response to VAD Regimen and Stem Cell Collection	
Complete response	5%
Very good partial response*	12%
Partial response	61%
Stable disease	22%
Stem Cell Collection	
G-CSF priming	75%
Stem cell factor + G-CSF	4%
Cyclophosphamide + G-CSF	21%
Median number of CD34 infused	5 (range: 1.2–132) × 10^6/kg

G-CSF, granulocyte-colony stimulating factor
*Ninety percent decrease in serum paraprotein level

4. After completion of high-dose chemotherapy (HDT) and PBSCT, treatment with **recombinant interferon alfa** 3 million International Units was given by subcutaneous injection 3 times weekly after granulocytes exceeded 1500/mm^3 and platelets exceeded 100,000/mm^3 during the first year after transplantation. Interferon was continued at participating physicians' discretion in case of disease progression or when it induced severe and persistent adverse effects. The value of maintenance interferon in this or any setting is uncertain

REGIMEN
MAINTENANCE THERAPY—MULTIPLE MYELOMA

BORTEZOMIB

Sonneveld P et al. J Clin Oncol 2012;30:2946–2955

Induction:
Bortezomib 1.3 mg/m² per dose by intravenous injection over 3–5 seconds for 4 doses on days 1, 4, 8, and 11, every 28 days for 3 cycles (total dosage/cycle = 5.2 mg/m²)
Doxorubicin 9 mg/m² per day by slow intravenous injection over 3–5 minutes for 4 consecutive days on days 1–4, every 28 days for 3 cycles (total dosage/cycle = 36 mg/m²)
Dexamethasone 40 mg/dose orally for 12 doses on days 1–4, days 9–12, and days 17–20 for 3 cycles (total dose/cycle = 480 mg)

Notes:
- Stem cell collection was performed 4–6 weeks after induction
- One or 2 cycles of high-dose melphalan (HDM) 200 mg/m², and autologous stem cell transplantation (ASCT) were administered
- Starting 4 weeks after HDM, patients received maintenance with bortezomib 1.3 mg/m² intravenously every 2 weeks for 2 years
- Patients with an HLA-identical sibling could proceed to nonmyeloablative allogeneic stem cell transplantation (alloSCT) after HDM
- Maintenance therapy was not given after alloSCT

Maintenance therapy (starting 4 weeks after HDM):
Bortezomib 1.3 mg/m² per dose by intravenous injection over 3–5 seconds, continually, every 2 weeks for 2 years (total dosage/2-week course = 1.3 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential with bortezomib is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir) throughout bortezomib induction

See Chapter 47 for more information

(*continued*)

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Geerts WH et al. Chest 2008;133(6 Suppl):381S–453S
Multiple Myeloma, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)
Palumbo A et al. Leukemia 2008;22:414–423
Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Treatment Modifications

Bortezomib Dose Level	
Starting dose	1.3 mg/m² per dose on days 1, 4, 8, and 11
Level –1	1.0 mg/m² per dose on days 1, 4, 8, and 11
Level –2	0.7 mg/m² per dose on days 1, 4, 8, and 11
Level –3	1.3 mg/m² per dose on days 1 and 8

Adverse Event	Treatment Modification
G3 thrombocytopenia (<50,000/mm³)	Reduce bortezomib dosage by 1 dose level

Treatment Modification for Bortezomib-Induced Peripheral Neuropathy*

Severity of Peripheral Neuropathy	Modification of Dose and Schedule
G1 (paresthesias or loss of reflexes) without pain or loss of function	No action
G1 with pain or G2 (interferes with function but not with activities of daily living)	Reduce bortezomib dosage by 1 dose level
G2 with pain or G3 (interferes with activities of daily living)	Withhold bortezomib treatment until toxicity resolves, then reinitiate reducing bortezomib dosage by 1 dose level
G4 (permanent sensory loss that interferes with function)	Discontinue treatment

*Richardson PG et al. J Clin Oncol 2006;24:3113–3120

Patient Population Studied

Patients were newly diagnosed with MM Durie-Salmon stages II to III, WHO PS 0 to 2, or WHO 3 when caused by MM. Exclusion criteria included systemic amyloid light chain amyloidosis, nonsecretory MM, and neuropathy G ≥2. Local RT was allowed for painful MM lesions

Efficacy

An analysis of PFS calculated in 645 patients from the time of last high-dose melphalan (HDM) indicated that posttransplantation bortezomib contributed to improvement of PFS

Toxicity

- Bortezomib-emergent peripheral neuropathy (BiPN) was the prevalent toxicity during induction, preventing a substantial number of patients from starting maintenance therapy
- In those who started maintenance, 5% experienced G3/4 BiPN
- Prolonged administration of bortezomib on the once every-2-weeks schedule was deemed feasible; therefore, it is important to prevent BiPN during induction, which enables patients to continue into maintenance
- The tolerability of bortezomib given every-2-weeks is similar to the weekly schedule
- Subcutaneous bortezomib administration may further improve tolerability

Bortezomib Maintenance After Bortezomib + Doxorubicin + Dexamethasone Induction (N = 229)

Still on treatment after 6 months	90%
Still on treatment after 12 months	76%
Still on treatment after 18 months	64%
Still on treatment after 24 months	47%

Safety Profile and Toxicities

Variable	Bortezomib + Doxorubicin + Dexamethasone Induction (n = 410)		Bortezomib Maintenance (n = 229)

Thrombosis	6	4	1	1
Peripheral neuropathy	37	24	33	5

AE, adverse event (including infection); N/A, not applicable; SAE, serious adverse event

Therapy Monitoring

1. Blood counts and physical examinations at regular intervals (1 to 3 months)
2. Serum and urinary protein electrophoresis studies as indicated at regular intervals (1 to 3 months)

REGIMEN
MAINTENANCE THERAPY—MULTIPLE MYELOMA

LENALIDOMIDE

Attal M et al. N Engl J Med 2012;366:1782–1791
Dimopoulos M A et al. Haematologica 2013;98:784–788
McCarthy PL et al. N Engl J Med 2012;366:1770–1781
Palumbo A et al. N Engl J Med 2012;366:1759–1769

Lenalidomide 10 mg/day orally, continually, for 21 consecutive days, on days 1–21, every 28 days (total dose/cycle = 210 mg)

or

Lenalidomide 15 mg/day orally, continually, for 21 consecutive days, on days 1–21, every 28 days (total dose/cycle = 315 mg)

Notes:

- Maintenance treatment may begin with lenalidomide 10 mg/day for 21 consecutive days every 28 days, and if tolerated, escalated to lenalidomide 15 mg/day for 21 consecutive days every 28 days
- Maintenance therapy is continued until disease progression or the development of unacceptable rates of adverse effects

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Lenalidomide Dose Levels	
Starting dose	25 mg/dose
Level –1	20 mg/dose
Level –2	15 mg/dose
Level –3	10 mg/dose
Level –4	5 mg/dose
Level –5	Discontinue

Adverse Event	Treatment Modification
G3/4 neutropenia	Hold lenalidomide dosing for up to 21 days to resolve toxicity and then restart at the same dose or reduce the lenalidomide dose by 1 dose level
Febrile neutropenia (ANC $<1000/mm^3$ with fever $\geq 38°C$)	
G3/4 nonhematologic toxicity	Hold lenalidomide dosing for up to 21 days to resolve toxicity to G ≤ 2 and then restart at the same dose or reduce the lenalidomide dose by 1 dose level

(*continued*)

Thromboprophylaxis

Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3
Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin**, targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease

*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Patient Population Studied

Patients with symptomatic, measurable, newly diagnosed MM who were not candidates for transplantation (≥65 years of age) were eligible for this trial. Exclusion criteria were an ANC <1500/mm³, platelet count <75,000/mm³, a hemoglobin level <8.0 g/dL, a serum creatinine level of >2.5 mg/dL [>221 μmol/L], and peripheral neuropathy of G ≥2. A total of 459 patients were randomly assigned to receive nine 4-week cycles of melphalan-prednisone-lenalidomide induction (MPR) followed by lenalidomide maintenance therapy until a relapse or disease progression occurred (152 patients) or to receive MPR (153 patients) or melphalan-prednisone (MP) (154 patients) without maintenance therapy. Maintenance consisted of lenalidomide 10 mg daily for the first 21 days of 28-day cycles until disease progression or the development of unacceptable toxicity. The primary end point was progression-free survival

Palumbo A et al. N Engl J Med 2012;366:1759–1769

Patients with MM between 18 and 70 years of age, an Eastern Cooperative Oncology Group performance status of 0 or 1, symptomatic disease requiring treatment (Durie–Salmon stage ≥1) and any induction regimen of 2 to 12 months' duration, who had received ≤2 induction regimens (excluding dexamethasone alone). Patients with stable disease or a marginal, partial, or complete response during the first 100 days after stem cell transplantation were eligible. After disease restaging, patients were randomly assigned in a blinded manner to lenalidomide or placebo between days 100 and 110 after transplantation. A total of 460 patients <71 years of age with stable disease or a marginal, partial, or complete response 100 days after undergoing stem cell transplantation were randomly assigned to lenalidomide or placebo, which was administered until disease progression. The starting dose of lenalidomide was 10 mg/day (range: 5–15 mg/day). The time to disease progression was the primary end point

McCarthy PL et al. N Engl J Med 2012;366:1770–1781

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation

See Chapter 43 for more information

Efficacy

(*continued*)

Patient Population Studied (*continued*)

Study patients were <65 years of age with MM that had not progressed during the interval between first-line autologous stem cell transplantation (1 or 2 procedures) within the previous 6 months, serum creatinine <1.8 mg/dL (<160 μmol/L), an ANC ≥1000/mm^3, and platelet count >75,000/mm^3. After undergoing transplantation, patients received consolidation treatment with 2 cycles of lenalidomide 25 mg daily for the first 21 days of 28-day cycles, and then, based on prior random assignment, received maintenance therapy with either placebo or lenalidomide 10 mg daily for the first 3 months, which, if tolerated, could be increased to 15 mg daily on the same administration schedule. Treatment was continued until the patient withdrew consent, disease progressed, or toxicity was unacceptable. Randomization was stratified according to baseline levels of serum β_2-microglobulin (≤3 mg/L or >3 mg/L), the presence or absence of a 13q deletion by FISH and treatment response after transplantation (a complete or very good partial response vs. a partial response or stable disease). The primary end point was progression-free survival

Attal M et al. N Engl J Med 2012;366:1782–1791

Nonmelanoma Skin Cancers				
Basal-cell carcinoma	**2**	**1**	**5 (2)**	**3 (1)**
Squamous-cell carcinoma	**2**	**2**		

*Thirty-two second primary cancers in 26 patients were reported in the lenalidomide group versus 12 second primary cancers in 11 patients in the placebo group. The incidence of second primary cancers was 3.1 per 100 patient-years in the lenalidomide group versus 1.2 per 100 patient-years in the placebo group ($P = 0.002$). In the multivariate analysis, the incidence of second primary cancers was significantly related to study-group assignment, age, sex, and International Staging System stage

†Median time to diagnosis of a hematologic cancer after randomization was 28 months (range: 12–46 months) in patients in the lenalidomide group, and 30 months in the 1 hematologic cancer in the placebo group. The median time to the diagnosis of a solid tumor cancer after randomization was 15 months (range: 3–51 months) in the lenalidomide group and 21 months (range: 6–34 months) in the placebo group

‡AML or MDS

Therapy Monitoring

1. Blood counts and physical examinations at regular intervals (1–3 months)
2. Serum and urinary protein electrophoresis studies as indicated at regular intervals (1–3 months)

REGIMEN
MAINTENANCE THERAPY—MULTIPLE MYELOMA

THALIDOMIDE

Morgan GJ et al. Blood 2012;119:7–15

Thalidomide 50 mg/day orally, continually (total dose/week = 350 mg). If tolerated for 4 weeks, dose was increased to:
Thalidomide 100 mg/day orally, continually until disease progression (total dose/week = 700 mg)

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Thromboprophylaxis
Risk assessment and recommendations for VTE prophylaxis in patients with multiple myeloma with individual or myeloma-related risk factors, or risk factors related to treatment

Individual risk factors • Obesity (BMI ≥30 kg/m²) • H/O VTE • CVAD or pacemaker • Comorbid pathologies Cardiac disease Chronic renal disease Diabetes Acute infection Immobilization • Surgery General surgery Any anesthesia Trauma • Medications Erythropoietin (epoetin alfa, darbepoetin) Estrogenic compounds Bevacizumab • Clotting disorders Thrombophilia **Myeloma-related risk factors** • Diagnosis of multiple myeloma • Hyperviscosity	≤1 Individual or myeloma risk factor present: • **Aspirin** 81–325 mg daily ≥2 Individual or myeloma risk factors present: • **LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* • **Warfarin**, targeting an INR = 2–3

(*continued*)

Treatment Modifications

Thalidomide Dose Levels	
Dose Level 1	200 mg daily
Dose Level –1	100 mg daily
Dose Level –2	50 mg daily
Adverse Event	**Treatment Modification**
Febrile neutropenia	Withhold therapy until fever abates, then resume therapy
G4 hematologic toxicity	Withhold therapy until ANC >750/mm³ and platelets >50,000/mm³, then resume therapy with thalidomide dose decreased by 1 dose level
G3/4 nonhematologic toxicity G ≥3 thalidomide neuropathy	Interrupt therapy and follow clinically. After toxicity abates to G ≤2, resume therapy with thalidomide dose decreased by 1 dose level

Patient Population Studied

Patients ≥18 years of age with newly diagnosed MM. Exclusion criteria included asymptomatic myeloma, solitary bone plasmacytoma, and extramedullary plasmacytoma. Patients were assigned to induction treatment via either an "intensive" or a "nonintensive" treatment pathway, as determined by performance status, informed discussion, and patient preference. There was no rigid age cutoff. Patients who completed induction therapy were randomly assigned (1:1) to maintenance therapy with open-label thalidomide (n = 408) or no maintenance (n = 410). Maintenance randomization was not allowed for those who developed progressive disease or relapse. The target dose of thalidomide was 50 mg/day, which, if tolerated, was increased to 100 mg/day after 4 weeks at the lower dose and continued until disease progression

Standard iFISH (interphase FISH) analysis was used for cytogenetic profiling. "Adverse" iFISH was defined as the cytogenetic abnormalities gain(1q), t(4;14), t(14;16), t(14;20), and del(17p); del(1p32) was an adverse prognostic factor only in younger patients. "Favorable" iFISH was defined by the absence of these cytogenetic abnormalities and predominantly included hyperdiploidy, t(6;14), and t(11;14)

(continued)

Concomitant treatment-related risk factors Thalidomide or lenalidomide in combination with: • High-dose dexamethasone (≥480 mg/month) • Doxorubicin • Multiagent chemotherapy	**LMWH*, equivalent to enoxaparin sodium** 40 mg/day *or* **dalteparin sodium** 5000 IU/day; administer subcutaneously, *or* **Warfarin,** targeting an INR = 2–3

CVAD, central vascular access device; INR, international normalized ratio; LMWH, low-molecular-weight heparin; VTE, venous thromboembolic disease
*LMWHs should be used with caution in individuals with impaired renal function (creatinine clearance <30 mL/min). Refer to product labeling for information about doses and administration schedules in renally impaired patients, and guidance for monitoring antifactor Xa concentrations

Venous Thromboembolic Disease, V.2.2013. National Comprehensive Cancer Network, Inc., 2013. (Accessed October 8, 2013, at http://www.nccn.org)

Bisphosphonates

All patients receiving primary therapy for symptomatic multiple myeloma should receive a bisphosphonate adjunctively; *for example*:

- **Pamidronate disodium** 90 mg; administer intravenously over 2–4 hours, every month, *or*
- **Zoledronic acid** 4 mg; administer intravenously over at least 15 minutes, every month

Consider baseline bone densitometry evaluation
See Chapter 43 for more information

Therapy Monitoring

1. Blood counts and physical examinations at regular intervals (1–3 months)
2. Serum and urinary protein electrophoresis studies as indicated at regular intervals (1–3 months)

Efficacy

Summary of Key Trials Evaluating Thalidomide Maintenance Therapy in Multiple Myeloma*

Trial	N	Primary Treatment	Maintenance	Cytogenetic Testing	EFS or PFS	OS
Brinker	112	BU/CY/VP-16 or HDM + ABMT or ASCT	THAL vs observation	—	—	Median OS 65 vs 54 months $P = 0.05^{\dagger}$
IFM-9902	597	Double ASCT	THAL/PAM vs no maintenance	del(13) only‡	3-year EFS 52% vs 37% $P < 0.009$	4-year OS 87% vs 74% $P < 0.04$
Total Therapy 2	668	Double ASCT	THAL vs no maintenance until disease progression	Any abnormality vs none	5-year EFS 56% vs 45% $P = 0.0005$	5-year OS 67% vs 65% $P = 0.09$
Spencer et al	243	Single ASCT	THAL (12 months) + PRED vs PRED	None	3-year PFS 42% vs 23% $P < 0.001$	3-year OS 86% vs 75% $P = 0.004$
Ludwig et al	128	THAL/DEX vs MP	THAL/IFN vs IFN until disease progression	None	Median PFS 27.7 vs 13.2 months $P < 0.0068$	Median OS 52.6 vs 51.4 months P = NS

NA, not applicable; SAE, serious adverse event

**P* value for comparison of maintenance ($n = 246 + 164 = 410$) versus no maintenance ($n = 247 + 163 = 410$)

†Irrespective of suspected association with study drugs; patients who had >1 type of adverse event have been listed against all relevant types of events, but patients who had >1 occurrence of the same type of event are recorded only once

‡Suspected association with study drugs

28. Ovarian Cancer

Eddie Reed, MD

Epidemiology

Incidence: 21,980 (Estimated new cases for 2014 in the United States)
Deaths: Estimated 14,270 in 2014
Median age: 63 years

Stage at presentation
Limited (Stage I-II): 25–30%
Advanced (Stage III-IV): 70–75%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2014)

Pathology

WHO classification of malignant ovarian tumors

1. Common epithelial tumors (60% of all neoplasms of ovary; 90% of all malignant neoplasms of ovary)
2. Sex cord–stromal tumor (5% of malignant neoplasms of ovary)
3. Lipid (lipoid) cell tumors (rare)
4. Gonadoblastoma (rare)

Tumor Grade

- Grade 1—Well differentiated
- Grade 2—Moderately differentiated
- Grade 3—Poorly differentiated

Note: Serous carcinoma can be classified into either low grade or high grade

Ozols RF, Schwartz PE, Eifel PJ. In: DeVita VT Jr, Hellman S, Rosenberg SA, eds. Cancer: Principles & Practice of Oncology, 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2001:1596–1632

5-year Relative Survival by Stage at Diagnosis

Stage at Diagnosis	5-year Relative Survival (%)
Localized (confined to primary site)	91.9
Regional (spread to regional lymph nodes)	72.0
Distant (cancer has metastasized)	27.3

Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Treatment and survival by stage cannot be summarized simply for ovarian cancer. Each stage is strongly influenced by whether the disease is amenable to surgery, by the histologic type and grade, by the bulk of residual disease after the completion of surgery, and by other factors

Differences in survival among patients with the same stage of disease may indicate incomplete staging. When comprehensive staging is performed, a substantial number of patients initially believed to have disease confined to the pelvis will be staged upward

Work-up

1. Personal and family history, physical examination
2. Liver function tests, BUN, creatinine, LDH
3. CBC with platelets, PT, PTT, INR
4. Tumor markers (CA-125, α-fetoprotein (AFP), HCG)
5. CT scan of abdomen and pelvis, and chest x-ray. CT of chest if chest x-ray is abnormal
6. Radiographic tests of unclear utility: MRI of abdomen and pelvis, PET scan

Staging

Primary Tumor (T)

TNM Category	FIGO Stage	
TX		Primary tumor cannot be assessed
T0		No evidence of primary tumor
T1	I	Tumor limited to ovaries (one or both)
T1a	IA	Tumor limited to one ovary; capsule intact, no tumor on ovarian surface. No malignant cells in ascites or peritoneal washings
T1b	IB	Tumor limited to both ovaries; capsules intact, no tumor on ovarian surface. No malignant cells in ascites or peritoneal washings
T1c	IC	Tumor limited to one or both ovaries with any of the following: capsule ruptured, tumor on ovarian surface, malignant cells in ascites or peritoneal washings
T2	II	Tumor involves 1 or both ovaries with pelvic extension and/or implants
T2a	IIA	Extension and/or implants on uterus and/or tube(s). No malignant cells in ascites or peritoneal washings
T2b	IIB	Extension to and/or implants on other pelvic tissues. No malignant cells in ascites or peritoneal washings
T2c	IIC	Pelvic extension and/or implants (T2a or T2b) with malignant cells in ascites or peritoneal washings
T3	III	Tumor involves one or both ovaries with microscopically confirmed peritoneal metastasis outside the pelvis
T3a	IIIA	Microscopic peritoneal metastasis beyond pelvis (no macroscopic tumor)
T3b	IIIB	Macroscopic peritoneal metastasis beyond pelvis 2 cm or less in greatest dimension
T3c	IIIC	Peritoneal metastasis beyond pelvis more than 2 cm in greatest dimension and/or regional lymph node metastasis

Note: Liver capsule metastasis T3/Stage III; liver parenchymal metastasis M1/Stage IV
Pleural effusion must have positive cytology for M1/Stage IV

Regional Lymph Nodes (N)

TNM Category	FIGO Stage	
NX		Regional lymph nodes cannot be assessed
N0		No regional lymph node metastasis
N1	IIIC	Regional lymph node metastasis

Distant Metastasis (M)

TNM Category	FIGO Stage	
M0		No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	IV	Distant metastasis (excludes peritoneal metastasis)

Staging

Group	T	N	M
I	T1	N0	M0
IA	T1a	N0	M0
IB	T1b	N0	M0
IC	T1c	N0	M0
II	T2	N0	M0
IIA	T2a	N0	M0
IIB	T2b	N0	M0
IIC	T2c	N0	M0
III	T3	N0	M0
IIIA	T3a	N0	M0
IIIB	T3b	N0	M0
IIIC	T3c	N0	M0
Any T	N1	M0	
IV	Any T	Any N	M1

Expert Opinion

Chemotherapy

Early Stage Disease

1. In good-prognosis, early stage disease, surgery alone is adequate therapy: there is a 95% 10-year survival rate (Ia or Ib)
2. In early stage patients who have an increased risk for recurrence (poorly differentiated histologies):
   - Three cycles of cisplatin + cyclophosphamide, reduced the risk of recurrence and improve survival
   - A comparable European study gives similar data for cisplatin alone versus ^{32}P
   - Three cycles of paclitaxel and carboplatin may offer as much benefit, but the data are not yet conclusive

Bolis G et al. Ann Oncol 1995;6:887–893
Young RC et al. J Clin Oncol 2003;21:4350–4355
Young RC. Semin Oncol 2000;27(3 Suppl 7):8–10

Advanced-Stage Disease (≥IIc)

1. Standard of care for advanced-stage disease: depends in part on the amount of residual disease
   - Patients with stage III disease that is optimally debulked with no residual mass greater than 1 cm in diameter after surgery should be treated, if possible, with intraperitoneal cisplatin and paclitaxel
   - Six cycles of paclitaxel + carboplatin are used if debulking surgery was not optimal
2. Benefit of 3-drug combinations in this setting is uncertain:
   - Paclitaxel + carboplatin, + topotecan
   - Paclitaxel + carboplatin + gemcitabine
   - Paclitaxel + cisplatin + cyclophosphamide (most effective 3-drug regimen)
3. Generally, dose-intense approaches requiring stem cell support are ill advised
4. Benefit of "consolidation" therapy, after an initial 6 cycles of systemic treatment is uncertain
   - Consolidation regimens: Several additional cycles of single-agent paclitaxel or a paclitaxel combination

Kohn EC et al. Gynecol Oncol 1996;62:181–191
McGuire WP et al. N Engl J Med 1996;334:1–6
Ozols RF et al. J Clin Oncol 2003;21:3194–200
Sarosy GA, Reed E. [Editorial] Ann Intern Med 2000;133:555–556

Recurrent Disease

1. Treatment of recurrent disease is complex. Decisions should be based on:
   - Likelihood of sensitivity/resistance to agents given in the past: platinum-sensitive or platinum-resistant disease
   - Residual toxicity from prior treatments
   - Comorbid illnesses, including renal, hepatic, and cardiac function
   - Desires of the patient
2. *Platinum-sensitive disease*
   - Epithelial ovarian cancer that recurs ≥1–2 years after platinum-based chemotherapy
   - Response rate to retreatment with another platinum agent-based regimen tends to be high (<70%)
3. *Platinum-resistant disease*
   - Disease progression in the face of appropriate initial platinum-based treatment
   - Disease recurrence within the first 6 months after an initial response to platinum-based therapy
   - Poor prognosis, especially if disease progresses during their initial 6 cycles of therapy with platinum agents
   - Use of non--cross-resistant agents in the second-line and third-line setting is critically important

Leitao MM Jr et al. Gynecol Oncol 2003;91:123–129
Markman M et al. J Cancer Res Clin Oncol 2004;130:25–28
Markman M et al. Gynecol Oncol 2004;93:699–701
Reed E et al. Gynecol Oncol 1992;46:326–329

Platinum Hypersensitivity

1. Platinum hypersensitivity can develop in patients who have received ≥6 cycles of cisplatin or carboplatin
2. A desensitization regimen should be used
3. Rarely, desensitization is unsuccessful. In this situation, consider doxorubicin with cyclophosphamide

Surgery

1. Ideally, a gynecologic oncologist should perform all surgical procedures for ovarian cancer, including:
   - Initial staging and debulking surgery
   - Second-look procedure (if done)
   - Any interval surgical debulking procedure
2. Goals of initial surgical procedure:
   - Stage disease
   - Remove all visible disease from the abdominopelvic cavity; or, if surgeon cannot remove all visible disease, remove all disease possible (debulking surgery)
3. Debulking important because subsequent survival and response to chemotherapy are linked to:
   - Dimension of the largest remaining tumor lesion after completion of surgery
   - Possibly, the overall volume of residual disease
4. Surgery alone is the preferred approach to patients with good-prognosis, early stage epithelial ovarian cancer:
   - Stage: Ia or Ib
   - Any epithelial histology other than clear cell
   - Well-differentiated or moderately well-differentiated histologic grade (low grade). (Any early stage patient other than the latter should have postsurgery chemotherapy.)
5. Neoadjuvant chemotherapy (has not received widespread acceptance):
   - Two to 3 cycles of chemotherapy before an initial staging and debulking procedure
   - Data suggest a less-morbid operation with reduced blood loss and a shorter operative procedure

Hoskins WJ et al. Am J Obstet Gynecol 1994;170:974–979; discussion 979–980
Schwartz PE, Zheng W. Gynecol Oncol 2003;90:644–650
Schwartz PE et al. Gynecol Oncol 1999;72:93–99

Germ Cell Tumors

The recommended laboratory evaluation for germ cell tumors should include:
1. A comprehensive metabolic panel, CBC with platelets, magnesium level, LDH, AFP, and HCG levels
2. Pulmonary function studies may be obtained
3. Complete surgical staging is recommended as initial surgery, with fertility-sparing surgery considered in those desiring fertility

Stage I dysgerminoma or immature teratoma

1. Patients who have had complete surgical staging and no evidence of disease is found outside the ovary should be observed
2. Patients who have had incomplete surgical staging for whom observation without chemotherapy is being considered, should undergo a complete staging procedure. If no evidence of disease is found outside the ovary these patients may be observed. If, at the time of a complete surgical staging, tumor is found outside the ovary, patients should receive bleomycin + etoposide + cisplatin (BEP) in the postoperative period

Stages II–IV dysgerminoma or stage I, grades 2–3 immature teratoma or embryonal tumors or endodermal sinus tumors

1. These patients should receive chemotherapy for 3–4 cycles with bleomycin + etoposide + cisplatin (BEP)
2. Patients achieving a complete clinical response should be observed clinically every 2–4 months with AFP and HCG levels (if initially elevated) for 2 years
3. Patients with radiographic evidence of residual tumor but with normal AFP and HCG levels should be considered for surgical resection of the tumor; observation can be considered
4. Patients with persistently elevated AFP and/or HCG after chemotherapy, or with clinically or radiographically evident disease, should receive chemotherapy or radiation or supportive care. Acceptable regimens for recurrent disease include:
   - Cisplatin + etoposide
   - VIP (etoposide + ifosfamide + cisplatin)
   - VeIP (vinblastine + ifosfamide + cisplatin)
   - VAC (vincristine + dactinomycin + cyclophosphamide)

Radiation

1. External beam radiation therapy:
   - Very useful in the treatment of some subsets of patients with early stage disease
   - Has fallen out of favor in the United States
   - Commonly used in some academic centers in Canada and Europe
   - Major drawback is the reduction in reserve function of organs within the radiation field, such as the bone marrow
   - Useful in the management of tumor masses that might cause extreme pain, bleeding, or other medical problems and in cases in which surgery is not a good option
   - On occasion, large lesions in the pelvis or metastases to bone (unusual) respond readily to radiation
2. Intraperitoneal colloidal ^{32}P:
   - Useful in the treatment of early stage disease
   - Can be of palliative value in other settings
   - Has fallen out of favor in the United States
3. Gamma-knife, intensity-modulated radiation therapy (IMRT), and standard whole-brain radiation:
   - Metastases to the brain occur uncommonly but are no longer considered rare
   - Several approaches are effective in controlling CNS disease
   - Use of these approaches depends on the clinical setting and the technology available

Ovarian Stromal Tumors

1. Patients with stages IA–C ovarian stromal tumors desiring fertility should be treated with fertility-sparing surgery. Otherwise, complete staging is recommended to all other patients
2. Those with surgical findings of stage I tumor should be observed
3. Patients having high-risk stage I (tumor rupture, poorly differentiated tumor, tumor size >10–15 cm) or stages II–IV tumors can be observed, or can receive radiation therapy or undergo cisplatin-based chemotherapy with germ cell regimens preferred
4. Patients subsequently having a clinical relapse may consider secondary cytoreductive surgery, enter a clinical trial, or be offered supportive care

Toxicities: Ovarian Cancer Chemotherapy

1. **Myelosuppression**

   Associated with all the agents listed in this chapter except tamoxifen. All 3 lineages are affected. Persistent thrombocytopenia is associated with the platinum compounds
2. **Nausea and vomiting**

   Preventive treatment is very important. Delayed nausea and vomiting is very common. Steroids, serotonin (HT_3)-receptor antagonists, and neurokinin (NK_1)-receptor antagonists are recommended for routine use with platinum-containing regimens
3. **Renal dysfunction**

   Seen with cisplatin and with carboplatin, but usually more clinically significant with cisplatin. Serum creatinine may be normal in the face of a markedly reduced creatinine clearance. This is important because other drugs that are eliminated by the kidney may be needed (eg, antibiotics). Platinum-related renal insufficiency is nonoliguric: be vigilant
4. **Neurotoxicity**

   Clinically occurs before detectable changes on EMG/NCTs. Bilateral paresthesias in stocking-and-glove distribution usually are progressive with repeated platinum doses and can become severe. Cisplatin is more likely to cause this problem than carboplatin
5. **Fatigue/weakness**

   May be related to anemia, but is a common side effect of several newer agents, including gemcitabine and topotecan
6. **Altered sexual function**

   A common side effect, but is seldom discussed spontaneously by a patient. It can be an underlying contributing factor to family disruption and clinical reactive depression; usually is a combined function of surgery and effect of neuroactive anticancer agent (platinum agents)
7. **Clinical depression**

   A common side effect. Many patients request medication for this. Sometimes may be a severe problem
8. **Rare toxicities**

   Acute hypersensitivity to paclitaxel. Acute hypersensitivity to cisplatin/carboplatin (usually occurs after 6–8 cycles of therapy). Desensitization is occasionally appropriate and can be successful. On most occasions, switch to another agent right away

Epithelial Ovarian Cancer (EOC), Primary Peritoneal Cancer (PPC), Fallopian Tube Cancer Chemotherapy: Expert Opinion

Early stage disease [IA, IB, IC]

1. IA, grades 1/2 and IB, grades 1/2 (good prognosis, early stage disease):
   - Surgery alone is adequate therapy with a 95% 10-year survival rate
2. IA, grade 3, IB, grade 3, IC, grades 1/2/3, and some IA/IB grade 2 (early stage patients who are at increased risk for recurrence):
   - Three cycles of cisplatin + cyclophosphamide: reduced risk of recurrence, and improved survival
   - A comparable European study gives similar data for cisplatin alone versus ^{32}P
   - Three to 6 cycles of paclitaxel and carboplatin may offer as much benefit, but the data are not yet conclusive

Bolis G et al. Ann Oncol 1995;6:887–893
Young RC et al. J Clin Oncol 2003;21:4350–4355
Young RC. Semin Oncol 2000;27(3 Suppl 7):8–10

Advanced stage disease (Stage II, III or IV)

1. **Standard of care** for advanced stage disease:
   - Six to 8 cycles of paclitaxel + carboplatin, after debulking surgery
2. Additional standard option in <1 cm, optimally debulked, Stages II/II patients:
   - **Intraperitoneal (IP) chemotherapy** every 3 weeks for 6 cycles
     - (Day 1) Paclitaxel 135 mg/m² by continuous intravenous infusion over 24 hours
     - (Day 2) Cisplatin 75–100 mg/m² intraperitoneally
     - (Day 8) Paclitaxel 60 mg/m² intraperitoneally
3. **Three-drug combinations** in this setting provide no added benefit
   - GOG 182/ICON5: Five-arm randomized trial, to determine if adding either topotecan, gemcitabine, or pegylated liposomal doxorubicin in the frontline setting would extend PFS or OS. Control arm = paclitaxel and carboplatin IV every 3 weeks × 8 cycles. Accrual >1200 patients/year; 4312 women enrolled. None of the 3-drug regimens demonstrated an improvement in either PFS or OS. Survival analyses of groups defined by size of residual disease (optimal or suboptimal cytoreduction) also failed to show experimental benefit in any subgroup (Bookman et al. J Clin Oncol 2009)

(continued)

Epithelial Ovarian Cancer (EOC), Primary Peritoneal Cancer (PPC), Fallopian Tube Cancer

Chemotherapy: Expert Opinion (*continued*)

4. **Dose-dense weekly paclitaxel**
   - A randomized phase III trial comparing a dose-dense regimen of weekly paclitaxel (days 1, 8, and 15) in combination with carboplatin every 3 weeks versus both agents administered once every 3 weeks, showed statistically significant improvement with the dose-dense paclitaxel regimen in: (a) PFS (28.0 vs. 17.2) and (b) OS at 3 years (72.1% vs. 65.1% [hazard ratio = 0.75; confidence interval, 0.57–0.98]). However, patient dropout was higher in the dose-dense group, primarily related to hematologic toxicity (Katsumata et al. Lancet 2009)
5. Generally, **dose-intense approaches requiring stem cell support** are ill advised
6. Benefit of **"consolidation" therapy** is uncertain (ie, several additional cycles of single-agent paclitaxel or a paclitaxel combination, after an initial 6 cycles of systemic treatment)
7. Whether **maintenance therapy** can increase PFS and, most importantly, increase OS is under evaluation. Most maintenance therapy strategies continue a regimen with lower toxicity and often include agents used in the primary treatment regimen
   - SWOG and GOG randomized women who achieved a CR with primary therapy to either 3 or 12 cycles of maintenance IV paclitaxel. Twelve cycles resulted in a 7-month PFS advantage but an uncertain OS advantage because of early termination
   - In Europe, Pecorelli et al. reported no gains in PFS or OS in patients given an additional 6 cycles of paclitaxel *after a complete response* from initial therapy
   - GOG 212 is ongoing (Paclitaxel or Polyglutamate Paclitaxel or Observation in Treating Patients With Stage III or Stage IV Ovarian Epithelial or Peritoneal Cancer or Fallopian Tube Cancer)
8. The benefit of adding **bevacizumab** to a standard frontline IV paclitaxel/carboplatin regimen administered every 3 weeks is under debate. Evidence suggests that in standard-risk patients, it does not confer any benefit. It remains to be determined whether it may be beneficial in high-risk patients. The GOG-218 and ICON7 trials suggest a role for maintenance bevacizumab in ovarian cancer; however, the absolute benefit in PFS is very modest, and neither trial showed an OS benefit. There is no level I evidence for (a) *the use of bevacizumab in patients receiving intraperitoneal (IP) chemotherapy,* or (b) *the use of bevacizumab as neoadjuvant chemotherapy prior to surgical cytoreduction.* In addition to resolving whether this therapy is indicated, future trials will need to address (a) an optimal bevacizumab dosage (7.5 mg/kg or 15 mg/kg every 3 weeks); (b) the optimal duration of bevacizumab maintenance (1 year, until progression, or beyond progression); and (c) any biologic predictors given bevacizumab's modest activity and substantial toxicity and cost
   - GOG 218 (3 arms): (a) cyclophosphamide + paclitaxel (CP); (b) CP + concomitant bevacizumab only, and (c) CP + concomitant and maintenance bevacizumab. After a median follow-up of 17.4 months, PFS was significantly prolonged with CP + concomitant and maintenance bevacizumab compared with CP alone (14.1 vs. 10.3 months; hazard ratio [HR] = 0.717; p <0.0001). Importantly there was no PFS advantage for CP + *concomitant bevacizumab only* over the CP-alone control arm (11.2 vs. 10.3 months; HR = 0.908; p = 0.080)
   - ICON7: Median PFS 19.8 months for women receiving concurrent and maintenance bevacizumab compared with 17.4 months for those in the control arm ($P = 0.039$). Overall survival, among all participants was not improved (HR for death of 0.85, 95% CI, 0.69–1.04). But in the high risk subgroup—stage III with ≥1 cm residual tumor after surgery and all stage IV patients—the HR was 0.64, 95% CI, 0.48–0.85, $P = 0.002$

Recurrent disease

1. Treatment of recurrent disease is complex. Decisions should be based on:
   - Likelihood of sensitivity/resistance to agents given in the past: platinum-sensitive or -resistant disease
   - Residual toxicity from prior treatments
   - Comorbid illnesses including renal, hepatic, and cardiac function
   - Desires of the patient

Definitions:

Platinum-refractory disease

- Disease that grows through initial platinum-containing therapy

- **Platinum-sensitive disease**
- Epithelial ovarian cancer that recurs, ≥1–2 years after platinum-based chemotherapy
- Response rate to retreatment with another platinum agent-based regimen tends to be high (<70%)

Platinum-resistant disease

- *Definition:* Disease progression in the face of appropriate initial platinum-based treatment or disease recurrence within the first 6 months after an initial response to platinum-based therapy
- *Prognosis:* Poor, especially if disease progresses during the initial 6 cycles of therapy with platinum agents
- *Chemotherapy recommendations:* Use of non–cross-resistant agents in the second-line and third-line settings is critically important

(*continued*)

Epithelial Ovarian Cancer (EOC), Primary Peritoneal Cancer (PPC), Fallopian Tube Cancer

Chemotherapy: Expert Opinion (*continued*)

2. Patients with disease progression without evidence of benefit after the initial 2 therapies should either be enrolled on a clinical trial or enroll in hospice
3. Patients who have not received chemotherapy should be approached as discussed above under **Advanced stage disease (Stage II, III, or IV)**
4. Patients with "platinum-sensitive disease" can receive platinum doublets including:
   - **Carboplatin + paclitaxel**
   - **Cisplatin + paclitaxel**
   - **Cisplatin + cyclophosphamide**
   - **Carboplatin + weekly paclitaxel**
   - **Carboplatin + docetaxel**
   - **Carboplatin + gemcitabine**
   - **Carboplatin + liposomal doxorubicin**
   - **Cisplatin + gemcitabine**
   - **Single-agent cisplatin**
   - **Single-agent carboplatin**
   - **Bevacizumab**
5. Agents with activity in both platinum-sensitive and platinum-refractory disease include:
   - **Docetaxel**
   - **Pemetrexed**
   - **Oral etoposide**
   - **Gemcitabine**
   - **Liposomal doxorubicin**
   - **Weekly paclitaxel**
   - **Topotecan**
   - **Fluorouracil**
   - **Altretamine (hexamethylmelamine)**
6. **Bevacizumab** seems to be well tolerated and active in second-line and third-line treatments of patients with EOC/PPC. However, there is no evidence indicating that this is better tolerated or more active than myriad other agents previously examined in similar patients. Evidence must yet be developed to support its use in the second-line (or later) setting as a single agent or in combination with a cytotoxic drug (Burger RA et al. J Clin Oncol 2007; Cannistra SA et al. J Clin Oncol 2007)
   - OCEANS: A phase III trial comparing carboplatin and gemcitabine ± bevacizumab in women with platinum-sensitive recurrent ovarian cancer. A 3.7-month PFS advantage for women using bevacizumab, with an interim analysis of OS demonstrating a 5.6-month advantage for the bevacizumab arm

Epithelial Ovarian Cancer (EOC), Primary Peritoneal Cancer (PPC), Fallopian Tube Cancer

Surgery: Expert Opinion

1. Ideally, a gynecologic oncologist should perform all surgical procedures for ovarian cancer, including:
   - Initial staging and debulking surgery
   - "Second look" procedures (if done)
   - Any interval surgical debulking procedure
2. Goals of initial surgical procedure:
   - Stage the disease
   - Remove all visible disease from the abdominopelvic cavity, or
   - If surgeon cannot remove all visible disease, remove all disease possible (debulking surgery)
3. Debulking is important because subsequent survival and response to chemotherapy are linked to:
   - Dimension of the largest remaining tumor lesions after the completion of surgery
   - Possibly the overall volume of residual disease
4. Surgery alone, is the preferred approach to patients with good prognosis early stage epithelial ovarian cancer:
   - *Stages:* IA or IB
   - *Histology:* Any epithelial histology other than clear cell
   - *Histologic grade:* Well-differentiated or moderately well-differentiated (any early stage patient other than these should have chemotherapy after surgery)
5. Neoadjuvant chemotherapy:
   - Two to 3 cycles of chemotherapy before an initial staging and debulking procedure
   - Data suggest a less-morbid operation, with reduced blood loss and a shorter operative procedure
   - Has not received widespread acceptance

PLATINUM-SENSITIVE REGIMEN

CARBOPLATIN + PACLITAXEL

Ozols RF et al. J Clin Oncol 2003;21:3194–3200

Note: Regimen for optimally debulked ovarian cancer and suboptimally debulked disease as well

Premedication for paclitaxel:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg/dose; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 175 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 3 hours, on day 1, every 3 weeks (total dosage/cycle = 175 mg/m^2)

Carboplatin (calculated dose) AUC = 7.5*; administer intravenously in 0.9% NS or D5W 100–500 mL over 60 minutes, on day 1 after completing paclitaxel, every 3 weeks for 6 cycles (total dosage/cycle calculated to produce a target AUC = 7.5 mg/mL • min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
At start of a cycle, ANC ≤1000/mm^3 or platelets ≤100,000/mm^3	Delay start of cycle up to 2 weeks until ANC >1000/mm^3 and platelets >100,000/mm^3
ANC ≤1000/mm^3 or platelets ≤100,000/mm^3 for more than 2 but less than 3 weeks after scheduled start of next cycle	Reduce paclitaxel and carboplatin dosages by 20% (140 mg/m^2 and AUC = 6, respectively)
At start of a cycle, ANC ≤1000/mm^3 and platelets ≤100,000/mm^3 despite dose reduction	Delay start of cycle until ANC >1000/mm^3 and platelets >1000/mm^3; then administer filgrastim 5 mcg/kg per day subcutaneously for 14 days with same chemotherapy dosages
Serum creatinine >2 mg/dL (>177 µmol/L) or G ≥3 peripheral neuropathy	Delay start of cycle up to 2 weeks; if serum creatinine is not ≤2 mg/dL (≤177 µmol/L) or G <3 peripheral neuropathy, discontinue therapy

Toxicity* (Carboplatin: N = 392)

	% G3	% G4
Hematologic		
Leukopenia	53	6
Granulocytopenia	17	72
Thrombocytopenia	19	20

†Primarily peripheral neuropathy

(continued)

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A randomized study of 792 women with pathologically verified Stage III epithelial ovarian cancer who were left with no residual disease >1 cm in diameter; 400 cisplatin arm and 392 carboplatin arm. McGuire et al. (N Engl J Med 1996;334:1–6) had shown that cisplatin plus paclitaxel was superior to cisplatin plus cyclophosphamide in advanced-stage epithelial ovarian cancer. This study was a **noninferiority trial** of cisplatin and paclitaxel versus carboplatin and paclitaxel to show equivalence of the 2 regimens

Efficacy (Carboplatin: N = 392)

Median progression-free survival	20.7 months
Median overall survival	57.4 months

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes, magnesium, calcium, BUN, and creatinine

PLATINUM-SENSITIVE REGIMEN

CISPLATIN + PACLITAXEL

Ozols RF et al. J Clin Oncol 2003;21:3194–3200

Premedication with **Dexamethasone** 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **Ranitidine** 50 mg, **Famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 135 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 24 hours on day 1, every 3 weeks, for 6 cycles (total dosage/cycle = 135 mg/m²)
Cisplatin 75 mg/m²; administer intravenously in 0.9% NS 100–250 mL over 1 hour, on day 2 after completing paclitaxel, every 3 weeks, for 6 cycles (total dosage/cycle = 75 mg/m²)
Note: Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential during paclitaxel administration is ***LOW***
Emetogenic potential during and after cisplatin administration is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (Comparison of Regimens)

Treatment Modifications

Adverse Event	Dose Modification
Delay in achieving ANC ≥1000/mm³ and platelets ≥100,000/mm³ <2 weeks	No dose adjustment; no filgrastim
Delay in achieving ANC ≥1000/mm³ and platelets ≥100,000/mm³ ≥2 weeks but ≤3 weeks	Reduce cisplatin dosage by 20%
Recurrent delays in achieving ANC ≥1000/mm³ and platelets ≥100,000/mm³ ≥2 weeks but ≤3 weeks	Add filgrastim 5 mcg/kg per day subcutaneously. Start 24 hours after completing chemotherapy, and continue for 14 days without further dosage modification
Episode of febrile neutropenia after earlier delay in achieving ANC and platelets led to a reduction in cisplatin dosage	Add filgrastim 5 mcg/kg per day subcutaneously. Start 24 hours after completing chemotherapy, and continue for 14 days without further dosage modification
G3/4 Neurologic toxicity that has not resolved even after a 3-week delay	Discontinue therapy
Creatinine clearance* <30 mL/min (<0.5 mL/s)	Discontinue therapy

*Creatinine clearance used as a measure of glomerular filtration rate (GFR)

Notes

There were no differences in efficacy between the cisplatin + paclitaxel and the carboplatin + paclitaxel treatment regimens. However, there were differences with respect to toxicities. The authors interpreted the data as showing that the carboplatin + paclitaxel regimen was equally efficacious and significantly less toxic than the cisplatin + paclitaxel regimen

PLATINUM-SENSITIVE REGIMEN

INTRAPERITONEAL CISPLATIN AND PACLITAXEL

Armstrong DK et al. N Engl J Med 2006;354:34–43
Walker JL et al. Gynecol Oncol 2006;100:27–32
GOG Protocol #0172

Note: Regimen for Stage III epithelial ovarian or peritoneal carcinoma optimally debulked with no residual mass greater than 1 cm in diameter after surgery. Suboptimally debulked disease should not be treated with this regimen

Premedication for paclitaxel:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg/dose; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 135 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 24 hours on day 1, every 21 days, for 6 cycles (total dosage of paclitaxel intravenously/cycle = 135 mg/m²)

Intraperitoneal cisplatin
Hydration before cisplatin: ≥1000 mL 0.9% NS; administer by intravenous infusion over a minimum of 2–4 hours
Note: If a large amount of ascites is present, it should be drained prior to the instillation of cisplatin
Cisplatin 100 mg/m²; administer intraperitoneally as rapidly as possible in warmed (37°C [98.6°F]) 0.9% NS 2000 mL through an implanted peritoneal catheter on day 2, every 21 days, for 6 cycles (total dosage/21-day cycle = 100 mg/m²). Following the infusion, patients alternate position from prone, supine, and left and right lateral decubitus every 15 minutes over 2 hours to maximize drug distribution throughout the peritoneal cavity
Note: Do not attempt to retrieve the infusate
Hydration after cisplatin: ≥1000 mL 0.9% NS; administer by intravenous infusion over a minimum of 3–4 hours. Also encourage high oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour

Intraperitoneal paclitaxel
Note: If a large amount of ascites is present, it should be drained prior to the instillation of paclitaxel
Paclitaxel 60 mg/m²; administer intraperitoneally as rapidly as possible in warmed (37°C [98.6°F]) 0.9% NS or D5W 1000 mL through an implanted peritoneal catheter, followed by an additional 1000 mL of 0.9% NS or D5W on day 8, every 21 days, for 6 cycles (total dosage of paclitaxel administered intraperitoneally/21-day cycle = 60 mg/m²)
Note: Do not attempt to retrieve the infusate

Systemic cisplatin
If intraperitoneal therapy is discontinued, substitute:
Cisplatin 75 mg/m²; administer intravenously in 250 mL 0.9% NS over 30–60 minutes on day 2, every 21 days, for 3 cycles (total dosage/cycle = 75 mg/m²)

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential on days 1 and 8 is **LOW***
*Emetogenic potential on day 2 is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

(*continued*)

Treatment Modifications

Dose Modification Levels for Treatment

	IV Paclitaxel	IP Cisplatin	IP Paclitaxel
Starting dose	135 mg/m²	100 mg/m²	60 mg/m²
Level −1	110 mg/m²	75 mg/m²	45 mg/m²

Note: No dose escalations performed

Dose Escalations for Hematologic Toxicity

Adverse Event	Treatment Modification
ANC <1500/mm³ or platelet count <100,000/mm³ on day 1 of a cycle	Delay start of next cycle until ANC ≥1500/mm³ and platelet count ≥100,000/mm³. Do not adjust dosages or add filgrastim if the delay is less than 2 weeks
>2 weeks, but ≤3 weeks delay to start next cycle because ANC <1500/mm³ or platelet count <100,000/mm³ on day 1	Reduce intravenous paclitaxel dosage 1 level
>2 weeks delay in start of a cycle because ANC <1500/mm³ or platelet count <100,000/mm³ on day 1 despite 1 dose reduction	Add filgrastim 5 mcg/kg per day beginning 24 hours after completion of intravenous chemotherapy and continue use for 14 days
>3 weeks delay to start next cycle because ANC <1500/mm³ or platelet count <100,000/mm³ on day 1 regardless of whether filgrastim was or was not used	Discontinue therapy
ANC <1500/mm³ or platelet count <100,000/mm³ on day 8 of a cycle	Do not delay nor adjust intraperitoneal paclitaxel dosage
Uncomplicated WBC or ANC nadirs	Do not modify dosages

(*continued*)

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Arthralgia and myalgia G ≦2 associated with chemotherapy

Dexamethasone 4–8 mg/dose orally twice daily for 6 doses after chemotherapy

(continued)

Patient Population Studied

A study of 205 women with Stage III epithelial ovarian or peritoneal carcinoma optimally debulked with no residual mass greater than 1 cm in diameter after surgery. All patients had a Gynecologic Oncology Group (GOG) performance status of 0–2

Efficacy (N = 205)

Variable	Months
Median progression-free survival (PFS)	23.8
PFS in patients with gross residual disease	18.3
PFS in patients without visible residual disease	37.6
Median overall survival	65.6

Treatment Modifications (continued)

Adverse Event	Treatment Modification
ANC <500/mm³ on day 8	Add filgrastim 5 mcg/kg per day until ANC >5000–10,000/mm³
Nadir platelet count <25,000/mm³	Reduce intravenous paclitaxel dosage 1 dose level
First episode of febrile neutropenia or sepsis requiring intravenous antibiotics	Reduce intravenous paclitaxel dosage 1 dose level. Do not add filgrastim
Febrile neutropenia or sepsis requiring intravenous antibiotics despite reduction of paclitaxel 1 dosage level	Add filgrastim beginning 24 hours after completion of IV chemotherapy and continuing for 14 days without additional dosage modification

Abdominal Pain Score	
G0	No pain
G1	Mild pain. Opioid analgesia not required; pain causes minimal interference with daily activities and lasts for less than 72 hours
G2	Moderate pain. Opioid analgesia required; pain causes moderate interference with daily activities and lasts longer than 72 hours
G3	Severe pain. Opioid analgesia required; pain confines patient to bed and causes severe interference with daily activities

Other	11	9

Walker JL et al. Gynecol Oncol 2006;100:27–32

Notes

1. Among all randomized phase III trials conducted by the GOG among patients with advanced ovarian cancer, this therapy yielded the longest median survival (65.6 months)
2. Only 42% of patients received all 6 cycles of intraperitoneal therapy
3. The primary reason for discontinuation of intraperitoneal therapy was catheter-related complications
4. Among 205 patients randomly allocated to the intraperitoneal arm, 58% (119) did not complete all 6 cycles of intraperitoneal therapy. Of these 119 patients, 34% (40/119 = 34%) discontinued intraperitoneal therapy primarily as a result of catheter complications, whereas 29% (34/119 = 29%) discontinued for unrelated reasons. Additionally, 37% (45/119 = 37%) discontinued for reasons that were possibly related to the intraperitoneal treatment (see table under toxicities)
5. Hysterectomy, appendectomy, small bowel resection, and ileocecal resection were not associated with failure to complete 6 cycles
6. There appears to be an association between rectosigmoid colon resection and the ability to initiate intraperitoneal therapy. Intraperitoneal therapy was not initiated 16% of patients who had a left colon or rectosigmoid colon resection versus 5% of those who did not have such a resection (p = 0.015)
7. Intraperitoneal therapy should begin as soon as possible after surgery. A delay of intraperitoneal therapy allows opportunity for adhesions to develop and may limit intraperitoneal distribution of the IP fluid
8. The 2 L of intraperitoneal fluid administered with the intraperitoneal therapy does not replace the need for intravascular hydration administration and adequate urine output. Administration of at least 1 L of 0.9% sodium chloride injection both prior to and after cisplatin is essential

Armstrong DK et al. N Engl J Med 2006;354:34–43
Walker JL et al. Gynecol Oncol 2006;100:27–32

Therapy Monitoring

1. *Prior to start of therapy:* PE, CBC with differential, electrolytes, serum creatinine, BUN, mineral panel, LFTs, CA-125, audiogram only in patients with a history of hearing loss, and chest x-ray
2. *Weekly:* CBC with differential
3. *Prior to each cycle:* PE, CBC with differential, electrolytes, serum creatinine, BUN, mineral panel, LFTs

Treatment Modifications (*continued*)

Adverse Event	Treatment Modification
G2 abdominal pain	Reduce intraperitoneal cisplatin or paclitaxel, whichever is causing symptoms, by 1 dose level
Recurrent G2 abdominal pain after a dose reduction or G3 abdominal pain or complications involving the intraperitoneal catheter prohibiting further intraperitoneal therapy	Discontinue intraperitoneal therapy and administer intravenous cisplatin instead
Any grade gastrointestinal toxicity	Hospitalize patient if necessary but do not adjust chemotherapy dosages
G2 peripheral neuropathy	Reduce cisplatin dosage by 1 dose level
G3/4 peripheral neuropathy	Hold therapy until peripheral neuropathy G ≤1 then restart therapy with cisplatin dosage reduced by 1 dose level. Consider discontinuing therapy if not recovered to baseline by 2–3 weeks
Increase in serum creatinine >0.7–1.0 mg/dL (>62–88 μmol/L) above baseline	Hold therapy until serum creatinine returns to baseline and reduce intraperitoneal cisplatin 1 dosage level. Consider discontinuing therapy if not recovered to baseline by 2–3 weeks

PLATINUM-SENSITIVE REGIMEN

CISPLATIN AND CYCLOPHOSPHAMIDE

Young RC et al. J Clin Oncol 2003;23:4350–4355

Cyclophosphamide 1000 mg/m²; administer intravenously in 1000 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes, on day 1, every 21 days, for 3 cycles (total dosage/cycle = 1000 mg/m²)
Cisplatin 100 mg/m²; administer intravenously in 250 mL 0.9% NS over 30–60 minutes, on day 1, after cyclophosphamide, every 21 days, for 3 cycles (total dosage/cycle = 100 mg/m²)
Note: Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Prospective randomized clinical trial conducted by the GOG of 251 patients: 124 patients randomized to ^{32}P and 127 randomized to chemotherapy. Eligible patients were either FIGO Stage Ia or Ib (grade 3), or Stage Ic or II (any grade). In addition, all Stages I and II patients with clear cell histology (any grade) were eligible

Efficacy

10-Year Cumulative Incidence of Recurrence	
All patients	28%
Stage I	24%
Stage II	39%

Toxicity

	% G3/4
Hematologic	
Leukopenia	69.5
Granulocytopenia	68
Thrombocytopenia	8.5
Nonhematologic	
Gastrointestinal	11.9
Renal	1.7
Ototoxicity	0.8
Bowel perforation	0

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes, magnesium, calcium, BUN, and creatinine

Notes

Although compared with intraperitoneal ^{32}P, there were no statistically significant differences in survival, the authors concluded: "The lower cumulative recurrence seen with CP (cisplatin + cyclophosphamide) and complications of ^{32}P administration make platinum-based combinations the preferred adjuvant therapy for early ovarian cancer patients at high-risk for recurrence"

Treatment Modifications

(Specific Recommendations Not Provided by Authors)

Adverse Event	Dose Modification
Creatinine clearance* 30–60 mL/min (0.5–1 mL/s)	Reduce cisplatin so that dose in milligrams equals the creatinine clearance value in mL/min†
Creatinine clearance* <30 mL/min (<0.5 mL/s)	Hold cisplatin
If on day 1 of a cycle, leukocyte count <3000/mm³, ANC <1000/mm³, or platelets <100,000/mm³	Hold chemotherapy for 1 week, then resume treatment if leukocytes ≥3000/mm³, ANC ≥1000/mm³, and platelets >100,000/mm³
If on day 1 of a cycle, G ≥2 nonhematologic adverse event or serum creatinine ≥1.8 mg/dL (≥159 μmol/L)	Hold chemotherapy for 1 week, then resume with chemotherapy dose reduced by 20–30% if nonhematologic toxicity resolved to G ≤1 and creatinine ≤1.5 mg/dL (≤133 μmol/L)
G4 neutropenia (with or without fever)	Add prophylaxis with filgrastim 5 mcg/kg per day subcutaneously for 14 days with same chemotherapy doses during all subsequent cycles
Febrile neutropenia despite filgrastim support	Hold treatment until adverse event resolves, then resume chemotherapy with chemotherapy dosage reduced by 20–30%

*Creatinine clearance used as a measure of glomerular filtration rate (GFR)
†Also applies to patients with creatinine clearance (GFR) of 30–60 mL/min (0.5–1 mL/s) at outset of treatment

PLATINUM-SENSITIVE REGIMEN

PLATINUM RETREATMENT (CISPLATIN OR CARBOPLATIN)

Leitao M et al. Gynecol Oncol 2003;91:123–129

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3–4 hours. Monitor and replace magnesium/electrolytes as needed

Cisplatin 80–100 mg/m^2; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/3-week cycle = 80–100 mg/m^2)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3–4 hours. Also encourage high oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour

or

Carboplatin (calculated dose) AUC = 6; administer by intravenous infusion in 50–150 mL D5W over 15–30 minutes on day 1, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL · min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MODERATE–HIGH** (carboplatin) or **HIGH** (cisplatin). Potential for delayed symptoms with either carboplatin or cisplatin*

See Chapter 39 for antiemetic recommendations

(continued)

Treatment Modifications

Adverse Event	Dose Modification
Cisplatin	
Creatinine clearance 40–60 mL/min (0.66–1 mL/s)	Reduce cisplatin so that dose in milligrams equals the creatinine clearance* value in mL/min*
Creatinine clearance <40 mL/min (<0.66 mL/s)	Hold cisplatin
On treatment day 1, serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Reduce cisplatin dosage by 25%
On treatment day 1, serum creatinine >2 mg/dL (>177 µmol/L)	Hold cisplatin until serum creatinine ≤2.0 mg/dL (≤177 µmol/L)
Day 1 WBC <2000/mm^3 or platelet count <100,000/mm^3	Delay cisplatin for 1 week or until myelosuppression resolves, whichever occurs later
Second treatment delay because of myelosuppression	Delay cisplatin for 1 week, or until myelosuppression resolves, then decrease cisplatin dosage to 60–80 mg/m^2 during subsequent treatments
Sepsis during an episode of neutropenia	
Bleeding associated with thrombocytopenia	Reduce cisplatin dosage to 60–80 mg/m^2
Carboplatin	
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3 or febrile neutropenia	Reduce carboplatin dosage to AUC = 5 mg/mL · min if previous cycle dose was AUC = 6; or to AUC = 4 if previous cycle dose was AUC = 5
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia after 2 carboplatin dose reductions (AUC in previous cycle = 4 mg/mL · min)	Decrease carboplatin dosage to AUC = 3 mg/mL · min

(continued)

(*continued*)

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm^3 on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before repeating myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW–INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Arthralgia and myalgia G ≥2 associated with chemotherapy
Dexamethasone 4–8 mg/dose orally twice daily for 6 doses after chemotherapy

Efficacy (N = 30)

Variable	No. of Patients	% PR
Best Response to Last Platinum Regimen		
Complete or partial response	14	43
Stable or progressive disease	16	6
Platinum-Free Interval		
≤6 months	2	0
6–12 months	8	63
>12 months	20	10
Number of Intervening Nonplatinum Agents		
≤3	20	35
>3	10	0
Time to Progression After Last Platinum Regimen		
≤6 months	23	17
>6 months	6	50
Number of Prior Platinum Regimens		
1 prior regimen	9	33
2 or 3 prior regimens	21	19

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Day 1 ANC <1500/mm^3 or platelets <100,000/mm^3	Delay chemotherapy until ANC >1500/mm^3 and platelets >100,000/mm^3, for maximum delay of 2 weeks
Delay of >2 weeks in reaching ANC >1500/mm^3 or platelets >100,000/mm^3	Discontinue therapy
Bleeding associated with thrombocytopenia	Reduce carboplatin dosages to AUC 4–5 mg/mL · min

*Creatinine clearance used as a measure of glomerular filtration rate
†This also applies to patients with creatinine clearance (GFR) of 40–60 mL/min (0.66–1 mL/s) at the outset of treatment

Patient Population Studied

A study of 30 patients with platinum-resistant ovarian cancer, who received nonplatinum chemotherapy for recurrent epithelial ovarian cancer before additional platinum therapy. Platinum resistance was defined as less than a partial response to platinum therapy or progression within 6 months of the last platinum therapy

Therapy Monitoring

1. *Before repeated cycles:* PE, CBC with differential, serum electrolytes, magnesium, calcium, BUN, and creatinine
2. *Every month:* Serum CA-125 level
3. *Every 2–3 months:* Restaging radiographic studies

Toxicity

Cisplatin

(PLATINOL-AQ [cisplatin injection] product label, November 2002. Bristol-Myers Squibb)

Individual and cumulative dose-related renal toxicity: Increased serum creatinine, uric acid, and BUN *Renal tubular damage with electrolyte wasting:* Hypomagnesemia, hypocalcemia, hyponatremia, hypokalemia, and hypophosphatemia	28–36%*
Dose-related, cumulative peripheral neuropathies: Bilateral paresthesias, areflexia, loss of proprioception and vibratory sensation, motor neuropathies	30–100% depending on cumulative doses
Optic neuritis, papilledema, and cerebral blindness	Rare
Cumulative ototoxicity: With tinnitus or high frequency hearing loss. Vestibular toxicity	31%*
Nausea and vomiting at any dose: Severe and delayed emesis at dosages ≥50 mg/m²	Varies (moderate to severe in virtually all patients without effective antiemetic prophylaxis)
Transiently increased liver transaminases	Rare
Hypersensitivity reactions: Anaphylactoid reactions, facial edema, wheezing, tachycardia, and hypotension	1–20%
Coombs-positive hemolytic anemia	Rare
Dose-related leukopenia, thrombocytopenia, anemia	25–30%*

Carboplatin

(PARAPLATIN [carboplatin aqueous solution] Injection product label, January 2004. Bristol-Myers Squibb)

Nausea and vomiting	92%†
Diarrhea, constipation, other GI side effects	21%
Thrombocytopenia: <100,000/mm³ <50,000/mm³	62% 35%
Neutropenia: <1000/mm³	21%
Anemia: <11 g/dL <8 g/dL	90% 21%
Nephrotoxicity: Increased serum creatinine Increased BUN	10% 22%
Hyponatremia, hypomagnesemia, hypocalcemia, hypokalemia	47%, 43%, 31%, 28%
Peripheral neuropathies: Paresthesia, ataxia, distal motor deficits; decreased vibratory sense, light touch, pinprick, and joint position; areflexia	
Cumulative ototoxicity: Tinnitus, high-frequencies hearing loss, audiogram deficits	1.1%
Increased alkaline phosphatase, AST, total bilirubin	37%
Alopecia	19%
Hypersensitivity reactions: Facial flushing, generalized urticaria, hypotension, rash, pruritus, bronchospasm, shortness of breath	5%

*Incidence after a single treatment with cisplatin 50 mg/m²

†All data are based on the experience of 553 patients with previously treated ovarian carcinoma who received single-agent carboplatin, without regard for their baseline status

EPITHELIAL OVARIAN CANCER REGIMEN

GEMCITABINE + CARBOPLATIN

Pfisterer J et al. J Clin Oncol 2006;24:4699–4707

Gemcitabine 1000 mg/m² per dose; administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 2000 mg/m²)
Note: On day 1, administer after hydration for carboplatin, then follow with carboplatin

Carboplatin (calculated dose) AUC = 4 mg/mL • min*; administer intravenously in 0.9% NS or 5% dextrose injection 100–500 mL over 1 hour, on day 1 after completing gemcitabine, every 3 weeks (total dosage/cycle calculated to produce a target AUC = 4 mg/mL • min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential on days with gemcitabine alone is **LOW***
*Emetogenic potential on days with carboplatin is **MODERATE**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with platinum-sensitive recurrent ovarian cancer were randomly assigned to receive either gemcitabine plus carboplatin or carboplatin alone. The primary objective was to compare progression-free survival (PFS)

Dose Modifications

Adverse Event	Dose Modifications
ANC <1500/mm³ or platelet count <100,000/mm³	Hold day 1 chemotherapy until ANC ≥1500/mm³ and platelet count ≥100,000/mm³
ANC <1500/mm³ or platelet count <100,000/mm³ ≥2 weeks	Discontinue therapy
Intracycle: G1/2 nonhematologic toxicity or G1–3 nausea or vomiting	100% gemcitabine dosage on day 8
Intracycle: G3 nonhematologic toxicity, except nausea, vomiting, and alopecia	Reduce gemcitabine dosage by 50% on day 8, or hold treatment at clinician's discretion
Intracycle: G4 nonhematologic toxicity	Hold gemcitabine
Day 8 ANC ≥1000–1400/mm³ and/or platelet count ≥75,000–99,000/mm³	Reduce gemcitabine dosage by 50%
Day 8 ANC <1000/mm³ and platelet count <75,000/mm³	Hold gemcitabine

(*continued*)

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count on days 1, 8, and 15 of each cycle

Dose Modifications (*continued*)

Adverse Event	Dose Modifications
Febrile neutropenia, *or* ANC <500/mm^3 for >5 days, *or* ANC <100/mm^3 for >3 days, *or* Platelet count <25,000/mm^3, *or* Platelet count <50,000/mm^3 with bleeding, *or* G3/4 nonhematologic toxicity (except nausea/vomiting), *or* treatment delay for toxicity ≥1 week	Reduce gemcitabine dosage to 800 mg/m^2 per dose *Note:* If gemcitabine dosage is 800 mg/m^2 then discontinue gemcitabine
Significant hypersensitivity reaction to carboplatin (hypotension, dyspnea, and angioedema requiring therapy)*	Discontinue therapy

*Patients who experience G1/2 carboplatin hypersensitivity reactions may continue treatment if there is evidence of tumor response and appropriate preventive measures are instituted

EPITHELIAL OVARIAN CANCER REGIMEN

LIPOSOMAL DOXORUBICIN + CARBOPLATIN

Pujade-Lauraine E et al. J Clin Oncol 2010;28:3323–3329

Doxorubicin HCl liposome injection (liposomal doxorubicin) 30 mg/m²; administer intravenously in 250 mL (doses ≤90 mg) 5% dextrose injection over 60 minutes, on day 1 before carboplatin, every 4 weeks (total dosage/cycle = 30 mg/m²)

Note: Doxorubicin HCl liposome injection should be administered at an initial rate of 1 mg/min to minimize the risk of infusion reactions. If no infusion-related adverse events are observed, the rate of infusion can be increased to complete administration of the drug over 1 hour

Note: Experience with doxorubicin HCl liposome injection at high cumulative doses is too limited to have established its effects on the myocardium. Therefore, it should be assumed that it will have myocardial toxicity similar to conventional formulations of doxorubicin HCl. Irreversible myocardial toxicity leading to congestive heart failure often unresponsive to cardiac supportive therapy may be encountered as the total cumulative lifetime dosage of doxorubicin HCl approaches **450–550 mg/m²**. Prior anthracyclines or anthracenediones will reduce the total dose of doxorubicin HCl that can be given without associated cardiac toxicity. Cardiac toxicity also may occur at lower cumulative doses in patients receiving concurrent cyclophosphamide therapy

Carboplatin (calculated dose) AUC = 5*; administer intravenously in 0.9% sodium chloride injection or D5W 100–500 mL over 60 minutes, on day 1 after completing liposomal doxorubicin administration, every 4 weeks (total dosage/cycle calculated to produce a target AUC = 5 mg/mL • min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: URL: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE****. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

(*continued*)

Patient Population Studied

Patients with histologically proven ovarian cancer with recurrence ≥6 months after first- or second-line platinum and taxane-based therapies. Randomization against paclitaxel + carboplatin. Primary end point was progression-free survival (PFS); secondary end points were toxicity, quality of life, and overall survival

Efficacy

Efficacy (> Median Follow-up of 22 Months)*

PFS (intent-to-treat population)	11.3 months
Progression according to RECIST	79%
Progression according to CA-125 GCIG criteria	21%

*In the absence of unacceptable toxicity or disease progression, patients were treated for a total of 6 courses of therapy. In the event disease stabilization or partial response was achieved after 6 courses of therapy, patients were allowed to remain on therapy until progression

(continued)

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine
- Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patients who have developed G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE

Therapy Monitoring

1. Baseline: LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination including a gynecologic examination
2. Baseline ECG and left ventricular ejection fraction measurement by echocardiogram or multigated angiography. A left ventricular ejection fraction measurement before each course of therapy if cumulative anthracycline dose exceeds 450 mg/m^2
3. Follow-up: CBC with differential and platelet count on days 1, 8, and 15 of each cycle, and LFTs prior to commencing repeated cycles

Toxicity

†Graded as 1, partial hair loss, or 2, complete hair loss
‡Grades 2 and 3 only (no reported grade 4 toxicities)

Note: Because of rounding, percentages may not total 100

Dose Modifications

Adverse Event	Dose Modifications
ANC $<1000/mm^3$ or platelet count $<75{,}000/mm^3$	Hold day 1 chemotherapy until ANC $\geq 1000/mm^3$ and platelet count $\geq 75{,}000/mm^3$
ANC $<1000/mm^3$ or platelet count $<75{,}000/mm^3$ ≥ 3 weeks	Discontinue therapy
G3/4 nonhematologic toxicity	Reduce carboplatin dosage to AUC = 4 mg/mL · min. If toxicity occurred at carboplatin dosage of AUC = 4 consider discontinuing therapy. Reduce liposomal doxorubicin dosage by 25% or add filgrastim support
Febrile neutropenia, *or* ANC $<500/mm^3$ for ≥ 7 days, *or* Platelet count $<10{,}000/mm^3$, *or* Platelet count 10,000–50,000/mm^3 with bleeding, or treatment delay for hematological toxicity >1 week	
Total cumulative lifetime doxorubicin dosage ≥ 450 mg/m^2	Obtain a left ventricular ejection fraction measurement before each course of therapy
Acute liposomal doxorubicin-associated infusion reactions, including: flushing, shortness of breath, facial swelling, headache, chills, back pain, tightness in the chest or throat, and/or hypotension	Decrease liposomal doxorubicin administration rate or terminate the infusion depending on the severity. Mild infusion reactions can be managed conservatively with a slowing of the rate of infusion*
G1 Palmar plantar erythrodysesthesia (PPE) = Mild erythema, swelling, or desquamation not interfering with daily activities†	Continue next cycle at the same liposomal doxorubicin dosage, unless patient has experienced previous G3/4 toxicity. If so, delay up to 2 weeks and decrease dosage by 25%. Return to original dose interval
G2 PPE = Erythema, desquamation, or swelling interfering with, but not precluding normal physical activities; small blisters or ulcerations <2 cm in diameter†	Delay liposomal doxorubicin dosing up to 2 weeks or until resolved to G0/1. If after 2 weeks there is no resolution discontinue liposomal doxorubicin
G3 PPE = Blistering, ulceration, or swelling interfering with walking or normal daily activities; cannot wear regular clothing†	Delay liposomal doxorubicin administration up to 2 weeks or until resolved to G0/1. Decrease liposomal doxorubicin dosage by 25% and return to original dose interval. If after 2 weeks there is no resolution, discontinue liposomal doxorubicin
G4 Palmar plantar erythrodysesthesia (PPE) = Diffuse or local process causing infectious complications, or a bed ridden state or hospitalization†	
G1 stomatitis = Painless ulcers, erythema, or mild soreness	Continue next cycle at the same liposomal doxorubicin dosage, unless patient has experienced previous G 3/4 toxicity. If so, delay up to 2 weeks and decrease liposomal doxorubicin dosage by 25%. Return to original dose interval
G2 stomatitis = Painful erythema, edema, or ulcers, but can eat	Delay liposomal doxorubicin administration up to 2 weeks or until resolved to G0/1. If at >2 weeks there is no resolution, discontinue liposomal doxorubicin
G3 stomatitis = Painful erythema, edema, or ulcers, but cannot eat	Delay liposomal doxorubicin administration up to 2 weeks or until resolved to G0/1. Decrease liposomal doxorubicin dosage by 25% and return to original dose interval. If at >2 weeks there is no resolution, discontinue liposomal doxorubicin
G4 stomatitis = Requires parenteral or enteral support	
Serum bilirubin 1.2–3 mg/dL (20.5–51.3 μmol/L)	Reduce dosage of liposomal doxorubicin by 50%
Serum bilirubin >3 mg/dL (>51.3 μmol/L)	Reduce dosage of liposomal doxorubicin by 75%
Significant hypersensitivity reaction to carboplatin (hypotension, dyspnea and angioedema requiring therapy)‡	Discontinue therapy

*For patients with a history of asthma or allergic reactions to drugs consider parenteral pre-medication with 100 mg hydrocortisone with or without 25–50 mg diphenhydramine

†Preventive measures for PPE include wearing loose-fitting clothes, avoiding activities that can lead to trauma to the vasculature of palms or soles, and use of ice packs to promote vasoconstriction and reduce inflammation. Patients should be advised to avoid hot baths and showers (jacuzzis and steam baths included) for 24 hours before and 72 hours after liposomal doxorubicin. Cool baths are recommended. Topical steroid creams provide no benefit. Topical antihistamine and anesthetic preparations may aggravate skin toxicity. Emollients and petroleum-based balms may provide some relief

‡Patients who experience G1/2 carboplatin hypersensitivity reactions may continue treatment if there is evidence of tumor response and appropriate preventive measures are instituted

EPITHELIAL OVARIAN CANCER REGIMEN

CARBOPLATIN + DOCETAXEL

Strauss HG et al. Gynecol Oncol 2007;104:612–616

Premedication with **Dexamethasone** 8 mg/dose; administer orally twice daily for 3 days (6 doses), starting on the day before docetaxel administration (total dose/cycle = 48 mg) *or* Dexamethasone 4 mg/dose; administer orally for 3 doses during the evening before, morning of, and evening after docetaxel administration (total dose/cycle = 12 mg)
Docetaxel 75 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 30 minutes on day 1 before carboplatin, every 3 weeks for 6 cycles (total dosage/cycle = 75 mg/m^2), *followed by:*

Carboplatin [calculated dose] AUC = 5*; administer intravenously in 0.9% NS or D5W 100–500 mL over 60 minutes, on day 1 after completing docetaxel, every 3 weeks for 6 cycles (total dosage/cycle calculated to produce a target AUC = 5 mg/mL • min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target Area Under the plasma concentration versus time Curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE*** *Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Eligible patients had recurrent ovarian, peritoneal or tubal cancer (platinum-free interval >6 months), performance status 0–2. Patients with had undergone surgical debulking for recurrent disease were excluded from the study. First-line chemotherapy in 25 patients included carboplatin/paclitaxel (21), carboplatin/docetaxel (1), carboplatin/cyclophosphamide (1), and carboplatin alone (2). Patients with preexisting peripheral neuropathy G ≥2 (NCI Common Toxicity Criteria, version 2.0; 1998) were excluded

Efficacy

Efficacy (N = 25)*

Strauss et al. Gynecol Oncol 2007;104:612–616

Intent-to-Treat Population (N = 25)	
Overall response rate*,†	72% [95% CI, 60%–84%]
Median progression-free survival	19 months [95% CI, 4–40 months]
Overall survival‡	26 months [95% CI, 11–44 months]
Efficacy-Evaluable Patients (N = 23)	
Overall response rate*,†	78.3% [95% CI, 64–86%]
Complete response*	69.6% (16/23)
Partial response†	8.7 % (2/23)
Remission duration	50% (8/16 CR) at a median follow-up of 40.4 months

**Complete response:* Disappearance of all measurable disease assessed by imaging, disappearance of clinical signs and symptoms and normalization of CA-125 serum values without clinical evidence of progression for ≥4 weeks
†*Partial response:* Reduction of ≥50% in the sum of the greatest perpendicular diameters of all measurable lesions without appearance of new lesions for ≥4 weeks, no enlargement of any existing lesion, and decrease of elevated CA-125 values ≥50% from the pretherapeutic level
‡In an unplanned retrospective analysis, patients with a platinum-free interval ≥12 months showed significantly better OS than those with a platinum-free interval <12 months (p = 0.003/HR 8.6 [95% CI, 5.4–10.8])

Dose Modifications

Adverse Event	Dose Modifications
ANC <1000/mm³ or platelet count <75,000/mm³*	Hold day 1 chemotherapy until ANC ≥1000/mm³ and platelet count ≥75,000/mm³
ANC <1000/mm³ or platelet count <75,000/mm³ ≥3 weeks	Discontinue therapy
G3/4 nonhematologic toxicity	Reduce carboplatin dosage to AUC 4 mg/mL · min. If toxicity occurred at carboplatin dosage of AUC = 4 mg/mL · min, consider discontinuing therapy. Reduce docetaxel dosage to 60 mg/m²
ANC <1500/mm³ or platelet count <100,000/mm³ on day 1 of a cycle, *or* Febrile neutropenia, *or* ANC <500/mm³ despite filgrastim prophylaxis, *or* ANC <500/mm³ for ≥7 days, *or* Platelet count <25,000/mm³	Reduce carboplatin dosage to AUC = 4 mg/mL · min. Reduce docetaxel dosage to 60 mg/m²
Second episode of febrile neutropenia	Continue docetaxel 60 mg/m², carboplatin AUC = 4 mg/mL · min, and give filgrastim* during subsequent cycles
ANC <1500/mm³ or platelet count <100,000/mm³ on despite 2-week delay, *or* febrile neutropenic despite filgrastim support, *or* Febrile neutropenia at docetaxel dosage of 60 mg/m² and carboplatin AUC 4 mg/mL · min, *or* Nonhematologic toxicity G >2 except mucositis, nausea or alopecia, *or* Significant hypersensitivity reaction to docetaxel or carboplatin (hypotension, dyspnea and angioedema requiring therapy)†	Discontinue therapy
G ≥3 peripheral neuropathy	Hold therapy for a maximum of 2 weeks, until toxicity G ≤2. Reinstitute therapy reducing docetaxel dosage to 30 mg/m². If toxicity recurs at docetaxel dosage = 30 mg/m², reduce carboplatin dosage to AUC = 4 mg/mL · min

*Filgrastim 5 mcg/kg per day subcutaneously for 8 consecutive days, days 3–10
†Patients who experience G1/2 carboplatin hypersensitivity reactions may continue treatment if there is evidence of tumor response and appropriate preventive measures are instituted

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination, including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count at least weekly through leukocyte and platelet count nadirs, and prior to beginning repeated cycles, and LFTs before commencing repeated cycles

EPITHELIAL OVARIAN CANCER REGIMEN

CARBOPLATIN + DOCETAXEL

Kushner DM et al. Gynecol Oncol 2007;105:358–364

Premedication:

Dexamethasone 4 mg/dose; administer orally for 3 doses during the evening before, morning of, and evening after docetaxel administration (total dose/cycle = 12 mg)

Docetaxel 35 mg/m² per dose (maximum single dose limited to 70 mg)*; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL, over 60 minutes for 3 doses, before carboplatin on days 1, 8, and 15, every 28 days (total dosage/cycle = 105 mg/m²; maximum dose/cycle = 210 mg), *followed by:*

Carboplatin (calculated dose) AUC = 2†; administer intravenously in 0.9% NS or D5W 100–500 mL over 30 minutes for 3 doses, after completing docetaxel on days 1, 8, and 15, every 28 days (total dosage/cycle calculated to produce a cumulative target AUC = 6 mg/mL • min)

Notes: Carboplatin hypersensitivity led to 11 subjects coming off trial (31%). Diphenhydramine premedication produced a nonsignificant decrease in reaction rate

In the clinical trial, treatment was continued until evidence of disease progression, intolerable toxicity, patient refusal of further treatment, or physician decision that it was in the best interest of a patient to discontinue therapy. Patients who achieved a complete response (CR) continued therapy for 2 cycles following documentation of CR

*Patients with G2 neurotoxicity were treated at an initial docetaxel dosage of 30 mg/m²

†Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

(*continued*)

Patient Population Studied

Thirty-six patients were enrolled in a prospective phase II study of a weekly docetaxel and carboplatin regimen. Patients eligible for the trial had an initial diagnosis of ovarian or primary peritoneal carcinoma. Initial treatment with a platinum-based regimen was required, with a treatment-free interval of at least 3 months. Patients could have received 1 prior regimen for recurrence. At the time of enrollment, patients were required to have a Gynecologic Oncology Group performance status of <2, neuropathy (sensory and motor) grade ≤2 (NCI Common Toxicity Criteria), and recovered from effects of recent surgery, radiotherapy, or chemotherapy. Biologically evaluable disease (CA-125) could be followed only if measurable disease was not present. The majority of patients had ovarian cancer (89%) and Stages III/IV (97%) disease, with a median initial disease-free interval of 12 months. Most subjects were treated for first recurrence (81%) and had measurable disease (58%)

Toxicity

Hematologic and Nonhematologic Toxicity*

	Grade of Worst Event (Per Patient, N=36)				
Toxicity	% No Toxicity	% G1	% G2	% G3	% G4
Leukopenia	17	23	29	31	0
Neutropenia	26	9	17	34	14
Anemia	31	46	17	6	0
Thrombocytopenia	69	23	6	3	0
Gastrointestinal	14	43	34	3	6
Neurologic	63	20	17	0	0
Carboplatin reaction†	63	11	11	14	0

*There was no detectable difference in quality of life as a consequence of therapy

†Carboplatin hypersensitivity reactions led to 11 subjects coming off trial (31%)

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Dose Modifications

Adverse Event	Dose Modifications
ANC <1000/mm³ or platelet count <75,000/mm³*	Hold day 1 chemotherapy until ANC ≥1000/mm³ and platelet count ≥75,000/mm³
ANC <1500/mm³ or platelet count <100,000/mm³ on day 1 of a cycle	Reduce docetaxel dosage to 30 mg/m². If adverse effect occurred with docetaxel 30 mg/m², reduce each carboplatin dosage to AUC = 1 mg/mL · min per dose on the same administration schedule
ANC <1000/mm³ or platelet count <75,000/mm³ ≥3 weeks	Discontinue therapy
ANC <1000/mm³, *or* Platelet count <100,000/mm³, *or* G ≥3 renal toxicity, *or* G ≥2 toxicities with an adverse effect on organ function	Omit the scheduled weekly dose
ANC <500/mm³ or platelet count <25,000/mm³ for ≥7 days, *or* ANC <500/mm³ despite filgrastim prophylaxis, *or* G4 neutropenia associated with fever, *or* G ≥3 anemia, *or* G ≥3 renal toxicity, *or* G ≥3 hepatic toxicity (bilirubin > ULN or transaminases >5 × ULN), *or* Uncontrolled G ≥3 nausea/vomiting, *or* G ≥2 stomatitis, *or* Other G ≥2 nonhematologic toxicities with an adverse effect on organ function, *or* Omission of 2 consecutive weekly doses	Reduce docetaxel dosage to 30 mg/m² per dose. If adverse effect occurred with docetaxel 30 mg/m², reduce carboplatin dosage to AUC = 1 mg/mL · min per dose on the same administration schedule
ANC <1500/mm³ or platelet count <100,000/mm³ despite 2-week delay, *or* Febrile neutropenia despite filgrastim support, *or* Febrile neutropenia at docetaxel dosages of 30 mg/m² and carboplatin AUC = 1 mg/mL · min, *or* Significant hypersensitivity reaction to docetaxel or carboplatin (hypotension, dyspnea and angioedema requiring therapy)*	Discontinue therapy
G ≥3 peripheral neuropathy	Hold therapy for a maximum of 2 weeks until toxicity G ≤2. Reinstitute therapy but reduce docetaxel dosage to 30 mg/m² per dose. If adverse effect occurred with docetaxel 30 mg/m², reduce carboplatin dosage to AUC = 1 mg/mL · min per dose on the same administration schedule

ULN, upper limit of normal range

*Patients who experience G1/2 carboplatin hypersensitivity reactions may continue treatment if there is evidence of tumor response and appropriate preventive measures are instituted

Efficacy*

Intention to Treat (N = 36)†	
Overall response rate (ORR)	50% (18/36)
Complete response	11% (4/36)
Partial response	39% (14/36)
Evaluable for Response (N = 27)†	
Overall response rate (ORR)	67% (18/27)
Complete response	15% (4/27)
Partial response	52% (14/27)
ORR biologically evaluable	65% (11/17)
ORR measurable disease	70% (7/10)
ORR platinum-resistant (treatment-free interval <6 months)	60% (3/5)
ORR platinum-sensitive disease (treatment-free interval >6 months)	68% (15/22)

Note: Data were not available concerning time to progression or survival

*RECIST (Response Evaluation Criteria in Solid Tumors) criteria were used to define response. If CA-125 was increased at baseline, normalization was required for a complete response (CR). Patients without measurable disease were evaluated by CA-125 values as described by Rustin et al. (J Clin Oncol 1996;14:1545–1551). Complete response = normalization of CA-125 lasting ≥4 weeks, documented with at least 3 normal values. Partial response (PR) = 50–75% improvement in the CA-125 level, lasting ≥ weeks. This could be documented in 1 of 2 ways: (a) 4 CA-125 levels, 2 initial elevated and 1 showing a 50% decrease requiring confirmation by a fourth sample, or (b) 3 CA-125 levels with a serial decrease of at least 75%. Progressive disease = a rise ≥50% documented on 2 separate occasions 1 week apart. Stable disease = any condition not meeting the above parameters

†Patients who received 1 or more cycles of drug and lived at least 3 weeks were evaluable for response. Twenty-seven patients were evaluable for response. Nine subjects were removed from study prior to the first response evaluation. Eight of these were removed because of toxicity and 1 subject withdrew consent for reasons other than toxicity

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination, including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count on days 1, 8, and 15, and LFTs before commencing repeated cycles

EPITHELIAL OVARIAN CANCER REGIMEN

CISPLATIN + GEMCITABINE

Rose PG et al. Gynecol Oncol 2003;88:17–21

Gemcitabine 750 mg/m² per dose; administer intravenously in 50–250 mL sodium chloride injection (0.9% NS) over 30–60 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 1500 mg/m²), *followed by*:

Hydration before cisplatin with ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3–4 hours
Cisplatin 30 mg/m² per dose; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes for 2 doses, on days 1and 8, every 21 days (total dosage/cycle = 60 mg/m²)
Hydration after cisplatin with ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3–4 hours

Notes: Encourage increased oral intake of nonalcoholic fluids. Goal is to achieve a urine output ≥100 mL/hour. Monitor and replace electrolytes as needed (potassium, magnesium, sodium)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE–HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Thirty-six patients with ovarian or peritoneal cancers whose disease was platinum- and paclitaxel-refractory, and who had failed to benefit from multiple second-line agents, were treated with a combination of gemcitabine and cisplatin. Tumors were defined as platinum-resistant if disease had progressed on or within 6 months after patients had completed their most recent platinum regimen. Patients had received a median of 2 (range: 1–5) prior platinum- or paclitaxel-based regimens, were heavily pretreated, and had received a median of 3 nonplatinum/nonpaclitaxel regimens (range: 0–6 regimens). Despite this, the majority of patients had an excellent performance status: ECOG = 0

Efficacy

Intention to Treat (N = 36)	
Overall response rate	41.6% (15/36)
Complete response	11.1% (4/36)
Partial response	30.5% (11/36)
Duration of Benefit (N = 35)	
Progression-free survival	6 months (range: 1–14 months)
Overall survival	12 months
Median response duration, responding patients	11 months (range: 4–14 months)
Intention to Treat/Evaluable Disease (N = 5)*,†	
Overall response rate	40% (2/5)
Intention to Treat/Measurable Disease (N = 31)†	
Overall response rate	42% (13/31)
Response According to Platinum-Free Interval	
<6 months	16.6% (1/6)
6–12 months	37.5% (3/8)
>12 months	50% (11/22)
Progression on Prior Gemcitabine (N = 6)	
Partial response	66% (4/6)

*In patients with "nonmeasurable" disease with only increased CA-125, a partial response was defined as a reduction in CA-125 value by ≥50%
†Neither maximum disease diameter nor a pretreatment CA-125 level correlated with response

Dose Modifications

Adverse Event	Dose Modifications
ANC $<1500/mm^3$ or platelet count $<100,000/mm^3$	Hold day 1 chemotherapy until ANC $\geq 1500/mm^3$ and platelet count $\geq 100,000/mm^3$
ANC $<1500/mm^3$ or platelet count $<100,000/mm^3$ ≥ 2 weeks	Discontinue therapy
Intracycle: G1/2 nonhematologic toxicity or G1–3 nausea or vomiting	100% gemcitabine dosage on day 8
Intracycle: G3 nonhematologic toxicity, except nausea, vomiting, and alopecia	Reduce gemcitabine dosage by 50% on day 8, or hold treatment at clinician's discretion
Intracycle: G4 nonhematologic toxicity	Hold gemcitabine
Intracycle: Day 8 ANC $<1000/mm^3$ or platelet count $<75,000/mm^3$	Do not administer day 8 therapy. In subsequent cycles, administer gemcitabine 600 mg/m² per dose on days 1 and 8. If adverse event occurred with gemcitabine 600 mg/m², administer gemcitabine 400 mg/m² per dose on days 1 and 8. If adverse event occurred with gemcitabine 400 mg/m², administer gemcitabine 300 mg/m² per dose on days 1 and 8.
Intracycle: Day 8 ANC $1000–1400/mm^3$ and/or platelet count $75,000–100,000/mm^3$	Reduce gemcitabine dosage to 600 mg/m². If adverse event occurred with gemcitabine 600 mg/m², administergemcitabine 400 mg/m² per dose on days 1 and 8. If adverse event occurred with gemcitabine 400 mg/m², administergemcitabine 300 mg/m² per dose on days 1 and 8

(continued)

Toxicity (continued)

Dose Reductions with Repeated Administrations

Toxicity Responsible for Reduction	Number of Dose Reductions			
	0	1	2	3
Thrombocytopenia and/or neutropenia	47.2	36.1	5.6	11.1

*Grade 1 peripheral neurotoxicity developed in all patients who received more than 8 cycles
†After 6 courses of therapy

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry (including potassium, magnesium, and sodium), CBC with differential and platelet count, and CA-125. Complete history and physical examination, including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count at least weekly through leukocyte and platelet count nadirs, and serum potassium, magnesium, and sodium before repeated treatment
3. Repeat LFTs before commencing repeated cycles

Dose Modifications (continued)

Adverse Event	Dose Modifications
Neutropenia and sepsis, *or* severe thrombocytopenia (platelets <20,000/mm^3)	Administer gemcitabine 600 mg/m^2. If adverse event occurred with gemcitabine 600 mg/m^2, administer gemcitabine 400 mg/m^2 per dose on days 1 and 8. If adverse event occurred with gemcitabine 400 mg/m^2, administer gemcitabine 300 mg/m^2 per dose on days 1 and 8
G2 peripheral neuropathy	Reduce cisplatin dosage to 25 mg/m^2 per dose on days 1 and 8
G3/4 peripheral neuropathy	Hold therapy until peripheral neuropathy G ≤1, then restart therapy with cisplatin dosage reduced to cisplatin 20–25 mg/m^2 per dose on days 1 and 8. Consider discontinuing therapy if not recovered to baseline by 2–3 weeks
Creatinine clearance 40–60 mL/min (0.66–1 mL/s)	Reduce cisplatin so that dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance <40 mL/min (<0.66 mL/s)	Hold cisplatin
On treatment day, serum creatinine 1.6–2 mg/dL (141–177 μmol/L)	Reduce cisplatin dosage by 25%
On treatment day 1, serum creatinine >2 mg/dL (>177 μmol/L)	Hold cisplatin until serum creatinine ≤2 mg/dL (≤177 μmol/L)

*Creatinine clearance is used as a measure of glomerular filtration rate
†This also applies to patients with creatinine clearance of 40–60 mL/min (0.66–1 mL/s) at the outset of treatment

EPITHELIAL OVARIAN CANCER REGIMEN

CARBOPLATIN + WEEKLY (DOSE-DENSE) PACLITAXEL

Katsumata N et al. Lancet 2009;374:1331–1338

Note: Regimen for optimally debulked ovarian cancer. Suboptimally debulked disease can be treated with this regimen as well

Premedication:

Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel, *or*

Dexamethasone 20 mg/dose; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel on days 1, 8, and 15 (total dose/cycle = 60 mg)

Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel

Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 80 mg/m² per dose; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 60 minutes for 3 doses, on days 1, 8, and 15, every 3 weeks (total dosage/cycle = 240 mg/m²)

Carboplatin (calculated dose) AUC = 6*; administer intravenously in 0.9% NS or D5W 100–500 mL over 60 minutes, on day 1 after completing paclitaxel, every 3 weeks (total dosage/cycle calculated to produce a target AUC = 6 mg/mL · min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 \pm \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value for patients with normal renal function. No greater estimated GFR values should be used U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm228974.htm

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with carboplatin is **HIGH**. Potential for delayed symptoms*

*Emetogenic potential on days with paclitaxel alone is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

(continued)

Patient Population Studied

Phase III, open-label, randomized trial conducted in 95 centers in Japan. Patients had a histologically or cytologically proven diagnosis of Stages II to IV epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer. Eastern Cooperative Oncology Group (ECOG) performance status of 0–3, and adequate organ function. Patients were excluded if they had an ovarian tumor with a low malignant potential. Previous chemotherapy was not allowed

Dose Modifications

Adverse Event	Dose Modifications
ANC <1000/mm³ or platelet count <75,000/mm³	Hold day 1 chemotherapy until ANC ≥1000/mm³ and platelet count ≥75,000/mm³
ANC <1000/mm³ or platelet count <75,000/mm³ ≥3 weeks	Discontinue therapy
If on days 8 or 15, ANC <500/mm³ or platelet count <50,000/mm³	Hold chemotherapy until ANC ≥500/mm³ and platelet count ≥50,000/mm³
G3/4 nonhematologic toxicity	Reduce paclitaxel dosage to 70 mg/m²
G3/4 nonhematologic toxicity with paclitaxel 70 mg/m²	Reduce paclitaxel dosage to 60 mg/m²
With carboplatin target AUC = 6 mg/mL · min: Febrile neutropenia, *or* ANC <500/mm³ for ≥7 days, *or* Platelet count <10,000/mm³, *or* Platelet count 10,000–50,000/mm³ with bleeding, *or* Treatment delay for hematologic toxicity >1 week	Reduce carboplatin dosage to target an AUC = 5 mg/mL · min

(continued)

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Significant hypersensitivity reaction to carboplatin (hypotension, dyspnea, and angioedema requiring therapy)*	Discontinue therapy

*Patients who experience G1/2 carboplatin hypersensitivity reactions may continue treatment if there is evidence of tumor response and appropriate preventive measures are instituted

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination, including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count at least weekly through leukocyte and platelet count nadirs, and before beginning *repeated* cycles
3. *Before beginning repeated cycles:* Repeat LFTs

EPITHELIAL OVARIAN CANCER REGIMEN

PEMETREXED

Miller DS et al. J Clin Oncol 2009;27:2686–2691
Vergote I et al. Eur J Cancer 2009;45:1415–1423

Ancillary medications:
Folic acid 350–1000 mcg; administer daily beginning 1–2 weeks before the first dose of pemetrexed and continue until 3 weeks after the last pemetrexed dose
Cyanocobalamin (vitamin B_{12}) 1000 mcg; administer by intramuscular injection every 9 weeks, beginning 1–2 weeks before the first dose of pemetrexed, and continue until 3 weeks after the last pemetrexed dose
Dexamethasone 4 mg; administer orally twice daily for 3 days (6 doses) starting the day before each pemetrexed dose (total dose/cycle = 24 mg)
Notes: Nonsteroidal antiinflammatory drugs should be held for 2 days before and 2 days after pemetrexed administration
Pemetrexed 500 mg/m^2; administer intravenously in 10 mL 0.9% sodium chloride injection (0.9% NS) over 10 minutes on day 1, every 21 days, for a maximum of 6 cycles (unless there was earlier evidence of disease progression or intolerance of the study treatment) (total dosage/cycle = 500 mg/m^2)
Note: In a randomized double blind phase II study, pemetrexed 500 mg/m^2 had comparable activity with a more favorable toxicity profile than a dosage of 900 mg/m^2

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***

Dose Modifications

Adverse Event	Dose Modifications
ANC <1500/mm^3 *or* Platelet count <100,000/mm^3, or G ≥2 nonhematologic toxicity	Hold day 1 chemotherapy until: ANC ≥1500/mm^3, platelet count ≥100,000/mm^3, and nonhematologic toxicity is G ≤1
ANC <1500/mm^3 ≥2 weeks, *or* Platelet count <100,000/mm^3 ≥2 weeks, *or* G ≥2 nonhematologic toxicity ≥2 weeks	Discontinue therapy
Febrile neutropenia and/or G4 neutropenia persisting for >7 days, or G4 thrombocytopenia, or G2 bleeding	Reduce pemetrexed dosage by 100 mg/m^2 or discontinue therapy
G3/4 nonhematologic toxicity	Reduce pemetrexed dosage by 100 mg/m^2 or discontinue therapy
G>2 peripheral neuropathy	Reduce pemetrexed dosage by 100 mg/m^2 or discontinue therapy

Patient Population Studied

Patients with histologically confirmed recurrent or metastatic epithelial ovarian cancer or primary peritoneal cancer. Their disease had to be considered platinum-resistant or refractory according to standard GOG criteria (treatment-free interval after platinum-based therapy of less than 6 months or progression during platinum-based therapy). Patients must have had, and were allowed to receive, no more than 1 prior platinum-based chemotherapeutic regimen, containing carboplatin, cisplatin, or another organoplatinum compound, for management of primary disease. GOG performance status of 0–2

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count at least weekly through leukocyte and platelet count nadirs, and before beginning *repeated* cycles
3. *Before beginning repeated cycles:* Repeat LFTs

EPITHELIAL OVARIAN CANCER REGIMEN

DOCETAXEL

Kaye SB et al. Eur J Cancer 1995;31A(Suppl 4):S14–S17

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days (6 doses) starting on the day before docetaxel administration (total dose/cycle = 48 mg) *or*
Dexamethasone 4 mg/dose; administer orally for 3 doses during the evening before, morning of, and evening after docetaxel administration (total dose/cycle = 12 mg)
Docetaxel 75–100 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a docetaxel concentration within the range of 0.3–0.74 mg/mL over 60 minutes on day 1, every 21 days, for 4 cycles (total dosage per cycle = 75–100 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is LOW–MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Evaluation of docetaxel administration in 293 patients with advanced ovarian cancer in 3 phase II trials. All patients had previously received cisplatin and/or carboplatin as first-line treatment. In all 3 studies, docetaxel 100 mg/m^2 was administered every 3 weeks, without premedication for hypersensitivity reactions or emesis. At the time of the analysis, 200 patients were evaluable for response

Therapy Monitoring

1. *Baseline:* LFTs, serum chemistry, CBC with differential and platelet count, and CA-125. Complete history and physical examination including a gynecologic examination
2. *Follow-up:* CBC with differential and platelet count at least weekly through leukocyte and platelet count nadirs, and prior to beginning *repeated cycles*
3. *Before beginning repeated cycles:* Repeat LFTs

Toxicity

Incidence and Severity of Major Adverse Effects of 100 mg/m^2 Docetaxel

Adverse Effect	Incidence
Neutropenia (grade 3 or 4)	83/99 patients (84%)
Acute hypersensitivity (grades 2–4)	13/207 patients (6%)
Skin reactions (grades 2–4)	98/188 patients (52%)
Fluid retention or effusions	102/181 patients (56%)*
Neuropathy (grades 2–3)	11/95 patients (12%)

*Incidence was 66% in patients who received 6 courses of docetaxel

Treatment Modifications

Adverse Events	Treatment Modifications
ANC <1500/mm^3 on day of planned treatment*	Delay treatment until ANC ≥1500/mm^3; administer filgrastim during subsequent cycles[¶]
ANC <500/mm^3 ≥7 days	Reduce docetaxel dosage by 20% during subsequent cycles (or add filgrastim[¶])
First episode of febrile neutropenia	Reduce docetaxel dosage by 20% during subsequent cycles (or add filgrastim[¶])
Second episode of febrile neutropenia	Continue docetaxel and give filgrastim[†] during subsequent cycles
Third episode of febrile neutropenia	Add ciprofloxacin[‡]
First episode of G4 documented infection	Reduce docetaxel dosage by 20% during subsequent cycles
Second episode of G4 documented infection	Continue docetaxel and give filgrastim[¶] and ciprofloxacin[‡] during subsequent cycles
Third episode of G4 documented infection	Discontinue docetaxel

*Although an ANC of 1500/mm^3 is often identified as a minimum acceptable ANC to safely proceed with treatment, recent data show that an ANC ≥1000/mm^3 is acceptable if filgrastim is given after chemotherapy
[†]Filgrastim 5 mcg/kg per day subcutaneously for 8 consecutive days, days 3–10
[‡]Ciprofloxacin 500 mg orally twice daily for 7 consecutive days starting on day 5

Efficacy*

ECTG, Early Clinical Trials Group of the European Organisation for Research and Treatment of Cancer; CSG, Clinical Screening Group of the EORTC; MDACC, The University of Texas MD Anderson Cancer Center, Houston, Texas, USA; N, number of patients enrolled; E, number of patients evaluable; ORR, overall response rate
*Response criteria were those accepted by UICC. Although CA-125 measurements were made with every course of treatment, the results were not used in the response assessment

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

FLUOROURACIL + LEUCOVORIN

Reed E et al. Gynecol Oncol 1992;46:326–329

Leucovorin 500 mg/m² per dose; administer intravenously in 25–100 mL 0.9% sodium chloride injection or 5% dextrose injection over 30 minutes, daily for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 2500 mg/m²), *followed after 1 hour by:*
Fluorouracil 375 mg/m² per dose; administer by intravenous injection over 3–5 minutes, daily, 1 hour after the completion of leucovorin, for 5 consecutive days, days 1–5, every 21 days (total dosage/cycle = 1875 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 29 patients with recurrent advanced-stage ovarian cancer of epithelial histology who had progressive disease while receiving or had suffered relapse after high-dose cisplatin therapy

Efficacy (N = 29)

	Relapsed After Response to Platinum-Based Therapy (n = 8)	Progressive Disease on Platinum-Based Therapy (n = 21)
CR	13%	5%
PR	—	5%
SD*	38%	38%
PD	50%	52%

*SD: 5, 5, 7, 8, 8, 8, 10, 13, 14, 21, and 27 months

Toxicity* (N = 29/204 Cycles)

	Number of Cycles			
	G1	G2	G3	G4
Hematologic				
Neutropenia	1	5	7	4
Thrombocytopenia	7	2	4	4
Anemia	4	6	5	1
Nonhematologic				
Nausea/vomiting	9	3	2	0
Stomatitis	9	5	4	2
Diarrhea	11	3	3	0

*National Cancer Institute Common Toxicity Criteria, version 2

Treatment Modifications

Adverse Event	Dose Modification
G2 nonhematologic toxicity	Reduce fluorouracil daily dosage by 25% on the same administration schedule
WBC <3000/mm³ or platelet count <75,000/mm³ on treatment day	Delay cycle 1 week until WBC >3000/mm³ and platelet count >75,000/mm³

If no toxicity G >1 is documented in a cycle, then increase fluorouracil daily dosage by 25% on the same administration schedule

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes

Notes

Because this regimen is well tolerated, it represents an option for patients when more attractive options have been exhausted

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

GEMCITABINE

Markman M et al. Gynecol Oncol 2003;90:593–596

Gemcitabine 1000 mg/m² per dose; administer intravenously diluted to a concentration ≥0.1 mg/mL in 0.9% sodium chloride injection over 30 minutes for 3 doses, on days 1, 8, and 15, every 28 days (total dosage/cycle = 3000 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 51 patients with ovarian (41), fallopian tube (1), and primary peritoneal cancer (9) and prior chemotherapy with a platinum agent (cisplatin or carboplatin) and a taxane (paclitaxel or docetaxel). If a patient had previously responded to such therapy, and the treatment-free interval had been 3 months, the patient had to be retreated with a platinum agent or a taxane to confirm clinical resistance

Efficacy (N = 51)

Partial response	8%
≥75% decrease in CA-125	8%
Median duration of response	4 months
Survival (all patients)	7 months
Survival (patients with response)	15 months

Toxicity (N = 51)

	% Patients
Hematologic	
G4 neutropenia	24
G3 thrombocytopenia	7
Nonhematologic	
G3 fatigue	10
Fever/chills (no neutropenia)	15
Rash	4
Conjunctivitis	4

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <1000/mm³ or platelet count nadir ≤100,000/mm³	Hold treatment until ANC recovers to ≥ 1000/mm³ and platelets to >100,000/mm³, then resume with gemcitabine dosage decreased by 200 mg/m² per dose
Second occurrence of ANC nadir ≤1000/mm³ or platelet count nadir ≤100,000/mm³	Hold treatment until ANC recovers to >1000/mm³ and platelets to >100,000/mm³, then resume with gemcitabine dosage decreased by an additional 200 mg/m² per dose
Third occurrence of ANC nadir ≤1000/mm³ or platelet count nadir ≤100,000/mm³	Discontinue gemcitabine therapy
G3 nonhematologic toxicity	Hold treatment until toxicities resolve to G <1, then resume with gemcitabine dosage decreased by 200 mg/m² per dose
Second occurrence of G3 nonhematologic toxicity	Hold treatment until toxicities resolve to G ≤1, then resume with gemcitabine dosage decreased by an additional 200 mg/m² per dose

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes, magnesium, calcium, BUN, creatinine, and LFTs

Notes

Gemcitabine dosages of 1250 mg/m² resulted in excessive toxicity

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

ORAL ALTRETAMINE (HEXAMETHYLMELAMINE)

Chan JK et al. Gynecol Oncol 2004;92:368–371

Altretamine 65 mg/m² per dose; administer orally 4 times daily, after meals and at bedtime, for 14 consecutive days, on days 1–14, every 28 days (total dosage/cycle = 3640 mg/m²) *or*
Altretamine 65 mg/m² per dose; administer orally 4 times daily, after meals and at bedtime, for 21 consecutive days, on days 1–21, every 28 days (total dosage/cycle = 5460 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MODERATE–HIGH
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A report of 2 women with recurrent ovarian cancer. Includes review of the literature

Efficacy

Response to altretamine appears to be:
1. Correlated with response to initial platinum therapy: Higher in patients whose disease responded to initial therapy
2. Correlated with treatment-free interval after an initial response to platinum therapy: The longer the interval, the higher the response
3. Higher in platinum-sensitive (PS) disease than in platinum-resistant (PR) disease: Response rates for PS disease in several studies range from 17–50%, whereas response rates for PR disease range from 0–35%

Toxicity

Hematologic	
Moderate-to-severe anemia	13%
Platelet counts <50,000/mm³	≤10%
WBC counts <2000/mm³	≤1%
Nonhematologic	
Nausea and vomiting	33%*
Severe nausea and vomiting	1%*
Moderate-to-severe peripheral sensory neuropathy	9%*
Mild sensory neuropathy	22%
Increased alkaline phosphatase	9%
Mood disorders*: depression, insomnia, confusion, personality changes, anxiety	≤1%
Movement and coordination disorders*	1%
Fatigue, malaise, lethargy	1%

*Symptoms are more likely to occur in patients who receive continuous daily treatment with high doses of altretamine than with moderate doses administered on an intermittent schedule

Treatment Modifications

Adverse Event	Dose Modification
GI intolerance unresponsive to symptomatic measures	Discontinue altretamine for ≥14 days, then resume at 50 mg/m² per dose 4 times daily for the same planned treatment duration
WBC <2000/mm³ or ANC <1000/mm³	
Platelet count <75,000/mm³	
Progressive neurotoxicity	
Progressive neurotoxicity that does not stabilize on a reduced altretamine dosage	Discontinue altretamine indefinitely

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes, magnesium, calcium, BUN, and creatinine

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

DOXORUBICIN HCL LIPOSOME INJECTION (LIPOSOMAL DOXORUBICIN)

Lorusso D et al. Oncology 2004;67:243–249
Thigpen JT et al. Gynecol Oncol 2005;96:10–18

Doxorubicin HCl liposome injection 40–50 mg/m²; administer intravenously diluted in 250 mL 5% dextrose injection (D5W) for doses ≤90 mg and in 500 mL D5W for doses >90 mg every 3–4 weeks (total dosage/cycle = 40–50 mg/m²)
Note: Administer at an initial rate of 1 mg/min for 10–15 minutes. If infusion reactions are not observed, the rate may be increased to complete drug administration over 60 minutes

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial Primary Prophylaxis to be Considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patients who have developed G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine, 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE.

Patient Population Studied

A study of 37 patients with advanced ovarian cancer in whom first-line therapy had failed to provide benefit

Efficacy

Response rates of 7.7–26% have been reported in several studies with a median progression-free survival of 4–6 months

Treatment Modifications

Adverse Event	Dose Modification
Hand-foot syndrome	Reduce dosage to 40 mg/m²
G3/4 nonhematologic toxicity	
Stomatitis G ≥2	
Persistent (>3 weeks) G1/2 toxicity	Increase dosing interval to 4 weeks
Persistent (>4 weeks) G3/4 toxicity	Discontinue therapy

Therapy Monitoring

Before repeated cycles: PE, CBC with differential, and serum electrolytes, magnesium, calcium, BUN, and creatinine

Notes

The consensus of experts in the management of ovarian carcinoma:
1. Based on survival and toxicity advantages and a once-monthly administration schedule, liposomal doxorubicin is considered by some to be the first-choice nonplatinum agent for relapsed ovarian cancer
2. Tolerability is improved with the use of liposomal doxorubicin 40 mg/m² on an every-4-week schedule. Hand-foot syndrome (PPE) is the most commonly reported adverse event associated with liposomal doxorubicin. Avoid this toxicity by using lower dosages of liposomal doxorubicin (40 mg/m² every 4 weeks, or 10 mg/m² weekly), rather than omitting or decreasing doses as a consequence of adverse events

Thigpen JT et al. Gynecol Oncol 2005;96:10–18

Toxicity (N = 37)

	% G1	% G2	% G3	% G4

Note: Toxicity grades for palmar plantar erythrodysesthesia (PPE):
G1 Mild erythema, swelling or desquamation not interfering with daily activities
G2 Erythema, swelling, or desquamation interfering with daily activities; small blisters or ulcerations <2 cm
G3 Blistering, ulcerations, or swelling interfering with daily activities; patient cannot wear regular clothing
G4 Diffuse or local process causing infectious complications, a bedridden state, or hospitalization

Lorusso D et al. Oncology 2004;67:243–249

REGIMEN

VINORELBINE

Rothenberg ML et al. Gynecol Oncol 2004;95: 506–512

Vinorelbine 30 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 60 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Decreased bowel motility

Give a bowel regimen to prevent constipation based initially on stool softeners

Toxicity* (N = 79)

	% G0	% G1	% G2	% G3	% G4
Hematologic

*National Cancer Institute Common Toxicity Criteria, version 2

Treatment Modifications

Adverse Event	Dose Modification
ANC <1000/mm³ or platelet count <75,000/mm³ on the day before or the day of vinorelbine administration	Hold vinorelbine dose on this day
ANC 1000–1499/mm³ or platelet count 75,000–99,999/mm³ on the day before or the day of vinorelbine administration	Administer vinorelbine, but reduce vinorelbine dosage by 7.5 mg/m²
On the day before or the day of repeated vinorelbine administration, ANC 1000–1499/mm³ or platelet count 75,000–99,999/mm³ after vinorelbine 15 mg/m²	Discontinue therapy

Patient Population Studied

A study of 79 patients with recurrent or resistant epithelial ovarian cancer after treatment with platinum and paclitaxel

Efficacy (N = 79)

Partial response (n = 71)	3%
Median time to progression	3 months
6-month survival rate	65%
Median Survival	
All patients (N = 79)	10.1 months
Chemotherapy-resistant (n = 52)	8 months
Chemotherapy-sensitive (n = 27)	16 months

Therapy Monitoring

Before repeated cycles: CBC with differential

Notes

During the initial 10 weeks of treatment, vinorelbine did not appear to be effective in relieving the symptom-related distress or progressive impairment of physical functioning associated with refractory ovarian cancer

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

PACLITAXEL (24-HOUR PACLITAXEL INFUSION EVERY 3 WEEKS; WEEKLY PACLITAXEL)

For both treatment strategies, give premedication for paclitaxel with:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg/dose; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

24-Hour Paclitaxel
Omura GA et al. J Clin Oncol 2003;21:2843–2848
Paclitaxel 175 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 3 hours, on day 1, every 3 weeks (total dosage/cycle = 175 mg/m^2)

or

Weekly Paclitaxel Regimens
Ghamande S et al. Int J Gynecol Cancer 2003;13:142–147
Paclitaxel 70–80 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 60 minutes, weekly for a minimum of 6 consecutive weeks (total dosage/6-week cycle = 420–480 mg/m^2), *or*
Paclitaxel 70–80 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL, over 60 minutes for 3 doses, on days 1, 8, and 15, every 28 days (total dosage/28-day cycle = 210–240 mg/m^2)

Supportive Care
Antiemetic prophylaxis for 24-hour (every-3-weeks) and weekly paclitaxel regimens
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis for the 24-hour regimen
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm^3 on 2 measurements temporally separated by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering another dose of paclitaxel. Do not administer pegfilgrastim within 14 days before a dose of paclitaxel

See Chapter 43 for more information

Hematopoietic growth factor (CSF) prophylaxis for the weekly regimen
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection
- Begin use approximately 24 hours after myelosuppressive chemotherapy is completed
- Discontinue use at least 24 hours before administering subsequent paclitaxel doses

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW–INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
24-Hour Paclitaxel Infusion Every 3 Weeks	
G ≥3 Nonhematologic toxicity	Reduce paclitaxel dose to 135 mg/m^2
Delay in achieving ANC ≥1000/mm^3 and platelets ≥100,000/mm^3 <2 weeks	No dose adjustment
Recurrent delays in achieving ANC ≥1000/mm^3 and platelets ≥100,000/mm^3 ≥2 weeks but ≤3 weeks	Add filgrastim 5 mcg/kg per day without further dosage modification If already using filgrastim, reduce paclitaxel dose to 135 mg/m^2
G3/4 neurologic toxicity that has not resolved even after a 3-week delay	Discontinue therapy
Weekly Paclitaxel Regimen	
WBC <2500/mm^3	Hold chemotherapy until WBC >2500/mm^3
ANC <1500/mm^3	Hold chemotherapy until ANC >1500/mm^3
Platelets <75,000/mm^3	Hold chemotherapy until Platelets >75,000/mm^3
G3/4 neurologic toxicity that has not resolved even after a 3-week delay	Discontinue therapy

Patient Population Studied

A study of 164 patients with epithelial ovarian cancer who had been treated with not more than 1 platinum-based regimen and no prior taxane

Omura GA et al. J Clin Oncol 2003;21:2843–2848

A study of 23 patients with advanced recurrent ovarian cancer with disease deemed resistant to platinum agents and paclitaxel (defined as either progression of disease while on therapy or progression within 12 months of prior paclitaxel therapy)

Ghamande S et al. Int J Gynecol Cancer 2003;13:142–147

Efficacy

24-Hour Paclitaxel Infusion Every 3 Weeks (N = 164)	
Median time to death	13.1 months
Platinum-Resistant Disease	
Complete response	5%
Partial response	17%
No response	78%
Platinum-Sensitive Disease	
Complete response	15%

Ghamande S et al. Int J Gynecol Cancer 2003;13:142–147

Therapy Monitoring

1. *Before repeated cycles:* CBC with differential
2. *Twice per week:* Obtain CBC with differential in patients treated with the weekly regimen

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

TOPOTECAN HCL

Bhoola SM et al. Gynecol Oncol 2004;95:564–569

Topotecan HCl 2.25–4 mg/m² (median: 3.7 mg/m²) per dose; administer intravenously in 50–250 mL 0.9% sodium chloride injection or 5% dextrose injection over 30 minutes, weekly, continually (total dosage/week = 2.25–4 mg/m²)

or

Topotecan HCl 1.5 mg/m² per dose; administer intravenously in 50–250 mL 0.9% NS or D5W over 30 minutes for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 7.5 mg/m²)

Supportive Care for Both Weekly and Every-3-Weeks Regimens

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
G3/4 neutropenia on treatment day 1 (every 21 day regimen)	Hold topotecan until ANC ≥1000/mm³ ± Reduce topotecan dose 10–20% ± Administer filgrastim in subsequent cycles*
G3/4 neutropenia on treatment day 1 (weekly regimen)	Hold topotecan until ANC ≥1000/mm³ ± reduce topotecan dose 10–20% ± administer filgrastim in subsequent cycles* ± change schedule to 2 weeks on/1 week off
G ≥2 anemia	Administer erythropoietin
G ≥2 fatigue	Administer erythropoietin

*With every 21-day administration schedule administer filgrastim 5 mcg/kg per day subcutaneously beginning 24 hours after the day 5 dose and continuing until ANC >10,000/mm³ on 2 consecutive measurements

Toxicity: Weekly Regimen (N = 50)

	% G2	% G3	% G4
Hematologic			
Anemia	42	24	0

Patient Population Studied

A study of 50 patients with ovarian cancer who had received multiple prior regimens

Efficacy: Weekly Regimen (N = 42*)

Measurable Disease (n = 35)		
Partial response	31%	
Stable disease	43%	
Progressive disease	26%	
↑CA-125†		
	All with↑ CA-125 (n = 41)	**↑CA-125† Only (n = 7)**
Partial response	27	29
Stable disease	24	29
Progressive disease	49	42
Platinum-Sensitive Disease		
Partial response	39	
Stable disease	43	
Progressive disease	18	
Platinum-Resistant or Platinum-Refractory Disease		
Partial response	21	
Stable disease	37	
Progressive disease	42	

*Includes only patients who received ≥2 cycles
†Partial response defined as a 50% reduction in CA-125 levels maintained for ≥1 month. Progressive disease defined as a 25% increase in CA-125 levels

Therapy Monitoring

Before repeated cycles: CBC with differential

Notes

A retrospective chart review of patients with rapidly progressive disease or clinical deterioration excluded from analysis. Efficacy of both regimens are comparable; toxicity of weekly regimen tolerable

PLATINUM-REFRACTORY OR PLATINUM-RESISTANT REGIMEN

ORAL ETOPOSIDE

Moosavi AS et al. J Obstet Gynaecol 2004;24:292–293

Etoposide 50 mg/day; administer orally once daily for 21 consecutive days, days 1–21, every 4 weeks (total dose/cycle = 1050 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Nausea and vomiting*	Ingest doses with food
G3/4 ANC	Hold therapy. Resume treatment when ANC $\geq 1500/mm^3$ using an alternative schedule† (every other day, MWF, 2 of every 3 days, M–F)

*Nausea and vomiting are more common after oral etoposide administration than after parenteral administration with bioequivalent doses. Food ingestion does not affect absorption of etoposide doses <200 mg

†The 50-mg etoposide capsules cannot be opened or broken because they contain a liquid product

Therapy Monitoring

Every week: CBC with differential and platelet count

Patient Population Studied

Ten patients with epithelial ovarian cancer and evidence of disease progression; GOG performance status ≤2

Efficacy (N = 10)

Partial response rate	20%*
Response duration	3.5 and 6 months
Median progression-free interval	7.5 months
Median survival time	8.5 months

*Both patients who responded were deemed to have platinum-sensitive disease

Toxicity (N = 10)

	% Patients
Hematologic	
G1 ANC	50%
G2 ANC	30%
Nonhematologic	
Nausea/vomiting	40%
Mild mucositis	10%
Alopecia	100%

Notes

Although oral etoposide has activity in recurrent ovarian cancer, response and survival durations are short with a high rate of complications

REGIMEN

TAMOXIFEN

Markman M et al. Gynecol Oncol 2004;93:390–393

Tamoxifen 10 mg/dose; administer orally twice daily, continually (total dose/week = 140 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 56 patients with recurrent ovarian (n = 44), fallopian tube (n = 3), or primary peritoneal carcinoma (n = 9). All patients had a prior response to primary platinum/taxane–based therapy or a platinum therapy used in the second-line setting and a treatment-free interval of ≥3 months. *Patients had no symptoms believed to be caused by recurrent cancer*

Efficacy (N = 57)

Duration of tamoxifen therapy in asymptomatic patients with recurrent ovarian cancer (n = 57 episodes; one patient received tamoxifen after both primary and secondary-treatments)

Median duration of treatment	3 mo
Patients remaining on therapy ≥6 mo	42%
Patients remaining on treatment ≥12 mo	19%
Patients with recurrence after primary therapy remaining on treatment ≥12 mo (n = 45)	18%
Patients with recurrence after second-line therapy remaining on treatment ≥12 mo (n = 12)	25%

Treatment Modifications

Grade 3 toxicities with this dose of tamoxifen are very uncommon and usually do not require dose reductions

Toxicity

No patient discontinued tamoxifen because of unacceptable side effects. This is a very well-tolerated dose schedule. The most common toxicities in females are hot flashes and some degree of vaginal discharge and, in premenopausal females, menstrual irregularities, such as irregular menses or amenorrhea. The risk for thromboembolic events increases with tamoxifen treatment, but is very low at this dose and usually administered for a short period of time. Neuropsychiatric (depression and other mood disorders) toxicities are uncommon. Liver and dermatologic toxicities can be very serious, but are rare

Therapy Monitoring

1. *Every month:* Serum CA-125 level
2. *Every 2–3 months*: Restaging radiographic studies

Notes

Best used in asymptomatic cases with a rising CA-125, or in cases in which comorbid illnesses argue against more aggressive therapy

29. Pancreatic Cancer

Ramesh K. Ramanathan, MD, PhD, Sc and Daniel D. Von Hoff, MD, FACP

Epidemiology

Incidence: 46,420 (male: 23,530; female: 22,890. Estimated new cases for 2014 in the United States) (13.9 per 100,000 males; 10.9 per 100,000 females)
Deaths: Estimated 39,590 in 2014 (male: 20,170; female: 19,420)
Median age: 71 years
Male to female ratio: ~1:1

Stage at presentation:
Stage I: 20%
Stage II: 40%
Stage III–IV: 40%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology, and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)
Takhar AS et al. BMJ 2004;329:668–673

Pathology

Most cancers of the pancreas arise in the head of the pancreas (60–70%), 15% in the body, and 5% in the tail; in 20%, the neoplasm diffusely involves the entire gland

Malignant Tumors of Pancreatic Origin

Ductal adenocarcinoma	85–90%
Acinar cell carcinoma	1–2%
Undifferentiated carcinoma (anaplastic giant cell, osteoclastic giant cell)	<1%
Sarcomatoid carcinoma/ carcinosarcoma	<1%

de Braud F et al. Crit Rev Oncol Hematol 2004;50: 147–155
Solcia E et al. Tumors of the pancreas. In: Atlas of Tumor Pathology, 3rd series. Washington, DC: Armed Forces Institute; 1997

Work-up

The diagnosis of pancreatic cancer is based on imaging studies and histologic confirmation performed by fine-needle aspiration by endoscopic ultrasonography (EUS), biopsy under CT or US guidance, or during laparotomy

- History and physical examination
- CBC and differential, serum electrolytes, creatinine, LFTs, PT, PTT, CA19-9
- Imaging:
  - Spiral CT: Spiral or a helical CT of the abdomen according to a defined pancreatic protocol is essential. CT provides localization, size of the primary tumor, and evidence of metastasis and evaluates major vessels adjacent to the pancreas for neoplastic invasion or thrombosis. CT is almost 100% accurate in predicting unresectable disease. However, the positive predictive value of the test is low and approximately 25–50% of patients predicted to have resectable disease on CT turn out to have unresectable lesions at laparotomy
  - Endoscopic retrograde cholangiopancreatography (ERCP) can also be useful in patients whom a CT scan is equivocal, because fewer than 3% of patients with pancreatic carcinoma have normal pancreatograms
  - EUS is a relatively new technique and provides useful information. However, EUS needs to be performed in centers with experience in this procedure. EUS is useful for characterizing cystic lesions and assessment of vascular invasion by tumor. In addition, an aspirate can be done for histologic diagnosis. A celiac plexus block can be done via EUS for relief of abdominal pain

Agawam B. Am J Gastroenterol 2004;99:844–850

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma in situ
T1	Tumor limited to the pancreas, 2 cm or less in greatest dimension
T2	Tumor limited to the pancreas, more than 2 cm in greatest dimension
T3	Tumor extends beyond the pancreas but without involvement of the celiac axis or the superior mesenteric artery
T4	Tumor involves the celiac axis or the superior mesenteric artery (unresectable primary tumor)

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph node metastasis

Distant Metastasis (M)

M0	No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	Distant metastasis

Stage	T	N	M
0	Tis	N0	M0
IA	T1	N0	M0
IB	T2	N0	M0
IIA	T3	N0	M0
IIB	T1	N1	M0
	T2	N1	M0
	T3	N1	M0
III	T4	Any N	M0
IV	Any T	Any N	M1

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Expert Opinion

Pancreatic cancer can be broadly divided into 2 groups: *surgically resectable* or *unresectable/advanced cancer*. Patients should be enrolled to suitable dinical trials for all stages of pancreatic cancer if possible

Surgery

- The only curative therapy for pancreatic cancer is resection of the tumor and the surrounding tissues. Patients with resectable disease comprise the smallest group (~15%)
- Criteria for unresectable tumors include:
  - Distant metastases
  - SMA, celiac encasement
  - SMV, portal vein occlusion
  - Aortic or IVC invasion, or encasement
  - Invasion of SMV below the transverse mesocolon
- Borderline resectable pancreatic cancer
  - Patients who present with localized pancreatic cancer but who have a high likelihood of a positive surgical margin (R1) are classified as borderline resectable. A commonly used criteria is as follows:
    - Severe unilateral SMV/Portal impingement
    - Tumor abutment on SMA
    - GDA encasement up to origin of hepatic artery
    - SMV occlusion, if of a short segment with open vein both proximally and distally
    - Adrenal, colon or kidney invasion

Key: GDA, Gastroduodenal artery; IVC, inferior vena cava; SMA, superior mesenteric artery; SMV, superior mesenteric vein

Preoperative Therapy

Treatment regimens include chemoradiation with fluorouracil similar to the regimen used in RTOG 97-04 (Regine et al.). Concurrent involved field radiation with gemcitabine is an alternate regimen. The E4201 study (Loehrer et al.) administered concurrent gemcitabine with RT to patients with locally advanced cancer. RT (50.4 GY in 28 fractions) plus gemcitabine (600 mg/m^2 per week for 6 weeks)

Loehrer P et al. Proc Am Soc Clin Oncol 2008;26(15S, Part I of II):214s [abstract 4506]
Regine WF et al. JAMA 2008;299:1019–1026

(*continued*)

Survival

1-Year survival for all stages	19%
5-Year survival for all stages	4%
5-Year survival in resected patients	25%

Jemal A et al. CA Cancer J Clin 2009;59:225–249
Katz MH. CA Cancer J Clin 2008;58:111–125
Li D et al. Lancet 2004;363:1049–1057

Expert Opinion (*continued*)

Adjuvant Therapy

- Following surgery, adjuvant therapy should be considered for patients who have recovered from surgery. Approximately 20–25% of patients will have a prolonged convalescence and/or a suboptimal performance status following surgery and will not be candidates for adjuvant therapy
- Evaluate all patients for adjuvant therapy. Gemcitabine 1000 mg/m² administered intravenously, may be given weekly for 3 consecutive weeks every 4 weeks for 6 cycles
- Administer radiation with chemosensitizing fluorouracil or capecitabine in addition to gemcitabine as a component of adjuvant therapy for patients at high risk of recurrence. These are patients with a microscopic positive margin (R1 resection), extracapsular lymph node extension, and multiple involved regional nodes (≥4) at resection
- Adjuvant therapy with gemcitabine with or without concurrent chemoradiation with fluorouracil should be considered in most patients
- The efficacy of combined radiation and fluorouracil as adjuvant therapy for pancreatic cancer was first demonstrated by a small prospective randomized study conducted by the Gastrointestinal Tumor Study Group (GITSG). Twenty-two patients were randomized to no adjuvant treatment and 21 patients were assigned to receive combined modality therapy

Radiation Therapy

- Two courses of 2000 cGy, each given for 5 days separated by an interval of 2 weeks +
- Fluorouracil 500 mg/m² per day, administered intravenously in 25–250 mL 0.9% sodium chloride (0.9% NS) or 5% dextrose injection (D5W), USP, over 10–30 minutes for 3 consecutive days for the first 3 days of each 2000-cGy segment of radiation therapy (total dosage/3-day course = 1500 mg/m²). Subsequently, treatment resumed 1 month after completion of radiation with fluorouracil 500 mg/m² per dose administered intravenously for 3 consecutive days, on days 1–3 of each week for 2 years of therapy
- The median survival for the treatment group was 20 months vs. 11 months for the control group, and the median disease-free survival was 11 months for the treated group vs. 9 months for the control group

This study and data from a subsequent confirmatory study of an additional 30 patients treated with the similar regimen of fluorouracil and RT provided evidence for the role of adjuvant therapy in resected pancreatic cancer

Gastrointestinal Tumor Study Group. Cancer 1987;59:2006–2010
Kalser MH et al. Arch Surg 1985;120:899–903

- The benefit of gemcitabine monotherapy was demonstrated by Oettle et al. This multicenter study randomized 368 patients following surgery to observation or adjuvant therapy starting 6 weeks after surgical resection:

  Gemcitabine 1000 mg/m² per dose administered intravenously in 0.9% NS, over 30 minutes for 3 doses on days 1, 8, and 15 every 4 weeks for 6 months (total dosage/4-week cycle = 3000 mg/m²)
- Therapy with gemcitabine was well tolerated. The primary endpoint of disease-free survival was significantly improved in the treatment group (13.4 months vs. 6.9 months, $P < 0.001$); the median survival (22.1 vs. 20.2 months) was similar in both groups

Oettle H et al. JAMA 2007;297:267–277

- The European Study Group for Pancreatic Cancer (ESPAC 1, 2, and 3) evaluated the role of fluorouracil, gemcitabine, and RT as adjuvant therapy and support the role of chemotherapy alone as adjuvant therapy. The role of RT and the detrimental effect of RT seen in these studies have been controversial as a result of the lack of quality control and central review. ESPAC-3 (n = 1088) compared gemcitabine to fluorouracil as adjuvant therapy. The median survival for both groups was approximately 23 months. However, the safety profile favors gemcitabine as the preferred regimen for adjuvant therapy

(*continued*)

Expert Opinion (*continued*)

Therapy of Patients with Metastatic Pancreatic Cancer and "Good" Performance Status—*First line regimen*

In this group are patients with an ECOG performance status of 0 or 1 and with minimal cancer-related symptoms. Meta-analyses have indicated that patients with a good performance status can benefit from combination therapy with gemcitabine regimens. Two regimens are considered to have activity and *are recommended in first line*:

- ***nab*-Paclitaxel + gemcitabine:** MPACT was a large, international study performed at community and academic centers. ***nab*-Paclitaxel + gemcitabine** was superior to gemcitabine monotherapy across all efficacy endpoints, had an acceptable toxicity profile. *nab*-Paclitaxel + gemcitabine is a new option for the treatment of metastatic pancreatic cancer that will now be studied in the adjuvant and locally advanced setting
- **FOLFIRINOX:** As compared with gemcitabine, **FOLFIRINOX [oxaliplatin + irinotecan + fluorouracil + leucovorin]** was associated with a survival advantage and had increased toxicity. FOLFIRINOX is an option for the treatment of patients with metastatic pancreatic cancer and a good performance status [younger than 76 years and who have a good performance status (ECOG 0 or 1), no cardiac ischemia, and normal or nearly normal bilirubin levels]

Therapy of Patients with Metastatic Pancreatic Cancer and "Good" Performance Status—*Second line regimen*

In second line one can consider the alternate regimen of the two above or the **OFF regimen**

Conroy T et al. N Engl J Med 2011;364:1817–1825
Pelzer et al. European J Cancer 2011;47:1676–1681
Von Hoff DD et al. J Clin Oncol 2011;29:4548–4554
Von Hoff et al. J Clin Oncol 31, 2013(Suppl; abstr 4005)

- An intergroup study (RTOG 97-04) provides support for concurrent chemoradiation as adjuvant therapy. This study provided central review and quality assurance for RT. Regine et al., randomly assigned patients (n = 451) to 1 of 2 chemotherapy regimens following a pancreatectomy for 3 weeks prior to chemoradiation therapy, and then for an additional 12 weeks, starting 3–5 weeks after completing chemoradiation:

  Pre-chemoradiation regimens

  - **Group 1:**
    Fluorouracil 250 mg/m² per day in 25–500 mL 0.9% NS or D5W administered intravenously over 10--30 minutes, daily for 3 weeks (total dosage/3-week course = 5250 mg/m²)
  - **Group 2:**
    Gemcitabine 1000 mg/m² per dose diluted with 0.9% NS to concentrations as low as 0.1 mg/mL administered intravenously over 30 minutes once weekly for 3 weeks (total dosage/3-week course = 3000 mg/m²)

  During chemoradiation

  - **Groups 1 and 2:**
    Fluorouracil 250 mg/m² per day in 25–1000 mL 0.9% NS or D5W administered by continuous intravenous infusion over 24 hours, daily throughout radiation therapy

  Post-chemoradiation regimens:

  - **Group 1:**
    Fluorouracil 250 mg/m² per day in 25–500 mL 0.9% NS or D5W administered intravenously over 10–30 minutes, daily for 4 consecutive weeks (28 days) every 6 weeks for two 6-week cycles (total dosage/6-week cycle = 7000 mg/m²)
  - **Group 2:**
    Gemcitabine 1000 mg/m² per dose diluted with 0.9% NS to concentrations as low as 0.1 mg/mL, administered intravenously over 30 minutes once weekly for 3 consecutive weeks every 4 weeks for three 4-week cycles (total dosage/4-week cycle = 3000 mg/m²)
- Chemoradiation was given for a total dose of 50.4 Gy with fluorouracil. On multivariate analysis, patients with pancreatic head tumors (n = 388) had a survival advantage when treated in the gemcitabine arm with median survival of 20.5 months and 3-year survival of 31% compared to 16.9 months and 22%, respectively, in the fluorouracil arm (P = 0.5). There were no differences in survival for the overall study population

Regine WF et al. JAMA 2008;299:1019–1026

(*continued*)

Expert Opinion (*continued*)

Patients who have positive margins following surgery have a poor outcome. In this group of patients who have "borderline resectable" cancer, preoperative chemoradiation could be administered with or without 2–4 months of systemic chemotherapy followed by pancreatic resection

Treatment for Metastatic Disease

Chemotherapy similar to treatment of patients with metastatic disease is preferred. Concurrent chemoradiation is also an option. Evaluate patients after 4–6 cycles of systemic therapy. Patients who continue to have disease confined to the pancreas may be considered for concurrent chemoradiation therapy. Continuous infusion fluorouracil or capecitabine administration with radiation to the pancreas is preferred. There is limited experience with concurrent radiation and gemcitabine and these regimens should be administered with caution

We evaluate patients for therapy based on either a "good" or "poor" performance status

Therapy of Patients with "Poor" Performance Status

Outcome and survival are poor for a patient with an ECOG performance status ≥2 with severe fatigue, rapid weight loss, and/or biliary obstruction. This group of patients may be considered for treatment with gemcitabine alone or gemcitabine and erlotinib. Palliative care with symptom management should also be discussed with the patient and family

- Gemcitabine may be administered over 30 minutes or at a fixed dose rate (10 mg/m² per minute)
- The addition of erlotinib to gemcitabine was demonstrated in a randomized phase III trial to improve survival and progression-free survival in advanced pancreatic cancer. In this phase III trial, a total of 569 patients were randomly assigned to receive gemcitabine with erlotinib or placebo:
  Gemcitabine 1000 mg/m² per dose diluted with 0.9% NS to concentrations as low as 0.1 mg/mL, administered intravenously over 30 minutes once weekly
  - *Cycle 1:* Gemcitabine was given on days 1, 8, 15, 22, 29, 36, and 43 during the initial 8-week cycle (total dosage = 7000 mg/m²)
  - *Subsequent cycles:* Gemcitabine was given on days 1, 8, and 15 every 4 weeks (total dosage/4-week cycle = 3000 mg/m²)
  - **Erlotinib** 100 mg/day or 150 mg/day orally, continually *or* placebo orally, continually
  - Most patients received erlotinib 100 mg/day, orally
- In the control arm of gemcitabine, the median survival was 5.91 months and 1-year overall survival was 17%. One-year survival was also greater with erlotinib plus gemcitabine (23% vs. 17%; P = 0.023). Patients who developed a skin rash following therapy with erlotinib had the best outcome and longest survival. The median survival for patients without a rash was 5.3 months (1-year survival = 16%) compared to 10.5 months (1-year survival 43%) for those who had a grade 2 + rash with treatment

Therapy of Patients with "Good" Performance Status

In this group are patients with an ECOG performance status of 0 or 1 and with minimal cancer-related symptoms. Meta-analyses have indicated that patients with a good performance status can benefit from combination therapy with gemcitabine regimens. Two new regimens are considered to have activity:

- ***nab*-Paclitaxel + gemcitabine:** MPACT was a large, international study performed at community and academic centers. ***nab*-Paclitaxel + gemcitabine** was superior to gemcitabine monotherapy across all efficacy endpoints, had an acceptable toxicity profile. *nab*-Paclitaxel + gemcitabine is a new option for the treatment of metastatic pancreatic cancer that will now be studied in the adjuvant and locally advanced setting
- **FOLFIRINOX:** As compared with gemcitabine, **FOLFIRINOX [oxaliplatin + irinotecan + fluorouracil + leucovorin]** was associated with a survival advantage and had increased toxicity. FOLFIRINOX is an option for the treatment of patients with metastatic pancreatic cancer and a good performance status [younger than 76 years and who have a good performance status (ECOG 0 or 1), no cardiac ischemia, and normal or nearly normal bilirubin levels]

ADJUVANT THERAPY REGIMEN

GEMCITABINE + RADIATION THERAPY (RTOG 97-04)

Regine WF et al. JAMA 2008;299:1019–1026

Pre-chemoradiation:
Gemcitabine 1000 mg/m² per dose diluted with 0.9% sodium chloride injection (0.9% NS) to concentrations as low as 0.1 mg/mL administer intravenously over 30 minutes once weekly for 3 consecutive weeks (total dosage/3-week course = 3000 mg/m²), *followed 1–2 weeks later by*
Chemoradiation therapy:
Radiation therapy for a total dose of 5040 cGy (28 fractions 5 days/week with a boost of 540 cGy) with
Fluorouracil 250 mg/m² per day in 25–1000 mL 0.9% NS or D5W administer by continuous intravenous infusion over 24 hours throughout radiation therapy, *followed 3–5 weeks later by*
Post-chemoradiation:
Gemcitabine 1000 mg/m² per dose diluted with 0.9% NS to concentrations as low as 0.1 mg/mL administer intravenously over 30 minutes once weekly for 3 consecutive weeks every 4 weeks for a total of 12 weeks (total dosage/4-week cycle = 3000 mg/m²)

Supportive Care
Emetogenic potential: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 451 patients (388 with pancreatic head tumors) with resected pancreatic adenocarcinoma who were randomized and 221 who received the study arm of gemcitabine and fluorouracil/RT. The control group received fluorouracil and fluorouracil/RT. The margin positive rate following surgery (R 1) was 34%. In patients with pancreatic head tumors there was an increase in survival, but this did not reach statistical significance (P = 0.5)

Toxicity (N = 221 Treated with Gemcitabine and Concurrent Chemoradiation)

Grade 3/4 Toxicity	Percentage (%)
Grade 3/4 hematologic	58
Grade 4 hematologic	14
Diarrhea	15
Stomatitis/mucositis	10
Nausea/vomiting	10

Comment: Grade 3/4 hematologic toxicity was higher in the gemcitabine arm than in the fluorouracil arm (58% vs. 9%, respectively). However, there was no difference in the incidence of febrile neutropenia or infection There was no difference in the ability to deliver chemotherapy (90% vs. 87%) or radiation therapy between the gemcitabine and fluorouracil groups (88% vs. 86%, respectively)

Treatment Modifications

Modifications for gemcitabine: see single-agent gemcitabine dosing

Burris HA et al. J Clin Oncol 1997;15:2403–2413

Concurrent chemoradiation dose modifications:
The following guidelines may be considered as Regine et al. did not specify modifications (Talamonti MS et al. J Clin Oncol 2000;18:3384–3389)
- Hold radiation therapy for grade 3/4 GI or grade 4 hematologic toxicity, and resume after toxicity resolves
- Dose reduce fluorouracil by 25% for grade 3 hematologic toxicity
- Hold fluorouracil in the case of grade 4 hematologic toxicity, grade 3/4 GI tract and other nonhematologic toxicity. Resume fluorouracil at a 25% reduced dose after toxicity resolves
- Hold fluorouracil for grade 2/3 hand-foot syndrome until symptoms resolve and resume with a 25% dose reduction

Efficacy

Pancreatic Head Tumors (N = 388)	Gemcitabine + Fluorouracil Arm	Fluorouracil Arm
Median survival	20.5 months	16.9 months
3-Year survival	31%	22%

Therapy Monitoring

1. *Every week:* CBC with differential
2. During the period of RT, monitor patients for toxicity every week
3. *Before each cycle of chemotherapy:* H&P, CBC, complete chemistry panel including electrolytes, liver function tests, and magnesium; CA19-9 level if initially elevated

Surveillance
1. H&P every 3–6 months for 2–3 years and then annually
2. At every visit, H&P, CBC, complete chemistry panel including electrolytes, liver function tests, and magnesium; CA19-9 level if initially elevated
3. CT scans for surveillance every 6 months for 2–3 years then annually

METASTATIC DISEASE REGIMEN

GEMCITABINE

Burris HA et al. J Clin Oncol 1997;15:2403–2413

Gemcitabine 1000 mg/m² per dose; administer by intravenous infusion in 50–250 mL 0.9% sodium chloride injection over 30 minutes on days 1, 8, and 15, every 28 days (total dosage/cycle = 3000 mg/m²)

- In the referenced trial, for the first cycle, patients received gemcitabine 1000 mg/m² once weekly for up to 7 weeks. Thereafter, gemcitabine was administered once weekly for 3 consecutive weeks out of every 4 weeks
- Single-agent gemcitabine given at the dose of 1500 mg/m² at the rate of 10 mg/min over 150 minutes is an alternative regimen

Tempero M et al. J Clin Oncol 2003;15:3402–3408

Supportive Care

Antiemetic prophylaxis

Emetogenic potential with gemcitabine: LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Persistent rash or flulike symptoms after gemcitabine:
Consider Dexamethasone 10 mg orally or intravenously before starting gemcitabine

Patient Population Studied

Study of 63 patients with locally advanced or metastatic pancreatic cancer not amenable to curative surgical resection treated with single-agent gemcitabine. Patients who had received previous chemotherapy were not eligible

Efficacy (N = 63)

Median survival	5.65 months
Survival rate at 12 months	18%
Clinical benefit response*	23.8%

**Clinical benefit response (CBR)* is a composite measurement of pain, performance status, and weight that was sustained more than 4 weeks in at least 1 parameter without the worsening in any other parameter. The median time to achieve CBR in gemcitabine-treated patients was 7 weeks and duration of benefit was 18 weeks

Note: In this pivotal phase III clinical trial, gemcitabine was compared in a randomized fashion with fluorouracil (600 mg/m² per week). The median survival in the fluorouracil arm was 4.41 months, survival rate at 12 months was 2%, and clinical benefit response was 4.8%

Therapy Monitoring

1. *Every week:* CBC with differential
2. *Before each cycle:* CBC with differential, serum electrolytes, creatinine, mineral panel, and LFT
3. *Response assessment:* CT scans every 2 months and CA19-9 monthly

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <1000/mm³ to 500/mm³ or platelets <99,000/mm³ to 50,000/mm³ on day of treatment	Reduce gemcitabine dosages by 25%
G ≥3 nonhematologic adverse event during the previous treatment cycle	
WBC <500/mm³ or platelet <50,000/mm³ on day of treatment	Delay chemotherapy for up to 2 weeks
Treatment delay >2 weeks for recovery from hematologic adverse event	Discontinue treatment

Adverse Events (N = 63)

WHO Grade (%)	Grade I	Grade II	Grade III	Grade IV
WBC	26	36	10	0

Nausea/vomiting	29	22	10	3

METASTATIC DISEASE REGIMEN

GEMCITABINE + ERLOTINIB

Moore MJ et al. J Clin Oncol 2007;25:1960–1966

Gemcitabine 1000 mg/m² per dose; administer by intravenous infusion in 50–250 mL 0.9% sodium chloride injection over 30 minutes on days 1, 8, and 15, every 28 days (total dosage/cycle = 3000 mg/m²)

- In the referenced trial, for the first cycle, patients received gemcitabine 1000 mg/m² once weekly for 7 consecutive weeks during an 8-week cycle. Thereafter, gemcitabine was administered once weekly for 3 consecutive weeks out of every 4 weeks

Erlotinib was administered orally 100 mg/day (n = 262) or 150 mg/day (n = 23), continually, until progression or intolerable toxicity

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is: ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially, then 2 mg orally every 2 hours during waking hours, plus **Loperamide** 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize patient for IV hydration

Persistent or severe diarrhea (G ≥3):

- Interrupt erlotinib treatment until symptoms resolve, then consider resuming at a decreased dose

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–178

Adverse Events for Gemcitabine and Erlotinib

Grade 3/4 Toxicity	Percentage (%)
Diarrhea	6
Fatigue	15
Any infection	17
Rash	6

Consider regimen for patients with ECOG performance status 0–2 and total bilirubin ≤ ULN or ≤1.8 mg/dL (≤30.8 µmol/L); ALT and AST ≤5× ULN

Therapy Monitoring

1. *Every week:* CBC with differential
2. *Before each cycle:* CBC, complete chemistry panel including electrolytes, liver function tests, and magnesium; CA19-9 level if initially elevated
3. *Response assessment:* Every 8 weeks with CT scans or earlier if clinically indicated; CA19-9 monthly

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <1000/mm³ to 500/mm³ or platelets <99,000/mm³ to 50,000/mm³ on day of treatment	Reduce gemcitabine dosages by 50%
WBC <500/mm³ or platelet <50,000/mm³ on day of treatment	Delay gemcitabine for up to 2 weeks
Patients with grade 4 granulocytopenia, thrombocytopenia, or nonhematologic toxicity during the previous treatment cycle	Reduce gemcitabine dosages by 25%

Erlotinib dose modifications

- Dose reductions should be made in 50-mg decrements
- Pulmonary symptoms: If acute onset (or worsening) of pulmonary symptoms (eg, dyspnea, cough, fever), interrupt treatment and evaluate for drug-induced interstitial lung disease; discontinue permanently with development of interstitial lung disease
- Severe skin reaction: Reduce dose or temporarily interrupt treatment

Patient Population Studied

A total of 569 patients were randomly assigned to receive erlotinib/placebo with gemcitabine. Locally advanced unresectable patients comprised 24% of the population. The majority received erlotinib at the dose of 100 mg/day

Efficacy (N = 569)

Variable	Gemcitabine + Erlotinib N = 285	Gemcitabine + Placebo N = 284
Median survival	6.24 months	5.91 months
1-Year survival	23%	17%

Of patients receiving gemcitabine+ erlotinib, 16% had at least 1 dose reduction compared to 5% in the control group

ADVANCED OR METASTATIC PANCREATIC CANCER REGIMEN

GEMCITABINE + *nab*-PACLITAXEL

Von Hoff DD et al. J Clin Oncol 2011;29:4548–4554
Von Hoff DD et al. J Clin Oncol 2013;31(Suppl; abstr 4005)

Paclitaxel protein-bound particles for injectable suspension (*nab*-paclitaxel) 125 mg/m² per dose intravenously once weekly for 3 doses on days 1, 8, and 15 every 28 days (total dosage/cycle = 375 mg/m²), followed by
Gemcitabine HCl 1000 mg/m² per dose intravenously in 50–250 mL 0.9% sodium chloride injection for 3 doses on days 1, 8, and 15 every 28 days (total dosage/cycle = 3000 mg/m²), *followed by:*

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information
(Filgrastim may be given according to institutional guidelines for the treatment of neutropenic fever or infections associated with neutropenia and for the prevention of febrile neutropenia in patients with an ANC <500/mm³. Patients not experiencing resolution of neutropenia within 21 days, despite uninterrupted filgrastim should discontinue therapy)

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information
(*Prophylaxis Against Sepsis:* At the first occurrence of fever ≥38.5°C [101.3°F] [regardless of ANC], institution of ciprofloxacin (500 mg orally, twice daily)—or amoxicillin/clavulanate [Augmentin, 500 mg orally, 2–3 times daily] in patients with allergy to fluoroquinolones—should be initiated. On their first visit, patients should be provided with enough ciprofloxacin [or the alternative antibiotic] for use at home, and they should be instructed to begin taking it when they first record a temperature of ≥38.5°C [101.3°F] [or if they feel they are developing a fever and a thermometer is not available]. They should also immediately contact their physician for guidance on where to go for blood counts to be evaluated for sepsis as soon as possible. Hospitalization or evaluation in the emergency room may be required depending on the clinical presentation)

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

(*continued*)

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Note

Interstitial Pneumonitis

Monitor patients carefully for signs and symptoms of pneumonitis (ie, episodes of transient or repeated dyspnea with unproductive persistent cough or fever) and, if observed, perform immediate clinical evaluation and timely institution of appropriate management (emphasizing the need for corticosteroids if an infectious process has been ruled out, as well as appropriate ventilation and oxygen support when required)

Treatment Modifications

Dose Adjustments on Day 1 of Each Treatment Cycle for Hematologic Toxicity

ANC		Platelets	Timing
≥1500/mm³	AND	≥100,000/mm³	Treat on time
<1500/mm³	OR	<100,000/mm³	Delay by 1 week intervals until recovery

Dose Levels

	nab-Paclitaxel (mg/m²)	Gemcitabine HCl (mg/m²)
Starting dose	125	1000
Dose level −1	100	800
Dose level −2	75	600

Dose Adjustments within a Treatment Cycle for Hematologic Toxicity

Day 8			Day 15		
Blood Counts	*nab*-Paclitaxel	Gemcitabine	Blood Counts	*nab*-Paclitaxel	Gemcitabine
ANC >1000/mm³ *and* platelets ≥75,000/mm³	100%		ANC >1000/mm³ *and* platelets ≥75,000/mm³	100%	
			ANC 500–1000/mm³ *or* platelets 50,000–74,999/mm³	Full dose (treat on time) and administer filgrastim*	
			ANC <500/mm³ *or* platelets <50,000/mm³	Hold and administer filgrastim*	
ANC 500–1000/mm³ *or* platelets 50,000–74,999/mm³	Decrease dose by 1 level (treat on time)		ANC >1000/mm³ *and* platelets ≥75,000/mm³	Return to previous dose level (treat on time) and administer filgrastim*	
			ANC 500–1000/mm³ *or* platelets 50,000–74,999/mm³	Same dose as day 8 (treat on time) and administer filgrastim*	
			ANC <500/mm³ *or* platelets <50,000/mm³	Hold and administer filgrastim*	
ANC <500/mm³ *or* platelets <50,000/mm³	Hold		ANC >1000/mm³ *and* platelets ≥75,000/mm³	Decrease day 8 dose by 1 level (treat on time) and administer filgrastim*	
			ANC 500–1000/mm³ *or* platelets 50,000–74,999/mm³	Decrease day 8 dose by 1 level (treat on time) and administer filgrastim*	
			ANC <500/mm³ *or* platelets <50,000/mm³	Hold and administer filgrastim*	

*Febrile patients (regardless of ANC) should have chemotherapy treatment interrupted. A full sepsis diagnostic work-up should be performed while continuing broad-spectrum antibiotics. If cultures are positive, guide antibiotic therapy by the sensitivity profile of the isolated organism. Patients with persisting fever after 3 weeks, despite uninterrupted antibiotic treatment, should discontinue therapy. Febrile neutropenic patients can also receive filgrastim, in addition to antibiotic treatment, to hasten resolution of their febrile neutropenia

(*continued*)

Treatment Modifications (*continued*)

Dose Adjustments on Day 1 of Each Treatment Cycle for Nonhematologic Toxicity and/or Dose Hold with Previous Cycle

Toxicity/Dose Held	*nab*-Paclitaxel + Gemcitabine Dose This Cycle
G0/1/2 toxicity	Same as day 1 previous cycle (except for G2 cutaneous toxicity where doses of gemcitabine and *nab*-paclitaxel should be reduced to next lower dose level)
G3 toxicity*	Decrease *nab*-paclitaxel and gemcitabine to next lower dose level*
G ≥3 peripheral neuropathy	Hold *nab*-paclitaxel treatment but continue gemcitabine administration if indicated. Resume *nab*-paclitaxel treatment at next lower dose level after the peripheral neuropathy improves to G ≤1
G4 toxicity	Hold therapy†
Dose held in 2 previous consecutive cycles	Decrease gemcitabine to next lower dose level and continue throughout the rest of treatment

*Except for cutaneous toxicity: If the toxicity only affects neuropathy, then only *nab*-paclitaxel should be reduced
†The decision as to which drug should be modified depends upon the type of nonhematologic toxicity seen and which course is medically most sound in the judgment of the physician

Dose Adjustments within a Treatment Cycle for Nonhematologic Toxicity

CTC Grade	Percent of Day 1 *nab*-Paclitaxel + Gemcitabine Dose
G1/2, G3 nausea/vomiting and alopecia	100%*
G3 (except G3 nausea/vomiting and alopecia)	Hold either 1 or both drugs until resolution to G ≤1. Then resume treatment at the next lower dose level
G ≥3 peripheral neuropathy	Hold *nab*-paclitaxel treatment but continue gemcitabine administration if indicated. Resume *nab*-paclitaxel treatment at next lower dose level after the peripheral neuropathy improves to G ≤1
G4	Hold therapy†

*Except for cutaneous toxicity: If the toxicity only affects neuropathy, then only *nab*-paclitaxel should be reduced
†The decision as to which drug should be modified depends upon the type of nonhematologic toxicity seen and which course is medically most sound in the judgment of the physician

Patient Population Studied

Patients with histologically or cytologically confirmed metastatic pancreatic ductal adenocarcinoma (PDA) who had not previously received treatment for metastatic disease. Prior adjuvant treatment with fluorouracil or gemcitabine administered as a radiation sensitizer during and up to 4 weeks after radiation therapy was allowed. If a patient received adjuvant therapy, tumor recurrence must have occurred >6 months after the last treatment. Patients had an ECOG PS of 0 or 1. Twenty, 44, and 3 patients received 100, 125, and 150 mg/m² *nab*-paclitaxel, respectively

ECOG, Eastern Cooperative Oncology Group; *nab*-paclitaxel, paclitaxel protein-bound particles for injectable suspension (albumin bound)

*Upper limit for normal range was <37 units/mL. Approximately 10–15% of patients with pancreatic cancer lack Lewis antigens and thus lack the ability to secrete CA19-9

MPACT Trial

A total of 861 patients with metastatic pancreatic ductal adenocarcinoma (PDA) and a Karnofsky performance status (KPS) ≥70 were randomized at 151 community and academic centers 1:1 to receive *nab*-paclitaxel 125 mg/m² + gemcitabine 1000 mg/m² days 1, 8, and 15 every 4 weeks or gemcitabine alone 1000 mg/m² weekly for 7 weeks followed by 1 week of rest (cycle 1) and then days 1, 8, and 15 every 4 weeks (cycle ≥2). The median age was 63 years (range: 27–88 years). KPS was 100 (16%), 90 (44%), 80 (32%), and 70 (7%). Patients had advanced disease with liver metastases (84%), ≥3 metastatic sites (46%), and CA19-9 ≥59 × upper limit of normal (46%)

Efficacy

Response Result	Gemcitabine 1000 mg/m² + *nab*-Paclitaxel 125 mg/m² (n = 44)		Gemcitabine 1000 mg/m² + *nab*-Paclitaxel 100, 125, or 150 mg/m² (n = 67)

*Improved to grade ≤1 in median 29 days, and 44% of patients resumed *nab*-Paclitaxel treatment

Von Hoff et al. J Clin Oncol 2013;31(Suppl; abstr 4005)

Treatment Monitoring

1. *Days 1, 8, and 15:* CBC with differential

ADVANCED OR METASTATIC PANCREATIC CANCER REGIMEN

OXALIPLATIN + IRINOTECAN + FLUOROURACIL + LEUCOVORIN (FOLFIRINOX)

Conroy T et al. N Engl J Med 2011;364:1817–1825

Oxaliplatin 85 mg/m² intravenously in 250 mL 5% dextrose injection (D5W) over 2 hours on day 1, every 2 weeks (total dosage/cycle = 85 mg/m²)

Note: Oxaliplatin must not be mixed with sodium chloride injection

Either: **(racemic) Leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m² intravenously in 25–500 mL D5W or 0.9% sodium chloride injection over 2 hours on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed 30 minutes after administration begins by:*

Irinotecan 180 mg/m² intravenously over 90 minutes in 500 mL D5W on day 1, 30 minutes after leucovorin (or levoleucovorin) administration begins, every 2 weeks (total dosage/cycle = 180 mg/m²), *followed by:*

(*bolus*) **Fluorouracil** 400 mg/m² by intravenous injection over 1–2 minutes after leucovorin (or levoleucovorin) and irinotecan administration are completed on day 1, every 2 weeks, *followed by:*

Fluorouracil 2400 mg/m² by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1 every 2 weeks (total dosage/cycle = 2800 mg/m²)

Important note: This regimen is difficult for patients. Thus, FOLFIRINOX is a first-line option for patients with metastatic pancreatic cancer who are younger than 76 years and who have a good performance status (ECOG 0 or 1), no cardiac ischemia, and normal or nearly normal bilirubin levels

Notes:

- Patients must be instructed in the use of loperamide as treatment for diarrhea, and must have a supply of this drug upon starting FOLFIRINOX
- Filgrastim is not recommended as primary prophylaxis, but it could be considered for high-risk patients
- The dose of leucovorin is not modified for toxicity, but is omitted if fluorouracil is omitted. Once a fluorouracil dose is decreased, it is not re-escalated

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

(*continued*)

(*continued*)

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Event	Delay of Cycle	Dosage Reductions		
		Irinotecan	Oxaliplatin	Fluorouracil
First occurrence of ANC <1500/mm^3 on day 1	Hold treatment up to 2 weeks until granulocytes ≥1500/mm^3 In case of nonrecovery >2 weeks delay, stop treatment	Reduce dosage to 150 mg/m^2	Do not reduce dosage	Delete bolus fluorouracil
Second occurrence of ANC <1500/mm^3 on day 1		Maintain the dosage at 150 mg/m^2	Reduce the dosage to 60 mg/m^2	Continue without bolus fluorouracil
Third occurrence of ANC <1500/mm^3 on day 1	Discontinue treatment			
First occurrence of platelets <75,000/mm^3 on day 1	Hold treatment up to 2 weeks until platelets ≥75,000/mm^3. In case of nonrecovery >2 weeks delay, stop treatment	Do not reduce dosage	Reduce the dosage to 60 mg/m^2	Reduce both bolus and CI by 25% of original dosages
Second occurrence of platelets <75,000/mm^3 on day 1		Reduce the dosage to 150 mg/m^2	Maintain the dosage at 60 mg/m^2	Continue both bolus and CI at 75% of original dosages
Third occurrence of platelets <75,000/mm^3 on day 1	Discontinue treatment			
First occurrence febrile neutropenia or G4 neutropenia >7 days or infection with concomitant G3/4 neutropenia		Reduce the dosage to 150 mg/m^2	Do not reduce dosage	Delete bolus fluorouracil
Second occurrence febrile neutropenia or G4 neutropenia >7 days or infection with concomitant G3/4 neutropenia		Maintain the dosage at 150 mg/m^2	Reduce the dosage to 60 mg/m^2	Continue without bolus fluorouracil
		Note: Consider the use of filgrastim for recurrent G3/4 neutropenia despite a first-dose reduction or after febrile neutropenia		

(*continued*)

Treatment Modifications (*continued*)

Event	Delay of Cycle	Dosage Reductions		
		Irinotecan	Oxaliplatin	Fluorouracil
Third occurrence febrile neutropenia or G4 neutropenia >7 days or infection with concomitant G3/4 neutropenia	Discontinue treatment			
First occurrence G3/4 thrombocytopenia		Do not reduce dosage	Reduce the dosage to 60 mg/m²	Reduce both bolus and CI fluorouracil by 25% of the original dosages
Second occurrence G3/4 thrombocytopenia		Reduce the dosage to 150 mg/m²	Maintain the dosage at 60 mg/m²	Continue with bolus fluorouracil at 75% of the original dosage and reduce CI by an additional 25–50% of the original dosage
Third occurrence G3/4 thrombocytopenia	Discontinue treatment			
First occurrence G3/4 diarrhea, or diarrhea + fever and/or diarrhea + G3/4 neutropenia		Reduce the dosage to 150 mg/m². Do not retreat with irinotecan until recovered from diarrhea without loperamide for at least 24 hours	Do not reduce dosage	Delete bolus fluorouracil
Second occurrence G3/4 diarrhea, or diarrhea + fever and/or diarrhea + G3/4 neutropenia		Maintain the dosage at 150 mg/m². Do not retreat with irinotecan until recovered from diarrhea without loperamide for at least 24 hours	Reduce the dosage to 60 mg/m²	Continue without bolus fluorouracil and reduce the CI by 25% of the original dosage
Third occurrence G3/4 diarrhea or diarrhea + fever and/or diarrhea + G3/4 neutropenia	Discontinue treatment			
Diarrhea ≥48 hours despite high doses of loperamide		No systematic reduction of the irinotecan, oxaliplatin, or fluorouracil doses after complete recovery, unless G3/4 diarrhea, or diarrhea + fever, and/or concomitant neutropenia G3/4		
G3/4 mucositis or "hand-foot" syndrome		Do not reduce dosage	Do not reduce dosage	Reduce both bolus and CI fluorouracil by 25% of the original dosages
Angina pectoris or of myocardial infarction		Do not reduce dosage	Do not reduce dosage	Discontinue fluorouracil
Any toxicity G ≥2, except anemia and alopecia		Consider reducing the dosage to 150 mg/m²	Consider reducing the dosage to 60 mg/m²	Consider reducing both bolus and CI fluorouracil by 25% of the original dosages
Total bilirubin ≥1.5× ULN		Do not administer	Do not reduce dosage	Do not reduce dosage

CI, continuous infusion; ULN, upper limit of normal of laboratory value

Efficacy

Objective Responses in the Intention-to-Treat Population

95% CI, 95% confidence interval; HR, hazard ratio; OS, overall survival; PFS, progression-free survival
*FOLFIRINOX = oxaliplatin + irinotecan + fluorouracil + leucovorin
†Defined as percentage of patients who had a complete response or partial response
‡Defined as the percentage of patients who had a complete response, partial response, or stable disease
§Synchronous metastases, albumin level <3.5 g/dL (<35 g/L), hepatic metastases, and age >65 years were identified as independent adverse prognostic factors for overall survival

Patient Population Studied

Patients with histologically and cytologically confirmed metastatic pancreatic adenocarcinoma not previously treated with chemotherapy. Other inclusion criteria were an Eastern Cooperative Oncology Group (ECOG) performance status score of 0 or 1 and adequate bone marrow, liver function (total bilirubin ≤1.5 times the upper limit of normal range), and renal function. Exclusion criteria included an age ≥76 years and previous radiotherapy for measurable lesions

Patient Characteristics

Age (years)	
Median	61
Range	25–76

Vomiting	24/166 (14.5)	14/169 (8.3)	NS†
Diarrhea	21/165 (12.7)	3/169 (1.8)	<0.001
Sensory neuropathy	15/166 (9.0)	0/169	<0.001
↑ Alanine aminotransferase	12/165 (7.3)	35/168 (20.8)	<0.001
Thromboembolism	11/166 (6.6)	7/169 (4.1)	NS†

*Events listed are those that occurred in more than 5% of patients in either group
†NS denotes not significant

Note: Despite the higher incidence of adverse events associated with the FOLFIRINOX regimen, a significant increase in the time to definitive deterioration of the quality of life was observed in the FOLFIRINOX group as compared with the gemcitabine group

Treatment Monitoring

1. *At start of every cycle:* medical history, complete physical examination, CBC with differential and serum electrolytes and LFTs
2. *Weekly:* CBC with differential

ADVANCED OR METASTATIC PANCREATIC CANCER REGIMEN—SECOND LINE

OXALIPLATIN + FOLINIC ACID (Leucovorin) + FLUOROURACIL (OFF) + BSC (Best Supportive Care)

Pelzer U et al. Eur J Cancer 2011;47:1676–1681

Days 1, 8, 15, and 22 during 6-week cycles:
Leucovorin calcium 200 mg/m² per dose intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes for 4 doses on days 1, 8, 15, and 22, every 6 weeks (total dosage/6-week cycle = 800 mg/m²), *followed by:*
Fluorouracil 2000 mg/m² per dose by continuous intravenous infusion in 100–1000 mL 0.9% NS or D5W over 24 hours for 4 doses on days 1, 8, 15, and 22, every 6 weeks (total dosage/6-week cycle = 8000 mg/m²)

Days 8 and 22 during 6-week cycles:
Oxaliplatin 85 mg/m² per dose administer intravenously in 250 mL D5W over 2–4 hours for 2 doses prior to leucovorin and fluorouracil on days 8 and 22 (total dosage/6-week cycle = 170 mg/m²)

Note: Oxaliplatin must not be mixed with sodium chloride injection. If leucovorin or fluorouracil are diluted in solutions containing sodium chloride injection and administered through the same tubing or vascular access device as oxaliplatin, the fluid pathway should be flushed with D5W before administering oxaliplatin

Best supportive care (BSC) according to current palliative care guidelines includes:
- Adequate pain management
- Therapy of infection
- Biliary stent intervention if needed
- Social support and on-demand psychooncologic intervention
- Nutrition consultation/intervention

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with fluorouracil and leucovorin is **LOW***
*Emetogenic potential on days with oxaliplatin is **MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Wadler S et al. J Clin Oncol 1998;16:3169–3178

Dose Modifications

Fluorouracil and Oxaliplatin	
Any G2/3/4 nonhematologic toxicity	Delay start of next cycle until the severity of all toxicities are G ≤1
ANC ≤1500/mm^3 or platelet count ≤100,000/mm^3	Delay start of next cycle until ANC >1500/mm^3 and platelet count >100,000/mm^3
G3/4 Nonneurologic	Reduce fluorouracil and oxaliplatin dosages by 20%
G3/4 ANC	Reduce oxaliplatin dosage by 20%
Persistent (≥14 days) paresthesias	Reduce oxaliplatin dosage by 20%
Temporary (7–14 days) painful paresthesias	
Temporary (7–14 days) functional impairment	
Persistent (≥14 days) painful paresthesias	Discontinue oxaliplatin
Persistent (≥14 days) functional impairment

Efficacy

	OFF	Best Supportive Care	Statistics
Median survival with therapy	4.82 months (95% CI: 4.29–5.35)	2.30 months (95% CI: 1.76–2.83)	HR 0.45 (95% CI: 0.24–0.83) p = 0.008
Median survival since diagnosis	9.09 months (95% CI: 6.97–11.21)	7.90 months (95% CI: 4.95–10.84)	HR 0.50 (95% CI: 0.27–0.95) p = 0.031

Treatment Monitoring

1. *At start of every cycle:* Medical history, complete physical examination, CBC with differential and serum electrolytes and LFTs
2. *Weekly:* CBC with differential

Patient Population Studied

Patients with histologically confirmed advanced pancreatic cancer whose disease had progressed during first-line gemcitabine therapy. Patients had a Karnofsky performance status (KPS) >60% and good hepatic function, defined as AST (aspartate aminotransferase) and ALT (alanine aminotransferase) <2.5× the upper normal limit (UNL), or, in case of liver metastasis <5× UNL

Total number of patients	23
Sex, male-to-female ratio	14/9
Median age (range)	60 (38–76)
Karnofsky Performance Status 70–80%	12
Karnofsky Performance Status 90–100%	11
Gemcitabine first-line therapy	23/23
PFS on gemcitabine <3 months	6
PFS on gemcitabine 3–6 months	10
PFS on gemcitabine >6 months	7
M0/M1 disease	6/17

Toxicity

Toxicity (NCI CTC 2.0)				
	G1	G2	G3	G4
	(Number of Patients)			
Hemoglobin	5	1	1	0
Leucopenia	4	0	0	0
Thrombocytopenia	2	2	0	0
Diarrhea	5	1	2	0
Nausea/emesis	6	4	1	0
Paresthesia	10	1	0	0

Mean (range) cumulative doses administered:
Oxaliplatin 281 mg (0–850 mg)
Folinic acid 1591 mg (200–8000 mg)
Fluorouracil 15, 630 mg (2000–20,000 mg)

30. Pancreatic Endocrine Tumors

Sara Ekeblad, MD, PhD and Britt Skogseid, MD, PhD

Epidemiology

Incidence: 1/100,000
~85% sporadic; ~15% hereditary, for example, multiple endocrine neoplasia (MEN1), von Hippel-Lindau disease
Median age: 53–57 years
Male to female ratio: 0.8--1.3:1

Ekeblad SB et al. Clin Cancer Res 2008;14:7798–7803
Fischer L et al. Br J Surg 2008;95:627–635

Tomassetti PD et al. Ann Oncol 2005;16:1806–1810

Pathology

WHO classification: Pancreatic endocrine tumors

1. Well-differentiated *neuroendocrine tumor* (20–35%): no gross invasion
   - *Benign:* no angio- or perineural invasion, size <2 cm, <2 mitoses/10 high-power fields (HPF), <2% of cells Ki67-positive
   - *Of uncertain behavior:* angio- and/or perineural invasion and/or >2 cm and/or 2–10 mitoses/10 HPF and/or >2% of cells Ki67-positive
2. Well-differentiated *neuroendocrine carcinoma* (51–71%): gross local invasion and/or metastases
3. Poorly differentiated *neuroendocrine carcinoma* (9–21%): >10 mitoses/10 HPF

Functional status:
Nonfunctioning: 59–76%
Insulinoma: 8–17%
Gastrinoma: 10–14%
Glucagonoma: 1–6%
VIPoma: 2–5%

Ekeblad SB et al. Clin Cancer Res 2008;14:7798–7803
Fischer L et al. Br J Surg 2008;95:627–635
Pape U-F et al. Cancer 2008;113:256–265
Rindi G, Klöppel G. Neuroendocrinology 2004;80 (Suppl 1):12–15

Work-up

Radiology

1. Body CT or MRI
2. Somatostatin receptor scintigraphy: Uses *radioactive octreotide*, a drug similar to somatostatin that attaches to tumor cells that have somatostatin receptors
3. Positron emission tomography (PET) scan (in selected cases)
   - [^{11}C]5-hydroxy-L-tryptophan (5-HTP) PET for well-differentiated tumors
   - Fluorodeoxyglucose (FDG) PET for poorly differentiated tumors
4. Endoscopic ultrasound
5. Intraoperative ultrasound
   - To localize small tumors not visualized by other modalities but suspected because of biochemical findings
   - To localize multiple tumors in MEN1 patients

Biochemistry

1. In all patients with suspected pancreatic endocrine tumor
   - Fasting levels of:
     - insulin, proinsulin, blood glucose
     - gastrin
     - glucagon
     - pancreatic polypeptide
     - vasoactive intestinal peptide (VIP)
     - chromogranin A
2. If insulinoma is suspected (high fasting insulin or symptoms of hypoglycemia):
   - 72-hour fast with measurements of insulin, proinsulin, and plasma glucose
   - Consider differential diagnoses, for example, measurement of sulfonylurea in blood to exclude abuse of oral hypoglycemic drugs

(*continued*)

Work-up (*continued*)

3. If gastrinoma is suspected (high fasting gastrin in the absence of treatment with proton pump inhibitors, multiple ulcers, and/or steatorrhea):
   - Measure gastrin after *secretin stimulation test* (after withdrawal of proton pump inhibitors, ideally for 1 week)
   - Measure gastric pH together with fasting gastrin
4. If ectopic Cushing syndrome is suspected to be caused by a pancreatic tumor:
   - Measure 24-hour urine free cortisol excretion, *or* free cortisol to creatinine ratio
     A ratio of cortisol >95 mcg per gram of creatinine helps confirm hypercortisolism
   - Measure adrenocorticotropic hormone (ACTH) and corticotropin-releasing factor (CRF)

Biopsies

1. If possible, radiologically verified tumors should be biopsied under ultrasound guidance
2. Ideally, biopsy specimens should be evaluated by pathologists knowledgeable in endocrine pathology and stained for:
   - *General markers for pancreatic endocrine tumors:* Chromogranin A, synaptophysin
   - *Specific hormones:* Insulin, gastrin, glucagon, VIP, pancreatic polypeptide
   - *Markers of proliferation:* Ki67

MEN1 investigation

1. If MEN1 is suspected (family history, hyperparathyroidism)
   - Measure serum calcium, PTH, prolactin
   - Perform genetic testing

Staging

Stage	Location/Size/Extension	Percent of Cases
I	Limited to pancreas, <2 cm	5–31
IIa	Limited to pancreas, 2–4 cm	8–9
IIb	Limited to pancreas, >4 cm, *or* Invading duodenum or bile duct	5–7
IIIa	Invading adjacent organs (stomach, spleen, colon, adrenal gland), *or* Invading the wall of large vessels (celiac axis or superior mesenteric artery)	3–8
IIIb	Regional lymph node metastasis	14–15
IV	Distant metastasis	29–60

Ekeblad SB et al. Clin Cancer Res 2008;14:7798–7803
Fischer L et al. Br J Surg 2008;95:627–635
Pape U-F et al. Cancer 2008;113:256–265
Rindi G, Klöppel G. Virchows Arch 2006;449:395–401

Survival

5-Year: 55–64%
10-Year: 44%
Median survival: 90–99 months

Stage	Mean Survival
I	231 months (≈19 years)
IIa	222 months (≈18.5 years)
IIb	153 months (≈13 years)
IIIa	94 months (≈8 years)
IIIb	133 months (≈11 years)
IV	76 months (≈6 years)

Expert Opinion

Pancreatic endocrine tumors are rare, and there is a lack of solid evidence on treatment and outcomes. The following is our view of their management, based on available evidence and many years of clinical experience

Diagnosis and work-up

1. Always measure hormone levels if symptoms of a functioning tumor occur or a pancreatic mass is demonstrated
2. Obtain a CT scan if hormone levels are elevated
3. Obtain somatostatin receptor scintigraphy (radioactive octreotide scan) or 5-HTP PET if unclear
4. Patient history: always probe for family history, history of kidney stones, and history of hyperparathyroidism (MEN1)
5. If MEN1 is suspected, discuss performing genetic testing
6. For known MEN1 carriers, perform annual biochemical screening beginning in adolescence. CT and/or 5-HTP PET if hormone levels are elevated
7. Radiologically visualized tumor: biopsy if radical surgery seems impossible

Surgery

1. Preferably performed by experienced endocrine surgeon at a high-volume center
2. Radical surgery of tumors that can be demonstrated by imaging
3. For tumors that can only be detected biochemically, if fully confident of the analyses, perform a surgical exploration. If a tumor is identified, proceed to resection if possible
4. Aim for pancreas-preserving surgery. If MEN1, distal pancreatectomy in combination with enucleation of lesions in the head of the pancreas are preferable. In addition, consider duodenotomy in case of MEN1 gastrinoma
5. Use intraoperative ultrasound to localize possible additional tumors or very small functioning tumors (especially important for MEN1 tumors)
6. If there is evidence of disease dissemination, consider:
   - Radiofrequency ablation of liver metastases
     - Useful for limited numbers of liver metastases
     - One study showed 45% of patients rendered tumor-free with relatively few complications (Eriksson J et al. World J Surg 2008;32:930–938)
     - Metastases usually recur, but radiofrequency ablation can be performed repeatedly
     - Can alleviate hormonal symptoms
   - Liver embolization
     - Useful if there are a larger number of liver metastases than can be treated with radiofrequency ablation
     - Lessens tumor burden in many patients
     - Can alleviate hormonal symptoms

Systemic treatment

Treat inoperable tumors at once; do not wait for tumor progression to initiate treatment

1. Streptozocin + fluorouracil or streptozocin + doxorubicin have long been considered is the first choice for patients with *well-differentiated tumors*
2. Carboplatin + etoposide is effective, and, generally, the first choice in patients with *poorly differentiated carcinomas*
3. Temozolomide used as second-line treatment after the combinations mentioned above, or for patients who cannot tolerate more intensive chemotherapy
   - Easy to use for the patient as it is taken orally; thus, it can easily be taken in an outpatient setting
   - Test tumor material for O_6-methylguanine-methyltranferase, low levels of which might predict a favorable response to temozolomide
4. Two additional options for patients with well and moderately differentiated tumors include sunitinib malate and everolimus. There is no consensus on whether these agents should be used before or after cytotoxic chemotherapy regimens such as streptozocin + fluorouracil
5. Somatostatin analogs should be used to alleviate hormonal symptoms, and might possibly also have antitumor effects, although this is still unclear. Somatostatin analogs can be used in combination with chemotherapy
6. Radionuclide-tagged somatostatin analogs (^{177}Lu-DOTA^0, Tyr^3) are increasingly used although only in a trial setting
   - A recent study showed a 42% response rate with an acceptable safety profile

(*continued*)

Expert Opinion (*continued*)

Supportive care:
Regardless of the therapy used, attention should be given to symptom management as many patients present with debilitating symptoms for which amelioration can significantly improve the quality of their lives:

- *Gastric hyperacidity (patients with a diagnosis of gastrinoma):*

  Omeprazole 40–60 mg per day orally, or an equivalent **proton pump inhibitor** or **histamine (H_2) receptor antagonist** may be used
- *Steatorrhea:*

  Consider supplementation with **pancreatic enzymes** whenever steatorrhea or changes in bowel habits suggest malabsorption
- *Diarrhea*:*

  Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
  Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
  Loperamide 4 mg; administer orally every 4 hours during hours of sleep
  - Continue for at least 12 hours after diarrhea resolves
  - Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
  - Rehydrate orally with fluids and electrolytes during a diarrheal episode
  - If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Tincture of opium: Doses are individually titrated. Begin with 2–4 drops mixed in water; administer orally 2–3 times per day, and titrate by decreasing or increasing the number of drops per dose as needed
Octreotide 50–200 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Diarrhea in patients who have undergone ileocecal resection:

Cholestyramine 4 g/dose; administer orally for 2–6 doses per day (up to 24 g/day)

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg; administer orally every 12 hours) if absolute neutrophil count is <500/mm^3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

REGIMEN

SOMATOSTATIN ANALOGS
OCTREOTIDE ACETATE

Arnold R et al. Gut 1996;38:430–438

Starting dose: **Octreotide acetate** 50 mcg; administer by subcutaneous injection 3 times daily for 3 days

Followed by: **Octreotide acetate** 100 mcg; administer by subcutaneous injection 3 times daily for 3 days

Followed by: **Octreotide acetate** 200 mcg; administer by subcutaneous injection 3 times daily continually, starting on day 7

Duration of treatment: Treatment is continued indefinitely

Supportive Care

Supplemental therapy for all somatostatin analogs: Pancreatic enzymes to avoid steatorrhea. Individualize dosage by giving the number of tablets or capsules that optimally minimize steatorrhea

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Treatment Modification
Steatorrhea	Increase dose of pancreatic enzyme supplement to 3 capsules with every meal

Toxicity

	All Grades
Diarrhea	34%
Flatulence	27%
Pain at injection site	27%
Vomiting	11%
Steatorrhea	8%
Hyperglycemia	3%
Gall stones	2%
Septicemia	1%

Patient Population Studied

- One-hundred three patients with gastroenteropancreatic neuroendocrine tumors given somatostatin analogs in a multicenter phase II trial
- Patients with functional or nonfunctional, poorly differentiated, intermediate or small cell carcinoma with high-grade malignant behavior were not included

Efficacy (N = 52)

- No objective tumor regression was seen
- Of patients with progressive pancreatic endocrine tumor, 28% had stabilization of tumor growth for ≥3 months

Tumor Growth in 52 Patients with Confirmed Progression Before Treatment

	Responses Reassessed During Months 6–12			
Responses at Month 3	Death	Progression	Stable Disease	Regression
Death (8)	8			
Progression (30)	11	14	5	0
Stable disease (14)	3	4	7	0
Regression (0)	0	0	0	0
Total (52)	22	18	12	0

Response to octreotide occurred in 19 patients according to the study protocol. WHO criteria used. However, tumors growing slowly but continuously with progression of ≤25% within 3 months were also judged as "progression" if progression ≥25% occurred within 12 months

Response = stable disease or decrease in tumor growth after confirmed progression before treatment, or decrease in tumor growth after stable disease within the pretreatment period, if lasting for at least 3 months

(*continued*)

Efficacy (N = 52) (*continued*)

Effect of Octreotide on Flushing, Diarrhea, and Hormone Secretion in Patients with Functional Endocrine GEP Tumors

Symptoms	Normalization	Improvement >50%	No Change	Worse
Diarrhea*				
Month 3 (n = 28)	32.1%	32.1%	21.5%	14.3%
Month 12 (n = 20)	45%	40%	5%	10%
Flushing*				
Month 3 (n = 40)	35%	40%	22.5%	2.5%
Month 12 (n = 27)	44.4%	40.8%	11.1%	3.7%
Hormone secretion				
Month 3 (n = 61)	11.5%	29.5%	34.4%	24.6%
Month 12 (n = 39)	5.1%	28.2%	38.5%	28.2%

GEP tumors, gastroenteropancreatic neuroendocrine tumors
*Patients with carcinoid syndrome, patients with functional tumors

Therapy Monitoring

1. *Every 3 months:* Complete history and physical examination
2. *Every 3–6 months:* Conventional imaging (CT, MRI, or ultrasound), serum electrolytes and serum glucose
3. *Every year:* Somatostatin receptor scintigraphy (OctreoScan Kit for the Preparation of Indium In-111 Pentetreotide; Mallinckrodt Inc., St. Louis, MO) is controversial
4. *New symptoms:* Somatostatin receptor scintigraphy (OctreoScan)

REGIMEN

LONG-ACTING SOMATOSTATIN ANALOGS

Kvols LK et al. N Engl J Med 1986;315:663–666
Öberg K et al. Ann Oncol 2004;15:966–973

Octreotide acetate injection 100–500 mcg per dose subcutaneously 2 or 3 times daily, doubling the dose at 3- to 4-day intervals until maximum control of symptoms is achieved

or

Octreotide acetate for injectable suspension 10–30 mg per dose intragluteally every 4 weeks (avoid intramuscular injection into the deltoids)

or

Lanreotide acetate (powder for suspension for injection) 30 mg per dose intramuscularly every 10–14 days (not available in the United States)

Supportive Care

Supplemental therapy for all somatostatin analogs: Pancreatic enzymes to avoid steatorrhea. Individualize dosage by giving the number of tablets or capsules that optimally minimize steatorrhea

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Primary symptomatic treatment in 25 patients with hormonally active tumors

Efficacy (N = 25)

(Octreotide 150 mcg/dose 3 times daily; 18 months' follow-up)

Biochemical response*	72%
Biochemical stable disease	28%
Tumor size stable (n = 13)	100%
Symptomatic relief†	76%

*>50% decrease in 24-hour urinary 5-HIAA
†>50% decrease in flushing and diarrhea

Kvols LK et al. N Engl J Med 1986;315:663–666

Toxicity (N = 25)

Steatorrhea*,†	Frequent (~66%)
Loose stools†	Common
Nausea†	Common
Abdominal cramps†	Common
Flatulence†	Common
Hyperglycemia‡/hypoglycemia	<10%
Gallbladder stone/sludge	50%
Bradycardia	<2%
Pain/erythema at injection site	Occasional
Gastric atony	Very rare

*Occurs frequently unless pancreatic enzyme supplements are administered. Etiology is presumed to be transient inhibition of pancreatic exocrine function and malabsorption of fat
†Starts within hours of the first subcutaneous injection and usually subsides spontaneously within the first few weeks of treatment
‡From transient inhibition of insulin secretion

Kvols LK et al. N Engl J Med 1986;315:663–666
Öberg K et al. Ann Oncol 2004;15:966–973

Treatment Modifications

(Patients Receiving Octreotide Acetate for Injectable Suspension or Lanreotide Acetate)

Escape from antisecretory response	Administer octreotide acetate injection 100–500 mcg per dose subcutaneously 2 or 3 times daily. Increase dose or reduce interval between doses of the long-acting preparation as needed
Steatorrhea	Increase dose of pancreatic enzyme supplement to 3 capsules with every meal

Therapy Monitoring

1. *Every 3 months:* Complete history and physical examination
2. *Every 3–6 months:* Conventional imaging (CT, MRI, or ultrasound), serum electrolytes, and serum glucose
3. *Every year:* Somatostatin receptor scintigraphy (OctreoScan Kit for the Preparation of Indium In-111 Pentetreotide; Mallinckrodt Inc., St. Louis, MO) is controversial
4. *New symptoms:* Somatostatin receptor scintigraphy (OctreoScan)

Notes

1. Performing an OctreoScan provides information about the somatostatin receptor status of the patient's tumor and should be performed before treatment with a somatostatin analog is initiated. Patients with receptor-positive tumors more frequently respond to such treatment than those with receptor-negative tumors
2. Because of adverse events, administration of the immediate-release formulation is recommended before administration of the intramuscular depot formulation
3. Patients should begin therapy with octreotide acetate injection subcutaneously for 3–7 days to test for tolerability before receiving a long-acting formulation (octreotide acetate for injectable suspension or lanreotide acetate) intramuscularly
4. Increase the dosage of the short-acting octreotide acetate injection until control of symptoms is achieved by doubling the dosage at 3- to 4-day intervals
5. Patients who are considered to be "responders" to the drug and who tolerate the short-acting formulation can then receive octreotide acetate for injectable suspension or lanreotide acetate
6. The subcutaneous injections should be continued for at least 14 days after the start of the long-acting formulation to allow time for therapeutic levels to be achieved
7. Conversion to the long-acting formulation provides greater patient convenience. If the dose of the short-acting formulation was 200–600 mcg per day, begin with a 20-mg dose of the long-acting formulation. If the dose of the short-acting formulation was 750–1500 mcg per day, begin with a 30-mg dose of the long-acting formulation
8. Supplementary ("rescue") administration of the short-acting octreotide acetate injection should be given to patients escaping the antisecretory effects of the long-acting octreotide acetate for injectable suspension. If the rescue therapy is required during the week before the next dose of the long-acting formulation, a reduction in the dosing interval by 1 week is recommended. If the rescue medication is administered sporadically throughout the month, then increasing the dose of octreotide acetate for injectable suspension stepwise in increments of 10 mg per month, up to 60 mg per month

Supplemental therapy for all somatostatin analogs: Pancreatic enzymes to avoid steatorrhea

Individualize dosage by giving the number of tablets or capsules that optimally minimize steatorrhea

Select Pancrelipase products with a high lipase content to avoid steatorrhea. In some patients, enteric-coated enzyme tablets may not dissociate as intended and may pass through the bowel intact

Administer Pancrelipase with meals or snacks

Adjust doses slowly; monitor symptoms and response

- Do not crush or chew enteric-coated products or the enteric-coated contents of opened capsules
- Capsules may be opened and shaken onto a small quantity of soft food that is not hot and does not require chewing
- Pancrelipase should be immediately swallowed without chewing to prevent mucosal irritation
- Ingested doses should be followed with a glass of juice or water to ensure complete ingestion
- Avoid mixing pancrelipase with foods that have a pH >5.5, which can dissolve enteric coatings

REGIMEN

STREPTOZOCIN + FLUOROURACIL

Eriksson B et al. Cancer 1990;65:1883–1890
Moertel CG et al. N Engl J Med 1980;303:1189–1194
Moertel CG et al. N Engl J Med 1992;326:519–523

Premedications and hydration:
≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously, starting 1.5 hours before administration of chemotherapy, continuing during administration, and for approximately 1.5 hours afterward

Induction course:
Streptozocin 1000 mg/day; administer intravenously in 100–1000 mL 0.9% NS or 5% dextrose injection (D5W) over 30–120 minutes for 5 consecutive days, on days 1–5 (total dose/cycle = 5000 mg)
Fluorouracil 400 mg/m^2 per day; administer by intravenous injection over 1–2 minutes for 3 consecutive days, days 1–3 (total dosage/cycle = 1200 mg/m^2)

Subsequent courses: (beginning 3 weeks after the induction cycle)
Streptozocin 2000 mg intravenously in 100–1000 mL 0.9% NS or D5W over 30–120 minutes on day 1, every 3 weeks (total dose/cycle = 2000 mg)
Fluorouracil 400 mg/m^2 by intravenous injection over 1–2 minutes on day 1, every 3 weeks (total dosage/cycle = 400 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with streptozocin is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Populations Studied

- One-hundred eighteen patients with metastatic carcinoid tumor were randomly assigned to receive treatment with streptozocin combined with cyclophosphamide or with fluorouracil (Moertel CG et al. N Engl J Med 1980;303:1189–1194)
- A prospective, nonrandomized trial. Of 84 patients with advanced pancreatic endocrine tumor, 19 received streptozocin + fluorouracil (Eriksson B et al. Cancer 1990;65:1883–1890)
- A multicenter randomized trial in which responses to streptozocin + fluorouracil, streptozocin + doxorubicin, or chlorozotocin monotherapy were compared. One-hundred five patients with advanced pancreatic endocrine tumors (Moertel CG et al. N Engl J Med 1992;326:519–523)

Treatment Modifications

Adverse Event	Treatment Modification
Creatinine clearance on day 1 of a second and subsequent cycles = 60–75 mL/min (1–1.25 mL/s)	Give streptozocin 1000 mg/day for 2 consecutive days, on days 1 and 2 (total dose/cycle = 2000 mg)
Creatinine clearance on day 1 of a second and subsequent cycles = 50–60 mL/min (0.83–1 mL/s)	Give streptozocin 1000 mg on day 1 only (total dose/cycle = 1000 mg)
Creatinine clearance on day 1 of a second and subsequent cycles <50 mL/min (<0.83 mL/s)	Discontinue streptozocin. Resume treatment after creatinine clearance >50 mL/min
Altered LFTs	No streptozocin adjustments recommended since hepatic metabolism does not appear to be important. Hold fluorouracil if total bilirubin >5 mg/dL (>85.5 μmol/L). In individual patients, titrate fluorouracil dosage to keep hematologic toxicities no greater than mild-to-moderate
Hematologic toxicities	Streptozocin and fluorouracil doses are titrated to produce no greater than mild-to-moderate hematologic toxicities

Efficacy

Study	Objective Response Rate	Median Duration of Response
Moertel et al, 1980	63% (CR 33%)	17 months
Eriksson et al, 1990*	45%	27.5 months
Moertel et al, 1992	45%	6.9 months

*Combined results of streptozocin in combination with fluorouracil or doxorubicin as first-line treatment

Toxicity

	All Grades	Grades 1/2	Grades 3/4
Nausea	54–85%	—	22–41% (severe)
Anemia	9%	N/A	N/A
Leukopenia	2–56%	—	25% G3; 4% G4
Thrombocytopenia	15–25%	4%	6–11%
Elevated creatinine	30–36%	N/A	N/A
Renal failure	—	—	7% (G4)
Diarrhea	—	33% (mild)	2% (severe)
Stomatitis	—	5–19% (mild)	5% (severe)
Urinary albumin >30 mg/day	65%	—	—
>1.25-times increase in LFTs	34%	—	—

Therapy Monitoring

Before each cycle of treatment: WBC with differential and platelet count, liver function tests, renal function tests

REGIMEN

STREPTOZOCIN + DOXORUBICIN

Moertel CG et al. N Engl J Med 1992;326:519–523

Premedications and hydration:
1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously, starting 1.5 hours before administration of chemotherapy, continuing during administration and for approximately 1.5 hours afterward

Induction course:
Streptozocin 1000 mg/day; administer intravenously in 100–1000 mL 0.9% NS or 5% dextrose injection (D5W) over 30–120 minutes for 5 consecutive days, on days 1–5 (total dose/cycle = 5000 mg)
Doxorubicin 40 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1 (total dosage/cycle = 40 mg/m^2)

Subsequent courses: (beginning 3 weeks after the induction cycle)
Streptozocin 2000 mg; administer intravenously in 100–1000 mL 0.9% NS or D5W over 30–120 minutes on day 1, every 3 weeks (total dose/cycle = 2000 mg)
Doxorubicin 40 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1 (total dosage/cycle = 40 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with streptozocin is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Populations Studied

- A prospective study of 84 patients with neuroendocrine pancreatic tumors. Fifty-nine (70%) had malignant tumors and received 1 or more types of medical treatment (Eriksson B et al. Cancer 1990;65:1883–1890)
- A multicenter randomized trial comparing streptozocin + fluorouracil, streptozocin + doxorubicin, and chlorozotocin alone. One-hundred five patients with advanced islet-cell carcinoma (Moertel CG et al. N Engl J Med 1992;326:519–523)

Therapy Monitoring

1. *Before each cycle of treatment:* WBC with differential and platelet count, liver function tests, renal function tests
2. *Before initiation of treatment with doxorubicin, and before every third cycle:* Myocardial scintigraphy to assess cardiac function

Toxicity

	All Grades	Grades 1/2	Grades 3/4
Nausea	80%	—	20% (severe)
Anemia	9%	N/A	N/A
Leukopenia	57%	—	5%
Elevated creatinine	46%	N/A	N/A
Renal failure	—	—	4% (G4)
Diarrhea	—	5% (mild)	—
Stomatitis	—	5% (mild)	—

Treatment Modifications

Adverse Event	Treatment Modification
Creatinine clearance on day 1 of a second and subsequent cycles = 60–75 mL/min (1–1.25 mL/s)	Give streptozocin 1000 mg/day for 2 consecutive days, on days 1 and 2 (total dose/cycle = 2000 mg)
Creatinine clearance on day 1 of a second and subsequent cycles = 50–60 mL/min (0.83–1 mL/s)	Give streptozocin 1000 mg on day 1 only (total dose/cycle = 1000 mg)
Creatinine clearance on day 1 of a second and subsequent cycles <50 mL/min (<0.83 mL/s)	Discontinue streptozocin. Resume treatment after creatinine clearance >50 mL/min
Cumulative dose of doxorubicin ≥550 mg/m^2 (450 mg/m^2 in patients >70 years of age)	Monitor cardiac ejection fraction at baseline and reevaluate before repeating a treatment cycle or every other cycle
Altered LFTs	No streptozocin adjustments recommended since hepatic metabolism does not appear to be important Hold doxorubicin if total bilirubin >5 mg/dL (>85.5 μmol/L)
Hematologic toxicities	Streptozocin and doxorubicin doses are titrated to produce no greater than mild-to-moderate hematologic toxicities

Efficacy

Study	Objective Response Rate	Median Duration of Response
Eriksson et al, 1990*	45%	27.5 months
Moertel et al, 1992	69%	20 months

*Combined results of streptozocin in combination with fluorouracil or doxorubicin as first-line treatment

REGIMEN

SUNITINIB MALATE

Raymond E et al. N Engl J Med 2011;364:501–513

Sunitinib malate 37.5 mg per day orally, continually (total dose/week = 262.5 mg)

Notes:

In patients without an objective tumor response who had grade ≤1 nonhematologic or grade ≤2 hematologic treatment-related adverse events during the first 8 weeks, the dose may be increased to 50 mg per day

Patients can receive somatostatin analogs as needed

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(*continued*)

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist using water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand–foot reaction (palmar–plantar erythrodysesthesia, PPE)

For patients who develop a hand–foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications

Adverse Event	Treatment Modification
Sunitinib Dose Levels	
Starting dose: Level 1	37.5 mg once daily
Level −1	25 mg once daily
Level +1	50 mg once daily
Cutaneous Toxicities	
Rash G ≥2	Hold sunitinib and provide immediate symptomatic treatment
If treatment is withheld for more than 3 weeks because of cutaneous toxicity	Discontinue therapy
When cutaneous toxicity resolves to G ≤1	Restart sunitinib at 1 dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at reduced sunitinib doses	Again, hold sunitinib until the toxicity resolves to G ≤1, at which time sunitinib should be restarted at 1 dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at dose level −1	Discontinue therapy
If cutaneous toxicity does not recur at reduced sunitinib doses with or without continued treatment for symptoms	The dose of sunitinib may be increased 1 dose level to the dose level administered at the time the cutaneous toxicity developed. Interrupt treatment by withholding sunitinib if toxicity recurs following the increase. When toxicity again resolves to G ≤1, resume sunitinib at the reduced dose previously tolerated

(*continued*)

Treatment Modifications (*continued*)

Diarrhea	
G1/2 diarrhea	Focus on treatment for symptoms designed to resolve the diarrhea. No dose modifications will be made for G1/2 diarrhea unless G2 diarrhea persists for >2 weeks
If G2 diarrhea persists for more than 2 weeks	Follow the guidelines below for G3/4 diarrhea
If the diarrhea cannot be controlled with the preventive measures outlined, and is G3/4 or worsens by 1 grade level (G3 to G4) while on sunitinib and is not alleviated within 48 hours by antidiarrheal treatment	Hold sunitinib. Also withhold sunitinib if persistent G2 diarrhea (lasting >2 weeks) is not alleviated by antidiarrheal treatment while sunitinib use continues
If sunitinib is held for more than 3 weeks and the diarrhea does not resolve to G ≤1	Discontinue therapy
If within 3 weeks of holding sunitinib, diarrhea resolves to G ≤1	Restart sunitinib at 1 dose level less than the dose level administered at the time toxicity developed
If G3/4 diarrhea or persistent G2 diarrhea recurs at reduced sunitinib doses and the dose level at which persistent G2 diarrhea occurs is greater than dose level −1 (persistent is defined as lasting for >2 weeks)	Again, withhold sunitinib until the toxicity resolves to CTCAE (Common Terminology Criteria for Adverse Events) G ≤1, at which time sunitinib should be restarted at 1 dose level less than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If G3/4 diarrhea or persistent G2 diarrhea recurs at dose level −1 (persistent defined as lasting for more >2 weeks)	Discontinue therapy
If diarrhea does not recur at the reduced sunitinib doses with or without continued treatment for symptoms	The dose of sunitinib may be increased 1 dose level to the dose level administered at the time diarrhea developed. Interrupt treatment by withholding sunitinib if toxicity recurs following the increase. When toxicity again resolves to G ≤1, resume sunitinib at the reduced dose previously tolerated
Hypertension *Note:* Patients should have their blood pressure checked once weekly during their first 24 weeks of therapy and for an 8-week period after an adjustment in their sunitinib dose	
G1 Hypertension	Continue sunitinib at same dose and schedule
G2 Asymptomatic	Treat with antihypertensive medications and continue sunitinib at same dose and schedule
G2 Symptomatic, or persistent G2 despite antihypertensive medications, or diastolic BP >110 mm Hg, or G3 hypertension	Treat with antihypertensive medications. Hold sunitinib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue sunitinib at 1 dose level lower. *Note:* Discontinue therapy if sunitinib is withheld >3 weeks
G4 Hypertension	Discontinue therapy
Other Adverse Events	
Any other adverse event	Interrupt treatment. Resume at 25 mg/day when toxicity resolves to G ≤1. If symptoms do not recur, try increasing dose to the starting dose level, 37.5 mg daily
Recurrence of adverse event once dose increased to 37.5 mg/day	Interrupt treatment. Resume at 25 mg/day when toxicity resolves to G ≤1 but do not increase dose to the starting dose level, 37.5 mg daily
Coadministration of potent CYP3A4 inhibitors (eg, atazanavir, clarithromycin, itraconazole, ketoconazole, ritonavir, telithromycin, voriconazole)	Reduce sunitinib dose
Coadministration of potent CYP3A4 inducers (eg, carbamazepine, dexamethasone, phenytoin, phenobarbital, rifampin, St. John's wort)	Increase sunitinib dose (to a maximum of 87.5 mg daily)

Efficacy

Summary of Efficacy Measures in the Intention-to-Treat Population*

Outcome	Sunitinib (N = 86)	Placebo (N = 85)	*p* Value
Progression-Free Survival*			
Patients with events—no. (%)	30 (35)	51 (60)	
Progression	27 (31)	48 (56)	
Death without progression	3 (3)	3 (4)	
Patients with data censored—no. (%)	56 (65)	34 (40)	
Probability event-free at 6 months—% (95% CI)	71.3 (60.0–82.5)	43.2 (30.3–56.1)	
Estimated median progression-free survival, months	11.4 (7.4–19.8)	5.5 (3.6–7.4)	
Hazard ratio for progression or death (95% CI)	0.42 (0.26–0.66)		<0.001
Overall Survival			
Deaths—no. (%)	9 (10)	21 (25)	
Patients with data censored—no. (%)	77 (90)	64 (75)	
Survival probability at 6 months—% (95% CI)	92.6 (86.3–98.9)	85.2 (77.1–93.3)	
Estimated median overall survival	Not reached	Not reached	
Hazard ratio for death (95% CI)	0.41 (0.19–0.89)		0.02
Objective Tumor Response			
Best observed RECIST response—no. (%)			
Complete response	2 (2)	0	
Partial response	6 (7)	0	
Stable disease	54 (63)	51 (60)	
Progressive disease	12 (14)	23 (27)	
Could not be evaluated	12 (14)	11 (13)	
Objective response rate—%	9.3	0	0.007

CI, confidence interval; RECIST, Response Evaluation Criteria in Solid Tumors (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
*Data for a total of 3 patients (1 in the sunitinib group and 2 in the placebo group) were censored at day 1 in the analysis of PFS because of inadequate baseline tumor assessment

Patient Population Studied

A multinational, double-blind, placebo-controlled, phase III trial that randomly assigned patients in a 1:1 ratio to receive orally once daily placebo or sunitinib 37.5 mg. Patient characteristics included the following:

Demographic and Baseline Characteristics of the Patients	Sunitinib (N = 86)	Placebo (N = 85)
Variable		
Age		
Median—years	56	57
Range—years	25–84	26–78
≥65 y—no. (%)	22 (26)	23 (27)
Sex—no. (%)		
Male	42 (49)	40 (47)
Female	44 (51)	45 (53)
ECOG performance status—no. (%)		
0	53 (62)	41 (48)
1	33 (38)	43 (51)
2	0	1 (1)
Inherited genetic conditions—no. (%)		
Multiple endocrine neoplasia type 1	0	2 (2)
von Hippel–Lindau disease	2 (2)	0
Time since diagnosis—years		
Median	2.4	3.2
Range	0.1–25.6	0.1–21.3
Tumor functionality—no. (%)*		
Nonfunctioning	42 (49)	44 (52)
Functioning	25 (29)	21 (24)
Not specified	19 (22)	20 (24)
Ki-67 index		
Number of patients with data that could be evaluated	36	36

(continued)

Toxicity

Common Adverse Events in the Safety Population*

Event	Sunitinib (N = 83)			Placebo (N = 82)		
	All Grades	G1/2	G3/4	All Grades	G1/2	G3/4
	Number of Patients (%)					
Diarrhea	49 (59)	45 (54)	4 (5)	32 (39)	30 (37)	2 (2)
Nausea	37 (45)	36 (43)	1 (1)	24 (29)	23 (28)	1 (1)
Asthenia	28 (34)	24 (29)	4 (5)	22 (27)	19 (23)	3 (4)
Vomiting	28 (34)	28 (34)	0	25 (30)	23 (28)	2 (2)
Fatigue	27 (32)	23 (28)	4 (5)	22 (27)	15 (18)	7 (8)
Hair-color changes	24 (29)	23 (28)	1 (1)	1 (1)	1 (1)	0
Neutropenia	24 (29)	14 (17)	10 (12)	3 (4)	3 (4)	0
Abdominal pain	23 (28)	19 (23)	4 (5)	26 (32)	18 (22)	8 (10)
Hypertension	22 (26)	14 (17)	8 (10)	4 (5)	3 (4)	1 (1)
Palmar–plantar erythrodysesthesia	19 (23)	14 (17)	5 (6)	2 (2)	2 (2)	0
Anorexia	18 (22)	16 (19)	2 (2)	17 (21)	16 (20)	1 (1)
Stomatitis	18 (22)	15 (18)	3 (4)	2 (2)	2 (2)	0
Dysgeusia	17 (20)	17 (20)	0	4 (5)	4 (5)	0
Epistaxis	17 (20)	16 (19)	1 (1)	4 (5)	4 (5)	0
Headache	15 (18)	15 (18)	0	11 (13)	10 (12)	1 (1)
Insomnia	15 (18)	15 (18)	0	10 (12)	10 (12)	0
Rash	15 (18)	15 (18)	0	4 (5)	4 (5)	0
Thrombocytopenia	14 (17)	11(13)	3 (4)	4 (5)	4 (5)	0
Mucosal inflammation	13 (16)	12 (14)	1 (1)	6 (7)	6 (7)	0
Weight loss	13 (16)	12 (14)	1 (1)	9 (11)	9 (11)	0
Constipation	12 (14)	12 (14)	0	16 (20)	15 (18)	1 (1)
Back pain	10 (12)	10 (12)	0	14 (17)	10 (12)	4 (5)

*Adverse events were defined on the basis of the National Cancer Institute, Common Terminology Criteria for Adverse Events, version 3.0. Events listed are those of any grade that occurred in more than 15% of patients in either group.

Therapy Monitoring

1. *Every 6 weeks to 3 months:* Physical examination and routine laboratory tests including thyroid function tests
2. *Response assessment:* Every 2–3 cycles. A cycle is defined as a 6-week period

Patient Population Studied (*continued*)

Demographic and Baseline Characteristics of the Patients	Sunitinib (N = 86)	Placebo (N = 85)
Index—no. (%)		
≤2%	7 (19)	6 (17)
>2%–5%	16 (44)	14 (39)
>5%–10%	5 (14)	10 (28)
>10%	8 (22)	6 (17)
No. of sites of disease—no. (%)°		
1	30 (35)	23 (27)
2	31 (36)	26 (31)
≥3	24 (28)	35 (41)
Not reported	1 (1)	1 (1)
Presence of distant metastases—no. (%)		
Any, including hepatic	82 (95)	80 (94)
Extrahepatic	21 (24)	34 (40)
Previous treatment—no. (%)		
Surgery	76 (88)	77 (91)
Radiation therapy	9 (10)	12 (14)
Chemoembolization	7 (8)	14 (16)
Radiofrequency ablation	3 (3)	6 (7)
Percutaneous ethanol injection	1 (1)	2 (2)
Somatostatin analogs†	30 (35)	32 (38)
Previous systemic chemotherapy—no. (%)		
Any	57 (66)	61 (72)
Streptozocin	24 (28)	28 (33)
Anthracyclines	27 (31)	35 (41)
Fluoropyrimidines	20 (23)	25 (29)

*Tumor functionality was reported by investigators. On the basis of the investigators' assessment, patients included in the "unknown" category had clinical symptoms but no identified corresponding neuropeptide secretion

†This category includes patients who received somatostatin analogs (predominantly octreotide acetate and lanreotide acetate) before the first dose of study drug, regardless of whether they continued receiving somatostatin analogs concomitantly with the study drug

REGIMEN

EVEROLIMUS

Yao JC et al. N Engl J Med 2011;364:514–523

Everolimus 10 mg/day orally, continually (total dose/week = 70 mg)

Notes:
- Everolimus tablets should be swallowed whole (without breaking, crushing, or chewing) with water
- Everolimus tablets and tablets for oral suspension may be taken with or without food, but should be taken consistently either with or without food
- Commercially available formulations (a) tablets and (b) tablets for oral suspension should not be used in combination to administer a dose

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:
- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist using water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Invasive systemic fungal infection	Discontinue everolimus and treat with appropriate antifungal therapy
Noninfectious pneumonitis without symptoms with only radiologic changes	Observe carefully. Specific therapies or drug interruption may not be necessary
Noninfectious pneumonitis with mild-to-moderate symptoms	Withhold therapy. Glucocorticoids may be initiated. Resume everolimus at a reduced dose depending on the individual clinical circumstances
Noninfectious pneumonitis with severe symptoms (including a decrease in DL_{CO} on pulmonary function tests)	Discontinue therapy and consider administering high doses of glucocorticoids
ANC $<1000/mm^3$ or platelet count $<75{,}000/mm^3$	Withhold therapy. Resume everolimus when symptoms improve to G ≤2 with everolimus dose reduced to 5 mg/day or 5 mg every other day but not <15 mg/week
Any nonhematologic G3/4 toxicity	Withhold therapy. Restart everolimus when symptoms improve to G ≤2 with everolimus dose reduced to 5 mg/day or 5 mg every-other-day but not <15 mg/week
G1/2 oral ulcerations	Topical treatments are recommended, but alcohol- or peroxide-containing mouthwashes should be avoided. Focus on pain control, oral hygiene, and IV fluid replacement or parenteral nutrition if severe
Hyperglycemia	Monitor blood sugar levels and institute oral hypoglycemic agent or insulin as needed
Hypertriglyceridemia	Monitor triglycerides, instituting dietary interventions for minor elevations and lipid-lowering agents for levels >500 mg/dL (>5.65 mmol/L)

(*continued*)

- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Patient Population Studied

International, multicenter, double-blind, phase III study. Patients were randomly assigned to treatment with oral everolimus 10 mg or matching placebo, both administered once daily in conjunction with best supportive care. Patients initially assigned to placebo who met criteria for disease progression could switch to open-label everolimus. Of the 203 patients initially assigned to receive placebo, 148 (73%) crossed over to open-label everolimus

Demographic and Baseline Clinical Characteristics of the Patients

Characteristic	Everolimus (N = 207)	Placebo (N = 203)
Age—years		
Median	58	57
Range	23–87	20–82

*Drug-related adverse events occurring in ≥10% of patients
†Median follow-up period of 17 months
‡Ratio of administered doses to planned doses
§Reductions or temporary interruptions
¶Includes stomatitis, aphthous stomatitis, mouth ulceration, and tongue ulceration
**Includes all types of infections
††Includes pneumonitis, interstitial lung disease, lung infiltration, and pulmonary fibrosis

Therapy Monitoring

1. *Prior to starting treatment and periodically thereafter:* Renal function, CBC with differential, blood glucose, and serum lipid profiles
2. *ECG:* A 12-lead ECG should be performed before the start of treatment, weekly for at least the first 2 weeks. Additional ECGs may be performed depending on the QTc. If the dose is increased, then at least 1 additional ECG should be obtained
3. *Safety assessment:* Every 2–4 weeks for the first 3 cycles; every 4–8 weeks, thereafter
4. *Response assessment:* Every 8–12 weeks

REGIMEN

CISPLATIN + ETOPOSIDE

Fjällskog M-LH et al. Cancer 2001;92:1101–1107
Moertel CG et al. Cancer 1991;68:227–232

Hydration days 2 and 3:
≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously at a rate that produces a diuresis ≥100 mL/h, starting at least 2 hours before chemotherapy administration. Continue hydration during chemotherapy administration and for at least 2 hours afterward. Mannitol or furosemide may be given as needed to enhance diuresis and prevent excessive fluid retention. Encourage increased oral intake of nonalcoholic fluids. Monitor and replace electrolytes as needed (potassium, magnesium, sodium)
Etoposide 100 mg/m² per day; administer intravenously, diluted in a volume of 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL, over 60 minutes on 3 consecutive days, on days 1–3, every 4 weeks (total dosage/cycle = 300 mg/m²)
Cisplatin 45 mg/m² per day; administer intravenously in 100–250 mL 0.9% NS over 1 hour on 2 consecutive days, on days 2 and 3, every 4 weeks (total dosage/cycle = 90 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***LOW***
Emetogenic potential on days 2 and 3 is ***HIGH****, with a potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

	All Grades	Grades 1/2	Grades 3/4
Nephrotoxicity	53–66%	—	2% (severe)
Anemia	89%	Decreased Hb: 1–3 g/dL (38%); 3–4 g/dL (29%); >4 g/dL (22%)	
Leukopenia	100%	35%	65%
Thrombocytopenia	—	49%	35%
Peripheral neuropathy	—	17%	75%
Ototoxicity	—	2–8%	—
Diarrhea	16%	—	—
Stomatitis	13%	11%	2%
Nausea	96%	83%	13%
Alopecia	100%	—	—
Dermatitis	—	4%,	—
Fever	—	—	2%

Patient Populations Studied

- Nonrandomized study of 15 patients with malignant pancreatic endocrine tumors (4 were poorly differentiated endocrine carcinomas) treated with cisplatin + etoposide as second- or third-line treatment (Fjällskog M-LH et al. Cancer 2001;92:1101–1107)
- Prospective, nonrandomized study of 45 patients with neuroendocrine tumors among whom 14 had well-differentiated pancreatic endocrine tumors (Moertel CG et al. Cancer 1991;68:227–232)

Efficacy

Study	Objective Response Rate	Median Duration of Response
Moertel et al, 1991*	67%	8 months
Fjällskog et al, 2001†	53%	9 months

*Tumor response was unrelated to primary site, endocrine hyperfunction, or prior therapy experience. The median survival of all patients with anaplastic tumors was 19 months
†Includes foregut carcinoids and endocrine pancreatic tumors. No difference in response between patients with well-differentiated or poorly differentiated endocrine pancreatic carcinoma

Treatment Modifications

Adverse Event	Treatment Modification
Day 1 ANC <1500/mm³ or platelets <100,000/mm³	Delay treatment 1 week or until ANC >1500/mm³ and platelets >100,000/mm³, then administer full doses
ANC at nadir <500/mm³	Administer filgrastim during subsequent cycles: • Administer filgrastim on days 4–11, *or* • Administer pegfilgrastim at least 24 hours after completing chemotherapy, *and/or* • Decrease etoposide dosage by 25%
Albumin <3.2 g/dL (<32 g/L)	Reduce etoposide dosage by 50%
Albumin <2.5 g/dL (<25 g/L)	Discontinue etoposide until albumin ≥2.5 g/dL (≥25 g/L)

Therapy Monitoring

1. *Before and during each cycle of treatment:* Body weight to detect excessive fluid retention
2. *Days 7, 10, and 14 of each cycle:* WBC with differential count
3. *Every cycle:* Liver and renal function tests

SECOND-LINE REGIMEN FOR INOPERABLE WELL- AND POORLY-DIFFERENTIATED NEUROENDOCRINE TUMORS AND FOR PATIENTS WHO CANNOT TOLERATE MORE INTENSIVE THERAPIES

TEMOZOLOMIDE

Ekeblad S et al. Clin Cancer Res 2007;13:2986–2991

Induction course:
Temozolomide 150 mg/m^2 per day; administer orally for 5 consecutive days, days 1–5 (total dosage during cycle 1 = 750 mg/m^2)

Subsequent courses:
Temozolomide 200 mg/m^2 per day; administer orally for 5 consecutive days, days 1–5, every 4 weeks (total dosage/cycle = 1000 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Populations Studied

Retrospective study of 36 patients with advanced neuroendocrine tumors, among whom 12 had a diagnosis of pancreatic endocrine tumor

Treatment Modifications

Adverse Event	Treatment Modification
Leukopenia G ≥2 on day 1 of a new cycle	Delay starting the cycle for 1 week. Then, decrease temozolomide dosage by 50 mg/m^2 each day it is given; eg, from 200 mg/m^2 per day to 150 mg/m^2 per day, from 150 mg/m^2 per day to 100 mg/m^2 per day

Therapy Monitoring

Before each treatment cycle: WBC including differential and platelet count

Efficacy (N = 12)

Ekeblad S et al. Clin Cancer Res 2007;13:2986–2991

Complete response	0
Partial response	8%
Stable disease	67%
Progressive disease	25%
Median time to progression for whole group	7 months

Toxicity

Ekeblad S et al. Clin Cancer Res 2007;13:2986–2991

	Grade 1	Grade 2	Grade 3	Grade 4
Anemia	9 (26%)	1 (3%)	1 (3%)	0
Thrombocytopenia	8 (23%)	0	5 (14%)	0
Leukopenia	3 (9%)	1 (3%)	1 (3%)	0
Neutropenia	0	1 (3%)	0	1 (3%)
Fatigue	8 (23%)	3 (9%)	2 (6%)	1 (3%)
Nausea (with premedication)	10 (29%)	0	0	0

SECOND-LINE REGIMEN FOR INOPERABLE WELL- AND POORLY DIFFERENTIATED NEUROENDOCRINE TUMORS

^{177}Lu-OCTREOTATE ([^{177}Lu-DOTA^0, Tyr^3] OCTREOTATE) SOMATOSTATIN ANALOGS LABELED WITH RADIOACTIVE [^{177}Lu-DOTA^0, Tyr^3]

de Keizer B et al. Eur J Nucl Med Mol Imaging 2008;35:749–755

Pretreatment:
Long-acting somatostatin analogs were discontinued 1 month before starting ^{177}Lu-octreotate therapy, and replaced with octreotide acetate solution. Octreotide acetate solution was discontinued 1 day before starting ^{177}Lu-octreotate

Preparation of ^{177}Lu-octreotate ([^{177}Lu-DOTA^0,Tyr^3]octreotate)
[DOTA^0,Tyr^3]octreotate is obtained from Mallinckrodt Inc., St. Louis, MO
$^{177}LuCl_3$ is obtained from a facility with a nuclear reactor
^{177}Lu-octreotate is prepared locally

Premedication:
Granisetron 1–3 mg *or* **ondansetron** 8 mg acetate solution intravenously
An admixture of amino acids (lysine 2.5% and arginine 2.5%) in 1000 mL 0.9% sodium chloride injection) acetate solution intravenously over 4 hours starting 30 minutes before ^{177}Lu-octreotate administration

Administration of ^{177}Lu-octreotate ([^{177}Lu-DOTA^0,Tyr^3]octreotate)
^{177}Lu-octreotate is administered intravenously over 30 minutes
Cycle dosages: 100 mCi (3.7 GBq), 150 mCi (5.6 GBq) or 200 mCi (7.4 GBq) with 200 mCi (7.4 GBq) used most frequently
Interval between treatments: 6–10 weeks
Treatment duration: Treatment is continued up to a cumulative dose of 750–800 mCi (27.8–29.6 GBq; corresponding with a radiation dose to the bone marrow of 2 Gy)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Populations Studied

- Nonrandomized prospective study of 310 patients with gastroenteropancreatic neuroendocrine tumors, among whom 91 had a diagnosis of pancreatic endocrine tumor. Of the whole group, 89% had liver metastases (Kwekkeboom DJ et al. J Clin Oncol 2008;26:2124–2130)
- Retrospective analysis of 479 patients with gastroenteropancreatic neuroendocrine tumors, among whom 159 had a diagnosis of pancreatic endocrine tumor. Of the group, 88% had liver metastases and 26% had bone metastases (de Keizer B et al. Eur J Nucl Med Mol Imaging 2008;35:749–755)

Treatment Modifications

Adverse Event	Treatment Modification
If dosimetric calculations indicate radiation dose to the kidneys will exceed 23 Gy	Reduce the cumulative dose to 500–700 mCi

Toxicity

de Keizer B et al. Eur J Nucl Med Mol Imaging 2008;35:749–755
Kwekkeboom DJ et al. J Clin Oncol 2008;26:2124–2130

Toxicity	All Grades
Nausea	25%
Vomiting	10%
Abdominal discomfort	10%
G3/4 hematologic toxicity	9.5% of patients (3.6% of administrations)
WHO G1 reversible hair loss	62%
Serious liver toxicity	<1%
Myelodysplastic syndrome*	<1%
Hormonal crisis	1.3%†‡

*Two to 3 years after the last treatment with ^{177}Lu-octreotate
†Two of 3 patients with VIPoma
‡Hormone-release crisis occurred immediately or within 48 hours after ^{177}Lu-octreotate administration during 10 of 1691 (0.6%) treatments. The crisis was characterized by flushing and severe diarrhea in all patients ± nausea, hypotension, and metabolic abnormalities

Efficacy (N = 91)

- A 43% objective radiologic response
- Median time to progression 40 months in patients who did not have progressive disease

Tumor Responses 3 Months After the Last Administration of ^{177}Lu-Octreotate

Tumor Type	Response: Number of Patients (%)				
	CR	PR	MR	SD	PD
Nonfunctioning pancreatic	4 (6%)	26 (36%)	13 (18%)	19 (26%)	10 (14%)
Gastrinoma	—	5 (42%)	4 (33%)	2 (17%)	1 (8%)
Insulinoma	—	3 (60%)	—	1 (20%)	1 (20%)
VIPoma	—	1 (50%)	—	—	1 (50%)
Total	4 (5%)	35 (38%)	17 (19%)	22 (24%)	13 (14%)

CR, Complete response; PR, partial response; MR, minimal response; SD, stable disease; PD, progressive disease; VIPoma, vasoactive intestinal peptide-secreting tumor

Therapy Monitoring

Before each therapy: CBC with differential, and renal and liver function tests

31. Pheochromocytoma

Karel Pacak, MD, PhD, DSc and Tito Fojo, MD, PhD

Epidemiology

Incidence*: 3–8 cases per one million population
Median age: 42 years
Male to female ratio: 1:1

*The annual incidence of pheochromocytoma in the United States is not precisely known, but the high prevalence (0.05%) of pheochromocytomas found in autopsy series indicates that the tumor is underdiagnosed and that the annual incidence is likely to be higher than indicated

Eisenhofer G et al. Endocr Relat Cancer 2004;11:423–436
Neumann HPH et al. N Engl J Med 2002;346:1459–1466
Pacak K et al. Nat Clin Pract Endocrinol Metab 2007;3:91–102

Pathology

- Approximately 80–85% of pheochromocytomas are located in the adrenal gland. The remaining 15–20% are located along the paraaortic sympathetic chain, aortic bifurcation, and urinary bladder
- Bilateral tumors occur in ~10% of patients and are much more common in familial pheochromocytomas
- 5–36% of pheochromocytomas are malignant, but no widely accepted pathologic criteria exist for differentiating between benign and malignant pheochromocytoma
- A diagnosis of malignancy requires evidence of metastases at nonchromaffin sites distant from that of the primary tumor
- Although most cases of pheochromocytomas are sporadic, a significant proportion occur secondary to several hereditary syndromes. Hereditary contribution is approximately 30%. The propensity of malignancy in hereditary pheochromocytoma syndromes is highly variable

Pheochromocytoma in Hereditary Syndromes

Hereditary Syndrome	Gene	Frequency*	Predisposition to Malignancy	Adrenal Disease	Extraadrenal Disease
Von Hippel-Lindau disease (VHL)	*VHL*	6–20%	3%	++	+
Multiple endocrine neoplasia types IIA and IIB (MEN IIA, MEN IIB)	*RET*	30–50%	<3%	++	–
Neurofibromatosis type 1 (NF1)	*NF*	1–5%	<3%	++	+
Familial paraganglioma and/or pheochromocytoma caused by mutation of succinate dehydrogenase gene family members	SDHB	4–9%	66–83%	+	++
	SDHD	2–8%	<2%	+	++
	SDHC	<1%	Not described	–	+ (head and neck)
	SDHA	<5%	Not described	+	+
	SDHAF2	Rare	Not described	–	+ (head and neck)
None described	TMEM127	3%	Not described	+	Unknown

++, very common; +, common; –, rare
*Frequency in sporadic tumors

Qin Y et al. Nat Genet 2010;42:229–233

Evaluation

The diagnosis of pheochromocytoma is confirmed by biochemical evidence of elevated catecholamine production (preferably with measurement of plasma metanephrines) and by radiologic studies (Figure 31–1)

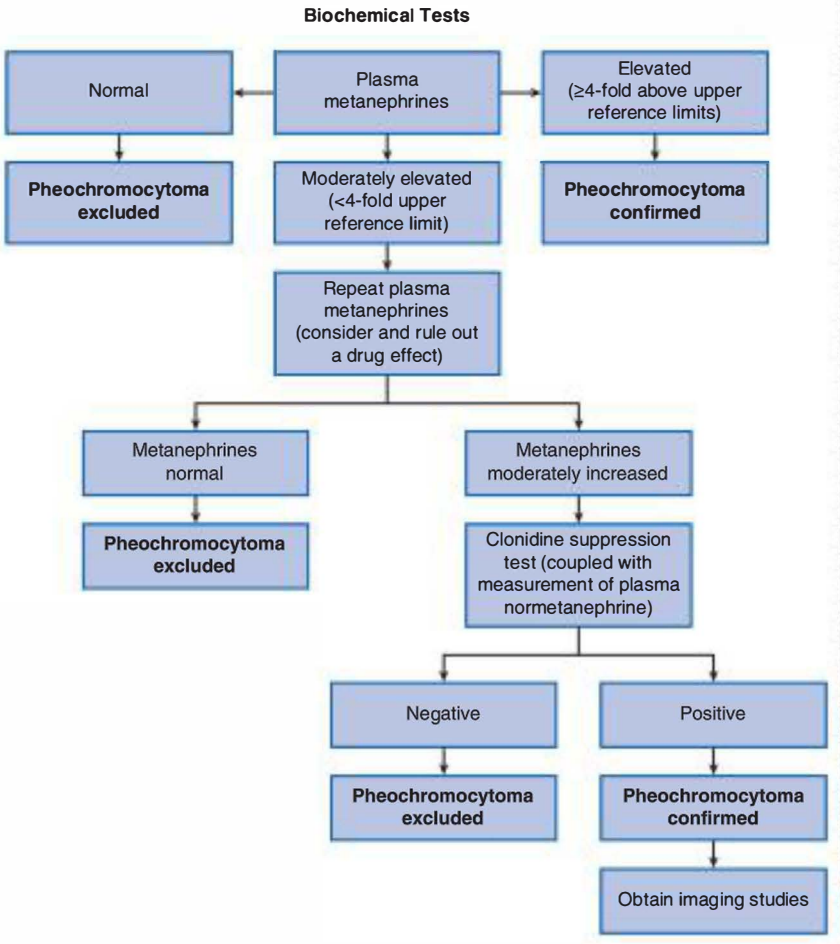

Figure 31–1. Biochemical tests.

Acetaminophen may interfere with measurement of plasma metanephrines. Other drugs, including benzodiazepines, buspirone, diuretics, levodopa, tricyclic antidepressants, and α- and β-adrenergic blockers, may cause false-positive elevations of plasma or urine catecholamines or metanephrines. Currently, there is no drug interference using the new liquid chromatography tandem mass spectrometry method

de Jong WHA et al. Clin Chem 2007;53:1684–1693

Survival

For patients with resectable pheochromocytoma, the overall survival is equal to that of the age-matched normal population. Although the 5-year survival of malignant pheochromocytomas is less than 50%, malignant pheochromocytomas can be slow-growing, and patients may have minimal morbidity and survive as long as 20 years

Remine WH et al. Ann Surg 1974;179:740–748
van Heerden JA et al. Surgery 1982;91:367–373

Imaging Studies

- *CT or MRI of abdomen (90–100% sensitivity):* Because of inadequate specificity, detection of a mass by these tests does not justify a diagnosis. ^{123}I metaiodobenzylguanidine (MIBG) scintigraphy is needed for confirmation
- *MIBG scan:* Used to confirm diagnosis when CT or MRI detects a tumor mass. In addition, if abdominal imaging is negative, whole-body evaluation by CT or MRI and MIBG scan are indicated to investigate for extraadrenal pheochromocytoma. Drugs that may interfere with MIBG study include labetalol, calcium channel blockers, guanethidine, reserpine, sympathomimetics, tricyclic antidepressants
- *6-[^{18}F] Fluorodopamine positron emission tomography:* This is used when the biochemical tests are positive, but conventional studies cannot locate the tumor
- *6-[^{18}F]-Fluorodeoxyglucose positron emission tomography:* This is used in patients with *SDHB*-related metastatic pheochromocytoma as the first-line imaging study
- *6-[^{18}F]-Fluorodopa positron emission tomography:* This is recommended to be used in *SDHx*-related head and neck paraganglioma as the first-line imaging study (unpublished observations)

Timmers HJLM et al. J Clin Oncol 2007;25:2262–2269

Staging

There is no accepted staging system for pheochromocytoma

Treatment Notes

Surgery

- The definitive treatment for pheochromocytoma is surgical excision of the tumor. Surgical removal can cure pheochromocytoma in up to 90% of cases, whereas, if left untreated, the tumor can prove fatal. Laparoscopic adrenalectomy is now considered the standard approach for excision of most pheochromocytomas with the exception of very large (>10 cm) tumors. The survival rates after surgery are 97.7–100%
- Surgery for **malignant** pheochromocytoma is rarely curative, but resection of the primary mass or metastases can reduce exposure of the cardiovascular system and organs to toxic levels of circulating catecholamines. Consequently, aggressive surgical resection of accessible primary or recurrent disease or metastases should be attempted if the surgery renders the patient free of gross disease with the potential for normal biochemical determinations
- Surgery for **malignant** pheochromocytoma may be indicated for lesions in life-threatening or debilitating anatomic locations
- The value of surgical debulking for **malignant** pheochromocytoma before chemotherapy or radiation therapy is not proved
- The median time for recurrence of pheochromocytoma after initial resection is approximately 6 years and may be as long as 20 years
- Alternatives to surgical resection include external beam radiation, cryoablation, radiofrequency ablation, transcatheter arterial embolization, chemotherapy, and radiopharmaceutical therapy
- Biochemical testing should always be repeated after recovery from surgical resection of a primary mass to exclude any remaining disease or metastasis
- Postoperative follow-up of patients includes evaluation of plasma metanephrine levels 6 weeks and 6 and 12 months after surgery, then yearly. Imaging studies should be performed on the basis of follow-up test results. Exceptions: (a) Patients with SDHB because they have a higher risk of malignancy and (b) those with an extraadrenal tumor or a primary >5 cm who should be followed up more frequently (every 6 months for the first 5 years)
- Before surgery, patients with pheochromocytoma must undergo pharmacologic blockage of catecholamine synthesis and activity as well as volume expansion because they have reduced intravascular volume as a result of a persistent vasoconstricted state. The combination of phenoxybenzamine (an irreversible, nonselective α-adrenergic receptor antagonist) or doxazosin, terazosin, or prazosin (selective α_1-adrenergic receptor antagonists), with atenolol (a selective β_1-adrenergic receptor antagonist) and metyrosine (a tyrosine hydroxylase inhibitor), and liberal salt intake starting 2–3 weeks before surgery leads to better control of blood pressure and decreases surgical risks
- Routine preoperative use of phenoxybenzamine opposes catecholamine-induced vasoconstriction. A β-adrenoceptor blocker (atenolol) is added to prevent the reflex tachycardia associated with α-blockade. The pressor effects of a pheochromocytoma must be controlled by α-blockade before β-blockers are initiated

  Note: β-Blockade **alone** can be dangerous in patients with pheochromocytoma and is contraindicated because it does not prevent and can actually augment effects of catecholamines at α-adrenoceptors
- Metyrosine is used to reduce the synthesis of new catecholamines by the tumor

Drug	Mechanism	Oral Dose	Side Effects
Phenoxybenzamine hydrochloride	Long-acting nonselective α-adrenergic antagonist	Initial dose: 10 mg twice daily, gradually increased to 20 and 40 mg 2 or 3 times daily (approximately 1–2 mg/kg per day). Final dose is determined by the patient's blood pressure	Tachycardia, orthostatic hypotension, nausea, abdominal pain, nasal congestion, fatigue, and retrograde or difficulty in ejaculation
Atenolol	Long-acting β_1-selective (cardioselective) β-adrenergic antagonist	Initial dose: 25 mg once a day. This can be increased to 25 mg twice daily and 50 mg twice daily if needed. Dose should be decreased in renal impairment	Hypotension, bradycardia, postural hypotension, cardiac failure, dizziness, tiredness, fatigue, and depression
Metyrosine	Competitively inhibits tyrosine hydroxylase, the rate-limiting enzyme in catecholamine synthesis	Initially, 250 mg 4 times daily. This may be increased by 250–500 mg daily to a maximum dose of 66.7 mg/kg per day or 4000 mg/day (whichever is less); eg, 1000 mg 4 times daily. Doses should be decreased in renal failure and given as divided doses	Extrapyramidal neurologic symptoms, crystalluria, diarrhea, anxiety, depression, headache, fatigue, and xerostomia
Doxazosin mesylate	Short-acting α_1-antagonist	Initial dose: 1–2 mg daily. This can be gradually increased to 10–16 mg/day Recommended maximum daily dose is 16 mg as a single daily dose with either immediate- or extended-release formulations	Postural dizziness and vertigo, postural hypotension, syncope
Terazosin hydrochloride	Short-acting α_1-antagonist	Initial dose: 1–2 mg daily. This can be gradually increased to 5 mg/day Recommended maximum daily dose is 20 mg, either as a single daily dose, or 10 mg every 12 hours	
Prazosin hydrochloride	Short-acting α_1-antagonist	Initial dose: 1 mg 2 or 3 times daily. This can be gradually increased to 2–5 mg/dose, 2 or 3 times daily Recommended maximum daily dose is 20 mg given in 2 or 3 divided doses	

(*continued*)

Treatment Notes (*continued*)

Important note:
Several drugs (including some commonly used by oncologists) may lead to a hypertensive crisis in a patient with a diagnosis of pheochromocytoma and should be avoided. These include:

- ACTH
- Amphetamines
- Antibiotics such as linezolid
- Cocaine
- Droperidol*
- Glucagon*
- Histamine*
- **Morphine**
- **Metoclopramide*, chlorpromazine, prochlorperazine**
- Saralasin
- **Tricyclic and other antidepressants**
- Tyramine
- Weight-loss medications

*Has been used as a provocative test for pheochromocytoma

REGIMEN

CYCLOPHOSPHAMIDE, VINCRISTINE, DACARBAZINE (CVD)

Averbuch SD et al. Ann Intern Med 1988;109:267–273

Recommendation: Hospitalization while first cycle is administered given that a rare patient may have worsening of their hypertension or even a hypertensive crisis during administration or shortly thereafter

Cyclophosphamide 750 mg/m²; administer intravenously in 100–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes on day 1, every 21 days (total dosage/cycle = 750 mg/m²)

Vincristine 1.4 mg/m²; administer by intravenous injection over 1–2 minutes on day 1, every 21 days (total dosage/cycle = 1.4 mg/m²)

Dacarbazine 600 mg/m² per dose; administer intravenously in 100–250 mL 0.9% NS or D5W over 15–30 minutes for 2 doses on days 1 and 2, every 21 days (total dosage/cycle = 1200 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1 and 2 is ***HIGH****. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (N = 14)

Tumor Response	
Complete response	2 (14%)
Partial response	6 (43%)
Overall response	57%
Median duration	21 months
Biochemical Response	
Complete response	3 (21%)
Partial response	8 (57%)
Overall response	78%
Median duration	22 months

Toxicity (N = 14)

Hematologic	
WBC nadir <1000/mm³	21% (3/14)
Mean nadir WBC	2100/mm³
Platelet count nadir <50,000/mm³	29% (4/14)
Mean nadir platelet count	144,000/mm³
Nonhematologic	
Mild sensory impairment	Mean grade 0.9/4
Paresthesias	Mean grade 0.9/4
Nausea and vomiting	Mean grade 1.6/4
Hypotension	4 episodes

Treatment Modifications

Counts on Day 1 of Repeated Cycles	
WBC 3000–3999/mm³ or platelets 75,000–100,000/mm³	Vincristine 100%. Reduce cyclophosphamide and dacarbazine dosages by 25%
WBC 2000–2999/mm³ or platelets 50,000–75,000/mm³	Vincristine 100%. Reduce cyclophosphamide and dacarbazine dosages by 50%
WBC 1000–1999/mm³ or platelets 25,000–50,000/mm³	Vincristine 100%. Hold cyclophosphamide and dacarbazine
Total bilirubin 1.5–2 mg/dL (25.7–34.2 µmol/L) or serum AST 75–150 units/L	Reduce vincristine dosage by 50%
Total bilirubin 3–5.9 mg/dL (51.3–100.9 µmol/L) or serum AST 151–300 units/L	Reduce vincristine dosage by 75%
Total bilirubin >6 mg/dL (>102.6 µmol/L) or serum AST >300 units/L	Hold vincristine
G1/2 neuropathy	Decrease vincristine dosage by 50%
G3/4 neuropathy	Hold vincristine
Nadir Counts During the Previous Cycle	
WBC 1000–1999/mm³ or platelets 50,000–75,000/mm³	Vincristine 100%. Reduce cyclophosphamide and dacarbazine dosages by 50%
WBC <1000/mm³ or platelets <50,000/mm³	Vincristine 100%. Reduce cyclophosphamide and dacarbazine dosages by 75%

Notes

Several drugs (including some commonly used by oncologists) may lead to a hypertensive crisis in a patient with a diagnosis of pheochromocytoma and should be avoided:

1. ACTH
2. Amphetamines
3. Antibiotics such as linezolid
4. Cocaine
5. Droperidol
6. Glucagon*
7. Histamine*
8. **Morphine**
9. **Metoclopramide***, chlorpromazine, prochlorperazine
10. Saralasin
11. **Tricyclic and other antidepressants**
12. Tyramine
13. Weight-loss medications

*Used as a provocative test for pheochromocytoma

Patient Population

A study of 14 patients with advanced malignant pheochromocytoma

Therapy Monitoring

1. *During initial treatment cycles:* Careful hemodynamic monitoring
2. *Before each cycle:* Plasma/serum metanephrines and catecholamines, CBC with differential, LFTs, and neurologic exam

32. Prostate Cancer

Avni Shah, MD, Wenhui Zhu, MD, PhD, and William L. Dahut, MD

Epidemiology

Incidence: 233,000 (Estimated new cases for 2014 in the United States) 152 per 100,000 males per year
Deaths: Estimated 29,480 in 2014
Median age: 66 years

Stage at Presentation
Stage I: 50%
Stage II: 20%
Stage III: 17%
Stage IV: 13%

Transitional cell*:	<1%
Small cell*:	<1%

Gleason Score at Presentation
(Radical prostatectomy specimens)
2–4: 6%
5–6: 54%
7: 30%
8–9: 10%

*Poor prognosis
Kantoff PW et al. Prostate Cancer: Principles & Practice. Philadelphia: Lippincott

Work-up

Bone scan if:
- T1 and PSA >20
- T2 and PSA >10
- Gleason > or >8
- T3/T4 disease
- Symptomatic

Pelvic CT/MRI if:
- T3/T4
- T1/2 and normogram indicates probability of LN invasion >10%

Staging

Primary Tumor (T)

Tx	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Clinically inapparent tumor neither palpable nor visible by imaging
T1a	Tumor incidental histologic finding in 5% or less of tissue resected
T1b	Tumor incidental histologic finding in more than 5% of tissue resected
T1c	Tumor identified by needle biopsy (eg, because of elevated PSA)
T2	Tumor confined within prostate*
pT2	Organ confined
T2a	Tumor involves one-half of 1 lobe or less
pT2a	Unilateral, one-half of 1 side or less
T2b	Tumor involves more than one-half of 1 lobe but not both lobes
pT2b	Unilateral, involving more than one-half of side but not both sides
T2c	Tumor involves both lobes
pT2c	Bilateral disease
T3	Tumor extends through the prostate capsule†
pT3	Extraprostatic extension
T3a	Extracapsular extension (unilateral or bilateral)
pT3a	Extraprostatic extension or microscopic invasion of bladder neck‡
T3b	Tumor invades seminal vesicle(s)
pT3b	Seminal vesicle invasion
T4	Tumor is fixed or invades adjacent structures other than seminal vesicles: such as external sphincter, rectum, bladder, levator muscles, and/or pelvic wall
pT4	Invasion of rectum, levator muscles, and/or pelvic wall

Note: There is no pathologic T1 classification
*Tumor found in one or both lobes by needle biopsy, but not palpable or reliably visible by imaging, is classified as T1c
†Invasion into the prostatic apex or into (but not beyond) the prostatic capsule is classified not as T3 but as T2
‡Positive surgical margin should be indicated by an R1 descriptor (residual microscopic disease)

Staging Groups

Group	T	N	M	PSA	Gleason
I	T1a–c	N0	M0	PSA <10	Gleason ≤6
	T2a	N0	M0	PSA <10	Gleason ≤6
	T1–2a	N0	M0	PSA X	Gleason X
IIA	T1a–c	N0	M0	PSA <20	Gleason 7
	T1a–c	N0	M0	PSA ≥10 <20	Gleason ≤6
	T2a	N0	M0	PSA <20	Gleason ≤7
	T2b	N0	M0	PSA <20	Gleason ≤7
	T2b	N0	M0	PSA X	Gleason X
IIB	T2c	N0	M0	Any PSA	Any Gleason
	T1–2	N0	M0	PSA ≥20	Any Gleason
	T1–2	N0	M0	Any PSA	Gleason ≥8
III	T3a–b	N0	M0	Any PSA	Any Gleason
IV	T4	N0	M0	Any PSA	Any Gleason
	Any T	N1	M0	Any PSA	Any Gleason
	Any T	Any N	M1	Any PSA	Any Gleason

When either PSA or Gleason is not available, grouping should be determined by T stage and/or either PSA or Gleason as available

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Regional Lymph Nodes (N)

NX	Regional lymph nodes were not assessed
pNX	Regional nodes not sampled
N0	No regional lymph node metastasis
pN0	No positive regional nodes
N1	Metastasis in regional lymph node(s)
pN1	Metastases in regional node(s)

Distant Metastasis (M)

M0	No distant metastasis
M1	Distant metastasis
M1a	Nonregional lymph node(s)
M1b	Bone(s)
M1c	Other site(s) with or without bone disease

Note: When more than 1 site of metastasis is present, the most advanced category is used. pM1c is most advanced

15-Year Relative Survival

Stages I–II	81%
Stage III	57%
Stage IV	6%

Predicting 15-year Prostate Cancer Specific Mortality After Radical Prostatectomy

Gleason Score	Mortality (from PrCa)
<6	0.2%–1.2%
3+4/4+3	4.2%–6.5%/6.6%–11%
8–10	26%–37%

Eggener et al. J Urol 2011;185:869–875

10-Year Free Disease Survival

(After radical prostatectomy for localized disease)

Gleason score 2–4	96%
Gleason score 5–6	82%
Gleason score 7	52%
Gleason score 8–9	35%

Expert Opinion

Screening for prostate cancer:
The optimal use of PSA in the diagnosis of prostate cancer remains a subject of continued controversy. In 2012 the USPSTF recommended against the use of PSA-based screening for prostate cancer to the general population, regardless of age. The American Urological Association has also revised their guidelines in response, advising against routine PSA based screening. However, in high-risk men ages 40–54 or all men between 55–69 the AUA advises the test to be a man's decision after a discussion of the full understanding of the risks and benefits of testing. Both groups agree that men above the age of 70 or under the age of 40 do not undergo screening

http://annals.org/article.aspx?articleID=1216568 (The Annals of Internal Medicine article for the USPSTF by Virginia A Moyer, 17 July 2012)
http://www.auanet.org/education/guidelines/prostate-cancer-detection.cfm (AUA guidelines)

The traditionally employed PSA threshold of 4 ng/mL has only a 70–80% sensitivity and 60–70% specificity. The positive predictive value of a PSA between 4 and 10 ng/mL is only 25%, and approximately 20% of patients with PSA between 2 and 4 ng/mL will have prostate cancer on biopsy. Free PSA percentage (<10%) has been shown to improve the positive predictive value in patients with total PSA between 4 and 10 ng/mL. In the Prostate Cancer Prevention Trial, 21.1% of prostate cancers were diagnosed in men with a PSA level between 2.6 and 3.9 ng/mL and 15.4% of the prostate cancers had a Gleason score of 7–10 when PSA was ≤2.5 ng/mL

Initial assessment and staging evaluation:
Patients are stratified at diagnosis for an initial treatment plan based on anticipated life expectancy and clinical symptoms
- For asymptomatic patients with life expectancy <10 years, treatment may be delayed until symptoms appear
- Once an abnormal digital rectal exam and/or an elevated PSA suggest prostate cancer is present, an ultrasound-guided prostate core biopsy with 10–12 cores is performed to help establish the diagnosis, and the 2 most common cellular patterns of the tumor are graded pathologically using the Gleason scale
- Pelvic CT or MRI is recommended for patients with T3/T4 tumor or T1/T2 tumor with a predicted probability of lymph node involvement >20%
- Bone scan is recommended for patients with T3/T4 tumor, symptomatic disease, or a T1/T2 tumor with PSA >20 ng/mL or a Gleason score ≥8

Localized prostate cancer:
Patients with newly diagnosed clinically localized prostate cancer are divided into 3 risk groups of occult metastasis and relapse after local initial therapy
- *Low risk:* PSA <10 ng/mL, Gleason score ≤6, T1/T2a tumor
- *Intermediate risk:* PSA 10–20 ng/mL, Gleason score 7, T2b/T2c tumor
- *High risk:* PSA >20 ng/mL, Gleason score 8–10, T3/T4 tumor

Treatment options for localized prostate cancer include active surveillance, radical prostatectomy (RP; including open surgery, laparoscopic, and robot-assisted procedures), and radiation therapy (RT; including high-dose external beam radiation therapy with 3D conformal or intensity-modulated radiation therapy, and brachytherapy with or without external beam therapy)
- The treatment decision is based on the probability of organ-confined disease, patient's life expectancy, and risk of relapse and metastasis
- Active surveillance is an option for patients with low-risk prostate cancer. Serial biopsy and close PSA monitoring are used to attempt to identify patients who may benefit from definitive local treatment. Some have suggested intervention if PSA doubling time is less than 3 years or Gleason grade progression to a predominant Gleason 4 pattern
- For patients with organ-confined disease, both RT and RP remain the standard of care, although surgery is not commonly performed in patients >70 years of age
- In nonrandomized patient cohort studies RP and RT appear to provide equivalent PSA-free relapse, but differ in the type and frequency of side effects. At 5 years, the rate of event-free survival was 81% for RP, 81% for high-dose external beam radiation therapy, and 83% for brachytherapy in 2991 patients with clinical stage T1-T2 localized prostate cancer treated between 1990 and 1998
- Patients undergoing RP should have extended pelvic lymph node dissection (PLND), except those with a low predicted probability of nodal metastasis by nomograms
- For T3/T4 disease, RP may be considered for selected patients with well-differentiated tumors. Most high-risk patients will receive XRT plus hormonal ablation
- For RP, nerve-sparing procedures with radical retropubic and robotic-assisted laparoscopic prostatectomy are the most common techniques. The main determinants of outcome are PSA level, Gleason score, and the TNM clinical stage. Adverse effects from surgery include incontinence, erectile dysfunction, bladder neck stricture, and bowel incontinence
- The biochemical control rate after RT depends largely upon the risk features associated with individual tumors. The probability of biochemical control 5 years after RT without hormonal ablation is 84% for low-risk disease, 62% for intermediate-risk disease, and 43% for high-risk disease

Adjuvant therapies after initial definitive therapies
- Adjuvant RT after RP should be considered for patients with positive surgical margins, seminal vesicle involvement, or pathological evidence of T3/T4 disease
- Immediate postoperative RT for patients with pathologic T3 disease improves PSA progression-free survival significantly (74% vs. 53% for placebo after 5 years of follow up), although there is no overall survival benefit
- Due to exclusion of patients with node positive disease in most clinical trials, it remains unclear whether adjuvant RT after RP should be considered in this subset of patients

(*continued*)

Expert Opinion (*continued*)

- Immediate androgen-deprivation therapy (ADT) provides significant overall survival benefit in patients with microscopically positive lymph nodes treated with RP, compared to hormonal therapy started at the time of symptomatic local recurrence or metastasis
- Neoadjuvant/adjuvant ADT of 2–3 years in combination with RT is the standard for high-risk patients. Neoadjuvant/adjuvant ADT (for 6 months) in combination with RT may improve progression-free disease and prostate cancer-specific and overall survival for patients with PSA >10 ng/mL, a Gleason score ≥7, or radiographic evidence of extraprostatic disease. This needs confirmation in a larger study limited only to intermediate-risk patients

Androgen-deprivation therapy

- Optimal ADT includes medical castration with a GnRH antagonist, an LHRH agonist, or surgical castration with bilateral orchiectomy. The addition of an antiandrogen can reduce the initial disease flare that may follow introduction of a LHRH agonist, but does not appear to add significantly to survival
- Side effects of ADT include osteoporosis, hot flashes, loss of libido, erectile dysfunction, fatigue, gynecomastia, cognitive dysfunction, depression, anemia, loss of muscle mass, glucose intolerance, and changes in lipids profile and increased risk of cardiovascular disease
- Hot flashes from hormonal therapy can be treated with clonidine (0.1 mg daily, orally), low-dose estrogens, or antidepressants
- Prophylactic breast XRT can reduce the incidence of painful gynecomastia
- Patients receiving long-term ADT should have a baseline bone density scan and supplemental vitamin D and calcium. Consider bisphosphonates if an evaluation demonstrates evidence of either osteopenia or osteoporosis

PSA Failure

PSA failure after RP:

- Following RP, it is expected that PSA will be undetectable. Biochemical recurrence following RP is defined as either failure to achieve an undetectable PSA level or a PSA rise after surgery on 2 or more laboratory determinations. The American Urological Association Prostate Guideline Update Panel has chosen a PSA level ≥0.2 ng/mL as the threshold
- Patients with biochemical recurrence because of local failure and without distant metastasis (clinical features include PSA <2 ng/mL, slow PSA doubling time, a long interval to failure after surgery) should be evaluated for salvage RT. Salvage RT provides durable disease-free survival in 60–70% of patients, but no confirmed overall survival benefits. Predictors of progression after salvage RT include a Gleason score of 8–10, pre-RT PSA >2 ng/mL, negative surgical margins, and a PSA doubling time <10 months

PSA failure after RT:

- PSA failure after RT is defined as a PSA rise ≥2 ng/mL above the nadir (the Phoenix definition)
- Patients with original clinical stage T1–T2, a life expectancy >10 years, and a current PSA <10 ng/mL may be candidates for local therapy such as salvage RP, cryotherapy, or brachytherapy. However, morbidity is high and there are no randomized trials that demonstrate improved survival. Further work-up is indicated to rule out distant metastasis before local therapy

For patients with PSA failure, timing of ADT is affected by PSA velocity, patient preference, and other medical comorbidities. Early implementation of ADT may delay the appearance of metastases; however, there are no data indicating early ADT provides any overall survival benefit

Advanced prostate cancer

- In patients with metastatic prostate cancer, local therapies are used primarily for symptom management. There are no conclusive data that local therapies improve survival
- ADT should begin immediately in the presence of tumor-related symptoms or overt metastasis
- **Combined androgen blockage** (castration combined with an antiandrogen) provides no definite survival improvement over castration alone in patients with metastatic disease
- Initiation of treatment with LHRH agonists is associated with a transient increase in testosterone production with initial use (tumor flare). For patients with overt metastases who are at risk of developing symptoms (such as spinal cord compression, worsening pain, or urinary outlet obstruction) an antiandrogen should be given concurrently with a LHRH agonist for at least 7 days after initiating treatment with the latter to competitively block testosterone at androgen receptors, and prevent potential exacerbation of disease. **Ketoconazole** may also be used in patients who are at high risk for complications associated with tumor flare
- Intermittent ADT can be used to reduce side effects and cost of ADT, but its long-term efficacy remains unproven
- **Abiraterone acetate** has been approved in patients pre-chemotherapy based on improved progression-free survival. The study was stopped before an overall-survival benefit could be seen, but there was a trend towards OS improvement as well [Ryan et al. N Engl J Med 2013;368:138–148]. **Enzalutamide** may be shown to be beneficial in this setting as well
- Second-line hormonal management includes antiandrogens, antiandrogen withdrawal, adrenal androgen inhibitors (**aminoglutethimide or ketoconazole with hydrocortisone replacement**), and estrogens. **Abiraterone acetate** targets cytochrome P450 17A1 (CYP17A1), leading to a decrease in the production of testosterone. It received FDA approval based on a study that demonstrated improved survival in patients who received it after docetaxel chemotherapy. **Abiraterone acetate** is administered daily in combination with prednisone. **Enzalutamide**, a potent anti-androgen, has also been approved for use post-chemotherapy based on an OS benefit. One advantage of enzalutamide over abiraterone acetate is that it does not require concomitant prednisone which can have side-effects in patients with prostate cancer. Selected patients may respond to sequential hormonal manipulations

(*continued*)

Expert Opinion (*continued*)

- **Sipuleucel-T** is a cellular immunotherapy consisting of peripheral blood mononuclear cells obtained by leukapheresis and cultured (activated) with a recombinant human protein consisting of prostatic acid phosphatase linked to granulocyte-macrophage colony-stimulating factor (PAP-GM-CSF). In a randomized trial this product had no effect on time to progression, but lead to an improvement in overall survival.
- Chemotherapy with **docetaxel** every 3 weeks plus prednisone is the preferred first-line chemotherapy for advanced prostate cancer, providing improved survival. **Cabazitaxel** is a semisynthetic derivative of a natural taxoid, which, when combined with prednisone, improved survival in patients who had progressed on docetaxel and prednisone. Alternative regimens include **every 3-week docetaxel and estramustine**, **weekly docetaxel and prednisone**, and **every 3-week mitoxantrone and prednisone**
- **Cabazitaxel** is approved as a second-line chemotherapeutic agent
- *Metastatic small cell carcinoma of the prostate* should be treated with a platinum-containing regimen, but mixed tumors (adenocarcinoma and small cell) may have some initial response to hormonal ablation
- **Zoledronic acid** prevents skeletal-related events in patients with castrate resistant prostate cancer and bone metastases
- **Radium-223** has been approved by the FDA-for prostate cancer and selectively targets bone metastases with alpha particles. It has been shown to improve overall survival but it remains to be seen where exactly it will be used in patients and whether or not it will be combined with other approved agents

REGIMEN

ABIRATERONE ACETATE METASTATIC CASTRATION-RESISTANT PROSTATE CANCER—NO PRIOR CHEMOTHERAPY

Ryan CJ et al. N Engl J Med 2013;368:138–148

Abiraterone acetate 1000 mg orally once daily, continually for 28 consecutive days (total dose/28-day cycle = 28,000 mg)
Note: No food should be consumed for at least 2 hours before a dose of abiraterone acetate is taken and for at least 1 hour after a dose of abiraterone acetate is taken. Exposure (area under the curve) of abiraterone acetate increases up to 10-fold when abiraterone acetate is taken with meals

Prednisone 5 mg orally twice daily, continually for 28 consecutive days (total dose/28-day cycle = 280 mg)

Notes:
- For patients with baseline moderate hepatic impairment (Child-Pugh Class B), reduce the dose of abiraterone acetate to 250 mg once daily
- Avoid abiraterone acetate in patients with baseline severe hepatic impairment (Child-Pugh Class C), as abiraterone acetate has not been studied in this population, and no dose adjustment can be predicted
- Abiraterone acetate is an inhibitor of the polymorphically expressed cytochrome P450 (CYP) enzyme, CYP2D6
  - **Avoid coadministration** of abiraterone acetate with CYP2D6 substrates that have a low therapeutic index. If an alternative treatment cannot be used, exercise caution and consider a dose reduction of concomitantly used CYP2D6 substrates
- Monitor for symptoms and signs of adrenocortical insufficiency. Increased dosage of corticosteroids may be indicated before, during, and after stressful situations
- Monitor for signs and symptoms of mineralocorticoid excess, including hypokalemia, fluid retention, and hypertension. Prednisone dose may have to be supplemented in some patients or augmented with an aldosterone antagonist such as eplerenone
- Use abiraterone acetate with caution in patients with a history of cardiovascular disease. Control hypertension and correct hypokalemia before initiating treatment
- Abiraterone acetate is a substrate of CYP3A4. Avoid or use with caution strong CYP3A4 inhibitors (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole) or inducers (eg, carbamazepine, phenobarbital, phenytoin, rifabutin, rifapentine, rifampin) during abiraterone acetate treatment
- Abiraterone acetate was a strong inhibitor of CYP1A2 and CYP2D6, and a moderate inhibitor of CYP2C9, CYP2C19, and CYP3A4/5 in experimental systems. It is not yet known whether its effects on CYP1A2, CYP2C subfamily, or CYP3A subfamily enzymes in in vitro systems are representative of a potential for clinically important drug interactions
- Use abiraterone acetate with caution in patients with a history of cardiovascular disease. The safety of abiraterone acetate in patients with LVEF <50% or NYHA Class III or IV heart failure is not established. Control hypertension and correct hypokalemia before treatment

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modification

Adverse Event	Dose Modification
G2 hepatotoxicity	Hold abiraterone acetate until toxicity remits to G ≤1, then resume treatment at a dose of 750 mg once daily
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal [ULN] or total bilirubin >3 × ULN) in a patient with baseline normal hepatic function	Withhold abiraterone acetate. Treatment may be restarted at a dose of 750 mg once daily following return of liver function tests to a patient's baseline or to AST and ALT G ≤1 (2.5 × ULN) and total bilirubin G ≤1 (≤1.5 × ULN). For patients who resume treatment, monitor serum transaminases
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal [ULN] or total bilirubin >3 × ULN) in a patient with baseline normal hepatic impairment on a reduced dose of 750 mg/day because of prior hepatotoxicity at 1000 mg/day	Withhold abiraterone acetate. Treatment may be restarted at a dose of 500 mg once daily following return of liver function tests to a patient's baseline or to AST and ALT G ≤1 (2.5 × ULN) and total bilirubin G ≤1 (≤1.5 × ULN). For patients who resume treatment, monitor serum transaminases
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal or total bilirubin >3 × ULN) in a patient with baseline normal hepatic impairment on a reduced dose of 500 mg/day because of prior hepatotoxicity at 750 mg/day	Discontinue abiraterone acetate

(*continued*)

Efficacy

Prespecified Secondary and Exploratory Efficacy End Points*

	Abiraterone + Prednisone (N = 546)	Prednisone Alone (N = 542)	Value (95% CI)†	P Value
End Point				
Secondary End Points				
Median Times in Months to:				
Opioid use for cancer-related pain	Not Reached	23.7	0.69 (0.57–0.83)	<0.001
Starting cytotoxic chemotherapy	25.2	16.8	0.58 (0.49–0.69)	<0.001
Decline in ECOG PS by ≥1 point	12.3	10.9	0.82 (0.71–0.94)	0.005
PSA progression‡	11.1	5.6	0.49 (0.42–0.57)	<0.001
Exploratory End Points§				
Median Times in Months to:				
Increase in pain‹	26.7	18.4	0.82 (0.67–1.00)	0.049
Functional status decline**	12.7	8.3	0.78 (0.66–0.92)	0.003

Patients with Measurable Disease at Baseline and a RECIST Response (%)				
	N = 220	N = 218		
Defined objective response	36	16	2.27 (1.59–3.25)‡‡	<0.001
Stable disease	61	69		
Progressive disease	2	15		

CI, Confidence interval; FACT-P, Functional Assessment of Cancer Therapy–Prostate; HR, hazard ratio; PS, performance score; PSA, prostate-specific antigen; RECIST, Response Evaluation Criteria in Solid Tumors

*Percentages may not sum to 100 because of rounding

†Values are hazard ratios unless otherwise specified

‡Based on Prostate Cancer Clinical Trials Working Group 2 (PCWG2) criteria

§The exploratory analyses are reported with no adjustment for multiplicity

‹Increase in pain is defined as an increase in the baseline pain level by 30% or more, as measured by the average of the pain scores on the Brief Pain Inventory–Short Form (range: 0–10, with higher scores indicating worse average pain) at 2 consecutive visits, without a decrease in analgesic use

**Defined as months from randomization to the first date a patient has a decrease of 10 points or more on the FACT-P instrument (range: 0–156, with higher scores indicating better overall quality of life)

††A decline ≥50% in the PSA level was based on modified PCWG2 criteria

‡‡Values are relative risks

Treatment Modification (*continued*)

Adverse Event	Dose Modification
G3 hepatotoxicity (elevations in ALT and/or AST >5 × ULN or total bilirubin >3 × ULN) in a patient with baseline moderate hepatic impairment on a reduced dose of 750 mg abiraterone acetate daily	Discontinue abiraterone acetate
G4 hepatotoxicity (elevations in ALT and/or AST >20 × ULN or total bilirubin >10 × ULN) in a patient with baseline moderate hepatic impairment	Discontinue abiraterone acetate
Hypertension, hypokalemia, and fluid retention caused by mineralocorticoid excess	Withhold abiraterone acetate. Ensure corticosteroids are being administered appropriately. Manage hypokalemia and hypertension
Suspicion of adrenocortical insufficiency	Perform appropriate tests to confirm the diagnosis of adrenocortical insufficiency. Consider administering increased corticosteroid doses during and after stressful situations

Adverse Events of Special Interest†

Adverse Event	Abiraterone + Prednisone (N = 542)		Prednisone Alone (N = 540)	
	G 1–4	G 3 or 4	G 1–4	G 3 or 4
Fluid retention or edema	150 (28)	4 (<1)	127 (24)	9 (2)
Hypokalemia	91 (17)	13 (2)	68 (13)	10 (2)
Hypertension	118 (22)	21 (4)	71 (13)	16 (3)
Cardiac disorder‡	102 (19)	31 (6)	84 (16)	18 (3)
Atrial fibrillation	22 (4)	7 (1)	26 (5)	5 (<1)
ALT increased	63 (12)	29 (5)	27 (5)	4 (<1)
AST increased	58 (11)	16 (3)	26 (5)	5 (<1)

ALT, Alanine aminotransferase; AST, aspartate aminotransferase

*Most common adverse events leading to death were general disorders, including disease progression, decline in physical health, and infections including pneumonia and respiratory tract infection

†Adverse events of special interest were selected on the basis of the safety profile of phase 2 and phase 3 studies of abiraterone

‡Cardiac disorders included ischemic heart disease, myocardial infarction, supraventricular tachyarrhythmia, ventricular tachyarrhythmia, cardiac failure, and possible arrhythmia-related investigations, signs, and symptoms

Patient Population Studied

Inclusion criteria: (a) metastatic, histologically or cytologically confirmed adenocarcinoma of the prostate; (b) PSA progression according to Prostate Cancer Clinical Trials Working Group 2 (PCWG2) criteria or radiographic progression in soft tissue or bone ± PSA progression; (c) ongoing androgen deprivation with a serum testosterone level <50 ng/dL (<1.7 nmol/L); (d) ECOG performance status grade of 0 or 1; (e) no symptoms or mild symptoms, as defined according to the Brief Pain Inventory–Short Form (BPI-SF; scores of 0 to 1 [asymptomatic] or 2 to 3 [mildly symptomatic], respectively). Exclusion criteria: (a) No previous therapy with an antiandrogen; (b) visceral metastases; (c) previous ketoconazole >7 days

Treatment Monitoring

1. CBC every 8 weeks for the first 24 weeks, and then, every 12 weeks
2. *Evaluation including PSA:* Every 8 weeks for the first 24 weeks, and then, every 12 weeks
3. Monitor blood pressure, serum potassium, and symptoms of fluid retention at least every 8 weeks
4. Measure serum transaminases (ALT and AST) and bilirubin levels prior to starting treatment with abiraterone acetate, every 2 weeks for the first 3 months of treatment, and monthly thereafter. Modify, interrupt, or discontinue abiraterone acetate dosing as recommended
5. In patients with baseline moderate hepatic impairment receiving a reduced abiraterone acetate dose of 250 mg/day, measure ALT, AST, and bilirubin prior to the start of treatment, every week for the first month, every 2 weeks for the following 2 months of treatment, and monthly, thereafter. Promptly measure serum total bilirubin, AST, and ALT if clinical symptoms or signs suggestive of hepatotoxicity develop
6. For patients who resume treatment after LFTs return to G ≤1 from a G2/3/4 toxicity, monitor serum transaminases and bilirubin at a minimum of every 2 weeks for 3 months and monthly thereafter
7. Monitor for symptoms and signs of adrenocortical insufficiency. Increased dosage of corticosteroids may be indicated before, during, and after stressful situations

REGIMEN

DOCETAXEL + PREDNISONE

Tannock IF et al. N Engl J Med 2004;351:1502–1512

Dexamethasone 8 mg/dose orally for 3 doses at 12 hours, 3 hours, and 1 hour before docetaxel treatment commences (total dose/cycle = 24 mg)
Docetaxel 75 mg/m^2 intravenously over 1 hour, in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a solution with concentration within the range 0.3–0.74 mg/mL, on day 1, every 21 days (total dosage/cycle = 75 mg/m^2)
Prednisone 5 mg/dose orally twice daily, continually, for 21 consecutive days, on days 1–21, every 3 weeks (total dose/cycle = 210 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 335 patients with castration-refractory metastatic prostate cancer and no prior chemotherapy other than estramustine

Efficacy

	Docetaxel + Prednisone	Mitoxantrone + Prednisone
Median survival	18.9 months (n = 335)	16.5 months (n = 357)
Pain response	35% (n = 153)	22% (n = 157)
50% ↓ PSA	45% (n = 291)	32% (n = 300)

Toxicity (N = 332)

	% All Grades	% G3/4
Hematologic		
Neutropenia	—	32
Anemia	—	5
Thrombocytopenia	—	1
Febrile neutropenia	3	—
Infection	—	6
Nonhematologic		
Fatigue	53	5
Nausea/vomiting	42	—
Diarrhea	32	2
Sensory neuropathy	30	—
Stomatitis	20	—
Dyspnea	15	—
Peripheral edema	15	—
Myalgia	14	—

Treatment Modifications

Adverse Event	Dose Modification
G4 Neutropenia ≥7 days duration, febrile neutropenia, infection, or ANC <1500/mm^3 on day of therapy	Delay therapy until ANC >1500/mm^3 *or* reduce dose of docetaxel by 25%
G3/4 thrombocytopenia	Delay therapy until thrombocytopenia G ≤2, or reduce dosage of docetaxel by 25%
G3/4 toxicities other than those listed above	Wait for toxicity to recover to G ≤1, then reduce docetaxel dosage to 60 mg/m^2
G3/4 neurotoxicity	Stop therapy
G4 nonhematologic toxicity that occurs with 60 mg/m^2 docetaxel	
Aspartate/alanine aminotransferase (AST/ALT) >1.5 × upper limits of normal (ULN) and alkaline phosphatase >2.5 × ULN Bilirubin > ULN	Hold docetaxel until resolved

Therapy Monitoring

Before each cycle: CBC with differential, liver function tests, PSA if indicated

REGIMEN

MITOXANTRONE + PREDNISONE (M + P)

Hussain M et al. Semin Oncol 1999;26(5 Suppl 17):55–60
Tannock IF et al. J Clin Oncol 1996;14:1756–1764

Mitoxantrone 12 mg/m² intravenously in 50 mL 0.9% sodium chloride injection or 5% dextrose injection over 5–30 minutes, on day 1, every 21 days (total dosage/cycle = 12 mg/m²)
Prednisone 5 mg/dose orally twice daily continually, for 21 consecutive days, on days 1–21, every 3 weeks (total dose/cycle = 210 mg)
Usually administered for a total of 6 cycles

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with metastatic castration-refractory prostate cancer with symptoms (including pain) and disease progression despite standard hormonal therapy. Randomized comparison with prednisone alone

Efficacy (N = 80)

Palliative response*	29–38%
Palliative response duration	43 weeks

*Defined as a decrease in pain parameters

Efficacy: PSA Response (N = 57)

≥50% decrease	33%
≥75% decrease	23%

Toxicity* (N = 654 and 796 cycles)

	% Cycles	
	% G1/2	% G3/4
Hematologic (N = 796 cycles)		
Neutropenia	NA	45
Febrile neutropenia	NA	7
Thrombocytopenia	4.2	0.6
Nonhematologic (N = 654 cycles)		
Nausea/vomiting	29	0.5
Alopecia	24	—
Cardiac dysfunction	2.5	1.7

*WHO criteria

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm³, ANC <1500/mm³, or platelet <100,000/mm³	Delay therapy until WBC >3000/mm³, ANC >1500/mm³, platelet >100,000/mm³
Nadir ANC <500/mm³, or nadir platelet <50,000/mm³	Reduce mitoxantrone dosage by 2 mg/m² per dose
Nadir ANC >1000/mm³, and nadir platelet >100,000/mm³, and minimal nonhematologic toxicity	May increase mitoxantrone dosage to 14 mg/m² per dose
Patients who received a total cumulative lifetime mitoxantrone dosage of 140 mg/m²	Stop mitoxantrone, but continue prednisone

Therapy Monitoring

1. *Before starting therapy:* Echocardiogram
2. *Before each cycle:* CBC with differential, LFTs, PSA if indicated

ADVANCED DISEASE REGIMEN

ABIRATERONE ACETATE
METASTATIC CASTRATION-RESISTANT PROSTATE CANCER—PRIOR CHEMOTHERAPY

Fizazi K et al. Lancet Oncol 2012;13:983–992

Abiraterone acetate 1000 mg orally once daily on an empty stomach, continually for 28 consecutive days (total dose/28-day cycle = 28,000 mg)

Note: No food should be consumed for at least 2 hours before a dose of abiraterone acetate is taken and for at least 1 hour after a dose of abiraterone acetate is taken. Exposure (area under the curve) of abiraterone increases up to 10-fold when abiraterone acetate is taken with meals

Prednisone 5 mg orally, twice daily, continually for 28 consecutive days (total dose/28-day cycle = 280 mg)

Notes:

- For patients with baseline moderate hepatic impairment (Child-Pugh Class B), reduce the dose of abiraterone acetate to 250 mg once daily
- Avoid abiraterone acetate in patients with baseline severe hepatic impairment (Child-Pugh Class C), as abiraterone acetate has not been studied in this population, and no dose adjustment can be predicted
- Abiraterone acetate is an inhibitor of the polymorphically expressed cytochrome P450 (CYP) enzyme, CYP2D6
  - **Avoid coadministration** of abiraterone acetate with CYP2D6 substrates that have a low therapeutic index. If an alternative treatment cannot be used, exercise caution and consider a dose reduction of concomitantly used CYP2D6 substrates
- Monitor for symptoms and signs of adrenocortical insufficiency. Increased dosage of corticosteroids may be indicated before, during, and after stressful situations
- Monitor for signs and symptoms of mineralocorticoid excess, including hypokalemia, fluid retention, and hypertension. Prednisone dose may have to be supplemented in some patients or augmented with an aldosterone antagonist such as eplerenone
- Use abiraterone acetate with caution in patients with a history of cardiovascular disease. Control hypertension and correct hypokalemia before initiating treatment
- Abiraterone acetate is a substrate of CYP3A4. Avoid or use with caution strong CYP3A4 inhibitors (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole) or inducers (eg, carbamazepine, phenobarbital, phenytoin, rifabutin, rifapentine, rifampin) during abiraterone acetate treatment
- Abiraterone acetate was a strong inhibitor of CYP1A2 and CYP2D6, and a moderate inhibitor of CYP2C9, CYP2C19, and CYP3A4/5 in experimental systems. It is not yet known whether its effects on CYP1A2, CYP2C subfamily, or CYP3A subfamily enzymes in in vitro systems are representative of a potential for clinically important drug interactions
- Use abiraterone acetate with caution in patients with a history of cardiovascular disease. The safety of abiraterone acetate in patients with LVEF <50% or NYHA Class III or IV heart failure is not established. Control hypertension and correct hypokalemia before treatment

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modification

Adverse Event	Dose Modification
G2 hepatotoxicity	Hold abiraterone acetate until toxicity remits to G ≤1, then resume treatment at a dose of 750 mg once daily
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal [ULN] or total bilirubin >3 × ULN) in a patient with baseline normal hepatic function	Withhold abiraterone acetate. Treatment may be restarted at a dose of 750 mg once daily following return of liver function tests to a patient's baseline or to AST and ALT G ≤1 (2.5 × ULN) and total bilirubin G ≤1 (≤1.5 × ULN). For patients who resume treatment, monitor serum transaminases
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal [ULN] or total bilirubin >3 × ULN) in a patient with baseline normal hepatic impairment on a reduced dose of 750 mg/day because of prior hepatotoxicity at 1000 mg/day	Withhold abiraterone acetate. Treatment may be restarted at a dose of 500 mg once daily following return of liver function tests to a patient's baseline or to AST and ALT G ≤1 (2.5 × ULN) and total bilirubin G ≤1 (≤1.5 × ULN). For patients who resume treatment, monitor serum transaminases
G3 hepatotoxicity (elevations in ALT and/or AST >5 × upper limit of normal [ULN] or total bilirubin >3 × ULN) in a patient with baseline normal hepatic impairment on a reduced dose of 500 mg/day because of prior hepatotoxicity at 750 mg/day	Discontinue abiraterone acetate

(continued)

Treatment Modification (continued)

Adverse Event	Dose Modification
G3 hepatotoxicity (elevations in ALT and/or AST >5 × ULN or total bilirubin >3 × ULN) in a patient with baseline moderate hepatic impairment on a reduced dose of 750 mg abiraterone acetate daily	Discontinue abiraterone acetate
G4 hepatotoxicity (elevations in ALT and/or AST >20 × ULN or total bilirubin >10 × ULN) in a patient with baseline moderate hepatic impairment	Discontinue abiraterone acetate
Hypertension, hypokalemia, and fluid retention caused by mineralocorticoid excess	Withhold abiraterone acetate. Ensure corticosteroids are being administered appropriately. Manage hypokalemia and hypertension
Suspicion of adrenocortical insufficiency	Perform appropriate tests to confirm the diagnosis of adrenocortical insufficiency. Consider administering increased corticosteroid doses during and after stressful situations

Patient Population Studied

A phase-3, double-blind, randomized placebo-controlled trial, in which men with histologically or cytologically confirmed metastatic castration-resistant prostate cancer were enrolled if they had (a) previous treatment with docetaxel and a maximum of 2 previous chemotherapies; (b) PSA progression according to Prostate Cancer Working Group criteria, or radiographic progression in soft tissue or bone ± PSA progression; (c) ongoing androgen deprivation to maintain serum testosterone concentration lower <50 ng/dL (<2.0 nmol/L by radioimmunoassay); and (d) ECOG performance status ≤2

LFTs, Liver function tests
*Cardiac disorders associated with abiraterone acetate treatment as defined by the standardized *Medical Dictionary for Regulatory Activities Queries* included ischemic heart disease, myocardial infarction, supraventricular tachyarrhythmias, ventricular tachyarrhythmias, cardiac failure, and possible arrhythmia-related investigations, signs, and symptoms

Treatment Monitoring

1. CBC before each cycle
2. *Evaluation including PSA:* Every 6 weeks
3. Monitor blood pressure, serum potassium, and symptoms of fluid retention at least monthly
4. Measure serum transaminases (ALT and AST) and bilirubin levels prior to starting treatment with abiraterone acetate, every 2 weeks for the first 3 months of treatment, and monthly thereafter. Modify, interrupt, or discontinue abiraterone acetate dosing as recommended
5. In patients with baseline moderate hepatic impairment receiving a reduced abiraterone acetate dose of 250 mg/day, measure ALT, AST, and bilirubin prior to the start of treatment, every week for the first month, every 2 weeks for the following 2 months of treatment, and monthly, thereafter. Promptly measure serum total bilirubin, AST, and ALT if clinical symptoms or signs suggestive of hepatotoxicity develop
6. For patients who resume treatment after LFTs return to G ≤1 from a G2/3/4 toxicity, monitor serum transaminases and bilirubin at a minimum of every 2 weeks for 3 months and monthly thereafter
7. Monitor for symptoms and signs of adrenocortical insufficiency. Increased dosage of corticosteroids may be indicated before, during, and after stressful situations

ADVANCED DISEASE REGIMEN

ENZALUTAMIDE
METASTATIC CASTRATION-RESISTANT PROSTATE CANCER—PRIOR CHEMOTHERAPY

Scher HI et al. N Engl J Med 2012;367:1187–1197

Enzalutamide 160 mg orally, once daily, continually

Notes:
- Can be taken with or without food
- Swallow capsules whole. Do not chew, dissolve, or open the capsules

Notes:
- If possible, avoid concomitant use of strong CYP2C8 inhibitors. If patients must receive a strong CYP2C8 inhibitor concomitantly, reduce the enzalutamide dose to 80 mg once daily. If coadministration of the strong inhibitor is discontinued, the enzalutamide dose should be returned to the dose used prior to initiation of a strong CYP2C8 inhibitor
- Coadministration of a strong CYP3A4 inhibitor (eg, itraconazole) increased the composite AUC of enzalutamide plus *N*-desmethyl enzalutamide by 1.3-fold in healthy volunteers
- The effects of CYP3A4 inducers on the pharmacokinetics of enzalutamide have not been evaluated in vivo
- Coadministration of enzalutamide with strong CYP3A4 inducers may decrease the plasma exposure of enzalutamide and should be avoided if possible
- Moderate CYP3A4 inducers and St. John's wort may also reduce the plasma exposure of enzalutamide and should be avoided if possible
- Enzalutamide is a strong CYP3A4 inducer and a moderate CYP2C9 and CYP2C19 inducer in humans. At steady state, enzalutamide reduced the plasma exposure to midazolam (CYP3A4 substrate), warfarin (CYP2C9 substrate), and omeprazole (CYP2C19 substrate). Concomitant use of enzalutamide with narrow therapeutic index drugs that are metabolized by CYP3A4, CYP2C9 (eg, phenytoin, warfarin) and CYP2C19 should be avoided, as enzalutamide may decrease their exposure. If coadministration with warfarin cannot be avoided, conduct additional INR monitoring

Treatment Modification

Adverse Event	Treatment Modification
G ≥3 adverse event or an intolerable side effect	Withhold dosing for 1 week or until symptoms improve to G ≤2, then resume at the same or a reduced dose (120 mg or 80 mg daily), if warranted
Occurrence of a seizure	Discontinue enzalutamide

Patient Population Studied

Patients had (a) a histologically or cytologically confirmed diagnosis of prostate cancer; (b) castrate levels of testosterone (<50 ng/dL; [<1.7 nmol/L]); (c) previous treatment with docetaxel; and (d) progressive disease defined according to Prostate Cancer Working Group 2 criteria (including 3 increasing values for PSA or radiographically confirmed progression with or without a rise in the PSA level)

Efficacy

Multivariate Analysis of Hazard Ratios for Death*

Variable	Measurement Estimates		Hazard Ratio for Death (95% CI)†
	Coefficient	P Value	
Study treatment (enzalutamide vs. placebo)	−0.54 ± 0.09	<0.001	0.58 (0.49–0.70)
ECOG performance score (0 or 1 vs. 2)	−0.33 ± 0.14	0.02	0.72 (0.55–0.95)
BPI-SF mean pain score (question no. 3) (<4 vs. ≥4)‡	−0.23 ± 0.10	0.02	0.79 (0.65–0.97)
Progression at study entry (PSA only vs. radiographic)	−0.29 ± 0.09	0.002	0.75 (0.62–0.90)
Visceral disease at screening (no vs. yes)	−0.47 ± 0.10	<0.001	0.63 (0.52–0.76)

Efficacy (continued)

Secondary End Points Related to Response and Disease Progression[§]

End Point	Enzalutamide (N = 800)	Placebo (N = 399)	Hazard Ratio (95% CI)	P Value
Confirmed PSA decline[§]				
≥1 Postbaseline PSA assessment—no. (%)	731 (91)	330 (83)		
PSA response—no./total no. (%)				
Decline ≥50% from baseline	395/731 (54)	5/330 (2)		<0.001
Decline ≥90% from baseline	181/731 (25)	3/330 (1)		<0.001
Soft-tissue objective response				
Patients with measurable disease—no. (%)	446 (56)	208 (52)		
CR or PR—no./total no. (%)	129/446 (29)	8/208 (4)		<0.001
FACT-P quality-of-life response[§]				
No (%) with ≥1 postbaseline assessment	651 (81)	257 (64)		
Quality-of-life response—no./total no. (%)[¶]	281/651 (43)	47/257 (18)		<0.001
Progression indicators				
Time to PSA progression			0.25 (0.20–0.30)	<0.001
Median, months	8.3	3.0		
95% CI	5.8–8.3	2.9–3.7		
Radiographic progression-free survival			0.40 (0.35–0.47)	<0.001
Median, months	8.3	2.9		
95% CI	8.2–9.4	2.8–3.4		
Time to first skeletal-related event			0.69 (0.57–0.84)	<0.001
Median, months	16.7	13.3		
95% CI	14.6–19.1	9.9–NYR		

BPI-SF, Brief Pain Inventory–Short Form; CI, confidence interval; CR, complete response; ECOG, Eastern Cooperative Oncology Group; FACT-P, Functional Assessment of Cancer Therapy–Prostate; LDH, lactate dehydrogenase; NYR, not yet reached; PR, partial response

*Patients alive at the time of analysis were censored at the date patient was last known to be alive

†Hazard ratios for death were calculated after adjustment for prognostic factors. These included age (<65 years vs. ≥65 years), region (North America vs. other), number of previous chemotherapy regimens (1 vs. 2), and baseline serum PSA level (per increase of 1 ng/mL). The Gleason score for prostate tumors was excluded owing to a large number of missing values

‡On the Brief Pain Inventory–Short Form (BPI-SF) scores of 0–3 indicate clinically significant pain is absent and scores of 4–10 indicate clinically significant pain is present. Higher scores indicate greater pain

§Only patients with both baseline and postbaseline assessments are included

¶Defined as 10-point improvement in the global score on the FACT-P questionnaire, as compared with baseline, on 2 consecutive measurements obtained at least 3 weeks apart

Toxicity

Adverse Events, According to Grade

	Enzalutamide (N = 800)		Placebo (N = 399)	
	Any Grade	G ≥3	Any Grade	G ≥3
Adverse Event	Number of Patients (Percent)			
≥1 Adverse event	785 (98)	362 (45)	390 (98)	212 (53)
Any serious adverse event	268 (34)	227 (28)	154 (39)	134 (34)
Discontinuation owing to adverse event	61 (8)	37 (5)	39 (10)	28 (7)
Adverse event leading to death	23 (3)	23 (3)	14 (4)	14 (4)
Frequent adverse events more common with enzalutamide*				
Fatigue	269 (34)	50 (6)	116 (29)	29 (7)
Diarrhea	171 (21)	9 (1)	70 (18)	1 (<1)
Hot flash	162 (20)	0	41 (10)	0
Musculoskeletal pain	109 (14)	8 (1)	40 (10)	1 (<1)
Headache	93 (12)	6 (<1)	22 (6)	0
Clinically significant adverse events				
Cardiac disorder				
Any	49 (6)	7 (1)	30 (8)	8 (2)
Myocardial infarction	2 (<1)	2 (<1)	2 (<1)	2 (<1)
Abnormality on liver-function testing†	8 (1)	3 (<1)	6 (2)	3 (<1)
Seizure	5 (<1)	5 (<1)	0	0

*Includes adverse events that occurred in >10% of patients in the enzalutamide group and those that occurred in the enzalutamide group at a rate ≥2% higher than in the placebo group
†Includes hyperbilirubinemia and increased levels of aspartate or alanine aminotransferases

Treatment Monitoring

Evaluation including PSA: Every 6 weeks

ADVANCED DISEASE REGIMEN

CABAZITAXEL + PREDNISONE

de Bono JS et al. Lancet 2010;376:1147–1154

Note: Severe hypersensitivity reactions can occur with cabazitaxel administration. These may include generalized rash/erythema, hypotension, and bronchospasm. Severe hypersensitivity reactions require immediate discontinuation of cabazitaxel infusion and administration of appropriate therapy. Patients should receive primary prophylaxis against hypersensitivity reactions as described below. Cabazitaxel must not be given to patients who have a history of severe hypersensitivity reactions to other drugs formulated with polysorbate 80, such as fosaprepitant dimeglumine (the parenteral formulation of aprepitant [Emend]), darbepoetin alfa, docetaxel, etoposide, recombinant human papillomavirus quadrivalent vaccine (Gardasil), and various vaccines. Patients should be observed closely for hypersensitivity reactions, especially during the first and second infusions. Hypersensitivity reactions may occur within a few minutes following the initiation of the cabazitaxel infusion, thus facilities and equipment for the treatment of hypotension and bronchospasm should be available

Premedication:

At least 30 minutes prior to each cabazitaxel dose, administer the following medications to reduce the risk and/or severity of hypersensitivity:

- **Diphenhydramine** 25 mg, or an equivalent H_1-receptor antihistamine, orally or intravenously
- **Dexamethasone** 8 mg or an equipotent glucocorticoid
- **Ranitidine** 50 mg intravenously or 150 mg orally, or an equivalent histamine (H_2)-receptor antagonist

Cabazitaxel 25 mg/m² intravenously over 60 minutes, diluted in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a solution with concentration within the range 0.1–0.26 mg/mL, on day 1, every 3 weeks (total dosage/cycle = 25 mg/m²)

Prednisone 10 mg/day orally, continually for 21 consecutive days (total dose/21-day cycle = 210 mg)

Note:

- Cabazitaxel is extensively metabolized in the liver (>95%), primarily by cytochrome P450 (CYP) CYP3A4/5 enzymes (80–90%), and, to a lesser extent, by the polymorphically expressed enzyme, CYP2C8. Consequently hepatic impairment is likely to increase cabazitaxel concentrations
- Although no formal drug interaction trials with cabazitaxel have been conducted, clinicians should use caution with respect to the following:
  - ***CYP3A4 inhibitors:*** Concomitant administration of strong CYP3A subfamily inhibitors (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole) is expected to increase concentrations of cabazitaxel. Therefore, coadministration with strong CYP3A inhibitors should be avoided. Caution should be exercised with concomitant use of moderate CYP3A subfamily inhibitors
  - ***CYP3A4 inducers:*** The concomitant administration of strong CYP3A subfamily inducers (eg, carbamazepine, phenobarbital, phenytoin, rifabutin, rifapentine, rifampin) is expected to decrease cabazitaxel concentrations. Therefore, coadministration with strong CYP3A inducers should be avoided. In addition, patients should also refrain from taking St. John's wort

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Prolonged grade ≥3 neutropenia (>1 week) despite appropriate medication including filgrastim	Delay treatment until neutrophil count is >1500 cells/mm³, then reduce cabazitaxel dosage to 20 mg/m². Use filgrastim for secondary prophylaxis
Prolonged grade ≥3 neutropenia (>1 week) despite appropriate medication including filgrastim at a cabazitaxel dosage of 20 mg/m²	Discontinue cabazitaxel
Febrile neutropenia	Delay treatment until improvement or resolution, and until neutrophil count is >1500 cells/mm³, then resume treatment with cabazitaxel dosage decreased to 20 mg/m². Use filgrastim for secondary prophylaxis
Febrile neutropenia at a cabazitaxel dosage of 20 mg/m²	Discontinue cabazitaxel
Grade ≥3 diarrhea or diarrhea that persists despite appropriate medication, fluid, and electrolytes replacement	Delay treatment until improvement or resolution, then resume treatment with cabazitaxel dosage decreased to 20 mg/m²
Grade ≥3 diarrhea or diarrhea that persists despite appropriate medication, fluid, and electrolytes replacement at a cabazitaxel dosage of 20 mg/m²	Discontinue cabazitaxel
Total bilirubin ≥ ULN, or AST and/or ALT ≥1.5 times ULN)	Discontinue cabazitaxel

Toxicity* (N = 371)

	% All Grades	% G ≥3

Median time to PSA progression (months)	3.1	6.4	0.001
Median time to pain progression (months)§	NR	11.1 (2.9-NR)	0.52

NR, Not reached
*Tumor response was evaluated only for patients with measurable disease according to RECIST
†PSA response was defined as ≥50% reduction in serum PSA concentrations, established only for patients with a serum PSA concentration of 20 mcg/L or more at baseline, confirmed by a repeat PSA measurement after at least 3 weeks
‡Pain response was established only for patients with a median present pain intensity (PPI) score ≥2, a mean analgesic score (AS) ≥10 points at baseline, or both, and was defined as a reduction from baseline median PPI score ≥2 points without an increased AS or a decrease ≥50% in the AS without an increase in the PPI score, maintained for at least 3 weeks
§Data for 265 patients in the cabazitaxel group and 279 patients in the mitoxantrone group were censored as a result of ≥2 PPI or AS assessments or both, being missed during the same week (unless a complete evaluation of ≥5 values showed pain progression)

Patient Population Studied

A study of 755 patients with pathologically proven castration-refractory prostate cancer with documented disease progression during or after completion of docetaxel treatment. Eligible patients had an Eastern Cooperative Oncology Group performance status of 0–2. Patients with measurable disease were required to have documented disease progression by Response Evaluation Criteria in Solid Tumors (RECIST) criteria with at least 1 metastatic visceral or soft-tissue lesion. Patients with nonmeasurable disease were required to have rising serum prostate-specific antigen (PSA) concentrations (at least 2 consecutive increases relative to a reference value measured at least a week apart) or the appearance of at least 1 new demonstrable radiographic lesion. Additional inclusion criteria were: previous and ongoing castration by orchiectomy, LHRH agonists, or both interventions

Therapy Monitoring

1. *Before each cycle:* Physical exam, CBC and LFTs
2. *Evaluation including PSA:* Every 6 weeks to every 3 months

ADVANCED DISEASE REGIMEN

KETOCONAZOLE + HYDROCORTISONE

Bok RA, Small EJ. Drug Saf 1999;20:451–458
Small EJ et al. J Urol 1997;157:1204–1207

Ketoconazole 400 mg orally every 8 hours, continually
Hydrocortisone 20 mg orally every morning, continually
Hydrocortisone 10 mg orally every evening, continually

Notes:

1. Ketoconazole absorption can be decreased with concurrent use of antacids, H_2-antagonist antihistamines, and proton pump inhibitors (PPIs). Avoid H_2-antagonists and PPIs. If antacid treatment is needed, ketoconazole should be taken at least 2 hours before antacids
2. To avoid nausea, start ketoconazole at a low dose (eg, 200 mg 3 times daily) and gradually increase to full doses after several days

Supportive Care

Antiemetic prophylaxis

The regimen is not emetogenic. Primary prophylaxis is not indicated

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 48 patients with castration-refractory metastatic prostate cancer with progression after antiandrogen withdrawal

Efficacy

>50% PSA decline (≥8 weeks)	62.5%
Median change in PSA	79.5% decline
Mean duration of response	3.5 months

Small EJ et al. J Urol 1997;157:1204–1207

Treatment Modifications

Adverse Event	Dose Modification
Toxicity G ≥2	Hold ketoconazole until adverse events have resolved

Note: Ketoconazole is a potent inhibitor of the cytochrome P450 enzyme, CYP3A4. It has been reported to inhibit the metabolism of many drugs and drug metabolites that are metabolized by CYP3A-subfamily enzymes, resulting in elevated concentrations of the drugs. Affected drugs include (but are not limited to):

1. Warfarin (enhances anticoagulant effect)
2. Dihydropyridine calcium channel antagonists (eg, amlodipine, felodipine, nifedipine)
3. Loratadine
4. Some HIV protease inhibitors (saquinavir, indinavir and nelfinavir)
5. Statin hypolipidemic drugs (HMG-CoA reductase inhibitors)
6. Many other drugs and natural products

Drugs that are susceptible to pharmacokinetic interactions because of concomitant use with ketoconazole may require dose or schedule adjustments. It may be prudent to consider alternative treatment options, or if clinically appropriate, discontinue drugs that are known to interact with ketoconazole

Therapy Monitoring

Monthly: LFTs including AST, ALT, bilirubin, alkaline phosphatase, PSA if indicated

Notes

1. Liver transaminases may be transiently increased. Therapy can be continued in a setting of a grade 1 increase in transaminases with close monitoring, but there is a small risk (0.1–1%) of idiosyncratic hepatitis, which can be fatal
2. Some clinicians administer higher doses of hydrocortisone (30 mg in the morning and 20 mg in the evening)
3. In addition to glucocorticoid replacement, some patients require mineralocorticoid supplementation with fludrocortisone 100–200 mcg daily orally in the morning

Toxicity (N = Varies)

	% Patients	
	Mild (G1/2)	Moderate/ Severe
Nausea/vomiting	10	—
LFT abnormalities*	4–20	—
Fulminant hepatitis	—	0.1–1
Fatigue	6	—
Edema	6	—
"Sticky skin"†,‡	10	—
Rash‡	4	—
Nail dystrophy‡	Common	—
Dry mouth‡	Often	—
Gynecomastia§	10–15	—
Adrenal insufficiency¶	Varies	
Impotence	Anticipated	

*Asymptomatic increases; usually resolve with discontinuation of treatment
†Subjective sensation of stickiness to the skin, usually noted in axillary area
‡Cutaneous and mucosal effects probably related to inhibitory effect on retinoic acid metabolism
§Not observed with ketoconazole 200–400 mg/day, but may occur with higher doses
¶Steroid replacement recommended

From Bok RA, Small EJ. Drug Saf 1999;20:451–458

ADVANCED DISEASE REGIMEN

RADIUM-223
METASTATIC CASTRATION-RESISTANT PROSTATE CANCER WITH BONE METASTASES

Parker et al. N Engl J Med 2013;369:213–223
XOFIGO (radium 223) Package Insert (http://labeling.bayerhealthcare.com/html/products/pi/Xofigo_PI.pdf)

Radium (Ra)-223 dichloride 50 kBq (^{223}Ra 1.35 μCi) per kilogram of body weight by slow intravenous injection over 1 minute every 4 weeks for 6 injections

Note:
- Flush the intravenous access line or cannula with 0.9% sodium chloride injection before and after injection of radium-223
- Safety and efficacy beyond 6 injections with radium-223 have not been studied

Calculate volume to be administered to a given patient using the:
- Patient's body weight (kg)
- Dosage level 50 kBq/kg body weight or 1.35 μCi/kg body weight
- Radioactivity concentration of the product (1000 kBq/mL; 27 μCi/mL) at the reference date
- Decay correction factor to correct for physical decay of radium-223

Calculate total volume to be administered as follows:

$$\text{Volume to be administered (mL)} = \frac{\text{Body weight in kg} \times 50\ \text{kBq/kg body weight}}{\text{Decay factor} \times 1000\ \text{kBq/mL}}$$

OR

$$\text{Volume to be administered (mL)} = \frac{\text{Body weight in kg} \times 1.35\ \mu\text{Ci/kg body weight}}{\text{Decay factor} \times 27\ \mu\text{Ci/mL}}$$

Decay Correction Factor Table

Days from Reference Date	Decay Factor	Days from Reference Date	Decay Factor
−14	2.296	0	0.982
−13	2.161	1	0.925
−12	2.034	2	0.870
−11	1.914	3	0.819
−10	1.802	4	0.771
−9	1.696	5	0.725
−8	1.596	6	0.683
−7	1.502	7	0.643
−6	1.414	8	0.605
−5	1.330	9	0.569
−4	1.252	10	0.536
−3	1.178	11	0.504
−2	1.109	12	0.475
−1	1.044	13	0.447
		14	0.420

The Decay Correction Factor Table is corrected to 12 noon Central Standard Time (CST). To determine the decay correction factor, count the number before or after the reference date. The Decay Correction Factor Table includes a correction to account for the 7-hour time difference between 12 noon European Time (CET) at the site of manufacture and 12 noon U.S. CST, which is 7 hours earlier than CET

(*continued*)

(*continued*)

Note: Immediately before and after administration, the net patient dose of administered radium-223 should be determined by measurement in an appropriate radioisotope dose calibrator that has been calibrated with a National Institute of Standards and Technology (NIST) traceable radium-223 standard and corrected for decay using the date and time of calibration

Safety Information: Radium-223 is primarily an alpha emitter, with 95.3% of energy emitted as alpha particles. Only 3.6% is emitted as beta particles and 1.1% as gamma radiation. Thus the external radiation exposure associated with handling of patient doses is expected to be low, because the typical treatment activity will be <8000 kBq (<216 μCi). Nevertheless care should be used as follows:

Precautions:

- The administration of radium-223 is associated with potential risks to other persons from radiation or contamination from spills of bodily fluids such as urine, feces, or vomit. Therefore, radiation protection precautions must be taken in accordance with national and local regulations
- Whenever possible, patients should use a toilet (commode) and the toilet should be flushed several times after each use. When handling bodily fluids, simply wearing gloves and hand washing will protect caregivers. Clothing soiled with radium-223 or patient fecal matter or urine should be washed promptly and separately from other clothing

Instructions to Patients:

- Stay well hydrated and monitor oral intake, fluid status, and urine output. Report signs of dehydration
- There are no restrictions regarding contact with other people after receiving radium-223. Follow good hygiene practices for at least 1 week after the last injection so as to minimize radiation exposure from bodily fluids to household members and caregivers
- Flush toilets several times after each use
- Promptly wash clothing soiled with fecal matter or urine separately from other clothing
- Caregivers should use universal precautions when handling body fluids to avoid contamination. When handling bodily fluids, wearing gloves and hand washing will protect caregivers
- Patients who are sexually active should use condoms and their female partners of reproductive potential should use a highly effective method of birth control during treatment and for 6 months following completion of radium-223 treatment

Toxicity

*Only 1 G5 hematologic adverse event was considered possibly related to study drug: thrombocytopenia in 1 patient in the radium-223 group

Patient Population Studied

Inclusion criteria: (a) histologically confirmed, progressive castration-resistant prostate cancer (b) 2 or more bone metastases detected on skeletal scintigraphy and no known visceral metastases; (c) received docetaxel, or were not healthy enough or declined to receive it, or it was not available; (d) symptomatic disease with regular use of analgesic medication or treatment with external beam radiation therapy required for cancer-related bone pain within the previous 12 weeks; (e) a baseline PSA ≥5 ng/mL or with evidence of progressively increasing PSA values (2 consecutive increases over the previous reference value); (f) an ECOG performance-status score of 0–2; and (g) a life expectancy ≥6 months. Exclusion criteria: (a) chemotherapy within the previous 4 weeks; (b) previous hemibody external radiotherapy; (c) systemic radiotherapy with radioisotopes within the previous 24 weeks; (d) a blood transfusion or use of erythropoietin-stimulating agents within the previous 4 weeks; (e) malignant lymphadenopathy ≥3 cm in the short-axis diameter; (f) history of or the presence of visceral metastases; and (g) imminent or established spinal cord compression

Castration-resistant disease was defined as a serum testosterone level ≤50 ng/dL (≤1.7 nmol/L) after bilateral orchiectomy or during maintenance treatment consisting of androgen-ablation therapy with a luteinizing hormone-releasing hormone agonist or polyestradiol phosphate. Patients with castration-resistant disease during maintenance treatment were required to continue that treatment throughout the study

Baseline Characteristics of the Patients*

Tyrrell CJ. Eur Urol 1994;26(Suppl 1):15–19

Treatment options:

1. Surgical castration: Orchiectomy
2. Medical castration: LHRH agonists
3. Nonsteroidal antiandrogens
4. Androgen-deprivation therapy (ADT)
   - GnRH antagonist
   - Orchiectomy + antiandrogen
   - LHRH agonist + antiandrogen

LHRH agonists:

1. **Leuprolide depot** 7.5 mg intramuscularly every month
2. **Leuprolide depot** 22.5 mg intramuscularly every 3 months
3. **Leuprolide depot** 30 mg intramuscularly every 4 months
4. **Leuprolide depot** 45 mg intramuscularly every 6 months
5. **Goserelin implant** 3.6 mg subcutaneously every 4 weeks
6. **Goserelin implant** 10.8 mg subcutaneously every 3 months

Nonsteroidal antiandrogens:

1. **Flutamide** 250 mg/dose orally 3 times per day, continually
2. **Bicalutamide** 50 mg or 150 mg/day if given as monotherapy orally, continually
3. **Nilutamide** 300 mg/day orally for 1 month with castration, followed by nilutamide 150 mg/day orally, continually

GnRH antagonist

Degarelix, starting dose, 240 mg given as two subcutaneous injections of 120 mg in the first month followed by maintenance dose of 80 mg given as one subcutaneous injection monthly thereafter

Supportive Care

Antiemetic prophylaxis

The regimens are not emetogenic. Primary prophylaxis is not indicated

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

Metastatic disease

1. LHRH agonists >85% response rate
2. No significant differences among LHRH agonists
3. Single-agent antiandrogen therapy may be inferior to medical (LHRH agonist) or surgical castration
4. Use of combined androgen blockade (CAB) as frontline therapy is controversial with limited evidence of clinical benefit

Locally advanced disease

Concurrent radiation and hormonal therapy in locally advanced disease appears to have a survival benefit. LHRH agonist + an antiandrogen are used for up to 3 months before, during, and for 3 years after radiation treatment

Patient Population Studied

Patients with metastatic and locally advanced prostate cancer treated with hormonal therapy

Therapy Monitoring

All antiandrogens

1. *Monthly for the first 4 months:* LFTs
2. *Every 2–3 months after the first 4 months:* LFTs

Nilutamide

1. Baseline chest x-ray before therapy
2. *For respiratory symptoms*: Discontinue therapy pending evaluation

Wysowski DK, Fourcroy JL. J Urol 1996;155:209–212

Toxicity

Common Toxicities of Androgen Deprivation

Hot flashes	LHRH Ag > AA
Loss of libido, impotence	LHRH Ag >> AA
Bone and muscle loss	LHRH Ag >> AA
Breast tenderness	AA >> LHRH Ag
Gynecomastia	AA >> LHRH Ag
Skin and hair changes	N/A
Weight gain	N/A
Asthenia	N/A

AA, antiandrogens; LHRH Ag, LHRH agonists

Toxicities of Individual Androgen Therapies

	% Patients
LHRH Agonists	
Tumor flare	Variable
Injection-site reactions	Variable
Flutamide	
Gynecomastia	45–50
Diarrhea	20
Nausea/vomiting	5
Hepatitis	2.5
Vertigo	2.5
Hot flashes	2.5
Bicalutamide	
Gynecomastia	49
Breast tenderness	40
Constipation	14
Aggravation reaction	13
Hot flashes	13
Asthenia	12
Urinary retention	10
Diarrhea	6
Nausea/vomiting	5
Nilutamide	
Hot flashes	28
Visual disturbance*	27–50
Nausea	10 (7–20)
Dyspnea	6
Interstitial pneumonitis	1–2
Gynecomastia	4
Alcohol intolerance	5–19
Increased LFTs†	4–8
Anemia	4

*Includes decreased adaptation to darkness, blurred vision
†Transient in a majority of patients

Notes

1. For patients with metastatic prostate cancer being treated with an LHRH agonist alone, a testosterone level should be checked at 1 month. If it is >20 ng/dL, consider orchiectomy or adding antiandrogen
2. Concurrent antiandrogen therapy can be used with LHRH agonist for the first 2–4 weeks of treatment to avoid tumor flare
3. Antiandrogen withdrawal should be considered the first therapeutic maneuver in men whose disease has progressed after treatment with combined androgen blockade. Approximately 20% of patients have a significant decrease in serum PSA when antiandrogen is withdrawn
4. Degarelix binds to the GnRH receptor in the pituitary gland and blocks LH/FSH release from the pituitary. Patients typically achieve castrate levels of testosterone by day 3 of treatment without a testosterone surge. A Phase 3, one year multicenter, randomized, open-label trial compared the efficacy and safety of degarelix with leuprolide. Six-hundred and ten patients with all stages of histologically confirmed prostate cancer for whom androgen deprivation therapy was indicated were enrolled. Patients receiving degarelix showed a significantly lower risk of PSA progression or death compared with leuprolide ($p = 0.05$). PSA recurrences occurred primarily in patients with advanced disease and exclusively in those with baseline PSA >20 ng/mL. The latter had a significantly longer time to PSA recurrence with degarelix. The results suggest degarelix offers improved PSA control compared with leuprolide. However, further studies are warranted to confirm these findings
5. With acute cord compression or other oncologic emergency caused by a growing prostate tumor, Degarelix is the preferred treatment

IMMUNOTHERAPY REGIMEN

SIPULEUCEL-T

Kantoff PW et al. N Engl J Med 2010;363:411–422

General notes:
- Patients are scheduled for 3 leukapheresis procedures (at weeks 0, 2, and 4), each followed approximately 3 days later by infusion of sipuleucel-T
- Infusions are prepared from PBMCs collected by means of a single standard leukapheresis processing 1.5 to 2 times a patient's estimated blood volume
- Sipuleucel-T is prepared at a designated manufacturing facility by culturing APCs for 36–44 hours at 37°C (98.6°F) with media containing PA2024. The cells are washed before final formulation

Premedication:
Acetaminophen 650 mg orally approximately 30 minutes prior to the administration of sipuleucel-T, *and*
Diphenhydramine 25–50 mg, or an equivalent H_1-receptor antihistamine orally approximately 30 minutes prior to the administration of sipuleucel-T

Sipuleucel-T suspension for intravenous infusion containing a minimum of 50 million autologous CD54+ cells activated with PAP-GM-CSF/dose in 250 mL lactated Ringer injection, intravenously over a period of approximately 60 minutes. Administer a total of 3 doses at approximately 2-week intervals (total dose/single treatment is at least 50 million autologous CD54+ cells activated with PAP-GM-CSF)

Notes for acute infusion reactions: Interrupt or slow infusion depending on the severity of the reaction. Administer appropriate medical therapy including:
- **Diphenhydramine** 25–50 mg, or an equivalent H_1-receptor antihistamine, intravenously
- **Ranitidine** 50 mg, **cimetidine** 300 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist, intravenously over 15–30 minutes
- *Note:* In healthy subjects, cimetidine reduces the clearance and volume of distribution of meperidine; thus, use caution when these drugs are used concomitantly
- **Meperidine** 10–25 mg intravenously as needed for chills

Important:
- Sipuleucel-T is for *autologous use only*. Before infusion, confirm that a patient's identity matches patient identifiers on the infusion containers
- Do not initiate infusion of expired sipuleucel-T. If, for any reason, a patient is unable to receive a scheduled infusion of sipuleucel-T, the patient will need to undergo an additional leukapheresis procedure if the course of treatment is to be continued. Patients should be advised of this possibility prior to initiating treatment
- The sipuleucel-T infusion bag must remain within its insulated polyurethane container until the time of administration. Do not remove the insulated polyurethane container from its outer cardboard shipping box
- DO NOT USE a cell filter to administer sipuleucel-T

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Acute infusion reactions	Interrupt or slow infusion depending on the severity of the reaction and administer appropriate medical therapy including intravenous H_1/H_2 antagonists ± low-dose meperidine

Patient Population Studied

A study of 512 patients with metastatic castration-resistant prostate cancer and an expected survival ≥6 months (341 randomized to sipuleucel-T and 171 to placebo). Initially, only men without disease-related symptoms and a Gleason score ≤7 were enrolled. Eligibility criteria were later amended to include men with any Gleason score, as well as those with minimal disease-related symptoms. Additional eligibility criteria were a serum PSA ≥5 mcg/L, a serum testosterone level <50 ng/dL (<1.7 nmol/L), and progressive disease on the basis of imaging studies or PSA measurements. Exclusion criteria included an Eastern Cooperative Oncology Group (ECOG) performance status ≥2, visceral metastases, pathologic long-bone fractures, spinal cord compression, and treatment within the previous 28 days with systemic glucocorticoids, external beam radiation, surgery, or systemic therapy for prostate cancer (except medical or surgical castration). Patients were also excluded if they had undergone chemotherapy within the previous 3 months. Continuation of medical castration or bisphosphonate therapy was required at least until the time of disease progression

Efficacy*

Median time to objective disease progression	14.6 weeks†
Adjusted HR for death, sipuleucel-T *vs.* placebo	0.78 (95% CI, 0.61–0.98)
Median overall survival	25.8 months‡
Estimated probability of survival at 36 months	31.7%§
Reductions of PSA ≥50% on two visits ≥4 weeks apart	2.6%¶
Antibody titers against the immunizing antigen, PA2024 >400 at any time after baseline	66.2%**,††
Antibodies titers against prostatic acid phosphatase >400 at any time after baseline	28.5%†,‡‡

*Median follow up time: 34.1 months
†Placebo group: 14.4 weeks
‡Placebo group: 21.7 months
§Placebo group: 23%
¶Placebo group: 1.3%
**Placebo group: 2.9%
††Placebo group: 1.4%
‡‡In prespecified analyses, patients in the sipuleucel-T group who had an antibody titer >400 against PA2024 or prostatic acid phosphatase at any time after baseline lived longer than those who had an antibody titer ≤400 (P <0.001 and P = 0.08, respectively, by the log-rank test)

Therapy Monitoring

1. *Before each cycle:* CBC with LFTs
2. *Evaluation including PSA:* Every 6 weeks

Toxicity*

	Sipuleucel-T (N = 338)		Placebo (N = 168)

Depression	2.4	0.3	6.5	0
	% Mild/Moderate (G1/2)		% Severe (G3)§	
Acute infusion reactions‡	67.7		3.5	

*NCI Common Terminology Criteria for Adverse Events, version 3
†Citrate toxicity has been associated with leukapheresis; paresthesia and oral paresthesia are likely symptoms of citrate toxicity
‡Acute infusion reactions (***reported within 1 day after infusion***) included chills, fever, fatigue, asthenia, dyspnea, hypoxia, bronchospasm, dizziness, headache, hypertension, tachycardia, muscle ache, nausea, and vomiting. The most common events (≥20%) were chills, fever, and fatigue. Fevers and chills generally resolved within 2 days (71.9% and 89.0%, respectively)
§The incidence of severe events was greater following the second sipuleucel-T infusion in comparison with the first infusion (2.1% vs. 0.8%, respectively), and decreased to 1.3% following the third infusion. Some (1.2%) patients in the sipuleucel-T group were hospitalized within 1 day after infusion for management of acute infusion reactions. No G4/5 acute infusion reactions were reported with sipuleucel-T

33. Renal Cell Cancer

Susan Bates, MD and Olivier Rixe, MD, PhD

Epidemiology

Incidence: 63,920 (male: 39,140; female: 24,780. Estimated new cases for 2014 in the United States) 21 per 100,000 men, 10.6 per 100,000 women
Deaths: Estimated 13,860 in 2014 (male: 8,900; female: 4,960)
Median age: 64 years
Male to female ratio: 1.6:1

Stage at Presentation:

Stage I:	50.4%
Stage II:	14.6%
Stage III:	20.7%
Stage IV:	14.3%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up (For Suspicious Renal Mass)

1. H&P
2. CBC, chemistry profile
3. Urinalysis
4. Chest x-ray
5. Abdominal and pelvic CT with contrast
6. Chest CT if abnormal chest x-ray or advanced lesion
7. MRI if CT suggests caval thrombosis or renal insufficiency
8. Bone scan or brain MRI if clinically indicated

Pathology

Clear cell	70–80%
Papillary	10–15%
Chromophobe	5%
Collecting duct	0.4–2.6%

Zambrano NR et al. J Urol 1999;162:1246–1258

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Tumor 7 cm or less in greatest dimension, limited to the kidney
T1a	Tumor 4 cm or less in greatest dimension, limited to the kidney
T1b	Tumor more than 4 cm but not more than 7 cm in greatest dimension, limited to the kidney
T2	Tumor more than 7 cm in greatest dimension, limited to the kidney
T2a	Tumor more than 7 cm but less than or equal to 10 cm in greatest dimension, limited to the kidney
T2b	Tumor more than 10 cm, limited to the kidney
T3	Tumor extends into major veins or perinephric tissues but not into the ipsilateral adrenal gland and not beyond Gerota's fascia
T3a	Tumor grossly extends into the renal vein or its segmental (muscle containing) branches, or tumor invades perirenal and/or renal sinus fat but not beyond Gerota's fascia
T3b	Tumor grossly extends into the vena cava below the diaphragm
T3c	Tumor grossly extends into the vena cava above the diaphragm or invades the wall of the vena cava
T4	Tumor invades beyond Gerota's fascia (including contiguous extension into the ipsilateral adrenal gland)

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph node metastasis

Distant Metastasis (M)

M0	No distant metastasis
M1	Distant metastasis

Staging Groups

	T	N	M
I	T1	N0	M0
II	T2	N0	M0
III	T1 or T2	N1	M0
	T3	N0 or N1	M0
IV	T4	Any N	M0
	Any T	Any N	M1

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Relative 5-Year Survival

Stage I	91%
Stage II	86%
Stage III	67%
Stage IV	17%

National Cancer Institute, Surveillance, Epidemiology, and End Results (SEER) Program

Risk Group Criteria

Memorial Sloan-Kettering Cancer Center (MSKCC) Criteria

(Motzer RJ et al. J Clin Oncol 2002;20:289–296)

1. <12 Months from initial RCC diagnosis to start of therapy
2. Lactate dehydrogenase >1.5 × ULN
3. Hemoglobin < lower limit of normal range
4. Corrected serum calcium > 10 mg/dL (>2.5 mmol/L)
5. Karnofsky performance score <80
6. ≥2 Metastatic sites

Favorable: 0 risk factors
Intermediate: 1 or 2 risk factors
Poor: ≥3 risk factors

Cleveland Clinic Foundation Criteria

(Mekhail TM et al. J Clin Oncol 2005;23:832–841)

1. <12 Months from initial RCC diagnosis to start of therapy
2. Lactate dehydrogenase >1.5 × ULN
3. Hemoglobin < lower limit of normal range
4. Corrected serum calcium >10 mg/dL (>2.5 mmol/L)
5. Prior radiotherapy
6. ≥2 Metastatic sites

Favorable: 0–1 risk factors
Intermediate: 2 risk factors
Poor: ≥3 risk factors

Expert Opinion

Primary Treatment:
Surgical candidates: Treatment-naïve patients. Important factors include:
1. MSKCC risk group
2. Histologic subtype
3. Patient-specific factors

Stage 1A:
1. Partial nephrectomy (preferred)
2. Radical nephrectomy (in patients with centrally located tumors, or when other reasons make partial nephrectomy impossible)
3. Thermal ablation or cryoablation (in nonsurgical candidates), although must be prepared to proceed to open resection if needed
4. Active surveillance (AS) in selected patients: Although the standard of care for treatment of renal masses has been surgical removal, many elderly patients are at high risk for perioperative morbidity and mortality. AS has emerged as a management option for these patients and for those who choose not to have surgery. Many studies show that most renal masses grow slowly and do not display aggressive behavior. The risk of AS is progression to metastatic disease, but, fortunately, the rate of metastases for renal masses during AS appears to be low

Stage 1B:
1. Partial nephrectomy (preferred)
2. Radical nephrectomy (in patients with centrally located tumors, or when other reasons make partial nephrectomy impossible)

Stages II, III:
1. Radical nephrectomy

Stage IV:
1. Partial or radical nephrectomy for cytoreduction prior to systemic therapy
2. Partial or radical nephrectomy plus metastasectomy if oligometastases are surgically resectable

Primary treatment references:
Flanigan RC et al. J Urol 2004;171:1071–1076
Mason RJ et al. Eur Urol 2011;59:863–867

(*continued*)

Expert Opinion (*continued*)

Systemic Therapy, Clear Cell Histology:

First-line therapy for treatment-naïve patients, MSKCC intermediate or favorable risk group, clear cell histology:

1. Sunitinib
2. Bevacizumab plus interferon alfa
3. Pazopanib
4. Sorafenib
5. High-dose aldesleukin (interleukin-2) for selected patients; only therapy with the potential to give long-term disease-free survival that can be assumed to be curative

First-line therapy for treatment-naïve patients, MSKCC poor risk group, clear cell histology:

1. Temsirolimus: There is level 1 evidence for a survival advantage compared with interferon alfa alone in the first-line setting

Second-line therapy, clear cell histology patients, after disease progression on first-line therapy:

1. Everolimus
2. Axitinib
3. Temsirolimus
4. Interferon alfa
5. Aldesleukin
6. Sunitinib
7. Pazopanib
8. Sorafenib
9. Bevacizumab

FDA Approved Indications:

- **Axitinib (Inlyta):** Advanced renal cell carcinoma after failure of one prior systemic therapy
- **Bevacizumab (Avastin):** Metastatic renal cell carcinoma in combination with interferon alfa
- **Everolimus (Afinitor):** Advanced renal cell carcinoma after failure of treatment with sunitinib or sorafenib
- **Pazopanib (Votrient):** Advanced renal cell carcinoma
- **Sorafenib (Nexavar):** Advanced renal cell carcinoma
- **Sunitinib (Sutent):** Advanced renal cell carcinoma
- **Temsirolimus (Torisel):** Advanced renal cell carcinoma

Systemic Therapy, Non–Clear Cell Histologies

First-line therapy for treatment-naïve patients, non–clear cell histologies:

1. Temsirolimus
2. Sorafenib
3. Sunitinib
4. Pazopanib
5. Erlotinib
6. Gemcitabine + doxorubicin (*Note:* sarcomatoid histology only)

Considerations in Selecting First- and Second-Line Therapies Clear Cell and Non–Clear Cell Histologies

1. Patients' comorbidities that could be exacerbated by agent-specific toxicities such as hypertension with VEGF-targeting agents (sunitinib, sorafenib, pazopanib, axitinib, bevacizumab)
2. Convenience of oral agents

Managing Hypertension Associated with Inhibitors of the VEGF Signaling Pathway Inhibitors (*VEGFi*)[1,2]

Graded Severity	Antihypertensive Therapy	Blood Pressure Monitoring	*VEGFi* Dose Modification
CTCAE G1 ***Pre-hypertension*** [SBP 120–139 mm Hg or DBP 80–89 mm Hg]	None	At least weekly initially and after changes in dose and administration schedule of the *VEGFi*. After stable BP is achieved increase monitoring intervals to every 2–3 wks or schedule to coincide with clinical evaluations	No change
CTCAE G2 ***Stage 1 HTN*** [SBP 140–159 mm Hg or DBP 90–99 mm Hg]; Recurrent or persistent (≥24 h) HTN; medical intervention indicated; Symptomatic increase by >20 mm Hg (diastolic) or to >140/90 mm Hg if previously WNL; monotherapy indicated	***Step 1:*** Initiate DHP-CCB treatment, and, if needed, after 24–48h, increase the dose in incremental steps every 24–48h until BP is controlled or a maximum antihypertensive dose is reached ***Step 2:*** If BP still is not controlled, add another antihypertensive, a BB, ACEI, ARB, or ABB. Increase dose of 2nd drug as described in Step 1 (above) ***Step 3:*** If BP still is not controlled, add 3rd drug from categories listed in Step 2; increase dose of 3rd drug as described in Step 1 (above) ***Step 4:*** If BP is still not controlled, consider either decreasing *VEGFi* dose one dose level or discontinuing *VEGFi* *Note:* If the dose of the *VEGFi* is reduced or the *VEGFi* is stopped, BP is expected to decrease. Monitor patient for hypotension and adjust number and doses of antihypertensive medications accordingly	Monitor BP as recommended by treating clinician	No changes except as described for Step 4 [If BP is still not controlled, consider either decreasing *VEGFi* dose one dose level or discontinuing *VEGFi*]
CTCAE G3 ***Stage 2 HTN*** [SBP ≥160 mm Hg or DBP ≥100 mm Hg]; medical intervention indicated; more than one drug or more intensive therapy than previously used indicated	Withhold *VEGFi* until systolic BP <159 mm Hg and diastolic BP <99 mm Hg. BP management identical to that for G2 ***(Stage 1) HTN*** ***(see Steps 1–4 above)*** with two exceptions: 1. If SBP >180 mm Hg or DBP >110 mm Hg *and patient is symptomatic*, optimal management should include intensive IV support in an ICU setting. Discontinue *VEGFi* and notify other medically responsible health care providers that stopping *VEGFi* may result in a decrease in BP 2. If SBP >180 mm Hg or DBP >110 mm Hg *and the patient is asymptomatic*, two new antihypertensives must be given together in Step 1, and dose escalated as in Step 1 *Note:* If the dose of the *VEGFi* is reduced or the *VEGFi* is stopped, BP is expected to decrease. Monitor patient for hypotension and adjust number and doses of antihypertensive medications accordingly	BP should be monitored as recommended by the treating clinician unless the patient is symptomatic with SBP >180 mm Hg or DBP >110 mm Hg in which cases, monitoring should be intensive	1. Withhold the *VEGFi* until SBP <159 mm Hg and DBP <99 mm Hg 2. If BP cannot be controlled after an optimal trial of antihypertensive medications, consider either reducing the dose of the *VEGFi* or discontinuing its use 3. If a patient requires hospitalization for symptomatic SBP >180 mm Hg or DBP >110 mm Hg, permanently discontinue the *VEGFi*, or if BP is controlled, resume the *VEGFi* at a reduced dose

(*continued*)

Managing Hypertension Associated with Inhibitors of the VEGF Signaling Pathway Inhibitors (*VEGFi*)[1,2] (*continued*)

Graded Severity	Antihypertensive Therapy	Blood Pressure Monitoring	*VEGFi* Dose Modification
CTCAE G4 Life-threatening consequences (eg, malignant hypertension, transient or permanent neurologic deficit, hypertensive crisis)	1. Optimal management with intensive parenteral support in an ICU setting 2. Discontinue the *VEGFi* and notify other medically responsible health care providers that stopping a *VEGFi* may result in a decrease in BP	Intensive	Permanently discontinue the *VEGFi*, or if BP is controlled, resume the *VEGFi* at a reduced dose

ABB, α/β-adrenergic blockers; ACEI, angiotensin converting enzyme inhibitors; ARB, angiotensin II receptor blockers; BB, selective β-adrenergic blockers; CTCAE, National Cancer Institute (USA), Common Terminology Criteria for Adverse Events; DBP, diastolic blood pressure; DHP-CCB, dihydropyridine calcium-channel blockers; HTN, hypertension; ICU, intensive (*or* critical) care unit; SBP, systolic blood pressure; VEGF, vascular endothelial growth factor; *VEGFi*, *VEGF* signaling pathway inhibitor

Notes:

- Hypertension grading is based on CTCAE, version 4.0 criteria
- When SBP and DBP fall into different categories, the higher category should be selected in classifying blood pressure status
- Discontinue the *VEGFi* if patients require delaying treatment >2 weeks for management of hypertension
- Discontinue the *VEGFi* if patients require >2 *VEGFi* dose reductions
- Patients may receive up to two drugs for managing hypertension prior to decreasing *VEGFi* doses
- Allow an interval of at least 24 hours between modifications of antihypertensive therapy
- Treatment with a *VEGFi*, including aflibercept, axitinib, bevacizumab, cediranib, pazopanib, sunitinib, sorafenib, and vandetanib has rarely been associated with developing reversible posterior leukoencephalopathy syndrome (RPLS). Presenting symptoms associated with RPLS have included mild to severe hypertension, headache, lethargy, decreased alertness, confusion, altered mental functioning, and visual loss, seizure, and other neurologic disturbances
  - Discontinue the *VEGFi* in patients experiencing signs and symptoms referable to RPLS
  - MRI is the most sensitive imaging modality for detecting RPLS, and is recommended in suspected cases to confirm the diagnosis
  - RPLS usually is reversible upon removal of precipitating factors and application of measures to alleviate symptoms and control blood pressure; however, some patients have experienced ongoing neurological effects and death

Commercially Available Orally Administered Antihypertensives

Pharmacological Categories	Drug Name† (formulation)	Doses and Administration Schedules*			Metabolism
		Initial	Intermediate	Maximum Recommended	
Dihydropyridine calcium-channel blockers (DHP-CCB)	Nifedipine (extended release)	30 mg daily	60 mg daily	90 mg daily	CYP3A4 substrate
	Amlodipine besylate[3]	2.5 mg daily	5 mg daily	10 mg daily	CYP3A4 substrate
	Felodipine (extended release)	2.5 mg daily	5 mg daily	10 mg daily	CYP3A4 substrate and inhibitor[4]
Selective β-adrenergic blockers (BB)	Metoprolol tartrate[3]	25 mg twice daily	50 mg twice daily	100 mg twice daily	CYP2D6 substrate
	Atenolol	25 mg daily	50 mg daily	100 mg daily	Eliminated unchanged in urine and feces
	Acebutolol HCl	100 mg twice daily	200–300 mg twice daily	400 mg twice daily	Yes (CYP450 unknown)
	Bisoprolol fumarate	2.5 mg daily	5–10 mg daily	20 mg daily	Substrate for CYP2D6 and CYP3A4; ~50% renally eliminated as intact bisoprolol
	Nebivolol HCl[5,6]	5 mg daily	—	40 mg daily	Substrate for CYP2D6 and UGT enzymes
		Caution: Consider use for BP maintenance rather than titration. Product labeling recommends dose adjustments not more frequently than every 2 weeks			

(*continued*)

Commercially Available Orally Administered Antihypertensives (*continued*)

Pharmacological Categories	Drug Name† (formulation)	Doses and Administration Schedules*			Metabolism
		Initial	Intermediate	Maximum Recommended	
Angiotensin converting enzyme inhibitors (ACEIs)	Captopril	12.5 mg three times daily	25 mg three times daily	50 mg three times daily	CYP2D6 substrate
	Enalapril maleate[7]	5 mg daily	10–20 mg daily	40 mg daily	CYP3A4 substrate
	Ramipril	2.5 mg daily	5 mg daily	10 mg daily	Metabolism by liver esterases and phase II metabolism; ie, not CYP450
	Lisinopril	5 mg daily	10–20 mg daily	40 mg daily	Minimally, not CYP450
	Fosinopril sodium	10 mg daily	20 mg daily	40 mg daily	Hydrolyzed by intestinal and hepatic esterases; ie, not CYP450
	Perindopril erbumine	4 mg daily	none	8 mg daily	Hydrolysis and phase II metabolism; ie, not CYP450
	Quinapril	10 mg daily	20 mg daily	40 mg daily	Hydrolysis to quinaprilat, which is renally eliminated
Angiotensin II receptor blockers (ARBs)	Losartan	25 mg daily	50 mg daily	100 mg daily	CYP3A4 substrate
	Candesartan	4 mg daily	8–16 mg daily	32 mg daily	CYP2C9 substrate
	Irbesartan[7]	75 mg daily	150 mg daily	300 mg daily	CYP2C9 substrate
	Telmisartan	40 mg daily	none	80 mg daily	Phase II metabolism; ie, not CYP450
	Valsartan	80 mg daily	none	160 mg daily	Minimally, not CYP450
α-/β-adrenergic blocker	Labetolol HCl	100 mg twice daily	200 mg twice daily	400 mg twice daily	CYP2D6 substrate and inhibitor

ABC, ATP binding cassette proteins; CYP450, cytochrome P450 superfamily microsomal enzymes; FMO, flavin-containing monooxygenase family microsomal enzymes; UGT, uridine diphosphate-glucuronosyltransferase

*Recommendations for use are for adult patients without renal or hepatic impairment. Consult complete prescribing information for use in persons with impaired renal and/or hepatic function and other special populations

†Drugs in emboldened characters are suggested as optimal choices to avoid or minimize potential drug interactions with *VEGFi* through unilateral or mutual effects on CYP3A4

Notes:

Axitinib

- A substrate for metabolism by CYP3A4/5 (primary catalyst) and, to a lesser extent, CYP1A2, CYP2C19, and UGT1A1 in an *in vitro* system
- In an *in vitro* system is an inhibitor of ABCB1 (P-glycoprotein, MDR1); however, it is not expected to inhibit ABCB1-mediated transport at therapeutic plasma concentrations

Pazopanib

- A substrate for metabolism by CYP3A4 (primary catalyst) with minor contributions from CYP1A2 and CYP2C8
- Drug interaction trials conducted in patients with cancer suggest that pazopanib is a weak inhibitor of CYP3A4, CYP2C8, and CYP2D6 *in vivo*, but had no effect on CYP1A2, CYP2C9, or CYP2C19. Consequently, concomitant use of pazopanib with CYP3A4, CYP2D6, or CYP2C8 substrates that have with low therapeutic indices or narrow ranges of therapeutic concentrations is not recommended
- Pazopanib has been shown to inhibit UGT1A1 and OATP1B1 in an *in vitro* system with IC_{50} of 1.2 μmol/L and 0.79 μmol/L, respectively, ie, systemically achievable concentrations. Thus, drugs eliminated by UGT1A1 and OATP1B1 may be increased during concomitant use with pazopanib

Sorafenib

- A substrate for phase I and II metabolism by CYP3A4 and UGT1A9, respectively
- Sorafenib inhibits UGT1A1[8] and UGT1A9, and ABCB1 (P-glycoprotein, MDR1) *in vitro*, and may increase the systemic exposure of concomitantly administered drug substrates for metabolism and/or transport by these proteins

Sunitinib and its primary active (*N*-deethylated) metabolite, SU12662

- Substrates for metabolism by CYP3A4. Consequently, concomitant administration of sunitinib with strong CYP3A4 inhibitors or inducers should be avoided

REGIMEN

SORAFENIB TOSYLATE

Escudier B et al. N Engl J Med 2007;356:125–134
Escudier B et al. J Clin Oncol 2009;27:3312–3318

Sorafenib tosylate 400 mg; administer orally every 12 hours (eg, morning and evening) continually in 28-day cycles (total dose/day = 800 mg; total dose/cycle = 22,400 mg)

Notes:

- Patients should swallow tablets whole with approximately 250 mL (8 oz) of water. Tablets may be taken with or without food
- *Special precautions:* Sorafenib is metabolized by cytochrome P450 (CYP) CYP3A subfamily enzymes and has been shown in preclinical studies to inhibit multiple CYP isoforms. Therefore, all patients who are taking concomitant medications metabolized by CYP enzymes should be closely observed for side effects associated with concomitantly administered medications. Special caution should be used with any of the following medications: ketoconazole, itraconazole, voriconazole, ritonavir, clarithromycin, cyclosporine, carbamazepine, phenytoin, and phenobarbital. Furthermore, patients taking medications with a low therapeutic index (eg, warfarin, quinidine, digoxin) should be monitored proactively. *Patients using sorafenib should be advised to avoid consuming grapefruit products for as long as they continue to use sorafenib*

Supportive Care: Hand-foot reaction
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical and/or oral steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day orally

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Patient Population Studied

A study of 903 patients (451 randomly assigned to sorafenib tosylate, 452 to placebo) with histologically confirmed metastatic clear cell renal cell carcinoma, which had progressed after 1 systemic treatment within the previous 8 months. Additional eligibility criteria included performance status of 0 or 1 on the basis of Eastern Cooperative Oncology Group (ECOG) criteria and an intermediate-risk or low-risk status, according to the Memorial Sloan-Kettering Cancer Center (MSKCC) prognostic score. Most patients (99%) had clear cell renal cell carcinoma. Of those patients, 51% had low-risk disease, and 49% had intermediate-risk disease according to MSKCC criteria. Most patients had undergone previous nephrectomy and had received cytokine-based treatment

Median age	59 years (range: 19–86 years)
Median time from diagnosis	2 years (range: <1–19 years)
Characteristic	
Clear cell	100%
ECOG PS 0/1/2	48%/49%/2%
Low Motzer criteria	52%
Intermediate Motzer criteria	48%
Prior nephrectomy	93%
Prior radiation	28%
Prior cytokine-based therapy	83%
Metastatic sites: 1/2/≥2	15%/27%/57%
Lung metastases	75%
Liver metastases	26%

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Sorafenib Dose Levels	
Starting dose: Level 1	400 mg every morning; 400 mg every evening
Level −1	200 mg every morning; 400 mg every evening
Level −2	200 mg every morning; 200 mg every evening
Level −3	200 mg once daily

Adverse Event	Dose Modification
Cutaneous Toxicities	
Rash G ≥2	Hold sorafenib and provide *immediate* symptomatic treatment
If treatment is withheld for more than 3 weeks because of cutaneous toxicity	Discontinue therapy
When toxicity resolves to G ≤1	Restart sorafenib at 1 dose level less than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at reduced sorafenib doses	Again, hold sorafenib until the toxicity resolves to G ≤1, at which time sorafenib should be restarted at 1 dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at dose levels −2 or lower	Discontinue therapy
If cutaneous toxicity does not recur at reduced sorafenib doses with or without continued treatment for symptoms	The dose of sorafenib may be increased 1 dose level to the dose level administered at the time cutaneous toxicity developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the sorafenib dose should be reduced 1 dose level

(*continued*)

Efficacy (N = 903)*

	Sorafenib (N = 451)	Placebo (N = 452)
Complete response	1 (<1%)	0
Partial response	43 (9.5%)	8 (1.7%)
Median progression-free survival (PFS)†	5.5 months	2.8 months
Median time to response	80 days (range: 35–275 days)	
Median duration of response	18 days (range: 36–378 days)	
Median overall survival‡	19.3 months	15.9 months
Median overall survival§	17.8 months	15.2 months
Median overall survival¶	17.8 months	14.3 months

*RECIST (Response Evaluation Criteria in Solid Tumors) (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

†Benefit in PFS was independent of age, MSKCC score, previous use of cytokine therapy, presence of lung or liver metastases, and the time since diagnosis (<1.5 years or ≥1.5 years)

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Diarrhea	
G1/2 diarrhea	Focus on treatment for symptoms designed to resolve the diarrhea. No dose modifications will be made for G1/2 diarrhea unless G2 diarrhea persists for more than 2 weeks
If G2 diarrhea persists for more than 2 weeks	Follow the guidelines below for G3/4 diarrhea
If diarrhea cannot be controlled with the preventive measures outlined, and is G3/4 or worsens by 1 grade level (G3 to G4) while on sorafenib and is not alleviated within 48 hours by antidiarrheal treatment	Hold sorafenib. Also, withhold sorafenib if persistent G2 diarrhea is not alleviated by antidiarrheal treatment while sorafenib use continues (persistent is defined as lasting for >2 weeks)
If sorafenib is held for more than 3 weeks and diarrhea does not resolve to G ≤1	Discontinue therapy
If within 3 weeks of withholding sorafenib, diarrhea resolves to G ≤1	Restart sorafenib at 1 dose level less than the dose level administered at the time toxicity developed
If G3/4 diarrhea or persistent G2 diarrhea recurs at reduced doses of sorafenib (persistent is defined as lasting >2 weeks)	Again, withhold sorafenib until the toxicity resolves to CTCAE G ≤1, at which time sorafenib should be restarted at one dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If G3/4 diarrhea or persistent G2 diarrhea recurs at dose level −2 (persistent defined as lasting for >2 weeks)	Discontinue therapy
If diarrhea does not recur at reduced sorafenib doses with or without continued treatment for symptoms	The dose of sorafenib may be increased 1 dose level to the dose level administered at the time the diarrhea developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the sorafenib dose should be reduced 1 dose level
Hypertension	
Note: Patients should have their blood pressure checked once weekly during their first 24 weeks of therapy and for an 8-week period after an adjustment in their sorafenib dose	
G1 hypertension	Continue sorafenib at same dose and schedule
G2 asymptomatic	Treat with antihypertensive medications and continue sorafenib at same dose and schedule
G2 symptomatic, or persistent G2 despite antihypertensive medications, or diastolic BP >110 mm Hg, or G3 hypertension	Treat with antihypertensive medications. Hold sorafenib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue sorafenib at 1 dose level lower *Note:* Discontinue therapy if sorafenib is withheld >3 weeks
G4 hypertension	Discontinue therapy

Therapy Monitoring

1. *Every 6 weeks to 3 months:* Physical examination and routine laboratory tests
2. *Response assessment:* Every 2–3 cycles. A cycle defined as 28 days of oral therapy

REGIMEN

SUNITINIB MALATE

Motzer RJ et al. N Engl J Med 2007;356:115–124
Motzer RJ et al. J Clin Oncol 2009;27:3584–3590

Sunitinib malate 50 mg; administer orally once daily, continually, without regard for meals, in 6-week cycles consisting of 4 consecutive weeks of daily treatment followed by 2 weeks without treatment (total dose/6-week cycle = 1400 mg)

Supportive Care: Hand-foot reaction
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical and/or oral steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day orally

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Patient Population Studied

A study of 375 patients with metastatic renal cell carcinoma with a clear cell histologic component, who had not previously received treatment with systemic therapy for renal cell carcinoma. Other key eligibility criteria included an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, and adequate hematologic, coagulation, hepatic, renal, and cardiac functions

Efficacy (N = 375)*

Confirmed PR[¶]	31% (95% CI, 26–36%)
Median progression-free survival (PFS)[‡]	11 months (95% CI, 10–12 months)
Median overall survival[§]	26.4 months (95% CI, 23.0–32.9 months)

[¶]RECIST (Therasse P et al. J Natl Cancer Inst 2000;92: 205–216)
[†]Central review; reference: Motzer RJ et al. N Engl J Med 2007;356:115–124
[‡]Central review and investigator assessment; reference: Motzer RJ et al. N Engl J Med 2007;356:115–124
[§]Motzer RJ et al. J Clin Oncol 2009;27:3584–3590: Median overall survival time was greater in the sunitinib group than in the interferon alfa group (HR = 0.821; 95% CI, 0.673–1.001; $P = 0.051$) based on the primary analysis of the unstratified log-rank test ($P = 0.013$ using the unstratified Wilcoxon test). By stratified log-rank test, the HR was 0.818 (95% CI, 0.669–0.999; $P = 0.049$)

Treatment Modifications

Sunitinib Dose Levels	
Starting dose: Level 1	50 mg once daily, 4 weeks on/2 weeks off
Level −1	37.5 mg once daily, 4 weeks on/2 weeks off
Level −2	25 mg once daily, 4 weeks on/2 weeks off

Adverse Event	Dose Modification
Cutaneous Toxicities	
Rash G ≥2	Hold sunitinib and provide *immediate* symptomatic treatment
If treatment is withheld for more than 3 weeks because of cutaneous toxicity	Discontinue therapy
When toxicity resolves to G ≤1	Restart sunitinib at 1 dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at reduced sunitinib doses	Again, hold sunitinib until the toxicity resolves to G ≤1, at which time sunitinib should be restarted at 1 dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at dose levels −2 or lower	Discontinue therapy
If cutaneous toxicity does not recur at reduced sunitinib doses with or without continued treatment for symptoms	The dose of sunitinib may be increased 1 dose level to the dose level administered at the time the cutaneous toxicity developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the sunitinib dose should be reduced 1 dose level
Diarrhea	
G1/2 diarrhea	Focus on treatment for symptoms designed to resolve the diarrhea. No dose modifications will be made for G1/2 diarrhea unless G2 diarrhea persists for more than 2 weeks
If G2 diarrhea persists for more than 2 weeks	Follow the guidelines below for G3/4 diarrhea
If the diarrhea cannot be controlled with the preventive measures outlined, and is G3/4 or worsens by 1 grade level (G3 to G4) while on sunitinib and is not alleviated within 48 hours by antidiarrheal treatment	Hold sunitinib. Also withhold sunitinib if persistent G2 diarrhea is not alleviated by antidiarrheal treatment while sunitinib use continues (persistent defined as lasting for >2 weeks)
If sunitinib is held for more than 3 weeks and the diarrhea does not resolve to G ≤1	Discontinue therapy

(*continued*)

Therapy Monitoring

1. Every 6 weeks to 3 months: Physical examination and routine laboratory tests including thyroid function tests
2. *Response assessment:* Every 2–3 cycles. A cycle is defined as a 6-week period (4 consecutive weeks of daily sunitinib use, followed by 2 consecutive weeks without sunitinib)

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
If within 3 weeks of holding sunitinib, diarrhea resolves to G ≤1	Restart sunitinib at 1 dose level less than the dose level administered at the time toxicity developed
If G3/4 diarrhea or persistent G2 diarrhea recurs at reduced sunitinib doses and the dose level at which persistent G2 diarrhea occurs is greater than dose level −1 (persistent is defined as lasting for >2 weeks)	Again, withhold sunitinib until the toxicity resolves to CTCAE G ≤1, at which time sunitinib should be restarted at 1 dose level less than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If G3/4 diarrhea or persistent G2 diarrhea recurs at dose level −2 (persistent defined as lasting for more >2 weeks)	Discontinue therapy
If diarrhea does not recur at the reduced sunitinib doses with or without continued treatment for symptoms	The dose of sunitinib may be increased 1 dose level to the dose level administered at the time diarrhea developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted, the sunitinib dose should be reduced 1 dose level
Hypertension	
Note: Patients should have their blood pressure checked once weekly during their first 24 weeks of therapy and for an 8-week period after an adjustment in their sunitinib dose	
G1 hypertension	Continue sunitinib at same dose and schedule
G2 asymptomatic	Treat with antihypertensive medications and continue sunitinib at same dose and schedule
G2 symptomatic, or persistent G2 despite antihypertensive medications, or diastolic BP >110 mm Hg, or G3 hypertension	Treat with antihypertensive medications. Hold sunitinib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue sunitinib at 1 dose level lower *Note:* Discontinue therapy if sunitinib is withheld >3 weeks
G4 hypertension	Discontinue therapy
Coadministration of potent CYP3A4 inhibitors (eg, ketoconazole, itraconazole, voriconazole, clarithromycin, atazanavir, ritonavir, telithromycin)	Reduce sunitinib dose
Coadministration of potent CYP3A4 inducers (eg, rifampin, phenytoin, phenobarbital, dexamethasone, carbamazepine, St. John's wort)	Increase sunitinib dose (to a maximum of 87.5 mg daily)

Toxicity (N = 375)*

*NCI Common Terminology Criteria for Adverse Events v3.0. Listed are all treatment-related adverse events of interest and those occurring in at least 10% of patients in the sunitinib group

†The incidence of a G3 decline in the LVEF was 2% with sunitinib. This was not associated with clinical sequelae and was reversible after dose modification or discontinuation of treatment. No G4 events were reported in this category

REGIMEN

PAZOPANIB HYDROCHLORIDE

Sternberg CN et al. J Clin Oncol 2010;28:1061–1068

Pazopanib HCl 800 mg; administer orally once daily at least 1 hour before or 2 hours after a meal

Note: Tablets are swallowed whole (without breaking, chewing, or crushing). Oral bioavailability was increased after crushing tablets and when ingested concurrently with a high-fat or low-fat meal, resulting in increased systemic exposure ($AUC_{[0–72\ hour]}$) and maximum concentration achieved

Note: Caution in patients with hepatic dysfunction

- In patients with baseline moderate hepatic impairment administer **pazopanib** 200 mg orally once daily
- The safety of pazopanib in patients with pr-existing severe hepatic impairment, defined as total bilirubin >3 × ULN with any level of ALT, is unknown. Treatment with pazopanib is not recommended in patients with severe hepatic impairment

Note: When using pazopanib, monitor patients electrocardiographically at baseline and periodically thereafter. Evaluate serum electrolytes (calcium, magnesium, potassium) at baseline and periodically thereafter, supplementing as needed to maintain electrolytes within normal ranges

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Wadler S et al. J Clin Oncol 1998;16:3169–3178

Patient Population Studied

A study of 435 patients enrolled in a placebo-controlled, randomized, double-blind, global, multicenter, phase III study. Randomization was stratified on the basis of ECOG PS (0 vs. 1), prior nephrectomy (yes vs. no), and prior systemic treatment for advanced RCC (treatment naïve vs. cytokine pretreated). Patients were centrally randomly assigned in a 2:1 ratio (290 vs. 145) to receive either 800 mg pazopanib HCl once daily or matching placebo. The study initially enrolled patients with advanced and/or metastatic RCC who had progressed on 1 prior cytokine-based systemic therapy but was subsequently amended to include treatment-naïve patients. Additional eligibility criteria included a diagnosis of clear cell or predominantly clear cell histology. Patients were excluded if they had poorly controlled hypertension (systolic blood pressure of ≥140 mm Hg or diastolic blood pressure of ≥90 mm Hg, despite antihypertensive therapy). The experimental and control arms were well balanced with regards to MSKCC risk category (94% vs. 92% with favorable/intermediate group, respectively) and prior nephrectomy (89% vs. 88%, respectively). Patients who experienced disease progression after treatment with placebo, had the option of receiving pazopanib via an open-label study provided they met predefined eligibility criteria. Seventy (48%) of 145 placebo-arm patients enrolled in the open-label study

Treatment Modifications

Pazopanib Dose Levels	
Starting dose: Level 1	800 mg once daily
Level −1	600 mg once daily
Level −2	400 mg once daily
Level −3	200 mg once daily

Adverse Event	Dose Modification
Hepatotoxicity	
Isolated ALT elevations between 3 × ULN and 8 × ULN	Continue pazopanib with weekly monitoring of LFTs until ALT returns to G1 or baseline
Isolated ALT elevations of >8 × ULN	Discontinue pazopanib administration until ALT decreases to G ≤1 or baseline. If the potential benefit for reinitiating treatment with pazopanib is considered to outweigh the risk for hepatotoxicity, then restart pazopanib at a reduced dose of not more than 400 mg once daily and measure serum liver tests weekly for 8 weeks
ALT >3 × ULN recurs after restarting pazopanib at a dose of 400 mg once daily	Discontinue pazopanib permanently
ALT >3 × ULN concurrently with bilirubin elevations >2 × ULN	Discontinue pazopanib permanently. Monitor patients until resolution *Note:* Pazopanib is a UGT1A1 inhibitor. Mild, indirect (unconjugated) hyperbilirubinemia may occur in patients with Gilbert syndrome. In these patients, an elevation in ALT >3 × ULN should be managed as per the recommendations outlined for isolated ALT elevations
Proteinuria	
G4 proteinuria	Discontinue pazopanib permanently
Diarrhea	
G1/2 diarrhea	Focus on treatment for symptoms designed to resolve the diarrhea. No dose modifications for G1/2 diarrhea unless G2 diarrhea persists for >2 weeks
G2 diarrhea that persists ≥2 weeks	Follow guidelines for G3/4 diarrhea (below)
If diarrhea cannot be controlled with preventive measures outlined, and is G3/4 or worsens by one grade level (G3 to G4) while on pazopanib, and is not alleviated by symptomatic treatment within 48 hours	Hold pazopanib. Also, withhold pazopanib if persistent G2 diarrhea while on pazopanib is not alleviated by treatment for symptoms (persistent defined as lasting for >2 weeks)
If pazopanib is held for >3 weeks and diarrhea does not resolve to G ≤1	Discontinue therapy
If within 3 weeks of withholding pazopanib diarrhea resolves to G ≤1	Restart pazopanib at 1 dose level less than the dose level administered at the time toxicity developed

(*continued*)

*NCI Common Terminology Criteria for Adverse Events v3.0

†Adverse events with an incidence of ≥10% in the pazopanib arm are displayed

‡Clinical laboratory abnormalities with an incidence of ≥30% in the pazopanib arm or with a 5% increase in incidence in the pazopanib arm compared with the placebo arm are displayed

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Diarrhea	
If G3/4 diarrhea or persistent G2 diarrhea recurs at reduced pazopanib doses (persistent defined as lasting for >2 weeks)	Again, withhold pazopanib until the toxicity resolves to CTCAE G ≤1, at which time pazopanib should be restarted at 1 dose level less than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If G3/4 diarrhea or persistent G2 diarrhea recurs at a dose of 200 mg once daily (persistent defined as lasting for >2 weeks)	Discontinue therapy
If diarrhea does not recur at reduced pazopanib doses with or without continued treatment for symptoms	The dose of pazopanib may be increased 1 dose level to the dose level that was being administered at the time diarrhea developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the pazopanib dose should be reduced 1 dose level
Hypertension	
Note: Patients should have their blood pressure checked once per week during their first 24 weeks of therapy and for an 8-week period after an adjustment is made in their pazopanib dose	
G1 hypertension	Continue pazopanib at same dose and schedule
G2 asymptomatic	Treat with antihypertensive medications and continue pazopanib at same dose and schedule
G2 symptomatic or persistent G2 despite anti-hypertensive medications or diastolic BP >110 mm Hg or G3 hypertension	Treat with antihypertensive medications. Hold pazopanib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue pazopanib at 1 dose level lower *Note:* Discontinue therapy if pazopanib is withheld >3 weeks
G4 hypertension	Discontinue therapy
QTc Abnormalities	
ECGs and electrolytes should be checked 3 times per week if any QTc abnormalities are noted	
QTc prolongation defined as: • A single measurement of ≥550 msec • An increase of ≥100 msec from baseline • Two consecutive measurements (within 48 hours of each other) that were ≥500 msec but ≤550 msec • An increase of ≥60 msec, but <100 msec from baseline to a value ≥480 msec	Hold pazopanib until QTc <480 msec, then resume pazopanib at 1 dose level lower

Therapy Monitoring

1. *At baseline, day 8, every 3 weeks until week 24, and every 4 weeks thereafter:* Physical examinations, vital signs, with blood pressure monitoring and clinical laboratory evaluations. Serum chemistries, particularly: calcium, magnesium, and potassium. 12-Lead ECG should be performed before the start of treatment (additional ECGs only if clinically indicated)
2. *Thyroid function tests:* Monitor every 12 weeks. If thyroid-stimulating hormone levels are abnormal, evaluations of free triiodothyronine and thyroxine should be obtained
3. *LFTs:* Monitor at baseline, once every 4 weeks for the first 4 months, then periodically thereafter
4. *Response assessment:* Every 2–3 cycles

Efficacy (N = 290)*

Pazopanib Response Rate, Overall Study Population		95% CI

48	95	23	−1.97	−9.02–5.09	0.58

*More patients in the placebo arm discontinued study treatment because of disease progression compared with patients in the pazopanib arm
†The minimal important differences for the questionnaires have been previously established as 5–10 for the EORTC-QLQ-C30, 0.08 for the EQ-5D Index, and 7 for the EQ-5D VAS. Values greater than 0 indicate a trend in favor of pazopanib, and values less than 0 indicate a trend in favor of placebo

REGIMEN

BEVACIZUMAB + INTERFERON ALFA-2A OR -2B

Escudier B et al. Lancet 2007;370:2103–2111
Escudier B et al. J Clin Oncol 2010;28:2144–2150
Rini BI et al. J Clin Oncol 2008;26:5422–5428
Rini BI et al. J Clin Oncol 2010;28:2137–2143

Bevacizumab 10 mg/kg per dose; administer intravenously in 100 mL 0.9% sodium chloride injection every 2 weeks until disease progression, unacceptable toxicity, or withdrawal of consent. No dose reduction permitted

Interferon alfa-2a *or* **interferon alfa-2b** 9 million IU/dose; administer by subcutaneous injection 3 times weekly for a maximum of 52 weeks, or until disease progression, unacceptable toxicity, or withdrawal of consent (total weekly dose = 27 million IU)

Note: If needed, the starting dose may be less than 9 million IU but every effort should be made to reach the recommended dose within the first 2 weeks of treatment

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Dose Levels	
Starting dose: Level 1	Interferon alfa-2a *or* -2b 9 million IU + bevacizumab 10 mg/kg
Level −1	Interferon alfa-2a *or* -2b 6 million IU + bevacizumab 10 mg/kg
Level −2	Interferon alfa-2a *or* -2b 3 million IU + bevacizumab 10 mg/kg

Note: Across all NSCLC studies, for example, bevacizumab was discontinued in 8.4–21% of patients because of adverse reactions

Adverse Event	Dose Modification
G3/4 nonhematologic toxicity attributable to interferon alfa at a dose of 9 million IU	Reduce dose of interferon alfa to 6 million IU
G3/4 nonhematologic toxicity attributable to interferon alfa at a dose of 6 million IU	Reduce dose of interferon alfa to 3 million IU
Gastrointestinal (GI) perforations, fistula formation in the GI tract, intraabdominal abscess, fistula formation involving an internal organ, serious hemorrhage (ie, requiring medical intervention)	Discontinue bevacizumab

(*continued*)

Patient Population Studied

A study of 649 patients with metastatic RCC who were randomly assigned to receive either interferon alfa-2 alone or interferon alfa-2 plus bevacizumab. The RCC had to have predominantly (>50%) clear cell renal cell carcinoma and patients had to have undergone a prior nephrectomy or partial nephrectomy (if resection margins were clearly negative of disease). Patients had to have a Karnofsky performance status ≥70%. The primary end point of the trial was OS. The study was designed to have 80% power to detect an improvement in OS with an HR of 0.76, assuming an improvement of median survival from 13 months to 17 months, at a two-sided alpha level of 0.05 (Escudier B et al. Lancet 2007;370:2103–2111)

A study of 732 patients with metastatic RCC who were randomly assigned to receive either interferon alfa-2 alone or interferon alfa-2 plus bevacizumab. The RCC had to have predominantly a clear cell histologic component. Prior systemic therapy for RCC was not allowed. Patients were required to have a Karnofsky performance status ≥70%. The primary end point was OS (Rini BI et al. J Clin Oncol 2008;26:5422–5428)

Treatment Modifications (*continued*)

Hypertensive crisis or hypertensive encephalopathy	Discontinue bevacizumab
Reversible posterior leukoencephalopathy syndrome (RPLS)*	Discontinue bevacizumab
Severe arterial thromboembolic event (ATE)—cerebral infarction, transient ischemic attacks, myocardial infarction, angina*	Discontinue bevacizumab *Note:* The safety of resumption of bevacizumab therapy after resolution of an ATE has not been studied
Nephrotic syndrome (proteinuria [>3.5 g/day], hypoalbuminemia, hyperlipidemia, and edema)*	Discontinue bevacizumab
Moderate-to-severe proteinuria	Suspend bevacizumab administration for proteinuria ≥2 g/24 hours and resume when proteinuria is <2 g/24 hours. Patients with moderate-to-severe proteinuria based on 24-hour urine collections should be monitored regularly until improvement or resolution is observed. The safety of continued treatment in patients with moderate to severe proteinuria has not been evaluated *Note:* Data from a postmarketing safety study showed poor correlation between urine protein-to-creatinine ratio and 24-hour urine protein
Protein in urine ≥2+ per dipstick measurement	Perform further assessment with a 24-hour urine collection
Wound dehiscence or wound healing complications requiring medical intervention	Discontinue bevacizumab
Prior surgery	Do not initiate bevacizumab for at least 28 days after surgery, and not before the surgical wound is fully healed
Serious hemorrhage or recent hemoptysis (≥2.5 mL red blood)	Do not administer bevacizumab
Planned elective surgery	Temporarily suspend bevacizumab for at least 4 weeks
Severe infusion reactions	Temporarily suspend bevacizumab and administer appropriate medical therapy

*The safety of resuming bevacizumab therapy in patients who experience RPLS, ATE, and moderate-to-severe proteinuria (nephrotic syndrome) is unknown

Hypertension

Note: Patients should have their blood pressure checked once weekly during their first 24 weeks of therapy and during an 8-week period after any adjustment is made in their bevacizumab dose

G1 hypertension	Continue bevacizumab at same dose and schedule
G2 asymptomatic hypertension	Treat with antihypertensive medications and continue bevacizumab at same dose and schedule
G2 symptomatic hypertension or persistent G2 hypertension despite antihypertensive medications, or diastolic BP >110 mm Hg, or G3 hypertension	Treat with antihypertensive medications. Hold bevacizumab (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then, continue bevacizumab at 1 dose level lower *Note:* Discontinue therapy if bevacizumab is withheld >3 weeks
G4 hypertension	Discontinue therapy

Therapy Monitoring

1. *ECG:* Unless additional ECGs are clinically indicated, 12-lead ECGs are performed before the start of treatment, weekly for the first 8 weeks, and then every 12 weeks thereafter. If the dose is increased, then weekly monitoring is indicated for approximately 6 weeks
2. *Response assessment:* Every 2–3 cycles
3. *BP monitoring:* Should be conducted every 2–3 weeks during treatment. Patients who develop hypertension may require BP monitoring at more frequent intervals (even if they have discontinued therapy)
4. *Proteinuria monitoring:* Patients should also be monitored for the development or worsening of proteinuria with serial urinalyses. Patients with a urine dipstick reading >2+ should undergo further assessment (24-hour urine collection) and should be monitored regularly until improvement or resolution is observed

Bevacizumab Toxicities

http://www.accessdata.fda.gov/drugsatfda_docs/label/2009/125085s0169lbl.pdf

Hypertension:

- Across clinical studies, the incidence of grade 3 or 4 hypertension ranged from 5–18%

Proteinuria and nephrotic syndrome:

- Across clinical studies, the incidence of grades 3–4 proteinuria (characterized as >3.5 g/24 hours) ranged up to 3% in bevacizumab-treated patients
- Nephrotic syndrome (proteinuria [>3.5 g/day], hypoalbuminemia, hyperlipidemia, and edema) occurred in <1% of patients who received bevacizumab in clinical trials, in some instances with fatal outcomes

Arterial thromboembolic events (ATEs):

- Across indications, the incidence of grade ≥3 ATEs (cerebral infarction, transient ischemic attacks, myocardial infarction, angina, and a variety of other ATEs) in the bevacizumab-containing arms was 2.4%
- Among patients who received bevacizumab in combination with chemotherapy, the risk of developing ATEs during therapy was increased in patients with a history of arterial thromboembolism, or age >65 years

Gastrointestinal (GI) perforation:

- The incidence of GI perforation ranged from 0.3–2.4% across clinical studies
- The typical presentation may include abdominal pain, nausea, emesis, constipation, and fever
- Perforation can be complicated by intraabdominal abscess and fistula formation
- The majority of cases occurred within the first 50 days after initiation of bevacizumab

Surgery and wound healing complications:

- The incidence of wound healing complications, including serious and fatal complications, in patients with metastatic colorectal cancer who underwent surgery during the course of bevacizumab treatment was 15%

Hemorrhage:

- Bevacizumab can result in 2 distinct patterns of bleeding: minor hemorrhage, most commonly grade 1 epistaxis, and serious, and, in some cases fatal, hemorrhagic events
- Severe or fatal hemorrhage, including hemoptysis, gastrointestinal bleeding, hematemesis, CNS hemorrhage, epistaxis, and vaginal bleeding occurred up to 5-fold more frequently in patients who received bevacizumab compared to patients who received only chemotherapy
- Across indications, the incidence of grade ≥3 hemorrhagic events among patients receiving bevacizumab ranged from 1.2–4.6%

REGIMEN

TEMSIROLIMUS

Hudes G et al. N Engl J Med 2007;356:2271–2281

Premedication:
Diphenhydramine 25–50 mg; administer intravenously approximately 30 minutes before each dose of temsirolimus as prophylaxis against hypersensitivity reactions (other histamine H_1-receptor antagonists may be substituted)

Temsirolimus 25 mg diluted in 250 mL 0.9% sodium chloride injection; administer intravenously over 30–60 minutes once weekly (total dose/week = 25 mg)

Notes:
- The concomitant use of strong cytochrome P450 (CYP) **CYP3A4 inhibitors** should be avoided. Ingestion of grapefruit products (fruit, juice) may also increase plasma concentrations of sirolimus (a major metabolite of temsirolimus) and should be avoided. If a strong **CYP3A4 inhibitor** must be administered, a temsirolimus dose reduction to 12.5 mg/week should be considered. However, there are no clinical data with this dose adjustment in patients receiving strong CYP3A4 inhibitors
- If a concomitantly administered strong **CYP3A4 inhibitor** is discontinued, a washout period of approximately 1 week should be allowed before the temsirolimus dose is adjusted back to the dose used prior to initiation of the strong CYP3A4 inhibitor
- The use of concomitant strong **CYP3A4 inducers** should be avoided. If a strong **CYP3A4 inducer** must be administered, a temsirolimus dose increase from 25 mg/week up to 50 mg/week should be considered. However, there are no clinical data with this dose adjustment in patients receiving strong CYP3A4 inducers
- If a concomitantly administered strong **CYP3A4 inducer** is discontinued, the temsirolimus dose should be returned to the dose used prior to initiation of the strong CYP3A4 inducer
- Temsirolimus has immunosuppressive properties and may predispose patients to infections. Localized and systemic infections (bacterial and invasive fungal infections) have occurred. Some of these infections have been severe or fatal. Complete the treatment for preexisting invasive fungal infections prior to starting treatment with temsirolimus
- Elevations in serum glucose can occur with temsirolimus. When possible, optimal glucose and lipid control should be achieved before starting a patient on temsirolimus

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 626 patients were randomly assigned to receive interferon (207), temsirolimus (209), or a combination of interferon and temsirolimus (210). Eligibility criteria included patients with histologically confirmed advanced renal cell carcinoma (stage IV or recurrent disease) and a Karnofsky performance score of ≥60 (on a scale of 0–100, with higher scores indicating better performance) who had not previously received systemic therapy for renal cancer. A fasting level of total cholesterol of no more than 350 mg/dL (≤9.1 mmol/L) and a triglyceride level of no more than 400 mg/dL (≤4.5 mmol/L) were required. At least 3 of the following 6 predictors of short survival were required: (a) a serum lactate dehydrogenase level ≥1.5-times the upper limit of normal range; (b) a hemoglobin level less than the lower limit of normal range; (c) a corrected serum calcium level >10 mg/dL (>2.5 mmol/L); (d) <1 year from initial diagnosis of renal cell carcinoma to randomization; (e) a Karnofsky performance score of 60 or 70; or (f) metastases in multiple organs

Treatment Modifications

Temsirolimus Dose Levels	
Starting dose: Level 1	25 mg once daily
Level −1	20 mg once daily
Level −2	15 mg once daily

Adverse Event	Dose Modification
Invasive systemic fungal infection	Discontinue temsirolimus and treat with appropriate antifungal therapy
Noninfectious pneumonitis without symptoms with only radiologic changes	Observe carefully. Specific therapies or drug interruption may not be necessary
Noninfectious pneumonitis with mild-to-moderate symptoms	Withhold therapy. Glucocorticoids may be initiated. Resume temsirolimus at a reduced dose depending on the individual clinical circumstances
Noninfectious pneumonitis with severe symptoms (including a decrease in DL_{CO} on pulmonary function tests)	Discontinue therapy and consider administering high doses of glucocorticoids
ANC $<1000/mm^3$ or platelet count $<75{,}000/mm^3$	Withhold therapy. Resume temsirolimus when symptoms improve to G ≤2 with temsirolimus dose reduced by 5 mg/week to a dose not less than 15 mg/week
Any nonhematologic G3/4 toxicity	Withhold therapy. Resume temsirolimus when symptoms improve to G ≤2 with temsirolimus dose reduced by 5 mg/week to a dose not less than 15 mg/week
G1/2 oral ulcerations	Topical treatments are recommended, but alcohol- or peroxide-containing mouthwashes should be avoided. Focus on pain control, oral hygiene, and IV fluid replacement, or total parenteral nutrition if severe
Hyperglycemia	Monitor blood sugar levels and institute oral hypoglycemic agent or insulin as needed
Hypertriglyceridemia	Monitor triglycerides, instituting dietary interventions for minor elevations and lipid-lowering agents for levels exceeding 500 mg/dL

Efficacy (N = 209)*

Percent objective response rate	8.6 (range: 4.8–12.4)
Median overall survival (95% CI), months	10.9 (range: 8.6–12.7)
Median progression-free survival (95% CI), months	5.5 (range: 3.9–7.0)
Median time to treatment failure (95% CI), months	3.8 (range: 3.5–3.9)

*RECIST (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

Therapy Monitoring

1. *Prior to starting treatment and periodically thereafter:* Renal function, CBC with differential, blood glucose, and serum lipid profile
2. *ECG:* A 12-lead ECG should be performed before the start of treatment, weekly for at least the first 2 weeks. Additional ECGs may be performed depending on the QTc. If the dose is increased then at least 1 additional ECG should be obtained
3. *Response assessment:* Every 8–12 weeks

Toxicity (N = 208)*

Adverse Event	% All Grades	% G3/4
Asthenia	51	11
Rash	47	4
Nausea	37	2
Anorexia	32	3
Pain	28	5

Increased aspartate aminotransferase level (AST)	8	1
Neutropenia	7	3
Leukopenia	6	1

*NCI Common Terminology Criteria for Adverse Events v3.0

SECOND-LINE REGIMEN

EVEROLIMUS

Motzer RJ et al. Lancet 2008;372:449–456
Motzer RJ et al. Cancer 2010;116:4256–4265

Everolimus 10 mg/day; administer orally in a fasting state or with a light, fat-free meal, continually. Treatment cycles are 28 days in duration (total dose/28-day cycle = 280 mg)

Notes:

- For patients with mild-to-moderate hepatic impairment (Child-Pugh Class B), reduce the dose to 5 mg daily
- Everolimus has not been evaluated in patients with severe hepatic impairment (Child-Pugh Class C) and should not be used in this population
- A missed dose may be taken up to 6 hours after the regular scheduled time; otherwise, it should be skipped. After missing a dose, take everolimus at the usual time the following day. Doubling doses on subsequent days to compensate for missed doses should not be attempted
- Everolimus has immunosuppressive properties and may predispose patients to infections. Localized and systemic infections (bacterial and invasive fungal infections) have occurred. Some of these infections have been severe or fatal. Complete treatment for preexisting invasive fungal infections prior to starting treatment with everolimus
- Elevations in serum glucose can occur with everolimus. When possible, optimal glucose and lipid control should be achieved before starting a patient on everolimus
- Avoid concomitant use with strong inhibitors of CYP3A4 or PgP (MDR1, ABCB1 transport protein). If coadministration with moderate CYP3A4 or PgP inhibitors is required, use caution and reduce the everolimus dose to 2.5 mg daily
- Increase the everolimus dose if coadministered with a strong CYP3A4 inducer

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Everolimus Dose Levels	
Starting dose: Level 1	10 mg once daily
Level −1	5 mg once daily
Level −2	2.5 mg once daily

(*continued*)

Patient Population Studied

A study of 410 patients with metastatic renal cell carcinoma that showed a clear cell component that had progressed either during or within 6 months after stopping treatment with sunitinib, sorafenib, or both drugs. Previous therapy with bevacizumab, aldesleukin (interleukin-2), or interferon alfa, was also permitted. Key eligibility criteria included a Karnofsky performance status score ≥70%. Patients were randomly assigned in a 2:1 ratio to receive everolimus 10 mg once daily (n = 272) or placebo (n = 138) in conjunction with best supportive care. Randomization was stratified by Memorial Sloan-Kettering Cancer Center prognostic score and previous anticancer therapy. The primary endpoint was progression-free survival

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Invasive systemic fungal infection	Discontinue everolimus and treat with appropriate antifungal therapy
Noninfectious pneumonitis without symptoms with only radiologic changes	Observe carefully. Specific therapies or drug interruption may not be necessary
Noninfectious pneumonitis with mild-to-moderate symptoms	Withhold therapy. Glucocorticoids may be initiated. Resume everolimus at a reduced dose depending on the individual clinical circumstances
Noninfectious pneumonitis with severe symptoms (including a decrease in DL_{CO} on pulmonary function tests)	Discontinue therapy and consider administering high doses of glucocorticoids
ANC $<1000/mm^3$ or platelet count $<75{,}000/mm^3$	Withhold therapy. Resume everolimus when symptoms improve to G $\leq$2 with everolimus dose reduced to 5 mg/day, or 5 mg every other day but not less than 15 mg/week
Any nonhematologic G3/4 toxicity	Withhold therapy. Restart everolimus when symptoms improve to G $\leq$2 with everolimus dose reduced to 5 mg/day, or 5 mg every other day but not less than 15 mg/week
G1/2 oral ulcerations	Topical treatments are recommended, but alcohol- or peroxide-containing mouthwashes should be avoided. Focus on pain control, oral hygiene, and IV fluid replacement, or total parenteral nutrition if severe
Hyperglycemia	Monitor blood sugar levels and institute oral hypoglycemic agent or insulin as needed
Hypertriglyceridemia	Monitor triglycerides, instituting dietary interventions for minor elevations and lipid-lowering agents for levels exceeding 500 mg/dL

Efficacy (Everolimus N = 272; Placebo N = 138)*

Partial response	1%
Median progression-free survival	4 months†
Probability of being progression-free at 6 months	26%‡
Median duration of treatment	95 days
Median overall survival§	Hazard ratio consistent with placebo: 14.8 months (everolimus) vs. 14.4 months (placebo) (HR: 0.87; P = 0.162)

*RECIST (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

†1.9 months in the placebo group. Predefined subset analyses (MSKCC risk classification) plus a series of exploratory analyses across relevant patient subgroups (number of previous VEGF receptor tyrosine kinase inhibitors, age, sex, and geographic region) indicated benefit was maintained across subgroups

‡2% in placebo group

§Confounded by crossover: Of the 98 patients in the placebo group whose disease progressed per investigator assessment, 79 crossed over to open-label everolimus after disease progression. Of these 79 patients, 60 developed progressive disease within 8 weeks after enrollment. By the rank-preserving structural failure time model, the survival corrected for crossover was 1.9-fold longer (95% CI, 0.5–8.5) with everolimus compared with placebo only. Independent prognostic factors for shorter OS in the study included low performance status, high corrected serum calcium, low hemoglobin, and prior sunitinib use (P <0.01) (Motzer RJ et al. Cancer 2010;116:4256–4265)

Therapy Monitoring

1. *Prior to starting treatment and periodically thereafter:* Renal function, CBC with differential, blood glucose, and serum lipid profiles
2. *ECG:* A 12-lead ECG should be performed before the start of treatment, weekly for at least the first 2 weeks. Additional ECGs may be performed depending on the QTc. If the dose is increased, then at least 1 additional ECG should be obtained
3. *Safety assessment:* Every 2–4 weeks for the first 3 cycles; every 4–8 weeks thereafter
4. *Response assessment:* Every 8–12 weeks

Toxicity (Placebo N = 135; Everolimus N = 269)*

Dose reduction with no previous interruption	5%	<1%

*NCI Common Terminology Criteria for Adverse Events v3.0
†Includes aphthous stomatitis, mouth ulceration, and stomatitis
‡Includes all infections
§Includes interstitial lung disease, lung infiltration, pneumonitis, pulmonary alveolar haemorrhage, and pulmonary toxicity

SECOND-LINE REGIMEN

AXITINIB

Rini BI et al. Lancet 2011;378:1931–1939

Axitinib 5 mg; administer orally twice daily (approximately every 12 hours), continually (total dose/week = 35 mg)

- Axitinib should be swallowed whole (no breaking, crushing, or chewing) with water
- Axitinib may be administered without respect to food ingestion

Notes:

1. Patients who tolerate axitinib for at least two consecutive weeks with no adverse reactions G >2, who remain normotensive, and are not receiving anti-hypertension medications may have their dose increased to 7 mg twice daily, and further to 10 mg twice daily using the same criteria
2. *Strong CYP3A4/5 Inhibitors:* The concomitant use of strong CYP3A4/5 inhibitors should be avoided (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, and voriconazole). Selection of an alternate concomitant medication with no or minimal CYP3A4/5 inhibition potential is recommended. Although axitinib dose adjustment has not been studied in patients receiving strong CYP3A4/5 inhibitors, if a strong CYP3A4/5 inhibitor must be co-administered, a dose decrease of axitinib by approximately half is recommended, as this dose reduction is predicted to adjust the axitinib area under the plasma concentration vs time curve (AUC) to the AUC range observed without inhibitors. Subsequent doses can be increased or decreased based on individual safety and tolerability. If co-administration of a strong inhibitor is discontinued, the axitinib dose should be returned (after 3–5 elimination half-lives of the inhibitor) to that used prior to initiation of the strong CYP3A4/5 inhibitor
3. The axitinib starting dose should be reduced by approximately half in patients with baseline moderate hepatic impairment (Child-Pugh class B)
4. If axitinib is interrupted, patients receiving antihypertensive medications should be monitored for hypotension

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Adverse Event	Treatment Discontinuation
Any hypertension	Treat as needed with standard anti-hypertensive therapy
Persistent hypertension despite use of anti-hypertensive medications	Reduce the dose of axitinib (10 → 7 → 5 → 3 → 2 mg twice daily)
Evidence of hypertensive crisis	Discontinue axitinib
Moderate to severe proteinuria	Reduce the dose of axitinib (10 → 7 → 5 → 3 → 2 mg twice daily), or withhold axitinib treatment until protein returns to baseline values

Patient Population Studied

Multicenter, phase 3, randomized, controlled trial that included patients with histologically or cytologically confirmed RCC with a clear cell component. All patients had RECIST-defined progressive disease after one previous systemic first-line regimen with a sunitinib-based, bevacizumab plus interferon alfa-based, temsirolimus-based, or cytokine-based regimen. Eligibility criteria included 2 weeks or more since the end of previous systemic treatment (4 weeks or more for bevacizumab plus interferon alfa) and an ECOG PS of 0 or 1. Exclusion criteria included present use or anticipated need for cytochrome P450 (CYP)3A4-inhibiting, CYP3A4-inducing, or CYP1A2-inducing drugs

Lipase elevation	91/338 (27%)	16/338 (5%)	148/319 (46%)	47/319 (15%)

PPE, Palmar-plantar erythrodysesthesia; NA, not available
*Denominator for each laboratory abnormality differed depending on the availability of baseline and at least one on-study test result

Treatment Monitoring

1. *At baseline, week 2, week 4, and every 4 weeks thereafter:* Clinical assessments including medical history and physical examination, vital signs, and CBC with differential
2. *At screening, after 6 and 12 weeks of therapy, and every 8 weeks thereafter:* Tumor assessments, including CT and MRI. Thyroid function tests. 24-hour or spot urine for protein measurement

REGIMEN

HIGH-DOSE ALDESLEUKIN (INTERLEUKIN-2 [IL-2])

Yang JC et al. J Clin Oncol 2003;21:3127–3132

Aldesleukin 720,000 units/kg per dose; administer intravenously in 50 mL of albumin (human) 5% over 15 minutes every 8 hours for a maximum of 15 doses/cycle, if tolerated, for 2 cycles (after treatment commences the administration schedule is preserved; treatment is not extended to replace doses that were omitted owing to adverse events). Each cycle is separated by 7–10 days of rest. Treatment is repeated every 2 months

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Ancillary medications: See special section below

Treatment Modifications: Guidelines for Delay or Discontinuation of Aldesleukin and for Treatment of Adverse Events

Relative Criteria	Absolute Criteria
Cardiac	
Sinus tachycardia (120–130 beats/min)	Sustained sinus tachycardia (>130 beats/min) despite correcting hypotension, fever, and tachycardia, and stopping dopamine) *ECG changes:* Atrial fibrillation Supraventricular tachycardia Ventricular arrhythmias (frequent PVCs, bigeminy tachycardia) Changes suggestive of ischemia *Laboratory:* Elevated CPK isoenzymes or troponin
Dermatologic	
	Moist desquamation
Gastrointestinal	
Diarrhea, 1000 mL/8 hours Ileus/abdominal distention *Laboratory:* Bilirubin >7 mg/dL (120 μmol/L)	Diarrhea, 1000 mL/8 hours × 2 Vomiting not responsive to medication Severe abdominal distention affecting breathing Severe abdominal pain, unrelenting
Hemodynamic	
Maximum phenylephrine 1–1.5 mg/kg per minute	Maximum phenylephrine 1.5–2 μg/kg per minute
Minimum phenylephrine >0.5 mg/kg per minute	Minimum phenylephrine >0.8 μg/kg per minute

(continued)

Patient Population Studied

A study of 156 patients with metastatic RCC without prior IL-2 therapy. Patients with brain metastases, coronary artery disease, active autoimmune disorder, or significant renal, pulmonary, or hepatic insufficiency were excluded

Efficacy (N = 155)

Complete response	6%
Partial response	15%

Treatment Modifications: Guidelines for Delay or Discontinuation of Aldesleukin and for Treatment of Adverse Events (*continued*)

Relative Criteria	Absolute Criteria
Hemorrhagic	
Guaiac-positive sputum, emesis, or stool *Laboratory:* Platelets 30,000–50,000/mm^3	Frank blood in sputum, emesis, or stool *Laboratory:* Platelets <30,000/mm^3
Infectious	
	Strong clinical suspicion or documented infection
Musculoskeletal	
Weight gain >15%	
Extremity tightness	Extremity paresthesias
Neurologic	
Vivid dreams	Hallucinations
Emotional lability	Persistent crying Mental status changes not reversible in 2 hours Inability to subtract serial 7s or spell words backwards Disorientation
Pulmonary	
Resting shortness of breath	
3–4 L O_2 by nasal cannula for saturation ≥95%	>4 L O_2 by nasal cannula for saturation ≥95% *or* 40% O_2 mask for saturation ≥95%
Rales one-third up lower chest	Endotracheal intubation Moist rales halfway up chest Pleural effusion requiring thoracentesis or chest tube while on therapy
Renal	
Urine 80–160 mL/shift Urine 10–20 mL/hour *Laboratory:* Creatinine 2.5–2.9 mg/dL (221–256 µmol/L)	Urine <80 mL/shift Urine <10 mL/hour *Laboratory:* Creatinine >3 mg/dL (>265 µmol/L)
When to Delay or Discontinue Aldesleukin	
Observation	**Action**
Any relative criteria	Initiate corrective measure ± delay aldesleukin
>3 Relative criteria	Initiate corrective measure, delay aldesleukin Stop aldesleukin if not easily reversible
Any absolute criteria	Initiate corrective measures, delay aldesleukin Stop aldesleukin if not easily reversible

Adapted from Schwartzentruber DJ. J Immunother 2001;24:287–293

(*continued*)

Toxicity* (N = 156)

Adverse Event	% G3/4
Hypotension	36
Malaise	21
Nausea or vomiting	13
Oliguria (<80 mL/8 hours)	12
CNS: Orientation	10
Thrombocytopenia	9
Diarrhea	9
Arrhythmia, atrial	4
Hyperbilirubinemia	3
Elevated ALT	3
CNS: level of consciousness	3
Infection	3
Peripheral edema	0.4

*All toxicities were reversible and no deaths occurred

Treatment Modifications: Guidelines for Delay or Discontinuation of Aldesleukin and for Treatment of Adverse Events (*continued*)

Corrective Measures for Aldesleukin Symptoms/Findings	
Symptom	**Corrective Measure**
Cardiac	
Tachycardia (sinus)	Correct fever, hypotension, hypoxia, anemia; consider discontinuation of dopamine if used
Arrhythmia (other than sinus tachycardia)	Stop aldesleukin (most arrhythmias); correct electrolytes, minerals, anemia, hypoxia; use medications as indicated
Creatine kinase elevation	Measure isoenzymes or troponin, and obtain ECG; if evidence of myocarditis, stop aldesleukin; will need exercise ECHO before next cycle of aldesleukin to rule out myocardial dysfunction; future aldesleukin may be considered if ECHO is normal
Troponin elevation	Must stop aldesleukin; will need exercise ECHO before next cycle of aldesleukin to rule out myocardial dysfunction; future aldesleukin may be considered if the ECHO is normal
Constitutional	
Chills (generally after first or second aldesleukin dose)	Warm blankets as first measure; intravenous meperidine if chills persist
Fever breakthrough	Increase indomethacin to every 6 hours; consider septic work-up if happens after first 24 hours of therapy (ie, high spike above baseline during therapy)
Nasal congestion	Room humidifier, decongestant (no aerosolized steroids)
Dermatologic	
Moist desquamation	Oatmeal baths, lotions (no steroid- or alcohol-containing lotions)
Pruritus	Oatmeal baths, lotions, antipruritics
Gastrointestinal	
Diarrhea	Antidiarrheals (alternate medications); avoid overuse because of complicating ileus and distention
Nausea/vomiting	Antiemetics (alternate medications and routes if any medication is not effective)
Abdominal pain	Evaluate cause; give indomethacin rectally; consider antacids
Mucositis/stomatitis	Frequent oral care, mouthwashes, topical anesthetics, room humidifier
Hemodynamic	
Hypotension	Initially fluids; add phenylephrine after 1–1.5 L of fluid boluses
Acidosis: CO_2 <20 mmol/L	Give 50 mEq sodium bicarbonate intravenously
Acidosis: CO_2 <18 mmol/L	Give 100 mEq sodium bicarbonate intravenously
Hemorrhagic	
Anemia	Transfuse packed red blood cells to maintain hematocrit above 28% during aldesleukin dosing
Thrombocytopenia	Consider transfusion if platelet count <20,000/mm^3

(*continued*)

Notes

1. Patients are retreated with another course of aldesleukin if disease is stable or regressing
2. Therapy is stopped and patients observed if they have 2 consecutive posttreatment evaluations that are unchanged
3. In a 2-arm comparison with low-dose aldesleukin (72,000 units/kg), there was no overall survival difference

Treatment Modifications: Guidelines for Delay or Discontinuation of Aldesleukin and for Treatment of Adverse Events (*continued*)

Corrective Measures for Aldesleukin Symptoms/Findings	
Symptom	**Corrective Measure**
Infectious	
Infection	Stop aldesleukin and treat infection as indicated
Laboratory	
Hypoalbuminemia	Observe
Hypocalcemia	Maintain above lowest normal value
Hypokalemia	Maintain potassium above 3.6 mmol/L
Hypomagnesemia	Maintain above lowest normal value
Musculoskeletal	
Weight gain >15%	Use fluids judiciously
Pulmonary	
Shortness of breath	Check transcutaneous O_2 saturation; if <95%, use O_2; use fluids judiciously; do not use aerosolized steroids
Renal	
Edema	Elevate symptomatic extremity; use fluids judiciously
Oliguria	Initially fluids; add dopamine after 1–1.5 L of fluid boluses

Adapted from Schwartzentruber DJ. J Immunother 2001;24:287–293

Ancillary Medications for Adverse Events Associated with High-Dose Aldesleukin Therapies

Adverse Event	Medication	Dose, Schedule, and Route of Administration
Scheduled Medications		
Fever/myalgia	Acetaminophen	650 mg/4 hours PO/PR
	Indomethacin	50–75 mg/6–8 hours PO/PR
Gastritis	Ranitidine HCl	50 mg/8 hours IV
Nausea	Granisetron HCl	0.01 mg/kg daily
Prevent central line sepsis	Cefazolin sodium Clindamycin phosphate	1000–2000 mg/6 hours, IV or 900 mg every 8 hours, IV
As Needed (PRN) Medications		
Agitation/ combativeness	Haloperidol lactate	1–5 mg/1 hour IV/IM
Anxiety	Lorazepam	0.5–1 mg/6 hours PO/IV
Chills	Meperidine HCl	25–50 mg/1 hour IV
Diarrhea	Loperamide HCl	2 mg/3 hours PO
	Diphenoxylate HCl/atropine sulfate	2.5 mg/0.025 mg every 3 hours PO
	Codeine sulfate	30–60 mg/4 hours PO

(*continued*)

Ancillary Medications for Adverse Events Associated with High-Dose Aldesleukin Therapies (*continued*)

Adverse Event	Medication	Dose, Schedule, and Route of Administration
As Needed (PRN) Medications		
Gastric upset	$Al(OH)_3/Mg(OH)_2$ simethicone	200 mg/200 mg/20 mg every 3 hours PO
Hypocalcemia	Calcium gluconate 10%	1000 mg over 1 hour IV
Hypokalemia	Potassium chloride	10 mEq over 1 hour IV
Hypomagnesemia	Magnesium sulfate	1000 mg (8.12 mEq) over 1 hour IV
Hypophosphatemia	Potassium phosphate	10–15 mmol over 6 hours IV
Hypotension	0.9% sodium chloride injection	250–500 mL IV
	Phenylephrine HCl	0.1–2 mcg/kg/min IV
Insomnia	Temazepam	15–30 mg at bedtime PO
	Zolpidem tartrate	5–10 mg at bedtime PO
Mucositis	Sodium bicarbonate	30 g (~6 tsp)/1500 mL, swish and swallow
Nausea	Prochlorperazine	25 mg/4 hours PR; or 10 mg/6 hours IV
	Ondansetron HCl	10 mg/8 hours IV
	Lorazepam	0.5–1 mg/6 hours PO/IV
Oliguria	0.9% sodium chloride injection	250–500 mL IV
	Dopamine HCl	2–5 mcg/kg per minute IV
Perianal discomfort	Tucks® (hamamelis water pads)	Apply locally
Pruritus	Hydroxyzine HCl	10–25 mg/6 hours PO
	Diphenhydramine HCl	25–50 mg/4 hours PO/IV
	Oatmeal powder/baths	Apply locally
	Lubriderm® (topical emollient)/ camphor/menthol	Apply locally
Sinus congestion	Pseudoephedrine HCl	30 mg/6 hours PO

Adapted from Schwartzentruber DJ. J Immunother 2001;24:287–293

Therapy Monitoring (In-Patient Aldesleukin Administration)

Parameter to Monitor	Not Requiring Vasopressors	Requiring ICU/ Vasopressors
1. *Monitoring during therapy*		
Vital signs	Every 4 hours	Every 1 hour
Intake and output	Every 8 hours	Every 1 hour
Weight	Daily	Daily
Mental status	Every 8 hours	Every 8 hours
IV site/injection site*	Every 8 hours	Every 8 hours
CBC and leukocyte differential count	Daily	Twice daily
Electrolytes, glucose, BUN, creatinine	Daily	Twice daily
AST, ALT, alkaline phosphatase, total bilirubin	Daily	Daily
Albumin, calcium, magnesium, phosphorus	Daily	Daily
Creatine phosphokinase	Daily	Daily
PTT, PT	Every 3 days	Every 3 days
Thyroid-stimulating hormone and free T_4	Each cycle	Each cycle
Urinalysis	Each cycle	Each cycle
ECG	Each cycle	Each cycle
Chest x-ray	Each cycle	Each cycle
2. *Response evaluation*		
Radiologic evaluation or physical measurement of all sites of disease	Every 2 months	

*Monitor for extravasation or irritation. Change peripheral IV site every 3 days

Rosenberg SA. Principles and Practice of the Biologic Therapy of Cancer, 3rd ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2000

REGIMEN

SUBCUTANEOUS LOW-DOSE ALDESLEUKIN (INTERLEUKIN-2 [IL-2])

Yang JC et al. J Clin Oncol 2003;21:3127–3132

Aldesleukin 250,000 units/kg; administer subcutaneously 5 days per week during the first week, *followed by:*
Aldesleukin 125,000 units/kg; administer subcutaneously 5 days per week during the next 5 weeks, followed by 2 weeks without aldesleukin (total dosage/cycle = 4,375,000 units/kg)
Eight-week treatment cycle = 6 consecutive weeks of treatment followed by 2 weeks without aldesleukin

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Therapy Monitoring (Outpatient IL-2 Administration)

Parameter to Monitor Outpatient	Frequency
1. *Monitoring during therapy*	
Vital signs	As needed
Intake and output	Not strictly measured
Weight	Daily
Mental status	Daily
IV site/injection site*	Daily
CBC and leukocyte differential counts	Weekly
Electrolytes, glucose, BUN, creatinine	Weekly
AST, ALT, alkaline phosphatase, bilirubin	Weekly
Albumin, calcium, magnesium, phosphorus	Each course
Creatine phosphokinase	Weekly
PTT, PT	Weekly
Thyroid-stimulating hormone and free T_4	Each course
Urinalysis	Each course
ECG	Each course
Chest x-ray	Each course
2. *Response evaluation*	
Radiologic evaluation or physical measurements of all sites of disease	Every 2 months

*Monitor for extravasation or irritation. Change peripheral IV site every 3 days

Rosenberg SA. Principles and Practice of the Biologic Therapy of Cancer, 3rd ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2000

Patient Population Studied

A study of 94 patients with metastatic RCC who had not previously received aldesleukin. Patients with brain metastases, coronary artery disease, active autoimmune disorder, or significant renal, pulmonary, or hepatic insufficiency were excluded

Efficacy (N = 93)

Complete response	2%
Partial response	8%

Toxicity (N = 94)

	% G3/4
Malaise	9*
Nausea or vomiting	4*
Diarrhea	2*
CNS: orientation	2
Oliguria (<80 mL/8 hours)	1
Infection	1*
Increased ALT	0.6
Hyperbilirubinemia	0
Peripheral edema	0
Thrombocytopenia	0
Hypotension	0
CNS: Level of consciousness	0

*All toxicities were reversible and no deaths occurred

Treatment Modifications

Adverse Event	Dose Modification
G3/4 toxicities except reversible G3 toxicities commonly seen with low-dose aldesleukin (see *Toxicity*)	Skip doses until toxicity resolves
G3/4 toxicities easily reversed by supportive measures	No dose adjustment or delay
Local inflammation at the injection site with or without nodular induration	No dose adjustment or delay. Apply local measures

Notes

1. Doses may be skipped, depending on patient tolerance
2. Patients are retreated with another course of aldesleukin if disease is stable or regressing
3. Therapy is stopped and patients observed if they have 2 consecutive posttreatment evaluations that are unchanged
4. Patients without evidence of disease receive 1 additional consolidation cycle
5. Comparison of objective responses achieved with high-dose intravenous aldesleukin and subcutaneous aldesleukin demonstrated a small, but statistically significant, difference that favored high-dose treatment

REGIMEN

INTERFERON ALFA-2A

Negrier S et al. N Engl J Med 1998;338:1272–1278

Induction:
Interferon alfa-2a 18 million units; administer subcutaneously, 3 doses per week for 10 weeks (total dose/10-week induction = 540 million units)

Maintenance:
Interferon alfa-2a 18 million units; administer subcutaneously, 3 doses per week for 13 weeks (total dose/13-week maintenance = 702 million units)
Note: Patients should take interferon doses around bedtime, allowing them to sleep through a period of the most severe symptoms

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Primary antipyretic prophylaxis
Acetaminophen 650–1000 mg orally *or* **ibuprofen** 400–600 mg orally, administer 1 hour before interferon, then every 4 hours as needed

Efficacy (N = 147)

Week 10	
Complete response	0%
Partial response	7%
Disease stabilization	31%
Disease progression	Not evaluated
Week 25	
Complete response	1%
Partial response	5%
Disease stabilization	13%
Disease progression	Not evaluated

Patient Population Studied

A study of 147 patients with RCC and progressive metastasis. Patients were excluded if they had brain metastases, cardiac dysfunction, any contraindications to the use of vasopressor agents, active infection, previous aldesleukin or interferon alfa treatment, chemotherapy, or radiation therapy within 6 weeks before enrollment, or current treatment with steroids

Therapy Monitoring

1. *Before each cycle:* CBC with differential, serum electrolytes, BUN, creatinine, LFTs, and mineral panel
2. *Response evaluation:* After each maintenance cycle

Toxicity* (N = 147)

	% G3/4
Impaired performance status	16
Anemia	6
Nausea or vomiting	5
Fever	5
Weight loss	4
Increased ALT or AST	3
Pulmonary symptoms	3
Diarrhea	1
Hypotension resistant to pressors	1
Neurologic symptom	1
Cardiac signs	1
Leukopenia	1
Infection	1
Cutaneous signs	0
Thrombocytopenia	0
Increased creatinine	0
Renal symptoms	0
Hyperbilirubinemia	0

*WHO criteria

Treatment Modifications

Adverse Event	Dose Modification
Hypotension resistant to intravenous vasopressors	Stop treatment. Resume cautiously if blo od pressure recovers
Life-threatening or persistent, severe toxic reactions	Discontinue therapy
WHO G ≥3 toxicity	Stop treatment. Resume when toxicity G ≤1 at original dose
Recurrent WHO G ≥3 toxicity	Stop treatment. Resume when toxicity G ≤1, with interferon alfa-2a dose decreased by 50%

Notes

Interferon alfa-2a has been used in the treatment of metastatic RCC at different doses (3–18 million units) and modes of administration with a median overall survival of 13 months

Motzer RJ et al. JCO 2002;20:289–296

34. Sarcomas

Brigitte Widemann, MD, Tito Fojo, MD, PhD, and Jean-Yves Blay, MD

Primary Malignant Bone Tumors

Epidemiology

Incidence: 3,020 (male: 1,680; female: 1,340. Estimated new cases for 2014 in the United States) 1.1 per 100,000 males, 0.8 per 100,000 females
Deaths: Estimated 1,460 in 2014 (male: 830; female: 630)
Median age: 42 years
Male to female ratio: 1.5:1

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Classification

WHO Classification of Malignant Bone Tumors

Osteogenic tumors
Osteosarcoma
- a. Conventional
  - Chondroblastic
  - Fibroblastic
  - Osteoblastic
- b. Telangiectatic
- c. Small cell
- d. Low-grade central
- e. Secondary
- f. Parosteal
- g. Periosteal
- h. High-grade surface

Ewing sarcoma/primitive neuroectodermal tumor
Ewing sarcoma

Cartilage tumors
Chondrosarcoma
- a. Central, primary, and secondary
- b. Peripheral
- c. Dedifferentiated
- d. Mesenchymal
- e. Clear cell

Fibrogenic tumors
Fibrosarcoma

Fibrohistiocytic tumors
Malignant fibrous histiocytoma

Giant cell tumor
Malignancy in giant cell tumor

Notochordal tumors
Chordoma

Vascular tumors
Angiosarcoma

Smooth muscle tumors
Leiomyosarcoma

Lipogenic tumors
Liposarcoma

Miscellaneous tumors
Adamantinoma

Hematopoietic tumors (see respective sections)
1. Plasma cell myeloma
2. Malignant lymphoma, NOS

Work-up

1. History and physical examination
2. *Laboratory tests:* CBC with differential; electrolytes; liver function tests; mineral panel, including alkaline phosphatase; lactate dehydrogenase
3. Plain films of affected bone
4. Chest x-ray (PA and lateral)
5. CT scan of chest, abdomen, and pelvis (particularly chest because 80% of metastatic lesions occur here)
6. MRI to ascertain extent of the tumor, involvement of surrounding neurovascular structures, invasion of the adjacent joint, and the presence of skip metastases
7. Bone scan to identify skip lesions within affected bones or distant metastatic disease
8. Bone marrow aspirate for light microscopy examination in the case of Ewing sarcoma
9. No radiologic studies are pathognomonic, so bone biopsy remains essential to diagnosis
10. Echocardiogram or MUGA scan to determine cardiac ejection fraction as clinically indicated
11. Audiogram before cisplatin chemotherapy

Surgical Staging

The surgical system as described by Enneking et al. is based on the GTM classification. Stage is determined by 3 different subcategories: grade (G), location or site (T), and lymph node involvement and metastases (M)

Grade [G]	
G1	Low grade, uniform cell type without atypia, few mitoses
G2	High grade, atypical nuclei, mitoses pronounced
Site [T]	
T1	Intracompartmental = Confined within limits of periosteum
T2	Extracompartmental = Breach in an adjacent joint cartilage, bone cortex (or periosteum) fascia lata, quadriceps, and joint capsule
Lymph Node Involvement and Metastases [M]	
M0	No identifiable skip lesions or distant metastases
M1	Any skip lesions, regional lymph nodes, or distant metastases

Enneking Staging System of Malignant Bone Tumors

Stage		G	T	M
IA	Low grade, intracompartmental	G1	T1	M0
IB	Low grade, extracompartmental	G1	T2	M0
IIA	High grade, intracompartmental	G2	T1	M0
IIB	High grade, extracompartmental	G2	T2	M0
IIIA	Low or high grade, intracompartmental with metastases	G1/2	T1	M1
IIIB	Low or high grade, extracompartmental with metastases	G1/2	T2	M1

Enneking WF et al. Clin Orthop 1980;153:106–120

Clinical Staging

IUCC and TNM Staging

Primary Tumor	
TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Tumor ≤8 cm in greatest dimension
T2	Tumor >8 cm in greatest dimension
T3	Discontinuous tumors in the primary bone site
Nodal Status	
NX	Regional lymph nodes cannot be assessed
N0	No regional metastasis
N1	Regional lymph nodes metastasis
Metastases	
MX	Distant metastasis cannot be assessed
M0	No distant metastases
M1	Distant metastases M1a Lung M1b Other distant sites, including lymph nodes

Grade	
GX	Grade cannot be assessed
G1	Well differentiated–low grade
G2	Moderately differentiated–low grade
G3	Poorly differentiated–high grade
G4	Undifferentiated–high grade

Stage Grouping

IA	G1,2	T1	N0	M0
IB	G1,2	T2	N0	M0
IIA	G3,4	T1	N0	M0
IIB	G3,4	T2	N0	M0
III	Any G	T3	N0	M0
IVA	Any G	Any T	N0	M1a
IVB	Any G	Any T	N1	Any M
IVB	Any G	Any T	Any N	M1b

International Union Against Cancer (IUCC) and American Joint Committee on Cancer (AJCC) TNM Staging, 6th ed. System for Bone Sarcomas

Reproduced by permission of the American Joint Committee on Cancer (AJCC), Chicago, Illinois. The original source for this material is the AJCC Cancer Staging Manual, 7th ed. (2009) published by Springer-Verlag, New York, NY, http://www.springeronline.com

Histologic Grading Systems for Assessing Response to Induction Chemotherapy in Osteosarcoma

Salzer-Kuntschik

I: No viable cells
II: Single viable tumor cells or cluster <0.5 cm
III: Viable tumor <10%
IV: Viable tumor 10–50%
V: Viable tumor >50%
VI: No effect on chemotherapy

Picci

Total response:	No viable tumor
Good response:	90–99% necrosis
Fair response:	60–89% necrosis
Poor response:	<60% necrosis

Huvos (Wunder et al)

IV: No histologic evidence of viable tumor
III: Only scattered foci of viable tumor cells
II: Areas of necrosis with areas of viable tumor
I: Little or no chemotherapy effect

Picci P et al. Cancer 1985;56:1515–1521
Salzer-Kuntschik M et al. Pathologe 1983;4:135–141
Wunder JS et al. J Bone Joint Surg Am 1998;80:1020–1033

5-Year Survival

Nonmetastatic (80% of Patients at Diagnosis)	
Good histologic response (>90% necrosis)	75%
Poor histologic response (<90% necrosis)	55%
Metastatic (20% of patients at diagnosis)	20%

Expert Opinion

Primary Bone Tumors

General

1. Rare, account for <0.2% of malignant tumors
2. ***Relatively high incidence in children and adolescents***, although even in the young, benign bone tumors are more common
3. Considerably outnumbered by metastases to the bone in older patients
4. Presentations:
   - Nonmechanical pain or night pain around the knee are cause for concern
   - Swelling only if tumor extends through the cortex distending periosteum
5. Referral to reference center is strongly encouraged
6. Frequently difficult to recognize as malignant by clinicians, radiologists as well as pathologists → major diagnostic difficulties in nonspecialized centers
7. Ideally, all cases of suspected bone tumor should be discussed at a multidisciplinary team meeting

Diagnosis and Local Staging

1. Conventional radiographs in 2 planes should be the first investigation
2. CT in the case of a diagnostic problem or doubt, to visualize calcification, periosteal bone formation, cortical destruction, or soft-tissue involvement
3. When malignancy is uncertain on radiographs, the next step is MRI, in particular for limbs
4. General staging to assess the extent of distant disease includes
   - Bone scintigraphy
   - Chest radiographs and chest CT
5. Whole-body MRI and PET under evaluation for staging and treatment assessment

Biopsy

1. Experienced physician(s) should biopsy suspicious sites, as exact staging of disease has impact on treatment and outcome (III, B)
2. Principles of biopsy:
   - Determine stage before the biopsy → may guide location of biopsy
   - Minimal contamination of normal tissues
   - Core needle biopsy often more than adequate often guided by ultrasound, X-ray, or CT
   - Samples for microbiologic culture as well as histology
   - Samples should be snap-frozen for future studies
   - An experienced pathologist should evaluate samples
   - Excision biopsy is contraindicated because it may contaminate tissue compartments
   - Open biopsy requires a longitudinal incision
   - In aggressive and malignant tumors of bone, consider biopsy tract contaminated with tumor and removed together with the resection specimen to avoid local recurrences
3. Spinal column involvement, avoid laminectomy or decompression resulting in incomplete resection unless necessary to relieve spinal cord compression

Prevention and Management of Pathologic Fracture

1. Pathologic fractures may disseminate tumor cells into surrounding tissues and increase the risk of local recurrence
2. Patients with weakened bone → immobilize following biopsy with an external splint. In cases of fracture, internal fixation is contraindicated as it disseminates tumor further into both bone and soft tissues increasing the risk of local recurrence. Neoadjuvant chemotherapy used with expectation of a good response will allow fracture hematoma to contract and allow subsequent resection
3. If response to chemotherapy is poor or in tumors unlikely to respond → consider early surgery obtaining wide margins including amputation
4. Consider postoperative radiotherapy to decrease the risk of local recurrence

Systemic Therapy

(Also see individual histologies)

1. Strongly consider treatment in reference centers or networks (IV, A)
2. High-grade osteosarcoma, Ewing sarcoma, and spindle cell sarcoma should receive primary chemotherapy

Surgery

(Also see individual histologies)

1. Surgery should be performed only after adequate preoperative staging, and, depending on the tumor, primary chemotherapy
2. Striving to obtain adequate surgical margins → narrower margins are associated with an increased risk of local recurrence

(*continued*)

Expert Opinion (*continued*)

3. If possible perform a wide en-bloc resection
   - General *intracompartmental* resection
   - Occasionally *extracompartmental* resection if entire bone/muscle compartment can be removed easily (III, B)
4. If postoperative radiotherapy is likely, risk areas and close margins should be identified with clips
5. Surgical reconstruction varies; discuss with patient

Follow-up

1. To detect local recurrence or metastatic disease when early treatment is still possible and might be effective
2. Recommended intervals for follow-up after completion of chemotherapy:
   - Every 6 weeks to 3 months for the first 2 years
   - Every 2–4 months for years 3–4
   - Every 6 months for years 5–10
   - Every 6–12 months thereafter

   Note: These suggested intervals of follow-up can be balanced against evidence that excessive exposure to radiation may increase the risk of developing leukemia, especially in children
3. Recommended intervals for follow-up for low-grade bone sarcoma
   - Every 6 months for 2 years, and then, annually
4. Late metastases as well as local recurrences and functional deficits may occur >10 years after diagnosis, and there is no universally accepted stopping point for tumor surveillance
5. It is important to evaluate long-term toxicity of therapy for >10 years. Secondary cancers and leukemia, particularly acute myeloid leukemia, may occur (III, B)

Note: Levels of Evidence (I–V) and Grades of Recommendation (A–D) are as used by the American Society of Clinical Oncology

Hogendoorn PCW et al. ESMO/EUROBONET Working Group Bone sarcomas: ESMO Clinical Practice Guidelines for diagnosis, treatment and follow-up. Ann Oncol 2010;21 Suppl 5:v204–v213

Osteosarcoma

Background:

1. Most frequent primary cancer of bone (incidence: 0.2–0.03/100,000/year)
2. Higher incidence in adolescents (0.8–1.1/100,000/year at ages 15–19 years); accounts for >10% of all solid cancers
3. Male to female ratio: 1.4:1
4. Usually arises in the metaphysis of a long bone, most commonly around the knee, axial skeleton, and craniofacial bones, primarily in adults
5. Risk factors:
   - Previous radiation therapy
   - Paget disease of bone
   - Germ-line abnormalities (Rb mutations, p53 mutations)

Staging and risk assessment:

1. 75% arise around the knee
2. Typically there is pain that begins insidiously, gradually becomes constant, may be present at night and is often nonmechanical in nature
3. Localized swelling and limitation of joint movement are later findings
4. Adverse prognostic or predictive factors:
   - Detectable metastases
   - Poor histologic response to preoperative chemotherapy
   - Axial or proximal extremity site
   - Large tumor volume
   - Elevated serum AP or LDH
   - Older age, >40 years (III, B)
   - Paget disease

Treatment: General

1. Changes in the size and ossification of tumor are not reliable indicators of response to neoadjuvant chemotherapy
2. Sequential dynamic MRI that evaluate changes in vascularity are reliable
3. Assessment of response usually is apparent only after several cycles of chemotherapy → do not discontinue and change chemotherapy regimen early

(*continued*)

Expert Opinion (*continued*)

Treatment: Radiation therapy

1. Limited role but may be appropriate in highly selected cases or for palliation (IV, C)
2. Consider boost techniques to increase local dose including intensity modulated radiotherapy (IMRT), proton therapy or samarium

Treatment: Multimodality

Localized disease

1. High-grade tumors should receive primary chemotherapy
2. Curative treatment for high-grade osteosarcoma = surgery + chemotherapy (I, A)
   Compared with surgery alone, multimodal treatment of high-grade osteosarcoma increases DFS probabilities from 10–20% to >60%
3. Goal of surgery is to safely remove the tumor and preserve as much function as possible → consider limb salvage
4. Whenever possible, patients should receive chemotherapy in the context of prospective trials
5. Agents with activity (I, A)
   - Doxorubicin
   - Cisplatin
   - High-dose methotrexate
   - Ifosfamide
6. Combinations:
   - Doxorubicin and cisplatin frequently are the basis of treatment
   - Evidence exists that combinations with methotrexate and/or ifosfamide might provide additional benefit over 2-drug schedules (II, A)
   - Ideal combination and optimal treatment durations (commonly given over periods of 6–12 months) are yet to be defined
7. Most current protocols include a period of preoperative chemotherapy → although not proven to add survival benefit over postoperative chemotherapy alone (I, B)
8. Extent of histologic response to preoperative chemotherapy offers important prognostic information (I, A)
9. The multimodal treatment principles were generated in children, adolescents and young adults with high-grade central osteosarcoma, but also relate to adults at least up to the age of 60 years (III, B)
10. Chemotherapy also is recommended for older patients with osteosarcoma using protocols extrapolated from those designed for pediatric/adolescent patients
11. Extraosseous osteosarcoma: Use high-grade soft-tissue sarcoma or osteosarcoma regimens. No consensus amongst experts as to best approach

Metastatic disease

1. Some have very similar or even identical prognosis to the prognosis of patients with localized disease, with surgical removal of all known metastatic lesions (III, B)
2. ≈30% of all patients with primary metastatic osteosarcoma and >40% of those who achieve a complete surgical remission become long-term survivors

Recurrent disease

1. Treatment is primarily surgical. Complete removal of all metastases must be attempted (III, B)
2. Prognosis is poor, with long-term post-relapse survival <20%. However, >1/3 with second surgical remission survive for >5 years
3. Multiple recurrences curable as long as they are resectable, and repeated thoracotomies are often warranted (III, B)
4. Role of second-line chemotherapy is less well-defined than that of surgery and there is no accepted standard regimen
5. Choice may take into account the prior disease-free interval, and often includes: ifosfamide, with or without etoposide, with or without carboplatin

Ewing Sarcoma

Background:

1. Second most common primary malignant bone cancer
2. Occurs most frequently in children and adolescents (median age: 15 years)
3. Male to female ratio: 1.5:1
4. ≈25% pelvic bones/≈50% extremity tumors
5. Occasionally arises in soft tissue

Staging and risk assessment:

1. All are high-grade tumors
2. All share common gene rearrangement involving the EWS gene on chromosome 22. Most involve reciprocal translocation
3. 20–25% of patients are diagnosed with metastatic disease (10% lung, 10% bones/bone marrow, 5% combinations or others)

(*continued*)

Expert Opinion (*continued*)

4. Work-up and staging
   - Scan to detect lung and bone metastases
   - Perform bone marrow biopsy and aspirate
   - Light microscopic analysis of bone marrow aspirates and biopsies from sites distal to the lesion (metastases) are mandatory
   - Most are recognized with classical hematoxylin and eosin (H&E) stain and immunohistochemistry, but translocation detection by FISH and RT-PCR is mandatory when diagnosis by light microscopy techniques are in doubt (II, B)
     - RT-PCR with frozen tissue
     - FISH with formalin-fixed paraffin-embedded tissue or touch preps (imprints)
5. Adverse prognostic or predictive factors:
   - Tumor size or volume
   - Serum LDH levels
   - Axial localization
   - Older age (>15 years)
   - Poor histologic response to preoperative chemotherapy
   - Incomplete or no surgery is possible (II, B)
   - The presence of bone metastases is associated with a poorer outcome than lung/pleura metastases (<20% compared with 20–40% 5-year survival)

Treatment: General

1. Change in the size of lesions on MRI is a rather reliable indicator of response
2. Dynamic MRI is not as reliable in evaluating response to treatment as in osteosarcoma
3. Sequential FDG-PET might be of value

Treatment: Radiation therapy

1. Radiation-responsive tumor
2. Radiotherapy, in combination with chemotherapy achieves local control
3. Incomplete surgery, even when combined with postoperative radiotherapy, is not superior to radiotherapy alone and should be avoided
4. If surgery is incomplete follow with postoperative radiotherapy
5. Give radiotherapy alone only if complete surgery is not possible
6. Consider postoperative RT if surgical margins are inadequate and consider RT after chemotherapy for patients who do not achieve a good response to chemotherapy (ie, >10% viable tumor cells) (IV, C)

Treatment: Multimodality

Localized disease

1. Should receive primary chemotherapy
2. Complete surgery, where feasible, best modality for local control
3. With surgery or radiotherapy alone, the 5-year survival is <10%
4. Current multimodality approaches include chemotherapy. Survival is ≈60–70% in localized and ≈20–40% in metastatic disease
5. Agents considered most active
   - Doxorubicin
   - Cyclophosphamide
   - Ifosfamide
   - Vincristine
   - Dactinomycin
   - Etoposide
6. Most protocols are based on 4- to 6-drug combinations (I, A). Current trials initially employ 3–6 cycles of chemotherapy after biopsy, followed by local therapy, then 6–10 cycles of chemotherapy (treatment duration ≈10–12 months)
7. Chemotherapy intensity is positively associated with outcome. However, high-dose chemotherapy with stem cell transplantation is still investigational in high-risk localized Ewing sarcoma
8. Treatment of adult patients follows the same principles as for younger patients, but be aware of tolerability of treatment
9. Extra-skeletal Ewing sarcoma same approach as for bone Ewing sarcoma

Metastatic disease

1. Patients with metastases at diagnosis have a worse prognosis; bone or bone marrow metastases are associated with a 5-year survival <20%
2. Experience with intensive, time-compressed, or high-dose chemotherapy approaches, followed by autologous stem cell transplantation are promising but evidence of benefit is pending (III, B)

(*continued*)

Expert Opinion (*continued*)

3. With lung metastases, whole-lung irradiation may confer a survival advantage (III, B)
4. Surgical resection of residual metastases is less well defined

Recurrent disease

1. With recurrent disease, 5-year survival is <20%, although relapse >2 years from initial diagnosis is associated with a better outcome (III, B)
2. Doxorubicin often cannot be used because of the cumulative lifetime dosages already administered
3. The choice of chemotherapy in relapse is not standardized (III, B):
   - Alkylating agents (cyclophosphamide, high-dose ifosfamide) in combination with topoisomerase inhibitors (etoposide, topotecan), *or*
   - Irinotecan with temozolomide

Chondrosarcoma

Background:

1. Most frequent bone sarcoma of adults (≈0.1/100,000 per year)
2. Male to female ratio: ~1:1
3. The majority are staged as low grade (grade I) rather than high-grade (grades II–III)
4. Most arise centrally in the diametaphyseal region of long bones
5. Most present as a painless mass → pain at the site of a cartilaginous lesion suggest malignancy

Staging and risk assessment:

1. Differentiation is difficult between benign enchondroma or osteochondroma and malignant grade I chondrosarcoma
2. Although they are extremely rare in hands and feet, lesions found in long bones and central cartilaginous lesions should be considered potential low-grade chondrosarcoma until proved otherwise
3. Inoperable, locally advanced, and metastatic lesions have poor prognosis because of resistance to radiotherapy and chemotherapy
4. Prognosis depends on histologic grade; however, assessing grade is difficult

Treatment: Radiation therapy

1. Role of radiotherapy is limited but may be appropriate in highly selected cases or for palliation (IV, C)

Treatment: Multimodality

1. Low-grade cartilage tumors are unlikely to metastasize, but may recur locally
2. Higher-grade chondrosarcomas and all chondrosarcomas of the pelvis or axial skeleton should be surgically excised with wide margins
3. Recent evidence suggests mesenchymal chondrosarcoma may be chemotherapy sensitive → consider for adjuvant or neoadjuvant therapy
4. Dedifferentiated chondrosarcoma
   - Uncertainty about chemotherapy sensitivity; often treated like osteosarcoma, but with a poorer outcome
   - There is a high risk of local recurrence following excision, particularly in the presence of a pathologic fracture

Spindle Cell Sarcomas of Bone (Malignant Fibrous Histiocytoma/Fibrosarcoma of Bone [MFH/FS])

Background:

1. Heterogeneous group of tumors including
   - Fibrosarcoma (FS)
   - Malignant fibrous histiocytoma (MFH)
   - Leiomyosarcoma
   - Undifferentiated sarcoma
2. 2–5% of primary bone malignancies
3. Similar age group as chondrosarcoma
4. Similar skeletal distribution as osteosarcoma
5. Typically present with pain and have a high incidence of fracture at presentation

Staging and risk assessment:

1. Typically present in an older patient with a lytic lesion in bone
2. Differential diagnosis includes a metastasis
3. Pathologic fractures are common

Treatment:

1. Treatment strategies are similar to those used for osteosarcoma, with chemotherapy and complete en-bloc resection including any soft-tissue component

REGIMEN

HIGH-DOSE METHOTREXATE, CISPLATIN, AND DOXORUBICIN

Meyers PA et al. J Clin Oncol 2005;23:2004–2011

The regimen consists of 10 weeks of induction chemotherapy followed by limb-sparing surgery or amputation, which is followed by adjuvant maintenance chemotherapy beginning in week 12 and continuing until week 31

Note: Adjuvant maintenance chemotherapy should begin at week 12 provided wound healing is adequate

Hydration before and after cisplatin: ≥1000 mL 0.45% sodium chloride injection (0.45% NS); administer intravenously over a minimum of 2–4 hours

Cisplatin 120 mg/m²; administer intravenously in 150–1000 mL 0.9% sodium chloride injection (0.9% NS) over 4 hours, for 4 cycles, during weeks 0 and 5 in the induction phase and weeks 12 and 17 in the maintenance phase (total dosage/cycle = 120 mg/m²)

Note: Encourage patients to increase oral intake of nonalcoholic fluids, and monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Doxorubicin 25 mg/m² per day; administer intravenously in 50–1000 mL 0.9% NS or 5% dextrose injection (D5W) over 24 hours for 3 consecutive days, on days 1–3, for 6 cycles, during weeks 0 and 5 in the induction phase, and weeks 12, 17, 22, and 27 in the maintenance phase (total dosage/cycle = 75 mg/m²)

Hydration: 1500–3000 mL/m² per day; administer intravenously. Use a solution containing a total amount of sodium not >0.9% NS (ie, ≤154 mEq sodium/1000 mL) by intravenous infusion during methotrexate administration and for at least 24 hours afterward

- Fluid administration may commence 2–12 hours before starting methotrexate, depending on a patient's fluid status
- Urine output should be at least 100 mL/hour before starting methotrexate infusion
- Maintain hydration at a rate that maintains urine output ≥100 mL/hour until the serum methotrexate concentration is <0.1 µmol/L
- Urine pH should be increased within the range ≥7.0 to ≤8.0 to enhance methotrexate solubility and ensure elimination
  - Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

Sodium bicarbonate 50–150 mEq/1000 mL is added to the parenteral solution to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	127–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose Injection (D5W)		
0 mEq/L	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	127–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
Delayed methotrexate clearance during weeks 3, 15, 20, and 25	Do not administer the scheduled course of methotrexate during the ensuing weeks (4, 16, 21, and 26) to ensure that doxorubicin is administered on schedule

Patient Population Studied

A prospective randomized intergroup phase III study of newly diagnosed patients with histologically confirmed high-grade, intramedullary osteosarcoma who were 30 years of age or younger. There were 677 patients enrolled without clinically detectable metastases; 340 received this regimen, including 168 who also received liposomal muramyl tripeptide

(*continued*)

Methotrexate 12,000 mg/m² (maximum dose = 20,000 mg); administer intravenously in 500–2000 mL 0.9% NS or D5W (or saline and dextrose combinations) over 4 hours for 12 cycles during weeks 3, 4, 8, and 9 in the induction phase, and weeks 15, 16, 20, 21, 25, 26, 30, and 31 in the maintenance phase (total dosage/cycle = 12,000 mg/m²; maximum dose/cycle = 20,000 mg)
Note: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion, or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Leucovorin 10 mg (a fixed dose); administer intravenously in 25–250 mL 0.9% NS or D5W over 15 minutes every 6 hours, starting 24 hours after methotrexate administration *began* and continuing until the serum methotrexate concentration is <0.1 µmol/L (ie, $<1 \times 10^{-7}$ mol/L, or <100 nmol/L)
Note: Leucovorin may be administered orally after completing 1 day of parenteral administration if patients are compliant, are not vomiting, and have no other potentially mitigating complications
Leucovorin 10 mg (fixed dose); administer orally every 6 hours until the serum methotrexate concentration is <0.1 µmol/L (ie, $<1 \times 10^{-7}$ mol/L, or <100 nmol/L)

Leucovorin rescue for delayed methotrexate excretion:
- Hydration, urinary alkalinization, and a more intensive leucovorin regimen are required if methotrexate excretion is delayed (eg, worsening renal function, effusions present)
- If 24 hours after the completion of methotrexate administration a patient's serum creatinine is increased by ≥50% above the baseline value, or if serum methotrexate concentration is ≥5 µmol/L ($\geq 5 \times 10^{-6}$ mol/L), increase the leucovorin dosage and schedule to 100 mg/m² per dose intravenously (*not* orally) every 3 hours until serum methotrexate level is <0.1 µmol/L ($<1 \times 10^{-7}$ mol/L, <100 nmol/L); then resume leucovorin 10 mg/dose orally or intravenously every 6 hours until serum methotrexate concentration is <0.05 µmol/L ($<5 \times 10^{-8}$ mol/L, or <50 nmol/L), or until undetectable (if the lower limit of assay sensitivity is ≥0.05 µmol/L [$\geq 5 \times 10^{-8}$ mol/L, or ≥50 nmol/L])

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential during cycles with cisplatin + doxorubicin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential with doxorubicin alone is **MODERATE***
*Emetogenic potential with methotrexate is **MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Sargramostim (GM-CSF) 250 mcg/m² per day by subcutaneous injection
- Begin use from 24–72 hours after doxorubicin is completed
- Discontinue use at least 24 hours before resuming chemotherapy

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(*continued*)

Efficacy (N = 172)

Event free-survival at 3 years	71%
Event free-survival at 5 years	64%
Second malignant neoplasm	3 occurrences
Favorable necrosis (Huvos III/IV)	43%

Toxicity (N = 172)

	Frequency
Elevations in ALT after methotrexate	Common
Stomatitis	Common
Infections	Common
Objective hearing loss	11%
Renal dysfunction	Rare

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Therapy Monitoring

1. *During treatment cycles:* Daily renal function
2. *After high-dose systemic methotrexate administration:* Daily methotrexate levels
3. *Before each cycle:* CBC with differential, serum electrolytes, BUN, and creatinine

REGIMEN

ETOPOSIDE + HIGH-DOSE IFOSFAMIDE + MESNA

Goorin AM et al. J Clin Oncol 2002;20:426–433

This regimen was initially developed for newly diagnosed osteosarcoma and included high-dose methotrexate, cisplatin, and doxorubicin as part of the continuation therapy. The protocol summarized here assumes that patients previously received high-dose methotrexate, cisplatin, and doxorubicin as part of their upfront therapy

	Induction Chemotherapy
Start: Hour 0 End: Hour 1	**Etoposide** 100 mg/m² per day; administer intravenously in 250 mL/m² 5% dextrose and 0.2% sodium chloride injection (D5W/0.2% NS) over 1 hour for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 500 mg/m²)
Start: Hour 1 End: Hour 5	An admixture containing **ifosfamide** 3500 mg/m² + **mesna** 700 mg/m² per day; administer intravenously in 800 mL/m² D5W/0.2% NS over 4 hours, starting immediately after etoposide administration is completed, for 5 consecutive days, on days 1–5, every 21 days (total ifosfamide dosage/cycle = 17,500 mg/m²)
Start: Hour 5 End: Hour 8	**Mesna** 700 mg/m² per day; administer by continuous intravenous infusion in 600 mL/m² D5W/0.2% NS over 3 hours, starting after ifosfamide administration is completed, for 5 consecutive days, on days 1–5, every 21 days
Start: Hour 8 End: Hour 14	**Hydration** with D5W/0.2% NS; administer intravenously at 150 mL/m² per hour for 6 hours for 5 consecutive days on days 1–5, every 21 days
Start: Hours 8, 11, and 14 End: 8:15, 11:15, and 14:15	**Mesna** 700 mg/m² per dose; administer intravenously diluted with 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration of 1–20 mg/mL, over 15 minutes, every 3 hours for 3 doses/day, starting 3 hours after ifosfamide administration is completed, for 5 consecutive days, on days 1–5, every 21 days (total mesna dosage/cycle = 17,500 mg/m²; this total also includes Hour 1 and Hour 5 doses)
Start: Hour 14 End: Hour 24	**Hydration** with D5W/0.2% NS; administer intravenously at 100 mL/m² per hour for 10 hours for 5 consecutive days on days 1–5, every 21 days

Note: After 2 cycles of treatment, radiologic evaluation is completed and patients should have surgery for any metastatic sites of disease. Surgical removal of all metastatic sites is recommended when feasible

	Continuation Chemotherapy
Start: Hour 0 End: Hour 1	**Etoposide** 100 mg/m² per day; administer intravenously in 250 mL/m² D5W/0.2% NS over 1 hour for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 500 mg/m²)
Start: Hour 1 End: Hour 5	An admixture containing **ifosfamide** 2400 mg/m² + **mesna** 480 mg/m² per day; administer intravenously in 800 mL/m² D5W/0.2% NS over 4 hours, starting immediately after etoposide administration is completed, for 5 consecutive days, on days 1–5, every 21 days (total ifosfamide dosage/cycle = 12,000 mg/m²)
Start: Hour 5 End: Hour 8	**Mesna** 480 mg/m² per day; administer intravenously in 600 mL/m² D5W/0.2% NS over 3 hours, starting after ifosfamide administration is completed, for 5 consecutive days, on days 1–5, every 21 days
Start: Hour 8 End: Hour 14	**Hydration** with D5W/0.2% NS; administer intravenously at 150 mL/m² per hour for 6 hours, for 5 consecutive days, on days 1–5, every 21 days
Start: Hours 8, 11, and 14 End: 8:15, 11:15, and 14:15	**Mesna** 480 mg/m² per dose; administer intravenously diluted with 0.9% NS or D5W to a concentration of 1–20 mg/mL, over 15 minutes, every 3 hours for 3 doses/day, starting 3 hours after ifosfamide administration is completed, for 5 consecutive days, on days 1–5, every 21 days (total mesna dosage/cycle = 12,000 mg/m²; this total also includes Hour 1 and Hour 5 doses)
Start: Hour 14 End: Hour 24	**Hydration** with D5W/0.2% NS; administer intravenously at 100 mL/m² per hour for 10 hours for 5 consecutive days, on days 1–5, every 21 days

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE*** *Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

(*continued*)

(continued)

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use on day 6, at least 24 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use after the neutrophil nadir until ANC ≥5000/mm^3 on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A prospective phases II/III trial in 41 evaluable patients ≤30 years of age with measurable, newly diagnosed, biopsy-proven, high-grade, metastatic osteosarcoma with normal renal, hepatic, and bone marrow profile and ECOG performance status ≤2

Efficacy (N = 23–41)

Response Rate*	
Combined pathologic + radiologic response (n = 39)	59% ± 8%
Pathologic response alone† (n = 23)	65% ± 10%
Radiologic response alone (n = 27)	52% ± 9%

*Assessed after 2 cycles of etoposide + ifosfamide with mesna
†As measured by necrosis of the primary tumor

Toxicity* (N = 41)

	% G3	% G4
Hematopoietic		
WBC count	2	83
ANC	2	29
Platelets	17	27
Hemoglobin	5	5
Nonhematopoietic		
Sepsis	10	—
Bacterial infection	7	—
Viral infection	2	—
Fanconi syndrome	7	—
Stomatitis	7	—
Sodium	2	—
Creatinine	2	—
Hematuria	2	—
Poor Karnofsky score	2	—
Vomiting	2	—
Potassium	2	—

*Toxicities listed are those pertaining only to the 2 cycles of induction chemotherapy using ifosfamide and etoposide

Treatment Modifications

Repeat chemotherapy 3 weeks after the initiation of treatment if ANC >1,000/μL and the platelet count >120,000/μL

Therapy Monitoring

1. *Before each cycle:* CBC with differential, serum electrolytes, BUN, and creatinine
2. *During treatment cycles:* Daily serum electrolytes, BUN, and creatinine; CBC with differential at least twice weekly

Notes

1. Although few patients were treated, the response to ifosfamide and etoposide seemed to be dose dependent
2. This combination may be more active against bony metastases than other regimens

REGIMEN

Recurrent or Refractory Bone [or Soft-Tissue Sarcoma] (Children and Young Adults)

GEMCITABINE + DOCETAXEL

Navid F et al. Cancer 2008;113:419–425

Gemcitabine 675 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration as low as 0.1 mg/mL, over 90 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 1350 mg/m²)

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting 1 day before docetaxel administration (total dose/cycle = 48 mg)

Optional premedication for docetaxel:
- **Diphenhydramine HCl** 25 mg; administer orally 30–60 minutes *or* intravenously 5–30 minutes prior to docetaxel administration
- **Ranitidine** 150 mg; administer orally 30–60 minutes prior to docetaxel administration, *or*
- **Ranitidine** 50 mg; administer intravenously 5–30 minutes prior to docetaxel administration

Docetaxel 75–100 mg/m²; administer intravenously, in a volume of 0.9% NS or D5W sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL, over 60 minutes, on day 8 after completing gemcitabine administration, every 21 days (total dosage/cycle = 75–100 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for one dose
- Begin use on cycle day 9; that is, 24 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A retrospective analysis of 22 patients with recurrent or progressive bone or soft-tissue sarcoma

Therapy Monitoring

1. *At start of therapy:* Clinical examination and laboratory testing
2. *Day 1 of each treatment cycle:* Physical examination, ECOG PS, complete blood count with leukocyte differential count, and serum chemistries
3. *Weekly CBC with leukocyte differential count:* At least the first 6 cycles of therapy
4. *After every 2 cycles of therapy:* Tumor measurements

Treatment Modifications

Adverse Event	Dose Modification
Febrile neutropenia or platelet count of less than 25,000/mm³ lasting >5 days	Reduce gemcitabine and docetaxel dosages by 25% in all subsequent cycles
ANC <1000/mm³ at start of next cycle	Withhold treatment until ANC ≥1000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
Platelet count <100,000/mm³ at start of next cycle	Withhold treatment until platelet count ≥100,000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
ANC <1000/mm³ or platelet count <100,000/mm³ despite 2-week delay	Discontinue therapy
Day 8 ANC 500–999/mm³, or day 8 platelet count 50,000–99,000/mm³	Reduce day 8 gemcitabine and docetaxel dosages by 25%
Day 8 ANC <500/mm³, or day 8 platelet count <50,000/mm³	Do not administer day 8 gemcitabine and docetaxel
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by 25%
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes, despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%

(*continued*)

Efficacy (N = 14)

Tumor Response Categorization Using RECIST in 14 Patients by Disease Type*

Disease Type	Number of Patients	RECIST Category			
		CR	PR	SD	PD
Osteosarcoma†	10	0	3	1	6
Ewing sarcoma family of tumors‡	2	0	0	1	1
Malignant fibrous histiocytoma	1	1	0	0	0
Undifferentiated sarcoma	1	0	0	0	1
Total	14	1	3	2	8

Median number of cycles	4 (range: 1–13)
Median duration of PR/CR	3.8 months (range: 1.6–9.7+ months)
Median time to progressive disease	2.3 months (range: 0.8–14 months)
Number of patients dead and cause of death	19 (18 from PD and 1 from unknown cause)
Patients alive	3 with osteosarcoma (alive with disease at 7, 52, and 69 months after recurrence)

RECIST, Response Evaluation Criteria in Solid Tumors; CR, complete response; PR, partial response; SD, stable disease; PD, progressive disease (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
*Eight of the 22 patients were not evaluable for objective tumor response: 5 patients had tumors that did not qualify as target lesions as defined by RECIST, 3 patients had no evidence of disease by imaging studies at the initiation of gemcitabine and docetaxel treatment, and 1 patient died before undergoing imaging for response evaluation. Of the 5 patients with no target lesions, 4 had tumors measuring <1 cm and 1 had pleural-based lung disease. Lesions decreased in size in 2 of these patients, were stable in 2 patients, and progressed in 1 patient during therapy
†Duration of SD: 13 months
‡Duration of SD: 3.5 months

Treatment Modifications (*continued*)

G ≥3 liver function test abnormalities	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by 25%
G ≥3 liver function test abnormalities despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%
G4 mucositis and diarrhea	Discontinue therapy
G2 neuropathy	Delay therapy 1 week. If symptoms do not resolve to G ≤1, reduce docetaxel dosage by 25%
G3 neuropathy	Discontinue therapy
Febrile neutropenia (T >38°C [>100.4°F] with ANC <1000/mm^3)	Reduce gemcitabine and docetaxel doses by 25%
G3/4 hematologic toxicity	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy

Toxicity (N = 22)

*Toxicities were graded according to National Cancer Institute Common Terminology Criteria for Adverse Events (v. 3.0)

Primary Malignant Bone Tumors: Ewing Sarcoma

Epidemiology

Incidence: Estimated annual incidence from birth to age 20 years is 2.9/million population. Approximately 10% of patients are 20–30 years of age. Cases in patients >30 years of age are infrequent
Median age: 14 years; 90% of patients, <20 years of age
Mortality rate: 0.05/100,000 population
Male to female ratio: Slightly more prevalent in males

Gurney JG et al. Malignant bone tumors. In: Reis LAG, Smith MA, Gurney JG et al., eds. Cancer incidence and survival among children and adolescents: United States SEER program, 1975–1995. NIH Pub. No. 99-4649. Bethesda, MD: National Cancer Institute SEER Program; 1999:99–110

Stage at Diagnosis

Nonmetastatic	80%
Metastatic	20%

5-Year Survival

Localized	60–70%
Metastatic	20%

Expert Opinion

Treatment of Ewing sarcoma is similar to that of osteosarcoma because it involves the use of neoadjuvant chemotherapy followed by local therapy (surgery or radiation), which is then followed by adjuvant chemotherapy

Chemotherapy

1. The most commonly used drugs are doxorubicin, vincristine, ifosfamide, etoposide, dactinomycin, and cyclophosphamide
2. The use of combination chemotherapy as part of a multidisciplinary approach has increased 5-year survival rates from <10% to approximately 60%

Local therapy

1. Local therapy in the treatment of Ewing sarcoma varies from surgery alone, to radiation alone, to a combination of both modalities, depending on where disease is located
2. Surgery remains the preferred route of local control. A wide surgical margin should be attempted
3. In contrast to osteosarcoma and the soft-tissue sarcomas, Ewing tumors are radiosensitive. Therefore, in patients in whom surgery is not possible or for those patients with marginal and intralesional surgery, radiation is an effective therapeutic option
4. The behavior of Ewing sarcoma and PNET (Primitive neuroectodermal tumors) in adults is no different from its behavior in children

Adverse prognostic factors

1. Metastatic disease
2. Pelvic localization
3. Tumor diameter >8–10 cm
4. Age >15 years
5. Elevated LDH
6. Poor histologic response to preoperative chemotherapy
7. Radiation therapy as the only local treatment

Grier HE et al. N Engl J Med 2003;348:694–701
Verrill MW et al. J Clin Oncol 1997;15:2611–2621

Pathology

Ewing sarcoma family of tumors (includes primitive neuroectodermal tumors):

1. Rare tumors arising in the bone marrow from primitive neural crest elements
2. Constitute approximately 10% of bone sarcomas
3. Subtypes include:
   - Classic Ewing sarcoma (most commonly associated with bone)
   - Primitive neuroectodermal tumor (generally not associated with bones)
4. Distinguished immunohistochemically from other pediatric tumors by expression of the MIC2 gene
5. Most commonly detected translocation is **t(11;22)(q24;q12)**, one of a series of related translocations that occur in >95% of the Ewing sarcoma family of tumors (including primitive neuroectodermal tumors)
6. The t(11;22) translocation joins the Ewing sarcoma gene *EWS* on chromosome 22 to friend leukemia insertion (*FLI1*) on chromosome 11 (ie, t[11;22])
   Note: FLI1 is a member of the *ETS (E-twenty six)* family
7. The *EWS-FLI1* fusion transcript encodes a 68-kDa protein with 2 primary domains
   - *EWS* domain = a potent transcriptional activator
   - *FLI1* domain = a highly conserved *ETS* DNA-binding domain

   The EWS-FLI1 fusion protein thus acts as an aberrant transcription factor
8. In an individual patient, t(11;22) fuses one of many observed combinations of exons from *EWS* and *FLI1* to form the fused message. Most common combination = *EWS* exon 7 fused to *FLI1* exon 6 ("7/6") in ≈50–64% of tumors of the Ewing sarcoma family

REGIMEN

Newly Diagnosed—Ewing Sarcoma, Primitive Neuroectodermal Tumor of Bone, Primitive Sarcoma of Bone

VINCRISTINE, CYCLOPHOSPHAMIDE, AND DOXORUBICIN OR DACTINOMYCIN ALTERNATING WITH IFOSFAMIDE AND ETOPOSIDE

Grier HE et al. N Engl J Med 2003;348:694–701

Patients receive 2 complete courses of alternating induction chemotherapy (1 course includes 1 cycle with vincristine, doxorubicin, and cyclophosphamide followed by 1 cycle with ifosfamide and etoposide). Local therapy (surgery or radiation) occurs at week 12 and, after recovery, adjuvant chemotherapy with the same chemotherapy regimens ensues for a further 7 cycles of vincristine, doxorubicin, and cyclophosphamide, in alternation with 6 cycles of ifosfamide and etoposide (total: 17 cycles of chemotherapy)

Cycles of vincristine, doxorubicin (or dactinomycin), and cyclophosphamide + mesna:
Vincristine 2 mg/m² (maximum single dose "capped" at 2 mg); administer by intravenous injection over 1–3 minutes on day 1, every 42 days (total dosage/cycle = 2 mg/m²; maximum dose/cycle = 2 mg)
Doxorubicin 75 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 42 days (total dosage/cycle = 75 mg/m²; total cumulative dosage permitted = 375 mg/m²)
• When a total doxorubicin dosage of 375 mg/m² has been administered, no additional doxorubicin is given. Instead, doxorubicin is *replaced by:*
Dactinomycin 1.25 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 42 days (total dosage/cycle = 1.25 mg/m²)
• Dactinomycin is used only after doxorubicin is discontinued from the regimen

An admixture containing **cyclophosphamide** 1200 mg/m² + **mesna** 240 mg/m²; administer intravenously in 100–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes on day 1 every 42 days (total cyclophosphamide dosage/cycle = 1200 mg/m²)
Then, either:
Mesna 240 mg/m² per dose; administer intravenously diluted with 0.9% NS or D5W to a concentration of 1–20 mg/mL, over 15 minutes for 2 doses at 4 hours and 8 hours after cyclophosphamide administration is completed, on day 1, every 42 days (total mesna dosage/cycle = 720 mg/m²; includes 240 mg dose given with cyclophosphamide), *or*
Mesna 480 mg/m² per dose; administer orally for 2 doses at 2 hours and 6 hours after cyclophosphamide administration is completed on day 1, every 42 days (total mesna dosage/cycle = 1200 mg/m²; includes 240 mg dose given with cyclophosphamide)

Cycles of ifosfamide + mesna and etoposide:
An admixture containing **ifosfamide** 1800 mg/m² + **mesna** 360 mg/m² per day; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce ifosfamide concentrations between 0.6 and 20 mg/mL, over 60 minutes for 5 consecutive days, on days 22–26, every 42 days (total ifosfamide dosage/cycle = 9000 mg/m²)
Then, either:
Mesna 360 mg/m² per dose; administer intravenously diluted with 0.9% NS or D5W to a concentration of 1–20 mg/mL, over 15 minutes for 2 doses per day at 4 hours and 8 hours after ifosfamide administration is completed, for 5 consecutive days, on days 22–26, every 42 days (total mesna dosage/cycle = 5400 mg/m²; includes 360 mg doses given daily with cyclophosphamide), *or*
Mesna 720 mg/m² per dose; administer orally for 2 doses per day at 2 hours and 6 hours after ifosfamide administration is completed, for 5 consecutive days, on days 22–26, every 42 days (total mesna dosage/cycle = 9000 mg/m²; includes 360 mg doses given daily with cyclophosphamide)
Etoposide 100 mg/m² per day; administer intravenously diluted with 0.9% NS to a concentration of 0.2–0.4 mg/mL over 60 minutes for 5 consecutive days, on days 22–26, every 42 days (total dosage/cycle = 500 mg/m²)

After the first 4 cycles of chemotherapy (2 complete courses, 12 weeks), local control is planned to consist of radiation therapy, surgery, or both

(*continued*)

Treatment Modifications

None specified

Patient Population Studied

This was a prospective randomized intergroup phase III study in newly diagnosed patients with primary bone tumors who were 30 years of age or younger. Patients had adequate renal, liver, and cardiac function; 300 patients were enrolled and 198 received this regimen

Efficacy (N = 198)

5-year event-free survival	69%
5-year overall survival	72%
Pattern of Treatment Failure	
Local progression	4.5%
Systemic progression	22.2%
Local and systemic progression	2%
Progression at unknown site	0.5%
Death	3.5%
Infection	3%
Hemorrhage	0.5%
Second malignant neoplasms	2%

(*continued*)

Radiation alone:
- Treat the extent of the initial soft tissue and osseous involvement with a 3-cm margin to a dose 4500 cGy
- Then treat with an additional 1080 cGy to the postchemotherapy, preradiation therapy tumor volume

Surgery without residual disease:
- No radiation therapy is administered

Gross residual tumor after surgery
- Treat as if treating with radiation alone

Microscopic residual disease after surgery
- Treat the extent of the initial soft tissue and osseous involvement with a 1-cm margin to a dose 4500 cGy

Supportive Care

Antiemetic prophylaxis

Emetogenic potential during cycles with vincristine, doxorubicin or dactinomycin, and cyclophosphamide is ***HIGH****.*
Potential for delayed symptoms
Emetogenic potential during cycles with ifosfamide and etoposide is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use at least 24 hours after myelosuppressive chemotherapy is completed (days 6 and 27)
- Continue daily filgrastim use after the neutrophil nadir until ANC $\geq$5000/mm^3 on 2 measurements separated temporally by $\geq$ 12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* CBC with differential, serum creatinine, liver function tests, and urinalysis
3. *Response evaluation:* At conclusion of first 4 cycles of chemotherapy

REGIMEN

CYCLOPHOSPHAMIDE + TOPOTECAN

Saylors RL, III et al. J Clin Oncol 2001;19:3463–3469

Pretreatment hydration: 500 mL/m² 0.9% sodium chloride injection (0.9% NS), *or* 0.45% sodium chloride injection, *or* 5% dextrose injection/0.45% sodium chloride injection; administer intravenously over 2–4 hours before starting chemotherapy

Cyclophosphamide 250 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or 5% dextrose injection (D5W) over 30 minutes for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 1250 mg/m²)
Topotecan HCl 0.75 mg/m² per day; administer intravenously in 50–250 mL 0.9% NS or D5W over 30 minutes for 5 consecutive days, after cyclophosphamide on days 1–5, every 21 days (total dosage/cycle = 3.75 mg/m²)

Posttreatment hydration: Hydration continues orally or intravenously at a rate of 3000 mL/m² per 24 hours until 24 hours after the last dose of chemotherapy is completed

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use at least 24 hours after myelosuppressive chemotherapy is completed (day 6)
- Continue daily filgrastim use after the neutrophil nadir until ANC ≥5000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Toxicity* (N = 307 Cycles)

	% of Cycles with G3/4
Neutropenia	53
Thrombocytopenia	44
Anemia	27
Infection†	11
Nausea/vomiting	0.65
Hematuria‡	0.65
Perirectal mucositis	0.33
Transaminase elevation	0.33

*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0
†Includes admissions for fever/neutropenia: 5 bacteremia or fungemia, 1 herpes zoster, 1 infectious cystitis
‡In 2 patients with history of hematuria on ifosfamide

Therapy Monitoring

1. *Daily during therapy:* Urinalysis
2. *Twice weekly:* CBC with differential until recovery from hematopoietic toxicity
3. *Weekly:* Physical examination
4. *Before each cycle:* Serum creatinine, LFTs with bilirubin, serum electrolytes, including calcium, magnesium, and phosphorus
5. *Response evaluation:* After the first and second cycles, then after every 2 cycles

Treatment Modifications

None specified

Patient Population Studied

A study of 91 pediatric patients with recurrent or refractory solid tumors, including Ewing sarcoma (n = 17), rhabdomyosarcoma (n = 15), and neuroblastoma (n = 13)

Efficacy

Ewing Sarcoma (n = 17)	
Complete response	12%
Partial response	24%
Rhabdomyosarcoma (n = 15)	
Complete response	0
Partial response	67%

Notes

Responses were observed in patients who had received >1 year of intensive alkylating agent therapy and/or ablative therapy with autologous stem cell rescue

REGIMEN

Relapsed/Refractory Ewing Sarcoma or Peripheral Neuroectodermal Tumor (PNET)

TEMOZOLOMIDE + IRINOTECAN

Casey DA et al. Pediatr Blood Cancer 2009;53:1029–1034
Wagner LM et al. Pediatr Blood Cancer 2007;48:132–139

Temozolomide 100 mg/m² per day; administer orally for 5 consecutive days, on days 1–5, 1 hour before irinotecan, every 21–28 days (total dosage/cycle = 500 mg/m²)
Note: Temozolomide doses are rounded to the nearest 5 mg by using commercially available products
Irinotecan 10–20 mg/m² per dose; administer intravenously, diluted with 5% dextrose injection to a concentration within the range of 0.12–2.8 mg/mL, over 90 minutes for 10 doses, on days 1–5 and days 8–12, every 21–28 days (total dosage/cycle = 100–200 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
- The potential for developing diarrhea and abdominal pain should be discussed with all patients and their caretakers, and instructions given to start loperamide immediately if these symptoms occur and to ensure adequate hydration is maintained. See "Dose Modifications" (below) for instructions

Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Dose Modifications

Irinotecan Dose Levels*	
Level 1 starting dosage	10–20 mg/m² per day
Level −1	7.5–15 mg/m² per day
Level −2	5–10 mg/m² per day

Temozolomide Dose Levels	
Level 1 starting dosage	100 mg/m² per day orally on days 1–5
Level −1	75 mg/m² per day orally on days 1–5
Level −2	50 mg/m² per day orally on days 1–5

Adverse Event	Dose Modification
G1 ANC 1500–1999/mm³, or G1 thrombocytopenia during a cycle	Maintain dose and schedule
G2 ANC 1000–1499/mm³, or G2 thrombocytopenia during a cycle	Reduce dosage of both agents by 1 dosage level
G4 neutropenia >7 days duration	Reduce dosage of both agents for the following cycle by 1 dose level
G3/4 infection	
Day 21 ANC <1000/mm³, or platelet count <75,000/mm³	Delay start of next cycle by 1 week and reduce dosage of both agents 1 level
Day 28 ANC still <1000/mm³, or platelet count still <75,000/mm³	Delay start of next cycle by 1 additional week and reduce dosage of both agents 1 level
Day 35 ANC still <1000/mm³, or platelet count still <75,000/mm³	Discontinue therapy

Diarrhea in Children 2–15 Years of Age	
Children 2–15 years, with first liquid stools	Begin oral loperamide liquid immediately with the first liquid stool at a dosage of 0.18 mg/kg per day (0.03 mg/kg administered orally every 4 hours)

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic primary prophylaxis and treatment during latent or delayed onset diarrhea:

Consider the following to prevent or lessen irinotecan-associated diarrhea:

- Prophylactic oral **cefixime** 8 mg/kg (maximum dose of 400 mg) orally once daily, beginning 1–2 days prior to the start of irinotecan therapy and continuing continue until completion of the cycle, *alternatively:*
- **Cefpodoxime proxetil** 5 mg/kg/day per day orally twice daily (maximum dose of 200 mg twice daily)
  - Previous studies suggest prophylaxis with cephalosporin antibiotics can ameliorate irinotecan-associated diarrhea by reducing the enteric bacteria responsible for producing β-glucuronidase, which regenerates in the gut irinotecan's toxic metabolite, SN-38, by cleaving the glucuronide moiety from SN-38 (Wagner LM et al. Pediatr Blood Cancer 2008;50:201–207)
- Alternatively, **activated charcoal** at a dose equal to 5 times the irinotecan dose up to a maximum dose of 260 mg orally 3 times daily during irinotecan therapy (Michael M et al. J Clin Oncol 2004;22:4410–4417)

Antibiotic treatment during latent or delayed onset diarrhea

- A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

Antibiotics should also be administered if a patient is hospitalized with prolonged diarrhea, and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Efficacy (N = 14)*

Wagner LM et al. Pediatr Blood Cancer 2007;48:132–139

Complete response	1 (7%)
Partial response	3 (21%)
Minor response	3 (21%)
Median duration of response	30 (range: 12–64) weeks
Median time to progression	20 weeks
Marked symptomatic pain relief with reduction in medication usage†	7 (50%)

*WHO criteria; 2 patients started treatment with no measurable disease following other salvage therapies. Consequently, only 14 patients were fully evaluable for response
†In first course of therapy, irrespective of ultimate imaging response

Dose Modifications (*continued*)

G3/4 diarrhea within the first 24 hours	Hospitalize for optimal managements. Begin loperamide 0.06 mg/kg every 4 hours. Reduce irinotecan dosage for the following cycle by 1 dose level
Delayed Diarrhea in Patients >15 Years of Age	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage of irinotecan by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage of irinotecan by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of both agents by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of both agents by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of both agents by 2 dosage levels

*Treatment should be stopped in case of recurrent toxicity at dose level −2, unless there is perceived clinical benefit from irinotecan that justifies continuation

Sarcomas: Soft-Tissue Sarcomas (Including Rhabdomyosarcoma, But Not Including GIST)

Epidemiology

Incidence: 12,020 (male: 6,550; female: 5,470. Estimated new cases for 2014 in the United States)
Deaths: Estimated 4,740 in 2014 (male: 2,550; female: 2,190)
Male to female ratio: 1.2:1

Siegel R et al. CA Cancer J Clin 2014;64:9–29

Cellular Classification of Adult Soft-Tissue Sarcoma

Soft-tissue sarcomas are classified histologically according to the soft-tissue cell of origin. The histologic grade reflects the metastatic potential of these tumors more accurately than the classic cellular classification listed below. Pathologists assign grade based on the number of mitoses per high-powered field, presence of necrosis, cellular and nuclear morphology, and the degree of cellularity. Discordance among expert pathologists can reach 40%

Alphabetical Listing (Percent of All Soft-Tissue Sarcomas)
(Note, however, that the frequency of histologic type is site dependent)

- Alveolar soft-part sarcoma (≤3%)
- Angiosarcoma (≤3%)
- Dermatofibrosarcoma protuberans (≤3%)
- Epithelioid sarcoma (≤3%)
- Extraskeletal chondrosarcoma (≤3%)
- Extraskeletal osteosarcoma (≤3%)
- Fibrosarcoma (≤3%)
- Gastrointestinal stromal tumor (GIST) (≤3%) (see separate section on GIST)
- **Leiomyosarcoma (≈12%)**
- **Liposarcoma (≈15–25%)**
- **Malignant fibrous histiocytoma (≈28–40%)**
- Malignant hemangiopericytoma (≤3%)
- Malignant mesenchymoma (≤3%)
- Malignant schwannoma (≤3%)
- **Malignant peripheral nerve sheath tumor (≈6%)**
- Peripheral neuroectodermal tumors (≤3%)
- **Rhabdomyosarcoma (≈5%)** (see separate section on rhabdomyosarcoma)
- **Synovial sarcoma (≈10%)**
- Sarcoma, NOS (not otherwise specified) (≤3%)

van Ruth S et al. Eur J Cancer 2002;38:1324–1328

Work-up

1. History and physical examination
2. *Laboratory tests:* CBC with differential, electrolytes, liver function tests, and mineral panel, including alkaline phosphatase and lactate dehydrogenase
3. Radiologic imaging modality is variable and dictated by the site of disease. This involves a combination of plain x-rays, CT, MRI, and PET imaging. Although CT remains the imaging modality of choice in the staging of retroperitoneal soft-tissue sarcoma, MRI is used more frequently to stage soft-tissue sarcoma of the extremity
4. Bone marrow aspirate for light microscopy examination in Ewing sarcoma
5. No radiologic studies are pathognomonic, so biopsy remains essential to diagnosis. Carefully plan biopsy to establish grade and histologic subtype and if needed molecular and cytogenetic studies
6. Echocardiogram or MUGA scan to determine cardiac ejection fraction as clinically indicated

Disease Distribution

Extremity	43%
Lower	30%
Upper	13%
Intraabdominal	34%
Visceral	19%
Retroperitoneal	15%
Trunk	10%
Other	13%

Soft tissue sarcoma. In: DeVita V, Lawrence T, Rosenberg S, eds. DeVita, Hellman, and Rosenberg's Cancer Principles & Practice of Oncology. 9th ed. (2011) published by Lippincott Williams & Wilkins: Philadelphia, 1533–1577

Soft-Tissue Sarcomas: Adult Soft-Tissue Sarcomas, Other Than GIST

Classification of Malignant Adult Soft-Tissue Sarcomas

1. Fibrous tumors
   a. Fibrosarcoma:
      (1) Adult fibrosarcoma
      (2) Inflammatory fibrosarcoma
2. Fibrohistiocytic tumors
   a. Malignant fibrous histiocytoma
      (1) Storiform-pleomorphic
      (2) Myxoid (myxofibrosarcoma)
      (3) Giant cell (malignant giant cell tumor of the soft parts)
      (4) Inflammatory
3. Lipomatous
   a. Liposarcoma
      (1) Well-differentiated liposarcoma
         (a) Lipoma-like liposarcomas
         (b) Sclerosing liposarcoma
         (c) Inflammatory liposarcoma
      (2) Dedifferentiated liposarcoma
      (3) Myxoid or round cell liposarcoma
      (4) Pleomorphic liposarcoma
4. Smooth muscle tumors
   a. Leiomyosarcoma
   b. Epithelioid leiomyosarcoma
5. Skeletal muscle tumors
   a. Rhabdomyosarcoma
      (1) Embryonal rhabdomyosarcoma
      (2) Botryoid rhabdomyosarcoma
      (3) Spindle cell rhabdomyosarcoma
      (4) Alveolar rhabdomyosarcoma
      (5) Pleomorphic rhabdomyosarcoma
   b. Rhabdomyosarcoma with ganglionic differentiation (ectomesenchymoma)
6. Tumors of the blood and lymph nodes
   a. Epithelioid hemangioendothelioma
   b. Angiosarcoma and lymphangiosarcoma
   c. Kaposi sarcoma
7. Perivascular tumors
   a. Malignant glomus tumor (glomangiosarcoma)
   b. Malignant hemangiopericytoma
8. Synovial tumors
   a. Malignant giant cell tumor of tendon sheath
9. Neural tumors
   a. Malignant peripheral nerve sheath tumor (MPNST)
      (1) Malignant triton tumor (MPSNT with rhabdomyosarcoma)
      (2) Glandular MPNST
      (3) Epithelioid MPNST
   b. Malignant granular cell tumor
   c. Primitive neuroectodermal tumor
      (1) Neuroblastoma
      (2) Ganglioneuroblastoma
      (3) Neuroepithelioma (peripheral neuroectodermal tumor)
10. Paraganglionic tumors
    a. Malignant paraganglioma
11. Extraskeletal cartilaginous and osseous tumors
    a. Extraskeletal chondrosarcoma
       (1) Myxoid chondrosarcoma
       (2) Mesenchymal chondrosarcoma
    b. Extraskeletal osteosarcoma
12. Pluripotential mesenchymal tumors
    a. Malignant mesenchyma
13. Miscellaneous tumors
    a. Alveolar soft-part sarcoma
    b. Epithelioid sarcoma
    c. Malignant extrarenal rhabdoid tumor
    d. Desmoplastic small cell tumor
    e. Ewing sarcoma—extraskeletal
    f. Clear cell sarcoma
    g. Gastrointestinal stromal tumors
    h. Synovial sarcoma
    i. Dermatofibrosarcoma protuberans

Brennan MF et al. Sarcomas of the soft tissues and bone. In: DeVita VT Jr, Hellman S, Rosenberg SA, eds. Cancer: Principles & Practice of Oncology, 7th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2005:1581–1637

Expert Opinion

Adult-Type Soft-Tissue Sarcomas Arising from Limbs and Superficial Trunk

Note: Levels of Evidence (I–V) and Grades of Recommendation (A–D) are as used by the American Society of Clinical Oncology

Casali PG, Blay JY. Soft tissue sarcomas: ESMO clinical practice guidelines for diagnosis, treatment and follow-up. ESMO/CONTICANET/EUROBONET Consensus Panel of experts. Ann Oncol 2010;21 Suppl 5:v198–v203

Incidence

Adult soft-tissue sarcomas are rare tumors, with an estimated incidence averaging 5/100,000 population per year in Europe

Diagnosis and General Guidelines

- Multidisciplinary approach is mandatory in all cases; ideally in referral centers
- Enrollment in clinical trials is highly encouraged
- Biopsy options:
  - Standard approach: multiple core needle biopsies (using needles >16G)
  - Excisional biopsy may be the most practical option for superficial lesions <5 cm
  - Open biopsy is another option
- Frozen-section technique for immediate diagnosis is not encouraged
- Biopsy should be performed in such a way that the biopsy pathway and the scar can be safely removed on definitive surgery. The biopsy entrance point is preferably tattooed
- Tumor samples should be fixed in formalin (Bouin fixation should be banned because it prevents molecular analysis)
- Recommend using a grading system that distinguishes 3 malignancy grades based on differentiation, necrosis, and mitotic rate (The Federation Nationale des Centres de Lutte Contre le Cancer [FNCLCC] grading system, also used by the WHO)
- If preoperative treatment was carried out, the pathology report should include a tumor response assessment. However, in contrast to osteosarcoma and Ewing sarcoma, no validated system is available at present, and no percentage of residual "viable cells" is considered to have a specific prognostic significance
- Collection of fresh-frozen tissue and tumor imprints (touch preps) with appropriate consent is encouraged, because new molecular pathology assessments could become available

Stage Classification and Risk Assessment

- The American Joint Committee on Cancer (AJCC)/International Union against Cancer (UICC) stage classification system stresses the importance of the malignancy grade in sarcoma. However, its use in routine practice is limited
- Prognostic factors:
  1. Tumor grade
  2. Tumor size
  3. Tumor depth
  4. Tumor resectability

Staging Procedures

A chest spiral CT scan is mandatory for staging purposes
Depending on the histologic type and other clinical features, further staging assessments may be recommended (ie, regional lymph node clinical assessment for synovial sarcoma, epithelioid sarcoma, alveolar soft-part sarcoma, clear cell sarcoma; abdominal CT scan for myxoid liposarcoma, etc)

Treatment

Limited Disease

- Surgery is the standard treatment for all patients with adult type, localized soft-tissue sarcomas
- Standard surgical procedure is a wide excision with negative margins (R0). This implies removing the tumor with a rim of normal tissue around
- An excision with small margins may be acceptable in highly selected cases, in particular for extracompartmental atypical lipomatous tumors

(*continued*)

Staging

UICC and TNM Staging (AJCC) TNM

Primary Tumor

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Tumor ≤5 cm in greatest dimension
T1a	Tumor above superficial fascia
T1b	Deep tumor*
T2	Tumor >5 cm in greatest dimension
T2a	Tumor above superficial fascia
T2b	Deep tumor

Nodal Status

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph nodes metastasis

Metastases

MX	Distant metastasis cannot be assessed
M0	No distant metastases
M1	Distant metastases
M1a	Lung
M1b	Other distant sites, including lymph nodes

GX	Grade cannot be assessed
G1	Well-differentiated—low-grade
G2	Moderately differentiated—low-grade
G3	Poorly differentiated—high-grade
G4	Undifferentiated—high-grade

Stage Groupings

Stage IA	T1a	N0	M0	G1, GX
	T1b	N0	M0	G1, GX
Stage IB	T2a	N0	M0	G1, GX
	T2b	N0	M0	G1, GX
Stage IIA	T1a	N0	M0	G2, G3
	T1b	N0	M0	G2, G3
Stage IIB	T2a	N0	M0	G2
	T2b	N0	M0	G2
Stage III	T2a, T2b	N0	M0	G3
	Any T	N1	M0	Any G
Stage IV	Any T	Any N	M1	Any G

*Deep tumors are tumors deep to the superficial fascia or those that have invaded through the fascia

Expert Opinion (*continued*)

Radiation Therapy (RT):

1. *High-grade, deep lesions, >5 cm:* Wide excision followed by RT
2. *High-grade, deep, <5 cm:* Surgery followed by RT
3. *Low-grade, superficial, >5 cm, and low-grade, deep, <5 cm STS:* RT occasionally used
4. *Low-grade, deep, >5 cm STS:* Discuss RT in a multidisciplinary fashion

Notes:

- RT is not given in the case of a truly compartmental resection of a tumor entirely contained within the compartment
- Overall, RT has been shown to improve local control, but not overall survival

5. *Postoperative RT:* Follows marginal or R1 (microscopic residual disease) or R2 (gross residual disease) excisions, if these cannot be rescued through reexcision; 50–60 Gy, 1.8–2 Gy fractions, possibly with boosts up to 66 Gy
6. *Preoperative RT:* 50 Gy
7. *Intraoperative radiation therapy (IORT) and brachytherapy:* In selected cases
8. *Local relapse:* Approach parallels approach to primary local disease, except for a wider resort to preoperative or postoperative radiation therapy, if not previously performed

Surgery:

- Definitions:
  - R0 resection—No residual microscopic disease
  - R1 resection—Microscopic residual disease (presence of tumor cells on resection margins)
  - R2 resection—Gross residual disease
- R1 resections: Consider reoperation if adequate margins can be achieved without major morbidity, taking into account tumor extent and tumor biology
- R2 surgery: Reoperation is mandatory, possibly with preoperative treatments if adequate margins cannot be achieved, or surgery is mutilating. In the latter case, the use of multimodal therapy with less-radical surgery requires shared decision making with the patient under conditions of uncertainty
- In nonresectable tumors, or those amenable only to mutilating surgery, options that can be considered include:
  - Chemotherapy and/or radiotherapy
  - Isolated hyperthermic limb perfusion with tumor necrosis factor-α (TNFα) + melphalan, if the tumor is confined to an extremity
  - Regional hyperthermia combined with chemotherapy

Note:

- These treatment modalities added to surgery should not be viewed as truly "adjuvant," the context being in fact that of a likely systemic disease
- In 1 large randomized phase III study (in patients with G2–3, deep, >5-cm soft-tissue sarcomas), regional hyperthermia in addition to systemic chemotherapy was associated with a local and disease-free survival advantage

Adjuvant chemotherapy

- Might improve, or at least delay, distant and local recurrence in high-risk patients
- A metaanalysis found a statistically significant, limited benefit in terms of both survival and relapse-free survival. However, studies are conflicting, and a final demonstration of efficacy is lacking
- Therefore, adjuvant chemotherapy is not standard treatment in adult-type soft-tissue sarcomas, but can be considered as an option in high-risk patients (having a G >1, deep, >5-cm tumor) (II, C)
- Adjuvant chemotherapy is not used in histologies known to be insensitive to chemotherapy
- If the decision is made to use chemotherapy as upfront treatment, it may well be used preoperatively, at least in part
- If used, adjuvant chemotherapy should consist of the combination chemotherapy regimens proven to be most active in advanced disease
- A local benefit may be gained, facilitating surgery. In one large randomized phase III study (patients with G2–3, deep, >5-cm soft-tissue sarcomas), regional hyperthermia + systemic chemotherapy was associated with a local and disease-free survival advantage (no survival benefit demonstrated)

(*continued*)

Follow-up

- There are no published data to indicate the optimal routine follow-up policy of surgically treated patients with localized disease
- Malignancy grade affects the likelihood and speed at which relapses may take place. Risk assessment is based on:
  - Tumor grade
  - Tumor size
  - Tumor site
- High-risk patients generally relapse within 2–3 years
- Low-risk patients may relapse later, although it is less likely
- Relapses most often occur to the lungs
- Early detection of local or metastatic recurrence to the lungs may have prognostic implications. Lung metastases typically are asymptomatic at a stage in which they are suitable for surgery

Expert Opinion (*continued*)

Extensive Disease

General guidelines:

- Metachronous resectable lung metastases without extrapulmonary disease are managed with complete excision of all lesions as standard treatment (IV, B). There is a lack of formal evidence that chemotherapy improves results
- Chemotherapy is preferably given before surgery, in order to assess tumor response and thus modulate the length of treatment
- In the case of lung metastases being synchronous, in the absence of extrapulmonary disease, standard treatment is chemotherapy (IV, B). Especially when patient benefit is achieved, surgery of lung metastases is an option
- Extrapulmonary disease is treated with chemotherapy as standard treatment (I, A)
- In highly selected cases, surgery of responding metastases may be offered as an option following a multidisciplinary evaluation

Chemotherapy:

- Standard chemotherapy is based on **anthracyclines** as first-line treatment (I, A)
- No formal demonstration multiagent chemotherapy is superior to single-agent chemotherapy with doxorubicin alone in terms of overall survival. However, a higher response rate may be expected in a number of sensitive histologic types according to several, although not all, randomized clinical trials
- Multiagent chemotherapy with **anthracyclines plus ifosfamide** may be the treatment of choice, especially when a tumor response is felt to give an advantage and patient performance status is good
- In angiosarcoma, **taxanes** are an alternative option (III, B)
- **Imatinib** is standard medical therapy for rare patients with dermatofibrosarcoma protuberans whose disease is not amenable to nonmutilating surgery or with metastases requiring medical therapy (III, B)
- After failure of **anthracycline-based chemotherapy** or if an anthracycline cannot be used, the following criteria may apply (although it lacks high-level evidence):
  - Patients who have already received chemotherapy may be treated with **ifosfamide**, if they did not receive it previously
  - **High-dose ifosfamide** ($\approx$14 g/m^2) may be an option for patients who have already received standard-dose ifosfamide (IV, C)
  - **Trabectedin** is a second-line option (II, B). It has proved effective in leiomyosarcoma and liposarcoma. Responses have also been observed in synovial sarcoma and other histotypes; however, it is not currently approved for use in the USA outside the context of a clinical trial
  - Single agent **gemcitabine** was also shown to have antitumor activity in leiomyosarcoma as a single agent
  - **Dacarbazine** has some activity as second-line therapy (mostly in leiomyosarcoma). It could also be combined **with gemcitabine**. One randomized trial has demonstrated a survival advantage with the combination of gemcitabine and dacarbazine (DTIC) over DTIC alone
  - **Best supportive care** is an option for pretreated patients with advanced soft-tissue sarcoma, particularly when secondary and later treatment options have already been used
- *Pretreated patients with advanced disease are candidates for clinical studies*

5-Year Survival

Nonmetastatic (80% of Patients at Diagnosis)	
Stage II	70%
Stage III	25%
Metastatic (20% of Patients at Diagnosis)	20%

SOFT-TISSUE SARCOMAS: RHABDOMYOSARCOMA

Epidemiology

Incidence: 350 estimated new cases in the United States per year; rhabdomyosarcoma represents 50% of all diagnosed soft-tissue sarcomas

Staging

For protocol purposes, patients are classified according to their risk of recurrence as low risk, intermediate risk, or high risk. The assignment proceeds as follows:

1. Determine the group (I, II, III, or IV)
2. Determine the stage (1, 2, 3, or 4)
3. Use the group and stage assignment together with histology to assign a risk category

Group classification system: A surgicopathologic grouping system with groups defined by the extent of disease and by the extent of initial surgical resection after pathologic review of the tumor specimens
Staging classification system: Classifies tumors based on primary site and size
Risk classification system: Used to assess the risk of recurrence as low, intermediate, and high risk; combines the clinical group and stage information

Group Classification System

Group	Extent of Disease and Initial Surgical Resection After Pathologic Review of Specimen	%*
I	Localized disease that is completely resected with no regional nodal involvement	14
IIA	Localized, grossly resected tumor with microscopic residual disease but no regional node involvement	20
IIB	Locoregional disease with tumor-involved lymph nodes with complete resection and no residual disease	
IIC	Locoregional disease with tumor-involved lymph nodes, grossly resected, but with evidence of microscopic residual tumor at the primary site and/or histologic involvement of the regional node (from the primary site)	
III	Localized, gross residual disease including incomplete resection or biopsy of the primary site	48
IV	Distant metastatic disease present at the time of diagnosis	18

*Percentage of all rhabdomyosarcomas

Staging Classification System

Stage	Description
1	Localized disease involving the orbit or head and neck (excluding parameningeal sites) or genitourinary region (excluding bladder/prostate sites) or biliary tract **(favorable sites)**
2	Localized disease of any other primary site not included in Stage 1 **(unfavorable sites)**. Primary tumor must be ≤5 cm in diameter with no clinical regional lymph node involvement by tumor
3	Localized disease of any other primary site not included in Stage 1 **(unfavorable sites)**. These patients differ from Stage 2 patients by having primary tumors >5 cm in diameter and/or regional node involvement
4	Metastatic disease at diagnosis

Lawrence W Jr et al. J Clin Oncol 1987;5:46–54

(*continued*)

Pathology

Embryonal Embryonal Botryoid* Spindle*	60–70%	Higher incidence in the 0–4 years age group
Alveolar	20%	Similar incidence throughout childhood
Pleomorphic	10–20%	

*These subtypes are associated with more favorable outcomes

Disease Sites at Diagnosis

Site	%
Parameningeal*	23
Nonparameningeal	8
Bladder and prostate	11
Non–bladder and prostate†	16
Limbs	16
Orbit	9
Other	17

*Sites in anatomic proximity to the base of the skull and adjacent meninges; eg, nasopharynx and middle ear
†Genitourinary other than bladder and prostate that include paratesticular, vagina, and uterus

Stevens MCG. Lancet Oncol 2005;6:77–84

5-Year Survival

Low risk	>90%
Intermediate risk	55–70%
High risk	20–25%

Staging (*continued*)

Risk Classification System

Risk	Histology	Stage	Group
Low	All	1	I, II, III
	Embryonal	2, 3	I, II
Intermediate	Embryonal	2, 3	III
	Embryonal*	4	IV
	Alveolar	1, 2, 3	I, II, III
	Undifferentiated	1, 2, 3	I, II, III
High	All†	4	IV
	Undifferentiated	4	IV

*Age <10 years
†Exception: Embryonal in children <10 years of age

Raney RB et al. J Pediatr Hematol Oncol 2001;23:215–220

Expert Opinion

1. Disease prognosis is related to the age of the adolescent, site of origin, resectability, presence of metastases, number of metastatic sites, and the unique biologic characteristics of the rhabdomyosarcoma tumor cells[1,2]
2. Distinctive molecular characteristics can be used to confirm alveolar and embryonal subtypes:
   Alveolar rhabdomyosarcoma: Unique translocation between the *FKHR* gene on chromosome 13 and either the *PAX3* gene on chromosome 2 (59% cases) or the *PAX7* gene on chromosome 1 (19% cases)
   Embryonal tumors: Often show loss of specific genomic material from the short arm of chromosome 11. The consistent loss of genomic material from the chromosome 11p15 region in embryonal tumors suggests the presence of a tumor suppressor gene. No such gene has yet been identified[3]
3. The variability with which rhabdomyosarcoma presents at different anatomic sites has a strong effect on treatment strategies

REGIMEN

VINCRISTINE + DACTINOMYCIN + CYCLOPHOSPHAMIDE (VAC)

Crist WM et al. J Clin Oncol 2001;19:3091–3102

Treatment Schedule

	Induction (Weeks 0–16)																
Drugs	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**	**16**
Vincristine (V)	V	V	V	V	V	V	V	V	V	V	V	V	V				V
Dactinomycin (A)	A			A			A										A
Cyclophosphamide (C)	C			C			C			C			C				C
										Radiation therapy							

	Continuation (Weeks 20–28)											
Drugs	**17**	**18**	**19**	**20**	**21**	**22**	**23**	**24**	**25**	**26**	**27**	**28**
Vincristine (V)				V	V	V	V	V	V			
Dactinomycin (A)				A			A					
Cyclophosphamide (C)				C			C					

Vincristine 1.5 mg/m² per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes on day 1 (total dosage during the weeks in which vincristine is administered = 1.5 mg/m²; maximum dose/treatment = 2 mg)
Dactinomycin 0.015 mg/kg per day (maximum single dose = 0.5 mg); administer by intravenous injection over 1–2 minutes for 5 consecutive days, on days 1–5 (total dosage during the weeks in which dactinomycin is administered = 0.075 mg/kg; maximum dose/cycle = 2.5 mg)
An admixture containing **cyclophosphamide** 2200 mg/m² + **mesna** 120 mg/m²; administer intravenously in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 10–30 minutes, on day 1 (total dosage during the weeks in which cyclophosphamide is administered = 2200 mg/m²), *followed by*
Mesna 1200 mg/m²; administer intravenously in 250–1000 mL of 0.9% NS or D5W over 24 hours (rate of 50 mg/m² per hour), starting immediately after each dose of cyclophosphamide (total dosage during the weeks in which cyclophosphamide is administered = 1320 mg/m²; includes 120 mg administered with cyclophosphamide)
• The administration schedules for vincristine, dactinomycin, and cyclophosphamide appears in the table (above)

Supportive Care: Antiemetic prophylaxis
Emetogenic potential during weeks with vincristine, dactinomycin, and cyclophosphamide is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days with vincristine and cyclophosphamide is ***HIGH***
Emetogenic potential on days with vincristine alone is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection
• Begin use from 24 hours after myelosuppressive chemotherapy is completed; that is, day 6 during VAC cycles and day 2 during vincristine and cyclophosphamide (VC) cycles
• Filgrastim may be given on days when vincristine is administered alone
• Continue daily filgrastim use until ANC ≥15,000/mm³
• Discontinue daily filgrastim use at least 24 hours before administering resuming myelosuppressive treatment (containing dactinomycin or cyclophosphamide)
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
• Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
• Antifungal—recommended
• Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)
See Chapter 47 for more information

Treatment Modifications

Percentage of Courses in Which ≥75% of Protocol-Specified Drugs Were Delivered	
Vincristine	81%
Dactinomycin	81%
Cyclophosphamide	86%

Patients with severe toxicity attributed to VAC (eg, venoocclusive disease of the liver) were switched to VIE (vincristine, ifosfamide and etoposide) therapy

Patient Population Studied

A study of 884 patients with previously untreated nonmetastatic rhabdomyosarcoma who had undergone surgery. Randomization to 1 of 4 study arms: VA (vincristine + dactinomycin, n = 134), VAC (n = 291), VAI (vincristine + dactinomycin + ifosfamide, n = 223), and VIE (vincristine, ifosfamide, and etoposide, n = 236). Patients with preexisting renal abnormalities predisposing to nephrotoxicity were assigned to VAC

Efficacy (N = 134)

	Failure-Free Survival (3-Year)	Overall Survival (3-Year)
Patients with preexisting renal abnormalities (n = 56)	75%*	80%*
All VAC patients (n = 134)	75%	84%

*Estimated

Toxicity* (N = 884†)

	% of Patients
Myelosuppression	>90
Severe infections	55
Severe renal toxicity	2
Second cancer‡	1.1
Death§	0.9

*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0
†Combined data for patients receiving either VA (vincristine + dactinomycin, n = 134) ,VAC (n = 291), VAI (vincristine + dactinomycin + ifosfamide, n = 223), or VIE (vincristine, ifosfamide, and etoposide, n = 236). There were no statistically significant differences in toxicities among the different regimens
‡Among 10 patients who developed a secondary malignancy, 6 were treated with VAC; 3-year estimated cumulative incidence of secondary malignancy was 2%
§Fatality rate (5%) was highest in patients with preexisting renal abnormalities who were treated with VAC

Therapy Monitoring

1. *Daily during therapy:* Urinalysis
2. *Twice per week:* CBC with differential until recovery from hematopoietic toxicity
3. *Weekly:* Physical examination
4. *Before each cycle:* Serum creatinine, LFTs with bilirubin, serum electrolytes, including calcium, magnesium, and phosphorus
5. *Response evaluation:* After the third, sixth, and eighth cycles

REGIMEN

IRINOTECAN

Cosetti M et al. J Pediatr Hematol Oncol 2002;24:101–105

Irinotecan 20 mg/m² per dose; administer intravenously in a volume of 5% dextrose injection (preferred) or 0.9% sodium chloride injection sufficient to produce a concentration within a range of 0.12–2.8 mg/mL over 60 minutes for 10 doses, on days 1–5 and days 8–12, every 21–28 days (total dosage/cycle = 200 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management

Latent or delayed onset diarrhea:*

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

SGOT, serum glutamic oxaloacetic transaminase (AST); SGPT, serum glutamic pyruvic transaminase (ALT)
*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0

Treatment Modifications

None specified; the following are suggested

Adverse Event	Dose Modification
WBC <4000/mm³, platelet count <100,000/mm³, or diarrhea	Delay start of cycle by 1 week until WBC >4000/mm³, platelet count >100,000/mm³, and no diarrhea
Day 8 or 15 WBC <3000/mm³ or platelet count <100,000/mm³	Hold irinotecan
G >1 diarrhea	Hold irinotecan
If WBC <1000/mm³, platelet count <50,000/mm³, or diarrhea G >2 at any time in cycle	Reduce subsequent irinotecan dosage by 50%

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* CBC with differential, LFTs with bilirubin
3. *Response evaluation:* After every 2 cycles

INTERMEDIATE RISK RHABDOMYOSARCOMA

*If primary RT is given, it is given at week 12. Primary surgery also occurs at week 12
†Doxorubicin omitted if radiation therapy (RT) being given concomitantly
‡If surgery follows primary RT, surgery is performed here. If RT follows surgery, RT begins here
§VDC given if D previously omitted at week 18 or 24, otherwise EI given

VINCRISTINE + DOXORUBICIN + CYCLOPHOSPHAMIDE (VDC)

Vincristine 1.5 mg/m² (maximum dose 2 mg); administer by intravenous injection over 1–2 minutes on day 1, during weeks 0, 1, 2, 6, 7, 8, 12, 18, 24, 30, and 36 (week 36, if VDC is given) (total dosage/week = 1.5 mg/m²; maximum dose/week = 2 mg)

Doxorubicin 37.5 mg/m² per day; administer by intravenous infusion in 25–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 18 hours for 2 consecutive days, on days 1 and 2, during weeks 0, 6, 12, 18, 24, 30, and 36 (if VDC is given) (total dosage/week = 75 mg/m²)

An admixture of **cyclophosphamide** 600 mg/m² plus **mesna** 360 mg/m² per dose; administer by intravenous infusion, in a volume of 0.9% NS or D5W sufficient to produce a mesna concentration within the range of 1–20 mg/mL, over 15–60 minutes for 2 consecutive days, on days 1 and 2, during weeks 0, 6, 12, 18, 24, 30, and 36 (week 36, if VDC is given) (total cyclophosphamide dosage/week = 1200 mg/m²), *followed each day by:*

Mesna 360 mg/m² per dose; administer by intravenous infusion, in a volume of 0.9% NS or D5W sufficient to produce a mesna concentration within the range of 1–20 mg/mL, over 15–60 minutes every 3 hours for 4 doses per day, starting 3 hours after commencing administration of cyclophosphamide + mesna (a total of 5 mesna doses/day), for 2 consecutive days, days 1 and 2, during weeks 0, 6, 12, 18, 24, 30, and 36 (if VDC is given) (total dosage/week = 3600 mg/m²; includes 360 mg doses given with cyclophosphamide)

(*continued*)

Dose Modifications

Adverse Event	Treatment Modification
G1 ANC 1500–1999/mm³, or G1 thrombocytopenia during a cycle	Maintain dosages and schedules. Administer filgrastim if not previously administered
Day 21 ANC <1000/mm³, or platelet count <75,000/mm³	Delay start of next cycle by 1 week. Reduce dosages in ensuing cycle or administer filgrastim if not previously administered
Day 28 ANC still <1000/mm³, or platelet count still <75,000/mm³	Delay start of next cycle by 1 additional week. Reduce dosages in ensuing cycle or administer filgrastim if not previously administered
Day 35 ANC still <1000/mm³, or platelet count still <75,000/mm³	Discontinue therapy
Postradiation mucositis	Reduce doxorubicin dosage
Decrease of cardiac ejection fraction from baseline	Reduce doxorubicin dosage
G2 neurotoxicity	Reduce vincristine dosage 50%
Foot drop	Reduce vincristine dosage 50%
G3/4 neurotoxicity	Discontinue vincristine
Any G1 nonhematologic toxicity	Maintain doses and schedules
Any G2/3 nonhematologic toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of drug(s) felt responsible for the toxicity in subsequent cycles by 25%
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of drug(s) felt responsible for the toxicity in subsequent cycles by 50%

(*continued*)

IFOSFAMIDE + ETOPOSIDE (IE)

An admixture of **ifosfamide** 1800 mg/m² plus **mesna** 360 mg/m² per dose; administer by intravenous infusion, in a volume of 0.9% NS or D5W sufficient to produce an ifosfamide concentration within the range of 0.6–20 mg/mL, and a mesna concentration within the range of 1–20 mg/mL over 15–60 minutes for 5 consecutive days, on days 1–5, during weeks 3, 9, 15, 21, 27, 33, 36 (week 36, if EI is given instead of VDC), and 39 (total ifosfamide dosage/week = 9000 mg/m²), *followed each day by:*

Mesna 360 mg/m² per dose; administer by intravenous infusion, in a volume of 0.9% NS or D5W sufficient to produce a mesna concentration within the range of 1–20 mg/mL, over 15–60 minutes, every 3 hours, for 4 doses per day, starting 3 hours after commencing administration of ifosfamide + mesna (a total of 5 mesna doses/day), for 5 consecutive days, on days 1–5, during weeks 3, 9, 15, 21, 27, 33, 36 (week 36, if EI is given instead of VDC), and 39 (total dosage/week = 9000 mg/m²; includes 360 mg doses given with cyclophosphamide)

Etoposide 100 mg/m² per day; administer intravenously, diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL, over 60 minutes for 5 consecutive days, on days 1–5, during weeks 3, 9, 15, 21, 27, 33, 36 (week 36, if EI is given instead of VDC), and 39 (total dosage/week = 500 mg/m²)

Notes:

- Patients with positive cerebrospinal fluid cytology: Administer triple **intrathecal** chemotherapy with **methotrexate, cytarabine, and hydrocortisone**

CNS treatment (confirmed CNS disease)—possible regimen:*
Methotrexate 6 mg per dose +
Cytarabine 30 mg per dose +
Hydrocortisone 15 mg per dose

Induction: All 3 drugs are given together, twice weekly for at least 4 consecutive weeks, or for 2 weeks after CSF specimens are without evidence of lymphoma, whichever is greater

Administer intrathecally in a volume of **preservative-free** 0.9% NS equivalent to the amount of CSF removed via lumbar puncture, intraventricular catheter or reservoir. Total doses/week:

- **Methotrexate** = 12 mg
- **Cytarabine** = 60 mg
- **Hydrocortisone** = 30 mg

Consolidation: All 3 drugs are given together, once weekly for 6 weeks. Administer intrathecally in a volume of **preservative-free** 0.9% NS equivalent to the amount of CSF removed via intraventricular catheter or reservoir. Total doses/week:

- **Methotrexate** = 6 mg
- **Cytarabine** = 30 mg
- **Hydrocortisone** = 15 mg

Maintenance: All 3 drugs are given together, once monthly for 6 months. Administer intrathecally in a volume of preservative-free 0.9% NS equivalent to the amount of CSF removed. Total doses/month:

- **Methotrexate** = 6 mg
- **Cytarabine** = 30 mg
- **Hydrocortisone** = 15 mg

**Note:* Monotherapy with methotrexate or cytarabine may be feasible in patients with sensitive disease

(*continued*)

Patient Population Studied

Patients with intermediate risk rhabdomyosarcoma defined as having Stage 2 or 3 (unfavorable site) Group III disease, or any nonmetastatic alveolar disease. Patients with metastatic disease were not eligible for the pilot study

Efficacy (N = 46)

Arndt CAS et al. Pediatr Blood Cancer 2008;50:33–36

Patients with parameningeal primaries	
5-year FFS*	82% (95% CI, 59%–93%)
5-year overall survival	82% (95% CI, 59%–93%)
Patients with nonparameningeal primaries	
Estimated 5-year FFS*	75%
Estimated 5-year FFS* for Stage 2 (n = 8)	63%
Estimated 5-year FFS* for Stage 3 (n = 12)	83%

*Failure-free survival (FFS) is defined as the time to the first occurrence of recurrence of rhabdomyosarcoma or death as a first event

(continued)

- Perform echocardiograms to monitor cardiac function at baseline and prior to weeks 12, 24, 30, at the end of therapy, 1 year after completion of therapy, and then, every 2 ± 5 years, depending on the result
- After week 12 (following 4 cycles of chemotherapy), patients undergo therapy for local control of the tumor. Either surgery or irradiation is used for local control. Patients receiving irradiation as primary local therapy should begin treatment at week 12, as soon as possible after completing doxorubicin. (*Example:* 5040 cGy in 28 fractions to the tumor followed by a boost of an additional 540 cGy in 3 fractions to the tumor plus a 2-cm margin.) If the patient undergoes surgery, postoperative irradiation is given for patients with gross or microscopic residual disease, or if the surgical margin is ≤1 cm. Postoperative irradiation then begins at week 21. (*Example:* Tumor bed plus a 3-cm margin for the initial 5040 cGy in 28 fractions, followed by a boost of an additional 540 cGy in three fractions to the tumor bed with a 2-cm margin.) Doxorubicin is not given during radiation therapy

Supportive Care

Antiemetic prophylaxis for the vincristine + doxorubicin + cyclophosphamide regimen

Emetogenic potential on days 1 and 2 is ***HIGH****. Potential for delayed symptoms*

Antiemetic prophylaxis for the ifosfamide + etoposide regimen

Emetogenic potential is ***MODERATE–HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection

- Begin use 24 hours after myelosuppressive chemotherapy is completed
- Discontinue filgrastim use at least 24 hours before administering myelosuppressive treatment
- Do not give filgrastim during radiation therapy

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of clotrimazole during periods of neutropenia, and in anticipation of mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(continued)

Toxicity (Feasibility)

Arndt CAS et al. Eur J Cancer 1998;34:1224–1229

VDC cycles delivered at full dose	169/191 (88%)
EI cycles delivered at full dose	196/212 (92%)
Reasons for reductions in doxorubicin dose	
Postradiation mucositis (all during maintenance)	10 cycles
Decrease of cardiac ejection fraction from baseline	2 cycles (1 patient)*
Decrease in doxorubicin and cyclophosphamide dosage (all during maintenance) as a result of delay in recovery of the neutrophil and platelet count	6 cycles
Vincristine dosage decreased because of foot drop	4 cycles (1 patient)
Reasons for decrease in etoposide and ifosfamide	
Delay in recovery of neutrophil and platelet count	13 maintenance cycles
Mucositis	2 maintenance cycles
EI cycles omitted because of prolonged cytopenias	3 patients
Mean duration of induction chemotherapy (start of treatment to start of week 12; scheduled time = 84 days)	
Patients without surgery prior to week 12	97 days (range: 82 ± 144)
Patients with surgery following first 4 cycles of chemotherapy (recovery from week 9)	106 days (range: 84 ± 126)
Mean duration of consolidation therapy (start of week 12 to start of week 21 therapy; scheduled time = 63 days)	80 days (range: 61 ± 154)
Mean duration of maintenance therapy (scheduled time = 144 days)	168 days (range: 90 ± 215)

*Although cardiac function still in the normal range

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Therapy Monitoring

1. *Prior to enrollment:* Complete medical history, clinical examination, performance status, hematologic and serum chemistries, and tumor target assessment
2. *Day 1 of each treatment cycle:* Physical examination, ECOG PS, complete blood count with leukocyte differential count, and serum chemistries
3. *Weekly CBC with leukocyte differential count:* At least the first 6 cycles of therapy
4. *After every 2 cycles of therapy:* Tumor measurements

REGIMEN

DOXORUBICIN

O'Bryan RM et al. Cancer 1973;32:1–8
O'Bryan RM et al. Cancer 1977;39:1940–1948

Doxorubicin 60 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days (total dosage/cycle = 60 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

(*continued*)

Patient Population Studied

Patients with metastatic or unresectable locoregional recurrent soft-tissue sarcoma

Efficacy (N = 64; N = 98)

	Partial Response*
All histologies (N = 64)	21 (32.8%)
Fibrosarcomas (n = 14)	2 (14.3%)
Leiomyosarcoma (n = 8)	3 (37.5%)
Hemangiosarcoma (n = 3)	2 (66.7%)
Other (n = 12)	4 (33.3%)
Rhabdomyosarcomas (n = 11)	3 (27.3%)
Osteogenic sarcoma (n = 9)	5 (55.5%)
Ewing sarcoma (n = 7)	2 (28.6%)

*Includes only patients who received 2 courses of doxorubicin

O'Bryan RM et al. Cancer 1973;32:1–8 (N = 64)

Risk Category and Dose (N = 98)*	Partial Response
Good risk; 75 mg/m² (n = 41)	15 (37%)
Good risk; 60 mg/m² (n = 10)	2 (20%)
Good risk; 45 mg/m² (n = 28)	5 (18%)
Poor risk; 50 mg/m² (n = 9)	1 (11%)
Poor risk; 25 mg/m² (n = 10)	0

*Patients were classified as "good risk" if in the opinion of the investigator they were able to tolerate 75 mg/m² for 3 doses. Poor-risk patients were expected to tolerate 50 mg/m² for 3 doses. The latter included those older than 65 years of age, those with prior radiation therapy or chemotherapy, and those with poor tolerance of myelosuppressive therapy

O'Bryan RM et al. Cancer 1977;39:1940–1948 (N = 98)

(*continued*)

- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm^3 or platelets <100,000/mm^3	Delay treatment 1 week until WBC ≥3000/mm^3 and platelets ≥100,000/mm^3
>2-Week delay in start of cycle	Reduce doxorubicin dose by 15 mg/m^2
WBC nadir <1000/mm^3 or platelet nadir <29,500/mm^3	Reduce doxorubicin dosage by 15 mg/m^2
WBC nadir 1000–1499/mm^3 or platelet nadir 30,000–49,500/mm^3	Reduce doxorubicin dosage by 30 mg/m^2
G ≥3 mucositis	Reduce doxorubicin dosage by 10–15 mg/m^2
Doxorubicin total cumulative lifetime dosage ≥400–450 mg/m^2	Obtain frequent MUGA scans to monitor cardiac function
A fall in ejection fraction (possible guidelines: resting cardiac ejection fraction decreased ≥10–15% below baseline or to <35–40%)	Discontinue therapy

Toxicity (N = 472; N = 818)

Toxicity			No. of Patients (%)
Hematologic			
WBC/mm^3	or	Platelets/mm^3	
3000–4000	or	75,000–100,000	91 (19.3)
2000–2999	or	50,000–74,500	113 (23.9)
1000–1999	or	25,000–49,500	91(19.3)
<1000	or	<25,000	52 (11)
Nonhematologic			
Mild gastrointestinal toxicity			40 (8.5)
Moderate gastrointestinal toxicity			152 (32.2)
Severe gastrointestinal toxicity			10 (2.1)

O'Bryan RM et al. Cancer 1973;32:1–8 (N = 472)

(*continued*)

Toxicity (N = 472; N = 818) (*continued*)

Hematologic Toxicity			% of Patients		
Dosage (mg/m²)			75	60	45
WBC/mm³	or	Platelets/mm³			
3000–4000	or	75,000–100,000	3	13	19
2000–2999	or	50,000–74,500	28	31	6
1000–1999	or	25,000–49,500	27	23	31
<1000	or	<25,000	14	15	13

O'Bryan RM et al. Cancer 1977;39:1940–1948 (N = 818)

Congestive Heart Failure: According to Cumulative Dosage	
Cumulative Dosage	No. of Patients (%)
<200 mg/m² (n = 491)	1 (0.2)
201–300 mg/m² (n = 145)	2 (1.4)
301–400 mg/m² (n = 84)	5 (5.9)
401–550 mg/m² (n = 98)	5 (5.1)
Total (N = 818)	13 (1.6)

O'Bryan RM et al. Cancer 1977;39:1940–1948 (N = 818)

General Summary of Toxicities	
Myelosuppression	Dose-limiting toxicity. Leukopenia more common than thrombocytopenia or anemia; nadir usually on days 10–14 with recovery by day 21 after treatment
Nausea and vomiting	Moderate severity on the day of treatment; delayed symptoms (>24 hours after treatment) uncommon
Mucositis and diarrhea	Common, but not dose limiting
Cardiotoxicity (acute)	Incidence not related to dosage. Presents within 3 days after treatment as arrhythmias, conduction abnormalities, ECG changes, pericarditis, and/or myocarditis. Usually transient and asymptomatic
Cardiotoxicity (chronic)	Dosage-dependent dilated cardiomyopathy associated with congestive heart failure. Risk increases with increasing cumulative doses
Strong vesicant	Avoid extravasation
Skin	Hand-foot syndrome, with skin rash, swelling, erythema, pain, and desquamation. Onset at 5–6 weeks after starting treatment. Hyperpigmentation of nails, rarely skin rash, urticaria. Potential for radiation recall
Alopecia	Common, but generally reversible within 3 months after discontinuing doxorubicin
Infusion reactions	Signs and symptoms include flushing, dyspnea, facial swelling, headache, back pain, chest and/or throat tightness, and hypotension May occur with a first treatment. Symptoms resolve within several hours to a day after discontinuing doxorubicin
Urine discoloration	Red-orange discoloration usually within 1–2 days after drug administration

Therapy Monitoring

1. *During treatment cycles:* CBC with differential weekly
2. *Before each cycle after a cumulative doxorubicin dosage of 400–450 mg/m²:* Cardiac ejection fraction

Notes

1. Single-agent doxorubicin remains the standard therapy for palliation of metastatic disease
2. Although some advocate higher dosages up to 70–75 mg/m² per dose, the accumulated evidence does not convincingly support the use of these higher doses

REGIMEN

IFOSFAMIDE

van Oosterom AT et al. Eur J Cancer 2002;38:2397–2406

Hydration and mannitol diuresis:
1000 mL 5% Dextrose and 0.9% sodium chloride injection (D5W/0.9% NS); administer intravenously over 2 hours, beginning 2 hours before the start of chemotherapy
Mannitol is given to patients who have received adequate hydration. **Mannitol** 20% 200 mL; administer intravenously over 30 minutes, starting 1 hour before the start of chemotherapy. It is *essential* to continue hydration after mannitol administration

Mesna 600 mg/m²; administer intravenously, diluted with 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the range of 1–20 mg/mL, over 15 minutes just before the start of the ifosfamide + mesna admixture (see "Note" below), *followed by:*
An admixture containing **ifosfamide** 5000 mg/m² + **mesna** 2500 mg/m²; administer intravenously, diluted in a volume of D5W/0.9% NS sufficient to produce an ifosfamide concentration within the range of 0.6–20 mg/mL, over 24 hours, on day 1, every 21 days (total ifosfamide dosage/cycle = 5000 mg/m²), *followed by:*
Mesna 1250 mg/m²; administer intravenously in 2000 mL D5W/0.9% NS over 12 hours, on day 2 after completing ifosfamide administration, every 21 days (total mesna dosage per cycle = 4350 mg/m²; includes mesna administered before and with ifosfamide)

or

Mesna 600 mg/m²; administer intravenously, diluted with 0.9% NS or D5W to a concentration within the range of 1–20 mg/mL, over 15 minutes for 3 consecutive days, on days 1–3, just before the start of the ifosfamide + mesna admixture (see "Note" below), *followed by:*
An admixture containing **ifosfamide** 3000 mg/m² + **mesna** 1500 mg/m² per day; administer intravenously, diluted in a volume of D5W/0.9% NS sufficient to produce an ifosfamide concentration within the range of 0.6–20 mg/mL, over 4 hours, daily for 3 consecutive days, on days 1–3, every 21 days (total ifosfamide dosage/cycle = 9000 mg/m²), *followed by:*
Mesna 500 mg/m² per dose; administer orally or intravenously diluted with 0.9% NS or D5W to a concentration within the range of 1–20 mg/mL, over 15 minutes, for 2 doses per day at 4 and 8 hours after completing ifosfamide administration, daily for 3 consecutive days, on days 1–3, every 21 days (total mesna dosage/cycle = 9300 mg/m²; includes mesna administered before and with ifosfamide)

Note: Although the use of mesna before ifosfamide administration was reported with both regimens, ifosfamide, like cyclophosphamide, has to be metabolized to active (and toxic) metabolites *before* there is a need to protect the uroepithelium. Consequently, pretreating with mesna may be of little value

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MODERATE** each day of ifosfamide administration*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 182 adult patients with metastatic or unresectable locoregional recurrent soft-tissue sarcoma

Treatment Modifications

Adverse Event	Dose Modification
WHO G1 WBC or platelets	Reduce ifosfamide and mesna dosages by 10%
WHO G2 WBC or platelets	Delay start of therapy until WBC or platelets are G ≤1, then reduce ifosfamide and mesna dosages by 10%
3-Week delay in start of cycle because WBC or platelets have not increased to WHO toxicity G ≤1	Discontinue therapy
WBC nadir <500/mm³ or platelet nadir <50,000/mm³	Reduce ifosfamide and mesna dosages by 20%, regardless of WBC or platelet count on day 1
Resting cardiac ejection fraction <40%	Discontinue therapy

Efficacy* (N = 174)

	5000 mg/m²	3000 mg/m² per day × 3 days

Therapy Monitoring

During treatment cycles: CBC with differential twice weekly

Notes

Despite differences in response rates in first-line therapy, there were no differences in survival between the 2 regimens

REGIMEN

DOXORUBICIN + IFOSFAMIDE

Le Cesne A et al. J Clin Oncol 2000;18:2676–2684

Hydration and mannitol diuresis:
1000 mL 5% Dextrose and 0.9% sodium chloride injection (D5W/0.9% NS); administer intravenously over 2 hours, starting 2 hours before the start of chemotherapy
Mannitol may be given to patients who have received adequate hydration
Mannitol 20% 200 mL; administer intravenously over 30 minutes, starting 1 hour before the start of chemotherapy. It is *essential* to continue hydration after mannitol administration

Doxorubicin 50 mg/m^2; administer by intravenous injection over 3–5 minutes, on day 1, every 21 days (total dosage/cycle = 50 mg/m^2), *followed by:*
Mesna 600 mg/m^2; administer intravenously, diluted with 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the range of 1–20 mg/mL, over 15 minutes just before the start of the ifosfamide + mesna admixture (see "Note" below), *followed by:*
An admixture containing **ifosfamide** 5000 mg/m^2 + **mesna** 2500 mg/m^2; administer intravenously, diluted in a volume of D5W/0.9% NS sufficient to produce an ifosfamide concentration within the range of 0.6–20 mg/mL, over 24 hours, on day 1, every 21 days (total ifosfamide dosage/cycle = 5000 mg/m^2), *followed by:*
Mesna 1250 mg/m^2; administer intravenously in 2000 mL D5W/0.9% NS over 12 hours, on day 2 after completing administration of the ifosfamide + mesna admixture, every 21 days (total mesna dosage/cycle = 4350 mg/m^2; includes mesna administered before and with ifosfamide)

Note: Although the use of mesna before ifosfamide administration was reported by the investigators, ifosfamide must be metabolized to active (and toxic) metabolites *before* there is a need to protect the uroepithelium. Consequently, pretreating with mesna may be of little value

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm^3 on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Patient Population Studied

A study of 294 adult patients with metastatic or unresectable locoregional recurrent soft-tissue sarcoma randomly assigned to receive ifosfamide with either standard-dose doxorubicin (50 mg/m^2; n = 147) or intensified doxorubicin (75 mg/m^2; n = 133) with sargramostim support

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm^3 or platelets <100,000/mm^3	Delay treatment 1 week until WBC ≥3000/mm^3 and platelets ≥100,000/mm^3
Treatment delay 3 times (3 weeks) without achieving a WBC ≥3000/mm^3 and platelets ≥100,000/mm^3	Discontinue therapy
Serum creatinine >1.7 mg/dL (>150 mmol/L) or creatinine clearance <50 mL/min (<0.83 mL/s)	Delay treatment until serum creatinine <1.7 mg/dL (<150 mmol/L) or creatinine clearance >50 mL/min (>0.83 mL/s)
Nonhematologic life-threatening toxicity	Discontinue therapy
Resting cardiac ejection fraction below 40%	Discontinue therapy

Efficacy (N = 147)

Complete response	3.4%
Partial response	17.7%
Early death from toxicity	1 patient
Median duration of response	47 weeks

(continued)

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Toxicity* (N = 147)

Toxicity	% of Patients or Levels
Hematologic	
G3/4 WBC	86
G3/4 ANC	92
Median ANC nadir (all cycles)	200/mm^3
Range of ANC nadir (all cycles)	0–5500/mm^3
Infection	4.6
G3/4 platelets	8
Median platelet nadir (all cycles)	141,000/mm^3
Range of platelet nadir (all cycles)	5–323,000/mm^3
Nonhematologic	
G3/4 asthenia	4.5
G3/4 stomatitis	3.9
G3/4 vomiting	10
G2/3 myocardial insufficiency	1.3
G ≥2 diarrhea	6.5
G3/4 fever	2.6
G ≥2 flu-like syndrome	1
G ≥2 bone pain/myalgia	6

*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0

Therapy Monitoring

1. *During treatment cycles:* CBC with differential twice weekly
2. *Before each cycle:* CBC with differential, serum electrolytes, BUN, and creatinine (creatinine clearance if serum creatinine >1.7 mg/dL (>150 mmol/L))
3. *Before each cycle after a cumulative doxorubicin dosage of 400–450 mg/m^2:* Cardiac ejection fraction

Notes

Combination chemotherapy may produce a higher response rate than single-agent therapy, but toxicity is greater and survival advantages for the more aggressive regimens have not been reproducibly reported

METASTATIC SOFT-TISSUE SARCOMA (PATIENTS ≥10 YEARS OF AGE)

GEMCITABINE + DOCETAXEL
GEMCITABINE ALONE

Maki RG et al. J Clin Oncol 2007;25:2755–2763

Gemcitabine 900 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration as low as 0.1 mg/mL, over 90 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 1800 mg/m²)

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting 1 day before docetaxel administration (total dose/cycle = 48 mg)
Optional premedication for docetaxel:
- **Diphenhydramine HCl** 25 mg; administer orally 30–60 minutes *or* intravenously 5–30 minutes prior to docetaxel administration
- **Ranitidine** 150 mg; administer orally 30–60 minutes prior to docetaxel administration, *or*
- **Ranitidine** 50 mg; administer intravenously 5–30 minutes prior to docetaxel administration

Docetaxel 100 mg/m²; administer intravenously, in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL, over 60 minutes, on day 8 after completing gemcitabine administration, every 21 days (total dosage/cycle = 100 mg/m²)

or

Gemcitabine 1200 mg/m² per dose; administer intravenously, diluted in 0.9% NS to a concentration as low as 0.1 mg/mL, over 2 hours for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 2400 mg/m²)

Notes:
- Patients with prior pelvic irradiation should begin therapy with gemcitabine or gemcitabine and docetaxel dosages decreased by 25%
- The investigators concluded that gemcitabine + docetaxel yielded superior progression-free and overall survival in comparison with gemcitabine alone, but with increased toxicity for the combination

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW–MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use on cycle day 9; that is, 24 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with a diagnosis of recurrent or progressive soft-tissue sarcoma (excluding GI stromal tumor and Kaposi sarcoma); age >10 years; zero to 3 prior chemotherapy regimens; ECOG PS ≤2; peripheral neuropathy grade ≤1 by National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3.0

Efficacy (N = 73)

Outcome	Percent of Patients (Number of Patients)	
	Gemcitabine + Docetaxel	Gemcitabine Alone
Complete response	3% (2)	0
Partial response	14% (10)	8% (4)
SD ≥24 weeks	15% (11)	18% (9)
SD <24 weeks	38% (28)	35% (17)
Disease progression	25% (18)	37% (18)
Not assessable	4% (3)	2% (1)
Median progression-free survival	6.2 months	3 months
Median overall survival	17.9 months	11.5 months

Treatment Modifications

Adverse Event	Dose Modification
Febrile neutropenia or platelet count of <25,000/mm³ lasting more than 5 days	Reduce gemcitabine and docetaxel dosages by 25% in all subsequent cycles
ANC <1000/mm³ at start of next cycle	Withhold treatment until ANC ≥1000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
Platelet count <100,000/mm³ at start of next cycle	Withhold treatment until platelet count ≥100,000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
ANC <1000/mm³ or Platelet count <100,000/mm³ despite 2-week delay	Discontinue therapy
Day 8 ANC 500–999/mm³ or day 8 platelet count 50,000–99,000/mm³	Reduce day 8 gemcitabine and docetaxel dosages by 25%
Day 8 ANC <500/mm³ or day 8 platelet count <50,000/mm³	Do not administer day 8 gemcitabine and docetaxel
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by 25%
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%
G ≥3 liver function test abnormalities	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by 25%
G ≥3 liver function test abnormalities despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%
G4 mucositis and diarrhea	Discontinue therapy
G2 neuropathy	Delay therapy 1 week. If symptoms do not resolve to G ≤1, reduce docetaxel dosage by 25%
G3 neuropathy	Discontinue therapy
Febrile neutropenia (T >38°C [>100.4°F] with ANC <1000/mm³)	Reduce gemcitabine and docetaxel dosages by 25%
G3/4 hematologic toxicity	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy

Toxicity

Toxicity	Percent of Patients	
	Gemcitabine + Docetaxel (N = 49)	Gemcitabine Alone (N = 73)
G3/4 neutrophils*	16%	28%
G3 hemoglobin	7%	13%
Blood transfusion	16%	20%
G3/4 platelets	40%	35%
Platelet transfusion	15%	11%
Febrile neutropenia	5%	7%
G3/4 pulmonary	7%	6%
G3/4 fatigue	16%	8%
G3 myalgias or muscle weakness	8%	2%
All other G3†	23%	2%

*National Cancer Institute Common Terminology Criteria for Adverse Events, version 3.0

†Includes (1 each except as noted): deep venous thrombosis/pulmonary embolus (n = 5), nausea/vomiting or anorexia (n = 4), lymphopenia (n = 4), edema (n = 3), GI bleeding (n = 2), high serum glucose, abdominal pain, diarrhea, mucositis, cough, pleural effusion, hiccups, bone pain, back spasm/pain, rash, nail changes, hypokalemia

Best Response by Histology*

CR, complete response; PR, partial response; PD, progressive disease; SD, stable disease; NA, not assessable; MFH/HGUPS, malignant fibrous histiocytoma/high-grade undifferentiated pleomorphic sarcoma

*Includes one Response Evaluation Criteria in Solid Tumors Group (RECIST; Therasse P et al. J Natl Cancer Inst 2000;92:205–216) unconfirmed PR on each arm: gemcitabine (MFH/HGUPS); gemcitabine-docetaxel (uterine leiomyosarcoma)

Therapy Monitoring

1. *At start of therapy:* Clinical examination and laboratory testing
2. *Day 1 of each treatment cycle:* Physical examination, ECOG PS, complete blood count with leukocyte differential count, and serum chemistries
3. *Weekly CBC with leukocyte differential count:* At least the first 6 cycles of therapy
4. *After every 2 cycles of therapy:* Tumor measurements

UNRESECTABLE/METASTATIC/ PROGRESSIVE SOFT-TISSUE SARCOMA

GEMCITABINE + DACARBAZINE

García-del-Muro X et al. J Clin Oncol 2011;29:2528–2533

Gemcitabine 1800 mg/m²; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration as low as 0.1 mg/mL, over 3 hours, on day 1, every 2 weeks, for a total of 12 cycles (24 weeks) (total dosage/cycle = 1800 mg/m²), *followed by:*
Dacarbazine 500 mg/m²; administer intravenously in 50–250 mL 0.9% NS or 5% dextrose injection over 20 minutes, on day 1, every 2 weeks, for a total of 12 cycles (24 weeks) (total dosage/cycle = 500 mg/m²)

Notes:
• Treatment after 24 weeks may be continued if it is thought the treatment is providing benefit

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
• Antibacterial—not indicated
• Antifungal—not indicated
• Antiviral—not indicated unless patient previously had an episode of HSV
See Chapter 47 for more information

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
• Encourage patients to maintain intake of non-alcoholic fluids
• Evaluate patients for oral pain and provide analgesic medications
• Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
• *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
• Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
• Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
• Patients may use saline or commercial bland, non-alcoholic rinses
  ▪ Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
• Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
• Rinse mouth several times a day to remove debris
  ▪ Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  ▪ Do not use mouthwashes that contain alcohols
• Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
• Advise patients who develop mucositis to:
  ▪ Choose foods that are easy to chew and swallow
  ▪ Take small bites of food, chew slowly, and sip liquids with meals
  ▪ Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  ▪ For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  ▪ Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

Patients 18 years or older with a histologic diagnosis of soft-tissue sarcoma with unresectable or metastatic progressive disease after prior treatment with anthracyclines and ifosfamide, or with contraindication for their use. Patients with rhabdomyosarcoma, chondrosarcoma, osteosarcoma, Ewing sarcoma, and gastrointestinal stromal tumor were excluded

Therapy Monitoring

1. *Pretreatment Evaluations:* History and physical examination; complete blood count with differential and platelet count; serum chemistries; electrocardiogram; chest X-ray; computed tomography (CT) scan of the chest, abdomen, and pelvis; and documentation of tumor measurements
2. *Weekly during treatment:* Complete blood cell counts with leukocyte differential count
3. *Before each cycle:* History and physical examinations and assessment of toxicities. Serum chemistries
4. *Every 3–4 cycles:* CT scans to assess response

Treatment Modifications

Dosage Levels

	Gemcitabine	Dacarbazine
Starting dosage level	1800 mg/m²	500 mg/m²
Dosage level −1	1500 mg/m²	400 mg/m²
Dosage level −2	1200 mg/m²	400 mg/m²

Adverse Event	Dose Modification
G3/4 thrombocytopenia, G4 granulocytopenia, or febrile neutropenia	Reduce gemcitabine and dacarbazine dosages by 1 dosage level
ANC <1000/mm³ at start of next cycle	Withhold treatment until ANC ≥1000/mm³, then reduce gemcitabine and dacarbazine dosages by 1 level
Platelet count <100,000/mm³ at start of next cycle	Withhold treatment until platelet count ≥100,000/mm³, then reduce gemcitabine and dacarbazine dosages by 1 level
ANC <1000/mm³ or platelet count <100,000/mm³ despite a 2-week delay	Withhold treatment until ANC ≥1000/mm³, then reduce gemcitabine and dacarbazine dosages by 1 level. If needed, administer cycles at 3-week intervals instead of 2-week intervals
G4 hepatotoxicity or G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. Resume treatment if toxicity resolves to G ≤1, but reduce gemcitabine and dacarbazine dosages by 1 dosage level
G2/3 skin rash	Reduce gemcitabine dosage to 1500 mg/m². If G2/3 rash recurs, reduce gemcitabine dosage to 1200 mg/m²
G ≥3 emesis	Discontinue dacarbazine

Toxicity (N = 57)

Worst Toxicity by Patient (NCI CTCAE v3.0*)

Adverse Events	% Patients All Grades	% Patients G3	% Patients G4

Alopecia	7	0	0

*National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3.0

Efficacy* (N = 57)

Progression-free rate at 3 months	56%
Median progression-free survival	4.2 months
Median overall survival	16.8 months
Overall response rate†	12%
Median duration of response	10.2 months (range: 2.7–12.3 months)
Median progression-free survival, leiomyosarcoma	4.9 months
Median overall survival, leiomyosarcoma	18.3 months
Median progression-free survival, nonleiomyosarcoma	2.1 months
Median overall survival, nonleiomyosarcoma	7.8 months

*RECIST 1.0 (Response Evaluation Criteria in Solid Tumors; Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

†Responses were seen in leiomyosarcoma (3 patients), undifferentiated pleomorphic sarcoma (1 patient), uterine sarcoma (1 patient), and nonclassifiable sarcoma (1 patient)

ADVANCED SOFT-TISSUE SARCOMA

TRABECTEDIN (ECTEINASCIDIN 743; ET-743)

Demetri GD et al. J Clin Oncol 2009;27:4188–4196
Garcia-Carbonero R et al. J Clin Oncol 2004;22:1480--1490
Grosso F et al. Lancet Oncol 2007;8:595–602

Trabectedin 1.5 mg/m²; administer intravenously over 24 hours on day 1, every 3 weeks (total dosage/cycle = 1.5 mg/m²)

Administration via:

- *Central venous access:* dilute trabectedin with a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration ≤0.03 mg/mL
- *Peripheral venous access:* dilute trabectedin with ≥1000 mL 0.9% NS or D5W

Note: Trabectedin has not received U.S. Food and Drug Administration approval for use in human subjects outside clinical trials

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Starting dosage level	1.5 mg/m²
Dosage level −1	1.2 mg/m²
Dosage level −2	1 mg/m²
Adverse Event	**Dose Modification**
Febrile neutropenia: T >38°C [>100.4°F] with ANC <1000/mm³	Reduce trabectedin dosage by 1 dose level
Platelet count <25,000/mm³ lasting more than 5 days	
G4 neutropenia >5 days	
ANC <1000/mm³ at start of next cycle	Withhold treatment until ANC ≥1000/mm³, then reduce trabectedin dosage by 1 dose level

(*continued*)

Treatment Modifications (*continued*)

Platelet count <100,000/mm³ at start of next cycle	Withhold treatment until platelet count ≥100,000/mm³, then reduce trabectedin dosage by 1 dose level
ANC <1000/mm³, or platelet count <100,000/mm³ despite a 3-week delay	Discontinue trabectedin therapy
G2/3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes	Hold trabectedin up to 3 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 3 weeks then discontinue trabectedin therapy. Resume treatment if toxicity resolves to G ≤1 within 3 weeks, but reduce trabectedin dosage by 1 dose level
G2/3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes despite a reduction in trabectedin by 1 dosage level	Hold trabectedin up to 3 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 3 weeks, discontinue trabectedin therapy. Resume treatment if toxicity resolves to G ≤1 within 3 weeks, but reduce trabectedin dosage by an additional dose level
G ≥3 liver function test abnormalities	Hold trabectedin up to 3 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 3 weeks, discontinue trabectedin therapy. Resume treatment if toxicity resolves to G ≤1 within 3 weeks, but reduce trabectedin dosage by 1 dose level
G ≥3 liver function test abnormalities despite a reduction in trabectedin 1 dosage level	Hold trabectedin up to 3 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 3 weeks, discontinue trabectedin therapy. Resume treatment if toxicity resolves to G ≤1 within 3 weeks, but reduce trabectedin dosage by an additional dose level

Efficacy*

Progressive Soft-Tissue Sarcoma

Garcia-Carbonero R et al. J Clin Oncol 2004;22:1480–1490

Response to Trabectedin According to Histologic Subtype

Histology	Complete Response	Partial Response	Minor Response	Overall Response
Leiomyosarcoma (n = 13)	0	8% (1)	0	8% (1)
Liposarcoma (n = 10)	10% (1)	10% (1)	10% (1)	20% (2)

All histologies (n = 36)	3% (1)	6% 92)	6% (2)	8% (3)

Median time to progression (TTP)	1.7 months (95% CI, 1.3–4.4 months)
Estimated 1-year TTP rate	9.4% (95% CI, 3.2–27.4%)
Median overall survival (OS)	12.1 months (95% CI, 8.1–26.5 months)
Estimated 1-year OS rate	53.1% (95% CI, 38.7–72.8%)

(*continued*)

Patient Populations Studied

Progressive Soft-Tissue Sarcoma

Garcia-Carbonero R et al. J Clin Oncol 2004;22: 1480–1490

Patients with histologically confirmed recurrent or metastatic soft-tissue sarcoma with disease progression despite prior chemotherapy with 2 or fewer prior regimens for advanced disease were eligible for the trial

Myxoid Liposarcoma

Grosso F et al. Lancet Oncol 2007;8:595–602

Retrospective analysis of 51 patients with advanced pretreated myxoid liposarcoma in a compassionate-use program

Metastatic Liposarcoma/Leiomyosarcoma

Demetri GD et al. J Clin Oncol 2009;27:4188–4196

Patients >18 years old with histologic confirmation of liposarcoma or leiomyosarcoma; unresectable and/or metastatic relapse or progressive disease after prior treatment with a regimen containing at least an anthracycline and ifosfamide (combined or sequential)

Efficacy* (continued)

Myxoid Liposarcoma

Grosso F et al. Lancet Oncol 2007;8:595–602

Overall (N = 51)	Percent (Number)	95% CI
Complete response	4% (2)	
Partial response	47% (24)	
Overall response rate (ORR)	51% (26)	36–65%
Minimal response	12% (6)	
Median follow-up	14 months	8.7–20 months
Median time to reach a response†	3.6 months	IQR 2.4–4.6 months
Median PFS	14 months	95% CI 13.1–21 months
PFS at 3 months	92%	85–99%
PFS at 6 months	88%	79–95%
Median PFS of patients with PR/CR‡	20.3 months	14–30.6 months
Median PFS of patients with SD/MR‡	12.5 months	8.1–21.4 months

*RECIST (Response Evaluation Criteria in Solid Tumors; Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
†In a subgroup of 40 patients only 6 of 23 with confirmed CR/PR achieved responses by first assessment; of the other 17 patients, 8 had MR and 9 SD at first assessment; median time to reach objective response was 3.6 months. In patients without confirmed CR/PR by first assessment, early alterations in tumor appearance were detected by CT/MRI—the hallmark feature was a decrease in tumor density without substantial changes in tumor dimensions. Same early signs were seen in 12 of the 15 patients with SD as their best response confirmed during central review
‡PFS during previous chemotherapy (ie, before starting trabectedin treatment) for 34 patients for whom data were available was 8.4 months (3.1–11.1 months)

Metastatic Liposarcoma/Leiomyosarcoma

Demetri GD et al. J Clin Oncol 2009;27:4188–4196

	Time/Percent	95% CI
Time to Progression, Months (Independent Review)		
Number of events	104 (76/5%)	
Median	3.7 months	2.1–5.4 months
Number PD at 3 months	53.4%	44.6–66.2%
Number PD at 6 months	37.2%	28.4–46%
Ratio: TTP with Trabectedin-to-TTP with Last Prior Therapy		
Last prior therapy		
Number	119	
Ratio >1.33	33.6% (40)	
Last prior therapy for advanced/metastatic disease		
Number	109	
Ratio >1.33	36.7% (40)	
Median progression-free survival	3.3 months	
Median overall survival	13.9 months	

Toxicity

Progressive Soft-Tissue Sarcoma

Garcia-Carbonero R et al. J Clin Oncol 2004;22:1480–1490

Therapy Monitoring

1. *Pretreatment evaluations:* History and physical examination; complete blood count with differential and platelet count; serum chemistries; electrocardiogram; chest x-ray; computed tomography (CT) scan of the chest, abdomen, and pelvis; and documentation of tumor measurements
2. *Weekly during treatment:* Complete blood cell counts with leukocyte differential count
3. *Before each cycle:* History and physical examinations and assessment of toxicities. Serum chemistries
4. *Every 2–3 cycles:* CT scans to assess response

UNRESECTABLE LEIOMYOSARCOMA

GEMCITABINE + DOCETAXEL

Hensley ML et al. J Clin Oncol 2002;20:2824–2831

Gemcitabine 900 mg/m² per dose; administer intravenously, diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration as low as 0.1 mg/mL, over 90 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 1800 mg/m²)

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting 1 day before docetaxel administration (total dose/cycle = 48 mg)
Optional premedication for docetaxel:
Diphenhydramine HCl 25 mg; administer orally 30–60 minutes *or* intravenously 5–30 minutes prior to docetaxel administration
Ranitidine 150 mg; administer orally 30–60 minutes prior to docetaxel administration, *or*
Ranitidine 50 mg; administer intravenously 5–30 minutes prior to docetaxel administration
Docetaxel 100 mg/m²; administer intravenously, in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL, over 60 minutes on day 8 after gemcitabine, every 21 days (total dosage/cycle = 100 mg/m²)

Notes:
• Patients previously treated with radiation therapy should receive ***reduced*** dosages as follows:
Gemcitabine 675 mg/m² per dose; administer intravenously, diluted in 0.9% NS to a concentration as low as 0.1 mg/mL, over 90 minutes for 2 doses, on days 1 and 8, every 21 days (total dosage/cycle = 1350 mg/m²)

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting 1 day before docetaxel administration (total dose/cycle = 48 mg)
Optional premedication for docetaxel:
Diphenhydramine HCl 25 mg; administer orally 30–60 minutes *or* intravenously 5–30 minutes prior to docetaxel administration
Ranitidine 150 mg; administer orally 30–60 minutes prior to docetaxel administration, *or*
Ranitidine 50 mg; administer intravenously 5–30 minutes prior to docetaxel administration
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 8 after gemcitabine, every 21 days (total dosage/cycle = 75 mg/m²)
• Patients who continue to respond after receiving 6 cycles may receive 2 additional cycles of therapy

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is LOW–MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
• Antibacterial—not indicated
• Antifungal—not indicated
• Antiviral—not indicated unless patient previously had an episode of HSV
See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Febrile neutropenia or platelet count <25,000/mm³ lasting more than 5 days	Reduce gemcitabine and docetaxel dosages by 25% in all subsequent cycles
ANC <1000/mm³ at start of next cycle	Withhold treatment until ANC ≥1000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
Platelet count <100,000/mm³ at start of next cycle	Withhold treatment until platelet count ≥100,000/mm³, then reduce gemcitabine and docetaxel dosages by 25%
ANC <1000/mm³ or platelet count <100,000/mm³ despite 2-week delay	Discontinue therapy
Day 8 ANC 500–999/mm³ or day 8 platelet count 50,000–99,000/mm³	Reduce day 8 gemcitabine and docetaxel dosages by 25%
Day 8 ANC <500/mm³ or day 8 platelet count <50,000/mm³	Do not administer day 8 gemcitabine and docetaxel
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks then discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks but reduce gemcitabine and docetaxel dosages by 25%
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%
G ≥3 liver function test abnormalities	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by 25%
G ≥3 liver function test abnormalities despite a 25% reduction in initial gemcitabine and docetaxel dosages	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks then discontinue therapy. Resume treatment if toxicity resolves to G ≤1 within 2 weeks, but reduce gemcitabine and docetaxel dosages by an additional 25%
G4 mucositis and diarrhea	Discontinue therapy
G2 neuropathy	Delay therapy 1 week. If symptoms do not resolve to G ≤1, reduce docetaxel dosage by 25%
G3 neuropathy	Discontinue therapy
Febrile neutropenia (T >38°C [>100.4°F] with ANC <1000/mm³)	Reduce gemcitabine and docetaxel doses by 25%
G3/4 hematologic toxicity	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue therapy

Efficacy

Leiomyosarcoma (LMS) (N = 34)*

Best Response	Percent (Number of Patients)	95% CI
Complete response	8.8 % (3)	
Partial response	44% (15)	
Minor response/stable disease	23.5% (8)	
Progression of disease	26.5% (9)	
Overall objective response†	53% (18)	35–70%
Median duration of response	4 months	3 months–NR‡
Median progression-free survival	5.6 months	4.3–9.9 months
Progression-free at 6 months	47%	32–68%
Median overall survival	17.9 months	11.6 months—NR
Alive at 6 months	66%	49–88%
Patients Previously Treated with Doxorubicin ± Ifosfamide (N = 16)		
Overall objective response	50% (8)	

NR, Not reached
*RECIST criteria (Response Evaluation Criteria in Solid Tumors; Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
†Among 5 patients with non-uterine primary LMS, 2 (40%) had PRs

Toxicity*

(N = 34 patients/160 cycles)

Sensory neuropathy	2	6	—	—
Allergic reaction	1	3	—	—
Venous thrombosis	—	—	1	3

*National Cancer Institute (USA), Common Toxicity Criteria, version 2.0

Patient Population Studied

Patients with histologically confirmed LMS of the uterus or of other primary site that was considered unresectable for cure and who had received zero to 2 previous chemotherapy regimens for treatment of LMS

Therapy Monitoring

1. *Pretreatment evaluations:* History and physical examination; complete blood count with differential and platelet count; serum chemistries; electrocardiogram; chest X-ray, computed tomography (CT) scan of the chest, abdomen, and pelvis; and documentation of tumor measurements
2. *Weekly during treatment:* Complete blood cell counts with leukocyte differential count
3. *Before each cycle:* History and physical examinations and assessment of toxicities. Serum chemistries
4. *Every 2–3 cycles:* CT scans to assess response

RELAPSED/REFRACTORY SOFT-TISSUE AND BONE SARCOMA

VINCRISTINE, ORAL IRINOTECAN, AND TEMOZOLOMIDE (VOIT)

Wagner LM et al. Pediatr Blood Cancer 2010;54:538–545

Temozolomide 150 mg/m² per day; administer orally for 5 consecutive days at least 1 hour before vincristine and irinotecan, on days 1–5, every 21 days (total dosage/cycle = 750 mg/m²)
- Temozolomide doses are rounded to the nearest 5 mg to utilize commercially available products

Vincristine 1.5 mg/m² (maximum dose = 2 mg); administer by intravenous injection over 1–2 minutes on day 1, every 21 days (total dosage/cycle = 1.5 mg/m²; maximum dose/cycle = 2 mg)
Irinotecan 90 mg/m² per day; administer orally for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 450 mg/m²)
- Doses were prepared from an injectable formulation of irinotecan
- Five doses were prepared in individual oral syringes and dispensed with instructions to store under refrigeration until they were used
- Irinotecan solution was mixed with cranberry-grape juice immediately before administration to mask its bitter flavor

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–5 is ***MODERATE–HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
- The potential for developing diarrhea and abdominal pain should be discussed with all patients and their caretakers, and instructions given to start loperamide immediately if these symptoms occur and to ensure adequate hydration is maintained. See "Dose Modifications" below for instructions

Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic primary prophylaxis and treatment during latent or delayed onset diarrhea:

Consider the following to prevent or lessen irinotecan-associated diarrhea:

- Prophylactic oral **cefixime** 8 mg/kg (maximum dose of 400 mg) orally once daily, beginning 1–2 days prior to the start of irinotecan therapy and continuing until completion of the cycle, *alternatively:*
- **Cefpodoxime proxetil** 5 mg/kg orally, twice daily (maximum dose of 200 mg twice daily)
  - Previous studies suggest prophylaxis with cephalosporin antibiotics can ameliorate irinotecan-associated diarrhea by reducing the enteric bacteria responsible for producing β-glucuronidase, which regenerates in the gut irinotecan's toxic metabolite, SN-38, by cleaving the glucuronide moiety from SN-38 (Wagner LM et al. Pediatr Blood Cancer 2008;50:201–207)
- Alternatively, **activated charcoal** at a dose equal to 5-times the irinotecan dose up to a maximum dose of 260 mg orally 3 times daily during irinotecan therapy (Michael M et al. J Clin Oncol 2004;22:4410–4417)

Antibiotic treatment during latent or delayed onset diarrhea

- A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

Antibiotics should also be administered if a patient is hospitalized with prolonged diarrhea, and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Dose Modifications

Irinotecan Dosage Levels*	
Level 1 starting dosage	90 mg/m² per day orally on days 1–5
Level −1	70 mg/m² per day orally on days 1–5
Level −2	50 mg/m² per day orally on days 1–5
Temozolomide Dosage Levels	
Level 1 starting dosage	150 mg/m² per day orally on days 1–5
Level −1	125 mg/m² per day orally on days 1–5
Level −2	100 mg/m² per day orally on days 1–5
Vincristine Dosage Levels	
Level 1 starting dosage	1.5 mg/m² (maximum single dose = 2 mg) by intravenous injection
Level −1	0.75 mg/m² (maximum single dose = 2 mg) by intravenous injection

(*continued*)

Patient Population Studied

Patients older than 12 months and younger than 21 years with solid tumors refractory to standard therapy and no other curative option. Patients were excluded if they had received treatment with agents known to affect irinotecan metabolism (eg, enzyme-inducing anticonvulsants), or if they had previously received treatment with temozolomide or irinotecan or had experienced prior progression of their tumor with either agent

Dose Modifications (*continued*)

Adverse Event	Dose Modification
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia during a given cycle	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia during a given cycle	Reduce dosage of irinotecan and temozolomide by 1 dosage level
G4 neutropenia >7 days duration	Reduce dosage of irinotecan and temozolomide for the following cycle by 1 dose level
G3/4 infection	
Day 21 ANC <1000/mm³ or platelet count <75,000/mm³	Delay start of next cycle by 1 week and reduce dosage of irinotecan and temozolomide by 1 level
Day 28 ANC still <1000/mm³ or platelet count still <75,000/mm³	Delay start of next cycle by 1 additional week and reduce dosage of irinotecan and temozolomide by 1 level
Day 35 ANC still <1000/mm³ or platelet count still <75,000/mm³	Discontinue therapy
Diarrhea in Children 2–15 Years of Age	
Children 2–15 years, with first liquid stools	Begin loperamide immediately with the first liquid stool at a dosage of loperamide 0.03 mg/kg administered orally every 4 hours (0.18 mg/kg/24h)
G3/4 diarrhea within the first 24 hours	Hospitalize for optimal management. Begin **loperamide** 0.06 mg/kg, orally, every 4 hours. Reduce irinotecan dosage for the following cycle by 1 dose level
Delayed Diarrhea in Patients >15 Years of Age	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of 1 or all agents by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of 1 or all agents by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage of 1 or all agents by 2 dosage levels
G 2 neurotoxicity	Reduce vincristine dosage by 50% (if receiving 2 mg maximum, reduce to 1 mg)
G 3/4 neurotoxicity	Discontinue vincristine

*Treatment should be stopped in case of recurrent toxicity at dose level −2, unless there is perceived clinical benefit from irinotecan that justifies continuation

André T et al. Eur J Cancer 1999;35:1343–1347
Camptosar irinotecan hydrochloride injection, product label, August 2010. Pharmacia & Upjohn Company, Division of Pfizer, Inc., New York, NY

Irino, Irinotecan; Tem, temozolomide

Therapy Monitoring

1. *Prior to enrollment:* Complete medical history, clinical examination, performance status, hematologic and serum chemistries, cardiac evaluation in case of prior treatment with anthracyclines or mediastinal irradiation, and tumor target assessment
2. *Day 1 of each treatment cycle:* Physical examination, ECOG PS, complete blood count with leukocyte differential count, and serum chemistries
3. *Weekly CBC:* At least during the first 6 cycles of therapy
4. *After every 2 cycles of therapy:* Tumor measurements

ADVANCED SOFT-TISSUE AND BONE SARCOMA

DOXORUBICIN + DACARBAZINE (AD)

Antman K et al. J Clin Oncol 1993;11:1276–1285

Doxorubicin 15 mg/m² per day; administer intravenously in 25–1000 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over 24 hours, for 4 consecutive days (96 hours), every 21 days (total dosage/cycle = 60 mg/m²)
Dacarbazine 250 mg/m² per day; administer intravenously, in 100–250 mL 0.9% NS or D5W over 24 hours for 4 consecutive days (96 hours), every 21 days (total dosage/cycle = 1000 mg/m²)

Important:
- Doxorubicin and dacarbazine are sensitive to photodegradation
  - Doxorubicin product containers should be protected from light
  - Prevent dacarbazine exposure to sunlight. Cover dacarbazine product containers with opaque material or foil and use light opaque or light resistant administration sets, or wrap tubing with opaque material or foil during drug administration

Notes:
Treatment courses were repeated at 21 days or when the WBC count reached 3000/mm³ and the platelet count reached 100,000/mm³

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with 1 of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC ≥10,000/mm³ on 2 measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm^3 or platelets <100,000/mm^3	Delay treatment 1 week until WBC ≥3000/mm^3 and platelets ≥100,000/mm^3
>2-week delay in start of cycle	Reduce doxorubicin and dacarbazine dosages by 25%
WBC nadir <1000/mm^3 or platelet nadir <30,000/mm^3	Reduce doxorubicin and dacarbazine dosages by 50%
WBC nadir 1000–1499/mm^3 or platelet nadir 30,000–49,500/mm^3	Reduce doxorubicin and dacarbazine dosages by 25%
G ≥3 mucositis	Reduce doxorubicin dosage 10–15 mg/m^2
Doxorubicin total cumulative lifetime dosage >400–450 mg/m^2	Obtain frequent MUGA scans to monitor cardiac function
Decreased cardiac ejection fraction (suggested guidelines): resting cardiac ejection fraction decreased ≥10–15% from baseline, or to absolute values <35–40%	Discontinue therapy

Patient Population Studied

At the time the study was designed, doxorubicin alone or with dacarbazine (AD) was considered the best available therapy for metastatic adult sarcomas. Ifosfamide was thought to be active in sarcomas that did not respond to a doxorubicin-based regimen. The study was designed to determine if ifosfamide added to doxorubicin and dacarbazine (ADI) significantly affected toxicity, response rate, and survival. Patients with measurable metastatic or unresectable sarcoma were randomly assigned to receive AD or ADI. Patients with chondrosarcomas, fibrosarcomas, and other sarcomas of bone were eligible, although those with osteosarcoma, rhabdomyosarcoma, Ewing sarcoma, Kaposi sarcoma, and mesothelioma were excluded, as were patients with prior chemotherapy for sarcoma or prior doxorubicin

Efficacy

Response Rates and Duration (N = 169)	
Complete response	2% (4)
Partial response	15% (25)
Responses by Measurements	
No further x-rays	2% (3)
Stable	41% (69)
Increasing disease	35% (59)
Early death, assumed no response	2% (4)
No evaluation, assumed no response	3% (5)
Total	100 (169)
Time to progression, median	4 months
Duration of response, median	8 months
Responses for Radiation-Associated Sarcomas (N = 13)	
Complete response	0
Partial response	8% (1)

Responses by Tumor Grade	Grade I or II	Grade III
Complete response	0% (0)	4% (4)
Partial response	12% (9)	17% (16)
Response by Measurements		
No further x-rays	1% (1)	2% (2)
Stable	43% (32)	39% (37)
Increasing disease	40% (30)	31% (29)
Early death, assumed no response	1% (1)	3% (3)
No evaluation, assumed no response	3% (2)	3% (3)
Total	100% (75)	100% (94)

Responses by Histology	% CR	% ORR
Leiomyosarcoma (N = 59)	2	16
Other common histologies (N = 7)	0	71
All other histologies (N = 44)	5	14

Toxicity

Number of Cases of Severe, Life-Threatening, and Lethal Toxicities (N = 170)

	Severe/Life-Threatening	Lethal
Anemia	11	0
Leukopenia	55	0
Granulocytopenia	64	0
Infections	0	0
Thrombocytopenia	7	0
Bladder, hematuria	0	0
Renal, other	0	0
Cardiac	2	0
Pulmonary embolism	0	1
CNS, somnolence/coma	0	0
Nausea/vomiting	15	0
Mucositis/ulcers/stomatitis	12	0
Diarrhea	1	0
Weight loss	0	0
Hepatic	0	0
Maximum grade of any toxicity	94 (55%)	1 (0.6%)

Therapy Monitoring

1. *Pretreatment evaluations:* History and physical examination; complete blood count with differential and platelet count; serum chemistries; electrocardiogram; chest x-ray, computed tomography (CT) scan of the chest, abdomen, and pelvis; and documentation of tumor measurements
2. *Weekly during treatment:* Complete blood cell counts with leukocyte differential count
3. *Before each cycle:* History and physical examinations and assessment of toxicities. Serum chemistries
4. *Every 2–3 cycles:* CT scans to assess response

DERMATOFIBROSARCOMA PROTUBERANS

IMATINIB MESYLATE

Rutkowski P et al. J Clin Oncol 2010;28:1772–1779

Note: Dermatofibrosarcoma protuberans (DFSP) is a dermal sarcoma typically carrying a translocation between chromosomes 17 and 22 that generates functional platelet-derived growth factor B (PDGFB)

Starting dose: **Imatinib mesylate** 400 mg/day; administer orally with food and a large glass of water (total dose/week = 2800 mg)
Dose escalation: **Imatinib mesylate** 600–800 mg/day; administer orally with food and a large glass of water (total dose/week = 4200–5600 mg)

Notes:
- 400- and 600-mg doses may be given once daily, or, alternatively, may be split into 2 equal doses, one given during morning hours and a second dose during the evening
- 800-mg daily doses should be given as two 400-mg doses, one during morning hours and a second dose during the evening
- For patients unable to swallow the film-coated tablets, imatinib mesylate may be dispersed in a glass of water or apple juice. The required number of tablets should be placed in an appropriate volume of beverage (approximately 50 mL for a 100-mg tablet, and 200 mL for a 400-mg tablet) and stirred with a spoon. The suspension should be administered immediately after the tablets have completely disintegrated

Note: Response rates and TTP did not differ between patients taking 400 mg daily versus 400 mg twice a day

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807

Dose Modifications

Dosage Levels*
800 mg
600 mg
400 mg
300 mg
200 mg

Adverse Event	Treatment Modification
Hematologic*	
G1/2	No modifications
Recurrence of a G2 toxicity	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 lower dose level
First episode of a G3/4 toxicity	Hold imatinib until toxicity resolves to G ≤1; then restart at the same dose
Second episode of a G3/4 toxicity	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 lower dose level
Recurrent G2/3/4 at a reduced dose	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 dose level lower, or for recurrent G4, consider discontinuing imatinib
Nonhematologic	
G1	No dose modifications
First episode of a G2 toxicity	Hold imatinib until toxicity resolves to G ≤1; then restart at the same dose
Recurrence of a G2 toxicity (second G2)	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 lower dose level
G3/4	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 lower dose level
Recurrent G2/3/4 at a reduced dose	Hold imatinib until toxicity resolves to G ≤1; then restart at 1 dose level lower, or for recurrent G4, consider discontinuing imatinib

*No dose modifications for anemia. Growth factors were allowed but not recommended

Patient Population Studied

Patients from 2 distinct phase II trials of imatinib (400–800 mg daily) in patients with locally advanced or metastatic DFSP were conducted and closed prematurely, one in Europe (European Organization for Research and Treatment of Cancer [EORTC]) with 14-week progression-free rate as the primary end point and the other in North America (Southwest Oncology Group [SWOG]) with confirmed objective response rate as the primary end point. In the EORTC trial, confirmation of *PDGFB* rearrangement was required, and surgery was undertaken after 14 weeks if feasible. The SWOG study confirmed t(17;22) after enrollment

Efficacy

Dermatofibrosarcoma Protuberans (DFSP) Best Response by Subtype (N = 24)

	Number of Patients

DFSP, Dermatofibrosarcoma protuberans; EORTC, European Organization for Research and Treatment of Cancer; SWOG, Southwest Oncology Group; No., number of patients; %, percentage of patients

*National Cancer Institute (USA), Common Terminology Criteria for Adverse Events, version 3.0

†Hypertension, arterial hypertension; H&N edema, head and neck edema; L/T/V edema: limbs/truncal/visceral edema

‡Grade 4; 2 toxic grade 4 events were noted in 1 patient with preexisting liver disturbances and alcohol abuse history: thrombocytopenia and increased serum AST

Therapy Monitoring

1. *Day 7 and at least monthly for 6 months, then every 3 months:* History and physical examination
2. *Weekly:* Complete blood count with leukocyte differential count
3. *Twice monthly first 2 months, then monthly for 6, then every 3 months:* Liver function tests
4. *At end of month 2 and every 3 months thereafter:* Radiographic assessments were using the same modality as had been performed at baseline

SOFT-TISSUE SARCOMAS: GI STROMAL TUMORS (GIST)

Epidemiology

Incidence: 2000–5000 estimated cases in the United States annually
Male to female ratio: 1:1

Gastrointestinal stromal tumors (GIST) account for <1% of all primary tumors of the gastrointestinal tract

Site of Disease	% of Patients
Stomach	60–70
Small bowel	20–30
Other*	10

*Large bowel, esophagus, rectum, mesentery, and omentum

Work-up

1. History and physical examination
2. *Laboratory tests:* CBC with differential, electrolytes, LFTs
3. PA and lateral chest x-ray
4. Contrast-enhanced CT scan of chest, abdomen, and pelvis
5. PET scan can complement conventional CT helping to differentiate benign from malignant tissue (Van den Abbeele A, Badawi R. Eur J Cancer 2002;38(Suppl 5):S60–S65)
6. Upper endoscopy or endoscopic ultrasound-guided (EUS) fine-needle biopsy to obtain a tissue diagnosis. EUS can usually accurately differentiate leiomyoma and leiomyosarcoma

Histologic Classification

Cell Type	% of Tumors
Spindle	70
Epithelioid	20
Mixed	10

KIT Mutations

Mutation	Site	% Incidence
Exon 11	Juxtamembrane domain	67
Exon 9	External domain	17
Exon 13	TK1	2
Exon 17	TK2	2
None*		13

*Wild-type *KIT*, although some have mutant *PDGFRA*
Heinrich MC et al. J Clin Oncol 2002;21:4342–4349

Expert Opinion

1. GIST consist of mesenchymal tumors that arise from the interstitial cells of Cajal (ICC) in the myenteric plexus
2. The true incidence of these tumors remains unknown, because until relatively recently, they were classified as tumors either of smooth muscle (eg, leiomyosarcomas) or of neural crest origin (eg, schwannomas)
3. Because nearly all GIST express the cell surface tyrosine kinase receptor, c-*KIT*, immunohistochemical staining facilitates the diagnosis
4. More than 90% of patients with GIST have activating *KIT* or *PDGFR*-α mutations (platelet-derived growth factor receptor-α)
5. Oncogenic mutations result in activation of *KIT* and its downstream pathways leading to uncontrolled cell division and resistance to apoptosis
6. Complete surgical resection remains the gold standard in the treatment of localized GIST. The goal of surgery is to remove all disease with negative resection margins. This is accomplished in up to 60% of GIST. Because nodal metastases are rare, lymphadenectomy is unnecessary. However, peritoneal surfaces and liver should be closely examined at laparotomy for evidence of metastatic spread
7. Despite curative resection, most patients subsequently have recurrence; the median time to recurrence is 1.5–2 years. The most acceptable and easily applied morphologic criteria for predicting tumor behavior are tumor size and mitotic rate
8. GIST is considered resistant to standard chemotherapy regimens for sarcomas such as doxorubicin and ifosfamide
9. Imatinib (STI571/Glivec/Gleevec) is an orally administered small-molecule selective tyrosine kinase inhibitor that is active in GIST (Demetri et al). Imatinib inhibits the activity of tyrosine kinases such as Bcr-Abl, PDGFR-α and the stem cell factor receptor c-*KIT*. As a competitive antagonist of ATP binding, imatinib blocks the ability of the kinases to transfer phosphate groups from ATP to tyrosine residues on substrate proteins, interrupting signal transduction
10. Clinical response to imatinib and survival rates seem to correlate with the presence or absence of certain *KIT* mutations: Mutations in exon 11 that encodes the intracellular juxtamembrane domain account for ≈70% of cases and are associated with an 85% response rate to imatinib
11. Imatinib is less effective in tumors without *KIT* mutations and in those with *KIT* mutations other than exon 11
12. The mutational status of *KIT* also seems to influence the progression-free survival, with longer survival in patients who harbor exon 11 mutations compared with those lacking an exon 11 mutation (Singer et al, J Clin Oncol 2002;20:3898–3905)
13. Because PDGFR-α is also an imatinib substrate, some tumors without *KIT* mutations respond to imatinib. However, unlike *KIT* mutations, most *PDGFR*-α mutations occur in the kinase domain and are unresponsive to imatinib
14. Over time, acquired resistance to imatinib is seen in approximately 20% of patients. In view of the high likelihood of tumor recurrence in these patients, imatinib is now recommended in the adjuvant setting. It is possible that it will have its maximal effect in the setting of minimal disease
15. The ACOSOG Z9001 trial demonstrated that the risk of recurrence in patients with resected GIST could be reduced by 1 year of adjuvant imatinib. Subsequently, the SSGXVIII/AIO trial demonstrated that 3 years of adjuvant imatinib was superior to 1 year of therapy in patients at high risk of recurrence after surgery by prolonging both recurrence-free survival and overall survival

Demetri GD et al. N Engl J Med 2002;347:472–480
Singer S et al. J Clin Oncol 2002;20:3898–3905

ADJUVANT REGIMEN

IMATINIB MESYLATE FOR 1 YEAR (ACOSOG Z9001)

DeMatteo RP et al. Lancet 2009;373:1097–1104

Starting dose: **Imatinib mesylate** 400 mg/day; administer orally with food and a large glass of water (total dose/week = 2800 mg)
Dose escalation: **Imatinib mesylate** 600--800 mg/day; administer orally with food and a large glass of water (total dose/week = 4200–5600 mg)

Notes:
- 400- and 600-mg doses may be given once daily, or, alternatively, may be split into 2 equal doses, one given during morning hours and a second dose during the evening
- 800-mg daily doses should be given as two 400-mg doses, one during morning hours and a second dose during the evening
- For patients unable to swallow the film-coated tablets, imatinib mesylate may be dispersed in a glass of water or apple juice. The required number of tablets should be placed in an appropriate volume of beverage (approximately 50 mL for a 100-mg tablet, and 200 mL for a 400-mg tablet) and stirred with a spoon. The suspension should be administered immediately after the tablets have completely disintegrated

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

ALT, alanine aminotransferase; AST, aspartate aminotransferase
*Grade 5:3 (1%)

Patient Population Studied

Randomized phase III, double-blind, placebo-controlled, multicenter trial. Eligible patients had complete gross resection of a primary GIST ≥3 cm in size and positive for the KIT protein by immunohistochemistry. Patients were randomly assigned to imatinib 400 mg (N = 359) or to placebo (N = 354) daily for 1 year after surgical resection. Patients and investigators were blinded to the treatment assignments. Patients assigned to placebo were eligible to crossover to imatinib treatment in the event of tumor recurrence. The primary end point was recurrence-free survival, and analysis was by intention-to-treat. Accrual was stopped early because the trial results crossed the interim analysis efficacy boundary for recurrence-free survival in favor of imatinib

Therapy Monitoring

1. *Day 7 and at least monthly for 6 months, then every 3 months:* History and physical examination
2. *Weekly:* Complete blood count with leukocyte differential count
3. *Twice monthly first 2 months, then monthly × 6, then every 3 months:* Liver function tests
4. *Every 3 months for the first 2 years, and every 6 months for the next 3 years:* CT scans with intravenous and oral contrast (or MRI with intravenous contrast) of the abdomen and pelvis

ADJUVANT REGIMEN

IMATINIB MESYLATE FOR 3 YEARS (SSGXVIII/AIO)

Joensuu H et al. JAMA 2012;307:1265–1272

Starting dose: **Imatinib mesylate** 400 mg/day; administer orally with food and a large glass of water (total dose/week = 2800 mg)
Dose escalation: **Imatinib mesylate** 600--800 mg/day; administer orally with food and a large glass of water (total dose/week = 4200–5600 mg)

Notes:
- 400- and 600-mg doses may be given once daily, or, alternatively, may be split into 2 equal doses, one given during morning hours and a second dose during the evening
- 800-mg daily doses should be given as two 400-mg doses, one during morning hours and a second dose during the evening
- For patients unable to swallow the film-coated tablets, imatinib mesylate may be dispersed in a glass of water or apple juice. The required number of tablets should be placed in an appropriate volume of beverage (approximately 50 mL for a 100-mg tablet, and 200 mL for a 400-mg tablet) and stirred with a spoon. The suspension should be administered immediately after the tablets have completely disintegrated

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Wadler S et al. J Clin Oncol 1998;16:3169–3178

Dose Modifications

Dosage Levels*	
Initial dose	400 mg/day
First dose reduction	300 mg/day
Second dose reduction	200 mg/day
Hematologic*	
G1/2	No modifications
Recurrence of a G2 toxicity	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 lower dose level
First episode of a G3/4 toxicity	Hold imatinib until toxicity resolves to G ≤1, then restart at the same dose
Second episode of a G3/4 toxicity	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 lower dose level
Recurrent G2/3/4 at a reduced dose	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 dose level lower, or for recurrent G4, consider discontinuing imatinib
Nonhematologic	
G1	No dose modifications
First episode of a G2 toxicity	Hold imatinib until toxicity resolves to G ≤1, then restart at the same dose
Recurrence of a G2 toxicity (second G2)	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 lower dose level
G3/4	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 lower dose level
Recurrent G2/3/4 at a reduced dose	Hold imatinib until toxicity resolves to G ≤1, then restart at 1 dose level lower, or for recurrent G4, consider discontinuing imatinib

*No dose modifications for anemia. Growth factors were allowed but not recommended

*Safety cohort

Patient Population Studied

A randomized phase III multicenter trial of adjuvant imatinib as treatment of operable GIST with a high risk of recurrence (SSGXVIII/AIO) according to the modified consensus criteria (Fletcher CDM et al. Hum Pathol 2002;33:459–465). Eligible patients had complete gross resection and of a primary GIST positive that was for the KIT protein by immunohistochemistry
Patients must also have a high risk of recurrence

- Tumor diameter >10 cm
- Tumor mitosis count >10/50 high-power fields, *or*
- Tumor rupture spontaneously or at surgery

Patients were randomly assigned to imatinib 400 mg daily for 1 or 3 years after surgical resection. Stratification: (a) R0 resection, no tumor rupture; (b) R1 resection *or* tumor rupture

Therapy Monitoring

First year:

1. *Every 1–3 months:* History and physical examination
2. *Every 2–12 weeks:* Complete blood counts with leukocyte differential and serum chemistry
3. *Every 6 months:* CT/MRI of abdomen and pelvis

Years 2 and 3:

1. *Every 6 months:* History and physical examination
2. *Every 6 months:* Complete blood counts with leukocyte differential and serum chemistry
3. *Every 6 months:* CT/MRI of abdomen and pelvis

†National Cancer Institute (USA), Common Toxicity Criteria, version 2.0 (NCI CTC v2.0)

Patient Population Studied

Seven-hundred forty-six patients metastatic or surgically unresectable GIST were eligible for this phase III open-label clinical trial. At registration, patients were randomly assigned to either standard- or high-dose imatinib with close interval follow-up. If objective progression occurred by RECIST, patients on the standard-dose arm could reregister to the trial and receive the high-dose imatinib regimen. Patients were required to have measurable or nonmeasurable, visceral or intraabdominal, biopsy-proven GIST, which were not surgically curable. Tumors had to express CD117 by immunohistochemical staining. Any number of prior chemotherapy regimens was allowed

Partial response	45%	48%
No change	32%	32%
Progression	13%	9%
Not assessable	5%	5%

*Verweij J et al. Lancet 2004;364:1127–1134
†RECIST

Notes: These studies confirmed the effectiveness of imatinib as primary systemic therapy for patients with incurable GIST but showed limited advantage to higher dose (800 mg) treatment. The authors concluded:

- It appears reasonable to initiate therapy with 400 mg daily and to consider dose escalation on progression of disease (Blanke CD et al. J Clin Oncol 2008;26:626–632)
- If response induction is the only aim of treatment, a daily dose of 400 mg of imatinib is sufficient; however, a dose of 400 mg twice daily achieves significantly longer progression-free survival (Verweij J et al. Lancet 2004;364:1127–1134)

Therapy Monitoring

1. *Day 7 and at least monthly for 6 months, then every 3 months:* History and physical examination
2. *Weekly:* Complete blood count with leukocyte differential
3. *Twice monthly for the first 2 months, then monthly for 6 months, then every 3 months:* Liver function tests
4. *At the end of month 2, and every 3 months thereafter:* Radiographic assessments using the same modality as had been performed at baseline

METASTATIC REGIMEN

SUNITINIB

Demetri GD et al. Lancet 2006;368:1329–1338

Starting dose: **Sunitinib malate** 50 mg; administer orally, daily, continually for 4 consecutive weeks followed by a 2-week period without treatment, every 6 weeks (total dose/week = 350 mg; total dose per 6-week cycle = 1400 mg)

Notes:

- Dose interruption and dose modifications in 12.5-mg increments or decrements are recommended based on individual safety and tolerability
- Strong CYP3A4 inhibitors may increase sunitinib plasma concentrations
  - When medically appropriate, replace concomitant strong CYP3A4 inhibitors with medications that do not or minimally inhibit CYP3A4
  - A dose reduction for sunitinib to 37.5 mg/day should be considered if sunitinib must be co-administered with a strong CYP3A4 inhibitor
- CYP3A4 inducers such as rifampin may decrease sunitinib plasma concentrations
  - When medically appropriate, replace concomitant CYP3A4 inducers with medications that do not or minimally induce CYP3A4
  - A dose increase for sunitinib to a maximum of 87.5 mg/day should be considered if sunitinib must be co-administered with a CYP3A4 inducer

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(*continued*)

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hypertension Management

Persistent **CTCAE G1** = Prehypertension: SBP 120–139 mm Hg; DBP 80–89 mm Hg

Antihypertensive therapy: None
Blood pressure monitoring: Standard
Sunitinib dose modification: No change

Persistent **CTCAE G1** = Stage 1 (moderate) HTN: SBP 140–159 mm Hg; DBP 90–99 mm Hg

Antihypertensive therapy:

Step 1 Initiate DHP-CCB treatment, and, if needed, after 24–48 hours, increase the dose in incremental steps every 24–48 hours until BP is controlled or a maximum dose is reached

Step 2 If BP still not controlled, add another antihypertensive, a BB, ACEI, ARB, or ABB. Increase dose of the second drug as described in Step 1

Step 3 If BP still not controlled, add a third drug from the antihypertensives listed in Step 2; increase dose of this drug as described in Step 1

Step 4 If BP is still not controlled, consider either 1 dose level reduction or discontinuing sunitinib

Note: Stopping or decreasing sunitinib doses is expected to cause a decrease in BP. Treating clinicians should monitor the patient for hypotension and adjust the number and dose of antihypertensive medications accordingly

Blood pressure monitoring: BP should be monitored as recommended by the treating clinician
Sunitinib dose modification: No changes except as described for Step 4

Persistent **CTCAE G3** = Stage 2 (severe) HTN: SBP >160 mm Hg; DBP >100 mm Hg

Antihypertensive therapy: Withhold sunitinib until systolic BP <159 mm Hg and diastolic BP <99 mm Hg
BP management is identical to that for Grade 2 (see Steps 1–4 above) with 2 major exceptions:

1. If SBP >180 mm Hg or DBP >110 mm Hg and the patient is symptomatic:
   Optimal management with intensive IV support in ICU. Discontinue sunitinib and notify other medically responsible healthcare providers that stopping sunitinib may result in a decrease in BP, *and*
2. If SBP >180 mm Hg or DBP >110 mm Hg and the patient is asymptomatic:
   Two new antihypertensives must be given together in Step 1 (and dose escalated appropriately as in Step 1)

Note: Stopping or decreasing sunitinib dose is expected to cause a decrease in BP. Treating clinicians should monitor the patient for hypotension and adjust the number and dose of antihypertensive medications accordingly

Blood pressure monitoring: BP should be monitored as recommended by the treating clinician unless the patient is symptomatic with SBP >180 mm Hg or DBP >110 mm Hg in which case, monitoring should be intensive

Sunitinib dose modification:

1. Withhold sunitinib until SBP <159 mm Hg and DBP <99 mm Hg
2. In most circumstances, if BP cannot be controlled after an optimal trial of antihypertensive medications, consider either 1 dose level reduction or discontinuing sunitinib
3. If a patient requires hospitalization for management of symptomatic SBP >180 mm Hg or DBP >110 mm Hg, permanently discontinue sunitinib, or if BP is controlled, resume sunitinib with dose decreased by 1 dose level

(*continued*)

Hypertension Management (*continued*)

CTCAE G4 = Life-threatening consequences of hypertension

Antihypertensive therapy:

1. Optimal management with intensive parenteral support in ICU
2. Discontinue sunitinib and notify other medically responsible healthcare providers that stopping sunitinib may result in a decrease in BP

Blood pressure monitoring: Intensive

Sunitinib dose modification: Permanently discontinue sunitinib, or if BP is controlled, resume sunitinib with dose decreased by one dose level

ABB, α/β-Adrenergic blockers; ACEI, angiotensin-converting enzyme inhibitors; ARB, angiotensin II receptor blockers; BB, selective β-adrenergic blockers; CTCAE, National Cancer Institute (USA), Common Terminology Criteria for Adverse Events; DBP, diastolic blood pressure; DHP-CCB, dihydropyridine calcium-channel blockers; HTN, hypertension; SBP, systolic blood pressure

Notes: (Hypertension grading is based on the CTCAE, version 4.0)

- When SBP and DBP fall into different categories, the higher category should be selected in classifying an individual's blood pressure status
- Discontinue sunitinib if patients require delaying treatment >2 weeks for management of hypertension
- Discontinue sunitinib if patients require >2 dose reductions
- Patients may receive up to 2 drugs for managing hypertension prior to decreasing sunitinib dose
- Allow an interval of at least 24 hours between modifications of antihypertensive therapy

Commercially Available Orally Administered Antihypertensives

Pharmacologic Categories	Drug Name* (formulation)	Initial Dose	Intermediate Dose	Maximum Recommended Dose	Metabolism
Dihydropyridine calcium-channel blockers (DHP-CCB)	**Nifedipine (extended release)**	**30 mg daily**	**60 mg daily**	**90 mg daily**	**CYP3A4 substrate**
	Amlodipine besylate	**2.5 mg daily**	**5 mg daily**	**10 mg daily**	**CYP3A4 substrate**
	Felodipine (extended release)	2.5 mg daily	5 mg daily	10 mg daily	CYP3A4 substrate and inhibitor
Selective β-adrenergic blockers (BB)	Metoprolol tartrate	25 mg twice daily	50 mg twice daily	100 mg twice daily	CYP2D6 substrate
	Atenolol	**25 mg daily**	**50 mg daily**	**100 mg daily**	**No**
	Acebutolol HCl	100 mg twice daily	200–300 mg twice daily	400 mg twice daily	Yes (CYP450 unknown)
	Bisoprolol fumarate	2.5 mg daily	5–10 mg daily	20 mg daily	Yes (CYP450 unknown)
Angiotensin-converting enzyme inhibitors (ACEIs)	Captopril	12.5 mg 3 times daily	25 mg 3 times daily	50 mg 3 times daily	CYP2D6 substrate
	Enalapril maleate	5 mg daily	10–20 mg daily	40 mg daily	CYP3A4 substrate
	Ramipril	2.5 mg daily	5 mg daily	10 mg daily	Liver esterases and phase II metabolism; ie, not CYP450
	Lisinopril	**5 mg daily**	**10–20 mg daily**	**40 mg daily**	**Minimally, not CYP450**
	Fosinopril sodium	10 mg daily	20 mg daily	40 mg daily	Hydrolyzed by intestinal and hepatic esterases; ie, not CYP450
	Perindopril erbumine • rarely used	**4 mg daily**	**None**	**8 mg daily**	**Hydrolysis and phase II metabolism; ie, not CYP450**
	Quinapril • rarely used	**10 mg daily**	**20 mg daily**	**40 mg daily**	**No**
Angiotensin II receptor blockers (ARBs)	Losartan	25 mg daily	50 mg daily	100 mg daily	CYP3A4 substrate
	Candesartan	4 mg daily	8–16 mg daily	32 mg daily	CYP2C9 substrate
	Irbesartan	75 mg daily	150 mg daily	300 mg daily	CYP2C9 substrate
	Telmisartan	**40 mg daily**	**None**	**80 mg daily**	**Phase II metabolism; ie, not CYP450**
	Valsartan	**80 mg daily**	**None**	**160 mg daily**	**Minimally, not CYP450**
α/β-Adrenergic blocker	Labetalol HCl	100 mg twice daily	200 mg twice daily	400 mg twice daily	CYP2D6 substrate and inhibitor

CYP450, cytochromes P450 superfamily enzymes

*Drugs in bold are suggested as optimal choices to avoid or minimize potential drug interactions with sunitinib through CYP3A4

Dose Modifications

Dose Levels	
Dose level +3	87.5 mg/day
Dose level +2	75 mg/day
Dose level +1	62.5 mg/day
Starting dose level	50 mg/day
Dose level −1	37.5 mg/day
Dose level −2	25 mg/day

Adverse Events	Treatment Modifications
G ≥3 hematologic or nonhematologic toxicity	Reduce by 1 dose level, or, if administering 25 mg/day, discontinue therapy
G ≥3 fatigue	
G ≥3 stomatitis	
G ≥3 abnormalities in liver functions/hepatic adverse event	
Clinical manifestations of congestive heart failure (CHF)	Discontinue sunitinib
Patients without clinical evidence of CHF but with an ejection fraction <50%, and >20% below baseline	Interrupt sunitinib treatment and/or reduce the dose or, if administering 25 mg/day, discontinue therapy
G2/3/4 serum lipase or serum amylase	Hold therapy until level G1, then resume therapy
Coadministration of potent CYP3A4 inhibitors (eg, ketoconazole, itraconazole, clarithromycin, atazanavir, ritonavir, telithromycin)*	Reduce sunitinib dose to a minimum of 37.5 mg daily
Coadministration of potent CYP3A4 inducers (eg, rifampin, phenytoin, phenobarbital, dexamethasone, carbamazepine, St. John's, wort)*	Increase sunitinib dose 1 level to a maximum of 87.5 mg daily

*If a medication with no effect on enzyme activity cannot be substituted

Patient Population Studied

Patients with histologically proven malignant gastrointestinal stromal tumor that was not amenable to surgery, radiation, or a combination of different approaches with curative intent. Patients also must have had confirmed objective failure of previous imatinib therapy based either on progression of disease or unacceptably severe toxic effects during imatinib therapy that precluded further treatment. The last imatinib should have been administered at least 2 weeks before randomization

Efficacy

Efficacy Endpoints

	Sunitinib	Placebo	Hazard Ratio
End point	Duration (95% CI)	Duration (95% CI)	HR (95% CI)
Median time to tumor progression for the ITT population (primary study end point)*	27.3 weeks (16–32.1)	6.4 weeks (4.4–10)	HR 0.33 (0.23–0.47) p <0.0001
Median duration of progression-free survival	24.1 weeks (11.1–28.3)	6 weeks (4.4–9.9)	HR 0.33 (0.24–0.47) p <0.0001
Percent progression-free ≥26 weeks†	16% (33)	1% (1)	—
Overall survival‡			HR 0.49 (0.29–0.83) p = 0.007
Median time to tumor response	10.4 weeks (9.7–16.1)		

Response Rates

	Partial Response	Stable Disease	Progressive Disease
Best tumor response (ITT population)	7% (14)§,ϵ	58% (120)	19% (39)
Patients who entered study > disease progression on imatinib (N = 198)	5.1% (10)		
Patients who crossed over to sunitinib from placebo group (N = 59)	10.2% (3.8–20.8)	7% (4)**	
Patients classified as intolerant to imatinib and randomized to sunitinib (N = 9)	44% (4)††		11% (1)

*Central radiology assessment
†26 weeks (≈6 months) predefined as point most clinicians agree clinically meaningful
‡Despite option to cross over. Also note that since > half the patients in sunitinib group were still alive at interim analysis, a median overall survival value could not be calculated
§Although low, higher than with placebo (7% [14] vs. none; 95% CI 3.7–11.1%; p = 0.006)
ϵOnly 3 of 14 had progression at interim analysis, so duration of response could not be reliably estimated; observed duration of response for the 3 patients: 15.9–29.9 weeks
**Stable disease for at least 26 weeks after crossover
††Although numbers small, seemed better in patients intolerant of imatinib than in those resistant to imatinib

Toxicity (N = 202)

Adverse Events That Occurred with a Frequency of at Least 5% Greater with Sunitinib Than Placebo in Per-Protocol Population*

	Number (%)		
	Grade 1/2	Grade 3	Grade 4
Nonhematologic			
Fatigue	58 (29%)	10 (5%)	0
Diarrhea	52 (26%)	7 (3%)	0
Skin discoloration	50 (25%)	0	0
Nausea	47 (23%)	1 (1%)	0
Anorexia	38 (19%)	0	0
Dysgeusia	36 (18%)	0	0
Stomatitis	30 (15%)	1 (1%)	0
Vomiting	30 (15%)	1 (1%)	0
Hand-foot syndrome	19 (9%)	9 (4%)	0
Rash	24 (12%)	2 (1%)	0
Asthenia	18 (9%)	6 (3%)	0
Mucosal inflammation	24 (12%)	0	0
Dyspepsia	22 (11%)	1 (1%)	0
Hypertension	15 (8%)	6 (3%)	0
Epistaxis	14 (7%)	0	0
Hair-color changes	14 (7%)	0	0
Dry mouth	13 (6%)	0	0
Glossodynia	11 (6%)	0	0
Hematologic			
Anemia	117 (58%)	7 (4%)	0
Leucopenia	104 (52%)	7 (4%)	0
Neutropenia	86 (43%)	17 (8%)	3 (2%)
Lymphopenia	80 (40%)	18 (9%)	1 (1%)
Thrombo-cytopenia	72 (36%)	8 (4%)	1 (1%)

*National Cancer Institute (USA), Common Terminology Criteria for Adverse Events, version 3.0

Therapy Monitoring

1. *Before initiation of treatment, during each cycle of treatment, and as clinically indicated:* History and physical examination. Complete blood count with leukocyte differential, liver and thyroid function tests
2. *As clinically indicated:* Monitor patients for signs and symptoms of congestive heart failure. Consider monitoring with on-treatment electrocardiograms and electrolytes
3. *Daily at first, then M-W-F, then biweekly, and then weekly:* Monitor blood pressure and treat as needed

Notes:

- Thyroid dysfunction may occur. Patients with signs and/or symptoms suggestive of hypothyroidism or hyperthyroidism should have laboratory monitoring of thyroid function performed and be treated as per standard medical practice
- Temporary interruption of therapy with sunitinib is recommended in patients undergoing major surgical procedures
- Adrenal hemorrhage was observed in animal studies. Monitor adrenal function in case of stress such as surgery, trauma or severe infection
- Patients who presented with cardiac events within 12 months prior to sunitinib administration, such as myocardial infarction (including severe/unstable angina), coronary/peripheral artery bypass graft, symptomatic CHF, cerebrovascular accident or transient ischemic attack, or pulmonary embolism, were excluded from clinical studies with sunitinib. It is unknown whether patients with these concomitant conditions may be at a greater risk for developing drug-related left ventricular dysfunction. Patients with preexisting cardiac pathologies should be carefully monitored for clinical signs and symptoms of CHF while receiving sunitinib. Baseline and periodic evaluations of LVEF should also be considered. In patients without cardiac risk factors, a baseline evaluation of ejection fraction should be considered

35. Testicular Cancer

Darren R. Feldman, MD and George J. Bosl, MD

Epidemiology

Incidence: 8,820 estimated new cases for 2014 in the United States
5.5 per 100,000 males per year
Deaths: Estimated 380 in 2014
Median age: 33 years

Siegel R et al. CA Cancer J Clin 2013;63:11–30
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Frequency of Stage at Presentation

	Seminoma	Nonseminoma
Stage I	85%	60%
Stage II	10%	20%
Stage III	5%	20%

Frequency of IGCCCG Risk Groups at Diagnosis for Patients Requiring Chemotherapy

IGCCCG Risk Group	Seminoma	Nonseminoma	All
Good	90%	56%	60%
Intermediate	10%	28%	26%
Poor	N/A	16%	14%

Pathology

Germ Cell Tumors (95%)

1. Seminoma
   a. Classic
   b. Spermatocytic
2. Nonseminoma
   a. Embryonal carcinoma
   b. Teratoma
      1. Teratoma (Mature or Immature)
      2. Teratoma with malignant transformation
   c. Choriocarcinoma
   d. Yolk sac (endodermal sinus) tumor

Note: Most common nonseminoma histology is a mixture of ≥2 histologies. Pure teratoma represents a fully malignant GCT

Non–Germ Cell Tumors (5%)

1. Sex cord-stromal (gonadal stromal) tumors
   a. Leydig cell
   b. Sertoli cell tumor
   c. Granulosa cell
2. Both germ cell and gonadal stromal elements
   a. Gonadoblastoma
3. Adnexal and paratesticular tumors
   a. Mesothelioma
   b. Carcinoma of rete testis
4. Miscellaneous neoplasms
   a. Carcinoid
   b. Lymphoma
   c. Sarcoma
   d. Other

Work-up

Suspicious Testicular Mass (by History or Exam)	Confirmed Testicular Mass (by Ultrasound)	Seminoma or Nonseminoma (S/P Orchiectomy)
History and physical	STM if not yet done	STM
AFP, hCG, and LDH (serum tumor markers [STM])	CBC, complete metabolic profile	CBC, complete metabolic profile
CBC, complete metabolic profile	CT A/P + either CXR or CT chest	CT C/A/P if >4 weeks since prior
Scrotal ultrasound	Bone scan or MRI Brain, ***only*** if clinically indicated	Bone scan or MRI Brain, ***only*** if clinically indicated Discussion of sperm banking if further treatment (surgery, chemotherapy, or XRT) is required

Staging

T: Primary Tumor Staging

pTx	Primary tumor cannot be assessed
pT0	No evidence of primary tumor
pTis	Intratubular germ cell neoplasia (testicular intraepithelial neoplasia)
pT1	Tumor limited to testis and epididymis without lymphovascular invasion (LVI); tumor may invade tunica albuginea but not tunica vaginalis
pT2	Tumor limited to the testis and epididymis with LVI or tumor extending through the tunica albuginea with involvement of the tunica vaginalis
pT3	Tumor invades the spermatic cord with or without LVI
pT4	Tumor invades the scrotum with or without LVI

N: Regional Lymph Nodes Clinical Staging

NX	Regional lymph nodes (LN) cannot be assessed
N0	No regional LN metastasis
N1	LN mass ≤2 cm in greatest dimension; or multiple LN, none >2 cm
N2	LN mass >2 cm but not >5 cm in greatest dimension; or multiple LN, any 1 mass >2 cm but not >5 cm
N3	Lymph node mass >5 cm in greatest dimension

N: Regional Lymph Nodes Pathologic Staging

NX	Regional LN cannot be assessed
N0	No regional LN metastasis
N1	Metastasis with a lymph node mass ≤2 cm in greatest dimension and ≤5 lymph nodes positive, none >2 cm
N2	Positive LN >2 cm but <5 cm in greatest dimension; or >5 positive LN, none >5 cm; or evidence of extranodal extension
N3	Positive lymph node >5 cm in greatest dimension

M: Metastatic Disease Staging

Mx	Distant metastasis cannot be assessed
M0	No distant metastasis
M1	Distant metastasis
M1a	Nonregional nodal or pulmonary metastasis
M1b	Nonpulmonary visceral metastases

S: Serum Tumor Markers Staging

Sx	Markers not available or not performed
S0	Marker levels within normal limits
S1	LDH <1.5× upper limit of normal (ULN) and human chorionic gonadotropin, beta subunit (hCG) <5000 mIU/L and alpha-fetoprotein (AFP) <1000 ng/mL
S2	LDH 1.5–10× ULN or hCG 5000--50,000 mIU/L or AFP 1000--10,000 ng/mL
S3	LDH >10× ULN or hCG >50,000 mIU/L or AFP >10,000 ng/mL

Caveats Regarding Staging

1. Except for pTis and pT4, extent of tumor is classified by radical orchiectomy. Use pTx in absence of orchiectomy
2. Histology (seminoma vs. nonseminoma) is incorporated into the risk classification system but not AJCC stage
3. Serum tumor markers (STM) for staging and IGCCCG risk prognostication should be drawn after orchiectomy or other tissue diagnosis but before chemotherapy. Elevated preoperative STM must be repeated postorchiectomy after marker half-life has been evaluated

TNM Stage Grouping		IGCCCG Risk Group Classification		
Stage	TNM	Risk Group (5-Year DFS)	Seminoma (Criteria)	Nonseminoma (Criteria)
0	pTis, N0, M0, S0	Good Nonseminoma (56% of cases) 5-y PFS 89% 5-y survival 92% Seminoma (90% of cases) 5-y PFS 82% 5-y survival 86%	Any primary site. Absence of nonpulmonary visceral metastasis. Normal AFP, any level hCG or LDH	*Must fulfill all of the following criteria:* Primary site not mediastinum (Testis/retroperitoneal primary); absence of nonpulmonary visceral metastasis; markers S0 or S1
I	pT1–4, N0, M0, Sx			
IA	pT1, N0, M0, S0			
IB	pT2–T4, N0, M0, S0			
IS	Any pT/Tx, N0, M0, S1–3			
II	Any pT/Tx, N1–3, M0, Sx	Intermediate Nonseminoma (28% of cases) 5-y PFS 75% 5-y survival 80% Seminoma (10% of cases) 5-y PFS 67% 5-y survival 72%	Any primary site. Presence of nonpulmonary visceral metastasis Normal AFP, any level hCG or LDH	*Must fulfill all of the following criteria:* Primary site not mediastinum (Testis/retroperitoneal primary); absence of nonpulmonary visceral metastasis; and markers S2
IIA	Any pT/Tx, N1, M0, S0–1			
IIB	Any pT/Tx, N2, S0–1			
IIC	Any pT/Tx, N3, S0–1			
III	Any pT/Tx, Any N, M1a, Sx			
IIIA	Any pT/Tx, Any N, M1a, S0–1	Poor Nonseminoma (16% of cases) 5-y PFS 41% 5-y survival 48% Seminoma (seminomas are not classified as poor prognosis)	N/A---Seminomas are never poor risk	*Must fulfill at least 1 of the following criteria:* Primary site mediastinum; or presence of nonpulmonary visceral metastases; or markers S3
IIIB	Any pT/Tx, Any N, M1a, S2 Any pT/Tx, N1–3, M0, S2			
IIIC	Any pT/Tx, N1–N3, M0, S3 Any pT/Tx, Any N, M1a, S3 Any pT/Tx, Any N, M1b, Any S			

International Germ Cell Cancer Collaborative Group (IGCCCG). J Clin Oncol 1997;15:594–603

Expert Opinion

I. Caveats

1. A testicular mass is malignant until proven otherwise. Radical inguinal orchiectomy is the indicated surgical procedure for all testicular masses; transscrotal orchiectomy and testicular biopsy are not recommended
2. Patients with seminoma and an elevated AFP level or any nonseminomatous histology, including teratoma, should be treated asa nonseminoma
3. Patients with pure testicular teratoma should be treated as a fully malignant nonseminoma
4. Primary mediastinal site and level of serum tumor markers (STMs) do not affect prognosis for seminoma patients
5. Sperm banking should be discussed with patients after orchiectomy before initiation of any further therapy
6. There is ≈2% lifetime risk of developing a contralateral testicular tumor; self-exam and MD exam are recommended at regular intervals. Such tumors are treated as new primary GCTs

II. Treatment Recommendations by AJCC Stage and Histology

A. Nonseminomas

Stage I

- Stage IA: surveillance is the preferred option for compliant patients. The risk of recurrence is ≈20% and if the disease recurs, >95% patients can be cured with chemotherapy (CT) using EP or BEP. For noncompliant patients, nerve-sparing retroperitoneal lymph node dissection (RPLND) may be preferred
- Stage IB: risk of relapse is ≈50%. RPLND, surveillance, or 1–2 cycles of BEP are all options. RPLND results in the least likelihood of patients receiving chemotherapy
- Stage IS: CT should be administered (EP × 4 or BEP × 3 for S1; BEP × 4 for S2–S3)

Stage II (S0 and S1 STM only; S2 and S3 STM qualify as Stage IIIB and IIIC, respectively)

- If adenopathy >2 cm or bilateral *or* STM are persistently elevated after orchiectomy, BEP × 3 or EP × 4 should be given
- If adenopathy <2 cm and unilateral/unifocal *and* STM are normal, RPLND or CT (EP × 4 or BEP × 3) can be considered depending on clinical circumstances. Following postchemotherapy RPLND, patients with complete resection should receive 2 cycles of EP or BEP if findings reveal pathologic stage IIB (pN2)

Stage III

- Treatment is based on IGCCCG risk classification
- Patients in the good-risk category should be given either EP × 4 or BEP × 3
- Patients in the intermediate- or poor-risk categories should be given BEP × 4
- VIP × 4 (etoposide, ifosfamide, cisplatin) is as effective as BEP × 4 in patients with poor-risk GCT, but VIP is associated with greater toxicity (primarily hematologic). VIP can be considered for patients in whom bleomycin is contraindicated (ie, pulmonary disease)

Residual masses

- In general, all sites of residual masses after completion of CT should be resected, if possible. PET is not routinely indicated for evaluation of post-CT residual masses

B. Seminomas

Stage I

- The risk of recurrence is 15–20%. The 3 treatment options are active surveillance, adjuvant radiation therapy (RT), and adjuvant carboplatin
- Surveillance is becoming the preferred option for compliant patients since RT and carboplatin overtreat ≥80% of patients. RT increases the risk of secondary cancers and data on the long-term risks with carboplatin are lacking
- RT, 2000–2500 cGy is an option for non-compliant patients but recognition of the increased incidence of secondary intra-abdominal malignancies has rapidly led to less frequent use. Carboplatin may be an alternative option for non-compliant patients but long-term follow-up is lacking such that the frequency of late relapses and late toxicity have not been established. For these reasons, the authors do not use carboplatin in their practice [Bosl SJ, Patil S. J Clin Oncol 2011;29:949]

Stage II

- Stage IIA: RT (3000–3500 cGy) to retroperitoneal and ipsilateral pelvic lymph nodes. CT (EP × 4 or BEP × 3) is an acceptable alternative to RT [Garcia-del-Muro X et al. J Clin Oncol 2008;26:5416]
- Small Stage IIB (single node <3 cm): either RT (≥3600 cGy) or CT with EP × 4 or BEP × 3
- Large (>3 cm) or multinodal Stage IIB, all Stage IIC and Stage III: Treatment is with chemotherapy based on IGCCCG risk stratification. EP × 4 or BEP × 3 are used for good-risk seminoma, BEP × 4 is used for intermediate-risk disease. Seminoma patients are never poor-risk

Residual masses

- Surgery is more difficult with seminoma and carries a higher complication rate
- PET scan is recommended to evaluate residual masses >3 cm. Additional treatment (surgical or medical) or diagnostic procedure may be indicated for PET-positive residual masses >3 cm. PET-negative lesions >3 cm require no further treatment, just active surveillance. Some patients with lesions <3 cm may benefit from PET scan evaluation. Since teratoma is rarely an issue with seminoma, false-negative results are uncommon

(*continued*)

Expert Opinion (*continued*)

III. Salvage Therapy

- We divide patients into 2 categories:
  1. *Patients with a favorable prognosis with conventional chemotherapy:* This group includes patients with a retroperitoneal or gonadal primary nonseminoma or a seminoma of any primary site who previously achieved a complete response (CR) or partial response (PR) with negative markers lasting >6 months to first-line therapy. We treat these patients with TIP, based on the 63% durable disease-free survival rate. These patients may be able to be cured without being subjected to the toxicity of high-dose chemotherapy. VIP and VeIP are additional options. Investigational treatments should also be considered
  2. *Patients with an unfavorable prognosis with conventional chemotherapy:* All patients who do not fit into the group above including (a) patients with mediastinal primary nonseminomas and (b) patients who do not achieve a CR or durable PR with negative markers. These patients should be treated with high-dose chemotherapy, which gives them the best chance of long-term survival (40–60%) [Feldman DR et al. J Clin Oncol 2010;28:1706]. Chance of cure with conventional chemotherapy is <10%. Investigational treatments should be considered

IV. Chemotherapy for Special Populations

- *Viable GCT upon resection after completing first-line chemotherapy:* Administer 2 additional cycles of adjuvant chemotherapy with EP
- *Late relapses:* defined as relapse after ≥2 years of being in remission after chemotherapy. These tumors tend to be more chemoresistant and difficult to cure than relapses occurring ≤2 years after completing treatment. Surgery is the treatment of choice when possible. When surgery is not possible, TIP (50% durable CR rate in 14 patients) and cisplatin plus epirubicin (30% durable CR rate in 21 patients) are 2 regimens that have shown promise. High-dose chemotherapy may be indicated in selected patients. Referral to a specialist center is recommended. Investigational treatments should be considered
- *Intermediate- or poor-risk patients with severe lung disease:* VIP can be substituted for BEP with equivalent efficacy but increased hematologic toxicity
- *Pulmonary toxicity developing during BEP × 3 for good-risk disease:* If DLCO or TVC decrease by ≥25% or there is physical exam or CXR evidence of bleomycin toxicity, then discontinuation of bleomycin is indicated with continuation of treatment with EP. Patients who require discontinuation of bleomycin prior to completing 3 full cycles of BEP can be given additional cycles of EP until a total of 4 cycles of chemotherapy have been administered (personal correspondence, Lawrence Einhorn, December 2008)

V. Mesna Dosing Schedules

- Ifosfamide 1200 mg/m² per day for 5 days
  a. Mesna 120 mg/m² by short intravenous infusion when ifosfamide administration commences, followed immediately afterward by Mesna 1200 mg/m² per day given by continuous intravenous infusion for 5 consecutive days (total dosage/5 days = 6120 mg/m²)
  b. Mesna 1200 mg/m² per day given intravenously for 5 consecutive days prepared as an admixture (in the same container) with ifosfamide (total dosage/5 days = 6000 mg/m²)
  c. Mesna 400 mg/m² per dose given intravenously when ifosfamide administration commences, and at 4 and 8 hours after ifosfamide for 3 doses per day such that equal total doses of mesna and ifosfamide are given daily; ie, 1200 mg/m² per day (total dosage/5 days = 6000 mg/m²)
- Ifosfamide 1500 mg/m² per day for 4 days
  a. Mesna 1500 mg/m² per day prepared as an admixture (in the same container) with ifosfamide (total dosage/4 days = 6000 mg/m²)
  b. Mesna 500 mg/m² per dose given intravenously with ifosfamide, and then at 4 hours and 8 hours after ifosfamide to equal the total amount of ifosfamide given daily; ie, 1500 mg/m² (total dosage/4 days = 6000 mg/m²)
  c. Mesna 500 mg/m² per dose given intravenously when ifosfamide administration commences followed by Mesna 1000 mg/m² per dose given orally at 4 and 8 hours after ifosfamide (for total of 2500 mg/m² mesna per day; total dosage/4 days from IV + oral routes = 10,000 mg/m²)

VI. Follow-up Schedules

- Follow-up guidelines based on disease stage, histology (seminoma vs. nonseminoma) and treatment type (radiation, chemotherapy, surgery, surveillance) have been published by various groups, primarily based on expert opinion rather than direct evidence from clinical trials. One commonly used set of guidelines is published by the National Comprehensive Cancer Network (NCCN) (http://www.nccn.org). Other guidelines are also available

For follow-up schedules, the authors consider the starting point to be the first day of definitive treatment (surgery, radiation, or chemotherapy) resulting in expected cure. For patients with metastatic disease who receive chemotherapy followed by surgery, the first day of the first cycle is considered to be the start of year 1 unless adjuvant therapy is required for persistent viable disease. When adjuvant chemotherapy is required, the start date of adjuvant therapy is used to mark the start of year 1

Motzer RJ et al. Cancer 1991;67:1305–1310
Rabbani F et al. Urology 2003;62:1092–1096

FIRST-LINE TREATMENT REGIMENS

ETOPOSIDE + CISPLATIN (EP)

Bosl GJ et al. J Clin Oncol 1988;6:1231–1238

Hydration for cisplatin: Administer intravenously 0.9% sodium chloride injection, USP (0.9% NS) to insure a urine output of at least 100 mL/hour prior to each dose of cisplatin. Hydration should be continued until the patient has completed chemotherapy and is able to take adequate oral liquids to prevent dehydration. Monitor and replace electrolytes/magnesium as needed

Etoposide 100 mg/m² per day; administer intravenously diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes, for 5 consecutive days, days 1–5, every 21 days for 3–4 cycles (total dosage/cycle = 500 mg/m²)

Cisplatin 20 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS over 30–60 minutes for 5 consecutive days, on days 1–5, every 21 days for 3–4 cycles (total dosage/cycle = 100 mg/m²)

EP × 3 indicates 3 treatment cycles; EP × 4 indicates 4 cycles

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–5: ***HIGH*** *Potential for delayed emetic symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
• Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

• Antibacterial—not indicated
• Antifungal—not indicated
• Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with good-risk GCT not previously treated with chemotherapy

Bajorin D et al. J Clin Oncol 1993;11:598–606
Bosl GJ et al. J Clin Oncol 1988;6:1231–1238
Culine S et al. Ann Oncol 2007;18:917–924
Kondagunta GV et al. J Clin Oncol 2005;9290–9294

Treatment Modifications

Toxicity	MSKCC*	Indiana
Neutropenia day 1	Delay by 1 week unless WBC ≥2500/mm³ *and* ANC ≥500/mm³*; consider granulocyte colony-stimulating factor (G-CSF) with next cycle	No delay. Hold etoposide on day 5 if ANC still ≤2500/mm³†‡; consider G-CSF with next cycle
Febrile Neutropenia (FN) or prior irradiation	Add G-CSF	Add G-CSF or reduce etoposide dosage by 25%§
FN despite G-CSF	Consider prophylactic antibiotic next cycle	Reduce etoposide dosage by 25%‡
Serum creatinine (Cr) ≥3.0 mg/dL (≥265.2 µmol/L)	Delay until Cr <3.0 mg/dL & CrCl creatinine clearance ≥50 mL/min (≥0.83 mL/s), then give full dose or substitute carboplatin if Cr does not return to <3.0 mg/dL or CrCl ≥50 mL/min	Delay until Cr <3.0 mg/dL‡

Therapy-Related Deaths N (%)	2 (1.5%)

Therapy Monitoring

1. *Every cycle:* CBC with differential, comprehensive metabolic profile, and serum tumor markers
2. *Response evaluation:* CT scan chest, abdomen, and pelvis and tumor markers after completion of cycle 4

REGIMEN

BLEOMYCIN, ETOPOSIDE, AND CISPLATIN (BEP)

Nichols CR et al. J Clin Oncol 1998;16:1287–1293

Hydration for cisplatin: 0.9% NS; administer intravenously to insure a urine output of ≥100 mL/hour prior to each dose of cisplatin and continue until the patient has completed chemotherapy and is able to take adequate oral liquids to prevent dehydration. We give 500 mL of 0.9% NS over 1 hour before cisplatin while premedications and etoposide are infused, and an additional 500 mL of 0.9% NS over 1 hour after cisplatin. Electrolytes/magnesium replaced as needed. Other hydration schedules are feasible

Bleomycin 30 units/week; administer by intravenous injection, weekly for 3–4 cycles (ie, 9–12 weeks; total dose/9-week course = 270 units; total dose/12-week course = 360 units)

Etoposide 100 mg/m² per day; administer intravenously diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL over 30–60 minutes for 5 consecutive days on days 1–5, every 21 days for 3–4 cycles (total dosage/cycle = 500 mg/m²)

Cisplatin 20 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS over 30–60 minutes for 5 consecutive days on days 1–5, every 21 days for 3–4 cycles (total dosage/cycle = 100 mg/m²)

BEP × 3 indicates 3 consecutive cycles; BEP × 4 indicates 4 consecutive cycles

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–5: ***HIGH****. Potential for delayed symptoms*

Emetogenic potential on days with bleomycin alone: ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
Myelosuppression not improving during the first 4 days of therapy	Omit day 5 etoposide. Administer full dose cisplatin
Febrile neutropenia	Add filgrastim during ongoing cycle and subsequent cycles so as to administer full dose chemotherapy
Febrile neutropenia while receiving filgrastim	Reduce etoposide dosage by 25%
Clinical (rales or inspiratory lag) or radiographic evidence of pulmonary toxicity or fibrosis	Discontinue bleomycin

Repeated treatment cycles should begin on schedule without regard for the degree of myelosuppression noted on the day of scheduled treatment. Daily CBC is obtained to document marrow recovery

Therapy Monitoring

1. *Every cycle:* CBC with differential, comprehensive metabolic profile, serum tumor markers, and evaluation for bleomycin pulmonary toxicity (Indiana—lung exam[1,2], MSKCC—PFTs[3])
2. After completion of BEP × 3 or BEP × 4, repeat CT scan of chest, abdomen, and pelvis, and tumor markers

[1]Loehrer P et al. J Clin Oncol 1995;13:470–476
[2]Nichols CR et al. J Clin Oncol 1998;16:1287–1293
[3]Bosl GJ et al. J Clin Oncol 1988;6:1231–1238

SALVAGE TREATMENT REGIMENS REGIMEN

PACLITAXEL + IFOSFAMIDE + CISPLATIN (TIP × 4)

Kondagunta GV et al. J Clin Oncol 2005;23:6549–6555

Indications:

1. First-line salvage chemotherapy for patients who relapsed after a complete response or partial response with negative markers lasting >6 months
2. Other patients who are not candidates for high-dose chemotherapy or have progressed after high-dose therapy and have not received paclitaxel

Premedication for paclitaxel: **Dexamethasone** 20 mg/dose; administer orally or intravenously for 2 doses at 14 and 7 hours prior to paclitaxel, plus **diphenhydramine** 50 mg and **cimetidine** 300 mg; administer both intravenously 1 hour prior to paclitaxel
Paclitaxel 250 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to yield a final concentration within the range of 0.3 and 1.2 mg/mL over 24 hours on day 1, every 21 days for 4 cycles (total dosage/cycle = 250 mg/m^2)
Hydration: 1000 mL 0.9% NS; administer intravenously over 2 hours on days 2–5 before or during ifosfamide administration. Consider additional intravenous fluid if medically appropriate until the patient has completed chemotherapy and is able to take adequate oral liquids to prevent dehydration. Monitor and replace electrolytes/magnesium as needed
Ifosfamide 1500 mg/m^2 per day; administer intravenously in 0.9% NS or D5W to produce a concentration within the range of 0.6 and 20 mg/mL, over 2–3 hours for 4 consecutive days on days 2–5, every 21 days for 4 cycles (total dosage/cycle = 6000 mg/m^2)
Mesna 500 mg/m^2 per dose; administer intravenously in D5W to yield a concentration of 20 mg/mL, for 3 doses/day starting just before or coincident with the start of ifosfamide, with repeated doses at 4 and 8 hours after ifosfamide for 4 consecutive days on days 2–5, every 21 days for 4 cycles (total daily dosage = 1500 mg/m^2; total dosage/cycle = 6000 mg/m^2)
(See Expert Opinion for alternative administration schemes)
Cisplatin 25 mg/m^2 per day; administer intravenously in 25–250 mL 0.9% NS, over 30–60 minutes for 4 consecutive days on days 2–5, every 21 days for 4 cycles (total dosage/cycle = 100 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1: ***LOW***
Emetogenic potential on days 2–5: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Discontinue daily filgrastim use if WBC >10,000/mm3 on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Dose Modifications

Toxicity	Modification
ANC <450/mm^3 on day 1	Delay until ANC >450/mm^3
Platelet count <75,000/mm^3 on day 1	Delay until platelet count is >75,000/mm^3
Platelets <10,000/mm^3 *or* platelets <50,000/mm^3 with bleeding	Transfuse platelets to >10,000/mm^3 if no bleeding, and to >50,000/mm^3 if bleeding
Hgb <8 g/dL	Transfuse RBC to keep Hgb >8 g/dL

Kondagunta GV et al. J Clin Oncol 2005;23:6549–6555

Therapy Monitoring

1. CBC with differential weekly
2. Comprehensive metabolic profile and serum tumor markers once to twice per cycle
3. *Response assessment:* CT scan of chest, abdomen, and pelvis, and tumor markers after completion of 4 cycles

Patient Population Studied (N = 46)

GCT patients fulfilling *all* of the following 3 criteria:
1. Gonadal primary tumor
2. Prior therapy with cisplatin-based treatment totaling 6 or fewer cycles
3. Prior CR or PR with negative markers lasting >6 months from completion of first-line chemotherapy

Kondagunta GV et al. J Clin Oncol 2005;23: 6549–6555

Toxicity

CR (complete response): disappearance of all clinical, radiographic, and biochemical evidence of disease for at least 4 weeks
IR (incomplete response): failure to achieve CR to chemotherapy with or without surgery, including patients who were observed to have failure of serum tumor marker normalization
NED (no evidence of disease)
*Median follow-up of 68 months

SALVAGE TREATMENT REGIMENS REGIMEN

VINBLASTINE + IFOSFAMIDE + CISPLATIN (VeIP × 4)

Loehrer PJ Sr et al. J Clin Oncol 1998;16:2500–2504

Indications:

1. First-line salvage chemotherapy for patients who relapsed after achieving a complete response or partial response with negative markers lasting >6 months
2. Other patients who progressed on or after first-line therapy who are not candidates for high-dose chemotherapy or progressed after high-dose therapy

Vinblastine 0.11 mg/kg per day; administer by intravenous injection over 1–2 minutes on 2 consecutive days, on days 1 and 2, every 3 weeks for 4 cycles (total dosage/cycle = 0.22 mg/kg)
Hydration: Administer 0.9% NS intravenously to insure a urine output of ≥100 mL/hour prior to each dose of cisplatin. Continue intravenous hydration until a patient has completed chemotherapy and is able to take adequate oral liquids to prevent dehydration
Suggested: 0.9% NS 500 mL over 1 hour before cisplatin and an additional 500 mL of 0.9% NS over 1 hour after cisplatin. Electrolytes/magnesium replaced as needed. Other hydration schedules are feasible
Cisplatin 20 mg/m² per day; administer intravenously in 25–250 mL of 0.9% NS over 30–60 minutes for 5 consecutive days on days 1–5, every 3 weeks for 4 cycles (total dosage/cycle = 100 mg/m²)
Ifosfamide 1200 mg/m² per day; administer intravenously in 0.9% NS or D5W sufficient to produce a concentration within the range of 0.6 and 20 mg/mL, over 30–60 minutes for 5 consecutive days on days 1–5, every 3 weeks for 4 cycles (total dosage/cycle = 6000 mg/m²)
Mesna 500 mg/m² per dose; administer intravenously in 25–50 mL 0.9% NS or D5W , over 15–30 minutes starting simultaneously with ifosfamide, followed by **Mesna** 1200 mg/m² per day by continuous intravenous infusion in a volume of 0.9% NS, D5W (or dextrose and saline combinations) sufficient to produce a concentration of 20 mg/mL over 24 hours for 5 consecutive days on days 1–5, every 3 weeks for 4 cycles (total dosage/cycle = 6500 mg/m²). (See Expert Opinion for alternative administration schemes)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–5: HIGH. Potential for delayed symptoms

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for one dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Discontinue daily filgrastim use if WBC >10,000/mm³ on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Dose Modification

Toxicity	Modification
Neutropenia on day 1	No delay. Omit ifosfamide on day 5 if ANC still ≤2500/mm³
Thrombocytopenia and bleeding, febrile neutropenia (FN), or prior irradiation	Reduce etoposide and vinblastine dosages by 25%*
Platelet count <100,000/mm³ on day 5	Omit day 5 of ifosfamide*
Serum creatinine >2 mg/dL (>176.8 µmol/L)	Decrease ifosfamide dosage by 25%*
>10 RBCs/HPF	Hold ifosfamide and continue mesna and hydration until <10 RBCs/HPF

*Loehrer PJ Sr et al. J Clin Oncol 1998;16:2500–2504

Therapy Monitoring

1. Weekly CBC with differential
2. Comprehensive metabolic profile and serum tumor markers once to twice per cycle
3. *Response assessment:* CT scan of chest, abdomen, and pelvis, and tumor markers after completion of 4 cycles

Patient Population Studied (N = 145)

Second-line therapy for GCT patients who progressed during or after first-line chemotherapy

Relapse From CR	24
Continuously NED	24

Progression-Free (PFS) and Overall Survival (OS)	
Median PFS	4.7 years
Median OS	1.3 years
OS at 2 years	38%
OS at 7 years	32%

CR (complete response): complete disappearance of all objective evidence of disease (clinical and radiographic) with normalization of hCG and AFP for at least 1 month
IR (incomplete response): any response that did not meet criteria of CR
NED (no evidence of disease) after VeIP + surgery

SALVAGE TREATMENT REGIMENS REGIMEN

ETOPOSIDE + IFOSFAMIDE + CISPLATIN (VIP × 4)

Nichols CR et al. J Clin Oncol 1998;16:1287–1293

Indication:
Initial therapy for intermediate- or poor-risk GCT patients who are not candidates for BEP (usually because of pulmonary compromise)

Order of administration: etoposide → cisplatin → ifosfamide/mesna
Hydration: 1000 mL 0.9% NS; administer intravenously over 2 hours. Consider additional intravenous fluid if medically appropriate until the patient has completed chemotherapy and is able to take adequate oral liquids to prevent dehydration. Monitor and replace electrolytes/magnesium as needed
Etoposide 75 mg/m² per day; administer intravenously diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes for 5 consecutive days on days 1 to 5, every 21 days for 4 cycles (total dosage/cycle = 375 mg/m²)
Cisplatin 20 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS over 30–60 minutes for 5 consecutive days on days 1–5, every 21 days for 4 cycles (total dosage/cycle = 100 mg/m²)
Ifosfamide 1200 mg/m² per day; administer intravenously in 0.9% NS or D5W sufficient to produce a concentration within the range of 0.6 and 20 mg/mL, over 30–120 minutes for 5 consecutive days on days 1–5, every 21 days for 4 cycles (total dosage/cycle = 6000 mg/m²)
Mesna 120 mg/m²; administer by intravenous injection on day 1 just before or coincident with the start of ifosfamide administration, followed by **Mesna** 1200 mg/m² per day; administer by continuous intravenous infusion over 24 hours for 5 consecutive days on days 1–5, every 21 days for 4 cycles (total dosage/cycle = 6120 mg/m²). (See Expert Opinion for alternative administration schemes)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days 1–5: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Discontinue daily filgrastim use if WBC >10,000/mm³ on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Therapy Monitoring

1. *Every cycle:* CBC with differential, comprehensive metabolic profile, and serum tumor markers
2. *Response evaluation:* CT scan of chest, abdomen, and pelvis, and tumor markers after completion of cycle 4

Patient Population Studied (N = 135)

Primarily intermediate- or poor-risk GCT patients not previously treated with chemotherapy

Nichols C et al. J Clin Oncol 1998;16:1287–1293

Toxicity

Hematologic Toxicity	% G3	% G4	% G5
Any hematologic toxicity	28	60	1

Nonhematologic Toxicity	% G3/G4
Nausea/vomiting	9
Neurologic	8
Infection	6
Genitourinary	5

Therapy-Related Deaths	Percent (%)
Sepsis	3
Cerebral hemorrhage	1

Nichols CR et al. J Clin Oncol 1998;16:1287–1293

Dose Modification

Toxicity	MSKCC	Indiana
Neutropenia day 1	Delay cycle by 1 week	No delay. Hold etoposide on day 5 if ANC still ≤2500/mm³*
Thrombocytopenia and bleeding (TB), febrile neutropenia (FN), or prior irradiation	TB—delay until platelet count is ≥100,000/mm³ FN—add G-CSF	Reduce etoposide dosage by 25%*
Serum creatinine >3 mg/dL (>265.2 μmol/L)	Delay cisplatin until Cr <3 mg/dL, continue etoposide and ifosfamide on schedule.* Substitute carboplatin for cisplatin if Cr does not return to <3.0 mg/dL	

*Nichols CR et al. J Clin Oncol 1998;16:1287–1293

Efficacy

	Percent (%)
CR to chemotherapy alone	48
CR to chemotherapy + surgery	6
Partial response	22
Favorable response*	63
Failure-free survival at 2 years†	64
Overall survival at 2 years	74

*Includes patients with partial response and negative markers without relapse for ≥2 years
†Includes patients with partial responses (marker-negative or marker-positive) who did not have progression within 2 years

Nichols CR et al. J Clin Oncol 1998;16:1287–1293

	IGCCCG Classification		
	Good Risk (N = 13)	Intermediate Risk (N = 39)	Poor Risk (N = 92)
OS	92%	77%	62%
PFS	92%	72%	56%

Hinton S et al. Cancer 2003;97:1869–1875 (Long-term follow-up of patients in Nichols study (cited above) but with patients reclassified by IGCCCG risk status. Median follow-up for both OS and PFS was 7.3 years)

36. Thymic Malignancies

Arun Rajan, MD and Giuseppe Giaccone, MD, PhD

Epidemiology

Incidence: 0.13 cases per 100,000 (0.2–1.5% of all malignancies)
Median age: 40–60 years
Male to female ratio: 1:1

Engels EA, Pfeiffer RM. Int J Cancer 2003;105:546–551
Schmidt-Wolf IGH et al. Ann Hematol 2003;82:69–76
Tomiak EM, Evans WK. Crit Rev Oncol Hematol 1993;15:113–124

Stage at Presentation (Masaoka Staging System)

Stage I:	32%
Stage II:	23%
Stage III:	34%
Stage IV:	11%

Pathology

Several histologic classifications of thymomas have been proposed. There is general agreement that the epithelial cells represent the malignant cells in this tumor type and the lymphocytic cells are considered benign

Classification of Thymic Epithelial Tumors

Muller-Hermelink	WHO Type	Levine and Rosai
Thymoma	Thymoma	Thymoma
Medullary type	Type A	Encapsulated
Mixed type	Type AB	—
Predominantly cortical	Type B1	Malignant type I (invasive)
Cortical type	Type B2	—
Well-differentiated carcinoma	Type B3	—
Thymic carcinoma	Type C	Malignant type II

Levine GD, Rosai J. Hum Pathol 1978;9:495–515
Müller-Hermelink HK, Marx A. Curr Opin Oncol 2000;12:426–433
Okumura M et al. Cancer 2002;94:624–632

Work-up

1. CT scan of the thorax
2. Extrathoracic disease such as metastases to the kidney, bone, liver, and brain are rare. Consequently, an extensive work-up for disease outside the thorax is not indicated in the absence of symptoms
3. Pleural or pericardial effusion represents the most common form of metastatic involvement
4. Proper intrathoracic staging is surgical

Ströbel P et al. Blood 2002;100:159–166
Thomas CR Jr et al. J Clin Oncol 1999;17:2280–2289

Five-Year Survival

Stage I	96–100%
Stage II	86–96%
Stage III	56–69%
Stage IV	11–50%

Schneider PM et al. Ann Surg Oncol 1997;4:46–56

Expert Opinion

- Despite their rarity as a group of cancers, thymic epithelial tumors are amongst the most common cancers of the anterior mediastinum in adults
- The clinical course can vary from relatively indolent in the case of some thymomas to highly aggressive in the case of thymic carcinomas
- Thymomas are often associated with a variety of autoimmune conditions; myasthenia gravis is the most common
- Complete surgical resection should be attempted whenever feasible
- Multimodality treatment is frequently required for locally advanced thymoma and thymic carcinoma
- Chemotherapy is offered to patients with advanced stages III to IV thymomas. The evidence for these recommendations is derived from small phase II studies in either the neoadjuvant or refractory/recurrent disease setting
- Platinum-based combination chemotherapy is the standard of care for unresectable, advanced disease. A combination of cisplatin, doxorubicin and cyclophosphamide (PAC) or cisplatin and etoposide (EP) are usually used as first-line regimens [Table]
- The molecular pathogenesis of thymic epithelial tumors and associated autoimmune conditions is gradually being unraveled and targeted therapy is being investigated for the management of advanced disease

Prospective Chemotherapy Trials in Extensive-Stage Inoperable Thymoma

Clinical Staging of Thymic Epithelial Tumors

Masaoka Staging of Thymic Malignancies With Modifications by Koga et al. and WHO Classification of Thymic Malignancies

Stage/Type	Definition
Stage	
I	Grossly and microscopically completely encapsulated
II (a)	Microscopic transcapsular invasion
II (b)	Macroscopic invasion into thymic or surrounding fatty tissue or grossly adherent to but not breaking through mediastinal pleura or pericardium
III	Macroscopic invasion of neighboring organs (ie, pericardium, great vessel, or lung)
IV (a)	Pleural or pericardial dissemination
IV (b)	Lymphatic or hematogenous metastasis
Histologic Type	**Description**
A	Neoplastic oval or spindle cells; no atypia; no lymphocytes
AB	Type A with foci of lymphocytes
B1	Plump epithelioid cells resembling normal thymic medulla
B2	Scattered foci of atypical epithelial cells with lymphocytes
B3	Round or polygonal epithelial cells with mild atypia with minor component of lymphocytes
Thymic carcinoma	Histologic subtyping required

Kelly RJ et al. J Clin Oncol 2011;29:4820–4827
Masaoka A et al. Cancer 1981;48:2485–2492

REGIMEN

DOXORUBICIN + CISPLATIN + VINCRISTINE + CYCLOPHOSPHAMIDE (ADOC)

Berruti A et al. Br J Cancer 1999;81:841–845

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over 2–4 hours before chemotherapy commences. Monitor and replace electrolytes/magnesium as needed
Doxorubicin 40 mg/m²; administer by intravenous injection over 3–5 minutes, on day 1, every 3 weeks (total dosage/cycle = 40 mg/m²)
Cisplatin 50 mg/m²; administer intravenously in 50–250 mL 0.9% NS over 1 hour on day 1, every 3 weeks (total dosage/cycle = 50 mg/m²)
Hydration after cisplatin: Administer intravenously 1000 mL 0.9% NS over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed
Vincristine 0.6 mg/m²; administer by intravenous injection over 1–2 minutes, on day 2, every 3 weeks (total dosage/cycle = 0.6 mg/m²)
Cyclophosphamide 700 mg/m²; administer intravenously in 50–150 mL 0.9% NS or 5% dextrose injection over 15 minutes, on day 4, every 3 weeks (total dosage/cycle = 700 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on day 2 is ***MINIMAL***
Emetogenic potential on day 4 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Notes: Encourage patients to increase oral fluids intake on the days on which cisplatin and cyclophosphamide are administered

Use of steroids is discouraged, except for patients with myasthenia gravis who were previously receiving a stable dose of steroids

Patient Population Studied

A study of 16 patients with unresectable locally advanced nonmetastatic thymomas and locally advanced disease after radical surgery. Ten patients with stage III disease, and 6 patients with stage IVa disease. Three patients had recurrent disease after previous surgery

Efficacy (N = 16)*

Complete response	6.25%
Partial response	75%
Stable disease	12.5%
Progressive disease	6.25%

*WHO criteria

Toxicity* (N = 16 patients/68 Cycles)

	% G3/4
Neutropenia	12.5
Anemia	—
Nausea/vomiting	6.25
Nephrotoxicity	—

*WHO criteria

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ or platelet count <100,000/mm³	Delay therapy a maximum of 2 weeks until ANC >1500/mm³ or platelet count >100,000/mm³
2-Week delay	Decrease dosage of all 4 drugs
Serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Hold therapy until serum creatinine <1.6 mg/dL (<141 µmol/L), then reduce cisplatin dosage by 25%
Serum creatinine ≥2 mg/dL (≥177 µmol/L)	Hold therapy until serum creatinine <1.6 mg/dL (<141 µmol/L), then reduce cisplatin dosage by 50%

Therapy Monitoring

1. *Pretreatment evaluation:* H&P, chest x-ray, CBC with differential, serum electrolytes, creatinine, LFTs, ECG, CT chest and abdomen, and anterior mediastinotomy with mediastinal biopsy
2. *Before each treatment cycle:* CBC with differential and serum creatinine
3. *Response evaluation:* Chest x-ray after 2 cycles. Complete restaging including CT of chest and abdomen after 4 cycles

Notes

1. Patients who achieve a CR or PR are referred for surgery after 4 cycles of ADOC chemotherapy
2. Additional ADOC is administered to patients with residual disease that is not surgically resectable for a maximum of 6 cycles
3. Patients with histologic evidence of malignancy at surgery receive fractionated RT (total dose = 45 Gy) followed by 2 additional cycles of ADOC

REGIMEN

CISPLATIN + ETOPOSIDE

Giaccone G et al. J Clin Oncol 1996;14:814–820

Hydration before cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 1 hour. Complete infusion before commencing cisplatin administration
Cisplatin 60 mg/m²; administer intravenously in 50–500 mL of 0.9% NS over 60 minutes on day 1, every 3 weeks (total dosage/cycle = 60 mg/m²)
Hydration after cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed
Etoposide 120 mg/m² per day; administer intravenously over 60 minutes, diluted in 0.9% NS or 5% dextrose injection to a concentration within the range of 0.2–0.4 mg/mL, for 3 consecutive days, days 1–3, every 3 weeks (total dosage/cycle = 360 mg/m²)

Notes: Patients who tolerate treatment well and do not progress can receive up to 8 consecutive cycles of therapy. Use of steroids is discouraged, except for patients with myasthenia gravis previously receiving a stable dose of steroids

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days 2 and 3 is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ or platelet count <100,000/mm³	Delay therapy a maximum of 2 weeks until ANC >1500/mm³ and platelet count >100,000/mm³
>2-week delay	Decrease dosage of both drugs by 25%

Dose reductions are also made based on nadir counts. If the leukocyte nadir and/or platelet nadir was 1000–1999/mm³ or 50,000–74,999/mm³ respectively, the doses of both drugs were reduced by 25% for subsequent cycles; if the nadirs were <1000/mm³ and/or <50,000/mm³ respectively, the doses of both drugs were reduced by 50% for subsequent cycles

Serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Hold therapy until serum creatinine <1.6 mg/dL (<141 µmol/L), then reduce cisplatin dosage by 25%
Serum creatinine ≥1.5 mg/dL (≥133 µmol/L and remained elevated for more than 2 weeks after the scheduled time of the next cycle)	Hold therapy until serum creatinine <1.5 mg/dL (<133 µmol/L), then reduce cisplatin dosage by 50%

Patient Population Studied

A study of 16 patients with recurrent or metastatic malignant thymoma that was considered incurable by excision and/or radiation therapy. Patients who previously received chemotherapy were eligible if they had not received cisplatin or etoposide. Patients receiving corticosteroids were not eligible for the study of previous radiation therapy

Efficacy (N = 15)

Complete response	5 (33%)
Partial response	4 (27%)
Stable disease	6 (40%)
Progressive disease	0 (0%)
Median survival	51.6 months

Toxicity* (N = 28)

Anemia	—
Hemorrhage	—
Nonhematologic	
Infection	6
Nausea and vomiting	81
Diarrhea	6
Alopecia	69
Mucositis	6
Peripheral neuropathy	—
Phlebitis	—

*CTC

Therapy Monitoring

1. *Pretreatment evaluation:* H&P, CBC with differential, serum creatinine, LFTs, electrolytes, chest x-ray; CT scan of the chest, and other tumor sites as indicated creatinine clearance if adequacy of renal function is in doubt
2. *Before each treatment cycle:* H&P, chest x-ray, CBC with differential, serum creatinine, LFTs, and electrolytes
3. *Response evaluation every 2 cycles:* CT scans of chest/abdomen

REGIMEN

CISPLATIN + DOXORUBICIN + CYCLOPHOSPHAMIDE (PAC)

Loehrer PJ Sr et al. J Clin Oncol 1997;15:3093–3099

Prechemotherapy hydration: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed
Cisplatin 50 mg/m²; administer intravenously in 50–150 mL of 0.9% NS over 15–30 minutes, on day 1, every 3 weeks (total dosage/cycle = 50 mg/m²)
Doxorubicin 50 mg/m²; administer by intravenous injection over 3–5 minutes, on day 1, every 3 weeks (total dosage/cycle = 50 mg/m²)
Cyclophosphamide 500 mg/m²; administer intravenously in 50–150 mL of 0.9% NS or 5% dextrose injection over 15–60 minutes, on day 1, every 3 weeks (total dosage/cycle = 500 mg/m²)
Postchemotherapy hydration: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours on day 1, after chemotherapy is completed

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ or platelet count <100,000/mm³	Delay therapy a maximum of 2 weeks until ANC >1500/mm³ or platelet count >100,000/mm³
2-Week delay	Decrease dosage of all 3 drugs
Serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Hold therapy until serum creatinine <1.6 mg/dL (<141 µmol/L) then reduce cisplatin dosage by 25%
Serum creatinine ≥2 mg/dL (≥ 177 µmol/L)	Hold therapy until serum creatinine <1.6 mg/dL (<141 µmol/L), then reduce cisplatin dosage by 50%

Therapy Monitoring

1. *Pretreatment evaluation:* H&P, CBC with differential, serum creatinine, LFTs, electrolytes, chest x-ray; creatinine clearance if adequacy of renal function is in doubt
2. *Before each treatment cycle:* H&P, CBC with differential, serum creatinine, LFTs, and electrolytes
3. *Disease evaluation every 2 cycles:* Response evaluated before starting RT

Notes

1. Patients who achieve a CR or PR after 2 or 4 cycles of chemotherapy are referred for RT (total dose = 5400 cGy) to primary tumor and mediastinal and bilateral hilar lymph nodes
2. A maximum of 6 additional cycles of PAC chemotherapy may be administered after completing RT

REGIMEN

PACLITAXEL + CARBOPLATIN

Lemma GL et al. J Clin Oncol 2011;29:2060–2065

Premedication (primary prophylaxis against hypersensitivity reactions from paclitaxel):
Dexamethasone 20 mg intravenously 30–60 minutes before paclitaxel
Diphenhydramine 25 mg by intravenous injection 15–30 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 50 mg, or famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); intravenously over 15–30 minutes, 30–60 minutes before starting paclitaxel administration

Paclitaxel 225 mg/m² intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection (D5W) sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours, on day 1, every 3 weeks (total dosage/cycle = 225 mg/m²)
Carboplatin [calculated dose] AUC = 6 mg/mL · min; intravenously in 50–150 mL D5W over 30 minutes, on day 1, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL · min) (see equation below)
Dexamethasone 8 mg/dose orally every 12 hours for 6 doses after chemotherapy if G ≥2 arthralgias/myalgias occur
- In patients who develop arthralgia or myalgia, include dexamethasone as prophylaxis against recurrent symptoms during subsequent treatment cycles

Carboplatin dose calculation is based on formulae developed to achieve consistent drug exposure within and among patients. Area under the plasma concentration versus time curve (AUC) is the targeted pharmacokinetic end point used to obtain consistent exposure

The method of Calvert et al:
Current product labeling for carboplatin approved by the U.S. Food and Drug Administration describes dose calculation based on a formula described by Calvert et al:

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be measured from a 24-hour urine collection or estimated from any among several equations, such as the method of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 - \text{age [year]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [year]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States will use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity
Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling
If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used
U.S. FDA. Carboplatin dosing. [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm

(*continued*)

Patient Population Studied

A phase II study of carboplatin and paclitaxel in 46 patients with unresectable thymoma or thymic carcinoma. Patients previously treated with preoperative or adjuvant chemotherapy for thymic malignancy were allowed to enroll, if disease-free survival before recurrence was longer than 1 year

Toxicity (N = 46)

Adverse Event	G3	G4
Neutropenia	NR	24.4
Febrile neutropenia	2.2	2.2
Sensory neuropathy	13.3	0

National Cancer Institute Common Toxicity Criteria, version 2.0

(*continued*)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is at least ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (N = 44)

Thymoma (N = 21)		
ORR (N = 21)*	42.9% (9)	90% CI, 24.5% to 62.8%
CR (N = 21)*	14.3% (3)	
PR (N = 21)*	28.6% (6)	
Median PFS	16.7 months	95% CI, 7.2 to 19.8 months

ORR (N = 22)	21.7% (5)	90% CI, 9.0–40.4%
CR (N = 22)	(0)	
PR (N = 22)	21.7 (5)	
Median PFS	5 months	95% CI, 3.0–8.3 months
Median OS	20 months	95% CI, 5.0–43.6 months
Median duration of response	4.5 months	95% CI, 3.4–9.9 months

*For patients with thymoma, no significant differences among various histologies were noted with respect to objective responses (A/AB v B1/B2 vs thymoma-NOS; $p = 0.49$), but the numbers were not large enough to make meaningful conclusions

Note: patients with thymoma have marginally improved PFS (logrank $p = 0.06$) and OS (logrank $p = 0.01$), compared with patients with thymic carcinoma. Cox regression analysis shows that the hazard ratio of thymic carcinoma over thymoma is 3.0 (95% CI, 1.2–7.8; $p = 0.02$) and 2.1 (95% CI, 1.0–4.5; $p = 0.06$) for OS and PFS, respectively

Therapy Monitoring

1. *Pretreatment evaluation:* H&P, performance status (PS) evaluation, CBC with differential, metabolic profile including LFTs, CT scan of the chest and abdomen, pregnancy test (in females with childbearing potential)
2. *Before each cycle:* H&P, PS evaluation, CBC with differential, metabolic profile including LFTs, assessment of toxicity
3. *Response evaluation:* Every 2 cycles

Treatment Modifications

Adverse Event	Treatment Modification
On day 1 of a cycle ANC $<1500/mm^3$ or platelet count $<100,000/mm^3$	Withhold paclitaxel and carboplatin until ANC $\geq 1500/mm^3$ and platelet count $\geq 100,000/mm^3$ for a maximum delay of 2 weeks
Delay of >2 weeks in reaching ANC $>1500/mm^3$ and platelet count $>100,000/mm^3$	Discontinue paclitaxel and carboplatin
After paclitaxel 225 mg/m² and carboplatin target AUC = 6 mg/mL · min: 1. Fever and neutropenia (ANC $<500/mm^3$ with fever >38°C) *or* 2. A delay of next cycle by >7 days for ANC $<1500/mm^3$, *or* 3. ANC $<500/mm^3$ >7 days	Reduce paclitaxel dosage to 175 mg/m² and carboplatin dose to target AUC = 5 mg/mL · min every 3 weeks
After paclitaxel 175 mg/m² and carboplatin target AUC = 5 mg/mL · min: 1. Fever and neutropenia (ANC $<500/mm^3$ with fever >38°C) *or* 2. A delay of next cycle by >7 days for ANC $<1500/mm^3$, *or* 3. ANC $<500/mm^3$ >7 days	Reduce paclitaxel dosage to 140 mg/m² and carboplatin dose to target AUC = 4 mg/mL · min every 3 weeks
After paclitaxel 140 mg/m² and carboplatin target AUC = 4 mg/mL · min: 1. Fever and neutropenia (ANC $<500/mm^3$ with fever >38°C) *or* 2. A delay of next cycle by >7 days for ANC $<1500/mm^3$, *or* 3. ANC $<500/mm^3$ >7 days	Discontinue paclitaxel and carboplatin
Platelet count $<50,000/mm^3$ at a paclitaxel dose of 225 mg/m² and carboplatin dose of AUC = 6 mg/mL · min every 3 weeks	Reduce paclitaxel dosage to 175 mg/m² and carboplatin dose to target AUC = 5 mg/mL · min every 3 weeks
Platelet count $<50,000/mm^3$ at a paclitaxel dose of 175 mg/m² and carboplatin dose of AUC = 5 mg/mL · min every 3 weeks	Discontinue paclitaxel and carboplatin
G3/4 sensory neuropathy at a paclitaxel dose of 225 mg/m² and carboplatin dose of AUC = 6 mg/mL · min every 3 weeks	Withhold paclitaxel and carboplatin until toxicity G ≤1, then reduce paclitaxel dosage to 175 mg/m² and carboplatin dose to target AUC = 5 mg/mL · min every 3 weeks
G2 Neurotoxicity	Reduce paclitaxel dosage to 200 mg/m²
G3 Neurotoxicity	Reduce paclitaxel dosage to 175 mg/m²
G3/4 Sensory neuropathy after paclitaxel 175 mg/m² and carboplatin dose of AUC = 5 mg/mL · min every 3 weeks	Withhold paclitaxel and carboplatin until toxicity G ≤1, then reduce paclitaxel dosage to 140 mg/m² and carboplatin dose to target AUC = 4 mg/mL · min every 3 weeks
G3/4 Sensory neuropathy after paclitaxel 140 mg/m² and carboplatin dose of AUC = 4 mg/mL · min every 3 weeks	Discontinue paclitaxel and carboplatin
G2 Arthralgia/myalgia despite dexamethasone	Reduce paclitaxel dosage to 200 mg/m²
G3 Arthralgia/myalgia despite dexamethasone	Reduce paclitaxel dosage to 175 mg/m²
G ≥2 AST or G ≥3 bilirubin	Hold paclitaxel
Moderate hypersensitivity	Patient may be retreated
Severe hypersensitivity	Discontinue therapy
Chest pain or arrhythmia during chemotherapy	Immediately stop chemotherapy and evaluate the patient
Symptomatic arrhythmias, or ≥ second-degree AV block, or an ischemic event	Discontinue therapy

REGIMEN

CAPECITABINE + GEMCITABINE

Palmieri G et al. Ann Oncol 2010;21:1168–1172

Capecitabine 650 mg/m² per dose orally twice daily with approximately 200 mL of water within 30 minutes after a meal for 28 doses on days 1–14 every 3 weeks (total dosage/cycle = 18,200 mg/m²)

Gemcitabine 1000 mg/m² per dose; intravenously in 50–250 mL 0.9% sodium chloride injection over 30 minutes for 2 doses, on days 1 and 8, every 3 weeks (total dosage/cycle = 2000 mg/m²)

Notes:

- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are given as combinations of 500-mg and 150-mg tablets
- If a dose is missed, do not double the next dose, continue with the original schedule
- Advise patients to stop taking capecitabine and to contact their medical care provider if they develop:
  1. Diarrhea: an additional 4 bowel movements per day in excess of what is normal, or any diarrhea at night
  2. Vomiting: more than once in a 24-hour period
  3. Nausea or anorexia
  4. Stomatitis
  5. Hand–foot syndrome
  6. Fever or infection

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–14 is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is *LOW*

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily

(*continued*)

Patient Population Studied

A phase II study of capecitabine and gemcitabine in 15 patients with metastatic thymic epithelial tumors. All had previously received chemotherapy, including a platinum agent in first-line treatment

Patient Characteristics (N = 15)

	Number of Patients (percent)
Gender	
Male	10 (66.7)
Female	5 (33.3)
Median age (range), 63 years (43–77 years)	
Histology	
Thymoma	12 (80)
B2	6 (40)
B2-B3	3 (20)
B3	3 (20)
Thymic carcinoma	3 (20)
Stage IVB	15 (100)
ECOG performance status	
0	8 (53.3)
1	6 (40)
2	1 (6.7)
Prior therapy	
Thymectomy	7 (46.7)
Mediastinal radiotherapy	8 (53.3)
Neoadjuvant chemotherapy	2 (13.3)
Chemotherapy for metastatic disease	15 (100)
Two prior chemotherapeutic regimens	15 (100)
Two prior regimens	8 (53.3)
Previous chemotherapy*	
Cisplatin	15 (100)
Anthracyclines	15 (100)
Cyclophosphamide	15 (100)
Somatostatin analog	14 (93.3)
Prednisone	14 (93.3)
Etoposide	13 (86.7)
Carboplatin	6 (40)

(*continued*)

(*continued*)

- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Hand–foot reaction (palmar–plantar erythrodysesthesia, PPE)

For patients who develop a hand–foot reaction, use topical emollients (eg, Aquaphor), topically or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine. Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day
- Patients who develop G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE

Efficacy (N = 15)

Response After 6 Cycles	Number of Patients (percent)
Overall response rate	6 (40%)
ORR, thymic carcinoma (N = 3)	1 (33%)
Complete response	3 (20%) (95% CI 10–35)
Partial response	3 (20%)
Stable disease	6 (40%)
Progression	3 (20%)
Median number of cycles	6 (3–9)
Median progression-free survival	11 months (95% CI 4–17)
Median progression-free survival, thymoma	11 months
Median progression-free survival, thymic carcinoma	6 months
1-Year survival rate	12/15 (80%)
2-Year survival rate	10/15 (67%)

Patient Population Studied (*continued*)

National Cancer Institute Common Terminology Criteria for Adverse Events, version 3.0

Treatment Modifications

Adverse Event	Dose Modification
First G2 nonhematologic toxicity	Hold capecitabine and gemcitabine and resume after adverse events resolve to G ≤1. No change in dosage required
Second G2 nonhematologic toxicity	Hold capecitabine and gemcitabine and resume after adverse events resolve to G ≤1. Reduce dosage of both drugs by 25%
Third G2 nonhematologic toxicity	Hold capecitabine and gemcitabine and resume after adverse events resolve to G ≤1. Reduce dosage of both drugs by 50%
Fourth G2 nonhematologic toxicity	Discontinue capecitabine and gemcitabine
First G3 or G4 hematologic or nonhematologic toxicity	Hold capecitabine and gemcitabine and resume after adverse events resolve to G ≤1. Reduce dosages of both drugs by 50%
Second G3 or G4 hematologic or nonhematologic toxicity	Discontinue capecitabine and gemcitabine
G3 or G4 toxicity persisting for >3 weeks	Discontinue capecitabine and gemcitabine
Diarrhea, nausea, and vomiting	Treat symptomatically. Resume previous dosage if toxicity is adequately controlled within 2 days after initiating treatment. If control takes longer, reduce the capecitabine dosage or if symptoms occur despite prophylaxis, reduce the capecitabine dosage by 25–50%
ANC 1000–1499/mm^3, WBC 1000–1999/mm^3, or platelets 50,000–99,999/mm^3 on day of treatment	Proceed with treatment, but decrease both drug dosages by 25%
ANC and WBC <1000/mm^3 or platelets <50,000/mm^3 on day of treatment	Hold treatment until ANC and WBC are >1000/mm^3 and platelets >50,000/mm^3. Resume treatment with gemcitabine dosage reduced by 50%
WHO G4 nonhematologic adverse events	Hold treatment until resolution to G ≤1, then resume with both drug dosages decreased by 50%

Adapted in part from NCI of Canada CTC

Therapy Monitoring

1. *Before each cycle:* H&P, PS evaluation, CBC with differential, metabolic profile including LFTs, assessment of toxicity
2. *Every week:* CBC with differential, metabolic profile including LFTs
3. *Response evaluation:* Every 2 cycles

37. Thyroid Cancer

Ann Gramza, MD and Sam Wells, MD

Epidemiology

Incidence: 62,980 (male: 15,190; female: 47,790. Estimated new cases for 2014 in the United States) (6.1 per 100,000 males 18.2 per 100,000 females)
Deaths: Estimated 1,890 in 2014 (male: 830; female: 1,060)
Median age: 50 years
Male to female ratio: 1:3

- One of the few cancers that has increased in incidence over the past several years
- Sixth most common cancer in women
- The number of new diagnoses is about double the number from 10 years ago
- Mainly affects young people. Nearly 2 of 3 cases are found in people between the ages of 20 and 55 years

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Epithelial Carcinomas	Incidence	Other Cell Types	Incidence
Papillary carcinomas	75%	**Medullary carcinoma**	<8%
Usual papillary	(75)	**Anaplastic carcinomas***	2%
Follicular variant	(15)	**Lymphoma**	Very rare
Tall cell variant	(4)	**Angiomatoid neoplasms**	Very rare
Columnar cell variant	(<1)	**Mucoepidermoid carcinomas**	Very rare
Diffuse sclerosing variant	(3)	**Malignant adult thyroid teratomas**	Very rare
Oxyphilic (Hürthle cell) variant	(2)	**Carcinomas with thymic features**	Very rare
Follicular carcinomas	10%	**Paragangliomas**	Very rare
Usual follicular	(76)		
Oxyphilic (Hürthle cell) variant	(20)		
Insular carcinoma	(4)		

*Evolved from papillary or follicular
Ain KB. Rev Endocr Metab Disord 2000;1:225–231
LiVolsi VA. Surgical Pathology of the Thyroid. Philadelphia, PA: WB Saunders, 1990

Papillary thyroid cancer (PTC)
1. Develops from the follicular cells in the normal thyroid
2. Usually found in 1 lobe; only 10–20% appear in both lobes
3. Considered a differentiated thyroid cancer
4. Together with follicular thyroid cancer, accounts for 80–90% of all thyroid cancers
5. Mutations in BRAF have been reported in 60–80% of patients with V600E (T1799A), the most common mutation

Follicular thyroid cancer (FTC)
1. Less common than PTC
2. Develops from the follicular cells in the normal thyroid
3. Considered a differentiated thyroid cancer
4. Together with PTC, accounts for 80–90% of all thyroid cancers
5. *Hürthle cell carcinoma* is usually assumed to be a variant of FTC, although its prognosis is worse
6. Mutations of codon 61 of N-***RAS*** (N2) have been reported in as many as 19% of follicular tumors

Medullary thyroid cancer (MTC)
1. Accounts for 5–10% of thyroid cancers
2. Develops in the C cells of the thyroid; has very little, if any, similarity to normal thyroid tissue
3. Occurs with multiple endocrine neoplasia type 2 (MEN 2A and MEN 2B2), in familial medullary thyroid carcinoma (FMTC) and as a sporadic form (≈80% of cases are sporadic)
4. Germline mutations in the *RET* (**RE**arranged during **T**ransfection) protooncogene cause hereditary MTC (MEN 2A, MEN 2B, and FMTC). In addition, up to 50% of patients with sporadic MTC have somatic *RET* mutations
5. MEN 2B: RET mutations in codons 918, 883, or compound heterozygotes (V804M + E805K, Y806C or S904C)

(continued)

Pathology (*continued*)

6. MEN 2A and FMTC: RET mutations in codons 609, 611, 618, 620, 630, 634, 768, 790, 791, 804, or 891
7. The constitutively active RET oncoproteins associated with MTC are sensitive to agents that inhibit RET kinase providing a rationale for targeting RET in patients with MTC

Anaplastic thyroid cancer (ATC)

1. Rare and fast-growing tumors. The majority present with extensive local invasion. 15–50% have metastatic disease at presentation with lung and pleura most common sites of metastases followed by bone, brain, and other organs
2. A poorly differentiated thyroid cancer that starts from differentiated thyroid cancer or a benign tumor of the gland. Approximately 50% have either a prior or a coexistent differentiated carcinoma
3. Loss or mutation of the p53 tumor suppressor is commonly found

Work-up

Initial Work-up of Thyroid Nodule

Thyroid nodule in clinically euthyroid patient

1. TSH level
2. Ultrasound of thyroid and central neck area
3. Fine-needle aspiration (FNA) biopsy of thyroid nodule

Note: No role for thyroid scanning unless thyrotoxic (TSH suppressed):

- If thyrotoxic and palpated nodule is "hot" on scan, it is likely benign and biopsy is unnecessary. Refer to an endocrinologist
- If nodule is "cold," proceed to FNA

Neck lymph node

1. FNA biopsy is appropriate

Mass at site distant from neck

2. Biopsy (resection) and immunohistochemistry for thyroglobulin; calcitonin

Initial Work-up (Histologic Diagnosis Established)

Papillary or follicular carcinomas and their subtypes (usually iodine avid)

1. *Do not use iodinated contrast for radiography of any type of papillary or follicular carcinomas.* This stable iodine can interfere with ^{131}I scans and therapy for up to 10 months
2. *Preop:*
   - Neck ultrasound or neck MRI
   - Noncontrast chest CT
   - CT or MRI for fixed, bulky substernal lesions
   - Evaluate vocal cord mobility
3. *Postop:*
   - ^{131}I scanning (see below)
   - Thyroglobulin (TG) level

Dedifferentiated papillary/follicular cancers (iodine nonavid, often not apparent initially)

1. *CT scans (may use contrast if known to be nonavid for iodine):* Often "fused" with PET scans
2. *Preop:*
   - Neck ultrasound or neck MRI
   - Noncontrast chest CT
   - CT or MRI for fixed, bulky substernal lesions
   - Evaluate vocal cord mobility
3. *Postop:*
   - ^{131}I scanning (see below)
   - Thyroglobulin (TG) level
4. *PET scans (^{18}F-deoxyglucose):* Sensitivity enhanced with recombinant human TSH pretreatment
5. Radiographic bone surveys (may not need if PET scan is negative and all other scans do not demonstrate any obvious evidence of disease in bone)

(*continued*)

Work-up (*continued*)

Medullary thyroid carcinoma

1. Complete CT survey (with contrast)
2. Neck ultrasound
3. Evaluate vocal cord mobility
4. Calcitonin level
5. CEA level
6. Serum calcium
7. *MEN2A and MEN2B:* Pheochromocytoma screening. Evaluate and treat appropriately before continuing

Note: If a germline mutation is found, genetic counseling and testing of first-degree relatives are recommended

Anaplastic carcinoma

1. Complete CT survey (with contrast)
2. Consider bone scan or PET scan (may not need bone scan if PET scan is done)
3. May need restaging at 2- to 4-week intervals because of rapid rate of tumor progression

Follow-up (Histologic Diagnosis Established)

Papillary or follicular carcinomas (and their subtypes)
In patients who have had thyroidectomy and are receiving suppressive doses of levothyroxine (maintain TSH ≤ 0.1 mIU/L):

1. Serial TG levels every 6 months (monitor for presence of interfering anti-TG antibodies)
   Note: The "normal range" for TG in this situation is "undetectable"
2. Physical exams, patient neck self-exams
3. ^{131}I whole-body scans (WBS) every 6 months until scan and TG are negative. ^{131}I therapy is administered if WBS is positive (see Initial ^{131}I WBS below)
4. CT of chest (noncontrast only) (interval defined by disease status)
5. PET scans if ^{131}I WBS is negative but TG is positive. Sensitivity correlates with tumor dedifferentiation and hexokinase I expression (interval defined by disease status)
6. Radiographic bone survey (interval defined by disease status)
7. Neck ultrasonography (interval defined by disease status)

Initial ^{131}I WBS: Prepare with hypothyroid protocol:

- ≈*6 Weeks before scan:* Stop levothyroxine therapy. Continue without levothyroxine >6 weeks if needed until TSH >30 mIU/L (first 4 weeks on **liothyronine sodium** 25 mcg orally twice per day)
- *2 Weeks before and during scan:* Institute low-iodine diet

If the ^{131}I WBS is positive or if the TG level is above the lowest detectable limit*	Treat with ^{131}I. Obtain ^{131}I WBS (posttreatment WBS) 48–72 hours after ^{131}I therapy. Value of subsequent treatments is based on verifying uptake on posttreatment WBS and/or significant decrease of stimulated TG
If the ^{131}I WBS is negative *despite* hypothyroid protocol *and* if TG level is undetectable	Resume levothyroxine therapy and confirm absence of dedifferentiated disease (see nos. 4–7 above). If still negative, in subsequent studies, use recombinant human TSH preparation protocol (below)

*The lowest detectable limit differs considerably from one TG assay to another. Check with laboratory

Follow-up ^{131}I WBS: Prepare with recombinant human TSH (thyrotropin alfa, Thyrogen®) protocol:

- *2 Weeks before and during scan:* Institute low-iodine diet
- *Days 1 and 2:* Administer **recombinant human TSH** 0.9 mg/day intramuscularly for 2 consecutive days
- *Day 3:* Administer 4–5 mCi ^{131}I orally
- *Day 5:* Perform ^{131}I WBS (≥30 min/view; ≥140,000 counts)
- *Day 5:* Obtain serum TG, antithyroglobulin autoantibody, and TSH levels

Note: Frequency of follow-up ^{131}I WBS and TG levels: Every 6 months until both ^{131}I WBS and TG levels are negative, then double the time interval between each negative study. Follow-up is life-long, considering current diagnostic modalities. Maximum interval between negative studies is 5 years

Note: A TG level greater than the lowest detectable limit is sufficient evidence for persistent/recurrent disease, even in the absence of positive ^{131}I WBS Antithyroglobulin autoantibodies occur in 20% of patients and interfere with the TG assay making it insensitive, but can sometimes be a surrogate marker for persistent disease

Medullary carcinoma

1. Complete CT survey (with contrast)
2. Calcitonin and CEA levels

Staging

Separate stage groupings are recommended for papillary or follicular (differentiated), medullary, and anaplastic (undifferentiated) carcinoma

Papillary or Follicular (Differentiated)

Younger than 45 Years

Group	T	N	M
I	Any T	Any N	M0
II	Any T	Any N	M1

Papillary or Follicular (Differentiated)

45 Years and Older

Group	T	N	M
I	T1	N0	M0
II	T2	N0	M0
III	T3	N0	M0
T1	N1a	M0	
T2	N1a	M0	
T3	N1a	M0	
IVA	T4a	N0	M0
T4a	N1a	M0	
T1	N1b	M0	
T2	N1b	M0	
T3	N1b	M0	
T4a	N1b	M0	
IVB	T4b	Any N	M0
IVC	Any T	Any N	M1

Medullary Carcinoma (All Age Groups)

Group	T	N	M
I	T1	N0	M0
II	T2	N0	M0
T3	N0	M0	
III	T1	N1a	M0
T2	N1a	M0	
T3	N1a	M0	
IVA	T4a	N0	M0
T4a	N1a	M0	
T1	N1b	M0	
T2	N1b	M0	
T3	N1b	M0	
T4a	N1b	M0	
IVB	T4b	Any N	M0
IVC	Any T	Any N	M1

Anaplastic Carcinoma

All anaplastic carcinomas are considered Stage IV

Group	T	N	M
IVA	T4a	Any N	M0
IVB	T4b	Any N	M0
IVC	Any T	Any N	M1

Regional Lymph Nodes (N)

Regional lymph nodes are the central compartment, lateral cervical, and upper mediastinal lymph nodes

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph node metastasis
N1a	Metastasis to Level VI (pretracheal, paratracheal, and prelaryngeal/ Delphian lymph nodes)
N1b	Metastasis to unilateral, bilateral, or contralateral cervical (Levels I, II, III, IV, or V) or retropharyngeal or superior mediastinal lymph nodes (Level VII)

Primary Tumor (T)

All categories may be subdivided: (s) solitary tumor and (m) multifocal tumor (the largest determines the classification)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Tumor 2 cm or less in greatest dimension, limited to the thyroid
T1a	Tumor 1 cm or less, limited to the thyroid
T1b	Tumor more than 1 cm but not more than 2 cm in greatest dimension, limited to the thyroid
T2	Tumor more than 2 cm but not more than 4 cm in greatest dimension, limited to the thyroid
T3	Tumor more than 4 cm in greatest dimension, limited to the thyroid, or any tumor with minimal extrathyroid extension (eg, extension to sternothyroid muscle or perithyroid soft tissues)
T4a	Moderately advanced disease. Tumor of any size extending beyond the thyroid capsule to invade subcutaneous soft tissues, larynx, trachea, esophagus, or recurrent laryngeal nerve
T4b	Very advanced disease. Tumor invades prevertebral fascia or encases carotid artery or mediastinal vessels

All anaplastic carcinomas are considered T4 tumors

T4a	Intrathyroidal anaplastic carcinoma
T4b	Anaplastic carcinoma with gross extrathyroid extension

Distant Metastasis (M)

M0	No distant metastasis (no pathologic M0; use clinical Mto complete stage group)
M1	Distant metastasis

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Expert Opinion

Surgical Approach

1. *Cytologically (or clinically) suspicious or indeterminate thyroid nodule:* Ipsilateral complete lobectomy and isthmusectomy followed by completion (during initial or subsequent procedure) of total thyroidectomy if malignancy confirmed, *unless there is a solitary intrathyroidal papillary microcarcinoma with no lymphadenopathy*
2. *Thyroid biopsy or extrathyroidal site biopsy positive for cancer:* Total thyroidectomy with ipsilateral and central modified node dissection unless it is a solitary intrathyroidal papillary microcarcinoma (≤1.0 cm) with no lymphadenopathy (in which case perform a lobectomy only)
3. *Grossly invasive tumor or bilateral disease:* Total thyroidectomy with bilateral and central modified node dissection (exception: thyroidectomy not necessary for lymphomas)
4. Medullary thyroid carcinoma requires total thyroidectomy with bilateral and central neck dissections
5. Anaplastic carcinoma requires as complete a local resection as possible, often despite grossly invasive disease. Initially unresectable tumor might be resected after a partial course of external beam radiation therapy

Radioactive Iodine (^{131}I) for Papillary and Follicular Carcinomas Including Hürthle Cell Carcinoma

(*Note:* Prepare with **hypothyroid protocol** [see Work-up: Initial ^{131}I WBS])

Initial ablation for papillary and follicular carcinomas

1. *Intrathyroidal disease with no metastases:* 100 mCi empiric dosing
2. *N1M0 disease:* 140–200 mCi empiric dosing
3. *T3-4 or M1 disease:* 200 mCi empiric dosing or treat to maximal red marrow tolerance (200 REM, ascertain with whole body/blood dosimetry analysis)

Proven thyroid bed uptake or suspected residual disease based on pathology, postoperative thyroglobulin, and surgical findings

1. 30–100 mCi adjuvant dosing to destroy residual thyroid function and sites of uptake

Follow-up treatments for:

- Positive ^{131}I WBS
- TG level greater than the lowest detection limit (1 ng/mL)
- Stimulated TG >10 ng/mL and negative scans (including PET)

1. 150–200 mCi empiric dosing with posttreatment ^{131}I imaging

Follow-up treatments for M1 disease

1. Single dose to maximal red marrow tolerance (200 REM; ascertain with whole-body/blood dosimetry analysis)
2. Adjuvant **lithium carbonate** to enhance ^{131}I tumor retention: **Lithium carbonate** 600 mg as loading dose orally, followed by **lithium carbonate** 300 mg orally every 8 hours. Begin lithium carbonate 2 days before the administration of ^{131}I and continue for an additional 5 days after ^{131}I (total 7 days)
3. *Note:* On the morning of ^{131}I therapy, obtain STAT trough lithium level. Titrate dose to a trough level of 0.6–1.2 mEq/L

Repeat Surgery

Indications:

1. Resection of macroscopic residual disease before ^{131}I
2. Localized non–iodine-avid tumor
3. Distant critical sites (eg, spinal cord, brain)
4. Bone metastases
5. Isolated distant metastases and palliation of recurrent disease

Suppression of TSH with Levothyroxine

Indication: Chronic (lifelong) tumorostatic therapy in all cases of papillary and follicular carcinomas
Goal: TSH ≤0.1 mIU/L, using minimal suppressive daily levothyroxine dosage
Note: May use a β-adrenergic blocker to mitigate tachycardia and risk of late left ventricular hypertrophy

(*continued*)

Three-Year Survival

Papillary Thyroid Cancer	
Stage I	100%
Stage II	100%
Stage III*	96%
Stage IV*	45%
Follicular Thyroid Cancer	
Stage I	100%
Stage II	100%
Stage III*	79%
Stage IV*	47%
Medullary Thyroid Cancer	
Stage I	100%
Stage II	97%
Stage III	78%
Stage IV	24%
Anaplastic Thyroid Cancer	
Stage IV†	9%

*All stages III and IV patients with follicular or papillary thyroid cancer are, by definition, more than 45 years old
†All anaplastic carcinomas are considered Stage IV

Expert Opinion (*continued*)

Bisphosphonate Therapy

Consider bisphosphonate therapy in patients with papillary, follicular, or medullary thyroid carcinoma who have symptomatic bone metastases or who have extensive disease that is not symptomatic, but who may need intervention if they progress

External Beam Radiation Therapy

Indications:

1. Localized non–iodine-avid disease (after surgical resection)
2. Protection of thoracic inlet after resection of anaplastic carcinoma (use hyperfractionation, if tolerated)
3. Palliation of distant sites of disease

Selected Multimodal Approaches

Anaplastic carcinoma: Complete primary resection followed by local external beam radiation. Restage to detect early recurrence or distant disease, then treat with chemotherapy using these sites to assess response

Systemic Chemotherapy

1. Clearly effective in thyroid lymphoma
2. Necessary (although usually futile) in anaplastic thyroid cancer
3. Should be considered in patients with symptomatic/metastatic MTC. See vandetanib regimen below
4. Despite reports of measured tumor shrinkage with some vascular endothelial growth factor (VEGF) tyrosine kinase inhibitors, evidence is still lacking that these therapies will either improve symptoms and quality of life or prolong survival. Consequently, because these therapies often have chronic and difficult side effects, patients with metastatic disease who have exhausted surgical and radiotherapy options and require systemic treatment should be referred for clinical trials
5. Inhibitors of Raf kinase have shown promising activity in preliminary reports and are undergoing extensive testing in patients with papillary thyroid carcinomas (as many as 80% of tumors harbor a mutant BRAF) with the expectation that they will likely be approved for this indication

^{18}F FDG PET Scans

As with most cancers, recommendations regarding the use of positron emission tomography (PET) scans in thyroid cancer are not evidence based at this time. In very few instances will a PET scan result alter management. General recommendations can be summarized as follows:

1. *Initial work-up of a thyroid nodule:* Although increased FDG accumulation may heighten suspicion and help identify a thyroid nodule as malignant, the poor sensitivity and high cost do not support the use of PET imaging as a tool for diagnosis
2. *DTC:* In patients considered intermediate- and high-risk, PET may have some utility in:
   - Assessing the extent of disease in patients with metastases, and
   - Assessing patients with high thyroglobulin (TG) levels and negative ^{131}I scans. In these patients, a positive PET may indicate dedifferentiation associated with tumor aggressiveness
3. *MTC:* The role of PET is limited
4. *ATC:* PET can help assess the extent of disease

REGIMEN

NEOADJUVANT + ADJUVANT DOXORUBICIN AND RADIATION WITH DEBULKING SURGERY

Nilsson O et al. World J Surg 1998;22:25–30
Tennvall J et al. Cancer 1994;74:1348–1354

TREATMENT A

Preoperative treatment:
Doxorubicin 20 mg/dose; administer by intravenous injection over 3–5 minutes starting 1–2 hours before radiation therapy, weekly, for 3 weeks (total dose/3-week course = 60 mg)
Radiation 100 cGy per fraction twice daily for 30 fractions with a minimum of 6 hours between fractions 5 days/week to a target dose of 3000 cGy in 3 weeks
Debulking surgery:
Around week 5 approximately 10–14 days after completing preoperative radiation therapy
Postoperative treatment:
Doxorubicin 20 mg/dose; administer by intravenous injection over 3–5 minutes, weekly, starting 1–2 hours before radiation therapy (total dose/week = 20 mg)
Radiation 100 cGy per fraction twice daily for 16 fractions with a minimum of 6 hours between fractions 5 days/week to a target dose of 1600 cGy (total cumulative radiation including preoperative dose = 4600 cGy over approximately 70 days)
Additional doxorubicin:
Doxorubicin 20 mg/dose; administer by intravenous injection over 3–5 minutes, weekly, in patients considered to be in "reasonably good condition" (maximum dosage/complete treatment = 750 mg/m^2)
Note: Doxorubicin is administered as a fixed dose (20 mg), but cumulative dosage is calculated as mg/m^2

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days doxorubicin is administered is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

TREATMENT B

Preoperative treatment:
Doxorubicin 20 mg/dose; administer by intravenous injection over 3–5 minutes, weekly, starting 1–2 hours before radiation therapy for 3 weeks (total dose/3-week course = 60 mg)
Radiation 130 cGy/per fraction twice daily for 23 fractions with a minimum of 6 hours between fractions, 5 days/week to a target dosage of 3000 cGy
Debulking surgery:
Around week 4 (approximately 2 weeks after completing preoperative radiation therapy)
Postoperative treatment:
Doxorubicin 20 mg/week; administer by intravenous injection over 3–5 minutes, weekly, starting 1 hour before radiation therapy (total dose/week = 20 mg)
Radiation 130 cGY/per fraction twice daily for 12 fractions with a minimum of 6 hours between fractions 5 days/week to a target dosage of 1600 cGY (total cumulative radiation dose including preoperative dose = 4600 cGy over approximately 50 days)
Additional doxorubicin:
Doxorubicin 20 mg/week; administer by intravenous injection over 3–5 minutes, weekly, in patients considered to be in "reasonably good condition" (maximum dosage/complete treatment = 400–440 mg)

Treatment Modifications

Postoperative doxorubicin was administered to patients with good performance status and in the absence of disease progression

Patient Population Studied

A study of 33 patients with anaplastic thyroid carcinoma treated with combined radiation, chemotherapy, and surgery. In later review, 160 patients were studied

Efficacy (N = 33)

	Treatment	
	A (n = 16)	B (n = 17)
Median survival	3.5 months	4.5 months
Local control	5 patients	11 patients
Local failure*	6 patients	2 patients
Persistent local disease*	5 patients	3 patients

*Cause of death

1. 24% of patient deaths attributed to local failure
2. 48% of patients had no signs of local recurrence
3. Preoperative doxorubicin and concomitant hyperfractionated radiation therapy converted unresectable tumors into a resectable state in 23 patients

Toxicity (N = 33)

1. WHO grades I and II mucosal and skin toxicity
2. Hematologic toxicity not observed
3. Treatment-related toxicities did not prevent any patient from completing planned treatment

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each treatment:* CBC with differential
3. *Every 2–3 cycles:* Imaging studies to evaluate response

Notes

Doxorubicin has been used historically; however, as a single agent, it is not considered an effective chemotherapeutic drug for anaplastic carcinoma

REGIMEN

96-HOUR CONTINUOUS-INFUSION PACLITAXEL AND WEEKLY PACLITAXEL

Ain KB et al. Thyroid 2000;10:587–594

Continuous 96-Hour IV Infusion

Optional premedication* (Primary prophylaxis against hypersensitivity reactions from paclitaxel):

Dexamethasone 20 mg/dose; administer orally for 2 doses on the evening before and the morning of chemotherapy before paclitaxel *plus*

Diphenhydramine 50 mg for 1 dose; administer by intravenous injection 30 minutes before paclitaxel *and*

Ranitidine 50 mg or **cimetidine** 300 mg for 1 dose; administer by intravenous infusion in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes given 30 minutes before paclitaxel

* The incidence of hypersensitivity reactions with 96-hour continuous infusion of paclitaxel is much lower than with other paclitaxel regimens, and in most patients premedication is not required. If a premedication regimen is not used, observe the patient carefully for at least 1 hour in the first cycle to ensure that no reaction occurs. If a reaction occurs, immediately stop paclitaxel infusion and administer the suggested premedication regimen, substituting intravenous dexamethasone

Paclitaxel 30–35 mg/m^2 per day; administer by continuous intravenous infusion in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 24 hours for 4 consecutive days, on days 1–4, every 3 weeks, for up to 6 cycles (total dosage/cycle for 30 mg/m^2 per day = 120 mg/m^2 for 35 mg/m^2 per day = 140 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Intermittent Weekly Administration

Note: Subsequent clinical experience suggests that optimal use of paclitaxel uses a 1-hour infusion of 175 mg/m^2 given weekly for 3 weeks every month, with restaging each month, and continuing until there is progressive disease or limiting toxicity. *This dose must be administered carefully with premedication against hypersensitivity reactions and growth factor support assessing patient before each dose with attention to occurrence of mucositis and neutropenia*

Primary prophylaxis against hypersensitivity reactions from paclitaxel:

Dexamethasone 20 mg/dose; administer orally for 2 doses on the evening before and the morning on which chemotherapy is given (eg, one dose 12 to 14 hours before paclitaxel plus a second dose 6 to 7 hours before paclitaxel):

Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel, *and*:

Ranitidine 50 mg or **cimetidine** 300 mg; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–30 minutes, 30 minutes before paclitaxel

Paclitaxel 175 mg/m^2; administer by intravenous infusion in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration of 0.3–1.2 mg/mL over 3 hours for 3 doses on 3 consecutive weeks every 28 days (monthly) (total dosage/cycle = 525 mg/m^2)

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
96-Hour Continuous Infusion Paclitaxel	
G2 hematologic adverse events	Hold paclitaxel until adverse events resolve to G1 or disappear, then resume paclitaxel with dosage reduced by 25%
G2/3 gastrointestinal, neurologic, cardiac, musculoskeletal toxicities, or mucositis	
G4 or unremitting G3 adverse events	Discontinue paclitaxel
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia	Reduce paclitaxel dosage by 25%
Day 1 ANC <1500/mm^3 or platelets <100,000/mm^3	Delay chemotherapy until ANC >1500/mm^3 and platelets >100,000/mm^3 for maximum delay of 2 weeks
Weekly Paclitaxel	
Day 1 ANC <1500/mm^3 or platelets <100,000/mm^3	Delay chemotherapy until ANC <1500/mm^3 and platelets >100,000/mm^3 for maximum delay of 2 weeks
Delay of <2 weeks in reaching ANC <1500/mm^3 and platelets >100,000/mm^3	Discontinue therapy
G2 neurotoxicity	Reduce paclitaxel dosage to 135 mg/m^2
G3 neurotoxicity	Discontinue paclitaxel
G2 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 135 mg/m^2
G3 arthralgia/myalgia despite dexamethasone prophylaxis	Discontinue paclitaxel
Moderate hypersensitivity	Patient may be retreated
Severe hypersensitivity	Discontinue therapy

Therapy Monitoring

1. *Before every cycle:* CBC with differential, platelet count, and LFTs
2. *Radiologic studies:* Every 2 cycles

REGIMEN

MEDULLARY THYROID CANCER

VANDETANIB

Wells SA Jr et al. J Clin Oncol 2010;28:767–772
Wells et al. J Clin Oncol 2012;30:134–141

Vandetanib 100–300 mg per day; administer orally, continually (total dose/week = 700–2100 mg)

Note:

- Patients should take vandetanib once daily at the same time each day. Vandetanib absorption is not affected by a meal, so it may be administered with or without food. Tablets should be swallowed whole (without chewing)
  - If a patient misses a scheduled dose of vandetanib, they may take the missed dose if the next scheduled dose is not due to be taken within the next 12 hours
  - If < 12 hours remain before the next scheduled dose is due, the patient should not take the missed dose but should wait and take the next regularly scheduled dose
  - If the patient vomits ≤15 minutes after taking vandetanib, another dose may be administered. The dose may only be repeated only once
  - If a patient vomits >15 minutes after an oral dose was administered, no attempt to supplement or replace the dose should be made
- If vandetanib tablets cannot be swallowed whole, they may be dispersed in a glass containing 2 ounces of non-carbonated water and stirred for approximately 10 minutes until the tablet is dispersed (tablets will not completely dissolve)
  - No other liquids should be used
  - The dispersion should be immediately swallowed or administered through nasogastric or gastrostomy tubes
  - To ensure the full dose is received, any residue in the glass should be mixed again with an additional 4 ounces of non-carbonated water and swallowed
- Vandetanib should be withheld in patients who develop electrolyte abnormalities associated with diarrhea until the electrolyte abnormalities are corrected because of the risk of QTc prolongation and subsequent arrhythmias

Note: Patients receive once-daily oral doses of vandetanib 300 mg until disease progression, or unacceptable toxicity

Note: **Although the starting dose is 300 mg per day, a majority of patients will experience an adverse event making a dose reduction necessary.** In the study cited:

1. Vandetanib dose was reduced or interrupted in 24 patients because of adverse events, most commonly diarrhea (n = 7)
2. Among the 24 patients who required dose reduction or interruption, 21 patients had a combination of dose reduction and dose interruption and 3 patients had a dose interruption without dose reduction
3. Some patients required more than a single dose reduction
4. For patients who required dose reductions, vandetanib was decreased to:
   200 mg/day (60%, 18/30)
   150 mg/day (3%, 1/30)
   100 mg/day (23%, 7/30)
   50 mg/day (6.6%, 2/30)
5. The median time to first dose reduction was 4.9 months (95% CI, 2.7–8.4 months)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Vandetanib Dose Levels	
Starting dose: Level 1	300 mg
Level −1	200 mg
Level −2	100 mg
Level −3	50 mg (100 mg every other day)
Adverse Event	**Dose Modification**
Cutaneous Toxicities	
Rash G ≥2	Hold vandetanib and provide *immediate* symptomatic treatment
If treatment held for more than 3 weeks because of cutaneous toxicity	Discontinue therapy
When toxicity resolves to G ≤1	Restart vandetanib at 1 dose level lower than that administered at the time the toxicity developed. Symptomatic treatment may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at a reduced doses of vandetanib	Again, hold vandetanib until the toxicity resolves to G ≤1 at which time vandetanib should be restarted at 1 dose level lower than that administered at the time the toxicity developed. Symptomatic treatment may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at dose level −2 or lower	Discontinue therapy
If with or without continued symptomatic treatment the cutaneous toxicity does not recur at the reduced doses of vandetanib	The dose of vandetanib may be increased 1 dose level to that which was being administered at the time the cutaneous toxicity developed. If toxicity recurs following this increase, then follow the guidelines above, with the exception that when drug is restarted the vandetanib dose should be reduced 1 dose level
Diarrhea	
G1/2 diarrhea	Focus on symptomatic treatment designed to resolve the diarrhea. No dose modifications will be made for G1/2 diarrhea unless G2 diarrhea persists for more than 2 weeks
If G2 diarrhea persists for more than 2 weeks	Then the guidelines below for G3/4 diarrhea should be followed

(continued)

Back pain	1	0.4	3	3
Syncope	0		2	2

*As defined according to the National Cancer Institute's Common Terminology Criteria for Adverse Events, v3 (and protocol-defined QTc prolongation)

Treatment Modifications (*continued*)

Diarrhea	
If the diarrhea cannot be controlled with the preventive measures outlined and is G3/4, or worsens by 1 grade level (G3 to G4) while on vandetanib and is not alleviated by symptomatic treatment within 48 hours	Hold vandetanib. Also, if persistent G2 diarrhea (persistent defined as lasting for more than 2 weeks) while on vandetanib is not alleviated by symptomatic treatment, hold vandetanib
If vandetanib is held for more than 3 weeks and the diarrhea does not resolve to G ≤1	Discontinue therapy
If within 3 weeks of holding therapy the diarrhea resolves to G ≤1	Restart vandetanib at 1 dose level lower than that administered at the time the toxicity developed
If diarrhea that is G3/4 or persistent G2 (persistent defined as lasting for more than 2 weeks) recurs at the reduced doses of vandetanib and this is greater than dose level −1	Again, hold vandetanib until the toxicity resolves to CTCAE G ≤1, at which time vandetanib should be restarted at 1 dose level lower than that administered at the time the toxicity developed. Symptomatic treatment may continue indefinitely as a preventive measure
If diarrhea that is G3/4 or persistent G2 (persistent defined as lasting for more than 2 weeks) recurs at dose level −2	Discontinue therapy
If with or without continued symptomatic treatment the diarrhea does not recur at the reduced doses of vandetanib	The dose of vandetanib may be increased 1 dose level to that which was being administered at the time the diarrhea developed. If toxicity recurs following this increase, then follow the guidelines above, with the exception that when drug is restarted the vandetanib dose should be reduced 1 dose level
Hypertension	
Note: Patients should have their blood pressure checked once per week during their first 24 weeks of therapy or for any 8-week period after any adjustment is made in their vandetanib dose	
G1 hypertension	Continue vandetanib at same dose and schedule
G2 asymptomatic	Treat with antihypertensive medications and continue vandetanib at same dose and schedule
G2 symptomatic or persistent G2 despite antihypertensive medications or diastolic BP >110 mm Hg or G3 hypertension	Treat with antihypertensive medications. Hold vandetanib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue vandetanib at 1 dose level lower *Note:* If vandetanib is held more than 3 weeks, then discontinue therapy
G4	Discontinue therapy
QTc Abnormalities	
ECGs and electrolytes should be checked 3 times per week if there are any QTc abnormalities noted	
QTc prolongation defined as: • A single measurement of ≥550 milliseconds • An increase of ≥100 milliseconds from baseline • Two consecutive measurements (within 48 hours) ≥500 milliseconds but <550 milliseconds • An increase of ≥60 milliseconds but <100 milliseconds from baseline to a value ≥480 milliseconds	Hold vandetanib until QTc <480 milliseconds, then resume vandetanib at 1 dose level lower

Therapy Monitoring

1. *ECGs:* Unless additional ECGs are clinically indicated, 12-lead ECGs are performed before the start of treatment, weekly for the first 8 weeks, and then every 12 weeks thereafter. If the dose is increased then weekly monitoring is indicated for approximately 6 weeks
2. *Response assessment:* Every 2–3 cycles

Efficacy

MTC, medullary thyroid cancer; *RET*, rearranged during transfection

MEDULLARY THYROID CANCER REGIMEN

CABOZANTINIB

Elsei et al. J Clin Oncol 2013;31:3639–3646

Cabozantinib 140 mg orally at least 2 hours after or at least 1 hour before after eating food, continually (total dose/week = 980 mg)

Notes:

- Capsules are swallowed whole (without opening or breaking)
- Do not take a missed dose within 12 hours of the next scheduled dose
- In light of the fact that 79% of patients starting at the 140-mg dose had a subsequent dose reduction and 27% discontinued the medication because of adverse effects, clinicians are advised to consider the following:
  - *Patients Taking CYP3A4 Inhibitors*
    - Avoid the use of concomitant strong CYP3A4 inhibitors (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole)
    - For patients who require treatment with a strong CYP3A4 inhibitor, reduce the daily cabozantinib dose by 40 mg. Resume the dose that was used prior to initiating the CYP3A4 inhibitor 2 to 3 days after discontinuing a strong inhibitor
  - *Patients Taking Strong CYP3A4 Inducers*
    - Avoid use of strong CYP3A4 inducers (eg, carbamazepine, phenobarbital phenytoin, rifabutin, rifampin, rifapentine) concomitantly with cabozantinib if alternative therapy is available
    - Inform patients not to ingest foods or nutritional supplements (eg, St. John's wort (*Hypericum perforatum*) known to induce cytochrome P450 activity
    - For patients who require treatment with a strong CYP3A4 inducer, increase the daily cabozantinib dose by 40 mg *only if tolerability on the dose without the inducer has been convincingly demonstrated*. Resume the dose that was used prior to initiating a CYP3A4 inducer 2 to 3 days after discontinuing a strong inducer. The daily cabozantinib dose should not exceed 180 mg

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then* **Loperamide** 2 mg every 2 hours while awake; every 4 hours during sleep

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control achieved.

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$

Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

Use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamines, or pyridoxine 50 to 200 mg/day

Dose Modifications

Adapted in part from Cometriq (cabozantinib) capsules, for oral use; 11/2012 product label. Exelixis, Inc., South San Francisco, CA

Adverse Event	Dose Modification
G ≥3 or intolerable G2 nonhematologic adverse event at a 140-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 100 mg daily
G ≥3 or intolerable G2 nonhematologic adverse event at a 100-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 60 mg daily
G ≥3 or intolerable G2 nonhematologic adverse event at a 60-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 60 mg daily, and, if not tolerated, discontinue cabozantinib
G4 hematologic adverse event at a 140-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 100 mg daily
G4 hematologic adverse event at a 100-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 60 mg daily
G4 hematologic adverse event at a 60-mg dose	Hold cabozantinib until return to baseline or resolution to G ≤1. Then, resume cabozantinib at a dose of 60 mg daily

Patient Population Studied

Locally advanced on metastatic medullary thyroid cancer. All had RECIST documented progressive disease within 14 months before screening, although the interval between scans was not fixed. There were no limits on the number of prior therapies; 95% had ECOG 0/1 PS. RET mutation status was "positive" in 46%, "negative" in 14%, and unknown in 40%. Of the studied population, 51% had bone metastases at baseline

Efficacy

	Cabozantinib	Placebo	Statistics
Median PFS, independent review (months)	11.2	4.0	HR 0.28 (95% CI: 0.19–0.40) P <0.0001

REGIMEN

SORAFENIB TOSYLATE
Late-stage (metastatic) differentiated thyroid cancer

Brose et al. ASCO 2013 Annual Meeting, J Clin Oncol 31, 2013 (Suppl; abstr 4)

Sorafenibtosylate 400 mg administer orally every 12 hours (eg, morning and evening) continually in 28-day cycles (total dose/day = 800 mg; total dose/cycle = 22,400 mg)

Notes:
- Patients should swallow tablets whole with approximately 250 mL (8 oz) of water. Tablets may be taken with or without food
- Special precautions: Sorafenib is metabolized by cytochrome P450 (CYP) CYP3A subfamily enzymes and has been shown in preclinical studies to inhibit multiple CYP isoforms. Therefore, all patients who are taking concomitant medications metabolized by CYP enzymes should be closely observed for side effects associated with concomitantly administered medications. Special caution should be used with any of the following medications: ketoconazole, itraconazole, voriconazole, ritonavir, clarithromycin, cyclosporine, carbamazepine, phenytoin, and phenobarbital. Furthermore, patients taking medications with a low therapeutic index (eg, warfarin, quinidine, digoxin) should be monitored proactively. *Patients using sorafenib should be advised to avoid consuming grapefruit products for as long as they continue to use sorafenib*

Supportive Care: Hand-foot reaction
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical and/or oral steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day orally

Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed-onset diarrhea:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stoploperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophilcount <500/mm3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Sorafenib Dose Levels	
Starting dose: Level 1	400 mg every morning; 400 mg every evening
Level −1	200 mg every morning; 400 mg every evening
Level −2	200 mg every morning; 200 mg every evening
Level −3	200 mg once daily

Adverse Event	Dose Modification
Cutaneous Toxicities	
Rash G ≥2	Hold sorafenib and provide immediate symptomatic treatment
If treatment is withheld for more than 3 weeks because of cutaneous toxicity	Discontinue therapy
When toxicity resolves to G ≤1	Restart sorafenib at one dose level less than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at reduced sorafenib doses	Again, hold sorafenib until the toxicity resolves to G ≤1, at which time sorafenib should be restarted at one dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure
If cutaneous toxicity G3/4 recurs at dose levels −2 or lower	Discontinue therapy
If cutaneous toxicity does not recur at reduced sorafenib doses with or without continued treatment for symptoms	The dose of sorafenib may be increased one dose level to the dose level administered at the time cutaneous toxicity developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the sorafenib
Diarrhea	
G1/2 diarrhea	Focus on treatment for symptoms designed to resolve the diarrhea. No dose modifications will be made for G1/2 diarrhea unless G2 diarrhea persists for more than 2 weeks
If G2 diarrhea persists for more than 2 weeks	Follow the guidelines below for G3/4 diarrhea
If diarrhea cannot be controlled with the preventive measures outlined, and is G3/4 or worsens by one grade level (G3 to G4) while on sorafenib and is not alleviated within 48 hours by antidiarrheal treatment	Hold sorafenib. Also, withhold sorafenib if persistent G2 diarrhea is not alleviated by antidiarrheal treatment while sorafenib use continues (persistent is defined as lasting for >2 weeks)
If sorafenib is held for more than 3 weeks and diarrhea does not resolve to G ≤1	Discontinue therapy
If within 3 weeks of withholding sorafenib, diarrhea resolves to G ≤1	Restart sorafenib at one dose level less than the dose level administered at the time toxicity developed
If G3/4 diarrhea or persistent G2 diarrhea recurs at reduced doses of sorafenib (persistent is defined as lasting >2 weeks)	Again, withhold sorafenib until the toxicity resolves to CTCAE G ≤1, at which time sorafenib should be restarted at one dose level lower than the dose level administered at the time toxicity developed. Treatment for symptoms may continue indefinitely as a preventive measure

(*continued*)

Patient Population Studied

Multicenter, double-blind, placebo-controlled trial conducted in 417 patients with locally recurrent or metastatic, progressive differentiated thyroid carcinoma refractory to radioactive iodine treatment. Patients had papillary (57 percent), follicular (25 percent), and poorly differentiated (10 percent) carcinomas. Metastases were present in 96% of the patients: lungs in 86%, lymph nodes in 51%, and bone in 27%. Approximately half of the patients were male, the median age was 63 years, 68 percent had no uptake of radioactive iodine (RAI), and 34 percent had received a cumulative dose of at least 600 mCi of RAI. The median cumulative RAI activity administered prior to study entry was 400 mCi

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
If G3/4 diarrhea or persistent G2 diarrhearecurs at dose level −2 (persistent defined as lasting for >2 weeks)	Discontinue therapy
If diarrhea does not recur at reduced sorafenib doses with or without continued treatment forsymptoms	The dose of sorafenib may be increased one dose level to the dose level administered at the time the diarrhea developed. If toxicity recurs following the increase, then follow the guidelines above, with the exception that when drug is restarted the sorafenib dose should be reduced one dose level

Hypertension

Note: Patients should have their blood pressure checked once weekly during their first 24 weeks of therapy and for an 8-week period after an adjustment in their sorafenib dose

G1 hypertension	Continue sorafenib at same dose and schedule
G2 asymptomatic	Treat with antihypertensive medications and continue sorafenib at same dose and schedule
G2 symptomatic, or persistent G2 despite antihypertensive medications, or diastolic BP >110 mm Hg, or G3 hypertension	Treat with antihypertensive medications. Hold sorafenib (maximum 3 weeks until symptoms resolve and diastolic BP <100 mm Hg); then continue sorafenib at one dose level lower. *Note:* Discontinue therapy if sorafenib is withheld >3 weeks
G4 hypertension	Discontinue therapy

Efficacy (N = 417)

Variable	Sorafenib (N = 207)	Placebo (N = 210)
Progression-free survival (PFS)	10.8 months (95% CI 9.1–12.9)	5.8 months (95% CI 5.3–7.8)
	HR = 0.587 (95% CI, 0.46–0.76, p <0.001)	
Median treatment duration	40 weeks	20 weeks
Overall survival*	HR 0.88 (95% CI, 0.63–1.24, p = 0.47)	

	Percent of Patients	
Partial response†	12.2%	0.5%
Reduction in size of target lesions	73%	27%
Stable disease ≥6 months	42%	33.5%

CI, confidence interval

*Overall survival was not statistically significantly different in patients who received sorafenib tosylate compared with patients who received placebo. The analysis was performed after 33% of the patients had died. Note that following investigator-determined disease progression, 157 (75 percent) patients randomly assigned to receive the placebo crossed over to open-label sorafenib tosylate, and it remains uncertain if this may have impacted or will impact the OS analysis

†Duration of response = 10.2 months

Therapy Monitoring

1. Every 6 weeks to 3 months: Physical examination and routine laboratory tests
2. Response assessment: Every 2–3 cycles. A cycle defined as 28 days of oral therapy

Toxicity

	Percent of Patient	
	Sorafenib	Placebo
Palmar-plantar erythrodysesthesia syndrome (PPES)	69%	8%
Diarrhea	68%	15%
Alopecia	67%	8%
Weight loss	49%	14%
Fatigue	41%	20%
Hypertension	41%	12%
Rash	35%	7%
Decreased appetite	30%	5%
Stomatitis	24%	3%
Nausea	21%	12%
Pruritus	20%	11%
Abdominal pain	20%	7%
G3/4 adverse reactions	65%	30%
Squamous cell carcinoma	3%	—
Secondary malignancy	4.3%	1.9%
Hypocalcemia	36%	N/R
Dose modification due to adverse event	77.8%	30.1%
Dose interruptions	66%	
Dose reductions	64%	
Treatment discontinuation due to adverse event	18.8%	3.8%

N/R, not reported

38. Vaginal Cancer

Leslie Boyd, MD and Franco Muggia, MD

Epidemiology

Incidence: 3,170 (Estimated new cases for 2014 in the United States)
Incidence of clear cell adenocarcinoma as a result of in utero diethylstilbestrol (DES) exposure estimated at 1/1000

Deaths: Estimated 880 in 2014

Median age: Squamous cell cancer (60–65 years); DES-related adenocarcinoma/clear cell (19 years)

Stage at Presentation

Stage I:	28%
Stage II:	43%
Stage III:	16%
Stage IV:	13%

Pathology

Histologic Classification of Vaginal Neoplasia

VAIN (VAginal Intraepithelial Neoplasms)

These are pre-malignant lesions of the vaginal squamous epithelium that can develop primarily in the vagina or as an extension from the cervix. Histologically, VAIN is defined in the same way as cervical intraepithelial neoplasia (CIN). Classification includes three grades: Grade 1 (VAIN I = mild dysplasia); Grade 2 (VAIN II = moderate dysplasia); and Grade 3 (VAIN III = severe dysplasia or carcinoma in situ)

Invasive carcinoma:

1. Squamous cell carcinoma	88%
2. Adenocarcinoma	5%
3. Other epithelial cell types (adenosquamous, adenoid cystic, undifferentiated)	1–2%
4. Mesenchymal tumors (leiomyosarcoma, sarcoma botryoides, endometrioid sarcoma)	2%
5. Mixed epithelial and mesenchymal tumors	<1%
6. Other histologies (melanoma, sarcoma, yolk sac tumors, lymphoma, carcinoid, small cell)	3–4%

Higinia R et al. Vagina. In: Hoskins WJ, Perez CA, Young RC, eds. Principles and Practice of Gynecologic Oncology. 4th ed. Philadelphia: Lippincott-Raven, 2005:707–742
Zaino RJ, Robboy SJ, Kurman RJ. Diseases of the vagina. In: Blaustein's Pathology of the Female Genital Tract. 5th ed. New York: Springer-Verlag, 2002:178–195

Work-up

VAIN (vaginal intraepithelial neoplasia):

1. H&P, including bimanual examination, palpation, and colposcopic examination of the vagina, vulva, and cervix
2. Multiple site-directed biopsies, including cervical and vulvar biopsies, to rule out invasive disease and metastatic lesions

Invasive carcinoma:

1. H&P including bimanual examination and palpation of vagina
2. Multiple site-directed biopsies, including cervical biopsies to rule out invasive disease and primary cervical cancer
3. Studies allowable for staging as per FIGO* guidelines: chest X-ray, cystoscopy, proctosigmoidoscopy, and intravenous pyelogram. Although not part of staging, pelvic MRI or CT scan may aid in planning of patient care
4. If clinically warranted, barium enema and CAT scan or MRI

Staging is best performed by gynecologic and radiation oncologists with the patient under general anesthesia. Additional biopsies of the vagina should be done to determine the limits of abnormal vaginal mucosa

*International Federation of Gynecology and Obstetrics (FIGO)

Hoskins WJ, Perez CA, Young RC, eds. Principles and Practice of Gynecologic Oncology. 2nd ed. Philadelphia: Lippincott-Raven, 1997

Staging

TNM Category	FIGO Stage	Primary Tumor (T)
TX		Primary tumor cannot be assessed
T0		No evidence of primary tumor
Tis	*	Carcinoma *in situ*
T1	I	Tumor confined to vagina
T2	II	Tumor invades paravaginal tissues but not to pelvic wall
T3	III	Tumor extends to pelvic wall†
T4	IVA	Tumor invades mucosa of the bladder or rectum and/or extends beyond the true pelvis (bullous edema is not sufficient evidence to classify a tumor as T4)

*FIGO staging no longer includes Stage 0 (Tis)
†Pelvic wall is defined as muscle, fascia, neurovascular structures, or skeletal portions of the bony pelvis

TNM Category	FIGO Stage	Regional Lymph Nodes (N)
NX		Regional lymph nodes cannot be assessed
N0		No regional lymph node metastasis
N1	III	Pelvic or inguinal lymph node metastasis

TNM Category	FIGO Stage	Distant Metastasis (M)
M0		No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	IVB	Distant metastasis

Staging*

	T	N	M
0	Tis	N0	M0
I	T1	N0	M0
II	T2	N0	M0
III	T1–T3	N1	M0
	T3	N0	M0
IVA	T4	Any N	M0
IVB	Any T	Any N	M1

*FIGO staging no longer includes Stage 0 (Tis)

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Expert Opinion

General:

1. Vaginal neoplasms are quite rare and are considered primary only if neither the vulva nor the cervix is involved at the time of diagnosis
2. A carcinoma involving the upper vagina and cervix should be considered a cervical primary and managed accordingly
3. Histologically most vaginal carcinomas are squamous, and chemotherapeutic management is usually based on extrapolation from experience with cervical carcinoma, given similarities in location, pattern of spread, histologic appearance, r elation to HPV, and response to radiation therapy

Therapeutic Principles:

1. *Vaginal intraepithelial neoplasia (VAIN):* Treated with local modalities such as CO_2 laser ablation, topical fluorouracil, local radiation, imiquimod, or surgical excision. Regression rates are excellent. Close cytologic surveillance is warranted
2. *Stages I and II:* Standard treatment by gynecologic or radiation oncologists is highly effective
3. *Stages III and IVA:* Radiation therapy alone has yielded suboptimal results. Reports of combined chemoradiation have been more encouraging, and because of similarities with cervical cancer, cisplatin-based chemoradiation has been advocated as standard therapy
4. *Stage IVB and recurrences are not amenable to locoregional therapy:* Anthracyclines and platinum compounds as single agents or in combinations have some activity, but experience is limited to small case series. Taxane-based therapy also is reasonable, particularly for adenocarcinoma. Considering the rarity of cases, care providers should consider clinical trials

REGIMEN

DOXORUBICIN (SINGLE AGENT)

Piver MS et al. Am J Obstet Gynecol 1978;131:311–313

Doxorubicin 60–90 mg/m²; administer by slow intravenous injection over 3–5 minutes on day 1, every 4 weeks (total dosage/cycle = 60 to 90 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

Myelosuppression	Dose-limiting toxicity. Leukopenia more common than thrombocytopenia or anemia. Nadir usually on days 10–14, with recovery by day 21 after treatment
Nausea and vomiting	Moderate severity on the day of treatment; delayed symptoms (>24 hours after treatment) uncommon
Mucositis and diarrhea	Common, but not dose limiting
Cardiotoxicity (acute)	Incidence not related to dosage. Presents within 3 days after treatment as arrhythmias, conduction abnormalities, ECG changes, pericarditis, and/or myocarditis. Usually transient and asymptomatic
Cardiotoxicity (chronic)	Dosage-dependent dilated cardiomyopathy associated with congestive failure. Risk increases with cumulative doses >550 mg/m²
Strong vesicant	Avoid extravasation
Skin	Hand-foot syndrome, with skin rash swelling, erythema, pain, and desquamation. Onset at 5–6 weeks after starting treatment. Hyperpigmentation of nails, rarely skin rash, urticaria. Potential for radiation recall
Alopecia	Common, but generally reversible within 3 months after discontinuing doxorubicin
Infusion reactions	Signs and symptoms include flushing, dyspnea, facial swelling, headache, back pain, chest and/or throat tightness, and hypotension. May occur with a first treatment. Symptoms resolve within several hours to a day after discontinuing doxorubicin
Urine discoloration	Red-orange discoloration usually within 1–2 days after drug administration

Patient Population Studied

Cervical or vaginal malignancies; 7 of 100 patients with advanced vaginal squamous cell carcinoma

Efficacy

(N = 7 Patients with Vaginal Cancer)

Complete response	1 patient
Partial response	1 patient*

*Treated with combination doxorubicin, cyclophosphamide, and fluorouracil

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3000/mm³ and platelet counts <100,000/mm³	Delay start of next cycle until WBC >3000/mm³ and platelet counts >100,000/mm³
>2-week delay in start of cycle	Reduce doxorubicin dose by 15 mg/m²
Doxorubicin total cumulative lifetime dosage ≥550 mg/m²	Obtain frequent MUGA scans to monitor cardiac function

Therapy Monitoring

1. *Before each treatment with doxorubicin (every 4 weeks):* H&P, CBC with differential, serum electrolytes, LFTs, BUN, and serum creatinine
2. *After patients receive a total cumulative lifetime doxorubicin dose of 550 mg/m²:* Check radionuclide left ventricular ejection fraction periodically (every 2 cycles)

Piver MS et al. Am J Obstet Gynecol 1978;131:311–313

REGIMEN

CISPLATIN (SINGLE AGENT)

Thigpen JT et al. Gynecol Oncol 1986;23:101–104

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS) administered intravenously over a minimum of 3–4 hours

Cisplatin 50 mg/m^2; administer intravenously in 50–250 mL 0.9% NS at a rate of 1 mg/min on day 1, every 3 weeks, (total dosage/cycle = 50 mg/m^2)

Hydration after cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS) administered intravenously over a minimum of 3–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: HIGH. Potential for delayed symptoms

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 22 patients with advanced or recurrent vaginal cancers

Efficacy (N = 22)

One complete response out of 22 evaluable patients with vaginal cancer (most were heavily pretreated)

Toxicity (N = 22)

Hematologic Toxicities		
	% G1	% G2
Leukopenia*	9	13.6
Thrombocytopenia†	9	—

Nonhematologic Toxicities			
	Mild	Moderate	Severe
Nephrotoxicity‡	27	—	—
Nausea/vomiting§	9	45	4.5
Fatigue	9	4.5	4.5

*Lowest WBC nadir = 2000 leukocytes/mm^3
†Lowest platelet nadir = 126,000 platelets/mm^3
‡Dose-limiting toxicity in 35–40%
§Most common adverse effect

Treatment Modifications

Adverse Events	Treatment Modifications
Serum creatinine ≥1.7 mg/dL (≥29.1 μmol/L)	Hold treatment until creatinine returns to pretreatment level, then reduce cisplatin dosage in subsequent cycles by 50%
G3/4 ototoxicity	Hold treatment until ≤ G2 then reduce cisplatin dosage in subsequent cycles by 50%
G3/4 neurotoxicity	Hold treatment until ≤ G2 then reduce cisplatin dosage in subsequent cycles by 50%

Toxicities Reported in other Studies

Neurotoxicity	Usually peripheral sensory neuropathy with bilateral paresthesia and anesthesia in a "stocking-and-glove" distribution. Risk increases with high individual doses and cumulatively. Motor and autonomic neuropathies may also occur. Neurotoxic effects may be irreversible
Ototoxicity	High-frequency hearing loss and tinnitus
Hypersensitivity	Facial edema, wheezing, bronchospasm, and hypotension within minutes of drug exposure
Hepatic	Transient increases in LFTs
Gustatory	Dysgeusia (metallic taste) and loss of appetite

Chu E, DeVita VT Jr, eds. Physicians' Cancer Chemotherapy Drug Manual 2001. Sudbury, MA: Jones and Bartlett; 100–105
Thigpen JT et al. Gynecol Oncol 1986;23:101–104

Therapy Monitoring

Before each treatment with cisplatin (every 4 weeks):
H&P, paying attention to history and objective findings of neurotoxicity, CBC with differential, LFTs, serum electrolytes, and creatinine

REGIMEN

PACLITAXEL (SINGLE AGENT)

Curtin JP et al. J Clin Oncol 2001;19:1275–1278

Premedications:
Dexamethasone 20 mg per dose; administer orally or intravenously for 2 doses, 14 hours and 7 hours before starting paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before starting paclitaxel
Ranitidine 50 mg; administer intravenously in 25–100 mL of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), over 30–60 minutes, 30 minutes before starting paclitaxel
Paclitaxel 170 mg/m²*; administer by continuous intravenous infusion diluted in 0.9% NS or D5W to a concentration within the range 0.3 and 1.2 mg/mL, over 24 hours on day 1, every 3 weeks (total dosage/cycle = 170 mg/m²*)

*Patients who previously received radiation treatment to the pelvis should be treated initially with a paclitaxel dosage of 135 mg/m². This may be increased according to the guidelines under dose modification

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential: **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Paclitaxel dosage levels:
110 mg/m² (minimum dosage to be administered)
135 mg/m²
170 mg/m²
200 mg/m² (maximum dosage to be administered)

Adverse Events	Treatment Modifications*
ANC <1500/mm³	Hold treatment until ANC ≥1500/mm³
Platelet count <100,000/mm³	Hold treatment until platelets ≥100,000/mm³
G1 hematologic toxicity	Increase paclitaxel dosage by 1 level
G2/3 hematologic toxicity	Administer same paclitaxel dosage
G4 hematologic toxicity	Decrease paclitaxel dosage by 1 level
G2 nonobstructive renal toxicity	Decrease paclitaxel dosage by 1 level
G3 hepatic toxicity	
G3 mucositis	
G4 GOG nonhematologic toxicity	

*Based on adverse events during previous cycles

Patient Population Studied

Study of 42 patients with advanced nonsquamous cell cervical cancer who had either no benefit from or progressive disease on standard chemotherapy

Toxicity (N = 42)

	Toxicity Grades*				
Toxicity†	0	1	2	3	4
Hematologic Toxicities					
Leukopenia	5	3	11	16	7
Neutropenia	7	1	3	5	26
Thrombocytopenia	35	5	1	1	0
Anemia	21	7	10	4	0
Nonhematologic Toxicities					
Nausea/vomiting	28	7	7	0	0
Gastrointestinal	31	5	5	0	1
Alopecia	16	7	19	0	0
Neurotoxicity	28	4	9	1	0
Edema	41	0	0	1	0

*Number of patients with toxicity
†The table identifies only toxicities where at least 1 patient experienced a G3 or G4 toxicity

Other Toxicities	
Febrile neutropenia	8 patients
Alopecia	26 patients
Mucositis	2 patients
Myalgia and arthralgia	Infrequent
Bradycardia grade 2	Incidence not specified

Efficacy

Complete response	9.5%
Partial response	21.5%
Median duration of response	4.8 months

Therapy Monitoring

Before each treatment: H&P, paying attention to history and objective findings of neurotoxicity, CBC with differential, LFTs, electrolytes, and creatinine

REGIMEN

CISPLATIN + FLUOROURACIL + RADIATION THERAPY

Roberts WS et al. Gynecol Oncol 1991;43:233–236

Hydration before cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2 hours
Cisplatin 50 mg/m^2; administer intravenously in 100–1000 mL 0.9% sodium chloride injection (0.9% NS), over 6 hours on day 1, every 4 weeks for 2 cycles (total dosage/4-week cycle = 50 mg/m^2)

Followed by:
Fluorouracil 1000 mg/m^2 per day; administer as a continuous intravenous infusion in 250–2000 mL 0.9% NS or 5% dextrose injection over 24 hours for 4 consecutive days, on days 1–4, every 4 weeks for 2 cycles (total dosage/4-week cycle = 4000 mg/m^2)

Hydration after cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2 hours. Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)
Concurrent with chemotherapy administer radiation therapy as follows:
External beam radiation with 20-MeV linear accelerator, 180 cGy/day fractions to a total dose of 4000–5000 cGy to the whole pelvis, ± periaortic radiation to a dose of 3600–4500 cGy
±
Additional external pelvic irradiation to limited fields to a total dose of 6480 cGy
±
Additional brachytherapy starting 2–3 weeks after external beam radiation

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1: ***HIGH*** *Potential for delayed symptoms*
Emetogenic potential on days 2–4: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 67 patients with advanced carcinomas of the lower female genital tract that were not amenable to resection were eligible, among whom 7 had vaginal cancers. Of the 7 patients with vaginal cancer, 5 had Stage III disease and 2 had recurrent disease

Efficacy*

Complete clinical response (all histologies)	85%
Partial response (all histologies)	9%
Stable disease (all histologies)	3%

*Not stated for the subset of patients with vaginal cancer. However, 3 of 7 patients with vaginal cancer were without recurrence or failure of the treatment for a median follow-up of 13 months

Treatment Modifications

Roberts WS et al. Gynecol Oncol 1991;43:233–236
Whitney CW et al. J Clin Oncol 1999;17:1339–1348*

Adverse Events	Treatment Modifications
Serum creatinine ≥1.7 mg/dL (≥29.1 µmol/L)	Hold cisplatin until serum creatinine returns to pre-treatment level, then reduce dosage by 50% in subsequent cycles
WBC ≤3000/mm^3 or platelet ≤100,000/mm^3	Delay cisplatin and fluorouracil until WBC ≥3000/mm^3 and platelet count ≥100,000/mm^3
>2-week delay in start of cycle	Reduce cisplatin and fluorouracil dosages by 50% each
G3/4 hematologic toxicity	Hold radiation therapy until hematologic toxicity is G ≤2

*Whitney et al. utilized a similar regimen for patients with cervical cancer; 91% completed both chemotherapy courses and had similar completion rates for radiation therapy

Toxicity

Acute Toxicities	
Neutropenia and thrombocytopenia	1 patient*
Radiation enteritis	5 patients†
Nausea, vomiting, and diarrhea	Very common
Renal, hepatic, or neurologic	Not significant
Delayed Toxicities	
Rectovaginal fistula	3 patients‡
Radiation proctitis	1 patient‡
Small bowel fistula	2 patients‡
Soft tissue necrosis	2 patients‡
Hemorrhagic cystitis	1 patient

*Resulted in 8- to 14-day treatment delay
†Resulted in 8- to >14-day treatment delay
‡Required surgery

Therapy Monitoring

Weekly: CBC with differential, LFTs, electrolytes, and creatinine

REGIMEN

NEODAJUVANT CISPLATIN + EPIRUBICIN

Zanetta G et al. Gynecol Oncol 1997;64:431–435

Hydration before cisplatin with ≥1000 mL 0.9% sodium chloride injection intravenously over a minimum of 2 hours
Cisplatin 50 mg/m² per dose intravenously in 50–250 mL 0.9% NS over 30–60 minutes once weekly for 9 doses (total dosage/9-week course = 450 mg/m²)

Hydration after cisplatin with ≥1000 mL 0.9% NS intravenously over a minimum of 2 hours
Notes: Encourage increased oral intake of nonalcoholic fluids. Goal is to achieve a urine output ≥100 mL/hour. Monitor and replace electrolytes as needed (potassium, magnesium, sodium)
Epirubicin HCl 70 mg/m² per dose intravenously by injection over 3–5 minutes *or* in 25–250 mL 0.9% NS or 5% dextrose injection over 15–20 minutes every 3 weeks, weeks 1, 4, and 7, for 3 doses (total dosage/9-week course = 210 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection daily for 5 days
- Begin use on the day after cisplatin (± epirubicin) is administered
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine) or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohol
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
ANC <2000/mm³ or platelets <75,000/mm³ on day of treatment	Delay treatment for 1 week

Patient Population Studied

The study population included 20 patients with locally advanced cervical adenocarcinoma (bulky IB–IIA, IIB) and 2 subjects with vaginal adenocarcinoma; mean age was 51 years (range: 15–67 years). Disease histology was adenocarcinoma in 18 subjects and adenosquamous in 4 subjects. Those with stages IB–IIA cervical carcinomas and those with vaginal adenocarcinoma were required to have tumors >4 cm in diameter, as assessed by alginate mold. All patients had a performance status <2 according to the World Health Organization criteria. Staging was done according to the International Federation of Gynecology and Obstetrics.

(*continued*)

- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Additional therapies given:

- In operable patients, Piver 3 radical hysterectomy with pelvic lymphadenectomy and aortic node sampling was performed within 30 days after the completion of chemotherapy
- Histologic analysis of all surgical specimens assessed the extent of cervical, vaginal, and parametrial disease and the status of all surgical margins and lymph nodes
- Patients with surgical detection of positive lymph nodes, parametrial infiltration, or peritoneal spread received adjuvant treatments
- Postoperative radiotherapy consisted of 4500 cGy with 18 MeV photons, given by means of a field up to L4–L5 in the case of negative nodes, and up to T11–T12 in the case of positive common iliac nodes for subjects with stable disease or minimal response
- Subjects achieving a good clinical response to neoadjuvant treatment received additional chemotherapy "in order to confirm this response"

Toxicity (N = 21*)

Grade	G0–1	G2	G3	G4
Leucopenia	5	6	8	2†
Thrombocytopenia	13	4	3	1
Anemia	11	6	4	—

39. Prophylaxis and Treatment of Chemotherapy-Induced Nausea and Vomiting

Thomas E. Hughes, PharmD, BCOP

Chemotherapy-Induced Nausea and Vomiting (CINV)

Neurotransmitters and their receptor targets implicated in CINV

- Serotonin and the serotonin subtype 3 (5-HT_3) receptor
- Dopamine and the dopamine subtype 2 (D_2) receptor
- Substance P and the neurokinin subtype 1 (NK_1) receptor
- Histamine, acetylcholine, opioids, and their respective receptors

Two Phases of CINV

Acute phase

- Occurs during the first 24 hours after exposure to emetogenic chemotherapy and is mediated by release of serotonin from enterochromaffin cells within GI tract
- Actual time of onset varies depending on the chemotherapeutic agent

Delayed phase

- Substance P and the NK_1 receptor may be more important than serotonin in delayed CINV
- Delayed CINV was initially described with cisplatin
- Delayed CINV has also been described with other chemotherapeutic agents, including carboplatin, cyclophosphamide, and the anthracyclines
- Although the onset of delayed emesis was initially defined as that which occurs 24 hours postchemotherapy, more recent evidence suggests that referable symptoms may occur as early as 16 hours after cisplatin
- The incidence of delayed vomiting after cisplatin is greatest during the 24-hour period from 48 to 72 hours after treatment, and, thereafter, declines progressively

Anticipatory Nausea and Vomiting

- Development is associated with poor emetic control during prior administration of chemotherapy
- Prevention is the best approach
- Pharmacologic interventions are usually not successful, but behavioral methods with systemic desensitization is effective and has been used with some success

Antiemetic Principles[1–7]

- 5-HT_3 receptor antagonists demonstrate comparable efficacy at equivalent doses. In general, they can be used interchangeably based on convenience, availability, and cost. Evidence from clinical trials suggests palonosetron may be more effective than other 5-HT_3-receptor antagonists in preventing delayed CINV. Clinical practice guidelines from the Multinational Association of Supportive Care in Cancer (2010), and the American Society of Clinical Oncology (2011 update) recommend palonosetron as the preferred 5-HT_3 receptor antagonist in prophylaxis for chemotherapy of moderate emetic potential when aprepitant is not included in the regimen.[2,4,6] The National Comprehensive Cancer Network antiemesis guideline (version 1.2012) recommends palonosetron as the preferred 5-HT_3 receptor antagonist in prophylaxis for both high and moderate emetic risk categories[3]
- The lowest established proven dose of each 5-HT_3 receptor antagonist should be used
- Single-dose prophylactic regimens of 5-HT_3 receptor antagonists and corticosteroids for acute phase CINV prophylaxis are effective and preferred
- At biologically equivalent doses, oral antiemetic regimens are equivalent to intravenous antiemetic regimens
- All patients receiving chemotherapy should have antiemetics available on a PRN basis for breakthrough nausea and vomiting. Rescue agents should be selected to complement, not duplicate the prophylactic regimen (ie, select drugs from a different pharmacologic class)
- For CINV prophylaxis where there is a high emetic potential (emetic incidence of >90%), an antiemetic regimen that includes a 5-HT_3 receptor antagonist, a corticosteroid, and aprepitant (NK_1 receptor antagonist) is recommended. This antiemetic regimen is also recommended for combination chemotherapy regimens that include an anthracycline (eg, doxorubicin, epirubicin) and cyclophosphamide (see Table 39-4)
- For CINV prophylaxis where there is a moderate emetic potential (emetic incidence of 30–90%), an antiemetic regimen that includes a 5-HT_3 receptor antagonist and a corticosteroid is recommended (see Table 39-4)
- A corticosteroid alone is the recommended prophylactic regimen for low or intermediate emetic potential chemotherapy (emetic incidence of 10–30%)

Table 39–1. Antiemetic Pharmacologic Classes and Class Side Effects

Pharmacologic Class	Agents/Generic Name (Trade Name) (U.S. FDA Approved)	Side-Effects Profile[8–13]
5-HT_3 receptor antagonists	Dolasetron (Anzemet) Granisetron (Kytril, Sancuso) Ondansetron (Zofran) Palonosetron (Aloxi)	Headache [C] Constipation [I] Light-headedness or dizziness [I] Transient elevations in liver enzymes [I] *ECG interval changes:* Prolongation of PR, QTc, and JT, and widening of QRS (especially dolasetron) [R]
Corticosteroids	Dexamethasone (Decadron, generic products) Methylprednisolone (Solu-Medrol, generic products)	Hyperglycemia Mood changes Increased appetite Diarrhea Perineal irritation with rapid IV administration of dexamethasone Fluid retention
NK_1 receptor antagonists	Aprepitant (Emend) Fosaprepitant (Emend)	In randomized trials, treatment side effects were similar with or without aprepitant
Dopaminergic antagonists: Phenothiazines	Chlorpromazine (Thorazine, generic products) Perphenazine (Trilafon, generic products) Prochlorperazine (Compazine, generic products) Promethazine (Phenergan, generic products) Thiethylperazine (Torecan, generic products)	Extrapyramidal side effects* Sedation Anticholinergic effects Hypotension with rapid IV administration, hypersensitivity Hepatotoxicity Cholestatic jaundice Leukopenia and agranulocytosis Hormonal dysfunction Neuroleptic malignant syndrome† Cardiovascular effects‡
Dopaminergic antagonists: Butyrophenones	Droperidol (Inapsine) Haloperidol (Haldol, generic products)	Extrapyramidal side effects* Sedation Agitation Dizziness Chills Hallucinations Hypotension or hypertension Prolongation of ECG intervals (QT prolongation) Arrhythmias (eg, torsades de pointes)
Substituted benzamides	Metoclopramide (Reglan) Trimethobenzamide (Tigan)	Sedation Diarrhea Extrapyramidal side effects* Neuroleptic malignant syndrome† Hypotension Arrhythmias
Benzodiazepines	Lorazepam (Ativan) Alprazolam (Xanax)	Sedation Lethargy Weakness Impaired coordination
Cannabinoids	Dronabinol (Marinol) Nabilone (Cesamet)	Mood changes Memory loss Euphoria Dysphoria Hallucinations Sedation Paranoid ideation Ataxia Motor incoordination Blurred vision Hunger Cardiovascular effects§ Syncope

(continued)

Table 39–1. *(continued)*

Pharmacologic Class	Agents/Generic Name (Trade Name) (U.S. FDA Approved)	Side-Effects Profile[8–13]
Atypical Antipsychotics	Olanzapine (Zyprexa) Mirtazapine (Remeron)	Sedation Extrapyramidal side effects* Neuroleptic malignant syndrome† Weight gain, hyperglycemia, and other features of metabolic syndrome may be seen with high doses and prolonged use
Antihistamines	Diphenhydramine (Benadryl, generic products) Hydroxyzine (Atarax, generic products) Meclizine (Antivert, generic products)	Sedation Dry mouth Constipation Blurred vision
Anticholinergics	Scopolamine (Transderm Scōp)	Dry mouth Somnolence Sedation Constipation

C, common; I, infrequent; R, rare. For other agents, order of frequency is less clear
*Extrapyramidal side effects: Akathisia, dyskinesias, parkinsonism, acute dystonias (oculogyric crisis, torticollis)
†Neuroleptic malignant syndrome: Hyperthermia, severe extrapyramidal dysfunction (eg, severe hypertonicity of skeletal muscles, altered mental status and/or level of consciousness, and autonomic instability)
‡Phenothiazine cardiovascular effects include hypotension, syncope, hypertension, bradycardia, and various ECG changes (nonspecific, reversible Q- and T-wave abnormalities). Cases of sudden death have also been reported, presumably secondary to ventricular arrhythmias
§The cardiovascular adverse effects of dronabinol are inconsistent but the following have been reported during therapy: hypotension, hypertension, syncope, tachycardia, palpitations, vasodilation, and facial flushing

Table 39–2. Pharmacokinetic Parameters of 5-HT_3 Receptor Antagonists[8–14]

Parameter	Ondansetron (0.15 mg/kg IV)	Granisetron (40 mcg/kg IV)	Dolasetron* (1.8 mcg/kg IV)	Palonosetron (10 mcg/kg IV)
Half-life (hours)	4.0†	8.95†	7.5†	40‡
Protein binding	70–76%	65%	69–77%	62%
Oral bioavailability	56%	60%	75%	NR
Metabolism CYP enzymes	Hepatic CYP3A4 (major) CYP2D6, CYP1A2	Hepatic CYP3A4	Hepatic CYP2D6 (major) CYP3A4 (minor)	Hepatic CYP2D6 (major) CYP3A4, 1A2
Urinary excretion (parent compound)	5%	12%	67%	40%

Decreased clearance in hepatic dysfunction Dosage adjustment in hepatic dysfunction	Yes Yes (in severe dysfunction)	Yes No	No (IV), Yes (PO) No	No No
Decreased clearance in renal dysfunction Dosage adjustment in renal dysfunction	Yes No	No No	Yes No	Yes No

*Dolasetron is rapidly converted to the active metabolite hydrodolasetron. All reported parameters refer to hydrodolasetron
†Data from cancer patients
‡Data from studies in healthy volunteers

Table 39–3. Classification of Emetic Risk[1–4]

Emetic Potential	Chemotherapy Drug	
High Frequency of emesis >90%	Carmustine (>250 mg/m²)[1,3] Cisplatin (≥50 mg/m²)[1,3,4] Cyclophosphamide (>1500 mg/m²)[1–4] Dacarbazine[1–4] Lomustine (>60 mg/m²)[1] Mechlorethamine[1–4] Streptozocin[1–4]	
Moderate Frequency of emesis 30–90%	Aldesleukin (IL-2) (>12–15 million IU/m²)[3] Altretamine[3] Arsenic Trioxide[3] Azacitidine[3,4] Bendamustine[3,4] Busulfan (IV, oral >4 mg/kg per day)[3,*] Carboplatin[1–4] Carmustine (≤250 mg/m²)[1,3] Cisplatin (<50 mg/m²)[1,3] Clofarabine[3,4] Cyclophosphamide (<1500 mg/m²)[1–4] Cytarabine (>1000 mg/m²)[1,2,4] Dactinomycin[3] Daunorubicin[2–4]	Doxorubicin[1–4] Epirubicin[2–4] Idarubicin[1–4] Interferon alfa (≥10 million IU/m²)[3] Ifosfamide[1–4] Irinotecan[1–4] Melphalan (IV)[1,3] Methotrexate (>250 mg/m²)[1,3] Oxaliplatin[2–4] Pentostatin* Procarbazine[1] Romidepsin* Temozolomide[3,4]
Low Frequency of emesis 10–30%	Aldesleukin (IL-2) (<12 million IU/m²)[3] Bortezomib[2,4] Cabazitaxel[3] Capecitabine[4] Cetuximab[2,4] Cytarabine (<1000 mg/m²)[1,2,4] Daunorubicin, Liposomal* Decitabine* Denileukin diftitox* Docetaxel[1–4] Doxorubicin, Liposomal[3,4] Eribulin[3] Etoposide[1–4] Everolimus[4] Fluorouracil[2–4] Gemcitabine[1–4] Imatinib* Interferon alfa (>5 to <10 million IU/m²)[3] Ixabepilone[3,4]	Lapatinib[4] Lenalidomide[4] Methotrexate (>50 mg/m² to <250 mg/m²)[1,3] Mitomycin[1–4] Mitoxantrone[2–4] Nelarabine* Paclitaxel[1–4] Paclitaxel, albumin-bound suspension[3] Panitumumab[4] Pazopanib* Pemetrexed[2–4] Pralatrexate[3] Sunitinib[4] Temsirolimus[4] Teniposide[1] Thalidomide[4] Thiotepa[1] Topotecan[1–4]
Minimal Frequency of emesis <10%	Alemtuzumab[3] Asparaginase[3] Bevacizumab[3,4] Bleomycin[1–4] Busulfan (oral, <4 mg/kg per day)[1] Chlorambucil[1,4] Cladribine[1–4] Dasatinib* Erlotinib[4] Fludarabine[1–4] Gefitinib[4] Hydroxyurea[1,4] Interferon alfa (≤5 million IU/m²)[3] Ipilimumab[3]	Melphalan (oral)[1,4] Mercaptopurine[1] Methotrexate (<50 mg/m²)[1,3,4] Nilotinib* Ofatumumab[3] Pegaspargase[3] Rituximab[2–4] Sorafenib[4] Thioguanine (oral)[1,4] Trastuzumab[3] Vinblastine[1–4] Vincristine[1–4] Vinorelbine[1–4]

Classifications are adapted from references 1–4. Each agent is referenced to a specific guideline. When discrepancies existed among guidelines, the author classified the agent on personal opinion and referenced the guideline that supported the classification chosen. If the agent was not classified by a clinical guideline or the clinical guideline classification was in doubt, the classification was based on the incidence of emesis documented in product labeling

*Classified based on the incidence of emesis documented in product labeling

Table 39–4. Antiemetic Regimens for Prophylaxis of CINV (Adults)[1–4]

Emetic Potential	Acute Nausea and Vomiting Antiemetic Regimen (First 24 Hours, Day 1)	Delayed Nausea and Vomiting Antiemetic Regimen (>24 Hours, Days 2–5)	Notes and Comments
High Frequency of emesis >90%	5-HT_3 antagonist + corticosteroid + aprepitant (all given as single doses 30–60 minutes prior to chemotherapy)	Aprepitant + corticosteroid	See Table 39-3 for emetic risk classification of chemotherapy agents and regimens Agents associated with delayed CINV include cisplatin, carboplatin, cyclophosphamide, anthracyclines (eg, doxorubicin, epirubicin) and drug combinations that include these agents See Table 39-5 for dosing recommendations for antiemetic agents Corticosteroids should *not* be used with regimens containing aldesleukin (IL-2)
Moderate Frequency of emesis 30–60%	5- HT_3 antagonist + corticosteroid ± aprepitant (all given as single doses 30–60 minutes prior to chemotherapy)	Aprepitant (if aprepitant is used for acute prophylaxis) *or* Corticosteroid *or* 5-HT_3 antagonist	See above Aprepitant should be utilized in patients treated with the combination of cyclophosphamide and an anthracycline (eg, doxorubicin or epirubicin). Aprepitant may be considered for other moderately emetogenic regimens, particularly in refractory patients
Low Frequency of emesis 10–30%	Corticosteroid (a single dose 30 minutes prior to chemotherapy *or* Dopaminergic antagonist (a single dose 30 minutes prior to chemotherapy) *Note:* Antiemetic prophylaxis may often be unnecessary	Not necessary	Dopaminergic antagonists include prochlorperazine, chlorpromazine, haloperidol, thiethylperazine, metoclopramide, perphenazine, and promethazine
Minimal Frequency of emesis <10%	Antiemetic prophylaxis is usually not necessary	Not necessary	See above

Table 39–5. Dosing Recommendations for CINV Prophylaxis (Adults) for Moderate to Highly Emetic Chemotherapy[1–4]

Agent	Acute CINV Prophylaxis (Day 1)*			Delayed CINV Prophylaxis (Days 2–5)	Dosage Forms
	Oral (PO)	Intravenous (IV)	Other		
5-HT_3 Receptor Antagonists					
Dolasetron mesylate (Anzemet)	100 mg PO	Not recommended		100 mg PO daily for 2–4 days	Injection Tablets: 50 mg, 100 mg
Granisetron HCl (Kytril)	2 mg PO	1 mg or 0.01 mg/kg IV		1 mg PO twice daily for 2–4 days	Injection Tablets: 1 mg
Granisetron HCl (Sancuso)	NA	NA	Apply 1 patch to the upper outer arm 24–48 hours before chemotherapy Patches are removed a minimum of 24 hours after emetogenic treatment is completed, and may be worn for up to 7 days		Transdermal system: 52-cm^2 patch delivers 3.1 mg/24 hours

(*continued*)

Table 39–5. *(continued)*

Agent	Acute CINV Prophylaxis (Day 1)*			Delayed CINV Prophylaxis (Days 2–5)†	Dosage Forms
	Oral (PO)	Intravenous (IV)	Other		
Ondansetron HCl (Zofran)	16–24 mg PO	8 mg or 0.15 mg/kg IV		8 mg PO twice daily for 2–4 days	Injection Tablets: 4 mg, 8 mg, 24 mg Oral solution: 4 mg/5 mL Orally disintegrating tablets: 4 mg, 8 mg
Ondansetron (Zuplenz)	8 mg PO, 30 minutes before emetogenic treatment, then 8 mg PO 8 hours after emetogenic treatment	NA		8 mg PO every 12 hours for 1–2 days	Oral soluble film: 4 mg, 8 mg
Palonosetron HCl (Aloxi)	0.5 mg PO, 60 minutes before emetogenic treatment	0.25 mg IV		NA	Injection Oral capsules‡: 0.5 mg
Notes: • Because of its long half-life, palonosetron is usually given as a single dose prior to moderately and highly emetogenic chemotherapy with demonstrable efficacy against developing delayed CINV symptoms on subsequent days • When utilized as prophylaxis in a multiple-day chemotherapy regimen, alternative palonosetron administration strategies have been employed (eg, days 1, 3, and 5, during a chemotherapy regimen in which cisplatin 20 mg/m^2 is given daily for 5 consecutive days)					
Corticosteroids					
Dexamethasone phosphate (Decadron)	8–20 mg PO	8–20 mg IV		4 mg twice daily *or* 8 mg PO daily *or* 8 mg twice daily for 2–4 days	Injection Tablets: numerous tablet strengths
Methylprednisolone sodium succinate (Solu-Medrol)	NA	40–125 mg IV		NA	Injection
Notes: • For highly emetogenic chemotherapy, dexamethasone doses of 20 mg have been shown to be more efficacious than lower doses. In moderately emetogenic chemotherapy, doses greater than 8 mg have not been shown superior to an 8-mg dose • When combined with aprepitant, IV doses of dexamethasone should be reduced by 25%, and PO doses of dexamethasone should be reduced by 50%. A 12-mg dose of dexamethasone for acute prophylaxis in combination with aprepitant is the only dexamethasone dose evaluated in large randomized trials					
NK_1 Receptor Antagonists					
Aprepitant (Emend)	125 mg PO	NA		80 mg PO daily for 2 days	Capsules: 80 mg, 125 mg
Fosaprepitant (Emend)	NA	115 mg IV *or* 150 mg IV		Not evaluated	Injection
Notes: • Aprepitant has been evaluated only in single-day chemotherapy regimens, and, therefore, is recommended to be given for 3 days, with an initial dose of aprepitant 125 mg on the day of chemotherapy plus 80 mg/day on days 2 and 3 after emetogenic treatment. If utilized in a multiple-day chemotherapy regimen, longer durations may be indicated (80 mg/day); however, the safety of durations exceeding 5 days has not been studied • Fosaprepitant has been evaluated in 2 dosing formats. It may be used in a 3-day regimen with fosaprepitant 115 mg IV on day 1, followed by 80 mg/day orally on days 2 and 3 after chemotherapy. It has also been studied in a single-dose regimen with fosaprepitant 150 mg on day 1 prior to chemotherapy with no additional aprepitant doses administered subsequently during the same course of emetogenic treatment. The single-dose fosaprepitant regimen was shown to be non-inferior to the alternative 3-dose aprepitant regimen in a randomized study of patients receiving a highly emetogenic, cisplatin-based chemotherapy regimen[17]					

NA, Not applicable

*For chemotherapy/biologic regimens where emetogenic agents are given either multiple times within the same day or by continuous IV infusions, alternative multiple-dose antiemetic regimens may be indicated

†Delayed CINV has been associated with cisplatin, carboplatin, cyclophosphamide, and anthracyclines (eg, doxorubicin, epirubicin)

‡As of October 24, 2013, palonosetron capsules for oral administration are not commercially available in the United States

Table 39–6. Antiemetics for Treatment of Chemotherapy-Induced Nausea and Vomiting (Adults)

Pharmacologic Classes/Agents	Dosage Form	Adult Dosages, Routes, and Schedules
Dopaminergic Antagonists: Phenothiazines		
Chlorpromazine (Thorazine, others)	Oral solution	25–50 mg PO every 4–6 hours
	Tablets	25–50 mg PO every 4–6 hours
	Injection	25–50 mg IVPB/IM every 4–6 hours*
Perphenazine (Trilafon)	Tablets	2–4 mg PO every 8 hours
Prochlorperazine (Compazine, others)	Tablets	5–20 mg PO every 4–6 hours
	Sustained release capsules	15 mg PO every 8–12 hours, *or* 30 mg PO every 12 hours
	Suppositories	25 mg PR every 4–6 hours
	Injection	5–20 mg IVPB/IM every 4–6 hours*
Promethazine (Phenergan)	Tablets	12.5–25 mg PO every 4–6 hours
	Suppositories	12.5–25 mg PR every 4–6 hours
	Injection	12.5–25 mg IV every 4–6 hours†
Thiethylperazine (Torecan)	Tablets	10–20 mg PO every 4–6 hours
Dopaminergic Antagonists: Butyrophenones		
Haloperidol (Haldol, others)	Tablets	1–4 mg PO every 6 hours
	Injection	1–4 mg IVPB/IM every 6 hours*
Substituted Benzamide		
Metoclopramide (Reglan, others)	Tablets	20–40 mg (*or* 0.5 mg/kg) PO every 6 hours
	Injection	20–40 mg (*or* 0.5 mg/kg) IV every 6 hours‡
Corticosteroids		
Dexamethasone	Tablets/oral solution	4–10 mg PO every 6–12 hours
	Injection	4–10 mg IV every 6–12 hours
Methylprednisolone	Injection	20–125 mg IV/IM every 6 hours
Benzodiazepines§		
Alprazolam (Xanax)	Tablets	0.125–0.5 mg PO every 8 hours
Lorazepam (Ativan)	Tablets	0.5–1 mg PO every 6–12 hours
	Injection	0.5–1 mg IV every 6–12 hours
Cannabinoids		
Dronabinol (Marinol)	Capsules	2.5–10 mg PO every 6 hours
Nabilone (Cesamet)	Capsules	1–2 mg PO every 8–12 hours

IM, Intramuscular; IV, intravenously; IVPB, IV piggyback (IV infusion of short duration); PO, orally; PR, per rectum (suppository)
*Rapid IV administration may induce hypotension. Administer slowly by IV infusion (eg, over 30 minutes)
†Promethazine injection is a potential vesicant. Use caution with intravenous administration, particularly during administration into a peripheral vein. Drug dilution and administration by IV infusion are techniques that may reduce vascular irritation
‡Greater metoclopramide doses have been utilized for the prophylaxis of CINV for highly emetic chemotherapy
§Benzodiazepines lack intrinsic antiemetic effects and should not be used as single agents against emetogenic chemotherapy

40. Drug Preparation and Administration

David R. Kohler, PharmD

The following tables describe appropriate handling and storage, and drug product preparation and administration procedures for antineoplastics and other selected medications often used concomitantly. The tables describe drug use under a variety of commonly encountered conditions, but do not identify all applications or conditions of product stability and compatibility. Likewise, the tables are not an exhaustive list of marketed products and should not be construed as an endorsement for any manufacturer's products or discriminating against products that were not specifically identified. Clinicians are advised to refer to product labeling for more complete information about individual products and up-to-date reference sources for information about drug compatibility and stability

The information contained in this chapter is derived from contemporary product labeling approved by the U.S. Food and Drug Administration (FDA), pharmaceutical manufacturers' websites, and, in some cases, from published studies and personal communications with pharmaceutical manufacturers

Occasionally, the package insert component of product labeling for drugs that have received FDA approval for commercial use is prefaced by prominent precautionary and warning summaries circumscribed by a rectangular border, commonly referred to as *black box warnings*, or, simply, *boxed warnings*. The boxed warnings reproduced in this chapter faithfully recapitulate the most current versions of manufacturers' product labeling available lacking only referent citations to information located elsewhere within product labeling. Referents are replaced here by an ellipsis (. . .). Health care providers are urged to consult the most current versions of product labeling and primary medical publications for more information

In 2001, the FDA Office of Generic Drugs requested manufacturers of sixteen similarly named drug pairs to voluntarily revise the appearance of those established drug names by enhancing distinguishing elements of otherwise very similar (look-alike) names. The Name Differentiation Project of 2001 encouraged manufacturers to supplement their applications with revised labeling that incorporated "Tall Man" letters within drug names to aid visual differentiation between those drug names with a goal toward minimizing medication errors by inappropriate drug selection, ie, capitalizing letters that aid in distinguishing between similar generic and proprietary drug names. With the exception of section titles, labeled identities, compendial names, and boxed warnings, drug names appear in this chapter with the Tall Man names and conventions established and recommended by the FDA (URL: http://www.fda.gov/Drugs/DrugSafety/MedicationErrors/ucm164587.htm [accessed February 14, 2014]) and the Institute for Safe Medication Practices, Horsham, PA. (URL: www.ismp.org [accessed, February 14, 2014])

Key to Abbreviations

0.45% NaCl	0.45% Sodium chloride injection, USP
0.9% NS	0.9% Sodium chloride injection, USP
1/6-M SLI	Sodium lactate injection, USP (1/6 molar [1.9%] sodium lactate)
3% NaCl	3% Sodium chloride injection (hypertonic)
AKA	Also known as
ANC	Absolute neutrophil count
AUC	Area under the concentration versus time curve
B0.9% NS	Bacteriostatic (antimicrobially preserved) 0.9% sodium chloride injection
BSA	Body surface area
BWFI	Bacteriostatic water for injection, USP
CYP	A prefix denoting cytochrome P450 enzymes
CSF	Cerebrospinal fluid
D10W	10% Dextrose injection, USP
D2.5W	2.5% Dextrose injection, USP
D2.5W/0.45% NaCl	2.5% Dextrose and 0.45% sodium chloride injection, USP
D5W	5% Dextrose injection, USP
D5W/0.2% NaCl	5% Dextrose and 0.20% sodium chloride injection, USP
D5W/0.33% NaCl	5% Dextrose and 0.33% sodium chloride injection, USP
D5W/0.45% NaCl	5% Dextrose and 0.45% sodium chloride injection, USP
D5W/0.9% NS	5% Dextrose and 0.9% sodium chloride injection, USP
D5W/LR	5% Dextrose injection in lactated Ringer's injection, USP
D5W/RI	5% Dextrose injection in Ringer's injection, USP
DEHP	di-2-ethylhexyl phthalate (a plasticizing ingredient commonly used in flexible PVC containers)
LRI	Lactated Ringer's injection, USP
NDC	National Drug Code
NF	"National Formulary," a portion of the official American pharmaceutical compendia, *United States Pharmacopeia-National Formulary*
PICC	Peripherally inserted central catheter
PK	Pharmacokinetic
PVC	Polyvinyl chloride
Q.S.	*Quantum sufficit* or *quantum satis* [Latin]: "As much as is sufficient"
RI	Ringer's injection, USP
SICC	Subclavian-inserted central catheter
SWFI	(Sterile) Water for injection, USP
USP	United States Pharmacopeia/U.S. Pharmacopeial Convention
VAD	Vascular access device (eg, catheter, port, other cannula)

ado-TRASTUZUMAB

KADCYLA™ (ado-trastuzumab emtansine) for injection, for intravenous use; product label, May 2013. Manufactured by: Genentech, Inc. A Member of the Roche Group, South San Francisco, CA

Do Not Substitute KADCYLA for or with Trastuzumab

WARNING: HEPATOTOXICITY, CARDIAC TOXICITY, EMBRYO-FETAL TOXICITY

- Hepatotoxicity: Serious hepatotoxicity has been reported, including liver failure and death in patients treated with KADCYLA. Monitor serum transaminases and bilirubin prior to initiation of KADCYLA treatment and prior to each KADCYLA dose. Reduce dose or discontinue KADCYLA as appropriate in cases of increased serum transaminases or total bilirubin…
- Cardiac Toxicity: KADCYLA administration may lead to reductions in left ventricular ejection fraction (LVEF). Evaluate left ventricular function in all patients prior to and during treatment with KADCYLA. Withhold treatment for clinically significant decrease in left ventricular function…
- Embryo-Fetal Toxicity: Exposure to KADCYLA can result in embryo-fetal death or birth defects. Advise patients of these risks and the need for effective contraception…

Boxed Warning for "KADCYLA™ (ado-trastuzumab emtansine) for injection, for intravenous use; May 2013 product label. Genentech, Inc., A Member of the Roche Group, South San Francisco, CA

Product Identification, Preparation, Storage, and Stability

- Ado-trastuzumab emtansine contains the humanized anti-HER2 IgG1, trastuzumab, covalently linked to the microtubule inhibitory drug DM1 (a maytansine derivative) via the stable thioether linker MCC (4-[*N*-maleimidomethyl] cyclohexane-1-carboxylate). Emtansine refers to the MCC-DM1 complex
- The commercial product, KADCYLA™, is a sterile, white to off-white, preservative-free, lyophilized powder in individually packaged, single-use vials that contain ado-trastuzumab emtansine 100 mg (NDC 50242-088-01) or 160 mg (NDC 50242-087-01)
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F) until time of reconstitution
- *Do not freeze or shake* intact vials

Reconstitution:

- In order to prevent medication errors it is important to check the vial labels to ensure that the drug being prepared and administered is KADCYLA™ (ado-trastuzumab emtansine), *NOT* trastuzumab
- Using a sterile syringe, slowly inject SWFI diluent into vials containing ado-trastuzumab emtansine as follows:

Vial Contents (ado-trastuzumab emtansine)	SWFI Volume for Reconstitution	ado-Trastuzumab Emtansine Concentration after Reconstitution
100 mg	5 mL	20 mg/mL
160 mg	8 mL	

- Swirl vials gently until the drug substance is completely dissolved
  - *Do not shake* vials to aid dissolution to avoid foaming
- After reconstitution, each vial contains ado-trastuzumab emtansine 20 mg/mL, polysorbate 20 0.02% (w/v), sodium succinate 10 mmol/L, and sucrose 6% (w/v), with a pH = 5.0 and density = 1.026 g/mL
- Inspect the reconstituted drug product (20 mg/mL) for particulates and discoloration
  - The solution should be clear to slightly opalescent, free of visible particulates, and colorless to pale brown
  - *Do not use* the reconstituted solution if it contains visible particulates or is cloudy or discolored
- The reconstituted lyophilized drug product should be used immediately following reconstitution, or, if not used immediately, reconstituted product may be stored for up to 24 hours under refrigeration at 2°–8°C (35.6°–46.4°F). *Do not freeze*
- Discard all unused ado-trastuzumab emtansine stored under refrigeration after 24 hours

Note: The reconstituted product contains no preservative and is intended for single use only

Dilution:

- Calculate the volume of concentrated reconstituted ado-trastuzumab emtansine solution (20-mg/mL) needed to prepare a patient's dose
- With a syringe, aseptically transfer from one or more vials the volume needed to a parenteral product container prefilled with 250 mL 0.9% NS
  - *Do not use* 5% dextrose injection as a diluent/vehicle solution
- Mix the diluted drug product by repeated gentle inversion of the container to avoid foaming
- After dilution, ado-trastuzumab emtansine admixture should be used immediately, but if not used immediately, it may be stored under refrigeration (2°–8°C) for up to 24 hours prior to use
  - The time under refrigeration for storing diluted ado-trastuzumab emtansine (24 h) is in addition to the time allowed for storing the reconstituted concentrated solution (20 mg/mL) in vials (24 h)
- Do not freeze or shake the diluted drug product

Selected incompatibility:

- Do not mix ado-trastuzumab emtansine with other medicinal products in the same container

Recommendations for Drug Administration and Ancillary Care

General:

- In order to prevent medication errors it is important to check the vial labels to ensure that the drug being prepared and administered is KADCYLA™ (ado-trastuzumab emtansine) *NOT* trastuzumab
  - In order to improve traceability of biological pharmaceutical products and prevent medication errors, the complete generic name or a distinguishing proprietary (brand) name of the administered product should be clearly recorded in a patient's medical records

Administration:

- *Do not mix* ado-trastuzumab emtansine with other medicinal products in the same container or during administration
- *Do not substitute* ado-trastuzumab emtansine for trastuzumab *or* trastuzumab for ado-trastuzumab emtansine
- The recommended dose of ado-trastuzumab emtansine is 3.6 mg/kg, given as an intravenous infusion every 3 weeks (21-day cycles)
  - *Do not administer* KADCYLA at dosages greater than 3.6 mg/kg
  - *Do not administer* ado-trastuzumab emtansine by intravenous injection or bolus
  - *Do not re-escalate* ado-trastuzumab emtansine dosages after a dosage reduction is made

Event	Administration	Monitoring	
First infusion	• Administer intravenously over 90 minutes	• Observe patients closely during the infusion and for at least 90 minutes following the initial dose for fever, chills, and other infusion-related reactions	• Patients should be observed closely for infusion-related reactions, especially during the first infusion • Administration should be slowed or interrupted if a patient develops an infusion-related reaction • Permanently discontinue KADCYLA™ for life-threatening infusion-related reactions
Second and subsequent infusions	• Administer intravenously over 30 minutes if prior administrations were well tolerated • Subsequent doses may be administered at the dosage and rate previously tolerated during the most recently administered treatment	• Observe patients during the infusion and for ≥30 minutes after administration	

- Administer ado-trastuzumab emtansine intravenously only with a 0.22-micrometer, in-line, polyethersulfone filter
- If a planned dose is delayed or missed, it should be administered as soon as possible
  - *Do not wait* until the next planned cycle
  - The schedule of administration should be adjusted to maintain a 3-week interval between doses

Notes:

- FDA-approved product labeling for ado-trastuzumab emtansine includes recommendations for treatment modifications for concomitant use with potentially interacting medications, co-morbid conditions, and adverse effects associated with treatment, including: increased serum liver transaminases (AST and ALT), hyperbilirubinemia or both conditions, and hepatic toxicity including nodular regenerative liver hyperplasia; left ventricular dysfunction, thrombocytopenia, pulmonary toxicity, and peripheral neuropathy (refer to current product labeling for detailed recommendations)
  - Management may require temporary delays, interruption, dose reduction, or treatment discontinuation
- Infusion-related reactions associated with ado-trastuzumab emtansine reported in clinical trials were characterized by one or more of the following: flushing, chills, pyrexia, dyspnea, hypotension, wheezing, bronchospasm, and tachycardia, and one episode of a serious allergic/anaphylactic reaction
  - The overall frequency of infusion-related reactions reported in one randomized trial was 1.4%
  - In most patients, reactions resolved over the course of several hours to a day after ado-trastuzumab emtansine administration was discontinued
  - Interrupt ado-trastuzumab emtansine treatment in patients who develop severe infusion-related reactions
  - ado-Trastuzumab emtansine should be permanently discontinued in the event of life-threatening infusion-related reactions

ALDESLEUKIN

PROLEUKIN® (aldesleukin) for injection, for intravenous infusion; product label, July 2012. Manufactured by Prometheus Laboratories, Inc., San Diego, CA at Bayer HealthCare Pharmaceuticals, Emeryville, CA

WARNINGS

Therapy with Proleukin® (aldesleukin) should be restricted to patients with normal cardiac and pulmonary functions as defined by thallium stress testing and formal pulmonary function testing. Extreme caution should be used in patients with a normal thallium stress test and a normal pulmonary function test who have a history of cardiac or pulmonary disease

Proleukin should be administered in a hospital setting under the supervision of a qualified physician experienced in the use of anticancer agents. An intensive care facility and specialists skilled in cardiopulmonary or intensive care medicine must be available

Proleukin administration has been associated with capillary leak syndrome (CLS) which is characterized by a loss of vascular tone and extravasation of plasma proteins and fluid into the extravascular space. CLS results in hypotension and reduced organ perfusion which may be severe and can result in death. CLS may be associated with cardiac arrhythmias (supraventricular and ventricular), angina, myocardial infarction, respiratory insufficiency requiring intubation, gastrointestinal bleeding or infarction, renal insufficiency, edema, and mental status changes

Proleukin treatment is associated with impaired neutrophil function (reduced chemotaxis) and with an increased risk of disseminated infection, including sepsis and bacterial endocarditis. Consequently, preexisting bacterial infections should be adequately treated prior to initiation of Proleukin therapy. Patients with indwelling central lines are particularly at risk for infection with gram positive microorganisms. Antibiotic prophylaxis with oxacillin, nafcillin, ciprofloxacin, or vancomycin has been associated with a reduced incidence of staphylococcal infections

Proleukin administration should be withheld in patients developing moderate to severe lethargy or somnolence; continued administration may result in coma

Boxed Warning for "PROLEUKIN® (aldesleukin) for injection, for intravenous infusion"; July 2012 product label; Prometheus Laboratories, Inc., San Diego, CA

Product Identification, Preparation, Storage, and Stability

- Proleukin is supplied in individually boxed single-use vials containing aldesleukin 22 million IU as a sterile, white to off-white, preservative-free, lyophilized powder (equivalent to a protein mass of 1.3 mg). NDC 65483-116-07
  - Aldesleukin biologic potency is determined by a lymphocyte proliferation bioassay and is expressed in international units (IU) as established by the World Health Organization 1st International Standard for Interleukin-2 (human)
- Store intact vials and reconstituted and diluted aldesleukin under refrigeration at 2°C–8°C (35.6°F–46.4°F). Protect from light. *Do not* freeze aldesleukin
- Reconstitute the contents of a vial with 1.2 mL of SWFI to produce a clear, colorless to slightly yellow solution with a biologic potency of 18 million IU aldesleukin/mL (equivalent to 1.1 mg of aldesleukin protein per milliliter)
  - Each milliliter of the reconstituted product also contains 50 mg mannitol and 0.18 mg sodium dodecyl sulfate, buffered with approximately 0.17 mg monobasic and 0.89 mg dibasic sodium phosphate to a pH of 7.5 (range: 7.2–7.8)
- During reconstitution, direct the stream of SWFI at the side wall of a vial rather than directly into the drug powder and gently swirl vials to avoid excessive foaming
- *Do not shake* vials to dissolve aldesleukin
- For intraVENous administration, dilute aldesleukin *only* with D5W to a final concentration between 0.5 and 1.1 million IU/mL (30–70 mcg/mL; see chart below). Drug delivery may be adversely affected by aldesleukin concentrations <30 mcg/mL or >70 mcg/mL

Aldesleukin (million IU)	Diluent Volume (D5W)
5–11	10 mL
7.5–16.5	15 mL
12.5–27.5	25 mL
25–55	50 mL
50–110	100 mL

- If it is necessary to administer aldesleukin in a concentration <30 mcg/mL (<0.5 million IU/mL), the drug should be diluted in D5W that contains Albumin Human, USP, in a concentration of 0.1% (1 mg/mL)
- Either glass bottles or PVC bags are acceptable containers for aldesleukin, but plastic containers provide more consistent drug delivery than glass containers
- Reconstituted and diluted aldesleukin solutions are stable for up to 48 hours at 2°–25°C (35.6°–77°F), but the Proleukin product does not contain a preservative
- Store reconstituted and diluted solutions under refrigeration, but allow diluted aldesleukin to warm to room temperature before administering it to a patient

Selected incompatibility:

- *Do not combine* aldesleukin with other drugs in the same container
- *Do not reconstitute or dilute* aldesleukin with 0.9% NS or antimicrobially-preserved diluents, which may increase protein aggregation

Recommendations for Drug Administration and Ancillary Care

General:

- Dose modification for toxicity should be accomplished by withholding or interrupting a dose rather than reducing the dose to be administered
- See Chapter 41 for recommended use in renal dysfunction
- Bring aldesleukin solution to room temperature before administration
- Administer aldesleukin by intraVENous infusion over 15 minutes
- *Do not filter* aldesleukin either during preparation or administration
- Complete administration within 48 hours after reconstitution

Pharmacodynamic interactions:

- Aldesleukin may affect CNS function, which may be exacerbated by concomitant administration of drugs with psychotropic activity, for example, opioids, analgesics, antiemetics, sedatives, hypnotics
- Aldesleukin may increase the nephrotoxic, myelotoxic, cardiotoxic, or hepatotoxic effects of other drugs if given concurrently
- Impaired kidney and liver function associated with aldesleukin use may delay elimination and increase the risk of adverse events from concomitantly administered medications
- Hypersensitivity reactions that consisted of erythema, pruritus, and hypotension, have been reported in patients who received combination regimens containing sequential high-dose aldesleukin and antineoplastic agents, specifically: dacarbazine, CISplatin, tamoxifen, and interferon alfa. Adverse reactions occurred within hours after administration of chemotherapy, and required medical intervention in some patients[1]
- In patients who received aldesleukin and interferon alfa concurrently:
  - The incidence of myocardial injury, including myocardial infarction, myocarditis, ventricular hypokinesia, and severe rhabdomyolysis, appears to be increased[2]
  - Exacerbation or initial presentation of autoimmune and inflammatory disorders has been observed, including: crescentic IgA glomerulonephritis, oculobulbar myasthenia gravis, inflammatory arthritis, thyroiditis, bullous pemphigoid, and Stevens-Johnson syndrome
- Glucocorticoids have been shown to reduce aldesleukin-induced side effects, including fever, renal insufficiency, hyperbilirubinemia, confusion, and dyspnea, but concomitant use should be avoided to preclude compromising aldesleukin's antitumor effectiveness[3]
- Beta-blockers and other antihypertensives may potentiate aldesleukin's hypotensive effects
- Aldesleukin use followed by administration of iodinated radiographic contrast media is associated with acute, atypical adverse reactions, including fever, chills, nausea, vomiting, pruritus, rash, diarrhea, hypotension, edema, and oliguria, with onset commonly within 1–4 hours after the administration of contrast media. In some cases, the reactions resemble the immediate side effects caused by aldesleukin administration; however, other than a temporal relationship between aldesleukin and iodinated contrast media administration the cause of aldesleukin-associated contrast reactions is not known. Although most events were reported to occur when contrast media was given within 4 weeks after the last dose of aldesleukin, events were also reported to occur when contrast media was given several months after aldesleukin[4-9]

ALEMTUZUMAB

CAMPATH® (alemtuzumab) Injection for intravenous use; product label, August 2009. Manufactured and distributed by Genzyme Corporation, Cambridge, MA

WARNINGS

CYTOPENIAS, INFUSION REACTIONS, and INFECTIONS

Cytopenias: Serious, including fatal, pancytopenia/marrow hypoplasia, autoimmune idiopathic thrombocytopenia, and autoimmune hemolytic anemia can occur in patients receiving Campath. Single doses of Campath greater than 30 mg or cumulative doses greater than 90 mg per week increase the incidence of pancytopenia…

Infusion Reactions: Campath administration can result in serious, including fatal, infusion reactions. Carefully monitor patients during infusions and withhold Campath for Grade 3 or 4 infusion reactions. Gradually escalate Campath to the recommended dose at the initiation of therapy and after interruption of therapy for 7 or more days…

Infections: Serious, including fatal, bacterial, viral, fungal, and protozoan infections can occur in patients receiving Campath. Administer prophylaxis against *Pneumocystis jirovecii* pneumonia (PCP) *[sic]* and herpes virus infections…

Boxed Warning for "Campath® (alemtuzumab)", Injection for intravenous use"; August 2009 product label; Genzyme Corporation, Cambridge, MA

Change in Product Availability

- As of September 4, 2012, Campath (alemtuzumab) injection for treatment of B-cell chronic lymphocytic leukemia was withdrawn from commercial availability in the United States
- Genzyme Corporation, the American distributor, announced activation of the "US Campath Distribution Program," which "…was developed to ensure continued access to Campath (alemtuzumab) for appropriate patients"
- An announcement at http://www.campath.com/ advises visitors, "Campath will no longer be available commercially, but will be provided through the Campath Distribution Program free of charge. In order to receive Campath, the healthcare provider is required to document and comply with certain requirements."
- The website provides contact telephone numbers for more information:
  - Campath Distribution Program: 1-877-422-6728
  - Genzyme Medical Information: 1-800-745-4447, Option #2
  - URL: http://www.campath.com/ (Last accessed October 7, 2013)

Product Identification, Preparation, Storage, and Stability

- Campath is packaged in clear, glass, single-use vials containing 30 mg alemtuzumab/mL NDC 58468-0357-3 (3 vials per carton). NDC 58468-0357-1 (single vial per carton)
  - Campath is a sterile, clear, colorless, isotonic solution for injection containing alemtuzumab 30 mg/mL at pH 6.8–7.4
  - Each milliliter of the commercial product also contains 8 mg sodium chloride, 1.44 mg dibasic sodium phosphate, 0.2 mg potassium chloride, 0.2 mg monobasic potassium phosphate, 0.1 mg polysorbate 80, and 0.0187 mg disodium edetate dihydrate
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F); protect vials from direct sunlight
- *Do not freeze* alemtuzumab. If the product is accidentally frozen, thaw at 2°–8°C before use
- *Do not shake* vials before use

1. Withdraw from a vial into a syringe an amount of alemtuzumab needed to prepare a patient's dose
   a. 0.1 mL Campath solution for a 1-mg dose
   b. 0.33 mL Campath solution for a 10-mg dose
   c. 1 mL Campath solution for a 30-mg dose
2. Inject the amount of drug needed to prepare a patient's dose into 100 mL of 0.9% NS or D5W in a plastic parenteral product container
3. Gently invert the bag to mix the solution

- Diluted alemtuzumab solutions may be stored at room temperature (15°C–30°C; 59°F--86°F) or under refrigeration
- The commercial drug product contains no antimicrobial preservatives. Use the product within 8 hours after dilution

Selected incompatibility:

- Alemtuzumab is compatible with PVC bags, PVC- or polyethylene-lined PVC administration sets
- No data are available concerning the compatibility of alemtuzumab with other drugs. Do not add or simultaneously infuse other drugs through the same intraVENous line with alemtuzumab

Recommendations for Drug Administration and Ancillary Care

General:

- Administer alemtuzumab only by intraVENous infusion over ≥2 hours
- Do not administer alemtuzumab by direct intraVENous injection or bolus injection

Infusion reactions and dose escalation:

- Alemtuzumab administration can result in serious infusion reactions commonly including: pyrexia, chills, hypotension, urticaria, and dyspnea
  - G3 and G4 pyrexia and/or chills occurred in approximately 10% of previously untreated patients and in approximately 35% of previously treated patients
  - The occurrence of infusion reactions was greatest during the initial week of treatment and decreased with subsequent doses
  - All patients were pretreated with antipyretics and antihistamines; additionally, 43% of previously untreated patients received glucocorticoid prior to alemtuzumab
- Gradual escalation to the recommended maintenance dose/schedule is required when initiating therapy and after treatment interruptions ≥7 days. Generally, escalation to a 30-mg dose can be accomplished in 3–7 days as follows:
  1. Initiate treatment with alemtuzumab 3 mg intraVENously over 2 hours
  2. After a 3-mg DAILY dose is tolerated (ie, infusion-related toxicities are grades ≤2), escalate DAILY dose to 10 mg/day and continue until tolerated
  3. After a 10-mg DAILY dose is tolerated (infusion-related toxicities grades ≤2), escalate to a maintenance dose and schedule of alemtuzumab 30 mg/dose on 3 nonconsecutive days for 3 doses per week (eg, Monday, Wednesday, and Friday) for a total treatment duration of 12 weeks, including the period of dose escalation

Concomitant medications:

- Give premedication 30 minutes before the first alemtuzumab dose, before dose escalations, and as clinically indicated, with:
  - **DiphenhydrAMINE** 50 mg orally or intraVENously
  - **Acetaminophen** 500–1000 mg orally
- Treat severe infusion-related events with:
  - **Hydrocortisone** intraVENously (anaphylactoid reactions)
  - **Meperidine** intraVENously (chills, rigors)
  - **Epinephrine 1:1000** (1 mg/mL) intraMUSCularly (preferred) or SUBCUTaneously (anaphylactoid reactions)
  - **Epinephrine 1:10,000** (0.1 mg/mL) intraVENously with cardiac monitoring (airway edema, severe bronchospasm, hypotension)
- Give antibacterial and antiviral primary prophylaxis during treatment and continue for at least 2 months after the last dose of alemtuzumab is administered or until CD4+ lymphocyte counts are ≥200/mm^3, whichever event occurs later, with:
  - **Cotrimoxazole** (trimethoprim 160 mg + sulfamethoxazole 800 mg) orally, twice daily for 3 days/week (or equivalent anti-PCP prophylaxis)
  - **Famciclovir** 250 mg orally twice daily (or equivalent anti-herpesvirus prophylaxis)

AMIFOSTINE

AMIFOSTINE FOR INJECTION; product label, May 2013. Manufactured by MedImmune Pharma B.V., Nijmegen, The Netherlands. Distributed by Bedford Laboratories, Bedford, OH

Product Identification, Preparation, Storage, and Stability

- Amifostine is packaged in 10-mL (capacity) single-use vials containing 500 mg (on an anhydrous basis) of amifostine trihydrate as a sterile lyophilized powder. NDC 55390-308-03 (3 vials per carton)
- Store intact vials at controlled room temperature, 20°–25°C (68°–77°F)
- Reconstitute amifostine with 9.7 mL of 0.9% NS to produce a solution with concentration of 500 mg amifostine/10 mL
- Amifostine may be further diluted in PVC containers with 0.9% NS to concentrations ranging from 5 to 40 mg/mL
- The reconstituted drug product (500 mg/mL) and diluted amifostine solutions are chemically stable for up to 5 hours at approximately 25°C and for up to 24 hours under refrigeration (2°–8°C; 35.6°–46.4°F)

Selected incompatibility:

- Product labeling advises admixture with solutions other than 0.9% NS with or without other (unspecified) additives is not recommended

Recommendations for Drug Administration and Ancillary Care

General:

- Administer intraVENously (see indication-specific recommendations below)
- Provide adequate hydration before amifostine infusion
- Administer antiemetic primary prophylaxis before amifostine
  - Emetic risk is related to amifostine dosage: low risk, ≤300 mg/m^2; moderate risk, >300 mg/m^2 (NCCN Clinical Practice Guidelines in Oncology [NCCN Guidelines®]: Antiemesis, V.1.2014. National Comprehensive Cancer Network, Inc., 2013. [Accessed October 8, 2013, at http://www.nccn.org.])
- Monitor a patient's blood pressure every 5 minutes during amifostine administration, and thereafter as clinically indicated
- Keep patients in a supine position during the amifostine infusion. Interrupt amifostine administration if systolic blood pressure (SBP) decreases significantly from baseline as follows:

Baseline SBP (mm Hg)	Decrease in SBP That Warrants Interrupting Amifostine Infusion
<100	20 mm Hg
100–119	25 mm Hg
120–139	30 mm Hg
140–179	40 mm Hg
≥180	50 mm Hg

- If BP returns to normal within 5 minutes and the patient is asymptomatic, resume administration to complete the planned dose
- If the planned dose cannot be administered, decrease the amifostine dosage during subsequent chemotherapy cycles from 910 mg/m^2 to 740 mg/m^2

To reduce cumulative renal toxicity with chemotherapy:

- Administer antiemetic primary prophylaxis before amifostine, including dexamethasone 20 mg intraVENously, a serotonin receptor (5-HT$_3$ subtype) antagonist, *plus* additional antiemetics as appropriate for the chemotherapy utilized
- Administer amifostine 910 mg/m^2 once daily by intraVENous infusion over 15 minutes, starting 30 minutes before chemotherapy
  - A 15-minute infusion is better tolerated than longer infusions

To decrease moderate-to-severe xerostomia from head and neck radiation:

- Administer antiemetic primary prophylaxis before amifostine, for example, a 5-HT$_3$ antagonist ± additional antiemetics if clinically appropriate
- Administer amifostine 200 mg/m^2 once daily by intraVENous infusion over 3 minutes, 15–30 minutes before standard-fraction radiation therapy (ie, 1.8–2 Gy/fraction)
- Monitor blood pressure at least before and immediately after the infusion, and thereafter as clinically indicated

ARSENIC TRIOXIDE

TRISENOX® (arsenic trioxide) injection, for intravenous use only; product label, June 2010. Manufactured for Cephalon Inc., Frazer, PA

WARNINGS

Experienced Physician and Institution: TRISENOX (arsenic trioxide) injection should be administered under the supervision of a physician who is experienced in the management of patients with acute leukemia

APL Differentiation Syndrome: Some patients with APL treated with TRISENOX have experienced symptoms similar to a syndrome called the retinoic-acid-Acute Promyelocytic Leukemia (RA-APL) or APL differentiation syndrome, characterized by fever, dyspnea, weight gain, pulmonary infiltrates and pleural or pericardial effusions, with or without leukocytosis. This syndrome can be fatal. The management of the syndrome has not been fully studied, but high-dose steroids have been used at the first suspicion of the APL differentiation syndrome and appear to mitigate signs and symptoms. At the first signs that could suggest the syndrome (unexplained fever, dyspnea and/or weight gain, abnormal chest auscultatory findings or radiographic abnormalities), high-dose steroids (dexamethasone 10 mg intraVENously BID) should be immediately initiated, irrespective of the leukocyte count, and continued for at least 3 days or longer until signs and symptoms have abated. The majority of patients do not require termination of TRISENOX therapy during treatment of the APL differentiation syndrome

ECG Abnormalities: Arsenic trioxide can cause QT interval prolongation and complete atrioventricular block. QT prolongation can lead to a torsade de pointes-type ventricular arrhythmia, which can be fatal. The risk of torsade de pointes is related to the extent of QT prolongation, concomitant administration of QT prolonging drugs, a history of torsade de pointes, preexisting QT interval prolongation, congestive heart failure, administration of potassium-wasting diuretics, or other conditions that result in hypokalemia or hypomagnesemia. One patient (also receiving amphotericin B) had torsade de pointes during induction therapy for relapsed APL with arsenic trioxide

ECG and Electrolyte Monitoring Recommendations: Prior to initiating therapy with TRISENOX, a 12-lead ECG should be performed and serum electrolytes (potassium, calcium, and magnesium) and creatinine should be assessed; preexisting electrolyte abnormalities should be corrected and, if possible, drugs that are known to prolong the QT interval should be discontinued. For QTc greater than 500 msec, corrective measures should be completed and the QTc reassessed with serial ECGs prior to considering using TRISENOX. During therapy with TRISENOX, potassium concentrations should be kept above 4 mEq/L and magnesium concentrations should be kept above 1.8 mg/dL. Patients who reach an absolute QT interval value >500 msec should be reassessed and immediate action should be taken to correct concomitant risk factors, if any, while the risk/benefit of continuing versus suspending TRISENOX therapy should be considered. If syncope, rapid or irregular heartbeat develops, the patient should be hospitalized for monitoring, serum electrolytes should be assessed, TRISENOX therapy should be temporarily discontinued until the QTc interval regresses to below 460 msec, electrolyte abnormalities are corrected, and the syncope and irregular heartbeat cease. There are no data on the effect of TRISENOX on the QTc interval during the infusion

Boxed Warning for "Trisenox® (arsenic trioxide) injection, For Intravenous Use Only"; June 2010 product label; Cephalon Inc., Frazer, PA

Product Identification, Preparation, Storage, and Stability

- Trisenox® is packaged in 10-mL, glass, single-use ampules containing 10 mg of arsenic trioxide (1 mg/mL). NDC 63459-600-10 (package of 10 ampules)
  - Trisenox® is formulated as a sterile, nonpyrogenic, clear, colorless, preservative-free solution of arsenic trioxide in water for injection. Sodium hydroxide and hydrochloric acid are used to adjust the pH to 7.5–8.5
- Store intact ampules at 25°C (77°F). Temperature excursions are permitted to 15°–30°C (59°–86°F)
- Dilute arsenic trioxide in 100–250 mL of 0.9% NS or D5W immediately after withdrawing the drug product from an ampule. Unused drug should be discarded in a manner appropriate for hazardous drugs
- Diluted arsenic trioxide solutions are chemically and physically stable for 24 hours when stored at room temperature and for up to 48 hours under refrigeration

Selected incompatibility:

Arsenic trioxide should not be mixed with other drugs

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in renal and hepatic dysfunction
- Administer arsenic trioxide by intraVENous infusion over 1–2 hours. The duration of administration may be extended to 4 hours for patients who experience acute vasomotor reactions
- A central VAD is not required for administering arsenic trioxide

ECG changes:

- QT/QTc prolongation should be expected during treatment with arsenic trioxide, and torsade de pointes and complete heart block have been reported
- In >460 ECG tracings from 40 patients evaluated for QTc prolongation, 16 patients (40%) demonstrated at least 1 QTc interval >500 msec
- QTc prolongation was observed between 1 and 5 weeks after arsenic trioxide administration, and then returned towards baseline by the end of 8 weeks after arsenic trioxide administration
- Neither sex nor age factors correlated with QT prolongation events
- Complete AV block has also been reported in association with arsenic trioxide treatment, including a case in a patient with acute promyelocytic leukemia

ASPARAGINASE, *ERWINIA CHRYSANTHEMI* SOURCE

Asparaginase *Erwinia chrysanthemi* ERWINAZE™ for injection, intramuscular use; product label, November 2011. Manufactured by EUSA Pharma (USA), Inc., Langhorne, PA

Product Identification, Preparation, Storage, and Stability

Erwinaze™ is a sterile, white lyophilized powder supplied in clear, 3-mL, glass vials. Each carton of the commercial product contains 5 vials (NDC 57902-249-05). Each vial (NDC 57902-249-01) contains 10,000 IU of asparaginase *Erwinia chrysanthemi*

- Store intact vials and cartons under refrigeration at 2°–8°C (35.6°--46.4°F)
- Protect intact vials and the reconstituted drug product from light

Preparation for intraMUSCular use:

- Asparaginase *Erwinia chrysanthemi* is reconstituted by slowly injecting 1 or 2 mL of preservative-free 0.9% NS against the inner vial wall
- DO NOT forcefully inject the diluent solution directly into the drug powder

Diluent Volume	Product Concentration
1 mL	10,000 IU/mL
2 mL	5000 IU/mL

- Dissolve the drug powder by gentle mixing or swirling after adding preservative-free 0.9% NS diluent. DO NOT shake or invert vials to solubilize the drug product
- After reconstitution, asparaginase *Erwinia chrysanthemi* should be a clear, colorless solution
- Discard the reconstituted product if visible particles or protein aggregates are present
- DO NOT freeze or refrigerate asparaginase *Erwinia chrysanthemi* solutions

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in hepatic dysfunction

IntraMUSCular administration:

- Asparaginase *Erwinia chrysanthemi* is administered ONLY by intraMUSCular injection
- Volumes for injection >2 mL should be distributed among 2 or more injection sites
- Withdraw from a vial into a polypropylene syringe within 15 minutes after reconstitution a volume of reconstituted asparaginase *Erwinia chrysanthemi* appropriate for a calculated dose
- Administer asparaginase *Erwinia chrysanthemi* within 4 hours after reconstitution

To substitute asparaginase *Erwinia chrysanthemi* for a dose of pegaspargase:

- For each planned dose of pegaspargase, the recommended dose of asparaginase *Erwinia chrysanthemi* is 25,000 IU/m^2 administered intraMUSCularly 3 times per week (eg, Monday, Wednesday, and Friday) for 6 doses

To substitute asparaginase *Erwinia chrysanthemi* for a dose of *Escherichia coli* asparaginase:

- The recommended dose is a single dose of asparaginase *Erwinia chrysanthemi* 25,000 IU/m^2 administered intraMUSCularly

ASPARAGINASE, *ESCHERICHIA COLI* SOURCE

ELSPAR (asparaginase) for injection, intravenous or intramuscular, product label, April 2010. Lundbeck, Inc, Deerfield, IL
Note: Information at http://www.lundbeck.com/us/products/customer-support [accessed January 11, 2014] states: As of January 18, 2013, Elspar was sold to Recordati Rare Diseases (Recordati). For access to Recordati's website for Elspar, go to http://www.recordatirarediseases.com/

Product Identification, Preparation, Storage, and Stability

Elspar® is packaged in individually boxed single-use vials containing asparaginase 10,000 IU as a sterile, white lyophilized plug or powder for intraVENous or intraMUSCular injection after reconstitution. NDC 67386-411-51

- Elspar® contains the enzyme L-asparagine amidohydrolase, type EC-2, derived from *Escherichia coli* and 80 mg of mannitol
  - One International Unit of asparaginase is defined as that amount of enzyme required to generate 1 μmol of ammonia per minute at pH 7.3 and 37°C
  - The product's specific activity is at least 225 IU/mg of protein
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F)
- After reconstitution, Elspar® is a clear, colorless solution
- Unused, reconstituted asparaginase should be stored at 2°–8°C and discarded after 8 hours or sooner if the reconstituted product becomes cloudy
- Asparaginase stability is dependent on solution pH and storage temperature[10]
  - Asparaginase is relatively stable at pH = 4.5–11; drug activity is lost at greater extremes of pH
  - Asparaginase also has a high stability to changes in temperature (37°–60°C), but both solution pH and storage temperature affect stability
  - Asparaginase activity was preserved for at least 7 days after dilution in 0.9% NS and storage under refrigeration (8°C) in polyolefin or polyethylene containers
  - Administer asparaginase by either intraVENous or intraMUSCular routes

For intraVENous use:

- Reconstitute vials containing asparaginase 10,000 IU with 5 mL of SWFI or 0.9% NS to produce a solution with concentration = 2000 IU/mL. Ordinary shaking during reconstitution does not inactivate the enzyme, but may cause foaming
- The reconstituted solution is suitable for direct intraVENous injection or may be diluted with 0.9% NS or LRI
- Asparaginase should be administered intraVENously over a period not less than 30 minutes
- Administer asparaginase within 8 hours after preparation and only if the solution remains clear
  1. Occasionally, a small number of gelatinous fiber-like particles may develop on standing
  2. Filtration through a 5-μm filter during administration removes the particles with no resultant loss in potency
  3. SOME LOSS OF POTENCY has been observed with the use of a 0.2-μm filter

For intraMUSCular use:

- Add 2 mL of 0.9% NS to a vial containing asparaginase 10,000 IU to produce a solution with concentration = 5000 IU/mL
- If a volume >2 mL is to be administered, 2 injection sites should be used
- Administer asparaginase within 8 hours and only if the solution remains clear

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in hepatic dysfunction

Intradermal skin test:

- Asparaginase administration is associated with allergic reactions. An intradermal skin test may be performed before initial administration and when asparaginase is given after an interval ≥1 week has elapsed between doses
- Observe a skin test site for at least 1 hour for a wheal or erythema; either sign indicates a positive reaction

Note: A *negative* skin test reaction does not preclude the possibility of an allergic reaction to asparaginase treatment; that is, be wary of false-negative results

Prepare a skin test solution as follows:

1. Reconstitute asparaginase 10,000 IU with 5 mL of 0.9% NS
2. From the solution prepared in the previous step (containing 2000 IU/mL), withdraw 0.1 mL and inject it into a vial containing 9.9 mL of 0.9% NS, yielding a skin test solution of approximately 20 IU/mL
3. Inject intradermally 0.1 mL of the skin test solution (approximately 2 IU)

Note: In patients who demonstrate hypersensitivity by skin testing, and in any patient who previously completed a course of asparaginase, retreatment should be instituted only after successful desensitization

Desensitization should be performed before administering a first dose of asparaginase in positive reactors, and before retreating patients who have not received asparaginase for a period >1 week

(*continued*)

Recommendations for Drug Administration and Ancillary Care (*continued*)

Desensitization[11,12]:

- Rapid intraVENous desensitization may be attempted with progressively increasing amounts of asparaginase if adequate precautions are taken to treat an acute allergic reaction should it occur
- The following schedule begins with a total of 1 IU, intraVENously and, provided no reaction has occurred, doubles the dose every 10 minutes, until the accumulated total amount given equals the planned dose for that day

Injection Number	Asparaginase Dose (IU)	Accumulated Total Dose
1	1	1
2	2	3
3	4	7
4	8	15
5	16	31
6	32	63
7	64	127
8	128	255
9	256	511

18	131,072	262,143

Example: A patient weighing 20 kg who is to receive 4000 IU would receive desensitization injections 1 through 12

ELSPAR® (ASPARAGINASE) product label, December 2005. Merck & Co., Inc., Whitehouse Station, NJ

IntraVENous administration:

- Infuse over at least 30 minutes through the side arm of a running infusion of 0.9% NS or D5W

IntraMUSCular administration:

- Limit the volume at a single injection site to ≤2 mL

AZACITIDINE

VIDAZA® (azacitidine for injection) for SC or IV use; product label, December 2012. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH, *or* Baxter Oncology GmbH, Halle/Westfalen, Germany, *or* BSP Pharmaceuticals S.r.l., Latina Scalo, Italy. Manufactured for Celgene Corporation, Summit, NJ

Product Identification, Preparation, Storage, and Stability

- Vidaza® is packaged in cartons with one single-use vial containing azaCITIDine 100 mg with 100 mg mannitol as a sterile, lyophilized, white to off-white powder for reconstitution as a suspension for SUBCUTaneous injection or as a solution for intraVENous infusion. NDC 59572-102-01
  - Store intact vials at 25°C (77°F); temperature excursions are permitted to 15°–30°C (59°–86°F)

Preparation for SUBCUTaneous administration:

1. Reconstitute lyophilized azaCITIDine powder by slowly injecting 4 mL of SWFI into a vial
2. Vigorously shake or roll the vial until a uniform cloudy suspension is formed. The resulting suspension contains 25 mg azaCITIDine per milliliter

Preparation for *immediate* SUBCUTaneous administration:

1. Divide doses >4 mL (>100 mg) equally into two syringes
2. Store reconstituted azaCITIDine suspension for up to 1 hour at room temperature, but the product must be administered within 1 hour after reconstitution

Preparation for *delayed* SUBCUTaneous administration:

1. Reconstituted azaCITIDine may be kept in the vial or drawn into a syringe
2. Divide doses >4 mL (>100 mg) equally into 2 syringes
3. Immediately place the product under refrigeration (2°–8°C; 35.6°–46.4°F) where it may be maintained for up to 8 hours
   a. If refrigerated SWFI was used in reconstituting azaCITIDine, the reconstituted product may be stored under refrigeration (2°–8°C) for up to 22 hours
   b. If *non*-refrigerated SWFI was used in reconstituting azaCITIDine, the reconstituted product may be stored under refrigeration (2°–8°C) for up to 8 hours, or for one hour if stored at room temperature (25°C [77°F])
4. After removal from refrigeration, the suspension may be allowed to equilibrate to room temperature for up to 30 minutes before administration

Preparation for *delayed* intraVENous administration:

1. Reconstitute an appropriate number of vials to achieve the desired dose. Inject 10 mL SWFI into each vial and vigorously shake or roll the vial until all solids are dissolved. The resulting solution should be clear and will contain azaCITIDine 10 mg/mL
2. Withdraw a volume of azaCITIDine solution appropriate to deliver the desired dose and inject it into 50–100 mL of 0.9% NS or LRI
3. After reconstitution for intraVENous administration, azaCITIDine may be stored at 25°C, but administration must be completed within 1 hour after reconstitution

Selected incompatibilities:

- D5W, Hespan® (6% hetastarch [hydroxyethyl starch] in 0.9% NS), and solutions that contain bicarbonate have the potential to increase the rate of azaCITIDine degradation and should be avoided

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in renal and hepatic dysfunction
- If patients experience an unexplained decrease in serum bicarbonate concentration to <20 mEq/L during or after treatment with azaCITIDine, the dosage should be decreased by 50% during the next treatment cycle
- If patients experience an unexplained increase in BUN or serum creatinine during treatment, the next cycle should be delayed until laboratory values return to normal or baseline and azaCITIDine dosage should be decreased by 50% on the next treatment course
- AzaCITIDine and its metabolites are substantially renally excreted. Elderly individuals and other patients with impaired renal function may be at increased risk of toxicity from azaCITIDine

For SUBCUTaneous administration only:

- Doses >4 mL (>100 mg) should be divided equally into 2 syringes and injected into 2 separate sites. Rotate sites for each injection (thigh, abdomen, or upper arm)
- New injections should be given at least 1 inch from an old site and never into areas where the site is tender, bruised, red, or hard
- For azaCITIDine suspension that is not administered immediately after preparation:
  - After removal from refrigeration, allow the suspension to equilibrate to room temperature for up to 30 minutes before administration
  - Resuspend the product before administration to provide a homogeneous suspension by vigorously shaking a vial or rolling syringes between the palms until a uniform cloudy suspension is formed

For IntraVENous administration:

- After reconstitution and further dilution, administer the total azaCITIDine dose over a period of 10–40 minutes
- Administration must be completed within 1 hour after initial reconstitution

BENDAMUSTINE HYDROCHLORIDE

TREANDA® (bendamustine hydrochloride) for Injection for Intravenous Infusion, product label, August 2013. Distributed by Teva Pharmaceuticals USA, Inc., North Wales, PA
TREANDA® (bendamustine hydrochloride) Injection for Intravenous Infusion; product label, September 2013. Distributed by Teva Pharmaceuticals USA, Inc., North Wales, PA
Note: Although "TREANDA® (bendamustine hydrochloride) Injection…" (product formulated in solution) received FDA approval in September 2013, it is not commercially available within the USA as of January 2014

Product Identification, Preparation, Storage, and Stability

Bendamustine HCl Injection (lyophilized product for reconstitution)

- TREANDA® is available in single-use, individually packaged, amber glass vials containing a sterile, non-pyrogenic, white to off-white, lyophilized powder available in two presentations:
  - 25 mg bendamustine HCl with 42.5 mg mannitol, USP; NDC 63459-390-08; *and*
  - 100 mg bendamustine HCl with 170 mg mannitol, USP; NDC 63459-391-20
- Store intact vials at temperatures up to 25°C (77°F); temperature excursions are permitted up to 30°C (86°F)
- Vials should be stored in the original packaging carton to protect bendamustine HCl from light
- Reconstitute the commercial products only with SWFI as follows:

Bendamustine HCl Content	SWFI (diluent) Volume	Resulting Bendamustine HCl Concentration
25 mg	5 mL	5 mg/mL
100 mg	20 mL	

  - Shake well to yield a clear and colorless to pale yellow solution with pH of 2.5–3.5
  - The lyophilized powder should completely dissolve within 5 minutes. If particulate matter is observed, the reconstituted product should not be used
- Within 30 minutes after reconstitution, transfer an amount of bendamustine HCl sufficient to prepare a patient's dose to a parenteral product container with a volume of 0.9% NS or D2.5W/0.45% NaCl sufficient to produce a clear and colorless to slightly yellow solution with a concentration within the range of 0.2–0.6 mg/mL
- Thoroughly mix the diluted product
- After reconstitution and dilution as described, the drug product is stable for 24 hours if stored under refrigeration (2°–8°C [35.6°–46.4°F]), or for 3 hours if stored at room temperature (15°–30°C [59°–86°F]) and exposed to room light
- Administration must be completed within the duration of known product stability
  - TREANDA® contains no antimicrobial preservatives. The admixture should be prepared as close as possible to the time of use

Bendamustine HCl Injection (product in solution)

- TREANDA® is packaged in single-use, individually cartoned, amber glass vials containing a clear, colorless-to-yellow solution of bendamustine HCl with a concentration of 90 mg/mL. The commercial product is available in two presentations:
  - Bendamustine HCl 45 mg/0.5 mL with propylene glycol, USP, 162 mg and 293 mg of *N,N*-dimethylacetamide, EP 293 mg; NDC 63459-395-02, *or*
  - Bendamustine HCl 180 mg/2 mL with propylene glycol, USP, 648 mg and 1172 mg of *N,N*-dimethylacetamide, EP 293 mg; NDC 63459-396-02
  - Each vial contains 0.2 mL of excess drug (overfill)
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F) in the original packaging carton to protect bendamustine HCl from light
- Aseptically transfer a volume of concentrated bendamustine HCl solution sufficient to prepare a patient's dose to a parenteral product container already containing a volume of 0.9% NS or D2.5W/0.45% NaCl sufficient to produce a clear colorless-to-yellow solution with a concentration within the range 0.2–0.7 mg/mL
- Thoroughly mix the diluted product
- After dilution, the admixture is stable for 24 hours if stored under refrigeration (2°–8°C), or for 2 hours if stored at room temperature (15°–30°C [59°–86°F]) and exposed to room light
- Administration must be completed within the duration of known product stability
  - TREANDA® contains no antimicrobial preservatives. The admixture should be prepared as close as possible to the time of use

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in renal and hepatic dysfunction
- Dosages and administration rates vary between FDA-approved indications:
  - In treatment for chronic lymphocytic leukemia, administer bendamustine HCl (100 mg/m^2 per day for 2 consecutive days, days 1 and 2, during a 28-day cycle) by intraVENous infusion over 30 minutes
  - In treatment for non-Hodgkin lymphoma, administer bendamustine HCl (120 mg/m^2 per day for 2 consecutive days, days 1 and 2, during a 21-day cycle) by intraVENous infusion over 60 minutes

Potential drug interactions:

- CYP1A2 catalyzes bendamustine metabolism to its active metabolites, γ-hydroxy-bendamustine (M3) and *N*-desmethyl-bendamustine (M4)
  - CYP1A2 inhibitors (eg, fluvoxamine, ciprofloxacin) have a potential to increase bendamustine concentration and decrease concentrations of its active metabolites in plasma
  - Conversely, CYP 1A2 inducers (eg, omeprazole, tobacco use) potentially may decrease plasma concentrations of bendamustine and its active metabolites
- *In vitro* studies suggest that P-glycoprotein (MDR1, ABCB1), breast cancer resistance protein (BCRP, ABCG2, MXR1), and other efflux transporters may have a role in bendamustine transport
- Based on *in vitro* data, bendamustine is not likely to inhibit metabolism via human CYP1A2, CYP2C9/10, CYP2D6, CYP2E1, or CYP3A4/5, or induce the metabolism of cytochrome P450 substrates

BEVACIZUMAB

AVASTIN® (bevacizumab) Solution for intravenous infusion; product label, December 2013. Manufactured by Genentech, Inc., A Member of the Roche Group, South San Francisco, CA

WARNING: GASTROINTESTINAL PERFORATIONS, SURGERY AND WOUND HEALING COMPLICATIONS, and HEMORRHAGE

Gastrointestinal Perforations
The incidence of gastrointestinal perforation, some fatal, in Avastin-treated patients ranges from 0.3 to 2.4%. Discontinue Avastin in patients with gastrointestinal perforation…

Surgery and Wound Healing Complications
The incidence of wound healing and surgical complications, including serious and fatal complications, is increased in Avastin-treated patients. Discontinue Avastin in patients with wound dehiscence. The appropriate interval between termination of Avastin and subsequent elective surgery required to reduce the risks of impaired wound healing/wound dehiscence has not been determined. Discontinue at least 28 days prior to elective surgery. Do not initiate Avastin for at least 28 days after surgery and until the surgical wound is fully healed…

Hemorrhage
Severe or fatal hemorrhage, including hemoptysis, gastrointestinal bleeding, central nervous systems (CNS) hemorrhage, epistaxis, and vaginal bleeding occurred up to five-fold more frequently in patients receiving Avastin. Do not administer Avastin to patients with serious hemorrhage or recent hemoptysis…

Boxed Warning for "AVASTIN® (bevacizumab) Solution for intravenous infusion"; December 2013 product label. Genentech, Inc., A Member of the Roche Group, South San Francisco, CA

Product Identification, Preparation, Storage, and Stability

- Avastin® is packaged in individually boxed, single-use, glass vials in 2 presentations containing either 100 mg or 400 mg bevacizumab preservative-free solution in a uniform concentration of 25 mg/mL. NDC 50242-060-01 (100 mg/4 mL). NDC 50242-061-01 (400 mg/16 mL)
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F) in the original carton to protect them from light
- *Do not freeze or shake* Avastin®
- The commercial product contains a clear to slightly opalescent, colorless to pale brown, sterile, solution of bevacizumab with pH = 6.2
  - The 100-mg product is formulated in 240 mg α,α-trehalose dihydrate, 23.2 mg sodium phosphate (monobasic, monohydrate), 4.8 mg sodium phosphate (dibasic, anhydrous), 1.6 mg polysorbate 20, and SWFI
  - The 400-mg product is formulated in 960 mg α,α-trehalose dihydrate, 92.8 mg sodium phosphate (monobasic, monohydrate), 19.2 mg sodium phosphate (dibasic, anhydrous), 6.4 mg polysorbate 20, and SWFI
- Withdraw from a vial an amount of bevacizumab sufficient to prepare a patient's dose and add it to a volume of 0.9% NS sufficient to produce a total volume of (Q.S.) 100 mL in a PVC or polyolefin container. Gently invert the container to mix diluted bevacizumab solution. Discard any unused bevacizumab that remains in a vial
- *Do not mix* bevacizumab with dextrose solutions
- After dilution, bevacizumab solutions may be stored at 2°–8°C for up to 8 hours
- After dilution in 0.9% NS, bevacizumab was stable for up to 24 hours under the following conditions:

Bevacizumab Concentrations (mg/mL)	Storage Temperatures	Container Composition	Results
0.9 2.25 3 6.6 7.5 16.5	30°C (86°F)	PVC, polyolefin, glass	No significant changes in protein concentration, pH, turbidity, or potency
1 12.5 25 (undiluted drug)	2°–8°C 30°C	Polyolefin	No change in protein concentration, turbidity, or potency

Genentech Medical Communications, Genentech, Inc., data on file, April 13, 2004

Selected incompatibility:

- Do not mix bevacizumab with dextrose solutions

Recommendations for Drug Administration and Ancillary Care

General:

- *Do not administer* bevacizumab by direct intraVENous injection or bolus injection
- Administer bevacizumab by intraVENous infusion after chemotherapy. The INITIAL DOSE is given over 90 minutes. If a dose given over 9 minutes was well tolerated, the administration duration may be decreased to 60 minutes during a subsequent infusion. If a 60-minute infusion was well tolerated, subsequent treatments may be administered over 30 minutes
- *Do not administer, mix, or flush* bevacizumab with dextrose solutions

BLEOMYCIN SULFATE

Bleomycin for Injection, USP; product label, July 2012. Product of Australia. Hospira, Inc. Lake Forest, IL
Bleomycin—bleomycin sulfate injection, powder, lyophilized, for solution; product label, April 2012. Manufactured by Teva Parenteral Medicines, Inc., Irvine, CA

WARNINGS

It is recommended that Bleomycin for Injection, USP, be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents. Appropriate management of therapy and complications is possible only when adequate diagnostic and treatment facilities are readily available

Pulmonary fibrosis is the most severe toxicity associated with bleomycin

The most frequent presentation is pneumonitis occasionally progressing to pulmonary fibrosis. Its occurrence is higher in elderly patients and in those receiving greater than 400 units total [cumulative] dose, but pulmonary toxicity has been observed in young patients and those treated with low doses

A severe idiosyncratic reaction consisting of hypotension, mental confusion, fever, chills, and wheezing has been reported in approximately 1% of lymphoma patients treated with bleomycin

Boxed Warning for "Bleomycin—bleomycin sulfate injection, powder, lyophilized, for solution"; April 2012 product label; Teva Parenteral Medicines, Inc., Irvine, CA

Product Identification, Preparation, Storage, and Stability

- Bleomycin is generically available as a lyophilized powder for reconstitution for injection in individually packaged vials
- Each vial contains sterile bleomycin sulfate equivalent to 15 units or 30 units of bleomycin
  - Sulfuric acid or sodium hydroxide are used, if necessary to adjust product pH
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F)
- One unit of bleomycin activity corresponds to 1 mg of bleomycin activity
  - Commercial products are a mixture of bleomycin glycopeptides. Measurement in activity units is a more precise indication of drug potency
- Reconstitute with 0.9% NS, SWFI, or BWFI as follows:

Bleomycin Content/ Vial	Diluent Volumes			
	0.9% NS for IntraVENous or Intrapleural Administration		0.9% NS, SWFI, or BWFI for SUBCUTaneous or IntraMUSCular Administration	
15 units	5 mL	Bleomycin concentration = 3 units/mL	1 mL	Bleomycin concentration = 15 units/mL
30 units	10 mL		2 mL	

- For *intrapleural administration* as a sclerosing agent, further dilute bleomycin 60 units in 50–100 mL of 0.9% NS
- *Do not reconstitute or dilute* bleomycin with dextrose-containing solutions
  - Bleomycins A_2 and B_2 potencies decrease after reconstitution or dilution in dextrose-containing solutions, which does not occur in 0.9% NS[13]
- After reconstitution in 0.9% NS, bleomycin is stable for 24 hours at room temperature
- Bleomycin is compatible with glass, PVC, and high-density polyethylene containers[13], and with polyethylene, PVC, and polybutadiene administration sets[14]

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal dysfunction
- Bleomycin is given by slow intraVENous injection over 10 minutes; by intraVENous infusion; and by the intraMUSCular, intrapleural, and SUBCUTaneous routes
- Bleomycin may be filtered during administration with filter membranes composed of cellulose ester[14,15], cellulose nitrate/cellulose acetate ester[16], or tetrafluoroethylene polymer (Teflon® [DuPont]), without a significant loss of drug potency

Idiosyncratic reactions:

- In approximately 1% of patients with lymphoma treated with bleomycin, a severe idiosyncratic reaction, similar to anaphylaxis, has been reported, consisting of: hypotension, mental confusion, fever, chills, and wheezing. Treatment is symptomatic including volume expansion, vasopressors, antihistamines, and glucocorticoids. The reaction may be immediate or delayed for several hours, and usually occurs after a first or second dose
  - Consequently, current FDA approved product labeling recommends because of the possibility of an anaphylactoid reaction, patients with lymphoma should receive not more than 2 units of bleomycin for the first 2 doses. If no acute reaction occurs, then the regular dosage schedule may be followed
    - The absence of hypersensitivity to test doses (≤2 units bleomycin) does not preclude hypersensitivity phenomena during subsequent administration at full treatment dosages
- Renal insufficiency markedly alters bleomycin elimination. Bleomycin terminal elimination half-life increases exponentially as creatinine clearance decreases
  - Patients with impaired renal function should be treated with caution and their renal function should be carefully monitored during the administration of bleomycin. Bleomycin dosage reduction may be required in renally impaired patients
  - See Chapter 41 for modifying bleomycin dosage in renal impairment

For intrapleural administration:

- Administer bleomycin through a thoracostomy tube after excess pleural fluid drainage and confirming complete lung expansion. The thoracostomy tube is clamped after bleomycin instillation. The patient is moved from the supine to the left and right lateral positions several times during the next 4 hours. The clamp is then removed and thoracostomy tube suction is reestablished. The amount of time a thoracostomy tube remains in place following sclerosis is dictated by the clinical situation

BORTEZOMIB

VELCADE® (bortezomib) for Injection, for subcutaneous or intravenous use; product label, October 2012. Distributed and marketed by Millennium Pharmaceuticals, Inc., Cambridge, MA

Product Identification, Preparation, Storage, and Stability

- VELCADE® is packaged in individually packaged, single-use, 10-mL vials containing bortezomib 3.5 mg as a white to off-white, sterile, lyophilized cake or powder. NDC 63020-049-01
  - Each vial also contains 35 mg mannitol, USP
- Store unopened vials at controlled room temperature 25°C (77°F); temperature excursions are permitted from 15°–30°C (59°–86°F). Retain the product in its original packaging to protect it from light

Preparation for intraVENous injection (1 mg/mL solution)

- Reconstitute bortezomib powder with 3.5 mL of 0.9% NS to produce a clear, colorless solution with concentration = 1 mg bortezomib/mL

Preparation for SUBCUTaneous Injection (2.5 mg/mL solution)

- Reconstitute bortezomib powder with 1.4 mL of 0.9% NS to produce a clear, colorless solution with concentration = 2.5 mg bortezomib/mL
- The reconstituted product may be stored in its original vial or a syringe at 25°C (excursions are permitted from 15°–30°C), and should be administered within 8 hours after preparation
- Bortezomib solution must be used within 8 hours after reconstitution if the product is exposed to normal indoor lighting

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction

Caution:

- Exercise caution in calculating the volume of bortezomib to be administered
  - Different volumes of 0.9% NS diluent are used to reconstitute the product for the different routes of administration
  - The concentration of reconstituted bortezomib for SUBCUTaneous administration (2.5 mg/mL) is greater than the concentration of reconstituted bortezomib for intraVENous administration (1 mg/mL)
- Stickers that identify the intended route of administration are provided with commercial VELCADE®, and should be placed on syringes containing prepared doses as a safeguard against administration via an unintended route
- The reconstituted product is suitable for direct injection

IntraVENous Administration:

- For administration by intraVENous injection over 3–5 seconds

SUBCUTaneous Administration:

- When administered SUBCUTaneously, rotate injection sites (thigh or abdomen). Administer repeated injections at least 1 inch from a previously injected site, and never where a site is tender, bruised, erythematous, or indurated
- If local injection site reactions occur after SUBCUTaneous administration of bortezomib prepared in a concentration of 2.5 mg/mL, a less-concentrated solution (1 mg/mL) may be administered SUBCUTaneously. Alternatively, consider intraVENous administration

Potential for drug interactions:

- Bortezomib is a substrate for metabolism by CYP3A4, CYP2C19, and CYP1A2
  - Concomitant administration with potent inhibitors or inducers of CYP3A subfamily enzymes has been shown to alter bortezomib's pharmacokinetic behavior
  - Avoid use of bortezomib with potent inhibitors or inducers of CYP3A subfamily enzymes

BRENTUXIMAB VEDOTIN

ADCETRIS™ (brentuximab vedotin) for Injection, For intravenous infusion; product label, September 2013. Manufactured by Seattle Genetics, Inc., Bothell, WA

WARNING: PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY (PML)

JC virus infection resulting in PML and death can occur in patients receiving ADCETRIS…

Boxed Warning for "ADCETRIS™ (brentuximab vedotin) for Injection, For intravenous infusion"; September 2013 product label; Seattle Genetics, Inc., Bothell, WA

Product Identification, Preparation, Storage, and Stability

- ADCETRIS™ (brentuximab vedotin) for injection is supplied as a sterile, white to off-white, preservative-free, lyophilized cake or powder in individually boxed single-use vials containing 50 mg brentuximab vedotin. NDC 51144-050-01
  - The reconstituted product contains a solution of brentuximab vedotin 5 mg/mL with 70 mg/mL trehalose dihydrate, 5.6 mg/mL sodium citrate dihydrate, 0.21 mg/mL citric acid monohydrate, and 0.20 mg/mL polysorbate 80 and water for injection. The pH is approximately 6.6
- Store intact vials at 2°–8°C (35.6°–46.4°F) in the original carton to protect brentuximab vedotin from light
- *Caution:* Calculate a patient's dose and the number of ADCETRIS™ vials required to prepare a dose. A dose for patients weighing >100 kg should be calculated based on a weight of 100 kg

- *Reconstitution*
  1. Reconstitute brentuximab vedotin with 10.5 mL of SWFI, to produce a solution containing 5 mg brentuximab vedotin/mL
  2. Direct the stream of SWFI toward the vial wall, not directly into the drug product
  3. Gently swirl vial to aid drug dissolution. *Do not shake* a vial to aid dissolution
  4. The reconstituted solution should be clear to slightly opalescent, colorless, and free of visible particulates. Following reconstitution, dilute brentuximab vedotin immediately, or store the solution at 2°–8°C and use it within 24 hours after reconstitution. *Do not freeze* brentuximab vedotin
  5. Discard any unused portion of brentuximab vedotin left in a vial

- *Dilution*
  1. Immediately add reconstituted brentuximab vedotin (5 mg/mL) to a parenteral product container containing a minimum volume of 100 mL 0.9% NS, D5W, or LRI to achieve a final diluted concentration within the range, 0.4–1.8 mg/mL brentuximab vedotin
  2. Gently invert the product container to mix the solution
  3. Following dilution, administer brentuximab vedotin solution immediately, or store the solution at 2°–8°C and use the product within 24 hours after reconstitution. *Do not freeze* brentuximab vedotin

Recommendations for Drug Administration and Ancillary Care

General:

- The recommended initial dosage is brentuximab vedotin 1.8 mg/kg body weight administered intraVENously over 30 minutes every 3 weeks
  - Doses for patients whose body weight is >100 kg should be calculated based on a weight of 100 kg; that is, the maximum single brentuximab vedotin dose is 180 mg
  - *Do not administer* brentuximab vedotin by direct intraVENous injection or over a period <30 minutes

Cautions:

- In vitro, the binding of monomethyl auristatin E (MMAE, the microtubule disrupting portion of brentuximab vedotin) to human plasma proteins ranged from 68–82%. MMAE is not likely to displace or to be displaced by highly protein-bound drugs
- *In vitro*, MMAE was a substrate but was not a potent inhibitor of the P-glycoprotein transport protein (P-gp, ABCB1, MDR1)
  - Avoid concomitant use of brentuximab vedotin with moderate and more potent inhibitors of the ABCB1 transport protein
- *In vitro* data indicate that MMAE is largely eliminated in urine and feces as unchanged drug; however, a small portion of MMAE is a substrate for metabolism by CYP3A4/5. *In vitro* studies using human liver microsomes indicate MMAE inhibits CYP3A4/5 but not other CYP isoforms
  - Avoid concomitant use of brentuximab vedotin with potent inhibitors and inducers of CYP3A subfamily enzymes
- Concomitant use of brentuximab vedotin and bleomycin is contraindicated because of a greater incidence rate of noninfectious pulmonary toxicity with concurrent use than a historical comparison of the incidence of pulmonary toxicity reported with the ABVD (DOXOrubicin, bleomycin, vinBLAStine, dacarbazine) regimen
  - Patients typically reported cough and dyspnea. Interstitial infiltration and inflammation were observed on chest radiographs and CT. Most patients responded to steroids

(*continued*)

Recommendations for Drug Administration and Ancillary Care (*continued*)

Adverse events:

- Infusion-related reactions, including anaphylaxis, have occurred with brentuximab vedotin. Continually monitor patients during drug administration
  - If anaphylaxis occurs, immediately and permanently discontinue brentuximab vedotin administration and administer appropriate medical therapy
  - In the event of less-severe manageable infusion-related reactions, interrupt brentuximab vedotin administration and institute appropriate medical management
    - Patients who experience an infusion-related hypersensitivity reaction should receive prophylaxis against hypersensitivity reactions before retreatment with brentuximab vedotin
    - Medications for hypersensitivity prophylaxis may include acetaminophen, an antihistamine, and a glucocorticoid
- Peripheral neuropathy should be managed using a combination of dose delay and dosage reduction to 1.2 mg/kg
  - For new or worsening G2 or G3 neuropathy, withhold brentuximab vedotin until neuropathy improves to G1 or baseline, then restart treatment with brentuximab vedotin 1.2 mg/kg per dose
  - Discontinue brentuximab vedotin treatment for G4 peripheral neuropathy
- JC virus infection resulting in PML and death has been reported in patients treated with brentuximab vedotin
  - Other possible contributory factors include prior therapies and underlying disease that may cause immunosuppression
  - Consider a diagnosis of PML in any patient presenting with new-onset signs and symptoms of CNS abnormalities
  - Evaluation for PML includes, but is not limited to, consultation with a neurologist, brain MRI, and lumbar puncture or brain biopsy
  - Withhold brentuximab vedotin for any suspected case of PML and discontinue use if a diagnosis of PML is confirmed
- Neutropenia should be managed by dose delay and dosage reduction
  - Withhold brentuximab vedotin for neutropenia G $\geq$3 until ANC resolves to baseline or G $\leq$2 neutropenia
  - Hematopoietic growth factor support should be considered for subsequent cycles in patients who experience neutropenia G $\geq$3
  - Also consider dosage reduction to brentuximab vedotin 1.2 mg/kg in patients with recurrent G4 neutropenia despite the use of hematopoietic growth factors

BUSULFAN

BUSULFEX® (busulfan) injection; product label, May 2011. Manufactured by DSM Pharmaceuticals, Inc., Greenville, NC. Distributed and marketed by Otsuka America Pharmaceutical, Inc., Rockville, MD

WARNINGS

BUSULFEX® (busulfan) Injection is a potent cytotoxic drug that causes profound myelosuppression at the recommended dosage. It should be administered under the supervision of a qualified physician who is experienced in allogeneic hematopoietic stem cell transplantation, the use of cancer chemotherapeutic drugs and the management of patients with severe pancytopenia. Appropriate management of therapy and complications is only possible when adequate diagnostic and treatment facilities are readily available…

Boxed Warning for "BUSULFEX® (busulfan) Injection"; May 2011 product label; Otsuka America Pharmaceutical, Inc., Rockville, MD

Product Identification, Preparation, Storage, and Stability

- BUSULFEX® (busulfan) injection is supplied as a clear, colorless, sterile solution in 10-mL, single-use, clear, glass vials each containing busulfan 60 mg/10 mL (6 mg/mL) dissolved in *N,N*-dimethylacetamide (DMA) 33% (v/v) and polyethylene glycol 400, 67% (v/v). NDC 59148-070-90
- BUSULFEX® is distributed as a unit carton containing 8 vials. NDC 59148-070-91
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F)

Dilution for clinical use:

- The solubility of busulfan in water is 100 mg/L and the pH of BUSULFEX® diluted to approximately 0.5 mg busulfan/mL in 0.9% NS or D5W as recommended reflects the pH of the diluent used, and ranges from 3.4 to 3.9
- BUSULFEX® must be diluted for clinical use with either 0.9% NS or D5W
  - The volume of diluent should be 10-times the volume of BUSULFEX® solution, such that the final concentration of busulfan for clinical use is approximately 0.5 mg/mL
- Mix busulfan thoroughly by inverting the product container several times
- After dilution in 0.9% NS or D5W, BUSULFEX® is stable at room temperature, 25°C (77°F), for up to 8 hours, but administration must be completed within that time[17]
- After dilution in 0.9% NS, BUSULFEX® is stable under refrigeration at 2°–8°C for up to 12 hours, but administration must be completed within that time

Preparation and administration precautions:

- *Do not use* polycarbonate syringes or polycarbonate filter needles in transferring or administering busulfan solutions
- *Do not inject* BUSULFEX® solution (6 mg/mL) into a parenteral product container that does not contain 0.9% NS or D5W
  - Always add BUSULFEX® to a diluent (vehicle) solution, not the reverse

Selected incompatibility:

- *Do not mix* BUSULFEX® with another solution unless compatibility is known

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with hepatic dysfunction
- Select an administration set with minimal intraluminal priming volume (≤5 mL) to administer busulfan
- Prime the administration set tubing with diluted busulfan solution to allow accurate determination of the start of busulfan administration
  - It is important to accurately identify administration starting and completion times in order to modify busulfan dosage based on its pharmacokinetic behavior in individual patients
- A rate-controlling device (infusion pump) should be used to administer diluted busulfan by intraVENous infusion via a central VAD over 2 hours
  - More rapid administration has not been tested and is not recommended
- Before starting and after completing busulfan administration, flush the patient's VAD with approximately 5 mL of 0.9% NS or D5W. *Do not mix* BUSULFEX® with another solution unless compatibility is known
  - Flushing is particularly important if blood samples for pharmacokinetically guided busulfan dose adjustment must be acquired from the same VAD used to administer the drug

Concomitant drug use:

- Busulfan crosses the blood–brain barrier and induces seizures. All patients should receive anticonvulsant prophylaxis with phenytoin prior to starting busulfan
  - Although phenytoin decreases busulfan AUC_{plasma} by 15%, other anticonvulsants may increase busulfan AUC_{plasma}, and increase the risk of venoocclusive disease or seizures
  - Busulfan pharmacokinetics were studied in patients treated with phenytoin, and its

(*continued*)

Recommendations for Drug Administration and Ancillary Care (*continued*)

clearance at the recommended dose may be less and exposure (AUC) greater in patients not treated with phenytoin
  - Plasma busulfan exposure should be monitored in cases where other anticonvulsants must be used
- Acetaminophen use should be avoided within 72 hours before and concurrently with busulfan use
  - Busulfan is eliminated via conjugation with glutathione. Acetaminophen is known to decrease glutathione concentrations in blood and tissues. Concurrent use with busulfan may result in reduced busulfan clearance, potentially prolonged systemic exposure to busulfan, and enhanced adverse effects

Busulfan dosage as a component of the "BuCy" conditioning regimen before hematopoietic stem cell transplantation:

- The usual adult dosage is based on the lesser of either ideal or actual body weight, and is 0.8 mg/kg per dose, every 6 hours, for a total of 16 doses (total daily dosage = 3.2 mg/kg per day for 4 consecutive days, or a total dosage/4-day course = 12.8 mg/kg)
- Busulfan clearance is best predicted when doses are based on adjusted ideal body weight (AIBW)
  - Dose calculations based on actual body weight, ideal body weight, or other factors can produce significant differences in busulfan clearance among lean, normal, and obese patients
- Busulfan dosage in obese patients is based on adjusted ideal body weight as follows:

  Ideal body weight and adjusted ideal body weight calculations (IBW and AIBW, respectively):
  - IBW for men (kg) = 50 + 0.91 × ([height in cm] − 152)
  - IBW for women (kg) = 45 + 0.91 × ([height in cm] − 152)
  - AIBW men and women (kg) = IBW + 0.25 × ([actual body weight] − IBW)
- Where available, pharmacokinetic monitoring may be considered to optimize therapeutic targeting
  - Therapeutic target AUC_{plasma} = 1125 μmol · min

CABAZITAXEL

JEVTANA® (cabazitaxel) injection, 60 mg/1.5 mL, for intravenous infusion only; product label May 2013. sanofi-aventis U.S. LLC, Bridgewater, NJ

WARNING

Neutropenic deaths have been reported. In order to monitor the occurrence of neutropenia, frequent blood cell counts should be performed on all patients receiving JEVTANA. JEVTANA should not be given to patients with neutrophil counts of ≤1,500 cells/mm^3

Severe hypersensitivity reactions can occur and may include generalized rash/erythema, hypotension and bronchospasm. Severe hypersensitivity reactions require immediate discontinuation of the JEVTANA infusion and administration of appropriate therapy… Patients should receive premedication… JEVTANA must not be given to patients who have a history of severe hypersensitivity reactions to JEVTANA or to other drugs formulated with polysorbate 80…

Boxed Warning for "JEVTANA® (cabazitaxel) Injection, 60 mg/1.5 mL, for intravenous infusion only"; May 2013 product label; sanofi-aventis U.S. LLC, Bridgewater, NJ

Product Identification, Preparation, Storage, and Stability

- JEVTANA® (cabazitaxel) injection 60 mg/1.5 mL (NDC 0024-5824-11) is supplied as a kit consisting of 2 vials in a blister pack in 1 carton, including:
  - one single-use vial contains 60 mg of cabazitaxel (anhydrous and solvent-free) in 1.5 mL of polysorbate 80 (1.56 g) as a sterile, nonpyrogenic, clear yellow to brownish-yellow, viscous solution. Each milliliter of the concentrated drug product contains cabazitaxel (anhydrous) 40 mg and 1.04 g of polysorbate 80
  - one vial contains Diluent for JEVTANA®, a clear, colorless, sterile, nonpyrogenic solution containing 13% (w/w) ethanol in water for injection, approximately 5.7 mL
- Both the JEVTANA® injection and Diluent for JEVTANA® vials contain excess drug and diluent solutions (overfill), respectively, to compensate for volume lost during preparation
- Store JEVTANA® injection and Diluent for JEVTANA® at 25°C (77°F); temperature excursions are permitted between 15°–30°C (59°–86°F)
- *Do not refrigerate* JEVTANA® Injection and Diluent for JEVTANA®
- JEVTANA® requires 2 dilutions before it may be administered to patients:
  - The concentrated drug product should be diluted only with the supplied Diluent for JEVTANA®, followed by dilution in either 0.9% NS or D5W
  - Do not use PVC infusion containers or polyurethane administration sets during preparation or administration of JEVTANA®

Initial dilution:

1. With a syringe, aseptically withdraw the entire contents of a Diluent for JEVTANA® vial and inject it into a vial containing the JEVTANA® drug product
   a. When transferring the diluent, direct the needle onto the inside wall of the drug product vial and inject slowly to limit foaming
2. Remove the syringe and needle and gently mix the initially diluted solution by repeated inversions for at least 45 seconds to assure a homogeneous mixture of the drug and diluent. *Do not shake* initially diluted JEVTANA® to avoid foaming
3. Let the solution stand for a few minutes to allow any foam to dissipate, and check that the solution is homogeneous and contains no visible particulate matter
   a. It is not required that all foam dissipate prior to continuing preparation
   b. The resulting initially diluted JEVTANA® solution (10 mg cabazitaxel/mL) requires further dilution before it may be given to patients

Caution: Secondary dilution must be completed within 30 minutes after completing initial dilution to obtain a product appropriate for administration to patients

Secondary dilution:

1. With a syringe, aseptically withdraw an amount of the initially diluted JEVTANA® solution (10 mg cabazitaxel/mL) appropriate for a patient's dose and transfer it to a volume of 0.9% NS or D5W to produce a cabazitaxel concentration within the range 0.1–0.26 mg/mL
   a. Product concentrations must not exceed 0.26 mg cabazitaxel/mL. Discard any unused portion of the initially diluted JEVTANA® solution
2. Thoroughly mix the secondarily diluted product by manual rotation and by gently inverting the container
3. After the second dilution in either 0.9% NS or D5W, JEVTANA® should be used within 8 hours if maintained at ambient temperatures (including the 1-hour administration time), or may be used within 24 hours after preparation (including the 1-hour administration time) if stored under refrigeration at 2°–8°C (35.6°–46.4°F)

Cautions: JEVTANA® should not be mixed with any other drugs

Chemical and physical stability of cabazitaxel solution has been demonstrated for 24 hours under refrigerated conditions; however, both the initially diluted and secondarily diluted solutions are supersaturated. Consequently, if crystals or particulates appear in either solution, the solutions must not be used and should be discarded

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Cabazitaxel is administered intraVENously over 60 minutes in combination with predniSONE 10 mg/day administered orally, continually throughout treatment with cabazitaxel

Primary prophylaxis against hypersensitivity reactions:

- At least 30 minutes before each dose of cabazitaxel give the following medications intraVENously to decrease the risk or severity of hypersensitivity:
  - A histamine H_1-subtype receptor antagonist, for example, dexchlorpheniramine 5 mg, diphenhydramine 25 mg, or equivalent antihistamine, *plus*
  - A glucocorticoid, for example, dexamethasone 8 mg, or another steroid at a glucocorticoid-equivalent dose, *plus*
  - A histamine H_2-subtype receptor antagonist, for example, ranitidine 50 mg or equivalent

- After secondary dilution, JEVTANA® solution (concentration 0.1–0.26 mg cabazitaxel/mL) should be administered intraVENously over 60 minutes at room temperature through an in-line filter with nominal pore size of 0.22 µm
- Although it is recommended the secondarily diluted solution should be used immediately, storage time can be longer under specific conditions:
  - Up to 8 hours after preparation if maintained at ambient temperatures (including the 1-hour administration time), *or*
  - Up to 24 hours after preparation (including the 1-hour administration time) if stored under refrigeration at 2°–8°C

Caution with medications given concomitantly:

- Cabazitaxel is a substrate for metabolism catalyzed by CYP3A subfamily enzymes
  - *Avoid concomitant use* of moderate and more potent CYP3A subfamily enzyme inhibitors, which may increase systemic exposure to cabazitaxel (eg, atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole)
  - *Avoid concomitant use* of strong CYP3A subfamily enzyme inducers (eg, carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort), which may be expected to decrease cabazitaxel concentrations
- Cabazitaxel is a substrate of P-glycoprotein (P-gp, MDR1, ABCB1) in vitro, but is not a substrate of MRP1, MRP2, or the breast cancer resistance protein (BCRP, ABCG2, MXR1)
  - In vitro, cabazitaxel inhibited the transport of P-gp and BRCP, at concentrations at least 38-fold greater than what is observed clinically
- A risk of cabazitaxel perturbing the pharmacokinetic behavior of concurrently used medications by inhibiting P-gp or BCRP is unlikely at clinically used dosages

CARBOPLATIN

Carboplatin injection; product label, August 2007. Hospira, Inc., Lake Forest, IL
CARBOPLATIN–carboplatin injection, solution (50-, 150-, and 450-mg multidose vials); product label, October 2011. Manufactured by Pharmachemie B.V., Haarlem, The Netherlands. Manufactured for Teva Pharmaceuticals USA, Sellersville, PA, *and*
CARBOPLATIN INJECTION; product label, January 2008. APP Pharmaceuticals LLC, Schaumburg, IL

WARNINGS

Carboplatin injection should be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents. Appropriate management of therapy and complications is possible only when adequate treatment facilities are readily available

Bone marrow suppression is dose related and may be severe, resulting in infection and/or bleeding. Anemia may be cumulative and may require transfusion support. Vomiting is another frequent drug-related side effect

Anaphylactic-like reactions to carboplatin have been reported and may occur within minutes of carboplatin injection administration. Epinephrine, corticosteroids, and antihistamines have been employed to alleviate symptoms

Boxed Warnings for "Carboplatin Injection"; August 2007 product label; Hospira, Inc., Lake Forest, IL

Product Identification, Preparation, Storage, and Stability

- CARBOplatin is marketed as branded and generic products from several manufacturers in multidose (*or* multiuse) vials containing 50 mg, 150 mg, 450 mg, or 600 mg CARBOplatin per vial
- CARBOplatin injection is a sterile aqueous solution of CARBOplatin at a concentration of 10 mg/mL (1%); the pH of a 1% solution of CARBOplatin is 5–7
- Store unopened vials under temperature conditions indicated for individual products, generally within a range between 20°C and 25°C (68°F and 77°F). Available products often indicate temperature excursions to 15°–30°C (59°–86°F) are permitted. Protect unopened vials from light
- CARBOplatin injection in multidose vials maintain microbial, chemical, and physical stability for up to 14 days (Teva Pharmaceuticals USA product) or 15 days (Hospira, Inc. product) at 25°C following multiple needle entries
- CARBOplatin injection may be further diluted to concentrations as low as 0.5 mg/mL with either D5W or 0.9% NS. After dilution, CARBOplatin may be stored at room temperature (25°C [77°F]) for up to 8 hours before use

Selected incompatibility:

- Avoid admixture with solutions with pH >6.5 (eg, solutions containing fluorouracil or sodium bicarbonate)
- Avoid admixture with mesna
- Aluminum reacts with CARBOplatin, causing precipitation and loss of drug potency. *Do not prepare or administer* CARBOplatin with needles or administration sets that contain aluminum parts that may come into contact with the drug

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal dysfunction
- Administer CARBOplatin intraVENously over at least 15 minutes. Pre- or post-treatment hydration and forced diuresis are not required
- Prescriptions and medication orders should identify the drug by its complete generic name, "CARBOplatin", to prevent confusion with other platinum compounds

CARFILZOMIB

KYPROLIS™ (carfilzomib) for Injection, for intravenous use; product label, July 2012. Manufactured by Onyx Pharmaceuticals, Inc., South San Francisco, CA

Product Identification, Preparation, Storage, and Stability

- KYPROLIS™ (carfilzomib) for injection is supplied in individually cartoned single-use vials containing carfilzomib 60 mg as a sterile, white to off-white, lyophilized cake or powder with sulfobutylether beta-cyclodextrin 3000 mg, citric acid 57.7 mg, and sodium hydroxide sufficient to adjust the product pH to 3.5. NDC 76075-101-01
- Store unopened vials under refrigeration between 2°C and 8°C (35.6°F and 46.4°F) in the original packaging to protect carfilzomib from light
- Preparation:
  1. Remove a vial from refrigeration just prior to use
  2. Slowly inject 29 mL of SWFI by directing the solution onto the inside vial wall, not into the drug product to minimize foaming
  3. Gently swirl or slowly and repeatedly invert the vial for approximately 1 minute, or until the drug cake or powder has completely dissolved. DO NOT SHAKE carfilzomib to avoid generating foam
  4. If foaming occurs, set the vial aside for approximately 2–5 minutes, to allow the foam to dissipate
  5. After reconstitution, the resulting solution should be clear and colorless and contains carfilzomib at a concentration of 2 mg/mL
- Carfilzomib stability

Storage Conditions After Reconstitution (Carfilzomib 2 mg/mL)	Stability as a Function of Product Container*		
	Vial	Syringe	Diluted with D5W and Stored in a Plastic Container (Bag)
Refrigeration (2°–8°C)	24 hours		
Room temperature (15°–30°C [59°–86°F])	4 hours		

*Total time from reconstitution to administration should not exceed 24 hours

6. Dilute carfilzomib in a parenteral product container with 50 mL of D5W
7. Discard vials containing unused drug solution

Recommendations for Drug Administration and Ancillary Care

Supportive Care:

Hydration

- Prior to administering carfilzomib, evaluate a patient's fluid status to ensure they are well hydrated
- Patients should receive hydration with carfilzomib to reduce the risk of developing renal toxicity and tumor lysis syndrome (TLS)
  - Overall, TLS occurred in <1% of patients, but patients with multiple myeloma and a high tumor burden should be considered at greater risk for TLS
  - Monitor for evidence of TLS during treatment, and manage promptly
  - Interrupt carfilzomib treatments until TLS is resolved
- Maintain patients' fluid volume status and monitor blood chemistries closely throughout treatment with carfilzomib
  - During cycle 1:
    - Give 250–500 mL 0.9% NS or another fluid intraVENously as clinically appropriate before each carfilzomib dose
    - Give an additional 250–500 mL of fluids intraVENously as needed after completing each carfilzomib dose
  - During repeated treatment cycles, continue intraVENous hydration as needed
- Monitor patients for fluid overload

Prophylaxis against hypersensitivity/infusion-related reactions

- Hypersensitivity reactions may occur immediately after or during the first 24 hours after carfilzomib administration
- Infusion-related reactions may be characterized by any of the following: fever, chills, arthralgia, myalgia, facial flushing, facial edema, vomiting, weakness, shortness of breath, hypotension, syncope, chest tightness, angina
- To mitigate the incidence and severity of infusion reactions, administer **dexamethasone** 4 mg orally or intraVENously prior to each carfilzomib dose during cycle 1 and prior to each carfilzomib dose during the cycle in which carfilzomib dosage is escalated to 27 mg/m^2
- Continue or resume prophylaxis with **dexamethasone** 4 mg orally or intraVENously if symptoms develop or reappear during subsequent cycles

General:

- Carfilzomib is administered only by intraVENous infusion over 2–10 minutes, on 2 consecutive days, weekly, for three consecutive weeks every 28 days, that is administration on days 1, 2, 8, 9, 15, and 16, during a 28-day treatment cycle
- Flush with 0.9% NS or D5W the administration set tubing and VAD through which carfilzomib is given immediately before beginning and after completing carfilzomib administration
- Do not mix carfilzomib with other medicinal products or administer it through the same intraVENous VAD with other medicinal products

Carfilzomib dose calculation:

- Carfilzomib dose is calculated using a patient's actual BSA calculated at baseline. Patients with a BSA >2.2 m^2 should receive a dose based upon a BSA of exactly 2.2 m^2
- There is no need to make dose adjustments for changes in body weight ≤20%

Carfilzomib dosage escalation:

- During cycle 1, carfilzomib is administered at a dosage of 20 mg/m^2 each day of treatment
- If carfilzomib is well tolerated at 20 mg/m^2 per dose, the dosage during cycle 2 may be escalated to 27 mg/m^2 for each day of treatment, and continued at 27 mg/m^2 per dose during subsequent cycles

CARMUSTINE

BiCNU® (carmustine for injection); product label, May 2011. BiCNU® manufactured by Ben Venue Laboratories, Inc., Bedford, OH, *or* Emcure Pharmaceuticals Ltd., Hinjwadi, Pune 411057, INDIA. Diluent manufactured by Luitpold Pharmaceuticals, Inc., Shirley, NY. Distributed by Bristol-Myers Squibb Company, Princeton, NJ

WARNINGS

BiCNU® (carmustine for injection) should be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents

Bone marrow suppression, notably thrombocytopenia and leukopenia, which may contribute to bleeding and overwhelming infections in an already compromised patient, is the most common and severe of the toxic effects of BiCNU…

Since the major toxicity is delayed bone marrow suppression, blood counts should be monitored weekly for at least 6 weeks after a dose… At the recommended dosage, courses of BiCNU should not be given more frequently than every 6 weeks

The bone marrow toxicity of BiCNU is cumulative and therefore dosage adjustment must be considered on the basis of nadir blood counts from prior dose…

Pulmonary toxicity from BiCNU appears to be dose related. Patients receiving greater than 1400 mg/m^2 cumulative dose are at significantly higher risk than those receiving less

Delayed pulmonary toxicity can occur years after treatment, and can result in death, particularly in patients treated in childhood…

Boxed Warning for "BiCNU® (carmustine for injection)"; May 2011 product label; Bristol-Myers Squibb Company, Princeton, NJ

Product Identification, Preparation, Storage, and Stability[18]

- BiCNU®, NDC 0015-3012-60, packaging includes 2 containers, including:
  - One vial containing 100 mg of carmustine as sterile, lyophilized, pale-yellow flakes or a congealed mass
  - An ampule containing 3 mL of sterile dehydrated alcohol injection, USP, which is used to initially dissolve carmustine before attempting further dilution with aqueous media
- Dehydrated alcohol injection, USP, may be stored at room temperature 15°–30°C (59°–86°F) or under refrigeration at 2°–8°C (35.6°–46.4°F)
- Intact vials containing the drug product, carmustine, are stable for at least 3 years if stored under refrigeration at 2°–8°C, but for only 7 days if stored at room temperature (up to 25°C [≤77°F]). The lyophilized formulation does not contain a preservative and is intended for a single use
  - *Caution:* BiCNU® has a low melting point (30.5°–32°C [86.9°–89.6°F])
    - Exposure of the drug to this or greater temperatures will cause the drug to liquefy, becoming an oily film on the interior surface of a vial; a sign of decomposition indicating affected vials should be discarded
    - If upon receipt appropriate storage during transportation is in question, immediately examine the vial containing carmustine in each individual carton by holding it to a bright light for inspection
    - If carmustine appears as a very small amount of dry flakes or a dry congealed mass, the product is suitable for use and should be refrigerated immediately

Preparation

1. Dissolve carmustine with 3 mL of the supplied diluent (dehydrated alcohol injection, USP)
2. *Only after* the drug product has been completely dissolved, aseptically add 27 mL of SWFI
   a. The resulting solution is clear, colorless to yellowish, and contains 3.3 mg carmustine/mL in 10% ethanol
      - After reconstitution as recommended, carmustine is stable for 8 hours at room temperature (25°C) if it is protected from light exposure, and for at least 24 hours if stored under refrigeration and protected from light
        - Reconstituted vials should be examined for crystal formation prior to use
        - If crystals are observed, they may be re-dissolved by warming the vial to room temperature with agitation

Administration

- For administration to patients, carmustine should be further diluted to a concentration of 0.2 mg/mL with D5W and *stored only* in glass or polyolefin parenteral product containers[19]
- Carmustine adsorption to PVC, ethylene vinyl acetate (EVA), and polyurethane containers results in substantial drug loss as a result of drug adsorption to the container material

Stability as a Function of Carmustine Concentration and Storage Temperature[20, 21]

Diluent Solution	Carmustine Concentration	Storage Temperature	Duration of Stability
D5W	0.5–1 mg/mL	25°C (77°F)	4 hours
	0.1–1 mg/mL	4°C (39.2°F)	24 hours

- Initial solubilization with ethanol produces a carmustine solution that can be very irritating to vascular endothelium during intraVENous administration. Consequently, several investigators have evaluated alternative preparation schemes to decrease or eliminate ethanol from carmustine for intraVENous administration. Although these methods are not advocated by the product manufacturer, and may present some logistical challenges with respect to material resources, 2 methods for producing an ethanol-free solution for intraVENous administration are described below

Alternative Preparation Schemes

Method 1[22]:

- To a vial containing 100 mg carmustine, add 30 mL of preservative-free D5W
- Heat the vial to 60°C (140°F) in a water bath for 5 minutes, and, during heating, vigorously shake the vial 3 times
- The preparation scheme produces a solution with a carmustine concentration of 3.3 mg/mL and a stability half-life of 46 hours
  - The investigators demonstrated an 8% loss in concentration after product filtration
  - Although carmustine must be diluted before it is administered to patients, the investigators did not describe secondary dilution

Method 2[23]:

- To a vial containing 100 mg carmustine, add 25 mL of preservative-free D5W warmed to 37°C (98.6°F)
- Shake the vial by hand or in a water bath warmed to 37°C for approximately 5 minutes
- The preparation scheme produces a solution with a carmustine concentration of ~4 mg/mL and a mean stability half-life of 6.8 hours
  - When prepared with ethanol according to the manufacturer's instruction, carmustine must be diluted before it is administered to patients. Tepe et al. did not describe secondary dilution

Selected incompatibility:

- Avoid admixture with solutions of pH >6 (eg, solutions containing sodium bicarbonate)[24]
- Photodegradation occurs after exposure to strong light sources (>500 Lux; >46 foot-candles)

Recommendations for Drug Administration and Ancillary Care[25]

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer by intraVENous infusion over at least 1–2 hours
  - Carmustine is irritating to vascular endothelium largely because of the ethanol used to initially dissolve the drug. Administration over <1 hour may produce sensations of intense pain and burning at the site of administration
- *Use only* polyethylene or polyethylene-lined administration sets
  - A substantial amount of carmustine may be lost from solution as a result of adsorption to the surfaces of ethylene vinyl acetate, PVC, and polyurethane product containers and administration sets
- *Do not* mix carmustine with solutions containing sodium bicarbonate
- Carmustine should not be given more frequently than every 6 weeks

CETUXIMAB

ERBITUX® (cetuximab) injection, for intravenous infusion; product label, August 2013. Manufactured by ImClone LLC, a wholly owned subsidiary of Eli Lilly and Company, Branchburg, NJ. Distributed and marketed by Bristol-Myers Squibb Company, Princeton, NJ. Comarketed by Eli Lilly and Company, Indianapolis, IN

WARNING: SERIOUS INFUSION REACTIONS and CARDIOPULMONARY ARREST

Infusion Reactions: Serious infusion reactions occurred with the administration of Erbitux in approximately 3% of patients in clinical trials, with fatal outcome reported in less than 1 in 1000… Immediately interrupt and permanently discontinue Erbitux infusion for serious infusion reactions…

Cardiopulmonary Arrest: Cardiopulmonary arrest and/or sudden death occurred in 2% of patients with squamous cell carcinoma of the head and neck treated with Erbitux and radiation therapy in Study 1 and in 3% of patients with squamous cell carcinoma of the head and neck treated with European Union (EU)-approved cetuximab in combination with platinum-based therapy with 5-fluorouracil (5-FU) in Study 2. Closely monitor serum electrolytes, including serum magnesium, potassium, and calcium, during and after Erbitux administration…

Boxed Warning for "ERBITUX® (cetuximab) injection, for intravenous infusion"; August 2013 product label; Co-marketed by Bristol-Myers Squibb Company, Princeton, NJ, and Eli Lilly and Company, Indianapolis, IN

Product Identification, Preparation, Storage, and Stability

- ERBITUX® is supplied in individually packaged, single-use vials containing cetuximab 100 mg/50 mL (NDC 66733-948-23) or 200 mg/100 mL (NDC 66733-958-23) as a sterile, preservative-free, clear and colorless, injectable liquid with pH = 7.0–7.4
  - The commercial product contains cetuximab 2 mg/mL with 8.48 mg/mL sodium chloride, 1.88 mg/mL sodium phosphate dibasic heptahydrate, 0.41 mg/mL sodium phosphate monobasic monohydrate, and SWFI
- Store vials under refrigeration at 2°–8°C (35.6°–46.4°F). *Do not freeze* the product
- The product may contain a small amount of easily visible, white, amorphous cetuximab particulates
  - Increased particulate formation may occur at temperatures ≤0°C (≤32°F)
- Cetuximab stored in parenteral product containers is chemically and physically stable for up to 12 hours at 2°–8°C and for up to 8 hours at controlled room temperature (20°–25°C; 68°–77°F)
  - Discard any unused cetuximab within 8 hours or within 12 hours after preparation for products maintained at controlled room temperature or under refrigeration (2°– 8°C), respectively
  - Discard any unused portions of cetuximab remaining in a vial
- *Do not shake or dilute* cetuximab solution

Recommendations for Drug Administration and Ancillary Care

General:

- Administer cetuximab by intraVENous infusion with an infusion pump or syringe pump
- *Do not administer* cetuximab by direct intraVENous injection or bolus injection

Premedication:

- Give primary prophylaxis against infusion-related reactions with an antihistamine (H_1-receptor) antagonist (eg, diphenhydrAMINE 50 mg IV, *or* equivalent H_1 antagonist) 30–60 minutes before a first dose of cetuximab
  - Infusion reactions have occurred in 15–21% of patients across studies, and included: pyrexia, chills, rigors, dyspnea, bronchospasm, angioedema, urticaria, hypertension, and hypotension
    - Grades 3 and 4 infusion reactions occurred in 2–5% of patients, and were fatal in 1 patient
  - Premedication for subsequent cetuximab doses should be based upon clinical judgment and the presence and severity of infusion reactions during prior doses

Administration:

- Administer cetuximab through a low protein binding, 0.22-µm, inline filter (placed as proximal to the patient as practical)
- Administer cetuximab 400 mg/m² doses over 2 hours (120 min); administer 250 mg/m² doses over 1 hour (60 min)
  - The MAXIMUM INFUSION RATE should be ≤5 mL/min (≤10 mg/min), which is ≤300 mL/hour (≤600 mg/hour)
  - Use 0.9% NS to flush the line at the end of infusion

Patient monitoring:

- A 1-hour observation period is recommended after completing cetuximab administration in a setting with resuscitation equipment and other agents necessary to treat anaphylaxis (eg, epinephrine, bronchodilators, oxygen, and parenteral steroids and antihistamines)
  - Continue monitoring to confirm resolution of an acute event in patients who required treatment for infusion reactions
  - Longer observation periods may be required in patients who experience infusion reactions
- Patients should be periodically monitored for hypomagnesemia, hypocalcemia, and hypokalemia, during and following cetuximab administration. The same electrolyte analyses should be continually monitored for approximately 8 weeks after

(continued)

Recommendations for Drug Administration and Ancillary Care (*continued*)

the last dose administered, that is, a period of time commensurate with the half-life and persistence of cetuximab

- The onset of electrolyte abnormalities has been reported to occur from days to months after cetuximab administration. Electrolyte supplementation may be necessary in some patients and, in severe cases, intraVENous replacement may be required. The time to resolution of electrolyte abnormalities is not known

Patient counseling:

Advise patients:

- To report signs and symptoms of infusion reactions such as fever, chills, or breathing problems
- Of the potential risks of using cetuximab during pregnancy or breast-feeding and of the need to use adequate contraception in both males and females during treatment, and for 6 months following the last dose of cetuximab
- That breast-feeding is not recommended during, and for 2 months following the last dose of cetuximab therapy
- To limit sun exposure (use sunscreen, wear hats) while receiving cetuximab and for 2 months following the last dose of cetuximab

CISPLATIN

CISPLATIN INJECTION; product label, January 2008. APP Pharmaceuticals, LLC, Schaumburg, IL
PLATINOL–cisplatin injection, powder, lyophilized, for solution; product label, October 2010. Made in Italy. Manufactured for Bristol-Myers Squibb Company Princeton, NJ
CISPLATIN–cisplatin injection, solution; product label, February 2012 Teva Parenteral Medicines, Inc. Manufactured in The Netherlands by Pharmachemie B.V., Haarlem, The Netherlands. Manufactured for Teva Pharmaceuticals USA, Sellersville, PA

WARNINGS

[CISplatin] . . .should be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents. Appropriate management of therapy and complications is possible only when adequate diagnostic and treatment facilities are readily available

Cumulative renal toxicity associated with cisplatin is severe. Other major dose-related toxicities are myelosuppression, nausea, and vomiting

Ototoxicity, which may be more pronounced in children, and is manifested by tinnitus, and/or loss of high frequency hearing and occasionally deafness, is significant

Anaphylactic-like reactions to [CISplatin] . . .have been reported. Facial edema, bronchoconstriction, tachycardia, and hypotension may occur within minutes of [CISplatin] . . .administration. Epinephrine, corticosteroids, and antihistamines have been effectively employed to alleviate symptoms. . .

Exercise caution to prevent inadvertent [CISplatin] . . .overdose. Doses greater than 100 mg/m^2/cycle once every 3 to 4 weeks are rarely used. Care must be taken to avoid inadvertent [CISplatin] . . .overdose due to confusion with. . . carboplatin . . .or prescribing practices that fail to differentiate daily doses from total dose per cycle

Boxed Warnings for "CISPLATIN INJECTION"; January 2008 product label; APP Pharmaceuticals, LLC, Schaumburg, IL; "PLATINOL—cisplatin injection, powder, lyophilized, for solution"; October 2010 product label; Bristol-Myers Squibb Company Princeton, NJ; and "CISPLATIN—cisplatin injection, solution"; February 2012 product label; Teva Pharmaceuticals USA, Sellersville, PA

- Prescriptions and medication orders should identify the drug by its complete generic name, "CISPLATIN", to prevent confusion with other platinum compounds
- Product labeling advises pharmacists to contact health care providers who prescribe CISplatin dosages >100 mg/m^2 per cycle for dose confirmation

Product Identification, Preparation, Storage, and Stability

- CISplatin is generically available from several manufacturers in multiuse vials in at least 2 presentations, including:
  - A sterile, clear, light yellow, aqueous solution for injection (CISplatin injection)
    - Commercially available products contain 50 mg, 100 mg, or 200 mg CISplatin in individually packaged, multiple-dose, amber vials
      - Each milliliter contains CISplatin 1 mg and sodium chloride 9 mg
      - Additional excipients may be present in some product formulations
    - CISplatin Injection (1 mg/mL) must be diluted before it is administered to patients
  - A white to light yellow lyophilized powder for reconstitution (CISplatin for injection)
    - Commercially available products contain 50 mg CISplatin in individually packaged, multiple-dose, amber vials
    - Reconstitute lyophilized CISplatin with 50 mL of SWFI to obtain a solution containing 1 mg CISplatin and sodium chloride 9 mg/mL
      - Additional excipients may be present in some formulations
    - Reconstituted CISplatin (1 mg/mL) must be diluted before it is administered to patients
- Consult product labeling for manufacturer recommendations about acceptable storage temperatures for intact vials
  - Acceptable storage temperatures for products in solution (CISplatin injection) vary within a range from 15°C (59°F) or 20°C (68°) for a lower temperature limit to an upper limit of 25°C (77°F)
  - At least 1 commercial product formulated as a lyophilized powder for reconstitution (CISplatin for injection) specifies storage at controlled room temperature (25°C [77°F])
- *Do not store* CISplatin in solution (1 mg/mL) under refrigeration, under which condition it is more likely to precipitate
- Protect unopened containers from light
- Dilute CISplatin in a convenient volume of fluid. The diluting fluid MUST CONTAIN a chloride concentration ≥0.225% sodium chloride (≥38.5 mEq/L), for example, 0.45% NaCl, 0.9% NS, 3% NaCl, and saline and dextrose solutions with chloride concentrations >0.225%[26]
- Mannitol is compatible and may be added to diluted CISplatin solutions
- Protect CISplatin solutions that are not used within 6 hours after preparation from exposure to light
- CISplatin that remains in an amber vial after initial entry is stable for 28 days if protected from light or for 7 days under fluorescent room lighting

Selected incompatibility:

- *Aluminum* reacts with CISplatin causing precipitation and loss of drug potency
  - *Do not prepare or administer* CISplatin with needles or administration sets that contain aluminum parts that may come into contact with the drug
- *Do not dilute* CISplatin in solutions with chloride content less than the concentration found in 0.225% NaCl, that is, *not less than* 38.5 mEq/L
- CISplatin is incompatible in admixtures with mesna

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal dysfunction
- Hydration with 1000–2000 mL of fluid administered intraVENously is recommended starting at least 2 hours before CISplatin administration commences
  - Consider continuing hydration during and after CISplatin administration is completed, particularly in patients who receive a diuretic before, during, or after CISplatin to augment urine formation
  - Maintain increased hydration via oral, parenteral, or both routes, and urine output for at least 24 hours after CISplatin administration
- Administer CISplatin intraVENously. Infusion duration generally is within a range of 15–120 minutes, but may be prolonged in some regimens (8–24 hours)

CLADRIBINE

CLADRIBINE INJECTION for intravenous infusion only; product label, January 2008. APP Pharmaceuticals, LLP, Schaumburg, IL
LEUSTATIN® (cladribine) injection, PRODUCT INFORMATION; product label, August 2, 2012. Janssen-Cilag Pty Ltd., Macquarie Park NSW, Australia
CLADRIBINE injection, Rx only, for intravenous infusion only; product label, August 2006. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH

WARNINGS

Cladribine Injection should be administered under the supervision of a qualified physician experienced in the use of antineoplastic therapy. Suppression of bone marrow function should be anticipated. This is usually reversible and appears to be dose dependent. Serious neurological toxicity (including irreversible paraparesis and quadraparesis) has been reported in patients who received cladribine injection by continuous infusion at high doses (four to nine times the recommended dose for Hairy Cell Leukemia). Neurologic toxicity appears to demonstrate a dose relationship; however, severe neurological toxicity has been reported rarely following treatment with standard cladribine dosing regimens

Acute nephrotoxicity has been observed with high doses of cladribine (four to nine times the recommended dose for Hairy Cell Leukemia), especially when given concomitantly with other nephrotoxic agents/therapies

Boxed Warning for "CLADRIBINE INJECTION For Intravenous Infusion Only"; January 2008 product label; APP Pharmaceuticals, LLP, Schaumburg, IL

Product Identification, Preparation, Storage, and Stability

- Cladribine injection is generically available packaged in single-use, clear flint glass, 20-mL (capacity) vials containing cladribine 10 mg/10 mL (1 mg/mL) as a sterile, clear, colorless, preservative-free, isotonic solution
  - Each milliliter of commercially available products also contains 1 mg cladribine and 9 mg (0.15 mEq) of sodium chloride
  - The solution has a pH in the range of 5.5–8.0. Phosphoric acid and/or dibasic sodium phosphate may have been added to adjust the pH to 6.3 ± 0.3
- Presentations vary among manufacturers with respect to product packaging: vials may be packaged individually or in cases containing multiple vials
- Store intact vials under refrigeration 2°–8°C (35.6°–46.4°F) and protected from light during storage
- Cladribine *must be diluted* before administration

24-Hour drug supply (daily bag exchanges):

- Dilute in 500 mL of 0.9% NS an amount of cladribine needed to provide treatment for a single day
  - Compared with dilution in 0.9% NS, dilution in D5W increases the rate of cladribine degradation and is not recommended
  - Cladribine admixtures in 0.9% NS in PVC containers (eg, Viaflex Container, Baxter Healthcare Corporation, Deerfield, IL) are chemically and physically stable for at least 24 hours at room temperature under normal fluorescent lighting

(*continued*)

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer only by intraVENous infusion over 2–24 hours
- Cladribine should be administered promptly, or, after dilution, stored under refrigeration (2°–8°C [35.6°–46.4°F]) for not more than 8 hours before starting administration
- Cladribine should not be mixed with other drugs or additives or administered simultaneously with other drugs via a common intraVENous line

Product Identification, Preparation, Storage, and Stability (*continued*)

7-Day drug supply:

- A 7-day infusion solution should only be prepared with B0.9% NS (preserved with 0.9% benzyl alcohol) as follows:
  1. Add to a plastic container an amount of cladribine needed for a 7-day supply of medication
  2. Add to the same plastic container a calculated amount of B0.9% NS sufficient to produce a total volume of (Q.S.) 100 mL
     a. Both cladribine and the diluent solution should be transferred into a parenteral product container through a sterile, disposable, hydrophilic syringe filter with pore size ≤0.22 μm to minimize the risk of microbial contamination
     b. Inject cladribine through the filter first followed by the B0.9% NS vehicle solution to flush into the product container any cladribine remaining in the filter
        - Solutions prepared with B0.9% NS for individuals weighing >85 kg may have reduced preservative effectiveness because of displacement of the benzyl alcohol-containing diluent by the volume of drug, that is, >53.6 mg in a total volume to deliver of 100 mL
        - Admixtures prepared with antimicrobially preserved diluent have demonstrated acceptable chemical and physical stability for at least 7 days in a SIMS Deltec, Inc., Medication Cassette Reservoir
  3. Aseptically connect to the drug product container (reservoir) any tubing that will be used to connect the reservoir to a patient's VAD during drug administration
  4. Aseptically remove air from the product container and any connected tubing
  5. Aseptically cap with a sterile Luer locking cap, closure, or seal any tubing attached to the drug reservoir for storage if the product is not immediately connected to a patient's VAD after preparation is completed
- Cladribine may precipitate when exposed to low temperatures, but can be resolubilized by warming at ambient room temperature and vigorous shaking
- *Do not* attempt to resolubilize cladribine by heating or microwaving
- Freezing does not adversely affect the solution. If freezing occurs, thaw at room temperature, but *do not* thaw cladribine by radiant thermal or microwave heating
- After thawing, vials are stable until the expiration date on the product label if stored under refrigeration
- *Do not* refreeze cladribine
- Any unused portion of cladribine remaining in a single-use vial should be discarded

CLOFARABINE

Clolar® (clofarabine) injection for intravenous use; product label, April 2013. Manufactured by Teva Pharmachemie, Haarlem, The Netherlands. Manufactured for Genzyme Corporation, Cambridge, MA. Distributed by Genzyme Corporation, Cambridge, MA

Product Identification, Preparation, Storage, and Stability

- Clolar® is packaged in 20-mL-capacity, flint glass, single-use vials containing 20 mL of a clear, practically colorless, preservative-free solution of clofarabine 1 mg/mL (20 mg/20 mL) (NDC 0024-5860-01)
  - The commercial product is formulated in 20 mL of unbuffered 0.9% NS. The pH range of the solution is 4.5–7.5
- Store intact vials at 25°C (77°F). Temperature excursions are permitted to 15°–30°C (59°–86°F)
- Clofarabine solution must be filtered before dilution. Use a sterile filter with a pore size equal to 0.2 μm either when aspirating the drug into a syringe *or* when expelling drug from the syringe into a diluent solution
- Dilute clofarabine with a volume of 0.9% NS or D5W sufficient to produce a concentration between 0.15 and 0.4 mg/mL before administering it to patients
- Diluted solutions may be stored at 15°–30°C, but must be used within 24 hours after preparation

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for comments about use in patients with renal and hepatic dysfunction
- Administer diluted clofarabine solutions by intraVENous infusion over 2 hours
- Provide supportive care, such as intraVENous fluids, allopurinol, and alkalinize urine throughout a 5-day treatment course to reduce the effects of tumor lysis and other adverse events
- Monitor patients taking medications known to affect blood pressure. Monitor cardiac function during clofarabine administration
  - Avoid medications that produce or exacerbate hypotension during the days on which clofarabine is administered
- Evaluate and monitor patients receiving clofarabine treatment for signs and symptoms of cytokine release (eg, tachypnea, tachycardia, hypotension, pulmonary edema) that could develop into systemic inflammatory response syndrome (SIRS), capillary leak syndrome, and organ dysfunction
- Immediately discontinue clofarabine in the event of clinically significant signs or symptoms of SIRS or capillary leak syndrome and provide appropriate supportive measures, which may include steroids, diuretics, and albumin
  - Glucocorticoid prophylaxis (eg, hydrocortisone 100 mg/m^2 per day for 3 days [days 1–3]) may prevent signs or symptoms of SIRS or capillary leak syndrome
- Monitor renal and hepatic function closely during a 5-day treatment course with clofarabine
  - Although clofarabine has not been studied in patients with renal or hepatic impairment, 49–60% of a dose was renally eliminated as unchanged drug within 24 hours after administration to pediatric patients
  - Avoid medications that adversely affect kidney and liver function during the days on which clofarabine is administered
  - Clofarabine should be immediately discontinued if Grades ≥3 increases in serum creatinine or bilirubin are observed during treatment
    - Clofarabine treatment may resume after a patient's condition has stabilized and organ function has returned to baseline, generally with a 25% reduction in clofarabine dose
- Discontinue clofarabine administration if a Grade 4 noninfectious nonhematologic adverse event occurs

Selected incompatibility:

- Do not administer other medications through the same intraVENous line as clofarabine
  - Clofarabine compatibility with other drugs is not yet known

CYCLOPHOSPHAMIDE

Cyclophosphamide for injection, USP; product label, February 2013. Product made in Germany. Manufactured by Baxter Healthcare Corporation, Deerfield, IL

Product Identification, Preparation, Storage, and Stability

- Cyclophosphamide is available as a sterile white powder for reconstitution for injection in individually packaged single-use vials containing 500 mg (NDC 10019-955-01), 1000 mg (NDC 10019-956-01), or 2000 mg (NDC 10019-957-01) of cyclophosphamide monohydrate
- Store cyclophosphamide at temperatures ≤25°C (≤77°F)
- Cyclophosphamide may melt if exposed to high temperatures during transportation or storage
  - Melted cyclophosphamide appears as a clear or yellowish viscous liquid usually found in connection with portions of the drug that have remained in powdered form, or as droplets that have become separated from a portion of the drug that remains in powdered form
  - *Do not use* cyclophosphamide that exhibits signs of melting
- Commercially marketed cyclophosphamide products may not contain an antimicrobial preservative
- Reconstitute cyclophosphamide with 0.9% NS* or SWFI†, as follows:

Cyclophosphamide Content per Vial	Diluent Volume	Cyclophosphamide Concentration After Reconstitution
500 mg	25 mL	20 mg/mL
1000 mg	50 mL	
2000 mg	100 mL	

*After reconstitution with 0.9% NS, cyclophosphamide is suitable for direct intravenous, intraMUSCular, intraperitoneal, or intrapleural injection
†Reconstitution with SWFI yields a hypotonic product, which should not be administered by intraVENous injection, but may be administered by intraVENous infusion after further dilution with 1 of the following solutions: D5W, 0.45% NaCl, 0.9% NS, D5W/RI, D5W/0.9% NS, LRI, sodium lactate injection, USP (1/6 molar sodium lactate)

- After reconstituting cyclophosphamide with SWFI, the resulting solution is hypotonic. Reconstitution with SWFI and 0.9% NS to a concentration of 20 mg/mL yields solutions with the following osmolarity:

Cyclophosphamide and Diluent	Osmolarity
100 mg cyclophosphamide in 5 mL of SWFI	74 mOsm/L
100 mg cyclophosphamide in 5 mL of 0.9% NS	374 mOsm/L

- After adding a diluent solution, shake cyclophosphamide vials vigorously to dissolve the drug powder
  - If cyclophosphamide does not readily and completely dissolve, allow the vials to stand for a few minutes and, if necessary, resuming shaking
- Reconstitution to a concentration of 20 mg cyclophosphamide/mL yields a product that is chemically and physically stable for 24 hours at room temperature or for 6 days under refrigeration (2°–8°C [35.6°–46.4°F])
- After reconstitution with 0.9% NS or SWFI to a concentration of 20 mg cyclophosphamide per milliliter, the reconstituted solution may be further diluted
  - Product labeling identifies cyclophosphamide stability diluted with three vehicle solutions as follows:

	Storage Temperature	
Solution	Room Temperature	Refrigeration
0.45% NaCl	up to 24 hours	up to 6 days
D5W	up to 24 hours	up to 36 hours
D5W/0.9% NS	up to 24 hours	up to 36 hours

Recommendations for Drug Administration and Ancillary Care

General:

- After reconstitution with 0.9% NS to a concentration of 20 mg cyclophosphamide/mL the drug product is suitable for administration by direct intraVENous injection, intraVENous infusion, intraMUSCular intraperitoneal, or intrapleural injection
- Solutions prepared by reconstituting cyclophosphamide with SWFI are hypotonic, and *are not recommended* for intraVENous injection, but may be administered by intraVENous infusion if further diluted with any of the following solutions: D5W, 0.45% NaCl, 0.9% NS, D5W/RI, D5W/0.9% NS, LRI, sodium lactate injection, USP

CYTARABINE

Cytarabine injection for intravenous, intrathecal and subcutaneous use only; product label, April 2012. Manufactured by Zydus Hospira Oncology Private Ltd., Gujarat, India. Manufactured for Hospira, Inc. Lake Forest, IL
Cytarabine injection NOT FOR INTRATHECAL USE—CONTAINS BENZYL ALCOHOL FOR INTRAVENOUS OR SUBCUTANEOUS USE ONLY; product label, April 2012. Manufactured by Zydus Hospira Oncology Private Ltd., Gujarat, India. Manufactured for Hospira, Inc. Lake Forest, IL
Cytarabine injection PHARMACY BULK PACKAGE—NOT FOR DIRECT INFUSION; product label, April 2012. Manufactured by Zydus Hospira Oncology Private Ltd., Gujarat, India. Manufactured for Hospira, Inc. Lake Forest, IL
Cytarabine for injection USP, for intravenous, intrathecal, or subcutaneous use only; product label, September 2008. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH

WARNING

Only physicians experienced in cancer chemotherapy should use Cytarabine Injection

For induction therapy patients should be treated in a facility with laboratory and supportive resources sufficient to monitor drug tolerance and protect and maintain a patient compromised by drug toxicity. The main toxic effect of Cytarabine Injection is bone marrow suppression with leukopenia, thrombocytopenia and anemia. Less serious toxicity includes nausea, vomiting, diarrhea and abdominal pain, oral ulceration, and hepatic dysfunction

The physician must judge possible benefit to the patient against known toxic effects of this drug in considering the advisability of therapy with Cytarabine Injection. Before making this judgment or beginning treatment, the physician should be familiar with… [all other elements of product labeling]

Boxed Warning for "Cytarabine Injection For Intravenous, Intrathecal and Subcutaneous Use Only"; April 2012 product label; Hospira, Inc., Lake Forest, IL

Product Identification, Preparation, Storage, and Stability

- Cytarabine is generically available from several manufacturers. Products are available in lyophilized (powdered) or solution formulations. Presentations include products packaged for a single use or multiple doses, and for pharmaceutical admixture and compounding (eg, *Pharmacy Bulk Package*)

Cautions: Among products in solution (ie, "cytarabine injection…"):
  - Cytarabine concentrations are not consistently the same among available products
  - Products may or may not contain an antimicrobial preservative
- In general, cytarabine products are stored at controlled room temperatures around 20°–25°C (68°–77°F), with temperature excursions permitted to 15°–30°C (59°–86°F)
  - Acceptable storage temperatures vary among products from different manufacturers
  - Refer to product packaging and labeling for storage conditions appropriate for different products
- *Do not use* bacteriostatically preserved drug and diluent products for intraTHECAL use and for preparing cytarabine for high-dose treatments (dosages ≥1000 mg/m^2)
- Refer to product packaging and labeling for storage conditions appropriate for different products
- Reconstitute lyophilized cytarabine as follows
  - Diluent selection depends on route of administration (see below):

Cytarabine Content per Vial	Diluent Volume	Reconstituted Cytarabine Concentration
100 mg	5 mL	20 mg/mL
500 mg	10 mL	50 mg/mL
1000 mg	10 mL	100 mg/mL
2000 mg	20 mL	100 mg/mL

- Promptly use reconstituted cytarabine solutions that do not contain an antimicrobial preservative and those in which the concentration of preservatives is not adequate to inhibit microbial growth
- Solutions reconstituted with BWFI may be stored at controlled room temperature, 15°–30°C (59°–86°F), for up to 48 hours
- Discard solutions in which a slight haze develops

(*continued*)

Product Identification, Preparation, Storage, and Stability (*continued*)

For intraVENous or SUBCUTaneous use:

- Reconstitute cytarabine for injection with 0.9% NS, SWFI, or BWFI preserved with benzyl alcohol
  - *Do not use* bacteriostatically preserved diluents when preparing cytarabine doses ≥1000 mg/m²
- The reconstituted product may be further diluted to a convenient volume in 0.9% NS or D5W

For intraTHECAL use:

- Reconstitute cytarabine *only* with PRESERVATIVE-FREE 0.9% NS to produce a solution with concentration ≤20 mg/mL. Typical administration volumes range from 5 to 10 mL, and should closely approximate the volume of cerebrospinal fluid removed
- Admixtures with hydrocortisone sodium succinate for intraTHECAL administration (with or without methotrexate) should be prepared just before use and administered as soon as possible (within minutes) after preparation because of the instability of the hydrocortisone component

Caution: ***Do not use*** **an antimicrobially preserved diluent to prepare cytarabine for intraTHECAL use**

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer by intraVENous, intraTHECAL, or SUBCUTaneous routes
  - Use products prepared for intraTHECAL administration immediately after they are prepared
- If cytarabine is given intraMUSCularly, administration sites should be rotated
- Although the amount of drug administered is a modulating factor, patients generally can tolerate higher total doses given by rapid intraVENous injection than by slow infusion because of cytarabine's rapid inactivation and the relatively brief cellular exposure to cytotoxic concentrations that occur after rapid administration

CYTARABINE LIPOSOME INJECTION

DepoCyt®–cytarabine injection, lipid complex, for intrathecal use only DEPOCYT® (cytarabine liposome injection) for intrathecal use only, 50 mg vial; product label, September 2011. Manufactured by Pacira Pharmaceuticals, Inc. San Diego, CA. Distributed by Sigma-Tau Pharmaceuticals, Inc., Gaithersburg, MD

WARNINGS

DepoCyt® (cytarabine liposome injection) should be administered only under the supervision of a qualified physician experienced in the use of intrathecal cancer chemotherapeutic agents. Appropriate management of complications is possible only when adequate diagnostic and treatment facilities are readily available. In all clinical studies, chemical arachnoiditis, a syndrome manifested primarily by nausea, vomiting, headache and fever, was a common adverse event. If left untreated, chemical arachnoiditis may be fatal. The incidence and severity of chemical arachnoiditis can be reduced by coadministration of dexamethasone… Patients receiving DepoCyt should be treated concurrently with dexamethasone to mitigate the symptoms of chemical arachnoiditis…

Boxed Warning (excerpt) for "DepoCyt® - cytarabine injection, lipid complex, For Intrathecal Use Only DEPOCYT® (cytarabine liposome injection) For Intrathecal Use Only, 50 mg vial"; September 2011 product label; Sigma-Tau Pharmaceuticals, Inc., Gaithersburg, MD

Product Identification, Preparation, Storage, and Stability

- DepoCyt® is packaged in individually packaged, glass, 5-mL, single-use, vials containing a sterile, nonpyrogenic, white to off-white, ready-to-use, preservative-free suspension of cytarabine encapsulated into multivesicular lipid-based particles (liposomes). NDC 57665-331-01
  - The liposome particles are suspended in sodium chloride 0.9% (w/v) in SWFI
  - Cytarabine 50 mg is present at a concentration of 10 mg/mL. Inactive ingredients at their respective approximate concentrations, include cholesterol 4.4 mg/mL, triolein 1.2 mg/mL, dioleoylphosphatidylcholine 5.7 mg/mL, and dipalmitoylphosphatidylglycerol 1 mg/mL. The product pH is within the range 5.5-–8.5
- The drug product does not contain a preservative and should be stored under refrigeration at 2°–8°C (35.6°–46.4°F). Protect DepoCyt® from freezing
- DepoCyt® is intended for direct administration without further dilution
- Allow vials to warm to room temperature before use
- Gently agitate or repeatedly invert a vial to resuspend drug particles before transferring its contents to a syringe. *Avoid* aggressively agitating the drug product
  - DepoCyt® drug particles are denser than the solution in which they are suspended, and tend to settle with time and must be resuspended before use
- Administer a dose immediately after withdrawing the product from a vial. If treatment is delayed, do not use DepoCyt® more than 4 hours after withdrawing the product from a vial
- Any portion of vial contents not used to prepare a dose should be discarded

Selected incompatibility:

- *Do not mix* DepoCyt® with other medications

Recommendations for Drug Administration and Ancillary Care

General:

- Patients should receive dexamethasone 4 mg either orally or intraVENously twice daily for 5 days, beginning on the day of DepoCyt® injection to mitigate the symptoms of chemical arachnoiditis
- Inject DepoCyt® 50 mg slowly, over a period of 1–5 minutes directly into the cerebrospinal fluid via an intraventricular reservoir or by direct injection into the lumbar sac
  - Do not use inline filters when administering DepoCyt®
- Patients should be instructed to lie flat for 1 hour after DepoCyt® administration by lumbar puncture
- Continually monitor patients for immediate adverse reactions after DepoCyt® injection
  - If drug-related neurotoxicity develops, the dose should be reduced to 25 mg. If it persists, discontinue DepoCyt® treatment
- Advise patients about the expected adverse events of headache, nausea, vomiting, and fever, and about the early signs and symptoms of neurotoxicity
  - Emphasize at the initiation of each treatment cycle the importance of concurrent dexamethasone use
  - Patients should be instructed to seek medical attention if signs or symptoms of neurotoxicity develop, or if oral dexamethasone is not well tolerated

Note: DepoCyt® particles are similar in size and appearance to white blood cells: care must be taken in interpreting CSF examinations following DepoCyt® administration

DACARBAZINE

DACARBAZINE for injection, USP; product label, September 2007. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH
Dacarbazine for injection, USP; product label, July 2007. Hospira Inc., Lake Forest, IL
DACARBAZINE for injection, USP; product label, January 2008. APP Pharmaceuticals LLC, Schaumburg, IL

WARNINGS

It is recommended that dacarbazine be administered under the supervision of a qualified physician experienced in the use of cancer chemotherapeutic agents

1. Hemopoietic depression is the most common toxicity with dacarbazine…
2. Hepatic necrosis has been reported…
3. Studies have demonstrated this agent to have a carcinogenic and teratogenic effect when used in animals
4. In treatment of each patient, the physician must weigh carefully the possibility of achieving therapeutic benefit against the risk of toxicity

Boxed Warning (excerpt) for "Dacarbazine for Injection, USP", labeling for products from:
Bedford Laboratories™, Bedford, OH (dated, September 2007)
Hospira Inc., Lake Forest, IL (dated, July 2007)
APP Pharmaceuticals LLC, Schaumburg, IL (dated, January 2008)

Product Identification, Preparation, Storage, and Stability

- Dacarbazine is generically available from several manufacturers. In general, the drug is packaged in single-use, amber glass vials, containing either 100 mg or 200 mg dacarbazine per vial
  - Commercial formulations also include mannitol and citric acid
  - Packaging varies among manufacturers' products, including: individually packaged vials and boxes containing 10 vials
- Dacarbazine is a white to pale yellow solid that is sensitive to light
- Store intact vials under refrigeration at 2°–8°C (35.6°–46.4°F) and protect from light exposure
- Reconstitute dacarbazine with SWFI as follows:

Dacarbazine Content per Vial	Diluent (SWFI) Volume	Dacarbazine Concentration After Reconstitution
100 mg	9.9 mL	10 mg/mL
200 mg	19.7 mL	

- The resulting clear, yellowish solution has a pH from 3.0 to 4.0, and is highly sensitive to degradation as a result of exposure to light[27]
- The reconstituted solution is suitable for intraVENous injection, or it may be further diluted in up to 250 mL of D5W or 0.9% NS and given by intravenous infusion
- Product labeling includes the following stability information:
  - After reconstitution, dacarbazine solution (10 mg/mL) may be stored in the product vial at 4°C (39.2°F) for up to 72 hours or at normal room temperature and (fluorescent) lighting conditions for up to 8 hours[28]
  - After dilution in D5W or 0.9% NS, the resulting product may be stored at 4°C (39.2°F) for up to 24 hours or under normal room conditions (ambient temperature and artificial lighting) for up to 8 hours[28]
  - See comments under "Dacarbazine Degradation," below
- Change in solution color from pale yellow or ivory to pink or red is a sign of decomposition
  - Dacarbazine solutions that exhibit changes in color toward pink or red should not be used

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer dacarbazine only by intraVENous routes:
  - By intraVENous injection over 1 minute *or* by intraVENous infusion over 15–30 minutes
- Cover parenteral product containers containing dacarbazine solutions with light-opaque materials (bags, aluminum foil)
- Use opaque or light-resistant (light-shielded) VAD to administer dacarbazine, or cover VAD used to administer dacarbazine to protect the drug from light; eg, with opaque sleeves or by wrapping tubing with aluminum foil

Dacarbazine degradation:

- Dacarbazine degrades to active and potentially toxic products, including 2-azahypoxanthine by photolysis[27,29] and hydrolysis
  - Photodegradation products are associated with adverse effects encountered during dacarbazine administration, including local venous pain, nausea, and vomiting
    - In small case series, venous pain ± other symptoms and signs of toxicity were eliminated or reduced during administration in a room illuminated by a red photographic lamp[30] and when the drug in vials and VAD tubing was protected from light exposure[31]
- Dacarbazine degradation is accelerated by light exposure and storage temperature
  - Sunlight causes more rapid photolysis than fluorescent lighting[32]
  - For dacarbazine exposed to sunlight during preparation or administration:
    - Cover parenteral containers with opaque material or foil during administration[32,33]
    - Use light-resistant or opaque administration sets, or wrap tubing with opaque material or foil during administration[32,33]
  - Prepare dacarbazine just before it is used, or store reconstituted and diluted products under refrigeration and protected from light until used[28,32]

DACTINOMYCIN

Cosmegen® for Injection (dactinomycin for injection) (Actinomycin D); product label, February 2013. Manufactured by Baxter Oncology GmbH, Halle/Westfalen, Germany. Manufactured for Recordati Rare Diseases Inc., Lebanon, NJ
DACTINOMYCIN FOR INJECTION USP; product label, August 2012. Manufactured by Ben Venue Laboratories, Inc. Manufactured for Bedford Laboratories, Bedford, OH

WARNING

COSMEGEN® (dactinomycin for injection) should be administered only under the supervision of a physician who is experienced in the use of cancer chemotherapeutic agents. This drug is **HIGHLY TOXIC** and both powder and solution must be handled and administered with care. Inhalation of dust or vapors and contact with skin or mucous membranes, especially those of the eyes, must be avoided. Avoid exposure during pregnancy. Due to the toxic properties of dactinomycin (eg, corrosivity, carcinogenicity, mutagenicity, teratogenicity), special handling procedures should be reviewed prior to handling and followed diligently. Dactinomycin is extremely corrosive to soft tissue. If extravasation occurs during intravenous use, severe damage to soft tissues will occur. In at least one instance, this has led to contracture of the arms

Boxed warning for: Cosmegen® for Injection (dactinomycin for injection) (Actinomycin D); product label, February 2013. Manufactured by Baxter Oncology GmbH, Halle/Westfalen, Germany. Manufactured for Recordati Rare Diseases Inc., Lebanon, NJ

Product Identification, Preparation, Storage, and Stability

- DACTINomycin is marketed in individually packaged, single-use vials containing DACTINomycin 500 mcg (0.5 mg) and 20 mg mannitol as a sterile, yellow to orange, lyophilized powder. NDC 67386-811-55
- Store intact vials at 20°–25°C (68°–77°F). Temperature excursions to 15°–30°C (59°–86°F) are permitted. Protect vials from light and humidity
- Reconstitute the drug product by injecting 1.1 mL of SWFI (without preservative) into a vial to produce a clear, gold-colored solution that contains approximately 500 mcg (0.5 mg) DACTINomycin per milliliter
  - Reconstituted DACTINomycin is chemically stable, but the product does not contain an antimicrobial preservative
  - Diluents preserved with benzyl alcohol or parabens may cause drug precipitation and *should not* be used to reconstitute DACTINomycin
- *Do not filter* DACTINomycin during preparation. Filtration through cellulose ester filters may remove DACTINomycin from the solution being filtered
- DACTINomycin may be added to the tubing or side arm of a rapidly flowing intraVENous infusion of D5W or 0.9% NS. Alternatively, it may be prepared as an admixture in the same solutions for administration by intraVENous infusion or isolation perfusion techniques
  - DACTINomycin may be prepared as an admixture in 0.9 NS or D5W to concentrations ≥10 mcg/mL (≥0.01 mg/mL) in glass or PVC containers for intraVENous infusion
  - DACTINomycin is reported to be most stable at pH 5–7[3,4]
- Use a "2-needle technique" if DACTINomycin is to be injected percutaneously directly into a vein
  - DACTINomycin is corrosive to skin, irritating to the eyes and respiratory tract mucosa, highly toxic by the oral route, and a vesicant if extravasated
  - The "2-needle technique" prevents soft-tissue exposure to DACTINomycin that remains on the external surfaces of needles used to reconstitute the drug product

Two-needle technique for preparing DACTINomycin for percutaneous administration:

1. Use 1 sterile needle to reconstitute and withdraw from a vial a measured amount of DACTINomycin needed to deliver a patient's dose
2. Aspirate all drug solution from the needle and needle hub into the syringe, and replace the first needle with a second sterile needle
3. With a second sterile needle on the syringe, carefully express air without expelling drug from the tip of the needle and inject DACTINomycin through an injection port into the tubing of a rapidly running intravenously administered solution

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with hepatic dysfunction
- For intraVENous administration *only*, by direct intraVENous injection over approximately 1 minute or intraVENous infusion over 15–30 minutes
- When diluted at concentrations of ≥10 mcg/mL in SWFI, 0.9% NS, or D5W in glass or PVC containers, DACTINomycin is chemically stable for up to 10 hours when stored at ambient room temperature
  - DACTINomycin should be diluted *only* with 0.9% NS or D5W for intraVENous infusion
  - *Caution*: After initial reconstitution with SWFI, further dilution with SWFI decreases DACTINomycin osmolality, which may result in an extremely hypotonic solution. Depending on administration rate and blood flow, administration of hypotonic solutions may result in some degree of intravascular hemolysis
- The dosage for DACTINomycin is calculated in micrograms (mcg)
  - The dose intensity per 2-week cycle for adults or children *should not exceed* 15 mcg/kg per day or 400–600 mcg/m^2 per day intraVENously for 5 days
  - Dosage calculations for obese or edematous patients should be performed on the basis of body surface area to more closely relate dosage to lean body mass
- Please review the 2-needle technique for direct intraVENous injection (see above). The procedure prevents soft-tissue exposure to DACTINomycin that remains on the external surfaces of needles used during drug preparation
- *Do not filter* DACTINomycin during administration
  - Filtration through 0.22-μm pore size filter membranes composed of cellulose ester (cellulose nitrate/cellulose acetate) or polytetrafluoroethylene (PTFE, Teflon) were shown to remove a substantial portion of DACTINomycin from the solution being filtered[16,35]
  - Filtration through a 0.22-μm pore size cellulose ester filter membranes resulted in approximately 13% of the total amount of filtered DACTINomycin bound by the filter[36]

Caution: DACTINomycin is a vesicant and may cause severe local soft-tissue necrosis if administered by injection into soft tissues or extravasated

DAUNORUBICIN HYDROCHLORIDE

CERUBIDINE (Daunorubicin HCl) FOR INJECTION; product label, February 2008. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH
DAUNORUBICIN HYDROCHLORIDE injection; product label, June 2013. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH
DAUNORUBICIN HYDROCHLORIDE–daunorubicin hydrochloride injection, solution; product label, September 2012. Manufactured by Teva Parenteral Medicines, Inc., Irvine, CA

WARNINGS

1. Daunorubicin hydrochloride injection must be given into a rapidly flowing intravenous infusion. It must never be given by the intramuscular or subcutaneous route. Severe local tissue necrosis will occur if there is extravasation during administration
2. Myocardial toxicity manifested in its most severe form by potentially fatal congestive heart failure may occur either during therapy or months to years after termination of therapy. The incidence of myocardial toxicity increases after a total cumulative dose exceeding 400 to 550 mg/m² in adults, 300 mg/m² in children more than 2 years of age, or 10 mg/kg in children less than 2 years of age
3. Severe myelosuppression occurs when used in therapeutic doses; this may lead to infection or hemorrhage
4. It is recommended that daunorubicin hydrochloride be administered only by physicians who are experienced in leukemia chemotherapy and in facilities with laboratory and supportive resources adequate to monitor drug tolerance and protect and maintain a patient compromised by drug toxicity. The physician and institution must be capable of responding rapidly and completely to severe hemorrhagic conditions and/or overwhelming infection
5. Dosage should be reduced in patients with impaired hepatic or renal function

Boxed Warning for "Daunorubicin Hydrochloride Injection"; September 2012 product label; Teva Parenteral Medicines, Inc., Irvine, CA; and "Daunorubicin Hydrochloride Injection"; July 1999 product label; Bedford Laboratories™, Bedford, OH

Product Identification, Preparation, Storage, and Stability

- DAUNOrubicin HCl injection (solution) and DAUNOrubicin HCl for injection (lyophilized powder) are generically available from several manufacturers. DAUNOrubicin is a sterile, deep red to red-orange product packaged in glass single-use vials
- Products are formulated either as a sterile, deep red to red-orange solution, or hygroscopic, crystalline lyophilized powder packaged in glass single-use vials
  - DAUNOrubicin HCl injection (solution) is available in vials containing 20 mg/4 mL (packaged in cartons containing 10 vials) or 50 mg (individually packaged) DAUNOrubicin base per milliliter
  - DAUNOrubicin HCl for Injection (lyophilized powder) is packaged in cartons containing 10 vials each containing 20 mg of DAUNOrubicin base
- Storage:
  - Store unreconstituted DAUNOrubicin HCl for injection (lyophilized powder) at controlled room temperature, 15°–30°C (59°–86°F)
  - Store DAUNOrubicin HCl injection (solution) under refrigeration at 2°–8°C (35.6°–46.4°F)
- Protect DAUNOrubicin from exposure to light by storing unused vials in their packaging carton

Reconstitution for lyophilized DAUNOrubicin:

- Reconstitute DAUNOrubicin HCl lyophilized powder with 4 mL of SWFI to produce a solution with concentration equal to 5 mg DAUNOrubicin base per milliliter

Stability (solution and lyophilized formulations):

- After reconstitution, DAUNOrubicin HCl (lyophilized powder formulation) is stable for 24 hours at 15°–30°C (59°–86°F) and 48 hours under refrigeration (2°–8°C [35.6°–46.4°F])
- DAUNOrubicin HCl injection (formulations already in solution) are stable for 24 hours at 15°–30°C (59°–86°F)
- DAUNOrubicin HCl diluted with D5W (pH = 4.36) or 0.9% NS (pH = 5.20 or 6.47) to a concentration of 98 µg/mL (estimated) in PVC containers stored at 25°C, 4°C or –20°C was stable for 43 days under all conditions evaluated[37]
  - DAUNOrubicin HCl for injection reconstituted with SWFI and diluted with 0.9% NS or D5W to an estimated concentration of 98 µg/mL stored in PVC containers for 43 days did not degrade during or after 11 repeated cycles of freezing (–20°C) and thawing at ambient temperature (25°C)[37]
- DAUNOrubicin HCl for injection reconstituted with SWFI to a concentration of 2 mg/mL was stable for at least 43 days when stored in polypropylene syringes at 4°C[37]

(*continued*)

Product Identification, Preparation, Storage, and Stability (*continued*)

- DAUNOrubicin solutions undergo photodegradation
  - The rate and extent of photodegradation are inversely related to DAUNOrubicin concentrations in solution[38]
    - At DAUNOrubicin concentrations ≥100 µg/mL (≥0.1 mg/mL) stored at 25°C for 168 h under artificial room lighting (four 65/80-Watt fluorescent tubes mounted approximately 1 m above the samples), little or no photodegradation occurred in clear or amber glass or opaque polyethylene containers[38]
    - At DAUNOrubicin concentrations ≥500 µg/mL (≥0.5 mg/mL), no special precautions are necessary to protect freshly prepared solutions from exposure to artificial light or sunlight[38]

Selected incompatibility:

- Product labeling recommends *not mixing* DAUNOrubicin with heparin or other drugs

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- A calculated dose is withdrawn into a syringe with 10–15 mL of 0.9% NS for intraVENous injection
- Inject DAUNOrubicin into the tubing or side-arm of a rapidly flowing intraVENous infusion of D5W or 0.9% NS
- Severe hepatic or renal impairment may enhance adverse effects associated with DAUNOrubicin
  - Clinical laboratory evaluation of hepatic and renal function should be completed before administering DAUNOrubicin. Consult recommendations for modifying DAUNOrubicin dosage and schedule in hepatic or renal impairment

Caution: DAUNOrubicin is a vesicant and can produce severe local soft-tissue necrosis if extravasation occurs. *NEVER inject DAUNOrubicin by the intraMUSCular, SUBCUTaneous, or intraTHECAL routes*

- The current standard of care for managing anthracycline extravasation, including extravasation of DAUNOrubicin, is a 3-day course of intraVENously administered dexrazoxane (Totect, Savene)
- Advise patients DAUNOrubicin HCl may transiently impart a red discoloration to urine after administration

DAUNORUBICIN CITRATE LIPOSOME INJECTION

DaunoXome® (daunorubicin citrate liposome injection); product label, December 2011. Manufactured for Galen US Inc, Souderton, PA

WARNINGS

1. Cardiac function should be monitored regularly in patients receiving DaunoXome (daunorubicin citrate liposome injection) because of the potential risk for cardiac toxicity and congestive heart failure. Cardiac monitoring is advised especially in those patients who have received prior anthracyclines or who have pre-existing cardiac disease or who have had prior radiotherapy encompassing the heart
2. Severe myelosuppression may occur
3. DaunoXome should be administered only under the supervision of a physician who is experienced in the use of cancer chemotherapeutic agents
4. Dosage should be reduced in patients with impaired hepatic function…
5. A triad of back pain, flushing, and chest tightness has been reported in 13.8% of the patients (16/116) treated with DaunoXome in the Phase III clinical trial, and in 2.7% of treatment cycles (27/994). This triad generally occurs during the first five minutes of the infusion, subsides with interruption of the infusion, and generally does not recur if the infusion is then resumed at a slower rate

Boxed Warning (excerpt) for "DaunoXome® (daunorubicin citrate liposome injection)"; December 2011 product label; Galen US Inc, Souderton, PA

Product Identification, Preparation, Storage, and Stability

- DaunoXome® is a translucent, red, liposomal dispersion of DAUNOrubicin citrate equivalent to 50 mg DAUNOrubicin base in 25 mL (2 mg/mL) packaged in single-use vials (NDC 10885-001-01)
- Store DaunoXome® under refrigeration at 2°–8°C (35.6°–46.4°F). Do not freeze DaunoXome. Protect it from exposure to light
- Withdraw the calculated volume of DaunoXome® needed for a patient's dose from a vial into a syringe, and transfer it into a sterile parenteral product container containing an equivalent volume of D5W (1:1 dilution) to produce a concentration after dilution = 1 mg DAUNOrubicin per milliliter of solution
- The product does not contain a preservative or bacteriostatic agent. Partially used vials should be discarded as hazardous waste
- If diluted DaunoXome® is not used immediately, it should be refrigerated at 2°–8°C (35.6°–46.4°F) for a maximum of 6 hours

Caution: The only fluid with which DaunoXome® may be mixed is D5W

Selected incompatibility:

- *Do not mix* DaunoXome® with any solution other than D5W

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer DaunoXome® intraVENously over 60 minutes immediately after dilution
- *Do not filter* DaunoXome® during administration
- *Do not mix* DaunoXome® with other drugs

DECITABINE

DACOGEN® (decitabine) for INJECTION; product label, March 2010. Manufactured by Pharmachemie B.V. Haarlem, The Netherlands. Manufactured for Eisai Inc., Woodcliff Lake, NJ

Product Identification, Preparation, Storage, and Stability

- Decitabine is a sterile, lyophilized, white to almost-white powder, individually packaged in clear, colorless, single-use, 20-mL, glass vials containing 50 mg decitabine, 68 mg monobasic potassium phosphate (potassium dihydrogen phosphate), and 11.6 mg sodium hydroxide. NDC 62856-600-01
- Store intact vials at 25°C (77°F); temperature excursions are permitted to 15°–30°C (59°–86°F)
- Caution: BEFORE BEGINNING reconstitution, evaluate whether decitabine administration will begin within 15 minutes after the lyophilized product is reconstituted
  - Decitabine hydrolyzes spontaneously after reconstitution
  - If drug administration commences within 15 minutes after reconstitution began, there is no need to used prechilled diluents, but preparation should not commence until just before the drug is needed
  - If drug administration begins >15 minutes to within 7 hours after reconstitution, use prechilled solutions (2°–8°C [35.6°–46.4°F]) to reconstitute and dilute decitabine
- Reconstitution with 10 mL of SWFI produces a solution with concentration of 5 mg decitabine/mL at pH 6.7–7.3
- After powdered decitabine is completely dissolved, immediately withdraw with a syringe the calculated volume of drug needed for a patient's dose from a vial and transfer it into a sterile plastic or glass parenteral product container containing a volume of 0.9% NS, D5W, or LRI sufficient to produce a decitabine concentration between 0.1–1.0 mg/mL
  - If decitabine cannot be used within 15 minutes after diluent was introduced into a vial, the product should be promptly refrigerated and may be stored for up to 7 hours after reconstitution
  - Reconstituted and diluted products that have not been used within the time limits identified above and all materials potentially contaminated with decitabine during product preparation should be discarded as hazardous waste
- If a decitabine-containing solution was prepared and refrigerated as described (above) and used within 7 hours after reconstitution, administration should be completed within 3 hours after the product was transferred from refrigeration to room temperature conditions

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- If decitabine is not prepared with chilled solutions and promptly refrigerated after preparation, administration MUST BEGIN within 15 minutes after reconstitution
- If decitabine was prepared with chilled solutions and stored under refrigeration promptly after preparation, administration MAY BEGIN up to 7 hours after reconstitution
  - Drug administration should begin promptly after stored products are transferred from refrigeration to room temperature conditions
- Administer decitabine by intraVENous infusion over 3 hours

DENILEUKIN DIFTITOX

ONTAK® (denileukin diftitox) Injection for intravenous infusion; product label August 2011. Manufactured and Distributed by Eisai Inc., Woodcliff Lake, NJ

WARNING

SERIOUS INFUSION REACTIONS, CAPILLARY LEAK SYNDROME AND LOSS OF VISUAL ACUITY

The following adverse reactions have been reported:

- Serious and fatal infusion reactions. Administer Ontak in a facility equipped and staffed for cardiopulmonary resuscitation. Immediately stop and permanently discontinue Ontak for serious infusion reactions…
- Capillary leak syndrome resulting in death. Monitor weight, edema, blood pressure and serum albumin levels prior to and during Ontak treatment…
- Loss of visual acuity and color vision…

Boxed Warning (excerpt) for "ONTAK® (denileukin diftitox) Injection for intravenous infusion"; August 2011 product label, Eisai Inc., Woodcliff Lake, NJ

Product Identification, Preparation, Storage, and Stability

- ONTAK® is supplied in single-use vials as a sterile, frozen solution intended for intraVENous administration (6 vials/package; NDC 62856-603-01)
- Each vial contains 300 mcg of recombinant denileukin diftitox in 2 mL (150 mcg/mL) in a sterile solution of citric acid 20 mmol/L, EDTA 0.05 mmol/L, and polysorbate 20 (<1%) in SWFI. The solution has a pH range of 6.9–7.2
- Store ONTAK® at ≤ −10°C (≤14°F)
- Thaw vials either:
  1. Under refrigeration at 2°–8°C (35.6°–46.4°F) for not more than 24 hours, *or*
  2. At room temperature for 1–2 hours
     - *Do not heat* ONTAK® to thaw the product
     - *Do not refreeze* ONTAK® after thawing
- Allow ONTAK® to equilibrate with room temperature (up to 25°C [77°F]) before preparing a dose
- Mix ONTAK® solution in a vial by gentle swirling. *Do not shake* ONTAK® solution
  - After thawing, a haze may be visible. The haze should clear when the solution is at room temperature. Do not use the solution unless it is clear, colorless, and without visible particulate matter
- Prepare and contain diluted denileukin diftitox in plastic syringes or soft plastic parenteral product containers
  1. Do not use glass containers because an unpredictable portion of the drug may be lost because of adsorption to glass surfaces
  2. With a syringe, withdraw from 1 or more vials the amount of denileukin diftitox needed to prepare a patient's dose and inject it into an empty plastic parenteral product container (bag or syringe)
     - Denileukin diftitox concentration must be ≥15 mcg/mL during all preparation steps
  3. Add to the product container *no more than* 9 mL of preservative-free 0.9% NS for each 1 mL of denileukin diftitox in the container
- *Do not* mix denileukin diftitox with other drugs
- Partially used vials should be discarded immediately

Selected incompatibility:

- Product labeling recommends *not* mixing denileukin diftitox with other drugs

Recommendations for Drug Administration and Ancillary Care

Premedication:

- Premedicate with acetaminophen and an antihistamine (H_1-receptor antagonist) before each denileukin diftitox infusion

General:

- Withhold denileukin diftitox administration in a patient whose serum albumin is <3 g/dL
- Administer denileukin diftitox intraVENously over 30–60 minutes within 6 hours after preparation was completed
  - There is no clinical experience with prolonged infusion times (>80 minutes)
  - *Do not administer* denileukin diftitox by rapid or "bolus" intraVENous injection
- If infusion-related adverse events occur, denileukin diftitox administration should be discontinued, or the delivery rate should be decreased depending on the severity of the reaction
  - Immediately stop and permanently discontinue denileukin diftitox administration for serious infusion reactions
  - Resuscitative equipment should be available during denileukin diftitox administration
- *Do not mix* denileukin diftitox with other drugs
- *Do not filter* denileukin diftitox during administration

DEXRAZOXANE

Utilized as a Cardioprotectant

Zinecard® (dexrazoxane for injection); product label, June 2012. Distributed by Pharmacia & Upjohn Company, Division of Pfizer Inc., New York, NY
Dexrazoxane for injection; product label, June 2005. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Bedford Laboratories, Bedford, OH
DEXRAZOXANE HYDROCHLORIDE; product label, September 2012. Manufactured by Gland Pharma Limited, Hyderabad-500 043, India. Manufactured for Mylan Institutional LLC, Rockford, IL

Product Identification, Preparation, Storage, and Stability

Product and Manufacturer	Dexrazoxane for Injection (generic)		Zinecard® (dexrazoxane for injection) Pharmacia & Upjohn
	Bedford Laboratories™	Mylan Institutional LLC	
Product presentation	Dexrazoxane for Injection is packaged in cartons containing two single-use vials: 1. A vial containing sterile, pyrogen-free, lyophilized dexrazoxane HCl equivalent to dexrazoxane 250 mg or dexrazoxane 500 mg 2. A vial containing 0.167 mol/L (0.167 M, 1/6 Molar, M/6) Sodium Lactate Injection, USP, for reconstitution		Zinecard® is packaged in cartons containing sterile, pyrogen-free, lyophilized dexrazoxane HCl equivalent to dexrazoxane 250 mg or dexrazoxane 500 mg
Formulation excipients	Hydrochloric Acid, NF, is added to adjust product pH		
Diluent	• 50 mL Sodium Lactate Injection, USP, 0.167 mol/L is packaged with dexrazoxane for injection 500 mg • 25 mL Sodium Lactate Injection, USP, 0.167 mol/L is packaged with dexrazoxane for injection 250 mg		• Reconstituted *only* with SWFI • Diluent is not included in Zinecard® products
NDC numbers			
500 mg/vial	55390-060-02	67457-208-50	0013-8727-89
250 mg/vial	55390-014-02	67457-207-25	0013-8717-62
Reconstitution	Dexrazoxane for Injection *must be* reconstituted with 0.167 M Sodium Lactate Injection, USP, to produce a solution with a concentration of 10 mg/mL, thus: **Dexrazoxane Content per Vial** / **Diluent Volume (0.167 M Sodium Lactate, USP)** 250 mg / 25 mL 500 mg / 50 mL • pH for the reconstituted solution is within the range of 3.5–5.5		Zinecard® *must be* reconstituted with SWFI to produce a solution with a concentration of 10 mg/mL, thus: **Dexrazoxane Content per Vial** / **Diluent Volume (SWFI)** 250 mg / 25 mL 500 mg / 50 mL • pH for the reconstituted solution is within the range of 1.0–3.0
Dilution for clinical use	• The reconstituted solution may be transferred to a parenteral product container and diluted with either 0.9% NS or D5W to a concentration within the range of 1.3–5 mg/mL • All unused dexrazoxane solutions should be discarded		• The reconstituted solution may be transferred to a parenteral product container and diluted *only* with LRI to a concentration within the range of 1.3–3 mg/mL • The resulting solution pH is within the range of 3.5–5.5 • All unused dexrazoxane solutions should be discarded
Storage	• Store intact vials at 20°–25°C (68–77°F)		• Store intact vials at 25°C (77°F) • Temperature excursions are permitted to 15°–30°C (59°–86°F)
Stability	• Dexrazoxane (10 mg/mL) is stable for 6 hours after the time of reconstitution with 0.167 M Sodium Lactate Injection when stored at controlled room temperature, 20°–25°C, or under refrigeration, 2°–8°C (35.6°–46.4°F) • Diluted dexrazoxane is stable for 6 hours when stored at controlled room temperature or under refrigeration		• Dexrazoxane (10 mg/mL) is stable for 30 minutes after reconstitution with SWFI when stored at room temperature, or for up to 3 hours if stored under refrigeration, 2°–8°C (35.6°–46.4°F) • After dilution in LRI, dexrazoxane is stable for 1 hour at controlled room temperature, or for up to 4 hours if stored under refrigeration
Selected incompatibility	• Product labeling recommends *not* mixing dexrazoxane with other drugs		

Recommendations for Dexrazoxane Utilization as a Cardioprotectant

General:

- See Chapter 41 for recommended use in patients with hepatic dysfunction

Administration:

Product Source	Route and Rate of Administration
Bedford Laboratories™	Administer dexrazoxane by slow intraVENous injection *or* a rapid intraVENous infusion over a period of <30 minutes due to the temporal relationship between dexrazoxane and DOXOrubicin administration
Mylan Institutional LLC	
Pharmacia & Upjohn (Zinecard®)	Administer dexrazoxane *only* by intraVENous infusion over a period of <30 minutes

- DOXOrubicin administration must be completed within 30 minutes after dexrazoxane administration began
- Recommended dosage ratios of dexrazoxane to DOXOrubicin:
  - Patients with creatinine clearance ≥40 mL/min (≥0.66 mL/s), dexrazoxane to DOXOrubicin ratio is 10 : 1; eg, 500 mg dexrazoxane/m^2 : 50 mg DOXOrubicin/m^2
  - Patients with creatinine clearance <40 mL/min (<0.66 mL/s), dexrazoxane to DOXOrubicin ratio is 5 : 1; eg, 250 mg dexrazoxane/m^2 : 50 mg DOXOrubicin/m^2

DEXRAZOXANE

Utilized in Treating Anthracycline Extravasation

TOTECT® Kit (dexrazoxane) for injection, for intravenous infusion only; product label, May 2011. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH, and Hameln Pharmaceuticals GmbH, Hameln, Germany. Manufactured for Topotarget A/S, Copenhagen, Denmark. Distributed by Integrated Commercialization Solutions, Brooks, KY. Marketed by Topotarget USA Inc., Rockaway, NJ

Savene 20 mg/mL powder for concentrate and diluent for solution for infusion. Summary of Product Characteristics, August 16, 2011. Last accessed: April 7, 2012, at: http://www.ema.europa.eu. Marketing authorization holder is SpePharm Holding B.V., Amsterdam, The Netherlands

Notes: On April 2, 2013, BIOCODEX USA (San Bruno, CA) announced acquisition of Totect® (at http://www.totect.com/ [accessed January 7, 2014]), and Totect® currently is not available

Norgine BV (Amsterdam, The Netherlands) has acquired the distribution rights of the product portfolio of SpePharm Holding, including Savene® (at: http://www.spepharm.com/ [accessed January 7, 2014])

Product Identification, Preparation, Storage, and Stability

- TOTECT® is packaged as a kit (NDC 38423-110-01) containing twenty 50-mL Type I glass vials, including:
  - 10 single-use vials, each containing 589 mg dexrazoxane hydrochloride (equivalent to 500 mg dexrazoxane) as a lyophilized powder, *plus*
  - 10 Vials each containing 50 mL of sodium lactate injection, USP, 0.167 mol/L (0.167 M, 1/6 M, M/6) diluent for reconstituting dexrazoxane hydrochloride
- Store the unreconstituted product in its carton to protect it from light at 25°C (77°F). Temperature excursions are permitted to 15°–30°C (59°–86°F)
- Add 50 mL of 0.167 M sodium lactate injection, USP, to each vial of lyophilized dexrazoxane to produce a slightly yellow solution with dexrazoxane concentration of 10 mg/mL
  - The manufacturer recommends using reconstituted dexrazoxane solution within 2 hours after reconstitution
- Dilute the reconstituted product by injecting a volume of dexrazoxane appropriate for a patient's dose into 1000 mL of 0.9% NS
- After dilution, TOTECT® is stable for 4 hours when stored at temperatures <25°C (<77°F)
- Discard any unused portion of dexrazoxane solutions

Selected incompatibility:

- Product labeling recommends *not* mixing or administering dexrazoxane with any other drugs

Recommendations for Drug Administration and Ancillary Care for Dexrazoxane

Utilized as an Antidote for Anthracycline* Extravasations

General:

- Dexrazoxane dosage should be decreased by 50% in persons whose creatinine clearance is <40 mL/min (<0.66 mL/s)
- Dimethylsulfoxide (DMSO) should not be applied topically to treat anthracycline extravasations in patients who are receiving dexrazoxane
  - Anecdotal clinical reports and experimental evidence in mice indicate concomitant use of topical DMSO at the site of anthracycline extravasation decreases the efficacy of systemically administered dexrazoxane
- Dexrazoxane is a cytotoxic drug and may produce myelosuppression additive to what is expected from antineoplastic treatments
- Reversible increases in liver enzymes (serum AST, ALT, bilirubin) may follow dexrazoxane use

Dosage and administration:

- Cooling packs (if used) should be removed from an extravasation site at least 15 minutes before dexrazoxane administration to improve blood flow to the affected site
  - Vasoconstriction caused by local hypothermia may compromise dexrazoxane distribution to the affected area
- **Dexrazoxane administration must begin within 6 hours** after an extravasation event to be optimally effective
- Administer dexrazoxane via a large-caliber vein:

Day 1 Dexrazoxane 1000 mg/m² (maximum recommended single dose = 2000 mg) in 1000 mL of 0.9% NS intraVENously over 1–2 hours, via an administration site not affected by the extravasation

Day 2† Dexrazoxane 1000 mg/m² (maximum recommended single dose = 2000 mg) in 1000 mL of 0.9% NS intraVENously over 1–2 hours via an administration site not affected by the extravasation

Day 3† Dexrazoxane 500 mg/m² (maximum recommended single dose = 1000 mg) in 1000 mL of 0.9% NS intraVENously over 1–2 hours via an administration site not affected by the extravasation (total dosage/3-day course = 2500 mg/m²; maximum recommended dose/3-day course = 5000 mg)

*Anthracyclines, including DAUNOrubicin, DOXOrubicin, epirubicin, and IDArubicin

†Product labeling recommends administering successive 24 hours (±3 hours) after a previously administered dose

DOCETAXEL

[*One- vial formulation*] TAXOTERE® (docetaxel) injection concentrate, intravenous infusion (IV); product label January 2013. sanofi-aventis U.S. LLC, Bridgewater, NJ
[*Two-vial formulation*] TAXOTERE® (docetaxel) injection concentrate, intravenous infusion (IV); product label January 2013. sanofi-aventis U.S. LLC, Bridgewater, NJ
Docetaxel injection, USP, for intravenous infusion only, product label May 2013. Manufactured by Zydus Hospira Oncology Private Ltd., Gujarat, India. Distributed by Hospira, Inc., Lake Forest, IL
Docetaxel injection for intravenous infusion only; product label June 2011. Manufactured for Sandoz, Princeton, NJ. Manufactured by EBEWE Pharma Ges.m.b.H. Nfg.KG, A-4866 Unterach, Austria
DOCEFREZ™ (docetaxel) for injection, intravenous infusion; product label, May 2011. Manufactured by Sun Pharmaceutical Ind. Ltd., Halol-389 350, Gujarat, India. Distributed by Caraco Pharmaceutical Laboratories, Ltd., Detroit, MI

Product-Specific Identification, Storage, and Stability

Product Name (Manufacturer or Distributor)	Product Identification	Product Storage
[*One-vial formulation*] TAXOTERE® (sanofi-aventis U.S. LLC)	[*One-vial formulation*] TAXOTERE® (docetaxel) Injection Concentrate, Intravenous infusion (IV) is a sterile, nonpyrogenic, pale yellow to brownish-yellow, nonaqueous solution in *single-use* vials containing 20 mg DOCEtaxel (anhydrous), 0.54 g polysorbate 80 and 0.395 g dehydrated alcohol solution per milliliter in three presentations: TAXOTERE® (docetaxel) Injection Concentrate 20 mg docetaxel in 1 mL in 50/50 (v/v) ratio polysorbate 80/dehydrated alcohol in a blister pack in 1 carton (NDC 0075-8003-01) *and* TAXOTERE® (docetaxel) injection concentrate 80 mg docetaxel in 4 mL in 50/50 (v/v) ratio polysorbate 80/dehydrated alcohol in a blister pack in 1 carton (NDC 0075-8004-04) *and* TAXOTERE® (docetaxel) Injection Concentrate 160 mg DOCEtaxel in 8 mL of 50/50 (v/v) ratio polysorbate 80 / dehydrated alcohol in a blister pack in one carton (NDC 0075-8005-01)	Store TAXOTERE® vials between 2° and 25°C (35.6° and 77°F) in the original packaging to protect the product from bright light Freezing does not adversely affect the product
[*Two-vial formulation*] TAXOTERE® (sanofi-aventis U.S. LLC)	[*Two-vial formulation*] TAXOTERE® (docetaxel) Injection Concentrate, intravenous infusion (IV) is a sterile, nonpyrogenic, clear, yellow to brownish-yellow, viscous solution in *single-use* vials Each milliliter of TAXOTERE® concentrate contains 40 mg DOCEtaxel (anhydrous) and 1040 mg polysorbate 80 TAXOTERE® injection concentrate *must be diluted twice:* (1) with a sterile, nonpyrogenic, diluent supplied for that purpose, and (2) with 0.9% NS or D5W before it is administered to a patient. The diluent packaged with concentrated TAXOTERE® contains 13% ethanol in water for injection, and is supplied in *single-use* vials Both drug and diluent components are blister packaged together in individual cartons in 1 of 2 presentations: • TAXOTERE® (docetaxel) Injection Concentrate 80 mg docetaxel in 2 mL of polysorbate 80 plus Diluent for TAXOTERE® 80 mg (NDC 0075-8001-80) *and* • TAXOTERE® (docetaxel) Injection Concentrate 20 mg DOCEtaxel in 0.5 mL of polysorbate 80 plus Diluent for TAXOTERE® 20 mg (NDC 0075-8001-20)	
Docetaxel Injection (Hospira, Inc.)	Docetaxel Injection is a sterile, nonpyrogenic, clear, colorless to pale yellow, nonaqueous solution, available in individually packaged vials in a *single-use* formulation: • DOCEtaxel 20 mg/2 mL (NDC 0409-0201-02); and in individually packaged *multi-use* vials in 2 presentations: • DOCEtaxel 80 mg/8 mL (NDC 0409-0201-10) *and* • DOCEtaxel (anhydrous) 160 mg/16 mL (NDC 0409-0201-20) Each milliliter of solution contains 10 mg DOCEtaxel (anhydrous) in 260 mg polysorbate 80, NF; 4 mg citric acid, USP; 23% (v/v) dehydrated alcohol, USP; and PEG 300, NF	Store at 20°–25°C (68°–77°F) in the original packaging carton to protect the product from bright light Freezing does not adversely affect the product. After first use and following multiple needle entries and product withdrawals, DOCEtaxel injection multiuse vials are stable for up to 28 days when stored between 2° and 8°C (35.6° and 46.4°F) and protected from light

(*continued*)

Product-Specific Identification, Storage, and Stability (*continued*)

Docetaxel Injection (Sandoz)	Docetaxel Injection is a sterile, nonpyrogenic, clear, colorless to pale yellow solution in *multiple dose* vials available in 3 presentations: • DOCEtaxel 20 mg/2 mL (NDC 66758-050-01), • DOCEtaxel 80 mg/8 mL (NDC 66758-050-02), *and* • DOCEtaxel 160 mg/16 mL (NDC 66758-050-03) Each milliliter of solution contains 10 mg DOCEtaxel 275.9 mg alcohol 96% (v/v), 4 mg citric acid, 648 mg polyethylene glycol 300, and 80 mg polysorbate 80	Store intact vials between 2° and 25°C (35.6° and 77°F) in the original packaging to protect from bright light Freezing does not adversely affect the product After initial entry, the multiple dose vials are stable for 28 days when stored between 2° and 8°C (35.6° and 46.4°F) and at room temperature, with or without protection from light
DOCEFREZ™ (Sun Pharmaceutical Ind. Ltd)	DOCEFREZ™ (docetaxel) for injection, intravenous infusion is a sterile, lyophilized, nonpyrogenic, white powder and is available in single-use vials available in 2 presentations: • DOCEtaxel (anhydrous) 20 mg (NDC 47335-285-41) *and* • DOCEtaxel (anhydrous) 80 mg (NDC 47335-286-41) Both product presentations are packaged with a sterile, nonpyrogenic, single-dose vial of diluent solution containing 35.4% (w/w) ethanol in polysorbate 80 in a tray packaged in a single carton	Store DOCEFREZ™ between 2° and 8°C (35.6° and 46.4°F) in the original packaging to protect from bright light

General Guidance

- Do not use plasticized PVC equipment or devices that will come into contact with DOCEtaxel solutions during drug preparation or administration
  - Phthalate plasticizers (including DEHP; di-2-ethylhexyl phthalate) may be leached from PVC containers and administration sets
- Glass, polypropylene, and polyolefin devices and equipment, and containers and tubing with surfaces in contact with drug products composed of those materials are appropriate for use in manipulating, containing, and administering DOCEtaxel solutions and minimize patient exposure to phthalate plasticizers[19]

Product-Specific Preparation and Stability

Preparing the Following Products for Clinical Use:

Docetaxel Injection For Intravenous Infusion Only (Hospira, Inc.), **Docetaxel Injection For Intravenous Infusion Only** (Sandoz, Inc.), and ***One-vial formulation*** **of TAXOTERE®** (sanofi-aventis U.S. LLC)

- *Do not use* the one-vial formulation of TAXOTERE® with the two-vial formulation of TAXOTERE® (Injection Concentrate and diluent)
- After removing TAXOTERE® (one-vial formulation) from refrigeration, allow the vials to stand at room temperature for approximately 5 minutes before proceeding

Dilute the concentrated drug product:

1. Use only a 21-gauge needle to withdraw the drug product from a vial
   - Larger bore needles (eg, 18- and 19-gauge) may result in stopper coring and introduce particulate matter into the drug product
2. With a calibrated syringe, aseptically withdraw the an amount of concentrated DOCEtaxel solution required for a patient's dose and transfer it into an appropriate parenteral product bag or bottle containing a volume of either 0.9% NS or D5W sufficient to produce a final DOCEtaxel concentration within the range 0.3–0.74 mg/mL
   - *CAUTION: Product concentrations vary among commercial DOCEtaxel injection products:*
     - The generic products from Hospira, Inc. and Sandoz, Inc. contain DOCEtaxel at a concentration of 10 mg/mL
     - The concentration for the single-vial formulation of Taxotere® (sanofi-aventis U.S. LLC) is 2 times greater, that is 20 mg/mL
   - Product concentrations *must not exceed* 0.74 mg DOCEtaxel per milliliter
3. Thoroughly mix the admixture by manual rotation and by gently inverting the product container
4. When prepared as described with the one-vial formulation of TAXOTERE® and stored between 2°–25°C (35.6°–77°F), DOCEtaxel solutions are stable for 6 hours
   - Physical and chemical in-use stability of TAXOTERE® (one-vial formulation) when prepared as recommended in non-PVC containers and stored at 2°–8°C has been demonstrated for up to 48 hours

     Caution: Product labeling for the *one-vial formulation* of TAXOTERE® (only) includes a warning about product stability after dilution:
     - TAXOTERE® infusion solution produced with the *one-vial formulation* (a solution diluted for administration to patients) is supersaturated; therefore, over time, crystals may appear in solution
     - Solutions in which crystals or particulate matter appear should not be used but should be discarded
     - A similar warning does not appear in product labeling for other DOCEtaxel products identified in this section

Preparing the *2-vial formulation* of TAXOTERE® (sanofi-aventis U.S. LLC)

- *Do not use* the 2-vial formulation (injection concentrate and diluent) with the 1-vial formulation

(*continued*)

Product-Specific Preparation and Stability (*continued*)

Prepare an initial dilution:

1. After removing TAXOTERE® and diluent vials from refrigeration, allow them to stand at room temperature for approximately 5 minutes before proceeding
2. Use only a 21-gauge needle to withdraw the drug product from a vial because larger-bore needles (eg, 18- and 19-gauge) may result in stopper coring and introduce particulate matter into the drug product
3. Aseptically withdraw the entire contents of an appropriate diluent vial (approximately 1.8 mL for Taxotere 20 mg and approximately 7.1 mL for Taxotere 80 mg) into a syringe by partially inverting the vial, and transfer the solution to the vial of TAXOTERE® concentrate with which it was co-packaged to produce an initially diluted solution containing 10 mg DOCEtaxel/mL
   - *CAUTION: Product concentrations vary among commercial docetaxel injection products:*
     - After initial dilution, the concentration of the 2-vial formulation of TAXOTERE® (sanofi-aventis U.S. LLC) is 10 mg/mL
     - In contrast, the concentration for the single-vial formulation of TAXOTERE® is 2 times greater, that is, 20 mg/mL
4. *Do not shake* the vials. Mix the initially diluted solution by repeatedly inverting for at least 45 seconds the Taxotere concentrate vials into which the ethanol-in-water diluent was injected
5. The initially diluted TAXOTERE® solution should be clear; however, there may be some foam on top of the solution caused by polysorbate 80. If foam is present, allow the vials to stand for a few minutes to allow any foam to dissipate. It is not necessary to wait for all foam to dissipate before continuing preparation
   - The initially diluted solution may be used immediately or stored under refrigeration or at room temperature for a maximum of 8 hours

Prepare a final dilution for administration to patients:

1. With a calibrated syringe, aseptically withdraw an amount of initially diluted TAXOTERE® solution (10 mg/mL) required for a patient's dose and transfer it into an appropriate parenteral product bag or bottle containing a volume of either 0.9% NS or D5W sufficient to produce a final DOCEtaxel concentration within the range, 0.3–0.74 mg/mL
   - Product concentrations *must not exceed* concentrations >0.74 mg docetaxel/mL
2. Thoroughly mix the infusion by manual rotation and by gently inverting the product container
3. When prepared as described with the two-vial formulation of DOCEtaxel and stored between 2° and 25°C (35.6° and 77°F), DOCEtaxel solutions are stable for 4 hours

Preparing DOCEFREZ™ (Sun Pharmaceutical Ind. Ltd)

Reconstitute the lyophilized drug product:

1. After removing DOCEFREZ™ and diluent from refrigeration, allow the drug product and diluent (35.4% ethanol in polysorbate 80) vials to stand at room temperature for approximately 5 minutes before proceeding
2. With a syringe, aseptically withdraw and transfer a volume of diluent solution appropriate for the amount of drug product used

DOCEFREZ™ Vial Content	Volume of Diluent Needed for Reconstitution
20 mg	1 mL
80 mg	4 mL

3. Shake the drug product vials well to completely dissolve the lyophilized drug
   CAUTION: The concentration of reconstituted Docefrez is not the same for the 20- and 80-mg products:

DOCEFREZ™ Vial Content	DOCEtaxel Concentration after Reconstitution
20-mg vials	25 mg/mL (20 mg in 0.8 mL)
80-mg vials	24 mg/mL

4. If air bubbles are present in the drug product after solubilization is complete, allow the solution to stand for a few minutes to allow suspended air bubbles to dissipate
5. The reconstituted solution may be used immediately or stored either in under refrigeration or at room temperature for a maximum of 8 hours

Prepare a final dilution for infusion:

1. Aseptically withdraw an amount of DOCEFREZ™ required for a patient's dose with a calibrated syringe and transfer it into an appropriate parenteral product bag or bottle containing a volume of either 0.9% NS or D5W sufficient to produce a final DOCEtaxel concentration within the range, 0.3–0.74 mg/mL
2. Product concentrations *must not exceed* 0.74 mg docetaxel/mL
3. Thoroughly mix the infusion by manual rotation and by gently inverting the product container
   - When prepared as described and stored between 2° and 25°C (35.6° and 77°F), DOCEtaxel solutions are stable for 4 hours

Recommendations for Drug Administration and Ancillary Care

Premedication:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- FDA-approved product labeling recommends that all patients who are treated with DOCEtaxel should receive a steroid before, during, and after DOCEtaxel administration to reduce the incidence and severity of fluid retention and the severity of hypersensitivity reactions
  - For patients with hormone-refractory metastatic prostate cancer already receiving predniSONE concurrently:
    - **Dexamethasone** 8 mg/dose for 3 doses, at 12 hours, 3 hours, and 1 hour before DOCEtaxel administration
  - Other patients:
    - **Dexamethasone** 8 mg orally twice daily for 3 days (6 doses), starting 1 day before DOCEtaxel administration

General:

- Visually inspect the infusion product for particulate matter or discoloration prior to administration. All DOCEtaxel-containing solutions that are not clear or appear to contain a precipitate should be discarded
- When prepared as described to a concentration within the range of range 0.3–0.74 mg/mL and stored between 2°–25°C (35.6°–77°F), DOCEtaxel solutions are stable as follows:

Product (Manufacturer)	Duration of Stability*
TAXOTERE® one-vial formulation (sanofi-aventis U.S. LLC)	6 hours
DOCEtaxel injection (Hospira, Inc.)	4 hours
DOCEtaxel injection (Sandoz, Inc.)	
TAXOTERE® two-vial formulation (sanofi-aventis U.S. LLC)	
DOCEFREZ® (Sun Pharmaceutical Ind. Ltd)	

*Includes an administration duration of 60 minutes

- Administer DOCEtaxel by intraVENous infusion over one hour at ambient room temperature (<25°C; <77°F) and lighting conditions
- To minimize patient exposure to phthalate plasticizers (eg, DEHP), which may be leached from PVC containers and administration sets:
  - Administer DOCEtaxel *only* through polyethylene-lined administration sets

Potential drug interactions:

- DOCEtaxel is a substrate for metabolism by CYP3A4 and for extracellular transport by P-glycoprotein (MDR1, ABCB1)
  - Avoid concomitant use of DOCEtaxel with potent inhibitors and inducers of CYP3A subfamily enzymes and P-glycoprotein

Hypersensitivity reactions:

- Patients should be observed closely for hypersensitivity reactions, especially during the first and second infusions
  - Hypersensitivity reactions may occur within a few minutes after initiating DOCEtaxel administration
- Severe hypersensitivity reactions characterized by generalized rash/erythema, hypotension and/or bronchospasm, or very rarely fatal anaphylaxis, have been reported in patients who received steroid premedication
  - Severe hypersensitivity reactions require immediate discontinuation of the DOCEtaxel administration and aggressive supportive therapy
  - Patients with a history of severe hypersensitivity reactions should not be rechallenged with DOCEtaxel
- Minor events, including flushing, rash with or without pruritus, chest tightness, back pain, dyspnea, drug fever, or chills, have been reported and resolved after discontinuing DOCEtaxel administration and instituting appropriate therapy
- Treatment interruption is not required for minor reactions such as flushing or localized skin reactions

DOXORUBICIN HYDROCHLORIDE

ADRIAMYCIN® (DOXOrubicin HCl) for injection, USP, and ADRIAMYCIN® (DOXOrubicin HCl) injection, USP, for intravenous use only; product label, April 2012. Manufactured by Bedford Laboratories, Bedford, OH
DOXORUBICIN HYDROCHLORIDE–doxorubicin hydrochloride injection; product label, September 2011. Teva Parenteral Medicines, Inc., Irvine CA
Doxorubicin Hydrochloride Injection, USP (For IV Use Only); product label, January 2013. Made in India. Manufactured for SAGENT Pharmaceuticals, Schaumburg, IL

WARNING

1. Severe local tissue necrosis will occur if there is extravasation during administration… Doxorubicin must not be given by the intramuscular or subcutaneous route
2. Myocardial toxicity manifested in its most severe form by potentially fatal congestive heart failure (CHF) may occur either during therapy or months to years after termination of therapy. The probability of developing impaired myocardial function based on a combined index of signs, symptoms, and decline in left ventricular ejection fraction (LVEF) is estimated to be 1 to 2% at a total cumulative dose of 300 mg/m^2 of doxorubicin, 3 to 5% at a dose of 400 mg/m^2, 5 to 8% at 450 mg/m^2 and 6 to 20% at 500 mg/m^2. The risk of developing CHF increases rapidly with increasing total cumulative doses of doxorubicin in excess of 400 mg/m^2. Risk factors (active or dormant cardiovascular disease, prior [*or* previous] or concomitant radiotherapy to the mediastinal/pericardial area, previous therapy with other anthracyclines or anthracenediones, concomitant use of other cardiotoxic drugs) may increase the risk of cardiac toxicity. Cardiac toxicity with doxorubicin may occur at lower cumulative doses whether or not cardiac risk factors are present. Pediatric patients are at increased risk for developing delayed cardiotoxicity
3. Secondary acute myelogenous leukemia (AML) or myelodysplastic syndrome (MDS) have been reported in patients treated with anthracyclines, including doxorubicin… The occurrence of refractory secondary AML or MDS is more common when anthracyclines are given in combination with DNA-damaging anti-neoplastic agents or radiotherapy, when patients have been heavily pretreated with cytotoxic drugs, or when doses of anthracyclines have been escalated. The rate of developing secondary AML or MDS has been estimated in an analysis of 8563 patients with early breast cancer treated in 6 studies conducted by the National Surgical Adjuvant Breast and Bowel Project (NSABP), including NSABP B-15. Patients in these studies received standard doses of doxorubicin and standard or escalated doses of cyclophosphamide (AC) adjuvant chemotherapy and were followed for 61,810 patient years. Among 4483 such patients who received conventional doses of AC, 11 cases of AML or MDS were identified, for an incidence of 0.32 cases per 1000 patient years (95% CI 0.16 to 0.57) and a cumulative incidence at 5 years of 0.21% (95% CI 0.11 to 0.41%). In another analysis of 1474 patients with breast cancer who received adjuvant treatment with doxorubicin-containing regimens in clinical trials conducted at University of Texas M.D. Anderson Cancer Center, the incidence was estimated at 1.5% at 10 years. In both experiences, patients who received regimens with higher cyclophosphamide dosages, who received radiotherapy, or who were aged 50 or older had an increased risk of secondary AML or MDS. Pediatric patients are also at risk of developing secondary AML
4. Dosage should be reduced in patients with impaired hepatic function
5. Severe myelosuppression may occur
6. Doxorubicin should be administered only under the supervision of a physician who is experienced in the use of cancer chemotherapeutic agents

Boxed Warning (excerpt) for "ADRIAMYCIN® (DOXOrubicin HCl) for Injection, USP, ADRIAMYCIN® (DOXOrubicin HCl) Injection, USP, For Intravenous Use Only"; April 2012 product label; Bedford Laboratories™, Bedford, OH, and "Doxorubicin Hydrochloride Injection, USP (For IV Use Only)"; January 2013 product label. SAGENT Pharmaceuticals, Schaumburg, IL

Product Identification, Preparation, Storage, and Stability

- **DOXOrubicin Hydrochloride for Injection, USP** (ADRIAMYCIN® for injection, USP; Bedford Laboratories), is a sterile, red-orange, lyophilized powder packaged in single-dose vials as follows:

Content DOXOrubicin HCl	No. Vials/Package Unit	NDC No.
10 mg/vial	Carton of 10 vials	55390-231-10
20 mg/vial	Carton of 10 vials	55390-232-10
50 mg/vial	Individually boxed	55390-233-01

- Store intact vials (unreconstituted drug product) at controlled room temperature, 15°–30°C (59°–86°F) in the packaging carton to protect them from light

(*continued*)

Product Identification, Preparation, Storage, and Stability (*continued*)

- Reconstitute the lyophilized powder with 0.9% NS as follows to produce a final concentration of 2 mg DOXOrubicin HCl/mL:

DOXOrubicin HCl Content per Vial	Diluent Volume
10 mg	5 mL
20 mg	10 mL
50 mg	25 mL

- After adding the diluent, vials should be shaken and the contents allowed to dissolve
- After initially entering a sealed vial, DOXOrubicin solution is stable for 7 days at room temperature and under normal room light (100 foot-candles) and for 15 days at 2°–8°C (35.6°–46.4°F). Protect DOXOrubicin from exposure to sunlight. Promptly discard partially used vials
- One-hundred, twenty-four days after reconstitution to a concentration of 2 mg/mL and storage in the manufacturer's original glass vials at 4°C (39.2°F) and 23°C (73.4°F) DOXOrubicin retained >90% of its initial concentration, remained clear, and had exhibited no changes in pH or absorbance by ultraviolet-visible spectrophotometry[39]
  - Mass balance analysis indicated approximately 3.5% of DOXOrubicin stored at 23°C and about 1% stored at 4°C had degraded at 124 days after reconstitution[39]
- Protect DOXOrubicin from exposure to sunlight. Promptly discard partially used vials

- **DOXOrubicin hydrochloride injection, USP**, is available from several manufacturers. The products contain a red-orange, sterile, isotonic solution with a concentration of 2 mg DOXOrubicin HCl/mL. Products may be packaged individually or are sold in cartons containing multiple vials:

DOXOrubicin HCl Content
10 mg in 5 mL, single-dose vials
20 mg in 10 mL, single-dose vials
50 mg in 25 mL, single-dose vials
150 mg in 75 mL, multiple-dose vials
200 mg in 100 mL, multiple-dose vials

- Store vials under refrigeration at 2°–8°C (35.6°–46.4°F) in their packaging carton to protect them from light
  - Storage of DOXOrubicin HCl solution for injection under refrigeration can result in the formation of a gelled product. The gelled product will return to a slightly viscous to mobile solution after 2 hours to a maximum of 4 hours equilibration at controlled room temperature 15°–30°C (59°–86°F)
  - After preparing a single dose, discard any unused portion of products formulated for a single use
  - Unused solution remaining in multidose containers should be discarded after the recommended storage times

- DOXOrubicin HCl Injection (2 mg/mL), and DOXOrubicin HCl for Injection after reconstitution (2 mg/mL), are suitable for intraVENous injection but may also be diluted for administration to patients
  - Dilution in 0.9% NS, D5W, or LRI to concentrations as low as 0.01 mg/mL results in products stable for at least 24 hours when stored at room temperature under fluorescent lighting or in the dark
    - DOXOrubicin stability is inversely related to solution concentration

(*continued*)

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with hepatic dysfunction
- Administer DOXOrubicin by slow intraVENous injection into the tubing of a freely running intraVENous infusion of 0.9% NS or D5W. The tubing should be attached to a needle or cannula inserted preferably into a large vein. If possible, avoid veins over joints and in extremities with compromised venous or lymphatic drainage
- The rate of administration is dependent on vein size and DOXOrubicin dosage, but a dose should be administered over not less than 3–5 minutes
- *Caution*: DOXOrubicin is a powerful vesicant and can produce severe local soft tissue necrosis if extravasation occurs. DOXOrubicin *must not be given* by the intraMUSCular, SUBCUTaneous, or intraTHECAL routes
  - The current standard of care for managing anthracycline extravasation, including extravasation of DOXOrubicin, is a 3-day course of intraVENously administered dexrazoxane (Totect®, Savene®)
- Erythematous streaking along a vein as well as facial flushing may indicate an administration rate that is too rapid. Burning or stinging sensations may be indicative of perivenous infiltration and the infusion should be immediately terminated, and, if resumed, restarted in another vein. Extravasation also may occur painlessly

Inadvertent exposure:

- DOXOrubicin HCl spills and leaks on environmental surfaces should be treated with dilute sodium hypochlorite (1% available chlorine) solution, preferably by soaking, and then rinsing with water
- In case of skin contact, thoroughly wash the affected area with soap and water or sodium bicarbonate solution. *Do not abrade* the skin by using a scrub brush
- Treat accidental contact with the eyes immediately by copious lavage with water

Product Identification, Preparation, Storage, and Stability (*continued*)

- DOXOrubicin has been shown to adsorb to PVC containers
  - The proportion of a dose lost to sorption may be expected to vary inversely with the surface area of a container with which the drug is in contact
  - The concentration of DOXOrubicin diluted with 0.9% NS (estimated concentration, 95.2 µg/mL) stored in 100-mL-capacity PVC containers at 4°C was shown to decrease over a period of 8 days, possibly representing initial adsorption to container surfaces followed by a protracted absorption and migration into the container matrix before equilibration was achieved, or adsorption of DOXOrubicin degradation products to container surfaces similar to the parent compound[37]
    - Loss of DOXOrubicin due to adsorption was [1] greater from solutions in which the vehicle solution was 0.9% NS in comparison with D5W, and [2] greatest at higher storage temperatures (25°C > 4°C > –20°C), and [3] greater at solution pH of 5.20 and 6.47 (0.9% NS) than at pH of 4.36 (D5W) at all temperatures conditions evaluated
- DOXOrubicin HCl solutions (estimated concentration, 95.2 µg/mL) stored in PVC containers at 25°C, 4°C, or –20°C was more stable at more acidic solution pH under the conditions of pH evaluated (4.36, 5.20, and 6.47)[37]
- DOXOrubicin HCl for injection reconstituted with SWFI and diluted with 0.9% NS or D5W to an estimated concentration of 95.2 µg/mL stored in PVC containers for 43 days did not degrade during or after 11 repeated cycles of freezing (–20°C) and thawing at ambient temperature (25°C)[37]
- DOXOrubicin HCl for injection reconstituted with SWFI to a concentration of 2 mg/mL was stable for at least 43 days when stored in polypropylene syringes at 4°C[37]
- DOXOrubicin solutions undergo photodegradation
  - The rate and extent of photodegradation are inversely related to DOXOrubicin concentrations in solution[38] and directly related to solution pH (rate of degradation increases at pH >5.0)[37]
  - At DOXOrubicin concentrations ≥100 µg/mL (≥0.1 mg/mL) stored at 25°C for 168 h under artificial room lighting (four 65/80-Watt fluorescent tubes mounted approximately 1 m above the samples), little or no photodegradation occurred in clear or amber glass or opaque polyethylene containers[38]
    - A 10-fold difference in lability to photodegradation was demonstrated for DOXOrubicin at a concentration of 0.01 mg/mL than a concentration of 0.1 mg/mL
  - At DOXOrubicin concentrations ≥500 µg/mL (0.5 mg/mL), no special precautions are necessary to protect freshly prepared solutions from exposure to artificial light or sunlight[38]

Selected incompatibility:

- Antimicrobially preserved diluents are not recommended for use in reconstituting DOXOrubicin for injection (lyophilized powder formulations)
- *Do not mix* DOXOrubicin with heparin or fluorouracil. The admixtures are incompatible and will precipitate
- *Do not mix* DOXOrubicin with alkaline solutions (eg, solutions containing sodium bicarbonate), which may cause hydrolytic degradation of DOXOrubicin

DOXORUBICIN HYDROCHLORIDE LIPOSOME INJECTION

DOXIL® (doxorubicin HCl liposome injection) for intravenous infusion; product label, March 2013. Manufactured by Ben Venue Laboratories, Inc., Bedford, OH. Manufactured for Janssen Products, LP, Horsham, PA

Doxorubicin Hydrochloride Liposome Injection for intravenous infusion; product label, September 2012. Manufactured by Sun Pharmaceutical Ind. Ltd., Gujarat, India. Distributed by Caraco Pharmaceutical Laboratories, Ltd., Detroit, MI

WARNING: INFUSION REACTIONS, MYELOSUPPRESSION, CARDIOTOXICITY, LIVER IMPAIRMENT, ACCIDENTAL SUBSTITUTION

1. The use of [doxorubicin hydrochloride liposome injection] may lead to cardiac toxicity. Myocardial damage may lead to congestive heart failure and may occur as the total cumulative dose of doxorubicin HCl approaches 550 mg/m². In a clinical study in patients with advanced breast cancer, 250 patients received [doxorubicin hydrochloride liposome injection] …at a starting dose of 50 mg/m² every 4 weeks. At all cumulative anthracycline doses between 450–500 mg/m² or between 500–550 mg/m², the risk of cardiac toxicity for patients treated with [doxorubicin hydrochloride liposome injection] …was 11%. Prior use of other anthracyclines or anthracenediones should be included in calculations of total cumulative dosage. Cardiac toxicity may also occur at lower cumulative doses in patients with prior mediastinal irradiation or who are receiving concurrent cyclophosphamide therapy…
2. Acute infusion-related reactions including, but not limited to, flushing, shortness of breath, facial swelling, headache, chills, back pain, tightness in the chest or throat, and/or hypotension have occurred in up to 10% of patients treated with… [doxorubicin hydrochloride liposome injection]. In most patients, these reactions resolve over the course of several hours to a day once the infusion is terminated. In some patients, the reaction has resolved with slowing of the infusion rate. Serious and sometimes life-threatening or fatal allergic/anaphylactoid-like infusion reactions have been reported. Medications to treat such reactions, as well as emergency equipment, should be available for immediate use. [Doxorubicin hydrochloride liposome injection doses >60 mg] …should be administered at an initial rate of 1 mg/min to minimize the risk of infusion reactions…
3. Severe myelosuppression may occur…
4. Dosage should be reduced in patients with impaired hepatic function…
5. Accidental substitution of [doxorubicin hydrochloride liposome injection] …for doxorubicin HCl has resulted in severe side effects. [Doxorubicin hydrochloride liposome injection] …should not be substituted for doxorubicin HCl on a mg per mg basis…

Boxed Warning (excerpts) from "DOXIL® (doxorubicin HCl liposome injection) for intravenous infusion"; March 2013 product label; Janssen Products, LP, Horsham, PA, and "Doxorubicin Hydrochloride Liposome Injection for intravenous infusion"; September 2012 product label. Caraco Pharmaceutical Laboratories, Ltd., Detroit, MI

Product Identification, Preparation, Storage, and Stability

Characteristics common to both products:

- Both products contain DOXOrubicin HCl, >90% of which is encapsulated in a proprietary liposome carrier
  - Both products are sometimes referred to as liposomal DOXOrubicin and "PEGylated DOXOrubicin", because the microscopic liposomes in which DOXOrubicin is encapsulated are formulated with surface-bound methoxypolyethylene glycol, which protects the liposomes from detection by the mononuclear phagocyte system and increases the circulation time in blood
- DOXOrubicin HCl liposome injection is a translucent, red, liposomal dispersion; it is neither clear nor a solution
- Store unopened vials at 2°–8°C (35.6°–46.4°F)
  - DOXOrubicin HCl liposome injection does not contain an antimicrobial preservatives or bacteriostatic agents
- Avoid freezing DOXOrubicin HCl liposome injection. Prolonged freezing may adversely affect liposomal drug products
  - Freezing for periods <1 month does not appear to adversely affect DOXOrubicin HCl liposome injection
- Dilute DOXOrubicin HCl liposome injection with D5W before administration as follows:

Note: Do not dilute DOXOrubicin HCl liposome injection with any solution other than D5W

Dose to Administer	Volume of D5W for Dilution
≤90 mg	250 mL
>90 mg	500 mL

- After dilution, the products will not clarify, but remain a translucent, red, liposomal dispersion
- After dilution, liposomal DOXOrubicin should be refrigerated (2°–8°C) and used within 24 hours
- *Do not filter* liposomal DOXOrubicin either before or after dilution

DOXIL®:

- Available products include six, individually packaged, vials containing DOXOrubicin HCl at a concentration of 2 mg/mL. Two presentations are available:
  - 20 mg DOXOrubicin HCl/10 mL in 10-mL (capacity) glass, single-use vials (NDC 59676-960-01), and
  - 50 mg DOXOrubicin HCl/25 mL in 30-mL (capacity) glass, single-use vials (NDC 59676-960-02)

(generic) DOXOrubicin Hydrochloride Liposome Injection:

- DOXOrubicin hydrochloride liposome injection is provided as a sterile, translucent, red, liposomal dispersion in individually cartoned, 10- or 30-mL capacity, glass, single-use vials
- Each vial contains DOXOrubicin hydrochloride, USP at a concentration of 2 mg/mL in two presentations:

(*continued*)

Product Identification, Preparation, Storage, and Stability (*continued*)

- DOXOrubicin HCl 20 mg in 10 mL; NDC 47335-049-40
- DOXOrubicin HCl 50 mg in 25 mL; NDC 47335-050-40

Characteristics and excipients common to both products:

- Each milliliter of both products also contains ammonium sulfate (approximately) 2 mg, histidine as a buffer, sucrose to maintain isotonicity, and hydrochloric acid and/or sodium hydroxide to maintain a pH of 6.5
- The pegylated liposome carriers are composed of cholesterol 3.19 mg/mL, fully hydrogenated soy phosphatidylcholine (HSPC) 9.58 mg/mL, and *N*-(carbonyl-methoxypolyethylene glycol 2000)-1,2-distearoyl-sn-glycero-3-phosphoethanolamine sodium salt (MPEG-DSPE) 3.19 mg/mL

Selected incompatibilities (both products):

- *Do not mix* liposomal DOXOrubicin with other drugs
- *Do not mix* liposomal DOXOrubicin with solutions that contain a bacteriostatic agent, such as benzyl alcohol

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with hepatic dysfunction
- Liposomal DOXOrubicin must be diluted before administration
- Administer liposomal DOXOrubicin by intraVENous infusion:
  - Give doses ≤60 mg over 60 minutes
  - Doses >60 mg should initially be administered no more rapidly than 1 mg/minute (60 mg/hour) to minimize the risk of adverse reactions during infusion
  - If no reactions are observed, the delivery rate may be increased to complete administration over one hour
  - Infusion reactions may respond to slowing the rate of administration or temporarily interrupting treatment, and resuming administration at a slower rate after signs and symptoms abate
    - Infusion-related adverse events have included life-threatening and fatal allergic or anaphylactoid reactions
    - Infusion-related adverse events have included one or more of the following:
      - Flushing, shortness of breath, facial swelling, headache, chills, chest pain, back pain, chest and throat tightness, fever, tachycardia, pruritus, rash, cyanosis, syncope, bronchospasm, asthma, apnea, hypotension
- *Do not filter* liposomal DOXOrubicin during administration
- *Do not rapidly flush* an administration set used to administer liposomal DOXOrubicin to complete drug delivery
  - Utilize a technique to empty an administration set containing liposomal DOXOrubicin that will not substantially increase the rate at which the dose was being administered
- *Caution:* liposomal DOXOrubicin has been associated with vesicant reactions after extravasation and may produce severe local necrosis if infiltration into soft tissues occurs[40]
  - Extravasation may occur during intravenous administration with or without an accompanying stinging or burning sensation, and in spite of easy blood aspiration (good blood return) from the vascular access device through which liposomal DOXOrubicin is administered
  - If signs or symptoms of extravasation occur during liposomal DOXOrubicin administration, the infusion should be immediately discontinued at the affected access site, but may be restarted in another vein
    - Liposomal DOXOrubicin *must never be given* by the intraMUSCular or SUBCUTaneous routes

Note:

- Advise patients that liposomal DOXOrubicin after treatment may impart a reddish-orange color to urine and other body fluids; a nontoxic reaction due to the color of the product that will dissipate as the drug is eliminated from the body

EPIRUBICIN HYDROCHLORIDE

ELLENCE® (epirubicin hydrochloride injection); product label, February 2013. Distributed by Pharmacia & Upjohn Co., Division of Pfizer Inc., New York, NY
EPIRUBICIN HYDROCHLORIDE—epirubicin hydrochloride injection, solution; product label, February 2013. Teva Parenteral Medicines, Inc., Irvine, CA
Epirubicin Hydrochloride injection; product label, January 2012. Product of Australia. Hospira, Inc., Lake Forest, IL
Epirubicin Hydrochloride for injection; product label, November 2007. Hospira, Inc., Lake Forest, IL

WARNING: RISK OF TISSUE NECROSIS, CARDIAC TOXICITY, SECONDARY ACUTE MYELOGENOUS LEUKEMIA, AND MYELOSUPPRESSION

1. Severe local tissue necrosis will occur if there is extravasation during administration. ELLENCE must not be given by the intramuscular or subcutaneous route…
2. Cardiac toxicity, including fatal congestive heart failure (CHF), may occur either during therapy with ELLENCE or months to years after termination of therapy. The probability of developing clinically evident CHF is estimated as approximately 0.9% at a cumulative dose of 550 mg/m², 1.6% at 700 mg/m², and 3.3% at 900 mg/m². In the adjuvant treatment of breast cancer, the maximum cumulative dose used in clinical trials was 720 mg/m². The risk of developing CHF increases rapidly with increasing total cumulative doses of ELLENCE in excess of 900 mg/m²; this cumulative dose should only be exceeded with extreme caution. Active or dormant cardiovascular disease, prior or concomitant radiotherapy to the mediastinal/pericardial area, previous therapy with other anthracyclines or anthracenediones, or concomitant use of other cardiotoxic drugs may increase the risk of cardiac toxicity. Cardiac toxicity with ELLENCE may occur at lower cumulative doses whether or not cardiac risk factors are present…
3. Secondary acute myelogenous leukemia (AML) has been reported in patients with breast cancer treated with anthracyclines, including epirubicin. The occurrence of refractory secondary leukemia is more common when such drugs are given in combination with DNA-damaging antineoplastic agents, when patients have been heavily pretreated with cytotoxic drugs, or when doses of anthracyclines have been escalated. The cumulative risk of developing treatment-related AML or myelodysplastic syndrome (MDS), in 7110 patients with breast cancer who received adjuvant treatment with ELLENCE-containing regimens, was estimated as 0.27% at 3 years, 0.46% at 5 years, and 0.55% at 8 years…
4. Severe myelosuppression may occur…

Boxed Warning (excerpt) from "ELLENCE® (epirubicin hydrochloride injection)"; February 2013 product label; Pharmacia & Upjohn Co., Division of Pfizer Inc., New York, NY

Product Identification, Preparation, Storage, and Stability

- **Epirubicin HCl injection** is available in individually packaged single-use vials containing a sterile, preservative-free, ready-to-use, clear, red solution containing 2 mg epirubicin hydrochloride/mL
  - Product presentations vary among manufacturers, but include vials containing 10 mg, 50 mg, 150 mg, and 200 mg epirubicin HCl
    - Inactive ingredients include sodium chloride, USP, and SWFI. Product pH is adjusted to 3.0 with hydrochloric acid, NF
- Store unopened vials under refrigeration between 2° and 8°C (35.6° and 46.4°F), but *do not freeze* epirubicin
  - Storage at refrigerated temperatures can result in the formation of a gelled product, which will return to a slightly viscous to mobile solution after 2 hours to a maximum of 4 hours equilibration at controlled room temperature (15°–25°C [59°–77°F])
- **Epirubicin Hydrochloride for injection** is a sterile, orange-red, lyophilized powder in single-use vials containing 50 mg or 200 mg of epirubicin hydrochloride
  - Each 50-mg and 200-mg vial also contains 250 mg and 1000 mg of lactose, respectively
- Epirubicin HCl for injection must be reconstituted prior to use with SWFI, resulting in a solution concentration of 2 mg/mL with a pH of 4.7 to 5.0

Epirubicin HCl Content per Vial	Diluent Volume
50 mg	25 mL
200 mg	100 mL

- Shake vials vigorously to aid dissolution
  - It may take up to 4 minutes for epirubicin hydrochloride to completely dissolve
- The manufacturers' product labeling indicates reconstituted solutions are stable for 24 hours when stored at 2°–8°C (35.6°–46.4°F) and protected from light, or 25°C (77°F) under normal lighting conditions
- Epirubicin HCL for injection may be further diluted with sterile water for injection, USP
  - Epirubicin HCl for injection reconstituted with 0.9% NS to a concentration of 2 mg/mL stored in polypropylene syringes at either 4°C and protected from light exposure or stored at 25°C and either protected from light or under illumination (~50 lumens/m²) was stable for 14 days at 25 ± 1°C (77° ± 1.8°F) and for 180 days at 4 ± 1°C (39.2° ± 1.8°F)[41]
  - Epirubicin HCl for injection reconstituted with SWFI to a concentration of 2 mg/mL was stable for at least 43 days when stored in polypropylene syringes at 4°C[37]
  - Epirubicin HCl for injection reconstituted with SWFI and diluted with D5W or 0.9% NS (to pH = 4.36 or 5.20, respectively) was stable for up to 43 days when stored in PVC containers at 25°C, 4°C, or –20°C (–4°F)[37]
    - Epirubicin HCl solutions (estimated concentration, 95.2 µg/mL) stored in PVC containers was more stable at more acidic solution pH under the conditions of pH evaluated (4.36, 5.20, and 6.47)
    - A significant loss in potency (≥10%) occurred at 20 days for epirubicin HCl admixtures in 0.9% NS (pH = 6.47) stored in PVC at 25°C, but not for epirubicin admixtures in 0.9% NS (pH = 5.20) stored in PVC at 25°C
  - Epirubicin HCl for injection reconstituted with SWFI and diluted

(continued)

Product Identification, Preparation, Storage, and Stability (*continued*)

with 0.9% NS or D5W to an estimated concentration of 95.2 µg/mL stored in PVC containers for 43 days did not degrade during or after 11 repeated cycles of freezing (–20°C) and thawing at ambient temperature (25°C)

- Adsorption of epirubicin (diluted in D5W or 0.9% NS to a concentration of ~95.2 mg/mL) to PVC container surfaces during the 8 days after admixture preparation correlated inversely with solution pH (4.36 < 5.20 < 6.47) and directly with storage temperatures (25°C > 4°C > –20°C)[37]
  - Drug loss from PVC mini-bags appeared to be due to a combination of epirubicin degradation and adsorption to container surfaces

- Epirubicin solutions undergo photodegradation
  - The rate and extent of photodegradation are inversely related to epirubicin concentrations in solution[38] and directly related to solution pH (rate of degradation increases at pH >5.0)[37]
  - At epirubicin concentrations ≥100 µg/mL (≥0.1 mg/mL) stored at 25°C for 168 h under artificial room lighting (four 65/80-Watt fluorescent tubes mounted approximately 1 m above the samples), little or no photodegradation occurred in clear or amber glass or opaque polyethylene containers[38]
  - At epirubicin concentrations ≥500 µg/mL (0.5 mg/mL), no special precautions are necessary to protect freshly prepared solutions from exposure to artificial light or sunlight[38]
- Epirubicin HCl solution is suitable for direct intraVENous administration
- Use epirubicin HCl solution within 24 hours after first penetrating vial stoppers
- Discard partially used vials after dose preparation

Selected incompatibility:

- *Do not mix* epirubicin with other drugs in the same container
- Epirubicin is most stable at pH 4–5, and hydrolyzes spontaneously at alkaline pH
- Epirubicin is chemically incompatible with heparin and fluorouracil

Recommendations for Drug Administration and Ancillary Care

General:

- See Chapter 41 for recommended use in patients with renal and hepatic dysfunction
- Administer epirubicin by slow intraVENous injection into the tubing of a freely running intraVENous infusion of 0.9% NS or D5W over 3–20 minutes, depending on the dosage to be given and vein size
- Initial therapy within a dosage range of 100–120 mg/m² should generally be administered over 15–20 minutes
  - The administration time may be proportionally decreased, for lesser dosages, but SHOULD NOT BE <3 minutes
- Do *not* inject epirubicin directly into a vein because of the risk of extravasation, which may occur even in the presence of adequate blood return during aspiration. Venous sclerosis may result from injection into small vessels or repeated injections into the same vein
- Avoid administration into veins over joints or in extremities with compromised venous or lymphatic drainage
- *Caution:* Epirubicin is a vesicant and can produce severe local soft tissue necrosis if extravasation occurs. Epirubicin *must not be given* by the intraMUSCular. SUBCUTaneous, or intraTHECAL routes
  - The current standard of care for managing anthracycline extravasation, including extravasation of epirubicin, is a 3-day course of intraVENously administered dexrazoxane (Totect, Savene)
- Erythematous streaking along the vein through which epirubicin is administered and facial flushing may indicate too rapid an administration rate, and may precede local phlebitis or thrombophlebitis. Burning or stinging sensations may be indicative of perivenous infiltration and the infusion should be immediately terminated and resumed in another vein. Perivenous infiltration may occur painlessly

Caution:

- Do not administer epirubicin in combination with other cardiotoxic agents unless the patient's cardiac function is closely monitored
  - Administering epirubicin after stopping treatment with other cardiotoxic agents may also increase the risk of developing cardiotoxicity
  - Avoid when possible epirubicin therapy for up to 24 weeks after a last dose of trastuzumab
    - Monitor cardiac function carefully if epirubicin is used within 24 weeks after stopping trastuzumab
  - Concomitant use of epirubicin with cardioactive compounds that could cause heart failure (eg, calcium channel blockers) requires close monitoring of cardiac function throughout treatment
- Coadministration of cimetidine increased epirubicin's mean AUC by 50% and decreased its plasma clearance by 30%
